Let us denote by u the entropic solution of (1) *satisfying* (3) *and u^h the solution of the numerical scheme* (9), (13)*. Then u^h converges towards u in $L^1_{loc}(\mathbb{R}^d \times \mathbb{R}_+)$, and we have the following estimate: For all compact E of $\mathbb{R}^d \times \mathbb{R}_+$, there exists a constant $\mathcal{C}$ depending only on E, S, F, u_0, and a such that:*

$$\int_E |u^h(x,t) - u(x,t)| dx dt \leq \mathcal{C} h^{\frac{1}{20}}. \tag{71}$$

Proof. From the result of Proposition 6.3 and the estimates (93), (103), (117) given in Appendix A of μ_h, ν_ϵ, and λ, respectively, one gets:

$$\begin{aligned}
&\int_E |u^h(x,t) - u^\epsilon(x,t)| dx dt \leq \int_{\mathbb{R}^d} |u^h(x,0) - u^\epsilon(x,0)| \rho(|x|^\delta) \frac{1}{T} dx \\
&+ \mathcal{C} \left(h + \sqrt{h} + \delta + \frac{\sqrt{h}}{\gamma} + \frac{h}{\delta} + \frac{h}{\gamma} + \frac{h}{\gamma^2} + \frac{\delta}{\gamma} + \gamma + \frac{h}{\delta \gamma \epsilon^{\frac{1}{2}}} + \frac{h}{\delta \epsilon^{\frac{5}{2}}} + \frac{h}{\epsilon^3 \delta^2} + \frac{\epsilon}{\gamma} \right),
\end{aligned}$$

where $\mathcal{C} = \mathcal{C}(u_0, F, S, a, T, \Omega)$. The integral at $t = 0$ is bounded by:

$$\begin{aligned}
\int_{\mathbb{R}^d} |u^h(x,0) - u^\epsilon(x,0)| \rho(|x|^\delta) \frac{1}{T} dx &\leq C(T) \int_{\mathbb{R}^d} |u^h(x,0) - u^\epsilon(x,0)| dx \\
&\leq C(T) \left(\sum_{i \in P} \omega_i |u^h(x_i,0) - u^\epsilon(x_i,0)| + \sum_{i \in P} \int_{\Omega_i} |u^\epsilon(x_i,0) - u^\epsilon(x,0)| dx \right) \\
&\leq C(T, u_0)(h + \epsilon),
\end{aligned}$$

so that we have:

$$\begin{aligned}
\int_E |u^h(x,t) - u^\epsilon(x,t)| dx dt \leq \mathcal{C} \Bigg(& h + \sqrt{h} + \epsilon + \gamma + \delta + \frac{\sqrt{h}}{\gamma} + \frac{h}{\delta} + \frac{h}{\gamma} + \frac{h}{\gamma^2} + \frac{\delta}{\gamma} \\
& + \frac{h}{\delta \gamma \epsilon^{\frac{1}{2}}} + \frac{h}{\delta \epsilon^{\frac{5}{2}}} + \frac{h}{\epsilon^3 \delta^2} + \frac{\epsilon}{\gamma} \Bigg).
\end{aligned}$$

The optimal values of ϵ, γ, and δ are $\epsilon = h^{\frac{1}{10}}$, $\gamma = h^{\frac{1}{20}}$, and $\delta = h^{\frac{1}{4}}$, respectively. By combining this with the convergence result (Theorem 4.3) of u^ϵ towards the exact solution of (1) u, one gets the final result (71) and the proof of convergence. ∎

Because of the problems related to the definition of the renormalized derivative operator, as explained in section 5, we used the Kruskov–Kuznetsov entropy method in order to prove the convergence of the weak renormalized meshfree scheme. The advantage of this method is that an error estimate is obtained, and the proof can be applied to problems with irregular initial conditions, as the initial condition can always be regularized in order to be BV. However, the rate of convergence of $\frac{1}{20}$ is not the right convergence rate as it is much less than what we observe in real computations.

Appendix A. Remainders and their estimates. In this appendix section, we give the definition of all of the estimates presented within the article and an upper bound of their absolute value. We recall that $\frac{\Delta t}{h} = O(1)$ and $\frac{\varepsilon}{h} = O(1)$ (see the hypothesis of Theorem 7.1).

A.1. Measure μ_h. We note that $||D\varphi|| = ||D\varphi(.,y,.,s)||$ for any operator D and any norm.

$$\langle \mu_h, \varphi \rangle = R_1^h(\varphi) + R_2^h(\varphi) + R_3^h(\varphi) + R_4^h(\varphi) + R_5^h(\varphi), \tag{72}$$

$$R_1^h(\varphi) = R_{11}^h(\varphi) + R_{12}^h(\varphi) + R_{13}^h(\varphi), \tag{72a}$$

$$R_{11}^h(\varphi) = \sum_{n\geq 0} \Delta t \sum_{i,j\in P} w_i^n \varphi_i^n w_j^n Q_{ij}^{\eta_\delta,n} ||A_{ij}^n||, \tag{72a(i))}$$

$$R_{12}^h(\varphi) = \sum_{n\geq 0} \Delta t \sum_{i,j\in P} w_i^n \varphi_i^n w_j^n (H_{\delta,j}^n - H_{\delta,i,ij}^n + H_{\delta,i}^n - H_{\delta,j,ij}^n).A_{ij}^n, \tag{72a(ii))}$$

$$R_{13}^h(\varphi) = \sum_{n\geq 0} \Delta t \, (H_\delta, \nabla\varphi - \nabla_h\varphi)_h^n \,, \tag{72a(iii))}$$

$$R_2^h(\varphi) = -\sum_{n;i,j\in P} \Delta t w_i^n \Psi_{\delta,i}^{c,n}.w_j^n(\varphi_j^n - \varphi_i^n)A_{ij}^n + 2\sum_{n;i,j\in P} \Delta t w_i^n \varphi_i^n w_j^n \Psi_{\delta,i,ij}^{c,n}.A_{ij}^n, \tag{72b}$$

$$\begin{aligned} R_3^h(\varphi) = \sum_{n;i,j\in P} \Delta t w_i^n sign_\delta(u_i^{h,n+1})\varphi_i^n w_j^n (F(c,x_i,t^n) - F(c,x_{ij},t^n) \\ + F(c,x_j,t^n) - F(c,x_{ij},t^n)).A_{ij}^n, \end{aligned} \tag{72c}$$

$$R_4^h(\varphi) = R_{41}^h(\varphi) + R_{42}^h(\varphi), \tag{72d}$$

(72d(i))

$$\begin{aligned} R_{41}^h(\varphi) &= \sum_{n\geq 0} \Delta t \left((H_\delta(u^{h,n+1},.,t^n) - H_\delta(u^{h,n},.,t^n)), \nabla_h(\varphi^n) \right)_h^n \\ &+ \sum_{n\geq 0} \Delta t \left(sign_\delta(\tilde{u^h}^{n+1})(\mathrm{div}_{h,x}^* F(u^{h,n+1},.,t^n) - \mathrm{div}_{h,x}^* F(u^{h,n},.,t^n)), \varphi^n \right)_h^n \\ &- \sum_{n\geq 0} \Delta t \left(sign_\delta(\tilde{u^h}^{n+1})(S(u^{h,n+1},.,t^n) - S(u^{h,n},.,t^n)), \varphi^n \right)_h^n \\ &- \sum_{n\geq 0} \Delta t \left((\mathrm{div}_{h,x}^* H_\delta(u^{h,n+1},.,t^n) - \mathrm{div}_{h,x}^* H_\delta(u^{h,n},.,t^n)), \varphi^n \right)_h^n, \end{aligned}$$

$$\begin{aligned} R_{42}^h(\varphi) = \sum_{n\geq 0} \Delta t \Big((sign_\delta(u^{h,n+1}) - sign_\delta(\tilde{u^h}^{n+1})) \\ (\mathrm{div}_{h,x}^* F(u^{h,n+1},.,t^n) - S(u^{h,n+1},.,t^n)), \varphi^n \Big)_h^n, \end{aligned} \tag{72d(ii))}$$

$$R_5^h(\varphi) = R_{51}^h(\varphi) + R_{52}^h(\varphi) + R_{53}^h(\varphi) + R_{54}^h(\varphi) + R_{55}^h(\varphi) + R_{56}^h(\varphi), \tag{72e}$$

$$R_{51}^h(\varphi) = \sum_{n;i\in P} w_i^{n+1} |u_i^{h,n+1} - c|^\delta (\varphi_i^{n+1} - \varphi_i^n) - \int_Q |u^h - c|^\delta \frac{d\varphi}{dt} dxdt, \tag{72e(i))}$$

$$\begin{aligned} R_{52}^h(\varphi) = \sum_{n;i\in P} \int_{t^n}^{t^{n+1}} \int_{\Omega_i^n} H_\delta^c(u_i^{h,n+1},x,t).\nabla\varphi(x,t) \\ - H_\delta^c(u_i^{h,n+1},x_i,t^n).\nabla\varphi(x_i,t^n) dxdt, \end{aligned} \tag{72e(ii))}$$

(72e(iii)) $$R_{53}^h(\varphi) = \sum_{n,i\in P} \int_{t^n}^{t^{n+1}} \int_{\Omega_i^n} (u_i^{h,n+1} sign_\delta(u_i^{h,n+1}-c) - |u_i^{h,n+1}-c|^\delta) \\ (\mathrm{div}a(x,t)\varphi(x,t) - \mathrm{div}a(x_i,t^n)\varphi(x_i,t^n))dxdt,$$

(72e(iv)) $$R_{54}^h(\varphi) = \sum_{n\geq 0}\sum_i \int_{t^n}^{t^{n+1}} \int_{\Omega_i^n} (\varphi(x_i,t^n) sign_\delta(u_i^{h,n+1}-c) \\ - \varphi(x,t) sign_\delta(u^h(x,t)-c))\overline{\mathrm{div}}_h^* F(c,x,t)dxdt,$$

(72e(v)) $$R_{55}^h(\varphi) = \sum_{n;i\in P} \int_{t^n}^{t^{n+1}} \int_{\Omega_i^n} sign_\delta(u_i^{h,n+1}) S(u_i^{h,n+1},x_i,t^n)\varphi(x_i,t^n) \\ - sign_\delta(u_i^{h,n+1}) S(u_i^{h,n+1},x,t)\varphi(x,t)dxdt,$$

(72e(vi)) $$R_{56}^h(\varphi) = \sum_{i\in P} w_i^0 \varphi_i^0 |u_i^{h,0}-c|^\delta - \int_\Omega |u^h(x,0)-c|^\delta \varphi(x,0)dx.$$

The remainders R_i^h, $i=1,\dots,5$, are estimated as follows.

Remainder R_1^h:

- R_{11}^h: Since we chose $Q_{ij}^{\eta_\delta,n}$ to be antisymmetric, we rewrite $R_{11}^h(\varphi)$ as follows:

$$R_{11}^h(\varphi) = \frac{1}{2}\sum_{n\geq 0}\Delta t \sum_{i,j\in P} w_i^n w_j^n Q_{ij}^{\eta_\delta,n}(\varphi_i^n - \varphi_j^n)||A_{ij}^n||.$$

Let A and B be two real variables not depending on i and j. We have:

$$R_{11}^h(\varphi) = \frac{1}{2}\sum_{n\geq 0}\Delta t \sum_{i,j\in P} w_i^n w_j^n Q_{ij}^{\eta_\delta,n}(\varphi_i^n - \varphi_j^n + A - B)||A_{ij}^n||.$$

We know that $2h_{\delta,ij}^n = H_{\delta,i,ij}^n.n_{ij} + H_{\delta,j,ij}^n.n_{ij} - Q_{ij}^{\eta_\delta,n}$, and thus:

$$R_{11}^h(\varphi) = -\sum_{n\geq 0}\Delta t \sum_{i,j\in P} w_i^n w_j^n (h_{\delta,ij}^n - H_{\delta,i,ij}^n.n_{ij})(\varphi_i^n - \varphi_j^n + A - B)||A_{ij}^n|| \\ + \frac{1}{2}\sum_{n\geq 0}\Delta t \sum_{i,j\in P} w_i^n w_j^n (H_{\delta,i,ij}^n - H_{\delta,j,ij}^n)(\varphi_i^n - \varphi_j^n + A - B).A_{ij}^n \\ = R_{11}^{1,h}(\varphi) + R_{11}^{2,h}(\varphi).$$

We set $A = \inf_i \inf_{x\in\Omega_i}(\varphi(t,x)-\varphi(t,x_i))$ and $B = \sup_i \sup_{x\in\Omega_i}(\varphi(t,x) - \varphi(t,x_i))$.

- *Term* $R_{11}^{1,h}(\varphi)$: Let us recall the following inequality proved in [1]:

(73) $$h_e(n,u,v) - H(u,x,t).n \leq \eta'(u)(g(n,u,v) - F(u,x,t).n).$$

Since we have $-(\varphi_i^n - \varphi_j^n + A - B) \geq 0$, by applying (73), we get:

$$R_{11}^{1,h}(\varphi) \leq \frac{1}{2}\sum_{n\geq 0}\Delta t \sum_{i,j\in P} w_i^n w_j^n (\varphi_i^n - \varphi_j^n + A - B) \\ sign_\delta(u_i^{h,n}) \underbrace{(g_{ij}^n - F_{i,ij}^n.n_{ij})}_{=C_{ij}^n(u_i^{h,n}-u_j^{h,n})} ||A_{ij}^n||.$$

By using the Cauchy–Schwartz inequality and Proposition 4.2 of [10], one gets:

$$|R_{11}^{1,h}(\varphi)| \leq C(T, |\Omega|, u_0, F, S, a)||\nabla\varphi||_\infty h^{\frac{1}{2}}. \tag{74}$$

– *Term* $R_{11}^{2,h}(\varphi)$: Since $A_{ij}^n = -A_{ji}^n$, and knowing that $|B-A| \leq ||\nabla\varphi||_\infty h$:

$$\begin{aligned}|R_{11}^{2,h}(\varphi)| \leq\ & ||\nabla\varphi||_{L^\infty(Q)} h \sum_{n;i\in P} \Delta t w_i^n \\ & \left(\sup_{v;||v||_\infty \leq C_\infty} ||H_\delta(v,.,.)||_\infty \left| \sum_{j\in P} w_j^n A_{ij}^n \right| \right. \\ & \left. + \sup_{v;||v||_\infty \leq C_\infty} ||\mathrm{div}_x H_\delta(v,.,.)||_\infty \sum_{j\in P} w_j^n |x_i - x_{ij}|\ |A_{ij}^n| \right).\end{aligned}$$

From (14), (23), and the regularity of F (2), we get:

$$|R_{11}^{2,h}(\varphi)| \leq C(F, u_0, a, S, \Omega, T)||\nabla\varphi||_\infty h. \tag{75}$$

- R_{12}^h: We have

$$R_{12}^h(\varphi) = \sum_{n\geq 0} \Delta t \sum_i w_i^n \sum_{j\in P} w_j^n (H_{\delta,i}^n - H_{\delta,i,ij}^n).(\varphi_i^n - \varphi_j^n) A_{ij}^n.$$

From (14), (23), and the regularity of F (2), one gets:

$$\begin{aligned}|R_{12}^h(\varphi)| &\leq C \sup_{v;|v|\leq C(u_0)} ||\mathrm{div}_x H_\delta(v,.,.)||_\infty ||\nabla\varphi||_\infty h \\ &\leq C(u_0, F, S, a, T, \Omega)||\nabla\varphi||_\infty h.\end{aligned} \tag{76}$$

- R_{13}^h: By using (8), (23), and the regularity of φ and F (2), one gets:

$$|R_{13}^h(\varphi)| \leq C(u_0, F, S, a, T, \Omega)||D^2\varphi||_{L^\infty(Q)} h. \tag{77}$$

- *Conclusion for* $R_1^h(\varphi)$: From (74), (75), (76), and (77), one gets:

$$\underline{|R_1^h(\varphi)| \leq C(u_0, F, S, a, T, \Omega) \left(||\varphi||_{L^\infty([0,T], C_c^1(\Omega))} \sqrt{h} + ||\varphi||_{L^\infty([0,T], C_c^2(\Omega))} h \right).} \tag{78}$$

Remainder R_2^h: This remainder is bounded by using inequalities (21):

$$|R_2^h(\varphi)| \leq \left(\sup_{u;||u||\leq C} ||C_{\Psi(u)}||_\infty(Q) + \sup_{u;||u||\leq C} ||C'_{\Psi(u)}||_\infty \right) C|\Omega|T(2||\varphi||_\infty + ||\nabla\varphi||_\infty)\delta. \tag{79}$$

Since u^h is L^∞ stable and $c = u^\epsilon$ is also bounded in $\mathbb{R}$ by a constant depending on u_0, $\sup_{u;||u||\leq C} ||C_{\Psi(u)}||_\infty$ and $\sup_{u;||u||\leq C} ||C'_{\Psi(u)}||_\infty$ are both bounded by $C(u_0, F, S, a, \Omega, T)$. Consequently:

$$\underline{|R_2^h(\varphi)| \leq C(u_0, F, S, a, T, \Omega)(||\varphi||_\infty + ||\nabla\varphi||_\infty)\delta.} \tag{80}$$

Remainder R_3^h: By using (14) and the regularity of F (2), one gets:

$$\underline{|R_3^h(\varphi)| \leq C(u_0, F, S, a, T, \Omega)||\nabla\varphi||_\infty h.} \tag{81}$$

Remainder R_4^h:

- *Term* $R_{41}^h(\varphi)$: From the regularity (2) on F, S, and thus H_δ, we have:

$$|R_{41}^h(\varphi)| \leq \left\{ \left(\sup_{u;||u||\leq C} ||\partial_u H_\delta(u,.,.)||_\infty + \sup_{u;||u||\leq C} ||\partial_u \mathrm{div} H_\delta(u,.,.)||_\infty \right) ||\nabla\varphi||_\infty \right.$$
$$+ \left(||sign_\delta||_\infty (\sup_{u;||u||\leq C} ||\partial_u F(u,.,.)||_\infty + \sup_{u;||u||\leq C} ||\partial_u \mathrm{div} F(u,.,.)||_{L^\infty(Q)} \right.$$
$$\left. \left. + \sup_{u;||u||\leq C} ||\partial_u S(u,.,.)||_{L^\infty(Q)}) \right) \ ||\varphi||_{L^\infty(Q)} \right\} \sum_{n;i\in P} \Delta t w_i^n |u_i^{h,n+1} - u_i^{h,n}| \ .$$

From Proposition 4.3 of [10] and (23), we get $|R_{41}^h(\varphi)| \leq C(F,S,a,u_0,T,\Omega)$ $(||\varphi||_\infty + ||\nabla\varphi||_\infty)(h+\sqrt{h})$.

- *Term* $R_{42}^h(\varphi)$: By using the finite increases theorem, we have:

$$|R_{42}^h(\varphi)| \leq 2C \left(\sup_{u;||u||\leq C} ||F(u,.,.)||_\infty + \sup_{u;||u||\leq C} ||\nabla_x F(u,.,.)||_\infty \right.$$
$$\left. + \sup_{u;||u||\leq C} ||S(u,.,.)||_\infty \right) ||\varphi||_\infty ||(sign_\delta)'||_{L^\infty(\mathbb{R})} \sum_n \Delta t \sum_{i\in P} w_i^n |\tilde{u^h}_i^{n+1} - u_i^{h,n+1}|.$$

From Propositions 4.2 and 4.3 in [10], we get:

$$|R_{42}^h(\varphi)| \leq C(u_0,F,S,a,T,\Omega)||\varphi||_\infty \frac{h}{\delta}. \tag{82}$$

- *Conclusion for* $R_4^h(\varphi)$: Estimates on $R_{41}^h(\varphi)$ and $R_{42}^h(\varphi)$ finally lead to:

$$|R_4^h(\varphi)| \leq C(F,S,a,u_0,T,\Omega) \left(||\varphi||_\infty \left(h + \sqrt{h} + \frac{h}{\delta} \right) + ||\nabla\varphi||_\infty (h+\sqrt{h}) \right). \tag{83}$$

Remainder R_5^h: Each term of R_5^h is estimated by using Lemma A.1 given in the appendix of [9, page 293].

- $R_{51}^h(\varphi)$, $R_{52}^h(\varphi)$, $R_{53}^h(\varphi)$, $R_{55}^h(\varphi)$:

$$R_{51}^h(\varphi) = \sum_{n;i\in P} \Delta t \omega_i J_i^{n+1} |u_i^{h,n+1} - c|^\delta \frac{(\varphi_i^{n+1} - \varphi_i^n)}{\Delta t} - \int_Q J(\xi,t)|u^h(x,t) - c|^\delta \frac{d\varphi}{dt} d\xi dt$$
$$= \sum_{n;i\in P} \int_{t^n}^{t^{n+1}} \int_{\Omega_i} J_i^{n+1} |u^h(x,t) - c|^\delta \frac{(\varphi_i^{n+1} - \varphi_i^n)}{\Delta t} - J(\xi,t)|u^h(x,t) - c|^\delta \frac{d\varphi}{dt} d\xi dt$$
$$\leq ||u^h||_\infty \sum_{n;i\in P} \int_{t^n}^{t^{n+1}} \int_{\Omega_i} \left| J_i^{n+1} \frac{(\varphi_i^{n+1} - \varphi_i^n)}{\Delta t} - J(\xi,t) \frac{d\varphi}{dt} \right| d\xi dt,$$

$J(\xi,t)$ being the Jacobian of the transformation into Lagrangian coordinates. We can now use Lemma A.1 of [9] with $b \leftarrow J$ and $\varphi \leftarrow \varphi$:

$$|R_{51}^h(\varphi)| \leq C_2 ||J||_{C^1(Q)} ||\varphi||_{C^2(Q)} (\Delta t + h) \leq C(u_0,F,S,a,T,|\Omega|)||\varphi||_{C^2(Q)} h. \tag{84}$$

By using a similar method, we get:

$$|R_{52}^h(\varphi)| \leq C_3||J||_{C^1}||H_\delta^c \nabla\varphi||_{C^1} \leq C(u_0, F, S, a, T, |\Omega|)||\varphi||_{C^1(Q)}h, \tag{85}$$

$$|R_{53}^h(\varphi)| \leq C(u_0, F, S, a, T, |\Omega|)||\varphi||_{C^1(Q)}h, \tag{86}$$

$$|R_{55}^h(\varphi)| \leq C(u_0, F, S, a, T, \Omega)||\varphi||_{C^1(Q)}h. \tag{87}$$

- $R_{54}^h(\varphi)$: We split this term into two parts:

$$\begin{aligned} R_{54}^h(\varphi) = &\sum_{n;i\in P}\int_{t^n}^{t^{n+1}}\int_{\Omega_i^n}\varphi(x_i,t^n)(sign_\delta(u_i^{h,n+1}-c)-sign_\delta(u^h(x,t)-c)) \\ &\overline{\mathrm{div}_h^*}F(c,x,t)dxdt + \sum_{n;i\in P}\int_{t^n}^{t^{n+1}}\int_{\Omega_i^n}(\varphi(x_i^n,t^n) \\ &-\varphi(x,t))sign_\delta(u^h(x,t)-c)\overline{\mathrm{div}_h^*}F(c,x,t)dxdt. \end{aligned} \tag{88}$$

Since $\overline{\mathrm{div}_h^*}F(c,x,t)$ is bounded, one can prove, by using the definition of u_h (13), that:

$$\begin{aligned} &\left|\sum_{n;i\in P}\int_{t^n}^{t^{n+1}}\int_{\Omega_i^n}\varphi(x_i,t^n)(sign_\delta(u_i^{h,n+1}-c)\right. \\ &\qquad\left.-sign_\delta(u^h(x,t)-c))\overline{\mathrm{div}_h^*}F(c,x,t)dxdt\right| \\ &\leq C(F,u_0)||\varphi||_\infty\sum_{n;i\in P}\int_{t^n}^{t^{n+1}}\int_{\Omega_i}J_i^n|sign_\delta(u_i^{h,n+1}-c)-sign_\delta(u^h(x,t)-c)|dxdt \\ &\leq C(F,u_0)||\varphi||_\infty||sign_\delta||_{L^\infty(\mathbb{R})}\sum_{n;i\in P}\int_{t^n}^{t^{n+1}}\int_{\Omega_i}\|J_i^n-J_i^{n+1}|dxdt \\ &\leq C(u_0,F,a,T,\Omega)||\varphi||_\infty h. \end{aligned}$$

By using Lemma A.1 of [9] with $b \leftarrow J$, $\varphi \leftarrow \varphi$ for the second integral of (89), we get:

$$|R_{54}^h(\varphi)| \leq C(u_0, F, S, a, T, \Omega)||\varphi||_{C_c^1(Q)}h. \tag{89}$$

- $R_{56}^h(\varphi)$:

$$|R_{56}^h(\varphi)| \leq \sum_{i\in P}|u_i^{h,0}-c|\left|\int_{\Omega_i}\varphi(\xi_i,0)-\varphi(\xi,0)d\xi\right| \leq C(u_0)||\nabla_x\varphi(0,.)||_{L^\infty(\Omega)}h. \tag{90}$$

- *Conclusion for* $R_5^h(\varphi)$: By using (84), (85), (86), (89), (87), and (90), we finally get

$$\underline{|R_5^h(\varphi)| \leq C(u_0, F, S, a, T, |\Omega|)||\varphi||_{C_c^2(Q)}h.} \tag{91}$$

Conclusion for μ_h: There exist $C(u_0, F, S, a, T, \Omega)$ such that:

$$\begin{aligned}\langle \mu_h, \varphi(.,y,.,s)\rangle \leq C \Big(& ||\varphi(.,y,.,s)||_{C^2(Q)} h + ||\varphi(.,y,.,s)||_{L^\infty([0,T];C^1(\Omega)} \sqrt{h} \\ & + ||\varphi(.,y,.,s)||_{L^\infty([0,T];C^1(\Omega))} \delta + ||\varphi(.,y,.,s)||_\infty \frac{h}{\delta} \Big).\end{aligned} \tag{92}$$

By integrating the previous inequality over y and s, and using the properties 6.134 in [9] and the upper bounds 6.89 in [9] of the chosen test function φ, one gets:

$$\boxed{\int_{\tilde{Q}} \langle \mu_h, \varphi(.,y,.,s)\rangle dyds \leq \mathcal{C} \left(h + \sqrt{h} + \delta + \gamma + \frac{\sqrt{h}}{\gamma} + \frac{h}{\gamma} + \frac{h}{\gamma^2} + \frac{h}{\delta} + \frac{\delta}{\gamma} \right).} \tag{93}$$

A.2. Measure ν_ϵ.

$$\langle \nu_\epsilon, \varphi\rangle = R_1^\epsilon(\varphi) + R_2^\epsilon(\varphi) + R_3^\epsilon(\varphi), \tag{94}$$

$$R_1^\epsilon(\varphi) = \epsilon \int_{\tilde{Q}} \nabla(sign_\delta(u^\epsilon)\nabla u^\epsilon)\varphi dyds, \tag{94a}$$

$$R_2^\epsilon(\varphi) = \int_{\tilde{Q}} \Psi_\delta^c.\nabla\varphi + \mathrm{div}\Psi_\delta^c \varphi dyds, \tag{94b}$$

$$\begin{aligned} R_3^\epsilon = & \int_{\tilde{Q}} \varphi(y,s) sign_\delta(u^\epsilon(y,s)) \overline{\mathrm{div}_h^*} F(c,y,s) dyds \\ & + \int_{\tilde{Q}} F(c,y,s).\nabla(\varphi sign_\delta(u^\epsilon)) dyds. \end{aligned} \tag{94c}$$

We now denote that $||D\varphi|| = ||D\varphi(x,.,t,.)||$ for any operator D and any norm.

Remainder R_1^ϵ: From the estimates (Lemma 4.1) on u^ϵ, we get:

$$\begin{aligned} \underline{|R_1^\epsilon(\varphi)|} & \leq \epsilon ||sign_\delta||_\infty ||\nabla\varphi||_\infty \sup_{t\in[0,T]} ||\nabla u^\epsilon(.,t)||_{L^1(\Omega)} \\ & \leq \underline{C(u_0,F,S,a,T,\Omega)||\nabla\varphi||_\infty \epsilon}. \end{aligned} \tag{95}$$

Remainder R_2^ϵ: We use similar arguments to estimate R_2^ϵ and get:

$$\underline{|R_2^\epsilon(\varphi)| \leq C(u_0,F,S,a,T,\Omega)(||\varphi||_\infty + ||\nabla\varphi||_\infty)\delta}. \tag{96}$$

Remainder R_3^ϵ: We split this remainder into $R_3^\epsilon = R_{31}^\epsilon + R_{32}^\epsilon + R_{33}^\epsilon + R_{34}^\epsilon$ with

$$\begin{aligned} R_{31}^\epsilon = & \sum_{n;i\in P} \int_{t^n}^{t^{n+1}} \int_{\Omega_i^n} (\varphi(y,s) \\ & sign_\delta(u^\epsilon(y,s)) - \varphi(x_i^n,t^n) sign_\delta(u^\epsilon(x_i^n,t^n))) \overline{\mathrm{div}_h^*} F(c,y,s) dyds, \\ R_{32}^\epsilon = & -\sum_{n;i\in P} \int_{t^n}^{t^{n+1}} \int_{\Omega_i^n} (F(c,x_i^n,t^n) - F(c,y,s)).\nabla_h(\varphi sign_\delta(u^\epsilon))(x_i^n,t^n) dyds, \\ R_{33}^\epsilon = & -\sum_{n;i\in P} \int_{t^n}^{t^{n+1}} \int_{\Omega_i^n} F(c,y,s).(\nabla_h(\varphi \\ & sign_\delta(u^\epsilon))(x_i^n,t^n) - \nabla(\varphi sign_\delta(u^\epsilon))(x_i^n,t^n)) dyds, \\ R_{34}^\epsilon = & -\sum_{n;i\in P} \int_{t^n}^{t^{n+1}} \int_{\Omega_i^n} F(c,y,s).(\nabla(\varphi sign_\delta(u^\epsilon))(y,s) - \nabla(\varphi sign_\delta(u^\epsilon))(x_i^n,t^n)) dyds. \end{aligned}$$

- *Estimate of* R_{31}^{ϵ}: The remainder R_{31}^{ϵ} is bounded by:

$$|R_{31}^{\epsilon}| \leq ||F||_{\infty} Ch \Big(||sign_{\delta}||_{\infty} (||\nabla \varphi||_{\infty} + ||\partial_s \varphi||_{\infty}) + ||\varphi||_{\infty} ||sign'_{\delta}||_{\infty} (||\partial_t u^{\epsilon}||_{L^1(\tilde{Q})} + ||\nabla u^{\epsilon}||_{L^1(\tilde{Q})}) \Big),$$

which leads to, by considering the estimates on u^{ϵ} (4.1) and (4.2):

$$|R_{31}^{\epsilon}| \leq C(u_0, F, S, a, T, \Omega)(||\nabla \varphi||_{\infty} + ||\partial_s \varphi||_{\infty} + ||\varphi||_{\infty})h. \tag{97}$$

- *Estimate of* R_{32}^{ϵ}: One can prove, by using estimates (4.1) and (4.2) that

$$|R_{32}^{\epsilon}| \leq \left(\sup_{v, |v| \leq C(u_0)} ||\nabla F(v, ., .)||_{\infty} + \sup_{v, |v| \leq C(u_0)} ||\partial_t F(v, ., .)||_{\infty} \right) Ch \left| \int_0^T \int_{\Omega} \nabla_h (\varphi sign_{\delta}(u^{\epsilon}))(y, s) dy ds \right| \leq C(u_0, F, S, a, \Omega, T) h ||\nabla \varphi||_{L^{\infty}([0,T]; C_c^1(\Omega))}. \tag{98}$$

- *Estimate of* R_{33}^{ϵ}: Using Proposition 4.2, one can deduce that

$$|R_{33}^{\epsilon}| \leq C||F^c||_{\infty} ||D^2(\varphi sign_{\delta}(u^{\epsilon}))||_{\infty} h. \tag{99}$$

By using (4.1) and (4.2), $\exists C = C(u_0, F, S, a, T, \Omega)$ such that (s.t.):

$$|R_{33}^{\epsilon}| \leq Ch \left(||D^2 \varphi||_{\infty} + \frac{1}{\delta \epsilon^{\frac{1}{2}}} ||\nabla \varphi||_{\infty} + ||\varphi||_2 \frac{1}{\epsilon^{\frac{5}{2}} \delta} + ||\varphi||_{\infty} \frac{1}{\epsilon^3 \delta^2} \right). \tag{100}$$

- *Estimate of* R_{34}^{ϵ}: By taking the $W^{1,\infty}$ of $\nabla(\varphi sign_{\delta}(u^{\epsilon}))$, one gets:

$$|R_{34}^{\epsilon}| \leq h||F^c||_{\infty} ||D^2(\varphi sign_{\delta}(u^{\epsilon}))||_{\infty}. \tag{101}$$

We thus obtain the same upper bound as for the remainder R_{33}^{ϵ}.

Conclusion for $\boldsymbol{\nu_{\epsilon}}$: There exist $C = C(u_0, F, S, a, T, \Omega)$ such that:

$$\langle \nu_{\epsilon}, \varphi(x, ., t, .) \rangle \leq C \Bigg((||\varphi(x, ., t, .)||_{C_c^1(\tilde{Q})} + ||D_y^2 \varphi(x, ., t, .)||_{\infty})h + ||\varphi(x, ., t, .)||_{L^{\infty}([0, T+\gamma]; C_c^1(\tilde{\Omega}))} \left(\epsilon + \delta + \frac{h}{\delta \epsilon^{\frac{1}{2}}} \right) + ||\varphi(x, ., t, .)||_{\infty} \left(\frac{h}{\delta \epsilon^{\frac{5}{2}}} + \frac{h}{\delta^2 \epsilon^3} \right) \Bigg). \tag{102}$$

By integrating the previous inequality over x and t, and using the properties 6.134 in [9] and the upper bounds 6.89 in [9] of the chosen test function φ, one gets:

$$\boxed{\int_Q \langle \nu_{\epsilon}, \varphi(x, ., t, .) \rangle dx dt \leq \mathcal{C} \left(\delta + h + \frac{\delta}{\gamma} + \frac{\epsilon}{\gamma} + \frac{h}{\gamma} + \frac{h}{\gamma^2} + \frac{h}{\delta \gamma \epsilon^{\frac{1}{2}}} + \frac{h}{\delta \epsilon^{\frac{5}{2}}} + \frac{h}{\epsilon^3 \delta^2} \right).} \tag{103}$$

A.3. Measure λ. The remainders of λ are defined by:

$$\langle \lambda, \varphi \rangle = \sum_{i=1}^{10} R_i^c(\varphi) + R^{c,L^1}(\psi), \tag{104}$$

$$R_1^c(\varphi) = \int_{Q\times\tilde{Q}} \left(|u^h(x,t) - u^\epsilon(y,s)| - |u^h(x,t) - u^\epsilon(y,s)|^\delta \right) \psi_t(t,x)\zeta^\gamma(x-y)\bar{\zeta}^\gamma(t-s)dxdydsdt, \tag{104a}$$

$$R_2^c(\varphi) = \int_{Q\times\tilde{Q}} \left(|u^h(x,t) - u^\epsilon(y,s)| - |u^h(x,t) - u^\epsilon(y,s)|^\delta \right) a(x,t) .\nabla\psi(t,x)\zeta^\gamma(x-y)\bar{\zeta}^\gamma(t-s)dxdydsdt, \tag{104b}$$

$$R_3^c(\varphi) = \int_{Q\times\tilde{Q}} |u^h(x,t) - u^\epsilon(y,s)|^\delta (\mathrm{div}a(y,s) - \mathrm{div}a(x,t)) \psi(t,x)\zeta^\gamma(x-y)\bar{\zeta}^\gamma(t-s)dxdydtds, \tag{104c}$$

$$R_4^c(\varphi) = 2\int_{Q\times\tilde{Q}} \left(|u^h(x,t) - u^\epsilon(y,s)|^\delta - |u^h(x,t) - u^\epsilon(y,s)| \right) \mathrm{div}a(x,t) \psi(t,x)\zeta^\gamma(x-y)\bar{\zeta}^\gamma(t-s)dxdydtds, \tag{104d}$$

$$R_5^c(\varphi) = \int_{Q\times\tilde{Q}} sign_\delta(u^h(x,t) - u^\epsilon(y,s))u^\epsilon(y,s)(\mathrm{div}(x,t) - \mathrm{div}(y,s)) \psi(t,x)\zeta^\gamma(x-y)\bar{\zeta}^\gamma(t-s)dxdydtds, \tag{104e}$$

$$R_6^c(\varphi) = \int_{Q\times\tilde{Q}} sign_\delta(u^h(x,t) - u^\epsilon(y,s)) \left(\overline{\mathrm{div}_x^{h,*}} F(u^h(x,t),x,t) - \overline{\mathrm{div}_x^{h,*}} F(u^h(x,t),y,s) \right) \psi(t,x)\zeta^\gamma(x-y)\bar{\zeta}^\gamma(t-s)dxdydtds, \tag{104f}$$

$$R_7^c(\varphi) = \int_{Q\times\tilde{Q}} sign_\delta(u^h(x,t) - u^\epsilon(y,s)) \left(S(u^\epsilon(y,s),y,s) - S(u^\epsilon(y,s),x,t) \right) \psi(t,x)\zeta^\gamma(x-y)\bar{\zeta}^\gamma(t-s)dxdydtds, \tag{104g}$$

$$R_8^c(\varphi) = \int_{\Omega\times\tilde{Q}} \left(|u^h(x,0) - u^\epsilon(y,s)|^\delta - |u^h(x,0) - u^\epsilon(y,s)| \right) \psi(x,0)\zeta^\gamma(x-y)\bar{\zeta}^\gamma(s)dxdyds, \tag{104h}$$

$$R_9^c(\varphi) = \int_{Q\times\tilde{Q}} (1 + C_\psi(T-t)) \left(|u^h(x,t) - u^\epsilon(y,s)| - |u^h(x,t) - u^\epsilon(x,t)| \right) \psi(t,x)\zeta^\gamma(x-y)\bar{\zeta}^\gamma(t-s)dxdydsdt, \tag{104i}$$

$$R_{10}^c(\varphi) = \int_{\Omega\times\tilde{Q}} (|u^h(x,0) - u^\epsilon(y,s)| - |u^h(x,0) - u^\epsilon(x,0)|) \psi(0,x)\zeta^\gamma(x-y)\bar{\zeta}^\gamma(s)dxdyds, \tag{104j}$$

$$R^{c,L^1}(\psi) = \int_{Q\times\tilde{Q}} |u^\epsilon(x,t) - u^\epsilon(y,s)| \, |\psi(t,x)| \chi_{[-\gamma,0]}(t-s)\chi_{B(0,\gamma)}(x-y)dydsdxdt. \tag{104k}$$

Remainder $R_1^c(\varphi)$, $R_2^c(\varphi)$, $R_4^c(\varphi)$, $R_8^c(\varphi)$: From (20), $|\,|u|^\delta - |u|\,| \le C\delta$. Thus:

$$|R_1^c(\varphi)| \le C(u_0,F,S,a,T,\Omega)\delta||\partial_t\psi||_\infty, \tag{105}$$

$$\underline{|R_2^c(\varphi)| \le C(u_0,F,S,a,T,\Omega)\delta||\nabla\psi||_\infty}, \tag{106}$$

$$|R_4^c(\varphi)| \le C(u_0,F,S,a,T,\Omega)\delta||\psi||_\infty, \tag{107}$$

$$\underline{|R_8^c(\varphi)| \le C(u_0)\delta||\psi(.,0)||_{L^1(\Omega)} \le C(u_0)|\Omega|\delta||\psi(.,0)||_{L^\infty(\Omega)}}. \tag{108}$$

Remainder $R_3^c(\varphi)$: From hypothesis (2), Proposition 4.2 of [10], and Lemma 4.1, we have:

$$\begin{aligned}|R_3^c(\varphi)| &\leq (||\partial_t \mathrm{div} a||_\infty + ||\nabla_x \mathrm{div} a||_\infty)\,(||u^\epsilon||_\infty + ||u^h||_\infty)\gamma||\psi||_{L^1(Q)} \\ &\leq C(u_0, F, S, a, T, \Omega)\gamma||\psi||_\infty.\end{aligned} \tag{109}$$

Remainder $R_5^c(\varphi)$: From hypothesis (2) for a and Lemma 4.1 for u^ϵ, we get:

$$|R_5^c(\varphi)| \leq C(u_0, F, S, a, T, \Omega)\gamma||\psi||_\infty. \tag{110}$$

Remainder $R_6^c(\varphi)$: We prove in [9, page 218] that $\overline{\mathrm{div}^*_{h,x}}F$ is Lipschitz with respect to x and t:

$$|\overline{\mathrm{div}^*_{h,x}}F(u^h(x,t),x,t) - \overline{\mathrm{div}^*_{h,x}}F(u^h(x,t),y,s)| \leq C(|t^m - t^n| + |x_i - x_k| + O(h))$$

$$\begin{aligned}\Rightarrow |R_6^c(\varphi)| &\leq C\sum_{n,m}\int_{t^n}^{t^{n+1}}\int_{s^m}^{s^{m+1}}\sum_{i,k}\int_{\Omega_i}\int_{\Omega_k}|\psi(x,t)|\zeta^\gamma(x-y)\zeta^\gamma(t-s) \\ &\qquad (|t^m - t^n| + |x_i - x_k| + O(h))dxdydtds \\ &\leq C(u_0, F, S, a, T, \Omega)(h+\gamma)||\psi||_\infty.\end{aligned} \tag{111}$$

The last upper bound comes from: If $x \in \Omega_i$ and $y \in \Omega_k$, then $|x_i - x_k| \leq |x_i - x| + |x - y| + |y - x_k|$.

Remainder $R_7^c(\varphi)$: From hypothesis (2) for S, we have:

$$\begin{aligned}&|R_7^c(\varphi)| \leq ||sign_\delta||_\infty||\psi||_1(\sup_{c;||c||\leq C}\{||\mathrm{div}_x S(c,.,.)||_\infty\} \\ &+\sup_{c;||c||\leq C}\{||\partial_t S(c,.,.)||_\infty\})\gamma \leq C(u_0, F, S, a, T, \Omega)\gamma||\psi||_\infty.\end{aligned} \tag{112}$$

Remainders $R_9^c(\varphi)$ and $R^{c,L^1}(\psi)$: From the definition of the functions ζ and $\bar{\zeta}$ and the fact that $C_\psi = C(u_0, T, \Omega, S, F, a)$, $R_9^c(\varphi)$ and $R^{c,L^1}(\psi)$ are linked by:

$$|R_9^c(\varphi)| \leq C(u_0, T, \Omega, S, F, a)R^{c,L^1}(\psi). \tag{113}$$

By using the regularity of u^ϵ in Lemma 4.1, one gets:

$$\begin{aligned}&\int_{Q\times\bar{Q}}|\varphi(x,y,t,s)|\;|u^\epsilon(y,s) - u^\epsilon(x,t)|dxdydsdt \\ &\leq C||\psi||_\infty\int_{Q\times\bar{Q}}\int_0^1\sup_{|\tau_x|\leq\gamma}(|\nabla_x u^\epsilon(x+\tau_x, t+\theta(s-t))|\;|x-y| \\ &\qquad + |\partial_t u^\epsilon(x+\tau_x, t+\theta(s-t))|\;|t-s|)d\theta \\ &\qquad \chi_{[-\gamma,0]}(t-s)\chi_{B(0,\gamma)}(x-y)dxdydtds.\end{aligned}$$

Let τ_x^0 be the value for which the sup value is reached, and we then can bound by L^1 norms of ∇u^ϵ and $\partial_t u^\epsilon$:

$$R^{c,L^1}(\psi) \leq C||\psi||_\infty\gamma\int_0^T(||\nabla_x u^\epsilon(.,t+\tau_t)||_{L^1(\tilde{\Omega})} + ||\partial_t u^\epsilon(.,t+\tau_t)||_{L^1(\tilde{\Omega})})dt,$$

where $t + \tau_t$ is between 0 and $T + \gamma$, so that we can use estimates (4.1) and get:

$$\underline{R^{c,L^1}(\psi) \leq C(u_0, F, S, a, T, \Omega)\gamma||\psi||_\infty.} \tag{114}$$

Remainder $R_{10}^c(\varphi)$: We first have

$$|R_{10}^c(\varphi)| \leq C \int_{Q\times\tilde{Q}} |u^\epsilon(y,s) - u^\epsilon(x,0)|\ |\psi(x,0)| \chi_{[-\gamma,0]}(-s)\chi_{B(0,\gamma)}(x-y)dxdyds. \tag{115}$$

We then proceed exactly as for the remainder R^{c,L^1} with $t=0$, and we get:

$$\underline{|R_{10}^c(\varphi)| \leq C(u_0,F,S,a,\Omega)\gamma||\psi||_\infty.} \tag{116}$$

A.3.1. Conclusion for λ. From (106), (107), (109), (108), (110), (111), (112), (113), (116), (114), and the upper bounds on the norms of ψ 6.89 in [9], we get:

$$\boxed{\langle \lambda, \varphi\rangle \leq C(u_0,F,S,a,T,\Omega)\left(\delta+\gamma+h+\frac{h}{\gamma}+\frac{h}{\gamma^2}\right).} \tag{117}$$

Appendix B. L^1 terms.

$$T_{L^1} = T_2 + T_5 + T_6' + T_7' + T_8' + T_9', \tag{118}$$

$$\begin{aligned} T_2 = \int_{Q\times\tilde{Q}} & |u^h(x,t) - u^\epsilon(y,s)|^\delta (a(x,t)-a(y,s)).\psi(t,x) \\ & \nabla\zeta^\gamma(x-y)\bar{\zeta}^\gamma(t-s)dxdydsdt, \end{aligned} \tag{118a}$$

$$\begin{aligned} T_5 = \int_{Q\times\tilde{Q}} & sign_\delta(u^h(x,t)-u^\epsilon(y,s))\left(F(u^h(x,t),x,t)\right. \\ & \left. - F(u^h(x,t),y,s)\right).\psi(t,x)\nabla_x\zeta^\gamma(x-y)\bar{\zeta}^\gamma(t-s) \\ & + sign_\delta(u^h(x,t)-u^\epsilon(y,s))\left(F(u^\epsilon(y,s),y,s)\right. \\ & \left. - F(u^\epsilon(y,s),x,t)\right)\psi(t,x).\nabla_x\zeta^\gamma(x-y)\bar{\zeta}^\gamma(t-s)dxdydtds, \end{aligned} \tag{118b}$$

$$T_6' = 2\int_{Q\times\tilde{Q}} |u^h(x,t)-u^\epsilon(y,s)|\mathrm{div}a(x,t)\psi(t,x)\zeta^\gamma(x-y)\bar{\zeta}^\gamma(t-s)dxdydtds, \tag{118c}$$

$$\begin{aligned} T_7' = \int_{Q\times\tilde{Q}} & sign_\delta(u^h(x,t)-u^\epsilon(y,s))(u^h(x,t)-u^\epsilon(y,s))\mathrm{div}a(x,t) \\ & \psi(t,x)\zeta^\gamma(x-y)\bar{\zeta}^\gamma(t-s)dxdydtds, \end{aligned} \tag{118d}$$

$$\begin{aligned} T_8' = \int_{Q\times\tilde{Q}} & sign_\delta(u^h(x,t)-u^\epsilon(y,s))\left(\overline{\mathrm{div}^*_{h,x}}F(u^\epsilon(y,s),x,t)\right. \\ & \left. - \overline{\mathrm{div}^*_{h,x}}F(u^h(x,t),x,t)\right)\psi(t,x)\zeta^\gamma(x-y)\bar{\zeta}^\gamma(t-s)dxdydtds, \end{aligned} \tag{118e}$$

$$\begin{aligned} T_9' = \int_{Q\times\tilde{Q}} & sign_\delta(u^h(x,t)-u^\epsilon(y,s))\left(S(u^\epsilon(y,s),x,t)\right. \\ & \left. - S(u^h(x,t),x,t)\right)\psi(t,x)\zeta^\gamma(x-y)\bar{\zeta}^\gamma(t-s)dxdydtds. \end{aligned} \tag{118f}$$

Appendix C. Table of symbols.

Notations	Definitions
P, d	Set of particles, space dimension (section 2)
$\Omega_i(t),\ w_i(t),\ \ i \in P$	Particle volumes and weights at time t (section 2)
$h,\ \varepsilon$	Characteristic distance between particles—smoothing length (section 2)
$\left(A_{ij}^n\right), B_i^n$	Shape vector (6), renormalization matrices (7)
D_h, D_h^*	Derivative approximation operator (5) and its adjoint
$\eta(u), \eta_\delta(u), \delta$	Entropy function, regularized Kruskov entropy (18), and reg. parameter
u	Exact solution of the conservation law (1)
u^ϵ,ϵ	Solution of the pseudoviscous problem (27) and reg. parameter
u^h	Solution of the numerical scheme (9), (13)
$a, F(v,x,t), S(v,x,t), u_0(x)$	Transport, flux, source, and initial condition of the conservation law (1)
L_a, L_a^*	Transport operator and its adjoint
$n(x),\ n_{ij}$	Normal vector, normal vector from i to j
$g(n(x),u,v), Q(n(x),u,v)$	Numerical flux and viscosity of the scheme
$\Delta t,\ \overline{\Delta x_i^n}$	Time step—mean distance between i and its neighbors (12)
$h_e(n(x),u,v), h_\delta$	Entropic numerical flux (17) and Kruskov entropic numerical flux
$H(u,x,t),\ H_\delta,\ H_\delta^c,\ \Psi_\delta^c$	General entropy flux and regularized Kruskov entropy flux (19)
$Q^\eta(n(x),u,v), Q^{\eta_\delta}$	Entropic numerical viscosity and Kruskov entropic numerical viscosity (see (17))
$\mu_h,\ R^h$	Measure and remainders related to u^h entropy inequality
$\nu_\epsilon,\ R^\epsilon$	Measure and remainders related to u^ϵ entropy inequality
$\lambda,\ \lambda_1,\ R^c$	Measures and remainders due to the comparison of u^h and u^ϵ entropy inequalities
$\varphi,\ \psi,\ \zeta,\ \bar{\zeta},\ \Omega,\ T,\ \gamma$	Test function and its parameters (Definition 6.1)

A FAST FOURIER–GALERKIN METHOD FOR SOLVING SINGULAR BOUNDARY INTEGRAL EQUATIONS*

HAOTAO CAI† AND YUESHENG XU‡

Abstract. We propose in this paper a convenient way to compress the dense matrix representation of a compact integral operator with a smooth kernel under the Fourier basis. The compression leads to a sparse matrix with only $\mathcal{O}(n \log n)$ nonzero entries, where $2n$ or $2n+1$ denotes the order of the matrix. Based on this compression strategy, we develop a fast Fourier–Galerkin method for solving a class of singular boundary integral equations. We prove that the fast Fourier–Galerkin method gives the optimal convergence order $\mathcal{O}(n^{-t})$, where t denotes the degree of regularity of the exact solution. Moreover, we design a fast scheme for solving the corresponding truncated linear system. We show that solving this system requires only an $\mathcal{O}(n \log^2 n)$ number of multiplications. We present numerical examples to confirm the theoretical estimates and to demonstrate the efficiency and accuracy of the proposed algorithm.

Key words. singular boundary integral equations, Fourier–Galerkin methods, fast solutions

DOI. 10.1137/070703478

1. Introduction.

The Galerkin method using the trigonometric polynomial basis (which we call the Fourier basis) among other numerical methods (cf. [1, 2, 3, 4, 10, 12, 13, 14, 18, 20, 21]) is a standard numerical treatment for solving singular boundary integral equations. In this paper, we call such a method the *Fourier–Galerkin method*. This method enjoys nice convergence properties but at the same time suffers from having large computational costs. The coefficient matrix (which we call the Galerkin matrix) of the corresponding discrete linear system is a dense matrix. As a result, it has $\mathcal{O}(n^2)$ nonzero entries, where $2n$ or $2n+1$ denotes the order of the system. When n is large, the computational cost needed to set up the Galerkin matrix and then to solve the system is large. Therefore, approximating the dense Galerkin matrix by a sparse matrix is practically important.

The main purpose of this paper is to develop a fast Fourier–Galerkin method for solving the equation by compressing the dense Galerkin matrix to a sparse matrix. A large class of boundary integral operators can be written in the form $\mathcal{A}+\mathcal{B}$, where $\mathcal{A}$ is a singular but simple integral operator and $\mathcal{B}$ is a compact integral operator with a smooth kernel. Operator $\mathcal{A}$ carries the main singularity characteristic of the boundary integral operator, and it has the Fourier basis functions as its eigenfunctions. Hence, the matrix representation of the operator $\mathcal{A}$ under the Fourier basis is a diagonal matrix, and we observe that the matrix representation of the compact operator $\mathcal{B}$

under the same basis can be compressed to a sparse matrix without loss of critical information encoded in the matrix. This serves as the base for the development of the fast Fourier–Galerkin method for solving the boundary integral equations. We propose a truncation strategy for the Galerkin matrix. We prove that the truncated sparse matrix has only $\mathcal{O}(n \log n)$ nonzero entries, when the trigonometric polynomials of degree n are used in the Galerkin method and that the approximate solution obtained from the truncated Fourier–Galerkin method has the same convergence order as that obtained from the conventional Fourier–Galerkin method. In other words, the proposed compression strategy preserves the convergence property of the conventional Fourier–Galerkin method but reduces the number of nonzero entries of the Galerkin matrix from $\mathcal{O}(n^2)$ to $\mathcal{O}(n \log n)$. We also develop a fast solver for the corresponding compressed linear system and prove that solving the linear system in the proposed way requires only an $\mathcal{O}(n \log^2 n)$ number of multiplications.

We organize this paper in seven sections. In section 2, we review the Fourier–Galerkin method for solving boundary integral equations. A truncation strategy for the matrix representation of a compact integral operator with a smooth kernel under the Fourier basis is proposed in section 3. This truncation strategy leads to a *truncated* Fourier–Galerkin method for solving boundary integral equations. We show that the truncated Galerkin matrix has only $\mathcal{O}(n \log n)$ nonzero entries. We prove in section 4 the stability of the truncated Fourier–Galerkin method, which ensures the unique solvability of the truncated method. In section 5, we establish the optimal convergence order of the truncated method, which is the same as that of the conventional Fourier–Galerkin method. Section 6 is devoted to the development of a fast solver for the linear system resulting from the truncated Fourier–Galerkin method. The fast algorithm is based on a multilevel augmentation method proposed in [6]. We prove that this fast solution of the linear system will not ruin the convergence order of the truncated Fourier–Galerkin method and show that the total number of multiplications required for solving the linear system is $\mathcal{O}(n \log^2 n)$. Finally in section 7, we present numerical examples to demonstrate the efficiency and accuracy of the proposed algorithm.

2. The Fourier–Galerkin method for boundary integral equations. We describe in this section the Fourier–Galerkin method for solving singular boundary integral equations.

Let us first recall the formulation of boundary integral equations. As examples, we present three specific boundary integral equations which are reformulations of the two-dimensional Laplace equation with either the Dirichlet or the Neumann boundary condition. We begin with an introduction of appropriate Sobolev spaces. For $k \in \mathbb{Z} := \{\dots, -1, 0, 1, \dots\}$, we set

$$e_k(x) := \frac{1}{\sqrt{2\pi}} e^{ikx}, \quad x \in I := [0, 2\pi],$$

where i is the imaginary unit such that $i^2 := -1$. For $s \geq 0$, we denote by $H^s(I)$ the Sobolev space of functions $\phi \in L^2(I)$ with property $\sum_{k\in\mathbb{Z}}(1+k^2)^s|\phi_k|^2 < +\infty$, where ϕ_k are the Fourier coefficients of ϕ defined by $\phi_k := \int_I \phi(x) e_k(x) dx, \ k \in \mathbb{Z}$. The inner product of space $H^s(I)$ is defined by

$$(\phi, \psi)_s := \sum_{k\in\mathbb{Z}} (1+k^2)^s \phi_k \overline{\psi}_k, \quad \phi, \psi \in H^s(I),$$

and its norm is defined by $\|\phi\|_s := (\phi, \phi)^{\frac{1}{2}}_s$.

For two nonnegative numbers s_1 and s_2, we suppose that $X \subseteq H^{s_1}(I)$ and $Y \subseteq H^{s_2}(I)$ are two subspaces and that $\mathcal{A} : X \to Y$ is a bounded linear operator defined by

$$(\mathcal{A}w)(x) = \int_I a(x,y)w(y)dy, \quad x \in I,$$

which has a bounded inversion $\mathcal{A}^{-1} : Y \to X$. The kernel a of the operator $\mathcal{A}$ is either weakly singular, strongly singular, or hypersingular. We assume that $\mathcal{B} : X \to Y$ is a compact operator defined by

$$(\mathcal{B}w)(x) = \int_I b(x,y)w(y)dy, \quad x \in I,$$

with a smooth kernel b. We consider solving the operator equation

$$(\mathcal{A} + \mathcal{B})u = g, \tag{2.1}$$

where $g \in Y$ is a given function and $u \in X$ is the unknown to be determined.

Many boundary integral equations have the form (2.1). We now follow [1, 11] to describe three boundary integral equations in the form (2.1). To this end, we let D be a bounded open simply connected region in $\mathbb{R}^2$ and ∂D be its boundary. We suppose that the boundary ∂D has a parametrization γ defined by $\gamma(x) = (\gamma_1(x), \gamma_2(x))$, $x \in I$. We denote by $\mathbf{n}_P$ the unit normal vector at the point P on the boundary ∂D.

In the first case, we consider the interior Dirichlet problem in the plane

$$\begin{cases} \triangle U(P) = 0, & P \in D, \\ U(P) = f(P), & P \in \partial D. \end{cases} \tag{2.2}$$

The solution U of (2.2) can be expressed as a single-layer potential in the form

$$U(P) = \int_{\partial D} \rho(Q) \log |P - Q| ds_Q, \quad P \in D,$$

where the unknown density function ρ satisfies the boundary integral equation of the first kind

$$\int_{\partial D} \rho(Q) \log |P - Q| ds_Q = f(P), \quad P \in \partial D. \tag{2.3}$$

We next rewrite (2.3) in the form (2.1) by introducing two kernels

$$a(x,y) := -\frac{1}{\pi} \log \left| 2e^{-1} \sin \frac{y-x}{2} \right|, \quad x, y \in I, \tag{2.4}$$

and

$$b(x,y) := \begin{cases} -\frac{1}{\pi} \log \left| \frac{e^{\frac{1}{2}} |\gamma(x) - \gamma(y)|}{|2 \sin(\frac{x-y}{2})|} \right|, & x - y \neq 2k\pi, \quad k \in \mathbb{Z}, \\ -\frac{1}{\pi} \log |e^{\frac{1}{2}} \gamma'(y)|, & \text{otherwise}, \end{cases} \qquad x, y \in I.$$

We also let $g(x) := -\frac{1}{\pi} f(\gamma(x))$ and $u(x) := \rho(\gamma(x))|\gamma'(x)|$, for $x \in I$. It is known (cf. [1, 3, 20, 22]) that u satisfies (2.1) with the kernel a being weakly singular when the boundary is smooth. In this case, the domain space and the range space for the corresponding integral operators are $X = H^0(I)$ and $Y = H^1(I)$, respectively.

The second boundary integral equation is for the interior Neumann problem

$$\begin{cases} \triangle U(P) = 0, & P \in D, \\ \frac{\partial U(P)}{\partial \mathbf{n}_P} = f(P), & P \in \partial D. \end{cases} \tag{2.5}$$

The solution U of (2.5) can be expressed by a double-layer potential

$$U(P) := \int_{\partial D} \rho(Q) \frac{\partial}{\partial \mathbf{n}_Q} \log |P - Q| ds_Q, \quad P \in D. \tag{2.6}$$

Likewise, we define two kernels by

$$a(x, y) := \frac{\sin(y - x)}{2(1 - \cos(y - x))}, \quad x, y \in I, \tag{2.7}$$

and

$$b(x, y) := \frac{\gamma'(x) \cdot (\gamma(y) - \gamma(x))}{|\gamma(x) - \gamma(y)|^2} - \frac{\sin(y - x)}{2(1 - \cos(y - x))}, \quad x, y \in I,$$

and introduce functions $g(x) := f(\gamma(x))|\gamma'(x)|$ and $u(x) := \frac{d\rho(\gamma(x))}{dx}$ for $x \in I$. According to [1, 15] we find that the unknown u satisfies (2.1) with the kernels defined above. Note that the kernel a has a strong singularity along the diagonal. The domain space and the range space of the corresponding integral operators are $X = Y = H_0^0(I)$, where

$$H_0^0(I) := \left\{ \phi \in H^0(I) : \int_I \phi(x) dx = 0 \right\}.$$

The third case is the hypersingular integral equation reformulation of the interior Neumann problem (2.5). Again, we express the solution U of (2.5) as a double-layer potential (2.6). This time, we choose the kernels differently. Specifically, we let

$$a(x, y) := -\frac{1}{4\pi} \csc^2 \frac{y - x}{2}, \quad x, y \in I, \tag{2.8}$$

$$b(x, y) := \frac{1}{\pi} \frac{\partial}{\partial y} \left[\frac{\gamma(x) \cdot (\gamma(y) - \gamma(x))}{|\gamma(x) - \gamma(y)|^2} - \frac{\sin(y - x)}{2(1 - \cos(y - x))} \right], \quad x, y \in I,$$

$g(x) := \frac{1}{\pi} f(\gamma(x))|\gamma'(x)|$, and $u(x) := \rho(\gamma(x))$ for $x \in I$. Then it is known (cf. [15]) that u satisfies the hypersingular boundary integral equation having the form (2.1). The domain space and the range space for the corresponding integral operators are $X = H_0^0(I) \cap H^1(I)$ and $Y = H_0^0(I)$, respectively.

We now turn to describing the Fourier–Galerkin method for solving the boundary integral equations (2.1). To this end, we introduce several index sets: $\mathbb{N} := \{1, 2, \dots\}$, $\mathbb{N}_0 := \{0, 1, 2, \dots\}$, $\mathbb{Z}_n^+ := \{1, 2, \dots, n\}$, and $\mathbb{Z}_n := \mathbb{Z}_n^+ \cup \{0\}$. For each $n \in \mathbb{N}$, we define a finite-dimensional subspace X_n by $X_n := \operatorname{span}\{e_k(x) : |k| \in \mathbb{Z}_n^*\}$, where $\mathbb{Z}_n^*$ denotes either $\mathbb{Z}_n$ or $\mathbb{Z}_n^+$, according to the type of integral operators $\mathcal{A}$ in (2.1). For example, if the operator is weakly singular, then we choose $\mathbb{Z}_n^* := \mathbb{Z}_n$, and if it is strongly singular or hypersingular, then we choose $\mathbb{Z}_n^* := \mathbb{Z}_n^+$.

The Fourier–Galerkin method for solving (2.1) is to project the equation onto the space X_n generated by the Fourier basis. Let $\mathcal{P}_n$ be the orthogonal projection from

X to X_n. It is well known (cf. [1, 11]) that there exists a positive constant c such that, for any $v \in H^\mu(I)$ and for any $\nu \in [0, \mu]$,

$$\|v - \mathcal{P}_n v\|_\nu \le c n^{\nu-\mu} \|v\|_\mu, \tag{2.9}$$

and $\lim_{n\to\infty} \|v - \mathcal{P}_n v\|_\mu = 0$. Thus, there exists a positive constant ς such that, for all n, $\|\mathcal{P}_n\|_\mu \le \varsigma$. The Fourier–Galerkin method for solving (2.1) is to seek $u_n \in X_n$ such that

$$(\mathcal{P}_n\mathcal{A} + \mathcal{P}_n\mathcal{B})u_n = \mathcal{P}_n g. \tag{2.10}$$

Throughout this paper, we always assume that the operator $\mathcal{A}$ has the Fourier basis functions e_k as its eigenfunctions. Note that the singular integral operators $\mathcal{A}$ in the three boundary integral equation examples all have this property. Thus, the operator $\mathcal{A}$ commutes with the projection $\mathcal{P}_n$; that is,

$$\mathcal{A}\mathcal{P}_n = \mathcal{P}_n\mathcal{A}. \tag{2.11}$$

Equation (2.11) is equivalent to

$$\mathcal{A}^{-1}\mathcal{P}_n = \mathcal{P}_n\mathcal{A}^{-1}. \tag{2.12}$$

Let $\mathcal{B}_n := \mathcal{P}_n\mathcal{B}|_{X_n}$ and $g_n := \mathcal{P}_n g$. By condition (2.11), (2.10) is rewritten as:

$$(\mathcal{A} + \mathcal{B}_n)u_n = g_n. \tag{2.13}$$

Once a solution of this equation is solved, we can obtain an approximation of $U(P)$ via the potential. Efficient numerical methods for computation of the potential may be found in [19].

The following stability and convergence results regarding the Fourier–Galerkin method can be found in [1, 11].

THEOREM 2.1. *Suppose that* (2.1) *has the unique solution* u. *Then there exist a positive integer* n_0 *and a positive constant* ρ *such that, for* $n \ge n_0$ *and any* $w \in X_n$,

$$\|(\mathcal{A} + \mathcal{B}_n)w\|_{s_2} \ge \rho \|w\|_{s_1}, \tag{2.14}$$

and there exists a positive constant c *such that, for all* $n \in \mathbb{N}$,

$$\|u - u_n\|_{s_1} \le c\|u - \mathcal{P}_n u\|_{s_1}.$$

Moreover, if $u \in X \cap H^{s_1+t}(I)$, *then there exists a positive constant* c *such that*

$$\|u - u_n\|_{s_1} \le c n^{-t} \|u\|_{s_1+t}.$$

To close this section, we make remarks for the regularity of the solution of the boundary integral equations (2.1) and the corresponding convergence order of the Fourier–Galerkin method for the equations if operator $\mathcal{A}$ is one of the three singular integral operators described earlier.

In the case when operator $\mathcal{A}$ is the weakly singular integral operator defined by the kernel (2.4), we have $s_1 = 0$ and $s_2 = 1$. By following [1, 11], if $b(\cdot, y) \in H^{t+1}(I)$ for any $y \in I$ and $g \in H^{t+1}(I)$, then $u \in H^t(I)$, and, thus, there exists a positive constant c such that

$$\|u - u_n\|_0 \le c n^{-t} \|u\|_t. \tag{2.15}$$

In the case when operator $\mathcal{A}$ is the strongly singular integral operator defined by the kernel (2.7), we have $s_1 = 0$ and $s_2 = 0$. By following [1, 15], we conclude that if $b(\cdot, y) \in H^t(I)$ for any $y \in I$ and $g \in H_0^0(I) \cap H^t(I)$, then $u \in H_0^0(I) \cap H^t(I)$, and, thus, there exists a positive constant c such that

$$\|u - u_n\|_0 \le cn^{-t}\|u\|_t. \tag{2.16}$$

Finally, in the case when operator $\mathcal{A}$ is the hypersingular integral operator defined by the kernel (2.8), we have $s_1 = 1$ and $s_2 = 0$. By following [1, 4], if $b(\cdot, y) \in H^t(I)$ for any $y \in I$ and $g \in H_0^0(I) \cap H^t(I)$, then $u \in H_0^0(I) \cap H^{t+1}(I)$. Thus, in this case, there exists a positive constant c such that

$$\|u - u_n\|_1 \le cn^{-t}\|u\|_{t+1}. \tag{2.17}$$

3. A matrix truncation strategy. In this section, we introduce a truncation strategy for the Galerkin matrix of operator $\mathcal{A} + \mathcal{B}$.

We first present the Galerkin matrix. The Fourier–Galerkin method (2.13) is to seek a function $u_n \in X_n$ in the form

$$u_n(x) := \sum_{|k| \in \mathbb{Z}_n^*} a_k e_k(x), \quad x \in I,$$

that satisfies the equation

$$((\mathcal{A} + \mathcal{B})u_n, e_k)_{s_2} = (g, e_k)_{s_2}, \quad |k| \in \mathbb{Z}_n^*. \tag{3.1}$$

We next write a matrix form of (3.1). For $|k|, |l| \in \mathbb{Z}_n$, we define

$$a_{k,l} := \int_I \int_I a(x, y) e_k(x) e_l(y) dx dy$$

and introduce 2×2 matrices

$$A_{k,l} := \begin{bmatrix} a_{-k,l} & a_{-k,-l} \\ a_{k,l} & a_{k,-l} \end{bmatrix}.$$

Throughout this paper, we write $\mathbf{v} = [v_k, v_{-k} : k \in \mathbb{Z}_n^+]$ to denote the vector $\mathbf{v} = [v_1, v_{-1}, \ldots, v_n, v_{-n}]$ and write $\mathbf{v} = [v_k, v_{-k} : k \in \mathbb{Z}_n]$ to denote the vector $\mathbf{v} = [v_0, v_1, v_{-1}, \ldots, v_n, v_{-n}]$. We also write $\mathbf{v}^- = [v_{-k}, v_k : k \in \mathbb{Z}_n^*]$. With this notation, we then define matrices

$$\begin{aligned} &A_1 := [A_{k,l} : k, l \in \mathbb{Z}_n^+], \quad A' := [a_{0,0}], \\ &A'' := [a_{0,k}, a_{0,-k} : k \in \mathbb{Z}_n^+], \quad A''' := [a_{-k,0}, a_{k,0} : k \in \mathbb{Z}_n^+]^T. \end{aligned}$$

We let

$$\mathbf{A}_n := A_1 \ \text{ if } \ \mathbb{Z}_n^* := \mathbb{Z}_n^+ \ \text{ and } \ \mathbf{A}_n := \begin{bmatrix} A' & A'' \\ A''' & A_1 \end{bmatrix} \ \text{ if } \ \mathbb{Z}_n^* := \mathbb{Z}_n.$$

By replacing the kernel a by the kernel b, we likewise define the matrix $\mathbf{B}_n$ and its corresponding blocks. For $|k| \in \mathbb{Z}_n$, we let

$$\widetilde{g}_k := \int_I g(x) e_k(x) dx, \quad \mathbf{g}^- := [\widetilde{g}_{-k}, \widetilde{g}_k : k \in \mathbb{Z}_n^*]^T.$$

Associated with u_n, the solution of (2.13), we introduce the vector $\mathbf{u}_n := [a_k, a_{-k} : k \in \mathbb{Z}_n^*]^T$. By using these matrix and vector notations, we have the following matrix form of (3.1):

$$(\mathbf{A}_n + \mathbf{B}_n)\mathbf{u}_n = \mathbf{g}^-. \tag{3.2}$$

In general, the Galerkin matrix $\mathbf{A}_n + \mathbf{B}_n$ is a dense matrix. When n is large, it requires large computational effort to set up the matrix and to solve the corresponding linear system subsequently. We propose a truncation strategy which allows us to approximate the dense coefficient matrix by a sparse matrix and preserves the optimal convergence order of the conventional Fourier–Galerkin method for the truncated method.

We first consider the matrix $\mathbf{A}_n$. Under the hypothesis that, for each $k \in \mathbb{Z}$, e_k is an eigenfunction of the operator $\mathcal{A}$, matrix $\mathbf{A}_n$ is diagonal. This is the case when the operator $\mathcal{A}$ is one of the three singular boundary integral operators described in the last section. In fact, the matrices $\mathbf{A}_n$ of the singular boundary integral operator $\mathcal{A}$ corresponding to the kernel a having the form (2.4), (2.7), and (2.8) are given, respectively, by

$$\mathbf{A}_n := \operatorname{diag}\left(1, 1, 1, \frac{1}{2}, \frac{1}{2}, \ldots, \frac{1}{n}, \frac{1}{n}\right), \quad \mathbf{A}_n := \operatorname{diag}\left(\pi i, -\pi i, \pi i, -\pi i, \ldots, \pi i, -\pi i\right), \quad \text{and}$$

$$\mathbf{A}_n := \operatorname{diag}\left(1, -1, 2, -2, \ldots, n, -n\right).$$

The matrix $\mathbf{B}_n$, which is usually dense, requires a truncation. We now describe the truncation strategy. For each $n \in \mathbb{N}$, the truncation strategy uses the *hyperbolic* curve $kl = n$. We keep only the blocks $B_{k,l}$ for the pairs (k, l) satisfying $kl \le n$ and replace all of the blocks $B_{k,l}$ by the 2×2 zero matrix $0_{2\times 2}$ for the pairs (k, l) satisfying $kl > n$. Specifically, for $k, l \ge 1$, we define a block truncation matrix from $\mathbf{B}_n$ by setting

$$\widetilde{B}_{k,l} := \begin{cases} B_{k,l}, & kl \le n, \\ 0_{2\times 2}, & \text{otherwise}, \end{cases} \quad \text{and} \quad \widetilde{B}_1 := [\widetilde{B}_{k,l} : k, l \in \mathbb{Z}_n^+] \tag{3.3}$$

and letting

$$\widetilde{\mathbf{B}}_n := \widetilde{B}_1 \ \text{ if } \ \mathbb{Z}_n^* := \mathbb{Z}_n^+ \ \text{ and } \ \widetilde{\mathbf{B}}_n := \begin{bmatrix} B' & B'' \\ B''' & \widetilde{B}_1 \end{bmatrix} \ \text{ if } \ \mathbb{Z}_n^* := \mathbb{Z}_n.$$

By replacing the dense matrix $\mathbf{B}_n$ in (3.2) by the sparse matrix $\widetilde{\mathbf{B}}_n$, we obtain the truncated linear system

$$(\mathbf{A}_n + \widetilde{\mathbf{B}}_n)\widetilde{\mathbf{u}}_n = \mathbf{g}^-, \tag{3.4}$$

where $\widetilde{\mathbf{u}}_n := [\widetilde{a}_k, \widetilde{a}_{-k} : k \in \mathbb{Z}_n^*]^T$. We call this numerical method the truncated Fourier–Galerkin method. Now that the coefficient matrix of the truncated linear system is sparse, it is a fast method. Issues regarding the truncated Fourier–Galerkin method include: (1) How sparse is the matrix? (2) Does the truncated linear system have a unique solution? (3) How does the solution of (3.4) approximate the exact solution of the boundary integral equation? We answer the first question at the end of this section and postpone the other two questions to the next two sections.

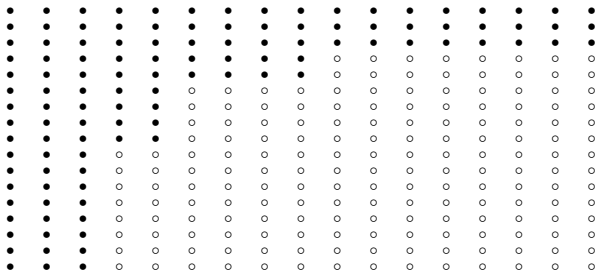

FIG. 1. *Sparse matrix* $\widetilde{\mathbf{B}}_8$ *when* $\mathbb{Z}_8^* = \mathbb{Z}_8$.

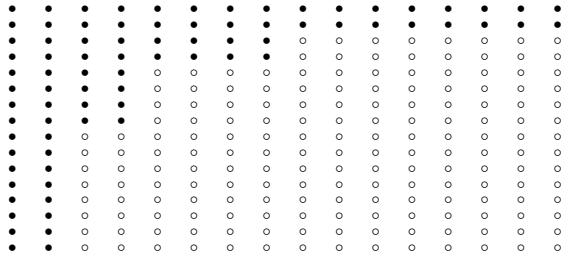

FIG. 2. *Sparse matrix* $\widetilde{\mathbf{B}}_8$ *when* $\mathbb{Z}_8^* = \mathbb{Z}_8^+$.

In the next theorem we estimate precisely the number of nonzero entries in matrix $\widetilde{\mathbf{B}}_n$. To this end, we use $\mathcal{N}(\mathbf{G})$ to denote the number of nonzero entries in matrix $\mathbf{G}$ and $\lfloor x \rfloor$ to denote the largest integer not greater than x.

THEOREM 3.1. *There exists a positive constant* c *such that, for all* $n \in \mathbb{N}$,

$$\mathcal{N}(\widetilde{\mathbf{B}}_n) \leq cn \log n.$$

Proof. For $k, l \geq 1$, by using truncation strategy (3.3) and the fact that $\mathcal{N}(\widetilde{B}_{kl}) \leq 4$, we have

$$\mathcal{N}(\widetilde{B}_1) = \sum_{k \in \mathbb{Z}_n^+} \sum_{l \in \mathbb{Z}_n^+} \mathcal{N}(\widetilde{B}_{k,l}) \leq 4 \sum_{k \in \mathbb{Z}_n^+} \left\lfloor \frac{n}{k} \right\rfloor \leq 4n \sum_{k \in \mathbb{Z}_n^+} \frac{1}{k}.$$

Employing the equation

$$\sum_{k \in \mathbb{Z}_n} \frac{1}{k} = \mathcal{O}(\log n)$$

in the last inequality, we conclude that $\mathcal{N}(\widetilde{B}_1) \leq 4n \log n$. By noting that

$$\mathcal{N}(B') \leq 1, \quad \mathcal{N}(B'') \leq 2n, \quad \mathcal{N}(B''') \leq 2n,$$

we have the desired estimate. ∎

We call this truncation strategy a Γ-type truncation strategy. This truncation strategy admits a fast algorithm to generate the coefficient matrix of linear system (3.4) and to solve it subsequently.

The Γ-type truncation strategy is illustrated in Figures 1 and 2, where the dots indicate the entries kept and the circles indicate the entry replaced by zero. Figure 1 illustrates the truncation strategy for the weakly singular boundary integral equation and Figure 2 for the strongly singular or hypersingular boundary integral equation.

4. Stability analysis. We analyze in this section the stability of the fast algorithm presented in the last section.

We first present four technical lemmas necessary for the stability analysis. For a vector $\mathbf{d} := [d_k : k \in \mathbb{Z}_n^+]^T$, we let $\|\mathbf{d}\|$ denote its spectral norm, and, for a nonnegative number μ, we define a weighted vector $\mathbf{d}_\mu := [(1+k^2)^{\frac{\mu}{2}} d_k : k \in \mathbb{Z}_n^+]^T$. We set

$$\mathbb{J}_n := \left\{(k,l) : l = \left\lceil \frac{n}{k} \right\rceil, \left\lceil \frac{n}{k} \right\rceil + 1, \ldots, n, k \in \mathbb{Z}_n^+\right\},$$

where $\lceil x \rceil$ denotes the smallest integer not less than x.

LEMMA 4.1. *If a sequence $f_{k,l} \in \mathbb{C}$, $k,l \in \mathbb{Z}_n^+$, satisfies the condition that there exists a positive constant θ such that, for all $n \in \mathbb{N}$,*

$$\sum_{k \in \mathbb{Z}_n^+} \sum_{l \in \mathbb{Z}_n^+} (1+k^2)^{\mu+\nu}(1+l^2)^{\mu+\nu}|f_{k,l}|^2 \le \theta^2, \tag{4.1}$$

for some nonnegative constants μ and ν, then, for two arbitrary vectors $\mathbf{d} := [d_k : k \in \mathbb{Z}_n^+]^T$ and $\mathbf{h} := [h_k : k \in \mathbb{Z}_n^+]^T$,

$$\sum_{(k,l) \in \mathbb{J}_n} |(1+k^2)^{\mu} d_k h_l f_{k,l}| \le \theta \|\mathbf{d}_\mu\| \|\mathbf{h}\| n^{-\nu}. \tag{4.2}$$

Proof. Associated with the sequence $f_{k,l}$, for $k,l \in \mathbb{Z}_n^+$, we define

$$g_{k,l} := (1+k^2)^{\frac{\mu+\nu}{2}}(1+l^2)^{\frac{\mu+\nu}{2}}|f_{k,l}|,$$

and, associated with the vectors $\mathbf{d}$ and $\mathbf{h}$, we define

$$h_{k,l} := (1+k^2)^{\frac{\mu-\nu}{2}}(1+l^2)^{-\frac{\mu+\nu}{2}}|d_k||h_l|.$$

We then let S denote the inner product of these two sequences on the index set $\mathbb{J}_n$; that is,

$$S := \sum_{(k,l) \in \mathbb{J}_n} h_{k,l} g_{k,l}.$$

Applying the Cauchy–Schwartz inequality to the inner product S yields

$$S \le \left(\sum_{(k,l) \in \mathbb{J}_n} h_{k,l}^2 \right)^{\frac{1}{2}} \left(\sum_{(k,l) \in \mathbb{J}_n} g_{k,l}^2 \right)^{\frac{1}{2}}. \tag{4.3}$$

By using hypothesis (4.1), we obtain

$$\sum_{(k,l) \in \mathbb{J}_n} g_{k,l}^2 \le \theta^2. \tag{4.4}$$

Substituting (4.4) and the inequality

$$\sum_{(k,l) \in \mathbb{J}_n} h_{k,l}^2 \le \|\mathbf{d}_\mu\|^2 \|\mathbf{h}\|^2 n^{-2\nu}$$

into the right-hand side of (4.3) yields the estimate (4.2). ∎

In the next lemma, we estimate the difference between two matrices $\mathbf{B}_n$ and $\widetilde{\mathbf{B}}_n$. To this end, for $\mathbf{v}^- := [v_{-k}, v_k : k \in \mathbb{Z}_n^+]^T \in \mathbb{C}^{2n}$ and a nonnegative number μ, we define $\mathbf{v}_\mu^- := [(1+k^2)^{\frac{\mu}{2}} v_{-k}, (1+k^2)^{\frac{\mu}{2}} v_k : k \in \mathbb{Z}_n^+]^T$.

LEMMA 4.2. *If there exists a positive constant β such that, for all n,*

$$\sum_{k\in\mathbb{Z}_n^+}\sum_{l\in\mathbb{Z}_n^+}(1+k^2)^{\mu+\nu}(1+l^2)^{\mu+\nu}|b_{k,l}|^2 \le \beta^2, \tag{4.5}$$

for some nonnegative constants μ and ν, then, for two arbitrary vectors $\mathbf{v}^-, \mathbf{w} \in \mathbb{C}^{2n}$,

$$|{\mathbf{v}_{2\mu}^-}^T(\mathbf{B}_n - \widetilde{\mathbf{B}}_n)\mathbf{w}| \le 4\beta\|\mathbf{v}_\mu^-\|\|\mathbf{w}\|n^{-\nu}. \tag{4.6}$$

Proof. According to the truncation strategy (3.3), we write ${\mathbf{v}_{2\mu}^-}^T(\mathbf{B}_n - \widetilde{\mathbf{B}}_n)\mathbf{w}$ in the form

(4.7)

$${\mathbf{v}_{2\mu}^-}^T(\mathbf{B}_n-\widetilde{\mathbf{B}}_n)\mathbf{w} = \sum_{(k,l)\in\mathbb{J}_n}(1+k^2)^{\mu}(v_k w_l b_{-k,l}+v_{-k}w_l b_{-k,-l}+v_k w_{-l}b_{k,l}+v_{-k}w_{-l}b_{k,-l}).$$

Upon introducing four summations

$$I_1 := \sum_{(k,l)\in\mathbb{J}_n}(1+k^2)^{\mu}v_k w_l b_{-k,l}, \quad I_2 := \sum_{(k,l)\in\mathbb{J}_n}(1+k^2)^{\mu}v_{-k}w_l b_{-k,-l},$$
$$I_3 := \sum_{(k,l)\in\mathbb{J}_n}(1+k^2)^{\mu}v_k w_{-l} b_{k,l}, \quad I_4 := \sum_{(k,l)\in\mathbb{J}_n}(1+k^2)^{\mu}v_{-k}w_{-l}b_{k,-l},$$

we rewrite (4.7) as

$${\mathbf{v}_{2\mu}^-}^T(\mathbf{B}_n - \widetilde{\mathbf{B}}_n)\mathbf{w} = I_1 + I_2 + I_3 + I_4. \tag{4.8}$$

It suffices to estimate I_k for $k = 1, 2, 3, 4$. We first estimate I_1. In Lemma 4.1, we choose $f_{k,l} := b_{-k,l}$, $\mathbf{d}_\mu := [(1+k^2)^{\frac{\mu}{2}} v_k : k \in \mathbb{Z}_n^+]^T$, and $\mathbf{h} := [w_k : k \in \mathbb{Z}_n^+]^T$. Clearly, the sequence $f_{k,l}$ satisfies condition (4.1), and vectors $\mathbf{d}_\mu$ and $\mathbf{h}$ have the bounds

$$\|\mathbf{d}_\mu\| \le \|\mathbf{v}_\mu^-\| \quad \text{and} \quad \|\mathbf{h}\| \le \|\mathbf{w}\|,$$

respectively. By Lemma 4.1 with the above bounds, we obtain the bound for I_1 given by

$$|I_1| \le \beta\|\mathbf{v}_\mu^-\|\|\mathbf{w}\|n^{-\nu}. \tag{4.9}$$

In a similar manner, we obtain the following estimates for I_k:

$$|I_k| \le \beta\|\mathbf{v}_\mu^-\|\|\mathbf{w}\|n^{-\nu}, \quad k = 2, 3, 4. \tag{4.10}$$

Substituting estimates (4.9) and (4.10) into (4.8) yields the desired estimate. ∎

Let $\widetilde{\mathcal{B}}_n$ be the linear operator such that its matrix representation under the basis $\{e_k : |k| \in \mathbb{Z}_n^*\}$ is $\widetilde{\mathbf{B}}_n$. The next lemma translates the estimate in the last lemma to an estimate of the difference $\mathcal{B} - \mathcal{B}_n$.

LEMMA 4.3. *If there exists a positive constant β such that, for all n, (4.5) with $\mu = s_2$ and $\nu = t > 0$ holds, then there exists a positive integer n_0 such that, for all $n \ge n_0$ and for each $w \in X$,*

$$\|(\mathcal{B}_n - \widetilde{\mathcal{B}}_n)\mathcal{P}_n w\|_{s_2} \le 4\beta\|w\|_0 n^{-t}. \tag{4.11}$$

Proof. By the definition of norm,

$$\begin{aligned}\|(\mathcal{B}_n-\widetilde{\mathcal{B}}_n)\mathcal{P}_n w\|_{s_2} &= \sup_{v\in Y,\|v\|_{s_2}=1}\left|\Big((\mathcal{B}_n-\widetilde{\mathcal{B}}_n)\mathcal{P}_n w, v\Big)_{s_2}\right| \\ &= \sup_{v\in Y,\|v\|_{s_2}=1}\left|\Big((\mathcal{B}_n-\widetilde{\mathcal{B}}_n)\mathcal{P}_n w, \mathcal{P}_n v\Big)_{s_2}\right|.\end{aligned} \tag{4.12}$$

For $v\in Y$ and $w\in X$, we express their projection onto X_n as

$$(\mathcal{P}_n v)(x)=\sum_{|k|\in\mathbb{Z}_n^*} v_k e_{-k}(x),\quad (\mathcal{P}_n w)(x)=\sum_{|k|\in\mathbb{Z}_n^*} w_k e_k(x),\quad x\in I. \tag{4.13}$$

Two coefficient vectors in (4.13) are denoted by $\mathbf{v}^- := [v_{-k}, v_k : k\in\mathbb{Z}_n^+]^T$ and $\mathbf{w} := [w_k, w_{-k} : k\in\mathbb{Z}_n^+]^T$, respectively. It can be verified that

$$\|\mathbf{v}^-_{s_2}\|\le\|v\|_{s_2},\quad \|\mathbf{w}\|\le\|w\|_0. \tag{4.14}$$

From (4.13) and the definition of the operators $\mathcal{B}_n$ and $\widetilde{\mathcal{B}}_n$, we obtain

$$((\mathcal{B}_n-\widetilde{\mathcal{B}}_n)\mathcal{P}_n w,\mathcal{P}_n v)_{s_2} = {\mathbf{v}^-_{2s_2}}^T(\mathbf{B}_n-\widetilde{\mathbf{B}}_n)\mathbf{w}. \tag{4.15}$$

By applying Lemma 4.2 to the right-hand side of (4.15) with the estimate (4.14), we have

$$\left|((\mathcal{B}_n-\widetilde{\mathcal{B}}_n)\mathcal{P}_n w,\mathcal{P}_n v)_{s_2}\right|\le 4\beta\|v\|_{s_2}\|w\|_0 n^{-t}. \tag{4.16}$$

Substituting the above estimate into (4.12) yields the desired estimate of this lemma. ∎

To continue the stability analysis, we need a regularity hypothesis on kernel b. Let $L^2(I^2)$ denote the Hilbert space with inner product defined by

$$(\phi,\varphi) := \int_I\int_I \phi(x,y)\overline{\varphi(x,y)}dxdy.$$

For $\mu,\nu\ge 0$, let $H^{\mu,\nu}(I^2)$ denote the space of functions $\phi\in L^2(I^2)$ with the property

$$\sum_{k\in\mathbb{Z}}\sum_{l\in\mathbb{Z}}(1+k^2)^\mu(1+l^2)^\nu|\phi_{k,l}|^2<+\infty,$$

where $\phi_{k,l}$ is the Fourier coefficient of ϕ defined by

$$\phi_{k,l} := \int_I\int_I \phi(x,y)e_k(x)e_l(y)dxdy,\quad k,l\in\mathbb{Z}.$$

The space $H^{\mu,\nu}(I^2)$ is a Hilbert space with norm

$$\|\phi\|_{\mu,\nu} := \left\{\sum_{k,l\in\mathbb{Z}}(1+k^2)^\mu(1+l^2)^\nu|\phi_{k,l}|^2\right\}^{1/2};$$

see, for example, [16, 17]. By using integration by parts, we can verify that if the kernel $b(x,y)$ has 2π-periodic and continuous $\lceil s_2+t\rceil$th partial derivatives with respect to both variables x and y, then $b\in H^{s_2+t,s_2+t}(I^2)$.

LEMMA 4.4. *If $b \in H^{s_2+t,s_2+t}(I^2)$ for $t > 0$, then there exists a positive integer n_0 such that, for all $n \geq n_0$ and for each $w \in X$,*

$$\|(\mathcal{B}_n - \widetilde{\mathcal{B}}_n)\mathcal{P}_n w\|_{s_2} \leq 4\|b\|_{s_2+t,s_2+t}\|w\|_0 n^{-t}. \tag{4.17}$$

Proof. Because $b \in H^{s_2+t,s_2+t}(I^2)$, by the definition of the norm,

$$\sum_{k\in\mathbb{Z}_n^+}\sum_{l\in\mathbb{Z}_n^+}(1+k^2)^{s_2+t}(1+l^2)^{s_2+t}|b_{k,l}|^2 = \|b\|^2_{s_2+t,s_2+t} < +\infty. \tag{4.18}$$

Hence, estimate (4.17) follows directly from Lemma 4.3 with (4.18). ∎

We are now ready to present the stability result.

THEOREM 4.5. *If $b \in H^{s_2+t,s_2+t}(I^2)$ for $t > 0$, then there exists a positive integer n_0 such that, for all $n \geq n_0$ and for all $w \in X_n$,*

$$\|(\mathcal{A} + \widetilde{\mathcal{B}}_n)w\|_{s_2} \geq \frac{\rho}{2}\|w\|_{s_1}, \tag{4.19}$$

where $\rho > 0$ is the constant that appears in Theorem 2.1.

Proof. The proof is done by employing the stability of the Fourier–Galerkin method (Theorem 2.1) and Lemma 4.4.

Since $b \in H^{s_2+t,s_2+t}(I^2)$, we have $\|b\|^2_{s_2+t,s_2+t} < +\infty$. By Lemma 4.4 with the fact that $n^{-t} \to 0$ as $n \to \infty$ and the inequality $\|w\|_0 \leq \|w\|_{s_1}$, we conclude that there exists a positive integer n_0 such that, for all $n \geq n_0$ and for all $w \in X_n$,

$$\|(\mathcal{B}_n - \widetilde{\mathcal{B}}_n)w\|_{s_2} \leq \frac{\rho}{2}\|w\|_{s_1}. \tag{4.20}$$

It follows from (2.14) and (4.20) that

$$\|(\mathcal{A} + \widetilde{\mathcal{B}}_n)w\|_{s_2} \geq \|(\mathcal{A} + \mathcal{B}_n)w\|_{s_2} - \|(\mathcal{B}_n - \widetilde{\mathcal{B}}_n)w\|_{s_2} \geq \frac{\rho}{2}\|w\|_{s_1},$$

proving the stability estimate (4.19). ∎

Theorem 4.5 ensures that for $n \geq n_0$ the equation

$$(\mathcal{A} + \widetilde{\mathcal{B}}_n)\widetilde{u}_n = g_n \tag{4.21}$$

has a unique solution

$$\widetilde{u}_n(x) := \sum_{|k|\in\mathbb{Z}_n^*} \widetilde{a}_k e_k(x), \quad x \in I. \tag{4.22}$$

In other words, the truncated linear system (3.4), which is equivalent to (4.21), has a unique solution $\widetilde{\mathbf{u}}_n$ for $n \geq n_0$.

5. Convergence analysis. Now we turn to considering the convergence order of the solution $\widetilde{u}_n$ of (4.21). We will show that the truncation strategy will not ruin the convergence order of the conventional Fourier–Galerkin method.

THEOREM 5.1. *If $b \in H^{s_2+t,s_2+t}(I^2)$ and $g \in H^{s_2+t}(I)$ for $t > 0$, then there exist a positive constant c and a positive integer n_0 such that, for all $n \geq n_0$,*

$$\|u - \widetilde{u}_n\|_{s_1} \leq cn^{-t}\|u\|_{s_1+t}.$$

Proof. By our general hypothesis, if $b \in H^{s_2+t,s_2+t}(I^2)$, then $u \in X \cap H^{s_1+t}(I)$. By applying the triangle inequality, we obtain

$$\|u - \widetilde{u}_n\|_{s_1} \le \|u - \mathcal{P}_n u\|_{s_1} + \|\mathcal{P}_n u - \widetilde{u}_n\|_{s_1}. \tag{5.1}$$

We first study the second term in the right-hand side of (5.1). Since $b \in H^{s_2+t,s_2+t}(I^2)$, we can employ the stability theorem established in the last section. By Theorem 4.5, there exist a positive constant c and a positive integer n_0 such that, for all $n \ge n_0$,

$$\|\mathcal{P}_n u - \widetilde{u}_n\|_{s_1} \le c\|(\mathcal{I} + \mathcal{A}^{-1}\widetilde{\mathcal{B}}_n)(\mathcal{P}_n u - \widetilde{u}_n)\|_{s_1}. \tag{5.2}$$

On the other hand, by applying the operator $\mathcal{A}^{-1}\mathcal{P}_n$ to both sides of (2.1) with a help of (2.12), we observe that

$$\mathcal{P}_n(\mathcal{I} + \mathcal{A}^{-1}\mathcal{B})u = \mathcal{A}^{-1} g_n. \tag{5.3}$$

Substituting (4.21) into the right-hand side of (5.3) yields

$$\mathcal{P}_n(\mathcal{I} + \mathcal{A}^{-1}\mathcal{B})u = (\mathcal{I} + \mathcal{A}^{-1}\widetilde{\mathcal{B}}_n)\widetilde{u}_n. \tag{5.4}$$

A direct computation using (2.12) and (5.4) confirms that there holds the equation

$$(\mathcal{I} + \mathcal{A}^{-1}\widetilde{\mathcal{B}}_n)(\mathcal{P}_n u - \widetilde{u}_n) = \mathcal{P}_n(\mathcal{I} + \mathcal{A}^{-1}\mathcal{B})(\mathcal{P}_n u - u) + \mathcal{A}^{-1}(\widetilde{\mathcal{B}}_n - \mathcal{B}_n)\mathcal{P}_n u. \tag{5.5}$$

Consequently, we have

$$\|(\mathcal{I} + \mathcal{A}^{-1}\widetilde{\mathcal{B}}_n)(\mathcal{P}_n u - \widetilde{u}_n)\|_{s_1} \le c\|\mathcal{P}_n u - u\|_{s_1} + c\|(\widetilde{\mathcal{B}}_n - \mathcal{B}_n)\mathcal{P}_n u\|_{s_2}. \tag{5.6}$$

By substituting (5.6) into the right-hand side of (5.2) and then substituting the resulting inequality into (5.1), we obtain the inequality

$$\|u - \widetilde{u}_n\|_{s_1} \le c\|\mathcal{P}_n u - u\|_{s_1} + c\|(\widetilde{\mathcal{B}}_n - \mathcal{B}_n)\mathcal{P}_n u\|_{s_2}. \tag{5.7}$$

Since $u \in X \cap H^{s_1+t}(I)$, by estimate (2.9) with $\nu = s_1$ and $\mu = s_1 + t$, there exist a positive constant c and a positive integer n_0 such that, for all $n \ge n_0$,

$$\|u - \mathcal{P}_n u\|_{s_1} \le cn^{-t}\|u\|_{s_1+t}. \tag{5.8}$$

By using Lemma 4.4 and the inequality $\|u\|_0 \le \|u\|_{s_1+t}$, the second term of (5.7) is also bounded by the same quantity. This proves the desired estimate of this theorem. ∎

Theorem 5.1 confirms that the truncated Fourier–Galerkin method gives the optimal order of convergence.

When applying the fast Fourier–Galerkin method to solve the three types of singular boundary integral equations described in section 2, by using Theorem 5.1 and the regularity of the solutions of these equations, we have the following three corollaries regarding their convergence order.

COROLLARY 5.2. *If operator $\mathcal{A}$ is the weakly singular integral operator defined by the kernel* (2.4) *and if $b \in H^{t+1,t+1}(I^2)$ and $g \in H^{t+1}(I)$, then there exist a positive constant c and a positive integer n_0 such that, for all $n \ge n_0$,*

$$\|u - \widetilde{u}_n\|_0 \le cn^{-t}\|u\|_t.$$

COROLLARY 5.3. *If operator $\mathcal{A}$ is the strongly singular integral operator defined by the kernel* (2.7) *and if $b \in H^{t,t}(I^2)$ and $g \in H_0^0(I) \cap H^t(I)$, then there exist a positive constant c and a positive integer n_0 such that, for all $n \geq n_0$,*

$$\|u - \widetilde{u}_n\|_0 \leq cn^{-t}\|u\|_t.$$

COROLLARY 5.4. *If operator $\mathcal{A}$ is the hypersingular integral operator defined by the kernel* (2.8) *and if $b \in H^{t,t}(I^2)$ and $g \in H_0^0(I) \cap H^t(I)$, then there exist a positive constant c and a positive integer n_0 such that, for all $n \geq n_0$,*

$$\|u - \widetilde{u}_n\|_1 \leq cn^{-t}\|u\|_{t+1}.$$

6. A fast solver for the truncated linear system. In this section we develop a fast solver for the truncated linear system by taking advantage of the structure of the truncated matrix $\widetilde{\mathbf{B}}_n$. The idea of this algorithm comes from the multilevel augmentation method presented in [6, 7] (see also [5, 8, 9]). We consider only the case $\mathbb{Z}_n^* = \mathbb{Z}_n^+$ since the other case can be similarly handled.

To present the fast algorithm, we assume that $n := 2^{m+q}$, where both m and q are positive integers with m *fixed*. The integer m here will be used to denote the initial level of approximation. We write $\widetilde{\mathbf{B}}_n$ in a block form

$$\widetilde{\mathbf{B}}_n := \begin{bmatrix} \overline{\mathbf{B}}_{0,0} & \overline{\mathbf{B}}_{0,1} & \cdots & \overline{\mathbf{B}}_{0,q} \\ \overline{\mathbf{B}}_{1,0} & \overline{\mathbf{B}}_{1,1} & \cdots & \overline{\mathbf{B}}_{1,q} \\ \vdots & \vdots & & \vdots \\ \overline{\mathbf{B}}_{q,0} & \overline{\mathbf{B}}_{q,1} & \cdots & \overline{\mathbf{B}}_{q,q} \end{bmatrix}, \tag{6.1}$$

where $\overline{\mathbf{B}}_{0,0}$ has order $2^{m+1} \times 2^{m+1}$, $\overline{\mathbf{B}}_{0,k}$ has order $2^{m+1} \times 2^{m+k}$, $\overline{\mathbf{B}}_{k,0}$ has order $2^{m+k} \times 2^{m+1}$ for $k = 1, 2, \ldots, q$, and $\overline{\mathbf{B}}_{j,l}$ has order $2^{m+j} \times 2^{m+l}$ for $j, l = 1, 2, \ldots, q$. For each $k = 0, 1, 2, \ldots, q$, we define a submatrix $\mathbf{G}_{m,k}$ of $\widetilde{\mathbf{B}}_n$ by replacing the subscript q in the right-hand side matrix of (6.1) with k. Clearly, $\mathbf{G}_{m,0} := \overline{\mathbf{B}}_{0,0}$, $\mathbf{G}_{m,q} := \widetilde{\mathbf{B}}_n$, and $\mathbf{G}_{m,k}$ is obtained from $\mathbf{G}_{m,k-1}$ by adding new rows and columns. We split $\mathbf{G}_{m,k}$ into two matrices

$$\mathbf{C}_{m,k} := \begin{bmatrix} \overline{\mathbf{B}}_{0,0} & \overline{\mathbf{B}}_{0,1} & \cdots & \overline{\mathbf{B}}_{0,k} \\ 0 & 0 & \cdots & 0 \\ \vdots & \vdots & & \vdots \\ 0 & 0 & \cdots & 0 \end{bmatrix} \quad \text{and} \quad \mathbf{D}_{m,k} := \begin{bmatrix} 0 & 0 & \cdots & 0 \\ \overline{\mathbf{B}}_{1,0} & \overline{\mathbf{B}}_{1,1} & \cdots & \overline{\mathbf{B}}_{1,k} \\ \vdots & \vdots & & \vdots \\ \overline{\mathbf{B}}_{k,0} & \overline{\mathbf{B}}_{k,1} & \cdots & \overline{\mathbf{B}}_{k,k} \end{bmatrix}.$$

Matrix $\mathbf{C}_{m,k}$ consists of the "low frequency" component of the matrix $\mathbf{G}_{m,k}$, and matrix $\mathbf{D}_{m,k}$ consists of its "high frequency" component. By using this splitting, (2.13) with $n = 2^{m+k}$ becomes

$$(\mathbf{A}_{2^{m+k}} + \mathbf{C}_{m,k})\mathbf{u}_{2^{m+k}} = g^-_{2^{m+k}} - \mathbf{D}_{m,k}\mathbf{u}_{2^{m+k}} \tag{6.2}$$

for $k = 0, 1, \ldots, q$. Note that the matrices $\mathbf{A}_{2^{m+k}} + \mathbf{C}_{m,k}$ have a very simple structure: $\mathbf{A}_{2^{m+k}}$ are diagonal, and all blocks of $\mathbf{C}_{m,k}$ except those in the first row are zero. The computational cost for inverting these matrices is comparable to that for inverting the matrix $\mathbf{A}_{2^m} + \mathbf{C}_{m,0}$. Equation (6.2) leads to the following fast algorithm.

ALGORITHM 6.1. *Let $m > 0$ be a fixed positive integer.*

Step 1*: Solve $\mathbf{u}^*_{2^m}$ from an equation of the initial step*

$$(\mathbf{A}_{2^m} + \mathbf{C}_{m,0})\mathbf{u}^*_{2^m} = \mathbf{g}^-_{2^m}. \tag{6.3}$$

Step 2: *For $k = 1, 2, \ldots, q$, suppose that $\mathbf{u}^*_{2^{m+k-1}}$ has been obtained, and do the following:*

- *Augment the matrices $\mathbf{C}_{m,k-1}$ and $\mathbf{D}_{m,k-1}$ to form $\mathbf{C}_{m,k}$ and $\mathbf{D}_{m,k}$, respectively.*
- *Augment the vector $\mathbf{u}^*_{2^{m+k-1}}$ by setting $\mathbf{v}^*_{2^{m+k}} = \begin{bmatrix} \mathbf{u}^*_{2^{m+k-1}} \\ \mathbf{0}_{2\times 2} \end{bmatrix}$.*
- *Solve $\mathbf{u}^*_{2^{m+k}}$ from the equation*

$$(\mathbf{A}_{2^{m+k}} + \mathbf{C}_{m,k})\mathbf{u}^*_{2^{m+k}} = \mathbf{g}^-_{2^{m+k}} - \mathbf{D}_{m,k}\mathbf{v}^*_{2^{m+k}}. \tag{6.4}$$

At each step, we need only to solve (6.4). Due to the structure of the matrix $\mathbf{A}_{2^{m+k}} + \mathbf{C}_{m,k}$, the computational effort to invert (6.4) is comparable to that to invert (6.3), which is fixed, independent of n. Hence, the main computational effort for solving the entire problem is concentrated on matrix-vector-multiplication $\mathbf{D}_{m,k}\mathbf{v}^*_{2^{m+k}}$. The computational effort of this algorithm is analyzed in the next theorem.

THEOREM 6.2. *The total number of multiplications required for obtaining $\mathbf{u}^*_{2^{m+q}}$ is $\mathcal{O}(n \log^2 n)$.*

Proof. We assume that the number of multiplications required for computing $\mathbf{u}^*_{2^m}$ is $\mathcal{M}(m)$. From Algorithm 6.1, the total number of multiplications required for obtaining $\mathbf{u}^*_{2^{m+q}}$ is

$$(q+1)\mathcal{M}(m) + \sum_{k=1}^{q} \mathcal{N}(\mathbf{A}_{2^{m+k}} + \mathbf{C}_{m,k} + \mathbf{D}_{m,k}). \tag{6.5}$$

Because the matrix $\mathbf{A}_{2^{m+k}}$ is diagonal, we have

$$\mathcal{N}(\mathbf{A}_{2^{m+k}}) = 2^{m+k+1}. \tag{6.6}$$

Based on the truncation strategy, we conclude that

$$\mathcal{N}(\mathbf{C}_{m,k} + \mathbf{D}_{m,k}) \le 4 \sum_{j=1}^{2^{m+k}} \frac{2^{m+q}}{j} \le 5(2^{m+q})(m+k). \tag{6.7}$$

By using (6.6) and (6.7), we obtain

$$\sum_{k=1}^{q} \mathcal{N}(\mathbf{A}_{2^{m+k}+p_0} + \mathbf{C}_{m,k} + \mathbf{D}_{m,k}) \le c(2^{m+q} + p_0)(m+q)^2.$$

This with (6.5) gives the desired result. ∎

Suppose that the output of Algorithm 6.1 is the vector $\mathbf{u}^*_n := [a^*_k, a^*_{-k} : k \in \mathbb{Z}^*_n]^T$. As in (4.22), we define

$$u^*_n(x) := \sum_{|k| \in \mathbb{Z}^*_n} a^*_k e_k(x), \quad x \in I. \tag{6.8}$$

The function u^*_n can be viewed as a new approximation of u. The next theorem shows that this new approximate solution has the same optimal order of convergence as $\widetilde{u}_n$.

THEOREM 6.3. *If $b \in H^{s_2+t, s_2+t}(I^2)$, then there exist a positive integer m_0 and a positive constant c such that, for all $m \ge m_0$ and all $q \in \mathbb{N}$,*

$$\|u - u^*_n\|_{s_1} \le cn^{-t}\|u\|_{s_1+t},$$

where $n = 2^{m+q}$.

Proof. The convergence order of Algorithm 6.1 is a direct consequence of Theorem 2.2 in [6]. ∎

TABLE 1

7. Numerical examples. In this section we present numerical examples to illustrate the efficiency and accuracy of the proposed methods. All computer programs are run on a personal computer with a 1.70 GHz celeron CPU and 256 M memory.

In the numerical results reported in this section, the remaining nonzero entries in the truncated Galerkin matrix are computed by using a numerical quadrature scheme based on the fast Fourier transform. Moreover, we use m to denote the initial level in Algorithm 6.1. We denote by $N(n)$ the order of the matrix $\widetilde{\mathbf{B}}_n$. The notations "C.R." and "C.O." stand for the compression rate and convergence order defined, respectively, by

$$\text{C.R.} = \frac{\mathcal{N}(\widetilde{\mathbf{B}}_n)}{\mathcal{N}(\mathbf{B}_n)} \quad \text{and} \quad \text{C.O.} = \log_2 \frac{\|u-u_{2n}^*\|_{s_1}}{\|u-u_n^*\|_{s_1}}.$$

The symbol "C.T." denotes the computing time measured in seconds, used in solving the truncated linear system by Algorithm 6.1.

Example 1. In this example, we consider solving the boundary integral equation (2.1) with the weakly singular kernel a as in (2.4) and a smooth kernel

$$b(x,y) := e^{\sin x \cos 2y} \log|\cos y + 5|, \quad x, y \in I,$$

by using Algorithm 6.1. We choose the right-hand side function g so that $u(x) := x$ is the exact solution of the equation. The integral equation is solved by Algorithm 6.1 with the initial level $m = 6$. Since u is not a periodic function, $u \in H^{0.5-\epsilon}(I)$, with $\epsilon > 0$ being an arbitrary number, and, thus, the theoretical convergence order is $\mathcal{O}(n^{-0.5+\epsilon})$. The numerical results are presented in Table 1.

Example 2. Consider solving the interior Dirichlet problem (2.2) with the domain D bounded by the curve

$$\gamma(x) := (\cos x, 0.4 \sin x), \quad x \in I.$$

We choose the boundary function f so that the exact solution is given by $U(x,y) := e^x \sin y$, $(x,y) \in D$. The associated boundary integral equation is given by (2.1) with the kernel a as in (2.4), a kernel

$$b(x,y) := -\frac{1}{2\pi}\left\{1 + \log\left[\sin^2\frac{x+y}{2} + 0.16\cos^2\frac{x+y}{2}\right]\right\}, \quad x, y \in I,$$

and the right-hand side function

$$g(x) := -\frac{1}{\pi} e^{\cos x} \cos(0.4 \sin x), \quad x \in I.$$

An approximate solution $\widetilde{u}_n$ of the boundary integral equation is solved by Algorithm 6.1 with the initial level $m = 5$. The corresponding approximate solution U_n of the

Dirichlet problem is given by

$$U_n(x,y) := \frac{1}{2}\int_I \widetilde{u}_n(z)\log[(x-\cos z)^2+(y-0.4\sin z)^2]dz, \quad (x,y)\in D.$$

In Table 2, we present the errors of the approximate solution U_n at the points $P_k := \gamma_k(\cos\frac{\pi}{4}, \sin\frac{\pi}{4})$, $k=1,2,3,4$, with $\gamma_1 = 0.2$, $\gamma_2 = 0.4$, $\gamma_3 = 0.6$, and $\gamma_4 = 0.8$, where $\delta_k := |U(P_k) - U_n(P_k)|$, $k=1,2,3,4$.

Example 3. We consider solving the boundary integral equation (2.1) with the strongly singular kernel a as in (2.7) and the smooth kernel

$$b(x,y) := e^{\cos x \sin 2y}\sin x \sin 2y \log|\sin y + 5|, \quad x,y\in I.$$

The right-hand side function g is chosen so that the exact solution $u(x) := \frac{1}{12}(3x^2 - 6\pi x + 2\pi^2)$. It can be seen that $u\in H^{1.5-\epsilon}(I)$, with $\epsilon > 0$ being an arbitrary number. We solve the boundary integral equation by Algorithm 6.1 with the initial level $m = 6$.

In Table 3, we list the numerical results for this example. Note that, since the exact solution $u\in H^{1.5-\epsilon}$, the theoretical convergence order is $\mathcal{O}(n^{-1.5+\epsilon})$, which is confirmed by the computed order of convergence.

Example 4. Consider solving the interior Neumann problem (2.5) with the domain D bounded by the curve by

$$\gamma(x) := (\cos x, 2\sin x), \quad x\in I.$$

We choose the boundary function f so that the exact solution is given by $U(x,y) = e^x \sin y$ for $(x,y)\in D$. The associated boundary integral equation is given by (2.1) with a strongly singular kernel a as in (2.7), a smooth kernel

$$b(x,y) := \frac{3\sin(x+y)}{10+6\cos(x+y)}, \quad x,y\in I,$$

and the right-hand side function

$$g(x) := 2e^{\cos x}\sin(2\sin x)\cos x + e^{\cos x}\cos(2\sin x)\sin x, \quad x\in I.$$

We solve the boundary integral equation by Algorithm 6.1 with the initial level $m = 5$ and obtain an approximate solution $\widetilde{u}_n$ having the form $\widetilde{u}_n = \sum_{|k|\in\mathbb{Z}_n^+} \widetilde{a}_k e^{ikx}$. The corresponding approximate solution of the interior Neumann problem is then given by

$$U_n(x,y) := \int_I \widetilde{\rho}_n(z) K(x,y,z)dz, \quad (x,y) \in D,$$

where

$$\widetilde{\rho}_n(x) := \sum_{|k|\in\mathbb{Z}_n^+} \frac{\operatorname{sign}(k)}{|k|} \widetilde{a}_k e^{ikx}, \quad x \in I,$$

and

$$K(x,y,z) = \frac{-2\cos z(x-\cos z) + \sin z(y-2\sin z)}{(x-\cos z)^2 + (y-2\sin z)^2}, \quad (x,y) \in D, \quad z \in I.$$

In Table 4, we present the error of the approximate solution $\delta_k := |U(P_k) - U_n(P_k)|$, where P_k, $k = 1, 2, 3, 4$, are the same points as those in Example 2.

Example 5. We consider solving the boundary integral equation (2.1) with the hypersingular kernel a as in (2.8) and a smooth kernel

$$b(x,y) := (x-\pi)(y-\pi), \quad x, y \in I.$$

We choose the right-hand side function g so that $u(x) := \frac{1}{12}(3x^2 - 6\pi x + 2\pi^2)$ is the exact solution of the equation. The integral equation is solved by Algorithm 6.1 with the initial level $m = 6$. Since $u \in H^{1.5-\epsilon}(I)$, with $\epsilon > 0$ being an arbitrary number, the theoretical convergence order is $\mathcal{O}(n^{-0.5+\epsilon})$. This is confirmed by the numerical result presented in Table 5.

Example 6. Consider the same interior Neumann problem as in Example 4. But this time we reformulate the Neumann problem as a boundary integral equation (2.1) with the hypersingular kernel a as in (2.8), the smooth kernel

$$b(x,y) := \frac{1}{\pi} \frac{30\cos(x+y) + 18}{(10 + 6\cos(x+y))^2}, \quad x, y \in I,$$

TABLE 6

q	$N(n)$	δ_1	δ_2	δ_3	δ_4	C.T.
0	64	$3.1598e-03$	$5.8998e-03$	$6.8311e-03$	$3.7228e-03$	< 0.01
1	128	$9.4629e-05$	$1.9808e-05$	$9.0284e-06$	$3.9735e-05$	< 0.01
2	256	$7.9961e-07$	$9.9455e-07$	$1.7150e-08$	$2.1955e-08$	0.015
3	512	$3.4572e-11$	$8.4628e-11$	$3.0479e-11$	$4.6393e-11$	0.031
4	1024	$2.6701e-14$	$6.1506e-14$	$4.2855e-14$	$3.8636e-14$	0.062

and the right-hand side function

$$g(x) := -\frac{2}{\pi}e^{\cos x}\sin(2\sin x)\cos x - \frac{1}{\pi}e^{\cos x}\cos(2\sin x)\sin x, \quad x \in I.$$

We solve the boundary integral equation by using Algorithm 6.1 with the initial level $m = 5$ and obtain an approximate solution. A corresponding approximate solution of the interior Neumann problem is then obtained by

$$U_n(x,y) := \int_I \widetilde{u}_n(z)K(x,y,z)dz, \quad (x,y) \in D,$$

where $K(x,y,z)$ is the same kernel as in Example 4. In Table 6, we report the error of the approximate solution at points P_k for $k = 1, 2, 3, 4$.

CONSTRAINED SPLINE SMOOTHING*

K. KOPOTUN†, D. LEVIATAN‡, AND A. V. PRYMAK§

Abstract. Several results on constrained spline smoothing are obtained. In particular, we establish a general result, showing how one can constructively smooth any monotone or convex piecewise polynomial function (ppf) (or any q-monotone ppf, $q \geq 3$, with one additional degree of smoothness) to be of minimal defect while keeping it close to the original function in the $\mathbb{L}_p$-(quasi)norm. It is well known that approximating a function by ppfs of minimal defect (splines) avoids introduction of artifacts which may be unrelated to the original function; thus it is always preferable. On the other hand, it is usually easier to construct constrained ppfs with as few requirements on smoothness as possible. Our results allow us to obtain shape-preserving splines of minimal defect with equidistant or Chebyshev knots. The validity of the corresponding Jackson-type estimates for shape-preserving spline approximation is summarized; in particular, we show that the $\mathbb{L}_p$-estimates, $p \geq 1$, can be immediately derived from the $\mathbb{L}_\infty$-estimates.

Key words. splines, smoothing, minimal defect, moduli of smoothness, degree of approximation, Jackson-type estimates

AMS subject classifications. 65D07, 65D10, 41A15, 41A29, 41A25, 26A15

DOI. 10.1137/060658746

1. Introduction and the main results.

1.1. Notation. Let $\mathcal{S}_r(\mathbf{z}_n)$ be the space of all piecewise polynomial functions (ppf) of degree r (order $r+1$) with the knots $\mathbf{z}_n := (z_i)_{i=0}^n$, $-1 =: z_0 < z_1 < \cdots < z_{n-1} < z_n := 1$. In other words, we say that $s \in \mathcal{S}_r(\mathbf{z}_n)$ if, on each interval (z_i, z_{i+1}), $0 \leq i \leq n-1$, $s \in \Pi_r$, where Π_r denotes the space of algebraic polynomials of degree $\leq r$. Also, let $\widetilde{\mathcal{S}}_r(\mathbf{z}_n) := \mathcal{S}_r(\mathbf{z}_n) \cap \mathbb{C}^{r-1}$ be the corresponding space of splines of minimal defect (highest smoothness).

As usual, $\mathbb{L}_p(J)$, $0 < p \leq \infty$, denotes the space of all measurable functions f on an interval J such that $\|f\|_{\mathbb{L}_p(J)} < \infty$, where $\|f\|_{\mathbb{L}_p(J)} := (\int_J |f(x)|^p\,dx)^{1/p}$ if $p < \infty$, and $\|f\|_{\mathbb{L}_\infty(J)} := \operatorname{ess\,sup}_{x\in J} |f(x)|$. For $\mu \in \mathbb{N}$, the space of all μ-times continuously differentiable functions on J is denoted by $\mathbb{C}^\mu(J)$. Also, $\mathbb{C}(J)$ and $AC(J)$ denote the spaces of all continuous and locally absolutely continuous functions, respectively. (Note that if $f \in \mathbb{C}(J)$, then $\|f\|_{\mathbb{C}(J)} = \|f\|_{\mathbb{L}_\infty(J)}$.) The Sobolev space is defined by $\mathbb{W}_p^r(J) := \big\{f \in \mathbb{L}_p(J) \mid f^{(r-1)} \in AC(J) \text{ and } f^{(r)} \in \mathbb{L}_p(J)\big\}$.

For $k \in \mathbb{N}_0$, define

$$\Delta_h^k(f,x,J) := \begin{cases} \displaystyle\sum_{i=0}^{k} \binom{k}{i} (-1)^{k-i} f(x - kh/2 + ih) & \text{if } x \pm kh/2 \in J, \\ 0 & \text{otherwise.} \end{cases}$$

The kth modulus of smoothness of $f \in \mathbb{L}_p(J)$ is defined by

$$\omega_k(f,t,J)_p := \sup_{0<h\le t} \left\|\Delta_h^k(f,\cdot,J)\right\|_{\mathbb{L}_p(J)},$$

and the Ditzian–Totik moduli of smoothness is

$$\omega_k^\varphi(f,t)_p := \sup_{0<h\le t} \left\|\Delta_{h\varphi(\cdot)}^k(f,\cdot)\right\|_{\mathbb{L}_p[-1,1]},$$

where $\varphi(x) := \sqrt{1-x^2}$.

The set of q-monotone functions on J is denoted by $\Delta^q(J)$. Recall that $f \in \Delta^q(J)$ if the divided differences $[f;t_0,\dots,t_q]$ of order q of f are nonnegative for all choices of $(q+1)$ distinct points $t_0,\dots,t_q$ in J. If f is continuous, then $f \in \Delta^q(J)$ if $\Delta_h^q(f,x,J) \ge 0$ for all $x \in J$ and $h > 0$. It is well known that, for $q \ge 2$ and an open interval J, $f \in \Delta^q(J)$ if and only if $f^{(q-2)}$ exists and is convex on J.

The error of unconstrained approximation of f from a set U is denoted by

$$E(f,U)_p := \inf_{u\in U} \|f-u\|_{\mathbb{L}_p(J)},$$

and the error of q-monotone approximation (i.e., approximation of f by q-monotone elements of U) is

$$E^{(q)}(f,U)_p := E(f, U\cap\Delta^q(J))_p.$$

Throughout this paper, we also use the notation $\|f\|_p := \|f\|_{\mathbb{L}_p[-1,1]}$, $\Delta^q := \Delta^q[-1,1]$, $|J| := \operatorname{meas}(J)$, and

$$\omega_k(f,J)_p := \omega_k(f,|J|,J)_p \quad \text{and} \quad \omega_k(f,t)_p := \omega_k(f,t,[-1,1])_p.$$

Given a partition $\mathbf{z}_n := (z_i)_{i=0}^n$, $-1 =: z_0 < z_1 < \cdots < z_{n-1} < z_n := 1$, we say that the partition $\tilde{\mathbf{z}}_m = (\tilde z_i)_{i=0}^m$ is a *δ-remesh* of $\mathbf{z}_n$ if, for each $0 \le j \le n-1$,

$$\max\{\tilde z_{i+1} - \tilde z_i \mid [\tilde z_i, \tilde z_{i+1}] \cap (z_j, z_{j+1}) \ne \emptyset\} \le \delta \min_{\nu=j-1,j,j+1} |z_{\nu+1} - z_\nu|$$

with z_{-1} and z_{n+1} defined to be (in this definition only!) $-\infty$ and $+\infty$, respectively. In other words, the largest interval $[\tilde z_i, \tilde z_{i+1}]$ intersecting (z_j, z_{j+1}) should have length at most δ times the length of $[z_j, z_{j+1}]$ or the lengths of (one or two) intervals adjacent to $[z_j, z_{j+1}]$, whichever is smaller. The class of all δ-remeshes of $\mathbf{z}_n$ is denoted by $\mathcal{R}_\delta(\mathbf{z}_n)$.

Clearly, m, n, and δ are not independent. The smallest m such that there is $\tilde{\mathbf{z}}_m$ in $\mathcal{R}_\delta(\mathbf{z}_n)$ is determined not only by n and δ but also by the scale of the partition $\mathbf{z}_n$ (see (1.1)).

It is well known that it is easier and less costly to obtain a good piecewise approximation to a function f than to assure, at the same time, the maximum smoothness of the approximating ppfs. On the other hand, replacing f by a ppf with minimal defect (spline) avoids introduction of artifacts which are unrelated to the original function, and may affect and complicate the problem one deals with. Thus, given two partitions $\mathbf{z}_n$ and $\tilde{\mathbf{z}}_m$ with the only requirement that $\tilde{\mathbf{z}}_m$ is somewhat denser than $\mathbf{z}_n$ (more precisely, $\tilde{\mathbf{z}}_m$ is an *arbitrary* δ-remesh of $\mathbf{z}_n$), we show in this paper how to smooth a general ppf on $\mathbf{z}_n$ to a spline of maximum smoothness on $\tilde{\mathbf{z}}_m$, while staying close to the original ppf and preserving its shape characteristics. We prove that

such a $\delta > 0$ exists that splines on an arbitrary δ-remesh of $\mathbf{z}_n$ may be constructed to satisfy the above requirements. In particular, as an illustration of these general results, we consider two special kinds of partitions of $[-1,1]$ which are important in applications: the *uniform* partition $\mathbf{u}_n := (-1+2j/n)_{j=0}^n$ and the *Chebyshev* partition $\mathbf{t}_n := (-\cos(j\pi/n))_{j=0}^n$.

The following are some properties of classes $\mathcal{R}_\delta(\mathbf{z}_n)$.

- For any partition $\mathbf{z}_n$ and $0 < \delta_1 \le \delta_2$, $\mathcal{R}_{\delta_1}(\mathbf{z}_n) \subset \mathcal{R}_{\delta_2}(\mathbf{z}_n)$.
- If a partition $\mathbf{z}^*_{kn}$ is a refinement of the partition $\mathbf{z}_n$ obtained by subdividing each interval in $\mathbf{z}_n$ into k equal subintervals, and $\tilde{\mathbf{z}}_m \in \mathcal{R}_\delta(\mathbf{z}_n)$, then $\tilde{\mathbf{z}}_m \in \mathcal{R}_{k\delta}(\mathbf{z}^*_{kn})$.
- If $0 < \delta < 1$ and $\tilde{\mathbf{z}}_m \in \mathcal{R}_\delta(\mathbf{z}_n)$, then any interval in $\tilde{\mathbf{z}}_m$ is contained in the union of at most two intervals in $\mathbf{z}_n$.
- For any $m \ge n/\delta$, $\mathbf{u}_m \in \mathcal{R}_\delta(\mathbf{u}_n)$.
- For any $m \ge \max\{25/\delta, 1\}n$, $\mathbf{t}_m \in \mathcal{R}_\delta(\mathbf{t}_n)$.

1.2. Constrained smoothing. Let $\mathbf{z}_n := \{z_0, \dots, z_n | -1 =: z_0 < z_1 < \cdots < z_n := 1\}$ be a partition of $[-1,1]$, and extend the notation by setting $z_j := z_0$, $j < 0$, and $z_j := z_n$, $j > n$. We denote the scale of the partition $\mathbf{z}_n$ by

$$\vartheta(\mathbf{z}_n) := \max_{0\le j\le n-1} \frac{|J_{j\pm1}|}{|J_j|}, \tag{1.1}$$

where $J_j := [z_j, z_{j+1}]$. We also denote $\mathfrak{I}_j := [(z_{j-1}+z_j)/2, (z_j+z_{j+1})/2]$.

The following theorem is our main result on constrained spline smoothing.

THEOREM 1.1. *Let $q \in \mathbb{N}$, $r \in \mathbb{N}$, and let $\mathbf{z}_n = (z_i)_{i=0}^n$ be a partition of $[-1,1]$. There is a constant $\delta = \delta(q,r)$ such that for each $s \in \mathcal{S}_{q+r}(\mathbf{z}_n) \cap \Delta^q$ such that*

$$s \in \mathbb{C}^{q-1}[-1,1], \tag{1.2}$$

and any $\tilde{\mathbf{z}}_m \in \mathcal{R}_\delta(\mathbf{z}_n)$ (i.e., $\tilde{\mathbf{z}}_m$ is a δ-remesh of $\mathbf{z}_n$), there exists a spline $\tilde{s} \in \widetilde{\mathcal{S}}_{q+r}(\tilde{\mathbf{z}}_m) \cap \Delta^q$ satisfying

$$\|s - \tilde{s}\|_{\mathbb{L}_p(\mathfrak{I}_j)} \le c(p,q,r)\omega_{q+r+1}(s, \mathfrak{I}_j)_p, \quad 0 \le j \le n,$$

for all $0 < p \le \infty$. Moreover, the construction of $\tilde{s}$ does not depend on p.

The proof of Theorem 1.1 (as well as the proof of Theorem 1.2 below) is postponed until section 3.

Recall that, for any $q \ge 2$, $\Delta^q \subset \mathbb{C}^{q-2}(-1,1)$; i.e., any q-monotone function is in $\mathbb{C}^{q-2}$. Hence, the smoothness provided by shape itself does not guarantee the applicability of the above result; one needs to assume/gain one additional smoothness degree.

It turns out that for $q = 1$ and $q = 2$ the gain of this additional degree of smoothness is not difficult (see section 3.2), and so we get the following stronger result in the case for $q \le 2$.

THEOREM 1.2. *Let $q = 1$ or 2, $r \in \mathbb{N}$, and let $\mathbf{z}_n = (z_i)_{i=0}^n$ be a partition of $[-1,1]$. There is a constant $\delta = \delta(r)$ such that for each $s \in \mathcal{S}_{q+r}(\mathbf{z}_n) \cap \Delta^q$ and any $\tilde{\mathbf{z}}_m \in \mathcal{R}_\delta(\mathbf{z}_n)$ there exists a spline $\tilde{s} \in \widetilde{\mathcal{S}}_{q+r}(\tilde{\mathbf{z}}_m) \cap \Delta^q$ satisfying*

$$\|s - \tilde{s}\|_{\mathbb{L}_p(\mathfrak{I}_j)} \le c(p,r)\omega_{q+r+1}(s, \mathfrak{I}_j)_p, \quad 0 \le j \le n,$$

for all $0 < p \le \infty$.

Note that an analog of Theorem 1.2 is also valid (and is actually simpler) in the case $r = 0$ (see Lemma 3.8 and Corollary 3.9).

In case the partitions $\mathbf{z}_n$ and $\tilde{\mathbf{z}}_m$ are either both uniform or both Chebyshev, Theorem 1.1 can be restated as follows.

COROLLARY 1.3. *Let $q \in \mathbb{N}$, $r \in \mathbb{N}$, and let $\mathbf{z}_n = (z_i)_{i=0}^n$ denote either $\mathbf{u}_n$ or $\mathbf{t}_n$. There is a constant $m_0 = m_0(q,r)$ such that for each $s \in \mathcal{S}_{q+r}(\mathbf{z}_n) \cap \Delta^q \cap \mathbb{C}^{q-1}[-1,1]$, and any $m \ge m_0 n$, there exists a spline $\tilde{s} \in \widetilde{\mathcal{S}}_{q+r}(\mathbf{z}_m) \cap \Delta^q$, where $\mathbf{z}_m$ is either $\mathbf{u}_m$ or $\mathbf{t}_m$, respectively, satisfying*

$$\|s - \tilde{s}\|_{\mathbb{L}_p(\mathcal{I}_j)} \le c(p,q,r)\omega_{q+r+1}(s, \mathcal{I}_j)_p, \quad 0 \le j \le n,$$

for all $0 < p \le \infty$.

We remark that in view of Theorem 1.2, in the case $q = 1$ and $q = 2$, the condition that s is in $\mathbb{C}^{q-1}[-1,1]$ in Corollary 1.3 can be removed.

Finally, we remark that it is still an open question whether the condition (1.2) in the statement of Theorem 1.1 can be removed if $q \ge 3$.

2. Applications: Jackson-type estimates.

2.1. Monotone and convex spline approximation: $p = \infty$. The following theorem is rather well known. Its positive part follows from Whitney's inequality ($q = 1$ and $1 \le k + \nu \le 2$), [11, Lemma 2] ($q = 1$, $\nu \ge 1$), [13, Corollary 2.4] ($q = 2$, $\nu \ge 2$), and [6] ($q = 2$, $2 \le k + \nu \le 3$). The negative part follows from [17] and [15, p. 141].

THEOREM 2.1 ($p = \infty$). *Let $q = 1$ or 2, and $k, \nu \in \mathbb{N}_0$ be such that either $\nu \ge q$ or $q \le k + \nu \le q + 1$ (see Figures 1 and 2). Then, for every $f \in \Delta^q \cap \mathbb{C}^\nu[-1,1]$, $n \in \mathbb{N}$, and any partition $\mathbf{z}_n = (z_i)_{i=0}^n$ of $[-1,1]$, there exists $s \in \mathcal{S}_{k+\nu-1}(\mathbf{z}_n) \cap \Delta^q$ such that*

$$\|f - s\|_{\mathbb{L}_\infty(J_j)} \le c(k,\nu,\vartheta(\mathbf{z}_n))|J_j|^\nu \omega_k(f^{(\nu)}, J_j)_\infty, \qquad 0 \le j \le n-1.$$

Moreover, this estimate is no longer true in general for k and ν which do not satisfy the above conditions. (This means that for each partition $\mathbf{z}_n$ and any constant $c(k,\nu,\vartheta(\mathbf{z}_n))$, there exists a function $f \in \Delta^q \cap \mathbb{C}^\nu[-1,1]$, such that the above estimate is invalid for any $s \in \mathcal{S}_{k+\nu-1}(\mathbf{z}_n) \cap \Delta^q$.)

We note that the case $q = 2$, $k + \nu = 1$ is excluded from the statement of Theorem 2.1 (as well as the statements of Theorem 2.4 and Corollaries 2.2, 2.3, 2.5, and 2.6). Indeed, the only convex piecewise constant ppfs are constant functions on $[-1,1]$.

Using Theorem 1.2 we can now obtain the following consequence of this result for monotone and convex approximation by splines of any smoothness.

COROLLARY 2.2 ($p = \infty$). *Let $q = 1$ or 2, and $k, \nu \in \mathbb{N}_0$ be such that either $\nu \ge q$ or $q \le k + \nu \le q + 1$. Then, for any $r \ge k + \nu - 1$ and partition $\mathbf{z}_n = (z_i)_{i=0}^n$ of $[-1,1]$, there exists a constant $\delta = \delta(r)$ such that for any $\tilde{\mathbf{z}}_m \in \mathcal{R}_\delta(\mathbf{z}_n)$ and every $f \in \Delta^q \cap \mathbb{C}^\nu[-1,1]$, there exists a spline $\tilde{s} \in \widetilde{\mathcal{S}}_r(\tilde{\mathbf{z}}_m) \cap \Delta^q$ satisfying*

$$\|f - \tilde{s}\|_{\mathbb{L}_\infty(\mathcal{I}_j)} \le c(k,\nu,r,\vartheta(\mathbf{z}_n))|J_j|^\nu \omega_k(f^{(\nu)}, [z_{j-1}, z_{j+1}])_\infty$$

for all $0 \le j \le n$. Moreover, this estimate is no longer true in general for k and ν which do not satisfy the above conditions.

Taking into account Corollary 1.3 and the fact that $|J_j| = n^{-1}$ (if $\mathbf{z}_n = \mathbf{u}_n$) and $|J_j| \sim \varphi(x)n^{-1} + n^{-2}$, $x \in J_j$ (if $\mathbf{z}_n = \mathbf{t}_n$), this, in turn, immediately implies the following result.

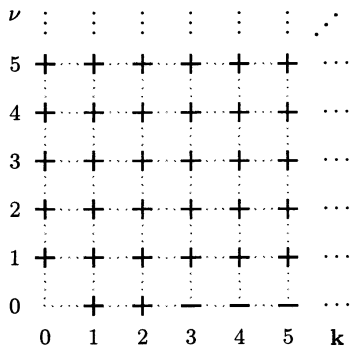

FIG. 1. $q = 1, p = \infty$.

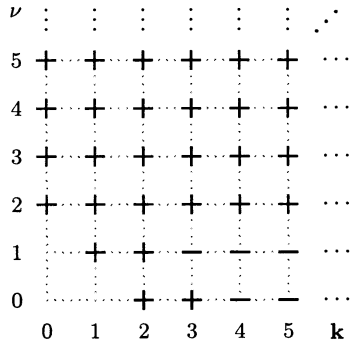

FIG. 2. $q = 2, p = \infty$.

COROLLARY 2.3. *Let $q = 1$ or 2, and $k, \nu \in \mathbb{N}_0$ be such that either $\nu \geq q$ or $q \leq k + \nu \leq q + 1$. Then, for every $f \in \Delta^q \cap \mathbb{C}^\nu[-1, 1]$, $n \in \mathbb{N}$, and $r \geq k + \nu - 1$, we have*

$$E^{(q)}(f, \widetilde{\mathcal{S}}_r(\mathbf{u}_n))_\infty \leq c(k, \nu, r) n^{-\nu} \omega_k(f^{(\nu)}, n^{-1})_\infty \tag{2.1}$$

and

$$E^{(q)}(f, \widetilde{\mathcal{S}}_r(\mathbf{t}_n))_\infty \leq c(k, \nu, r) n^{-\nu} \omega_k^\varphi(f^{(\nu)}, n^{-1})_\infty. \tag{2.2}$$

Moreover, these estimates are no longer true in general for k and ν which do not satisfy the above conditions.

For the reader's convenience we describe the above results using arrays in Figures 1 and 2. In these figures as well as Figures 3 and 4 in the case $1 \leq p < \infty$ (with obvious modifications), the symbols "−" and "+" have the following meaning.

- The symbol "+" in the position (k, ν) means that inequalities (2.1) and (2.2) are valid for all $f \in \Delta^q \cap \mathbb{C}^\nu[-1, 1]$.
- The symbol "−" in the position (k, ν) means that inequalities (2.1) and (2.2) are not true in general, i.e., there are functions $f \in \Delta^q \cap \mathbb{C}^\nu[-1, 1]$ for which these inequalities fail.

We remark that the estimates in Corollary 2.3 (and the arrays in Figures 1 and 2) are well known for algebraic polynomials as well as splines of low smoothness. For splines of minimal defect, only some special cases when $\mathbf{z}_n = \mathbf{u}_n$ were known (see, e.g., [3, Theorem 1], [10, Theorem 2.1], [2, Theorem 1], [8, Corollaries 5.3 and 5.4]).

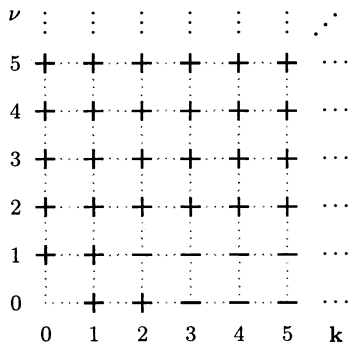

FIG. 3. $q = 1, 1 \le p < \infty$.

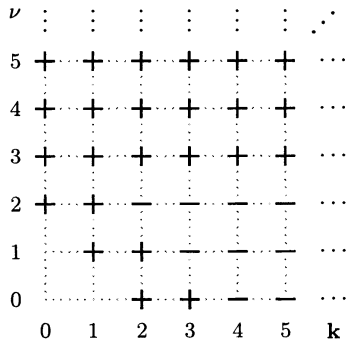

FIG. 4. $q = 2, 1 \le p < \infty$.

2.2. Monotone and convex spline approximation: $1 \le p < \infty$.

THEOREM 2.4 ($1 \le p < \infty$). *Let $q = 1$ or 2, $1 \le p < \infty$, and $k, \nu \in \mathbb{N}_0$ be such that either $\nu \ge q+1$ or $q \le k+\nu \le q+1$. Then, for every $f \in \Delta^q \cap \mathbb{W}_p^\nu[-1,1]$, $n \in \mathbb{N}$, and any partition $\mathbf{z}_n = (z_i)_{i=0}^n$ of $[-1,1]$, there exists $s \in \mathcal{S}_{k+\nu-1}(\mathbf{z}_n) \cap \Delta^q$ such that*

$$\|f - s\|_{\mathbb{L}_p(J_j)} \le c(k, \nu, \vartheta(\mathbf{z}_n))|J_j|^\nu \omega_k(f^{(\nu)}, J_j)_p, \quad 0 \le j \le n-1.$$

Moreover, this estimate is no longer true in general for k and ν which do not satisfy the above conditions.

The positive part of Theorem 2.4 for $\nu \ge 1$ follows from Theorem 2.1 and the well-known inequality

$$\omega_{r+1}(f, J)_\infty \le c|J|^{1-1/p}\, \omega_r(f', J)_p,$$

where J is a closed interval, $f \in \mathbb{W}_p^1(J)$, $1 \le p < \infty$, and $r \in \mathbb{N}_0$. For $\nu = 0$, the case $(q,k) = (1,1)$ is straightforward, $(q,k) = (2,3)$ is shown in [4, Theorem 1.2], and the cases $(q,k) = (1,2)$ and $(2,2)$ are established following the proof of [4, Theorem 1.2] using piecewise linear ppfs which interpolate f at the knots instead of piecewise quadratic functions in [4, Lemma 2.2]. The negative part of Theorem 2.4 is a consequence of [7, Theorem 1].

As in the case $p = \infty$, Theorem 1.2 yields the following stronger result for monotone and convex approximation by splines of any smoothness.

COROLLARY 2.5 ($1 \le p < \infty$). *Let $q = 1$ or 2, $1 \le p < \infty$, and $k, \nu \in \mathbb{N}_0$ be such that either $\nu \ge q+1$ or $q \le k+\nu \le q+1$. Then, for any $r \ge k+\nu-1$ and*

any partition $\mathbf{z}_n = (z_i)_{i=0}^n$ *of* $[-1,1]$, *there exists a constant* $\delta = \delta(r)$ *such that for any* $\tilde{\mathbf{z}}_m \in \mathcal{R}_\delta(\mathbf{z}_n)$ *and every* $f \in \Delta^q \cap \mathbb{W}_p^\nu[-1,1]$ *there exists a spline* $\tilde{s} \in \widetilde{\mathcal{S}}_r(\tilde{\mathbf{z}}_m) \cap \Delta^q$ *satisfying*

$$\|f - \tilde{s}\|_{\mathbb{L}_p(\mathcal{I}_j)} \le c(k,\nu,r,\vartheta(\mathbf{z}_n))|J_j|^\nu \omega_k(f^{(\nu)},[z_{j-1},z_{j+1}])_p$$

for all $0 \le j \le n$. *Moreover, this estimate is no longer true in general for* k *and* ν *which do not satisfy the above conditions.*

Recalling that for $f \in \mathbb{L}_p[-1,1]$, $1 \le p < \infty$, and $k, \mu \in \mathbb{N}$ the following estimates are true (see, e.g., [14], [5]):

$$\sum_{j=0}^{n-\mu-1} \omega_k\left(f, \cup_{i=j}^{j+\mu} J_i\right)_p^p \le \begin{cases} c(k,\mu)\,\omega_k(f,n^{-1})_p^p & \text{if } \mathbf{z}_n = \mathbf{u}_n, \\ c(k,\mu)\,\omega_k^\varphi(f,n^{-1})_p^p & \text{if } \mathbf{z}_n = \mathbf{t}_n, \end{cases}$$

we get the following consequence of Corollary 2.5.

COROLLARY 2.6. *Let* $q = 1$ *or* 2, $1 \le p < \infty$, *and* $k, \nu \in \mathbb{N}_0$ *be such that either* $\nu \ge q+1$ *or* $q \le k+\nu \le q+1$. *Then, for any* $f \in \Delta^q \cap \mathbb{W}_p^\nu[-1,1]$, $n \in \mathbb{N}$, *and* $r \ge k+\nu-1$, *we have*

$$E^{(q)}(f, \widetilde{\mathcal{S}}_r(\mathbf{u}_n))_p \le c(k,\nu,r) n^{-\nu} \omega_k(f^{(\nu)}, n^{-1})_p \tag{2.3}$$

and

$$E^{(q)}(f, \widetilde{\mathcal{S}}_r(\mathbf{t}_n))_p \le c(k,\nu,r) n^{-\nu} \omega_k^\varphi(f^{(\nu)}, n^{-1})_p. \tag{2.4}$$

Moreover, these estimates are no longer true in general for k *and* ν *which do not satisfy the above conditions.*

3. Further results and proofs. Everywhere in this section, if p is a polynomial piece of a spline s on an interval J, i.e., $p := s|_J$, then $p(x)$ for $x \notin J$ is the polynomial extension of $s|_J$.

3.1. Constrained spline smoothing: Proof of Theorem 1.1.

LEMMA 3.1 (see [9, Lemma 2.4 and Corollary 2.5]). *Let* $s \in \mathcal{S}_r(\mathbf{z}_n)$, *and suppose that the polynomials* $p_j := s|_{[z_j,z_{j+1}]}$, $0 \le j \le n-1$. *Then, for every* $1 \le j \le n-1$ *and all* $0 < p \le \infty$,

$$|J_j|^{k+1/p}|p_j^{(k)}(z_j) - p_{j-1}^{(k)}(z_j)| \le c(p,r,\vartheta(\mathbf{z}_n))\omega_{r+1}(s,[z_{j-1},z_{j+1}])_p$$

for $0 \le k \le r$, *and*

$$\|p_j - p_{j-1}\|_{\mathbb{L}_p[z_{j-1},z_{j+1}]} \le c(p,r,\vartheta(\mathbf{z}_n))\omega_{r+1}(s,[z_{j-1},z_{j+1}])_p.$$

LEMMA 3.2 (Markov's inequality). *For any polynomial* $\mathfrak{p} \in \Pi_r$,

$$\|\mathfrak{p}'\|_{\mathbb{C}[a,b]} \le \frac{2r^2}{b-a}\,\|\mathfrak{p}\|_{\mathbb{C}[a,b]}.$$

LEMMA 3.3. *Let* $r \in \mathbb{N}$, $S \in \mathcal{S}_r(\{-1,0,1\})$ *(i.e., S is a ppf of degree* $\le r$ *on* $[-1,1]$ *with the only breakpoint at* 0*), and let* p_1 *and* p_2 *be the polynomial pieces of* S: $p_1 := S|_{[-1,0)}$, $p_2 := S|_{(0,1]}$. *If* S *is nonnegative on* $[-1,1]$, *then there exists an interval* I, $I \subset [-1,0]$ *or* $I \subset [0,1]$ *such that* $|I| \ge \frac{1}{4r^2}$ *and*

$$S(x) \ge c_1(r)\,\|p_1 - p_2\|_\infty \quad \textit{for all } x \in I.$$

Proof. Let $p \in \Pi_r$ be nonnegative on $[0,1]$ (the same argument applies for $[-1,0]$). Then, there exists an interval $I \subset [0,1]$, $|I| \geq \frac{1}{4r^2}$ such that

$$p(x) \geq \frac{1}{2} \|p\|_{\mathbb{C}[0,1]} \quad \text{for all } x \in I.$$

Indeed, let $x^* \in [0,1]$ be a point satisfying $p(x^*) = \|p\|_{\mathbb{C}[0,1]}$. By Lemma 3.2, $\|p'\|_{\mathbb{C}[0,1]} \leq 2r^2 \|p\|_{\mathbb{C}[0,1]}$, and so

$$p(x) \geq p(x^*) - 2r^2 \|p\|_{\mathbb{C}[0,1]} |x - x^*|, \quad x \in [0,1].$$

Hence, if $x \in [0,1]$ and $|x - x^*| \leq \frac{1}{4r^2}$, then $p(x) \geq \frac{1}{2} \|p\|_{\mathbb{C}[0,1]}$, as required.

Now suppose, without loss of generality, that $\|p_2\|_\infty \geq \|p_1\|_\infty$. Then

$$\|p_1 - p_2\|_\infty \leq \|p_1\|_\infty + \|p_2\|_\infty \leq 2 \|p_2\|_\infty \leq c(r) \|p_2\|_{\mathbb{C}[0,1]},$$

and the above observation can be used with $p := p_2$. ∎

The following lemma follows from Beatson [1, Lemma 3.2].

LEMMA 3.4. *Let $r \in \mathbb{N}$, $d := 2r^2$, and $\mathfrak{p}_1, \mathfrak{p}_2 \in \Pi_r$. For any knot sequence $\mathbf{x}_d := (x_i)_{i=0}^d$, $a = x_0 < x_1 < \cdots < x_d = b$, there exists a spline $s \in \widetilde{\mathbb{S}}_r(\mathbf{x}_d)$ such that*

(i) *$s(x)$ is a number between $\mathfrak{p}_1(x)$ and $\mathfrak{p}_2(x)$ for $x \in [a,b]$,*

(ii) *$s \equiv \mathfrak{p}_1$ on $(-\infty, a]$, and $s \equiv \mathfrak{p}_2$ on $[b, \infty)$.*

LEMMA 3.5. *Let $r \in \mathbb{N}$, $S \in \mathbb{S}_r(\{-1,0,1\})$ (i.e., S is a ppf of degree $\leq r$ on $[-1,1]$ with the only breakpoint at 0), and assume that S is nonnegative on $[-1,1]$. Suppose that $d := 2r^2$, and a knot sequence $\mathbf{z}_{2d+1} := (z_i)_{i=0}^{2d+1}$, $-1 < z_0 < z_1 < \cdots < z_{2d+1} < 1$ is such that $z_d \leq 0 \leq z_{d+1}$ (in other words, there are $(d+1)$ knots to the left and to the right of zero). Then, there exists $\widetilde{S} \in \widetilde{\mathbb{S}}_r(\mathbf{z}_{2d+1})$ satisfying*

(i) *$\widetilde{S} \geq 0$ on $[-1,1]$,*

(ii) *$\widetilde{S}(x) = S(x)$ for all $x \notin [z_0, z_{2d+1}]$,*

(iii) *$\|S - \widetilde{S}\|_\infty \leq 2 \|p_1 - p_2\|_\infty$, where $p_1 := S|_{[-1,0)}$, $p_2 := S|_{(0,1]}$ are the polynomial pieces of S.*

Proof. Let $\tilde{p}(x) := p_1(x) + \|p_1 - p_2\|_\infty$. Note that $\tilde{p}(x) \geq p_1(x) \geq 0$ for $x \in [-1,0]$, and $\tilde{p}(x) \geq p_2(x) \geq 0$ for $x \in [0,1]$.

We now use Lemma 3.4 twice. First, we "glue" p_1 with $\tilde{p}$ using Lemma 3.4 with $\mathfrak{p}_1 = p_1$, $\mathfrak{p}_2 = \tilde{p}$, $\mathbf{x}_d = (z_i)_{i=0}^d$, and $[a,b] = [z_0, z_d]$. Second, we "glue" $\tilde{p}$ with p_2 using Lemma 3.4 with $\mathfrak{p}_1 = \tilde{p}$, $\mathfrak{p}_2 = p_2$, $\mathbf{x}_d = (z_i)_{i=d+1}^{2d+1}$, and $[a,b] = [z_{d+1}, z_{2d+1}]$. As a result, we get a spline $\widetilde{S} \in \widetilde{\mathbb{S}}_r(\mathbf{z}_{2d+1})$ such that $\tilde{p} \geq \widetilde{S} \geq p_1 \geq 0$ on $[z_0, z_d]$, $\tilde{p} \geq \widetilde{S} \geq p_2 \geq 0$ on $[z_{d+1}, z_{2d+1}]$, $\widetilde{S}(x) = S(x) \geq 0$ for $x \notin [z_0, z_{2d+1}]$, and $\widetilde{S}(x) = \tilde{p}(x) \geq 0$ for $x \in [z_d, z_{d+1}]$. Clearly,

$$\left\| S - \widetilde{S} \right\|_\infty \leq \max_{i=1,2} \|\tilde{p} - p_i\|_\infty \leq 2 \|p_1 - p_2\|_\infty,$$

and the proof is complete. ∎

The following lemma is the main tool for constrained smoothing.

LEMMA 3.6. *Let $q \in \mathbb{N}$, $r \in \mathbb{N}$. There exists a constant $\delta(q,r) > 0$ such that, for each ppf $s \in \Delta^q \cap \mathbb{C}^{q-1}[-1,1]$ of degree $\leq q + r$ with the only knot at 0 (i.e., $s \in \mathbb{S}_{q+r}(\{-1,0,1\})$), and each partition $\mathbf{z}_l = (z_i)_{i=0}^l$, $-1 = z_0 < z_1 < \cdots < z_{l-1} < z_l = 1$ with*

$$\max_{0 \leq i \leq l-1} (z_{i+1} - z_i) =: \delta < \delta(q,r),$$

there exists a spline $\tilde{s} \in \Delta^q \cap \widetilde{\mathbb{S}}_{q+r}(\mathbf{z}_l)$ *(i.e.,* $\tilde{s}$ *is a spline of minimal defect) such that* $\tilde{s} \equiv s$ *in neighborhoods of* -1 *and* 1*, and*

$$\|s - \tilde{s}\|_p \le c(p,q,r)\omega_{q+r+1}(s,1)_p \tag{3.1}$$

for all $0 < p \le \infty$.

Proof. Since $s^{(q-1)}$ is absolutely continuous and differentiable everywhere except for 0 (because it is a continuous ppf of degree $\le r+1$ with the only breakpoint at 0), we conclude that $S := s^{(q)}$ is a nonnegative ppf of degree $\le r$ with the only knot at 0. Let $p_1 := S|_{[-1,0)}$, $p_2 := S|_{(0,1]}$ be the polynomial pieces of S, and denote $\eta := \|p_1 - p_2\|_\infty$ and $d := 2r^2$. Lemma 3.3 implies that there exists an interval I (without loss of generality, we may assume that it is a subset of $[0,1]$) such that $|I| \ge (2d)^{-1}$ and

$$S(x) \ge c_1\eta \quad \text{for all } x \in I, \tag{3.2}$$

where c_1 depends on r only.

If $P_1 := s|_{[-1,0)}$, $P_2 := s|_{(0,1]}$ are the original polynomial pieces of s, then $p_1 = P_1^{(q)}$, $p_2 = P_2^{(q)}$, and using Lemma 3.2 as well as Lemma 3.1 we have

$$\begin{aligned}\eta &= \left\|P_1^{(q)} - P_2^{(q)}\right\|_\infty \le (q+r)^{2q}\|P_1 - P_2\|_\infty \\ &\le c(p,q,r)\|P_1 - P_2\|_p \le c(p,q,r)\omega_{q+r+1}(s,1)_p.\end{aligned}$$

Now, let I' be the subinterval of I with the same right endpoint as I and length $|I'| = (5d)^{-1}$, so that

$$I' \cap [-(5d)^{-1}, (5d)^{-1}] = \emptyset.$$

Suppose now that the index $i^\star$ is such that $z_{i^\star} \le 0 < z_{i^\star+1}$, and that $\delta < (5d(d+2))^{-1}$. Then each of the intervals $[-(5d)^{-1}, 0]$ and $[0, (5d)^{-1}]$ contains at least $(d+1)$ points from $\mathbf{z}_l$:

$$(z_i)_{i=i^\star-d}^{i^\star} \subset [-(5d)^{-1}, 0] \quad \text{and} \quad (z_i)_{i=i^\star+1}^{i^\star+d+1} \subset [0, (5d)^{-1}].$$

We can apply Lemma 3.5 to construct a nonnegative spline $\widetilde{S}$ of degree r and highest smoothness ($\widetilde{S} \in \mathbb{C}^{r-1}$) having knots $(z_i)_{i=i^\star-d}^{i^\star+d+1}$ only, coinciding with S outside $J_\star := [z_{i^\star-d}, z_{i^\star+d+1}]$, and such that

$$\left\|S - \widetilde{S}\right\|_\infty \le 2\eta.$$

We define s_* to be such that $s_*^{(q)} \equiv \widetilde{S}$ and $s_*^{(\nu)}(-1) = s^{(\nu)}(-1)$ for all $0 \le \nu \le q-1$. Therefore,

$$s_*(x) := \sum_{\nu=0}^{q-1} \frac{s^{(\nu)}(-1)}{\nu!}(x+1)^\nu + \frac{1}{(q-1)!}\int_{-1}^{x}(x-t)^{q-1}\widetilde{S}(t)\,dt.$$

The spline s_* is almost what we need. Namely, it is in $\Delta^q \cap \widetilde{\mathbb{S}}_{q+r}(\mathbf{z}_l)$, it coincides with s in a neighborhood of -1, and since S and $\widetilde{S}$ may differ only on an interval $J_\star$ of length $|J_\star| \le (2d+1)\delta$, we have

$$\begin{aligned}\|s - s_*\|_\infty &\le \left\|\frac{1}{(q-1)!}\int_{-1}^{x}(x-t)^{q-1}\left(S(t) - \widetilde{S}(t)\right)\,dt\right\|_\infty \\ &\le \frac{2^q\eta}{(q-1)!}|J_\star| \le 2^q(2d+1)\eta\delta =: c_2\eta\delta.\end{aligned}$$

The only property that s_* does not have is that it may not be coinciding with s in a neighborhood of 1. To remedy this, we use Lemma 3.4 and "glue" s_* to s on the interval I' preserving its properties.

Let $[a,b] := I'$ and recall that $b-a=(5d)^{-1}$. Now, let $d_1 := 2(q+r)^2$ and take $\delta < h := \frac{b-a}{2(d_1+1)} = \frac{1}{10d(d_1+1)}$. Then, each interval $[a+jh, a+(j+1)h]$, $0 \le j \le 2d_1+1$, contains at least one point z_{i_j} from $\mathbf{z}_l$, and we set $\mathbf{x}_{d_1} = (x_j)_{j=0}^{d_1}$, where $x_j := z_{i_{(2j)}}$, $0 \le j \le d_1$. Note that

$$\max_{0\le j\le d_1}(x_{j+1}-x_j) \le 3h \quad \text{and} \quad \min_{0\le j\le d_1}(x_{j+1}-x_j) \ge h.$$

Taking into account that both s and s_* are polynomials of degree $\le q+r$ on I', Lemma 3.4 implies that there exists a spline $\tilde{s} \in \widetilde{\mathcal{S}}_{q+r}(\mathbf{z}_l)$ such that the only knots of $\tilde{s}$ inside I' are x_j, $0 \le j \le d_1$, $\tilde{s}(x)$ is a number between $s(x)$ and $s_*(x)$ for $x \in [x_0, x_{d_1}] \subset I'$, and $\tilde{s}$ coincides with s_* on $[-1,x_0]$ and with s on $[x_{d_1},1]$. Hence,

$$\|s-\tilde{s}\|_\infty \le \|s-s_*\|_\infty \le c_2\eta\delta$$

(so that (3.1) immediately follows), and it only remains to verify that $\tilde{s} \in \Delta^q[x_0, x_{d_1}]$. To this end, it suffices to show that $\tilde{s}^{(q)}(x) \ge 0$ for all $x \in J_j := [x_j, x_{j+1}]$, $0 \le j \le d_1-1$. Let such an interval J_j be fixed. Using Lemma 3.2 and the fact that $\tilde{s}-s$ is a polynomial of degree $\le q+r$ on J_j, we have

$$\begin{aligned}\left\|\tilde{s}^{(q)} - s^{(q)}\right\|_{\mathbb{C}(J_j)} &\le \left(\frac{2(q+r)^2}{|J_j|}\right)^q \|s-\tilde{s}\|_{\mathbb{C}(J_j)} \le \left(\frac{2(q+r)^2}{h}\right)^q c_2\eta\delta \\ &= (10dd_1(d_1+1))^q\, c_2\eta\delta =: c_3\eta\delta,\end{aligned}$$

where c_3 depends only on r and q. Therefore, for every $x \in J_j$, using (3.2) we have

$$\tilde{s}^{(q)}(x) \ge s^{(q)}(x) - c_3\eta\delta \ge c_1\eta - c_3\eta\delta \ge 0,$$

provided $\delta \le c_1/c_3$. Combining the above restrictions on δ we see that it is possible to take

$$\delta(q,r) := \min\left\{(10d(d_1+1))^{-1}, c_1/c_3\right\},$$

and the construction of $\tilde{s}$ is complete. □

COROLLARY 3.7. *Let $q \in \mathbb{N}$, $r \in \mathbb{N}$. Then there exists a constant $\delta(q,r) > 0$ such that, for each ppf $s \in \Delta^q \cap \mathbb{C}^{q-1}[a,b]$ of degree $\le q+r$ with the only knot at $c \in (a,b)$ (i.e., $s \in \mathcal{S}_{q+r}(\{a,c,b\})$), and each partition $\mathbf{z}_l = (z_i)_{i=0}^l$, $a = z_0 < z_1 < \cdots < z_{l-1} < z_l = b$ with*

$$\max_{0\le i\le l-1}(z_{i+1}-z_i) < \delta(q,r)\min\{b-c, c-a\},$$

there exists a spline $\tilde{s} \in \Delta^q \cap \widetilde{\mathcal{S}}_{q+r}(\mathbf{z}_l)$ (i.e., $\tilde{s}$ is a spline of minimal defect) such that $\tilde{s} \equiv s$ in neighborhoods of a and b, and

$$\|s-\tilde{s}\|_{\mathbb{L}_p[a,b]} \le c(p,q,r)\omega_{q+r+1}(s,[a,b])_p$$

for all $0 < p \le \infty$.

Proof. Without loss of generality, assume $c \ge (b+a)/2$. We apply Lemma 3.6 to $s^*(x) := s(c+(b-c)x)$ and those knots $(z_i-c)/(b-c)$ which belong to $[-1,1]$. Now, extending the resulting ppf $\tilde{s}^*$ polynomially from $[-1,1]$ to all $\mathbb{R}$, we can go back to the original interval $[a,b]$ using $\tilde{s}(t) := \tilde{s}^*((t-c)/(b-c))$. □

Proof of Theorem 1.1. It is sufficient to apply Corollary 3.7 with $[a,b] = \mathfrak{I}_j$ and $c = z_j$, for each $1 \le j \le n-1$. Construction of $\tilde{s}$ is now obvious. □

3.2. Convex and monotone spline smoothing: Auxiliary results for the proof of Theorem 1.2. Recall that for a partition $\mathbf{z}_n := (z_i)_{i=0}^n$, $a =: z_0 < z_1 < \cdots < z_{n-1} < z_n := b$ of an interval $[a,b]$, $z_j := a$, $j < 0$, and $z_j := b$, $j > n$, and that $J_j = [z_j, z_{j+1}]$. The following lemma shows how a piecewise polynomial convex function can be smoothed to be continuously differentiable without adding any extra knots and keeping the error small.

LEMMA 3.8 (convex smoothing). *Let $r \in \mathbb{N}_0$, $\mathbf{z}_n := (z_i)_{i=0}^n$, $a =: z_0 < z_1 < \cdots < z_{n-1} < z_n := b$ be a partition of $[a,b]$, and let $s \in \Delta^2 \cap \mathcal{S}_{r+2}(\mathbf{z}_n)$. Then, there exists $\tilde{s} \in \Delta^2 \cap \mathcal{S}_{r+2}(\mathbf{z}_n) \cap \mathbb{C}^1[a,b]$ such that, for any $1 \le j \le n-1$ and all $0 < p \le \infty$,*

$$\|s - \tilde{s}\|_{\mathbb{L}_p[z_{j-1}, z_{j+1}]} \le c(p, r, \vartheta(\mathbf{z}_n))\omega_{r+3}(s, [z_{j-2}, z_{j+2}])_p \tag{3.3}$$

and

$$\|s' - \tilde{s}'\|_{\mathbb{L}_p[z_{j-1}, z_{j+1}]} \le c(p, r, \vartheta(\mathbf{z}_n))\omega_{r+2}(s', [z_{j-2}, z_{j+2}])_p. \tag{3.4}$$

Moreover,

$$\tilde{s}^{(\nu)}(a) = s^{(\nu)}(a) \quad \text{and} \quad \tilde{s}^{(\nu)}(b) = s^{(\nu)}(b), \quad \nu = 0, 1. \tag{3.5}$$

Proof. This lemma is actually a simpler version of [12, Lemma 1] (see also [16]). It was not proved in [12] for all $p > 0$, and the construction of $\tilde{s}$ was more involved there (because s was allowed to change convexity). For completeness, we recall this construction from [12], adopting it to our case and showing how the estimates can be obtained for all $p > 0$.

With $p_i := s|_{J_i}$, $0 \le i \le n-1$, denote

$$a_i(x) := \frac{(z_{i+2} - z_{i+1})\left(p_{i+1}'(z_{i+1}) - p_i'(z_{i+1})\right)}{2(z_{i+1} - z_i)(z_{i+2} - z_i)}(x - z_i)^2, \quad 0 \le i \le n-2,$$

and

$$b_i(x) := \frac{(z_i - z_{i-1})\left(p_i'(z_i) - p_{i-1}'(z_i)\right)}{2(z_{i+1} - z_i)(z_{i+1} - z_{i-1})}(x - z_{i+1})^2, \quad 1 \le i \le n-1,$$

and also set $a_{n-1}(x) \equiv 0$ and $b_0(x) \equiv 0$. Then, for $x \in [z_i, z_{i+1}]$, $0 \le i \le n-1$, we define

$$\tilde{s}(x) := p_i(x) + a_i(x) + b_i(x).$$

It is now straightforward to verify that s is a continuously differentiable convex function satisfying (3.5), and it remains to prove (3.3) and (3.4). For $1 \le j \le n-1$, we have

$$\begin{aligned}
\|s - \tilde{s}\|_{\mathbb{L}_p[z_{j-1}, z_{j+1}]} &\le 2^{1/p} \max_{i=j-1,j} \|a_i + b_i\|_{\mathbb{L}_p[z_i, z_{i+1}]} \\
&\le c(p, r, \vartheta(\mathbf{z}_n))|J_i|^{1+1/p} \max_{i=j-1,j,j+1\,;\,1\le i\le n-1} \left|p_i'(z_i) - p_{i-1}'(z_i)\right| \\
&\le c(p, r, \vartheta(\mathbf{z}_n))\omega_{r+3}(s, [z_{j-2}, z_{j+2}])_p,
\end{aligned}$$

where the last inequality follows from Lemma 3.1. Similarly, Lemma 3.1 implies

$$\begin{aligned}
\|s' - \tilde{s}'\|_{\mathbb{L}_p[z_{j-1}, z_{j+1}]} &\le 2^{1/p} \max_{i=j-1,j} \|a_i' + b_i'\|_{\mathbb{L}_p[z_i, z_{i+1}]} \\
&\le c(p, r, \vartheta(\mathbf{z}_n))|J_i|^{1/p} \max_{i=j-1,j,j+1\,;\,1\le i\le n-1} \left|p_i'(z_i) - p_{i-1}'(z_i)\right| \\
&\le c(p, r, \vartheta(\mathbf{z}_n))\omega_{r+2}(s', [z_{j-2}, z_{j+2}])_p. \qquad \square
\end{aligned}$$

Lemma 3.8 immediately implies the following result for monotone spline smoothing.

COROLLARY 3.9 (monotone smoothing). *Let $r \in \mathbb{N}_0$, $\mathbf{z}_n := (z_i)_{i=0}^n$, $a =: z_0 < z_1 < \cdots < z_{n-1} < z_n := b$ be a partition of $[a,b]$, and let $s \in \Delta^1 \cap \mathcal{S}_{r+1}(\mathbf{z}_n)$. Then, there exists $\tilde{s} \in \Delta^1 \cap \mathcal{S}_{r+1}(\mathbf{z}_n) \cap \mathbb{C}[a,b]$ such that, for any $1 \le j \le n-1$ and $0 < p \le \infty$,*

$$\|s - \tilde{s}\|_{\mathbb{L}_p[z_{j-1}, z_{j+1}]} \le c(p, r, \vartheta(\mathbf{z}_n))\omega_{r+2}(s, [z_{j-2}, z_{j+2}])_p.$$

Moreover,

$$\tilde{s}(a) = s(a) \quad \text{and} \quad \tilde{s}(b) = s(b).$$

In the case $n = 2$, i.e., when a ppf has only one breakpoint inside an interval $[a,b]$, we get the following corollaries for convex and monotone spline smoothing.

COROLLARY 3.10. *Let $r \in \mathbb{N}_0$, $\mathfrak{z} := (z_i)_{i=0}^2$, $a =: z_0 < z_1 < z_2 := b$ be a partition of $[a,b]$, and let $s \in \Delta^2 \cap \mathcal{S}_{r+2}(\mathfrak{z})$. Then, there exists $\tilde{s} \in \Delta^2 \cap \mathcal{S}_{r+2}(\mathfrak{z}) \cap \mathbb{C}^1[a,b]$ such that*

$$\|s - \tilde{s}\|_{\mathbb{L}_p[a,b]} \le c(p, r, \vartheta(\mathfrak{z}))\omega_{r+3}(s, [a,b])_p$$

for any $0 < p \le \infty$. Moreover,

$$\tilde{s}^{(\nu)}(a) = s^{(\nu)}(a) \quad \text{and} \quad \tilde{s}^{(\nu)}(b) = s^{(\nu)}(b), \quad \nu = 0, 1.$$

COROLLARY 3.11. *Let $r \in \mathbb{N}_0$, $\mathfrak{z} := (z_i)_{i=0}^2$, $a =: z_0 < z_1 < z_2 := b$ be a partition of $[a,b]$, and let $s \in \Delta^1 \cap \mathcal{S}_{r+1}(\mathfrak{z})$. Then, there exists $\tilde{s} \in \Delta^1 \cap \mathcal{S}_{r+1}(\mathfrak{z}) \cap \mathbb{C}[a,b]$ such that*

$$\|s - \tilde{s}\|_{\mathbb{L}_p[a,b]} \le c(p, r, \vartheta(\mathfrak{z}))\omega_{r+2}(s, [a,b])_p$$

for any $0 < p \le \infty$. Moreover, $\tilde{s}(a) = s(a)$ and $\tilde{s}(b) = s(b)$.

Proof of Theorem 1.2. Let $\mathbf{z}_{3n}^\star$ be a refinement of $\mathbf{z}_n$ obtained by adding two extra knots l_i and r_i in each interval $J_i = [z_i, z_{i+1}]$, $0 \le i \le n-1$, where $l_i := z_i + |J_i|/4$ and $r_i := z_{i+1} - |J_i|/4$. We now apply Corollaries 3.10 and 3.11 for every $1 \le i \le n-1$, with $\mathfrak{z} = (r_{i-1}, z_i, l_i)$ to obtain $s^\star \in \mathcal{S}_{q+r}(\mathbf{z}_{3n}^\star) \cap \Delta^q \cap \mathbb{C}^{q-1}[-1,1]$ satisfying

$$\|s - s^\star\|_{\mathbb{L}_p[r_{i-1}, l_i]} \le c(p,r)\omega_{q+r+1}(s, [r_{i-1}, l_i])_p, \qquad 1 \le j \le n-1.$$

Moreover, $s^\star \equiv s$ on $[l_i, r_i]$, $1 \le i \le n-2$, and on $[-1, r_0]$ and $[l_{n-1}, 1]$, and therefore

$$\|s - s^\star\|_{\mathbb{L}_p(\mathfrak{I}_j)} \le c(p,r)\omega_{q+r+1}(s, \mathfrak{I}_j)_p, \qquad 0 \le j \le n. \tag{3.6}$$

Now, using Theorem 1.1 with $s^\star$ and $\mathbf{z}_{3n}^\star$ instead of s and $\mathbf{z}_n$, respectively, and taking into account that, if $\tilde{\mathbf{z}}_m \in \mathcal{R}_\delta(\mathbf{z}_n)$, then $\tilde{\mathbf{z}}_m \in \mathcal{R}_{4\delta}(\mathbf{z}_{3n}^\star)$, we conclude that

$$\|s^\star - \tilde{s}\|_{\mathbb{L}_p(\tilde{\mathfrak{I}}_j)} \le c(p,q,r)\omega_{q+r+1}(s^\star, \tilde{\mathfrak{I}}_j)_p, \qquad 0 \le j \le n,$$

where $\tilde{\mathfrak{I}}_j$ stands for $[(l_{i-1}+r_{i-1})/2, (r_{i-1}+z_i)/2]$, $[(r_{i-1}+z_i)/2, (z_i+l_i)/2]$, or $[(z_i+l_i)/2, (l_i+r_i)/2]$, and $l_i = r_i := -1$ if $i < 0$, and $l_i = r_i := 1$ if $i \ge n$. Finally, we notice that $(l_i + r_i)/2 = (z_i + z_{i+1})/2$ and, hence,

$$\|s^\star - \tilde{s}\|_{\mathbb{L}_p(\mathfrak{I}_j)} \le c(p,q,r)\omega_{q+r+1}(s^\star, \mathfrak{I}_j)_p, \qquad 0 \le j \le n,$$

which, together with (3.6), completes the proof of the theorem. ∎

A LOCAL DISCONTINUOUS GALERKIN METHOD FOR THE CAMASSA–HOLM EQUATION*

YAN XU† AND CHI-WANG SHU‡

Abstract. In this paper, we develop, analyze, and test a local discontinuous Galerkin (LDG) method for solving the Camassa–Holm equation which contains nonlinear high-order derivatives. The LDG method has the flexibility for arbitrary h and p adaptivity. We prove the L^2 stability for general solutions and give a detailed error estimate for smooth solutions, and provide numerical simulation results for different types of solutions of the nonlinear Camassa–Holm equation to illustrate the accuracy and capability of the LDG method.

Key words. local discontinuous Galerkin method, Camassa–Holm equation, stability, error estimate

DOI. 10.1137/070679764

1. Introduction.

In this paper, we consider numerical approximations to the Camassa–Holm (CH) equation [4, 5]

$$u_t - u_{xxt} + 2\kappa u_x + 3uu_x = 2u_x u_{xx} + uu_{xxx}, \tag{1.1}$$

where κ is a constant. Such nonlinearly dispersive partial differential equations (PDEs) support peakon solutions. The lack of smoothness at the peak of the peakon introduces high-frequency dispersive errors into the calculation. It is a challenge to design stable and accurate numerical schemes for solving this equation.

We develop a class of local discontinuous Galerkin (LDG) methods for this nonlinear CH equation. Our proposed scheme is high-order accurate, nonlinear stable, and flexible for arbitrary h and p adaptivity. The proof of the L^2 stability of the scheme is given for general solutions. Error estimates are given for smooth solutions. To our best knowledge, this is the first provably stable finite element method for the CH equation.

The main motivation for the algorithm discussed in this paper originates from the LDG techniques which have been developed for convection-diffusion equations (containing second derivatives) [9] and nonlinear wave equations with high-order derivatives [32, 33, 24, 27, 28, 29, 30]. In these papers, stable LDG methods for quite general nonlinear wave equations including multidimensional and system cases have been developed. The proofs of the nonlinear L^2 stability of these methods are usually given and successful numerical experiments demonstrate their capability. These results indicate that the LDG method is a good tool for solving nonlinear equations in mathematical physics.

There are only a few works in the literature for error estimates of the LDG method for nonlinear wave equations with high-order derivatives. In [31], a priori error estimates are given for the LDG method for nonlinear convection-diffusion equations and KdV equations. There are technical difficulties to derive the L^2 a priori error estimates from the cell entropy inequality and approximation results, because of the possible lack of control on some of the jump terms at cell boundaries, which appear because of the discontinuous nature of the finite element space for the discontinuous Galerkin (DG) method. The remedy in [31] to handle such jump terms is via a special projection, which eliminates such troublesome jump terms in the error equation. It is more challenging to perform L^2 a priori error estimates for nonlinear PDEs with high-order derivatives than for first-order hyperbolic PDEs in [34].

The CH equation (1.1) was derived as a model for the propagation of the unidirectional gravitational waves in a shallow water approximation, with u representing the free surface of water over a flat bed [4, 5, 18]. The CH equation has a very intriguing structure. For instance, it is completely integrable and models wave breaking for a large class of initial data. This equation has attracted a lot of attention in the literature. Lenells gave a detailed discussion of its conservation law in [23] and also classified all the weak traveling wave solutions in [22]. Johnson [19] implemented the inverse-scattering transform method to the solution of the CH equation. Li and Zhang [25] used the same method to solve a multiple-soliton solution for the CH equation. Bressan and Constantin [2, 3] developed a new approach for its analysis, particularly for the investigation of the wave breaking.

There are only a few numerical works in the literature to solve the CH equation. Holden and Raynaud [17] proved the convergence of a finite difference method for the CH equation and they also developed a convergent numerical scheme based on multipeakon in [16]. Several different aspects of periodic traveling wave solutions of the CH equation were numerically explored in [20] and the error analysis of a spectral projection of the periodic CH equation was given in [21]. A finite-volume method was developed in [1] to simulate the dynamics of peakons.

The DG method we discuss in this paper is a class of finite element methods using completely discontinuous piecewise polynomial space for the numerical solution and the test functions in the spatial variables. The DG discretization results in an extremely local, element based discretization, which is beneficial for parallel computing and maintaining high-order accuracy on unstructured meshes. In particular, DG methods are well suited for *hp*-adaptation, which consists of local mesh refinement and/or the adjustment of the polynomial order in individual elements. They also have excellent provable nonlinear stability. The LDG method for the CH equation (1.1) that we design in this paper shares all these nice properties. More general information about DG methods can be found in [7, 10, 11, 12]. Recently, Eskilsson and Sherwin [13, 14, 15] also presented discontinuous spectral element methods for simulating one-dimensional linear Boussinesq-type equations, dispersive shallow water systems, and two-dimensional Boussinesq equations.

The paper is organized as follows. In section 2, we present and analyze our LDG method for the CH equation (1.1). In section 2.2, we present the LDG method. Details related to the implementation of the method are described in section 2.3. We give a proof of the L^2 stability in section 3, and present an a priori error estimate in section 4. Section 5 contains numerical results to demonstrate the accuracy and capability of the methods. Concluding remarks are given in section 6. Some of the more technical proofs of several lemmas are collected in the appendix.

2. The LDG method for the CH equation.

2.1. Notation. We denote the mesh by $I_j = [x_{j-\frac{1}{2}}, x_{j+\frac{1}{2}}]$ for $j = 1, \ldots, N$. The center of the cell is $x_j = \frac{1}{2}(x_{j-\frac{1}{2}} + x_{j+\frac{1}{2}})$ and the mesh size is denoted by $h_j = x_{j+\frac{1}{2}} - x_{j-\frac{1}{2}}$, with $h = \max_{1\le j\le N} h_j$ being the maximum mesh size. We assume that the mesh is regular, namely the ratio between the maximum and the minimum mesh sizes stays bounded during mesh refinements. We define the piecewise polynomial space V_h as the space of polynomials of the degree up to k in each cell I_j, i.e.,

$$V_h = \{v : v \in P^k(I_j) \text{ for } x \in I_j,\ j = 1, \ldots, N\}.$$

Note that functions in V_h are allowed to have discontinuities across element interfaces.

The solution of the numerical scheme is denoted by u_h, which belongs to the finite element space V_h. We denote by $(u_h)^+_{j+\frac{1}{2}}$ and $(u_h)^-_{j+\frac{1}{2}}$ the values of u_h at $x_{j+\frac{1}{2}}$, from the right cell I_{j+1} and from the left cell I_j, respectively. We use the usual notations $[u_h] = u_h^+ - u_h^-$ and $\bar{u}_h = \frac{1}{2}(u_h^+ + u_h^-)$ to denote the jump and the mean of the function u_h, respectively, at each element boundary point.

2.2. The LDG method. In this section, we define our LDG method for the CH equation (1.1), written in the following form:

$$u - u_{xx} = q, \tag{2.1}$$

$$q_t + f(u)_x = \frac{1}{2}(u^2)_{xxx} - \frac{1}{2}((u_x)^2)_x \tag{2.2}$$

with an initial condition

$$u(x, 0) = u_0(x) \tag{2.3}$$

and periodic boundary conditions

$$u(x, t) = u(x + L, t), \tag{2.4}$$

where L is the period in the x direction and $f(u) = 2\kappa u + \frac{3}{2}u^2$. Notice that the assumption of periodic boundary conditions is for simplicity only and is not essential: the method can be easily designed for nonperiodic boundary conditions.

To define the LDG method, we further rewrite (2.1) as a first-order system:

$$\begin{aligned} u - r_x &= q, \\ r - u_x &= 0. \end{aligned} \tag{2.5}$$

The LDG method for (2.5), where q is assumed known and we would want to solve for u, is formulated as follows: Find u_h, $r_h \in V_h$ such that, for all test functions ρ, $\phi \in V_h$,

$$\int_{I_j} u_h \rho dx + \int_{I_j} r_h \rho_x dx - (\widehat{r}_h \rho^-)_{j+\frac{1}{2}} + (\widehat{r}_h \rho^+)_{j-\frac{1}{2}} = \int_{I_j} q_h \rho dx, \tag{2.6}$$

$$\int_{I_j} r_h \phi dx + \int_{I_j} u_h \phi_x dx - (\widehat{u}_h \phi^-)_{j+\frac{1}{2}} + (\widehat{u}_h \phi^+)_{j-\frac{1}{2}} = 0. \tag{2.7}$$

The "hat" terms in (2.6)–(2.7) in the cell boundary terms from integration by parts are the so-called *numerical fluxes*, which are single-valued functions defined on the

edges and should be designed based on different guiding principles for different PDEs to ensure stability. For the standard elliptic equation (2.5), we can take the simple choices such that

$$\widehat{r}_h = r_h^-, \quad \widehat{u}_h = u_h^+, \tag{2.8}$$

where we have omitted the half-integer indices $j + \frac{1}{2}$ as all quantities in (2.8) are computed at the same points (i.e., the interfaces between the cells). We remark that the choice of the fluxes (2.8) is not unique. We can, for example, also choose the following numerical flux

$$\widehat{r}_h = r_h^+, \quad \widehat{u}_h = u_h^-. \tag{2.9}$$

For (2.2), we can also rewrite it into a first-order system:

$$\begin{aligned} q_t + f(u)_x - p_x + B(r)_x &= 0, \\ p - (b(r)u)_x &= 0, \\ r - u_x &= 0, \end{aligned} \tag{2.10}$$

where $B(r) = \frac{1}{2}r^2$ and $b(r) = B'(r) = r$. Now we can define an LDG method to (2.10), resulting in the following scheme: Find q_h, p_h, $r_h \in V_h$ such that, for all test functions φ, ψ, $\eta \in V_h$,

$$\begin{aligned} &\int_{I_j} (q_h)_t \varphi dx - \int_{I_j} (f(u_h) - p_h + B(r_h))\varphi_x dx \\ &\quad + ((\widehat{f} - \widehat{p}_h + \widehat{B(r_h)})\varphi^-)_{j+\frac{1}{2}} - ((\widehat{f} - \widehat{p}_h + \widehat{B(r_h)})\varphi^+)_{j-\frac{1}{2}} = 0, \end{aligned} \tag{2.11}$$

$$\int_{I_j} p_h \psi dx + \int_{I_j} b(r_h) u_h \psi_x dx - (\widehat{b(r_h)}\widetilde{u}_h \psi^-)_{j+\frac{1}{2}} + (\widehat{b(r_h)}\widetilde{u}_h \psi^+)_{j-\frac{1}{2}} = 0, \tag{2.12}$$

$$\int_{I_j} r_h \eta dx + \int_{I_j} u_h \eta_x dx - (\widehat{u}_h \eta^-)_{j+\frac{1}{2}} + (\widehat{u}_h \eta^+)_{j-\frac{1}{2}} = 0. \tag{2.13}$$

The numerical fluxes in (2.11)–(2.13) are chosen as

$$\widehat{p}_h = p_h^-, \ \widehat{u}_h = u_h^+, \ \widehat{B(r_h)} = B(r_h^-), \ \widehat{b(r_h)} = \frac{B(r_h^+) - B(r_h^-)}{r_h^+ - r_h^-}, \ \widetilde{u}_h = u_h^+. \tag{2.14}$$

Here $\widehat{f}(u_h^-, u_h^+)$ is a monotone flux for solving conservation laws; i.e., it is Lipschitz continuous in both arguments, consistent ($\widehat{f}(u_h, u_h) = f(u_h)$), nondecreasing in the first argument, and nonincreasing in the second argument. Examples of monotone fluxes which are suitable for DG methods can be found in, e.g., [8]. We could, for example, use the simple Lax–Friedrichs flux

$$\widehat{f}(u_h^-, u_h^+) = \frac{1}{2}(f(u_h^-) + f(u_h^+) - \alpha(u_h^+ - u_h^-)), \quad \alpha = \max |f'(u_h)|,$$

where the maximum is taken over a relevant range of u_h. This Lax–Friedrichs flux is used in the numerical experiments in next section. The definition of the algorithm is now complete.

We remark that the choice of the fluxes (2.14) is not unique. In fact the crucial part is taking $\widehat{p}_h$ and $\widehat{u}_h$ from opposite sides and $\widehat{B(r_h)}$ and $\widetilde{u}_h$ from opposite sides.

2.3. Algorithm flowchart. In this section, we give details related to the implementation of the method.

- First, from (2.6)–(2.8), we obtain q_h in the following matrix form:

$$\boldsymbol{q}_h = \mathbf{A}\boldsymbol{u}_h, \tag{2.15}$$

  where $\boldsymbol{q}_h$ and $\boldsymbol{u}_h$ are the vectors containing the degrees of freedom for q_h and u_h, respectively.
- From (2.11)–(2.14), we obtain the LDG discretization of the residual $-f(u)_x + \frac{1}{2}(u^2)_{xxx} - \frac{1}{2}((u_x)^2)_x$ in the following vector form:

$$(\boldsymbol{q}_h)_t = \mathbf{res}(\boldsymbol{u}_h). \tag{2.16}$$

- We then combine (2.15) and (2.16) to obtain

$$\mathbf{A}(\boldsymbol{u}_h)_t = \mathbf{res}(\boldsymbol{u}_h). \tag{2.17}$$

- We use a time discretization method to solve

$$(\boldsymbol{u}_h)_t = \mathbf{A}^{-1}\mathbf{res}(\boldsymbol{u}_h). \tag{2.18}$$

  This step involves a linear solver with the matrix $\mathbf{A}$. We perform an LU decomposition for $\mathbf{A}$ at the beginning and use it for all time steps. Any standard ODE solvers can be used here, for example the Runge–Kutta methods.

The LDG matrix $\mathbf{A}$ is a sparse block matrix, hence its multiplication with vectors and a linear solver, involving it as the coefficient matrix, can be implemented efficiently.

3. L^2 stability of the LDG method. In this section, we prove the L^2 stability of the LDG method for the CH equation defined in the previous section.

PROPOSITION 3.1 (L^2 stability). *The solution to the schemes* (2.6)–(2.8) *and* (2.11)–(2.14) *satisfies the L^2 stability*

$$\frac{d}{dt}\int_0^L (u_h^2 + r_h^2)dx \le 0. \tag{3.1}$$

Proof. For (2.6), we first take the time derivative and get

$$\int_{I_j} (u_h)_t \rho dx + \int_{I_j} (r_h)_t \rho_x dx - (\widehat{(r_h)_t}\rho^-)_{j+\frac{1}{2}} + (\widehat{(r_h)_t}\rho^+)_{j-\frac{1}{2}} = \int_{I_j} (q_h)_t \rho dx. \tag{3.2}$$

Since (3.2), (2.7), and (2.11)–(2.13) hold for any test functions in V_h, we can choose

$$\rho = -u_h, \quad \phi = (r_h)_t, \quad \varphi = u_h, \quad \psi = -r_h, \quad \eta = p_h.$$

With these choices of test functions and summing up the five equations in (3.2), (2.7), and (2.11)–(2.13), we obtain

$$\begin{aligned}
&\int_{I_j} ((u_h)_t u_h + (r_h)_t r_h)dx - \int_{I_j} f(u_h)(u_h)_x dx + (\widehat{f(u_h)}u_h^-)_{j+\frac{1}{2}} - (\widehat{f(u_h)}u_h^+)_{j-\frac{1}{2}} \\
&\quad + \int_{I_j} (p_h u_h)_x dx - (\widehat{p}_h u_h^- + \widehat{u}_h p_h^-)_{j+\frac{1}{2}} + (\widehat{p}_h u_h^+ + \widehat{u}_h p_h^+)_{j-\frac{1}{2}} \\
&\qquad - \int_{I_j} (B(r_h)u_h)_x dx + (\widehat{B(r_h)}u_h^- + \widehat{b(r_h)}\widetilde{u}_h r_h^-)_{j+\frac{1}{2}} - (\widehat{B(r_h)}u_h^+ + \widehat{b(r_h)}\widetilde{u}_h r_h^+)_{j-\frac{1}{2}}
\end{aligned}$$

$$+\int_{I_j}((r_h)_t u_h)_x dx - (\widehat{(r_h)}_t u_h^- + \widehat{u}_h(r_h^-)_t)_{j+\frac{1}{2}} + (\widehat{(r_h)}_t u_h^+ + \widehat{u}_h(r_h^+)_t)_{j-\frac{1}{2}} = 0.$$

Taking $F(u_h) = \int^{u_h} f(\tau)d\tau$, we have

$$\int_{I_j}((u_h)_t u_h + (r_h)_t r_h)dx + \Psi_{j+\frac{1}{2}} - \Psi_{j-\frac{1}{2}} + \Theta_{j-\frac{1}{2}} = 0, \tag{3.3}$$

where the numerical entropy fluxes are given by

$$\begin{aligned}\Psi_{j+\frac{1}{2}} = \Big(&-F(u_h^-) + \widehat{f}u_h^- + p_h^- u_h^- - (\widehat{p}_h u_h^- + \widehat{u}_h p_h^-)\\ &- B(r_h^-)u_h^- + \widehat{B(r_h)}u_h^- + \widehat{b(r_h)}\widetilde{u}_h r_h^- + (r_h^-)_t u_h^- - (\widehat{(r_h)}_t u_h^- + \widehat{u}_h(r_h^-)_t)\Big)_{j+\frac{1}{2}},\end{aligned}$$

and the extra term Θ is given by

$$\begin{aligned}\Theta_{j-\frac{1}{2}} = \Big(&[F(u_h)] - \widehat{f}[u_h] - [p_h u_h] + \widehat{p}_h[u_h] + \widehat{u}_h[p_h]\\ &+ [B(r_h)u_h] - \widehat{b(r_h)}\widetilde{u}_h[r_h] - \widehat{B(r_h)}[u_h] - [(r_h)_t u_h] + \widehat{(r_h)}_t[u_h] + \widehat{u}_h[(r_h)_t]\Big)_{j-\frac{1}{2}}.\end{aligned}$$

With the definitions (2.8) and (2.14) of the numerical fluxes and after some algebraic manipulation, we easily obtain

$$\begin{aligned}-[p_h u_h] + \widehat{p}_h[u_h] + \widehat{u}_h[p_h] &= 0,\\ [B(r_h)u_h] - \widehat{b(r_h)}\widetilde{u}_h[r_h] - \widehat{B(r_h)}[u_h] &= 0,\\ -[(r_h)_t u_h] + \widehat{(r_h)}_t[u_h] + \widehat{u}_h[(r_h)_t] &= 0,\end{aligned}$$

and hence

$$\Theta_{j-\frac{1}{2}} = ([F(u_h)] - \widehat{f}[u_h])_{j-\frac{1}{2}} \geq 0,$$

where the last inequality follows from the monotonicity of the flux

$$[F(u_h)] - \widehat{f}[u_h] = \int_{u_h^-}^{u_h^+}(f(s) - \widehat{f}(u_h^-, u_h^+))ds \geq 0.$$

By summing up the cell entropy inequalities, we obtain the desired L^2 stability (3.1). ∎

4. Error estimates of the LDG method. In this section, we present the procedure to obtain a priori error estimates of the LDG method for the CH equation.

4.1. Notations, definitions, and auxiliary results. In this section we introduce notations and definitions to be used later in the paper and also present some auxiliary results. We first review an important quantity measuring the relationship between the numerical flux and physical flux introduced in [34, 31]. We then define some projections and present certain interpolation and inverse properties for the finite element spaces that will be used in the error analysis.

4.1.1. Notations for different constants. We will adopt the following convention for different constants. These constants may have a different value in each occurrence.

We will denote by C a positive constant independent of h, which may depend on the solution of the problem considered in this paper. Especially, to emphasize the nonlinearity of the flux $f(u)$ (or other nonlinear fluxes), we will denote by $C_\star$ a positive constant depending on the maximum of $|f''|$ or/and $|f'''|$. We remark that $C_\star = 0$ for a linear flux $f = cu$ with a constant c. For problems considered in this section, the exact solution is assumed to be smooth with periodic or compactly supported boundary condition. Also, $0 \le t \le T$ for a fixed T. Therefore, the exact solution is always bounded. We follow the convention [34] to redefine the nonlinear functions $f(u)$, $B(u)$, etc. outside their ranges such that the derivatives of these nonlinear functions, $f'(u)$, $f''(u)$, etc., become globally bounded functions.

4.1.2. A quantity related to the numerical flux. For notational convenience we would like to introduce the following numerical flux related to the DG spatial discretization. $\widehat{f}(\omega^-, \omega^+)$ is a given monotone numerical flux that depends on the two values of the function ω at the discontinuity point $x_{j+\frac{1}{2}}$, namely $\omega^{\pm}_{j+\frac{1}{2}} = \omega(x^{\pm}_{j+\frac{1}{2}})$. The numerical flux $\widehat{f}(\omega^-, \omega^+)$ satisfies the following conditions:

(a) it is locally Lipschitz continuous, so it is bounded when $\omega^{\pm}$ are in a bounded interval;
(b) it is consistent with the flux $f(\omega)$, i.e., $\widehat{f}(\omega, \omega) = f(\omega)$;
(c) it is a nondecreasing function of its first argument, and a nonincreasing function of its second argument.

In [34], Zhang and Shu introduced an important quantity to measure the difference between the numerical flux and the physical flux. In [31], Xu and Shu introduced the idea of "uniform dissipative flux." For completeness, we give their definition in the following lemma.

LEMMA 4.1 (see [34]). *For any piecewise smooth function $\omega \in L^2(0,1)$, on each cell boundary point we define*

$$\alpha(\widehat{f};\omega) \equiv \alpha(\widehat{f};\omega^-,\omega^+) \triangleq \begin{cases} [\omega]^{-1}(f(\bar{\omega}) - \widehat{f}(\omega)), & \text{if} [\omega] \neq 0; \\ \frac{1}{2}|f'(\bar{\omega})|, & \text{if} [\omega] = 0, \end{cases} \tag{4.1}$$

where $\widehat{f}(\omega) \equiv \widehat{f}(\omega^-, \omega^+)$ is a monotone numerical flux consistent with the given flux f. Then $\alpha(\widehat{f};\omega)$ is nonnegative and bounded for any $(\omega^-, \omega^+) \in \mathbb{R}^2$. Moreover, we have

$$\frac{1}{2}|f'(\bar{\omega})| \le \alpha(\widehat{f};\omega) + C_\star|[\omega]|, \tag{4.2}$$

$$-\frac{1}{8}f''(\bar{\omega})[\omega] \le \alpha(\widehat{f};\omega) + C_\star|[\omega]|^2. \tag{4.3}$$

Remark 4.1. Examples of monotone fluxes which are suitable for the DG methods can be found in, e.g., [8]. For our error estimates, we rewrite the numerical flux in a viscosity form

$$\widehat{f}(\omega^-, \omega^+) = \frac{1}{2}(f(\omega^-) + f(\omega^+) - \lambda(\omega^-, \omega^+)(\omega^+ - \omega^-)), \tag{4.4}$$

and assume that the viscosity coefficient $\lambda(\omega^-, \omega^+)$ satisfies

$$\lambda(\omega^-, \omega^+) \ge \lambda_0 > 0, \quad \lambda_0 \text{ is constant.} \tag{4.5}$$

We call such flux a "uniform dissipative flux" [31]. The well-known Lax–Friedrichs flux is a uniform dissipative flux with a proper choice of λ. This property is necessary in our proof because of a lack of control for certain jump terms at cell boundaries due to the nonlinear terms and the high-order derivative terms.

We would also like to use the following simplified notation. For any functions ω and ϕ, we denote

$$\alpha(\widehat{f};\omega)[\phi]^2 = \sum_{1\le j\le N} \alpha(\widehat{f};\omega)_{j+\frac{1}{2}}[\phi]^2_{j+\frac{1}{2}}.$$

4.1.3. Projection and interpolation properties. In what follows, we will consider the standard L^2 projection of a function ω with $k+1$ continuous derivatives into space V_h, denoted by $\mathcal{P}$; i.e., for each j,

$$\int_{I_j} (\mathcal{P}\omega(x) - \omega(x))v(x)dx = 0 \quad \forall v \in P^k(I_j), \tag{4.6}$$

and the special projection $\mathcal{P}^{\pm}$ into V_h, which satisfy, for each j,

$$\begin{aligned}&\int_{I_j} (\mathcal{P}^+\omega(x) - \omega(x))v(x)dx = 0 \quad \forall v \in P^{k-1}(I_j), \quad \text{and} \quad \mathcal{P}^+\omega(x^+_{j-\frac{1}{2}}) = \omega(x_{j-\frac{1}{2}}),\\ &\int_{I_j} (\mathcal{P}^-\omega(x) - \omega(x))v(x)dx = 0 \quad \forall v \in P^{k-1}(I_j), \quad \text{and} \quad \mathcal{P}^-\omega(x^-_{j+\frac{1}{2}}) = \omega(x_{j+\frac{1}{2}}).\end{aligned} \tag{4.7}$$

For the projections mentioned above, it is easy to show that (cf. [6])

$$\|\omega^e\| + h\|\omega^e\|_\infty + h^{\frac{1}{2}}\|\omega^e\|_{\Gamma_h} \le Ch^{k+1}, \tag{4.8}$$

where $\omega^e = \mathcal{P}\omega - \omega$ or $\omega^e = \mathcal{P}^{\pm}\omega - \omega$. The positive constant C, solely depending on ω, is independent of h. Γ_h denotes the set of boundary points of all elements I_j.

4.1.4. Inverse properties. Finally, we list some inverse properties of the finite element space V_h that will be used in our error analysis. For any $\omega_h \in V_h$, there exists a positive constant C independent of ω_h and h, such that

(4.9)

$$\text{(i) } \|\partial_x\omega_h\| \le Ch^{-1}\|\omega_h\|, \quad \text{(ii) } \|\omega_h\|_{\Gamma_h} \le Ch^{-\frac{1}{2}}\|\omega_h\|, \quad \text{(iii) } \|\omega_h\|_\infty \le Ch^{-\frac{1}{2}}\|\omega_h\|.$$

For more details of these inverse properties, we refer the readers to [6].

4.2. The main error estimate result. We state the main error estimates of the semidiscrete LDG scheme for the CH equation.

THEOREM 4.2. *Let u be the exact solution of the problem* (2.1)–(2.2)*, which is sufficiently smooth with bounded derivatives, and assume that $f \in C^3$. Let u_h be the numerical solution of the semidiscrete LDG scheme,* (2.6)–(2.8) *and* (2.11)–(2.14)*, and denote the corresponding numerical error by $e_u = u - u_h$ and $e_r = r - r_h$, where $r = u_x$ is defined by* (2.5)*. For regular triangulations of $I = (0,1)$, if the finite element space V_h is the piecewise polynomials of degree $k \ge 2$, then for small enough h the following error estimates hold:*

$$\|u - u_h\|^2 + \|r - r_h\|^2 \le Ch^{2k}, \tag{4.10}$$

where the constant C depends on the final time T, k, $\|u\|_{k+1}$, $\|r\|_{k+1}$, and the bounds on the derivatives $|f^{(m)}|$, $m = 1,2,3$. Here $\|u\|_{k+1}$ and $\|r\|_{k+1}$ are the maximum over $0 \le t \le T$ of the standard Sobolev $k+1$ norm in space.

Remark 4.2. Although we could not obtain the optimal error estimates $O(h^{k+1})$ for u due to some extra boundary terms arising from high-order derivatives, numerical examples in section 5 verify the optimal order $O(h^{k+1})$ for u. For the solution r_h, our numerical results indicate that kth-order accuracy is sharp.

4.2.1. The error equation. In order to obtain the error estimate to smooth solutions for the considered semidiscrete LDG scheme (2.6)–(2.8) and (2.11)–(2.14), we need to first obtain the error equation.

Notice that the scheme (2.6) and (2.11)–(2.13) is also satisfied when the numerical solutions are replaced by the exact solutions. We then obtain the error equation

$$\begin{aligned}
&\int_{I_j}(u-u_h)_t\rho dx-\int_{I_j}\Big((q-q_h)_t(\rho+\varphi)+(r-r_h)\phi+(p-p_h)\psi+(r-r_h)\eta\Big)dx\\
&\quad+\int_{I_j}(r-r_h)_t\rho_x dx-((r_t-\widehat{(r_h)}_t)\rho^-)_{j+\frac12}+((r_t-\widehat{(r_h)}_t)\rho^+)_{j-\frac12}\\
&\quad+\int_{I_j}(u-u_h)\phi_x dx-((u-\widehat{u}_h)\phi^-)_{j+\frac12}+((u-\widehat{u}_h)\phi^+)_{j-\frac12}\\
&\quad+\int_{I_j}(p-p_h)\varphi_x dx-((p-\widehat{p}_h)\varphi^-)_{j+\frac12}+((p-\widehat{p}_h)\varphi^+)_{j-\frac12}\\
&\quad+\int_{I_j}(u-u_h)\eta_x dx-((u-\widehat{u}_h)\eta^-)_{j+\frac12}+((u-\widehat{u}_h)\eta^+)_{j-\frac12}\\
&\qquad-\int_{I_j}(B(r)-B(r_h))\varphi_x dx+((B(r)-\widehat{B(r_h)})\varphi^-)_{j+\frac12}-((B(r)-\widehat{B(r_h)})\varphi^+)_{j-\frac12}\\
&\quad+\int_{I_j}(b(r)u-b(r_h)u_h)\psi_x dx-((b(r)u-\widehat{b(r_h)}\widetilde{u}_h)\psi^-)_{j+\frac12}+((b(r)u-\widehat{b(r_h)}\widetilde{u}_h)\psi^+)_{j-\frac12}\\
&\qquad-\int_{I_j}(f(u)-f(u_h))\varphi_x dx+((f(u)-\widehat{f})\varphi^-)_{j+\frac12}-((f(u)-\widehat{f})\varphi^+)_{j-\frac12}=0
\end{aligned}$$

for all ρ, ϕ, φ, ψ, $\eta\in V_h$.

Define

(4.11)

$$\begin{aligned}
&\mathcal{B}_j(u-u_h,q-q_h,p-p_h,r-r_h;\rho,\phi,\varphi,\psi,\eta)\\
&\quad=\int_{I_j}(u-u_h)_t\rho dx-\int_{I_j}\Big((q-q_h)_t(\rho+\varphi)+(r-r_h)\phi+(p-p_h)\psi+(r-r_h)\eta\Big)dx\\
&\qquad+\int_{I_j}(r-r_h)_t\rho_x dx-((r_t-\widehat{(r_h)}_t)\rho^-)_{j+\frac12}+((r_t-\widehat{(r_h)}_t)\rho^+)_{j-\frac12}\\
&\qquad+\int_{I_j}(u-u_h)\phi_x dx-((u-\widehat{u}_h)\phi^-)_{j+\frac12}+((u-\widehat{u}_h)\phi^+)_{j-\frac12}\\
&\qquad+\int_{I_j}(p-p_h)\varphi_x dx-((p-\widehat{p}_h)\varphi^-)_{j+\frac12}+((p-\widehat{p}_h)\varphi^+)_{j-\frac12}\\
&\qquad+\int_{I_j}(u-u_h)\eta_x dx-((u-\widehat{u}_h)\eta^-)_{j+\frac12}+((u-\widehat{u}_h)\eta^+)_{j-\frac12},
\end{aligned}$$

(4.12)

$$\mathcal{H}_j(f;u,u_h;\varphi)=\int_{I_j}(f(u)-f(u_h))\varphi_x dx-((f(u)-\widehat{f})\varphi^-)_{j+\frac12}+((f(u)-\widehat{f})\varphi^+)_{j-\frac12},$$

and

(4.13)
$$\begin{aligned}&\mathbf{R}_j(b,B;r,u,r_h,u_h;\varphi,\psi)\\&=\int_{I_j}(B(r)-B(r_h))\varphi_x dx-((B(r)-\widehat{B(r_h)})\varphi^-)_{j+\frac12}+((B(r)-\widehat{B(r_h)})\varphi^+)_{j-\frac12}\\&-\int_{I_j}(b(r)u-b(r_h)u_h)\psi_x dx+((b(r)u-\widehat{b(r_h)}\widetilde{u}_h)\psi^-)_{j+\frac12}-((b(r)u-\widehat{b(r_h)}\widetilde{u}_h)\psi^+)_{j-\frac12}.\end{aligned}$$

Summing over j, the error equation becomes

$$\begin{aligned}&\sum_{j=1}^{N}\mathcal{B}_j(u-u_h,q-q_h,p-p_h,r-r_h;\rho,\phi,\varphi,\psi,\eta)\\&\qquad=\sum_{j=1}^{N}\Big(\mathcal{H}_j(f;u,u_h;\varphi)+\mathbf{R}_j(b,B;r,u,r_h,u_h;\varphi,\psi)\Big)\end{aligned}\tag{4.14}$$

for all ρ, ϕ, φ, ψ, $\eta\in V_h$.

Denoting

$$\begin{aligned}&s=\mathcal{P}^+u-u_h,\qquad &&s^e=\mathcal{P}^+u-u,\\&\xi=\mathcal{P}q-q_h,\qquad &&\xi^e=\mathcal{P}q-q,\\&v=\mathcal{P}p-p_h,\qquad &&v^e=\mathcal{P}p-p,\\&\sigma=\mathcal{P}r-r_h,\qquad &&\sigma^e=\mathcal{P}r-r\end{aligned}\tag{4.15}$$

and taking the test functions

$$\rho=-s,\quad \phi=\sigma_t,\quad \varphi=s,\quad \psi=-\sigma,\quad \eta=v,$$

we obtain the important *energy equality*

$$\begin{aligned}&\sum_{j=1}^{N}\mathcal{B}_j(s-s^e,\xi-\xi^e,v-v^e,\sigma-\sigma^e;-s,\sigma_t,s,-\sigma,v)\\&\qquad=\sum_{j=1}^{N}\Big(\mathcal{H}_j(f;u,u_h;s)+\mathbf{R}_j(b,B;r,u,r_h,u_h;s,-\sigma)\Big).\end{aligned}\tag{4.16}$$

4.2.2. Proof of the main result. In this subsection, we will follow the idea of [31] to present the main proof of Theorem 4.2. We shall prove the theorem by analyzing each term of the energy equation (4.16).

First, we consider the left-hand side of the energy equation (4.16). The estimates for the left-hand side of the energy equation are given in the following lemma. The proof of this lemma will be given in Appendix A.1.

LEMMA 4.3. *The following equation holds*:

$$\begin{aligned}&\sum_{j=1}^{N}\mathcal{B}_j(s-s^e,\xi-\xi^e,v-v^e,\sigma-\sigma^e;-s,\sigma_t,s,-\sigma,v)\\&\qquad=\int_0^1(ss_t+\sigma_t\sigma)dx-\int_0^1 s_t^e s dx-\sum_{j=1}^{N}((\widehat{v^e}+\widehat{\sigma_t^e})[s])_{j+\frac12}.\end{aligned}\tag{4.17}$$

To deal with the nonlinearity of the flux $f(u)$ we would like to make an a priori assumption that, for small enough h, there holds

$$\|u - u_h\| \le h. \tag{4.18}$$

We will justify the validity of this a priori assumption later. For the linear flux $f(u) = cu$, this a priori assumption is unnecessary.

COROLLARY 4.4. *Suppose that the interpolation property* (4.8) *is satisfied; then the a priori assumption* (4.18) *implies that*

$$\|e_u\|_\infty \le Ch^{\frac{1}{2}} \quad \textit{and} \quad \|\mathbb{Q}u - u_h\|_\infty \le Ch^{\frac{1}{2}}, \tag{4.19}$$

where $\mathbb{Q} = \mathcal{P}$ *or* $\mathbb{Q} = \mathcal{P}^{\pm}$ *is the projection operator.*

Next, we consider the right-hand side of the energy equation (4.16). We can rewrite it into the following form:

$$\begin{aligned}
&\sum_{j=1}^{N} \mathcal{H}_j(f; u, u_h; s) = \sum_{j=1}^{N} \int_{I_j} (f(u) - f(u_h)) s_x dx \\
&\quad + \sum_{j=1}^{N} ((f(u) - f(\bar{u}_h))[s])_{j+\frac{1}{2}} + \sum_{j=1}^{N} ((f(\bar{u}_h) - \widehat{f})[s])_{j+\frac{1}{2}}, \qquad (4.20)\\
&\sum_{j=1}^{N} \mathbf{R}_j(b, B; r, u, r_h, u_h; s, -\sigma) \\
&\quad = \sum_{j=1}^{N} \int_{I_j} (B(r) - B(r_h)) s_x dx + \sum_{j=1}^{N} ((B(r) - B(r_h^-))[s])_{j+\frac{1}{2}} \qquad (4.21)\\
&\qquad + \sum_{j=1}^{N} \int_{I_j} (b(r)u - b(r_h)u_h)\sigma_x dx + \sum_{j=1}^{N} ((b(r)u - \widehat{b}(r_h)u_h^+)[\sigma])_{j+\frac{1}{2}},
\end{aligned}$$

where we take into account the periodic boundary condition and recall that the average $\bar{u}_h$ is defined by $\bar{u}_h = \frac{1}{2}(u_h^+ + u_h^-)$.

The estimate for (4.20) is given in the following lemma.

LEMMA 4.5. *Suppose that the interpolation property* (4.8) *is satisfied; then we have the following estimate for* (4.20)*:*

$$\begin{aligned}
&\sum_{j=1}^{N} \mathcal{H}_j(f; u, u_h; s) \qquad (4.22)\\
&\quad \le -\frac{1}{4}\alpha(\widehat{f}; u_h)[s]^2 + (C + C_\star(\|s\|_\infty + h^{-1}\|e_u\|_\infty^2))\|s\|^2 + (C + C_\star h^{-1}\|e_u\|_\infty^2)h^{2k+1}.
\end{aligned}$$

Remark 4.3. For the proof of this lemma, we refer readers to Lemmas 3.4 and 3.5 in [31]. For $f(u) = 2\kappa u + \frac{3}{2}u^2$ in the CH equation (1.1), we have $f'''(u) = 0$ and we do not need the estimate for $\mathcal{T}_6$ in [31].

The estimate for (4.21) is given in the following lemma. The proof of this lemma will be given in Appendix A.2.

LEMMA 4.6. *Suppose that the interpolation property* (4.8) *is satisfied, then we have the following estimate for* (4.21)*:*

$$\left|\sum_{j=1}^{N}\mathbf{R}_j(b,B;r,u,r_h,u_h;s,-\sigma)\right| \le \sum_{j=1}^{N}(|b'(r)u\bar{\sigma^e}[\sigma]|+|b(r)(\sigma^e)^-[s]|)_{j+\frac12}+\frac12\|s\|^2+C\|\sigma\|^2+Ch^{2k+2}. \tag{4.23}$$

Now we are ready to get the final error estimates (4.10). Combining (4.16), (4.17), (4.22), and (4.23), we obtain

$$\begin{aligned}&\int_0^1(s_ts+\sigma_t\sigma)dx+\frac14\alpha(\widehat{f};u_h)[s]^2\\ &\quad\le\int_0^1 s_t^e s\,dx+\sum_{j=1}^{N}((\widehat{v^e}+\widehat{\sigma_t^e})[s])_{j+\frac12}+\sum_{j=1}^{N}(|b'(r)u\bar{\sigma^e}[\sigma]|+|b(r)(\sigma^e)^-[s]|)_{j+\frac12}\\ &\qquad+(C+C_\star(\|s\|_\infty+h^{-1}\|e_u\|_\infty^2))\|s\|^2+(C+C_\star h^{-1}\|e_u\|_\infty^2)h^{2k+1}+C\|\sigma\|^2.\end{aligned}$$

Again by Young's inequality and the interpolation property (4.8), the inequality becomes

$$\begin{aligned}&\int_0^1(s_ts+\sigma_t\sigma)dx+\frac18\alpha(\widehat{f};u_h)[s]^2\\ &\quad\le(C+C_\star(\|s\|_\infty+h^{-1}\|e_u\|_\infty^2))\|s\|^2+(C+C_\star h^{-1}\|e_u\|_\infty^2)h^{2k+1}+Ch^{2k}+C\|\sigma\|^2,\end{aligned}$$

where we use the uniform dissipation property of the numerical flux $\widehat{f}$. Using the results (4.19) implied by the a priori assumption (4.18) and the positive property of $\alpha(\widehat{f};u_h)$, we can get the following error estimate:

$$\frac12\frac{d}{dt}\int_0^1(s^2+\sigma^2)dx\le C(\|s\|^2+\|\sigma\|^2)+Ch^{2k}.$$

Thus Theorem 4.2 follows by the triangle inequality and the interpolating property (4.8).

To complete the proof, let us verify the a priori assumption (4.18). For $k\ge2$, we can consider h small enough so that $Ch^k<\frac12 h$, where C is the constant in (4.10) determined by the final time T. Then, if $t^*=\sup\{t:\|u(t)-u_h(t)\|\le h\}$, we would have $\|u(t^*)-u_h(t^*)\|=h$ by continuity if t^* is finite. On the other hand, our proof implies that (4.10) holds for $t\le t^*$, in particular $\|u(t^*)-u_h(t^*)\|\le Ch^k<\frac12 h$. This is a contradiction if $t^*<T$. Hence $t^*\ge T$ and our a priori assumption (4.18) is justified.

5. Numerical results. In this section we provide numerical examples to illustrate the accuracy and capability of the method. Time discretization is by the third-order explicit TVD Runge–Kutta method in [26]. This is not the most efficient method for the time discretization to our LDG scheme. However, we will not address the issue of time discretization efficiency in this paper. We have verified with the aid of successive mesh refinements that, in all cases, the results shown are numerically convergent. We will give the numerical test results for the CH equation

$$u_t-u_{xxt}+3uu_x=2u_xu_{xx}+uu_{xxx} \tag{5.1}$$

TABLE 5.1

with different initial conditions.

Example 5.1. Smooth solution. In this example, we test the scheme with smooth traveling waves. Smooth traveling waves are solutions of the form

$$u(x,t) = \phi(x - ct), \tag{5.2}$$

where ϕ is a solution of the second-order ODE

$$\phi_{xx} = \phi - \frac{\alpha}{(\phi - c)^2}. \tag{5.3}$$

In order to get a smooth traveling wave, we choose the constants c and α as in [16], i.e., $\alpha = c = 3$. The initial conditions for ϕ is

$$\phi(0) = 1, \quad \frac{d\phi}{dx}(0) = 0. \tag{5.4}$$

It gives rise to a smooth traveling wave with period $a \simeq 6.46954603635$. We use fourth-order explicit Runge–Kutta method with 100000 points to approximate the solution of (5.3). This high-precision solution is used as a reference solution for the smooth traveling wave. The L^2 and L^∞ errors and the numerical orders of accuracy for u at time $t = 0.5$ with uniform meshes are contained in Table 5.1. Periodic boundary conditions are used. We can see that the method with P^k elements gives a uniform $(k+1)$th order of accuracy for u in both norms. For the solution r_h, the accuracy is of kth order in both norms for $k \geq 1$ and this indicates that our error estimates result for r is sharp.

Example 5.2. Accuracy test. The peakon solutions of the CH equation (5.1) are well known and are the only traveling waves for which there is a simple explicit formula. The peaked traveling wave solution is

$$u(x,t) = ce^{-|x-ct|}, \tag{5.5}$$

where c is the wave speed. We give the accuracy test with $c = 0.25$. The accuracy is measured in smooth parts of the solution, 1/5 of the computational domain away from the peak. The L^2 and L^∞ errors and the numerical orders of accuracy for u at time $t = 1$ with uniform meshes in $[-25, 25]$ are contained in Table 5.2. We can see

TABLE 5.2
Accuracy test for the CH equation (5.1) *with the exact solution* (5.5). *Periodic boundary condition.* $c = 0.25$. *Uniform meshes with* N *cells at time* $t = 1$.

	N	L^2 error	Order	L^∞ error	Order

	80	3.54E-06	2.99	1.29E-05	2.90

that the method with P^k elements gives a uniform $(k+1)$th order of accuracy for u in both norms.

Example 5.3. Peakon solution. In this example, we present the wave propagation of the periodized version of the solution (5.5). In the single peak case, the initial condition is

$$u_0(x) = \begin{cases} \dfrac{c}{\cosh(a/2)} \cosh(x - x_0), & |x - x_0| \le a/2, \\ \dfrac{c}{\cosh(a/2)} \cosh(a - (x - x_0)), & |x - x_0| > a/2, \end{cases} \tag{5.6}$$

where x_0 is the position of the trough and a is the period. We present the wave propagation for the CH equation with parameters $c = 1$, $a = 30$, and $x_0 = -5$. The computational domain is $[0, a]$. In Figure 1, the peak profile at $t = 0$, 5, 10 and the space time graph of the solutions up to $t = 10$ are shown. The lack of smoothness at the peak of peakon introduces high-frequency dispersive errors into the calculation and will cause numerical oscillation near the peak. In our computation of the LDG method, we use the P^5 element with $N = 320$ cells to resolve the peak. We can see clearly that the moving peak profile is resolved very well.

Example 5.4. Two-peakon interaction. In this example, we consider the two-peakon interaction of the CH equation with the initial condition

$$u_0(x) = \phi_1(x) + \phi_2(x), \tag{5.7}$$

where

$$\phi_i(x) = \begin{cases} \dfrac{c_i}{\cosh(a/2)} \cosh(x - x_i), & |x - x_i| \le a/2, \\ \dfrac{c_i}{\cosh(a/2)} \cosh(a - (x - x_i)), & |x - x_i| > a/2, \end{cases} \quad i = 1, 2. \tag{5.8}$$

The parameters are $c_1 = 2$, $c_2 = 1$, $x_1 = -5$, $x_2 = 5$, $a = 30$. The computational domain is $[0, a]$. We use the P^5 element with $N = 320$ cells in our computation of the LDG method. In Figure 2, the two-peakon interaction at $t = 0$, 5, 12, and 18 is shown. We can see clearly that the moving peak interaction is resolved very well.

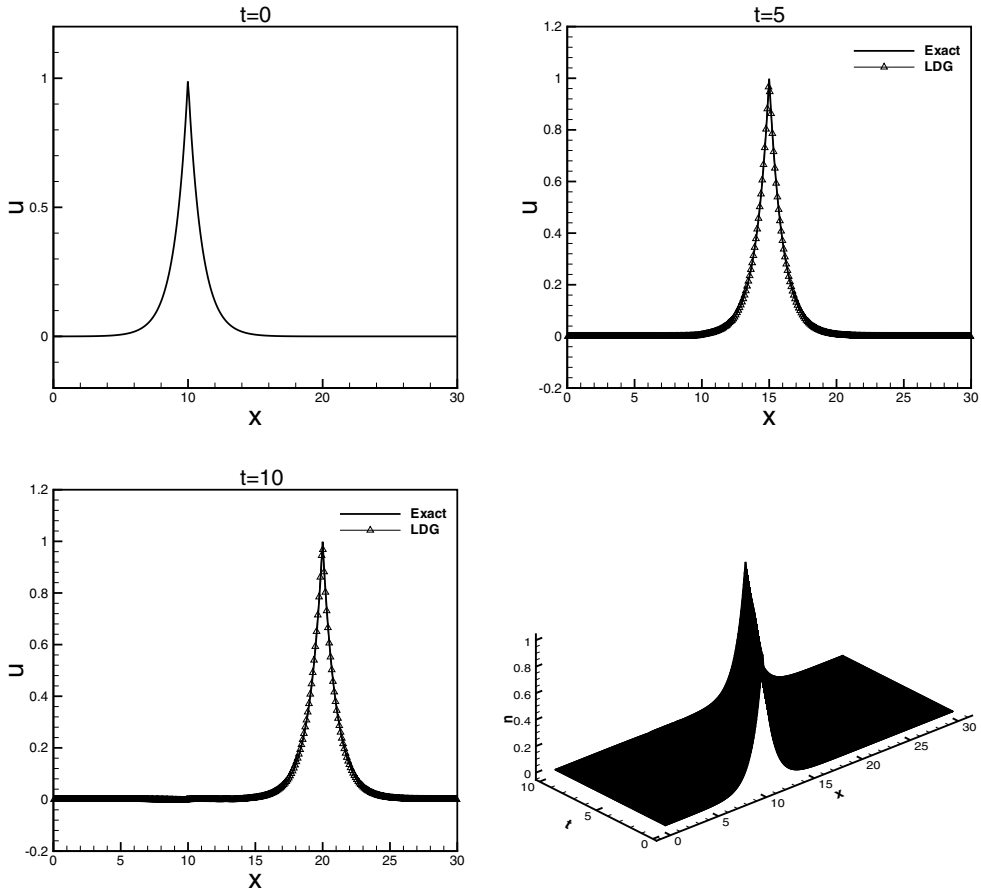

FIG. 1. *The peak profile of the CH equation* (5.1) *with the initial condition* (5.6). *Periodic boundary condition in* $[0, 30]$. P^5 *elements and a uniform mesh with* $N = 320$ *cells.*

Example 5.5. Three-peakon interaction. In this example, we consider the three-peakon interaction of the CH equation with the initial condition

$$u_0(x) = \phi_1(x) + \phi_2(x) + \phi_3(x), \tag{5.9}$$

where ϕ_i, $i = 1, 2, 3$, are defined as in (5.8). The parameters are $c_1 = 2$, $c_2 = 1$, $c_3 = 0.8$, $x_1 = -5$, $x_2 = -3$, $x_3 = -1$, $a = 30$. The computational domain is $[0, a]$. We use the P^5 element with $N = 320$ cells in our computation of the LDG method. In Figure 3, the three-peakon interaction at $t = 0$, 1, 2, 3, 4, and 6 is shown. We can see clearly that the moving peak interaction is resolved very well.

Example 5.6. Solution with a discontinuous derivative. In this example, we consider an initial data function u_0 which has a discontinuous derivative as in [16]. The initial condition is

$$u_0(x) = \frac{10}{(3 + |x|)^2}. \tag{5.10}$$

The computational domain is $[-30, 30]$. We use the P^2 element with $N = 640$ cells in our computation of the LDG method. The solutions at time $t = 5$, 10, 15, and 20 are

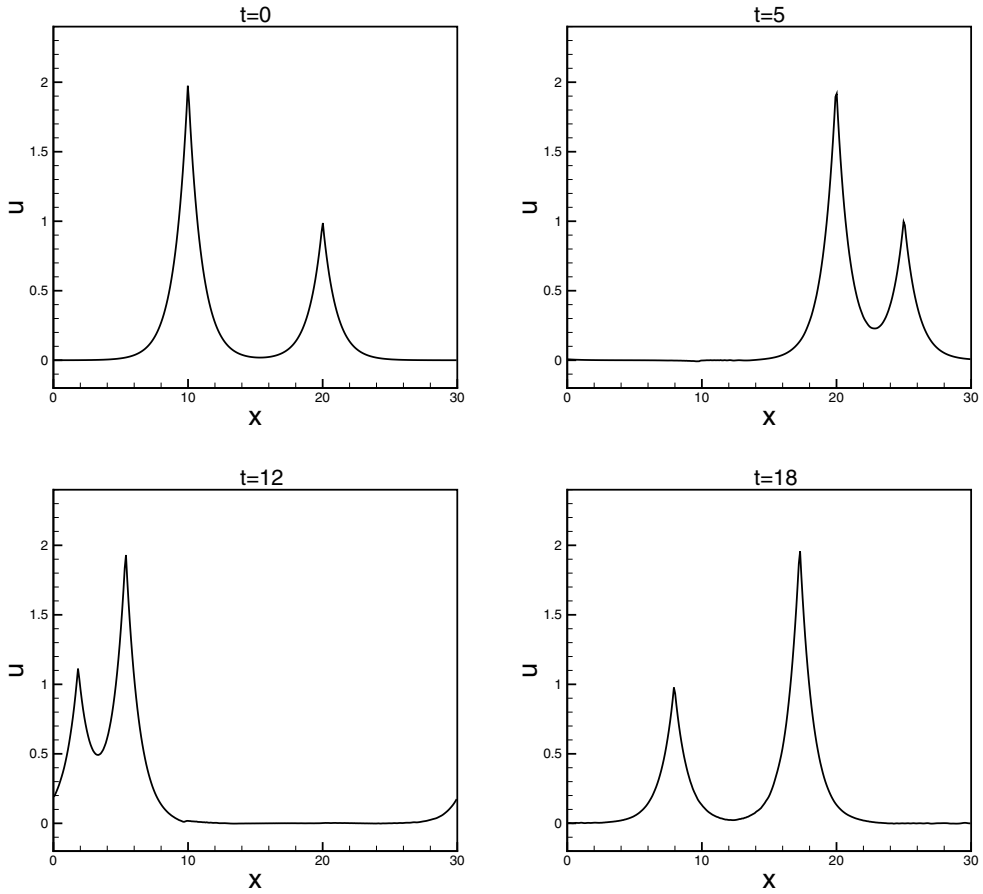

FIG. 2. *The two-peakon interaction of the CH equation* (5.1) *with the initial condition* (5.7). *Periodic boundary condition in* $[0, 30]$. P^5 *elements and a uniform mesh with* $N = 320$ *cells.*

shown in Figure 4. Even if we do not use higher-order polynomials and more cells, we still obtain a good resolution of the solution comparable with that in [16].

Example 5.7. Breakup of the plateau traveling wave. In this example, we consider a cutoff peakon in [1], i.e., a plateau function $u(x,t) = \phi(x - ct)$ with

$$\phi(x) = \begin{cases} ce^{x+k}, & x \le -k, \\ c, & |x| \le k, \\ ce^{-x+k}, & x \ge k. \end{cases} \tag{5.11}$$

We put $c = 0.6$ and $k = 5$. The computational domain is $[-40, 40]$. We use the P^2 element with $N = 800$ cells in our computation of the LDG method. The breakup of the plateau traveling wave is shown in Figure 5 at different time. The solution is resolved very well compared with the result in [1].

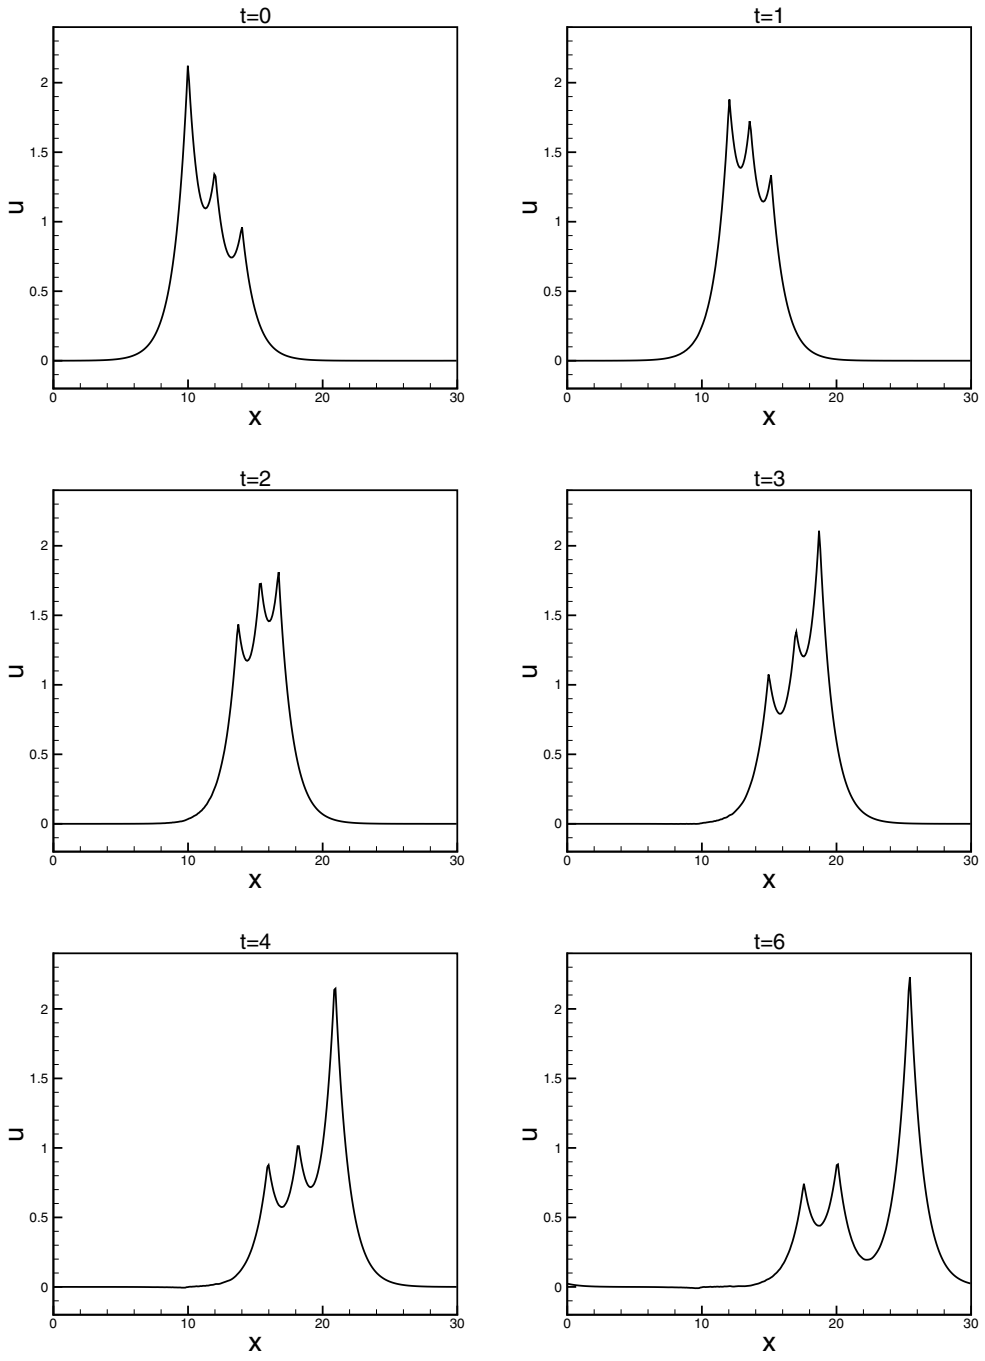

FIG. 3. *The three-peakon interaction of the CH equation* (5.1) *with the initial condition* (5.9). *Periodic boundary condition in* $[0, 30]$. P^5 *elements and a uniform mesh with* $N = 320$ *cells.*

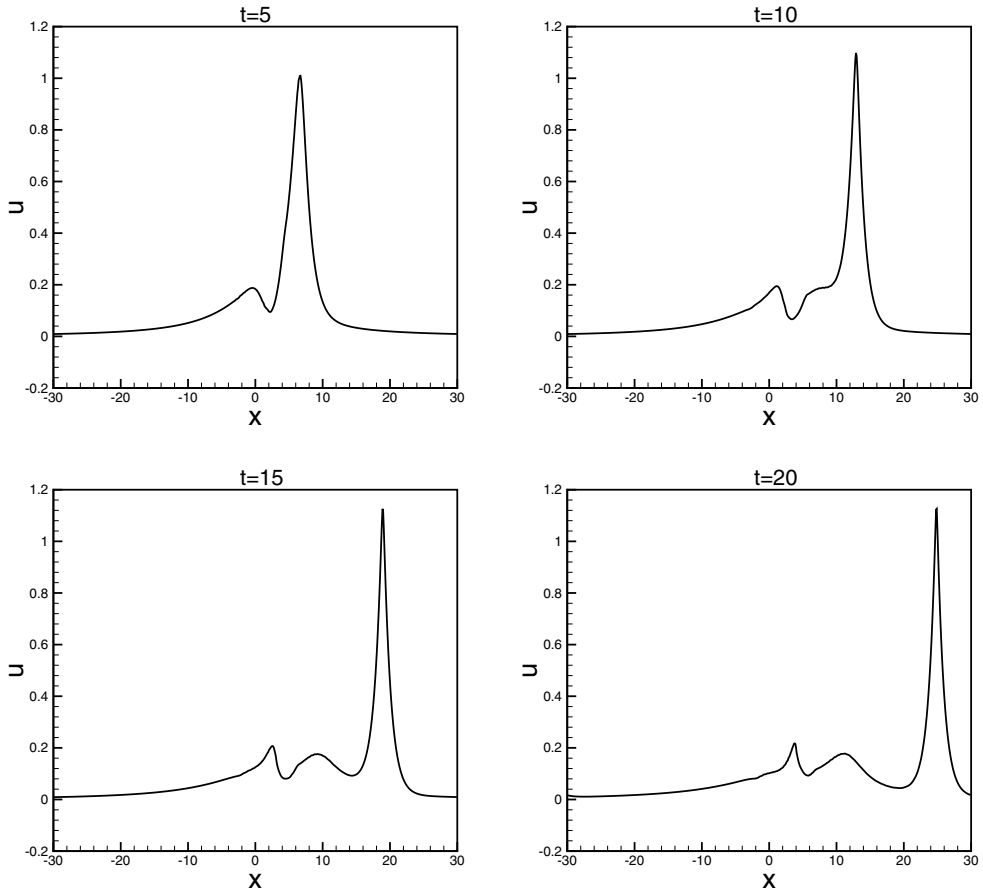

FIG. 4. *The solution with discontinuous derivative of the CH equation* (5.1) *with the initial condition* (5.10). *Periodic boundary condition in* $[-30, 30]$. P^2 *elements and a uniform mesh with* $N = 640$ *cells.*

6. Conclusion. We have developed an LDG method to solve the CH equation. L^2 stability is proven for general solutions, and an a priori error estimate is obtained for smooth solutions. Numerical examples are given to illustrate the accuracy and capability of the methods. Although not addressed in this paper, the LDG methods are flexible for general geometry, unstructured meshes and *hp*-adaptivity, and have excellent parallel efficiency. The LDG method has a good potential in solving the CH equation and similar nonlinear equations in mathematical physics.

Appendix A. Proof of several lemmas.

A.1. Proof of Lemma 4.3.

$$\begin{aligned}(\text{A.1})\quad &\mathcal{B}_j(s - s^e, \xi - \xi^e, v - v^e, \sigma - \sigma^e; -s, \sigma_t, s, -\sigma, v)\\ &= \mathcal{B}_j(s, \xi, v, \sigma; -s, \sigma_t, s, -\sigma, v) - \mathcal{B}_j(s^e, \xi^e, v^e, \sigma^e; -s, \sigma_t, s, -\sigma, v).\end{aligned}$$

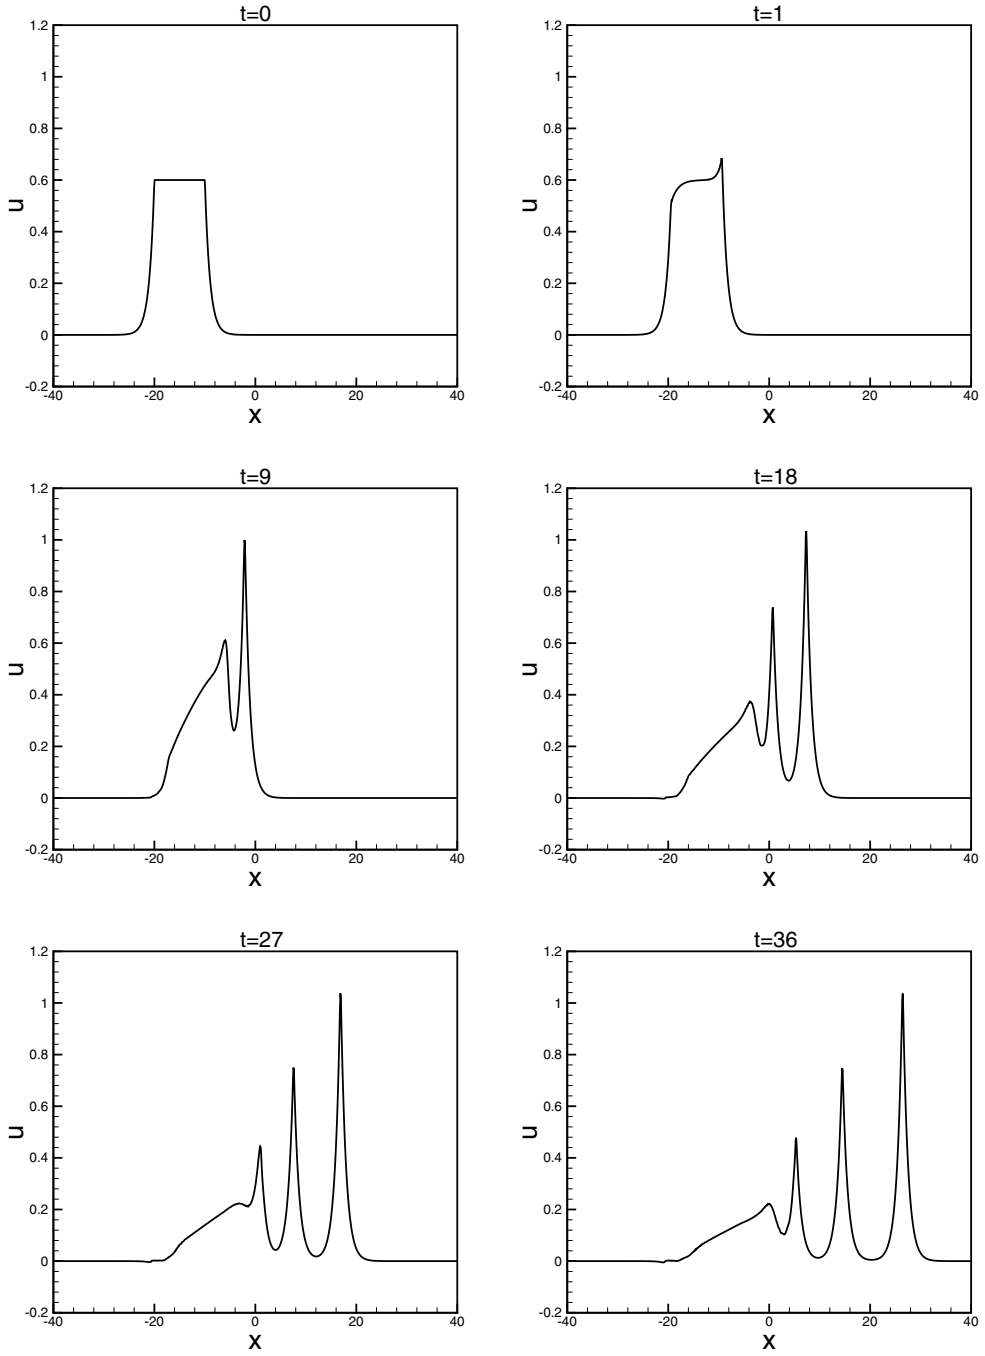

FIG. 5. *The break up of plateau traveling wave of the CH equation* (5.1) *with the initial condition* (5.11). *Periodic boundary condition in* $[-40, 40]$. P^2 *elements and a uniform mesh with* $N = 800$ *cells.*

By the same argument as that used for the L^2 stability in Proposition 3.1, the first term of the right-hand side in (A.1) becomes

$$\mathcal{B}_j(s,\xi,v,\sigma;-s,\sigma_t,s,-\sigma,v)=\int_{I_j}(s_ts+\sigma_t\sigma)dx+\Psi_{j+\frac{1}{2}}-\Psi_{j-\frac{1}{2}}, \tag{A.2}$$

where $\Psi=v^-s^--\widehat{v}s^--\widetilde{s}v^-+\sigma_t^-s^--\widehat{\sigma}_ts^--\widehat{s}\sigma_t^-$.

As to the second term of the right-hand side in (A.1), we have

(A.3)

$$\begin{aligned}&\mathcal{B}_j(s^e,\xi^e,v^e,\sigma^e;-s,\sigma_t,s,-\sigma,v)\\&\quad=\int_{I_j}(s_t^es+\sigma^e\sigma_t)dx+\int_{I_j}(\sigma^ev-v^e\sigma)dx+\int_{I_j}(\sigma_t^es_x+s^e(\sigma_t)_x+v^es_x+s^ev_x)dx\\&\qquad+((\widehat{v^e}+\widehat{\sigma_t^e})[s])_{j-\frac{1}{2}}+(\widehat{s^e}[\sigma_t])_{j-\frac{1}{2}}+(\widetilde{s^e}[v])_{j-\frac{1}{2}}+\Phi_{j+\frac{1}{2}}-\Phi_{j-\frac{1}{2}},\end{aligned}$$

where $\Phi=-\widehat{v^e}s^--\widetilde{s^e}v^--\widehat{\sigma_t^e}s^--\widehat{s^e}\sigma_t^-$. Because $\mathcal{P}$ is a local L^2 projection, and $\mathcal{P}^+$, even though not a local L^2 projection, does have the property that $s-\mathcal{P}^+s$ is locally orthogonal to all polynomials of degree up to $k-1$, we have

$$\int_{I_j}\sigma^e\sigma_tdx+\int_{I_j}(\sigma^ev-v^e\sigma)dx+\int_{I_j}(\sigma_t^es_x+s^e(\sigma_t)_x+v^es_x+s^ev_x)dx=0.$$

Noticing the special interpolating property of the projection $\mathcal{P}^-$, we also have

$$(\widehat{s^e}[\sigma_t])_{j-\frac{1}{2}}+(\widetilde{s^e}[v])_{j-\frac{1}{2}}=0.$$

Equation (A.3) then becomes

$$\mathcal{B}_j(s^e,\xi^e,v^e,\sigma^e;-s,\sigma_t,s,-\sigma,v)=\int_{I_j}s_t^esdx+((\widehat{v^e}+\widehat{\sigma_t^e})[s])_{j-\frac{1}{2}}+\Phi_{j+\frac{1}{2}}-\Phi_{j-\frac{1}{2}}.$$

Combining the above equation with (A.2), summing over j, and taking into account the periodic boundary condition, we obtain the desired equality (4.17).

A.2. Proof of Lemma 4.6. The proof of Lemma 4.6 is similar to that of Lemma 3.5 in [31]. The main difference is that we take $\bar{r}_h=\frac{1}{2}(r_h^++r_h^-)$, and u_h^+ and r_h^- as the reference values of the functions r_h and u_h at each boundary point. For the nonlinear terms $b(r)u$ and $B(r)$, we use the following Taylor expansions:

$$\begin{aligned}&B(r)-B(r_h)=b(r)\sigma-\frac{1}{2}b'(r)\sigma^2-b(r)\sigma^e+b'(r)\sigma\sigma^e-\frac{1}{2}b'(r)(\sigma^e)^2,\\&B(r)-B(r_h^-)=b(r)\sigma^--\frac{1}{2}b'(r)(\sigma^-)^2-b(r)(\sigma^e)^-+b'(r)\sigma^-(\sigma^e)^--\frac{1}{2}b'(r)((\sigma^e)^-)^2,\end{aligned}$$

where we use the properties $B'(r)=b(r)$ and $b^{(m)}(r)=0, m\geq 2$,

$$\begin{aligned}&b(r)u-b(r_h)u_h\\&\quad=b'(r)u\sigma+b(r)s-b'(r)s\sigma-b'(r)u\sigma^e-b(r)s^e+b'(r)s\sigma^e+b'(r)\sigma s^e-b'(r)\sigma^es^e,\\&b(r)u-\widehat{b}(r_h)u_h^+\\&\quad=b'(r)u\bar{\sigma}+b(r)s^+-b'(r)\bar{\sigma}s^+-b'(r)u\bar{\sigma}^e-b(r)(s^e)^+\end{aligned}$$

$$+ b'(r)s^+\bar{\sigma}^e + b'(r)\bar{\sigma}(s^e)^+ - b'(r)\bar{\sigma}^e(s^e)^+.$$

These imply the following representation:

$$\sum_{j=1}^{N} \mathbf{R}_j(b, B; r, u, r_h, u_h; s, -\sigma) = \mathcal{S}_1 + \mathcal{S}_2 + \mathcal{S}_3 + \mathcal{S}_4 + \mathcal{S}_5, \tag{A.4}$$

where

$$\begin{aligned}
\mathcal{S}_1 &= \sum_{j=1}^{N} \int_{I_j} b'(r)u\sigma\sigma_x dx + \sum_{j=1}^{N} (b'(r)u\bar{\sigma}[\sigma])_{j+\frac{1}{2}} \\
&\quad + \sum_{j=1}^{N} \int_{I_j} b(r)(s\sigma)_x dx + \sum_{j=1}^{N} (b(r)(s^+[\sigma] + \sigma^-[s]))_{j+\frac{1}{2}}, \\
\mathcal{S}_2 &= -\frac{1}{2}\left(\sum_{j=1}^{N} \int_{I_j} b'(r)(s\sigma^2)_x dx + \sum_{j=1}^{N} (b'(r)(2s^+\bar{\sigma}[\sigma] + (\sigma^-)^2[s]))_{j+\frac{1}{2}} \right), \\
\mathcal{S}_3 &= -\sum_{j=1}^{N} \int_{I_j} b'(r)u\sigma^e\sigma_x dx - \sum_{j=1}^{N} (b'(r)u\bar{\sigma}^e[\sigma])_{j+\frac{1}{2}} \\
&\quad - \sum_{j=1}^{N} \int_{I_j} b(r)(\sigma^e s_x + s^e\sigma_x) dx - \sum_{j=1}^{N} (b(r)((s^e)^+[\sigma] + (\sigma^e)^-[s]))_{j+\frac{1}{2}}, \\
\mathcal{S}_4 &= \sum_{j=1}^{N} \int_{I_j} b'(r)\sigma^e(s\sigma)_x dx + \sum_{j=1}^{N} (b'(r)(s^+\bar{\sigma}^e[\sigma] + (\sigma^e)^-\sigma^-[s]))_{j+\frac{1}{2}} \\
&\quad + \sum_{j=1}^{N} \int_{I_j} b'(r)s^e\sigma\sigma_x dx + \sum_{j=1}^{N} (b'(r)\bar{\sigma}(s^e)^+[\sigma])_{j+\frac{1}{2}}, \\
\mathcal{S}_5 &= -\frac{1}{2}\left(\sum_{j=1}^{N} \int_{I_j} b'(r)((\sigma^e)^2 s_x + 2\sigma^e s^e\sigma_x) dx \right. \\
&\quad \left. + \sum_{j=1}^{N} (b'(r)(2(s^e)^+\bar{\sigma}^e[\sigma] + ((\sigma^e)^-)^2[s]))_{j+\frac{1}{2}} \right)
\end{aligned}$$

will be estimated separately.

- The $\mathcal{S}_1$ term.
  After a simple integration by parts, it is easy to obtain

$$\mathcal{S}_1 = -\frac{1}{2}\sum_{j=1}^{N} \int_{I_j} (b'(r)u)_x\sigma^2 dx - \sum_{j=1}^{N} \int_{I_j} (b(r))_x s\sigma dx \le C\|\sigma\|^2 + \frac{1}{8}\|s\|^2. \tag{A.5}$$

- The $\mathcal{S}_2$ term.
  After a simple integration by parts, it is easy to obtain

$$\mathcal{S}_2 = \frac{1}{2}\sum_{j=1}^{N} \int_{I_j} (b'(r))_x s\sigma^2 dx = 0. \tag{A.6}$$

- The $\mathcal{S}_3$ term.
  We can rewrite $\mathcal{S}_3$ into the following form

$$\begin{aligned}\mathcal{S}_3 = &-\sum_{j=1}^{N}\int_{I_j}(b'(r)u - b'(r_j)u_j)\sigma^e\sigma_x dx - \sum_{j=1}^{N}\int_{I_j} b'(r_j)u_j\sigma^e\sigma_x dx\\ &-\sum_{j=1}^{N}\int_{I_j}(b(r)-b(r_j))(\sigma^e s_x + s^e\sigma_x)dx - \sum_{j=1}^{N}\int_{I_j} b(r_j)(\sigma^e s_x + s^e\sigma_x)dx\\ &-\sum_{j=1}^{N}(b'(r)u\bar{\sigma}^e[\sigma])_{j+\frac{1}{2}} - \sum_{j=1}^{N}(b(r)(\sigma^e)^-[s])_{j+\frac{1}{2}} - \sum_{j=1}^{N}(b(r)(s^e)^+[\sigma])_{j+\frac{1}{2}}.\end{aligned}$$

  The second, the fourth, and the last terms in the above equation are zero by the definition of the special projection. Since $|b'(r)u - b'(r_j)u_j| = O(h)$ on each element I_j, then by the inverse property (i) in (4.9), together with the interpolation property (4.8), the first term in the above equation is estimated by

$$\left|\sum_{j=1}^{N}\int_{I_j}(b'(r)u - b'(r_j)u_j)\sigma^e\sigma_x dx\right| \le C\|\sigma^e\|\|\sigma\| \le C\|\sigma\|^2 + Ch^{2k+2}.$$

  By the same argument we can also get the estimate for the third term

$$\left|\sum_{j=1}^{N}\int_{I_j}(b(r)-b(r_j))(\sigma^e s_x + s^e\sigma_x)dx\right| \le C\|\sigma\|^2 + \frac{1}{8}\|s\|^2 + Ch^{2k+2}.$$

  Now we can get the estimate of $\mathcal{S}_3$,

$$\mathcal{S}_3 \le \sum_{j=1}^{N}(|b'(r)u\bar{\sigma^e}[\sigma]| + |b(r)(\sigma^e)^-[s]|)_{j+\frac{1}{2}} + C\|\sigma\|^2 + \frac{1}{8}\|s\|^2 + Ch^{2k+2}. \tag{A.7}$$

- $\mathcal{S}_4$ and $\mathcal{S}_5$ terms.
  Because $\mathcal{S}_4$ and $\mathcal{S}_5$ are high-order terms in the Taylor expansion, it is easy to show by Young's inequality and the inverse properties (i) and (ii) in (4.9) that

$$\mathcal{S}_4 \le Ch^{-1}(\|\sigma^e\|_\infty + \|s^e\|_\infty)\|\sigma\|\|s\| \le C\|\sigma\|^2 + \frac{1}{8}\|s\|^2, \tag{A.8}$$

$$\mathcal{S}_5 \le Ch^{-1}\|\sigma^e\|_\infty(\|\sigma^e\|\|s\| + \|s^e\|\|\sigma\|) \le C\|\sigma\|^2 + \frac{1}{8}\|s\|^2 + Ch^{2k+2}. \tag{A.9}$$

Therefore, summing up the above estimates from (A.5) to (A.9), we complete the proof of Lemma 4.6.

HIGH-ORDER EXPONENTIAL OPERATOR SPLITTING METHODS FOR TIME-DEPENDENT SCHRÖDINGER EQUATIONS*

MECHTHILD THALHAMMER†

Abstract. In this paper, we deduce high-order error bounds for exponential operator splitting methods. The employed techniques are specific to linear differential equations of the form $u'(t) = A\,u(t) + B\,u(t)$, $t \geq 0$, involving an unbounded operator A. In particular, evolutionary Schrödinger equations with sufficiently regular initial values are included in the analysis.

Key words. exponential operator splitting, Schrödinger equations, high-order methods, convergence, stability

DOI. 10.1137/060674636

1. Introduction.

In this paper, we study exponential operator splitting methods for initial value problems of the form

$$u'(t) = A\,u(t) + B\,u(t), \quad t \geq 0, \qquad u(0) \text{ given.} \tag{1.1}$$

We are primarily interested in evolution equations that are related to time-dependent linear Schrödinger equations or spatial discretizations thereof. That is, we allow the operator norm of A to be of arbitrary size and suppose B to be a bounded linear operator.

For the time integration of (1.1), we consider exponential operator splitting methods composed by several exponentials

$$u_n = \prod_{j=1}^{s} \mathrm{e}^{\,b_j h B}\, \mathrm{e}^{a_j h A}\, u_{n-1}, \quad n \geq 1, \qquad u_0 \text{ given,} \tag{1.2}$$

with coefficients $a_j, b_j \in \mathbb{R}$ for $1 \leq j \leq s$. In particular, the symmetric second-order splitting scheme

$$u_n = \mathrm{e}^{\frac{1}{2} h B}\, \mathrm{e}^{h A}\, \mathrm{e}^{\frac{1}{2} h B}\, u_{n-1}, \quad n \geq 1, \qquad u_0 \text{ given,} \tag{1.3}$$

referred to as *Strang* [20] or *symmetric Trotter* [21] splitting, is contained in the method class (1.2).

In Jahnke and Lubich [11] error bounds for (1.3) when applied to pseudospectral discretizations of time-dependent linear Schrödinger equations are given. In the present paper, we extend this approach to splitting methods of the general form (1.2).

So far, despite the fact that exponential operator splitting methods are widely used in the time integration of partial differential equations, it remains open to provide a convergence analysis for the numerical method class (1.2) when applied to stiff problems. In this work, we deduce a theoretical result on the convergence and stability behavior of exponential operator splitting methods that contributes to filling the blank

for evolutionary linear Schrödinger equations and to justifying the practical use of example methods proposed in the literature for this type of problem; for instance, our error bound is applicable to symmetric symplectic fourth- and sixth-order methods, given in Blanes and Moan [3], and it shows that the schemes retain their convergence orders for time-dependent linear Schrödinger equations with sufficiently regular data.

This paper is organized as follows. In section 2, we introduce the precise assumptions on the linear evolution equation (1.1). Our abstract framework is based on the theory of $\mathscr{C}_0$-(semi)groups on Banach spaces and includes evolutionary linear Schrödinger equations; a thorough treatment of one-parameter (semi)groups and applications to partial differential equations is found in [7, 10, 17]. In section 3, we derive an expansion for the local error of the exponential operator splitting method (1.2) that remains valid within the analytic framework of section 2; for that purpose, extending Jahnke and Lubich [11, Proof of Thm. 2.1], we associate the order conditions with quadrature order conditions for multiple integrals. In section 4, we then prove a global error bound under reasonable regularity requirements on the initial value. Essential tools for our convergence analysis are estimates for repeated commutators; for instance, such bounds are valid for time-dependent linear Schrödinger equations subject to periodic boundary conditions, provided that the potential is sufficiently regular. The error estimate is finally illustrated by a numerical example.

A variety of works is concerned with exponential splitting methods for differential equations; as a small excerpt from the literature we mention [1, 2, 12, 18, 19] and the recent contributions [4, 5, 6, 15]; see also the references therein. In particular, we refer the reader to Lubich [14], where a rigorous convergence analysis of the Strang splitting for the cubic Schrödinger equation is given; Magnus integrators for linear Schrödinger equations involving a time-dependent potential are analyzed in Hochbruck and Lubich [9]. Basic information on splitting methods is also found in the survey article of McLachlan and Quispel [16] and the monograph of Hairer, Lubich, and Wanner [8].

2. Splitting methods for evolutionary Schrödinger equations. In this section, we give the basic hypotheses on the abstract differential equation (1.1). As illustration, we consider time-dependent linear Schrödinger equations and formulate them as evolution equations; for notational simplicity, we restrict ourselves to one space dimension. Moreover, we restate the exponential operator splitting method (1.2) and introduce several auxiliary abbreviations used throughout.

2.1. Evolution equations. We employ the following assumptions on the abstract initial value problem (1.1); see also Engel and Nagel [7, Thm. II.3.8]. To simplify matters, following Jahnke and Lubich [11], we require e^{tA} to be bounded by one.

HYPOTHESIS 1. *Let $(X, \|\cdot\|_X)$ denote the underlying Banach space and $\|\cdot\|_{X\leftarrow X}$ the induced operator norm. We assume that the densely defined and closed linear operator $A : D \subset X \to X$ is the infinitesimal generator of a $\mathscr{C}_0$-semigroup $\left(\mathrm{e}^{tA}\right)_{t\geq 0}$ on X satisfying the bound*

$$\left\|\mathrm{e}^{tA}\right\|_{X\leftarrow X} \leq 1, \qquad 0 \leq t \leq T. \tag{2.1}$$

Further, we suppose $B : X \to X$ to be a bounded linear operator.

The above assumptions ensure that for $u(0) \in D$ the uniquely determined (classical) solution $u \in \mathscr{C}^1([0,\infty), X)$ of the initial value problem (1.1) is given by

$$u(t) = \mathrm{e}^{t(A+B)}\, u(0), \qquad t \geq 0. \tag{2.2a}$$

Moreover, the following representation by the variation-of-constants formula

$$u(t) = \mathrm{e}^{tA}\, u(0) + \int_0^t \mathrm{e}^{(t-\tau)A}\, B\, u(\tau)\, \mathrm{d}\tau, \qquad t \geq 0, \tag{2.2b}$$

is valid; see [7, Chap. II.6/III.1].

For some $\omega \in \mathbb{R}$ and $\vartheta > 0$ the fractional powers A_ω^ϑ of the shifted operator $A_\omega = A - \omega I$ are well defined on a subspace of X (see [7, Chap. II.5c]); we denote by $\big(X_\vartheta, \|\cdot\|_{X_\vartheta}\big)$ the domain of A_ω^ϑ, endowed with the graph norm

$$\|v\|_{X_\vartheta} = \|v\|_X + \big\|A_\omega^\vartheta\, v\big\|_X, \qquad v \in X_\vartheta;$$

in particular, we set $A^0 = I$ and $X_0 = X$.

Henceforth, we assume that the linear operator B remains bounded on X_ϑ for some $\vartheta \geq 0$, that is, there exists a constant $C > 0$ such that

$$\big\|B\big\|_{X_\vartheta \leftarrow X_\vartheta} \leq C; \tag{2.3a}$$

consequently, the bound

$$\big\|\mathrm{e}^{tB}\big\|_{X_\vartheta \leftarrow X_\vartheta} \leq C, \qquad 0 \leq t \leq T, \tag{2.3b}$$

holds with some constant $C > 0$. Hypothesis 1 implies that $\mathrm{e}^{tA} : X \to X$ is uniformly bounded on finite time intervals; furthermore, for any $\vartheta \geq 0$ it follows that

$$\big\|\mathrm{e}^{tA}\big\|_{X_\vartheta \leftarrow X_\vartheta} \leq 1, \quad \big\|\mathrm{e}^{t(A+B)}\big\|_{X_\vartheta \leftarrow X_\vartheta} \leq C, \qquad 0 \leq t \leq T, \tag{2.3c}$$

with some constant $C > 0$.

For integers $j \geq 0$, the linear operators $\varphi_j(tB)$ are defined through

$$\varphi_0(z) = \mathrm{e}^z, \qquad \varphi_j(z) = \frac{1}{(j-1)!} \int_0^1 \tau^{j-1}\, \mathrm{e}^{(1-\tau)z}\, \mathrm{d}\tau, \quad j \geq 1, \qquad z \in \mathbb{C}. \tag{2.4a}$$

We conclude from the above relation (2.3b) that the estimate

$$\big\|\varphi_j(tB)\big\|_{X_\vartheta \leftarrow X_\vartheta} \leq \frac{1}{j!}\, C, \qquad 0 \leq t \leq T, \tag{2.4b}$$

is valid for $j \geq 0$.

In the situation of Hypothesis 1, the exponential operator splitting method (1.2) is well defined provided that $a_j \geq 0$ for $1 \leq j \leq s$. For schemes with negative coefficients, we employ a stronger framework; in particular, relation (2.3c) then remains valid for $0 \leq |t| \leq T$.

Hypothesis 2. *The densely defined closed linear operator $A : D \subset X \to X$ generates a $\mathscr{C}_0$-group $\big(\mathrm{e}^{tA}\big)_{t\in\mathbb{R}}$ on X such that the bound*

$$\big\|\mathrm{e}^{tA}\big\|_{X \leftarrow X} \leq 1, \qquad 0 \leq |t| \leq T, \tag{2.5}$$

is satisfied.

In order to obtain high-order error bounds for (1.2), we require the solution of the initial value problem (1.1) to fulfill certain commutator bounds on fractional power spaces of A. We henceforth employ the standard notation

$$\mathrm{ad}_A^0(B) = B, \qquad \mathrm{ad}_A^j(B) = \big[A, \mathrm{ad}_A^{j-1}(B)\big], \quad j \geq 1, \tag{2.6}$$

where $[A, L] = AL - LA$ for some linear operator L; e.g., see [8, Chap. III.4.1].

HYPOTHESIS 3. *We suppose that for certain $\vartheta, \widetilde{\vartheta} \geq 0$ the estimate*

$$\big\|\mathrm{ad}_A^j(B)\big\|_{X_\vartheta \leftarrow X_{\tilde{\vartheta}}} \leq C$$

is valid with constant $C > 0$.

As indicated in section 2.2, the above hypothesis is reasonable in connection with evolutionary linear Schrödinger equations that are subject to periodic boundary conditions and involve a smooth potential.

2.2. Time-dependent Schrödinger equations. Let $V : \Omega = [-\pi, \pi] \to \mathbb{R}$ be a periodic map that fulfills suitable regularity requirements. We consider the time-dependent linear Schrödinger equation

$$\mathrm{i}\,\partial_t U(x,t) = -\,\Delta\, U(x,t) + V(x)\, U(x,t), \qquad x \in \Omega, \quad t \geq 0, \tag{2.7}$$

subject to periodic boundary conditions on Ω and an initial condition $U(x,0) = U_0(x)$, $x \in \Omega$.

The above initial-boundary value problem is interpreted as an initial value problem of the form (1.1) by setting $u(t) = U(\cdot, t)$ and

$$\big(A\, v\big)(x) = \mathrm{i}\,\Delta\, v(x), \qquad \big(B\, v\big)(x) = -\,\mathrm{i}\, V(x)\, v(x)$$

for $v : \Omega \to \mathbb{C}$ a sufficiently regular function. Similarly as in Pazy [17, Chap. 7.5], it is shown that the linear operators $A : D \to X$ and $B : X \to X$ satisfy the assumptions of Hypothesis 1 with $X = L^2(\Omega, \mathbb{C})$ and $D = \big\{v \in H^2(\Omega, \mathbb{C}) : v \text{ periodic on } \Omega\big\}$. Furthermore, it holds that $X_{k/2} = \big\{v \in H^k(\Omega, \mathbb{C}) : v \text{ periodic on } \Omega\big\}$ for integers $k \geq 1$.

We note that Hypothesis 3 is fulfilled with $\vartheta = k/2$ and $\widetilde{\vartheta} = \vartheta + j/2$ for integers $j, k \geq 0$, provided that V is sufficiently often differentiable. In fact, the commutator of the one-dimensional Laplace operator $\mathscr{A} = \partial_x^2$ and a jth-order differential operator

$$\mathscr{B} = \sum_{\ell=0}^{j} \beta_\ell(x)\, \partial_x^\ell$$

with smooth space-dependent coefficients β_ℓ, $0 \leq \ell \leq j$, yields a differential operator of order $j + 1$. More precisely, it follows that

$$\big[\mathscr{A}, \mathscr{B}\big] = \mathscr{A}\mathscr{B} - \mathscr{B}\mathscr{A} = \sum_{\ell=0}^{j} \big(2\, \beta_\ell'\, \partial_x^{\ell+1} + \beta_\ell''\, \partial_x^\ell\big).$$

Proceeding by induction, we conclude that the iterated commutator $\mathrm{ad}_{\mathscr{A}}^j(V)$ is a differential operator of order j and therefore obtain

$$\big\|\mathrm{ad}_{\mathscr{A}}^j(V)\, v\big\|_{H^k(\Omega)} \leq C \|v\|_{H^{k+j}(\Omega)}, \qquad v \in H^{k+j}(\Omega),$$

for $k, j \geq 0$.

It is straightforward to generalize the above considerations to higher space dimensions.

2.3. Exponential operator splitting methods. Throughout, the gridpoints associated with a constant stepsize $h > 0$ are denoted by $t_n = nh$ for $n \geq 0$. For an exponential operator splitting method with real coefficients $a_j, b_j \in \mathbb{R}$, $1 \leq j \leq s$, numerical approximation values $u_n \approx u(t_n)$ to the true solution of (1.1) are given by the recurrence formula

$$u_n = \mathrm{e}^{b_s hB}\, \mathrm{e}^{a_s hA} \cdots \mathrm{e}^{b_2 hB}\, \mathrm{e}^{a_2 hA}\, \mathrm{e}^{b_1 hB}\, \mathrm{e}^{a_1 hA}\, u_{n-1}, \quad n \geq 1, \qquad u_0 \text{ given;} \tag{2.8a}$$

see Hypotheses 1 and 2. We note that the linear operators arising in the above product do not commute in general.

In order to write (2.8a) in short notation, it is useful to employ the following abbreviations. For linear operators $L_j : X \to X$, $\ell \leq j \leq k$, we define

$$\prod_{j=\ell}^{k} L_j = L_k \cdots L_{\ell+1}\, L_\ell, \quad k \geq \ell, \qquad \prod_{j=\ell}^{k} L_j = I, \quad k < \ell.$$

Here, $I : X \to X$ denotes the identity operator on X. Furthermore, for $k \leq s$ we set

$$P_k = \prod_{j=1}^{k} \mathrm{e}^{b_j hB}\, \mathrm{e}^{a_j hA}, \tag{2.8b}$$

and thus the exponential operator splitting method (2.8a) takes the compact form

$$u_n = P_s\, u_{n-1}, \quad n \geq 1, \qquad u_0 \text{ given;} \tag{2.8c}$$

see (1.2).

Inserting the exact solution values into the numerical scheme (2.8c) defines the defect at time t_n

$$u(t_n) = P_s\, u(t_{n-1}) + d_n, \qquad n \geq 1. \tag{2.9}$$

As a consequence, a recurrence relation for the error of the splitting method

$$e_n = u_n - u(t_n) = P_s\, e_{n-1} - d_n, \qquad n \geq 1,$$

follows. Resolving this recursion, we finally obtain

$$e_n = P_s^n\, e_0 - \sum_{j=0}^{n-1} P_s^{n-j-1}\, d_{j+1}, \qquad n \geq 0. \tag{2.10}$$

Our main result in section 4 is a convergence estimate for (2.8). Its proof is based on the above representation; that is, suitable estimations of the splitting operator and the defects are required; in this context, several auxiliary results provided in section 3.1 are of use.

3. Local error. In the present section, our concern is to deduce a suitable expansion of the local error

$$d_n = u(t_n) - P_s\, u(t_{n-1}), \qquad n \geq 1, \tag{3.1}$$

that remains well defined within the analytical framework of section 2; see (2.9). Furthermore, from this representation, the order conditions for the exponential operator splitting method (2.8) follow.

We start with expanding the exact solution and the splitting operator.

3.1. Auxiliary expansions. (i) *Exact solution.* An expansion of the exact solution value $u(t_n)$ that is specific to evolutionary Schrödinger equations is obtained by means of a reapplication of the variation-of-constants formula (2.2b). Namely, replacing in

$$u(t_n) = u(t_{n-1}+h) = \mathrm{e}^{hA}\, u(t_{n-1}) + \int_0^h \mathrm{e}^{(h-\tau_1)A}\, B\, u(t_{n-1}+\tau_1)\,\mathrm{d}\tau_1$$

the solution value $u(t_{n-1}+\tau_1)$ by

$$u(t_{n-1}+\tau_j) = \mathrm{e}^{\tau_j A}\, u(t_{n-1}) + \int_0^{\tau_j} \mathrm{e}^{(\tau_j-\tau_{j+1})A}\, B\, u(t_{n-1}+\tau_{j+1})\,\mathrm{d}\tau_{j+1}, \tag{3.2}$$

where $j=1$, yields the following relation:

$$\begin{aligned} u(t_n) &= \mathrm{e}^{hA}\, u(t_{n-1}) + \int_0^h \mathrm{e}^{(h-\tau_1)A}\, B\, \mathrm{e}^{\tau_1 A}\, u(t_{n-1})\,\mathrm{d}\tau_1 \\ &\quad + \int_0^h \int_0^{\tau_1} \mathrm{e}^{(h-\tau_1)A}\, B\, \mathrm{e}^{(\tau_1-\tau_2)A}\, B\, u(t_{n-1}+\tau_2)\,\mathrm{d}\tau_2\,\mathrm{d}\tau_1. \end{aligned} \tag{3.3}$$

Henceforth, we employ the compact vector notation $\tau = (\tau_1, \tau_2, \ldots, \tau_k) \in \mathbb{R}^k$ and set

$$f_k(\tau) = \prod_{\ell=1}^{k} \Big(\mathrm{e}^{(\tau_{k-\ell} - \tau_{k-\ell+1})A}\, B \Big), \qquad g_k(\tau) = f_k(\tau)\, \mathrm{e}^{\tau_k A}, \tag{3.4a}$$

with $\tau_0 = h$; as before, the product is defined downwards. Applying repeatedly the substitution (3.2) to (3.3), we therefore obtain

$$\begin{aligned} u(t_n) &= \mathrm{e}^{hA}\, u(t_{n-1}) + \sum_{k=1}^{p} I_k\, u(t_{n-1}) + R_{p+1}^{(1)}, \\ I_k &= \int_{\Delta_k} g_k(\tau)\,\mathrm{d}\tau, \qquad R_{p+1}^{(1)} = \int_{\Delta_{p+1}} f_{p+1}(\tau)\, u(t_{n-1}+\tau_{p+1})\,\mathrm{d}\tau, \end{aligned} \tag{3.4b}$$

where $\Delta_k = \big\{ \tau \in \mathbb{R}^k : 0 \le \tau_\ell \le \tau_{\ell-1}, 1 \le \ell \le k \big\}$. We note that the above expansion remains well defined in the situation of Hypothesis 1; see also section 4.

(ii) *Splitting operator.* We next specify a representation for the splitting operator P_s that allows, in an easy manner, a comparison with (3.4b). Our main tool for deducing such an expansion is a recurrence formula for the φ-functions

$$\varphi_j(z) = \frac{1}{j!} + z\, \varphi_{j+1}(z), \qquad j \ge 0, \quad z \in \mathbb{C}, \tag{3.5a}$$

obtained from (2.4a) by a partial integration. Moreover, we make use of the identity

$$\prod_{j=1}^{k} \big(K_j + L_j\big) = \prod_{\ell=1}^{k} K_\ell + \sum_{j=1}^{k} \prod_{\ell=j+1}^{k} K_\ell\; L_j \prod_{\ell=1}^{j-1} \big(K_\ell + L_\ell\big) \tag{3.5b}$$

that is valid for (noncommuting) linear operators K_j, L_j, $1 \le j \le k$. By applying the relations (3.5) to P_s, we obtain

$$P_s = \prod_{j=1}^{s} \mathrm{e}^{\,b_j h B}\, \mathrm{e}^{a_j h A} = \prod_{j=1}^{s} \Big(\mathrm{e}^{a_j h A} + h\, b_j\, B\, \varphi_1\big(b_j h B\big)\, \mathrm{e}^{a_j h A} \Big), \tag{3.6}$$

and further the representation

$$P_s = \mathrm{e}^{c_s hA} + h \sum_{j=1}^{s} b_j \, \mathrm{e}^{(c_s - c_j)\, hA} \, B \, \varphi_1(b_j hB) \, \mathrm{e}^{a_j hA} \, P_{j-1}. \tag{3.7}$$

Here, we employ the abbreviation

$$c_k = \sum_{j=1}^{k} a_j, \qquad 1 \le k \le s. \tag{3.8a}$$

Regarding the h-expansions (3.4b) and (3.7), it is seen that in (3.1) the $\mathscr{O}(1)$ term vanishes, provided that

$$c_s = 1; \tag{3.8b}$$

thus, we henceforth suppose the above order condition to be fulfilled. For the following considerations, it is useful to introduce the abbreviations

$$\begin{gathered} \Phi_j(\lambda) = F(\lambda) \, \varphi_j(b_{\lambda_k} hB) \, \mathrm{e}^{a_{\lambda_k} hA} \, P_{\lambda_k - 1}, \\ F(\lambda) = \prod_{\ell=1}^{k} b_{\lambda_\ell} \, f_k(c_\lambda h), \qquad G(\lambda) = F(\lambda) \, \mathrm{e}^{c_{\lambda_k} hA} = \prod_{\ell=1}^{k} b_{\lambda_\ell} \, g_k(c_\lambda h), \end{gathered} \tag{3.9}$$

where we set $c_\lambda = (c_{\lambda_1}, c_{\lambda_2}, \dots, c_{\lambda_k})$ for multi-indices $\lambda = (\lambda_1, \lambda_2, \dots, \lambda_k) \in \mathbb{N}^k$ and $\lambda_0 = s$; see (3.4a). With the help of this notation, relation (3.7) can be written as

$$P_s = \mathrm{e}^{hA} + h \sum_{\lambda_1 = 1}^{s} \Phi_1(\lambda_1). \tag{3.10}$$

In order to expand the splitting operator P_s further, we proceed by induction; that is, we repeatedly apply a recurrence relation for Φ_j to (3.10) which we derive next. Formula (3.5a) implies

$$\Phi_j(\lambda) = \frac{1}{j!} \, F(\lambda) \, \mathrm{e}^{a_{\lambda_k} hA} \, P_{\lambda_k - 1} + h \, \Phi_{j+1}(\lambda, \lambda_k);$$

moreover, from the analogue of (3.7),

$$\begin{aligned} \mathrm{e}^{a_{\lambda_k} hA} \, P_{\lambda_k - 1} = \mathrm{e}^{c_{\lambda_k} hA} \\ + h \sum_{\lambda_{k+1} = 1}^{\lambda_k - 1} b_{\lambda_{k+1}} \, \mathrm{e}^{(c_{\lambda_k} - c_{\lambda_{k+1}})\, hA} \, B \, \varphi_1(b_{\lambda_{k+1}} hB) \, \mathrm{e}^{a_{\lambda_{k+1}} hA} \, P_{\lambda_{k+1} - 1}, \end{aligned}$$

we obtain the recurrence formula

$$\Phi_j(\lambda) = \frac{1}{j!} \, G(\lambda) + h \left(\Phi_{j+1}(\lambda, \lambda_k) + \sum_{\lambda_{k+1} = 1}^{\lambda_k - 1} \frac{1}{j!} \, \Phi_1(\lambda, \lambda_{k+1}) \right). \tag{3.11}$$

As an illustration, we apply the above relation twice to (3.10). In a first step, we get

$$\begin{gathered} P_s = \mathrm{e}^{hA} + Q_1 + r_2^{(2)}, \\ Q_1 = h \sum_{\lambda_1 = 1}^{s} G(\lambda_1), \qquad r_2^{(2)} = h^2 \Bigg(\sum_{\lambda_1 = 1}^{s} \Phi_2(\lambda_1, \lambda_1) + \sum_{\lambda_1 = 1}^{s} \sum_{\lambda_2 = 1}^{\lambda_1 - 1} \Phi_1(\lambda_1, \lambda_2) \Bigg). \end{gathered}$$

A further expansion of $r_2^{(2)}$ by means of (3.11) yields

$$P_s = \mathrm{e}^{hA} + \sum_{k=1}^{2} Q_k + r_3^{(2)},$$

$$Q_1 = h \sum_{\lambda_1=1}^{s} G(\lambda_1), \qquad Q_2 = h^2 \Bigg(\sum_{\lambda_1=1}^{s} \tfrac{1}{2}\, G(\lambda_1,\lambda_1) + \sum_{\lambda_1=1}^{s} \sum_{\lambda_2=1}^{\lambda_1-1} G(\lambda_1,\lambda_2) \Bigg), \tag{3.12a}$$

with remainder $r_3^{(2)}$ given by

$$\begin{aligned} r_3^{(2)} = h^3 \Bigg(& \sum_{\lambda_1=1}^{s} \Phi_3(\lambda_1,\lambda_1,\lambda_1) + \sum_{\lambda_1=1}^{s} \sum_{\lambda_2=1}^{\lambda_1-1} \tfrac{1}{2}\, \Phi_1(\lambda_1,\lambda_1,\lambda_2) \\ & + \sum_{\lambda_1=1}^{s} \sum_{\lambda_2=1}^{\lambda_1-1} \Phi_2(\lambda_1,\lambda_2,\lambda_2) + \sum_{\lambda_1=1}^{s} \sum_{\lambda_2=1}^{\lambda_1-1} \sum_{\lambda_3=1}^{\lambda_2-1} \Phi_1(\lambda_1,\lambda_2,\lambda_3) \Bigg). \end{aligned} \tag{3.12b}$$

By reason of brevity, we write Q_2 as

$$Q_2 = h^2 \sum_{\lambda_1=1}^{s} \sum_{\lambda_2=1}^{\lambda_1} \alpha_{\lambda_1\lambda_2}\, G(\lambda_1,\lambda_2), \qquad \alpha_{\lambda_1\lambda_2} = \begin{cases} \frac{1}{2} & \text{if } \lambda_2 = \lambda_1, \\ 1 & \text{if } \lambda_2 \le \lambda_1 - 1. \end{cases} \tag{3.12c}$$

Applying (3.11) several times to (3.12), we finally end up with the expansion

$$P_s = \mathrm{e}^{hA} + \sum_{k=1}^{p} Q_k + r_{p+1}^{(2)}. \tag{3.13a}$$

Here, the multiple sum Q_k comprises terms of the form $h^k\, \alpha_\lambda\, G(\lambda)$ for certain $\alpha_\lambda \in \mathbb{R}$; more precisely, we have

$$Q_k = h^k \sum_{\lambda \in \Lambda_k} \alpha_\lambda\, G(\lambda) = h^k \sum_{\lambda_1=1}^{s} \sum_{\lambda_2=1}^{\lambda_1} \cdots \sum_{\lambda_k=1}^{\lambda_{k-1}} \alpha_{\lambda_1\lambda_2\cdots\lambda_k}\, G(\lambda_1,\lambda_2,\ldots,\lambda_k), \tag{3.13b}$$

where we denote $\Lambda_k = \big\{\lambda \in \mathbb{N}^k : 1 \le \lambda_\ell \le \lambda_{\ell-1}, 1 \le \ell \le k\big\}$ with $\lambda_0 = s$, according to (3.4). The coefficients α_λ are displayed in Table A.1 for $1 \le k \le 4$. The remainder $r_{p+1}^{(2)}$ is given by

$$r_{p+1}^{(2)} = h^{p+1} \sum_{j=1}^{p+1} \sum_{\lambda \in \Lambda_{p+1}} \widetilde{\alpha}_{j\lambda}\, \Phi_j(\lambda) \tag{3.13c}$$

for certain $\widetilde{\alpha}_{j\lambda} \in \mathbb{R}$; we omit further details and refer the reader to the MATLAB code `recurrence`, available at http://techmath.uibk.ac.at/mecht/research/research.html, that determines the coefficients α_λ and $\widetilde{\alpha}_{j\lambda}$.

(iii) *Quadrature formulas.* From the above considerations, we obtain the following expansion of the defect:

$$d_n = \sum_{k=1}^{p} \big(I_k - Q_k\big)\, u(t_{n-1}) + R_{p+1}^{(1)} - R_{p+1}^{(2)}, \qquad R_{p+1}^{(2)} = r_{p+1}^{(2)}\, u(t_{n-1}); \tag{3.14}$$

see also (3.1), (3.4), (3.8), and (3.13). We next relate the difference $I_k - Q_k$ to the error of quadrature formulas for multiple integrals. Regarding (3.9) and (3.13b), we write Q_k as

$$Q_k = h^k \sum_{\lambda \in \Lambda_k} \beta_\lambda \, g_k(c_\lambda h), \qquad \beta_\lambda = \beta_{\lambda_1 \lambda_2 \cdots \lambda_k} = \alpha_{\lambda_1 \lambda_2 \cdots \lambda_k} \prod_{\ell=1}^{k} b_{\lambda_\ell}; \tag{3.15}$$

see (3.4a) for the definition of g_k. As usual, in order to determine the defects of the quadrature formula (3.15), we employ a Taylor series expansion of order $M = p - k$:

$$\begin{aligned} g_k(\tau) &= \sum_{m=0}^{p-k} \frac{1}{m!} \, g_k^{(m)}(0) \, \tau^m + \varrho_{k,p-k+1}(\tau), \\ \varrho_{k,M+1}(\tau) &= \frac{1}{M!} \int_0^1 (1-z)^M \, g_k^{(M+1)}(z\,\tau) \, \tau^{M+1} \, \mathrm{d}z. \end{aligned} \tag{3.16a}$$

In view of section 4, we next specify the mth derivative of g_k. It holds that

$$g_k^{(m)}(\sigma) \, \tau^m = \sum_{\substack{\mu \in \mathbb{N}^k \\ |\mu| = m}} \frac{m!}{\mu!} \, \partial_\tau^\mu g_k(\sigma) \, \tau^\mu; \tag{3.16b}$$

here, for $\mu = (\mu_1, \mu_2, \ldots, \mu_k) \in \mathbb{N}^k$ and $\tau = (\tau_1, \tau_2, \ldots, \tau_k) \in \mathbb{R}^k$, we let

$$|\mu| = \sum_{\ell=1}^{k} \mu_\ell, \qquad \mu! = \prod_{\ell=1}^{k} \mu_\ell!, \qquad \tau^\mu = \prod_{\ell=1}^{k} \tau_\ell^{\mu_\ell}, \qquad \partial_\tau^\mu = \prod_{\ell=1}^{k} \partial_{\tau_\ell}^{\mu_\ell}. \tag{3.16c}$$

Proceeding by induction, it follows that

$$\partial_\tau^\mu \, g_k(\tau) = (-1)^{|\mu|} \prod_{\ell=1}^{k} \bigl(\mathrm{e}^{(\tau_{k-\ell} - \tau_{k-\ell+1})A} \, \mathrm{ad}_A^{\mu_{k-\ell+1}}(B) \bigr) \, \mathrm{e}^{\tau_k A}; \tag{3.16d}$$

we recall definition (2.6) of the repeated commutators. In particular, we have

$$\partial_\tau^\mu \, g_k(0) = (-1)^{|\mu|} \, \mathrm{e}^{hA} \prod_{\ell=1}^{k} \mathrm{ad}_A^{\mu_{k-\ell+1}}(B). \tag{3.16e}$$

Inserting the Taylor series expansion (3.16) into

$$I_k - Q_k = \int_{\Delta_k} g_k(\tau) \, \mathrm{d}\tau - h^k \sum_{\lambda \in \Lambda_k} \beta_\lambda \, g_k(c_\lambda h)$$

(see (3.4b) and (3.15)) and making use of the fact that

$$\int_{\Delta_k} \tau^\mu \, \mathrm{d}\tau = h^{k+|\mu|} \prod_{\ell=1}^{k} \frac{1}{\mu_\ell + \cdots + \mu_k + k - \ell + 1}, \tag{3.17}$$

we obtain the representation

$$\begin{aligned} I_k - Q_k = \sum_{m=0}^{p-k} h^{k+m} \sum_{\substack{\mu \in \mathbb{N}^k \\ |\mu| = m}} \frac{1}{\mu!} \biggl(\prod_{\ell=1}^{k} \frac{1}{\mu_\ell + \cdots + \mu_k + k - \ell + 1} - \sum_{\lambda \in \Lambda_k} \beta_\lambda \, c_\lambda^\mu \biggr) \partial_\tau^\mu g_k(0) \\ + \int_{\Delta_k} \varrho_{k,p-k+1}(\tau) \, \mathrm{d}\tau - h^k \sum_{\lambda \in \Lambda_k} \beta_\lambda \, \varrho_{k,p-k+1}(c_\lambda h). \end{aligned}$$

Altogether, inserting the above relation into (3.14) implies

$$d_n = \sum_{k=1}^{p} \sum_{m=0}^{p-k} h^{k+m} \sum_{\substack{\mu\in\mathbb{N}^k \\ |\mu|=m}} \frac{1}{\mu!} \Big(\prod_{\ell=1}^{k} \frac{1}{\mu_\ell + \cdots + \mu_k + k - \ell + 1} - \sum_{\lambda\in\Lambda_k} \beta_\lambda \, c_\lambda^\mu \Big)$$
$$\times \, \partial_\tau^\mu g_k(0)\, u(t_{n-1}) + R_{p+1}^{(1)} - R_{p+1}^{(2)} + R_{p+1}^{(3)},$$
$$R_{p+1}^{(3)} = \sum_{k=1}^{p} \Big(\int_{\Delta_k} \varrho_{k,p-k+1}(\tau)\, \mathrm{d}\tau - h^k \sum_{\lambda\in\Lambda_k} \beta_\lambda \, \varrho_{k,p-k+1}(c_\lambda h) \Big)\, u(t_{n-1});$$

see also (3.4b) and (3.13c) for the definition of $R_{p+1}^{(1)}$ and $R_{p+1}^{(2)}$.

3.2. Local error expansion and order conditions. In Lemma 1, we restate the expansion for the defect (3.1) deduced in section 3.1. In view of section 4, we resume the employed abbreviations; see also (2.2a), (2.4a), (2.6), and (3.16c).

LEMMA 1. *We set* $\Lambda_k = \big\{\lambda = (\lambda_1, \lambda_2, \ldots, \lambda_k) \in \mathbb{N}^k : 1 \le \lambda_\ell \le \lambda_{\ell-1}, 1 \le \ell \le k\big\}$ *and* $\Delta_k = \big\{\tau = (\tau_1, \tau_2, \ldots, \tau_k) \in \mathbb{R}^k : 0 \le \tau_\ell \le \tau_{\ell-1}, 1 \le \ell \le k\big\}$, *where* $\lambda_0 = s$ *and* $\tau_0 = h$. *Further, we denote* $c_k = a_1 + a_2 + \cdots + a_k$ *for* $1 \le k \le s$. *Provided that the condition* $c_s = 1$ *is fulfilled, the defect of the exponential operator splitting method* (2.8) *equals*

(3.18)
$$d_n = \sum_{k=1}^{p} \sum_{\substack{\mu\in\mathbb{N}^k \\ |\mu|\le p-k}} \frac{(-1)^{|\mu|}}{\mu!}\, h^{k+|\mu|} \Big(\prod_{\ell=1}^{k} \frac{1}{\mu_\ell + \cdots + \mu_k + k - \ell + 1} - \sum_{\lambda\in\Lambda_k} \alpha_\lambda \prod_{\ell=1}^{k} b_{\lambda_\ell} c_{\lambda_\ell}^{\mu_\ell} \Big)$$
$$\times \, \mathrm{e}^{hA} \prod_{\ell=1}^{k} \mathrm{ad}_A^{\mu_{k-\ell+1}}(B)\, \mathrm{e}^{t_{n-1}(A+B)}\, u(0) + R_{p+1}.$$

The remainder $R_{p+1} = R_{p+1}^{(1)} - R_{p+1}^{(2)} + R_{p+1}^{(3)}$ *is given by*

$$R_{p+1}^{(1)} = \int_{\Delta_{p+1}} \prod_{j=1}^{p+1} \Big(\mathrm{e}^{(\tau_{p+1-j} - \tau_{p+1-j+1})A}\, B \Big)\, \mathrm{e}^{(t_{n-1}+\tau_{p+1})(A+B)}\, u(0)\, \mathrm{d}\tau,$$
$$R_{p+1}^{(2)} = h^{p+1} \sum_{j=1}^{p+1} \sum_{\lambda\in\Lambda_{p+1}} \widetilde{\alpha}_{j\lambda} \prod_{\ell=1}^{p+1} \Big(b_{\lambda_\ell}\, \mathrm{e}^{(c_{\lambda_{p-\ell+1}} - c_{\lambda_{p-\ell+2}})\, hA}\, B \Big)$$
$$\times \, \varphi_j(b_{\lambda_{p+1}} hB)\, \mathrm{e}^{a_{\lambda_{p+1}} hA}\, P_{\lambda_{p+1}-1}\, \mathrm{e}^{t_{n-1}(A+B)}\, u(0),$$

$$\varrho_{k,p-k+1}(\tau) = (p-k+1) \int_0^1 (1-z)^{p-k} \sum_{\substack{\mu\in\mathbb{N}^k \\ |\mu|=p-k+1}} \frac{(-1)^{|\mu|}}{\mu!}$$
$$\times \prod_{\ell=1}^{k} \Big(\mathrm{e}^{(\tau_{k-\ell} - \tau_{k-\ell+1})\, zA}\, \mathrm{ad}_A^{\mu_{k-\ell+1}}(B) \Big)\, \mathrm{e}^{\tau_k z A}\, \tau^\mu\, \mathrm{d}z,$$

$$R_{p+1}^{(3)} = \sum_{k=1}^{p} \Big(\int_{\Delta_k} \varrho_{k,p-k+1}(\tau)\, \mathrm{d}\tau - h^k \sum_{\lambda\in\Lambda_k} \alpha_\lambda \prod_{\ell=1}^{k} b_{\lambda_\ell}\, \varrho_{k,p-k+1}(c_\lambda h) \Big)\, \mathrm{e}^{t_{n-1}(A+B)}\, u(0).$$

The coefficients α_λ and $\widetilde{\alpha}_{m\lambda}$ are obtained by recurrence.[1]

Obviously, the first term in the local error expansion (3.18) vanishes whenever (combinations of) the coefficients

$$C_\mu = \prod_{\ell=1}^{k} \frac{1}{\mu_\ell + \cdots + \mu_k + k - \ell + 1} - \sum_{\lambda \in \Lambda_k} \alpha_\lambda \prod_{\ell=1}^{k} b_{\lambda_\ell} c_{\lambda_\ell}^{\mu_\ell} \tag{3.19}$$

vanish for all $1 \le k \le p$ and $|\mu| \le p - k$. In order to show that the classical order conditions for a general exponential operator splitting method (2.8) coincide with the stiff order conditions, we meanwhile assume (1.1) to be a *nonstiff* problem; that is, we require the linear operator A to be bounded on X. In this situation, the expansion

$$\mathrm{e}^{hA} = \sum_{j=0}^{\infty} \frac{1}{j!}\, h^j A^j$$

is well defined on X and further yields

$$d_\mu = \sum_{\substack{k \ge 1,\, j \ge 0,\, \mu \in \mathbb{N}^k \\ k + j + |\mu| \le p}} \frac{(-1)^{|\mu|}}{j!\,\mu!}\, h^{k+j+|\mu|}\, C_\mu\, E_{j\mu}(A,B)\, \mathrm{e}^{t_{\mu-1}(A+B)}\, \mu(0) + \mathscr{O}(\mu^{p+1}),$$

$$E_{j\mu}(A,B) = A^j \prod_{\ell=1}^{k} \mathrm{ad}_A^{\mu_{k-\ell+1}}(B).$$

The splitting method is consistent of order p iff for any $1 \le q \le p$ the term involving h^q vanishes. Thus, taking into account all combinations of $k \ge 1$, $j \ge 0$, and $\mu \in \mathbb{N}^k$ such that $k + |j| + |\mu| = q$ for some $1 \le q \le p$ fixed, we conclude that

$$\sum_{\substack{k \ge 1,\, j \ge 0,\, \mu \in \mathbb{N}^k \\ k + j + |\mu| = q}} \frac{(-1)^{|\mu|}}{j!\,\mu!}\, C_\mu\, E_{j\mu}(A,B) = 0.$$

For $j > 0$, due to lower order conditions, the corresponding terms vanish; if $j = 0$, the same conditions as in the stiff case arise.

Alternatively, in order to show that for evolutionary Schrödinger equations the stiff and nonstiff order conditions coincide, one could also derive the classical order conditions by means of the Campbell–Baker–Hausdorff formula (see [8]); however, as further tedious calculations are involved, we did not follow this approach here.

The proof of our convergence result for general exponential operator splitting methods (2.8) relies on a suitable estimation of the local error expansion given in Lemma 1. Provided that the conditions

$$\sum_{\ell=1}^{s} a_\ell = 1,$$

$$\sum_{\lambda \in \Lambda_k} \alpha_\lambda \prod_{\ell=1}^{k} b_{\lambda_\ell} c_{\lambda_\ell}^{\mu_\ell} = \prod_{\ell=1}^{k} \frac{1}{\mu_\ell + \cdots + \mu_k + k - \ell + 1}, \qquad 1 \le k \le p, \quad |\mu| \le p - k, \tag{3.20}$$

[1] A MATLAB code `recurrence` is available at http://techmath.uibk.ac.at/mecht/research/research.html.

are fulfilled (see also (3.19)), the first term in the local error expansion vanishes and it remains to estimate R_{p+1}. Clearly, for *nonstiff* problems (1.1), the iterated commutators are bounded; however, whenever the differential equation involves an unbounded linear operator A, this is not true in general. For evolutionary Schrödinger equations, reasonable regularity assumptions on the initial value allow us to estimate the decisive term $R^{(3)}_{p+1}$ by means of Hypothesis 3.

3.3. Example methods. As an illustration, we next specify various exponential operator splitting methods and verify that the conditions (3.20) are satisfied; see also Appendix A. Our main result in section 4 ensures that the example methods retain their convergence orders for evolutionary Schrödinger equations.

Order 1. The conditions for $p = 1$ are given in (A.1a). In particular, for $s = 1$ it follows that $a_1 = 1 = b_1$, and we retain the *Lie–Trotter* splitting

$$u_n = \mathrm{e}^{hB}\,\mathrm{e}^{hA}\,u_{n-1}, \quad n \geq 1, \qquad u_0 \text{ given.}$$

Order 2. For $p = 2$ the additional conditions are given in (A.1b). Choosing $s = 2$ and simplifying (A.1a) and (A.1b) yields $a_1 + a_2 = 1$, $b_1 + b_2 = 1$, and $b_1 a_1 + b_2 = \frac{1}{2}$. For the choice $a_1 = 0$ we thus retain the *Strang* splitting (1.3); alternatively, by setting $a_1 = \frac{1}{2}$ it follows that

$$u_n = \mathrm{e}^{\frac{1}{2}hA}\,\mathrm{e}^{hB}\,\mathrm{e}^{\frac{1}{2}hA}\,u_{n-1}, \quad n \geq 1, \qquad u_0 \text{ given.}$$

Order 4/6. Symmetric symplectic methods that can be cast in the form (2.8) are proposed in Blanes and Moan [3, Tables 2–3]. The coefficients of a fourth- and sixth-order scheme are collected in Table 3.1; the conditions (3.20) are fulfilled (up to machine precision) for $p = 4$ and $p = 6$, respectively (see also Appendix A).

4. Global error. In this section, we derive a convergence result for the exponential operator splitting method (2.8) when applied to the abstract initial value problem (1.1) and further illustrate the error bound by a numerical example.

4.1. Global error bound in terms of the initial value. In the formulation of Theorem 1, we focus on evolutionary linear Schrödinger equations; that is, the unbounded linear operator A is related to the Laplacian. Provided that the method coefficients a_j are nonnegative for $1 \leq j \leq s$, it suffices to require that A generates a $\mathscr{C}_0$-semigroup; see Hypothesis 1.

THEOREM 1. *Assume that the coefficients of the exponential operator splitting method* (2.8) *fulfill the classical order conditions for some integer* $p \geq 1$. *Suppose further that the linear operators* A *and* B *satisfy the requirements of Hypotheses* 2 *and* 3 *with* $\vartheta = k/2$ *and* $\widetilde{\vartheta} = (j+k)/2$ *for integers* $j, k \geq 0$ *such that* $j + k \leq p$. *Then, provided that* $u(0) \in X_{p/2}$, *the error estimate*

$$\big\|u_n - u(t_n)\big\|_X \leq C\,\big\|u(0) - u_0\big\|_X + C\,h^p\,\big\|u(0)\big\|_{X_{p/2}}, \qquad 0 \leq nh \leq T,$$

is valid with some constant $C > 0$ depending in particular on T but not on n and h.

Proof. Our main tools for deriving the above convergence result are a stability bound for the splitting operator and an estimate for the defect of the exponential operator splitting method (2.8). For notational simplicity, we do not distinguish the arising constants.

We first verify the boundedness of P_s^n. To that purpose, we employ the relation

$$P_s = \prod_{j=1}^{s} \big(I + h\, b_j\, B\, \varphi_1(b_j h B)\big)\, \mathrm{e}^{a_j h A}$$

obtained by means of (3.5a); see also (3.6). Applying (2.3) and (2.4) and using that $1 + z \le \mathrm{e}^z$ for $z > 0$, it follows that

$$\begin{aligned} \big\|P_s\big\|_{X\leftarrow X} &\le \prod_{j=1}^{s} \big\|I + h\, b_j\, B\, \varphi_1\big(b_j h B\big)\big\|_{X\leftarrow X}\, \big\|\mathrm{e}^{a_j h A}\big\|_{X\leftarrow X} \\ &\le \prod_{j=1}^{s} \big(1 + C\, h\, |b_j|\big) \le \mathrm{e}^{Ch}. \end{aligned}$$

Furthermore, we conclude that for any $h > 0$ the estimate

$$\big\|P_s^n\big\|_{X\leftarrow X} \le C, \qquad 0 \le nh \le T, \tag{4.1}$$

holds true on finite time intervals with constant $C > 0$ depending on T but not on n and h.

We next deduce a suitable bound for the defects. Regarding the expansion given in Lemma 1 and using that the order conditions (3.20) are fulfilled, it remains to estimate the remainder. By means of (2.3), we obtain

$$\begin{aligned} \big\|R_{p+1}^{(1)}\big\|_X &\le \int_{\Delta_{p+1}} \prod_{j=1}^{p+1} \Big(\big\|\mathrm{e}^{(\tau_{k-j} - \tau_{k-j+1})A}\big\|_{X\leftarrow X}\, \|B\|_{X\leftarrow X}\Big) \\ &\quad \times \big\|\mathrm{e}^{(t_{n-1} + \tau_{p+1})(A+B)}\big\|_{X\leftarrow X}\, \big\|u(0)\big\|_X\, \mathrm{d}\tau \\ &\le C\, h^{p+1}\, \big\|u(0)\big\|_X; \end{aligned}$$

set $|\mu| = 0$ in (3.17). In a similar manner, it follows that

$$\big\|R_{p+1}^{(2)}\big\|_X \le C\, h^{p+1} \big\|u(0)\big\|_X.$$

Hypothesis 3, together with (2.3), implies

$$\big\|\varrho_{k,p-k+1}(\tau)\big\|_{X\leftarrow X_{\vartheta_k}} \le C \sum_{|\mu| = p-k+1} \frac{\tau^\mu}{\mu!}, \qquad \vartheta_k = \frac{p-k+1}{2}\,. \tag{4.2}$$

Thus, by means of (3.17), we obtain

$$\begin{aligned} \Big(\int_{\Delta_k} \big\|\varrho_{k,p-k+1}(\tau)\big\|_{X\leftarrow X_{\vartheta_k}}\, \mathrm{d}\tau + h^k \sum_{\lambda\in\Lambda_k} \alpha_\lambda \prod_{\ell=1}^{k} |b_{\lambda_\ell}|\, \big\|\varrho_{k,p-k+1}(c_\lambda h)\big\|_{X\leftarrow X_{\vartheta_k}}\Big) \\ \times \big\|\mathrm{e}^{t_{n-1}(A+B)}\big\|_{X_{\vartheta_k}\leftarrow X_{\vartheta_k}}\, \big\|u(0)\big\|_{X_{\vartheta_k}} \\ \le C\, h^{p+1}\, \big\|u(0)\big\|_{X_{\vartheta_k}}. \end{aligned}$$

Employing the reasonable assumption

$$\|v\|_{X_\vartheta} \le \|v\|_{X_{\widetilde{\vartheta}}}, \qquad \vartheta \le \widetilde{\vartheta}, \quad v \in X_{\widetilde{\vartheta}}, \tag{4.3}$$

this finally gives the bound

$$\big\|R_{p+1}^{(3)}\big\|_X \le C\, h^{p+1}\, \big\|u(0)\big\|_{X_{p/2}}.$$

From the above considerations, we obtain the following estimate for the defect:

$$\big\|d_n\big\|_X = \big\|R_{p+1}\big\|_X \le C\, h^{p+1} \big\|u(0)\big\|_{X_{p/2}};$$

see also Lemma 1, (3.20), and (4.3). With the help of (4.1), it is now straightforward to estimate the global error; see (2.10). Altogether, we obtain

$$\begin{aligned} \big\|e_n\big\|_X &\le \big\|P_s^n\big\|_{X\leftarrow X}\, \big\|e_0\big\|_X + \sum_{j=0}^{n-1} \big\|P_s^{n-j-1}\big\|_{X\leftarrow X}\, \big\|d_{j+1}\big\|_X \\ &\le C\, \big\|e_0\big\|_X + C\, h^p\, \big\|u(0)\big\|_{X_{p/2}}, \qquad 0 \le nh \le T, \end{aligned}$$

with constant $C > 0$ depending in particular on T. □

In the present situation, as seen in the proof of Theorem 1, general exponential splitting methods remain stable for any choice of the time stepsize $0 < h \le T$; however, for evolutionary Schrödinger equations (1.1) involving a time-dependent or solution-dependent operator B, in general, a stepsize restriction is expected; see [9, 14].

The above error bound implies that the example methods given in section 3.2 retain their convergence orders when applied to time-dependent Schrödinger equations subject to a periodic boundary condition, provided that the data are sufficiently differentiable. For less regular initial values, the following convergence result holds true; order reduction phenomena for the Strang splitting are also studied in [11, 13].

COROLLARY 1. *Under the assumptions of Theorem* 1*, whenever* $u(0) \in X_{k/2}$ *but* $u(0) \notin X_{(k+1)/2}$ *for some* $1 \le k \le p-1$*, the error bound*

$$\big\|u_n - u(t_n)\big\|_X \le C\, \big\|u(0) - u_0\big\|_X + C\, h^k\, \big\|u(0)\big\|_{X_{k/2}}, \qquad 0 \le nh \le T,$$

is valid with constant $C > 0$ *depending on* T *but not on* n *and* h*.*

We note that the above convergence analysis also applies to equations involving a differential operator of higher order; in this case, the relation between the quantities $\vartheta, \widetilde{\vartheta}$ arising in Hypothesis 3 has to be adapted.

4.2. Numerical example. We next illustrate the error bound of Theorem 1 by a numerical example for a time-dependent linear Schrödinger equation. In the present paper, we do not recapitulate how the obtained results for abstract differential equations are applicable to pseudospectral discretizations of time-dependent linear Schrödinger equations; in this respect and for a more detailed description of the realization of the numerical example, we refer the reader to Jahnke and Lubich [11, sect. 3].

As test problem, we consider (2.7) with $V(x) = 1 - \cos x$; in order to study numerically the influence of the initial value on the temporal convergence order of an exponential operator splitting method, we choose various initial data that correspond to $u(0) \in X_{k/2}$ for $2 \le k \le 6$. The initial-boundary value problem is discretized in space by the Fourier pseudospectral method with $M = 2^{13}$ gridpoints.

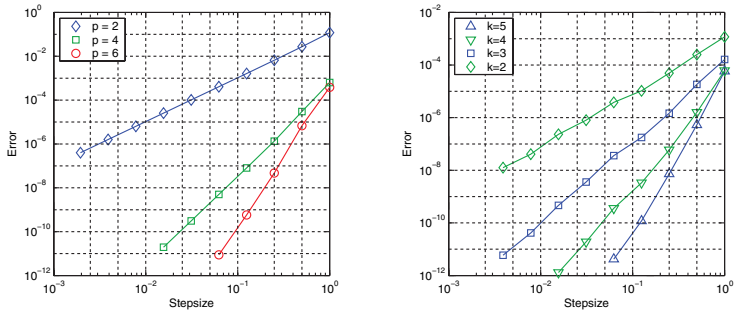

FIG. 4.1. *Numerically observed convergence orders of exponential operator splitting methods. Schemes of various orders (left picture). Initial values of various regularity (right picture).*

For a sufficiently regular initial value, i.e., $k = 6$, we apply the second-order Strang splitting and the fourth- and sixth-order schemes proposed by Blanes and Moan [3] for various time stepsizes (see section 3.3); a reference solution at final time $T = 1$ is computed by the sixth-order splitting method with stepsize $h = 2^{-11}$. The obtained temporal errors, displayed in Figure 4.1 (left picture), confirm the assertion of Theorem 1; the splitting methods retain their convergence orders for time-dependent Schrödinger equations.

For less regular initial values, the order reduction predicted by Corollary 1 is also observed numerically; for the sixth-order scheme the numerical convergence orders are displayed in Figure 4.1 (right picture).

Appendix A. In this appendix, we state the coefficients α_λ, $\lambda \in \Lambda_k$ (see Table A.1), and further specify the conditions (3.20) for $1 \le k \le p = 4$:

$$\sum_{\ell=1}^{s} a_\ell = 1, \qquad \sum_{\lambda_1=1}^{s} b_{\lambda_1} = 1, \tag{A.1a}$$

$$\sum_{\lambda_1=1}^{s} b_{\lambda_1} c_{\lambda_1} = \frac{1}{2}, \qquad \sum_{\lambda_1=1}^{s} \frac{1}{2}\, b_{\lambda_1}^2 + \sum_{\lambda_1=1}^{s} \sum_{\lambda_2=1}^{\lambda_1-1} b_{\lambda_1} b_{\lambda_2} = \frac{1}{2}, \tag{A.1b}$$

TABLE A.1
Coefficients $\alpha_{\lambda_\kappa} = \alpha_{\lambda_{\kappa_1}\lambda_{\kappa_2}\cdots\lambda_{\kappa_k}}$ *for* $\kappa = (\kappa_1, \kappa_2, \ldots, \kappa_k)$.

REDUCED BASIS ERROR BOUND COMPUTATION OF PARAMETER-DEPENDENT NAVIER–STOKES EQUATIONS BY THE NATURAL NORM APPROACH*

SIMONE DEPARIS†

Abstract. This work focuses on the a posteriori error estimation for the reduced basis method applied to partial differential equations with quadratic nonlinearity and affine parameter dependence. We rely on natural norms—*local* parameter-dependent norms—to provide a sharp and computable lower bound of the inf-sup constant. We prove a formulation of the Brezzi–Rappaz–Raviart existence and uniqueness theorem in the presence of two distinct norms. This allows us to relax the existence condition and to sharpen the field variable error bound. We also provide a robust algorithm to compute the Sobolev embedding constants involved in the error bound and in the inf-sup lower bound computation. We apply our method to a steady natural convection problem in a closed cavity, with a Grashof number varying from 10 to 10^7.

Key words. reduced basis methods, a posteriori error estimation, Brezzi–Rappaz–Raviart theory, steady incompressible Navier–Stokes equations, natural convection

1. Introduction.

In this work we are interested in the numerical approximation of parameter- ($\boldsymbol{\mu}$-) dependent quadratic nonlinear partial differential equations—in particular the natural convection problem for Navier–Stokes equations—and the prediction of an "output of interest" which is a functional of the field variable $\boldsymbol{u}^{\mathrm{e}}(\boldsymbol{\mu})$,

$$s^{\mathrm{e}}(\boldsymbol{\mu}) = \ell(\boldsymbol{u}^{\mathrm{e}}(\boldsymbol{\mu})) \in \mathbb{R}, \tag{1.1}$$

where ℓ is a continuous linear form. The solution $\boldsymbol{u}^{\mathrm{e}}(\boldsymbol{\mu})$ may not be unique; nevertheless, we consider only one solution branch; hence we presume local uniqueness.

The outputs are related to energies or forces, stresses or strains, flow rates or pressure drops, temperatures or fluxes and are functions of an "input" parameter P-vector $\boldsymbol{\mu} \in \mathcal{D} \subset \mathbb{R}^P$, which is related to geometry, physical properties, boundary conditions, or loads.

We directly adopt the description and notation of Sen et al. [32], where the natural norms are introduced and applied to the error bound computation of coercive and noncoercive linear elliptic partial differential equations.

The field variable $\boldsymbol{u}^{\mathrm{e}}(\boldsymbol{\mu}) \in X^{\mathrm{e}}$—say, velocity, pressure, or temperature—satisfies in weak form the $\boldsymbol{\mu}$-parametrized nonlinear partial differential equation

$$a(\boldsymbol{u}^{\mathrm{e}}(\boldsymbol{\mu}), \boldsymbol{v}; \boldsymbol{\mu}) = f(\boldsymbol{v}) \quad \forall\, \boldsymbol{v} \in X^{\mathrm{e}}. \tag{1.2}$$

Here X^{e} is the appropriate function space with norm $\|\cdot\|_X$, $a(\cdot, \cdot; \boldsymbol{\mu})$ is continuous, quadratic in the first variable, and linear in the second one, and f is a continuous linear form.

Unfortunately, to achieve the desired accuracy, the evaluation $\boldsymbol{\mu} \to s^{\mathrm{e}}(\boldsymbol{\mu})$ by discrete projection methods such as finite element or spectral methods is simply too costly in the many-query and real-time contexts often of interest in engineering. Low-order models—we consider here reduced basis approximations—are increasingly popular in the engineering analysis, parameter estimation, design optimization, and control contexts.

In the reduced basis approach [1, 18, 6, 22, 20, 13, 23, 11, 12, 25], we approximate $s^{\mathrm{e}}(\boldsymbol{\mu})$, $\boldsymbol{u}^{\mathrm{e}}(\boldsymbol{\mu})$ with $s_N(\boldsymbol{\mu}), \boldsymbol{u}_N(\boldsymbol{\mu})$: Given $\boldsymbol{\mu} \in \mathcal{D}$,

$$s_N(\boldsymbol{\mu}) = \ell(\boldsymbol{u}_N(\boldsymbol{\mu})),$$

where $\boldsymbol{u}_N(\boldsymbol{\mu}) \in W_N$ satisfies[1]

$$a(\boldsymbol{u}_N(\boldsymbol{\mu}), \boldsymbol{v}; \boldsymbol{\mu}) = f(\boldsymbol{v}) \quad \forall\, \boldsymbol{v} \in W_N. \tag{1.3}$$

Here W_N is a problem-specific space of dimension $N \le N_{\max}$ that focuses on the (typically very smooth) parametric manifold of interest—$\{\boldsymbol{u}^{\mathrm{e}}(\boldsymbol{\mu}) \,|\, \boldsymbol{\mu} \in \mathcal{D}\}$—and thus the reduced basis method enjoys very rapid convergence as N increases [6, 15]; $N_{\max}$ is the maximal size of our reduced basis.

Our own effort is dedicated to the development of a posteriori error estimators for reduced basis approximations in the nonlinear case [13, 23, 35, 17, 11, 12, 24]. Since, in general, we cannot find the exact (our superscript "e" above) solution, we replace $s^{\mathrm{e}}(\boldsymbol{\mu}), \boldsymbol{u}^{\mathrm{e}}(\boldsymbol{\mu})$ with a Galerkin finite element approximation[2] $s^{\mathcal{N}}(\boldsymbol{\mu})$, $\boldsymbol{u}^{\mathcal{N}}(\boldsymbol{\mu})$. $\mathcal{N}$ represents the dimension of our finite element space.

For some fixed sufficiently large $\mathcal{N} = \mathcal{N}_{\mathrm{t}}$, we presume that the finite element and the exact solution are very close. We shall call $\boldsymbol{u}^{\mathcal{N}_t}(\boldsymbol{\mu})$ a "truth" solution, upon which we provide inexpensive—complexity *independent* of $\mathcal{N}_{\mathrm{t}}$—and sharp error bounds $\Delta_N(\boldsymbol{\mu})$ and $\Delta_N^s(\boldsymbol{\mu})$ such that

$$\|\boldsymbol{u}^{\mathcal{N}_{\mathrm{t}}}(\boldsymbol{\mu}) - \boldsymbol{u}_N(\boldsymbol{\mu})\|_X \le \Delta_N(\boldsymbol{\mu}) \quad \text{and}$$
$$|s^{\mathcal{N}_{\mathrm{t}}}(\boldsymbol{\mu}) - s_N(\boldsymbol{\mu})| \le \Delta_N^s(\boldsymbol{\mu}) \quad \forall\, \boldsymbol{\mu} \in \mathcal{D}.$$

In the absence of such rigorous error bounds we cannot efficiently determine if N is too small—and our reduced basis approximation unacceptably inaccurate—or if N is too large—and our reduced basis approximation unnecessarily expensive—or we cannot establish the very *existence* of a "truth" solution $\boldsymbol{u}^{\mathcal{N}_{\mathrm{t}}}(\boldsymbol{\mu})$ [8, 34, 33]. We cannot determine in "real time" if critical design conditions and constraints are satisfied. In fact, we cannot even construct an efficient and well-conditioned reduced basis approximation space W_N [17, 16].

The dramatic *dimension reduction*—from $\mathcal{N}_t$ to N—in conjunction with *offline/online computational procedures* [13, 23, 2, 9], yields very large savings in the many-query and real-time contexts: The online complexity depends only on the size of the reduced basis space N, which is typically orders of magnitude smaller than the dimension of the finite element space $\mathcal{N}_{\mathrm{t}}$. Hence we may consider a highly accurate "truth" approximation, at the detriment of the offline complexity only.

Relative to earlier work [35, 17, 34, 33], we adapt the *natural norms* technique proposed in [32] to the quadratic case in order to improve the construction and evaluation of a lower bound of the inf-sup constant (which we shall subsequently call the

[1] For simplicity, we consider a purely primal approach; we shall subsequently describe also a primal-dual formulation.

[2] Other projection methods, such as spectral or spectral elements methods, may be used as well; cf. [11, 12].

"inf-sup lower bound"). We also extend the Brezzi–Rappaz–Raviart theory for the case of mixed norms (in our case, X and natural norms); this enables one to better control the effectivity of our error bound and to significantly reduce the constraint on the dual norm of the residual for the existence and uniqueness of a (finite element) solution in the neighborhood of our reduced basis approximation.

The effectivity relative to the natural norm of the field variable error is proven to be very accurate: locally of order one when the dual norm of the residual is small. However, when considering only a primal formulation—as in the example that we provide—we have no control of the effectivity on the output. To partially address this issue, we also propose a primal-dual formulation, whose apparent advantages would require further investigation, in particular in conjunction with deflation.

Our improvements enable a feasible and fast inf-sup lower bound construction based on a relatively small number of local norms. The inf-sup lower bound is of order one in the *local* natural norm and hence is intrinsically much simpler to compute than in existing works [34, 17, 33]. The lower bound components are also simplified: They rely on the computation of Sobolev embedding constants and eigenvalues with respect to the natural norms. We develop robust tools to compute them based on multiple initial guesses modes and, regarding the Sobolev embedding constants, the restriction to a small discrete subspace to provide the initial guess and on a fixed point algorithm.

As a result, we are now able to cover much larger parameter sets than in earlier works. For example, in [17, 33] the authors considered natural convection with a Grashof number (ratio buoyancy over viscosity) from 10 to 10^4. Instead, we have applied the reduced basis method for a Grashof number up to 10^7 without increasing—actually by simplifying—the complexity of the error bound computation. To enable the finite element resolution of our problem at these values of the Grashof number and to speed up the offline work, we implemented a parallel code and a domain decomposition preconditioner based on a sequential one proposed in [5].

We first introduce the basic assumptions that we are going to use throughout the paper and define our natural norms for nonlinear partial differential equations (section 2). We then prove an existence and unicity result based on the Brezzi–Rappaz–Raviart theory and provide an output error bound based on a pure primal approach (section 3). In section 4 we develop our inf-sup lower bound construction that enables a feasible offline/online computational strategy (section 5). We then apply our approach to a steady natural convection problem (section 6), provide the numerical results (section 7), and present our conclusions (section 8). The appendix is devoted to the output error bound by a primal-dual formulation.

2. Problem statement.

2.1. Reduced basis formulation. For any $\boldsymbol{\mu} \equiv (\mu_1, \ldots, \mu_P)$ in the closed input domain $\mathcal{D} \subset \mathbb{R}^P$, $a(\cdot, \cdot; \boldsymbol{\mu})\colon X^{\mathrm{e}} \times X^{\mathrm{e}} \to \mathbb{R}$ is a parameter-dependent form, which is quadratic with respect to its first argument and linear with respect to the second one. The forms ℓ and $f\colon X^{\mathrm{e}} \to \mathbb{R}$ are parameter-independent and linear (extension to parameter-dependent linear forms is straightforward; we provide also an extension to quadratic outputs).

Our "truth" or "reference" finite element approximation to the exact output and field variable $s(\boldsymbol{\mu}) \equiv s^{\mathcal{N}_{\mathrm{t}}}(\boldsymbol{\mu})$ and $\boldsymbol{u}(\boldsymbol{\mu}) \equiv \boldsymbol{u}^{\mathcal{N}_{\mathrm{t}}}(\boldsymbol{\mu}) \in X^{\mathcal{N}_{\mathrm{t}}} \equiv X$, for a given $\boldsymbol{\mu} \in \mathcal{D}$,

$$\begin{aligned} s(\boldsymbol{\mu}) &= \ell(\boldsymbol{u}(\boldsymbol{\mu})) \quad \text{and} \\ a(\boldsymbol{u}(\boldsymbol{\mu}), \boldsymbol{v}; \boldsymbol{\mu}) &= f(\boldsymbol{v}) \quad \forall\, \boldsymbol{v} \in X. \end{aligned} \tag{2.1}$$

We assume that $\mathcal{N}_\mathrm{t}$ is chosen sufficiently large so that $s(\boldsymbol{\mu})$ and $\boldsymbol{u}(\boldsymbol{\mu})$ are essentially indistinguishable from $s^\mathrm{e}(\boldsymbol{\mu})$ and $\boldsymbol{u}^\mathrm{e}(\boldsymbol{\mu})$, respectively. We shall build our reduced basis approximation upon this "truth" approximation, and we shall evaluate the error in our reduced basis approximation with respect to this "truth" approximation. The online complexity (and stability) of our reduced basis approach is *independent* of $\mathcal{N}_\mathrm{t}$ (cf. [17, 33, 32]); hence, we may choose $\mathcal{N}_\mathrm{t}$ to be "arbitrarily" large at *no detriment to (online) performance*.

We shall suppose that our form a is "affine" in the parameter: For some fixed integers Q_0 and Q_1—typically larger than P, sometimes by a considerable factor—we require that

$$a(\boldsymbol{u},\boldsymbol{v};\boldsymbol{\mu}) = \sum_{q=1}^{Q_0} \Theta_0^q(\boldsymbol{\mu}) a_0^q(\boldsymbol{u},\boldsymbol{v}) + \frac{1}{2}\sum_{q=1}^{Q_1} \Theta_1^q(\boldsymbol{\mu}) a_1^q(\boldsymbol{u},\boldsymbol{u},\boldsymbol{v}) \quad \forall\, \boldsymbol{u},\boldsymbol{v}\in X,\ \forall\, \boldsymbol{\mu}\in\mathcal{D}, \tag{2.2}$$

where $\Theta_0^q, \Theta_1^q\colon\ \mathcal{D}\to\mathbb{R}$, $a_0^q\colon X\times X\to\mathbb{R}$, $1\le q\le Q_0$, and $a_1^q\colon X\times X\times X\to\mathbb{R}$, $1\le q\le Q_1$, are parameter-dependent functions and parameter-independent continuous bilinear and trilinear forms, respectively. (In particular, this assumption presumes a quadratic nonlinearity in our partial differential equation.) Without loss of generality, we assume that, for $1\le q\le Q_1$ and $\forall \boldsymbol{u},\boldsymbol{v},\boldsymbol{w}\in X$, $a_1^q(\boldsymbol{u},\boldsymbol{w},\boldsymbol{v}) = a_1^q(\boldsymbol{w},\boldsymbol{u},\boldsymbol{v})$. We shall further assume that $\Theta_i^q\in\mathcal{C}^1(\mathcal{D})$, $1\le q\le Q_i$, $i=0,1$.

We denote the inner product and norm associated with our Hilbert space $X(\equiv X^{\mathcal{N}_\mathrm{t}}$, finite-dimensional) as $(\boldsymbol{w},\boldsymbol{v})_X$ and $\|\boldsymbol{v}\|_X = \sqrt{(\boldsymbol{v},\boldsymbol{v})_X}$, respectively. We further define the dual norm for any bounded linear functional f as

$$\|f\|_{X'} \equiv \sup_{\boldsymbol{v}\in X} \frac{f(\boldsymbol{v})}{\|\boldsymbol{v}\|_X}.$$

For example, when considering two-dimensional Navier–Stokes equations, the exact space X^e shall satisfy $H_0^1(\Omega)\times H_0^1(\Omega)\times L_0^2(\Omega)\subset X^\mathrm{e}\subset H^1(\Omega)\times H^1(\Omega)\times L^2(\Omega)$: Here $\Omega\subset\mathbb{R}^2$ is a spatial domain with suitably regular boundary $\partial\Omega$; $L^2(\Omega)$ is the Hilbert space of integrable functions; $H^1(\Omega)$ is the usual Hilbert space of derivative-square-integrable functions; $H_0^1(\Omega)$ indicates the functions with null trace on $\partial\Omega$ and $L_0^2(\Omega)$ the zero mean ones. The typical choice for our inner product $(\cdot,\cdot)_X$ is the standard $H^1(\Omega)\times H^1(\Omega)\times L^2(\Omega)$ inner product.

If in this example the Reynolds number is the parameter, then the affine decomposition (2.2) becomes, for $\boldsymbol{\mu}=(\mathrm{Re})$, $\boldsymbol{u}=(u_1,u_2,p)$, $\boldsymbol{v}=(v_1,v_2,q)$, $Q_0=2$, and $Q_1=1$,

$$\begin{aligned}
a_0^1(\boldsymbol{u},\boldsymbol{v}) &= -\int_\Omega p\partial_i v_i - \int_\Omega q\partial_i u_i + \lambda\int_\Omega p + \gamma\int_\Omega q, && \Theta_0^1(\boldsymbol{\mu}) = 1,\\
a_0^2(\boldsymbol{u},\boldsymbol{v}) &= \int_\Omega \partial_i u_j \partial_i v_j, && \Theta_0^2(\boldsymbol{\mu}) = \mathrm{Re}^{-1},\\
a_1^1(\boldsymbol{u},\boldsymbol{z},\boldsymbol{v}) &= \int_\Omega u_j\partial_i z_i v_j + \int_\Omega z_j\partial_i u_i v_j, && \Theta_1^1(\boldsymbol{\mu}) = 1
\end{aligned}$$

(with summation over repeated indices and partial derivatives with respect to x_1, x_2).

By recalling (2.2) and the symmetry of the a_1^q's in the first two variables, the Fréchet derivative of $a(\cdot,\cdot;\boldsymbol{\mu})$ with respect to the first variable at a point $\boldsymbol{w}\in X$ can be expressed as

$$da(\boldsymbol{w};\boldsymbol{\mu})(\boldsymbol{u},\boldsymbol{v}) = \sum_{q=1}^{Q_0} \Theta_0^q(\boldsymbol{\mu}) a_0^q(\boldsymbol{u},\boldsymbol{v}) + \sum_{q=1}^{Q_1} \Theta_1^q(\boldsymbol{\mu}) a_1^q(\boldsymbol{u},\boldsymbol{w},\boldsymbol{v}) \quad \forall\, \boldsymbol{u},\boldsymbol{v}\in X,\ \forall\, \boldsymbol{\mu}\in\mathcal{D}.$$

For any $\boldsymbol{\mu}$ in $\mathcal{D}$ and any solution $\boldsymbol{u}(\boldsymbol{\mu})$ of (2.1) in the region of our interest, we assume that $da(\boldsymbol{u}(\boldsymbol{\mu});\boldsymbol{\mu})$ is "stable" and continuous in the sense that there exist $\beta_0 > 0$ and $\gamma_0 \in \mathbb{R}$ such that, $\forall \boldsymbol{\mu} \in \mathcal{D}$,

$$0 < \beta_0 < \beta(\boldsymbol{\mu}) \equiv \inf_{\boldsymbol{w}\in X} \sup_{\boldsymbol{v}\in X} \frac{da(\boldsymbol{u}(\boldsymbol{\mu});\boldsymbol{\mu})(\boldsymbol{w},\boldsymbol{v})}{\|\boldsymbol{w}\|_X \|\boldsymbol{v}\|_X}, \tag{2.3}$$

$$\infty > \gamma_0 > \gamma(\boldsymbol{\mu}) \equiv \sup_{\boldsymbol{w}\in X} \sup_{\boldsymbol{v}\in X} \frac{da(\boldsymbol{u}(\boldsymbol{\mu});\boldsymbol{\mu})(\boldsymbol{w},\boldsymbol{v})}{\|\boldsymbol{w}\|_X \|\boldsymbol{v}\|_X}.$$

It then follows that in the neighborhood of $\boldsymbol{u}(\boldsymbol{\mu})$ the solution to (2.1) is unique. We further assume that ℓ and f are in X'—bounded linear functionals.

2.2. Natural norms. Let $\boldsymbol{u}_N(\boldsymbol{\mu})$ be the reduced basis approximation to $\boldsymbol{u}(\boldsymbol{\mu})$ given by (1.3). We next introduce [35, 17, 7, 14, 32] the parametrized linear operator $T_N^{\boldsymbol{\mu}}\colon X \to X$ such that

$$(T_N^{\boldsymbol{\mu}}\boldsymbol{w},\boldsymbol{v})_X = da(\boldsymbol{u}_N(\boldsymbol{\mu});\boldsymbol{\mu})(\boldsymbol{w},\boldsymbol{v}) \quad \forall\, \boldsymbol{v},\boldsymbol{w} \in X. \tag{2.4}$$

Our method—in particular our inf-sup lower bound construction—requires a discrete set of K parameter values $\mathcal{V}^K \equiv \{\overline{\boldsymbol{\mu}}_1,\dots,\overline{\boldsymbol{\mu}}_K\} \subset \mathcal{D}$—upon which to construct local norms—a fixed integer $\overline{N} \le N_{\max}$,[3] and an indicator function $\mathcal{I}^K\colon\ \mathcal{D} \to \mathcal{V}^K$ which associates to any $\boldsymbol{\mu}$ in $\mathcal{D}$ a member of $\mathcal{V}^K$.[4] Typically, $\mathcal{I}^K$ defines the "closest"—in a sense that we have to define—element of $\mathcal{D}$.

We assume that, $\forall \overline{\boldsymbol{\mu}} \in \mathcal{V}^K$,

$$0 < \beta_{\overline{N}}(\overline{\boldsymbol{\mu}}) \equiv \inf_{\boldsymbol{w}\in X} \sup_{\boldsymbol{v}\in X} \frac{da(\boldsymbol{u}_{\overline{N}}(\overline{\boldsymbol{\mu}});\overline{\boldsymbol{\mu}})(\boldsymbol{w},\boldsymbol{v})}{\|\boldsymbol{w}\|_X \|\boldsymbol{v}\|_X} \equiv \inf_{\boldsymbol{w}\in X} \frac{\|T_{\overline{N}}^{\overline{\boldsymbol{\mu}}}\boldsymbol{w}\|_X}{\|\boldsymbol{w}\|_X}, \tag{2.5}$$

$$\infty > \gamma_{\overline{N}}(\overline{\boldsymbol{\mu}}) \equiv \sup_{\boldsymbol{w}\in X} \sup_{\boldsymbol{v}\in X} \frac{da(\boldsymbol{u}_{\overline{N}}(\overline{\boldsymbol{\mu}});\overline{\boldsymbol{\mu}})(\boldsymbol{w},\boldsymbol{v})}{\|\boldsymbol{w}\|_X \|\boldsymbol{v}\|_X} \equiv \sup_{\boldsymbol{w}\in X} \frac{\|T_{\overline{N}}^{\overline{\boldsymbol{\mu}}}\boldsymbol{w}\|_X}{\|\boldsymbol{w}\|_X}. \tag{2.6}$$

Note that this is true if $\boldsymbol{u}_{\overline{N}}(\overline{\boldsymbol{\mu}})$ is close enough to $\boldsymbol{u}(\overline{\boldsymbol{\mu}})$ (even though this is not required here); from the Cauchy–Schwarz inequality, $\boldsymbol{v} = T_{\overline{N}}^{\overline{\boldsymbol{\mu}}}\boldsymbol{w}$ is the inner supremizer in (2.5) and (2.6).

We then introduce, for any given $\overline{\boldsymbol{\mu}} \in \mathcal{V}^K$ and $\overline{N}$, our "natural norm"

$$|||\boldsymbol{v}|||_{\overline{\boldsymbol{\mu}}} \equiv \|T_{\overline{N}}^{\overline{\boldsymbol{\mu}}}\boldsymbol{v}\|_X \quad \forall\, \boldsymbol{v} \in X. \tag{2.7}$$

(To simplify the notation we have dropped the index $\overline{N}$ from the norm symbol.) This norm is the extension of the natural norm introduced in [32] for the linear case. Note that, thanks to our assumptions on $\beta_{\overline{N}}(\overline{\boldsymbol{\mu}})$ and $\gamma_{\overline{N}}(\overline{\boldsymbol{\mu}})$, (2.7) does indeed define a norm, which is equivalent to $\|\cdot\|_X$.

2.3. Trilinear forms continuity constants. In the development of our error bound, we assume that there exists a positive $\rho_{\overline{\boldsymbol{\mu}}}(\boldsymbol{\mu})$ such that

$$\left|da(\boldsymbol{z}^2;\boldsymbol{\mu})(\boldsymbol{v},\boldsymbol{w}) - da(\boldsymbol{z}^1;\boldsymbol{\mu})(\boldsymbol{v},\boldsymbol{w})\right| \le \rho_{\overline{\boldsymbol{\mu}}}(\boldsymbol{\mu})\, |||\boldsymbol{z}^2 - \boldsymbol{z}^1|||_{\overline{\boldsymbol{\mu}}}\, |||\boldsymbol{v}|||_{\overline{\boldsymbol{\mu}}}\, \|\boldsymbol{w}\|_X \tag{2.8}$$

for all $\boldsymbol{z}^1$, $\boldsymbol{z}^2$, $\boldsymbol{v}$, and $\boldsymbol{w}$ in X.

[3] In practice, $\overline{N}$ may depend on $\overline{\boldsymbol{\mu}}$, and the results of this work still hold.

[4] The process by which we select "good" $\mathcal{V}^K$ and $\mathcal{I}^K$ is described in section 5.

Similarly, in the construction of an inf-sup lower bound, we assume that there exists a positive $\rho_{X,\overline{\boldsymbol{\mu}}}$ such that

$$\left|\sum_{q=1}^{Q_1}\Theta_1^q(\overline{\boldsymbol{\mu}})a_1^q(\boldsymbol{v},\boldsymbol{z},\boldsymbol{w})\right| \le \rho_{X,\overline{\boldsymbol{\mu}}}\,\|\boldsymbol{z}\|_X\,|||\boldsymbol{v}|||_{\overline{\boldsymbol{\mu}}}\,\|\boldsymbol{w}\|_X, \tag{2.9}$$

$$\left|\sum_{q=1}^{Q_1}\left(\Theta_1^q(\boldsymbol{\mu})-\Theta_1^q(\overline{\boldsymbol{\mu}})\right)a_1^q(\boldsymbol{v},\boldsymbol{z},\boldsymbol{w})\right| \le \max_{q=1,\dots,Q_1}\frac{|\Theta_1^q(\boldsymbol{\mu})-\Theta_1^q(\overline{\boldsymbol{\mu}})|}{|\Theta_1^q(\overline{\boldsymbol{\mu}})|}\rho_{X,\overline{\boldsymbol{\mu}}}\,\|\boldsymbol{z}\|_X\,|||\boldsymbol{v}|||_{\overline{\boldsymbol{\mu}}}\,\|\boldsymbol{w}\|_X \tag{2.10}$$

for all $\boldsymbol{z}$, $\boldsymbol{v}$, and $\boldsymbol{w}$ in X.

To a given problem, we have to provide these constants; in sections 6.3 and 6.5 we show how to compute these constants, which are related to the Sobolev embedding theorem, for the model problem at hand. The algorithm proposed in section 6.5 can be easily extended to other examples.

3. Existence and uniqueness. Let $\boldsymbol{\mu}\in\mathcal{D}$, $\overline{\boldsymbol{\mu}}\in\mathcal{V}^K$, $N\le N_{\max}$, and $\overline{N}\le N_{\max}$; we define (implicitly dropping the subscripts $_{\overline{N}}$ and $_N$)

$$\beta_{\overline{\boldsymbol{\mu}}}(\boldsymbol{\mu}) \equiv \inf_{\boldsymbol{w}\in X}\sup_{\boldsymbol{v}\in X}\frac{(T_N^{\boldsymbol{\mu}}\boldsymbol{w},\boldsymbol{v})_X}{|||\boldsymbol{w}|||_{\overline{\boldsymbol{\mu}}}||\boldsymbol{v}||_X} = \inf_{\boldsymbol{w}\in X}\frac{\|T_N^{\boldsymbol{\mu}}\boldsymbol{w}\|_X}{|||\boldsymbol{w}|||_{\overline{\boldsymbol{\mu}}}} = \inf_{\boldsymbol{w}\in X}\frac{\|T_N^{\boldsymbol{\mu}}\boldsymbol{w}\|_X}{\|T_{\overline{N}}^{\overline{\boldsymbol{\mu}}}\boldsymbol{w}\|_X}, \tag{3.1}$$

$$\gamma_{\overline{\boldsymbol{\mu}}}(\boldsymbol{\mu}) \equiv \sup_{\boldsymbol{w}\in X}\sup_{\boldsymbol{v}\in X}\frac{(T_N^{\boldsymbol{\mu}}\boldsymbol{w},\boldsymbol{v})_X}{|||\boldsymbol{w}|||_{\overline{\boldsymbol{\mu}}}||\boldsymbol{v}||_X} = \sup_{\boldsymbol{w}\in X}\frac{\|T_N^{\boldsymbol{\mu}}\boldsymbol{w}\|_X}{|||\boldsymbol{w}|||_{\overline{\boldsymbol{\mu}}}} = \sup_{\boldsymbol{w}\in X}\frac{\|T_N^{\boldsymbol{\mu}}\boldsymbol{w}\|_X}{\|T_{\overline{N}}^{\overline{\boldsymbol{\mu}}}\boldsymbol{w}\|_X}. \tag{3.2}$$

We assume that $\beta_{\overline{\boldsymbol{\mu}}}(\boldsymbol{\mu})>0$ (this is the case when $\beta(\boldsymbol{\mu})>0$ (cf. (2.3)) and $\boldsymbol{u}_N(\boldsymbol{\mu})$ is "nearby" to $\boldsymbol{u}(\boldsymbol{\mu})$) and also that we explicitly know either $\beta_{\overline{\boldsymbol{\mu}}}(\boldsymbol{\mu})$ or a rigorous positive lower bound to it. The results in this section extend straightforwardly in the latter case by replacing $\beta_{\overline{\boldsymbol{\mu}}}(\boldsymbol{\mu})$ by its lower bound.

3.1. Uniqueness. We are now ready to prove a uniqueness result in the neighborhood—with respect to the natural norms—of a given reduced basis approximation. Let $B_{\overline{\boldsymbol{\mu}}}(\boldsymbol{u},\epsilon)$ be an open ball around $\boldsymbol{u}\in X$, of radius $\epsilon>0$, and metric induced by $|||\cdot|||_{\overline{\boldsymbol{\mu}}}$.

LEMMA 3.1. *Assume that $\beta_{\overline{\boldsymbol{\mu}}}(\boldsymbol{\mu})>0$. There can be at most one solution $\boldsymbol{u}(\boldsymbol{\mu})$ to* (2.1) *such that*

$$\boldsymbol{u}(\boldsymbol{\mu})\in B_{\overline{\boldsymbol{\mu}}}\left(\boldsymbol{u}_N(\boldsymbol{\mu}),\frac{\beta_{\overline{\boldsymbol{\mu}}}(\boldsymbol{\mu})}{\rho_{\overline{\boldsymbol{\mu}}}(\boldsymbol{\mu})}\right).$$

Proof. The proofs of this lemma and the following one are based on the original proofs in [4] and are extended to the case of two distinct norms. For these proofs we need to introduce the operators $A(\cdot;\boldsymbol{\mu}):X\mapsto X'$ and $DA(\boldsymbol{z},\boldsymbol{\mu}):X\mapsto X'$, for $\boldsymbol{z}$ in X, associated to a (and f) and da, and the operator $H(\cdot;\boldsymbol{\mu}):X\to X$,

$$\langle A(\boldsymbol{u};\boldsymbol{\mu}),\boldsymbol{v}\rangle = a(\boldsymbol{u},\boldsymbol{v};\boldsymbol{\mu})-f(\boldsymbol{v}) \quad \forall \boldsymbol{u},\boldsymbol{v}\in X,$$

$$\langle DA(\boldsymbol{z},\boldsymbol{\mu})\boldsymbol{u},\boldsymbol{v}\rangle = da(\boldsymbol{z};\boldsymbol{\mu})(\boldsymbol{u},\boldsymbol{v}) \quad \forall \boldsymbol{u},\boldsymbol{v}\in X, \tag{3.3}$$

$$H(\boldsymbol{w};\boldsymbol{\mu}) = \boldsymbol{w}-DA(\boldsymbol{u}_N(\boldsymbol{\mu});\boldsymbol{\mu})^{-1}A(\boldsymbol{w};\boldsymbol{\mu}). \tag{3.4}$$

$DA(\boldsymbol{u}_N(\boldsymbol{\mu});\boldsymbol{\mu})$ is invertible thanks to our assumption that $\beta_{\overline{\boldsymbol{\mu}}}(\boldsymbol{\mu})>0$. A fixed point of H must be a solution to (2.1) and vice versa; we are going to show that there exists at most one.

We consider $H(\boldsymbol{z}^2,\boldsymbol{\mu})-H(\boldsymbol{z}^1,\boldsymbol{\mu})$, which from the definition (3.4) can be expressed as

$$H(\boldsymbol{z}^2,\boldsymbol{\mu})-H(\boldsymbol{z}^1,\boldsymbol{\mu})=(\boldsymbol{z}^2-\boldsymbol{z}^1)-DA(\boldsymbol{u}_N(\boldsymbol{\mu});\boldsymbol{\mu})^{-1}\left(A(\boldsymbol{z}^2;\boldsymbol{\mu})-A(\boldsymbol{z}^1;\boldsymbol{\mu})\right). \tag{3.5}$$

We observe that, since our nonlinearity is quadratic,

$$A(\boldsymbol{z}^2;\boldsymbol{\mu})-A(\boldsymbol{z}^1;\boldsymbol{\mu})=DA\left(\frac{\boldsymbol{z}^1+\boldsymbol{z}^2}{2};\boldsymbol{\mu}\right)(\boldsymbol{z}^2-\boldsymbol{z}^1). \tag{3.6}$$

Applying (3.5) and (3.6) gives

$$\begin{aligned}&DA(\boldsymbol{u}_N(\boldsymbol{\mu});\boldsymbol{\mu})\left(H(\boldsymbol{z}^2;\boldsymbol{\mu})-H(\boldsymbol{z}^1;\boldsymbol{\mu})\right)\\&\quad=DA(\boldsymbol{u}_N(\boldsymbol{\mu});\boldsymbol{\mu})\left(\boldsymbol{z}^2-\boldsymbol{z}^1\right)-\left(A(\boldsymbol{z}^2;\boldsymbol{\mu})-A(\boldsymbol{z}^1;\boldsymbol{\mu})\right)\\&\quad=\left[DA(\boldsymbol{u}_N(\boldsymbol{\mu});\boldsymbol{\mu})-DA\left(\frac{\boldsymbol{z}^1+\boldsymbol{z}^2}{2};\boldsymbol{\mu}\right)\right](\boldsymbol{z}^2-\boldsymbol{z}^1).\end{aligned}$$

We then have, by recalling (2.8),

$$\begin{aligned}&\left\langle DA(\boldsymbol{u}_N(\boldsymbol{\mu});\boldsymbol{\mu})(H(\boldsymbol{z}^2;\boldsymbol{\mu})-H(\boldsymbol{z}^1;\boldsymbol{\mu})),\boldsymbol{v}\right\rangle\\&\quad\le\rho_{\overline{\boldsymbol{\mu}}}(\boldsymbol{\mu})\left|\!\left|\!\left|\boldsymbol{u}_N(\boldsymbol{\mu})-\frac{1}{2}(\boldsymbol{z}^2+\boldsymbol{z}^1)\right|\!\right|\!\right|_{\overline{\boldsymbol{\mu}}}|||\boldsymbol{z}^2-\boldsymbol{z}^1|||_{\overline{\boldsymbol{\mu}}}\|\boldsymbol{v}\|_X.\end{aligned}$$

Furthermore, from the definition of $\beta_{\overline{\boldsymbol{\mu}}}(\boldsymbol{\mu})$, $T_N^{\boldsymbol{\mu}}$, and $DA(\boldsymbol{u}_N(\boldsymbol{\mu});\boldsymbol{\mu})$, ((3.1), (2.4), and (3.3), respectively), we have

$$\begin{aligned}&\beta_{\overline{\boldsymbol{\mu}}}(\boldsymbol{\mu})|||H(\boldsymbol{z}^2;\boldsymbol{\mu})-H(\boldsymbol{z}^1;\boldsymbol{\mu})|||_{\overline{\boldsymbol{\mu}}}\|T_N^{\boldsymbol{\mu}}(H(\boldsymbol{z}^2;\boldsymbol{\mu})-H(\boldsymbol{z}^1;\boldsymbol{\mu}))\|_X\\&\quad\le\left\langle DA(\boldsymbol{u}_N(\boldsymbol{\mu});\boldsymbol{\mu})(H(\boldsymbol{z}^2;\boldsymbol{\mu})-H(\boldsymbol{z}^1;\boldsymbol{\mu})),T_N^{\boldsymbol{\mu}}(H(\boldsymbol{z}^2;\boldsymbol{\mu})-H(\boldsymbol{z}^1;\boldsymbol{\mu}))\right\rangle.\end{aligned} \tag{3.7}$$

Let $\alpha>0$; if $\boldsymbol{z}^1$ and $\boldsymbol{z}^2$ are in $B_{\overline{\boldsymbol{\mu}}}(\boldsymbol{u}_N(\boldsymbol{\mu}),\alpha)$, then $|||\boldsymbol{u}_N(\boldsymbol{\mu})-\frac{1}{2}(\boldsymbol{z}^2+\boldsymbol{z}^1)|||_{\overline{\boldsymbol{\mu}}}<\alpha$, and the last two inequalities give

$$|||H(\boldsymbol{z}^2;\boldsymbol{\mu})-H(\boldsymbol{z}^1;\boldsymbol{\mu})|||_{\overline{\boldsymbol{\mu}}}<\frac{\rho_{\overline{\boldsymbol{\mu}}}(\boldsymbol{\mu})\alpha}{\beta_{\overline{\boldsymbol{\mu}}}(\boldsymbol{\mu})}|||\boldsymbol{z}^2-\boldsymbol{z}^1|||_{\overline{\boldsymbol{\mu}}},$$

which implies that $H(\cdot;\boldsymbol{\mu})$ is a contraction mapping for

$$\alpha<\frac{\beta_{\overline{\boldsymbol{\mu}}}(\boldsymbol{\mu})}{\rho_{\overline{\boldsymbol{\mu}}}(\boldsymbol{\mu})}.$$

It follows that there can be only (at most) one fixed point of $H(\cdot;\mu)$ inside $B_{\overline{\boldsymbol{\mu}}}(\boldsymbol{u}_N(\boldsymbol{\mu}),\frac{\beta_{\overline{\boldsymbol{\mu}}}(\boldsymbol{\mu})}{\rho_{\overline{\boldsymbol{\mu}}}(\boldsymbol{\mu})})$ and hence at most one solution $\boldsymbol{u}(\boldsymbol{\mu})$. ∎

3.2. Existence. We define the following quantities:

$$\epsilon_N(\boldsymbol{\mu})\equiv\|A(\boldsymbol{u}_N(\boldsymbol{\mu});\boldsymbol{\mu})\|_{X'}, \tag{3.8}$$

$$\tau_{N,\overline{\boldsymbol{\mu}}}(\boldsymbol{\mu})\equiv\frac{2\rho_{\overline{\boldsymbol{\mu}}}(\boldsymbol{\mu})\epsilon_N(\boldsymbol{\mu})}{\beta_{\overline{\boldsymbol{\mu}}}(\boldsymbol{\mu})^2}, \tag{3.9}$$

$$\Delta_{N,\overline{\boldsymbol{\mu}}}(\boldsymbol{\mu})\equiv\frac{\beta_{\overline{\boldsymbol{\mu}}}(\boldsymbol{\mu})}{\rho_{\overline{\boldsymbol{\mu}}}(\boldsymbol{\mu})}\left[1-\sqrt{1-\tau_{N,\overline{\boldsymbol{\mu}}}(\boldsymbol{\mu})}\right]. \tag{3.10}$$

LEMMA 3.2. *If $\beta_{\overline{\boldsymbol{\mu}}}(\boldsymbol{\mu}) > 0$ and $\tau_{N,\overline{\boldsymbol{\mu}}}(\boldsymbol{\mu}) \le 1$, there exists a unique solution $\boldsymbol{u}(\boldsymbol{\mu})$ to (2.1) such that*

$$\boldsymbol{u}(\boldsymbol{\mu}) \in B_{\overline{\boldsymbol{\mu}}}\Big(\boldsymbol{u}_N(\boldsymbol{\mu}), \Delta_{N,\overline{\boldsymbol{\mu}}}(\boldsymbol{\mu})\Big).$$

Proof. Let $\alpha > 0$ and $\boldsymbol{z}$ in $B_{\overline{\boldsymbol{\mu}}}(\boldsymbol{u}_N(\boldsymbol{\mu}), \alpha)$; consider

$$\begin{aligned} H(\boldsymbol{z};\boldsymbol{\mu}) - \boldsymbol{u}_N(\boldsymbol{\mu}) &= \boldsymbol{z} - \boldsymbol{u}_N(\boldsymbol{\mu}) \\ &- DA(\boldsymbol{u}_N(\boldsymbol{\mu});\boldsymbol{\mu})^{-1}\left(A(\boldsymbol{z};\boldsymbol{\mu}) - A(\boldsymbol{u}_N(\boldsymbol{\mu});\boldsymbol{\mu})\right) - DA(\boldsymbol{u}_N(\boldsymbol{\mu});\boldsymbol{\mu})^{-1}A(\boldsymbol{u}_N(\boldsymbol{\mu});\boldsymbol{\mu}). \end{aligned}$$

By using arguments similar to those invoked in the previous lemma (among others, that $\boldsymbol{u}(\boldsymbol{\mu})$ is a fixed point of $H(\cdot;\boldsymbol{\mu})$), we have

$$\begin{aligned} &\langle DA(\boldsymbol{u}_N(\boldsymbol{\mu});\boldsymbol{\mu})(H(\boldsymbol{z};\boldsymbol{\mu}) - \boldsymbol{u}_N(\boldsymbol{\mu})), \boldsymbol{v}\rangle \\ &= \langle DA(\boldsymbol{u}_N(\boldsymbol{\mu});\boldsymbol{\mu})(\boldsymbol{z} - \boldsymbol{u}_N(\boldsymbol{\mu})), \boldsymbol{v}\rangle - \langle A(\boldsymbol{z};\boldsymbol{\mu}) - A(\boldsymbol{u}_N(\boldsymbol{\mu});\boldsymbol{\mu}), \boldsymbol{v}\rangle - \langle A(\boldsymbol{u}_N(\boldsymbol{\mu});\boldsymbol{\mu}), \boldsymbol{v}\rangle \\ &= \left\langle \left[DA(\boldsymbol{u}_N(\boldsymbol{\mu});\boldsymbol{\mu}) - DA\left(\frac{\boldsymbol{z} + \boldsymbol{u}_N(\boldsymbol{\mu})}{2};\boldsymbol{\mu}\right)\right](\boldsymbol{z} - \boldsymbol{u}_N(\boldsymbol{\mu})), \boldsymbol{v}\right\rangle - \langle A(\boldsymbol{u}_N(\boldsymbol{\mu});\boldsymbol{\mu}), \boldsymbol{v}\rangle \\ &\le \frac{1}{2}\rho_{\overline{\boldsymbol{\mu}}}(\boldsymbol{\mu})|||\boldsymbol{z} - \boldsymbol{u}_N(\boldsymbol{\mu})|||^2_{\overline{\boldsymbol{\mu}}}\,\|\boldsymbol{v}\|_X + \epsilon_{N,\overline{\boldsymbol{\mu}}}(\boldsymbol{\mu})\|\boldsymbol{v}\|_X \end{aligned} \tag{3.11}$$

for all $\boldsymbol{v}$ in X. Similarly to (3.7),

$$\begin{aligned} \beta_{\overline{\boldsymbol{\mu}}}(\boldsymbol{\mu})|||H(\boldsymbol{z};\boldsymbol{\mu}) - \boldsymbol{u}_N(\boldsymbol{\mu})|||_{\overline{\boldsymbol{\mu}}}\|T_N^{\boldsymbol{\mu}}(H(\boldsymbol{z};\boldsymbol{\mu}) - \boldsymbol{u}_N(\boldsymbol{\mu}))\|_X \\ \le \langle DA(\boldsymbol{u}_N(\boldsymbol{\mu});\boldsymbol{\mu})(H(\boldsymbol{z};\boldsymbol{\mu}) - \boldsymbol{u}_N(\boldsymbol{\mu})), T_N^{\boldsymbol{\mu}}(H(\boldsymbol{z};\boldsymbol{\mu}) - \boldsymbol{u}_N(\boldsymbol{\mu}))\rangle\,. \end{aligned} \tag{3.12}$$

Since $\boldsymbol{z}$ is in the open ball $B_{\overline{\boldsymbol{\mu}}}(\boldsymbol{u}_N(\boldsymbol{\mu}), \alpha)$, choosing $\boldsymbol{v} = T_N^{\boldsymbol{\mu}}(H(\boldsymbol{z};\boldsymbol{\mu}) - \boldsymbol{u}_N(\boldsymbol{\mu}))$, (3.11), and (3.12) gives

$$|||H(\boldsymbol{z};\boldsymbol{\mu}) - \boldsymbol{u}_N(\boldsymbol{\mu})|||_{\overline{\boldsymbol{\mu}}} \le \frac{\rho_{\overline{\boldsymbol{\mu}}}(\boldsymbol{\mu})}{2\beta_{\overline{\boldsymbol{\mu}}}(\boldsymbol{\mu})}|||\boldsymbol{z} - \boldsymbol{u}_N(\boldsymbol{\mu})|||^2_{\overline{\boldsymbol{\mu}}} + \frac{\epsilon_{N,\overline{\boldsymbol{\mu}}}(\boldsymbol{\mu})}{\beta_{\overline{\boldsymbol{\mu}}}(\boldsymbol{\mu})} < \frac{\rho_{\overline{\boldsymbol{\mu}}}(\boldsymbol{\mu})\alpha^2}{2\beta_{\overline{\boldsymbol{\mu}}}(\boldsymbol{\mu})} + \frac{\epsilon_{N,\overline{\boldsymbol{\mu}}}(\boldsymbol{\mu})}{\beta_{\overline{\boldsymbol{\mu}}}(\boldsymbol{\mu})}. \tag{3.13}$$

We now look for values of α (in particular, the smallest will give us a sharper error bound) such that

$$\frac{\rho_{\overline{\boldsymbol{\mu}}}(\boldsymbol{\mu})\alpha^2}{2\beta_{\overline{\boldsymbol{\mu}}}(\boldsymbol{\mu})} + \frac{\epsilon_{N,\overline{\boldsymbol{\mu}}}(\boldsymbol{\mu})}{\beta_{\overline{\boldsymbol{\mu}}}(\boldsymbol{\mu})} \le \alpha.$$

Provided that $\tau_{N,\overline{\boldsymbol{\mu}}}(\boldsymbol{\mu}) \le 1$, we have that the smallest value is given by $\alpha = \Delta_{N,\overline{\boldsymbol{\mu}}}(\boldsymbol{\mu})$. Then for this choice and from (3.13) we have

$$|||H(\boldsymbol{z};\boldsymbol{\mu}) - \boldsymbol{u}_N(\boldsymbol{\mu})|||_{\overline{\boldsymbol{\mu}}} < \alpha;$$

i.e., H maps $\in B_{\overline{\boldsymbol{\mu}}}(\boldsymbol{u}_N(\boldsymbol{\mu}), \Delta_{N,\overline{\boldsymbol{\mu}}}(\boldsymbol{\mu}))$ into itself. The proof follows from $\Delta_{N,\overline{\boldsymbol{\mu}}}(\boldsymbol{\mu}) \le \frac{\beta_{\overline{\boldsymbol{\mu}}}(\boldsymbol{\mu})}{\rho_{\overline{\boldsymbol{\mu}}}(\boldsymbol{\mu})}$, the fact that H is a contraction (cf. the proof of the previous lemma), and the contraction mapping theorem. ∎

3.3. A posteriori error estimation.

THEOREM 3.3. *Let $\boldsymbol{\mu} \in \mathcal{D}$, and assume that, for a $\overline{\boldsymbol{\mu}} \in \mathcal{V}^K$, $\beta_{\overline{\boldsymbol{\mu}}}(\boldsymbol{\mu}) > 0$ and $\tau_{\overline{\boldsymbol{\mu}}}(\boldsymbol{\mu}) \le 1$. Then there exists a unique solution $\boldsymbol{u}(\boldsymbol{\mu})$ such that*

$$|||\boldsymbol{u}(\boldsymbol{\mu}) - \boldsymbol{u}_N(\boldsymbol{\mu})|||_{\overline{\boldsymbol{\mu}}} < \frac{\beta_{\overline{\boldsymbol{\mu}}}(\boldsymbol{\mu})}{\rho_{\overline{\boldsymbol{\mu}}}(\boldsymbol{\mu})};$$

the error with respect to the natural norm is

$$|||\boldsymbol{u}(\boldsymbol{\mu}) - \boldsymbol{u}_N(\boldsymbol{\mu})|||_{\overline{\boldsymbol{\mu}}} \leq \Delta_{N,\overline{\boldsymbol{\mu}}}(\boldsymbol{\mu}) \tag{3.14}$$

with effectivity

$$\Delta_{N,\overline{\boldsymbol{\mu}}}(\boldsymbol{\mu}) \leq \left[\frac{2\gamma_{\overline{\boldsymbol{\mu}}}(\boldsymbol{\mu})}{\beta_{\overline{\boldsymbol{\mu}}}(\boldsymbol{\mu})} + \tau_{\overline{\boldsymbol{\mu}}}(\boldsymbol{\mu})\right] |||\boldsymbol{u}(\boldsymbol{\mu}) - \boldsymbol{u}_N(\boldsymbol{\mu})|||_{\overline{\boldsymbol{\mu}}}. \tag{3.15}$$

This theorem provides an error bound with respect to the natural norms that, compared to previous results (cf. [17, 33]), first provides better effectivity in the field variable, since we expect $\gamma_{\overline{\boldsymbol{\mu}}}(\boldsymbol{\mu})$ and $\beta_{\overline{\boldsymbol{\mu}}}(\boldsymbol{\mu})$ to be of order one and second indirectly sharpens the existence's condition since in (3.9) again $\beta_{\overline{\boldsymbol{\mu}}}(\boldsymbol{\mu})$ is of order one.

Note that we expect that $\gamma_{\overline{\boldsymbol{\mu}}}(\boldsymbol{\mu})$ and $\beta_{\overline{\boldsymbol{\mu}}}(\boldsymbol{\mu})$ are of order one, since $\overline{\boldsymbol{\mu}} = \mathcal{I}^K(\boldsymbol{\mu})$ is "close" to $\boldsymbol{\mu}$ and hence $T_N^{\boldsymbol{\mu}}$ and $T_N^{\overline{\boldsymbol{\mu}}}$ have similar spectra. In (3.9) the term that is the worse controlled is $\rho_{\overline{\boldsymbol{\mu}}}(\boldsymbol{\mu})$; this is related to a Sobolev embedding constant (cf. [33] and section 6). However, the equivalent condition in [33] reads

$$\tau_N(\boldsymbol{\mu}) = \frac{2\rho\,\epsilon_N(\boldsymbol{\mu})}{\beta_N(\boldsymbol{\mu})^2},$$

where ρ and $\beta_N(\boldsymbol{\mu})$ are the Sobolev embedding constants and equivalent to (2.8) and (3.1), respectively, with respect to the X-norm only. Since $\beta_{\overline{\boldsymbol{\mu}}}(\boldsymbol{\mu}) \geq \frac{\beta_N(\boldsymbol{\mu})}{\gamma(\overline{\boldsymbol{\mu}})}$ and $\rho_{\overline{\boldsymbol{\mu}}}(\boldsymbol{\mu}) \leq \frac{\rho}{\beta(\overline{\boldsymbol{\mu}})^2}$, we have

$$\tau_{N,\overline{\boldsymbol{\mu}}}(\boldsymbol{\mu}) \leq \tau_N(\boldsymbol{\mu}) \frac{\gamma(\overline{\boldsymbol{\mu}})^2}{\beta(\overline{\boldsymbol{\mu}})^2};$$

i.e., if $\gamma_{\overline{\boldsymbol{\mu}}}(\boldsymbol{\mu})$ and $\beta_{\overline{\boldsymbol{\mu}}}(\boldsymbol{\mu})$ are of order one, the condition $\tau_{N,\overline{\boldsymbol{\mu}}}(\boldsymbol{\mu}) \leq 1$ is less stringent than $\tau_N(\boldsymbol{\mu}) < 1$, which is required in [33].

In our simulations, for a large Grashof number, we actually get that $\rho_{\overline{\boldsymbol{\mu}}}(\boldsymbol{\mu})$ is one order smaller than $\frac{\rho}{\beta_N(\boldsymbol{\mu})^2}$, and hence $\tau_{N,\overline{\boldsymbol{\mu}}}(\boldsymbol{\mu})$ is also one order smaller than $\tau_N(\boldsymbol{\mu})$.

Proof. We just need to prove (3.15). Let $\boldsymbol{e}(\boldsymbol{\mu}) = \boldsymbol{u}(\boldsymbol{\mu}) - \boldsymbol{u}_N(\boldsymbol{\mu})$ and $\hat{\boldsymbol{e}}(\boldsymbol{\mu})$ such that

$$\begin{aligned}(\hat{\boldsymbol{e}}(\boldsymbol{\mu}), \boldsymbol{v})_X &= -\langle A(\boldsymbol{u}_N(\boldsymbol{\mu}); \boldsymbol{\mu}), \boldsymbol{v}\rangle \\ &= f(\boldsymbol{v}) - a(\boldsymbol{u}_N(\boldsymbol{\mu}), \boldsymbol{v}; \boldsymbol{\mu}) = a(\boldsymbol{u}(\boldsymbol{\mu}), \boldsymbol{v}; \boldsymbol{\mu}) - a(\boldsymbol{u}_N(\boldsymbol{\mu}), \boldsymbol{v}; \boldsymbol{\mu}).\end{aligned} \tag{3.16}$$

Note that, from (3.8), $\|\hat{\boldsymbol{e}}(\boldsymbol{\mu})\|_X = \epsilon_{N,\overline{\boldsymbol{\mu}}}(\boldsymbol{\mu})$ and that, since our nonlinearity is quadratic,

$$\begin{aligned}&a(\boldsymbol{u}(\boldsymbol{\mu}), \boldsymbol{v}; \boldsymbol{\mu}) - a(\boldsymbol{u}_N(\boldsymbol{\mu}), \boldsymbol{v}; \boldsymbol{\mu}) \\ &\qquad = da(\boldsymbol{u}_N(\boldsymbol{\mu}); \boldsymbol{\mu})(\boldsymbol{e}(\boldsymbol{\mu}), \boldsymbol{v}) + \frac{1}{2}\Big(da(\boldsymbol{u}(\boldsymbol{\mu}); \boldsymbol{\mu}) - da(\boldsymbol{u}_N(\boldsymbol{\mu}); \boldsymbol{\mu})\Big)(\boldsymbol{e}(\boldsymbol{\mu}), \boldsymbol{v})\end{aligned}$$

for all $\boldsymbol{v}$ in X. This, (3.16), (3.2), and (2.8) yield to

$$\begin{aligned}\|\hat{\boldsymbol{e}}(\boldsymbol{\mu})\|_X^2 &= da(\boldsymbol{u}_N(\boldsymbol{\mu}); \boldsymbol{\mu})(\boldsymbol{e}(\boldsymbol{\mu}), \hat{\boldsymbol{e}}(\boldsymbol{\mu})) + \frac{1}{2}\Big(da(\boldsymbol{u}(\boldsymbol{\mu}); \boldsymbol{\mu}) - da(\boldsymbol{u}_N(\boldsymbol{\mu}); \boldsymbol{\mu})\Big)(\boldsymbol{e}(\boldsymbol{\mu}), \hat{\boldsymbol{e}}(\boldsymbol{\mu})) \\ &\leq \gamma_{\overline{\boldsymbol{\mu}}}(\boldsymbol{\mu}) |||\boldsymbol{e}(\boldsymbol{\mu})|||_{\overline{\boldsymbol{\mu}}} \|\hat{\boldsymbol{e}}(\boldsymbol{\mu})\|_X + \frac{1}{2}\rho_{\overline{\boldsymbol{\mu}}}(\boldsymbol{\mu})\, |||\boldsymbol{e}(\boldsymbol{\mu})|||_{\overline{\boldsymbol{\mu}}}^2 \|\hat{\boldsymbol{e}}(\boldsymbol{\mu})\|_X\end{aligned}$$

and therefore

$$\epsilon_{N,\overline{\boldsymbol{\mu}}}(\boldsymbol{\mu}) \le \gamma_{\overline{\boldsymbol{\mu}}}(\boldsymbol{\mu})|||\boldsymbol{e}(\boldsymbol{\mu})|||_{\overline{\boldsymbol{\mu}}} + \frac{1}{2}\rho_{\overline{\boldsymbol{\mu}}}(\boldsymbol{\mu})|||\boldsymbol{e}(\boldsymbol{\mu})|||^2_{\overline{\boldsymbol{\mu}}}. \tag{3.17}$$

Since $0 \le \tau_{N,\overline{\boldsymbol{\mu}}}(\boldsymbol{\mu}) \le 1$ and $1 - \sqrt{1 - \tau_{N,\overline{\boldsymbol{\mu}}}(\boldsymbol{\mu})} \le \tau_{N,\overline{\boldsymbol{\mu}}}(\boldsymbol{\mu})$, from (3.9)–(3.10) we get

$$\Delta_{N,\overline{\boldsymbol{\mu}}}(\boldsymbol{\mu}) \le 2\frac{\epsilon_{N,\overline{\boldsymbol{\mu}}}(\boldsymbol{\mu})}{\beta_{\overline{\boldsymbol{\mu}}}(\boldsymbol{\mu})} \quad \text{and} \tag{3.18}$$

$$\frac{\rho_{\overline{\boldsymbol{\mu}}}(\boldsymbol{\mu})}{\beta_{\overline{\boldsymbol{\mu}}}(\boldsymbol{\mu})}\Delta_{N,\overline{\boldsymbol{\mu}}}(\boldsymbol{\mu}) \le \tau_{N,\overline{\boldsymbol{\mu}}}(\boldsymbol{\mu}). \tag{3.19}$$

Then, from (3.17) and (3.18)

$$\Delta_{N,\overline{\boldsymbol{\mu}}}(\boldsymbol{\mu}) \le \frac{2\gamma_{\overline{\boldsymbol{\mu}}}(\boldsymbol{\mu})}{\beta_{\overline{\boldsymbol{\mu}}}(\boldsymbol{\mu})}|||\boldsymbol{e}(\boldsymbol{\mu})|||_{\overline{\boldsymbol{\mu}}} + \frac{\rho_{\overline{\boldsymbol{\mu}}}(\boldsymbol{\mu})}{\beta_{\overline{\boldsymbol{\mu}}}(\boldsymbol{\mu})}|||\boldsymbol{e}(\boldsymbol{\mu})|||^2_{\overline{\boldsymbol{\mu}}};$$

we split the square of $|||\boldsymbol{e}(\boldsymbol{\mu})|||_{\overline{\boldsymbol{\mu}}}$ and get

$$\begin{aligned}\Delta_{N,\overline{\boldsymbol{\mu}}}(\boldsymbol{\mu}) &\le \frac{2\gamma_{\overline{\boldsymbol{\mu}}}(\boldsymbol{\mu})}{\beta_{\overline{\boldsymbol{\mu}}}(\boldsymbol{\mu})}|||\boldsymbol{e}(\boldsymbol{\mu})|||_{\overline{\boldsymbol{\mu}}} + \frac{\rho_{\overline{\boldsymbol{\mu}}}(\boldsymbol{\mu})}{\beta_{\overline{\boldsymbol{\mu}}}(\boldsymbol{\mu})}|||e(\boldsymbol{\mu})|||_{\overline{\boldsymbol{\mu}}}\Delta_{N,\overline{\boldsymbol{\mu}}}(\boldsymbol{\mu}) \\ &\le \frac{2\gamma_{\overline{\boldsymbol{\mu}}}(\boldsymbol{\mu})}{\beta_{\overline{\boldsymbol{\mu}}}(\boldsymbol{\mu})}|||\boldsymbol{e}(\boldsymbol{\mu})|||_{\overline{\boldsymbol{\mu}}} + \tau_{N,\overline{\boldsymbol{\mu}}}(\boldsymbol{\mu})|||\boldsymbol{e}(\boldsymbol{\mu})|||_{\overline{\boldsymbol{\mu}}},\end{aligned}$$

thanks to (3.14) in the first inequality and (3.19) in the second one. ∎

3.4. Output error bound. Often the precision required in the prediction of the output is obtained by the primal approximation alone. This is the case in the model problems that we propose; in fact, the requirements to ensure existence and unicity already imply a very small error in the output.

For a given $\boldsymbol{\mu} \in \mathcal{D}$, we are interested in bounding the error on the output $s(\boldsymbol{\mu}) = \ell(\boldsymbol{u}(\boldsymbol{\mu}))$. For $\overline{\boldsymbol{\mu}} \in \mathcal{V}^K$, the *natural* dual norm of the output linear functional is defined as

$$|||\ell|||_{\overline{\boldsymbol{\mu}}'} = \sup_{\boldsymbol{v}\in Y} \frac{|\ell(\boldsymbol{v})|}{|||\boldsymbol{v}|||_{\overline{\boldsymbol{\mu}}}}.$$

(Note that, in the case of an affine output, $|||\ell|||_{\overline{\boldsymbol{\mu}}'} \le \sum_{q=1}^{Q_\ell} |\theta^q_\ell(\boldsymbol{\mu})|\ |||\ell^q|||_{\overline{\boldsymbol{\mu}}'}$.) If $\beta_{\overline{\boldsymbol{\mu}}}(\boldsymbol{\mu}) > 0$ and $\tau_{N,\overline{\boldsymbol{\mu}}}(\boldsymbol{\mu}) \le 1$, we can then state the output error bound as

$$|s(\boldsymbol{\mu}) - s_N(\boldsymbol{\mu})| \le |||\ell|||_{\overline{\boldsymbol{\mu}}'}\Delta_{N,\overline{\boldsymbol{\mu}}}(\boldsymbol{\mu}) \equiv \Delta^s_{N,\overline{\boldsymbol{\mu}}}(\boldsymbol{\mu}).$$

However, we do not have any effectivity result about these bounds. In our example, the effectivities are at high values of the Grashof number reasonable but not as accurate at low values. In the appendix we propose a dual approach that partially addresses this issue; further improvements shall require deflation (cf. [32]).

4. Lower bound of the inf-sup constant. We are going to build a lower bound for the inf-sup parameter $\beta_{\overline{\boldsymbol{\mu}}}(\boldsymbol{\mu})$. The ingredients, similarly to [32], are the selection of a candidate supremizer, a Taylor expansion with the remainder, and a lower bound for the terms in the Taylor expansion.

It is clear that, for $\boldsymbol{\mu} = \overline{\boldsymbol{\mu}}$ in (3.1) and (3.2), $\beta_{\overline{\boldsymbol{\mu}}}(\overline{\boldsymbol{\mu}}) = \gamma_{\overline{\boldsymbol{\mu}}}(\overline{\boldsymbol{\mu}}) = 1$; the natural norm can thus be viewed as a generalization of the usual energy norm (for symmetric, coercive operators) to the nonlinear case. It can be demonstrated that

$$\beta(\overline{\boldsymbol{\mu}})\beta_{\overline{\boldsymbol{\mu}}}(\boldsymbol{\mu}) \le \beta(\boldsymbol{\mu}) \le \beta_{\overline{\boldsymbol{\mu}}}(\boldsymbol{\mu})\gamma(\overline{\boldsymbol{\mu}}).$$

In what follows we shall require an "intermediate" inf-sup parameter—an approximation to $\beta_{\overline{\boldsymbol{\mu}}}(\boldsymbol{\mu})$—which we denote as $\overline{\beta}_{\overline{\boldsymbol{\mu}}}(\boldsymbol{\mu})$: For given $\boldsymbol{\mu} \in \mathcal{D}$ and $\overline{\boldsymbol{\mu}} \in \mathcal{V}^K$,

$$\overline{\beta}_{\overline{\boldsymbol{\mu}}}(\boldsymbol{\mu}) \equiv \inf_{\boldsymbol{w}\in X} \frac{(T_N^{\boldsymbol{\mu}}\boldsymbol{w}, T_N^{\overline{\boldsymbol{\mu}}}\boldsymbol{w})_X}{|||\boldsymbol{w}|||^2_{\overline{\boldsymbol{\mu}}}}.$$

It follows directly from the Cauchy–Schwarz inequality—or, equivalently, we may observe that $T_N^{\overline{\boldsymbol{\mu}}}\boldsymbol{w}$ is a candidate supremizer $\boldsymbol{v}$ in (3.1)—that

$$\overline{\beta}_{\overline{\boldsymbol{\mu}}}(\boldsymbol{\mu}) \le \beta_{\overline{\boldsymbol{\mu}}}(\boldsymbol{\mu}) \quad \forall\, \boldsymbol{\mu} \in \mathcal{D}.$$

(Note that $\overline{\beta}_{\overline{\boldsymbol{\mu}}}(\boldsymbol{\mu})$ is not necessarily positive.)

We can also show that $\overline{\beta}_{\overline{\boldsymbol{\mu}}}(\boldsymbol{\mu})$ is a "good" lower bound for $\beta_{\overline{\boldsymbol{\mu}}}(\boldsymbol{\mu})$.

LEMMA 4.1. *Let*

$$\delta_{\overline{\boldsymbol{\mu}}}^{\boldsymbol{\mu}} = \sup_{\boldsymbol{w}\in X} \frac{\left(T_N^{\boldsymbol{\mu}}\boldsymbol{w} - T_N^{\overline{\boldsymbol{\mu}}}\boldsymbol{w}, T_N^{\boldsymbol{\mu}}\boldsymbol{w} + T_N^{\overline{\boldsymbol{\mu}}}\boldsymbol{w}\right)_X}{\|T_N^{\overline{\boldsymbol{\mu}}}\boldsymbol{w}\|_X^2},$$

and assume that

$$\sup_{\boldsymbol{w}\in X} \frac{\|T_N^{\boldsymbol{\mu}}\boldsymbol{w} - T_N^{\overline{\boldsymbol{\mu}}}\boldsymbol{w}\|_X}{\|T_N^{\overline{\boldsymbol{\mu}}}\boldsymbol{w}\|_X} = o(\delta_{\overline{\boldsymbol{\mu}}}^{\boldsymbol{\mu}})$$

as $\boldsymbol{\mu} \to \overline{\boldsymbol{\mu}}$. *Then*

$$1 - \beta_{\overline{\boldsymbol{\mu}}}(\boldsymbol{\mu}) = -\frac{1}{2}\delta_{\overline{\boldsymbol{\mu}}}^{\boldsymbol{\mu}} + o(|\delta_{\overline{\boldsymbol{\mu}}}^{\boldsymbol{\mu}}|^2), \tag{4.1}$$

and there exists $c(\overline{\boldsymbol{\mu}}, \boldsymbol{\mu})$ *in* $[0,1]$ *such that*

$$c(\overline{\boldsymbol{\mu}}, \boldsymbol{\mu})\,[1 - \beta_{\overline{\boldsymbol{\mu}}}(\boldsymbol{\mu})] + 2\left[\,\overline{\beta}_{\overline{\boldsymbol{\mu}}}(\boldsymbol{\mu}) - \beta_{\overline{\boldsymbol{\mu}}}(\boldsymbol{\mu})\right] = o(|\delta_{\overline{\boldsymbol{\mu}}}^{\boldsymbol{\mu}}|^2). \tag{4.2}$$

In general, we can assume that $\delta_{\overline{\boldsymbol{\mu}}}^{\boldsymbol{\mu}}$ is of order $o(|\boldsymbol{\mu} - \overline{\boldsymbol{\mu}}|)$; hence, as for the linear case [32], $1 - \beta_{\overline{\boldsymbol{\mu}}}(\boldsymbol{\mu}) = o(|\boldsymbol{\mu} - \overline{\boldsymbol{\mu}}|)$ as $\boldsymbol{\mu} \to \overline{\boldsymbol{\mu}}$ and

$$0 \le \beta_{\overline{\boldsymbol{\mu}}}(\boldsymbol{\mu}) - \overline{\beta}_{\overline{\boldsymbol{\mu}}}(\boldsymbol{\mu}) \le \frac{1}{2}\,[1 - \beta_{\overline{\boldsymbol{\mu}}}(\boldsymbol{\mu})] + o(|\overline{\boldsymbol{\mu}} - \boldsymbol{\mu}|^2).$$

Proof. From the definition of $\beta_{\overline{\boldsymbol{\mu}}}(\boldsymbol{\mu})$ and $\overline{\beta}_{\overline{\boldsymbol{\mu}}}(\boldsymbol{\mu})$, $1 - \beta_{\overline{\boldsymbol{\mu}}}(\boldsymbol{\mu})^2 = -\delta_{\overline{\boldsymbol{\mu}}}^{\boldsymbol{\mu}}$ and $\overline{\beta}_{\overline{\boldsymbol{\mu}}}(\boldsymbol{\mu})^2 \le \beta_{\overline{\boldsymbol{\mu}}}(\boldsymbol{\mu})^2 \le \overline{\beta}_{\overline{\boldsymbol{\mu}}}(\boldsymbol{\mu})^2 + \frac{1}{2}\delta_{\overline{\boldsymbol{\mu}}}^{\boldsymbol{\mu}} + o(|\delta_{\overline{\boldsymbol{\mu}}}^{\boldsymbol{\mu}}|^2)$; hence

$$\overline{\beta}_{\overline{\boldsymbol{\mu}}}(\boldsymbol{\mu})^2 - \beta_{\overline{\boldsymbol{\mu}}}(\boldsymbol{\mu})^2 = -\frac{c(\overline{\boldsymbol{\mu}}, \boldsymbol{\mu})}{2}\delta_{\overline{\boldsymbol{\mu}}}^{\boldsymbol{\mu}} + o(|\delta_{\overline{\boldsymbol{\mu}}}^{\boldsymbol{\mu}}|^2),$$

where $c(\overline{\boldsymbol{\mu}}, \boldsymbol{\mu}) \in [0,1]$. From the Taylor series of the square root follows (4.1) and

$$\overline{\beta}_{\overline{\boldsymbol{\mu}}}(\boldsymbol{\mu}) - \beta_{\overline{\boldsymbol{\mu}}}(\boldsymbol{\mu}) = \frac{c(\overline{\boldsymbol{\mu}}, \boldsymbol{\mu})}{4}\frac{\delta_{\overline{\boldsymbol{\mu}}}^{\boldsymbol{\mu}}}{\beta_{\overline{\boldsymbol{\mu}}}(\boldsymbol{\mu})} + o(|\delta_{\overline{\boldsymbol{\mu}}}^{\boldsymbol{\mu}}|^2).$$

Since $\frac{1}{1-x} = 1 + x + o(x)$, and from (4.1), $\overline{\beta}_{\overline{\boldsymbol{\mu}}}(\boldsymbol{\mu}) - \beta_{\overline{\boldsymbol{\mu}}}(\boldsymbol{\mu}) = \frac{c(\overline{\boldsymbol{\mu}}, \boldsymbol{\mu})}{4}\delta_{\overline{\boldsymbol{\mu}}}^{\boldsymbol{\mu}} + o(|\delta_{\overline{\boldsymbol{\mu}}}^{\boldsymbol{\mu}}|^2)$, which proves (4.2). ∎

4.1. Local lower bound. For a fixed $\overline{\boldsymbol{\mu}}$ in $\mathcal{V}^K$, we expand $\overline{\beta}_{\overline{\boldsymbol{\mu}}}(\boldsymbol{\mu})$ as follows:

(4.3)
$$\overline{\beta}_{\overline{\boldsymbol{\mu}}}(\boldsymbol{\mu}) = \inf_{\boldsymbol{w}\in X} \frac{\left(T_N^{\boldsymbol{\mu}}\boldsymbol{w}, T_{\overline{N}}^{\overline{\boldsymbol{\mu}}}\boldsymbol{w}\right)_X}{|||\boldsymbol{w}|||^2_{\overline{\boldsymbol{\mu}}}}$$

$$= \inf_{\boldsymbol{w}\in X} \left\{ 1 + \frac{1}{|||\boldsymbol{w}|||^2_{\overline{\boldsymbol{\mu}}}} \sum_{q=1}^{Q_0} \left(\Theta_0^q(\boldsymbol{\mu}) - \Theta_0^q(\overline{\boldsymbol{\mu}})\right) a_0^q(\boldsymbol{w}, T_{\overline{N}}^{\overline{\boldsymbol{\mu}}}\boldsymbol{w}) \right. \tag{4.3a}$$

$$+ \frac{1}{|||\boldsymbol{w}|||^2_{\overline{\boldsymbol{\mu}}}} \sum_{q=1}^{Q_1} \left(\Theta_1^q(\boldsymbol{\mu}) - \Theta_1^q(\overline{\boldsymbol{\mu}})\right) a_1^q(\boldsymbol{w}, \boldsymbol{u}_{\overline{N}}(\overline{\boldsymbol{\mu}}), T_{\overline{N}}^{\overline{\boldsymbol{\mu}}}\boldsymbol{w}) \tag{4.3b}$$

$$+ \frac{1}{|||\boldsymbol{w}|||^2_{\overline{\boldsymbol{\mu}}}} \sum_{q=1}^{Q_1} \Theta_1^q(\overline{\boldsymbol{\mu}})\, a_1^q(\boldsymbol{w},\, \boldsymbol{u}_N(\boldsymbol{\mu}) - \boldsymbol{u}_{\overline{N}}(\overline{\boldsymbol{\mu}})\,, T_{\overline{N}}^{\overline{\boldsymbol{\mu}}}\boldsymbol{w}) \tag{4.3c}$$

$$\left. + \frac{1}{|||\boldsymbol{w}|||^2_{\overline{\boldsymbol{\mu}}}} \sum_{q=1}^{Q_1} \left(\Theta_1^q(\boldsymbol{\mu}) - \Theta_1^q(\overline{\boldsymbol{\mu}})\right) a_1^q(\boldsymbol{w},\, \boldsymbol{u}_N(\mu) - \boldsymbol{u}_{\overline{N}}(\overline{\boldsymbol{\mu}})\,, T_{\overline{N}}^{\overline{\boldsymbol{\mu}}}\boldsymbol{w}) \right\}. \tag{4.3d}$$

We approximate the partial derivative of $\frac{\partial \boldsymbol{u}_{\overline{N}}}{\partial \mu_p}$ at $\overline{\boldsymbol{\mu}}$ with respect to the pth parameter in our reduced space $W_{\overline{N}}$:

$$da(\boldsymbol{u}_{\overline{N}}(\overline{\boldsymbol{\mu}}); \overline{\boldsymbol{\mu}}) \left(\frac{\partial \boldsymbol{u}_{\overline{N}}}{\partial \mu_p}(\overline{\boldsymbol{\mu}}), \boldsymbol{v} \right) \tag{4.4}$$
$$= -\left[\sum_{q=1}^{Q_0} \frac{\partial \Theta_0^q(\overline{\boldsymbol{\mu}})}{\partial \mu_p} a_0^q(\boldsymbol{u}_{\overline{N}}(\overline{\boldsymbol{\mu}}), \boldsymbol{v}) + \frac{1}{2} \sum_{q=1}^{Q_1} \frac{\partial \Theta_1^q(\overline{\boldsymbol{\mu}})}{\partial \mu_p} a_1^q(\boldsymbol{u}_{\overline{N}}(\overline{\boldsymbol{\mu}}), \boldsymbol{u}_{\overline{N}}(\overline{\boldsymbol{\mu}}), \boldsymbol{v}) \right]$$

for all $\boldsymbol{v}$ in $W_{\overline{N}}$. (If f affinely depends on the parameter, we have to add $\sum_{q=1}^{Q_f} \frac{\partial \Theta^f(\overline{\boldsymbol{\mu}})}{\partial \mu_p} f^q(\boldsymbol{v})$ to the right-hand side of (4.4).) We then rewrite

$$a_1^q(\boldsymbol{w}, \boldsymbol{u}_N(\boldsymbol{\mu}) - \boldsymbol{u}_{\overline{N}}(\overline{\boldsymbol{\mu}}), T_{\overline{N}}^{\overline{\boldsymbol{\mu}}}\boldsymbol{w})$$
$$= \sum_{p=1}^{P} \kappa_p \left(\mu_p - \overline{\mu}_p\right) a_1^q \left(\boldsymbol{w}, \frac{\partial \boldsymbol{u}_{\overline{N}}}{\partial \mu_p}(\overline{\mu}), T_{\overline{N}}^{\overline{\boldsymbol{\mu}}} w \right) + a_1^q(\boldsymbol{w}, \boldsymbol{\alpha}(\boldsymbol{\mu}, \overline{\boldsymbol{\mu}}, \boldsymbol{\kappa}), T_{\overline{N}}^{\overline{\boldsymbol{\mu}}}\boldsymbol{w}),$$

where $\boldsymbol{\kappa} \in \mathbb{R}^P$ and $\boldsymbol{\alpha}(\boldsymbol{\mu}, \overline{\boldsymbol{\mu}}, \boldsymbol{\kappa}) \in W_{N_{\max}}$ is defined as

$$\boldsymbol{\alpha}(\boldsymbol{\mu}, \overline{\boldsymbol{\mu}}, \boldsymbol{\kappa}) = \boldsymbol{u}_N(\boldsymbol{\mu}) - \boldsymbol{u}_{\overline{N}}(\overline{\boldsymbol{\mu}}) - \sum_{p=1}^{P} \kappa_p \left(\mu_p - \overline{\mu}_p\right) \frac{\partial \boldsymbol{u}_{\overline{N}}}{\partial \mu_p}(\overline{\boldsymbol{\mu}}).$$

As for the linear case [32], we perform a Taylor expansion with respect to $\boldsymbol{\mu}$ at $\overline{\boldsymbol{\mu}}$. The first-order terms in (4.3a), (4.3b), and (4.3c) are collected: For $p = 1, \ldots, P$,

(4.5)
$$a_p^{\overline{\boldsymbol{\mu}}}(\cdot,\cdot) \equiv \sum_{q=1}^{Q_0} \frac{\partial \Theta_0^q}{\partial \mu_p}(\overline{\boldsymbol{\mu}}) a_0^q(\cdot,\cdot) + \sum_{q=1}^{Q_1} \frac{\partial \Theta_1^q}{\partial \mu_p}(\overline{\boldsymbol{\mu}}) a_1^q(\cdot, \boldsymbol{u}_{\overline{N}}(\overline{\boldsymbol{\mu}}), \cdot) + \sum_{q=1}^{Q_1} \Theta_1^q(\overline{\boldsymbol{\mu}}) a_1^q \left(\cdot, \frac{\partial \boldsymbol{u}_{\overline{N}}}{\partial \mu_p}(\overline{\boldsymbol{\mu}}), \cdot\right).$$

We denote the extreme eigenvalues with respect to $|||\cdot|||_{\overline{\boldsymbol{\mu}}}$ of $a_p^{\overline{\boldsymbol{\mu}}}$, a_0^q, and $a_1^q(\cdot, \boldsymbol{u}_{\overline{N}}(\overline{\boldsymbol{\mu}}), \cdot)$ as

$$\lambda_{p,\inf}^{\overline{\boldsymbol{\mu}}} = \inf_{\boldsymbol{w}\in X} \frac{a_p^{\overline{\boldsymbol{\mu}}}(\boldsymbol{w}, T_{\overline{N}}^{\overline{\boldsymbol{\mu}}}\boldsymbol{w})}{|||\boldsymbol{w}|||_{\overline{\boldsymbol{\mu}}}^2}, \quad \lambda_{p,\sup}^{\overline{\boldsymbol{\mu}}} = \sup_{\boldsymbol{w}\in X} \frac{a_p^{\overline{\boldsymbol{\mu}}}(\boldsymbol{w}, T_{\overline{N}}^{\overline{\boldsymbol{\mu}}}\boldsymbol{w})}{|||\boldsymbol{w}|||_{\overline{\boldsymbol{\mu}}}^2}, \quad p = 1, \ldots, P,$$

$$\gamma_{0,q,\inf}^{\overline{\boldsymbol{\mu}}} = \inf_{\boldsymbol{w}\in X} \frac{a_0^q(\boldsymbol{w}, T_{\overline{N}}^{\overline{\boldsymbol{\mu}}}\boldsymbol{w})}{|||\boldsymbol{w}|||_{\overline{\boldsymbol{\mu}}}^2}, \quad \gamma_{0,q,\sup}^{\overline{\boldsymbol{\mu}}} = \sup_{\boldsymbol{w}\in X} \frac{a_0^q(\boldsymbol{w}, T_{\overline{N}}^{\overline{\boldsymbol{\mu}}}\boldsymbol{w})}{|||\boldsymbol{w}|||_{\overline{\boldsymbol{\mu}}}^2}, \quad q = 1, \ldots, Q_0,$$

$$\gamma_{1,q,\inf}^{\overline{\boldsymbol{\mu}}} = \inf_{\boldsymbol{w}\in X} \frac{a_1^q(\boldsymbol{w}, \boldsymbol{u}_{\overline{N}}(\overline{\boldsymbol{\mu}}), T_{\overline{N}}^{\overline{\boldsymbol{\mu}}}\boldsymbol{w})}{|||\boldsymbol{w}|||_{\overline{\boldsymbol{\mu}}}^2},$$

$$\gamma_{1,q,\sup}^{\overline{\boldsymbol{\mu}}} = \sup_{\boldsymbol{w}\in X} \frac{a_1^q(\boldsymbol{w}, \boldsymbol{u}_{\overline{N}}(\overline{\boldsymbol{\mu}}), T_{\overline{N}}^{\overline{\boldsymbol{\mu}}}\boldsymbol{w})}{|||\boldsymbol{w}|||_{\overline{\boldsymbol{\mu}}}^2}, \quad q = 1, \ldots, Q_1.$$

From our assumption (2.9) we have

$$\frac{1}{|||\boldsymbol{w}|||_{\overline{\boldsymbol{\mu}}}^2} \left| \sum_{q=1}^{Q_1} \Theta_1^q(\overline{\boldsymbol{\mu}}) a_1^q(\boldsymbol{w}, \boldsymbol{\alpha}(\boldsymbol{\mu}, \overline{\boldsymbol{\mu}}, \boldsymbol{\kappa}), T_{\overline{N}}^{\overline{\boldsymbol{\mu}}}\boldsymbol{w}) \right| \le \rho_{X,\overline{\boldsymbol{\mu}}} \|\boldsymbol{\alpha}(\boldsymbol{\mu}, \overline{\boldsymbol{\mu}}, \boldsymbol{\kappa})\|_X. \tag{4.6}$$

Similarly, from (2.10),

$$\frac{1}{|||\boldsymbol{w}|||_{\overline{\boldsymbol{\mu}}}^2} \left| \sum_{q=1}^{Q_1} \left(\Theta_1^q(\boldsymbol{\mu}) - \Theta_1^q(\overline{\boldsymbol{\mu}})\right) a_1^q(\boldsymbol{w}, \boldsymbol{u}_N(\boldsymbol{\mu}) - \boldsymbol{u}_{\overline{N}}(\overline{\boldsymbol{\mu}}), T_{\overline{N}}^{\overline{\boldsymbol{\mu}}}\boldsymbol{w}) \right|$$
$$\le \max_{q=1,\ldots,Q_1} \frac{|\Theta_1^q(\boldsymbol{\mu}) - \Theta_1^q(\overline{\boldsymbol{\mu}})|}{|\Theta_1^q(\overline{\boldsymbol{\mu}})|} \rho_{X,\overline{\boldsymbol{\mu}}} \|\boldsymbol{u}_N(\boldsymbol{\mu}) - \boldsymbol{u}_{\overline{N}}(\overline{\boldsymbol{\mu}})\|_X.$$

As a result, our bound to (4.3) is defined, for any $\boldsymbol{\kappa}$ in $\mathbb{R}^P$, as

$$\begin{aligned}
\overline{\beta}_{\overline{\boldsymbol{\mu}}}(\boldsymbol{\mu}) \ge & \overline{B}_{\overline{\boldsymbol{\mu}}}^{LB}(\boldsymbol{\mu}, \boldsymbol{\kappa}) \equiv 1 + \sum_{p=1}^{P} \min_{\lambda_p = \lambda_{p,\,\inf\,|\,\sup}^{\overline{\boldsymbol{\mu}}}} \kappa_p(\mu_p - \overline{\mu}_p)\lambda_p \\
& + \sum_{q=1}^{Q_0} \min_{\gamma_q = \gamma_{0,q,\,\inf\,|\,\sup}^{\overline{\boldsymbol{\mu}}}} \left(\Theta_0^q(\boldsymbol{\mu}) - \Theta_0^q(\overline{\boldsymbol{\mu}}) - \sum_{p=1}^{P} \kappa_p(\mu_p - \overline{\mu}_p) \frac{\partial \Theta_0^q}{\partial \mu_p}(\overline{\boldsymbol{\mu}}) \right) \gamma_q \\
& + \sum_{q=1}^{Q_1} \min_{\gamma_q = \gamma_{1,q,\,\inf\,|\,\sup}^{\overline{\boldsymbol{\mu}}}} \left(\Theta_1^q(\boldsymbol{\mu}) - \Theta_1^q(\overline{\boldsymbol{\mu}}) - \sum_{p=1}^{P} \kappa_p(\mu_p - \overline{\mu}_p) \frac{\partial \Theta_1^q}{\partial \mu_p}(\overline{\boldsymbol{\mu}}) \right) \gamma_q \\
& - \rho_{X,\overline{\boldsymbol{\mu}}} \left(\|\boldsymbol{\alpha}(\boldsymbol{\mu}, \overline{\boldsymbol{\mu}}, \boldsymbol{\kappa})\|_X + \max_{q=1,\ldots,Q_1} \frac{|\Theta_1^q(\boldsymbol{\mu}) - \Theta_1^q(\overline{\boldsymbol{\mu}})|}{|\Theta_1^q(\overline{\boldsymbol{\mu}})|} \|\boldsymbol{u}_N(\boldsymbol{\mu}) - \boldsymbol{u}_{\overline{N}}(\overline{\boldsymbol{\mu}})\|_X \right),
\end{aligned} \tag{4.7}$$

where we denote the minimum of a function g over two values as

$$\min_{\lambda=\lambda_{\inf\,|\,\sup}} g(\lambda) \equiv \min\left\{g(\lambda_{\inf}), g(\lambda_{\sup})\right\}.$$

Since (4.7) is valid for any $\boldsymbol{\kappa} \in \mathbb{R}^P$, we define our inf-sup lower bound as

$$\overline{B}_{\overline{\boldsymbol{\mu}}}^{LB}(\boldsymbol{\mu}) \equiv \max_{\boldsymbol{\kappa}\in\mathbb{R}^P} \overline{B}_{\overline{\boldsymbol{\mu}}}^{LB}(\boldsymbol{\mu}, \boldsymbol{\kappa}). \tag{4.8}$$

4.2. $\boldsymbol{\kappa}$ optimization. Ideally, for a given $\boldsymbol{\mu}$, we have to find the value of $\boldsymbol{\kappa}$ that maximizes $\overline{B}^{LB}_{\overline{\boldsymbol{\mu}}}(\boldsymbol{\mu},\boldsymbol{\kappa})$. The optimization of $\boldsymbol{\kappa}$ relies on quadratic programming. We propose a simpler heuristic method: The bound involving the eigenvalues $\lambda^{\overline{\boldsymbol{\mu}}}_{p,\inf|\sup}$ is sharper than (4.6), and therefore we compute $\boldsymbol{\kappa}$ such that $\|\boldsymbol{\alpha}(\boldsymbol{\mu},\overline{\boldsymbol{\mu}},\boldsymbol{\kappa})\|_X$ is the smallest. Moreover, in our algorithms we will require an X-orthonormal basis for $W_{N_{\max}}$; hence this minimization is achieved by the least-square solution $\boldsymbol{\kappa}^*$ that satisfies

$$\begin{aligned}(4.9)\qquad &\left[\begin{array}{c}\vdots\\ (\mu_p-\overline{\mu}_p)\partial_p U_{\overline{N},j}(\overline{\boldsymbol{\mu}})\\ \vdots\end{array}\right]^T_{j,p}\left[\begin{array}{c}\vdots\\ (\mu_p-\overline{\mu}_p)\partial_p U_{\overline{N},j}(\overline{\boldsymbol{\mu}})\\ \vdots\end{array}\right]_{j,p}\boldsymbol{\kappa}^*\\ &\qquad=\left[\begin{array}{c}\vdots\\ (\mu_p-\overline{\mu}_p)\partial_p U_{\overline{N},j}(\overline{\boldsymbol{\mu}})\\ \vdots\end{array}\right]^T_{j,p}\left[\begin{array}{c}\vdots\\ U_{N,j}(\boldsymbol{\mu})-U_{\overline{N},j}(\overline{\boldsymbol{\mu}})\\ \vdots\end{array}\right]_{j},\end{aligned}$$

where $U_{N,j}(\boldsymbol{\mu})$, $U_{\overline{N},j}(\overline{\boldsymbol{\mu}})$, and $\partial_p U_{\overline{N},j}(\overline{\boldsymbol{\mu}})$ are the jth components of $\boldsymbol{u}_N(\boldsymbol{\mu})$, $\boldsymbol{u}_{\overline{N}}(\overline{\boldsymbol{\mu}})$, and $\frac{\partial \boldsymbol{u}_{\overline{N}}(\overline{\boldsymbol{\mu}})}{\partial \mu_p}$ with respect to the basis of $W_{N_{\max}}$.

5. Computational strategy.

5.1. Offline algorithm. Our offline algorithm includes the computation of the reduced basis ingredients—optimal selection of the basis and computation of matrices and vector in the reduced space (cf., e.g., [32])—and of the a posteriori error estimation ingredients—selection of $\mathcal{V}^K=\{\overline{\boldsymbol{\mu}}_1,\dots,\overline{\boldsymbol{\mu}}_K\}$, solution of the eigenvalue problems, and computation of the Sobolev embedding constants. Because of the presence of the reduced basis approximations $\boldsymbol{u}_{\overline{N}}(\overline{\boldsymbol{\mu}})$ in the definition of the natural norms, these two stages are dependent on each other. (In the linear case (cf. [32]) these steps are ordered: first to compute the a posteriori error estimation ingredients, then to select the reduced basis.)

In the first step, we provide surrogates $\overline{B}^{LB}_{\overline{\boldsymbol{\mu}}}(\boldsymbol{\mu})$ and $\rho_{\overline{\boldsymbol{\mu}}}(\overline{\boldsymbol{\mu}})$ in order to compute an error bound extrapolation. We expect that $\overline{B}^{LB}_{\overline{\boldsymbol{\mu}}}(\boldsymbol{\mu})$ is of order one, so we set its surrogate to, say, 0.2; to compute a surrogate $\rho_{\overline{\boldsymbol{\mu}}}(\overline{\boldsymbol{\mu}})$, we replace $\boldsymbol{u}_{\overline{N}}(\overline{\boldsymbol{\mu}})$ by $\boldsymbol{u}(\overline{\boldsymbol{\mu}})$ in (2.4) (hence in (2.7))—in other words we do not need a reduced basis. As a result we have an efficient—online fast—tool to approximately compute the error for a given $\boldsymbol{\mu}$ in $\mathcal{D}$.

In the second step, we compute the eigenvalues and the Sobolev embedding constants that we need in our inf-sup lower bound construction.

We hence propose the following algorithm:

1. Manually set K, select a representative set $\mathcal{V}^K=\{\overline{\boldsymbol{\mu}}_1,\dots,\overline{\boldsymbol{\mu}}_K\}$, and compute surrogates for each $\rho_{\overline{\boldsymbol{\mu}}}$;
2. start an optimal search algorithm: For a large random[5] set of $\boldsymbol{\mu}$'s
   (a) solve the reduced basis problem with the existing basis;
   (b) select the "nearest" $\overline{\boldsymbol{\mu}}$ in $\mathcal{V}^K$, and compute $\epsilon_N(\mu)$, $\tau_{N,\overline{\boldsymbol{\mu}}}(\boldsymbol{\mu})$, and $\Delta_{N,\overline{\boldsymbol{\mu}}}(\boldsymbol{\mu})$ by replacing $\rho_{\overline{\boldsymbol{\mu}}}$ and $\beta_{\overline{\boldsymbol{\mu}}}(\boldsymbol{\mu})$ by their surrogates;
   (c) select the optimal $\boldsymbol{\mu}$ as follows:

[5]This can be replaced by a deterministic search over a large set of sample points.

   i. If for some $\boldsymbol{\mu}$'s, (2a) did not converge, select the "furthest" from the previously selected ones;
   ii. if for some $\boldsymbol{\mu}$'s, $\tau_{N,\overline{\boldsymbol{\mu}}}(\boldsymbol{\mu})$ is bigger than 1, select the one with the largest $\tau_{N,\overline{\boldsymbol{\mu}}}(\boldsymbol{\mu})$;
   iii. otherwise, select the one with the largest $\Delta_{N,\overline{\boldsymbol{\mu}}}(\boldsymbol{\mu})$.
3. Solve the finite element problem (2.1) for the selected $\boldsymbol{\mu}$;
4. increase N and enrich the reduced basis space[6] W_N with $\boldsymbol{u}(\boldsymbol{\mu})$;[7]
5. if the maximum number of bases wished or the tolerance requested for $\Delta_{N,\overline{\boldsymbol{\mu}}}(\boldsymbol{\mu})$ are achieved, go to 6; otherwise, go to 2;
6. set $\overline{N}$ to the reached number of basis functions, and compute all of the ingredients for the computation of $\overline{B}^{LB}_{\overline{\boldsymbol{\mu}}}(\boldsymbol{\mu})$;
7. start a random process: For a large set of $\boldsymbol{\mu}$'s check that the reduced basis problem can be solved, that $\overline{B}^{LB}_{\overline{\boldsymbol{\mu}}}(\boldsymbol{\mu})$ is positive for at least one $\overline{\boldsymbol{\mu}}$, and that $\tau_{N,\overline{\boldsymbol{\mu}}}(\boldsymbol{\mu}) \leq 1$ for this $\overline{\boldsymbol{\mu}}$.
   If this is ok, then all of the online components are ready, and we set $N_{\max} = N$; otherwise, either add some $\overline{\boldsymbol{\mu}}$'s to $\mathcal{V}^K$ and go to 6 or go to 2 and replace $\beta_{\overline{\boldsymbol{\mu}}}(\boldsymbol{\mu})$ by $\overline{B}^{LB}_{\overline{\boldsymbol{\mu}}}(\boldsymbol{\mu})$ instead of by 0.2.

Steps 2(a) and 2(b) are online fast. Moreover, in our parallel offline code, each processor performs the optimal search on a different random set. As a result, we can explore our parameter space very rapidly.

To ensure that we are on a selected solution branch, in the finite element resolution we perform a homotopy procedure in $\boldsymbol{\mu}$ starting from an already computed solution at a nearby parameter; in the reduced basis we simply start from a solution at a nearby parameter used to generate the W_N. (In some applications, it may be necessary to perform homotopy also in the reduced basis context.)

Note that we can admit small errors in the resolution of (2.1); indeed, we need approximations to $\boldsymbol{u}(\boldsymbol{\mu})$ at selected parameter points to build our reduced basis. However, the error bound is given with respect to the exact "truth" solution $\boldsymbol{u}(\boldsymbol{\mu})$.

The reader is referred to [33] and [32] for the exact offline procedure to compute the reduced basis and a posteriori error estimation components.

5.2. Online algorithm. The online procedure, for given $\boldsymbol{\mu} \in \mathcal{D}$ and $N \leq N_{\max}$, reads:

I. Solve the reduced basis problem (1.3)[8] and compute $s_N(\boldsymbol{\mu}) = \ell(\boldsymbol{u}(\boldsymbol{\mu}))$;
II. compute $\epsilon_N(\boldsymbol{\mu})$;
III. order $\mathcal{V}^K$ in increasing distance[9] from $\boldsymbol{\mu}$. Compute $\overline{B}^{LB}_{\overline{\boldsymbol{\mu}}}(\boldsymbol{\mu})$ and $\tau_{N,\overline{\boldsymbol{\mu}}}(\boldsymbol{\mu})$ until we find $\overline{\boldsymbol{\mu}}$ in $\mathcal{V}$ such that $\overline{B}^{LB}_{\overline{\boldsymbol{\mu}}}(\boldsymbol{\mu}) > 0$ and $\tau_{N,\overline{\boldsymbol{\mu}}}(\boldsymbol{\mu}) \leq 1$. We set $\mathcal{I}^K(\boldsymbol{\mu}) = \overline{\boldsymbol{\mu}}$;
IV. compute $\Delta_{N,\overline{\boldsymbol{\mu}}}(\boldsymbol{\mu})$ and $\Delta^s_{N,\overline{\boldsymbol{\mu}}}(\boldsymbol{\mu})$.

If in step III we do not find any $\overline{\boldsymbol{\mu}}$, our method fails: We cannot provide an error bound nor even existence; if possible, N must be increased; otherwise, our basis is not rich enough.

[6] This step involves Gramm–Schmidt orthogonalization and the computation of the matrix- and scalar-products necessary for the reduced basis matrices and the online computation of the Y-dual norm of the residual (cf. [23, 32]).

[7] In our model problems, $\boldsymbol{u}(\boldsymbol{\mu})$ is split into its physical components and a stabilizing supremizer is computed; the reduced space is hence enriched by four functions (cf. section 6.2).

[8] We solve this by a Newton algorithm with the initial guess a solution at a nearby parameter used to generate the reduced basis.

[9] The distance function in $\mathcal{D}$ is arbitrary.

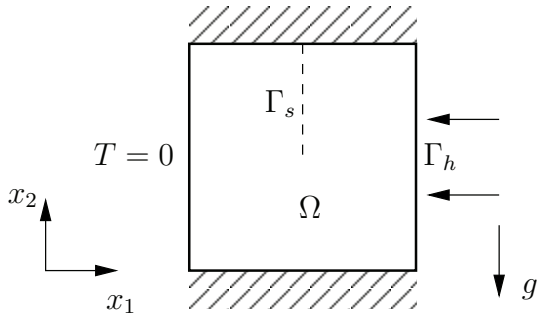

FIG. 1. *Closed cavity. On the left the temperature is constant, on the right the heat flux is constant, and the top and bottom are insulated.*

The computational effort is independent of $\mathcal{N}$: Steps I and II have dominant complexities $N^3 + Q_1 N^2$ times the number of Newton iterations required and $Q_1^2 N^4 + Q_0 Q_1 N^3$, respectively. The complexity of steps III and IV is dominated by that of step II.

6. Application: Steady natural convection. We are interested in solving a natural convection problem in a two-dimensional square cavity under vertical gravity (Figure 1), with constant temperature on one side, heated on the opposite side, insulated at the top and bottom, and Prandtl number $\mathrm{Pr} = 1$ (dissipation to conduction ratio). We consider one parameter $\boldsymbol{\mu} = (\frac{1}{\sqrt{\mathrm{Gr}}})$, where Gr is the Grashof number, which is defined as $(\beta \Delta T g L^3)/\nu^2$ (g is the gravity constant, β is the thermal expansion coefficient, ΔT is the temperature difference, L is the length scale, and ν is the kinematic viscosity).

We impose homogeneous Dirichlet boundary conditions for the velocity (u_1, u_2), while for the temperature θ we impose homogeneous Dirichlet boundary conditions on the left side, homogeneous Neumann boundary conditions on the top and the bottom, and constant unitary Neumann boundary conditions on the heated side Γ_h ($\partial_n \theta = 1$ on Γ_h). We scale the pressure such that $\int_\Omega p = 0$.

Our domain $\Omega \subset \mathbb{R}^2$ is a closed square cavity with unitary sides. We want to solve (with summation over repeated indices and partial derivatives with respect to x_1 and x_2)

$$
\begin{aligned}
u_j \partial_j u_1 &= -\partial_1 p + \frac{1}{\sqrt{\mathrm{Gr}}} \partial^2_{jj} u_1, \\
u_j \partial_j u_2 &= -\partial_2 p + \theta + \frac{1}{\sqrt{\mathrm{Gr}}} \partial^2_{jj} u_2, \\
\partial_i u_i &= 0, \\
u_j \partial_j \theta &= \frac{1}{\sqrt{\mathrm{Gr}}\,\mathrm{Pr}} \partial^2_{jj} \theta
\end{aligned}
$$

in Ω.

Our outputs of interest are the inverse of the Nusselt number and the flux through the middle half section Γ_s parallel to Γ_h:

$$
s_{(1)}(\boldsymbol{\mu}) = \frac{1}{|\Gamma_h|} \int_{\Gamma_h} \theta(\boldsymbol{\mu}), \qquad s_{(2)}(\boldsymbol{\mu}) = \frac{1}{|\Gamma_s|} \int_{\Gamma_s} u_1(\boldsymbol{\mu}).
$$

6.1. Affine decomposition. Our reference finite element space X is a subset of $H_0^1(\Omega)\times H_0^1(\Omega)\times H^1(\Omega)\times L^2(\Omega)\times\mathbb{R}$. We denote elements in X as $\boldsymbol{u}=(u_1,u_2,\theta,p,\lambda)$, $\boldsymbol{v}=(v_1,v_2,\chi,q,\gamma)$, and $\boldsymbol{z}=(z_1,z_2,\zeta,\dots)$.

Recalling (2.2), a decomposes into $Q_0=2$ bilinear and $Q_1=1$ trilinear components,

$$a_0^1(\boldsymbol{u},\boldsymbol{v})=-\int_\Omega p\partial_i v_i-\int_\Omega q\partial_i u_i+\lambda\int_\Omega p+\gamma\int_\Omega q-\int_\Omega \theta v_2, \qquad \Theta_0^1(\boldsymbol{\mu})=1,$$

$$a_0^2(\boldsymbol{u},\boldsymbol{v})=\int_\Omega \partial_i u_j\partial_i v_j+\int_\Omega \partial_i\theta\partial_i\chi, \qquad \Theta_0^2(\boldsymbol{\mu})=\mu_1,$$

$$a_1^1(\boldsymbol{u},\boldsymbol{z},\boldsymbol{v})=\int_\Omega u_j\partial_i z_i v_j+\int_\Omega z_j\partial_i u_i v_j+\int_\Omega z_i\partial_i\theta\,\chi+\int_\Omega u_i\partial_i\zeta\,\chi, \qquad \Theta_1^1(\boldsymbol{\mu})=1.$$

The right-hand side, which linearly depends on μ_1, and the (linear) outputs take the form

$$f^1(\boldsymbol{v})=\int_{\Gamma_h}\chi, \qquad \Theta_f^1(\boldsymbol{\mu})=\mu_1,$$

$$\ell_{(1),0}^1(\boldsymbol{v})=\int_{\Gamma_h}\chi, \qquad \Theta_{\ell,(1)}^1(\boldsymbol{\mu})=1,$$

$$\ell_{(2),0}^1(\boldsymbol{v})=\int_{\Gamma_s}v_1, \qquad \Theta_{\ell,(2)}^1(\boldsymbol{\mu})=1.$$

6.2. Reduced basis and supremizer. To achieve faster convergence (cf. [17, 33]), in step 4 of the algorithm in section 5.1, the solution $\boldsymbol{u}(\boldsymbol{\mu})=(u_1,u_2,\chi,p,\lambda)$ is split into its physical components. To ensure solvability of the reduced system, we preliminarily add the constant pressure $(0,0,0,1,0)$ and Lagrange multiplier $(0,0,0,0,1)$ to our reduced space. To ensure stability, to each new added pressure mode, we add a supremizer (cf. [26, 27]) $\sigma(\boldsymbol{u}(\boldsymbol{\mu}))\in X$, defined by a null temperature, pressure, and Lagrange multiplier, and

$$(\boldsymbol{\sigma}(\boldsymbol{u}(\boldsymbol{\mu})),\boldsymbol{v})_X=\int_\Omega p\partial_i v_i \quad \forall\boldsymbol{v}\in X.$$

(Note that there are alternative definitions of the supremizer; cf. [26, 27].)

Therefore step 4 is replaced by

4bis. Add the three basis functions $(u_1,u_2,0,0,0)$, $(0,0,\chi,0,0)$, and $(0,0,0,p,0)$ as well as the supremizer $\boldsymbol{\sigma}(\boldsymbol{u}(\boldsymbol{\mu}))$ to our reduced basis space.

6.3. Sobolev embedding constant. We define a seminorm $|\cdot|_4$ as the restriction of the L^4-norm to the velocity and temperature fields:

$$|\boldsymbol{v}|_4^4=\int_\Omega\left(v_1^2+v_2^2+\chi^2\right)^2.$$

PROPOSITION 6.1. *For all $\boldsymbol{u}$, $\boldsymbol{v}$, and $\boldsymbol{z}$ in X,*

$$\left|a_1^1(\boldsymbol{u},\boldsymbol{z},\boldsymbol{v})\right|\le 2|\boldsymbol{u}|_4\,\|\boldsymbol{z}\|_X\,|\boldsymbol{v}|_4+|\boldsymbol{u}|_4\,|\boldsymbol{z}|_4\,\|\boldsymbol{v}\|_X.$$

Proof. We denote that $u_3 = \theta$, $v_3 = \chi$, and $z_3 = \zeta$; we then have

$$\int_\Omega \sum_{i=1}^{2}\sum_{j=1}^{3} u_i \partial_i z_j v_j \le \int_\Omega \left(\sum_{j=1}^{3} v_j^2\right)^{\frac12} \left(\sum_{j=1}^{3}\left(\sum_{i=1}^{2} u_i \partial_i z_j\right)^2\right)^{\frac12} \tag{6.1}$$

$$\le \left[\int_\Omega \left(\sum_{j=1}^{3} v_j^2\right)^2\right]^{\frac14} \left[\int_\Omega \left(\sum_{j=1}^{3}\left(\sum_{i=1}^{2} u_i \partial_i z_j\right)^2\right)^{\frac23}\right]^{\frac34}$$

$$\le |\boldsymbol{v}|_4 \left[\int_\Omega \left(\sum_{i=1}^{2} u_i^2\right)^{\frac23} \left(\sum_{j=1}^{3}\sum_{i=1}^{2} (\partial_i z_j)^2\right)^{\frac23}\right]^{\frac34}$$

$$\le |\boldsymbol{v}|_4 \left[\int_\Omega \left(\sum_{i=1}^{2} u_i^2\right)^2\right]^{\frac14} \left[\int_\Omega \sum_{j=1}^{3}\sum_{i=1}^{2} (\partial_i z_j)^2\right]^{\frac12}$$

$$\le |\boldsymbol{v}|_4 \, \|(u_1,u_2)\|_{L^4(\Omega)^2} \, |(z_1,z_2,z_3)|_{H^1(\Omega)^3}.$$

From

$$\sum_{i=1}^{2}\sum_{j=1}^{3} \partial_i (u_j z_i) = \sum_{i=1}^{2}\sum_{j=1}^{3} u_j \partial_i z_i + \sum_{i=1}^{2}\sum_{j=1}^{3} z_i \partial_i u_j,$$

integration by parts, and $z_1 = z_2 = 0$ on $\partial\Omega$, we have

$$\int_\Omega \sum_{i=1}^{2}\sum_{j=1}^{3} z_i \partial_i u_j v_j = -\int_\Omega \sum_{i=1}^{2}\sum_{j=1}^{3} u_j z_i \partial_i v_j - \int_\Omega \sum_{i=1}^{2}\sum_{j=1}^{3} u_j \partial_i z_i v_j.$$

We bound the first term on the right-hand side by applying (6.1) and the second one by

$$\int_\Omega \sum_{i=1}^{2}\sum_{j=1}^{3} u_j \partial_i z_i v_j \le |\boldsymbol{v}|_4 \left[\int_\Omega \left(\sum_{j=1}^{3} u_j^2 \sum_{i=1}^{2} (\partial_i z_i)^2\right)^{\frac23}\right]^{\frac34}$$

$$\le |\boldsymbol{v}|_4 \left[\int_\Omega \left(\sum_{j=1}^{3} u_j^2\right)^2\right]^{\frac14} \left[\int_\Omega \sum_{i=1}^{2} (\partial_i z_i)^2\right]^{\frac12} = |\boldsymbol{v}|_4 \, |\boldsymbol{u}|_4 \, |(z_1,z_2)|_{H^1_{\mathrm{div}}(\Omega)^2}.$$

$\|(u_1,u_2)\|_{L^4(\Omega)^2} \le |\boldsymbol{u}|_4$, $|(z_1,z_2,z_3)|_{H^1(\Omega)^3} < \|\boldsymbol{z}\|_X$, $|(z_1,z_2)|_{H^1_{\mathrm{div}}(\Omega)^2} < \|\boldsymbol{z}\|_X$, and the definition of a_1^1 complete the proof. ∎

From the Sobolev embedding theorem we know that there exists a constant ρ_X such that

$$|\boldsymbol{v}|_4 \le \rho_X \|\boldsymbol{v}\|_X \;\forall\; \boldsymbol{v} \in X \tag{6.2}$$

and from the equivalence of the norms $\|\cdot\|_X$ and $|||\cdot|||_{\overline{\boldsymbol{\mu}}}$ that there exists a constant $\rho_{\overline{\boldsymbol{\mu}}} \le \frac{\rho_X}{\beta(\overline{\boldsymbol{\mu}})}$ such that

$$|\boldsymbol{v}|_4 \le \rho_{\overline{\boldsymbol{\mu}}} |||\boldsymbol{v}|||_{\overline{\boldsymbol{\mu}}} \;\forall\; \boldsymbol{v} \in X. \tag{6.3}$$

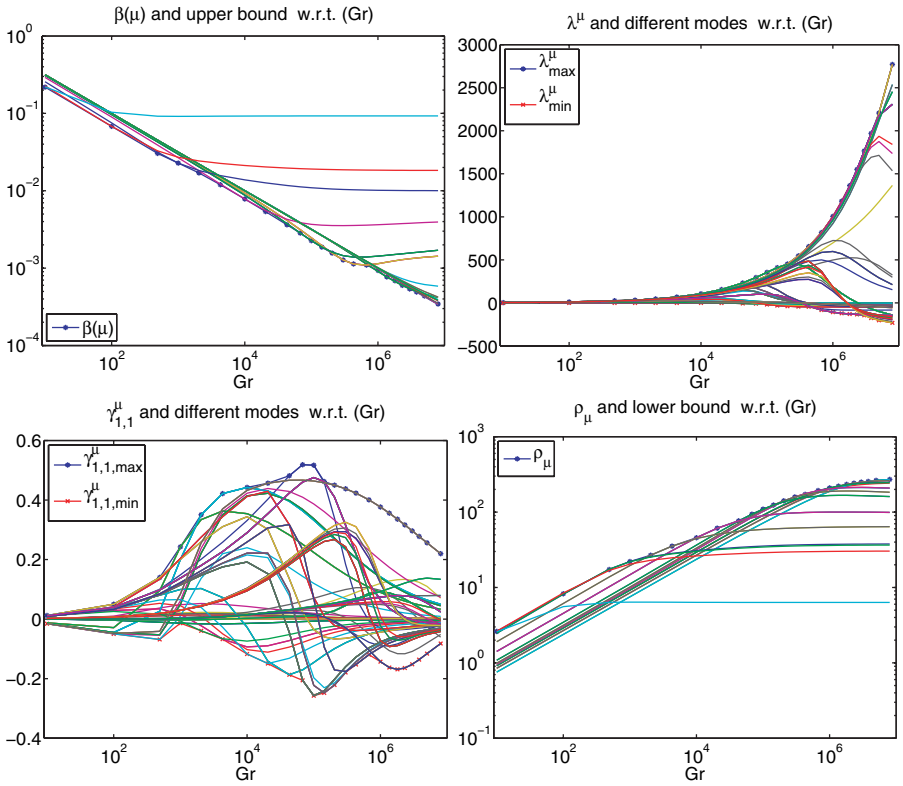

FIG. 2. *Upper left:* $\beta(\overline{\boldsymbol{\mu}})$ *and upper bounds given by the Rayleigh quotients of the minimizing modes. Upper right and lower left:* $\lambda_1^{\overline{\boldsymbol{\mu}}}$ *and* $\gamma_{1,1}^{\overline{\boldsymbol{\mu}}}$*, respectively, and Rayleigh quotients of several maximizing modes (those relative to* $\lambda^{\overline{\boldsymbol{\mu}}}$*,* $\gamma_{0,1}^{\overline{\boldsymbol{\mu}}}$*,* $\gamma_{0,2}^{\overline{\boldsymbol{\mu}}}$*, and* $\gamma_{1,1}^{\overline{\boldsymbol{\mu}}}$*). Lower right:* $\rho_{\overline{\boldsymbol{\mu}}}$ *and lower bounds given by the quotients of our* L^4 *seminorm and natural norm of the maximizing modes. The* x*-axis represents the Grashof number relative to* $\overline{\boldsymbol{\mu}}$*.*

With

$$\rho_{\overline{\boldsymbol{\mu}}}(\boldsymbol{\mu}) \equiv \frac{\rho_{\overline{\boldsymbol{\mu}}}\rho_X}{\beta(\overline{\boldsymbol{\mu}})} + 2\rho_{\overline{\boldsymbol{\mu}}}^2 \quad \text{and} \quad \rho_{X,\overline{\boldsymbol{\mu}}} \equiv 3\rho_{\overline{\boldsymbol{\mu}}}\rho_X,$$

the assumptions (2.8), (2.9), and (2.10) are satisfied.

6.4. Computation of the eigenvalues. The computation of the inf-sup constants $\beta(\overline{\boldsymbol{\mu}})$ and of the extreme eigenvalues $\lambda_{p,\,\inf|\sup}^{\overline{\boldsymbol{\mu}}}$, $p = 1, \ldots, P$, $\gamma_{i,q,\,\inf|\sup}^{\overline{\boldsymbol{\mu}}}$, $q = 1, \ldots, Q_i$, $i = 0, 1$, heavily depends on the initial guesses. We start by computing $\beta(\overline{\boldsymbol{\mu}})$ for all $\overline{\boldsymbol{\mu}}$ in $\mathcal{V}^K$ from low to high Grashof numbers by inverse iterations. We store all of the modes, and at each $\overline{\boldsymbol{\mu}}$ we select the initial guess as the stored mode with the smallest Rayleigh quotient.

Then we compute the remaining eigenvalues, also by selecting among the stored modes and by storing the new modes found. In this case, we use a locally optimized block preconditioned gradient method [10]. Figure 2 shows $\beta(\overline{\boldsymbol{\mu}})$, $\lambda_{1,\,\inf|\sup}^{\overline{\boldsymbol{\mu}}}$, $\gamma_{1,1,\,\inf|\sup}^{\overline{\boldsymbol{\mu}}}$, and the comparison with the stored modes; some maximizing modes are almost identical for different values of $\overline{\boldsymbol{\mu}}$.

6.5. Computation of the Sobolev embedding constants. We have developed an algorithm [19] for the computation of the Sobolev embedding constants ρ_X and $\rho_{\overline{\boldsymbol{\mu}}}$ in (6.2) and (6.3).

Let $\boldsymbol{u}^* \in X$, $\|\boldsymbol{u}^*\| = 1$, be the (possibly nonunique) supremizer of

$$\rho = \sup_{\boldsymbol{v} \in X} \frac{|\boldsymbol{v}|_4}{\|\boldsymbol{v}\|}, \tag{6.4}$$

where $\|\cdot\|$ denotes the X or the natural norms, and let $z : X \to L^2(\Omega)$,

$$z(\boldsymbol{v}) = \frac{v_1^2 + v_2^2 + \chi^2}{|\boldsymbol{v}|_4^2}.$$

Note that $\|z(\boldsymbol{v})\|_{L^2(\Omega)} = 1$ for all $\boldsymbol{v}$ in X.

For a nonnegative function $z \in L^2(\Omega)$, we introduce the eigenproblem: Find $\boldsymbol{u} = (u_1, u_2, \theta, \dots) \in X$ and $\lambda \in \mathbb{R}$ such that $\|\boldsymbol{u}\| = 1$ and

$$\int_\Omega z\,(u_1 v_1 + u_2 v_2 + \theta\chi) = \lambda\,(\boldsymbol{u}, \boldsymbol{v}) \quad \forall \boldsymbol{v} = (v_1, v_2, \chi, \dots) \in X,$$

where $(\cdot,\cdot)$ is the X or natural scalar products. We denote by $\lambda_{\max}(z)$ and $\boldsymbol{u}_{\max}(z)$ the largest eigenvalue and associated eigenfunction, respectively. Note that we choose the eigenfunctions always in the same half-space.

We observe that $\lambda_{\max}(z(\boldsymbol{u}^*)) = \rho^2$ and $\boldsymbol{u}_{\max}(z(\boldsymbol{u}^*)) = \boldsymbol{u}^*$, which suggests the following fixed point algorithm:

Let $\boldsymbol{u}^0 \in X$ be our initial guess; for $k \geq 0$, define

$$\boldsymbol{u}^{k+1} = \boldsymbol{u}_{\max}\left(z(\boldsymbol{u}^k)\right), \qquad \lambda^{k+1} = \lambda_{\max}\left(z(\boldsymbol{u}^k)\right).$$

A fixed point of this algorithm is not necessarily the supremizer of (6.4), but it is at least a local supremizer. In fact

$$\lambda^{k+1} - \lambda^k = |\boldsymbol{u}^{k-1}|_4^2 \int_\Omega (z(\boldsymbol{u}^{k-1}) - z(\boldsymbol{u}^{k-2}))z(\boldsymbol{u}^{k-1}) + o(\|z(\boldsymbol{u}^{k-1}) - z(\boldsymbol{u}^{k-2})\|^2_{L^2(\Omega)}),$$

and, since $\|z(\boldsymbol{v})\|_{L^2(\Omega)} = 1$,

$$\int_\Omega (z(\boldsymbol{u}^{k-1}) - z(\boldsymbol{u}^{k-2}))z(\boldsymbol{u}^{k-1}) \geq 0;$$

if $z(\boldsymbol{u}^{k-1})$ and $z(\boldsymbol{u}^{k-2})$ are not parallel (i.e, not equal), this integral is strictly positive.

The most critical point of this algorithm is hence the initial guess. To provide a robust initial guess, we first look for the maximizing mode in the low-dimensional subspace generated by the eigenmodes of $T_N^{\overline{\boldsymbol{\mu}}}$ and the already computed supremizers of (6.4). We apply our algorithm in this space, and we select our initial guesses among the basis elements (i.e., among the eigenmodes of $T_N^{\overline{\boldsymbol{\mu}}}$ and the supremizers of (6.4)). This process depends on the order that we choose in $\mathcal{V}^K$; to relax this dependency, when the computations are completed for all $\overline{\boldsymbol{\mu}}$ in $\mathcal{V}^K$, we store the modes and restart the computation of all of the embedding constants. The last picture in Figure 2 shows the embedding constants and the comparison with the quotient (6.4) of the stored modes. In Figure 3 note how, for a high Grashof number, $\rho_{\overline{\boldsymbol{\mu}}}$ deflates significantly from its upper bound $\rho_X/\beta(\boldsymbol{\mu})$.

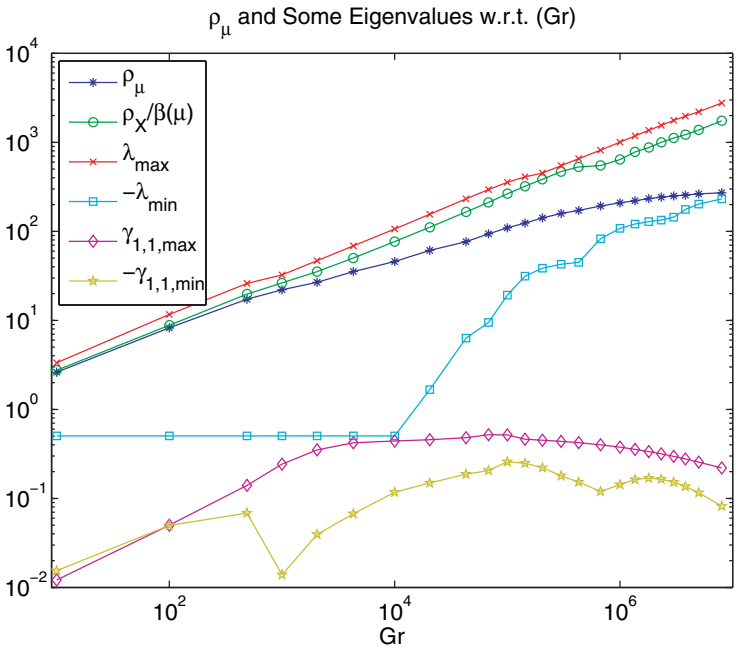

FIG. 3. *Plot of* $\rho_{\overline{\boldsymbol{\mu}}}$, $\rho_X/\beta(\overline{\boldsymbol{\mu}})$, $\lambda^{\overline{\boldsymbol{\mu}}}_{1,\inf|\sup}$, *and* $\gamma^{\overline{\boldsymbol{\mu}}}_{1,1,\inf|\sup}$. *Note that* $\rho_{\overline{\boldsymbol{\mu}}} \leq \rho_X/\beta(\overline{\boldsymbol{\mu}})$ *and that they are similar for a low Grashof number, but that at a higher Grashof number the difference is almost of one order of magnitude. This encourages one to use the mixed formulation of the Brezzi–Rappaz–Raviart theory.*

7. Numerical results.

7.1. Finite element solver. We implemented a parallel finite element solver that uses the Trilinos [36] library, in particular Epetra as MPI interface, Amesos [31, 30] as dense direct solver, Aztec00 as linear iterative solver with domain decomposition preconditioners from IFPACK [29], and Anasazi as eigenvalue solver, in particular LOBPCG [10].

We exploited the PSC resources [37].

We used Taylor–Hood P1/P2 finite elements for a total of 38000 degrees of freedom. We modified a preconditioner proposed by Elman, David, and Wathen [5]: At a point $\boldsymbol{u} \in X$, we define P^0 as $da(\boldsymbol{u}, \boldsymbol{\mu})$ where the divergence operator is replaced by the pressure mass matrix on the pressure block diagonal. We then construct a one-level Schwarz preconditioner P [29, 28] to P^0 and perform a local LU factorization. We solve the Jacobian system with restarted PGMRES(500) with preconditioner P. The resulting operator P, which depends on $\boldsymbol{u}$ and $\boldsymbol{\mu}$, is fast, distributed, and an effective preconditioner for our problem up to $\mathrm{Gr} = 10^7$.

We are interested in one solution branch; therefore, we use homotopy with respect to the Grashof number when solving the finite element problem. In contrast, in our example, the reduced basis problem does not need homotopy: Our initial guess is a known solution for a nearby parameter (a solution that has generated our reduced space).

In Figures 4 and 5 we present the streamlines and the profiles for an increasing Grashof number. We note the development of two vortices and a boundary layer against the wall. We also show the behavior of the Reynolds number (given by

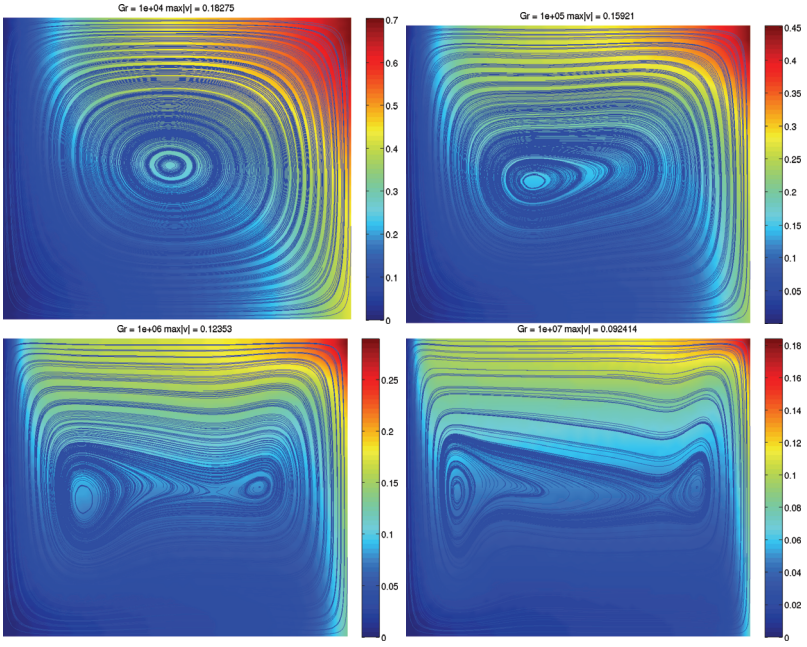

FIG. 4. *Streamlines at Grashof number* 10^4, 10^5, 10^6, *and* 10^7.

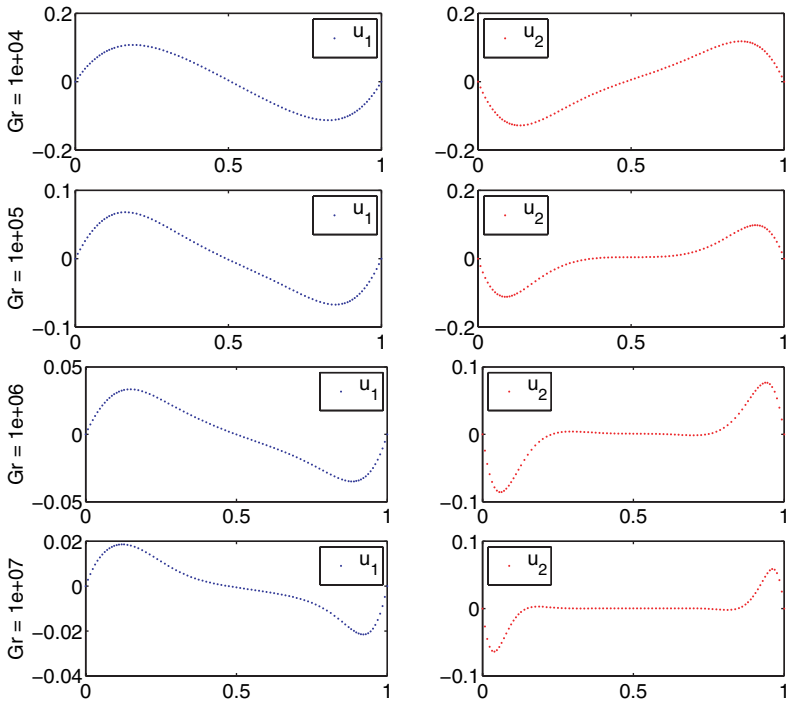

FIG. 5. *Profiles at Grashof number* 10^4, 10^5, 10^6, *and* 10^7. *On the left is the vertical central section, on the right the horizontal one.*

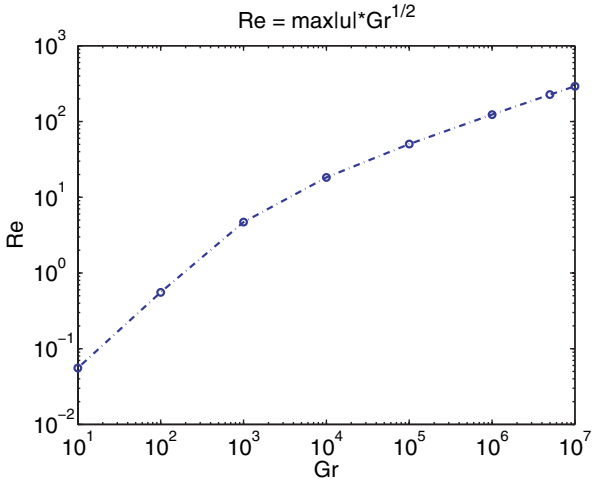

FIG. 6. *Approximative relation between Grashof and Reynolds numbers.*

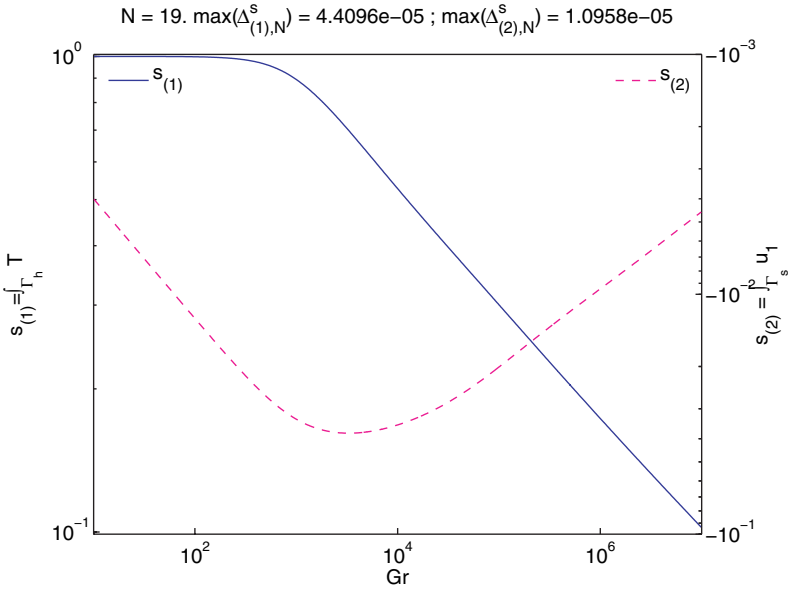

FIG. 7. *Outputs* $s_{(1)}(\boldsymbol{\mu}) = \frac{1}{|\Gamma_h|}\int_{\Gamma_h}\theta(\boldsymbol{\mu})$ *and* $s_{(2)}(\boldsymbol{\mu}) = \frac{1}{|\Gamma_s|}\int_{\Gamma_s}u_1(\boldsymbol{\mu})$ *with* $N = N_{\max} = 2{+}4{\cdot}19$.

$\sqrt{\mathrm{Gr}}\cdot\max|(u_1,u_1)|$) with respect to the Grashof number (Figure 6) and our outputs (Figure 7, computed by the reduced basis method).

The offline computation, i.e., the computation of the reduced basis and the inf-sup lower bound ingredients, required about 36 wall-time hours on a 16 CPU cluster.

7.2. Reduced basis resolution and error bounds. Table 1 compares the CPU time needed by an online reduced basis resolution and a finite element resolution. In the latter, we optimize the initial guess by taking the reduced basis solution such that the X-dual norm of the residual is already below 10^{-6} and two Newton iterations

TABLE 1

Convergence rate and CPU time comparison over 1000 *random samples (different for different* N*).* $\tau_{N,\overline{\boldsymbol{\mu}}}(\boldsymbol{\mu}) = \infty$ *means that for some parameters our inf-sup lower bound is negative. The maximal error bounds are taken over the samples for which we can provide existence and unicity. The RBcpu counts the mean CPU time for solving the reduced basis plus the time to compute the error bound (dual norm of the residual and inf-sup lower bounds); the FEcpu counts the mean CPU time for computing the finite element solution with a dual norm of the residual smaller than* 10^{-10} *and the reduce basis solution as the initial guess.*

are usually enough to reduce it to 10^{-10}. Although this optimization is very generous with the finite element code, the wall time is about two orders of magnitude smaller when using the reduced basis method. Moreover, the online reduced basis problem can be solved on a notebook (one CPU and about 1 GB of memory), while the finite element problem has been solved on a cluster using 16 CPUs.

Once $\tau_{N,\overline{\boldsymbol{\mu}}}(\boldsymbol{\mu}) \leq 1$, our greedy algorithm seeks for a reduction in the error, not in $\tau_{N,\overline{\boldsymbol{\mu}}}(\boldsymbol{\mu})$ itself; our random set changes at every new search, which explains why in the last two lines of the table $\tau_{N,\overline{\boldsymbol{\mu}}}(\boldsymbol{\mu})$ increases.

Figure 8 shows that our inf-sup lower bound is everywhere between 0.1 and 1. We also recognize the elements of $\mathcal{V}^K = \{\overline{\boldsymbol{\mu}}_1, \ldots, \overline{\boldsymbol{\mu}}_{24}\}$ where $\overline{B}^{LB}_{\overline{\boldsymbol{\mu}}}(\boldsymbol{\mu}) = 1$.

The error bounds for $N = 2{+}4{\cdot}19$ are small, and, also important, the effectivities are small thanks to our natural norms approach (cf. (3.15) and Figure 9). Note how the error bounds are closely related to the parameters that generate our reduced basis,

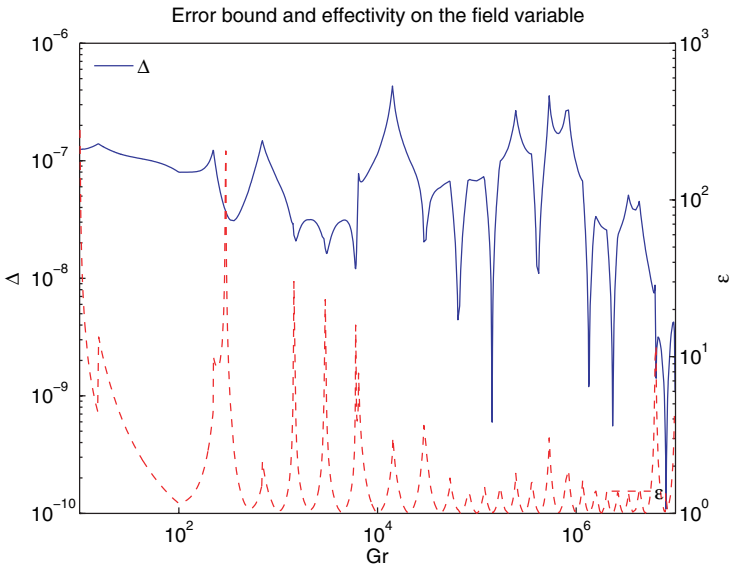

FIG. 9. *Error bound and effectivities* $\Delta_N/\|u-u_N\|_{\overline{\boldsymbol{\mu}}}$ *over* 1000 *random samples,* $N = N_{\max} = 2{+}4{\cdot}19$.

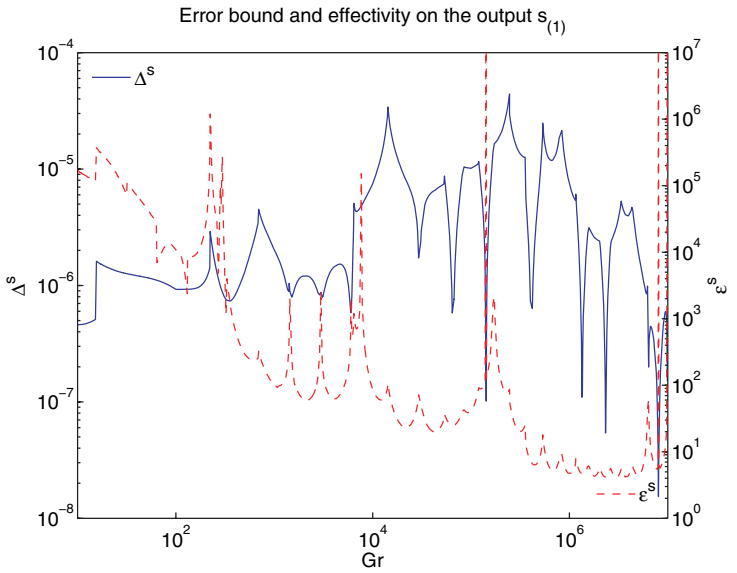

FIG. 10. *Error bound and effectivities* $\Delta_N^s/|s-s_N|$ *over* 1000 *random samples for output* $s_{(1)}$, $N = N_{\max} = 2{+}4{\cdot}19$.

while the effectivities are closely related to the inf-sup lower bound (Figure 8). Since our inf-sup lower bound is better "nearby a $\overline{\boldsymbol{\mu}}$" (cf. (4.1) and (4.2)) the effectivity is better "nearby a $\overline{\boldsymbol{\mu}}$."

In Figure 7 we show our outputs $s_{(1)}$ and $s_{(2)}$ with respect to the Grashof number, computed with our reduced basis on 1000 random points; the error bound is always smaller than $5{\cdot}10^{-5}$. The effectivities for the first output (Figure 10) are less sharp than for the field variable; anyway, when the error bound is small, a "bad" effectivity is acceptable, and when the error bound is the largest, the effectivity is good.

8. Conclusions. We have modified the Brezzi–Rappaz–Raviart theory and defined the natural norm in the quadratic case; the latter enables a feasible and locally sharp inf-sup lower bound construction. These three components provide a fast and feasible error bound computation, which is essential in both the online and the offline stages of the reduced basis method. Our approach has proven good effectivities in the field variable error bounds and empirical good effectivities in the output error bounds.

One essential point is that the error bounds—with respect to the *truth* finite element solution—are exact; hence, the computation of the inf-sup lower bound components have to be exact, too. We have developed an algorithm to remedy a robust Sobolev embedding constant computation.

We are hence able, first, to prepare all of the inf-sup lower bound components offline with a clear methodology and in a reasonable CPU wall time and, second, to solve online quadratic partial differential equations—natural convection with a Grashof number up to 10^7—and provide fast and reliable error bounds, with gains in term of online resources—a notebook against a 16 processor cluster—and in terms of CPU wall time—two orders of magnitude.

Future work will be to show that even in the multiparameter case our approach is feasible; i.e., the offline CPU time is acceptable and the online performance is not affected (preliminary tests with Grashof and Prandl numbers as parameters are promising), including in the presence of geometrical changes (where, e.g., the aspect ratio of the cavity is a further parameter).

We have presumed that the (parameter-dependent) solution lays on an isolated branch. The natural norm approach should also allow us to consider bifurcations since with respect to the "local" norm the inf-sup constant is of order one. Nevertheless, the natural norm degenerates near the bifurcation because of a singular mode. This mode probably has to be treated by deflation, and the eigenvalue solver should take into account the norm degeneration.

Appendix. Dual approximation. In addition to our "truth" primal problem, we may also consider a "truth" dual (or adjoint) problem [23, 14, 3, 21, 33, 32] associated with our particular output functional to improve the convergence of the output.

In this section we consider the case of the quadratic, parameter-independent output (the extension to the linear or the affine-dependent cases is straightforward)

$$\ell(\boldsymbol{v}) = \ell_0(\boldsymbol{v}) - \ell_1(\boldsymbol{v}, \boldsymbol{v}),$$

where ℓ_0 is continuous and linear and ℓ_1 continuous, symmetric, and bilinear.

For a given approximation $\boldsymbol{u}_N(\boldsymbol{\mu})$ in W_N to $\boldsymbol{u}(\boldsymbol{\mu})$, the dual problem reads: Find $\boldsymbol{\psi}^N$ in X such that

$$da(\boldsymbol{u}_N(\boldsymbol{\mu}); \boldsymbol{\mu})(\boldsymbol{v}, \boldsymbol{\psi}^N(\boldsymbol{\mu})) = -\ell_0(\boldsymbol{v}) - 2\ell_1(\boldsymbol{u}_N(\boldsymbol{\mu}), \boldsymbol{v}) \quad \forall \boldsymbol{v} \in X. \tag{A.1}$$

We apply our reduced basis method to solve the dual problem (A.1) and solve for the reduced basis solution $\boldsymbol{\psi}_N^N(\boldsymbol{\mu})$ in W_N^{du} such that

$$da(\boldsymbol{u}_N(\boldsymbol{\mu}); \boldsymbol{\mu})(\boldsymbol{v}, \boldsymbol{\psi}_N^N(\boldsymbol{\mu})) = -\ell_0(\boldsymbol{v}) - 2\ell_1(\boldsymbol{u}_N(\boldsymbol{\mu}), \boldsymbol{v}) \quad \forall \boldsymbol{v} \in W_N^{du},$$

where W_N^{du} (in general different from W_N) is a reduced basis space of dimension N (for simplicity in this presentation, we consider the same dimension for the reduced

primal and dual spaces). We denote the primal and dual residuals as

$$\begin{aligned} r(\boldsymbol{v};\boldsymbol{\mu}) &= a(\boldsymbol{u}(\boldsymbol{\mu}),\boldsymbol{v};\mu) - a(\boldsymbol{u}_N(\boldsymbol{\mu}),\boldsymbol{v};\boldsymbol{\mu}) = f(\boldsymbol{v}) - a(\boldsymbol{u}_N(\boldsymbol{\mu}),\boldsymbol{v};\boldsymbol{\mu}) \quad \forall \boldsymbol{v}\in X,\\ r^{N,du}(\boldsymbol{v};\boldsymbol{\mu}) &= da(\boldsymbol{u}_N(\boldsymbol{\mu});\boldsymbol{\mu})(\boldsymbol{v},\boldsymbol{\psi}^N(\boldsymbol{\mu})) - da(\boldsymbol{u}_N(\boldsymbol{\mu});\boldsymbol{\mu})(\boldsymbol{v},\boldsymbol{\psi}_N^N(\boldsymbol{\mu}))\\ &= -\ell_0(\boldsymbol{v}) - 2\ell_1(\boldsymbol{u}_N(\boldsymbol{\mu}),\boldsymbol{v}) - da(\boldsymbol{u}_N(\boldsymbol{\mu});\boldsymbol{\mu})(\boldsymbol{v},\boldsymbol{\psi}_N^N(\boldsymbol{\mu})) \quad \forall \boldsymbol{v}\in X, \end{aligned}$$

respectively, and the primal error as $\boldsymbol{e}(\boldsymbol{\mu}) = \boldsymbol{u}(\boldsymbol{\mu}) - \boldsymbol{u}_N(\boldsymbol{\mu})$. We define the dual corrected output as

$$s_N^{N,du}(\boldsymbol{\mu}) = \ell(\boldsymbol{u}_N(\boldsymbol{\mu})) - r(\boldsymbol{\psi}_N^N(\boldsymbol{\mu});\boldsymbol{\mu}).$$

The following lemma holds.

LEMMA A.1.

$$\begin{aligned} &s(\boldsymbol{\mu}) - s_N^{N,du}(\boldsymbol{\mu})\\ &= \ell_1(\boldsymbol{e}(\boldsymbol{\mu}),\boldsymbol{e}(\boldsymbol{\mu})) - r^{N,du}(\boldsymbol{e}(\boldsymbol{\mu});\boldsymbol{\mu}) + \frac{1}{2}\Big[da(\boldsymbol{u}(\boldsymbol{\mu});\boldsymbol{\mu}) - da(\boldsymbol{u}_N(\boldsymbol{\mu});\boldsymbol{\mu})\Big](\boldsymbol{e}(\boldsymbol{\mu}),\boldsymbol{\psi}_N^N(\boldsymbol{\mu})). \end{aligned} \tag{A.2}$$

Proof.

$$\begin{aligned} s(\mu) - s_N^{N,du}(\mu) &= \ell_0(\boldsymbol{u}(\boldsymbol{\mu})) - \ell_0(\boldsymbol{u}_N(\boldsymbol{\mu})) + \ell_1\left(\boldsymbol{u}(\boldsymbol{\mu}) - \boldsymbol{u}_N(\boldsymbol{\mu}), \boldsymbol{u}(\boldsymbol{\mu}) - \boldsymbol{u}_N(\boldsymbol{\mu})\right)\\ &\quad + 2\,\ell_1\left(\boldsymbol{u}(\boldsymbol{\mu}) - \boldsymbol{u}_N(\boldsymbol{\mu}), \boldsymbol{u}_N(\boldsymbol{\mu})\right) + r(\boldsymbol{\psi}_N^N(\boldsymbol{\mu});\boldsymbol{\mu})\\ &= \ell_0(\boldsymbol{e}(\boldsymbol{\mu})) + \ell_1\left(\boldsymbol{e}(\boldsymbol{\mu}),\boldsymbol{e}(\boldsymbol{\mu})\right) + 2\,\ell_1\left(\boldsymbol{u}_N(\boldsymbol{\mu}),\boldsymbol{e}(\boldsymbol{\mu})\right)\\ &\quad + a(\boldsymbol{u}(\boldsymbol{\mu}),\boldsymbol{\psi}_N^N(\boldsymbol{\mu});\boldsymbol{\mu}) - a(\boldsymbol{u}_N(\boldsymbol{\mu}),\boldsymbol{\psi}_N^N(\boldsymbol{\mu});\boldsymbol{\mu})\\ &= \ell_1(\boldsymbol{e}(\boldsymbol{\mu}),\boldsymbol{e}(\boldsymbol{\mu})) - r^{N,du}(\boldsymbol{e}(\boldsymbol{\mu});\boldsymbol{\mu}) - da(\boldsymbol{u}_N(\boldsymbol{\mu});\boldsymbol{\mu})\left(\boldsymbol{e}(\boldsymbol{\mu}),\boldsymbol{\psi}_N^N(\boldsymbol{\mu})\right)\\ &\quad + \frac{1}{2}\Big[da(\boldsymbol{u}(\boldsymbol{\mu});\boldsymbol{\mu}) + da(\boldsymbol{u}_N(\boldsymbol{\mu});\boldsymbol{\mu})\Big](\boldsymbol{e}(\boldsymbol{\mu}),\boldsymbol{\psi}_N^N(\boldsymbol{\mu})). \qquad \square \end{aligned}$$

We are now able to compute an upper bound for the dual corrected output. Let

$$\begin{aligned} |||\ell_1|||_{\overline{\boldsymbol{\mu}}\overline{\boldsymbol{\mu}}} &\equiv \sup_{\boldsymbol{v}\in X} \frac{|\ell_1(\boldsymbol{v},\boldsymbol{v})|}{|||\boldsymbol{v}|||_{\overline{\boldsymbol{\mu}}}^2},\\ \|r^{N,du}(\cdot;\boldsymbol{\mu})\|_{\overline{\boldsymbol{\mu}}'} &\equiv \sup_{\boldsymbol{v}\in X} \frac{|r^{N,du}(\boldsymbol{v};\boldsymbol{\mu})|}{|||\boldsymbol{v}|||_{\overline{\boldsymbol{\mu}}}}, \end{aligned} \tag{A.3}$$

and

$$\Delta_{N,\overline{\mu}}^s(\mu) \equiv \|r^{N,du}(\cdot;\boldsymbol{\mu})\|_{\overline{\boldsymbol{\mu}}'}\Delta_{N,\overline{\boldsymbol{\mu}}}(\boldsymbol{\mu}) + \left(\frac{1}{2}\rho_{\overline{\boldsymbol{\mu}}}(\boldsymbol{\mu})\|\boldsymbol{\psi}_N^N(\boldsymbol{\mu})\|_X + |||\ell_1|||_{\overline{\boldsymbol{\mu}}\overline{\boldsymbol{\mu}}}\right)\Delta_{N,\overline{\boldsymbol{\mu}}}(\boldsymbol{\mu})^2. \tag{A.4}$$

Then, from (2.8), (3.14), (A.2), and (A.3), the following output error bound holds.

THEOREM A.2.

$$|s(\boldsymbol{\mu}) - s_N^{N,du}(\boldsymbol{\mu})| \le \Delta_{N,\overline{\boldsymbol{\mu}}}^s(\boldsymbol{\mu}).$$

As we expect from the dual approach, the error bound is quadratic with respect to the dual norm of the residuals r and $r^{N,du}$. The main advantage of (A.4) is that there is no dependence on $\beta(\overline{\boldsymbol{\mu}})$, which is the square root of the worse mode of $T_N^{\overline{\boldsymbol{\mu}}}$;

however, this mode may be hidden behind other terms like the natural dual norm of the dual residual or $\rho_{\overline{\boldsymbol{\mu}}}(\boldsymbol{\mu})$ (both explicitly) or in $\Delta_{N,\overline{\boldsymbol{\mu}}}(\boldsymbol{\mu})$.

Note that, to simplify the offline work, the term $\|r^{N,du}(\cdot;\boldsymbol{\mu})\|_{\overline{\boldsymbol{\mu}}'}$ may also be replaced by using

$$\|r^{N,du}(\cdot;\boldsymbol{\mu})\|_{\overline{\boldsymbol{\mu}}'} \leq \frac{1}{\beta(\overline{\boldsymbol{\mu}})}\|r^{N,du}(\cdot;\boldsymbol{\mu})\|_{X'}$$

at the detriment of the independency on $\beta(\overline{\boldsymbol{\mu}})$.

Acknowledgments. I thank Professor Anthony T. Patera for his valuable comments and many contributions. I am grateful to Dr. Karen Veroy–Grepl and Dr. Gianluigi Rozza for many discussions on the subject.

A POSTERIORI ANALYSIS AND IMPROVED ACCURACY FOR AN OPERATOR DECOMPOSITION SOLUTION OF A CONJUGATE HEAT TRANSFER PROBLEM*

D. ESTEP†, S. TAVENER‡, AND T. WILDEY‡

Abstract. We consider the accuracy of an operator decomposition finite element method for a conjugate heat transfer problem consisting of two materials coupled through a common boundary. We derive accurate a posteriori error estimates that account for the transfer of error between components of the operator decomposition method as well as the differences between the adjoints of the full problem and the discrete iterative system. We use these estimates to guide adaptive mesh refinement. In addition, we address a loss of order of convergence that results from the decomposition and show that the order of convergence is limited by the accuracy of the transferred gradient information. We employ a boundary flux recovery method to regain the expected order of accuracy in an efficient manner.

Key words. a posteriori error analysis, adaptive mesh refinement, adjoint problem, boundary flux method, conjugate heat transfer, domain decomposition, finite element method, generalized Green's function, goal-oriented error estimates, operator decomposition, residual, transfer error

1. Introduction.

In this paper, we consider the solution of a conjugate heat transfer problem by an operator decomposition approach. The goal is to compute a functional of the temperature of a body composed of two distinct components that share a common boundary or interface. The two components may have different conductivities and be subject to different heat sources and boundary conditions. Our problem therefore consists of a pair of elliptic boundary value problems that are coupled through boundary conditions posed at the common interface. More generally, our interest is in situations where there is a small number of interfaces between the components.

One approach to solve a conjugate heat transfer problem is to directly discretize the system of coupled elliptic problems and to solve the resulting large global system. However, there are situations in which this approach is infeasible, e.g., because of the size of the full global system or because different numerical methods and codes are to be used for the component problems. Operator decomposition provides an alternative strategy to solving the fully coupled system. We compute the solution in each component individually subject to the conditions on the common interface that

are obtained from a numerical solution of the other component. Obtaining a solution of the full system by operator decomposition therefore requires a (nominally) infinite iteration in which updated boundary conditions are passed between components.

Operator decomposition is a widely used technique for solving multiphysics, multiscale problems. The general approach is to decompose the problem into components involving simpler physics over a relatively limited range of scales and then to seek the solution of the entire system through an iterative procedure involving solutions of the individual components. This approach is appealing because there is generally a good understanding of how to solve a broad spectrum of single physics problems accurately and efficiently and because it provides an alternative to accommodating multiple scales in one discretization. In some situations, operator decomposition can be viewed as domain decomposition that allows for very different discretizations in each component. However, operator decomposition presents an entirely new set of accuracy and stability issues, some of which are obvious and some subtle and all of which are difficult to correct. In the case of the conjugate heat transfer, the operator decomposition causes a loss in the order of the numerical approximation.

In this paper, we perform an a posteriori error analysis of a finite element implementation of the operator decomposition technique and obtain accurate error estimates that are used to guide an adaptive discretization strategy. Our approach is based on the standard techniques using variational analysis, residuals, and the generalized Green's function solution to an adjoint problem [3, 6, 15, 17, 18, 22], which we modify to account for several new features arising from the operator decomposition. These include the following:

- Numerical errors in the solution of each component are propagated to the other component through the boundary conditions that are applied.
- Numerical errors in the solution of each of the components at one step of the iterative procedure are propagated to the next step.
- The adjoint of the full problem and the adjoint of the iterative procedure are distinct operators whose differences must be recognized when seeking to obtain accurate error estimates.

These kinds of effects are characteristic of operator decomposition discretizations, e.g., [9, 10, 14], and generally require extensions of the usual a posteriori analysis techniques.

In addition to obtaining accurate estimates, we seek to improve the accuracy of the operator decomposition method in an efficient way. In particular, we adapt the "boundary flux recovery" technique developed by Wheeler [26] and Carey [7, 8] to compute normal derivatives on a boundary and show that this can be used to improve accuracy and, in particular, restore the order of convergence of the numerical approximation that is lost due to the operator decomposition.

The operator decomposition method we consider is closely related to the nonoverlapping domain decomposition methods as described in, for example, [24, 29, 25, 30]. The major concern of these authors is, however, the convergence of different iterative methods and the design of effective preconditioners or relaxation parameters, while the accuracy of the final finite element approximation is usually not addressed, despite the fact that some of the numerical results indicate a loss of accuracy. To our knowledge, this paper is the first to address the loss of accuracy. Our results would extend to this particular type of nonoverlapping domain decomposition.

In section 2, we introduce the conjugate heat transfer problem and provide some notation. We describe the iterative operator decomposition finite element method

and some modifications in section 3, as well as the boundary flux recovery method used to compute gradients on the common interface. We perform two a posteriori error analyses in section 4, by using first the adjoint to the fully coupled problem and then the adjoint to the iterative scheme, and present numerical results to highlight the differences between the two. We end the section with a brief discussion of adaptive mesh refinement. In section 5, we carry out an analysis which identifies the transferred gradient information as being responsible for the loss of order of the numerical approximation and show that using the recovered boundary flux restores the order of convergence. Our conclusions are presented in section 6.

2. The model for conjugate heat transfer. Let Ω_1 and Ω_2 be polygonal domains in $\mathbb{R}^2$ or $\mathbb{R}^3$ with boundaries $\partial\Omega_1$ and $\partial\Omega_2$, respectively, intersecting along an interface $\Gamma = \partial\Omega_1 \cap \partial\Omega_2$. We consider a system of second order linear elliptic problems, where the components are coupled through boundary conditions imposed on Γ,

$$\begin{cases} L_1 u_1 = f_1, & \mathbf{x} \in \Omega_1, \\ u_1 = 0, & \mathbf{x} \in \partial\Omega_1 \backslash \Gamma, \\ \begin{cases} u_1 = u_2, \\ A_1 \partial_n u_1 = A_2 \partial_n u_2, \end{cases} & \mathbf{x} \in \Gamma, \\ L_2 u_2 = f_2, & \mathbf{x} \in \Omega_2, \\ u_2 = 0, & \mathbf{x} \in \partial\Omega_2 \backslash \Gamma, \end{cases} \tag{2.1}$$

where, for $i = 1, 2$, $L_i u_i = -\nabla \cdot (A_i \nabla u_i) + c_i u_i$, $A_i \geq A_{i,0} > 0, c_i, f_i$ are sufficiently smooth functions and ∂_n is the partial derivative in the direction of the unit normal vector that is directed outwards from $\partial\Omega_1$. The results of this paper extend easily to general elliptic operators and general Dirichlet, Neumann, and Robin boundary conditions on the boundaries in the complement of the interface.

We let $L^2(\Omega_i)$ denote the space of square integrable functions on Ω_i with inner product $(\cdot,\cdot)_{\Omega_i}$ and norm $\|\cdot\|_{\Omega_i}$, but we use $(\cdot,\cdot) = (\cdot,\cdot)_{\Omega_i}$ when the domain is clear. We use $H^s(\Omega_i)$ to denote the Sobolev space with real index s associated with the norm $\|\cdot\|_{\Omega_i,s}$ and seminorm $|\cdot|_{\Omega_i,s}$. We also use the subspaces $H_0^1(\Omega_i) = \left\{v \in H^1(\Omega_i), v = 0 \text{ on } \partial\Omega_i \backslash \Gamma\right\}$.

The weak formulation of (2.1) seeks $u_i \in H_0^1(\Omega_i)$ such that $u_1 = u_2$ on Γ and

$$\sum_{i=1}^{2} a_i(u_i, v_i) = \sum_{i=1}^{2} (f_i, v_i) \tag{2.2}$$

for all $v_i \in H_0^1(\Omega_i)$, with $a_i(u_i, v) = \int_{\Omega_i} (A_i \nabla u_i \cdot \nabla v + c_i u_i v)\, dx$ for $i = 1, 2$. By assuming that each $a_i(\cdot,\cdot)$ is coercive, (2.2) admits a unique weak solution in $H_0^1(\Omega_i)$ [2, 5, 11].

3. An iterative operator decomposition method. We consider iterative operator decomposition methods to compute the numerical solution of (2.1). Let $u_2^{(0)}$ be an initial guess for the Dirichlet data along the interface. We solve

$$\begin{cases} L_1 u_1^{\{k\}} = f_1, & \mathbf{x} \in \Omega_1, \\ u_1^{\{k\}} = 0, & \mathbf{x} \in \partial\Omega_1 \backslash \Gamma, \\ u_1^{\{k\}} = u_2^{\{k-1\}}, & \mathbf{x} \in \Gamma, \end{cases} \tag{3.1}$$

followed by

$$\begin{cases} L_2 u_2^{\{k\}} = f_2, & \mathbf{x} \in \Omega_2, \\ u_2^{\{k\}} = 0, & \mathbf{x} \in \partial\Omega_2 \backslash \Gamma, \\ A_1 \partial_n u_1^{\{k\}} = A_2 \partial_n u_2^{\{k\}}, & \mathbf{x} \in \Gamma, \end{cases} \tag{3.2}$$

for $k = 1, 2, \ldots, N$, and iterate until (hopefully) a convergence criteria is satisfied. Throughout this paper, we iterate until $\|u_1^{\{k\}} - u_2^{\{k\}}\|_\Gamma$ is less than a prescribed tolerance, i.e., until the continuity condition in the fully coupled problem is satisfied to within a given tolerance.

3.1. Finite element discretization. We let $T_{i,h}$ be a triangulation of Ω_i into elements K where the length of the longest edge is h_K and $h = \max_{K \in T_{i,h}} h_K$. We assume that each triangulation is locally quasi-uniform and $\overline{\Omega}_i = \cup_{K \in T_{i,h}} K$. However, the triangulations on either side of Γ are not assumed to be aligned.

We use the piecewise polynomial spaces

$$S_1 = \left\{ v \text{ continuous on } \Omega_1,\ v \in P^1(K) \text{ for all } K \in T_{1,h} \right\},$$
$$S_2 = \left\{ v \text{ continuous on } \Omega_2,\ v \in P^1(K) \text{ for all } K \in T_{2,h} \right\}$$

and the associated spaces

$$S_{1,0} = \left\{ v \in S_1 \mid v = 0, \mathbf{x} \in \partial\Omega_1 \right\},$$
$$S_{2,0} = \left\{ v \in S_2 \mid v = 0, \mathbf{x} \in \partial\Omega_2 \backslash \Gamma \right\},$$

where $P^1(K)$ denotes the space of linear polynomials on an element K. We let π_i be a projection into S_i as well as the projection into S_i along the interface Γ.

For the finite element approximation, given $U_2^{\{0\}}$ along Γ, compute $U_1^{\{k\}} \in S_1$ satisfying

$$\begin{cases} a_1(U_1^{\{k\}}, v) = (f_1, v)_{\Omega_1} & \text{for all } v \in S_{1,0}, \\ U_1^{\{k\}} = 0, & \mathbf{x} \in \partial\Omega_1 \backslash \Gamma, \\ U_1^{\{k\}} = \pi_1 U_2^{\{k-1\}}, & \mathbf{x} \in \Gamma, \end{cases} \tag{3.3}$$

followed by $U_2^{\{k\}} \in S_2$ such that

$$\begin{cases} a_2(U_2^{\{k\}}, v) = (f_2, v)_{\Omega_2} - (A_1 \partial_n U_1^{\{k\}}, v)_\Gamma & \text{for all } v \in S_{2,0}, \\ U_2^{\{k\}} = 0, & \mathbf{x} \in \partial\Omega_2 \backslash \Gamma, \end{cases} \tag{3.4}$$

for $k = 1, 2, \ldots, N$, and iterate until $\|U_1^{\{k\}} - \pi_1 U_2^{\{k\}}\|_\Gamma$ is smaller than a given tolerance.

3.2. Relaxed iterations. Unfortunately, the simple iterative given by (3.3)–(3.4) may not converge. In particular, the convergence depends on the values of A_1 and A_2 along the interface and the geometry of each region [21, 24, 29]. As a result, we also consider the following relaxation scheme.

We choose $\alpha \in [0, 1)$ and update the Dirichlet interface values with

$$U_1^{\{k\}} = \alpha U_1^{\{k-1\}} + (1 - \alpha) \pi_1 U_2^{\{k-1\}}. \tag{3.5}$$

Optimal values of α can be found in [24, 29] for $A_1 = A_2$, but optimal relaxation parameters are often difficult to find for the general problem. Recognition of this difficulty has prompted the development of, for example, Newton–Krylov methods [31, 16]. We do not pursue this issue further but rather choose to focus on analyzing the loss accuracy in the case that the iterations can be forced to converge.

3.3. Flux correction. In section 5, we show that operator decomposition results in a loss of order of convergence of the finite element solution with mesh size h. This is not completely unexpected due to the lower order of accuracy in the derivative, specifically $\mathbf{O}(h)$ rather than $\mathbf{O}(h^2)$ for the approximation spaces used here. This reduces the order of the overall approximation to first order. To mitigate this effect, we use a postprocessing technique developed by Wheeler [26] and Carey [7, 8] to compute a more accurate boundary flux.

We define the set of elements in $T_{1,h}$ that intersect the boundary by

$$T_{1,h}^{\Gamma} = \{K \in T_{1,h} \mid \overline{K} \cap \partial\Omega \neq \emptyset\}$$

and the corresponding space

$$W_h = \{v \in P^1(K) \text{ with } K \in T_{1,h}^{\Gamma},\ v(\eta_i) = 0 \text{ if } \eta_i \notin \partial\Omega\}, \tag{3.6}$$

where $\{\eta_i\}$ denotes the nodes of element K, so the degrees of freedom correspond to the nodes on the boundary. This space will arise later as the difference between a projection onto $T_{1,h}$ and a second projection onto $T_{1,h}$ that is also required to be zero on the boundary. We seek $\sigma^{\{k\}} \in W_h$ satisfying

$$-(\sigma^{\{k\}}, v)_{\Gamma} = (f_1, v)_{\Omega_1} - a_1(U_1^{\{k\}}, v) \quad \text{for all } v \in W_h, \tag{3.7}$$

where $U_1^{\{k\}}$ solves (3.3). Green's identity implies that $\sigma^{\{k\}}$ gives an approximation to the normal flux on the boundary which is relatively inexpensive to compute.

In general, the accuracy of the recovered boundary flux approximation depends on the regularity of an associated Green's function [20, 27]. In some cases, though perhaps not all, the postprocessed flux is $\mathbf{O}(h^2)$ rather than the standard $\mathbf{O}(h)$ for the normal flux of a piecewise linear finite element approximation. However, we show that the recovered boundary flux leads to a cancellation of the "transfer error" term in the error representation formula, which is the source of the loss of order. This fortunate cancellation of errors means that the accuracy of this recovered boundary flux is only of peripheral interest for our purposes.

We stress that $\sigma^{\{k\}}$ is not assumed to be continuous. In fact, if the domain has a corner on the boundary, the normal derivative is, in general, discontinuous due to the jump in the normal vector. When Dirichlet conditions are given on each boundary segment, we implement the method described in [8] and allow two degrees of freedom to account for the discontinuity. For the application to more general boundary conditions, such as a Neumann or Robin condition on one segment, or an interface condition on both, we refer the reader to [28].

Now, as an alternative to (3.4), we may solve

$$\begin{cases} a_2(U_2^{\{k\}}, v) = (f_2, v)_{\Omega_2} - (\sigma^{\{k\}}, v)_{\Gamma} & \text{for all } v \in S_{2,0}, \\ U_2^{\{k\}} = 0, & \mathbf{x} \in \partial\Omega_2 \backslash \Gamma. \end{cases} \tag{3.8}$$

Other possible approaches to mitigating the loss of order include approximating the boundary flux by using a gradient recovery technique such as the Zienkiewicz–Zhu patch recovery technique [33] or the polynomial-preserving recovery method [32] or by using higher order polynomials near the interface to improve the accuracy of the finite element flux [1, 22]. We had mixed computational success using these other approaches.

4. A posteriori error analysis. To estimate the error of the operator decomposition finite element approximation, we apply a posteriori techniques based on variational analysis and the adjoint problem. In this case, however, the adjoint for the fully coupled original problem differs significantly from the adjoint problem associated with the discretization of the decomposed system. The motivation to use operator decomposition suggests that the adjoint of the full problem is unavailable in practice, and therefore the decomposed adjoint needs to be used to compute error estimates. The difference between the adjoint problems can be reduced by increasing the computational work used to solve the decomposed adjoint; however, in practice, we must consider the issue that the two adjoints lead to significantly different error representations.

In order to understand the differences, we derive a posteriori error estimates by using both adjoints. Both analyses begin in the same way. We wish to estimate the difference between the exact solution to the full problem and the numerical approximation to the solution of the iterative procedure, i.e., $E^{\{k\}} = u - U^{\{k\}}$. We decompose the error:

$$E^{\{k\}} = u - U^{\{k\}} = \left(u - u^{\{k\}}\right) + \left(u^{\{k\}} - U^{\{k\}}\right) = c^{\{k\}} + e^{\{k\}}.$$

The first component $c^{\{k\}}$ measures the difference between the exact solution to the full problem and the exact solution to the iterative problem. If the iterative method converges, then $c^{\{k\}} \to 0$. The second component $e^{\{k\}}$ measures the numerical error in solving the iterative problem. The adjoint of the fully coupled system can be used to estimate the total error $E^{\{k\}}$, while the decomposed adjoint estimates $e^{\{k\}}$. The two estimates are nearly identical if $c^{\{k\}} \approx 0$.

It is helpful to remark that, in the conventional approach, the adjoint problem is defined in such a way as to make the formal bilinear identity hold [23, 19], i.e., to make the boundary terms arising from integration by parts equal to zero. In the analysis below, we find it convenient to consider the values passed between components as quantities of interest defined on the common boundary, and we have to alter the definition of the adjoint problem accordingly.

4.1. The adjoint to the fully coupled problem. The adjoint boundary value problem for the quantity of interest $(\boldsymbol{\psi}, \boldsymbol{u}) = (\psi_1, u_1) + (\psi_2, u_2)$ for the coupled problem (2.1) is

$$\begin{cases} L_1^* \phi_1 = \psi_1, & \mathbf{x} \in \Omega_1, \\ \phi_1 = 0, & \mathbf{x} \in \partial\Omega_1 \backslash \Gamma, \\ \begin{cases} \phi_1 = \phi_2, \\ A_1 \partial_n \phi_1 = A_2 \partial_n \phi_2, \end{cases} & \mathbf{x} \in \Gamma, \\ L_2^* \phi_2 = \psi_2, & \mathbf{x} \in \Omega_2, \\ \phi_2 = 0, & \mathbf{x} \in \partial\Omega_2 \backslash \Gamma, \end{cases} \tag{4.1}$$

where $L_i^* \phi_i = -\nabla \cdot (A_i \nabla \phi_i) + c_i \phi_i$. We solve (4.1) numerically by using an iterative operator decomposition approach as for the forward problem. The iterations are completely independent of the forward iterations.

We can derive an error representation formula for the basic scheme (3.1)–(3.2) and a weighted relaxation technique (3.5) or when using the postprocessed flux as in (3.8). In the discussion below, we use $\theta_h^{\{k\}}$ to denote the numerical flux passed at the kth iteration from Ω_1 to Ω_2.

To begin, we multiply by $(\psi_1, \psi_2)^T$, integrate, and apply the divergence theorem, noting that $u_1 = u_2$ and $A_1\partial_n\phi_1 = A_2\partial_n\phi_2$ along Γ, to obtain

$$(\psi_1, e_1) + (\psi_2, e_2) = a_1(e_1, \phi_1) + a_2(e_2, \phi_2) + (U_1^{\{k\}}, A_1\partial_n\phi_1)_\Gamma - (U_2^{\{k\}}, A_2\partial_n\phi_2)_\Gamma.$$

Observe that the test space $S_{1,0}$ consists of functions that are zero along the interface, while, in general, ϕ_1 is not zero along Γ. This means that the projection of ϕ_1 into $S_{1,0}$ cannot be the interpolant. We define a new projection $\pi_1^0 : H^2 \to S_{1,0}$ such that for any node x_i

$$\pi_1^0\phi(x_i) = \begin{cases} \pi_1\phi(x_i), & x_i \notin \Gamma, \\ 0, & x_i \in \Gamma. \end{cases} \tag{4.2}$$

We also observe that

$$a_2(e_2, \pi_2\phi_2) = -(A_1\partial_n u_1, \pi_2\phi_2)_\Gamma + (\theta_h^{\{k\}}, \pi_2\phi_2)_\Gamma,$$

and

$$a_1(u_1, \phi_1 - \pi_1^0\phi_1) = (f_1, \phi_1 - \pi_1^0\phi_1) + (A_1\partial_n u_1, \phi_1)_\Gamma,$$
$$a_2(u_2, \phi_2 - \pi_2\phi_2) = (f_2, \phi_2 - \pi_2\phi_2) - (A_1\partial_n u_1, \phi_2 - \pi_2\phi_2)_\Gamma,$$

since the adjoint solutions are not zero along Γ.

By using the projection (4.2) when invoking Galerkin orthogonality and the equalities above, we have

$$\begin{aligned}(\psi_1, e_1) + (\psi_2, e_2) = {} & (f_1, \phi_1 - \pi_1^0\phi_1) - a_1(U_1^{\{k\}}, \phi_1 - \pi_1^0\phi_1) \\ & + (f_2, \phi_2 - \pi_2\phi_2) - a_2(U_2^{\{k\}}, \phi_2 - \pi_2\phi_2) \\ & + (U_1^{\{k\}} - U_2^{\{k\}}, A_1\partial_n\phi_1)_\Gamma + (\theta_h^{\{k\}}, \pi_2\phi_2)_\Gamma.\end{aligned}$$

Next, we define $\pi_\partial\phi_1 = \pi_1\phi_1 - \pi_1^0\phi_1$, which is nonzero only near the interface due to the definition of $\pi_1^0\phi_1$ and is an element of W_h defined in (3.6). Substituting $\pi_1^0\phi_1 = \pi_1\phi_1 - \pi_\partial\phi_1$ gives

$$\begin{aligned}(\psi_1, e_1) + (\psi_2, e_2) = {} & (f_1, \phi_1 - \pi_1\phi_1) - a_1(U_1^{\{k\}}, \phi_1 - \pi_1\phi_1) \\ & + (f_2, \phi_2 - \pi_2\phi_2) - a_2(U_2^{\{k\}}, \phi_2 - \pi_2\phi_2) \\ & + (f_1, \pi_\partial\phi_1) - a_1(U_1^{\{k\}}, \pi_\partial\phi_1) \\ & + (U_1^{\{k\}} - U_2^{\{k\}}, A_1\partial_n\phi_1)_\Gamma + (\theta_h^{\{k\}}, \pi_2\phi_2)_\Gamma.\end{aligned}$$

Finally (3.7) implies that the recovered boundary flux $\sigma^{\{k\}}$ satisfies

$$-(\sigma^{\{k\}}, \pi_\partial\phi_1)_\Gamma = (f_1, \pi_\partial\phi_1)_{\Omega_1} - a_1(U_1^{\{k\}}, \pi_\partial\phi_1).$$

Since $\pi_\partial\phi_1 = \pi_1\phi_1$ along Γ, we conclude the following result.

THEOREM 4.1. *The errors $e_1 = u_1 - U_1^{\{k\}}$ and $e_2 = u_2 - U_2^{\{k\}}$ satisfy*

$$\begin{aligned}(\psi_1, e_1) + (\psi_2, e_2) = {} & (f_1, \phi_1 - \pi_1\phi_1) - a_1(U_1^{\{k\}}, \phi_1 - \pi_1\phi_1) \\ & + (f_2, \phi_2 - \pi_2\phi_2) - a_2(U_2^{\{k\}}, \phi_2 - \pi_2\phi_2) \\ & + (U_1^{\{k\}} - U_2^{\{k\}}, A_1\partial_n\phi_1)_\Gamma \\ & + (\theta_h^{\{k\}}, \pi_2\phi_2)_\Gamma - (\sigma^{\{k\}}, \pi_1\phi_1)_\Gamma.\end{aligned} \tag{4.3}$$

The error has been decomposed into two typical discretization components, an iterative component, and a component reflecting the error arising from the transfer of derivative information. The iterative component can be decomposed:

$$(U_1^{\{k\}} - U_2^{\{k\}}, A_1\partial_n\phi_1)_\Gamma = (U_1^{\{k\}} - \pi_1 U_2^{\{k\}}, A_1\partial_n\phi_1)_\Gamma + (\pi_1 U_2^{\{k\}} - U_2^{\{k\}}, A_1\partial_n\phi_1)_\Gamma,$$

which represents an iteration error and a projection error. The choice of derivative information transferred from Ω_1 to Ω_2 has a significant impact on the transfer component.

- Suppose that we set $\theta_h^{\{k\}} = A_1\partial_n U_1^{\{k\}}$, and then

$$(\theta_h^{\{k\}}, \pi_2\phi_2)_\Gamma - (\sigma^{\{k\}}, \pi_1\phi_1)_\Gamma \\ = (A_1\partial_n U_1^{\{k\}} - \sigma^{\{k\}}, \pi_2\phi_2)_\Gamma + (\sigma^{\{k\}}, \pi_2\phi_2 - \pi_1\phi_1)_\Gamma,$$

  which represents a transfer error and a projection error.
- Suppose that we set $\theta_h^{\{k\}} = \sigma^{\{k\}}$, and then

$$(\theta_h^{\{k\}}, \pi_2\phi_2)_\Gamma - (\sigma^{\{k\}}, \pi_1\phi_1)_\Gamma = (\sigma^{\{k\}}, \pi_2\phi_2 - \pi_1\phi_1)_\Gamma,$$

  which represents only a projection error with *no transfer error*.

4.2. The adjoint to the operator decomposition iterative scheme. Next, we derive an error representation by using the natural adjoint for the iterative system (3.1)–(3.2), where we set $U_1^{\{k\}} = \pi_1 U_2^{\{k-1\}}$ and $A_2\partial_n U_2^{\{k\}} = A_1\partial_n U_1^{\{k\}}$. This adjoint avoids the formulation of a globally coupled adjoint and reads

$$\begin{cases} L_1^*\phi_1^{\{k\}} = \psi_1^{\{k\}}, & \mathbf{x} \in \Omega_1, \\ \phi_1^{\{k\}} = 0, & \mathbf{x} \in \partial\Omega_1\backslash\Gamma, \\ \phi_1^{\{k\}} = \phi_2^{\{k\}}, & \mathbf{x} \in \Gamma, \end{cases} \tag{4.4}$$

$$\begin{cases} L_2^*\phi_2^{\{k\}} = \psi_2^{\{k\}}, & \mathbf{x} \in \Omega_2, \\ \phi_2^{\{k\}} = 0, & \mathbf{x} \in \partial\Omega_2\backslash\Gamma, \\ A_2\partial_n\phi_2^{\{k\}} = A_1\partial_n\phi_1^{\{k+1\}}, & \mathbf{x} \in \Gamma, \end{cases} \tag{4.5}$$

for $k = N, \ldots, 1$, with $A_1\partial_n\phi_1^{\{N+1\}} = 0$. Note that the adjoint system is defined as "backwards." In the reasonable case in which we seek information from the final iterate, the data for the adjoint problem would be $\psi_1^{\{1\}} = \psi_2^{\{1\}} = \cdots = \psi_1^{\{N-1\}} = \psi_2^{\{N-1\}} = 0$, with $\psi_1^{\{N\}}$ and $\psi_2^{\{N\}}$ chosen appropriately.

We derive the error representation formula for this system by observing that

$$\sum_{k=1}^{N} \left((\psi_1^{\{k\}}, e_1^{\{k\}}) + (\psi_2^{\{k\}}, e_2^{\{k\}})\right) = \sum_{k=1}^{N} \left((L_1^*\phi_1^{\{k\}}, e_1^{\{k\}}) + (L_2^*\phi_2^{\{k\}}, e_2^{\{k\}})\right)$$

and applying the steps used to derive (4.3). This provides the following theorem.

THEOREM 4.2. *The errors* $e_1^{\{1\}}, e_2^{\{1\}}, \ldots, e_1^{\{N\}}, e_2^{\{N\}}$ *satisfy*

$$\begin{aligned}(4.6)\quad &\sum_{k=1}^{N}\left((\psi_1^{\{k\}}, e_1^{\{k\}}) + (\psi_2^{\{k\}}, e_2^{\{k\}})\right)\\ &\quad= \sum_{k=1}^{N}\Bigg((f_1, \phi_1^{\{k\}} - \pi_1\phi_1^{\{k\}}) - a_1(U_1^{\{k\}}, \phi_1^{\{k\}} - \pi_1\phi_1^{\{k\}})\\ &\qquad + (f_2, \phi_2^{\{k\}} - \pi_2\phi_2^{\{k\}}) - a_2(U_2^{\{k\}}, \phi_2^{\{k\}} - \pi_2\phi_2^{\{k\}})\\ &\qquad\quad + (U_1^{\{k\}} - U_2^{\{k-1\}}, A_1\partial_n\phi_1^{\{k\}})_\Gamma\\ &\qquad\qquad + (A_1\partial_n U_1^{\{k\}}, \pi_1\phi_1^{\{k\}})_\Gamma - (\sigma^{\{k\}}, \pi_2\phi_2^{\{k\}})_\Gamma\Bigg).\end{aligned}$$

It is possible to define adjoints for more complicated iterative methods, but it may be difficult. For example, relaxation techniques couple $U_1^{\{k\}}$ to both $U_2^{\{k-1\}}$ and $U_1^{\{k-1\}}$, which affects how the adjoint variables are coupled. In addition, using the postprocessed numerical flux given in section 3.2 requires defining the adjoint of the postprocessing procedure.

4.3. Numerical results. We illustrate the a posteriori estimates in sections 4.1 and 4.2.

Example 4.1. We triangulate the domains $\Omega_1 = [-0.25, 0.25] \times [-0.25, 0.25]$ and $\Omega_2 = ([-1,1]\times[-1,1])\backslash\Omega_1$ independently (see Figure 4.1) and consider the elliptic interface problem

$$(4.7)\qquad \begin{cases} -\nabla\cdot(A_1\nabla u_1) = f_1, & \mathbf{x}\in\Omega_1,\\ \begin{cases} u_1 = u_2,\\ A_1\partial_n u_1 = A_2\partial_n u_2, \end{cases} & \mathbf{x}\in\Gamma,\\ -\nabla\cdot(A_2\nabla u_2) = f_2, & \mathbf{x}\in\Omega_2,\\ u_2 = 0, & \mathbf{x}\in\partial\Omega_2\backslash\Gamma, \end{cases}$$

with very different diffusion coefficients $A_1 = 1$, $A_2 = 10^3$. The data $f_1(x,y)$ and $f_2(x,y)$ are chosen so the true solutions are $u_1 = 10^3\sin(4\pi x)\sin(4\pi y)$ and $u_2 = \sin(4\pi x)\sin(4\pi y)$. We solve this by using (3.3)–(3.4) with $U_1^{\{k\}} = \pi_1 U_2^{\{k-1\}}$ and

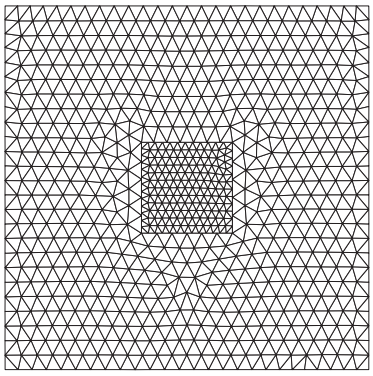

FIG. 4.1. *Triangulations of* Ω_1 *and* Ω_2 *that do not match along the interface.*

iterate until $\|U_1 - \pi_1 U_2\|_\Gamma < 1E-6$. We consider several quantities of interest:

1. the global average value,
2. the average value over Ω_1,
3. the average value over Ω_2,
4. the value of u_1 at the point $(0,0)$ computed by using the approximate delta function $\hat{\delta}_0(x,y) = \frac{400}{\pi}\exp(-400x^2 - 400y^2)$.

First, we use an independent iterative scheme to solve the adjoint of the fully coupled problem and iterate until our convergence criteria are met. We display the error estimates for each of the quantities of interest in Table 4.1.

Next, we solve the adjoint to the operator decomposition method and give these results in Table 4.2. Note that the number of iterations as well as the values of the relaxation parameters are determined by the number of iterations used in the solution of the forward operator decomposition method. In this case, four iterations were required with $\alpha = 0$.

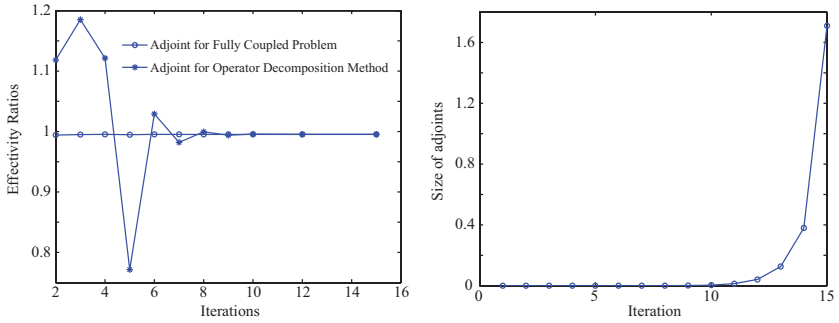
Note that, when the forward iterations have fully converged, the error estimates provided by the fully coupled and operator decomposition adjoints are nearly identical.

Example 4.2. Next we consider neighboring domains $\Omega_1 = [0,1]\times[0,1]$ and $\Omega_2 = ([1,2]\times[0,1])$ with independent triangulations and the elliptic interface problem

$$\begin{cases} -\nabla\cdot(A_1\nabla u_1) = f_1, & \mathbf{x}\in\Omega_1,\\ u_1 = 0, & \mathbf{x}\in\partial\Omega_1\backslash\Gamma,\\ \begin{cases} u_1 = u_2,\\ A_1\partial_n u_1 = A_2\partial_n u_2, \end{cases} & \mathbf{x}\in\Gamma,\\ -\nabla\cdot(A_2\nabla u_2) = f_2, & \mathbf{x}\in\Omega_2,\\ u_2 = 0, & \mathbf{x}\in\partial\Omega_2\backslash\Gamma, \end{cases} \tag{4.8}$$

where $A_1 = 1$, $A_2 = 3$, and $f_1(x,y)$ and $f_2(x,y)$ are chosen so the true solutions are $u_2 = \sin(2\pi x)\sin(2\pi y)$ and $u_1 = 3u_2$. The quantity of interest is the average value over $\Omega_1\cup\Omega_2$, so $\psi_1 = \psi_2 = 1$.

This experiment demonstrates that the error representation formulas (4.3) and (4.6) may give different estimates if the operator decomposition method used to solve the forward problem has failed to converge completely. We fix the number of iterations



(a) Effectivity ratios (b) Decay of influence

FIG. 4.2. *On the left, we show a comparison of the effectivity ratios using the two adjoints for a given number of iterations used for the operator decomposition method for the forward problem. On the right, we plot* $\|\phi_1^{\{k\}}\| + \|\phi_2^{\{k\}}\|$ *to show the decay of influence of errors that occur in previous iterations.*

in the operator decomposition method for (4.8) and use (3.3) and (3.4) to approximate the solution. We solve the fully coupled adjoint iteratively by using a sufficiently large number of iterations for convergence. However, the number of iterations for the adjoint of the iterative system (4.4)–(4.5) is determined by the number of iterations for the forward problem.

In Figure 4.2(a), we plot the effectivity ratios for the two estimates against the number of iterations. We observe that the adjoint for the operator decomposition method does not produce accurate estimates until a sufficient number of iterations for the forward problem have been carried out. This implies that, during the early part of the iterative process, the iterative component of the error $c^{\{k\}} = u - u^{\{k\}}$ dominates the estimate.

If the iterative method converges, we expect that the effect of the initial guess and the first few iterations would diminish. This is reflected in Figure 4.2(b), where we fix the number of iterations $N = 15$ and plot the L^2 norm of the iterative adjoint $\phi_1^{\{k\}}$ and $\phi_2^{\{k\}}$ over Ω_1 and Ω_2, respectively, at each iteration for $1 \le k \le 15$. We observe that the norm decays rapidly as k decreases from N. Recall that the adjoint to the iterative system is solved "backwards" from $N = 15$. The rapid decay indicates that the norm of the fixed-point operator, and hence the norm of the adjoint fixed-point operator, is smaller than one. Thus, the influence of errors in previous iterations is rapidly damped and has little influence on the current error. This implies that we can compute accurate estimates by using the truncated series

$$
\begin{aligned}
(4.9)\quad & (\psi_1^{\{N\}}, e_1^{\{N\}}) + (\psi_2^{\{N\}}, e_2^{\{N\}}) \\
&= \sum_{k=M}^{N} \Big((f_1, \phi_1^{\{k\}} - \pi_1\phi_1^{\{k\}}) - a_1(U_1^{\{k\}}, \phi_1^{\{k\}} - \pi_1\phi_1^{\{k\}}) \\
&\qquad + (f_2, \phi_2^{\{k\}} - \pi_2\phi_2^{\{k\}}) - a_2(U_2^{\{k\}}, \phi_2^{\{k\}} - \pi_2\phi_2^{\{k\}}) \\
&\qquad\quad + (U_1^{\{k\}} - U_2^{\{k-1\}}, A_1\partial_n\phi_1^{\{k\}})_\Gamma \\
&\qquad\qquad + (A_1\partial_n U_1^{\{k\}}, \pi_1\phi_1^{\{k\}})_\Gamma - (\sigma^{\{k\}}, \pi_2\phi_2^{\{k\}})_\Gamma \Big),
\end{aligned}
$$

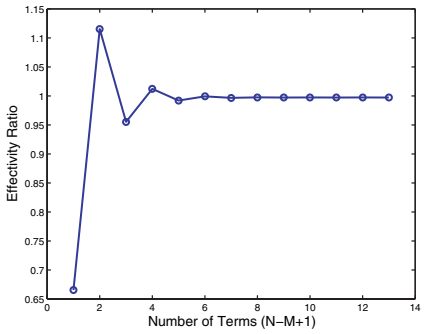


FIG. 4.3. *A comparison of the effectivity ratios computed by using a truncated error representation.*

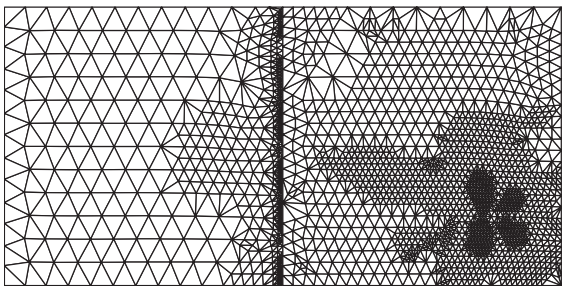

FIG. 4.4. *Adaptive mesh for the quantity of interest equal to the value of* u_2 *at the point* $(1.75, 0.25)$.

where $1 \leq M \leq N$, in place of the full series (4.6). This significantly reduces the computational cost associated with computing a series of adjoint problems. In Figure 4.3 we plot the effectivity ratio for the global average value where we truncate the error representation and compute only the last $N - M + 1$ terms.

4.4. Adaptive refinement. We use the a posteriori error estimate as the basis for adaptivity by employing the standard "optimization framework" after writing the estimate as a sum of element contributions and introducing norms [12, 13, 4, 3]. An element K is marked for refinement when the local error indicator is larger than a local tolerance, usually the global tolerance divided by the current number of elements.

Example 4.3. We demonstrate the adaptive procedure on the model problem (4.8) with the quantity of interest equal to the value of u_2 at the point $(1.75, 0.25)$, which we approximate by choosing $\psi_1 = 0$ and $\psi_2 = 400/\pi \exp(-400(x-1.75)^2 - 400(y-0.25)^2)$. Figure 4.4 shows the results after 3 refinement steps. We solve (3.3)–(3.4) and observe that refinement occurs within Ω_1 along Γ, which reflects the impact of numerical errors in the normal derivative on the quantity of interest.

5. An analysis of the loss of order. In practice, the iterative operator decomposition technique (3.3) and (3.4) is occasionally observed to result in $\mathbf{O}(h)$ convergence rather than the $\mathbf{O}(h^2)$ convergence that is obtained when solving the fully coupled problem. This loss of order results from passing the normal derivative of the finite element approximation, which is only $\mathbf{O}(h)$. Passing the recovered boundary flux restores the full order of convergence. We use the adjoint for the fully coupled problem to derive a posteriori error bounds for the iterative approximations. Numerical examples are provided at the end of the section.

5.1. L^2 error bounds. Let $u_1 \in H^{1+\alpha_1}(\Omega_1)$ and $u_2 \in H^{1+\alpha_2}(\Omega_2)$ be the solutions to (2.1), with $0 \leq \alpha_1, \alpha_2 \leq 1$, and $U_1^{\{k\}}$ and $U_2^{\{k\}}$ be the solutions of the operator decomposition scheme at the kth iteration. Let $\theta_h^{\{k\}}$ denote the flux passed at the kth iteration. Let $\phi_1 \in H^{1+\alpha_1}(\Omega_1)$ and $\phi_2 \in H^{1+\alpha_2}(\Omega_2)$, and pose the adjoint problem (4.1) with $\psi_1 = e_1/\|e_1\|_{\Omega_1}$ and $\psi_2 = e_2/\|e_2\|_{\Omega_2}$. Starting with (4.3), integration by parts over each element K gives

$$\|e_1\|_{\Omega_1} + \|e_2\|_{\Omega_2} = I_1 + I_2 + I_3 + I_4,$$

where

$$\begin{aligned}
I_1 &= \sum_{K \in T_{1,h}} \left(f_1 - L_1 U_1^{\{k\}}, \phi_1 - \pi_1\phi_1\right)_K + \frac{1}{2}\left([A_1\partial_n U_1^{\{k\}}], \phi_1 - \pi_1\phi_1\right)_{\partial K} \\
&\quad + \sum_{K \in T_{2,h}} \left(f_2 - L_2 U_2^{\{k\}}, \phi_2 - \pi_2\phi_2\right)_K + \frac{1}{2}\left([A_2\partial_n U_2^{\{k\}}], \phi_2 - \pi_2\phi_2\right)_{\partial K}, \\
I_2 &= \left(A_2\partial_n U_2^{\{k\}}, \phi_2 - \pi_2\phi_2\right)_\Gamma - \left(A_1\partial_n U_1^{\{k\}}, \phi_1 - \pi_1\phi_1\right)_\Gamma, \\
I_3 &= \left(A_1\partial_n\phi_1, U_1^{\{k\}} - U_2^{\{k\}}\right)_\Gamma, \\
I_4 &= \left(\theta_h^{\{k\}}, \pi_2\phi_2\right)_\Gamma - \left(\sigma^{\{k\}}, \pi_1\phi_1\right)_\Gamma,
\end{aligned}$$

where $[A_i\partial_n U_i^{\{k\}}]$ denotes the jump in the normal derivative across an element edge.

The first term I_1 is a standard a posteriori error bound for elliptic problems and is not affected by nonmatching triangulations along the interface or by transfer error. The second term I_2 is similar to the jump terms along element edges in I_1. The third term I_3 represents the jump in the Dirichlet values across the interface. Finally, the fourth term I_4 represents the difference between the flux passed from Ω_1 to Ω_2 and the flux obtained via the boundary flux recovery technique.

We construct Lemmas 5.1–5.4 below to bound I_1–I_4 individually. In each of these lemmas we first provide the general bound when the triangulations do not match across the boundary and then show the simplification that arises for matching triangulations. We then combine these four lemmas into Theorems 5.5 and 5.7, which give error bounds for the basic iteration (3.3) and (3.4) and when using the recovered boundary flux (3.8), respectively. These two theorems describe the general result when the triangulations do not match across the boundary, while the simplification given matching triangulations is provided as a corollary.

In the following analysis, it is useful to define a smooth function to separate the discretization error arising within an iteration from the transfer and iteration errors. Let $\tilde{u}_1^{\{k\}} \in H^{1+\alpha_1}(\Omega_1)$ solve

$$\begin{cases} a_1(\tilde{u}_1^{\{k\}}, v) = (f_1, v)_{\Omega_1} & \text{for all } v \in H_0^1(\Omega_1), \\ \tilde{u}_1^{\{k\}} = 0, & \mathbf{x} \in \partial\Omega_1 \backslash \Gamma, \\ \tilde{u}_1^{\{k\}} = g_1^{\{k\}}, & \mathbf{x} \in \Gamma, \end{cases} \tag{5.1}$$

where $g_1^{\{k\}}$ is a smooth function, with $\pi_1 g_1^{\{k\}}$ the Dirichlet data provided on Γ at the kth iteration.

Similarly, let $\tilde{u}_2^{\{k\}} \in H^{1+\alpha_2}(\Omega_2)$ solve

$$\begin{cases} a_2(\tilde{u}_2^{\{k\}}, v) = (f_2, v)_{\Omega_2} + (g_2^{\{k\}}, v)_\Gamma & \text{for all } v \in H_0^1(\Omega_2), \\ \tilde{u}_2^{\{k\}} = 0, & \mathbf{x} \in \partial\Omega_2 \backslash \Gamma, \end{cases} \tag{5.2}$$

where $g_2^{\{k\}}$ is a smooth function such that the L^2 projection of $g_2^{\{k\}}$ is the Neumann data on Γ at the kth iteration, namely, $\theta_h^{\{k\}}$.

Standard finite element theory can be applied to bound

$$\|\tilde{u}_1^{\{k\}} - U_1^{\{k\}}\|_{\Omega_1,1} \le Ch_1^{\alpha_1}\left(\|f_1\|_{\Omega_1} + \|g_1^{\{k\}}\|_\Gamma\right),$$
$$\|\tilde{u}_2^{\{k\}} - U_2^{\{k\}}\|_{\Omega_2,1} \le Ch_2^{\alpha_2}\left(\|f_2\|_{\Omega_2} + \|g_2^{\{k\}}\|_\Gamma\right).$$

LEMMA 5.1 (bound on I_1).

$$I_1 \le \sum_{K\in T_{1,h}} \begin{pmatrix} \|f_1 - L_1U_1^{\{k\}}\|_K \\ \frac{1}{2}\|h_K^{-1/2}[A_1\partial_n U_1^{\{k\}}]\|_{\partial K}\end{pmatrix} \cdot \begin{pmatrix} Ch_K^{1+\alpha_1}|\phi_1|_{K,1+\alpha_1} \\ Ch_K^{1+\alpha_1}|\phi_1|_{K,1+\alpha_1}\end{pmatrix}$$
$$+ \sum_{K\in T_{2,h}} \begin{pmatrix} \|f_2 - L_2U_2^{\{k\}}\|_K \\ \frac{1}{2}\|h_K^{-1/2}[A_2\partial_n U_2^{\{k\}}]\|_{\partial K}\end{pmatrix} \cdot \begin{pmatrix} Ch_K^{1+\alpha_2}|\phi_2|_{K,1+\alpha_2} \\ Ch_K^{1+\alpha_2}|\phi_2|_{K,1+\alpha_2}\end{pmatrix}.$$

Proof. Apply standard arguments by using the Cauchy–Schwarz inequality and a trace inequality. ∎

Remark 5.1. If $u_1^{\{k\}} \in H^2(\Omega_1)$, we add and subtract $A_1\partial_n\tilde{u}_1^{\{k\}}$ and use the Cauchy–Schwarz and trace inequalities to bound the jump terms

$$\|[A_1\partial_n U_1^{\{k\}}]\|_{\partial K} \le Ch_K^{1/2}\|\tilde{u}_1^{\{k\}}\|_{2,K}.$$

A similar analysis shows that

$$\|[A_2\partial_n U_2^{\{k\}}]\|_{\partial K} \le Ch_K^{1/2}\|\tilde{u}_2^{\{k\}}\|_{2,K}$$

for $u_2^{\{k\}} \in H^2(\Omega_2)$. Substituting these bounds above shows that I_1 converges $\mathbf{O}(h_1^2 + h_2^2)$ as expected.

LEMMA 5.2 (bound on I_2). *If the triangulations $T_{1,h}$ and $T_{2,h}$ do not match along the interface, then*

$$I_2 \le \left(\|h_1^{-1/2}(\theta_h^{\{k\}} - A_1\partial_n U_1^{\{k\}})\|_\Gamma\right)\cdot\left(Ch_1^{1+\alpha_1}|\phi_1|_{1+\alpha_1}\right)$$
$$+ \left(\|h_2^{-1/2}(A_2\partial_n U_2^{\{k\}} - \theta_h^{\{k\}})\|_\Gamma\right)\cdot\left(Ch_2^{1+\alpha_2}|\phi_2|_{1+\alpha_2}\right)$$
$$+ \left(\|\theta_h^{\{k\}}\|_\Gamma\right)\cdot\left(\|\pi_1\phi_1 - \pi_2\phi_2\|_\Gamma\right),$$

where

$$\|\pi_1\phi_1 - \pi_2\phi_2\|_\Gamma \le \|\pi_1\phi_1 - \phi_1\|_\Gamma + \|\phi_2 - \pi_2\phi_2\|_\Gamma$$
$$\le C_1h_1^{1/2+\alpha_1}|\phi_1|_{\Gamma,1/2+\alpha_1} + C_2h_2^{1/2+\alpha_2}|\phi_2|_{\Gamma,1/2+\alpha_2}.$$

If the triangulations $T_{1,h}$ and $T_{2,h}$ match along the interface, then

$$I_2 \le \left(\|h_1^{-1/2}(\theta_h^{\{k\}} - A_1\partial_n U_1^{\{k\}})\|_\Gamma\right)\cdot\left(Ch_1^{1+\alpha_1}|\phi_1|_{1+\alpha_1}\right)$$
$$+ \left(\|h_2^{-1/2}(A_2\partial_n U_2^{\{k\}} - \theta_h^{\{k\}})\|_\Gamma\right)\cdot\left(Ch_2^{1+\alpha_2}|\phi_2|_{1+\alpha_2}\right).$$

Proof. We add and subtract $(\theta_h^{\{k\}}, \phi_1 - \pi_1\phi_1)_\Gamma$ and $(\theta_h^{\{k\}}, \phi_2 - \pi_2\phi_2)_\Gamma$ and use the fact that $\phi_1 = \phi_2$ on the interface to give

$$I_2 = (\theta_h^{\{k\}} - A_1\partial_n U_1^{\{k\}}, \phi_1 - \pi_1\phi_1)_\Gamma + (A_2\partial_n U_2^{\{k\}} - \theta_h^{\{k\}}, \phi_2 - \pi_2\phi_2)_\Gamma + (\theta_h^{\{k\}}, \pi_1\phi_1 - \pi_2\phi_2)_\Gamma.$$

Observe that $\pi_1\phi_1 = \pi_2\phi_2$ if the triangulations match along the interface. We apply the Cauchy–Schwarz and trace inequalities and an interpolation result to complete the proof. ∎

Remark 5.2. If we assume that $\tilde{u}_1^{\{k\}} \in H^2(\Omega_1)$ and $\tilde{u}_2^{\{k\}} \in H^2(\Omega_2)$, then we can bound

$$\|\theta_h^{\{k\}} - A_1\partial_n U_1^{\{k\}}\|_\Gamma \le C h_1^{1/2} \|\tilde{u}_1^{\{k\}}\|_{2,\Omega_1},$$
$$\|A_2\partial_n U_2^{\{k\}} - \theta_h^{\{k\}}\|_\Gamma \le C h_2^{1/2} \|\tilde{u}_2^{\{k\}}\|_{2,\Omega_2},$$

by adding and subtracting $A_1\partial_n\tilde{u}_1^{\{k\}}$ and $g_2^{\{k\}}$ to the first and second equations, respectively, and applying standard finite element results and the fact that the recovered boundary flux is at least as accurate as the finite element flux [26, 7, 8, 27]. Note that the first equation is zero if $\theta_h^{\{k\}} = A_1\partial_n U_1^{\{k\}}$. Substituting these bounds above shows that I_2 converges $\mathbf{O}(h_1^2 + h_2^2)$.

LEMMA 5.3 (bound on I_3). *If the triangulations $T_{1,h}$ and $T_{2,h}$ do not match along the interface, then*

$$I_3 \le (\|A_1\partial_n\phi_1\|_\Gamma) \cdot \left(\|U_1^{\{k\}} - \pi_1 U_2^{\{k\}}\|_\Gamma\right) + (\|A_1\partial_n\phi_1\|_\Gamma) \cdot \left(\|\pi_1 U_2^{\{k\}} - U_2^{\{k\}}\|_\Gamma\right),$$

where

$$\|\pi_1 U_2^{\{k\}} - U_2^{\{k\}}\|_\Gamma \le C_1 h_1^{1/2+\alpha_1} |\hat{u}^{\{k\}}|_{\Gamma,1/2+\alpha_1} + C_2 h_2^{1/2+\alpha_2} |\hat{u}^{\{k\}}|_{\Gamma,1/2+\alpha_2},$$

with $\hat{u}^{\{k\}}$ a smooth function defined on the interface such that $\pi_1\hat{u}^{\{k\}} = \pi_1 U_2^{\{k\}}$ and $\pi_2\hat{u}^{\{k\}} = U_2^{\{k\}}$. If the triangulations $T_{1,h}$ and $T_{2,h}$ match along the interface, then

$$I_3 \le (\|A_1\partial_n\phi_1\|_\Gamma) \cdot \left(\|U_1^{\{k\}} - \pi_1 U_2^{\{k\}}\|_\Gamma\right).$$

Proof. Rewrite I_3 by adding and subtracting $(A_1\partial_n\phi_1, \pi_1 U_2^{\{k\}})_\Gamma$ to get

$$I_3 = (A_1\partial_n\phi_1, \pi_1 U_1^{\{k\}} - \pi_1 U_2^{\{k\}})_\Gamma + (A_1\partial_n\phi_1, \pi_1 U_2^{\{k\}} - U_2^{\{k\}})_\Gamma.$$

To bound $\|\pi_1 U_2^{\{k\}} - U_2^{\{k\}}\|_\Gamma$ we add and subtract $\hat{u}^{\{k\}}$ and apply Cauchy–Schwarz and trace inequalities giving

$$\|\pi_1 U_2^{\{k\}} - U_2^{\{k\}}\|_\Gamma \le C_1 h_1^{1/2+\alpha_1} |\hat{u}^{\{k\}}|_{\Gamma,1/2+\alpha_1} + C_2 h_2^{1/2+\alpha_2} |\hat{u}^{\{k\}}|_{\Gamma,1/2+\alpha_2}.$$

Observe that $\pi_1 U_2^{\{k\}} = U_2^{\{k\}}$ if the triangulations match along the interface. We apply the Cauchy–Schwarz inequality to complete the proof. ∎

LEMMA 5.4 (bound on I_4).

(i) *If the triangulations $T_{1,h}$ and $T_{2,h}$ do not match along the interface and $\theta_h^{\{k\}} = A_1\partial_n U_1^{\{k\}}$, then*

$$I_4 \le \left(\|A_1\partial_n U_1^{\{k\}} - A_1\partial_n \tilde{u}_1^{\{k\}}\|_\Gamma + \|A_1\partial_n \tilde{u}_1^{\{k\}} - \sigma^{\{k\}}\|_\Gamma\right)\cdot\left(\|\pi_2\phi_2\|_\Gamma\right) + \left(\|\sigma^{\{k\}}\|_\Gamma\right)\cdot\left(\|\pi_2\phi_2 - \pi_1\phi_1\|_\Gamma\right),$$

where

$$\|\pi_2\phi_2 - \pi_1\phi_1\|_\Gamma \le C_1 h_1^{1/2+\alpha_1}|\phi_1|_{\Gamma,1/2+\alpha_1} + C_2 h_2^{1/2+\alpha_2}|\phi_2|_{\Gamma,1/2+\alpha_2}.$$

(ii) *If the triangulations $T_{1,h}$ and $T_{2,h}$ match along the interface and $\theta_h^{\{k\}} = A_1\partial_n U_1^{\{k\}}$, then*

$$I_4 \le \left(\|A_1\partial_n U_1^{\{k\}} - A_1\partial_n \tilde{u}_1^{\{k\}}\|_\Gamma + \|A_1\partial_n \tilde{u}_1^{\{k\}} - \sigma^{\{k\}}\|_\Gamma\right)\cdot\left(\|\pi_2\phi_2\|_\Gamma\right).$$

(iii) *If the triangulations $T_{1,h}$ and $T_{2,h}$ do not match along the interface and $\theta_h^{\{k\}} = \sigma^{\{k\}}$, then*

$$I_4 \le \left(\|\sigma^{\{k\}}\|_\Gamma\right)\cdot\left(\|\pi_2\phi_2 - \pi_1\phi_1\|_\Gamma\right),$$

where

$$\|\pi_2\phi_2 - \pi_1\phi_1\|_\Gamma \le C_1 h_1^{1/2+\alpha_1}|\phi_1|_{\Gamma,1/2+\alpha_1} + C_2 h_2^{1/2+\alpha_2}|\phi_2|_{\Gamma,1/2+\alpha_2}.$$

(iv) *If the triangulations $T_{1,h}$ and $T_{2,h}$ match along the interface and $\theta_h^{\{k\}} = \sigma^{\{k\}}$, then*

$$I_4 = 0.$$

Proof. We add and subtract $(\sigma^{\{k\}}, \pi_2\phi_2)_\Gamma$ and use $\phi_1 = \phi_2$ along Γ to get

$$I_4 = (\theta_h^{\{k\}} - \sigma^{\{k\}}, \pi_2\phi_2)_\Gamma + (\sigma^{\{k\}}, \pi_2\phi_2 - \pi_1\phi_1)_\Gamma.$$

Clearly, if $\theta_h^{\{k\}} = \sigma^{\{k\}}$, then the first term drops out. If the triangulations match along the interface, then $\pi_1\phi_1 = \pi_2\phi_2$, and the second term drops out. We add and subtract $(A_1\partial_n\tilde{u}_1^{\{k\}}, \pi_2\phi_2)_\Gamma$ to the first term and apply the Cauchy–Schwarz inequality to complete the proof. ∎

Remark 5.3. In practice, the error in the normal derivative is typically the same accuracy as the H^1 error, namely, $\mathbf{O}(h_1^{\alpha_1})$. However, an application of the trace theorem proves only $\mathbf{O}(h_1^{\alpha_1/2})$ accuracy. This is not an important issue, however, since we intend to use the fact that this term is less accurate than the others and therefore pollutes the L^2 error. We assume the error in the normal derivative can be bounded

$$\|A_1\partial_n U_1^{\{k\}} - \tilde{u}_1^{\{k\}}\|_\Gamma \le C h_1^{\beta_1}\|f_1\|_{\Omega_1}$$

for $\alpha_1/2 \le \beta_1 \le \alpha_1$. The error in the recovered boundary flux can be bounded

$$\|A_1\partial_n \tilde{u}_1^{\{k\}} - \sigma^{\{k\}}\|_\Gamma \le C S_1 h_1^{\beta_2}\|f_1\|_{\Omega_1}$$

for $\beta_1 \leq \beta_2 \leq \alpha_1 + 1$, where S_1 is a stability factor defined by an associated Green's function [20, 27]. In certain situations, the recovered boundary flux is the same order as the finite element approximation [26, 7, 8], but this result is not known in general. We emphasize that the accuracy of the recovered boundary flux is immaterial due to the cancellation in the error representation.

The bounds in Lemmas 5.1–5.4 are combined in the following theorems and corollaries. First we consider the case $\theta_h^{\{k\}} = A_1 \partial_n U_1^{\{k\}}$.

THEOREM 5.5. *Assume that the triangulations $T_{1,h}$ and $T_{2,h}$* do not *match along the interface Γ. If $U_1^{\{k\}}$ and $U_2^{\{k\}}$ solve* (3.3) *and* (3.4)*, respectively, then the errors $e_1 = u_1 - U_1^{\{k\}}$ and $e_2 = u_2 - U_2^{\{k\}}$ satisfy*

$$\begin{aligned}
\|e_1\|_{\Omega_1} + \|e_2\|_{\Omega_2} \leq & \sum_{K \in T_{1,h}} \begin{pmatrix} \|f_1 - L_1 U_1^{\{k\}}\|_K \\ \frac{1}{2}\|h_K^{-1/2}[A_1 \partial_n U_1^{\{k\}}]\|_{\partial K} \end{pmatrix} \cdot \begin{pmatrix} C h_K^{1+\alpha_1} |\phi_1|_{K,1+\alpha_1} \\ C h_K^{1+\alpha_1} |\phi_1|_{K,1+\alpha_1} \end{pmatrix} \\
& + \sum_{K \in T_{2,h}} \begin{pmatrix} \|f_2 - L_2 U_2^{\{k\}}\|_K \\ \frac{1}{2}\|h_K^{-1/2}[A_2 \partial_n U_2^{\{k\}}]\|_{\partial K} \end{pmatrix} \cdot \begin{pmatrix} C h_K^{1+\alpha_2} |\phi_2|_{K,1+\alpha_2} \\ C h_K^{1+\alpha_2} |\phi_2|_{K,1+\alpha_2} \end{pmatrix} \\
& + \left(\|h_2^{-1/2}(A_2 \partial_n U_2^{\{k\}} - \theta_h^{\{k\}})\|_\Gamma \right) \cdot \left(C h_2^{1+\alpha_2} |\phi_2|_{1+\alpha_2} \right) \\
& + \left(\|A_1 \partial_n \phi_1\|_\Gamma \right) \cdot \left(\|U_1^{\{k\}} - \pi_1 U_2^{\{k\}}\|_\Gamma \right) \\
& + \left(C h_1^{\beta_1} \|f_1\|_{\Omega_1} + C S_1 h_1^{\beta_2} \|f_1\|_{\Omega_1} \right) \cdot \left(\|\pi_2 \phi_2\|_\Gamma \right) \\
& + C_1 h_1^{1/2+\alpha_1} \left((S_2 + S_3) |\phi_1|_{\Gamma,1/2+\alpha_1} + S_4 |\hat{u}|_{\Gamma,1/2+\alpha_1} \right) \\
& + C_2 h_2^{1/2+\alpha_2} \left((S_2 + S_3) |\phi_2|_{\Gamma,1/2+\alpha_2} + S_4 |\hat{u}|_{\Gamma,1/2+\alpha_2} \right),
\end{aligned}$$

with $\alpha_1/2 \leq \beta_1 \leq \alpha_1$, $\beta_1 \leq \beta_2 \leq \alpha_1 + 1$, S_1 is a stability factor independent of h, $S_2 = \|A_1 \partial_n U_1^{\{k\}}\|_\Gamma$, $S_3 = \|\sigma^{\{k\}}\|_\Gamma$, and $S_4 = \|A_1 \partial_n \phi_1\|_\Gamma$.

COROLLARY 5.6. *Assume that the triangulations $T_{1,h}$ and $T_{2,h}$ match along the interface Γ. If $U_1^{\{k\}}$ and $U_2^{\{k\}}$ solve* (3.3) *and* (3.4)*, respectively, then the errors $e_1 = u_1 - U_1^{\{k\}}$ and $e_2 = u_2 - U_2^{\{k\}}$ satisfy*

$$\begin{aligned}
\|e_1\|_{\Omega_1} + \|e_2\|_{\Omega_2} \leq & \sum_{K \in T_{1,h}} \begin{pmatrix} \|f_1 - L_1 U_1^{\{k\}}\|_K \\ \frac{1}{2}\|h_K^{-1/2}[A_1 \partial_n U_1^{\{k\}}]\|_{\partial K} \end{pmatrix} \cdot \begin{pmatrix} C h_K^{1+\alpha_1} |\phi_1|_{K,1+\alpha_1} \\ C h_K^{1+\alpha_1} |\phi_1|_{K,1+\alpha_1} \end{pmatrix} \\
& + \sum_{K \in T_{2,h}} \begin{pmatrix} \|f_2 - L_2 U_2^{\{k\}}\|_K \\ \frac{1}{2}\|h_K^{-1/2}[A_2 \partial_n U_2^{\{k\}}]\|_{\partial K} \end{pmatrix} \cdot \begin{pmatrix} C h_K^{1+\alpha_2} |\phi_2|_{K,1+\alpha_2} \\ C h_K^{1+\alpha_2} |\phi_2|_{K,1+\alpha_2} \end{pmatrix} \\
& + \left(\|h_2^{-1/2}(A_2 \partial_n U_2^{\{k\}} - \theta_h^{\{k\}})\|_\Gamma \right) \cdot \left(C h_2^{1+\alpha_2} |\phi_2|_{1+\alpha_2} \right) \\
& + \left(\|A_1 \partial_n \phi_1\|_\Gamma \right) \cdot \left(\|U_1^{\{k\}} - \pi_1 U_2^{\{k\}}\|_\Gamma \right) \\
& + \left(C h_1^{\beta_1} \|f_1\|_{\Omega_1} + C S_1 h_1^{\beta_2} \|f_1\|_{\Omega_1} \right) \cdot \left(\|\pi_2 \phi_2\|_\Gamma \right),
\end{aligned}$$

with $\alpha_1/2 \leq \beta_1 \leq \alpha_1$, $\beta_1 \leq \beta_2 \leq \alpha_1 + 1$, and S_1 is a stability factor independent of h_1.

The theorem is valid independently of the size of $\|U_1^{\{k\}} - \pi_1 U_2^{\{k\}}\|_\Gamma$, but, when the iteration converges such that this term is negligible, it is clear that the term

containing h_1^β decreases at a slower rate than the other terms. In fact, if we assume that $u_1 \in H^2(\Omega_1)$ and $u_2 \in H^2(\Omega_2)$, then the other terms are $\mathbf{O}(h_1^2)$ or $\mathbf{O}(h_2^2)$, while the finite element flux is $\mathbf{O}(h_1)$ at best. Suppose that instead we set $\theta_h^{\{k\}} = \sigma^{\{k\}}$ instead of the finite element flux. As shown in Lemma 5.4, this reduces I_4 to

$$I_4 = (\sigma^{\{k\}}, \pi_2\phi_2 - \pi_1\phi_1)_\Gamma,$$

resulting in the following theorem.

THEOREM 5.7. *Assume that the triangulations $T_{1,h}$ and $T_{2,h}$* do not *match along the interface Γ. If $U_1^{\{k\}}$ and $U_2^{\{k\}}$ solve* (3.3) *and* (3.8)*, respectively, then the errors $e_1 = u_1 - U_1^{\{k\}}$ and $e_2 = u_2 - U_2^{\{k\}}$ satisfy*

$$\begin{aligned}
\|e_1\|_{\Omega_1} + \|e_2\|_{\Omega_2} \le & \sum_{K\in T_{1,h}} \begin{pmatrix} \|f_1 - L_1U_1^{\{k\}}\|_K \\ \frac{1}{2}\|h_K^{-1/2}[A_1\partial_n U_1^{\{k\}}]\|_{\partial K}\end{pmatrix} \cdot \begin{pmatrix} Ch_K^{1+\alpha_1}|\phi_1|_{K,1+\alpha_1} \\ Ch_K^{1+\alpha_1}|\phi_1|_{K,1+\alpha_1}\end{pmatrix} \\
& + \sum_{K\in T_{2,h}} \begin{pmatrix} \|f_2 - L_2U_2^{\{k\}}\|_K \\ \frac{1}{2}\|h_K^{-1/2}[A_2\partial_n U_2^{\{k\}}]\|_{\partial K}\end{pmatrix} \cdot \begin{pmatrix} Ch_K^{1+\alpha_2}|\phi_2|_{K,1+\alpha_2} \\ Ch_K^{1+\alpha_2}|\phi_2|_{K,1+\alpha_2}\end{pmatrix} \\
& + \left(\|h_1^{-1/2}(\sigma^{\{k\}} - A_1\partial_n U_1^{\{k\}})\|_\Gamma\right) \cdot \left(Ch_1^{1+\alpha_1}|\phi_1|_{1+\alpha_1}\right) \\
& + \left(\|h_2^{-1/2}(A_2\partial_n U_2^{\{k\}} - \sigma^{\{k\}})\|_\Gamma\right) \cdot \left(Ch_2^{1+\alpha_2}|\phi_2|_{1+\alpha_2}\right) \\
& + \left(\|A_1\partial_n\phi_1\|_\Gamma\right) \cdot \left(\|U_1^{\{k\}} - \pi_1 U_2^{\{k\}}\|_\Gamma\right) \\
& + C_1h_1^{1/2+\alpha_1}\left((S_2+S_3)|\phi_1|_{\Gamma,1/2+\alpha_1} + S_4|\hat{u}|_{\Gamma,1/2+\alpha_1}\right) \\
& + C_1h_2^{1/2+\alpha_2}\left((S_2+S_3)|\phi_2|_{\Gamma,1/2+\alpha_2} + S_4|\hat{u}|_{\Gamma,1/2+\alpha_2}\right),
\end{aligned}$$

where $S_2 = \|\sigma^{\{k\}}\|_\Gamma$, $S_3 = \|\sigma^{\{k\}}\|_\Gamma$, and $S_4 = \|A_1\partial_n\phi_1\|_\Gamma$.

COROLLARY 5.8. *Assume that the triangulations $T_{1,h}$ and $T_{2,h}$ match along the interface Γ. If $U_1^{\{k\}}$ and $U_2^{\{k\}}$ solve* (3.3) *and* (3.8)*, respectively, then the errors $e_1 = u_1 - U_1^{\{k\}}$ and $e_2 = u_2 - U_2^{\{k\}}$ satisfy*

$$\begin{aligned}
\|e_1\|_{\Omega_1} + \|e_2\|_{\Omega_2} \le & \sum_{K\in T_{1,h}} \begin{pmatrix} \|f_1 - L_1U_1^{\{k\}}\|_K \\ \frac{1}{2}\|h_K^{-1/2}[A_1\partial_n U_1^{\{k\}}]\|_{\partial K}\end{pmatrix} \cdot \begin{pmatrix} Ch_K^{1+\alpha_1}|\phi_1|_{K,1+\alpha_1} \\ Ch_K^{1+\alpha_1}|\phi_1|_{K,1+\alpha_1}\end{pmatrix} \\
& + \sum_{K\in T_{2,h}} \begin{pmatrix} \|f_2 - L_2U_2^{\{k\}}\|_K \\ \frac{1}{2}\|h_K^{-1/2}[A_2\partial_n U_2^{\{k\}}]\|_{\partial K}\end{pmatrix} \cdot \begin{pmatrix} Ch_K^{1+\alpha_2}|\phi_2|_{K,1+\alpha_2} \\ Ch_K^{1+\alpha_2}|\phi_2|_{K,1+\alpha_2}\end{pmatrix} \\
& + \left(\|h_1^{-1/2}(\sigma^{\{k\}} - A_1\partial_n U_1^{\{k\}})\|_\Gamma\right) \cdot \left(Ch_1^{1+\alpha_1}|\phi_1|_{1+\alpha_1}\right) \\
& + \left(\|h_2^{-1/2}(A_2\partial_n U_2^{\{k\}} - \sigma^{\{k\}})\|_\Gamma\right) \cdot \left(Ch_2^{1+\alpha_2}|\phi_2|_{1+\alpha_2}\right) \\
& + \left(\|A_1\partial_n\phi_1\|_\Gamma\right) \cdot \left(\|U_1^{\{k\}} - \pi_1 U_2^{\{k\}}\|_\Gamma\right).
\end{aligned}$$

Comparing Theorem 5.7 with Theorem 5.5 and Corollary 5.8 with Corollary 5.6, we see that the terms involving h^{β_1} and h^{β_2} have dropped out and the optimal order of convergence of the numerical approximation has been restored.

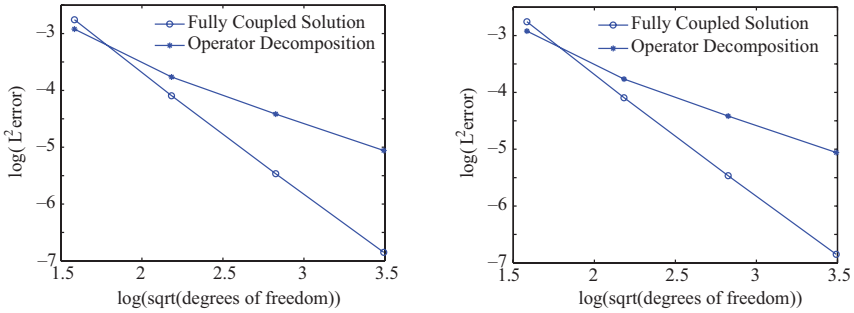

FIG. 5.1. *Comparison of the L^2 error in the fully coupled approximation and the operator decomposition approximation over Ω_1 (left) and Ω_2 (right) with mixed boundary conditions on $\partial\Omega_i\backslash\Gamma$ for $i = 1, 2$.*

5.2. Numerical results.

Example 5.1. Let $\Omega_1 = [0,1] \times [0,1]$ and $\Omega_2 = [1,2] \times [0,1]$, and assume that the triangulations match along $\Gamma = \{(x,y) |\ x = 1,\ 0 \le y \le 1\}$. Consider the elliptic interface problem

$$\begin{cases} -\nabla \cdot (\nabla u_1) = f_1, & x \in \Omega_1, \\ \begin{cases} u_1 = u_2, \\ \partial_n u_1 = \partial_n u_2, \end{cases} & x \in \Gamma, \\ -\nabla \cdot (\nabla u_2) = f_2, & x \in \Omega_2, \end{cases} \tag{5.3}$$

where the data $f_1(x,y)$ and $f_2(x,y)$ are chosen so the true solutions are $u_1 = u_2 = \sin(\pi x/2)\sin(2\pi y)$. The purpose of this experiment is to show how the asymptotic $\mathbf{O}(h_1^\beta)$ convergence rate may be masked by apparently minor changes to the problem and therefore may be difficult to observe in all situations. We first solve (5.3) with the boundary conditions

$$\begin{cases} u_1 = 0 & \text{along } x = 0 \text{ and } y = 0, \\ \partial_n u_1 = 2\pi \sin(\pi x/2) & \text{along } y = 1, \\ u_2 = 0 & \text{along } x = 2 \text{ and } y = 0, \\ \partial_n u_2 = 2\pi \sin(\pi x/2) & \text{along } y = 1. \end{cases}$$

We set $\alpha = 1/2$ and iterate until the convergence criteria is met. For comparison, we also solve (5.3) by using a fully coupled method on the same mesh in *COMSOL*. We see, in Figure 5.1, that the fully coupled solution converges quadratically, while the iterative solution converges linearly. Next, we solve (5.3) with Dirichlet boundary conditions

$$\begin{cases} u_1 = 0, & x \in \partial\Omega_1\backslash\Gamma, \\ u_2 = 0, & x \in \partial\Omega_2\backslash\Gamma, \end{cases}$$

and again we also solve the fully coupled problem for comparison. In Figure 5.2, we observe that the operator decomposition solution appears to converge quadratically, but eventually the $\mathbf{O}(h_1^\beta)$ term dominates and the convergence is ultimately linear.

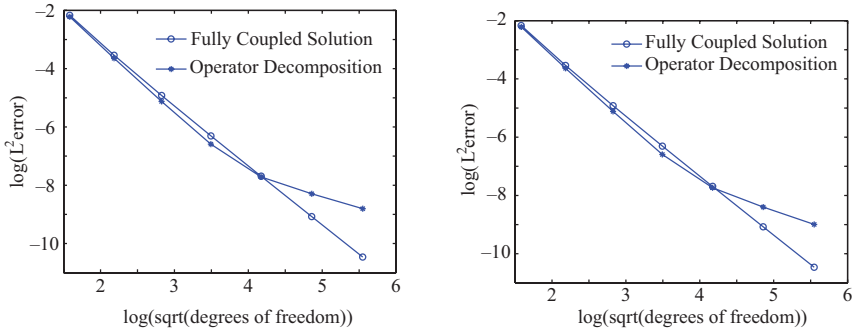

FIG. 5.2. *Comparison of the L^2 error in the fully coupled approximation and the iterative approximation over Ω_1 (left) and Ω_2 (right) with Dirichlet boundary conditions on $\partial\Omega_i\backslash\Gamma$ for $i = 1, 2$.*

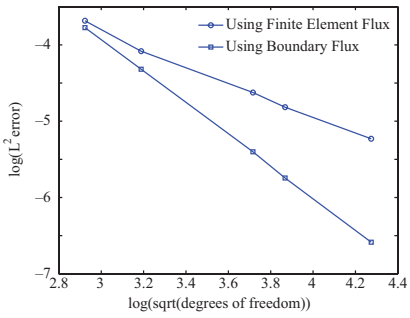

FIG. 5.3. *Comparison of the L^2 error in the iterative approximation using the finite element flux and the recovered boundary flux over $\Omega_1 \cup \Omega_2$ with mixed boundary conditions on $\partial\Omega_i\backslash\Gamma$ for $i = 1, 2$.*

Example 5.2. In the final example we assume that the triangulations do not match along the interface and consider (5.3) with the mixed boundary conditions

$$\begin{cases} u_1 = 0 & \text{along } x = 0, \\ A_1\partial_n u_1 = 2\pi \sin(\pi x/2) & \text{along } y = 1, \\ A_1\partial_n u_1 = -2\pi \sin(\pi x/2) & \text{along } y = 0, \\ u_2 = 0 & \text{along } x = 2, \\ A_2\partial_n u_2 = 2\pi \sin(\pi x/2) & \text{along } y = 1, \\ A_2\partial_n u_2 = -2\pi \sin(\pi x/2) & \text{along } y = 0. \end{cases}$$

First, we solve the problem iteratively by using operator decomposition by passing the finite element flux $A_1\partial_n U_1^{\{k\}}$. Next, we use the recovered boundary flux method to compute and pass $\sigma^{\{k\}}$. In Figure 5.3, we compare the L^2 errors over $\Omega_1 \cup \Omega_2$ on a series of meshes. We see that the approximations using the finite element flux converge linearly, while the approximations using the recovered boundary flux converge quadratically.

6. Conclusion. We have conducted an a posteriori error analysis of a finite element implementation of a number of operator decomposition strategies for a canonical conjugate heat transfer problem. By modifying the standard approach based on variational analysis, residuals, and the generalized Green's function, we derive accurate

error estimates and use these estimates to guide adaptive mesh refinement. Modifications to the standard error analysis account for the transfer of error between components of the decomposed operator and interpolation error. Our analysis also accounts for the differences between the adjoints of the full problem and the operator decomposition system. We show that the loss of order typically observed in the operator decomposition method is due to inaccuracy of the transferred gradient information, and we show how the boundary flux method can be used to efficiently regain the expected optimal order of convergence.

A BDDC ALGORITHM FOR MORTAR DISCRETIZATION OF ELASTICITY PROBLEMS*

HYEA HYUN KIM†

Abstract. A balancing domain decomposition by constraints (BDDC) algorithm is developed for compressible elasticity problems in three dimensions with mortar discretization on geometrically nonconforming subdomain partitions. Material parameters of the elasticity problems may have jump across the subdomain interface. Coarse basis functions in the BDDC algorithm are constructed from primal constraints on faces, which are similar to the average matching condition and the moment matching condition considered in [A. Klawonn and O. B. Widlund, *Comm. Pure Appl. Math.*, 59 (2006), pp. 1523–1572] and [H. H. Kim, *A FETI-DP Formulation of Three Dimensional Elasticity Problems with Mortar Discretization*, Technical report, New York University, 2005]. A condition number bound is proved to be $C(1+\log(H/h))^3$ for geometrically nonconforming partitions and to be $C(1+\log(H/h))^2$ for geometrically conforming partitions. The bound is not affected by the jump of the material parameters across the subdomain interface. Numerical results are included.

Key words. BDDC algorithm, mortar discretization, preconditioner, elasticity problems

1. Introduction.

This study is intended for development of an efficient balancing domain decomposition by constraints (BDDC) algorithm for solving mortar discretization of elasticity problems. The mortar discretization is applied to geometrically nonconforming subdomain partitions. In the geometrically nonconforming partitions, a pair of subdomains can intersect over only part of a subdomain face or a subdomain edge. Allowing geometrically nonconforming partitions makes mortar discretizations much more practical for problems given on three-dimensional complex structures with composite materials.

BDDC algorithms have been studied extensively in [16, 18, 14, 13, 15, 7] since their introduction by Dohrmann [3]. A coarse component of BDDC preconditioners is built from the weighted sum of functions that minimize discrete local energies subject to certain primal constraints across the subdomain interface. The BDDC algorithms solve linear systems of primal unknowns, in contrast to FETI-DP algorithms, which have been applied successfully to solving algebraic systems of dual unknowns during the last decade [4, 11, 12, 10, 6, 9]. This feature makes the BDDC algorithms more robust and more flexible than the FETI-DP algorithms; see [18, 15]. On the other hand, the BDDC and FETI-DP algorithms have much in common. They share the same spectra except the eigenvalues 0 and 1 when the same set of primal constraints is chosen; see [16, 14]

Both of these methods have been applied to solving problems arising from mortar discretizations. In a recent study by the author jointly with Dryja and Widlund [7], a BDDC algorithm is developed for elliptic problems. This algorithm was shown to share the same spectra with the FETI-DP algorithm considered in [8] by the author

and Lee. In addition, it is generalized to the geometrically nonconforming partitions with a slightly weaker condition number bound, $C(1+\log(H_i/h_i))^3$. The FETI-DP algorithm in [8] has been extended to solving elasticity problems by the author [6]. However, the work is limited to geometrically conforming partitions. This study aims at developing a BDDC algorithm for the elasticity problems that allows the geometrically nonconforming partitions.

FETI-DP algorithms for compressible elasticity problems employing the exact matching condition have been developed by Klawonn and Widlund [10]. Even for the compressible case, extending FETI-DP algorithms to the three-dimensional elasticity problems needed much more effort than the standard second-order problems, i.e., elliptic problems. A special difficulty arises in building certain functionals dual to six rigid body motions. These functionals are important in providing a condition number bound independent of the number of subdomains. The most important ingredient of this study is a new set of primal constraints that makes it possible to construct such functionals in geometrically nonconforming partitions employing the mortar matching condition. Using the new set of primal constraints, we build a scalable BDDC algorithm with its condition number bound, $C(1+\log(H_i/h_i))^3$.

This paper is organized as follows. In section 2, we introduce a model compressible elasticity problem. In section 3, a BDDC algorithm is developed for mortar discretization of the elasticity problem employing coarse basis functions related to the primal constraints across the subdomain interface. Section 4 is devoted to analyzing the condition number bound of the BDDC algorithm. Numerical results are provided in section 5.

Throughout the paper, c and C denote generic positive constants independent of mesh parameters, number of subdomains, and coefficients of the elasticity problems. We will use h_i and H_i to denote the mesh size and the subdomain size of Ω_i, respectively.

2. A model problem. Let Ω be a polyhedral domain in $\mathbf{R}^3$. The Sobolev space $H^1(\Omega)$ is a set of functions in $L^2(\Omega)$ that are square integrable up to first weak derivatives, and it is equipped with the Sobolev norm

$$\|v\|^2_{1,\Omega} := |v|^2_{1,\Omega} + \frac{1}{H^2}\|v\|^2_{0,\Omega},$$

where $|v|^2_{1,\Omega} = \int_\Omega \nabla v \cdot \nabla v \, dx$, $\|v\|^2_{0,\Omega} = \int_\Omega v^2 \, dx$, and H is the diameter of Ω.

We assume that $\partial\Omega$ is divided into two parts, $\partial\Omega_D$ and $\partial\Omega_N$, on which a Dirichlet boundary condition and a natural boundary condition are given, respectively. The subspace $H^1_D(\Omega) \subset H^1(\Omega)$ is a set of functions having zero trace on $\partial\Omega_D$. We introduce the vector-valued Sobolev spaces, $[H^1_D(\Omega)]^3$ and $[H^1(\Omega)]^3$, equipped with the usual product norm.

We then consider the elasticity problem: Find $\mathbf{u} \in [H^1_D(\Omega)]^3$ such that

$$\int_\Omega G(\mathbf{x})\varepsilon(\mathbf{u}) : \varepsilon(\mathbf{v}) \, d\mathbf{x} + \int_\Omega G(\mathbf{x})\beta(\mathbf{x})\nabla\cdot\mathbf{u}\nabla\cdot\mathbf{v} \, d\mathbf{x} = \langle \mathbf{F}, \mathbf{v}\rangle \quad \forall \mathbf{v} \in [H^1_D(\Omega)]^3, \tag{2.1}$$

where $G = E/(1+\nu)$ and $\beta = \nu/(1-2\nu)$ are material parameters depending on the Young's modulus $E > 0$ and the Poisson ratio $\nu \in (0, 1/2]$. We assume that ν is bounded away from $1/2$ so that we exclude the case of incompressible elasticity problems. We note that $G(\mathbf{x})$ and $\beta(\mathbf{x})$ can be discontinuous; i.e., they can have

different values at different parts of Ω. The linearized strain tensor is defined by

$$\varepsilon_{ij}(\mathbf{u}) := \frac{1}{2}\left(\frac{\partial u_i}{\partial x_j} + \frac{\partial u_j}{\partial x_i}\right), \quad i,j = 1,2,3,$$

and the tensor product and the force term are given by

$$\varepsilon(\mathbf{u}) : \varepsilon(\mathbf{v}) = \sum_{i,j=1}^{3} \varepsilon_{ij}(\mathbf{u})\varepsilon_{ij}(\mathbf{v}), \quad \langle \mathbf{F}, \mathbf{v}\rangle = \int_{\Omega} \mathbf{f}\cdot\mathbf{v}\, d\mathbf{x} + \int_{\partial\Omega_N} \mathbf{g}\cdot\mathbf{v} d\sigma.$$

Here $\mathbf{f}$ is the body force and $\mathbf{g}$ is the surface force on the natural boundary part $\partial\Omega_N$.

The space $\mathbf{ker}(\varepsilon)$ has the following six rigid body motions as its basis, which are three translations

$$\mathbf{r}_1 = \begin{pmatrix}1\\0\\0\end{pmatrix}, \quad \mathbf{r}_2 = \begin{pmatrix}0\\1\\0\end{pmatrix}, \quad \mathbf{r}_3 = \begin{pmatrix}0\\0\\1\end{pmatrix}, \tag{2.2}$$

and three rotations

$$\mathbf{r}_4 = \frac{1}{H}\begin{pmatrix}x_2 - \widehat{x}_2\\ -x_1 + \widehat{x}_1\\ 0\end{pmatrix}, \quad \mathbf{r}_5 = \frac{1}{H}\begin{pmatrix}-x_3 + \widehat{x}_3\\ 0\\ x_1 - \widehat{x}_1\end{pmatrix}, \quad \mathbf{r}_6 = \frac{1}{H}\begin{pmatrix}0\\ x_3 - \widehat{x}_3\\ -x_2 + \widehat{x}_2\end{pmatrix}. \tag{2.3}$$

Here $\widehat{\mathbf{x}} = (\widehat{x}_1, \widehat{x}_2, \widehat{x}_3) \in \Omega$ and H is the diameter of Ω. This shift and the scaling make the L_2-norm of the six vectors scale in the same way with H.

When Ω is partitioned into a set of subdomains, the elasticity problem given on a floating subdomain has purely natural boundary condition. The Korn inequalities provided in section 6 of [10] concern this case. In the following, Σ is any open subset of $\partial\Omega$ with positive measure and its diameter is comparable to that of Ω. Let $(\mathbf{u},\mathbf{r})_\Sigma$ be an L_2-inner product given by

$$(\mathbf{u},\mathbf{r})_\Sigma = \int_\Sigma \mathbf{u}\cdot\mathbf{r}\, ds.$$

We introduce two seminorms provided for the space $[H^{1/2}(\Sigma)]^3$, which is a trace space of $[H^1(\Omega)]^3$,

$$|\mathbf{u}|_{1/2,\Sigma} := \inf_{\substack{\mathbf{v}\in[H^1(\Omega)]^3\\ \mathbf{v}|_\Sigma = \mathbf{u}}} |\mathbf{v}|_{1,\Omega}, \quad |\mathbf{u}|_{E(\Sigma)} := \inf_{\substack{\mathbf{v}\in[H^1(\Omega)]^3\\ \mathbf{v}|_\Sigma = \mathbf{u}}} \|\varepsilon(\mathbf{v})\|_{0,\Omega}.$$

The following Korn inequality is provided in [10, Lemma 6.4].

LEMMA 2.1. *Let Ω be a* Lipschitz *domain and let Σ be a subset of $\partial\Omega$ with positive measure. Then there exists a constant $c > 0$ such that*

$$c|\mathbf{u}|_{1/2,\Sigma} \le |\mathbf{u}|_{E(\Sigma)} \le |\mathbf{u}|_{1/2,\Sigma}$$

for $\mathbf{u} \in [H^{1/2}(\Sigma)]^3$ satisfying $(\mathbf{u},\mathbf{r})_\Sigma = 0$ for all $\mathbf{r} \in \mathbf{ker}(\varepsilon)$.

Another important inequality can be found in [10, Lemma 6.6].

LEMMA 2.2. *Let Ω be a* Lipschitz *domain of the diameter H and let $\Sigma \subset \partial\Omega$ be an open subset with positive measure. Then there exists a constant $C > 0$ such that*

$$\inf_{\mathbf{r}\in\mathbf{ker}(\varepsilon)} \|\mathbf{u} - \mathbf{r}\|_{0,\Sigma}^2 \le CH|\mathbf{u}|_{E(\Sigma)}^2 \quad \forall \mathbf{u} \in [H^{1/2}(\Sigma)]^3.$$

We note that the infimum above occurs when $\mathbf{u} - \mathbf{r}$ satisfies

$$(\mathbf{u} - \mathbf{r}, \mathbf{s})_\Sigma = 0 \quad \forall \mathbf{s} \in \mathbf{ker}(\varepsilon).$$

3. BDDC formulation for elasticity.

3.1. Mortar discretization. We divide the domain Ω into a geometrically nonconforming partition $\{\Omega_i\}_{i=1}^N$, which is shape regular. We consider a compressible elasticity problem with coefficients $G(\mathbf{x})$ and $\beta(\mathbf{x})$ positive constants in each subdomain

$$G(\mathbf{x})|_{\Omega_i} = G_i, \quad \beta(\mathbf{x})|_{\Omega_i} = \beta_i.$$

The conforming P_1-finite element space $\mathbf{X}_i$ is associated with a quasi-uniform triangulation T_i of each subdomain Ω_i. In addition, functions in the space $\mathbf{X}_i$ satisfy the Dirichlet boundary condition on $\partial\Omega_i \cap \partial\Omega_D$. The triangulations $\{T_i\}_{i=1}^N$ may not match across the subdomain interface. We note that it is more economical to use larger mesh sizes for larger values G_i, since there are only small changes in the solution when $\mathbf{F}$ in (2.1) does not reflect the jump in the coefficient $G(\mathbf{x})$, so that allowing nonmatching triangulations is useful for implementing such adaptivity. We denote by $\mathbf{W}_i$ the trace space of $\mathbf{X}_i$ on $\partial\Omega_i$ and define the spaces

$$\mathbf{X} = \prod_{i=1}^N \mathbf{X}_i, \quad \mathbf{W} = \prod_{i=1}^N \mathbf{W}_i.$$

Functions in these spaces can be discontinuous across the subdomain interface.

In three dimensions, a pair of subdomains can have a face, an edge, or a vertex in common. We will regard only the common faces as the subdomain interface. In a geometrically nonconforming partition, a common face can be only a part of a subdomain face. The union of all common faces is denoted by

$$\Gamma = \left(\bigcup_{ij} \partial\Omega_i \cap \partial\Omega_j \right) \setminus \partial\Omega.$$

Among the subdomain faces, we can select a collection of faces F_l (see [17, section 4.1]) such that

$$\bigcup_l \overline{F}_l = \overline{\Gamma}, \quad F_l \cap F_k = \emptyset,\ l \neq k.$$

We call F_l nonmortar faces. They are a full subdomain face.

Since the subdomain partition can be geometrically nonconforming, a single nonmortar face $F_l \subset \partial\Omega_i$ may intersect with several subdomain boundaries $\partial\Omega_j$. This provides F_l with a partition

$$\overline{F}_l = \bigcup_j \overline{F}_{ij}, \quad F_{ij} = \partial\Omega_i \cap \partial\Omega_j.$$

We call the opposite part F_{ij} mortar neighbors of F_l.

A dual or a standard Lagrange multiplier space $\mathbf{M}_l$ is given for each nonmortar face F_l. The space $\mathbf{M}_l$ is required to have the same dimension as the space

$$\overset{\circ}{\mathbf{W}}(F_l) := \mathbf{W}_i|_{F_l} \cap [H_0^1(F_l)]^3 \tag{3.1}$$

and to contain constant functions. Constructions of such Lagrange multiplier spaces have been studied in [1, 2, 19, 5]. On a nonmortar face $F_l \subset \partial\Omega_i$, a function $\boldsymbol{\phi}$, that is provided from its mortar neighbors of F_l, is given by

$$\boldsymbol{\phi} = \mathbf{v}_j \text{ on } F_{ij} \quad \forall j,$$

where $\mathbf{v} = (\mathbf{v}_1, \ldots, \mathbf{v}_N) \in \mathbf{X}$. The mortar matching condition on $\mathbf{v} \in \mathbf{X}$ is

$$\int_{F_l} (\mathbf{v}_i - \boldsymbol{\phi}) \cdot \boldsymbol{\lambda}\, ds = 0 \quad \forall \boldsymbol{\lambda} \in \mathbf{M}_l,\ \forall F_l. \tag{3.2}$$

The mortar discretization of the problem (2.1) is to approximate the solution by Galerkin's method in the mortar finite element space,

$$\widehat{\mathbf{X}} := \{\mathbf{v} \in \mathbf{X} \,:\, \mathbf{v} \text{ satisfies the mortar matching condition (3.2)}\}.$$

3.2. Primal constraints and change of variables. We will first select certain primal constraints on functions in $\mathbf{X}$ (or $\mathbf{W}$) from the mortar matching condition (3.2) to construct coarse basis functions. These basis functions will be used to build a preconditioner in our BDDC algorithm. In addition, we introduce a change of variables (basis) for the unknowns (functions) in the space $\mathbf{W}$ to make the primal constraints explicit.

On a nonmortar face F_l, we consider the rigid body motions $\{\mathbf{r}_k\}_{k=1}^6$ as in (2.2) and (2.3), where H is the diameter of the face F_l and $\widehat{\mathbf{x}}$ is a point in F_l. We define a nodal interpolant $I_{F_l} : L^2(F_l) \to M_l$ such that

$$I_{F_l}(w)(x) = \sum_m w(x_m)\psi_m(x), \tag{3.3}$$

where ψ_m is the basis element of M_l to the node x_m in the finite element space $\overset{\circ}{\mathbf{W}}(F_l)$; see (3.1). We extend the nodal interpolant to the product spaces $[L^2(F_l)]^3$ and $\mathbf{M}_l (= [M_l]^3)$, and we denote it by $\mathbf{I}_{F_l}$. By using the interpolated rigid body motions $\{\mathbf{I}_{F_l}(\mathbf{r}_k)\}_{k=1}^6$, we select the following six primal constraints from (3.2) on each nonmortar face $F_l \subset \partial\Omega_i$:

$$\int_{F_l} (\mathbf{w}_i - \boldsymbol{\phi}) \cdot \mathbf{I}_{F_l}(\mathbf{r}_k)\, ds = 0 \quad \forall k = 1, \ldots, 6, \tag{3.4}$$

where $\boldsymbol{\phi} = \mathbf{w}_j$ on $F_{ij}\, (= \partial\Omega_i \cap \partial\Omega_j) \subset F_l$.

In geometrically conforming partitions, i.e., F_l is a full face of two subdomains, the above constraints with $\{\mathbf{I}_{F_l}(\mathbf{r}_k)\}_{k=1}^3$ are face average matching conditions because $\mathbf{I}_{F_l}(\mathbf{r}_k) = \mathbf{r}_k$, $k = 1, 2, 3$, and $\boldsymbol{\phi} = \mathbf{w}_j$ on F_l. The remaining constraints with $\{\mathbf{I}_{F_l}(\mathbf{r}_k)\}_{k=4}^6$ are similar to the moment matching constraints which were introduced for fully primal edges in [10]. We call the constraints with $\{\mathbf{I}_{F_l}(\mathbf{r}_k)\}_{k=1}^3$ average constraints and call the other constraints with $\{\mathbf{I}_{F_l}(\mathbf{r}_k)\}_{k=4}^6$ moment constraints.

We now introduce a change of variables to make the primal constraints explicit; see Li and Widlund [14] or Kim, Dryja, and Widlund [7]. The change of variables leads to much simpler analysis of the BDDC algorithms.

On a nonmortar face $F_l \subset \partial\Omega_i$, unknowns $\mathbf{w}_i$ are represented by new unknowns $(\widehat{\mathbf{w}}_{\Delta,i}, \widehat{\mathbf{w}}_{\Pi,i})$ using a transform T_l such that

$$\mathbf{w}_i|_{F_l} = T_l \begin{pmatrix} \widehat{\mathbf{w}}_{\Delta,i} \\ \widehat{\mathbf{w}}_{\Pi,i} \end{pmatrix}, \tag{3.5}$$

with the unknowns $\widehat{\mathbf{w}}_{\Pi,i}$ of six components,

$$(\widehat{\mathbf{w}}_{\Pi,i})_k = \frac{\int_{F_l} \mathbf{w}_i \cdot \mathbf{I}_{F_l}(\mathbf{r}_k)\, ds}{\int_{F_l} \mathbf{I}_{F_l}(\mathbf{r}_k) \cdot \mathbf{I}_{F_l}(\mathbf{r}_k)\, ds}, \qquad k = 1, \ldots, 6,$$

and with $\widehat{\mathbf{w}}_{\Delta,i}$ giving the following six values zero, i.e.,

$$\int_{F_l} \mathbf{w}_{\Delta,i} \cdot \mathbf{I}_{F_l}(\mathbf{r}_k)\, ds = 0, \quad k = 1, \ldots, 6, \qquad \text{with } \mathbf{w}_{\Delta,i} = T_l \begin{pmatrix} \widehat{\mathbf{w}}_{\Delta,i} \\ 0 \end{pmatrix}.$$

We call $\widehat{\mathbf{w}}_{\Pi,i}$ primal unknowns. In addition, the transform can be built in such a way that it changes unknowns of which nodal basis are supported in the face F_l and it retains the other unknowns. Therefore, the transform can be applied to each nonmortar face F_l independently; see [7, section 2.2] for a detailed construction.

We now consider a change of variables on mortar neighbors of F_l. The nonmortar face F_l is partitioned into $\{F_{ij}\}_j$, where $F_{ij} = \partial\Omega_i \cap \partial\Omega_j$. On each mortar interface F_{ij} we introduce primal variables $\widehat{\mathbf{w}}_{\Pi,ij}$ of six components,

$$(\widehat{\mathbf{w}}_{\Pi,ij})_k = \frac{\int_{F_{ij}} \mathbf{w}_j \cdot \mathbf{I}_{F_l}(\mathbf{r}_k)\, ds}{\int_{F_{ij}} \mathbf{I}_{F_l}(\mathbf{r}_k) \cdot \mathbf{I}_{F_l}(\mathbf{r}_k)\, ds}, \qquad k = 1, \ldots, 6.$$

Similarly as before, we take a transform T_{ij} such that

$$\mathbf{w}_j|_{F_{ij}} = T_{ij} \begin{pmatrix} \widehat{\mathbf{w}}_{\Delta,ij} \\ \widehat{\mathbf{w}}_{\Pi,ij} \end{pmatrix},$$

with $\widehat{\mathbf{w}}_{\Delta,ij}$ giving the following six values zero:

$$\int_{F_{ij}} \mathbf{w}_{\Delta,ij} \cdot \mathbf{I}_{F_l}(\mathbf{r}_k)\, ds = 0, \quad k = 1, \ldots, 6, \qquad \text{with } \mathbf{w}_{\Delta,ij} = T_{ij} \begin{pmatrix} \widehat{\mathbf{w}}_{\Delta,ij} \\ 0 \end{pmatrix}.$$

The primal constraints (3.4) on F_l are then written as

$$(\widehat{\mathbf{w}}_{\Pi,i})_k = \sum_j A_{jk} (\widehat{\mathbf{w}}_{\Pi,ij})_k, \quad k = 1, \ldots, 6, \tag{3.6}$$

where

$$A_{jk} = \frac{\int_{F_{ij}} \mathbf{I}_{F_l}(\mathbf{r}_k) \cdot \mathbf{I}_{F_l}(\mathbf{r}_k)\, ds}{\int_{F_l} \mathbf{I}_{F_l}(\mathbf{r}_k) \cdot \mathbf{I}_{F_l}(\mathbf{r}_k)\, ds},$$

and $(\mathbf{v})_k$ denotes the kth component of the vector $\mathbf{v}$.

Remark 3.1. We note that the primal constraints (3.6) are new. In the previous work on elliptic problems [7], primal constraints are given on every piece F_{ij} of F_l

$$\int_{F_{ij}} (w_i - w_j)\, \psi_{ij}\, ds,$$

where ψ_{ij} is the sum of basis of M_l supported in $\overline{F}_{ij}$. Note that $\psi_{ij} = 1$ for the geometrically conforming partitions.

Remark 3.2. Instead of the interpolant $\mathbf{I}_{F_l}$, we might be able to introduce the interpolant $\mathbf{I}_{F_{ij}} \colon [L^2(F_{ij})]^3 \to \mathbf{M}_{ij}$, where $\mathbf{M}_{ij}$ is the space with its basis $\boldsymbol{\psi} \in \mathbf{M}_l$ supported in $\overline{F}_{ij}$. Correspondingly, we might select primal constraints similar to those in [7] such that

$$\int_{F_{ij}} (\mathbf{w}_i - \mathbf{w}_j) \cdot \mathbf{I}_{F_{ij}}(\mathbf{r}_k)\, ds = 0.$$

However, the above constraints need more primal unknowns on the nonmortar face F_l than those in (3.6).

These transforms can be applied independently to each nonmortar face F_l and each mortar interface F_{ij}. After applying the change of variables, we write the unknowns in each subdomain boundary as

$$\widehat{\mathbf{w}}_i = \begin{pmatrix} \widehat{\mathbf{w}}_{\Delta}^{(i)} \\ \widehat{\mathbf{w}}_{\Pi}^{(i)} \end{pmatrix},$$

where the subscript Π denotes the primal unknowns. To simplify notation, we will omit the hat notation for the new unknowns. Accordingly, the space $\mathbf{W}_i$ can be decomposed into

$$\mathbf{W}_i = \mathbf{W}_{\Delta}^{(i)} \times \mathbf{W}_{\Pi}^{(i)}.$$

Here the space $\mathbf{W}_{\Pi}^{(i)}$ consists of primal unknowns in Ω_i and $\mathbf{W}_{\Delta}^{(i)}$ is the space of the other unknowns. Similarly, after the change of unknowns (basis), the Schur complement matrix S_i and the Schur complement forcing vector $\mathbf{g}_i$ of the local elasticity problem can be written as

$$S_i = \begin{pmatrix} S_{\Delta\Delta}^{(i)} & S_{\Delta\Pi}^{(i)} \\ S_{\Pi\Delta}^{(i)} & S_{\Pi\Pi}^{(i)} \end{pmatrix}, \quad \mathbf{g}_i = \begin{pmatrix} \mathbf{g}_{\Delta}^{(i)} \\ \mathbf{g}_{\Pi}^{(i)} \end{pmatrix}.$$

We note that S_i is obtained from the stiffness matrix K_i of the local elasticity problem after the elimination of the interior unknowns:

$$K_i = \begin{pmatrix} K_{II}^{(i)} & K_{I\Delta}^{(i)} & K_{I\Pi}^{(i)} \\ K_{\Delta I}^{(i)} & K_{\Delta\Delta}^{(i)} & K_{\Delta\Pi}^{(i)} \\ K_{\Pi I}^{(i)} & K_{\Pi\Delta}^{(i)} & K_{\Pi\Pi}^{(i)} \end{pmatrix},$$

$$S_i = \begin{pmatrix} K_{\Delta\Delta}^{(i)} & K_{\Delta\Pi}^{(i)} \\ K_{\Pi\Delta}^{(i)} & K_{\Pi\Pi}^{(i)} \end{pmatrix} - \begin{pmatrix} K_{\Delta I}^{(i)} \\ K_{\Pi I}^{(i)} \end{pmatrix} {K_{II}^{(i)}}^{-1} \begin{pmatrix} K_{I\Delta}^{(i)} & K_{I\Pi}^{(i)} \end{pmatrix}.$$

We introduce the space $\widetilde{\mathbf{W}}$ of functions satisfying the primal constraints:

$$\widetilde{\mathbf{W}} = \{\mathbf{w} \in \mathbf{W} \,:\, \mathbf{w} \text{ satisfies the primal constraints (3.4)}\}.$$

In the following, we derive a matrix representation of the mortar matching condition (3.2) on functions in this space $\widetilde{\mathbf{W}}$.

We denote by $\mathbf{W}_{\Pi}$ the space of primal unknowns of all mortar faces and by $\mathbf{W}_{\Delta}$ the space of unknowns other than the primal unknowns, i.e.,

$$\mathbf{W}_{\Delta} = \prod_{i=1}^{N} \mathbf{W}_{\Delta}^{(i)}.$$

We call $\mathbf{W}_{\Pi}$ the space of global primal unknowns. From the relation (3.6), we can define the mapping from the global primal unknowns to the local primal unknowns:

$$R_{\Pi}^{(i)} \,:\, \mathbf{W}_{\Pi} \to \mathbf{W}_{\Pi}^{(i)}. \tag{3.7}$$

The matrix $R_{\Pi}^{(i)}$ is not a Boolean matrix for the geometrically nonconforming case, while it is a Boolean matrix for the geometrically conforming case. The mortar matching condition (3.2) on $\mathbf{w} \in \widetilde{\mathbf{W}}$ can be written as

$$B_{\Delta}\mathbf{w}_{\Delta} + B_{\Pi}\mathbf{w}_{\Pi} = 0. \tag{3.8}$$

Since $\mathbf{w} \in \widetilde{\mathbf{W}}$ satisfies the primal constraints (3.4) that are selected from (3.2), the above constraints (3.8) are redundant on $\mathbf{w} \in \widetilde{\mathbf{W}}$. We can make them nonredundant after deleting six equations from (3.8) corresponding to each nonmortar face F_l. We will use the same notation (3.8) for the nonredundant mortar matching constraints.

We further decompose

$$\mathbf{W}_{\Delta} = \mathbf{W}_{\Delta,n} \times \mathbf{W}_{\Delta,m},$$

where n and m denote unknowns at nonmortar faces (open) and the remaining unknowns, respectively. The condition (3.8) is then written as

$$B_n\mathbf{w}_n + B_m\mathbf{w}_m + B_{\Pi}\mathbf{w}_{\Pi} = 0. \tag{3.9}$$

We note that B_n is square and invertible, since the above equations are nonredundant and the number of unknowns $\mathbf{w}_n$ is equal to the number of the equations in (3.9).

3.3. A BDDC algorithm. We now formulate a BDDC operator for the mortar discretization of the elasticity problem (2.1). Since the matrix B_n in (3.9) is invertible,

$$\mathbf{w}_n = -B_n^{-1}(B_m\mathbf{w}_m + B_{\Pi}\mathbf{w}_{\Pi}). \tag{3.10}$$

We then define the matrix

$$R_{\Gamma} = \begin{pmatrix} -B_n^{-1}B_m & -B_n^{-1}B_{\Pi} \\ I & 0 \\ 0 & I \end{pmatrix}, \tag{3.11}$$

which maps the unknowns $(\mathbf{w}_m^t, \mathbf{w}_{\Pi}^t)^t$ to the unknowns $(\mathbf{w}_n^t, \mathbf{w}_m^t, \mathbf{w}_{\Pi}^t)^t$ satisfying the mortar matching condition (3.9). In practical implementation, it is beneficial to use the original mortar matching matrices without the change of unknowns. When $\mathbf{w}_m$ and $\mathbf{w}_{\Pi}$ are given, we perform the computation R_{Γ} as follows. From $\mathbf{w}_m$ and $\mathbf{w}_{\Pi}$, we can recover the original unknowns $\mathbf{w}_j$ on each nonmortar interface $F_{ij} \subset F_l$ using the transform T_{ij}. We denote by $\overline{\mathbf{w}}_m$ the unknowns $\mathbf{w}_j$ on the mortar interfaces F_{ij} and the unknowns in the boundary of the nonmortar face F_l. Let $\overline{\mathbf{w}}_n$ be the unknowns in the nonmortar face F_l except those on the boundary of F_l. Then we obtain $\overline{\mathbf{w}}_n$ by solving

$$\overline{\mathbf{w}}_n = \overline{B}_n^{-1}\overline{B}_m\overline{\mathbf{w}}_m.$$

Here $\overline{B}_n$ and $\overline{B}_m$ are the mortar matching matrix before the change of unknowns. After obtaining $\overline{\mathbf{w}}_n$, we perform a change of unknowns to $\overline{\mathbf{w}}_n$ and then take only the dual part $\mathbf{w}_n$ of $\overline{\mathbf{w}}_n$, so that $\mathbf{w}_n$ satisfies (3.10) for the given $\mathbf{w}_m$ and $\mathbf{w}_{\Pi}$. Lagrange multiplier spaces with dual basis give $\overline{B}_n$ a diagonal matrix, while the one with standard basis gives $\overline{B}_n$ a sparse matrix. The computation $\overline{B}_n^{-1}$ is much simpler and more efficient for the case with dual basis than for the standard case.

The mortar finite element space $\widehat{\mathbf{W}}$ can be described as

$$\widehat{\mathbf{W}} = \{\mathbf{w} = (\mathbf{w}_n, \mathbf{w}_m, \mathbf{w}_{\Pi}) \ : \ \mathbf{w} \text{ satisfies (3.9)}\}.$$

Here $\mathbf{w}_n$, $\mathbf{w}_m$, and $\mathbf{w}_\Pi$ are unknowns in the spaces $\mathbf{W}_{\Delta,n}$, $\mathbf{W}_{\Delta,m}$, and $\mathbf{W}_\Pi$, respectively. In addition, we express unknowns $(\mathbf{w}_n, \mathbf{w}_m, \mathbf{w}_\Pi)$ in the space $\widehat{\mathbf{W}}$ by using the matrix R_Γ and the unknowns $(\mathbf{w}_m, \mathbf{w}_\Pi)$:

$$\begin{pmatrix} \mathbf{w}_n \\ \mathbf{w}_m \\ \mathbf{w}_\Pi \end{pmatrix} = R_\Gamma \begin{pmatrix} \mathbf{w}_m \\ \mathbf{w}_\Pi \end{pmatrix}.$$

The mortar discretization of the elasticity problem is then given by

$$R_\Gamma^t \widetilde{S} R_\Gamma \begin{pmatrix} \mathbf{w}_m \\ \mathbf{w}_\Pi \end{pmatrix} = R_\Gamma^t \begin{pmatrix} \mathbf{g}_m \\ \mathbf{g}_\Pi \end{pmatrix}, \tag{3.12}$$

where

$$\widetilde{S} = \begin{pmatrix} S_{\Delta\Delta} & S_{\Delta\Pi} \\ S_{\Pi\Delta} & S_{\Pi\Pi} \end{pmatrix}, \quad \mathbf{g}_m = \begin{pmatrix} \mathbf{g}_m^{(1)} \\ \vdots \\ \mathbf{g}_m^{(N)} \end{pmatrix}, \quad \mathbf{g}_\Pi = \sum_i (R_\Pi^{(i)})^t \mathbf{g}_\Pi^{(i)}, \tag{3.13}$$

with $\mathbf{g}_m^{(i)}$ the part of $\mathbf{g}_\Delta^{(i)}$ to the unknowns except those interior to the nonmortar face, and

$$\begin{aligned} &S_{\Delta\Delta} = \mathrm{diag}_i \left(S_{\Delta\Delta}^{(i)} \right), \\ &S_{\Pi\Delta} = \textstyle\sum_i (R_\Pi^{(i)})^t S_{\Pi\Delta}^{(i)}, \quad S_{\Delta\Pi} = S_{\Pi\Delta}^t, \\ &S_{\Pi\Pi} = \textstyle\sum_i (R_\Pi^{(i)})^t S_{\Pi\Pi}^{(i)} R_\Pi^{(i)}. \end{aligned} \tag{3.14}$$

We note that $R_\Pi^{(i)}$ is the mapping defined in (3.7).

Our BDDC algorithm aims at solving (3.12) efficiently by the PCGM (preconditioned conjugate gradient method) with an appropriate preconditioner. The preconditioner will have local problems in Ω_i and a coarse problem in Ω as its building blocks.

The coarse problem is obtained from the coarse finite element space that is related to the primal constraints in (3.4) or (3.6). The coarse finite element space is spanned by the columns of the matrix Ψ,

$$\Psi = \begin{pmatrix} \Psi^{(1)} R_\Pi^{(1)} \\ \vdots \\ \Psi^{(N)} R_\Pi^{(N)} \end{pmatrix}, \quad \Psi^{(i)} = \begin{pmatrix} \Psi_\Delta^{(i)} \\ I_\Pi^{(i)} \end{pmatrix} = \begin{pmatrix} -(S_{\Delta\Delta}^{(i)})^{-1} S_{\Delta\Pi}^{(i)} \\ I_\Pi^{(i)} \end{pmatrix}, \tag{3.15}$$

where the matrix $I_\Pi^{(i)}$ is the identity matrix of size equal to the number of primal unknowns in Ω_i. We note that $\Psi_\Delta^{(i)}$ satisfies

$$\begin{pmatrix} S_{\Delta\Delta}^{(i)} & S_{\Delta\Pi}^{(i)} \\ S_{\Pi\Delta}^{(i)} & S_{\Pi\Pi}^{(i)} \end{pmatrix} \begin{pmatrix} \Psi_\Delta^{(i)} \\ I_\Pi^{(i)} \end{pmatrix} = \begin{pmatrix} 0 \\ F_{\Pi\Pi}^{(i)} \end{pmatrix}, \tag{3.16}$$

with

$$F_{\Pi\Pi}^{(i)} = S_{\Pi\Pi}^{(i)} - S_{\Pi\Delta}^{(i)} {S_{\Delta\Delta}^{(i)}}^{-1} S_{\Delta\Pi}^{(i)}. \tag{3.17}$$

Each column $\boldsymbol{\psi}$ of the matrix Ψ is related to one primal unknown in $\mathbf{W}_\Pi$. Since $\boldsymbol{\psi} \in \mathbf{W}$ satisfies the primal constraints (3.6), we take $\overline{\boldsymbol{\psi}} = (\boldsymbol{\psi}_\Delta^t, \boldsymbol{\psi}_\Pi^t)^t$ from the vector $\boldsymbol{\psi}$ so that $\boldsymbol{\psi}_\Delta \in \mathbf{W}_\Delta$ and $\boldsymbol{\psi}_\Pi \in \mathbf{W}_\Pi$. The matrix $\overline{\Psi}$ with the columns $\overline{\boldsymbol{\psi}}$ is then expressed by

$$\overline{\Psi} = R_\Pi^t - \sum_{i=1}^{N} (R_\Delta^{(i)})^t (S_{\Delta\Delta}^{(i)})^{-1} S_{\Delta\Pi}^{(i)} R_\Pi^{(i)}, \tag{3.18}$$

where $R_\Pi^t : \mathbf{W}_\Pi \to \mathbf{W}_\Delta \times \mathbf{W}_\Pi$ and $(R_\Delta^{(i)})^t : \mathbf{W}_\Delta^{(i)} \to \mathbf{W}_\Delta \times \mathbf{W}_\Pi$ are zero extensions.

We introduce

$$R_{D,\Gamma} = \begin{pmatrix} D_{nn} & & \\ & D_{mm} & \\ & & D_{\Pi\Pi} \end{pmatrix} R_\Gamma, \tag{3.19}$$

where the matrices D_{nn}, D_{mm}, and $D_{\Pi\Pi}$ will be specified later. We then propose the following preconditioner M^{-1} for the problem (3.12) with the local and coarse problems as its building blocks:

$$M^{-1} = R_{D,\Gamma}^t \left\{ \begin{pmatrix} S_{\Delta\Delta}^{-1} & 0 \\ 0 & 0 \end{pmatrix} + \overline{\Psi} (\Psi^t S \Psi)^{-1} \overline{\Psi}^t \right\} R_{D,\Gamma}, \tag{3.20}$$

where

$$S = \operatorname{diag}_i (S_i), \quad S_i = \begin{pmatrix} S_{\Delta\Delta}^{(i)} & S_{\Delta\Pi}^{(i)} \\ S_{\Pi\Delta}^{(i)} & S_{\Pi\Pi}^{(i)} \end{pmatrix},$$

and $S_{\Delta\Delta}$ is given in (3.14).

We will now express (3.20) in a simpler form. From the definition of Ψ in (3.15), we have

$$\Psi^t S \Psi = \sum_{i=1}^{N} (R_\Pi^{(i)})^t (\Psi^{(i)})^t S_i \Psi^{(i)} R_\Pi^{(i)}.$$

From (3.15)–(3.17), we obtain

$$\Psi^t S \Psi = \sum_{i=1}^{N} (R_\Pi^{(i)})^t F_{\Pi\Pi}^{(i)} R_\Pi^{(i)} = S_{\Pi\Pi} - S_{\Pi\Delta} S_{\Delta\Delta}^{-1} S_{\Delta\Pi}. \tag{3.21}$$

We define

$$F_{\Pi\Pi} = S_{\Pi\Pi} - S_{\Pi\Delta} S_{\Delta\Delta}^{-1} S_{\Delta\Pi}.$$

The definitions of the above matrices are given in (3.14). Using the block Cholesky factorization of $\widetilde{S}$ as in Li and Widlund [14] and above (see also (3.13)), we have

$$\begin{aligned} \widetilde{S}^{-1} = & \begin{pmatrix} S_{\Delta\Delta}^{-1} & 0 \\ 0 & 0 \end{pmatrix} \\ & + \left(R_\Pi^t - \sum_{i=1}^{N} (R_\Delta^{(i)})^t (S_{\Delta\Delta}^{(i)})^{-1} S_{\Delta\Pi}^{(i)} R_\Pi^{(i)} \right) F_{\Pi\Pi}^{-1} \\ & \times \left(R_\Pi^t - \sum_{i=1}^{N} (R_\Delta^{(i)})^t (S_{\Delta\Delta}^{(i)})^{-1} S_{\Delta\Pi}^{(i)} R_\Pi^{(i)} \right)^t. \end{aligned}$$

By combining the above equation with (3.18) and (3.21), we obtain

$$\widetilde{S}^{-1} = \begin{pmatrix} S_{\Delta\Delta}^{-1} & 0 \\ 0 & 0 \end{pmatrix} + \overline{\Psi}(\Psi^t S \Psi)^{-1} \overline{\Psi}^t.$$

Therefore, the BDDC operator (see (3.12)) with the preconditioner M^{-1} in (3.20) can be simply written as

$$B_{DDC} = R_{D,\Gamma}^t \widetilde{S}^{-1} R_{D,\Gamma} R_\Gamma^t \widetilde{S} R_\Gamma. \tag{3.22}$$

To help understand the BDDC algorithm we compare its implementation with the standard BDDC algorithm employing the direct matching condition, i.e., $u_i(x) = u_j(x)$ for the nodal points x on the subdomain interface.

Step 1. Set local stiffness matrices K_i and mortar matching matrices B_i.

Step 2. Perform change of basis to K_i depending on the primal constraints.

Step 3. Order K_i into interior, dual, and primal unknowns and B_i into unknowns in nonmortar faces (open) and the other unknowns:

$$K_i = \begin{pmatrix} K_{II}^{(i)} & K_{I\Delta}^{(i)} & K_{I\Pi}^{(i)} \\ K_{\Delta I}^{(i)} & K_{\Delta\Delta}^{(i)} & K_{\Delta\Pi}^{(i)} \\ K_{\Pi I}^{(i)} & K_{\Pi\Delta}^{(i)} & K_{\Pi\Pi}^{(i)} \end{pmatrix}, \quad B_i = \begin{pmatrix} B_n^{(i)} & B_m^{(i)} \end{pmatrix}.$$

Step 4. Compute LU factorization for $K_{II}^{(i)}$, $K_{rr}^{(i)}$, and $B_n^{(i)}$ (note that $K_{rr}^{(i)}$ stands for the part of K_i except the rows and columns to the primal unknowns).

Step 5. Compose the coarse problem matrix $F_{\Pi\Pi}$ and perform LU factorization for it:

$$F_{\Pi\Pi} = \sum_i (R_\Pi^{(i)})^t (K_{\Pi\Pi}^{(i)} - K_{\Pi r}^{(i)} (K_{rr}^{(i)})^{-1} K_{r\Pi}^{(i)}) R_\Pi^{(i)}.$$

Step 5. Perform CG iterations with the preconditioner. In each iteration, we perform the matrix-vector multiplications for the given residual r_Γ,

$$y_\Gamma = R_\Gamma^t \widetilde{S} R_\Gamma r_\Gamma, \quad z_\Gamma = R_{D,\Gamma}^t \widetilde{S}^{-1} R_{D,\Gamma} y_\Gamma.$$

We note that in Step 5 the LU factorizations of $K_{II}^{(i)}$ are used in the matrix-vector multiplication with $\widetilde{S}$, and the LU factorizations of $K_{rr}^{(i)}$ and $F_{\Pi\Pi}$ are used in the matrix-vector multiplication with $\widetilde{S}^{-1}$. In addition, LU factorizations of $B_n^{(i)}$ are used in $R_{\Gamma,D}$ and R_Γ. We note that B_i denotes the original mortar matching matrix without the change of unknowns. The computation R_Γ can be done using B_i as explained in the beginning of section 3.3. Additional complication compared to the standard BDDC algorithms is that we need to build the mortar matching matrices B_i and to perform the change of unknowns based on the primal constraints selected from the mortar matching condition. We also need to perform LU factorization to $B_n^{(i)}$. The other part of the BDDC algorithm is the same as the standard one.

4. Condition number estimate. In this section, we provide a condition number bound of the BDDC algorithm. We will first construct functionals $\{f_m\}_{m=1}^6$, dual to the space $\mathbf{ker}(\varepsilon)$, which satisfy the following properties:

$$f_m(\mathbf{r}_k) = \delta_{mk}, \quad m, k = 1, \ldots, 6,$$

$$|f_m(\mathbf{v})|^2 \le C \frac{\|\mathbf{v}\|_{0,\partial\Omega_i}^2}{H_i^2} \quad \text{for } \mathbf{v} \in [L^2(\partial\Omega_i)]^3. \tag{4.1}$$

Here $\mathbf{r}_k$ are basis of $\mathbf{ker}(\varepsilon)$ scaled with respect to a face $F \subset \partial\Omega_i$; this means that we take $\widehat{\mathbf{x}} \in F$ and $H = \mathrm{diam}(F)$ in (2.3). Such dual functionals were first introduced by Klawonn and Widlund [10]. An arbitrary rigid body motion $\mathbf{r}$ can then be represented by a linear combination of the elements of the basis $\{\mathbf{r}_k\}_{k=1}^6$,

$$\mathbf{r} = \sum_{k=1}^{6} f_k(\mathbf{r})\mathbf{r}_k.$$

We now introduce six linearly independent functionals $\left\{g_k^l\right\}_{k=1}^6$ related to the primal constraints across a nonmortar face $F_l \subset \partial\Omega_i$,

$$g_k^l(\mathbf{v}) = \frac{\int_{F_l} \mathbf{v} \cdot \mathbf{I}_{F_l}(\mathbf{r}_k^l)\, ds}{\int_{F_l} \mathbf{I}_{F_l}(\mathbf{r}_k^l) \cdot \mathbf{I}_{F_l}(\mathbf{r}_k^l)\, ds} \quad \text{for } \mathbf{v} \in [L^2(F_l)]^3,\ k = 1, \ldots, 6, \tag{4.2}$$

where $\mathbf{I}_{F_l}(\mathbf{r}_k^l)$ is the nodal interpolant defined in (3.3) and $\left\{\mathbf{r}_k^l\right\}_{k=1}^6$ are six rigid body motions scaled with respect to the face F_l. Since these functionals are linearly independent, they provide a basis of the dual space $(\mathbf{ker}(\varepsilon))'$. Thus there exists $\{\beta_{mk}\}_{m,k=1}^6$ such that

$$f_m^l = \sum_{k=1}^{6} \beta_{mk} g_k^l, \quad f_m^l(\mathbf{r}_k^l) = \delta_{mk}, \quad m = 1, \ldots, 6. \tag{4.3}$$

We will now show that $\{f_m^l\}_m$ satisfy (4.1). Since $\mathbf{r}_k^l$ are linear functions, one can show that

$$\|\mathbf{I}_{F_l}(\mathbf{r}_k^l)\|_{0,F_l}^2 \geq C H_i^2. \tag{4.4}$$

Here the constant C does not depend on any mesh parameters for sufficiently small h_i. From (4.2), (4.4), and Hölder's inequality, we obtain

$$|g_k^l(\mathbf{v})|^2 \leq C \frac{\|\mathbf{v}\|_{0,\partial\Omega_i}^2}{H_i^2} \quad \text{for } \mathbf{v} \in [L^2(\partial\Omega_i)]^3.$$

From this bound and (4.3), $\left\{f_m^l\right\}_{m=1}^6$ satisfy the bound in (4.1). We note that for $\mathbf{w} = (\mathbf{w}_1, \ldots, \mathbf{w}_N) \in \widetilde{\mathbf{W}}$, that satisfies the primal constraints, we have $g_k^l(\mathbf{w}_i) = g_k^l(\boldsymbol{\phi})$ (see (4.2) and (3.4)), so that

$$f_m^l(\mathbf{w}_i) = f_m^l(\boldsymbol{\phi}), \quad m = 1, \ldots, 6,$$

where $\boldsymbol{\phi} = \mathbf{w}_j$ on $F_{ij} \subset F_l$.

In the following, we will provide several lemmas which will be used to analyze the condition number bound of the BDDC operator. For a face $F \subset \partial\Omega_i$, the space $H_{00}^{1/2}(F)$ consists of the functions whose zero extension to the whole boundary $\partial\Omega_i$ belongs to the space $H^{1/2}(\partial\Omega_i)$ and is equipped with the norm

$$\|v\|_{H_{00}^{1/2}(F)} := \left(|v|_{H^{1/2}(F)}^2 + \int_F \frac{v(x)^2}{\mathrm{dist}(x, \partial F)}\, ds(x) \right)^{1/2},$$

where

$$|v|_{H^{1/2}(F)}^2 = \int_F \int_F \frac{|v(x) - v(y)|^2}{|x - y|^3}\, ds(x)\, ds(y).$$

The norm can be extended to the product space $[H_{00}^{1/2}(F)]^3$ by using the usual product norm.

We now provide several inequalities for the mortar projection of functions. We recall the space $\mathring{\mathbf{W}}(F_l)$ (see (3.1)) and the Lagrange multiplier space $\mathbf{M}_l$ given on the nonmortar face $F_l \subset \partial\Omega_i$.

DEFINITION 4.1. *The mortar projection* $\pi_l : [L^2(F_l)]^3 \to \mathring{\mathbf{W}}(F_l)$ *is defined by*

$$\int_{F_l} (\pi_l(\mathbf{v}) - \mathbf{v}) \cdot \boldsymbol{\psi}\, ds = 0 \quad \forall \boldsymbol{\psi} \in \mathbf{M}_l.$$

The mortar projection is continuous in both the L^2- and the $H_{00}^{1/2}$-norms when appropriate Lagrange multiplier spaces $\mathbf{M}_l$ are chosen; see [5, 19].

Let $F_l \subset \partial\Omega_i$ be a nonmortar face that is partitioned into $\{F_{ij}\}_j$ with $F_{ij} = \partial\Omega_i \cap \partial\Omega_j$, and let $\boldsymbol{\phi} = \mathbf{w}_j$ on F_{ij}. We then have the following result; see [7, Lemma 4.4 and Remark 4.5].

LEMMA 4.2.

$$\|\pi_l(\mathbf{w}_i)\|^2_{H_{00}^{1/2}(F_l)} \le C \left(1 + \log \frac{H_i}{h_i}\right)^2 \|\mathbf{w}_i\|^2_{1/2,\partial\Omega_i},$$

$$\|\pi_l(\boldsymbol{\phi})\|^2_{H_{00}^{1/2}(F_l)} \le C \left(1 + \log \frac{H_i}{h_i}\right)^3 \sum_j \|\mathbf{w}_j\|^2_{1/2,\partial\Omega_j}.$$

Remark 4.3. The additional factor $(1 + \log(H_i/h_i))$ in the second estimate came from the geometric nonconformity that causes $\boldsymbol{\phi} \in H^{1/2-\epsilon}(F_l)$, with $\epsilon > 0$. When F_l has only one mortar part, i.e., $F_l = F_{ij}$ and $\boldsymbol{\phi} = \mathbf{w}_j$, we obtain the usual estimate

$$\|\pi_l(\mathbf{w}_j)\|^2_{H_{00}^{1/2}(F_l)} \le C \left(1 + \log \frac{H_i}{h_i}\right)^2 \|\mathbf{w}_j\|^2_{1/2,\partial\Omega_j}. \tag{4.5}$$

The proof of the following lemma is provided in [6, Lemma 4.6].

LEMMA 4.4. *For the basis* $\{\mathbf{r}_m^l\}_{m=1}^6$ *of* $\mathbf{ker}(\varepsilon)$, *scaled with respect to the face* $F_l \subset \partial\Omega_i$, *we have*

$$\|\pi_l(\mathbf{r}_m^l)\|^2_{H_{00}^{1/2}(F_l)} \le C \left(1 + \log \frac{H_i}{h_i}\right) H_i \|\mathbf{r}_m^l\|^2_{\infty,F_l}.$$

DEFINITION 4.5. *A nonmortar face* $F_l \subset \partial\Omega_i$ *is called a simple face if it has only one mortar subdomain* Ω_j *such that* $F_l = \partial\Omega_i \cap \partial\Omega_j$.

Assumption 4.6. On each simple face F_l $(= \partial\Omega_i \cap \partial\Omega_j)$, its nonmortar subdomain Ω_i and its mortar subdomain Ω_j have been chosen so as to satisfy $G_i \le G_j$.

LEMMA 4.7. *Let* $F_l \subset \Omega_i$ *be a simple face, i.e.,* $F_l = \partial\Omega_i \cap \partial\Omega_j$, *and satisfy Assumption* 4.6. *Then, for* $\mathbf{w} = (\mathbf{w}_1, \ldots, \mathbf{w}_N) \in \widetilde{\mathbf{W}}$, *we have*

$$G_i \|\pi_l(\mathbf{w}_i - \mathbf{w}_j)\|^2_{H_{00}^{1/2}(F_l)} \le C \left(1 + \log \frac{H_i}{h_i}\right)^2 \left(|\mathbf{w}_i|^2_{S_i} + |\mathbf{w}_j|^2_{S_j}\right),$$

where $|\mathbf{w}_l|^2_{S_l} = \langle S_l \mathbf{w}_l, \mathbf{w}_l \rangle$ *for* $l = i, j$.

Proof. Let $\{\mathbf{r}_m^l\}_{m=1}^6$ be basis of $\mathbf{ker}(\varepsilon)$ scaled with respect to the face F_l, and let $\{f_m^l\}_{m=1}^6$ be the corresponding dual functionals to the basis. Since $\mathbf{w} =$

$(\mathbf{w}_1,\ldots,\mathbf{w}_N)\in\widetilde{\mathbf{W}}$ satisfies the primal constraints across the face F_l, the following identity holds:

$$\sum_{m=1}^{6} f_m^l(\mathbf{w}_i)\mathbf{r}_m^l = \sum_{m=1}^{6} f_m^l(\mathbf{w}_j)\mathbf{r}_m^l.$$

We then have

$$\begin{aligned}\|\pi_l(\mathbf{w}_i-\mathbf{w}_j)\|^2_{H_{00}^{1/2}(F_l)} \le\ & 2\left\|\pi_l\left(\mathbf{w}_i-\sum_{m=1}^{6} f_m^l(\mathbf{w}_i)\mathbf{r}_m^l\right)\right\|^2_{H_{00}^{1/2}(F_l)}\\ & +2\left\|\pi_l\left(\mathbf{w}_j-\sum_{m=1}^{6} f_m^l(\mathbf{w}_j)\mathbf{r}_m^l\right)\right\|^2_{H_{00}^{1/2}(F_l)}.\end{aligned}$$

We now estimate

$$\begin{aligned}&\left\|\pi_l\left(\mathbf{w}_i-\sum_{m=1}^{6} f_m^l(\mathbf{w}_i)\mathbf{r}_m^l\right)\right\|^2_{H_{00}^{1/2}(F_l)}\\ &\quad=\left\|\pi_l\left(\mathbf{w}_i-\mathbf{r}_i-\sum_{m=1}^{6} f_m^l(\mathbf{w}_i-\mathbf{r}_i)\mathbf{r}_m^l\right)\right\|^2_{H_{00}^{1/2}(F_l)}\\ &\quad\le C\left(\|\pi_l(\mathbf{w}_i-\mathbf{r}_i)\|^2_{H_{00}^{1/2}(F_l)}+\sum_{m=1}^{6}|f_m^l(\mathbf{w}_i-\mathbf{r}_i)|^2\|\pi_l(\mathbf{r}_m^l)\|^2_{H_{00}^{1/2}(F_l)}\right),\end{aligned}$$

where $\mathbf{r}_i\in\ \mathbf{ker}\ (\varepsilon)$ is an arbitrary rigid body motion. We note that for any $\mathbf{r}\in\ \mathbf{ker}\ (\varepsilon)$, $\mathbf{r}=\sum_{m=1}^{6} f_m^l(\mathbf{r})\mathbf{r}_m^l$.

From Lemmas 4.2, 2.1, and 2.2, the first term of the above expression is bounded by

(4.6)
$$\|\pi_l(\mathbf{w}_i-\mathbf{r}_i)\|^2_{H_{00}^{1/2}(F_l)} \le C\left(1+\log\frac{H_i}{h_i}\right)^2|\mathbf{w}_i|^2_{E(\partial\Omega_i)} \le C\frac{1}{G_i}\left(1+\log\frac{H_i}{h_i}\right)^2|\mathbf{w}_i|^2_{S_i},$$

and from (4.1) and Lemmas 4.4 and 2.2, the second term is bounded by

$$\begin{aligned}&|f_m^l(\mathbf{w}_i-\mathbf{r}_i)|^2\ \|\pi_l(\mathbf{r}_m^l)\|^2_{H_{00}^{1/2}(F_l)}\\ &\quad\le C\frac{\|\mathbf{w}_i-\mathbf{r}_i\|^2_{0,\partial\Omega_i}}{H_i^2}\left(1+\log\frac{H_i}{h_i}\right)H_i\|\mathbf{r}_m^l\|^2_{\infty,F_l}\\ &\quad\le C\left(1+\log\frac{H_i}{h_i}\right)|\mathbf{w}_i|^2_{E(\partial\Omega_i)}\\ &\quad\le C\frac{1}{G_i}\left(1+\log\frac{H_i}{h_i}\right)|\mathbf{w}_i|^2_{S_i}.\end{aligned}\tag{4.7}$$

Similarly, we obtain

$$\|\pi_l(\mathbf{w}_j-\mathbf{r}_j)\|^2_{H_{00}^{1/2}(F_l)} \le C\frac{1}{G_j}\left(1+\log\frac{H_i}{h_i}\right)^2|\mathbf{w}_j|^2_{S_j}$$

and

$$|f_m^l(\mathbf{w}_j - \mathbf{r}_j)|^2 \, \|\pi_l(\mathbf{r}_m^l)\|^2_{H_{00}^{1/2}(F_l)} \leq C \frac{1}{G_j} \left(1 + \log \frac{H_i}{h_i}\right) |\mathbf{w}_j|^2_{S_j}.$$

Using Assumption 4.6, i.e., $G_i \leq G_j$, the required bound has been shown. ∎

DEFINITION 4.8. *A pair of subdomains Ω_j and Ω_k has a* simple path *if there exists a path $(\Omega_j, \Omega_{k_1}, \ldots, \Omega_{k_p}, \Omega_k)$ connecting Ω_j and Ω_k through simple nonmortar faces, i.e., all common faces appearing in the path are simple faces.*

DEFINITION 4.9. *We say that a nonmortar face $F_l \subset \partial\Omega_i$, that is not a simple face, has* simple mortar neighbors *if any pair of subdomains (Ω_j, Ω_k) in its mortar neighbors has a simple path whose length is less than TOL and the subdomains Ω_m in the path satisfy*

$$\frac{G_i}{G_m} \leq TOL,$$

where G_i and G_m are the coefficients given in the subdomains Ω_i and Ω_m, respectively.

Assumption 4.10. We assume that any nonmortar face, that is not a simple face, has simple mortar neighbors.

Remark 4.11. When most of the nonmortar faces are simple faces and when nonmortar subdomains are chosen to have smaller G_i, Assumption 4.10 can be satisfied for such partitions with a relatively small TOL.

LEMMA 4.12. *Let a nonmortar face $F_l \subset \Omega_i$, that is not a simple face, satisfy Assumption* 4.10. *For $\mathbf{w} = (\mathbf{w}_1, \ldots, \mathbf{w}_N) \in \widetilde{\mathbf{W}}$, we then have*

$$G_i \|\pi_l(\mathbf{w}_i - \boldsymbol{\phi})\|^2_{H_{00}^{1/2}(F_l)} \leq C(TOL) \left(1 + \log \frac{H_i}{h_i}\right)^3 \left(|\mathbf{w}_i|^2_{S_i} + \sum_{m \in P(F_l)} |\mathbf{w}_m|^2_{S_m}\right),$$

where $P(F_l)$ is the set of subdomain indices appearing in the simple paths connecting any two mortar neighbors in $\{\Omega_j\}_j$ and the constant $C(TOL)$ depends only on TOL.

Proof. Let

$$\mathcal{F}_l(\mathbf{v}) = \sum_{m=1}^{6} f_m^l(\mathbf{v}) \mathbf{r}_m^l,$$

where $\{f_m^l\}_m$ are dual functionals provided for the basis $\{\mathbf{r}_m^l\}_m$, that are scaled with respect to the face F_l. We note that $\mathcal{F}_l(\mathbf{r}) = \mathbf{r}$ for any rigid body motion $\mathbf{r}$. On F_l, we define $\boldsymbol{\phi} = \mathbf{w}_j$ on $F_{ij}\,(:= \partial\Omega_i \cap \partial\Omega_j) \subset F_l$. Since $\mathbf{w}$ satisfies the primal constraints, we have $\mathcal{F}_l(\mathbf{w}_i) = \mathcal{F}_l(\boldsymbol{\phi})$ and obtain

$$\begin{aligned} &\|\pi_l(\mathbf{w}_i - \boldsymbol{\phi})\|^2_{H_{00}^{1/2}(F_l)} \\ &\qquad \leq 2\|\pi_l\left(\mathbf{w}_i - \mathcal{F}_l(\mathbf{w}_i)\right)\|^2_{H_{00}^{1/2}(F_l)} + \|\pi_l\left(\boldsymbol{\phi} - \mathcal{F}_l(\boldsymbol{\phi})\right)\|^2_{H_{00}^{1/2}(F_l)}. \end{aligned} \tag{4.8}$$

We can estimate the first term of (4.8) as in (4.6) and (4.7),

$$\|\pi_l\left(\mathbf{w}_i - \mathcal{F}_l(\mathbf{w}_i)\right)\|^2_{H_{00}^{1/2}(F_l)} \leq C \frac{1}{G_i} \left(1 + \log \frac{H_i}{h_i}\right)^2 |\mathbf{w}_i|^2_{S_i}. \tag{4.9}$$

Applying Lemma 4.2 to the second term of (4.8) gives

$$\|\boldsymbol{\phi}-\mathcal{F}_l(\boldsymbol{\phi})\|^2_{H^{1/2}_{00}(F_l)} \leq \left(1+\log\frac{H_i}{h_i}\right)^3 \sum_j \|\mathbf{w}_j-\mathcal{F}_l(\boldsymbol{\phi})\|^2_{1/2,\partial\Omega_j}.$$

It suffices to prove that

$$\sum_j \|\mathbf{w}_j-\mathcal{F}_l(\boldsymbol{\phi})\|^2_{1/2,\partial\Omega_j} \leq C \sum_{m\in P(F_l)} \frac{1}{G_m}|\mathbf{w}_m|^2_{S_m}, \tag{4.10}$$

where $P(F_l)$ is the set of subdomain indices appearing in the simple paths connecting any two subdomains in $\{\Omega_j\}_j$ that are mortar neighbors of Ω_i across F_l.

We now consider

$$\begin{aligned}
&\|\mathbf{w}_j-\mathcal{F}_l(\boldsymbol{\phi})\|^2_{1/2,\partial\Omega_j}\\
&\quad\leq 2\|\mathbf{w}_j-\mathbf{r}_j\|^2_{1/2,\partial\Omega_j}+2\|\mathbf{r}_j-\mathcal{F}_l(\boldsymbol{\phi})\|^2_{1/2,\partial\Omega_j}\\
&\quad\leq C\frac{1}{G_j}|\mathbf{w}_j|^2_{S_j}+2\|\mathcal{F}_l(\mathbf{r}_j-\boldsymbol{\phi})\|^2_{1/2,\partial\Omega_j}. \qquad (4.11)
\end{aligned}$$

The second term in (4.11) is estimated by

$$\begin{aligned}
&\|\mathcal{F}_l(\mathbf{r}_j-\boldsymbol{\phi})\|^2_{1/2,\partial\Omega_j}\\
&\quad\leq C\frac{\|\mathbf{r}_j-\boldsymbol{\phi}\|^2_{0,F_l}}{H_i^2}\max_m\left\{\|\mathbf{r}^l_m\|^2_{1/2,\partial\Omega_j}\right\}\\
&\quad\leq C\frac{1}{H_i^2}\frac{H_j^3}{H_i^2}\sum_{k,\,F_{ik}\subset F_l}\|\mathbf{r}_j-\mathbf{w}_k\|^2_{0,F_{ik}}\\
&\quad\leq C\frac{1}{H_i}\sum_{k,\,F_{ik}\subset F_l}\|\mathbf{r}_j-\mathbf{w}_k\|^2_{0,F_{ik}}. \qquad (4.12)
\end{aligned}$$

Here we have used the regularity of the partition, i.e., $H_i \simeq H_j$ for neighboring subdomains Ω_i and Ω_j, and

$$\|\mathbf{r}^l_m\|^2_{1/2,\partial\Omega_j} \leq \|\mathbf{r}^l_m\|^2_{1,\Omega_j} \leq CH_j^3/H_i^2.$$

We now consider the term $\|\mathbf{r}_j-\mathbf{w}_k\|^2_{0,F_{ik}}$. When $k=j$, from Lemmas 2.2 and 2.1 we obtain

$$\frac{1}{H_i}\|\mathbf{r}_j-\mathbf{w}_j\|^2_{0,F_{ij}} \leq C\frac{1}{G_j}|\mathbf{w}_j|^2_{S_j}.$$

When $k\neq j$, we note that there exists a path $(\Omega_j,\Omega_{k_1},\ldots,\Omega_{k_p},\Omega_k)$, where each pair of neighboring subdomains Ω_q and Ω_r in the path intersect on a simple face F_{qr}. Let

$$\mathcal{F}_{qr}(\mathbf{v})=\sum_m f^{qr}_m(\mathbf{v})\mathbf{r}^{qr}_m,$$

where $\{f^{qr}_m\}_m$ are dual functionals to the basis $\{\mathbf{r}^{qr}_m\}_m$ of $\mathbf{ker}(\varepsilon)$ scaled with respect to the face F_{qr}. We note that $\mathcal{F}_{qr}(\mathbf{w}_q)=\mathcal{F}_{qr}(\mathbf{w}_r)$.

We then obtain

$$
\begin{aligned}
&\|\mathbf{r}_j - \mathbf{w}_k\|^2_{0,F_{ik}} \\
&\quad = \|\mathbf{r}_j - \mathcal{F}_{jk_1}(\mathbf{w}_j) + \mathcal{F}_{jk_1}(\mathbf{w}_{k_1}) - \mathcal{F}_{k_1k_2}(\mathbf{w}_{k_1}) \\
&\qquad + \cdots + \mathcal{F}_{k_{p-1}k_p}(\mathbf{w}_{k_p}) - \mathcal{F}_{k_pk}(\mathbf{w}_{k_p}) + \mathcal{F}_{k_pk}(\mathbf{w}_k) - \mathbf{w}_k\|^2_{0,F_{ik}} \\
&\quad \le C\Big(\|\mathcal{F}_{jk_1}(\mathbf{r}_j - \mathbf{w}_j)\|^2_{0,F_{il}} \\
&\qquad + \|\mathcal{F}_{jk_1}(\mathbf{w}_{k_1} - \mathbf{r}_{k_1})\|^2_{0,F_{ik}} + \|\mathcal{F}_{k_1k_2}(\mathbf{w}_{k_1} - \mathbf{r}_{k_1})\|^2_{0,F_{ik}} \\
&\qquad + \cdots + \|\mathcal{F}_{k_{p-1}k_p}(\mathbf{w}_{k_p} - \mathbf{r}_{k_p})\|^2_{0,F_{ik}} + \|\mathcal{F}_{k_pk}(\mathbf{w}_{k_p} - \mathbf{r}_{k_p})\|^2_{0,F_{ik}} \\
&\qquad + \|\mathcal{F}_{k_pk}(\mathbf{w}_k - \mathbf{r}_k)\|^2_{0,F_{ik}} + \|\mathbf{r}_k - \mathbf{w}_k\|^2_{0,F_{ik}} \Big). \qquad (4.13)
\end{aligned}
$$

We note that the rigid body motions $\{\mathbf{r}_m^{qr}\}_{m=1}^6$ scaled with respect to the face F_{qr} in the path satisfy

$$\|\mathbf{r}_m^{qr}\|_{\infty,F_{ik}} \le C(TOL),$$

since the length of the path is less than TOL and the subdomain partition is regular. Using the above bound and Lemma 2.2, each term in (4.13) can be bounded in a similar way to

$$
\begin{aligned}
\|\mathcal{F}_{k_{p-1}k_p}(\mathbf{w}_{k_p} - \mathbf{r}_{k_p})\|^2_{0,F_{ik}} &\le C\frac{1}{H_{k_p}^2}\|\mathbf{w}_{k_p} - \mathbf{r}_{k_p}\|^2_{F_{k_{p-1}k_p}} \max_m \left\{\|\mathbf{r}_m^{k_{p-1}k_p}\|^2_{\infty,F_{ik}}\right\} H_i^2 \\
&\le C(TOL)\frac{H_i^2}{H_{k_p}}\frac{1}{H_{k_p}}\|\mathbf{w}_{k_p} - \mathbf{r}_{k_p}\|^2_{0,\partial\Omega_{k_p}} \\
&\le C(TOL)\frac{H_i^2}{H_{k_p}}|\mathbf{w}_{k_p}|^2_{E(\partial\Omega_{k_p})}.
\end{aligned}
$$

Therefore we obtain

$$
\begin{aligned}
\frac{1}{H_i}\|\mathbf{r}_j - \mathbf{w}_k\|^2_{0,F_{ik}} &\le C(TOL)\sum_{m\in P(j,k)}\frac{H_i}{H_m}|\mathbf{w}_m|^2_{E(\partial\Omega_m)} \\
&\le C(TOL)\sum_{m\in P(j,k)}\frac{1}{G_m}|\mathbf{w}_m|^2_{S_m}, \qquad (4.14)
\end{aligned}
$$

where $P(j,k)$ is the set of subdomain indices appearing in the path from Ω_j to Ω_k. Since the subdomain partition is regular, the factors H_i and H_m cancel each other in the final estimate. Combining (4.14) with (4.12) and (4.11), we obtain the estimate (4.10). Using $G_i/G_m \le TOL$ for $m \in P(j,k)$, the desired bound follows. ∎

A condition number analysis of BDDC algorithms has been carried out using an appropriate average operator by Li and Widlund [13]. The same technique was used for a condition number estimate of the BDDC algorithm for mortar discretization by

Kim, Dryja, and Widlund [7]. A bound for an average operator E_D in a certain norm is central in the analysis. We recall the definitions of R_Γ and $R_{D,\Gamma}$ in (3.11) and (3.19), respectively. We note that

$$R_\Gamma : \mathbf{W}_{\Delta,m} \times \mathbf{W}_\Pi \to \mathbf{W}_{\Delta,n} \times \mathbf{W}_{\Delta,m} \times \mathbf{W}_\Pi,$$

where $\mathbf{W}_\Pi$ is the space of the global primal unknowns, $\mathbf{W}_{\Delta,n}$ is the space of unknowns on nonmortar faces except the primal unknowns, and $\mathbf{W}_{\Delta,m}$ is the space of the remaining unknowns. We also note that

$$\mathbf{W}_\Delta = \mathbf{W}_{\Delta,n} \times \mathbf{W}_{\Delta,m}, \quad \widetilde{\mathbf{W}} = \mathbf{W}_\Delta \times \mathbf{W}_\Pi.$$

We now define the operator E_D by

$$E_D = R_\Gamma R_{D,\Gamma}^t. \tag{4.15}$$

Here the weight matrix D in (3.19) will be chosen so that

(P1) $R_\Gamma^t R_{D,\Gamma} = R_{D,\Gamma}^t R_\Gamma = I$,

(P2) $|E_D \mathbf{w}|_{\widetilde{S}}^2 \le C \max_i \left\{ \left(1 + \log \frac{H_i}{h_i}\right)^3 \right\} |\mathbf{w}|_{\widetilde{S}}^2$,

where $|\mathbf{w}|_{\widetilde{S}}^2 = \langle \widetilde{S}\mathbf{w}, \mathbf{w} \rangle$; see (3.13). We then have

$$R_\Gamma^t R_{D,\Gamma} \begin{pmatrix} \mathbf{w}_m \\ \mathbf{w}_\Pi \end{pmatrix} = \begin{pmatrix} -B_m^t (B_n^t)^{-1} D_{nn} \mathbf{z}_n + D_{mm} \mathbf{w}_m \\ -B_\Pi^t (B_n^t)^{-1} D_{nn} \mathbf{z}_n + D_{\Pi\Pi} \mathbf{w}_\Pi \end{pmatrix},$$

where

$$\mathbf{z}_n = -B_n^{-1}(B_m \mathbf{w}_m + B_\Pi \mathbf{w}_\Pi).$$

In order to satisfy property (P1), the weight matrix D is chosen to be

$$D_{nn} = 0, \quad D_{mm} = I, \quad D_{\Pi\Pi} = I. \tag{4.16}$$

Using Lemma 4.12, we can establish property (P2) for the operator E_D with the weight matrix D just given.

LEMMA 4.13. *With Assumptions* 4.6 *and* 4.10, *the operator* E_D *satisfies*

$$|E_D \mathbf{w}|_{\widetilde{S}}^2 \le C(TOL) \max_i \left\{ \left(1 + \log \frac{H_i}{h_i}\right)^3 \right\} |\mathbf{w}|_{\widetilde{S}}^2.$$

Proof. With the weight matrix D in (4.16), the operator E_D in (4.15) is given by

$$E_D \begin{pmatrix} \mathbf{w}_n \\ \mathbf{w}_m \\ \mathbf{w}_\Pi \end{pmatrix} = \begin{pmatrix} \mathbf{w}_n - B_n^{-1}(B_n \mathbf{w}_n + B_m \mathbf{w}_m + B_\Pi \mathbf{w}_\Pi) \\ \mathbf{w}_m \\ \mathbf{w}_\Pi \end{pmatrix}.$$

Let

$$\mathbf{z}_n = \mathbf{w}_n - B_n^{-1}(B_n \mathbf{w}_n + B_m \mathbf{w}_m + B_\Pi \mathbf{w}_\Pi).$$

We take $\mathbf{z}_i$ by restricting the unknowns $(\mathbf{z}_n, \mathbf{w}_m, \mathbf{w}_\Pi)$ to the subdomain Ω_i. Similarly, we take $\mathbf{w}_i$ from $(\mathbf{w}_n, \mathbf{w}_m, \mathbf{w}_\Pi)$. Let

$$\mathbf{z} = (\mathbf{z}_1, \dots, \mathbf{z}_n), \quad \mathbf{w} = (\mathbf{w}_1, \dots, \mathbf{w}_n).$$

We note that $\mathbf{w}$ satisfies the primal constraints and $\mathbf{z}$ satisfies the mortar matching condition. Each $\mathbf{z}_i$ is of the form

$$\mathbf{z}_i = \mathbf{w}_i - \sum_{F \subset \partial\Omega_i} E_F^{(i)} \pi_F(\mathbf{w}_i - \boldsymbol{\phi}),$$

where F is a nonmortar face in $\partial\Omega_i$, π_F is the mortar projection given on the face F, $E_F^{(i)}$ is the zero extension of functions defined on F to $\partial\Omega_i$, and $\boldsymbol{\phi} = \mathbf{w}_j$ on $F_{ij} (:= \partial\Omega_j \cap \partial\Omega_i) \subset F$. We then obtain

$$\begin{aligned}
|E_D\mathbf{w}|_{\widetilde{S}}^2 &= \sum_{i=1}^N \langle S_i \mathbf{z}_i, \mathbf{z}_i \rangle \\
&\le C \sum_{i=1}^N \left(\langle S_i \mathbf{w}_i, \mathbf{w}_i \rangle + \sum_{F \subset \partial\Omega_i} \langle S_i E_F^{(i)} \pi_F(\mathbf{w}_i - \boldsymbol{\phi}), E_F^{(i)} \pi_F(\mathbf{w}_i - \boldsymbol{\phi}) \rangle \right) \\
&\le C \sum_{i=1}^N \langle S_i \mathbf{w}_i, \mathbf{w}_i \rangle + \sum_{i=1}^N \sum_{F \subset \partial\Omega_i} G_i \|\pi_F(\mathbf{w}_i - \boldsymbol{\phi})\|_{H_{00}^{1/2}(F)}^2 \\
&\le C(TOL) \max_i \left\{ \left(1 + \log \frac{H_i}{h_i} \right)^3 \right\} \sum_{i=1}^N \langle S_i \mathbf{w}_i, \mathbf{w}_i \rangle \\
&\le C(TOL) \max_i \left\{ \left(1 + \log \frac{H_i}{h_i} \right)^3 \right\} \langle \widetilde{S}\mathbf{w}, \mathbf{w} \rangle.
\end{aligned}$$

Here we have used $\langle S_i \mathbf{w}_i, \mathbf{w}_i \rangle \le C G_i |\mathbf{w}_i|_{H^{1/2}(\partial\Omega_i)}^2$, $|E_F^{(i)} \pi_F(\mathbf{w}_i - \boldsymbol{\phi})|_{H^{1/2}(\partial\Omega_i)} \simeq \|\pi_F(\mathbf{w}_i - \boldsymbol{\phi})\|_{H_{00}^{1/2}(F)}$, and Lemma 4.12. ∎

By using the properties (P1) and (P2), we can show the following condition number bound of the BDDC operator in (3.22); see [7, Theorem 4.7] for the proof.

THEOREM 4.14. *If E_D satisfies the properties* (P1) *and* (P2), *then the BDDC operator has the following condition number bound*:

$$\kappa(B_{DDC}) \le C(TOL) \max_i \left\{ \left(1 + \log \frac{H_i}{h_i} \right)^3 \right\}.$$

Remark 4.15. The analysis above can be modified for the partitions where all nonmortar faces are simple, i.e., they have only one mortar interface. For such a case, geometrically conforming partitions as an example, we have a better condition number bound (see Lemma 4.7),

$$\kappa(B_{DDC}) \le C \max_i \left\{ \left(1 + \log \frac{H_i}{h_i} \right)^2 \right\}.$$

5. Numerical results. We present numerical results on a simple model problem to show the scalability of the suggested BDDC algorithm. We consider a model problem of (2.1) in a parallelepiped domain $\Omega = [0,1] \times [0,1] \times [0,1/2]$ with a zero Dirichlet boundary condition on $\partial\Omega$. We perform the BDDC algorithm for the case when the exact solution is zero, i.e., $\mathbf{F}$ is zero in (2.1). In the CG iteration, we start with a nonzero initial and perform the iteration up to the relative residual norm reduced by a factor of 10^6.

We consider a geometrically nonconforming partition of Ω for a given N as follows. We first partition Ω into N^3 uniform parallelepiped subregions. Each subregion has a geometrically nonconforming partition that consists of three subdomains as in Figure 1. One is a parallelepiped and the other two are cubes. As a result, we obtain a geometrically nonconforming subdomain partition of Ω. In the partition, we have cubical subdomains and parallelepiped subdomains. For a given n, the cubical subdomains are equipped with $(n-1)^3$ uniform cubic elements, and the parallelepiped subdomains are equipped with uniform parallelepiped elements by dividing their x, y, and z directional edges into $n-1$, $n+2$, and $n-1$ intervals, respectively. We test the BDDC algorithm in both the cases when the coefficient $G(x)$ is continuous and when $G(x)$ is discontinuous across the subdomain interface. Lagrange multipliers with dual basis developed in [5] are used in our computation.

We first present the result when $G(x) = 1$, i.e., continuous across the subdomain interface. We perform the BDDC algorithm as the number of subdomains increases and as the subdomain problem size increases. Table 1 presents the number of iterations and the condition numbers. The number of iterations and the condition numbers get stable with the increase of the number of the subdomains. Moreover, the con-

dition numbers show $\log^2$-behavior with the increase of the local problem size. We note that in our computation the nonmortar faces were selected to be simple, i.e., to have only one mortar face, so that we have the $\log^2$-bound for this case even in the geometrically nonconforming partitions; see Figure 2.

We perform the BDDC algorithm when $G(x)$ has jump across the subdomain interface. We select $G_i = 1$ for cubical subdomains and $G_i = 100$ for parallelepiped subdomains. Table 2 presents the performance of the algorithm with the increase of the number of subdomains and with the increase of the local problem size. To justify Assumption 4.6, we test both the cases when the selection of mortar and nonmortar faces satisfies and violates Assumption 4.6. The results confirm that the performance is nice when Assumption 4.6 is satisfied, while the performance is very poor when Assumption 4.6 is not satisfied. We can also observe that the condition number bound $C(1+\log(H/h))^2$ is in fact optimal for both cases when $G(x) = 1$ and $G(x) = G_i$, once the selection of mortar and nonmortar faces satisfies Assumption 4.6 and all nonmortar faces are simple; see Figure 2.

Acknowledgment. The author is grateful to Professor Olof B. Widlund at the Courant Institute for suggesting this problem.

INEXACT NEWTON DOGLEG METHODS*

ROGER P. PAWLOWSKI†, JOSEPH P. SIMONIS‡, HOMER F. WALKER‡, AND JOHN N. SHADID†

Abstract. The dogleg method is a classical trust-region technique for globalizing Newton's method. While it is widely used in optimization, including large-scale optimization via truncated-Newton approaches, its implementation in general inexact Newton methods for systems of nonlinear equations can be problematic. In this paper, we first outline a very general dogleg method suitable for the general inexact Newton context and provide a global convergence analysis for it. We then discuss certain issues that may arise with the standard dogleg implementational strategy and propose modified strategies that address them. Newton–Krylov methods have provided important motivation for this work, and we conclude with a report on numerical experiments involving a Newton–GMRES dogleg method applied to benchmark CFD problems.

Key words. dogleg methods, trust-region methods, inexact Newton methods, Newton's method, Newton iterative methods, Newton–Krylov methods, Newton–GMRES methods, truncated-Newton methods, globalized Newton methods, fully-coupled solution methods, Navier–Stokes equations

1. Introduction.

The problem of interest is a system of nonlinear equations

$$F(x) = 0, \tag{1.1}$$

where $F : \mathbb{R}^n \to \mathbb{R}^n$ is continuously differentiable. A classical algorithm for solving (1.1) is *Newton's method*, which generates a sequence of iterates $\{x_k\}$ through steps $s_k = x_{k+1} - x_k$ that satisfy the linear *Newton equation*

$$F'(x_k)s_k = -F(x_k). \tag{1.2}$$

An *inexact Newton method*, defined in [9], is an extension of Newton's method having the following basic form:

Algorithm IN. INEXACT NEWTON METHOD [9]

Let x_0 be given.
For $k = 0, 1, \ldots$ (until convergence) do:
  Choose $\eta_k \in [0, 1)$ and s_k^{IN} such that

$$\|F(x_k) + F'(x_k)\, s_k^{\mathrm{IN}}\| \le \eta_k \|F(x_k)\|. \tag{1.3}$$

  Set $x_{k+1} = x_k + s_k^{\mathrm{IN}}$.

The *inexact Newton condition* (1.3) is a relaxation of (1.2) that expresses the defining property of an inexact Newton method. The usual point of view is that, for each k, the *inexact Newton step* s_k^{IN} is chosen to reduce the norm of $F(x_k) + F'(x_k)s$, the *local linear model* of F at x_k, to an extent specified by η_k. Viewed in this way, η_k is often called a *forcing term* (cf. [13]).

While there is no restriction in Algorithm IN on how s_k^{IN} satisfying (1.3) is determined, inexact Newton methods are often implemented as *Newton iterative methods*, in which s_k^{IN} is found by applying an iterative linear algebra method to (1.2) until (1.3) holds for a specified η_k. For most large-scale applications, the most robust and efficient such methods are *Newton–Krylov methods*, in which the iterative linear algebra methods are *Krylov subspace methods*.[1] Newton–Krylov methods, which have provided considerable motivation for this paper, can enable the efficient solution of (1.2) on large-scale distributed architectures and may also allow "matrix-free" implementations (see [25]) that do not require the evaluation or storage of F'. The term "Newton–Krylov" appears to have originated in [3], but these methods date back at least to the *truncated Newton method* for optimization introduced in [10] (see also [28] and [46], which anticipated some algorithmic features), in which the Krylov subspace method is the preconditioned conjugate-gradient (PCG) method or its Lanczos variant. A Newton–Krylov method that uses a specific Krylov subspace method is often designated by appending the name of the Krylov solver to "Newton," as in the *Newton–GMRES method*, which uses the generalized minimal residual (GMRES) method [38]. For recent general references on Newton–Krylov methods, see [24], [25], and [30].

Inexact Newton methods, like all Newton-like methods, must usually be *globalized*, i.e., augmented with certain auxiliary procedures (*globalizations*) that increase the likelihood of convergence to a solution when good initial approximate solutions are not available. Globalizations are typically constructed to test whether a trial step gives satisfactory progress toward a solution and, if necessary, to modify it in some way to obtain a step that does give satisfactory progress. There are two major categories of globalizations: *backtracking* (*linesearch*, *damping*) methods, in which step lengths are adjusted (usually shortened) to obtain satisfactory steps; and *trust-region* methods, in which a step is ideally chosen to minimize the norm of the local linear model of F within a specified "trust region."[2] (More specifically, the trust-region step from an approximate solution x_k is ideally $\arg\min_{\|s\|\le\delta}\|F(x_k) + F'(x_k)s\|$, where $\delta > 0$ is a given *trust-region radius* and $\|\cdot\|$ is a norm of interest.) Both backtracking and trust-region methods have strong theoretical support; see, e.g., [11], [7], and [12] and the references therein. Backtracking methods are relatively easy to implement; however, each step direction is restricted to be that of the initial trial step. While this step is normally constructed to be a descent direction for $\|F\|$, and is always a descent direction for $\|F\|$ if the step satisfies (1.3) [4, Prop. 3.3], [12, Lem. 7.1], it may be only a weak descent direction, especially if the Jacobian is ill-conditioned [42]. Since trust-region steps are increasingly nearly in the steepest-descent direction as the trust-region radius decreases, trust-region methods have the potential advantage of producing modified steps that may be stronger descent directions than the initial trial step; however, their implementation in practical methods may be problematic.

[1] An introduction to Krylov subspace methods is beyond the scope of this paper; we refer the reader to the surveys [16] and [20] and the books [19], [37], and [48].

[2] See [11, Ch. 6] for a general discussion of classical globalizations and [7] for a more recent and very extensive treatment of trust-region methods.

A fundamental issue is that it is often not feasible to compute the ideal trust-region step with much accuracy (see, e.g., [11, Ch. 6] and [7, Ch. 7]), and various ways of approximating it have been devised.

The *dogleg method* [33], [32] provides perhaps the most popular way of approximating the trust-region step. In the traditional dogleg method for solving (1.1), given an approximate solution x_k, one defines the *dogleg curve* Γ_k^{DL} to be the piecewise-linear curve joining 0, the *Cauchy point* s_k^{CP} (defined to be the minimizer of $\|F(x_k) + F'(x_k)s\|$ in the steepest-descent direction, provided $\|\cdot\|$ is an inner-product norm),[3] and the Newton step $s_k^{\mathrm{N}} \equiv -F'(x_k)^{-1}F(x_k)$. Then, given a trust-region radius $\delta > 0$, the dogleg step s_k is defined as follows: If $\|s_k^{\mathrm{N}}\| \leq \delta$, then $s_k = s_k^{\mathrm{N}}$; otherwise, s_k is chosen on Γ_k^{DL} such that $\|s_k\| = \delta$. It can be shown (see, e.g., [11, Ch. 6]) that, as a point s traverses Γ_k^{DL} from 0 to s_k^{N}, $\|s\|$ is monotone increasing and $\|F(x_k) + F'(x_k)s\|$ is monotone decreasing. Thus, the dogleg step s_k is uniquely defined, and $s_k = \arg\min_{s \in \Gamma_k^{\mathrm{DL}},\ \|s\| \leq \delta} \|F(x_k) + F'(x_k)s\|$. Moreover, if δ is sufficiently small (specifically, if $\delta \leq \|s_k^{\mathrm{CP}}\|$), then s_k is a short step in the steepest-descent direction.

One can extend the dogleg method to the inexact Newton context in a straightforward way by substituting s_k^{IN} for s_k^{N} in the definition of Γ_k^{DL}. The resulting dogleg curve retains the appealing property of offering a continuum of steps ranging from s_k^{IN} to short steps in the steepest-descent direction. However, some desirable properties are lost. First, for any $\eta_k > 0$, no matter how small, the local linear model norm may not decrease monotonically along Γ_k^{DL} between s_k^{CP} and s_k^{IN}. For example, this will be the case if s_k^{N} is nearly on and interior to the line segment joining s_k^{CP} and s_k^{IN}, as illustrated on the left in Figure 1.1. Note that, in this illustration, the point on Γ_k^{DL} having norm δ does not minimize the local linear model norm along Γ_k^{DL} within the trust region. Second, unless η_k is sufficiently small, $\|s\|$ may not increase monotonically as s traverses Γ_k^{DL} from s_k^{CP} to s_k^{IN}; as a consequence, Γ_k^{DL} may have more than one point of intersection with the trust-region boundary, as illustrated on the right in Figure 1.1. (If, in this illustration, s_k^{IN} were moved to the right along the same contour to a point slightly outside the trust-region boundary, then Γ_k^{DL} would have *three* points of intersection with the trust-region boundary.) Thus, with this straightforward extension, the dogleg step cannot be reliably characterized as the unique point on Γ_k^{DL} having norm δ; neither can we always expect a point on Γ_k^{DL} having norm δ to minimize the local linear model norm along Γ_k^{DL} within the trust region.

Remark. These issues do not arise in the case of a truncated Newton method for minimizing $f : \mathbb{R}^n \to \mathbb{R}^1$. In this case, PCG is applied to (1.2) with $F(x_k) = \nabla f(x_k)$ and $F'(x_k) = \nabla^2 f(x_k)$ until either a specified inexact-Newton condition holds, a PCG iterate falls outside of the trust region, or a nonpositive eigenvalue of $\nabla^2 f(x_k)$ is detected. In this context, the model of interest is the local quadratic model of f, rather than the local linear model of $F = \nabla f$. One can show [44, Th. 2.1], [7, section 7.5] that, in an appropriate norm $\|\cdot\|$, the first PCG iterate is the Cauchy point for the local quadratic model and, with the minimizing properties of the PCG iterates, that the model is monotone decreasing along the dogleg curve joining 0, the Cauchy point, and any subsequent PCG iterate. Moreover, the PCG iterate norms are monotone

[3] Our definition of the Cauchy point follows that in [11, Ch. 6]. In [7], the Cauchy point is defined to be the minimizer in the steepest-descent direction *within the trust region*. In section 2 below, we recall the definition of the steepest-descent direction with respect to an inner-product norm of interest and discuss potential difficulties in evaluating it.

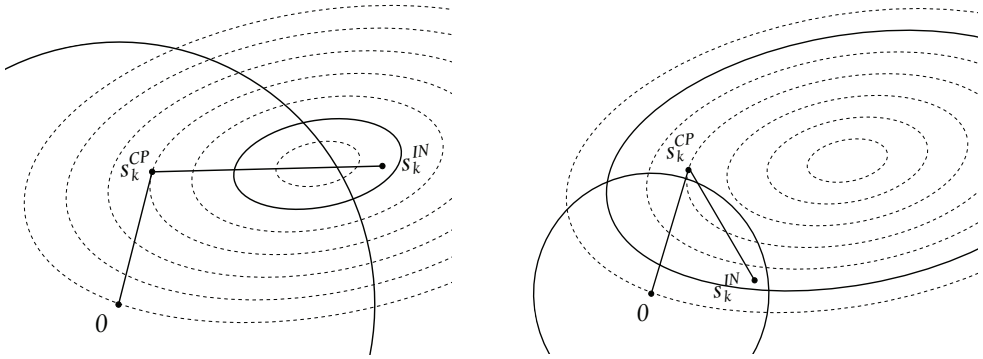

FIG. 1.1. *Illustrative inexact Newton dogleg curves in* $\mathbf{R}^2$. *The ellipses represent level curves of the local linear model norm. The solid ellipses represent* $\{s \in \mathbf{R}^n : \|F(x_k) + F'(x_k)s\| = \eta_k\|F(x_k)\|\}$. *The circular arcs represent trust-region boundaries.*

increasing [44, Th. 2.1], [7, Th. 7.5.1], and it follows that $\|s\|$ is monotone increasing as s traverses the dogleg curve from 0 to the final PCG iterate.

With these issues in mind, our goal in this paper is to develop an understanding of dogleg methods in the general inexact Newton context that will place them on a firm footing, both theoretically and practically. In section 2, we outline a very general inexact Newton dogleg method and provide a convergence analysis for it. Since computing exact Cauchy points may be undesirably expensive or infeasible, as discussed further in section 2, the method allows approximations of these points in addition to inexact Newton steps in defining the dogleg curves.[4] The method also allows a great deal of flexibility in determining steps along the dogleg curves in order to accommodate a variety of strategies for selecting steps. In section 3, we address specific step-selection strategies, noting possible shortcomings of the traditional strategy and suggesting certain alternatives and enhancements. In section 4, we discuss implementational details and report on numerical experiments with Newton–GMRES dogleg methods applied to benchmark problems involving the steady-state Navier–Stokes equations.[5] We conclude with summary observations in section 5.

2. The general method. We assume throughout that $\langle \cdot, \cdot \rangle$ is an inner product of interest and that $\| \cdot \|$ is the associated norm. We use $\langle \cdot, \cdot \rangle_2$ and $\| \cdot \|_2$ to denote the Euclidean inner product and norm, and recall that there is a unique symmetric positive-definite $D \in \mathbb{R}^{n \times n}$ such that $\langle u, v \rangle = \langle u, Dv \rangle_2$ for all $u, v \in \mathbb{R}^n$. (In practice, D is likely to be explicitly available, but this is not assumed here.) We define the merit function

$$f(x) \equiv \frac{1}{2}\|F(x)\|^2$$

[4]The use of approximate Cauchy points is particularly relevant in the context of interest here. In order to keep the focus on the issues of major interest, we do not consider inaccuracy from other sources. See [6] for a general discussion of inaccuracy in inexact Newton methods and [2] and [5] for a treatment of the effects of particular sources of inaccuracy in Jacobian-vector products.

[5]Globalization is usually less critical for time-dependent problems, since time-steps are usually sufficiently small to maintain convergence of inexact Newton iterates in implicit time-stepping methods. However, globalization has been used to advantage in some cases; for example, it has been observed in groundwater flow simulations that globalization appears necessary (and a linesearch globalization is sufficient) to achieve desirably long time steps [49].

and note that f is continuously differentiable since F is, with $\nabla f(x) = F'(x)^T DF(x)$. One has that $\nabla f(x)^T s = \langle \nabla f(x), s\rangle_2 = \langle D^{-1}\nabla f(x), s\rangle$; hence, the steepest-descent direction for f with respect to $\langle\cdot,\cdot\rangle$ is

$$d(x) \equiv -D^{-1}\nabla f(x) = -D^{-1}F'(x)^T DF(x). \tag{2.1}$$

Accurately evaluating $d(x)$ may be problematic in practice for at least two reasons: first, solving systems with D may be undesirable, even if D is available; second, multiplication by $F'(x)^T$ may be infeasible, e.g., in applications of "matrix-free" Newton–Krylov methods in which $F'(x)$ is unavailable. However, useful approximations of $d(x)$ may be available in many circumstances. If $F'(x)^T$-products can be evaluated, then $-\nabla f(x)$ may be an acceptable substitute for $d(x)$; see Remark 2 after Theorem 2.1. If accurate $F'(x)^T$-products are not available, then one may be able to approximate them using approximations of $F'(x)$ that can be readily computed, e.g., by omitting terms in $F'(x)$ that cannot be easily evaluated or that lie outside a desirable sparsity pattern. Additionally, in the Newton–Krylov context, certain approximations of $d(x)$ may be available at little cost, as explained further at the end of this section. Thus, in outlining our general inexact Newton dogleg method, we allow at each iterate x_k an approximate steepest-descent direction $\hat{d}_k \approx d(x_k)$ and prescribe in Theorem 2.1 how good this approximation must be in order to ensure desirable convergence properties of the method.

With each $\hat{d}_k$, we have an approximate Cauchy point

$$\hat{s}_k^{\mathrm{CP}} \equiv \arg\min\{\|F(x_k) + F'(x_k)s\| :\ s = \lambda\hat{d}_k, -\infty < \lambda < \infty\}.$$

(Here, and in the following, we use "ˆ" to designate approximations derived from $\hat{d}_k$.) Then, given an inexact Newton step s_k^{IN}, we define an approximate dogleg curve $\hat{\Gamma}_k^{\mathrm{DL}}$ to be the piecewise-linear curve connecting 0, $\hat{s}_k^{\mathrm{CP}}$, and s_k^{IN}. Our general method allows great latitude in selecting trial steps on this approximate dogleg curve within the trust region, imposing only very mild minimum-length requirements.

Our test for accepting a step is based on a comparison of the actual reduction of $\|F\|$ and the reduction "predicted" by the local linear model, defined at the kth iteration by, respectively,

$$\begin{aligned} ared_k &\equiv \|F(x_k)\| - \|F(x_k + s_k)\|, \\ pred_k &\equiv \|F(x_k)\| - \|F(x_k) + F'(x_k)\, s_k\|. \end{aligned} \tag{2.2}$$

Specifically, our test requires $ared_k \geq t \cdot pred_k > 0$ for each k, where $t \in (0,1)$ is independent of k. Tests of this type have been used by a number of others; see, e.g., [14], [15], [34], and [12] for such tests applied to systems of nonlinear equations and [27], [43], and [7] for analogous tests applied to unconstrained minimization.

The following is our general inexact Newton dogleg method. See section 4 for the specific parameter values and ancillary procedures used in our test implementation.

Algorithm INDL. Inexact newton dogleg method

Let x_0, $\eta_{\max} \in [0,1)$, $t \in (0,1)$, $\theta_{\max} \in (0,1)$, $\delta_{\min} > 0$ and $\delta \geq \delta_{\min}$ be given.
For $k = 0, 1, \ldots$ (until convergence) do:
Choose $\eta_k \in [0, \eta_{\max}]$ and s_k^{IN} such that
$$\|F(x_k) + F'(x_k)\, s_k^{\mathrm{IN}}\| \leq \eta_k \|F(x_k)\|.$$

Determine $\hat{d}_k$ and evaluate $\hat{s}_k^{\mathrm{CP}}$.
Determine $s_k \in \hat{\Gamma}_k^{\mathrm{DL}}$ with $\min\{\delta_{\min}, \|s_k^{\mathrm{IN}}\|\} \le \|s_k\| \le \delta$.
While $ared_k < t \cdot pred_k$ do:
    If $\delta = \delta_{\min}$, stop; else choose $\theta \in (0, \theta_{\max}]$.
    Update $\delta \leftarrow \max\{\theta\delta, \delta_{\min}\}$.
    Redetermine $s_k \in \hat{\Gamma}_k^{\mathrm{DL}}$ with $\min\{\delta_{\min}, \|s_k^{\mathrm{IN}}\|\} \le \|s_k\| \le \delta$.
Set $x_{k+1} = x_k + s_k$ and update δ in $[\delta_{\min}, \infty)$.

As it is stated, Algorithm INDL requires determining both s_k^{IN} and $\hat{s}_k^{\mathrm{CP}}$ before determining the initial $s_k \in \hat{\Gamma}_k^{\mathrm{DL}}$. In a practical implementation, only one of these may be needed; see section 3.1.

The algorithm employs $\delta_{\min} > 0$ that serves as a lower bound on allowable trust-region radii and is also used in determining a lower bound on admissible dogleg step lengths. This $\delta_{\min}$ is used in the proof of Theorem 2.1. Such a $\delta_{\min}$ is likely to be a part of any practical algorithm and, in practice, can be related to a step-length stopping tolerance or taken so small that it does not undesirably restrict choices of the trust-region radii or the dogleg steps.

It is easily verified that the while-loop cannot continue indefinitely; that is, once an initial s_k has been obtained, either an acceptable s_k is determined or the algorithm terminates with $\delta = \delta_{\min}$ after at most a finite number of iterations of the while-loop. For the purposes of Theorem 2.1, there is complete freedom in choosing $\theta \in (0, \theta_{\max}]$. In particular, because of the constrained update $\delta \leftarrow \max\{\theta\delta, \delta_{\min}\}$, it is not necessary to impose a positive lower bound on θ, although one may well do this in practice. (There are a number of practical possibilities for choosing θ; see, in particular, [11] for choices based on minimizing interpolating polynomials over a fixed subinterval $[\theta_{\min}, \theta_{\max}] \subset (0, 1)$.) Similarly, for the purposes of Theorem 2.1, there is complete freedom in updating δ in $[\delta_{\min}, \infty)$ following the while-loop. Of course, one would want to do this judiciously in practice; see, e.g., [11] and [7] for practically effective procedures.

Our global convergence result for Algorithm INDL is given in Theorem 2.1 below. For this, we recall that $x \in \mathbb{R}^n$ is a *stationary point* of $\|F\|$ if $\|F(x)\| \le \|F(x) + F'(x)\, s\|$ for every $s \in \mathbb{R}^n$. In the present context, x is a stationary point if and only if $\nabla f(x) = 0$.

THEOREM 2.1. *Assume that F is continuously differentiable. Suppose that $\{x_k\}$ is produced by Algorithm* INDL *and that, for d defined in* (2.1) *and some $\epsilon > 0$,*

$$\frac{\langle \hat{d}_k, d(x_k)\rangle}{\|\hat{d}_k\|\|d(x_k)\|} \ge \epsilon \tag{2.3}$$

for every k. If x_* is a limit point of $\{x_k\}$, then x_* is a stationary point of $\|F\|$. If, additionally, $F'(x_*)$ is nonsingular, then $F(x_*) = 0$ and $x_k \to x_*$. Moreover, for all sufficiently large k, the initial s_k is accepted without modification in the while-loop, and $s_k = s_k^{\mathrm{IN}}$ is an admissible step.

Remark 1. In Theorem 2.1, we implicitly assume that $F(x_k)$, $\hat{d}_k$, and $d(x_k)$ are nonzero for every k.

Remark 2. Inequality (2.3) states that the vectors $\hat{d}_k$ are uniformly bounded away from orthogonality with the vectors $d(x_k)$. Note that

$$\frac{\langle -\nabla f(x_k), d(x_k)\rangle}{\|-\nabla f(x_k)\|\|d(x_k)\|} = \frac{\|\nabla f(x_k)\|_2^2}{\langle \nabla f(x_k), D\nabla f(x_k)\rangle_2^{1/2} \langle \nabla f(x_k), D^{-1}\nabla f(x_k)\rangle_2^{1/2}} \ge \epsilon$$

for $0 < \epsilon \le \kappa_2(D)^{-1/2}$, where $\kappa_2(D) = \|D\|_2\|D^{-1}\|_2$. Thus (2.3) holds for some $\epsilon > 0$ if $\hat{d}_k$ is $-\nabla f(x_k)$ or a sufficiently accurate approximation of it.

Remark 3. If $x_k \to x_*$ with $F(x_*) = 0$ and $F'(x_*)$ nonsingular and if $s_k = s_k^{\mathrm{IN}}$ for all sufficiently large k, then the convergence is ultimately governed by the choices of the forcing terms η_k as in the local convergence theory of [9] and [13].

Proof. Let $\{x_k\}$ be produced by Algorithm INDL and suppose that (2.3) holds for every k. Since $\langle F'(x_k)\hat{d}_k, F(x_k)\rangle = -\langle \hat{d}_k, d(x_k)\rangle \neq 0$ by (2.3), we have that $F'(x_k)\hat{d}_k \neq 0$ for every k. Then a straightforward calculation yields

$$\|\hat{s}_k^{\mathrm{CP}}\| = \frac{|\langle F(x_k), F'(x_k)\hat{d}_k\rangle|}{\|F'(x_k)\hat{d}_k\|^2}\|\hat{d}_k\|, \tag{2.4}$$

$$\hat{\eta}_k^{\mathrm{CP}} \equiv \frac{\|F(x_k) + F'(x_k)\hat{s}_k^{\mathrm{CP}}\|}{\|F(x_k)\|} = \sqrt{1 - \frac{\langle F(x_k), F'(x_k)\hat{d}_k\rangle^2}{\|F(x_k)\|^2\|F'(x_k)\hat{d}_k\|^2}}. \tag{2.5}$$

Our plan is to build on (2.4)–(2.5) to obtain upper bounds on $\|\hat{s}_k^{\mathrm{CP}}\|$ and $\hat{\eta}_k^{\mathrm{CP}}$ at points of interest that will allow us to use results from [12], which are stated as Theorem 2.2 following the proof. Equation (2.4) immediately gives

$$\|\hat{s}_k^{\mathrm{CP}}\| \le \frac{\|F(x_k)\|\,\|\hat{d}_k\|}{\|F'(x_k)\hat{d}_k\|}\,. \tag{2.6}$$

Also, from (2.3), we obtain

$$\begin{aligned}\epsilon \le \frac{\langle \hat{d}_k, d(x_k)\rangle}{\|\hat{d}_k\|\,\|d(x_k)\|} &= -\frac{\langle \hat{d}_k, F'(x_k)^T DF(x_k)\rangle_2}{\|\hat{d}_k\|\,\|d(x_k)\|} \\ &= -\frac{\langle F'(x_k)\hat{d}_k, F(x_k)\rangle}{\|\hat{d}_k\|\,\|d(x_k)\|} \le \frac{\|F'(x_k)\hat{d}_k\|}{\|\hat{d}_k\|}\cdot\frac{\|F(x_k)\|}{\|d(x_k)\|}\,,\end{aligned}$$

whence

$$\frac{\|\hat{d}_k\|}{\|F'(x_k)\hat{d}_k\|} \le \frac{\|F(x_k)\|}{\epsilon\|d(x_k)\|}\,.$$

Then (2.6) yields

$$\|\hat{s}_k^{\mathrm{CP}}\| \le \frac{\|F(x_k)\|^2}{\epsilon\|d(x_k)\|}\,. \tag{2.7}$$

From (2.3), we also have

$$\begin{aligned}-\frac{\langle F(x_k), F'(x_k)\hat{d}_k\rangle}{\|F(x_k)\|\,\|F'(x_k)\hat{d}_k\|} &= \frac{\langle \hat{d}_k, d(x_k)\rangle}{\|\hat{d}_k\|\,\|d(x_k)\|}\cdot\frac{\|\hat{d}_k\|\,\|d(x_k)\|}{\|F(x_k)\|\,\|F'(x_k)\hat{d}_k\|} \\ &\ge \epsilon\cdot\frac{\|\hat{d}_k\|}{\|F'(x_k)\hat{d}_k\|}\cdot\frac{\|d(x_k)\|}{\|F(x_k)\|} \ge \frac{\epsilon}{\|F'(x_k)\|}\cdot\frac{\|d(x_k)\|}{\|F(x_k)\|}\,,\end{aligned}$$

and it follows from (2.5) that

$$\hat{\eta}_k^{\mathrm{CP}} \le \sqrt{1 - \frac{\epsilon^2}{\|F'(x_k)\|^2}\cdot\frac{\|d(x_k)\|^2}{\|F(x_k)\|^2}}\,. \tag{2.8}$$

Let x_* be a limit point of $\{x_k\}$, and suppose that x_* is not a stationary point of $\|F\|$. Then $F(x_*) \neq 0$. Additionally, $d(x_*) = -D^{-1}\nabla f(x_*) \neq 0$ since x_* is not a stationary point of $\|F\|$. Then, by continuity, there is a neighborhood N_* of x_* such that $0 < \inf_{x\in N_*} \|F(x)\| \leq \sup_{x\in N_*} \|F(x)\| < \infty$, $0 < \inf_{x\in N_*} \|d(x)\|$, and $0 < \inf_{x\in N_*} \|F'(x)\| \leq \sup_{x\in N_*} \|F'(x)\| < \infty$. Then one sees from (2.7)–(2.8) that there are bounds M and $\eta_{\max}^{\mathrm{CP}} < 1$ such that $\|\hat{s}_k^{\mathrm{CP}}\| \leq M$ and $\hat{\eta}_k^{\mathrm{CP}} \leq \eta_{\max}^{\mathrm{CP}}$ whenever $x_k \in N_*$.

Suppose that $x_k \in N_*$ and s_k is determined by Algorithm INDL. If s_k lies on $\hat{\Gamma}_k^{\mathrm{DL}}$ between $\hat{s}_k^{\mathrm{CP}}$ and s_k^{IN}, then it follows from norm convexity that

$$\|F(x_k) + F'(x_k)\, s_k\| \leq \max\{\hat{\eta}_k^{\mathrm{CP}}, \eta_k\}\|F(x_k)\| \leq \max\{\eta_{\max}^{\mathrm{CP}}, \eta_{\max}\}\|F(x_k)\|. \tag{2.9}$$

If s_k lies on $\hat{\Gamma}_k^{\mathrm{DL}}$ between 0 and $\hat{s}_k^{\mathrm{CP}}$, then $\min\{\delta_{\min}, \|s_k^{\mathrm{IN}}\|\} \leq \|s_k\| \leq \|\hat{s}_k^{\mathrm{CP}}\|$. We have

$$\|F(x_k)\| - \|F'(x_k)s_k^{\mathrm{IN}}\| \leq \|F(x_k) + F'(x_k)s_k^{\mathrm{IN}}\| \leq \eta_k\|F(x_k)\| \leq \eta_{\max}\|F(x_k)\|,$$

which implies

$$\|s_k^{\mathrm{IN}}\| \geq \frac{(1-\eta_{\max})}{\|F'(x_k)\|}\|F(x_k)\|. \tag{2.10}$$

The right-hand side of (2.10) is bounded away from zero for $x_k \in N_*$; thus, there is a $\bar{\delta} > 0$ such that $\bar{\delta} \leq \min\{\delta_{\min}, \|s_k^{\mathrm{IN}}\|\}$ whenever $x_k \in N_*$. Since the local linear model norm is monotone decreasing along the segment of $\hat{\Gamma}_k^{\mathrm{DL}}$ between 0 and $\hat{s}_k^{\mathrm{CP}}$, we have, again using norm convexity, that

$$\begin{aligned}
\|F(x_k) + F'(x_k)\, s_k\| &\leq \left\|F(x_k) + F'(x_k)\, \left(\frac{\bar{\delta}}{\|\hat{s}_k^{\mathrm{CP}}\|}\hat{s}_k^{\mathrm{CP}}\right)\right\| \\
&\leq \left(1 - \frac{\bar{\delta}}{\|\hat{s}_k^{\mathrm{CP}}\|}\right)\|F(x_k)\| + \frac{\bar{\delta}}{\|\hat{s}_k^{\mathrm{CP}}\|}\|F(x_k) + F'(x_k)\,\hat{s}_k^{\mathrm{CP}}\| \\
&\leq \left[1 - \frac{\bar{\delta}}{\|\hat{s}_k^{\mathrm{CP}}\|}(1-\hat{\eta}_k^{\mathrm{CP}})\right]\|F(x_k)\| \\
&\leq \left[1 - \frac{\bar{\delta}}{M}(1-\eta_{\max}^{\mathrm{CP}})\right]\|F(x_k)\|.
\end{aligned} \tag{2.11}$$

From (2.9) and (2.11), one concludes that whenever $x_k \in N_*$, we have $\|F(x_k) + F'(x_k)\, s_k\| \leq \bar{\eta}\|F(x_k)\|$, where

$$\bar{\eta} \equiv \max\left\{\eta_{\max}^{\mathrm{CP}}, \eta_{\max}, 1 - \frac{\bar{\delta}}{M}(1-\eta_{\max}^{\mathrm{CP}})\right\} < 1;$$

therefore, with $pred_k$ defined as in (2.2),

$$\frac{pred_k}{\|F(x_k)\|} = \frac{\|F(x_k)\| - \|F(x_k) + F'(x_k)\, s_k\|}{\|F(x_k)\|} \geq (1-\bar{\eta}) > 0. \tag{2.12}$$

Since $x_k \in N_*$ for infinitely many values of k, (2.12) implies that $\sum_{k=0}^{\infty} pred_k/\|F(x_k)\|$ diverges, and it follows from Theorem 2.2 that $F(x_*) = 0$. This is a contradiction; therefore, x_* must be a stationary point of $\|F\|$.

Suppose now that x_* is a limit point of $\{x_k\}$ and that $F'(x_*)$ is nonsingular. Then x_* must be a stationary point of $\|F\|$, and, since $F'(x_*)$ is nonsingular, we must have

$F(x_*) = 0$. Additionally, we can let N_* be a neighborhood of x_* such that $F'(x)$ is invertible for $x \in N_*$ and $\sup_{x\in N_*}\{\|F(x)\|, \|F'(x)\|, \|F'(x)^{-1}\|\} < \infty$. Noting that

$$\frac{\|F(x_k)\|}{\|d(x_k)\|} \leq \| \left[D^{-1}F'(x_k)^T D\right]^{-1} \|, \tag{2.13}$$

we have from (2.7) that, for $x_k \in N_*$,

$$\|\hat{s}_k^{\mathrm{CP}}\| \leq \frac{1}{\epsilon} \| \left[D^{-1}F'(x_k)^T D\right]^{-1} \| \, \|F(x_k)\|. \tag{2.14}$$

One concludes that there is again a bound M such that $\|\hat{s}_k^{\mathrm{CP}}\| \leq M$ whenever $x_k \in N_*$. Moreover, it follows from (2.13) and (2.8) that, for $x_k \in N_*$,

$$\hat{\eta}_k^{\mathrm{CP}} \leq \sqrt{1 - \frac{\epsilon^2}{\|F'(x_k)\|^2 \, \| \left[D^{-1}F'(x_k)^T D\right]^{-1} \|^2}} \, .$$

Consequently, there is again a bound $\eta_{\max}^{\mathrm{CP}} < 1$ such that $\hat{\eta}_k^{\mathrm{CP}} \leq \eta_{\max}^{\mathrm{CP}}$ whenever $x_k \in N_*$.

Suppose that $x_k \in N_*$ and s_k is determined by Algorithm INDL. If s_k lies on $\hat{\Gamma}_k^{\mathrm{DL}}$ between $\hat{s}_k^{\mathrm{CP}}$ and s_k^{IN}, then (2.9) holds as before. If s_k lies on $\hat{\Gamma}_k^{\mathrm{DL}}$ between 0 and $\hat{s}_k^{\mathrm{CP}}$, then we again have $\min\{\delta_{\min}, \|s_k^{\mathrm{IN}}\|\} \leq \|s_k\| \leq \|\hat{s}_k^{\mathrm{CP}}\|$. Reasoning as before, we have that

$$\begin{aligned}
\|F(x_k) + F'(x_k)\, s_k\| \;&\leq\; \left\| F(x_k) + F'(x_k) \left(\frac{\min\{\delta_{\min}, \|s_k^{\mathrm{IN}}\|\}}{\|\hat{s}_k^{\mathrm{CP}}\|} \hat{s}_k^{\mathrm{CP}} \right) \right\| \\
&\leq\; \left(1 - \frac{\min\{\delta_{\min}, \|s_k^{\mathrm{IN}}\|\}}{\|\hat{s}_k^{\mathrm{CP}}\|} \right) \|F(x_k)\| \\
&\qquad + \frac{\min\{\delta_{\min}, \|s_k^{\mathrm{IN}}\|\}}{\|\hat{s}_k^{\mathrm{CP}}\|} \|F(x_k) + F'(x_k)\, \hat{s}_k^{\mathrm{CP}}\| \\
&\leq\; \left[1 - \frac{\min\{\delta_{\min}, \|s_k^{\mathrm{IN}}\|\}}{\|\hat{s}_k^{\mathrm{CP}}\|} (1 - \hat{\eta}_k^{\mathrm{CP}}) \right] \|F(x_k)\| \\
&\leq\; \left[1 - \min\left\{ \frac{\delta_{\min}}{M}, \frac{\|s_k^{\mathrm{IN}}\|}{\|\hat{s}_k^{\mathrm{CP}}\|} \right\} (1 - \eta_{\max}^{\mathrm{CP}}) \right] \|F(x_k)\|.
\end{aligned} \tag{2.15}$$

Inequality (2.10) again holds, and (2.10) and (2.14) yield

$$\frac{\|s_k^{\mathrm{IN}}\|}{\|\hat{s}_k^{\mathrm{CP}}\|} \geq \frac{\epsilon(1-\eta_{\max})}{\|F'(x_k)\| \, \| \left[D^{-1}F'(x_k)^T D\right]^{-1} \|} \geq \inf_{x\in N_*} \frac{\epsilon(1-\eta_{\max})}{\|F'(x)\| \, \| \left[D^{-1}F'(x)^T D\right]^{-1} \|} > 0.$$

It follows that there is a $\bar{\delta} > 0$ independent of k such that

$$\bar{\delta} \leq \min\left\{ \frac{\delta_{\min}}{M}, \frac{\|s_k^{\mathrm{IN}}\|}{\|\hat{s}_k^{\mathrm{CP}}\|} \right\},$$

and we have from (2.15) that

$$\|F(x_k) + F'(x_k)\, s_k\| \leq \left[1 - \bar{\delta}(1 - \eta_{\max}^{\mathrm{CP}})\right] \|F(x_k)\|.$$

As before, one concludes that (2.12) holds whenever $x_k \in N_*$, with $\bar{\eta}$ now given by

$$\bar{\eta} \equiv \max\{\eta_{\max}^{\mathrm{CP}}, \eta_{\max}, 1 - \bar{\delta}(1 - \eta_{\max}^{\mathrm{CP}})\} < 1,$$

and we again have that $\sum_{k=0}^{\infty} pred_k/\|F(x_k)\|$ diverges. Since $F'(x_*)$ is nonsingular, it follows from Theorem 2.2 below that $x_k \to x_*$.

To complete the proof, we note that, since $x_k \to x_*$ as $k \to \infty$ with $F(x_*) = 0$ and $F'(x_*)$ nonsingular, it follows from (2.14) that $\hat{s}_k^{\mathrm{CP}} \to 0$ as $k \to \infty$. Additionally, writing $F'(x_k)\, s_k = -F(x_k) + r_k$ with $\|r_k\| \le \eta_k \|F(x_k)\|$, we have that

$$\begin{aligned} \|s_k^{\mathrm{IN}}\| &= \|F'(x_k)^{-1}[-F(x_k) + r_k]\| \le \|F'(x_k)^{-1}\|\,(1 + \eta_k)\,\|F(x_k)\| \\ &\le 2\,\|F'(x_k)^{-1}\|\,\|F(x_k)\|. \end{aligned}$$

Consequently, $s_k^{\mathrm{IN}} \to 0$ as $k \to \infty$. One easily verifies that, for all sufficiently large k, every admissible $s_k \in \hat{\Gamma}_k^{\mathrm{DL}}$ must be sufficiently small that $ared_k \ge t \cdot pred_k$ holds; thus, for all sufficiently large k, the initial s_k is accepted without modification. Finally, for all sufficiently large k, one has $\|s_k^{\mathrm{IN}}\| \le \delta_{\min} \le \delta$, and $s_k = s_k^{\mathrm{IN}}$ is admissible. ∎

The following is the result from [12] used in the proof of Theorem 2.1.

THEOREM 2.2 (see [12, Cor. 3.6]). *Let $F : \mathbb{R}^n \to \mathbb{R}^n$ be continuously differentiable and assume that $\{x_k\} \subset \mathbb{R}^n$ is such that $pred_k \ge 0$ and $ared_k \ge t \cdot pred_k$ for each k, where $t \in (0, 1)$ is independent of k and $ared_k$ and $pred_k$ are given by (2.2) with $s_k \equiv x_{k+1} - x_k$. If $\sum_{k \ge 0} pred_k/\|F(x_k)\|$ is divergent, then $F(x_k) \to 0$. If, in addition, x_* is a limit point of $\{x_k\}$ such that $F'(x_*)$ is invertible, then $F(x_*) = 0$ and $x_k \to x_*$.*

Applications to Newton–GMRES and Newton–Arnoldi methods. It follows from observations in [3, section 4] that if either GMRES or the Arnoldi method [35] is used (without restarting) to solve (1.2), then the orthogonal projection of $d(x_k)$ determined by (2.1) onto each Krylov subspace generated by the method is available at very little cost. Using results from [4], we show how Theorem 2.1 can be applied when these projections are used in Algorithm INDL to approximate the vectors $d(x_k)$, provided that the condition numbers $\kappa(F'(x_k)) \equiv \|F'(x_k)\|\,\|F'(x_k)^{-1}\|$ are bounded uniformly in k. In the spirit of [4], we show this for orthogonal projections onto subspaces that are not necessarily Krylov subspaces.

Suppose that $x \in \mathbb{R}^n$, $\mathcal{K}$ is a subspace of $\mathbb{R}^n$, and $s \in \mathcal{K}$ is such that $\|F(x) + F'(x)s\| \le \eta \|F(x)\|$ for some $\eta \in [0, 1)$. Let $\hat{d}$ denote the orthogonal projection onto $\mathcal{K}$ of $d(x)$ given by (2.1). A straightforward extension of [4, Cor. 3.5] to the context of a general inner-product norm gives

$$\|\hat{d}\| \ge \frac{1 - \eta}{(1 + \eta)\kappa(F'(x))} \|d(x)\|.$$

Since $\langle \hat{d}, d(x) \rangle = \|\hat{d}\|^2$, it follows that

$$\frac{|\langle \hat{d}, d(x) \rangle|}{\|\hat{d}\|\,\|d(x)\|} = \frac{\|\hat{d}\|}{\|d\|} \ge \frac{1 - \eta}{(1 + \eta)\kappa(F'(x))}. \tag{2.16}$$

This immediately gives the following corollary of Theorem 2.1.

COROLLARY 2.3. *Assume that F is continuously differentiable and that $\{x_k\}$ is produced by Algorithm* INDL. *For each k, suppose that there is a subspace $\mathcal{K}_k \subseteq \mathbb{R}^n$*

such that $s_k^{\mathrm{IN}} \in \mathcal{K}_k$*, and let* $\hat{d}_k$ *denote the orthogonal projection onto* $\mathcal{K}_k$ *of* $d(x_k)$ *determined by* (2.1)*. If* $\{\kappa(F'(x_k))\}$ *is bounded and if* x_* *is a limit point of* $\{x_k\}$*, then* $F(x_*) = 0$ *and* $x_k \to x_*$*. Moreover, for all sufficiently large* k*, the initial* s_k *is accepted without modification in the while-loop, and* $s_k = s_k^{\mathrm{IN}}$ *is an admissible step.*

Proof. Let M be such that $\kappa(F'(x_k)) \le M$ for all k. Then, since $\eta_k \in [0, \eta_{\max}]$, (2.16) implies that

$$\frac{|\langle \hat{d}_k, d(x_k)\rangle|}{\|\hat{d}_k\|\,\|d(x_k)\|} \ge \frac{1-\eta_{\max}}{(1+\eta_{\max})M}$$

for each k, and (2.3) holds with $\epsilon = \frac{1-\eta_{\max}}{(1+\eta_{\max})M}$. The result follows from Theorem 2.1. ∎

3. Step selection strategies. Algorithm INDL allows great flexibility in determining each step $s_k \in \hat{\Gamma}_k^{\mathrm{DL}}$, and particular choices of the steps may strongly affect the behavior of the algorithm. In this section, we discuss specific strategies for selecting admissible steps, first recalling the traditional strategy and then suggesting an alternative that may have advantages. We conclude by outlining certain refinements with which these strategies can be augmented.

3.1. Two strategies. The traditional strategy outlined in the following is a straightforward adaptation of the usual procedure for determining dogleg steps in the exact-Newton context (see, e.g., [11]).

Procedure 3.1. Traditional strategy

If $\|s_k^{\mathrm{IN}}\| \le \delta$, set $s_k = s_k^{\mathrm{IN}}$.
Else,
  If $\|\hat{s}_k^{\mathrm{CP}}\| \ge \delta$, set $s_k = (\delta/\|\hat{s}_k^{\mathrm{CP}}\|)\hat{s}_k^{\mathrm{CP}}$.
  Else, set $s_k = (1-\gamma)\hat{s}_k^{\mathrm{CP}} + \gamma s_k^{\mathrm{IN}}$ for $\gamma \in (0,1)$
    such that $\|s_k\| = \delta$.

This procedure always determines s_k uniquely, notwithstanding that, as noted in section 1, the usual exact-Newton characterization of the dogleg step may fail to do so. However, there are still issues that may be of concern. As seen in the left illustration in Figure 1.1, for any $\eta_k > 0$, no matter how small, s_k determined by Procedure 3.1 may not minimize the local linear model norm along $\hat{\Gamma}_k^{\mathrm{DL}}$ within the trust region. Perhaps of greater concern is that, if η_k is not small, then, as seen in the right illustration in Figure 1.1, the procedure may specify $s_k = s_k^{\mathrm{IN}}$ without taking $\hat{s}_k^{\mathrm{CP}}$ into account, even though there are steps in the $\hat{s}_k^{\mathrm{CP}}$-direction, or biased toward it, that give significantly greater reduction of the local linear model norm along $\hat{\Gamma}_k^{\mathrm{DL}}$ within the trust region.

As a step toward addressing these concerns, we offer the following.

Procedure 3.2. Alternative strategy

If $\|\hat{s}_k^{\mathrm{CP}}\| \ge \delta$, set $s_k = (\delta/\|\hat{s}_k^{\mathrm{CP}}\|)\hat{s}_k^{\mathrm{CP}}$.
Else,
  If $\|F(x_k) + F'(x_k)\,\hat{s}_k^{\mathrm{CP}}\| \le \eta_k\|F(x_k)\|$, set $s_k = \hat{s}_k^{\mathrm{CP}}$.
  Else,
    If $\|s_k^{\mathrm{IN}}\| \le \delta$, set $s_k = s_k^{\mathrm{IN}}$.
    Else, set $s_k = (1-\gamma)\hat{s}_k^{\mathrm{CP}} + \gamma s_k^{\mathrm{IN}}$ for $\gamma \in (0,1)$
      such that $\|s_k\| = \delta$.

In Procedure 3.2, $\hat{s}_k^{\mathrm{CP}}$ is examined first. If it lies outside the trust region, then, as in the traditional strategy in the exact-Newton context, s_k is a step in the $\hat{s}_k^{\mathrm{CP}}$-direction and scaled to lie on the trust-region boundary. If $\hat{s}_k^{\mathrm{CP}}$ lies within the trust region and also satisfies the prescribed inexact Newton condition, then $\hat{s}_k^{\mathrm{CP}}$ achieves the desired linear model norm reduction, and we take $s_k = \hat{s}_k^{\mathrm{CP}}$. If $\hat{s}_k^{\mathrm{CP}}$ does not satisfy the inexact Newton condition, then s_k^{IN} is examined, and s_k is taken to be either s_k^{IN}, if it lies within the trust region, or, otherwise, the unique point between $\hat{s}_k^{\mathrm{CP}}$ and s_k^{IN} at which $\hat{\Gamma}_k^{\mathrm{DL}}$ intersects the trust-region boundary, as in the traditional strategy in the exact-Newton context.

Note that, in a practical implementation within Algorithm INDL, Procedure 3.2 would require computing $\hat{s}_k^{\mathrm{CP}}$ for each k but would require computing s_k^{IN} only when $\hat{s}_k^{\mathrm{CP}}$ lies within the trust region and does not satisfy the inexact Newton condition. In contrast, Procedure 3.1 would require computing s_k^{IN} for each k but would require computing $\hat{s}_k^{\mathrm{CP}}$ only when s_k^{IN} lies outside the trust region. Also, in the Newton-iterative context, Procedure 3.2 offers the possibility of using $\hat{s}_k^{\mathrm{CP}}$ as the initial approximate solution in the iterative solver when it is necessary to compute s_k^{IN}, thereby allowing advantage to be taken of the linear model norm reduction already achieved by $\hat{s}_k^{\mathrm{CP}}$.

3.2. Further refinements. As noted in section 1 and seen in the left illustration in Figure 1.1, the local linear model norm may not be monotone decreasing along the dogleg curve and, indeed, may not be minimized at the intersection of the dogleg curve and the trust-region boundary. Note that, in this illustration, this intersection would be the dogleg step determined by both Procedure 3.1 and Procedure 3.2. We reproduce this illustration on the left in Figure 3.1 and include the point s_{min} at which the local linear model norm is minimized along the dogleg curve within the trust region. As we show in the following, minimizers such as s_{min} can be readily computed; thus s_{min} is likely to be the preferred dogleg step.

To show further possibilities, we include the illustration on the right in Figure 3.1, in which the minimizer of the local linear model norm within the trust region along the line joining s_k^{CP} and s_k^{IN} (again denoted by s_{min}) occurs *beyond* the end of the dogleg curve. In this illustration, both Procedure 3.1 and Procedure 3.2 would determine the dogleg step to be s_k^{IN}. (In practice, Procedure 3.1 would do so without computing s_k^{CP}, while Procedure 3.2 would compute both s_k^{CP} and s_k^{IN}.) Since s_{min} satisfies the inexact Newton condition satisfied by s_k^{IN}, we can regard it as an admissible dogleg step simply by replacing s_k^{IN} by s_{min} in determining the dogleg curve. Since this s_{min} can also be readily computed, it is likely to be the preferred dogleg step in this case.

In the following, we formulate refinements of Procedures 3.1 and 3.2 that determine dogleg steps to be local linear model norm minimizers such as those illustrated in Figure 3.1. In these refinements, we modify the procedures to minimize explicitly only along the line joining $\hat{s}_k^{\mathrm{CP}}$ and s_k^{IN} in the final steps, when both $\hat{s}_k^{\mathrm{CP}}$ and s_k^{IN} would have been computed in a practical implementation. Minimizing along the line joining zero and $\hat{s}_k^{\mathrm{CP}}$ is already ensured by the definition of $\hat{s}_k^{\mathrm{CP}}$ and the convexity of the local linear model norm along that line. Additionally, it seems unlikely to be worthwhile to compute either $\hat{s}_k^{\mathrm{CP}}$ or s_k^{IN} only for the purposes of minimization when the procedures do not otherwise require them. For example, in the illustration on the right in Figure 1.1, computing both $\hat{s}_k^{\mathrm{CP}}$ (which is just s_k^{CP} in this case) and s_k^{IN} would, in fact, allow one to determine the minimizer along the entire dogleg curve within the trust region; however, not much would be gained over the scaled step in the s_k^{CP}-direction determined by Procedure 3.2. In any event, it would be easy to further modify the procedures to perform this additional minimization, if desired.

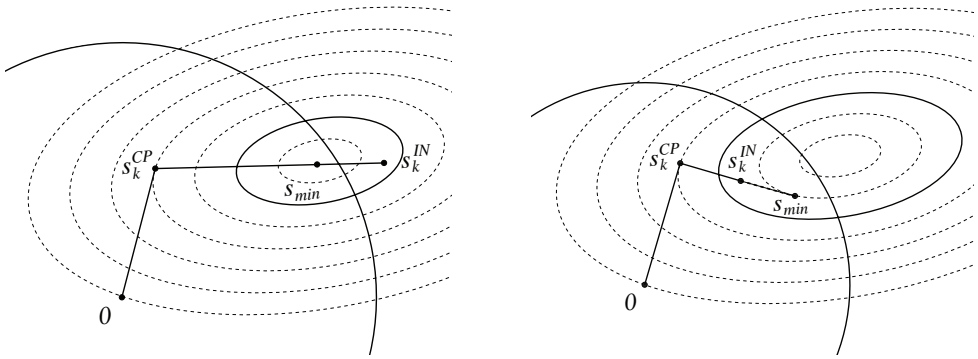

FIG. 3.1. *Illustrative local linear model norm minimizers in* $\boldsymbol{R}^2$. *The ellipses represent level curves of the local linear model norm. The solid ellipses represent* $\{s \in \boldsymbol{R}^n : \|F(x_k) + F'(x_k)s\| = \eta_k\|F(x_k)\|\}$. *The circular arcs represent trust-region boundaries. Each point* s_{min} *is the minimizer of the local linear model norm along the line joining* $s_k^{\rm CP}$ *and* $s_k^{\rm IN}$.

We begin with two elementary propositions, the proofs of which are left to the reader. These are included primarily to show what might be involved in computing minimizing steps. In these, we define

$$s(\gamma) \equiv (1-\gamma)\hat{s}_k^{\rm CP} + \gamma s_k^{\rm IN}.$$

PROPOSITION 3.3. *If* $F'(x_k)(\hat{s}_k^{\rm CP} - s_k^{\rm IN}) \neq 0$, *then* $\|F(x_k) + F'(x_k)s(\gamma)\|$ *is minimized at* $\gamma = \gamma_{\min}$, *given by*

$$\gamma_{\min} \equiv \frac{\langle F(x_k) + F'(x_k)\hat{s}_k^{\rm CP},\ F'(x_k)(\hat{s}_k^{\rm CP} - s_k^{\rm IN})\rangle}{\|F'(x_k)(\hat{s}_k^{\rm CP} - s_k^{\rm IN})\|^2} = \frac{\langle \hat{r}_k^{\rm CP},\ \hat{r}_k^{\rm CP} - r_k^{\rm IN}\rangle}{\|\hat{r}_k^{\rm CP} - r_k^{\rm IN}\|^2}, \tag{3.1}$$

where $\hat{r}_k^{\rm CP} \equiv F(x_k) + F'(x_k)\hat{s}_k^{\rm CP}$ *and* $r_k^{\rm IN} \equiv F(x_k) + F'(x_k)s_k^{\rm IN}$.

One sees from (3.1) that, if $\hat{r}_k^{\rm CP}$ and $r_k^{\rm IN}$ are already available, then $\gamma_{\min}$ can be determined with only a modest amount of arithmetic. If these are not available, then one or, at most, two Jacobian-vector products may be required in addition to some arithmetic.

PROPOSITION 3.4. *If* $\|\hat{s}_k^{\rm CP}\| < \delta$ *and* $s_k^{\rm IN} \neq \hat{s}_k^{\rm CP}$, *then* $\|s(\gamma)\| = \delta$ *for exactly two values* $\gamma = \gamma_\delta^+$ *and* $\gamma = \gamma_\delta^-$, *given by*

$$\gamma_\delta^\pm = \frac{\langle \hat{s}_k^{\rm CP},\ \hat{s}_k^{\rm CP} - s_k^{\rm IN}\rangle \pm \sqrt{\langle \hat{s}_k^{\rm CP},\ \hat{s}_k^{\rm CP} - s_k^{\rm IN}\rangle^2 + (\delta^2 - \|\hat{s}_k^{\rm CP}\|^2)\|\hat{s}_k^{\rm CP} - s_k^{\rm IN}\|^2}}{\|\hat{s}_k^{\rm CP} - s_k^{\rm IN}\|^2}. \tag{3.2}$$

One sees from (3.2) that $\gamma_\delta^\pm$ can be computed with a modest amount of arithmetic. Also, we have that $\gamma_\delta^- < 0 < \gamma_\delta^+$. Additionally, in the context of interest, viz., the final steps of Procedures 3.1 and 3.2, the assumption that $\|\hat{s}_k^{\rm CP}\| < \delta$ and $s_k^{\rm IN} \neq \hat{s}_k^{\rm CP}$ always holds. Indeed, in this context, we have $\|\hat{s}_k^{\rm CP}\| < \delta < \|s_k^{\rm IN}\|$ in Procedure 3.1 and both $\|\hat{s}_k^{\rm CP}\| < \delta$ and $\|F(x_k) + F'(x_k)s_k^{\rm IN}\| \leq \eta_k < \|F(x_k) + F'(x_k)\hat{s}_k^{\rm CP}\|$ in Procedure 3.2. Note that the first pair of inequalities implies that $\gamma_\delta^+ < 1$, and it follows from the final pair that $\gamma_{\min} > 0$.

The following are our refinements of Procedures 3.1 and 3.2. In these, $\gamma_{\min}$ and $\gamma_\delta^\pm$ are defined by (3.1) and (3.2), respectively. In Procedure 3.6, some simplification is allowed in the last step by the fact that $\gamma_{\min} > 0$ there, as noted above.

Procedure 3.5. Traditional strategy with model norm minimization

If $\|s_k^{\mathrm{IN}}\| \le \delta$, set $s_k = s_k^{\mathrm{IN}}$.
Else,
  If $\|\hat{s}_k^{\mathrm{CP}}\| \ge \delta$, set $s_k = (\delta/\|\hat{s}_k^{\mathrm{CP}}\|)\hat{s}_k^{\mathrm{CP}}$.
  Else, set $s_k = (1-\gamma)\hat{s}_k^{\mathrm{CP}} + \gamma s_k^{\mathrm{IN}}$ for $\gamma = \max\{\gamma_\delta^-, \min\{\gamma_{\min}, \gamma_\delta^+\}\}$.

Procedure 3.6. Alternative strategy with model norm minimization

If $\|\hat{s}_k^{\mathrm{CP}}\| \ge \delta$, set $s_k = (\delta/\|\hat{s}_k^{\mathrm{CP}}\|)\hat{s}_k^{\mathrm{CP}}$.
Else,
  If $\|F(x_k) + F'(x_k)\,\hat{s}_k^{\mathrm{CP}}\| \le \eta_k\|F(x_k)\|$, set $s_k = \hat{s}_k^{\mathrm{CP}}$.
  Else, set $s_k = (1-\gamma)\hat{s}_k^{\mathrm{CP}} + \gamma s_k^{\mathrm{IN}}$ for $\gamma = \min\{\gamma_{\min}, \gamma_\delta^+\}$.

Note that, in the circumstance illustrated on the left in Figure 3.1, both Procedure 3.5 and Procedure 3.6 would yield $s_k = s_{min}$. However, in the circumstance illustrated on the right, Procedure 3.6 would produce $s_k = s_{min}$, but Procedure 3.5 would result in $s_k = s_k^{\mathrm{IN}}$ because s_k^{CP} would not be computed in this case.

It is observed in section 3.1 that, in a Newton-iterative implementation of Procedure 3.2, it may be advantageous to use $\hat{s}_k^{\mathrm{CP}}$ as the initial approximate solution in the iterative solver when it is necessary to compute s_k^{IN}. If this is done and if the iterative method is unrestarted GMRES or a mathematically equivalent method, then the minimization of Procedure 3.6 would be unneccesary. Indeed, Procedure 3.2 would produce the same step as Procedure 3.6, since the GMRES step from $\hat{s}_k^{\mathrm{CP}}$ to s_k^{IN} already minimizes the local linear model norm over the Krylov subspace in which it lies and, in particular, minimizes it along the line joining $\hat{s}_k^{\mathrm{CP}}$ and s_k^{IN}.

We also note an additional possibility with Procedures 3.2 and 3.6: If $\|\hat{s}_k^{\mathrm{CP}}\| < \delta$ and $\|F(x_k) + F'(x_k)\,\hat{s}_k^{\mathrm{CP}}\| \le \eta_k\|F(x_k)\|$, then, rather than take $s_k = \hat{s}_k^{\mathrm{CP}}$, one can reduce η_k so that $\eta_k < \|F(x_k) + F'(x_k)\,\hat{s}_k^{\mathrm{CP}}\|$ and compute s_k^{IN} for the reduced η_k. With this s_k^{IN}, the final steps of Procedures 3.2 and 3.6 should yield steps that further reduce the local linear model norm within the trust region.

4. Numerical experiments. In this section, we report on numerical experiments in which a Newton–GMRES implementation of Algorithm INDL employing step-selection strategies from section 3 and certain other options was applied to several well-known benchmark problems involving the steady-state Navier–Stokes equations. In the following, we outline details of the implementation and the overall computational environment, describe the test problems, and give the results of the experiments. These experiments involve challenging large-scale problems and advanced computing platforms but are somewhat limited in scope. Our primary goal is to demonstrate the basic effectiveness of Algorithm INDL with the selected strategies and options on these test problems, and not to provide a definitive comparison of all algorithmic possibilities on a broad variety of applications.

4.1. The implementation and the computational environment. In our implementation of Algorithm INDL, each inexact Newton step s_k^{IN} was determined using restarted GMRES with a restart value of 200. Up to three restarts (600 total GMRES iterations) were allowed for each k. The preconditioner was an additive Schwarz preconditioner with an ILUT [36] factorization and solve on each subdomain. With this preconditioner, GMRES almost never restarted in our experiments. For each k, the initial approximate solution in GMRES was either zero or, optionally, the approximate Cauchy point $\hat{s}_k^{\mathrm{CP}}$ determined by $\hat{d}_k = -\nabla f(x_k)$, which could be

evaluated analytically by our codes and for which condition (2.3) of Theorem 2.1 holds for $0 < \epsilon \le \kappa_2(D)^{-1/2}$ (see Remark 2 following Theorem 2.1). Products of the Jacobian with vectors needed by GMRES were also evaluated analytically.

We used two choices for each forcing term η_k in our experiments: a small constant choice $\eta_k = 10^{-4}$, which should result in fast linear convergence in a neighborhood of a solution; and an adaptive choice from [13], called "Choice 1" there and given by

$$\eta_k = \min\left\{\eta_{\max}, \frac{\left|\|F(x_k)\| - \|F(x_{k-1}) + F'(x_{k-1})\, s_{k-1}\|\right|}{\|F(x_{k-1})\|}\right\},\ k = 1, 2, \ldots, \tag{4.1}$$

which should yield a certain superlinear convergence near a solution [13, Th. 2.2]. As in [13], (4.1) was followed with the safeguard

$$\eta_k \leftarrow \max\{\eta_k, \eta_{k-1}^{(1+\sqrt{5})/2}\} \quad \text{whenever } \eta_{k-1}^{(1+\sqrt{5})/2} > 0.1$$

to prevent the forcing terms from becoming too small too quickly away from a solution. In our implementation, we used $\eta_0 = .01$ and $\eta_{\max} = .9$.

Dogleg steps were selected using the standard and alternative strategies described in Procedures 3.1 and 3.2, respectively. Since, as noted previously, GMRES rarely restarted, Procedure 3.6 almost always produced the same steps as Procedure 3.2 when GMRES was started from the approximate Cauchy point. Thus there seemed to be no significant advantage in using Procedure 3.6 rather than Procedure 3.2 in this case. For consistency, then, we used Procedures 3.1 and 3.2 rather than Procedures 3.5 and 3.6 throughout.

In the test $ared_k < t \cdot pred_k$ at the top of the while-loop, we took $t = 10^{-4}$, so that even very modest agreement would result in accepting the step. Within the while-loop, we used the fixed choice $\theta = .25$ for each update $\delta \leftarrow \max\{\theta\delta, \delta_{\min}\}$. In updating δ in $[\delta_{\min}, \infty)$ following the while-loop, we used a procedure similar to that outlined in [11], in which the trust region is shrunk (subject to the constraint $\delta \ge \delta_{\min}$) if $\|F(x_k + s_k)\|$ and $\|F(x_k) + F'(x_k)\, s_k\|$ do not agree well, expanded if they agree especially well, and left unchanged otherwise. The specific procedure, in which $0 < \rho_s < \rho_e < 1$, $0 < \beta_s < 1 < \beta_e$, and $\delta_{\max} > \delta_{\min}$, is as follows:

Procedure 4.1.

If $ared_k/pred_k < \rho_s$,
  If $\|s_k^{IN}\| < \delta$, update $\delta \leftarrow \max\{\|s_k^{IN}\|, \delta_{\min}\}$.
  Else, update $\delta \leftarrow \max\{\beta_s\delta, \delta_{\min}\}$.
Else,
  If $ared_k/pred_k > \rho_e$ and $\|s_k\| = \delta$, update $\delta \leftarrow \min\{\beta_e\delta, \delta_{\max}\}$.

In our implementation, we took $\rho_s = 0.1$, $\rho_e = 0.75$, $\beta_s = .25$, $\beta_e = 4.0$, $\delta_{\min} = 10^{-6}$, and $\delta_{\max} = 10^{10}$. The initial δ was determined after the computation of s_0^{IN} as follows: If $\|s_0^{IN}\| < \delta_{\min}$, then $\delta = 2\delta_{\min}$; otherwise, $\delta = \|s_0^{IN}\|$.

Our implementation of Algorithm INDL was done within the NOX nonlinear solver package [26], a C++ object-oriented library developed at Sandia National Laboratories for the efficient solution of systems of nonlinear equations. The GMRES implementation and preconditioners were provided by the AztecOO package [22], an extension of the Aztec library [47], which provides an extensive suite of Krylov solvers and preconditioners for the parallel solution of linear systems. The parallel finite-element reacting-flow code MPSalsa [40] was used to set up the finite-element discretization of the test problems described in section 4.2 and also to invoke

the solvers. MPSalsa uses Chaco [21], a general graph partitioning tool, to partition the FE mesh into subdomains and assign subdomains to processors. Successful termination of the nonlinear solution algorithm was declared if both of the following held: (1) $\frac{1}{n}\|Ws_k\| < 1$, where n is the total number of unknowns and W is a diagonal weighting matrix with entries $W_{ii} = 1/(\varepsilon_r|x_k^{(i)}| + \varepsilon_a)$, in which $x_k^{(i)}$ is the ith component of x_k (see [1]); (2) $\|F(x_k)\| \le \epsilon_F\|F(x_0)\|$. In our tests, $\varepsilon_r = 10^{-3}$, $\varepsilon_a = 10^{-8}$, and $\epsilon_F = 10^{-2}$. The first criterion is employed by MPSalsa and, in our experiments, was typically more stringent than the second and necessary to ensure that finer physical details of solutions are adequately resolved.

Our experiments were performed on an IBM cluster at Sandia National Laboratories having 16 nodes, with each node containing two one-GHz Pentium III processors with one GB of RAM each. Tests on the 2D problems were done using four nodes (eight processors); tests on the 3D problems were done using 15 nodes (30 processors).

4.2. The test problems. The three benchmark problems considered here have been widely studied. We describe these in only qualitative terms and refer the reader to [30] and [41] for more specific descriptions of the governing partial differential equations, boundary conditions, and discretizations used in these experiments.

The problems are flow problems involving the steady-state Navier–Stokes equations for low-speed, incompressible flow, specifically the equations for momentum transport, total mass conservation, and, in one case, thermal energy transport. The unknowns are the fluid velocity vector, the hydrodynamic pressure, and, in the one case, the temperature. See [30] for precise formulations of the equations and the boundary conditions in each case. In each of our experiments, an algebraic system of the form (1.1) was obtained from the PDEs using a stabilized finite-element formulation following [23] and [45]. The Jacobian of the system is nonsymmetric and, when needed, was evaluated analytically in our tests.

Our first test problem is the thermal-convection problem [8]. This involves modelling the flow of fluid in a differentially heated square box in the presence of gravity. The PDEs are the equations for momentum and thermal energy transport and for mass conservation. The unknowns include the temperature as well as the fluid velocity and pressure. The temperature is held fixed at different values on two opposite faces of the box, with zero heat flux imposed on the remaining sides. The fluid velocity is zero on all sides. When suitably nondimensionalized, the equations involve two parameters: the Rayleigh number Ra and the Prandtl number Pr. As Ra increases for fixed Pr, the nonlinear effects of the convection terms increase and the solution becomes increasingly difficult to obtain. In our experiments, we took Pr = 1 and varied Ra. We considered 2D and 3D forms of this problem. The 2D problem was discretized on a 100×100 equally spaced mesh, which resulted in 40,804 unknowns for the discretized problem. In 3D, the discretization was on a $32 \times 32 \times 32$ equally spaced mesh, resulting in 179,685 unknowns.

Our second test problem is the lid-driven cavity problem [18], [39]. This requires simulating flow in the unit square in $\mathbb{R}^2$ or the unit cube in $\mathbb{R}^3$ driven by a moving upper boundary. The PDEs are the momentum transport and mass conservation equations; the unknowns are the fluid velocity and pressure. The fluid velocity on the top side is fixed at a nonzero value in the x-axis direction and held at zero on all other sides. An appropriately nondimensionalized form of the PDEs leads to the Reynolds number Re, a nondimensional parameter expressing the ratio of convective to diffusive momentum transport. As Re increases, the nonlinear components of the equations

become more dominant and the problem becomes more difficult. We considered this problem in both 2D and 3D. The 2D computations were done on a 100×100 equally spaced grid, which led to 30,603 unknowns for the discretized problem. In 3D, the discretization was a $32 \times 32 \times 32$ equally spaced grid, yielding 143,748 unknowns.

Our third test problem is the backward-facing step problem [17]. This involves the simulation of flow through a rectangular channel that is initially constricted and subsequently expands over a reentrant backward-facing step. As above, the PDEs are those for momentum transport and mass conservation, and the unknowns are the fluid velocity and pressure. The nondimensionalized form of the equations is again parametrized by the Reynolds number Re, with problem difficulty increasing as Re increases. We considered this problem only in 2D. The flow was computed only in the expanded portion of the channel; flow entering from the constricted portion was simulated by imposing a parabolic velocity profile in the upper half of the inlet boundary and zero velocity on the lower half. See [30] for further details of the domain and boundary conditions. The problem was discretized on a 20×400 unequally spaced mesh (with a finer mesh near the step), which resulted in 25,263 unknowns.

4.3. The test results. In our experiments, we first conducted a robustness study. In this, we applied our implementation of Algorithm INDL with the algorithmic options described in section 4.1 to the test problems in section 4.2 and tabulated the numbers of failures with different options as problem parameters varied. The specific parameter values considered are as follows:

2D and 3D Thermal Convection	$\mathrm{Ra} = 10^3, 10^4, 10^5, 10^6,$
2D Lid-Driven Cavity	$\mathrm{Re} = 1,000, 2,000, \ldots, 10,000,$
3D Lid-Driven Cavity	$\mathrm{Re} = 100, 200, \ldots, 1,000,$
2D Backward-Facing Step	$\mathrm{Re} = 100, 200, \ldots, 700, 750, 800.$

The results of the robustness study are given in Table 4.1. For comparison, the table also includes results for NOX Newton–GMRES implementations with no globalization and with a backtracking globalization from [12] (see also [41], [31], [30]); these results were obtained in an earlier study involving identical test conditions (see [29, Tables 2–3]). Table 4.1 shows that both the dogleg and backtracking globalizations significantly improved robustness in these experiments, reducing the total numbers of failures with both forcing terms by 69% to 77%, compared to the method without globalization. Improvement was especially pronounced when adaptive forcing terms were used, a result consistent with other studies of globalized Newton–GMRES methods [31], [41], [30]. As also observed elsewhere [3], [41, section 5], [30], the dogleg and backtracking globalizations performed fairly comparably overall on these test problems, although there were some differences in the numbers of failures and where failures occurred. In view of the limited scope of these tests, we feel that further testing is needed to assess more fully the comparative robustness of these methods.

We next conducted an efficiency study of the dogleg methods, in which we compiled run times and other statistics for Algorithm INDL with different options on a selected set of test problem cases. This set included all cases considered in the robustness study in which all of the dogleg methods succeeded. Additionally, since all dogleg methods using the small constant forcing terms failed on the 2D lid-driven cavity problem for each value of Re above $1,000$, we included cases of this problem with $100 \leq \mathrm{Re} \leq 1,000$. The specific cases considered are as follows:

TABLE 4.1

*Robustness study: For each method, the upper and lower rows to the right show the numbers of failures with, respectively, the adaptive and small constant forcing terms. "TC," "LDC," and "BFS" denote, respectively, the thermal-convection, lid-driven cavity, and backward-facing step problems. * GMRES solves starting from zero. ** GMRES solves starting from the approximate Cauchy point.*

Method	2D problems			3D problems		Failure totals	
	TC	LDC	BFS	TC	LDC		
Algorithm INDL, Procedure 3.1	0	0	0	0	0	0	10
	1	9	0	0	0	10	
Algorithm INDL, Procedure 3.2*	0	2	0	0	0	2	12
	0	9	0	0	1	10	
Algorithm INDL, Procedure 3.2**	0	0	0	0	0	0	9
	0	9	0	0	0	9	
Backtracking globalization	0	0	0	0	0	0	10
	0	9	1	0	0	10	
No globalization	1	9	5	1	0	16	39
	1	10	7	1	4	23	

2D Thermal Convection	$\mathrm{Ra} = 10^3, 10^4, 10^5,$
3D Thermal Convection	$\mathrm{Ra} = 10^3, 10^4, 10^5, 10^6,$
2D Lid-Driven Cavity	$\mathrm{Re} = 100, 200, \ldots, 1,000,$
3D Lid-Driven Cavity	$\mathrm{Re} = 100, 200, \ldots, 900,$
2D Backward-Facing Step	$\mathrm{Re} = 100, 200, \ldots, 700, 750, 800.$

The results of the efficiency study are given in Table 4.2.[6] One sees that, as before, the forcing terms significantly influenced the performance of the methods. The adaptive forcing terms resulted in more inexact Newton steps on average than the more aggressive small constant forcing terms; however, the adaptive forcing terms led to significantly fewer GMRES iterations, both overall and per inexact Newton step. In the balance, the adaptive forcing terms yielded smaller run times. For a particular choice of forcing terms (adaptive or small constant), the methods performed fairly similarly, although when small constant forcing terms were used, the methods with Procedure 3.2 were somewhat less efficient in all statistics.

5. Concluding summary. In the preceding, we provide a theoretical framework and practical strategies for implementing dogleg globalizations of general inexact Newton methods for solving a nonlinear system (1.1).

In section 2, we outline a very general inexact Newton dogleg method. In this, the dogleg curves are defined using general inexact Newton steps together with approximate steepest-descent directions and Cauchy points. To be admissible, trial steps along these curves must satisfy only mild minimum-length requirements in addition to being within trust regions. A convergence theorem for this method is given; this asserts that if the approximate steepest-descent directions are bounded away from

[6] See [30, Table 5.2] for a similar study comparing Algorithm INDL using Procedure 3.1 with backtracking and linesearch globalizations.

orthogonality with the exact steepest-descent directions, then every limit point of a sequence of iterates generated by the method is a stationary point of $\|F\|$. Moreover, if there is a limit point at which the Jacobian of F is nonsingular, then that point must be a solution of (1.1) and the iterates must converge to it. In this case, initial trial steps are ultimately accepted without modification by the method, and the inexact Newton steps are ultimately admissible trial steps.

In section 3, we discuss strategies for selecting trial steps along the dogleg curves. It is noted that the step-selection strategy traditionally used in the exact-Newton case may exhibit certain shortcomings, principally that, when the forcing term is not small, this strategy may select the inexact Newton step even though a step biased toward the approximate Cauchy point may give significantly greater linear model norm reduction within the trust region. An alternative strategy is proposed that avoids this shortcoming. As a refinement of these strategies, simple modifications are introduced that further determine each dogleg step to minimize the local linear model norm along the dogleg curve within the trust region, provided both the approximate Cauchy point and the inexact Newton step have been computed.

In section 4, we report on numerical experiments in which a Newton–GMRES implementation of the general inexact Newton dogleg method in section 2 using the step-selection strategies in section 3 was applied to several two- and three-dimensional benchmark problems involving the steady-state Navier–Stokes equations. Although somewhat limited in scope, these experiments demonstrate the robustness of the method with these step-selection strategies and other algorithmic options on these challenging problems. They also provide an indication of the relative efficiency of these strategies and options. The use of adaptive forcing terms resulted in significantly greater robustness and some improvement in efficiency compared to the constant forcing term strategy; these results are consistent with previous studies of globalized inexact Newton methods. Otherwise, these experiments do not show dramatic differences in performance among the strategies and options that we tested. We feel that this may reflect the particular nature of the limited test set and also the rather modest problem sizes; there may be more pronounced differences in performance on other, broader test sets and higher-resolution problems. A more comprehensive numerical study will be the subject of future work.

Acknowledgment. The authors thank the anonymous referees for their thoughtful reviews, which led to significant improvements in this paper.

AN OPTIMAL-ORDER ERROR ESTIMATE FOR A FAMILY OF ELLAM-MFEM APPROXIMATIONS TO POROUS MEDIUM FLOW*

HONG WANG†

Abstract. Mathematical models used to describe porous medium flow lead to coupled systems of time-dependent nonlinear partial differential equations, which present serious mathematical and numerical difficulties. Standard methods tend to generate numerical solutions with nonphysical oscillations or numerical dispersion along with spurious grid-orientation effect. The ELLAM-MFEM time-stepping procedure, in which an Eulerian–Lagrangian localized adjoint method (ELLAM) is used to solve the transport equation and a mixed finite element method (MFEM) is used for the pressure equation, simulates porous medium flow accurately even if large spatial grids and time steps are used. In this paper we prove an optimal-order error estimate for a family of ELLAM-MFEM approximations.

1. Introduction.

Mathematical models used to describe porous medium flow processes in petroleum reservoir simulation, groundwater contaminant transport, and other applications lead to coupled systems of time-dependent nonlinear partial differential equations (PDEs) [2, 11]. Due to the advection-diffusion feature of the transport PDEs, the nonlinearity and couplings of the PDEs in the systems, and the strong effect of sources and sinks, these systems admit solutions with moving steep fronts and complicated structures. Consequently, these problems present serious mathematical and numerical difficulties. Standard finite difference or finite element methods (FDMs and FEMs, respectively) tend to generate solutions with nonphysical oscillations. Upwind methods are often used to stabilize the numerical approximations, but they often produce numerical dispersion and the grid-orientation effect [11]. Extensive research has been carried out on the development of improved methods for advection-diffusion PDEs [16, 18, 21].

An FEM-MFEM time-stepping procedure was presented and analyzed in [8, 9]. In the procedure, a mixed finite element method (MFEM) scheme [4, 5, 20] was used to solve the pressure PDE, and an FEM was used to solve the transport PDE. MFEM schemes generate an accurate approximation to the Darcy velocity, which is required for accurate approximation to the concentration because advection and diffusion dispersion in the transport PDE are governed by Darcy velocity. MFEMs minimize the numerical difficulties occurring in FDMs or FEMs caused by differentiation of the pressure and then multiplication by rough coefficients [22]. Subsequently, an MMOC-MFEM time-stepping procedure was proposed and analyzed in [12, 13], in which the modified method of characteristics (MMOC) [10] was used to replace the FEM scheme in [9]. The MMOC symmetrizes and stabilizes the transport PDE, greatly reduces temporal errors, and so allows for large time steps in a simulation without loss of

†Department of Mathematics, University of South Carolina, Columbia, SC 29208 (hwang@math.sc.edu).

accuracy. However, the MMOC fails to conserve mass and has difficulties in handling general boundary conditions.

The Eulerian–Lagrangian localized adjoint method (ELLAM) framework [6, 21] provides a systematic approach to solve transient advection-diffusion PDEs with general boundary conditions in a mass-conservative manner, while maintaining accuracy and efficiency of Eulerian–Lagrangian methods. Numerical experiments show that the ELLAM is very competitive in the context of model transport PDEs [26, 28] and miscible porous medium flow [3, 17, 30, 32]. Nevertheless, corresponding theoretical analysis falls far behind. To date, error estimates for the ELLAM and related schemes have been proved in the context of linear advection-dominated transport PDEs [1, 14, 15, 24, 25, 27, 29, 31]. This is partly due to the fact that the analyses are more complex than those for the MMOC and related methods [10, 29, 21]. In this paper we derive an optimal-order error estimate for an ELLAM-MFEM approximation to the coupled system of miscible porous medium flow.

The rest of the paper is organized as follows: In section 2 we review the mathematical model. In section 3 we describe the ELLAM-MFEM time-stepping procedure. In section 4 we present known theoretical results used in the analysis. In section 5 we prove an optimal-order error estimate for the ELLAM-MFEM time-stepping procedure. In section 6 we prove several lemmas used in section 5.

2. Mathematical model and notation. We present a mathematical model for porous medium flow and introduce the functional spaces used in this paper.

2.1. Mathematical model. Let $c(\mathbf{x},t)$ be the concentration of an invading fluid or a concerned solute/solvent, and let $p(\mathbf{x},t)$ and $\mathbf{u}(\mathbf{x},t)$ be the pressure and Darcy velocity of the fluid mixture, respectively. The mass conservation for the fluid mixture incorporated with the incompressibility condition, Darcy's law, and the mass conservation for the invading fluid lead to the following system of PDEs [2, 11]:

$$\nabla\cdot\mathbf{u}=q,\qquad \mathbf{u}=-\frac{\mathbf{K}}{\mu(c)}(\nabla p-\rho g\nabla d),\qquad \mathbf{x}\in\Omega,\quad t\in[0,T], \tag{2.1}$$

$$\phi\frac{\partial c}{\partial t}+\nabla\cdot(\mathbf{u}c-\mathbf{D}(\mathbf{x},\mathbf{u})\nabla c)=\bar{c}q,\qquad \mathbf{x}\in\Omega,\quad t\in[0,T], \tag{2.2}$$

$$\begin{aligned}\mathbf{u}\cdot\mathbf{n}&=(\mathbf{D}\nabla c)\cdot\mathbf{n}=0, && \mathbf{x}\in\partial\Omega,\quad t\in[0,T],\\ c(\mathbf{x},0)&=c_0(\mathbf{x}), && \mathbf{x}\in\Omega.\end{aligned} \tag{2.3}$$

We assume that the medium is homogeneous vertically and take $\Omega\subset\mathbb{R}^2$ with a nonuniform local elevation. $\phi(\mathbf{x})$ and $\mathbf{K}(\mathbf{x})$ are the porosity and the permeability tensor of the medium, respectively, $\mu(c)$ and ρ are the viscosity and the density of the fluid mixture, respectively, g is the gravitational acceleration, $d(\mathbf{x})$ is the reservoir depth, and $q(\mathbf{x},t)$ is the source and sink term. $\mathbf{D}(\mathbf{x},\mathbf{u})=\phi(\mathbf{x})d_m\,\mathbf{I}+d_t|\mathbf{u}|+(d_l-d_t)(u_iu_j)_{i,j=1}^2/|\mathbf{u}|$ is the diffusion-dispersion tensor, with d_m, d_t, and d_l being the molecular diffusion and the transverse and longitudinal dispersivities, respectively, and $\mathbf{I}$ is the identity tensor. $\bar{c}(\mathbf{x},t)$ is specified at sources and $\bar{c}(\mathbf{x},t)=c(\mathbf{x},t)$ at sinks. $c_0(\mathbf{x})$ is the initial concentration.

The combination of the first equations in (2.1) and (2.3) implies that q has mean 0. In addition, (2.1) with the noflow boundary condition (2.3) can determine the pressure $p(\mathbf{x},t)$ only up to an additive constant for all the time $t\in[0,T]$. But this indeterminacy is of no consequence since $\mathbf{u}$ is uniquely determined by Darcy's law, and only $\mathbf{u}$ (not p) is needed in (2.2).

2.2. Notation. Let $W_q^m(\Omega)$ be the Sobolev spaces consisting of functions whose derivatives up to order-m are qth integrable on Ω, and $H^m(\Omega) := W_2^m(\Omega)$. Let $L_0^2(\Omega)$ be the subspace of $L^2(\Omega)$ with mean 0. We introduce vector-valued Sobolev spaces

$$H^m(\mathrm{div};\Omega) := \Big\{\mathbf{f}(\mathbf{x}) = (f_1, f_2) \ : \ f_1, f_2, \nabla\cdot\mathbf{f} \in H^m(\Omega)\Big\},$$
$$\|\mathbf{f}\|_{H^m(\mathrm{div};\Omega)} := \Big(\|f_1\|^2_{H^m(\Omega)} + \|f_2\|^2_{H^m(\Omega)} + \|\nabla\cdot\mathbf{f}\|^2_{H^m(\Omega)}\Big)^{1/2},$$
$$H_0(\mathrm{div};\Omega) := \Big\{\mathbf{f}(\mathbf{x}) \in H^0(\mathrm{div};\Omega) \ : \ \mathbf{f}(\mathbf{x})\cdot\mathbf{n}(\mathbf{x}) = 0,\ \mathbf{x}\in\partial\Omega\Big\}.$$

We drop Ω in these notations when it is clear from the context.

For any Banach space X, we introduce Sobolev spaces involving time

$$W_q^m(t_1,t_2;X) := \left\{ f(\mathbf{x},t) \ : \ \Big\|\frac{\partial^\alpha f}{\partial t^\alpha}(\cdot,t)\Big\|_X \in L^q(t_1,t_2),\ 0\le\alpha\le m,\ 1\le q\le\infty \right\},$$
$$\|f\|_{W_q^m(t_1,t_2;X)} := \begin{cases} \displaystyle\left(\sum_{\alpha=0}^m \int_{t_1}^{t_2} \Big\|\frac{\partial^\alpha f}{\partial t^\alpha}(\cdot,t)\Big\|_X^q dt\right)^{1/q}, & 1\le q<\infty, \\ \displaystyle\max_{0\le\alpha\le m} \mathrm{esssup}_{t\in(t_1,t_2)} \Big\|\frac{\partial^\alpha f}{\partial t^\alpha}(\cdot,t)\Big\|_X, & q=\infty. \end{cases}$$

We also define the discrete norms

$$\|f\|_{\hat{L}_c^\infty(0,T;X)} := \max_{0\le n\le N}\|f(\mathbf{x},t_n^c)\|_X, \qquad \|f\|_{\hat{L}_p^\infty(0,T;X)} := \max_{0\le m\le M}\|f(\mathbf{x},t_m^p)\|_X,$$
$$\|f\|_{\hat{L}_c^2(0,T;X)} := \left(\sum_{n=0}^N \|f(\mathbf{x},t_n^c)\|_X^2 \Delta t_n^c\right)^{1/2},$$

with t_n^c and t_m^p being defined in (3.1) and (3.11), respectively. If $(t_1,t_2) = (0,T)$, we drop it from these notations.

In this paper we use ε to denote an arbitrarily small positive number, A_i, K_i, and Q_i to denote fixed positive constants, and Q to denote a generic positive constant that could assume different values at different occurrences. All of these constants are independent of spatial and temporal grid parameters.

3. An ELLAM-MFEM time-stepping procedure. In this procedure an ELLAM scheme is used to solve the transport PDE (2.2), and an MFEM scheme is used for the pressure system (2.1).

3.1. An ELLAM formulation for the transport equation. We define a temporal partition on the interval $[0,T]$ by

$$0 =: t_0^c < t_1^c < \cdots < t_n^c < \cdots < t_{N-1}^c < t_N^c := T, \tag{3.1}$$

with $\Delta t_n^c := t_n^c - t_{n-1}^c$ and $\Delta t_c := \max_{1\le n\le N}\Delta t_n^c$.

By multiplying (2.2) by any space-time test functions z that are continuous and piecewise smooth, vanish outside the space-time strip $\Omega\times(t_{n-1}^c, t_n^c]$, and are discon-

tinuous in time at time t_{n-1}^c, we obtain a weak formulation for (2.2)

$$\begin{aligned}
&\int_\Omega \phi(\mathbf{x}) c(\mathbf{x}, t_n^c) z(\mathbf{x}, t_n^c) d\mathbf{x} + \int_{t_{n-1}^c}^{t_n^c} \int_\Omega \nabla z(\mathbf{y}, \theta) \cdot \mathbf{D}(\mathbf{y}, \mathbf{u}(\mathbf{y}, \theta)) \nabla c(\mathbf{y}, \theta) d\mathbf{y} d\theta \\
&\quad - \int_{t_{n-1}^c}^{t_n^c} \int_\Omega c(\mathbf{y}, \theta) \left[\phi(\mathbf{y}) \frac{\partial z(\mathbf{y}, \theta)}{\partial \theta} + \mathbf{u}(\mathbf{y}, \theta) \cdot \nabla z(\mathbf{y}, \theta) \right] d\mathbf{y} d\theta \\
&\quad = \int_\Omega \phi(\mathbf{x}) c(\mathbf{x}, t_{n-1}^c) z(\mathbf{x}, t_{n-1}^{c,+}) d\mathbf{x} + \int_{t_{n-1}^c}^{t_n^c} \int_\Omega \bar{c}(\mathbf{y}, \theta) q(\mathbf{y}, \theta) z(\mathbf{y}, \theta) \, d\mathbf{y} d\theta,
\end{aligned} \tag{3.2}$$

where $z(\mathbf{x}, t_{n-1}^{c,+}) := \lim_{t \to t_{n-1}^c,\ t > t_{n-1}^c} z(\mathbf{x}, t)$ accounts for the discontinuity of $z(\mathbf{x}, t)$ in time at time t_{n-1}^c. We replace the dummy variables $\mathbf{x}$ and t in the space-time integrals in (3.2) by $\mathbf{y}$ and θ and reserve $\mathbf{x}$ for the point in Ω at time t_n^c or t_{n-1}^c.

In the ELLAM framework [6, 21, 30], the test functions in (3.2) are defined to be the solutions of the adjoint equation of the hyperbolic part of (2.2)

$$\phi(\mathbf{y}) \, \frac{\partial z(\mathbf{y}, \theta)}{\partial \theta} + \mathbf{u}(\mathbf{y}, \theta) \cdot \nabla z(\mathbf{y}, \theta) = 0, \quad \mathbf{y} \in \overline{\Omega}, \quad \theta \in [t_{n-1}^c, t_n^c]. \tag{3.3}$$

Thus, the last term on the left-hand side of (3.2) vanishes. Once the test functions $z(\mathbf{x}, t_n^c)$ are specified in Ω, they are determined in the space-time strip $\Omega \times (t_{n-1}^c, t_n^c]$ by constant extension along the characteristics $\mathbf{y} = \mathbf{r}(\theta; \mathbf{x}, t_n^c)$ defined by

$$\frac{d\mathbf{r}}{d\theta} = \frac{\mathbf{u}(\mathbf{r}, \theta)}{\phi(\mathbf{r})} \quad \text{and} \quad \mathbf{r}(\theta; \bar{\mathbf{x}}, \bar{t})\Big|_{\theta = \bar{t}} = \bar{\mathbf{x}}. \tag{3.4}$$

Evaluating the source term in (3.2) by the Euler formula at time t_n^c yields

$$\begin{aligned}
&\int_{t_{n-1}^c}^{t_n^c} \int_\Omega \bar{c}(\mathbf{y}, \theta) q(\mathbf{y}, \theta) z(\mathbf{y}, \theta) \, d\mathbf{y} d\theta \\
&\quad = \int_\Omega \int_{t_{n-1}^c}^{t_n^c} \bar{c}(\mathbf{r}(\theta; \mathbf{x}, t_n^c), \theta) q(\mathbf{r}(\theta; \mathbf{x}, t_n^c), \theta) z(\mathbf{x}, t_n^c) \det \left(\frac{\partial \mathbf{r}(\theta; \mathbf{x}, t_n^c)}{\partial \mathbf{x}} \right) d\theta d\mathbf{x} \\
&\quad = \Delta t_n^c \int_\Omega \bar{c}(\mathbf{x}, t_n^c) q(\mathbf{x}, t_n^c) z(\mathbf{x}, t_n^c) d\mathbf{x} + E_q(\bar{c}, z),
\end{aligned} \tag{3.5}$$

where $E_q(\bar{c}, z)$ is the local truncation error term given by

$$\begin{aligned}
E_q(\bar{c}, z) := - \int_\Omega z(\mathbf{x}, t_n^c) \Bigg\{ \int_{t_{n-1}^c}^{t_n^c} \Bigg[&\bar{c}(\mathbf{x}, t_n^c) q(\mathbf{x}, t_n^c) \\
&- \bar{c}(\mathbf{r}(\theta; \mathbf{x}, t_n^c), \theta) q(\mathbf{r}(\theta; \mathbf{x}, t_n^c), \theta) \det \left(\frac{\partial \mathbf{r}(\theta; \mathbf{x}, t_n^c)}{\partial \mathbf{x}} \right) \Bigg] d\theta \Bigg\} d\mathbf{x}.
\end{aligned} \tag{3.6}$$

In (3.5) we have implicitly used the fact that the traceback operator $\mathbf{r}$ is a diffeomorphism and the determinant is positive [10].

Likewise, we evaluate the diffusion-dispersion term in (3.2) to obtain

$$
\begin{aligned}
&\int_{t_{n-1}^c}^{t_n^c}\int_\Omega \nabla z(\mathbf{y},\theta)\cdot\mathbf{D}(\mathbf{y},\mathbf{u}(\mathbf{y},\theta))\nabla c(\mathbf{y},\theta)d\mathbf{y}d\theta\\
&\quad=\int_\Omega\int_{t_{n-1}^c}^{t_n^c}\nabla_{\mathbf{r}} z(\mathbf{x},t_n^c)\cdot(\mathbf{D}(\mathbf{r}(\theta;\mathbf{x},t_n^c),\mathbf{u}(\mathbf{r}(\theta;\mathbf{x},t_n^c),\theta))\\
&\qquad\qquad\nabla c_{\mathbf{r}}(\mathbf{r}(\theta;\mathbf{x},t_n^c),\theta))\det\left(\frac{\partial\mathbf{r}(\theta;\mathbf{x},t_n^c)}{\partial\mathbf{x}}\right)d\theta d\mathbf{x}\\
&\quad=\int_\Omega\int_{t_{n-1}^c}^{t_n^c}\det\left(\frac{\partial\mathbf{r}(\theta;\mathbf{x},t_n^c)}{\partial\mathbf{x}}\right)\left(\frac{\partial\mathbf{r}(\theta;\mathbf{x},t_n^c)}{\partial\mathbf{x}}\right)^{-1}\nabla z(\mathbf{x},t_n^c)\\
&\qquad\cdot(\mathbf{D}(\mathbf{r}(\theta;\mathbf{x},t_n^c),\mathbf{u}(\mathbf{r}(\theta;\mathbf{x},t_n^c),\theta))\nabla c_{\mathbf{r}}(\mathbf{r}(\theta;\mathbf{x},t_n^c),\theta))d\theta d\mathbf{x}\\
&\quad=\Delta t_n^c\int_\Omega\nabla z(\mathbf{x},t_n^c)\cdot\mathbf{D}(\mathbf{x},\mathbf{u}(\mathbf{x},t_n^c))\nabla c(\mathbf{x},t_n^c)\;d\mathbf{x}+E_{\mathbf{D}}(c,z).
\end{aligned}
\tag{3.7}
$$

The subscript $\mathbf{r}$ emphasizes that the gradient is taken with respect to $\mathbf{r}$. The local truncation error $E_{\mathbf{D}}(c,z)$ is given by

$$
\begin{aligned}
E_{\mathbf{D}}(c,z):=&\int_\Omega\int_{t_{n-1}^c}^{t_n^c}\left(\det\left(\frac{\partial\mathbf{r}(\theta;\mathbf{x},t_n^c)}{\partial\mathbf{x}}\right)\left(\frac{\partial\mathbf{r}(\theta;\mathbf{x},t_n^c)}{\partial\mathbf{x}}\right)^{-1}-\mathbf{I}\right)\nabla z(\mathbf{x},t_n^c)\\
&\qquad\cdot(\mathbf{D}(\mathbf{r}(\theta;\mathbf{x},t_n^c),\mathbf{u}(\mathbf{r}(\theta;\mathbf{x},t_n^c),\theta))\nabla c(\mathbf{r}(\theta;\mathbf{x},t_n^c),\theta))d\theta d\mathbf{x}\\
&-\int_\Omega\int_{t_{n-1}^c}^{t_n^c}\nabla z(\mathbf{x},t_n)\cdot(\mathbf{D}(\mathbf{x},\mathbf{u}(\mathbf{x},t_n^c))\nabla c(\mathbf{x},t_n^c)\\
&\qquad\qquad-\mathbf{D}(\mathbf{r}(\theta;\mathbf{x},t_n^c),\mathbf{u}(\mathbf{r}(\theta;\mathbf{x},t_n^c),\theta))\nabla c(\mathbf{r}(\theta;\mathbf{x},t_n^c),\theta))d\theta d\mathbf{x}.
\end{aligned}
\tag{3.8}
$$

We substitute (3.5) and (3.7) into (3.2) to obtain an ELLAM reference equation for the transport PDE (2.2)

$$
\begin{aligned}
&\int_\Omega\phi(\mathbf{x})c(\mathbf{x},t_n^c)z(\mathbf{x},t_n^c)d\mathbf{x}+\Delta t_n^c\int_\Omega\nabla z(\mathbf{x},t_n^c)\cdot\mathbf{D}(\mathbf{x},\mathbf{u}(\mathbf{x},t_n^c))\nabla c(\mathbf{x},t_n^c)d\mathbf{x}\\
&\quad=\int_\Omega\phi(\mathbf{x})c(\mathbf{x},t_{n-1}^c)z(\mathbf{x},t_{n-1}^{c,+})d\mathbf{x}+\Delta t_n^c\int_\Omega\bar{c}(\mathbf{x},t_n^c)q(\mathbf{x},t_n^c)z(\mathbf{x},t_n^c)d\mathbf{x}\\
&\qquad-E_{\mathbf{D}}(c,z)+E_q(\bar{c},z).
\end{aligned}
\tag{3.9}
$$

3.2. An MFEM formulation for the pressure and Darcy velocity. We multiply the second equation in (2.1) by $\mu(c)\mathbf{K}^{-1}(\mathbf{x})$ and any test functions $\mathbf{v}\in H_0(\mathrm{div};\Omega)$ and apply the divergence theorem to the ∇p term. We then multiply the first equation in (2.1) by any test functions $w(\mathbf{x})\in L_0^2(\Omega)$ and integrate over Ω. The system (2.1) is expressed as a time-parameterized saddle-point problem of finding a map $(\mathbf{u}(\mathbf{x},t),p(\mathbf{x},t))\in H_0(\mathrm{div};\Omega)\times L_0^2(\Omega)$ such that

$$
\begin{aligned}
\int_\Omega\mu(c)\mathbf{K}^{-1}\mathbf{u}\cdot\mathbf{v}d\mathbf{x}-\int_\Omega p\nabla\cdot\mathbf{v}d\mathbf{x}&=\int_\Omega\rho g\nabla d\cdot\mathbf{v}d\mathbf{x},\\
\int_\Omega w\nabla\cdot\mathbf{u}d\mathbf{x}&=\int_\Omega q(\mathbf{x},t)wd\mathbf{x}\\
\forall(\mathbf{v}(\mathbf{x}),w(\mathbf{x}))\in H_0(\mathrm{div};\Omega)\times L_0^2(\Omega),t\in[0,T].&
\end{aligned}
\tag{3.10}
$$

It was proved [4, 8] that problem (3.10) has a unique solution $(\mathbf{u}(\mathbf{x},t),p(\mathbf{x},t)) \in H_0(\mathrm{div};\Omega)\times L_0^2(\Omega)$ for all $t\in[0,T]$.

Let $V^k \subset H_0(\mathrm{div};\Omega)$ and $S_p^k \subset L_0^2(\Omega)$ be MFEM spaces of index $k\geq 0$ on a quasi-uniform partition of $\Omega = \cup\Omega_e^p$ with the diameter h_p [5, 20]. We define a temporal partition on the time interval $[0,T]$ for the pressure grid by

$$0 =: t_0^p < t_1^p < \cdots < t_m^p < \cdots < t_{M-1}^p < t_M^p := T, \tag{3.11}$$

with $\Delta t_m^p := t_m^p - t_{m-1}^p$ and $\Delta t_p := \max_{1\leq m\leq M}\Delta t_m^p$.

Given a concentration approximation $c_h(\mathbf{x},t_m^p)$ at time t_m^p, the MFEM scheme determines the velocity $\mathbf{u}_h(\mathbf{x},t_m^p)\in V^k$ and the pressure $p_h(\mathbf{x},t_m^p)\in S_p^k$ such that

$$\begin{aligned}
&\int_\Omega \mu(c_h(\mathbf{x},t_m^p))\mathbf{K}^{-1}(\mathbf{x})\mathbf{u}_h(\mathbf{x},t_m^p)\cdot\mathbf{v}_h(\mathbf{x})d\mathbf{x} - \int_\Omega p_h(\mathbf{x},t_m^p)\nabla\cdot\mathbf{v}_h(\mathbf{x})d\mathbf{x}\\
&\quad = \int_\Omega \rho g\nabla d(\mathbf{x})\cdot\mathbf{v}_h(\mathbf{x})d\mathbf{x} \qquad\qquad \forall \mathbf{v}_h(\mathbf{x})\in V^k,\\
&\int_\Omega w_h(\mathbf{x})\nabla\cdot\mathbf{u}_h(\mathbf{x},t_m^p)d\mathbf{x} = \int_\Omega q(\mathbf{x},t_m^p)w_h(\mathbf{x})d\mathbf{x} \qquad \forall w_h(\mathbf{x})\in S_p^k.
\end{aligned} \tag{3.12}$$

3.3. An ELLAM-MFEM time-stepping procedure. The velocity field usually changes less rapidly than the concentration. Moreover, at each time step the MFEM system (3.12) is more expensive to solve than the ELLAM scheme for the transport PDE (2.2). Therefore, we allow a larger time step for the pressure than that for the concentration [9]. It is often computationally convenient to define the time partition (3.1) for the concentration by subdividing the time partition (3.11) for the pressure. Namely, there exist $0 =: N_0 < N_1 < \cdots < N_m < \cdots < N_{M-1} < N_M := N$ such that $t_{N_m}^c = t_m^p$ for $m = 1,2,\ldots,M$. For $n = N_{m-1}+1, N_{m-1}+2,\ldots,N_m$, the concentration time step t_n^c relates to the pressure time steps by $t_{m-1}^p < t_n^c \leq t_m^p$. In the ELLAM scheme we define a velocity approximation $\mathbf{u}_h^{\mathrm{E}}(\mathbf{x},t_n^c)$ by an extrapolation of $\mathbf{u}_h(\mathbf{x},t_{m-1}^p)$ and earlier values [9]

$$\mathbf{u}_h^{\mathrm{E}}(\mathbf{x},t_n^c) := \begin{cases} \left(1+\dfrac{t_n^c - t_{m-1}^p}{\Delta t_{m-1}^p}\right)\mathbf{u}_h(\mathbf{x},t_{m-1}^p) - \dfrac{t_n^c - t_{m-1}^p}{\Delta t_{m-1}^p}\mathbf{u}_h(\mathbf{x},t_{m-2}^p), \\ \qquad N_{m-1}+1\leq n\leq N_m, \quad 2\leq m\leq M, \\ \mathbf{u}_h(\mathbf{x},0), \quad 1\leq n\leq N_1, \quad m=1. \end{cases} \tag{3.13}$$

Let $S_c^l \subset W_\infty^1(\Omega)$ be an FEM space, which contains the space of continuous piecewise polynomials of degree at most l on a quasi-uniform partition of diameter h_c. For example, the FEM space S_c^l could be the space of piecewise polynomials of degree at most l on triangular elements or the space of piecewise polynomials of degree at most l in each coordinate direction on rectangular elements. We often utilize the fact that velocity is smoother than the concentration to use a much larger grid size h_p than h_c and to further reduce computational cost since (3.12) is more expensive to solve than (3.14).

Let $c_h(\mathbf{x},0)$ be an approximation to $c_0(\mathbf{x})$ (e.g., its L^2 or Ritz projection, or interpolation). An ELLAM-MFEM time-stepping procedure is formulated as follows: For $m = 1,\ldots,M$, solve the MFEM scheme (3.12) at the pressure time step t_{m-1}^p. For $n = N_{m-1}+1, N_{m-1}+2,\ldots,N_m$, solve the following ELLAM scheme at each

concentration time step t_n^c: Find $c_h(\mathbf{x}, t_n^c) \in S_c^l$ such that for all $z_h(\mathbf{x}, t_n^c) \in S_c^l$

$$\begin{aligned}&\int_\Omega \phi(\mathbf{x}) c_h(\mathbf{x}, t_n^c) z_h(\mathbf{x}, t_n^c) d\mathbf{x} \\ &+ \Delta t_n^c \int_\Omega \nabla z_h(\mathbf{x}, t_n^c) \cdot \mathbf{D}(\mathbf{x}, \mathbf{u}_h^E(\mathbf{x}, t_n^c)) \nabla c_h(\mathbf{x}, t_n^c) d\mathbf{x} \\ &= \int_\Omega \phi(\mathbf{x}) c_h(\mathbf{x}, t_{n-1}^c) z_h(\mathbf{x}, t_{n-1}^{c,+}) d\mathbf{x} + \Delta t_n^c \int_\Omega \bar{c}_h(\mathbf{x}, t_n^c) q(\mathbf{x}, t_n^c) z_h(\mathbf{x}, t_n^c) d\mathbf{x}.\end{aligned} \tag{3.14}$$

All of the integrals in (3.14), except for the first on the right-hand side, are in Eulerian coordinates and can be evaluated as in FEMs. The first term on the right-hand side of (3.14) is in Lagrangian coordinates and requires extra attention. By definition, the test functions z in the ELLAM reference equation (3.9) are constant along the characteristics $\mathbf{r}$ defined by the initial-value problem (3.4). Set

$$\tilde{\mathbf{x}} := \mathbf{r}(t_n^c; \mathbf{x}, t_{n-1}^c) = \mathbf{x} + \int_{t_{n-1}^c}^{t_n^c} \frac{\mathbf{u}(\mathbf{r}(\theta; \mathbf{x}, t_{n-1}^c), \theta)}{\phi(\mathbf{r}(\theta; \mathbf{x}, t_{n-1}^c))} d\theta; \tag{3.15}$$

the test function $z(\mathbf{x}, t_{n-1}^c)$ in (3.9) is determined by

$$z(\mathbf{x}, t_{n-1}^{c,+}) = z(\tilde{\mathbf{x}}, t_n^c). \tag{3.16}$$

Unlike in linear advection-diffusion PDEs [6, 26], the velocity $\mathbf{u}$ is unknown. In (3.14) we compute an approximate characteristic $\mathbf{r}_h(t_n^c; \mathbf{x}, t_{n-1}^c)$ by solving a numerical analogue of problem (3.4)

$$\frac{d\mathbf{r}_h}{d\theta} = \frac{\mathbf{u}_h^{\mathrm{E}}(\mathbf{r}_h, \theta)}{\phi(\mathbf{r}_h)} \quad \text{and} \quad \mathbf{r}_h(\theta; \bar{\mathbf{x}}, \bar{t})\Big|_{\theta=\bar{t}} = \bar{\mathbf{x}}. \tag{3.17}$$

For clarity of exposition, we assume an Euler tracking and set

$$\begin{aligned}\tilde{\mathbf{x}}_h := \mathbf{r}_h(t_n^c; \mathbf{x}, t_{n-1}^c) &= \mathbf{x} + \int_{t_{n-1}^c}^{t_n^c} \frac{\mathbf{u}_h^{\mathrm{E}}(\mathbf{r}_h(\theta; \mathbf{x}, t_{n-1}^c), \theta)}{\phi(\mathbf{r}_h(\theta; \mathbf{x}, t_{n-1}^c))} d\theta \\ &= \mathbf{x} + \frac{\mathbf{u}_h^{\mathrm{E}}(\mathbf{x}, t_{n-1}^c)}{\phi(\mathbf{x})} \Delta t_n^c.\end{aligned} \tag{3.18}$$

The test functions $z_h(\mathbf{x}, t_{n-1}^c)$ in the ELLAM scheme (3.14) are evaluated by

$$z_h(\mathbf{x}, t_{n-1}^{c,+}) = z_h(\tilde{\mathbf{x}}_h, t_n^c). \tag{3.19}$$

This further complicates the analysis for the ELLAM-MFEM procedure.

4. Preliminaries. This section cites well-established estimates to be used in the proof of the main theorem in section 5.

The finite element space S_c^l has the approximation and inverse properties [7] for $1 \le m \le l+1, 1 \le p, q \le \infty$

$$\inf_{z_h \in S_c^l} (\|z - z_h\|_{L^q} + h_c \|z - z_h\|_{W_q^1}) \le A_1 h_c^{m+1+(\frac{2}{q} - \frac{2}{p})} \|z\|_{W_p^m} \ \forall z \in W_p^m(\Omega) \tag{4.1}$$

and

$$\begin{aligned}&\|z_h\|_{H^1} \le K_1 h_c^{-1} \|z_h\|_{L^2}, \qquad \|z_h\|_{L^\infty} \le K_1 \, |\ln h_c|^{1/2} \|z_h\|_{H^1}, \\ &\|z_h\|_{W_q^m} \le K_1 h_c^{-(1-\frac{2}{q})} \|z_h\|_{H^m} \quad \forall z_h \in S_c^l, \ m = 0, 1.\end{aligned} \tag{4.2}$$

The MFEM spaces (V^k, S_p^k) have the approximation and inverse properties [4, 5, 7, 19] for $2 \le q \le +\infty$ and $1 \le m \le k+1$

$$
\begin{aligned}
&\inf_{\mathbf{v}_h \in V^k} \|\mathbf{v} - \mathbf{v}_h\|_{L^q} \le A_2 h_p^{m-(1-\frac{2}{q})} \|\mathbf{v}\|_{H^m} && \forall \mathbf{v} \in H^m, \\
&\inf_{\mathbf{v}_h \in V^k} \|\mathbf{v} - \mathbf{v}_h\|_{H(\mathrm{div})} \le A_2 h_p^m \|\mathbf{v}\|_{H^m(\mathrm{div})} && \forall \mathbf{v} \in H^m(\mathrm{div}), \\
&\inf_{g_h \in S_p^k} \|g - g_h\|_{L^2} \le A_2 h_p^m \|g\|_{H^m} && \forall g \in H^m
\end{aligned} \tag{4.3}
$$

and

$$
\begin{aligned}
&\|\mathbf{v}_h\|_{L^q} \le K_2 h_p^{-(1-\frac{2}{q})} \|\mathbf{v}_h\|_{L^2} && \forall \mathbf{v}_h \in V^k, \\
&\|\mathbf{v}_h\|_{W_q^1} \le K_2 h_p^{-1} \|\mathbf{v}_h\|_{L^q} && \forall \mathbf{v}_h \in V^k.
\end{aligned} \tag{4.4}
$$

It is understood in (4.4) that

$$
\|\mathbf{v}_h\|_{W_q^1} := \begin{cases} \displaystyle\left(\sum_{\Omega_e^p \subset \Omega} \|\mathbf{v}_h\|_{W_q^1(\Omega_e^p)}^q \right)^{1/q} & \text{for } \ 2 \le q < +\infty, \\ \displaystyle\max_{\forall \Omega_e^p \subset \Omega} \|\mathbf{v}_h\|_{W_q^1(\Omega_e^p)} & \text{for } \ q = +\infty, \end{cases}
$$

where $\Omega_e^p \subset \Omega$ are all of the elements of the pressure mesh.

Let $\Pi c(\mathbf{x}, t) \in S_c^l,\ t \in [0, T]$, be the Ritz projection of $c(\mathbf{x}, t)$ defined by [23, 33]

$$
\begin{aligned}
&\int_\Omega \chi(\mathbf{x})(\Pi c(\mathbf{x}, t) - c(\mathbf{x}, t)) d\mathbf{x} \\
&\quad + \int_\Omega \nabla \chi(\mathbf{x}) \cdot \mathbf{D}(\mathbf{x}, \mathbf{u}(\mathbf{x}, t)) \nabla (\Pi c(\mathbf{x}, t) - c(\mathbf{x}, t)) d\mathbf{x} = 0 \quad \forall \chi \in S_c^l.
\end{aligned} \tag{4.5}
$$

The following estimates hold [7, 19, 23, 33] for $2 \le q \le +\infty,\ 1 \le m \le l+1$:

$$
\begin{aligned}
\|\Pi c - c\|_{L^\infty(L^q)} + h_c \|\Pi c - c\|_{L^\infty(W_q^1)} &\le A_1 h_c^m \|c\|_{L^\infty(W_q^m)}, \\
\|\Pi c - c\|_{H^1(L^q)} &\le A_1 h_c^m \|c\|_{H^1(W_q^m)}.
\end{aligned} \tag{4.6}
$$

Here the constant A_1 is independent of c and h_c.

Let $\mathrm{I}c(\mathbf{x}, t) \in S_c^l,\ t \in [0, T]$, be the interpolation of $c(\mathbf{x}, t)$. We use the estimates (4.1) with $p = 2$ and $q = +\infty$, (4.2) with $q = +\infty$, and (4.6) with $q = 2$ to conclude that for $c \in L^\infty(W_\infty^1 \cap H^2)$

$$
\begin{aligned}
\|\Pi c\|_{L^\infty(W_\infty^1)} &\le \|\Pi c - \mathrm{I}c\|_{L^\infty(W_\infty^1)} + \|\mathrm{I}c - c\|_{L^\infty(W_\infty^1)} + \|c\|_{L^\infty(W_\infty^1)} \\
&\le K_1 h_c^{-1} \|\Pi c - \mathrm{I}c\|_{L^\infty(H^1)} + (A_1 + 1) \|c\|_{L^\infty(W_\infty^1)} \\
&\le K_1 h_c^{-1} \big(\|\Pi c - c\|_{L^\infty(H^1)} + \|\mathrm{I}c - c\|_{L^\infty(H^1)} \big) \\
&\quad + (A_1 + 1) \|c\|_{L^\infty(W_\infty^1)} \\
&\le 2 A_1 K_1 \|c\|_{L^\infty(H^2)} + (A_1 + 1) \|c\|_{L^\infty(W_\infty^1)} =: K_3.
\end{aligned} \tag{4.7}
$$

We similarly define a mapping $(\Pi\mathbf{u}, \Pi p)$ from $H(\mathrm{div}) \times L_0^2$ to $V^k \times S_p^k$ by

$$\begin{aligned}
&\int_\Omega \mu(c(\mathbf{x},t))\mathbf{K}^{-1}(\mathbf{x})(\Pi\mathbf{u}(\mathbf{x},t) - \mathbf{u}(\mathbf{x},t)) \cdot \mathbf{v}_h(\mathbf{x})d\mathbf{x} \\
&\qquad - \int_\Omega (\Pi p(\mathbf{x},t) - p(\mathbf{x},t))\nabla \cdot \mathbf{v}_h(\mathbf{x})d\mathbf{x} = 0 \quad \forall \mathbf{v}_h \in V^k, \\
&\int_\Omega w_h(\mathbf{x})\nabla \cdot (\Pi\mathbf{u}(\mathbf{x},t) - \mathbf{u}(\mathbf{x},t))d\mathbf{x} = 0 \qquad \forall w_h \in S_p^k.
\end{aligned} \tag{4.8}$$

The following estimates hold, e.g., for Raviart–Thomas spaces [4, 8, 9]:

$$\begin{aligned}
&\|\Pi\mathbf{u} - \mathbf{u}\|_{L^\infty(H(\mathrm{div}))} + \|\Pi p - p\|_{L^\infty(L^2)} \\
&\quad \le A\left(\inf_{\mathbf{v}_h \in V^k} \|\mathbf{u} - \mathbf{v}_h\|_{L^\infty(H(\mathrm{div}))} + \inf_{g_h \in S_p^k} \|p - g_h\|_{L^\infty(L^2)}\right) \\
&\quad \le A_2 h_p^{k+1}(\|\mathbf{u}\|_{L^\infty(H^{k+1}(\mathrm{div}))} + \|p\|_{L^\infty(H^{k+1})}).
\end{aligned} \tag{4.9}$$

Here A_2 is independent of h_p, u, p, and c.

We let I be an interpolation operator from $H(\mathrm{div}) \times L_0^2$ to $V^k \times S_p^k$ for $t \in [0,T]$. We use the estimates (4.4) and (4.9) to conclude that

$$\begin{aligned}
\|\Pi\mathbf{u}\|_{L^\infty(L^\infty)} &\le \|\Pi\mathbf{u} - \mathrm{I}\mathbf{u}\|_{L^\infty(L^\infty)} + \|\mathrm{I}\mathbf{u} - \mathbf{u}\|_{L^\infty(L^\infty)} + \|\mathbf{u}\|_{L^\infty(L^\infty)} \\
&\le K_2 h_p^{-1}\|\Pi\mathbf{u} - \mathrm{I}\mathbf{u}\|_{L^\infty(L^2)} + (A_2+1)\|\mathbf{u}\|_{L^\infty(L^\infty)} \\
&\le K_2 h_p^{-1}\big(\|\Pi\mathbf{u} - \mathbf{u}\|_{L^\infty(L^2)} + \|\mathrm{I}\mathbf{u} - \mathbf{u}\|_{L^\infty(L^2)}\big) \\
&\quad + (A_2+1)\|\mathbf{u}\|_{L^\infty(L^\infty)} \\
&\le 2A_2K_2\big(\|\mathbf{u}\|_{L^\infty(H^1(\mathrm{div}))} + \|p\|_{L^\infty(H^1)}\big) \\
&\quad + (A_2+1)\|\mathbf{u}\|_{L^\infty(L^\infty)} =: K_4.
\end{aligned} \tag{4.10}$$

For the analysis in section 5 we introduce an extrapolation of the exact velocity $\mathbf{u}$

$$\mathbf{u}^{\mathrm{E}}(\mathbf{x}, t_n^c) := \begin{cases} \left(1 + \dfrac{t_n^c - t_{m-1}^p}{\Delta t_{m-1}^p}\right)\mathbf{u}(\mathbf{x}, t_{m-1}^p) - \dfrac{t_n^c - t_{m-1}^p}{\Delta t_{m-1}^p}\mathbf{u}(\mathbf{x}, t_{m-2}^p), \\ \qquad N_{m-1}+1 \le n \le N_m, \quad 2 \le m \le M, \\ \mathbf{u}(\mathbf{x},0), \quad 1 \le n \le N_1, \quad m = 1. \end{cases} \tag{4.11}$$

Then we routinely see that for $2 \le q \le +\infty$

$$\begin{aligned}
&\|\mathbf{u}^E(\mathbf{x},t) - \mathbf{u}(\mathbf{x},t)\|_{L^q} \\
&\quad \le \begin{cases} A_3(\Delta t_p)^{\frac{3}{2}}\|\mathbf{u}\|_{H^2(t_{m-2}^p, t_m^p; L^q)} & \forall t \in [t_{m-1}^p, t_m^p],\ m \ge 2, \\ A_3\Delta t_p^1\|\mathbf{u}\|_{W_1^\infty(t_0^p, t_1^p; L^q)} & \forall t \in [t_0^p, t_1^p], \quad m = 1. \end{cases}
\end{aligned} \tag{4.12}$$

5. An optimal-order error estimate. In this section we prove an optimal-order error estimate for the ELLAM-MFEM time-stepping procedure with any order of approximating polynomials ($k \ge 0$, $l \ge 1$).

5.1. On the main theorem and its proof. Note that the test functions in the ELLAM formulation are defined by (3.3), which can be evaluated by using (3.19). However, the velocity $\mathbf{u}$ is unknown. This is in contrast to the ELLAM schemes for

linear transport PDEs in which the true velocity is known and is used to evaluate characteristics [6, 21, 26]. In the ELLAM-MFEM time-stepping procedure in section 3, we have to use the numerical velocity $\mathbf{u}_h^{\mathrm{E}}$ to evaluate the approximate characteristics $\mathbf{r}_h$ by solving problem (3.17). These issues further complicate the analysis [21, 25].

THEOREM 5.1. *Suppose that the solution* $(c, p, \mathbf{u})$ *of problem* (2.1)–(2.3) *satisfies* $c \in L^\infty(W^{l+1}_{2+\gamma}) \cap L^\infty(W^1_\infty) \cap H^1(H^{l+1})$ *for some* $\gamma > 0$, $p \in L^\infty(H^{k+1})$, *and* $\mathbf{u} \in L^\infty(H^{k+1}(\mathrm{div}) \cap W^1_\infty) \cap W^1_\infty(L^\infty) \cap H^2(L^2)$. *Let* $(c_h(\mathbf{x}, t_n^c), p_h(\mathbf{x}, t_m^p), \mathbf{u}_h(\mathbf{x}, t_m^p))$ *be the solution of the ELLAM-MFEM time-stepping procedure* (3.12) *and* (3.14) *with* $l \geq 1$ *and* $k \geq 0$. *Assume that the discretization parameters obey the relations*

$$\Delta t_c = O(h_p), \quad h_c^{l+1} = o(h_p), \quad \Delta t_p^1 = O(h_p^{2/3}), \quad \Delta t_p = O(h_p^{1/2}). \tag{5.1}$$

There exist positive constants h_c^*, h_p^*, Δt_c^*, Δt_p^*, *and* Q^* *such that the following optimal-order error estimate holds for* $0 < h_c \leq h_c^*$, $0 < h_p \leq h_p^*$, $0 < \Delta t_c \leq \Delta t_c^*$, *and* $0 < \Delta t_p \leq \Delta t_p^*$:

$$\begin{aligned}
&\|c_h - c\|_{\hat{L}_c^\infty(L^2)} + |\mathbf{D}|_{min}^{1/2} \|c_h - c\|_{\hat{L}_c^2(H^1)} \\
&\quad + \|\mathbf{u}_h - \mathbf{u}\|_{\hat{L}_p^\infty(H(\mathrm{div}))} + \|p_h - p\|_{\hat{L}_p^\infty(L^2)} \\
&\leq Q^* \Delta t_c \left(\|\bar{c}\|_{L^2(L^2)} + \|c\|_{L^2(H^1)} + \left\| \frac{d\bar{c}}{dt} \right\|_{L^2(L^2)} + \left\| \frac{dc}{dt} \right\|_{L^2(H^1)} \right) \\
&\quad + Q^* ((\Delta t_p^1)^{3/2} + (\Delta t_p)^2) \|\mathbf{u}\|_{H^2(L^2)} + Q^* h_c^{l+1} (\|c\|_{L^\infty(W^{l+1}_{2+\gamma})} \\
&\quad + \|c\|_{H^1(H^{l+1})}) + Q^* h_p^{k+1} (\|\mathbf{u}\|_{L^\infty(H^{k+1}(\mathrm{div}))} + \|p\|_{L^\infty(H^{k+1})}).
\end{aligned} \tag{5.2}$$

Here $\frac{d}{dt}$ *refers to the material derivative along the characteristics defined in* (3.4). *The constant* $Q^* = Q^*(h_c^*, h_p^*, \Delta t_c^*, \Delta t_p^*, T)$, *but* Q^* *is independent of the discretization parameters* h_c, h_p, Δt_c, *or* Δt_p.

To prove the theorem, we use (3.10), (3.12), and (4.8) to derive a relation

$$\begin{aligned}
&\int_\Omega \mu(c_h(\mathbf{x}, t_m^p)) \mathbf{K}^{-1}(\mathbf{x}) (\mathbf{u}_h(\mathbf{x}, t_m^p) - \Pi \mathbf{u}(\mathbf{x}, t_m^p)) \cdot \mathbf{v}_h(\mathbf{x}) d\mathbf{x} \\
&\qquad - \int_\Omega (p_h(\mathbf{x}, t_m^p) - \Pi p(\mathbf{x}, t_m^p)) \nabla \cdot \mathbf{v}_h(\mathbf{x}) d\mathbf{x} \\
&\qquad = \int_\Omega (\mu(c(\mathbf{x}, t_m^p)) - \mu(c_h(\mathbf{x}, t_m^p))) \mathbf{K}^{-1}(\mathbf{x}) \Pi \mathbf{u}(\mathbf{x}, t_m^p) \cdot \mathbf{v}_h(\mathbf{x}) d\mathbf{x}, \\
&\int_\Omega w_h(\mathbf{x}) \nabla \cdot (\mathbf{u}_h(\mathbf{x}, t_m^p) - \Pi \mathbf{u}(\mathbf{x}, t_m^p)) d\mathbf{x} = 0 \quad \forall (\mathbf{v}_h, w_h) \in V^k \times S_p^k.
\end{aligned}$$

Combining this equation with (4.10) yields an estimate [4, 5, 8]

$$\begin{aligned}
&\|\mathbf{u}_h(\mathbf{x}, t_m^p) - \Pi \mathbf{u}(\mathbf{x}, t_m^p)\|_{H(\mathrm{div})} + \|p_h(\mathbf{x}, t_m^p) - \Pi p(\mathbf{x}, t_m^p)\| \\
&\quad \leq Q(1 + \|\Pi \mathbf{u}(\mathbf{x}, t_m^p)\|_{L^\infty}) \, \|c_h(\mathbf{x}, t_m^p) - c(\mathbf{x}, t_m^p)\| \\
&\quad \leq Q_1 \|c_h(\mathbf{x}, t_m^p) - c(\mathbf{x}, t_m^p)\|, \qquad 0 \leq m \leq M.
\end{aligned} \tag{5.3}$$

For convenience, we have dropped the subscript L^2.

The estimates (4.9) and (5.3) show that the bound on $\|\mathbf{u}_h-\mathbf{u}\|_{\hat{L}_p^\infty(H(\mathrm{div}))}+\|p_h-p\|_{\hat{L}_p^\infty(L^2)}$ in (5.2) is a consequence of the bound on $\|c_h-c\|_{\hat{L}_c^\infty(L^2)}$.

5.2. Proof of the key estimate. To bound $\|c_h-c\|_{\hat{L}_c^\infty(L^2)}$, we set $\xi(\mathbf{x},t_n^c):=c_h(\mathbf{x},t_n^c)-\Pi c(\mathbf{x},t_n^c)$ and $\eta(\mathbf{x},t_n^c):=\Pi c(\mathbf{x},t_n^c)-c(\mathbf{x},t_n^c)$. Note that $c_h-c=\xi+\eta$ and that the estimate for η is known from (4.6). The key to prove the theorem is to derive an estimate of the form (5.2) for ξ.

Proof. We subtract (3.14) from (3.9) for $n=N_{m-1}+1,\dots,N_m$ to generate an error equation for any $z_h(\mathbf{x},t_n^c)\in S_c^l$

$$\begin{aligned}
&\int_\Omega \phi(\mathbf{x})(c_h(\mathbf{x},t_n^c)-c(\mathbf{x},t_n^c))z_h(\mathbf{x},t_n^c)d\mathbf{x}\\
&\quad+\Delta t_n^c\int_\Omega \nabla z_h(\mathbf{x},t_n^c)\cdot(\mathbf{D}(\mathbf{x},\mathbf{u}_h^E(\mathbf{x},t_n^c))\nabla c_h(\mathbf{x},t_n^c)-\mathbf{D}(\mathbf{x},\mathbf{u}(\mathbf{x},t_n^c))\nabla c(\mathbf{x},t_n^c))d\mathbf{x}\\
&=\int_\Omega \phi(\mathbf{x})(c_h(\mathbf{x},t_{n-1}^c)-c(\mathbf{x},t_{n-1}^c))z_h(\mathbf{x},t_{n-1}^{c,+})d\mathbf{x}\\
&\quad+\Delta t_n^c\int_\Omega(\bar{c}_h(\mathbf{x},t_n^c)-\bar{c}(\mathbf{x},t_n^c))q(\mathbf{x},t_n^c)z_h(\mathbf{x},t_n^c)d\mathbf{x}\\
&\quad+E_{\mathbf{D}}(c,z_h)-E_q(\bar{c},z_h).
\end{aligned}$$

In the second term on the right-hand side, $\bar{c}_h:=\bar{c}$ is specified at sources so the difference $\bar{c}_h-\bar{c}$ vanishes. At sinks $q=q^-$ is specified but $\bar{c}_h=c_h$ and $\bar{c}=c$. We rewrite the preceding equation with $z_h=\xi$ as

$$\begin{aligned}
&\int_\Omega \phi(\mathbf{x})\xi^2(\mathbf{x},t_n^c)d\mathbf{x}+\Delta t_n^c\int_\Omega \nabla\xi(\mathbf{x},t_n^c)\cdot\mathbf{D}(\mathbf{x},\mathbf{u}_h^E(\mathbf{x},t_n^c))\nabla\xi(\mathbf{x},t_n^c)d\mathbf{x}\\
&\quad=\int_\Omega \phi(\mathbf{x})\xi(\mathbf{x},t_{n-1}^c)\xi(\mathbf{x},t_{n-1}^{c,+})d\mathbf{x}+\int_\Omega \phi(\mathbf{x})\eta(\mathbf{x},t_{n-1}^c)\xi(\mathbf{x},t_{n-1}^{c,+})d\mathbf{x}\\
&\qquad+\Delta t_n^c\int_\Omega q^-(\mathbf{x},t_n^c)\xi^2(\mathbf{x},t_n^c)d\mathbf{x}+\Delta t_n^c\int_\Omega q^-(\mathbf{x},t_n^c)\eta(\mathbf{x},t_n^c)\xi(\mathbf{x},t_n^c)d\mathbf{x}\\
&\qquad-\Delta t_n^c\int_\Omega \nabla\xi(\mathbf{x},t_n^c)\cdot(\mathbf{D}(\mathbf{x},\mathbf{u}_h^E(\mathbf{x},t_n^c))-\mathbf{D}(\mathbf{x},\mathbf{u}(\mathbf{x},t_n^c)))\nabla\Pi c(\mathbf{x},t_n^c)d\mathbf{x}\\
&\qquad-\Delta t_n^c\int_\Omega \nabla\xi(\mathbf{x},t_n^c)\cdot\mathbf{D}(\mathbf{x},\mathbf{u}(\mathbf{x},t_n^c))\nabla\eta(\mathbf{x},t_n^c)d\mathbf{x}\\
&\qquad-\int_\Omega \phi(\mathbf{x})\eta(\mathbf{x},t_n^c)\xi(\mathbf{x},t_n^c)d\mathbf{x}+E_{\mathbf{D}}(c,\xi)-E_q(\bar{c},\xi).
\end{aligned}\tag{5.4}$$

We bound the third and fourth terms on the right-hand side of (5.4) by

$$\begin{aligned}
&\left|\Delta t_n^c\int_\Omega q^-(\mathbf{x},t_n^c)\xi^2(\mathbf{x},t_n^c)d\mathbf{x}+\Delta t_n^c\int_\Omega q^-(\mathbf{x},t_n^c)\eta(\mathbf{x},t_n^c)\xi(\mathbf{x},t_n^c)d\mathbf{x}\right|\\
&\quad\le Q\Delta t_n^c\|\xi(\mathbf{x},t_n^c)\|^2+\Delta t_n^c\|\eta(\mathbf{x},t_n^c)\|^2\\
&\quad\le Q\Delta t_n^c\|\xi(\mathbf{x},t_n^c)\|^2+A_1^2\Delta t_n^c h_c^{2l+2}\|c\|^2_{L^\infty(H^{l+1})}.
\end{aligned}$$

We use (4.5) and (4.6) to bound the sixth term on the right-hand side of (5.4)

$$\begin{aligned}
&\left|\Delta t_n^c \int_\Omega \nabla\xi(\mathbf{x},t_n^c)\cdot\mathbf{D}(\mathbf{x},\mathbf{u}(\mathbf{x},t_n^c))\nabla\eta(\mathbf{x},t_n^c)d\mathbf{x}\right| \\
&\quad= \left|\Delta t_n^c \int_\Omega \xi(\mathbf{x},t_n^c)\eta(\mathbf{x},t_n^c)d\mathbf{x}\right| \\
&\quad\le Q\Delta t_n^c\|\xi(\mathbf{x},t_n^c)\|^2 + \Delta t_n^c\|\eta(\mathbf{x},t_n^c)\|^2 \\
&\quad\le Q\Delta t_n^c\|\xi(\mathbf{x},t_n^c)\|^2 + A_1^2\Delta t_n^c h_c^{2l+2}\|c\|^2_{L^\infty(H^{l+1})}.
\end{aligned}$$

The fifth term on the right-hand side of (5.4) is bounded in Lemma 6.3

$$\begin{aligned}
&\left|\Delta t_n^c \int_\Omega \nabla\xi(\mathbf{x},t_n^c)\cdot(\mathbf{D}(\mathbf{x},\mathbf{u}_h^E(\mathbf{x},t_n^c)) - \mathbf{D}(\mathbf{x},\mathbf{u}(\mathbf{x},t_n^c)))\nabla\Pi c(\mathbf{x},t_n^c)d\mathbf{x}\right| \\
&\quad\le \varepsilon\Delta t_n^c\|\nabla\xi(\mathbf{x},t_n^c)\|^2 + Q\Delta t_n^c(\|\xi(\mathbf{x},t_{m-1}^p)\|^2 + \|\xi(\mathbf{x},t_{m-2}^p)\|^2) \\
&\qquad + Q\Delta t_n^c\Big(h_c^{2l+2}\|c\|^2_{L^\infty(H^{l+1})} + h_p^{2k+2}(\|\mathbf{u}\|^2_{L^\infty(H^{k+1}(\mathrm{div}))} + \|p\|^2_{L^\infty(H^{k+1})}) \\
&\qquad + \delta_{m,1}(\Delta t_p^1)^2\|\mathbf{u}\|^2_{W_1^\infty(0,t_1^p;L^2)} + (1-\delta_{m,1})(\Delta t_p)^3\|\mathbf{u}\|^2_{H^2(t_{m-2}^p,t_m^p;L^2)}\Big),
\end{aligned} \tag{5.5}$$

where $\delta_{i,j}=1$ if $i=j$ or 0 otherwise.

Note that the evaluation of source and sink terms and the diffusion-dispersion term in the ELLAM scheme (3.14) does not involve any characteristic tracking. Hence, (3.6) and (3.8) still hold, leading to the estimate

$$\begin{aligned}
|E_q(\bar c,\xi)| &= \left|\int_\Omega \xi(\mathbf{x},t_n^c)\int_{t_{n-1}^c}^{t_n^c}\left\{\int_\theta^{t_n^c}\frac{d}{dt}(\bar c(\mathbf{r}(t;\mathbf{x},t_n^c),t)q(\mathbf{r}(t;\mathbf{x},t_n^c),t))dt\right.\right. \\
&\qquad \left.\left. + \bar c(\mathbf{r}(\theta;\mathbf{x},t_n^c),\theta)q(\mathbf{r}(\theta;\mathbf{x},t_n^c),\theta)\left[\det\left(\frac{\partial\mathbf{r}(\theta;\mathbf{x},t_n^c)}{\partial\mathbf{x}}\right)-1\right]\right\}d\theta d\mathbf{x}\right| \\
&\le Q\Delta t_n^c\|\xi(\mathbf{x},t_n^c)\|^2 + Q(\Delta t_n^c)^2\left(\|\bar c\|^2_{L^2(t_{n-1}^c,t_n^c;L^2)} + \left\|\frac{d\bar c}{dt}\right\|^2_{L^2(t_{n-1}^c,t_n^c;L^2)}\right).
\end{aligned}$$

We use the estimates (6.1) and (6.2) in Lemma 6.1 to bound $|E_{\mathbf{D}}(c,\xi)|$ by

$$\begin{aligned}
|E_{\mathbf{D}}(c,\xi)| &\le \left|\int_\Omega\int_{t_{n-1}^c}^{t_n^c}\left(\det\left(\frac{\partial\mathbf{r}(\theta;\mathbf{x},t_n^c)}{\partial\mathbf{x}}\right)\left(\frac{\partial\mathbf{r}(\theta;\mathbf{x},t_n^c)}{\partial\mathbf{x}}\right)^{-1} - \mathbf{I}\right)\nabla\xi(\mathbf{x},t_n^c)\right. \\
&\qquad \left.\cdot(\mathbf{D}(\mathbf{r}(\theta;\mathbf{x},t_n^c),\mathbf{u}(\mathbf{r}(\theta;\mathbf{x},t_n^c),\theta))\nabla c(\mathbf{r}(\theta;\mathbf{x},t_n^c),\theta))d\theta d\mathbf{x}\right| \\
&\quad + \left|\int_\Omega\int_{t_{n-1}^c}^{t_n^c}\nabla\xi(\mathbf{x},t_n)\cdot(\mathbf{D}(\mathbf{x},\mathbf{u}(\mathbf{x},t_n^c))\nabla c(\mathbf{x},t_n^c)\right. \\
&\qquad \left. - \mathbf{D}(\mathbf{r}(\theta;\mathbf{x},t_n^c),\mathbf{u}(\mathbf{r}(\theta;\mathbf{x},t_n^c),\theta))\nabla c(\mathbf{r}(\theta;\mathbf{x},t_n^c),\theta))d\theta d\mathbf{x}\right| \\
&\le \varepsilon\Delta t_n^c\|\nabla\xi(\mathbf{x},t_n^c)\|^2 + Q(\Delta t_n^c)^2\left(\|c\|^2_{L^2(t_{n-1}^c,t_n^c;H^1)} + \left\|\frac{dc}{dt}\right\|^2_{L^2(t_{n-1}^c,t_n^c;H^1)}\right).
\end{aligned}$$

The first term on the right-hand side of (5.4) is estimated in Lemma 6.4

$$\begin{aligned}
&\left|\int_\Omega \phi(\mathbf{x})\xi(\mathbf{x},t_{n-1}^c)\xi(\mathbf{x},t_{n-1}^{c,+})d\mathbf{x}\right| \\
&\quad\le \frac{1}{2}\int_\Omega \phi(\mathbf{x})\xi^2(\mathbf{x},t_{n-1}^c)d\mathbf{x} + \frac{1}{2}\int_\Omega \phi(\mathbf{x})\xi^2(\mathbf{x},t_n^c)d\mathbf{x} + \varepsilon\Delta t_n^c(\|\nabla\xi(\mathbf{x},t_n^c)\|^2 \\
&\qquad + \|\nabla\xi(\mathbf{x},t_{n-1}^c)\|^2) + Q\Delta t_n^c(\|\xi(\mathbf{x},t_n^c)\|^2 + \|\xi(\mathbf{x},t_{n-1}^c)\|^2).
\end{aligned} \tag{5.6}$$

The second and seventh terms on the right-hand side of (5.4) are estimated in Lemma 6.5

$$\begin{aligned}
&\left|\int_\Omega \phi(\mathbf{x})\eta(\mathbf{x},t_n^c)\xi(\mathbf{x},t_n^c)d\mathbf{x} - \int_\Omega \phi(\mathbf{x})\eta(\mathbf{x},t_{n-1}^c)\xi(\mathbf{x},t_{n-1}^{c,+})d\mathbf{x}\right| \\
&\quad\le \varepsilon\Delta t_n^c\ \|\nabla\xi(\mathbf{x},t_n^c)\|^2 + Q\Delta t_n^c\ \|\xi(\mathbf{x},t_n^c)\|^2 \\
&\qquad + Qh_c^{2l+2}\|c\|^2_{H^1(t_{n-1}^c,t_n^c;H^{l+1})} + Q\Delta t_n^c h_c^{2l+2}\|c\|^2_{L^\infty(W^{l+1}_{2+\gamma})}.
\end{aligned} \tag{5.7}$$

We incorporate the preceding estimates into (5.4) to get

$$\begin{aligned}
&\int_\Omega \phi(\mathbf{x})\xi^2(\mathbf{x},t_n^c)d\mathbf{x} + |\mathbf{D}|_{min}\ \Delta t_n^c\|\nabla\xi(\mathbf{x},t_n^c)\|^2 \\
&\quad\le \frac{1}{2}\int_\Omega \phi(\mathbf{x})\xi^2(\mathbf{x},t_n^c)d\mathbf{x} + \frac{1}{2}\int_\Omega \phi(\mathbf{x})\xi^2(\mathbf{x},t_{n-1}^c)d\mathbf{x} + 3\varepsilon\Delta t_n^c\|\nabla\xi(\mathbf{x},t_n^c)\|^2 \\
&\qquad + \varepsilon\Delta t_n^c\|\nabla\xi(\mathbf{x},t_{n-1}^c)\|^2 + Q\Delta t_n^c\Big(\|\xi(\mathbf{x},t_n^c)\|^2 + \|\xi(\mathbf{x},t_{n-1}^c)\|^2 \\
&\qquad + \|\xi(\mathbf{x},t_{m-1}^p)\|^2 + \|\xi(\mathbf{x},t_{m-2}^p)\|^2\Big) + Q(\Delta t_n^c)^2\Big(\|\bar c\|^2_{L^2(t_{n-1}^c,t_n^c;L^2)} \\
&\qquad + \|c\|^2_{L^2(t_{n-1}^c,t_n^c;H^1)} + \Big\|\frac{d\bar c}{dt}\Big\|^2_{L^2(t_{n-1}^c,t_n^c;L^2)} + \Big\|\frac{dc}{dt}\Big\|^2_{L^2(t_{n-1}^c,t_n^c;H^1)}\Big) \\
&\qquad + Q\Delta t_n^c\Big(\delta_{m,1}(\Delta t_p^1)^2\|\mathbf{u}\|^2_{W^1_\infty(0,t_1^p;L^2)} + (1-\delta_{m,1})(\Delta t_p)^3\|\mathbf{u}\|^2_{H^2(t_{m-2}^p,t_m^p;L^2)}\Big) \\
&\qquad + Qh_c^{2l+2}\Big(\Delta t_n^c\|c\|^2_{L^\infty(W^{l+1}_{2+\gamma})} + \|c\|^2_{H^1(t_{n-1}^c,t_n^c;H^{l+1})}\Big) \\
&\qquad + Q\Delta t_n^c h_p^{2k+2}\Big(\|\mathbf{u}\|^2_{L^\infty(H^{k+1}(\mathrm{div}))} + \|p\|^2_{L^\infty(H^{k+1})}\Big).
\end{aligned} \tag{5.8}$$

We choose $\varepsilon = |\mathbf{D}|_{min}/8$, sum this estimate for $n = 1, 2, \ldots, n^*$, with $n^* \le N_m$, and cancel like terms to obtain

$$\begin{aligned}
&\int_\Omega \phi(\mathbf{x})\xi^2(\mathbf{x},t_{n^*}^c)d\mathbf{x} + |\mathbf{D}|_{min}\sum_{n=1}^{n^*}\Delta t_n^c\|\nabla\xi(\mathbf{x},t_n^c)\|^2 \\
&\quad\le Q\sum_{n=1}^{n^*}\Delta t_n^c\|\xi(\mathbf{x},t_n^c)\|^2 + Q(\Delta t_n^c)^2\Big(\|\bar c\|^2_{L^2(L^2)} + \|c\|^2_{L^2(H^1)} \\
&\qquad + \Big\|\frac{d\bar c}{dt}\Big\|^2_{L^2(L^2)} + \Big\|\frac{dc}{dt}\Big\|^2_{L^2(H^1)}\Big) + Q\big((\Delta t_p)^4 + (\Delta t_p^1)^3\big)\|\mathbf{u}\|^2_{H^2(L^2)} \\
&\qquad + Qh_c^{2l+2}\big(\|c\|^2_{L^\infty(W^{l+1}_{2+\gamma})} + \|c\|^2_{H^1(H^{l+1})}\big) \\
&\qquad + Qh_p^{2k+2}\big(\|\mathbf{u}\|^2_{L^\infty(H^{k+1}(\mathrm{div}))} + \|p\|^2_{L^\infty(H^{k+1})}\big).
\end{aligned} \tag{5.9}$$

Here we have used the estimate (6.8) to bound the initial value $\|\xi(\mathbf{x},0)\|$ that has appeared on the right-hand side.

We choose Δt_n^c small enough such that $Q\Delta t_n^c < \phi_{min}/2$ and apply Gronwall inequality to (5.9) to get

$$
\begin{aligned}
&\|\xi\|^2_{\hat{L}_c^\infty(0,t^c_{n^*};L^2)} + |\mathbf{D}|_{min}\,\|\nabla\xi\|^2_{\hat{L}_c^2(0,t^c_{n^*};L^2)} \\
&\quad \le Q(\Delta t_n^c)^2\Big(\|\bar{c}\|^2_{L^2(L^2)} + \|c\|^2_{L^2(H^1)} + \Big\|\frac{d\bar{c}}{dt}\Big\|^2_{L^2(L^2)} + \Big\|\frac{dc}{dt}\Big\|^2_{L^2(H^1)}\Big) \\
&\quad + Q\big((\Delta t_p)^4 + (\Delta t_p^1)^3\big)\|\mathbf{u}\|^2_{H^2(L^2)} + Qh_c^{2l+2}\big(\|c\|^2_{L^\infty(W^{l+1}_{2+\gamma})} + \|c\|^2_{H^1(H^{l+1})}\big) \\
&\quad + Q\,h_p^{2k+2}\big(\|\mathbf{u}\|^2_{L^\infty(H^{k+1}(\mathrm{div}))} + \|p\|^2_{L^\infty(H^{k+1})}\big).
\end{aligned}
\tag{5.10}
$$

Combining this estimate with (4.6) finishes the proof. ∎

5.3. Discussion. The error estimate (5.2) contains only the H^1 norm of c and its material derivative in the Δt_c term. These norms are much smaller than those of the temporal derivatives c due to the Lagrangian nature of the transport PDEs. Hence, larger time steps and spatial grids can be used in the ELLAM-MFEM time-stepping procedure. In other words, Theorem 5.1 theoretically justifies the mathematical and numerical strength of the ELLAM-MFEM time-stepping procedure, which was previously observed numerically [3, 17, 21, 30, 32].

In the ELLAM-MFEM time-stepping procedure (3.12) and (3.14), a linear extrapolation in time is used to define the numerical velocity field $\mathbf{u}_h^{\mathrm{E}}(\mathbf{x},t_n^c)$ in (3.13). A constant-in-time interpolation can be used instead:

$$
\mathbf{u}_h^{\mathrm{E}}(\mathbf{x},t_n^c) := \mathbf{u}_h(\mathbf{x},t_{m-1}^p) \qquad \text{for} \quad N_{m-1}+1 \le n \le N_m,\ 1 \le m \le M.
$$

The proof in Theorem 5.1 still goes through, leading to an estimate of the form

$$
\begin{aligned}
&\|c_h - c\|_{\hat{L}_c^\infty(L^2)} + \|\mathbf{u}_h - \mathbf{u}\|_{\hat{L}_p^\infty(H(\mathrm{div}))} + \|p_h - p\|_{\hat{L}_p^\infty(L^2)} \\
&\quad \le Q(h_c^{l+1} + h_p^{k+1} + \Delta t_c + \Delta t_p).
\end{aligned}
$$

An error estimate similar to Theorem 5.1 was proved in [9] for a Galerkin FEM-MFEM time-stepping procedure for problem (2.1)–(2.3) and in [13] for an MMOC-MFEM time-stepping procedure. These estimates require a restrictive condition that

$$
\Delta t_c = o(h_p). \tag{5.11}
$$

In other words, these procedures are guaranteed to converge only if the Courant number tends to zero asymptotically, which is more restrictive than the CFL condition for an explicit scheme. This is especially important for the MMOC-MFEM time-stepping procedure, since the strength of the MMOC scheme is really reflected in the large time steps the MMOC scheme allows.

In Theorem 5.1 the restriction (5.11) is relaxed to be

$$
\Delta t_c = O(h_p). \tag{5.12}
$$

This implies that the ELLAM-MFEM time-stepping procedure converges for any size of Courant numbers. Thus, Theorem 5.1 provides a solid theoretical foundation to show the competitiveness of the ELLAM-MFEM procedure, which was previously illustrated and observed numerically [21, 30, 32].

6. Auxiliary lemmas. In this section we prove several lemmas that were used in the proof of Theorem 5.1.

6.1. Estimates on tracking. In this subsection, we derive various bounds for tracking-related transformations.

LEMMA 6.1. *Assume that* $\phi \in W^1_\infty$ *and* $\mathbf{u} \in L^\infty(W^1_\infty)$. *Then the Jacobian matrix of the characteristic* $\mathbf{r}(t; x, t^c_{n-1})$ *is bounded in the Frobenius norm* $|\cdot|_2$ *by*

$$\left| \frac{\partial \mathbf{r}(t; \mathbf{x}, t^c_{n-1})}{\partial \mathbf{x}} - \mathbf{I} \right|_2 \le Q(t - t^c_{n-1}), \qquad t \in [t^c_{n-1}, t^c_n]. \tag{6.1}$$

Here Q *depends on* $\|\mathbf{u}\|_{L^\infty(W^1_\infty)}$ *but not on discretization parameters. In addition,*

$$\det\left(\frac{\partial \mathbf{r}(t; \mathbf{x}, t^c_{n-1})}{\partial \mathbf{x}} \right) = 1 + O(t - t^c_{n-1}), \qquad t \in [t^c_{n-1}, t^c_n]. \tag{6.2}$$

Proof. Differentiating (3.15) with respect to $\mathbf{x}$ yields, for $t \in [t^c_{n-1}, t^c_n]$,

$$\frac{\partial \mathbf{r}(t; \mathbf{x}, t^c_{n-1})}{\partial \mathbf{x}} - \mathbf{I} = \int_{t^c_{n-1}}^{t} \nabla \left(\frac{\mathbf{u}(\mathbf{r}(\theta; \mathbf{x}, t^c_{n-1}), \theta)}{\phi(\mathbf{r}(\theta; \mathbf{x}, t^c_{n-1}), \theta)} \right) \frac{\partial \mathbf{r}(\theta; \mathbf{x}, t^c_{n-1})}{\partial \mathbf{x}} d\theta. \tag{6.3}$$

We apply Cauchy inequality to bound the Frobenius norm of $\frac{\partial \mathbf{r}}{\partial \mathbf{x}} - \mathbf{I}$ by

$$\begin{aligned}
\left| \frac{\partial \mathbf{r}(t; \mathbf{x}, t^c_{n-1})}{\partial \mathbf{x}} - \mathbf{I} \right|^2_2 &\le (t - t^c_{n-1}) \int_{t^c_{n-1}}^{t} \left| \nabla \left(\frac{\mathbf{u}(\mathbf{r}(\theta; \mathbf{x}, t^c_{n-1}), \theta)}{\phi(\mathbf{r}(\theta; \mathbf{x}, t^c_{n-1}), \theta)} \right) \frac{\partial \mathbf{r}(\theta; \mathbf{x}, t^c_{n-1})}{\partial \mathbf{x}} \right|^2_2 d\theta \\
&\le (t - t^c_{n-1}) \left\| \frac{\mathbf{u}}{\phi} \right\|^2_{L^\infty(W^1_\infty)} \int_{t^c_{n-1}}^{t} \left| \frac{\partial \mathbf{r}(\theta; \mathbf{x}, t^c_{n-1})}{\partial \mathbf{x}} \right|^2_2 d\theta \\
&\le Q(t - t^c_{n-1})^2 + Q(t - t^c_{n-1}) \int_{t^c_{n-1}}^{t} \left| \frac{\partial \mathbf{r}(\theta; \mathbf{x}, t^c_{n-1})}{\partial \mathbf{x}} - \mathbf{I} \right|^2_2 d\theta.
\end{aligned}$$

Applying Gronwall inequality finishes the proof of (6.1), which directly gives (6.2). ∎

LEMMA 6.2. *Under the assumptions of Theorem* 5.1,

$$h_p^{-1} h_c^{l+1} \|c_0\|_{H^{l+1}} \le 1, \tag{6.4}$$

and

$$\frac{\Delta t_c}{h_p} \le Q_2, \qquad \frac{\Delta t_p}{h_p^{1/2}} \le Q_2, \qquad \frac{\Delta t_p^1}{h_p^{2/3}} \le Q_2, \tag{6.5}$$

we have the following estimate for the difference $\tilde{\mathbf{x}}_h - \tilde{\mathbf{x}}$*:*

$$\|\tilde{\mathbf{x}}_h - \tilde{\mathbf{x}}\|_{L^q} \le Q_3 \Delta t^c_n h_p^{\frac{2}{q}}. \tag{6.6}$$

Proof. We use (3.15) and (3.18) and the estimates (4.3) and (5.3) to bound $\|\tilde{\mathbf{x}}_h - \tilde{\mathbf{x}}\|_{L^q}$ for $2 \le q \le +\infty$ by

$$
\begin{aligned}
\|\tilde{\mathbf{x}}_h - \tilde{\mathbf{x}}\|_{L^q} &= \left\| \frac{\mathbf{u}_h^{\mathrm{E}}(\mathbf{x}, t_{n-1}^c)}{\phi(\mathbf{x})} \Delta t_n^c - \int_{t_{n-1}^c}^{t_n^c} \frac{\mathbf{u}(\mathbf{r}(\theta; \mathbf{x}, t_{n-1}^c), \theta)}{\phi(\mathbf{r}(\theta; \mathbf{x}, t_{n-1}^c))} d\theta \right\|_{L^q} \\
&= \left\| \Delta t_n^c \left(\frac{\mathbf{u}_h^{\mathrm{E}}(\mathbf{x}, t_{n-1}^c) - \mathbf{u}^E(\mathbf{x}, t_{n-1}^c)}{\phi(\mathbf{x})} + \frac{\mathbf{u}^E(\mathbf{x}, t_{n-1}^c) - \mathbf{u}(\mathbf{x}, t_{n-1}^c)}{\phi(\mathbf{x})} \right) \right. \\
&\qquad \left. - \int_{t_{n-1}^c}^{t_n^c} \left(\frac{\mathbf{u}(\mathbf{r}(\theta; \mathbf{x}, t_{n-1}^c), \theta)}{\phi(\mathbf{r}(\theta; \mathbf{x}, t_{n-1}^c))} - \frac{\mathbf{u}(\mathbf{x}, t_{n-1}^c)}{\phi(\mathbf{x})} \right) d\theta \right\|_{L^q} \qquad (6.7) \\
&\le 3\phi_{min}^{-1} \Delta t_n^c \Big(\|\mathbf{u}_h - \mathbf{u}\|_{\hat{L}_p^\infty(t_{m-2}^p, t_{m-1}^p; L^q)} + \delta_{m,1} \Delta t_p^1 \|\mathbf{u}\|_{W_1^\infty(t_0^p, t_1^p; L^q)} \\
&\quad + (1 - \delta_{m,1})(\Delta t_p)^{3/2} \|\mathbf{u}\|_{H^2(t_{m-2}^p, t_m^p; L^q)} + Q \Delta t_n^c \Big).
\end{aligned}
$$

Here Q depends on $\|\frac{d\mathbf{u}}{dt}\|_{L^\infty(L^\infty)}$ and $\|\mathbf{u}\|_{L^\infty(L^\infty)}$ but not on discretization parameters.

We combine (4.1), (4.6), and (5.3) to conclude that

$$
\begin{aligned}
\|\xi(\mathbf{x}, 0)\| &\le \|c_h(\mathbf{x}, 0) - \Pi c_0(\mathbf{x})\| \qquad (6.8) \\
&\le \|c_h(\mathbf{x}, 0) - c_0(\mathbf{x})\| + \|\Pi c_0(\mathbf{x}) - c_0(\mathbf{x})\| \le 2A_1 h_c^{l+1} \|c_0\|_{H^{l+1}}
\end{aligned}
$$

and

$$
\begin{aligned}
&\|(\mathbf{u}_h - \Pi \mathbf{u})(\mathbf{x}, 0)\|_{L^q} \\
&\le K_2 h_p^{-(1-\frac{2}{q})} \|(\mathbf{u}_h - \Pi \mathbf{u})(\mathbf{x}, 0)\| \le K_2 Q_1 h_p^{-(1-\frac{2}{q})} \|c_h(\mathbf{x}, 0) - c_o(\mathbf{x})\| \qquad (6.9) \\
&\le A_1 K_2 Q_1 h_p^{-(1-\frac{2}{q})} h_c^{l+1} \|c_o\|_{H^{l+1}} \le A_1 K_2 Q_1 h_p^{\frac{2}{q}},
\end{aligned}
$$

provided that condition (6.4) is true.

By (4.4) and (5.1), the estimate (6.7) reduces to the following for $n = 1, 2, \ldots, N_1$:

$$
\begin{aligned}
\|\tilde{\mathbf{x}}_h - \tilde{\mathbf{x}}\|_{L^q} &\le 3\phi_{min}^{-1} \Delta t_n^c \Big(\|(\mathbf{u}_h - \mathbf{u})(\mathbf{x}, 0)\|_{L^q} + \Delta t_p^1 \|\mathbf{u}\|_{W_1^\infty(t_0^p, t_1^p; L^q)} + Q \Delta t_n^c \Big) \\
&\le 3\phi_{min}^{-1} \Delta t_n^c \Big(A_2 K_2 h_p^{k+\frac{2}{q}} (\|\mathbf{u}\|_{L^\infty(H^{k+1}(\mathrm{div}))} + \|p\|_{L^\infty(H^{k+1})}) \qquad (6.10) \\
&\qquad + A_1 K_2 Q_1 h_p^{\frac{2}{q}} + \Delta t_p^1 \|\mathbf{u}\|_{W_1^\infty(t_0^p, t_1^p; L^q)} + Q \Delta t_n^c \Big) \\
&\le Q_4 \Delta t_n^c h_p^{\frac{2}{q}}.
\end{aligned}
$$

For $n = N_{m-1} + 1, 2, \ldots, N_m$, we use (4.4), (5.1), (5.2), and (6.5) to bound (6.7) as follows:

$$
\begin{aligned}
&\|\tilde{\mathbf{x}}_h - \tilde{\mathbf{x}}\|_{L^q} \\
&\le 3\phi_{min}^{-1} \Delta t_n^c \Big[\|\mathbf{u}_h - \mathbf{u}\|_{\hat{L}_p^\infty(t_{m-2}^p, t_{m-1}^p; L^q)} + \delta_{m,1} \Delta t_p^1 \|\mathbf{u}\|_{W_1^\infty(t_0^p, t_1^p; L^q)} \\
&\quad + (1 - \delta_{m,1})(\Delta t_p)^{3/2} \|\mathbf{u}\|_{H^2(t_{m-2}^p, t_m^p; L^q)} + Q \Delta t_n^c \Big] \\
&\le 3\phi_{min}^{-1} \Delta t_n^c h_p^{\frac{2}{q}} \Big[(A_2 + Q^*) K_2 h_p^k (\|\mathbf{u}\|_{L^\infty(H^{k+1}(\mathrm{div}))} + \|p\|_{L^\infty(H^{k+1})}) \qquad (6.11) \\
&\quad + Q^* Q_2 \Big(\|\bar{c}\|_{L^2(L^2)} + \|c\|_{L^2(H^1)} + \Big\| \frac{d\bar{c}}{d\tau} \Big\|_{L^2(L^2)} + \Big\| \frac{dc}{d\tau} \Big\|_{L^2(H^1)} \Big) \\
&\quad + Q^* Q_2 \|\mathbf{u}\|_{H^2(L^2)} + Q^* \Big] \\
&\le Q_3 \Delta t_n^c h_p^{\frac{2}{q}}. \qquad \square
\end{aligned}
$$

6.2. Miscellaneous estimates. In this subsection we prove the estimates (5.5), (5.6), and (5.7) for the fifth, the first, and the second and seventh terms on the right-hand side of (5.4), respectively.

LEMMA 6.3. *Under the conditions of Theorem* 5.1*, estimate* (5.5) *holds for* $n = N_{m-1}+1,\dots,N_m$.

Proof. It is straightforward to see that [8]

$$|\mathbf{D}(\mathbf{x},\mathbf{u})-\mathbf{D}(\mathbf{x},\mathbf{v})| \le Q_4\ |\mathbf{u}-\mathbf{v}|.$$

With this we bound the left-hand side of (5.5) by

$$\begin{aligned}
&\left|\Delta t_n^c \int_\Omega \nabla\xi(\mathbf{x},t_n^c)\cdot(\mathbf{D}(\mathbf{x},\mathbf{u}_h^E(\mathbf{x},t_n^c))-\mathbf{D}(\mathbf{x},\mathbf{u}(\mathbf{x},t_n^c)))\nabla\Pi c(\mathbf{x},t_n^c)d\mathbf{x}\right| \\
&\quad\le Q_4\Delta t_n^c\|\nabla\xi(\mathbf{x},t_n^c)\|\ \|\mathbf{u}_h^E(\mathbf{x},t_n^c)-\mathbf{u}(\mathbf{x},t_n^c)\|\ \|\Pi c(\mathbf{x},t_n^c)\|_{W_\infty^1} \\
&\quad\le K_3Q_4\Delta t_n^c\|\nabla\xi(\mathbf{x},t_n^c)\|\ (\|\mathbf{u}_h^E(\mathbf{x},t_n^c)-(\Pi\mathbf{u})^E(\mathbf{x},t_n^c)\| \\
&\qquad+\|(\Pi\mathbf{u})^E(\mathbf{x},t_n^c)-\mathbf{u}^E(\mathbf{x},t_n^c)\|+\|\mathbf{u}^E(\mathbf{x},t_n^c)-\mathbf{u}(\mathbf{x},t_n^c)\|),
\end{aligned} \tag{6.12}$$

where at the last "$\le$" sign we have used (4.7).

The last term in the bracket is bounded in (4.12). We use the estimate (4.9) to bound the second term in the bracket to get

$$\begin{aligned}
&\|(\Pi\mathbf{u})^E(\mathbf{x},t_n^c)-\mathbf{u}^E(\mathbf{x},t_n^c)\| \\
&\quad\le Q(\|\Pi\mathbf{u}(\mathbf{x},t_{m-2}^p)-\mathbf{u}(\mathbf{x},t_{m-2}^p)\|+\|\Pi\mathbf{u}(\mathbf{x},t_{m-1}^p)-\mathbf{u}(\mathbf{x},t_{m-1}^p)\|) \\
&\quad\le Qh_p^{k+1}(\|\mathbf{u}\|_{L^\infty(H^{k+1}(\mathrm{div}))}+\|p\|_{L^\infty(H^{k+1})}).
\end{aligned}$$

We use (4.6) and (5.3) to bound the first term in the bracket of (6.12) by

$$\begin{aligned}
&\|\mathbf{u}_h^E(\mathbf{x},t_n^c)-(\Pi\mathbf{u})^E(\mathbf{x},t_n^c)\| \\
&\quad\le Q\ (\|\mathbf{u}_h(\mathbf{x},t_{m-2}^p)-\Pi\mathbf{u}(\mathbf{x},t_{m-2}^p)\|+\|\mathbf{u}_h(\mathbf{x},t_{m-1}^p)-\Pi\mathbf{u}(\mathbf{x},t_{m-1}^p)\|) \\
&\quad\le Q\ (\|c_h(\mathbf{x},t_{m-2}^p)-c(\mathbf{x},t_{m-2}^p)\|+\|c_h(\mathbf{x},t_{m-1}^p)-c(\mathbf{x},t_{m-1}^p)\|) \\
&\quad\le Q\ (\|\xi(\mathbf{x},t_{m-2}^p)\|+\|\xi(\mathbf{x},t_{m-1}^p)\|)+Qh_c^{l+1}\|c\|_{L^\infty(H^{l+1})}.
\end{aligned}$$

We combine these two estimates with (4.12) to complete the proof. ∎

LEMMA 6.4. *Under the conditions of Theorem* 5.1*, estimate* (5.6) *holds for* $n = N_{m-1}+1,\dots,N_m$.

Proof. The first term on the right-hand side of (5.4) can be written as

$$\begin{aligned}
\int_\Omega \phi(\mathbf{x})\xi(\mathbf{x},t_{n-1}^c)\xi(\mathbf{x},t_{n-1}^{c,+})d\mathbf{x} &= \int_\Omega \phi(\mathbf{x})\xi(\mathbf{x},t_{n-1}^c)\xi(\tilde{\mathbf{x}}_h,t_n^c)d\mathbf{x} \\
&= \int_\Omega \phi(\mathbf{x})\xi(\mathbf{x},t_{n-1}^c)\xi(\tilde{\mathbf{x}},t_n^c)d\mathbf{x} \\
&\quad+\int_\Omega \phi(\mathbf{x})\xi(\mathbf{x},t_{n-1}^c)(\xi(\tilde{\mathbf{x}}_h,t_n^c)-\xi(\tilde{\mathbf{x}},t_n^c))d\mathbf{x}.
\end{aligned} \tag{6.13}$$

We use estimate (6.2) to bound the first term on the right-hand side of (6.13)

$$
\begin{aligned}
&\left|\int_\Omega \phi(\mathbf{x})\xi(\mathbf{x},t_{n-1}^c)\xi(\tilde{\mathbf{x}},t_n^c)d\mathbf{x}\right| \\
&\quad\le \frac{1}{2}\int_\Omega \phi(\mathbf{x})\xi^2(\mathbf{x},t_{n-1}^c)d\mathbf{x}+\frac{1}{2}\int_\Omega \phi(\mathbf{x})\xi^2(\tilde{\mathbf{x}},t_n^c)d\mathbf{x} \\
&\quad= \frac{1}{2}\int_\Omega \phi(\mathbf{x})\xi^2(\mathbf{x},t_{n-1}^c)d\mathbf{x}+\frac{1}{2}\int_\Omega \phi(\tilde{\mathbf{x}})\xi^2(\tilde{\mathbf{x}},t_n^c)\det\Big(\frac{\partial \mathbf{x}}{\partial \tilde{\mathbf{x}}}\Big)d\tilde{\mathbf{x}} \\
&\quad\quad+\frac{1}{2}\int_\Omega (\phi(\mathbf{x})-\phi(\tilde{\mathbf{x}}))\xi^2(\tilde{\mathbf{x}},t_n^c)\det\Big(\frac{\partial \mathbf{x}}{\partial \tilde{\mathbf{x}}}\Big)d\tilde{\mathbf{x}} \\
&\quad\le \frac{1}{2}\int_\Omega \phi(\mathbf{x})\xi^2(\mathbf{x},t_{n-1}^c)d\mathbf{x}+\frac{1}{2}\int_\Omega \phi(\mathbf{x})\xi^2(\mathbf{x},t_n^c)d\mathbf{x}+Q\Delta t_n^c\|\xi(\mathbf{x},t_n^c)\|^2.
\end{aligned}
\tag{6.14}
$$

Here we have rewritten $\tilde{\mathbf{x}}$ as $\mathbf{x}$ in the second term.

We use (4.2), (6.6), and the relationship

$$
\xi(\tilde{\mathbf{x}}_h,t_n^c)-\xi(\tilde{\mathbf{x}},t_n^c)=(\tilde{\mathbf{x}}_h-\tilde{\mathbf{x}})\cdot\int_0^1 \nabla\xi(\tilde{\mathbf{x}}+s(\tilde{\mathbf{x}}_h-\tilde{\mathbf{x}}),t_n^c)ds,
\tag{6.15}
$$

to bound the second term on the right-hand side of (6.13) by

$$
\begin{aligned}
&\left|\int_\Omega \phi(\mathbf{x})\xi(\mathbf{x},t_{n-1}^c)(\xi(\tilde{\mathbf{x}}_h,t_n^c)-\xi(\tilde{\mathbf{x}},t_n^c))d\mathbf{x}\right| \\
&\quad\le Q\|\xi(\mathbf{x},t_{n-1}^c)\|_{L^\infty}\|\tilde{\mathbf{x}}_h-\tilde{\mathbf{x}}\|\left(\int_0^1\int_\Omega |\nabla\xi(\tilde{\mathbf{x}}+s(\tilde{\mathbf{x}}_h-\tilde{\mathbf{x}}),t_n^c)|^2d\mathbf{x}ds\right)^{1/2} \\
&\quad\le K_1Q|\ln h_c|^{1/2}\|\xi(\mathbf{x},t_{n-1}^c)\|_{H^1}\|\tilde{\mathbf{x}}_h-\tilde{\mathbf{x}}\|\ \|\nabla\xi(\mathbf{x},t_{n-1}^c)\| \\
&\quad\le \varepsilon\Delta t_n^c(\|\nabla\xi(\mathbf{x},t_n^c)\|^2+\|\nabla\xi(\mathbf{x},t_{n-1}^c)\|^2+\|\xi(\mathbf{x},t_{n-1}^c)\|^2),
\end{aligned}
\tag{6.16}
$$

provided that

$$
2K_1QQ_3h_p^{2q}|\ln h_c|^{1/2}\le\varepsilon,\qquad 2K_1QQ_4h_p^{2q}|\ln h_c|^{1/2}\le\varepsilon. \qquad \square
\tag{6.17}
$$

LEMMA 6.5. *Under the conditions of Theorem* 5.1, *estimate* (5.7) *holds for* $n=N_{m-1}+1,\dots,N_m$.

Proof. We decompose the second and seventh terms on the right-hand side of (5.4) as follows:

$$
\begin{aligned}
&\int_\Omega \phi(\mathbf{x})\eta(\mathbf{x},t_n^c)\xi(\mathbf{x},t_n^c)d\mathbf{x}-\int_\Omega \phi(\mathbf{x})\eta(\mathbf{x},t_{n-1}^c)\xi(\mathbf{x},t_{n-1}^{c,+})d\mathbf{x} \\
&\quad=\int_\Omega \phi(\mathbf{x})\left[\int_{t_{n-1}^c}^{t_n^c}\frac{\partial\eta(\mathbf{x},t)}{\partial t}dt\right]\xi(\mathbf{x},t_n^c)d\mathbf{x} \\
&\quad\quad-\int_\Omega \phi(\mathbf{x})\eta(\mathbf{x},t_{n-1}^c)(\xi(\tilde{\mathbf{x}}_h,t_n^c)-\xi(\tilde{\mathbf{x}},t_n^c))d\mathbf{x} \\
&\quad\quad-\int_\Omega \phi(\mathbf{x})\eta(\mathbf{x},t_{n-1}^c)(\xi(\tilde{\mathbf{x}},t_n^c)-\xi(\mathbf{x},t_n^c))d\mathbf{x}.
\end{aligned}
\tag{6.18}
$$

The first term on the right-hand side of (6.18) is bounded by

$$
\begin{aligned}
&\left|\int_\Omega \phi(\mathbf{x})\left[\int_{t_{n-1}^c}^{t_n^c}\frac{\partial\eta(\mathbf{x},t)}{\partial t}dt\right]\xi(\mathbf{x},t_n^c)d\mathbf{x}\right| \\
&\quad\le Q(\Delta t_n^c)^{1/2}\ \|\xi(\mathbf{x},t_n^c)\|\ \|\eta\|_{H^1(t_{n-1}^c,t_n^c;L^2)} \\
&\quad\le Q\Delta t_n^c\ \|\xi(\mathbf{x},t_n^c)\|^2+A_1^2h_c^{2l+2}\|c\|^2_{H^1(t_{n-1}^c,t_n^c;H^{l+1})}.
\end{aligned}
\tag{6.19}
$$

We use (3.15) to bound the third term on the right-hand side of (6.18)

$$\begin{aligned}
&\left|\int_\Omega \phi(\mathbf{x})\eta(\mathbf{x},t_{n-1}^c)(\xi(\tilde{\mathbf{x}},t_n^c)-\xi(\mathbf{x},t_n^c))d\mathbf{x}\right| \\
&\quad=\left|\int_\Omega \phi(\mathbf{x})\eta(\mathbf{x},t_{n-1}^c)(\tilde{\mathbf{x}}-\mathbf{x})\cdot\int_0^1 \nabla\xi(\mathbf{x}+s(\tilde{\mathbf{x}}-\mathbf{x}),t_n^c)d\mathbf{x}\right| \\
&\quad\le Q\Delta t_n^c\|\nabla\xi(\mathbf{x},t_n)\|\ \|\eta(\mathbf{x},t_{n-1}^c)\| \\
&\quad\le \varepsilon\Delta t_n^c\ \|\nabla\xi(\mathbf{x},t_n^c)\|^2+Q\Delta t_n^c h_c^{2l+2}\|c\|^2_{L^\infty(H^{l+1})}.
\end{aligned} \tag{6.20}$$

We use the estimate (6.6) with $q=2(2+\gamma)/\gamma$ and the generalized Hölder inequality to bound the second term on the right-hand side of (6.18) in a similar manner to the estimate of (6.16) as follows:

$$\begin{aligned}
&\left|\int_\Omega \phi(\mathbf{x})\eta(\mathbf{x},t_{n-1}^c)(\xi(\tilde{\mathbf{x}}_h,t_n^c)-\xi(\tilde{\mathbf{x}},t_n^c))d\mathbf{x}\right| \\
&\quad\le Q\left\|\tilde{\mathbf{x}}_h-\tilde{\mathbf{x}}\right\|_{L^{\frac{2(2+\gamma)}{\gamma}}}\|\eta(\mathbf{x},t_{n-1}^c)\|_{L^{2+\gamma}}\|\nabla\xi(\mathbf{x},t_n^c)\| \\
&\quad\le \varepsilon\Delta t_n^c\|\nabla\xi(\mathbf{x},t_n^c)\|^2+Q\Delta t_n^c h_c^{2l+2}\|c\|^2_{L^\infty(W^{l+1}_{2+\gamma})},
\end{aligned} \tag{6.21}$$

provided that

$$QQ_3h_p^{\frac{\gamma}{2+\gamma}}\le\varepsilon,\qquad QQ_4h_p^{\frac{\gamma}{2+\gamma}}\le\varepsilon. \qquad \square \tag{6.22}$$

Acknowledgments. The author expresses his sincere thanks to the referees for their very helpful comments and suggestions, which greatly improved the quality of this paper.

DOMAIN DECOMPOSITION FOR LESS REGULAR SUBDOMAINS: OVERLAPPING SCHWARZ IN TWO DIMENSIONS*

CLARK R. DOHRMANN†, AXEL KLAWONN‡, AND OLOF B. WIDLUND§

Abstract. In the theory of domain decomposition methods, it is often assumed that each subdomain is the union of a small set of coarse triangles or tetrahedra. In this study, extensions to the existing theory which accommodate subdomains with much less regular shapes are presented; the subdomains are required only to be John domains. Attention is focused on overlapping Schwarz preconditioners for problems in two dimensions with a coarse space component of the preconditioner, which allows for good results even for coefficients which vary considerably. It is shown that the condition number of the domain decomposition method is bounded by $C(1 + H/\delta)(1 + \log(H/h))^2$, where the constant C is independent of the number of subdomains and possible jumps in coefficients between subdomains. Numerical examples are provided which confirm the theory and demonstrate very good performance of the method for a variety of subregions including those obtained when a mesh partitioner is used for the domain decomposition.

Key words. domain decomposition, overlapping Schwarz, preconditioners, iterative methods, irregular subdomains, John domains

1. Introduction.

In the theory for overlapping Schwarz domain decomposition methods, we typically assume that each subdomain is quite regular, e.g., the union of a small set of coarse triangles or tetrahedra; see, e.g., [28, Assumption 4.3]. However, this is often unrealistic, especially if the subdomains result from using a mesh partitioner. The subdomain boundaries might then not even be uniformly Lipschitz continuous; i.e., the number of patches required to cover the boundary of the region, in each of which the boundary is the graph of a Lipschitz continuous function, might not be uniformly bounded independently of the finite element mesh size. We note that the existing theory for iterative substructuring establishes bounds on the convergence rates of the algorithms which are insensitive to even large jumps in the material properties across subdomain boundaries as reflected in the coefficients of the problem. The theory for overlapping Schwarz methods is less restrictive as far as the subdomain shapes are concerned (see, e.g., [28, Chapter 3]) but relatively little has been known about the effect of large changes in the coefficients; see, however, [25] and recent work reported in [13, 26].

The purpose of this paper is to begin the development of a theory under much weaker assumptions on the partitioning; a companion study for iterative substruc-

turing methods, by Rheinbach and the second and third authors of this paper, has also been completed [16]. Our results in this paper concern an overlapping Schwarz algorithm which combines a coarse space adopted from an iterative substructuring method (see [28, Algorithm 5.16] and [11]) with local preconditioner components selected as in classical overlapping Schwarz methods, i.e., based on solving problems on overlapping subdomains. This choice of the coarse component will allow us to prove results which are independent of coefficient jumps. We note that there are earlier studies on multilevel methods [10, 24] in which the coarsest components are similarly borrowed from iterative substructuring algorithms.

We will use nonoverlapping subdomains and denote them by $\Omega_i, i = 1, \ldots, N$, as well as overlapping subdomains $\Omega'_j, j = 1, \ldots, N'$. The interface between the Ω_i will be denoted by Γ.

So far, complete results have been obtained only for problems in the plane. To simplify our presentation, we will also confine ourselves to scalar elliptic problems of the following form:

$$-\nabla \cdot (\rho(x)\nabla u(x)) \;=\; f(x), \quad x \in \Omega \subset \mathbb{R}^2, \tag{1.1}$$

with a Dirichlet boundary condition on a measurable subset $\partial\Omega_D$ of $\partial\Omega$, the boundary of Ω, and a Neumann condition on $\partial\Omega_N = \partial\Omega \setminus \partial\Omega_D$. The coefficient $\rho(x)$ is strictly positive and assumed to be a constant ρ_i for $x \in \Omega_i$. We use piecewise linear, continuous finite elements and triangulations with shape-regular elements and assume that each subdomain is the union of a set of elements. The weak formulation of the elliptic problem is written in terms of the bilinear form

$$a(u,v) \;:=\; \sum_{i=1}^{N} a_i(u,v) \;:=\; \sum_{i=1}^{N} \rho_i \int_{\Omega_i} \nabla u \cdot \nabla v dx.$$

Our study requires the generalization of some technical tools used in the proof of a bound of the convergence rate of this type of algorithm. Some of the standard tools, such as those collected in [28, section 4.6], are no longer available, and we therefore also have to modify the reasoning in the proof of our main result. Three auxiliary results, namely, a Poincaré inequality, a Sobolev-type inequality for finite element functions, and a bound for certain edge terms, will be required in our proof; see Lemmas 2.2, 3.2, and 3.4. We will work with John domains, introduced in section 2, and will be able to express our bounds on the convergence of our algorithm in terms of a few geometric parameters.

2. A Poincaré inequality and John domains. In any analysis of any domain decomposition method with more than one level, we need a Poincaré inequality. This inequality is closely related to an isoperimetric inequality; see [12, 20, 18, 21, 22].

LEMMA 2.1 (isoperimetric inequality). *Let $\Omega \subset \mathbb{R}^n$ be a domain—an open, bounded, and connected set—and let u be sufficiently smooth. Then*

$$\inf_{c \in R} \left(\int_\Omega |u - c|^{n/(n-1)}\, dx \right)^{(n-1)/n} \leq \gamma(\Omega, n) \int_\Omega |\nabla u|\, dx$$

if and only if

$$(\min(|A|, |B|))^{1-1/n} \leq \gamma(\Omega, n) |\partial A \cap \partial B|. \tag{2.1}$$

Here $A \subset \Omega$ is an arbitrary open set, and $B = \Omega \setminus \bar{A}$; $\gamma(\Omega, n)$ is the best possible constant, and $|A|$ is the measure of the set A, etc.

We note that the domain does not need to be star-shaped or Lipschitz. A small value of $\gamma(\Omega, n)$ is desirable for our purposes. Thus, the domain cannot be very thin, and its boundary should not have very pointed parts.

For two dimensions, we immediately obtain a standard Poincaré inequality by using the Cauchy–Schwarz inequality. The best choice of c is $\bar{u}_\Omega$, the average of u over the domain.

LEMMA 2.2 (Poincaré's inequality). *Consider a domain $\Omega \subset \mathbb{R}^2$. Then*

$$\|u - \bar{u}_\Omega\|^2_{L_2(\Omega)} \leq (\gamma(\Omega, 2))^2 |\Omega| \|\nabla u\|^2_{L_2(\Omega)} \quad \forall u \in H^1(\Omega).$$

For $n = 3$, a similar bound is obtained by using Hölder's inequality several times. In Lemma 2.2, we then should replace $|\Omega|$ by $|\Omega|^{2/3}$.

Throughout, we will use weighted $H^1(\Omega_i)$-norms defined by

$$\|u\|^2_{H^1(\Omega_i)} := |u|^2_{H^1(\Omega_i)} + 1/H_i^2 \|u\|^2_{L_2(\Omega_i)} := \int_{\Omega_i} \nabla u \cdot \nabla u dx + 1/H_i^2 \int_{\Omega_i} |u|^2 dx.$$

Here H_i is the diameter of Ω_i. The weight originates from a dilation of a domain with diameter 1. We will use Lemma 2.2 to remove L_2-terms from full H^1-norms.

We will also use another variant of the Poincaré inequality; in fact we will use it only in the simple case when the region is a circular disk.

LEMMA 2.3 (Poincaré, L_1-variant). *Consider a domain $\Omega \subset \mathbb{R}^2$. Then*

$$\|u - \bar{u}_\Omega\|_{L_1(\Omega)} \leq \gamma(\Omega, 2) |\Omega|^{1/2} \|\nabla u\|_{L_1(\Omega)} \quad \forall u \in W^{1,1}(\Omega).$$

Proof. By the Cauchy–Schwarz inequality,

$$\|u - \bar{u}_\Omega\|_{L_1(\Omega)} \leq |\Omega|^{1/2} \|u - \bar{u}_\Omega\|_{L_2(\Omega)}.$$

The proof is then completed by using Lemma 2.1. ∎

We next give a definition of a John domain; see [14] and the references therein.

DEFINITION 2.4 (John domain). *A domain $\Omega \subset \mathbb{R}^n$ is a John domain if there exists a constant $C_J \geq 1$ and a distinguished central point $x_0 \in \Omega$ such that each $x \in \Omega$ can be joined to it by a rectifiable curve $\gamma : [0, 1] \to \Omega$ such that $\gamma(0) = x_0$, $\gamma(1) = x$, and* distance$(\gamma(t), \partial\Omega) \geq C_J^{-1} |x - \gamma(t)|$ *for all $t \in [0, 1]$.*

This condition can be viewed as a twisted cone condition. We note that certain snowflake curves with fractal boundaries are John domains and that the length of the boundary of a John domain can be arbitrarily much larger than its diameter; see Figure 5.1. We also note that, by restricting the refinement to the neighborhood of a point, the contribution to the length of the boundary from a small neighborhood of the point can be made to dominate. A John domain can have cusps facing inwards but not outwards; this means, however, that there can be no cusps on the interface since any cusp would face outwards for one of two neighboring subdomains; see [21, 22] for further information.

We note that, for any choice of the point x_0, there is a point $x \in \Omega$ at a distance of at least diameter$(\Omega)/2$. We find that diameter$(\Omega) \leq 2C_J r_\Omega$, where r_Ω is the radius of the largest ball inscribed in Ω and centered at x_0.

It is known that any simply connected plane domain with a finite Poincaré parameter $\gamma(\Omega, 2)$ is a John domain; see [7]. It is also known (see [2]) that any John domain has a bounded Poincaré parameter $\gamma(\Omega, n)$. Since we have been unable to find a simple estimate of $\gamma(\Omega, n)$ in terms of C_J in the literature, we have chosen to express our results in terms of both of these geometric parameters.

3. The algorithm, technical tools, and the main result. The domain $\Omega \subset \mathbb{R}^2$ of the elliptic problem is decomposed into nonoverlapping subdomains Ω_i, each of which is the union of elements, and with the finite element nodes on the boundaries of neighboring subdomains matching across the interface Γ, which is the union of the parts of the subdomain boundaries which are common to at least two subdomains. The interface Γ is composed of edges and vertices. An edge $\mathcal{E}^{ik}$ is an open subset of Γ, which contains the nodes which are shared only by the boundaries of a particular pair of subdomains Ω_i and Ω_k. The subdomain vertices $\mathcal{V}^\ell$ are end points of edges and are typically shared by more than two; see [17, Definition 3.1] for more details on how these sets can be defined for quite general situations. We denote the standard finite element space of continuous, piecewise linear functions on Ω_i by $V^h(\Omega_i)$ and assume that these functions vanish at the nodes on $\partial\Omega_i \cap \partial\Omega_D$.

We will view our algorithm as an additive Schwarz method, as in [28, Chapters 2 and 3], defined in terms of a set of subspaces. To simplify the discussion, we will use exact solvers for both the coarse problem and the local ones. All that is then required for the analysis of our algorithm is an estimate of a parameter in a stable decomposition of any function in the finite element space; see [28, Assumption 2.2 and Lemma 2.5]. Thus, we need to estimate C_0^2 in

$$a(u_0, u_0) + \sum_{j=1}^{N'} a_{\Omega'_j}(u_j, u_j) \leq C_0^2 a(u, u) \quad \forall u \in V^h,$$

for some decomposition $\{u_j\}$, such that

$$u = \sum_{j=0}^{N'} R_j^T u_j, \quad u_j \in V_j.$$

Here $a_{\Omega'_j}(u, v)$ is the bilinear form obtained by integrating only over the subdomain Ω'_j, and $R_j^T : V_j \longrightarrow V^h$ is an interpolation operator from the space of the jth subproblem V_j into the space V^h. The local spaces $V_j, j = 1, \ldots N'$, are defined as

$$V_j = V^h(\Omega'_j) \cap H_0^1(\Omega'_j), \tag{3.1}$$

except for subdomains with a boundary which intersects $\partial\Omega_N$. In the latter case, the functions of the local space are constrained to vanish only at the nodes of $\partial\Omega'_j \setminus \partial\Omega_N$. This is the same standard choice as in [28, Chapter 3]. We will assume that each Ω'_j has a diameter comparable to those of the subdomains Ω_i which it intersects.

Associated with each local space V_j is a projection P_j defined by

$$a_{\Omega'_j}(\tilde{P}_j u, v) = a(u, R_j^T v) \quad \forall v \in V_j, \text{ and } P_j = R_j^T \tilde{P}_j.$$

The coarse space V_0 is spanned by vertex and edge functions extended as discrete harmonic functions into the interiors of the subdomains Ω_i. The discrete harmonic extensions minimize the energy; see [28, section 4.4]. There will be one basis function $\theta_{\mathcal{V}^\ell}(x)$ for each subdomain vertex; it is the discrete harmonic extension of the interface values of the standard nodal basis function. For each edge $\mathcal{E}^{ik}$ there is also a basis function $\theta_{\mathcal{E}^{ik}}(x) \in V^h$, which equals 1 at all nodes on the edge and vanishes at all other interface nodes. The vertex and edge functions provide a partition of unity on the interface Γ. We will use a projection P_0 onto V_0, which is defined by

$$a(P_0 u, v) = a(u, v) \quad \forall v \in V_0. \tag{3.2}$$

The additive Schwarz operator, the preconditioned operator used in our iteration, is given by

$$P_{ad} = \sum_{j=0}^{N'} P_j.$$

By using [28, Lemmas 2.5 and 2.10], we find that the condition number $\kappa(P_{ad})$ of the additive Schwarz operator can be bounded by $(N^C + 1)C_0^2$, where N^C is the minimal number of colors required to color the subdomains Ω_j' such that no pair of intersecting subdomains have the same color.

The overlap between the subdomains is characterized by parameters δ_j, as in [28, Assumption 3.1]; δ_j is the minimum width of the subset Ω_{j,δ_j} of Ω_j' which is also covered by at least one neighboring overlapping subdomain.

We can now formulate our main result, which is also valid for compressible elasticity with piecewise constant Lamé parameters, with jumps only across the interface, provided that the coarse space is enriched to include all rigid body functions; see [8]. The extension to the case of linear elasticity requires a Korn inequality; see [1, 17], and [28, Chapter 8]. We note that there are also recent results on almost incompressible elasticity discretized by mixed finite elements with discontinuous pressure spaces; see [9].

THEOREM 3.1 (condition number estimate). *Let $\Omega \subset \mathbb{R}^2$ be partitioned into nonoverlapping subdomains Ω_i, which are John domains, each with a shape-regular triangulation. The condition number of our domain decomposition method then satisfies*

$$\kappa(P_{ad}) \leq C\,(1 + H/\delta)(1 + \log(H/h))^2,$$

where $C > 0$ is a constant which depends only on the John and Poincaré parameters of the subdomains, the number of colors required for the overlapping subdomains, and the shape regularity of the elements.

As in many domain decomposition results, H/h is shorthand for $\max_i(H_i/h_i)$, where h_i is the diameter of the smallest element of Ω_i. Similarly, H/δ is the largest ratio of H_i and the smallest of the δ_j of the overlapping subregions that intersect Ω_i.

The logarithmic bound of our main result can be improved to a first power if all of the subregions have boundaries which are uniformly Lipschitz. This is true, in particular, if they satisfy [28, Assumption 4.3]. If, in addition, the coefficients do not have any large jumps across the interface and the coarse space is enriched to contain all piecewise linear functions on a coarse mesh as in [28, Assumption 4.3], we can also eliminate the logarithmic factors altogether by using ideas from the proof of [28, Theorem 3.13].

To prove Theorem 3.1, we need two auxiliary results, in addition to Poincaré's inequality. The first is a discrete Sobolev inequality.

LEMMA 3.2 (discrete Sobolev inequality). *Let Ω_i be a John domain in the plane with diameter H. Then*

$$\|u - \bar{u}_{\Omega_i}\|^2_{L_\infty(\Omega_i)} \leq C(1 + \log(H/h))|u|^2_{H^1(\Omega_i)} \quad \forall u \in V^h(\Omega_i). \tag{3.3}$$

The constant $C > 0$ depends only on the John parameter $C_J(\Omega_i)$, the Poincaré parameter $\gamma(\Omega_i, 2)$, and the shape regularity of the elements.

We note that this lemma is well-known in the theory of iterative substructuring methods. Proofs for domains satisfying an interior cone condition are given in [4] and

in [6, section 4.9]; see also [3]. For a different proof, see [28, Lemma 4.15]. For a proof that this inequality is sharp, see [5].

In preparation for our proof of this result for John domains, we will formulate and prove a lemma which is directly inspired by a paper by Hajłasz [14]. We first introduce a set of open circular disks. We consider a John domain Ω_i with diameter H and with a triangulation using a mesh size h. Let $\gamma(t)$ be a John curve from a central point $x_0 \in \Omega_i$ to an arbitrary point x. A family of circular disks $B_i,\ i \geq 0$, is introduced as follows: the first disk is $B_0 := B(x_0, \text{dist}(x_0, \partial\Omega_i)/4)$, the open disk centered at x_0 and with radius $r_0 = \text{dist}(x_0, \partial\Omega_i)/4$. We will assume that x lies outside $2B_0$, the concentric disk with twice the radius of B_0; the other case is trivial. The other disks are defined similarly as $B_i := B(x_i, r_i)$, centered at x_i and with radius $r_i := |x - x_i|/4C_J, i \geq 1$. All of the x_i's lie on the John curve, and all of the B_i's are clearly subsets of Ω_i. Given B_i, we select $x_{i+1} \in \partial B_i$ as the last point of exit of $\gamma(t)$ from B_i.

Several properties of the B_i can now be established.

LEMMA 3.3. *There exists a constant $M = M(C_J)$ such that*

1. *no point in Ω_i belongs to more than M of the B_i (finite covering);*
2. *$|B_i \cup B_{i+1}| \leq M|B_i \cap B_{i+1}|$;*
3. *$r_i \to 0$ and $x_i \to x$ as $i \to \infty$;*
4. *the number of x_i that are at a distance larger than r from x can be estimated by $M \log(H/r)$.*

Proof. Our proof will rely heavily on arguments developed in [14], in particular, on the proof of Theorem 10 of that paper, which we will reproduce in part; see also references to earlier contributions in that paper.

Let a point y belong to $B_k, B_{k+1}, \ldots B_{k+p}$. Then

$$|x - y| \leq |x - x_{k+m}| + |x_{k+m} - y| \leq (4C_J + 1)r_{k+m}, \quad m = 0, \ldots, p.$$

Similarly,

$$4C_J r_{k+n} = |x - x_{k+n}| \leq |x - y| + |y - x_{k+n}| \leq |x - y| + r_{k+n}, \quad n = 0, \ldots, p.$$

Therefore, we have

$$(4C_J - 1)r_{k+n} \leq (4C_J + 1)r_{k+m}, \quad m, n = 0, \ldots, p.$$

Since no center of a disk belongs to any other disk, it is then easy to show that, for $m \neq n$,

$$|x_{k+n} - x_{k+m}| \geq (4C_J - 1)/(4C_J + 1)r_k, \tag{3.4}$$

which provides a uniform bound on p since only a finite number of such x_i can satisfy (3.4) while being within r_i of the common point y.

The second statement now follows easily by using the bound on the ratio of the radii of the two circles and elementary geometry.

We next consider a circle, centered at x, which covers all of Ω_i. We decompose this circle into annuli with a fixed ratio between the outer and inner circles of any annulus. It is easy to see that the number of x_i contained in each annulus will be uniformly bounded since the radii of the disks associated with an annulus are determined by the distance to x. This shows that $r_i \to 0$ and also that we can, by a simple covering argument, bound the number of x_i's that are at a distance larger than r from x by $M \log(H/r)$. ∎

Proof of Lemma 3.2. We will now confine x to be a centroid of an element K; by following [6, Formula (4.9.6)] we can then easily obtain our estimate for any $x \in K$. We denote by $N = N(h)$ the index of the first B_i which lies entirely inside K.

We will work with averages $\bar{u}_{B_i}$ of sufficiently smooth functions over the circular disks. We note that the average of a linear function over a circular disk B_i coincides with the value at its center if $B_i \subset K$.

Then, by following [14] and using the triangle inequality, we find that

$$|u(x_N) - \bar{u}_{B_0}| \le \sum_{i=0}^{N-1} |\bar{u}_{B_i} - \bar{u}_{B_{i+1}}|$$

$$\le \sum_{i=0}^{N-1} (|\bar{u}_{B_i} - \bar{u}_{B_i \cap B_{i+1}}| + |\bar{u}_{B_i \cap B_{i+1}} - \bar{u}_{B_{i+1}}|). \tag{3.5}$$

The expression $\bar{u}_{B_i} - \bar{u}_{B_i \cap B_{i+1}}$ is invariant under a shift of u by a constant. By replacing u by $u - \bar{u}_{\mathcal{B}_i}$, we therefore find that

$$|\bar{u}_{B_i} - \bar{u}_{B_i \cap B_{i+1}}| \le \frac{1}{|B_i \cap B_{i+1}|} \int_{B_i \cap B_{i+1}} |u - \bar{u}_{\mathcal{B}_i}|$$

$$\le \frac{1}{|B_i \cap B_{i+1}|} \int_{B_i} |u - \bar{u}_{\mathcal{B}_i}| = \frac{|B_i|}{|B_i \cap B_{i+1}|} \fint_{B_i} |u - \bar{u}_{B_i}|.$$

Here $\fint_{B_i} v$ denotes the average of v over the disk B_i. The second term of (3.5) can be estimated similarly, and we can now use the second statement of Lemma 3.3 to obtain

$$|u(x_N) - \bar{u}_{B_0}| \le (2M) \sum_{i=0}^{N-1} \fint_{B_i} |u - \bar{u}_{B_i}|.$$

By using Lemma 2.3 for the disks B_i, we obtain

$$\fint_{B_i} |u - \bar{u}_{B_i}| \le C \int_{B_i} \frac{|\nabla u(z)|}{r_i} dz.$$

We now use the Cauchy–Schwarz inequality and obtain

$$|u(x_N) - \bar{u}_{B_0}|^2 \le CN \sum_{i=0}^{N-1} \int_{B_i} |\nabla u(z)|^2 dz.$$

By using the finite covering property—the first statement of Lemma 3.3—this sum can be estimated by $\int_{\Omega_i} |\nabla u(z)|^2 dz$.

Given that B_N is the first disk which is a subset of K and that x_N lies on the boundary of B_{N-1}, we find that $\operatorname{dist}(x_N, \partial K) \le 2r_{N-1}$. We also know that

$$r_{N-1} \le \frac{4C_J + 1}{4C_J - 1} r_N \quad \text{and that} \quad r_N = \frac{|x - x_N|}{4C_J}.$$

Since

$$\operatorname{dist}(x, \partial K) \le |x_N - x| + \operatorname{dist}(x_N, \partial K),$$

we see that $|x - x_N|$ is bounded from below by $c(C_J)h$, where $c(C_J) > 0$ and h is the diameter of the element K. We can now use the logarithmic estimate of N—the fourth statement of Lemma 3.3—and find that

$$|u(x_N) - \bar{u}_{B_0}|^2 \leq C(1 + \log(H/h)) \int_{\Omega_i} |\nabla u(z)|^2 dz.$$

It is also elementary to estimate $|\bar{u}_{B_0} - \bar{u}_{\Omega_i}|$. We find that

$$|\bar{u}_{B_0} - \bar{u}_{\Omega_i}| \leq |B_0|^{-1} \|u - \bar{u}_{\Omega_i}\|_{L_1(B_0)} \leq |B_0|^{-1} \|u - \bar{u}_{\Omega_i}\|_{L_1(\Omega_i)}.$$

We complete the argument by using the Cauchy–Schwarz inequality, Lemma 2.2, and the fact that there is a bound on $|\Omega_i|$ in terms of $|B_0|$. We note that this term does not require any logarithmic factor.

We then have a bound for one point in the element K, and, as already indicated, we can easily estimate the difference between the values at any pair of points in the element K as in [6, Formula (4.9.6)]. ∎

A second important tool provides estimates of the edge functions.

LEMMA 3.4. *The edge function $\theta_{\mathcal{E}^{ik}}$ can be bounded as follows:*

$$\|\theta_{\mathcal{E}^{ik}}\|^2_{H^1(\Omega_i)} \leq C(1 + \log(H_i/h_i)), \tag{3.6}$$

and

$$\|\theta_{\mathcal{E}^{ik}}\|^2_{L_2(\Omega_i)} \leq CH_i^2(1 + \log(H_i/h_i)). \tag{3.7}$$

Here the constant C depends only on the John parameter $C_J(\Omega_i)$. We can remove the logarithmic factor from (3.7) *if all angles in the triangulation are acute, i.e.,*

$$\|\theta_{\mathcal{E}^{ik}}\|^2_{L_2(\Omega_i)} \leq CH_i^2. \tag{3.8}$$

A proof of this lemma is given in [16].

4. Proof of Theorem 3.1. As in many other proofs of results on domain decomposition algorithms, we will work with one subdomain Ω_i at a time. With local bounds, there are now no difficulties in handling variations of the coefficients across the interface.

We recall that the coarse space is spanned by the $\theta_{\mathcal{V}^\ell}$, the discrete harmonic extensions of the restrictions of the standard nodal basis functions to Γ, and the edge functions $\theta_{\mathcal{E}^{ik}}$. The coarse space component $u_0 \in V_0$ in the decomposition of an arbitrary finite element function $u(x)$ can be chosen as

$$u_0(x) \;=\; \sum_\ell u(\mathcal{V}^\ell)\theta_{\mathcal{V}^\ell}(x) + \sum_{ik} \bar{u}_{\mathcal{E}^{ik}} \theta_{\mathcal{E}^{ik}}(x). \tag{4.1}$$

Here $\bar{u}_{\mathcal{E}^{ik}}$ is the average of u over the edge. This interpolation formula is a two-dimensional analog of [28, Formula (5.13)].

Since the operator defined by (4.1) reproduces constants, we can replace u by $u - \bar{u}_{\Omega_i}$ and u_0 by $u_0 - \bar{u}_{\Omega_i}$. We now estimate the terms of the right-hand side of the resulting formula term by term. The energy of the vertex basis functions is uniformly bounded, and the values of $u(\mathcal{V}^\ell) - \bar{u}_{\Omega_i}$ are bounded by using Lemma 3.2. Turning to the edge terms, we use Lemma 3.4 to estimate the energy of the edge basis functions. The coefficient $\bar{u}_{\mathcal{E}^{ik}} - \bar{u}_{\Omega_i}$ is bounded by $\|u - \bar{u}_{\Omega_i}\|_{L_\infty(\Omega_i)}$. Thus,

$$|u_0|^2_{H^1(\Omega_i)} = |u_0 - \bar{u}_{\Omega_i}|^2_{H^1(\Omega_i)} \leq C(1 + \log(H/h))^2 |u|^2_{H^1(\Omega_i)}, \tag{4.2}$$

and we find that

$$a(u_0, u_0) \leq C(1 + \log(H/h))^2 a(u, u).$$

Remark 1. If the subdomains Ω_i have Lipschitz boundaries, we can estimate the edge averages by using the Cauchy–Schwarz inequality and an elementary trace theorem; see Nečas [23, Theorem 1.2]. This eliminates one of the two logarithmic factors.

Similarly, we can prove that

$$\|u - u_0\|^2_{L_2(\Omega_i)} \leq C(1 + \log(H/h))^2 H_i^2 |u|^2_{H^1(\Omega_i)}. \tag{4.3}$$

If all angles of the triangulation of Ω_i are acute, then by using (3.8) of Lemma 3.4 we can remove one of the logarithmic factors, and if the subdomain boundaries are Lipschitz, no logarithmic factors are required on the right-hand side of (4.3); see [28, Lemma 4.25] for a three-dimensional result for regular subdomains.

Remark 2. In the case of linear elasticity, we must include the restriction of all rigid body modes to the edges in the coarse space; see [19] or [27] for a discussion of the necessity of this null space property. In this case, we should extend the values given on the interface into the subdomains by solving homogeneous discrete elasticity problems.

We now turn to the estimate related to the local spaces. Again, we will carry out the work on one subdomain Ω_i at a time. Let $w := u - u_0$, and define a local term in the decomposition by $u_j = I^h(\theta_j w)$. We can borrow extensively from [28, sections 3.2 and 3.6]. Thus, I^h interpolates into V^h, and the $\theta_j \in R_j^T V_j$ provide a partition of unity. These functions vary between 0 and 1, and their gradients are bounded by $|\nabla \theta_j| \leq C/\delta_j$ and vanish outside the regions of overlap Ω_{j,δ_j} .

We note that the number of Ω_j' that intersect Ω_i is uniformly bounded; we will consider only the contribution from one of them, Ω_j'. As in our earlier work [28, section 3.5], the only term that requires a careful consideration is $\nabla \theta_j w$. We cover the set $\Omega_{j,\delta_j} \cap \Omega_i$ by square patches with sides on the order of δ_j and note that on the order of H_i/δ_j of them will suffice. Just as in the proof of [28, Lemma 3.10], we have

$$\int_{\Omega_i} |\nabla \theta_j w|^2 \leq C/\delta_j^2 (\delta_j^2 |w|^2_{H^1(\Omega_i)} + (H_i/\delta_j)\delta_j^2 \|w\|^2_{H^1(\Omega_i)}).$$

The proof is completed by combining this inequality with the bounds in (4.2) and (4.3).

Remark 3. Should the overlap between the subdomains be more generous in places, we can modify the relevant θ_j by making them vary from 0 to 1 over a distance of δ_j, effectively making the set Ω_{j,δ_j} more evenly wide.

5. Numerical examples. Numerical examples are presented in this section for the three different types of subdomains shown in Figure 5.1. Type 1 subdomains have a square geometry and are partitioned into square bilinear elements. Type 2 subdomains also consist of square bilinear elements, but their boundaries have a ragged shape. For type 3 subdomains, we employ equilateral linear triangular elements, and the edges of the subdomains have both straight-line and fractal segments. Numerical examples are also presented for subdomains obtained from a mesh partitioner; see Figure 5.5.

The main purpose of this first set of numerical examples is to verify certain estimates used in the proof of Theorem 3.1. For type 1 and 2 subdomains, the ratio

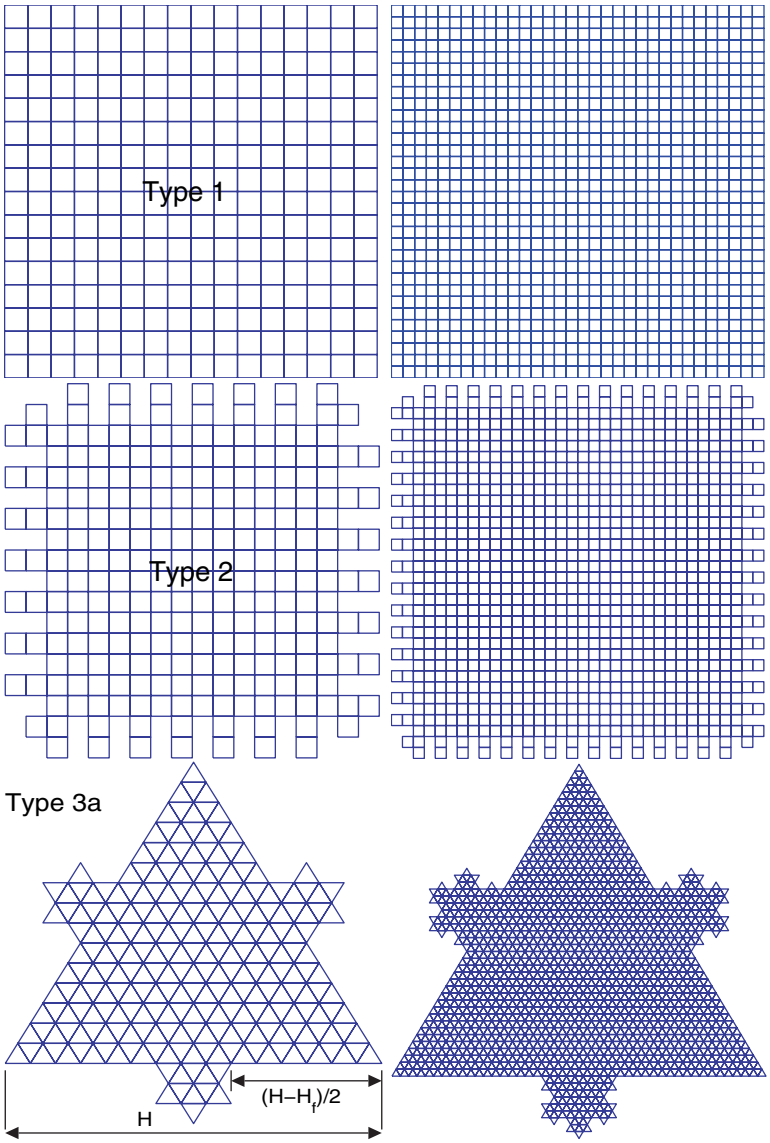

FIG. 5.1. *Three types of subdomains used in the numerical examples. Two levels of mesh refinement are shown, and the type* 3 *subdomains have a constant value of* $H/H_f = 5$. *For each refinement of type* 3 *subdomains, every element edge on the fractal part of the boundary is first divided into three shorter edges of* $1/3$ *the length. The middle one of these edges is then replaced by two other edges with which it forms an equilateral triangle. Thus, for fixed* H/H_f, *the length of the fractal part of the boundary increases by a factor of* $4/3$ *with each additional level of refinement.*

H/h is increased by a factor of 2 with each additional level of mesh refinement. At the ith ($i \geq 0$) level of refinement for type 3 subdomains,

$$H/h = (H/H_f)3^{i+1},$$

where $H/H_f = 5$ is fixed for type 3a subdomains and $H/H_f = 5 + 2i$ for type 3b. We note that in the asymptotic limit the fractal segment lengths grow by a factor of $4/3$ with each mesh refinement for both type 3 subdomains, whereas the straight-line

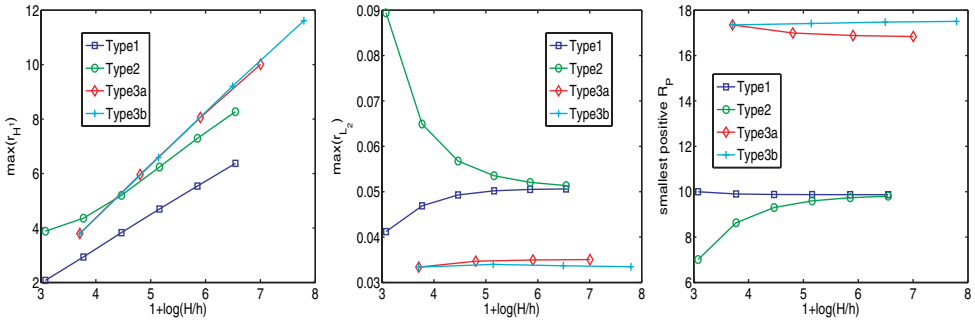

FIG. 5.2. *Rayleigh quotients for different subdomain types.*

segment lengths remain bounded. The primary difference between type 3a and 3b subdomains is that H/H_f is fixed in the former while H/H_f increases without bound in the latter. Thus, for type 3b subdomains, the protruding regions bounded by fractal segments decrease in area, while fractal segment lengths continue to increase with mesh refinement.

We recall the estimates (4.2) and (4.3) from the proof of Theorem 3.1 and consider the associated Rayleigh quotients

$$r_{H^1} = \frac{|u_0|^2_{H^1(\Omega_i)}}{|u|^2_{H^1(\Omega_i)}} \quad \text{and} \quad r_{L_2} = \frac{\|u - u_0\|^2_{L_2(\Omega_i)}}{|u|^2_{H^1(\Omega_i)}}$$

and also the Rayleigh quotient

$$r_P = \frac{|u|^2_{H^1(\Omega_i)}}{\|u\|^2_{L_2(\Omega_i)}}.$$

Stationary values of these Rayleigh quotients correspond to eigenvalues of generalized eigenproblems. For example, a stationary value of r_P is an eigenvalue λ of

$$K\phi = \lambda M\phi,$$

where K and M are the stiffness and mass matrices, respectively, of the finite element discretization of Ω_i with Neumann boundary conditions. We note in this case that the reciprocal of the smallest positive eigenvalue provides an estimate of the constant in Lemma 2.2. Maximum values of r_{H^1} and r_{L_2}, along with the smallest positive stationary value of r_P, are plotted versus $1 + \log(H/h)$ in Figure 5.2. We observe essentially the same dependence on $\log(H/h)$ for all four subdomain types. The maximum value of r_{H^1} appears to vary linearly with $\log(H/h)$ in the asymptotic limit, whereas the maximum value of r_{L_2} appears to be converging to a constant. This behavior is consistent with (4.2) and (4.3), but the estimates do not appear to be sharp for the different subdomain types and ranges of H/h considered. Consistent with the isoperimetric inequality, the rightmost plot in Figure 5.2 suggests that the smallest positive stationary value of r_P is uniformly bounded from below. We have yet to identify a subdomain shape with numerical behavior essentially different from the regular-shaped case.

The next group of numerical examples are for the domain decompositions shown in Figure 5.3. For type 3 subdomains, we fix $H/H_f = 5$. Homogeneous essential

	405	107	37	30.14	1,313,010

boundary conditions are applied to the bottom edge of each domain, and $\rho_i = 1$ for each subdomain. Preconditioned conjugate gradients are used to solve the associated linear systems to a relative residual tolerance of 10^{-8} for random right-hand sides. The amount of overlap is specified by the integer d_j. If $\Omega_{i,h}$ contains all of the nodes in the closure of Ω_i, then the nodes in overlapping subdomain Ω_i' are the union of $\Omega_{i,h}$ with all nodes a graph distance d_j or less from one or more nodes in $\Omega_{i,h}$. We note that nodes on the boundary of subdomain Ω_i are also contained in $\Omega_{i,h}$; the designation nonoverlapping refers to an element rather than to a nodal decomposition.

The numbers of iterations and condition number estimates from conjugate gradient iterations are reported in Table 5.1. The condition numbers from Table 5.1 are also plotted in Figure 5.4. Provided the overlap $d_j + 1$ remains in a fixed proportion to H/h, i.e., H/δ is constant, the growth in condition number appears to be bounded by $C(1 + \log(H/h))$ for all three subdomain types considered. These results are consistent with Theorem 3.1 but suggest that the estimate in the theorem may not be sharp.

The next group of examples is identical to the previous one, but we now set $\rho_i = 1$ for the bottom two rows of subdomains and $\rho_i = \sigma$ for the top two rows

of subdomains in Figure 5.3. Consistent with the theory, the results in Table 5.2 suggest that condition numbers are bounded independently of material property jumps between subdomains.

The final group of examples deals with subdomains generated by a mesh partitioner. Consider a graph in which each vertex of the graph corresponds to a finite element. There is an edge between two vertices in the graph if the corresponding finite elements share an edge, i.e., they have two nodes in common. The graph partitioning software Metis [15] is then used to decompose such graphs into N subdomains. Example domain decompositions obtained in this manner are shown in Figure 5.5 for the same square geometry as in the previous examples. Results in Table 5.3 suggest that using a general-purpose mesh partitioner to generate subdomains does not degrade performance significantly. Results are also shown in the table for problems in which

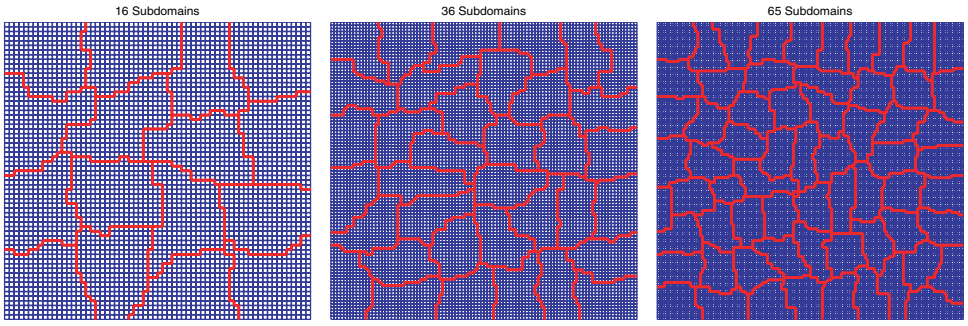

FIG. 5.5. *Sample domain decompositions obtained from a mesh partitioner.*

TABLE 5.3

Results for square subdomains and subdomains obtained from a mesh partitioner, where N designates the number of subdomains. In the upper right quadrant of the square domain $\rho(x) = \sigma$, and elsewhere $\rho(x) = 1$. For $N = 64$ and $H/h = 16$, the mesh partitioner generated one subdomain consisting of two disconnected components. These two components were treated as distinct subdomains resulting in $N = 65$. Results in the bottom part of the table are for a checkerboard arrangement of material properties.

				Square subdomains		Mesh partitioner

30		10^{-4}	3			36	16.69	6480
		1				34	13.09	
		10^{4}				43	24.44	

$\rho(x) = \sigma$ in the upper right quadrant of the square domain and $\rho(x) = 1$ elsewhere. The bottom part of Table 5.3 shows results for a 5×5 checkerboard where $\rho(x) = 1$ in red squares and $\rho(x) = \sigma$ in black squares. Except for the checkerboard problem decomposed into 25 square subdomains, the subdomain boundaries are not aligned with jumps in material properties. Although our theory does not apply to such cases, good performance is evident for both regular and irregular domain decompositions.

Acknowledgments. The authors are grateful to Professor Fanghua Lin of the Courant Institute for introducing the third author to John domains and Poincaré's

inequality for very general domains. They are also grateful to Professors Piotr Hajłasz and Marcus Sarkis for their interest and insight.

SMOOTHNESS ANALYSIS OF SUBDIVISION SCHEMES ON REGULAR GRIDS BY PROXIMITY*

PHILIPP GROHS†

Abstract. Subdivision is a powerful way of approximating a continuous object $f(x, y)$ by a sequence $((S^l p_{i,j})_{i,j\in\mathbb{Z}})_{l\in\mathbb{N}}$ of discrete data on finer and finer grids. The rule S that maps an approximation on a coarse grid $S^l p$ to the approximation on the next finer grid $S^{l+1}p$ is called a subdivision scheme. If for a given scheme S every continuous object $f(x, y)$ constructed by S is of C^k smoothness, then S is said to have smoothness order k. Subdivision schemes are well understood if they are linear. However, for various applications the data have values in a manifold which is not a vector space (for example, when our data are positions of a moving rigid body). Under these circumstances, subdivision schemes become nonlinear and much harder to analyze. One way of analyzing such schemes is to relate them to a given linear scheme and to establish a so-called proximity condition between the two schemes, which helps in proving that the two schemes share the same smoothness. The present paper uses this method to show the C^1-smoothness of a wide class of nonlinear multivariate schemes.

1. Introduction.

Subdivision is a powerful way of approximating a continuous object $f(x, y)$ by a sequence $((S^l p_{i,j})_{i,j\in\mathbb{Z}})_{l\in\mathbb{N}}$ of discrete data on finer and finer grids. The rule S that maps an approximation on a coarse grid $S^l p$ to the approximation on the next finer grid $S^{l+1}p$ is called a subdivision scheme. Generally this rule depends on l but we will assume that it is always the same rule. The subdivision scheme is then called stationary; this is the class of schemes in which we are interested. If for a given scheme S every continuous object $f(x, y)$ constructed by S is of C^k-smoothness, we say that the smoothness order of S is k. The fact that in this introduction we use a bivariate function $f(x, y)$ is immaterial; this paper is concerned with the general multivariate case.

To store a continuous object which is constructed via subdivision, one needs only to store a coarse approximation and the subdivision scheme constructing the object. This fact makes subdivision a valuable tool in computer-aided geometric design. Another application of subdivision schemes is data compression and noise removal via wavelet-type transforms associated with the subdivision scheme [2, 3]. All of these concepts can be applied to manifold-valued data using nonlinear subdivision schemes if the underlying nonlinear scheme is of sufficient smoothness [10, 4].

Subdivision schemes are especially well understood if they are linear. However, for various applications the data have values in a manifold which is not a vector space (for example, when our data are positions of a moving rigid body). Under these circumstances, subdivision schemes become nonlinear and much harder to analyze. One way of analyzing such schemes is to relate them to a given linear scheme and to establish

†Institut für Diskrete Mathematik und Geometrie, Technische Universität Wien, Wiedner Hauptstr. 8-10/104, A-1040 Wien, Austria (grohs@geometrie.tuwien.ac.at).

a so-called proximity condition between the two schemes, which helps in proving that the two schemes share the same smoothness. In [12, 14] this method has been used to prove smoothness properties for certain nonlinear curve schemes. The problem in proving higher-order smoothness is to verify sufficient proximity conditions. In [15] it has been shown that on the sphere and related manifolds any univariate nonlinear scheme that is constructed from an interpolatory linear scheme via closest-point projection shares the smoothness of the linear scheme.

All of these results apply only to univariate schemes. The present paper treats the general multivariate case and shows the C^1-smoothness of a wide class of nonlinear multivariate schemes. We follow the lines of [12] and also remove a condition on the decay rates of the linear scheme needed there.

1.1. An example: The Kobbelt scheme and its log-exp analogue. First we describe, as an example, the construction of a nonlinear subdivision scheme for matrix groups which is analogous to a well-known interpolatory linear scheme (we construct the log-exp version of Kobbelt's scheme [8]).

The Kobbelt scheme for regular input data is the bivariate tensor product rule of the interpolatory four-point scheme [5] with itself. It is defined as

$$\begin{aligned}
Sp_{2i,2j} &= p_{i,j}, \quad Sp_{2i+1,2j} = p_{i,j} - \frac{1}{16}(v_{-1,0} + 9v_{1,0} - v_{2,0}),\\
Sp_{2i,2j+1} &= p_{i,j} - \frac{1}{16}(v_{0,-1} + 9v_{0,1} - v_{0,2}),\\
Sp_{2i+1,2j+1} &= p_{i,j} + \frac{1}{256}(v_{2,2} - 9v_{2,1} - 9v_{2,0} + v_{2,-1} - 9v_{1,2} + 81v_{1,1} + 81v_{1,0} -\\
&\qquad 9v_{1,-1} - 9v_{0,2} + 81v_{0,1} - 9v_{0,-1} + v_{-1,2} - 9v_{-1,1} - 9v_{-1,0} + v_{-1,-1}),
\end{aligned}$$

where $v_{k,l} := p_{i+k,j+l} - p_{i,j}$ is the vector pointing from $p_{i,j}$ to $p_{i+k,j+l}$ and $(Sp_{i,j})_{i,j\in\mathbb{Z}}$ means the grid function produced from $(p_{i,j})_{i,j\in\mathbb{Z}}$ via subdivision.

The rules that define the usual Kobbelt scheme are all of the form

$$Sp_{2i+k,2j+l} = p_{i,j} + \sum_{r,s} \lambda^{k,l}_{r,s} v_{r,s}, \tag{1.1}$$

where the vector $\sum_{r,s} \lambda^{k,l}_{r,s} v_{r,s}$ is added to the point $p_{i,j}$. In a matrix group, this point-vector addition of a point p and a vector v is realized with the matrix-exponential function exp, as $p \cdot \exp(v)$. The vector pointing from a group element p to the group element q is given by

$$\overrightarrow{pq} = \log(p^{-1}q). \tag{1.2}$$

We can thus define an analogue of the Kobbelt scheme which works in matrix groups as follows: for the rule given by (1.1), we define its log-exp analogue as

$$Tp_{2i+k,2j+l} = p_{i,j} \cdot \exp\left(\sum_{r,s} \lambda^{k,l}_{r,s} v_{r,s}\right), \quad v_{r,s} = \log(p_{i,j}^{-1} p_{i+u,j+v}).$$

To what extent does this nonlinear scheme share the properties of the Kobbelt scheme? It is certainly interpolatory, but does it converge? If so, does it produce smooth limit functions? As we will see, the answer to both questions is yes.

1.2. Other ways of constructing nonlinear analogues of linear schemes. Aside from the log-exp approach there are two other nonlinear variants that we want to study. They both rely on the observation in [14] that every affinely invariant scheme can be expressed in terms of the affine averaging operator

$$\mathrm{av}_\lambda(x,y) = \lambda x + (1-\lambda)y, \quad \lambda \in \mathbb{R}.$$

In Euclidean space $\mathbb{R}^n$, the shortest path from a point x to another point y is described by the curve $c(t) := tx + (1-t)y$. We see that $\mathrm{av}_\lambda(x,y)$ is given by $c(\lambda)$. This can be generalized to surfaces in $\mathbb{R}^n$, and Riemannian manifolds as well: in such spaces geodesics play the role of straight lines, and if we define the *geodesic average* $\text{g-av}_\lambda(x,y) := c(\lambda)$, where c is the shortest geodesic, with $c(0) = x$ and $c(1) = y$, we can replace every ocurrence of the av_λ-operator by the g-av_λ-operator. This gives us an analogue of a linear scheme that assumes its values on a given manifold. A unique shortest geodesic connecting two points need not always exist. However, it always exists locally, and, if the distances between consecutive points in the grid function we want to subdivide are sufficiently small, we will not run into any problems (cf. the discussion in [12]).

Another approach is to apply a projection operator to the averages. A projection operator for a surface $\mathcal{M} \subseteq \mathbb{R}^n$ in our setting is a smooth function $P : \mathbb{R}^n \to \mathcal{M}$ with the property that $P(x) = x$ for all $x \in \mathcal{M}$. For the nonlinear scheme we apply the operator $P \circ \mathrm{av}_\lambda(x,y)$ instead of $\mathrm{av}_\lambda(x,y)$. This defines the *projection analogue* of a linear scheme.

2. Outline of this paper. In this work we analyze nonlinear subdivision schemes that satisfy a proximity condition with a certain linear scheme and show that if the linear scheme is convergent (resp., smooth), then the nonlinear scheme is convergent (resp., smooth). In section 3 we review some basic concepts of subdivision. Section 4 derives results of the linear theory needed for our analysis. Section 5 shows that if a scheme is in proximity with a linear convergent scheme, it is convergent. Section 6 does the same with smoothness. In section 7 we verify that a proximity condition holds for various nonlinear analogues of linear schemes. Section 8 summarizes the results, until then valid only for surfaces and matrix groups, and extends them to abstract Lie groups and Riemannian manifolds.

3. Preliminaries. Let $(p_\gamma)_{\gamma\in\mathbb{Z}^s}$ be a bounded grid function of points $p_\gamma \in \mathbb{R}^n$ for $n \in \mathbb{N}$. In that case $(p_\gamma)_{\gamma\in\mathbb{Z}^s}$ can be viewed as an element of $(l^\infty(\mathbb{Z}^s))^n$. A subdivision scheme on a regular grid is a mapping that maps such a grid function to a new grid function $(Sp_\gamma)_{\gamma\in\mathbb{Z}^s}$ under the condition that there exists an integer $N > 1$ with the property that for all grid functions p, q with $q_\gamma = p_{\gamma+\delta_i}$, where δ_i is the ith canonical basis vector in $\mathbb{Z}^s$, the relation $(Sq)_\gamma = (Sp)_{\gamma+N\delta_i}$ holds. N is called the dilation factor of S (typically $N = 2$). The case $s = 1$ corresponds to curve subdivison and $s = 2$ to surface subdivision as in our example in section 1. A subdivision scheme S is called linear if S is a linear mapping. It is easy to see that for a linear scheme there exists a sequence $(S_\gamma)_{\gamma\in\mathbb{Z}^s}$ with the property

$$(Sp)_\gamma = \sum_{\beta\in\mathbb{Z}^s} S_{\gamma-N\beta} p_\beta.$$

This sequence is called the mask of S. We consider only subdivision schemes with a finite mask, meaning that $S_\gamma \neq 0$ only for a finite number of γ's. Thus the assumption

that the grid function $(p_\gamma)_{\gamma\in\mathbb{Z}^s}$ is bounded is not actually a restriction, because a finite mask means that the subdivison operator is local.

If the elements S_γ of the mask are $n\times n$ matrices, one speaks of matrix subdivision schemes, and if they are scalars, i.e., elements of $\mathbb{R}$, we speak of scalar subdivision schemes. In this paper we are concerned only with the analysis of scalar subdivision schemes.

An interpretation of the definition of a subdivision scheme would be to view $(p_\gamma)_{\gamma\in\mathbb{Z}^s}$ as a discrete approximation of some continuous data defined in some domain in $\mathbb{R}^s$. The subdivision operator S maps this approximation to a finer approximation on the grid $\frac{1}{N}\mathbb{Z}^s$, S^2 maps the approximation on the even finer grid $\frac{1}{N^2}\mathbb{Z}^s$, and so on. If this sequence of approximations converges to a function defined on $\mathbb{R}^s$, the subdivision scheme is called convergent or, more precisely (see [1, Definition 2.1]), the following.

DEFINITION 3.1. *Let $S : (l^\infty(\mathbb{Z}^s))^n \to (l^\infty(\mathbb{Z}^s))^n$ be a subdivision scheme with dilation factor N. S is called convergent if for any $p \in (l^\infty(\mathbb{Z}^s))^n$ there exists a continuous function $f : \mathbb{R}^s \to \mathbb{R}^n$ with*

$$\lim_{k\to\infty} \max_{\gamma\in\mathbb{Z}^s} |(S^k p)_\gamma - f(N^{-k}\gamma)| = 0,$$

where $|\cdot|$ is a fixed norm on $\mathbb{R}^n$. Moreover, if always $f \in C^k(\mathbb{R}^s, \mathbb{R}^n)$, S is called C^k, $k \in \mathbb{N}$.

Clearly this definition is equivalent to saying that the functions $\mathcal{F}_l(S^l p)$, given by the piecewise s-multilinear interpolation of $S^l p$ on $\frac{1}{N^l}\mathbb{Z}^s$, converge uniformly to f, as $l \to \infty$.

4. Linear theory. We review some results from the theory of linear schemes. For further information concerning linear schemes, the reader may consult [1, 6, 17, 7]. We let $n = 1$; i.e., the points p_γ are elements of $\mathbb{R}$. This is no restriction, since convergence and smoothness properties can be treated componentwise in the case of scalar linear schemes. In the univariate setting, the (unique) difference operator plays an important role. On grids we look at all of the difference operators in the different directions on the grid simultaneously. This allows us to define derived schemes as discrete analogues of the left derivatives.

Let Δ_i be the operator that maps grid function $(p_\gamma)_{\gamma\in\mathbb{Z}^s}$ to the grid function $(p_\gamma - p_{\gamma-\delta_i})_{\gamma\in\mathbb{Z}^s}$, where δ_i denotes the ith canonical basis vector in $\mathbb{Z}^s$.

DEFINITION 4.1. *For $p \in l^\infty(\mathbb{Z}^s)$ we define $\mathbf{\Delta} p \in (l^\infty(\mathbb{Z}^s))^s$ as*

$$\mathbf{\Delta} p := \big(\Delta_1 p\ ,\ \Delta_2 p\ ,\ \dots\ ,\ \Delta_s p\big)^T.$$

For a subdivision scheme to converge, we need the distance between consecutive points to become small.

DEFINITION 4.2. *$D(p) := \sup_{\gamma\in\mathbb{Z}^s} \|\mathbf{\Delta} p_\gamma\|$, where $\|\mathbf{\Delta} p_\gamma\| := \max_{i=1,\dots,s} |\Delta_i p_\gamma|$.*

While a linear scheme is always defined for all input data, this is no longer true for a nonlinear subdivision scheme T, which is, in general, defined only on certain grid functions with values in some subset $\mathcal{D}(T) \subseteq \mathbb{R}^n$ and maps such grid functions to grid functions with values in $\mathcal{D}(T)$. The definition of convergence and smoothness is the same as in the linear case; it has to hold only for all grid functions where T is defined. Typically the set $\mathcal{D}(T)$ will be a manifold.

The mth derived scheme of a linear multivariate subdivision scheme S is defined by the relation

$$S^{[m]}\mathbf{\Delta}^m = N^m \mathbf{\Delta}^m S \quad \text{for } m \geq 1, \quad \text{and } S^{[0]} = S.$$

Note that for $s > 1$ the derived schemes are always matrix subdivision schemes. It is possible to characterize the smoothness of a linear subdivision scheme by the decay of the derived schemes.

THEOREM 4.3. *Let S be a linear subdivision scheme. If there exists a constant $\mu_0 < 1$ such that for some $l \in \mathbb{Z}^+$*

$$D(S^l p) \le \mu_0 D(p) \text{ for all } p, \tag{4.1}$$

then S is convergent. Convergence of S implies the existence of $S^{[1]}$.

If in addition there exists a constant $\mu_1 < 1$ with

$$D((S^{[1]})^l \mathbf{\Delta} p) \le \mu_1 D(\mathbf{\Delta} p) \text{ for all } p, \tag{4.2}$$

then S is C^1.

The sufficient conditions (4.1) and (4.2) are almost necessary for convergence (resp., smoothness).

THEOREM 4.4 (see [6]). *Let S be a convergent linear subdivison scheme. Then $S^{[1]}$ exists and there is $l \in \mathbb{Z}^+$ such that S^l satisfies* (4.1) *with $\mu_{0l} = \frac{1}{N^l}\|(S^{[1]})^l|_{\mathbf{\Delta}}\| < 1$. If in addition S is C^1 and $S^{[2]}$ exists, then there exists $l \in \mathbb{Z}^+$ such that $(S^{[1]})^l$ satisfies* (4.2) *with $\mu_{1l} = \frac{1}{N^l}\|(S^{[2]})^l|_{\mathbf{\Delta}^2}\| < 1$.*

Remark 4.5. With the notation of Theorem 4.4 we may assume that there exists a constant A such that $\|(S^{[1]})^k|_{\mathbf{\Delta}}\| < A$ for all $k \in \mathbb{Z}^+$. This follows from the fact that the derived scheme $S^{[1]}$ converges to the first derivative of the limit function of S. This immediately implies that the spectral radius

$$\rho_\infty\big((S^{[1]})|_{\mathbf{\Delta}}\big) = \liminf_{k\to\infty} \|(S^{[1]})^k|_{\mathbf{\Delta}}\|^{1/k} = 1. \tag{4.3}$$

Remark 4.6. The existence of the first derived scheme $S^{[1]}$ is equivalent to a purely algebraic condition on the mask of S, namely,

$$\sum_{\beta\in\mathbb{Z}^s} S_{\gamma - N\beta} = 1 \quad \text{for all } \gamma \in \mathbb{Z}^s.$$

This property of S is in the literature usually referred to as *reproduction of constants*.

For a linear convergent scheme S, the rate of convergence is known (compare [6, Proposition 6.7]):

LEMMA 4.7. *Let S be a linear subdivision scheme, and assume that $S^{[1]}$ exists. Then there exists a constant $C > 0$ with*

$$\|\mathcal{F}_{j+1}(Sp) - \mathcal{F}_j(p)\|_\infty \le C D(p) \tag{4.4}$$

and

$$\sup_{\gamma\in\mathbb{Z}^s} \inf_{\beta\in\mathbb{Z}^s} |(Sp)_\gamma - p_\beta| \le C D(p). \tag{4.5}$$

If in addition $S^{[2]}$ exists, then there exists another constant $C > 0$ with

$$\|\mathcal{F}_{j+1}(S^{[1]}\mathbf{\Delta} p) - \mathcal{F}_j(\mathbf{\Delta} p)\|_\infty \le C D(\mathbf{\Delta} p). \tag{4.6}$$

Here, $\mathcal{F}_j$ is applied componentwise.

5. Convergence and well definedness. In this section we show that a nonlinear scheme is convergent if it satisfies a proximity condition with a linear and convergent scheme. Since most of the nonlinear schemes we are interested in are not defined for all input data, we have to restrict our analysis to initial data defined in certain subsets of $\mathbb{R}^n$. The following type of subsets is useful.

DEFINITION 5.1. *$\mathcal{P}_{M,\varepsilon}$ denotes the set of grid functions p, whose values p_γ are contained in a subset M of the domain of definition $\mathcal{D}(T)$ of T and which fulfill the condition $D(p) \leq \varepsilon$.*

We want to obtain convergence and smoothness properties for nonlinear schemes derived from linear ones, and we would like these properties to be directly related to the respective properties of the original linear schemes. For this purpose we need a condition that ensures that the nonlinear scheme is not too far apart from the linear scheme. As we will see, the following proximity condition serves us well. The next definition is the multivariate analogue of Definition 7 in [12].

DEFINITION 5.2. *Let S and T be two subdivision schemes. We say that S and T satisfy a proximity condition for the class $\mathcal{P}_{M,\varepsilon}$ of order $\alpha > 1$ if there is a constant C such that, for all $p \in \mathcal{P}_{M,\varepsilon}$,*

$$\sup_{\gamma \in \mathbb{Z}^s} |Sp_\gamma - Tp_\gamma| \leq C \cdot D(p)^\alpha. \tag{5.1}$$

From Theorem 4.4 we know that for a convergent linear scheme S there exists a contractivity constant $\mu_0 < 1$, with

$$D(S^l p) \leq \mu_0 D(p) \tag{5.2}$$

for some $l \in \mathbb{Z}^+$. The idea about how to prove that a nonlinear scheme T in proximity with a linear convergent scheme S is convergent is as follows: from the proximity condition we show that if S satisfies (5.2), i.e., is convergent, then T satisfies a similar condition. After that we show that if such a condition is satisfied for a nonlinear scheme T in proximity with a linear scheme S, the scheme T is itself convergent. We make the following definition.

DEFINITION 5.3. *A subdivision scheme T is said to satisfy a convergence condition with factor $\mu_0 < 1$ and the class $\mathcal{P}_{M,\varepsilon}$ if there exists $l \in \mathbb{Z}^+$ such that*

$$D(T^l p) \leq \mu_0 D(p) \tag{5.3}$$

for all initial data $p \in \mathcal{P}_{M,\varepsilon}$.

The following central lemma shows that a nonlinear scheme T satisfies a convergence condition if it is in proximity with a convergent linear scheme. Unfortunately, the proof of (5.3) requires us to deal with the additional difficulty that choosing initial data in a set $\mathcal{P}_{M,\varepsilon}$ will result in data with values no longer contained in M. We are therefore forced to employ various different sets of type $\mathcal{P}_{M,\varepsilon}$. Essentially we must show that it is possible to restrict the domain of definition of T a little bit such that all iterates of T are well defined and additionally (5.3) is valid.

In what follows we denote the constant from (4.5) by C'. Recall that the subdivision scheme T maps input data with values in its domain of definition $\mathcal{D}(T)$ to data with values in $\mathcal{D}(T)$. We use the notation $\rho \cdot B$ for the ball of radius ρ, and $M + \rho \cdot B$ is a Minkowski sum; i.e., the set of points whose distance from M does not exceed ρ (w.r.t. the norm $|\cdot|$ on $\mathbb{R}^n$).

LEMMA 5.4. *Let S and T satisfy the proximity condition as in Definition 5.2 for input data in $\mathcal{P}_{M,\varepsilon}$. Assume that S is linear and satisfies a convergence condition*

with factor $\mu_0 < 1$. Then for any $M' \subseteq M$ which stays away from the boundary of M, i.e., $\exists\, \rho > 0$ with

$$(M' + \rho \cdot B) \cap \mathcal{D}(T) \subseteq M, \tag{5.4}$$

there is $\delta \in (0, \varepsilon)$ and $\overline{\mu_0} < 1$ such that data $T^l p$ are contained in $\mathcal{P}_{M,\delta}$ for all l and T satisfies a convergence condition with factor $\overline{\mu_0}$ for input data p in $\mathcal{P}_{M',\delta}$. By choosing δ small enough, we can achieve that $\overline{\mu_0} - \mu_0$ is arbitrarily small.

Proof. To make the proof easier to follow, we assume without loss of generality that the convergence condition for S is satisfied with $l = 1$. We choose $\delta \in (0, \varepsilon)$ small enough to satisfy the following two conditions:

$$\overline{\mu_0} := \mu_0 + 2C\delta^{\alpha-1} < 1 \tag{5.5}$$

and

$$\delta \left(\frac{C'}{1 - \overline{\mu_0}} + \frac{C\delta^{\alpha-1}}{1 - \overline{\mu_0}^{\alpha}} \right) < \rho. \tag{5.6}$$

Condition (5.6) will ensure that the sequence $T^l p$ stays within M. We show that for $p \in \mathcal{P}_{M',\delta}$ the norm of the difference sequence $D(Tp)$ can be estimated by $\overline{\mu_0} D(p)$:

$$D(Tp) \le D(Sp - Tp) + D(Sp) \le 2 \sup_{\gamma \in \mathbb{Z}^s} |Sp_\gamma - Tp_\gamma| + D(Sp).$$

Since S is convergent with contractivity constant μ_0 and T is in proximity with S, we can deduce that

$$D(Tp) \le 2CD(p)^\alpha + \mu_0 D(p) \le D(p)(\mu_0 + 2C\delta^{\alpha-1}) = \overline{\mu_0} D(p). \tag{5.7}$$

Now we show that Tp is still contained in $\mathcal{P}_{M,\delta}$:

$$\begin{aligned} \sup_{\gamma \in \mathbb{Z}^s} \inf_{x \in M'} |Tp_\gamma - x| &\le \sup_{\gamma \in \mathbb{Z}^s} \inf_{\beta \in \mathbb{Z}^s} |Tp_\gamma - p_\beta| \\ &\le \sup_{\gamma \in \mathbb{Z}^s} \inf_{\beta \in \mathbb{Z}^s} (|Tp_\gamma - Sp_\gamma| + |Sp_\gamma - p_\beta|) \\ &\le \sup_{\gamma \in \mathbb{Z}^s} |Sp_\gamma - Tp_\gamma| + C'D(p) \le CD(p)^\alpha + C'D(p) < \rho. \end{aligned}$$

By (5.4) and the fact that $Tp_\gamma \in \mathcal{D}(T)$, the grid function Tp takes values in M. Together with (5.7) we have $Tp \in \mathcal{P}_{M,\delta}$.

Now we use induction on l to prove that $D(T^l p) \le \overline{\mu_0}^l D(p)$ and that $T^l p \in \mathcal{P}_{M,\delta}$ under the assumption that $T^{l-1} p \in \mathcal{P}_{M,\delta}$ and $D(T^{l-1} p) \le \overline{\mu_0}^{l-1} D(p)$. First,

$$D(T^l p) \le D(T^l p - ST^{l-1} p) + D(ST^{l-1} p) \le 2 \sup_{\gamma \in \mathbb{Z}^s} |ST^{l-1} p_\gamma - TT^{l-1} p_\gamma| + D(ST^{l-1} p).$$

By the proximity condition and the convergence condition satisfied by S, we get

$$D(T^l p) \le 2CD(T^{l-1} p)^\alpha + \mu_0 D(T^{l-1} p) \le \overline{\mu_0} D(T^{l-1} p) \le \overline{\mu_0}^l D(p).$$

It remains to show that $T^l p \in \mathcal{P}_{M,\delta}$ (for initial data $p \in \mathcal{P}_{M',\delta}$). To this end we

estimate

$$\begin{aligned}\sup_{\gamma\in\mathbb{Z}^s}\inf_{x\in M'}|T^l p_\gamma - x| &\le \sup_{\gamma\in\mathbb{Z}^s}\inf_{\beta\in\mathbb{Z}^s}|T^l p_\gamma - p_\beta| \le \sum_{j=1}^{l}\sup_{\gamma\in\mathbb{Z}^s}\inf_{\beta\in\mathbb{Z}^s}|T^j p_\gamma - T^{j-1}p_\beta| \\ &\le \sum_{j=1}^{l}\sup_{\gamma\in\mathbb{Z}^s}\inf_{\beta\in\mathbb{Z}^s}(|T^j p_\gamma - ST^{j-1}p_\gamma| + |ST^{j-1}p_\gamma - T^{j-1}p_\beta|) \\ &\le \sum_{j=1}^{l} CD(T^{j-1}p)^\alpha + C'D(T^{j-1}p) \\ &\le \sum_{j=0}^{l-1} C\overline{\mu_0}^{j\alpha}D(p)^\alpha + C'\overline{\mu_0}^{j}D(p) \\ &< \rho.\end{aligned}$$

The last estimate follows from summing the geometric series and using condition (5.6) on δ.

The same reasoning as for the case $l = 1$ above and the assumption (5.4) establishes the fact that $T^l p \in \mathcal{P}_{M,\delta}$, and the induction is complete.

The statement regarding the difference $\overline{\mu_0} - \mu_0$ is immediate. ∎

PROPOSITION 5.5. *Under the assumptions of Lemma* 5.4*, the subdivision scheme* T *is convergent for all initial data* $p \in \mathcal{P}_{M',\delta}$.

Proof. We have

$$\begin{aligned}\|\mathcal{F}_{j+1}(T^{j+1}p) - \mathcal{F}_j(T^j p)\|_\infty &\le \|\mathcal{F}_{j+1}(T^{j+1}p) - \mathcal{F}_{j+1}(ST^j p)\|_\infty \\ &\quad + \|\mathcal{F}_{j+1}(ST^j p) - \mathcal{F}_j(T^j p)\|_\infty \\ &\le C\cdot D(T^j p)^\alpha + C'\cdot D(T^j p)\end{aligned}$$

by the proximity condition and by (4.4). By Proposition 5.4, this expression is bounded by a factor times μ^j, with $\mu < 1$. It follows that $T^j p$ is a Cauchy sequence with respect to the sup norm. ∎

6. Smoothness. In this section we show that a nonlinear scheme that is in proximity with a linear smooth scheme is itself smooth. To facilitate our analysis, we assume that the second derived scheme exists, which is not really a restriction (see [1]). We begin with a sufficient condition for a possibly nonlinear subdivision scheme to converge to a smooth limit (see [7] for a proof).

LEMMA 6.1. *Let* T *be a subdivision scheme and* $p^l := T^l p$*. Assume that* $\mathcal{F}_l(p^l)$ *converges to a continuous function* f *in the sup norm. If* $g_l := \mathcal{F}_l(N^l\mathbf{\Delta}p^l)$ *is a Cauchy sequence and* $\lim_{l\to\infty} D(N^l\mathbf{\Delta}p^l) = 0$*, then* f *is* C^1.

DEFINITION 6.2. *A subdivision scheme* T *is said to satisfy a mixed smoothness condition if* T *satisfies a convergence condition and there is* $\mu_1 < 1$ *such that*

$$D(N\mathbf{\Delta}T^l p) \le \mu_1^l P_1(l)D(p) \text{ for all } l, p, \tag{6.1}$$

where P_1 *is a linear function with positive coefficients.*

LEMMA 6.3. *Suppose that* S *and* T *satisfy a proximity condition for* $p \in \mathcal{P}_{M,\varepsilon}$ *with* $\alpha > 1$ *and that* S *satisfies a smoothness condition with factors* μ_0, μ_1 *such that*

$$\mu_0 < \mu_0^* = N^{-1/\alpha}, \quad \mu_1 < 1. \tag{6.2}$$

Then there is a $\delta > 0$ such that T satisfies a mixed smoothness condition with factors $\overline{\mu_0}, \overline{\mu_1}$ which also satisfy (6.2)*, for all $p \in \mathcal{P}_{M',\delta}$, where M' is a subset of M satisfying* (5.4).

Proof. By Proposition 5.4 we know that there exists a $\delta > 0$ and a $\overline{\mu_0} < 1$ so that

$$D(T^l p) \le \overline{\mu_0}^l D(p) \text{ for } D(p) < \delta.$$

We want to show that there is a $\overline{\mu_1} < 1$ and a linear polynomial with positive coefficients $\overline{P_1}$ such that $D(N^l \mathbf{\Delta} T^l p) \le \overline{\mu_1}^l \overline{P_1}(l) D(p)$, for all p with $D(p) < \delta$. We write $d_l := D(N^l \mathbf{\Delta} T^l p)$ and $q := T^{l-1} p$. Next we proceed just as in the proof of Theorem 5.4 and make use of the fact that $\sup_{\gamma \in \mathbb{Z}^s} \|\mathbf{\Delta} S q_\gamma - \mathbf{\Delta} T q_\gamma\| \le 2 \sup_{\gamma \in \mathbb{Z}^s} |Sq - Tq|$.

$$\begin{aligned} d_l = D(N^l \mathbf{\Delta} T q) &\le D(N^l \mathbf{\Delta} S q) + 2N^l \sup_{\gamma \in \mathbb{Z}^s} \|\mathbf{\Delta} S q_\gamma - \mathbf{\Delta} T q_\gamma\| \\ &\le D(N^l \mathbf{\Delta} S q) + 4N^l \sup_{\gamma \in \mathbb{Z}^s} |S q_\gamma - T q_\gamma| \\ &\le \mu_1 D(N^{l-1} \mathbf{\Delta} q) + 4N^l C D(q)^\alpha, \end{aligned} \tag{6.3}$$

because of the smoothness condition satisfied by S and the proximity condition. We can estimate the last summand as follows:

$$4N^l C D(q)^\alpha \le 4N^l C (\overline{\mu_0}^{l-1} D(p))^\alpha = 4NC (N \overline{\mu_0}^\alpha)^{l-1} D(p)^\alpha.$$

Because of Proposition 5.4, (6.2), and the fact that we can make $D(p)$ arbitrarily small, we can choose $\overline{\mu_0} := \overline{\mu_0} \le N^{-1/\alpha} < 1$, and thus

$$4CN^l D(q)^\alpha \le \tilde{\mu_1}^{l-1} D(p)^\alpha P_0,$$

with a positive constant P_0. Substituting into (6.3) yields

$$d_l \le d_{l-1} \mu_1 + P_0 D(p)^\alpha \sum_{j=0}^{l-1} \mu_1^{l-j-1} \tilde{\mu_1}^j.$$

Now we define $\overline{\mu_1} := \max\{\mu_1, \tilde{\mu_1}\}$ and get

$$d_l \le \overline{\mu_1}^l d_0 + D(p)^\alpha \overline{\mu_1}^{l-1} l P_0.$$

There is a constant $C' > 0$, with $\frac{1}{\delta^{\alpha-1} C'} < \overline{\mu_1}$, so that we have

$$D(p)^\alpha \overline{\mu_1}^{l-1} \le D(p) C' \overline{\mu_1}^l.$$

This shows that $d_l \le \overline{\mu_1}^l \left(D(\mathbf{\Delta} p) + C' D(p) l P_0\right) \le \overline{\mu_1}^l (2 + C' l P_0) D(p)$, and the proof is complete. ∎

Condition (6.2) is automatically fulfilled if the second derived scheme of S exists.

LEMMA 6.4. *Assume that S produces C^1 limit functions. If the derived schemes $S^{[1]}$ and $S^{[2]}$ exist, then* (6.2) *holds for an iterate of S.*

Proof. For the iterated schemes S^k condition (6.2) reads $\mu_{0k} \le N^{-k/\alpha}$, where μ_{0k} is the first contractivity constant of S^k given by $\frac{\|(S^{[1]})^k|_{\mathbf{\Delta}}\|}{N^k}$. Thus the statement of the lemma is equivalent to

$$\rho_\infty(\|S^{[1]}|_{\mathbf{\Delta}}\|) < N^{1-1/\alpha}. \tag{6.4}$$

By Remark 4.5 the spectral radius of the first derived scheme is equal to 1, and thus (6.4) is satisfied for every $\alpha > 1$. ∎

Now we can show that a nonlinear scheme T in proximity with a linear C^1 scheme that satisfies (6.2) is itself C^1.

PROPOSITION 6.5. *Let S be linear and of finite mask with C^1 limits such that $S^{[1]}$ and $S^{[2]}$ exist. Then the limit function $\lim_{l\to\infty} \mathcal{F}_l(T^l p)(x_1,\dots,x_s)$ is C^1.*

Proof. First of all we have $D(N^l \mathbf{\Delta} T^l p) \to 0$ by Proposition 6.3. Since we assume the affine invariance of the derived scheme $S^{[1]}$, (4.6) implies that

$$\|\mathcal{F}_{j+1}(S^{[1]}\mathbf{\Delta} p) - \mathcal{F}_j(\mathbf{\Delta} p)\|_\infty \le C \cdot D(\mathbf{\Delta} p),$$

with a constant $C > 0$. Note that the smoothness condition is nothing but a convergence condition for the derived scheme $S^{[1]}$. Then

$$\begin{aligned}
&\|\mathcal{F}_{l+1}(N^{l+1}\mathbf{\Delta} T^{l+1} p) - \mathcal{F}_l(N^l \mathbf{\Delta} T^l p)\|_\infty \\
&\le \|\mathcal{F}_{l+1}(N\mathbf{\Delta} T - S^{[1]}\mathbf{\Delta}) N^l T^l p\|_\infty + \|(\mathcal{F}_{l+1} S^{[1]} - \mathcal{F}_l)\mathbf{\Delta} N^l T^l p\|_\infty \\
&\le (2N) \sup_{\gamma\in\mathbb{Z}^s} |(T-S)(N^l T^l p)_\gamma| + C D(\mathbf{\Delta} N^l T^l p) \\
&\le (2N) C' N^l (\mu_0 D(p))^{\alpha l} + C \mu_1^l P_1(l) D(p) =: \beta_l.
\end{aligned}$$

By Lemma 6.4 we may assume that $\mu_0^\alpha N < 1$ and $\sum_l \beta_l < \infty$. Therefore the sequence $\mathcal{F}_l(N^l \mathbf{\Delta} T^l p)$ is a Cauchy sequence, so we can apply Lemma 6.1 to complete the proof. ∎

7. Verification of the proximity conditions. In order to show that a proximity condition actually holds between an affinely invariant subdivision scheme and the perturbations that we want to study, we use a generalization of Lemma 5 in [12].

LEMMA 7.1. *Let S be a linear subdivision scheme on $\mathbb{Z}^s$ that reproduces constants. Then S is expressible by the repeated application of the affine averaging operator given by*

$$\mathrm{av}_\lambda(x,y) = \lambda x + (1-\lambda) y, \quad \lambda \in [0,1].$$

Assume that $(f_\lambda(x,y))_{\lambda\in[0,1]}$ is a family of functions from $\mathbb{R}^n \times \mathbb{R}^n \to \mathbb{R}^n$ satisfying

$$|\mathrm{av}_\lambda(x,y) - f_\lambda(x,y)| \le C \cdot |x-y|^2 \tag{7.1}$$

for a constant $C > 0$. If T is defined by exchanging the affine averaging operators av_λ by f_λ, then S and T satisfy a proximity condition of order 2 in the sense of Definition 5.2.

Proof. The fact that S is expressible via the affine averaging operator is just Theorem 1 in [12]. For the second assertion we perform induction on the number of iterations of averaging operators. For a subdivision scheme with dilation factor N we have N^s different rules, and for each of them we have to verify

$$|S p_{\alpha+N\beta} - T p_{\alpha+N\beta}| \le C \cdot D(p)^2. \tag{7.2}$$

Let m be the number of iterations of the averaging operator for the rule associated with $\beta \in \mathbb{Z}^s$. For $m = 1$ we get

$$S p_{\alpha+N\beta} = \mathrm{av}_{\lambda_\beta}(p_{\alpha+r_\beta}, p_{\alpha+s_\beta}).$$

Then by (7.1) there exists a constant C such that (7.2) holds true. Now we perform an induction step. Assume that our assertion is correct for m. Let y and z be

points obtained from at most m iterations of affine averaging operators and y', z' the corresponding points obtained by replacing the averaging operators by f. By the induction hypothesis,

$$|y - y'|,\ |z - z'| \le C' \cdot D(p)^2, \text{ with a constant } C' > 0. \tag{7.3}$$

Clearly we also have

$$|y - z| \le C \cdot D(p), \tag{7.4}$$

with a constant $C > 0$. Let $x := \mathrm{av}_\lambda(y, z)$, $x' := f_\lambda(y', z')$, and $x'' := \mathrm{av}_\lambda(y', z')$. We need to show that there exists a constant $\tilde{C} > 0$, with

$$|x - x'| \le \tilde{C} \cdot D(p)^2. \tag{7.5}$$

We estimate

$$\begin{aligned} |x - x'| &\le |x' - x''| + |x - x''| \le C'' \cdot |y' - z'|^2 + |\mathrm{av}_\lambda(y - y', z - z')| \\ &\le C'' \cdot (|y - y'| + |y - z| + |z - z'|)^2 + C''' \cdot \max(|y - y'|, |z - z'|). \end{aligned}$$

Because of (7.3) and (7.4) this implies (7.5). ∎

7.1. Geodesic averaging. For a surface embedded in the Euclidean space $\mathbb{R}^n$ we construct the geodesic analogue of a linear scheme S by replacing the affine averaging operators av_λ by the geodesic averaging operators g-av_λ, where $\text{g-av}_\lambda(x, y) := c(\lambda)$, with c the shortest geodesic with $c(0) = x$ and $c(1) = y$. Lemma 4 in [12] states that (7.1) is fulfilled with $f_\lambda = \text{g-av}_\lambda$, and therefore, by Lemma 7.1, a proximity condition holds between a linear scheme and its geodesic analogue.

7.2. Projection analogue. Another possibility of perturbing a linear scheme that is studied in this paper is obtained by applying a projection operator P to the subdivided points; i.e., we set $f_\lambda := P \circ \mathrm{av}_\lambda$. P is required only to be smooth and leave the points of the manifold fixed. In [12] it has been shown that (7.1) holds for this class of schemes, and therefore a proximity condition holds between S and the perturbed scheme.

7.3. Log-exp scheme. We go on to prove that a proximity condition holds between a linear scheme S and its log-exp analogue T. In [13] a different log-exp analogue is analyzed, and a proximity condition that ensures C^2-smoothness is proven. However, this different log-exp analogue is not capable of being generalized to the multivariate setting.

PROPOSITION 7.2. *Let S be a linear subdivision scheme that reproduces constants and T its G-valued* log-exp *analogue for a matrix group G. Then for every bounded subset $M \subseteq G$ such that* $\exp|_M$ *is a diffeomorphism, S and T satisfy a proximity condition for initial data p with $D(p)$ small enough.*

Proof. The matrix exponential function is given by

$$\exp(v) = I + v + \frac{v^2}{2} + \frac{v^3}{3!} \dots,$$

where $v \in \mathbb{R}^{m \times m}$. Since exp is a diffeomorphism in a neighborhood of the identity matrix I, we can choose $\delta_1 > 0$ such that $\|\exp(v) - I\| < \delta_1$ implies that

$$\alpha_1 \|\exp(v) - I\| \le \|v\| \le \alpha_2 \|\exp(v) - I\| \quad \text{for some } \alpha_1,\ \alpha_2 > 0, \tag{7.6}$$

where $\|v\| := \sqrt{tr(v^T v)}$, the Frobenius norm.

Since we are operating in a bounded subset of G, we can assume that $\|p_\alpha\| \leq \gamma_1$, $\|p_\alpha^{-1}\| \leq \gamma_2$ for some $\gamma_1, \gamma_2 > 0$.

As explained in section 1 the construction of new points in a linear subdivision scheme S and its log-exp analogue T has the form

$$\begin{aligned} s &= p + \sum_{\beta \in F} \lambda_\beta (q_\beta - p) \qquad \text{(linear)}, \\ t &= p \cdot \exp\Big(\sum_{\beta \in F} \lambda_\beta v_\beta \Big) \quad \text{(nonlinear)}, \end{aligned}$$

where $q_\beta = p \cdot \exp(v_\beta)$ and F is a finite subset of $\mathbb{Z}^s$. We show that

$$\|s - t\| \leq C \cdot \max_{\beta \in F} \|q_\beta - p\|^2 \quad \text{for a } C > 0, \tag{7.7}$$

which is clearly equivalent to the required proximity condition

$$\begin{aligned} \|s - t\| &= \left\| p \cdot \left(I + \sum_{\beta \in F} \lambda_\beta (\exp(v_\beta) - I) - \exp\left(\sum_{\beta \in F} \lambda_\beta v_\beta \right) \right) \right\| \\ &\leq \gamma_1 \left\| \sum_{\beta \in F} \lambda_\beta \left(\frac{v_\beta^2}{2} + \frac{v_\beta^3}{3!} + \cdots \right) - \frac{1}{2} \left(\sum_{\beta \in F} \lambda_\beta v_\beta \right)^2 - \frac{1}{3!} \left(\sum_{\beta \in F} \lambda_\beta v_\beta \right)^3 - \cdots \right\| \\ &\leq C_1 \max_{\beta \in F} \|v_\beta\|^2 \end{aligned} \tag{7.8}$$

for $\|v_\beta\|$ small enough for the series to converge. By (7.6) we can estimate

$$\begin{aligned} \|v_\beta\| &\leq \alpha_2 \| \exp(v_\beta) - I\| = \alpha_2 \|p^{-1} q_\beta - I\| \\ &\leq \alpha_2 \|p^{-1}\| \|q_\beta - p\| \leq \alpha_2 \gamma_2 \|q_\beta - p\|. \end{aligned} \tag{7.9}$$

If we combine (7.9) with (7.8), we get the proximity condition that we want to establish. ∎

8. Results. In the previous section we verified that a proximity condition holds between a linear subdivision scheme and the nonlinear analogues we want to study. We combine these results with the inequalities obtained in sections 5 and 6 and are able to state some theorems.

THEOREM 8.1. *Let S be a linear subdivision scheme with a finite mask defined on $\mathbb{Z}^s$, $s \geq 1$. If S is convergent and produces continuous limit functions, then, for initial data p with $D(p)$ sufficiently small, the following hold:*

(i) *If T is the geodesic analogue of S in a smooth surface $\mathcal{M}$, then T is convergent.*

(ii) *If T is the projection analogue of S obtained from a smooth projection mapping $P : \mathbb{R}^n \to \mathcal{M}$, with $P(x) = x$ for all $x \in \mathcal{M}$, then T is convergent.*

(iii) *If $(G, \cdot)$ is a matrix group and T is the G-valued* log-exp *version of S, then T is convergent.*

Proof. By the results of section 7, a proximity condition is satisfied between T and S, and therefore, by Proposition 5.5, the scheme T produces continuous limit functions. ∎

The assumption that $D(p)$ is sufficiently small does not mean that there exists a global constant $\delta > 0$ such that $T^l p$ converges for all initial data with $D(p) < \delta$. Such

a constant in general just exists locally. If the surface (resp., Lie group) is compact, there exists such a global constant. A global δ also exists in the following situations (compare [12] where the univariate situation is discussed):

- for the geodesic analogue if the normal curvatures of the surface are bounded,
- for the projection analogue if the gradient and second derivative of P are bounded,
- in general if p is contained in a compact set.

For certain special cases, for example, the geodesic analogue of the Chaikin algorithm, it is possible to show that the nonlinear analogue is convergent for all initial data [16].

THEOREM 8.2. *Let S be a linear subdivision scheme with a finite mask defined on $\mathbb{Z}^s$, $s \geq 1$, that produces C^1 limit functions. Assume that the first and second derived schemes $S^{[1]}$ and $S^{[2]}$ exist. Then the limit curves of T enjoy C^1-smoothness in the following situations:*

(i) *T is the geodesic analogue of S,*

(ii) *T is the projection analogue of S obtained from a smooth projection mapping $P : \mathbb{R}^n \to \mathcal{M}$, with $P(x) = x$ for all $x \in \mathcal{M}$,*

(iii) *if $(G, \cdot)$ is a matrix group and T is the G-valued* log-exp *version of S.*

Proof. This is a direct consequence of the proximity condition and Proposition 6.5. ∎

Up to this point we have considered only surfaces embedded in the Euclidean space for the geodesic approach. This assumption can be dropped since, by Nash's global embedding theorem [9], any abstract Riemannian manifold can be smoothly embedded in some Euclidean space $\mathbb{R}^n$. Therefore the following theorem is true.

THEOREM 8.3. *Both Theorems* 8.1(i) *and* 8.2(i) *also hold if $\mathcal{M}$ is an abstract Riemannian manifold.*

In a similar manner one can define the log-exp analogue for a general finite dimensional Lie group $(G, \cdot)$ with Lie algebra $\mathfrak{g}$: if a subdivision rule is given by $p_{i,j} + \sum_{r,s} \lambda_{r,s} v_{r,s}$, as in (1.1), we define the associated log-exp rule by

$$p_{i,j} \cdot \exp\left(\sum_{r,s} \lambda_{r,s} v_{r,s}\right), \text{ where } v_{r,s} := \log(p_{i,j}^{-1} \cdot p_{i+r,j+s}) \in \mathfrak{g}.$$

The mapping "exp" is the exponential mapping of G. The log function which is the inverse of the exponential mapping is not defined globally but only for a certain neighborhood of e in G. Since we are dealing only with schemes with a finite mask, we can restrict ourselves to a small neighborhood of the identity element e of G. By Ado's theorem [11] every finite-dimensional Lie group is locally isomorphic to a local matrix group, and therefore, for $D(p)$ small enough, the previous results also apply to general finite-dimensional Lie groups.

THEOREM 8.4. *Theorems* 8.1(iii) *and* 8.2(iii) *also hold if $(G, \cdot)$ is an abstract finite-dimensional Lie group.*

Acknowledgments. The author wants to thank Johannes Wallner for his continuing support and the anonymous referee for valuable suggestions.

AN ARTIFICIAL BOUNDARY METHOD FOR AMERICAN OPTION PRICING UNDER THE CEV MODEL*

HOI YING WONG† AND JING ZHAO‡

Abstract. The Black–Scholes asset price dynamics is well known to be inadequate for capturing the volatility smile in the financial market. Therefore, the constant elasticity of variance (CEV) model has become a popular alternative to valuing options fitting to the smile. American option pricing, however, is computationally intensive, as there are no analytical formulas available. This paper proposes an artificial boundary method for partial differential equations (PDEs) to compute American option prices and Greeks under the CEV model. The idea is to reduce the infinite computational domain to a finite one by introducing an artificial boundary on which an exact boundary condition is derived. We then develop a Crank–Nicolson scheme to solve the PDE with the artificial boundary condition implemented with a numerical Laplace inversion. With a finite computational domain, the optimal exercise boundary can be determined efficiently. Our numerical examples show that the proposed scheme is accurate, robust with respect to the truncation size, and more efficient than alternative methods for accurate option prices.

Key words. American option, artificial boundary, constant elasticity of variance model, finite difference method

1. Introduction.

The American feature in an option contract represents the right for the option holders to exercise their option prematurely. American options are actually the most popular derivatives in the financial market in the sense that their trading volume is even larger than that of their European counterparts. The corresponding valuation has been a fundamental challenge in financial engineering, as it involves a determination of the early exercise strategy within the pricing mechanism.

Under the Black–Scholes asset price dynamics, the valuation of American options has been studied thoroughly. Merton [17] formulates it as a dynamic programming problem. Kim [14] finds that the American option price can be expressed as a European option plus an early exercise premium. Carr, Jarrow, and Myneni [3] formulate the problem as a free boundary value problem for a partial differential equation (PDE). Although they manage to write the solution in a closed form that depends on the early exercise boundary, the option value should be determined numerically, as the early exercise boundary is not known in advance. An alternative way to obtain the option value applies numerical PDE methods, such as the lattice approach, finite difference methods (FDMs), and finite element methods. We refer to [19] for more details on this topic.

In fact, the lattice approach, which can be viewed as an explicit FDM, is usually derived from the probabilistic approach. It is well known that an explicit FDM is conditionally stable; i.e., a condition of the type $\Delta t \sim \Delta x^2$ is required for stability. In contrast, an implicit FDM can achieve unconditional stability. The Crank–Nicolson (CN)

method, which is an average between forward-difference and backward-difference, is unconditionally stable and is a second higher order scheme in time and state [20]. Unfortunately, implicit schemes, including both the implicit FDM and CN method are originally constructed for a PDE with a bounded domain. Therefore, their implementation requires the truncation of the infinite domain into a finite one. Kwok, Wong, and Lau [15] demonstrate that, when the CN scheme is applied to value path-dependent options, the boundary condition can be tricky and the order of accuracy deteriorates near the prescribed boundaries. Kangro and Nicolaides [13] study the far-field boundary conditions for Black–Scholes equations. Han and Wu [12] propose an artificial Neumann boundary condition for PDEs for pricing American options. This method works very well under Black–Scholes dynamics.

In the financial market, the volatility implied by option prices shows a smile shape across strike prices. This means that the constant volatility assumption of the Black–Scholes model is incorrect. To capture the volatility smile, one popular alternative is the constant elasticity of variance (CEV) model suggested by Cox [5]. The implications of the CEV model are studied by Becker [1]. It has been shown that this model can fit the volatility skew of equity options. Emanuel and MacBeth [9] derive a closed-form solution for European options under positive elasticity. Davydov and Linetsky [6] study the pricing and hedging of barrier and lookback options under CEV. Detemple and Tian [7] derive a recursive integral equation for the exercise boundary under CEV, which can be used as a starting point for numerical methods of American option valuation. Although its computational accuracy and efficiency are not reported in the paper, the recursive integral equation is computationally intensive. In practice, the FDM is the most common numerical tool for pricing options because of its efficiency and robustness. Our interest is in developing an FDM for option pricing under CEV. Lu and Hsu [16] obtain a binomial tree approximation for European options under CEV and speculate that it is also useful for American option pricing. However, its efficiency and stability are not reported.

This study generalizes the artificial boundary method of Han and Wu [12] to the CEV model. This extension is nontrivial. The Black–Scholes equation can be transformed into the standard heat equation in which the artificial boundary is classic [11], [21]. For the CEV model, the PDE cannot be transformed into a linear equation with constant coefficients, and the corresponding artificial boundary condition has not been considered before. We derive the artificial boundary condition (ABC) by using the Laplace transform and give several demonstrations of the application. An efficient CN scheme is then constructed by approximating the artificial boundary condition with a numerical Laplace inversion. Numerical examples show that the proposed artificial boundary approach is efficient, accurate, and robust with respect to the truncation size. In addition, it outperforms the binomial method and the CN scheme using the far-field boundary condition. We also prove that the artificial boundary condition is exact and the proposed CN scheme is unconditionally stable. This lays the theoretical grounds for option pricing under CEV with an FDM.

The remainder of the paper is organized as follows. Section 2 presents some basic results in option pricing under CEV. Section 3 formulates the proposed artificial boundary approach. Some theoretical results are obtained. Numerical examples are demonstrated in section 4. Section 5 concludes.

2. Option pricing under CEV. The CEV model assumes that, under the risk-neutral probability measure, the underlying asset price evolves according to the stochastic differential equation:

$$\mathrm{d}S = (r-q)S\mathrm{d}t + \sigma S^{\alpha}\,\mathrm{d}Z, \tag{2.1}$$

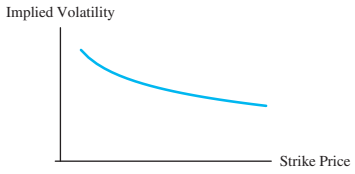

FIG. 2.1. *Volatility smile for equities.*

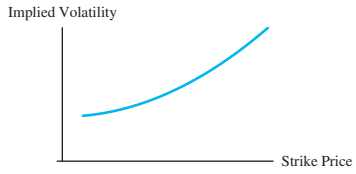

FIG. 2.2. *Volatility smile for options on futures.*

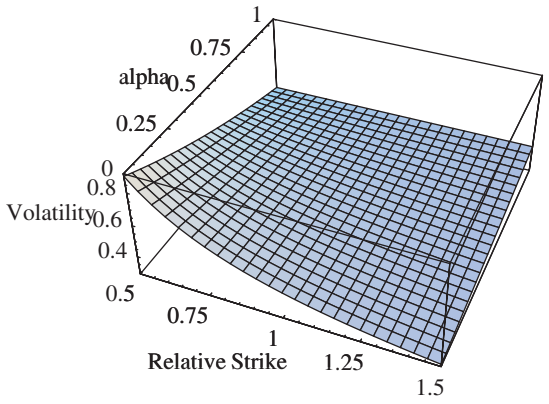

FIG. 2.3. *The CEV skew for varying values of* α.

where r is the risk-free rate, q is the dividend yield, Z is a Wiener process, σ is a volatility parameter, and α is a constant known as the elasticity factor.

The CEV model nests several asset price processes as special cases. For instance, it incorporates a local volatility given by $\sigma(S) = \sigma S^{\alpha-1}$. When $\alpha = 1$, the process (2.1) becomes the geometric Brownian motion and is reduced to the Black–Scholes model. We have the Ornstein–Uhlenbeck process by setting α to zero. If $\alpha = \frac{1}{2}$, then the square-root model is obtained.

There are interesting interpretations of the CEV model. When $\alpha < 1$, the local volatility increases as the stock price decreases. This creates a probability distribution similar to the empirical distribution of equities that has a heavy left tail and a less heavy right tail. Since the financial crisis of 1987, the volatility smile used by traders to price equity options (both on individual stocks and on stock indices) has had the general form shown in Figure 2.1. When $\alpha > 1$, the local volatility increases as the stock price increases. This creates a probability distribution with a heavy right tail and a less heavy left tail, which corresponds to a volatility smile in which the implied volatility is an increasing function of the strike price. This volatility smile often appears for options on futures, as shown in Figure 2.2.

The parameters of the CEV model can be estimated by calibration, that is, to fit the model prices of vanilla options as closely as possible to market prices by minimizing the sum of the squared differences between them.

Figure 2.3 shows the volatility skew under the CEV model by varying the value of α. The plot uses a current stock price of 100, a time to maturity of one year, an interest rate of 5%, and an at-the-money volatility of 45%. When α gets close to zero, the CEV model generates a steeper skew for the implied volatility smile. Conversely, the skew becomes flatter as α tends to one and ultimately becomes as flat as the Black–Scholes model.

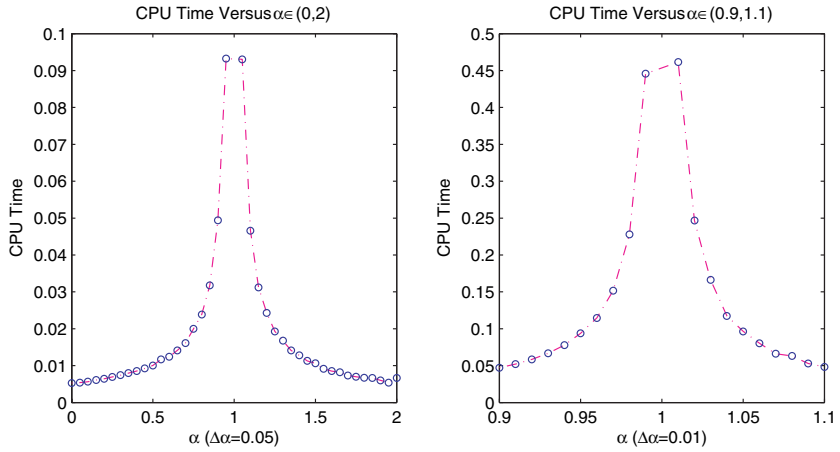

FIG. 2.4. *Computational time for different* α.

2.1. The valuation of European options. Closed-form pricing formulas of European call and put options are available for the CEV model. Specifically, Cox [5] shows that

$$C_E = S_0 e^{-qT}[1-\chi^2(b, c+2, d)] - Ke^{-rT}\chi^2(d, c, b), \tag{2.2}$$
$$P_E = Ke^{-rT}[1-\chi^2(d, c, b)] - S_0 e^{-qT}\chi^2(b, c+2, d),$$

when $\alpha < 1$, and Emanuel and MacBeth [9] derive

$$C_E = S_0 e^{-qT}[1-\chi^2(d, -c, b)] - Ke^{-rT}\chi^2(b, 2-c, d), \tag{2.3}$$
$$P_E = Ke^{-rT}[1-\chi^2(b, 2-c, d)] - S_0 e^{-qT}\chi^2(d, -c, b),$$

when $\alpha > 1$, where

$$b = \frac{[Ke^{-(r-q)T}]^{2(1-\alpha)}}{(1-\alpha)^2 w}, \quad c = \frac{1}{1-\alpha}, \tag{2.4}$$
$$d = \frac{S^{2(1-\alpha)}}{(1-\alpha)^2 w}, \quad w = \frac{\sigma^2}{2(r-q)(\alpha-1)}[e^{2(r-q)(\alpha-1)T}-1],$$

and $\chi^2(z, k, \ell)$ is the cumulative distribution function (cdf) of a noncentral chi-squared random variable with noncentrality parameter ℓ and k degrees of freedom.

These formulas feature the noncentral chi-squared cdf, which is available in some computational software. For instance, Matlab provides the NCX2CDF function to compute it as a series expansion in terms of chi-squared cdfs with Poisson weights. Schroder [18], however, points out that the evaluation of the infinite sum can be computationally expensive when both z and ℓ are large (i.e., α is close to 1, volatility is low, or T is small in the CEV model).

Figure 2.4 shows the computational time of the closed-form European call price against α, where the current stock price is 100, strike price 110, time to expiry 6 months, $r = 5\%$, $q = 0$, and at-the-money volatility 20%. It can be seen that the computational time increases significantly when α gets close to 1.

The numerical PDE method offers an efficient alternative approach to evaluating option prices under CEV. We compare the computational accuracy of the closed-form

TABLE 2.1
Values of European put options for different α.

α	0.999	0.9999	0.99999	BS price	1.00001	1.0001	1.001
Closed-form	10.199	10.201	10.261	10.191	10.275	10.200	10.199
CPU(s)	3.9586	35.9467	367.35		397.62	35.3435	3.745
FDM	10.190	10.191	10.191	10.191	10.191	10.191	10.191
CPU(s)	1.1444	1.1421	1.1453		1.1425	1.1430	1.149

solution with that of the FDM when α gets close to 1. We consider α near 1 because the Black–Scholes pricing formula provides a base to compare the accuracy. Table 2.1 indicates that the closed-form formula is unstable and inefficient for α close to 1. Consequently, an efficient and accurate numerical method for option pricing under CEV is invaluable. Table 2.1 also shows that the traditional CN FDM with 500 grid points converges to the Black–Scholes (BS) price more efficiently. The computational times are similar for all values of α. Moreover, the FDM generates option values on the entire grid of S value. Thus, interpolation can be employed to obtain option prices for all initial stock prices.

The aforementioned CN scheme is based on the PDE for CEV option pricing with a far-field boundary condition. Following the arguments of Carr, Jarrow, and Myneni [3], the price of a European option is the unique solution of the following problem under general diffusion processes:

$$\begin{cases} \frac{\partial V}{\partial t} - rV + \frac{1}{2}\sigma^2(S)S^2\frac{\partial^2 V}{\partial S^2} + (r-q)S\frac{\partial V}{\partial S} = 0, \quad 0 \le S, \quad t \le T, \\ V(S,T) = V_T(S), \quad 0 \le S. \end{cases} \tag{2.5}$$

The payoff function $V_T(S)$ is determined by the contractual agreement of the option. For example, the payoffs of vanilla calls and puts are given by

$$V(S,T) = \max(\theta(S-K),0), \quad 0 \le S, \tag{2.6}$$

where $\theta = 1$ for a call option and -1 for a put option.

To make the option payoff an initial condition, we reverse the time by setting $t^* = T - t$ and then substituting it into (2.5):

$$\begin{cases} \frac{\partial V}{\partial t^*} + rV - \frac{1}{2}\sigma^2(S)S^2\frac{\partial^2 V}{\partial S^2} - (r-q)S\frac{\partial V}{\partial S} = 0, \quad 0 \le S, \quad t^* \le T, \\ V(S,0) = V_T(S), \quad 0 \le S. \end{cases} \tag{2.7}$$

FDMs are simple and robust approaches that have been widely used to solve PDEs numerically. As (2.7) is defined for $S \in [0,\infty)$, the option should be valued over an unbounded domain, which is computationally infeasible for implicit schemes. A traditional approach works on a truncated domain $[0, S_{max}]$ for some suitably large S_{max}. The left and right boundary conditions can be approximated through the option's properties as follows:

$$P_E(0,t^*) = Ke^{-rt^*}, \quad P_E(S_{max},t^*) \approx 0, \tag{2.8}$$

where $P_E(S,t^*)$ represents a European put option price. By the put-call parity, equivalent boundary conditions for a European call $C_E(S,t^*)$ can be obtained as follows:

$$C_E(0,t^*) = 0, \quad C_E(S_{max},t^*) \approx S_{max}e^{-qt^*} - Ke^{-rt^*}. \tag{2.9}$$

Note that the origin is an absorbing boundary for S to guarantee the absence of arbitrage. Implicit schemes can then be implemented over the bounded domain with the imposed approximate boundary conditions.

2.2. The valuation of American options. As there is no closed-form solution for finite maturity American options under CEV, the valuation should rely on numerical methods. Let $P_A(S,t)$ be the American put option price and $S_p^*(t)$ be the optimal exercise price. Then the entire domain is divided into two regions separated by a free boundary. In the exercise region $[0, S_p^*(t)] \times [0,T]$, we have

$$\begin{cases} \frac{\partial P_A}{\partial t} - rP_A + \frac{1}{2}\sigma^2 S^{2\alpha} \frac{\partial^2 P_A}{\partial S^2} + (r-q)S\frac{\partial P_A}{\partial S} < 0, \\ P_A(S,t) = K - S = \max(K-S,0). \end{cases} \tag{2.10}$$

In the continuation region $(S_p^*(t), \infty) \times [0,T]$, we have

$$\begin{cases} \frac{\partial P_A}{\partial t} - rP_A + \frac{1}{2}\sigma^2 S^{2\alpha} \frac{\partial^2 P_A}{\partial S^2} + (r-q)S\frac{\partial P_A}{\partial S} = 0, \\ P_A(S,t) > \max(K-S,0). \end{cases} \tag{2.11}$$

On the free boundary, we should have

$$P_A(S_p^*(t),t) = K - S_p^*(t)$$

and

$$\frac{\partial P_A(S_p^*(t),t)}{\partial S}(S_p^*(t),t) = -1. \tag{2.12}$$

Equation (2.12) is known as the high-contact condition for American put options. This condition must hold for all continuous asset price processes, including the CEV model [3]. The inequality (2.10) describes a situation in which the value of the option if exercised exceeds its value if held. Thus, it is optimal to exercise the option prematurely. If $P_A(S,t) > \max(K-S,0)$, then we should hold the option for an obvious reason, and hence the option value satisfies the governing equation. When $P_A(S,t) > \max(K-S,0)$, $P_A(S,t-\Delta t) > P_A(S,t)$ for any positive Δt.

From the facts above, it is easy to see that the following inequality holds: $S_p^*(t) > S_p^*(t-\Delta t), \Delta t > 0$, which implies that $S_p^*(t)$ is an increasing function of t. It is known that $S_p^\infty \le S_p^*(t) \le S_p^0, 0 \le t \le T$, where S_p^∞ is the optimal exercise price of the perpetual American put option and $S_p^0 = S_p^*(T) = \min(\frac{rK}{q}, K)$. Moreover,

$$\lim_{S\to\infty} P_A(S,t) = 0. \tag{2.13}$$

This PDE problem is defined on a semi-infinite domain. To implement an implicit FDM, the domain could be truncated by utilizing the far-field boundary conditions:

$$P_A(0,t^*) = K, \quad P_A(S_{max},t^*) \approx 0. \tag{2.14}$$

The numerical valuation of American options is similar that of European options, except that early exercise opportunities are required to be searched for at each time point. If the optimal exercise strategy depends only on the current value of the underlying process and time, then the value of the option can be determined by using the Bellman principle of dynamic programming:

$$P_A(S) = \max\{f(S), PV_t[P_A(S+\mathrm{d}S, t+\mathrm{d}t)]\}, \tag{2.15}$$

where $PV_t[\cdot]$ is the present value at time t and $f(S)$ is the intrinsic value of the option.

This principle is easily implemented with the lattice approach or an FDM because it simply means looking for early exercise opportunities at each node at each time point. If it is optimal to exercise early at a particular node, then the option value is replaced with the intrinsic value at that node. However, this can be time-consuming for a large domain.

According to the put-call symmetry for American options, if the local volatility $\sigma(S,t)$ depends solely on S, then the following relations hold [22]:

$$C_A(S,t;r,q,\sigma(S)) = P_A(E^2/S,t;q,r,\sigma(S))S/E, \tag{2.16}$$
$$P_A(S,t;r,q,\sigma(S)) = C_A(E^2/S,t;q,r,\sigma(S))S/E.$$

Thus, it suffices to consider the valuation of either the American put or call option. In this paper, we focus on the put option.

2.3. How "far" is enough? To deal with an unbounded domain, we usually impose boundary conditions at a place that is far away from the region of interest so that, even if the imposed boundary conditions are imperfect, the solution will not be affected materially. This approach is referred to as the far-field boundary condition [13].

How far is sufficient? To produce an accurate result, a large domain is preferred, but we have to deal with many points for an evenly spaced grid. Consequently, the computational time is increased. Although a small domain results in fast computation, the accuracy can be greatly affected by the error associated with the imposed boundary conditions. In addition, the effect of the far-field boundary condition for the CEV model is not known, and it lacks theoretical support.

There is always a trade-off between accuracy and efficiency with the far-field approach. The more accurately the boundary conditions conform to the characteristics of the desired solution, the closer we can place the boundary to the domain of interest. Thus, an artificial boundary method is a remedy for this implementation problem. Although not demonstrated in this paper, an unevenly spaced grid (fine spacing near the strike price and coarse spacing near the boundaries) can offer considerable computational advantages on top of the proposed artificial boundary method.

3. The proposed approach. In this section, we derive a class of exact artificial boundary conditions for the CEV model on an unbounded domain. An exact artificial boundary condition represents a boundary condition by which we obtain an initial boundary value (IBV) problem on a bounded domain that shares the same solution with the original initial value problem. Therefore, we perform FDM on the IBV problem on the introduced bounded domain.

3.1. Standardized form of the CEV model. Under the Black–Scholes model, the governing equation can be transformed into a heat equation so that classical numerical methods can be applied. Here we transform the PDE under CEV into a standard form. We consider the standard time-reversing transformation $t^* = T - t$ and (2.5). By setting $V = e^{-rt^*}V_1$, the equation is reduced to

$$\frac{\sigma^2(S)}{2}S^2\frac{\partial^2 V_1}{\partial S^2} + (r-q)S\frac{\partial V_1}{\partial S} = \frac{\partial V_1}{\partial t^*}. \tag{3.1}$$

To eliminate the drift term, we introduce a new variable $S' = Se^{(r-q)t^*}$ and transform the PDE into

$$\frac{\sigma^2(S)}{2}S'^2\frac{\partial^2 V_1}{\partial S'^2} = \frac{\partial V_1}{\partial t^*}. \tag{3.2}$$

After recognizing $\sigma(S) = \sigma S^{\alpha-1}$ in the CEV model, the governing equation (3.2) is given by

$$\frac{\sigma^2 S'^{2\alpha}}{2}\frac{\partial^2 V_1}{\partial S'^2} = \frac{\partial V_1}{\partial t^*}e^{(r-q)t^*(2\alpha-2)}. \tag{3.3}$$

We reparameterize the elasticity by letting $2\alpha = 2 - \frac{1}{\nu}$. The PDE now becomes

$$\frac{\sigma^2 S'^{(2-\frac{1}{\nu})}}{2}\frac{\partial^2 V_1}{\partial S'^2} = \frac{\partial V_1}{\partial t^*}e^{(r-q)t^*(-\frac{1}{\nu})}. \tag{3.4}$$

To simplify the left-hand side of (3.4), we let $X = S'^{\frac{1}{\nu}}$ and obtain

$$\sigma^2 X\frac{\partial^2 V_1}{\partial X^2} + \sigma^2(1-\nu)\frac{\partial V_1}{\partial X} = 2\nu^2 e^{(r-q)t^*(-\frac{1}{\nu})}\frac{\partial V_1}{\partial t^*}. \tag{3.5}$$

The right-hand side of (3.5) can be further simplified by introducing a new time variable τ for

$$d\tau = \frac{1}{2\nu^2}e^{(r-q)t^*(\frac{1}{\nu})}dt^* \Rightarrow \tau = \frac{1}{2\nu(r-q)}(e^{\frac{(r-q)(T-t)}{\nu}} - 1).$$

Consequently, we arrive at the standardized CEV equation

$$\frac{\partial V_1}{\partial \tau} = \sigma^2 X\frac{\partial^2 V_1}{\partial X^2} + \sigma^2(1-\nu)\frac{\partial V_1}{\partial X}. \tag{3.6}$$

This governing equation can be linked to a simple parabolic equation with a nonconstant drift by letting $Y = \frac{2}{\sigma}X^{\frac{1}{2}}$:

$$\frac{\partial V_1}{\partial \tau} = \frac{\partial^2 V_1}{\partial Y^2} + \frac{1-2\nu}{Y}\frac{\partial V_1}{\partial Y}. \tag{3.7}$$

The overall changes are summarized as follows:

$$\begin{cases} \tau = \frac{1}{2\nu(r-q)}(e^{\frac{(r-q)(T-t)}{\nu}} - 1), \\ \quad \text{when } t = 0, \ \ \tau = \frac{1}{2\nu(r-q)}(e^{\frac{(r-q)T}{\nu}} - 1) = T^*, \\ \quad \text{when } t = T, \ \ \tau = 0, \\ 2\alpha = 2 - \frac{1}{\nu}, \\ Y = \frac{2}{\sigma}(Se^{(r-q)(T-t)})^{\frac{1}{2\nu}}, \\ \quad \text{when } t = 0, \ \ Y = \frac{2}{\sigma}(Se^{(r-q)T})^{\frac{1}{2\nu}}, \\ \quad \text{when } t = T, \ \ Y = \frac{2}{\sigma}S^{\frac{1}{2\nu}}, \\ V_1 = e^{r(T-t)}V, \\ \quad \text{when } t = 0, \ \ V_1 = e^{rT}V, \\ \quad \text{when } t = T, \ \ V_1 = V. \end{cases} \tag{3.8}$$

The American option pricing problem under the CEV model can be formulated as

$$\begin{cases} \frac{\partial V_1}{\partial \tau} = \frac{\partial^2 V_1}{\partial Y^2} + \frac{1-2\nu}{Y}\frac{\partial V_1}{\partial Y}, \ \ Y > 0, \ 0 \le \tau, \\ V_1|_{\tau=0} = \max(K - (\frac{\sigma Y}{2})^{2\nu}, 0), \ \ Y_p^*(\tau) \le Y, \\ V_1\,|_{Y_p^*(\tau)} = Ke^{r(T-t)} - \left(\frac{\sigma Y_p^*(\tau)}{2}\right)^{2\nu}e^{q(T-t)}, \\ \frac{\partial V_1}{\partial Y}\big|_{Y=Y_p^*(\tau)} = -\nu\sigma^{2\nu}\left(\frac{Y_p^*(\tau)}{2}\right)^{2\nu-1}e^{q(T-t)}, \end{cases} \tag{3.9}$$

where $Y_p^*(\tau)$ is the optimal exercise value of Y at time τ and satisfies

$$Y_p^*(\tau) = \frac{2}{\sigma}(S_p^*(t)e^{(r-q)(T-t)})^{\frac{1}{2\nu}}. \tag{3.10}$$

The last equation of (3.9) comes from the high-contact condition (2.12) of the original problem. Its derivation is the direct consequence of the transformation (3.8) and the fact that $\frac{\partial}{\partial S} = \frac{\partial Y}{\partial S}\frac{\partial}{\partial Y}$. In the continuation region, we have

$$V_1(Y,\tau) > \max\left(Ke^{r(T-t)} - \left(\frac{\sigma Y}{2}\right)^{2\nu} e^{q(T-t)}, 0\right). \tag{3.11}$$

3.2. Exact artificial boundary conditions. Armed with the standardized CEV equation, this is the right moment to derive the exact artificial boundary condition for American put options. We consider the artificial boundary on the asset value to be larger than the strike price K as the optimal exercise price is less than K. When $\alpha = 1$, the CEV model reduces to the Black–Scholes model, and the corresponding artificial boundary has been studied by Han and Wu [12]. Thus, we focus on the remaining two cases: $\alpha > 1$ and $\alpha < 1$.

3.2.1. Case 1: $\frac{1}{\nu} < 0$ ($\alpha > 1$). This case is simple. From (3.8), we recognize that $Y = \frac{2}{\sigma}(Se^{(r-q)(T-t)})^{\frac{1}{2\nu}}$ is a decreasing function of S. When $S \to \infty$, $Y \to 0$. By the exact boundary condition of (2.13), we deduce that

$$\lim_{Y\to 0} V_1(Y,\tau) = 0. \tag{3.12}$$

Therefore, the original PDE defined on the unbounded domain $(S_p^*(t), \infty) \times [0, T]$ is converted into a new PDE defined on the bounded domain $(0, Y_p^*(\tau)) \times [0, T^*]$ with the exact boundary condition (3.12) and the initial condition

$$V_1(Y,0) = \max\left(K - \left(\frac{\sigma Y}{2}\right)^{2\nu}, 0\right). \tag{3.13}$$

Moreover, the value of an American put option should respect the constraint:

$$V_1(Y,\tau) \geq \max\left(Ke^{r(T-t)} - \left(\frac{\sigma Y}{2}\right)^{2\nu} e^{q(T-t)}, 0\right). \tag{3.14}$$

Thus, the CN scheme can be applied to the PDE (3.9) defined on this bounded domain.

3.2.2. Case 2: $\frac{1}{\nu} > 0$ ($\alpha < 1$). The challenge goes to the case in which $\alpha < 1$. From (3.8), $Y = \frac{2}{\sigma}(Se^{(r-q)(T-t)})^{\frac{1}{2\nu}}$ is an increasing function of S under the present situation. We recall that the governing equation

$$\frac{\partial V_1}{\partial \tau} = \frac{\partial^2 V_1}{\partial Y^2} + \frac{1-2\nu}{Y}\frac{\partial V_1}{\partial Y} \tag{3.15}$$

is defined on an unbounded domain $\Omega(\tau)$ as

$$\Omega(\tau) = \{(Y,\tau) \in R^2 \mid Y_p^*(\tau) \leq Y < +\infty, 0 \leq \tau \leq T^*\}. \tag{3.16}$$

We now introduce an artificial boundary Γ_a:

$$\Gamma_a = \{(Y,\tau) \mid Y = a, 0 \le \tau \le T^*\}, \tag{3.17}$$

where a is a constant prespecified by the user. Exact boundary conditions are derived to ensure that the solution on the computational (truncated) domain coincides with the exact solution of the original problem.

The unbounded domain $\Omega(\tau)$ is divided by Γ_a into the bounded time-dependent interior domain

$$\Omega_{\text{int}}(\tau) = \{(Y,\tau) \in R^2 \mid Y_p^*(\tau) \le Y < a, 0 \le \tau \le T^*\} \tag{3.18}$$

and the unbounded time-independent exterior domain

$$\Omega_{\text{ext}} = \{(Y,\tau) \in R^2 \mid Y > a, 0 \le \tau \le T^*\}. \tag{3.19}$$

We postulate that the initial condition is compactly supported in the interior (bounded) domain $\Omega_{\text{int}}(\tau)$ so that the initial condition is zero in the exterior (unbounded) domain. Hence, the artificial boundary should be above the free boundary.

For the derivation of the exact artificial boundary condition at Γ_a, we consider the exterior problem:

$$\begin{cases} \frac{\partial V_1}{\partial \tau} = \frac{\partial^2 V_1}{\partial Y^2} + \frac{1-2\nu}{Y}\frac{\partial V_1}{\partial Y}, \quad (Y,\tau) \in \Omega_{\text{ext}}, \\ V_1 \mid_{\tau=0} = 0, \quad Y > a, \\ V_1 \mid_{Y=a} = V_1(a,\tau), \quad 0 \le \tau \le T^*, V_1(a,0) = 0, \\ V_1 \to 0 \ \text{ when } \ Y \to +\infty, 0 \le \tau \le T^*. \end{cases} \tag{3.20}$$

As $V_1(a,\tau)$ is an unknown function, the problem of (3.20) is not a complete-posed problem and cannot be solved independently. Certainly, it becomes a well-posed problem once we determine the value of $V_1(Y,\tau)$ on the artificial boundary Γ_a. For the moment, we consider $V_1(a,\tau) = V_0$ and solve the exterior problem (3.20) by using the Laplace transform, as follows:

$$\hat{V_1}(Y,s) = \int_0^\infty V_1(Y,\tau)e^{-s\tau}d\tau := L_s(V_1(Y,\tau)), \tag{3.21}$$

where $s > 0$ is the parameter of the Laplace transform. Then the subsidiary equation for (3.20) with a zero initial condition is

$$\frac{d^2\hat{V_1}}{dY^2} + \frac{1-2\nu}{Y}\frac{d\hat{V_1}}{dY} = s\hat{V_1}. \tag{3.22}$$

The corresponding boundary conditions are

$$\lim_{Y\to\infty} \hat{V_1} = 0, \qquad \hat{V_1}(a) = \frac{V_0}{s}. \tag{3.23}$$

Let $\hat{V_1} = Y^\nu \overline{V}_1$ and $z = \sqrt{s}Y$. Then the ordinary differential equation (3.22) is transformed into the modified Bessel differential equation:

$$\frac{d^2\overline{V}_1}{dz^2} + \frac{1}{z}\frac{d\overline{V}_1}{dz} - \left(1 + \frac{\nu^2}{z^2}\right)\overline{V}_1 = 0. \tag{3.24}$$

The solution of (3.24) is classic:

$$\overline{V}_1 = AI_\nu(z) + BK_\nu(z), \tag{3.25}$$

where $I_\nu(z)$ and $K_\nu(z)$ are, respectively, the modified Bessel functions of the first and the second kind. The constants A and B are chosen such that $\overline{V}_1$ satisfies the boundary conditions (3.23). A simple calculation shows that

$$A = 0, \qquad B = \frac{V_0}{sa^\nu K_\nu(\sqrt{s}a)}. \tag{3.26}$$

Hence, we obtain

$$\hat{V}_1 = \left(\frac{Y}{a}\right)^\nu \frac{V_0 K_\nu(\sqrt{s}Y)}{sK_\nu(\sqrt{s}a)}. \tag{3.27}$$

By inverting the Laplace transform, the solution of (3.20) defined on the exterior domain with a zero initial condition and a constant boundary condition over Γ_a is found:

$$V_1 = L_s^{-1}\left(\left(\frac{Y}{a}\right)^\nu \frac{V_0 K_\nu(\sqrt{s}Y)}{sK_\nu(\sqrt{s}a)}\right). \tag{3.28}$$

Thus, we identify the function as follows:

$$G(Y,\tau) = L_s^{-1}\left(\left(\frac{Y}{a}\right)^\nu \frac{K_\nu(\sqrt{s}Y)}{sK_\nu(\sqrt{s}a)}\right)\Bigg|_{t=\tau}. \tag{3.29}$$

By using Duhamel's theorem [4], we conclude that

$$\begin{aligned} V_1(Y,\tau) &= \int_0^\tau V_1(a,\lambda)\frac{\partial}{\partial\tau}G(Y,\tau-\lambda)d\lambda = -\int_0^\tau V_1(a,\lambda)\frac{\partial}{\partial\lambda}G(Y,\tau-\lambda)d\lambda \\ &= -V_1(a,\lambda)G(Y,\tau-\lambda)\,|_{\lambda=0}^{\lambda=\tau} + \int_0^\tau \frac{\partial V_1(a,\lambda)}{\partial\lambda}G(Y,\tau-\lambda)d\lambda. \end{aligned} \tag{3.30}$$

As $V_1(a,0) = 0$ and $G(Y,0) = 0$, (3.30) reads

$$V_1(Y,\tau) = \int_0^\tau \frac{\partial V_1(a,\lambda)}{\partial\lambda}G(Y,\tau-\lambda)d\lambda. \tag{3.31}$$

An exact Neumann boundary condition can be obtained from (3.31). Consider

$$\frac{\partial V_1}{\partial Y} = \int_0^\tau \frac{\partial V_1(a,\lambda)}{\partial\lambda}\frac{\partial G(Y,\tau-\lambda)}{\partial Y}d\lambda, \tag{3.32}$$

where

$$\frac{\partial G(Y,\tau-\lambda)}{\partial Y} = L_s^{-1}\left(\frac{\partial}{\partial Y}\left[\left(\frac{Y}{a}\right)^\nu \frac{K_\nu(\sqrt{s}Y)}{sK_\nu(\sqrt{s}a)}\right]\right)\Bigg|_{t=\tau-\lambda}.$$

Due to the fact that

$$zK_\nu'(z) + \nu K_\nu(z) = -zK_{\nu-1}(z), \tag{3.33}$$

we define the integral kernel as

$$\frac{\partial G(Y,\tau-\lambda)}{\partial Y}\bigg|_{Y=a} = L_s^{-1}\left(\frac{-K_{\nu-1}(\sqrt{s}a)}{\sqrt{s}K_\nu(\sqrt{s}a)}\right)\bigg|_{t=\tau-\lambda} = H_\nu(\tau-\lambda). \tag{3.34}$$

Then we are able to write

$$\frac{\partial V_1(Y,\tau)}{\partial Y}\bigg|_{Y=a} = \int_0^\tau \frac{\partial V_1(a,\lambda)}{\partial \lambda} H_\nu(\tau-\lambda)d\lambda. \tag{3.35}$$

The above computation shows the following proposition.

PROPOSITION 3.1. *For $\alpha < 1$, the solution of the original problem* (3.9) *over an unbounded domain satisfies the following PDE over a bounded domain:*

$$\begin{cases} \frac{\partial V_1}{\partial \tau} = \frac{\partial^2 V_1}{\partial Y^2} + \frac{1-2\nu}{Y}\frac{\partial V_1}{\partial Y}, \quad Y_p^*(\tau) \le Y \le a, \quad 0 \le \tau \le T^*, \\ V_1\,|_{\tau=0} = \max(K - (\frac{\sigma Y}{2})^{2\nu}, 0), \quad Y_p^*(\tau) \le Y \le a, \\ V_1\,|_{Y_p^*(\tau)} = Ke^{r(T-t)} - \left(\frac{\sigma Y_p^*(\tau)}{2}\right)^{2\nu} e^{q(T-t)}, \\ \frac{\partial V_1}{\partial Y}|_{Y=a} = \int_0^\tau \frac{\partial V_1(a,\lambda)}{\partial \lambda} H_\nu(\tau-\lambda)d\lambda. \end{cases} \tag{3.36}$$

It remains for us to show that the solution to (3.36) is unique so that we are allowed to use the numerical solution of (3.36) to approximate that of (3.9).

PROPOSITION 3.2. *The solution of* (3.36) *is unique.*

Proof. Suppose that $V_{11}(Y,\tau)$ and $V_{12}(Y,\tau)$ are two solutions to problem (3.36). We define their difference to be $\varepsilon(Y,\tau) = V_{11}(Y,\tau) - V_{12}(Y,\tau)$. In Ω_{int}, $\varepsilon(Y,\tau)$ satisfies

$$\begin{cases} \frac{\partial \varepsilon}{\partial \tau} = \frac{\partial^2 \varepsilon}{\partial Y^2} + \frac{1-2\nu}{Y}\frac{\partial \varepsilon}{\partial Y}, \quad Y_p^*(\tau) \le Y \le a, \quad 0 \le \tau \le T^*, \\ \varepsilon\,|_{\tau=0} = 0, \quad Y_p^*(\tau) \le Y \le a, \\ \varepsilon\,|_{Y_p^*(\tau)} = 0, \quad 0 \le \tau \le T^*, \\ \frac{\partial \varepsilon}{\partial Y}\,|_{Y=a} = \int_0^\tau \frac{\partial \varepsilon(a,\lambda)}{\partial \lambda} H_\nu(\tau-\lambda)d\lambda. \end{cases} \tag{3.37}$$

By multiplying $Y\varepsilon$ by both sides of the PDE in (3.37) and performing integrations over Ω_{int}, we obtain

$$\begin{aligned} &\int_0^{T^*}\int_{Y_p^*(\tau)}^a Y\left(\frac{\partial \varepsilon}{\partial Y}\right)^2 dY d\tau + \frac{1}{2}\int_{Y_p^*(\tau)}^a Y\varepsilon^2\bigg|_{t=T^*} dY \\ &- \int_0^{T^*} \varepsilon Y \frac{\partial \varepsilon}{\partial Y}\bigg|_{Y=a} d\tau + 2\nu\int_0^{T^*} \frac{\varepsilon^2}{2}\bigg|_{Y=a} d\tau = 0. \end{aligned} \tag{3.38}$$

We then consider the following problem on the unbounded domain Ω_{ext}:

$$\begin{cases} \frac{\partial \varepsilon^*}{\partial \tau} = \frac{\partial^2 \varepsilon^*}{\partial Y^2} + \frac{1-2\nu}{Y}\frac{\partial \varepsilon^*}{\partial Y}, \quad a \le Y \le \infty, \quad 0 \le \tau \le T^*, \\ \varepsilon^*\,|_{\tau=0} = 0, \quad a \le Y \le \infty, \\ \varepsilon^*\,|_{Y=a} = \varepsilon\,|_{Y=a}, \quad 0 \le \tau \le T^*, \\ \varepsilon^* \to 0 \ \text{ when } \ Y \to \infty. \end{cases} \tag{3.39}$$

Given $\varepsilon(Y,\tau)$, problem (3.39) has a unique solution $\varepsilon^*(Y,\tau)$. Moreover,

$$\frac{\partial \varepsilon^*}{\partial Y}\bigg|_{Y=a} = \int_0^\tau \frac{\partial \varepsilon(a,\lambda)}{\partial \lambda} H_\nu(\tau-\lambda)d\lambda = \frac{\partial \varepsilon}{\partial Y}\bigg|_{Y=a}. \tag{3.40}$$

By multiplying $Y\varepsilon^*$ by both sides of (3.39) and integrating over Ω_{ext}, we obtain

$$\begin{aligned}(3.41)\qquad &\int_0^{T^*}\int_a^{\infty} Y\left(\frac{\partial \varepsilon^*}{\partial Y}\right)^2 dY d\tau + \frac{1}{2}\int_a^{\infty} Y\varepsilon^{*2}\Big|_{t=T^*} dY \\ &= -\int_0^{T^*} \varepsilon^* Y \frac{\partial \varepsilon^*}{\partial Y}\Big|_{Y=a} d\tau + 2\nu \int_0^{T^*} \frac{\varepsilon^{*2}}{2}\Big|_{Y=a} d\tau \geq 0.\end{aligned}$$

According to (3.38),

$$\begin{aligned}(3.42)\qquad &-\int_0^{T^*} \varepsilon^* Y \frac{\partial \varepsilon^*}{\partial Y}\Big|_{Y=a} d\tau + 2\nu \int_0^{T^*} \frac{\varepsilon^{*2}}{2}\Big|_{Y=a} d\tau \\ &= -\int_0^{T^*} \varepsilon Y \frac{\partial \varepsilon}{\partial Y}\Big|_{Y=a} d\tau + 2\nu \int_0^{T^*} \frac{\varepsilon^{2}}{2}\Big|_{Y=a} d\tau \leq 0.\end{aligned}$$

By combining (3.41)–(3.42) with (3.39), we end up with $\varepsilon(Y,\tau)\equiv 0$. The proof is then completed. □

PROPOSITION 3.3. *For $\alpha < 1$, according to the transformations in* (3.8)*, the American put price $P_A(S,t)$ under the CEV model can be expressed as follows:*

$$P_A(S,t) = \begin{cases} e^{-r(T-t)}\int_0^{\tau} \frac{\partial V_1(a,\lambda)}{\partial \lambda} G(Y,\tau-\lambda)d\lambda \quad when \quad S > (\frac{\sigma a}{2})^{2\nu} e^{-(r-q)(T-t)}, \\ V_1(Y,\tau)e^{-r(T-t)} \quad when \quad S_p^*(t) < S \leq (\frac{\sigma a}{2})^{2\nu} e^{-(r-q)(T-t)}, \\ K - S \quad when \quad 0 \leq S \leq S_p^*(t), \end{cases} \tag{3.43}$$

where $V_1(Y,\tau)$ is the solution of (3.36)*,*

$$\begin{aligned} G(Y,\tau) &= L_s^{-1}\left[\left(\frac{Y}{a}\right)^{\nu} \frac{K_\nu(\sqrt{s}Y)}{sK_\nu(\sqrt{s}a)}\right]\Big|_{t=\tau}, \\ &= 1 + \frac{2}{\pi}\left(\frac{Y}{a}\right)^{\nu} \int_0^{\infty} e^{-u^2\tau} \frac{J_\nu(uY)Z_\nu(ua) - Z_\nu(uY)J_\nu(ua)}{J_\nu^2(ua) + Z_\nu^2(ua)} \frac{du}{u}, \end{aligned}$$

and $J_\nu(z)$ and $Z_\nu(z)$ are, respectively, the Bessel functions of the first and the second kind. In addition,

$$S_p^*(t) = \left(\frac{\sigma Y_p^*(\tau)}{2}\right)^{2\nu} e^{-(r-q)(T-t)}.$$

Proof. The proof is a direct consequence of Proposition 3.1 and (3.31). □

3.3. Integral kernels and numerical Laplace inversion. The function

$$H_\nu(\tau-\lambda) = L_s^{-1}\left[\frac{-K_{\nu-1}(\sqrt{s}a)}{\sqrt{s}K_\nu(\sqrt{s}a)}\right]\Big|_{t=\tau-\lambda},$$

which appears in the exact artificial boundary condition (3.36), requires a Laplace inversion. By the inversion theorem, we have

$$(3.44)\quad H_\nu(t) = -\frac{1}{2\pi i}\int_{\gamma-i\infty}^{\gamma+i\infty} \frac{K_{\nu-1}(\sqrt{s}a)}{\sqrt{s}K_\nu(\sqrt{s}a)} ds = -\frac{4}{\pi^2}\int_0^{\infty} \frac{e^{-u^2 t}}{au\{J_\nu^2(au) + Z_\nu^2(au)\}} du.$$

Therefore, the numerical method involves the computation of this integral over a semi-infinite domain, which, if not handled carefully, may deteriorate the efficiency once the analytic solution of the Laplace inversion is not available.

In this paper, we use a mixture of the Euler summation and the fast Fourier transform (FFT) to compute the Laplace inversion numerically. These methods are summarized in the appendix. FFT can significantly reduce the computational time, especially for inverting $H_\nu(t)$ for many t-values. As is discussed in [8], FFT methods are effective only when a large number of terms is involved. Specifically, FFT deals with the finite Fourier transform pairs $(X(j), A(k))$:

$$X(j) = \sum_{k=0}^{N-1} A(k) \exp\left(\frac{2\pi i}{N} jk\right), \qquad j = 0, 1, \ldots, N-1. \tag{3.45}$$

A direct calculation of (3.45) requires N^2 operations. FFT is a well-constructed algorithm that reduces the computation to an order of $N \log_2 N$, where $\log_2 N$ is an integer.

However, it is easy to see that $H_\nu(t)$ has a complicated infinity at $t = 0$. Because the Laplace inversion calculated by the FFT has a large error for values near singularity, i.e., when the option is close to maturity in the finance term, we employ the Euler summation for the first several points. This not only accelerates the convergence but also avoids divergent series generated from the singularity. The advantage of the Euler algorithm is obvious for a few t-values. This mixture of the FFT and the Euler summation reduces the computational error remarkably and retains the efficiency.

Let $\mathbf{e} = (e_0, e_1, \ldots, e_{N-1})^T$ be the error vector of N components such that

$$e_j = \widehat{H}_\nu(t_j) - H_\nu(t_j), \qquad j = 0, 1, \ldots, N-1, \tag{3.46}$$

where t_j are the elements of the time vector $\mathbf{t} = (t_0, t_1, \ldots, t_{N-1})$, $\widehat{H}_\nu(t_j)$ is obtained by the numerical Laplace inversion, and $H_\nu(t_j)$ is the exact value of the integral kernel. The L_1, L_2, and L_∞ norms of the error vector $\mathbf{e}$ are defined as follows:

$$\|\mathbf{e}\|_{L_1} = \sum_{i=0}^{N-1} |e_i|, \quad \|\mathbf{e}\|_{L_2} = \left(\frac{1}{N} \sum_{i=0}^{N-1} |e_i^2|\right)^{1/2}, \quad \|\mathbf{e}\|_{L_\infty} = \max_{0 \le i \le N-1} |e_i|. \tag{3.47}$$

The efficiency and accuracy of our method is investigated. For comparison, we look at several special cases in which simplification can be applied to compute the integral kernel.

When $\nu = \frac{1}{2}$, the modified Bessel functions in the integrand of $H_\nu(t)$ can be expressed in terms of trigonometric functions:

$$J_{\frac{1}{2}}(z) = Z_{-\frac{1}{2}}(z) = \left(\frac{1}{2}\pi z\right)^{-\frac{1}{2}} \sin z, \quad Z_{\frac{1}{2}}(z) = -J_{-\frac{1}{2}}(z) = -\left(\frac{1}{2}\pi z\right)^{-\frac{1}{2}} \cos z. \tag{3.48}$$

In fact, the Bessel functions with the order $\nu = n + \frac{1}{2}$ $(n = 0, \pm 1, \pm 2, \ldots)$ are elementary functions. In addition, for $n = 0, 1, 2, \ldots$,

$$J_{-n-\frac{1}{2}}(z) = (-1)^{n+1} Z_{n+\frac{1}{2}}(z), \quad Z_{-n-\frac{1}{2}}(z) = (-1)^n J_{n+\frac{1}{2}}(z), \tag{3.49}$$

$$J_{n+\frac{1}{2}}(z) = (-1)^n \left(\frac{1}{2}\pi z\right)^{-\frac{1}{2}} z^{n+1} \left(\frac{d}{z dz}\right)^n \frac{\sin z}{z},$$

TABLE 3.1

and

$$Z_{n+\frac{1}{2}}(z) = -(-1)^n \left(\frac{1}{2}\pi z\right)^{-\frac{1}{2}} z^{n+1} \left(\frac{d}{zdz}\right)^n \frac{\cos z}{z}. \tag{3.50}$$

Two integral kernels are used in our numerical examples:

1. When $\nu = \frac{1}{2}$ $(\alpha = 0)$,

$$H_{\frac{1}{2}}(t) = -\frac{4}{\pi^2}\int_0^\infty \frac{\pi e^{-u^2 t}}{2} du = -\frac{1}{\sqrt{\pi t}}\mathrm{Erf}(+\infty) = -\frac{1}{\sqrt{\pi t}}. \tag{3.51}$$

2. When $\nu = \frac{3}{2}$ $(\alpha = \frac{2}{3})$,

$$H_{\frac{3}{2}}(t) = -\int_0^\infty \frac{2a^2u^2e^{-u^2t}}{\pi(1+a^2u^2)} du = -\frac{1}{\sqrt{\pi t}} + \frac{1}{a}\exp\left(\frac{t}{a^2}\right)\mathrm{Erfc}\left(\frac{\sqrt{t}}{a}\right). \tag{3.52}$$

Consider the values of $H_\nu(t)$ for $t \in (0, 3)$. The errors under different norms for the numerical Laplace inversion are shown in Table 3.1. The points near singularity are computed by the Euler summation, whereas the others are computed by the FFT. If N increases, then more points will be placed in the neighborhood of the singularity and computed by the Euler summation. The CPU times are similar for different integral kernels and are less than 0.04 seconds for 512 points. It is clear that the mixture of the FFT method and the Euler summation achieves a high level of accuracy and efficiency.

4. Numerical experiments. As the closed-form pricing formulas of European options under the CEV model are available as shown in (2.4), we first investigate the sensitivity on the truncation parameter a to European option prices by using the proposed numerical method. Then we present the results for a European put option with different grid points. This attempts to show the convergence of the proposed scheme and demonstrate that our method outperforms the traditional CN scheme. Finally, we implement our method with American put options and make comparisons with alternative approaches.

As there is no exact solution for American options, Han and Wu [12] regard the binomial method with many time steps as true values to examine their numerical scheme. We subscribe to the same notion and use the lattice methods for the CEV model, as proposed by Lu and Hsu [16], with many time steps as the benchmark.

After imposing an artificial boundary Γ_a to bound the domain $\Omega_{\text{int}} = \{(Y, \tau) \in R^2 \mid Y_p^*(\tau) \le Y < a, 0 \le \tau \le T^*\}$, we need only to solve problem (3.36) with

the derived exact artificial boundary condition (3.35). Although all FDMs for the boundary value problem are possible choices, we consider the CN scheme with an evenly spaced grid, as it is the most widely used method for option pricing.

4.1. The numerical scheme. The interval $[0, T^*]$ is divided into N equally time-spaced subintervals, namely,

$$0 = \tau_0 < \tau_1 < \cdots < \tau_n < \cdots < \tau_N = T^*. \tag{4.1}$$

The interval $[0, a]$ for the state variable Y is divided into M subintervals with equal length, namely,

$$0 = Y_0 < Y_1 < \cdots < Y_m < \cdots < Y_M = a. \tag{4.2}$$

The central-time and central-space finite difference approximations are used as follows:

$$\frac{\partial V_1}{\partial \tau} \approx \frac{u_m^{n+1} - u_m^n}{\Delta \tau}, \tag{4.3}$$

$$\frac{\partial V_1}{\partial Y} \approx \frac{1}{2}\left(\frac{u_{m+1}^{n+1} - u_{m-1}^{n+1}}{2\Delta Y} + \frac{u_{m+1}^{n} - u_{m-1}^{n}}{2\Delta Y}\right), \tag{4.4}$$

$$\frac{\partial^2 V_1}{\partial Y^2} \approx \frac{1}{2}\left(\frac{u_{m+1}^{n+1} - 2u_m^{n+1} + u_{m-1}^{n+1}}{\Delta Y^2} + \frac{u_{m+1}^{n} - 2u_m^{n} + u_{m-1}^{n}}{\Delta Y^2}\right), \tag{4.5}$$

where $u_m^n = V_1(Y_m, \tau_n)$. The truncation error of the scheme is $O(\Delta Y^2, \Delta \tau^2)$.

By substituting the approximations into (3.36), we obtain

$$\begin{aligned}\frac{u_m^{n+1} - u_m^n}{\Delta \tau} = {} & \frac{1}{2}\left(\frac{u_{m+1}^{n+1} - 2u_m^{n+1} + u_{m-1}^{n+1}}{\Delta Y^2} + \frac{u_{m+1}^{n} - 2u_m^{n} + u_{m-1}^{n}}{\Delta Y^2}\right) \\ & + \frac{1 - 2\nu}{m \times \Delta Y} \times \frac{1}{2}\left(\frac{u_{m+1}^{n+1} - u_{m-1}^{n+1}}{2\Delta Y} + \frac{u_{m+1}^{n} - u_{m-1}^{n}}{2\Delta Y}\right).\end{aligned} \tag{4.6}$$

Let

$$g(Y, \tau) = \max\left(Ke^{r(T-t)} - \left(\frac{\sigma Y}{2}\right)^{2\nu} e^{q(T-t)}, 0\right), \tag{4.7}$$

$$g_m^n = g(Y_m, \tau_n). \tag{4.8}$$

A linear system of equations is established to compute the numerical values across each time interval, as follows:

$$\begin{aligned}\left(-\frac{\rho}{2} + \frac{1-2\nu}{4m}\rho\right) u_{m-1}^{n+1} + (\rho + 1) u_m^{n+1} + \left(-\frac{\rho}{2} - \frac{1-2v}{4m}\rho\right) u_{m+1}^{n+1} = \\ \left(\frac{\rho}{2} - \frac{1-2\nu}{4m}\rho\right) u_{m-1}^{n} + (-\rho + 1) u_m^{n} + \left(\frac{\rho}{2} + \frac{1-2v}{4m}\rho\right) u_{m+1}^{n},\end{aligned} \tag{4.9}$$

$$u_m^n \geq g_m^n, \tag{4.10}$$

$$u_m^0 = g_m^0, \tag{4.11}$$

where $n = 0, 1, 2, \ldots, N-1$, $m = 1, 2, \ldots, M$, and $\rho = \frac{\Delta \tau}{\Delta Y^2}$ is the mesh ratio.

For the exact artificial boundary condition on Γ_a, we use the approximation

$$\left.\frac{\partial V_1(Y,\tau)}{\partial Y}\right|_{Y=a} = \int_0^\tau \frac{\partial V_1(a,\lambda)}{\partial \lambda} H_\nu(\tau-\lambda)d\lambda \approx \frac{1}{\Delta\tau}\sum_{\ell=0}^{n-1}(u_M^{\ell+1}-u_M^\ell)\int_{\tau_\ell}^{\tau_{\ell+1}} H_\nu(\tau_n-\lambda)d\lambda, \tag{4.12}$$

where the truncation error is $O(\Delta\tau^\beta)$, with β depending on the integral kernel. For instance, $\beta = 3/2$ when $\alpha = 0$ [21].

We approximate the exact artificial boundary condition as follows:

$$\left.\frac{\partial V_1(Y,\tau)}{\partial Y}\right|_{Y=a} \approx \sum_{\ell=0}^{n-1}(u_M^{\ell+1}-u_M^\ell)\times\frac{H_\nu(\tau_n-\tau_{\ell+1})+H_\nu(\tau_n-\tau_\ell)}{2}, \tag{4.13}$$

where the function $H_\nu(t)$ can be evaluated by the numerical Laplace inversion shown in the appendix. The approximation in (4.13) is in fact the trapezoid rule, which approximates the integral $\int_a^b f(x)dx$ by $(b-a)\frac{f(a)+f(b)}{2} + O((b-a)^3)$. Thus, the aggregated error associated with the approximated boundary condition should be of $O(\Delta t^\beta + \Delta t^2)$. As β depends on the integral kernel, which is generally obtained from the Laplace inversion, determining the aggregated error for the approximated boundary involves tedious calculation. However, the most important thing should be the error for the numerical option price itself. Numerical examples are used to check the accuracy for European and American option prices. As a byproduct, we also check the order of convergence.

In the traditional CN scheme, the domains for the PDEs (2.7) and (2.11) are truncated to $[0, S_{max}]$ for a large S_{max}. In our example, we set S_{max} to twice the strike price for a put option. The far-field boundary condition is then given by

$$P_E(S_{max},\tau) \approx 0. \tag{4.14}$$

By expressing the problem in matrix-vector form, the values for u_m^n can be solved efficiently in the matrix-friendly Matlab program. All of the computations are implemented on a PC with an Intel Core 2 Duo E6300 1.86G Hz CPU and 1.0 GB of RAM. For the above discrete problem (4.11)–(4.14), we perform the following stability analysis.

PROPOSITION 4.1. *The discrete problem* (4.7)–(4.10) *is unconditionally stable, in the sense that* $\|u^n\|_\infty \le \|u^0\|_\infty, n = 1, 2, \ldots, N$, *independent of the time step and mesh spacing.*

Proof. Let $\{u^n\}$ be the solution of (4.7)–(4.10). Denote that

$$u_m^n = \|u^n\|_\infty = \max_{1\le i\le M}\{u_i^n\}. \tag{4.15}$$

Moreover, note that $u_m^n \ge g_m^n$. If $u_m^n = g_m^n$, then we have

$$u_m^n = \|u^n\|_\infty = g_m^n \le g_m^{n-1} \le u_m^{n-1} \le u_m^n = \|u^{n-1}\|_\infty,$$

where $n = 1, 2, \ldots, N$.

Otherwise, by (4.9), we have

$$\left(-\frac{\rho}{2}+\frac{1-2\nu}{4m}\rho\right)u_{m-1}^n + (\rho+1)u_m^n + \left(-\frac{\rho}{2}-\frac{1-2v}{4m}\rho\right)u_{m+1}^n = \left(\frac{\rho}{2}-\frac{1-2\nu}{4m}\rho\right)u_{m-1}^{n-1} + (-\rho+1)u_m^{n-1} + \left(\frac{\rho}{2}+\frac{1-2v}{4m}\rho\right)u_{m+1}^{n-1},$$

and hence we can obtain

$$(\rho+1)\|u^n\|_\infty \le \left(\frac{\rho}{2}+\frac{1-2\nu}{4m}\rho+\frac{\rho}{2}-\frac{1-2\nu}{4m}\rho\right)\|u^n\|_\infty + \left(\frac{\rho}{2}-\frac{1-2\nu}{4m}\rho-\rho+1+\frac{\rho}{2}+\frac{1-2\nu}{4m}\rho\right)\|u^{n-1}\|_\infty,$$

which can be simplified as

$$\|u^n\|_\infty \le \|u^{n-1}\|_\infty, \quad n=1,2,\ldots,N.$$

The proof is then completed by recurrence on n. □

Remark 1. Note that an evenly spaced grid is employed not solely for computational convenience but also for comparison to the widely used CN scheme. The proposed scheme can be further enhanced by considering variably sized time steps to obtain quadratic convergence. We refer to [10] for details.

Remark 2. For $\alpha > 1$, the artificial boundary condition is not required after transforming the original PDE into the standardized CEV equation. When $\alpha > 1$, the standardization procedure in section 3 leads to the PDE (3.9) defined on the bounded domain $(0, Y_p^*(\tau))\times[0,T^*]$ in which the exact boundary condition $\lim_{Y\to 0} V_1(Y,\tau) = 0$ is observed. For American put options, the early exercise boundary $S_p^\infty \le S_p^*(t) \le S_p^0$ for $0 \le t \le T$ corresponds to that using a new set of independent variables: $Y_p^0 \le Y_p^*(\tau) \le Y_p^\infty$ for $0 \le \tau \le T^*$. Thus, the traditional CN scheme can be implemented over the bounded domain $(0, Y_p^\infty)$ for $\alpha > 1$.

4.2. Sensitivity on the truncation size. The sensitivity on the truncation parameter a plays a key role in the proposed numerical method. According to the transformation $Y = \frac{2}{\sigma}(Se^{(r-q)(T-t)})^{\frac{1}{2\nu}}$, we choose

$$a = \max\left(\frac{2}{\sigma}(S_{max}e^{(r-q)T})^{\frac{1}{2\nu}}, \frac{2}{\sigma}(S_{max})^{\frac{1}{2\nu}}\right). \tag{4.16}$$

Figure 4.1 plots the errors of the proposed ABC scheme and the traditional CN scheme (FDM) against the value of S_{max}. The computation is based on 256×256 grids, a current stock price of 100, $r = 5\%$, and $q = 0$. The value of σ is set such that the local volatility is σ_0 given the value of α. It can be seen from Figures 4.1(c) and 4.1(d) that the ABC method is more robust with respect to the truncation size and the model parameters than is the FDM. In particular, the sufficiently large S_{max} is of levity in the FDM, and a large domain is often required to secure the accuracy, especially when the volatility is high and/or the maturity is long. Therefore, the literature suggests setting S_{max} to twice the strike price.

Figures 4.1(a) and 4.1(b) show that the errors of the proposed method are less than 0.001 once $S_{max} \ge 120$. Thus, imposing an artificial boundary condition around 1.2 times the strike price gives a reasonably good numerical values for the option price.

As the size of the computational domain and the grids are the same for the ABC and the FDM, Figure 4.1 indicates that the enhanced performance of the ABC approach is not because of a finer grid spacing. To further evaluate the costs and benefits of the FDM and the ABC, it is more desirable to make a comparison based on computational times and errors.

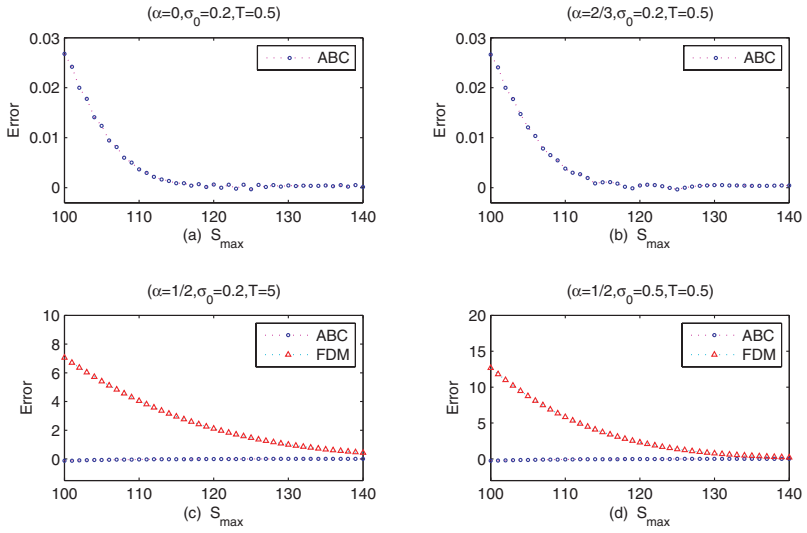

FIG. 4.1. *Sensitivity of the errors on the truncation parameter.*

4.3. Examples. We now give several examples to show the use of the proposed artificial boundary method for CEV option pricing.

Example 4.1. Consider the pricing of European and American put options with $\nu = \frac{1}{2}$, which corresponds to $\alpha = 0$. We have discussed the properties of the integral kernel under this situation in section 3.3. It is clear that the standardized CEV equation is reduced to a heat equation when $\nu = \frac{1}{2}$.

Comparisons are made by using the closed-form put pricing formula in (2.2)–(2.4). The current stock price is 100, the time to expiry is six months, $r = 5\%$, $q = 0$ (nondividend), and the at-the-money volatility is 20%. We choose $S_{max} = 120$ for the ABC and $S_{max} = 200$ for the traditional CN scheme (FDM), respectively. It can be seen from Table 4.1 that the ABC method is efficient and accurate. Answers accurate

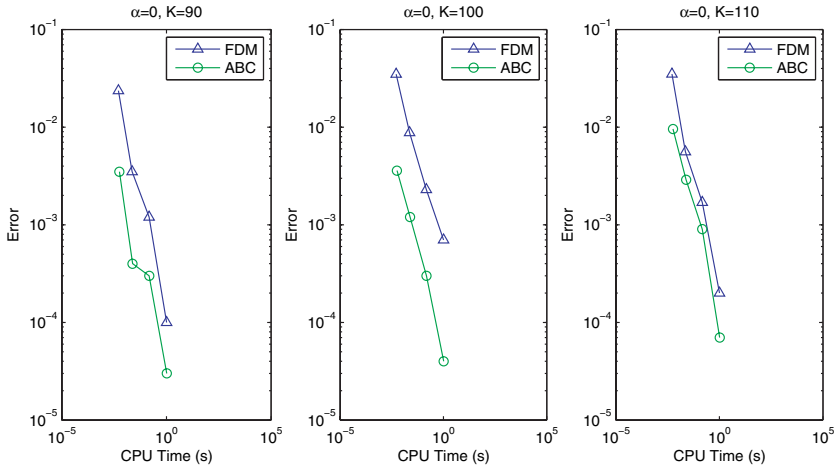

FIG. 4.2. *Error for the FDM and the ABC with* $\alpha = 0$.

to within 0.01 are given by using 64×64 grids for all three cases. The CPU time is even less than in the closed-form method. Compared to the traditional CN method with 128×128 grids, the proposed method is more than four times faster, with the same level of accuracy. We stress that the finite difference scheme computes not one, but many, option prices at the same time. For the case of 64×64 grids, the computational time refers to the time to obtain 64 option prices. By using interpolation, we are able to obtain the option value on the entire domain. These many option prices are useful for computing option Greeks, such as Delta and Gamma. The binomial method with 5000 time steps also generates accurate results but is much less efficient.

The performance of the proposed method for valuing American options is investigated next. As no closed-form solution is available, we compare the results of the ABC to those obtained by the FDM with many more grid points and the binomial method with 5000 time steps. Once again, the ABC method outperforms the traditional CN scheme with its high convergent speed. Moreover, the ABC method exceeds the binomial method with its greater efficiency. From Table 4.1, when the strike price is set to 110, the result of the traditional CN scheme with 512×512 grids is 10.7504 with an evaluation time of 1.0424 seconds. By using the ABC method, a result of 10.7507 is obtained for 128×128 grids, and the computational time is only 0.0320 seconds. The binomial method is much more time-consuming for the same level of accuracy.

We plot the computational error against the execution time for different K in Figure 4.2. The lower the curve, the better the performance of the scheme. It is obvious that, for all three cases, the ABC method outperforms the traditional CN scheme, especially for out-of-the-money and at-the-money options.

Example 4.2. We now take a look at a situation in which $0 < \alpha < 1$. In particular, we consider $\alpha = 2/3$, which is equivalent to $\nu = 3/2$. We use the properties in section 3.3 to implement the ABC method. The other parameters are the same as those in Example 4.1.

Table 4.2 summarizes the computational results. First we concentrate on the European put option. Unlike in Example 4.1, the integral kernel involves the computation of the error function in the present case. The evaluation time will be a little bit longer. However, the ABC method still outperforms the traditional CN scheme and

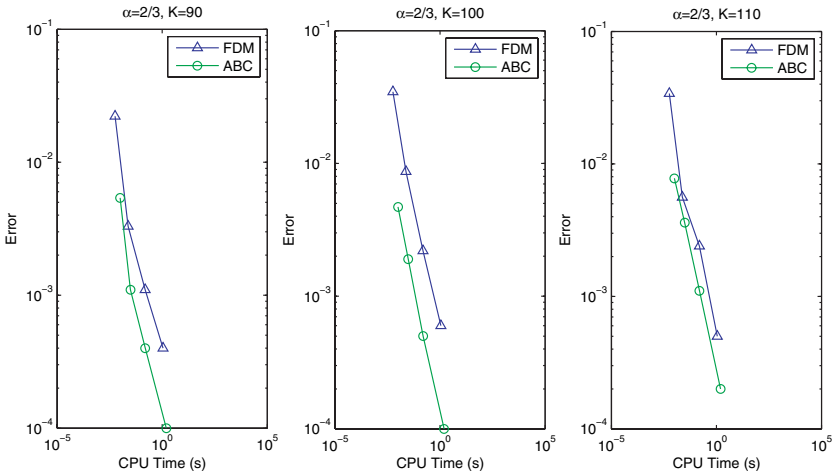

FIG. 4.3. *Error for the FDM and the ABC with* $\alpha = 2/3$.

the binomial method with 5000 time steps in terms of both efficiency and accuracy. When the error is plotted against the evaluation time in Figure 4.3, the superiority of the ABC method becomes obvious.

The ABC method is still very efficient when we use it to price American options, as reported in Table 4.2. For example, the ABC method with 256×256 grids generates the same accuracy level as the traditional CN scheme with 512×512 grids. The evaluation time is much less than the binomial methods with 5000 time steps.

Figure 4.3 gives a more complete picture to compare the performance. It can be seen that the curve corresponding to the ABC is always beneath that of the FDM approach. We are comfortable with concluding that the ABC approach outperforms the FDM ones for $\alpha = 2/3$.

Example 4.3. Another example is used to verify the performance of the ABC method. As the empirical results cited by Davydov and Linetsky [6] suggest that $\alpha = -3$ may be appropriate for the S&P 500 index, this example demonstrates the effect of this choice on the European and American option prices and their corresponding Greeks. Except for the value of α, the other parameters are the same as those in Example 4.1.

The results of the European and American put options are displayed in Table 4.3. Because the analytical solution of the integral kernel is unavailable, we resort to the numerical Laplace inversion. Hence, the evaluation time will be a little longer. The ABC method clearly outperforms the binomial method with 5000 time steps in both the European and the American options.

To compare the ABC method with the FDM, Figure 4.4 is constructed to examine the trade-off between accuracy and efficiency in both approaches. It can be seen that both approaches exhibit similar performance if one accepts that the error can be larger than 5×10^{-3}. In practice, option prices correct to three decimal places are quoted because deeply out-of-money option prices are typically low. Therefore, it is practical to consider the error to be less than or equal to 10^{-3}. For this range of errors, the ABC approach outperforms the FDM because all of the curves corresponding to the ABC are beneath those of the FDM, as shown in Figure 4.4. The ABC method has a clear practical advantage for the CEV model.

As important as option prices are the hedging parameters: *delta*, *gamma*, *vega*, *theta*, and *rho*. In the financial market, the aim of the trader is to manage the Greeks so that all risks are acceptable. Because finite difference calculations generate option values on an entire grid of S values, the calculation of *delta*, *gamma*, and *theta* can be determined with a negligible additional computational cost. The evaluation of

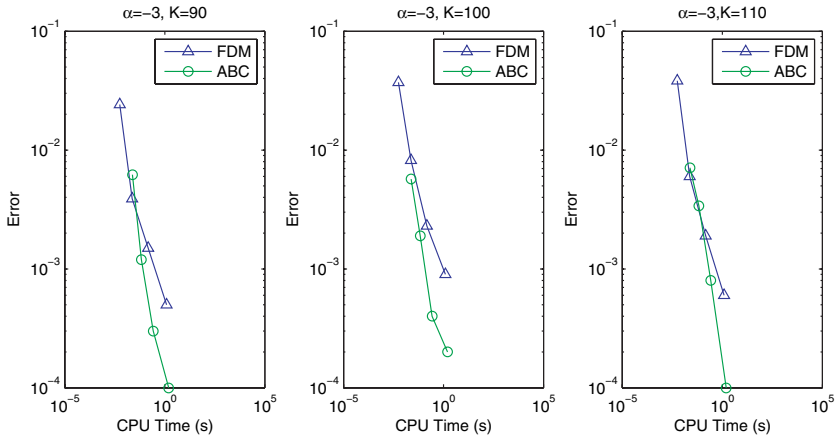

FIG. 4.4. *Error for the FDM and the ABC with* $\alpha = -3$.

the other hedging parameters in this manner requires the repeated solution of the equation for the option value. In Table 4.3, the results of the Greeks for European and American put options are obtained by using the ABC method with 256×256 grids. Our method works well.

4.4. Order of convergence. To show the order of convergence of the proposed scheme numerically, we consider Examples 4.1–4.3 again. As these examples share the same set of parameters, except for α, we can examine the order of convergence for different values of α, given other things being fixed.

Let $\mathbf{V_1}$ be a vector of option prices calculated by using the proposed scheme and $\mathbf{u}$ be that by using the exact solution. The exact solution for European put option is clear. We regard the numerical value obtained from the binomial method with very fine time steps as the exact solution of the American put option. We speculate that the error in the L_2 norm takes approximately the following form:

$$||\mathbf{V_1} - \mathbf{u}||_{L_2} \approx C\Delta\tau^p, \tag{4.17}$$

where C and p are constant values. To investigate the order of convergence with respect to the time step size, we estimate the order parameter p by using a linear regression:

$$\log ||\mathbf{V_1} - \mathbf{u}||_{L_2} \approx p \log \Delta\tau + \log C. \tag{4.18}$$

The estimated value of p is denoted as $\hat{p}$. To get a better estimate for p, we expand our calculation to cover grids of 32×32, 64×64, 128×128, 256×256, 512×512, 1024×1024, and 2048×2048.

Table 4.4 shows the results for European and American options with different combinations of K and α. It can be seen that all of the values of $\hat{p}$ are consistently larger than 1.5, and some of them even come close to 2. As the option payoff, or equivalently the initial condition of the PDE, is not a smooth function at the at-the-money point, quadratic convergence is impossible for an evenly grid CN scheme. Forsyth and Vetzal [10] propose a penalty approach that automatically generates variably sized time steps to obtain the quadratic convergence. Their method can be applied to our case as it does not conflict with the exact artificial boundary condition

TABLE 4.4
Estimated order of convergence $\hat{p}$.

approach. As the present paper concentrates on the ABC approach, we would like to highlight its effect and thus do not implement the Forsyth and Vetzal [10] approach here.

5. Conclusion. We study the artificial boundary finite difference method for pricing American options under the CEV model. The exact artificial boundary condition is derived and implemented in several practical examples. Our numerical experiments show that the proposed approach outperforms the classical FDM and the binomial method in terms of both efficiency and robustness for highly accurate option prices.

Appendix A. Numerical Laplace inversion. The numerical Laplace inversion computes the original function $f(t)$ for a given single value of t. The FFT algorithm can often be exploited. The method used in this paper belongs to the Dubber–Abate family, which starts with the complex inversion formula

$$f(t) = \frac{1}{2\pi i}\int_{a-i\infty}^{a+i\infty} e^{st}F(s)ds, \tag{A.1}$$

where it is assumed that $F(s)$ is holomorphic in a right-half plane such that a can be any positive number. By assuming that $F(s)$ is real in the sense that $F(\bar{s}) = \overline{F(s)}$, the formula is transformed into

$$f(t) = \frac{2e^{at}}{\pi}\int_0^\infty \Re[F(a+iu)]\cos(ut)du = -\frac{2e^{at}}{\pi}\int_0^\infty \Im[F(a+iu)]\sin(ut)du,$$

where $\Re$ stands for the real part and $\Im$ stands for the imaginary part. The cosine-transform integral is numerically evaluated by means of the trapezoidal rule, which is a numerical approximation of the integral defined as follows:

$$\int_{x_0}^{x_1} g(x)\mathrm{d}x = \frac{x_1 - x_0}{2}(g(x_0) + g(x_1)) - \frac{1}{12}g''(c)\left(\frac{x_1 - x_0}{2}\right)^3, \tag{A.2}$$

where c lies somewhere between x_0 and x_1.

With step size h, we obtain

$$f(t) \approx f_h(t) := h\left\{\frac{e^{at}}{\pi}\Re[F(a)] + \frac{2e^{at}}{\pi}\sum_{k=1}^{\infty}\Re[F(a+ikh)]\cos(kht)\right\}. \tag{A.3}$$

For the given t and a positive number A, let us choose the step $h = \frac{\pi}{T}$, which yields the formula

$$f_h(t) := \frac{2e^{at}}{T}\left\{\frac{1}{2}\Re[F(a)] + \sum_{k=1}^{\infty}\Re\left[F\left(a + \frac{k\pi i}{T}\right)\right]\cos\left(\frac{k\pi}{T}t\right)\right\}. \tag{A.4}$$

We now cast the method into a form compatible with the finite Fourier transform (3.45) as follows:

$$f_h(t) := \frac{e^{at}}{T}\left\{\sum_{n=-\infty}^{+\infty} \Re\left[F\left(a+i\frac{\pi n}{T}\right)\right]\exp\left(i\frac{n\pi}{T}t\right)\right\}. \tag{A.5}$$

If $|f(t)|$ is bounded by a constant K, we obtain the error estimator (see [8]):

$$|error| = |f_h(t) - f(t)| \le \exp(-aT + at)\cosh(at)/\sinh(aT). \tag{A.6}$$

Since the error becomes prohibitively large as t approaches T, our representation is restricted to the interval $0 \le t \le T/2$. Now let the situation be such that we require $f(t)$ for the equidistant points $t = j\Delta t$, where $j = 0, 1, 2, \ldots, N = N_1/2$. Then Δt is the desired sampling interval, and the maximum t-value is $t_{max} = N\Delta t$. We have $T = 2t_{max}$ or $T = 2N\Delta t = N_1\Delta t$. By using these definitions, we are able to manipulate the series so that (A.5) can be put into the following form:

$$\frac{f(j\Delta t)}{b(j)} = \sum_{k=0}^{N_1-1} A(k)\exp\left(\frac{2\pi i}{N_1}jk\right), \tag{A.7}$$

where

$$A(k) = \frac{1}{N_1\Delta t}\sum_{n=-\infty}^{+\infty} \Re\left[F\left(a+\frac{2\pi i}{N_1}(k+nN_1)\right)\right], \quad b(j) = 2\exp(aj\Delta t). \tag{A.8}$$

The right-hand side of (A.7) is of the same form as (3.45), thereby permitting the use of FFT on the problem. The procedure is as follows:

1. Compute $A(k)$ from $F(s)$ by use of (A.8).
2. Let $A(k)$ be the input to the FFT subroutine. The output will be $X(j)$ for $j = 0, 1, 2, \ldots, N_1 - 1$.
3. The inverse function is given by $f(j\Delta t) = b(j)X(j)$, where $b(j)$ is defined by (A.8). However, due to our error analysis we accept only $b(j)X(j)$ as a representation of the function f for $j = 0, 1, 2, \ldots, N_1/2 = N$.

For the t-values near singularity, we employ another version of the Fourier series method with Euler summation. The cosine factor in (A.3) may be eliminated by choosing the step $h = \frac{\pi}{2t}$, i.e., $T = 2t$, and the integration abscissa $a = \frac{A}{2t}$ such that a nearly alternating series results:

$$f_h(t) := \frac{e^{A/2}}{2t}F\left(\frac{A}{2t}\right) + \frac{e^{A/2}}{t}\sum_{k=1}^{\infty}(-1)^k\Re\left[F\left(\frac{A+2k\pi i}{2t}\right)\right]. \tag{A.9}$$

However, the coefficients then become t-dependent and must be evaluated for each new value of t. The remaining problem is to evaluate the above infinite sum. Because we have a nearly alternating series, an acceleration method for alternating series, i.e., the Euler summation, is proposed. With

$$s_n(t) := \frac{e^{A/2}}{2t}F\left(\frac{A}{2t}\right) + \frac{e^{A/2}}{t}\sum_{k=1}^{n}(-1)^k\Re\left[F\left(\frac{A+2k\pi i}{2t}\right)\right], \tag{A.10}$$

the Euler summation is applied to m terms after an initial n (typically $m = 11$ and $n = 15$):

$$f(t) \approx f_h(t) \approx E(m,n,t) := \sum_{k=0}^{m} \left(\begin{array}{c} m \\ k \end{array} \right) 2^{-m} s_{n+k}(t). \tag{A.11}$$

It is possible to gain some insight into the discretization error that results from passing from $f(t)$ to $f_h(t)$. To establish this result, we use the formula derived by the discrete Laplace transform:

$$\sum_{k=0}^{\infty} f(kT+\tau)e^{-kTs} = pv\frac{1}{T}\sum_{k=-\infty}^{\infty} F\left(s + i\frac{2\pi}{T}k\right)\exp\left[\left(s + i\frac{2\pi}{T}k\right)\tau\right], \tag{A.12}$$

where pv means principle value. The formula holds for $0 < \tau < T$. By substituting t for τ, b for s, and $T = 2\pi/h$, we obtain

$$\sum_{k=0}^{\infty} f\left(t + k\frac{2\pi}{h}\right)e^{-k2\pi b/h} = pv\frac{h}{2\pi}\sum_{k=-\infty}^{\infty} F(b+ihk)\exp[(b+ihk)t] \tag{A.13}$$

and, with $h = \pi/t$ and $b = A/(2t)$,

$$\sum_{k=0}^{\infty} f((2k+1)t)e^{-kA} = pv\frac{e^{A/2}}{2t}\sum_{k=-\infty}^{\infty} F\left(\frac{A+2\pi ik}{2t}\right)(-1)^k. \tag{A.14}$$

This can be written as

$$\begin{aligned} &f(t) + \sum_{k=1}^{\infty} f((2k+1)t)e^{-kA} \\ &= \frac{e^{A/2}}{2t}F\left(\frac{A}{2t}\right) + pv\frac{e^{A/2}}{2t}\sum_{k=1}^{\infty}(-1)^k \Re\left[F\left(\frac{A+2\pi ik}{2t}\right)\right]. \end{aligned} \tag{A.15}$$

Therefore,

$$f(t) = f_h(t) - \sum_{k=1}^{\infty} f((2k+1)t)e^{-kA}. \tag{A.16}$$

This shows that the sampling error associated with the trapezoidal rule is given by

$$err_d = \sum_{k=1}^{\infty} f[(2k+1)t]e^{-kA}. \tag{A.17}$$

If we know, for example, that $|f(t)|$ is bounded by a constant K, then we obtain the estimate

$$|err_d| \le K\frac{e^{-A}}{1-e^{-A}} \approx Ke^{-A} \tag{A.18}$$

when e^{-A} is small.

CONVERGENCE OF GODUNOV-TYPE SCHEMES FOR SCALAR CONSERVATION LAWS UNDER LARGE TIME STEPS*

JING-MEI QIU† AND CHI-WANG SHU†

Abstract. In this paper, we consider convergence of classical high-order Godunov-type schemes towards entropy solutions for scalar conservation laws. It is well known that sufficient conditions for such convergence include total variation boundedness of the reconstruction and cell or wavewise entropy inequalities. We prove that under large time steps, we only need total variation boundedness of the reconstruction to guarantee such convergence. We discuss high-order total variation bounded reconstructions to fulfill this sufficient condition and provide numerical examples on one-dimensional convex conservation laws to assess the performance of such large time step Godunov-type methods. To demonstrate the generality of this approach, we also prove convergence and give numerical examples for a large time step Godunov-like scheme involving Sanders' third-order total variation diminishing reconstruction using both cell averages and point values at cell boundaries.

Key words. hyperbolic conservation laws, Godunov-type scheme, high-order accuracy, total variation diminishing, total variation bounded, convergence, entropy solution

1. Introduction.

In this paper, we consider the Cauchy problem of the scalar conservation law,

$$\begin{cases} u_t + \nabla \cdot f(u) = 0 & \text{in } \mathbb{R}^m \times [0,T], \\ u(x,0) = u_0(x) & \text{in } \mathbb{R}^m, \end{cases} \tag{1.1}$$

where $u_0(x) \in \mathrm{BV}$, the space of functions with bounded variation. We do not consider boundary conditions and assume that the initial condition is either compactly supported or periodic. In most of our presentation we will concentrate on the one-dimensional case $m = 1$, and will point out similarities and differences for higher dimensions $m > 1$. The scheme under consideration is the classical Godunov-type scheme, consisting of the following three stages to evolve the cell averages from time level n (denoted by $\bar{u}^n$) to time level $n+1$ (denoted by $\bar{u}^{n+1}$).

1. *Reconstruction:* obtain a high-order piecewise polynomial reconstruction $u^n(x)$ whose cell averages agree with the given cell averages $\bar{u}^n$. We denote this reconstruction operator as $Re(\bar{u}^n)$.
2. *Evolution:* evolve $u^n(x)$ by the conservation law (1.1) *exactly* for a time step Δt to obtain a solution $\tilde{u}^{n+1}(x)$, which is in general *not* piecewise polynomial anymore. We denote this evolution operator as $S_{\Delta t}(u^n)$.
3. *Averaging:* average the function $\tilde{u}^{n+1}(x)$ to obtain the cell averages $\bar{u}^{n+1}$ at time level $n+1$. We denote this averaging operator as $A(\tilde{u}^{n+1})$.

The Godunov-type scheme, using the notations introduced above, can be described abstractly as

$$\begin{cases} \bar{u}^0 = A(u_0), \\ \bar{u}^{n+1} = A \circ S_{\Delta t} \circ Re\,(\bar{u}^n), \qquad n = 0, 1, \ldots, N-1. \end{cases} \tag{1.2}$$

The purpose of the reconstruction step is to increase the formal accuracy of the scheme. It is usually achieved by using cell averages of several neighboring cells to obtain a high-order reconstructed polynomial. In order to be more specific, let us first introduce some notations. For example, in the one-dimensional case, the mesh is given by $I_j = [x_{j-\frac{1}{2}}, x_{j+\frac{1}{2}}]$. The center of the cell I_j is given by $x_j = \frac{1}{2}(x_{j-\frac{1}{2}} + x_{j+\frac{1}{2}})$, and the size of the cell I_j is denoted by $\Delta x = x_{j+\frac{1}{2}} - x_{j-\frac{1}{2}}$, which is considered to be a constant (uniform mesh) in this paper for simplicity of notations. The cell average of a function $u(x)$ in the cell I_j is defined as

$$\bar{u}_j = A(u)_j = \frac{1}{\Delta x} \int_{x_{j-\frac{1}{2}}}^{x_{j+\frac{1}{2}}} u(x)\,dx.$$

A second-order reconstruction would be a piecewise linear function, and the linear reconstruction $p_j(x)$ in cell I_j could be the unique linear polynomial satisfying

$$\frac{1}{\Delta x} \int_{x_{j-\frac{3}{2}}}^{x_{j-\frac{1}{2}}} p_j(x)\,dx = \bar{u}_{j-1}, \qquad \frac{1}{\Delta x} \int_{x_{j-\frac{1}{2}}}^{x_{j+\frac{1}{2}}} p_j(x)\,dx = \bar{u}_j,$$

namely, $p_j(x)$ agrees with the given cell averages of $u(x)$ over the two cells $\{I_{j-1}, I_j\}$, which is called the *stencil* of the reconstruction $p_j(x)$. Usually, we require that the stencil for the reconstruction in cell I_j contain at least I_j itself. Additional cells in the stencil can be chosen according to symmetry or stability (nonoscillation) considerations. For example, the stencil for the linear polynomial $p_j(x)$ above could also be $\{I_j, I_{j+1}\}$, which would of course produce a different reconstructed linear polynomial.

The reconstruction is called (formally) kth-order accurate, namely,

$$|Re(\bar{u})(x) - u(x)| \le C\Delta x^k, \qquad x \in I_j, \tag{1.3}$$

if the reconstructed polynomial in I_j is of $(k-1)$th degree with a stencil of k cells over which the function $u(x)$ is smooth. Here and below, C (or $\tilde{C}$) will denote a generic constant independent of the mesh sizes Δx and Δt, which may have different values in different locations. For more details of second- and higher-order reconstructions, we refer the reader to [14, 21].

A reconstruction is called total variation bounded (TVB) if

$$TV(Re(\bar{u})) \le (1 + C\Delta x) TV(\bar{u}), \tag{1.4}$$

and it is called total variation diminishing (TVD) if (1.4) holds with $C = 0$. Here the total variation of a piecewise smooth function $g(x)$ is defined as usual,

$$TV(g) = \int |g'(x)|\,dx,$$

and the total variation of $\bar{u}$ in (1.4) is defined with $\bar{u}$ considered as a piecewise constant function.

Since the exact evolution operator $S_{\Delta t}$ and the averaging operator A do not increase the total variation of a function, the total variation of the final solution $\bar{u}^N$ of the Godunov-type scheme at a fixed time $T = N\Delta t$ is bounded by a constant C independent of the mesh sizes Δx and Δt, when both of them go to zero, if the reconstruction is TVB. This constant C is the total variation of the initial data if the reconstruction is TVD.

By compactness, the sequence of numerical solutions of a Godunov-type scheme with a TVB reconstruction, when the mesh sizes Δx and Δt both go to zero, has a convergent subsequence in L^1. Since the scheme is conservative, the limit of such a convergent subsequence is a weak solution to (1.1). However, because of the nonuniqueness of weak solutions, we cannot conclude the convergence of the original sequence of numerical solutions, nor can we claim that the limit of a convergent subsequence is the physically relevant entropy solution. Typically, we would need an additional cell entropy inequality, e.g., [18], or a wavewise entropy inequality, e.g., [24], to imply such convergence. Such cell or wavewise entropy inequalities are very difficult to obtain for high-order schemes, especially for nonconvex conservation laws for which such entropy inequalities are needed for all entropies rather than just for one of them. As far as we know, within self-similar finite difference or finite volume framework, such cell or wavewise entropy inequalities have been obtained only for second-order MUSCL-type schemes for scalar one-dimensional convex conservation laws [18, 24], and for a special second-order scheme for general conservation laws which evolves cell averages and cell slopes independently [2]. These schemes are all explicit schemes with the usual CFL restriction $\Delta t = O(\Delta x)$. It seems that for such situations a cell or wavewise entropy inequality is necessary for convergence towards entropy solutions; see, for example, [18] in which it is proven that finite volume schemes (those which evolve only cell averages and rely on reconstruction to achieve higher-order accuracy) which satisfy all entropy conditions are necessarily only first-order accurate, [1] in which an entropy condition can be obtained only when a first-order antidiffusive scheme is suitably modified and enhanced, and [23] in which a counterexample is shown to demonstrate that a second-order TVD Godunov-type scheme can converge to an entropy violating solution for nonconvex conservation laws. We remark that cell entropy inequality for the square entropy can be obtained in more general situations (arbitrary order of accuracy, general triangulation in multispace dimensions, arbitrary scalar conservation laws) for the semidiscrete discontinuous Galerkin method [9], but this is a totally different class of schemes in which no reconstruction is involved and the complete polynomial within a cell is evolved in time to obtain high-order accuracy.

We now mention a few papers in the literature which directly motivated our work in this paper. Lions and Souganidis [16] proved the convergence of an implicit MUSCL scheme to the entropy solution of strictly convex scalar one-dimensional Hamilton–Jacobi equation and conservation law under a large time step assumption, namely, $\Delta x = o(\Delta t)$. For one-dimensional convex Hamilton–Jacobi equations, which are very closely related to conservation laws (1.1), Ferretti [5] proved the convergence of a semi-Lagrangian scheme to the viscosity solution (the solution corresponding to the entropy solution for conservation laws), again under a large time step assumption $\Delta x = o(\Delta t)$. This convergence holds for quite general high-order reconstructions, e.g., the ENO reconstruction [8] up to fifth order and WENO reconstruction [10] up to ninth order; see [5, 3]. The message in [16, 5, 3] seems to be that it is easier to prove convergence for large time step ($\Delta x = o(\Delta t)$) schemes. Of course, such a choice of the time step violates the traditional CFL condition for local explicit schemes. One would

need to take either implicit time discretization, as in [16], or semi-Lagrangian time discretization, namely following the characteristics, as in [5, 3]. In related work, we mention the large time step generalization of the first-order accurate Godunov method in [13], which involves an approximate but not exact entropy solution evolution. We also mention the large time step semi-Lagrangian method in [4], for which an entropy condition can be proven for convex scalar one-dimensional conservation laws.

In this paper we prove that, indeed, the large time step assumption $\Delta x = o(\Delta t)$ allows us to bypass the verification of cell or wavewise entropy conditions and prove the convergence towards the entropy solution of Godunov-type schemes solely under the assumption of a TVB reconstruction, for general scalar conservation laws (1.1). Since self-similar TVB reconstruction is available in one dimension to third-order accuracy [15], we then have third-order accurate Godunov-type schemes in one dimension which can be proven convergent towards the entropy solution. Of course, to actually implement the large time step Godunov-type schemes is not trivial. We discuss an effective implementation, similar to the semi-Lagrangian scheme in [5, 3] for Hamilton–Jacobi equations, for one-dimensional scalar convex conservations.

The paper is organized as follows. Section 2 contains our main convergence result and its proof. In section 3, the TVB property of the numerical solution is considered. Examples of high-order TVB reconstruction are given. Section 4 discusses an effective implementation of the large time step Godunov-type scheme for one-dimensional scalar convex conservation laws and provides numerical results verifying the performance of such schemes. In order to demonstrate the generality of this approach, we consider in section 5 a Godunov-like scheme using a third-order TVD reconstruction due to Sanders [19], which uses both cell averages and point values at cell boundaries for the reconstruction and does not exactly fit our large time step Godunov-type scheme framework, but the convergence can be obtained along similar lines. Concluding remarks are given in section 6.

2. Convergence of large time step Godunov-type schemes. We consider the Godunov-type scheme (1.2) for solving the scalar conservation law (1.1) under the following three assumptions:

1. the reconstruction operator Re satisfies

$$\|\bar{u} - Re(\bar{u})\|_{L^1} \le C\,\Delta x TV(\bar{u}) \tag{2.1}$$

   for any piecewise constant function $\bar{u}$;
2. the total variation of the numerical solution is uniformly bounded,

$$TV(\bar{u}^n) \le C \tag{2.2}$$

   for all mesh sizes Δx and Δt satisfying $n\Delta t \le T$;
3. large time step condition is

$$\lim_{\Delta x \to 0} \frac{\Delta x}{\Delta t} = 0. \tag{2.3}$$

We have the following convergence result under these assumptions.

THEOREM 2.1. *The numerical solution of the Godunov-type scheme* (1.2) *for solving the scalar conservation law* (1.1) *converges in* L^1 *to the entropy solution of* (1.1) *when the mesh size* Δx *goes to zero if the three assumptions* (2.1), (2.2), *and* (2.3) *are satisfied.*

Proof. We denote the exact entropy solution of (1.1) at time level t^n by $u(\cdot, t^n)$ and the L^1 difference between this exact solution and the reconstructed numerical solution $u^n = Re(\bar{u}^n)$ at time level t^n by e^n,

$$e^n = \|u(\cdot, t^n) - Re(\bar{u}^n)\|_{L^1}. \tag{2.4}$$

First, we notice that

$$\begin{aligned}
\|A(u(\cdot, t^n)) - \bar{u}^n\|_{L^1} &= \|A(u(\cdot, t^n)) - A \circ S_{\Delta t} \circ Re\,(\bar{u}^{n-1})\|_{L^1} \\
&= \|A\,\left(u(\cdot, t^n) - S_{\Delta t} \circ Re\,(\bar{u}^{n-1})\right)\|_{L^1} \\
&\le \|u(\cdot, t^n) - S_{\Delta t} \circ Re\,(\bar{u}^{n-1})\|_{L^1} \\
&= \|S_{\Delta t}\,(u(\cdot, t^{n-1})) - S_{\Delta t} \circ Re\,(\bar{u}^{n-1})\|_{L^1} \\
&\le \|u(\cdot, t^{n-1}) - Re\,(\bar{u}^{n-1})\|_{L^1} = e^{n-1}, \qquad (2.5)
\end{aligned}$$

where the third inequality is due to the fact that the averaging operator A does not increase the L^1 norm of a function, and the fifth inequality is due to the L^1 contraction property of the exact entropy solution operator $S_{\Delta t}$ of (1.1); see [12]. Also for a bounded variation function w, it is easy to verify that

$$\|w - A(w)\|_{L^1} \le C\Delta x TV(w). \tag{2.6}$$

In fact, for the one-dimensional case

$$\begin{aligned}
\|w - A(w)\|_{L^1} &= \sum_j \int_{I_j} |w(x) - \bar{w}_j| dx \\
&\le \sum_j \Delta x \left(\sup_{x \in I_j} w(x) - \inf_{x \in I_j} w(x) \right) \le \Delta x TV(w).
\end{aligned}$$

The proof for the multidimensional case is similar.

We can now proceed to prove the desired convergence,

$$\begin{aligned}
e^n &= \|u(\cdot, t^n) - Re(\bar{u}^n)\|_{L^1} \\
&\le \|u(\cdot, t^n) - A(u(\cdot, t^n))\|_{L^1} + \|A(u(\cdot, t^n)) - \bar{u}^n\|_{L^1} + \|\bar{u}^n - Re(\bar{u}^n)\|_{L^1} \\
&\le C\Delta x TV(u(\cdot, t^n)) + e^{n-1} + C\Delta x TV(\bar{u}^n) \\
&\le \tilde{C}\Delta x + e^{n-1} \\
&\le \cdots \\
&\le \tilde{C} n \Delta x + e^0 \\
&= \tilde{C} T \frac{\Delta x}{\Delta t} + e^0 \to 0 \qquad \text{as} \quad \Delta x \to 0, \qquad (2.7)
\end{aligned}$$

where for the third inequality we have used (2.6), (2.5), and the assumption (2.1), for the fourth inequality we have used the fact that the exact entropy solution $u(\cdot, t^n)$ is of bounded variation and the assumption (2.2), and for the last limit we have used the large time step assumption (2.3). ∎

Next, we prove that the assumption (2.1) is satisfied by all commonly used reconstructions, including the high-order ENO and WENO reconstructions [8, 10]. As before, for simplicity we divide the computational domains into uniform cells (in one dimension these are nonoverlapping intervals of the same length Δx covering the whole

computational domain). We require the reconstruction to be a piecewise polynomial function; namely, it is a polynomial over each cell I_j. The reconstructed polynomial in I_j is uniquely determined by requiring that it have the same cell average as the given one over each cell in a stencil, which is a set of finitely many cells (the number of cells in this set is fixed and does not depend on the mesh size Δx) and contains the given cell I_j. For such reconstructions we have the following result.

LEMMA 2.2. *The assumption* (2.1) *is satisfied by any piecewise polynomial reconstruction with a local stencil containing finitely many cells.*

Proof. We prove this lemma for the one-dimensional case. The proof for the multidimensional case is similar. Assume the reconstruction stencil for cell I_j is $I_{j-l(j)}, \ldots, I_{j+r(j)}$. Since the stencil contains I_j and has only finitely many cells, we have $0 \le l(j), r(j) \le M$ for a fixed integer M. The reconstructed polynomial in cell I_j can be written as

$$p(x) = \sum_{i=-l(j)}^{r(j)} p_i\left(\frac{x - x_j}{\Delta x}\right) \bar{u}_{j+i}, \tag{2.8}$$

where $p_i(\xi)$ are polynomials independent of Δx and the location I_j; see, for example, [21] for the explicit expression of $p_i(\xi)$. We therefore have $|p_i(\xi)| \le C$ for some constant C when ξ is in the relevant range $|\xi| \le \frac{1}{2}$. Also, by consistency (i.e., the reconstruction is exact if $\bar{u}_j \equiv 1$), we have

$$\sum_{i=-l(j)}^{r(j)} p_i\left(\frac{x - x_j}{\Delta x}\right) = 1.$$

Hence

$$p(x) - \bar{u}_j = \sum_{i=-l(j)}^{r(j)} p_i\left(\frac{x - x_j}{\Delta x}\right) (\bar{u}_{j+i} - \bar{u}_j).$$

We now have

$$\begin{aligned}
\|\bar{u} - Re(\bar{u})\|_{L^1} &= \sum_j \|\bar{u} - Re(\bar{u})\|_{L^1(I_j)} \\
&= \sum_j \int_{I_j} \left| \sum_{i=-l(j)}^{r(j)} p_i\left(\frac{x - x_j}{\Delta x}\right) (\bar{u}_{j+i} - \bar{u}_j) \right| dx \\
&\le CM(2M+1)\Delta x \sum_j |\bar{u}_{j+1} - \bar{u}_j| \\
&= \tilde{C}\Delta x TV(\bar{u}). \qquad \square
\end{aligned}$$

Clearly, Lemma 2.2 covers both the linear reconstructions, for which the reconstruction stencil relative to I_j is fixed, i.e., $l(j)$ and $r(j)$ do not depend on j, as well as the ENO reconstruction [8], for which the reconstruction stencil depends on the local smoothness of the data $\bar{u}$. Since the WENO reconstructions [10] are linear combinations of fixed stencil reconstructions with bounded weights (linear combination coefficients, which depend on the local smoothness of the data $\bar{u}$), Lemma 2.2 also covers WENO reconstructions. Notice that Lemma 2.2 is valid for reconstructions of arbitrarily high-order accuracy.

Remark 2.3. By combining the results in Theorem 2.1 and Lemma 2.2, we conclude that, if the reconstruction operator Re is based on piecewise polynomial reconstruction with a local stencil containing finitely many cells, then the numerical solution of the Godunov-type scheme (1.2) for solving the scalar conservation law (1.1) converges in L^1 to the entropy solution of (1.1) when the mesh size Δx goes to zero, provided that the two assumptions (2.2) and (2.3) are satisfied.

Remark 2.4. The proof (2.7) for Theorem 2.1 gives a pessimistic error bound of $O(\Delta x/\Delta t)$ for the scheme. While there is reason to believe that this pessimistic error bound could actually be sharp for general bounded variation solutions, e.g., for the example given in [23] where the Godunov-type scheme converges to an entropy violating solution for $\Delta t = O(\Delta x)$, for smooth solutions the convergence rate is expected to be much better. To look at the local truncation error, assume we start from the cell averages $\bar{u}_j^n = Au(\cdot, t^n)|_{I_j}$ of the exact solution $u(\cdot, t)$ of the PDE and use our scheme to advance for one time step to obtain the numerical solution $\bar{u}^{n+1}$. The error at the end of this one time step is estimated by

$$\begin{aligned}\|Au(\cdot, t^{n+1}) - \bar{u}^{n+1}\|_{L^1} &= \|A \circ S_{\Delta t}(u(\cdot, t^n)) - A \circ S_{\Delta t} \circ Re(\bar{u}^n)\|_{L^1} \\ &\le \|S_{\Delta t}(u(\cdot, t^n)) - S_{\Delta t} \circ Re(\bar{u}^n)\|_{L^1} \\ &\le \|u(\cdot, t^n) - Re(\bar{u}^n)\|_{L^1}.\end{aligned}$$

That is, the L^1 error at next time step is no larger than the reconstruction error in L^1. For general bounded variation solutions this reconstruction error is expected to be $O(\Delta x)$, by combining Lemma 2.2 and (2.6). Therefore, the local truncation error, which is this error divided by Δt, is at most $O(\Delta x/\Delta t)$, which would go to zero by our choice of a large time step Δt. For a smooth solution u, a more detailed analysis indicates that the local truncation error is of the order $O(\Delta x^k)$ for a kth-order reconstruction using piecewise polynomials of degree $k-1$. We include this analysis in the appendix, since it is quite technical but does reveal the somewhat surprising result that the local truncation error is independent of the time step Δt.

3. TVB property of the numerical solution and examples of the TVB reconstruction operator. The result of the previous section indicates that, apart from the large time step assumption (2.3), which causes difficulties in the actual implementation of the scheme and will be discussed in more detail in next section, we would only need to have a TVB numerical solution to imply convergence. If the reconstruction operator Re is TVB, i.e., it satisfies (1.4), then we easily have

$$\begin{aligned}TV(\bar{u}^n) &= TV(A \circ S_{\Delta t} \circ Re\,(\bar{u}^{n-1})) \\ &\le TV(Re(\bar{u}^{n-1})) \\ &\le (1 + C\Delta x) TV(\bar{u}^{n-1}) \\ &\le \cdots \\ &\le (1 + C\Delta x)^n\, TV(\bar{u}^0) \\ &\le (1 + C\Delta t)^n\, TV(u_0) \\ &\le e^{CT} TV(u_0)\end{aligned}$$

for any n and Δt such that $n\Delta t \le T$. Here we have used the fact that neither the averaging operator A nor the exact entropy solution evolution operator $S_{\Delta t}$ increases the total variation of a function for the second inequality, and the assumption (2.3) for the sixth inequality (in fact, here we do not need the large time step assumption; we

just need the assumption that $\Delta x \leq C\Delta t$). We therefore only need to verify the total variation boundedness of the reconstruction (1.4) in order to guarantee convergence towards entropy solutions for a large time step Godunov-type scheme.

Next we discuss two examples of TVB reconstructions (1.4). We concentrate our attention on self-similar reconstructions, namely, reconstructions which do not depend explicitly on the mesh size Δx (see the example of the reconstruction (2.8) in which the polynomials $p_i(\xi)$ do not depend on Δx [21]). In fact, almost all known self-similar TVB reconstructions are actually TVD. It is very difficult to obtain self-similar TVB reconstructions in two or higher dimensions [6]; hence we restrict our attention to one dimension.

1. *Second-order MUSCL reconstruction.* This reconstruction [22] is piecewise linear and is second-order accurate except at extrema, where it degenerates to first-order accuracy. The reconstructed polynomial in cell I_j is given by

$$p(x) = \bar{u}_j + s_j\,(x - x_j)\,, \tag{3.1}$$

where the slope s_j is given by

$$s_j = m\left(\frac{\bar{u}_{j+1} - \bar{u}_j}{\Delta x}, \frac{\bar{u}_j - \bar{u}_{j-1}}{\Delta x}\right)$$

with the usual definition of the *minmod* function m (see [7])

$$m(a,b) = \frac{\operatorname{sign}(a) + \operatorname{sign}(b)}{2}\min(|a|,|b|).$$

In words, the slope is taken as the smaller one (in magnitude) between those of the two reconstruction linear polynomials based on the stencils $\{I_{j-1}, I_j\}$ and $\{I_j, I_{j+1}\}$, unless these two slopes are of opposite sign (i.e., we are at an extremum of the cell average $\bar{u}$), in which case the slope is taken as zero. This reconstruction is clearly TVD.

2. *Third-order nonoscillatory central reconstruction.* This reconstruction [15] is piecewise quadratic and is third-order accurate except at extrema, where it degenerates to second-order accuracy. The reconstructed polynomial in cell I_j is based on $q_j(x)$, the reconstructed quadratic polynomial over the stencil $\{I_{j-1}, I_j, I_{j+1}\}$, with modification to satisfy a nonoscillatory property (no new extremum) and a maximum principle. The first step is to obtain the nonoscillatory property and is given by

$$p_j^1(x) = \bar{u}_j + \theta_j\,(q_j(x) - \bar{u}_j)\,, \tag{3.2}$$

where the limiter θ_j is defined as

$$\theta_j = \begin{cases} \min\left(\dfrac{M_{j+\frac{1}{2}} - \bar{u}_j}{M_j - \bar{u}_j}, \dfrac{m_{j-\frac{1}{2}} - \bar{u}_j}{m_j - \bar{u}_j}, 1\right) & \text{if } \bar{u}_{j-1} < \bar{u}_j < \bar{u}_{j+1}, \\ \min\left(\dfrac{M_{j-\frac{1}{2}} - \bar{u}_j}{M_j - \bar{u}_j}, \dfrac{m_{j+\frac{1}{2}} - \bar{u}_j}{m_j - \bar{u}_j}, 1\right) & \text{if } \bar{u}_{j-1} > \bar{u}_j > \bar{u}_{j+1}, \\ 1 & \text{if } (\bar{u}_{j+1} - \bar{u}_j)\,(\bar{u}_j - \bar{u}_{j-1}) \leq 0, \end{cases}$$

where

$$M_j = \max_{x \in I_j} q_j(x), \qquad m_j = \min_{x \in I_j} q_j(x),$$

$$M_{j\pm\frac{1}{2}} = \max\left(\frac{1}{2}(\bar{u}_j + \bar{u}_{j\pm1}), q_{j\pm1}(x_{j\pm\frac{1}{2}})\right),$$
$$m_{j\pm\frac{1}{2}} = \min\left(\frac{1}{2}(\bar{u}_j + \bar{u}_{j\pm1}), q_{j\pm1}(x_{j\pm\frac{1}{2}})\right).$$

The second step is to further modify $p_j^1(\mathrm{x})$ to satisfy a maximum principle. If we denote

$$M = \max_{x\in R} u_0(x), \qquad m = \min_{x\in R} u_0(x)$$

and

$$M_j^1 = \max_{x\in I_j} p_j^1(x), \qquad m_j^1 = \min_{x\in I_j} p_j^1(x),$$

then the final reconstructed polynomial is given by

(3.3)
$$p_j(x) = \begin{cases} \varepsilon^{(1)}\left(p_j^1(x) - M_j^1\right) + M & \text{when} \quad M_j^1 > M,\ m_j^1 \geq m, \\ \varepsilon^{(2)}\left(p_j^1(x) - m_j^1\right) + m & \text{when} \quad M_j^1 \leq M,\ m_j^1 < m, \\ \varepsilon^{(1)}\left(p_j^1(x) - M_j^1\right) + M & \text{when} \quad \varepsilon^{(1)} < \varepsilon^{(2)},\ M_j^1 > M, m_j^1 < m, \\ \varepsilon^{(2)}\left(p_j^1(x) - m_j^1\right) + m & \text{when} \quad \varepsilon^{(1)} \geq \varepsilon^{(2)},\ M_j^1 > M, m_j^1 < m, \\ p_j^{(1)}(x) & \text{when} \quad M_j^1 \leq M,\ m_j^1 \geq m, \end{cases}$$

with

$$\varepsilon^{(1)} = \frac{M - \bar{u}_j}{M_j^1 - \bar{u}_j}, \qquad \varepsilon^{(2)} = \frac{m - \bar{u}_j}{m_j^1 - \bar{u}_j}.$$

It is proven in [15] that the reconstruction (3.3) is TVB. Moreover, we have

$$\|p_j^1(x) - \bar{u}_j\|_{L^1} = \theta_j \|q_j(x) - \bar{u}_j\|_{L^1}$$

and

$$\|p_j(x) - \bar{u}_j\|_{L^1} = \varepsilon^{(i)}\|p_j^1(x) - \bar{u}_j\|_{L^1}, \quad i = 1, 2, \quad \text{or}$$
$$\|p_j(x) - \bar{u}_j\|_{L^1} = \|p_j^1(x) - \bar{u}_j\|_{L^1}$$

with $0 \leq \theta_j \leq 1$ and $0 \leq \varepsilon^{(i)} \leq 1$. Therefore,

$$\|p_j(x) - \bar{u}_j\|_{L^1} \leq \|p_j^1(x) - \bar{u}_j\|_{L^1} \leq \|q_j(x) - \bar{u}_j\|_{L^1}.$$

Hence clearly assumption (2.1) is also satisfied by this reconstruction, using Lemma 2.2.

Other possible TVB reconstructions in one dimension include the very high-order TVD reconstructions in [17] (however, these reconstructions degenerate to first-order accuracy at smooth extrema), or the high-order TVB reconstructions in [20] (however, the reconstructions are no longer self-similar).

4. Implementation of the scheme and numerical examples for one-dimensional scalar convex conservation laws. In this section, we discuss a practical implementation of the large time step Godunov-type scheme discussed in the previous section, for one-dimensional scalar convex conservation laws, using a

semi-Lagrangian-type scheme similar to that used in [5, 3] for Hamilton–Jacobi equations. However, we emphasize that our implementation in this section is exactly the Godunov-type scheme discussed in the convergence analysis in previous sections. No extra error (other than computer roundoff errors) has been introduced. In particular, the scheme is conservative, unlike many semi-Lagrangian-type schemes.

Recall that there are three stages to evolve the cell averages $\bar{u}^n$ at time level n to $\bar{u}^{n+1}$ at time level $n+1$, that is, reconstruction (Re), exact evolution ($S_{\Delta t}$), and averaging (A).

1. Reconstruction: reconstruct a piecewise polynomial function $u^n(x)$ from the cell averages $\bar{u}^n$. Specifically, for second-order TVD or third-order TVB reconstruction, the implementation follows the procedure described in (3.1) and (3.2).
2. Evolution: evolve $u^n(x)$ by (1.1) exactly for a time step Δt to obtain the solution $\tilde{u}^{n+1}$. In general, it is very difficult to numerically obtain $\tilde{u}^{n+1}$.
3. Averaging: average $\tilde{u}^{n+1}$ over each cell I_j to obtain $\bar{u}^{n+1}$.

Fortunately, we do not need the detailed information about $\tilde{u}^{n+1}$ in the second stage above (which would be very difficult to obtain exactly), but only its cell averages $\bar{u}^{n+1}$ over each cell. Therefore, we will combine the second stage ($S_{\Delta t}$) and third stage (A) together in our implementation.

We make the following observations on the x-t plane (see Figure 1).

Observation 1. At each of the cell boundary points at time level $n+1$, say $(x_{j+\frac{1}{2}}, t^{n+1})$, there exists a backward characteristic line, denoted as $\Gamma_{j+\frac{1}{2}}$, with the foot located on time level n at $y_{j+\frac{1}{2}}$. These backward characteristic lines, $\{\Gamma_{j+\frac{1}{2}}\}$, do not cross each other in the x-t plane, which is a property of the entropy solution. Along each of these characteristic lines, the entropy solution remains a constant. For example, the solution along $\Gamma_{j+\frac{1}{2}}$ is $u^n(y_{j+\frac{1}{2}})$ if the function $u^n(x)$ is continuous at $x = y_{j+\frac{1}{2}}$. The slope of the characteristic line is also known. For example, the slope of $\Gamma_{j+\frac{1}{2}}$ is $f'(u^n(y_{j+\frac{1}{2}}))$.

Observation 2. For each cell I_j at time level $n+1$, there is a trapezoid region Ω_j (see Figure 1) with four vertices $(x_{j-\frac{1}{2}}, t^{n+1})$, $(x_{j+\frac{1}{2}}, t^{n+1})$, $(y_{j-\frac{1}{2}}, t^n)$, and $(y_{j+\frac{1}{2}}, t^n)$. These trapezoid regions are mutually disjoint and they together cover the whole computational domain times the interval $[t^n, t^{n+1}]$.

Based on the two observations listed above, for each cell I_j, we apply the integral form of conservation laws over the region Ω_j,

$$\int_{\Omega_j} (u_t + f(u)_x) dx dt = 0. \tag{4.1}$$

By the divergence theorem and Observation 1, the left-hand side of (4.1) can be written in the following explicit form:

$$\begin{aligned} \int_{\Omega_j} (u_t + f(u)_x) dx dt &= \int_{\partial\Omega_j} (u n_t + f(u) n_x) ds \\ &= \int_{y_{j-\frac{1}{2}}}^{y_{j+\frac{1}{2}}} u dx + \int_{\Gamma_{j+\frac{1}{2}}} (u n_t + f(u) n_x) ds \end{aligned} \tag{4.2}$$

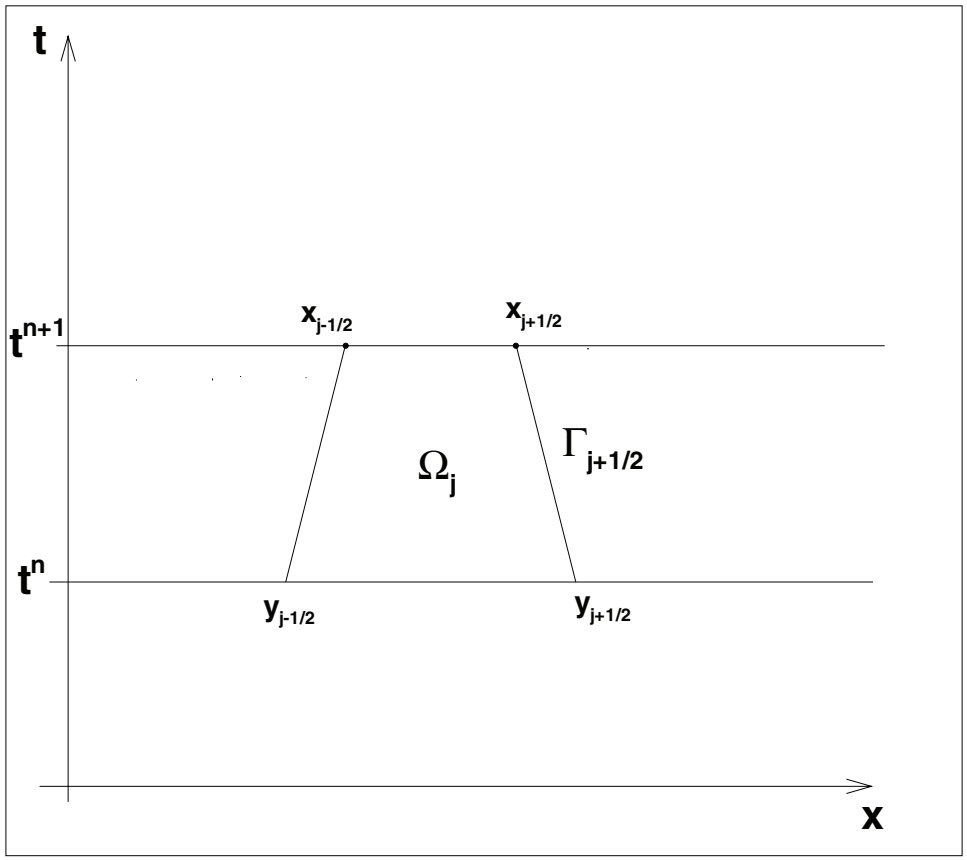

FIG. 1. *The trapezoid region Ω_j in the x-t plane.*

$$-\Delta x\bar{u}_j^{n+1} + \int_{\Gamma_{j-\frac{1}{2}}} (un_t + f(u)n_x)ds \tag{4.3}$$

$$= \int_{y_{j-\frac{1}{2}}}^{y_{j+\frac{1}{2}}} u^n(x)dx - \left(\Delta t f(u_{j+\frac{1}{2}}) + (y_{j+\frac{1}{2}} - x_{j+\frac{1}{2}})u_{j+\frac{1}{2}}\right)$$

$$-\Delta x\bar{u}_j^{n+1} + \left(\Delta t f(u_{j-\frac{1}{2}}) + (y_{j-\frac{1}{2}} - x_{j-\frac{1}{2}})u_{j-\frac{1}{2}}\right), \tag{4.4}$$

where (n_x, n_t) is the unit outward normal vector for the boundaries of the region Ω_j. Hence, we can obtain the following formula for computing $\bar{u}_j^{n+1}$:

$$\Delta x\bar{u}_j^{n+1} = \int_{y_{j-\frac{1}{2}}}^{y_{j+\frac{1}{2}}} u^n(x)dx - \left(\Delta t f\left(u_{j+\frac{1}{2}}\right) + \left(y_{j+\frac{1}{2}} - x_{j+\frac{1}{2}}\right)u_{j+\frac{1}{2}}\right)$$

$$+ \left(\Delta t f\left(u_{j-\frac{1}{2}}\right) + \left(y_{j-\frac{1}{2}} - x_{j-\frac{1}{2}}\right)u_{j-\frac{1}{2}}\right). \tag{4.5}$$

This is the formula we use in coding up the algorithm. Clearly, if we can find the backward characteristic line $\Gamma_{j+\frac{1}{2}}$, hence also the (constant) value of the entropy solution $u_{j+\frac{1}{2}}$ along it, for each point $(x_{j+\frac{1}{2}}, t^{n+1})$, then the Godunov-type scheme discussed in the previous sections in the convergence analysis is implemented exactly, only subject to roundoff errors.

Now, the only difficulty left for the implementation of the Godunov-type scheme is to find the backward characteristic line $\Gamma_{j+\frac{1}{2}}$ for each target point $(x_{j+\frac{1}{2}}, t^{n+1})$. Notice that there might be multiple forward characteristic lines from $u^n(x)$ in the previous time level which cross at the target point. Even though only one of those characteristic lines (or at most two if the solution happens to be discontinuous at $(x_{j+\frac{1}{2}}, t^{n+1})$ should be correct and the remaining forward characteristic lines will have crossed other characteristic lines before the time t^{n+1} and should be ignored as they are no longer valid after such crossing, it seems difficult to numerically implement the finding of this correct characteristic line with low computational cost.

We propose the following method to obtain the backward characteristic line $\Gamma_{j+\frac{1}{2}}$ for $(x_{j+\frac{1}{2}}, t^{n+1})$.

(a) At time level n, for each cell I_i, we determine its domain of influence J_i, and for each cell boundary point $x_{i+\frac{1}{2}}$, we determine its domain of influence $\tilde{J}_{i+\frac{1}{2}}$.
- If the function $u^n(x)$ is monotone in $[x_{i-\frac{1}{2}}, x_{i+\frac{1}{2}}]$, then J_i is determined by the two forward characteristics from the cell boundaries $(x^{\pm}_{i\mp\frac{1}{2}}, t^n)$. Specifically, from $(x^{\pm}_{i\mp\frac{1}{2}}, t^n)$, the forward characteristic lines cross $t = t^{n+1}$ at $\xi^{\pm}_{i\mp\frac{1}{2}}$, respectively. If $\xi^{+}_{i-\frac{1}{2}} \le \xi^{-}_{i+\frac{1}{2}}$, then J_i is simply the interval $[\xi^{+}_{i-\frac{1}{2}}, \xi^{-}_{i+\frac{1}{2}}]$. Otherwise $J_i = \emptyset$, since the forward characteristics have crossed each other before they reach t^{n+1}. If the function $u^n(x)$ is not monotone in $[x_{i-\frac{1}{2}}, x_{i+\frac{1}{2}}]$, then we divide the interval $[x_{i-\frac{1}{2}}, x_{i+\frac{1}{2}}]$ into a union of several nonoverlapping subintervals; in each of them the function $u^n(x)$ is monotone. Since $u^n(x)$ is a reconstructed polynomial in $[x_{i-\frac{1}{2}}, x_{i+\frac{1}{2}}]$, we have at most k such subintervals, where k is the polynomial degree. For each such subinterval we use the previous technique to determine its domain of influence J_i^{ℓ}. J_i is then the union of all these J_i^{ℓ}.
- $\tilde{J}_{i+\frac{1}{2}}$ is determined by the two forward characteristics from the cell boundary $(x^{\mp}_{i+\frac{1}{2}}, t^n)$. Specifically, from $(x^{\mp}_{i+\frac{1}{2}}, t^n)$, the forward characteristic lines cross $t = t^{n+1}$ at $\xi^{\mp}_{i+\frac{1}{2}}$, respectively. If $\xi^{-}_{i+\frac{1}{2}} \le \xi^{+}_{i+\frac{1}{2}}$, then $\tilde{J}_{i+\frac{1}{2}}$ is simply the interval $[\xi^{-}_{i+\frac{1}{2}}, \xi^{+}_{i+\frac{1}{2}}]$. Otherwise $\tilde{J}_{i+\frac{1}{2}} = \emptyset$, since the boundary point $(x_{i+\frac{1}{2}}, t^n)$ generates a shock.

(b) For each of the target points $(x_{j+\frac{1}{2}}, t^{n+1})$, find the set of candidate intervals, denoted as $C_{j+\frac{1}{2}}$, and the set of candidate cell boundary points, denoted as $\tilde{C}_{j+\frac{1}{2}}$, such that

$$C_{j+\frac{1}{2}} = \left\{ i : \ x_{j+\frac{1}{2}} \in J_i \right\}, \qquad \tilde{C}_{j+\frac{1}{2}} = \left\{ i : \ x_{j+\frac{1}{2}} \in \tilde{J}_{i+\frac{1}{2}} \right\}. \tag{4.6}$$

In words, a candidate interval or a candidate cell boundary point should be the one with the target point contained in its domain of influence. Because of the convexity of $f(u)$ and hence the monotonicity of $f'(u)$, the sets $C_{j+\frac{1}{2}}$ and $\tilde{C}_{j+\frac{1}{2}}$ include all candidate intervals and cell boundary points at time level t^n which contain forward characteristic lines crossing the target point $(x_{j+\frac{1}{2}}, t^{n+1})$. Furthermore, we can use the minimum and maximum values of $f'(u^n)$ to estimate the largest possible region of dependency for the point $(x_{j+\frac{1}{2}}, t^{n+1})$ at the time level t^n, and search for candidates of the sets $C_{j+\frac{1}{2}}$

and $\tilde{C}_{j+\frac{1}{2}}$ only within this region of dependency to save computational cost.

(c) Find the candidate trace-back points within the sets $C_{j+\frac{1}{2}}$ and $\tilde{C}_{j+\frac{1}{2}}$. For each J_i (or J_i^ℓ if J_i is a union of at least two of them) with $i \in C_{j+\frac{1}{2}}$, we can find a unique forward characteristic line from (x_i^*, t^n), for some point $x_i^* \in I_i$, such that it crosses the target point $(x_{j+\frac{1}{2}}, t^{n+1})$. The solution $u^* = u^n(x_i^*)$ is a constant along this line, which can be found through the implicit characteristic equation

$$u^* = u^n\left(x_{j+\frac{1}{2}} - f'(u^*)\,\Delta t\right). \tag{4.7}$$

For the Burgers equation with piecewise polynomial reconstruction of degree no larger than 4, u^* can be obtained analytically. For the general situation a Newton iteration might be needed to find u^*. Likewise, for each $\tilde{J}_{i+\frac{1}{2}}$ with $i \in \tilde{C}_{j+\frac{1}{2}}$, we can find a unique forward characteristic line from $(x_{i+\frac{1}{2}}, t^n)$ with a solution value u^* between $u^n(x^-_{i+\frac{1}{2}})$ and $u^n(x^+_{i+\frac{1}{2}})$, such that it crosses the target point $(x_{j+\frac{1}{2}}, t^{n+1})$. The solution u^* can be found by the characteristic equation which is simpler than (4.7),

$$f'(u^*) = \frac{x_{j+\frac{1}{2}} - x_{i+\frac{1}{2}}}{\Delta t}. \tag{4.8}$$

(d) Use the Lax–Hopf formula to pick the correct foot of the backward characteristic line of the entropy solution among all the $\{x_i^*, u^*\}$ and $\{x_{i+\frac{1}{2}}, u^*\}$ that we have found in the previous step. The classical Lax formula [11] is as follows:

$$g\left(y_{j+\frac{1}{2}}\right) = \min_y g(y), \quad \text{where} \quad g(y) = \int_{-\infty}^{y} u^n(\xi)d\xi + \Delta t L\left(\frac{x_{j+\frac{1}{2}} - y}{\Delta t}\right), \tag{4.9}$$

where the lower limit $-\infty$ in the integral is irrelevant and can be replaced by any fixed point, and

$$L(v) = \int^{v} (f')^{-1}(u)du$$

is the Legendre transform of $f(u)$. For convex conservation laws, the Legendre transform of $f(u)$ can be obtained in closed form as

$$L(v) = v(f')^{-1}(v) - f((f')^{-1}(v)).$$

Especially, in (4.9),

$$L\left(\frac{x_{j+\frac{1}{2}} - y}{\Delta t}\right) = \frac{x_{j+\frac{1}{2}} - y}{\Delta t}u^* - f(u^*) = f'(u^*)u^* - f(u^*) \tag{4.10}$$

with u^* solved from (4.7) or (4.8).

If there are multiple minimizers to $g(y)$, corresponding to the situation that the solution is discontinuous at $(x_{j+\frac{1}{2}}, t^{n+1})$, then we will just take the smallest minimizer as $y_{j+\frac{1}{2}}$, corresponding to the left limit value of the solution at the discontinuity $(x_{j+\frac{1}{2}}, t^{n+1})$. It is here that we use the property that

the conservation law has a convex flux $f(u)$, as the Lax formula is only valid for convex conservation laws. Notice that the minimum is taken over finitely many candidates $\{x_i^*, u^*\}$ and $\{x_{i+\frac{1}{2}}, u^*\}$ that we have found in the previous step; hence there is no error incurred in this step either.

We now summarize our implementation of the large time step Godunov-type scheme for a scalar one-dimensional convex conservation law (1.1), from $\bar{u}^n$ to $\bar{u}^{n+1}$.

1. Perform a reconstruction to obtain a piecewise polynomial $u^n(x)$. For example, for second-order TVD or third-order TVB reconstruction, the implementation follows the procedure described in (3.1) and (3.2).
2. Find the domain of influence J_i for each cell I_i and the domain of influence $\tilde{J}_{i+\frac{1}{2}}$ for each cell boundary point $x_{i+\frac{1}{2}}$.
3. Find the set $C_{j+\frac{1}{2}}$ of all candidate intervals and the set $\tilde{C}_{j+\frac{1}{2}}$ of all candidate cell boundary points at time level t^n which will contain forward characteristic lines crossing the target point $(x_{j+\frac{1}{2}}, t^{n+1})$, via (4.6).
4. For each J_i with $i \in C_{j+\frac{1}{2}}$, or for each J_i^ℓ if J_i is a union of at least two of them, find a forward characteristic line from (x_i^*, t^n) with the solution value u^*, via (4.7). Likewise, for each $\tilde{J}_{i+\frac{1}{2}}$ with $i \in \tilde{C}_{j+\frac{1}{2}}$, find a forward characteristic line from $(x_{i+\frac{1}{2}}, t^n)$ with a solution value u^*, via (4.8).
5. Use the Lax formula (4.9) to determine the correct backward characteristic line $\{y_{j+\frac{1}{2}}, u_{j+\frac{1}{2}}\}$ among all the (finitely many) $\{x_i^*, u^*\}$ and $\{x_{i+\frac{1}{2}}, u^*\}$ that we have found above.
6. Use (4.5) to obtain $\bar{u}_j^{n+1}$ for all j.

Remark 4.1. In general, there might be errors introduced in the exact evolution stage of our scheme; for example, the exact characteristics may not be easy to obtain and an approximation is used instead. Let $\tilde{S}_{\Delta t}$ be the approximate evolution operator and let

$$\|\tilde{S}_{\Delta t}(u) - S_{\Delta t}(u)\|_{L^1} \le \delta(\Delta x, \Delta t) \tag{4.11}$$

for our piecewise polynomial, bounded variation numerical solution u, or weaker still

$$\|A \circ \tilde{S}_{\Delta t}(u) - A \circ S_{\Delta t}(u)\|_{L^1} \le \delta(\Delta x, \Delta t). \tag{4.12}$$

A reasonable assumption is that $\delta(\Delta x, \Delta t) \le C\Delta x$. Under this assumption, Theorem 2.1 still holds with a very minor modification in the proof. Specifically,

$$\begin{aligned}
\|A(u(\cdot, t^n)) - \bar{u}^n\|_{L^1} &= \|A(u(\cdot, t^n)) - A \circ \tilde{S}_{\Delta t} \circ Re\,(\bar{u}^{n-1})\|_{L^1} \\
&\le \|A(u(\cdot, t^n)) - A \circ S_{\Delta t} \circ Re\,(\bar{u}^{n-1})\|_{L^1} \qquad (4.13) \\
&\quad + \|A \circ S_{\Delta t} \circ Re\,(\bar{u}^{n-1}) - A \circ \tilde{S}_{\Delta t} \circ Re\,(\bar{u}^{n-1})\|_{L^1} \\
&\le \|u(\cdot, t^n) - S_{\Delta t} \circ Re\,(\bar{u}^{n-1})\|_{L^1} + C\Delta x \\
&= \|S_{\Delta t}\,(u(\cdot, t^{n-1})) - S_{\Delta t} \circ Re\,(\bar{u}^{n-1})\|_{L^1} + C\Delta x \\
&\le \|u(\cdot, t^{n-1}) - Re\,(\bar{u}^{n-1})\|_{L^1} + C\Delta x \qquad (4.14) \\
&= e^{n-1} + C\Delta x, \qquad (4.15)
\end{aligned}$$

and according to (2.7), $e^n \to 0$ as $\Delta x \to 0$. Again, with the assumption (4.11) or

(4.12), the local truncation error of our scheme would be

$$\begin{aligned}\|Au(\cdot,t^{n+1})-\bar{u}^{n+1}\|_{L^1} &= \|A\circ S_{\Delta t}(u(\cdot,t^n))-A\circ\tilde{S}_{\Delta t}\circ Re(\bar{u}^n)\|_{L^1}\\ &\le \|A\circ S_{\Delta t}(u(\cdot,t^n))-A\circ S_{\Delta t}\circ Re(\bar{u}^n)\|_{L^1}\\ &\quad +\|A\circ S_{\Delta t}\circ Re(\bar{u}^n)-A\circ\tilde{S}_{\Delta t}\circ Re(\bar{u}^n)\|_{L^1}\\ &\le \|S_{\Delta t}(u(\cdot,t^n))-S_{\Delta t}\circ Re(\bar{u}^n)\|_{L^1}+\delta(\Delta x,\Delta t)\\ &\le \|u(\cdot,t^n)-Re(\bar{u}^n)\|_{L^1}+\delta(\Delta x,\Delta t).\end{aligned}$$

That is, the local truncation error is no larger than the reconstruction error plus the error in the evolution operator.

In the following we provide numerical results of the large time step Godunov-type scheme applied to the Burgers equation, namely (1.1) with $f(u)=\frac{u^2}{2}$, for several different reconstructions and for both smooth and discontinuous solutions. We take $\Delta t=\Delta x^{0.9}$ in all runs.

Example 4.2. Burgers equation with the initial condition

$$u_0(x)=\sin(\pi x)+0.5,\qquad -1\le x<1, \tag{4.16}$$

with periodic boundary condition.

The solution at $t=0.2$ is still smooth, and we record the L^1 errors and numerical orders of accuracy in Table 4.1 for the first-order Godunov method (no reconstruction), second-order MUSCL reconstruction, and third-order nonoscillatory reconstruction in [15]. All these cases correspond to TVB reconstructions and hence provable convergence for the large time step Godunov-type scheme according to the discussions in the previous two sections. Moreover, since the solution is smooth, we expect the accuracy should be that of the reconstruction. We can see clearly from Table 4.1 that all schemes achieve their designed order of accuracy.

Even though the third-order linear central reconstruction (namely, the stencil for reconstructing the polynomial in I_j is fixed as $\{I_{j-1},I_j,I_{j+1}\}$) and the third-order ENO reconstruction [8] are not proven to be TVB, they perform well in this smooth test case, yielding the expected third-order accuracy for the large time step Godunov-type scheme; see Table 4.2.

Next, we continue the numerical simulation to $t=0.97$ when a shock has already appeared. We record the L^1 errors and numerical orders of accuracy in Table 4.3 for the first-order Godunov method (no reconstruction), the second-order MUSCL reconstruction, the third-order nonoscillatory reconstruction in [15], and the third-order ENO reconstruction [8]. Our theory predicts convergence for such discontinuous solutions for the first three reconstructions, which are TVB, but only guarantees a

pessimistic error bound $\Delta x/\Delta t$; see (2.7). In the actual numerical test, we observe much better convergence rates, often close to the order of the reconstruction, even for this solution with a shock, although the convergence rate is not uniform, indicating a fluctuation in the accuracy of the solution in the shocked cell.

In Figure 2, we plot the numerical solution (cell averages) versus the exact cell averages of the entropy solution, for the third-order nonoscillatory reconstruction in [15] with various mesh sizes. We see clearly that the scheme can even resolve the transition cell average inside the shock very well. It would be interesting to study in more detail this good convergence behavior; however, the tools in previous sections are not enough for this detailed analysis. Finally, even though the ENO reconstruction is not TVB and hence is not covered by our theory, the convergence for this shocked problem is also very good; see again Table 4.3.

Example 4.3. Burgers equation with a discontinuous initial condition,

$$u_0(x) = \begin{cases} 1 & \text{if } -1 \le x < 0, \\ 3 & \text{if } 0 \le x < 1, \end{cases} \tag{4.17}$$

with periodic boundary condition. The solutions of the large time step Godunov-type scheme at $t = 0.2$ for different reconstructions are shown in Figure 3. We can see in general good agreement between the numerical and the exact entropy solutions. The first-order Godunov scheme is showing some stair-like features in the rarefaction region, which is well known, and the schemes based on linear reconstructions, namely the second-order upwind reconstruction (for this case with $f'(u) > 0$ the stencil for reconstructing the polynomial in I_j is fixed as $\{I_{j-1}, I_j\}$) and the third-order central reconstruction are both slightly oscillatory. The schemes based on MUSCL, Liu–Osher nonoscillatory, and ENO reconstructions are all nonoscillatory as expected.

5. Convergence of the large time step Godunov-like scheme based on Sanders' TVD reconstruction. Sanders [19] proposed a third-order accurate TVD (he called it total variation nonexpansive) scheme by evolving both the cell average and the values at two end points of a cell. He can then obtain a third-order TVD scheme instead of the usual Godunov-type TVD scheme which degenerates to second order at best. This scheme does not fit the framework of Godunov-type schemes that we have discussed before, since it evolves not just the cell averages but also point values of the solution at cell boundaries. However, the solution procedure is sufficiently similar to Godunov-type schemes, and therefore we will call it a Godunov-like scheme. The scheme is based on a reconstruction operator Rs, which produces a piecewise quadratic function. After a suitable initialization to obtain a piecewise quadratic initial numerical solution $u^0(x)$, the Godunov-type scheme based on Sanders' reconstruction operator Rs can be summarized as follows:

1. *Evolution:* evolve $u^n(x)$ by the conservation law (1.1) *exactly* for a time step Δt, to obtain a solution $\tilde{u}^{n+1}(x)$ which is in general *not* piecewise polynomial anymore. Recall that this evolution operator is denoted as $S_{\Delta t}(u^n)$.
2. *Reconstruction:* obtain a piecewise quadratic polynomial reconstruction $u^n(x)$ by Sanders' reconstruction. We denote this reconstruction operator as $u^{n+1} = Rs(\tilde{u}^{n+1})$.

This Godunov-like scheme, using the notations introduced above, can be described abstractly as

$$\text{(5.1)} \qquad \begin{cases} u^0 = Rs(u_0), \\ u^{n+1} = Rs \circ S_{\Delta t}(u^n), \qquad n = 0, 1, \ldots, N-1. \end{cases}$$

We will first discuss the TVD reconstruction operator Rs, then prove the convergence of the large time step Godunov-like scheme based on this reconstruction. Finally, we will discuss the implementation of this scheme, again for one-dimensional scalar convex conservation laws, and provide numerical examples.

5.1. Sanders' TVD reconstruction. Sanders' reconstruction Rs maps a bounded variation function $u(x)$ to a piecewise quadratic polynomial, satisfying the following four properties:

1. agreement of the cell averages:

$$\text{(5.2)} \qquad \int_{I_j} Rs(u)(x)dx = \int_{I_j} u(x)dx \qquad \forall j;$$

2. TVD:

$$\text{(5.3)} \qquad TV(Rs(u)) \le TV(u);$$

3. maximum (and minimum) principle:

$$\sup Rs(u)(x) \le \sup u(x), \qquad \inf Rs(u)(x) \ge \inf u(x);$$

4. third-order accuracy:

$$Rs(u)(x) = u(x) + O(\Delta x^3)$$

when u is locally smooth.

Let us now describe the details of the reconstruction operator Rs. First, given the cell average $\bar{u}_j$ and the cell boundary values $u^+_{j-\frac{1}{2}}$ and $u^-_{j+\frac{1}{2}}$, we can easily construct a unique quadratic polynomial $q_j(x)$ such that

$$\frac{1}{\Delta x}\int_{x_{j-\frac{1}{2}}}^{x_{j+\frac{1}{2}}} q_j(x)\,dx = \bar{u}_j, \qquad q_j\left(x_{j-\frac{1}{2}}\right) = u^+_{j-\frac{1}{2}}, \qquad q_j\left(x_{j+\frac{1}{2}}\right) = u^-_{j+\frac{1}{2}}.$$

In fact, if we denote

$$a = u^+_{j-\frac{1}{2}} - \bar{u}_j, \qquad b = u^-_{j+\frac{1}{2}} - \bar{u}_j, \tag{5.4}$$

then the quadratic polynomial $q_j(x)$ is given by

$$q_j(x) = \hat{q}(a,b)(x) + \bar{u}_j = 3(a+b)\left(\frac{x-x_j}{\Delta x}\right)^2 + (b-a)\left(\frac{x-x_j}{\Delta x}\right) - \frac{1}{4}(a+b) + \bar{u}_j. \tag{5.5}$$

We define M to be the larger (in magnitude) of a and b and m the smaller one, $\rho = \frac{m}{M}$,

$$E = \begin{cases} \sup\limits_{I_j}(u - \bar{u}_j) & \text{if} \quad M \le 0, \\ \inf\limits_{I_j}(u - \bar{u}_j) & \text{if} \quad M > 0, \end{cases} \tag{5.6}$$

and $\hat{E} = \frac{E}{M}$. Let

$$\tau_+ = -\hat{E}\cdot\frac{3(1+\rho)}{1+\rho+\rho^2}, \qquad \tau_- = -\frac{1}{2}\left((\rho+3\hat{E}) - 3(\hat{E}-\rho)(3\hat{E}+\rho)^{\frac{1}{2}}\right),$$

and

$$\tau_l = \begin{cases} 1 & \text{if} \quad -1 \le \rho \le -\frac{1}{2}, \\ 1 & \text{if} \quad -\frac{1}{2} < \rho < 0 \quad \text{and} \quad a = M, \\ \min(\tau_-, 1) & \text{if} \quad -\frac{1}{2} < \rho < 0 \quad \text{and} \quad b = M, \\ \min(\tau_+, 1) & \text{if} \quad 0 \le \rho \le 1, \end{cases}$$

$$\tau_r = \begin{cases} 1 & \text{if} \quad -1 \le \rho \le -\frac{1}{2}, \\ 1 & \text{if} \quad -\frac{1}{2} < \rho < 0 \quad \text{and} \quad b = M, \\ \min(\tau_-, 1) & \text{if} \quad -\frac{1}{2} < \rho < 0 \quad \text{and} \quad a = M, \\ \min(\tau_+, 1) & \text{if} \quad 0 \le \rho \le 1; \end{cases}$$

then the TVD reconstruction in I_j is defined by

$$Rs(u)(x) = \hat{q}(\tau_l a, \tau_r b)(x) + \bar{u}_j \tag{5.7}$$

with $\hat{q}$ defined in (5.5). It is proved in [19] that the reconstruction Rs is third-order accurate and TVD.

5.2. Convergence of the Godunov-like scheme based on Sanders' reconstruction. In this subsection we prove the convergence of the Godunov-like scheme (5.1) based on Sanders' reconstruction.

THEOREM 5.1. *The numerical solution of the Godunov-like scheme* (5.1) *with Sanders' reconstruction* (5.7) *for solving the scalar conservation law* (1.1) *converges*

in L^1 to the entropy solution of (1.1) *when the mesh size Δx goes to zero if the large time step assumption* (2.3) *is satisfied.*

Proof. We again denote the exact entropy solution of (1.1) at time level t^n by $u(\cdot, t^n)$ and the L^1 difference between this exact solution and the numerical solution u^n at time level t^n by e^n,

$$e^n = \|u(\cdot, t^n) - u^n\|_{L^1}. \tag{5.8}$$

First, the total variation of the numerical solution is bounded (in fact, diminishing),

$$\begin{aligned} TV(u^n) &= TV(Rs \circ S_{\Delta t}\,(u^{n-1})) \\ &\le TV(u^{n-1}) \\ &\le \cdots \\ &\le TV(u^0) \le TV(u_0), \end{aligned} \tag{5.9}$$

where we have used the fact that neither the reconstruction operator Rs nor the exact entropy solution evolution operator $S_{\Delta t}$ increases the total variation of a function, for the second inequality.

We now proceed to prove the desired convergence

$$\begin{aligned} e^n &= \|u(\cdot, t^n) - u^n\|_{L^1} \\ &\le \|u(\cdot, t^n) - S_{\Delta t}(u^{n-1})\|_{L^1} + \|S_{\Delta t}(u^{n-1}) - A \circ S_{\Delta t}(u^{n-1})\|_{L^1} \\ &\quad + \|A \circ S_{\Delta t}(u^{n-1}) - u^n\|_{L^1} \\ &= \|S_{\Delta t}(u(\cdot, t^{n-1})) - S_{\Delta t}(u^{n-1})\|_{L^1} + \|S_{\Delta t}(u^{n-1}) - A \circ S_{\Delta t}(u^{n-1})\|_{L^1} \\ &\qquad + \|A \circ Rs \circ S_{\Delta t}(u^{n-1}) - Rs \circ S_{\Delta t}(u^{n-1})\|_{L^1} \\ &\le \|u(\cdot, t^{n-1}) - u^{n-1}\|_{L^1} + C\Delta x TV(S_{\Delta t}(u^{n-1})) + C\Delta x TV(Rs \circ S_{\Delta t}(u^{n-1})) \\ &\le e^{n-1} + C\Delta x TV(u^{n-1}) + C\Delta x TV(u^{n-1}) \\ &\le e^{n-1} + \tilde{C}\Delta x \\ &\le \cdots \\ &\le \tilde{C} n \Delta x + e^0 \\ &= \tilde{C} T \frac{\Delta x}{\Delta t} + e^0 \to 0 \qquad \text{as} \quad \Delta x \to 0, \end{aligned}$$

where for the third equality we have used the cell average preserving property (5.2) of Rs; for the fourth inequality we have used the fact that the exact entropy solution operator $S_{\Delta t}$ is an L^1 contraction, and the inequality (2.6) with $w = S_{\Delta t}(u^{n-1})$ and $w = Rs \circ S_{\Delta t}(u^{n-1})$, respectively; for the fifth inequality we have used the fact that the reconstruction operator Rs and the exact entropy solution operator $S_{\Delta t}$ are both TVD; and for the sixth inequality we have used the fact that the total variation of the numerical solution is bounded (5.9). ∎

5.3. Implementation and numerical examples. For one-dimensional scalar convex conservation law (1.1), the implementation of the large time step Godunov-like scheme based on Sanders' reconstruction operator Rs is similar to that for the large time step Godunov-type scheme described in detail in section 4. This is because the procedure described in section 4 provides both the cell average $\bar{u}_j^{n+1}$ and the cell boundary values $u_{j-\frac{1}{2}}$ and $u_{j+\frac{1}{2}}$; hence a and b in (5.4) are available. The only additional information needed is the relevant extremum value E in (5.6), which is in

TABLE 5.1

608	8.40E-10	2.82	8.40E-10	2.82

general difficult to obtain. We follow Sanders [19] and take instead the corresponding extremum value E at the previous time level t^n between the feet of the characteristics $y_{j-\frac{1}{2}}$ and $y_{j+\frac{1}{2}}$. This approximation of E is exact if there is no discontinuity within the trapezoid Ω_j (see Figure 1), and is overestimating (larger for the sup and smaller for the inf) if there is at least one shock within Ω_j. It does not affect the accuracy and TVD property of the reconstruction Rs.

In the numerical experiments we take $\Delta t = \Delta x^{0.9}$ as before. We test the large time step Godunov-like scheme based on both an unmodulated third-order reconstruction (q_j as given by (5.5)) and Sanders' TVD reconstruction Rs.

We again first test the smooth solution as in Example 4.1. The L^1 errors and numerical orders of accuracy at $t = 0.2$ are shown in Table 5.1. We can see clearly third-order accuracy for the scheme based on both reconstructions.

Next, we record the L^1 errors and numerical orders of accuracy at $t = 0.97$, when the shock has already appeared, in Table 5.2. We observe again that the convergence rates are surprisingly good for both reconstructions, close to that of the reconstruction, even though the solution contains a shock. In Figures 4 and 5, we plot the numerical solution (cell averages) versus the exact cell averages of the entropy solution, for the scheme based on Sanders' TVD reconstruction Rs and based on the unmodulated third-order reconstruction (5.5), respectively, with various mesh sizes. We again observe that the scheme can resolve the transition cell average inside the shock very well.

Next, we test the discontinuous solution as in Example 4.2. Figure 6 displays the numerical solution. We can again see good agreement between the numerical and the exact entropy solutions. The scheme based on the unmodulated third-order reconstruction is slightly oscillatory, and the scheme based on Sanders' TVD reconstruction is not oscillatory, as expected.

6. Concluding remarks. The main result of this paper is the proof of convergence towards entropy solutions of large time step Godunov-type schemes with TVB

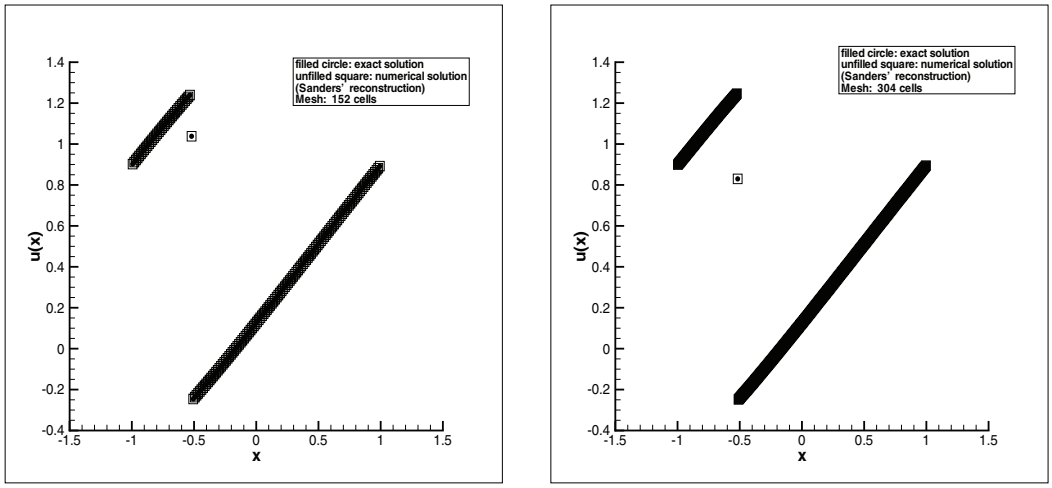

FIG. 4. *Burgers equation with the discontinuous initial condition* (4.16), $t = 0.97$. *Sanders' TVD reconstruction. Left*: 152 *uniform cells*; *right*: 304 *uniform cells.*

reconstructions for general scalar conservation laws. It is somewhat surprising that no cell or wavewise entropy inequalities are needed in the proof. An intuitive explanation is that larger time step sizes lead to fewer time steps (asymptotically much less than $O(1/\Delta x)$) to reach the final time; hence there are fewer reconstructions performed, which are the main source of possible erroneous entropy production. We have also discussed practical implementation of such large time step Godunov-type schemes for scalar one-dimensional convex conservation laws and have provided numerical examples to demonstrate the performance of these schemes. Future work will include investigations on practical implementation for more general equations, and on possible elimination of the TVB assumption on the reconstruction (or the replacement of this condition by a weaker condition easier to satisfy for high-order reconstructions in multispace dimensions), at least for conservation laws with convex fluxes.

Appendix A. Truncation error analysis. To look at the local truncation error of the scheme (1.2), we assume that we start from the cell averages $\bar{u}_j^n = Au(\cdot, t^n)|_{I_j}$ of the exact solution $u(\cdot, t)$ of the PDE at time level t^n and use the scheme to advance for one time step to obtain the numerical solution $\bar{u}^{n+1}$.

Let $\bar{u}_j^{e,n} = \bar{u}_j^n = Au(\cdot, t^n)|_{I_j}$ and $\bar{u}_j^{e,n+1} = Au(\cdot, t^{n+1})|_{I_j}$. The local truncation error is therefore defined as

$$LTE_j = \frac{1}{\Delta t}\left(\bar{u}_j^{e,n+1} - \bar{u}_j^{n+1}\right). \tag{A.1}$$

We will prove below that this local truncation error is at the level of $O(\Delta x^k)$ when piecewise polynomial of degree at most $k-1$ is used in the reconstruction, for smooth solutions, regardless of the size of Δt.

Evolving the PDE (1.1) from the two sets of initial data, the exact solution $u(\cdot, t^n)$ and the reconstructed solution $Re(\bar{u}^n)$ from the exact cell averages, respectively, give us $y^e_{j+\frac{1}{2}}$ and $y_{j+\frac{1}{2}}$, the feet of the traced-back characteristic lines from $x_{j+\frac{1}{2}}$ at t^n (see Figure 1), as well as $u^e_{j+\frac{1}{2}}$ and $u_{j+\frac{1}{2}}$, the values of the solution along these traced-back characteristics.

When the solution is smooth, according to the characteristic equations,

$$u_{j+\frac{1}{2}} = u^n\left(x_{j+\frac{1}{2}} - f'\left(u_{j+\frac{1}{2}}\right)\Delta t\right), \tag{A.2}$$

$$u^e_{j+\frac{1}{2}} = u\left(x_{j+\frac{1}{2}} - f'\left(u^e_{j+\frac{1}{2}}\right)\Delta t, t^n\right) = u^n\left(x_{j+\frac{1}{2}} - f'\left(u^e_{j+\frac{1}{2}}\right)\Delta t\right) + \mathcal{O}(\Delta x^k), \tag{A.3}$$

we have

$$|u^e_{j+\frac{1}{2}} - u_{j+\frac{1}{2}}| \sim \mathcal{O}(\Delta x^k), \qquad |y^e_{j+\frac{1}{2}} - y_{j+\frac{1}{2}}| \sim \mathcal{O}(\Delta x^k \Delta t). \tag{A.4}$$

Again if the solution is smooth, we have

$$u_{j+\frac{1}{2}} - u_{j-\frac{1}{2}} \sim \mathcal{O}(\Delta x), \qquad y_{j+\frac{1}{2}} - y_{j-\frac{1}{2}} \sim \mathcal{O}(\Delta x). \tag{A.5}$$

From the scheme, we can obtain the formula (4.5) for computing $\bar{u}_j^{n+1}$. Similarly, evolving (1.1) with the initial data $u(\cdot, t^n)$ gives us

$$\begin{aligned}\Delta x \bar{u}_j^{e,n+1} = &\int_{y^e_{j-\frac{1}{2}}}^{y^e_{j+\frac{1}{2}}} u(x,t^n)dx - \left(\Delta t f(u^e_{j+\frac{1}{2}}) + \left(y^e_{j+\frac{1}{2}} - x_{j+\frac{1}{2}}\right) u^e_{j+\frac{1}{2}}\right) \\ &+ \left(\Delta t f(u^e_{j-\frac{1}{2}}) + \left(y^e_{j-\frac{1}{2}} - x_{j-\frac{1}{2}}\right) u^e_{j-\frac{1}{2}}\right). \end{aligned} \tag{A.6}$$

Subtracting (4.5) from (A.6), we obtain

$$\begin{aligned}\Delta x(\bar{u}_j^{e,n+1} - \bar{u}_j^{n+1}) = &\left(\int_{y^e_{j-\frac{1}{2}}}^{y^e_{j+\frac{1}{2}}} u(x,t^n)dx - \int_{y_{j-\frac{1}{2}}}^{y_{j+\frac{1}{2}}} u^n(x)dx\right) \\ &- \left(\Delta t\left(f\left(u^e_{j+\frac{1}{2}}\right) - f\left(u_{j+\frac{1}{2}}\right)\right) - \Delta t\left(f\left(u^e_{j-\frac{1}{2}}\right) - f\left(u_{j-\frac{1}{2}}\right)\right)\right) \\ &+ \left(\left(y^e_{j+\frac{1}{2}} - x_{j+\frac{1}{2}}\right) u^e_{j+\frac{1}{2}} - \left(y_{j+\frac{1}{2}} - x_{j+\frac{1}{2}}\right) u_{j+\frac{1}{2}}\right. \\ &\quad \left. - \left(y^e_{j-\frac{1}{2}} - x_{j-\frac{1}{2}}\right) u^e_{j-\frac{1}{2}} + \left(y_{j-\frac{1}{2}} - x_{j-\frac{1}{2}}\right) u_{j-\frac{1}{2}}\right). \end{aligned} \tag{A.7}$$

By (A.4), the first term on the second line of (A.7) is of the size $\mathcal{O}(\Delta x^k \Delta t)$. The second term on that line is identical to the first term with a shift of the spatial grid index from $j+\frac{1}{2}$ to $j-\frac{1}{2}$. By (A.5) and the smoothness of the leading coefficient of the error term $\mathcal{O}(\Delta x^k \Delta t)$, the difference of the two terms on the second line of (A.7) gives an additional $\mathcal{O}(\Delta x)$; that is, this line is of the size $\mathcal{O}(\Delta x^{k+1}\Delta t)$. With the same reason, the difference of the two terms on the third and fourth lines of (A.7) is also of the order $\mathcal{O}(\Delta x^{k+1}\Delta t)$. Now let us look at the two terms on the right-hand side of the first line of (A.7). Without loss of generality, we assume that $y^e_{j-\frac{1}{2}} > y_{j-\frac{1}{2}}$ and $y^e_{j+\frac{1}{2}} > y_{j+\frac{1}{2}}$. We also assume that $y_{j-\frac{1}{2}}$ and $y^e_{j-\frac{1}{2}}$ fall into the same interval, say I_{jl}, and that $y_{j+\frac{1}{2}}$ and $y^e_{j+\frac{1}{2}}$ fall into the same neighboring interval $I_{jr} = I_{jl+1}$. Other situations can be handled similarly. We now have

$$\begin{aligned}&\int_{y^e_{j-\frac{1}{2}}}^{y^e_{j+\frac{1}{2}}} u(x,t^n)dx - \int_{y_{j-\frac{1}{2}}}^{y_{j+\frac{1}{2}}} u^n(x)dx \\ &\quad = \left(\int_{y^e_{j-\frac{1}{2}}}^{x_{jl+\frac{1}{2}}} + \int_{x_{jr-\frac{1}{2}}}^{y^e_{j+\frac{1}{2}}}\right) u(x,t^n)dx - \left(\int_{y_{j-\frac{1}{2}}}^{x_{jl+\frac{1}{2}}} + \int_{x_{jr-\frac{1}{2}}}^{y_{j+\frac{1}{2}}}\right) u^n(x)dx \\ &\quad = \left(\left(\int_{x_{jr-\frac{1}{2}}}^{y^e_{j+\frac{1}{2}}} + \int_{x_{jl-\frac{1}{2}}}^{x_{jl+\frac{1}{2}}} - \int_{x_{jl-\frac{1}{2}}}^{y^e_{j-\frac{1}{2}}}\right) u(x,t^n)dx\right) \\ &\qquad - \left(\left(\int_{x_{jr-\frac{1}{2}}}^{y_{j+\frac{1}{2}}} + \int_{x_{jl-\frac{1}{2}}}^{x_{jl+\frac{1}{2}}} - \int_{x_{jl-\frac{1}{2}}}^{y_{j-\frac{1}{2}}}\right) u^n(x)dx\right) \\ &\quad = \left(\int_{x_{jr-\frac{1}{2}}}^{y_{j+\frac{1}{2}}} - \int_{x_{jl-\frac{1}{2}}}^{y_{j-\frac{1}{2}}}\right)(u(x,t^n) - u^n(x))dx + \left(\int_{y_{j+\frac{1}{2}}}^{y^e_{j+\frac{1}{2}}} - \int_{y_{j-\frac{1}{2}}}^{y^e_{j-\frac{1}{2}}}\right) u(x,t^n)dx, \end{aligned} \tag{A.8}$$

where we have used the fact that the integrals of $u(x,t^n)$ and of $u^n(x)$ over any cell I_i are the same. The first term in the last line of (A.8) is a difference of two integrals,

TABLE A.1

with the integrand of the order $\mathcal{O}(\Delta x^k)$ and the length of the integral interval of the order $\min(\Delta x, \Delta t)$. Therefore, this first term is a difference of two identical $\mathcal{O}(\Delta x^k \min(\Delta x, \Delta t))$ terms with only a shift of the spatial grid index from $j+\frac{1}{2}$ to $j-\frac{1}{2}$. As before, we conclude that this first term is of the order $\mathcal{O}(\Delta x^{k+1} \min(\Delta x, \Delta t))$, or no more than the order $\mathcal{O}(\Delta x^{k+1}\Delta t)$. The second term in the last line of (A.8) is a difference of two integrals, with the integrand of the order $\mathcal{O}(1)$ and the length of the integral interval of the order $\mathcal{O}(\Delta x^k \Delta t)$. Hence, this second term is also of the order $\mathcal{O}(\Delta x^{k+1}\Delta t)$.

We can now conclude that the right-hand side of (A.7), $\Delta x(\bar{u}_j^{e,n+1} - \bar{u}_j^{n+1})$, is, therefore, of order $\mathcal{O}(\Delta x^{k+1}\Delta t)$. This implies that the local truncation error (A.1) is of the order $\mathcal{O}(\Delta x^k)$.

We can numerically verify the analysis above by giving the L^1 norm and order of accuracy of the local truncation error (A.1) for evolving the Burgers equation for one time step with different choices of Δt. In Table A.1 we list the results for the choice of $\Delta t = \Delta x^{0.5}$ with different orders of reconstruction, verifying that the local truncation error (A.1) is of the order $\mathcal{O}(\Delta x^k)$. We have also performed the numerical experiments for other choices of Δt, including $\Delta t = \Delta x^0, \Delta x^1$, and Δx^2, obtaining the same orders of accuracy for the local truncation error. We omit these error tables to save space.

Acknowledgment. We would like to thank the anonymous referees for their helpful and constructive comments, which led to an improvement of the paper.

ON NUMERICAL ALGORITHMS FOR THE SOLUTION OF A BELTRAMI EQUATION*

DENIS GAIDASHEV† AND DMITRY KHMELEV

Abstract. The paper concerns numerical algorithms for solving the Beltrami equation $f_{\bar{z}}(z) = \mu(z)f_z(z)$ for a compactly supported μ. First, we study an efficient algorithm that has been proposed in [P. Daripa, *J. Comput. Phys.*, 106 (1993), pp. 355–365] and [P. Daripa and D. Mashat, *Numer. Algorithms*, 18 (1998), pp. 133–157] and present its rigorous justification. We then propose a different scheme for solving the Beltrami equation which has a comparable speed and accuracy, but has the virtue of easier implementation by avoiding the use of the Hilbert transform. The present paper can also be viewed as a prologue to one important application of the Beltrami equation: it provides a detailed description of the algorithm that has been used in [D. Gaidashev, *Nonlinearity*, 20 (1998), pp. 713–741] and [D. Gaidashev and M. Yampolsky, *Experiment. Math.*, 16 (2007), pp. 215–226] to address an important issue in complex dynamics—conjectural universality for Siegel disks.

Key words. Beltrami equation, Hilbert transform, Cauchy transform, measurable Riemann mapping, quasi-conformal map

1. Introduction.

The problem of existence of a quasi-conformal mapping g with a given complex dilatation μ is one of the central problems of classical complex analysis.

We will first recall a definition of a quasi-conformal map. Given an open set $\Omega \subset \mathbb{C}$, a map $f : \Omega \to f(\Omega) \subset \mathbb{C}$ is said to be absolutely continuous on lines (ACL) in a rectangle $R \subset \Omega$ with sides parallel to the x and y axes if f is absolutely continuous on almost every horizontal and vertical line in R. The map f is ACL on Ω if it is ACL on every rectangle in Ω. Partial derivatives $f_z = (f_x - if_y)/2$ and $f_{\bar{z}} = (f_x + if_y)/2$ of such a map exist a.e. in Ω.

DEFINITION 1.1. *A homeomorphism $f : \Omega \to f(\Omega)$ is K-quasi-conformal if and only if the following hold:*

(i) *f is ACL on Ω.*

(ii) *$|f_{\bar{z}}| \le \frac{K-1}{K+1}|f_z|$ a.e. in Ω.*

The complex dilatation of a quasi-conformal homeomorphism f defined a.e. is

$$\mu_f(z) = f_{\bar{z}}(z)/f_z(z).$$

A mapping f with a prescribed complex dilatation μ solves the following *Beltrami equation.*

$$f_{\bar{z}}(z) = \mu(z)f_z(z). \tag{1.1}$$

The question of existence of a solution of (1.1) is addressed in the famous Ahlfors–Bers–Boyarskii theorem (see [3] and [6]) (below, $\hat{\mathbb{C}}$ signifies the Riemann sphere).

*Received by the editors September 19, 2005; accepted for publication (in revised form) May 30, 2007; published electronically May 9, 2008. This project was completed by the first author after D. Khmelev's sudden passing.

THEOREM 1.2 (Ahlfors and Bers [3], Boyarskii [6]). *Let $\mu \in L_\infty(\hat{\mathbb{C}})$ satisfy $\|\mu\|_\infty \le k < 1$. Then there exists a unique map $f^\mu : \hat{\mathbb{C}} \to \hat{\mathbb{C}}$ such that f^μ satisfies the Beltrami equation $f^\mu_{\bar{z}}(z) = \mu(z) f^\mu_z(z)$, f^μ fixes 0, 1, and ∞, and f^μ is a $(1+k)/(1-k)$-quasi-conformal map.*

The goal of the present paper will be to study two algorithms for finding the normalized solution of the Beltrami equation numerically.

There seem to be three main techniques that have been used over time to solve a Beltrami equation with a compactly supported differential, or to find a quasi-conformal map of a simply or multiply connected domain to a "canonical" domain (disk, rectangle, etc.): finite differences, circle packings, and a numerical version of Ahlfors and Bers' original method, which we will later describe in greater detail.

Several works have proposed numerical constructions of quasi-conformal mappings by solving a system of elliptic equations with finite difference techniques. Reference [21] presents a finite difference construction of a quasi-conformal map of a simply connected domain in $\mathbb{C}$ onto a rectangle. Finite-difference techniques have been also used in [26] and [27] to find quasi-conformal maps from simply, doubly, and triply connected domains. One particular application is finite grid generation [4], [22].

Another method that has been used to solve the Beltrami equation numerically is circle packings. A circle packing—a collection of closed disks with disjoint interiors and prescribed tangencies—was suggested by W. Thurston for a geometric proof of the Riemann mapping theorem. The details of this proof have been worked out by Rodin and Sullivan in [24]. A generalization of this scheme to the Ahlfors–Bers–Boyarskii theorem has been given in [16] and [18]. A numerical implementation of this procedure was studied in [19].

In this paper we will study a third method: an algorithm first proposed in [11] and based on the original iterative scheme of Ahlfors and Bers which uses singular integral transforms.

According to Ahlfors and Bers' classical proof of Theorem 1.2, a solution of the Beltrami equation can be constructed with the help of two operators, the first operator being the Hilbert transform,

$$T[h](z) = \frac{i}{2\pi} \lim_{\epsilon \to 0} \int\int_{\mathbb{C}\setminus B(z,\epsilon)} \frac{h(\xi)}{(\xi - z)^2}\, d\bar{\xi} \wedge d\xi, \tag{1.2}$$

and the second the Cauchy transform,

$$P[h](z) = \frac{i}{2\pi} \int\int_{\mathbb{C}} \frac{h(\xi)}{\xi - z} - \frac{h(\xi)}{\xi}\, d\bar{\xi} \wedge d\xi. \tag{1.3}$$

If the differential μ is compactly supported, then the quasi-conformal homeomorphism f is constructed in two steps. First, one solves the following equation:

$$h^* = T[\mu h^*] + T[\mu]. \tag{1.4}$$

If h^* satisfying (1.4) is found, then f solving (1.1) on the Riemann sphere $\hat{\mathbb{C}}$, normalized as to fix 0, 1, and ∞, is given by

$$f(z) = P[\mu(h^* + 1)](z) + z.$$

The operator P is well-defined and is Hölder continuous for $h \in L^p(\mathbb{C})$, $p > 2$. This implies that a solution to (1.4) must also be constructed in $L_p(\mathbb{C})$, $p > 2$. The celebrated Calderon–Zygmund inequality (cf. [9]) states that

$$\|T[h]\|_p \le C_p \|h\|_p$$

for all $h \in L_p(\mathbb{C})$, where C_p is some constant, depending only on p, which can be chosen so that $C_p \to 1$ as $p \to 2$. While the optimal value of C_p for all p is not known, it is known that $C_2 = 1$, and T is an isometry in $L_2(\mathbb{C})$:

$$\|T[h]\|_2 = \|h\|_2.$$

To solve (1.4) one has to choose a p such that $kC_p < 1$. Then the operator $h \mapsto T[\mu h]$ is a contraction in $L_p(\mathbb{C})$ and iterations

$$h^{n+1} = T[\mu h^n] + T[\mu] \tag{1.5}$$

converge to a solution of (1.4): $h^n \to h^*$ as $n \to \infty$.

We can now state the extended version of the Ahlfors–Bers–Boyarskii theorem for compactly supported differentials.

THEOREM 1.3. *Let $\mu \in L_\infty(\mathbb{C})$ be compactly supported and satisfy $\|\mu\|_\infty \le k < 1$. Then for every $p > 2$ such that $C_p k < 1$, the operator $h \to T[\mu(h+1)]$ is a contraction on $L_p(\mathbb{C})$ with a unique fixed point h^*. Moreover, the solution of the Beltrami equation, f^μ, is given by*

$$f^\mu = P[\mu(h^* + 1)] + \mathrm{id}, \tag{1.6}$$

where id *is the identity function, and is such that $f(0) = 0$, f is continuous and has distributional derivatives, and $f_z - 1 \in L_p(\mathbb{C})$.*

We will concentrate on the numerical implementation of the procedure described in this theorem. This is an important practical problem which has been addressed by various authors.

Efficient algorithms for computing the two required transforms T and P have been proposed in [11], [12], and [13]. We will proceed with a very brief description of these algorithms.

As we have pointed out, the Cauchy transform of an L_p-function, $p > 2$, is well-defined and is known to be Hölder continuous with exponent $1 - 2/p$ (cf. [2], [20]). In [11] an effective algorithm for the numerical computation of the following integral transform was suggested:

$$\tilde{P}[h](z) = \frac{i}{2\pi} \int\int_{\mathbb{C}} \frac{h(\xi)}{(\xi - z)}\, d\bar{\xi} \wedge d\xi. \tag{1.7}$$

A comparison with (1.3) immediately shows that

$$P[h](z) = \tilde{P}[h](z) - \tilde{P}[h](0). \tag{1.8}$$

Represent h and $\tilde{P}[h]$ as a Fourier series:

$$h(re^{i\theta}) = \sum_{k=-\infty}^{\infty} h_k(r) e^{ik\theta}, \tag{1.9}$$

$$\tilde{P}[h](re^{i\theta}) = \sum_{k=-\infty}^{\infty} p_k(r) e^{ik\theta}, \tag{1.10}$$

where the coefficients of the $\tilde{P}$-transform are given by

$$p_k(r) = \frac{1}{2\pi} \int_0^{2\pi} e^{-ik\theta} \tilde{P}[h](re^{i\theta})\, d\theta. \tag{1.11}$$

Then, according to [11],

$$p_k(r) = \begin{cases} 2\displaystyle\int_0^r \left(\frac{r}{\rho}\right)^k h_{k+1}(\rho)d\rho, & k<0, \\ -2\displaystyle\int_r^\infty \left(\frac{r}{\rho}\right)^k h_{k+1}(\rho)d\rho, & k\geq 0. \end{cases} \tag{1.12}$$

Next, to obtain similar formulae for the Hilbert transform, assume that h is a Hölder continuous function compactly supported in an open disk around zero of radius R, $B(0,R)\subset\mathbb{C}$. The Hilbert transform of such a function is well-defined (see the next section). Represent the Hilbert transform as a Fourier series:

$$T[h](re^{i\theta}) = \sum_{k=-\infty}^{\infty} c_k(r)e^{ik\theta}, \quad c_k(r) = \frac{1}{2\pi}\int_0^{2\pi} e^{-ik\theta}T[h](re^{i\theta})\, d\theta. \tag{1.13}$$

In [12] and [13] the authors arrive at the following expressions for these coefficients:

$$c_0(0) = -2\lim_{\epsilon\to 0}\int_\epsilon^R \frac{h_2(\rho)}{\rho}d\rho, \text{ and } c_k(0)=0, \text{ whenever } k\neq 0, \tag{1.14}$$

$$c_k(r) = A_k\int_0^r \frac{r^k}{\rho^{k+1}}h_{k+2}(\rho)d\rho + B_k\int_r^R \frac{r^k}{\rho^{k+1}}h_{k+2}(\rho)d\rho + h_{k+2}(r), \tag{1.15}$$

where

$$A_k = \begin{cases} 0, & k\geq 0, \\ 2(k+1), & k<0, \end{cases} \quad \text{and} \quad B_k = \begin{cases} -2(k+1), & k\geq 0, \\ 0, & k<0. \end{cases} \tag{1.16}$$

Given values of h, for instance, on a circular $N\times M$ grid that contains the compact support of h, one can use a fast Fourier transform (FFT; cf. [23]) to find the values of the coefficients h_k at the radii r_i, $1\leq i\leq M$. Next, one can use these values to construct a piecewise constant, a piecewise linear, or a spline approximation of the functions h_k (the choice of approximation, of course, depends on the known or expected smoothness of h_k). This allows one to compute integrals in (1.12) and in (1.14)–(1.15). Armed with these implementations of the Hilbert and Cauchy transforms, one can try to solve the Beltrami equation (1.1), first by running iterations (1.5) for some time, and, finally, applying (1.6). It is convenient to use the pointwise multiplication of grid values of h and $\mu+1$ inside the Hilbert transform in (1.5), rather than the multiplication of their Fourier series: the order of the computational complexity of the pointwise multiplication is $O(NM)$, as opposed to $O(NM^2)$ for the series. The transition from the representation of h as a Fourier series to point values at each iteration step can be performed with the help of the FFT. This way, the computational complexity of one iteration step becomes $O(NM\log_2 M)$.

The objective of our paper is manifold. First, we will present a rigorous mathematical justification of the formulae (1.14)–(1.15) for the singular operator T different from that of [13]. Second, we will propose an algorithm which avoids programming formulae (1.14)–(1.15) altogether. It should be noted that in our experience writing the code for the Hilbert transform can be rather cumbersome; therefore this second algorithm can be viewed as an improvement.

Furthermore, we would like to reiterate the well-known fact that solutions of the Beltrami equation are often the central ingredient of many uniformization problems

appearing, in particular, in complex dynamics. In this light, the present paper can be also viewed as a detailed account of the numerical algorithms that have been used, in particular, in [14] and [15] to address an important issue in complex dynamics—conjectural universality for Siegel disks. The interested reader is referred to [14] for a description of a parallelized implementation of the algorithms of the present paper, which also includes rigorous computer-assisted bounds on the difference between a numerical approximation of the solution of the Beltrami equation with the true one.

2. An alternative justification of Daripa and Mashat's algorithm for the Hilbert transform. The Hilbert transform is a singular integral transform, and therefore, first of all, one has to specify the conditions under which this integral can be computed. The issue of existence of a rather general class of singular integral transforms (including the Hilbert transform) has been addressed in the classical work [9] of Calderon and Zygmund. The sufficient condition for the existence of the Hilbert transform itself can be stated in a very concise way (cf. [2], [10]).

LEMMA 2.1. *If h is Hölder continuous, then the Hilbert integral transform of h exists as a Cauchy principle value.*

In this light, the main result of [13] can be stated as follows.

THEOREM 2.1. *If $T[h](z)$ exists as a Cauchy principle value, then the Fourier coefficients of this Hilbert transform are given by formulae* (1.14)–(1.15).

The proof of this theorem, presented in [13], starts with an observation that according to (1.2) and (1.13), coefficients of the Hilbert transform are given by the following formula:

$$c_k(r) = -\frac{1}{2\pi^2}\int_0^{2\pi} e^{-ik\theta}\lim_{\epsilon\to 0}\int\int_{\mathbb{C}\setminus B(re^{i\theta},\epsilon)} \frac{h(\rho e^{i\alpha})}{(\rho e^{i\alpha}-re^{i\theta})^2}\ \rho d\rho d\alpha d\theta. \tag{2.1}$$

Daripa and Mashat proceed in their proof by computing the Hilbert transform in the problematic region (ρ close to r) explicitly. We will take a different route here: a crucial step in our proof will be to interchange the order of the first integration and the limit in (2.1).

We will now proceed with our argument. Let h be Hölder continuous with exponent γ and constant A, and let it be compactly supported in an open disk around zero of radius R, $B(0,R)\subset\mathbb{C}$. Notice that the variable z in (1.2) can range over all of $\mathbb{C}$ and not only over $B(0,R)$. We will start by showing that the Hilbert transform of a Hölder continuous function is bounded.

Choose a $\delta < 1/R$. For all $\epsilon < \delta R$ define

$$\begin{aligned} T_\epsilon[h](z) &= \frac{i}{2\pi}\int\int_{B(0,R)\setminus B(z,\epsilon)} \frac{h(\xi)}{(\xi-z)^2}\ d\bar{\xi}\wedge d\xi \\ &= \frac{i}{2\pi}\int\int_{B(0,R)\setminus B(z,\delta R)} \frac{h(\xi)}{(\xi-z)^2}\ d\bar{\xi}\wedge d\xi \\ &\quad + \frac{i}{2\pi}\int\int_{B(z,\delta R)\setminus B(z,\epsilon)} \frac{h(\xi)}{(\xi-z)^2}\ d\bar{\xi}\wedge d\xi \\ &= T^1[h](z) + T^2_\epsilon[h](z). \end{aligned} \tag{2.2}$$

LEMMA 2.2. *There exists a constant C such that $\left|T^2_\epsilon[h](z)\right| < C$ for all $0<\epsilon<\delta R$ and all $z\in\overline{B(0,R)}$.*

Proof.

$$\begin{aligned}
\left|T_\epsilon^2[h](z)\right| &= \left|\frac{i}{2\pi}\int\int_{B(z,\delta R)\setminus B(z,\epsilon)} \frac{h(\xi)}{(\xi-z)^2}\, d\bar{\xi}\wedge d\xi\right| \\
&= \left|-\frac{1}{\pi}\int_\epsilon^{\delta R}\int_0^{2\pi} \frac{h(z+\rho e^{i\theta})}{\rho^2 e^{2i\theta}}\rho\, d\rho d\theta\right| \\
&= \left|-\frac{1}{\pi}\int_\epsilon^{\delta R}\int_0^{\frac{\pi}{2}} \frac{h\left(z+\rho e^{i\theta}\right)-h\left(z+\rho e^{i(\theta+\pi/2)}\right)}{\rho e^{2i\theta}} d\rho d\theta\right. \\
&\quad \left.-\frac{1}{\pi}\int_\epsilon^{\delta R}\int_0^{\frac{\pi}{2}} \frac{h\left(z+\rho e^{i(\theta+\pi)}\right)-h\left(z+\rho e^{i(\theta+3\pi/2)}\right)}{\rho e^{2i\theta}} d\rho d\theta\right| \\
&\le \frac{1}{\pi}\int_\epsilon^{\delta R}\int_0^{\frac{\pi}{2}} \frac{\left|h\left(z+\rho e^{i\theta}\right)-h\left(z+\rho e^{i(\theta+\pi/2)}\right)\right|}{\rho}\, d\rho d\theta \\
&\quad +\frac{1}{\pi}\int_\epsilon^{\delta R}\int_0^{\frac{\pi}{2}} \frac{\left|h\left(z+\rho e^{i(\theta+\pi)}\right)-h\left(z+\rho e^{i(\theta+3\pi/2)}\right)\right|}{\rho}\, d\rho d\theta \\
&\le \frac{1}{2}\int_\epsilon^{\delta R} \frac{A\rho^\gamma\left|1-e^{i\frac{\pi}{2}}\right|^\gamma}{\rho}\, d\rho + \frac{1}{2}\int_\epsilon^{\delta R} \frac{A\rho^\gamma\left|1-e^{i\frac{\pi}{2}}\right|^\gamma}{\rho}\, d\rho \\
&\le A\left|1-i\right|^\gamma \frac{1}{\gamma}(\delta R)^\gamma = C,
\end{aligned}$$

where we have used Hölder continuity. ∎

Next, we will derive the expressions for the Fourier coefficients of the Hilbert transform separately for $z \in \mathrm{int}B(0,R)-\{0\}$, $z \in \partial B(0,R)$, $z=0$, and $z \in \mathbb{C}\setminus\overline{B(0,R)}$.

2.1. Case $z \in \mathbf{int}B(0,R)-\{0\}$.

COROLLARY 2.2.

$$\begin{aligned}
c_k(r) &= -\frac{1}{2\pi^2}\lim_{\epsilon\to 0}\int_0^{r-\epsilon}\int_0^{2\pi} h(\rho e^{i\alpha})\int_0^{2\pi} \frac{e^{-ik\theta}}{(\rho e^{i\alpha}-re^{i\theta})^2}\, d\theta d\alpha\rho d\rho \\
&\quad -\frac{1}{2\pi^2}\lim_{\epsilon\to 0}\int_{r+\epsilon}^{R}\int_0^{2\pi} h(\rho e^{i\alpha})\int_0^{2\pi} \frac{e^{-ik\theta}}{(\rho e^{i\alpha}-re^{i\theta})^2}\, d\theta d\alpha\rho d\rho + h_{k+2}(r)
\end{aligned}$$

for all $0<r<R$.

Proof. Let $z=re^{i\theta}$. Recall that $T_\epsilon[h]=T^1[h]+T_\epsilon^2[h]$, where $T^1[h]$ and $T_\epsilon^2[h]$ are as in (2.2). The first of these operators is clearly bounded, and the second is bounded by the preceding lemma. Therefore, $|T_\epsilon[h](z)|$ is bounded by a constant function, while the function $\psi_\epsilon(\theta)=e^{-i\theta}T_\epsilon[h](re^{i\theta})$ is bounded by $\mathrm{const}\cdot e^{-i\theta}$, which is certainly in $L_1([0,2\pi))$. A direct application of the Lebesgue dominated convergence theorem shows that the limiting procedure and the integration over the circle can be interchanged:

$$\begin{aligned}
c_k(r) &= \frac{i}{4\pi^2}\int_0^{2\pi}\lim_{\epsilon\to 0}\psi_\epsilon(\theta)d\theta = \frac{i}{4\pi^2}\lim_{\epsilon\to 0}\int_0^{2\pi}\psi_\epsilon(\theta)d\theta \\
&= \frac{i}{4\pi^2}\lim_{\epsilon\to 0}\int_0^{2\pi}\int\int_{B(0,R)\setminus B(z,\epsilon)} h(\xi)\frac{e^{-ik\theta}}{(\xi-re^{i\theta})^2}\, d\bar{\xi}\wedge d\xi d\theta = \lim_{\epsilon\to 0} c_k^\epsilon(r).
\end{aligned}$$

We will denote $\Omega = B(0, r+\epsilon) \setminus (B(0, r-\epsilon) \cup B(z, \epsilon))$ for the purpose of notational brevity. Then, for an arbitrary but fixed ϵ, one can interchange the order of integration (according to Fubini's theorem) in the following way:

$$\begin{aligned}
c_k^\epsilon(r) &= \frac{i}{4\pi^2}\int_0^{2\pi}\int\int_{B(0,r-\epsilon)} h(\xi)\frac{e^{-ik\theta}}{(\xi - re^{i\theta})^2}\, d\bar{\xi}\wedge d\xi d\theta \\
&+ \frac{i}{4\pi^2}\int_0^{2\pi}\int\int_{B(0,R)\setminus B(0,r+\epsilon)} h(\xi)\frac{e^{-ik\theta}}{(\xi - re^{i\theta})^2}\, d\bar{\xi}\wedge d\xi d\theta \\
&+ \frac{i}{4\pi^2}\int_0^{2\pi}\int\int_{\Omega} h(\xi)\frac{e^{-ik\theta}}{(\xi - re^{i\theta})^2}\, d\bar{\xi}\wedge d\xi d\theta \\
&= -\frac{1}{2\pi^2}\int_0^{r-\epsilon}\int_0^{2\pi} h(\rho e^{i\alpha})\int_0^{2\pi}\frac{e^{-ik\theta}}{(\rho e^{i\alpha} - re^{i\theta})^2}\, d\theta d\alpha\rho d\rho \\
&- \frac{1}{2\pi^2}\int_{r+\epsilon}^{R}\int_0^{2\pi} h(\rho e^{i\alpha})\int_0^{2\pi}\frac{e^{-ik\theta}}{(\rho e^{i\alpha} - re^{i\theta})^2}\, d\theta d\alpha\rho d\rho \\
&+ \frac{i}{4\pi^2}\int_0^{2\pi}\int\int_{\Omega} h(\xi)\frac{e^{-ik\theta}}{(\xi - re^{i\theta})^2}\, d\bar{\xi}\wedge d\xi d\theta. \qquad (2.3)
\end{aligned}$$

Next, define $\Omega_2 = B(z, \epsilon^\beta) \setminus B(z, \epsilon)$ for some real positive $\beta < 1$ to be specified later ($B(z,\epsilon) \subset B(z,\epsilon^\beta)$ since ϵ is always less than 1 by our choice of δ), and $\Omega_1 = \Omega \setminus \Omega_2$. Using Hölder continuity once again, one can show that the difference

$$I_\epsilon = \left| \frac{i}{4\pi^2}\int_0^{2\pi}\int\int_{\Omega}\frac{h(\xi)e^{-ik\theta}}{(\xi - z)^2}\, d\bar{\xi}\wedge d\xi d\theta - \frac{i}{4\pi^2}\int_0^{2\pi}\int\int_{\Omega}\frac{h(z)e^{-ik\theta}}{(\xi - z)^2}\, d\bar{\xi}\wedge d\xi d\theta \right| \qquad (2.4)$$

can be bounded in the following way:

$$\begin{aligned}
I_\epsilon &\le \frac{1}{4\pi^2}\int_0^{2\pi}\int\int_{\Omega}\frac{|h(\xi) - h(z)|}{|\xi - z|^2}\, d\bar{\xi}\wedge d\xi d\theta \\
&\le \frac{1}{4\pi^2}\int_0^{2\pi}\int\int_{\Omega} A|\xi - z|^{\gamma-2}\, d\bar{\xi}\wedge d\xi d\theta \\
&\le \frac{A}{2\pi}\int\int_{\Omega}\rho^{\gamma-2}\, d\alpha\rho d\rho.
\end{aligned}$$

If $\gamma \ge 1$, then I_ϵ can be clearly bounded by

$$I_\epsilon \le \frac{A}{2\pi}\epsilon^{\gamma-2}\mathrm{Area}(\Omega) \le \frac{A}{2\pi}\epsilon^{\gamma-2}4\pi r\epsilon = 2Ar\epsilon^{\gamma-1}. \qquad (2.5)$$

Otherwise

$$\begin{aligned}
I_\epsilon &\le \frac{A}{2\pi}\int\int_{\Omega_1}\rho^{\gamma-2}\, d\alpha\rho d\rho + \frac{A}{2\pi}\int\int_{\Omega_2}\rho^{\gamma-2}\, d\alpha\rho d\rho \\
&\le \frac{A}{2\pi}\epsilon^{\beta(\gamma-2)}\mathrm{Area}(\Omega_1) + \frac{A}{\gamma}(\epsilon^{\beta\gamma} - \epsilon^\gamma) \le \frac{A}{2\pi}\epsilon^{\beta(\gamma-2)}4\pi r\epsilon + \frac{A}{\gamma}(\epsilon^{\beta\gamma} - \epsilon^\gamma) \\
&\le 2Ar\epsilon^{\beta(\gamma-2)+1} + \frac{A}{\gamma}(\epsilon^{\beta\gamma} - \epsilon^\gamma).
\end{aligned}$$

Notice that in both cases

$$\lim_{\epsilon\to 0} I_\epsilon = 0 \tag{2.6}$$

as long as $\beta(2-\gamma)<1$. Now, it is not hard to show that

$$\frac{i}{4\pi^2}\int\int_\Omega \frac{d\bar{\xi}\wedge d\xi}{(\xi-z)^2} = \frac{1}{2\pi}\frac{(r-\epsilon)^2}{z^2} \tag{2.7}$$

(see [13]) and, therefore, combining (2.6) and (2.7), that

$$\begin{aligned}
&\left|\frac{i}{4\pi^2}\lim_{\epsilon\to 0}\int_0^{2\pi}\int\int_\Omega \frac{h(\xi)e^{-ik\theta}}{(\xi-z)^2}\, d\bar{\xi}\wedge d\xi d\theta - \frac{1}{2\pi}\int_0^{2\pi} h(z)e^{-ik\theta}\frac{r^2}{z^2}\, d\theta\right| \\
&= \left|\frac{i}{4\pi^2}\lim_{\epsilon\to 0}\int_0^{2\pi}\int\int_\Omega \frac{h(\xi)e^{-ik\theta}}{(\xi-z)^2}\, d\bar{\xi}\wedge dd\xi d\theta - \frac{1}{2\pi}\lim_{\epsilon\to 0}\int_0^{2\pi} h(z)e^{-ik\theta}\frac{(r-\epsilon)^2}{z^2}\, d\theta\right| \\
&= \lim_{\epsilon\to 0}\left|\frac{i}{4\pi^2}\int_0^{2\pi}\int\int_\Omega \frac{h(\xi)e^{-ik\theta}}{(\xi-z)^2}\, d\bar{\xi}\wedge d\xi d\theta - \frac{1}{2\pi}\int_0^{2\pi} h(z)e^{-ik\theta}\frac{(r-\epsilon)^2}{z^2}\, d\theta\right| \\
&= \lim_{\epsilon\to 0}\left|\frac{i}{4\pi^2}\int_0^{2\pi}\int\int_\Omega \frac{h(\xi)e^{-ik\theta}}{(\xi-z)^2}\, d\bar{\xi}\wedge d\xi d\theta - \frac{i}{4\pi^2}\int_0^{2\pi}\int\int_\Omega \frac{h(z)e^{-ik\theta}}{(\xi-z)^2}\, d\bar{\xi}\wedge d\xi d\theta\right| \\
&\le \lim_{\epsilon\to 0} I_\epsilon = 0,
\end{aligned}$$

where in the first equality we again used the Lebesgue dominated convergence theorem. We conclude that

$$\frac{i}{4\pi^2}\lim_{\epsilon\to 0}\int_0^{2\pi}\int\int_\Omega \frac{h(\xi)e^{-ik\theta}}{(\xi-z)^2}\, d\bar{\xi}\wedge d\xi d\theta = \frac{1}{2\pi}\int_0^{2\pi} h(z)e^{-ik\theta}\frac{r^2}{z^2}\, d\theta. \tag{2.8}$$

Observe that

$$\frac{1}{2\pi}\int_0^{2\pi} h(z)e^{-ik\theta}\frac{r^2}{z^2}\, d\theta = \frac{1}{2\pi}\int_0^{2\pi}\frac{e^{-ik\theta}\sum_{n=-\infty}^{\infty} h_n(r)e^{in\theta}}{e^{2i\theta}}\, d\theta = h_{k+2}(r). \tag{2.9}$$

The claim of the corollary follows from (2.3), (2.8), and (2.9). □

Now, consider

$$I(\xi,r) = \int_0^{2\pi}\frac{e^{-ik\theta}}{(\xi-re^{i\theta})^2}\, d\theta = \frac{1}{r^2}\int_0^{2\pi}\frac{e^{-ik\theta}}{(\xi/r-e^{i\theta})^2}\, d\theta = \frac{1}{ir^2}\oint_{\mathbb{T}^1}\frac{1}{w^{k+1}(\xi/r-w)^2}\, dw.$$

We will first compute this integral in the case when $|\xi|/r>1$:

$$I(\xi,r) = \frac{2\pi}{r^2}\mathrm{Res}\left[\frac{1}{w^{k+1}(\xi/r-w)^2}\right]_{w=0} = -B_k\pi\frac{r^k}{\xi^{k+2}},$$

where

$$B_k = \begin{cases} -2(k+1), & k\ge 0, \\ 0, & k<0. \end{cases}$$

Similarly, for $|\xi|/r < 1$,

$$I(\xi,r) = \frac{2\pi}{r^2}\mathrm{Res}\left[\frac{1}{w^{k+1}(\xi/r-w)^2}\right]_{w=\frac{\xi}{r}} + \frac{2\pi}{r^2}\mathrm{Res}\left[\frac{1}{w^{k+1}(\xi/r-w)^2}\right]_{w=0} = -A_k\pi\frac{r^k}{\xi^{k+2}},$$

where

$$A_k = \begin{cases} 0, & k \geq 0, \\ 2(k+1), & k < 0. \end{cases}$$

Finally, we obtain

$$\begin{aligned} c_k(r) &= \frac{A_k}{2\pi}\int_0^r\int_0^{2\pi} h(\rho e^{i\alpha})\frac{r^k}{\xi^{k+2}}\ \rho d\rho d\alpha + \frac{B_k}{2\pi}\int_r^R\int_0^{2\pi} h(\rho e^{i\alpha})\frac{r^k}{\xi^{k+2}}\ \rho d\rho d\alpha + h_{k+2}(r) \\ &= \frac{A_k}{2\pi}\int_0^r\int_0^{2\pi} \frac{r^k\sum_{-\infty}^{\infty} h_n(\rho)e^{in\alpha}}{\rho^{k+1}e^{i(k+2)\alpha}}\ d\rho d\alpha + \frac{B_k}{2\pi}\int_r^R\int_0^{2\pi} \frac{r^k\sum_{-\infty}^{\infty} h_n(\rho)e^{in\alpha}}{\rho^{k+1}e^{i(k+2)\alpha}}\ d\rho d\alpha \\ &+ h_{k+2}(r) = A_k\int_0^r \frac{r^k}{\rho^{k+1}}h_{k+2}(\rho)d\rho + B_k\int_r^R \frac{r^k}{\rho^{k+1}}h_{k+2}(\rho)d\rho + h_{k+2}(r). \end{aligned}$$

2.2. Case $z \in \partial B(0,R)$. We will briefly outline a counterpart of Corollary 2.2 for $|z| = R$.

Corollary 2.3.

$$c_k(R) = -\frac{1}{2\pi^2}\lim_{\epsilon\to 0}\int_0^{R-\epsilon}\int_0^{2\pi} h(\rho e^{i\alpha})\int_0^{2\pi}\frac{e^{-ik\theta}}{(\rho e^{i\alpha}-Re^{i\theta})^2}\ d\theta d\alpha\rho d\rho.$$

Proof. According to Lemma 2.2, we can exchange the order of the integration and the limit:

$$\begin{aligned} c_k(R) &= \frac{i}{4\pi^2}\int_0^{2\pi}\lim_{\epsilon\to 0}\int\int_{B(0,R)\setminus B(z,\epsilon)} h(\xi)\frac{e^{-ik\theta}}{(\xi-Re^{i\theta})^2}\ d\bar{\xi}\wedge d\xi d\theta \\ &= \frac{i}{4\pi^2}\lim_{\epsilon\to 0}\int_0^{2\pi}\int\int_{B(0,R)\setminus B(z,\epsilon)} h(\xi)\frac{e^{-ik\theta}}{(\xi-Re^{i\theta})^2}\ d\bar{\xi}\wedge d\xi d\theta = \lim_{\epsilon\to 0} c_k^{\epsilon}(R). \end{aligned}$$

Denote $\Omega = B(0,R)\setminus(B(0,R-\epsilon)\cup B(z,\epsilon))$. Then we obtain for an arbitrary but fixed ϵ:

$$\begin{aligned} c_k^{\epsilon}(R) &= -\frac{1}{2\pi^2}\int_0^{R-\epsilon}\int_0^{2\pi} h(\rho e^{i\alpha})\int_0^{2\pi}\frac{e^{-ik\theta}}{(\rho e^{i\alpha}-Re^{i\theta})^2}\ d\theta d\alpha\rho d\rho \\ &+ \frac{i}{4\pi^2}\int_0^{2\pi}\int\int_{\Omega} h(\xi)\frac{e^{-ik\theta}}{(\xi-Re^{i\theta})^2}\ d\bar{\xi}\wedge d\xi d\theta. \end{aligned} \tag{2.10}$$

Again, define $\Omega_2 = B(z,\epsilon^{\beta})\setminus B(z,\epsilon)$ for some real positive $\beta < 1$, and $\Omega_1 = \Omega\setminus\Omega_2$. As in Corollary 2.2, one shows that the difference (2.4) can be bounded by $Ar\epsilon^{\gamma-1}$ if $\gamma \geq 1$, and by $Ar\epsilon^{\beta(\gamma-2)+1} + (A/2\gamma)(\epsilon^{\beta\gamma}-\epsilon^{\gamma})$ otherwise, and that $\lim_{\epsilon\to 0} I_{\epsilon} = 0$ as long as $\beta(2-\gamma) < 1$. However, $h(z) \equiv 0$ for all $z \in \partial B(0,R)$; hence

$$I_{\epsilon} = \left|\frac{i}{4\pi^2}\int_0^{2\pi}\int\int_{\Omega}\frac{h(\xi)e^{-ik\theta}}{(\xi-z)^2}\ d\bar{\xi}\wedge d\xi d\theta\right|$$

and therefore

$$\frac{i}{4\pi^2}\lim_{\epsilon\to 0}\int_0^{2\pi}\int\!\!\int_{\Omega} h(\xi)\frac{e^{-ik\theta}}{(\xi-Re^{i\theta})^2}\,d\bar{\xi}\wedge d\xi d\theta = 0. \tag{2.11}$$

The claim of the lemma follows from (2.10) and (2.11). □

To obtain an expression for $c_k(R)$, consider the integral $\int_0^{2\pi} e^{-ik\theta}/(\xi - Re^{i\theta})^2\,d\theta$. It is not hard to show that this integral is equal to $-A_k\pi R^k/\xi^{k+2}$, and, therefore,

$$\begin{aligned}
c_k(R) &= -\frac{1}{2\pi^2}\lim_{\epsilon\to 0}\int_0^{R-\epsilon}\int_0^{2\pi} h(\rho e^{i\alpha})\int_0^{2\pi}\frac{e^{-ik\theta}}{(\rho e^{i\alpha}-Re^{i\theta})^2}\,d\theta d\alpha\rho d\rho \\
&= \frac{1}{2\pi}\int_0^R\int_0^{2\pi} h(\rho e^{i\alpha})A_k\frac{R^k}{\xi^{k+2}}\,d\alpha\rho d\rho \\
&= \frac{A_k}{2\pi}\int_0^R\int_0^{2\pi}\frac{R^k\sum_{n=-\infty}^{\infty}h_n(\rho)e^{in\theta}}{\rho^{k+1}e^{i(k+2)\theta}}\,d\rho d\theta \\
&= A_k\int_0^R\frac{R^k}{\rho^{k+1}}h_{k+2}(\rho)\,d\rho.
\end{aligned}$$

2.3. Case $z = 0$. We will prove a counterpart of Corollary 2.2, at the same time obtaining an expression for $c_k(0)$.

COROLLARY 2.4.

$$c_k(0) = \begin{cases} 0, & k\neq 0, \\ -2\int_0^R \frac{h_2(\rho)}{\rho}d\rho, & k = 0. \end{cases}$$

Proof. As before, according to Lemma 2.2, for an arbitrary but fixed ϵ, one can use the Lebesgue dominated convergence theorem to change the order of the integration and the limit:

$$\begin{aligned}
c_k(0) &= \frac{i}{4\pi^2}\int_0^{2\pi}\lim_{\epsilon\to 0}\int\!\!\int_{B(0,R)\setminus B(0,\epsilon)} h(\xi)\frac{e^{-ik\theta}}{\xi^2}\,d\bar{\xi}\wedge d\xi d\theta \\
&= \frac{i}{4\pi^2}\lim_{\epsilon\to 0}\int_0^{2\pi}\int\!\!\int_{B(0,R)\setminus B(0,\epsilon)} h(\xi)\frac{e^{-ik\theta}}{\xi^2}\,d\bar{\xi}\wedge d\xi d\theta \\
&= -\frac{1}{2\pi^2}\lim_{\epsilon\to 0}\int_\epsilon^R\int_0^{2\pi}\frac{h(\rho e^{i\alpha})}{\rho^2 e^{2i\alpha}}\int_0^{2\pi} e^{-ik\theta}\,d\theta d\alpha\rho d\rho \\
&= -\frac{1}{2\pi^2}\int_0^R\int_0^{2\pi}\frac{\sum_{n=-\infty}^{n=\infty}h_n(\rho)e^{in\alpha}}{\rho^2 e^{2i\alpha}}\int_0^{2\pi} e^{-ik\theta}\,d\theta d\alpha\rho d\rho \\
&= \begin{cases} 0, & k\neq 0, \\ -2\int_0^R \frac{h_2(\rho)}{\rho}d\rho, & k = 0. \end{cases}
\end{aligned}$$

The Hölder property of h and the fact that $h_2(0) = 0$ show that the last integral ($k = 0$) is convergent. □

2.4. Case $z \in \mathbb{C} \setminus \overline{B(0,R)}$. In this case the limiting procedure and the angular integration in (2.1) can be interchanged right away.

$$\int_0^{2\pi} \frac{e^{-ik\theta}}{(\xi - re^{i\theta})^2}\, d\theta = \frac{2\pi}{r^2}\mathrm{Res}\left[\frac{1}{w^{k+1}(\xi/r - w)^2}\right]_{w=0} = -A_k \pi \frac{r^k}{\xi^{k+2}}$$

and

$$\begin{aligned} c_k(r) &= \frac{i}{4\pi^2}\int\int_{B(0,R)} h(\xi) A_k \frac{r^k}{\xi^{k+2}}\, d\bar{\xi}\wedge d\xi \\ &= \frac{A_k}{2\pi}\int\int_{B(0,R)} \sum_{n=-\infty}^{\infty} h_n(\rho) e^{in\theta}\frac{r^k}{\xi^{k+2}}\, \rho d\rho d\theta \\ &= A_k \int_0^R \frac{r^k}{\rho^{k+1}} h_{k+2}(\rho)\, d\rho. \end{aligned}$$

3. Recursive formulae. Define

$$d_k(r,r') = 2(k+1)\int_r^{r'} \frac{1}{\rho}\left(\frac{r'}{\rho}\right)^k h_{k+2}(\rho)\, d\rho.$$

Then, using (1.14)–(1.16), one readily gets the following recursive formula for the coefficients of the Hilbert transform,

$$c_k(r) = \left(\frac{r}{r'}\right)^k (c_k(r') - h_{k+2}(r') - d_k(r,r')) + h_{k+2}(r), \tag{3.1}$$

which holds for any pair of nonnegative radii r and r' for which the ratio $(r/r')^k$ is defined.

We will also note that it is convenient to compute $p_k(r)$ in (1.12) using the following recursive relations:

$$p_k(r) = \left(\frac{r}{r'}\right)^k p_k(r') - e_k(r,r'), \qquad e_k(r,r') = 2\int_r^{r'} \left(\frac{r}{\rho}\right)^k h_{k+1}(\rho) d\rho. \tag{3.2}$$

These recursive formulae are extremely useful because they allow us to compute the value of a coefficient at the ith radius using its value at either the $(i+1)$th or the $(i-1)$th radius, thus avoiding the full integration in formulae (1.12) and (1.14)–(1.16).

For reference purposes we will rewrite formulae (3.1) and (3.2) for a piecewise-constant interpolation of data $h_k(r_i)$ in the appendix (section 6). Strictly speaking, our derivation of the expressions for the Fourier coefficients of the Hilbert transform does not hold for a discontinuous h with piecewise-constant coefficients. However, given an $\epsilon > 0$ there always is a Hölder continuous function whose coefficients are ϵ-close to $h_k(r)$ in the L_1 norm, and, therefore, there always is a Hölder continuous smoothing of piecewise-constant data such that the coefficients of its Hilbert transform are arbitrarily close to those given by expressions (6.1)–(6.3) in the sup norm.

4. Another way to compute T. In this section we propose an alternative way for computing $T[h]$. By a theorem presented in [2], the following identity holds for all $h \in C_0^2$ (twice differentiable h with a compact support):

$$T[h](z) = \partial_z P[h](z) = \partial_z \tilde{P}[h](z). \tag{4.1}$$

As we have already mentioned, in [12] Daripa suggested an effective algorithm for a numerical computation of integral transform (1.7). The algorithm in [12] for computing $\tilde{P}$ is defined in terms of a circular $N \times M$ grid, and its computational complexity is $O(NM \log_2 M)$. In order to use this algorithm it is necessary to find an approximation for h_z, given the values of h on a circular grid. A formula for h_z in polar coordinates is supplied in the following lemma, whose easy proof will be omitted.

LEMMA 4.1. *Suppose that f is $C^1(\mathbb{R}^2)$, and in polar coordinates f is represented by g, i.e., $f(x,y) = g(r,\theta)$, where $x + iy = re^{i\theta}$. Then*

$$f_z(x,y) = \frac{e^{-i\theta}}{2}(g_r(r,\theta) + g_\theta(r,\theta)/ir), \tag{4.2}$$

$$f_{\bar{z}}(x,y) = \frac{ie^{i\theta}}{2}(-ig_r(r,\theta) + g_\theta(r,\theta)/r). \tag{4.3}$$

5. Comparison of the two algorithms. We have implemented the algorithm for the Cauchy transform (see formulae (1.7)–(1.12) and (3.2)) and both algorithms for the Hilbert transform ((1.13)–(1.16), (3.1), and (4.1)) for the piecewise linear approximation of Fourier coefficients as a set of routines in the programming language Ada 95 (cf. [25] for the language standard). We have used the public version 3.15p of the GNAT compiler [1]. Our programs can be found at [17].

Of particular interest to us will be a comparison of the two implementations of the iteration scheme $h \mapsto T[\mu(h+1)]$:

(1) *In the first of them, the Hilbert transform has been computed through formula* (3.1). *This technique will be referred to as* Scheme 1.
(2) *In the other, the Hilbert transform is calculated as the z-derivative of transform* (1.7). *This method will be called* Scheme 2.

The prototypical Beltrami differential for algorithm testing in the literature seems to be $\mu(z) = z^p \bar{z}^q$ in some disk and $\mu(z) = 0$ outside of that disk. Both Hilbert and Cauchy transforms of this differential, as well as the solution of the Beltrami equation itself, can be found exactly. Here we will quote the formula for the Hilbert transform:

$$T[z^p \bar{z}^q] = \frac{p\,\eta(R-|z|)}{q+1} z^{p-1} \bar{z}^{q+1} + [\eta(q+1-p) - \eta(R-|z|)]\,\frac{p-q-1}{q+1} R^{2(q+1)} z^{p-q-2}, \tag{5.1}$$

where η is the Heaviside step function. The derivation of this formula is relatively straightforward and can be done either by direct calculation or by differentiating the expression for the Cauchy transform of $z^p \bar{z}^q$ which have appeared in several publications (cf., e.g., [11]).

This formula suggests yet one more algorithm for the Hilbert transform of C_0^k functions representable as finite power series on its compact support:

(3) *Let $h(z,\bar{z}) = \eta(R-|z|) \sum_{i,j=0}^{m,n} a_{i,j} z^i \bar{z}^j$ be such a function. Then one can first use the linearity of the Hilbert transform to represent $T[h]$ as*

$$T[h](z,\bar{z}) = \sum_{i,j=0}^{m,n} a_{i,j} T[z^i \bar{z}^j],$$

compute each $T[z^i \bar{z}^j]$ in this series using (5.1), *and sum up. We will refer to this procedure as* Scheme 3.

TABLE 1
Convergence rate ($\|h^n - h^{n-1}\|_\infty$) for the two iteration schemes.

Number of iterations, n	5	10	20
Scheme 1	1.17×10^{-6}	3.83×10^{-11}	1.80×10^{-14}
Scheme 2	1.20×10^{-6}	3.91×10^{-10}	6.79×10^{-14}

Of course, this scheme has a limited value, as many differentials do not have sufficient smoothness, or are sometimes given in numerical experiments simply as an array of values on a grid.

Here, we will use a quartic test Beltrami differential which readily yields itself to the procedure that we just described:

$$\mu(z) = \begin{cases} a - \frac{a}{s^2} z\bar{z} + \frac{a}{4s^4} z^2 \bar{z}^2, & |z| \le \sqrt{2}s, \\ 0, & |z| > \sqrt{2}s, \end{cases} \tag{5.2}$$

where a and s are some real positive parameters. Our μ is given by a real-valued, nonnegative, radially symmetric C_0^2 function on $\mathbb{C}$ with a single maximum at zero, compactly supported in the disk of radius $\sqrt{2}s$. We would like to emphasize that iterations $h^{n+1} \mapsto T[h^n(\mu+1)]$ can be performed *exactly* using Scheme 3 (that is, the only error is the rounding error of our computing device). In particular, there is no need for any approximation of the functions being transformed, as it was the case with the choice of the spline approximation of the coefficients h_k in formulae (1.14)–(1.15). We will use Scheme 3 as a measuring stick for the accuracy of Schemes 1 and 2.

Let $g(r,\theta) = \sum_k g_k(r) e^{ik\theta}$ be smooth. Then it follows from (4.2) that the Fourier coefficients of the z-derivative of this function, denoted by $\tilde{g}$, are given by the following exact expression:

$$\tilde{g}_{k-1}(r) = \frac{g_k'(r) + k g_k(r)/r}{2}. \tag{5.3}$$

We have used this formula to compute the coefficients of the z-derivative of the iteration $h \mapsto \partial_z P[\mu(h+1)]$ for our choice (5.2) of μ; $g_k'(r)$'s were supplied by right two-point approximations through values of $g_k(r)$ on the radial grid.

We should also mention that we have used the FFT together with the pointwise multiplication of function values on the grid to perform the multiplication of μ and h in both schemes. Indeed, the computational cost of the FFT is of order $O(NM \log_2 M)$, and that of the pointwise multiplication of functional values is $O(NM)$; at the same time, the complexity of the multiplication of two Fourier series representing μ and h would be $O(NM^2)$.

We subjected the two schemes to several tests on a 1.5 GHz Intel Pentium class PC. Our first test was that of convergence of the two iteration schemes. Table 1 compares the convergence rate (measured by the norm $\|h^n - h^{n-1}\|_\infty$ rounded to 3 significant figures) for both iteration schemes and several values of n. We have used zero initial conditions, $h^0 = \mu$ in both cases. We have fixed the values of the parameters in the Beltrami differential to be $a = 0.5$ and $s = 1.0$. The dimensions of the radial grid were $N = 500$ (i.e., the disk of radius $\sqrt{2}$ contained 500 radii of the grid) and $M = 512$.

It is not surprising that the convergence rates of the schemes are comparable: these rates should depend only on the value of the essential supremum of μ and not on the particular realization of the Hilbert transform.

TABLE 2
Execution time for several grids (in seconds).

$N \times M$	500×256	1000×512	5000×1024	7000×2048
Scheme 1	8	31	313	965
Scheme 2	10	38	375	1166

TABLE 3
Comparison of the performance of Schemes 1 *and* 2 *against Scheme* 3.

$N \times M$	500×256	1000×512	5000×1024	7000×2048
$\|h_1^{10} - h_3^{10}\|_\infty$	4.00×10^{-7}	1.00×10^{-7}	7.12×10^{-8}	1.89×10^{-7}
$\|h_2^{10} - h_3^{10}\|_\infty$	8.39×10^{-5}	4.20×10^{-5}	8.39×10^{-6}	5.99×10^{-6}

Next, we have measured the execution time (rounded to the nearest second) of 10 iteration steps for several grids. Table 2 displays the results (the values of a, s, and h^0 are as before).

As should be expected, Scheme 2 takes somewhat longer: the computational complexity of both integral transforms is the same, $O(NM \log_2 M)$; however, the iteration $h \mapsto \partial_z P[\mu(h+1)]$ also involves a differentiation whose computational complexity is $O(NM)$. Nevertheless, for the tested range of grids, the speed benefits of Scheme 1 probably do not justify an extra effort in programming the Hilbert transform: as we have already mentioned, in our experience writing and testing such code might be rather cumbersome and lengthy, and could significantly increase the project development time.

The l_∞ norm of the difference of the outcomes of Schemes 1 and 3 and Schemes 2 and 3 after 10 steps (with the same parameters and initial conditions as before) for several grids is reported in Table 3. As we have already explained, Scheme 3 serves as a measuring stick for our purposes.

With regards to the accuracy of Schemes 1 and 2, Table 3 demonstrates that Scheme 1 is the scheme of choice. A bigger error in Scheme 2 can be attributed to the fact that we are using a numerical approximation for the differentiation in the iteration $h \mapsto \partial_z P[\mu(h+1)]$. This approximation introduces an extra error which is absent in Scheme 1. However, if the degree of differentiability of h is known, one can use a proper spline approximation of the derivative and thus significantly reduce this error. We still feel that in those cases when a high accuracy is not required, Scheme 2 can be more preferable.

6. Appendix. We will now return to formula (3.1). Consider a collection of real numbers $0 = r_1 < r_2 < \cdots < r_{L-1} < r_L = R < r_{L+1} < \cdots < r_N$ that specify a radial grid. We will denote the midpoint of the interval $[r_i, r_{i+1}]$ by ϱ_i; ϱ_0 will be 0 by definition.

If h_k's are compactly supported *piecewise-constant* functions

$$h_k(r) = \begin{cases} h_{k,i}, & r \in [\varrho_{i-1}, \varrho_i), \quad 1 \le i \le L, \\ 0, & r > \varrho_{L+1}, \end{cases}$$

then the coefficients of the Cauchy and the Hilbert transforms are given by the following set of expressions.

Coefficients of the Hilbert transform for piecewise-constant data.

• $r = r_1$:

$$c_k(r_1) = \begin{cases} c_0(r_2) - s_2(r_2) - 2s_2(r_2)\ln\frac{r_2}{\varrho_0}, & k = 0, \\ 0, & k \neq 0. \end{cases} \tag{6.1}$$

• $r \in (\varrho_{i-1}, \varrho_i]$, $1 \le i \le L$:

$$c_k(r) = \begin{cases} \left(\frac{r}{r_{i+1}}\right)^k (c_k(r_{i+1}) - s_{k+2}(r_{i+1})) - d_{k,i}(r) + s_{k+2}(r), & k \ge 1, \\ c_0(r_{i+1}) - s_2(r_{i+1}) - 2s_2(r_{i+1})\ln\frac{r_{i+1}}{\varrho_i} - 2s_2(r_i)\ln\frac{\varrho_i}{r} + s_2(r), & k = 0, \\ \left(\frac{r}{r_{i-1}}\right)^k (c_k(r_{i-1}) - s_{k+2}(r_{i-1})) + b_{k,i}(r) + s_{k+2}(r), & k < 0, \end{cases} \tag{6.2}$$

where

$$d_{k,i}(r) = 2\frac{k+1}{k}\left[s_{k+2}(r_{i+1})\left(\frac{r^k}{\varrho_i^k} - \frac{r^k}{r_{i+1}^k}\right) + s_{k+2}(r_i)\left(1 - \frac{r^k}{\varrho_i^k}\right)\right],$$

$$b_{k,i}(r) = 2\frac{k+1}{k}\left[s_{k+2}(r_{i-1})\left(\frac{r^k}{r_{i-1}^k} - \frac{r^k}{\varrho_{i-1}^k}\right) + s_{k+2}(r_i)\left(\frac{r^k}{\varrho_{i-1}^k} - 1\right)\right].$$

• $r \in (\varrho_{i-1}, \varrho_i]$, $L < i \le N$:

$$c_k(r) = \begin{cases} 0, & k \neq 0, \\ \frac{r^k}{r_{i-1}^k} c_k(r_{i-1}), & k < 0. \end{cases} \tag{6.3}$$

Coefficients of the Cauchy transform for piecewise-constant data.

• $r = r_1$:

$$c_k(r_1) = \begin{cases} c_0(r_2) - 2s_1(r_2)\varrho_0 - 2s_1(r_2)(r_2 - \varrho_1), & k = 0, \\ 0, & k \neq 0. \end{cases}$$

• $r \in (\varrho_{i-1}, \varrho_i]$, $1 \le i \le L$:

$$c_k(r) = \begin{cases} \left(\frac{r}{r_{i+1}}\right)^k c_k(r_{i+1}) - d_{k,i}(r), & k > 1, \\ \frac{r}{r_{i+1}} c_1(r_{i+1}) - 2rs_2(r_i)\ln\frac{\varrho_i}{r} - 2rs_2(r_{i+1})\ln\frac{r_{i+1}}{\varrho_i}, & k = 1, \\ \left(\frac{r}{r_{i-1}}\right)^k c_k(r_{i-1}) + b_{k,i}(r), & k <= 0, \end{cases}$$

where

$$d_{k,i}(r) = \frac{2r}{1-k}\left[s_{k+1}(r_i)\left(\frac{r^{k-1}}{\varrho_i^{k-1}} - 1\right) + s_{k+1}(r_{i+1})\left(\frac{r^{k-1}}{r_{i+1}^{k-1}} - \frac{r^{k-1}}{\varrho_i^{k-1}}\right)\right],$$

$$b_{k,i}(r) = \frac{2r}{1-k}\left[s_{k+1}(r_{i-1})\left(\frac{\varrho_{i-1}^{1-k}}{r^{1-k}} - \frac{r_{i-1}^{1-k}}{r^{1-k}}\right) + s_{k+1}(r_i)\left(1 - \frac{\varrho_{i-1}^{1-k}}{r^{1-k}}\right)\right].$$

• $r \in (\varrho_{i-1}, \varrho_i]$, $L < i \le N$:

$$c_k(r) = \begin{cases} 0, & k \neq 0, \\ \frac{r^k}{r_{i-1}^k} c_k(r_{i-1}), & k < 0. \end{cases}$$

A LEGENDRE–GALERKIN SPECTRAL METHOD FOR OPTIMAL CONTROL PROBLEMS GOVERNED BY ELLIPTIC EQUATIONS*

YANPING CHEN†, NIANYU YI‡, AND WENBIN LIU§

Abstract. In this paper, we study the Legendre–Galerkin spectral approximation for a constrained optimal control problem. We first derive a priori error estimates for the spectral approximation of optimal control problems. Then a posteriori error estimates are obtained for both the state and the control approximation. A preconditioning projection algorithm is proposed with some numerical tests.

Key words. Legendre–Galerkin, spectral method, convex optimal control, a priori error, a posteriori error, preconditioning projection algorithms

DOI. 10.1137/070679703

1. Introduction.

The spectral method employs global polynomials as the trial functions for the discretization of PDEs. It provides very accurate approximations with a relatively small number of unknowns when the solutions are smooth. Recently the spectral method has been extended to approximate unconstrained optimal control problems; see, for example, [10].

However spectral accuracy generally cannot be achieved when the approximated solutions have lower regularities, and this is typically the case when, for example, there exist control constraints in an optimal control problem (the so-called constrained optimal control problem). Thus the spectral method is not widely used in solving constrained distributed optimal control problems where the solutions often have singularities at the boundary of constraints even though all the initial data are smooth. Thus although there has been much work on the finite element method for numerically solving constrained optimal control problems, it seems that there has not been much work on the spectral method. Furthermore, the optimality conditions, which are normally the starting point of spectral approximation, are just PDE systems for unconstrained control problems, while those for constrained control problems contain variational inequalities, as shown later on. This also raises new issues in analyzing and solving the systems discretized using the spectral method.

In this work we study a constrained optimal control problem. It in fact represents a class of useful optimal control problems. We show that the solution of this particular control problem can be infinitely smooth if the initial data are so. Then we propose to use the Galerkin spectral method to approximate the solution. As there

are variational inequalities in optimal conditions of constrained optimal control problems, approaches have to be used that are different from those used in dealing with spectral approximation of unconstrained optimal control, such as the methods used in [10]. The purpose of this work is to derive a priori and a posteriori error estimates for the spectral approximation of the optimal control problem. Also we propose a preconditioning projection algorithm to solve the control problem with some numerical tests.

We are interested in the following distributed convex optimal control problem:

$$\min_{u\in K}\left\{\frac{1}{2}\int_\Omega (y-y_0)^2+\frac{1}{2}\int_\Omega u^2\right\}, \tag{1.1}$$

$$-\Delta y = f+u \ \text{ in } \Omega, \quad y|_{\partial\Omega}=0, \tag{1.2}$$

where K is a set defined by

$$K=\left\{v\in L^2(\Omega): \int_\Omega v\geq 0\right\}.$$

The details will be specified later.

The outline of this paper is as follows: In section 2, we discuss the spectral approximation of the optimal control problem. In section 3, we establish some important properties of this control problem and study the regularity of its solution. In section 4, a priori error estimates are derived for the optimal control problem. In section 5, a posteriori error estimates in the H^1 and L^2 norms are derived for the optimal control problem. And in section 6 we discuss the *hp* spectral element method for the optimal control problem. In section 7, we propose a preconditioning projection algorithm and present some numerical results.

Let $\Omega\subset\mathbb{R}^d$ ($d=1,2,$ or 3) be a convex open domain with a Lipschitz boundary $\partial\Omega$. In this paper we adopt the standard notation $W^{m,q}(\Omega)$ for Sobolev spaces on Ω with the norm $||\cdot||_{W^{m,q}(\Omega)}$ and the seminorm $|\cdot|_{W^{m,q}(\Omega)}$. We set $W_0^{m,q}(\Omega)\equiv\{w\in W^{m,q}(\Omega):\ w|_{\partial\Omega}=0\}$. We denote $W^{m,2}(\Omega)$ ($W_0^{m,2}(\Omega)$) by $H^m(\Omega)$ ($H_0^m(\Omega)$). In addition, C denotes a general positive constant independent of N, the order of the spectral approximation.

2. Optimal control problem and its spectral approximation. In this section we study Galerkin spectral approximation of the optimal control problem (1.1)–(1.2). We first introduce a weak formulation of the problem. Let $V=H_0^1(\Omega)$ and $U=L^2(\Omega)$. Let

$$a(y,w)=\int_\Omega(\nabla y)\cdot(\nabla w)\qquad \forall y,w\in V,$$

$$(u,v)_U=\int_\Omega uv\qquad \forall (u,v)\in U\times U.$$

Then the standard weak formulation for the state equation reads as follows: find $y(u)\in V$ such that

$$a(y(u),w)=(f+u,w)\qquad \forall w\in V,$$

where $(\cdot,\cdot)$ is the inner product in $L^2(\Omega)$. Therefore the optimal control problem (1.1)–(1.2) can be restated as follows: (OCP) find (y,u) such that

$$\min_{u\in K}\left\{\frac{1}{2}\int_\Omega (y-y_0)^2+\frac{1}{2}\int_\Omega u^2\right\}, \tag{2.1}$$

$$a(y(u),w)=(f+u,w)\quad \forall w\in V. \tag{2.2}$$

It is well known (see, e.g., [20]) that the optimal control problem (OCP) (2.1)–(2.2) has a unique solution (y^*, u^*), and (y^*, u^*) is the solution if and only if there is a costate $p^* \in V$ such that the triplet (y^*, p^*, u^*) satisfies the following optimality conditions: (OCP-OPT)

$$a(y^*, w) = (f + u^*, w) \qquad \forall w \in V, \tag{2.3}$$

$$a(q, p^*) = (y^* - y_0, q) \qquad \forall q \in V, \tag{2.4}$$

$$(u^* + p^*, v - u^*)_U \geq 0 \qquad \forall v \in K \subset U. \tag{2.5}$$

Let us investigate the spectral approximation of the optimal control problem (OCP) (2.1)–(2.2). Here we consider only the Legendre–Galerkin spectral method. From now on, we assume that $\Omega = (-1, 1)^d$.

Let us first introduce some basic notation which will be used in what follows. For $x_i,\ i = 1, \ldots, d$, we denote by $L_r(x_i)$ the rth degree Legendre polynomial in the variable x_i, and we set

$$X_N^i = \text{span}\{L_0(x_i),\ L_1(x_i), \ldots, L_N(x_i)\},$$

where $N \geq 0$ is an integer. We define a product space such as

$$X_N = \prod_{i=1}^{d} X_N^i.$$

We introduce the finite dimensional spaces $V_N = X_N \bigcap V$, $U_N = X_N \bigcap U$, and $K_N = X_N \bigcap K$.

Then the Legendre–Galerkin approximation for (OCP) is $(\text{OCP})^N$

$$\min_{u_N \in K_N \subset U_N} \left\{ \frac{1}{2} \int_\Omega (y_N - y_0)^2 + \frac{1}{2} \int_\Omega u_N^2 \right\}, \tag{2.6}$$

$$a(y_N, w_N) = (f + u_N, w_N) \quad \forall w_N \in V_N \subset H_0^1(\Omega). \tag{2.7}$$

This is a finite dimensional optimization problem and may be solved by existing mathematical programming methods such as the steepest decent method, the conjugate gradient method, the trust domain method, and the sequential quadratic programming method.

It follows that the control problem $(\text{OCP})^N$ has a solution (y_N^*, u_N^*), and (y_N^*, u_N^*) is the solution if and only if there is a costate $p_N^* \in V_N$ such that the triplet (y_N^*, p_N^*, u_N^*) satisfies the following optimality conditions: $(\text{OCP-OPT})^N$

$$a(y_N^*, w_N) = (f + u_N^*, w_N) \qquad \forall w_N \in V_N, \tag{2.8}$$

$$a(q_N, p_N^*) = (y_N^* - y_0, q_N) \qquad \forall q_N \in V_N, \tag{2.9}$$

$$(u_N^* + p_N^*, v_N - u_N^*)_U \geq 0 \qquad \forall v_N \in K_N. \tag{2.10}$$

Let $y(u)$ and $y_N(u_N)$ be the solutions of (2.2) and (2.7), respectively. Set

$$J(u) = \left\{ \frac{1}{2} \int_\Omega (y - y_0)^2 + \frac{1}{2} \int_\Omega u^2 \right\},$$

$$J_N(u_N) = \left\{ \frac{1}{2} \int_\Omega (y_N - y_0)^2 + \frac{1}{2} \int_\Omega u_N^2 \right\}.$$

It is clear that $J(\cdot)$ is uniformly convex. Then there is a $c > 0$ independent of N such that

$$(J^{'}(u^*) - J^{'}(u_N^*), u^* - u_N^*)_U \geq c||u^* - u_N^*||^2_{L^2(\Omega)}, \tag{2.11}$$

where u^* and u_N^* are the solutions of (2.1)–(2.2) and (2.6)–(2.7), respectively.

For any $u \in L^2(\Omega)$, we define the orthogonal projection operator $P_N : \ L^2(\Omega) \to U_N$ which satisfies

$$(P_N u - u, w_N) = 0 \qquad \forall w_N \in U_N.$$

It can be shown (see [6]) that

$$P_N u = \sum_{\max\limits_{1\leq i\leq d}\{k_i\}\leq N} \hat{u}_k \phi_k, \qquad \hat{u}_k = \prod_{i=1}^{d} \left(k_i + \frac{1}{2}\right) \int_\Omega u(x)\phi_k(x),$$

where $k = (k_1, \ldots, k_d)$ and $\phi_k(x) = L_{k_1}(x_1) \cdots L_{k_d}(x_d)$.

For any $u \in H_0^1(\Omega), P_{1,N}^0 : \ H_0^1(\Omega) \to V_N$ is defined by

$$\int_\Omega \nabla(u - P_{1,N}^0 u) \cdot \nabla w = 0 \qquad \forall w \in V_N.$$

The following lemma is important for deriving a posteriori error estimates of residual type. It can be found in the reference book [6].

LEMMA 2.1. *For all $u \in H^m(\Omega)$ $(m \geq 0)$, we have that*

$$||u - P_N u||_{H^l(\Omega)} \leq C N^{\sigma(l)-m} ||u||_{H^m(\Omega)}, \qquad 0 \leq l \leq m,$$

where $\sigma(l) = 0$ if $l = 0$, and $\sigma(l) = 2l - \frac{1}{2}$ for $l > 0$. If $u \in H_0^1(\Omega) \cap H^m(\Omega), m \geq 1$, then we have that

$$||u - P_{1,N}^0 u||_{H^\mu(\Omega)} \leq C N^{\mu-m} ||u||_{H^m(\Omega)}, \qquad 0 \leq \mu \leq 1.$$

3. Preliminary properties of the optimal control problem. In general, regularity of the optimal control for a constrained optimal control is quite low, say only in $H^1(\Omega)$; see [19]. When the constraint set is of obstacle type $\{u : u \geq 0\}$, for example, we have the following relationship between the optimal control u and the costate p: $u = \max(0, -p)$; see [19]. Thus the gradient of u has jumps along the boundary of the zero-set of p, whose location is generally unknown. Due to the special structure of our control constraint set K, we are able to show that the optimal control of our optimal control problem can be infinitely smooth if the initial data are so. To this end we first derive an important relationship between the optimal control and the optimal costate of (OCP-OPT). This relationship is key to our analysis and numerical algorithms.

THEOREM 3.1. *Let (y^*, p^*, u^*) be the solution of* (OCP-OPT). *Then we have*

$$u^* = \max\{0, \overline{p^*}\} - p^*,$$

where $\overline{p} = \int_\Omega p \Big/ \int_\Omega 1$ denotes the integral average on Ω of the function p.

Proof. For any function $p \in V$ we show that

$$u = \max\{0, \overline{p}\} - p$$

satisfies the variational inequality

$$(u+p, v-u)_U \geq 0 \qquad \forall v \in K.$$

If $\overline{p} > 0$, then $u = \overline{p} - p$ and

$$\begin{aligned}(u+p, v-u)_U &= \int_\Omega (u+p)(v-u) \\ &= \int_\Omega \overline{p}(v-\overline{p}+p) \\ &= \overline{p}\int_\Omega v \geq 0 \qquad \text{for } \ v \in K.\end{aligned}$$

If $\overline{p} \leq 0$, then $u = -p$ and

$$(u+p, v-u)_U = 0.$$

Now, note that for the costate solution p^* the solution of (2.5) is unique. Thus we have proved the theorem. ∎

THEOREM 3.2. *Let (y_N^*, p_N^*, u_N^*) be the solution of* (OCP-OPT)^N. *Then we have*

$$u_N^* = \max\{0, \overline{p_N^*}\} - p_N^*.$$

Proof. The proof is similar to the proof of Theorem 3.1. ∎

It follows from Theorem 3.1 that we can derive regularity of the optimal control.

THEOREM 3.3. *Let (y^*, p^*, u^*) satisfy the optimality conditions* (OCP-OPT). *Assume that the data functions f, y_0, and the domain Ω are infinitely smooth. Then the optimal control $u^* \in C^\infty(\bar{\Omega})$.*

Proof. Applying the standard regularity argument of elliptic problems, it is clear that $y \in H^2(\Omega)$ so that $p^* \in H^4(\Omega)$. It follows from the relationship between the control and the costate

$$u^* = \max\{0, \overline{p^*}\} - p^*$$

that $u^* \in H^4(\Omega)$. Thus $y^* \in H^6(\Omega)$. By repeating the above process, we can conclude that $u^* \in C^\infty(\bar{\Omega})$. ∎

Remark 3.1. If Ω is a convex open domain with a Lipschitz boundary $\partial\Omega$ and $f, y_0 \in L^2(\Omega)$, then we have $u^* \in H^2(\Omega)$.

4. A priori error estimates. In this section, we show that u_N^* converges to u^* in spectral accuracy provided that the data are sufficiently smooth. Defining $J(\cdot)$ and $J_N(\cdot)$ as before, it can be shown that (see [20])

$$(J'(u^*), v)_U = (u^* + p^*, v)_U, \tag{4.1}$$

$$(J_N'(u_N^*), v)_U = (u_N^* + p_N^*, v)_U, \tag{4.2}$$

$$(J'(u_N^*), v)_U = (u_N^* + p(u_N^*), v)_U, \tag{4.3}$$

where $p(u_N^*)$ is the solution of the auxiliary equation:

$$a(y(u_N^*), w) = (f + u_N^*, w) \qquad \forall w \in V = H_0^1(\Omega), \tag{4.4}$$

$$a(q, p(u_N^*)) = (y(u_N^*) - y_0, q) \quad \forall q \in V = H_0^1(\Omega). \tag{4.5}$$

THEOREM 4.1. *Let (y^*, p^*, u^*) and (y_N^*, p_N^*, u_N^*) be the solutions of (2.3)–(2.5) and (2.8)–(2.10), respectively. Assume that the solution (y^*, p^*, u^*) is sufficiently regular. Then for any integer $k > 0$ there exists $C > 0$, independent of N, such that*

$$||u^* - u_N^*||_{L^2(\Omega)} + ||y^* - y_N^*||_{H^1(\Omega)} + ||p^* - p_N^*||_{H^1(\Omega)} \le CN^{-k} \qquad \forall k \in \mathbb{Z}^+. \tag{4.6}$$

Proof. First, it follows from the convexity of $J(\cdot)$, (4.1), (4.3), the optimal conditions (2.5) and (2.10), and the Schwarz inequality that for any $v_N \in K_N$,

$$\begin{aligned}
c||u^* - u_N^*||_{L^2(\Omega)}^2 &\le (J'(u^*), u^* - u_N^*)_U - (J'(u_N^*), u^* - u_N^*)_U \\
&= (u^* + p^*, u^* - u_N^*)_U - (u_N^* + p(u_N^*), u^* - u_N^*)_U \\
&= (u^* + p^*, u^* - v_N)_U + (u^* + p^*, v_N - u_N^*)_U \\
&\quad + (u_N^* + p_N^*, u_N^* - v_N)_U + (u_N^* + p_N^*, v_N - u^*)_U \\
&\quad + (p_N^* - p(u_N^*), u^* - u_N^*)_U \\
&\le (u^* + p^*, v_N - u^*)_U + (u_N^* - u^*, v_N - u^*)_U \\
&\quad + (u^* + p^*, v_N - u^*)_U + (p_N^* - p(u_N^*), v_N - u^*)_U \\
&\quad + (p(u_N^*) - p^*, v_N - u^*)_U + (p_N^* - p(u_N^*), u^* - u_N^*)_U \\
&\le 2(u^* + p^*, v_N - u^*)_U \\
&\quad + ||u_N^* - u^*||_{L^2(\Omega)}||v_N - u^*||_{L^2(\Omega)} \\
&\quad + ||p_N^* - p(u_N^*)||_{L^2(\Omega)}||v_N - u^*||_{L^2(\Omega)} \\
&\quad + ||p(u_N^*) - p^*||_{L^2(\Omega)}||v_N - u^*||_{L^2(\Omega)} \\
&\quad + ||p_N^* - p(u_N^*)||_{L^2(\Omega)}||u^* - u_N^*||_{L^2(\Omega)} \\
&\le 2(u^* + p^*, v_N - u^*)_U \\
&\quad + C(\delta)||v_N - u^*||_{L^2(\Omega)}^2 + C(\delta)||p_N^* - p(u_N^*)||_{L^2(\Omega)}^2 \\
&\quad + \delta||p(u_N^*) - p^*||_{L^2(\Omega)}^2 + 2\delta||u^* - u_N^*||_{L^2(\Omega)}^2,
\end{aligned} \tag{4.7}$$

where $\delta > 0$ is a sufficiently small constant.

Next, we note that

$$||y_N^* - y^*||_{H^1(\Omega)} \le ||y_N^* - y(u_N^*)||_{H^1(\Omega)} + ||y(u_N^*) - y^*||_{H^1(\Omega)},$$

$$||p_N^* - p^*||_{H^1(\Omega)} \le ||p_N^* - p(u_N^*)||_{H^1(\Omega)} + ||p(u_N^*) - p^*||_{H^1(\Omega)}.$$

From (2.3) and (4.4), we can obtain the following error equation of the intermediate variable:

$$a(y(u_N^*) - y^*, w) = (u_N^* - u^*, w) \qquad \forall w \in V.$$

Setting $w = y(u_N^*) - y^*$ in the above equation, we have that

$$||y(u_N^*) - y^*||_{H^1(\Omega)} \le c_1||u_N^* - u^*||_{L^2(\Omega)}, \tag{4.8}$$

where $c_1 = C(\Omega) > 0$ is the coefficient of the Poincaré inequality

$$||w||_{H_0^1(\Omega)} \le C(\Omega)||\nabla w||_{L^2(\Omega)}.$$

Using (2.8) and (4.4), we have

$$a(y_N^* - y(u_N^*), w_N) = 0 \qquad \forall w_N \in V_N. \tag{4.9}$$

Hence,

$$\begin{aligned}||y_N^*-y(u_N^*)||^2_{H^1(\Omega)} &\le Ca(y_N^*-y(u_N^*),y_N^*-y(u_N^*))\\ &= Ca(y_N^*-y(u_N^*),y_N^*-y(u_N^*)+w_N)\\ &\le C||y_N^*-y(u_N^*)||_{H^1(\Omega)}\cdot\inf_{w_N\in V_N}||y(u_N^*)-w_N||_{H^1(\Omega)}.\end{aligned}$$

Thus,

$$\begin{aligned}||y_N^*-y(u_N^*)||_{H^1(\Omega)} &\le C\inf_{w_N\in V_N}||y(u_N^*)-w_N||_{H^1(\Omega)}\\ &\le C||y(u_N^*)-P^0_{1,N}y(u_N^*)||_{H^1(\Omega)}\le CN^{-k}\qquad\forall k\in\mathbb{Z}^+,\end{aligned}\tag{4.10}$$

where $P^0_{1,N}$ is the orthogonal projection operator defined in section 2.

Similarly, for the costate we also have that

$$||p(u_N^*)-p^*||_{H^1(\Omega)}\le c_1||y(u_N^*)-y^*||_{L^2(\Omega)}\le c_1||u_N^*-u^*||_{L^2(\Omega)}.\tag{4.11}$$

Using (2.9) and (4.5), we have

$$\begin{aligned}||p(u_N^*)-p_N^*||^2_{H^1(\Omega)} &\le C(||p(u_N^*)-p_N^*-P_N(p(u_N^*)-p_N^*)||_{H^1(\Omega)}||p(u_N^*)-p_N^*||_{H^1(\Omega)}\\ &\quad+||y(u_N^*)-y_N^*||_{L^2(\Omega)}||p(u_N^*)-p_N^*-P_N(p(u_N^*)-p_N^*)||_{L^2(\Omega)}\\ &\quad+||y(u_N^*)-y_N^*||_{L^2(\Omega)}||p(u_N^*)-p_N^*||_{L^2(\Omega)})\\ &\le CN^{-2k}\qquad\forall k\in\mathbb{Z}^+.\end{aligned}\tag{4.12}$$

Then, apply (4.11)–(4.12) in (4.7) to obtain that

$$\begin{aligned}c||u^*-u_N^*||^2_{L^2(\Omega)} &\le (J^{'}(u^*),u^*-u_N^*)_U-(J^{'}(u_N^*),u^*-u_N^*)_U\\ &\le 2(u^*+p^*,v_N-u^*)_U+C(\delta)||v_N-u^*||^2_{L^2(\Omega)}\\ &\quad+C(\delta)N^{-2k}+(2+c_1)\delta||u^*-u_N^*||^2_{L^2(\Omega)},\end{aligned}\tag{4.13}$$

where $\delta>0$ is a sufficiently small constant. Thus, we choose $\delta=c/(4+2c_1)$ to derive that

$$||u^*-u_N^*||^2_{L^2(\Omega)}\le 2(u^*+p^*,v_N-u^*)_U+C(\delta)||v_N-u^*||^2_{L^2(\Omega)}+C(\delta)N^{-2k}.\tag{4.14}$$

Now, set $v_N=P_Nu^*\in U_N$ in (4.14), where P_N is the L^2 orthogonal projection operator defined in section 2. Note that

$$(u^*-P_Nu^*,v)=0\qquad\forall v\in P_N,$$

and especially letting $v=1\in P_N$ we have

$$(u^*-P_Nu^*,v)=\int_\Omega(u^*-P_Nu^*)=0;$$

thus

$$\int_\Omega P_Nu^*=\int_\Omega u^*\ge 0.$$

Then $v_N\in K_N\subset U_N$. It follows from Lemma 2.1 that

$$||u^*-v_N||_{L^2(\Omega)}\le CN^{-k}.\tag{4.15}$$

Applying (4.15) in (4.14), we can obtain that

$$||u^*-u_N^*||_{L^2(\Omega)}\le CN^{-k}.\tag{4.16}$$

Finally, combining (4.8)–(4.12) with (4.16) implies the error estimates (4.6). ∎

5. A posteriori error estimates. In this section, we derive a posteriori error estimates for the spectral approximation of (OCP). First, we use the L^2 norm for estimating the control approximation error and the H^1 norm for the state and costate approximation error, namely, the L^2-H^1 posteriori error estimates. Now, we assume that Ω is a convex open domain with a Lipschitz boundary $\partial\Omega$ and $f, y_0 \in L^2(\Omega)$.

In the following lemma, we can derive a posteriori error estimates for the intermediate variable.

LEMMA 5.1. *Let $y(u_N^*)$, $p(u_N^*)$, y_N^*, and p_N^* be the solutions of* (4.4), (4.5), (2.8), *and* (2.9), *respectively. Then*

$$||y(u_N^*) - y_N^*||_{H^1(\Omega)} + ||p(u_N^*) - p_N^*||_{H^1(\Omega)} \le C\eta, \tag{5.1}$$

where the estimator η is defined as

$$\eta = N^{-1}||y_N^* - y_0 + \Delta p_N^*||_{L^2(\Omega)} + N^{-1}||f + u_N^* + \Delta y_N^*||_{L^2(\Omega)}.$$

Proof. Set $e_p = p(u_N^*) - p_N^*$, and let $e_p^N = P_{1,N}^0 e_p \in V_N$ be the orthogonal projection of e_p. Then it follows from (2.9), (4.5), and Lemma 2.1 that

$$\begin{aligned} c_1^{-1}||p(u_N^*) - p_N^*||_{H^1(\Omega)}^2 &\le (\nabla e_p, \nabla e_p) = (\nabla(e_p - e_p^N), \nabla e_p) + (\nabla e_p^N, \nabla e_p) \\ &= (y(u_N^*) - y_0 + \Delta p_N^*, e_p - e_p^N) + (y(u_N^*) - y_N^*, e_p^N) \\ &= (y_N^* - y_0 + \Delta p_N^*, e_p - e_p^N) + (y(u_N^*) - y_N^*, e_p) \\ &\le ||y_N^* - y_0 + \Delta p_N^*||_{L^2(\Omega)} \cdot ||e_p - e_p^N||_{L^2(\Omega)} + (y(u_N^*) - y_N^*, e_p) \\ &\le CN^{-1}||y_N^* - y_0 + \Delta p_N^*||_{L^2(\Omega)}||e_p||_{H^1(\Omega)} \\ &\quad + ||y(u_N^*) - y_N^*||_{L^2(\Omega)}||e_p||_{L^2(\Omega)} \\ &\le CN^{-2}||y_N^* - y_0 + \Delta p_N^*||_{L^2(\Omega)}^2 + C||y(u_N^*) - y_N^*||_{L^2(\Omega)}^2 \\ &\quad + 2\delta||e_p||_{H^1(\Omega)}^2. \end{aligned}$$

Choosing that $\delta = \frac{1}{4c_1}$, we have

$$||p(u_N^*) - p_N^*||_{H^1(\Omega)}^2 \le CN^{-2}||y_N^* - y_0 + \Delta p_N^*||_{L^2(\Omega)}^2 + C||y(u_N^*) - y_N^*||_{L^2(\Omega)}^2. \tag{5.2}$$

Similarly, set $e_y = y(u_N^*) - y_N^*$, and let $e_y^N = P_{1,N}^0 e_y \in V_N$ be the orthogonal projection of e_y. Then, using (4.9), (2.8), (4.4), and Lemma 2.1, we have that

$$\begin{aligned} c_1^{-1}||y(u_N^*) - y_N^*||_{H^1(\Omega)}^2 &\le (\nabla e_y, \nabla e_y) = (\nabla(e_y - e_y^N), \nabla e_y) \\ &= (f + u_N^* + \Delta y_N^*, e_y - e_y^N) \\ &\le CN^{-2}||f + u_N^* + \Delta y_N^*||_{L^2(\Omega)}^2 + \delta||y(u_N^*) - y_N^*||_{H^1(\Omega)}^2. \end{aligned}$$

Choosing that $\delta = \frac{1}{2c_1}$, we have

$$||y(u_N^*) - y_N^*||_{H^1(\Omega)}^2 \le CN^{-2}||f + u_N^* + \Delta y_N^*||_{L^2(\Omega)}^2. \tag{5.3}$$

Then we combine (5.2) and (5.3) to derive our estimates (5.1). ∎

THEOREM 5.1. *Let (y^*, p^*, u^*) and (y_N^*, p_N^*, u_N^*) be the solutions of* (2.3)–(2.5) *and* (2.8)–(2.10), *respectively. Then we have that*

$$||u^* - u_N^*||_{L^2(\Omega)} + ||y^* - y_N^*||_{H^1(\Omega)} + ||p^* - p_N^*||_{H^1(\Omega)} \le C\eta, \tag{5.4}$$

where η is defined in Lemma 5.1.

Proof. Let $y(u_N^*)$ and $p(u_N^*)$ be the intermediate variables defined in (4.4) and (4.5). For $v_N = P_N u^* \in X_N$, it follows from (4.1)–(4.3), (OCP-OPT) and (OCP-OPT)^N, and Theorem 3.2 that

$$\begin{aligned} c||u^* - u_N^*||^2_{L^2(\Omega)} &\le (J^{'}(u^*), u^* - u_N^*)_U - (J^{'}(u_N^*), u^* - u_N^*)_U \\ &\le -(J^{'}(u_N^*), u^* - u_N^*)_U \\ &= (J_N^{'}(u_N^*), u_N^* - u^*)_U + (J_N^{'}(u_N^*) - J^{'}(u_N^*), u^* - u_N^*)_U \\ &\le (J_N^{'}(u_N^*), v_N - u^*)_U + (J_N^{'}(u_N^*) - J^{'}(u_N^*), u^* - u_N^*)_U \\ &= (J_N^{'}(u_N^*) - J^{'}(u_N^*), u^* - u_N^*)_U \\ &= (p_N^* - p(u_N^*), u^* - u_N^*) \\ &\le C||p(u_N^*) - p_N^*||_{L^2(\Omega)}||u^* - u_N^*||_{L^2(\Omega)}. \end{aligned}$$

Therefore, from Lemma 5.1, we have that

$$||u^* - u_N^*||_{L^2(\Omega)} \le C||p_N^* - p(u_N^*)||_{L^2(\Omega)}. \tag{5.5}$$

Note that

$$\begin{aligned} ||y^* - y_N^*||_{H^1(\Omega)} &\le ||y^* - y(u_N^*)||_{H^1(\Omega)} + ||y(u_N^*) - y_N^*||_{H^1(\Omega)}, \\ ||p^* - p_N^*||_{H^1(\Omega)} &\le ||p^* - p(u_N^*)||_{H^1(\Omega)} + ||p(u_N^*) - p_N^*||_{H^1(\Omega)}. \end{aligned} \tag{5.6}$$

By using (5.5)–(5.6), (4.8), (4.11), and Lemma 5.1, we can obtain the result (5.4). ∎

In many control applications, one is also interested in L^2 estimation of the state and costate approximation error.

In order to estimate $||p(u_N^*) - p_N^*||_{L^2(\Omega)}$, we assume that the auxiliary problem

$$-\Delta\xi = f, \qquad x \in \Omega, \qquad \xi|_{\partial\Omega} = 0, \tag{5.7}$$

possesses the following regularity estimates (see [18], for example):

$$||\xi||_{H^2(\Omega)} \le C||f||_{L^2(\Omega)}. \tag{5.8}$$

Then, we can show that the following lemma holds.

LEMMA 5.2. *Let $(y(u_N^*), p(u_N^*))$ and (y_N^*, p_N^*) be the solutions of* (4.4)–(4.5) *and* (2.8)–(2.9)*, respectively. Then*

$$||p(u_N^*) - p_N^*||_{L^2(\Omega)} + ||y(u_N^*) - y_N^*||_{L^2(\Omega)} \le C\eta_1, \tag{5.9}$$

where

$$\eta_1 = N^{-2}||y_N^* - y_0 + \Delta p_N^*||_{L^2(\Omega)} + N^{-2}||f + u_N^* + \Delta y_N^*||_{L^2(\Omega)}.$$

Proof. Let ξ be the solution of (5.7) with $f(x) = p(u_N^*) - p_N^*$, let $\xi^N = P^0_{1,N}\xi \in V_N$ be the orthogonal projection of ξ. Then it follows from (2.9), (4.5), and Lemma 2.1 that

$$\begin{aligned} ||p(u_N^*) - p_N^*||^2_{L^2(\Omega)} &= (\nabla\xi, \nabla(p(u_N^*) - p_N^*)) \\ &= (\nabla(\xi - \xi^N), \nabla(p(u_N^*) - p_N^*)) + (\nabla\xi^N, \nabla(p(u_N^*) - p_N^*)) \\ &= (y(u_N^*) - y_0 + \Delta p_N^*, \xi - \xi^N) + (y(u_N^*) - y_N^*, \xi^N) \\ &= (y_N^* - y_0 + \Delta p_N^*, \xi - \xi^N) + (y(u_N^*) - y_N^*, \xi) \\ &\le C\big(N^{-2}||y_N^* - y_0 + \Delta p_N^*||_{L^2(\Omega)} + ||y(u_N^*) - y_N^*||_{L^2(\Omega)}\big) \cdot ||\xi||_{H^2(\Omega)} \\ &\le C\big(N^{-2}||y_N^* - y_0 + \Delta p_N^*||_{L^2(\Omega)} + ||y(u_N^*) - y_N^*||_{L^2(\Omega)}\big) \cdot ||f||_{L^2(\Omega)}. \end{aligned} \tag{5.10}$$

Thus we have

$$||p(u_N^*)-p_N^*||_{L^2(\Omega)} \le CN^{-2}||y_N^*-y_0+\Delta p_N^*||_{L^2(\Omega)}+C||y(u_N^*)-y_N^*||_{L^2(\Omega)}. \tag{5.11}$$

Similarly, let ξ be the solution of (5.7) with $f(x)=y(u_N^*)-y_N^*$, and let $\xi^N = P_{1,N}^0\xi \in V_N$ be the orthogonal projection of ξ. Then it follows from (2.8), (4.4), and Lemma 2.1 that

$$\begin{aligned}||y(u_N^*)-y_N^*||^2_{L^2(\Omega)} &= (\nabla\xi, \nabla(y(u_N^*)-y_N^*))\\ &= (\nabla(\xi-\xi^N), \nabla(y(u_N^*)-y_N^*)) + (\nabla\xi^N, \nabla(y(u_N^*)-y_N^*))\\ &= (f+u_N^*+\Delta y_N^*, \xi-\xi^N)\\ &\le CN^{-2}||f+u_N^*+\Delta y_N^*||_{L^2(\Omega)}\cdot||\xi||_{H^2(\Omega)}\\ &\le CN^{-2}||f+u_N^*+\Delta y_N^*||_{L^2(\Omega)}\cdot||f||_{L^2(\Omega)}.\end{aligned}$$

Then

$$||y(u_N^*)-y_N^*||_{L^2(\Omega)} \le CN^{-2}||f+u_N^*+\Delta y_N^*||_{L^2(\Omega)}. \tag{5.12}$$

Thus (5.10)–(5.12) implies (5.9). ∎

THEOREM 5.2. *Let (y^*,p^*,u^*) and (y_N^*,p_N^*,u_N^*) be the solutions of* (2.3)–(2.5) *and* (2.8)–(2.10)*, respectively. Then, we have*

$$||u^*-u_N^*||_{L^2(\Omega)}+||y^*-y_N^*||_{L^2(\Omega)}+||p^*-p_N^*||_{L^2(\Omega)} \le C\eta_1, \tag{5.13}$$

where η_1 is defined in Lemma 5.2.

Proof. By using (5.5)–(5.6), (4.8), (4.11), and Lemma 5.2, we can obtain the result (5.13). ∎

6. *hp* spectral element method for optimal control problem. In this section, we extend the above estimates to the spectral element method. In fact we derive a posteriori error estimates for the *hp* spectral element method. Spectral element methods, proposed by Patera [27], combine the advantages of Galerkin spectral methods with those of finite element methods by a simple application of the spectral method per element. As in finite element methods, the domain is divided into N_τ nonoverlapping subdomains (elements) $\tau_i, 1 \le i \le N_\tau$:

$$\overline{\Omega} = \bigcup_{i=1}^{N_\tau} \overline{\tau_i}, \qquad \tau_i \bigcap \tau_j = \emptyset, \quad i \ne j, \quad 1 \le i,j \le N_\tau.$$

We first consider the *hp* spectral element approximation of (OCP). Let $\mathcal{T} = \{\tau\}$ be a local quasi-uniform partitioning of Ω into nonoverlapping regular elements τ. We denote by $\hat{\tau} = (-1,1)^2$ the reference element. We let $\mathcal{E}(\mathcal{T})$ denote all edges, and let $\mathcal{E}_0(\mathcal{T})$ denote all edges which do not lie on the boundary $\partial\Omega$. Each element τ can be the image of the reference element $\hat{\tau}$ under an affine map $F_\tau : \hat{\tau} \to \tau$. We write $h_\tau :=$ diam τ. We assume that the triangulation is γ-shape regular; i.e.,

$$h_\tau^{-1}\|F_\tau'\| + h_\tau\|(F_\tau')^{-1}\| \le \gamma. \tag{6.1}$$

For γ-shape regular meshes $\mathcal{T}$ on the domain Ω, we associate with each element $\tau \in \mathcal{T}$ a polynomial degree $p_\tau \in \mathbb{N}_0$; these polynomial degrees $\{p_\tau\}$ are collected into

the polynomial degree vector $\boldsymbol{p} = \{p_\tau\}$. Then we can define the spaces of spectral element approximation $U^{\boldsymbol{p}}(\mathcal{T},\Omega)$, $S^{\boldsymbol{p}}(\mathcal{T},\Omega)$, $S_0^{\boldsymbol{p}}(\mathcal{T},\Omega)$ as follows:

$$U^{\boldsymbol{p}}(\mathcal{T},\Omega) := \{u \in L^2(\Omega) : u|_e \circ F_\tau \in \mathcal{P}_{p_\tau}(\hat{\tau})\},$$

$$S^{\boldsymbol{p}}(\mathcal{T},\Omega) := \{v \in H^1(\Omega) : v|_e \circ F_\tau \in \mathcal{P}_{p_\tau}(\hat{\tau})\},$$

$$S_0^{\boldsymbol{p}}(\mathcal{T},\Omega) := S^{\boldsymbol{p}}(\mathcal{T},\Omega) \bigcap H_0^1(\Omega),$$

where $\mathcal{P}_{p_\tau}(\hat{\tau})$ denotes the spaces of polynomials in $\hat{\tau}$ of degree $\le p_\tau$ in each variable, respectively. As to polynomial degree distribution $\boldsymbol{p}$, similarly to (6.1), we assume that the polynomial degrees of neighboring elements are comparable; i.e., there is a constant $\gamma > 0$ such that

$$\gamma^{-1}(p_\tau + 1) \le p_{\tau'} + 1 \le \gamma(p_\tau + 1) \quad \forall \tau, \tau' \in \mathcal{T}, \quad \bar{\tau} \bigcap \bar{\tau}' \neq \emptyset. \tag{6.2}$$

Convergence is obtained either by increasing the degree of the polynomials or by increasing the number of elements N_τ.

Let $K^{h,\boldsymbol{p}} := K \bigcap U^{\boldsymbol{p}}(\mathcal{T},\Omega)$ be the space of approximation for the control, and let $S_0^{\boldsymbol{p}}(\mathcal{T},\Omega)$ be the space of approximation for the state and costate. Then the spectral element approximation to (OCP) reads as

$$\min_{u_{hp} \in K^{h,\boldsymbol{p}}} \left\{ \frac{1}{2} \int_\Omega (y_{hp} - y_0)^2 + \frac{1}{2} \int_\Omega u_{hp}^2 \right\}, \tag{6.3}$$

$$a(y_{hp}, w_{hp}) = (f + u_{hp}, w_{hp}) \quad \forall w_{hp} \in S_0^{\boldsymbol{p}}(\mathcal{T},\Omega). \tag{6.4}$$

It follows that (6.3)–(6.4) has a solution $(y_{hp}, u_{hp}) \in S_0^{\boldsymbol{p}}(\mathcal{T},\Omega) \times K^{h,\boldsymbol{p}}$, and (y_{hp}, u_{hp}) is the solution if and only if there is a costate $p_{hp} \in S_0^{\boldsymbol{p}}(\mathcal{T},\Omega)$ such that the triplet (y_{hp}, p_{hp}, u_{hp}) satisfies the following optimality conditions:

$$a(y_{hp}, w_{hp}) = (f + u_{hp}, w_{hp}) \qquad \forall w_{hp} \in S_0^{\boldsymbol{p}}(\mathcal{T},\Omega), \tag{6.5}$$

$$a(q_{hp}, p_{hp}) = (y_{hp} - y_0, q_{hp}) \qquad \forall q_{hp} \in S_0^{\boldsymbol{p}}(\mathcal{T},\Omega), \tag{6.6}$$

$$(u_{hp} + p_{hp}, v_{hp} - u_{hp})_U \ge 0 \qquad \forall v_{hp} \in K^{h,\boldsymbol{p}}. \tag{6.7}$$

Let $(y(u_{hp}), p(u_{hp}))$ be the solution of the auxiliary equations

$$a(y(u_{hp}), w) = (f + u_{hp}, w) \qquad \forall w \in H_0^1(\Omega), \tag{6.8}$$

$$a(q, p(u_{hp})) = (y(u_{hp}) - y_0, q) \qquad \forall q \in H_0^1(\Omega). \tag{6.9}$$

In what follows, we introduce two lemmas which generalize the well-known Clément-type interpolation operators of [9] and [28] to the *hp* context. The reader is referred to [25] for details.

LEMMA 6.1 (Clément-type quasi interpolation). *Let $\mathcal{T}$ be a γ-shape regular triangulation (see* (6.1)*) of a domain $\Omega \in \mathcal{R}^2$, and let $\boldsymbol{p}$ be a polynomial degree distribution which is comparable (see* (6.2)*). Then there exists a bounded linear operator $\Pi : L^1(\Omega) \to S^{\boldsymbol{p}}(\mathcal{T},\Omega)$, and there exists a constant $C > 0$, which depends only on γ, such that for every $u \in H^1(\Omega)$, all elements $\tau \in \mathcal{T}$, and all edges $e \in \mathcal{E}(\tau)$,*

$$\|u-\Pi u\|_{L^2(\tau)}+\frac{h_\tau}{p_\tau}\|\nabla(u-\Pi u)\|_{L^2(\tau)}\le C\frac{h_\tau}{p_\tau}\|\nabla u\|_{L^2(\omega_\tau)}, \tag{6.10}$$

$$\|u-\Pi u\|_{L^2(e)}\le C\sqrt{\frac{h_e}{p_e}}\|\nabla u\|_{L^2(\omega_e)}, \tag{6.11}$$

where h_e is the length of the edge e and $p_e=\max(p_\tau,p_{\tau'})$, where τ,τ' are elements sharing the edge e, and ω_τ, ω_e are patches covering τ and e with a few layers, respectively. See [25] *for more details on ω_τ and ω_e.*

LEMMA 6.2 (Scott–Zhang-type quasi interpolation). *Let $\mathcal{T}$ be a γ-shape regular triangulation (see* (6.1)*) of a domain $\Omega\in\mathcal{R}^2$, and let $\boldsymbol{p}$ be a polynomial degree distribution which is comparable (see* (6.2)*). Then there exists a linear operator $\hat{\Pi}: H_0^1(\Omega)\to S_0^{\boldsymbol{p}}(\mathcal{T},\Omega)$, and there exists a constant $C>0$, which depends only on γ, such that for every $u\in H_0^1(\Omega)$, all elements $\tau\in\mathcal{T}$, and all edges $e\in\mathcal{E}(\tau)$,*

$$\|u-\hat{\Pi}u\|_{L^2(\tau)}+\frac{h_\tau}{p_\tau}\|\nabla(u-\hat{\Pi}u)\|_{L^2(\tau)}\le C\frac{h_\tau}{p_\tau}\|\nabla u\|_{L^2(\omega_\tau)}, \tag{6.12}$$

$$\|u-\hat{\Pi}u\|_{L^2(e)}\le C\sqrt{\frac{h_e}{p_e}}\|\nabla u\|_{L^2(\omega_e)}, \tag{6.13}$$

where h_e is the length of the edge e and $p_e=\max(p_\tau,p_{\tau'})$, where τ,τ' are elements sharing the edge e, and ω_τ, ω_e are patches covering τ and e with a few layers, respectively. See [25] *for more details on ω_τ and ω_e.*

In what follows, we will derive a posteriori estimates for the optimal control problem. First, we define some notation to represent the error bound as follows:

$$\eta_2^2:=\sum_{\tau\in\mathcal{T}}\left(\frac{h_\tau^2}{p_\tau^2}\|f+u_{hp}+\Delta y_{hp}\|_{L^2(\tau)}^2+\sum_{e\subset(\partial\tau\bigcap\Omega)\bigcap\mathcal{E}_0(\mathcal{T})}\frac{h_e}{2p_e}\left\|\left[\frac{\partial y_{hp}}{n_e}\right]\right\|_{L^2(e)}^2\right), \tag{6.14}$$

$$\eta_3^2:=\sum_{\tau\in\mathcal{T}}\left(\frac{h_\tau^2}{p_\tau^2}\|y_{hp}-y_0+\Delta p_{hp}\|_{L^2(\tau)}^2+\sum_{e\subset(\partial\tau\bigcap\Omega)\bigcap\mathcal{E}_0(\mathcal{T})}\frac{h_e}{2p_e}\left\|\left[\frac{\partial p_{hp}}{n_e}\right]\right\|_{L^2(e)}^2\right), \tag{6.15}$$

$$\eta_4^2:=\sum_{\tau\in\mathcal{T}}\frac{h_\tau^2}{p_\tau^2}\|\nabla(u_{hp}+p_{hp})\|_{L^2(\tau)}^2, \tag{6.16}$$

where we denote the jump of v across the edges by $[v]$ and n_e is the unit outer normal on e.

Using the above notation, we now give the following a posteriori error estimates.

LEMMA 6.3. *Let (y,p,u), (y_{hp},p_{hp},u_{hp}), and $(y(u_{hp}),p(u_{hp}))$ be the solutions of* (2.3)–(2.5)*,* (6.5)–(6.7)*, and* (6.8)–(6.9)*, respectively. Then we have*

$$\|u-u_{hp}\|_{L^2(\Omega)}^2\le C(\eta_4^2+\|p_{hp}-p(u_{hp})\|_{L^2(\Omega)}^2), \tag{6.17}$$

where η_4 is defined by (6.16)*.*

Proof. It follows from (2.5) and (6.7) that for any $v_{hp}\in K^{h,\boldsymbol{p}}$

$$\begin{aligned}||u-u_{hp}||_{L^2(\Omega)}^2&=(u,u-u_{hp})_U-(u_{hp},u-u_{hp})_U\\&\le(-p,u-u_{hp})_U-(u_{hp},u-u_{hp})_U+(u_{hp}+p_{hp},v_{hp}-u_{hp})_U\\&=(u_{hp}+p_{hp},v_{hp}-u)_U+(p_{hp}-p,u-u_{hp})_U.\end{aligned} \tag{6.18}$$

It follows from (2.3), (2.4), (6.8), and (6.9) that we have

$$a(y(u_{hp}) - y, w) = (u_{hp} - u, w) \qquad \forall w \in H_0^1(\Omega),$$

$$a(q, p(u_{hp}) - p) = (y(u_{hp}) - y, q) \qquad \forall q \in H_0^1(\Omega).$$

Let $w = p(u_{hp}) - p$ and $q = y(u_{hp}) - y$. Then

$$(u_{hp} - u, p(u_{hp}) - p) = (y(u_{hp}) - y, y(u_{hp}) - y) \geq 0.$$

It follows from (6.18) that we have

$$\begin{aligned} ||u - u_{hp}||^2_{L^2(\Omega)} &\leq (u_{hp} + p_{hp}, v_{hp} - u)_U + (p_{hp} - p(u_{hp}), u - u_{hp})_U \\ &\quad - (p(u_{hp}) - p, u_{hp} - u)_U \\ &\leq \sum_\tau (u_{hp} + p_{hp}, v_{hp} - u)_\tau + C(\delta)\|p_{hp} - p(u_{hp})\|^2_{H^1(\Omega)} \\ &\quad + \delta||u - u_{hp}||^2_{L^2(\Omega)}. \end{aligned}$$

Let $v_{hp} = Pu$ be the L^2-projection of u in $U^{\boldsymbol{p}}(\mathcal{T}, \Omega)$. As in Theorem 4.1, we have $Pu \in K^{h,\boldsymbol{p}}$. Let Π be the Clément-type interpolator defined in Lemma 6.1. Then we have

(6.19)
$$\begin{aligned} ||u - u_{hp}||^2_{L^2(\Omega)} &\leq \sum_\tau (u_{hp} + p_{hp}, v_{hp} - u)_\tau + C(\delta)\|p_{hp} - p(u_{hp})\|^2_{H^1(\Omega)} \\ &\quad + \delta||u - u_{hp}||^2_{L^2(\Omega)} \\ &= \sum_\tau (u_{hp} + p_{hp} - \Pi(u_{hp} + p_{hp}), P(u - u_{hp}) - (u - u_{hp}))_\tau \\ &\quad + C(\delta)\|p_{hp} - p(u_{hp})\|^2_{H^1(\Omega)} + \delta||u - u_{hp}||^2_{L^2(\Omega)} \\ &\leq C(\delta) \sum_\tau \frac{h_\tau^2}{p_\tau^2} \|\nabla(u_{hp} + p_{hp})\|^2_{L^2(\tau)} + C(\delta)\|p_{hp} - p(u_{hp})\|^2_{H^1(\Omega)} \\ &\quad + 2\delta||u - u_{hp}||^2_{L^2(\Omega)}. \end{aligned}$$

Now choosing $\delta = \frac{1}{4}$, we obtain (6.17). ∎

In the following lemma, we derive a posteriori error estimates for the intermediate variables.

LEMMA 6.4. *Let* (y_{hp}, p_{hp}, u_{hp}) *and* $(y(u_{hp}), p(u_{hp}))$ *be the solutions of* (6.5)–(6.7) *and* (6.8)–(6.9)*, respectively. Then we have*

$$\|y(u_{hp}) - y_{hp}\|^2_{H^1(\Omega)} + \|p(u_{hp}) - p_{hp}\|^2_{H^1(\Omega)} \leq C(\eta_2^2 + \eta_3^2), \tag{6.20}$$

where η_2, η_3 *are defined by* (6.14), (6.15).

Proof. Set $e^p = p(u_{hp}) - p_{hp}$, and let $e_I^p = \hat{\Pi} e^p$, where $\hat{\Pi} : H_0^1(\Omega) \to S_0^{\boldsymbol{p}}(\mathcal{T}, \Omega)$ is the Scott–Zhang-type interpolator defined in Lemma 6.2. Then it follows from (6.6), (6.9), and Lemma 6.2 that

(6.21)
$$
\begin{aligned}
c||p(u_{hp})-p_{hp}||^2_{H^1(\Omega)} &\le (\nabla e^p,\nabla e^p)=(\nabla(e^p-e_I^p),\nabla e^p)+(\nabla e_I^p,\nabla e^p)\\
&=(y(u_{hp})-y_0,e^p)+(\nabla(e^p-e_I^p),\nabla p_{hp})+(y_{hp}-y_0,e_I^p)\\
&=\sum_{\tau\in\mathcal{T}}\int_\tau (y_{hp}-y_0+\Delta p_{hp})(e^p-e_I^p)\\
&\quad-\sum_{e\in\mathcal{E}_0(\mathcal{T})}\int_e\left[\frac{\partial p_{hp}}{n_e}\right](e^p-e_I^p)+(y(u_{hp})-y_{hp},e^p)\\
&\le C\sum_{\tau\in\mathcal{T}}\|y_{hp}-y_0+\Delta p_{hp}\|_{L^2(\tau)}\|e^p-e_I^p\|_{L^2(\tau)}\\
&\quad+C\sum_{e\in\mathcal{E}_0(\mathcal{T})}\left\|\left[\frac{\partial p_{hp}}{n_e}\right]\right\|_{L^2(e)}\|e^p-e_I^p\|_{L^2(e)}\\
&\quad+C\|y(u_{hp})-y_{hp}\|_{L^2(\Omega)}\|e^p\|_{L^2(\Omega)}\\
&\le C\sum_{\tau\in\mathcal{T}}\frac{h_\tau}{p_\tau}\|y_{hp}-y_0+\Delta p_{hp}\|_{L^2(\tau)}\|\nabla e^p\|_{L^2(\omega_\tau)}\\
&\quad+C\sum_{e\in\mathcal{E}_0(\mathcal{T})}\sqrt{\frac{h_e}{p_e}}\left\|\left[\frac{\partial p_{hp}}{n_e}\right]\right\|_{L^2(e)}\|\nabla e^p\|_{L^2(\omega_e)}\\
&\quad+C\|y(u_{hp})-y_{hp}\|_{L^2(\Omega)}\|e^p\|_{L^2(\Omega)}\\
&\le C(\delta)\eta_3^2+C(\delta)\|y(u_{hp})-y_{hp}\|^2_{L^2(\Omega)}+\delta\|e^p\|^2_{H^1(\Omega)}.
\end{aligned}
$$

Letting $\delta=\frac{c}{2}$, we have

$$
||p(u_{hp})-p_{hp}||^2_{H^1(\Omega)}\le C\eta_3^2+C\|y(u_{hp})-y_{hp}\|^2_{L^2(\Omega)}. \tag{6.22}
$$

Similarly, set $e^y=y(u_{hp})-y_{hp}$, and let $e_I^y=\hat{\Pi}e^y$ be the Scott–Zhang interpolator of e^y defined in Lemma 6.2. Then, using (6.5), (6.8), and Lemma 6.3, we have that

$$
\begin{aligned}
c||y(u_{hp})-y_{hp}||^2_{H^1(\Omega)} &\le (\nabla e^y,\nabla e^y)=(\nabla(e^y-e_I^y),\nabla e^y)\\
&=\sum_{\tau\in\mathcal{T}}\int_\tau (f+u_{hp}+\Delta y_{hp})(e^y-e_I^y)\\
&\quad-\sum_{e\in\mathcal{E}_0(\mathcal{T})}\int_e\left[\frac{\partial y_{hp}}{n_e}\right](e^p-e_I^p)\\
&\le C\sum_{\tau\in\mathcal{T}}\frac{h_\tau}{p_\tau}\|f+u_{hp}+\Delta y_{hp}\|_{L^2(\tau)}\|\nabla e^y\|_{L^2(\omega_\tau)}\\
&\quad+C\sum_{e\in\mathcal{E}_0(\mathcal{T})}\sqrt{\frac{h_e}{p_e}}\left\|\left[\frac{\partial y_{hp}}{n_e}\right]\right\|_{L^2(e)}\|\nabla e^y\|_{L^2(\omega_e)}\\
&\le C(\delta)\eta_2^2+\delta\|e^y\|^2_{H^1(\Omega)}.
\end{aligned}
$$

Choosing that $\delta=\frac{1}{2c_1}$, we have

$$
||y(u_{hp})-y_{hp}||^2_{H^1(\Omega)}\le C\eta_2^2. \tag{6.23}
$$

Then, we combine (6.22) and (6.23) to derive our estimates (6.20). ∎

THEOREM 6.1. *Let* (y,p,u) *and* (y_{hp},p_{hp},u_{hp}) *be the solutions of* (2.3)–(2.5) *and* (6.5)–(6.7)*, respectively. Then we have that*

$$||u-u_{hp}||^2_{L^2(\Omega)}+||y-y_{hp}||^2_{H^1(\Omega)}+||p-p_{hp}||^2_{H^1(\Omega)}\le C(\eta_2^2+\eta_3^2+\eta_4^2), \tag{6.24}$$

where $\eta_2^2,\eta_3^2,\eta_4^2$ *are defined by* (6.14)–(6.16).

Proof. We can prove (6.24) as in Theorem 5.1 by using Lemmas 6.3 and 6.4. ∎

7. A preconditioning projection algorithm. In this section, we will present four numerical examples. For the minimization problem consider

$$\min_{u\in K} H(u)=\left\{\frac{1}{2}\int_\Omega (y-y_0)^2+\frac{1}{2}\int_\Omega u^2\right\} \tag{7.1}$$

and

$$K=\left\{v\in L^2(\Omega):\int_\Omega v\geqslant 0\right\}\subset U=L^2(\Omega).$$

We define the iterative scheme $(n=0,1,2,\dots)$

$$\begin{cases}(u_{n+\frac{1}{2}},v)=(u_n,v)-\rho_n(H^{'}(u_n),v) & \forall v\in U,\\ u_{n+1}=P_K(u_{n+\frac{1}{2}}),\end{cases} \tag{7.2}$$

where ρ_n will be specified later. Now define the projection operator $P_K: U\to K$ satisfying the following: For given $w\in U$ find $P_Kw\in K$ such that

$$(P_Kw-w,P_Kw-w)=\min_{u\in K}(u-w,u-w),$$

which is equivalent to

$$(P_Kw-w,v-P_Kw)\ge 0 \qquad \forall v\ \in K. \tag{7.3}$$

Let U_n be the coordinates of u_n in R^n, and let $DH(U_n)$ be the gradient of $H(U_n)$. Then the matrix form of the above algorithm reads as

$$U_{n+\frac{1}{2}}=U_n-\rho_nM_N^{-1}DH(u_n),$$

where M_N is the mass matrix of $(\cdot,\cdot)_{U_N}$, the preconditioner. For the above scheme we have the following convergence result (see [19]).

LEMMA 7.1. *Assume that* $H^{'}$ *is Lipschitz and uniformly monotone in the sense that there are positive constants* c, C *such that*

$$|H^{'}(u)-H^{'}(v)|\le C||u-v||_U \qquad \forall u,v\in U,$$
$$(H^{'}(u)-H^{'}(v),u-v)\ge c||u-v||^2_U \qquad \forall u,v\in U.$$

Then there are $0<\delta<1,\ \epsilon>0$ *such that*

$$||u-u_n||\le\delta^n||u-u_0||, \qquad n=0,1,2,\dots,$$

provided that $\rho_n<\epsilon$.

Remark 7.1. To have the convergence result, we should select ρ_n satisfying $0\le 1+\rho_n(C\rho_n-c)\le\delta$.

Now, it is obvious that the objection functional in (1.1)

$$H(u) = J(u) = \left\{ \frac{1}{2} \int_\Omega (y(u) - y_0)^2 + \frac{1}{2} \int_\Omega u^2 \right\}$$

satisfies all the conditions in Lemma 6.1. Thus, we can apply the above algorithm to compute the discrete elliptic optimal control problem $(\mathrm{OCP})^N$.

Let U_N and K_N be defined in section 2, and let P_{K_N} be the discrete projection operator $P_{K_N} : U_N \to K_N$ satisfying the following: For given $w \in U_N$ find $P_{K_N} w \in K_N$ such that

$$(P_{K_N} w - w, P_{K_N} w - w) = \min_{u \in K_N} (u - w, u - w),$$

which is equivalent to

$$(P_{K_N} w - w, v - P_{K_N} w) \geq 0 \qquad \forall v \ \in K_N. \tag{7.4}$$

It follows from Theorem 3.2 that for any $u_N \in U_N$

$$P_{K_N} u_N = -\min\{0, \overline{u_N}\} + u_N.$$

Then it follows from (7.2) that

$$u_{n+1} = P_{K_N}(u_{n+\frac{1}{2}}) = -\min\{0, \overline{u_{n+\frac{1}{2}}}\} + u_{n+\frac{1}{2}}.$$

For the discrete space U_N, we can apply (7.2) to construct the following algorithm for the discrete elliptic control problem $(\mathrm{OCP})^N$.

Algorithm.

$$\begin{array}{ll} (u_{n+\frac{1}{2}}, v) = (u_n, v) - \rho_n (J'(u_n), v), & u_{n+\frac{1}{2}}, u_n \in U_N \quad \forall v \in U_N, \\ a(y_n, w) = (f + u_n, w), & y_n \in V_N \quad \forall w \in V_N, \\ a(q, p_n) = (y_n - y_0, q), & p_n \in V_N \quad \forall q \in V_N, \\ u_{n+1} = P_{K_N}(u_{n+\frac{1}{2}}) = -\min\{0, \overline{u_{n+\frac{1}{2}}}\} + u_{n+\frac{1}{2}}, & \end{array} \tag{7.5}$$

where we have omitted the subscript N for all the functions in the discrete spaces. In practice, we select the step size $\rho_n \in (0, 1/4)$.

7.1. One-dimensional case. Following [30], we choose the $\phi_k = c_k(L_k(x) - L_{k+2}(x))$ as the basis functions in the spectral approximation with

$$c_k = \frac{1}{\sqrt{4k+6}}.$$

Let $V_N = \mathrm{span}\{\phi_0, \phi_1, \ldots, \phi_{N-2}\}$. It can be verified that (see [30])

$$a_{jk} = (\phi_k', \phi_j') = \begin{cases} 1, & k = j, \\ 0, & k \neq j, \end{cases}$$

$$b_{jk} = b_{kj} = (\phi_k, \phi_j) = \begin{cases} c_k c_j \left(\frac{2}{2j+1} + \frac{2}{2j+5}\right), & k = j, \\ -c_k c_j \frac{2}{2k+1}, & k = j+2, \\ 0 & \text{otherwise.} \end{cases}$$

Example 1. In this example, we let

$$\begin{array}{lll} p = \sin(\pi x), & f = (1 + \pi^4)p, & y_0 = 0, \\ y = y_0 + \pi^2 p, & u = \max\{0, \overline{p}\} - p. & \end{array}$$

Let us denote

$$
\begin{aligned}
&f_k = (P_N f, \phi_k), \qquad F = (f_0, f_1, \ldots, f_{N-2})^T,\\
&g_k = (-P_N y_0, \phi_k), \qquad G = (g_0, g_1, \ldots, g_{N-2})^T,\\
&y_N = \sum_{n=0}^{N-2} \varphi_n \phi_n(x), \qquad \varphi = (\varphi_0, \varphi_1, \ldots, \varphi_{N-2})^T,\\
&p_N = \sum_{n=0}^{N-2} \psi_n \phi_n(x), \qquad \psi = (\psi_0, \psi_1, \ldots, \psi_{N-2})^T,\\
&u_N = \sum_{n=0}^{N-2} \tau_n \phi_n(x), \qquad \tau = (\tau_0, \tau_1, \ldots, \tau_{N-2})^T,\\
&A = (a_{jk}), \qquad B = (b_{jk}), \qquad 0 \le j, k \le N-2.
\end{aligned}
$$

Then, in this case, the algorithm (7.5) is equivalent to

$$
\left\{
\begin{array}{l}
Bu_{n+\frac{1}{2}} = Bu_n - \rho_n(u_n + p_n),\\
Ay_n = F + Bu_n,\\
Ap_n = By_n + G,\\
u_{n+1} = -\min\{0, \overline{u_{n+\frac{1}{2}}}\} + u_{n+\frac{1}{2}}.
\end{array}
\right. \tag{7.6}
$$

We now describe the main steps for solving numerical Example 1:

- *Step* 1. Compute Legendre–Gauss–Lobatto points $\{x_j\}$.
- *Step* 2. Compute the matrixes F, G, A, and B.
- *Step* 3. Use the preconditioning projection algorithm to solve the linear equations (7.6) to obtain $\{\varphi_n\}$, $\{\psi_n\}$, and $\{\tau_n\}$.
- *Step* 4. For every $\{x_j\}$, $j = 0, 1, \ldots, N$, evaluate

$$
\begin{aligned}
y_N(x_j) &= \sum_{n=0}^{N-2} \varphi_n \phi_n(x_j),\\
p_N(x_j) &= \sum_{n=0}^{N-2} \psi_n \phi_n(x_j),\\
u_N(x_j) &= \sum_{n=0}^{N-2} \tau_n \phi_n(x_j).
\end{aligned}
$$

- *Step* 5. Compute the maximum pointwise error of $y - y_N$, $p - p_N$, and $u - u_N$.

The approximation errors are presented in Table 7.1.

We plot the exact solutions and the spectral approximated solutions in Figure 7.1 (in the case of $N = 64$).

TABLE 7.1
The maximum pointwise error of $y - y_N$, $p - p_N$, and $u - u_N$.

N	4	8	16	32	64
$\max\|y - y_N\|$	0.514254	0.000117075	4.04958e-009	4.04958e-009	4.04958e-009
$\max\|p - p_N\|$	0.102066	1.32049e-005	5.22898e-010	5.24445e-010	5.25692e-010
$\max\|u - u_N\|$	0.102066	1.32049e-005	5.22898e-010	5.24444e-010	5.25691e-010

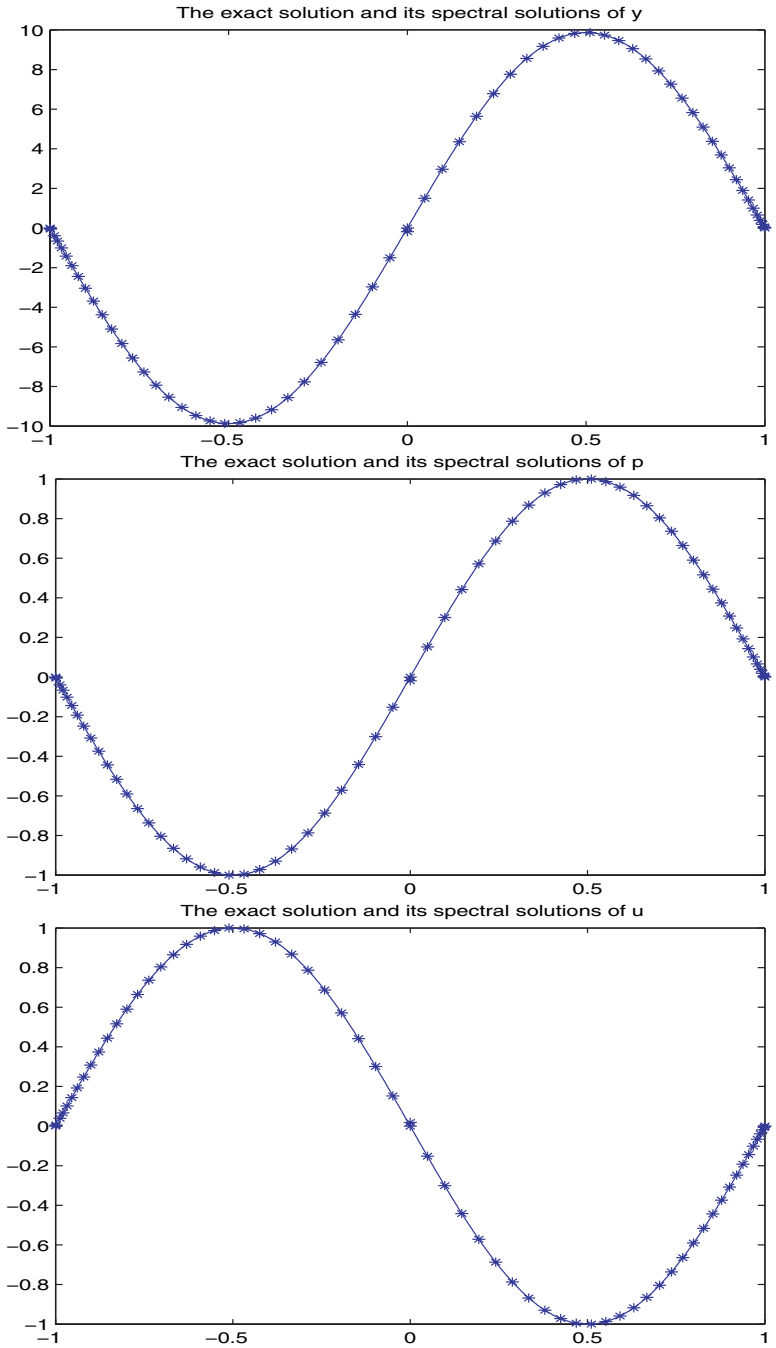

FIG. 7.1. *The exact solutions (solid line) and the approximated solutions (∗).*

Example 2. In this example, we let

$$p = \sin \pi x, \quad y_0 = 1 - |x|^3, \quad y = y_0 + \pi^2 p,$$
$$f = (1 + \pi^4)p, \qquad u = -p.$$

As in Example 1, we can also get the approximation errors (see Table 7.2).

TABLE 7.2
The maximum pointwise error of $y - y_N$, $p - p_N$, and $u - u_N$.

N	4	8	16	32	64
$\max\|y - y_N\|$	0.594161	0.0574371	0.0155496	0.00406608	0.00104092
$\max\|p - p_N\|$	0.142789	0.0201929	0.0052457	0.00134375	0.000340603
$\max\|u - u_N\|$	0.142789	0.0201929	0.0052457	0.00134375	0.000340603

TABLE 7.3
The maximum pointwise error of $y - y_N$, $p - p_N$, and $u - u_N$.

N	4	8	16	32	64
$\max\|y - y_N\|$	0.521042	0.00336548	0.000874284	0.000223959	5.67671e-005
$\max\|p - p_N\|$	0.115384	0.00957285	0.0025916	0.000677681	0.000173486
$\max\|u - u_N\|$	0.115384	0.00957285	0.0025916	0.000677681	0.000173486

In this example, the optimal control is not infinitely smooth due to the absolute function in the initial data. Thus the spectral accuracy is not achieved.

Example 3. In this example, we let

$$p = \sin \pi x + \frac{|x|^3}{6} - \frac{1}{6}, \quad u = -p, \quad y = \pi^2 \sin \pi x,$$
$$y_0 = |x|, \qquad f = (1 + \pi^4) \sin \pi x + \frac{|x|^3}{6} - \frac{1}{6}.$$

We can get the approximation errors presented in Table 7.3.

7.2. Two-dimensional case. In the two-dimensional case, the discrete space for the state and costate is constructed as follows:

$$V_N^2 = \operatorname{span}\{\phi_i(x_1)\phi_j(x_2) : \quad i,\ j = 0, 1, \ldots, N-2\}.$$

Let us denote

$$f_{ij} = (P_N f, \phi_i(x_1)\phi_j(x_2)), \qquad F = (f_{ij}),$$
$$g_{ij} = (-P_N y_0, \phi_i(x_1)\phi_j(x_2)), \quad G = (g_{ij}),$$
$$y_N = \sum_{i,j=0}^{N-2} \varphi_{ij}\phi_i(x_1)\phi_j(x_2), \qquad Y = (\varphi_{ij}),$$
$$p_N = \sum_{i,j=0}^{N-2} \psi_{ij}\phi_i(x_1)\phi_j(x_2), \qquad P = (\psi_{ij}),$$
$$u_N = \sum_{i,j=0}^{N-2} \tau_{ij}\phi_i(x_1)\phi_j(x_2), \qquad U = (\tau_{ij}),$$
$$u_{N+\frac{1}{2}} = \sum_{i,j=0}^{N-2} \sigma_{ij}\phi_i(x_1)\phi_j(x_2), \qquad U_{\frac{1}{2}} = (\sigma_{ij}),$$
$$A = (a_{ij}), \qquad B = (b_{ij}).$$

Taking $w_N,\ q_N = \phi_l(x_1)\phi_m(x_2),\ l,m = 0,1,\ldots,N-2$ in (2.8)–(2.9), we find that the algorithm (7.5) is equivalent to the following matrix equations:

$$\begin{aligned}
&BU_{\frac{1}{2}}B = BUB - \rho_n B(U+P)B,\\
&YB + BY = F + BUB,\\
&PB + BP = G + BYB,\\
&BUB = cD + BU_{\frac{1}{2}}B,
\end{aligned}$$

where $c = -\min\{0, \overline{u_{\frac{1}{2}}}\}$ and $D = (d_{ij}) = (1, \phi_i(x_1)\phi_j(x_2)),\ d_{00} = \frac{2}{3},\ d_{ij} = 0$, when $i \neq 0,\ j \neq 0$.

In particular, these equations can be solved by the matrix decomposition method described in [5], which is well known in the field of spectral methods as the matrix diagonalization method [14]. To this end, let Λ be the diagonal matrix whose diagonal entries $\{\lambda_p\}$ are the eigenvalues of B, and let E be the matrix whose columns are the eigenvectors of B. Then we have

$$E^{-1}BE = \Lambda.$$

Now setting $Y = EV,\ P = EW,\ U = EQ,\ U_{\frac{1}{2}} = EQ_{\frac{1}{2}}$, the equations become

$$\begin{aligned}
&Q^T_{\frac{1}{2}} = Q^T - \rho_n(Q^T + W^T),\\
&BV^T + V^T\Lambda = F^T E^{-T} + BQ^T\Lambda,\\
&BW^T + W^T\Lambda = G^T E^{-T} + BV^T\Lambda,\\
&Q^T = cB^{-1}D^T\Lambda^{-T} + Q^T_{\frac{1}{2}}.
\end{aligned}$$

These equations can be solved in columns (see [30] for the details).

We now describe the main steps for numerically solving the two-dimensional optimal control problem:

- *Step* 1. Compute the eigenvalues $\{\lambda_p\}$ and eigenvectors e_p of B.
- *Step* 2. Compute $F' = F^T E^{-T},\ G' = G^T E^{-T}$.
- *Step* 3. Obtain V, W, Q.
- *Step* 4. Set $Y = EV$, $P = EW$, $U = EQ$.
- *Step* 5. Obtain $y_N,\ p_N,\ u_N$.
- *Step 6.* Compute the maximum pointwise error of $y - y_N,\ p - p_N$, and $u - u_N$.

Now we apply the algorithm to the following example.

Example 4. In this example, the data and solutions are given as follows:

$$\begin{aligned}
&p = \sin(\pi x_1)\sin(\pi x_2), \quad f = (1 + 4\pi^4)p, \quad y_0 = 0,\\
&y = y_0 + 2\pi^2 p, \qquad u = \max\{0, \overline{p}\} - p.
\end{aligned}$$

We can obtain the approximation errors presented in Table 7.4.

TABLE 7.4
The maximum pointwise error of $y - y_N$, $p - p_N$, and $u - u_N$.

N	4	8	16	32	64
$y - y_N$	0.9223248	0.000348741	8.02892e-009	8.04805e-009	8.09281e-009

CONDITIONAL STABILITY AND CONVERGENCE OF A FULLY DISCRETE SCHEME FOR THREE-DIMENSIONAL NAVIER–STOKES EQUATIONS WITH MASS DIFFUSION*

F. GUILLÉN-GONZÁLEZ† AND J. V. GUTIÉRREZ-SANTACREU†

Abstract. We construct a fully discrete numerical scheme for three-dimensional incompressible fluids with mass diffusion (in density-velocity-pressure formulation), also called the Kazhikhov–Smagulov model. We will prove conditional stability and convergence, by using at most C^0-finite elements, although the density of the limit problem will have H^2-regularity. The key idea of our argument is first to obtain pointwise estimates for the discrete density by imposing the constraint $\lim_{(h,k)\to 0} h/k = 0$ on the time and space parameters (k, h). Afterwards, under the same constraint on the parameters, strong estimates for the discrete density in $l^\infty(H^1)$ and for the discrete Laplacian of the density in $l^2(L^2)$ are obtained. From here, the compactness and convergence of the scheme can be concluded with similar arguments as we used in [*Math. Comp.*, to appear], where a different scheme is studied for two-dimensional domains which is unconditionally stable and convergent. Moreover, we study the asymptotic behavior of the numerical scheme as the diffusion parameter λ goes to zero, obtaining convergence as $(k, h, \lambda) \to 0$ towards a weak solution of the density-dependent Navier–Stokes system provided that the constraint $\lim_{(\lambda,h,k)\to 0} h/(\lambda^2 k) = 0$ on (h, k, λ) is satisfied.

Key words. three-dimensional Kazhikhov–Smagulov models, density-dependent Navier–Stokes equations, finite elements, stability, convergence

1. Introduction.

1.1. The model. Let $\Omega \subset \mathbb{R}^3$ be an open bounded set with boundary Γ. We denote by $[0, T]$ $(0 < T < +\infty)$ the time interval of observation. We will use the notation $Q = \Omega \times (0, T)$, $\Sigma = \Gamma \times (0, T)$, and $\boldsymbol{n}(\boldsymbol{x})$ the outwards unit normal vector to Γ at the point $\boldsymbol{x} \in \Gamma$.

We consider the Navier–Stokes system with mass diffusion (the so-called Kazhikhov–Smagulov model) in Q:

$$\left\{ \begin{array}{rcl} \rho \boldsymbol{u}_t + ((\rho \boldsymbol{u} - \lambda \nabla \rho) \cdot \nabla)\boldsymbol{u} - \nabla \cdot (\mu \nabla \boldsymbol{u} - \lambda \rho (\nabla \boldsymbol{u})^t) + \nabla p &=& \rho \boldsymbol{f}, \\ \nabla \cdot \boldsymbol{u} = 0, \qquad \rho_t + \boldsymbol{u} \cdot \nabla \rho - \lambda \Delta \rho &=& 0. \end{array} \right. \tag{1.1}$$

The unknowns for this model are $\rho : Q \to \mathbb{R}^+$, the density of the fluid, $\boldsymbol{u} : Q \to \mathbb{R}^3$, the incompressible (averaged) velocity vector field, and $p : Q \to \mathbb{R}$, a potential function (modified pressure).

Model (1.1) can be derived from the compressible Navier–Stokes system, by imposing that the compressible velocity $\boldsymbol{v}$ can be decomposed as $\boldsymbol{v} = \boldsymbol{u} - \lambda \nabla \log \rho$, with $\nabla \cdot \boldsymbol{u} = 0$ (it decomposes into an incompressible part $\boldsymbol{u}$ and a potential part $-\lambda \nabla \log \rho$), and eliminating λ^2-terms (see [11]).

†Departamento E.D.A.N., University of Sevilla, Aptdo. 1160, 41080 Sevilla, Spain (guillen@us.es, juanvi@us.es).

We complete (1.1) with the boundary conditions on Σ:

$$\boldsymbol{u}_{|\Sigma} = 0, \quad \left.\frac{\partial \rho}{\partial \boldsymbol{n}}\right|_{\Sigma} = 0 \tag{1.2}$$

and the initial conditions in Ω:

$$\rho|_{t=0} = \rho_0, \qquad \boldsymbol{u}|_{t=0} = \boldsymbol{u}_0, \tag{1.3}$$

where $\rho_0 : \Omega \to \mathbb{R}^+$ and $\boldsymbol{u}_0 : \Omega \to \mathbb{R}^d$ are given functions.

Throughout this work, we assume the hypothesis on the initial density:

$$0 < m \leq \rho_0(\boldsymbol{x}) \leq M \quad \text{in } \Omega. \tag{1.4}$$

1.2. Known results. Concerning the simplified model (1.1), Kazhikhov and Smagulov [12] proved, via a semi-Galerkin method, the existence of global weak solutions, under the following hypothesis:

$$\lambda < 2\mu/(M-m), \tag{1.5}$$

and the existence of local strong solutions (which is global in the two-dimensional case). Salvi [14] proved the existence of weak solutions for noncylindrical domains. On the other hand, Secchi [16] studied the problem for $\Omega = \mathbb{R}^3$, proving the local existence and uniqueness of strong solutions by using a fixed point argument.

For the complete model (including the λ^2-terms), Beirão da Veiga [2] and Secchi [15] established the local existence of strong solutions by using linearization and a fixed point argument. In [15], global existence and uniqueness are shown for two-dimensional (2D) domains by imposing that λ/μ is small enough as well as the asymptotic behavior as $\lambda \to 0$ towards a weak solution of the density-dependent Navier–Stokes problem:

$$\left\{\begin{array}{rl} & \rho\left[\boldsymbol{u}_t + (\boldsymbol{u}\cdot\nabla)\boldsymbol{u}\right] - \mu\Delta\boldsymbol{u} + \nabla p = \rho\boldsymbol{f} \quad \text{in } Q, \\ & \nabla\cdot\boldsymbol{u} = 0, \quad \rho_t + \boldsymbol{u}\cdot\nabla\rho = 0 \quad \text{in } Q, \\ \boldsymbol{u} = 0 \quad \text{on } \Sigma, & \boldsymbol{u}|_{t=0} = \boldsymbol{u}_0, \quad \rho|_{t=0} = \rho_0 \quad \text{in } \Omega. \end{array}\right. \tag{1.6}$$

In the case of nonnegative initial density and 3D domains, Guillén-González [9] proved the global existence of weak solutions and the behavior, as $\lambda \to 0$, towards the density-dependent Navier–Stokes system (1.6). Recently, the existence and regularity of strong solutions have been proved in [10] by means of an iterative method (jointly with some error estimates).

A time-space numerical scheme has been recently developed by using C^0-finite elements for density and velocity in [11] for model (1.1) in 2D domains, which is unconditionally stable and convergent towards the (unique) weak solution of the continuous problem. This scheme is of the backward Euler type, where in each time step the computation of the density and the velocity pressure are decoupled, by means of linear problems.

Concerning the numerical analysis for the density-dependent Navier–Stokes problem, a stable and convergent scheme is proposed in [13], by using in particular a discontinuous Galerkin finite element method to approximate the density transport equation.

1.3. Main results of the paper. Our main objective is to design a linear scheme by using finite elements to approximate all unknowns (density, velocity, and pressure) of problem (1.1)–(1.3). To this end, we consider for simplicity a uniform partition of $[0,T]$, $(t_n = nk)_{n=0}^{n=N}$, with $k = T/N$ being the time step, and propose a backward Euler time scheme, implicit with respect to the diffusion terms and semi-implicit with respect to the convection terms. The finite element spaces must verify specific properties which we will describe in section 3.1.

In what follows we consider the notation $(\cdot,\cdot)$ and $|\cdot|$ for the $L^2(\Omega)$-inner product and the $L^2(\Omega)$-norm, respectively. Also, we denote that $\|u\| = |\nabla u|$, which is an equivalent norm to the usual one in $H_0^1(\Omega)$.

The scheme is described as follows:

Initialization: Let $(\boldsymbol{u}_h^0, \rho_h^0) \in \boldsymbol{V}_h \times W_h$ be an approximation of $(\boldsymbol{u}_0, \rho_0)$ as $h \to 0$.

Time step $n+1$: Given $(\rho_h^n, \boldsymbol{u}_h^n, p_h^n) \in W_h \times \boldsymbol{V}_h \times M_h$,

1. find $(\boldsymbol{w}_h^n, q_h^n) \in \widetilde{\boldsymbol{V}}_h \times \widetilde{M}_h$ such that, for each $(\bar{\boldsymbol{w}}_h, \bar{q}_h) \in \widetilde{\boldsymbol{V}}_h \times \widetilde{M}_h$,

$$\left(\nabla \boldsymbol{w}_h^n, \nabla \bar{\boldsymbol{w}}_h\right) - \left(q_h^n, \nabla \cdot \bar{\boldsymbol{w}}_h\right) = \left(\nabla \boldsymbol{u}_h^n, \nabla \bar{\boldsymbol{w}}_h\right), \quad \left(\nabla \cdot \boldsymbol{w}_h^n, \bar{q}_h\right) = 0; \tag{1.7}$$

2. find $\rho_h^{n+1} \in W_h$ such that, for each $\bar{\rho}_h \in W_h$,

$$\left(\frac{\rho_h^{n+1} - \rho_h^n}{k}, \bar{\rho}_h\right) + \left(\boldsymbol{w}_h^n \cdot \nabla \rho_h^{n+1}, \bar{\rho}_h\right) + \lambda\left(\nabla \rho_h^{n+1}, \nabla \bar{\rho}_h\right) = 0; \tag{1.8}$$

3. find $(\boldsymbol{u}_h^{n+1}, p_h^{n+1}) \in \boldsymbol{V}_h \times M_h$ such that, for each $(\bar{\boldsymbol{u}}_h, \bar{p}_h) \in \boldsymbol{V}_h \times M_h$,

$$\begin{cases} \left(\rho_h^n \dfrac{\boldsymbol{u}_h^{n+1} - \boldsymbol{u}_h^n}{k}, \bar{\boldsymbol{u}}_h\right) + \dfrac{1}{2}\left(\dfrac{\rho_h^{n+1} - \rho_h^n}{k}\boldsymbol{u}_h^{n+1}, \bar{\boldsymbol{u}}_h\right) + a\left(\rho_h^{n+1}, \boldsymbol{u}_h^{n+1}, \bar{\boldsymbol{u}}_h\right) \\ + c\left(\rho_h^{n+1}\boldsymbol{u}_h^n - \lambda \nabla \rho_h^{n+1}, \boldsymbol{u}_h^{n+1}, \bar{\boldsymbol{u}}_h\right) = \left(\rho_h^{n+1}\boldsymbol{f}^{\,n+1}, \bar{\boldsymbol{u}}_h\right) + \left(p_h^{n+1}, \nabla \cdot \bar{\boldsymbol{u}}_h\right), \end{cases} \tag{1.9}$$

$$\left(\nabla \cdot \boldsymbol{u}_h^{n+1}, \bar{p}_h\right) = 0, \tag{1.10}$$

where

$$\boldsymbol{f}^{\,n+1} = \frac{1}{k}\int_{t_n}^{t_{n+1}} \boldsymbol{f}(t)\,dt,$$

$$a(\rho, \boldsymbol{u}, \boldsymbol{v}) = \mu(\nabla \boldsymbol{u}, \nabla \boldsymbol{v}) + \lambda \int_\Omega \left(\frac{\widetilde{M} + \widetilde{m}}{2} - \rho\right)(\nabla \boldsymbol{u})^t : \nabla \boldsymbol{v}\,d\boldsymbol{x},$$

with $\widetilde{M} > M$, $0 < \widetilde{m} < m$ such that $\lambda\frac{\widetilde{M} - \widetilde{m}}{2} < \mu$ (here (1.5) is imposed), and

$$c(\boldsymbol{w}, \boldsymbol{u}, \boldsymbol{v}) = \frac{1}{2}\left[((\boldsymbol{w} \cdot \nabla)\boldsymbol{u}, \boldsymbol{v}) - \left((\boldsymbol{w} \cdot \nabla)\boldsymbol{v}, \boldsymbol{u}\right)\right].$$

The following properties of continuity and coercivity hold:

$$\begin{aligned} &a(\rho, \boldsymbol{u}, \boldsymbol{u}) \geq \frac{\mu_1}{2}\|\boldsymbol{u}\|^2 \ \text{ if } \ \widetilde{m} \leq \rho \leq \widetilde{M}, \ \text{ with } \ \frac{\mu_1}{2} = \mu - \lambda\frac{\widetilde{M} - \widetilde{m}}{2} (> 0), \\ &a(\rho, \boldsymbol{u}, \boldsymbol{v}) \leq C_\lambda \|\boldsymbol{u}\|\,\|\boldsymbol{v}\| \quad (\text{if } \|\rho\|_{L^\infty(\Omega)} \leq C), \\ &c(\boldsymbol{w}, \boldsymbol{u}, \boldsymbol{u}) = 0, \quad c(\boldsymbol{w}, \boldsymbol{u}, \boldsymbol{v}) \leq C\,\|\boldsymbol{w}\|_{L^3}\|\boldsymbol{u}\|\,\|\boldsymbol{v}\|. \end{aligned} \tag{1.11}$$

Here and in what follows, we denote by C_λ and C different positive constants independent of (h,k) and (h,k,λ), respectively.

From the computational point of view, scheme (1.7)–(1.10) decouples density ρ_h^{n+1} and velocity pressure $(\boldsymbol{u}_h^{n+1}, p_h^{n+1})$, whereas $\boldsymbol{w}_h^n$ is an intermediate velocity obtained as the H^1 orthogonal projection of $\boldsymbol{u}_h^n$ onto a discrete free-divergence space. We will see that scheme (1.7)–(1.10) is conditionally stable and convergent. As in many practical situations, the diffusion parameter is small; we will prove that, when the diffusion parameter λ and the space and time parameters (h,k) goes to zero, scheme (1.7)–(1.10) approximates to a weak solution of the density-dependent Navier–Stokes system (1.6), under a constraint involving the parameters h, k, and λ. In fact, to our knowledge, it is the first convergent scheme to (1.6) based on C^0-finite elements for the discrete density, avoiding to perform directly an algorithm for (1.6) which presents important difficulties by itself, mainly for the approximation of the density transport equation. Recall that in [13] a convergent scheme for (1.6) is given based on a discontinuous Galerkin method for the density.

The corresponding study for the complete model, with λ^2-terms, will be the subject of a forthcoming paper.

By defining in $[0,T]$ piecewise constant functions $\boldsymbol{u}_{h,k}, \rho_{h,k}$ such that $\boldsymbol{u}_{h,k}$, $\rho_{h,k}\big|_{(t_{n-1},t_n]} = \boldsymbol{u}_h^n, \rho_h^n$, respectively, that we will denote by $\boldsymbol{u}_{h,k,\lambda}, \rho_{h,k,\lambda}$ when the case of diffusion parameter $\lambda \to 0$ is considered, we present the following main results of this paper.

THEOREM 1.1. *Assume hypotheses* (H0)–(H5) *given in section* 3.1. *If the constraint on the parameters*

$$h/k \to 0 \quad \text{as } (h,k) \to 0 \tag{S}$$

holds, then there exists a convergent subsequence of $(\boldsymbol{u}_{h,k}, \rho_{h,k})$ *(denoted in the same way) as* $(h,k) \to 0$ *towards a weak solution* $(\boldsymbol{u}, \rho)$ *of problem* (1.1)–(1.3) *(see Definition* 2.1*), in the following sense:* $(\boldsymbol{u}_{h,k}, \rho_{h,k}) \to (\boldsymbol{u}, \rho)$ *in* $L^2(0,T;\boldsymbol{L}^2(\Omega)) \times L^2(0,T;H^1(\Omega))$*-strong, in* $L^\infty(0,T;\boldsymbol{L}^2(\Omega)) \times (H^1(\Omega) \cap L^\infty(\Omega))$*-weak*$\star$*, and in* $L^2(0,T;\boldsymbol{H}_0^1(\Omega)) \times L^4(0,T;W^{1,3}(\Omega))$*-weak. Moreover,* $\widetilde{m} \le \rho_{h,k} \le \widetilde{M}$.

THEOREM 1.2. *Under the hypotheses of Theorem* 1.1 *and by extending* (H2) *by* (H2′) *(given in section* 8.1*) and changing* (S) *by the more restrictive constraint*

$$h/(k\lambda^2) \to 0 \quad \text{as } (\lambda,h,k) \to 0, \tag{S′}$$

then there exists a convergent subsequence of $(\boldsymbol{u}_{h,k,\lambda}, \rho_{h,k,\lambda})$ *as* $(h,k,\lambda) \to 0$ *towards a weak solution* $(\boldsymbol{u}, \rho)$ *of the density-dependent Navier–Stokes problem* (1.6) *(see Definition* 8.1*) in the following sense:* $\boldsymbol{u}_{h,k,\lambda} \to \boldsymbol{u}$ *in* $L^2(0,T;\boldsymbol{L}^2(\Omega))$*-strong, in* $L^\infty(0,T;\boldsymbol{L}^2(\Omega))$*-weak*$\star$*, and in* $L^2(0,T;\boldsymbol{H}_0^1(\Omega))$*-weak, and* $\rho_{h,k,\lambda} \to \rho$ *in* $L^\infty(Q)$*-weak*$\star$.

The main ideas for the derivation of this scheme can be found in [11], where the following scheme has been studied:

Time step $(n+1)$: Given $(\rho_h^n, \boldsymbol{u}_h^n, p_h^n) \in W_h \times \boldsymbol{V}_h \times M_h$,

1. find $\rho_h^{n+1} \in W_h$ such that, for each $\bar{\rho}_h \in W_h$,

$$\left(\frac{\rho_h^{n+1} - \rho_h^n}{k}, \bar{\rho}_h\right) + \lambda\Big(\nabla\rho_h^{n+1}, \nabla\bar{\rho}_h\Big) = -\Big(\boldsymbol{u}_h^n \cdot \nabla\rho_h^n, \bar{\rho}_h\Big); \tag{1.12}$$

2. find $(\boldsymbol{u}_h^{n+1}, p_h^{n+1}) \in \boldsymbol{V}_h \times M_h$ such that, for each $(\bar{\boldsymbol{u}}_h, \bar{p}_h) \in \boldsymbol{V}_h \times M_h$,

$$\left\{\begin{array}{l} \left([\rho_h^n]_T \dfrac{\boldsymbol{u}_h^{n+1}-\boldsymbol{u}_h^n}{k}, \bar{\boldsymbol{u}}_h\right) + \dfrac{1}{2}\left(\dfrac{[\rho_h^{n+1}]_T - [\rho_h^n]_T}{k}, \boldsymbol{u}_h^{n+1}\cdot\bar{\boldsymbol{u}}_h\right) \\ +a\Big([\rho_h^{n+1}]_T, \boldsymbol{u}_h^{n+1}, \bar{\boldsymbol{u}}_h\Big) + c\Big(\rho_h^{n+1}\boldsymbol{u}_h^n - \lambda\nabla\rho_h^{n+1}, \boldsymbol{u}_h^{n+1}, \bar{\boldsymbol{u}}_h\Big) \\ -\Big(p_h^{n+1}, \nabla\cdot\bar{\boldsymbol{u}}_h\Big) = \Big([\rho_h^{n+1}]_T \boldsymbol{f}^{\,n+1}, \bar{\boldsymbol{u}}_h\Big), \end{array}\right. \tag{1.13}$$

$$\Big(\nabla\cdot\boldsymbol{u}_h^{n+1}, \bar{p}_h\Big) = 0, \tag{1.14}$$

where

$$[w_h]_T(\boldsymbol{x}_i) = \left\{\begin{array}{lll} w_h(\boldsymbol{x}_i) & \text{if} & w_h(\boldsymbol{x}_i)\in[m,M], \\ m & \text{if} & w_h(\boldsymbol{x}_i) < m, \\ M & \text{if} & w_h(\boldsymbol{x}_i) > M, \end{array}\right.$$

with $\boldsymbol{x}_i$ the nodes of the mesh $\mathcal{T}_h$ of Ω.

By comparing both schemes we can observe the following differences: The discrete density involved in the mixed variational problem for velocity pressure (1.13)–(1.14), which requires the property of the maximum principle, are truncated, whereas this truncation is not necessary for scheme (1.7)–(1.10). Moreover, in (1.12) the convective term for the density scheme is considered in the explicit form $(\boldsymbol{u}_h^n\cdot\nabla\rho_h^n, \bar{\rho}_h)$, and it is now taken in the semi-implicit form $(\boldsymbol{w}_h^n\cdot\nabla\rho_h^{n+1}, \bar{\rho}_h)$, where $\boldsymbol{w}_h^n$ is a projection of $\boldsymbol{u}_h^n$ onto a discrete zero-divergence space. This space is chosen to hold $(\nabla\cdot\boldsymbol{w}_h^n, \bar{\rho}_h\bar{\rho}_h) = 0$ for all $\bar{\rho}_h \in W_h$.

Concerning the numerical analysis we remark on the following three main differences between both schemes:

1. The argument to obtain pointwise estimates for the discrete density under the constraints (S) done in subsection 3.4 of this paper is completely new. Moreover, the extension of this argument to the scheme studied in [11] is not clear even assuming some constraints on the discrete parameters. This justifies the presence of the truncation operator in the discrete momentum system (1.13). On the other hand, the scheme (1.12)–(1.14) of [11] is unconditionally stable, and now the scheme (1.7)–(1.10) is stable and convergent under the constraint (S).
2. Strong estimates for the discrete density are obtained in two different ways in [11] and in the present paper. In [11], we used the discrete version of the *Gagliardo–Nirenberg* interpolation inequality $\|\nabla\rho\|_{L^4}^2 \le C\,\|\rho\|_{H^1}\|\Delta\rho\|_{L^2}$ which does not need pointwise estimates for the discrete density. Since this interpolation is exclusive for two-dimensional domains, we cannot use it for three-dimensional domains. Accordingly, we change this Gagliardo–Nirenberg interpolation by a discrete version of the interpolation inequality $\|\nabla\rho\|_{L^4}^2 \le C\,\|\rho\|_{L^\infty}\|\Delta\rho\|_{L^2}$ and make a discrete integration by parts (which mimics the argument of the exact problem to obtain strong estimates of the density). Observe that we have to assure a maximum principle or at least pointwise estimates for the discrete density in order for this other interpolation to work.
3. Another difference is the asymptotic behavior with respect to the diffusion parameter λ (jointly with the discretization parameters (k,h)). Due to the fact that the convective term of the discrete density equation is handled in

different ways, we find that the strong estimates of the discrete density furnished in [11] degenerate when $\lambda \to 0$, and we cannot pass to the limit towards a weak solution of the density-dependent Navier–Stokes problem (1.6). However, now the dependence of λ is improved, and the scheme (1.14)–(1.10) gives a numerical approximation for the density-dependent Navier–Stokes problem (1.6) by means of continuous finite elements.

The rest of the paper can be described as follows. The main ideas for the mathematical analysis of problem (1.1)–(1.3) are provided in section 2. In section 3, by using appropriate auxiliary schemes, we establish conditional stability estimates, energy estimates for the velocity, and pointwise estimates for the density. In section 4, strong estimates for the density are obtained, by using the discrete Laplacian of the density. In sections 5, 6, and 7, weak and strong convergences and the passage to the limit are shown, respectively, concluding the proof of Theorem 1.1. In section 8, we study the asymptotic behavior as the diffusion parameter λ goes to zero, proving Theorem 1.2.

2. Analysis of the continuous model. To define the concept of a weak solution of problem (1.1)–(1.3), we introduce the following function spaces:

$$\begin{aligned}
\boldsymbol{H} &= \{\boldsymbol{u} : \boldsymbol{u} \in \boldsymbol{L}^2(\Omega), \nabla \cdot \boldsymbol{u} = 0 \text{ in } \Omega, \boldsymbol{u} \cdot \boldsymbol{n} = 0 \text{ on } \Gamma\},\\
\boldsymbol{V} &= \{\boldsymbol{u} : \boldsymbol{u} \in \boldsymbol{H}_0^1(\Omega), \nabla \cdot \boldsymbol{u} = 0 \text{ in } \Omega\},\\
L_0^2(\Omega) &= \left\{ p : p \in L^2(\Omega), \int_\Omega p(\boldsymbol{x}) d\boldsymbol{x} = 0 \right\},\\
H_N^2(\Omega) &= \left\{ \rho \in H^2(\Omega) : \frac{\partial \rho}{\partial \boldsymbol{n}} = 0 \text{ on } \Gamma, \int_\Omega \rho(\boldsymbol{x}) d\boldsymbol{x} = \int_\Omega \rho_0(\boldsymbol{x}) d\boldsymbol{x} \right\}.
\end{aligned}$$

In $\boldsymbol{V}$ the $\|\boldsymbol{u}\|_{H^1(\Omega)}$-norm is equivalent to $|\nabla \boldsymbol{u}|$ (which will be denoted by $\|\boldsymbol{u}\|$). $H_N^2(\Omega)$ is an affine space: $H_N^2(\Omega) = \frac{1}{|\Omega|}\int_\Omega \rho_0(\boldsymbol{x})d\boldsymbol{x} + H_{N,0}^2(\Omega)$, and in $H_{N,0}^2(\Omega)$ (zero-average function space) the norm $\|\rho\|_{H^1(\Omega)}$ is equivalent to $|\nabla\rho|$ and the norm $\|\rho\|_{H^2(\Omega)}$ is equivalent to $|\Delta\rho|$. In particular, in $H_N^2(\Omega)$ the following norms are equivalents: $\|\rho - \frac{1}{|\Omega|}\int_\Omega \rho_0\|_{H^1(\Omega)} \sim |\nabla\rho|$ and $\|\nabla\rho\|_{H^1(\Omega)} \sim |\Delta\rho|$.

DEFINITION 2.1. *A pair* $(\rho, \boldsymbol{u})$ *is called a weak solution of* (1.1)–(1.3) *in* $(0,T)$ *if it verifies:*

(a) $\boldsymbol{u} \in L^\infty(0,T;\boldsymbol{H}) \cap L^2(0,T;\boldsymbol{V})$, $\rho \in L^\infty(0,T;H^1(\Omega)) \cap L^2(0,T;H_N^2(\Omega))$, *with* $0 < m \le \rho(\boldsymbol{x},t) \le M$, *a.e.* $(\boldsymbol{x},t) \in Q$.

(b) $\forall\, \phi \in C^1([0,T];\boldsymbol{V})$ *such that* $\phi(T) = 0$,

$$\begin{aligned}
&\int_0^T \left\{ -\Big(\boldsymbol{u}, \rho\phi_t + (\rho\boldsymbol{u} - \lambda\nabla\rho)\cdot\nabla\phi\Big) + \Big(\mu\nabla\boldsymbol{u} - \lambda\rho(\nabla\boldsymbol{u})^t, \nabla\phi\Big)\right\} dt\\
&= \int_0^T \Big(\rho\boldsymbol{f}, \phi\Big)\, dt + \Big(\rho_0\boldsymbol{u}_0, \phi(0)\Big).
\end{aligned}$$

(c) *The equation of mass diffusion* $(1.1)_c$ *is verified a.e. in* Q.

Remark 2.2. As usual, the pressure p can be obtained by using (b) and De Rham's lemma [18].

We state the existence of (global in time) weak solutions of problem (1.1)–(1.3) (see [12, 1]).

THEOREM 2.3. *Let* $\boldsymbol{u}_0 \in \boldsymbol{H}$, $\rho_0 \in H^1(\Omega)$ *satisfying* (1.4), *and* $\boldsymbol{f} \in L^2(0,T;\boldsymbol{L}^{6/5}(\Omega))$. *Suppose that the constants* λ, μ, m, *and* M *satisfy* (1.5). *Then there exists at least a weak solution of* (1.1)–(1.3) *in* $(0,T)$.

Proof (outline of proof). The proof is divided into four steps:

(a) Pointwise estimates for the density. From the maximum principle applied to the density equation $(1.1)_c$ and hypothesis (1.4), one gets

$$0 < m \leq \rho(\boldsymbol{x}, t) \leq M \quad \text{in} \quad Q.$$

(b) Weak estimates for the velocity. Adding the momentum system $(1.1)_a$ by $\boldsymbol{u}$ to the density equation $(1.1)_c$ by $\frac{1}{2}\boldsymbol{u}\cdot\boldsymbol{u}$, one arrives at the following energy equality:

$$\frac{1}{2}\frac{d}{dt}\int_\Omega \rho|\boldsymbol{u}|^2 d\boldsymbol{x} + \mu\|\boldsymbol{u}\|^2 = \lambda\int_\Omega \rho(\nabla\boldsymbol{u})^t : \nabla\boldsymbol{u}\, d\boldsymbol{x} + (\rho\boldsymbol{f}, \boldsymbol{u}). \tag{2.1}$$

The first term on the right-hand side of (2.1) can be rewritten as

$$\lambda\int_\Omega \rho(\nabla\boldsymbol{u})^t : \nabla\boldsymbol{u}\, d\boldsymbol{x} = \lambda\int_\Omega \left(\rho - \frac{M+m}{2}\right)(\nabla\boldsymbol{u})^t : \nabla\boldsymbol{u}\, d\boldsymbol{x} \leq \lambda\frac{M-m}{2}\|u\|^2,$$

where we have used the pointwise inequality $|\,\rho - (M+m)/2\,| \leq (M-m)/2$ (obtained from $m \leq \rho \leq M$). By imposing the constraint on the coefficients (1.5), one arrives at the estimate

$$\max_{0\leq t\leq T}|\boldsymbol{u}(t)|^2 + \int_0^T \|\boldsymbol{u}(t)\|^2 dt \leq C.$$

(c) Strong estimates for the density. By multiplying the density equation $(1.1)_c$ by $-\Delta\rho$ and bounding the convective term (previously integrated by parts) thanks to the interpolation inequality

$$\|\nabla\rho\|_{L^4(\Omega)} \leq C\|\rho\|_\infty^{1/2}|\Delta\rho|^{1/2} \leq C|\Delta\rho|^{1/2}, \tag{2.2}$$

as

$$\int_\Omega \boldsymbol{u}\cdot\nabla\rho\,\Delta\rho \leq C\int_\Omega |\nabla\boldsymbol{u}|\,|\nabla\rho|^2 \leq C\,|\nabla\boldsymbol{u}|\,\|\nabla\rho\|_{L^4}^2 \leq C\,|\nabla\boldsymbol{u}|\,|\Delta\rho|,$$

the following estimate holds:

$$\max_{0\leq t\leq T}|\nabla\rho(t)|^2 + \int_0^T |\Delta\rho(t)|^2 dt \leq C_\lambda.$$

(d) Compactness for the velocity. By using a rather technical argument [1], one can get the following estimate of the "time fractional derivative":

$$\int_0^{T-\delta} |\boldsymbol{u}(t+\delta) - \boldsymbol{u}(t)|^2\, dt \leq C_\lambda\,\delta^{1/2} \quad \forall\delta \in (0,T),$$

which implies [17] compactness for the velocity $\boldsymbol{u}$ in $L^2(0,T;\boldsymbol{L}^2(\Omega))$.

From here, it is rather standard to obtain the existence of weak solutions, by using, for instance, the *semi-Galerkin* method [1]. □

3. Weak and pointwise estimates. Since (1.7), (1.8), and (1.9)–(1.10) can be reduced to three independent algebraic linear systems, it suffices to check the uniqueness of the solution to guarantee that these problems are well-posed. In particular, the uniqueness will be a consequence of the weak and pointwise estimates that we will obtain in this section.

3.1. Hypotheses. Throughout this work the following hypotheses will be assumed:

(H0) Hypotheses for the data: Assume (1.5), and let $\widetilde{M} > M$ and $0 < \widetilde{m} < m$ such that $\lambda\frac{\widetilde{M}-\widetilde{m}}{2} < \mu$. Let $\boldsymbol{u}_0 \in \boldsymbol{V}$, $\rho_0 \in H^1(\Omega)$, with $0 < m \le \rho_0 \le M$ in Ω, and $\boldsymbol{f} \in L^2(0,T;\boldsymbol{L}^{6/5}(\Omega))$.

(H1) Assume that Ω is an open, bounded set of $\mathbb{R}^3$ whose boundary is polyhedral and such that the continuous dependence in H^2-norm of the Poisson–Neumann problem and in the $\boldsymbol{H}^2 \times H^1$-norm of the Stokes problem holds (see (4.4) and (3.6), respectively). This is verified, for example, if Ω is convex [8].

(H2) The triangulation of Ω and the discrete spaces verify

- the inverse inequalities:

$$|\nabla\bar\rho_h| \le C\,h^{-1}|\bar\rho_h|, \quad \|\nabla\bar\rho_h\|_{L^3(\Omega)} \le C\,h^{-1/2}|\nabla\bar\rho_h| \quad \forall\,\bar\rho_h \in W_h,$$
$$\|\bar\rho_h\|_{L^\infty(\Omega)} \le C\,h^{-1/2}\|\bar\rho_h\|_{H^1(\Omega)} \quad \forall\,\bar\rho_h \in W_h,$$

- and the interpolation errors:

$$\|\bar{\boldsymbol{u}} - \widetilde{J}_h\bar{\boldsymbol{u}}\|_{H^1(\Omega)} + \|\bar{\boldsymbol{u}} - J_h\bar{\boldsymbol{u}}\|_{H^1(\Omega)} \le C\,h|\bar{\boldsymbol{u}}|_{H^2(\Omega)} \quad \forall\,\bar{\boldsymbol{u}} \in \boldsymbol{H}^2(\Omega)\cap\boldsymbol{H}^1_0(\Omega),$$
$$|\bar p - \widetilde{K}_h\bar p| + |\bar p - K_h\bar p| \le C\,h|\bar p|_{H^1(\Omega)} \quad \forall\,\bar p \in H^1(\Omega)\cap L^2_0(\Omega),$$
$$\|\bar\rho - I_h\bar\rho\|_{L^\infty(\Omega)\cap W^{1,3}(\Omega)} \le C\,h^{1/2}|\bar\rho|_{H^2(\Omega)} \quad \forall\,\bar\rho \in H^2(\Omega),$$
$$|\bar\rho - I_h\bar\rho| + h\,\|\bar\rho - I_h\bar\rho\|_{H^1(\Omega)} \le C\,h^2|\bar\rho|_{H^2(\Omega)} \quad \forall\,\bar\rho \in H^2(\Omega),$$

where J_h, $\widetilde{J}_h$, K_h, $\widetilde{K}_h$, and I_h are interpolation operators from $\boldsymbol{H}^2(\Omega)\cap\boldsymbol{H}^1_0(\Omega)$ into $\boldsymbol{V}_h$, $\boldsymbol{H}^2(\Omega)\cap\boldsymbol{H}^1_0(\Omega)$ into $\widetilde{\boldsymbol{V}}_h$, $H^1(\Omega)\cap L^2_0(\Omega)$ into M_h, $H^1(\Omega)\cap L^2_0(\Omega)$ into $\widetilde{M}_h$, and $H^2(\Omega)$ into W_h, respectively. Here and in what follows, we denote by $|v|_{H^k(\Omega)} = \sum_{|\alpha|=k}|D^\alpha v|$ the standard seminorm of higher order derivatives.

(H3) Inf-sup conditions. There exist $\beta > 0$ and $\widetilde{\beta} > 0$ (independent of h) such that, $\forall\,\bar p_h \in M_h$ and $\forall\,\bar q_h \in \widetilde{M}_h$,

$$\|\bar p_h\|_{L^2_0(\Omega)} \le \beta \sup_{\bar{\boldsymbol{u}}_h \in \boldsymbol{V}_h\setminus\{0\}} \frac{\left(\bar p_h, \nabla\cdot\bar{\boldsymbol{u}}_h\right)}{\|\bar{\boldsymbol{u}}_h\|}, \quad \|\bar q_h\|_{L^2_0(\Omega)} \le \widetilde{\beta} \sup_{\bar{\boldsymbol{w}}_h \in \widetilde{\boldsymbol{V}}_h\setminus\{0\}} \frac{\left(\bar q_h, \nabla\cdot\bar{\boldsymbol{w}}_h\right)}{\|\bar{\boldsymbol{w}}_h\|}.$$

(H4) Compatibility condition between $\widetilde{M}_h$ and W_h: $(W_h\cdot W_h)\cap L^2_0(\Omega) \subset \widetilde{M}_h$, i.e.,

$$\forall\,\bar\rho^1_h,\,\bar\rho^2_h \in W_h, \quad \bar\rho^1_h\,\bar\rho^2_h - \frac{1}{|\Omega|}\int_\Omega \bar\rho^1_h(\boldsymbol{x})\,\bar\rho^2_h(\boldsymbol{x})\,d\boldsymbol{x} \in \widetilde{M}_h.$$

(H5) Compatibility condition between $(M_h, \widetilde{M}_h)$:

$$M_h \subset \widetilde{M}_h.$$

For instance, a way of defining the discrete spaces $(W_h, \boldsymbol{V}_h, M_h, \widetilde{\boldsymbol{V}}_h, \widetilde{M}_h)$ verifying (H2)–(H5) is the following: Let $\{\mathcal{T}_h\}_{h>0}$ be a regular, quasi-uniform family of triangulations of Ω, with $h = \max_{K\in\mathcal{T}_h} h_K$ (h_K = diameter of K), and

$$X^l_h = \{x_h \in C^0(\overline{\Omega}) \text{ such that } x_h|_K \in \mathbb{P}_l(K)\ \forall K \in \mathcal{T}_h,\}.$$

Then we define $W_h = X_h^1$. There are several possibilities to define $(\boldsymbol{V}_h, M_h)$ [8], by using the Taylor–Hood element $(\mathbb{P}_2 \times \mathbb{P}_1)$ or the minielement $(\mathbb{P}_1 + \text{bubble} \times \mathbb{P}_1)$, for instance. For the spaces $(\widetilde{\boldsymbol{V}_h}, \widetilde{M_h})$ we choose $\widetilde{\boldsymbol{V}_h} = \boldsymbol{X}_h^3 \cap \boldsymbol{H}_0^1(\Omega)$ and $\widetilde{M_h} = X_h^2 \cap L_0^2(\Omega)$.

Note that if $\boldsymbol{V}_h = \widetilde{\boldsymbol{V}_h}$ and $M_h = \widetilde{M_h}$ are chosen, we need not consider the projection problem (1.7).

Remark 3.1. Hypothesis (H4) implies that $(\nabla \cdot \boldsymbol{w}_h^n, \bar{\rho}_h^1 \bar{\rho}_h^2) = 0$ for all $\bar{\rho}_h^1, \bar{\rho}_h^2 \in W_h$ (this property will play an important role in our analysis). Indeed, we shall write

$$0 = \left(\nabla \cdot \boldsymbol{w}_h^n, \bar{\rho}_h^1 \bar{\rho}_h^2 - \frac{1}{|\Omega|}\int_\Omega \bar{\rho}_h^1 \bar{\rho}_h^2\right) = \left(\nabla \cdot \boldsymbol{w}_h^n, \bar{\rho}_h^1 \bar{\rho}_h^2\right) - \frac{1}{|\Omega|}\int_\Omega \bar{\rho}_h^1 \bar{\rho}_h^2 \int_\Omega \nabla \cdot \boldsymbol{w}_h^n$$
$$= \left(\nabla \cdot \boldsymbol{w}_h^n, \bar{\rho}_h^1 \bar{\rho}_h^2\right).$$

As a consequence, by taking $\bar{\rho}_h = 1$ in (1.8) we have that $\int_\Omega \rho_h^n = \int_\Omega \rho_h^0$, for each n. This property is the discrete version of the continuous one $\int_\Omega \rho(\boldsymbol{x}, t_1)\, d\boldsymbol{x} = \int_\Omega \rho(\boldsymbol{x}, t_2)\, d\boldsymbol{x}$ for any $t_1, t_2 \in [0, T]$, whose physical meaning is the conservation of mass.

3.2. Auxiliary truncated scheme. To prove a priori estimates for scheme (1.7)–(1.10), we will introduce an auxiliary scheme in which some of the densities appearing in the discrete problem of the momentum system are truncated between $\widetilde{m}$ and $\widetilde{M}$ as follows:

Initialization: Let $\boldsymbol{u}_h^0$ and ρ_h^0 be given as in scheme (1.7)–(1.10).

Time step $n+1$: Given $(\rho_h^n, \boldsymbol{u}_h^n, p_h^n) \in W_h \times \boldsymbol{V}_h \times M_h$,

1. find $(\boldsymbol{w}_h^n, q_h^n) \in \widetilde{\boldsymbol{V}_h} \times \widetilde{M_h}$ such that, for each $(\bar{\boldsymbol{w}}_h, \bar{q}_h) \in \widetilde{\boldsymbol{V}_h} \times \widetilde{M_h}$,

$$\left(\nabla \boldsymbol{w}_h^n, \nabla \bar{\boldsymbol{w}}_h\right) - \left(q_h^n, \nabla \cdot \bar{\boldsymbol{w}}_h\right) = \left(\nabla \boldsymbol{u}_h^n, \nabla \bar{\boldsymbol{w}}_h\right), \quad \left(\nabla \cdot \boldsymbol{w}_h^n, \bar{q}_h\right) = 0; \tag{3.1}$$

2. find $\rho_h^{n+1} \in W_h$ such that, for each $\bar{\rho}_h \in W_h$,

$$\left(\frac{\rho_h^{n+1} - \rho_h^n}{k}, \bar{\rho}_h\right) + \left(\boldsymbol{w}_h^n \cdot \nabla \rho_h^{n+1}, \bar{\rho}_h\right) + \lambda\left(\nabla \rho_h^{n+1}, \nabla \bar{\rho}_h\right) = 0; \tag{3.2}$$

3. find $(\boldsymbol{u}_h^{n+1}, p_h^{n+1}) \in \boldsymbol{V}_h \times M_h$ such that, for each $(\bar{\boldsymbol{u}}_h, \bar{p}_h) \in \boldsymbol{V}_h \times M_h$,

$$\left\{\begin{array}{l} \displaystyle\left([\rho_h^n]_T \frac{\boldsymbol{u}_h^{n+1} - \boldsymbol{u}_h^n}{k}, \bar{\boldsymbol{u}}_h\right) + \frac{1}{2}\left(\frac{[\rho_h^{n+1}]_T - [\rho_h^n]_T}{k}\boldsymbol{u}_h^{n+1}, \bar{\boldsymbol{u}}_h\right) \\ \qquad\qquad + a\left([\rho_h^{n+1}]_T, \boldsymbol{u}_h^{n+1}, \bar{\boldsymbol{u}}_h\right) \\ \displaystyle + c\left(\rho_h^{n+1}\boldsymbol{u}_h^n - \lambda \nabla \rho_h^{n+1}, \boldsymbol{u}_h^{n+1}, \bar{\boldsymbol{u}}_h\right) = \left([\rho_h^{n+1}]_T \boldsymbol{f}^{n+1}, \bar{\boldsymbol{u}}_h\right) + \left(p_h^{n+1}, \nabla \cdot \bar{\boldsymbol{u}}_h\right), \end{array}\right. \tag{3.3}$$

$$\left(\nabla \cdot \boldsymbol{u}_h^{n+1}, q_h\right) = 0. \tag{3.4}$$

Here the truncation $[\cdot]_T$ is defined as follows: Given $\rho_h \in W_h$, then

$$[\rho_h]_T(\boldsymbol{x}) = \left\{\begin{array}{ll} \rho_h(\boldsymbol{x}) & \text{if} \quad \rho_h(\boldsymbol{x}) \in [\widetilde{m}, \widetilde{M}], \\ \widetilde{m} & \text{if} \quad \rho_h(\boldsymbol{x}) < \widetilde{m}, \\ \widetilde{M} & \text{if} \quad \rho_h(\boldsymbol{x}) > \widetilde{M}. \end{array}\right.$$

The idea was to truncate in those density terms which required to hold either L^∞ estimates or positivity in order to obtain weak energy estimates (see the proof of Theorem 2.3).

We may again deduce that (3.1), (3.2), and (3.3)–(3.4) are well-posed problems, obtaining a priori estimates.

3.3. Weak estimates for the truncated scheme.

LEMMA 3.2. *The solution of scheme* (3.1)–(3.4) *verifies the following estimates:*

$$\text{(i)}\ \max_{0\le n\le N}|\boldsymbol{u}_h^n|\le C,\quad \text{(ii)}\ k\sum_{n=0}^{N}\|\boldsymbol{u}_h^n\|^2\le C,\quad \text{(iii)}\ \sum_{n=0}^{N-1}|\boldsymbol{u}_h^{n+1}-\boldsymbol{u}_h^n|^2\le C,$$

$$\text{(iv)}\ \max_{0\le n\le N}|\rho_h^n|\le C,\quad \text{(v)}\ \lambda k\sum_{n=0}^{N-1}|\nabla\rho_h^{n+1}|^2\le C,\quad \text{(vi)}\ \sum_{n=0}^{N-1}|\rho_h^{n+1}-\rho_h^n|^2\le C,$$

where $C>0$ depends on the data $(\rho_0,\boldsymbol{u}_0,\boldsymbol{f})$ but is independent of k,h, and λ.

Proof. To obtain a priori estimates for the velocity $(\boldsymbol{u}_h^n)$, we take $\bar{\boldsymbol{u}}_h=2k\boldsymbol{u}_h^{n+1}$ and $\bar{p}_h=p_h^{n+1}$ as test functions in (3.3)–(3.4), resulting in [11]:

$$\begin{aligned}&|\sqrt{[\rho_h^{n+1}]_T}\boldsymbol{u}_h^{n+1}|^2-|\sqrt{[\rho_h^n]_T}\boldsymbol{u}_h^n|^2+|\sqrt{[\rho_h^n]_T}(\boldsymbol{u}_h^{n+1}-\boldsymbol{u}_h^n)|^2+\mu_1k\|\boldsymbol{u}_h^{n+1}\|^2\\&\le 2k\Big([\rho_h^{n+1}]_T\boldsymbol{f}^{n+1},\boldsymbol{u}_h^{n+1}\Big)\le 2k\|[\rho_h^{n+1}]_T\|_{L^\infty(\Omega)}\|\boldsymbol{f}^{n+1}\|_{L^{6/5}(\Omega)}\|\boldsymbol{u}_h^{n+1}\|_{L^6(\Omega)}\\&\le\frac{\mu_1k}{2}\|\boldsymbol{u}_h^{n+1}\|^2+C\,k\|\boldsymbol{f}^{n+1}\|^2_{L^{6/5}(\Omega)}.\end{aligned}$$

Consequently,

$$\begin{aligned}&|\sqrt{[\rho_h^{n+1}]_T}\boldsymbol{u}_h^{n+1}|^2-|\sqrt{[\rho_h^n]_T}\boldsymbol{u}_h^n|^2+|\sqrt{[\rho_h^n]_T}(\boldsymbol{u}_h^{n+1}-\boldsymbol{u}_h^n)|^2\\&\quad+\frac{\mu_1}{2}k\|\boldsymbol{u}_h^{n+1}\|^2\le C\,k\|\boldsymbol{f}^{n+1}\|^2_{L^{6/5}(\Omega)}.\end{aligned}\tag{3.5}$$

By adding (3.5) for $n=0,\dots,r$ with any $r<N$, estimates (i), (ii), and (iii) hold.

On the other hand, to obtain weak energy estimates for the density (ρ_h^n), we take $\bar{\rho}_h=2\,k\,\rho_h^{n+1}$ in (3.2) and use the fact that $(\nabla\cdot\boldsymbol{w}_h^n,(\rho_h^{n+1})^2)=0$ (see Remark 3.1):

$$|\rho_h^{n+1}|^2-|\rho_h^n|^2+|\rho_h^{n+1}-\rho_h^n|^2+2\,\lambda\,k|\nabla\rho_h^{n+1}|^2=0.$$

By adding over n, one deduces estimates (iv), (v), and (vi). ∎

COROLLARY 3.3. *The following estimates hold:*

$$\text{(vii)}\ \max_{0\le n\le N}|\boldsymbol{w}_h^n|\le C,\quad \text{(viii)}\ k\sum_{n=0}^{N}\|\boldsymbol{w}_h^n\|^2\le C,$$

where $C>0$ is independent of k, h, and λ.

Proof. By taking $\bar{\boldsymbol{w}}_h=\boldsymbol{w}_h^n$ in (1.7) and using (H5), $(\nabla(\boldsymbol{w}_h^n-\boldsymbol{u}_h^n),\nabla\boldsymbol{w}_h^n)=0$, and hence one has $|\nabla\boldsymbol{w}_h^n|\le|\nabla\boldsymbol{u}_h^n|$. So from (ii) we get (viii). Now we are going to get estimate (vii) by using a duality technique and the constraint (S). Indeed, let $(\boldsymbol{z},\xi)\in(\boldsymbol{V}\cap\boldsymbol{H}^2(\Omega))\times(L^2_0(\Omega)\cap H^1(\Omega))$ be the strong solution of the Stokes problem

$$-\Delta\boldsymbol{z}+\nabla\xi=\boldsymbol{w}_h^n-\boldsymbol{u}_h^n,\quad\nabla\cdot\boldsymbol{z}=0\text{ in }\Omega,\quad\boldsymbol{z}=0\text{ on }\Gamma.\tag{3.6}$$

By taking $\boldsymbol{w}_h^n-\boldsymbol{u}_h^n$ as a test function in the variational formulation of (3.6), we get

$$|\boldsymbol{w}_h^n-\boldsymbol{u}_h^n|^2=\Big(\nabla\boldsymbol{z},\nabla(\boldsymbol{w}_h^n-\boldsymbol{u}_h^n)\Big)+\Big(\xi,\nabla\cdot(\boldsymbol{w}_h^n-\boldsymbol{u}_h^n)\Big).\tag{3.7}$$

Let $(\boldsymbol{z}_h, \xi_h) \in \widetilde{V_h} \times \widetilde{M_h}$ be the discrete approximation of (3.6) defined as

$$\begin{cases} \Big(\nabla \boldsymbol{z}_h, \nabla \bar{\boldsymbol{w}}_h\Big) - \Big(\xi_h, \nabla \cdot \bar{\boldsymbol{w}}_h\Big) = \Big(\boldsymbol{w}_h^n - \boldsymbol{u}_h^n, \bar{\boldsymbol{w}}_h\Big) \quad \forall \bar{\boldsymbol{w}}_h \in \widetilde{\boldsymbol{V}_h}, \\ \Big(\nabla \cdot \boldsymbol{z}_h, \bar{q}_h\Big) = 0 \quad \forall \bar{q}_h \in \widetilde{M_h}. \end{cases}$$

In view of hypothesis (H5), $(K_h\xi, \nabla \cdot (\boldsymbol{w}_h^n - \boldsymbol{u}_h^n)) = 0$, and hence we write (3.7) as follows:

$$|\boldsymbol{w}_h^n - \boldsymbol{u}_h^n|^2 = \Big(\nabla \boldsymbol{z} - \nabla \boldsymbol{z}_h, \nabla(\boldsymbol{w}_h^n - \boldsymbol{u}_h^n)\Big) + \Big(\nabla \boldsymbol{z}_h, \nabla(\boldsymbol{w}_h^n - \boldsymbol{u}_h^n)\Big) + \Big(\xi - K_h\xi, \nabla \cdot (\boldsymbol{w}_h^n - \boldsymbol{u}_h^n)\Big),$$

where K_h is the interpolation operator defined in hypothesis (H2). From (1.7), it follows that $(\nabla \boldsymbol{z}_h, \nabla(\boldsymbol{w}_h^n - \boldsymbol{u}_h^n)) = 0$. Thus, we find

$$\begin{aligned} &|\boldsymbol{w}_h^n - \boldsymbol{u}_h^n|^2 \le |\nabla \boldsymbol{z} - \nabla \boldsymbol{z}_h||\nabla(\boldsymbol{w}_h^n - \boldsymbol{u}_h^n)| + |\xi - K_h\xi||\nabla \cdot (\boldsymbol{w}_h^n - \boldsymbol{u}_h^n)| \\ &\le Ch(\|\boldsymbol{z}\|_{H^2(\Omega)} + \|\xi\|_{H^1(\Omega)})|\nabla(\boldsymbol{w}_h^n - \boldsymbol{u}_h^n)| \le Ch|\boldsymbol{w}_h^n - \boldsymbol{u}_h^n||\nabla(\boldsymbol{w}_h^n - \boldsymbol{u}_h^n)|, \end{aligned}$$

where in the second line we have used the approximation property (see [8]) $|\nabla \boldsymbol{z} - \nabla \boldsymbol{z}_h| \le C\, h(\|\boldsymbol{z}\|_{H^2} + \|\xi\|_{H^1})$, the interpolation error $|\xi - K_h\xi| \le C\, h\|\xi\|_{H^1(\Omega)}$ assumed in (H2), and the $H^2 \times H^1$ continuous dependency of the Stokes problem (3.6) $\|\boldsymbol{z}\|_{H^2(\Omega)} + \|\xi\|_{H^1(\Omega)} \le C\, |\boldsymbol{w}_h^n - \boldsymbol{u}_h^n|$ assumed in (H1).

Therefore, we have

$$|\boldsymbol{w}_h^n - \boldsymbol{u}_h^n| \le C\, h|\nabla(\boldsymbol{w}_h^n - \boldsymbol{u}_h^n)|. \tag{3.8}$$

Now, in view of (S), we may get $h \le Ck$ for (h, k) small enough. Then, since $k^{1/2}|\nabla \boldsymbol{w}_h^n| \le k^{1/2}|\nabla \boldsymbol{u}_h^n| \le C$ (thanks to the estimate $|\nabla \boldsymbol{w}_h^n| \le |\nabla \boldsymbol{u}_h^n|$ and estimate (ii) of Lemma 3.2), it is easy to see that $|\boldsymbol{w}_h^n| \le Ck^{1/2} + |\boldsymbol{u}_h^n| \le C$, and we get estimate (vii). ∎

3.4. Discrete maximum principle (of the truncated scheme). In this subsection we prove that the discrete density of scheme (3.2) has pointwise estimates by excess and defect with respect to the upper and lower bounds of the initial density ρ_0, respectively. Namely, we will see that $\widetilde{m} \le \rho_h^n \le \widetilde{M}$ in Ω for all k and h small enough satisfying constraint (S).

3.4.1. Study of an auxiliary time discrete scheme. We define a sequence (ρ^n) associated to $(\boldsymbol{w}_h^n)$ by means of the following time discrete scheme:

Initialization: Let $\rho^0 = \rho_0$.

Time step $n+1$: Given ρ^n, we compute $\rho^{n+1} \in H^2(\Omega)$, verifying

$$\frac{\rho^{n+1} - \rho^n}{k} + \boldsymbol{w}_h^n \cdot \nabla \rho^{n+1} - \lambda \Delta \rho^{n+1} = 0 \text{ in } \Omega, \quad \frac{\partial \rho^{n+1}}{\partial \boldsymbol{n}} = 0 \text{ on } \Gamma. \tag{3.9}$$

LEMMA 3.4. *Let* $\{\boldsymbol{w}_h^n\}_{n=0}^N \subset \boldsymbol{H}_0^1(\Omega)$ *such that* $k\sum_{n=0}^N \|\boldsymbol{w}_h^n\|^2 \le C$. *Then there exists a unique solution* $\rho^{n+1} \in H^2(\Omega)$ *of* (3.9), *which also verifies:*

$$\begin{aligned} &0 < m \le \rho^{n+1}(\boldsymbol{x}) \le M \quad \forall \boldsymbol{x} \in \Omega, \quad \forall\, n = 0, \dots, N-1, \\ &\lambda^2\, k \sum_{n=0}^{N-1} \|\rho^{n+1}\|_{H^2(\Omega)}^2 \le C, \end{aligned} \tag{3.10}$$

where $C > 0$ *is a constant independent of* k, h, *and* λ.

Proof. The proof of this lemma can be found in Appendix A. ∎

3.4.2. Error estimates between $\boldsymbol{\rho^{n+1}}$ and $\boldsymbol{\rho_h^{n+1}}$. Denote by $e_\rho^{n+1} = \rho^{n+1} - \rho_h^{n+1}$ the difference between the solutions of problems (3.9) and (3.2). Our intention now is to state the following error estimate:

$$\|e_\rho^{n+1}\|_{H^1(\Omega)} \leq C\left(\frac{h^2}{\lambda\sqrt{\lambda}k} + \frac{h\sqrt{h}}{\lambda^2 k} + \frac{hh^{1/4}}{\lambda^{3/2}k^{3/4}} + \frac{h}{\lambda\sqrt{k}}\right). \tag{3.11}$$

Indeed, by subtracting (3.9) multiplied by $\bar\rho_h \in W_h$ and (3.2), one has

$$\left(\frac{e_\rho^{n+1}-e_\rho^n}{k}, \bar\rho_h\right) + \Big(\boldsymbol{w}_h^n\cdot\nabla e_\rho^{n+1}, \bar\rho_h\Big) + \lambda\Big(\nabla e_\rho^{n+1}, \nabla\bar\rho_h\Big) = 0$$

for each $\bar\rho_h \in W_h$. By decomposing the convective term as

$$\Big(\boldsymbol{w}_h^n\cdot\nabla e_\rho^{n+1}, \bar\rho_h\Big) = \Big(\boldsymbol{w}_h^n\cdot\nabla(\rho^{n+1} - I_h\rho^{n+1}), \bar\rho_h\Big) + \Big(\boldsymbol{w}_h^n\cdot\nabla(I_h\rho^{n+1} - \rho_h^{n+1}), \bar\rho_h\Big),$$

taking $\bar\rho_h = 2k(e_\rho^{n+1} - \rho^{n+1} + I_h\rho^{n+1}) = 2\,k(I_h\rho^{n+1} - \rho_h^{n+1})$, with $I_h\rho^{n+1} \in W_h$, and using the fact that $(\nabla\cdot\boldsymbol{w}_h^n, \bar\rho_h^2) = 0$ for all $\bar\rho_h \in W_h$ (see Remark 3.1), we get

$$\begin{aligned}
&|e_\rho^{n+1}|^2 - |e_\rho^n|^2 + |e_\rho^{n+1} - e_\rho^n|^2 + 2\lambda k|\nabla e_\rho^{n+1}|^2\\
&\leq 2\Big(e_\rho^{n+1} - e_\rho^n, \rho^{n+1} - I_h\rho^{n+1}\Big) - 2k\Big(\boldsymbol{w}_h^n\cdot\nabla(\rho^{n+1} - I_h\rho^{n+1}), e_\rho^{n+1}\Big)\\
&-k\Big(\nabla\cdot\boldsymbol{w}_h^n, (\rho^{n+1} - I_h\rho^{n+1})^2\Big) + 2\lambda\,k\Big(\nabla e_\rho^{n+1}, \nabla(\rho^{n+1} - I_h\rho^{n+1})\Big).
\end{aligned}$$

Next, by integrating by parts the second term on the right-hand side and bounding adequately, we infer that

$$\begin{aligned}
&|e_\rho^{n+1}|^2 - |e_\rho^n|^2 + |e_\rho^{n+1} - e_\rho^n|^2 + 2\lambda k|\nabla e_\rho^{n+1}|^2\\
&\leq 2|e_\rho^{n+1} - e_\rho^n|\,|\rho^{n+1} - I_h\rho^{n+1}| + Ck\|\boldsymbol{w}_h^n\|\,\|e_\rho^{n+1}\|_{H^1(\Omega)}\,\|\rho^{n+1} - I_h\rho^{n+1}\|_{L^3(\Omega)}\\
&+k\|\boldsymbol{w}_h^n\|\|\rho^{n+1} - I_h\rho^{n+1}\|^2_{L^4(\Omega)} + 2\lambda\,k|\nabla e_\rho^{n+1}|\,|\nabla(\rho^{n+1} - I_h\rho^{n+1})|\\
&\leq \frac{1}{2}|e_\rho^{n+1} - e_\rho^n|^2 + C|\rho^{n+1} - I_h\rho^{n+1}|^2 + C\lambda k|\nabla(\rho^{n+1} - I_h\rho^{n+1})|^2\\
&+\frac{C}{\lambda}k\|\boldsymbol{w}_h^n\|^2\|\rho^{n+1} - I_h\rho^{n+1}\|^2_{L^3} + k\|\boldsymbol{w}_h^n\|\|\rho^{n+1} - I_h\rho^{n+1}\|^2_{L^4} + \lambda k|e_\rho^{n+1}|^2 + \lambda k|\nabla e_\rho^{n+1}|^2,
\end{aligned}$$

and then, by taking into account the interpolation errors

$$|\rho^{n+1} - I_h\rho^{n+1}| + h|\nabla(\rho^{n+1} - I_h\rho^{n+1})| \leq C\,h^2\|\rho^{n+1}\|_{H^2},$$

and

$$\|\rho^{n+1} - I_h\rho^{n+1}\|_{L^3} \leq C\,h^{3/2}\|\rho^{n+1}\|_{H^2}, \qquad \|\rho^{n+1} - I_h\rho^{n+1}\|_{L^4} \leq C\,h^{5/4}\|\rho^{n+1}\|_{H^2}$$

(the last two are a consequence of the previous one and the 3D interpolation inequalities $\|\rho\|_{L^3} \leq C|\rho|^{1/2}\|\rho\|^{1/2}_{H^1}$ and $\|\rho\|_{L^4} \leq C|\rho|^{1/4}\|\rho\|^{3/4}_{H^1}$) and the estimate $k\|\boldsymbol{w}_h^n\|^2 \leq C$ thanks to estimate (vii) of Corollary 3.3, one arrives at

$$\begin{aligned}
&|e_\rho^{n+1}|^2 - |e_\rho^n|^2 + \lambda\,k\,|\nabla e_\rho^{n+1}|^2\\
&\qquad\leq C\left(h^4 + \frac{h^3}{\lambda} + k^{1/2}h^{5/2} + \lambda\,k\,h^2\right)\|\rho^{n+1}\|^2_{H^2} + \lambda\,k|e_\rho^{n+1}|^2.
\end{aligned}$$

By adding up for $n = 0, \dots, l$ and using the fact that $\lambda^2\, k \sum_{n=0}^{l} \|\rho^{n+1}\|_{H^2}^2 \le C$ and by virtue of the generalized discrete Gronwall lemma, we infer that for all (k, λ), with $\lambda\, k < 1$ (for instance, $\lambda\, k \le 1/2$), there exists $C > 0$ independent of λ such that

$$|e_\rho^{l+1}|^2 + \lambda\, k \sum_{n=0}^{l} |\nabla e_\rho^{n+1}|^2 \le C \left(\frac{h^4}{\lambda^2 k} + \frac{h^3}{\lambda^3 k} + \frac{h^{5/2}}{\lambda^2 k^{1/2}} + \frac{h^2}{\lambda} + |e_\rho^0|^2 \right).$$

By taking $|e_\rho^0|^2 = |\rho^0 - \rho_h^0|^2 \le C\, h^2$, we deduce the bound

$$|e_\rho^{n+1}|^2 + \lambda k \sum_{n=0}^{l} |\nabla e_\rho^{n+1}|^2 \le C \left(\frac{h^4}{\lambda^2 k} + \frac{h^3}{\lambda^3 k} + \frac{h^{5/2}}{\lambda^2 k^{1/2}} + \frac{h^2}{\lambda} \right),$$

whence, in particular, (3.11) holds.

3.4.3. Pointwise estimates of the truncated scheme. Here we will prove the following pointwise estimates [6]:

$$\begin{aligned} \rho_h^{n+1} &\ge m - C\, h^{-1/2} \left(\frac{h^2}{\lambda^{3/2} k} + \frac{h\sqrt{h}}{\lambda^2 k} + \frac{h h^{1/4}}{\lambda^2 k^{3/4}} + \frac{h}{\lambda\sqrt{k}} \right), \\ \rho_h^{n+1} &\le M + C\, h^{-1/2} \left(\frac{h^2}{\lambda^{3/2} k} + \frac{h\sqrt{h}}{\lambda^2 k} + \frac{h h^{1/4}}{\lambda^2 k^{3/4}} + \frac{h}{\lambda\sqrt{k}} \right). \end{aligned} \tag{3.12}$$

To prove (3.12) it suffices to prove that

$$\|\rho_h^{n+1} - \rho^{n+1}\|_{L^\infty(\Omega)} \le C\, h^{-1/2} \left(\frac{h^2}{\lambda^{3/2} k} + \frac{h\sqrt{h}}{\lambda^2 k} + \frac{h h^{1/4}}{\lambda^2 k^{3/4}} + \frac{h}{\lambda\sqrt{k}} \right).$$

For this, from the triangle inequality

$$\begin{aligned} \|\rho_h^{n+1} - \rho^{n+1}\|_{L^\infty(\Omega)} &\le \|\rho_h^{n+1} - I_h \rho^{n+1}\|_{L^\infty(\Omega)} + \|I_h \rho^{n+1} - \rho^{n+1}\|_{L^\infty(\Omega)} \\ &\le \|\rho_h^{n+1} - I_h \rho^{n+1}\|_{L^\infty(\Omega)} + C\, \frac{h^{1/2}}{\lambda\, k^{1/2}}, \end{aligned}$$

where in the last line we have used the approximation inequality $\|\rho^{n+1} - I_h \rho^{n+1}\|_{L^\infty} \le C\, h^{1/2} \|\rho^{n+1}\|_{H^2}$ and the estimate $\|\rho^{n+1}\|_{H^2} \le \frac{C}{\lambda\, k^{1/2}}$ (see (3.10)). Hence, it suffices to obtain the inequality

$$\|\rho_h^{n+1} - I_h \rho^{n+1}\|_{H^1(\Omega)} \le C \left(\frac{h^2}{\lambda^{3/2} k} + \frac{h\sqrt{h}}{\lambda^2 k} + \frac{h h^{1/4}}{\lambda^2 k^{3/4}} + \frac{h}{\lambda\sqrt{k}} \right) \tag{3.13}$$

and to use the inverse inequality (see [3]) $\|\bar\rho_h\|_{L^\infty(\Omega)} \le C\, h^{-1/2}\, \|\bar\rho_h\|_{H^1(\Omega)}\ \forall \bar\rho_h \in W_h$. Let us prove (3.13). From the triangle inequality,

$$\|\rho_h^{n+1} - I_h \rho^{n+1}\|_{H^1(\Omega)} \le \|\rho_h^{n+1} - \rho^{n+1}\|_{H^1(\Omega)} + \|\rho^{n+1} - I_h \rho^{n+1}\|_{H^1(\Omega)},$$

and, by using the error estimate (3.11) and the interpolation error $\|w - I_h w\|_{H^1(\Omega)} \le h \|w\|_{H^2(\Omega)}$ for $w = \rho^{n+1}$ jointly with the estimate $h\|\rho^{n+1}\|_{H^2} \le C\, h/\lambda\sqrt{k}$ (thanks to (3.10)), one easily deduces (3.13).

Now, by taking into account hypothesis (S), one has

$$\lim_{(h,k)\to 0}\left(\frac{h^2}{k}+\frac{h\sqrt{h}}{k}+\frac{hh^{1/4}}{k^{3/4}}\right)\Big/\left(\frac{h}{\sqrt{k}}\right)=0,$$

and consequently, for each (h,k) small enough,

$$C\,h^{-1/2}\left(\frac{h^2}{\lambda^{3/2}k}+\frac{h\sqrt{h}}{\lambda^2 k}+\frac{h}{\lambda\sqrt{k}}\right)\le C\,h^{-1/2}\frac{h}{\sqrt{k}}=C\sqrt{\frac{h}{k}}.$$

In particular, thanks to (3.12), by imposing $h\le h_0$, $k\le k_0$ such that

$$C\sqrt{\frac{h}{k}}\le \min\{m-\widetilde{m},\widetilde{M}-M\}, \tag{3.14}$$

one gets $0<\widetilde{m}\le \rho_h^{n+1}\le \widetilde{M}$.

3.4.4. Identification between the truncated and nontruncated schemes. Now it is clear that if ρ_h^{n+1} is the solution of the truncated scheme, then $[\rho_h^{n+1}]_T=\rho_h^{n+1}$, and consequently the truncated scheme and the nontruncated scheme coincide, arriving at the following result.

THEOREM 3.5. *Assume that $h\le h_0$, $k\le k_0$ satisfying* (3.14) *and $\lambda\,k\le 1/2$; then scheme* (1.7)–(1.10) *is well-posed and verifies estimates* (i)–(vi) *of Lemma* 3.2, (vii)–(viii) *of Corollary* 3.3, *and $0<\widetilde{m}\le\rho_h^{n+1}\le\widetilde{M}$ in Ω.*

4. Strong estimates for the density. Let $-\Delta_h : W_h\to W_h$ be the linear operator defined as follows:

$$-\Big(\Delta_h\rho_h,\bar\rho_h\Big)=\Big(\nabla\rho_h,\nabla\bar\rho_h\Big)\quad\forall\,\bar\rho_h\in W_h. \tag{4.1}$$

Then the discrete density equation (1.8) can be rewritten as

$$\left(\frac{\rho_h^{n+1}-\rho_h^n}{k},\bar\rho_h\right)+\Big(\boldsymbol{w}_h^n\cdot\nabla\rho_h^{n+1},\bar\rho_h\Big)-\lambda\Big(\Delta_h\rho_h^{n+1},\bar\rho_h\Big)=0. \tag{4.2}$$

THEOREM 4.1. *Under the hypotheses of Theorem* 3.5, *the solution ρ_h^{n+1} of scheme* (1.8) *verifies the following estimates, for each h and k small enough:*

$$\text{(ix) } \lambda\max_{0\le n\le N}|\nabla\rho_h^n|^2\le C,\qquad \text{(x) } \lambda^2\,k\sum_{n=0}^{N}|\Delta_h\rho_h^{n+1}|^2\le C,$$
$$\text{(xi) } \lambda\sum_{n=0}^{N-1}|\nabla(\rho_h^{n+1}-\rho_h^n)|^2\le C,$$

where $C>0$ is independent of h, k, and λ.

Proof. By taking $\bar\rho_h=-2k\Delta_h\rho_h^{n+1}$ in (4.2), we arrive at:

$$|\nabla\rho_h^{n+1}|^2-|\nabla\rho_h^n|^2+|\nabla(\rho_h^{n+1}-\rho_h^n)|^2+2\lambda k|\Delta_h\rho_h^{n+1}|^2=2k\Big(\boldsymbol{w}_h^n\cdot\nabla\rho_h^{n+1},\Delta_h\rho_h^{n+1}\Big):=I. \tag{4.3}$$

To bound I, we use an idea given in [11], where a regular function associated to the discrete Laplacian function $-\Delta_h\rho_h^{n+1}$ is considered. But here, the type of estimates

used in [11] must be changed, making use of the pointwise estimates of ρ_h^{n+1}. We define $\rho(h) \in H^2(\Omega)$ as the solution of the problem:

$$-\Delta\rho(h) = -\Delta_h \rho_h^{n+1} \ \text{ in } \Omega, \quad \frac{\partial \rho(h)}{\partial \boldsymbol{n}}\Big|_{\partial\Omega} = 0, \quad \int_\Omega \rho(h) = \int_\Omega \rho_h^0. \tag{4.4}$$

From the H^2-regularity of the previous problem $\|\rho(h) - \frac{1}{|\Omega|}\int \rho_h^0\|_{H^2(\Omega)} \le C\,|\Delta_h \rho_h^{n+1}|$, and hence one has in particular

$$|\rho(h)|_{H^2(\Omega)} \le C|\Delta_h \rho_h^{n+1}|. \tag{4.5}$$

We write I as $I = 2k(\boldsymbol{w}_h^n \cdot \nabla\rho(h), \Delta\rho(h)) + 2k(\boldsymbol{w}_h^n \cdot \nabla(\rho_h^{n+1} - \rho(h)), \Delta_h\rho_h^{n+1})$. By integrating by parts the first term on the right-hand side, and using (2.2),

$$\begin{aligned} 2k\Big(\boldsymbol{w}_h^n \cdot \nabla\rho(h), \Delta\rho(h)\Big) &= -2k\Big(\nabla \boldsymbol{w}_h^n, \nabla\rho(h) \otimes \nabla\rho(h)\Big) - 2k\Big((\boldsymbol{w}_h^n \cdot \nabla)\nabla\rho(h), \nabla\rho(h)\Big) \\ &= -2k\Big(\nabla \boldsymbol{w}_h^n, \nabla\rho(h) \otimes \nabla\rho(h)\Big) + k\Big(\nabla \cdot \boldsymbol{w}_h^n, |\nabla\rho(h)|^2\Big) \\ &\le C\,k\|\boldsymbol{w}_h^n\|\|\nabla\rho(h)\|_{L^4(\Omega)}^2 \le C\,k\|\boldsymbol{w}_h^n\|\,\|\rho(h)\|_{L^\infty(\Omega)}|\Delta\rho(h)| \\ &\le C\,k\|\boldsymbol{w}_h^n\|\,\|\rho(h)\|_{L^\infty(\Omega)}|\Delta_h\rho_h^{n+1}|, \end{aligned}$$

where $\boldsymbol{a} \otimes \boldsymbol{b}$ denotes the tensorial product matrix of two vectors $\boldsymbol{a} = (a_i)_{i=1}^2, \boldsymbol{b} = (b_i)_{i=1}^2$, with coefficients $(\boldsymbol{a} \otimes \boldsymbol{b})_{i,j} = a_i b_j$. Accordingly,

$$I \le C\,k\|\boldsymbol{w}_h^n\|\Big(\|\rho(h)\|_{L^\infty(\Omega)} + \|\nabla(\rho_h^{n+1} - \rho(h))\|_{L^3(\Omega)}\Big)|\Delta_h\rho_h^{n+1}|. \tag{4.6}$$

Now we will prove the inequality:

$$\|\nabla(\rho_h^{n+1} - \rho(h))\|_{L^3(\Omega)} \le C\,h^{1/2}|\rho(h)|_{H^2(\Omega)}. \tag{4.7}$$

For this, we write

$$\|\nabla(\rho_h^{n+1} - \rho(h))\|_{L^3} \le \|\nabla(\rho_h^{n+1} - I_h\rho(h))\|_{L^3} + \|\nabla(I_h\rho(h) - \rho(h))\|_{L^3}. \tag{4.8}$$

By multiplying (4.4) by $\bar\rho_h \in W_h$ and subtracting to (4.1), one gets

$$\Big(\nabla\rho_h^{n+1} - \nabla\rho(h), \nabla\bar\rho_h\Big) = 0 \quad \forall\,\bar\rho_h \in W_h.$$

By adding and subtracting $\nabla I_h\rho(h)$, and considering $\bar\rho_h = \rho_h^{n+1} - I_h\rho(h) \in W_h$, we obtain

$$\begin{aligned} |\nabla\rho_h^{n+1} - \nabla I_h\rho(h)|^2 &= -\Big(\nabla I_h\rho(h) - \nabla\rho(h), \nabla\rho_h^{n+1} - \nabla I_h\rho(h)\Big) \\ &\le |\nabla I_h\rho(h) - \nabla\rho(h)|\,|\nabla\rho_h^{n+1} - \nabla I_h\rho(h)|, \end{aligned}$$

whence

$$|\nabla\rho_h^{n+1} - \nabla I_h\rho(h)| \le |\nabla I_h\rho(h) - \nabla\rho(h)| \le C\,h|\rho(h)|_{H^2(\Omega)} \tag{4.9}$$

$$|\nabla\rho_h^{n+1} - \nabla\rho(h)| \le C\,h|\rho(h)|_{H^2(\Omega)}. \tag{4.10}$$

Thus, by using the inverse inequality [7]

$$\|\nabla\rho_h^{n+1} - \nabla I_h\rho(h)\|_{L^3(\Omega)} \le Ch^{-1/2}|\nabla\rho_h^{n+1} - \nabla I_h\rho(h)|$$

and (4.9), we arrive at

$$\|\nabla\rho_h^{n+1} - \nabla I_h\rho(h)\|_{L^3(\Omega)} \le C\,h^{1/2}|\rho(h)|_{H^2(\Omega)}. \tag{4.11}$$

So, from (4.8) and (4.11) one gets (4.7) by taking into account the interpolation error $\|\nabla(\rho(h) - I_h\rho(h))\|_{L^3(\Omega)} \le Ch^{1/2}|\rho(h)|_{H^2(\Omega)}$.

By getting back to (4.6) and using (4.7), we bound

$$I \le C\,k\|\boldsymbol{w}_h^n\|\Big(\|\rho(h) - \rho_h^{n+1}\|_{L^\infty} + \|\rho_h^{n+1}\|_{L^\infty} + h^{1/2}|\rho(h)|_{H^2}\Big)|\Delta_h\rho_h^{n+1}|. \tag{4.12}$$

Now we write

$$\|\rho_h^{n+1} - \rho(h)\|_{L^\infty(\Omega)} \le \|\rho_h^{n+1} - I_h\rho(h)\|_{L^\infty(\Omega)} + \|I_h\rho(h) - \rho(h)\|_{L^\infty(\Omega)}.$$

By using the interpolation error $\|\rho(h)-I_h\rho(h)\|_{L^\infty(\Omega)} \le Ch^{1/2}|\rho(h)|_{H^2(\Omega)}$, the inverse inequality in 3D

$$\begin{aligned}\|\rho_h^{n+1} - I_h\rho(h)\|_{L^\infty(\Omega)} &\le C\,h^{-1/2}\|\rho_h^{n+1} - I_h\rho(h)\|_{H^1(\Omega)}\\ &\le C\,h^{-1/2}(\|\rho_h^{n+1} - \rho(h)\|_{H^1(\Omega)} + \|\rho(h) - I_h\rho(h)\|_{H^1(\Omega)})\\ &\le C\,h^{-1/2}(|\nabla(\rho_h^{n+1} - \rho(h))| + h\,|\rho(h)|_{H^2(\Omega)}),\end{aligned}$$

where the generalized Poincare inequality has been used in the last line, since $\int_\Omega \rho_h^{n+1} = \int_\Omega \rho_h^0$ (see Remark 3.1) and $\int_\Omega \rho_h^0 = \int_\Omega \rho(h)$ (see (4.4)). By using (4.10) and (4.5),

$$\|\rho_h^{n+1} - \rho(h)\|_{L^\infty(\Omega)} \le C\,h^{1/2}|\rho(h)|_{H^2(\Omega)} \le C\,h^{1/2}|\Delta_h\rho_h^{n+1}|.$$

By applying the above estimate in (4.12), we bound

$$\begin{aligned}I &\le C\,k\|\boldsymbol{w}_h^n\|\Big(h^{1/2}|\Delta_h\rho_h^{n+1}| + \widetilde{M}\Big)|\Delta_h\rho_h^{n+1}|\\ &\le C\,k\|\boldsymbol{w}_h^n\|h^{1/2}|\Delta_h\rho_h^{n+1}|^2 + \frac{C}{\lambda}k\|\boldsymbol{w}_h^n\|^2 + \frac{\lambda}{2}k|\Delta_h\rho_h^{n+1}|^2.\end{aligned}$$

By Corollary 3.3 we infer the bound $\|\boldsymbol{w}_h^n\| \le C/k^{1/2}$ (with C independent of λ, h, k), and, by choosing h and k small enough such that

$$C\sqrt{\frac{h}{k}} \le \frac{1}{2}\lambda,$$

we get

$$I \le \frac{C}{\lambda}k\|\boldsymbol{w}_h^n\|^2 + \lambda\,k|\Delta_h\rho_h^{n+1}|^2.$$

Therefore, from (4.3) we get the inequality

$$|\nabla\rho_h^{n+1}|^2 - |\nabla\rho_h^n|^2 + |\nabla(\rho_h^{n+1} - \rho_h^n)|^2 + \lambda k|\Delta_h\rho_h^{n+1}|^2 \le C\,\frac{k}{\lambda}\|\boldsymbol{w}_h^n\|^2. \tag{4.13}$$

By adding (4.13) for $n = 0, \dots, r$, with $r < N$, we arrive at

$$\lambda|\nabla\rho_h^{r+1}|^2 + \lambda\sum_{n=0}^{r}|\nabla(\rho_h^{n+1} - \rho_h^n)|^2 + \lambda^2\,k\sum_{n=0}^{r}|\Delta_h\rho_h^{n+1}|^2 \le C\,k\sum_{n=0}^{r}\|\boldsymbol{w}_h^n\|^2 + \lambda|\nabla\rho_h^0|^2.$$

Finally, from estimate (ii) of Lemma 3.2, one gets the desired estimates (ix)–(xi). ∎

COROLLARY 4.2. *The following inequality holds:*

$$\|\nabla\rho_h^{n+1}\|_{L^3(\Omega)} \le C\,|\nabla\rho_h^{n+1}|^{1/2}|\Delta_h\rho_h^{n+1}|^{1/2}. \tag{4.14}$$

Consequently, under the hypotheses of Theorem 4.1*, one has the estimate*

$$\lambda^3 k\sum_{n=0}^{N-1}\|\rho_h^{n+1}\|_{W^{1,3}(\Omega)}^4 \le C,$$

where $C>0$ is independent of h,k, and λ.

Proof. Thanks to estimates (ix) for (ρ_h^n) and (x) for $(\Delta_h\rho_h^n)$, it suffices to prove (4.14). For this, by considering $\rho(h)$ the solution of problem (4.4), we have

$$\|\nabla\rho_h^{n+1}\|_{L^3(\Omega)} \le \|\nabla(\rho_h^{n+1}-\rho(h))\|_{L^3(\Omega)} + \|\nabla\rho(h)\|_{L^3(\Omega)}.$$

By using inequality (4.7) and the interpolation inequality

$$\|\nabla\rho(h)\|_{L^3(\Omega)} \le C|\nabla\rho(h)|^{1/2}\|\nabla\rho(h)\|_{H^1(\Omega)}^{1/2} \le C|\nabla\rho(h)|^{1/2}|\rho(h)|_{H^2(\Omega)}^{1/2},$$

we arrive at

$$\|\nabla\rho_h^{n+1}\|_{L^3(\Omega)} \le C\,h^{1/2}|\rho(h)|_{H^2(\Omega)} + C\,|\nabla\rho(h)|^{1/2}|\rho(h)|_{H^2(\Omega)}^{1/2}.$$

Next, we bound the term $|\nabla\rho(h)|$ by using (4.10) as follows:

$$|\nabla\rho(h)| \le |\nabla(\rho(h)-\rho_h^{n+1})| + |\nabla\rho_h^{n+1}| \le C\,h\,|\rho(h)|_{H^2(\Omega)} + |\nabla\rho_h^{n+1}|.$$

Therefore, by using (4.5)

$$\begin{aligned}\|\nabla\rho_h^{n+1}\|_{L^3(\Omega)} &\le C\,h^{1/2}|\rho(h)|_{H^2(\Omega)} + C\,|\nabla\rho_h^{n+1}|^{1/2}|\rho(h)|_{H^2(\Omega)}^{1/2}\\ &\le C\,h^{1/2}|\Delta_h\rho_h^{n+1}| + C\,|\nabla\rho_h^{n+1}|^{1/2}|\Delta_h\rho_h^{n+1}|^{1/2}.\end{aligned}$$

On the other hand, by considering $\bar\rho_h = -\Delta_h\rho_h^{n+1}$ in (4.1), we get

$$|\Delta_h\rho_h^{n+1}|^2 \le |\nabla\rho_h^{n+1}||\nabla\Delta_h\rho_h^{n+1}| \le \frac{C}{h}|\nabla\rho_h^{n+1}||\Delta_h\rho_h^{n+1}|,$$

where we have used the inverse inequality between L^2 and H^1. The last two estimates imply (4.14). ∎

5. Weak convergence. To study the convergence of scheme (1.8)–(1.10), we define the following functions.

DEFINITION 5.1. *One defines $\boldsymbol{u}_{h,k}$ (respectively, $\widehat{\boldsymbol{u}}_{h,k}$, $\widehat{\boldsymbol{w}}_{h,k}$, and $p_{h,k}$) as the piecewise constant functions taking values $\boldsymbol{u}_h^{n+1}$ on $(t_n,t_{n+1}]$ (respectively, $\boldsymbol{u}_h^n$, $\boldsymbol{w}_h^n$, and p_h^{n+1}). Analogously, we define $\rho_{h,k}$ and $\widehat\rho_{h,k}$. Moreover, one defines $\widetilde\rho_{h,k}\in C^0([0,T];\boldsymbol{V}_h)$ as the piecewise linear functions such that $\widetilde\rho_{h,k}(t_n)=\rho_h^n$.*

Lemma 3.2, Corollary 3.3, Theorem 3.5, Theorem 4.1, and Corollary 4.2 imply the following estimates (independent of h and k, but some of them depend on λ):

$$\begin{gathered}\{\boldsymbol{u}_{h,k}\}_{h,k},\ \{\widehat{\boldsymbol{u}}_{h,k}\}_{h,k},\ \{\widehat{\boldsymbol{w}}_{h,k}\}_{h,k} \text{ in } L^\infty(0,T;\boldsymbol{L}^2(\Omega))\cap L^2(0,T;\boldsymbol{H}_0^1(\Omega)),\\ \{\widetilde\rho_{h,k}\}_{h,k},\ \{\rho_{h,k}\}_{h,k},\ \{\widehat\rho_{h,k}\}_{h,k} \text{ in } L^\infty(0,T;H^1(\Omega))\cap L^\infty(Q),\\ \{\rho_{h,k}\}_{h,k} \text{ in } L^4(0,T;W^{1,3}(\Omega)).\end{gathered}$$

Now let us pass to the limit in both discrete free-divergence equations (1.10) and (3.1). Consider $q \in C^0([0,T];C^\infty(\Omega))$ such that $\int_\Omega q(\boldsymbol{x})\,d\boldsymbol{x}=0$, $q_h^n = K_h q(t_n) \in M_h$, and $\bar{q}_h^n = \widetilde{K}_h q(t_n) \in \widetilde{M}_h$. Define $q_{h,k}$ and $\bar{q}_{h,k}$ as $p_{h,k}$ in Definition 5.1. On the other hand, we know that there exist two limit functions $\boldsymbol{w}$ and $\boldsymbol{u}$ belonging to $\boldsymbol{H}_0^1(\Omega)$ such that $\boldsymbol{u}_{h,k} \to \boldsymbol{u}$ and $\boldsymbol{w}_{h,k} \to \boldsymbol{w}$ weakly in $L^2(0,T;\boldsymbol{H}_0^1(\Omega))$ as $(h,k) \to 0$. Thus, we write from (1.10)

$$0 = k\sum_{n=1}^{N}(\nabla\cdot\boldsymbol{u}_h^n, q_h^n) = \int_0^T (\nabla\cdot\boldsymbol{u}_{h,k}, q_{h,k})\,dt \to \int_0^T (\nabla\cdot\boldsymbol{u}, q)\,dt = 0$$

for all $q \in C^0([0,T];C^\infty(\Omega))$, with $\int_\Omega q(\boldsymbol{x})\,d\boldsymbol{x}=0$. A density argument says $\boldsymbol{u} \in \boldsymbol{V}$. In an analogous way, we can also prove that $\boldsymbol{w} \in \boldsymbol{V}$.

Next, we wish to derive a test function for (1.7), a discrete free-divergence approximation of a function $\boldsymbol{v} \in \boldsymbol{C}_c^\infty(\Omega)$, with $\nabla\cdot\boldsymbol{v}=0$.

LEMMA 5.2. *Let $\bar{\boldsymbol{w}} \in \boldsymbol{C}_c^\infty(\Omega)$. Then there exists $\bar{\boldsymbol{w}}_h \in \widetilde{\boldsymbol{V}}_h$ such that:*

$$\bar{\boldsymbol{w}}_h \to \bar{\boldsymbol{w}} \ \text{ in } \boldsymbol{H}_0^1(\Omega) \quad \text{and} \quad (\nabla\cdot\bar{\boldsymbol{w}}_h, \bar{q}_h) = (\nabla\cdot\bar{\boldsymbol{w}}, \bar{q}_h)\ \forall\,\bar{q}_h \in \widetilde{M}_h.$$

A proof of this result can be found in [11].

By taking into account previous arguments, we can arrive at the following result.

LEMMA 5.3. *Under the hypotheses of Theorem* 3.5 *there exist subsequences of $\{\boldsymbol{u}_{h,k}\}_{h,k}$, $\{\widehat{\boldsymbol{u}}_{h,k}\}_{h,k}$, $\{\widehat{\boldsymbol{w}}_{h,k}\}_{h,k}$, $\{\rho_{h,k}\}_{h,k,\lambda}$, $\{\widehat{\rho}_{h,k}\}_{h,k}$, and $\{\widetilde{\rho}_{h,k}\}_{h,k}$ (denoted in the same way) and limit functions $\boldsymbol{u}$, ρ verifying the following weak convergences as $(h,k) \to 0$:*

$$\boldsymbol{u}_{h,k} \to \boldsymbol{u}, \quad \widehat{\boldsymbol{u}}_{h,k} \to \boldsymbol{u}, \quad \widehat{\boldsymbol{w}}_{h,k} \to \boldsymbol{u} \quad \text{in} \begin{cases} L^2(0,T;\boldsymbol{H}_0^1(\Omega))\text{-weak}, \\ L^\infty(0,T;\boldsymbol{L}^2(\Omega))\text{-weak}*, \end{cases}$$

$$\rho_{h,k} \to \rho, \quad \widehat{\rho}_{h,k} \to \rho, \quad \widetilde{\rho}_{h,k} \to \rho \quad \text{in} \begin{cases} L^\infty(Q)\text{-weak}*, \\ L^\infty(0,T;H^1(\Omega))\text{-weak}*, \end{cases}$$

$$\widehat{\rho}_{h,k} \to \rho \ \text{in } L^4(0,T;W^{1,3}(\Omega))\text{-weak}.$$

Proof. Let us prove only that $\widehat{\boldsymbol{w}}_{h,k} \to \boldsymbol{u}$ in $L^2(0,T;\boldsymbol{H}_0^1(\Omega))$-weak. Consider $\boldsymbol{v} \in C^0([0,T];\boldsymbol{C}_c^\infty(\Omega))$, with $\nabla\cdot\boldsymbol{v}=0$ and $\boldsymbol{v}_h^n \in \widetilde{\boldsymbol{V}}_h$ an approximation of $\boldsymbol{v}(t_n)$ given by Lemma 5.2. Define $\boldsymbol{v}_{h,k} \in L^\infty(0,T;\widetilde{\boldsymbol{V}}_h)$ as the piecewise constant functions taking values $\boldsymbol{v}_h^{n+1}$ on $(t_n,t_{n+1}]$ which verifies $\boldsymbol{v}_{h,k} \to \boldsymbol{v}$ in $L^\infty(0,T;\boldsymbol{H}_0^1(\Omega))$. Next, by testing (1.7) by the test function $\boldsymbol{v}_h^n$, we have $(\nabla(\boldsymbol{w}_h^n - \boldsymbol{u}_h^n), \nabla\boldsymbol{v}_n^n) = 0$, since the pressure term vanishes. By multiplying by the time step k, summing over n, and passing to limit as (h,k) tend to zero, we infer that

$$\int_0^T (\nabla(\boldsymbol{w}-\boldsymbol{u}), \nabla\boldsymbol{v}) = 0 \quad \forall\boldsymbol{v} \in C^0([0,T];\boldsymbol{C}_c^\infty(\Omega)), \ \text{with } \nabla\cdot\boldsymbol{v}=0.$$

A density argument provides that this equality holds for any $\boldsymbol{v} \in L^2(0,T;\boldsymbol{V})$. Therefore, we can choose $\boldsymbol{v} = \boldsymbol{w}-\boldsymbol{u}$ (since $\nabla\cdot\boldsymbol{u} = 0$ and $\nabla\cdot\boldsymbol{w} = 0$); then $\boldsymbol{w}=\boldsymbol{u}$. ∎

6. Strong convergence. As usual for nonlinear systems, strong convergence in some suitable space is necessary to identify the limit of the nonlinear terms.

6.1. Strong convergence for the density in $L^2(\Omega)$.

LEMMA 6.1. *Under the hypotheses of Theorem* 4.1*, one has:*

$$k\sum_{n=0}^{N}\left|\frac{\rho_h^{n+1}-\rho_h^n}{k}\right|^{4/3}\leq C_\lambda,$$

where $C_\lambda>0$ is independent of h and k (but depends on λ).

Proof. We consider $P_h: L^2(\Omega)\to W_h$ the orthogonal projector, defined as $(P_hw-w,w_h)=0$ for any $w_h\in W_h$. Let $w\in L^2(\Omega)$. By taking in (1.8) as a test function $w_h=P_hw$, we arrive at

$$\left(\frac{\rho_h^{n+1}-\rho_h^n}{k},w\right)+\left(\boldsymbol{w}_h^n\cdot\nabla\rho_h^{n+1},P_hw\right)-\lambda\Big(\Delta_h\rho_h^{n+1},w\Big)=0,$$

where we have used the definition of P_h in the first and last terms. By taking into account the stability of the projector operator $|P_hw|\leq|w|$, we get

$$\left|\frac{\rho_h^{n+1}-\rho_h^n}{k}\right|\leq\|\boldsymbol{w}_h^n\|_{L^6(\Omega)}\|\nabla\rho_h^{n+1}\|_{L^3(\Omega)}+\lambda\,|\Delta_h\rho_h^{n+1}|.$$

By summing up over n and using the estimates of $\{\widehat{\boldsymbol{w}}_{h,k}\}_{h,k}$ in $L^2(0,T;\boldsymbol{L}^6(\Omega))$ (due to the estimates in $L^2(0,T;\boldsymbol{H}^1(\Omega))$), of $\{\lambda\,\Delta_h\rho_{h,k}\}_{h,k}$ in $L^2(0,T;L^2(\Omega))$, and of $\{\nabla\rho_{h,k}\}_{h,k}$ in $L^4(0,T;\boldsymbol{L}^3(\Omega))$ (this last estimate depends on λ), we can conclude the result. ∎

Remark 6.2. As a consequence of the previous lemma, the estimate

$$\left\|\frac{d}{dt}\widetilde{\rho}_{h,k}\right\|_{L^{4/3}(0,T;L^2(\Omega))}\leq C_\lambda$$

holds. On the other hand, from Lemma 3.2, we get $\|\widetilde{\rho}_{h,k}\|_{L^\infty(0,T;H^1(\Omega))}\leq C_\lambda$. Then, thanks to an Aubin–Lions compactness argument, one has $\widetilde{\rho}_{h,k}\to\rho$ in $L^\infty(0,T;L^p(\Omega))$ as $(h,k)\to0$, with $p<6$. From this convergence, we deduce that $\rho_{h,k}$, $\widehat{\rho}_{h,k}\to\rho$ in $L^2(0,T;L^2(\Omega))$ as $(h,k)\to0$, since

$$\|\widetilde{\rho}_{h,k}-\rho_{k,h}\|^2_{L^2(0,T;L^2(\Omega))}\leq\|\widehat{\rho}_{h,k}-\rho_{k,h}\|^2_{L^2(0,T;L^2(\Omega))}=k\sum_{n=0}^{N-1}|\rho_h^{n+1}-\rho_h^n|^2\leq C\,k.$$

6.2. Strong convergence for the velocity.

PROPOSITION 6.3. *Under the hypotheses of Theorem* 4.1*, the following estimate holds:*

$$\int_0^{T-\delta}\left|\sqrt{\rho_{h,k}(t+\delta)}(\boldsymbol{u}_{h,k}(t+\delta)-\boldsymbol{u}_{h,k}(t))\right|^2dt\leq C_\lambda\,\delta^{1/4}\quad\forall\,\delta:\quad0<\delta<T,\tag{6.1}$$

where $C_\lambda>0$ is independent of h, k, and δ (but depends on λ).

Proof. Throughout the proof we will keep in mind Lemmas 3.2 and 4.1 and Remark 3.3. As $\rho_{h,k}$ and $\boldsymbol{u}_{h,k}$ are piecewise constant functions, it suffices to suppose that δ is proportional to the time step k, i.e., $\delta=r\,k$ for any $r=0,\ldots,N$. Then, to obtain (6.1), it suffices to prove that

$$k\sum_{m=0}^{N-r}|\sqrt{\rho_h^{m+r}}(\boldsymbol{u}_h^{m+r}-\boldsymbol{u}_h^m)|^2\leq C_\lambda\,(r\,k)^{1/4}\quad\forall\,r:0\leq r\leq N.\tag{6.2}$$

Let us write the time derivative of the discrete momentum system (1.9) in conservative form. By adding at the right- and left-hand sides of (1.9) the term

$$\frac{1}{2}\left(\frac{\rho_h^{n+1}-\rho_h^n}{k}, \boldsymbol{u}_h^{n+1}\cdot\bar{\boldsymbol{u}}_h\right):$$

$$\begin{cases}\left(\dfrac{\rho_h^{n+1}\boldsymbol{u}_h^{n+1}-\rho_h^n\boldsymbol{u}_h^n}{k},\bar{\boldsymbol{u}}_h\right)+a\Big(\rho_h^{n+1},\boldsymbol{u}_h^{n+1},\bar{\boldsymbol{u}}_h\Big)-\Big(p_h^{n+1},\nabla\cdot\bar{\boldsymbol{u}}_h\Big)\\ +c\Big(\rho_h^{n+1}\boldsymbol{u}_h^n-\lambda\nabla\rho_h^{n+1},\boldsymbol{u}_h^{n+1},\bar{\boldsymbol{u}}_h\Big)=\Big(\rho_h^{n+1}\boldsymbol{f}^{\,n+1},\bar{\boldsymbol{u}}_h\Big)+\dfrac{1}{2}\left(\dfrac{\rho_h^{n+1}-\rho_h^n}{k},\boldsymbol{u}_h^{n+1}\cdot\bar{\boldsymbol{u}}_h\right).\end{cases} \tag{6.3}$$

By multiplying (6.3) by k and summing for $n=m,\dots,m-1+r$, we have

$$\begin{cases}\Big(\rho_h^{m+r}\boldsymbol{u}_h^{m+r}-\rho_h^m\boldsymbol{u}_h^m,\bar{\boldsymbol{u}}_h\Big)+k\displaystyle\sum_{n=m}^{m-1+r}a\Big(\rho_h^{n+1},\boldsymbol{u}_h^{n+1},\bar{\boldsymbol{u}}_h\Big)-\sum_{n=m}^{m-1+r}\Big(p_h^{n+1},\nabla\cdot\bar{\boldsymbol{u}}_h\Big)\\ +k\displaystyle\sum_{n=m}^{m-1+r}c\Big(\rho_h^{n+1}\boldsymbol{u}_h^n-\lambda\nabla\rho_h^{n+1},\boldsymbol{u}_h^{n+1},\bar{\boldsymbol{u}}_h\Big)\\ =k\displaystyle\sum_{n=m}^{m-1+r}\Big(\rho_h^{n+1}\boldsymbol{f}^{\,n+1},\bar{\boldsymbol{u}}_h\Big)+\frac{k}{2}\sum_{n=m}^{m-1+r}\left(\frac{\rho_h^{n+1}-\rho_h^n}{k},\boldsymbol{u}_h^{n+1}\cdot\bar{\boldsymbol{u}}_h\right).\end{cases}$$

By taking $\bar{\boldsymbol{u}}_h=\boldsymbol{u}_h^{m+r}-\boldsymbol{u}_h^m$ and making use of the identity

$$\rho_h^{m+r}\boldsymbol{u}_h^{m+r}-\rho_h^m\boldsymbol{u}_h^m=\rho_h^{m+r}(\boldsymbol{u}_h^{m+r}-\boldsymbol{u}_h^m)+(\rho_h^{m+r}-\rho_h^m)\boldsymbol{u}_h^m, \tag{6.4}$$

we get

$$\begin{cases}|\sqrt{\rho_h^{m+r}}(\boldsymbol{u}_h^{m+r}-\boldsymbol{u}_h^m)|^2=-\Big(\rho_h^{m+r}-\rho_h^m,\boldsymbol{u}_h^m\cdot(\boldsymbol{u}_h^{m+r}-\boldsymbol{u}_h^m)\Big)\\ -k\displaystyle\sum_{n=m}^{m-1+r}\Big\{a\Big(\rho_h^{n+1},\boldsymbol{u}_h^{n+1},\boldsymbol{u}_h^{m+r}-\boldsymbol{u}_h^m\Big)+c\Big(\rho_h^{n+1}\boldsymbol{u}_h^n-\lambda\nabla\rho_h^{n+1},\boldsymbol{u}_h^{n+1},\boldsymbol{u}_h^{m+r}-\boldsymbol{u}_h^m\Big)\Big\}\\ +k\displaystyle\sum_{n=m}^{m-1+r}\left\{\Big(\rho_h^{n+1}\boldsymbol{f}^{\,n+1},\boldsymbol{u}_h^{m+r}-\boldsymbol{u}_h^m\Big)+\frac{1}{2}\left(\frac{\rho_h^{n+1}-\rho_h^n}{k},\boldsymbol{u}_h^{n+1}\cdot(\boldsymbol{u}_h^{m+r}-\boldsymbol{u}_h^m)\right)\right\}.\end{cases} \tag{6.5}$$

On the other hand, by taking $\bar{\rho}_h=\rho_h^{m+r}-\rho_h^m$ as a test function in the density scheme (4.2), multiplying by k, and summing for $n=m,\dots,m-1+r$, we obtain

$$\begin{aligned}|\rho_h^{m+r}-\rho_h^m|^2&=-k\sum_{n=m}^{m-1+r}\Big(\boldsymbol{w}_h^n\cdot\nabla\rho_h^{n+1}-\lambda\,\Delta_h\rho_h^{n+1},\rho_h^m-\rho_h^{m+r}\Big)\\ &\le k\sum_{n=m}^{m-1+r}(\|\boldsymbol{w}_h^n\|_{\boldsymbol{L}^6(\Omega)}\|\nabla\rho_h^n\|_{\boldsymbol{L}^3(\Omega)}+\lambda|\Delta_h\rho_h^{n+1}|)|\rho_h^m-\rho_h^{m+r}|.\end{aligned}$$

Therefore,

$$\begin{aligned}|\rho_h^m-\rho_h^{m+r}|&\le C\left(k\sum_{n=m}^{m-1+r}\|\boldsymbol{w}_h^n\|^2_{\boldsymbol{L}^6(\Omega)}\right)^{1/2}\left(k\sum_{n=m}^{m-1+r}\|\nabla\rho_h^n\|^4_{\boldsymbol{L}^3(\Omega)}\right)^{1/4}(rk)^{1/4}\\ &\quad+C\left(k\sum_{n=m}^{m-1+r}\lambda|\Delta_h\rho_h^{n+1}|^2\right)^{1/2}(rk)^{1/2}\le C_\lambda\,(rk)^{1/4}+C(rk)^{1/2},\end{aligned}$$

where $C_\lambda > 0$ is a constant independent of h and k (and depending on λ). Then we have

$$\max_{1\le m\le N} |\rho_h^m - \rho_h^{m+r}| \le C_\lambda\,(r\,k)^{1/4}. \tag{6.6}$$

By multiplying (6.5) by k and summing for $m = 0,\dots,N-r$, we are going to get the desired bound (6.2) using (6.6). Indeed, from (6.6), one can obtain (with a similar argument as in [11])

$$-k\sum_{m=0}^{N-r}\left(\rho_h^m - \rho_h^{m+r}, \boldsymbol{u}_h^m\cdot(\boldsymbol{u}_h^{m+r}-\boldsymbol{u}_h^m)\right) \le C_\lambda (rk)^{1/4}.$$

We analyze only the two terms whose estimates will be different from the ones done in [11]:

$$J_1 := -k^2\sum_{m=0}^{N-r}\sum_{n=m}^{m-1+r} c\left(\rho_h^{n+1}\boldsymbol{u}_h^n - \lambda\nabla\rho_h^{n+1}, \boldsymbol{u}_h^{n+1}, \boldsymbol{u}_h^{m+r}-\boldsymbol{u}_h^m\right),$$

$$J_2 := \frac{k^2}{2}\sum_{m=0}^{N-r}\sum_{n=m}^{m-1+r}\left(\frac{\rho_h^{n+1}-\rho_h^n}{k}, \boldsymbol{u}_h^{n+1}\cdot(\boldsymbol{u}_h^{m+r}-\boldsymbol{u}_h^m)\right).$$

To estimate J_1, we use (1.11) as follows:

$$J_1 \le C\,k^2\sum_{m=0}^{N-r}\sum_{n=m}^{m-1+r}\|\rho_h^{n+1}\boldsymbol{u}_h^n - \lambda\nabla\rho_h^{n+1}\|_{\boldsymbol{L}^3(\Omega)}\|\boldsymbol{u}_h^{n+1}\|\|\boldsymbol{u}_h^{m+r}-\boldsymbol{u}_h^m\|$$

$$\le C\,k^2\sum_{m=0}^{N-r}\sum_{n=m}^{m-1+r}\left(\|\rho_h^{n+1}\|_{L^\infty(\Omega)}\|\boldsymbol{u}_h^n\|_{\boldsymbol{L}^3(\Omega)} + \lambda\|\nabla\rho_h^{n+1}\|_{\boldsymbol{L}^3(\Omega)}\right)\|\boldsymbol{u}_h^{n+1}\|\|\boldsymbol{u}_h^{m+r}-\boldsymbol{u}_h^m\|.$$

By interchanging the sum order (Fubini's discrete rule) and using the fact that $\|\rho_h^{n+1}\|_{L^\infty(\Omega)} \le C$,

$$J_1 \le\ C\,k^2\sum_{n=0}^{N-1}\left(\|\boldsymbol{u}_h^n\|_{\boldsymbol{L}^3(\Omega)} + \lambda\|\nabla\rho_h^{n+1}\|_{\boldsymbol{L}^3(\Omega)}\right)\|\boldsymbol{u}_h^{n+1}\|\sum_{m=\overline{n-r+1}}^{\overline{n}}\|\boldsymbol{u}_h^{m+r}-\boldsymbol{u}_h^m\|,$$

where

$$\overline{n} = \begin{cases} 0 & \text{if} \quad n<0,\\ n & \text{if} \quad 0\le n\le N-r,\\ N-r & \text{if} \quad n>N-r.\end{cases}$$

Next, by taking into account that $|\overline{n} - \overline{n-r+1}| \le r$ and Corollary 4.2, we get

$$J_1 \le C\,k\sum_{n=0}^{N-1}\left(\|\boldsymbol{u}_h^n\|_{L^3(\Omega)} + \lambda\|\nabla\rho_h^{n+1}\|_{L^3(\Omega)}\right)\|\boldsymbol{u}_h^{n+1}\|$$

$$\left(\sum_{m=\overline{n-r+1}}^{\overline{n}} k\|\boldsymbol{u}_h^{m+r}-\boldsymbol{u}_h^m\|^2\right)^{1/2}\left(\sum_{m=\overline{n-r+1}}^{\overline{n}} k\right)^{1/2}$$

$$\le\ C(r\,k)^{1/2}\left(k\sum_{n=0}^{N-1}\left(\|\boldsymbol{u}_h^n\|_{L^3(\Omega)} + \lambda\|\nabla\rho_h^{n+1}\|_{L^3(\Omega)}\right)^2\right)^{1/2}\left(k\sum_{n=0}^{N-1}\|\boldsymbol{u}_h^{n+1}\|^2\right)^{1/2}$$

$$\le C\,(r\,k)^{1/2}.$$

In the same way, we can bound the term $k^2\sum_{m=0}^{N-r}\sum_{n=m}^{m-1+r} a(\rho_h^{n+1}, \boldsymbol{u}_h^{n+1}, \boldsymbol{u}_h^{m+r}-\boldsymbol{u}_h^m)$.

We bound J_2 as follows:

$$J_2 \le C\,k^2 \sum_{m=0}^{N-r}\sum_{n=m}^{m-1+r}\left|\frac{\rho_h^{n+1}-\rho_h^n}{k}\right| \|\boldsymbol{u}_h^{n+1}\|_{L^3(\Omega)}\|\boldsymbol{u}_h^{m+r}-\boldsymbol{u}_h^m\|$$

$$\text{(Fubini)} \le C\,k^2 \sum_{n=0}^{N-1}\left|\frac{\rho_h^{n+1}-\rho_h^n}{k}\right| \|\boldsymbol{u}_h^{n+1}\|^{1/2}|\boldsymbol{u}_h^{n+1}|^{1/2} \sum_{m=\overline{n-r+1}}^{\overline{n}} \|\boldsymbol{u}_h^{m+r}-\boldsymbol{u}_h^m\|$$

$$\le C\,k \sum_{n=0}^{N-1}\left|\frac{\rho_h^{n+1}-\rho_h^n}{k}\right| \|\boldsymbol{u}_h^{n+1}\|^{1/2} \left(k \sum_{m=\overline{n-r+1}}^{\overline{n}} \|\boldsymbol{u}_h^{m+r}-\boldsymbol{u}_h^m\|^2\right)^{1/2} (rk)^{1/2}$$

$$\le C\,(rk)^{1/2} \left(k\sum_{n=0}^{N-1}\left|\frac{\rho_h^{n+1}-\rho_h^n}{k}\right|^{4/3}\right)^{3/4} \left(k\sum_{n=0}^{N-1}\|\boldsymbol{u}_h^{n+1}\|^2\right)^{1/4}$$

$$\le C_\lambda (rk)^{1/2}. \qquad \square$$

Remark 6.4. From the weak estimates of the discrete velocity $\boldsymbol{u}_{h,k}$ in $L^\infty(0,T;\boldsymbol{L}^2(\Omega))\cap L^2(0,T;\boldsymbol{H}_0^1(\Omega))$ and the fractional in time estimate of $\boldsymbol{u}_{h,k}$ given in (6.1), we can apply a compactness result [17] and obtain $\boldsymbol{u}_{h,k}\to\boldsymbol{u}$ in $L^2(0,T;\boldsymbol{L}^2(\Omega))$-strong. Consequently, thanks to estimate (iii), $\widehat{\boldsymbol{u}}_{h,k}\to\boldsymbol{u}$ in $L^2(0,T;\boldsymbol{L}^2(\Omega))$-strong. Finally, since $\{\boldsymbol{u}_{h,k}\}_{h,k}$ is bounded in $L^\infty(0,T;\boldsymbol{L}^2(\Omega))$ we improve the compactness of $\{\boldsymbol{u}_{h,k}\}_{h,k}$ to the $L^p(0,T;\boldsymbol{L}^2(\Omega))$ space, with $p<\infty$.

6.3. Strong convergence for the density in $\boldsymbol{H^1(\Omega)}$. By using the compactness of the discrete density in $L^2(0,T;\boldsymbol{L}^2(\Omega))$ and comparing the equation for the discrete Laplacian and its limit (see [11]), one can obtain the convergence of the $L^2(0,T;\boldsymbol{L}^2(\Omega))$-norm of $\nabla\rho_{h,k}$ towards the same norm of $\nabla\rho$. Consequently, one has

$$\|\rho_{h,k}-\rho\|_{L^2(0,T;H^1(\Omega))}\to 0 \text{ as } (h,k)\to 0.$$

7. Passing to the limit.

7.1. Convergence for the density scheme. Thanks to the previous convergences, we can prove [11] the convergence of the density scheme as $(h,k)\to 0$, obtaining

$$\rho_t + \boldsymbol{u}\cdot\nabla\rho - \lambda\Delta\rho = 0 \text{ in } Q, \quad \frac{\partial\rho}{\partial\boldsymbol{n}}\Big|_\Sigma = 0, \quad \rho(0)=\rho_0 \text{ in } \Omega. \tag{7.1}$$

7.2. Convergence for the momentum scheme. We use the following convergence result, which is similar to Lemma 5.2.

LEMMA 7.1. *Let $\bar{\boldsymbol{u}}\in\boldsymbol{C}_c^\infty(\Omega)$. Then there exists $\bar{\boldsymbol{u}}_h\in\boldsymbol{V}_h$ such that:*

$$\bar{\boldsymbol{u}}_h\to\bar{\boldsymbol{u}} \ \text{ in } \boldsymbol{H}_0^1(\Omega) \ \text{ and } \ \Big(\nabla\cdot\bar{\boldsymbol{u}}_h, q_h\Big) = \Big(\nabla\cdot\bar{\boldsymbol{u}}, q_h\Big)\ \forall\, q_h\in M_h.$$

To pass to the limit in the discrete momentum system, we consider $\boldsymbol{v}\in C^1([0,T];\mathbf{C}_c^\infty(\Omega))$, with $\nabla\cdot\boldsymbol{v}=0$ and $\boldsymbol{v}(T)=0$. We define $\boldsymbol{v}_h^n$ as the projection of $\boldsymbol{v}(t^n)$ furnished by Lemma 7.1. We define $\boldsymbol{v}_{h,k}\in L^\infty(0,T;\boldsymbol{V}_h)$ as the piecewise constant functions taking values $\boldsymbol{v}_h^{n+1}$ on $(t_n,t_{n+1}]$ and let $\widetilde{\boldsymbol{v}}_{h,k}\in C^0([0,T];\boldsymbol{V}_h)$ be the piecewise linear, globally continuous functions and such that $\widetilde{\boldsymbol{v}}_{h,k}(t_n)=\boldsymbol{v}_h^n$. It is known that, as $(h,k)\to 0$,

$$\boldsymbol{v}_{h,k}\to\boldsymbol{v} \quad \text{in } L^\infty(0,T;\boldsymbol{H}_0^1(\Omega)), \quad \widetilde{\boldsymbol{v}}_{h,k}\to\boldsymbol{v} \quad \text{in } W^{1,\infty}(0,T;\boldsymbol{H}_0^1(\Omega)).$$

By taking $\bar{\boldsymbol{u}}_h = \boldsymbol{v}_h^{n+1}$ as a test function in (6.3), multiplying by k, summing over n, and using the expression (discrete integration by parts in time)

$$\sum_{n=0}^{N-1}\Big(\rho_h^{n+1}\boldsymbol{u}_h^{n+1}-\rho_h^n\boldsymbol{u}_h^n,\boldsymbol{v}_h^{n+1}\Big)=\Big(\rho_h^N\boldsymbol{u}_h^N,\boldsymbol{v}_h^N\Big)-\sum_{n=0}^{N-1}\Big(\rho_h^n\boldsymbol{u}_h^n,\boldsymbol{v}_h^{n+1}-\boldsymbol{v}_h^n\Big)-\Big(\rho_{0h}\boldsymbol{u}_{0h},\boldsymbol{v}_h^0\Big)$$

and the fact that $\boldsymbol{v}_h^N = 0$ (since $\boldsymbol{v}(T) = 0$), the following "conservative" formulation holds:

$$\left\{\begin{array}{l} -\,k\displaystyle\sum_{n=0}^{N-1}\Big(\rho_h^n\boldsymbol{u}_h^n,\frac{\boldsymbol{v}_h^{n+1}-\boldsymbol{v}_h^n}{k}\Big)-\Big(\rho_{0h}\boldsymbol{u}_{0h},\boldsymbol{v}_h^0\Big)\\ +\,k\displaystyle\sum_{n=0}^{N-1}c(\rho_h^{n+1}\boldsymbol{u}_h^n-\lambda\nabla\rho_h^{n+1},\boldsymbol{u}_h^{n+1},\boldsymbol{v}_h^{n+1})+k\sum_{n=0}^{N-1}a(\boldsymbol{u}_h^{n+1},\boldsymbol{v}_h^{n+1})\\ =k\displaystyle\sum_{n=0}^{N-1}\Big(\rho_h^{n+1}\boldsymbol{f}^{\,n+1},\boldsymbol{v}_h^{n+1}\Big)+k\sum_{n=0}^{N-1}\frac{1}{2}\left(\frac{\rho_h^{n+1}-\rho_h^n}{k},\boldsymbol{u}_h^{n+1}\cdot\boldsymbol{v}_h^{n+1}\right).\end{array}\right.$$

Next, by taking into account Definition 5.1,

$$\left\{\begin{array}{l} -\displaystyle\int_0^T\Big(\widehat{\rho}_{h,k}\widehat{\boldsymbol{u}}_{h,k},\frac{\partial}{\partial t}\widetilde{\boldsymbol{v}}_{h,k}\Big)-\Big(\rho_{0h}\boldsymbol{u}_{0h},\boldsymbol{v}_h^0\Big)\\ +\displaystyle\int_0^T c\Big(\rho_{h,k}\widehat{\boldsymbol{u}}_{h,k}-\lambda\nabla\rho_{h,k},\boldsymbol{u}_{h,k},\boldsymbol{v}_{h,k}\Big)+\sum_{n=0}^{N-1}a\Big(\rho_{h,k},\boldsymbol{u}_{h,k},\boldsymbol{v}_{h,k}\Big)\\ =\displaystyle\int_0^T\Big(\rho_{h,k}\boldsymbol{f}_k,\boldsymbol{v}_{h,k}\Big)+\frac{1}{2}\int_0^T\left(\frac{\partial}{\partial t}\widetilde{\rho}_{h,k},\boldsymbol{u}_{h,k}\cdot\boldsymbol{v}_{h,k}\right).\end{array}\right.$$

This variational formulation of the discrete momentum system allows us to pass to the limit in a standard way. We pass to the limit only in the last term on the right-hand side since this term does not appear in the theoretical analysis. We know that $\frac{\partial}{\partial t}\widetilde{\rho}_{h,k}\to\frac{\partial}{\partial t}\rho$ weakly in $L^{4/3}(0,T;L^2(\Omega))$ and $\boldsymbol{u}_{h,k}\to\boldsymbol{u}$ strongly in $L^p(0,T;L^2(\Omega))$, with $p<\infty$, and is bounded in $L^4(0,T;\boldsymbol{L}^3(\Omega))$, and hence $\frac{\partial}{\partial t}\widetilde{\rho}_{h,k}\boldsymbol{u}_{h,k}\to\frac{\partial}{\partial t}\rho\boldsymbol{u}$ weakly in $L^1(0,T;\boldsymbol{L}^{6/5}(\Omega))$. As $\boldsymbol{v}_{h,k}\to\boldsymbol{v}$ in $L^\infty(0,T;\boldsymbol{H}_0^1(\Omega))$, we have

$$\int_0^T\left(\frac{\partial}{\partial t}\widetilde{\rho}_{h,k},\boldsymbol{u}_{h,k}\cdot\boldsymbol{v}_{h,k}\right)\to\int_0^T\left(\frac{\partial}{\partial t}\rho,\boldsymbol{u}\cdot\boldsymbol{v}\right)\ \text{ as } (h,k)\to 0.$$

This concludes the proof of Theorem 1.1. ∎

Remark 7.2. A variant of the Kazhikhoz–Smagulov model is obtained by replacing the linear diffusion term $-\nabla\cdot(\mu\nabla\boldsymbol{u})$ in (1.1) by a nonlinear diffusion term $-\lambda\nabla\cdot(\rho\nabla\boldsymbol{u})$ (i.e., taking $\mu=\lambda\rho$). It is a model of pollution studied by Bresch, Essoufi, and Sy in [4, 5], where they prove the existence of a global in time weak solution, without imposing the restrictive hypothesis (1.5) on the coefficients.

The scheme that we design for this model is obtained by replacing the stabilizing term of the momentum system

$$-\lambda\int_\Omega\frac{M+m}{2}(\nabla\boldsymbol{u}_h^{n+1})^t:\nabla\bar{\boldsymbol{u}}_h\,d\boldsymbol{x}$$

by the term $\frac{\lambda m}{2}(\nabla\cdot\boldsymbol{u}_h^{n+1},\nabla\cdot\bar{\boldsymbol{u}}_h)$ and the remainder with the following scheme:

Given $(\rho_h^n,\boldsymbol{u}_h^n,p_h^n)\in W_h\times\boldsymbol{V}_h\times M_h$,

1. find $(\boldsymbol{w}_h^n, q_h^n) \in \widetilde{\boldsymbol{V}_h} \times \widetilde{M_h}$ such that, for each $(\bar{\boldsymbol{w}}_h, \bar{q}_h) \in \widetilde{\boldsymbol{V}_h} \times \widetilde{M_h}$,

$$\Big(\nabla \boldsymbol{w}_h^n, \nabla \bar{\boldsymbol{w}}_h\Big) - \Big(q_h^n, \nabla \cdot \bar{\boldsymbol{w}}_h\Big) = \Big(\nabla \boldsymbol{u}_h^n, \nabla \bar{\boldsymbol{w}}_h\Big), \quad \Big(\nabla \cdot \boldsymbol{w}_h^n, \bar{q}_h\Big) = 0; \tag{7.2}$$

2. find $\rho_h^{n+1} \in W_h$ such that, for each $\bar{\rho}_h \in W_h$,

$$\left(\frac{\rho_h^{n+1} - \rho_h^n}{k}, \bar{\rho}_h\right) + \Big(\boldsymbol{w}_h^n \cdot \nabla \rho_h^{n+1}, \bar{\rho}_h\Big) + \lambda \Big(\nabla \rho_h^{n+1}, \nabla \bar{\rho}_h\Big) = 0; \tag{7.3}$$

3. find $(\boldsymbol{u}_h^{n+1}, p_h^{n+1}) \in \boldsymbol{V}_h \times M_h$ such that, for each $(\bar{\boldsymbol{u}}_h, \bar{p_h}) \in \boldsymbol{V}_h \times M_h$,

$$\begin{cases} \left(\rho_h^n \dfrac{\boldsymbol{u}_h^{n+1} - \boldsymbol{u}_h^n}{k}, \bar{\boldsymbol{u}}_h\right) + \dfrac{1}{2}\left(\dfrac{\rho_h^{n+1} - \rho_h^n}{k}, \boldsymbol{u}_h^{n+1} \cdot \bar{\boldsymbol{u}}_h\right) \\ + c\Big(\rho_h^{n+1} \boldsymbol{u}_h^n - \lambda \nabla \rho_h^{n+1}, \boldsymbol{u}_h^{n+1}, \bar{\boldsymbol{u}}_h\Big) \\ + \lambda \Big(\rho_h^{n+1} (\nabla \boldsymbol{u}_h^{n+1} - (\nabla \boldsymbol{u}_h^{n+1})^t), \nabla \bar{\boldsymbol{u}}_h\Big) + \dfrac{\lambda\, m}{2}\Big(\nabla \cdot \boldsymbol{u}_h^{n+1}, \nabla \cdot \bar{\boldsymbol{u}}_h\Big) \\ = \Big(\rho_h^{n+1} \boldsymbol{f}^{\,n+1}, \bar{\boldsymbol{u}}_h\Big) + \Big(p_h^{n+1}, \nabla \cdot \bar{\boldsymbol{u}}_h\Big), \end{cases} \tag{7.4}$$

$$\Big(\nabla \cdot \boldsymbol{u}_h^{n+1}, \bar{p}_h\Big) = 0. \tag{7.5}$$

By following the arguments of this paper, one may establish the same conclusions of Theorem 1.1 for this scheme.

8. Asymptotic behavior when $\boldsymbol{\lambda \to 0}$. In this section we are interested in the asymptotic behavior of scheme (1.8)–(1.10) when the diffusion parameter λ goes to zero. More precisely, we will see that, by imposing the stability condition

$$h/(k\lambda^2) \to 0 \quad \text{as } (\lambda, h, k) \to 0 \tag{S$'$}$$

and completing (H2) with the additional approximation property

$$|\bar{\rho} - I_h \bar{\rho}| \le C\, h^{2/3} \|\bar{\rho}\|_{W^{1,3/2}(\Omega)} \quad \forall\, \bar{\rho} \in W^{1,3/2}(\Omega), \tag{H2$'$}$$

then scheme (1.8)–(1.10) approximates, as $(h, k, \lambda) \to 0$, to a weak solution of the density-dependent Navier–Stokes problem (1.6), which is defined as follows.

DEFINITION 8.1. *A pair $(\rho, \boldsymbol{u})$ is said to be a weak solution of* (1.6) *in* $(0, T)$ *if:*

(a) $\boldsymbol{u} \in L^\infty(0, T; \boldsymbol{L}^2(\Omega)) \cap L^2(0, T; \boldsymbol{V})$, $\rho \in L^\infty(Q)$, *with* $0 < m \le \rho(\boldsymbol{x}, t) \le M$ *a.e.* $(\boldsymbol{x}, t) \in Q$;

(b) *for all* $\phi \in C^1([0, T]; \boldsymbol{V})$, *with* $\phi(T) = 0$,

$$\int_0^T \{-(\rho \boldsymbol{u}, \phi_t + (\boldsymbol{u} \cdot \nabla)\phi) + \mu(\nabla \boldsymbol{u}, \nabla \phi)\}\, dt = \int_0^T (\rho \boldsymbol{f}, \phi)\, dt + (\rho_0 \boldsymbol{u}_0, \phi(0));$$

(c) *for all* $\varphi \in C^1([0, T]; \boldsymbol{H}^1(\Omega))$, *with* $\varphi(T) = 0$,

$$-\int_0^T (\rho, \varphi_t)\, dt - \int_0^T (\rho \boldsymbol{u}, \nabla \varphi)\, dt = (\rho_0, \varphi(0)).$$

The rest of this section is devoted to the proof of Theorem 1.2.

8.1. Uniform estimates with respect to (h,k,λ). By following arguments of the previous sections and assuming (S′) and (h,k,λ) small enough, we can obtain the following estimates independent of h, k, and λ (now we denote piecewise functions associated to the scheme also with the parameter λ explicitly):

$$\begin{aligned}
\{\boldsymbol{u}_{h,k,\lambda}\}_{h,k,\lambda},\ \{\widehat{\boldsymbol{u}}_{h,k,\lambda}\}_{h,k,\lambda},\{\widehat{\boldsymbol{w}}_{h,k,\lambda}\}_{h,k,\lambda} &\text{ in } L^\infty(0,T;\boldsymbol{L}^2(\Omega))\cap L^2(0,T;\boldsymbol{H}^1_0(\Omega)),\\
\{\widetilde{\rho}_{h,k,\lambda}\}_{h,k,\lambda},\ \{\rho_{h,k,\lambda}\}_{h,k,\lambda},\ \{\widehat{\rho}_{h,k,\lambda}\}_{h,k,\lambda} &\text{ in } L^\infty(Q),\\
\lambda^{1/2}\{\rho_{h,k,\lambda}\}_{h,k,\lambda},\ \lambda^{1/2}\{\widehat{\rho}_{h,k,\lambda}\}_{h,k,\lambda} &\text{ in } L^\infty(0,T;H^1(\Omega)),\\
\lambda^{3/4}\{\rho_{h,k,\lambda}\}_{h,k,\lambda} &\text{ in } L^4(0,T;W^{1,3}(\Omega)),\\
\lambda^{3/4}\left\{\frac{\partial}{\partial t}\widetilde{\rho}_{h,k,\lambda}\right\}_{h,k,\lambda} &\text{ in } L^{4/3}(0,T;L^2(\Omega)).
\end{aligned}$$

In addition, $0<\widetilde{m}\le\rho_{h,k,\lambda},\widehat{\rho}_{h,k,\lambda},\widetilde{\rho}_{h,k,\lambda}\le\widetilde{M}$ in Q,

$$\begin{aligned}
&\|\widetilde{\rho}_{h,k,\lambda}-\rho_{h,k,\lambda}\|_{L^2(0,T;L^2(\Omega))}\le\|\rho_{h,k,\lambda}-\widehat{\rho}_{h,k,\lambda}\|_{L^2(0,T;L^2(\Omega))}\le C\sqrt{k},\\
&\|\boldsymbol{u}_{h,k,\lambda}-\widehat{\boldsymbol{u}}_{h,k,\lambda}\|_{L^2(0,T;\boldsymbol{H}^1_0(\Omega))}\le C\sqrt{k}.
\end{aligned}$$

In fact, we have the following result.

LEMMA 8.2. *By assuming* (S′) *and* (h,k,λ) *small enough, there exist subsequences of* $\{\boldsymbol{u}_{h,k,\lambda}\}_{h,k}$, $\{\widehat{\boldsymbol{u}}_{h,k,\lambda}\}_{h,k}$, $\{\rho_{h,k,\lambda}\}_{h,k,\lambda}$, $\{\widehat{\rho}_{h,k,\lambda}\}_{h,k}$, *and* $\{\widetilde{\rho}_{h,k,\lambda}\}_{h,k}$ *(denoted in the same way) and limit functions* $\boldsymbol{u}$ *and* ρ, *such that* $\nabla\cdot\boldsymbol{u}=0$ *a.e. in* Ω, *and the following weak convergences hold as* $(h,k,\lambda)\to 0$*:*

$$\begin{aligned}
&\boldsymbol{u}_{h,k,\lambda}\to\boldsymbol{u},\quad \widehat{\boldsymbol{u}}_{h,k,\lambda}\to\boldsymbol{u},\quad \widehat{\boldsymbol{w}}_{h,k,\lambda}\to\boldsymbol{u}\quad \textit{in}\ \begin{cases} L^2(0,T;\boldsymbol{H}^1_0(\Omega))\textit{-weak},\\ L^\infty(0,T;\boldsymbol{L}^2(\Omega))\textit{-weak}*,\end{cases}\\
&\widetilde{\rho}_{h,k,\lambda}\to\rho,\quad \rho_{h,k,\lambda}\to\rho,\quad \widehat{\rho}_{h,k,\lambda}\to\rho\quad \textit{in } L^\infty(Q)\textit{-weak}*\,.
\end{aligned}$$

8.2. Compactness.

PROPOSITION 8.3. *Under the hypotheses of Lemma* 8.2*, the estimate*

$$\int_0^{T-\delta}\left|\sqrt{\rho_{h,k,\lambda}(t+\delta)}(\boldsymbol{u}_{h,k,\lambda}(t+\delta)-\boldsymbol{u}_{h,k,\lambda}(t))\right|^2 dt\le C\,\delta^{1/2}\quad\forall\,\delta:0<\delta<T \tag{8.1}$$

holds, with $C>0$ *independent of* h, k, δ, *and* λ.

In particular, since $\rho_{h,k,\lambda}\ge\widetilde{m}$, then

$$\boldsymbol{u}_{h,k,\lambda}\to\boldsymbol{u},\quad \boldsymbol{w}_{h,k,\lambda}\to\boldsymbol{u}\quad\text{in } L^2(0,T;\boldsymbol{L}^2(\Omega))\ \text{ as } (h,k,\lambda)\to 0.$$

Proof. Again, since $\rho_{h,k,\lambda}$ and $\boldsymbol{u}_{h,k,\lambda}$ are piecewise constant functions, (8.1) is equivalent to

$$k\sum_{m=0}^{N-r}|\sqrt{\rho_h^{m+r}}(\boldsymbol{u}_h^{m+r}-\boldsymbol{u}_h^m)|^2\le C\,(r\,k)^{1/2}\quad\forall\,r:0\le r\le N. \tag{8.2}$$

By following the proof of Proposition 6.3, one observes that the terms which are not necessarily bounded independent of λ are

$$T_1:=k^2\sum_{m=0}^{N-r}\sum_{n=m}^{m-1+r}\left(\frac{\rho_h^{n+1}-\rho_h^n}{k},\boldsymbol{u}_h^{n+1}\cdot(\boldsymbol{u}_h^{m+r}-\boldsymbol{u}_h^m)\right)$$

and

$$T_2 := -k \sum_{m=0}^{N-r} \left(\rho_h^{m+r} - \rho_h^m, \boldsymbol{u}_h^m \cdot (\boldsymbol{u}_h^{m+r} - \boldsymbol{u}_h^m)\right).$$

Here we are going to bound these terms.

We consider the projection operator on W_h with respect to $L^2(\Omega)$-inner product:

$$P_h : L^2(\Omega) \to W_h \quad \text{such that} \quad (P_h v, w) = (v, w) \quad \forall w \in W_h.$$

We take $\bar{\rho}_h = P_h(\boldsymbol{u}_h^{n+1} \cdot (\boldsymbol{u}_h^{m+r} - \boldsymbol{u}_h^m)) \in W_h$ in (4.2), arriving at

$$\begin{aligned} &\left(\frac{\rho_h^{n+1} - \rho_h^n}{k}, \boldsymbol{u}_h^{n+1} \cdot (\boldsymbol{u}_h^{m+r} - \boldsymbol{u}_h^m)\right) + (\boldsymbol{w}_h^n \cdot \nabla \rho_h^{n+1}, P_h(\boldsymbol{u}_h^{n+1} \cdot (\boldsymbol{u}_h^{m+r} - \boldsymbol{u}_h^m))) \\ &\quad - \lambda\Big(\Delta_h \rho_h^{n+1}, \boldsymbol{u}_h^{n+1} \cdot (\boldsymbol{u}_h^{m+r} - \boldsymbol{u}_h^m)\Big) = 0, \end{aligned} \tag{8.3}$$

where we have used the definition of projection operator in $L^2(\Omega)$ in the first and the last term. Thus, we decompose $T_1 = T_{1,1} + T_{1,2}$, where:

$$T_{1,1} = -k^2 \sum_{m=0}^{N-r} \sum_{n=m}^{m-1+r} (\boldsymbol{w}_h^n \cdot \nabla \rho_h^{n+1}, P_h(\boldsymbol{u}_h^{n+1} \cdot (\boldsymbol{u}_h^{m+r} - \boldsymbol{u}_h^m))),$$

$$T_{1,2} = \lambda k^2 \sum_{m=0}^{N-r} \sum_{n=m}^{m-1+r} (\Delta_h \rho_h^{n+1}, \boldsymbol{u}_h^{n+1} \cdot (\boldsymbol{u}_h^{m+r} - \boldsymbol{u}_h^m)).$$

By writing $T_{1,1}$ as follows:

$$\begin{aligned} T_{1,1} = &-k^2 \sum_{m=0}^{N-r} \sum_{n=m}^{m-1+r} (\boldsymbol{w}_h^n \cdot \nabla \rho_h^{n+1}, P_h(\boldsymbol{u}_h^{n+1} \cdot (\boldsymbol{u}_h^{m+r} - \boldsymbol{u}_h^m)) - \boldsymbol{u}_h^{n+1} \cdot (\boldsymbol{u}_h^{m+r} - \boldsymbol{u}_h^m)) \\ &- k^2 \sum_{m=0}^{N-r} \sum_{n=m}^{m-1+r} (\boldsymbol{w}_h^n \cdot \nabla \rho_h^{n+1}, \boldsymbol{u}_h^{n+1} \cdot (\boldsymbol{u}_h^{m+r} - \boldsymbol{u}_h^m)) := T_{1,1}^1 + T_{1,1}^2, \end{aligned}$$

we bound it as

$$T_{1,1}^1 \leq C\, k^2 \sum_{m=0}^{N-r} \sum_{n=m}^{m-1+r} \|\boldsymbol{w}_h^n\|_{L^6(\Omega)} \|\nabla \rho_h^{n+1}\|_{L^3(\Omega)} h^{2/3} \|\boldsymbol{u}_h^{n+1}\| \|\boldsymbol{u}_h^{m+r} - \boldsymbol{u}_h^m\|,$$

where we have used the inequalities $|\bar{\rho} - P_h\bar{\rho}| \leq |\bar{\rho} - I_h\bar{\rho}| \leq C\, h^{2/3} \|\bar{\rho}\|_{W^{1,3/2}(\Omega)}$ and $\|\boldsymbol{u}_h^{n+1} \cdot (\boldsymbol{u}_h^{m+r} - \boldsymbol{u}_h^m)\|_{W^{1,3/2}(\Omega)} \leq \|\boldsymbol{u}_h^{n+1}\| \|\boldsymbol{u}_h^{m+r} - \boldsymbol{u}_h^m\|$. Next, by taking (λ, h, k) small enough and such that

$$h^{2/3} \leq C\, \lambda^{3/4} k^{1/2}, \tag{8.4}$$

using the fact that $\lambda^{3/4} k^{1/2} \|\nabla \rho_h^{n+1}\|_{L^3(\Omega)} \leq C$ (with C independent of λ, h, k), and applying the discrete Fubini rule, we arrive at the estimate $T_{1,1}^1 \leq C\,(rk)^{1/2}$.

The bound $T_{1,1}^2 \le C\,(rk)^{1/2}$ is obtained easily by integrating by parts and using the pointwise bound $\|\rho_h^{n+1}\|_{L^\infty(\Omega)} \le C$ (where C is independent of λ):

$$\begin{aligned}T_{1,1}^2 &\le k^2 \sum_{m=0}^{N-r}\sum_{n=m}^{m-1+r} (|\nabla\cdot \boldsymbol{w}_h^n||\boldsymbol{u}_h^{n+1}\cdot(\boldsymbol{u}_h^{m+r}-\boldsymbol{u}_h^m)| + \|\boldsymbol{w}_h^n\|_{L^6}|\nabla \boldsymbol{u}_h^{n+1}|\|\boldsymbol{u}_h^{m+r}-\boldsymbol{u}_h^m\|_{L^3})\\ &\quad + k^2 \sum_{m=0}^{N-r}\sum_{n=m}^{m-1+r} \|\boldsymbol{w}_h^n\|_{L^6}\|\boldsymbol{u}_h^{n+1}\|_{L^3}|\nabla(\boldsymbol{u}_h^{m+r}-\boldsymbol{u}_h^m)|\\ &\le C\,k^2 \sum_{n=0}^{N-1} \|\boldsymbol{w}_h^n\|\|\boldsymbol{u}_h^{n+1}\| \sum_{m=\overline{n-r+1}}^{\overline{n}} \|\boldsymbol{u}_h^{m+r}-\boldsymbol{u}^m\| \le C(r\,k)^{1/2}.\end{aligned}$$

The bound $T_{1,2} \le C(rk)^{1/2}$ is obtained using the fact that $\lambda^2\,k\sum_{n=0}^{N-1}|\Delta_h\rho_h^{n+1}|^2 \le C$ and Fubini's rule.

By summing up (8.3) multiplied by k^2 for $n = m,\dots,m+r-1$ and then summing up for $m = 0,\dots,N-r$, we can write T_2 as:

$$T_2 = -k^2 \sum_{m=0}^{N-r}\sum_{n=m}^{m+r-1} (\boldsymbol{w}_h^n\cdot\nabla\rho_h^n, P_h(\boldsymbol{u}_h^m\cdot(\boldsymbol{u}_h^{m+r}-\boldsymbol{u}_h^m)) - \lambda(\Delta_h\rho_h^{n+1}, \boldsymbol{u}_h^m\cdot(\boldsymbol{u}_h^{m+r}-\boldsymbol{u}_h^m)).$$

These new terms are bounded in an analogous manner (now, without using Fubinis's rule), resulting in

$$T_2 \le C(rk)^{1/2}.$$

Note that the restriction on the parameters (8.4) imposed to get the bound of $T_{1,1}^1$ is included in the constraint (S′) imposed to obtain a priori estimates. Indeed, (8.4) is equivalent to $\frac{1}{\lambda^{3/4}}\frac{h^{2/3}}{k^{1/4}} \le C$. But as

$$\lim_{(h,k,\lambda)\to 0}\left(\frac{1}{\lambda}\sqrt{\frac{h}{k}}\right)\Big/\left(\frac{1}{\lambda^{3/4}}\frac{h^{2/3}}{k^{1/4}}\right) = \lim_{(h,k,\lambda)\to 0}\frac{1}{\lambda^{1/4}k^{1/2}h^{1/6}} = \infty,$$

then $\frac{1}{\lambda^{3/4}}\frac{h^{2/3}}{k^{1/4}} \le C\frac{1}{\lambda}\sqrt{\frac{h}{k}} \to 0$ (thanks to (S′)). ∎

Remark 8.4. By comparing the fractional in time estimates for the discrete velocity in the case of λ fixed (done in Proposition 6.3) with respect to the case of $\lambda \to 0$ (done now in Proposition 8.3), one can observe that condition (8.4) on the parameters h and k imposed now in the proof of Proposition 8.3 is not necessary in the case of λ fixed; however, in this case only order $(rk)^{1/4}$ is obtained. Now, in the case $\lambda \to 0$, we have to impose constraint (8.4), and the estimate order is improved from $(rk)^{1/4}$ to $(rk)^{1/2}$.

8.3. Passing to the limit.

8.3.1. Density equation. Let $\eta \in C^1([0,T];C_c^\infty(\Omega))$ such that $\eta(T) = 0$. We define η_h^n as the interpolation in W_h of $\eta(t_n)$ and $\eta_{h,k} \in L^\infty(0,T;W_h))$ as the piecewise constant function taking values η_h^{n+1} in $(t_n,t_{n+1}]$ and let $\widetilde{\eta}_{h,k} \in C^0([0,T];W_h))$ be the piecewise linear, globally continuous function such that $\widetilde{\eta}_{h,k}(t_n) = \eta_h^n$. One has, as $(h,k) \to 0$,

$$\eta_{k,h} \to \eta \quad \text{in } L^\infty(0,T;H^1(\Omega)) \quad \text{and} \quad \widetilde{\eta}_{k,h} \to \eta \quad \text{in } W^{1,\infty}(0,T;H^1(\Omega)).$$

By using these discrete test functions in the discrete density formulation (1.8), together with an integration by parts in time, we arrive [11] at the formulation

$$\int_0^T \Big(\widehat{\rho}_{h,k,\lambda}, -\frac{d}{dt}\widetilde{\eta}_{h,k}\Big) + \lambda(\nabla\rho_{h,k,\lambda}, \nabla\eta_{h,k}) + (\widehat{\boldsymbol{w}}_{h,k,\lambda}\cdot\nabla\rho_{h,k,\lambda}, \eta_{h,k}) = (\rho_{0h}, \eta_h^0). \tag{8.5}$$

Before taking a limit in (8.5), we rewrite the convective term in the following form:

$$\int_0^T (\widehat{\boldsymbol{w}}_{h,k,\lambda}\cdot\nabla\rho_{h,k,\lambda}, \eta_{h,k})\,dt = -\int_0^T (\nabla\cdot\widehat{\boldsymbol{w}}_{h,k,\lambda}\rho_{h,k,\lambda}, \eta_{h,k})\,dt,$$
$$-\int_0^T (\rho_{h,k,\lambda}\widehat{\boldsymbol{w}}_{h,k,\lambda}, \nabla\eta_{h,k})\,dt = -\int_0^T (\rho_{h,k,\lambda}\widehat{\boldsymbol{w}}_{h,k,\lambda}, \nabla\eta_{h,k})\,dt,$$

where we have used Remark 3.1. Therefore, (8.5) remains as

$$\int_0^T \Big(\widehat{\rho}_{h,k,\lambda}, -\frac{d}{dt}\widetilde{\eta}_{h,k}\Big) + \lambda(\nabla\rho_{h,k,\lambda}, \nabla\eta_{h,k}) - (\widehat{\boldsymbol{w}}_{h,k,\lambda}\,\rho_{h,k,\lambda}, \nabla\eta_{h,k}) = (\rho_{0h}, \eta_h^0).$$

By taking into account the weak and strong convergences obtained in previous subsections, it is possible to pass to the limit. Notice that, by arguing as in [9], one can prove that

$$\lambda\int_0^T (\nabla\rho_{h,k,\lambda}, \nabla\eta_{h,k})\,dt \to 0 \quad \text{as } (h,k,\lambda)\to 0.$$

8.3.2. Velocity system. Before taking a limit in the discrete momentum system (1.9), we will write (1.9) in a completely conservative form. For this, summing to both sides of (1.9) the terms

$$\frac{1}{2}\left(\frac{\rho_h^{n+1}-\rho_h^n}{k}, \boldsymbol{u}_h^{n+1}\cdot\bar{\boldsymbol{u}}_h\right) - \frac{1}{2}(\rho_h^{n+1}\boldsymbol{u}_h^n - \lambda\nabla\rho_h^{n+1}, \nabla(\boldsymbol{u}_h^{n+1}\cdot\bar{\boldsymbol{u}}_h))$$

provides that, for each $\bar{\boldsymbol{u}}_h \in \mathbf{V}_h$,

$$\begin{cases} \left(\dfrac{\rho_h^{n+1}\boldsymbol{u}_h^{n+1}-\rho_h^n\boldsymbol{u}_h^n}{k}, \bar{\boldsymbol{u}}_h\right) - ((\rho_h^{n+1}\boldsymbol{u}_h^n - \lambda\nabla\rho_h^{n+1})\otimes\boldsymbol{u}_h^{n+1}, \nabla\bar{\boldsymbol{u}}_h) \\ + a\Big(\rho_h^{n+1}, \boldsymbol{u}_h^{n+1}, \bar{\boldsymbol{u}}_h\Big) = (\rho_h^{n+1}\boldsymbol{f}^{\,n+1}, \bar{\boldsymbol{u}}_h) + (p_h^{n+1}, \nabla\cdot\bar{\boldsymbol{u}}_h) \\ + \dfrac{1}{2}\left(\dfrac{\rho_h^{n+1}-\rho_h^n}{k}, \boldsymbol{u}_h^{n+1}\cdot\bar{\boldsymbol{u}}_h\right) - \dfrac{1}{2}(\rho_h^{n+1}\boldsymbol{u}_h^n - \lambda\nabla\rho_h^{n+1}, \nabla(\boldsymbol{u}_h^{n+1}\cdot\bar{\boldsymbol{u}}_h)). \end{cases} \tag{8.6}$$

Now we consider Q_h the projector operator onto W_h with respect to the H^1-norm:

$$Q_h : H^1(\Omega) \to W_h \text{ such that } (Q_h v, w)_{H^1(\Omega)} = (v,w)_{H^1(\Omega)} \quad \forall w \in W_h,$$

where $(\cdot,\cdot)_{H^1(\Omega)}$ denotes the usual H^1-inner product.

By subtracting from the second member of (8.6) the result of taking $\bar\rho_h = \frac12 Q_h(\boldsymbol{u}_h^{n+1}\cdot \bar{\boldsymbol{u}}_h)$ as a test function in (1.8) and integrating by parts the convective term, one has

$$\begin{cases} \left(\dfrac{\rho_h^{n+1}\boldsymbol{u}_h^{n+1}-\rho_h^n\boldsymbol{u}_h^n}{k},\bar{\boldsymbol{u}}_h\right)-\Big((\rho_h^{n+1}\boldsymbol{u}_h^n-\lambda\nabla\rho_h^{n+1})\otimes\boldsymbol{u}_h^{n+1},\nabla\bar{\boldsymbol{u}}_h\Big)\\ +a\Big(\rho_h^{n+1},\boldsymbol{u}_h^{n+1},\bar{\boldsymbol{u}}_h\Big)=\Big(\rho_h^{n+1}\boldsymbol{f}^{\,n+1},\bar{\boldsymbol{u}}_h\Big)+\Big(p_h^{n+1},\nabla\cdot\bar{\boldsymbol{u}}_h\Big)\\ +\dfrac12\left(\dfrac{\rho_h^{n+1}-\rho_h^n}{k},\boldsymbol{u}_h^{n+1}\cdot\bar{\boldsymbol{u}}_h-Q_h(\boldsymbol{u}_h^{n+1}\cdot\bar{\boldsymbol{u}}_h)\right)\\ -\dfrac12\Big(\rho_h^{n+1}\boldsymbol{w}_h^n,\nabla(\boldsymbol{u}_h^{n+1}\cdot\bar{\boldsymbol{u}}_h-Q_h(\boldsymbol{u}_h^{n+1}\cdot\bar{\boldsymbol{u}}_h))\Big)\\ -\dfrac12\Big(\rho_h^{n+1}(\boldsymbol{u}_h^n-\boldsymbol{w}_h^n),\nabla(\boldsymbol{u}_h^{n+1}\cdot\bar{\boldsymbol{u}}_h)\Big)+\dfrac12\Big(\nabla\cdot\boldsymbol{w}_h^n\,\rho_h^{n+1},Q_h(\boldsymbol{u}_h^{n+1}\cdot\bar{\boldsymbol{u}}_h)\Big)\\ -\dfrac{\lambda}{2}\Big(\rho_h^{n+1},\boldsymbol{u}_h^{n+1}\cdot\bar{\boldsymbol{u}}_h-Q_h(\boldsymbol{u}_h^{n+1}\cdot\bar{\boldsymbol{u}}_h)\Big), \end{cases}$$

where we have used the definition of Q_h in the last term on the right-hand side. Note that the term $(\nabla\cdot\boldsymbol{w}_h^n\,\rho_h^{n+1},Q_h(\boldsymbol{u}_h^{n+1}\cdot\bar{\boldsymbol{u}}_h))=0$ thanks to Remark 3.1.

In a similar way to section 7, we arrive at

$$\begin{cases} -\displaystyle\int_0^T\Big(\widehat\rho_{h,k,\lambda}\widehat{\boldsymbol{u}}_{h,k,\lambda},\frac{\partial}{\partial t}\widetilde{\boldsymbol{v}}_{h,k}\Big)-\Big(\rho_{0h}\boldsymbol{u}_{0h},\boldsymbol{v}_h^0\Big)\\ -\displaystyle\int_0^T\Big(\rho_{h,k,\lambda}\widehat{\boldsymbol{u}}_{h,k}-\lambda\nabla\rho_{h,k,\lambda}\otimes\boldsymbol{u}_{h,k,\lambda},\nabla\boldsymbol{v}_{h,k}\Big)+a\Big(\rho_{h,k,\lambda},\boldsymbol{u}_{h,k,\lambda},\boldsymbol{v}_{h,k}\Big)\\ =\displaystyle\int_0^T\Big(\rho_{h,k,\lambda}\boldsymbol{f}_k,\boldsymbol{v}_{h,k}\Big)+\frac12\int_0^T\left(\frac{\partial}{\partial t}\widetilde\rho_{h,k},\boldsymbol{u}_{h,k,\lambda}\cdot\boldsymbol{v}_{h,k}-Q_h(\boldsymbol{u}_{h,k,\lambda}\cdot\boldsymbol{v}_{h,k})\right)\\ -\dfrac12\displaystyle\int_0^T\Big(\rho_{h,k,\lambda}\widehat{\boldsymbol{w}}_{h,k,\lambda},\nabla(\boldsymbol{u}_{h,k,\lambda}\cdot\boldsymbol{v}_{h,k}-Q_h(\boldsymbol{u}_{h,k,\lambda}\cdot\boldsymbol{v}_{h,k}))\Big)\\ -\dfrac12\displaystyle\int_0^T\Big(\rho_{h,k,\lambda}(\widehat{\boldsymbol{u}}_{h,k,\lambda}-\widehat{\boldsymbol{w}}_{h,k,\lambda}),\nabla(\boldsymbol{u}_{h,k,\lambda}\cdot\boldsymbol{v}_{h,k}-Q_h(\boldsymbol{u}_{h,k,\lambda}\cdot\boldsymbol{v}_{h,k}))\Big)\\ -\dfrac{\lambda}{2}k\displaystyle\int_0^T\Big(\rho_{h,k,\lambda},\boldsymbol{u}_{h,k,\lambda}\cdot\boldsymbol{v}_{h,k}-Q_h(\boldsymbol{u}_{h,k,\lambda}\cdot\boldsymbol{v}_{h,k})\Big)\\ :=\displaystyle\int_0^T\Big(\rho_{h,k,\lambda}\boldsymbol{f}_k,\boldsymbol{v}_{h,k}\Big)+R_1+R_2+R_3+R_4, \end{cases}$$

where $\boldsymbol{v}_{h,k}$ and $\widetilde{\boldsymbol{v}}_{h,k}$ are suitable approximations of a test function $\boldsymbol{v}\in C^1([0,T];\boldsymbol{C}_c^\infty(\Omega))$.

Again, by using the estimates independent of λ and arguing as in the continuous case [9], one can prove that

$$\lambda\int_0^T(\nabla\rho_{h,k,\lambda}\otimes\boldsymbol{u}_{h,k,\lambda},\nabla\boldsymbol{v}_{h,k})\to0\quad\text{ as }(h,k,\lambda)\to0,$$

$$\lambda\int_0^T\left(\rho_{h,k,\lambda}-\frac{\widetilde M+\widetilde m}{2}\right)(\nabla\boldsymbol{u}_{h,k,\lambda})^t,\nabla\boldsymbol{v}_{h,k}\to0\quad\text{ as }(h,k,\lambda)\to0.$$

To finish the passage to the limit, we show only that the residual terms R_i vanish as $(h,k,\lambda)\to 0$. For this, we impose that the sequence of test functions $\boldsymbol{v}_{h,k}$ is bounded in $L^\infty(0,T;\boldsymbol{W}^{1,3}(\Omega)\cap\boldsymbol{L}^\infty(\Omega))$.

We bound R_1, thanks to estimates (ii) and (vi) of Lemma 3.2, as follows:

$$R_1 \le C\sum_{n=0}^{N-1}|\rho_h^{n+1}-\rho_h^n|h\|\boldsymbol{u}_h^{n+1}\|\|\boldsymbol{v}_h^n\|_{W^{1,3}\cap L^\infty}\le C\frac{h}{k}\to 0\quad\text{(thanks to (S$'$))}.$$

By integrating by parts R_2,

$$\begin{aligned}R_2 &= -\int_0^T\Big(\widehat{\boldsymbol{u}}_{h,k,\lambda}\cdot\nabla\rho_{h,k,\lambda},\boldsymbol{u}_{h,k,\lambda}\cdot\boldsymbol{v}_{h,k}-Q_h(\boldsymbol{u}_{h,k,\lambda}\cdot\boldsymbol{v}_{h,k})\Big)\\ &\quad-\int_0^T\Big(\nabla\cdot\widehat{\boldsymbol{u}}_{h,k,\lambda}\,\rho_{h,k,\lambda},\boldsymbol{u}_{h,k,\lambda}\cdot\boldsymbol{v}_{h,k}-Q_h(\boldsymbol{u}_{h,k,\lambda}\cdot\boldsymbol{v}_{h,k})\Big):=R_2^1+R_2^2.\end{aligned}$$

By using the (duality) result of the Aubin–Nitsche type $|u-Q_hu|\le C\,h\|u\|_{H^1(\Omega)}$, the first term of R_2 can be estimated as follows:

$$\begin{aligned}R_2^1&\le\int_0^T\|\widehat{\boldsymbol{u}}_{h,k,\lambda}\|\|\nabla\rho_{h,k,\lambda}\|_{L^3(\Omega)}h\|\boldsymbol{u}_{h,k,\lambda}\|\|\boldsymbol{v}_{h,k}\|_{W^{1,\infty}(\Omega)}\\ &\le C\frac{h}{k^{1/4}\lambda^{3/4}}\|\widehat{\boldsymbol{u}}_{h,k,\lambda}\|_{L^2(0,T;H_0^1(\Omega))}\lambda^{3/4}k^{1/4}\|\nabla\rho_{h,k,\lambda}\|_{L^\infty(0,T;L^3(\Omega))}\\ &\qquad\|\boldsymbol{u}_{h,k,\lambda}\|_{L^2(0,T;H_0^1(\Omega))}\\ &\le C\frac{h}{k^{1/4}\lambda^{3/4}}\lambda^{3/4}\|\nabla\rho_{h,k,\lambda}\|_{L^4(0,T;L^3(\Omega))}\le C\frac{h}{k^{1/4}\lambda^{3/4}}\to 0\quad\text{(thanks to (S$'$))}.\end{aligned}$$

The convergence to zero of the other term R_2^2 can be made in a similar way.

The term R_3 is handled as follows:

$$\begin{aligned}R_3&\le\int_0^T\|\rho_{h,k,\lambda}\|_{L^\infty(\Omega)}|\widehat{\boldsymbol{u}}_{h,k,\lambda}-\widehat{\boldsymbol{w}}_{h,k,\lambda}||\nabla(\boldsymbol{u}_{h,k,\lambda}\cdot\boldsymbol{v}_{h,k}-Q_h(\boldsymbol{u}_{h,k,\lambda}\cdot\boldsymbol{v}_{h,k}))|\\ &\le C\,h\int_0^T\|\widehat{\boldsymbol{u}}_{h,k,\lambda}-\widehat{\boldsymbol{w}}_{h,k,\lambda}\|\|\boldsymbol{u}_{h,k,\lambda}\|\|\boldsymbol{v}_{h,k}\|_{W^{1,3}(\Omega)\cap L^\infty(\Omega)}\le C\,h\to 0,\end{aligned}$$

where we have used (3.8) and the stability property of Q_h in the H^1-norm.

Finally, the convergence to zero of R_4 is easy to deduce. This concludes the proof of Theorem 1.2. ∎

Remark 8.5. The asymptotic behavior as λ goes to zero of the scheme (7.2)–(7.5) (see Remark 7.2), associated to a problem with density-dependent diffusion, remains as an open problem. In fact, when $\lambda\to 0$, both diffusion coefficients (viscosity and mass diffusion) vanish. Therefore, we find a viscosity-vanishing problem, which is an open problem even in the continuous case.

Appendix A: Proof of Lemma 3.4. We consider the following auxiliary semi-discrete scheme: Find $\rho^{n+1}\in H^2(\Omega)$ as the solution of the problem:

$$\text{(A.1)}\qquad \frac{\rho^{n+1}-\rho^n}{k}+\boldsymbol{w}_h^n\cdot\nabla T_m^M\rho^{n+1}-\lambda\Delta\rho^{n+1}=0\ \text{ in }\Omega,\quad \frac{\partial\rho^{n+1}}{\partial\boldsymbol{n}}\Big|_{\partial\Omega}=0,$$

where

$$T_m^M\rho^{n+1}(\boldsymbol{x},t)=\begin{cases}\rho^{n+1}(\boldsymbol{x},t) & \text{if}\quad \rho^{n+1}(\boldsymbol{x},t)\in[m,M],\\ m & \text{if}\quad \rho^{n+1}(\boldsymbol{x},t)<m,\\ M & \text{if}\quad \rho^{n+1}(\boldsymbol{x},t)>M.\end{cases}$$

LEMMA A.1. *Problem* (A.1) *has a unique solution.*

Proof. Let $R : H^1(\Omega) \to H^1(\Omega)$ be defined by $Rw = v$, where v is the weak solution of the elliptic problem:

$$\frac{v}{k} - \lambda\Delta v = -\boldsymbol{w}_h^n \cdot \nabla T_m^M w + \frac{1}{k}\rho^n \text{ in } \Omega, \quad \frac{\partial v}{\partial \boldsymbol{n}}\Big|_{\partial\Omega} = 0. \tag{A.2}$$

Notice that $T_m^M w$ is defined a.e. in Q. In addition, as $-\boldsymbol{w}_h^n \cdot \nabla T_m^M w + \frac{1}{k}\rho^n \in H^1(\Omega)'$, R is well-defined, that is, there exists a unique $v \in H^1(\Omega)$ such that $Rw = v$.

By using v as a test function in (A.2) and integrating by parts, we arrive at

$$\frac{1}{k}|v|^2 + \lambda|\nabla v|^2 \le |\nabla \cdot \boldsymbol{w}_h^n|\,\|T_m^M w\|_{L^\infty(\Omega)}|v| + |\boldsymbol{w}_h^n|\|T_m^M w\|_{L^\infty(\Omega)}|\nabla v| + \frac{1}{k}|\rho^n|\,|v|.$$

Since $\|T_m^M w\|_{L^\infty(\Omega)} = M$, then $\|v\|_{H^1(\Omega)} \le C$, with $C > 0$ a constant independent of w. Therefore, by taking any $r \ge C$, one has that if $\|w\|_{H^1(\Omega)} \le r$, then $\|Rw\|_{H^1(\Omega)} \le r$. To apply Schauder's fixed point theorem we have to prove that $R : H^1(\Omega) \to H^1(\Omega)$ is continuous and compact. For this, it suffices to demonstrate that

$$\text{if} \quad w_l \rightharpoonup w \ \text{ in } H^1(\Omega), \quad \text{then} \quad Rw_l \to Rw \text{ in } H^1(\Omega) \text{ as } l \to \infty.$$

Indeed, from $w_l \rightharpoonup w$ in $H^1(\Omega)$, it holds by compactness that $w_l \to w$ in $L^2(\Omega)$. Therefore, there exists a subsequence, that to simplify notation is denoted in the same way, such that $w_l \to w$ a.e. in Ω. By virtue of dominated convergence theorem, we have

$$\boldsymbol{w}_h^n \cdot \nabla T_m^M w_l + \frac{1}{k}\rho^n \longrightarrow \boldsymbol{w}_h^n \cdot \nabla T_m^M w + \frac{1}{k}\rho^n \text{ in } H^1(\Omega)' \text{ as } l \to \infty. \tag{A.3}$$

On the other hand, the mapping $h \in H^1(\Omega)' \to z \in H^1(\Omega)$, where z is the solution

$$\frac{1}{k}\Big(z, \bar{z}\Big) - \lambda\Big(\nabla z, \nabla \bar{z}\Big) = \Big\langle h, \bar{z}\Big\rangle_{H^1(\Omega)' H^1(\Omega)} \quad \forall \bar{z} \in H^1(\Omega),$$

is linear and continuous (by the Lax–Milgram theorem). Then from (A.3) we have $Rw_l \to Rw$ in $H^1(\Omega)$.

In conclusion, $R|_{\overline{B}(0,r)} : \overline{B}(0,r) \to \overline{B}(0,r)$ is continuous and compact. By Schauder's fixed point theorem, we have the desired result after a regularity result for elliptic equations. ∎

THEOREM A.2. *The solution of problem* (A.1) *verifies the maximum principle; i.e., if* $m \le \rho^0 \le M$, *then* $m \le \rho^n \le M$ *for each* $n \ge 1$.

Proof. Let us first see that if $\rho^n \le M$, then $\rho^{n+1} \le M$. By multiplying (A.1) by $(\rho^{n+1} - M)_+$ and integrating over Ω (we denote $f(x)_+ = \begin{cases} f(x) & \text{if } f(x) > 0, \\ 0 & \text{if } f(x) \le 0, \end{cases}$), this gives us

$$\begin{aligned}&\left(\frac{\rho^{n+1} - \rho^n}{k}, (\rho^{n+1} - M)_+\right) + \Big(\boldsymbol{w}_h^n \cdot \nabla T_m^M \rho^{n+1}, (\rho^{n+1} - M)_+\Big) \\ &+ \lambda(\nabla\rho^{n+1}, \nabla(\rho^{n+1} - M)_+) = 0.\end{aligned}$$

By using properties of the positive part function and the fact that $T_m^M \rho^{n+1} = M$ as $(\rho^{n+1} - M)_+ \ne 0$, we rewrite it as

$$\left(\frac{\rho^{n+1} - \rho^n}{k}, (\rho^{n+1} - M)_+\right) + \lambda\Big(\nabla(\rho^{n+1} - M)_+, \nabla(\rho^{n+1} - M)_+\Big) = 0. \tag{A.4}$$

Therefore, we deduce from (A.4) that $(\rho^{n+1}-\rho^n,(\rho^{n+1}-M)_+)\le 0$. By adding and subtracting M, one arrives at $((\rho^{n+1}-M)-(\rho^n-M),(\rho^{n+1}-M)_+)\le 0$. Again, by the properties of the positive part function, we obtain

$$\big((\rho^{n+1}-M),(\rho^{n+1}-M)_+\big)=\big((\rho^{n+1}-M)_+,(\rho^{n+1}-M)_+\big)=|(\rho^{n+1}-M)_+|^2.$$

By the induction hypothesis $\rho^n-M\le 0$, and then $(\rho^n-M,(\rho^{n+1}-M)_+)\le 0$. Consequently, $|(\rho^{n+1}-M)_+|^2\le(\rho^n-M,(\rho^{n+1}-M)_+)\le 0$, and then $\rho^{n+1}\le M$ holds.

The proof of the other bound—if $\rho^n\ge m$, then $\rho^{n+1}\ge m$—can be obtained in the same way. ∎

Corollary A.3. *Problem* (A.1) *is equivalent to problem* (3.9).

Proof. Since ρ^{n+1} the solution of problem (A.1) verifies the maximum principle $m\le\rho^{n+1}\le M$, then, in particular from the definition of truncating operator T_m^M, one has $T_m^M\rho^{n+1}=\rho^{n+1}$, and problem (A.1) is rewritten as problem (3.9). ∎

From the uniqueness of the solution of problem (3.9), we have, in particular, that problem (3.9) verifies the maximum principle

$$0<m\le\rho^n(\boldsymbol{x})\le M\quad\forall\boldsymbol{x}\in\Omega\quad\forall\, n.$$

Therefore, to finish the proof of Lemma 3.4, it remains to prove strong estimates (independent of λ,h,k) for the ρ^{n+1} solution of (3.9). For this, it will be fundamental to use the pointwise estimates $m\le\rho^{n+1}\le M$ in Q.

We define $\eta^{n+1}=\rho^{n+1}-\frac{1}{|\Omega|}\int_\Omega\rho^{n+1}$, and hence $\frac{1}{|\Omega|}\int_\Omega\eta^{n+1}=0$. Then the $\|\eta^{n+1}\|_{H^1}$-norm is equivalent to $|\nabla\eta^{n+1}|$, and the $\|\eta^{n+1}\|_{H^2}$-norm is equivalent to $|\Delta\eta^{n+1}|$. Since $m\le\frac{1}{|\Omega|}\int_\Omega\rho^{n+1}\le M$, the estimates for $\|\eta^{n+1}\|_{H^1}$ and $\|\eta^{n+1}\|_{H^2}$ imply estimates for $\|\rho^{n+1}\|_{H^1}$ and $\|\rho^{n+1}\|_{H^2}$, respectively.

With this definition of η^{n+1}, problem (3.9) can be rewritten as:

$$\frac{\eta^{n+1}-(\rho^n-\frac{1}{|\Omega|}\int_\Omega\rho^{n+1})}{k}+\boldsymbol{w}_h^n\cdot\nabla\eta^{n+1}-\lambda\Delta\eta^{n+1}=0\ \text{ in }\Omega,\quad\frac{\partial\eta^{n+1}}{\partial\boldsymbol{n}}\Big|_{\partial\Omega}=0.$$

By multiplying by $-2\,k\,\Delta\eta^{n+1}$, we arrive at

$$\begin{aligned}&|\nabla\eta^{n+1}|^2-\left|\nabla\left(\rho^n-\frac{1}{|\Omega|}\int_\Omega\rho^{n+1}\right)\right|^2+|\nabla(\rho^{n+1}-\rho^n)|^2+2\lambda\,k|\Delta\eta^{n+1}|^2\\&\le 2k\Big(\boldsymbol{w}_h^n\cdot\nabla\eta^{n+1},\Delta\eta^{n+1}\Big):=K_1.\end{aligned}$$

By integrating by parts in K_1,

$$K_1=-2k(\nabla\boldsymbol{w}_h^n,\nabla\eta^{n+1}\otimes\nabla\eta^{n+1})+k(\nabla\cdot\boldsymbol{w}_h^n,|\nabla\eta^{n+1}|^2).$$

By using $\|\nabla\eta^{n+1}\|_{L^4(\Omega)}\le C\,\|\eta^{n+1}\|_{L^\infty}^{1/2}|\Delta\eta^{n+1}|^{1/2}\le C\,|\Delta\eta^{n+1}|^{1/2}$, we get

$$K_1\le Ck\|\boldsymbol{w}_h^n\|\,\|\nabla\eta^{n+1}\|_{L^4(\Omega)}^2\le Ck\|\boldsymbol{w}_h^n\|\,|\Delta\eta^{n+1}|\le\frac{C_\varepsilon}{\lambda}\,k\,\|\boldsymbol{w}_h^n\|^2+\varepsilon\,\lambda\,k|\Delta\eta^{n+1}|^2.$$

Therefore,

$$|\nabla\eta^{n+1}|^2-\left|\nabla\left(\rho^n-\frac{1}{|\Omega|}\int_\Omega\rho^{n+1}\right)\right|^2+\lambda k|\Delta\eta^{n+1}|^2\le\frac{C}{\lambda}\,k\|\boldsymbol{w}_h^n\|^2.$$

By using the fact that $\nabla(\rho^n - \frac{1}{|\Omega|}\int \rho^{n+1}) = \nabla\rho^n = \nabla\eta^n$, we have

$$\lambda\|\eta^{n+1}\|_{H^1}^2 - \lambda\|\eta^n\|_{H^1}^2 + \lambda\|\rho^{n+1} - \rho^n\|_{H^1}^2 + \lambda^2 k\,\|\eta^{n+1}\|_{H^2}^2 \leq C\,k\|\boldsymbol{w}_h^n\|^2.$$

By summing over n and applying $k\sum_{n=1}^N \|\boldsymbol{w}_h^n\|^2 \leq C$, we get the following bounds:

$$\lambda \max_{0\leq n\leq N}\|\rho^n\|_{H^1(\Omega)}^2 \leq C, \quad \lambda^2\,k\sum_{n=1}^N \|\rho^n\|_{H^2(\Omega)}^2 \leq C,$$

where $C > 0$ is independent of λ, h, k. This concludes the proof of Lemma 3.4. ∎

A SPARSE GRID STOCHASTIC COLLOCATION METHOD FOR PARTIAL DIFFERENTIAL EQUATIONS WITH RANDOM INPUT DATA*

F. NOBILE†, R. TEMPONE‡, AND C. G. WEBSTER§

Abstract. This work proposes and analyzes a Smolyak-type sparse grid stochastic collocation method for the approximation of statistical quantities related to the solution of partial differential equations with random coefficients and forcing terms (input data of the model). To compute solution statistics, the sparse grid stochastic collocation method uses approximate solutions, produced here by finite elements, corresponding to a deterministic set of points in the random input space. This naturally requires solving uncoupled deterministic problems as in the Monte Carlo method. If the number of random variables needed to describe the input data is moderately large, full tensor product spaces are computationally expensive to use due to the *curse of dimensionality*. In this case the sparse grid approach is still expected to be competitive with the classical Monte Carlo method. Therefore, it is of major practical relevance to understand in which situations the sparse grid stochastic collocation method is more efficient than Monte Carlo. This work provides error estimates for the fully discrete solution using L^q norms and analyzes the computational efficiency of the proposed method. In particular, it demonstrates algebraic convergence with respect to the total number of collocation points and quantifies the effect of the dimension of the problem (number of input random variables) in the final estimates. The derived estimates are then used to compare the method with Monte Carlo, indicating for which problems the former is more efficient than the latter. Computational evidence complements the present theory and shows the effectiveness of the sparse grid stochastic collocation method compared to full tensor and Monte Carlo approaches.

Introduction. Mathematical modeling and computer simulations are nowadays widely used tools to predict the behavior of physical and engineering problems. Whenever a particular application is considered, the mathematical models need to be equipped with input data, such as coefficients, forcing terms, boundary conditions, geometry, etc. However, in many applications, such input data may be affected by a relatively large amount of uncertainty. This can be due to an intrinsic variability

in the physical system, as, for instance, in the mechanical properties of many biomaterials, polymeric fluids, and composite materials or the action of wind or seismic vibrations on civil structures.

In other situations, uncertainty may come from our difficulty in characterizing accurately the physical system under investigation, as in the study of groundwater flows, where the subsurface properties such as porosity and permeability in an aquifer have to be extrapolated from measurements taken only in a few spatial locations.

Such uncertainties can be included in the mathematical model adopting a probabilistic setting, provided enough information is available for a complete statistical characterization of the physical system. In this framework, the input data are modeled as *random variables* or, more generally, as *random fields* with a given spatial (or temporal) correlation structure.

Therefore, the goal of the mathematical and computational analysis becomes the prediction of statistical moments of the solution (mean value, variance, covariance, etc.) or statistics of some given responses of the system (sometimes also called quantities of physical interest which are real valued functionals of the solution), given the probability distribution of the input random data. Examples of quantities of interest could be the solution values in a given region, fluxes across given boundaries, etc.

In order to parametrize the input data for a given partial differential equation (PDE), random fields that are either coefficients or loads can often be expanded as an infinite combination of random variables by, for instance, the so-called Karhunen–Loève [23, 24] or polynomial chaos (PC) expansions [34, 38]. Although such random fields are properly described only by means of an infinite number of random variables, whenever the realizations are slowly varying in space, with a correlation length comparable to the size of the domain, only a few terms in the above-mentioned expansions are typically needed to describe the random field with sufficient accuracy. Therefore, in this case, it is reasonable to limit the analysis to just a few random variables in the expansion (see, e.g., [2, 16]).

In this work we focus on PDEs whose coefficients and forcing terms are described by a finite-dimensional random vector. This is often called *finite-dimensional noise assumption* and may hold either because the problem itself can be described by a finite number of random variables or because the input coefficients are modeled as truncated random fields.

The most popular approach to solving mathematical problems in a probabilistic setting is the Monte Carlo method (see, e.g., [15] and the references therein). The Monte Carlo method is easy to implement and allows one to reuse available deterministic codes. However, the convergence rate is typically very slow, although with a mild dependence on the number on sampled random variables.

In the last few years, other approaches have been proposed, which in certain situations feature a much faster convergence rate. We mention, among others, the spectral Galerkin method [20, 37, 4, 5, 16, 26, 22, 28], stochastic collocation [3, 30, 25, 36], and perturbation methods or Neumann expansions [17, 35, 1, 31].

For certain classes of problems, the solution may have a very regular dependence on the input random variables. For instance, it was shown in [3] and [4] that the solution of a linear elliptic PDE with diffusivity coefficient and/or forcing term described as truncated expansions of random fields is analytic in the input random variables. In such situations, spectral Galerkin or stochastic collocation methods based on orthogonal tensor product polynomials feature a very fast convergence rate.

In particular, our earlier work [3] proposed a stochastic collocation/finite element

method based on standard finite element approximations in space and a collocation on a tensor grid built upon the zeros of orthogonal polynomials with respect to the joint probability density function of the input random variables. It was shown that for an elliptic PDE the error converges exponentially fast with respect to the number of points employed for each random input variable.

The stochastic collocation method can be easily implemented and leads naturally to the solution of uncoupled deterministic problems as in the Monte Carlo method, even in the presence of input data which depend nonlinearly on the driving random variables. It can also treat efficiently the case of nonindependent random variables with the introduction of an auxiliary density and can handle, for instance, cases with log-normal diffusivity coefficient, which is not bounded in $\Omega \times D$ but has bounded realizations. When the number of input random variables is small, stochastic collocation is a very effective numerical tool.

On the other hand, approximations based on tensor product grids suffer from the *curse of dimensionality* since the number of collocation points in a tensor grid grows exponentially fast in the number of input random variables.

If the number of random variables is moderately large, one should rather consider sparse tensor product spaces as first proposed by Smolyak [29] and further investigated by, e.g., [18, 6, 16, 36], which will be the primary focus of this paper. It is natural to expect that the use of sparse grids will reduce dramatically the number of collocation points, while preserving a high level of accuracy and thus being able to successfully compete with Monte Carlo. Our main purpose is to clarify the limitations of the previous statement and to understand in which situations the sparse grid stochastic collocation method is more efficient than Monte Carlo.

Motivated by the above, this work proposes and analyzes a Smolyak-type sparse grid stochastic collocation method for the approximation of statistical quantities related to the solution of PDEs whose input data are described through a finite number of random variables. The sparse tensor product grids are built upon either Clenshaw–Curtis [11] or Gaussian abscissas. After outlining the method, this work provides strong error estimates for the fully discrete solution and analyzes its computational efficiency. In particular, it proves algebraic convergence with respect to the total number of collocation points or, equivalently, the total computational work which is directly proportional to the number of collocation points. The exponent of such algebraic convergence is connected to both the regularity of the solution and the number of input random variables, N, and essentially deteriorates with N by a $1/\log(N)$ factor. Then these error estimates are used to compare the method with the standard Monte Carlo method, indicating for which problems the former is more efficient than the latter.

Moreover, this work addresses the case where the input random variables come from suitably truncated expansions of random fields. There it discusses how to relate the number of points in the sparse grid to the number of random variables retained in the truncated expansion in order to balance discretization error with truncation error in the input random fields. Computational evidence complements the present theory and shows the effectiveness of the sparse grid stochastic collocation method. It also includes a comparison with full tensor and Monte Carlo methods.

The outline of the work is the following: Section 1 introduces the mathematical problem and basic notation and states a regularity assumption to be used later in the error analysis. Section 2 summarizes various collocation techniques and describes the sparse approximation method under study. It also describes two types of abscissas,

Clenshaw–Curtis and Gaussian, that will be employed in the sparse approximation method.

Section 3 is the core of the work. We first develop strong error estimates for the fully discrete solution using L_P^∞ and L_P^2 norms for Clenshaw–Curtis and Gaussian abscissas, respectively (P being the probability measure considered). These norms control the error in the approximation of expected values of smooth functionals of the solution. Then in section 3.2 these error estimates are used to compare the method with the standard Monte Carlo method, explaining cases where the former is more efficient than the latter.

Sections 4 and 5 focus on applications to linear elliptic PDEs with random input data. In section 4 we verify that the assumptions under which our general theory works hold in this particular case. Then we present in section 5 some numerical results showing the effectiveness of the proposed method when compared to the full tensor and Monte Carlo methods.

1. Problem setting. We begin by focusing our attention on a differential operator $\mathcal{L}$, linear or nonlinear, on a domain $D \subset \mathbb{R}^d$, which depends on some coefficients $a(\omega, x)$ with $x \in D$, $\omega \in \Omega$, where $(\Omega, \mathcal{F}, P)$ is a complete probability space. Here Ω is the set of outcomes, $\mathcal{F} \subset 2^\Omega$ is the σ-algebra of events, and $P : \mathcal{F} \to [0,1]$ is a probability measure. Similarly the forcing term $f = f(\omega, x)$ can be assumed random as well.

Consider the stochastic boundary value problem: find a random function, $u : \Omega \times \overline{D} \to \mathbb{R}$, such that P-a.e. in Ω, or in other words almost surely (a.s.), the following equation holds:

$$\mathcal{L}(a)(u) = f \quad \text{in } D \tag{1.1}$$

equipped with suitable boundary conditions. Before introducing some assumptions we denote by $W(D)$ a Banach space of functions $v : D \to \mathbb{R}$ and define, for $q \in [1, \infty]$, the stochastic Banach spaces

$$L_P^q(\Omega; W(D)) = \Big\{ v : \Omega \to W(D) \mid v \text{ is strongly measurable and } \int_\Omega \|v(\omega, \cdot)\|_{W(D)}^q dP(\omega) < +\infty \Big\}$$

and

$$L_P^\infty(\Omega; W(D)) = \Big\{ v : \Omega \to W(D) \mid v \text{ is strongly measurable and } P - \operatorname*{ess\,sup}_{\omega \in \Omega} \|v(\omega, \cdot)\|_{W(D)}^2 < +\infty \Big\}.$$

Of particular interest is the space $L_P^2(\Omega; W(D))$, consisting of Banach valued functions that have finite second moments.

We will now make the following assumptions:

(A_1) The solution to (1.1) has realizations in the Banach space $W(D)$, i.e., $u(\cdot, \omega) \in W(D)$ a.s. and $\forall \omega \in \Omega$

$$\|u(\cdot, \omega)\|_{W(D)} \le C \|f(\cdot, \omega)\|_{W^*(D)},$$

where we denote $W^*(D)$ to be the dual space of $W(D)$, and C is a constant independent of the realization $\omega \in \Omega$.

(A_2) The forcing term $f \in L^2_P(\Omega; W^*(D))$ is such that the solution u is unique and bounded in $L^2_P(\Omega; W(D))$.

Here we give two example problems that are posed in this setting.

Example 1.1. The linear problem

$$\begin{cases} -\nabla \cdot (a(\omega,\cdot)\nabla u(\omega,\cdot)) = f(\omega,\cdot) & \text{in } \Omega \times D, \\ u(\omega,\cdot) = 0 & \text{on } \Omega \times \partial D, \end{cases} \tag{1.2}$$

with $a(\omega,\cdot)$ uniformly bounded and coercive, i.e.,

$$\text{there exists } a_{min}, a_{max} \in (0,+\infty) \text{ such that}$$
$$P(\omega \in \Omega :\ a(\omega,x) \in [a_{min}, a_{max}] \quad \forall x \in \overline{D}) = 1$$

and $f(\omega,\cdot)$ square integrable with respect to P, satisfies assumptions A_1 and A_2 with $W(D) = H^1_0(D)$ (see [3]).

Example 1.2. Similarly, for $k \in \mathbb{N}^+$, the nonlinear problem

$$\begin{cases} -\nabla \cdot (a(\omega,\cdot)\nabla u(\omega,\cdot)) + u(\omega,\cdot)^{2k+1} = f(\omega,\cdot) & \text{in } \Omega \times D, \\ u(\omega,\cdot) = 0 & \text{on } \Omega \times \partial D, \end{cases} \tag{1.3}$$

with $a(\omega,\cdot)$ uniformly bounded and coercive and $f(\omega,\cdot)$ square integrable with respect to P, satisfies assumptions A_1 and A_2 with $W(D) = H^1_0(D) \cap L^{2k+2}(D)$.

Remark 1.3 (goals of the computation). As said in the introduction, the goal of the mathematical and computational analysis is the prediction of statistical moments of the solution u to (1.1) (mean value, variance, covariance, etc.) or statistics of some given quantities of physical interest $\psi(u)$. Examples of quantities of interest could be the average value of the solution in a given region $D_c \subset D$,

$$\psi(u) = \frac{1}{|D_c|} \int_{D_c} u dx,$$

and similarly average fluxes on a given direction $n \in \mathbb{R}^d$. In the case of Examples 1.1 and 1.2 these fluxes can be written as

$$\psi(u) = \frac{1}{|D_c|} \int_{D_c} a \frac{\partial u}{\partial n} dx.$$

1.1. On finite-dimensional noise. In some applications, the coefficient a and the forcing term f appearing in (1.1) can be described by a random vector $[Y_1, \ldots, Y_N] : \Omega \to \mathbb{R}^N$, as in the following examples. In such cases, we will emphasize such dependence by writing a_N and f_N.

Example 1.4 (piecewise constant random fields). Let us consider again problem (1.2), where the physical domain D is the union of nonoverlapping subdomains D_i, $i = 1, \ldots, N$. We consider a diffusion coefficient that is piecewise constant and random on each subdomain, i.e.,

$$a_N(\omega, x) = a_{min} + \sum_{i=1}^{N} \sigma_i\, Y_i(\omega) 1_{D_i}(x).$$

Here 1_{D_i} is the indicator function of the set D_i, σ_i, a_{min} are positive constants, and the random variables Y_i are nonnegative with unit variance.

In other applications the coefficients and forcing terms in (1.1) may have another type of spatial variation that is amenable to being described by an expansion. Depending on the decay of such an expansion and the desired accuracy in our computations we may retain just the first N terms.

Example 1.5 (Karhunen–Loève expansion). We recall that any second order random field $g(\omega, x)$, with continuous covariance function $\mathrm{cov}[g] : \overline{D \times D} \to \mathbb{R}$, can be represented as an infinite sum of random variables by means, for instance, of a Karhunen–Loève expansion [23, 24]. To this end, introduce the compact and self-adjoint operator $T_g : L^2(D) \to L^2(D)$, which is defined by

$$T_g v(\cdot) := \int_D \mathrm{cov}[g](x, \cdot)\, v(x)\, dx \quad \forall v \in L^2(D).$$

Then consider the sequence of nonnegative decreasing eigenvalues of T_g, $\{\lambda_i\}_{i=1}^{\infty}$, and the corresponding sequence of orthonormal eigenfunctions, $\{b_i\}_{i=1}^{\infty}$, satisfying

$$T_g b_i = \lambda_i b_i, \quad (b_i, b_j)_{L^2(D)} = \delta_{ij} \ \text{ for } \ i, j \in \mathbb{N}_+.$$

In addition, define mutually uncorrelated real random variables

$$Y_i(\omega) := \frac{1}{\sqrt{\lambda_i}} \int_D (g(\omega, x) - E[g](x))\, b_i(x) dx, \quad i = 1, \ldots,$$

with zero mean and unit variance, i.e., $E[Y_i] = 0$ and $E[Y_i Y_j] = \delta_{ij}$ for $i, j \in \mathbb{N}_+$. The truncated Karhunen–Loève expansion g_N, of the stochastic function g, is defined by

$$g_N(\omega, x) := E[g](x) + \sum_{i=1}^{N} \sqrt{\lambda_i}\, b_i(x)\, Y_i(\omega) \quad \forall N \in \mathbb{N}_+.$$

Then by Mercer's theorem (cf. [27, p. 245]), it follows that

$$\lim_{N \to \infty} \left\{ \sup_D E\left[(g - g_N)^2\right] \right\} = \lim_{N \to \infty} \left\{ \sup_D \left(\sum_{i=N+1}^{\infty} \lambda_i b_i^2 \right) \right\} = 0.$$

Observe that the N random variables in (1.5), describing the random data, are then weighted differently due to the decay of the eigenpairs of the Karhunen–Loève expansion. The decay of eigenvalues and eigenvectors has been investigated, e.g., in the works [16] and [31].

The above examples motivate us to consider problems whose coefficients are described by finitely many random variables. Thus, we will seek a random field $u_N : \Omega \times \overline{D} \to \mathbb{R}$, such that a.s. the following equation holds:

$$\mathcal{L}(a_N)(u_N) = f_N \quad \text{in } D. \tag{1.4}$$

We assume that (1.4) admits a unique solution $u_N \in L_P^2(\Omega; W(D))$. Therefore, following the same argument as in [3, p. 1010] yields that the solution u_N of the stochastic boundary value problem (1.4) can be described by the $[Y_1, \ldots, Y_N]$ random variables, i.e., $u_N = u_N(\omega, x) = u_N(Y_1(\omega), \ldots, Y_N(\omega), x)$.

We underline that the coefficients a_N and f_N in (1.4) may be an exact representation of the input data as in Example 1.4 or a suitable truncation of the input data

as in Example 1.5. In the latter case, the solution u_N will also be an approximation of the exact solution u in (1.1) and the truncation error $u - u_N$ has to be properly estimated (see section 3.2).

Remark 1.6 (nonlinear coefficients). In certain cases, one may need to ensure qualitative properties on the coefficients a_N and f_N, and it may be worthwhile describing them as nonlinear functions of Y. For instance, in Example 1.1 one is required to enforce positiveness on the coefficient $a_N(\omega, x)$, say $a_N(\omega, x) \geq a_{min}\ \forall x \in D$, a.s. in Ω. Then a better choice is to expand $\log(a_N - a_{min})$. The following standard transformation guarantees that the diffusivity coefficient is bounded away from zero a.s.:

$$\log(a_N - a_{min})(\omega, x) = b_0(x) + \sum_{1 \leq n \leq N} \sqrt{\lambda_n} b_n(x) Y_n(\omega), \tag{1.5}$$

i.e., one performs a Karhunen–Loève expansion for $\log(a_N - a_{min})$, assuming that $a_N > a_{min}$ a.s. On the other hand, the right-hand side of (1.4) can be represented as a truncated Karhunen–Loève expansion $f_N(\omega, x) = c_0(x) + \sum_{1 \leq n \leq N} \sqrt{\mu_n} c_n(x) Y_n(\omega)$.

For this work we denote by $\Gamma_n \equiv Y_n(\Omega)$ the image of Y_n, where we assume $Y_n(\omega)$ to be bounded. Without loss of generality we can assume $\Gamma_n = [-1, 1]$. We also let $\Gamma^N = \prod_{n=1}^N \Gamma_n$ and assume that the random variables $[Y_1, Y_2, \ldots, Y_N]$ have a joint probability density function

$$\rho : \Gamma^N \to \mathbb{R}_+, \quad \text{with} \quad \rho \in L^\infty(\Gamma^N). \tag{1.6}$$

Thus, the plan is to approximate the function $u_N = u_N(y, x)$ for any $y \in \Gamma^N$ and $x \in \overline{D}$ (see [3, 4]).

Remark 1.7 (unbounded random variables). By using a similar approach to the work [3] we can easily deal with unbounded random variables, such as Gaussian or exponential ones. For the sake of simplicity in the presentation we focus our study on bounded random variables only.

The convergence properties of the collocation techniques that will be developed in the next section depend on the regularity that the solution u_N has with respect to y. Denote $\Gamma_n^* = \prod_{\substack{j=1 \\ j \neq n}}^N \Gamma_j$, and let y_n^* be an arbitrary element of Γ_n^*. Here we require the solution to problem (1.1) to satisfy the following assumption.

Assumption 1.8 (regularity). For each $y_n \in \Gamma_n$, there exists $\tau_n > 0$ such that the function $u_N(y_n, y_n^*, x)$ as a function of y_n, $u_N : \Gamma_n \to C^0(\Gamma_n^*; W(D))$ admits an analytic extension $u(z, y_n^*, x)$, $z \in \mathbb{C}$, in the region of the complex plane

$$\Sigma(\Gamma_n; \tau_n) \equiv \{z \in \mathbb{C},\ \ \text{dist}(z, \Gamma_n) \leq \tau_n\}. \tag{1.7}$$

Moreover, $\forall z \in \Sigma(\Gamma_n; \tau_n)$,

$$\|u_N(z)\|_{C^0(\Gamma_n^*; W(D))} \leq \lambda \tag{1.8}$$

with λ a constant independent of n.

This assumption is sound in several problems; in particular, it can be verified for the linear problem that will be analyzed in section 4. In the more general case, this assumption should be verified for each particular application and will have implications on the allowed regularity of the input data, e.g., coefficients, loads, etc., of the stochastic PDE under study. See also Remark 3.14 for related results based on fewer regularity requirements.

2. Collocation techniques. We seek a numerical approximation to the exact solution of (1.4) in a suitable finite-dimensional subspace. To describe such a subspace properly, we introduce some standard approximation subspaces:

- $W_h(D) \subset W(D)$ is a standard finite element space of dimension N_h, which contains continuous piecewise polynomials defined on regular triangulations $\mathcal{T}_h$ that have a maximum mesh-spacing parameter $h > 0$. We suppose that W_h has the following deterministic approximation property: for a given function $\varphi \in W(D)$,

$$\min_{v \in W_h(D)} \|\varphi - v\|_{W(D)} \leq C(s;\varphi)\, h^s, \tag{2.1}$$

where s is a positive integer determined by the smoothness of φ and the degree of the approximating finite element subspace, and $C(s;\varphi)$ is independent of h.

Example 2.1. Let D be a convex polygonal domain and $W(D) = H_0^1(D)$. For piecewise linear finite element subspaces we have

$$\min_{v \in W_h(D)} \|\varphi - v\|_{H_0^1(D)} \leq c\, h\, \|\varphi\|_{H^2(D)}.$$

That is, $s = 1$ and $C(s;\varphi) = c\|\varphi\|_{H^2(D)}$; see, for example, [7].

We will also assume that there exists a finite element operator $\pi_h : W(D) \to W_h(D)$ with the optimality condition

$$\|\varphi - \pi_h\varphi\|_{W(D)} \leq C_\pi \min_{v \in W_h(D)} \|\varphi - v\|_{W(D)} \quad \forall \varphi \in W(D), \tag{2.2}$$

where the constant C_π is independent of the mesh size h. It is worth noticing that in general the operator π_h will depend on the specific problem, as well as on y, i.e., $\pi_h = \pi_h(y)$.

- $\mathcal{P}_{\mathbf{p}}(\Gamma^N) \subset L^2_\rho(\Gamma^N)$ is the span of tensor product polynomials with degree at most $\mathbf{p} = (p_1, \ldots, p_N)$, i.e., $\mathcal{P}_{\mathbf{p}}(\Gamma^N) = \bigotimes_{n=1}^N \mathcal{P}_{p_n}(\Gamma_n)$, with

$$\mathcal{P}_{p_n}(\Gamma_n) = \operatorname{span}(y_n^k,\, k = 0, \ldots, p_n), \quad n = 1, \ldots, N.$$

Hence the dimension of $\mathcal{P}_{\mathbf{p}}(\Gamma^N)$ is $N_p = \prod_{n=1}^N (p_n + 1)$.

Stochastic collocation entails the evaluation of approximate values $\pi_h u_N(y_k) = u_h^N(y_k) \in W_h(D)$ to the solution u_N of (1.4) on a suitable set of points $y_k \in \Gamma^N$. Then the fully discrete solution $u_{h,\mathbf{p}}^N \in C^0(\Gamma^N; W_h(D))$ is a global approximation (sometimes an interpolation) constructed by linear combinations of the point values. That is,

$$u_{h,\mathbf{p}}^N(y,\cdot) = \sum_{k \in \mathcal{K}} u_h^N(y_k,\cdot) l_k^{\mathbf{p}}(y), \tag{2.3}$$

where, for instance, the functions $l_k^{\mathbf{p}}$ can be taken as the Lagrange polynomials (see sections 2.1 and 2.2). This formulation can be used to compute the mean value or variance of u, as described in [3, section 2], or to approximate expected values of functionals $\psi(u)$ (cf. Remark 1.3) by

$$E[\psi(u)] \approx E[\psi(u_{h,\mathbf{p}}^N)] \approx \sum_{k \in \mathcal{K}} \psi(u_h^N(y_k))\, E[l_k^{\mathbf{p}}].$$

In the next sections we consider different choices of the evaluation points y_k and corresponding weights $E[l_k^{\mathbf{p}}]$ in the associated quadrature formula.

2.1. Full tensor product interpolation. In this section we briefly recall interpolation based on Lagrange polynomials. We first introduce an index $i \in \mathbb{N}_+$, $i \geq 1$. Then, for each value of i, let $\{y_1^i, \ldots, y_{m_i}^i\} \subset [-1,1]$ be a sequence of abscissas for Lagrange interpolation on $[-1,1]$.

For $u \in C^0(\Gamma^1; W(D))$ and $N = 1$ we introduce a sequence of one-dimensional Lagrange interpolation operators $\mathscr{U}^i : C^0(\Gamma^1; W(D)) \to V_{m_i}(\Gamma^1; W(D))$,

$$\mathscr{U}^i(u)(y) = \sum_{j=1}^{m_i} u(y_j^i)\, l_j^i(y) \quad \forall u \in C^0(\Gamma^1; W(D)), \tag{2.4}$$

where $l_j^i \in \mathcal{P}_{m_i-1}(\Gamma^1)$ are the Lagrange polynomials of degree $m_i - 1$, i.e., $l_j^i(y) = \prod_{\substack{k=1 \\ k\neq j}}^{m_i} \frac{(y-y_k^i)}{(y_j^i - y_k^i)}$, and

$$V_m(\Gamma^1; W(D)) = \left\{ v \in C^0(\Gamma^1; W(D)) \,:\, v(y,x) = \sum_{k=1}^{m} \widetilde{v}_k(x) l_k(y),\ \{\widetilde{v}_k\}_{k=1}^m \in W(D) \right\}.$$

Formula (2.4) reproduces exactly all polynomials of degree less than m_i. Now, in the multivariate case $N > 1$, for each $u \in C^0(\Gamma^N; W(D))$ and the multi-index $\mathbf{i} = (i_1, \ldots, i_N) \in \mathbb{N}_+^N$ we define the full tensor product interpolation formulas

$$\mathcal{I}_{\mathbf{i}}^N u(y) = \left(\mathscr{U}^{i_1} \otimes \cdots \otimes \mathscr{U}^{i_N}\right)(u)(y) = \sum_{j_1=1}^{m_{i_1}} \cdots \sum_{j_N=1}^{m_{i_N}} u\left(y_{j_1}^{i_1}, \ldots, y_{j_N}^{i_N}\right) \left(l_{j_1}^{i_1} \otimes \cdots \otimes l_{j_N}^{i_N}\right). \tag{2.5}$$

Clearly, the above product needs $\prod_{n=1}^N m_{i_n}$ function evaluations. These formulas will also be used as the building blocks for the Smolyak method, described next.

2.2. Smolyak approximation. Here we follow closely the work [6] and describe the Smolyak *isotropic* formulas $\mathscr{A}(\mathrm{w}, N)$. The Smolyak formulas are just linear combinations of product formulas (2.5) with the following key properties: only products with a relatively small number of points are used. With $\mathscr{U}^0 = 0$ and for $i \in \mathbb{N}_+$ define

$$\Delta^i := \mathscr{U}^i - \mathscr{U}^{i-1}. \tag{2.6}$$

Moreover, given an integer $\mathrm{w} \in \mathbb{N}_+$, hereafter called the *level*, we define the sets

$$X(\mathrm{w}, N) := \left\{ \mathbf{i} \in \mathbb{N}_+^N, \mathbf{i} \geq \mathbf{1} \,:\, \sum_{n=1}^N (i_n - 1) \leq \mathrm{w} \right\}, \tag{2.7a}$$

$$\widetilde{X}(\mathrm{w}, N) := \left\{ \mathbf{i} \in \mathbb{N}_+^N, \mathbf{i} \geq \mathbf{1} \,:\, \sum_{n=1}^N (i_n - 1) = \mathrm{w} \right\}, \tag{2.7b}$$

$$Y(\mathrm{w}, N) := \left\{ \mathbf{i} \in \mathbb{N}_+^N, \mathbf{i} \geq \mathbf{1} \,:\, \mathrm{w} - N + 1 \leq \sum_{n=1}^N (i_n - 1) \leq \mathrm{w} \right\}, \tag{2.7c}$$

and for $\mathbf{i} \in \mathbb{N}_+^N$ we set $|\mathbf{i}| = i_1 + \cdots + i_N$. Then the isotropic Smolyak formula is given by

$$\mathscr{A}(\mathrm{w}, N) = \sum_{\mathbf{i} \in X(\mathrm{w}, N)} \left(\Delta^{i_1} \otimes \cdots \otimes \Delta^{i_N}\right). \tag{2.8}$$

Equivalently, formula (2.8) can be written as (see [33])

$$\mathscr{A}(\mathrm{w},N)=\sum_{\mathbf{i}\in Y(\mathrm{w},N)}(-1)^{\mathrm{w}+N-|\mathbf{i}|}\binom{N-1}{\mathrm{w}+N-|\mathbf{i}|}\cdot\left(\mathscr{U}^{i_1}\otimes\cdots\otimes\mathscr{U}^{i_N}\right). \tag{2.9}$$

To compute $\mathscr{A}(\mathrm{w},N)(u)$, one only needs to know function values on the "sparse grid"

$$\mathscr{H}(\mathrm{w},N)=\bigcup_{\mathbf{i}\in Y(\mathrm{w},N)}\left(\vartheta^{i_1}\times\cdots\times\vartheta^{i_N}\right)\subset[-1,1]^N, \tag{2.10}$$

where $\vartheta^i=\left\{y_1^i,\ldots,y_{m_i}^i\right\}\subset[-1,1]$ denotes the set of abscissas used by $\mathscr{U}^i$. If the sets are nested, i.e., $\vartheta^i\subset\vartheta^{i+1}$, then $\mathscr{H}(\mathrm{w},N)\subset\mathscr{H}(\mathrm{w}+1,N)$ and

$$\mathscr{H}(\mathrm{w},N)=\bigcup_{\mathbf{i}\in\widetilde{X}(\mathrm{w},N)}\left(\vartheta^{i_1}\times\cdots\times\vartheta^{i_N}\right). \tag{2.11}$$

The Smolyak formula is actually interpolatory whenever nested points are used. This result has been proved in [6, Proposition 6, p. 277].

By comparing (2.11) and (2.10), we observe that the Smolyak approximation that employs nested points requires fewer function evaluations than the corresponding formula with nonnested points. In the next section we introduce two particular sets of abscissas, nested and nonnested, respectively. Also, Figure 1 shows, as an example, the sparse grid $\mathscr{H}(5,2)$ obtained in those two cases. Note that the Smolyak approximation formula, as presented in this section, is isotropic, since all directions are treated equally. This can be seen from (2.8) observing that if a multi-index $\mathbf{i}=(i_1,i_2,\ldots,i_N)$ belongs to the set $X(\mathrm{w},N)$, then any permutation of $\mathbf{i}$ also belongs to $X(\mathrm{w},N)$ and contributes to the construction of the Smolyak approximation $\mathscr{A}(\mathrm{w},N)$.

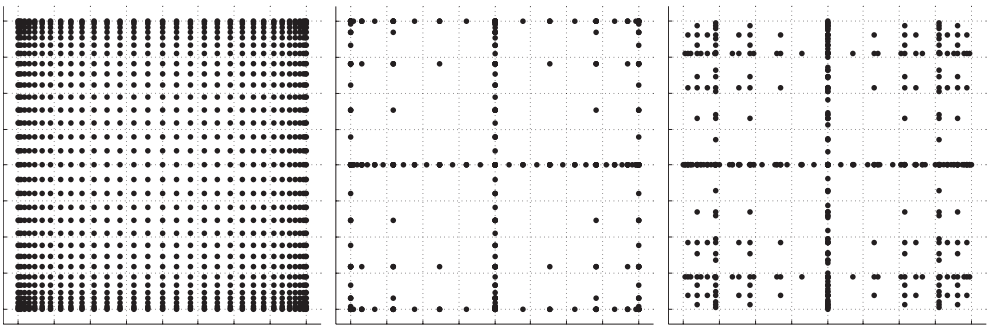

FIG. 1. *For a two-dimensional parameter space ($N=2$) and maximum level* $\mathrm{w}=5$*, we plot the full tensor product grid using the Clenshaw–Curtis abscissas (left) and isotropic Smolyak sparse grids $\mathscr{H}(5,2)$, utilizing the Clenshaw–Curtis abscissas (middle) and the Gaussian abscissas (right).*

2.3. Choice of interpolation abscissas.

Clenshaw–Curtis abscissas. We first suggest using Clenshaw–Curtis abscissas (see [11]) in the construction of the Smolyak formula. These abscissas are the extrema of Chebyshev polynomials and, for any choice of $m_i>1$, are given by

$$y_j^i=-\cos\left(\frac{\pi(j-1)}{m_i-1}\right),\quad j=1,\ldots,m_i. \tag{2.12}$$

In addition, one sets $y_1^i = 0$ if $m_i = 1$ and lets the number of abscissas m_i in each level grow according to the following formula:

$$m_1 = 1 \quad \text{and} \quad m_i = 2^{i-1} + 1 \text{ for } i > 1. \tag{2.13}$$

With this particular choice, one obtains nested sets of abscissas, i.e., $\vartheta^i \subset \vartheta^{i+1}$ and thereby $\mathscr{H}(\mathrm{w}, N) \subset \mathscr{H}(\mathrm{w}+1, N)$. It is important to choose $m_1 = 1$ if we are interested in optimal approximation in relatively large N, because in all other cases the number of points used by $\mathscr{A}(\mathrm{w}, N)$ increases too fast with N.

Gaussian abscissas. We also propose using Gaussian abscissas, i.e., the zeros of the orthogonal polynomials with respect to some positive weight. However, these Gaussian abscissas are in general not nested. Regardless, as in the Clenshaw–Curtis case, we choose the number m_i of abscissas that are used by $\mathscr{U}^i$ as in (2.13). See the work [32] for an insightful comparison of quadrature formulas based on Clenshaw–Curtis and Gaussian abscissas. The natural choice of the weight should be the probability density function ρ of the random variables $Y_i(\omega)$, $i = 1, \ldots, N$. Yet, in the general multivariate case, if the random variables Y_i are not independent, the density ρ does not factorize, i.e., $\rho(y_1, \ldots, y_n) \neq \prod_{n=1}^N \rho_n(y_n)$. To this end, we first introduce an auxiliary probability density function $\hat{\rho} : \Gamma^N \to \mathbb{R}^+$ that can be seen as the joint probability of N independent random variables, i.e., it factorizes as

$$\hat{\rho}(y_1, \ldots, y_n) = \prod_{n=1}^N \hat{\rho}_n(y_n) \ \ \forall y \in \Gamma^N \qquad \text{and is such that} \quad \left\| \frac{\rho}{\hat{\rho}} \right\|_{L^\infty(\Gamma^N)} < \infty. \tag{2.14}$$

For each dimension $n = 1, \ldots, N$, let the m_n Gaussian abscissas be the roots of the m_n degree polynomial that is $\hat{\rho}_n$-orthogonal to all polynomials of degree $m_n - 1$ on the interval $[-1, 1]$. The auxiliary density $\hat{\rho}$ should be chosen as close as possible to the true density ρ, so as to have the quotient $\rho/\hat{\rho}$ not too large. Indeed, such a quotient will appear in the final error estimate (see section 3.1.2).

Examples of isotropic sparse grids, constructed from the nested Clenshaw–Curtis abscissas and the nonnested Gaussian abscissas, are shown in Figure 1. There, we consider a two-dimensional parameter space and a maximum level $\mathrm{w} = 5$ (sparse grid $\mathscr{H}(5, 2)$). To see the reduction in function evaluations with respect to full tensor product grids, we also include a plot of the corresponding Clenshaw–Curtis isotropic full tensor grid having the same maximum number of points in each direction, namely, $2^{\mathrm{w}}+1 = 33$. Observe that if we take m points in each direction, the isotropic full tensor grid will contain m^N points, while the analogous isotropic Smolyak grid $\mathscr{H}(\mathrm{w}, N)$ will contain much fewer points. Figure 2 shows the total number of points contained in the full tensor grid and in the Smolyak sparse grid as a function of the level w (or the corresponding maximum number m of points in each direction) for dimensions $N = 5, 11, 21$.

3. Error analysis. In this section we develop error estimates that will help us compare the efficiency of the isotropic Smolyak approximation with other alternatives, for instance, the Monte Carlo method as explained in section 3.2. Much about this has been claimed in the existing literature based on particular numerical examples. Our main goal is therefore to understand in which situations the sparse grid stochastic collocation method is more efficient than Monte Carlo.

As explained in section 2, it is possible to use collocation methods to approximate the solution $u_N \in C^0(\Gamma^N; W(D))$ using finitely many function values, each of them

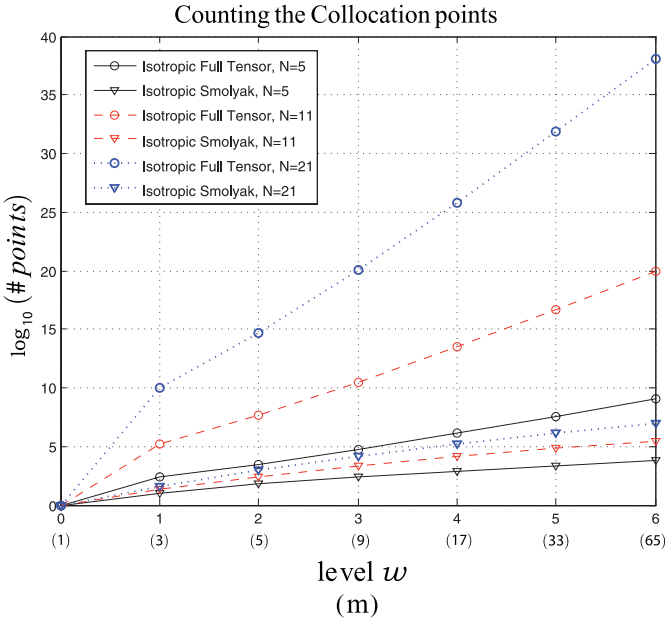

FIG. 2. *For a finite-dimensional* Γ^N *with* $N = 5, 11,$ *and* 21 *we plot the* log *of the number of distinct Clenshaw–Curtis collocation points used by the isotropic Smolyak method and the corresponding isotropic full tensor product method versus the level* w *(or the maximum number of points* m *employed in each direction).*

computed by finite elements. Recall that by Assumption 1.8, u_N admits an analytic extension. Let the fully discrete numerical approximation be $\mathscr{A}(\mathrm{w}, N)\pi_h u_N$. The aim of this section is to give a priori estimates for the total error

$$e = u - \mathscr{A}(\mathrm{w}, N)\pi_h u_N,$$

where the operator $\mathscr{A}(\mathrm{w}, N)$ is described by (2.8) and π_h is the finite element projection operator described by (2.2). We will investigate the error

$$\|u - \mathscr{A}(\mathrm{w}, N)\pi_h u_N\| \le \underbrace{\|u - u_N\|}_{(I)} + \underbrace{\|u_N - \pi_h u_N\|}_{(II)} + \underbrace{\|\pi_h u_N - \mathscr{A}(\mathrm{w}, N)\pi_h u_N\|}_{(III)} \tag{3.1}$$

evaluated in the norm $L^q_P(\Omega; W(D))$ with either $q = 2$ or $q = \infty$. This yields also control of the error in the expected value of u, $\|E[e]\|_{W(D)} \le E\big[\,\|e\|_{W(D)}\,\big] \le \|e\|_{L^q_P(\Omega;W(D))}$, and the error in the approximation of $E[\psi(u)]$, with ψ being a smooth functional of u. In such a case we have

$$|E[\psi(u) - \psi(\mathscr{A}(\mathrm{w}, N)\pi_h u_N)]| \le \left(\int_0^1 \|\delta_e \psi(u + \theta e)\|_{L^{q^*}_P(\Omega;W^*(D))} d\theta\right) \|e\|_{L^q_P(\Omega;W(D))},$$

with $1/q + 1/q^* = 1$ and $\delta_e \psi(u + \theta e)$ denoting the Fréchet derivative of ψ at $u + \theta e$. Although in the previous inequalities it is suboptimal to estimate expectations of Sobolev norms rather than a Sobolev norm of expectations, we will content ourselves in this work with providing estimates for $\|e\|_{L^q_P(\Omega;W(D))}$. Sharper estimates could be obtained generalizing the ideas given in [4, Theorem 5.1].

The quantity (I) controls the truncation error for the case where the input data a_N and f_N are suitable truncations of random fields. This contribution to the total error will be considered in section 3.2. The quantity (I) is otherwise zero if the representation of a_N and f_N is exact, as in Example 1.4. The second term, (II), controls the convergence with respect to h, i.e., the finite element error, which will be dictated by standard approximability properties of the finite element space $W_h(D)$, given by (2.1), and the regularity in space of the solution u (see, e.g., [10, 7]). For example, if we let $q = 2$, we have

$$\|u_N - \pi_h u_N\|_{L^2_\rho(\Gamma^N;W(D))} \le h^s \left(\int_{\Gamma^N} (C_\pi(y) C(s; u(y)))^2 \rho(y)\, dy \right)^{1/2}.$$

The full tensor product convergence results are given by [3, Theorem 1], and therefore we will concern ourselves only with the convergence results when implementing the Smolyak approximation formula described in section 2.2. Namely, our primary concern will be to analyze the Smolyak approximation error

$$(III) = \|\pi_h u_N - \mathscr{A}(\mathrm{w}, N)\pi_h u_N\|_{L^q_\rho(\Gamma^N;W(D))}$$

for both the Clenshaw–Curtis and Gaussian versions of the Smolyak formula.

Under the very reasonable assumption that the semidiscrete finite element solution $\pi_h u_N$ admits an analytic extension as described in Assumption 1.8 with the same analyticity region as for u_N, the behavior of the error (III) will be analogous to $\|u_N - \mathscr{A}(\mathrm{w}, N)u_N\|_{L^q_\rho(\Gamma^N;W(D))}$. For this reason in the next sections we will analyze the latter.

Remark 3.1 (on the randomness of approximate and exact solutions). It is important to emphasize that the exact solution u and its numerical approximation $\bar{u} := \mathscr{A}(\mathrm{w}, N)\pi_h u_N$ do not depend on the same randomness. Therefore, when considering both solutions we should in principle work with a product of probability spaces. For instance, assume now that $\mu_{u,\bar{u}}$ is a joint distribution for u and $\bar{u}$. It is key to recall that we are interested only in the approximation of statistics of u, which depend only on the marginal distribution μ_u, by the corresponding statistics of $\bar{u}$, which depend only on the marginal distribution $\mu_{\bar{u}}$. Let us introduce an auxiliary approximate solution, $\hat{u}$, with the same law as $\bar{u}$ but different joint distribution, $\mu_{u,\hat{u}}$. We have

$$\begin{aligned} |E^{\mu_u}[\psi(u)] - E^{\mu_{\bar{u}}}[\psi(\bar{u})]| &= |E^{\mu_u}[\psi(u)] - E^{\mu_{\hat{u}}}[\psi(\hat{u})]| \\ &= |E^{\mu_{u,\hat{u}}}[\psi(u) - \psi(\hat{u})]| \\ &\le E^{\mu_{u,\hat{u}}}[(\psi(u) - \psi(\hat{u}))^2]^{1/2}. \end{aligned}$$

Observe now that for the purpose of estimating the difference $|E^{\mu_u}[\psi(u)] - E^{\mu_{\bar{u}}}[\psi(\bar{u})]|$ the choice of the auxiliary joint distribution $\mu_{u,\hat{u}}$ is arbitrary. To this end, for the remainder of the work we select the joint distribution $\mu_{u,\hat{u}}$ such that u and $\hat{u}$ are driven by the same random variables Y. We will also avoid making any distinction in the notation between $\hat{u}$ and $\bar{u}$.

3.1. Analysis of the approximation error. In this work the technique to develop error bounds for multidimensional Smolyak approximation is based on one-dimensional results. Therefore, we first address the case $N = 1$. Let us recall the best approximation error for a function $v : \Gamma^1 \to W(D)$ which admits an analytic extension in the region $\Sigma(\Gamma^1; \tau) = \{z \in \mathbb{C},\ \mathrm{dist}(z, \Gamma^1) < \tau\}$ of the complex plane for

some $\tau > 0$. We will still denote the extension by v; in this case, τ is smaller than the distance between $\Gamma^1 \subset \mathbb{R}$ and the nearest singularity of $v(z)$ in the complex plane. Since we are considering only the case of bounded random variables, we recall the following result, whose proof can be found in [3, Lemma 7] and which is an immediate extension of the result given in [12, Chapter 7, section 8].

LEMMA 3.2. *Given a function $v \in C^0(\Gamma^1; W(D))$ which admits an analytic extension in the region of the complex plane $\Sigma(\Gamma^1; \tau) = \{z \in \mathbb{C}, dist(z, \Gamma^1) \leq \tau\}$ for some $\tau > 0$, there holds*

$$E_{m_i} \equiv \min_{w \in V_{m_i}} \|v - w\|_{C^0(\Gamma^1; W(D))} \leq \frac{2}{e^{\hat{\sigma}} - 1} e^{-\hat{\sigma}\, m_i} \max_{z \in \Sigma(\Gamma^1; \tau)} \|v(z)\|_{W(D)}, \tag{3.2}$$

where $0 < \hat{\sigma} = \log\left(\frac{2\tau}{|\Gamma^1|} + \sqrt{1 + \frac{4\tau^2}{|\Gamma^1|^2}}\right)$.

Remark 3.3 (approximation with unbounded random variables). A related result with weighted norms holds for unbounded random variables whose probability density decays as the Gaussian density at infinity (see [3]).

In the multidimensional case, the size of the analyticity region, τ_n (see, e.g., the problem considered in section 4), will depend, in general, on the direction n and on the $(N-1)$ values of the remainder y components, denoted by y_n^* in Assumption 1.8. The same holds for the decay coefficient $\hat{\sigma}_n$. In what follows, we set

$$\hat{\sigma} \equiv \min_{1 \leq n \leq N} \min_{y_n^* \in \Gamma_n^*} \hat{\sigma}_n \tag{3.3}$$

and assume that $\hat{\sigma}$ is strictly positive. Similarly to that, the norm $\max_{z \in \Sigma(\Gamma^1; \tau)} \|v(z)\|_{W(D)}$ appearing in Lemma 3.2 also depends on the direction n and the remainder vector y_n^* and should be replaced, in the multidimensional case, by

$$M(v) = \max_{1 \leq n \leq N} \max_{y_n^* \in \Gamma_n^*} \max_{z \in \Sigma(\Gamma_n; \tau_n)} \|v(z)\|_{W(D)},$$

which will be assumed bounded hereafter. Both assumptions on $\hat{\sigma}$ and $M(v)$ have to be verified for each problem under consideration. In particular, they are satisfied for the application described in section 4.

3.1.1. Interpolation estimates for the Clenshaw–Curtis abscissas. In this section we develop L^∞ error estimates for the Smolyak interpolant based on Clenshaw–Curtis abscissas (cf. (2.12) and (2.13)) applied to analytic functions $u \in C^0(\Gamma^N; W(D))$ that satisfy Assumption 1.8. We remind the reader that even though in the global estimate (3.1) it is enough to bound the approximation error (III) in the $L^2_\rho(\Gamma^N; W(D))$ norm, we will still work with the more stringent $L^\infty(\Gamma^N; W(D))$ norm.

In our notation the norm $\|\cdot\|_{\infty,N}$ is shorthand for $\|\cdot\|_{L^\infty(\Gamma^N; W(D))}$ and will be used henceforth. We also define $I_N : \Gamma^N \to \Gamma^N$ as the identity operator on an N-dimensional space. We begin by letting E_m be the error of the best approximation to functions $u \in C^0(\Gamma^1; W(D))$ by functions $w \in V_m$. Similarly to [6], since the interpolation $\mathscr{U}^i$ is exact on the subspace $V_{m_i - 1}$ we can apply the general formula

$$\left\|u - \mathscr{U}^i(u)\right\|_{\infty,1} \leq E_{m_i - 1}(u) \cdot (1 + \Lambda_{m_i}), \tag{3.4}$$

where Λ_m is the Lebesgue constant for our choice (2.12). It is known that

$$\Lambda_m \leq \frac{2}{\pi} \log(m - 1) + 1 \tag{3.5}$$

for $m \geq 2$; see [13]. Using Lemma 3.2, the best approximation $E_{m_i}(u)$ to functions $u \in C^0(\Gamma^1; W(D))$ that admit an analytic extension as described by Assumption 1.8 is bounded by (3.2). Moreover, for the choice of m_i given in (2.13), it is easy to show that $(1 + \Lambda_{m_i}) \leq 2i \ \forall i > 0$. Hence (3.2)–(3.4) implies

$$\begin{aligned}\left\|(I_1 - \mathscr{U}^i)(u)\right\|_{\infty,1} &\leq C\, i e^{-\sigma 2^i} M(u),\\ \left\|\Delta^i(u)\right\|_{\infty,1} &= \left\|(\mathscr{U}^i - \mathscr{U}^{i-1})(u)\right\|_{\infty,1}\\ &\leq \left\|(I_1 - \mathscr{U}^i)(u)\right\|_{\infty,1} + \left\|(I_1 - \mathscr{U}^{i-1})(u)\right\|_{\infty,1} \leq 2C\, i e^{-\sigma 2^{i-1}} M(u)\end{aligned}$$

$\forall i \in \mathbb{N}_+$, with positive constants

$$C = \frac{4}{e^{2\sigma} - 1} \quad \text{and} \quad \sigma = \frac{\hat{\sigma}}{2} \quad (\text{with } \hat{\sigma} \text{ as in Lemma 3.2}).$$

Since the value $M(u)$ affects the error estimates as a multiplicative constant, from now on we assume it to be one without loss of generality.

The convergence proof will be split into several steps, the main results being given in Theorems 3.7 and 3.10, which state the convergence rates in terms of the level w and the total number of collocation points, respectively. We denote by I_d the identity operator applicable to functions which depend on the first d variables $y_1, \ldots, y_d$. Then the following result holds.

LEMMA 3.4. *For functions $u \in C^0(\Gamma^N; W(D))$ satisfying the assumption of Lemma* 3.2 *the isotropic Smolyak formula* (2.8) *based on Clenshaw–Curtis abscissas satisfies*

$$\left\|\left(I_N - \mathscr{A}(\mathrm{w}, N)\right)(u)\right\|_{\infty,N} \leq \sum_{d=1}^{N} R(\mathrm{w}, d) \tag{3.6}$$

with

$$R(\mathrm{w}, d) := \frac{1}{2} \sum_{\mathbf{i} \in \tilde{X}(\mathrm{w},d)} (2C)^d \left(\prod_{n=1}^{d} i_n\right) e^{-\sigma h(\mathbf{i},d)} \tag{3.7}$$

and

$$h(\mathbf{i}, d) = \sum_{n=1}^{d} 2^{i_n - 1}. \tag{3.8}$$

Proof. We start by providing an equivalent representation of the isotropic Smolyak formula:

$$\begin{aligned}\mathscr{A}(\mathrm{w}, N) &= \sum_{\mathbf{i} \in X(\mathrm{w},N)} \bigotimes_{n=1}^{N} \Delta^{i_n}\\ &= \sum_{\mathbf{i} \in X(\mathrm{w},N-1)} \bigotimes_{n=1}^{N-1} \Delta^{i_n} \otimes \sum_{j=1}^{1+\mathrm{w}-\sum_{n=1}^{N-1}(i_n-1)} \Delta^{j}\\ &= \sum_{\mathbf{i} \in X(\mathrm{w},N-1)} \bigotimes_{n=1}^{N-1} \Delta^{i_n} \otimes \mathscr{U}^{1+\mathrm{w}-\sum_{n=1}^{N-1}(i_n-1)}.\end{aligned}$$

Introducing the one-dimensional identity operator $I_1^{(n)} : \Gamma_n \to \Gamma_n$ for $n = 1, \ldots, N$, we can compute the error estimate recursively using the previous representation, namely,

$$
\begin{aligned}
I_N - \mathscr{A}(\mathrm{w}, N) &= I_N - \sum_{\mathbf{i} \in X(\mathrm{w}, N-1)} \bigotimes_{n=1}^{N-1} \Delta^{i_n} \otimes \left(\mathscr{U}^{1+\mathrm{w}-\sum_{n=1}^{N-1}(i_n-1)} - I_1^{(N)} \right) \\
&\quad - \sum_{\mathbf{i} \in X(\mathrm{w}, N-1)} \bigotimes_{n=1}^{N-1} \Delta^{i_n} \otimes I_1^{(N)} \\
&= \sum_{\mathbf{i} \in X(\mathrm{w}, N-1)} \bigotimes_{n=1}^{N-1} \Delta^{i_n} \otimes \left(I_1^{(N)} - \mathscr{U}^{1+\mathrm{w}-\sum_{n=1}^{N-1}(i_n-1)} \right) \\
&\quad + (I_{N-1} - \mathscr{A}(\mathrm{w}, N-1)) \otimes I_1^{(N)} \\
&= \sum_{d=2}^{N} \left[\tilde{R}(\mathrm{w}, d) \bigotimes_{n=d+1}^{N} I_1^{(n)} \right] + \left(I_1^{(1)} - \mathscr{A}(\mathrm{w}, 1) \right) \bigotimes_{n=2}^{N} I_1^{(n)},
\end{aligned}
\tag{3.9}
$$

where, for a general dimension d, we define

$$
\tilde{R}(\mathrm{w}, d) = \sum_{\mathbf{i} \in X(\mathrm{w}, d-1)} \bigotimes_{n=1}^{d-1} \Delta^{i_n} \otimes \left(I_1^{(d)} - \mathscr{U}^{\hat{i}_d} \right)
$$

and, for any $(i_1, \ldots, i_{d-1}) \in X(\mathrm{w}, d-1)$, we have set $\hat{i}_d = 1 + \mathrm{w} - \sum_{n=1}^{d-1}(i_n - 1)$. Observe that with this definition, the d-dimensional vector $\mathbf{j} = (i_1, \ldots, i_{d-1}, \hat{i}_d)$ belongs to the set $\tilde{X}(\mathrm{w}, d)$, defined in (2.7), and the term $\tilde{R}(\mathrm{w}, d)$ can now be bounded as follows:

$$
\begin{aligned}
\left\| \tilde{R}(\mathrm{w}, d)(u) \right\|_{\infty,d} &\le \sum_{\mathbf{i} \in X(\mathrm{w}, d-1)} \prod_{n=1}^{d-1} \left\| (\Delta^{i_n})(u) \right\|_{\infty,d} \left\| \left(I_1^{(d)} - \mathscr{U}^{\hat{i}_d} \right)(u) \right\|_{\infty,d} \\
&\le \frac{1}{2} \sum_{\mathbf{i} \in X(\mathrm{w}, d-1)} (2C)^d \left(\prod_{n=1}^{d-1} i_n \right) \hat{i}_d \, e^{-\sigma\left(\sum_{n=1}^{d-1} 2^{i_n - 1} + 2^{\hat{i}_d}\right)} \\
&\le \frac{(2C)^d}{2} \sum_{\mathbf{i} \in \tilde{X}(\mathrm{w}, d)} \left(\prod_{n=1}^{d} i_n \right) e^{-\sigma\, h(\mathbf{i}, d)} =: R(\mathrm{w}, d).
\end{aligned}
$$

Hence, the Smolyak approximation error satisfies

$$
\left\| (I_N - \mathscr{A}(\mathrm{w}, N))(u) \right\|_{\infty,N} \le \sum_{d=2}^{N} R(\mathrm{w}, d) + \left\| (I_1^{(1)} - \mathscr{A}(\mathrm{w}, 1))(u) \right\|_{\infty,1}.
$$

Observe that the last term in the previous equation can also be bounded by $R(\mathrm{w}, 1)$

defined in (3.7). Indeed, the set $\tilde{X}(\mathrm{w},1)$ contains only the point $i_1 = 1+\mathrm{w}$ and

$$\begin{aligned}\left\|\left(I_1^{(1)} - \mathscr{A}(\mathrm{w},1)\right)(u)\right\|_{\infty,1} &= \left\|\left(I_1^{(1)} - \mathscr{U}^{1+\mathrm{w}}\right)(u)\right\|_{\infty,1} \\ &\le C\,(1+\mathrm{w})e^{-\sigma\,2^{1+\mathrm{w}}} \\ &\le \sum_{i_1\in\tilde{X}(\mathrm{w},1)} C\,i_1\,e^{-\sigma\,2^{i_1-1}} =: R(\mathrm{w},1),\end{aligned}$$

and this concludes the proof. ∎

LEMMA 3.5. *Let $\delta > 0$. Under the assumptions of Lemma 3.4 the following bound holds for the term $R(\mathrm{w},d)$, $d = 1,\dots,N$:*

$$R(\mathrm{w},d) \le \frac{C_1(\sigma,\delta)^d}{2}\,\exp\left(-\sigma d\left(2^{\mathrm{w}/d} - \delta\tilde{C}_2(\sigma)\mathrm{w}\right)\right), \tag{3.10}$$

where

$$\tilde{C}_2(\sigma) := 1 + \frac{1}{\log(2)}\sqrt{\frac{\pi}{2\sigma}} \tag{3.11}$$

and

$$C_1(\sigma,\delta) := \frac{4C}{e\delta\sigma}\exp\left(\delta\sigma\left\{\frac{1}{\sigma\log^2(2)} + \frac{1}{\log(2)\sqrt{2\sigma}} + 2\left(1+\frac{1}{\log(2)}\sqrt{\frac{\pi}{2\sigma}}\right)\right\}\right). \tag{3.12}$$

Proof. The proof is divided into several steps.

1. Expand the function $h(\mathbf{i},d)$ up to second order around the point $\mathbf{i}^* = (1+\mathrm{w}/d,\dots,1+\mathrm{w}/d)$ on the subspace $\{\mathbf{x}\in\mathbb{R}^d :, |\mathbf{x}-\mathbf{1}| = \mathrm{w}\}$. Observe that $\mathbf{i}^*$ is a constrained minimizer of $h(\mathbf{i},d)$ and
$$h(\mathbf{i},d) \ge d2^{\mathrm{w}/d} + \frac{\log^2(2)}{2}\sum_{n=1}^{d}(i_n - (1+\mathrm{w}/d))^2 \quad \forall\mathbf{i}\in\tilde{X}(\mathrm{w},d). \tag{3.13}$$
2. Combining (3.7) and (3.13), estimate
$$\begin{aligned}R(\mathrm{w},d) &\le \frac{(2C)^d}{2}e^{-\sigma d2^{\mathrm{w}/d}}\sum_{\mathbf{i}\in\tilde{X}(\mathrm{w},d)}\left(\prod_{n=1}^{d} i_n\right)\,e^{-\sigma\,\frac{\log^2(2)}{2}\sum_{n=1}^{d}(i_n-(1+\mathrm{w}/d))^2} \\ &\le \frac{(2C)^d}{2}e^{-\sigma d2^{\mathrm{w}/d}}\left(\sum_{i=1}^{\mathrm{w}+1} i\,e^{-\sigma\,\frac{\log^2(2)}{2}(i-(1+\mathrm{w}/d))^2}\right)^d.\end{aligned} \tag{3.14}$$
3. Next, use (A.2) from Corollary A.4 of the appendix to estimate the term $T_1 := \sum_{i=1}^{\mathrm{w}+1} i\,e^{-\sigma\,\frac{\log^2(2)}{2}(i-(1+\mathrm{w}/d))^2}$. We have
$$T_1 \le 2\left(\frac{1}{\sigma\log^2(2)} + \frac{1}{\log(2)\sqrt{2\sigma}}\right) + 2(\mathrm{int}\,\{\mathrm{w}/d\}+2)\left(1+\frac{1}{\log(2)}\sqrt{\frac{\pi}{2\sigma}}\right), \tag{3.15}$$
where $\mathrm{int}\,\{\cdot\}$ denotes the integer part of a real number. Combine (3.14) and (3.15), arriving at
$$R(\mathrm{w},d) \le C_1(\sigma,d,\mathrm{w})e^{-\sigma d\,2^{\mathrm{w}/d}} \tag{3.16}$$

with

$$C_1(\sigma,d,\mathrm{w}) \le \frac{1}{2}\,(4C)^d \left\{ \left(\frac{1}{\sigma \log^2(2)} + \frac{1}{\log(2)\sqrt{2\sigma}} \right) + (\mathrm{int}\,\{\mathrm{w}/d\}+2)\,\left(1+\frac{1}{\log(2)}\sqrt{\frac{\pi}{2\sigma}}\right)\right\}^d.$$

Now let $\delta > 0$ and use the inequality $x+1 \le e^x$, $x \ge 0$, to bound

$$\begin{aligned} & C_1(\sigma,d,\mathrm{w}) \\ & \le \frac{1}{2}\left(\frac{4C}{\delta\sigma}\right)^d \exp\left(d\delta\sigma \left\{ \left(\frac{1}{\sigma \log^2(2)} + \frac{1}{\log(2)\sqrt{2\sigma}} \right) \right.\right. \\ & \qquad \left.\left. + (\mathrm{int}\,\{\mathrm{w}/d\}+2)\,\left(1+\frac{1}{\log(2)}\sqrt{\frac{\pi}{2\sigma}}\right)\right\} - d \right) \\ & \le \frac{C_1(\sigma,\delta)^d}{2} \exp\left(\delta\sigma \left(1+\frac{1}{\log(2)}\sqrt{\frac{\pi}{2\sigma}}\right)\mathrm{w}\right), \end{aligned} \tag{3.17}$$

with $C_1(\sigma,\delta) := \frac{4C}{e\delta\sigma} \exp\left(\delta\sigma\left\{ \frac{1}{\sigma\log^2(2)} + \frac{1}{\log(2)\sqrt{2\sigma}} + 2\left(1+\frac{1}{\log(2)}\sqrt{\frac{\pi}{2\sigma}}\right)\right\}\right)$ defined as in (3.12).

Estimate (3.10) follows from (3.16) and (3.17). The proof is now complete. ∎

Remark 3.6 (alternative estimate). Observe that an alternative upper bound for T_1 in (3.15) is

$$T_1 \le \exp\left(\sigma\,\log^2(2)\left(1+\frac{\mathrm{w}}{d}\right)\right)\,\frac{(2+\mathrm{w})^2}{2}, \tag{3.18}$$

which remains bounded as $\sigma \to 0$. This does not happen with the bound $C_1(\sigma,d)$ (cf. (3.12)), which blows up as $\sigma \to 0$. As an implication of (3.18), we have

$$R(\mathrm{w},d) \le \frac{(C(2+\mathrm{w})^2)^d}{2}\, e^{-\sigma d(2^{\mathrm{w}/d} - \frac{\mathrm{w}}{d}\log^2(2))},$$

which is an alternative to the estimate (3.10) that has an extra polynomial growth in w but remains bounded for small values of σ.

THEOREM 3.7. *For functions $u \in C^0(\Gamma^N; W(D))$ satisfying the assumption of Lemma* 3.2 *the isotropic Smolyak formula* (2.8) *based on Clenshaw–Curtis abscissas satisfies*

$$\begin{aligned} \|(I_N - \mathscr{A}(\mathrm{w},N))\,(u)\|_{\infty,N} \le & \inf_{\delta\in(0,\frac{\chi}{\sqrt{\pi}})} \hat{C}(\sigma,\delta,N) \\ & \times \begin{cases} e^{-\sigma\mathrm{w}(e\log(2)-\delta\tilde{C}_2(\sigma))} & \text{if } 0 \le \mathrm{w} \le \dfrac{N}{\log(2)}, \\ e^{-\sigma\mathrm{w}\left(\frac{N}{\mathrm{w}}2^{\mathrm{w}/N}-\delta\tilde{C}_2(\sigma)\right)} & \text{otherwise,} \end{cases} \end{aligned} \tag{3.19}$$

where function $\hat{C}(\sigma,\delta,N) = \frac{C_1(\sigma,\delta)}{2}\,\frac{1-C_1(\sigma,\delta)^N}{1-C_1(\sigma,\delta)}$. The values of $\tilde{C}_2(\sigma)$ and $C_1(\sigma,\delta)$ have been defined in (3.11) *and* (3.12)*, respectively.*

Proof. From Lemmas 3.4 and 3.5 we obtain the following bound for the approximation error:

$$\|(I_N - \mathscr{A}(\mathrm{w},N))\,(u)\|_{\infty,N} \le \frac{1}{2}\sum_{d=1}^{N} C_1(\sigma,\delta)^d\, e^{-\sigma d(2^{\mathrm{w}/d}-\frac{\mathrm{w}}{d}\delta\tilde{C}_2(\sigma))},$$

with $C_1(\sigma,\delta)$ defined in (3.12). Then

$$\begin{aligned}\left\|\left(I_N-\mathscr{A}(\mathrm{w},N)\right)(u)\right\|_{\infty,N} &\le \frac{1}{2}\max_{1\le d\le N} e^{-\sigma \mathrm{w}\left(\frac{d}{\mathrm{w}}2^{\mathrm{w}/d}-\delta\tilde{C}_2(\sigma)\right)}\sum_{d=1}^{N} C_1(\sigma,\delta)^d \\ &\le \hat{C}(\sigma,\delta,N)e^{\sigma \mathrm{w}\delta\tilde{C}_2(\sigma)}\max_{1\le d\le N} e^{-\sigma \mathrm{w}\left(\frac{d}{\mathrm{w}}2^{\mathrm{w}/d}\right)},\end{aligned}$$

with

$$\begin{aligned}\hat{C}(\sigma,\delta,N) &:= \frac{1}{2}\sum_{d=1}^{N} C_1(\sigma,\delta)^d \\ &= \frac{C_1(\sigma,\delta)}{2}\,\frac{1-C_1(\sigma,\delta)^N}{1-C_1(\sigma,\delta)}.\end{aligned} \tag{3.20}$$

To finish the proof we further bound

$$\begin{aligned}\left\|\left(I_N-\mathscr{A}(\mathrm{w},N)\right)(u)\right\|_{\infty,N} &\le \hat{C}(\sigma,\delta,N)\, e^{\sigma \mathrm{w}\delta\tilde{C}_2(\sigma)}\, e^{-\sigma \mathrm{w}\left(\min_{1\le d\le N}\frac{d}{\mathrm{w}}2^{\mathrm{w}/d}\right)} \\ &\le \hat{C}(\sigma,\delta,N)\, e^{\sigma \mathrm{w}\delta\tilde{C}_2(\sigma)}\, e^{-\sigma \mathrm{w}\left(\min_{s\in[\mathrm{w}/N,\mathrm{w}]}\frac{1}{s}2^{s}\right)}\end{aligned}$$

and observe that

$$\min_{s\in[w/N,w]}\frac{1}{s}2^s = \begin{cases} e\log(2) & \text{if } 0\le \mathrm{w}\le \dfrac{N}{\log(2)}, \\ \dfrac{N}{\mathrm{w}}2^{\mathrm{w}/N} & \text{otherwise.}\end{cases} \qquad \square$$

Remark 3.8 (alternative estimate). Following Remark 3.6 we have an alternative to (3.19) in the estimate

$$\begin{aligned}\left\|\left(I_N-\mathscr{A}(\mathrm{w},N)\right)(u)\right\|_{\infty,N} &\le \frac{C(2+\mathrm{w})^2}{2}\,\frac{(C(2+\mathrm{w})^2)^N-1}{C(2+\mathrm{w})^2-1} \\ &\quad\times\begin{cases} e^{-\sigma \mathrm{w}\chi} & \text{if } 0\le \mathrm{w}\le \dfrac{N}{\log(2)}, \\ e^{-\sigma \mathrm{w}\left(\frac{N}{\mathrm{w}}2^{\mathrm{w}/N}-\log^2(2)\right)} & \text{otherwise.}\end{cases}\end{aligned} \tag{3.21}$$

Here we used the notation $\chi=\log(2)\,(e-\log(2))\approx 1.4037$. The previous estimate can be used to produce estimates like those in Theorems 3.10 and 3.11. The alternative estimates have constants which do not blow up as $\sigma\to 0$ but have the drawback of exhibiting additional multiplicative powers of $\log(\eta)$, η being the total number of collocation points. A completely identical discussion applies to the estimates based on Gaussian abscissas (see section 3.1.2) and will not be repeated there.

Now we relate the number of collocation points, $\eta=\eta(\mathrm{w},N)=\#\mathscr{H}(\mathrm{w},N)$, to the level w of the isotropic Smolyak formula. We state the result in the following lemma.

LEMMA 3.9. *Using the isotropic Smolyak interpolant described by* (2.8) *with Clenshaw–Curtis abscissas, the total number of points required at level* w *satisfies the following bounds:*

$$N(2^{\mathrm{w}}-1)\le \eta \le (2eN)^{\mathrm{w}}\min\{\mathrm{w}+1,2eN\}. \tag{3.22}$$

Moreover, as a direct consequence of (3.22) *we get that*

$$\frac{\log(\eta)}{1+\log(2)+\log(N)} - 1 \leq \mathrm{w}. \tag{3.23}$$

Proof. By using formula (2.8) and exploiting the nested structure of the Clenshaw–Curtis abscissas, the number of points $\eta = \eta(\mathrm{w}, N) = \#\mathscr{H}(\mathrm{w}, N)$ can be counted in the following way:

$$\eta = \sum_{\mathbf{i}\in X(\mathrm{w},N)} \prod_{n=1}^{N} r(i_n), \text{ where } r(i) := \begin{cases} 1 & \text{if } i = 1, \\ 2 & \text{if } i = 2, \\ 2^{i-2} & \text{if } i > 2. \end{cases} \tag{3.24}$$

Now notice that $\forall n = 1, 2, \ldots, N$ the following bound holds:

$$2^{i_n-2} \leq r(i_n) \leq 2^{i_n-1}. \tag{3.25}$$

We now produce a lower bound and an upper bound for η.

A lower bound on the number η of points can be obtained considering only the contribution from certain tensor grids. Indeed, for a fixed value of $\tilde{\mathrm{w}} = 1, \ldots, \mathrm{w}$, let us consider the N grids with indices $i_n = 1$ for $n \neq m$ and $i_m = \tilde{\mathrm{w}} + 1$, $m = 1, \ldots, N$. Since each of those N grids has $2^{\tilde{\mathrm{w}}-1}$ points, we have

$$\eta \geq \sum_{\tilde{\mathrm{w}}=1}^{\mathrm{w}} N\, 2^{\tilde{\mathrm{w}}-1} = N(2^{\mathrm{w}} - 1).$$

On the other hand, to produce an upper bound for η, we recall that $|\mathbf{i} - \mathbf{1}| = \sum_{n=1}^{N}(i_n - 1) \leq \mathrm{w}$, so the following bounds hold:

$$\begin{aligned}
\eta &= \sum_{\mathbf{i}\in X(\mathrm{w},N)} \prod_{n=1}^{N} r(i_n) \leq \sum_{\mathbf{i}\in X(\mathrm{w},N)} 2^{|\mathbf{i}-\mathbf{1}|} \leq \sum_{j=0}^{\mathrm{w}} \sum_{|\mathbf{i}-\mathbf{1}|=j} 2^j \\
&\leq \sum_{j=0}^{\mathrm{w}} 2^j \binom{N-1+j}{N-1} \leq \sum_{j=0}^{\mathrm{w}} 2^j \prod_{s=1}^{N-1} \left(1 + \frac{j}{s}\right) \\
&\leq \sum_{j=0}^{\mathrm{w}} 2^j \exp\left(\sum_{s=1}^{N-1} \frac{j}{s}\right) \leq \sum_{j=0}^{\mathrm{w}} 2^j \exp\left(j(1+\log(N))\right) \\
&\leq \sum_{j=0}^{\mathrm{w}} (2eN)^j \leq \min\{(\mathrm{w}+1)(2eN)^{\mathrm{w}}, (2eN)^{\mathrm{w}+1}\},
\end{aligned}$$

and this finishes the proof. ∎

The next theorem provides an error bound in terms of the total number η of collocation points. The proof follows directly from the results in Theorem 3.7 (taking $\delta = (e\log(2) - 1)/\tilde{C}_2(\sigma)$) and Lemma 3.9; it is therefore omitted.

THEOREM 3.10 (algebraic convergence). *For functions $u \in C^0(\Gamma^N; W(D))$ satisfying the assumption of Lemma* 3.2 *the isotropic Smolyak formula* (2.8) *based on Clenshaw–Curtis abscissas satisfies*

$$\begin{gathered}
\left\| \left(I_N - \mathscr{A}(\mathrm{w}, N)\right)(u) \right\|_{\infty,N} \leq \frac{C_1(\sigma, \delta^*) e^{\sigma}}{|1 - C_1(\sigma, \delta^*)|} \max\{1, C_1(\sigma, \delta^*)\}^N \eta^{-\mu_1}, \\
\text{with } \mu_1 = \frac{\sigma}{1 + \log(2N)}.
\end{gathered} \tag{3.26}$$

Here $\delta^* = (e\log(2)-1)/\tilde{C}_2(\sigma)$ *and the constants* $\tilde{C}_2(\sigma)$ *and* $C_1(\sigma,\delta^*)$*, defined in* (3.11) *and* (3.12)*, respectively, do not depend on* η*.*

Observe that the previous result indicates at least *algebraic convergence* with respect to the number of collocation points η. Under the same assumptions as those of the previous theorem and with a completely similar derivation, for large values of w we have the following sharper estimate.

THEOREM 3.11 (subexponential convergence). *Under the same assumptions as those of Theorem* 3.10 *and for* $\mathrm{w} > \frac{N}{\log(2)}$ *it holds that*

$$\left\|\left(I_N - \mathscr{A}(\mathrm{w},N)\right)(u)\right\|_{\infty,N} \leq \frac{C_1(\sigma,\delta^*)}{e^{\sigma\delta^*\tilde{C}_2(\sigma)}} \frac{\max\{1,C_1(\sigma,\delta^*)\}^N}{|1-C_1(\sigma,\delta^*)|}\ \eta^{\mu_3}\, e^{-\frac{N\sigma}{2^{1/N}}\eta^{\mu_2}}, \tag{3.27}$$

$$\text{with} \qquad \mu_2 = \frac{\log(2)}{N(1+\log(2N))} \qquad \text{and} \qquad \mu_3 = \frac{\sigma\delta^*\tilde{C}_2(\sigma)}{1+\log(2N)},$$

and with constant $C_1(\sigma,\delta^*)$ *defined in* (3.12) *and independent of* η*.*

Proof. We start from the result stated in Theorem 3.7 and observe that for $\mathrm{w} > N/\log(2)$ the function

$$g(\mathrm{w}) = \sigma(N2^{\mathrm{w}/N} - \mathrm{w}\delta\tilde{C}_2(\sigma))$$

is increasing in w for all values of $\delta < \log(2)e/\tilde{C}_2(\sigma)$. Hence, combining (3.19) with the lower bound (3.23) we obtain the desired result. ∎

The previous theorem indicates at least asymptotic *subexponential convergence* with respect to the number of collocation points η. It should be pointed out, however, that the large values of $w > N/\log(2)$ under which the bound holds are seldom used in practical computations. Therefore, from this point of view estimate (3.27) is less useful than (3.26).

Remark 3.12 (deterioration of the estimates with respect to the dimension N). Depending on the distance to the singularities of the solution, related to the parameter τ introduced in Lemma 3.2, the constant $C_1(\sigma,\delta^*)$ may be less than 1. In such a case the only dependence of the error bounds for $\left\|\left(I_N - \mathscr{A}(\mathrm{w},N)\right)(u)\right\|_{\infty,N}$ is in the exponent, whose denominator slowly grows like $\log(2N)$.

Remark 3.13 (full tensor versus Smolyak). An isotropic full tensor product interpolation converges roughly like $C(\sigma,N)\exp(-\sigma p)$, where p is the order of the polynomial space. Since the number of collocation points relates to p in this case as $\eta = (1+p)^N$ then $\log(\eta) = N\log(1+p) \leq Np$ and with respect to η the convergence rate can be bounded as $C(\sigma,N)\eta^{-\sigma/N}$. The slowdown effect that the dimension N has on the last convergence is known as the *curse of dimensionality*, and it is the reason for not using isotropic full tensor interpolation for large values of N. On the other hand, the isotropic Smolyak approximation seems to be better suited for this case. Indeed, from the estimate (3.26) we see that the Smolyak algebraic convergence has the faster exponent $\mathcal{O}(\frac{\sigma}{\log(2N)})$. This is a clear advantage of the isotropic Smolyak method with respect to the full tensor and justifies our claim that the use of Smolyak approximation greatly reduces the curse of dimensionality. In section 5 numerical results will give computational ground to this claim.

Remark 3.14 (estimates based on bounded mixed derivatives). We can proceed in a similar way to analyze the approximation error for functions that have a bounded mixed derivative of order $(k,\ldots,k)$. In that case, the one-dimensional best approximation error is $\|u-\mathcal{U}^i(u)\| \leq Cm_i^{-k}(1+\Lambda_{m_i})$, with C depending on u and k but not

on m_i, and using again the recursion (3.9) yields

$$\|(I_N - \mathscr{A}(\mathrm{w}, N))(u)\|_{\infty,N} \leq \frac{C}{|C(1+2^k)-1|}(C(1+2^k))^N(\mathrm{w}+1)^{2N}2^{-k\mathrm{w}}. \tag{3.28}$$

Finally, the combination of (3.28) with the counting estimates in Lemma 3.9 yields

$$\|(I_N - \mathscr{A}(\mathrm{w}, N))(u)\|_{\infty,N} \leq \frac{(C(1+2^k))^N}{|1+2^k-1/C|}\left(1+\log_2\left(1+\frac{\eta}{N}\right)\right)^{2N} \min\left\{2^k\eta^{-\frac{k\log(2)}{1+\log(2N)}}, \eta^{-k}\left(1+\log_2\left(1+\frac{\eta}{N}\right)\right)^{Nk}\right\}.$$

This estimate improves the one derived in [6]. Analogous results can be derived for Gaussian abscissas and L^2 norms.

3.1.2. Approximation estimates for Gaussian abscissas. Similarly to the previous section, we now develop error estimates for Smolyak approximation using Gaussian abscissas (cf. section 2.3) of $C^0(\Gamma^N; W(D))$ analytic functions described by Assumption 1.8. As before, we remind the reader that in the global estimate (3.1) we need to bound the approximation error (III) in the norm $L^2_\rho(\Gamma^N; W(D))$. Yet, the Gaussian abscissas defined in section 2.3 are constructed for the auxiliary density $\hat{\rho} = \prod_{n=1}^N \hat{\rho}_n$, still yielding control of the desired norm

$$\|v\|_{L^2_\rho(\Gamma^N;W(D))} \leq \left\|\frac{\rho}{\hat{\rho}}\right\|^{1/2}_{L^\infty(\Gamma^N)} \|v\|_{L^2_{\hat{\rho}}(\Gamma^N;W(D))} \quad \forall v \in C^0(\Gamma^N; W(D)).$$

In what follows we will use the shorthand notation $\|\cdot\|_{\hat{\rho},N}$ for $\|\cdot\|_{L^2_{\hat{\rho}}(\Gamma^N;W(D))}$ and restrict out analysis to the case where $W(D)$ is a Hilbert space. We now quote a useful result from Erdös and Turán [14].

LEMMA 3.15. *For every function $u \in C^0(\Gamma^1; W(D))$ the interpolation error with Lagrange polynomials based on Gaussian abscissas satisfies*

$$\|u - \mathscr{U}^i(u)\|_{\hat{\rho},1} \leq 2\sqrt{\int_{\Gamma^1}\hat{\rho}(y)\,dy}\inf_{v\in V_{m_i}}\|u-v\|_{\infty,1}. \tag{3.29}$$

Similarly to section 3.1.1, the combination of (3.2) with (3.29) yields

$$\left\|(I_1 - \mathscr{U}^i)(u)\right\|_{\hat{\rho},1} \leq \widetilde{C}\,e^{-\sigma 2^i}M(u), \quad \text{with } \tilde{C} = \frac{8}{e^{2\sigma}-1}\sqrt{\int_{\Gamma^1}\hat{\rho}(y)\,dy},$$

$$\begin{aligned}\left\|\Delta^i(u)\right\|_{\hat{\rho},1} &= \left\|(\mathscr{U}^i - \mathscr{U}^{i-1})(u)\right\|_{\hat{\rho},1}\\ &\leq \left\|(I_1-\mathscr{U}^i)(u)\right\|_{\hat{\rho},1} + \left\|(I_1-\mathscr{U}^{i-1})(u)\right\|_{\hat{\rho},1}\\ &\leq 2\widetilde{C}\,e^{-\sigma 2^{i-1}}M(u)\end{aligned}$$

$\forall i \in \mathbb{N}_+$. As in section 3.1.1 we assume the value $M(u)$ to be one without loss of generality. We then present the following lemma and theorem whose proofs follow, with minor changes, those given in Lemma 3.5 and Theorem 3.10, respectively. For instance, we apply (A.1) from Corollary A.4 to bound the corresponding T_1 sum in the estimate of $R(\mathrm{w}, d)$.

LEMMA 3.16. *For functions* $u \in C^0(\Gamma^N; W(D))$ *satisfying the assumption of Lemma* 3.2 *the isotropic Smolyak formula* (2.8) *based on Gaussian abscissas satisfies*

$$\|(I_N - \mathscr{A}(\mathrm{w}, N))(u)\|_{\rho,N} \le \sqrt{\|\rho/\hat{\rho}\|_{L^\infty(\Gamma^N)}}\frac{\tilde{C}_1(\sigma)}{2}\,\frac{1-\tilde{C}_1(\sigma)^N}{1-\tilde{C}_1(\sigma)} \times \begin{cases} e^{-\sigma e \log(2)\,\mathrm{w}} & \text{if } 0 \le \mathrm{w} \le \dfrac{N}{\log(2)}, \\ e^{-\sigma N 2^{\mathrm{w}/N}} & \text{otherwise.} \end{cases} \tag{3.30}$$

Here we have

$$\tilde{C}_1(\sigma) := 4\tilde{C}\left(1 + \frac{1}{\log(2)}\sqrt{\frac{\pi}{2\sigma}}\right). \tag{3.31}$$

Now we relate the number of collocation points $\eta = \eta(\mathrm{w}, N) = \#\mathscr{H}(\mathrm{w}, N)$ to the level w of the Smolyak formula. We state the result in the following lemma.

LEMMA 3.17. *Using the Smolyak formula described by* (2.9) *with Gaussian abscissas, the total number of points required at level* w *satisfies the following bounds:*

$$N(2^{\mathrm{w}} + 1) \le \eta \le (e\, 2^{1+\log_2(1.5)} N)^{\mathrm{w}} \min\{(\mathrm{w}+1), e\, 2^{1+\log_2(1.5)} N\}, \tag{3.32}$$

which implies

$$\frac{\log(\eta)}{\zeta + \log(N)} - 1 \le \mathrm{w},$$

with $\zeta := 1 + (1 + \log_2(1.5))\log(2) \approx 2.1$.

Proof. By using formula (2.9), where we collocate using the Gaussian abscissas, the number of points $\eta = \eta(\mathrm{w}, N) = \#\mathscr{H}(\mathrm{w}, N)$ can be counted in the following way:

$$\eta = \sum_{\mathbf{i} \in Y(\mathrm{w}, N)} \prod_{n=1}^{N} \widetilde{r}(i_n), \text{ where } 2^{i-1} \le \widetilde{r}(i) := \begin{cases} 1 & \text{if } i = 1, \\ 2^{i-1} + 1 & \text{if } i \ge 2. \end{cases} \tag{3.33}$$

Proceeding in a similar way as for the proof of Lemma 3.9, we obtain the following lower bound on the number of points η:

$$\eta \ge N \sum_{\tilde{\mathrm{w}}=\mathrm{w}-N+1}^{\mathrm{w}} \left(2^{\tilde{\mathrm{w}}} + 1\right) \ge N(2^{\mathrm{w}} + 1).$$

On the other hand, an upper bound on η can be obtained following along the same lines as in the proof of Lemma 3.9 and observing that $2^{i-1} \le \widetilde{r}(i) \le 2^{(1+\epsilon)(i-1)}$, with $\epsilon = \log_2(1.5) \approx 0.585$. ∎

Finally, the next theorem relates the error bound (3.30) to the number of collocation points $\eta = \eta(\mathrm{w}, N) = \#\mathscr{H}(\mathrm{w}, N)$, described by Lemma 3.17.

THEOREM 3.18 (algebraic convergence). *For functions* $u \in C^0(\Gamma^N; W(D))$ *satisfying the assumption of Lemma* 3.2 *the isotropic Smolyak formula* (2.8) *based on Gaussian abscissas satisfies*

$$\|(I_N - \mathscr{A}(\mathrm{w}, N))(u)\|_{\rho,N} \le \sqrt{\|\rho/\hat{\rho}\|_{L^\infty(\Gamma^N)}}\, e^{\sigma\, e \log(2)}\, \tilde{C}_1(\sigma)\, \frac{\max\{1, \tilde{C}_1(\sigma)\}^N}{|1 - \tilde{C}_1(\sigma)|}\, \eta^{-\tilde{\mu}_1}, \tag{3.34}$$

$$\tilde{\mu}_1 = \frac{\sigma\, e \log(2)}{\zeta + \log(N)},$$

with $\zeta := 1 + (1 + \log_2(1.5))\log(2) \approx 2.1$. *The constant* $\tilde{C}_1(\sigma)$ *was defined in* (3.31).

Similarly to section 3.1.1 and with the same assumptions as those of the previous theorem, for large values of w we have the following sharper estimate.

THEOREM 3.19 (subexponential convergence). *If* $\mathrm{w} > \frac{N}{\log(2)}$, *then*

(3.35)
$$\left\|\left(I_N - \mathscr{A}(\mathrm{w}, N)\right)(u)\right\|_{\rho,N} \leq \sqrt{\|\rho/\hat{\rho}\|_{L^\infty(\Gamma^N)}}\tilde{C}_1(\sigma)\,\frac{\max\{1, \tilde{C}_1(\sigma)\}^N}{|1 - \tilde{C}_1(\sigma)|}\,e^{-\frac{N\sigma}{2^{1/N}}\eta^{\tilde{\mu}_2}},$$

$$\textit{with } \tilde{\mu}_2 = \frac{\log(2)}{N(\zeta + \log(N))}$$

and $\zeta := 1 + (1 + \log_2(1.5))\log(2) \approx 2.1$.

3.2. Influence of truncation errors. In this section we consider the case where the coefficients a_N and f_N from (1.4) are suitably truncated random fields. Therefore, the truncation error $u - u_N$ is nonzero and contributes to the total error. Such a contribution should be considered as well in the error analysis. In particular, understanding the relationship of this error with the discretization error allows us to compare the efficiency of the isotropic Smolyak method with other computational alternatives, for instance, the Monte Carlo method.

To this end, we make the assumption that the truncation error $u - u_N$ decays as

$$\|u - u_N\|_{L^2_P(\Omega;W(D))} \leq \zeta(N) \tag{3.36}$$

for some monotonic decreasing function $\zeta(N)$ such that $\zeta(N) \to 0$ as $N \to \infty$. For example, if one truncates the input random fields with a Karhunen–Loève expansion (see [16]), the function $\zeta(N)$ is typically related to the decay of the eigenpairs of their covariance operators.

Now, given a desired computational accuracy to achieve, tol > 0, our aim is to choose the dimension $N = N(\mathrm{tol})$ and the level $\mathrm{w} = \mathrm{w}(\mathrm{tol})$ (or equivalently $\eta = \eta(\mathrm{tol})$, the number of collocation points) such that

$$\|u - \mathscr{A}(\mathrm{w}, N)(u_N)\|_{L^2_P(\Omega;W(D))} \leq \zeta(N) + \|u_N - \mathscr{A}(\mathrm{w}, N)(u_N)\|_{L^2_P(\Omega;W(D))} \approx \mathrm{tol}.$$

More precisely, we will impose that both error contributions should be of size tol, i.e.,

$$\zeta(N) \approx \mathrm{tol} \tag{3.37}$$

and

$$\|u_N - \mathscr{A}(\mathrm{w}, N)(u_N)\|_{L^2_P(\Omega;W(D))} \approx \mathrm{tol}. \tag{3.38}$$

Condition (3.37) determines the dimension $N(\mathrm{tol})$, while (3.38) determines the necessary number of collocation points in the isotropic Smolyak approximation. Then this number of collocation points is compared to the number of samples required in the standard Monte Carlo method to approximate a statistical quantity of interest with accuracy tol. The latter is $\mathcal{O}(\mathrm{tol}^{-2})$.

We detail only the procedure for the choice of Clenshaw–Curtis abscissas, since the discussion for Gaussian abscissas is identical. To impose condition (3.38), we apply Theorem 3.7, with the choice $\delta^* = (e\log(2) - 1)/\tilde{C}_2(\sigma)$ and $\tilde{C}_2(\sigma)$ as in (3.11), yielding

$$\|u_N - \mathscr{A}(\mathrm{w}, N)(u_N)\|_{L^2_\rho(\Gamma^N;W(D))} \leq \frac{C_1(\sigma, \delta^*)}{|1 - C_1(\sigma, \delta^*)|}\max\{1, C_1(\sigma, \delta^*)\}^N e^{-\sigma \mathrm{w}},$$

where the constant $C_1(\sigma, \delta^*)$ is defined in (3.12). Now define the constants $C = \frac{C_1(\sigma,\delta^*)}{|1-C_1(\sigma,\delta^*)|}$ and $F = \max\{1, C_1(\sigma, \delta^*)\}$. With this notation and using (3.23), we have an upper bound in terms of the number of collocation points,

$$\begin{aligned}\|u_N - \mathscr{A}(\mathrm{w}, N)(u_N)\|_{L^2_\rho(\Gamma^N;W(D))} &\le C\, F^N e^{-\sigma \mathrm{w}} \\ &\le C\, F^N e^{\sigma}\, \eta^{-\frac{\sigma}{1+\log(2N)}} \approx \mathrm{tol}.\end{aligned}$$

Then, given the value of $N(\mathrm{tol})$, we can find

$$\eta(\mathrm{tol}) \approx \left(\frac{C F^N e^{\sigma}}{\mathrm{tol}}\right)^{\frac{1+\log(2N)}{\sigma}} \tag{3.39}$$

and compare with the number of samples needed to achieve accuracy tol with Monte Carlo, which is $\eta_{MC} \approx \mathrm{tol}^{-2}$.

Exponential truncation error. Here we have $\zeta(N) = \theta e^{-\gamma N}$, with θ and γ positive constants. Therefore the dimension depends on the required accuracy like

$$N(\mathrm{tol}) = \frac{1}{\gamma} \log\left(\frac{\theta}{\mathrm{tol}}\right),$$

and the number of corresponding collocation points, following (3.39), is

$$\eta(\mathrm{tol}) \approx \left(C e^{\sigma} F^{\frac{1}{\gamma}\log(\theta)}\right)^{\frac{\log(2e/\gamma)+\log(\log(\theta/\mathrm{tol}))}{\sigma}} \mathrm{tol}^{-(1+\log(F)/\gamma)\left(\frac{\log(2e/\gamma)+\log(\log(\theta/\mathrm{tol}))}{\sigma}\right)}.$$

From here we can see roughly that for the exponential truncation error case the isotropic Smolyak method would be more efficient than Monte Carlo only if

$$\left(1 + \frac{\log(F)}{\gamma}\right) \frac{\log(2e/\gamma) + \log(\log(\theta/\mathrm{tol}))}{\sigma} < 2.$$

Observe that for sufficiently stringent accuracy requirements, i.e., tol sufficiently small, the Monte Carlo method will have a better convergence rate. On the other hand, due to the very slow growth of the $\log(\log(\theta/\mathrm{tol}))$ term above, these values of tol may be much smaller than the ones we need in practice. Thus, the range of parameters for which the isotropic Smolyak approximation gives a better convergence rate than Monte Carlo can still be relevant in many practical problems with truncated coefficients.

Observe, moreover, that whenever the parameter γ is large, the behavior of the one-dimensional interpolation error varies widely with respect to the different y directions. In such a case, it is likely that the isotropic Smolyak method uses too many points in the directions with fastest decay. For such a case, the isotropic Smolyak method may still be better than Monte Carlo, yet we recommend the use of an anisotropic version of the Smolyak method to obtain faster convergence. For instance, see [19, 8], where anisotropic Smolyak formulas have been proposed.

Algebraic truncation error. Here we have $\zeta(N) = \theta N^{-r}$, with θ and r positive constants. Therefore the dimension is $N(\mathrm{tol}) = (\mathrm{tol}/\theta)^{-\frac{1}{r}}$ and we have

$$\frac{\mathrm{tol}}{F^{(\theta/\mathrm{tol})^{1/r}}} \approx C e^{\sigma} \eta^{\frac{\sigma}{\log(2e)+\frac{1}{r}\log(\theta/\mathrm{tol})}}.$$

After denoting $\widehat{\text{tol}} = \frac{\text{tol}}{F^{(\theta/\text{tol})^{1/r}}} \leq \text{tol}$, the corresponding number of collocation points is

$$\eta(\text{tol}) \approx \left(Ce^{\sigma}\,\widehat{\text{tol}}\right)^{-\frac{\log(2e)+\frac{1}{r}\log(\theta/\text{tol})}{\sigma}}. \tag{3.40}$$

Observe that even for the case where $F = 1$ we now have an asymptotically faster growth of $\eta(\text{tol})$ than in the exponential truncation case. In fact, for such a case we need to have

$$\frac{\log(2e) + \frac{1}{r}\log(\theta/\text{tol})}{\sigma} < 2$$

for the isotropic Smolyak method to be more efficient than Monte Carlo. If $F > 1$, then $\widehat{\text{tol}} < \text{tol}$ and this makes, as tol gets smaller, the comparison even more favorable to Monte Carlo; cf. (3.40).

4. Application to linear elliptic PDEs with random input data. In this section we apply the theory developed so far to the particular linear problem described in Example 1.1. Problem (1.2) can be written in a weak form as follows: Find $u \in L^2_P(\Omega; H^1_0(D))$ such that

$$\int_D E[a\nabla u \cdot \nabla v]\,dx = \int_D E[fv]\,dx \quad \forall\, v \in L^2_P(\Omega; H^1_0(D)). \tag{4.1}$$

A straightforward application of the Lax–Milgram theorem allows one to state the well-posedness of problem (4.1) and yields

$$\|u(\omega)\|_{H^1_0(D)} \leq \frac{C_P}{a_{min}}\|f(\omega,\cdot)\|_{L^2(D)} \quad \text{a.s.},$$

$$\|u\|_{L^2_P(\Omega;H^1_0(D))} \leq \frac{C_P}{a_{min}}\left(\int_D E[f^2]\,dx\right)^{1/2},$$

where C_P denotes the constant appearing in the Poincaré inequality: $\|v\|_{L^2(D)} \leq C_P\|\nabla v\|_{L^2(D)}\ \forall v \in H^1_0(D)$.

Once we have the input random fields described by a finite set of random variables, i.e., $a(\omega, x) = a_N(Y_1(\omega), \ldots, Y_N(\omega), x)$, and similarly for $f(\omega, x)$, the "finite-dimensional" version of the stochastic variational formulation (4.1) has a "deterministic" equivalent, which is the following: Find $u_N \in L^2_\rho(\Gamma^N; H^1_0(D))$ such that

$$\begin{aligned}\int_{\Gamma^N} (a_N\nabla u_N, \nabla v)_{L^2(D)}\,\rho(y)dy \\ = \int_{\Gamma^N} (f_N, v)_{L^2(D)}\,\rho(y)dy \quad \forall\, v \in L^2_\rho(\Gamma^N; H^1_0(D)),\end{aligned} \tag{4.2}$$

where $\rho(y)$ is the joint probability density function defined by (1.6). Observe that in this work the gradient notation, ∇, always means differentiation with respect to $x \in D$ only, unless otherwise stated. The stochastic boundary value problem (4.1) now becomes a deterministic Dirichlet boundary value problem for an elliptic partial differential equation with an N-dimensional parameter. Then it can be shown that problem (4.1) is equivalent to

$$\int_D a_N(y)\nabla u_N(y) \cdot \nabla\phi\,dx = \int_D f_N(y)\phi\,dx \quad \forall \phi \in H^1_0(D),\ \ \rho\text{-a.e. in } \Gamma^N. \tag{4.3}$$

For our convenience, we will suppose that the coefficient a_N and the forcing term f_N admit a smooth extension on the ρ-zero measure sets. Then (4.3) can be extended a.e. in Γ^N with respect to the Lebesgue measure (instead of the measure ρdy).

It has been proved in [3] that problem (4.3) satisfies the analyticity result stated in Assumption 1.8. For instance, if we take the diffusivity coefficient as in Example 1.4 and a deterministic load, the size of the analyticity region is given by

$$\tau_n = \frac{a_{min}}{4\sigma_n}. \tag{4.4}$$

On the other hand, if we take the diffusivity coefficient as a truncated expansion as in Remark 1.6, then the analyticity region $\Sigma(\Gamma_n; \tau_n)$ is given by

$$\tau_n = \frac{1}{4\sqrt{\lambda_n}\|b_n\|_{L^\infty(D)}}. \tag{4.5}$$

Observe that, in the latter case, as $\sqrt{\lambda_n}\|b_n\|_{L^\infty(D)} \to 0$ for a regular enough covariance function (see [16]), the analyticity region increases as n increases. This fact introduces, naturally, an anisotropic behavior with respect to the "direction" n. This effect will not be exploited in the numerical methods proposed in the next sections but is the subject of ongoing research.

The finite element operator π_h can be introduced for this problem by projecting (4.3) onto the subspace $W_h(D)$ for each $y \in \Gamma^N$, i.e., $u_h^N(y) = \pi_h u_N(y)$ satisfies

$$\int_D a_N(y)\nabla u_h^N(y) \cdot \nabla \phi_h \, dx = \int_D f_N(y)\phi_h \, dx \quad \forall \phi_h \in W_h(D) \text{ for a.e. } y \in \Gamma^N. \tag{4.6}$$

Notice that the finite element functions $u_h^N(y)$ satisfy the optimality condition (2.2) $\forall y \in \Gamma^N$. Finally, the Smolyak formula (2.8) can be applied to u_h^N to obtain the fully discrete solution. The error estimates for the Smolyak approximation, stated in Theorems 3.10 and 3.11 for Clenshaw–Curtis abscissas and Theorems 3.18 and 3.19 for Gaussian abscissas, hold in this case, with parameter

$$\sigma = \frac{1}{2} \min_{n=1,\dots,N} \log\left(\frac{2\tau_n}{|\Gamma_n|} + \sqrt{1 + \frac{4{\tau_n}^2}{|\Gamma_n|^2}}\right). \tag{4.7}$$

5. Numerical examples. This section illustrates the convergence of the sparse collocation method for the stochastic linear elliptic problem in two spatial dimensions, as described in section 4. The computational results are in accordance with the convergence rates predicted by the theory. Actually, we observe a faster convergence than stated in Theorems 3.10 and 3.18, which hints that the current estimates may be improved.

We will also use this section to compare the convergence of the isotropic Smolyak approximation, described and analyzed in sections 2.2 and 3.1, respectively, with other ensemble-based methods such as the anisotropic adaptive full tensor product method described in the work [5, section 9] and the Monte Carlo method. The problem is to solve

$$\begin{cases} -\nabla \cdot (a(\omega,\cdot)\nabla u(\omega,\cdot)) = f(\omega,\cdot) & \text{in } \Omega \times D, \\ u(\omega,\cdot) = 0 & \text{on } \Omega \times \partial D, \end{cases} \tag{5.1}$$

with $D = [0,d]^2$ and $d = 1$. We consider a deterministic load $f(\omega,x,z) = \cos(x)\sin(z)$ and construct the random diffusion coefficient $a_N(\omega,x)$ with one-dimensional (layered)

spatial dependence as

$$\log(a_N(\omega,x)-0.5) = 1 + \mathrm{Y}_1(\omega)\left(\frac{\sqrt{\pi}L}{2}\right)^{1/2} + \sum_{n=2}^{N} \zeta_n\,\varphi_n(x)\,\mathrm{Y}_n(\omega), \tag{5.2}$$

where

$$\zeta_n := \left(\sqrt{\pi}L\right)^{1/2} \exp\left(\frac{-\left(\lfloor \frac{n}{2} \rfloor \pi L\right)^2}{8}\right) \quad \text{if } n>1 \tag{5.3}$$

and

$$\varphi_n(x) := \begin{cases} \sin\left(\frac{\lfloor \frac{n}{2} \rfloor \pi x}{L_p}\right) & \text{if } n \text{ even}, \\ \cos\left(\frac{\lfloor \frac{n}{2} \rfloor \pi x}{L_p}\right) & \text{if } n \text{ odd}. \end{cases} \tag{5.4}$$

In this example, the random variables $\{Y_n(\omega)\}_{n=1}^{\infty}$ are independent, have zero mean and unit variance, i.e., $E[Y_n]=0$ and $E[Y_nY_m]=\delta_{nm}$ for $n,m\in\mathbb{N}_+$, and are uniformly distributed in the interval $[-\sqrt{3},\sqrt{3}]$. Consequently, the auxiliary probability density $\hat{\rho}$ defined by (2.14) can be taken equal to the joint probability density function ρ defined by (1.6). Expression (5.2) represents the truncation of a one-dimensional random field with stationary covariance

$$\begin{aligned} &\operatorname{cov}[\log(a_N-0.5)](x_1,x_2) \\ &\quad = E\big[(\log(a)(x_1)-E[\log(a)](x_1))\,(\log(a)(x_2)-E[\log(a)](x_2))\big] \\ &\quad = \exp\left(\frac{-(x_1-x_2)^2}{L_c^2}\right). \end{aligned}$$

For $x\in[0,d]$, let L_c be a desired physical correlation length for the coefficient a, meaning that the random variables $a(x)$ and $a(y)$ become essentially uncorrelated for $|x-y|\gg L_c$. Then the parameter L_p in (5.4) is $L_p=\max\{d,2L_c\}$ and the parameter L in (5.2) and (5.3) is $L=L_c/L_p$.

The rate of convergence of the isotropic Smolyak method is dictated by the decay coefficient σ defined by (4.7), which in this case can be bounded as

$$\sigma \geq \frac{1}{2}\log\left(1+\sqrt{\frac{1}{24\sqrt{\pi}L}}\right). \tag{5.5}$$

From (5.5) we notice that larger correlation lengths will have negative effects on the rate of convergence, i.e., the coefficient σ appearing in the estimates (3.26)–(3.27) and (3.34)–(3.35) is approaching 1 as L_c becomes large. Hence, the effect of increasing L_c is a deterioration of the rate of convergence.

Recall from section 2.3 that the Clenshaw–Curtis abscissas are nested and therefore, in practice, we exploit this fact and construct the isotropic Smolyak interpolant using formula (2.8). Hence, the number of points $\eta=\eta(\mathrm{w},N)=\#\mathscr{H}(\mathrm{w},N)$ can be counted as in formula (3.24). On the other hand, the Gaussian abscissas, which in this case are the roots of the Legendre polynomials, are not nested, and to reduce the number of points necessary to build the isotropic Smolyak formula one utilizes the variant of (2.8), given by (2.9). Consequently, we can count the number of points η used by the Smolyak formula as in (3.33).

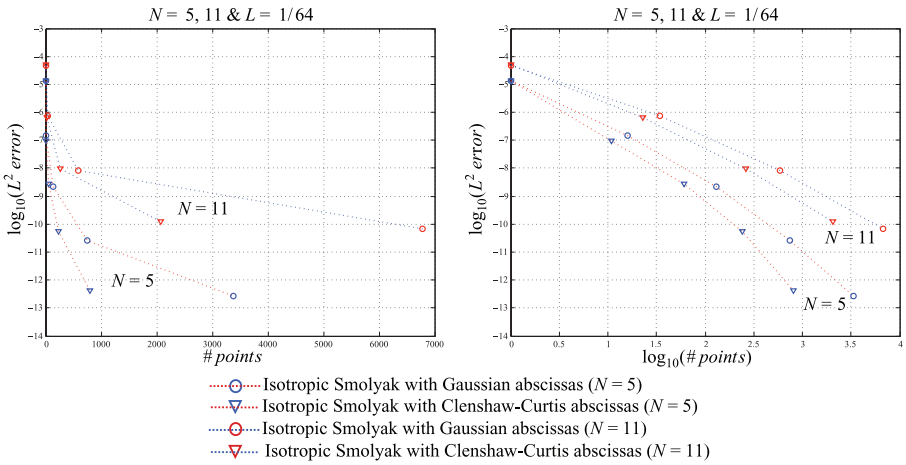

FIG. 3. *The rate of convergence of the isotropic Smolyak approximation for solving problem* (5.1) *with correlation length* $L_c = 1/64$ *using both the Gaussian and Clenshaw–Curtis abscissas. The finite element space for the spatial discretization is the span of continuous functions that are piecewise polynomials with degree two over a uniform triangulation of D with 4225 unknowns.

Observe that the collocation method requires only the solution of uncoupled deterministic problems over the set of collocation points, even in the presence of a diffusivity coefficient which depends nonlinearly on the random variables as in (5.2). This is a significant advantage that the collocation method offers compared to the classical stochastic-Galerkin finite element method as considered, for instance, in [4, 16, 26, 37]. To study the convergence of the isotropic Smolyak approximation we consider a problem with a fixed dimension N and investigate the behavior when the level w in the Smolyak formula is increased linearly.

The computational results for the $L^2(D)$ error to the expected value, $E[u]$, using the isotropic Smolyak approximation, are shown in Figure 3. Here we consider the truncated probability space to have dimensions $N = 5$ and $N = 11$. To estimate the computational error in the level w we approximate $\|E[\epsilon]\| \approx \|E[\mathscr{A}(\mathrm{w}, N)\pi_h u_N - \mathscr{A}(\mathrm{w}+1, N)\pi_h u_N]\|$. The results reveal, as expected, that for a small nondegenerate correlation length, i.e., $L_c = 1/64$, the error decreases (sub)exponentially, as the level w increases. We also observe that the convergence rate is dimension dependent and slightly deteriorates as N increases.

To investigate the performance of the isotropic Smolyak approximation by varying the correlation length L_c we also include the cases where $L_c = 1/16$, $L_c = 1/4$, and $L_c = 1/2$ for both $N = 5$ and $N = 11$, as seen in Figure 4. As predicted by (5.5), we observe that the larger correlation lengths do indeed slow down the rate of convergence. Our final interest, then, is to compare our isotropic sparse tensor product method with the Monte Carlo approach, as well as with the anisotropic full tensor product method, proposed in [5].

The anisotropic full tensor product algorithm can be described in the following way: Given a tolerance tol the method computes a multi-index $\mathbf{p} = (p_1, p_2, \ldots, p_N)$, corresponding to the order of the approximating polynomial spaces $\mathcal{P}_{\mathbf{p}}(\Gamma^N)$. This

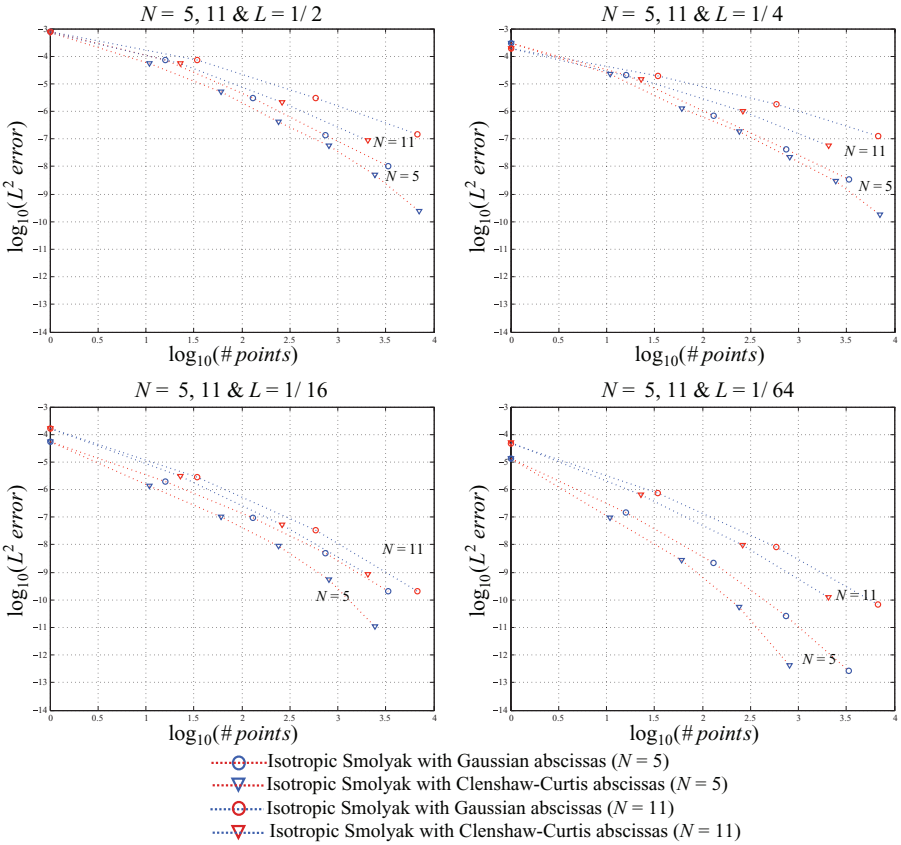

FIG. 4. *The convergence of the isotropic Smolyak approximation for solving problem* (5.1) *with given correlation lengths* $L_c = 1/2, 1/4, 1/16$, *and* $1/64$ *using both the Gaussian and Clenshaw–Curtis abscissas. adaptive algorithm increases the tensor polynomial degree with an anisotropic strategy: it increases the order of approximation in one direction as much as possible before considering the next direction. Tables 1 and 2 show the values of components of the 11-dimensional multi-index $\mathbf{p}$ for different values of tol, corresponding to $L_c = 1/2$ and $L_c = 1/64$, respectively. These tables also give insight into the anisotropic behavior of each particular problem. Notice, in particular, that for the case $L_c = 1/64$ the algorithm predicts a multi-index $\mathbf{p}$ which is equal in all directions, i.e., an isotropic tensor product space. A convergence plot for $L_c = 1/2$ and $L_c = 1/64$ can be constructed by examining each row of Table 1 and Table 2, respectively, and plotting the number of points in the tensor product grid versus the error in expectation. We estimate the error in expectation by $\|E[\epsilon]\| \approx \|E[u^N_{h,\mathbf{p}} - u^N_{h,\widetilde{\mathbf{p}}}]\|$, with $\widetilde{\mathbf{p}} = (p_1 + 1, p_2 + 1, \ldots, p_N + 1)$. This entails an additional computational cost, which is bounded by the factor $\exp\left(\sum_{n=1}^{N} 1/p_n\right)$ times the work to compute $E[u^N_{h,\mathbf{p}}]$.

The standard Monte Carlo finite element method is a popular choice for solving stochastic problems such as (5.1) (see, e.g., [21, 9, 5] and the references therein). If the aim is to compute a functional of the solution such as the expected value, one would approximate $E[u]$ numerically by sample averages of independant and identically dis-

tributed (i.i.d.) realizations of the stochastic input data. Given a number of realizations, $M \in \mathbb{N}_+$, we compute the sample average as follows: For each $k = 1, \ldots, M$, sample i.i.d. realizations of $a(\omega_k, \cdot)$ and $f(\omega_k, \cdot)$, solve problem (5.1), and construct finite element approximations $u_h^N(\omega_k, \cdot)$. We note that once we have fixed $\omega = \omega_k$, the problem is completely deterministic, and may be solved by standard methods as in the collocation approach. Finally, approximate $E[u]$ by the sample average: $\overline{E}[u_{h,k}^N; M](\cdot) := \frac{1}{M} \sum_{k=1}^{M} u_h^N(\omega_k, \cdot)$.

For the cases $L_c = 1/2, 1/4, 1/16$, and $1/64$ we take $M = 2^i$, $i = 0, 1, 2, \ldots, 11$, realizations and compute the approximation to the error in expectation by $\|E[\epsilon]\| \approx \|\overline{E}[u_{h,k}^N; M] - E[\mathscr{A}(\overline{\mathrm{w}}+1, N)\pi_h u_N]\|$, with $\overline{\mathrm{w}} = 4$, so that $\mathscr{A}(5, N)$ is a highly enriched Clenshaw–Curtis isotropic sparse solution.

To study the advantages of utilizing an isotropic sparse tensor product space as opposed to an anisotropic full tensor product space, we show in Figure 5 the convergence of these methods when solving problem (5.1), using correlation lengths $L_c = 1/2, 1/4, 1/16$, and $1/64$ with $N = 11$. We also include five ensembles of the Monte Carlo method described previously. Figure 5 reveals that for the isotropic case with $L_c = 1/64$ the isotropic Smolyak method obtains a faster rate of convergence than the anisotropic full tensor product method. This is due to a slower decay of the eigenvalues expansion (5.2) and hence an almost equal weighing of all $N = 11$ random variables. On the contrary, opposite behavior can be observed for $L_c = 1/2$. Since, in this case, the rate of decay of the expansion is faster, the anisotropic full tensor method weighs heavily the important modes and, therefore, achieves a faster convergence than the isotropic Smolyak method.

In all four cases we observe that the two methods outperform the Monte Carlo method. We know that the amount of work to reach the accuracy ϵ in the Monte Carlo approach can be approximated by $\epsilon \approx O(M^{-1/2})$ times the amount of work per sample, where M is the number of samples. This is affected only by the problem dimension through the eventual increase of the work per sample. Nevertheless, the convergence rate is quite slow and a high level of accuracy is achieved only when a

TABLE 3

For $N = 11$, *we compare the number of function evaluations required by the anisotropic full tensor product method (AF) using Gaussian abscissas, isotropic smolyak (IS) using Clenshaw–Curtis abscissas, and the Monte Carlo (MC) method using random abscissas to reduce the original error of problem* (5.1), *in expectation, by a factor of* 10^4.

L_c	AF	IS	MC
1/2	2.5×10^2	2.5×10^3	5.0×10^9
1/4	1.2×10^3	4.0×10^3	2.0×10^9
1/16	2.0×10^3	5.0×10^2	1.6×10^9
1/64	2.0×10^5	3.6×10^2	1.3×10^9

large amount of function evaluations are required. This can been seen from Figure 5, where we include reference lines with slopes $-1/2$ and -1, respectively, or in Table 3, where, for $N = 11$, we compare the work, proportional to the number of samples, which is the number of collocation points, required by each method to decrease the original error by a factor of 10^4 for all four correlation lengths $L_c = 1/2, 1/4, 1/16,$ and $1/64$.

6. Conclusions. In this work we proposed and analyzed a sparse grid stochastic collocation method for solving PDEs whose coefficients and forcing terms depend on a finite number of random variables. The sparse grids are constructed from the Smolyak formula, utilizing either Clenshaw–Curtis or Gaussian abscissas. The method leads to the solution of uncoupled deterministic problems and, as such, it is simple to implement, allows for the use of legacy codes, and is fully parallelizable like a Monte Carlo method.

This method is an improvement of the stochastic collocation method on tensor product grids proposed in [3]. The use of sparse grids considered in the present work (as opposed to full tensor grids) reduces considerably the curse of dimensionality and allows us to treat effectively problems that depend on a moderately large number of random variables, while keeping a high level of accuracy.

Upon assumption that the solution depends analytically on each random variable (which is a reasonable assumption for a certain class of applications; see [4, 3]), we derived strong error estimates for the fully discrete sparse grid stochastic collocation solution and analyzed its computational efficiency. In particular, the main result is the algebraic convergence with respect to the total number of collocation points; cf. Theorems 3.10 and 3.18. The exponent of such algebraic convergence depends on both the regularity of the solution and the number of input random variables, N. The exponent essentially deteriorates with N by a factor of $1/\log(N)$. The theory is confirmed numerically by the examples presented in section 5. We also utilized the error estimates to compare the method with Monte Carlo in terms of computational work to achieve a given accuracy, indicating for which problems the former is more efficient than the latter. To this effect, in section 3.2 we considered a case where the input random variables come from suitably truncated expansions of random fields and related the number of collocation points in the sparse grid to the number of random variables retained in the truncated expansion. We also developed error estimates with fewer regularity requirements in Remark 3.14.

The sparse grid method is very effective for problems whose input data depend on a moderate number of random variables, which "weigh equally" in the solution. For such an isotropic situation the displayed convergence is faster than standard collocation techniques built upon full tensor product spaces.

On the other hand, the convergence rate deteriorates when we attempt to solve highly anisotropic problems, such as those appearing when the input random variables come, e.g., from Karhunen–Loève truncated expansions of "smooth" random fields. In such cases, a full anisotropic tensor product approximation, as proposed in [5, 3], may still be more effective for a small or moderate number of random variables.

Future directions of this research will include the development and analysis of an anisotropic version of the sparse grid stochastic collocation method, which will combine an optimal treatment of the anisotropy of the problem while reducing the curse of dimensionality via the use of sparse grids.

Appendix. Additional estimates. Here we present auxiliary results that are used in section 3. Let us recall the definition for the integer and fractional parts of a nonnegative real number x that satisfy $x = frac\{x\} + \mathrm{int}\{x\}\ \forall x \in \mathbb{R}^+$, with $\mathrm{int}\{x\}$ being the largest natural number that is smaller than or equal to x.

LEMMA A.1. *Given* $\mathrm{w} \in \mathbb{N}_+$, *for any* $\alpha > 0$ *and* $0 \le \beta < \mathrm{w}$, *we have*

$$\sum_{i=0}^{\mathrm{w}} e^{-\alpha(i-\beta)^2} \le 2e^{-\alpha(\min\{frac\{\beta\},1-frac\{\beta\}\})^2} \left(1 + \frac{1}{2}\sqrt{\frac{\pi}{\alpha}}\right).$$

Proof. Let us write $\beta = \operatorname{int}\{\beta\} + \mathit{frac}\{\beta\}$. Then

$$\begin{aligned}\sum_{i=0}^{\mathrm{w}} e^{-\alpha(i-\beta)^2} &= \sum_{j=-\operatorname{int}\{\beta\}}^{\mathrm{w}-\operatorname{int}\{\beta\}} e^{-\alpha(j-\mathit{frac}\{\beta\})^2} \\ &= \sum_{j=-\operatorname{int}\{\beta\}}^{0} e^{-\alpha(j-\mathit{frac}\{\beta\})^2} + \sum_{j=1}^{\mathrm{w}-\operatorname{int}\{\beta\}} e^{-\alpha(j-\mathit{frac}\{\beta\})^2} \\ &= \sum_{j=0}^{\operatorname{int}\{\beta\}} e^{-\alpha(j+\mathit{frac}\{\beta\})^2} + \sum_{j=0}^{\mathrm{w}-\operatorname{int}\{\beta\}-1} e^{-\alpha(j+(1-\mathit{frac}\{\beta\}))^2}.\end{aligned}$$

Finally, estimate

$$\begin{aligned}\sum_{i=0}^{\mathrm{w}} e^{-\alpha(i-\beta)^2} &\le 2e^{-\alpha(\min\{\mathit{frac}\{\beta\},1-\mathit{frac}\{\beta\}\})^2} \sum_{j=0}^{\infty} e^{-\alpha j^2} \\ &\le 2e^{-\alpha(\min\{\mathit{frac}\{\beta\},1-\mathit{frac}\{\beta\}\})^2} \left(1 + \sum_{j=1}^{\infty} e^{-\alpha j^2}\right) \\ &\le 2e^{-\alpha(\min\{\mathit{frac}\{\beta\},1-\mathit{frac}\{\beta\}\})^2} \left(1 + \int_0^{\infty} e^{-\alpha x^2} dx\right) \\ &\le 2e^{-\alpha(\min\{\mathit{frac}\{\beta\},1-\mathit{frac}\{\beta\}\})^2} \left(1 + \frac{1}{2}\sqrt{\frac{\pi}{\alpha}}\right). \qquad \square\end{aligned}$$

Now we state and prove an auxiliary estimate, to be used later on in the proof of Lemma A.3.

LEMMA A.2. *If $\alpha > 0$, we have*

$$\sum_{k=1}^{\infty} k\, e^{-\alpha k^2} \le \frac{1}{\alpha} + \frac{1}{\sqrt{2\alpha}}.$$

Proof. Observe first that $xe^{-\alpha x^2} \le \frac{1}{\sqrt{2e\alpha}}$ $\forall x \ge 0$ and that the bound is attained at $x^* = \frac{1}{\sqrt{2\alpha}}$. Then, for any integer $k_0 \ge x^*$, we can estimate

$$\sum_{k=1}^{\infty} k\, e^{-\alpha k^2} \le \frac{k_0}{\sqrt{2e\alpha}} + \int_{k_0}^{+\infty} xe^{-\alpha x^2}\, dx \le \frac{k_0}{\sqrt{2e\alpha}} + \frac{e^{-\alpha k_0^2}}{2\alpha}.$$

Finally, choosing $k_0 = \operatorname{int}\{x^*\}+1 = \operatorname{int}\{1/\sqrt{2\alpha}\}+1$, the desired result follows. $\square$

LEMMA A.3. *Given* $\mathrm{w} \in \mathbb{N}_+$, *for any* $\alpha > 0$ *and* $0 \le \beta < \mathrm{w}$, *we have*

$$\begin{aligned}\sum_{i=1}^{\mathrm{w}} i\, e^{-\alpha(i-\beta)^2} &\le 2\, e^{-\alpha(1-\mathit{frac}\{\beta\})^2} \left(\frac{1}{\alpha} + \frac{1}{\sqrt{2\alpha}}\right) \\ &\quad + (\operatorname{int}\{\beta\} + 1)\, 2\, e^{-\alpha(\min\{\mathit{frac}\{\beta\},1-\mathit{frac}\{\beta\}\})^2} \left(1 + \frac{1}{2}\sqrt{\frac{\pi}{\alpha}}\right).\end{aligned}$$

Proof. Write

$$\begin{aligned}\sum_{i=0}^{\mathrm{w}} i\, e^{-\alpha(i-\beta)^2} &= \sum_{j=-\operatorname{int}\{\beta\}}^{\mathrm{w}-\operatorname{int}\{\beta\}} (j+\operatorname{int}\{\beta\}) e^{-\alpha(j-frac\{\beta\})^2} \\ &= \sum_{j=-\operatorname{int}\{\beta\}}^{\mathrm{w}-\operatorname{int}\{\beta\}} (j-1)\, e^{-\alpha(j-frac\{\beta\})^2} \\ &\quad + (\operatorname{int}\{\beta\}+1) \sum_{j=-\operatorname{int}\{\beta\}}^{\mathrm{w}-\operatorname{int}\{\beta\}} e^{-\alpha(j-frac\{\beta\})^2}\end{aligned}$$

and bound

$$\begin{aligned}\sum_{i=0}^{\mathrm{w}} i\, e^{-\alpha(i-\beta)^2} &\le \sum_{j=1}^{\mathrm{w}-\operatorname{int}\{\beta\}} (j-1)\, e^{-\alpha(j-frac\{\beta\})^2} \\ &\quad + (\operatorname{int}\{\beta\}+1)\, 2e^{-\alpha(\min\{frac\{\beta\},1-frac\{\beta\}\})^2} \left(1+\frac{1}{2}\sqrt{\frac{\pi}{\alpha}}\right) \\ &\le e^{-\alpha(1-frac\{\beta\})^2} \sum_{j=1}^{\mathrm{w}-\operatorname{int}\{\beta\}} (j-1)\, e^{-\alpha(j-1)^2} \\ &\quad + (\operatorname{int}\{\beta\}+1)\, 2e^{-\alpha(\min\{frac\{\beta\},1-frac\{\beta\}\})^2} \left(1+\frac{1}{2}\sqrt{\frac{\pi}{\alpha}}\right).\end{aligned}$$

Finally, use the auxiliary Lemma A.2 to estimate

$$\sum_{j=0}^{\mathrm{w}-\operatorname{int}\{\mathrm{w}/d\}} j\, e^{-\alpha j^2} \le \sum_{j=1}^{\infty} j\, e^{-\alpha j^2} \le \left(\frac{1}{\alpha}+\frac{1}{\sqrt{2\alpha}}\right). \qquad \square$$

We have, as a direct consequence of Lemmas A.1 and A.3 the following estimates.

COROLLARY A.4. *There holds*

$$\sum_{i=0}^{\mathrm{w}} e^{-\sigma\frac{\log^2(2)}{2}(i-\mathrm{w}/d)^2} \le 2\left(1+\frac{1}{\log(2)}\sqrt{\frac{\pi}{2\sigma}}\right) \tag{A.1}$$

and

$$\begin{aligned}\sum_{i=0}^{\mathrm{w}} (1+i)\, e^{-\sigma\frac{\log^2(2)}{2}(i-\mathrm{w}/d)^2} &\le 2\left(\frac{1}{\sigma\log^2(2)}+\frac{1}{\log(2)\sqrt{2\sigma}}\right) \\ &\quad + 2(\operatorname{int}\{\mathrm{w}/d\}+2)\left(1+\frac{1}{\log(2)}\sqrt{\frac{\pi}{2\sigma}}\right).\end{aligned} \tag{A.2}$$

A FETI-DP FORMULATION OF THREE DIMENSIONAL ELASTICITY PROBLEMS WITH MORTAR DISCRETIZATION*

HYEA HYUN KIM†

Abstract. In this paper, a FETI-DP formulation for three dimensional elasticity on nonmatching grids over geometrically nonconforming subdomain partitions is considered. To resolve the nonconformity of the finite elements, a mortar matching condition is imposed on the subdomain interfaces (faces). A FETI-DP algorithm is then built by enforcing the mortar matching condition in dual and primal ways. In order to make the FETI-DP algorithm scalable, a set of primal constraints, which include average and momentum constraints over interfaces, are selected from the mortar matching condition. A condition number bound, $C(1 + \log(H/h))^2$, is then proved for the FETI-DP formulation for the elasticity problems with discontinuous material parameters. Only some faces need to be chosen as primal faces on which the average and momentum constraints are imposed. Numerical results are included.

Key words. FETI-DP, mortar methods, preconditioner, elasticity

1. Introduction.

We will develop an efficient dual-primal finite element tearing and interconnecting (FETI-DP) algorithm for solving linear systems arising from certain nonconforming discretizations of compressible elasticity problems in three dimensions. We consider a nonconforming finite element space with triangulations that are nonmatching across subdomain interfaces. Allowing such triangulations helps make adaptivity for problems with singular points or with jumps in the material parameters easier and more economical and helps save the cost for mesh generation, especially for three dimensional problems. Furthermore, we allow geometrically nonconforming partitions that are useful for biomechanics with joints or with heterogeneous elasticity.

Mortar methods have been developed as nonconforming approximations with the goal of obtaining as accurate an approximate solution as possible for a conforming approximation; see [3, 1, 13, 28]. For this purpose, a mortar matching condition is imposed on the subdomain solutions across the interface. In more detail, the jumps of the solutions across the subdomain interface are orthogonal to a certain Lagrange multiplier space. This condition can be enforced directly on the nonconforming finite element functions to produce elements of the mortar finite element space. Another approach is to impose the condition weakly by introducing Lagrange multipliers, which leads to a saddle-point problem similar to that considered in FETI-type algorithms.

FETI-type algorithms were originally developed for second order elliptic problems with conforming discretizations. These algorithms belong to the iterative substructuring domain decomposition methods of dual type. A separate set of interface unknowns is assigned to each subdomain. Pointwise continuity of solutions across the interface is then enforced using dual Lagrange multipliers, leading to a saddle-point problem. The

subdomain unknowns are then eliminated and the resulting linear system for the dual variables is solved iteratively using a preconditioner. These algorithms have evolved from the one-level FETI methods into two-level FETI and FETI-DP methods; see [12, 11, 9]. In FETI-DP methods, a certain set of continuity constraints is enforced throughout the iteration while the remaining constraints are imposed weakly by dual Lagrange multipliers. FETI-DP algorithms have been further developed for three dimensional elliptic problems with discontinuous coefficients by Klawonn, Widlund, and Dryja [23].

FETI-type algorithms have also been applied to the saddle-point problems resulting from mortar discretizations. A numerical study in [26] showed that such methods applied to these saddle-point problems are as efficient as the FETI methods for conforming discretizations. Lee and the author [16] introduced a FETI-DP algorithm for two dimensional elliptic problems with discontinuous coefficients and showed a condition number bound, $C(1 + \log(H/h))^2$, with a constant C independent of the coefficients and mesh parameters. Numerical results show that it is most efficient for problems with jump coefficients; see [5]. This preconditioner is similar to previously developed FETI-DP preconditioners [7, 8] except that its weights equal zero at the interface unknowns on the mortar sides. We call this preconditioner the Neumann–Dirichlet preconditioner. This algorithm has later been extended to the Stokes problem and to three dimensional elliptic problems; see [17, 14].

The purpose of this study is to extend the FETI-DP algorithm of [16] to three dimensional compressible elasticity problems with mortar discretizations on geometrically nonconforming partitions. FETI-DP methods for three dimensional elasticity problems, with conforming discretization, have been studied extensively both theoretically and numerically; see [10, 20, 22]. In [10], Farhat, Lesoinne, and Pierson introduced face average constraints in addition to vertex constraints as primal constraints and observed that these additional constraints help produce a scalable algorithm. Later Klawonn and Widlund [22] considered various primal constraints for elasticity problems with discontinuous Lamé parameters. In their work, some faces and edges were selected as fully primal faces and fully primal edges. Edge average constraints on fully primal faces and edge average and moment constraints on fully primal edges were then enforced to get a scalable algorithm. In our FETI-DP formulation, we will introduce face average and face moment constraints selected from the mortar matching condition.

This paper is organized as follows. In section 2, we introduce a compressible elasticity problem and Korn inequalities. In section 3, we approximate the solution of the model problem using the mortar discretization. We then build a FETI-DP algorithm considering the mortar matching condition just like the pointwise continuity constraints in conforming finite element approximations. Some primal constraints are selected from the mortar matching condition. In order to make them explicit, we perform a change of unknowns. Section 4 is devoted to our condition number analysis of the FETI-DP algorithm. In the final section, numerical results will be presented to verify the efficiency of the suggested algorithm under heterogeneous elasticity and geometrically nonconforming partitions.

Throughout this paper, c and C denote generic positive constants independent of the mesh size, the number of subdomains, and the problem coefficients. We will use h_i and H_i to denote the mesh size and the subdomain size of Ω_i, respectively.

2. A model problem and Korn's inequality. Let Ω be a polyhedral domain in $\mathbf{R}^3$. The Sobolev space $H^1(\Omega)$ is the set of functions in $L^2(\Omega)$ which are square

integrable up to its first derivatives and equipped with the Sobolev norm;

$$\|v\|_{1,\Omega}^2 := |v|_{1,\Omega}^2 + \frac{1}{H^2}\|v\|_{0,\Omega}^2,$$

where $|v|_{1,\Omega}^2 = \int_\Omega \nabla v \cdot \nabla v \, dx$, $\|v\|_{0,\Omega} = \int_\Omega v^2 \, dx$, and H denotes the diameter of Ω.

We assume that $\partial\Omega$ is divided into two parts $\partial\Omega_D$ and $\partial\Omega_N$ on which a Dirichlet boundary condition and a natural boundary condition, respectively, are specified. The subspace $H_D^1(\Omega) \subset H^1(\Omega)$ is the set of functions having zero traces on $\partial\Omega_D$. We introduce the vector valued Sobolev spaces $[H_D^1(\Omega)]^3$ and $[H^1(\Omega)]^3$, equipped with the usual product norm.

We then consider the elasticity problem:

Find $\mathbf{u} \in [H_D^1(\Omega)]^3$ such that

$$\int_\Omega G(\mathbf{x})\varepsilon(\mathbf{u}) : \varepsilon(\mathbf{v}) \, d\mathbf{x} + \int_\Omega G(\mathbf{x})\beta(\mathbf{x})\nabla\cdot\mathbf{u}\,\nabla\cdot\mathbf{v}\, d\mathbf{x} = \langle \mathbf{F}, \mathbf{v}\rangle \quad \forall \mathbf{v} \in [H_D^1(\Omega)]^3, \tag{2.1}$$

where $G = E/(1+\nu)$ and $\beta = \nu/(1-2\nu)$ are material parameters which depend on the Young's modulus $E > 0$ and the Poisson ratio $\nu \in (0, 1/2)$. We assume that ν is bounded from above away from $1/2$, excluding the case of incompressible elasticity problems. The linearized strain tensor is defined by

$$\varepsilon(\mathbf{u})_{ij} := \frac{1}{2}\left(\frac{\partial u_i}{\partial x_j} + \frac{\partial u_j}{\partial x_i}\right), \quad i, j = 1, 2, 3,$$

and the tensor product and the force term are given by

$$\varepsilon(\mathbf{u}) : \varepsilon(\mathbf{v}) = \sum_{i,j=1}^{3} \varepsilon_{ij}(\mathbf{u})\varepsilon_{ij}(\mathbf{v}), \quad \langle \mathbf{F}, \mathbf{v}\rangle = \int_\Omega \mathbf{f}\cdot\mathbf{v}\, d\mathbf{x} + \int_{\partial\Omega_N} \mathbf{g}\cdot\mathbf{v} d\sigma.$$

Here $\mathbf{f}$ is the body force and $\mathbf{g}$ is the surface force on the natural boundary part $\partial\Omega_N$.

The space $\mathbf{ker}(\varepsilon)$ has the following six rigid body motions as its basis elements. They are the three translations,

$$\mathbf{r}_1 = \begin{pmatrix} 1 \\ 0 \\ 0 \end{pmatrix}, \ \mathbf{r}_2 = \begin{pmatrix} 0 \\ 1 \\ 0 \end{pmatrix}, \ \mathbf{r}_3 = \begin{pmatrix} 0 \\ 0 \\ 1 \end{pmatrix}, \tag{2.2}$$

and the three rotations,

$$\mathbf{r}_4 = \frac{1}{H}\begin{pmatrix} x_2 - \widehat{x}_2 \\ -x_1 + \widehat{x}_1 \\ 0 \end{pmatrix}, \ \mathbf{r}_5 = \frac{1}{H}\begin{pmatrix} -x_3 + \widehat{x}_3 \\ 0 \\ x_1 - \widehat{x}_1 \end{pmatrix}, \ \mathbf{r}_6 = \frac{1}{H}\begin{pmatrix} 0 \\ x_3 - \widehat{x}_3 \\ -x_2 + \widehat{x}_2 \end{pmatrix}. \tag{2.3}$$

Here $\widehat{\mathbf{x}} = (\widehat{x}_1, \widehat{x}_2, \widehat{x}_3) \in \widehat{\Omega}$ and H is the diameter of $\widehat{\Omega}$. This shift and the scaling make the L_2-norm of the six vectors scale in the same way with H. When Ω is partitioned into a set of subdomains, the elasticity problem given on a floating subdomain has a purely natural boundary condition. The Korn inequalities in [22, section 6] address this case. Let $\Sigma \subset \partial\Omega$ be of positive measure. We define an L_2–inner product $(\mathbf{u}, \mathbf{r})_\Sigma$ by

$$(\mathbf{u}, \mathbf{r})_\Sigma = \int_\Sigma \mathbf{u}\cdot\mathbf{r}\, ds.$$

The following Korn inequality is provided in [22, Lemma 6.4].

LEMMA 2.1. *Let Ω be a Lipschitz domain and Σ be a subset of $\partial\Omega$ with positive measure. Then there exist a constant $c > 0$, invariant under dilation, such that*

$$c|\mathbf{u}|_{1,\Omega} \leq \|\varepsilon(\mathbf{u})\|_{0,\Omega} \leq |\mathbf{u}|_{1,\Omega},$$

where $\mathbf{u} \in [H^1(\Omega)]^3$ satisfies $(\mathbf{u}, \mathbf{r})_\Sigma = 0$ for all $\mathbf{r} \in \mathbf{ker}(\varepsilon)$.

Furthermore, we have similar inequalities for seminorms defined in the space $[H^{1/2}(\Sigma)]^3$ which is the trace space of $[H^1(\Omega)]^3$ on $\Sigma \subset \partial\Omega$. For $\mathbf{u} \in [H^{1/2}(\Sigma)]^3$, we define two seminorms by

$$|\mathbf{u}|_{1/2,\Sigma} := \inf_{\substack{\mathbf{v} \in [H^1(\Omega)]^3 \\ \mathbf{v}|_\Sigma = \mathbf{u}}} |\mathbf{v}|_{1,\Omega}, \quad |\mathbf{u}|_{E(\Sigma)} := \inf_{\substack{\mathbf{v} \in [H^1(\Omega)]^3 \\ \mathbf{v}|_\Sigma = \mathbf{u}}} \|\varepsilon(\mathbf{v})\|_{0,\Omega}. \tag{2.4}$$

LEMMA 2.2. *Let Ω be a Lipschitz domain and Σ be a subset of $\partial\Omega$ with positive measure. Then there exists a constant $c > 0$, invariant under dilation, such that*

$$c|\mathbf{u}|_{1/2,\Sigma} \leq |\mathbf{u}|_{E(\Sigma)} \leq |\mathbf{u}|_{1/2,\Sigma},$$

for $\mathbf{u} \in [H^{1/2}(\Sigma)]^3$ satisfying $(\mathbf{u}, \mathbf{r})_\Sigma = 0$ for all $\mathbf{r} \in \mathbf{ker}(\varepsilon)$.

This lemma can be found in [22, Lemma 6.5]. Another important inequality, which follows from this inequality, is given in [22, Lemma 6.6].

LEMMA 2.3. *Let Ω be a Lipschitz domain of diameter H and $\Sigma \subset \partial\Omega$ be an open subset with positive measure. Then there exists a constant $C > 0$ such that*

$$\inf_{\mathbf{r} \in \mathbf{ker}(\varepsilon)} \|\mathbf{u} - \mathbf{r}\|^2_{0,\Sigma} \leq CH|\mathbf{u}|^2_{E(\Sigma)} \quad \forall \mathbf{u} \in [H^{1/2}(\Sigma)]^3.$$

Here the infimum occurs when $\mathbf{r}$ satisfies $(\mathbf{u} - \mathbf{r}, \mathbf{q})_\Sigma = 0$ for all $\mathbf{q} \in \ker(\varepsilon)$.

3. FETI-DP formulation.

3.1. Mortar discretization. We divide the domain Ω into a geometrically nonconforming partition $\{\Omega_i\}_{i=1}^N$, where Ω_i are polyhedral and equipped with quasiuniform triangulations T_i.

Assumption 3.1. The subdomain partition $\{\Omega_i\}_{i=1}^N$ is locally quasiuniform, i.e., neighboring subdomains have comparable diameters and each subdomain is polyhedral.

We consider a model compressible elasticity problem (2.1) with coefficients $G(\mathbf{x})$ and $\beta(\mathbf{x})$ positive constants in each subdomain

$$G(\mathbf{x})|_{\Omega_i} = G_i, \quad \beta(\mathbf{x})|_{\Omega_i} = \beta_i.$$

A conforming P_1–finite element space $\mathbf{X}_i$ is associated with each triangulation T_i. In addition, functions in the space $\mathbf{X}_i$ satisfy the Dirichlet boundary condition on $\partial\Omega_i \cap \partial\Omega_D$. We define the union of the subdomain boundaries by

$$\Gamma = \left(\bigcup_{i=1}^N \partial\Omega_i \right) \setminus \partial\Omega.$$

The triangulations $\{T_i\}_{i=1}^N$ may not match across the subdomain boundaries. We further introduce the finite element space $\mathbf{W}_i$ that is the trace space of $\mathbf{X}_i$ on $\partial\Omega_i \cap \Gamma$.

We note that the nodal unknowns corresponding to nodes at $\partial\Omega_N$ are considered as unknowns at the interior of the subdomains.

We denote the interface of two subdomains Ω_i and Ω_j by F_{ij}, which can be only part of a face of Ω_i or Ω_j. Among the subdomain faces, we select nonmortar faces F_l such that

$$\bigcup_l \overline{F}_l = \bigcup_{i,j} \overline{F}_{ij}, \quad F_l \cap F_k = \emptyset,\ l \neq k.$$

Here each F_l is a full face of a subdomain that we call the nonmortar subdomain of F_l. We call the subdomains on the other part across F_l the mortar subdomains.

Since the subdomain partition can be geometrically nonconforming, a single nonmortar face $F_l \subset \partial\Omega_i$ may intersect several subdomain boundaries $\partial\Omega_j$. This provides F_l with a partition,

$$\overline{F}_l = \bigcup_j \overline{F}_{ij}, \quad F_{ij} = \partial\Omega_i \cap \partial\Omega_j.$$

DEFINITION 3.2. *An interface $F_{ij} = \partial\Omega_i \cap \partial\Omega_j$ is substantial if it is shape regular and its diameter is comparable to H_i and H_j.*

Assumption 3.3. Let TOL_G be a given constant. On each interface $F_{ij} = \partial\Omega_i \cap \partial\Omega_j$, the nonmortar side Ω_i and the mortar side Ω_j are selected so that

$$\frac{G_i}{G_j} \leq TOL_G.$$

Remark 3.4. It is clearly possible to construct a set of subdomains such that Assumption 3.3 is not satisfied in geometrically nonconforming cases. We note that this problem arises from the specification of the mortar method itself.

We now introduce the finite element space

$$\overset{\circ}{\mathbf{W}}(F_l) = \left\{ \mathbf{w} \in [H_0^1(F_l)]^3 \ :\ \mathbf{w} = \mathbf{v}|_{F_l} \text{ for } \mathbf{v} \in \mathbf{X}_i \right\}, \tag{3.1}$$

where i denotes the index of the nonmortar subdomain of the face F_l and $\mathbf{v}|_{F_l}$ denotes the trace of $\mathbf{v}$ on the face F_l. This space is spanned by the nodal basis $\{\boldsymbol{\phi}_k\}_{k=1}^n$ of the nodes in F_l given by the triangulation T_i. Based on the space $\overset{\circ}{\mathbf{W}}(F_l)$, we construct a dual Lagrange multiplier space $\mathbf{M}(F_l)$ with a basis $\{\boldsymbol{\psi}_k\}_{k=1}^n$ satisfying

$$\int_{F_l} \boldsymbol{\phi}_m \cdot \boldsymbol{\psi}_k \, ds = \delta_{mk} \int_{F_l} \boldsymbol{\phi}_m \, ds \quad \forall\, m, k = 1, \ldots, n.$$

We refer to [13, 29] for a detailed construction of such a dual Lagrange multiplier space. The result of our paper is also applicable to the standard Lagrange multiplier space that was introduced in [2] for three dimensions. However, the dual Lagrange multiplier space leads to a computationally more efficient algorithm and also makes the implementation easier than it was with the older version. We note that both spaces contain the constant functions. The mortar matching condition is then written as

$$\int_{F_l} (\mathbf{v}_i - \boldsymbol{\phi}) \cdot \boldsymbol{\lambda} \, ds = 0 \quad \forall \boldsymbol{\lambda} \in \mathbf{M}(F_l),\ \forall F_l, \tag{3.2}$$

where $\mathbf{v}_i$ is a function from the nonmortar side and $\boldsymbol{\phi}$ is a function from the corresponding mortar parts. More precisely, $\boldsymbol{\phi} = \mathbf{v}_j$ on each $F_{ij} \subset F_l$.

We next introduce several finite element spaces,

$$\mathbf{X} = \prod_{i=1}^{N} \mathbf{X}_i, \tag{3.3}$$

$$\mathbf{W} = \prod_{i=1}^{N} \mathbf{W}_i,$$

$$\mathbf{W}_n = \prod_{F_l,\text{nonmortar}} \mathring{\mathbf{W}}(F_l),$$

$$\mathbf{M} = \prod_{F_l,\text{nonmortar}} \mathbf{M}(F_l).$$

Here the spaces $\mathbf{W}_n$ and $\mathbf{M}$ consist of functions defined on the nonmortar faces, while the spaces $\mathbf{W}$ and $\mathbf{X}$ consist of functions defined on both mortar and nonmortar faces, with elements that can be discontinuous across the interfaces. The space $\mathbf{W}$ can be considered as the trace space of the space $\mathbf{X}$ on the subdomain boundaries. In addition, we define the mortar finite element space,

$$\widehat{\mathbf{X}} = \{\mathbf{v} \in \mathbf{X} \,:\, \mathbf{v} \text{ satisfies (3.2)}\}.$$

The mortar discretization looks for an approximate solution of (2.1) in the space $\widehat{\mathbf{X}}$. In what follows, we derive a FETI-DP algorithm for the mortar discretization of (2.1).

3.2. Primal constraints in the FETI-DP formulation. We will build a FETI-DP algorithm that solves the model problem (2.1) in the space X defined in (3.3) by enforcing the mortar matching condition (3.2) across subdomain interfaces in dual and primal ways. We select some constraints from the mortar matching condition and enforce them strongly for the functions in the space X. We call them the primal constraints. The other constraints will be imposed weakly using Lagrange multipliers.

A proper selection of primal constraints is important for obtaining a scalable FETI-DP algorithm. In the work by Klawonn and Widlund [22] on elasticity problems, edge average and edge moment constraints and vertex constraints are selected. Furthermore, the concepts of an acceptable face path and an acceptable vertex path are introduced in an attempt to reduce the number of primal constraints.

We now select primal constraints from the mortar matching condition. We consider a nonmortar face $F \subset \partial\Omega_i$ and its partition $\{F_{ij}\}_j$ by mortar neighbors, i.e., $F_{ij} = \partial\Omega_i \cap \partial\Omega_j$. We define the space $\mathbf{M}(F_{ij})$ as a subspace of $\mathbf{M}(F)$ of functions that are supported in $\overline{F}_{ij}$. Six primal constraints are now introduced for each F_{ij} in the following way.

On each face F_{ij}, we first consider the six rigid body motions $\{\mathbf{r}_l\}_{l=1}^{6}$ as in (2.2) and (2.3), with H the diameter of the face F_{ij} and $\widehat{\mathbf{x}}$ a point on F_{ij}. We define a nodal interpolant $I_{M(F_{ij})} : [C(\overline{F}_{ij})]^3 \to \mathbf{M}(F_{ij})$ by

$$I_{M(F_{ij})}(\mathbf{v})(x) = \mathbf{v}(x), \quad x \in \mathbf{M}_{ij}^h,$$

where $\mathbf{M}_{ij}^h$ is the set of nodes corresponding to the Lagrange multiplier space $\mathbf{M}(F_{ij})$ and $C(\overline{F}_{ij})$ denotes the set of continuous functions on F_{ij}; see Figure 1 for a two dimensional case. We now select six primal constraints using the interpolated rigid

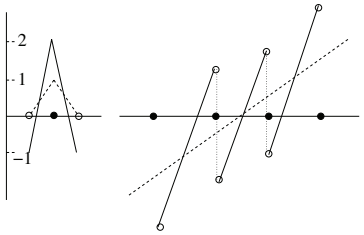

FIG. 1. *A dual Lagrange basis element (left, the solid line), a nodal basis element (left, the dashed line), and the nodal interpolant $I_{M(F_{ij})}(v)$ (right, the solid lines) to the linear function v (the dashed line).*

body motions,

$$\int_{F_{ij}} (\mathbf{v}_i - \mathbf{v}_j) \cdot I_{M(F_{ij})}(\mathbf{r}_l)\, ds = 0 \quad \forall l = 1, \ldots, 6.$$

Remark 3.5. When F_{ij} is the whole nonmortar face F, $\mathbf{M}(F_{ij})$ contains constant functions. The constraints with $\{I_{M(F_{ij})}(\mathbf{r}_l)\}_{l=1}^{3}$ are then nothing but the average matching condition across F_{ij} because $I_{M(F_{ij})}(\mathbf{r}_l) = \mathbf{r}_l$, for $l = 1, 2, 3$. The remaining constraints with $\{I_{M(F_{ij})}(\mathbf{r}_l)\}_{l=4}^{6}$, are similar to the moment matching constraints which were introduced for fully primal edges in [22] except that our constraints use the interpolated rotational rigid body motions and are enforced across faces. We call the constraints based on $\{I_{M(F_{ij})}(\mathbf{r}_l)\}_{l=4}^{6}$ the moment constraints.

Even though we have introduced a set of primal constraints to make the FETI-DP method more efficient, the enlarged coarse problem can be a bottleneck for the computation. To reduce the size of the coarse problem, we will select some interfaces as primal and impose the six constraints over them only. For the remaining constraint, the nonprimal faces, we assume that they each satisfy an acceptable face path condition. This assumption leads to a FETI-DP method, with primal constraints only for the primal interfaces, that has a condition number bound comparable to one obtained when the six primal constraints are imposed on all interfaces.

We now define an acceptable face path. Here, H_{ij} denotes the diameter of an interface F_{ij}.

DEFINITION 3.6 (acceptable face path). *Let L and TOL_P be given constants. For a pair of subdomains (Ω_i, Ω_j) having a common interface F_{ij}, an acceptable face path is a path*

$$\{\Omega_i, \Omega_{k_1}, \ldots, \Omega_{k_n}, \Omega_j\}$$

from Ω_i to Ω_j such that the coefficient G_{k_l} of Ω_{k_l} satisfies the condition

$$TOL_P * (1 + log(H_{ij}/h_i))^{-1} (1 + log(H_i/h_i))^2 * G_{k_l} \geq \min(G_i, G_j).$$

Moreover, the path from one subdomain to another must always be through a primal face, and the number of subdomains appearing in the path is bounded by the constant L.

3.3. The FETI-DP formulation with a change of basis. Let A_i be the stiffness matrix obtained from the finite element discretization of the bilinear form in the space $\mathbf{X}_i$,

$$a_i(\mathbf{u}_i, \mathbf{v}_i) := G_i \int_{\Omega_i} \varepsilon(\mathbf{u}_i) : \varepsilon(\mathbf{v}_i)\, dx + G_i \beta_i \int_{\Omega_i} \nabla \cdot \mathbf{u}_i \nabla \cdot \mathbf{v}_i\, dx \quad \forall \mathbf{u}_i, \mathbf{v}_i \in \mathbf{X}_i.$$

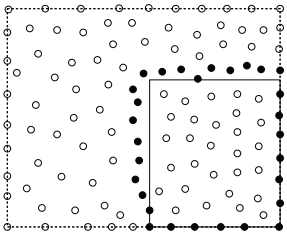

FIG. 2. *A primal interface F (solid line rectangle) of a face (dashed line rectangle) of subdomain Ω_i. The supports of the basis elements corresponding to the black nodes and the white nodes inside F intersect F; the values at the black nodes are unaffected by the transform T_F.*

Let S_i be the Schur complement of the matrix A_i that is obtained by eliminating the interior unknowns. We then write the mortar matching condition for $\mathbf{w} = (\mathbf{w}_1, \ldots, \mathbf{w}_N) \in W$ as

$$\sum_{i=1}^{N} B_i \mathbf{w}_i = 0.$$

We will express the matrices S_i and B_i in a new set of unknowns after a change of basis (unknowns). This idea was first presented in [21, 24] and algorithmic details were later described by Klawonn and Widlund [22]. The change of unknowns leads to a much simpler presentation of the algorithm as well as a more robust implementation; see [19, 18].

Let $\mathbf{w}_i$ denote the unknowns (or a function) in the space $\mathbf{W}_i$. We consider a primal interface $F \subset \partial\Omega_i$. Since the partition can be geometrically nonconforming, F might be only part of a face of Ω_i. Let $\mathbf{w}_F$ denote the restriction of a function $\mathbf{w}$ to a primal face $F \subset \Omega_i$. In other words, $\mathbf{w}_F$ is the vector of unknowns corresponding to the nodal basis elements with supports that intersect F; see Figure 2. For each primal face $F \subset \partial\Omega_i$, we define a transformation T_F by

$$\mathbf{w}_F = T_F \begin{pmatrix} \mathbf{w}_{F,\Pi} \\ \mathbf{w}_{F,\Delta} \end{pmatrix}, \tag{3.4}$$

where the six components of $\mathbf{w}_{F,\Pi}$ are given by

$$(\mathbf{w}_{F,\Pi})_l = \frac{\int_F \mathbf{w}_F \cdot I_{M(F)}(\mathbf{r}_l)\, ds}{H_F^2},\ l = 1, \ldots, 6, \tag{3.5}$$

and $\mathbf{v} = T_F\left(\begin{smallmatrix} 0 \\ \mathbf{w}_{F,\Delta} \end{smallmatrix}\right)$ has the six components of zero, i.e.,

$$\int_F \mathbf{v} \cdot I_{M(F)}(\mathbf{r}_l)\, ds = 0,\ l = 1, \ldots, 6. \tag{3.6}$$

Here H_F denotes the diameter of F. In addition, the transformation T_F retains the unknowns at the nodes other than those inside F. Since only the unknowns at the nodes inside F have been changed, each transform corresponding to an individual primal interface F can be applied independently.

We build such a transform T_F as follows. We first obtain six vectors $\{\boldsymbol{p}_l\}_{l=1}^6$ such that

$$\boldsymbol{p}_l^t \boldsymbol{w} = \frac{1}{H_F^2} \int_F \boldsymbol{w} \cdot I_{M(F)}(\mathbf{r}_l)\, ds,\ l = 1, \ldots, 6.$$

We then select six primal unknowns $\{w_{\Pi_l}\}_{l=1}^6$ among the unknowns of $\boldsymbol{w}$ at the interior of F so that $\boldsymbol{p}_l^t \boldsymbol{e}_{\Pi_l} \neq 0$, $l = 1, \ldots, 6$. Here $\boldsymbol{e}_{\Pi_l}$ is the coordinate unit vector with its value one at the location of the primal unknown v_{Π_l} and zero at the other unknowns. We then find six vectors $\{\boldsymbol{t}_{\Pi_l}\}_{l=1}^6$ in the space spanned by the vectors $\{\boldsymbol{e}_{\Pi_l}\}_{l=1}^6$ that are orthonormal to $\{\boldsymbol{p}_l\}_{l=1}^6$, i.e., $\boldsymbol{p}_l^t \boldsymbol{t}_{\Pi_k} = \delta_{lk}$, $l, k = 1, \ldots, 6$.

For the other unknowns $\{w_k\}_k$ of $\boldsymbol{w}$ at the interior of F, we build vectors $\mathbf{s}_k$ such that $(\boldsymbol{s}_k)_k = 1$, $(\boldsymbol{s}_k)_{\Pi_l} = a_{k,\Pi_l}$, $l = 1, \ldots, 6$, and the other components of $\boldsymbol{s}_k$ are zero. In other words, the components of $\boldsymbol{s}_k$ are zero except at the kth row and at the six rows corresponding to the primal unknowns. The values $\{a_{k,\Pi_l}\}_{l=1}^6$ are determined to satisfy $\boldsymbol{p}_l^t \boldsymbol{s}_k = 0$, $l = 1, \ldots, 6$. To build T_F, we first let T_F be the identity matrix and then replace each column of T_F by $\{\boldsymbol{t}_{\Pi_l}\}_{l=1}^6$ and $\{\boldsymbol{s}_k\}_k$ at the corresponding locations. We can see that this transform satisfies all of the requirements in (3.4)–(3.6) with $\{w_{\Pi_l}\}_{l=1}^6$ and $\{w_k\}_k$ as the six primal unknowns and the remaining dual unknowns, respectively. The resulting transform T_F is different from the identity matrix at the six rows and at the six columns corresponding to the primal unknowns.

The face-based primal constraints give change of basis involving unknowns at subdomain faces. Compared to the edge-based primal constraints in [22], our approach gives less sparse matrices after the change of basis. However, it does not significantly destroy the sparsity, since the transform T_F that we just introduced is different from the identity matrix at the six columns and the six rows corresponding to the primal unknowns.

After the change of unknowns, we order the unknowns $\mathbf{w}_i$ and the matrices S_i and B_i as

$$\mathbf{w}_i = \begin{pmatrix} \mathbf{w}_\Delta^{(i)} \\ \mathbf{w}_\Pi^{(i)} \end{pmatrix}, \quad S_i = \begin{pmatrix} S_{\Delta\Delta}^{(i)} & S_{\Delta\Pi}^{(i)} \\ S_{\Pi\Delta}^{(i)} & S_{\Pi\Pi}^{(i)} \end{pmatrix}, \quad B_i = \begin{pmatrix} B_\Delta^{(i)} & B_\Pi^{(i)} \end{pmatrix}, \tag{3.7}$$

where Π denotes the primal unknowns and Δ denotes the others, which we call the dual displacement unknowns. Any interface of a pair of subdomains is either a primal face or has an acceptable face path, so that each subdomain is connected to at least one neighbor through a primal face. This fact ensures that the matrix $S_{\Delta\Delta}^{(i)}$ is invertible, since the six primal constraints are linearly independent; a proof will be provided in Lemma 4.2.

According to the separation of the unknowns, the space $\mathbf{W}_i$ is decomposed into

$$\mathbf{W}_i = \mathbf{W}_\Delta^{(i)} \times \mathbf{W}_\Pi^{(i)},$$

where $\mathbf{W}_\Delta^{(i)}$ contains the dual unknowns and $\mathbf{W}_\Pi^{(i)}$ the primal unknowns. We further decompose the space $\mathbf{W}_\Delta^{(i)}$ of dual unknowns into

$$\mathbf{w}_\Delta^{(i)} = (\mathbf{w}_{\Delta,n}^{(i)}, \mathbf{w}_{\Delta,m}^{(i)}) \in \mathbf{W}_{\Delta,n}^{(i)} \times \mathbf{W}_{\Delta,m}^{(i)},$$

where n denotes the unknowns of the nonmortar faces and m denotes the remaining unknowns.

After enforcing the primal constraints on each primal face, we define the following space:

$$\widetilde{\mathbf{W}} = \{\mathbf{w} \in \mathbf{W} \,:\, \mathbf{w} \text{ satisfies the primal constraints across the primal faces}\}.$$

It can be decomposed into

$$\widetilde{\mathbf{W}} = \mathbf{W}_\Delta \times \mathbf{W}_\Pi,$$

where $\mathbf{W}_\Delta = \prod_{i=1}^N \mathbf{W}_\Delta^{(i)}$ and $\mathbf{W}_\Pi$ is the space of global primal unknowns. The space $\mathbf{W}_\Delta$ is further decomposed into

$$\mathbf{W}_\Delta = \mathbf{W}_{\Delta,n} \times \mathbf{W}_{\Delta,m},$$

where n and m refer to the nonmortar and the other part.

Throughout this paper, we use the same notation for a function and the corresponding vector of unknowns representing the function. Thus, $\mathbf{w}_\Delta^{(i)}$ denotes a vector of dual unknowns of $\mathbf{w}_i$ or the corresponding finite element function. The same convention applies to the spaces $\mathbf{W}_{\Delta,n}$, $\mathbf{W}$, $\mathbf{M}$, etc.

We now consider the mortar matching matrices B_i. When the mortar matching constraints are imposed on $\mathbf{w}$ in $\widetilde{\mathbf{W}}$, they are redundant, since the six primal constraints on each primal interface already have been enforced on $\mathbf{w}$. We therefore eliminate six equations from the rows of B_i for each primal interface $F \subset \partial\Omega_i$ and obtain the mortar matching constraints for the space $\widetilde{\mathbf{W}}$ that are nonredundant. We will use the same notation B_i after we have made them nonredundant.

By introducing Lagrange multipliers $\boldsymbol{\lambda}$ for the mortar matching constraints, we obtain the following mixed formulation of the problem (2.1):

$$\begin{pmatrix} S_{\Delta\Delta} & S_{\Delta\Pi} & B_\Delta^t \\ S_{\Pi\Delta} & S_{\Pi\Pi} & B_\Pi^t \\ B_\Delta & B_\Pi & 0 \end{pmatrix} \begin{pmatrix} \mathbf{w}_\Delta \\ \mathbf{w}_\Pi \\ \boldsymbol{\lambda} \end{pmatrix} = \begin{pmatrix} \mathbf{g}_\Delta \\ \mathbf{g}_\Pi \\ 0 \end{pmatrix}, \tag{3.8}$$

where each of the block matrices are obtained from subassembly of blocks of S_i and B_i in (3.7) at the global primal unknowns and at the dual unknowns.

The FETI-DP algorithm solves this mixed problem iteratively after eliminating all unknowns other than $\boldsymbol{\lambda}$. The elimination of the unknowns $\mathbf{w}_\Delta$ and $\mathbf{w}_\Pi$ leads to

$$F_{DP}\boldsymbol{\lambda} = \boldsymbol{d}. \tag{3.9}$$

We note that the matrix F_{DP} is symmetric and positive definite and satisfies the well-known relation (see [25, Lemma 4.3])

$$\langle F_{DP}\boldsymbol{\lambda}, \boldsymbol{\lambda}\rangle = \max_{\mathbf{w}\in\widetilde{\mathbf{W}}} \frac{\langle B\mathbf{w}, \boldsymbol{\lambda}\rangle^2}{\langle S\mathbf{w}, \mathbf{w}\rangle}, \tag{3.10}$$

where

$$S = \begin{pmatrix} S_{\Delta\Delta} & S_{\Delta\Pi} \\ S_{\Pi\Delta} & S_{\Pi\Pi} \end{pmatrix}, \quad B = \begin{pmatrix} B_\Delta & B_\Pi \end{pmatrix}.$$

The FETI-DP algorithm solves (3.9) for $\boldsymbol{\lambda}$ using a preconditioned conjugate gradient method with an appropriate preconditioner.

We now introduce a preconditioner $\widehat{M}^{-1}$ given by

$$\langle \widehat{M}\boldsymbol{\lambda}, \boldsymbol{\lambda}\rangle = \max_{\mathbf{w}_{\Delta,n}\in\mathbf{W}_{\Delta,n}} \frac{\langle BE(\mathbf{w}_{\Delta,n}), \boldsymbol{\lambda}\rangle^2}{\langle SE(\mathbf{w}_{\Delta,n}), E(\mathbf{w}_{\Delta,n})\rangle}, \tag{3.11}$$

where $E(\mathbf{w}_{\Delta,n})$ is the zero extension of $\mathbf{w}_{\Delta,n}$ into the space $\widetilde{\mathbf{W}}$. To be more precise,

$$E(\mathbf{w}_{\Delta,n}) = (\mathbf{w}_{\Delta,n}, 0, 0) \in \mathbf{W}_{\Delta,n} \times \mathbf{W}_{\Delta,m} \times \mathbf{W}_\Pi = \widetilde{\mathbf{W}}.$$

We then obtain

(3.12)
$$\langle \widehat{M}\boldsymbol{\lambda},\boldsymbol{\lambda}\rangle = \max_{\mathbf{w}_{\Delta,n}\in\mathbf{W}_{\Delta,n}} \frac{\langle BE(\mathbf{w}_{\Delta,n}),\boldsymbol{\lambda}\rangle^2}{\langle SE(\mathbf{w}_{\Delta,n}),E(\mathbf{w}_{\Delta,n})\rangle} \le \max_{\mathbf{w}\in\widetilde{\mathbf{W}}} \frac{\langle B\mathbf{w},\boldsymbol{\lambda}\rangle^2}{\langle S\mathbf{w},\mathbf{w}\rangle} = \langle F_{DP}\boldsymbol{\lambda},\boldsymbol{\lambda}\rangle.$$

Therefore the lower bound of the FETI-DP algorithm is bounded from below by 1.

The explicit form of the preconditioner

$$\widehat{M}^{-1} = \sum_{i=1}^{N} B_i D_i S_i D_i B_i^t \tag{3.13}$$

is similar to other FETI-DP preconditioners except that the weight matrix D_i is given differently. The weight matrix D_i to the preconditioner $\widehat{M}^{-1}$ in (3.11) is expressed by

$$D_i = \begin{pmatrix} ((B_{\Delta,n}^{(i)})^t B_{\Delta,n}^{(i)})^{-1} & 0 & 0 \\ 0 & 0 & 0 \\ 0 & 0 & 0 \end{pmatrix},$$

where $B_{\Delta,n}^{(i)}$ is the matrix with the columns of $B_{\Delta}^{(i)}$ corresponding to the unknowns in the space $\mathbf{W}_{\Delta,n}^{(i)}$; see (3.7). We note that $B_{\Delta,n}^{(i)}$ is square and invertible and that the weight matrix D_i is applied to the unknowns in the space $\mathbf{W}_i = \mathbf{W}_{\Delta,n}^{(i)} \times \mathbf{W}_{\Delta,m}^{(i)} \times \mathbf{W}_{\Pi}^{(i)}$. We can further express the preconditioner in a much simpler form,

$$\widehat{M}^{-1} = \sum_{i=1}^{N} \begin{pmatrix} \left(B_{\Delta,n}^{(i)\ t}\right)^{-1} & 0 & 0 \end{pmatrix} S_i \begin{pmatrix} B_{\Delta,n}^{(i)\ -1} \\ 0 \\ 0 \end{pmatrix}. \tag{3.14}$$

This form shows that multiplying $\widehat{M}^{-1}$ by a vector involves solving local elasticity problems with natural boundary condition on the nonmortar faces and the zero Dirichlet boundary condition on the other part. We call $\widehat{M}^{-1}$ the Neumann–Dirichlet preconditioner.

4. Condition number analysis. In this section, we will analyze the condition number bound of the proposed FETI-DP algorithm. First, we will construct functionals $\{f_l\}_{l=1}^6$, dual to the space $\mathbf{ker}(\varepsilon)$, that satisfy

$$f_m(\mathbf{r}_k) = \delta_{mk}, \quad m,k = 1,\dots,6,$$

$$|f_m(\mathbf{w})|^2 \le C\frac{\|\mathbf{w}\|_{0,F}^2}{H^2} \quad \text{for } \mathbf{w}\in[L^2(F)]^3. \tag{4.1}$$

Here $\{\mathbf{r}_k\}_{k=1}^6$ is a basis of $\mathbf{ker}\ (\varepsilon)$ with six rigid body motions scaled with respect to a face $F\subset\partial\Omega_i$; this means that we take $\widehat{\mathbf{x}}\in F$ and $H=\operatorname{diam}(F)$ in (2.2) and (2.3). Such a dual basis was introduced by Klawonn and Widlund [22].

We will now introduce six functionals which are closely related to the primal constraints applied across a primal face F,

$$g_l(\mathbf{w}) = \frac{\int_F \mathbf{w}\cdot I_{M(F)}(\mathbf{r}_l)\,ds}{H^2} \quad \text{for } \mathbf{w}\in[L^2(F)]^3,\ l=1,\dots,6. \tag{4.2}$$

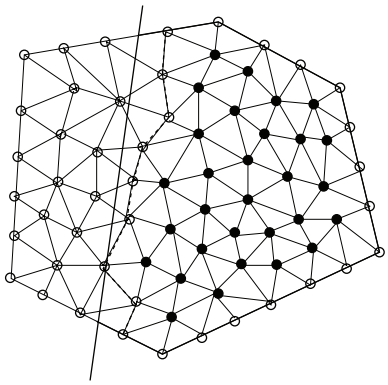

FIG. 3. *The face F, to the right of the solid line, is part of a nonmortar face, the whole face. The Lagrange multiplier basis to the black nodes are supported in F; $M(F)$ is the space spanned by these basis elements. The union of their supports is F_I, a subset of F that is to the right of the dashed lines.*

Here, $I_{M(F)}(\mathbf{r}_l)$ is the nodal interpolant to the Lagrange multiplier space $\mathbf{M}(F)$ provided for the face F and H is the diameter of F. For any real valued function g, we use the same notation $I_{M(F)}(g)$ for the nodal interpolant to the Lagrange multiplier space $M(F)$. We note that the vector valued Lagrange multiplier space is given by

$$\mathbf{M}(F) = [M(F)]^3.$$

LEMMA 4.1. *For any bounded function f and any linear function g, we have*

$$\left| \int_F f \left(g - I_{M(F)}(g) \right) \, ds \right| \leq ChH \|f\|_\infty \|g\|_\infty,$$

where H is the diameter of the face F and h is the mesh size of $M(F)$.

Proof. We consider the case when F is a part of a nonmortar face as in Figure 3. The subset F_I of F is the union of the supports of the basis elements in $M(F)$. Since g is linear, we obtain, at each nodal point $x \in F_I$,

$$|g(x) - I_{M(F)}(g)(x)| \leq Ch|g'| \leq C\frac{h}{H}\|g\|_\infty. \tag{4.3}$$

The above bound also holds for any $x \in F_I$, because both g and $I_{M(F)}(g)$ are linear in each triangle in F_I. We note that $I_{M(F)}(g)$ vanishes outside F_I.

We now have

$$\int_F f \left(g - I_{M(F)}(g) \right) \, ds = \int_{F_I} f \left(g - I_{M(F)}(g) \right) \, ds + \int_{F \setminus F_I} fg \, ds.$$

From the above bound and (4.3), using $|F_I| \leq CH^2$ and $|F \setminus F_I| \leq ChH$, the required bound then follows. ∎

LEMMA 4.2. *The functionals $\{g_l\}_{l=1}^6$ are linearly independent in the space $(ker(\varepsilon))'$, when h is sufficiently small.*

Proof. It suffices to show that the matrix G with the following entries is invertible:

$$G_{jk} = \int_F \mathbf{r}_j \cdot I_{M(F)}(\mathbf{r}_k) \, ds, \quad j,k = 1, \ldots, 6.$$

We first select $\widehat{x}_i$ in $\{\mathbf{r}_k\}_{k=4}^6$ so that

$$\int_F \frac{1}{H}(x_i - \widehat{x}_i)\, ds = 0, \quad i = 1, 2, 3.$$

The rigid body motions $\{\mathbf{r}_k\}_{k=4}^6$ are then orthogonal to $\{\mathbf{r}_k\}_{k=1}^3$ with respect to the inner product,

$$(\mathbf{r}, \boldsymbol{q})_F = \int_F \mathbf{r} \cdot \boldsymbol{q}\, ds.$$

We define $\widetilde{\mathbf{r}}_5$ and $\widetilde{\mathbf{r}}_6$ by

$$\widetilde{\mathbf{r}}_5 = \mathbf{r}_5 - a_4\mathbf{r}_4, \quad \widetilde{\mathbf{r}}_6 = \mathbf{r}_6 - b_4\mathbf{r}_4 - b_5\widetilde{\mathbf{r}}_5,$$

where

$$a_4 = \frac{(\mathbf{r}_4, \mathbf{r}_5)_F}{(\mathbf{r}_4, \mathbf{r}_4)_F},\ b_4 = \frac{(\mathbf{r}_4, \mathbf{r}_6)_F}{(\mathbf{r}_4, \mathbf{r}_4)_F},\ b_5 = \frac{(\widetilde{\mathbf{r}}_5, \mathbf{r}_6)_F}{(\widetilde{\mathbf{r}}_5, \widetilde{\mathbf{r}}_5)_F}.$$

The constants a_4, b_4, and b_5 are invariant to scaling. In other words, they are independent of H and h. We denote by $\{\widetilde{\mathbf{r}}_i\}_{i=1}^6$ the rigid body motions $\{\mathbf{r}_i\}_{i=1}^6$ with $\mathbf{r}_5$ and $\mathbf{r}_6$ replaced by $\widetilde{\mathbf{r}}_5$ and $\widetilde{\mathbf{r}}_6$. The rigid body motions $\{\widetilde{\mathbf{r}}_i\}_{i=1}^6$ are then orthogonal and the values of $(\widetilde{\mathbf{r}}_i, \widetilde{\mathbf{r}}_i)_F$ are scaling invariant. In other words, they are constants independent of H and h.

Using Lemma 4.1, we obtain

$$\left| \int_F \widetilde{\mathbf{r}}_j \cdot \widetilde{\mathbf{r}}_k\, ds - \int_F \widetilde{\mathbf{r}}_j \cdot I_{M(F)}(\widetilde{\mathbf{r}}_k)\, ds \right| \le ChH, \tag{4.4}$$

where C is a constant independent of H and h. We now consider a matrix $\widetilde{G}$ with entries

$$\widetilde{G}_{jk} = \int_F \widetilde{\mathbf{r}}_j \cdot I_{M(F)}(\widetilde{\mathbf{r}}_k), \quad j, k = 1, \ldots, 6.$$

Since the $\widetilde{\mathbf{r}}_i$ is orthogonal, we see, using the bound in (4.4), that $\widetilde{G}$ is diagonally dominant when h is sufficiently small. Therefore, $\widetilde{G}$ is invertible when h is small enough. The matrix G can be obtained from the invertible matrix $\widetilde{G}$ by using certain column and row operations and is therefore invertible. □

Remark 4.3. The proof of Lemma 4.2 also holds for an interface F that is not a flat surface.

Since the six functionals $\{g_l\}_{l=1}^6$ are linearly independent, they provide a basis of the dual space $(\mathbf{ker}(\varepsilon))'$. Thus there exists $\{\beta_{ml}\}_{m,l=1}^6$ such that

$$f_m = \sum_{l=1}^6 \beta_{ml} g_l, \quad m = 1, \ldots, 6. \tag{4.5}$$

Using Lemma 4.1, for any linear functions f and g we have

$$\left| \int_F fg\, ds - \int_F I_{M(F)}(f) I_{M(F)}(g)\, ds \right| \le C\|f\|_\infty \|g\|_\infty hH.$$

When h is small enough, we then find

$$(I_{M(F)}(\mathbf{r}_k), I_{M(F)}(\mathbf{r}_k))_F \leq C(\mathbf{r}_k, \mathbf{r}_k)_F \leq CH^2. \tag{4.6}$$

From (4.2), (4.6), and the Cauchy–Schwarz inequality, we obtain

$$|g_l(\mathbf{w})|^2 \leq C\frac{\|\mathbf{w}\|^2_{0,F}}{H^2}.$$

The inequality (4.1) follows from (4.5) and the above bound. We denote the dual functionals described above by $\{f_l^F\}_{l=1}^6$ for the given face F. We can then express any rigid body motion $\mathbf{r} \in \mathbf{ker}(\varepsilon)$ as a linear combination using the dual basis

$$\mathbf{r} = \sum_{l=1}^{6} f_l^F(\mathbf{r})\mathbf{r}_l.$$

In the following, we will provide several lemmas which will be used to provide an upper bound of the FETI-DP algorithm equipped with the preconditioner $\widehat{M}^{-1}$ given in (3.11); see also (3.14). We note that a lower bound with the constant 1 is provided in (3.12).

For a face $F \subset \partial\Omega_i$, the space $H_{00}^{1/2}(F)$ consists of the functions whose zero extension to the whole boundary $\partial\Omega_i$ belongs to the space $H^{1/2}(\partial\Omega_i)$; it is equipped with the norm

$$\|w\|_{H_{00}^{1/2}(F)} := \left(|w|^2_{1/2,F} + \int_F \frac{w(x)^2}{\operatorname{dist}(x,\partial F)}\, ds(x)\right)^{1/2},$$

where

$$|w|^2_{1/2,F} = \int_F\int_F \frac{|w(x)-w(y)|^2}{|x-y|^3}\, ds(x)ds(y).$$

In addition, a norm for the space $H^{1/2}(F)$ is defined by

$$\|w\|_{1/2,F} = \left(|w|^2_{1/2,F} + \frac{1}{H_F}\|w\|^2_{0,F}\right)^{1/2},$$

where H_F is the diameter of F.

These norms can be extended to the product spaces $[H_{00}^{1/2}(F)]^3$ and $[H^{1/2}(F)]^3$ by using the usual product norms. Similarly, we can extend the edge and face lemmas given below to product spaces. These lemmas can be found in Toselli and Widlund [27, Lemmas 4.24 and 4.25]. In the following, $W(F)$ denotes any conforming P_1-finite element space provided for a face F with its mesh size comparable to that of its nonmortar subdomain. Since the face F can be only part of a full face of its nonmortar subdomain Ω_i, the triangulation equipped for the face F can be different from that of Ω_i. We use $\mathbf{W}(F)$ to denote the corresponding vector valued finite element space, i.e., $\mathbf{W}(F) = [W(F)]^3$.

LEMMA 4.4 (edge lemma). *Let E be an edge of a face $F_{ij} \subset \partial\Omega_i$ and F_{ij} has Ω_i as its nonmortar subdomain. Then, for any $\mathbf{w} \in \mathbf{W}(F_{ij})$, we have*

$$\|\mathbf{w}\|^2_{0,E} \leq C\left(1+\log\frac{H_{ij}}{h_i}\right)\|\mathbf{w}\|^2_{1/2,F_{ij}}.$$

Let $C(\overline{F})$ be the space of continuous functions defined on F. For any subset $A \subset \overline{F}$, we define an interpolant $I_A : C(\overline{F}) \to W(F)$ by

$$I_A(w)(x) = \begin{cases} w(x) & \text{for } x \in A \cap N^h, \\ 0 & \text{for the other nodes,} \end{cases} \tag{4.7}$$

where N^h is the set of nodes of the finite element space $W(F)$. We note that $I_F(w)$, when $A = F$, vanishes at the boundary of F. We can extend the interpolant to a vector valued function $\mathbf{w} \in [C(\overline{F})]^3$ and we also denote it by $I_A(\mathbf{w})$.

LEMMA 4.5 (face lemma). *Let F_{ij} be a face of $\partial\Omega_i$ with Ω_i as its nonmortar subdomain. Then, for any $\mathbf{w} \in \mathbf{W}(F_{ij})$, we have*

$$\|I_{F_{ij}}(\mathbf{w})\|^2_{\mathbf{H}_{00}^{1/2}(F_{ij})} \le C\left(1 + \log\frac{H_{ij}}{h_i}\right)^2 \|\mathbf{w}\|^2_{1/2,F_{ij}}.$$

We now derive several inequalities for the mortar projection of functions. We recall that the spaces $\overset{\circ}{\mathbf{W}}(F_l)$ and $\mathbf{M}(F_l)$ are given on the nonmortar face F_l; see section 3.1.

DEFINITION 4.6 (mortar projection). *The mortar projection $\pi_l : [L^2(F_l)]^3 \to \overset{\circ}{\mathbf{W}}(F_l)$ is defined by*

$$\int_{F_l} (\pi_l(\mathbf{w}) - \mathbf{w}) \cdot \boldsymbol{\psi}\, ds = 0 \quad \forall \boldsymbol{\psi} \in \mathbf{M}(F_l).$$

It is known that the mortar projection is bounded in both the L^2- and the $H_{00}^{1/2}$-norms; see [1, 29].

For any function w defined on $F_{ij} \subset F_l$, we define $\chi_{F_{ij}} w$ by

$$\chi_{F_{ij}} w(x) = \begin{cases} w(x), & x \in F_{ij}, \\ 0, & x \in F_l \setminus F_{ij}. \end{cases}$$

LEMMA 4.7. *Let $F_l \subset \partial\Omega_i$ be a nonmortar face with its partition $\{F_{ij}\}_j$, and let $\mathbf{w}$ be a function in $[H^{1/2}(\partial\Omega_k)]^3$, $k = i, j$. When F_{ij} is substantial, we obtain*

$$\|\pi_l(\chi_{F_{ij}}\mathbf{w})\|^2_{H_{00}^{1/2}(F_l)} \le C\left(1 + \log\frac{H_{ij}}{h_i}\right)^2 \|\mathbf{w}\|^2_{1/2,\partial\Omega_k}, \quad k = i, j.$$

Proof. We may assume that $\mathbf{w} \in [H^{1/2}(\partial\Omega_j)]^3$. For the other case, the proof is the same. On the interface F_{ij}, we consider a quasiuniform triangulation of which mesh size is comparable to h_i, that of its nonmortar subdomain Ω_i, and denote the corresponding conforming P_1-finite element space by $\mathbf{W}(F_{ij})$. We then define the L^2-projection,

$$Q : [L^2(F_{ij})]^3 \to \mathbf{W}(F_{ij}). \tag{4.8}$$

We obtain

$$\|\pi_l(\chi_{F_{ij}}\mathbf{w})\|^2_{H_{00}^{1/2}(F_l)} \le 2\|\pi_l(\chi_{F_{ij}}(\mathbf{w}-Q\mathbf{w}))\|^2_{H_{00}^{1/2}(F_l)} + 2\|\pi_l(\chi_{F_{ij}}(Q\mathbf{w}))\|^2_{H_{00}^{1/2}(F_l)}. \tag{4.9}$$

The first term in the previous inequality is estimated by

$$\begin{aligned}\|\pi_l(\chi_{F_{ij}}(\mathbf{w}-Q\mathbf{w}))\|^2_{H^{1/2}_{00}(F_l)} &\le Ch_i^{-1}\|\pi_l(\chi_{F_{ij}}(\mathbf{w}-Q\mathbf{w}))\|^2_{0,F_l}\\ &\le Ch_i^{-1}\|(\mathbf{w}-Q\mathbf{w})\|^2_{0,F_{ij}}\\ &\le C\|\mathbf{w}\|^2_{1/2,\partial\Omega_j}. \qquad (4.10)\end{aligned}$$

Here we have used an inverse inequality, the continuity of π_l in the L^2-norm, and the approximation property of the projection Q combined with an interpolation argument (see [4, Chapter II])

$$\|\mathbf{w}-Q\mathbf{w}\|_{0,F_{ij}} \le Ch_i\|\mathbf{w}\|_{1,F_{ij}}, \quad \|Q\mathbf{w}\|_{1,F_{ij}} \le C\|\mathbf{w}\|_{1,F_{ij}}.$$

We now decompose $Q\mathbf{w}$ into interior and boundary parts, using the interpolant $I_A(\mathbf{w})$ defined in (4.7) to the space $\mathbf{W}(F_{ij})$,

$$Q\mathbf{w} = I_{F_{ij}}(Q\mathbf{w}) + I_{\partial F_{ij}}(Q\mathbf{w}).$$

Since $I_{F_{ij}}(Q\mathbf{w})$ is zero at the boundary of F_{ij}, we have

$$\chi_{F_{ij}}(I_{F_{ij}}(Q\mathbf{w})) \in [H^{1/2}_{00}(F_l)]^3, \quad I_{F_{ij}}(Q\mathbf{w}) \in [H^{1/2}_{00}(F_{ij})]^3.$$

Since F_{ij} is substantial, the definition of the $H^{1/2}_{00}$-norm states that

$$\|\chi_{F_{ij}}(I_{F_{ij}}(Q\mathbf{w}))\|_{H^{1/2}_{00}(F_l)} \le \|I_{F_{ij}}(Q\mathbf{w})\|_{H^{1/2}_{00}(F_{ij})}.$$

The second term in (4.9) is then bounded by

$$\begin{aligned}&\|\pi_l(\chi_{F_{ij}}(Q\mathbf{w}))\|^2_{H^{1/2}_{00}(F_l)}\\ &\le 2\|\pi_l(\chi_{F_{ij}}(I_{F_{ij}}(Q\mathbf{w})))\|^2_{H^{1/2}_{00}(F_l)} + 2\|\pi_l(\chi_{F_{ij}}(I_{\partial F_{ij}}(Q\mathbf{w})))\|^2_{H^{1/2}_{00}(F_l)}\\ &\le C\left(\|\chi_{F_{ij}}(I_{F_{ij}}(Q\mathbf{w}))\|^2_{H^{1/2}_{00}(F_l)} + h_i^{-1}\|(I_{\partial F_{ij}}(Q\mathbf{w}))\|^2_{0,F_{ij}}\right)\\ &\le C\left(\|I_{F_{ij}}(Q\mathbf{w})\|^2_{H^{1/2}_{00}(F_{ij})} + h_i^{-1}h_i\|(I_{\partial F_{ij}}(Q\mathbf{w}))\|^2_{0,\partial F_{ij}}\right). \qquad (4.11)\end{aligned}$$

Here we have used an inverse inequality and the continuity of π_l in the L^2- and $H^{1/2}_{00}$-norms.

By applying Lemmas 4.5 and 4.4 to the two terms in (4.11) and using that F_{ij} is substantial, we obtain

$$\begin{aligned}\|\pi_l(\chi_{F_{ij}}(Q\mathbf{w}))\|^2_{H^{1/2}_{00}(F_l)} &\le C\left(1+\log\frac{H_{ij}}{h_i}\right)^2\|Q\mathbf{w}\|^2_{1/2,F_{ij}}\\ &\le C\left(1+\log\frac{H_i}{h_i}\right)^2\|\mathbf{w}\|^2_{1/2,\partial\Omega_j}. \qquad (4.12)\end{aligned}$$

We obtain the required bound from (4.9)–(4.12). ∎

Remark 4.8. In our recent work [15], also on geometrically nonconforming partitions, progress has been made. The same bound, $C(1+\log(H/h))^2$, was proved for

the interfaces F_{ij} that do not need to be substantial, i.e., can be a narrow interface or only a small part of its nonmortar face F_l.

The following lemma is a simple modification of a result in Dryja, Smith, and Widlund [6, Lemma 4.4].

LEMMA 4.9. *Let F_{ij} be a face and $I_{F_{ij}}(\phi)$ be the nodal interpolant of ϕ to the finite element space equipped for F_{ij}. For a linear function ϕ, we have*

$$\|I_{F_{ij}}(\phi)\|^2_{H^{1/2}_{00}(F_{ij})} \leq C\left(1+\log\frac{H_{ij}}{h_i}\right)H_{ij}\|\phi\|^2_{\infty,F_{ij}},$$

where h_i is the mesh size and H_{ij} is the diameter of F_{ij}.

LEMMA 4.10. *Let $F_{ij}\subset F_l$, where F_l is a nonmortar face of $\partial\Omega_i$. For a linear function ϕ and a substantial interface F_{ij}, we have*

$$\|\pi_l(\chi_{F_{ij}}\phi)\|^2_{H^{1/2}_{00}(F_l)} \leq C\left(1+\log\frac{H_{ij}}{h_i}\right)H_{ij}\|\phi\|^2_{\infty,F_{ij}}.$$

Proof. By applying the estimate in (4.11) of Lemma 4.7 to ϕ, we have

$$\|\pi_l(\chi_{F_{ij}}(Q\phi))\|^2_{H^{1/2}_{00}(F_l)} \leq C\left(\|I_{F_{ij}}(Q\phi)\|^2_{H^{1/2}_{00}(F_{ij})}+\|I_{\partial F_{ij}}(Q\phi)\|^2_{0,\partial F_{ij}}\right),$$

where Q is the L^2-projection described in (4.8). Since $Q\phi=\phi$, the required bound follows by using Lemma 4.9. ∎

LEMMA 4.11. *Let $F_l\subset\partial\Omega_i$ be a nonmortar face with a partition $\{F_{ij}\}_j$ by its mortar neighbors. We assume that all interfaces F_{ij} are substantial and each interface F_{ij} is either primal or has an acceptable face path. In addition, the subdomain partition satisfies Assumption* 3.1. *Then, for $\mathbf{w}=(\mathbf{w}_1,\dots,\mathbf{w}_N)\in\widetilde{\mathbf{W}}$, we have*

$$\begin{aligned}G_i\|\pi_l(\mathbf{w}_i-\boldsymbol{\phi})\|^2_{H^{1/2}_{00}(F_l)} \leq C\Bigg\{&\left(1+\log\frac{H_i}{h_i}\right)^2|\mathbf{w}_i|^2_{S_i}\\ &+\sum_j L(F_{ij})*\sum_{k\in A(i,j)}\left(1+\log\frac{H_{ij}}{h_i}\right)\frac{G_i}{G_k}|\mathbf{w}_k|^2_{S_k}\\ &+\sum_j\frac{G_i}{G_j}\left(1+\log\frac{H_i}{h_i}\right)^2|\mathbf{w}_j|^2_{S_j}\Bigg\}.\end{aligned}$$

Here the restriction of $\boldsymbol{\phi}$ to F_{ij} is $\mathbf{w}_j$, $A(i,j)$ is the set of subdomain indices of the acceptable face path of F_{ij}, the constant $L(F_{ij})$ is the number of the subdomains in the path, and $|\mathbf{w}_i|^2_{S_i}:=\langle S_i\mathbf{w}_i,\mathbf{w}_i\rangle$.

Proof. Since $\{F_{ij}\}_j$ is a partition of the nonmortar face F_l, we can write

$$\mathbf{w}_i-\boldsymbol{\phi}=\sum_j\chi_{F_{ij}}\left(\mathbf{w}_i-\mathbf{w}_j\right),$$

and it suffices to estimate each term in the above expression.

Let $\{\Omega_i,\Omega_{k_1},\dots,\Omega_{k_n},\Omega_j\}$ be the related acceptable face path of F_{ij} which passes through the primal interfaces $\{F_{ik_1},F_{k_1k_2},\dots,F_{k_nj}\}$. When F_{ij} is primal, the path is simply $\{\Omega_i,\Omega_j\}$. Let $\{\mathbf{r}^{ik_1}_m\}$, $\{\mathbf{r}^{k_1k_2}_m\},\dots,\{\mathbf{r}^{k_nj}_m\}$ be bases of $\mathbf{ker}(\varepsilon)$ scaled with respect

to the faces F_{ik_1}, $F_{k_1k_2},\ldots,F_{k_nj}$, respectively. We denote the dual basis to $\{\mathbf{r}_m^{lk}\}_m$ by $\{f_m^{lk}\}_m$. We introduce the notation,

$$f_{lk}(\mathbf{w}) = \sum_{m=1}^{6} f_m^{lk}(\mathbf{w})\mathbf{r}_m^{lk}.$$

We note that $f_{lk}(\mathbf{r}) = \mathbf{r}$ for any rigid body motion $\mathbf{r}$ and that $f_{lk}(\mathbf{w}_l) = f_{lk}(\mathbf{w}_k)$, since $\mathbf{w}$ satisfies the primal constraints on the primal interface F_{lk}.

We then have

$$\begin{aligned}\mathbf{w}_i - \mathbf{w}_j &= (\mathbf{w}_i - \mathbf{r}_i) - f_{ik_1}(\mathbf{w}_i - \mathbf{r}_i) + f_{ik_1}(\mathbf{w}_{k_1} - \mathbf{r}_{k_1}) - f_{k_1k_2}(\mathbf{w}_{k_1} - \mathbf{r}_{k_1})\\ &\quad + f_{k_1k_2}(\mathbf{w}_{k_2} - \mathbf{r}_{k_2}) - f_{k_2k_3}(\mathbf{w}_{k_2} - \mathbf{r}_{k_2}) + \cdots\\ &\quad + f_{k_nj}(\mathbf{w}_j - \mathbf{r}_j) - (\mathbf{w}_j - \mathbf{r}_j),\end{aligned} \tag{4.13}$$

where $\mathbf{r}_k$ denotes any rigid body motions.

We apply Lemma 4.7 to the first and last terms of the above equation and obtain

$$\begin{aligned}&G_i\left(\|\pi_l(\chi_{F_{ij}}(\mathbf{w}_i - \mathbf{r}_i))\|^2_{H_{00}^{1/2}(F_l)} + \|\pi_l(\chi_{F_{ij}}(\mathbf{w}_j - \mathbf{r}_j))\|^2_{H_{00}^{1/2}(F_l)}\right)\\ &\le C\left(1+\log\frac{H_{ij}}{h_i}\right)^2\left(G_i\|\mathbf{w}_i - \mathbf{r}_i\|^2_{1/2,\partial\Omega_i} + G_i\|\mathbf{w}_j - \mathbf{r}_j\|^2_{1/2,\partial\Omega_j}\right)\\ &\le C\left(1+\log\frac{H_{ij}}{h_i}\right)^2\left(|\mathbf{w}_i|^2_{E(\partial\Omega_i)} + \frac{G_i}{G_j}|\mathbf{w}_j|^2_{E(\partial\Omega_j)}\right)\\ &\le C\left(1+\log\frac{H_i}{h_i}\right)^2\left(|\mathbf{w}_i|^2_{S_i} + \frac{G_i}{G_j}|\mathbf{w}_j|^2_{S_j}\right).\end{aligned}$$

Here we have also used Lemmas 2.2 and 2.3 combined with the bound

$$|\mathbf{w}_i|^2_{E(\partial\Omega_i)} \le |\mathbf{w}_i|^2_{S_i},$$

and the assumption that the interface F_{ij} is substantial.

We next consider the other terms in (4.13). From (4.1) and Lemmas 4.10 and 2.3, each term can be estimated as

$$\begin{aligned}&G_i|f_m^{k_1k_2}(\mathbf{w}_{k_2} - \mathbf{r}_{k_2})|^2\ \|\pi_l(\chi_{F_{ij}}\mathbf{r}_m^{k_1k_2})\|^2_{H_{00}^{1/2}(F_l)}\\ &\le CG_i\frac{\|\mathbf{w}_{k_2} - \mathbf{r}_{k_2}\|^2_{0,\partial\Omega_{k_2}}}{H^2_{k_1k_2}}\left(1+\log\frac{H_{ij}}{h_i}\right)H_{ij}\|\mathbf{r}_m^{k_1k_2}\|^2_{\infty,F_{ij}}\\ &\le C*\frac{G_i}{G_{k_2}}\left(1+\log\frac{H_{ij}}{h_i}\right)|\mathbf{w}_{k_2}|^2_{S_{k_2}}\frac{H_{k_2}H_{ij}}{H^2_{k_1k_2}}\|\mathbf{r}_m^{k_1k_2}\|^2_{\infty,F_{ij}}.\end{aligned}$$

We will show that the factor $(H_{k_2}H_{ij}/H^2_{k_1k_2})\|\mathbf{r}_m^{k_1k_2}\|^2_{\infty,F_{ij}}$ is bounded by a constant that depends only on $L(F_{ij})$. The assumption of the acceptable face path gives that $L(F_{ij}) \le L$ for a given constant L. Since the length of the face path is less than or equal to L and the subdomain partition is locally quasiuniform, the diameter of

the subdomains in the path is comparable to H_i. In addition, the diameter of any primal interface in the path is comparable to H_i, because it is substantial. From these observations, we obtain

$$\|\mathbf{r}_m^{k_1k_2}\|_{\infty,F_{ij}} \leq CL(F_{ij}), \quad \frac{H_{k_2}H_{ij}}{H_{k_1k_2}^2} \leq C\frac{H_{ij}}{H_i},$$

and have proved the bound

$$\frac{H_{k_2}H_{ij}}{H_{k_1k_2}^2}\|\mathbf{r}_m^{k_1k_2}\|_{\infty,F_{ij}}^2 \leq CL(F_{ij})^2. \tag{4.14}$$

The remaining terms in (4.13) can be bounded in a similar way leading to the required bound of $G_i\|\pi_l(\mathbf{w}_i - \boldsymbol{\phi})\|^2_{H_{00}^{1/2}(F_l)}$. ∎

Remark 4.12. The proof for the bound in (4.14) suggests that it is beneficial that the diameter of the nonprimal interface F_{ij} is smaller than those of the primal interfaces in the acceptable face path. In addition, the definition of an acceptable face path shows that a smaller diameter of F_{ij} provides more chances of finding an acceptable path of F_{ij} for a given TOL_P and L.

Remark 4.13. From our recent work [15], the same bound in Lemma 4.11 can also be obtained when F_{ij} is not substantial, i.e., can be a narrow strip or only a small part of its nonmortar face F_l.

We note that the acceptable face path in Definition 3.6 and Assumption 3.3 gives

$$\left(1+\log\frac{H_{ij}}{h_i}\right)\frac{G_i}{G_{k_l}} \leq TOL_P * \left(1+\log\frac{H_i}{h_i}\right)^2, \quad L(F_{ij}) \leq L, \quad \frac{G_i}{G_j} \leq TOL_G,$$

where $L(F_{ij})$ is the number of subdomains in the acceptable face path of F_{ij}. Therefore the bound in Lemma 4.11 is reduced to

$$G_i\|\pi_l(\mathbf{w}_i - \boldsymbol{\phi})\|^2_{H_{00}^{1/2}(F_l)} \leq C\left(1+\log\frac{H_i}{h_i}\right)^2 \sum_{l\in N_l}|\mathbf{w}_l|^2_{S_l}, \tag{4.15}$$

where N_l is the set of subdomain indices that appear on the acceptable face path of $F_{ij} \subset F_l$. The constant C depends on TOL_G, TOL_P, and L but does not depend on any mesh parameters nor on the coefficients G_i.

LEMMA 4.14. *Assume that every nonprimal interface satisfies the acceptable face path condition with given TOL_P, L, and coefficients G_i, and that all interfaces are substantial. In addition, Assumptions* 3.1 *and* 3.3 *hold with a given TOL_G. We then obtain*

$$\max_{\mathbf{w}\in\widetilde{\mathbf{W}}}\frac{\langle B\mathbf{w},\boldsymbol{\lambda}\rangle^2}{\langle S\mathbf{w},\mathbf{w}\rangle} \leq C\max_{i=1,\ldots,N}\left\{\left(1+log\frac{H_i}{h_i}\right)^2\right\}\langle\widehat{M}\boldsymbol{\lambda},\boldsymbol{\lambda}\rangle,$$

where the constant C depends on the TOL_G, TOL_P, and L, but not on any mesh parameters and coefficients G_i.

Proof. We consider

$$\langle B\mathbf{w},\boldsymbol{\lambda}\rangle^2 = \left(\sum_{F_l,\text{nonmortar}}\int_{F_l}(\mathbf{w}_i-\boldsymbol{\phi})\cdot\boldsymbol{\lambda}\,ds\right)^2$$

$$= \left(\sum_{F_l,\ \text{nonmortar}}\int_{F_l}\pi_l(\mathbf{w}_i-\boldsymbol{\phi})\cdot\boldsymbol{\lambda}\,ds\right)^2.$$

Since $\mathbf{w}\in\widetilde{\mathbf{W}}$, $\mathbf{w}$ satisfies the primal constraints on any primal interface F_{ij}, i.e.,

$$\int_{F_{ij}}(\mathbf{w}_i-\boldsymbol{\phi})\cdot I_{M(F_{ij})}(\mathbf{r}_m)\,ds=0,\quad m=1,\dots,6.$$

This implies that $\pi_l(\mathbf{w}_i-\boldsymbol{\phi})$ also satisfies the primal constraints

$$\int_{F_{ij}}\pi_l(\mathbf{w}_i-\boldsymbol{\phi})\cdot I_{M(F_{ij})}(\mathbf{r}_m)\,ds=0,\quad m=1,\dots,6,$$

because $I_{M(F_{ij})}(\mathbf{r}_m)$ belongs to the Lagrange multiplier space $\mathbf{M}(F_l)$. Therefore, $\mathbf{z}_n$, defined on each nonmortar face F_l by

$$\mathbf{z}_n|_{F_l}=\pi_l(\mathbf{w}_i-\boldsymbol{\phi}),$$

belongs to $\mathbf{W}_{\Delta,n}$. In other words, $\mathbf{z}_n$ has all its six primal components zero on each primal face. We then define by $\mathbf{z}=E(\mathbf{z}_n)$ the extension of $\mathbf{z}_n$ to $\widetilde{\mathbf{W}}(=\mathbf{W}_{\Delta,n}\times\mathbf{W}_{\Delta,m}\times\mathbf{W}_{\Pi})$ by zero.

By the definition of $\widehat{M}$ in (3.11), we find that

$$\langle B\mathbf{w},\boldsymbol{\lambda}\rangle^2=\langle B\mathbf{z},\boldsymbol{\lambda}\rangle^2$$

$$\le\langle\widehat{M}\boldsymbol{\lambda},\boldsymbol{\lambda}\rangle\langle S\mathbf{z},\mathbf{z}\rangle.$$

It suffices to show that

$$\langle S\mathbf{z},\mathbf{z}\rangle\le C\max_{i=1,\dots,N}\left\{\left(1+\log\frac{H_i}{h_i}\right)^2\right\}\langle S\mathbf{w},\mathbf{w}\rangle. \tag{4.16}$$

We now consider

$$\langle S\mathbf{z},\mathbf{z}\rangle=\sum_{i=1}^{N}\langle S_i\mathbf{z}_i,\mathbf{z}_i\rangle$$

$$\le C\sum_{i=1}^{N}\sum_{F_l,\ \text{nonmortar}}G_i|\mathcal{H}^i\left(\pi_l(\mathbf{w}_i-\boldsymbol{\phi})\right)|^2_{1,\Omega_i}$$

$$\le C\sum_{i=1}^{N}\sum_{F_l,\ \text{nonmortar}}G_i\|\pi_l(\mathbf{w}_i-\boldsymbol{\phi})\|^2_{H_{00}^{1/2}(F_l)}, \tag{4.17}$$

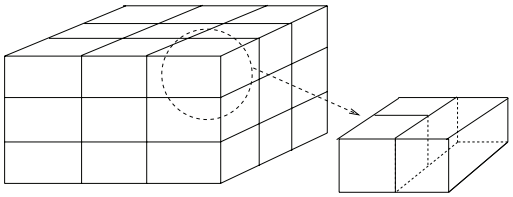

FIG. 4. *Partition of the domain into uniform parallelepipes when $N = 3$ (left), partition of each parallelepipe into geometrically nonconforming subdomains with good aspect ratio of interfaces (right).*

where $\mathcal{H}^i$ is the discrete harmonic extension into X_i and π_l is the mortar projection corresponding to the nonmortar face F_l. Here we have used that (see Lemma 2.2 and (2.4))

$$\langle S_i \mathbf{z}_i, \mathbf{z}_i \rangle \leq C G_i |\mathcal{H}^i(\mathbf{z}_i)|^2_{1,\Omega_i}.$$

From the bound (4.15) and (4.17), we obtain (4.16) with a constant C which depends on TOL_G, TOL_P, and L. □

The lower bound in (3.12) and the bound in Lemma 4.14, combined with (3.10), lead to the following condition number bound.

THEOREM 4.15. *We assume that the assumptions in Lemma* 4.14 *hold. We then obtain the condition number bound*

$$\kappa(\widehat{M}^{-1} F_{DP}) \leq C \max_{i=1,\ldots,N} \left\{ \left(1 + log \frac{H_i}{h_i} \right)^2 \right\}.$$

Here the constant C is independent of the mesh parameters and the coefficients G_i, but depends on the given constants TOL_G, TOL_P, and L.

Remark 4.16. We note that the result can be extended to the general case when all interfaces do not need to be substantial; see [15] and numerical results provided in the following section.

5. Numerical results. We perform numerical tests for the model elasticity problem (2.1) in a domain $\Omega = [0,1] \times [0,1] \times [0,1/2]$ and the material parameter $\beta(x) = 1$. The coefficient $G(x)$ can be heterogeneous. We let $\mathbf{F}$ be zero so that the exact solution of our model problem is zero. We start the FETI-DP iteration with a nonzero initial and terminate the iteration when the relative residual norm becomes less than a factor of 10^6.

We first test the performance of the suggested algorithm in regards to high contrast of the coefficients for the subdomain partitions of which interfaces are substantial and have a good aspect ratio. We obtain such geometrically nonconforming partitions in the following way. For a given N, we partition Ω into N^3 uniform parallelepipes and then partition each parallelepipe into geometrically nonconforming subdomains as in Figure 4. All interfaces are then substantial. We set $G(x) = G_i$ in each subdomain Ω_i. The values of G_i can be 1, 100, or 1000.

We consider the uniform coefficient case and the high contrast case as in Figure 5. For the high contrast case, we select the nonmortar and mortar sides to satisfy Assumption 3.3 or not for a given TOL_G. For the three cases, the number of iterations and condition numbers are presented in Table 1 as an increase of the number of subdomains and in Table 2 as an increase of the local problem size. We can see that

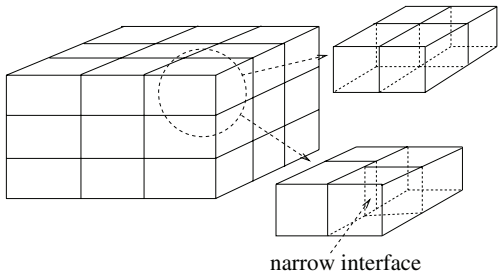

FIG. 6. *Partition of the domain into uniform parallelepipes when $N = 3$ (left), partition of each parallelepipe into geometrically conforming subdomains (right up), and into geometrically nonconforming subdomains with a bad aspect ratio of interfaces, i.e., narrow interfaces (right down).*

Assumption 3.3 is essential to achieving a good performance. In addition, the high contrast case gives results as good as those from the uniform case once its selection of nonmortar and mortar faces fulfills Assumption 3.3. The condition numbers agree well to our theory provided in section 4. In fact, these results show that the estimate of the condition number bound is optimal.

In our second test, we verify that our algorithm is also robust to partitions with a bad aspect ratio of interfaces that are not substantial. For a given N, we partition Ω into N^3 uniform parallelepipes and then partition each parallelepipe into four

TABLE 3

Performance of the FETI-DP algorithm when $G(x) = 1$ as the increase of n; conforming partition with good aspect ratio ($\alpha = 1.0$) of interfaces vs. geometrically nonconforming partition with bad aspect ratio ($\alpha = 3/(n-1)$); Cond (condition number), Iter (the number of iterations), nonprimal (bad aspect ratio interfaces are nonprimal), primal (bad aspect ratio interfaces are primal).

12	31.85	34	66.88	42

subdomains that are geometrically conforming and geometrically nonconforming; see Figure 6. In the geometrically conforming case, the aspect ratio is always 1, while the aspect ratio gets worse as the increase of the local problem size in the geometrically nonconforming case. Here, the coefficients are uniform, i.e., $G(x) = 1$. Table 3 shows the number of iterations and condition numbers as the increase of the local problem size. We note that the aspect ratio gets worse as the local problem size increases. In the geometrically nonconforming case, we test our algorithm for the two cases when the narrow interfaces are nonprimal and when they are primal, respectively. From the result, we can see that the narrow interfaces are harmless to the performance of our algorithm regardless of selecting them as nonprimal interfaces or primal interfaces. Moreover, the narrow interface case also shows the optimal behavior of the condition number bound as the increase of the local problem size. In fact, there is only a slight increase in the number of iterations and condition numbers compared to the case of good aspect ratio of interfaces.

In the final test, we investigate whether or not the face path assumption is nec-

essary for subdomain partitions with bad aspect ratio of interfaces and with a high contrast of coefficients. We consider two cases that satisfy the face path assumption with a smaller TOL_P and with a larger TOL_P, respectively; see Figure 7 and Definition 3.6. Numerical results in Table 4 show that the larger value of TOL_P in the face path assumption gives a worse performance. Therefore, the face path assumption is in fact necessary to handle the bad aspect ratio interfaces with the high contrast of coefficients.

Acknowledgment. The author is deeply grateful to Professor Olof B. Widlund at Courant Institute for his support and encouragement, as well as valuable discussions.

CONVERGENCE RATE OF MONOTONE NUMERICAL SCHEMES FOR HAMILTON–JACOBI EQUATIONS WITH WEAK BOUNDARY CONDITIONS*

KNUT WAAGAN†

Abstract. We study a class of monotone numerical schemes for time-dependent Hamilton–Jacobi equations with weak Dirichlet boundary conditions. We get a convergence rate of $\frac{1}{2}$ under some usual assumptions on the data, plus an extra assumption on the Hamiltonian $H(Du, x)$ at the boundary $\partial\Omega$. More specifically the mapping $p \to H(p, x)$ must satisfy a monotonicity condition for all p in a certain subset of $\mathbf{R}^n$ given by Ω. This condition allows the use of the interior subsolution conditions at the boundary in the comparison arguments. We also prove a comparison result and Lipschitz regularity of the exact solution. As an example we construct a Godunov-type scheme that can handle the weakened boundary conditions.

Key words. Hamilton–Jacobi equations, viscosity solutions, weak boundary conditions, numerical approximation

1. Introduction.

Let the scalar function $u(x, t)$ solve the Hamilton–Jacobi equation

$$u_t + H(Du, x) = 0 \tag{1.1}$$

for x in an open and bounded set $\Omega \in \mathbf{R}^n$ and t in a bounded interval $(0, T)$. We will show well-posedness and Lipschitz regularity and will study numerical approximations to this equation under the Cauchy–Dirichlet boundary condition

$$\begin{aligned} u(x, 0) &= u_0(x), \quad x \in \bar{\Omega}, \\ u(x, t) &= g(x), \quad x \in \partial\Omega,\ 0 \le t < T. \end{aligned} \tag{1.2}$$

Note that $g = u_0|_{\partial\Omega}$. The mapping $p \to H(p, x)$ is assumed to tend uniformly to $+\infty$ as $|p| \to \infty$ and to do so in a later specified monotone way. In addition, some Lipschitz estimates on the data and some geometric conditions on the domain will be prescribed.

Classical solutions to (1.1) may develop discontinuities in the first derivative in finite time, hence viscosity solutions, as defined in [10], are more natural to study, since they are only continuous. Overviews of this subject are found in [9], [8], and [2]. The term "viscosity solution" comes from the vanishing viscosity method, in which a solution to the first order equation is sought by solving $u_t + H(Du, x) = \epsilon\,\Delta u$ and letting $\epsilon \to 0$, typically resulting in a viscosity solution. The viscosity solution concept also ensures causality in the sense that characteristics are not allowed to emanate from the singularities in Du. These facts reveal a connection to the entropy solution of scalar conservation laws which is more than superficial, but the two theories are

independent. However, numerical schemes for Hamilton–Jacobi equations are often derived from numerical schemes for conservation laws.

Since characteristics may be directed out of the boundary, the Cauchy–Dirichlet problem may be overdetermined both classically and in the original viscosity solutions setting, hence a weakened boundary condition is called for. The papers [5] and [14] both describe what has turned out to be the natural way to perform such a generalization, since the consistency with both control theory and vanishing viscosity approximation is maintained. This theory also includes other types of boundary data, as seen in, for example, [14] and [9], with Neumann conditions as another special case.

Before continuing, we need to specify what we mean by a viscosity solution. First, we state that by $C^1(\bar{\Omega} \times [0,T])$ we mean the class of all functions ψ such that ψ is a restriction to $\bar{\Omega} \times [0,T]$ of a function in $C^1(R^n \times R)$.

We define a viscosity solution to (1.1)–(1.2) as follows.

DEFINITION 1. *Let $\psi \in C^1(\bar{\Omega} \times [0,T])$. A function $u(x,t)$ is a subsolution of* (1.1)–(1.2) *if whenever $u^* - \psi$ has a local maximum at $(x,t) \in \bar{\Omega} \times [0,T]$, then*

$$\begin{aligned} \psi_t(x,t) + H(D\psi(x,t),x) &\le 0, \quad x \in \Omega,\ 0 < t \le T, \\ \min\left(u^*(x,t) - g(x), \psi_t(x,t) + H(D\psi(x,t),x)\right) &\le 0, \quad x \in \partial\Omega,\ t > 0, \\ u^*(x,0) &\le u_0(x), \quad x \in \bar{\Omega}. \end{aligned} \tag{1.3}$$

A function v is a supersolution of (1.1)–(1.2) *if whenever $v_* - \psi$ has a local minimum at $(x,t) \in \bar{\Omega} \times [0,T]$, then*

$$\begin{aligned} \psi_t(x,t) + H(D\psi(x,t),x) &\ge 0, \quad x \in \Omega,\ 0 < t \le T, \\ \max\left(v_*(x,t) - g(x), \psi_t(x,t) + H(D\psi(x,t),x)\right) &\ge 0, \quad x \in \partial\Omega,\ t > 0, \\ v_*(x,0) &\ge u_0(x), \quad x \in \bar{\Omega}. \end{aligned} \tag{1.4}$$

A function u is a viscosity solution of (1.1)–(1.2) *if it is both a sub- and a supersolution.*

The notations $\cdot^*$ and $\cdot_*$ refer to the usual upper and lower semicontinuous envelope, that is,

$$u^*(x,t) = \limsup_{y \in \bar{\Omega} \to x,\ s \in [0,T] \to t} u(y,s) \quad \text{and} \quad u_*(x,t) = \liminf_{y \in \bar{\Omega} \to x,\ s \in [0,T] \to t} u(y,s). \tag{1.5}$$

We have chosen to simply include the endpoint $t = T$ in our definition, but leaving the time interval open would have been equivalent. This is due to the monotone dependence on u_t in (1.1), which also makes weakening the initial condition redundant (see [5]).

The uniqueness of viscosity solutions follows if one can prove that $u \le v$ for all subsolutions u and supersolutions v. This is referred to as a comparison result.

In [5] there is a comparison result for (1.1)–(1.2) under some common continuity assumptions on the data and a nondegeneracy condition at the boundary. This nondegeneracy condition has uniform coercivity of H as a special case. We prefer to give a new comparison proof here since the proof in [5] requires uniform continuity of $p \to H(p,x)$, which can be avoided in our setting.

In [7] a uniform coercivity condition on $p \to H(p,x)$ is shown to imply $u^*|_{\partial\Omega} \le g$ and a comparison result for subsolutions that are lower Lipschitz bounded in time. The authors then construct a solution where this holds for initial data such that

$H(Du_0, \cdot) \leq 0$ using vanishing viscosity arguments. They also prove Lipschitz continuity of subsolutions that are nondecreasing in time under assumptions which are no stronger than will be made here.

The solution given by Definition 1 is the optimal value function for a finite horizon control problem where the cost stops running once a trajectory reaches $\partial\Omega$. This problem is covered in [13]. When the boundary condition is only weakly satisfied at $x \in \partial\Omega$, it is because the optimal trajectory starting at x does not exit Ω immediately.

The uniform convergence of monotone approximation schemes for the Cauchy problem was studied in [11] and [16]. The solution remains Lipschitz continuous if it is initially, and the convergence rate is $\frac{1}{2}$. In [6], locally uniform convergence for quite general boundary value problems is proved for the more general case of second order degenerate elliptic equations. The main condition in the proof is that the approximated problem satisfies a comparison principle. No explicit error estimate is given, and since schemes that form boundary layers are allowed, a uniform convergence rate would not be possible. Putting these results into practice for first order equations is the subject of [1]. Triangular grids are considered, and a Godunov scheme is extended to the boundary by reinterpreting the Hamiltonian as the Legendre transform of a control problem. Furthermore a Lax–Friedrichs scheme is also extended to the boundary, and certain nonconvex cases are also treated. Uniform coercivity of the Hamiltonian is shown to imply Lipschitz continuity of approximations to the stationary equation. No control theory will be used in this article, but our extension of the Godunov scheme to the boundary is very similar to that of [1].

Our main result is an estimate of $\frac{1}{2}$ for the convergence rate of monotone numerical schemes for problem (1.1)–(1.2). To achieve this result, we add conditions on H and Ω. Roughly speaking, we will require that as long as $p \cdot n < 0$ for the inward normal vector n, then $p \to H(p, x)$ is nondecreasing in the direction of $-n$. Special cases included are radially symmetric H on convex Ω, and H given by $H(u_{x_1}^2, \ldots, u_{x_n}^2)$, where H is nondecreasing in each argument and Ω is a rectangle oriented like $(0, 1)^n$. The proof is built on the treatment of the Cauchy problem in [11] and [16].

After stating some assumptions and preliminary results, we will specify the requirements at the boundary. Next a comparison result is given, from which existence and regularity follows. A generic numerical scheme is then defined, for which we state the main result on convergence rate. This is formulated in the tradition of [11] and [16], with the necessary extensions made to include the boundary conditions.

Finally we formulate a Godunov type scheme as an example. This turns out to have some theoretical difficulties other than just stating what happens at the grid points, since how to interpolate between the boundary and interior grid points is generally not obvious. Hence only stating what happens at the grid points is insufficient in this setting, although it may make sense for the Cauchy problem. The simple numerical boundary condition $u(x, t) = g(x)$ is not included in the analysis. Of course, we would not generally expect a uniform estimate for such a scheme since boundary layers could form, as they do for vanishing viscosity approximations. Our numerical results demonstrate convergence properties that are similar to what is known for pure Cauchy problems, as our convergence estimate predicts.

2. Assumptions and preliminary results. This section sums up some assumptions, definitions, and results we will need. The L^∞-norm of a function f is denoted $\|f\|$, and hence $\|Df\|$ denotes the Lipschitz seminorm of f, since a Lipschitz continuous function is differentiable almost everywhere by Rademacher's theorem.

We will make the following Lipschitz assumptions.

ASSUMPTION 1. *The mapping $p \to H(p,x)$ is continuous, and for any $R > 0$ there exists $C_R > 0$ such that*

$$|H(p,x) - H(p,y)| \le C_R|x-y| \quad \forall x, y \in \bar{\Omega},\ |p| \le R. \tag{2.1}$$

The initial value u_0 is Lipschitz continuous, so one may define

$$L_0 = \max(\|Du_0\|, p_0), \quad \text{where } p_0 = \sup_{x\in\Omega}\{|p| : H(p,x) = 0\} < \infty. \tag{2.2}$$

By uniform coercivity, we mean, as in [3], [4], and [7] the following.

ASSUMPTION 2. *The mapping $p \to H(p,x)$ is uniformly coercive, that is, for any $C \in \mathbf{R}$ there exists $r > 0$ such that $H(p,x) > C$ for all $|p| > r$ and $x \in \bar{\Omega}$.*

This is used to get Lipschitz continuity of u, and it also gives the following proposition. It requires yet another assumption, this one on Ω, which we state first. It is an exterior sphere condition given locally.

ASSUMPTION 3. *For each $x \in \partial\Omega$, there exist $r_x > 0$ and $z_x \in \mathbf{R}^n$ defining an open ball $B(z_x, r_x)$ such that $\bar{B}(z_x, r_x) \cap \bar{\Omega} = \{x\}$.*

PROPOSITION 2.1. *If Assumptions 2 and 3 hold, then*

$$u^*(x,t) \le g(x) \quad \forall x \in \partial\Omega,\ t \in [0,T] \tag{2.3}$$

holds for any subsolution u of (1.1)–(1.2) that is bounded above.

Our proof essentially copies the one in [7], which treated C^1 boundaries. A more intuitive motivation for this result is the fact that superdifferentials become unbounded on $\partial\Omega$.

Proof. Assume in order to obtain a contradiction that there exists $(x_0, t_0) \in \partial\Omega \times (0,T]$ such that $u^*(x_0,t_0) > g(x_0)$. Consider

$$\Psi(x,t) = u^*(x,t) - \frac{(t-t_0)^2}{2\beta^2} - \frac{1}{\alpha}\left(|x - z_{x_0}| - |x_0 - z_{x_0}|\right), \quad \alpha,\ \beta > 0. \tag{2.4}$$

The point z_{x_0} is given by Assumption 3, hence the last term of Ψ is nonnegative. Denote the maximum point of Ψ in $\bar{\Omega} \times [0,T]$ by $(\hat{x}, \hat{t})$. Now,

$$u^*(x_0,t_0) = \Psi(x_0,t_0) \le \Psi(\hat{x},\hat{t}) \le u^*(\hat{x},\hat{t}) - C\left(|\hat{x} - z_{x_0}| - |x_0 - z_{x_0}|\right) - \frac{(\hat{t}-t_0)^2}{2\beta^2}. \tag{2.5}$$

Since u^* is bounded by, say, $R > 0$, this means that $(|\hat{x} - z_{x_0}| - |x_0 - z_{x_0}|) \le 2R\alpha$ and $|\hat{t} - t_0| \le 2\sqrt{R}\beta$. This implies $u^*(\hat{x},\hat{t}) \to u^*(x_0,t_0)$ as α and β go to zero; hence, taking α and β small enough, we have $u^*(\hat{x},\hat{t}) > g(\hat{x})$. That means we may use the differential equation, so

$$\frac{\hat{t} - t_0}{\beta^2} + H\left(\frac{\hat{x} - z_{x_0}}{\alpha|\hat{x} - z_{x_0}|}, \hat{x}\right) \le 0. \tag{2.6}$$

By uniform coercivity of H, this implies

$$\frac{1}{\alpha} \le \Gamma_\beta \tag{2.7}$$

for some $\Gamma_\beta < \infty$. So choosing $\alpha < \frac{1}{\Gamma_\beta}$ produces the contradiction. ∎

2.1. Subsolutions on the boundary. In this section we state the monotonicity requirement of H at $\partial\Omega$. The aim is to give conditions such that the interior subsolution condition holds on all $\bar{\Omega}$, at least for test functions of the form typically used in a doubling of variables argument. The key observation is that the gradient of such a test function points out of the domain for certain choices of H and Ω. Hence, monotonicity of $p \to H(p,x)$ only needs to hold for p in a subset of $\mathbf{R}^n$. This is similar to the results of [12] and [17] with the exception that these require global monotonicity of H. In the simplest case that $\partial\Omega$ is C^1 and convex, with inward normal vector $n(x)$, we need

$$H(k(x-z)-\mu n(x),x) \geq H(k(x-z),x) \quad \forall\, k,\mu>0,\ x\in\partial\Omega,\ z\in\bar{\Omega}. \tag{2.8}$$

However, to allow corners, we require the following.

ASSUMPTION 4. *There exists a nonnegative function $d \in C^1(\Omega)\cap C^0(\bar{\Omega})$ such that $d(x)=0$ if and only if $x\in\partial\Omega$. Furthermore, for every $x_0\in\partial\Omega$, $k>0$, positive function $\mu:\Omega\to\mathbf{R}$, and $z\in\bar{\Omega}$,*

$$\liminf_{x\to x_0} H(k(x-z)-\mu(x)Dd(x),x) \geq H(k(x_0-z),x_0). \tag{2.9}$$

We cannot simply state the monotonicity property at the point x_0, since $Dd(x_0)$ will be 0 at any corner, and because we need to allow $\mu(x)$ to go to infinity at $\partial\Omega$. Note, however, that where $\partial\Omega$ is C^1, $Dd(x)$ must be parallel to the inward normal vector $n(x)$, and hence (2.8) suffices.

We could have reduced the domain of z by restricting $|z-x_0|$, but that would be a bit technically complicated to use in the proof of convergence rate. The assumption becomes useful through the following lemma.

LEMMA 2.2. *Let Assumption 4 hold. Let u be a bounded subsolution of (1.1)–(1.2) such that*

$$u^*(x,t) = \limsup_{y\in\Omega\to x,\, s\in(0,T)\to t} u(y,s). \tag{2.10}$$

Suppose the mapping

$$(x,t) \to u^*(x,t) - \frac{k}{2}(x-z)^2 - \eta(t)$$

attains its maximum over $\bar{\Omega}\times[0,T]$ at (x_0,t_0) with $x_0\in\partial\Omega$, $t_0>0$, $k>0$, $z\in\bar{\Omega}$, and $\eta\in C^1((0,T))$. Then

$$\eta_t(t_0) + H(k(x_0-z),x_0) \leq 0. \tag{2.11}$$

Proof. Without losing generality, we may assume the maximum is strict. Consider

$$\Psi(x,t) = u^*(x,t) - \frac{k}{2}(x-z)^2 - \eta(t) - \frac{\epsilon}{d(x)}. \tag{2.12}$$

Because of (2.10), Ψ will have a local maximum (x_ϵ,t_ϵ) with $x_\epsilon\in\Omega$ such that $(x_\epsilon,t_\epsilon)\to(x_0,t_0)$ as ϵ goes to 0. Hence

$$0 \geq \eta_t(t_\epsilon) + H\left(k(x_\epsilon-z) - \epsilon\frac{Dd(x_\epsilon)}{d(x_\epsilon)^2}, x_\epsilon\right). \tag{2.13}$$

Letting $\epsilon\to 0$, the lemma follows from Assumption 4. ∎

2.1.1. Examples. An example where Assumption 4 holds is if $p \to H(p,x)$ is radially symmetric with a unique minimum at $p=0$ (i.e., $H(p,x)=h(|p|,x)$, where $h:[0,\infty)\times\mathbf{R}^n\to\mathbf{R}$ is nondecreasing in the first variable), Ω is convex, and $\partial\Omega$ is piecewise C^1. The function d can be chosen as the product of the distances to each C^1 subset of $\partial\Omega$.

As a second example consider $\Omega=(0,1)^n$. Then the assumption holds for any Hamiltonian $H(p,x)=H_2\left(p_1^2,p_2^2,\dots,p_n^2,x\right)$ if $p_i^2\to H_2$ is nondecreasing for all $1\le i\le n$. We can choose $d(x_1,\dots,x_n)=\Pi_1^n x_i(1-x_i)$.

An example where the Lemma fails is if $H=H(p):\mathbf{R}^2\to\mathbf{R}$ has level sets that are ellipses with no axis parallel to the normal vector Dd. To demonstrate this we consider for simplicity $\Omega=\{x=(\xi,\eta):\xi>0\}\in\mathbf{R}^2$ (hence $d(x)=\xi$ is a reasonable choice of d) and take

$$H(Du)=\hat{H}(u_\xi,u_\eta)=(u_\xi-u_\eta)^2+\frac{1}{4}(u_\xi+u_\eta)^2-1. \tag{2.14}$$

For instance, we may choose k, x_0, and z in Lemma 2.2 such that $k(x_0-z)=(0,-1)$ and get

$$H(k(x_0-z))=\hat{H}\,(0,-1)>\hat{H}(-\mu,-1)=H\left(k(x_0-z)-\mu Dd(x_0)\right) \tag{2.15}$$

for all $\mu\in(0,\frac{6}{5})$. Hence Assumption 4 fails at the line $\xi=0$ for $H=\hat{H}$.

2.1.2. Translation of the zero gradient. In Assumption 4, the value $p=0$ is always included in the region of $\mathbf{R}^n$ where $p\to H(p,x)$ has to be monotone along Dd, but such a restriction may be remedied by a translation. Consider the situation that Assumption 4 holds for the Hamiltonian $p\to H(p-m(x),x)$ and that there exists a differentiable f such that $Df=m$. Then $w(x,t)=u(x,t)+f(x)$ will solve

$$\begin{aligned} w_t+H(Dw-m(x),x)=0,\quad w(x,0)=u_0(x)+f(x)\quad \forall x\in\Omega,\\ w(x,t)=g(x)+f(x)\quad \forall x\in\partial\Omega \end{aligned} \tag{2.16}$$

in the viscosity sense.

As a special case consider $\Omega=(0,1)\in\mathbf{R}$. Then, according to the above, $H(p,0)$ must be decreasing for $p<a$ and $H(p,1)$ must be increasing for $p>b$ for some constants a and b.

3. Uniqueness, existence, and regularity. In this section we prove the following theorem.

THEOREM 3.1. *Let Assumptions* 1–4 *hold. Then there exists one and only one viscosity solution* u *of* (1.1)–(1.2) *in* $C^0(\bar{\Omega}\times[0,T])$. *Furthermore,*

$$\|u_t\|\le L_t \ \text{ and } \ \|Du\|\le L, \tag{3.1}$$

where

$$L_t=\sup_{|p|\le L_0,x\in\Omega}|H(p,x)|$$

and L *is any number such that* $H(p,x)>L_t$ *for all* $|p|>L$ *and* $x\in\Omega$.

Note that $L\ge L_0$ and that L may be finite because of the uniform coercivity condition.

We first state that it is enough to prove the theorem for problem (1.1)–(1.2) with a truncated Hamiltonian, more specifically, the problem

$$\begin{aligned} u_t + H_R(Du, x) &= 0 \qquad \forall x \in \Omega,\, t \in (0,T), \\ u(x,0) &= u_0(x), \quad x \in \bar{\Omega}, \\ u(x,t) &= g(x), \quad x \in \partial\Omega,\, 0 \le t < T, \end{aligned} \tag{3.2}$$

where $H_R(p,x) = \min(H(p,x), R)$ for some finite $R > L_t$. The advantage is that H_R is globally Lipschitz in the x-variable. Clearly the solution of (3.2) also solves the original problem (1.1)–(1.2) because of (3.1). The uniqueness statement of Theorem 3.1 follows since we also show that comparison holds for (1.1)–(1.2) provided either the subsolution or the supersolution is Lipschitz continuous. The Hamiltonian H_R satisfies Assumption 4 but not Assumption 2, and hence Proposition 2 does not apply. However, it is enough to prove Theorem 3.1 for the problem (3.2) under the explicit assumption that the solution u of (3.2) satisfies $u|_{\partial\Omega} \le g$.

The crucial point is the following comparison result.

THEOREM 3.2. *Assume Assumptions* 1 *and* 4 *hold and that one of the following assumptions holds:*

1. *Let u be a bounded subsolution and v a bounded supersolution of* (3.2)*. Let u satisfy* (2.10)*, and let $u^*|_{\partial\Omega} \le g$.*
2. *Let u be a bounded subsolution and v a bounded supersolution of* (1.1)–(1.2)*. Let u satisfy* (2.10) *and assume either u or v is Lipschitz continuous.*

Then

$$u^* \le v_* \tag{3.3}$$

in $\bar{\Omega} \times [0,T]$.

Note that provided $u^*|_{\partial\Omega} \le g$, the function $\limsup_{y \in \Omega \to x, s \in (0,T) \to t} u(y,s)$ is a subsolution. Hence the comparison result implies that given a viscosity solution u of (3.2) such that $u^*|_{\partial\Omega} \le g$, we have that u_* is in $C^0(\bar{\Omega} \times [0,T])$ and is a viscosity solution of (3.2). However, u can be discontinuous at the boundary in general.

The proof is standard due to Lemma 2.2; the only new problem is handling the boundary condition for the supersolution, which can be done quite easily.

Proof. Define

$$M = \sup(u^*(x,t) - v_*(x,t) - 2\delta t) \tag{3.4}$$

We assume $M > 0$ and proceed to show that this leads to a contradiction for any constant $\delta > 0$. Let

$$\Psi(x,t,y,s) = u^*(x,t) - v_*(y,s) - \delta(t+s) - \frac{(x-y)^2}{2\epsilon^2} - \frac{(t-s)^2}{2\epsilon^2}. \tag{3.5}$$

Let

$$(x_\epsilon, t_\epsilon, y_\epsilon, s_\epsilon) \in \left(\bar{\Omega} \times [0,T]\right)^2 \tag{3.6}$$

be a maximum point of Ψ in $\left(\bar{\Omega} \times [0,T]\right)^2$.

Then,

$$\begin{aligned} &u^*(x_\epsilon, t_\epsilon) - v_*(y_\epsilon, s_\epsilon) - \delta(t_\epsilon + s_\epsilon) - \frac{(x_\epsilon - y_\epsilon)^2}{2\epsilon^2} - \frac{(t_\epsilon - s_\epsilon)^2}{2\epsilon^2} \\ &\qquad = \Psi(x_\epsilon, t_\epsilon, y_\epsilon, s_\epsilon) \ge \Psi(x,t,x,t) \ge u^*(x,t) - v_*(x,t) - 2\delta t. \end{aligned} \tag{3.7}$$

Taking the supremum of the last expression, we see that

$$u^*(x_\epsilon, t_\epsilon) - v_*(y_\epsilon, s_\epsilon) - \delta(t_\epsilon + s_\epsilon) \geq M, \tag{3.8}$$

and by standard arguments (see, for example, [2]), and taking a subsequence if necessary, we also get

$$x_\epsilon \to x^*,\ y_\epsilon \to x^*, \quad t_\epsilon \to t^*,\ s_\epsilon \to t^*, \tag{3.9}$$

where the supremum in (3.4) is obtained at (x^*, t^*). If $x^* \in \Omega$, or if $t^* = 0$, the proof is similar to the standard case.

If $x^* \in \partial\Omega$, we need to consider the possibilities that x_ϵ or y_ϵ are in $\partial\Omega$ as $\epsilon \to 0$. The case $x_\epsilon \in \partial\Omega$ can be treated in the same way as if $x_\epsilon \in \Omega$ due to Lemma 2.2. If $y_\epsilon \in \partial\Omega$, there are essentially two cases. First, if there are arbitrarily small ϵ such that $v_*(y_\epsilon, s_\epsilon) < g(y_\epsilon)$, we may argue as above. Otherwise, we may consider ϵ such that $v_*(y_\epsilon, s_\epsilon) \geq g(y_\epsilon)$, in which case (3.8) implies

$$\begin{aligned} M &\leq u^*(x_\epsilon, t_\epsilon) - v_*(y_\epsilon, s_\epsilon) \\ &\leq u^*(x_\epsilon, t_\epsilon) - g(y_\epsilon), \quad y_\epsilon \in \partial\Omega. \end{aligned} \tag{3.10}$$

Then, by (3.9) and $u^*|_{\partial\Omega} \leq g$,

$$M \leq \limsup_{\epsilon \to 0} \{u^*(x_\epsilon, t_\epsilon) - u_0(y_\epsilon)\} \leq u^*(x^*, t^*) - u_0(x^*) \leq 0. \qquad \square \tag{3.11}$$

We can prove the existence of a viscosity solution such that $u|_{\partial\Omega} \leq g$ by a standard application of Perron's method as adapted to viscosity solutions; see, for example, [2]. Note that as a supersolution we can take $u_0(x) + 2L\text{dist}(x)$, where $\text{dist}(x)$ is the distance function to $\partial\Omega$, and as a subsolution we can take $u_0(x) - L_t t$.

From the comparison result we easily get the following.

PROPOSITION 3.3. *Let Assumptions* 1 *and* 4 *hold, and let* $u \in C^0(\bar{\Omega} \times [0, T])$ *be a viscosity solution of* (3.2) *such that* $u|_{\partial\Omega} \leq g$. *Then*

$$\|u(\cdot, t)\| \leq \|u_0\| + C_0 t, \quad C_0 = \max_{x \in \bar{\Omega}} |H(0, x)|, \tag{3.12}$$

and

$$|u(x, t) - u_0(x)| \leq L_t t. \tag{3.13}$$

Proof. This follows from $\|u_0\| + C_0 t$ and $u_0(x) + L_t t$ being supersolutions and $-\|u_0\| - C_0 t$ and $u_0(x) - L_t t$ being subsolutions. $\square$

We now turn to Lipschitz regularity.

THEOREM 3.4. *Let Assumptions* 1 *and* 4 *hold, and let* $u \in C^0(\bar{\Omega} \times [0, T])$ *be a viscosity solution of* (3.2) *such that* $u|_{\partial\Omega} \leq g$. *Then*

$$u(x, t + \tau) - u(x, t) \leq L_t \tau \tag{3.14}$$

for $\tau > 0$.

Proof. This follows from

$$\tilde{u}(x, t) = u(x, t + \tau) - L_t \tau \tag{3.15}$$

being a subsolution. This is easily seen for $t > 0$ and $x \in \Omega$, and by Proposition 3.3,

$$\tilde{u}(x, 0) = u(x, \tau) - L_t \tau \leq u_0(x). \tag{3.16}$$

Finally, at the boundary points $x \in \partial\Omega$, we have $\tilde{u}(x, t) \leq u(x, t) \leq g(x)$. $\square$

The lower bound on u_t follows similarly by

$$(x,t) \mapsto u(x,t+\tau) + L_t\tau \tag{3.17}$$

being a subsolution. A coercivity argument could also have been used for the upper bound.

The Lipschitz continuity in x follows from Assumption 2, since it implies that

$$\underline{u}(x,t) = \sup_{y\in\overline{\Omega}}\{u(y,t) - k|y-x|\} \tag{3.18}$$

is a subsolution whenever $k > L$ with L defined as in Theorem 3.1. Consider first $t = 0$. Clearly there exists y_0 such that

$$u_0(y) - k|x-y| \le \underline{u}(x,0) = u_0(y_0) - k|x-y_0|.$$

More specifically, $u_0(x) \le u_0(y_0) - k|x-y_0|$; hence, unless $y_0 = x$, we get the contradiction $k \le L_0 \le L$, so $\underline{u}(x,0) = u_0(x)$. Next, consider $\underline{u}(x,t) - \psi(x,t)$ having a maximum point (x_0,t_0) with $t_0 > 0$. Then there exists y_0 such that

$$u(y,t) - k|y-x| - \psi(x,t) \le u(y_0,t_0) - k|y_0-x_0| - \psi(x_0,t_0). \tag{3.19}$$

If $x_0 \neq y_0$, we get

$$\psi_t(x_0,t_0) + H_R\left(k\frac{x_0-y_0}{|x_0-y_0|}, y_0\right) \le 0, \tag{3.20}$$

but by the Lipschitz continuity in time $|\psi_t(x_0,t_0)| \le L_t$, which contradicts $k > L$. Hence $x_0 = y_0$, so, by (3.19),

$$\psi_t(x_0,t_0) + H_R\left(D\psi(x_0,t_0), x_0\right) \le 0. \tag{3.21}$$

Because of Lemma 2.2, this also holds if $y_0 \in \partial\Omega$.

4. The convergence result. The convergence result may now be stated. We consider a scheme $S^\lambda(\rho) : B_g \to B_g$, where B_g is a class of functions in $L^\infty(\bar{\Omega})$ such that all Lipschitz continuous functions U satisfying $U|_{\partial\Omega} \le g$ are included in B_g. Furthermore, $S^\lambda(\rho)$ is defined for all $\lambda > 0$ sufficiently small, and $0 \le \rho \le \lambda$.

We define our approximate solution $U(x,t) : \bar{\Omega}\times[0,T] \to \mathbf{R}$ inductively by setting

$$U(x,0) = u(x,0), \quad x \in \bar{\Omega}, \tag{4.1}$$

and for $t \in (t_n, t_{n+1})$, where $t_n = n\Delta t$ with $0 \le \Delta t \le \lambda$:

$$U(x,t) = S^\lambda(t-t_n)U(\cdot,t_n)(x), \quad x \in \bar{\Omega}. \tag{4.2}$$

The time step Δt must be chosen such that for $\rho < \Delta t$, $S^\lambda(\rho)$ satisfies the following conditions:

1.

$$\left\|S^\lambda(\rho)U\right\| \le \|U\| + \tilde{C}_0\rho \tag{4.3}$$

for a constant $\tilde{C}_0$ independent of λ.

2.

$$\left\|S^\lambda(\rho)U - U\right\| \leq C_S(\|DU\|)\rho, \tag{4.4}$$

where $C_S(\cdot) \in C^0 : \mathbf{R}_0^+ \to \mathbf{R}_0^+$ and independent of λ.

3. Let $\psi(x) = \frac{k}{2}(x-z)^2 + K$ and $\theta(x) = -\frac{k}{2}(x-z)^2 + K$ for some $z \in \bar{\Omega}$ and constants $k, K \geq 0$. Then there is a $C > 0$ such that the following holds for all $x \in \Omega$: given $U \in B_g$, we have either that

$$\frac{(S^\lambda(\rho)\theta)_*(x) - \theta(x)}{\rho} + H(D\theta, x) \geq -C\left(1 + \|D\theta\| + \left\|D^2\theta\right\|\right)\lambda \tag{4.5}$$

whenever $\theta \leq U$ or that $(\xi, \tau) \to S^\lambda(\tau)U(\xi)$ is a supersolution of (1.1) in a neighborhood of (x, ρ).

4. There exists an operator $S_b^\lambda : L^\infty(\bar{\Omega}) \to L^\infty(\bar{\Omega})$ such that for any $U \in B_g$, $S^\lambda(\rho)U \leq S_b^\lambda(\rho)U$ and

$$S^\lambda(\rho)U(x) = \min\left(g(x), S_b^\lambda(\rho)U(x)\right) \quad \forall\, x \in \partial\Omega. \tag{4.6}$$

Furthermore, S_b^λ satisfies

$$\begin{aligned} &\frac{(S_b^\lambda(\rho)\theta)_*(x) - \theta(x)}{\rho} + H(D\theta(x), x) \geq -C\left(1 + \|D\theta\| + \left\|D^2\theta\right\|\right)\lambda, \\ &\frac{(S_b^\lambda(\rho)\psi)^*(x) - \psi(x)}{\rho} + H(D\psi(x), x) \leq C\left(1 + \|D\psi\| + \left\|D^2\psi\right\|\right)\lambda \end{aligned} \tag{4.7}$$

for all $x \in \bar{\Omega}$.

5. S^λ and S_b^λ are monotone in the sense that if $U_1(x) \leq U_2(x)$ for all $x \in \bar{\Omega}$, then

$$S^\lambda(\rho)U_1(x) \leq S^\lambda(\rho)U_2(x) \quad \text{and} \quad S_b^\lambda(\rho)U_1(x) \leq S_b^\lambda(\rho)U_2(x)$$

for all $x \in \bar{\Omega}$.

6. S^λ is also monotone in g in the following sense: for any function $\bar{g} \geq g$, there exists an operator $S_{\bar{g}}^\lambda : B_{\bar{g}} \to B_{\bar{g}}$ with $B_g \subseteq B_{\bar{g}}$ such that the above assumptions hold with g replaced by $\bar{g}$, and

$$S^\lambda(\rho)U \leq S_{\bar{g}}^\lambda(\rho)U \tag{4.8}$$

for any $U \in B_g$.

7. There exists $L_S \geq L_0$ such that one of the following two conditions holds: (i) For all $y \in \partial\Omega$ and $k \geq L_S$,

$$S_{\bar{g}}^\lambda(\rho)[\, g(y) + k|x-y|] \;\leq\; g(y) + k|x-y|, \tag{4.9}$$

where $\bar{g}$ here denotes $k|x-y| + g(y)$ restricted to $\partial\Omega$. (ii) We have the Lipschitz estimate

$$\left\|DS^\lambda(\rho)U\right\| \leq \|DU\| + L_S(1 + \|DU\|)\rho. \tag{4.10}$$

Our main result follows.

THEOREM 4.1. *Let Assumptions* 1–4 *hold. Then* $U(x,t)$ *converges uniformly to the unique viscosity solution* u *of* (1.1)–(1.2) *in* $C^0(\bar{\Omega}\times[0,T])$, *and*

$$|U(x,t)-u(x,t)| \le K(\lambda^{\frac{1}{2}}+\lambda) \quad \forall (x,t)\in \bar{\Omega}\times[0,T] \tag{4.11}$$

for a constant K *given by* $\|u_0\|, C, C_0, \tilde{C}_0, C_{2L}, C_S(L_0), L_t, L, L_S,$ *and* T.

Requiring both monotonicity and (4.7) means that schemes like S^λ exist only for a certain class of Hamiltonians and domains. However, this class should coincide reasonably well with the one specified by Assumption 4, since S_b^λ needs to be consistent only for gradients of the form $k(x-z)$ for which H is monotone. Unfortunately, Lemma 2.2 does not translate directly to a corresponding lemma for approximations.

Before proving the theorem, we show how monotonicity and consistency of S^λ imply that U is in a sense almost a sub- and a supersolution (at least with respect to the test functions we consider).

LEMMA 4.2. *Define*

$$\psi(x,t)=\frac{k}{2}(x-z)^2+\eta(t)$$

with $k\ge 0$, $z\in\bar{\Omega}$, *and* $\eta\in C^2([0,T])$. *If* $U^*(x,t)-\psi(x,t)$ *has a global maximum in* $(x_0,t_0)\in\bar{\Omega}\times(0,T]$ *for* $t_0>0$, *then*

$$\eta_t(x_0,t_0)+H(k(x_0-z),x_0)\le \big(\|\eta_{tt}\|+C(1+k\,\mathrm{diam}(\Omega)+k)\big)\lambda, \tag{4.12}$$

where $\mathrm{diam}(\Omega)=\sup_{x,y\in\Omega}|x-y|$.

Proof. By assumption,

$$U(x,t_n)\le U^*(x,t_n)\le \psi(x,t_n)+U^*(x_0,t_0)-\psi(x_0,t_0). \tag{4.13}$$

We may assume that $\psi(x_0,t_0)=U^*(x_0,t_0)$, since only the derivatives of ψ are relevant. Monotonicity of S_b^λ then implies

$$S^\lambda(t_0-t_n)U(\cdot,t_n)(x)\le S_b^\lambda(t_0-t_n)\psi(\cdot,t_n)(x)+U^*(x_0,t_0)-\psi(x_0,t_0) \tag{4.14}$$

with $t_n<t_0\le t_{n+1}$. If we take the upper semicontinuous envelope on both sides, and set $x=x_0$, this becomes

$$0\le [S_b^\lambda(t_0-t_n)\psi(\cdot,t_n)]^*(x_0)-\psi(x_0,t_0), \tag{4.15}$$

which can be rewritten as

$$0\le \frac{[S_b^\lambda(t_0-t_n)\psi(\cdot,t_n)]^*(x_0)-\psi(x_0,t_n)}{t_0-t_n}+\frac{\psi(x_0,t_n)-\psi(x_0,t_0)}{t_0-t_n}, \tag{4.16}$$

and hence from consistency (4.7):

$$\begin{aligned} 0\le&\frac{[S_b^\lambda(t_0-t_n)\psi(\cdot,t_n)]^*(x_0)-\psi(x_0,t_0)}{t_0-t_n}-\psi_t(x_0,t_0)-\|\psi_{tt}\|(t_0-t_n)\\ \le&-H(D\psi(x_0,t_0),x_0)-\psi_t(x_0,t_0)+\|\psi_{tt}\|\lambda+C(1+\|D\psi\|+\|D^2\psi\|)\lambda. \end{aligned} \tag{4.17}$$

□

Analogously, we have the next lemma.

LEMMA 4.3. *Let $\theta(x,t) = -\frac{k}{2}(x-z)^2 + \eta(t)$ with $k \geq 0$, $z \in \bar{\Omega}$, and $\eta \in C^2[0,T]$, and let $U_*(y,s) - \theta(y,s)$ have a global minimum in $(y_0,s_0) \in \bar{\Omega} \times (0,T]$. Assume also $U(y_0,s_0) < g(y_0)$ if $y_0 \in \partial\Omega$. Then*

$$\theta_s(y_0,s_0) + H(D\theta(y_0,s_0),y_0) \geq -\Big(\|\theta_{ss}\| + C\left(1 + \|D\theta\| + \left\|D^2\theta\right\|\right)\Big)\lambda. \tag{4.18}$$

Note that in the case $y_0 \in \partial\Omega$ and $U(y_0,s_0) = g(y_0)$, this fails to hold. However, then the Lipschitz type estimate (4.22) given below is sufficient for our purpose.

Proof. Following the arguments (4.14)–(4.17) (note that we have $U(x,t_n) \geq \theta(x,t_n)$), we get

$$\begin{aligned} 0 \geq & -H(D\theta(0,s_0),0) - \theta_s(0,s_0) \\ & - \|\theta_{ss}\|\,(s_0 - s_n) - C(1 + \|D\theta\| + \left\|D^2\theta\right\|)\lambda. \end{aligned} \tag{4.19}$$

For $y_0 \in \partial\Omega$, use (4.7) instead of (4.5). □

Before proving Theorem 4.1, we need some regularity estimates on U at the boundary and initially.

PROPOSITION 4.4. *Let U be defined by (4.1)–(4.2). Then, for all $(x,t) \in \bar{\Omega} \times [0,T]$ and $y \in \partial\Omega$,*

$$|U(x,t)| \leq \|u_0\| + C_0 t, \tag{4.20}$$

$$|U(x,t) - u_0(x)| \leq C_S(L_0)t, \tag{4.21}$$

$$U^*(x,t) \leq g(y) + \tilde{L}_S|x-y|, \tag{4.22}$$

where $\tilde{L}_S \in [0,\infty)$ is given by L_0, L_S, and T.

Proof. We first prove (4.21). The proof of (4.20) is similar and easier. Clearly this holds for $t \leq \Delta t$. Assume for induction that

$$U(x,t_n) \geq u_0(x) - C_S(L_0)t_n.$$

Then, for $t_n < t \leq t_{n+1}$,

$$\begin{aligned} U(x,t) &= S^\lambda(t-t_n)U(\cdot,t_n)(x) \geq S^\lambda(t-t_n)[u_0 - C_S(L_0)t_n](x) \\ &\geq u_0(x) - C_S(L_0)t, \end{aligned} \tag{4.23}$$

since $\|D(u_0 - C_S(L_0)t_n)\| \leq L_0$. To prove the opposite inequality, assume that $U(x,t_n) \leq u_0(x) + C_S(L_0)t_n$. Now, S^λ applied to the right-hand side is not defined since $(u_0 + C_S(L_0)t_n)|_{\partial\Omega} > g$. However, taking $\bar{g} = g + C_S(L_S)T$, we can use (4.8) to get

$$\begin{aligned} U(x,t) &= S^\lambda(t-t_n)U(\cdot,t_n)(x) \leq S^\lambda_{\bar{g}}(t-t_n)U(\cdot,t_n)(x) \\ &\leq S^\lambda_{\bar{g}}(t-t_n)[u_0 + C_S(L_0)t_n](x) \leq u_0(x) + C_S(L_0)t, \quad t_n < t \leq t_{n+1}, \end{aligned} \tag{4.24}$$

which is the desired estimate.

To prove (4.22) we start with the inequality

$$u_0(x,t) \leq k|x-y| + g(y), \tag{4.25}$$

where $k \geq L_S \geq L_0$. If (4.9) holds, we get that

$$S^\lambda(\rho)u_0(x,t) \leq S^\lambda_{\bar{g}}(\rho)u_0(x,t) \leq S^\lambda_{\bar{g}}(\rho)(k|x-y| + g(y)) \leq k|x-y| + g(y), \tag{4.26}$$

where $\bar{g}$ denotes $k|x-y|+g(y)$ restricted to $\partial\Omega$. It hence follows by induction that

$$U^*(x,t) \le g(y) + L_S|x-y|. \tag{4.27}$$

If on the other hand the assumption (4.10) holds, we get that

$$\|DU\| \le (L_0+1)\exp L_S t - 1. \tag{4.28}$$

To see this, observe that (4.10) applied inductively constitutes an Euler approximation to the ordinary differential equation $\|U_x\|_t = L_S(1+\|U_x\|)$. From this the result holds with

$$\tilde{L}_S = (L_0+1)\exp L_S T - 1. \qquad \square \tag{4.29}$$

4.1. Proof of Theorem 4.1. For completeness, we include the whole doubling of variables argument, although most of it is standard procedure due to Lemmas 4.2 and 4.18. The exception comes when we have a supersolution assuming the boundary condition strongly, in which case we use the regularity of u or (4.22).

We want to estimate $U(x,t)-u(x,t)$ from above first, so we define

$$M = \sup(U^*(x,t)-u(x,t)) \tag{4.30}$$

and assume $M>0$. From here we follow the doubling of variables strategy as in [11] or [16]. Let

$$\Psi(x,t,y,s) = U^*(x,t) - u(y,s) - \frac{(x-y)^2}{2\epsilon^2} - \frac{(t-s)^2}{2\epsilon^2} - \frac{t+s}{4T}M. \tag{4.31}$$

By upper semicontinuity Ψ attains a maximum in $\left(\bar{\Omega}\times[0,T]\right)^2$. Let

$$(x_0,t_0,y_0,s_0) \in \left(\bar{\Omega}\times[0,T]\right)^2 \tag{4.32}$$

be this maximum point.

Then we have

$$\begin{aligned} &U^*(x_0,t_0) - u(y_0,s_0) - \frac{(x_0-y_0)^2}{2\epsilon^2} \\ &\qquad \ge \Psi(x_0,t_0,y_0,s_0) \ge \Psi(x,t,x,t) \ge U^*(x,t) - u(x,t) - \frac{M}{2}. \end{aligned} \tag{4.33}$$

Taking the supremum of the last expression, we see that

$$U^*(x_0,t_0) - u(y_0,s_0) \ge M/2. \tag{4.34}$$

Using the Lipschitz continuity of u, we can show that

$$|x_0-y_0| \le 2L\epsilon^2, \quad |t_0-s_0| \le \left(L_t + \frac{R}{2T}\right)\epsilon^2 \tag{4.35}$$

with $R = \|u_0\| + \max(C_0,\tilde{C}_0)T$. Clearly, $|\frac{t_0-s_0}{2\epsilon^2} - \frac{M}{4T}| \le L_t$ by (3.1), and hence the last estimate follows from $M \le 2R$. To see the first, note that

$$u(y_0,s_0) + \frac{(x_0-y_0)^2}{2\epsilon^2} \le u(x_0,s_0), \tag{4.36}$$

which gives

$$\frac{(x_0-y_0)^2}{2\epsilon^2} \le u(x_0,s_0)-u(y_0,s_0) \le L|x_0-y_0|. \tag{4.37}$$

In the following let

$$\begin{aligned}\theta(y,s) &= -\frac{(x_0-y)^2}{2\epsilon^2}-\frac{(t_0-s)^2}{2\epsilon^2}-\frac{t_0+s}{4T}M,\\ \psi(x,t) &= \frac{(x-y_0)^2}{2\epsilon^2}+\frac{(t-s_0)^2}{2\epsilon^2}+\frac{t+s_0}{4T}M\end{aligned} \tag{4.38}$$

and observe that

$$D\theta(y_0,s_0)=D\psi(x_0,t_0) \quad \text{and} \quad |D\psi(x_0,t_0)|\le 2L. \tag{4.39}$$

Since u is a supersolution, and $u-\theta$ takes its minimum at (y_0,s_0),

$$\theta_s(y_0,s_0)+H(\theta(y_0,s_0),y_0)\ge 0 \tag{4.40}$$

unless $y_0\in\partial\Omega$ and $u(y_0,s_0)=g(y_0)$. Lemma 4.2 applies for $U^*-\psi$, so

(4.41)

$$\begin{aligned}\frac{M}{2T} &= \psi_t(x_0,t_0)-\theta_t(y_0,t_0)\\ &\le -H(D\psi(x_0,t_0),x_0)+H(D\theta(y_0,s_0),y_0)+\left(\frac{1}{\epsilon^2}+C\left(1+\frac{\operatorname{diam}(\Omega)}{\epsilon^2}+\frac{1}{\epsilon^2}\right)\right)\lambda\\ &\le C_{2L}|x_0-y_0|+\left(\frac{1}{\epsilon^2}+C\left(1+\frac{\operatorname{diam}(\Omega)}{\epsilon^2}+\frac{1}{\epsilon^2}\right)\right)\lambda\\ &\le C_{2L}2L\epsilon^2+\frac{1+C(1+\operatorname{diam}(\Omega)+\epsilon^2)}{\epsilon^2}\lambda\end{aligned}$$

whenever $t_0,s_0>0$.

If $t_0=0$ or $s_0=0$ we may use (3.1), (4.21), (4.34), and (4.35) to prove

(4.42)

$$M\le\left(C_S(L_0)\left(L_t+\frac{R}{T}\right)+2L_0L\right)\epsilon^2 \quad \text{or} \quad M\le\left(L_t\left(L_t+\frac{R}{T}\right)+2L_0L\right)\epsilon^2.$$

We consider $t_0\ge 0$ and $s_0=0$, which gives the first inequality of (4.42). The second is similar. From (4.34) we have

$$M/2\le U^*(x_0,t_0)-u(y_0,0)=U^*(x_0,t_0)-u_0(y_0). \tag{4.43}$$

Hence

$$M/2\le |U^*(x_0,t_0)-u_0(x_0)|+|u_0(x_0)-u_0(y_0)|\le C_S(L_0)t_0+L_0|x_0-y_0|, \tag{4.44}$$

which implies the first inequality by (4.35).

It remains to consider the case $y_0\in\partial\Omega$ and $u(y_0,s_0)=g(y_0)=u_0(y_0)$. From (4.34), (4.22), and (4.35) we have

$$\begin{aligned}M/2 &\le U^*(x_0,t_0)-u(y_0,s_0)\le u_0(y_0)+\tilde{L}_S|x_0-y_0|-u_0(y_0)\\ &\le 2\tilde{L}_SL\epsilon^2.\end{aligned} \tag{4.45}$$

Putting these estimates together and setting $\epsilon = \lambda^{1/4}$ gives

$$M \le K\Big(\|u_0\|, L_0, L, L_S, C, C_0, \tilde{C}_0, C_{2L}, L_t, C_S(L_0), T\Big)(\lambda^{\frac{1}{2}} + \lambda). \tag{4.46}$$

To estimate $U - u$ from below we consider

$$\Psi(x,t,y,s) = u(x,t) - U_*(y,s) - \frac{(x-y)^2}{2\epsilon^2} - \frac{(t-s)^2}{2\epsilon^2} - \frac{t+s}{4T}M \tag{4.47}$$

and use essentially the same argument.

5. Example. The proposed abstract scheme is not of much value if a numerically (or theoretically) useful one does not exist. In this section we will develop a Godunov-type scheme for an important example.

We will make the additional assumption on H that there exists $M_R > 0$ such that

$$|H(p,x) - H(q,x)| \le M_R|p-q| \qquad \forall x \in \bar{\Omega},\ \{p,q \in R^n :\ |p|,|q| \le R\}. \tag{5.1}$$

Also, we replace Assumption 1 with the existence of a $C_H \ge 0$ such that

$$|H(p,x) - H(p,y)| \le C_H(1+|p|)|x-y|; \tag{5.2}$$

however, we use this only for deriving a global bound on $|DU|$. Several monotone schemes for the Cauchy problem are given in [15]. Among them the Godunov scheme seems the most convenient to generalize to boundary problems.

5.1. One spatial dimension. Let us first concentrate on the one-dimensional case $\Omega = (0,1)$, $g(x) = 0$. The mapping $p \to H(p,x)$ is assumed to have a unique local minimum at $p = 0$ for all x. The Godunov scheme $\hat{S}^h(\rho)$ is defined here by

$$\hat{S}^h(\rho)u(x) = u(x) - \rho\hat{H}(\delta^- u(x), \delta^+ u(x), x) \tag{5.3}$$

for $h \le x \le 1-h$, where

$$\hat{H}(\alpha,\beta,x) = \begin{cases} \min_{\alpha \le p \le \beta} H(p,x), \alpha \le \beta, \\ \max_{\beta \le p \le \alpha} H(p,x), \beta \le \alpha, \end{cases} \tag{5.4}$$

and we have employed the one-sided difference operators

$$\delta^- u(x) = \frac{u(x) - u(x-h)}{h}, \quad \delta^+ u(x) = \frac{u(x+h) - u(x)}{h}. \tag{5.5}$$

More explicitly, for the Hamiltonian we study

$$\hat{H}(\alpha,\beta,x) = \begin{cases} H(\alpha,x), & \alpha,\beta \ge 0, \\ H(\beta,x), & \alpha,\beta > 0, \\ H(0,x), & \alpha < 0 < \beta, \\ \max(H(\alpha,x), H(\beta,x)), & \beta < 0 < \alpha. \end{cases} \tag{5.6}$$

At $x = 0$, we take

$$\hat{S}^h(\rho)u(0) = \min\left(u(0) - \rho H^-(\delta^+ u(0), 0),\ 0\right), \tag{5.7}$$

where $H^-(p,x) = H(\min(0,p),x) = \hat{H}(0,p,x)$. At $x=1$ we similarly take

$$\hat{S}^h(\rho)u(1) = \min\left(u(1) - \rho H^+(\delta^- u(1),1),\ 0\right), \tag{5.8}$$

where $H^+(p,x) = H(\max(0,p),x) = \hat{H}(p,0,x)$.

In order to use the convergence theory, we need to define $\hat{S}^h$ for all $0 \le x \le 1$. We will do this by extending u to $[-h, 1+h]$ and then applying the interior operator given by (5.3), from now on denoted by $\hat{S}_0^h$. We consider only $x=0$; the case $x=1$ is entirely similar.

We let $u(x) = u(0)$ for $-h \le x < 0$. This choice implies that $\hat{S}_0^h(\rho)u(0) = \hat{S}^h(\rho)u(0)$ whenever $\hat{S}^h(\rho)u(0) < 0$. The scheme $\hat{S}_0^h$ then satisfies all conditions of Theorem 4.1 except (4.6) and (4.9). In order to take the boundary condition into account, we take for $0 \le x < h$

$$\hat{S}^h(\rho)u(x) = \min\left(\hat{S}_0^h(\rho)u(x), \hat{L}_S x\right), \quad \tilde{L}_S = L_0 = \max\left(\|(u_0)_x\|, p_0\right). \tag{5.9}$$

If $\hat{S}_0^h(\rho)u(x) > \hat{L}_S x$, we can use that $\hat{L}_S x$ is a supersolution to (1.1). We can let B_g consist only of functions $u(x) \le U_S$ with $U_S(x) = \hat{L}_S \min(x, 1-x)$, since $u_0(x) \le U_S$, and $\hat{S}^h(\rho)U_S \le U_S$.

PROPOSITION 5.1. *The approximation scheme $\hat{S}^h : C^{0,1}([0,1]) \to C^{0,1}$ satisfies the conditions of Theorem* 4.1 *with $\lambda = h$, $C_S(L) = \sup_{|p|\le L,\, x\in\Omega} |H(p,x)|$, $\tilde{C}_0 = C_0, L_S = L_0$, provided*

$$\Delta t M_R \le h \quad \textit{for} \quad R = \|u_x\|. \tag{5.10}$$

Furthermore

$$\left\|(\hat{S}^h u)_x\right\| \le \max(\|u_x\|, L_0) + C_H\left(1 + \max(\|u_x\|, L_0)\right)\Delta t. \tag{5.11}$$

Proof. This result is standard except for the Lipschitz continuity (5.11). For that we need the next lemma.

LEMMA 5.2. *The Godunov Hamiltonian $\hat{H}$ satisfies*

$$|\hat{H}(\alpha,\beta,y) - \hat{H}(\alpha,\beta,x)| \le C_H(1 + \max(|\alpha|,|\beta|))|y-x|. \tag{5.12}$$

This follows easily from (5.4). Using our extension of u to $[-h,1+h]$, we first find a bound $\|(\hat{S}_0^h u)_x\|$ for the interior operator $\hat{S}_0^h$ for all $x \in [0,1]$. Define the translation operator τ_δ by $\tau_\delta u(x) = u(x+\delta)$. By Lemma 5.2

$$|\tau_\delta \hat{S}_0^h u(x) - \hat{S}_0^h \tau_\delta u(x)| \le C_H\left(1 + \max(\|u_x\|, p_0)\right)\Delta t\delta \tag{5.13}$$

whenever $x, x+\delta \in [0,1]$. Also $\hat{S}_0^h$ commutes with addition of constants ($\hat{S}_0^h(u+k) = \hat{S}_0^h(u)+k$), which from $u \le v + \|u-v\|$ and monotonicity implies $\|\hat{S}_0^h u - \hat{S}_0^h v\| \le \|u-v\|$. We can then conclude

$$\begin{aligned} |\hat{S}_0^h u(x+\delta) - \hat{S}_0^h u(x)| &\le |\hat{S}_0^h \tau_\delta u(x) - \hat{S}_0^h u(x)| + |\tau_\delta \hat{S}_0^h u(x) - \hat{S}_0^h \tau_\delta u(x)| \\ &\le \|u(x+\delta) + u(x)\| + C_H\left(1 + \max(\|u_x\|, p_0)\right)\Delta t\delta. \end{aligned} \tag{5.14}$$

The estimate (5.11) then follows immediately. ∎

As these considerations demonstrate, finding a scheme with the right properties in the vicinity of the boundary is a theoretical, but not computational, problem. For

the analysis, we just need to know that a monotone and consistent scheme exists everywhere.

We conclude as follows.

PROPOSITION 5.3. *Let $\Omega = (0,1)$, and let the mapping $p \to H(p,x)$ have a unique minimum at $p = 0$ for all x. Then (1.1)–(1.2) has a unique viscosity solution u in $C^0(\bar{\Omega} \times [0,T])$. Furthermore, the scheme $\hat{S}^h$ defines an approximation $U(x,t)$ such that $\|U - u\| \le O(\sqrt{h})$ if the CFL-condition $\Delta t M_R \le h$ holds with*

$$R = \|U_x(\cdot,t)\| \le (L_0 + 1)\exp C_H t - 1. \tag{5.15}$$

The estimate on (5.15), U_x, follows from (5.11). Observe that (5.11) applied inductively constitutes an Euler approximation to the ordinary differential equation

$$\max(\|U_x\|, L_0)_t = C_H(1 + \max(\|U_x\|, L_0)).$$

5.2. Two spatial dimensions. We will try to produce a two-dimensional example scheme using the same strategy. Consider now the spatial variables $(x,y) \in \Omega = (0,1)^2$ and a Hamiltonian

$$H(u_x, u_y) = h(u_x^2, u_y^2), \tag{5.16}$$

where h is increasing in both variables. Assumption 4 then clearly holds. As boundary condition we consider $g(x) = 0$. The Godunov scheme may be generalized to

$$\hat{S}^h(\rho)u = u - \rho\hat{H}(\delta_x^- u, \delta_x^+ u, \delta_y^- u, \delta_y^+ u) \tag{5.17}$$

with

$$\hat{H}(p_-,p_+,q_-,q_+) = \begin{cases} \min_{q_- \le q \le q_+} & \begin{cases} \min_{p_- \le p \le p_+} H(p,q), & p_- \le p_+ \\ \max_{p_+ \le p \le p_-} H(p,q), & p_+ \le p_- \end{cases}, q_- \le q_+, \\ \max_{q_+ \le q \le q_-} & \begin{cases} \min_{p_- \le p \le p_+} H(p,q), & p_- \le p_+ \\ \max_{p_+ \le p \le p_-} H(p,q), & p_+ \le p_- \end{cases}, q_+ \le q_-. \end{cases} \tag{5.18}$$

For the H given here, this becomes

$$\hat{H}((p_-,p_+,q_-,q_+) = H(p,q), \tag{5.19}$$

where

$$p = \begin{cases} p_+, & p_-, p_+ \le 0, \\ p_-, & p_-, p_+ \ge 0, \\ 0, & p_- < 0 < p_+, \\ \max(p_-,p_+), & p_+ < 0 < p_-, \end{cases} \qquad q = \begin{cases} q_+, & q_-, q_+ \le 0, \\ q_-, & q_-, q_+ \ge 0, \\ 0, & q_- < 0 < q_+, \\ \max(q_-,q_+), & q_+ < 0 < q_-. \end{cases} \tag{5.20}$$

At the boundaries we may simply replace the undefined finite differences with 0 in $\hat{H}$. That is,

$$\hat{S}_b^h(\rho)u = u - \rho \begin{cases} \hat{H}(0, \delta_x^+ u, \delta_y^- u, \delta_y^+ u), & x = 0,\ 0 < y < 1, \\ \hat{H}(\delta_x^- u, 0, \delta_y^- u, \delta_y^+ u), & x = 1,\ 0 < y < 1, \\ \hat{H}(\delta_x^- u, \delta_x^+ u, 0, \delta_y^+ u), & y = 0,\ 0 < x < 1, \\ \hat{H}(\delta_x^- u, \delta_x^+ u, \delta_y^- u, 0), & y = 1,\ 0 < x < 1, \end{cases} \tag{5.21}$$

and take

$$\hat{S}^h = \min(0, \hat{S}_b^h). \tag{5.22}$$

At the corners we have even less information, so we take

$$\hat{S}_b^h(\rho)u = u - \rho \begin{cases} \hat{H}(0, \delta_x^+ u, 0, \delta_y^+ u), & x = 0,\ y = 0, \\ \hat{H}(\delta_x^- u, 0, 0, \delta_y^+ u), & x = 1,\ y = 0, \\ \hat{H}(\delta_x^- u, 0, \delta_y^- u, 0), & x = 1,\ y = 1, \\ \hat{H}(0, \delta_x^+ u, \delta_y^- u, 0), & x = 0,\ y = 1. \end{cases} \tag{5.23}$$

This defines an approximation for $(x, y) \in [h, 1-h]^2 \cup \partial\Omega$. As in one dimension we need to do some work near the boundary. However, our strategy there carries over straightforwardly.

Given a function $u(x, y)$ defined on $[0, 1]^2$, we want to extend u to $(x, y) \in [-h, 0) \times [0, 1]$. We set $u(x, y) = u(0, y)$ there, and similarly around the rest of Ω, and apply the interior operator $\hat{S}_0^h$. In order to take the boundary condition into account, we take for $0 \le x < h$

$$\hat{S}^h(\rho)u(x, y) = \min\left(\hat{S}_0^h(\rho)u(x, y),\, \hat{U}_S(x, y)\right) \tag{5.24}$$

with

$$\hat{U}_S(x, y) = \hat{L}_S \min(x, y, 1-x, 1-y), \qquad \hat{L}_S = L_0 = \max(p_0, L_0), \tag{5.25}$$

which is a supersolution to (1.1)–(1.2). Since $\hat{S}^h(\rho)U_S \le U_S$, and $u_0 \le U_S$, we can let B_g only consist of functions such that $u \le U_S$. We may use the same method as in one dimension to estimate $\|D\hat{S}^h(\rho)u\|$.

Now we can conclude that the conditions of Theorem 4.1 also holds in this case, hence the next proposition.

PROPOSITION 5.4. *Let $\Omega = (0, 1)^2$ and H be defined by* (5.16). *Then* (1.1)–(1.2) *has a unique viscosity solution u in $C^0(\bar{\Omega} \times [0, T])$. Furthermore, the scheme $\hat{S}^h$ defines an approximation $U(x, t)$ such that $\|U - u\| \le O(\sqrt{h})$ if the CFL-condition $\Delta t C_{CFL} \le h$ holds for*

$$C_{CFL} = \max_{|p| \le \|U_x\|,\, |q| \le \|U_y\|} \left(|H_p(p, q)| + |H_q(p, q)| \right) \tag{5.26}$$

with

$$\max\left(\|U_x\|, \|U_y\|\right) \le (L_0 + 1) \exp C_H t - 1. \tag{5.27}$$

5.3. Numerical results. This two-dimensional scheme was implemented and tested. The domain was still $\Omega = (0, 1)^2$, while H and the boundary conditions varied. Some effects specific to the Cauchy–Dirichlet problem were noted, but in all cases we found that the error is governed by already well-known numerical phenomena.

5.3.1. Elliptic paraboloid. As an illustrative example, we chose $H(u_x, u_y) = u_x^2 + \frac{1}{4}u_y^2 - 1$ and $u_0(x, y) = -2u_s(x)$, where u_s is the stationary solution given by $u_s = \min(x, 1-x, 2y, 2(1-y))$. Figure 5.1 shows the results with discretization parameters

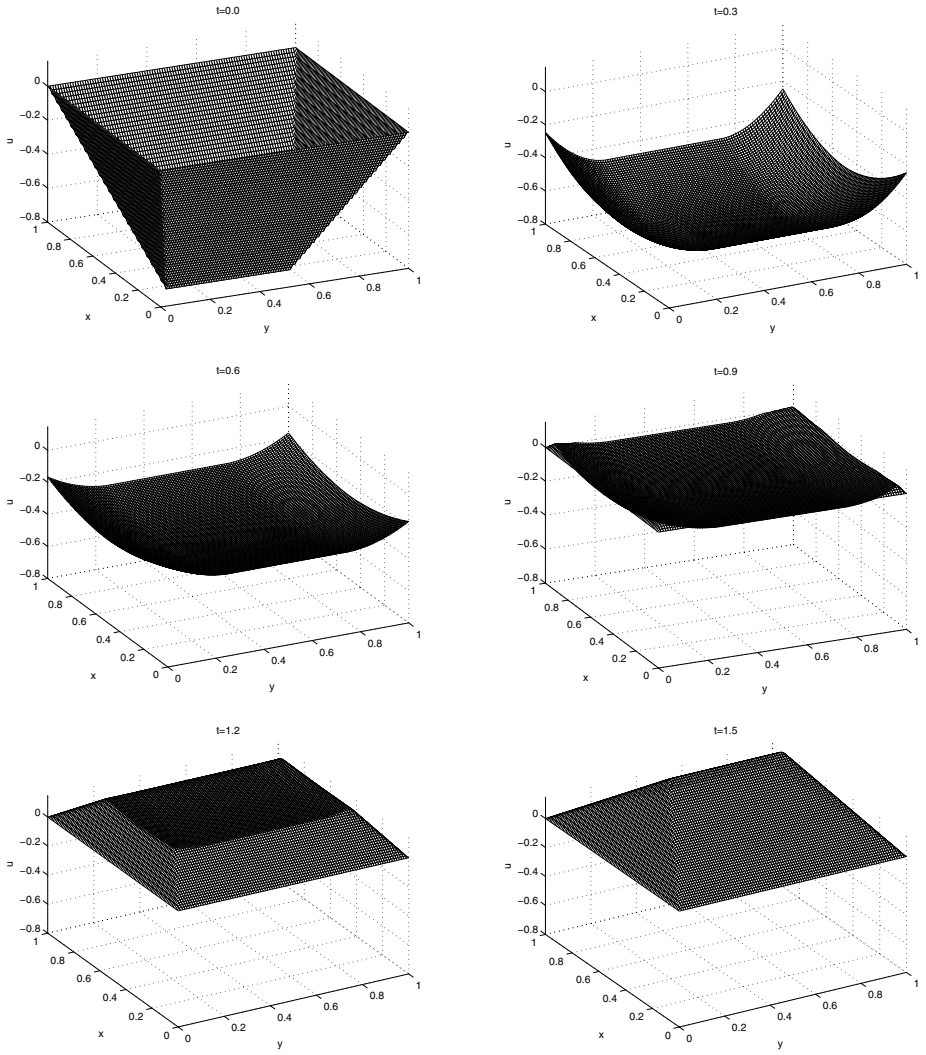

FIG. 5.1.

$h = 0.01$ and $\Delta t = \frac{h}{5}$. At first U satisfies the boundary condition only weakly, but at $t = 1.7$ it has reached the approximate stationary solution. The results look reasonable, and there is no sign that the weak boundary statement adds significantly to the error expected for a pure Cauchy or pure Dirichlet problem.

5.3.2. Piecewise linear H. The Hamiltonian $H(p,q) = |p| + |q| - 1$ allows simple explicit solutions. First, $u_s = \min(x, 1-x, y, (1-y))$ is the stationary solution. Starting with $u_0 = -u_s$, the solution will be $u(x,y,t) = \max(u_0(x,y), t - 0.5)$ until $t = 0.5$, as shown in Figure 5.2 to the left. At most points this is easy to check, but it should be proved for the line segment given by $x = y$ and $x \le 0.5$. At $x < t - 0.5$, it follows by the subdifferential

$$D^- u(x,x,t) = \{(p,q) : |p| + |q| = 1, q \le 0, p \le 0\}. \tag{5.28}$$

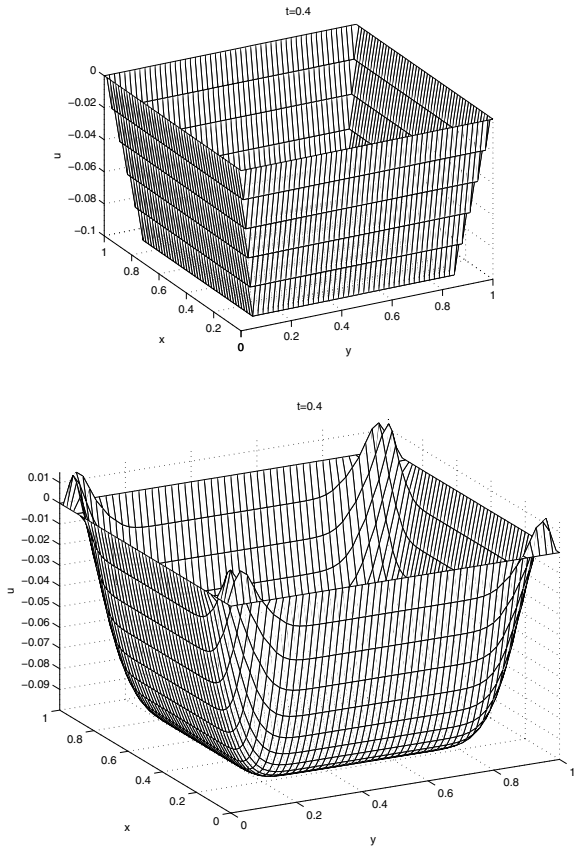

FIG. 5.2.

At $x = y = t - 0.5 = \hat{x}$, we have

$$u(\hat{x},\hat{x},t) - \psi(\hat{x},\hat{x},t) \le u(\hat{x}+h,\hat{x}+h,t-h) - \psi(\hat{x}+h,\hat{x}+h,t-h), \tag{5.29}$$

implying

$$\psi(\hat{x}+h,\hat{x}+h,t-h) - \psi(\hat{x},\hat{x},t) \le -h. \tag{5.30}$$

Letting $h \to 0$, we can conclude that

$$-\psi_x(\hat{x},t) - \psi_y(x_h,t) + \psi_t(\hat{x},t) - 1 \ge 0. \tag{5.31}$$

Obviously, $D^- u(\hat{x},\hat{x},t) \subseteq (-\infty,0)^2$, and hence the supersolution condition holds. In the numerical experiments, however, numerical smoothing causes the stationary solution u_s to appear prematurely near the corners. On the right in Figure 5.2 this is seen for $h = 0.02$ and $t = 0.01$.

With more grid points, the area where this effect occurs shrinks. Hence, the pointwise error is eventually unaffected by the boundary. Figure 5.3 shows one corner from a simulation with $h = 0.0025$ and $\Delta t = h/2$. These data were simulated for several h (with $\Delta t = h/2$), and the $\log_2$-values of the maximal error over the grid points at $t = 0.4$ are given in Table 5.1. The numbers fit well with the theoretical convergence rate of $\frac{1}{2}$.

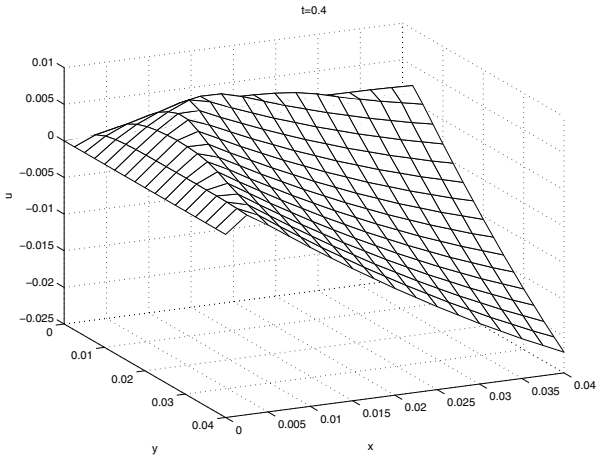

FIG. 5.3.

TABLE 5.1

h	Maximal error over grid	Observed convergence rate
0.04	0.0705	-
0.02	0.0501	0.493
0.01	0.0356	0.493
0.005	0.0252	0.498
0.0025	0.0178	0.502

5.3.3. Numerical diffusion of boundary values. Let $H(p,q) = |p| + |q| - 1$ as above. Then $u_s = \min(x,y)$ is a stationary solution if also $g(x,y) = \min(x,y)$. Figure 5.4 shows a simulation with u_s as initial data. The discretization parameters were $h = 0.02$ and $\Delta t = 0.01$. Due to numerical smoothing at the line $x = y$, the Dirichlet condition is not strongly satisfied in the discrete case.

FINITE ELEMENT APPROXIMATION OF THE FAST DIFFUSION AND THE POROUS MEDIUM EQUATIONS*

CARSTEN EBMEYER† AND W. B. LIU‡

Abstract. The fast diffusion equation $u_t = \Delta(|u|^{m-1}u)(0 < m < 1)$ and the porous medium equation $(1 < m < \infty)$ are studied in a parabolic cylinder $\Omega \times (0, T)$. A fully discrete Galerkin approximation is considered using C^0-piecewise linear finite elements in space and the backward Euler time discretization. A priori error estimates in quasi norms and rates of convergence are proved.

Key words. error estimates, fully discrete Galerkin scheme, free boundary problem, fast diffusion, slow diffusion, porous media

1. Introduction.

Let $\Omega \subset \mathbb{R}^d$, $d \geq 2$, be a bounded polyhedral domain and $T < \infty$. In this paper we are concerned with the finite element approximation of the degenerate parabolic equation

$$\begin{aligned} &u_t = \Delta(|u|^{m-1}u) && \text{in } \Omega \times (0, T], \\ &u(x, t) = 0 && \text{on } \partial\Omega \times (0, T], \\ &u(x, 0) = u_0(x) && \text{in } \Omega, \end{aligned} \tag{1.1}$$

where $u(x, t) : \Omega \times [0, T] \to \mathbb{R}$. We treat the *fast diffusion* case $(0 < m < 1)$ and the *slow diffusion* case $(1 < m < \infty)$, that is, the fast diffusion equation and the porous medium equation. We consider a fully discrete Galerkin approximation using C^0-piecewise linear finite elements in space and the backward Euler discretization in time. Our aim is to prove a priori error estimates and rates of convergence.

We may rewrite (1.1) in the form $u_t = \operatorname{div}(m|u|^{m-1}\nabla u)$. In the fast diffusion case $(0 < m < 1)$, the modulus of ellipticity $m|u|^{m-1}$ blows up whenever u vanishes. Hence, the fast diffusion equation is a singular equation. The following phenomenon is known: Each weak solution decays to zero in some finite time; see, e.g., [5, 9]. In particular, weak solutions may have singularities near $\partial\Omega$ or at the extinction time.

The porous medium equation $(1 < m < \infty)$ is not uniformly elliptic as it degenerates at unknown points where $u = 0$. An interesting feature is that the support of $u(\cdot, t)$ has a free boundary with a finite speed of propagation; see, e.g., [6, 33]. The porous medium equation is used to model a process obeying a Darcy law. It is one of the prototypes of degenerate parabolic equations modeling a free boundary with a finite speed of propagation. Further typical examples are the parabolic p–Laplace equation for $2 < p < \infty$,

$$u_t = \operatorname{div}(|\nabla u|^{p-2}\nabla u), \quad u|_{\partial\Omega} = 0, \quad u(x, 0) = u_0(x),$$

or the doubly nonlinear parabolic equations; cf. [14, 15, 16] and the references given therein. Even if the data are smooth, the free boundary may have singularities. In particular, weak solutions are not smooth at the free boundary.

For such degenerate or singular equations many existing techniques in the finite element method do not work well. The orders of a priori error bounds are frequently suboptimal and often tend to zero when the equations' parameters (like m) approximate some special values like zero or ∞. Furthermore, there are gaps between the regularities required for deriving error bounds and the known regularity achievable for sufficiently smooth data; see section 4 for more detailed explanations. In this sense all the known a priori estimates for (1.1) are suboptimal. First error estimates for fully discrete schemes for the porous medium equation can be found in [30]; regularization or linearization procedures are used in [28, 30] and [20, 21, 27, 29]; schemes for the degenerate equation itself are considered in [1, 12, 22, 31]. Semidiscretizations in time for the porous medium equation and the fast diffusion equation are studied in [17] and [23, 24]; fully discrete schemes for the fast diffusion equation are discussed in [22, 31]. We will give more detailed reviews later.

In this paper we introduce a quasi norm and prove a priori error estimates of the finite element approximation error in this quasi norm. Further, due to new regularity results in fractional order spaces (see [13]), for suitable data we obtain, for example, the convergence rate

$$\left(\int_0^T \int_\Omega |u-U||w-W|\right)^{\frac{1}{2}} + \left\| \int_0^T (w-W) \right\|_{H^1(\Omega)} \le c(\tau+h),$$

where $w := |u|^{m-1}u$, U and W are finite element approximations of u and w, τ is the step size, and h is the mesh size.

Such a quasi norm naturally arises in degenerate problems. In fact, the quasi-norm approach is one of the significant developments in error estimation for degenerate equations. For example, it provides optimal error estimates for the p-Laplacian; cf. [2, 3, 10, 14].

The outline of this paper is as follows. In section 2 the assumptions on the data are given and some properties of weak solutions are discussed. The discrete problem is stated in section 3. The quasi norm is introduced in section 4, and some useful inequalities are shown. The a priori error estimates are proved in section 5, and the convergence rate is estimated in section 6.

2. The continuous problem. The following assumptions are made on the data.

(H1) $\Omega \subset \mathbb{R}^d$, $d \ge 2$, is a bounded, convex polyhedral domain.

(H2) $\partial\Omega = \bigcup_{1\le k\le M} \overline{\Gamma_k}$, where each Γ_k is a $(d-1)$-dimensional polyhedron, and $\Gamma_i \cap \Gamma_k = \emptyset$ for $i \ne k$.

(H3) $\partial\Gamma_{k1} \cap \ldots \cap \partial\Gamma_{kj} = \emptyset$ if $j > d$ and $k_1 < \cdots < k_j$ (that is, there are at most d adjacent faces Γ_k).

(H4) $u_0 \in L^\infty(\Omega)$.

We call $u(x,t)$ a weak solution of (1.1) if

$$u \in L^\infty(0,T;L^\infty(\Omega)), \quad |u|^{m-1}u \in L^2(0,T;W_0^{1,2}(\Omega)),$$

and

$$-\int_0^T \int_\Omega u\,\varphi_t + \int_0^T \int_\Omega \nabla(|u|^{m-1}u)\nabla\varphi = \int_\Omega u_0\varphi_0 \tag{2.1}$$

for all $\varphi \in L^2(0,T;W_0^{1,2}(\Omega)) \cap W^{1,1}(0,T;L^1(\Omega))$ satisfying $\varphi(\cdot,T) \equiv 0$ in Ω, where $\varphi_0 := \varphi(\cdot,0)$.

It is well known that under these assumptions there exists a unique weak solution; see, e.g., [18]. Let us note that $u \in L^\infty(0,T;L^\infty(\Omega))$ follows from a comparison argument [18]. Now we discuss the regularity of the weak solution under the assumption that $w_0 \in L^\infty(\Omega) \cap H_0^1(\Omega)$, where $w := |u|^{m-1}u$. It is known that

$$w \in L^\infty(0,T;W^{1,2}(\Omega)) \qquad \forall m > 0 \tag{2.2}$$

and

$$\partial_t(|u|^{\frac{m-1}{2}}u) \in L^2(0,T;L^2(\Omega)) \qquad \forall m > 0; \tag{2.3}$$

see [18]. Further, in [13] it is shown that

$$\int_0^t w(\cdot,\tau)dt \in L^\infty(0,T;W^{2,2}(\Omega)) \qquad \forall m > 0; \tag{2.4}$$

thus, $\int_\Omega(\int_0^T \Delta w)^2 < \infty$. Furthermore, in [13] regularity of w in fractional order Nikolskii spaces $\mathcal{N}^{s,p}(\Omega)$ is proved: It holds that

$$w \in L^{\frac{m+1}{m}}(0,T;\mathcal{N}^{\frac{2m}{m+1},\frac{m+1}{m}}(\Omega)) \qquad \forall m \in (0,1) \tag{2.5}$$

and

$$w \in L^{\frac{m+1}{m}}(\delta,T;\mathcal{N}^{\frac{2m}{m+1},\frac{m+1}{m}}(\Omega)) \qquad \forall m > 1, \forall \delta > 0 \quad \text{if } u_0 \geq 0. \tag{2.6}$$

Moreover, in [4] it is shown that

$$w \in L^{\frac{m+1}{m}-\varepsilon}(\delta,T;W^{2,\frac{m+1}{m}-\varepsilon}(\Omega)) \qquad \forall \delta,\varepsilon > 0 \tag{2.7}$$

if $m > 1$ and $u_0 \geq 0$. This is an L^p-property of the second derivatives of w.

Remark. The imbedding theorem of Nikolskii spaces into Sobolev spaces

$$\mathcal{N}^{s,p}(\Omega) \to W^{s-\varepsilon,p}(\Omega) \qquad \forall \varepsilon > 0$$

implies regularity in fractional order Sobolev spaces. For instance, from (2.5) it follows that $w \in L^{\frac{m+1}{m}}(0,T;W^{\frac{2m}{m+1}-\varepsilon,\frac{m+1}{m}}(\Omega))$ for all $\varepsilon > 0$ if $m < 1$.

3. The discrete problem. We deal with a fully discrete scheme using continuous piecewise linear finite elements in space and the backward Euler time discretization. Let $\tau > 0$ be the step size of the time steps. We use the notation $t_n = n\tau (n = 0,\dots,N)$, $T = t_N$, $I_n = (t_{n-1},t_n)$, $v_n(x) = v(x,t_n)$, $\bar{v}^0(x) = v_0(x)$, and

$$\bar{v}^n(x) = \tau^{-1}\int_{I_n} v(x,s)ds \qquad \text{for } n \geq 1.$$

The domain Ω is a polyhedral domain. Let T_h be a family of decompositions of Ω into closed d-simplices where h denotes the mesh-size. We suppose that T_h is a regular triangulation; i.e., the intersection of two nondisjoint nonidentical elements of T_h is a common vertex or edge or surface, and there is a constant $c > 0$ such that

$$|K| \geq c(\operatorname{diam} K)^d$$

for all simplices $K \in T_h$. We introduce the space

$$S_h(\Omega) = \{\phi_h \in C^0(\overline{\Omega}) : \phi_h \text{ is piecewise linear w.r.t. } T_h, \phi_h = 0, \text{ on } \partial\Omega\}.$$

Let $\Pi_h v \in S_h$ denote the C^0-piecewise linear interpolant of the function v. Further, let $P_h : H^1(\Omega) \to S_h$ be the H^1-projection onto S_h defined by

$$(\nabla(v - P_h v), \nabla\chi) = 0 \qquad \forall \chi \in S_h.$$

Now we define the finite element approximation, Let $w := |u|^{m-1}u$. Thus, $\partial_t u = \Delta w$, and, in fact,

$$\partial_t \psi(w) = \Delta w, \tag{3.1}$$

where $\psi(s) := |s|^{\frac{1-m}{m}} s$ $(s \in \mathbb{R})$. Let the functions $W_n \in S_h$, $n = 1, 2, \ldots$, be the solutions of the algebraic system

$$\left(\frac{\psi(W_n) - \psi(W_{n-1})}{\tau}, \chi_n\right) + (\nabla W_n, \nabla\chi_n) = 0 \qquad \forall \chi \in S_h, \tag{3.2}$$

where $W_0 := \psi^{-1}(\Pi_h \psi(w_0))$.

Thus, the functions $W_n(x)$ are successively defined for $n = 0, 1, \ldots$, we now define the finite element approximation $W(x,t)$ of $w(x,t)$ by setting

$$W(x,t) = \begin{cases} W_0(x) & \text{if } t = 0, \\ W_n(x,t) & \text{if } t \in (t_{n-1}, t_n], 1 \le n \le N. \end{cases} \tag{3.3}$$

Let us note that the function $W(x,t)$ is piecewise constant with respect to t and discontinuous in t at the time points $t_0, \ldots, t_{N-1}$.

We conclude this section by proving the following results concerning existence, uniqueness, and regularity of W.

LEMMA 3.1. *There exist unique functions $W_1, \ldots, W_N \in S_h$ solving* (3.2).

Proof. Due to the theory of monotone operators it is easy to see that there exist solutions W_n for each $n \ge 1$; cf. [32]. Moreover, the functions W_n are unique. Indeed, suppose that W_n and $\hat{W}_n (n \ge 1)$ are solutions of (3.2). Putting $\chi_n = \tau^2 \sum_{k=n}^N (W_k - \hat{W}_k)$ in (3.2) and summing up it follows that

$$\tau \sum_{n=1}^N (\psi(W_n) - \psi(\hat{W}_n), W_n - \hat{W}_n) \le \left(\psi(W_0) - \psi(\hat{W}_0), \tau \sum_{k=1}^N (W_k - \hat{W}_k)\right).$$

Noting that $\psi(W_0) = \psi(\hat{W}_0)$,

$$(\psi(W_n) - \psi(\hat{W}_n), W_n - \hat{W}_n) \ge c \left\| \psi(W_n) - \psi(\hat{W}_n) \right\|_{L^{m+1}(\Omega)}^{\frac{m+1}{m}}$$

if $m > 1$, and

$$(\psi(W_n) - \psi(\hat{W}_n), W_n - \hat{W}_n) \ge c \left\| W_n - \hat{W}_n \right\|_{L^{\frac{m+1}{m}}(\Omega)}^{\frac{m+1}{m}}$$

if $0 < m < 1$, the uniqueness follows. ∎

LEMMA 3.2. *It holds that*

$$\sup_{1 \le n \le N} \|W_n\|_{L^{\frac{m+1}{m}}(\Omega)}^{\frac{m+1}{m}} + \tau \sum_{n=1}^N \|\nabla W_n\|_{L^2(\Omega)}^2 \le c.$$

Proof. Multiplying the nth equation of (3.2) by $\chi_n = W_n$ and summing over n, we get

$$\sum_{n=1}^{N}(\psi(W_n), W_n) + \tau\sum_{n=1}^{N}(\nabla W_n, \nabla W_n) = \sum_{n=1}^{N}(\psi(W_{n-1}), W_n).$$

Young's inequality yields $|\psi(W_{n-1})Wn| \le \frac{1}{m+1}|W_{n-1}|^{\frac{1}{m+1}} + \frac{m}{m+1}|W_n|^{\frac{m+1}{m}}$. Noting that $\psi(W_n)W_n = |W_n|^{\frac{m+1}{m}}$, we obtain

$$\tfrac{1}{m+1}\|W_N\|_{\frac{m+1}{m}}^{\frac{m+1}{m}} + \tau\sum_{n=1}^{N}\|\nabla W_n\|_2^2 \le \tfrac{1}{m+1}\|W_0\|_{\frac{m+1}{m}}^{\frac{m+1}{m}}.$$

Clearly, $\|W_0\|_{\frac{m+1}{m}} \le c$. Thus, the assertion follows. ∎

4. A quasi norm and motivations. We first try to explain why for degenerate problems only suboptimal error estimates (either a priori or a posteriori) can be obtained via the standard approaches. Let, for instance,

$$a(u,v) = \int_\Omega (|\nabla u|^{p-2}\nabla u, \nabla v),\ (f,v) = \int_\Omega fv.$$

Then the weak formulation of the p–Laplace equation reads

$$a(u,v) = (f,v) \qquad \forall v \in W_0^{1,p}(\Omega).$$

In order to obtain optimal error estimates, the standard approaches depend on the facts (in the underlaying space norm)

$$a(u,u-v) - a(v,u-v) \ge c\|u-v\|^2,$$

$$|a(u,w) - a(v,w)| \le C\|u-v\|\|w\|,$$

which may be true for the nondegenerate equations but are untrue for the degenerate equations; see [7] and [26].

The so called *quasi-norm approach* looks for a quasi norm $|u-v|_u$ (or its power), which often depends on the solutions u to measure the approximation error so that

$$a(u,u-v) - a(v,u-v) \ge c|u-v|_u^2 \tag{4.1}$$

and

$$|a(u,w) - a(v,w)| \le C(\gamma|u-v|_u^2 + \delta(\gamma)|w|_w^2) \qquad \forall\gamma > 0. \tag{4.2}$$

This implies that

$$a(u,u-v) - a(v,u-v) \cong |u-v|_u^2.$$

With this quasi norm one can derive sharp a priori and a posteriori error estimates. For instance, one has the following basic a priori error bound for the finite element approximation of the p-Laplacian (see [2]):

$$|u-u_h|_u \le \inf_{v_h\in V^h} C|u-v_h|_u. \tag{4.3}$$

Then one can further obtain sharp error estimates with different norms; see [25] and [26]. For example, in the case of the p-Laplacian it is known (cf. [26]) that for all $x, y \in \mathbb{R}^n$

$$(|x|^{p-2}x - |y|^{p-2}y, x - y) \geq c(|x| + |x - y|)^{p-2}|x - y|^2,$$

$$||x|^{p-2}x - |y|^{p-2}||x - y)| \leq C(|x| + |x - y|)^{p-2}|x - y|^2.$$

This is the motivation for introducing the following quasi norm:

$$|u - v|_u^2 = \int_\Omega (|\nabla u| + |\nabla(u - v)|)^{p-2}|\nabla(u - v)|^2,$$

and with some technical inequalities one can show (4.1)–(4.2).

Deriving explicit sharp error bounds from (4.3) is often nontrivial as it needs sharp interpolation error estimates in the quasi norms, which are quite technical to obtain. Moreover, error bounds of the optimal order can be obtained only under sufficient regularity assumptions for the solutions. However, for degenerate PDEs like the p-Laplacian, regularities have upper limits, and higher regularity may not be achievable even for infinitely smooth data; see [2]. In [14], from (4.3) we obtained the optimal estimates in terms of both error order and regularity requirements via the quasi-norm approach. Let u and u_h be the solution of the p-Laplacian and its piecewise linear finite element approximation, respectively. Then

$$|u - u_h|_u^2 \leq Ch^2 \int_\Omega |\nabla u|^{p-2}|D^2 u|^2,$$

where the right integral is finite for sufficiently smooth data. In the same manner, for the parabolic p-Laplacian very recently it was shown that

$$||u - U||^2_{L^\infty(I,L^2(\Omega))} + \int_0^T |u - U|_u^2 dt \leq C(\tau^2 + h^2)$$

under appropriate assumptions on the data; cf. [10].

In order to treat the fast diffusion and the porous medium equation, we shall apply a similar idea to derive some a priori error bounds in a quasi norm, which is defined as follows: For $v_1, v_2 \in L^p(\Omega)$ and $p > 1$ let

$$||v_2||^2_{(v_1,p)} := \int_\Omega (|v_1| + |v_2|)^{p-2}|v_2|^2.$$

This is a quasi norm. In fact, it holds that $||v_2||_{(v_1,p)} \geq 0$, $||v_2||_{(v_1,p)} = 0$ if and only if $v_2 = 0$, and $||v_1 + v_2||_{(v_3,p)} \leq c(||v_1||_{(v_3,p)} + ||v_2||_{v_3,p})$ for any $v_1, v_2, v_3 \in L^p(\Omega)$.

Furthermore, it is easy to see that

$$c||v_2||^p_{L^p(\Omega)} \leq ||v_2||_{(v_1,p)} \leq ||v_2||^{p/2}_{L^p(\Omega)} \qquad \text{for } 1 < p < 2$$

and

$$||v_2||^{p/2}_{L^p(\Omega)} \leq ||v_2||_{(v_1,p)} \leq c'||v_2||^p_{L^p(\Omega)} \qquad \text{for } 2 < p < \infty,$$

Where $c, c' > 0$ are constants depending on $||v_1||_{L^p(\Omega)}$ and $||v_2||_{L^p(\Omega)}$.

In particular, we have (see Lemma 4.2 below)

$$\int_0^T \|w-v\|^2_{(w,\frac{m+1}{m})} \cong \int_0^T (\psi(w)-\psi(v), w-v)$$

$$\cong \int_0^T \|\psi(w)-\psi(v)\|^2_{(\psi(w),m+1)} = \int_0^T \|u-\psi(v)\|^2_{(u,m+1)} \tag{4.4}$$

for all $v \in L^{\frac{m+1}{m}}(\Omega\times[0,T])$, where $u=\psi(w)$.

Let us prove some useful inequalities. We write $A(r,s) \cong B(r,s)$ if there are constants $0<c_1<c_2$ independent of r and s such that $c_1A(r,s) \le B(r,s) \le c_2A(r,s)$.

LEMMA 4.1. *For all $r,s\in\mathbb{R}$ there hold the equivalences*

$$(\psi(r))-\psi(s))(r-s) \cong (|r|+|s|)^{\frac{1-m}{m}}|r-s|^2 \tag{4.5}$$

$$\cong \left||r|^{\frac{1-m}{2m}}r - |s|^{\frac{1-m}{2m}}s\right|^2. \tag{4.6}$$

Proof. Utilizing the Taylor expansion, we get

$$(\psi(r)-\psi(s))(r-s) = |r-s|^2\int_0^1 \psi(tr+(1-t)s)dt.$$

In view of the fact that (see [19])

$$\int_0^1 |tr+(1-t)s|^{\frac{1-m}{m}}dt \cong (|r|+|s|)^{\frac{1-m}{m}}, \tag{4.7}$$

the equivalence (4.5) follows.

Next, let $\phi(s) := |s|^{\frac{1-m}{m}}s$. The Taylor expansion yields

$$\phi(r)-\phi(s) = (r-s)\int_0^1 \phi'(tr+(1-t)s)dt.$$

It is easy to see that $\phi'(s)\cong|s|^{\frac{1-m}{2m}}$ for all $s\in\mathbb{R}$. Noting that $\int_0^1 tr+(l-t)s)|^{\frac{1-m}{2m}}dt \cong (|r|+|s|)^{\frac{1-m}{2m}}$, we obtain the equivalence (4.6). ∎

LEMMA 4.2. *For all $v_1,v_2\in L^{\frac{m+1}{m}}(0,T;L^{\frac{m+1}{m}}(\Omega))$ it holds that*

$$\int_0^T \|v_1-v_2\|^2_{(v_1,\frac{m+1}{m})} \cong \int_0^T (\psi(v_1)-\psi(v_2), v_1-v_2) \tag{4.8}$$

$$\cong \int_0^T \|\psi(v_1)-\psi(v_2)\|^2_{(\psi(v_1),m+1)}. \tag{4.9}$$

Proof. Utilizing the Taylor expansion and (4.7), we obtain for $r,s\in\mathbb{R}$

$$|\psi(r)-\psi(s)| \cong (|r|+|s|)^{\frac{1-m}{m}}|r-s|.$$

Noting that $(|r|+|s|)\cong(|r|+|r-s|)$, we get

$$(\psi(r)-\psi(s))(r-s) \cong (|r|+|r-s|)^{\frac{1-m}{m}}|r-s|^2.$$

Due to

$$\int_0^T \|v_1 - v_2\|^2_{(v_1, \frac{m+1}{m})} = \int_0^T \int_\Omega (|v_1| + |v_1 - v_2|)^{\frac{1-m}{m}} |v_1 - v_2|^2$$

the equivalence (4.8) follows.

Next, let $\bar{r} = \psi(r)$ and $\bar{s} = \psi(s)$. Then $(\psi(r) - \psi)(s))(r - s) = (\bar{r} - \bar{s})$ $(\psi^{-1}(\bar{r}) - \psi^{-1}(\bar{s}))$, where $\psi^{-1}(\bar{r}) = |\bar{r}|^{m-1}\bar{r}$. Arguing as above, we deduce equivalence (4.9). ∎

LEMMA 4.3. *There is a Constant c such that*

$$\begin{aligned} &(\psi(r_1) - \psi(r_3))(r_1 - r_3) \\ &\le c[(\psi(r_1) - \psi(r_2))(r_1 - r_2) + (\psi(r_2) - \psi(r_3))(r_2 - r_3)] \end{aligned} \tag{4.10}$$

for all $r_1, r_2, r_3 \in \mathbb{R}$.

Proof. The triangle inequality yields

$$\begin{aligned} &\left| |r_1|^{\frac{1-m}{2m}} r_1 - |r_3|^{\frac{1-m}{2m}} r_3 \right|^2 \\ &\le c\left(\left| |r_1|^{\frac{1-m}{2m}} r_1 - |r_2|^{\frac{1-m}{2m}} \right|^2 + \left| |r_2|^{\frac{1-m}{2m}} r_2 - |r_3|^{\frac{1-m}{2m}} r_3 \right|^2 \right). \end{aligned}$$

Due to (4.5) and (4.6) we obtain the assertion. ∎

LEMMA 4.4. *For any $\delta > 0$ there is a constant c_δ such that for all $r_1, r_2, r_3 \in \mathbb{R}$*

$$\begin{aligned} |\psi(r_1) - \psi(r_2)||r_1 - r_3| &\le \delta(\psi(r_1) - \psi(r_2))(r_1 - r_2) \\ &\quad + c_\delta(\psi(r_1) - \psi(r_3))(r_1 - r_3). \end{aligned} \tag{4.11}$$

Proof. It is well known that

$$(s_1 + s_2)^q s_2 s_3 \le \delta(s_1 + s_2)^q s_2^2 + c_\delta(s_1 + s_3)^q s_3^2$$

for all $s_1, s_2, s_3 \ge 0$ and $q > -1$; see, e.g., [3]. Putting $s_1 = |r_1|$, $s_2 = |r_1 - r_2|$, and $s_3 = |r_1 - r_3|$ and noting that

$$|\psi(r) - \psi(s)| \cong (|r| + |r - s|)^{\frac{1-m}{m}} |r - s|$$

the assertion follows. ∎

Let us conclude this section by discussing some approximation properties of quasi norms. Consider the elliptic problem

$$\psi(v) - \Delta v = f \quad \text{in } \Omega, \qquad v = 0 \quad \text{on } \partial\Omega,$$

where f is sufficiently smooth. Clearly, there is a unique weak solution satisfying

$$(\psi(v), \varphi) + (\Delta v, \Delta\varphi) = (f, \varphi) \qquad \forall \varphi \in W_0^{1,2}(\Omega). \tag{4.12}$$

Let $V \in S_h$ be the finite element approximation given by

$$(\psi(V), \chi) + (\nabla V, \nabla\chi) = (f, \chi) \qquad \forall \chi \in S_h. \tag{4.13}$$

Then there is a constant independent of h such that

$$\begin{aligned} &\|v - V\|^2_{(v, \frac{m+1}{m})} + \|\nabla v - \nabla V\|^2_{L^2(\Omega)} \\ &\le c \inf_{v_h \in S_h} \left(\|v - v_h\|^2_{(v, \frac{m+1}{m})} + \|\nabla v - \nabla v_h\|^2_{L^2(\Omega)} \right). \end{aligned} \tag{4.14}$$

This may be seen as follows. Let us choose $\varphi = \chi$ in (4.12). Taking the difference between (4.12) and (4.13), we get

$$(\psi(v) - \psi(V), \chi) + (\nabla v - \nabla V, \nabla \chi) = 0. \tag{4.15}$$

Let $v_h \in S_h$ be arbitrary. Utilizing (4.15), we deduce

$$\begin{aligned}&(\psi(v) - \psi(V), v - V) + (\nabla v - \nabla V, \nabla v - \nabla V)\\ &= (\psi(v) - \psi(V), v - v_h) + (\nabla v - \nabla V, \nabla v - \nabla v_h).\end{aligned}$$

Inequality (4.11) implies that

$$(\psi(v) - \psi(V), v - v_h) \le \delta(\psi(v) - \psi(V), v - V) + c_\delta(\psi(v) - \psi(v_h), v - v_h).$$

Further, we have

$$(\nabla v - \nabla V, \nabla v - \nabla v_h) \le \delta(\nabla v - \nabla V, \nabla v - \nabla V) + c_\delta(\nabla v - \nabla v_h, \nabla v - \nabla v_h).$$

Thus (4.14) follows. Therefore, *V is the best approximation of v with respect to the quasi norm* $(\|\cdot\|^2_{(v,\frac{m+1}{m})} + |\cdot|^2_{W^{1,2}(\Omega)})^{\frac{1}{2}}$.

5. The a priori error estimate. The aim of this section is to prove an a priori error estimate of $w - W$ in a suitable quasi norm. Our result is as follows.

THEOREM 5.1. *For any $m > 0$ there is a constant c independent of h and τ such that*

$$\begin{aligned}&\int_0^T \|w - W\|^2_{(w,\frac{m+1}{m})} + \|\nabla(\bar w - \overline{W})\|^2_{L^2(\Omega)}\\ &\le c\left(\sum_{n=1,}^{N}\int_{I_n}\|w_n - w\|^2_{(w,\frac{m+1}{m})} + \int_0^T \|w - P_h w\|^2_{(w,\frac{m+1}{m})}\right.\\ &\qquad \left. + \left\|\tau\sum_{n=1}^{N}(\nabla \bar w^n - \nabla P_h \bar w^n)\right\|^2_{L^2(\Omega)} + \|\psi(w_0) - \Pi_h\psi(w_0)\|^2_{L^2(\Omega)}\right),\end{aligned}$$

where $\bar w(x) = \int_0^T w(x,t)dt$ and $\overline{W}(x) = \int_0^T W(x,t)dt$.

Proof. Integrating (3.1) over I_n, we find

$$\tau^{-1}(\psi(w_n) - \psi(w_{n-1})) - \Delta \bar w^n = 0. \tag{5.1}$$

Let $\chi_n \in S_h$. We multiply (5.1) and (3.2) by $\tau\chi_n$, take the difference, and sum over n. We get

$$\sum_{n-1}^{N}(\psi(w_n) - \psi(W_n) - (\psi(w_{n-1}) - \psi(W_{n-1})), \chi_n) + \sum_{n=1}^{N}\tau(\nabla \bar w^n - \nabla W_n, \nabla \chi n) = 0.$$

Utilizing the identity $\sum_{n=1}^{N}(a_n - a_{n-1})b_n = a_N b_N - a_0 b_0 + \sum_{n=o}^{N-1} a_n(b_n - b_{n+1})$, we obtain

$$\begin{aligned}&(\psi(w_N) - \psi(W_N), \chi_N) + \sum_{n=0}^{N-1}(\psi(w_n) - \psi(W_n), \chi_n - \chi_{n+1})\\ &\quad + \sum_{n=1}^{N}\tau(\nabla \bar w^n - \nabla W_n, \nabla \chi_n) = (\psi(w_0) - \psi(W_0), \chi_0).\end{aligned}$$

We put $\chi_n = \tau \sum_{k=n}^{N} (P_h \bar{w}^k - \Pi_h W_k)$ for $0 \le n \le N$. Let us note that $\Pi_h W_k = W_k$ for all $k \ge 1$ and $\chi_n - \chi_{n+1} = \tau(P_h \bar{w}^n - \Pi_h W_n)$. We get

$$\begin{aligned}
&\tau \sum_{n=0}^{N} (\psi(w_n) - \psi(W_n), P_h \bar{w}^n - \Pi_h W_n) \\
&\quad + \tau \sum_{n=1}^{N} (\nabla \bar{w}^n - \nabla W_n, \tau \sum_{k=n}^{N} (\nabla P_h \bar{w}^k - \nabla W_k)) \\
&= (\psi(w_0) - \psi(W_0), \tau \sum_{n=0}^{N} (P_h \bar{w}^n - \Pi_h W_n)). \qquad (5.2)
\end{aligned}$$

Now we subtract $\tau(\psi(w_0) - \psi(W_0), P_h \bar{w}^0 - \Pi_h W_0)$ on both sides of (5.2). Notice that

$$\begin{aligned}
(\psi(w_n) - \psi(W_n), P_h \bar{w}^n - W_n) &= (\psi(w_n) - \psi(W_n), P_h \bar{w}^n - w_n) \\
&\quad + (\psi(w_n) - \psi(W_n), w_n - W_n).
\end{aligned}$$

Further, in view of the identity

$$\sum_{n=1}^{N} \left(a_n \sum_{k=n}^{N} a_k \right) = \frac{1}{2} \left(\sum_{n=1}^{N} a_n \right)^2 + \frac{1}{2} \sum_{n=1}^{N} (a_n)^2$$

and the fact that P_h is the H^1-projection, we have

$$\begin{aligned}
&\tau \sum_{n=1}^{N} \left(\nabla \bar{w}^n - \nabla W_n, \tau \sum_{k=n}^{N} (\nabla P_h \bar{w}^k - \nabla W_k) \right) \\
&= \tau \sum_{n=1}^{N} \left(\nabla P_h \bar{w}^n - \nabla W_n, \tau \sum_{k=n}^{N} (\nabla P_h \bar{w}^k - \nabla W_k) \right) \\
&\ge \frac{1}{2} \int_\Omega \left| \tau \sum_{n=1}^{N} (\nabla P_h \bar{w}^n - \nabla W_n) \right|^2.
\end{aligned}$$

Hence, from (5.2) we deduce that

$$\begin{aligned}
J_1 + J_2 &:= \tau \sum_{n=1}^{N} (\psi(w_n) - \psi(W_n), w_n - W_n) + \frac{1}{2} \int_\Omega \left| \tau \sum_{n=1}^{N} (\nabla P_h w^n - \nabla W_n) \right|^2 \\
&\le \tau \sum_{n=1}^{N} (\psi(w_n) - \psi(W_n), w_n - P_h \bar{w}^n) \\
&\quad + (\psi(w_0) - \psi(W_0), \tau \sum_{n=1}^{N} (P_h \bar{w}^n - W_n)) \\
&=: J_3 + J_4. \qquad (5.3)
\end{aligned}$$

Utilizing inequality (4.11), we find

$$J_3 = \sum_{n=1}^{N} \int_{I_n} (\psi(w_n) - \psi(W_n), w_n - P_h w)$$

$$\begin{aligned}&\le \delta \sum_{n=1}^{N} \int_{I_n} (\psi(w_n) - \psi(W_n), w_n - W_n) \\ &\quad + c_\delta \sum_{n=1}^{N} \int_{I_n} (\psi(w_n) - \psi(P_h w), w_n - P_h w) \\ &=: J_{31} + J_{32}.\end{aligned}$$

For $\delta > 0$ sufficiently small we may absorb J_{31} into the left-hand side of (5.3). Due to (4.10) we get

$$J_{32} \le c \left[\sum_{n=1}^{N} \int_{I_n} (\psi(w_n) - \psi(w), w_n - w) + \sum_{n=1}^{N} \int_{I_n} (\psi(w) - \psi(P_h w), w - P_h w) \right].$$

Further, Hölder's and Young's inequalities yield for $\delta > 0$

$$J_4 \ge c_\delta \|\psi(w_0) - \psi(W_0)\|^2_{L^n(\Omega)} + \delta \left\| \tau \sum_{n=1}^{N} (P_h \bar{w}^n - W_n) \right\|^2_{L^2(\Omega)}.$$

Due to Poincaré's inequality we may absorb $\delta \|\tau \sum (P_h \bar{w}^n - W_n)\|_2^2$. Moreover, noting that $\psi(W_0) = \Pi_h \psi(w_0)$ it holds that $\|\psi(w_0) - \psi(W_0)\|_2^2 = \|\psi(w_0) - \Pi_h \psi(w_0)\|_2^2$. Next, inequality (4.10) yields

$$(\psi(w) - \psi(w_n), w - W_n) \le c[(\psi(w) - \psi(w_n), w - w_n) + (\psi(w_n) - \psi(W_n), w_n - W_n)];$$

hence,

$$J_1 \ge c \left(\sum_{n=1}^{N} \int_{I_n} (\psi(w) - \psi(W_n), w - W_n) - \sum_{n=1}^{N} \int_{I_n} (\psi(w) - \psi(w_n), w - w_n) \right).$$

Further, we estimate

$$\begin{aligned}J_2 &= \frac{1}{2} \int_\Omega \left| \tau \sum_{n=1}^{N} (\nabla P_h \bar{w}^n - \nabla W_n) \right|^2 \\ &\ge \frac{1}{4} \int_\Omega \left| \tau \sum_{n=1}^{N} (\nabla \bar{w}^n - \nabla W_n) \right|^2 - \frac{1}{2} \int_\Omega \left| \tau \sum_{n=1}^{N} (\nabla \bar{w}^n - \nabla P_h \bar{w}^n) \right|^2\end{aligned}$$

and note that

$$\frac{1}{4} \int_\Omega \left| \tau \sum_{n=1}^{N} (\nabla \bar{w}^n - \nabla W_n) \right|^2 = \frac{1}{4} \int_\Omega |\nabla(\bar{w} - \overline{W})|^2.$$

Altogether, we deduce that

$$\begin{aligned}&\int_0^T (\psi(w) - \psi(W), w - W) + \int_\Omega |\nabla(\bar{w} - \overline{W})|^2 \\ &\le c \left(\sum_{n=1}^{N} \int_{I_n} (\psi(w_n) - \psi(w), w_n - w) + \sum_{n=1}^{N} \int_{I_n} (\psi(w) - \psi(P_h w), w - P_h w) \right. \\ &\qquad \left. + \int_\Omega \left| \tau \sum_{n=1}^{N} (\nabla \bar{w}^n - \nabla P_h \bar{w}^n) \right|^2 + \|\psi(w_0) - \Pi_h \psi(w_0)\|^2_{L^2\Omega} \right).\end{aligned}$$

Thus, the assertion follows. ∎

Let us note that the proof also implies the following result.

COROLLARY 5.2. *There is a constant c independent of h and τ such that*

$$\int_0^T \|w - W\|^2_{(w,\frac{m+1}{m})} \le c\left(\sum_{n=1}^N \int_{In} \|w_n - w\|^2_{(w,\frac{m+1}{m})} + \int_0^T \|w - P_h w\|^2_{(w,\frac{m+1}{m})} + \|\psi(w_0) - \Pi_h\psi(w_0)\|^2_{L^2(\Omega)}\right).$$

Proof. The assertion follows from the estimate

$$\int_0^T (\psi(w) - \psi(W), w - W) + \int_\Omega \left|\tau \sum_{n=1}^N (\nabla P_h \bar{w}^n - \nabla W_n)\right|^2$$
$$\le c\left(\sum_{n=1}^N \int_{I_n} (\psi(w_n) - \psi(w), w_n - w) + \sum_{n=1}^N \int_{I_n} (\psi(w) - \psi(P_h w), w - P_h w) + \|\psi(w_0) - \Pi_h\psi(w_0)\|^2_{L^2(\Omega)}\right). \quad ∎$$

6. The convergence rate. In this section we discuss the rates of convergence of the finite element approximation. For $m < 1$ we prove the following result.

THEOREM 6.1. *Let $0 < m < 1$ and $w_0 \in L^\infty(\Omega) \cap \in W^{1,2}(\Omega)$. Then there is a constant c independent of h and τ such that*

$$\left(\int_o^T \|w - W\|^2_{(w,\frac{m+1}{m})} + \sup_{1\le n\le N} \left\|\int_0^{t_n} (w - W)\right\|^2_{H^1(\Omega)}\right)^{\frac{1}{2}} \le c(\tau + h). \tag{6.1}$$

COROLLARY 6.2. *Let the assumptions of Theorem* 6.1 *be satisfied. Then there is a constant c independent of h and τ such that*

$$\|u - U\|_{L^{m+1}(0,T;L^{m+1}(\Omega))} \le c(\tau + h),$$

where $U = \psi(W)$.

Our next theorem concerns the case of $m > 1$. We treat only the case in which w satisfies either (2.6) for $\delta = 0$ or (2.7) for $\delta, \varepsilon = 0$.

THEOREM 6.3. *Let $m > 1$, $\psi(w_0) \in L^\infty(\Omega) \cap W^{1,2}(\Omega)$, and $\psi(w_0) \ge 0$.*

(a) *Let w satisfy* (2.6) *for $\delta = 0$. Then there is a constant c independent of h and τ such that*

$$\left(\int_0^T \|w - W\|^2_{(w,\frac{m+1}{m})} + \sup_{1\le n\le N} \left\|\int_0^{t_n} (w - W)\right\|^2_{H^1(\Omega)}\right)^{\frac{1}{2}} \le c(\tau + h). \tag{6.2}$$

(b) *Let w satisfy* (2.7) *for $\delta, \varepsilon = 0$ and $\psi(w_0) \in W^{\frac{m+1}{m},2}(\Omega)$. Then there is a constant c independent of h and τ such that*

$$\left(\int_0^T \|w - W\|^2_{(w,\frac{m+1}{m})}\right)^{\frac{1}{2}} \le c(\tau + h^{\frac{m+1}{m}}). \tag{6.3}$$

COROLLARY 6.4. *Let the assumption of Theorem* 6.3(a) *be satisfied. Then there is a constant* c *independent of* h *and* τ *such that*

$$\|w - W\|_{L^{\frac{m+1}{m}}(0,T;L^{\frac{m+1}{m}}(\Omega))} \le c(\tau + h).$$

Based on the results above, we have the following corollary.

COROLLARY 6.5. *Let the assumptions in either Theorem* 6.1 *or Theorem* 6.3 *hold. Then*

$$\left(\int_o^T \int_\Omega |u - U\|w - W|\right)^{\frac{1}{2}} + \left\|\int_0^t (w - W)\right\|_{L^\infty(0,T;H^1(\Omega))} \le c(\tau + h).$$

Proof of Theorem 6.1. Let us set $v := |u|^{\frac{m-1}{2}}u$. Utilizing the estimates (4.8) and (4.6), we get

$$\int_{I_n} \|w_n - w\|^2_{(w,\frac{m+1}{m})} \le c\int_{I_n} (\psi(w_n) - \psi(w), w_n - w) \le c\int_{I_n}\int_\Omega |v_n - v|^2.$$

Notice that

$$\int_{I_n} |v_n - v|^2 = \int_{I_n}\left|\int_t^{t_n} v_t\right|^2 \le \int_{I_n}\int_t^{t_n} |v_t|^2|I_n| \le \tau^2\int_{I_n}|v_t|^2$$

and $|v_t|^2 = |\partial_t(|u|^{\frac{m-1}{2}}u)|^2$. In view of (2.3), we deduce

$$\sum_{n=1}^N \int_{I_n} \|w_n - w\|^2_{(w,\frac{m+1}{m})} \le c\tau^2\left\|\partial_t u^{\frac{m+1}{2}}\right\|^2_{L^2(0,T;L^2(\Omega))} \le c\tau^2. \tag{6.4}$$

Utilizing (2.5), we estimate

$$\begin{aligned}
&\int_0^T \|w - P_h w\|^2_{(w,\frac{m+1}{m})} = \int_0^T\int_\Omega (|w| + |w - P_h w|)^{\frac{1-m}{m}}|w - P_h w|^2\\
&\le c\left(\|w\|^{\frac{1-m}{m}}_{L_\infty(0,T;L_\infty(\Omega))}\|w - P_h w\|^2_{L^2(0,T;L^2(\Omega))} + \|w - P_h w\|^{\frac{m+1}{m}}_{L^{\frac{m+1}{m}}(0,T;L^{\frac{m+1}{m}}(\Omega))}\right)\\
&\le ch^2\left(\|\nabla w\|^2_{L^2(0,T;L^2(\Omega))} + \|w\|^{\frac{m+1}{m}}_{L^{\frac{m+1}{m}}(0,T;\mathcal{N}^{\frac{2m}{m+1},\frac{m+1}{m}}(\Omega))}\right)\\
&\le ch^2.
\end{aligned} \tag{6.5}$$

Here we have used an interpolation error estimate in the Nikolskii spaces. This may be proved in the same way as in [8]. Due to (2.4) we find

$$\|\nabla(\bar w - P_h\bar w)\|^2_{L^2(\Omega)} \le ch^2\|\nabla^2\bar w\|^2_{L^2(\Omega)} \le ch^2. \tag{6.6}$$

Further, $w_0 \in L^\infty(\Omega)\cap W^{1,2}(\Omega)$ implies that $\psi(w_0) \in W^{1,2}(\Omega)$; thus,

$$\|\psi(w_0) - \Pi_h\psi(w_0)\|^2_{L^2(\Omega)} \le ch^2\|\nabla\psi(w_0)\|^2_{L^2(\Omega)} \le ch^2. \tag{6.7}$$

From Theorem 5.1 and (6.4)–(6.7) we conclude that

$$\int_0^T \|w - W\|^2_{(w,\frac{m+1}{m})} + \|\nabla(\bar{w} - \overline{W})\|^2_{L^2(\Omega)} \le c(\tau^2 + h^2), \tag{6.8}$$

where $\bar{w}(x) = \int_0^T w(x,t)dt, \overline{W}(x) = \int_0^T W(x,t)dt$, and $T = t_N$. In the same manner we can estimate (6.8) for all $n \in \{1, \dots, N\}$. Noting that the Poincaré inequality yields a constant c such that

$$\left\| \int_0^{t_n} (w - W) \right\|^2_{L^2(\Omega)} \le c \left\| \nabla \int_0^{t_n} (w - W) \right\|^2_{L^2(\Omega)}$$

the assertion follows. □

Proof of Corollary 6.2. The Hölder inequality yields (with $p_1 = \frac{2}{1-m}$ and $p_2 = \frac{2}{m+1}$)

$$\begin{aligned}
&\int_0^T \int_\Omega |u - U|^{m+1} \\
&= \int_0^T \int_\Omega (|u| + |u - U|)^{\frac{(1-m)(m+1)}{2}} (|u| + |u - U|)^{\frac{(m-1)(m+1)}{2}} |u - U|^{m+1} \\
&\le \left[\int_0^T \int_\Omega (|u| + |u - U|)^{m+1} \right]^{\frac{1-m}{2}} \left[\int_0^T \int_\Omega (|u| + |u - U|)^{m-1} |u - U|^2 \right]^{\frac{m+1}{2}}.
\end{aligned}$$

The first integral on the right-hand side in bounded. Further, due to Lemma 4.2 we have

$$\int_0^T \int_\Omega (|u| + |u - U|)^{m-1} |u - U|^2 \cong \int_0^T \|w - W\|^2_{(w,\frac{m+1}{m})}.$$

Applying Theorem 6.1, we obtain

$$\|u - U\|^{m+1}_{L^{m+1}(0,T;L^{m+1}(\Omega))} \le c(\tau + h)^{m+1}.$$

This yields the assertion. □

Proof of Theorem 6.3. (a) Let us note that $\psi(w_0) \in L^\infty(\Omega) \cap W^{1,2}(\Omega)$ implies $w_0 \in W^{1,2}(\Omega)$. Due to (2.6) we estimate

$$\begin{aligned}
\int_0^T \|w - P_h w\|^2_{(w,\frac{m+1}{m})} &\le \int_o^T \|w - P_h w\|^{\frac{m+1}{m}}_{L^{\frac{m+1}{m}}(\Omega)} \\
&\le ch^2 \|w\|^{\frac{m+1}{m}}_{L^{\frac{m+1}{m}}(0,T;\mathcal{N}^{\frac{2m}{m+1},\frac{m+1}{m}}(\Omega))} \\
&\le ch^2. \qquad (6.9)
\end{aligned}$$

Utilizing Theorem 5.1, (6.4), (6.6), (6.7), and (6.9) the assertion (6.2) follows.

(b) Using (2.7), we find

$$\begin{aligned}
\int_0^T \|w - P_h w\|^2_{(w,\frac{m+1}{m})} &\le \int_0^T \|w - P_h w\|^{\frac{m+1}{m}}_{L^{\frac{m+1}{m}}(\Omega)} \\
&\le h^{2\frac{m+1}{m}} \|\nabla^2 w\|^{\frac{m+1}{m}}_{L^{\frac{m+1}{m}}(0,T;L^{\frac{m+1}{m}}(\Omega))} \\
&\le ch^{2\frac{m+1}{m}}. \qquad (6.10)
\end{aligned}$$

Moreover,

$$\|\psi(w_0) - \Pi_h \psi(w_0)\|^2_{L^2(\Omega)} \le c h^{2\frac{m+1}{m}} \|\psi(w_0)\|^2_{W^{\frac{m+1}{m},2}(\Omega)} \le c h^{2\frac{m+1}{m}}. \tag{6.11}$$

Due to Corollary 5.2, (6.4), (6.10), and (6.11) we get the assertion (6.3). □

Proof of Corollary 6.4. Utilizing the Hölder inequality (with $p_1 = \frac{2m}{m-1}$ and $p_2 = \frac{2m}{m+1}$ and (6.2), we obtain

$$\begin{aligned}
&\int_0^T \int_\Omega |w - W|^{\frac{m+1}{m}} \\
&= \int_0^T \int_\Omega (|w| + |w - W|)^{\frac{(m+1)(m-1)}{2m^2}} (|w| + |w - W|)^{\frac{(m+1)(1-m)}{2m^2}} |w - W|^{\frac{m+1}{m}} \\
&\le \left[\int_0^T \int_\Omega (|w| + |w - W|)^{\frac{m+1}{m}} \right]^{\frac{m-1}{2m}} \left[\int_0^T \int_\Omega (|w| + |w - W|)^{\frac{1-m}{m}} |w - W|^2 \right]^{\frac{m+1}{2m}} \\
&\le c(\tau + h)^{\frac{m+1}{m}}.
\end{aligned}$$

This yields the assertion. □

Proof of Corollary 6.5. Let $T_0 \in (t_{n-1}, t_n)$. Nothing that W is constant with respect to t in $(t_{n-1}, t_n]$, we may rewrite the Nth equation of (3.2) as follows:

$$\left(\frac{\psi(W(T_0)) - \psi(W(t_{N-1}))}{\tau}, \chi_N \right) + (\nabla W(T_0), \nabla \chi_N) = 0 \qquad \forall \chi_N \in S_h.$$

Hence, replace t_N by T_0 and W_N by $W(T_0)$ in the proofs of the Theorems 5.1, 6.1, and 6.3, we obtain

$$\left\| \int_0^{T_0} (w - W) \right\|_{H^1(\Omega)} \le c(h + \tau).$$

Thus, we may conclude the assertion. □

Remark. The porous medium equation has a well-known family of self-similar solutions, the Barenblatt solutions

$$u_*(x,t) = (t+\tau)^{-k} \left\{ \left[a^2 - \frac{k(m-1)}{2dm} \frac{|x|^2}{(t+\tau)^{2k/d}} \right]^+ \right\}^{\frac{1}{m-1}},$$

Where $a, \tau > 0$ and $k = (m - 1 + 2/d)^{-1}$. Let us note that, in general, weak solutions of the porous medium equation may have singularities at points where parts of the free boundary collide with each other or at a *close in*; that is, a hole in the support fills up. However, the Barenblatt solutions are more regular, for they have a *smooth* free boundary. Due to the regularity of these solutions we expect a convergence rate of at most

$$\left(\int_0^T \|w_* - W_*\|^2_{(w, \frac{m+1}{m})} \right)^{\frac{1}{2}} \le c(\tau + h^{\frac{m}{m-1}})$$

for $m \ge 2$. Let us note that this rate is very close to that given in (6.3).

The error estimates obtained in the above theorems and corollaries are optimal in their approximation orders, and the regularities required are known to be achievable

for sufficiently smooth data—at least for $\delta, \varepsilon > 0$. In the literature, various error estimates for, say, nonnegative solutions of the porous medium equation are given, although direct comparisons with our results may not be straightforward. The results in [31] are well known; a fully discrete scheme was examined:

$$\tau^{-1}(U^{n+1} - U^n, \chi) + (\nabla W^{n+1}, \nabla \chi) = (f^{n+1/2}, \chi) \qquad \forall \chi \in S_h,$$

where $W^{n+1} \in S_h$ and $U^{n+1} = P_{0h}\psi(W^{n+1})$. In that paper it was shown that

$$||u - U||_{L^\infty(0,T;H^{-1}(\Omega))} + ||w - W||_{L^2(0,T;L^2(\Omega))} \le c(\tau + (\ln(1/h))^\alpha h)$$

for $\alpha = \frac{1}{2m}$. This estimate is optimal in the approximation order with respect to τ, although the regularity requirement for t seems too high, because Lipschitz continuity of u in $L^1(\Omega)$ is required, which is not achievable at $t = 0$.

The same fully discrete scheme was used in [12], and the following estimates were obtained by exploiting the nondegeneracy property of the free boundary [11]: There is a function $\sigma(\varepsilon, T, h)$ such that

$$||w - W||_{L^2(0,T;L^2(\Omega))} \le c\sigma.$$

Putting $\tau = h^{\frac{5m-1}{2m-2}}$ and $\varepsilon = ch^{\frac{2m^2-2}{3m^2+m}}$, we get $O(h^{\frac{m+1}{2m}})$. Similarly, we obtain

$$||u - U||_{L^2(0,T;L^2(\Omega))} \le ch^\alpha$$

for $\alpha = \frac{m^2+4m+3}{6m^2+2m} \ge \frac{1}{6}$.

In [22], the following fully discrete scheme was used:

$$\tau^{-1}((U^{n+1}) - (U^n), \chi) + (\nabla(|U^{n+1}|^{m-1}U^{n+1}), \nabla \chi) = 0 \qquad \forall \chi \in S_h,$$

where $U^{n+1} \in S_h$. Let $U(t)$ be piecewise linear in t; then

$$||u - U||_{L^{m+1}(0,T;L^{m+1}(\Omega))} \le c(\tau^{\frac{1}{2}} + h + h^{\frac{1}{m}(d\frac{m-1}{2m+2}+1)})^{\frac{1}{m+1}}.$$

In [28] the following fully discrete scheme using numerical integration was examined:

$$\tau^{-1}(\Pi_h\psi_\varepsilon(W^{n+1}) - \Pi_h\psi_\varepsilon(W^n), \chi)_h + (\nabla W^{n+1}, \nabla \chi) = 0 \qquad \forall \chi \in S_h,$$

where $W^{n+1} \in S_h, \Pi_h$ is the interpolant, and ψ_ε is regularized such that it is linear near 0. The following estimates were obtained:

$$||u - U||_{L^\infty(0,T;H^{-1}(\Omega))} + ||w - W||_{L^2(0,T;L^2(\Omega))} + \left\| \int_0^t (w - W) \right\|_{L^\infty(0,T;H^1(\Omega))} \le c\sigma,$$

where $\sigma = \sigma(\varepsilon, \tau, h) = (\frac{h^2}{\varepsilon} + \frac{h^4}{\varepsilon^2\tau} + \tau)^{1/2}$. Putting $\tau = ch^{\frac{m+1}{m}}$ and $\varepsilon = ch^{\frac{m-1}{m}}$, one gets the convergence rate $O(h^{\frac{m+1}{2m}})$.

In [30], a regularized version of our approximation scheme was used. The following suboptimal result was shown, choosing the regularization parameter in an appropriate way:

$$\left(\tau \sum_n ||u(t_n) - U^n||^{m+1}_{L^{m+1}(\Omega)}\right)^{\frac{1}{m+1}} \le c(\tau^{\frac{1}{m}} + (\ln(1/h))^{\frac{1}{m(m+1)}} h^{\frac{2}{m}})$$

for $d = 2, 3$, under the assumption that $u_t \in L^{\frac{m+1}{m}}(\Omega \times (0, T))$.

Furthermore, $||w-W||_{L^2(0,T;L^2(\Omega))} + ||\int_0^t (w-W)||_{L^\infty(0,T;H^1(\Omega))} \le c\tau^{\frac{1}{4}}$ was obtained in [20], where a linearized semidiscrete scheme was considered. Moreover, an a priori error estimate for $||(u-U)(w-W)||_{L^1(0,T;L^1(\Omega))}$ was proved in [1]. Due to the low regularity of u this estimate implies a convergence rate which tends to 0 for $m \to \infty$. In [17] it was shown that

$$||u-U||_{L^\infty(0,T;H^{-1}(\Omega)} + \left(\int_0^T \int_\Omega |u-U||w-W|\right)^{\frac{1}{2}} + \left|\left|\int_0^T (w-W)\right|\right|^2_{H^1(\Omega)} \le c\tau^{\frac{1}{2}},$$

where a semidiscrete scheme was studied. In [29], for a regularized semidiscrete scheme,

$$||w-W||_{L^2(0,T;L^2(\Omega))} \le c\tau^{\frac{1}{2}}$$

was obtained.

For the case in which $m < 1$, there are only a few results. For the fully discrete schemes in [22] and [31], it was shown that

$$||u-U||_{L^2(0,T;L^{m+1}(\Omega))} \le c(\tau^{1/2} + h + h^{d\frac{m-1}{2m+2}+1})^{1/2} \qquad (\tfrac{2d}{d+1} < m < 1)$$

and

$$||u-U||_{L^\infty(0,T;H^{-1}(\Omega))} \le c(\tau + (\ln(1/h))^\alpha h)$$

for some $\alpha > 0$, respectively.

AN ANISOTROPIC SPARSE GRID STOCHASTIC COLLOCATION METHOD FOR PARTIAL DIFFERENTIAL EQUATIONS WITH RANDOM INPUT DATA*

F. NOBILE†, R. TEMPONE‡, AND C. G. WEBSTER§

Abstract. This work proposes and analyzes an anisotropic sparse grid stochastic collocation method for solving partial differential equations with random coefficients and forcing terms (input data of the model). The method consists of a Galerkin approximation in the space variables and a collocation, in probability space, on sparse tensor product grids utilizing either Clenshaw–Curtis or Gaussian knots. Even in the presence of nonlinearities, the collocation approach leads to the solution of uncoupled deterministic problems, just as in the Monte Carlo method. This work includes a priori and a posteriori procedures to adapt the anisotropy of the sparse grids to each given problem. These procedures seem to be very effective for the problems under study. The proposed method combines the advantages of isotropic sparse collocation with those of anisotropic full tensor product collocation: the first approach is effective for problems depending on random variables which weigh approximately equally in the solution, while the benefits of the latter approach become apparent when solving highly anisotropic problems depending on a relatively small number of random variables, as in the case where input random variables are Karhunen–Loève truncations of "smooth" random fields. This work also provides a rigorous convergence analysis of the fully discrete problem and demonstrates (sub)exponential convergence in the asymptotic regime and algebraic convergence in the preasymptotic regime, with respect to the total number of collocation points. It also shows that the anisotropic approximation breaks the *curse of dimensionality* for a wide set of problems. Numerical examples illustrate the theoretical results and are used to compare this approach with several others, including the standard Monte Carlo. In particular, for moderately large-dimensional problems, the sparse grid approach with a properly chosen anisotropy seems to be very efficient and superior to all examined methods.

the input data of the problem, such as model coefficients, forcing terms, boundary conditions, geometry, etc. Once the probability distribution of the input random data is known, the computational goal is the prediction of statistical moments of the solution (mean value, variance, covariance, etc.) or statistics of some given responses of the system (sometimes called quantities of physical interest which are real valued functionals of the solution). Examples of quantities of interest could include solution values in a given region, fluxes across given boundaries, etc.

In this work we focus on the solution of partial differential equations (PDEs) with random coefficients and forcing terms (input data of the model), and we especially address the situation where the input data are assumed to depend on a moderately large number of random variables.

The Monte Carlo method described in [11] is the classical and most widely applied technique for approximating expected values of quantities of interest depending on the solution of a PDE with random inputs. The algorithm approximates the desired expectation by a sample average of independent identically distributed (i.i.d.) realizations. When solving PDEs with random inputs this method employs the solution of one deterministic differential equation for each realization of the input parameters. This makes the method simple to implement, allows for maximal code reusability, and is straightforward to parallelize. The asymptotic numerical error of the Monte Carlo method is approximately $\mathcal{O}(1/\sqrt{M})$, where M is the number of realizations. The advantage of utilizing this approach is that the rate does not deteriorate with respect to the number of random variables in the problem, making the method very attractive for problems with large-dimensional random inputs. On the other hand, when solving large-scale applications, the exponent $1/2$ in the rate of convergence generates a huge amount of computational work required to achieve accurate solutions. Other ensemble-based methods like quasi-Monte Carlo, latin hypercube sampling, etc. (see, e.g., [23, 18] and the references therein), have been devised to produce faster convergence, $\mathcal{O}(\log(M)^r/M)$, where the coefficient $r > 0$ becomes larger with the dimension of the random input.

Another possible substitute for the Monte Carlo method is the so-called spectral Galerkin method. For more details see, e.g., [17]. It employs standard approximations in space (finite elements, finite volumes, spectral or h-p finite elements, etc.) and polynomial approximation in the probability domain, either by full polynomial spaces [30, 22, 16], tensor product polynomial spaces [2, 12, 25], or piecewise polynomial spaces [8, 2, 19, 28, 21]. This family of methods exploits the regularity of the solution to acquire faster convergence rates. However, in general, this technique requires solving a system of equations that couples all degrees of freedom in the approximation to the stochastic solution.

A new numerical technique, which has gained much attention recently by the computational community, is stochastic collocation (see [1, 13, 24, 20, 29]), which can be based on either full or sparse tensor product approximation spaces. As shown in [1], stochastic collocation essentially preserves the fast convergence of the spectral Galerkin method, even coinciding in particular cases, while maintaining an ensemble-based approach, just as Monte Carlo. Hence, stochastic collocation seems to be an ideal method for computing statistics from solutions of PDEs with random input data. The practical challenge to the use of stochastic collocation becomes evident when solving problems depending on a relatively large number of input random variables: any simple-minded approach requires unaffordable amounts of computational effort. This is a symptom of the *curse of dimensionality*, and it is our goal, therefore, to investi-

gate variants of this procedure to attain highly accurate solutions while significantly reducing the computational cost.

In particular, isotropic sparse approximations based on the Smolyak construction have been proposed and analyzed in [4] for the approximation of real valued functions and were first applied to PDEs with random coefficients in [29]. Our previous paper [24] provided a full convergence analysis for this approximation scheme under the assumption that the solution depends analytically on the input parameters, which is valid in many elliptic and parabolic problems.

Furthermore, the work [24] revealed that the isotropic sparse collocation algorithm is effective for problems whose input data depend on a moderate number of random variables, which "weigh equally" in the solution. For such isotropic situations the displayed convergence is faster than standard collocation techniques built upon full tensor product spaces. On the other hand, the convergence rate of the isotropic sparse collocation algorithm deteriorates for highly anisotropic problems, such as those appearing when the input random variables come, for example, from Karhunen–Loève-type truncations of "smooth" random fields. In such cases, a full anisotropic tensor product approximation [2, 1] may still be more effective for a small or modest number of random variables. However, if the number of random variables is large, the construction of the full tensor product spaces becomes infeasible, since the dimension of the approximating space grows exponentially fast with respect to the number of random variables in the problem.

The main contribution of this work is to propose and analyze a novel *anisotropic* sparse grid stochastic collocation method that is based on a weighted version of the Smolyak algorithm. In particular, we develop an original procedure, based on either a priori or a posteriori estimates for choosing the anisotropy of the sparse grid, and we show both theoretically and numerically the effectiveness of these methods for several problems. This approach is particularly attractive in the case of truncated expansions of random fields, since the anisotropy can be tuned to the decay properties of the expansion.

In this respect, the proposed method differs from the dimension-adaptive method developed in [15] and applied in the context of PDEs in [13], where the sparse approximation structure has to be uncovered only by successive enrichment, and does not exploit any a priori information of the solution.

A related approach is proposed in [26], where sparse wavelet chaos subspaces are constructed for the approximation of the solution of linear scalar elliptic PDEs with random coefficients. Those approximations are also anisotropic and use a priori regularity from the exact solution. The main difference with our approach is that the sparse approximation in [26] is the same for all problems, i.e., does not depend on the problem data, and it is used mainly to prove convergence rates.

This work provides a rigorous convergence analysis of our anisotropic sparse stochastic collocation method in the case where the solution depends analytically on the input parameters, and demonstrates (sub)exponential convergence in the asymptotic regime and algebraic convergence in the preasymptotic regime with respect to the total number of collocation points. Numerical examples illustrate the theoretical results and are used to compare this approach with the standard Monte Carlo method as well as the anisotropic full tensor product approach. In particular, for moderately large-dimensional problems, our approach with properly chosen anisotropy seems to be very efficient and superior to all examined methods. We also show that this method is able to break the curse of dimensionality in certain cases where the input random

variables come from a truncated Karhunen–Loève-type expansion of a smooth random field.

The outline of the paper is the following: In section 1 we introduce the mathematical problem and the main notation used throughout. Here, we also state assumptions on the parametrization of the random inputs, which is useful when later transforming the original stochastic problem into a deterministic parametric one, and on the problem solution's regularity, which is used to later prove the error estimates. In section 2 we introduce the anisotropic sparse collocation method as well as two interpolation techniques based on Clenshaw–Curtis or Gaussian abscissas. We also provide a priori and a posteriori procedures for tuning the anisotropy of our sparse grid method to the problem at hand. In section 3 we provide a detailed error analysis. Finally, in section 4 we present numerical results, including a comparison with the Monte Carlo method and the anisotropic full tensor product approach, showing the efficiency of the proposed method.

1. Problem setting. We begin by focusing our attention on an elliptic operator $\mathcal{L}$, linear or nonlinear, defined on a domain $D \subset \mathbb{R}^d$, which depends on some coefficients $a(\omega, x)$ with $x \in D$, $\omega \in \Omega$ and $(\Omega, \mathcal{F}, P)$ a complete probability space. Here Ω is the set of outcomes, $\mathcal{F} \subset 2^\Omega$ is the σ-algebra of events, and $P : \mathcal{F} \to [0,1]$ is a probability measure. Analogously, the forcing term $f = f(\omega, x)$ can be assumed to be random as well.

Consider the stochastic elliptic boundary value problem: Find a random function, $u : \Omega \times \overline{D} \to \mathbb{R}$, such that P-a.e. in Ω, or in other words almost surely (a.s.), the following equation holds:

$$\mathcal{L}(a)(u) = f \quad \text{in } D, \tag{1.1}$$

equipped with suitable boundary conditions. Before introducing some assumptions we denote by $W(D)$ a Banach space of functions $v : D \to \mathbb{R}$ and define, for $q \in [1, \infty]$, the stochastic Banach spaces

$$L_P^q(\Omega; W(D)) := \Bigg\{ v : \Omega \to W(D) \mid v \text{ is strongly measurable and } \int_\Omega \|v(\omega, \cdot)\|_{W(D)}^q dP(\omega) < +\infty \Bigg\}$$

and

$$L_P^\infty(\Omega; W(D)) := \Bigg\{ v : \Omega \to W(D) \mid v \text{ is strongly measurable and } P - \operatorname*{ess\,sup}_{\omega \in \Omega} \|v(\omega, \cdot)\|_{W(D)}^2 < +\infty \Bigg\}.$$

Of particular interest is the space $L_P^2(\Omega; W(D))$, consisting of Banach valued functions that have finite second moments.

We will now make the following assumptions:

(A_1) The solution to (1.1) has realizations in the Banach space $W(D)$, i.e., $u(\cdot, \omega) \in W(D)$ a.s. and $\forall \omega \in \Omega$

$$\|u(\cdot, \omega)\|_{W(D)} \le C \|f(\cdot, \omega)\|_{W^*(D)},$$

where we denote $W^*(D)$ to be the dual space of $W(D)$, and C is a constant independent of the realization $\omega \in \Omega$.

(A_2) The forcing term $f \in L^2_P(\Omega; W^*(D))$ is such that the solution u is unique and bounded in $L^2_P(\Omega; W(D))$.

Here we give two example problems that are posed in this setting.

Example 1.1. The linear problem

$$\begin{cases} -\nabla \cdot (a(\omega,\cdot)\nabla u(\omega,\cdot)) = f(\omega,\cdot) \text{ in } \Omega \times D, \\ u(\omega,\cdot) = 0 \text{ on } \Omega \times \partial D, \end{cases} \tag{1.2}$$

with $a(\omega,\cdot)$ uniformly bounded and coercive, i.e.,

$$\text{there exists } a_{min}, a_{max} \in (0,+\infty)$$
$$\text{such that } P(\omega \in \Omega : \ a(\omega,x) \in [a_{min}, a_{max}] \, \forall x \in \overline{D}) = 1$$

and $f(\omega,\cdot)$ square integrable with respect to P, satisfies assumptions A_1 and A_2 with $W(D) = H^1_0(D)$ (see [1]).

Example 1.2. Similarly, for $k \in \mathbb{N}^+$, the nonlinear problem

$$\begin{cases} -\nabla \cdot (a(\omega,\cdot)\nabla u(\omega,\cdot)) + u(\omega,\cdot)|u(\omega,\cdot)|^k = f(\omega,\cdot) \quad \text{in } \Omega \times D, \\ u(\omega,\cdot) = 0 \quad \text{on } \Omega \times \partial D, \end{cases} \tag{1.3}$$

with $a(\omega,\cdot)$ uniformly bounded and coercive and $f(\omega,\cdot)$ square integrable with respect to the probability measure, satisfies assumptions A_1 and A_2 with $W(D) = H^1_0(D) \cap L^{k+2}(D)$.

1.1. On finite-dimensional noise. In some applications, the coefficient a and the forcing term f appearing in (1.1) can be described by a random vector $[Y_1, \ldots, Y_N] : \Omega \to \mathbb{R}^N$. In these cases, we will emphasize such dependence by writing a_N and f_N.

An example is given by the case where a (and/or f) is a random field and a_N (and/or f_N) is obtained as a truncated Karhunen–Loève expansion (see [24] for details).

In what follows, we will focus on problems whose coefficients and forcing terms are described by a finite number of random variables (*finite-dimensional noise assumption*) and seek a random field $u_N : \Omega \times \overline{D} \to \mathbb{R}$, such that a.s. the following equation holds:

$$\mathcal{L}(a_N)(u_N) = f_N \quad \text{in } D. \tag{1.4}$$

Further, we assume that (1.4) admits a unique solution $u_N \in L^2_P(\Omega; W(D))$. We then have that the solution u_N of the stochastic elliptic boundary value problem (1.4) can be described by $u_N = u_N(\omega, x) = u_N(Y_1(\omega), \ldots, Y_N(\omega), x)$. We underline that the coefficients a_N and f_N in (1.4) may be either an exact or an approximate representation of the input data. In the latter case, the solution u_N will also be an approximation of the exact solution u in (1.1), and the truncation error $u - u_N$ has to be properly estimated; see, for instance, [24, section 4.2].

Remark 1.3. It is usual to have f_N and a_N independent, because the forcing terms and the parameters in the operator $\mathcal{L}$ are seldom related. In such a situation we have $a_N(Y(\omega), x) = a_N(Y_a(\omega), x)$ and $f_N(Y(\omega), x) = f_N(Y_f(\omega), x)$, with $Y = [Y_a, Y_f]$ and the vectors Y_a, Y_f are independent.

In this work we will adopt the following notation: we denote $\Gamma_n \equiv Y_n(\Omega)$ the image of Y_n, where we assume $Y_n(\omega)$ to be bounded. Without loss of generality we

can assume $\Gamma_n = [-1, 1]$. We also let $\Gamma^N = \prod_{n=1}^N \Gamma_n$ and assume that the random variables $[Y_1, Y_2, \ldots, Y_n]$ have a joint probability density function $\rho : \Gamma^N \to \mathbb{R}_+$, with $\rho \in L^\infty(\Gamma^N)$. Thus, the goal is to approximate the function $u_N = u_N(y, x)$ for any $y \in \Gamma^N$ and $x \in \overline{D}$ (see [1, 2]).

1.2. Regularity. Before discussing various collocation techniques and going through the convergence analysis of such methods, we need to state some regularity assumptions on the data of the problem and consequent regularity results for the exact solution u_N. We will perform a one-dimensional analysis in each direction y_n, $n = 1, \ldots, N$. For this, we denote $\Gamma_n^* = \prod_{\substack{j=1 \\ j \neq n}}^N \Gamma_j$, and let $\mathbf{y}_n^*$ be an arbitrary element of Γ_n^*. We require the solution to problem (1.1) to satisfy the following estimate.

Assumption 1.4. For each $y_n \in \Gamma_n$, there exists $\tau_n > 0$ such that the function $u_N(y_n, \mathbf{y}_n^*, x)$ as a function of y_n, $u_N : \Gamma_n \to C^0(\Gamma_n^*; W(D))$ admits an analytic extension $u(z, \mathbf{y}_n^*, x)$, $z \in \mathbb{C}$, in the region of the complex plane

$$\Sigma(\Gamma_n; \tau_n) \equiv \{z \in \mathbb{C}, \ \ \mathrm{dist}(z, \Gamma_n) \leq \tau_n\}. \tag{1.5}$$

Moreover, $\forall z \in \Sigma(\Gamma_n; \tau_n)$,

$$\|u_N(z)\|_{C^0(\Gamma_n^*; W(D))} \leq \lambda, \tag{1.6}$$

with λ a constant independent of n.

The previous assumption should be verified for each particular application. In particular, this has implications on the allowed regularity of the input data, e.g., coefficients, loads, etc., with respect to $y_n, n = 1, 2, \ldots, N$, of the PDE under study.

Please observe that this assumption does not preclude the possibility of having singularities in the solution with respect to the spatial variables.

Remark 1.5 (unbounded random variables). Following the approach in [1] we can also state and verify related regularity assumptions for the case where the input data depend on unbounded random variables, such as Gaussian or exponential ones. These regularity assumptions can be used to produce convergence estimates of anisotropic Smolyak approximations for such cases. For the sake of simplicity in this work we focus our study on bounded random variables only.

We recall now some theoretical results, which were proved in [1, section 3], for the linear problem introduced in Example 1.1. Once we have the input random fields described by a finite set of random variables, i.e., $a(\omega, x) = a_N(Y_1(\omega), \ldots, Y_N(\omega), x)$, and similarly for $f(\omega, x)$, the "finite-dimensional" version of the stochastic formulation (1.2) has a "deterministic" equivalent, which is the following: Find $u_N \in L^2_\rho(\Gamma^N; H^1_0(D))$ such that

$$\int_{\Gamma^N} \rho \, (a_N \nabla u_N, \nabla v)_{L^2(D)} \, dy = \int_{\Gamma^N} \rho \, (f_N, v)_{L^2(D)} \, dy \quad \forall \, v \in L^2_\rho(\Gamma^N; H^1_0(D)). \tag{1.7}$$

Observe that in this work the gradient notation, ∇, always means differentiation with respect to $x \in D$ only, unless otherwise stated. The stochastic boundary value problem (1.2) now becomes a deterministic Dirichlet boundary value problem for an elliptic PDE with an N-dimensional parameter. For convenience, we consider the solution u_N as a Banach valued function $u_N : \Gamma^N \to H^1_0(D)$ and use the notation $u_N(y)$ whenever we want to highlight the dependence on the parameter y. We use similar notation for the coefficient a_N and the forcing term f_N. Then it can be shown

that problem (1.7) is equivalent to

$$\int_D a_N(y)\nabla u_N(y)\cdot\nabla\phi\,dx = \int_D f_N(y)\phi\,dx \quad \forall\phi\in H_0^1(D),\ \ \rho\text{-a.e. in } \Gamma^N. \tag{1.8}$$

For our convenience, we will suppose that the coefficient a_N and the forcing term f_N admit a smooth extension on the ρ-zero measure sets. Then (1.8) can be extended a.e. in Γ^N with respect to the Lebesgue measure (instead of the measure ρdy).

It has been proved in [1] that problem (1.8) satisfies the analyticity result stated in Assumption 1.4. For instance, if we take the diffusivity coefficient as the truncated nonlinear expansion

$$a(\omega,x)\approx a_N(\omega,x)=a_{min}+\exp\left\{b_0(x)+\sum_{n=1}^{N}\sqrt{\lambda_n}b_n(x)Y_n(\omega)\right\}, \tag{1.9}$$

where (λ_n,b_n) are eigenpairs of the covariance operator associated to the random field $\log(a-a_{min})$ (see [24] for details), then a suitable analyticity region $\Sigma(\Gamma_n;\tau_n)$ is given by

$$\tau_n=\frac{1}{4\sqrt{\lambda_n}\|b_n\|_{L^\infty(D)}}. \tag{1.10}$$

Observe that, as $\sqrt{\lambda_n}\|b_n\|_{L^\infty(D)}\to 0$ for a regular enough covariance function (see [12]), the analyticity region increases as n increases. This fact naturally introduces an anisotropic behavior with respect to the "direction" n. This effect will be exploited in the numerical method proposed in the next sections.

2. Anisotropic sparse grid stochastic collocation. Stochastic collocation entails the sampling of approximate values to the solution u_N of (1.4) on a suitable set of abscissas $y_k\in\Gamma^N$. For that, we introduce some standard approximation spaces, namely:

- $W_h(D)\subset W(D)$ is a standard finite element space of dimension N_h, which contains continuous piecewise polynomials defined on regular triangulations $\mathcal{T}_h$ that have a maximum mesh-spacing parameter $h>0$. We suppose that W_h has the following deterministic approximability property: for a given function $\varphi\in W(D)$,

$$\min_{v\in W_h(D)}\|\varphi-v\|_{W(D)}\le C(s;\varphi)\,h^s, \tag{2.1}$$

where s is a positive integer determined by the smoothness of φ and the degree of the approximating finite element subspace and $C(s;\varphi)$ is independent of h.

Example 2.1. Let D be a convex polygonal domain and $W(D)=H_0^1(D)$. For piecewise linear finite element subspaces we have

$$\min_{v\in W_h(D)}\|\varphi-v\|_{H_0^1(D)}\le c\,h\,\|\varphi\|_{H^2(D)}.$$

That is, $s=1$ and $C(s;\varphi)=\|\varphi\|_{H^2(D)}$; see, for example, [5].

We will also assume that there exists a finite element operator $\pi_h: W(D)\to W_h(D)$ with the optimality condition

$$\|\varphi-\pi_h\varphi\|_{W(D)}\le C_\pi\min_{v\in W_h(D)}\|\varphi-v\|_{W(D)}\quad\forall\varphi\in W(D), \tag{2.2}$$

where the constant C_π is independent of the mesh size h.

- We also need to introduce global polynomial spaces

$$\mathcal{P}_{p_n}(\Gamma_n) = \text{span}(y_n^k,\, k = 0, \ldots, p_n), \quad n = 1, \ldots, N,$$

  which will be used as building blocks for the sparse approximation of the solution u_N with respect to the random variables.

Example 2.2. If we examine the linear problem (1.2), we can introduce the semidiscrete approximation $u_h^N : \Gamma^N \to W_h(D)$, obtained by projecting (1.8) onto the subspace $W_h(D)$ for each $y \in \Gamma^N$, i.e.,

$$\int_D a_N(y)\nabla u_h^N(y) \cdot \nabla \phi_h \, dx = \int_D f_N(y)\phi_h \, dx \quad \forall \phi_h \in W_h(D) \text{ for a.e. } y \in \Gamma^N. \tag{2.3}$$

Notice that the finite element functions $u_h^N(y)$ satisfy the optimality condition (2.2) $\forall y \in \Gamma^N$, with a constant C_π that might depend on y, i.e., $C_\pi = C_\pi(y)$.

The construction of a fully discrete approximation, $u_{h,\mathrm{w}}^N \in C^0(\Gamma^N; W_h(D))$, is based on a suitable interpolation of the sampled values. That is,

$$u_{h,\mathrm{w}}^N(y, \cdot) = \sum_k u_h^N(y_k, \cdot) l_k^{\mathrm{w}}(y), \tag{2.4}$$

where, for instance, the functions l_k^{w} can be taken as the Lagrange polynomials (see [24] and section 2.1). Here w is a suitable discretization parameter. This formulation can be used to approximate the mean value or variance of u, as

$$E[u] \approx \overline{u}_h^N \equiv \sum_k u_h^N(y_k, \cdot) \int_{\Gamma^N} l_k^{\mathrm{w}}(y)\rho(y)dy$$

and

$$\mathrm{Var}[u] \approx \sum_k \left(u_h^N(y_k, \cdot)\right)^2 \int_{\Gamma^N} l_k^{\mathrm{w}}(y)\rho(y)dy - \left(\overline{u}_h^N\right)^2.$$

Several choices are possible for the interpolation abscissas. We will discuss two of them, namely, Clenshaw–Curtis and Gaussian ones, in the next subsection. Regardless of the choice of interpolating abscissas, the approximation can be constructed by using either full tensor product polynomials [1] or the space of sparse polynomials [24].

2.1. Anisotropic Smolyak formula. To define the anisotropic Smolyak formula, let us briefly recall interpolation based on Lagrange polynomials. Let $i \in \mathbb{N}_+$ and $\{y_1^i, \ldots, y_{m_i}^i\} \subset [-1, 1]$ be a sequence of abscissas for Lagrange interpolation on $[-1, 1]$. For a univariate function $u \in C^0(\Gamma^1; W(D))$, with $\Gamma^1 = [-1, 1]$, we introduce a sequence of one-dimensional Lagrange interpolation operators $\mathscr{U}^i : C^0(\Gamma^1; W(D)) \to V_{m_i}(\Gamma^1; W(D))$,

$$\mathscr{U}^i(u)(y) = \sum_{j=1}^{m_i} u(y_j^i) \cdot l_j^i(y) \quad \forall u \in C^0(\Gamma^1; W(D)), \tag{2.5}$$

where $l_j^i \in \mathcal{P}_{m_i - 1}(\Gamma^1)$ are Lagrange polynomials of degree $p_i = m_i - 1$ and

$$V_m(\Gamma^1; W(D)) = \left\{ v \in C^0(\Gamma^1; W(D)) \,:\, v(y, x) = \sum_{k=1}^{m} \widetilde{v}_k(x) l_k(y),\, \{\widetilde{v}_k\}_{k=1}^m \in W(D) \right\}.$$

Here of course we have, for $i \in \mathbb{N}_+$, $l_j^i(y) = \prod_{\substack{k=1 \\ k \neq j}}^{m_i} \frac{(y - y_k^i)}{(y_j^i - y_k^i)}$. Using the convention $\mathscr{U}^0 = 0$, define

$$\Delta^i := \mathscr{U}^i - \mathscr{U}^{i-1} \quad \text{for } i = 1, 2, \ldots . \tag{2.6}$$

Next, we let $\mathbf{i} \in \mathbb{N}_+^N$ be a multi-index and, similar to [13, 14, 15], we let $\boldsymbol{\alpha} = (\alpha_1, \alpha_2, \ldots, \alpha_N) \in \mathbb{R}_+^N$ be an N-dimensional weight vector for the different stochastic dimensions. Furthermore, we denote $\underline{\alpha} := \min_{1 \leq n \leq N} \alpha_n$ and consider the following index set:

$$X_{\boldsymbol{\alpha}}(\mathrm{w}, N) = \left\{ \mathbf{i} \in \mathbb{N}_+^N, \mathbf{i} \geq \mathbf{1} \,:\, \sum_{n=1}^{N} (i_n - 1)\alpha_n \leq \mathrm{w}\underline{\alpha} \right\}. \tag{2.7}$$

Then, using (2.6) and (2.7), we introduce the anisotropic Smolyak formula, $\mathscr{A}_{\boldsymbol{\alpha}}(\mathrm{w}, N)$, as

$$\mathscr{A}_{\boldsymbol{\alpha}}(\mathrm{w}, N) = \sum_{\mathbf{i} \in X_{\boldsymbol{\alpha}}(\mathrm{w}, N)} \left(\Delta^{i_1} \otimes \cdots \otimes \Delta^{i_N} \right) \tag{2.8}$$

for a given *level* $\mathrm{w} \in \mathbb{N}$. Equivalently, (2.8) can be written as

$$\mathscr{A}_{\boldsymbol{\alpha}}(\mathrm{w}, N) = \sum_{\mathbf{i} \in Y_{\boldsymbol{\alpha}}(\mathrm{w}, N)} c_{\boldsymbol{\alpha}}(\mathbf{i}) (\mathscr{U}^{i_1} \otimes \cdots \otimes \mathscr{U}^{i_N}), \tag{2.9}$$

with

$$c_{\boldsymbol{\alpha}}(\mathbf{i}) = \sum_{\substack{\mathbf{j} \in \{0,1\}^N \\ \mathbf{i} + \mathbf{j} \in X_{\boldsymbol{\alpha}}(\mathrm{w}, N)}} (-1)^{|\mathbf{j}|}$$

and

$$Y_{\boldsymbol{\alpha}}(\mathrm{w}, N) = X_{\boldsymbol{\alpha}}(\mathrm{w}, N) \setminus X_{\boldsymbol{\alpha}} \left(\mathrm{w} - \frac{|\boldsymbol{\alpha}|}{\underline{\alpha}}, N \right). \tag{2.10}$$

Similarly to the isotropic case (see [24]), to compute $\mathscr{A}_{\boldsymbol{\alpha}}(\mathrm{w}, N)(u)$, one only needs to know function values on the *anisotropic sparse grid*

$$\mathscr{H}_{\boldsymbol{\alpha}}(\mathrm{w}, N) = \bigcup_{\mathbf{i} \in Y_{\boldsymbol{\alpha}}(\mathrm{w}, N)} \left(\vartheta^{i_1} \times \cdots \times \vartheta^{i_N} \right). \tag{2.11}$$

We note that the isotropic Smolyak method studied in [24, 29, 4] is a special case of the anisotropic algorithm. This can be observed by simply taking the components of the weight vector to be equal, i.e., $\alpha_1 = \alpha_2 = \cdots = \alpha_N$. We now describe two choices of abscissas to be used in (2.8).

Clenshaw–Curtis abscissas. These abscissas are the extrema of Chebyshev polynomials (see [7]) and, for any choice of $m_i > 1$, are given by

$$y_j^i = -\cos\left(\frac{\pi(j-1)}{m_i - 1} \right), \quad j = 1, \ldots, m_i. \tag{2.12}$$

In addition, one sets $y_1^i = 0$ if $m_i = 1$ and lets the number of abscissas m_i in each level grow according to the following formula:

$$m_1 = 1 \quad \text{and} \quad m_i = 2^{i-1} + 1 \text{ for } i > 1. \tag{2.13}$$

With this particular choice, one obtains nested sets of abscissas, i.e., $\vartheta^i \subset \vartheta^{i+1}$ and thereby $\mathscr{H}_{\boldsymbol{\alpha}}(\mathrm{w}, N) \subset \mathscr{H}_{\boldsymbol{\alpha}}(\mathrm{w}+1, N)$. It is important to choose $m_1 = 1$ if we are interested in optimal approximation in relatively large N, because in all other cases the number of points used by $\mathscr{A}_{\boldsymbol{\alpha}}(\mathrm{w}, N)$ increases too fast with N.

Gaussian abscissas. These abscissas are the zeros of the orthogonal polynomials with respect to some positive weight. However, they are in general not nested. Regardless, as in the Clenshaw–Curtis case, we choose the number m_i of abscissas that are used by $\mathscr{U}^i$ as in (2.13). See the work [27] for an insightful comparison of quadrature formulas based on Clenshaw–Curtis and Gaussian abscissas. The natural choice of the weight should be the probability density function ρ of the random variables $Y_i(\omega)$, $i = 1, \ldots, N$. Yet, in the general joint multivariate case, if the random variables Y_i are not independent, the density ρ does not factorize, i.e., $\rho(y_1, \ldots, y_n) \neq \prod_{n=1}^{N} \rho_n(y_n)$. To this end, we first introduce an auxiliary probability density function $\hat{\rho} : \Gamma^N \to \mathbb{R}^+$ that can be seen as the joint probability of N independent random variables; i.e., it factorizes as

$$\hat{\rho}(y_1, \ldots, y_n) = \prod_{n=1}^{N} \hat{\rho}_n(y_n) \quad \forall y \in \Gamma^N \qquad \text{and is such that} \quad \left\| \frac{\rho}{\hat{\rho}} \right\|_{L^\infty(\Gamma^N)} < \infty. \tag{2.14}$$

For each dimension $n = 1, \ldots, N$, let the m_n Gaussian abscissas be the roots of the m_n degree polynomial that is $\hat{\rho}_n$-orthogonal to all polynomials of degree $m_n - 1$ on the interval $[-1, 1]$. The auxiliary density $\hat{\rho}$ should be chosen as close as possible to the true density ρ, so as to have the quotient $\rho/\hat{\rho}$ not too large. Indeed, such quotient will appear in the final error estimate (see section 3.1.2).

In Figure 1, for $N = 2$ and $\mathrm{w} = 7$, we show the anisotropic Smolyak sparse grids obtained utilizing the Clenshaw–Curtis abscissas and corresponding to the anisotropy ratio $\alpha_2/\alpha_1 = 1$ (isotropic grid), $\alpha_2/\alpha_1 = 3/2$, and $\alpha_2/\alpha_1 = 2$, respectively. We also show the indices $\mathbf{i} \in X_{\boldsymbol{\alpha}}(7, 2)$ that were used to construct the anisotropic sparse interpolant $\mathscr{A}_{\boldsymbol{\alpha}}(7, 2)$. In accordance with the nested structure of the Clenshaw–Curtis abscissas, in Figure 1 we point out the difference between active points/indices and previously computed points/indices.

2.2. Selection of the $\boldsymbol{\alpha}$ weights. The ability to evaluate the stochastic dimensions differently is a necessity since many practical problems exhibit highly anisotropic behavior, as illustrated by the linear problem described in section 1, where the size τ_n of the analyticity region (1.10) associated to each random variable Y_n increases with n.

We now assume that the solution to our problem has analytic dependence with respect to each of the random variables; i.e., it satisfies Assumption 1.4. In such a case, we know that if we approximate the dependence on each random variable with polynomials, the *best approximation error* decays exponentially fast with respect to the polynomial degree. More precisely, for a univariate analytic function, we recall the following lemma, whose proof can be found in [1, Lemma 7] and which is an immediate extension of the result given in [9, Chapter 7, section 8].

LEMMA 2.3. *Given a function $v \in C^0(\Gamma^1; W(D))$ which admits an analytic extension in the region of the complex plane $\Sigma(\Gamma^1; \tau) = \{z \in \mathbb{C}, \ \mathit{dist}(z, \Gamma^1) \leq \tau\}$ for some $\tau > 0$, there holds*

$$E_{m_i} \equiv \min_{w \in V_{m_i}} \|v - w\|_{C^0(\Gamma^1; W(D))} \leq \frac{2}{e^{2g} - 1} e^{-2m_i g} \max_{z \in \Sigma(\Gamma^1; \tau)} \|v(z)\|_{W(D)},$$

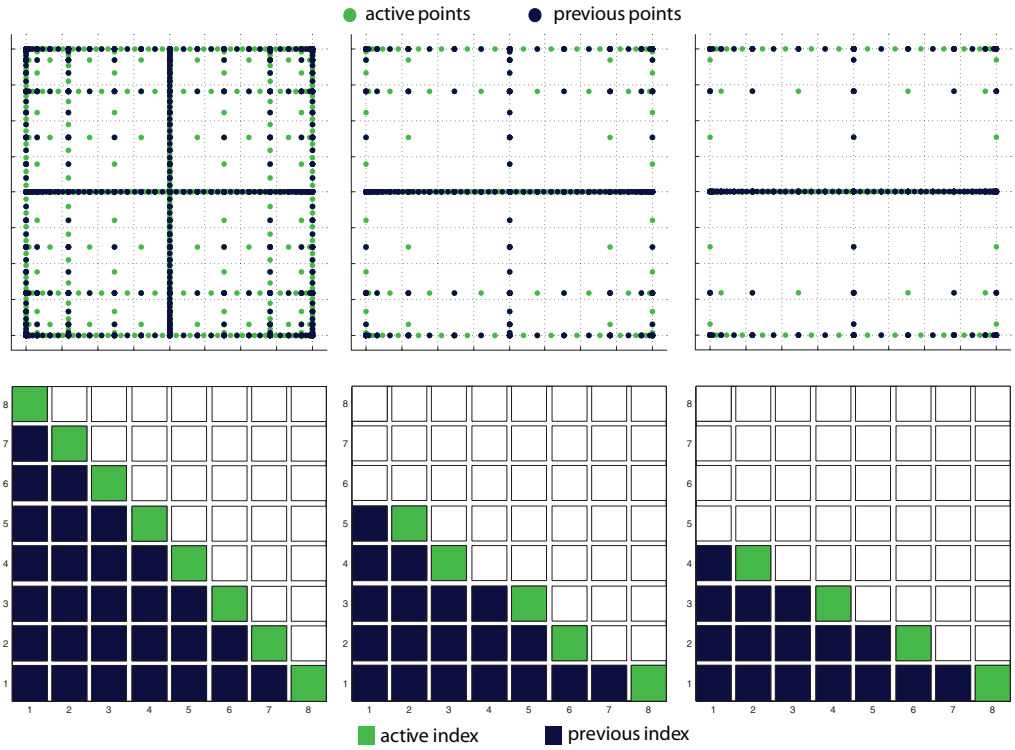

FIG. 1. *For a finite-dimensional* Γ^N *with* $N = 2$ *and* $\mathrm{w} = 7$ *we plot, in the top row, the anisotropic sparse grid with* $\alpha_2/\alpha_1 = 1$ *(isotropic),* $\alpha_2/\alpha_1 = 3/2$*, and* $\alpha_2/\alpha_1 = 2$*, utilizing the Clenshaw–Curtis abscissas. In the bottom row, we plot the corresponding indices* $(i_1, i_2) \in X_{\boldsymbol{\alpha}}(7, 2)$.

with

$$0 < g = \frac{1}{2} \log \left(\frac{2\tau}{|\Gamma^1|} + \sqrt{1 + \frac{4\tau^2}{|\Gamma^1|^2}} \right). \tag{2.15}$$

Remark 2.4 (approximation with unbounded random variables). A related result with weighted norms holds for unbounded random variables whose probability density decays as the Gaussian density at infinity (see [1]).

In the multivariate case, the size of the analyticity region, τ, will depend, in general, on the direction n (that is, $\tau = \tau_n$); cf. (1.10). As a consequence, the decay coefficient g will also depend on the direction, $n = 1, \ldots, N$, and will be denoted by $g(n)$.

The key idea of our anisotropic sparse stochastic collocation method is to place more points in those directions with slower convergence rate, i.e., with smaller $g(n)$. In particular, we propose to link the weights α_n with the rate of exponential convergence in the corresponding direction in the following way:

$$\alpha_n = g(n) \quad \forall n = 1, 2, \ldots, N. \tag{2.16}$$

In what follows we will use the notation

$$\underline{\alpha} = \underline{g} = \min_{1 \le n \le N} \{g(n)\} \quad \text{and} \quad \mathscr{G}(N) = \sum_{n=1}^{N} g(n). \tag{2.17}$$

As we will show in Remark 3.12, the choice $\boldsymbol{\alpha} = \mathbf{g}$ is optimal with respect to the error bound derived in Theorem 3.8. Observe that we have now transformed the problem of choosing $\boldsymbol{\alpha}$ into one of estimating the decay coefficients $\mathbf{g} = (g(1), \ldots, g(N))$. In the remainder of the section we will present two possible estimation strategies. The first uses a priori knowledge on the error decay in each direction, while the second approach uses a posteriori information from computations and fits the values of $\mathbf{g}$.

A priori selection. The estimation of the $\boldsymbol{\alpha} = \mathbf{g} \in \mathbb{R}_+^N$ coefficients can be achieved using a priori information, i.e., by first estimating suitable values for τ_n, and then taking $g(n)$ as in (2.15):

$$g(n) = \frac{1}{2} \log \left(\frac{2\tau_n}{|\Gamma_n|} + \sqrt{1 + \frac{4{\tau_n}^2}{|\Gamma_n|^2}} \right)$$

for $n = 1, 2, \ldots, N$. In the numerical examples presented in section 4 we have used the simpler and more conservative relation

$$g(n) = \frac{1}{2} \log \left(1 + \frac{2\tau_n}{|\Gamma_n|} \right). \tag{2.18}$$

A priori estimates for τ_n can be derived for certain classes of problems; see, for instance, the estimate (1.10), which applies to the linear problem (1.2) with random diffusivity coefficient as in (1.9). In section 4, we implement and test numerically this a priori choice of $\boldsymbol{\alpha}$ when solving problem (1.2).

A posteriori selection. In some practical applications it may not be possible to sharply estimate the vector $\mathbf{g}$ using a priori information. In this case, a computational alternative is given by a posteriori estimates. To do so, we can approximate the dependence of the solution on the nth parameter y_n by polynomial interpolation using either Clenshaw–Curtis or Gaussian abscissas, while freezing the other parameters y_n^* (for instance, we take $y_n^* = \mathbb{E}[Y_n^*]$, i.e., the mean value of the corresponding random variables). From Lemma 2.3, we expect the interpolation error to decay as

$$\varepsilon_n \approx d_n e^{-2p_n g(n)}, \tag{2.19}$$

where p_n is the number of collocation points in the direction n. Hence,

$$\log_{10}(\varepsilon_n) \approx \log_{10}(d_n) - 2p_n \log_{10}(e) g(n).$$

The error ε_n can be easily estimated by comparing two consecutive interpolants with p_n and $p_n + 1$ collocation points, respectively. Then, if we plot $\log_{10}(\varepsilon_n)$ versus p_n for each direction $n = 1, 2, \ldots, N$ and use a linear least squares approximation to fit the data, the slope of each line will give an estimate of $g(n)$.

In section 4 we will analyze the linear problem (1.2) with random diffusivity coefficient of the type (1.9) representing a Gaussian random field with a given correlation length L_c. Here we anticipate the results of the fitting of the coefficients $\mathbf{g}$ for a case with $N = 11$ random variables and correlation length $L_c = 1/64$ and $L_c = 1/2$. The former corresponds to an almost isotropic situation, while the latter corresponds to a highly anisotropic situation. Figure 2 shows the $L^2(D)$ approximation error in the expected value, $\mathbb{E}[\varepsilon_n]$. The results for $g(n)$, $n = 1, 2, \ldots, N = 11$, can be seen in Table 1, which reveals that the a posteriori selection of $\boldsymbol{\alpha} \in \mathbb{R}_+^N$ performs well at detecting the anisotropic feature of the problem in the two cases $L_c = 1/2$ and $1/64$.

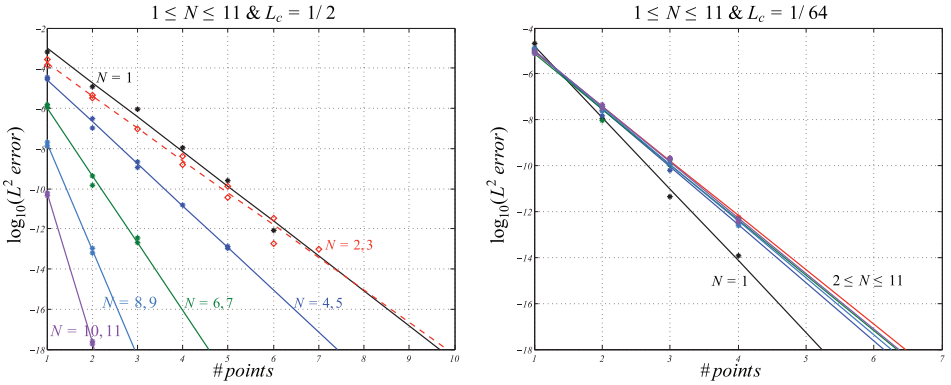

FIG. 2. *A linear least square approximation to fit* $\log_{10}(\|E[\varepsilon_n]\|_{L^2(D)})$ *versus* p_n *with* ε_n *defined by* (2.19). *For* $n = 1, 2, \ldots, N = 11$ *we plot the highly anisotropic case* $L_c = 1/2$ *(left) and the isotropic case* $L_c = 1/64$ *(right).*

TABLE 1

The $N = 11$ *values of the coefficients* $g(n)$ *constructed from a posteriori information. The values* $g(n)$, $n = 1, 2, \ldots, N$, *are the slopes of* N *linear least squares fits to univariate interpolation errors, when solving problem* (1.2) *with correlation lengths* $L_c = 1/2$ *and* $1/64$.

	$g(1)$	$g(2) = g(3)$	$g(4) = g(5)$	$g(6) = g(7)$	$g(8) = g(9)$	$g(10) = g(11)$
$L_c = 1/2$	0.85	0.80	1.0	1.6	2.6	3.7
$L_c = 1/64$	1.5	1.2	1.2	1.2	1.2	1.2

In the former case the vector $\boldsymbol{\alpha}$ weighs heavily in the higher dimensions, as opposed to the latter, which approximately weighs equally in all directions. Also, both cases $L_c = 1/2$ and $1/64$ reveal that $\underline{\alpha} = \alpha_2 = \alpha_3$.

Observe that in general the rate $g(n)$ also depends on the values $\mathbf{y}_n^* \in \Gamma_n^*$ of the other random variables. Our way of estimating the decay coefficients $g(n)$ is not conservative since we estimate them only at the single point $\mathbb{E}[Y_n^*]$. A more conservative estimate would consider the worst value of $\mathbf{y}_n^*$, i.e., the one that minimizes $g(n)$. This may be critical for nearly singular cases.

Finally, observe that the a posteriori selection of $\boldsymbol{\alpha} \in \mathbb{R}_+^N$, described above, is not restricted to random fields related to Karhunen–Loève-type expansions, and can be easily applied to any other case where the input data are described by a finite number of random variables.

3. Error analysis. Collocation methods can be used to approximate the solution $u_N \in C^0(\Gamma^N; W(D))$ using finitely many function values. By Assumption 1.4, u_N admits an analytic extension. Further, each function value will be computed by means of a finite element technique. In general, the semidiscrete finite element solution $\pi_h u_N$ also satisfies the regularity Assumption 1.4. In particular this is true for the linear problem (1.2) with random coefficients as in (1.9). Let the fully discrete approximation be $\mathscr{A}_{\boldsymbol{\alpha}}(\mathrm{w}, N)\pi_h u_N$. Our aim is to give a priori estimates for the total error

$$\epsilon = u - \mathscr{A}_{\boldsymbol{\alpha}}(\mathrm{w}, N)\pi_h u_N,$$

where the operator $\mathscr{A}_{\boldsymbol{\alpha}}(\mathrm{w}, N)$ is described by (2.8) and π_h is the finite element projection operator described by (2.2). We will investigate the error

(3.1)
$$\|u - \mathscr{A}_{\boldsymbol{\alpha}}(\mathrm{w}, N)\pi_h u_N\| \leq \underbrace{\|u - u_N\|}_{(I)} + \underbrace{\|u_N - \pi_h u_N\|}_{(II)} + \underbrace{\|\pi_h u_N - \mathscr{A}_{\boldsymbol{\alpha}}(\mathrm{w}, N)\pi_h u_N\|}_{(III)}$$

evaluated in the natural norm $L^2_P(\Omega; W(D))$. Since the error functions in (II) and (III) are finite-dimensional, the natural norm is equivalent to the $L^2_\rho(\Gamma^N; W(D))$ norm. By controlling the error in this natural norm we also control the error in the expected value of the solution, for example,

$$\|E[\epsilon]\|_{W(D)} \leq E\left[\|\epsilon\|_{W(D)}\right] \leq \|\epsilon\|_{L^2_P(\Omega; W(D))}.$$

The quantity (I) controls the truncation error for the case where the input data a_N and f_N are suitable truncations of random fields. This contribution to the total error was considered in [24, section 4.2]. The quantity (I) is otherwise zero if the representation of a_N and f_N is exact. The second term (II) controls the convergence with respect to h, i.e., the finite element error, which will be dictated by standard approximability properties of the finite element space $W_h(D)$, given by (2.1), and the regularity in space of the solution u (see, e.g., [6, 5]). Specifically,

$$\|u_N - \pi_h u_N\|_{L^2_\rho(\Gamma^N; W(D))} \leq h^s \left(\int_{\Gamma^N} C_\pi(y) C(s; u(y))^2 \rho(y)\, dy\right)^{1/2}$$

by the finite element approximability property (2.1).

In what follows, our primary concern will be to analyze the approximation error (III), namely,

$$\|\pi_h u_N - \mathscr{A}_{\boldsymbol{\alpha}}(\mathrm{w}, N)\pi_h u_N\|_{L^2_\rho(\Gamma^N; W(D))}, \tag{3.2}$$

for both the Clenshaw–Curtis and Gaussian versions of the anisotropic Smolyak algorithm.

Under the very reasonable assumption that the semidiscrete finite element solution $\pi_h u_N$ admits an analytic extension as described in Assumption 1.4 with the same analyticity region as for u_N, the behavior of the error (3.2) will be analogous to $\|u_N - \mathscr{A}_{\boldsymbol{\alpha}}(\mathrm{w}, N)u_N\|_{L^2_\rho(\Gamma^N; W(D))}$. For this reason, in the next sections we will analyze the latter.

3.1. Analysis of the anisotropic Smolyak approximation error. In order to get error bounds for the anisotropic Smolyak algorithm in the multidimensional case, we will connect the general case to the case $N = 1$ and then apply successively Lemma 2.3.

As stated in section 2.1, the anisotropic sparse grid construction treats all directions differently and relates the maximum number of collocation points used in each direction with the corresponding exponential convergence rate. We should expect, therefore, a faster convergence rate when compared to the isotropic Smolyak algorithm described in [29, 24] for such problems that exhibit strong anisotropic effects. We will analyze separately the two cases of Clenshaw–Curtis and Gaussian abscissas.

3.1.1. Interpolation estimates for the Clenshaw–Curtis abscissas. In this section we develop L^∞ error estimates for the anisotropic Smolyak interpolant

based on Clenshaw–Curtis abscissas, applied to analytic functions $u \in C^0(\Gamma^N; W(D))$ that satisfy Assumption 1.4. We remind the reader that even though in the global estimate (3.1) it is enough to bound the approximation error (III) in the $L^2_\rho(\Gamma^N; W(D))$ norm, we will still work with the more stringent $L^\infty(\Gamma^N; W(D))$ norm. In our notation the norm $\|\cdot\|_{\infty,N}$ is shorthand for $\|\cdot\|_{L^\infty(\Gamma^N;W(D))}$ and will be used henceforth.

We begin by letting E_m be the best approximation error, as in Lemma 2.3, to functions $u \in C^0(\Gamma_1; W(D))$ by polynomial functions $w \in V_m$. Since the interpolation formula $\mathscr{U}^{i_n}$, $n = 1, \dots, N$, is exact on polynomials in $V_{m_{i_n}-1}$, we can apply the general formula

$$\left\|u - \mathscr{U}^{i_n}(u)\right\|_{\infty,1} \le E_{m_{i_n}-1}(u) \cdot \left(1 + \Lambda_{m_{i_n}}\right), \tag{3.3}$$

where Λ_m is the Lebesgue constant corresponding to the abscissas (2.12). In this case, it is known that

$$\Lambda_m \le \frac{2}{\pi} \log(m-1) + 1 \tag{3.4}$$

for $m \ge 2$; see [10]. On the other hand, using Lemma 2.3 the best approximation to functions $u \in C^0(\Gamma_n; W(D))$ that admit an analytic extension as described by Assumption 1.4 is bounded by

$$E_{m_{i_n}}(u) \le \frac{2}{e^{2g(n)} - 1} e^{-2m_i g(n)} M(u), \tag{3.5}$$

where $M(u) = \max_{1\le n\le N} \max_{y_n^* \in \Gamma_n^*} \max_{z \in \Sigma(\Gamma_n;\tau_n)} \|u(z)\|_{W(D)}$. For $n = 1, 2, \dots, N$ denote the one-dimensional identity operator $I_1^{(n)} : C^0(\Gamma^n; W(D)) \to C^0(\Gamma^n; W(D))$, and use (3.3)–(3.5) to estimate

$$\begin{aligned} \left\|(I_1^{(n)} - \mathscr{U}^{i_n})(u)\right\|_{\infty,1} &\le \frac{4}{e^{2g(n)} - 1}\, i_n e^{-g(n)2^{i_n}}\, M(u), \\ \left\|(\Delta^{i_n})(u)\right\|_{\infty,1} &\le \frac{8}{e^{2g(n)} - 1}\, i_n e^{-g(n)2^{i_n - 1}} M(u). \end{aligned} \tag{3.6}$$

Since the value $M(u)$ affects the error estimates as a multiplicative constant, from here on we assume it to be one without any loss of generality.

The convergence proof will be split into several steps, the main results being given in Theorems 3.4 and 3.8, which state the convergence rates in terms of either the level w or, more interestingly, the total number of collocation points. For the purpose of error analysis we first introduce the set

$$\tilde{X}_{\boldsymbol{\alpha}}(\mathrm{w}, d) := \left\{ \mathbf{i} \in \mathbb{N}_+^d, \mathbf{i} \ge \mathbf{1} \,:\, \left(\sum_{n=1}^{d} (i_n - 1)\alpha_n - \underline{\alpha}\mathrm{w} \right) \in [0, \alpha_d] \right\}.$$

Moreover, we denote by I_d the identity operator applicable to functions which depend on the first d variables $y_1, \dots, y_d$. Then the following two lemmas, whose proofs are similar to the one presented in [24, Lemma 3.3], hold.

LEMMA 3.1 (error representation). *The following error representation holds for the Smolyak formula* (2.8)*:*

$$I_N - \mathscr{A}_{\boldsymbol{\alpha}}(\mathrm{w}, N) = \sum_{d=2}^{N} \left[\tilde{R}(\mathrm{w}, d) \bigotimes_{n=d+1}^{N} I_1^{(n)} \right] + \left(I_1^{(1)} - \mathscr{A}_{\boldsymbol{\alpha}}(\mathrm{w}, 1) \right) \bigotimes_{n=2}^{N} I_1^{(n)},$$

where, for $2 \le d \le N$, we have used the auxiliary notation

$$\tilde{R}(\mathrm{w}, d) = \sum_{\mathbf{i} \in X_{\boldsymbol{\alpha}}(\mathrm{w}, d-1)} \bigotimes_{n=1}^{d-1} \Delta^{i_n} \otimes \left(I_1^{(d)} - \mathscr{U}^{\hat{i}_d - 1} \right)$$

and, for any $(i_1, \ldots, i_{d-1}) \in X_{\boldsymbol{\alpha}}(\mathrm{w}, d-1)$, we have set $\hat{i}_d = \lfloor 2 + \mathrm{w}\frac{\alpha}{\alpha_d} - \sum_{n=1}^{d-1}(i_n - 1)\frac{\alpha_n}{\alpha_d} \rfloor$. Here $\lfloor \cdot \rfloor$ denotes the integer part of a real number.

LEMMA 3.2 (recursive estimate). *Let $u \in C^0(\Gamma^N; W(D))$ satisfy the assumptions of Lemma 2.3, and let the anisotropic Smolyak formula (2.8) be based on Clenshaw–Curtis abscissas. Then we have*

$$\left\| \left(I_N - \mathscr{A}_{\boldsymbol{\alpha}}(\mathrm{w}, N) \right)(u) \right\|_{L^\infty(\Gamma^N; W(D))} \le \sum_{d=1}^{N} R(\mathrm{w}, d), \tag{3.7}$$

with

$$R(\mathrm{w}, d) := \frac{8^d}{2} \sum_{\mathbf{i} \in \tilde{X}_{\boldsymbol{\alpha}}(\mathrm{w}, d)} \left(\prod_{n=1}^{d} \frac{i_n}{e^{2g(n)} - 1} \right) e^{-h(\mathbf{i}, d)} \tag{3.8}$$

and

$$h(\mathbf{i}, d) = \sum_{n=1}^{d} g(n) 2^{i_n - 1}. \tag{3.9}$$

LEMMA 3.3 (bound for $R(\mathrm{w}, d)$). *Let $\delta > 0$. Consider functions $u \in C^0(\Gamma^N; W(D))$ satisfying the assumption of Lemma 2.3 and the anisotropic Smolyak formula (2.8) based on Clenshaw–Curtis abscissas and weights $\alpha_n = g(n)$. Then the following bound holds for the term $R(\mathrm{w}, d)$, $d = 1, \ldots, N$, defined in (3.8):*

$$R(\mathrm{w}, d) \le C_1(\mathbf{g}, d, \delta) \exp\left\{ -\mathscr{G}(d)\, 2^{\mathrm{w}\frac{g}{\mathscr{G}(d)}} + \frac{d\delta}{2} \left\lfloor \mathrm{w}\frac{g}{\mathscr{G}(d)} \right\rfloor \right\}, \tag{3.10}$$

with

$$C_1(\mathbf{g}, d, \delta) := \frac{1}{2} \exp\left(\sum_{n=1}^{d} \left\{ \frac{1}{2} \left(\frac{1}{g(n)\log^2(2)} + \frac{1}{\log(2)\sqrt{2g(n)}} \right) + \frac{1}{\log(2)} \sqrt{\frac{\pi}{2g(n)}} \right\} \right) \times \prod_{n=1}^{d} \left(\frac{32 \exp(\delta)}{\delta e(\exp(2g(n)) - 1)} \right). \tag{3.11}$$

Proof. We follow closely the arguments in [24, Lemma 3.4]. First observe that $\forall \mathbf{i} \in \tilde{X}_{\boldsymbol{\alpha}}(\mathrm{w}, d)$ we have, denoting $\mathbf{i}^* = \left(1 + \mathrm{w}\frac{g}{\mathscr{G}(d)}, \ldots, 1 + \mathrm{w}\frac{g}{\mathscr{G}(d)}\right)$, the inequality

$$h(\mathbf{i}, d) \ge h(\mathbf{i}^*, d) + \sum_{n=1}^{d} \frac{g(n)\log^2(2)}{2} \left(i_n - \left(1 + \mathrm{w}\frac{g}{\mathscr{G}(d)} \right) \right)^2.$$

Therefore, combining the previous with (3.8) yields

$$R(\mathrm{w}, d) \le \frac{8^d}{2} e^{-h(\mathbf{i}^*, d)} \sum_{\mathbf{i} \in \tilde{X}_{\boldsymbol{\alpha}}(\mathrm{w}, d)} \left(\prod_{n=1}^{d} \frac{i_n}{e^{2g(n)} - 1} \right) \exp\left\{ -\sum_{n=1}^{d} \frac{g(n)\log^2(2)}{2} \left(i_n - \left(1 + \mathrm{w}\frac{g}{\mathscr{G}(d)} \right) \right)^2 \right\}.$$

Now recall that since $\mathbf{i} \in \tilde{X}_{\boldsymbol{\alpha}}(\mathrm{w}, d)$ we have

$$i_n \le i_{n,\max} = 1 + \left\lfloor \frac{\underline{\alpha}}{\alpha_n}\mathrm{w} + \frac{\alpha_d}{\alpha_n} \right\rfloor, \quad n = 1, \dots, d,$$

and this implies

$$R(\mathrm{w}, d) \le \frac{8^d}{2\prod_{n=1}^d (e^{2g(n)} - 1)} e^{-h(\mathbf{i}^*, d)} \prod_{n=1}^d \left(\underbrace{\sum_{i_n=1}^{i_{n,\max}} i_n \exp\left(-\frac{g(n)\log^2(2)}{2} \left(i_n - \left(1 + \mathrm{w}\frac{\underline{g}}{\mathscr{G}(d)} \right) \right)^2 \right)}_{=T(n)} \right).$$

Using the result in [24, Corollary A.4], we have the bound

$$T(n) \le \underbrace{2\left(\frac{1}{g(n)\log^2(2)} + \frac{1}{\log(2)\sqrt{2g(n)}} \right)}_{C_1} + 2\left(2 + \left\lfloor \mathrm{w}\frac{\underline{g}}{\mathscr{G}(d)} \right\rfloor \right) \left(1 + \underbrace{\frac{1}{\log(2)}\sqrt{\frac{\pi}{2g(n)}}}_{C_2} \right),$$

and

$$\begin{aligned} \prod_{n=1}^d T(n) &\le 4^d \prod_{n=1}^d \left(\frac{1}{2}C_1 + \left(1 + \frac{1}{2}\left\lfloor \mathrm{w}\frac{\underline{g}}{\mathscr{G}(d)} \right\rfloor \right)(1 + C_2) \right) \\ &\le 4^d \left(1 + \frac{1}{2}\left\lfloor \mathrm{w}\frac{\underline{g}}{\mathscr{G}(d)} \right\rfloor \right)^d \prod_{n=1}^d \left(\frac{1}{2}C_1 + (1 + C_2) \right) \\ &\le \left(\prod_{n=1}^d \frac{4e^\delta}{\delta e} \right) \exp\left(\frac{\delta d}{2}\left\lfloor \mathrm{w}\frac{\underline{g}}{\mathscr{G}(d)} \right\rfloor \right) \exp\left(\sum_{n=1}^d \left\{ \frac{1}{2}C_1 + C_2 \right\} \right). \end{aligned}$$

Observe that we have used the inequality $1 + x \le \exp(x)$ in the last step. Combining this bound with the previous estimate for $R(\mathrm{w}, d)$ leads to the desired result. ∎

THEOREM 3.4. *Consider functions $u \in C^0(\Gamma^N; W(D))$ satisfying the assumption of Lemma 2.3. The anisotropic Smolyak formula (2.8) based on Clenshaw–Curtis abscissas and weights $\alpha_n = g(n)$ satisfies the error estimate*

$$\left\| \left(I_N - \mathscr{A}_{\boldsymbol{\alpha}}(\mathrm{w}, N) \right)(u) \right\|_{L^\infty(\Gamma^N; W(D))} \le \hat{C}(\mathbf{g}, N) e^{\mathrm{w}\frac{\underline{g}}{2} - \lambda(\mathrm{w}, N)}, \tag{3.12}$$

where

$$\lambda(\mathrm{w}, N) := \begin{cases} \mathrm{w}\underline{g}\log(2)e & \text{if } 0 \le \mathrm{w} \le \frac{\mathscr{G}(N)}{\underline{g}\log(2)}, \\ \mathscr{G}(N) 2^{\mathrm{w}\frac{\underline{g}}{\mathscr{G}(N)}} & \text{otherwise}, \end{cases} \tag{3.13}$$

and the function $\hat{C}(\mathbf{g}, N) = \sum_{d=1}^{N} C_1(\mathbf{g}, d, \frac{\mathscr{G}(d)}{d})$ *does not depend on* w.

Proof. From Lemmas 3.2 and 3.3 and using constants $\delta_d > 0$, $d = 1, \ldots, N$, we obtain the following bound for the interpolation error:

$$\begin{aligned}
&\left\| \left(I_N - \mathscr{A}_{\boldsymbol{\alpha}}(\mathrm{w}, N)\right)(u) \right\|_{L^\infty(\Gamma^N; W(D))} \\
&\qquad \leq \sum_{d=1}^{N} C_1(\mathbf{g}, d, \delta_d) \exp\left(-\mathscr{G}(d)\, 2^{\mathrm{w}\frac{\underline{g}}{\mathscr{G}(d)}} + \frac{d\delta_d}{2} \left\lfloor \mathrm{w} \frac{\underline{g}}{\mathscr{G}(d)} \right\rfloor \right).
\end{aligned}$$

Now choose $\delta_d = \frac{\mathscr{G}(d)}{d}$ for $d = 1, \ldots, N$, yielding

$$\begin{aligned}
&\left\| \left(I_N - \mathscr{A}_{\boldsymbol{\alpha}}(\mathrm{w}, N)\right)(u) \right\|_{L^\infty(\Gamma^N; W(D))} \\
&\qquad \leq \sum_{d=1}^{N} C_1\left(\mathbf{g}, d, \frac{\mathscr{G}(d)}{d}\right) \exp\left(-\mathscr{G}(d) \left\{ 2^{\mathrm{w}\frac{\underline{g}}{\mathscr{G}(d)}} - \frac{1}{2} \left\lfloor \mathrm{w} \frac{\underline{g}}{\mathscr{G}(d)} \right\rfloor \right\} \right).
\end{aligned}$$

We now turn our attention to finding a minimum for $\widehat{\lambda}(\mathrm{w}, d) := \mathscr{G}(d) 2^{\mathrm{w}\frac{\underline{g}}{\mathscr{G}(d)}}$ for $1 \leq d \leq N$. Let us define, for $s \in \left[1, \frac{\mathscr{G}(N)}{\underline{g}}\right]$, the function

$$p(s) := s\, 2^{\frac{\mathrm{w}}{s}},$$

so that $\widehat{\lambda}(\mathrm{w}, d) = \underline{g} p\left(\frac{\mathscr{G}(d)}{\underline{g}}\right)$ and

$$\min_{1 \leq d \leq N} \widehat{\lambda}(\mathrm{w}, d) \geq \min_{s \in [1, \mathscr{G}(N)/\underline{g}]} \underline{g} p(s).$$

We have

$$\frac{dp}{ds} = 2^{\frac{\mathrm{w}}{s}} \left(1 - \left(\frac{\mathrm{w}}{s}\right) \log(2)\right) = 0,$$

yielding $s = \mathrm{w}\log(2)$. For w sufficiently large, the minimum of $p(s)$ falls outside the interval $\left[1, \frac{\mathscr{G}(N)}{\underline{g}}\right]$ and the function $p(s)$ is decreasing on this interval. Therefore, there are two cases to consider. The first is the situation when $\mathrm{w} > \frac{\mathscr{G}(N)}{\underline{g}\log(2)}$ and the second when $0 \leq \mathrm{w} \leq \frac{\mathscr{G}(N)}{\underline{g}\log(2)}$. In either case

$$\min_{1 \leq d \leq N} \widehat{\lambda}(\mathrm{w}, d) \geq \lambda(\mathrm{w}, N),$$

and hence

$$\max_{1 \leq d \leq N} e^{-\widehat{\lambda}(\mathrm{w}, d)} \leq e^{-\lambda(\mathrm{w}, N)}.$$

From this the result (3.12) follows by taking

$$\hat{C}(\mathbf{g}, N) = \sum_{d=1}^{N} C_1\left(\mathbf{g}, d, \frac{\mathscr{G}(d)}{d}\right). \tag{3.14}$$

∎

Remark 3.5 (behavior of $\hat{C}(\mathbf{g}, N)$ with respect to N). Denoting $k_1 = \frac{1}{2\log^2(2)}$ and $k_2 = \frac{1}{2\log(2)\sqrt{2}}(1+\sqrt{\pi})$, from (3.14) and (3.11) we observe that the constant $\hat{C}(\mathbf{g}, N)$ appearing in the convergence estimates of Theorem 3.4 has the form

(3.15)
$$\begin{aligned}\hat{C}(\mathbf{g}, N) &= \frac{1}{2}\sum_{d=1}^{N}\prod_{n=1}^{d}\left(\exp\left(k_1\frac{1}{g(n)} + k_2\frac{1}{\sqrt{g(n)}}\right)\frac{32\exp\left(g(n)\right)}{\frac{\mathscr{G}(d)}{d}e(\exp(2g(n))-1)}\right)\\ &= \frac{1}{2}\sum_{d=1}^{N}\left(\frac{16}{\frac{\mathscr{G}(d)}{d}e}\right)^{d}\exp\left(\sum_{n=1}^{N}\left\{k_1\frac{1}{g(n)} + k_2\frac{1}{\sqrt{g(n)}} - \log(\sinh(g(n)))\right\}\right).\end{aligned}$$

In the presence of anisotropic behavior, it is natural to assume that the monotone sequence $g(n)$ goes to infinity, which implies $\frac{\mathscr{G}(d)}{d} \to +\infty$. Clearly, in this situation the sum in (3.15) is convergent in N, so $\hat{C}(\mathbf{g}, N)$ does not deteriorate as the dimension of the problem grows to infinity. In particular, the more anisotropic the sequence $\mathbf{g}$ becomes (i.e., the faster $g(n)$ grows), the smaller the constant $\hat{C}(\mathbf{g}, N)$ becomes.

Observe that $\hat{C}(\mathbf{g}, N)$ goes to infinity when $\underline{g}$ tends to zero. We should note that in such case we lose convergence anyway. Sharper error estimates corresponding to small values of $g(n)$ are given in [24, Remark 3.5].

Now we relate the number of collocation points $\eta = \eta(\mathrm{w}, N) = \#\mathscr{H}_{\boldsymbol{\alpha}}(\mathrm{w}, N)$ to the level w of the anisotropic Smolyak algorithm. We state the result in the following lemma.

LEMMA 3.6. *Using the anisotropic Smolyak formula described by* (2.8)*, based on Clenshaw–Curtis abscissas, the total number of points required at level* w *satisfies the following bounds:*

$$2^{\mathrm{w}-1} \le \eta \le 2^{\mathrm{w}} e^{\mathrm{w}\sum_{n=1}^{N}\underline{\alpha}/\alpha_n}. \tag{3.16}$$

Moreover, as a direct consequence of (3.16) *we get that*

$$\frac{\log(\eta)}{\sum_{n=1}^{N}\frac{\underline{\alpha}}{\alpha_n} + \log(2)} \le \mathrm{w} \le \log_2(2\eta). \tag{3.17}$$

Proof. By using formula (2.8) and exploiting the nested structure of the Clenshaw–Curtis abscissas, we can count the number of points $\eta = \eta(\mathrm{w}, N) = \#\mathscr{H}_{\boldsymbol{\alpha}}(\mathrm{w}, N)$ in the following way:

$$\eta = \sum_{\mathbf{i}\in X_{\boldsymbol{\alpha}}(\mathrm{w},N)}\prod_{n=1}^{N} r(i_n), \quad \text{where } r(i) := \begin{cases} 1 & \text{if } i = 1,\\ 2 & \text{if } i = 2,\\ 2^{i-2} & \text{if } i > 2.\end{cases} \tag{3.18}$$

Begin by noticing that $\forall n = 1, 2, \ldots, N$ the following bound holds:

$$2^{i_n-2} \le r(i_n) \le 2^{i_n-1}. \tag{3.19}$$

Next, let $m \in [1, N]$ be the index corresponding to the minimum α, i.e., $\alpha_m = \min_{1\le n\le N}\{\alpha_n\} = \underline{\alpha}$. A lower bound on the number η of points can be obtained considering only the contribution from the tensor grid of indices $i_n = 1$ for $n \ne m$ and $i_m = \mathrm{w}+1$. On the other hand, it is easy to see that $|\mathbf{i}-\mathbf{1}| = \sum_{n=1}^{N}(i_n - 1) \le \mathrm{w}$,

so the following bounds hold:

$$2^{\mathrm{w}-1} \leq \eta = \sum_{\mathbf{i}\in X_{\boldsymbol{\alpha}}(\mathrm{w},N)} \prod_{n=1}^{N} r(i_n) \leq \sum_{\mathbf{i}\in X_{\boldsymbol{\alpha}}(\mathrm{w},N)} 2^{|\mathbf{i}-\mathbf{1}|} \leq 2^{\mathrm{w}} \# X_{\boldsymbol{\alpha}}(\mathrm{w},N).$$

We now need a bound for the cardinality of the set $X_{\boldsymbol{\alpha}}(\mathrm{w},N)$. Let us observe that the maximum index i_n^{max} allowable in each direction in the set $X_{\boldsymbol{\alpha}}(\mathrm{w},N)$ is $i_n^{max} = 1 + \lfloor \frac{\underline{\alpha}\mathrm{w}}{\alpha_n} \rfloor$, $n = 1\ldots,N$. It follows immediately that the cardinality of the set can be bound by

$$\# X_{\boldsymbol{\alpha}}(\mathrm{w},N) \leq \prod_{n=1}^{N} \left(\mathrm{w}\frac{\underline{\alpha}}{\alpha_n} + 1 \right). \tag{3.20}$$

Moreover we have

$$\# X_{\boldsymbol{\alpha}}(\mathrm{w},N) \leq \exp\left\{ \mathrm{w} \sum_{n=1}^{N} \frac{\underline{\alpha}}{\alpha_n} \right\}, \tag{3.21}$$

and the inequalities (3.16) and (3.17) follow. ∎

Remark 3.7. The bound for the cardinality of the set $\# X_{\boldsymbol{\alpha}}(\mathrm{w},N)$ given in (3.20) is not sharp when $\mathrm{w} \to \infty$, and actually one has instead the asymptotic behavior

$$\# X_{\boldsymbol{\alpha}}(\mathrm{w},N) \lesssim \frac{\mathrm{w}^N}{N!} \prod_{n=1}^{N} \frac{\underline{\alpha}}{\alpha_n},$$

which is consistent with the isotropic result given in [24]. Moreover, if we use Stirling's approximation for the factorial term, the previous bound becomes

$$\# X_{\boldsymbol{\alpha}}(\mathrm{w},N) \lesssim \frac{1}{\sqrt{N}} \prod_{n=1}^{N} \frac{e\mathrm{w}}{N} \frac{\underline{\alpha}}{\alpha_n} \leq \frac{1}{\sqrt{N}} \exp\left\{ \mathrm{w} \left(\frac{e}{N} \sum_{n=1}^{N} \frac{\underline{\alpha}}{\alpha_n} \right) \right\},$$

which greatly improves (3.21).

The next theorem provides an error bound in terms of the total number η of collocation points. The proof follows directly from the results in Theorem 3.4 and Lemma 3.6 and is therefore omitted.

THEOREM 3.8. *For functions $u \in L^2_\rho(\Gamma^N; W(D))$ satisfying the assumption of Lemma* 2.3 *the anisotropic Smolyak formula* (2.8)*, based on Clenshaw–Curtis abscissas and weights $\alpha_n = g(n)$, satisfies the following:*

- Algebraic convergence $\left(0 \leq \mathrm{w} \leq \frac{\mathscr{G}(N)}{\underline{g}\log(2)}\right)$:

$$\left\| \left(I_N - \mathscr{A}_{\boldsymbol{\alpha}}(\mathrm{w},N)\right)(u) \right\|_{L^\infty(\Gamma^N;W(D))} \leq \hat{C}(\mathbf{g},N)\eta^{-\mu_1}, \quad \mu_1 = \frac{\underline{g}\,(\log(2)e - 1/2)}{\log(2) + \sum_{n=1}^{N} \underline{g}/g(n)}. \tag{3.22}$$

- Subexponential convergence $\left(\mathrm{w} > \frac{\mathscr{G}(N)}{\underline{g}\log(2)}\right)$:

$$\left\| \left(I_N - \mathscr{A}_{\boldsymbol{\alpha}}(\mathrm{w},N)\right)(u) \right\|_{L^\infty(\Gamma^N;W(D))} \leq \hat{C}(\mathbf{g},N)\,\eta^{\frac{\mu_2}{2}}\, \exp\left(-\mathscr{G}(N)\eta^{\frac{\log(2)}{\mathscr{G}(N)}\mu_2}\right),$$

$$\textit{with} \qquad \mu_2 = \frac{\underline{g}}{\left(\log(2) + \sum_{n=1}^{N} \underline{g}/g(n)\right)}, \tag{3.23}$$

and constant $\hat{C}(\mathbf{g}, N)$ *defined in* (3.14) *and independent of* η.

Remark 3.9. The estimates given in (3.23) may be improved when $\mathrm{w} \to \infty$. Such an asymptotic estimate is obtained using the better counting result described in Remark 3.7.

Remark 3.10. We observe that subexponential rate of convergence is always faster than the algebraic one when $\mathrm{w} > \mathscr{G}(N)/(\underline{g}\log(2))$. Yet, this estimate is of little practical relevance since in practical computations such a high level w is seldom reached.

Remark 3.11 (on the curse of dimensionality). Suppose now that the stochastic input data are truncated expansions of random fields and that we are able to estimate the values $\{g(n)\}_{n=1}^{\infty}$. Whenever the sum $\sum_{n=1}^{\infty} \underline{g}/g(n)$ is finite then the algebraic exponent in (3.22) does not deteriorate as the truncation dimension N increases. This condition is satisfied, for instance, by the problem presented in the numerical section. This is a clear advantage with respect to the isotropic Smolyak method studied in [24]: since in this case we have $g(n) \to +\infty$, Remark 3.5 tells us that $\hat{C}(\mathbf{g}, N)$ does not deteriorate with N (i.e., it is bounded) and therefore the method does not suffer from the curse of dimensionality. In fact, in such a case we can work directly with the anisotropic Smolyak formula (2.8) in infinite dimensions: here the indices vectors become natural sequences and the constraint that defines the index set $X_{\boldsymbol{\alpha}}(\mathrm{w}, \infty)$ is $\sum_{n=1}^{\infty}(i_n - 1)g(n) \leq \mathrm{w}\underline{g}$.

The condition $\sum_{n=1}^{\infty} \underline{g}/g(n) < \infty$ is clearly sufficient to break the curse of dimensionality. In that case, even an anisotropic full tensor approximation also breaks the curse of dimensionality. The algebraic exponent for the convergence of the anisotropic full tensor approximation again deteriorates with the value of $\sum_{n=1}^{\infty} \underline{g}/g(n)$, but the constant of such convergence is $\sum_{n=1}^{N} \frac{2}{e^{2g(n)}-1}$. This constant is worse than that corresponding to the anisotropic Smolyak approximation, $\hat{C}(\mathbf{g}, N)$.

On the other hand, by considering the case where all $g(n)$ are equal and the results derived in [24], we see that in this work we have not estimated sharply the algebraic convergence exponent. We expect the anisotropic Smolyak method to break the curse of dimensionality in a wider set of problems; i.e., the condition $\sum_{n=1}^{\infty} \underline{g}/g(n) < \infty$ does not seem necessary to break the curse of dimensionality. This is in agreement with Remark 3.9.

Remark 3.12 (optimal choice of $\boldsymbol{\alpha}$). Looking at the exponential term $e^{-h(\mathbf{i},d)}$ in (3.8), which is the term determining the rate of convergence, we may try to choose the weight $\boldsymbol{\alpha}$ for $X_{\boldsymbol{\alpha}}(\mathrm{w}, N)$ as the solution to the optimization problem

$$\max_{\substack{\boldsymbol{\alpha}\in\mathbb{R}_+^d \\ |\boldsymbol{\alpha}|=1}} \min_{\mathbf{i}\in\tilde{X}_{\boldsymbol{\alpha}}(\mathrm{w},d)} h(\mathbf{i}, d).$$

This problem has the solution $\boldsymbol{\alpha} = \mathbf{g}$, and hence our choice of weights (2.16) is optimal.

3.1.2. Approximation estimates for Gaussian abscissas. By using a similar approach to that of our previous work [24, section 4.1.2] we can develop error estimates for approximating functions $u \in C^0(\Gamma^N; W(D))$ that admit an analytic extension as described by Assumption 1.4, using the anisotropic Smolyak formula based on Gaussian abscissas. We remind the reader that in the global estimate (3.1) we need to bound the approximation error (III) in the norm $L^2_\rho(\Gamma^N; W(D))$. However, the Gaussian abscissas described in section 2.1 are constructed for the auxiliary density

$\hat{\rho} = \prod_{n=1}^{N} \hat{\rho}_n$, and we have the following useful bound:

$$\|v\|_{L^2_\rho(\Gamma^N;W(D))} \leq \left\| \frac{\rho}{\hat{\rho}} \right\|_{L^\infty(\Gamma^N)} \cdot \|v\|_{L^2_{\hat{\rho}}(\Gamma^N;W(D))} \quad \forall v \in C^0(\Gamma^N; W(D)).$$

In what follows we will use the shorthand notation $\|\cdot\|_{\hat{\rho},N}$ for $\|\cdot\|_{L^2_{\hat{\rho}}(\Gamma^N;W(D))}$ and restrict our analysis to the case where $W(D)$ is a Hilbert space. Following [24], the one-dimensional interpolation error for Gaussian abscissas satisfies, $\forall i \in \mathbb{N}_+$,

$$\left\| (I_1^{(n)} - \mathscr{U}^{i_n})(u) \right\|_{\hat{\rho},1} \leq 2C_{\hat{\rho}} E_{m_{i_n}}(u) \leq \frac{4C_{\hat{\rho}}}{e^{2g(n)}-1} e^{-g(n)2^{i_n}} M(u),$$

$$C_{\hat{\rho}} = \max_{n=1,\ldots,N} \sqrt{\int_{\Gamma_n} \hat{\rho}_n(y)\, dy},$$

$$\left\| (\Delta^{i_n})(u) \right\|_{\hat{\rho},1} \leq 2C_{\hat{\rho}} (E_{m_{i_n}}(u) + E_{m_{i_{n-1}}}(u)) \leq \frac{8C_{\hat{\rho}}}{e^{2g(n)}-1} e^{-\frac{g(n)}{2}2^{i_n}} M(u).$$

The following theorem states the rate of convergence for the anisotropic Smolyak formula based on Gaussian abscissas. Since the proof is mostly similar to the one presented in the previous section for the Clenshaw–Curtis abscissas, we will provide a sketch of it and only the main differences will be highlighted.

THEOREM 3.13. *Let the function $u \in L^2_\rho(\Gamma^N; W(D))$ satisfy the assumptions of Lemma 2.3 and let the anisotropic Smolyak formula (2.8) be based on Gaussian abscissas. Then, choosing the anisotropy weights as $\alpha_n = g(n)$, we have the following:*

- Algebraic convergence $\left(0 \leq \mathrm{w} \leq \frac{\mathscr{G}(N)}{\underline{g}\log(2)}\right)$:

(3.24)
$$\|(I_N - \mathscr{A}_{\boldsymbol{\alpha}}(\mathrm{w}, N))(u)\|_{L^2_\rho(\Gamma^N;W(D))} \leq \hat{C}^G(\mathbf{g}, N)\eta^{-\mu_1}, \quad \mu_1 = \frac{\underline{g}\log(2)e}{2\log(2) + \sum_{n=1}^{N} \underline{g}/g(n)}.$$

- Subexponential convergence $\left(\mathrm{w} > \frac{\mathscr{G}(N)}{\underline{g}\log(2)}\right)$:

(3.25)
$$\|(I_N - \mathscr{A}_{\boldsymbol{\alpha}}(\mathrm{w}, N))(u)\|_{L^2_\rho(\Gamma^N;W(D))} \leq \hat{C}^G(\mathbf{g}, N) e^{-\frac{\mathscr{G}(N)}{2}\eta^{\mu_2}},$$
$$\textit{with} \qquad \mu_2 = \frac{\underline{g}\log(2)}{\mathscr{G}(N)\left(2\log(2) + \sum_{n=1}^{N} \underline{g}/g(n)\right)},$$

and the constant $\hat{C}^G(\mathbf{g}, N) := \frac{1}{2}\left\|\frac{\rho}{\hat{\rho}}\right\| \sum_{d=1}^{N} \exp\left(\frac{1}{\log(2)} \sum_{n=1}^{d} \sqrt{\frac{\pi}{2g(n)}}\right) \prod_{n=1}^{d} \frac{16C_{\hat{\rho}}}{e^{2g(n)}-1}$.

Proof. The recursion formula (3.7) still holds with the term $R(\mathrm{w}, d)$ defined now as

$$R(\mathrm{w}, d) = \left\|\frac{\rho}{\hat{\rho}}\right\| \frac{8^d}{2} \sum_{\mathbf{i} \in \tilde{X}_{\boldsymbol{\alpha}}(\mathrm{w},d)} e^{-h(\mathbf{i},d)} \prod_{n=1}^{d} \frac{1}{e^{2g(n)}-1}.$$

Notice that the negative effect of the Lebesgue constant for the Clenshaw–Curtis abscissas, which was responsible for the term $\prod_{n=1}^{d} i_n$ in the definition of $R(\mathrm{w}, d)$ (see (3.8)), is not present here. Then, following the guidelines of the proof of Lemma 3.3, this term can be bounded as

$$R(\mathrm{w}, d) \leq C_1^G(\mathbf{g}, d) \exp\left\{-\mathscr{G}(d) 2^{\mathrm{w}\frac{g}{\mathscr{G}(d)}}\right\},$$

with constant

$$C_1^G(\mathbf{g},d) = \left\|\frac{\rho}{\hat{\rho}}\right\| \exp\left(\frac{1}{\log(2)}\sum_{n=1}^{d}\sqrt{\frac{\pi}{2g(n)}}\right)\frac{1}{2}\prod_{n=1}^{d}\frac{16C_{\hat{\rho}}}{e^{2g(n)}-1}.$$

This leads to the estimate in terms of w,

$$\|(I_N - \mathscr{A}_{\boldsymbol{\alpha}}(\mathrm{w},N))(u)\|_{L^2_\rho(\Gamma^N;W(D))} \le \hat{C}^G(\mathbf{g},N)e^{-\lambda(\mathrm{w},N)}, \tag{3.26}$$

with the same $\lambda(\mathrm{w},N)$ as in (3.13) and $\hat{C}^G(\mathbf{g},N) = \sum_{d=1}^{N} C_1^G(\mathbf{g},d)$. Again, notice the great improvement with respect to the bound (3.12) holding for Clenshaw–Curtis abscissas. Finally, we observe that for a given level w, the number of Gauss points is larger than the number of Clenshaw–Curtis points (due to the nonnested structure), and, following [24], it is given by

$$\eta = \sum_{\mathbf{i}\in Y_{\boldsymbol{\alpha}}(\mathrm{w},N)}\prod_{n=1}^{N}\tilde{r}(i_n), \qquad \text{with} \quad \tilde{r}(i) := \begin{cases} 1 & \text{for } i=1,\\ 2^{i-1}+1 & \text{for } i>1, \end{cases} \tag{3.27}$$

where the set $Y_{\boldsymbol{\alpha}}(\mathrm{w},N)$ is defined in (2.10). Since

$$\prod_{n=1}^{N}\tilde{r}(i_n) \le \prod_{n=1}^{N}(2^{i_n-1}+1) \le 2^{2|i-1|} \le 2^{2\mathrm{w}},$$

the number of points can be bounded as

$$2^{\mathrm{w}-1} \le \eta \le 2^{2\mathrm{w}}\#Y_{\boldsymbol{\alpha}}(\mathrm{w},N) \le 2^{2\mathrm{w}}\#X_{\boldsymbol{\alpha}}(\mathrm{w},N),$$

which, substituted in (3.26), gives the desired result. ∎

Similar conclusions to those outlined in Remark 3.11 hold in this case. We can conclude, therefore, that this method breaks the curse of dimensionality as long as the sequence $g(n)$ goes to infinity sufficiently fast, meaning that the sum $\sum_{n\ge1}\frac{g}{g(n)}$ is convergent.

4. Numerical examples. This section illustrates the convergence of the anisotropic sparse collocation method for solving the stochastic linear elliptic problem described in Example 1.1 in two spatial dimensions. We will exemplify the algorithm using both the a priori and the a posteriori selection of the $\boldsymbol{\alpha}$ weights, described in section 2.2. The computational results are in accordance with the convergence rates predicted by the theory. Actually, we observe a faster convergence than stated in (3.22) and (3.24), which hints that the current estimates may still be improved.

We will also use this problem to compare the convergence of the anisotropic Smolyak method with other ensemble-based methods such as the isotropic Smolyak method described in [24], the anisotropic adaptive full tensor product method described in [3, section 9], and finally the well-known Monte Carlo method.

The problem is to solve

$$\begin{cases} -\nabla\cdot(a(\omega,\cdot)\nabla u(\omega,\cdot)) = f(\omega,\cdot) & \text{in } D\times\Omega,\\ u(\omega,\cdot) = 0 & \text{on } \partial D\times\Omega, \end{cases} \tag{4.1}$$

with $D=[0,d]^2$ and $d=1$. For this numerical example we take a deterministic load $f(\omega,x,z)=\cos(x)\sin(z)$ and construct the random diffusion coefficient $a_N(\omega,x)$ with

one-dimensional spatial dependence as

$$\log(a_N(\omega,x)-0.5) = 1 + \mathrm{Y}_1(\omega)\left(\frac{\sqrt{\pi}L}{2}\right)^{1/2} + \sum_{n=2}^{N} \zeta_n\,\varphi_n(x)\,\mathrm{Y}_n(\omega), \tag{4.2}$$

where

$$\zeta_n := \left(\sqrt{\pi}L\right)^{1/2} \exp\left(\frac{-\left(\lfloor \frac{n}{2} \rfloor \pi L\right)^2}{8}\right) \quad \text{if } n>1 \tag{4.3}$$

and

$$\varphi_n(x) := \begin{cases} \sin\left(\frac{\lfloor \frac{n}{2} \rfloor \pi x}{L_p}\right) & \text{if } n \text{ even}, \\ \cos\left(\frac{\lfloor \frac{n}{2} \rfloor \pi x}{L_p}\right) & \text{if } n \text{ odd}. \end{cases} \tag{4.4}$$

For $x \in [0,d]$ let L_c be a desired physical correlation length for the random field a, meaning that the random variables $a(x)$ and $a(y)$ become essentially uncorrelated for $|x-y| \gg L_c$. Then the parameter L_p in (4.4) can be taken as $L_p = \max\{d, 2L_c\}$ and the parameter L in (4.2) and (4.3) is $L = L_c/L_p$. Expression (4.2) represents a possible truncation of a one-dimensional random field with stationary covariance

$$\operatorname{cov}[\log(a_N - 0.5)](x_1,x_2) = \exp\left\{-\frac{(x_1-x_2)^2}{L_c^2}\right\}.$$

In this example, the random variables $\{Y_n(\omega)\}_{n=1}^{\infty}$ are independent, have zero mean and unit variance, i.e., $\mathbb{E}[Y_n]=0$ and $\mathbb{E}[Y_nY_m]=\delta_{nm}$ for $n,m \in \mathbb{N}_+$, and are uniformly distributed in the interval $[-\sqrt{3},\sqrt{3}]$.

We first consider an a priori selection of the weights $g(n)$ based on formula (2.18). For that, from (1.10) we can estimate the parameters τ_n by

$$\tau_n = \frac{1}{4\zeta_n \|\varphi\|_\infty} = \begin{cases} \sqrt{\frac{1}{8\sqrt{\pi}L}} & \text{for } n=1, \\ \sqrt{\frac{1}{16\sqrt{\pi}L}} \exp\left(\frac{\lfloor \frac{n}{2} \rfloor^2 \pi^2 L^2}{8}\right) & \text{for } n>1. \end{cases}$$

Then, using (2.18), the weight vector $\mathbf{g}$ becomes

$$g(n) = \begin{cases} \frac{1}{2}\log\left(1+\sqrt{\frac{1}{24\sqrt{\pi}L}}\right) & \text{for } n=1, \\ \frac{1}{2}\log\left(1+\sqrt{\frac{1}{48\sqrt{\pi}L}} \exp\left(\frac{\lfloor \frac{n}{2} \rfloor^2 \pi^2 L^2}{8}\right)\right) & \text{for } n>1. \end{cases} \tag{4.5}$$

In Table 2 we show the function values $g(n)$ for $n = 1,2,\ldots,N = 11$ using (4.5). With this a priori information we can construct the simplices $X_{\boldsymbol{\alpha}}(\mathrm{w},N)$ based on the weighting vector $\boldsymbol{\alpha} = \mathbf{g}$, which will be used for solving problem (4.1) with correlation lengths $L_c = 1/2, 1/4, 1/16$, and $1/64$. This table also yields insight into the anisotropic behavior of each problem. In the case of small correlation lengths, i.e., $L_c = 1/64$, we observe an almost equal weighing of all y-directions, except for the first one. The opposite behavior can be seen as we increase the correlation length. For example, when $L_c = 1/2$ the ratio between $g(11)$ and $\underline{g} = g(2) = g(3)$ is approximately $30:1$. Similar observations are made following Table 1, in section 2.2, where we utilized the a posteriori selection of the weights $g(n)$.

TABLE 2

The $N = 11$ values of the function $g(n)$ constructed from a priori information given by (4.5) for correlation lengths $L_c = 1/2, 1/4, 1/16, 1/64$.

	$g(1)$	$g(2) = g(3)$	$g(4) = g(5)$	$g(6) = g(7)$	$g(8) = g(9)$	$g(10) = g(11)$
$L_c = 1/2$	0.10	0.09	0.21	0.62	1.55	2.90
$L_c = 1/4$	0.13	0.10	0.13	0.18	0.28	0.45
$L_c = 1/16$	0.24	0.18	0.18	0.18	0.19	0.20
$L_c = 1/64$	0.39	0.31	0.31	0.31	0.31	0.31

Since the random variables Y_n are uniformly distributed, in this case the Gaussian abscissas correspond to the root of the Legendre polynomials. The finite element space for the spatial discretization is the span of continuous functions that are piecewise polynomials with degree two over a uniform triangulation of D with 4225 unknowns.

To study the convergence of the anisotropic Smolyak algorithm we consider a problem with a fixed dimension N and investigate the behavior as the level w increases. The computational results, using the a priori approach, for the $L^2(D)$ approximation error to the expected value, $\mathbb{E}[u]$, are shown in Figure 3. Here we consider

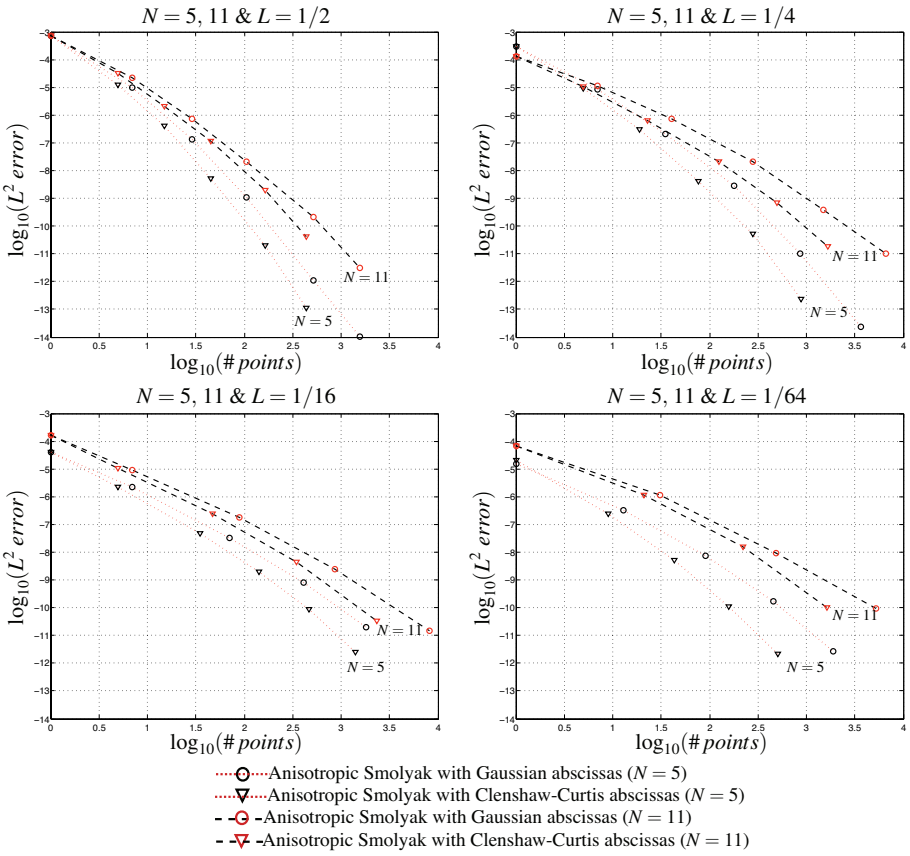

FIG. 3. *The convergence of the anisotropic Smolyak algorithm, with a priori selection of the $\boldsymbol{\alpha}$ weights, for solving problem (4.1) with given correlation lengths $L_c = 1/2, 1/4, 1/16$, and $1/64$ using both the Gaussian and Clenshaw–Curtis abscissas. For a finite-dimensional probability space Γ^N with $N = 5$ and $N = 11$ we plot the $L^2(D)$ approximation error in the expected value versus the number of collocation points.*

the truncated probability space to have dimensions $N = 5$ and $N = 11$ and compute approximate solutions up to a certain level $\overline{\mathrm{w}}$. To estimate the computational error in the level w, for $0 \le \mathrm{w} \le \overline{\mathrm{w}}$, we have computed a "reference" solution in the following way: Let us denote the maximum index utilized by $\mathscr{A}_{\boldsymbol{\alpha}}(\mathrm{w}, N)$ in each stochastic direction, $\boldsymbol{\kappa}(\boldsymbol{\alpha}, \mathrm{w}) \in \mathbb{N}_+^N$, given componentwise as

$$\kappa_n(\boldsymbol{\alpha}, \mathrm{w}) \equiv \max_{\mathbf{i} \in X_{\boldsymbol{\alpha}}(\mathrm{w}, N)} \{i_n\} = 1 + \left\lfloor \frac{\underline{\alpha}\mathrm{w}}{\alpha_n} \right\rfloor. \tag{4.6}$$

Then we introduce the enriched (reference) solution,

$$\mathscr{A}_{\widehat{\boldsymbol{\alpha}}}(\overline{\mathrm{w}}+1, N)\pi_h u_N, \quad \text{with } \widehat{\alpha}_n = \left(\frac{\kappa_n(\boldsymbol{\alpha}, \overline{\mathrm{w}}) - 1}{\kappa_n(\boldsymbol{\alpha}, \overline{\mathrm{w}})}\right)\left(\frac{\alpha_n}{\underline{\alpha}}\right), \tag{4.7}$$

and approximate the computational error for $\mathrm{w} = 0, 1, 2, \ldots, \overline{\mathrm{w}}$ as

$$\|\mathbb{E}[\epsilon]\| \approx \|\mathbb{E}[\mathscr{A}_{\boldsymbol{\alpha}}(\mathrm{w}, N)\pi_h u_N - \mathscr{A}_{\widehat{\boldsymbol{\alpha}}}(\overline{\mathrm{w}}+1, N)\pi_h u_N]\|. \tag{4.8}$$

By construction, the enriched solution possesses a maximum index $\boldsymbol{\kappa}(\widehat{\boldsymbol{\alpha}}, \overline{\mathrm{w}}+1)$ which is larger by one in each direction, i.e., $\kappa_n(\widehat{\boldsymbol{\alpha}}, \overline{\mathrm{w}}+1) = \kappa_n(\boldsymbol{\alpha}, \overline{\mathrm{w}})+1$, $n = 1, \ldots, N$. For $N = 11$, Tables 3 and 4 show the values $\boldsymbol{\kappa}(\boldsymbol{\alpha}, \mathrm{w})$ for computing $\mathscr{A}_{\boldsymbol{\alpha}}(\mathrm{w}, N)$, with $\mathrm{w} = 0, 1, 2, \ldots, \overline{\mathrm{w}}$, as well as the value $\boldsymbol{\kappa}(\widehat{\boldsymbol{\alpha}}, \overline{\mathrm{w}})$ for computing the enriched solution, $\mathscr{A}_{\widehat{\boldsymbol{\alpha}}}(\overline{\mathrm{w}}, N)$, for the cases $L_c = 1/2$ and $L_c = 1/64$, respectively.

The convergence plots in Figure 3 show that the error decreases more than algebraically as the level w increases linearly. We observe that the convergence rate is dimension-dependent and deteriorates slightly as N increases. The figure also shows the performance of the algorithm by varying the correlation length L_c. We notice that the larger correlation lengths have positive effects on the rate of convergence.

This can be explained by examining $g(n)$ defined by (4.5). From this we see that as L_c becomes large the higher dimensions weigh less, which greatly reduces the number of function evaluations required by the anisotropic sparse collocation method. On the other hand, the effect of decreasing L_c is a deterioration of the rate of convergence, due to the equal weighing of all directions. In this case, our anisotropic Smolyak algorithm and the isotropic Smolyak algorithm obtain an equivalent convergence rate (see also Figure 4).

We focus our interest next on comparing the anisotropic sparse collocation method with its isotropic counterpart, as well as with the anisotropic adaptive full tensor product method, proposed in [3, 12], and the standard Monte Carlo method. We will use the a priori selection of the $\boldsymbol{\alpha}$ weights in the anisotropic Smolyak method to make this comparison.

The isotropic Smolyak algorithm for solving problem (4.1) was analyzed in [24] and can be constructed by equally weighing all stochastic directions, i.e., $\boldsymbol{\alpha} = \mathbf{1} \in \mathbb{R}^N_+$. To estimate the computational error in the level w we approximate $\|\mathbb{E}[\epsilon]\| \approx \|\mathbb{E}[\mathscr{A}(\mathrm{w}, N)\pi_h u_N - \mathscr{A}(\mathrm{w}+1, N)\pi_h u_N]\|$ using either Gaussian or Clenshaw–Curtis abscissas.

The anisotropic full tensor product algorithm relies on a full tensor polynomial approximation. Let $\mathcal{P}_{\mathbf{p}}(\Gamma^N) = \bigotimes_{n=1}^N \mathcal{P}_{p_n}(\Gamma_n)$ be the span of tensor product polynomials with degree at most $\mathbf{p} = (p_1, \ldots, p_N)$. Its dimension is $N_p = \prod_{n=1}^N (p_n + 1)$. The adaptive algorithm proposed in [3] can be described in the following way: Given a tolerance tol, the method computes a multi-index $\mathbf{p} = (p_1, p_2, \ldots, p_N)$, corresponding to the order of the approximating polynomial spaces $\mathcal{P}_{\mathbf{p}}(\Gamma^N)$. This adaptive algorithm increases the tensor polynomial degree with an anisotropic strategy: it increases the order of approximation in one direction as much as possible before considering the next direction. Table 5 and Table 6 show the values of components of the 11-dimensional multi-index $\mathbf{p}$ for different values of tol, corresponding to $L_c = 1/2$ and $L_c = 1/64$, respectively. These tables can also give insight into the anisotropic behavior of each particular problem and should be compared with Table 3 and Table 4, respectively. Observe, in particular, that for the case $L_c = 1/64$ the algorithm predicts a multi-index $\mathbf{p}$ which is equal in all directions, i.e., an isotropic tensor product space. A convergence plot for $L_c = 1/2$ and $L_c = 1/64$ can be constructed by examining each row of Table 5 and Table 6, respectively, and plotting the number of points in the tensor product grid versus the error in expectation. We estimate the error in expectation by $\|\mathbb{E}[\epsilon]\| \approx \|\mathbb{E}[u^N_{h,\mathbf{p}} - u^N_{h,\widetilde{\mathbf{p}}}]\|$, with $\widetilde{\mathbf{p}} = (p_1 + 1, p_2 + 1, \ldots, p_N + 1)$. This entails an additional computational cost, which is bounded by the factor $\exp\big(\sum_{n=1}^N 1/p_n\big)$

times the work to compute $\mathbb{E}[u^N_{h,\mathbf{p}}]$.

The standard Monte Carlo finite element method is the most common choice when approximating statistics of the solution to (4.1). If, for instance, the aim is to approximate the solution's expected value, $\mathbb{E}[u]$, one approximates it numerically by a sample average of numerical solutions corresponding to i.i.d. realizations of the stochastic input data. Given a number of realizations, $M \in \mathbb{N}_+$, we compute the sample average as follows: For each $k = 1, \ldots, M$, sample i.i.d. realizations of $a(\omega_k, \cdot)$ and $f(\omega_k, \cdot)$, solve problem (4.1), and construct finite element approximations $u^N_h(\omega_k, \cdot)$. We note that once we have fixed the realization, $\omega = \omega_k$, the problem is completely deterministic and may be solved by standard methods as in the collocation approach. Finally, approximate $\mathbb{E}[u]$ by the sample average: $\overline{\mathbb{E}}[u^N_{h,k}; M](\cdot) := \frac{1}{M}\sum_{k=1}^{M} u^N_h(\omega_k, \cdot)$. For the cases $L_c = 1/2, 1/4, 1/16$, and $1/64$ we take $M = 2^i$, $i = 0, 1, 2, \ldots, 11$, realizations and compute the approximation to the error in expectation by $\|\mathbb{E}[\epsilon]\| \approx \|\overline{E}[u^N_{h,k}; M] - \mathbb{E}[\mathscr{A}_{\widehat{\boldsymbol{\alpha}}}(\overline{\mathrm{w}} + 1, N)\pi_h u_N]\|$, where $\mathscr{A}_{\widehat{\boldsymbol{\alpha}}}(\overline{\mathrm{w}} + 1, N)$ is the enriched anisotropic sparse solution defined previously.

To study the advantages of an anisotropic sparse approximation as opposed to the isotropic sparse or anisotropic full tensor product approximations, we show in Figure 4 the convergence of these methods when solving problem (4.1), using correlation lengths $L_c = 1/2, 1/4, 1/16$, and $L_c = 1/64$ with $N = 11$. We also include 5 ensembles of the Monte Carlo method described previously. Figure 4 reveals that for the isotropic case with $L_c = 1/64$ the anisotropic and isotropic Smolyak methods obtain a comparable convergence rate, both faster than the anisotropic full tensor product method. On the contrary, opposite behavior can be observed for $L_c = 1/2$. Since, in this case, the rate of decay in the expansion (4.2) is faster, the anisotropic full tensor method weighs heavily the important modes and, therefore, achieves a faster convergence than the isotropic Smolyak method. Similar conclusions can be made for the anisotropic Smolyak: the increased convergence for this method comes from the fact that it combines an optimal treatment of the problem anisotropy while reducing the curse of dimensionality via the use of sparse grids.

In all four cases we observe that all three methods outperform the Monte Carlo method. We know that the amount of work to reach the accuracy ϵ in the Monte Carlo approach can be approximated by $\epsilon \approx O(M^{-1/2})$ times the amount of work per sample, where M is the number of samples. This is affected only by the problem dimension through the increase of the work per sample. Nevertheless, the convergence rate is quite slow and a high level of accuracy is achieved only with a large amount of function evaluations. This can be seen from Figure 4, where we include reference lines with slopes $-1/2$ and -1, respectively, or in Table 7, where for $N = 11$ we compare the work required by each method to decrease the original error by a factor of 10^4, for all four correlation lengths $L_c = 1/2, 1/4, 1/16$, and $1/64$. Observe that the work is proportional to the number of samples (in the Monte Carlo method) or collocation points (for the stochastic collocation methods).

1/64	3.1×10^2	2.0×10^5	3.6×10^2	1.3×10^9

As shown in section 3.1, the ability to adaptively assess each stochastic dimension while maintaining the properties of sparse grid approximation has allowed us to make a substantial reduction in the curse of dimensionality. Therefore, our final numerical investigation concerns the convergence of the anisotropic sparse grid method when solving problem (4.1) for an increasing number of random variables (dimensions),

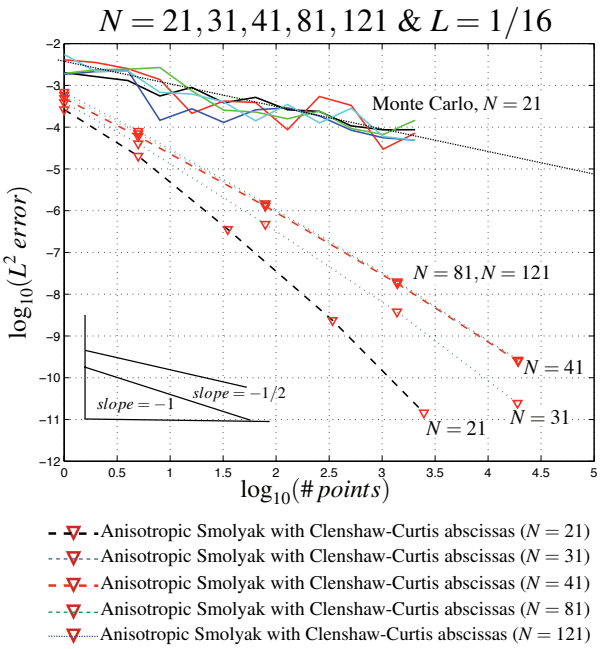

FIG. 5. *A* 21*-,* 31*-,* 41*-,* 81*-,* 121*-dimensional comparison of the anisotropic Smolyak method, with a posteriori selection of the* $\boldsymbol{\alpha}$ *weights, and a* 21*-dimensional Monte Carlo approach for solving problem* (4.1) *with correlation length* $L_c = 1/16$*. namely, $N = 21, 31, 41, 81$, and 121. In particular, we aim to confirm numerically the theoretical conclusion drawn in Remark 3.11, namely, that when the stochastic input data are truncated, expansions of random fields, the algebraic exponent in (3.22), does not deteriorate as the dimension N increases.

The computational comparison will be made with the Monte Carlo method only, since the isotropic Smolyak and anisotropic full tensor product methods require an excessively high number of points to compute accurate solutions in such high dimensions. The explosion in computational effort for these two methods is a symptom of the curse of dimensionality.

In this example we use the a posteriori selection of the $\boldsymbol{\alpha}$ weights to illustrate their practical use and consider only the case $L_c = 1/16$. The computational results are shown in Figure 5. Observe the remarkable performance of the anisotropic Smolyak method.

The convergence rate is dimension-dependent, but due to our algorithm's inherent capability to adapt itself to the eigenvalue decay of (4.2), we notice that this dependence is no longer evident as we increase the dimension from $N = 41$ to $N = 81$ and further to $N = 121$. Furthermore, the dominance of the anisotropic sparse grid method is displayed when comparing its convergence in 121 stochastic dimensions to that of Monte Carlo in only 21 dimensions.

5. Conclusions. This work proposed and analyzed a novel weighted Smolyak method, describing an optimal choice for the weight parameters. These weights tune the anisotropy of the approximation to each given problem. Their systematic choice can be based on both a priori or a posteriori information and is motivated by the regularity of the solution and the error estimates derived in this work.

The method proposed here can be viewed as a natural extension of previous works: the full tensor stochastic collocation method [1] and the isotropic sparse grid stochastic collocation method [29, 24].

The new technique consists of a Galerkin approximation in physical space and an anisotropic collocation in probability space at the zeros of sparse tensor product polynomials utilizing either Clenshaw–Curtis or Gaussian knots. As a consequence of the collocation approach our techniques naturally lead to the solution of uncoupled deterministic problems that are trivially parallelizable, as in the Monte Carlo method.

The error estimates derived in this work predict a rate of convergence that is at least algebraic with respect to the total number of collocation points. Similarly to the Monte Carlo method, the number of collocation points is directly proportional to the computational work required by the algorithm. Furthermore, the derived estimates provide a glimpse into future directions in this area. We observe that for problems possessing coefficients that are truncated expansions with proper decay in their random inputs, there may not be a deterioration in the exponent of the algebraic convergence with respect to the truncation dimension. This is a substantial advantage when compared to the previous works [1] and [29, 24].

The numerical examples included in this work gave computational ground to the theoretical results and suggest that the actual convergence rate of the method may be superior to the prediction yielded by the current error estimates. The numerical results include a comparison of the new weighted Smolyak method with the methods from [1, 24] and the standard Monte Carlo method. In particular, for moderately large-dimensional problems, the anisotropic sparse grid approach seems to be very efficient and superior to all examined methods.

Acknowledgments. The third author would like to thank Prof. Max Gunzburger for his insight, guidance, and many helpful discussions, and also Dr. John Burkardt for his assistance in implementing these numerical methods as well as his many useful visualizations.

SEMI-IMPLICIT TIME-DISCRETIZATION SCHEMES FOR THE BIDOMAIN MODEL*

MARC ETHIER† AND YVES BOURGAULT‡

Abstract. The bidomain model is a system of partial differential equations used to model the propagation of electrical potential waves in the myocardium. It is composed of coupled parabolic and elliptic partial differential equations, as well as at least one ordinary differential equation to model the ion activity through the cardiac cell membranes. The purpose of this paper is to propose and analyze several implicit, semi-implicit, and explicit time-stepping methods to solve that model, in particular to avoid the expensive resolution of a nonlinear system through the Newton–Raphson method. We identify necessary stability conditions on the time step Δt for the proposed methods through a theoretical analysis based on energy estimates. We next compare the methods for one- and two-dimensional test cases, in terms of both stability and accuracy of the numerical solutions. The theoretical stability conditions are seen to be consistent with those observed in practice. Our analysis allows us to recommend using either the Crank–Nicolson/Adams–Bashforth method or the second order semi-implicit backward differention method. These semi-implicit methods produce a good numerical solution; unlike the explicit methods, their stability does not depend on the spatial grid size; and unlike the implicit methods, they do not require the resolution of a system of nonlinear equations.

Key words. bidomain model, electrophysiology, finite elements, time-stepping schemes, stability analysis

1. Introduction.

The bidomain model is used in electrophysiology to model the propagation of electrical potential waves in the myocardium. It is obtained by homogenization over the discrete cells of the myocardium, in particular using the regular arrangement of these in fibers [7, 14]. At each point in the computational domain, two electrical potentials, namely, the intracellular potential u_i and the extracellular potential u_e, are recovered, representing the average of the electrical potential over the extracellular and the intracellular space, respectively, in the vicinity of that point.

There are many ways to write the bidomain model's equations. Many of them are introduced in [11], where their respective merits are also discussed. We will use the following formulation:

$$\frac{\partial u}{\partial t} = \frac{1}{\epsilon} f(u,v) + \nabla \cdot (\sigma_i \nabla u) + \nabla \cdot (\sigma_i \nabla u_e)\,, \tag{1.1}$$

$$\nabla \cdot (\sigma_i \nabla u + (\sigma_i + \sigma_e) \nabla u_e) = 0, \tag{1.2}$$

$$\frac{\partial v}{\partial t} = \epsilon g(u,v), \tag{1.3}$$

where $u = u_i - u_e$ is the action or transmembrane potential, σ_i and σ_e are second order tensors representing, respectively, the intracellular and the extracellular tissue's

electrical conductivity in each spatial direction, v is a lumped ionic variable, and ϵ is a parameter linked to the ratio between the repolarization rate and the tissue excitation rate [21]. It has been proved that the bidomain model has a unique solution [4, 7]. In [7] the bidomain model is formulated as a system of degenerate parabolic inequalities, while in [4] the analysis is based on the more standard theory of nonlinear parabolic PDEs. We chose to use this last formulation of the bidomain model as the basis of our numerical method because of its connection with standard parabolic and elliptic PDEs where the theory of finite element methods is well developed. We refer to [11, 19] for a more complete discussion on the different formulations of the bidomain model and their use in numerical simulations.

The equation (1.3) is not properly part of the bidomain model but rather models the ionic activity across the cellular membrane, responsible for the electrical activation of the tissue. Several models may be used for this task, the most widely known being the Hodgkin–Huxley model, originally introduced for the propagation of nerve influx inside neurons. Other models more adapted to the heart muscle have been derived, such as the Noble and Luo–Rudy models [14]. We will use the FitzHugh–Nagumo equations, which are a simplification of the Hodgkin–Huxley equations. We can therefore write the functions f and g as

$$f(u,v) = u - \frac{u^3}{3} - v, \tag{1.4}$$

$$g(u,v) = u + \beta - \gamma v, \tag{1.5}$$

where γ is a parameter controlling the ion transport and β is linked to cell excitability.

After an appropriate discretization in space, (1.1)–(1.3) read as a system of algebraic-differential equations, simply because the second equation (1.2) comes with no time derivative. The choice of a time-stepping method for that system of algebraic-differential equations has a strong impact on the stability, computational time, memory use, and quality of the numerical solution. Until recently, the numerical resolution of the bidomain model by low order explicit time-stepping methods had been very popular [11, 18, 22]. Explicit methods are easy to program and inexpensive in terms of memory use. Each time step costs typically little in terms of computational time with these methods. On the other hand, they suffer from strong limitations on the time step Δt to ensure the stability of the solution. Therefore, some of the efforts for solving the bidomain model migrated towards fully implicit [5, 11, 17], semi-implicit [9, 11, 13, 19], and operator-splitting [15, 16, 25, 26] methods. Implicit methods have much weaker conditions on the time step for their stability, but if the system to solve is nonlinear, as is the bidomain model with any ion kinetics, they require the solution of a large system of nonlinear equations at every time step. Semi-implicit methods—also called semi-explicit or implicit-explicit (IMEX)—combine explicit and implicit methods: they solve the linear terms implicitly and the nonlinear terms explicitly [1, 2, 23]. These methods are more stable than explicit methods but less so than implicit methods, and, while they require the solution of a system of equations at every time step, it is a system of linear equations.

So far, the semi-implicit methods used for the bidomain model have been only first order in time [9, 11, 13, 19], even if some of these rest on a splitting of the second order terms according to the Crank–Nicolson scheme. This is simply due to the fact that the ionic currents in the first equation (1.1) are taken explicitly as for the forward Euler scheme, lowering the global order of these semi-implicit methods. In [1, 2, 23], higher order semi-implicit schemes are proposed and analyzed. The goal of this paper

is precisely to study the use of these higher order semi-implicit schemes to solve the bidomain model.

The paper is organized as follows: we will introduce several time-stepping schemes in section 2 and then exhibit theoretical stability conditions on the time step in section 3. This will require an extension of the usual stability estimates for such semi-implicit schemes, such as done in [1], because the bidomain model can be rewritten as a system of nonlinear reaction-diffusion equations (see [4] for details) but is not solved as a standard reaction-diffusion equation. Indeed, the elliptic equation (1.2) is solved at each time step. We will obtain theoretical stability conditions showing the necessity of taking implicitly a portion of the second order terms in u and u_e, for time-stepping methods of all orders, to avoid time steps in $O(h^2)$. In section 4, numerical results will be shown with an emphasis on the stability and accuracy of the proposed schemes.

2. Numerical methods. The goal of this section is to introduce the different numerical methods studied in this article.

2.1. Space discretization. We first introduce a spatial semidiscretization of the bidomain model through first order simplicial Lagrange finite elements. Let us assume that the domain Ω can be covered by a regular partition $\mathscr{T}$ of simplexes—edges in one dimension, triangles in two dimensions, and tetrahedra in three dimensions—of maximal diameter h, with $N+1$ nodes, noted x_0 to x_N. Consider the space P_h^1 of continuous linear finite elements on $\mathscr{T}$ and the usual basis of hat functions $\Phi_0^h, \dots, \Phi_N^h$ attached to the nodes $x_0, \dots, x_N$, respectively. Here we suppose that homogeneous Neumann boundary conditions are used on $\partial\Omega$ for both u and u_e.

The semidiscrete bidomain problem then reads as: find a $[u, u_e, v] \in \mathscr{C}([0,T]; P_h^1)^3$ solution of the following variational equations:

$$\int_\Omega u_t \Phi_j^h \,\mathrm{d}\mathbf{x} = \frac{1}{\epsilon}\int_\Omega f(u,v)\Phi_j^h \,\mathrm{d}\mathbf{x} - \int_\Omega (\sigma_i \nabla(u+u_e))\cdot\nabla\Phi_j^h \,\mathrm{d}\mathbf{x}, \tag{2.1}$$

$$\int_\Omega (\sigma_i \nabla u)\cdot\nabla\Phi_j^h \,\mathrm{d}\mathbf{x} + \int_\Omega ((\sigma_i+\sigma_e)\nabla u_e)\cdot\nabla\Phi_j^h \,\mathrm{d}\mathbf{x} = 0, \tag{2.2}$$

$$\int_\Omega v_t \Phi_j^h \,\mathrm{d}\mathbf{x} = \epsilon\int_\Omega g(u,v)\Phi_j^h \,\mathrm{d}\mathbf{x} \tag{2.3}$$

for all $j = 0, \dots, N$.

By setting $u(t) = \sum_{i=0}^N u_i\Phi_i^h$, $u_e(t) = \sum_{i=0}^N u_{e,i}\Phi_i^h$, and $v(t) = \sum_{i=0}^N v_i\Phi_i^h$, we can rewrite these equations under matrix form:

$$M\mathbf{u}_t = \frac{1}{\epsilon}F(\mathbf{u},\mathbf{v}) - A_i(\mathbf{u}+\mathbf{u_e}), \tag{2.4}$$

$$A_i\mathbf{u} + (A_i+A_e)\mathbf{u_e} = \mathbf{0}, \tag{2.5}$$

$$M\mathbf{v}_t = \epsilon\, G(\mathbf{u},\mathbf{v}), \tag{2.6}$$

where $\mathbf{u} = [u_0, \dots, u_N]^T$, $\mathbf{u_e} = [u_{e,0}, \dots, u_{e,N}]^T$, $\mathbf{v} = [v_0, \dots, v_N]^T$, A_i and A_e are stiffness matrices obtained by integrating the second order terms, including, respectively, the tensors σ_i and σ_e, M is the mass matrix such that $M(i,j) = \int_\Omega \Phi_i^h\Phi_j^h \,\mathrm{d}\mathbf{x}$, and F and G are operators obtained by the integration of the zeroth order terms. For example, by using mass lumping to simplify the nonlinear operator F, we can define G and F as

$$G(\mathbf{u},\mathbf{v}) = M(\mathbf{u}-\gamma\mathbf{v}) + \beta\left[\int_\Omega \Phi_0^h \,\mathrm{d}\mathbf{x}, \dots, \int_\Omega \Phi_N^h \,\mathrm{d}\mathbf{x}\right]^T$$

and

$$F(\mathbf{u},\mathbf{v}) = M\left(\mathbf{u} - \frac{\mathbf{u^3}}{3} - \mathbf{v}\right),$$

where $\mathbf{u^3} = [u_0^3, \ldots, u_N^3]^T$.

2.2. Time discretization. We have considered a variety of explicit, implicit, and IMEX finite difference methods, using a constant time step Δt, for the time discretization. Note that the presence of (2.5) in the system has the effect that it is necessary to solve a system of equations at every time step, even for usually completely explicit methods such as the forward Euler scheme. Therefore, the following equation is part of every one of our time-discretization schemes:

$$A_i \mathbf{u^{n+1}} + (A_i + A_e)\mathbf{u_e^{n+1}} = \mathbf{0}.$$

That equation will not be repeated below, but it is understood that it is always part of the resulting fully discrete bidomain problem. We now present all of the schemes.

2.2.1. First order methods.

(i) forward Euler:

$$M\frac{\mathbf{u^{n+1}} - \mathbf{u^n}}{\Delta t} = \frac{1}{\epsilon}F(\mathbf{u^n},\mathbf{v^n}) - A_i(\mathbf{u^n} + \mathbf{u_e^n}), \tag{2.7}$$
$$M\frac{\mathbf{v^{n+1}} - \mathbf{v^n}}{\Delta t} = \epsilon G(\mathbf{u^n},\mathbf{v^n}).$$

(ii) forward-backward Euler:

$$M\frac{\mathbf{u^{n+1}} - \mathbf{u^n}}{\Delta t} = \frac{1}{\epsilon}F(\mathbf{u^n},\mathbf{v^n}) - A_i\left(\mathbf{u^{n+1}} + \mathbf{u_e^{n+1}}\right), \tag{2.8}$$
$$M\frac{\mathbf{v^{n+1}} - \mathbf{v^n}}{\Delta t} = \epsilon G(\mathbf{u^n},\mathbf{v^n}).$$

(iii) Crank–Nicolson–forward Euler (Crank–Nicolson (CN)):

$$M\frac{\mathbf{u^{n+1}} - \mathbf{u^n}}{\Delta t} = \frac{1}{\epsilon}F(\mathbf{u^n},\mathbf{v^n}) - \frac{1}{2}A_i\left(\mathbf{u^{n+1}} + \mathbf{u_e^{n+1}}\right) - \frac{1}{2}A_i(\mathbf{u^n} + \mathbf{u_e^n}), \tag{2.9}$$
$$M\frac{\mathbf{v^{n+1}} - \mathbf{v^n}}{\Delta t} = \epsilon G(\mathbf{u^n},\mathbf{v^n}).$$

(iv) IMEX first order Gear:

$$M\frac{\frac{3}{2}\mathbf{u^{n+1}} - 2\mathbf{u^n} + \frac{1}{2}\mathbf{u^{n-1}}}{\Delta t} = \frac{1}{\epsilon}F(\mathbf{u^n},\mathbf{v^n}) - A_i\left(\mathbf{u^{n+1}} + \mathbf{u_e^{n+1}}\right), \tag{2.10}$$
$$M\frac{\frac{3}{2}\mathbf{v^{n+1}} - 2\mathbf{v^n} + \frac{1}{2}\mathbf{v^{n-1}}}{\Delta t} = \epsilon G\left(\mathbf{u^{n+1}},\mathbf{v^{n+1}}\right).$$

(v) backward Euler:

$$M\frac{\mathbf{u^{n+1}} - \mathbf{u^n}}{\Delta t} = \frac{1}{\epsilon}F\left(\mathbf{u^{n+1}},\mathbf{v^{n+1}}\right) - A_i\left(\mathbf{u^{n+1}} + \mathbf{u_e^{n+1}}\right), \tag{2.11}$$
$$M\frac{\mathbf{v^{n+1}} - \mathbf{v^n}}{\Delta t} = \epsilon G\left(\mathbf{u^{n+1}},\mathbf{v^{n+1}}\right).$$

2.2.2. Second order methods.

(i) Crank–Nicolson/Adams–Bashforth (CNAB):

$$\begin{aligned} M\frac{\mathbf{u^{n+1}}-\mathbf{u^n}}{\Delta t} &= \frac{1}{\epsilon}\left(\frac{3}{2}F\left(\mathbf{u^n},\mathbf{v^n}\right)-\frac{1}{2}F\left(\mathbf{u^{n-1}},\mathbf{v^{n-1}}\right)\right) \\ &\quad -\frac{1}{2}A_i\left(\mathbf{u^{n+1}}+\mathbf{u_e^{n+1}}\right)-\frac{1}{2}A_i\left(\mathbf{u^n}+\mathbf{u_e^n}\right), \\ M\frac{\mathbf{v^{n+1}}-\mathbf{v^n}}{\Delta t} &= \epsilon\left(\frac{3}{2}G\left(\mathbf{u^n},\mathbf{v^n}\right)-\frac{1}{2}G\left(\mathbf{u^{n-1}},\mathbf{v^{n-1}}\right)\right). \end{aligned} \tag{2.12}$$

(ii) modified Crank–Nicolson/Adams–Bashforth (MCNAB):

$$\begin{aligned} M\frac{\mathbf{u^{n+1}}-\mathbf{u^n}}{\Delta t} &= \frac{1}{\epsilon}\left(\frac{3}{2}F\left(\mathbf{u^n},\mathbf{v^n}\right)-\frac{1}{2}F\left(\mathbf{u^{n-1}},\mathbf{v^{n-1}}\right)\right)-\frac{9}{16}A_i\left(\mathbf{u^{n+1}}+\mathbf{u_e^{n+1}}\right) \\ &\quad -\frac{3}{8}A_i\left(\mathbf{u^n}+\mathbf{u_e^n}\right)-\frac{1}{16}A_i\left(\mathbf{u^{n-1}}+\mathbf{u_e^{n-1}}\right), \\ M\frac{\mathbf{v^{n+1}}-\mathbf{v^n}}{\Delta t} &= \epsilon\left(\frac{3}{2}G\left(\mathbf{u^n},\mathbf{v^n}\right)-\frac{1}{2}G\left(\mathbf{u^{n-1}},\mathbf{v^{n-1}}\right)\right). \end{aligned} \tag{2.13}$$

(iii) second order semi-implicit backward differentiation (SBDF):

$$\begin{aligned} M\frac{\frac{3}{2}\mathbf{u^{n+1}}-2\mathbf{u^n}+\frac{1}{2}\mathbf{u^{n-1}}}{\Delta t} &= \frac{1}{\epsilon}\left(2F\left(\mathbf{u^n},\mathbf{v^n}\right)-F\left(\mathbf{u^{n-1}},\mathbf{v^{n-1}}\right)\right) \\ &\quad -A_i\left(\mathbf{u^{n+1}}+\mathbf{u_e^{n+1}}\right), \\ M\frac{\frac{3}{2}\mathbf{v^{n+1}}-2\mathbf{v^n}+\frac{1}{2}\mathbf{v^{n-1}}}{\Delta t} &= \epsilon\left(2G\left(\mathbf{u^n},\mathbf{v^n}\right)-G\left(\mathbf{u^{n-1}},\mathbf{v^{n-1}}\right)\right). \end{aligned} \tag{2.14}$$

(iv) implicit Gear:

$$\begin{aligned} M\frac{\frac{3}{2}\mathbf{u^{n+1}}-2\mathbf{u^n}+\frac{1}{2}\mathbf{u^{n-1}}}{\Delta t} &= \frac{1}{\epsilon}F\left(\mathbf{u^{n+1}},\mathbf{v^{n+1}}\right)-A_i\left(\mathbf{u^{n+1}}+\mathbf{u_e^{n+1}}\right), \\ M\frac{\frac{3}{2}\mathbf{v^{n+1}}-2\mathbf{v^n}+\frac{1}{2}\mathbf{v^{n-1}}}{\Delta t} &= \epsilon G\left(\mathbf{u^{n+1}},\mathbf{v^{n+1}}\right). \end{aligned} \tag{2.15}$$

2.2.3. Third order method. Third order SBDF:

$$\begin{aligned} M\frac{\frac{11}{6}\mathbf{u^{n+1}}-3\mathbf{u^n}+\frac{3}{2}\mathbf{u^{n-1}}-\frac{1}{3}\mathbf{u^{n-2}}}{\Delta t} &= \frac{1}{\epsilon}\big(3F\left(\mathbf{u^n},\mathbf{v^n}\right)-3F\left(\mathbf{u^{n-1}},\mathbf{v^{n-1}}\right) \\ &\quad +F\left(\mathbf{u^{n-2}},\mathbf{v^{n-2}}\right)\big)-A_i\left(\mathbf{u^{n+1}}+\mathbf{u_e^{n+1}}\right), \\ M\frac{\frac{11}{6}\mathbf{v^{n+1}}-3\mathbf{v^n}+\frac{3}{2}\mathbf{v^{n-1}}-\frac{1}{3}\mathbf{v^{n-2}}}{\Delta t} &= \epsilon\big(3G\left(\mathbf{u^n},\mathbf{v^n}\right)-3G\left(\mathbf{u^{n-1}},\mathbf{v^{n-1}}\right) \\ &\quad +G\left(\mathbf{u^{n-2}},\mathbf{v^{n-2}}\right)\big). \end{aligned} \tag{2.16}$$

By looking at (2.1)–(2.3), one can see that u_e appears in these equations only in the form of its gradient. Because of the Neumann boundary conditions, the variable u_e can be determined only modulo a constant. In other words, the numerical schemes

(2.7)–(2.16) give rise to singular systems of equations. There exist many ways to solve this problem [3]; we chose to fix u_e at a specific value on a particular node for every time step. Note that the indefiniteness on u is naturally removed by the nonlinear term in f in the first equation of the bidomain model. See [4] for details on that indefiniteness of the system, its physical significance, and its mathematical treatment for the continuous problem.

Even after removing the indefiniteness, the resulting linear systems are still very ill conditioned. The choice of linear solver is therefore hard. In the one-dimensional (1D) case, it is possible to use a direct solver such as the LU factorization. Because of memory constraints, this becomes much less possible in higher dimensions. Using an iterative method [10, 24] becomes necessary. Our numerical tests have convinced us that the conjugate gradient method is most appropriate in this case. We have also used the incomplete LU factorization to precondition the system. Our computer memory constraints drive the level of fill we may use with this preconditioner: in 2D with moderately fine meshes, we have been able to use two levels of fill, but finer meshes, as well as 3D meshes, would probably require us to use only one level of fill or none at all.

3. Numerical analysis of the schemes. This section is dedicated to demonstrating that the previously seen numerical schemes remain stable under appropriate conditions on the time step Δt. We also analyze the semidiscrete problem introduced in section 2.1 and prove that its solution is unconditionally stable.

In the rest of the paper, $\|\cdot\|_0$ refers to the L^2 norm over Ω and $|\cdot|_1$ to the H^1 seminorm over Ω. The constants m_i and m_e denote the infimum of the eigenvalues of σ_i and σ_e, respectively, and M_i and M_e the supremum of these eigenvalues, with the infimum and supremum taken all over Ω as well.

3.1. Stability of the semidiscrete method. We analyze the semidiscrete formulation (2.1)–(2.3) of the bidomain model. We first redefine the function g as $g(u,v) = u - \gamma v$ and set $S = \epsilon\beta$. This ensures that the graph of f and g goes through the origin. The term S then goes into the right-hand side of the PDE.

By using as test functions $\Phi_j^h = u(t)$, $u_e(t)$, and $v(t)$ in (2.1), (2.2), and (2.3), respectively, adding the three equations so obtained, and using the following lower bound for the diffusive terms:

$$\begin{aligned}\int_\Omega (\sigma_i\nabla(u+u_e))\cdot\nabla(u+u_e)\,\mathrm{d}\mathbf{x} + \int_\Omega (\sigma_e\nabla u_e)\cdot\nabla u_e\,\mathrm{d}\mathbf{x} &\geq m_i|u+u_e|_1^2 + m_e|u_e|_1^2 \\ &\geq \bar{m}(|u|_1^2 + |u_e|_1^2),\end{aligned} \tag{3.1}$$

where $\bar{m}$ depends on m_i and m_e by equivalence of seminorms, one easily obtains the following inequalities:

$$\begin{aligned}&\frac{d}{dt}\left[\|u\|_0^2 + \|v\|_0^2\right] + 2\bar{m}\left(|u|_1^2 + |u_e|_1^2\right) \\ &\qquad\leq \frac{2}{\epsilon}\left(\int_\Omega u^2\,\mathrm{d}\mathbf{x} - \frac{1}{3}\int_\Omega u^4\,\mathrm{d}\mathbf{x} - \int_\Omega uv\,\mathrm{d}\mathbf{x}\right) \\ &\qquad\quad + 2\epsilon\left(\int_\Omega uv\,\mathrm{d}\mathbf{x} - \gamma\int_\Omega v^2\,\mathrm{d}\mathbf{x}\right) + 2\int_\Omega Sv\,\mathrm{d}\mathbf{x} \\ &\qquad\leq \frac{2}{\epsilon}\|u\|_0^2 - 2\epsilon\gamma\|v\|_0^2 + \frac{\left|\frac{1}{\epsilon}-\epsilon\right|}{k}\|u\|_0^2 + \left|\frac{1}{\epsilon}-\epsilon\right| k\|v\|_0^2 + \frac{1}{r}\|S\|_0^2 + r\|v\|_0^2 \\ &\qquad\leq C_1\left[\|u\|_0^2 + \|v\|_0^2\right] + C_2\|S\|_0^2,\end{aligned} \tag{3.2}$$

where the constants k, $r > 0$, $C_1 = \max\{2/\epsilon + |1/\epsilon - \epsilon|/k, |1/\epsilon - \epsilon|k + r - 2\epsilon\gamma\}$, and $C_2 = 1/r$, owing to the fact that, for $a, b \in \mathbb{R}$ and for $k > 0$, $ab \le a^2/2k + b^2k/2$.

Applying Gronwall's lemma [8, Lemma 6.9, p. 284] to the inequality (3.2) gives:

$$\|u(t)\|_0^2 + \|v(t)\|_0^2 \le e^{C_1 t}\left[\|u(0)\|_0^2 + \|v(0)\|_0^2\right] + \int_0^t e^{C_1(t-\tau)}\left[C_2\|S\|_0^2 - 2\bar{m}\left(|u|_1^2 + |u_e|_1^2\right)\right]\mathrm{d}\tau \tag{3.3}$$

$$\Rightarrow \max_{t\in[0,T]}\left[\|u(t)\|_0^2 + \|v(t)\|_0^2\right] \le e^{C_1 T}\left[\|u_0\|_0^2 + \|v_0\|_0^2\right] + C_2\int_0^T e^{C_1(T-\tau)}\|S\|_0^2\,\mathrm{d}\tau,$$

where u_0 and $v_0 \in P_h^1$ are the initial data for the semidiscrete formulation. In other words, u and v remain bounded in $L^\infty(0,T;L^2(\Omega))$.

From (3.3), we obtain

$$2\bar{m}\int_0^T e^{C_1(T-\tau)}\left(|u|_1^2 + |u_e|_1^2\right)\mathrm{d}\tau \le e^{C_1 T}\left[\|u_0\|_0^2 + \|v_0\|_0^2\right] + C_2\int_0^T e^{C_1(T-\tau)}\|S\|_0^2\,\mathrm{d}\tau$$

$$\Rightarrow \int_0^T \left(|u|_1^2 + |u_e|_1^2\right)\mathrm{d}\tau \le \frac{e^{C_1 T}}{2\bar{m}}\left[\|u_0\|_0^2 + \|v_0\|_0^2\right] + \frac{C_2}{2\bar{m}}\int_0^T e^{C_1(T-\tau)}\|S\|_0^2\,\mathrm{d}\tau. \tag{3.4}$$

This shows that the $H^1(\Omega)$ seminorm of u and u_e remains L^2 bounded on any interval $[0,T]$.

By putting together the bounds obtained above, we find that the solution of the semidiscrete problem remains bounded in the following spaces:

$$\begin{aligned} u &\in L^\infty(0,T;L^2(\Omega)) \cap L^2(0,T;H^1(\Omega)),\\ u_e &\in L^2(0,T;H^1(\Omega)/\mathbb{R}),\\ v &\in L^\infty(0,T;L^2(\Omega)). \end{aligned} \tag{3.5}$$

In particular, the extracellular potential u_e is bounded only in $L^2(0,T;H^1(\Omega)/\mathbb{R})$, not in any $L^p(0,T;L^2(\Omega))$, since we can determine u_e only up to a constant. It is important to note that the relations (3.5) make use of the fact that the FitzHugh–Nagumo model is used for the ion activity. A nice feature is that the constants in the estimates (3.5) are independent from the cell size h of the space discretization. The semidiscrete problem is unconditionally stable. This is a main argument behind the existence proof given in [4].

3.2. Stability of the discrete methods. Let us now investigate the stability of some of the fully discrete numerical schemes introduced in section 2. We keep track as much as we can of the constants in the stability estimates to be able to identify the relevant parameters in the bidomain model controlling the stability of the numerical schemes.

3.2.1. Backward Euler. We consider the backward Euler method (2.11) as a representative of the implicit methods we have used. By using as test function Φ the

solutions u^{n+1}, u_e^{n+1}, and v^{n+1} in their respective variational equations, we obtain:

$$\int_\Omega \left[\frac{u^{n+1}-u^n}{\Delta t} - \frac{1}{\epsilon} f(u^{n+1}, v^{n+1})\right] u^{n+1}\,\mathrm{d}\mathbf{x} + \int_\Omega \left(\sigma_i \nabla(u^{n+1}+u_e^{n+1})\right)\cdot\nabla u^{n+1}\,\mathrm{d}\mathbf{x} = 0,$$

$$\int_\Omega (\sigma_i \nabla u^{n+1})\cdot\nabla u_e^{n+1}\,\mathrm{d}\mathbf{x} + \int_\Omega \left((\sigma_i+\sigma_e)\nabla u_e^{n+1}\right)\cdot\nabla u_e^{n+1}\,\mathrm{d}\mathbf{x} = 0,$$

$$\int_\Omega \left[\frac{v^{n+1}-v^n}{\Delta t} - \epsilon g(u^{n+1}, v^{n+1})\right] v^{n+1}\,\mathrm{d}\mathbf{x} = \int_\Omega S^n v^{n+1}\,\mathrm{d}\mathbf{x}. \tag{3.6}$$

By adding these three equations, using the identity

$$2(a^{n+1}-a^n)a^{n+1} = (a^{n+1})^2 + (a^{n+1}-a^n)^2 - (a^n)^2,$$

and proceeding as for the semidiscrete method, we get:

$$\begin{aligned}\|u^{n+1}\|_0^2 + \|u^{n+1}-u^n\|_0^2 - \|u^n\|_0^2 + \|v^{n+1}\|_0^2 + \|v^{n+1}-v^n\|_0^2 - \|v^n\|_0^2 \\ + 2\Delta t\,\bar m\left(|u^{n+1}|_1^2 + |u_e^{n+1}|_1^2\right) \\ \le \Delta t\, C_1\left[\|u^{n+1}\|_0^2 + \|v^{n+1}\|_0^2\right] + \Delta t\, C_2 \|S^n\|_0^2,\end{aligned} \tag{3.7}$$

where C_1 and C_2 are defined as they were in the semidiscrete case. Now denote by M the index of the final time step (i.e., $T = M\Delta t$), and sum the previous inequality for n going from 0 to $m-1$, $1 \le m \le M$, to obtain:

$$\begin{aligned}(1-\Delta t\, C_1)\left[\|u^m\|_0^2 + \|v^m\|_0^2\right] + 2\Delta t\bar m \sum_{n=1}^{m}\left(|u^n|_1^2 + |u_e^n|_1^2\right) \\ \le \|u^0\|_0^2 + \|v^0\|_0^2 + \Delta t\, C_1 \sum_{n=0}^{m-1}\left[\|u^n\|_0^2 + \|v^n\|_0^2\right] + \Delta t\, C_2 \sum_{n=0}^{m-1}\|S^n\|_0^2.\end{aligned} \tag{3.8}$$

Now, from the discrete Gronwall lemma [20, Lemma 1.4.2, p. 14], by assuming that $\Delta t < 1/C_1$, it can be concluded that

$$\begin{aligned}\max_{n=1,\dots,M}\left\{\|u^n\|_0^2 + \|v^n\|_0^2\right\} \le \Bigg(\frac{1}{1-\Delta t\, C_1}\left[\|u^0\|_0^2 + \|v^0\|_0^2\right] \\ + \frac{C_2}{1-\Delta t\, C_1}\sum_{n=0}^{M-1}\Delta t\,\|S^n\|_0^2\Bigg) e^{\frac{TC_1}{1-\Delta t C_1}}.\end{aligned} \tag{3.9}$$

Let us extend the numerical solutions at discrete times t_n to functions u and v piecewise constant in time and such that $u(n\Delta t) = u^n, v(n\Delta t) = v^n$ for $n = 0, \dots, M-1$. The last inequality means that $u, v \in L^\infty(0,T;L^2(\Omega))$. This property is true as long as $\sum_{n=0}^{M-1}\Delta t\|S^n\|_0^2$ remains bounded, which holds if $S \in L^2(0,T;L^2(\Omega))$.

Now return to (3.8). We can use that inequality to bound the other left-hand term:

$$\begin{aligned}\sum_{n=1}^{M}\Delta t\left(|u^n|_1^2 + |u_e^n|_1^2\right) \le \frac{1}{2\bar m}\left(\|u^0\|_0^2 + \|v^0\|_0^2\right) + \frac{TC_1}{2\bar m}\max_n\left\{\|u^n\|_0^2 + \|v^n\|_0^2\right\} \\ + \frac{C_2}{2\bar m}\sum_{n=0}^{M-1}\Delta t\,\|S^n\|_0^2.\end{aligned} \tag{3.10}$$

The left-hand term in this last inequality is nothing more—extending the solution u and u_e to piecewise functions as before—than the $L^2(0,T)$ norm of $|u|_1$ and $|u_e|_1$. We can thus conclude that the solutions u, u_e, and v of the fully discrete backward Euler method live in the same functional spaces as in the semidiscrete case. The difference is that we have here a constraint on the time step Δt. To ensure the stability of the method, we must have $\Delta t < 1/C_1$. Since $C_1 = O(1/\epsilon)$ for $\epsilon \ll 1$, the stability of the backward Euler scheme is guaranteed for $\Delta t = O(\epsilon)$. Note that this condition is independent of h. The parameter ϵ controls the thickness of the depolarization/repolarization fronts, meaning that the time step Δt must be small enough to resolve that front to ensure stability.

3.2.2. Second order SBDF. We shall now consider the stability of the second order SBDF method (2.14). With u^{n+1}, u_e^{n+1}, and v^{n+1} as test functions, the associated variational equations read as follows:

$$\begin{aligned}
&\int_\Omega \left[\frac{3u^{n+1}-4u^n+u^{n-1}}{2\Delta t} - \frac{1}{\epsilon}\left(2f(u^n,v^n)-f(u^{n-1},v^{n-1})\right)\right]u^{n+1}\,\mathrm{d}\mathbf{x} \\
&\qquad + \int_\Omega \left(\sigma_i\nabla(u^{n+1}+u_e^{n+1})\right)\cdot\nabla u^{n+1}\,\mathrm{d}\mathbf{x} = 0, \\
&\int_\Omega (\sigma_i\nabla u^{n+1})\cdot\nabla u_e^{n+1}\,\mathrm{d}\mathbf{x} + \int_\Omega \left((\sigma_i+\sigma_e)\nabla u_e^{n+1}\right)\cdot\nabla u_e^{n+1}\,\mathrm{d}\mathbf{x} = 0, \\
&\int_\Omega \left[\frac{3v^{n+1}-4v^n+v^{n-1}}{2\Delta t} - \epsilon\left(2g(u^n,v^n)-g(u^{n-1},v^{n-1})\right)\right]v^{n+1}\,\mathrm{d}\mathbf{x} \\
&\qquad = \int_\Omega S^n v^{n+1}\,\mathrm{d}\mathbf{x}.
\end{aligned} \tag{3.11}$$

Since the reaction terms are taken explicitly, a milder dependency of the reaction terms on the variables u and v must be assumed; e.g., we suppose that f and g satisfy the following Lipschitz condition:

$$\begin{aligned}
\|f(u,v)\|_0 &\le L_f\left[\|u\|_0+\|v\|_0\right], \\
\|g(u,v)\|_0 &\le L_g\left[\|u\|_0+\|v\|_0\right],
\end{aligned} \tag{3.12}$$

where L_f, $L_g > 0$.

Remark 3.1. The functions $f(u,v) = u - \frac{u^3}{3} - v$ and $g(u,v) = u - \gamma v$ in the FitzHugh–Nagumo ionic model are not Lipschitzian. However, if we make the hypothesis that $u \in L^\infty(\Omega)$ and that there exists a constant $\mathscr{C} > 0$ such that $\|u\|_\infty \le \mathscr{C}$ for all time $t \in [0,T]$, we have

$$\begin{aligned}
\|f(u,v)\|_0 \le \|u\|_0 + \frac{1}{3}\|u^3\|_0 + \|v\|_0 &\le \|u\|_0 + \frac{1}{3}\|u\|_\infty^2\|u\|_0 + \|v\|_0 \\
&\le \left(\frac{\mathscr{C}^2}{3}+1\right)\|u\|_0 + \|v\|_0 \\
&\le L_f\left[\|u\|_0+\|v\|_0\right],
\end{aligned}$$

where $L_f = \frac{\mathscr{C}^2}{3}+1$. We can also bound the function g:

$$\|g(u,v)\|_0 \le \|u\|_0 + \gamma\|v\|_0 \le L_g\left[\|u\|_0+\|v\|_0\right],$$

where $L_g = \max\{1,\gamma\}$. We do observe numerically that, provided that the initial solution $(u_0(x), v_0(x))$ at all points $x \in \Omega$ is in a properly chosen box in the (u,v)-plane,

$(u(x,t), v(x,t))$ remains in that box for all time. In other words, u remains bounded in $L^\infty(\Omega)$, and the constants L_f and L_g can be practically identified. Basically it would mean that we can replace the cubic function f of the FitzHugh–Nagumo model by an affine function $\tilde{f}$ outside of that box without changing the solution, the function $\tilde{f}$ now being Lipschitzian. It should be noted though that, as far as we know, such a maximum principle has not been proven for the bidomain model with FitzHugh–Nagumo ion kinetics.

By adding the equations of system (3.11) and applying the identity

$$\begin{aligned}(6a^{n+1} - 8a^n + 2a^{n-1})a^{n+1} = (a^{n+1})^2 + (2a^{n+1} - a^n)^2 + (\delta_{tt}a^{n+1})^2 \\ - (a^n)^2 - (2a^n - a^{n-1})^2,\end{aligned}$$

where $\delta_{tt}a^{n+1} = a^{n+1} - 2a^n + a^{n-1}$ to the time-discretization term, we obtain

$$\begin{aligned}&\|u^{n+1}\|_0^2 + \|2u^{n+1} - u^n\|_0^2 - \|u^n\|_0^2 - \|2u^n - u^{n-1}\|_0^2 + \|v^{n+1}\|_0^2 \\ &\quad + \|2v^{n+1} - v^n\|_0^2 - \|v^n\|_0^2 - \|2v^n - v^{n-1}\|_0^2 + 4\Delta t\,\bar{m}(|u^{n+1}|_1^2 + |u_e^{n+1}|_1^2) \\ &\quad \le \Delta t\,C_1\|u^{n+1}\|_0^2 + \Delta t\,C_2\|v^{n+1}\|_0^2 + \Delta t\,C_3\|u^n\|_0^2 + \Delta t\,C_4\|v^n\|_0^2 \\ &\quad + \Delta t\,C_5\|u^{n-1}\|_0^2 + \Delta t\,C_6\|v^{n-1}\|_0^2 + \Delta t\,C_7\|S^n\|_0^2. \qquad (3.13)\end{aligned}$$

Now sum this inequality for n going from 0 to $m-1$, where m is an integer between 1 and M. We will see the values u^{-1} and v^{-1} appear. They are used during the first time step using the second order SBDF scheme; we will take them equal to u^0 and v^0, respectively. This yields the following result:

$$\begin{aligned}&(1 - \Delta t\,C)\left[\|u^m\|_0^2 + \|v^m\|_0^2\right] + 4\Delta t\,\bar{m}\sum_{n=1}^{m}\left(|u^n|_1^2 + |u_e^n|_1^2\right) \\ &\le 2\left(\|u^0\|_0^2 + \|v^0\|_0^2\right) + \Delta t\,K\sum_{n=0}^{m-1}\left(\|u^n\|_0^2 + \|v^n\|_0^2\right) + \Delta t\,C_7\sum_{n=0}^{m-1}\|S^n\|_0^2, \qquad (3.14)\end{aligned}$$

where $C = \max\{C_1, C_2\}$ and $K = \max\{C_1 + C_3 + 2C_5, C_2 + C_4 + 2C_6\}$. Choose Δt such that $\Delta t < 1/C$, and, by applying the discrete Gronwall lemma to (3.14), obtain

$$\begin{aligned}\max_{n=1,\dots,M}\left\{\|u^n\|_0^2 + \|v^n\|_0^2\right\} \le \Bigg(&\frac{2}{1 - \Delta t\,C}\left[\|u^0\|_0^2 + \|v^0\|_0^2\right] \\ &+ \frac{C_7}{1 - \Delta t\,C}\sum_{n=0}^{M-1}\Delta t\,\|S^n\|_0^2\Bigg)e^{TK/(1-\Delta tC)}. \qquad (3.15)\end{aligned}$$

By combining (3.15) and (3.14), we write

$$\begin{aligned}\sum_{n=1}^{M}\Delta t\left(|u^n|_1^2 + |u_e^n|_1^2\right) \le \frac{1}{2\bar{m}}\left(\|u^0\|_0^2 + \|v^0\|_0^2\right) + \frac{TK}{4\bar{m}}\max_n\left\{\|u^n\|_0^2 + \|v^n\|_0^2\right\} \\ + \frac{C_7}{4\bar{m}}\sum_{n=0}^{M-1}\Delta t\,\|S^n\|_0^2. \qquad (3.16)\end{aligned}$$

This proves that the solutions u, u_e, and v remain bounded in the spaces described in (3.5) for the second order SBDF method, with the condition that $\Delta t < 1/C$ is met. C depends on C_1 and C_2, $C_1 = O(\frac{L_f}{\epsilon})$, and $C_2 = O(\epsilon L_g)$, so we can say that $C = O\left(\max\left\{L_f/\epsilon, \epsilon L_g\right\}\right)$. The stability of the method is guaranteed with $\Delta t = O(\min\{\frac{\epsilon}{L_f}, \frac{1}{\epsilon L_g}\}) = O(\epsilon/L_f)$ when $\epsilon \ll 1$ or $L_f \gg 1$.

3.2.3. Crank–Nicolson/Adams–Bashforth. Take $u^{n+1}+u^n$ and $v^{n+1}+v^n$ as test functions in (2.12) for the Crank–Nicolson/Adams–Bashforth method, and take $\frac{1}{2}(u_e^{n+1}+u_e^n)$ as a test function in (2.2) at times $t=t_n$ and $t=t_{n+1}$. The four resultant equations can then be summed, and by using the Lipschitz condition (3.12) and the equivalence of seminorms we get

$$\begin{aligned}\|u^{n+1}\|_0^2-\|u^n\|_0^2+\|v^{n+1}\|_0^2-\|v^n\|_0^2+\frac{\Delta t}{2}\,\bar{m}(|u^{n+1}+u^n|_1^2+|u_e^{n+1}+u_e^n|_1^2)\\ \le \Delta t\,C_1\|u^{n+1}\|_0^2+\Delta t\,C_2\|v^{n+1}\|_0^2+\Delta t\,C_3\|u^n\|_0^2+\Delta t\,C_4\|v^n\|_0^2\\ +\Delta t\,C_5\|u^{n-1}\|_0^2+\Delta t\,C_6\|v^{n-1}\|_0^2+\Delta t\,C_7\|S^n\|_0^2.\end{aligned}\tag{3.17}$$

By proceeding as we did for the second order SBDF scheme and using the discrete Gronwall lemma,

$$\begin{aligned}\max_{n=1,\dots,M}\left\{\|u^n\|_0^2+\|v^n\|_0^2\right\}\le\Bigg(\frac{1}{1-\Delta t\,C}\left[\|u^0\|_0^2+\|v^0\|_0^2\right]\\ +\frac{C_7}{1-\Delta t\,C}\sum_{n=0}^{M-1}\Delta t\,\|S^n\|_0^2\Bigg)e^{TK/(1-\Delta tC)}\end{aligned}\tag{3.18}$$

and

$$\begin{aligned}\sum_{n=0}^{M-1}\Delta t\big(|u^{n+1}+u^n|_1^2+|u_e^{n+1}+u_e^n|_1^2\big)\le\frac{2}{\bar{m}}\left(\|u^0\|_0^2+\|v^0\|_0^2\right)\\ +\frac{2TK}{\bar{m}}\max_n\left\{\|u^n\|_0^2+\|v^n\|_0^2\right\}+\frac{2C_7}{\bar{m}}\sum_{n=0}^{M-1}\Delta t\,\|S^n\|_0^2,\end{aligned}\tag{3.19}$$

with C and K defined as before and with $\Delta t<1/C$. This time, we need to extend our numerical solutions to functions u, u_e, and v piecewise affine in time, which shows that the solutions u, u_e, and v remain bounded in the spaces in (3.5) with the same conditions as for the second order SBDF scheme.

3.2.4. Forward Euler. The use of explicit methods, such as the forward Euler method considered here, requires more conditions on the time step Δt due to the fact that the diffusion terms are taken explicitly. We use u^{n+1} and v^{n+1} as test functions in (2.12) and u_e^{n+1} in (2.2) at time t_{n+1}, as with the backward Euler and second order SBDF methods, and by adding the resultant variational equations, we get

$$\begin{aligned}\|u^{n+1}\|_0^2+\|u^{n+1}-u^n\|_0^2+\|v^{n+1}\|_0^2+\|v^{n+1}-v^n\|_0^2+2\Delta t\,\bar{m}\left(|u^{n+1}|_1^2+|u_e^{n+1}|_1^2\right)\\ -2\Delta t\,M_i\left[|u^{n+1}-u^n|_1+|u_e^{n+1}-u_e^n|_1\right]|u^{n+1}|_1\\ \le\|u^n\|_0^2+\|v^n\|_0^2+\Delta t\,C_1\|u^{n+1}\|_0^2+\Delta t\,C_2\|v^{n+1}\|_0^2+\Delta t\,C_3\|u^n\|_0^2\\ +\Delta t\,C_4\|v^n\|_0^2+\Delta t\,C_5\|S^n\|_0^2.\end{aligned}\tag{3.20}$$

We must now bound the term with a negative sign in the left-hand side of the previous inequality. Let us rewrite the second variational equation of the system as

$$\begin{aligned}\int_\Omega\left((\sigma_i+\sigma_e)\nabla u_e^{n+1}\right)\cdot\nabla u_e^{n+1}\mathrm{d}\mathbf{x}=-\int_\Omega(\sigma_i\nabla u^{n+1})\cdot\nabla u_e^{n+1}\mathrm{d}\mathbf{x}\\ \Rightarrow|u_e^{n+1}|_1\le\frac{M_i}{m_i+m_e}|u^{n+1}|_1\\ \Rightarrow|u_e^{n+1}-u_e^n|_1\le\frac{M_i}{m_i+m_e}|u^{n+1}-u^n|_1\end{aligned}\tag{3.21}$$

by using the linearity of the second equation of the bidomain model.

By applying an inverse inequality [6, Theorem 3.2.6, p. 140] and the upper bound (3.21) to the inequality (3.20), we obtain the majoration for any constant $s > 0$:

$$\begin{aligned}\|u^{n+1}\|_0^2 + \left(1 - \Delta t \frac{\widetilde{\mathscr{C}}^2 M_i^2 \left(1 + \frac{M_i}{m_i+m_e}\right)^2}{h^2 s}\right) \|u^{n+1} - u^n\|_0^2 + \|v^{n+1}\|_0^2 \\ + \Delta t(2\bar{m} - s)\left(|u^{n+1}|_1^2 + |u_e^{n+1}|_1^2\right) \le \|u^n\|_0^2 + \|v^n\|_0^2 + \Delta t\, C_1 \|u^{n+1}\|_0^2 \\ + \Delta t\, C_2 \|v^{n+1}\|_0^2 + \Delta t\, C_3 \|u^n\|_0^2 + \Delta t\, C_4 \|v^n\|_0^2 + \Delta t\, C_5 \|S^n\|_0^2. \end{aligned} \tag{3.22}$$

To ensure the positivity of all of the terms on the left-hand side of the last inequality, we restrict s and Δt so that $s < 2\bar{m}$ and $1 - \Delta t\, \widetilde{\mathscr{C}}^2 M_i^2 (1 + \frac{M_i}{m_i+m_e})^2 / h^2 s \ge 0$; in other words,

$$\Delta t \le \frac{h^2 s}{\widetilde{\mathscr{C}}^2 M_i^2 \left(1 + \frac{M_i}{m_i+m_e}\right)^2} < \frac{2h^2 \bar{m}}{\widetilde{\mathscr{C}}^2 M_i^2 \left(1 + \frac{M_i}{m_i+m_e}\right)^2}. \tag{3.23}$$

Let $k = 2\bar{m} - s$, $C = \max\{C_1, C_2\}$, and $K = \max\{C_1 + C_3, C_2 + C_4\}$. Proceeding as with the previous methods yields

$$\begin{aligned}\max_{n=1,\dots,M} \left\{\|u^n\|_0^2 + \|v^n\|_0^2\right\} \le \Bigg(\frac{1}{1 - \Delta t\, C}\left[\|u^0\|_0^2 + \|v^0\|_0^2\right] \\ + \frac{C_5}{1 - \Delta t\, C} \sum_{n=0}^{M-1} \Delta t\, \|S^n\|_0^2\Bigg) e^{TK/(1-\Delta t C)}, \end{aligned} \tag{3.24}$$

$$\begin{aligned}\sum_{n=1}^{M} \Delta t \left(|u^n|_1^2 + |u_e^n|_1^2\right) \le \frac{1}{k}\left(\|u^0\|_0^2 + \|v^0\|_0^2\right) + \frac{TK}{k} \max_n \left\{\|u^n\|_0^2 + \|v^n\|_0^2\right\} \\ + \frac{C_5}{k} \sum_{n=0}^{M-1} \Delta t\, \|S^n\|_0^2. \end{aligned} \tag{3.25}$$

Therefore, if the conditions we have imposed on Δt are met, u, u_e, and v remain stable in the spaces of (3.5). These conditions are $\Delta t < 1/C$, with $C = O(\max\{L_f/\epsilon, \epsilon L_g\})$ and the condition (3.23). Clearly Δt must be $O(h^2)$, which limits the applicability of the forward Euler method.

3.2.5. Discussion on the stability conditions. We first want to quantify how small the time step must be to guarantee the stability of fully explicit methods, such as the forward Euler method. We need to estimate the constants in the stability condition (3.23), in particular, $\bar{m}$ and $\widetilde{\mathscr{C}}$.

The last inequality in majoration (3.1) can be rewritten as

$$\begin{aligned} m_i|x+y|^2 + m_e|y|^2 &= m_i|x|^2 + 2m_i\langle x, y\rangle + (m_i + m_e)|y|^2 \\ &= \begin{bmatrix} x & y \end{bmatrix} \begin{bmatrix} m_i & m_i \\ m_i & m_i + m_e \end{bmatrix} \begin{bmatrix} x \\ y \end{bmatrix} \\ &\ge \bar{m}\left(|x|^2 + |y|^2\right), \end{aligned} \tag{3.26}$$

with $\bar{m} > 0$ the smallest eigenvalue of the above matrix. A simple computation gives

$$\bar{m} = \frac{2m_i + m_e - \sqrt{4m_i^2 + m_e^2}}{2} = O(\min\{m_i, m_e\}). \tag{3.27}$$

Let us now estimate the constant $\widetilde{\mathscr{C}}$ that appears in the inverse inequality in [6, Theorem 3.2.6, p. 140]. We will start by evaluating $\widetilde{\mathscr{C}}$ in the 1D case. Consider the function $v_h(x) = a + (b-a)\,x/h \in P_h^1$ on the element $K = [0,h]$. When evaluating $\|v_h\|_0$ and $|v_h|_1$ on K for that function, one must have for the inverse inequality to be valid that:

$$\widetilde{\mathscr{C}} \geq h\frac{|v_h|_1}{\|v_h\|_0} = \left(\frac{3(a-b)^2}{a^2+ab+b^2}\right)^{1/2}. \tag{3.28}$$

It is easy to find that $\widetilde{\mathscr{C}} = 2\sqrt{3}$ is the lowest upper bound for the above rational function.

Now consider the 2D case. Let K be the linear triangular element adjacent to the nodes at $(0,0)$, $(0,h)$, and $(h/2,h/2)$. This is not the most general case, since $\widetilde{\mathscr{C}}$ is likely to depend on the shape of K, but it is nevertheless representative of the meshes we will work with in section 4. Let v_h be a function in P_h^1 on this element with the property that $v_h(0,0) = a$, $v_h(0,h) = b$, and $v_h(h/2,h/2) = c$, i.e., $v_h(x,y) = a + (2c-(a+b))\,x/h + (b-a)\,y/h$. Now let us compute $\|v_h\|_0$ and $|v_h|_1$ on K:

$$\|v_h\|_0 = \left(\int_K v_h^2\,\mathrm{d}\mathbf{x}\right)^{1/2} = \left(\frac{h^2}{24}\left(a^2+b^2+c^2+ab+ac+bc\right)\right)^{1/2}, \tag{3.29}$$

$$|v_h|_1 = \left(\int_K |\nabla v_h|^2\,\mathrm{d}\mathbf{x}\right)^{1/2} = \left(\frac{a^2}{2}+\frac{b^2}{2}+c^2-ac-bc\right)^{1/2}. \tag{3.30}$$

We must choose a value of $\widetilde{\mathscr{C}}$ such that

$$\widetilde{\mathscr{C}} \geq h\frac{|v_h|_1}{\|v_h\|_0} = \left(\frac{12a^2+12b^2+24c^2-24ac-24bc}{a^2+b^2+c^2+ab+ac+bc}\right)^{1/2}. \tag{3.31}$$

In this case, the optimal value for $\widetilde{\mathscr{C}}$ may be computed to be $6\sqrt{2}$.

We consider two cases for the conductivity values.

Case 1: Suppose that $m_i = m_e$ and $M_i = \lambda m_i$ for a certain value $\lambda > 1$. This is in fact a case where the bidomain model reduces to a monodomain model [7, 14]. By using the constants calculated above, the condition on the time step reads as

$$\begin{aligned}\Delta t &< \frac{(3-\sqrt{5})h^2}{\widetilde{\mathscr{C}}^2\lambda^2 m_i\left(1+\lambda+\frac{\lambda^2}{4}\right)}\\ \Rightarrow \Delta t &< \frac{\widetilde{K}h^2}{\lambda^4 m_i} = \frac{\widetilde{K}m_i^3}{M_i^4}h^2,\end{aligned}$$

where $\widetilde{K}$ is a constant that depends on $1/\widetilde{\mathscr{C}}^2$. In that case,

$$\Delta t = O\left(\min\left\{\frac{\epsilon}{L_f}, \frac{1}{\epsilon L_g}, \frac{m_i^3}{M_i^4}h^2\right\}\right).$$

When h becomes small, the last term is the most stringent with a time step that decreases also with the cube of the ratio $m_i/M_i < 1$ of the minimal to maximal intracellular conductivities on the domain.

TABLE 3.1
Stability conditions on Δt and on the model used for several methods.

Method	Δt	Model
Forward Euler	$O\left(\min\left\{\frac{\epsilon}{L_f}, \frac{m_i^3}{M_i^4}h^2\right\}\right)$	f, g Lipschitz
Second order SBDF	$O\left(\frac{\epsilon}{L_f}\right)$	f, g Lipschitz
Backward Euler	$O(\epsilon)$	FitzHugh–Nagumo

Case 2: Take values that approach the physical values found in the heart, for example, those seen in [12], i.e., $m_i = 0.0263$, $m_e = 0.1087$, and $M_i = 0.263$. By substituting these and the constants computed above in (3.23), this would mean in 1D that $\Delta t < 0.00256\,h^2$ and in 2D that $\Delta t < 0.000167\,h^2$. Not only must the maximal time step Δt for stability be in $O(h^2)$, but in practice the constant appearing in that bound is very small. In other words, an explicit method cannot be efficient, especially in higher dimensions or with fine meshes, due to the excessively large number of time steps needed.

Remark 3.2. Suppose that we change the conductivity over the domain while keeping it proportional to what it was before, i.e., replace the conductivity tensors $\sigma_{i,e}$ by $\mu\,\sigma_{i,e}$, just to see how the critical time step scales with the magnitude of the conductivity. Clearly, from condition (3.23), the time step Δt will have to be taken μ times smaller. Therefore increasing the conductivity of the domain will reduce the stability of the forward Euler method.

Table 3.1 summarizes our stability analysis for the numerical time-stepping schemes considered in this section, by supposing that $\epsilon \ll 1$. The stability of implicit and semi-implicit time-stepping schemes is controlled by the time scale of the ion kinetics without regard to the space step size, while for fully explicit methods the space step size also controls the stability through the second order conduction terms.

4. Numerical results. This section presents numerical tests for both 1D and 2D test cases.

4.1. Comparison of the methods in 1D. We have used in the 1D case a simple finite element code written in Matlab. Our linear systems are solved with the LU factorization included in Matlab. The ease of implementation of a 1D code and the ease of use of Matlab have allowed us to test a significant number of methods.

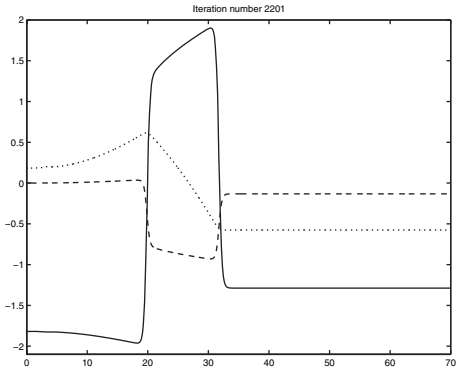
4.1.1. Problem. The 1D bidomain model can be written as

$$\frac{\partial u}{\partial t} = \frac{1}{\epsilon} f(u,v) + \frac{\partial}{\partial x}\left(\sigma_i \frac{\partial u}{\partial x}\right) + \frac{\partial}{\partial x}\left(\sigma_i \frac{\partial u_e}{\partial x}\right), \tag{4.1}$$

$$\frac{\partial}{\partial x}\left(\sigma_i \frac{\partial u}{\partial x}\right) + \frac{\partial}{\partial x}\left((\sigma_i + \sigma_e)\frac{\partial u_e}{\partial x}\right) = 0, \tag{4.2}$$

$$\frac{\partial u}{\partial t} = \epsilon g(u,v), \tag{4.3}$$

where $f(u,v) = u - \frac{u^3}{3} - v$ and $g(u,v) = u + \beta - \gamma v$, with Neumann boundary conditions $\partial_x u(0) = \partial_x u(L) = 0$ and $\partial_x u_e(0) = \partial_x u_e(L) = 0$. Recall that this system determines only u_e modulo a constant. To avoid trying to solve a singular system, we add the condition $u_e(0) = 0$. Our tests have been done over the domain $[0, L]$ with several values of L. We choose as parameter values $\epsilon = 0.1$, $\beta = 1.0$, and $\gamma = 0.5$ and



Solid: u; dashed: u_e; dotted: v

FIG. 4.1. *Solution of the* $1D$ *bidomain model's equations at* $t = 11$.

as conductivity tensors $\sigma_i = \sigma_e = 1.0$. Note that all of the parameter values and space and time measures we will use are nondimensional. For the initial condition, we take u and v constant at the equilibrium value of the system $f(u, v) = 0$ and $g(u, v) = 0$ and u_e constant at 0, except on the interval $[0, \frac{1}{20}L]$ where we fix u at a supercritical value, that is, $u(x) = 2$. This creates a traveling pulse wave that propagates through the domain at a constant speed. Figure 4.1 shows a typical wave form at time $t = 11$. Except where specifically mentioned, all tests in this section are done with $L = 70$, and the final time is $T = 30$.

4.1.2. Results. Given the impossibility of obtaining an exact solution to the problem, we have computed a very precise numerical reference solution (mesh resolution $h = 0.007$ and time step $\Delta t = 10^{-4}$) with the second order SBDF scheme (2.14). It is worth noting that, while it is easy to obtain a numerical solution that qualitatively looks like this reference solution, the numerical error may actually be important. The reason is that a space mesh that is too coarse, or a time step that is too large, often produces a traveling wave whose speed is incorrect. Therefore, we consider the relative error between the speed of the reference and numerical solutions as a good measure of the quality of the solution. We will also consider the L^2 error between both solutions.

Table 4.1 shows the value of the critical time step Δt_c, that is, the largest time step for which the solution remains bounded, for several methods and three space resolutions. We have noticed that, for values of Δt slightly inferior to Δt_c, oscillations often appear in regions where the solution has a sharp gradient, but these oscillations remain bounded and do not grow with time. This is probably due to the nonlinear reaction term, and it might be a loss of monotonicity rather than a loss of stability.

As expected from the theoretical stability analysis, the dependence of Δt_c on the mesh resolution varies between the different methods. The forward Euler method's critical time step seems proportional to h^2, in agreement with the analysis in section 3.2.4. By calculating the theoretical critical time steps for that method using the constants obtained in that section and $m_{i,e} = M_{i,e} = 1$, one gets $\Delta t_{c,th} = 5.55 \times 10^{-4}$, 1.39×10^{-4}, and 3.47×10^{-5} for $h = 0.14$, 0.07, and 0.035 ($N = 500$, 1000, and 2000), respectively. The theoretical critical time steps are about 6 times smaller than the experimental critical time steps, but this is not surprising as the theoretical stability conditions obtained above are only sufficient.

TABLE 4.1
Size of Δt_c for the numerical methods used.

Methods	$h = 0.14$	$h = 0.07$	$h = 0.035$
Forward Euler	0.003206	0.000813	0.000204
Forward-backward Euler	0.1395	0.1422	0.1415
Crank–Nicolson	0.1299	0.1044	0.08386
IMEX first order Gear	0.1594	0.1594	0.1594
Backward Euler	> 0.2	> 0.2	> 0.2
CNAB	0.06772	0.04951	0.04027
MCNAB	0.07538	0.075	0.075
Second order SBDF	0.09375	0.09404	0.09494
Implicit Gear	> 0.25	> 0.25	> 0.25
Third order SBDF	0.06834	0.07026	0.07126

For all of the other methods—the implicit, IMEX first order Gear, MCNAB, and second and third order SBDF methods—the critical time step shows limited dependence, if any, on the space step h. The fully implicit methods require the largest Δt_c, followed by the first order IMEX methods and then the higher order IMEX schemes, which require the smallest Δt_c. For the backward Euler scheme, we estimate that $\Delta t_{c,th} \approx 0.04$ by picking the optimal parameter k to equilibrate the leading order terms in $1/\epsilon$ in the stability condition of section 3.2.1. The theoretical step $\Delta t_{c,th}$ is about 5 times smaller than the experimental step Δt_c. Again the theoretical stability condition is only sufficient, which may explain the discrepancy between both values. For fully implicit methods, we have indicated a lower bound for Δt_c because, as Δt gets larger, the nonlinear system is harder to solve with Newton's method, leading to the stagnation of the iterative solver and making an accurate evaluation of Δt_c difficult. Only two semi-implicit methods required smaller Δt_c with smaller space steps h, namely, the CN and CNAB schemes. For those two methods, the dependence of Δt_c on the mesh resolution is at most of sublinear order, unless the asymptotic behavior of Δt_c when h goes to 0 has not yet been reached even with $h = 0.035$.

Figure 4.2 shows the position of the u wave at different times for different methods. The two top figures show the position of the waves at time $t = 20$ computed with all first order methods compared to the position of the reference solution. The bottom figure at the right shows the same thing but for second order methods. For second order methods, we used a time step twice as large as for first order methods to have a comparable workload at each time step and globally to reach a solution at a given time t. Clearly, for a comparable computational effort, second order methods offer greater accuracy with less phase lag compared to the reference solution. The figure at the bottom left shows the solutions obtained with the same second order methods at an earlier time. The phase error between the reference and numerical solution grows with time, as a result of the different wave speeds for the different time integration schemes. We will thus use the wave speed as a measure of error.

Table 4.2 shows the signed relative error between the speed of the numerical wave c_{num} and a reference value c_{ref}, where c_{num} is defined as the average speed at which the level curve for $u = 1$ moves on the interval $[25, 50]$. We have computed the traveling wave speed for our reference solution to be $c_{ref} = 2.577444$. For the section of Table 4.2 dealing with the forward Euler method, we have chosen to show the wave speed for a number of time steps nt approximately equal to the number of time steps necessary to ensure the stability and monotonicity of the solution, as well as for 1.5 and 2 times that number of time steps. For all of the other methods, we could use

the same standardized time steps, sufficiently small to ensure the stability of all of the methods.

Table 4.2 clearly shows that with an underresolved grid one cannot reliably compute waves with the right speed, irrespective of the time integration scheme used. It is only for grids with $h \leq 0.14$ that the wave speed error is below 1 %, at least for higher order methods. It had already been observed in [5] that, with a second order fully implicit Gear scheme, 2D action potential waves could travel with the wrong speed due to underresolved spatial grids. Here we emphasize that the grid resolution is only one aspect of the problem; the order of the time integration scheme matters. Finer grids give better accuracy with all methods, but the semi-implicit or implicit first order schemes (Crank–Nicolson, IMEX Gear, and forward-backward Euler in the table) can hardly provide a wave speed error below 1% even on the finest grids considered. It is only by reducing the time step to values comparable to what is used for the forward Euler method that these first order schemes can provide accurate results, at the price of a much higher workload to reach a solution at a given time than for second order methods. Indeed the forward Euler scheme gave the most accurate wave

speed on coarse grids and nearly as accurate results as second order schemes on fine grids, but this was done with a prohibitive number of time steps.

Except for circumstantial very accurate results (as with CNAB using $h = 0.07$ and $\Delta t = 0.005$), the most accurate wave speeds have been obtained with the third order SBDF scheme on fine enough grids. It is worth noting, however, that using methods of third order and over isn't necessarily an advantage. The effort in implementing a third order scheme is larger for a marginal gain in accuracy compared to second order schemes. The third order SBDF scheme was also subject to much more stringent numerical stability conditions than its companion second order scheme (see Table 4.1), and even when using a time step size below Δt_c the third order SBDF scheme was more subject to numerical artifacts (Figure 4.2, bottom right). We will come back to this point below when recommending methods.

Finally, Figure 4.3 shows the progression in time of the L^2 error between the reference and numerical solutions for $h = 0.14$. The top two images compare the first order methods to each other and to the second order methods. The two bottom images compare the second and third order methods for two values of Δt. We see that, after a certain time interval in which the action potential wave takes form, the L^2 error then seems to grow linearly in time, although with different slopes for different methods. Among the first order methods, the Crank–Nicolson scheme is the

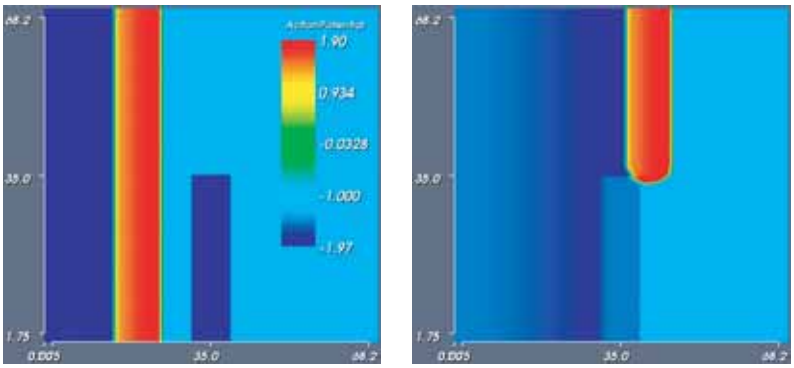
most accurate. Figure 4.3 confirms the conclusion reached with Table 4.2 that higher order methods are necessary to solve this problem. The error is consistently lower with higher order than first order methods, except for the forward Euler method, which produces results with a L^2 error about the size of the CNAB and implicit Gear schemes but with a much smaller time step than for these second order methods.

Looking back at Figure 4.2 at the bottom, small oscillations are observed in the recovery zone behind the repolarization front for the third order SBDF method. Note that these oscillations are also seen with the CNAB and MCNAB schemes, but they get smoothed out with the advance of time. The third order SBDF scheme gives a bounded solution, but more work must be done to make the instabilities disappear. This method, in fact, does not give better results when $h = 0.14$, as illustrated in Figure 4.3. We may therefore conclude that second order methods are in fact the optimal choice. Among these, we will concentrate on the IMEX schemes, due to the large cost of every time step with the implicit Gear scheme. The second order SBDF method appears to be the most interesting one. As seen in Table 4.1, it is more stable than the CNAB and MCNAB methods—which in fact produce very similar solutions. While it is true (see Figure 4.2 and Table 4.2) that for larger time steps (for example, $\Delta t = 0.04$) the second order SBDF does not preserve the wave speed quite as well as the other two, when smaller time steps are used, it produces an as-good solution. This method also has the advantage of requiring the computation of the diffusion term only at time step $n+1$. For all of these reasons, the second order SBDF method is recommended for solving the bidomain model.

4.2. Comparison of the methods in 2D. In order to solve the 2D bidomain model, we have used an object-oriented finite element code written in C++ based on the solver library PETSc [27]. This library allows the user to choose between many direct and iterative solvers and between many preconditioners. The tests we did on coarse grids have convinced us that the LU factorization is ideal for this problem, subject to memory constraints. When finer grids are used, iterative methods become necessary. Our tests have shown that, of all available solvers and preconditioners, the conjugate gradient method with an incomplete LU preconditioner (see [24]) use the least computation time. The tests shown in this section have been done with this solver and the incomplete LU preconditioner with two levels of fill.

4.2.1. Problem. We consider the 2D formulation of the bidomain model, including Neumann boundary conditions. The domain $[0, 70] \times [0, 70]$ is used—these values again being nondimensional. It is meshed with $4N^2$ triangular elements obtained by dividing the $N \times N$ squares into four congruent triangles. For all of our tests, $N = 300$ ($h = 0.233$). As in the 1D case, we fix the parameters $\epsilon = 0.1$, $\beta = 1.0$, and $\gamma = 0.5$. The degeneracy of the system is removed by fixing the value of u_e somewhere on the domain; we have chosen $u_e(0, 0) = 0$.

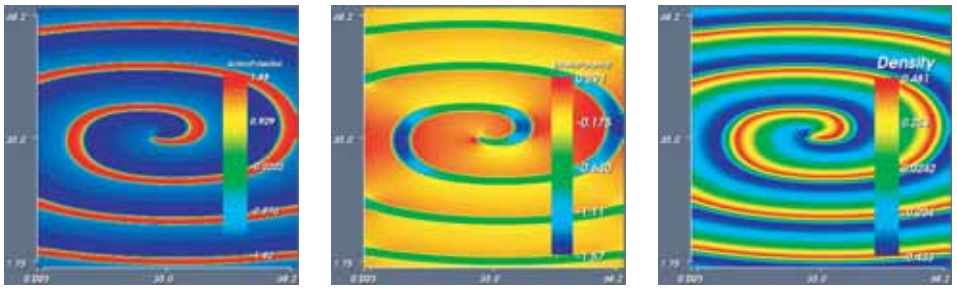
The initial condition used in all comparisons done below is obtained numerically as follows. We initiate a spiral (reentrant) wave by setting u and v at their equilibrium value and $u_e = 0$, except on $[0, 3.5] \times [0, 70]$, where we fix $u = 2$ as explained in section 4.1.1, and also on $[31, 39] \times [0, 35]$, where we fix $v = 2$, which creates a recovery zone. The result is a planar wave that travels at constant speed until hitting the recovery zone and then rolls around this zone, forming a spiral wave. Figure 4.4 illustrates the way this spiral wave is formed for the variable u. That spiral wave is then evolved during enough time steps to go through a transient initial stage and reach an established (unsteady) regime. The solution at a given time in that established regime is used as an initial condition. The initial condition is shown on Figure 4.5.



$t = 10$ $t = 20$

$t = 30$ $t = 40$

FIG. 4.4. *Solution for u of the 2D bidomain equations at different times.*



u u_e v

FIG. 4.5. *Initial condition for the 2D problem.*

Due to time and memory constraints, it is very difficult to obtain a precise reference solution in 2D, as was done with 10,000 grid points in 1D. Instead of increasing the number of grid points to a very large value in each direction to reach the grid independence of the numerical solution, we chose to use only $N = 300$ but pick values of the conductivity tensors that are large enough to avoid mesh effects by ensuring a thick enough de-/repolarization wave front. The conductivity tensors are thus taken as $\sigma_i = 25\,\mathrm{diag}\{0.263, 0.0263\}$ and $\sigma_e = 25\,\mathrm{diag}\{0.263, 0.1087\}$. These tensors

CN	X		X		X

are proportional to the values suggested by Hooks et al. [12] for the human heart conductivities.

4.2.2. Results. We compare the second order SBDF and the CNAB methods, given the good results they gave in the 1D tests, as well as the Crank–Nicolson–forward Euler method. We use as a comparison point between the different methods the trajectory of the spiral tip. The spiral tip is defined as the point where the level curves with value 0 for u and v meet. We will check if the form of the trajectory of the spiral tip is the same for the numerical solutions and for the reference solution and if there is a drift of the spiral tip.

To speed up computations at each time step, we compute and store the linear system and preconditioner matrices before the first time step and leave them unchanged afterwards. Note that we solve all three equations of the system simultaneously, resulting in matrices with $3 \times 4N^2$ rows for the grid used. These matrices involve the submatrices M, A_i, and A_e defined in section 2.1. Another strategy to reduce the memory requirements would be to solve each equation of the bidomain model separately and do subiterations to solve the coupled linear system at each time step.

The three methods that we have tested require only the two matrices mentioned above. However, they differ in the number of vectors that need assembling at each time step. Table 4.3 shows which vectors are used by each of these three schemes. We suppose that the next time step is the one that will compute the solution at time t_{n+1}. This table shows that the second order SBDF method forces an extra vector—the solution at time t_{n-1}—to be kept in memory but also approximates the diffusion term only at time t_{n+1}, which is included in the linear system matrix, while the other methods require computing the diffusion term at time t_n, needing reassembly at each time step. The assembly of the right-hand term is therefore more costly in terms of computation time for the Crank–Nicolson/Adams–Bashforth and Crank–Nicolson–forward Euler methods than for the second order SBDF method.

We have tested each second order method with three different time steps: $\Delta t = \frac{1}{50}$, $\Delta t = \frac{1}{30}$, and Δt near Δt_c. The Crank–Nicolson method has been tested only with $\Delta t = \frac{1}{50}$ and $\Delta t = \frac{1}{30}$. We have found our values of Δt close to Δt_c with tests with decreasing values of Δt until the method becomes stable. We are thus able to say that, for the initial solution shown in Figure 4.5, $\frac{1}{12} > \Delta t_c \geq \frac{1}{14}$ for the second order SBDF method and $\frac{1}{17} > \Delta t_c \geq \frac{1}{18}$ for the CNAB method. We therefore choose $\Delta t = \frac{1}{18}$ with CNAB and $\Delta t = \frac{1}{14}$ with SBDF. We notice that, just as in the 1D case (see Table 4.1), the SBDF method is slightly more stable than the CNAB method.

We first note that our largest values of Δt are not sufficient to ensure that the solution does not contain oscillations. This is obvious on the third image at the right on the first two lines of Figure 4.6. We already noticed in 1D that the potential wave lags behind when Δt is too large, for both the second order SBDF and CNAB methods (see Table 4.2). We can see in Figure 4.6 that this property remains true in 2D: the solutions for the largest values of Δt do not seem as advanced as for smaller Δt. We

$\Delta t = \frac{1}{50}$ $\Delta t = \frac{1}{30}$

FIG. 4.6. *Solution for u at $t = 80$ with several methods. The legend is the same as for Figure* 4.5.

also remark that the spiral tip drift is very important when Δt is too large, as shown in Figure 4.7(a). The dashed and short-dashed curves, respectively, CNAB with $\Delta t = \frac{1}{18}$ and SBDF2 with $\Delta t = \frac{1}{14}$, get further and further from the solid curve (CNAB with $\Delta t = \frac{1}{50}$) as the solution advances in time. The foot of the trajectory is found at the left in Figures 4.7(a)–(c), while for Figure 4.7(d) it is in the upper right corner.

As in the 1D case, we have been able to determine that first order methods such as the Crank–Nicolson–forward Euler method (2.9) are not really appropriate to solve this particular problem. Even when $\Delta t = \frac{1}{50}$, as seen in the first image of the third

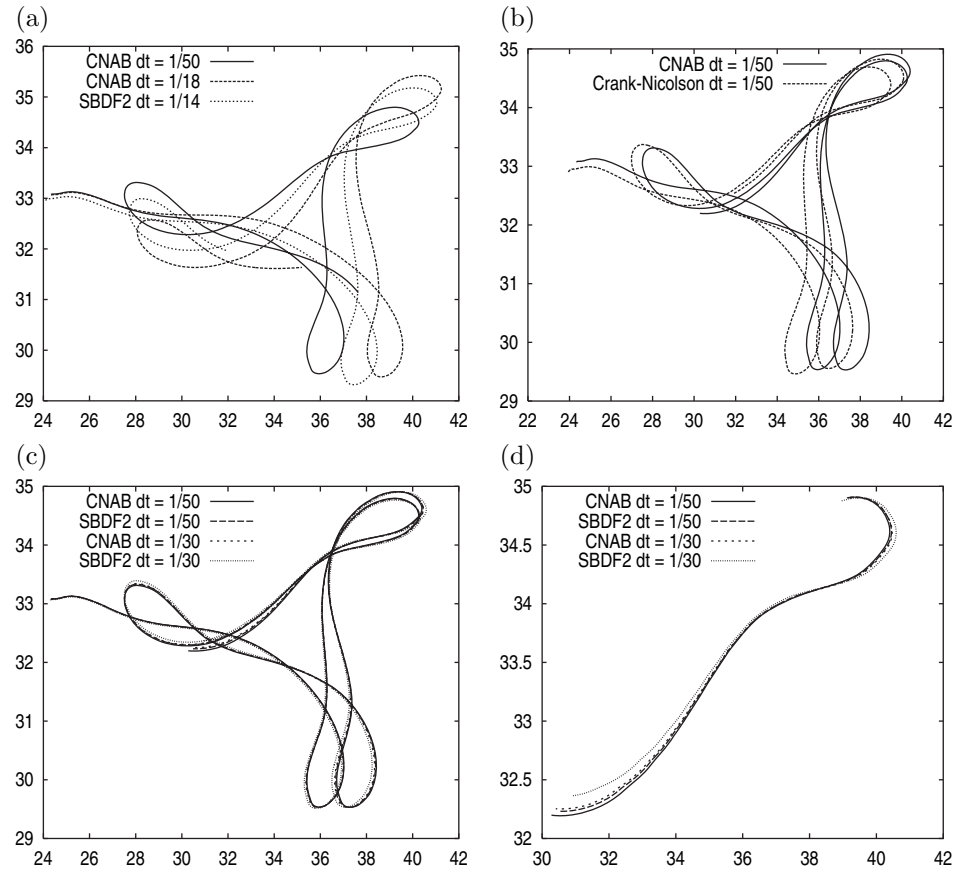

FIG. 4.7. *Trajectory of the spiral tip for:* (a) *second order methods and different values of* Δt, $t \in [10, 55]$*;* (b) *CNAB and CN for* $\Delta t = 1/50$, $t \in [10, 80]$*;* (c) *second order methods and different values of* Δt, $t \in [10, 80]$*;* (d) *second order methods and different values of* Δt, $t \in [70, 80]$.

row of Figure 4.6, the solution already shows an important phase error when compared with the second order methods with $\Delta t = \frac{1}{50}$ or even $\frac{1}{30}$. The error is also visible in Figure 4.7(b), which shows the trajectory of the spiral tip for Crank–Nicolson and CNAB with $\Delta t = \frac{1}{50}$. The error on the spiral tip has already shown up in the 10 time units preceding this image and then increases rapidly.

Figures 4.7(c)–(d) show the evolution of the spiral tip for both second order methods tested, with $\Delta t = \frac{1}{50}$ and $\Delta t = \frac{1}{30}$. The solutions are quite similar regardless of which method is used, but we can note that the solution obtained with the second order SBDF method with $\Delta t = \frac{1}{30}$ drifts slightly compared with the other more accurate results. This fact is more easily seen in Figure 4.7(d). On the other hand, the solution obtained with the CNAB method and $\Delta t = \frac{1}{30}$ follows very closely the more accurate solutions obtained with $\Delta t = \frac{1}{50}$. We recall that in our 1D tests the second order SBDF method produced a wave slightly lagging behind, while the wave computed with the CNAB method was more precisely located for larger values of Δt. Each time step is significantly more costly when solving the 2D problem than the 1D problem, so it is a good idea to use a method that tolerates larger values of Δt. Therefore, the Crank–Nicolson/Adams–Bashforth method seems a more optimal

choice when compared with the second order SBDF method. That being said, the second order SBDF method is almost as accurate as the CNAB method and presents the advantage, as already stated, that each time step is less costly than with the CNAB method, and it is likely that, just as it was with our 1D results, with values of Δt of the order of $\frac{1}{50}$ or less, the second order SBDF method would produce a better solution.

5. Conclusion. In this paper, we have proposed and studied several implicit, explicit, and IMEX time-stepping methods to solve the bidomain model. We have noted that the critical time steps for stability obtained through numerical tests, as seen in Table 4.1, are consistent with the stability analysis of section 3. Indeed, the numerical value of Δt_c depends on h^2 for the forward Euler method, while it has little or no dependence on h for the IMEX and implicit methods. We reached the conclusion that higher order IMEX methods are the most appropriate for solving the bidomain model. Indeed, they are quite stable, their stability does not depend on h, and they produce a good numerical solution even when the time step Δt is not so small. As shown with our numerical results in section 4.1.2, first order schemes, such as the Euler or the Crank–Nicolson methods commonly used for the bidomain model, provide the required accuracy only at the expense of very small time steps, while the second order schemes studied easily provided an error (well) below 1% on the wave speed. It is certainly one of the main conclusions of our work: a second order time-stepping scheme is required, and the Crank–Nicolson scheme the way it is usually implemented for the bidomain model with a fully explicit occurrence of the reaction term does not provide second order accuracy.

Another main advantage of these IMEX methods is that they also require only the solution of a linear system of equations, with both the system and preconditioner matrices constant over the time steps. Second order fully implicit methods are available and slightly more stable, but the matrices involved must be reassembled and factored during Newton–Raphson iterations at each time step.

We have also been able to discriminate between the higher order IMEX methods considered. Two of them have been especially impressive: the CNAB method and the second order SBDF method. We reached the conclusion that, while the SBDF method is more stable than the CNAB method, both methods require a time step about half of its critical value to produce an acceptable solution. With such a value of Δt, the SBDF method produces a solution whose delay compared to the reference solution is slightly larger than the solution obtained with the CNAB method. With yet smaller values of Δt the SBDF method does produce solutions closer to the reference solution than the CNAB method. However, the SBDF method also costs less in terms of computation time than the CNAB method, since it does not require reassembling the diffusion term every time step.

CONVERGENCE OF A FINITE ELEMENT-BASED SPACE-TIME DISCRETIZATION IN ELASTODYNAMICS*

ANDREAS PROHL†

Abstract. We study a finite element-based space-time discretization of the elastodynamics equation $u^\varepsilon_{tt} - \operatorname{div}\sigma(\nabla u^\varepsilon) - \varepsilon\Delta u^\varepsilon_t = 0$ for $\varepsilon \geq 0$, where $\sigma = D\phi$ and ϕ is a nonconvex function. The convergence for regularization parameters $\varepsilon > 0$ of iterates to weak solutions and for the limiting problem $\varepsilon = 0$ of iterates towards generalized solutions is shown in a general setting of data. Computational experiments are included to motivate formation and propagation of two-dimensional microstructures for decreasing values of the regularization parameter.

Key words. convergence analysis, finite element method, elastodynamics

1. Introduction.

We show the convergence of a fully discrete scheme to approximate generalized solutions $u^\varepsilon : \Omega_T \to \mathbb{R}^m$ of the nonlinear hyperbolic system

$$u^\varepsilon_{tt} - \operatorname{div}\sigma(\nabla u^\varepsilon) - \varepsilon\Delta u^\varepsilon_t = 0 \qquad \text{in } \Omega_T := (0,T)\times\Omega, \tag{1.1}$$

$$u^\varepsilon = 0 \qquad \text{on } \partial\Omega_T := (0,T)\times\partial\Omega, \tag{1.2}$$

$$u^\varepsilon(0,\cdot) = u_0, \quad u^\varepsilon_t(0,\cdot) = v_0 \qquad \text{on } \Omega \tag{1.3}$$

for $\varepsilon \geq 0$. Here, $\Omega \subset \mathbb{R}^n$ is a bounded Lipschitz domain, and $T > 0$. The stress $\sigma = D\phi$ is a nonmonotone function, with nonconvex potential $\phi : \mathbb{R}^{m\times n} \to \mathbb{R}$.

Problem (1.1)–(1.3) has been studied in several analytical contributions [1, 5, 6, 7, 8, 9, 10, 12, 13, 15, 16, 17]. The existence of weak solutions for $\varepsilon > 0$ has been verified in [8], where the implicit Euler method is used to semidiscretize the problem in time: Let $I_k = \{t_j\}_{j=1}^J$ be an equidistant net of mesh width $k = t_j - t_{j-1}$ to discretize $[0,T]$, with $j \geq 1$. We set

$$u^{-1}_\varepsilon := u_0 - kv_0 \qquad \text{and} \qquad u^0_\varepsilon := u_0. \tag{1.4}$$

For $j \geq 1$, and given $u^{j-i}_\varepsilon : \Omega \to \mathbb{R}^m$, for $i = 1, 2$, then $u^j_\varepsilon : \Omega \to \mathbb{R}^m$ solves

$$u^j_\varepsilon - 2u^{j-1}_\varepsilon + u^{j-2}_\varepsilon - k^2 \operatorname{div}\sigma(\nabla u^j_\varepsilon) - \varepsilon k\,\Delta\big[u^j_\varepsilon - u^{j-1}_\varepsilon\big] = 0 \quad \text{in } \Omega, \tag{1.5}$$

$$u^j_\varepsilon = 0 \quad \text{on } \partial\Omega. \tag{1.6}$$

Provided that ϕ satisfies certain smoothness and asymptotic growth assumptions, together with the Andrews–Ball condition (H3) given below, weak solutions of (1.1)–(1.3) may be constructed as proper limits of existing solutions to the semidiscretized problem. The uniqueness of weak solutions in the case of globally Lipschitz-continuous σ is also verified in [8]. Qualitative studies, including long-time dynamics, are performed in [9, 10, 1].

The existence of generalized solutions to (1.1)–(1.3) in the case $\varepsilon = 0$ is studied in [5, 6, 12]. In the first references, a time discretization by the implicit Euler method is again employed to construct Young-measure-valued solutions for every t_j ($j \in \mathbb{N}$), using relaxation theory. This direct approach, however, requires convexity of the relaxed energy to validate the crucial energy decay property for corresponding first moments of the Young-measure-valued solutions, to afterwards identify limits for $k \to 0$ as generalized solutions of (1.1)–(1.3). A different approach is proposed in [12], where generalized solutions to (1.1)–(1.3) ($\varepsilon = 0$) are constructed as proper limits of corresponding weak solutions for $\varepsilon > 0$; here, no (poly)convexity assumption of related relaxed energies as in [7] is needed, and the Andrews–Ball condition is sufficient to verify solvability.

So far, numerical analysis for (1.1)–(1.3) is only rare. In [2], the authors establish strong convergence with optimal rates for a fully discrete version of (1.5)–(1.6) in the case $\varepsilon = 1$, using low-order finite elements. However, the error analysis requires additional regularity assumptions for solutions of (1.1)–(1.3), which are not known to hold, in general, and it is pointed out in [2, Remarks (4) and (6) on pp. 76–77] that convergence towards weak solutions is not known and that "a mild constraint on discretization parameters in space and time might be necessary to guarantee convergence" in this context [2, Remark (5) on p. 77]. Moreover, usage of the discrete Gronwall's lemma leads to an exponential factor which grows in terms of $\varepsilon^{-1}T$ for general $\varepsilon > 0$, thus leaving unclear how to efficiently balance temporal and spatial discretization parameters with the regularization parameter to converge to solutions of (1.5)–(1.6) for $\varepsilon = 0$.

In [3], a fully discrete scheme is proposed for $\varepsilon = 0$, where a discrete Young-measure-valued solution which solves the problem is shown to exist. As is argued in [3, Remark 3.7], by first driving the spatial mesh size h to zero, and afterwards tending $k \to 0$, measure-valued solutions to the limiting problem (1.1)–(1.3) may be recovered. However, this leaves open the practically relevant question on whether solutions of the proposed scheme converge to those of (1.1)–(1.3) when spatial and temporal discretization parameters simultaneously tend to zero and whether a mesh constraint $F(k,h) \geq 0$ applies to make convergence hold for $(k,h) \to 0$ or not.

The goal of this paper is to approximate weak ($\varepsilon > 0$) and generalized ($\varepsilon = 0$) solutions of (1.1)–(1.3). In a first step, we study a finite element-based discretization (see scheme A in section 3) for values $\varepsilon > 0$, verify a discrete energy decay property for corresponding iterates, and establish convergence in Theorem 3.1 for $(k,h) \to 0$ towards weak solutions of (1.1)–(1.3), provided triangulations $\mathcal{T}_h$ of $\Omega \subset \mathbb{R}^n$ meet the requirements of [4]—which are satisfied in the case of quasi-uniform meshes, for example. This result answers the questions from above raised in [2] in the sense that discretization parameters may independently tend to zero in the construction process of weak solutions. Then we prove a discrete energy decay property for iterates of scheme A in the case that a mild constraint $F(\varepsilon,k) \geq 0$ is additionally met and eventually show a convergence towards generalized solutions of (1.1)–(1.3) (for $\varepsilon = 0$) when all (ε,k,h) simultaneously tend to zero; see Theorem 3.2. Hence, the latter result justifies a convergence of solutions of the proposed scheme A towards generalized solutions of (1.1)–(1.3) (for $\varepsilon = 0$) as an alternative approach to a direct discretization which uses discrete Young-measure-valued solutions.

The remainder of the paper is as follows: Section 2 provides necessary background material for problem (1.1)–(1.3) as well as further details on used notation. Section 3 proposes a fully discrete scheme and studies both stability and convergence for $(k,h) \to 0$ and $(\varepsilon,k,h) \to 0$. Section 4 reports on computational experiments to

study formation and propagation of two-dimensional (2D) microstructures in the case of positive and vanishing values of $\varepsilon \geq 0$ in (1.1)–(1.3).

2. Preliminaries and notation.

2.1. Weak solutions ($\varepsilon > 0$) (resp.) generalized solutions ($\varepsilon = 0$), of (1.1)–(1.3). For $\varepsilon > 0$, weak solutions to (1.1)–(1.3) are constructed in [8], provided $\sigma = D\phi$ satisfies the following hypotheses:

(H1) $\phi \in C^2(\mathbb{R}^{m\times n})$.

(H2) There exist constants $C_i > 0$ and $2 \leq p < \infty$ such that

$$C_1\,|F|^p - C_2 \leq \phi(F) \leq C_2\,(|F|^p + 1)\,,$$
$$|\sigma^{(i)}(F)| \leq C_2\left(|F|^{p-1-i} + 1\right) \quad \text{for } i = 0, 1.$$

(H3) There exists $K > 0$ such that

$$\langle \sigma(F_1) - \sigma(F_2), F_1 - F_2\rangle \geq -K|F_1 - F_2|^2 \quad \forall\, F_1, F_2 \in \mathbb{R}^{m\times n}.$$

Note that some polynomial asymptotic growth behavior for first and second order derivatives of ϕ is assumed in (H2). Hypothesis (H3) is often referred to as the Andrews–Ball condition. In the following, let $E[u, v] = \int_\Omega [\phi(\nabla u) + \frac{1}{2}|v|^2]\,\mathrm{d}x$ denote the corresponding energy functional.

DEFINITION 2.1. *Let $\Omega \subset \mathbb{R}^n$ be a bounded Lipschitz domain, fix $T > 0$ finite, and let ϕ satisfy assumptions* (H1), (H2), *and* (H3). *Suppose that $(u_0, v_0) \in W_0^{1,p}(\Omega, \mathbb{R}^m)\times L^2(\Omega, \mathbb{R}^m)$. A function $u^\varepsilon : \Omega_T \to \mathbb{R}^m$ is called a* weak solution *of* (1.1)–(1.3) *for $\varepsilon > 0$ if there hold*

(i) $u^\varepsilon \in L^\infty(0, T; W_0^{1,p}(\Omega, \mathbb{R}^m)) \cap W^{1,\infty}(0, T; L^2(\Omega, \mathbb{R}^m)) \cap W^{1,2}(0, T; W_0^{1,2}(\Omega, \mathbb{R}^m))$;

(ii) *initial data are attained, i.e., for $t \to 0$,*

$$u^\varepsilon(t, \cdot) \to u_0 \quad \text{in } L^2(\Omega, \mathbb{R}^m), \qquad u_t^\varepsilon(t, \cdot) \rightharpoonup v_0 \quad \text{in } L^2(\Omega, \mathbb{R}^m);$$

(iii) *for all $\xi \in C_0^\infty([0, T) \times \Omega; \mathbb{R}^m)$ there holds*

$$\int_0^T \int_\Omega [-u_t \cdot \xi_t + \sigma(\nabla u^\varepsilon) \cdot \nabla\xi + \varepsilon\,\nabla u_t^\varepsilon \cdot \nabla\xi]\,\mathrm{d}x\mathrm{d}t = \int_\Omega v_0 \cdot \xi(0, \cdot)\,\mathrm{d}x;$$

(iv) *for almost every $t \in [0, T]$,*

$$E\left[u^\varepsilon(t, \cdot), u_t^\varepsilon(t, \cdot)\right] - E\left[u_0, v_0\right] \leq -\varepsilon \int_0^t \int_\Omega |\nabla u_t^\varepsilon|^2\,\mathrm{d}x\mathrm{d}s.$$

The existence of weak solutions to (1.1)–(1.3) ($\varepsilon > 0$) has been shown in [8]; moreover, weak solutions are unique provided that σ is globally Lipschitz. For $\varepsilon = 0$, gradients of solutions of (1.1)–(1.3) are measure-valued, which leads to the following notion of generalized solutions. In the following, we employ Radon measures $\nu \equiv \{\nu_{t,x}\} \in L_w^\infty(\Omega_T, \mathcal{M}(\mathbb{R}^{m\times n})) := (L^1(\Omega_T; C_0(\mathbb{R}^{m\times n}))'$.

DEFINITION 2.2. *Let $\Omega \subset \mathbb{R}^n$ be a bounded Lipschitz domain, fix $T > 0$ finite, and let ϕ satisfy assumptions* (H1), (H2), *and* (H3). *Suppose that $(u_0, v_0) \in W_0^{1,p}(\Omega, \mathbb{R}^m)\times W^{1,2}(\Omega, \mathbb{R}^m)$. A tuple (u, ν) is called a* generalized solution *of* (1.1)–(1.3) *for $\varepsilon = 0$ if there hold*

(i) $(u, \nu) \in [L^\infty(0, T; W_0^{1,p}(\Omega, \mathbb{R}^m)) \cap W^{1,\infty}(0, T; L^2(\Omega, \mathbb{R}^m))] \times L_w^\infty(\Omega_T, \mathcal{M}(\mathbb{R}^{m\times n}))$, *where $\nu = \{\nu_{t,x}\}_{t,x}$ is a probability measure;*

(ii) *initial data are attained, i.e., for* $t \to 0$,

$$u(t,\cdot) \to u_0 \quad \text{in } L^2(\Omega,\mathbb{R}^m), \qquad u_t(t,\cdot) \rightharpoonup v_0 \quad \text{in } L^2(\Omega,\mathbb{R}^m);$$

(iii) *for all* $\xi \in C_0^\infty([0,T)\times\Omega;\mathbb{R}^m)$,

$$\int_0^T \int_\Omega \left[-u_t(t,x)\cdot\xi_t(t,x) + \nabla\xi(t,x) \cdot \int_{\mathbb{R}^{m\times n}} \sigma(\lambda)\,\mathrm{d}\nu_{t,x}(\lambda) \right] \mathrm{d}x\mathrm{d}t = \int_\Omega v_0\cdot\xi(0,\cdot)\,\mathrm{d}x$$

and

$$\nabla u(t,x) = \int_{\mathbb{R}^{n\times m}} \lambda\,\mathrm{d}\nu_{t,x}(\lambda) \quad \text{a.e. in } \Omega_T.$$

The existence of generalized solutions to (1.1)–(1.3) has been shown in [5, 6] for cases where the quasi convexification of ϕ is convex. In [12], generalized solutions are obtained as proper limits of weak solutions of (1.1)–(1.3) for $\varepsilon \to 0$, for which assumptions (H1), (H2), and (H3) are sufficient.

2.2. Finite element spaces, discrete time derivatives, and interpolation. Throughout this paper we assume that $\mathcal{T}_h$ is a regular triangulation of the polygonal- or polyhedral-bounded Lipschitz domain $\Omega \subset \mathbb{R}^n$ into triangles or tetrahedra of maximal diameter $h > 0$, for $n = 2, 3$, which satisfies the requirements stated in [4]. Let

$$V_h := \{v_h \in C(\overline{\Omega},\mathbb{R}^m) : v\big|_K \text{ affine function } \forall\, K \in \mathcal{T}_h\} \subset W^{1,p}(\Omega)$$

denote the lowest-order conforming finite element space. Given the set of all nodes (or vertices) $\mathcal{N}_h$ in $\mathcal{T}_h$ and letting $\{\varphi_z : z \in \mathcal{N}_h\}$ denote the nodal basis in V_h, we define the nodal interpolation operator $\mathcal{I}_h : C(\overline{\Omega},\mathbb{R}^m) \to V_h$ by $\mathcal{I}_h\psi := \sum_{z\in\mathcal{N}_h} \psi(z)\varphi_z$ for $\psi \in C(\overline{\Omega},\mathbb{R}^m)$. Projections $P_X : X \to V_h$, for $X = L^2(\Omega), W_0^{1,2}(\Omega)$ are defined via $(u - P_X u, \Phi)_X = 0$ for all $\Phi \in V_h$; in particular, there holds $P_X u \to u$ in X for $h \to 0$.

Given a time-step size $k > 0$ and a sequence $\{\varphi^j\}_{j\ge 0}$ in some vector space X, we set, for $j \ge 1$,

$$d_t\varphi^{j+1} := k^{-1}\left(\varphi^{j+1} - \varphi^j\right) \quad \text{and} \quad d_t^2\varphi^{j+1} := d_t\left(d_t\varphi^{j+1}\right).$$

The piecewise constant interpolations of φ^j are defined on $0 \le t \le Jk$ such that $t \in [jk,(j+1)k)$ for some $j \in \{0,..,J-1\}$ by

$$\varphi_k^-(t,\cdot) := \varphi^j \quad \text{and} \quad \varphi_k^+(t,\cdot) := \varphi^{j+1},$$

and a piecewise affine interpolation is defined through

$$\hat{\varphi}_k(t,\cdot) := \frac{t-jk}{k}\varphi^{j+1} + \frac{(j+1)k-t}{k}\varphi^j.$$

Note that $\|\varphi_k^+ - \hat{\varphi}_k\|_X + \|\varphi_k^- - \hat{\varphi}_k\|_X \le 2k\|\hat{\varphi}_t\|_X$.

Throughout the paper, let $C > 0$ be a generic constant which depends on given data Ω, T, u_0, v_0, and ϕ and geometric properties of $\mathcal{T}_h$.

3. A finite element-based discretization of (1.1)–(1.3) with $\varepsilon \geq 0$. In [8], the authors introduce and study the semidiscretization in time given by (1.4)–(1.6) for the case $\varepsilon = 1$, where iterates $u_\varepsilon^j : \Omega \to \mathbb{R}^m$ for $j \geq 1$ minimize $E_k^j : W_0^{1,p}(\Omega, \mathbb{R}^m) \to \mathbb{R}$, with

$$E_k^j[w] := \int_\Omega \left[\phi(\nabla w) + \frac{\varepsilon}{2k} |\nabla(w - u_\varepsilon^{j-1})|^2 + \frac{1}{2k^2} |w - 2u_\varepsilon^{j-1} + u_\varepsilon^{j-2}|^2 \right] \mathrm{d}x.$$

The attainment of minimizers follows from the convexity of $F \mapsto \tilde{\phi}(F) := \phi(F) + \frac{\varepsilon}{2k}|F|^2$ for $k \leq \frac{\varepsilon}{K}$, since (H3) implies that

$$\left\langle D\tilde{\phi}(F_1) - D\tilde{\phi}(F_2), F_1 - F_2 \right\rangle \geq \left(-K + \frac{\varepsilon}{k} \right) |F_1 - F_2|^2 \qquad \forall\, F_1, F_2 \in \mathbb{R}^{m \times n}.$$

As a consequence, $E_k^j : W_0^{1,p}(\Omega, \mathbb{R}^m) \to \mathbb{R}$ is weakly lower-semicontinuous for every $j \geq 1$.

The second step in their construction is to derive a (semi)discrete energy inequality to control iterates of (1.4)–(1.6). For every $\delta \in (0,1)$, and all $k \leq 2\frac{\delta\varepsilon}{K}$, there holds

$$\sup_{j \in \mathbb{N}_0} E\left[u_\varepsilon^j, d_t u_\varepsilon^j\right] + k \sum_{j=1}^{\infty} \int_\Omega \left[\varepsilon(1-\delta) |\nabla d_t u_\varepsilon^j|^2 + \frac{\varepsilon k}{2} |d_t^2 u^j|^2 \right] \mathrm{d}x \leq E[u_\varepsilon^0, v_\varepsilon^0]. \tag{3.1}$$

Therefore, uniform bounds are available, and the convergence of globally continuous, piecewise affine interpolations $\{\hat{u}_k\}$ to a limit $u^\varepsilon : \Omega_T \to \mathbb{R}^m$ for $k \to 0$ may be concluded, as well as

$$\left| \int_{\Omega_T} ((\hat{u}_k)_t - u_t^\varepsilon)\, \xi_t \, \mathrm{d}x\mathrm{d}t \right| + \varepsilon \left| \int_{\Omega_T} \nabla\left((\hat{u}_k)_t - u_t^\varepsilon\right) \cdot \nabla \xi \, \mathrm{d}x\mathrm{d}t \right| \to 0 \quad \forall\, \xi \in C_0^\infty\left(\Omega_T, \mathbb{R}^m\right).$$

The crucial last step now is to identify limits in the nonlinear term to obtain the second term in (iii) of Definition 2.1.

For this purpose, strong convergence $\nabla \hat{u}_k \to \nabla u^\varepsilon$ in $L^2(\Omega_T, \mathbb{R}^m)$ for $k \to 0$ is shown, which ensures enough compactness of sequences to pass to the limit in the second term in (iii) of Definition 2.1 and then proves $u^\varepsilon : \Omega_T \to \mathbb{R}^m$ to be a weak solution of (1.1)–(1.3).

The goal of this paper is to study the convergence properties of a fully discrete version of (1.4)–(1.6), where lowest-order conforming finite elements are used. Below, we drop the index ε such that $U_\varepsilon^j \equiv U^j \in V_h$ for every $j \geq -1$ and $V^j := k^{-1}(U^j - U^{j-1})$ for every $j \geq 0$. The practical scheme reads as follows for a given positive triple $(\varepsilon, k, h) > 0$.

Scheme A. Let $U^0 = P_{L^2} u_0 \in V_h$ and $V^0 = P_{L^2} v_0 \in V_h$. For $j \geq 1$, and given $U^{j-1}, U^{j-2} \in V_h$, find $U^j \in V_h$ such that for all $\Phi \in V_h$ there holds

$$(d_t^2 U^j, \Phi) + \left(\sigma(\nabla U^j), \nabla \Phi\right) + \varepsilon\left(\nabla d_t U^j, \nabla \Phi\right) = 0 \qquad \forall\, \Phi \in V_h. \tag{3.2}$$

Similar to above, solutions $U^j \in V_h$ minimize $E_{k,h}^j : V_h \to \mathbb{R}$, with

$$E_{k,h}^j[W] := \int_\Omega \left[\phi(\nabla W) + \frac{\varepsilon}{2k} |\nabla(W - U^{j-1})|^2 + \frac{1}{2k^2} |W - 2U^{j-1} + U^{j-2}|^2 \right] \mathrm{d}x.$$

The scheme has been proposed in [2]. The existence of solutions $\{U^j\}_{j \geq 1} \subset V_h$ follows from continuity and coercivity properties of $E_{k,h}^j$. The following lemma states

a discrete energy inequality for iterates $\{U^j\}_{j\geq -1} \subset V_h$ in the case $k = \mathcal{O}(\varepsilon)$. Let $V^j := d_t U^j \in V_h$ for $j \geq 1$.

LEMMA 3.1. *Let $\{U^j\}_{j\geq -1} \subset V_h$ solve scheme A. Given $\delta \in (0,1)$, for all $k \leq \frac{\delta\varepsilon}{K}$ there holds*

$$\sup_{j\in\mathbb{N}_0} E\left[U^j, V^j\right] + k\sum_{j=1}^{\infty}\int_\Omega \left[\varepsilon(1-\delta)|\nabla V^j|^2 + \frac{k}{2}|d_t V^j|^2\right] \mathrm{d}x \leq E[U^0, V^0]. \tag{3.3}$$

Proof. The proof is the same as in the context of semidiscretization [8, Lemma 2.2], which combines convexity properties of the above $\tilde{\phi}$ and uses (3.2) with $\Phi = d_t U^j$. ∎

We remark that the dissipative character of scheme A is the reason for the last term on the left-hand side of (3.3). As will be evident below, this control is necessary to verify convergence for the scheme.

We use $V^j = d_t U^j \in V_h$ to restate scheme A for $j \geq 0$ as follows:

$$(d_t V^j, \Phi) + \big(\sigma(\nabla U^j), \Phi\big) + \varepsilon\,(\nabla d_t U^j, \nabla\Phi) = 0, \quad (V^j, \Phi) - (d_t U^j, \Phi) = 0 \qquad \forall\,\Phi \in V_h. \tag{3.4}$$

We now use $(U_k^+, \hat{U}_k)$ (resp.) $(V_k^+, \hat{V}_k)$, which are constant and linear interpolations in time of the sequences $\{U^j\}$ (resp.) $\{V^j\}$. For notational brevity, most of the time we omit subindices k and use $(U^+, \hat{U})$ and $(V^+, \hat{V})$ to stand for $(U_k^+, \hat{U}_k)$ and $(V_k^+, \hat{V}_k)$, respectively.

In the next lemma, we restate scheme A for $\hat{U}, \hat{V} \in C([0,T]; V_h)$.

LEMMA 3.2. *Suppose that the assumptions of Lemma 3.1 are valid. For all $T > 0$, and $\Psi \in W^{1,1}(0,T;V_h) \cap L^2(0,T;V_h)$, there holds*

$$\begin{aligned}
&\left| \int_0^T \left[-(\hat{U}_t, \Psi_t) + \Big(\sigma(\nabla\hat{U}), \nabla\Psi\Big) + \varepsilon\,(\nabla\hat{U}_t, \nabla\Psi)\right] \mathrm{d}t \right. \\
&\quad \left. + \Big(\hat{V}(T,\cdot), \Psi(T,\cdot)\Big) - \big(V^0, \Psi(0,\cdot)\big) \right| \\
&\leq \left| \int_0^T (\hat{V} - V^+, \Psi_t)\,\mathrm{d}t \right| + \left| \int_0^T \Big(\sigma(\nabla\hat{U}) - \sigma(\nabla U^+), \nabla\Psi\Big)\,\mathrm{d}t \right|.
\end{aligned} \tag{3.5}$$

Proof. We rewrite (3.4) as follows: For all $\Psi, \Phi \in W^{1,1}(0,T;V_h) \cap L^2(0,T;V_h)$,

$$\int_0^T \left[(\hat{V}_t, \Psi) + \Big(\sigma(\nabla U^+), \nabla\Psi\Big) + \varepsilon\,(\nabla\hat{U}_t, \nabla\Psi)\right] \mathrm{d}s = 0, \tag{3.6}$$

$$\int_0^T \Big[(V^+, \Phi) - (\hat{U}_t, \Phi)\Big]\,\mathrm{d}s = 0. \tag{3.7}$$

Integration by parts in time in the first term of (3.6) leads to

$$\begin{aligned}
&\int_0^T \left[-(\hat{V}, \Psi_t) + \Big(\sigma(\nabla U^+), \nabla\Psi\Big) + \varepsilon\,(\nabla\hat{U}_t, \nabla\Psi)\right] \mathrm{d}s \\
&\qquad + \Big(\hat{V}(T,\cdot), \Psi(T,\cdot)\Big) - \Big(\hat{V}(0,\cdot), \Psi(0,\cdot)\Big) = 0.
\end{aligned}$$

Because of (3.7), we obtain

$$\begin{aligned}
&\int_0^T \left[-(\hat{U}_t, \Psi_t) + \Big(\sigma(\nabla\hat{U}), \nabla\Psi\Big) + \varepsilon\,(\nabla\hat{U}_t, \nabla\Psi)\right] \mathrm{d}s + \big(V^0, \Psi(0,\cdot)\big) \\
&\quad = \int_0^T \left[\Big(\hat{V} - V^+, \Psi_t\Big) + \Big(\sigma(\nabla\hat{U}) - \sigma(\nabla U^+), \nabla\Psi\Big)\right] \mathrm{d}s.
\end{aligned}$$

∎

The following result gives uniform bounds for $\{\hat{V}\}$.

LEMMA 3.3. *Let $p \geq 2$, and suppose that the assumptions of Lemma* 3.1 *are valid. Then*

$$\|\hat{V}_t\|_{L^2(0,T;W^{-1,p'})} + \|\hat{V}\|_{L^2(0,T;W^{1,2})} \leq C.$$

Proof. Use (3.6), (H2), and [4, Theorems 3 and 4] to conclude that

$$\begin{aligned}\|\hat{V}_t(s,\cdot)\|_{W^{-1,p'}} &:= \sup_{\varphi \in W_0^{1,p}} \frac{(\hat{V}_t(s,\cdot), P_{L^2}\varphi)}{\|\varphi\|_{W^{1,p}}} \\ &\leq C\left(1 + \|\nabla U^+(s,\cdot)\|_{L^p}^{p-1}\right) + C\varepsilon\|\nabla \hat{U}_t(s,\cdot)\|_{L^2}.\end{aligned}$$

Estimate (3.3) then implies the first part of the assertion. The second part follows from (3.3), and

$$\|\hat{V}\|_{L^2(0,T;W^{1,2})} \leq \|V^-\|_{L^2(0,T;W^{1,2})} + \|V^+\|_{L^2(0,T;W^{1,2})}. \qquad \square$$

It follows from Lemmas 3.1 and 3.3 and Hypothesis (H2) that, under the given mesh constraint, there exist $u^\varepsilon \in L^\infty(0,T;W_0^{1,p}(\Omega,\mathbb{R}^m)) \cap W^{1,\infty}(0,T;L^2(\Omega,\mathbb{R}^m)) \cap W^{1,2}(0,T;W_0^{1,2}(\Omega))$ and a convergent subsequence of $\{\hat{U}\}_{k,h}$ such that, for $(k,h) \to 0$,

$$\begin{aligned}
&\hat{U} \overset{*}{\rightharpoonup} u^\varepsilon \quad \text{in } L^\infty\left(0,T;W_0^{1,p}(\Omega,\mathbb{R}^m)\right) \cap W^{1,\infty}\left(0,T;L^2(\Omega,\mathbb{R}^m)\right), \\
&\hat{U} \rightharpoonup u^\varepsilon \quad \text{in } W^{1,2}\left(0,T;W_0^{1,2}(\Omega,\mathbb{R}^m)\right), \\
&\sigma(\nabla\hat{U}) \overset{*}{\rightharpoonup} \tilde{\sigma} \quad \text{in } L^\infty\left(0,T;L^{p'}(\Omega,\mathbb{R}^{m\times n})\right), \\
&\hat{V} \rightharpoonup u_t^\varepsilon \quad \text{in } W^{1,2}\left(0,T;W^{-1,p'}(\Omega,\mathbb{R}^m)\right) \cap L^2\left(0,T;W_0^{1,2}(\Omega,\mathbb{R}^m)\right), \\
&\hat{U} \to u^\varepsilon \quad \text{in } W^{1,2}\left(0,T;L^2(\Omega,\mathbb{R}^m)\right),
\end{aligned} \tag{3.8}$$

thanks to (3.7), $(3.8)_4$ is a consequence of the control

$$\|V^+ - \hat{V}\|_{L^2(\Omega_T)} \leq \sqrt{k}\left[\sqrt{k}\|\hat{V}_t\|_{L^2(\Omega_T)}\right] \leq \sqrt{k}E[U_0,V_0], \tag{3.9}$$

and $(3.8)_5$ follows from an Aubin–Lions compactness result. As can be concluded from, e.g., [14, Proposition 1.2, p. 106], $u^\varepsilon \in C([0,T];L^2(\Omega,\mathbb{R}^m))$. We are ready to prove the first main convergence theorem of this paper.

THEOREM 3.1. *Let $T > 0$, $\varepsilon > 0$, and $(u_0,v_0) \in W_0^{1,p}(\Omega,\mathbb{R}^m) \times L^2(\Omega,\mathbb{R}^m)$. Let assumptions* (H1), (H2), *and* (H3) *be satisfied, and let $k \leq \frac{\varepsilon}{2K}$. Then there exist $u^\varepsilon : \Omega_T \to \mathbb{R}^m$ and a subsequence of solutions $\{\hat{U}\}_{k,h}$ (denoted by the same notation) of scheme A such that for $(k,h) \to 0$*

$$\hat{U} \overset{*}{\rightharpoonup} u^\varepsilon \quad \text{in } L^\infty\left(0,T;W_0^{1,p}(\Omega,\mathbb{R}^m)\right) \cap W^{1,\infty}\left(0,T;L^2(\Omega,\mathbb{R}^m)\right).$$

Moreover, u^ε is a weak solution of (1.1)–(1.3).

This result complements the one in [2], because it verifies the convergence of solutions of scheme A to weak solutions of (1.1)–(1.3) and hence answers questions raised in [2, Remarks (5) and (6) on pp. 76–77]. Note that the result in the theorem is for a subsequence $\{\hat{U}\}_{k,h}$; weak convergence of the whole sequence holds in the

case of unique weak solutions, which is, e.g., valid for globally Lipschitz-continuous σ. Finally, thanks to [4] there holds

$$\big(U^0, V^0\big) \to (u_0, v_0) \quad \text{in } W_0^{1,p}(\Omega,\mathbb{R}^m) \times L^2(\Omega,\mathbb{R}^m) \quad (h \to 0).$$

Proof. Step 1: We may use $(3.8)_2$ and $(3.8)_4$ to verify for $(k,h) \to 0$

$$\begin{aligned} &\left| \int_0^T (\hat{U}_t - u_t^\varepsilon, \Psi_t) \mathrm{d}s \right| + \varepsilon \left| \int_0^T (\nabla[\hat{U}_t - u_t^\varepsilon], \nabla\Psi)\, \mathrm{d}s \right| \\ &\qquad + \big|\big(V^0 - v_0, \Psi(0,\cdot)\big)\big| + \left| \Big(\hat{V}(T,\cdot) - u_t^\varepsilon(T,\cdot), \Psi(T,\cdot)\Big) \right| \to 0 \end{aligned} \tag{3.10}$$

for all $\Psi(t,\cdot) = \mathcal{I}_h \xi(t,\cdot)$, and $\xi \in W^{1,1}(0,T;C_0^\infty(\Omega,\mathbb{R}^m)) \cap L^2(0,T;C_0^\infty(\Omega,\mathbb{R}^m))$. Since $\mathcal{I}_h\xi(t,\cdot) \to \xi(t,\cdot)$ in any $W^{1,p}(\Omega)$ $(1 \le p \le \infty)$ for $h \to 0$, again using (3.8), we may conclude that (3.10) holds for any $\Psi \in W^{1,1}(0,T;C_0^\infty(\Omega,\mathbb{R}^m)) \cap L^2(0,T;C_0^\infty(\Omega,\mathbb{R}^m))$.

Terms on the right-hand side of (3.5) vanish, which is a consequence of Lemma 3.1. We compute

$$\begin{aligned} \left| \int_0^T (V^+ - \hat{V}, \Psi_t)\, \mathrm{d}s \right| &\le C\sqrt{k} \left(k \int_0^T \|\hat{V}_t\|_{L^2}^2\, \mathrm{d}s \right)^{1/2} \left(\int_0^T \|\Psi_t\|_{L^2}^2\, \mathrm{d}s \right)^{1/2} \\ &\le C\sqrt{k} \left(\int_0^T \|\Psi_t\|_{L^2}^2\, \mathrm{d}s \right)^{1/2}. \end{aligned} \tag{3.11}$$

For the second term on the right-hand side of (3.5), we use (H2) and Lemma 3.1; without restriction, assume that $p > 2$ for the following calculation:

$$\begin{aligned} &\left| \int_0^T \Big(\sigma(\nabla\hat{U}) - \sigma(\nabla U^+), \nabla\Psi \Big)\, \mathrm{d}s \right| \\ &\quad \le C \int_{\Omega_T} \Big[1 + |\nabla\hat{U}|^{p-2} + |\nabla U^+|^{p-2} \Big] |\nabla[\hat{U} - U^+]| |\nabla\Psi|\, \mathrm{d}x\mathrm{d}s \\ &\quad \le C \left[\int_0^T \left(\int_\Omega \Big[1 + |\nabla\hat{U}|^p + |\nabla U^+|^p \Big]\, \mathrm{d}x \right)^{\frac{p-2}{p}} \left(\int_\Omega |\nabla[\hat{U} - U^+]|^{\frac{p}{2}}\, \mathrm{d}x \right)^{2/p} \mathrm{d}s \right] \\ &\qquad\qquad \|\Psi\|_{L^\infty(0,T;W^{1,\infty})} \\ &\quad \le C \|\Psi\|_{L^\infty(0,T;W^{1,\infty})} \int_0^T \|\nabla[\hat{U} - U^+]\|_{L^{p/2}}\, \mathrm{d}s. \end{aligned} \tag{3.12}$$

The following interpolation result is needed only for $p > 4$:

$$\|\nabla[U^+ - \hat{U}]\|_{L^{p/2}} \le C\, \|\nabla[U^+ - \hat{U}]\|_{L^p}^{\frac{[p-4]_+}{p-2}} \|\nabla[U^+ - \hat{U}]\|_{L^2}^{\min\{1, \frac{2}{p-2}\}},$$

where $[\cdot]_+ := \max\{\cdot, 0\}$. Hence, the last integral term in (3.12) may be controlled as follows, again using Lemma 3.1:

$$\begin{aligned} \int_0^T \|\nabla[U^+ - \hat{U}]\|_{L^{p/2}}\, \mathrm{d}s &\le C\, \|\nabla U^+\|_{L^\infty(0,T;L^p)}^{\frac{[p-4]_+}{p-2}} k^{\min\{1, \frac{2}{p-2}\}} \int_0^T \|\nabla\hat{U}_t\|_{L^2}^{\min\{1, \frac{2}{p-2}\}}\, \mathrm{d}s \\ &\le C k^{\min\{1, \frac{2}{p-2}\}} \|\nabla U^+\|_{L^\infty(0,T;L^p)}^{\frac{[p-4]_+}{p-2}} \|\nabla\hat{U}_t\|_{L^2(\Omega_T)}^{\min\{1, \frac{2}{p-2}\}} \\ &\le C k^{\min\{1, \frac{2}{p-2}\}} \varepsilon^{\max\{-\frac{1}{2}, -\frac{1}{p-2}\}}. \end{aligned} \tag{3.13}$$

Consequently, terms on the right-hand sides of (3.11) and (3.12) tend to zero for $k \to 0$, and hence the right-hand side (RHS) of (3.5) tends to zero. By (3.10), we may replace $\hat{U}$ and Ψ in terms one, three, four, and five on the left-hand side of (3.5) by corresponding ones with u^ε and ξ. Therefore it remains to verify that

$$\lim_{k,h\to 0} \int_0^T \Big(\sigma(\nabla \hat{U}) - \sigma(\nabla u^\varepsilon), \nabla \xi\Big)\, \mathrm{d}s = 0$$
$$\forall\, \xi \in W^{1,1}\left(0,T; C_0^\infty(\Omega,\mathbb{R}^m)\right) \cap L^2\left(0,T; C_0^\infty(\Omega,\mathbb{R}^m)\right),$$

which is done in the next step.

Step 2: In order to identify $\tilde{\sigma} = \sigma(\nabla u^\varepsilon)$ almost everywhere in Ω_T, we verify strong convergence $\hat{U} \to u^\varepsilon$ in $L^\infty(0,T,W^{1,2}(\Omega,\mathbb{R}^m))$ for $(k,h) \to 0$. So far, we have

$$\int_0^T \left[-(u_t^\varepsilon, \xi_t) + (\tilde{\sigma}, \nabla\xi) + \varepsilon\,(\nabla u_t^\varepsilon, \nabla\xi)\right] \mathrm{d}t + (u_t^\varepsilon(T,\cdot), \xi(T,\cdot)) - (v_0, \xi(0,\cdot)) = 0$$
$$\forall\, \xi \in W^{1,1}\left(0,T; C_0^\infty(\Omega,\mathbb{R}^m)\right) \cap L^2\left(0,T; C_0^\infty(\Omega,\mathbb{R}^m)\right). \tag{3.14}$$

Note that, by density and (3.8), identity (3.14) holds for all

$$\xi \in X := W^{1,1}\left(0,T; W_0^{1,p}(\Omega,\mathbb{R}^m)\right) \cap L^2\left(0,T; W_0^{1,2}(\Omega,\mathbb{R}^m)\right). \tag{3.15}$$

We subtract (3.14) from the left-hand side of (3.5) and choose $\xi = \Psi \in X \cap W^{1,1}(0,T; V_h) \cap L^2(0,T;V_h)$, where, for all $t \in [0,T]$, we take $\Psi(t,\cdot) = P_{L^2} e(t,\cdot)$, with $e := u^\varepsilon - \hat{U}$. We use $(e_t - P_{L^2} e_t, P_{L^2} e_t) = 0$ and

$$(\nabla e_t, \nabla P_{L^2} e) = (\nabla e_t, \nabla e) + (\nabla e_t, \nabla[P_{L^2} e - e]) = \frac{1}{2}\frac{d}{dt}\|\nabla e\|^2 - (\nabla e_t, \nabla[u^\varepsilon - P_{L^2} u^\varepsilon])$$

to conclude that

$$\begin{aligned} &\left| \int_0^T \left[-\|P_{L^2} e_t\|^2 + \Big(\tilde{\sigma} - \sigma(\nabla\hat{U}), \nabla P_{L^2} e\Big) + \frac{\varepsilon}{2}\frac{d}{dt}\|\nabla e\|^2 \right] \mathrm{d}t \right. \\ &\qquad \left. + (e_t(T,\cdot), P_{L^2} e(T,\cdot)) - \big(v_0 - V^0, P_{L^2} e(0,\cdot)\big) \right| \\ &\qquad \le |\mathrm{RHS}(P_{L^2} e)| + \left| \varepsilon \int_0^T (\nabla e_t, \nabla[u^\varepsilon - P_{L^2} u^\varepsilon])\, \mathrm{d}s \right|, \end{aligned} \tag{3.16}$$

where

$$\mathrm{RHS}(\Psi) := \left| \int_0^T (\hat{V} - V^+, \Psi_t)\, \mathrm{d}t \right| + \left| \int_0^T (\sigma(\nabla\hat{U}) - \sigma(\nabla U^+), \nabla\Psi)\, \mathrm{d}t \right|.$$

The left-hand side of (3.16) consists of five terms I, II, ..., V, which we now study independently, for $(k,h) \to 0$. The first tends to zero, owing to the L^2-stability of P_{L^2} and $(3.8)_5$.

$$\begin{aligned} \mathrm{II} &= \int_0^T \Big(\tilde{\sigma} - \sigma(\nabla\hat{U}), \nabla[P_{L^2} u^\varepsilon - u^\varepsilon]\Big)\, \mathrm{d}t \\ &+ \int_0^T \Big(\sigma(\nabla u^\varepsilon) - \sigma(\nabla\hat{U}), \nabla[u^\varepsilon - \hat{U}]\Big)\, \mathrm{d}t + \int_0^T \Big(\tilde{\sigma} - \sigma(\nabla u^\varepsilon), \nabla[u^\varepsilon - \hat{U}]\Big)\, \mathrm{d}t \\ &=: \mathrm{II}_a + \mathrm{II}_b + \mathrm{II}_c. \end{aligned} \tag{3.17}$$

We employ $[P_{L^2}-\mathrm{Id}]\varphi\to 0$ in $W^{1,p}(\Omega)$ $(h\to 0)$ for $\varphi\in W^{1,p}(\Omega)$, which follows from $W^{1,p}(\Omega)$-stability of the $L^2(\Omega)$-projection from [4, Theorems 3 and 4], and

$$\begin{aligned}\|\varphi-P_{L^2}\varphi\|_{W^{1,p}}&\le\inf_{W\in V_h}[\|\varphi-W\|_{W^{1,p}}+\|W-P_{L^2}\varphi\|_{W^{1,p}}]\\&\le C\inf_{W\in V_h}\|\varphi-W\|_{W^{1,p}}\end{aligned}$$

in combination with (H2), Lemma 3.1, $(3.8)_3$, and the bound $\||\nabla\hat U(t,\cdot)|^{p-1}\|_{L^{p'}}\le\|\nabla\hat U(t,\cdot)\|_{L^p}^{p-1}$ to conclude that $\lim_{h\to 0}\mathrm{II}_a=0$,

$$\begin{aligned}\mathrm{II}_a&\le\int_0^T\left[\|\tilde\sigma\|_{L^{p'}}+\|\sigma(\nabla\hat U)\|_{L^{p'}}\right]\|P_{L^2}u^\varepsilon-u^\varepsilon\|_{W^{1,p}}\,\mathrm{d}t\\&\le C_2\int_0^T\left[\|\tilde\sigma\|_{L^{p'}}+\||\nabla\hat U|^{p-1}\|_{L^{p'}}+1\right]\|P_{L^2}u^\varepsilon-u^\varepsilon\|_{W^{1,p}}\,\mathrm{d}t\\&\le CC_2\|P_{L^2}u^\varepsilon-u^\varepsilon\|_{L^1(0,T;W^{1,p})}\to 0\qquad(h\to 0).\end{aligned}$$

For the second term, we use (H3) to conclude that $\mathrm{II}_b\ge -K\int_0^T\|\nabla[u^\varepsilon-\hat U]\|_{L^2}^2\,\mathrm{d}s$. Because of $\nabla\hat U-\nabla u^\varepsilon\overset{*}{\rightharpoonup}0$ in $L^\infty(0,T;L^p(\Omega,\mathbb{R}^{m\times n}))$ for $(k,h)\to 0$, $\tilde\sigma,\sigma(\nabla u^\varepsilon)\in L^\infty(0,T;L^{p'}(\Omega,\mathbb{R}^{m\times n}))$ due to $(3.8)_{1,3}$, and (H2), this implies that $\lim_{k,h\to 0}\mathrm{II}_c=0$.

We show that term IV vanishes for $(k,h)\to 0$; for this purpose, we use the stability of the $L^2(\Omega)$-projection to conclude that $|(e_t(T,\cdot),P_{L^2}e(T,\cdot))|\le\|e_t(T,\cdot)\|_{L^2}\|e(T,\cdot)\|_{L^2}$ and $(3.8)_5$, which implies, for $(k,h)\to 0$, that

$$\|e(T,\cdot)\|_{L^2}\le\sqrt{T}\|e_t\|_{L^2(\Omega_T)}+\|e(0,\cdot)\|_{L^2}\to 0.$$

Finally, $\lim_{h\to 0}\mathrm{V}=0$ follows from $[P_{L^2}-\mathrm{id}]v_0,[P_{L^2}-\mathrm{id}]u_0\to 0$ in $L^2(\Omega)$ $(h\to 0)$.

We collect these results to restate estimate (3.16) in the form

$$\begin{aligned}&\frac{\varepsilon}{2}\|\nabla[u^\varepsilon(t,\cdot)-\hat U(t,\cdot)]\|_{L^2}^2\\&\le\frac{\varepsilon}{2}\|\nabla[u^\varepsilon(0,\cdot)-\hat U(0,\cdot)]\|_{L^2}^2+\eta(k,h)+K\int_0^t\|\nabla[u^\varepsilon(s,\cdot)-\hat U(s,\cdot)]\|_{L^2}^2\,\mathrm{d}s\end{aligned}\tag{3.18}$$

for almost every $t\in[0,T]$. For brevity, we introduce $0\le\eta(k,h)\le 1$ such that $\lim_{k,h\to 0}\eta(k,h)=0$. By Gronwall's inequality, this verifies that $\hat U\to u^\varepsilon$ in $L^\infty(0,T;W^{1,2}(\Omega,\mathbb{R}^m))$ for $(k,h)\to 0$.

But then we may identify $\tilde\sigma=\sigma(\nabla u^\varepsilon)$ a.e. in Ω_T, which then establishes assertion (iii) of Definition 2.1.

Step 3: The energy estimate given in Lemma 3.1 may be restated as follows:

$$\sup_{t\ge 0}E\left[U^+(t,\cdot),\hat U_t(t,\cdot)\right]+\varepsilon\int_0^t(1-\delta)|\nabla\hat U_t|^2\,\mathrm{d}x\le E\left[U^0V^0\right],\tag{3.19}$$

for all $t\ge 0$, and for all $k\le\frac{\delta\varepsilon}{K}$, given $\delta\in(0,1)$. A problem arises when passing to the limit $(k,h)\to 0$, due to the lack of a weakly lower-semicontinuity property on $W^{1,p}$

of $u \mapsto \int_\Omega \phi(\nabla u)\,\mathrm{d}x$; the following argument is taken from [8, p. 377]: Because of (H3), we exploit the convexity of $F \mapsto \hat{\phi}(F) := \phi(F) + \frac{K}{2}|F|^2$, to conclude, for $t \geq 0$, that

$$
\begin{aligned}
&\int_\Omega \phi\left(\nabla u^\varepsilon(t,\cdot)\right)\,\mathrm{d}x \\
&\quad = \int_\Omega \left[\hat{\phi}\left(\nabla u^\varepsilon(t,\cdot)\right) - \frac{K}{2}|\nabla u^\varepsilon(t,\cdot)|^2\right]\,\mathrm{d}x \\
&\quad \leq \liminf_{k,h\to 0} \int_\Omega \left[\hat{\phi}\left(\nabla \hat{U}(t,\cdot)\right) - \frac{K}{2}|\nabla u^\varepsilon(t,\cdot)|^2\right]\,\mathrm{d}x \\
&\quad \leq \liminf_{k,h\to 0} \int_\Omega \phi\left(\nabla \hat{U}(t,\cdot)\right)\,\mathrm{d}x + \liminf_{k,h\to 0} \frac{K}{2}\int_\Omega \left||\nabla \hat{U}(t,\cdot)|^2 - |\nabla u^\varepsilon(t,\cdot)|^2\right|\,\mathrm{d}x \qquad (3.20)\\
&\quad = \liminf_{k,h\to 0} \int_\Omega \phi\left(\nabla \hat{U}(t,\cdot)\right)\,\mathrm{d}x,
\end{aligned}
$$

thanks to $\hat{U} \to u^\varepsilon$ in $L^\infty(0,T;W^{1,2}(\Omega,\mathbb{R}^m))$ for $(k,h) \to 0$. Inserting this into (3.19) and using (3.8) yields to assertion (iv) of Definition 2.1.

Step 4: The initial data are attained in the sense of Definition 2.1(ii): Because of $u^\varepsilon \in C([0,T];L^2(\Omega,\mathbb{R}^m))$; (see below (3.9)), the function $u^\varepsilon(t,\cdot)$ is well-defined for each $t \geq 0$, and $u^\varepsilon(t,\cdot) \to u_0$ in $L^2(\Omega,\mathbb{R}^m)$ for $t \to 0$.

Convergence $u_t^\varepsilon(t,\cdot) \rightharpoonup v_0$ in $L^2(\Omega,\mathbb{R}^m)$ $(t \to 0)$ follows from the absolute continuity property of $u_t^\varepsilon(t,\cdot) : W^{-1,p'}(\Omega,\mathbb{R}^m) \to W^{-1,p'}(\Omega,\mathbb{R}^m)$, which is a consequence of $(3.8)_4$, and $u_t^\varepsilon \in L^\infty(0,T;L^2(\Omega,\mathbb{R}^m))$; see, e.g., [18, Lemma 1.4, p. 178]. ∎

Next, we study how to relate ε and (k,h), for all three parameters tending to zero, in order to construct generalized solutions in the sense of Definition 2.2 from scheme A. For this purpose, no strong convergence of gradients $\{\nabla \hat{U}_\varepsilon\}_{k,h}$ is needed if generalized solutions to (1.1)–(1.3) for $\varepsilon = 0$ are approximated and the strictest mesh constraint comes from (3.9). Then the following result shows that, for simultaneously tending $(\varepsilon,k,h) \to 0$, solutions $\hat{U} : \Omega_T \to \mathbb{R}^m$ to scheme A approximate generalized solutions to (1.1)–(1.3) for $\varepsilon = 0$.

THEOREM 3.2. *Let $T > 0$ and $(u_0,v_0) \in W_0^{1,p}(\Omega,\mathbb{R}^m) \times L^2(\Omega,\mathbb{R}^m)$. Let assumptions* (H1), (H2), *and* (H3) *be satisfied, and let $k = o(\varepsilon)$ in scheme A. Then there exist $u : \Omega_T \to \mathbb{R}^m$ and a subsequence of solutions $\{\hat{U}\}_{\varepsilon,k,h}$ (denoted by the same notation) of scheme A such that as $(\varepsilon,k,h) \to 0$*

$$
\begin{aligned}
\hat{U} &\overset{*}{\rightharpoonup} u \quad \text{in } L^\infty\left(0,T;W_0^{1,p}(\Omega,\mathbb{R}^m)\right) \cap W^{1,\infty}\left(0,T;L^2(\Omega,\mathbb{R}^m)\right),\\
\delta_{\nabla \hat{U}} &\overset{*}{\rightharpoonup} \nu \quad \text{in } L_w^\infty\left(\Omega_T;\mathcal{M}(\mathbb{R}^{m\times n})\right).
\end{aligned}
$$

Moreover, the tuple (u,ν) is a generalized solution to (1.1)–(1.3) *for $\varepsilon = 0$.*

Proof. Step 1: It follows from Lemmas 3.1 and 3.3 and Hypothesis (H2) that, under the given mesh constraint, there exist

$$
(u,\nu) \in \left[L^\infty\left(0,T;W_0^{1,p}(\Omega,\mathbb{R}^m)\right) \cap W^{1,\infty}\left(0,T;L^2(\Omega,\mathbb{R}^m)\right)\right] \times L_w^\infty\left(\Omega_T,\mathcal{M}(\mathbb{R}^{m\times n})\right)
$$

and a convergent subsequence of $\{\hat{U}\}_{\varepsilon,k,h}$ such that for $(\varepsilon,k,h)\to 0$

$$
\begin{aligned}
\hat{U} &\overset{*}{\rightharpoonup} u \quad \text{in } L^\infty\left(0,T;W_0^{1,p}(\Omega,\mathbb{R}^m)\right)\cap W^{1,\infty}\left(0,T;L^2(\Omega,\mathbb{R}^m)\right),\\
\sigma(\nabla\hat{U}) &\overset{*}{\rightharpoonup} \overline{\sigma} \quad \text{in } L^\infty\left(0,T;L^{p'}(\Omega,\mathbb{R}^{m\times n})\right),\\
\hat{V} &\rightharpoonup u_t \quad \text{in } W^{1,2}\left(0,T;W^{-1,p'}(\Omega,\mathbb{R}^m)\right),\\
\hat{U} &\to u \quad \text{in } L^2\left(\Omega_T,\mathbb{R}^m\right),\\
\delta_{\nabla\hat{U}} &\overset{*}{\rightharpoonup} \nu \quad \text{in } L^\infty_w\left(\Omega_T;\mathcal{M}(\mathbb{R}^{m\times n})\right).
\end{aligned}
\tag{3.21}
$$

Step 2: We compute the limit $\varepsilon\to 0$ of the third term on the left-hand side of (3.5):

$$
\left|\varepsilon\int_0^T\left(\nabla\hat{U}_t,\nabla\Psi\right)\,\mathrm{d}t\right|\le\sqrt{\varepsilon}\left[\sqrt{\varepsilon}\|\nabla\hat{U}_t\|_{L^2(\Omega_T)}\right]\|\nabla\Psi\|_{L^2(\Omega_T)}\to 0
$$

$$
\forall\,\Psi\in L^2\left(0,T;V_h\cap W_0^{1,2}(\Omega,\mathbb{R}^m)\right).
$$

Thanks to [11, Theorem 6.2], there holds

$$
\overline{\sigma}(t,x)=\int_{\mathbb{R}^{m\times n}}\sigma(\lambda)\,\mathrm{d}\nu_{t,x}(\lambda)\quad\text{a.e. in }\Omega_T.
$$

To identify limits in the remaining terms of (3.5) for $(\varepsilon,k,h)\to 0$ is as in the first step of the proof of Theorem 3.1; the arguments given there in step four may be adapted as well, which settles the proof. ∎

4. Computational experiments. In this section, we report on computational studies for fixed and decreasing values of $\varepsilon>0$ in (1.1)–(1.3) performed with scheme A. The nonlinear systems of equations in each time step were approximately solved by a simple fixed-point method. The scheme is implemented in MATLAB with a direct solver for linear systems of equations.

The first example is taken from the literature to allow for direct comparison of our computational results with those obtained with a finite difference method in [16, section 6.2]; we remark that no results of convergence are given in [16] to theoretically justify their scheme.

Example 4.1. For $\Omega=(1,2)^2$, choose $u_0(x,y)=x^2(x-1)y(y-1)$, $v_0(x,y)=0$, and $\phi(F)=\frac{1}{4}(|F|^2-1)^2$. The evolution (1.1)–(1.3) is approximated by scheme A for values $\varepsilon=0.25$, and $(k,h)=(5.\times 10^{-4},2^{-6})$.

Snapshots are displayed in Figure 1, together with the evolution of kinetic, elastic, and total energies, where

$$
E_{\mathrm{kin}}\left[d_tU^j\right]=\frac{1}{2}\int_\Omega|d_tU^j|^2\,\mathrm{d}x,\quad E_{\mathrm{ela}}\left[\nabla U^j\right]=\int_\Omega\phi(\nabla U^j)\,\mathrm{d}x.
$$

The results are in good agreement with those reported in [16, section 6.2].

In the second example, we study dynamics in the same setup of data for values of ε tending to zero.

Example 4.2. Choose data as in Example 4.1 for values $\varepsilon=0.1\cdot 2^{-\ell}$, $0\le\ell\le 2$.

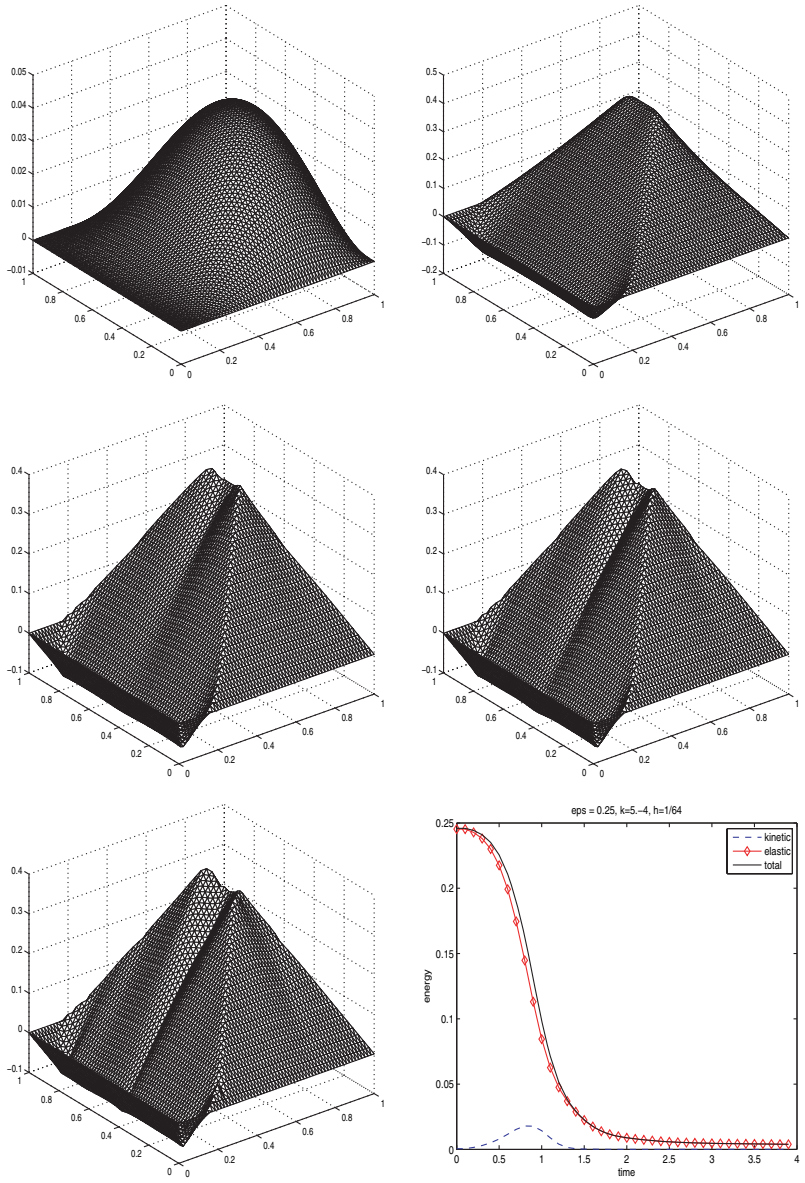

FIG. 1. *Example* 4.1*: Snapshots of* $t \mapsto U(t,\cdot)$*, for* $t = 0.1, 2, 4, 6, 8$*, and* $\varepsilon = 0.25$*. Evolution of kinetic, elastic, and total energy.*

As is known from [5, p. 149], the generalized solutions $u : \Omega_T \to \mathbb{R}$ of (1.1)–(1.3) ($\varepsilon = 0$) solve $u_{tt} = \operatorname{div} p(\nabla u)$, where $p := D\phi^{**}$, for the existing convexification

$$\phi^{**} = \sup\{f : f \le \phi,\ f \text{ convex}\}.$$

For our choice of ϕ, we easily compute $\phi^{**}(F) = \frac{1}{4}([|F|^2 - 1]_+)^2$, where $[\cdot]_+ = \max\{0, \cdot\}$. For the chosen initial data, we then find $u \equiv u_0$ in Ω_T. The snapshots in Figure 2 for decreasing values of ε show 2D microstructures which develop and propagate in time. The qualitative evolution of different energy contributions is comparable to the one depicted in Figure 1.

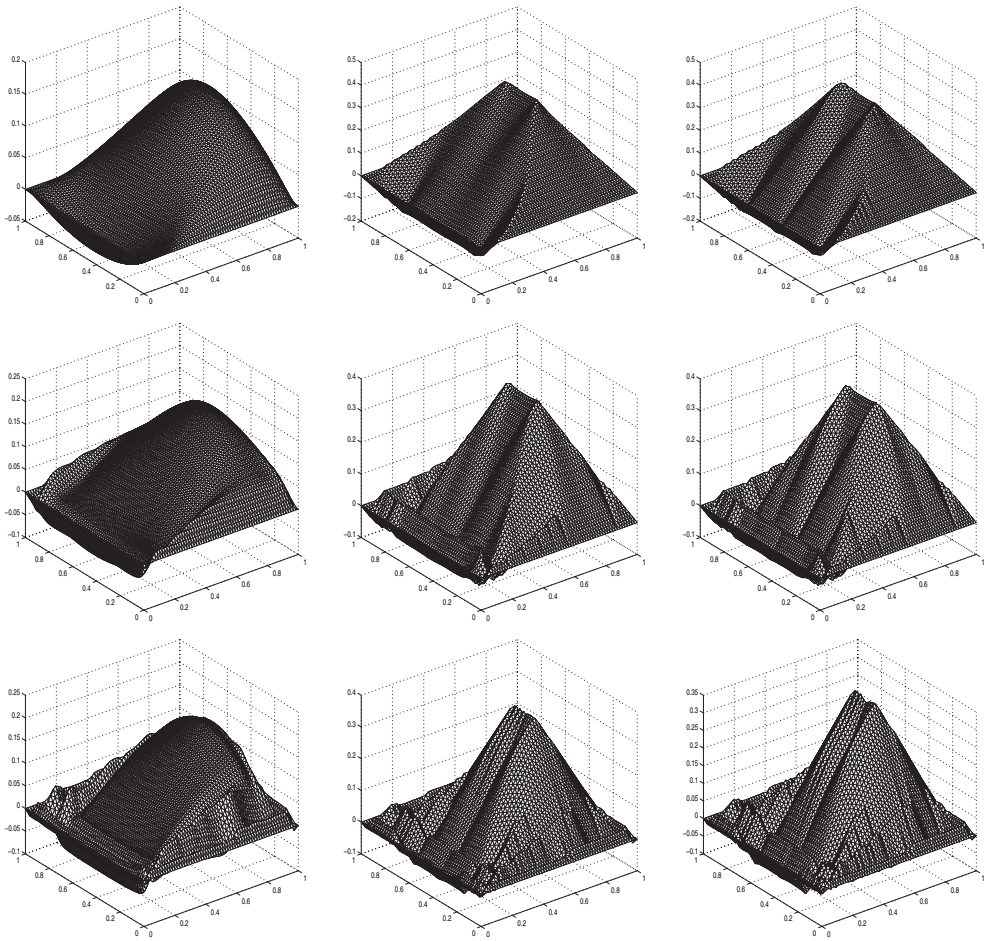

FIG. 2. *Example* 4.2*: Snapshots of* $t \mapsto U(t,\cdot)$ *at times* $t = 1, 2, 4$ *(left to right) for values* $\varepsilon = 0.1, 0.05, 0.025$ *(top to bottom).*

AN ANALYSIS OF A FETI–DP ALGORITHM ON IRREGULAR SUBDOMAINS IN THE PLANE*

AXEL KLAWONN†, OLIVER RHEINBACH†, AND OLOF B. WIDLUND‡

Abstract. In the theory for domain decomposition algorithms of the iterative substructuring family, each subdomain is typically assumed to be the union of a few coarse triangles or tetrahedra. This is an unrealistic assumption, in particular if the subdomains result from the use of a mesh partitioner, in which case they might not even have uniformly Lipschitz continuous boundaries. The purpose of this study is to derive bounds for the condition number of these preconditioned conjugate gradient methods which depend only on a parameter in an isoperimetric inequality, two geometric parameters characterizing John and uniform domains, and the maximum number of edges of any subdomain. A related purpose is to explore to what extent well-known technical tools previously developed for quite regular subdomains can be extended to much more irregular subdomains. Some of these results are valid for any John domain, while an extension theorem, which is needed in this study, requires that the subdomains have complements which are uniform. The results, so far, are complete only for problems in two dimensions. Details are worked out for a FETI–DP algorithm and numerical results support the findings. Some of the numerical experiments illustrate that care must be taken when selecting the scaling of the preconditioners in the case of irregular subdomains.

Key words. domain decomposition, preconditioners, iterative substructuring, dual-primal FETI, John and uniform domains, fractal subdomains

1. Introduction.

In the theory of domain decomposition methods of iterative substructuring type, we typically assume that each subdomain is quite regular, e.g., the union of a small set of coarse triangles or tetrahedra; see, e.g., [36, Assumption 4.3]. However, such an assumption is unlikely to hold especially if the subdomains result from using a mesh partitioner, in which case the subdomain boundaries might not even be uniformly Lipschitz continuous, i.e., the number of patches which cover $\partial\Omega$, and in each of which the boundary is the graph of a Lipschitz continuous function, might not be uniformly bounded independently of the finite element mesh size. We also note that the shape of the subdomains is likely to change if the mesh size is altered and a mesh partitioner is used. The purpose of this paper is to develop a theory for domain decomposition methods under much weaker assumptions on the partitioning and to categorize the rate of convergence in terms of a few geometric parameters. We will denote the nonoverlapping subdomains by Ω_i and the interface between them by Γ.

So far, complete results have been obtained only for problems in the plane. To simplify our presentation, we will also focus on scalar elliptic problems of the following

form:

$$-\mathrm{div}\,(\rho(x)\nabla u(x)) = f(x) \quad x \in \Omega, \tag{1.1}$$

with a homogeneous Dirichlet boundary condition on a measurable part, $\partial\Omega_D$, of $\partial\Omega$, the boundary of Ω, and a Neumann boundary condition on its complement $\partial\Omega_N$. The coefficient $\rho(x)$ is strictly positive and assumed to be a constant ρ_i for $x \in \Omega_i$. As for many other algorithms, our results hold equally well for compressible elasticity problems in two dimensions; see [36, Chapter 8] for a discussion, [24] for further details on FETI–DP for linear elasticity, and the discussion below.

We use linear continuous finite elements and triangulations with shape regular triangles, i.e., the diameter of an element is bounded uniformly by a constant times the radius of the largest inscribed circle. We assume that each subdomain is a union of elements. We denote the finite element space on Ω by $W^h(\Omega)$ and assume that all elements of $W^h(\Omega)$ vanish on $\partial\Omega_D$.

The analysis will be carried out for a FETI–DP algorithm but the results immediately carry over to the corresponding BDDC algorithm (see, e.g., [26]) as well as to a class of inexact FETI–DP methods; see [22]. The tools that we will develop can also be used in the analysis of a number of other domain decomposition algorithms, in particular, those of [12, 13, 14]; our study originated within this collaborative project with Clark Dohrmann. For a collection of auxiliary results used in the analysis of iterative substructuring algorithms, in the case of regular subdomains, see [36, section 4.6].

Thus, our study requires the generalization of some technical tools used in the proof of bounds of the convergence rate of the FETI–DP algorithm. We also have to modify the basic line of reasoning in the proof of our main result; a proof for triangular subdomains and constant coefficients was first given in [29]; see also [32, Chapter 2] for a proof more similar to ours. Four auxiliary results, namely a Poincaré inequality, a Sobolev-type inequality for finite element functions, bounds for certain edge terms, and a finite element extension theorem, will be required in our proof; see Lemmas 2.3, 4.3, 4.4, and 4.5. We will work with *John domains* and *uniform domains* (see Definitions 2.1 and 2.4); the latter are also known as Jones or (ε, ∞)-domains. We will express our bounds on the rate of convergence of our algorithm in terms of a few parameters identified in Definitions 2.1 and 2.4 and Lemma 2.2.

We will also consider the problem of linear, isotropic elasticity in two dimensions:

$$-\mathrm{div}\,(2\mu\varepsilon(\mathbf{u}) + \lambda \mathrm{tr}\,(\varepsilon(\mathbf{u}))I) = f \quad \text{in } \Omega \subset \mathbb{R}^2. \tag{1.2}$$

We assume zero Dirichlet conditions on one part of the boundary of $\partial\Omega$ with nonvanishing measure and traction conditions on the remaining part of the boundary. FETI–DP methods have been analyzed for linear elasticity and regular subdomains in [24]; see [21] and [23] for numerical results.

A crucial tool in any such study is the second Korn inequality, Lemma 2.6; for a proof for uniform domains, see Durán and Muschietti [16], and for John domains, see Acosta, Durán, and Muschietti [1]. The proof in [16] has many details in common with Jones' proof of extension theorems for Sobolev spaces, [20], and the constant in the inequality depends only on the same geometric parameters as the result of Lemma 2.5.

The remainder of this article is organized as follows. In section 2, we provide a Poincaré inequality for general domains and introduce John and uniform domains. In section 3, we describe our FETI–DP algorithm. In section 4, we develop a convergence theory for our FETI–DP algorithm for subdomains with complements which

are uniform. Finally, in section 5, we present numerical results which confirm our theoretical findings. We note that we find a striking difference in the performance of the iterative method between the scaling based on our theory and another based on diagonal elements of the stiffness matrix in cases when the subdomain boundaries are highly irregular.

2. A Poincaré inequality, John and uniform domains. We will first introduce John domains and then consider a Poincaré inequality for such domains. Subsequently, we will introduce uniform domains; the latter are needed in order to prove a finite element extension theorem. We note that this final assumption on the subdomains is not required in our analysis of domain decomposition algorithms based on overlapping subdomains; see [14, 13, 12].

We next give the definition of a John domain; see [19] and the references therein. In the proofs of several of our auxiliary results, we will assume that the subdomains belong to this class.

DEFINITION 2.1 (John domain). *A domain $\Omega \subset \mathbb{R}^n$—an open, bounded, and connected set—is a John domain if there exists a constant $C_J \geq 1$ and a distinguished central point $x_0 \in \Omega$ such that each $x \in \Omega$ can be joined to it by a rectifiable curve $\gamma : [0,1] \to \Omega$ with $\gamma(0) = x_0,\ \gamma(1) = x$, and $|x - \gamma(t)| \leq C_J \cdot \mathit{distance}(\gamma(t), \partial\Omega)$ for all $t \in [0,1]$.*

This condition can be viewed as a twisted cone condition. We note that certain snowflake curves with fractal boundaries are John domains (see section 5) and that the boundary of a John domain can be arbitrarily much longer than its diameter.

We note that for any choice of the point x_0, there is a point $x \in \Omega$ at a distance of at least $\mathit{diameter}(\Omega)/2$. We find that $\mathit{diameter}(\Omega) \leq 2C_J r_\Omega$, where r_Ω is the radius of the largest ball inscribed in Ω and centered at x_0. Conditions on the boundary are of course also imposed.

In any analysis of any domain decomposition method with a second, coarse level, we need a Poincaré inequality. This inequality is closely related to an isoperimetric inequality. The next lemma is due to Maz'ja [30] and Federer and Fleming [18]; see also Lin and Yang [27, Theorem 5.3.2] or Maz'ja [31].

LEMMA 2.2 (isoperimetric inequality). *Let $\Omega \subset \mathbb{R}^n$ be a domain, and let u be sufficiently smooth. Then,*

$$\inf_{c \in R} \left(\int_\Omega |u - c|^{n/(n-1)}\, dx \right)^{(n-1)/n} \leq \gamma(\Omega, n) \int_\Omega |\nabla u|\, dx$$

if and only if

$$[\min(|A|, |B|)]^{1-1/n} \leq \gamma(\Omega, n) |\partial A \cap \partial B|. \tag{2.1}$$

Here, $A \subset \Omega$ is an arbitrary open set, and $B = \Omega \setminus \bar{A}$; $\gamma(\Omega, n)$ is the best possible constant, and $|A|$ is the measure of the set A, etc.

We note that the domain does not need to be star-shaped or Lipschitz. For $n = 2$, the best choice of $c = \bar{u}_\Omega$, the average of u over the domain. A small value of $\gamma(\Omega, n)$ is desirable for our purposes.

It is known that any simply connected plane domain with a finite Poincaré parameter $\gamma(\Omega, 2)$ is a John domain; see [9]. It is also known (see [6]) that any John domain has a bounded Poincaré parameter $\gamma(\Omega, n)$. Since we have been unable to find a simple estimate of $\gamma(\Omega, n)$ in terms of C_J in the literature, we have chosen to express our results in terms of both of these geometric parameters. In two dimensions, we

immediately obtain the standard Poincaré inequality by using the Cauchy–Schwarz inequality.

LEMMA 2.3 (Poincaré's inequality). *Let Ω be a John domain in the plane. Then,*

$$\|u - \bar{u}_\Omega\|^2_{L_2(\Omega)} \leq (\gamma(\Omega, 2))^2 |\Omega| \|\nabla u\|^2_{L_2(\Omega)} \quad \forall u \in H^1(\Omega).$$

For $n = 3$ such a bound is obtained by using Hölder's inequality several times. In Lemma 2.3, we then should replace $|\Omega|$ by $|\Omega|^{2/3}$.

Throughout, we will use a weighted $H^1(\Omega_i)$-norm defined by

$$\|u\|^2_{H^1(\Omega_i)} := \int_{\Omega_i} \nabla u \cdot \nabla u dx + 1/H_i^2 \int_{\Omega_i} |u|^2 dx = |u|^2_{H^1(\Omega_i)} + 1/H_i^2 \int_{\Omega_i} |u|^2 dx.$$

Here H_i is the diameter of Ω_i. The weight for the L_2-term results from the standard H^1-norm on a domain with diameter one and a dilation. We will use Lemma 2.3 to remove L_2-terms in our estimates.

We finally consider uniform domains also known as (ϵ, ∞) domains. It is known, and easy to see, that any uniform domain is a John domain. It is also easy to construct John domains that are not uniform domains. According to Jones [20, Theorem 4], they form the largest class of finitely connected domains for which an extension theorem holds in two dimensions; see Lemma 2.5 below. According to [20, Theorem 2], every uniform domain in $\mathbb{R}^n$ allows for a bounded extension with respect to the seminorm of H^1. It also follows from [20, Theorem C] that if a simply connected domain, with a simply connected complement, is uniform, so is its complement.

DEFINITION 2.4 (uniform domains). *A domain $\Omega \subset \mathbb{R}^n$ is a uniform domain if there exists a constant C_U such that any pair of points $x_1 \in \Omega$ and $x_2 \in \Omega$ can be joined by a rectifiable curve $\gamma(t) : [0, 1] \to \Omega$ with $\gamma(0) = x_1$, $\gamma(1) = x_2$, and where the Euclidean arc length of $\gamma \leq C_U |x_1 - x_2|$ and $\min_{i=1,2} |x_i - \gamma(t)| \leq C_U \cdot$ distance$(\gamma(t), \partial\Omega)$ for all $t \in [0, 1]$.*

Remark 1. The complement of a bounded set is of course always infinite. What matters in our work, with any uniform domain, is its boundary. We can therefore, whenever required, remove the part of an infinite domain that is outside a sufficiently large circle and effectively work only with bounded domains.

We note that domains with boundaries formed by von Koch curves, as in section 5, are also uniform domains.

We will use a main result for uniform domains; see Jones [20, Theorem 2].

LEMMA 2.5. *Let $\Omega \subset \mathbb{R}^n$ be a uniform domain, and let P_0 be the space of constants. There then exists a bounded, linear operator $E_\Omega : H^1(\Omega)/P_0 \to H^1(\mathbb{R}^n)/P_0$, which extends any element in $H^1(\Omega)$ to one defined for all of $\mathbb{R}^n$, i.e., $(E_\Omega u)_{|\Omega} = u$ for all $u \in H^1(\Omega)/P_0$. The norm of this operator depends only on $C_U(\Omega)$.*

As previously noted, for a result on linear elasticity, we also need a second Korn inequality for uniform domains; see Durán and Muschietti [16, Corollary 2.8].

LEMMA 2.6 (Korn inequality for uniform domains). *Let $\Omega \subset \mathbb{R}^n$ be a bounded uniform domain. Then, there exists a constant $C > 0$, which depends only on the uniformity constant $C_U(\Omega)$ and the dimension n, such that*

$$|\mathbf{u}|^2_{H^1(\Omega)} \leq C \|\varepsilon(\mathbf{u})\|^2_{L_2(\Omega)}$$

for all $\mathbf{u} \in \{\mathbf{u} \in \mathbf{H^1}(\Omega) : \int_\Omega (\frac{\partial u_i}{\partial x_j} - \frac{\partial u_j}{\partial x_i}) dx = 0,\ i, j = 1, \ldots, n\}$.

3. The FETI–DP algorithm. Let a domain $\Omega \subset \mathbb{R}^2$ be decomposed into N nonoverlapping subdomains Ω_i of diameter H_i, each of which is a union of finite

elements with the finite element nodes on the boundaries of neighboring subdomains matching across the interface $\Gamma := \bigcup_{i \neq j} \partial\Omega_i \cap \partial\Omega_j$. Here $\partial\Omega_i$ and $\partial\Omega_j$ are the boundaries of Ω_i and Ω_j, respectively. The interface Γ is the union of edges and vertices. The nodes on an edge are shared by exactly two subdomains, and the edges are open subsets of Γ. The vertices are endpoints of the edges. For a more detailed definition of faces, edges, and vertices in two and three dimensions, see [24, section 3] and [21, section 2].

For each subdomain Ω_i, $i = 1, \ldots, N$, we assemble the subdomain stiffness matrices $K^{(i)}$ and load vectors $f^{(i)}$ from the contributions of the individual elements. We denote the vector of unknowns of the subdomain Ω_i by $u^{(i)}$ and then partition the unknowns of $u^{(i)}$ into a vector of primal variables $u_\Pi^{(i)}$ and a vector of nonprimal variables $u_B^{(i)}$. We can obtain fast convergence by choosing only vertices as primal variables, since we are considering only two dimensional problems; see [17, 29, 32]. To simplify the description of the algorithm, we will assume that all vertices are primal. The nonprimal variables are those of $u_I^{(i)}$, associated with the interior nodes of the subdomain, and the dual displacement variables of the vector $u_\Delta^{(i)}$, associated with the remaining edge nodes. We will enforce the continuity of the solution in the primal unknowns of $u_\Pi^{(i)}$ by making them global; we subassemble the subdomain stiffness matrices $K^{(i)}$ with respect to this set of variables and denote the resulting matrix by $\widetilde{K}$. For all other interface variables, i.e., those of the $u_\Delta^{(i)}$, we will introduce Lagrange multipliers to enforce continuity.

Here are some more details: we partition the stiffness matrices according to the different sets of unknowns and obtain

$$K^{(i)} = \begin{bmatrix} K_{BB}^{(i)} & K_{\Pi B}^{(i)\,T} \\ K_{\Pi B}^{(i)} & K_{\Pi\Pi}^{(i)} \end{bmatrix}, \quad K_{BB}^{(i)} = \begin{bmatrix} K_{II}^{(i)} & K_{\Delta I}^{(i)\,T} \\ K_{\Delta I}^{(i)} & K_{\Delta\Delta}^{(i)} \end{bmatrix},$$

$$\text{and} \qquad f^{(i)T} = [f_B^{(i)T}\ f_\Pi^{(i)T}], \quad f_B^{(i)^T} = [f_I^{(i)^T}\ f_\Delta^{(i)^T}].$$

Next we define the block diagonal matrices

$$K_{BB} = \operatorname{diag}_{i=1}^N(K_{BB}^{(i)}), \quad K_{\Pi B} = \operatorname{diag}_{i=1}^N(K_{\Pi B}^{(i)}), \quad K_{\Pi\Pi} = \operatorname{diag}_{i=1}^N(K_{\Pi\Pi}^{(i)}),$$

and load vectors $f_B^T = [f_B^{(1)\,T}, \ldots, f_B^{(N)\,T}]$, $f_\Pi^T = [f_\Pi^{(1)\,T}, \ldots, f_\Pi^{(N)\,T}]$.

Assembling the local subdomain matrices and load vectors with respect to the primal variables, we obtain the partially assembled global stiffness matrix $\widetilde{K}$ and the load vector $\tilde{f}$,

$$\widetilde{K} = \begin{bmatrix} K_{BB} & \widetilde{K}_{\Pi B}^T \\ \widetilde{K}_{\Pi B} & \widetilde{K}_{\Pi\Pi} \end{bmatrix}, \qquad \tilde{f} = \begin{bmatrix} f_B \\ \tilde{f}_\Pi \end{bmatrix},$$

where a tilde marks an assembled quantity. It is easy to see that, with all vertices primal, the matrix $\widetilde{K}$ is positive definite.

To enforce the continuity of the remaining interface variables $u_\Delta^{(i)}$, we introduce a jump operator B_B with entries $0, -1$, or 1 and a vector of Lagrange multipliers λ. The FETI–DP saddlepoint problem is then given by

$$\begin{bmatrix} K_{BB} & \widetilde{K}_{\Pi B}^T & B_B^T \\ \widetilde{K}_{\Pi B} & \widetilde{K}_{\Pi\Pi} & 0 \\ B_B & 0 & 0 \end{bmatrix} \begin{bmatrix} u_B \\ \tilde{u}_\Pi \\ \lambda \end{bmatrix} = \begin{bmatrix} f_B \\ \tilde{f}_\Pi \\ 0 \end{bmatrix}. \tag{3.1}$$

By eliminating u_B and $\tilde{u}_\Pi$ from (3.1), we obtain

$$F\lambda = d, \tag{3.2}$$

with

$$F = B_B K_{BB}^{-1} B_B^T + B_B K_{BB}^{-1} \widetilde{K}_{\Pi B}^T \widetilde{S}_{\Pi\Pi}^{-1} \widetilde{K}_{\Pi B} K_{BB}^{-1} B_B^T, \quad \widetilde{S}_{\Pi\Pi} = \widetilde{K}_{\Pi\Pi} - \widetilde{K}_{\Pi B} K_{BB}^{-1} \widetilde{K}_{\Pi B}^T,$$

$$\text{and} \qquad d = B_B K_{BB}^{-1} f_B - B_B K_{BB}^{-1} \widetilde{K}_{\Pi B}^T \widetilde{S}_{\Pi\Pi}^{-1} (\widetilde{f}_\Pi - \widetilde{K}_{\Pi B} K_{BB}^{-1} f_B).$$

To define the Dirichlet preconditioner M, we need to introduce a scaled variant of the jump operator B_B, which we denote by $B_{B,D} = [B_{B,D}^{(1)}, \ldots, B_{B,D}^{(N)}]$. The matrix $B_{B,D}^{(i)}$ is associated with the subdomain Ω_i and defined as follows: each row of $B_B^{(i)}$ with a nonzero entry corresponds to a Lagrange multiplier connecting the subdomain Ω_i with a neighboring subdomain Ω_j at a node $x \in \partial\Omega_{i,h} \cap \partial\Omega_{j,h}$. We obtain $B_{B,D}^{(i)}$ by multiplying each such row of $B_B^{(i)}$ by

$$\delta_i^\dagger := \frac{\rho_j}{\rho_j + \rho_i}; \tag{3.3}$$

see [24] or [36, section 6.4] for further details. We will refer to this scaling as the ρ-scaling. The Dirichlet preconditioner is then given by

$$M^{-1} = B_{B,D} (R_\Delta^B)^T S_{\Delta\Delta} R_\Delta^B B_{B,D}^T, \qquad \text{where}$$

$$S_{\Delta\Delta} = \operatorname{diag}_{i=1}^N (S_{\Delta\Delta}^{(i)}),\ S_{\Delta\Delta}^{(i)} = K_{\Delta\Delta}^{(i)} - K_{\Delta I}^{(i)} (K_{II}^{(i)})^{-1} K_{\Delta I}^{(i)T},\ \text{and } R_\Delta^B = \operatorname{diag}_{i=1}^N (R_\Delta^{B\,(i)}).$$

The matrices $R_\Delta^{B\,(i)}$ are restriction operators with entries 0 or 1 which restrict the nonprimal degrees of freedom $u_B^{(i)}$ of a subdomain to its dual part $u_\Delta^{(i)}$.

Our FETI–DP method is the preconditioned conjugate gradient algorithm applied to the symmetric, positive definite system (3.2), using the preconditioner M^{-1}. We note that, as usual for iterative substructuring methods, the local Schur complements $S_{\Delta\Delta}^{(i)}$ do not have to be built explicitly. Instead local linear systems are solved in each iteration step.

4. Convergence theory. We recall that $W^h(\Omega_i)$ is the standard finite element space of continuous, piecewise linear functions on Ω_i which vanish on $\partial\Omega_D$. The corresponding finite element trace spaces are denoted by $W^{(i)} := W^h(\partial\Omega_i \cap \Gamma), i = 1, \ldots, N$. The product space of the $W^{(i)}$ is denoted by W and its partially assembled subspace, with the primal variables global, is denoted by $\widetilde{W}$. We will denote by h_i the smallest diameter of the finite elements in the subdomain Ω_i.

We can now formulate our main result, which is also valid for compressible elasticity with Lamé parameters which are constant in each subdomain.

THEOREM 4.1 (condition number estimate). *Let the domain $\Omega \subset \mathbb{R}^2$ be partitioned into subdomains Ω_i, which are partitioned into shape regular elements and which have complements $\mathcal{C}\Omega_i$ that are uniform in the sense of Definition* 2.4. *Then, with M the Dirichlet preconditioner, F the FETI–DP operator, and with h_i the smallest diameter of any element in Ω_i, the condition number of the conjugate gradient method satisfies*

$$\kappa(M^{-1}F) \leq C \max_i (1 + \log(H_i/h_i))^2.$$

Here C is a constant which depends only on the parameters $C_J(\Omega_i)$ and $C_U(\mathcal{C}\Omega_i)$ of Definitions 2.1 *and* 2.4*, the Poincaré parameters $\gamma(\Omega_i, 2)$ of the subdomains, the maximum number of edges of any subdomain, and the shape regularity of the finite elements.*

We will denote by $\mathcal{H}$ the discrete harmonic extension operator; $\mathcal{H}(v)$ is the minimal energy extension of the restriction of the finite element function v to the interface Γ. For each edge $\mathcal{E}^{ij}$, we also need to define an edge cut-off function $\theta_{\mathcal{E}^{ij}}$, which is the discrete harmonic function which equals 1 at all nodes on the edge $\mathcal{E}^{ij}$, common to Ω_i and Ω_j, and which vanishes at all other interface nodes.

In order to prove Theorem 4.1, we need only establish the following result; see [24, section 8] for a proof of a three-dimensional counterpart for the case of tetrahedral subdomains. We denote the restriction operator from $\widetilde{W}$ to $W^{(i)}$ by $R^{(i)}, i = 1, \ldots, N$.

LEMMA 4.2. *Let $\mathcal{E}^{ij}$ be an edge common to the boundaries of Ω_i and Ω_j. For all $\tilde{w} \in \widetilde{W}$ and with $w^{(i)} := R^{(i)}w, w^{(j)} := R^{(j)}w$, we have*

$$\begin{aligned} \rho_i|\mathcal{H}(\theta_{\mathcal{E}^{ij}}\delta_i^\dagger(w^{(i)} - w^{(j)}))|^2_{H^1(\Omega_i)} \quad &\leq \quad C(1+\log(H_i/h_i))^2\rho_i|w^{(i)}|^2_{H^1(\Omega_i)} \\ &\quad + C(1+\log(H_j/h_j))^2\rho_j|w^{(j)}|^2_{H^1(\Omega_j)}. \end{aligned} \tag{4.1}$$

Remark 2. We note that when this lemma is used to prove Theorem 4.1, the maximum number of edges of any subdomain will enter the estimate.

To prove this lemma, we need three auxiliary results, in addition to Poincaré's inequality. The first is a discrete Sobolev inequality. This inequality, (4.2), is well known in the theory of iterative substructuring methods. Proofs for domains satisfying an interior cone condition are given in [7] and [8, section 4.9], and a different proof is given in [36, page 102]. For a proof for John domains, see [12].

LEMMA 4.3 (discrete Sobolev inequality). *Let $\Omega_i \subset \mathbb{R}^2$ be a John domain. Then*

$$\|u - \bar{u}_{\Omega_i}\|^2_{L_\infty(\Omega_i)} \leq C(1+\log(H_i/h_i))|u|^2_{H^1(\Omega_i)} \tag{4.2}$$

for all $u \in W^h(\Omega_i)$. The constant C depends only on the John parameter $C_J(\Omega_i)$ of Ω_i and the shape regularity of the finite elements.

Another important tool provides estimates of certain edge terms. For regular subdomains in two dimensions, this lemma was first given in [15].

LEMMA 4.4 (edge lemma). *Let Ω_i be a John domain, $\mathcal{E}^{ij} \subset \partial\Omega_i$ be an edge, and $\theta_{\mathcal{E}^{ij}} \in W^h(\Omega_i)$ be a finite element function which equals 1 at all nodes of $\mathcal{E}^{ij}$, vanishes at the other nodes on $\partial\Omega_i$, and is discrete harmonic in Ω_i. Then, for any $u \in W^h(\Omega_i)$, we have*

$$|\mathcal{H}(\theta_{\mathcal{E}^{ij}}u)|^2_{H^1(\Omega_i)} \leq C\,(1+\log(H_i/h_i))^2\|u\|^2_{H^1(\Omega_i)}, \tag{4.3}$$

$$|\theta_{\mathcal{E}^{ij}}|^2_{H^1(\Omega_i)} \leq C(1+\log(H_i/h_i)), \tag{4.4}$$

and

$$\|\theta_{\mathcal{E}^{ij}}\|^2_{L_2(\Omega_i)} \leq CH_i^2(1+\log(H_i/h_i)). \tag{4.5}$$

Here, C depends only on the John parameter $C_J(\Omega_i)$ of Ω_i and the shape regularity of the finite elements. The logarithmic factor in (4.5) *can be removed if all angles of the triangulation are acute.*

Proof. We will establish inequality (4.3) by using ideas similar to those of [36, Proofs of Lemmas 4.24 and 4.25.]. We will construct a function $\vartheta_{\mathcal{E}^{ij}}$ which has the

same boundary values as $\theta_{\mathcal{E}^{ij}}$ and which satisfies the two inequalities (4.3) and (4.4). Since $\theta_{\mathcal{E}^{ij}}$ and $\mathcal{H}(\theta_{\mathcal{E}^{ij}}u)$ are discrete harmonic, the two inequalities (4.3) and (4.4) will then hold. We note that $\vartheta_{\mathcal{E}^{ij}}$, which we will construct, will not be a finite element function, and that the same is true for $\vartheta_{\mathcal{E}^{ij}}u$. But it is easy to see that the gradient of the finite element interpolant of $\vartheta_{\mathcal{E}^{ij}}$ will satisfy the same bound as $\nabla\vartheta_{\mathcal{E}^{ij}}$. We then use [36, Lemma 4.31] to complete the argument for the linear interpolant of $\vartheta_{\mathcal{E}^{ij}}u$.

We first construct two curves, as in Definition 2.1, which connect the endpoints of the edge $\mathcal{E}^{ij}$ to the point x_0.

For each point of the curves, it is now possible to construct a circular disk, contained in Ω_i, with a radius as in Definition 2.1. We will replace this set by a union of rectangles contained in the union of a smaller family $\{B_k\}$ of disks creating two polygonal curves connecting the two endpoints of the edge. These two curves partition Ω_i into three parts. We will make $\vartheta_{\mathcal{E}_{ij}}$ identically 1 in the set next to the edge and make it vanish in the set farthest from the edge and we will bring the values of this function from 1 to 0 across the third, interior set.

The two John curves that meet in x_0 can be quite complicated. We will therefore replace them by the union of line segments which connect the centers of the family of circular disks $\{B_k\}$ for each of the John curves. These disks, in turn, will be used to construct the family of rectangles $\{R_{k,k+1}\}$. We are able to estimate the lengths of the sides of these rectangles as a function of the distance r to the closest endpoint of the edge $\mathcal{E}^{ij}$, and we will use the union of these rectangles to construct a function $\vartheta_{\mathcal{E}^{ij}}$ with a bound on its gradient which is inversely proportional to r.

The circular disks are constructed as in [12, section 3] in which a number of properties are also derived; they are collected in Lemma 3.3 of that paper. All of this material is essentially borrowed from [19]. We will recall some of these results.

Let $\gamma(t)$ be the chosen John curve from the central point $x_0 \in \Omega_i$ to x which is one of the endpoints of the edge $\mathcal{E}^{ij}$. A family of circular disks B_k, $k \geq 0$ is introduced as follows: the first disk is $B_0 := B(x_0, dist(x_0, \partial\Omega)/4)$, the open set centered at x_0 and with radius $r_0 = dist(x_0, \partial\Omega)/4$. The other disks are defined similarly as $B_k := B(x_k, r_k)$, centered at x_k and with radius $r_k := |x - x_k|/(4C_J), k \geq 1$. All the x_k lie on the John curve and all the B_k are subsets of Ω_i. Given B_k, we select $x_{k+1} \in \partial B_k$ as the last point of exit of $\gamma(t)$ from B_k.

The following properties are established in [12, Lemma 3.3]: there exists a constant $M(C_J)$ such that

1. no point in Ω belongs to more than M disks;
2. the number of x_k that are at a distance larger than r from x is bounded by $M\log(H/r)$;
3. $r_{k+1} \geq (4C_J - 1)/(4C_J + 1)\, r_k$.

Let the rectangle $R_{k,k+1}$ be the largest rectangle inscribed in the closure of $B_k \cup B_{k+1}$ and with two sides parallel to the line segment between x_k and x_{k+1}; see Figure 4.1. Since x_{k+1} is on ∂B_k, one side of the rectangle is of length $2r_k$. It is also easy to show, by using the lower bound on r_{k+1} given in 3. above, that the other is bounded from below by cr_k, where c is a positive constant independent of k. Therefore, the distance from any point on $[x_k, x_{k+1}]$ to the boundary of the rectangle exceeds $(c/2)r_k$, and the same is clearly true for the union of the rectangles.

We denote by $N(h)$ the index of the first x_k which lies in the union of the elements which have x, one of the endpoints of the edge $\mathcal{E}^{ij}$, as a vertex. We take the union of all rectangles $R_{k,k+1}$ with $k < N(h)$ and those elements next to x. We then triangulate the resulting region using only nodes on the boundary of this set. We assign the value

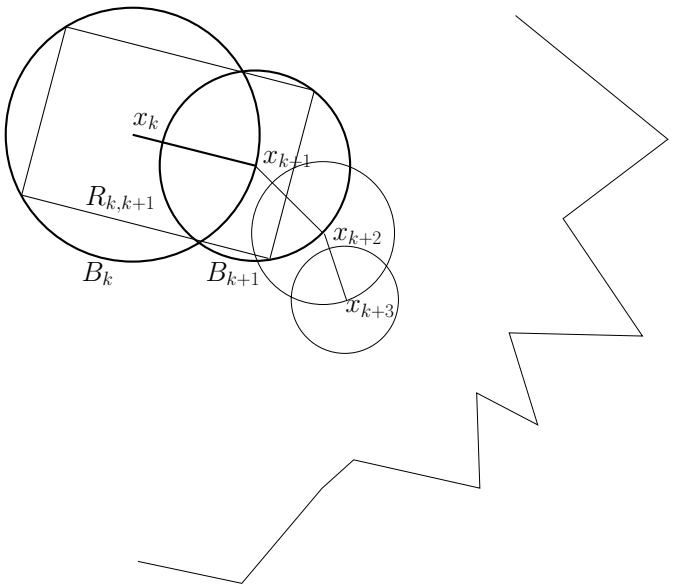

FIG. 4.1. *The circular disks B_k and B_{k+1}, their centers x_k and x_{k+1}, and the rectangle $R_{k,k+1}$.*

1 to $\vartheta_{\mathcal{E}^{ij}}$ on the side of this set which is closest to the edge $\mathcal{E}^{ij}$ and let this function vanish on the other side. In between, we use linear interpolation on the triangulation, just constructed, to define $\vartheta_{\mathcal{E}^{ij}}$.

For any rectangle $R_{k,k+1}$ and any triangulation of the domain, just constructed, we can estimate the gradient of $\vartheta_{\mathcal{E}^{ij}}$ by C/r_k, where C is constant, which depends only on C_J. Using Lemma 4.3, we then find that

$$|\vartheta_{\mathcal{E}^{ij}} u|^2_{H^1(R_{k,k+1})} \leq C(1+\log(H/h))\|u\|^2_{H^1(\Omega_i)}.$$

The contributions from the elements which have x as a vertex can be estimated quite easily. Inequality (4.4) now follows by using the upper bound $M\log(H/r)$ on the number of x_k.

The estimate of $|\vartheta_{\mathcal{E}^{ij}}|_{H^1(\Omega_i)}$ follows from the same type of arguments.

For the $L_2(\Omega_i)$-bound, we note that $\vartheta_{\mathcal{E}^{ij}} - \theta_{\mathcal{E}^{ij}}$ vanishes on the subdomain boundary, and that we can estimate the $L_2(\Omega_i)$-norm of $\vartheta_{\mathcal{E}^{ij}} - \theta_{\mathcal{E}^{ij}}$ in terms of the smallest eigenvalue of the Dirichlet problem for the Laplacian and the $H^1(\Omega_i)$-bound just established. The bound for $\theta_{\mathcal{E}^{ij}}$ then follows from the trivial bound $\|\vartheta_{\mathcal{E}^{ij}}\|_{L_2(\Omega_i)} \leq |\Omega_i|^{1/2}$.

If all angles of the triangulation are acute, then the finite element discretization will satisfy a maximum principle; see Ciarlet and Raviart [10]. Then $0 \leq \theta_{\mathcal{E}^{ij}} \leq 1$, and we can easily estimate the L_2-norm of $\theta_{\mathcal{E}^{ij}}$ in the same way as for $\vartheta_{\mathcal{E}^{ij}}$. ∎

The next lemma was proven for Lipschitz domains and quite general conforming finite elements in Widlund [37], using a technique by Astrakhatsev [2]; see also Toselli and Widlund [36] for a different proof. Here, we present a proof for more general domains by different means. We note that, in essence, this is a result, for a quite irregular interface, for the classical Dirichlet–Neumann algorithm for two subdomains as introduced in [36, section 1.3.3].

LEMMA 4.5 (extension lemma). *Let Ω_i and Ω_j, subsets of $\mathbb{R}^n$, be two subdomains with a common $(n-1)$-dimensional interface $\mathcal{E}^{ij}$. Furthermore, let Ω_i be a domain*

with a uniform complement, let

$$V_i^h = \{v_h \in W^h(\Omega_i) : v_h(x) = 0 \ \text{ at all nodes of } \ \partial\Omega_i \setminus \mathcal{E}^{ij}\},$$

and let

$$V_j^h = \{v_h \in W^h(\Omega_j) : v_h(x) = 0 \ \text{ at all nodes of } \ \partial\Omega_j \setminus \mathcal{E}^{ij}\}.$$

Then, there exists an extension operator

$$E_{ji}^h : V_j^h \longrightarrow V_i^h$$

with the following properties:

1. $(E_{ji}^h u_h)_{|\Omega_j} = u_h \quad \forall u_h \in V_j^h$,
2. $|E_{ji}^h u_h|_{H^1(\Omega_i)} \leq C|u_h|_{H^1(\Omega_j)} \quad \forall u_h \in V_j^h$,

where the constant $C > 0$ depends only on the uniformity parameter $C_U(\mathcal{C}\Omega_i)$ of the complement of Ω_i and the shape regularity of the finite elements and is otherwise independent of the finite element mesh sizes h_i and h_j and the diameters H_i and H_j.

Proof. The proof uses Lemma 2.5 and a result on finite element interpolation of nonsmooth functions given in Scott and Zhang [35]; see also Brenner and Scott [8, section 4.8]. Their results represent a refinement of well-known work by Clément [11].

From Lemma 2.5 and the fact that by assumption the complement of Ω_i is uniform, we know that there exists an extension operator

$$E_{\mathcal{C}\Omega_i} : H^1(\mathcal{C}\Omega_i) \longrightarrow H^1(\mathbb{R}^n)$$

and a positive constant C, which depends only on the uniformity constant $C_U(\mathcal{C}\Omega_i)$, such that

$$|E_{\mathcal{C}\Omega_i} u|_{H^1(\mathbb{R}^n)} \leq C\,|u|_{H^1(\mathcal{C}\Omega_i)} \quad \forall u \in H^1(\mathcal{C}\Omega_i), \tag{4.6}$$

with $(E_{\mathcal{C}\Omega_i} u)_{|\mathcal{C}\Omega_i} = u$ for $u \in H^1(\mathcal{C}\Omega_i)$.

Let $\Omega_{ij} = \Omega_i \cup \Omega_j \cup \mathcal{E}^{ij}$. It is shown in Scott and Zhang [35] that there exists a finite element interpolation operator

$$\Pi^h : H_0^1(\Omega_{ij}) \longrightarrow W^h(\Omega_{ij}) \cap H_0^1(\Omega_{ij}),$$

$$\text{with} \qquad \Pi^h v_h = v_h \quad \forall v_h \in W^h(\Omega_{ij}) \cap H_0^1(\Omega_{ij}), \tag{4.7}$$

$$\text{and} \qquad |\Pi^h v|_{H^1(\Omega_{ij})} \leq C\,|v|_{H^1(\Omega_{ij})} \quad \forall v \in H^1(\Omega_{ij}), \tag{4.8}$$

which preserves the boundary values of any finite element function on each individual element. The constant C is independent of the mesh parameters and H_i and H_j.

In their proof, Scott and Zhang construct a dual basis for the standard nodal basis of the finite element space in terms of integrals over elements or $(n-1)$-simplices, i.e., edges in two dimensions and faces in three dimensions. There is a great deal of flexibility and, in particular, for each node—and its associated degree or degrees of freedom—one can choose, in the construction, any element of which it is a vertex. For all nodes in $\overline{\Omega}_j$ we select elements of Ω_j and for the nodes in $\overline{\Omega}_i \setminus \mathcal{E}^{ij}$ elements of Ω_i. This will guarantee that the values in $\overline{\Omega}_j$ will not be changed when the operator Π^h is applied; cf. (4.7).

Any finite element function $u_h \in V_j^h$ can now be extended by zero outside of Ω_{ij}. This extended function, $\widetilde{u}$, has the same H^1-seminorm as u_h. We next define

$$E_{ji}^h u_h := \Pi^h(E_{\mathcal{C}\Omega_i}\widetilde{u}),$$

and obtain, by using (4.6) and (4.8),

$$|E_{ji}^h u_h|_{H^1(\Omega_i)} \leq C\,|E_{\mathcal{C}\Omega_i}\widetilde{u}|_{H^1(\mathbb{R}^n)} \leq C\,|\widetilde{u}|_{H^1(\mathcal{C}\Omega_i)} = C\,|u_h|_{H^1(\Omega_j)}.$$

The constant C depends only on the shape regularity of the finite elements and the uniformity constant $C_U(\mathcal{C}\Omega_i)$. By construction, we also have

$$(E_{ji}^h u_h)_{|\Omega_j} = u_h \quad \forall u_h \in V_j^h. \qquad \square$$

We now present a proof of Lemma 4.2.

Proof of Lemma 4.2. Consider an arbitrary $w \in \widetilde{W}$, and let $w^{(i)} := R^{(i)}w$ and $w^{(j)} := R^{(j)}w$. Our scaling factors (3.3) satisfy the following elementary estimate (see [24, Lemma 8.4])

$$\rho_i(\delta_i^\dagger)^2 = \rho_i \frac{\rho_j^2}{(\rho_i+\rho_j)^2} \leq \min\{\rho_i,\rho_j\}.$$

Proceeding as in [24] or [32], we find

$$\begin{aligned}
&\rho_i|\mathcal{H}(\theta_{\mathcal{E}^{ij}}\delta_i^\dagger(w^{(i)}-w^{(j)}))|^2_{H^1(\Omega_i)}\\
&= \rho_i|\mathcal{H}(\theta_{\mathcal{E}^{ij}}\delta_i^\dagger((w^{(i)}-\overline{w}_{i,\Omega_i})-(w^{(j)}-\overline{w}_{j,\Omega_j})+(\overline{w}_{i,\Omega_i}-\overline{w}_{j,\Omega_j})))|^2_{H^1(\Omega_i)}\\
&\leq 3\min\{\rho_i,\rho_j\}\Big(|\mathcal{H}(\theta_{\mathcal{E}^{ij}}(w^{(i)}-\overline{w}_{i,\Omega_i}))|^2_{H^1(\Omega_i)} + |\mathcal{H}(\theta_{\mathcal{E}^{ij}}(w^{(j)}-\overline{w}_{j,\Omega_j}))|^2_{H^1(\Omega_i)}\\
&\quad + |\theta_{\mathcal{E}^{ij}}(\overline{w}_{i,\Omega_i}-\overline{w}_{j,\Omega_j})|^2_{H^1(\Omega_i)}\Big).
\end{aligned}$$

We have added and subtracted the averages $\overline{w}_{i,\Omega_i} = \int_{\Omega_i} w^{(i)}dx/\int_{\Omega_i}1dx$ and $\overline{w}_{j,\Omega_j} = \int_{\Omega_j} w^{(j)}dx/\int_{\Omega_j}1dx$. We can estimate the first term above using Lemmas 2.3 and 4.4 and find that

$$\begin{aligned}
&\min\{\rho_i,\rho_j\}|\mathcal{H}(\theta_{\mathcal{E}^{ij}}(w^{(i)}-\overline{w}_{i,\Omega_i}))|^2_{H^1(\Omega_i)}\\
&\leq C(1+\log(H_i/h_i))^2\rho_i\|w^{(i)}-\overline{w}_{i,\Omega_i}\|^2_{H^1(\Omega_i)}\\
&\leq C(1+\log(H_i/h_i))^2\rho_i|w^{(i)}|^2_{H^1(\Omega_i)}.
\end{aligned}$$

We have the same type of bound for the second term. By using that the harmonic extension always has the least energy of all possible extensions, and Lemma 4.5, we obtain

$$\begin{aligned}
|\mathcal{H}(\theta_{\mathcal{E}^{ij}}(w^{(j)}-\overline{w}_{j,\Omega_j}))|^2_{H^1(\Omega_i)} &\leq |E_{ji}^h(\mathcal{H}(\theta_{\mathcal{E}^{ij}}(w^{(j)}-\overline{w}_{j,\Omega_j})))|^2_{H^1(\Omega_i)}\\
&\leq C\,|\mathcal{H}(\theta_{\mathcal{E}^{ij}}(w^{(j)}-\overline{w}_{j,\Omega_j}))|^2_{H^1(\Omega_j)}.
\end{aligned}$$

We can then proceed exactly as for the first term.

There remains to estimate the third term:

$$|\theta_{\mathcal{E}^{ij}}(\overline{w}_{i,\Omega_i} - \overline{w}_{j,\Omega_j})|^2_{H^1(\Omega_i)} = |\theta_{\mathcal{E}^{ij}}|^2_{H^1(\Omega_i)}|\overline{w}_{i,\Omega_i} - \overline{w}_{j,\Omega_j}|^2.$$

The energy of $\theta_{\mathcal{E}^{ij}}$ is estimated in Lemma 4.4. Adding and subtracting the common value $w_{i,\mathcal{V}^{ik}} = w_{j,\mathcal{V}^{ik}}$ at a primal vertex $\mathcal{V}^{ik}$, which is an endpoint of $\mathcal{E}^{ij}$, we find that

$$|\overline{w}_{i,\Omega_i} - \overline{w}_{j,\Omega_j}|^2 \leq 2|\overline{w}_{i,\Omega_i} - w_{i,\mathcal{V}^{ik}}|^2 + 2|\overline{w}_{j,\Omega_j} - w_{j,\mathcal{V}^{ik}}|^2.$$

For the first term on the right-hand side, we obtain, using the discrete Sobolev inequality (4.2),

$$\begin{aligned} |w_{i,\mathcal{V}^{ik}} - \overline{w}_{i,\Omega_i}|^2 &\leq \|w^{(i)} - \overline{w}_{i,\Omega_i}\|^2_{L_\infty(\Omega_i)} \\ &\leq C(1+\log(H_i/h_i))|w^{(i)}|^2_{H^1(\Omega_i)}. \end{aligned} \tag{4.9}$$

We can proceed in the same way with the second term. ∎

5. Numerical results. In this section, we present numerical results for some irregular (and regular) subdomains for the Poisson and linear elasticity problems in two dimensions using linear finite elements. In our FETI–DP algorithm, all subdomain vertices are primal and there are no additional primal variables. We solve the linear systems of equations by the conjugate gradient method until a relative residual reduction of rtol=$1e-10$ is reached. Our FETI–DP implementation [21] uses PETSc [4, 3, 5].

5.1. Geometries. We examine the effect of three different types of geometries. We first consider the case of the unit square, discretized using a structured mesh and decomposed into 4×4 subdomains. We consider a regular (see Figure 5.2 (upper)) and an irregular, ragged decomposition (see Figure 5.2 (lower)) of this mesh. The irregular decomposition is constructed in the following way. We start with quadrilateral elements and the unit square decomposed into square subdomains. We then reassign some elements to neighboring subdomains in the following way: all elements, except those touching the subdomain vertices, are reassigned in an alternating way. Each quadrilateral is then replaced by two triangles. Such ragged decompositions have previously been considered by Mandel, Dohrmann, and Tezaur; see, e.g., [28].

We then consider 3×3 subdomains and an unstructured mesh. We consider a standard, regular decomposition (see Figure 5.4) and one where the interface Γ is defined in a recursive way (see Figure 5.3) as a fractal snowflake. These subdomains are obtained by first partitioning the unit square into smaller squares. We then replace the middle third of each edge by two other edges of an equilateral triangle, increasing the length of the interface by a factor 4/3. The middle third of each of the resulting shorter edges is then replaced in the same way, and this process is repeated until the desired refinement level is reached. This procedure gives us an interface which is snowflake-like; see Figure 5.1.

5.2. Poisson's equation. We first consider the Poisson problem for our different geometries using homogeneous Dirichlet boundary conditions and different values of H/h. For unstructured meshes, we approximate H/h by $(\text{dof})^{1/2}$, the square root of the total number of degrees of freedom of a single subdomain. We compare the iteration numbers and the condition numbers for two different scalings. The ρ-scaling is the standard scaling as in (3.3) which uses the local coefficient of the PDE; see also [36, 25, 24]. The results of this paper are valid only for this type of scaling.

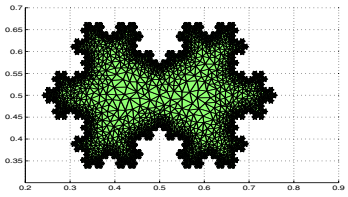

FIG. 5.1. *A snowflake-shaped subdomain, recursion level* 4.

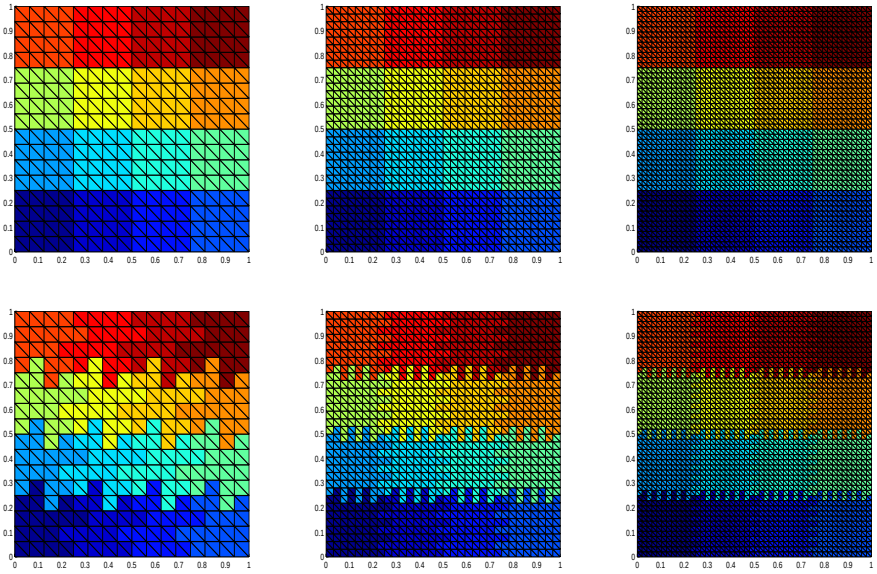

FIG. 5.2. *Upper: Structured mesh, regular subdomains,* $N = 16$, $H/h = 4, 8, 12$. *Lower: Structured mesh irregular (ragged) subdomains,* $N = 16$, $H/h = 4, 8, 12$.

Since we treat only problems with constant coefficients, the ρ-scaling reduces to the multiplicity scaling of [33, 34]. We can therefore describe this scaling as follows: the multiplicity of a node is the number of subdomains it belongs to. The multiplicity scaling then scales the contribution from and to each node by the inverse of the multiplicity.

The stiffness scaling, cf. [33, 34], refers to a common practice in iterative substructuring codes, which has been introduced for problems with variable coefficients to approximate the ρ-scaling. In the stiffness scaling, the diagonals of the local stiffness matrices are used to approximate the local coefficients. If we have constant coefficients, a structured mesh, and a regular decomposition into subdomains, then the stiffness scaling reduces to the multiplicity scaling, but this is not the case for an irregular decomposition.

Indeed, in the case of a structured mesh and a regular decomposition (see Figure 5.2 (upper)) we get the same results for the two types of scalings (see Table 5.1) and the expected $C(1+\log(H/h))^2$ behavior of the condition number (see Figure 5.6).

However, for an irregular decomposition as in Figure 5.2 (lower), a significant deterioration of the condition number is found and the rate of convergence for increasing

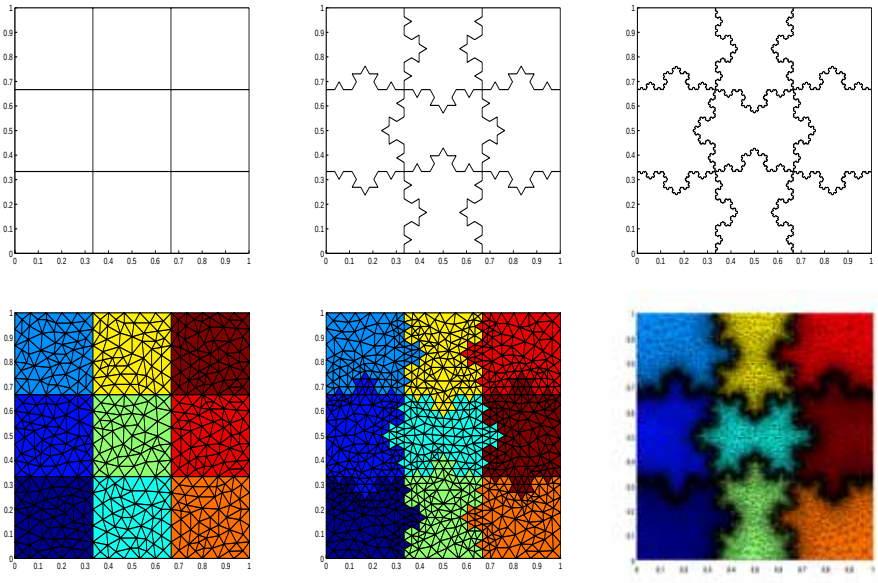

FIG. 5.3. *Unstructured mesh, irregular subdomains (snowflakes),* $N = 9$. *Level* 0, 2, *and* 4.

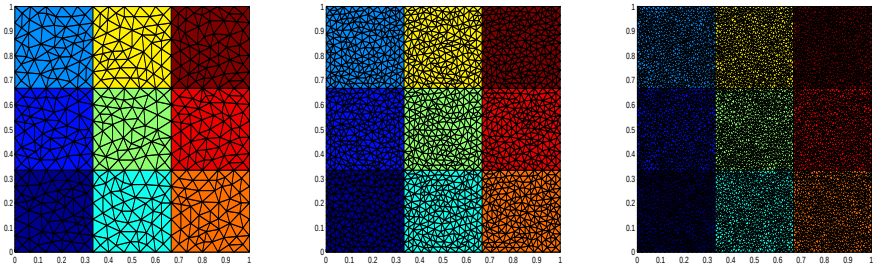

FIG. 5.4. *Unstructured mesh, regular subdomains,* $N = 9$. *Refinement level* 0, 1, *and* 2.

values of H/h; see Table 5.2 and Figure 5.5.

From Figure 5.5, we can see that for the ρ-scaling, we can again numerically confirm the expected $C(1 + \log(H/h))^2$ bound for the condition number. However, we see a linear growth in H/h of the condition number if the stiffness scaling is used. The growth of the condition number is also reflected in the iteration count.

In order to verify that the condition number is independent of the number of subdomains for a fixed H/h also in the irregular case, we choose $H/h = 16$ in Table 5.3 and increase the number of subdomains N. We see that the iteration count as well as the condition numbers are indeed uniformly bounded.

We then consider the case where we have an interface which is similar to a fractal snowflake. The finite element meshes are unstructured. We note that the number of nodes on the interface grows rapidly with the level of refinement of the snowflakes; cf. Tables 5.4 and 5.5. In spite of this, Tables 5.4 and 5.5, show that the condition number of the preconditioned FETI–DP operator only exceeds that of the trivial case by a factor of 3 resulting in a doubling of the number of conjugate gradient iterations

if ρ-scaling is used. Figure 5.7 indicates that the square root of the condition number grows linearly with the logarithm of the number of degrees of freedom of individual subdomains. We also get such a bound for the unstructured regular case; see Table 5.5

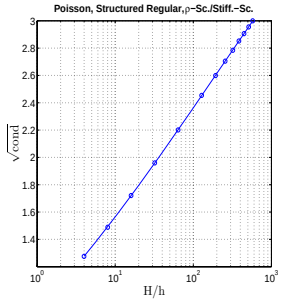

FIG. 5.6. *Poisson (Table 5.1): Structured regular, $N = 16$. Semilog plot of $\sqrt{cond}$ versus H/h. ρ-scaling and stiffness scaling give identical results.*

5.3. Elasticity. We have repeated all the experiments of section 5.2 for the problem of linear elasticity. We essentially get the same results; cf. Figures 5.9, 5.10, 5.11, 5.12, and Tables 5.6, 5.7, 5.8, 5.9, 5.10. We confirm the $C(1+\log(H/h))^2$ bound for all cases where the ρ-scaling is applied, and we see linear or even superlinear behavior in H/h of the condition number for the cases where the stiffness scaling is used with unstructured interfaces.

COMPUTING A^α, $\log(A)$, AND RELATED MATRIX FUNCTIONS BY CONTOUR INTEGRALS*

NICHOLAS HALE†, NICHOLAS J. HIGHAM‡, AND LLOYD N. TREFETHEN†

Abstract. New methods are proposed for the numerical evaluation of $f(\mathbf{A})$ or $f(\mathbf{A})b$, where $f(\mathbf{A})$ is a function such as $\mathbf{A}^{1/2}$ or $\log(\mathbf{A})$ with singularities in $(-\infty, 0]$ and $\mathbf{A}$ is a matrix with eigenvalues on or near $(0, \infty)$. The methods are based on combining contour integrals evaluated by the periodic trapezoid rule with conformal maps involving Jacobi elliptic functions. The convergence is geometric, so that the computation of $f(\mathbf{A})b$ is typically reduced to one or two dozen linear system solves, which can be carried out in parallel.

Key words. Cauchy integral, conformal map, contour integral, matrix function, quadrature, rational approximation, trapezoid rule

AMS subject classifications. 65F30, 65D30

DOI. 10.1137/070700607

1. Introduction.

It is well known that an analytic function f of a square matrix $\mathbf{A}$ can be represented as a contour integral,

$$f(\mathbf{A}) = \frac{1}{2\pi i} \int_\Gamma f(z)\,(z\mathbf{I} - \mathbf{A})^{-1}\,dz, \tag{1.1}$$

where Γ is a closed contour lying in the region of analyticity of f and winding once around the spectrum $\sigma(\mathbf{A})$ in the counterclockwise direction. However, this idea has not often been exploited for numerical computation. Here we propose efficient ways to make use of (1.1) in the case where $\mathbf{A}$ has eigenvalues on or near the positive real axis $(0, \infty)$, and $f(z)$ is a function such as z^α or $\log z$ that is analytic apart from singularities or a branch cut on or near the negative real axis $(-\infty, 0]$. To be precise, it is not the matrix $f(\mathbf{A})$ that we usually compute but the vector $f(\mathbf{A})b$ for a given vector b. The first method we propose is to transplant the problem by a conformal map to an annulus and then apply the trapezoid rule, which converges geometrically (section 2). This procedure will be especially effective in cases where $\mathbf{A}$ is what might be called a "backslash matrix": a large sparse matrix for which systems of equations $(z\mathbf{I} - \mathbf{A})x = b$ can be solved efficiently by sparse direct methods but Krylov subspace iterations and Schur reduction to triangular form are impractical. An example is the matrix corresponding to the standard 5-point finite difference discretization of the Laplacian in two dimensions.

We then consider two modifications to this technique to take advantage of a particular structure of f: first, if f has a branch cut but no singularities on $(-\infty, 0)$ (section 3); second, if $f(z) = z^{1/2}$ (section 4). (Here and throughout this paper, the notations $z^{1/2}$, z^α, and $\log z$ refer to the standard branches of these functions,

and $\mathbf{A}^{1/2}$ and so on to the corresponding principal branches of the matrix functions.) Significant improvements can be achieved in such cases, including the avoidance of complex arithmetic.

All our methods based on quadrature formulas can be interpreted as making implicit use of rational approximations $f(z) \approx r(z)$ in regions of the complex plane. In section 5 we examine how these implicitly constructed rational functions compare with those obtained by solving a rational approximation problem directly. For the case $f(z) = z^{1/2}$, we find that the combination of our conformal map with the trapezoid rule reproduces a best rational approximation discovered by Zolotarev in 1877.

In section 6 we consider the effect of complex eigenvalues on the convergence of our methods, and section 7 examines three further numerical examples.

Before beginning, we shall slightly change the starting point. We have found that for the problems considered here a better way to obtain $f(\mathbf{A})$ is often by computing $\mathbf{A} \cdot \mathbf{A}^{-1} f(\mathbf{A})$, replacing (1.1) with the formula

$$f(\mathbf{A}) = \frac{\mathbf{A}}{2\pi i} \int_\Gamma z^{-1} f(z) \, (z\mathbf{I} - \mathbf{A})^{-1} \, dz. \tag{1.2}$$

The reason is that the dz factor becomes large as Γ swings out into the complex plane, and the factor z^{-1} counters this effect. For the first two methods derived in sections 2 and 3, the use of (1.2) instead of (1.1) typically improves accuracy by a digit or two. For the method of section 4, its use is essential since the contour passes through $z = \infty$.

For general information about the theory and computation of functions of matrices, see [11].

2. Method 1: Conformal map from an annulus. Let $\mathbf{A}$ be a real matrix whose eigenvalues lie in the interval $(0, \infty)$. In many applications $\mathbf{A}$ will be symmetric, but we do not require this. The assumption that $\mathbf{A}$ is real will save a factor of two by allowing trapezoid sums to exploit symmetry. The assumption that the eigenvalues are real can be relaxed; our methods do not degrade very much if the eigenvalues move slightly off the real axis, as illustrated in section 6.

Let m and M be the minimum and maximum eigenvalues of $\mathbf{A}$, respectively. If $\mathbf{A}$ is symmetric, or more generally normal, then M/m is its 2-norm condition number, whereas for general $\mathbf{A}$ the condition number may be larger. We assume at the outset that m and M are known, although in practice it would often be necessary first to estimate them. We also suppose that $\sigma(\mathbf{A})$ more or less fills $[m, M]$ in the sense that we do not attempt to exploit any gaps in the spectrum.

The assumption we make initially about f is that it is analytic in the slit complex plane $\mathbb{C}\backslash(-\infty, 0]$. This is true, for example, if $f(z) = \log z$ or $f(z) = z^\alpha = e^{\alpha \log z}$ (for any $\alpha \in \mathbb{R}$) for the standard branches. It is also true of more complicated functions such as $f(z) = \Gamma(z)$ or $f(z) = \tanh(z^{1/2})$.

One numerical approach to (1.2) is to surround $[m, M]$ by a circle in the right half-plane and apply the trapezoid rule on this circle to approximate the integral, as sketched in Figure 1. However, this method will be terribly inefficient if $\mathbf{A}$ is ill-conditioned, requiring $O(M/m)$ or more linear system solves to get any accuracy at all [4], because Γ is contained in only a very narrow annulus of analyticity, the annulus centered at $(M + m)/2$ with outer radius $(M + m)/2$ and inner radius $(M - m)/2$. Our strategy will be to improve the problem by a change of variables in the complex plane, which will bring the count down to $O(\log(M/m))$. The idea of combining the trapezoid rule with a change of variables was put forward for real integrals by Sag and Szekeres in 1964 [20] and Schwartz in 1969 [22] and developed more fully in the

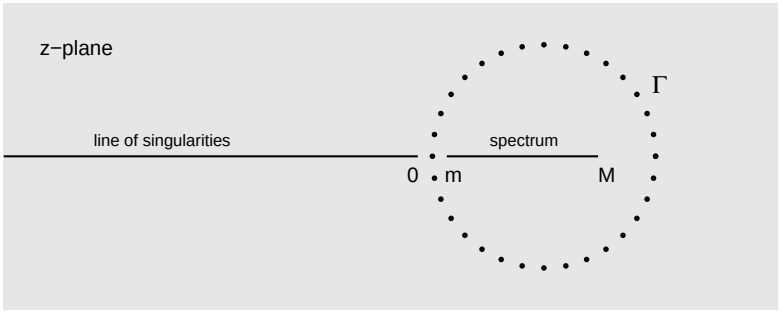

FIG. 1. *Depiction of the trapezoid rule applied directly to* (1.2)*, with the contour* Γ *taken as a circle. This method is highly inefficient if* $M \gg m$.

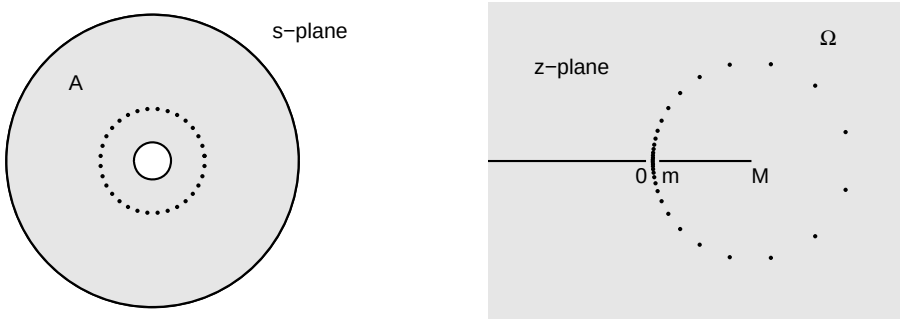

FIG. 2. *Conformal map for Method* 1. *First, transplant the entire doubly connected region of analyticity* Ω *conformally to an annulus* $\mathcal{A}$*, with the line of singularities mapping to the outer boundary circle and the interval containing the spectrum to the inner one. Then apply the trapezoid rule over a circle in the annulus. This will correspond to a nonuniform distribution of quadrature points in the z-plane. In this figure* $M/m = 8$ *and the annulus is quite thick. As* M/m *increases, it becomes thinner only logarithmically. The dots show quadrature nodes for* $N = 16$.

1970s by Iri, Moriguti, and Takasawa [12], Mori [17], Takahasi and Mori [28, 29], and Stenger [25, 26, 27], among others. For inverse Laplace transform contour integrals, such ideas were developed by Talbot in 1979 [30] and have been exploited by a variety of authors [10, 16, 23, 31], and the parameters have recently been optimized in various senses by Weideman and Trefethen [36], Weideman [35], and Trefethen, Weideman, and Schmelzer [33]. However, we are not aware of previous papers on such methods for the matrix function problems considered here.

Our aim is to transplant the region of analyticity of f and $(z\mathbf{I}-\mathbf{A})^{-1}$ conformally to an annulus

$$\mathcal{A} = \{z \in \mathbb{C} : r < |z| < R\}.$$

According to results going back in part to Poisson in the 1820s and first fully worked out by Davis in the 1950s [5], [6, section 4.6.5], the trapezoid rule applied over a circle within $\mathcal{A}$ will converge geometrically as $N \to \infty$, where N is the number of sample points. Moreover, this will be a thicker annulus than was available before the conformal map (Figure 1), which will make the convergence constant quite favorable.

This strategy is sketched in Figure 2. The region in question is the doubly connected set

$$\Omega = \mathbb{C}\backslash\big((-\infty, 0] \cup [m, M]\big).$$

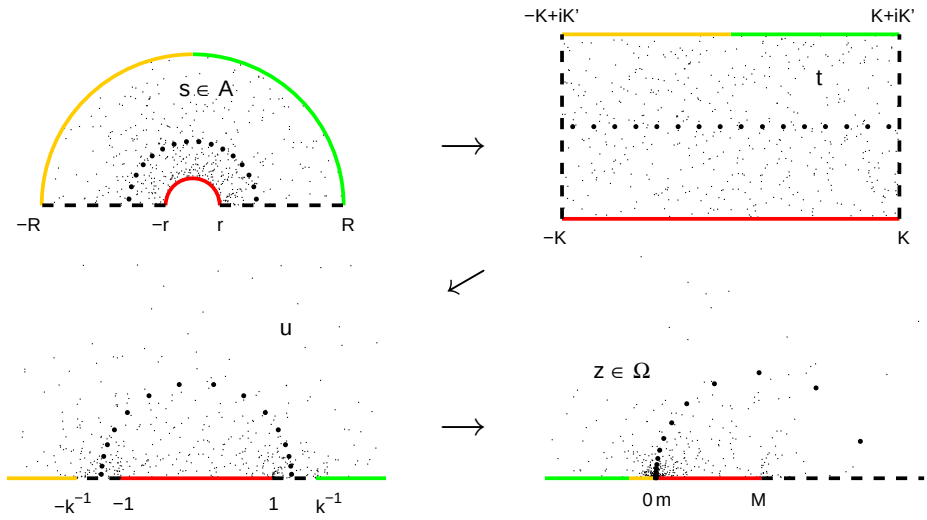

FIG. 3. *The map of Figure* 2, *constructed in three steps* $s \to t \to u \to z$. *Here* $m = 1$, $M = 20$. *The boundaries are shown in various colors and line styles together with* 500 *random interior points in the rectangle and a typical set of* $N = 16$ *quadrature points for the trapezoid rule in the* t*-plane. Notice how the narrow gap between* 0 *and* m *in the* z*-plane broadens to a comfortable ratio* $R/r \approx 5.8$ *in the annulus.*

We thus face a conformal mapping problem: How to map this domain Ω onto an annulus $\mathcal{A}$? More precisely it is the map from $\mathcal{A}$ to Ω that we shall need to compute. The radii R and r are not entirely at our disposal: The formulas below imply that R/r is determined by M/m.

The map can be carried out in three steps, as shown in Figure 3. First, the function

$$t = \frac{2Ki}{\pi} \log(-is/r)$$

carries the upper half of $\mathcal{A}$ to the rectangle with vertices $\pm K$ and $\pm K + iK'$. The numbers K and K' are complete elliptic integrals whose values are fixed by the next step of the conformal map. In this second step the Jacobi elliptic function

$$u = \mathrm{sn}(t) = \mathrm{sn}(t|k^2), \qquad k = \frac{\sqrt{M/m} - 1}{\sqrt{M/m} + 1}, \tag{2.1}$$

maps the rectangle to the upper half-plane, with the ends mapping to $[-k^{-1}, -1]$ and $[1, k^{-1}]$ (see [1, 9]). Finally, the Möbius transformation

$$z = \sqrt{mM} \left(\frac{k^{-1} + u}{k^{-1} - u} \right) \tag{2.2}$$

carries the upper half-plane to itself in such a way that $[-k^{-1}, -1]$ and $[1, k^{-1}]$ are sent to $[0, m]$ and $[M, \infty]$, respectively. We have now mapped the upper half of $\mathcal{A}$ to the upper half of Ω. Reflection across the interval (r, R) (using the Schwarz reflection principle) extends this map to all of $\mathcal{A}$ and all of Ω.

Conceptually, this map from $\mathcal{A}$ to Ω shows the essence of our method most clearly. To apply the trapezoid rule and derive corresponding theorems, however, we can

bypass $\mathcal{A}$ and work with the map from the K, K' rectangle in the t-plane to Ω. (Thus, although R/r is implicitly determined by K and K', we never make a choice of R or r individually, and they do not appear in our MATLAB programs.) By composing (2.2) and (2.1) we get

$$z = \sqrt{mM}\left(\frac{k^{-1}+\mathrm{sn}(t)}{k^{-1}-\mathrm{sn}(t)}\right), \qquad k = \frac{\sqrt{M/m}-1}{\sqrt{M/m}+1}. \tag{2.3}$$

The integral (1.2) can accordingly be written

$$f(\mathbf{A}) \;=\; \frac{-\mathbf{A}}{2\pi i}\int_{-K+iK'/2}^{3K+iK'/2} z^{-1} f(z(t))\,(z(t)-\mathbf{A})^{-1}\,\frac{dz}{du}\,\frac{du}{dt}\,dt;$$

the limits $-K+iK'/2$ to $K+iK'/2$ would correspond to the part of Γ in the upper half-plane (the dots in the fourth panel of Figure 3), and extending this to $3K+iK'/2$ brings in the part in the lower half-plane. With the aid of the identities

$$\frac{dz}{du} = \frac{2k^{-1}\sqrt{mM}}{(k^{-1}-u)^2}, \qquad \frac{du}{dt} = \mathrm{sn}'(t) = \sqrt{1-k^2u^2}\,\sqrt{1-u^2} = \mathrm{cn}(t)\,\mathrm{dn}(t),$$

where cn and dn are further Jacobi elliptic functions in standard notation [1], this becomes

$$f(\mathbf{A}) \;=\; \frac{-\mathbf{A}\sqrt{mM}}{\pi i k}\int_{-K+iK'/2}^{3K+iK'/2} \frac{z^{-1} f(z(t))\,(z(t)-\mathbf{A})^{-1}\,\mathrm{cn}(t)\,\mathrm{dn}(t)}{(k^{-1}-u)^2}\,dt. \tag{2.4}$$

Now since $\mathbf{A}$ is real, the integrand is real-symmetric, i.e., the values it takes at two points z and $\bar{z}$ are complex conjugate. It follows that $f(\mathbf{A})$ is twice the real part of the value obtained by integrating over the first half of the contour, or if we cancel the i in the denominator,

$$f(\mathbf{A}) = \frac{-2\mathbf{A}\sqrt{mM}}{\pi k}\;\mathrm{Im}\int_{-K+iK'/2}^{K+iK'/2} \frac{z^{-1} f(z(t))\,(z(t)-\mathbf{A})^{-1}\,\mathrm{cn}(t)\,\mathrm{dn}(t)}{(k^{-1}-u)^2}\,dt, \tag{2.5}$$

with $z(t)$ given by (2.3).

We now apply the trapezoid rule with N equally spaced points in $(-K+iK'/2, K+iK'/2)$,

$$t_j = -K + \frac{iK'}{2} + 2\frac{(j-\frac{1}{2})K}{N}, \quad 1 \le j \le N. \tag{2.6}$$

(Actually this choice should more precisely be called the midpoint rule. One could make it a true trapezoid rule by shifting the sample points to include the endpoints with weights 1/2.) The result becomes $f(\mathbf{A}) \approx f_N(\mathbf{A})$ with

$$f_N(\mathbf{A}) \;=\; \frac{-4K\mathbf{A}\sqrt{mM}}{\pi N k}\;\mathrm{Im}\sum_{j=1}^{N} \frac{f(z(t_j))\,(z(t_j)\mathbf{I}-\mathbf{A})^{-1}\,\mathrm{cn}(t_j)\,\mathrm{dn}(t_j)}{z(t_j)\,(k^{-1}-u(t_j))^2}. \tag{2.7}$$

(If A is not real, then extend the limits in (2.6) and (2.7) from N to $2N$, and in (2.7), replace $4K$ by $2K$ and multiply by $-i$ instead of extracting the imaginary part.)

The convergence of the method we have described is geometric, with the constant of convergence worsening only logarithmically as $M/m \to \infty$.

THEOREM 2.1. *Let* $\mathbf{A}$ *be a real matrix with eigenvalues in* $[m, M]$, $0 < m < M$, *and let* f *be a function analytic in* $\mathbb{C}\backslash(-\infty, 0]$. *Then the* N*-point conformally transplanted quadrature formula* (2.7) *converges at the rate*

$$\|f(\mathbf{A}) - f_N(\mathbf{A})\| = O\big(e^{\varepsilon - \pi K' N/(2K)}\big) \tag{2.8}$$

for any $\varepsilon > 0$ *as* $N \to \infty$, *and the constant in the exponent is asymptotically* $\pi K'/(2K) \sim \pi^2/\log(M/m)$ *as* $M/m \to \infty$. *For any* M *and* m *we have*

$$\|f(\mathbf{A}) - f_N(\mathbf{A})\| = O\big(e^{-\pi^2 N/(\log(M/m)+3)}\big). \tag{2.9}$$

Proof. The formula (2.7) for $f_N(\mathbf{A})$ comes from applying the trapezoid rule to a function in the t-plane that is analytic in a strip of half-width $a = K'/2$, with grid spacing $\Delta t = 2K/N$. Standard results on the trapezoid rule for periodic integrands imply convergence in such a context at the rate $O(e^{\varepsilon - 2\pi a/\Delta t})$ for any $\epsilon > 0$ [5, 6], and combining these numbers gives (2.8). The claim about asymptotics follows from the relationship $K'/K \sim \pi/(\log(16) - \log(1-k^2)) \sim -\pi/\log(1-k)$ as $k \to 1$ for Jacobi elliptic functions [1, eq. (17.3.26)] together with the relationship $\log(M/m) \sim -2\log(1-k)$ implied by (2.1). The bound $\pi^2/(\log(M/m)+3) < (\pi/2)(K'/K)$ needed to derive (2.9) from (2.8) was established numerically. ∎

We can illustrate Method 1 by the following MATLAB script. Standard MATLAB includes functions to evaluate $\mathrm{sn}(z)$ for real arguments only. This program needs complex arguments, and for this purpose it calls the functions `ellipkkp` and `ellipjc` from Driscoll's Schwarz–Christoffel Toolbox [7, 8], which is freely available online. The mathematical basis of these codes is outlined in [9].

This test code `method1`, like `method2` and `method3` to follow, computes the whole matrix function $f(\mathbf{A})$ rather than just a vector $f(\mathbf{A})b$. Our purpose is to illustrate convergence rates as a function of the number of sample points N, which we can do just as well for a small matrix that can be fully inverted. The matrix illustrated here is the 5×5 Pascal triangle matrix `pascal(5)`, with $M/m \approx 10^4$. The code begins by computing the minimal and maximal eigenvalues m and M, although, in practice, some kind of estimation would normally be used.

```
% method1.m - evaluate f(A) by contour integral.  The functions
%             ellipkkp and ellipjc are from Driscoll's SC Toolbox.

  f = @sqrt;                    % change this for another function f
  A = pascal(5);                % change this for another matrix A
  X = sqrtm(A);                 % change this if f is not sqrt
  I = eye(size(A));
  e = eig(A); m = min(e); M = max(e);   % use only for toy problems!
  k = (sqrt(M/m)-1)/(sqrt(M/m)+1);
  L = -log(k)/pi;
  [K,Kp] = ellipkkp(L);
  for N = 5:5:40
      t = .5i*Kp - K + (.5:N)*2*K/N;
      [u cn dn] = ellipjc(t,L);
      z = sqrt(m*M)*((1/k+u)./(1/k-u));
      dzdt = cn.*dn./(1/k-u).^2;
      S = zeros(size(A));
      for j = 1:N
          S = S + (f(z(j))/z(j))*inv(z(j)*I-A)*dzdt(j);
```

```
    end
    S = -4*K*sqrt(m*M)*imag(S)*A/(k*pi*N);
    error = norm(S-X)/norm(X);
    fprintf('%4d %10.2e\n', N, error)
end
```

Here are the relative errors $\|f(\mathbf{A}) - f_N(\mathbf{A})\|/\|f(\mathbf{A})\|$ printed by this program ($\|\cdot\|$ is the 2-norm), showing 15-digit precision for $N \approx 40$. If M/m were only 10^2 (assuming $\mathbf{A}$ is symmetric or more generally normal), then $N \approx 20$ would be enough to achieve the same accuracy. If $z^{1/2}$ is replaced by $\log z$, then the performance is about the same.

```

In a sequence of computations like this, one could reuse certain data points. For example, the resolvents evaluated for $N = 10$ are evaluated again for $N = 30$. We have not attempted to exploit this redundancy; if one were doing so, it would be advantageous to switch from the midpoint to the true trapezoid formulation, as discussed above, to make the overlaps occur at multiples of 2 rather than 3.

We conclude this section with an example involving a more challenging function f, with singularities all along $(-\infty, 0]$, and a nonnormal matrix with eigenvalues at $(3 \pm \sqrt{5})/2$:

$$\mathbf{A} = \begin{pmatrix} 1 & \frac{1}{2} \\ 2 & 2 \end{pmatrix}, \qquad f(z) = \Gamma(z).$$

The gamma function has poles at all the nonpositive integers, but that is not a problem for Method 1. Taking $N = 42$ is enough to give a result accurate to ten digits,

$$\Gamma(\mathbf{A}) = \begin{pmatrix} 2.0835578979 & -0.1960182234 \\ -0.7840728935 & 1.6915214512 \end{pmatrix},$$

as is readily checked by a diagonalization of $\mathbf{A}$. Of course the point of our method is that it is applicable also in cases where the dimension of $\mathbf{A}$ is such that diagonalization is impractical, or indeed, if $\mathbf{A}$ is not diagonalizable at all. Another approach to the computation of $\Gamma(\mathbf{A})$ based on a Hankel integral has been discussed in [21].

3. Method 2: When $(-\infty, 0)$ is just a branch cut. The assumption of the last section was that f might have arbitrary singularities on $(-\infty, 0]$. In practice, many functions of interest, including z^α and $\log z$, have a singularity at $z = 0$ but just a branch cut on $(-\infty, 0)$. This means that $f(z)$ can be analytically continued along any path that avoids $z = 0$; the difficulty for $z \neq 0$ is only that the value of $f(z)$ will change if the path winds around the origin. Thus we may regard f either as a single-valued function on the slit plane $\mathbb{C}\backslash(-\infty, 0]$ or as a multivalued function on a Riemann surface associated with the punctured plane $C\backslash\{0\}$.

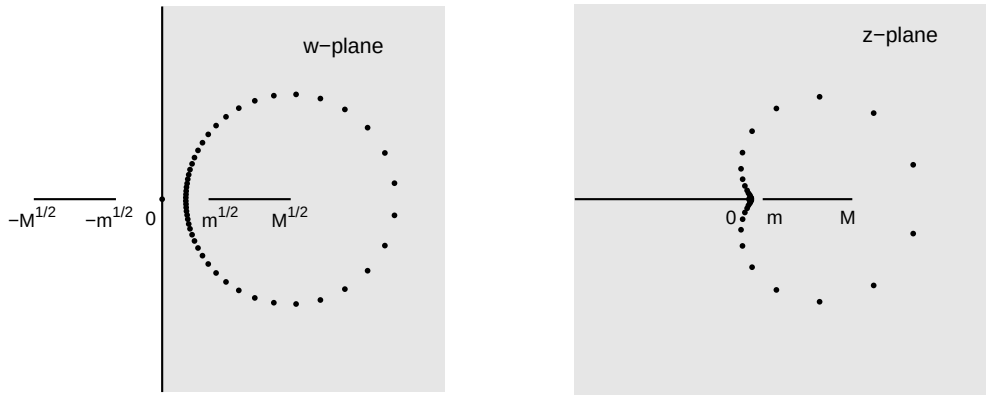

FIG. 4. *In Method 2, for problems where $f(z)$ has only a branch cut on $(-\infty, 0)$, we apply the same quadrature points seen in the fourth panel of Figure 3 to the function $f(w^2)$ in the w-plane (left). This square-roots the condition number and approximately doubles the rate of convergence. In the z-plane, the new method corresponds to a quadrature rule with the nodes shown on the right.*

For functions of this kind, Method 1 is not as efficient as it might be, since it employs a contour that avoids $[m, M]$ and all of $(-\infty, 0]$ rather than just $[m, M]$ and $\{0\}$. One way to improve matters is sketched in Figure 4. If we introduce a new variable $w = z^{1/2}$, $dz = 2w\,dw$, then (1.2) becomes

$$f(\mathbf{A}) = \frac{\mathbf{A}}{\pi i} \int_{\Gamma_w} w^{-1} f(w^2) \, (w^2 - \mathbf{A})^{-1} dw. \tag{3.1}$$

Under the square root, the branch cut of f along $(-\infty, 0]$ in the z plane unfolds to the imaginary axis in the w-plane. The assumption on $f(z)$ then implies that $f(w^2)$ can be analytically continued to an analytic function throughout the slit w-plane $\mathbb{C}\backslash(-\infty, 0]$. Thus we have a new contour integral problem, where the contour should lie in the slit plane and enclose $[m^{1/2}, M^{1/2}]$. The geometry is the same as in the last section, but with $[m, M]$ improved to $[m^{1/2}, M^{1/2}]$. Accordingly, we may use the same method as before. The formula for the new method applied to a real matrix $\mathbf{A}$ is

$$f_N(\mathbf{A}) = \frac{-8K\mathbf{A}(mM)^{1/4}}{\pi N k} \, \mathrm{Im} \sum_{j=1}^{N} \frac{f(w(t_j)^2) \, (w(t_j)^2 \mathbf{I} - \mathbf{A})^{-1} \, \mathrm{cn}(t_j) \mathrm{dn}(t_j)}{w(t_j) \, (k^{-1} - u(t_j))^2}, \tag{3.2}$$

where the t_j are again given by (2.6), but now (2.3) is modified to

$$w = (mM)^{1/4} \left(\frac{k^{-1} + \mathrm{sn}(t)}{k^{-1} - \mathrm{sn}(t)} \right), \qquad k = \frac{(M/m)^{1/4} - 1}{(M/m)^{1/4} + 1}, \tag{3.3}$$

and the values of K and K' are the complete elliptic integrals associated with this new parameter k. For a complex matrix $\mathbf{A}$ the modifications are as for Method 1.

Here is a MATLAB code.

```
% method2.m - Variant of method1.m for evaluating f(A) by contour
%             integration, assuming only a branch cut along (-inf,0).

  f = @sqrt;                    % change this for another function f
```

```
A = pascal(5);                % change this for another matrix A
X = sqrtm(A);                 % change this if f is not sqrt
I = eye(size(A));
e = eig(A); m = min(e); M = max(e);   % only for toy problems
k = ((M/m)^(1/4)-1)/((M/m)^(1/4)+1);
L = -log(k)/pi;
[K,Kp] = ellipkkp(L);
for N = 5:5:25
    t = .5i*Kp - K + (.5:N)*2*K/N;
    [u cn dn] = ellipjc(t,L);
    w = (m*M)^(1/4)*((1/k+u)./(1/k-u));
    dzdt = cn.*dn./(1/k-u).^2;
    S = zeros(size(A));
    for j = 1:N
        S = S + (f(w(j)^2)/w(j))*inv(w(j)^2*I-A)*dzdt(j);
    end
    S = -8*K*(m*M)^(1/4)*imag(S)*A/(k*pi*N);
    error = norm(S-X)/norm(X);
    fprintf('%4d %10.2e\n', N, error)
end
```

The new code converges a good deal faster than the previous one, as expected, getting close to full precision for $N \approx 25$ for this matrix with $M/m \approx 10^4$. Again the results are similar if $z^{1/2}$ is replaced by $\log z$.

The same arguments as before give us a convergence theorem. Asymptotically as $M/m \to \infty$, Method 2 is twice as fast as Method 1, though the improvement is less than a factor of 2 for finite M/m.

THEOREM 3.1. *Let* $\mathbf{A}$ *be a real matrix with eigenvalues in* $[m, M]$*, and let* f *be a function analytic in* $\mathbb{C}\backslash(-\infty, 0]$ *that can be continued analytically across* $(-\infty, 0)$ *from the upper half-plane to the lower half-plane. Then the* N*-point improved formula* (3.2) *converges at the rate*

$$\|f(\mathbf{A}) - f_N(\mathbf{A})\| = O\big(e^{\varepsilon - \pi K' N/(2K)}\big) \tag{3.4}$$

for any $\varepsilon > 0$*, where* K *and* K' *are the complete elliptic integrals associated with the parameter* k *of* (3.3)*, and the constant in the exponent is asymptotically* $\pi K'/(2K) \sim 2\pi^2/\log(M/m)$ *as* $M/m \to \infty$*. For any* M *and* m *we have*

$$\|f(\mathbf{A}) - f_N(\mathbf{A})\| = O\big(e^{-2\pi^2 N/(\log(M/m)+6)}\big). \tag{3.5}$$

4. Method 3: Special treatment for $f(z) = z^{1/2}$. The function $f(w^2)$ in the w-plane in the last section, as sketched in Figure 4, has a singularity in general at the origin; that is why the quadrature points must pass between 0 and $m^{1/2}$. For the particular case $f(z) = z^{1/2} = w$, however, there is no singularity, because the change

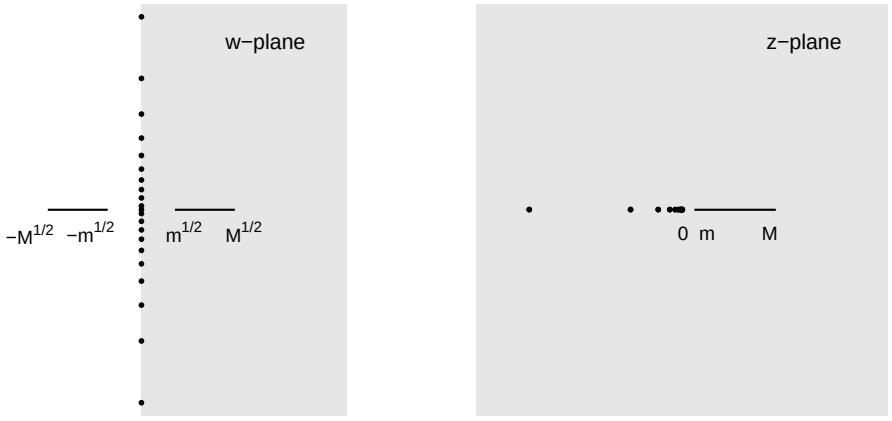

FIG. 5. *Quadrature points for Method* 3. *With* $f(z) = z^{1/2}$, *we can now fully exploit the symmetry in the w-plane. The points in the z-plane lie in* $(-\infty, 0]$, *so all of the matrix arithmetic is real.*

of variables from z to w has eliminated it. Equation (3.1) becomes simply

$$\mathbf{A}^{1/2} = \frac{\mathbf{A}}{\pi i} \int_{\Gamma_w} (w^2 - \mathbf{A})^{-1} dw, \tag{4.1}$$

where Γ_w is a closed contour surrounding $[m^{1/2}, M^{1/2}]$ but not $[-M^{1/2}, -m^{1/2}]$. This makes some further improvements possible. First of all, the quadrature points can now safely approach or even pass through 0. Second, we can use the symmetry to put them on the imaginary axis, corresponding to the negative real axis in the z-plane, thereby eliminating the complex arithmetic in the linear algebra problems. Indeed, since the integrand is of size $O(w^{-2})$, (4.1) is equivalent to an integral over the imaginary axis alone,

$$\mathbf{A}^{1/2} = \frac{i\mathbf{A}}{\pi} \int_{-i\infty}^{i\infty} (w^2 - \mathbf{A})^{-1} dw. \tag{4.2}$$

(Essentially the same formula appears as equation (6.1) in [11].) Third, we can save a factor of two in discretizing this integral since $(w^2-\mathbf{A})^{-1} = ((-w)^2-\mathbf{A})^{-1}$, regardless of the properties of $\mathbf{A}$, so it will no longer matter whether or not $\mathbf{A}$ is real.

Figure 5 shows how Figure 4 changes in this special case. Figure 6 shows the conformal map we can use to compute this transformation, which is essentially the middle step of Figure 3, in which a rectangle is mapped to the upper half-plane. The rectangle in the t-plane is the same as before, and the function $w = m^{1/2}\,\mathrm{sn}(t \mid k^2)$ with

$$k = m^{1/2}/M^{1/2} \tag{4.3}$$

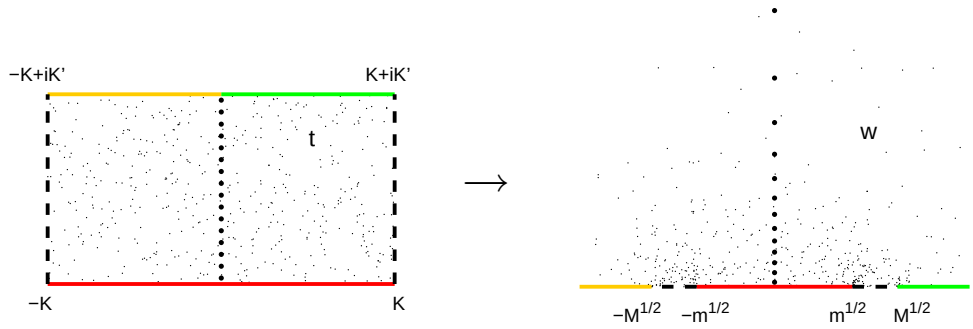

FIG. 6. *The conformal map for the quadrature points of Figure* 5 *is the scaled Jacobi sine function* $w = m^{1/2}\,\mathrm{sn}(t\,|\,k^2)$ *with* $k = m^{1/2}/M^{1/2}$. *Compare Figure* 3.

maps it onto the upper half w-plane. This time, however, it is the vertical midline of the rectangle, the imaginary interval $[0, iK']$, where the trapezoid rule is applied. This gives us the approximation

$$f_N(\mathbf{A}) \;=\; \frac{-2K'm^{1/2}\mathbf{A}}{\pi N}\;\sum_{j=1}^{N}(w(t_j)^2\mathbf{I}-\mathbf{A})^{-1}\,\mathrm{cn}(t_j)\,\mathrm{dn}(t_j) \tag{4.4}$$

with

$$t_j = i(j-\tfrac{1}{2})K'/N, \quad 1 \le j \le N. \tag{4.5}$$

Equation (4.4) works well, but like the algorithms of the past two sections, it has the disadvantage of requiring evaluation of elliptic functions for complex arguments. In this case, however, the arguments (4.5) are purely imaginary. This allows us to take advantage of equations (16.20.1)–(16.20.3) of [1], and the code below implements (4.4) requiring only MATLAB's standard elliptic routines `ellipke` and `ellipj`. For $M/m > 10^6$, however, this approach can be unstable, and better numerical stability is achieved by returning to `ellipkkp` and `ellipjc` from the SC Toolbox. The code has been constructed in such a way that this alteration can be carried out by replacing the line beginning `Kp = ⋯` by the two lines `L = -.5*log(k2)/pi; [K,Kp] = ellipkkp(L);` and the two lines beginning `[sn cn dn] = ⋯` and `cn = ⋯` by the single line `[sn cn dn] = ellipjc(t,L);`.

    S = (-2*Kp*sqrt(m)/(pi*N))*A*S;
    error(N) = norm(S-X)/norm(X);
    fprintf('%4d %10.2e\n', N, error(N))
end
```

Method 3 converges very quickly. For our matrix with condition number $M/m \approx 10^4$, nearly full precision is achieved with $N \approx 20$, and we get 6-digit precision with just 10 backslashes.

```

```

The map involved in Method 3 is essentially the same as that of Method 1, except with z improved to $w = z^{1/2}$. Accordingly, the same arguments as before lead to the following analogue of Theorem 2.1 with convergence rates twice as fast.

THEOREM 4.1. *Let* $\mathbf{A}$ *be a real or complex matrix with eigenvalues in* $[m, M]$. *Then the formulas* (4.3)–(4.5) *converge to* $\mathbf{A}^{1/2}$ *at the rate*

$$\|\mathbf{A}^{1/2} - f_N(\mathbf{A})\| = O\big(e^{\varepsilon - 2\pi KN/K'}\big) \tag{4.6}$$

for any $\varepsilon > 0$ *for the values of* K *and* K' *associated with the parameter* (4.3), *and the constant in the exponent is asymptotically* $\pi K'/(2K) \sim 2\pi^2/\log(M/m)$ *as* $M/m \to \infty$. *For any* M *and* m *we have*

$$\|\mathbf{A}^{1/2} - f_N(\mathbf{A})\| = O\big(e^{-2\pi^2 N/(\log(M/m)+3)}\big). \tag{4.7}$$

For $\mathbf{A} = \texttt{pascal(5)}$, for example, the theorem guarantees convergence at the rate $O(5^{-N})$, and for a matrix with $M/m = 10$ this rate increases to $O(41^{-N})$. Even with $M/m = 10^{10}$ the error is $O(2.1^{-N})$.

Figure 7 compares Methods 1, 2, and 3 for the function for which they are all applicable, $\mathbf{A}^{1/2}$, for two matrices with $M/m \approx 62.0$ and 2.06×10^7. Method 3 converges twice as fast as Method 1 in both cases, and it does not lose a factor of 2 if $\mathbf{A}$ is complex. (Its difficulties with rounding errors for the ill-conditioned matrix can be fixed by the use of the alternative formulation described above.) Method 2 has essentially the same convergence rate for the ill-conditioned matrix but falls between the other two methods for the well-conditioned one.

5. Connection with rational approximation. Since the time of Gauss it has been known that quadrature formulas are associated with rational functions: The nodes are the poles, and the weights are the residues. Thus the methods we have proposed can be interpreted as implicit descriptions of rational approximations

$$f(x) \approx r(x), \quad x \in [m, M]. \tag{5.1}$$

One might ask how close these approximations are to optimal. Conversely, if one constructs the optimal rational approximations, do they lead to good methods for

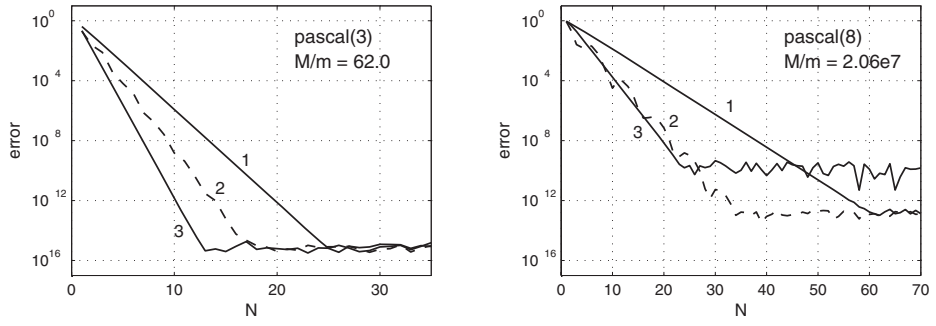

FIG. 7. *Convergence of Methods* 1, 2, *and* 3 *for computing* $\mathbf{A}^{1/2}$ *with* $\mathbf{A}$ = `pascal(3)` *and* `pascal(8)`. *Methods* 1 *and* 2 *are also applicable to more general functions than the square root. The loss of final accuracy in Method* 3 *can be fixed by the complex formulation described just above the listing of* `method3.m`.

evaluating $f(\mathbf{A})$? The same questions are considered in the context of Talbot contours for inverse Laplace transforms in [33].

The link to rational functions goes as follows. Suppose that by some quadrature procedure we derive an approximation

$$f(\mathbf{A}) \approx \mathbf{A} \sum_{j=1}^{N} \gamma_j (z_j - \mathbf{A})^{-1} \tag{5.2}$$

as in (2.7), (3.2), or (4.4), where f is assumed to have spectrum in $[m, M]$. This approximation defines a rational function of type (N, N) (numerator and denominator of degree $\le N$),

$$r(z) = \sum_{j=1}^{N} \frac{\gamma_j z}{z_j - z}. \tag{5.3}$$

It is easily seen that if the difference of the two sides of (5.2) has matrix norm ε, then $|f(\lambda) - r(\lambda)| \le \varepsilon$ must hold for any λ which is an eigenvalue of $\mathbf{A}$. Thus (5.1) certainly holds for the eigenvalues λ; presumably also for other $x \in [m, M]$ if the approximation was derived without reference to particular eigenvalues of $\mathbf{A}$. These comments apply whether A is normal or nonnormal; the difference in the nonnormal case is that whereas (5.2) implies (5.1) in the sense just discussed, the converse does not hold.

Figure 8 examines our three approximations from this point of view for the special case $f(z) = z^{1/2}$, $[m, M] = [1, 100]$, $N = 6$. The error curves $f(x) - r(x)$ are plotted for Methods 1, 2, and 3, and the fourth panel of the figure shows the error curve for the best supremum-norm approximation, which equioscillates 14 times. (Computing the best approximation for such problems is not a trivial matter. We used the Carathéodory–Fejér method [32], as outlined in [33].) An examination of the axis scales for these curves reveals that the approximations are very good, with that of Method 3 in particular quite close to optimal.

A deeper analysis of Figure 8 points to some interesting mathematics. The methods we have put forward in this paper are general, combining conformal mapping and trapezoid rule quadrature to handle general functions $f(z)$. The third panel of the figure, however, reveals an unexpected optimality property of the Method 3 variant for

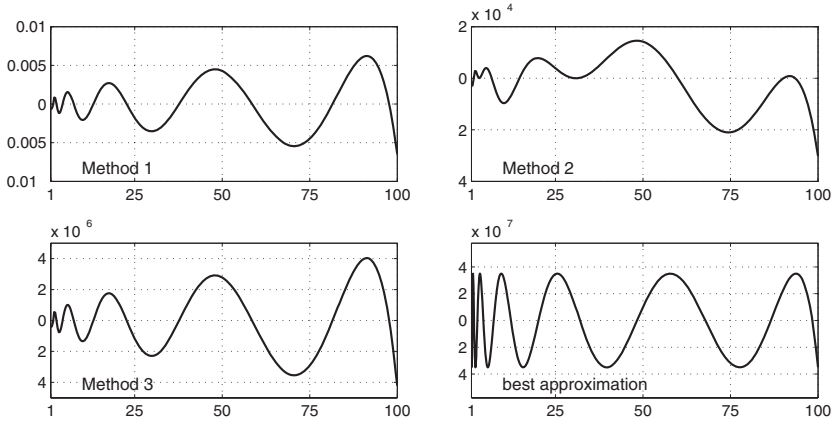

FIG. 8. *Errors* $z^{1/2} - r(z)$ *for various type* (N, N) *rational approximations to* $z^{1/2}$ *on* $[1, 100]$ *with* $N = 6$.

$f(z) = z^{1/2}$. If one scales this error curve by $z^{-1/2}$, it is found to perfectly equioscillate. From this equioscillation one can infer that (5.3) is in this case the optimal type (N, N) approximation to $z^{1/2}$ on $[m, M]$ with respect to the maximum norm weighted by $z^{-1/2}$. Is this best rational approximation already known? Yes indeed—it was discovered by Zolotarev in 1877, who showed that several approximation problems of this kind, though not the unweighted problem of Figure 8, can be solved by the use of Jacobi elliptic functions.[1] The poles for these best approximations, he found, are evenly spaced with respect to the variable we have called t [2, App. E]. (It is this even spacing that leads to our method getting the same result; we do not know a deeper reason why our approximations "had" to come out optimal for this particular weight function.) For more on the connection of Zolotarev's work to matrix functions, see [13, 14, 34].

In other words, the trapezoid rule has rediscovered for us one of Zolotarev's results from 130 years ago! For computing $\mathbf{A}^{1/2}$ when $\mathbf{A}$ has a positive real spectrum, it follows that there is probably no advantage in using the trapezoid rule rather than explicit rational approximations. Incidentally, the use of rational approximations to $\mathbf{A}^{1/2}$ becomes particularly interesting when $\mathbf{A}$ is singular, with eigenvalues in an interval $[0, M]$. It was a celebrated discovery of Newman in 1964 that whereas polynomial approximations to $z^{1/2}$ on such an interval converge only algebraically, rational approximations converge at a rate $O(\exp(-C\sqrt{N}))$ [18]. (Newman's paper deals with approximation of $|z|$, but the result can be carried over to $z^{1/2}$ by a change of variables.) It would be interesting to see whether this behavior can be recovered by a conformal map and the trapezoid rule, but we do not pursue this idea here as it is tied to the special case $f(z) = z^{1/2}$.

The advantage of the trapezoid rule technique is that it is general, applying to arbitrary functions f and to matrices whose spectra may not be all real, yet still readily yielding theorems about asymptotic rates of convergence. We now consider some of these matters.

[1] Egor Ivanovich Zolotarev was a student of Chebyshev, and he learned the theory of elliptic functions from Weierstrass during a visit to Berlin in 1872. Zolotarev made significant contributions to number theory as well as approximation theory before dying at age 31 as a result of being hit by a train at what is now called the Pushkin station outside St. Petersburg [24].

FIG. 9. *On the left, repetition of the right panel of Figure* 4*, now with curves shown inside the quadrature points. If the eigenvalues of* $\mathbf{A}$ *are not confined to the real interval* $[m, M]$ *(solid line) but lie within the innermost curve, for example, then Method* 2 *will still converge exponentially with a rate* 90% *as fast as before. The next curve corresponds to* 80%*, then* 70%*, and so on down to* 10%*. On the right, a closeup of the same figure near the origin (marked by a cross).*

6. Complex eigenvalues and eigenvalue estimates. The methods we have described are flexible. Though we have assumed that the spectrum of $\mathbf{A}$ lies in an interval $[m, M]$ and that m and M are known, the convergence rate degrades only slowly as these conditions are relaxed.

Figure 9 gives an indication of the mathematical reason for this robustness. The general explanation is that in an integral like (1.1), there is no need for the spectrum to be real, provided it is enclosed by the contour Γ. For a quantitative analysis we note that each of our Theorems 2.1, 3.1, and 4.1 are proved by reducing the original problem in the z-plane to a function analytic in a rectangle in the t-plane. The width of the rectangle determines the convergence rate, and if the spectrum of $\mathbf{A}$ moves off the real axis, this narrows the rectangle in a predictable way. For example, in the case of Theorem 2.1, the rectangle has half-width $K'/2$ and is shown in the second panel of Figure 3, where the bottom edge is the portion of the boundary that maps conformally to $[m, M]$. If the spectrum lies in a region in the z-plane larger than $[m, M]$, then this will narrow the rectangle of analyticity. The curves in the figure accordingly correspond to images in the z-plane of horizontal lines in the t-plane at distances $90\%, 80\%, \ldots, 10\%$ of the original distance $K'/2$ below the midline.

Perhaps it is instructive to focus on the middle of the nine curves in Figure 9. So long as the spectrum of $\mathbf{A}$ lies within this quite generous region, the convergence of Method 2 will slow down by at most a factor of 2. Similarly ample regions govern the convergence of Methods 1 and 3. In the case of Method 3, it can be shown that the 50% curve is exactly the circle of radius $M(1 - m/M)^{1/2}$ about the point $z = M$. For $M \gg m$ this is approximately the circle about $z = M$ that passes through the point $z = m/2$. Thus the loss if the spectrum widens from an interval to a disk, and a bigger disk at that, is at worst a factor of 2.

The arguments just made apply to our numerical methods with no adjustments of parameters, but if the spectrum of $\mathbf{A}$ is complex, such adjustments may be advantageous. For example, in the second panel of Figure 3, if the lower half of the rectangle must be narrowed by an amount α because $\mathbf{A}$ has a complex spectrum, then one can halve the impact on the convergence rate by moving the line of quadrature points upwards a distance $\alpha/2$.

Here is an example of the success of these methods for matrices with complex spectra. In MATLAB, `gallery('parter',32)` constructs the 32×32 nonsymmetric Toeplitz matrix with entries $a_{ij} = (i - j + \frac{1}{2})^{-1}$. The norm of $\mathbf{A}$ matches π to 15 digits, and the eigenvalues are complex numbers of absolute value slightly less than

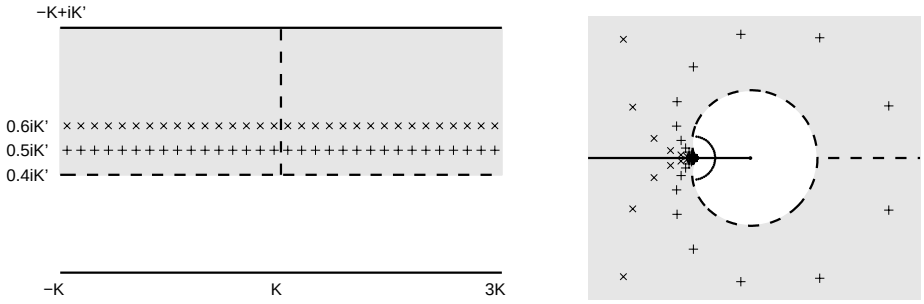

FIG. 10. *Example of the* 32×32 *Parter matrix. The plot on the left shows the rectangle in the t-plane with* 32 *quadrature points at heights* $0.5K'$ *(plusses) and* $0.6K'$ *(crosses). The plot on the right shows their images in the z-plane under the Method* 2 *map with parameters* $m = 0.25$, $M = 8$. *The dashed curve on the right encloses the eigenvalues of* $\mathbf{A}$, *which appear fused in a semicircle, and corresponds to the line at height* $0.4K'$ *on the left. Above this line, in the shaded strip, the integrand will be analytic, so convergence is guaranteed at a rate corresponding to the lower half-width* $0.1K'$ *for the plusses and* $0.2K'$ *for the crosses, that is,* 20% *and* 40% *of the rate given by Theorem* 3.1 *for a matrix with eigenvalues in* $[0.25, 8]$.

π lying approximately on a semicircle in the right half-plane. If Method 2 is applied to compute $\log(\mathbf{A})$ with parameters $m = 0.25$ and $M = 8$ (these parameters were obtained experimentally, not on the basis of analysis of the problem), and with the imaginary part of the quadrature points in (2.6) shifted from $0.5K'$ to $0.6K'$, then here are the results:

```
 5   1.31e-02
10   3.99e-05
15   3.53e-07
20   1.58e-09
25   2.76e-12
30   2.08e-14
```

We see that although the spectrum is complex, thanks to the better condition number, the convergence is nearly as fast as for the example of section 3. Figure 10 explains what is going on. If the imaginary part is fixed at $0.5K'$, then the convergence is about half as fast, becoming about three-quarters as fast in that case if M is increased to 64. If it is fixed at $0.7K'$, then the convergence can be improved further, but in this case the quadrature points in the z-plane cross the branch cut on the negative real axis, so for a successful computation certain values must be negated in accordance with the nonstandard branch of the square root.

This example illustrates that the methods we have put forward can be applied broadly, but also that parameter choices are involved. If these methods are to become the basis of general tools, then it will be necessary to develop systematic ways to estimate eigenvalues or related information from which to derive such parameters. For example, our programs `method1`–`method3` choose m and M by computing the eigenvalues of A and then finding their minimum and maximum. In practice this would usually be impractical, and in any case the codes as written will give the wrong result if the eigenvalues are complex.

7. Three more examples. We conclude with three more numerical examples illustrating a highly nonnormal matrix of small dimension, a fractional matrix power

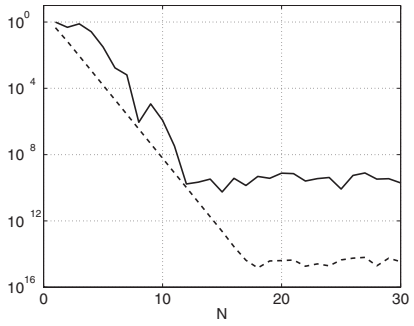

FIG. 11. *Convergence of Method* 3 *in computing* $\mathbf{A}^{1/2}$ *for* $\mathbf{A}$ = `gallery('frank',12)` *(solid curve) and for a diagonal matrix with the same eigenvalues (dashed).*

of medium dimension, and the square root of a sparse matrix of large dimension.

By a highly nonnormal matrix we mean a matrix whose eigenvectors, though a complete set may exist, are far from orthogonal. For an example of this kind we take a Frank matrix, an upper-Hessenberg matrix with integer entries $a_{ij} = n + 1 - j$ on and above the diagonal and $a_{ij} = n + 1 - i$ on the subdiagonal: MATLAB's `gallery('frank',n)`. All of the eigenvalues are real and positive, and it is well known that the condition numbers of the smaller eigenvalues increase rapidly as n increases. Thus the matrix is highly nonnormal. For the 12×12 Frank matrix we computed the square root using a modified version of `method3.m`, with parameters set to their true values $m \approx 0.031$, $M \approx 32.2$. For the exact square root we took the matrix computed in 64-digit arithmetic via diagonalization using MATLAB's symbolic math toolbox. The convergence shown in Figure 11 is rapid, the error reaching 1.7×10^{-10} at $N = 12$ and thereafter levelling off due to the effects of rounding errors. Convergence need not be monotonic, as is confirmed by the sharp increase in error at $N = 9$. It is interesting to note that the error in the square root computed by `sqrtm` is 2×10^{-9}, so contour integration is giving about one more digit of accuracy than the Schur method, which is the standard method of choice if a Schur decomposition can be computed [11].

The dashed curve in Figure 11, corresponding to a diagonal matrix with the same eigenvalues as the Frank matrix, shows that in this example the nonnormality has had a modest effect on the convergence and a great effect on the final accuracy. The reason for the latter is that Method 3 requires the computation of various matrix inverses $(w(t_j)^2\mathbf{I}-\mathbf{A})^{-1}$ (or solution of corresponding systems of equations, if computing $\mathbf{A}^{1/2}b$ instead of $\mathbf{A}^{1/2}$). The numbers $w(t_j)^2$ are far from the spectrum, but not from the ε-pseudospectra for $\varepsilon \ll 1$, so these matrix problems are well conditioned in the normal case but highly ill conditioned in the nonnormal case, causing great amplification of rounding errors. The right solution would be to employ an integration contour that avoids the pseudospectra as well as the spectrum.

For a second example, we use Method 2 to compute $\mathbf{A}^{1/7}b$, where b is a random vector and $\mathbf{A}$ is a 598×598 real nonsymmetric matrix with positive eigenvalues and $m \approx 2.5$, $M \approx 6.1 \times 10^9$. To be precise, $\mathbf{A}$ is the Chebyshev spectral differentiation matrix obtained by the MATLAB commands `A = gallery('chebspec',600)^2` followed by `A = A(2:end-1,2:end-1)`. One way to compute $\mathbf{A}^{1/7}b$ is by means of the identity $\mathbf{A}^{1/7} = \exp(\log(\mathbf{A})/7)$, or `expm(logm(A)/7)` in MATLAB; on a 2003 laptop, this takes 32 seconds. Another approach is to first orthogonally reduce $\mathbf{A}$ to Hessenberg form, then solve N Hessenberg systems of equations in the algorithm of

Method 2. With $N = 40$ this gets comparable accuracy in about 4 seconds. By increasing the dimension, one could increase the disparity in timings.

Our final example (Table 1) applies Method 3 to compute $\mathbf{A}^{1/2}b$, where $\mathbf{A}$ is the matrix generated by the MATLAB command `gallery('poisson',n)`, an $n^2 \times n^2$ matrix corresponding to a standard 5-point finite difference discretization of the Laplacian, and b is the vector of dimension n^2 of all ones. For m and M we take the estimates $2\pi^2/(n+1)^2$ and 8, respectively. This example shows that the methods described here are capable of handling large sparse matrices. The final column of the table compares against MATLAB's built-in method of forming `sqrtm(A)` (the full matrix) and then multiplying by b, a method that is impractical for larger dimensions.

TABLE 1

Computation of $\mathbf{A}^{1/2}b$ by Method 3 for discrete Laplacians of various dimensions. In each case N is chosen large enough for 10 digits of relative accuracy, and time is measured in seconds on a 2003 laptop.

QUASI-OPTIMAL CONVERGENCE RATE FOR AN ADAPTIVE FINITE ELEMENT METHOD*

J. MANUEL CASCON†, CHRISTIAN KREUZER‡, RICARDO H. NOCHETTO§, AND KUNIBERT G. SIEBERT‡

Abstract. We analyze the simplest and most standard adaptive finite element method (AFEM), with any polynomial degree, for general second order linear, symmetric elliptic operators. As is customary in practice, the AFEM marks exclusively according to the error estimator and performs a minimal element refinement without the interior node property. We prove that the AFEM is a contraction, for the sum of the energy error and the scaled error estimator, between two consecutive adaptive loops. This geometric decay is instrumental to derive the optimal cardinality of the AFEM. We show that the AFEM yields a decay rate of the energy error plus oscillation in terms of the number of degrees of freedom as dictated by the best approximation for this combined nonlinear quantity.

Key words. error reduction, convergence, optimal cardinality, adaptive algorithm

1. Introduction.

Let Ω be a bounded, polyhedral domain in $\mathbb{R}^d$, $d \geq 2$. We consider a homogeneous Dirichlet boundary value problem for a self-adjoint second order elliptic partial differential equation (PDE)

$$\begin{aligned} \mathcal{L}u := -\operatorname{div}(\mathbf{A}\nabla u) + c\,u &= f \quad \text{in } \Omega, \\ u &= 0 \quad \text{on } \partial\Omega. \end{aligned} \tag{1.1}$$

The choice of boundary condition is made for ease of presentation, since similar results are valid for other boundary conditions. Precise conditions on given data $\mathbf{D} := (\mathbf{A}, c)$ and f of $\mathcal{L}$ are stated in section 2.1. We refer to [5] for more general operators.

We analyze here a standard adaptive finite element method (AFEM) of the form

$$\mathsf{SOLVE} \to \mathsf{ESTIMATE} \to \mathsf{MARK} \to \mathsf{REFINE}. \tag{1.2}$$

Even though adaptivity has been a fundamental tool of engineering and scientific computing for about three decades, the convergence analysis is rather recent. It started with Dörfler [8], who introduced a crucial marking, from now on called

Dörfler's marking, and proved strict energy error reduction for the Laplacian provided the initial mesh $\mathcal{T}_0$ satisfies a fineness assumption. Morin, Nochetto, and Siebert [17, 18] showed that such strict energy error reduction cannot be expected in general. By introducing the concept of data oscillation and the interior node property, they proved convergence of the AFEM without restrictions on $\mathcal{T}_0$. The latter result, however, is valid only for $\mathbf{A}$ in (1.1) piecewise constant on $\mathcal{T}_0$ and vanishing c. Inspired by the work by Chen and Feng [6], Mekchay and Nochetto [16] extended this result to general second order elliptic operators upon dealing with the new concept of *total error*, namely, the sum of the energy error plus oscillation. They proved that the AFEM is a contraction for the total error, a property that will turn out to be essential in this paper as well. Recently, Diening and Kreuzer [7] proved a similar property for the p-Laplacian but avoided marking for oscillation by using the fact that oscillation appearing in the lower bound is dominated by the estimator.

In this paper we go back to the basis of the AFEM philosophy and consider the simplest possible approach to adaptivity for (1.1). In section 2 we first state precisely the problem and describe the modules of the AFEM: SOLVE computes the Ritz–Galerkin approximation; i.e., we assume an exact solution and integration; ESTIMATE computes the standard residual estimator; MARK resorts to Dörfler marking based solely on the estimator; and REFINE utilizes bisectioning of elements with the minimal refinement condition that marked elements are bisected at least once. In this respect the AFEM is a really standard algorithm in that it avoids marking for oscillation and circumvents the interior node property of [16, 17, 18] for marked elements. We would like to stress that removing these ingredients is very important from a practical point of view. The interior node property enforces six bisections of marked elements in three space dimensions and thus increases the number of DOFs between two iterations drastically. Additionally, since oscillation is not used by the AFEM, it does not have to be computed. Although computing time for oscillation may be negligible, this strongly improves on implementation requirements.

The first convergence result for such a standard AFEM is due to Morin, Siebert, and Veeser [20]. They proved recently, for a larger problem class and more general marking strategies, plain convergence of the AFEM but without an error reduction property. By relying on Dörfler marking we are able to prove a stronger result for self-adjoint elliptic operators of the form (1.1), namely, contraction of the quasi-error and quasi-optimal cardinality of the AFEM.

To summarize the main results, let $\{\mathcal{T}_k, \mathbb{V}_k, U_k, \eta_k, \operatorname{osc}_k\}_{k\geq 0}$ be the sequence of meshes, finite element spaces, discrete solutions, estimators, and oscillations produced by the AFEM in the kth step. Even though the energy error is monotone, strict error reduction fails when $U_{k+1} = U_k$, i.e., $|\!|\!| u - U_k |\!|\!|_\Omega = |\!|\!| u - U_{k+1} |\!|\!|_\Omega$; see [17, 18] for further details. On the other hand, the residual estimator $\eta_k = \eta_k(U_k)$ exhibits a strict reduction when $U_{k+1} = U_k$ but no monotone behavior in general; this is shown in section 3. The new insight of this paper is that the sum of the energy error and the scaled estimator, the so-called *quasi error* $(|\!|\!| u - U_k |\!|\!|_\Omega^2 + \gamma\, \eta_k^2)^{1/2}$, is strictly reduced by the AFEM even though each term may not be. In fact, we prove in section 4 that the AFEM is a contraction for this new error notion (see Theorem 4.1).

MAIN RESULT 1. There exist constants $\gamma > 0$ and $0 < \alpha < 1$ such that

$$|\!|\!| u - U_{k+1} |\!|\!|_\Omega^2 + \gamma\, \eta_{k+1}^2 \leq \alpha^2 \Big(|\!|\!| u - U_k |\!|\!|_\Omega^2 + \gamma\, \eta_k^2 \Big).$$

Quasi-optimal convergence rates for the AFEM, expressing energy error decay in terms of the number of DOFs as dictated by nonlinear approximation theory, were

first proved by Binev, Dahmen, and DeVore [3]. They resorted to a crucial, but somewhat artificial, coarsening step. Coarsening was later removed by Stevenson [23], who developed an optimality theory for a much more realistic AFEM but still included an inner loop to deal with oscillation. Both papers [3, 23] are restricted to the Laplace operator and rely on suitable marking by oscillation and the interior node property.

To derive convergence rates we need to seek a suitable error quantity and an associated approximation class $\mathbb{A}_s$. Since all decisions of the AFEM in MARK are based on the estimator η_k, a decay rate for the true error is closely related to the quality of the estimator, which is described by the *global lower bound*

$$\eta_k^2 \preccurlyeq |\!|\!| u - U_k |\!|\!|_\Omega^2 + \operatorname{osc}_k^2;$$

hereafter, *total error* refers to the square root of the right-hand side (see [16]). The lower bound states that the estimator is dominated by the error up to an oscillation term and overestimation may occur only when oscillation is large. Furthermore we observe that the total error is bounded again by the estimator—thanks to the upper bound $|\!|\!| u - U_k |\!|\!|_\Omega \preccurlyeq \eta_k$ and $\operatorname{osc}_k \le \eta_k$—and the estimator itself is an upper bound for the quasi error, which is the quantity reduced by the AFEM:

$$|\!|\!| u - U_k |\!|\!|_\Omega^2 + \operatorname{osc}_k^2 \;\approx\; \eta_k^2 \;\approx\; |\!|\!| u - U_k |\!|\!|_\Omega^2 + \gamma\, \eta_k^2.$$

In summary, the performance of the AFEM is intrinsically bonded to the total error, which measures both the approximability of u as well as of data, encoded in the oscillation term. For piecewise polynomial coefficients $(\mathbf{A}, c)$, oscillation reduces to approximation of the right-hand side f of (1.1). In the general case, approximation of data $(\mathbf{A}, c)$ in osc_k couples in a nonlinear fashion with the discrete solution U_k. In section 5 we start with the definition of an approximation class $\mathbb{A}_s$ based on the total error. Roughly speaking, $(u, f, \mathbf{D})$ belongs to $\mathbb{A}_s$ if the total error can be approximated within any tolerance $\epsilon > 0$ with $O(\epsilon^{-s})$ DOFs. We then prove the *quasi-optimal* convergence rate for the AFEM in terms of DOFs by assuming certain restrictions on the initial triangulation and the marking parameter $\theta \in (0, \theta_*)$ (see Theorem 5.11).

MAIN RESULT 2. If $(u, f, \mathbf{D}) \in \mathbb{A}_s$, then there exists a constant C such that

$$\left\{ |\!|\!| u - U_k |\!|\!|_\Omega^2 + \operatorname{osc}_k^2 \right\}^{1/2} \le C \left(\#\mathcal{T}_k - \#\mathcal{T}_0 \right)^{-s}.$$

Since the estimator is equivalent to the total error, we obtain the same decay rate for the estimator η_k. Besides the contraction property of the AFEM, crucial ingredients of the proof are a quasi-monotonicity property of oscillation as well as a localized upper bound, both proved in section 3. The latter refines a similar bound by Stevenson [23]. In contrast to former optimality proofs [3, 23], the present analysis stays within the class of conforming meshes. This is a necessary framework for the analysis when dealing with oscillation in the jump residual.

As already mentioned above, for piecewise polynomial coefficients $(\mathbf{A}, c)$ one can separate approximation of u and data f. When doing so and marking with respect to two quantities such as the estimator and oscillation, the role of marking becomes critical for proving optimality. To shed light on this issue, we conclude this article by discussing in section 6 the simultaneous adaptive approximation of two functions with distinct asymptotic error decays. The discussion reveals that separate marking might be suboptimal and explains why the AFEM designed by Morin, Nochetto, and Siebert [17, 18] is altered in former optimality proofs [3, 23].

2. Problem and adaptive finite element method. We first introduce the underlying problem and state assumptions on given data. We then describe the refinement framework and the AFEM along with its modules.

2.1. Weak formulation. Let Ω be a bounded, polyhedral domain in $\mathbb{R}^d$, $d \geq 2$, that is triangulated by a conforming triangulation $\mathcal{T}_0$. We assume that data of (1.1) have the following properties:

(a) $\mathbf{A}\colon \Omega \mapsto \mathbb{R}^{d\times d}$ is piecewise Lipschitz over $\mathcal{T}_0$ and is symmetric positive definite with eigenvalues in $0 < a_* \leq a^* < \infty$, i.e.,

$$a_*(x)\,|\xi|^2 \leq \mathbf{A}(x)\xi\cdot\xi \leq a^*(x)\,|\xi|^2 \quad \forall \xi \in \mathbb{R}^d,\ x \in \Omega;$$

(b) $c \in L^\infty(\Omega)$ is nonnegative, i.e., $c \geq 0$ in Ω;

(c) $f \in L^2(\Omega)$.

Now we turn to the weak formulation of (1.1). For any set $\omega \subset \mathbb{R}^d$ with a nonempty interior we denote by $H^1(\omega)$ the usual Sobolev space of functions in $L^2(\omega)$ whose first derivatives are also in $L^2(\omega)$, endowed with the norm

$$\|u\|_{H^1(\omega)} := \left(\|u\|^2_{L^2(\omega)} + \|\nabla u\|^2_{L^2(\omega)}\right)^{1/2}.$$

Moreover, we denote by $\langle .\,,.\rangle_\omega$ the $L^2(\omega)$ scalar product. Finally we let $\mathbb{V} := H^1_0(\Omega)$ be the space of functions in $H^1(\Omega)$ with vanishing trace on $\partial\Omega$. A weak solution of (1.1) is a function u satisfying

$$u \in \mathbb{V}: \qquad \mathcal{B}[u,v] = \langle f, v\rangle_\Omega \qquad \forall v \in \mathbb{V}, \tag{2.1}$$

where the bilinear form is defined to be

$$\mathcal{B}[u,v] := \langle \mathbf{A}\nabla u, \nabla v\rangle_\Omega + \langle c\,u, v\rangle_\Omega \qquad \forall u, v \in \mathbb{V}.$$

In view of the Poincaré–Friedrichs inequality, one has *coercivity* on $\mathbb{V}$

$$\mathcal{B}[v,v] = \langle \mathbf{A}\nabla v, \nabla v\rangle_\Omega + \langle c\,v, v\rangle_\Omega \geq \int_\Omega a_*\,|\nabla v|^2 + c\,v^2 \geq c_B\,\|v\|^2_{H^1(\Omega)},$$

and c_B depends only on data and Ω. The bilinear form $\mathcal{B}$ induces the so-called *energy norm*:

$$|\!|\!|v|\!|\!|_\Omega := \mathcal{B}[v,v]^{1/2} \qquad \forall v \in \mathbb{V}.$$

Note that the bilinear form also fulfills the *local continuity*

$$\mathcal{B}[v,w] \leq \sqrt{C_B}\;|\!|\!|v|\!|\!|_\omega\,\|w\|_{H^1(\omega)} \qquad \forall v, w \in H^1_0(\Omega),\ \mathrm{supp}(w) \subset \omega \subset \Omega,$$

with $|\!|\!|v|\!|\!|_\omega := \langle \mathbf{A}\nabla v, \nabla v\rangle_\omega + \langle c\,v, v\rangle_\omega$. This local continuity is essential in deriving *local lower bounds* in the a posteriori error analysis. Furthermore it implies continuity of $\mathcal{B}[\cdot,\cdot]$ on $H^1(\Omega)$ at once. Thanks to the coercivity and continuity of $\mathcal{B}$, the norm $|\!|\!|\cdot|\!|\!|_\Omega$ is equivalent to $\|\cdot\|_{H^1(\Omega)}$ on $H^1_0(\Omega)$. The existence and uniqueness of (2.1) thus follow from the Lax–Milgram theorem [9]. The restriction to a symmetric bilinear form and $c \geq 0$ can be relaxed, provided (2.1) admits a unique solution. This extension will be studied in [5].

2.2. Refinement framework. Refinement is based on shape-regular bisection of single elements. Any given simplex is subdivided into two subsimplices of the same size such that the minimal angle is uniformly bounded from below; we refer to [2, 13, 14, 15, 24, 25] or the monograph [21] and the references therein. In two dimensions, this is the newest vertex bisection. Bisectioning creates a unique *master forest* $\mathbb{F}$ of binary trees with infinite depth, where each node is a simplex, its two successors are the two children created by bisection, and the roots of the binary trees are the elements of the initial conforming triangulation $\mathcal{T}_0$. The master forest $\mathbb{F}$ contains full information of all possible subdivisions created from $\mathcal{T}_0$ by bisection, i.e., information about vertices, neighbors, refinement edges, etc., for any simplex that can be generated.

A finite subset $\mathcal{F} \subset \mathbb{F}$ is called a *forest* if $\mathcal{T}_0 \subset \mathcal{F}$ and the nodes satisfy:

(a) all nodes in $\mathcal{F} \setminus \mathcal{T}_0$ have a predecessor;

(b) all nodes in $\mathcal{F}$ have either two successors or none.

Any node of $\mathcal{F}$ is thus uniquely connected with a node of the initial triangulation $\mathcal{T}_0$. Furthermore, any forest may have interior nodes, i.e., nodes with successors, and does have leaf nodes, i.e., nodes without successors. Finally, each forest $\mathcal{F}$ corresponds one to one to a subdivision $\mathcal{T}(\mathcal{F})$ of Ω into simplices by defining $\mathcal{T}(\mathcal{F})$ as the set of leaf nodes of $\mathcal{F}$. Note that such a subdivison may be nonconforming.

If $\mathcal{F} \subset \mathcal{F}_*$ are two forests, we call $\mathcal{T}_* = \mathcal{T}(\mathcal{F}_*)$ a refinement of $\mathcal{T} = \mathcal{T}(\mathcal{F})$ and denote this by $\mathcal{T} \leq \mathcal{T}_*$. We define

$$\mathcal{R}_{\mathcal{T}\to\mathcal{T}_*} := \mathcal{T} \setminus (\mathcal{T}_* \cap \mathcal{T})$$

as the set of *refined elements*; i.e., $\mathcal{R}_{\mathcal{T}\to\mathcal{T}_*}$ is the set of leaf nodes of $\mathcal{F}$ that are interior nodes of $\mathcal{F}_*$. The class of all *conforming* refinements by bisection of $\mathcal{T}_0$ is

$$\mathbb{T} := \{\mathcal{T}(\mathcal{F}) \mid \mathcal{F} \subset \mathbb{F} \text{ is a forest and } \mathcal{T}(\mathcal{F}) \text{ is a conforming triangulation of } \Omega\}.$$

Given two forests $\mathcal{F}, \mathcal{F}_* \subset \mathbb{F}$ corresponding to subdivisions $\mathcal{T}$ and $\mathcal{T}_*$ of Ω, we define $\mathcal{F} \cup \mathcal{F}_*$ to be the union of the nodes of $\mathcal{F}$ and $\mathcal{F}_*$. Obviously, $\mathcal{F} \cup \mathcal{F}_* \subset \mathbb{F}$ and $\mathcal{T}_0 \subset \mathcal{F} \cup \mathcal{F}_*$. By construction, all nodes of $(\mathcal{F} \cup \mathcal{F}_*) \setminus \mathcal{T}_0$ have a predecessor, and all nodes of the union have either two successors or none: this implies that $\mathcal{F} \cup \mathcal{F}_*$ is a forest. We call the resulting unique subdivision of Ω the *overlay of* $\mathcal{T}$ *and* $\mathcal{T}_*$:

$$\mathcal{T} \oplus \mathcal{T}_* := \mathcal{T}(\mathcal{F} \cup \mathcal{F}_*).$$

For two conforming triangulations $\mathcal{T}, \mathcal{T}_* \in \mathbb{T}$ we prove in Lemma 3.7 below that $\mathcal{T} \oplus \mathcal{T}_* \in \mathbb{T}$ is the smallest conforming refinement of $\mathcal{T}, \mathcal{T}_*$ and satisfies

$$\#(\mathcal{T} \oplus \mathcal{T}_*) \leq \#\mathcal{T} + \#\mathcal{T}_* - \#\mathcal{T}_0. \tag{2.2}$$

We finally introduce some notations related to triangulations. For $T \in \mathcal{T}$ we denote by $h_T := |T|^{\frac{1}{d}}$ the local mesh size and by ω_T the union of all elements in $\mathcal{T}$ sharing one side with T. We further denote by $\mathcal{S}$ the skeleton of $\mathcal{T}$, i.e., the union of the interelement sides, and for an interior side $\sigma \in \mathcal{S}$ we let ω_σ be the union of the two adjacent elements sharing σ.

Thanks to the properties of bisection, all constants depending on shape regularity of $\mathcal{T} \in \mathbb{T}$ are uniformly bounded by a constant solely depending on $\mathcal{T}_0$ [14, 25].

2.3. The module SOLVE. Given any conforming triangulation $\mathcal{T} \in \mathbb{T}$, we define the finite element space

$$\mathbb{V}(\mathcal{T}) := \{V \in \mathbb{V} \mid V_{|T} \in \mathbb{P}_n(T),\ T \in \mathcal{T}\},$$

where $n \in \mathbb{N}$ is a fixed polynomial degree and $\mathbb{P}_n$ denotes the space of all polynomials of degree $\leq n$. Since the continuity and coercivity of $\mathcal{B}$ are inherited by any subspace of $\mathbb{V}$, the Lax–Milgram theorem implies the existence and uniqueness of the Ritz–Galerkin approximation in $\mathbb{V}(\mathcal{T})$ defined by

$$U \in \mathbb{V}(\mathcal{T}): \qquad \mathcal{B}[U, V] = \langle f, V \rangle_\Omega \qquad \forall\, V \in \mathbb{V}(\mathcal{T}). \tag{2.3}$$

We suppose that the module SOLVE outputs the exact Ritz–Galerkin solution on $\mathcal{T}$:

$$U = \mathsf{SOLVE}(\mathcal{T});$$

i.e., U is computed via exact linear algebra and exact integration. Optimal multilevel solvers can be incorporated as in [23], but quadrature is more delicate.

We observe that for any pair $\mathcal{T}, \mathcal{T}_* \in \mathbb{T}$, with $\mathcal{T} \leq \mathcal{T}_*$, there holds $\mathbb{V}(\mathcal{T}) \subset \mathbb{V}(\mathcal{T}_*)$; i.e., the discrete spaces are *nested*. This turns out to be a crucial property in the subsequent analysis in that the following *orthogonality* relation holds:

$$\|\!|u - U|\!\|_\Omega^2 = \|\!|u - U_*|\!\|_\Omega^2 + \|\!|U_* - U|\!\|_\Omega^2 . \tag{2.4}$$

This is a consequence of $\mathcal{B}[u - U_*, U_* - U] = 0$ or, equivalently, that $u - U_*$ and $U_* - U$ are orthogonal with respect to the scalar product induced by $\mathcal{B}[\cdot, \cdot]$.

2.4. The module ESTIMATE. For $\mathcal{T} \in \mathbb{T}$ and $V \in \mathbb{V}(\mathcal{T})$ we define the *element residual* and *jump residual* for V by

$$R(V)_{|T} := (f + \mathcal{L}\, V)_{|T}, \quad T \in \mathcal{T}, \qquad \text{and} \qquad J(V)_{|\sigma} := ([\![\mathbf{A}\nabla V]\!] \cdot \boldsymbol{\nu})_{|\sigma}, \quad \sigma \in \mathcal{S}.$$

Hereafter, $[\![q]\!]$ is the jump of q across an interior side σ, and $\boldsymbol{\nu}$ denotes a unit normal vector associate to side σ. The error indicator for V on $T \in \mathcal{T}$ is given by

$$\eta_{\mathcal{T}}^2(V, T) := h_T^2 \, \|R(V)\|_{L^2(T)}^2 + h_T \, \|J(V)\|_{L^2(\partial T \cap \Omega)}^2 , \tag{2.5}$$

where we recall that $h_T = |T|^{1/d}$. We assume that, given a triangulation $\mathcal{T}$ and the Ritz–Galerkin solution $U \in \mathbb{V}(\mathcal{T})$, the module ESTIMATE outputs the indicators

$$\{\eta_{\mathcal{T}}(U, T)\}_{T \in \mathcal{T}} = \mathsf{ESTIMATE}(U, \mathcal{T}).$$

The lower bound involves oscillation, which we define next. For $m \in \mathbb{N}_0$, we denote by Π_m^p the L^p-best approximation operator onto the set of discontinuous polynomials of degree $\leq m$ over either $T \in \mathcal{T}$ or $\sigma \in \mathcal{S}$, depending on the context. If $P_m^p := \mathrm{id} - \Pi_m^p$, then we define oscillation of $V \in \mathbb{V}(\mathcal{T})$ to be

$$\mathrm{osc}_{\mathcal{T}}^2(V, T) := h_T^2 \left\| P_{2n-2}^2 R(V) \right\|_{L^2(T)}^2 + h_T \left\| P_{2n-1}^2 J(V) \right\|_{L^2(\partial T \cap \Omega)}^2 .$$

Finally, for any subset $\mathcal{T}' \subset \mathcal{T}$ we set

$$\eta_{\mathcal{T}}^2(V, \mathcal{T}') := \sum_{T \in \mathcal{T}'} \eta_{\mathcal{T}}^2(V, T) \qquad \text{and} \qquad \mathrm{osc}_{\mathcal{T}}^2(V, \mathcal{T}') := \sum_{T \in \mathcal{T}'} \mathrm{osc}_{\mathcal{T}}^2(V, T).$$

Remark 2.1. Let $\mathcal{T} \in \mathbb{T}$ and $V \in \mathbb{V}(\mathcal{T})$ be given. We first observe that the indicator $\eta_{\mathcal{T}}(V, T)$ *dominates* oscillation $\mathrm{osc}_{\mathcal{T}}(V, T)$, i.e., $\mathrm{osc}_{\mathcal{T}}(V, T) \leq \eta_{\mathcal{T}}(V, T)$ for all $T \in \mathcal{T}$. In addition, the definitions of the error indicator and oscillation are fully localized to T; i.e., for any triangulation $\mathcal{T}_* \in \mathbb{T}$, with $T \in \mathcal{T}_*$, there holds

$\eta_{\mathcal{T}}(V,T) = \eta_{\mathcal{T}_*}(V,T)$ and $\operatorname{osc}_{\mathcal{T}}(V,T) = \operatorname{osc}_{\mathcal{T}_*}(V,T)$. Moreover, if $\mathcal{T}_* \geq \mathcal{T}$ is any refinement of $\mathcal{T}$, then, by combining the monotonicity of local mesh sizes and properties of the local L^2 projection, we deduce the *monotonicity* properties

$$\eta_{\mathcal{T}_*}(V,\mathcal{T}_*) \leq \eta_{\mathcal{T}}(V,\mathcal{T}) \quad \text{and} \quad \operatorname{osc}_{\mathcal{T}_*}(V,\mathcal{T}_*) \leq \operatorname{osc}_{\mathcal{T}}(V,\mathcal{T}) \qquad \forall V \in \mathbb{V}(\mathcal{T}).$$

We now recall the well-known upper and lower bounds for the energy error in terms of the residual-type estimator [1, 16, 17, 18, 23, 27].

LEMMA 2.2 (global a posteriori upper and lower bounds). *Let $u \in \mathbb{V}$ be the solution of (2.1), $\mathcal{T} \in \mathbb{T}$, and $U \in \mathbb{V}(\mathcal{T})$ be the Ritz–Galerkin solution (2.3).*

Then there exist a constant C_1, solely depending on $\mathcal{T}_0$ and $1/c_B$, such that

$$|||u - U|||_\Omega^2 \leq C_1\, \eta_{\mathcal{T}}^2(U,\mathcal{T}), \tag{2.6}$$

and a constant C_2, solely depending on $\mathcal{T}_0$ and $1/C_B$, such that

$$C_2\, \eta_{\mathcal{T}}^2(U,\mathcal{T}) \leq |||u - U|||_\Omega^2 + \operatorname{osc}_{\mathcal{T}}^2(U,\mathcal{T}). \tag{2.7}$$

2.5. The module MARK. In the selection of elements we rely on Dörfler marking. Given a grid $\mathcal{T}$, the set of indicators $\{\eta_{\mathcal{T}}(U,T\}_{T\in\mathcal{T}}$, and marking parameter $\theta \in (0,1]$, we suppose that MARK outputs a subset of *marked elements* $\mathcal{M} \subset \mathcal{T}$, i.e.,

$$\mathcal{M} = \mathsf{MARK}(\{\eta_{\mathcal{T}}(U,T\}_{T\in\mathcal{T}}, \mathcal{T}, \theta),$$

such that $\mathcal{M}$ satisfies Dörfler property

$$\eta_{\mathcal{T}}(U,\mathcal{M}) \geq \theta\, \eta_{\mathcal{T}}(U,\mathcal{T}). \tag{2.8}$$

2.6. The module REFINE. We suppose that a function REFINE is at our disposal that implements iterative or recursive bisection; see [2, 13, 14, 15, 24, 25]. When relying on recursive bisection, the distribution of refinement edges has to fulfill some compatibility conditions on $\mathcal{T}_0$. Given a fixed number $b \geq 1$, for any $\mathcal{T} \in \mathbb{T}$ and a subset $\mathcal{M} \subset \mathcal{T}$ of marked elements,

$$\mathcal{T}_* = \mathsf{REFINE}(\mathcal{T},\mathcal{M})$$

outputs a conforming triangulation $\mathcal{T}_* \in \mathbb{T}$, where at least all elements of $\mathcal{M}$ are bisected b times. In particular, this implies that $\mathcal{M} \subset \mathcal{R}_{\mathcal{T}\to\mathcal{T}_*}$.

To ensure conformity of $\mathcal{T}_*$ one usually has to refine additional elements in $\mathcal{T}\setminus\mathcal{M}$ once or several times. In general, the number of these additionally refined elements is not controlled by $\#\mathcal{M}$ that is, $\#\mathcal{T}_* - \#\mathcal{T}$ cannot be bounded by $C\,\#\mathcal{M}$ with a constant C independent of $\mathcal{T}$; C may depend on the refinement level. On the other hand, by arguing with the entire sequence $\{\mathcal{T}_k\}_{k\geq 0}$ of refinements, Binev, Dahmen, and DeVore showed in two dimensions that the *cumulative* number of elements added by conformity does not inflate the total number of marked elements [3, Theorem 2.4]. Stevenson generalized this result to higher dimensions [24, Theorem 6.1].

LEMMA 2.3 (complexity of REFINE). *Assume that $\mathcal{T}_0$ verifies condition* (b) *of section* 4 *in* [24]. *For $k \geq 0$ let $\{\mathcal{T}_k\}_{k\geq 0}$ be any sequence of refinements of $\mathcal{T}_0$ where $\mathcal{T}_{k+1}$ is generated from $\mathcal{T}_k$ by $\mathcal{T}_{k+1} = \mathsf{REFINE}(\mathcal{T}_k, \mathcal{M}_k)$ with a subset $\mathcal{M}_k \subset \mathcal{T}_k$.*

Then there exists a constant C_0 solely depending on $\mathcal{T}_0$ and b such that

$$\#\mathcal{T}_k - \#\mathcal{T}_0 \leq C_0 \sum_{j=0}^{k-1} \#\mathcal{M}_j \qquad \forall k \geq 1.$$

The original result is proved for a sequence of meshes generated by a loop

$$\mathsf{Mark} \to \mathsf{Subdivision} \to \mathsf{Complete},$$

where Mark selects certain elements, Subdivision bisects marked elements only once ($b = 1$), and Complete adds some additional subdivisions to generate a conforming triangulation. To apply the above result when REFINE performs $b > 1$ bisections, the set $\mathcal{M}_k$ is to be understood as a sequence of *single* bisections recorded in sets $\{\mathcal{M}_k(j)\}_{j=1}^b$, which belong to intermediate triangulations between $\mathcal{T}_k$ and $\mathcal{T}_{k+1}$ with $\#\mathcal{M}_k(j) \le 2^{j-1}\#\mathcal{M}_k$, $j = 1, \dots, b$. Then Lemma 2.3 is a direct consequence of [24, Theorem 6.1] because

$$\sum_{j=1}^{b} \#\mathcal{M}_k(j) \le \sum_{j=1}^{b} 2^{j-1}\#\mathcal{M}_k = (2^b - 1)\#\mathcal{M}_k.$$

2.7. Adaptive algorithm. In this section we now collect the modules described in the previous sections into the adaptive finite element method. In doing this, we replace the dependence on the actual triangulation $\mathcal{T}$ by the iteration counter $k \ge 0$, for instance, $\mathbb{V}_k = \mathbb{V}(\mathcal{T}_k)$. The basic loop of AFEM is then given by the following iteration:

AFEM

Given the initial grid $\mathcal{T}_0$ and marking parameter $0 < \theta \le 1$
set $k := 0$ and iterate

(1) $U_k = \mathsf{SOLVE}(\mathcal{T}_k)$;
(2) $\{\eta_k(U_k, T)\}_{T\in\mathcal{T}_k} = \mathsf{ESTIMATE}(U_k, \mathcal{T}_k)$;
(3) $\mathcal{M}_k = \mathsf{MARK}(\{\eta_k(U_k, T)\}_{T\in\mathcal{T}_k}, \mathcal{T}_k, \theta)$;
(4) $\mathcal{T}_{k+1} = \mathsf{REFINE}(\mathcal{M}_k, \mathcal{T}_k)$; $k := k + 1$.

We want to stress that the AFEM is really a *standard algorithm* in that it employs only the error indicators $\{\eta_k(U_k, T)\}_{T\in\mathcal{T}_k}$ and does not use the oscillation indicators $\{\mathrm{osc}_k(U_k, T)\}_{T\in\mathcal{T}_k}$. In addition, the AFEM relies only on a minimal refinement; i.e., an interior node property is not enforced for marked elements.

Several remarks are now in order:

- Recently, Morin, Siebert, and Veeser proved convergence of the above iteration for general marking strategies, including maximum and equidistribution besides Dörfler strategy [20]. The main result is a plain convergence result, i.e.,

$$\lim_{k\to\infty} \|u - U_k\|_{L^2(\Omega)} = \lim_{k\to\infty} \eta_k(U_k, \mathcal{T}_k) = 0.$$

  This does not provide a strict total error reduction between two successive iterations, which is one key ingredient in the optimality proof of section 5.
- By using similar techniques as Diening and Kreuzer for the p-Laplacian [7], we prove in section 4 a contraction property for $\|u - U_k\|^2_{L^2(\Omega)} + \gamma\, \eta_k^2(U_k, \mathcal{T}_k)$ between two successive iterations, with $\gamma > 0$ a suitable scaling factor; we observe that [7] still requires the interior node property. This in turn implies *linear convergence*. Crucial ingredients are the a posteriori *global upper bound* and *Dörfler marking*.

- We prove in section 5 that $\mathcal{T}_k$ exhibits *quasi-optimal cardinality* provided that
  (a) the marking parameter θ satisfies $\theta < \theta_*$, where θ_*, defined explicitly in Assumption 5.8, depends on the ratio $\sqrt{C_2/C_1}$ of constants in (2.6) and (2.7);
  (b) $\mathcal{M}_k$ satisfies (2.8) with minimal cardinality;
  (c) $\mathcal{T}_{k+1}$ is the smallest refinement of $\mathcal{T}_k$ such that $\mathcal{M}_k \subset \mathcal{R}_{\mathcal{T}_k \to \mathcal{T}_{k+1}}$.

  The proof hinges on the a posteriori *lower bound* and a *localized upper bound*.

3. Auxiliary results. In this section we prove a quasi-reduction property of the estimator, which is instrumental for convergence. We also show a perturbation result of oscillation and a localized upper bound, both between two discrete functions, that play an essential role in the optimality proof. Finally we discuss the overlay of two meshes and thereby prove (2.2).

Throughout this paper we use the notation $a \preccurlyeq b$ to indicate $a \le C\, b$, with generic constants C solely depending on shape regularity and thus on $\mathcal{T}_0$, the number of bisections b of marked elements, and the polynomial degree n. Dependence on data $\mathbf{D} = (\mathbf{A}, c)$ and f of (1.1) is traced explicitly. We denote $a \preccurlyeq b \preccurlyeq a$ by $a \approx b$.

3.1. Reduction of the error estimator and oscillation. We relate the error indicators and oscillation of two nested triangulations to each other. The link involves weighted maximum-norms of the coefficient functions $\mathbf{D}$ or their oscillation. These results are the basis for our analyses in sections 4 and 5.

We start by defining the weighted maximum-norm of the coefficients $\mathbf{D}$ and their oscillation. For $m \in \mathbb{N}_0$, $\mathcal{T} \in \mathbb{T}$, and $v \in L^\infty(\Omega)$, we recall that $\Pi_m^\infty v$ is the best $L^\infty(\Omega)$-approximation in the space of discontinuous polynomials of degree $\le m$. We further set $\Pi_{-1}^\infty v = 0$, $P_m^\infty v = v - \Pi_m^\infty v$, and

$$\eta_{\mathcal{T}}^2(\mathbf{D}, T) := h_T^2 \left(\|\operatorname{div} \mathbf{A}\|_{L^\infty(T)}^2 + h_T^{-2} \|\mathbf{A}\|_{L^\infty(\omega_T)}^2 + \|c\|_{L^\infty(T)}^2 \right),$$

$$\operatorname{osc}_{\mathcal{T}}^2(\mathbf{D}, T) := h_T^2 \Big(\left\| P_{n-1}^\infty \operatorname{div} \mathbf{A} \right\|_{L^\infty(T)}^2 + h_T^{-2} \|P_n^\infty \mathbf{A}\|_{L^\infty(\omega_T)}^2 + h_T^2 \left\| P_{n-2}^\infty c \right\|_{L^\infty(T)}^2 + \left\| P_{n-1}^\infty c \right\|_{L^\infty(T)}^2 \Big);$$

note that P_m^∞ is defined elementwise. For any subset $\mathcal{T}' \subset \mathcal{T}$ we finally set

$$\eta_{\mathcal{T}}(\mathbf{D}, \mathcal{T}') := \max_{T \in \mathcal{T}'} \eta_{\mathcal{T}}(\mathbf{D}, T) \qquad \text{and} \qquad \operatorname{osc}_{\mathcal{T}}(\mathbf{D}, \mathcal{T}') := \max_{T \in \mathcal{T}'} \operatorname{osc}_{\mathcal{T}}(\mathbf{D}, T).$$

Remark 3.1 (monotonicity). The use of best approximation in L^∞ in the definitions of $\eta_{\mathcal{T}}(\mathbf{D}, \mathcal{T})$ and $\operatorname{osc}_{\mathcal{T}}(\mathbf{D}, \mathcal{T})$ implies the following monotonicity property: for all $\mathcal{T}, \mathcal{T}_* \in \mathbb{T}$, with $\mathcal{T} \le \mathcal{T}_*$, there holds

$$\eta_{\mathcal{T}_*}(\mathbf{D}, \mathcal{T}_*) \le \eta_{\mathcal{T}}(\mathbf{D}, \mathcal{T}) \quad \text{and} \quad \operatorname{osc}_{\mathcal{T}_*}(\mathbf{D}, \mathcal{T}_*) \le \operatorname{osc}_{\mathcal{T}}(\mathbf{D}, \mathcal{T}).$$

The following lemma allows us to avoid any smoothness assumption on the coefficients $\mathbf{D}$ of the PDE.

LEMMA 3.2 (implicit interpolation). *Let ω be either a d or a $(d-1)$ simplex. For $\ell \in \mathbb{N}$ denote by $\Pi_m^p \colon L^p(\omega, \mathbb{R}^\ell) \to \mathbb{P}_m(\omega, \mathbb{R}^\ell)$ the operator of best L^p-approximation in ω, and set $P_m^p = \mathrm{id} - \Pi_m^p$. Then for all $v \in L^\infty(\omega, \mathbb{R}^\ell)$, $V \in \mathbb{P}_n(\omega, \mathbb{R}^\ell)$ and $m \ge n$, there holds*

$$\left\| P_m^2(vV) \right\|_{L^2(\omega)} \le \left\| P_{m-n}^\infty v \right\|_{L^\infty(\omega)} \|V\|_{L^2(\omega)}.$$

Proof. Since $V \in \mathbb{P}_n$ we obtain $\Pi^\infty_{m-n}(v)\cdot V \in \mathbb{P}_m$, and thus the orthogonality of the L^2-projection yields

$$\begin{aligned}\int_\omega (vV - \Pi^2_m(vV))(vV - \Pi^2_m(vV)) &= \int_\omega (vV - \Pi^2_m(vV))(v - \Pi^\infty_{m-n}(v))\cdot V \\ &\le \left\|P^2_m(vV)\right\|_{L^2(\omega)} \left\|P^\infty_{m-n} v\right\|_{L^\infty(\omega)} \|V\|_{L^2(\omega)},\end{aligned}$$

which finishes the proof. ∎

PROPOSITION 3.3 (local perturbation). *Let $\mathcal{T} \in \mathbb{T}$. For all $T \in \mathcal{T}$ and for any pair of discrete functions $V, W \in \mathbb{V}(\mathcal{T})$, we have*

$$\eta_{\mathcal{T}}(V,T) \le \eta_{\mathcal{T}}(W,T) + \bar{\Lambda}_1\, \eta_{\mathcal{T}}(\mathbf{D},T)\, \|V - W\|_{H^1(\omega_T)}, \tag{3.1}$$

$$\operatorname{osc}_{\mathcal{T}}(V,T) \le \operatorname{osc}_{\mathcal{T}}(W,T) + \bar{\Lambda}_1 \operatorname{osc}_{\mathcal{T}}(\mathbf{D},T)\|V - W\|_{H^1(\omega_T)}, \tag{3.2}$$

where ω_T is the union of elements in $\mathcal{T}$ sharing a side with T. The constant $\bar{\Lambda}_1 > 0$ depends only on the shape regularity of $\mathcal{T}_0$ and the polynomial degree n.

Proof. We prove only (3.2); estimate (3.1) is somewhat simpler and can be derived similarly. Recall the definition of the element residual $R(V) = f + \mathcal{L}(V)$ and the notation $P^p_m = \mathrm{id} - \Pi^p_m$. Since the L^2-projection Π^2_m is linear, by adding and subtracting W and using the triangle inequality, we obtain

$$\operatorname{osc}_{\mathcal{T}}(V,T) \le \operatorname{osc}_{\mathcal{T}}(W,T) + h_T \left\|P^2_{2n-2}\mathcal{L}(E)\right\|_{L^2(T)} + h_T^{1/2} \left\|P^2_{2n-1} J(E)\right\|_{L^2(\partial T)},$$

with $E := V - W$. It remains to show that the second and third terms are bounded by $\operatorname{osc}_{\mathcal{T}}(\mathbf{D},T)$ times the local H^1-norm of E. For $\mathcal{L}(E) = \operatorname{div}\mathbf{A}\nabla E - c\,E$ we have

$$\left\|P^2_{2n-2}\mathcal{L}(E)\right\|_{L^2(T)} \le \left\|P^2_{2n-2}(\operatorname{div}\mathbf{A}\nabla E)\right\|_{L^2(T)} + \left\|P^2_{2n-2}(cE)\right\|_{L^2(T)}.$$

We split the divergence term as

$$\operatorname{div}(\mathbf{A}\nabla E) = \operatorname{div}\mathbf{A}\cdot\nabla E + \mathbf{A}\colon D^2 E,$$

where D^2E is the Hessian of E. By invoking Lemma 3.2 with $\omega = T$ and observing that the polynomial degree of ∇E is $n-1$, we infer for the first term that

$$\left\|P^2_{2n-2}(\operatorname{div}\mathbf{A}\cdot\nabla E)\right\|_{L^2(T)} \le \left\|P^\infty_{n-1}\operatorname{div}\mathbf{A}\right\|_{L^\infty(T)} \|\nabla E\|_{L^2(T)}.$$

Since D^2E is a polynomial of degree $\le n-2$, by applying Lemma 3.2 again in conjunction with an inverse inequality, we have for the second term

$$\left\|P^2_{2n-2}(\mathbf{A} : D^2E)\right\|_{L^2(T)} \preccurlyeq h_T^{-1} \|P^\infty_n \mathbf{A}\|_{L^\infty(T)} \|\nabla E\|_{L^2(T)}.$$

To analyze the reaction term we write

$$\left\|P^2_{2n-2}(c\,E)\right\|_{L^2(T)} \le \left\|P^2_{2n-2}(c\,\Pi^2_0 E)\right\|_{L^2(T)} + \left\|P^2_{2n-2}(c\,P^2_0 E)\right\|_{L^2(T)}.$$

By applying again Lemma 3.2 we have for the first term

$$\left\|P^2_{2n-2}(c\,\Pi^2_0 E)\right\|_{L^2(T)} \le \left\|P^\infty_{2n-2} c\right\|_{L^\infty(T)} \|E\|_{L^2(T)}$$

and for the last one

$$\left\|P^2_{2n-2}(c\,P^2_0 E)\right\|_{L^2(T)} \preccurlyeq h_T \left\|P^\infty_{n-2} c\right\|_{L^\infty(T)} \|\nabla E\|_{L^2(T)}.$$

We now deal with the jump residual. Let $T' \in \mathcal{T}$ share an interior side σ with T. We write $J(E) = ((\mathbf{A}\nabla E)|_T - (\mathbf{A}\nabla E)|_{T'}) \cdot \boldsymbol{\nu}$ and use the linearity of Π^2_{2n-1}, Lemma 3.2 with $\omega = \sigma$, and the inverse inequality $\|\nabla E\|_{L^2(\sigma)} \preccurlyeq h_T^{-1/2} \|\nabla E\|_{L^2(T)}$ to deduce that

$$\left\|P^2_{2n-1}(\mathbf{A}\nabla E)|_T \cdot \boldsymbol{\nu}\right\|_{L^2(\sigma)} \preccurlyeq h_T^{-\frac{1}{2}} \|P^\infty_n \mathbf{A}\|_{L^\infty(T)} \|\nabla E\|_{L^2(T)}.$$

The same argument holds for T', and, since $\mathcal{T}$ is shape-regular, we can replace $h_{T'}$ by h_T. Finally, collecting the above estimates for T and all of its neighbors yields the assertion (3.2). ∎

The following two corollaries are global forms of the above lemma.

COROLLARY 3.4 (estimator reduction). *For $\mathcal{T} \in \mathbb{T}$ and $\mathcal{M} \subset \mathcal{T}$ let $\mathcal{T}_* \in \mathbb{T}$ be given by $\mathcal{T}_* := \mathsf{REFINE}(\mathcal{T}, \mathcal{M})$. If $\Lambda_1 := (d+1)\bar{\Lambda}_1^2/c_B$, with $\bar{\Lambda}_1$ from Proposition 3.3 and $\lambda := 1 - 2^{-\frac{b}{d}} > 0$, then there holds for all $V \in \mathbb{V}(\mathcal{T})$ and $V_* \in \mathbb{V}(\mathcal{T}_*)$ and any $\delta > 0$*

$$\begin{aligned}\eta^2_{\mathcal{T}_*}(V_*, \mathcal{T}_*) \le (1+\delta)\left\{\eta^2_{\mathcal{T}}(V, \mathcal{T}) - \lambda\, \eta^2_{\mathcal{T}}(V, \mathcal{M})\right\} \\ + (1+\delta^{-1})\Lambda_1 \eta^2_{\mathcal{T}_0}(\mathbf{D}, \mathcal{T}_0)\, |\!|\!| V_* - V |\!|\!|^2_\Omega .\end{aligned}$$

Proof. By applying Proposition 3.3 with $V_*, V \in \mathbb{V}(\mathcal{T}_*)$ over $T \in \mathcal{T}_*$ and using Young's inequality with parameter δ, we derive

$$\eta^2_{\mathcal{T}_*}(V_*, T) \le (1+\delta)\eta^2_{\mathcal{T}_*}(V, T) + (1+\delta^{-1})\bar{\Lambda}_1^2\, \eta^2_{\mathcal{T}_*}(\mathbf{D}, T)\, \|V_* - V\|^2_{H^1(\omega_T)}.$$

By summing over all elements $T \in \mathcal{T}_*$, using the finite overlap property of patches ω_T, and the equivalence of the H^1-norm and the energy norm in Ω, we have the following direct by-product:

$$\eta^2_{\mathcal{T}_*}(V_*, \mathcal{T}_*) \le (1+\delta)\eta^2_{\mathcal{T}_*}(V, \mathcal{T}_*) + (1+\delta^{-1})\Lambda_1 \eta^2_{\mathcal{T}_*}(\mathbf{D}, \mathcal{T}_*)\, |\!|\!| V_* - V |\!|\!|^2_\Omega .$$

For a marked element $T \in \mathcal{M}$, we set $\mathcal{T}_{*,T} := \{T' \in \mathcal{T}_* \mid T' \subset T\}$. Since $V \in \mathbb{V}(\mathcal{T})$ and $\mathbf{A}$ jumps only across sides of $\mathcal{T}_0$, we see that $J(V) = 0$ on sides of $\mathcal{T}_{*,T}$ in the interior of T. We then obtain

$$\sum_{T' \in \mathcal{T}_{*,T}} \eta^2_{\mathcal{T}_*}(V, T') \le 2^{-\frac{b}{d}} \eta^2_{\mathcal{T}}(V, T),$$

because refinement by bisection implies that $h_{T'} = |T'|^{\frac{1}{d}} \le (2^{-b}|T|)^{\frac{1}{d}} \le 2^{-\frac{b}{d}} h_T$ for all $T' \in \mathcal{T}_{*,T}$. For an element $T \in \mathcal{T} \setminus \mathcal{M}$, instead, Remark 2.1 yields $\eta_{\mathcal{T}_*}(V, T) \le \eta_{\mathcal{T}}(V, T)$. Hence, by summing over all $T \in \mathcal{T}_*$, we arrive at

$$\eta^2_{\mathcal{T}_*}(V, \mathcal{T}_*) \le \eta^2_{\mathcal{T}}(V, \mathcal{T} \setminus \mathcal{M}) + 2^{-\frac{b}{d}} \eta^2_{\mathcal{T}}(V, \mathcal{M}) = \eta^2_{\mathcal{T}}(V, \mathcal{T}) - \lambda \eta^2_{\mathcal{T}}(V, \mathcal{M}).$$

The assertion finally follows from the monotonicity $\eta_{\mathcal{T}_*}(\mathbf{D}, \mathcal{T}_*) \le \eta_{\mathcal{T}_0}(\mathbf{D}, \mathcal{T}_0)$ stated in Remark 3.1. ∎

COROLLARY 3.5 (perturbation of oscillation). *Let $\mathcal{T}, \mathcal{T}_* \in \mathbb{T}$, with $\mathcal{T} \le \mathcal{T}_*$, and let $\Lambda_1 = (d+1)\bar{\Lambda}_1^2/c_B$ be as in Corollary 3.4. For all $V \in \mathbb{V}(\mathcal{T})$ and $V_* \in \mathbb{V}(\mathcal{T}_*)$, we have*

$$\operatorname{osc}^2_{\mathcal{T}}(V, \mathcal{T} \cap \mathcal{T}_*) \le 2 \operatorname{osc}^2_{\mathcal{T}_*}(V_*, \mathcal{T} \cap \mathcal{T}_*) + 2\Lambda_1 \operatorname{osc}^2_{\mathcal{T}_0}(\mathbf{D}, \mathcal{T}_0)\, |\!|\!| V - V_* |\!|\!|^2_\Omega .$$

Proof. Remark 2.1 yields $\operatorname{osc}_{\mathcal{T}}(V, T) = \operatorname{osc}_{\mathcal{T}_*}(V, T)$ for all $T \in \mathcal{T} \cap \mathcal{T}_*$, whence

$$\operatorname{osc}^2_{\mathcal{T}}(V, T) \le 2 \operatorname{osc}^2_{\mathcal{T}_*}(V_*, T) + 2\bar{\Lambda}_1^2 \operatorname{osc}^2_{\mathcal{T}_*}(\mathbf{D}, T) \|V - V_*\|^2_{H^1(\omega_T)},$$

by (3.2) and Young's inequality. We now sum over $T \in \mathcal{T} \cap \mathcal{T}_*$ and use the equivalence of H^1 and energy norms in Ω, as well as the monotonicity property $\operatorname{osc}_{\mathcal{T}_*}(\mathbf{D}, \mathcal{T}_*) \le \operatorname{osc}_{\mathcal{T}_0}(\mathbf{D}, \mathcal{T}_0)$ stated in Remark 3.1, to prove the assertion. ∎

3.2. Localized upper bound. To prove the optimality of the AFEM, we need a localized upper bound for the distance between two nested solutions. This slightly improves a similar result by Stevenson [23] in the sense that the error can be estimated here by using only the indicators of refined elements without a buffer layer.

LEMMA 3.6 (localized upper bound). *For $\mathcal{T}, \mathcal{T}_* \in \mathbb{T}$, with $\mathcal{T} \leq \mathcal{T}_*$, let $\mathcal{R} = \mathcal{R}_{\mathcal{T}\to\mathcal{T}_*}$ be the set of refined elements. Let $U \in \mathbb{V}(\mathcal{T})$ and $U_* \in \mathbb{V}(\mathcal{T}_*)$ be the discrete solutions of* (2.1)*. Then the following localized upper bound is valid:*

$$|||U_* - U|||_\Omega^2 \leq C_1\, \eta_T^2(U, \mathcal{R}).$$

Proof. Let $\Omega_* = \bigcup\{T\colon T \in \mathcal{R}\}$ be the union of refined elements, and denote by Ω_i, $i = 1, \dots, I$, the connected components of its interior. For $i \in \{1, \dots, I\}$ we set $\mathcal{T}_i = \{T \in \mathcal{T} : T \subset \bar{\Omega}_i\}$ and let $\mathbb{V}(\mathcal{T}_i)$ be the restriction of $\mathbb{V}(\mathcal{T})$ to Ω_i. By using the Scott–Zhang interpolation operator $P_i\colon H^1(\Omega_i) \to \mathbb{V}(\mathcal{T}_i)$ over the triangulation $\mathcal{T}_i$, the following interpolation estimate holds true for all $v \in H^1(\mathcal{T}_i)$:

$$\sum_{T\in\mathcal{T}_i} h_T^{-2}\|v - P_i v\|_{L_2(T)}^2 + h_T^{-1}\|v - P_i v\|_{L_2(\partial T)}^2 \preccurlyeq \|\nabla v\|_{L^2(\Omega_i)}^2. \tag{3.3}$$

The constant hidden in "$\preccurlyeq$" does not depend on Ω_i but only on the shape-regularity of the underlying triangulation $\mathcal{T}_i$ and thus solely on $\mathcal{T}_0$ [22]. By construction, P_i preserves conforming boundary values, i.e., $P_i v = v$ on $\partial\Omega_i$ whenever $v = V$ on $\partial\Omega_i$ for some $V \in \mathbb{V}(\mathcal{T}_i)$.

For the error $E_* := U_* - U \in \mathbb{V}(\mathcal{T}_*)$ we construct an approximation $V \in \mathbb{V}(\mathcal{T})$ by setting

$$V := \begin{cases} P_i E_* & \text{in } \Omega_i, \\ E_* & \text{elsewhere.} \end{cases}$$

Since E_* has conforming boundary values on $\partial\Omega_i$ in $\mathbb{V}(\mathcal{T}_i)$, we conclude that V is continuous in Ω implying that $V \in \mathbb{V}(\mathcal{T})$ and V is an H^1-stable approximation to E_*.

Nesting of spaces $\mathbb{V}(\mathcal{T}) \subset \mathbb{V}(\mathcal{T}_*)$ implies Galerkin orthogonality $\mathcal{B}[E_*, E_*] = \mathcal{B}[E_*, E_* - V]$. In conjunction with $E_* - V = 0$ in $\Omega \setminus \Omega_*$ we thus obtain by standard arguments

$$\mathcal{B}[E_*, E_*] = \sum_{T\in\mathcal{R}} \langle R(U), E_* - V\rangle_T + \tfrac{1}{2}\langle J(U), E_* - V\rangle_{\partial T} \preccurlyeq \eta_{\mathcal{T}}(U, \mathcal{R})\|\nabla E_*\|_{L^2(\Omega_*)}.$$

In the last step we have used (3.3) on all connected components Ω_i of Ω_* with $v = E_*$. This, in conjunction with the coercivity of $\mathcal{B}$, proves the proposition. ∎

3.3. Overlay of meshes. We finish the auxiliary results with a counting argument for the overlay $\mathcal{T}_1 \oplus \mathcal{T}_2$ of two triangulations $\mathcal{T}_1$ and $\mathcal{T}_2$ from [23]. For the convenience of the reader we include a proof of this crucial result. As a consequence of the following lemma we see that for two conforming triangulations $\mathcal{T}_1, \mathcal{T}_2 \in \mathbb{T}$ the overlay is the smallest conforming triangulation $\mathcal{T} \in \mathbb{T}$, with $\mathcal{T}_1, \mathcal{T}_2 \leq \mathcal{T}$.

LEMMA 3.7 (overlay of meshes). *For $\mathcal{T}_1, \mathcal{T}_2 \in \mathbb{T}$ the overlay $\mathcal{T} := \mathcal{T}_1 \oplus \mathcal{T}_2$ is conforming, i.e., $\mathcal{T} \in \mathbb{T}$, and satisfies*

$$\#\mathcal{T} \leq \#\mathcal{T}_1 + \#\mathcal{T}_2 - \#\mathcal{T}_0.$$

Proof. Assume that $\mathcal{T}$ contains a nonconforming vertex z. Then there exist $T_1, T_2 \in \mathcal{T}$ with a common edge such that z is a vertex of T_1 and $z \in T_2$ but z is no

vertex of T_2. Without loss of generality let $T_1 \in \mathcal{T}_1$. Since $\mathcal{T}_1$ is conforming, there exists a $T' \in \mathcal{T}_1$, $T' \subset T_2$ such that z is a vertex of T'. Hence, T_2 cannot be a leaf node of $\mathcal{F}(\mathcal{T})$, i.e., $T_2 \notin \mathcal{T}$, a contradiction.

For $T \in \mathcal{T}_0$ and $i = 1, 2$ we denote by $\mathcal{F}_i(T) \subset \mathcal{F}(\mathcal{T})$ the binary trees with root T corresponding to $\mathcal{T}_i$ and let $\mathcal{T}_i(T)$ be the triangulation given by the leaf nodes of $\mathcal{F}_i(T)$. Since $\mathcal{T}(T) \subset \mathcal{T}_1(T) \cup \mathcal{T}_2(T)$, we infer that $\#\mathcal{T}(T) \leq \#\mathcal{T}_1(T) + \#\mathcal{T}_2(T)$. We now show that $\#\mathcal{T}(T) \leq \#\mathcal{T}_1(T) + \#\mathcal{T}_2(T) - 1$ by distinguishing two cases.

Case 1: $\mathcal{T}_1(T) \cap \mathcal{T}_2(T) \neq \emptyset$. Then there exists $T' \in \mathcal{T}_1(T) \cap \mathcal{T}_2(T)$, and so $T' \in \mathcal{T}(T)$. By counting T' only once in $\#(\mathcal{T}_1(T) \cup \mathcal{T}_2(T))$ we get $\#\mathcal{T}(T) \leq \#\mathcal{T}_1(T) + \#\mathcal{T}_2(T) - 1$.

Case 2: $\mathcal{T}_1(T) \cap \mathcal{T}_2(T) = \emptyset$. Then there exists $T' \in \mathcal{T}_1(T)$ (resp., $T' \in \mathcal{T}_2(T)$) so that $T' \notin \mathcal{T}(T)$, for otherwise $T' \in \mathcal{T}_2(T)$ (resp., $T' \in \mathcal{T}_1(T)$), thereby contradicting the assumption. We obtain again $\#\mathcal{T}(T) \leq \#\mathcal{T}_1(T) + \#\mathcal{T}_2(T) - 1$.

Finally, since $\mathcal{T}_i = \bigcup_{T \in \mathcal{T}_0} \mathcal{T}_i(T)$, the assertion follows by adding over $T \in \mathcal{T}_0$. ∎

4. Contraction property of the AFEM. We now prove that the AFEM is a contraction with respect to the sum of the energy error plus the scaled error estimator, the so-called *quasi error*. Consequently, the quasi error is reduced by a fixed rate at every step. This can be motivated heuristically as follows: in light of (2.4) the energy error $|||u - U_k|||_\Omega$ decreases strictly, unless $U_{k+1} = U_k$, in which case the estimator $\eta_k(U_k, \mathcal{T}_k)$ does according to Corollary 3.4. The theorem below makes this observation quantitative.

THEOREM 4.1 (contraction property). *Let $\theta \in (0, 1]$, and let $\{\mathcal{T}_k, \mathbb{V}_k, U_k\}_{k \geq 0}$ be the sequence of meshes, finite element spaces, and discrete solutions produced by the AFEM.*

Then there exist constants $\gamma > 0$ and $0 < \alpha < 1$, depending solely on the shape-regularity of $\mathcal{T}_0$, b, and the marking *parameter $0 < \theta \leq 1$, such that*

$$|||u - U_{k+1}|||_\Omega^2 + \gamma\, \eta_{k+1}^2(U_{k+1}, \mathcal{T}_{k+1}) \leq \alpha^2 \Big(|||u - U_k|||_\Omega^2 + \gamma\, \eta_k^2(U_k, \mathcal{T}_k) \Big).$$

Proof. For convenience, we use the notation

$$e_k := |||u - U_k|||_\Omega\,, \qquad E_k := |||U_{k+1} - U_k|||_\Omega\,,$$
$$\eta_k := \eta_k(U_k, \mathcal{T}_k), \quad \eta_k(\mathcal{M}_k) := \eta_k(U_k, \mathcal{M}_k), \quad \eta_0(\mathbf{D}) := \eta_0(\mathbf{D}, \mathcal{T}_0).$$

We combine the orthogonality (2.4) with Corollary 3.4 to write

$$e_{k+1}^2 + \gamma\, \eta_{k+1}^2 \leq e_k^2 - E_k^2 + (1 + \delta)\, \gamma \left(\eta_k^2 - \lambda\, \eta_k^2(\mathcal{M}_k) \right) + (1 + \delta^{-1})\, \gamma\, \Lambda_1\, \eta_0^2(\mathbf{D}) E_k^2.$$

We choose γ dependent on δ to be

$$\gamma := \frac{1}{(1 + \delta^{-1})\, \Lambda_1\, \eta_0^2(\mathbf{D})} \qquad \Leftrightarrow \qquad \gamma\,(1 + \delta) = \frac{\delta}{\Lambda_1\, \eta_0^2(\mathbf{D})} \tag{4.1}$$

to obtain

$$e_{k+1}^2 + \gamma\, \eta_{k+1}^2 \leq e_k^2 + (1 + \delta)\, \gamma\, \eta_k^2 - (1 + \delta)\, \lambda\, \gamma\, \eta_k^2(\mathcal{M}_k).$$

By invoking Dörfler marking (2.8), we deduce that

$$e_{k+1}^2 + \gamma\, \eta_{k+1}^2 \leq e_k^2 + (1 + \delta)\, \gamma\, \eta_k^2 - (1 + \delta)\, \lambda\, \theta^2\, \gamma\, \eta_k^2.$$

We rewrite this inequality as follows with any $\beta \in (0,1)$:

$$e_{k+1}^2 + \gamma\,\eta_{k+1}^2 \leq e_k^2 + (1+\delta)\,\gamma\,\eta_k^2 - \beta\,(1+\delta)\,\lambda\,\theta^2\,\gamma\,\eta_k^2 - (1-\beta)\,(1+\delta)\,\lambda\,\theta^2\,\gamma\,\eta_k^2,$$

apply the upper bound (2.6), and replace γ according to (4.1) to obtain

$$e_{k+1}^2 + \gamma\,\eta_{k+1}^2 \leq \alpha_1^2(\delta,\beta)\,e_k^2 + \gamma\,\alpha_2^2(\delta,\beta)\,\eta_k^2,$$

with

$$\alpha_1^2(\delta,\beta) := 1 - \beta\,\frac{\lambda\,\theta^2}{C_1\Lambda_1\,\eta_0^2(\mathbf{D})}\,\delta, \qquad \alpha_2^2(\delta,\beta) := (1+\delta)\big(1-(1-\beta)\,\lambda\,\theta^2\big).$$

Now choosing $\delta > 0$ small enough yields

$$\alpha^2 := \max\{\alpha_1^2,\,\alpha_2^2\} < 1,$$

which is the desired result. ∎

Remark 4.2 (ingredients for convergence). We stress that this new proof of linear convergence relies exclusively on the upper bound (2.6), the orthogonality relation (2.4), the error estimator reduction property of Corollary 3.4, and the Dörfler marking (2.8) for the estimator. It does not need any marking due to oscillation, which turns out to be problematic for optimality in light of the discussion in section 6. Equality (2.4) is used only to cancel, via (4.1), the contribution involving $\eta_0(\mathbf{D},\mathcal{T}_0)$ in Corollary 3.4. Its role is much less prominent than in [8, 16, 17, 18, 23].

Moreover, we use neither the lower bound (2.7) nor a discrete lower bound for proving convergence. The latter hinges on the rather demanding *interior node property*: every element of $\mathcal{M}_k$, as well as its adjacent elements, contains a node of $\mathcal{T}_{k+1}$ in their interior as well as in the interior of their common sides. However, the global lower bound (2.7) will be instrumental to prove optimality in section 5.

The treatment of oscillation and the interior node property is essential in [16, 17, 18] and so in [3, 23]. Our new approach simplifies the analysis and directly applies to any polynomial degree $n \geq 1$.

Remark 4.3 (optimal contraction factor α). Consider

$$D := \{(\delta,\beta) \in \mathbb{R}_+ \times [0,1] : \quad 0 \leq \alpha_1^2(\delta,\beta), \alpha_2^2(\delta,\beta) \leq 1\}.$$

This set is nonempty, according to the proof of Theorem 4.1, closed, and bounded; thus D is compact. Since α_1^2 and α_2^2 are continuous functions in D, $\alpha^2 = \max\{\alpha_1^2, \alpha_2^2\}$ attains its minimum in D. It turns out that $\alpha^2|_{\partial D} = 1$ by definition of D and $\alpha^2 < 1$ in the interior of D from the proof of Theorem 4.1. Consequently, α^2 attains an absolute minimum smaller than 1 and satisfies

$$\alpha^2 = \alpha_1^2 = \alpha_2^2.$$

To see this assume that $\alpha_1^2 < \alpha_2^2$, and decrease the value of δ slightly. Since α_1^2 increases whereas α_2^2 decreases, this yields a contradiction to the minimality of α^2. The case $\alpha_1^2 > \alpha_2^2$ is similar. In principle, this optimal value of α^2 can be computed explicity.

Remark 4.4 (range of γ and α). We see from (4.1) that $\gamma \approx \eta_0^{-2}(\mathbf{D},\mathcal{T}_0)$ provided that $\eta_0(\mathbf{D},\mathcal{T}_0)$ is large; this provides a lower bound for γ. An upper bound results from the condition $\alpha_1^2 > 0$ and $\delta \leq 1$, namely,

$$\alpha_1^2 = 1 - \frac{(1+\delta)\beta\lambda\theta^2}{C_1}\gamma \qquad \Rightarrow \qquad \gamma < \frac{C_1}{2\beta\lambda\theta^2} \approx C_1.$$

On the other hand, it is clear from the definitions of α_1 and α_2 that α deteriorates if either $\eta_0(\mathbf{D}, \mathcal{T}_0)$ increases or θ decreases. In fact, take $\beta = \frac{1}{2}$ and $\delta = \frac{1}{2}\lambda\theta^2$ to get

$$\alpha_1^2 = 1 - \frac{1}{C_1\Lambda_1\eta_0^2(\mathbf{D}, \mathcal{T}_0)}\Big(\frac{\lambda\theta^2}{2}\Big)^2, \qquad \alpha_2^2 = 1 - \Big(\frac{\lambda\theta^2}{2}\Big)^2.$$

Thus by the definition of α there exist constants $c, C > 0$ not depending on θ, with

$$1 - C\,\theta^4 \le \alpha^2 \le 1 - c\,\theta^4.$$

5. Quasi-optimal cardinality of the AFEM. Building on fundamental ideas of Binev, Dahmen, and DeVore [3] and Stevenson [23], used in the first optimality proofs for variants of the AFEM for the Poisson equation, we prove now the optimal cardinality of a *standard* AFEM for the general symmetric elliptic problem (1.1). We thus improve and extend the results of [3, 23].

5.1. Approximation class. Procedure MARK selects elements for refinement based on information provided by the error indicators $\eta_{\mathcal{T}}(U, T)$ for all $T \in \mathcal{T}$. Hence, a decay rate of the AFEM in terms of DOFs is closely related to the behavior of the estimator $\eta_{\mathcal{T}}(U, \mathcal{T})$. In order to link the estimator to the energy error $|\!|\!| u - U |\!|\!|_\Omega$, we observe that, according to the upper bound (2.6)

$$|\!|\!| u - U |\!|\!|_\Omega^2 \le C_1\,\eta_{\mathcal{T}}^2(U, \mathcal{T}),$$

a decay rate for the estimator directly implies a decay rate for the error. However, the error may decay faster than the estimator whenever overestimation occurs. The quality of the upper bound is described by the global lower bound (2.7)

$$C_2\,\eta_{\mathcal{T}}^2(U, \mathcal{T}) \le |\!|\!| u - U |\!|\!|_\Omega^2 + \operatorname{osc}_{\mathcal{T}}^2(U, \mathcal{T}).$$

Hence, the quality of the estimator strongly depends on the resolution of data $(\mathbf{D}, f)$ as well as the interaction of $\mathbf{D}$ with the discrete solution U, encoded in the oscillation term $\operatorname{osc}_{\mathcal{T}}(U, \mathcal{T})$. The latter cannot be removed as the following example shows.

Remark 5.1 (role of oscillation). The presence of $\operatorname{osc}_{\mathcal{T}}(U, \mathcal{T})$ in the lower bound is the price to pay for having a simple and computable estimator $\eta_{\mathcal{T}}(U, \mathcal{T})$. To see that oscillation cannot be removed, we let $\epsilon = 2^{-K}$ for K integer and extend the function $\frac{1}{2}x(\epsilon - |x|)$ defined on $(-\epsilon, \epsilon)$ to a 2ϵ-periodic C^1 function u on $\Omega = (-1, 1)$. We then consider u for data $\mathbf{D} = (1, 0)$ to be the exact solution, whence the corresponding right-hand side f is 2ϵ-periodic and piecewise constant with values $+1$ and -1 that change at multiples of ϵ.

Let $\mathcal{T}$ be a uniform mesh with mesh size $h = 2^{-k}$, with $k \ll K$. We consider piecewise linear approximation ($n = 1$), so that f is orthogonal to the space of piecewise constants, i.e., $\Pi_0^2 f = 0$. It is easy to verify that $U = 0$ and

$$|\!|\!| u - U |\!|\!|_\Omega = |\!|\!| u |\!|\!|_\Omega = \frac{\epsilon}{\sqrt{6}} = \frac{2^{-K}}{\sqrt{6}} \ll 2^{-k} = h = \|hf\|_\Omega = \operatorname{osc}_{\mathcal{T}}(U, \mathcal{T}) = \eta_{\mathcal{T}}(U, \mathcal{T}).$$

Therefore, the ratio between $|\!|\!| u - U |\!|\!|_\Omega$ and $\eta_{\mathcal{T}}(U, \mathcal{T})$ can be made arbitrarily small by increasing K/k, and $\operatorname{osc}_{\mathcal{T}}(U, \mathcal{T})$ accounts for the discrepancy. Moreover, if we were to express the oscillation in $H^{-1}(\Omega)$ as suggested in [3, 23], namely, $\|f - \Pi_0^2 f\|_{H^{-1}(\Omega)} = \|f\|_{H^{-1}(\Omega)} \approx \epsilon$, then $\operatorname{osc}_{\mathcal{T}}(U, \mathcal{T})$ would overestimate this quantity. This would correspond to evaluating the estimator in $H^{-1}(\Omega)$, which is impractical.

According to Remark 2.1 the estimator dominates oscillation, i.e., $\operatorname{osc}_{\mathcal{T}}^2(U,\mathcal{T}) \leq \eta_{\mathcal{T}}^2(U,\mathcal{T})$, which in combination with the upper bound yields

$$\|\!|u-U|\!\|_\Omega^2 + \operatorname{osc}_{\mathcal{T}}^2(U,\mathcal{T}) \leq (C_1+1)\,\eta_{\mathcal{T}}^2(U,\mathcal{T}).$$

We thus realize that

$$\eta_{\mathcal{T}}(U,\mathcal{T}) \approx \Big(\|\!|u-U|\!\|_\Omega^2 + \operatorname{osc}_{\mathcal{T}}^2(U,\mathcal{T})\Big)^{1/2},$$

where the right-hand side is the so-called *total error*. Since all decisions of the AFEM are based on the estimator, a decay rate for the AFEM can be characterized only by properties of the total error, and this has to be reflected in the definition of a suitable approximation class. By invoking the upper bound once again, we also see that the total error is equivalent to the quasi error

$$\|\!|u-U|\!\|_\Omega^2 + \operatorname{osc}_{\mathcal{T}}^2(U,\mathcal{T}) \approx \|\!|u-U|\!\|_\Omega^2 + \eta_{\mathcal{T}}^2(U,\mathcal{T}),$$

which is strictly reduced by the AFEM. Finally, the total error satisfies Cea's lemma.

LEMMA 5.2 (quasi optimality of the total error). *Let u be the solution of* (2.1)*, and for $\mathcal{T}\in\mathbb{T}$ let $U\in\mathbb{V}(\mathcal{T})$ be the Ritz–Galerkin approximation of* (2.3)*.*

Then there exists a constant $C_{\mathbf{D}}$ depending only on data $\mathbf{D}$ and shape-regularity of $\mathcal{T}_0$ such that

$$\|\!|u-U|\!\|_\Omega^2 + \operatorname{osc}_{\mathcal{T}}^2(U,\mathcal{T}) \leq C_{\mathbf{D}} \inf_{V\in\mathbb{V}(\mathcal{T})} \Big(\|\!|u-V|\!\|_\Omega^2 + \operatorname{osc}_{\mathcal{T}}^2(V,\mathcal{T})\Big).$$

Proof. For $\epsilon>0$ choose $V_\epsilon\in\mathbb{V}(\mathcal{T})$, with

$$\|\!|u-V_\epsilon|\!\|_\Omega^2 + \operatorname{osc}_{\mathcal{T}}^2(V_\epsilon,\mathcal{T}) \leq (1+\epsilon) \inf_{V\in\mathbb{V}(\mathcal{T})} \Big(\|\!|u-V|\!\|_\Omega^2 + \operatorname{osc}_{\mathcal{T}}^2(V,\mathcal{T})\Big).$$

Corollary 3.5 with $\mathcal{T}_*=\mathcal{T}$, $V=U$, and $V_*=V_\epsilon$ yields

$$\operatorname{osc}_{\mathcal{T}}^2(U,\mathcal{T}) \leq 2\,\operatorname{osc}_{\mathcal{T}}^2(V_\epsilon,\mathcal{T}) + 2\,\Lambda_1\,\operatorname{osc}_{\mathcal{T}_0}^2(\mathbf{D},\mathcal{T}_0)\,\|\!|U-V_\epsilon|\!\|_\Omega^2\,.$$

Since U is the Galerkin solution, $\|\!|u-U|\!\|_\Omega^2 + \|\!|U-V_\epsilon|\!\|_\Omega^2 = \|\!|u-V_\epsilon|\!\|_\Omega^2$, whence

$$\begin{aligned}\|\!|u-U|\!\|_\Omega^2 + \operatorname{osc}_{\mathcal{T}}^2(U,\mathcal{T}) &\leq \big(1+2\,\Lambda_1\,\operatorname{osc}_{\mathcal{T}_0}^2(\mathbf{D},\mathcal{T}_0)\big)\,\|\!|u-V_\epsilon|\!\|_\Omega^2 + 2\,\operatorname{osc}_{\mathcal{T}}^2(V_\epsilon,\mathcal{T})\\ &\leq (1+\epsilon)\,C_{\mathbf{D}}^2 \inf_{V\in\mathbb{V}(\mathcal{T})} \Big(\|\!|u-V|\!\|_\Omega^2 + \operatorname{osc}_{\mathcal{T}}^2(V,\mathcal{T})\Big),\end{aligned}$$

with $C_{\mathbf{D}} = \max\big\{2, 1+2\,\Lambda_1\,\operatorname{osc}_{\mathcal{T}_0}^2(\mathbf{D},\mathcal{T}_0)\big\}$, and the assertion follows from $\epsilon\to 0$. ∎

After collecting the above observations we are ready to define an approximation class $\mathbb{A}_s$ based on the total error. Let $\mathbb{T}_N\subset\mathbb{T}$ be the set of all possible conforming triangulations generated from $\mathcal{T}_0$ with at most N elements more than $\mathcal{T}_0$:

$$\mathbb{T}_N := \{\mathcal{T}\in\mathbb{T} \mid \#\mathcal{T} - \#\mathcal{T}_0 \leq N\}.$$

The quality of the best approximation to the total error in the set $\mathbb{T}_N$ is given by

$$\sigma(N;v,f,\mathbf{D}) := \inf_{\mathcal{T}\in\mathbb{T}_N} \inf_{V\in\mathbb{V}(\mathcal{T})} \Big(\|\!|v-V|\!\|_\Omega^2 + \operatorname{osc}_{\mathcal{T}}^2(V,\mathcal{T})\Big)^{1/2},$$

and for $s > 0$ we define the nonlinear approximation class $\mathbb{A}_s$ to be

$$\mathbb{A}_s := \Big\{(v, f, \mathbf{D}) \mid |v, f, \mathbf{D}|_s := \sup_{N>0} \big(N^s\, \sigma(N; v, f, \mathbf{D})\big) < \infty\Big\}.$$

Thanks to Lemma 5.2, the solution u of (1.1) with data $(\mathbf{D}, f)$ satisfies

$$\sigma(N; u, f, \mathbf{D}) \approx \inf_{\mathcal{T}\in\mathbb{T}_N} \big\{\eta_{\mathcal{T}}(U, \mathcal{T}) : U = \mathsf{SOLVE}(\mathcal{T})\big\}. \tag{5.1}$$

An important pending issue is the characterization of $\mathbb{A}_s$, which is beyond the scope of this paper. Nevertheless, we present a preliminary discussion now. We start by stressing that $\mathbb{A}_s$ is not a typical approximation class for functions, as known from approximation theory, because there is a nonlinear interaction between data $\mathbf{D} = (\mathbf{A}, c)$ and U through $\operatorname{osc}_{\mathcal{T}}(U, \mathcal{T})$. To avoid such an interaction, we first assume that coefficients $\mathbf{A}$ and c are piecewise polynomials of degree at most n and $n-2$ over $\mathcal{T}_0$, respectively. In this case, oscillation reduces to

$$\operatorname{osc}_{\mathcal{T}}(U, \mathcal{T}) = \big\|h(f - \Pi^2_{2n-2} f)\big\|_{L^2(\Omega)} \qquad \forall\, \mathcal{T} \in \mathbb{T},$$

which is independent of U. We have the following characterization of $\mathbb{A}_s$ in terms of standard approximation classes [3, 4, 23]:

$$\mathcal{A}_s := \Big\{v \in \mathbb{V} \mid \sup_{N>0} \big(N^s \inf_{\mathcal{T}\in\mathbb{T}_N} \inf_{V\in\mathbb{V}(\mathcal{T})} |\!|\!| v - V |\!|\!|_\Omega\big) < \infty\Big\},$$
$$\bar{\mathcal{A}}_s := \Big\{g \in L^2(\Omega) \mid \sup_{N>0} \big(N^s \inf_{\mathcal{T}\in\mathbb{T}_N} \big\|h(g - \Pi^2_{2n-2} g)\big\|_{L^2(\Omega)}\big) < \infty\Big\}.$$

LEMMA 5.3 (equivalence of classes). *If data $\mathbf{D} = (\mathbf{A}, c)$ are piecewise polynomials over $\mathcal{T}_0$, as specified above, then $(u, f, \mathbf{D}) \in \mathbb{A}_s$ if and only if $(u, f) \in \mathcal{A}_s \times \bar{\mathcal{A}}_s$.*

Proof. It is obvious that $(u, f, \mathbf{D}) \in \mathbb{A}_s$ implies that $(u, f) \in \mathcal{A}_s \times \bar{\mathcal{A}}_s$. In order to prove the reverse implication, let $(u, f) \in \mathcal{A}_s \times \bar{\mathcal{A}}_s$ and $\mathcal{T}_1, \mathcal{T}_2 \in \mathbb{T}_N$ be meshes so that $|\!|\!| u - U |\!|\!|_\Omega \preccurlyeq N^{-s}$ and $\big\|f - \Pi^2_{2n-2} f\big\|_{L^2(\Omega)} \preccurlyeq N^{-s}$. According to Lemma 3.7, the overlay $\mathcal{T} = \mathcal{T}_1 \oplus \mathcal{T}_2$ is a mesh with $\#\mathcal{T} - \#\mathcal{T}_0 \le 2N$, whence $\mathcal{T} \in \mathbb{T}_{2N}$ and

$$|\!|\!| u - U |\!|\!|_\Omega + \operatorname{osc}_{\mathcal{T}}(U, \mathcal{T}) \preccurlyeq N^{-s}.$$

This implies that $(u, f, \mathbf{D}) \in \mathbb{A}_s$, as asserted. ∎

A similar approximability condition $(u, f) \in \mathcal{A}_s \times \bar{\mathcal{A}}_s$ is imposed in [3, 23] to obtain quasi-optimal cardinality in terms of DOFs. In contrast to our approach, however, the two classes are handled separately (see section 6.2 for separate marking).

We now turn to the nonlinear interaction encoded in $\operatorname{osc}_{\mathcal{T}}(U, \mathcal{T})$. We first show, by using a priori arguments, that $(u, f, \mathbf{D}) \in \mathbb{A}_s$ for some $s > 0$.

LEMMA 5.4 (decay rate of oscillation). *The oscillation term $\operatorname{osc}_{\mathcal{T}}(U, \mathcal{T})$ has a decay rate of order at least $-1/d$, i.e.,*

$$\inf_{\mathcal{T}\in\mathbb{T}_N} \big\{\operatorname{osc}_{\mathcal{T}}(U, \mathcal{T}) \mid U = \mathsf{SOLVE}(\mathcal{T})\big\} \preccurlyeq N^{-1/d}. \tag{5.2}$$

Therefore, $(u, f, \mathbf{D}) \in \mathbb{A}_{r/d}$ for some $r \in (0, 1]$ depending on the regularity of $\mathbf{D}$ and Ω. Furthermore, if $u \in \mathcal{A}_s$ for some $s \in (0, 1/d]$, then $(u, f, \mathbf{D}) \in \mathbb{A}_s$.

Proof. Let $\mathcal{T} \in \mathbb{T}$ be generated by quasi-uniform refinement of $\mathcal{T}_0$ with $\#\mathcal{T} \approx N$. By applying (3.2) with $V = U$ and $W = 0$, we obtain for the oscillation term

$$\operatorname{osc}_{\mathcal{T}}(U, T) \le h_T \|P^2_{2n-2} f\|_T + \bar{\Lambda}_1 \operatorname{osc}_{\mathcal{T}}(\mathbf{D}, T) \|U\|_{H^1(\omega_T)} \preccurlyeq h_T \big(\|f\|_T + \|U\|_{H^1(\omega_T)}\big)$$

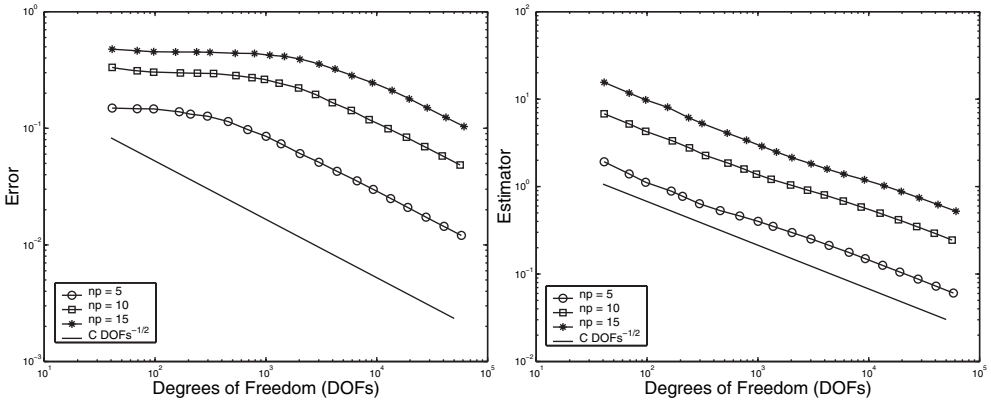

FIG. 5.1. *Decay of the energy error (left) and the estimator (right) for the smooth solution u_S of section 6.1 with frequencies 5, 10, and 15. The energy error exhibits a frequency-dependent plateau in the preasymptotic regime and later an optimal decay. This behavior is allowed by $\mathbb{A}_s$.*

by the definition of oscillation $\operatorname{osc}_{\mathcal{T}}(\mathbf{D}, T)$ and $\|P_n^\infty \mathbf{A}\|_{L^\infty(T)} \leq h_T \|\nabla \mathbf{A}\|_{L^\infty(T)}$. Quasi-uniform refinement yields the relation $h_T \approx N^{-1/d}$ for all $T \in \mathcal{T}$ which in turn implies (5.2). In the same vein, regularity $u \in H^{1+r}(\Omega)$ for some $0 < r \leq 1$ in any dimension d [11, Theorem 3] implies that a $\|\!|u - U|\!\|_\Omega \preccurlyeq N^{-r/d}$ by standard a priori estimates. Combining these estimates yields a decay rate $-r/d$ for the total error.

Finally, let $u \in \mathcal{A}_s$ and $\mathcal{T}_1 \in \mathbb{T}_N$ be such that $\|\!|u - U|\!\|_\Omega \preccurlyeq N^{-s}$. In view of (5.2), we find another grid $\mathcal{T}_2 \in \mathbb{T}_N$ with $\operatorname{osc}_{\mathcal{T}}(U, \mathcal{T}) \preccurlyeq N^{-1/d} \leq N^{-s}$. According to Lemma 3.7, the overlay $\mathcal{T} = \mathcal{T}_1 \oplus \mathcal{T}_2$ is a mesh with $\#\mathcal{T} - \#\mathcal{T}_0 \leq 2N$, i.e., $\mathcal{T} \in \mathbb{T}_{2N}$. The decay rate of total error is N^{-s} over $\mathcal{T}$, whence $(u, f, \mathbf{D}) \in \mathbb{A}_s$. ∎

Remark 5.5 (error notion). Lemma 5.4 states that for $s \leq 1/d$ oscillation exhibits a decay faster than the energy error; so the situation described in Remark 5.1 shows that the class $\mathbb{A}_s$ may fail to describe the behavior of $\|\!|u - U_k|\!\|_\Omega$ in the early stages of adaptivity. In fact, we recall that $\operatorname{osc}_k(U_k, \mathcal{T}_k) = \|h(f - \Pi_0^2 f)\|_\Omega$, the discrete solution $U_k = 0$, and $\|\!|u - U_k|\!\|_\Omega \approx 2^{-K}$ is constant for as many steps $k \leq K$ as desired. In contrast, $\eta_k(U_k, \mathcal{T}_k) = \operatorname{osc}_k(U_k, \mathcal{T}_k) = \|hf\|_\Omega$ reduces strictly for $k \leq K$ but overestimates $\|\!|u - U_k|\!\|_\Omega$. On the other hand, $\operatorname{osc}_k(U_k, \mathcal{T}_k) = 0$, and $\eta_k(U_k, \mathcal{T}_k) \approx \|\!|u - U_k|\!\|_\Omega$ dictates the asymptotics for $k > K$. This is consistent with Lemma 5.4 and $(u, f, \mathbf{D}) \in \mathbb{A}_1$. However, the fact that the preasymptotic regime $k \leq K$ for the energy error could be made arbitrarily long would be problematic if we were to focus exclusively on $\|\!|u - U_k|\!\|_\Omega$.

In practice, this effect is typically less dramatic because f is not orthogonal to $\mathbb{V}(\mathcal{T}_k)$. Figure 5.1 displays the behavior of the AFEM for the smooth solution u_S of section 6.1 with frequencies 5, 10, and 15. We can see that the error exhibits a frequency-dependent plateau in the preasymptotic regime and later an optimal decay. In contrast, the estimator decays always with the optimal rate. Since all decisions of the AFEM are based on the estimator, this behavior has to be expected and is consistent with our notion of the approximation class $\mathbb{A}_s$, which can be characterized just by the estimator; compare (5.1).

According to Lemma 5.4, the new approximation class $\mathbb{A}_s$ is completely determined by the standard approximation class $\mathcal{A}_s$ for $s \leq 1/d$. Furthermore, in practice oscillation is often much smaller than the true error, whence the asymptotic rate N^{-s} would be determined by $u \in \mathcal{A}_s$ for any $s > 0$. We point out the upper bound $s \leq n/d$ for polynomial degree $n \geq 1$ in dimension d, which can be easily seen for

uniform refinement; thus $s = 1/d$ is the highest attainable order with piecewise linears $n = 1$. A near characterization of $\mathcal{A}_s$ for $d = 2$ in terms of Besov spaces can be found in [3, 4]: $u \in \mathcal{A}_s$ implies that $u \in B_p^{2s+1}(L^p(\Omega))$ for $p = \frac{2}{2s+1}$ [3, Theorem 9.3]; $u \in B_p^{2s+1}(L^p(\Omega))$ for $p > \frac{2}{2s+1}$ implies that $u \in \mathcal{A}_s$ [3, Theorem 9.1]. Note that $p < 1$ for $s > 1/2$.

To motivate the case $n = 1$, $d = 2$, $s = 1/2$, we consider the following heuristic argument. Assume that a mesh $\mathcal{T} \in \mathbb{T}$ equidistributes the quantity $\Lambda = \|D^2 u\|_{L^1(T)}$. Polynomial interpolation theory then yields

$$\|\nabla(u - I_T u)\|_T \preccurlyeq \|D^2 u\|_{L^1(\omega_T)} \approx \Lambda \qquad \forall T \in \mathcal{T},$$

and thus

$$\|\nabla(u - I_{\mathcal{T}} u)\|_\Omega^2 = \sum_{T \in \mathcal{T}} \|\nabla(u - I_T u)\|_T^2 \preccurlyeq \Lambda^2 \#\mathcal{T}.$$

Since $\|D^2 u\|_{L^1(\Omega)} \approx \Lambda \#\mathcal{T}$, we deduce the error decay

$$\|\nabla(u - I_{\mathcal{T}} u)\|_\Omega \preccurlyeq \|D^2 u\|_{L^1(\Omega)} (\#\mathcal{T})^{-1/2}.$$

What this argument does not show is the existence of such a mesh $\mathcal{T} \in \mathbb{T}$ created by bisection from $\mathcal{T}_0$. This explains the need for a strict inequality in the characterization above. However, we still have the following optimal result.

LEMMA 5.6 (membership in $\mathbb{A}_{1/2}$). *Let $d = 2$, $n = 1$, and u be the solution of (1.1). Let $\Omega, \mathbf{A}, c$, and f satisfy the assumptions in section 2.1, and let $\mathbf{A}$ be globally Lipschitz. Then $(u, \mathbf{D}, f) \in \mathbb{A}_{1/2}$.*

Proof. By applying [10, Theorem 5.2.2], we deduce that $u \in W_p^2(\Omega)$ for some $p > 1$. The assertion follows upon combining [3, Theorem 9.1] for $s = 1/2$ with Lemma 5.4. ∎

A complete characterization of $\mathbb{A}_s$ for general d and n is still missing. It is important to realize that the nonlinear interaction between data $\mathbf{D}$ and U must be accounted for, thereby leading to a new concept of approximation class $\mathbb{A}_s$, which generalizes those in [3, 4, 23].

Remark 5.7 (conforming vs. nonconforming meshes). In contrast to [3, 23], our approach relies exclusively on conforming triangulations. When $\mathbf{D} = (\mathbf{I}, 0)$ and $n = 1$, the approximation class $\mathbb{A}_s$ is the same regardless of conformity [3]. The situation is quite different, however, in dealing with oscillation of a jump residual unless the depth of the nonconforming refinement is restricted beforehand.

Assume that $(u, f, \mathbf{D}) \in \mathbb{A}_s$ for some $s > 0$, where typically $s \le n/d$. We now prove that the approximation U_k generated by the AFEM converges to u with the same rate $(\#\mathcal{T}_k - \#\mathcal{T}_0)^{-s}$ as the best approximation described by $\mathbb{A}_s$ up to a multiplicative constant. We need to count elements marked by the estimator (the cardinality of $\mathcal{M}_k$) as well as those added to keep mesh conformity (see Lemma 2.3). To this end, we impose more stringent requirements than for convergence of the AFEM.

ASSUMPTION 5.8 (optimality). *We assume the following properties of the AFEM:*

(a) *The marking parameter θ satisfies $\theta \in (0, \theta_*)$, with*

$$\theta_*^2 = \frac{C_2}{1 + C_1(1 + 2\Lambda_1 \operatorname{osc}_{\mathcal{T}_0}^2(\mathbf{D}, \mathcal{T}_0))}.$$

(b) *Procedure* MARK *selects a set $\mathcal{M}_k$ of marked elements with minimal cardinality.*

(c) *The distribution of refinement edges on* $\mathcal{T}_0$ *satisfies condition (b) of section* 4 *in* [24].

The limit value θ_* depends on the ratio $\sqrt{C_2/C_1} \leq 1$, which quantifies the quality of estimator $\eta_{\mathcal{T}_k}(U_k, \mathcal{T}_k)$, as well as the oscillation $\operatorname{osc}_{\mathcal{T}_0}(\mathbf{D}, \mathcal{T}_0)$ of coefficients of the PDE on $\mathcal{T}_0$.

5.2. Cardinality of $\mathcal{M}_k$. The following lemma establishes a link between nonlinear approximation theory and the AFEM through the Dörfler marking strategy. Roughly speaking we prove that, if an approximation satisfies a suitable total error reduction from $\mathcal{T}$ to $\mathcal{T}_* \geq \mathcal{T}$, the error indicators of the coarser solutions must satisfy a Dörfler property on the set $\mathcal{R}_{\mathcal{T}\to\mathcal{T}_*}$. In other words, Dörfler marking and total error reduction are intimately connected.

LEMMA 5.9 (optimal marking). *Assume that the marking parameter* θ *verifies* (a) *of Assumption* 5.8. *Let* $\mathcal{T} \in \mathbb{T}$ *and* $U \in \mathbb{V}(\mathcal{T})$ *be the discrete solution of* (2.3). *Set* $\mu := \frac{1}{2}(1 - \frac{\theta^2}{\theta_*^2}) > 0$, *and let* $\mathcal{T}_* \in \mathbb{T}$ *be any refinement of* $\mathcal{T}$, *i.e.,* $\mathcal{T} \leq \mathcal{T}_*$, *such that the discrete solution* $U_* \in \mathbb{V}(\mathcal{T}_*)$ *satisfies*

$$|||u - U_*|||_\Omega^2 + \operatorname{osc}_{\mathcal{T}_*}^2(U_*, \mathcal{T}_*) \leq \mu \left\{ |||u - U|||_\Omega^2 + \operatorname{osc}_{\mathcal{T}}^2(U, \mathcal{T}) \right\}. \tag{5.3}$$

Then the set $\mathcal{R} := \mathcal{R}_{\mathcal{T}\to\mathcal{T}_*}$ *satisfies the Dörfler property*

$$\eta_{\mathcal{T}}(U, \mathcal{R}) \geq \theta\, \eta_{\mathcal{T}}(U, \mathcal{T}). \tag{5.4}$$

Proof. We first combine the lower bound (2.7) with (5.3) to obtain

$$\begin{aligned} (1 - 2\mu)\, C_2\, \eta_{\mathcal{T}}^2(U, \mathcal{T}) &\leq (1 - 2\mu) \left(|||u - U|||_\Omega^2 + \operatorname{osc}_{\mathcal{T}}^2(U, \mathcal{T}) \right) \\ &\leq |||u - U|||_\Omega^2 - |||u - U_*|||_\Omega^2 + \operatorname{osc}_{\mathcal{T}}^2(U, \mathcal{T}) - 2 \operatorname{osc}_{\mathcal{T}_*}^2(U_*, \mathcal{T}_*). \end{aligned} \tag{5.5}$$

We estimate separately the error and oscillation terms. We invoke the orthogonality (2.4) and the localized upper bound of Lemma 3.6 to arrive at

$$|||u - U|||_\Omega^2 - |||u - U_*|||_\Omega^2 = |||U_* - U|||_\Omega^2 \leq C_1\, \eta_{\mathcal{T}}^2(U, \mathcal{R}). \tag{5.6}$$

For the oscillation terms we argue according to whether an element $T \in \mathcal{T}$ belongs to the set of refined elements $\mathcal{R}$ or not. For $T \in \mathcal{R}$ we use the dominance

$$\operatorname{osc}_{\mathcal{T}}^2(U, T) \leq \eta_{\mathcal{T}}^2(U, T)$$

of Remark 2.1. For $T \in \mathcal{T} \cap \mathcal{T}_*$, Corollary 3.5 with $V = U$ and $V_* = U_*$ yields

$$\operatorname{osc}_{\mathcal{T}}^2(U, \mathcal{T} \cap \mathcal{T}_*) - 2 \operatorname{osc}_{\mathcal{T}_*}^2(U_*, \mathcal{T} \cap \mathcal{T}_*) \leq 2\Lambda_1 \operatorname{osc}_{\mathcal{T}_0}^2(\mathbf{D}, \mathcal{T}_0)\, |||U_* - U|||_\Omega^2.$$

By combining these two estimates with (5.6) we infer that

$$\operatorname{osc}_{\mathcal{T}}^2(U, \mathcal{T}) - 2 \operatorname{osc}_{\mathcal{T}_*}^2(U_*, \mathcal{T}_*) \leq (1 + 2\, C_1 \Lambda_1\, \operatorname{osc}_{\mathcal{T}_0}^2(\mathbf{D}, \mathcal{T}_0))\, \eta_{\mathcal{T}}^2(U, \mathcal{R}). \tag{5.7}$$

By collecting (5.5), (5.6), and (5.7), we finally deduce that

$$\eta_{\mathcal{T}}^2(U, \mathcal{R}) \geq \frac{(1 - 2\mu)\, C_2}{1 + C_1(1 + 2\,\Lambda_1 \operatorname{osc}_{\mathcal{T}_0}^2(\mathbf{D}, \mathcal{T}_0))}\, \eta_{\mathcal{T}}^2(U, \mathcal{T}) = \theta^2\, \eta_{\mathcal{T}}^2(U, \mathcal{T})$$

in light of the definitions of θ_*, θ, and μ. This concludes the proof. ∎

The key to relate the best mesh with AFEM triangulations is the fact that procedure MARK selects the marked set $\mathcal{M}_k$ with *minimal* cardinality. This crucial idea, due to Stevenson [23], is used next.

LEMMA 5.10 (cardinality of $\mathcal{M}_k$). *Assume that the marking parameter θ verifies* (a) *and procedure MARK satisfies* (b) *of Assumption* 5.8. *Let u be the solution of* (1.1), *and let $\{\mathcal{T}_k, \mathbb{V}_k, U_k\}_{k\geq 0}$ be the sequence of meshes, finite element spaces, and discrete solutions produced by the AFEM.*

If $(u, f, \mathbf{D}) \in \mathbb{A}_s$, then the following estimate is valid:

$$\#\mathcal{M}_k \preccurlyeq \left(1 - \frac{\theta^2}{\theta_*^2}\right)^{-\frac{1}{2s}} |u, f, \mathbf{D}|_s^{\frac{1}{s}} C_{\mathbf{D}}^{\frac{1}{2s}} \left\{ |\!|\!| u - U_k |\!|\!|_\Omega^2 + \operatorname{osc}_{\mathcal{T}_k}^2(U_k, \mathcal{T}_k) \right\}^{-\frac{1}{2s}}.$$

Proof. We set $\epsilon^2 := \mu\, C_{\mathbf{D}}^{-1}(|\!|\!| u - U_k |\!|\!|_\Omega^2 + \operatorname{osc}_{\mathcal{T}_k}^2(U_k, \mathcal{T}_k))$, where $\mu = \frac{1}{2}(1 - \frac{\theta^2}{\theta_*^2}) > 0$ and $C_{\mathbf{D}}$ is the constant in Lemma 5.2. Since $(u, f, \mathbf{D}) \in \mathbb{A}_s$, there exists a $\mathcal{T}_\epsilon \in \mathbb{T}$ and a $V_\epsilon \in \mathbb{V}(\mathcal{T}_\epsilon)$ such that

$$\#\mathcal{T}_\epsilon - \#\mathcal{T}_0 \preccurlyeq |u, f, \mathbf{D}|_s^{1/s} \epsilon^{-1/s}, \tag{5.8}$$

$$|\!|\!| u - V_\epsilon |\!|\!|_\Omega^2 + \operatorname{osc}_{\mathcal{T}_\epsilon}^2(V_\epsilon, \mathcal{T}_\epsilon) \leq \epsilon^2. \tag{5.9}$$

Let $\mathcal{T}_* := \mathcal{T}_\epsilon \oplus \mathcal{T}_k$ be the overlay of $\mathcal{T}_\epsilon$ and $\mathcal{T}_k$, and let $U_* \in \mathbb{V}(\mathcal{T}_*)$ be the discrete solution of (2.3) on $\mathcal{T}_*$. To show that there is a reduction by a factor μ of the total error between U_* and U_k, since $\mathcal{T}_* \geq \mathcal{T}_\epsilon$, we argue as in Lemma 5.2 and obtain

$$\begin{aligned} |\!|\!| u - U_* |\!|\!|_\Omega^2 + \operatorname{osc}_{\mathcal{T}_*}^2(U_*, \mathcal{T}_*) &\leq C_{\mathbf{D}} \left\{ |\!|\!| u - V_\epsilon |\!|\!|_\Omega^2 + \operatorname{osc}_{\mathcal{T}_\epsilon}^2(V_\epsilon, \mathcal{T}_\epsilon) \right\} \\ &\leq C_{\mathbf{D}}\, \epsilon^2 = \mu \left\{ |\!|\!| u - U_k |\!|\!|_\Omega^2 + \operatorname{osc}_k^2(U_k, \mathcal{T}_k) \right\}. \end{aligned}$$

Hence, we deduce from Lemma 5.9 that the subset $\mathcal{R} := \mathcal{R}_{\mathcal{T}_k \to \mathcal{T}_*} \subset \mathcal{T}_k$ verifies the Dörfler property (5.4) for $\theta < \theta_*$. The fact that procedure MARK selects a subset $\mathcal{M}_k \subset \mathcal{T}_k$ with minimal cardinality satisfying the same property translates into

$$\#\mathcal{M}_k \leq \#\mathcal{R} \leq \#\mathcal{T}_* - \#\mathcal{T}_k \leq \#\mathcal{T}_\epsilon - \#\mathcal{T}_0, \tag{5.10}$$

where Lemma 3.7 has been employed in the last step. Finally, by combining (5.10), (5.8), and the definition of ϵ, we end up with

$$\#\mathcal{M}_k \leq \#\mathcal{T}_\epsilon - \#\mathcal{T}_0 \preccurlyeq \mu^{-\frac{1}{2s}} |u, f, \mathbf{D}|_s^{\frac{1}{s}} C_{\mathbf{D}}^{\frac{1}{2s}} \left\{ |\!|\!| u - U_k |\!|\!|_\Omega^2 + \operatorname{osc}_k^2(U_k, \mathcal{T}_k) \right\}^{-\frac{1}{2s}},$$

which is the asserted estimate. ∎

5.3. Quasi optimality. As a consequence of the previous estimates and the fact that the AFEM is a contraction for the quasi error, we obtain quasi optimality of the total error.

THEOREM 5.11 (quasi optimality). *Let Assumption* 5.8 *be satisfied by the AFEM. Let u be the solution of* (1.1), *and let $\{\mathcal{T}_k, \mathbb{V}_k, U_k\}_{k\geq 0}$ be the sequence of meshes, finite element spaces, and discrete solutions produced by the AFEM.*

Let $(u, f, \mathbf{D}) \in \mathbb{A}_s$ and $\Theta(\theta, s) := \theta^{-4s}(1 - \frac{\theta^2}{\theta_*^2})^{-1/2}$ describe the asymptotics of the AFEM as $\theta \to \theta_*, 0$ or $s \to 0$. Then there exists a constant C, depending on data, the refinement depth b, and $\mathcal{T}_0$, but independent of s, such that

$$\left\{ |\!|\!| u - U_k |\!|\!|_\Omega^2 + \operatorname{osc}_k^2(U_k, \mathcal{T}_k) \right\}^{1/2} \leq C\, \Theta(\theta, s) |u, f, \mathbf{D}|_s \big(\#\mathcal{T}_k - \#\mathcal{T}_0\big)^{-s}.$$

Proof. By combining Lemmas 2.3 and 5.10 we deduce that

$$\#\mathcal{T}_k - \#\mathcal{T}_0 \preccurlyeq \sum_{j=0}^{k-1} \#\mathcal{M}_j \preccurlyeq M \sum_{j=0}^{k-1} \Big\{ |\!|\!| u - U_j |\!|\!|_\Omega^2 + \operatorname{osc}_j^2(U_j, \mathcal{T}_j) \Big\}^{-\frac{1}{2s}}, \tag{5.11}$$

with $M := (1 - \frac{\theta^2}{\theta_*^2})^{-\frac{1}{2s}} |u, f, \mathbf{D}|_s^{\frac{1}{s}} C_{\mathbf{D}}^{\frac{1}{2s}}$. We infer from the lower bound (2.7) that

$$\begin{aligned} |\!|\!| u - U_j |\!|\!|_\Omega^2 + \gamma \ \operatorname{osc}_j^2(U_j, \mathcal{T}_j) &\le |\!|\!| u - U_j |\!|\!|_\Omega^2 + \gamma \, \eta_j^2(U_j, \mathcal{T}_j) \\ &\le \left(1 + \frac{\gamma}{C_2}\right) \Big\{ |\!|\!| u - U_j |\!|\!|_\Omega^2 + \operatorname{osc}_j^2(U_j, \mathcal{T}_j) \Big\}. \end{aligned} \tag{5.12}$$

On the other hand, the linear rate $\alpha = \alpha(\theta) < 1$ of convergence of Theorem 4.1 for the sum of the energy error and the scaled error estimator implies that afor $0 \le j \le k-1$

$$|\!|\!| u - U_k |\!|\!|_\Omega^2 + \gamma \, \eta_k^2(U_k, \mathcal{T}_k) \le \alpha^{2(k-j)} \Big\{ |\!|\!| u - U_j |\!|\!|_\Omega^2 + \gamma \, \eta_j^2(U_j, \mathcal{T}_j) \Big\}. \tag{5.13}$$

We combine (5.11), (5.12), and (5.13) to obtain

$$\#\mathcal{T}_k - \#\mathcal{T}_0 \preccurlyeq M \left(1 + \frac{\gamma}{C_2}\right)^{\frac{1}{2s}} \Big\{ |\!|\!| u - U_k |\!|\!|_\Omega^2 + \gamma \, \eta_k^2(U_k, \mathcal{T}_k) \Big\}^{-\frac{1}{2s}} \sum_{j=1}^{k} \alpha^{\frac{j}{s}}.$$

Since $\alpha < 1$, the geometric series is bounded by the constant $S_\theta = \alpha^{1/s}(1 - \alpha^{1/s})^{-1}$. By recalling that the element residual dominates the oscillation, we end up with

$$\#\mathcal{T}_k - \#\mathcal{T}_0 \preccurlyeq S_\theta M \left(1 + \frac{\gamma}{C_2}\right)^{\frac{1}{2s}} \Big\{ |\!|\!| u - U_k |\!|\!|_\Omega^2 + \gamma \operatorname{osc}_k^2(U_k, \mathcal{T}_k) \Big\}^{-\frac{1}{2s}}. \tag{5.14}$$

To examine the asymptotics as $\theta, s \to 0$, hidden in S_θ, we use Remark 4.4 to get $\alpha \le (1-t)^{\frac{1}{2}}$, with $t = c\theta^4$, and observe that $\lim_{t \to 0} \frac{t}{1 - (1-t)^{\frac{1}{2s}}} = 2s$. Therefore

$$S_\theta^s \le \frac{\alpha}{t^s} \left(\frac{t}{1 - (1-t)^{1/2s}} \right)^s \approx \alpha s^s \theta^{-4s},$$

whence $S_\theta^s M^s \approx \Theta(\theta, s) |u, f, \mathbf{D}|_s \, C_{\mathbf{D}}^{1/2}$. By raising (5.14) to the sth power and reordering, we obtain the desired estimate for the total error with $C > 0$ independent of s. ∎

The same decay rate is obtained for the error estimator due to its equivalence to the total error.

COROLLARY 5.12. *Under the same requirements as in Theorem* 5.11*, there exists a constant C such that*

$$\eta_k \le C \, \Theta(\theta, s) |u, f, \mathbf{D}|_s \big(\#\mathcal{T}_k - \#\mathcal{T}_0 \big)^{-s}.$$

The constant C may differ from the one in Theorem 5.11.

6. The critical role of marking for optimality. We conclude the article by revisiting former optimality proofs by Binev, Dahmen, and DeVore [3] and Stevenson [23], which are based on the AFEM designed by Morin, Nochetto, and Siebert [17, 18], from now on called MNS. This is an adaptive loop of the form (1.2), which marks

separately for both the estimator and the oscillation in each iteration, which in turn yields a contraction for the energy error. It turns out that separate marking appears to be problematic for proving optimality, and thus variants of MNS are studied instead [3, 23]. The key issue is the delicate choice of marking parameters for the estimator and oscillation. To shed light on this intrinsic difficulty we first present some numerical experiments, then discuss the effect of separate marking, and finally comment on marking for an optimal AFEM.

6.1. Separate marking and MNS. The procedure ESTIMATE of MNS calculates both the error and oscillation indicators $\{\eta_k(U_k,T),\operatorname{osc}_k(U_k,T)\}_{T\in\mathcal{T}_k}$, and the procedure MARK uses Dörfler marking for both the estimator and oscillation. More precisely, the routine MARK of MNS is of the form: *given parameters* $0<\theta_{\rm est},\theta_{\rm osc}<1$,

(6.1a) *mark any subset* $\mathcal{M}_k\subset\mathcal{T}_k$ *such that* $\eta_k(U_k,\mathcal{M}_k)\geq\theta_{\rm est}\eta_k(U_k,\mathcal{T}_k)$;

(6.1b) *if necessary enlarge* $\mathcal{M}_k$ *to satisfy* $\operatorname{osc}_k(U_k,\mathcal{M}_k)\geq\theta_{\rm osc}\operatorname{osc}_k(U_k,\mathcal{T}_k)$.

Since oscillation is generically of higher order than the estimator, the issue at stake is whether elements added by oscillation, even though immaterial relative to the error, could ruin the optimality of MNS observed in experiments [17, 18, 16]. If $\eta_k(U_k,\mathcal{T}_k)$ has large indicators in a small area, then Dörfler marking for the estimator (6.1a) could select a set $\mathcal{M}_k$ with a small number of elements relative to $\mathcal{T}_k$. However, if $\operatorname{osc}_k(U_k,\mathcal{T}_k)$ were globally distributed in $\mathcal{T}_k$, then MNS would require additional marking of a large percentage of all elements to satisfy (6.1b); i.e., $\#\mathcal{M}_k$ could be large relative to $\#\mathcal{T}_k$.

To explore this idea computationally, we consider a simple modification of the two-dimensional Example 5.3 in [12, 17]

$$-\operatorname{div}\mathbf{A}\nabla u=f\qquad\text{in }\Omega,\qquad u=g\qquad\text{on }\Omega,$$

where $\Omega=(-1,1)^2$ and $\mathbf{A}:=a_i\mathbf{I}$ is a piecewise constant (checkerboard pattern), with $a_1=a_3$ in the first and third quadrants and $a_2=a_4$ in the second and fourth quadrants. The exact solution u is given as a sum: $u=u_K+u_S$. Function $u_K\in H^1(\Omega)$ is the weak solution of $\operatorname{div}(\mathbf{A}\nabla u_K)=0$ for parameters [12, 17, 18]

$$a_1=a_3=161.4476387975881,\qquad a_2=a_4=1;$$

the singularity $u_K\approx r^{0.1}$ at the origin is so extreme that it typically leads to marking of a handful of elements per step to satisfy (6.1a) (see [17, 18] for details). Function u_S is given in each quadrant by

$$u_S(x,y)=10^{-2}a_i^{-1}(x^2+y^2)\sin^2(4\pi x)\sin^2(4\pi y),\qquad 1\leq i\leq 4,$$

is smooth, and is of comparable magnitude with u_K, while the corresponding $f=-\operatorname{div}\mathbf{A}\nabla u_S$ exhibits an increasing amount of data oscillation away from the origin. Procedure MARK takes the usual value of $\theta_{\rm est}=0.5$ [8, 17, 18, 21], and procedure REFINE subdivides all elements in $\mathcal{M}_k$ by using two bisections.

The behavior of MNS for several values of $\theta_{\rm osc}$ is depicted in Figure 6.1. We can visualize the sensitivity of MNS with respect to parameter $\theta_{\rm osc}$. For values of $\theta_{\rm osc}\leq 0.4$ the rate of convergence appears to be quasi-optimal. However, beyond this threshold the curves for both the error and the estimator flatten out, thereby showing lack of optimality. The threshold value $\theta_{\rm osc}=0.4$, even though consistent with the practice of MNS, is tricky to find in general since it is problem-dependent.

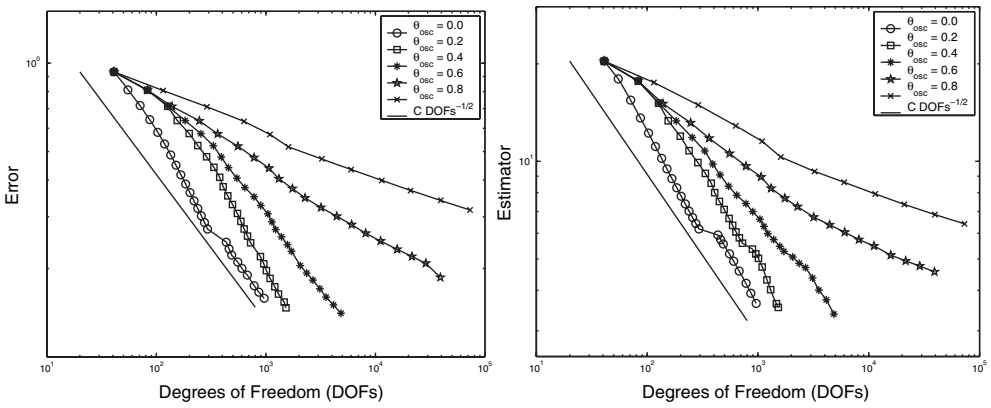

FIG. 6.1. *Decay of the error (left) and the estimator (right) vs. DOFs for* $\theta_{\mathrm{est}} = 0.5$ *and values* $\theta_{\mathrm{osc}} = 0.0, 0.2, 0.4, 0.6,$ *and* 0.8. *For values of* $\theta_{\mathrm{osc}} \leq 0.4$ *the rate of convergence is quasi-optimal, but for* $\theta_{\mathrm{osc}} > 0.4$ *the curves flatten out, thereby showing lack of optimality.*

Lemma 6.1 below provides theoretical insight on this matter. Altogether this indicates that an optimality proof for MNS is out of reach without restrictions on θ_{osc} and makes marking by oscillation (6.1b) questionable.

6.2. Analysis of separate marking. In this section we focus on the adaptive approximation of two given functions in an idealized scenario. We show that separate marking, similar to (6.1), may lead to suboptimal meshes in general. However, a suitable choice of marking parameters may restore optimality. The experiments of section 6.1 confirm this theoretical insight in the nonidealized case of MNS.

For the discussion, we assume that we have two functions u_i, $i = 1, 2$, and have access to their local approximation error

$$e_{\mathcal{T}}(u_i; T) = |u_i - I_{\mathcal{T}} u_i|_{i;T} \qquad \forall T \in \mathcal{T}$$

and global error $e^2_{\mathcal{T}}(u_i) = \sum_{T \in \mathcal{T}} e^2_{\mathcal{T}}(u_i; T)$; hereafter $|\cdot|_i$ are unspecified norms, and $I_{\mathcal{T}}$ is a local interpolation operator over $\mathcal{T} \in \mathbb{T}$. We define the *total error* to be

$$e^2_{\mathcal{T}} := e^2_{\mathcal{T}}(u_1) + e^2_{\mathcal{T}}(u_2)$$

and are interested in its asymptotic decay. If $\mathcal{T} = \mathcal{T}_k$, then we denote $e_k = e_{\mathcal{T}_k}$.

To explore the use of (6.1), we examine the effect of separate marking for $e_k(u_i)$ on a sequence of meshes $\mathcal{T}^i_k$ for $i = 1, 2$. We put ourselves in an idealized, but plausible, situation governed by the following three simplifying assumptions:

(6.2a) *Independence:* $\mathcal{T}^1_k$ *and* $\mathcal{T}^2_k$ *are generated from* $\mathcal{T}_0$ *and are independent of each other;*

(6.2b) *Marking: Separate Dörfler marking with parameters* $\theta_i \in (0, 1)$ *implies that* $e_k(u_i) \approx \alpha^k_i$ *on* $\mathcal{T}^i_k$, *with* $\alpha_i \in (0, 1)$;

(6.2c) *Approximability:* $e_k(u_i) \approx (\#\mathcal{T}^i_k - \#\mathcal{T}_0)^{-s_i}$, *with* $s_1 \leq s_2$ *maximal.*

We are interested in the decay of the total error e_k on the overlay $\mathcal{T}_k := \mathcal{T}^1_k \oplus \mathcal{T}^2_k$. This scenario is a simplification of the more realistic approximation of u_1 and u_2 with separate Dörfler marking on the same sequence of grids $\mathcal{T}_k$ but avoids the complicated interaction of the two marking procedures.

LEMMA 6.1 (separate marking). *Let assumptions* (6.2) *be satisfied.*

Then the decay of the total error e_k on the overlay $\mathcal{T}_k = \mathcal{T}_k^1 \oplus \mathcal{T}_k^2$ for separate marking is always suboptimal except when α_1 and α_2 satisfy

$$\alpha_2 \le \alpha_1 \le \alpha_2^{s_1/s_2}.$$

Proof. Assumption (6.2b) on the average reduction rate implies for the total error that

$$e_k \approx e_k(u_1) + e_k(u_2) \approx \max\{e_k(u_1), e_k(u_2)\} \approx \max\{\alpha_1^k, \alpha_2^k\}. \tag{6.3}$$

Combining (6.2b) and (6.2c) yields $\alpha_i^k \approx (\#\mathcal{T}_k^i - \#\mathcal{T}_0)^{-s_i}$, whence

$$\#\mathcal{T}_k^1 - \#\mathcal{T}_0 \approx \alpha_1^{-k/s_1} = \beta^k \alpha_2^{-k/s_2} \approx \beta^k (\#\mathcal{T}_k^2 - \#\mathcal{T}_0), \tag{6.4}$$

with $\beta = \alpha_1^{-1/s_1}\alpha_2^{1/s_2}$. In view of (2.2), this gives for the overlay $\mathcal{T}_k = \mathcal{T}_k^1 \oplus \mathcal{T}_k^2$

$$\#\mathcal{T}_k - \#\mathcal{T}_0 \approx \begin{cases} \#\mathcal{T}_k^1 - \#\mathcal{T}_0, & \beta \ge 1, \\ \#\mathcal{T}_k^2 - \#\mathcal{T}_0, & \beta < 1. \end{cases} \tag{6.5}$$

The optimal decay of total error e_k corresponds to $e_k \approx (\#\mathcal{T}_k - \#\mathcal{T}_0)^{-s_1}$ because $s_1 \le s_2$. In analyzing the relation of e_k to the number of elements $\#\mathcal{T}_k$ in the overlay $\mathcal{T}_k$, we distinguish three cases and employ (6.3), (6.4), and (6.5).

Case 1: $\alpha_1 < \alpha_2$. We note that $\alpha_1 < \alpha_2$ and $s_1 \le s_2$ yields $\beta \ge 1$. We thus deduce that

$$\begin{aligned} e_k &\approx \max\{\alpha_1^k, \alpha_2^k\} = \alpha_2^k = (\alpha_2/\alpha_1)^k \, \alpha_1^k \\ &\approx (\alpha_2/\alpha_1)^k \, (\#\mathcal{T}_k^1 - \#\mathcal{T}_0)^{-s_1} \approx (\alpha_2/\alpha_1)^k \, (\#\mathcal{T}_k - \#\mathcal{T}_0)^{-s_1}. \end{aligned}$$

Since $\alpha_2/\alpha_1 > 1$, the approximation of e_k on $\mathcal{T}_k$ is suboptimal.

Case 2: $\alpha_1 \ge \alpha_2$ and $\beta < 1$. We obtain

$$\begin{aligned} e_k &\approx \max\{\alpha_1^k, \alpha_2^k\} = \alpha_1^k \approx (\#\mathcal{T}_k^1 - \#\mathcal{T}_0)^{-s_1} \\ &\approx \beta^{-ks_1} (\#\mathcal{T}_k^2 - \#\mathcal{T}_0)^{-s_1} \approx \beta^{-ks_1} (\#\mathcal{T}_k - \#\mathcal{T}_0)^{-s_1}, \end{aligned}$$

whence the approximation of the total error on $\mathcal{T}_k$ is again suboptimal.

Case 3: $\alpha_1 \ge \alpha_2$ and $\beta \ge 1$. We infer that

$$e_k \approx \max\{\alpha_1^k, \alpha_2^k\} = \alpha_1^k \approx (\#\mathcal{T}_k^1 - \#\mathcal{T}_0)^{-s_1} \approx (\#\mathcal{T}_k - \#\mathcal{T}_0)^{-s_1}$$

and that $\mathcal{T}_k$ exhibits optimal cardinality. This exceptional case corresponds to the assertion and concludes the proof. ∎

We learn from Lemma 6.1 that separate marking requires a critical choice of parameters θ_i to obtain optimal cardinality of grids with respect to the total error e_k. By revisiting MNS in light of Lemma 6.1, we could identify the estimator η_k with the error $e_k(u_1)$ and oscillation osc_k with the error $e_k(u_2)$. We observe that $\mathrm{osc}_k \le \eta_k$ combined with (6.2b) implies that $\alpha_2 \le \alpha_1$ and that osc_k is generically of higher order than η_k, thereby yielding $s_1 < s_2$.

We wonder whether or not the optimality condition $\alpha_1 \le \alpha_2^{s_1/s_2}$ is valid. Note that $\alpha_2^{s_1/s_2}$ increases as the gap between s_1 and s_2 increases. Since the oscillation reduction estimate of [17] reveals that α_2 increases as θ_{osc} decreases, we see that

separate marking may be optimal for a wide range of marking parameters $\theta_{\mathrm{est}}, \theta_{\mathrm{osc}}$; this is confirmed by the numerical experiments in section 6.1 even though it is unclear whether η_k and osc_k satisfy (6.2). However, choosing marking parameters $\theta_{\mathrm{est}}, \theta_{\mathrm{osc}}$ is rather tricky in practice because neither the explicit dependence of average reduction rates α_1, α_2 on $\theta_{\mathrm{est}}, \theta_{\mathrm{osc}}$ nor the optimal exponents s_1, s_2 are known. In contrast to MNS, the standard AFEM of section 2.7 marks solely according to the estimator $\eta_{\mathcal{T}}(U, \mathcal{T})$ and thus avoids separate marking.

We conclude by reviewing how an alternative optimal AFEM for the Poisson problem compensates for the lack of optimality of separate marking. Binev, Dahmen, and DeVore [3] added a coarsening step to MNS to prove optimality. Veeser [26] was the first to mark oscillation relative to the error estimator to prove convergence of the AFEM for the p-Laplacian. More recently, Stevenson [23] resorted to a similar marking to prove optimality of the AFEM at the expense of an additional inner loop to reduce data oscillation. Since for the more general elliptic PDE (1.1) oscillation $\mathrm{osc}_{\mathcal{T}}(U, \mathcal{T})$ interacts nonlinearly with the discrete solution U, it is not clear how to follow the approaches in [3, 23] with separate marking.

Acknowledgments. We thank the editor and the anonymous referees for their constructive comments that helped to improve the presentation.

STABILITY OF FD–TD SCHEMES FOR MAXWELL–DEBYE AND MAXWELL–LORENTZ EQUATIONS*

BRIGITTE BIDÉGARAY-FESQUET†

Abstract. The stability of five finite difference–time domain (FD–TD) schemes coupling Maxwell equations to Debye or Lorentz models has been analyzed in [P. Petropoulos, *Stability and phase error analysis of FD–TD in dispersive dielectrics*, IEEE Trans. Antennas Propag., 42 (1994), pp. 62–69], where numerical evidence for specific media have been used. We use von Neumann analysis to give necessary and sufficient stability conditions for these schemes for any medium, in accordance with the partial results of [P. Petropoulos, *Stability and phase error analysis of FD–TD in dispersive dielectrics*, IEEE Trans. Antennas Propag., 42 (1994), pp. 62–69]. To make this approach tractable for two-dimensional and three-dimensional models, we have developed a computer algebra environment which has a wider range of applicability.

Key words. stability analysis, Maxwell–Debye, Maxwell–Lorentz

1. Introduction.

To describe the propagation of an electromagnetic wave through a dispersive medium, some extensions of Maxwell equations are used. They involve time differential equations which account for the constitutive laws of the material that link the displacement $\mathbf{D}$ to the electric field $\mathbf{E}$ or, equivalently, the polarization $\mathbf{P}$ to $\mathbf{E}$. We focus on two of these models (the Debye and Lorentz models) which are addressed in [10] in view of specific applications to the interaction of an electromagnetic wave with a human body. In [10], specific values for the physical and numerical constants are chosen and numeric calculations are performed to conclude stability or not. A survey of numerical couplings between Maxwell equations and various matter models may be found in [16], where stability conditions are given for Maxwell–Debye models, but there is no proof for some of them, and Maxwell–Lorentz formulae are considered too complex to be studied. In contrast with these two references, we are able to treat any medium which is described by these models. To this end we use von Neumann analysis.

1.1. Maxwell–Debye and Maxwell–Lorentz models.

In our context (no magnetization) we use different formulations of Maxwell equations where Faraday equations always read

$$\partial_t \mathbf{B}(t,\mathbf{x}) = -\ \mathrm{curl}\ \mathbf{E}(t,\mathbf{x}), \tag{1.1}$$

where $\mathbf{x} \in \mathbb{R}^N$. On the contrary, the Ampère equation may be cast using variables $\mathbf{B}$ and $\mathbf{D}$:

$$\partial_t \mathbf{D}(t,\mathbf{x}) = \frac{1}{\mu_0}\ \mathrm{curl}\ \mathbf{B}(t,\mathbf{x}); \tag{1.2a}$$

*Received by the editors October 2, 2006; accepted for publication (in revised form) February 13, 2008; published electronically June 18, 2008.
http://www.siam.org/journals/sinum/46-5/67125.html
†Laboratoire Jean Kuntzmann, Université de Grenoble et CNRS UMR 5224, B.P. 53, 38041 Grenoble Cedex 9, France (brigitte.bidegaray@imag.fr).

or the polarization $\mathbf{P}$:

$$\varepsilon_0\varepsilon_\infty\partial_t\mathbf{E}(t,\mathbf{x}) = \frac{1}{\mu_0}\ \mathrm{curl}\ \mathbf{B}(t,\mathbf{x}) - \partial_t\mathbf{P}(t,\mathbf{x}), \tag{1.2b}$$

where $\mathbf{P}(t,\mathbf{x}) = \mathbf{D}(t,\mathbf{x}) - \varepsilon_0\varepsilon_\infty\mathbf{E}(t,\mathbf{x})$ and ε_∞ is the relative infinite frequency permittivity. Denoting by $\mathbf{J}$ the time derivative of $\mathbf{P}$, we also have

$$\varepsilon_0\varepsilon_\infty\partial_t\mathbf{E}(t,\mathbf{x}) = \frac{1}{\mu_0}\ \mathrm{curl}\ \mathbf{B}(t,\mathbf{x}) - \mathbf{J}(t,\mathbf{x}). \tag{1.2c}$$

The system of Faraday and Ampère equations is closed by a linear constitutive law,

$$\mathbf{D}(t,\mathbf{x}) = \varepsilon_0\varepsilon_\infty\mathbf{E}(t,\mathbf{x}) + \varepsilon_0\int_{-\infty}^{t}\mathbf{E}(t-\tau,\mathbf{x})\chi(\tau)d\tau, \tag{1.3}$$

where χ is the linear susceptibility. The discretization of the integral expression (1.3) leads to recursive schemes (see, e.g., [7], [17]). However, differentiating (1.3) leads to a time differential equation for $\mathbf{D}$ which depends on the specific form of χ. For a Debye medium,

$$t_\mathrm{r}\partial_t\mathbf{D} + \mathbf{D} = t_\mathrm{r}\varepsilon_0\varepsilon_\infty\partial_t\mathbf{E} + \varepsilon_0\varepsilon_\mathrm{s}\mathbf{E}, \tag{1.4a}$$

where $t_\mathrm{r} > 0$ is the relaxation time and $\varepsilon_\mathrm{s} \geq \varepsilon_\infty$ is the relative static permittivity. An equivalent form of (1.4a) using variable $\mathbf{P}$ is

$$t_\mathrm{r}\partial_t\mathbf{P} + \mathbf{P} = \varepsilon_0(\varepsilon_\mathrm{s} - \varepsilon_\infty)\mathbf{E}, \tag{1.4b}$$

which can be coupled with the Ampère equation cast as (1.2b). For a Lorentz medium with one resonant frequency ω_1, we likewise have

$$\partial_t^2\mathbf{D} + \nu\partial_t\mathbf{D} + \omega_1^2\mathbf{D} = \varepsilon_0\varepsilon_\infty\partial_t^2\mathbf{E} + \varepsilon_0\varepsilon_\infty\nu\partial_t\mathbf{E} + \varepsilon_0\varepsilon_\mathrm{s}\omega_1^2\mathbf{E}, \tag{1.5a}$$

where $\nu \geq 0$ is a damping coefficient, or, equivalently,

$$\partial_t^2\mathbf{P} + \nu\partial_t\mathbf{P} + \omega_1^2\mathbf{P} = \varepsilon_0(\varepsilon_\mathrm{s} - \varepsilon_\infty)\omega_1^2\mathbf{E}. \tag{1.5b}$$

1.2. Yee-based numerical schemes. A classical and very efficient way to compute the Maxwell equations is the Yee scheme [14]. We restrict our study to existing Yee-based schemes. In contrast to the recursive schemes, we are interested in direct integration schemes which are based on the finite difference–time domain (FD–TD) discretization of (1.4a) to (1.5b) (see [5], [4], [15]). Other space discretizations may be found in the literature in the context of Maxwell–Debye and Maxwell–Lorentz equations; see, e.g., [3] for pseudo-spectral schemes or [12] for finite element–time domain (FE–TD) schemes.

The Yee scheme consists of discretizing $\mathbf{E}$ and $\mathbf{B}$ on staggered grids in space and time. This allows one to use only centered discrete differential operators. We denote by h the space step (supposed here to be the same in all directions in the case of multi-dimensional equations) and by k the time step. In space dimension 1, we consider only the dependence in the space variable z; classically, two polarizations for the field may be decoupled. For example, the transverse electric polarization involves only $E \equiv E_x$ and $B \equiv B_y$. The discretized variables are $E_j^n \simeq E(nk, jh)$ (and similar

notations for $D \equiv D_x$) and $B^{n+\frac{1}{2}}_{j+\frac{1}{2}} \simeq B((n+\frac{1}{2})k, (j+\frac{1}{2})h)$, and the Yee scheme for the Maxwell equation reads

$$\frac{B^{n+\frac{1}{2}}_{j+\frac{1}{2}} - B^{n-\frac{1}{2}}_{j+\frac{1}{2}}}{k} = -\frac{E^n_{j+1} - E^n_j}{h}, \tag{1.6}$$

coupled with one of the following:

$$\frac{D^{n+1}_j - D^n_j}{k} = -\mu_0 \frac{B^{n+\frac{1}{2}}_{j+\frac{1}{2}} - B^{n+\frac{1}{2}}_{j-\frac{1}{2}}}{h}, \tag{1.7a}$$

$$\varepsilon_0\varepsilon_\infty \frac{E^{n+1}_j - E^n_j}{k} = -\mu_0 \frac{B^{n+\frac{1}{2}}_{j+\frac{1}{2}} - B^{n+\frac{1}{2}}_{j-\frac{1}{2}}}{h} - \frac{P^{n+1}_j - P^n_j}{k}, \tag{1.7b}$$

$$\varepsilon_0\varepsilon_\infty \frac{E^{n+1}_j - E^n_j}{k} = -\mu_0 \frac{B^{n+\frac{1}{2}}_{j+\frac{1}{2}} - B^{n+\frac{1}{2}}_{j-\frac{1}{2}}}{h} - J^{n+\frac{1}{2}}_j. \tag{1.7c}$$

Usual Maxwell equations consist of taking $J^{n+\frac{1}{2}}_j \equiv 0$ in (1.7c) or, equivalently, $D^n_j = \varepsilon_0\varepsilon_\infty E^n_j$ in (1.7a) and lead to a stable second order scheme under a Courant–Friedrichs–Lewy (CFL) stability condition. Namely, if $c_\infty = 1/\sqrt{\varepsilon_0\varepsilon_\infty\mu_0}$ denotes the infinite frequency light speed, then the CFL condition reads $c_\infty k \le h/\sqrt{N}$.

1.3. Scheme naming. Since we deal with many schemes, we have to distinguish between them and name them. Numbers or names of first contributor(s) are not very meaningful, and we prefer here to have a descriptive name. Our description gives both the variables used (e.g., coupling (1.2a) and (1.4a) uses variables **B**, **E**, and **D**) and the location of discretized variables. Space occurs only as a parameter in Debye or Lorentz equations. To avoid interpolation, the reasonable choice is to always locate variables **D**, **P**, and **J** on the same space grid as **E**. The different schemes therefore differ only in the time location of variables: in (1.7a) and (1.7b) integer times are chosen; in (1.7c) half-integer times are chosen.

Our naming convention is the following: we separate variables at half-integer times from variables at integer times by an underscore sign, e.g., "B_ED" when coupling (1.6) and (1.7a). In Table 1.1 we give the correspondence between the article where the schemes have been derived first, the terminology of the survey [16] and our description.

1.4. Outline. The von Neumann stability analysis is recalled in section 2. We also describe the sketch of our proofs which is common for all of the schemes. In section 3, three one-dimensional direct integration schemes for Debye media are presented and analyzed, carefully pointing out the physical properties needed to ensure stability and the specific cases which have to be handled separately. Numerical applications to

physical media are also given. The same point of view is carried out for Lorentz media in section 4. To address two- and three-dimensional schemes which have too many variables to compute by hand, we have developed a computer algebra environment based on MAPLE, which is described in section 5. Two- and three dimensional results are given in section 6.

2. Principles of the von Neumann analysis. The von Neumann analysis allows one to localize roots of certain classes of polynomials, which proves to be crucial here. We recall the main principles of this technique. Details and proofs of theorems may be found in [13].

2.1. Schur and simple von Neumann polynomials. We define two families of polynomials: Schur polynomials and simple von Neumann polynomials.

DEFINITION 2.1. *A polynomial is a Schur polynomial if all its roots, r, satisfy $|r| < 1$.*

DEFINITION 2.2. *A polynomial is a simple von Neumann polynomial if all its roots, r, lie on the unit disk ($|r| \leq 1$) and its roots on the unit circle are simple roots.*

If a polynomial has a high degree or sophisticated coefficients, it may be difficult to locate its roots. However, there is a way to split this difficult problem into many simpler ones. For this, we construct a sequence of polynomials of decreasing degree. Let ϕ be written as

$$\phi(z) = c_0 + c_1 z + \cdots + c_p z^p,$$

where $c_0, c_1, \ldots, c_p \in \mathbb{C}$ and $c_p \neq 0$. We define its conjugate polynomial ϕ^* by

$$\phi^*(z) = c_p^* + c_{p-1}^* z + \cdots + c_0^* z^p.$$

Given a polynomial ϕ_0, we may define a sequence of polynomials

$$\phi_{m+1}(z) = \frac{\phi_m^*(0)\phi_m(z) - \phi_m(0)\phi_m^*(z)}{z}.$$

It is clear that $\deg\phi_{m+1} < \deg\phi_m$, if $\phi_m \not\equiv 0$.

THEOREM 2.3. *A polynomial ϕ_m is a Schur polynomial of exact degree d if and only if ϕ_{m+1} is a Schur polynomial of exact degree $d-1$ and $|\phi_m(0)| \leq |\phi_m^*(0)|$.*

THEOREM 2.4. *A polynomial ϕ_m is a simple von Neumann polynomial if and only if*

- *ϕ_{m+1} is a simple von Neumann polynomial and $|\phi_m(0)| \leq |\phi_m^*(0)|$*

or

- *ϕ_{m+1} is identically zero and ϕ_m' is a Schur polynomial.*

The main ingredient in the proof of both theorems is the Rouché theorem (see [9], [13]). To analyze ϕ_0, at each step m, conditions should be checked (leading coefficient is nonzero, $|\phi_m(0)| \leq |\phi_m^*(0)|$, ...) until a definitive negative answer arises or the degree is 1.

2.2. Stability analysis. The models we deal with are linear models. They may therefore be analyzed in the frequency domain. We can thus assume that the scheme handles a single vector-valued variable $U_{\mathbf{j}}^n$ with spatial dependence

$$U_{\mathbf{j}}^n = U^n \exp(i\boldsymbol{\xi} \cdot \mathbf{j}),$$

where $\boldsymbol{\xi}$ and $\mathbf{j} \in \mathbb{R}^N$, $N = 1, 2, 3$. The amplification matrix G is the matrix such that $U^{n+1} = GU^n$. We assume that G does not depend on time or on h and k separately

but only on the ratio h/k. Let ϕ_0 be the characteristic polynomial of G; then we have a sufficient stability condition.

THEOREM 2.5. *A sufficient stability condition is that ϕ_0 be a simple von Neumann polynomial.*

This condition is not necessary. A scheme is stable if and only if the sequence $(U^n)_{n\in\mathbb{N}}$ is bounded. Since we assume that G does not depend on time, then $U^n = G^nU^0$ and stability is also the boundedness of $(G^n)_{n\in\mathbb{N}}$. If the eigenvalues of G, i.e., the roots r of ϕ_0, lie inside the unit circle ($|r| < 1$), then $\lim_{n\to\infty} G^n = 0$ and the sequence is bounded. If any root lies outside the unit circle, then G^n grows exponentially and the scheme is unstable. The intermediate case when some roots may be on the unit circle (and the others inside) may lead to different situations. Consider, for example, the case when G is the identity. Then $U^n = U^0$ and the scheme is clearly stable. However, there are other examples of matrices with multiple roots on the unit circle that lead either to bounded or unbounded sequences $(G^n)_{n\in\mathbb{N}}$. It is clearly a property of the amplification matrix and not of its characteristic polynomial. If the dimension of eigensubspace associated with a root is equal to its multiplicity, then G^n is bounded (an example for this is the identity: $\mathrm{Id}^n = \mathrm{Id}$ remains bounded). In the opposite case G^n grows linearly. A paradigm for this is

$$\begin{pmatrix} 1 & 1 \\ 0 & 1 \end{pmatrix}^n = \begin{pmatrix} 1 & n \\ 0 & 1 \end{pmatrix},$$

which grows linearly with iterations, and only one eigenvector can be found. Such cases (which occur for our schemes) should therefore be handled specifically.

We will stick here to locating roots in the unit circle. Another way has already been developed in, e.g., [6], [11]. It consists of using a conformal map to locate roots in the left half-plane. This changes the problem in a Routh–Hurwitz problem, which reads as a list of sufficient conditions for the characteristic polynomial to be von Neumann ($|r| \le 1$). This has been implemented in the FIDE REDUCE package.

2.3. Sketch of proofs. In the next sections, we will not give the proofs, but only list in tables the arguments used for each situation. We describe here the general plan and give names to specific final arguments used. The detailed proofs may be found in [1] for space dimensions 1 and 2. The three-dimensional case has been performed *via* computer algebra simulations [2].

Usually the coupled system is given in an implicit form. The first step consists of writing it in an explicit form. This yields the amplification matrix G. Then we compute its characteristic polynomial ϕ_0. In order to perform a von Neumann analysis, we compute the series (ϕ_m). In the general case, under the assumption that the stability condition cannot be better than Yee's, we can apply either Theorem 2.3 (*Theorem* 2.3 argument) or Theorem 2.4 (*Theorem* 2.4 argument), checking estimates at each level until ϕ_m is a one degree polynomial. Special cases arise when $\varepsilon_s = \varepsilon_\infty$, $\sin(\xi/2) = 0$ or ± 1, and sometimes for limit values of physical coefficients. In these cases, different points of view have to be considered:

- Theorem 2.4 has to be used instead of Theorem 2.3.
- Some eigenvalues lie on the unit circle (mostly ± 1 or $\pm i$). Polynomial ϕ_0 is at best a simple von Neumann polynomial and we have to study the other eigenvalues which are roots of a lower degree polynomial (*subpolynomial* argument).
- Some eigenvalues lie on the unit circle and are not simple. Besides the study of the other eigenvalues (*subpolynomial* argument), we have to compare the

multiplicity of the root to the number of eigenvectors found. If they are equal (stable case), then this is usually checked directly on the form of matrix G (*G form* argument). The unstable case necessitates the computation of eigenvectors (*eigenvectors* argument).

If $\varepsilon_s = \varepsilon_\infty$, then Maxwell equations decouple from the other equations. We study this limit as a hint of how the numerical scheme may behave when ε_s is very close to ε_∞. For the same reason, we will study the undamped oscillator ($\nu = 0$) for Lorentz media.

3. Debye media. We address successively the three discretizations of Maxwell–Debye equations mentioned in Table 1.1.

3.1. Debye B_ED scheme. In [4], Joseph, Hagness, and Taflove close system (1.6)–(1.7a) by a discretization for (1.4a), namely

$$\varepsilon_0\varepsilon_\infty t_\mathrm{r}\frac{E_j^{n+1}-E_j^n}{k}+\varepsilon_0\varepsilon_\mathrm{s}\frac{E_j^{n+1}+E_j^n}{2}=t_\mathrm{r}\frac{D_j^{n+1}-D_j^n}{k}+\frac{D_j^{n+1}+D_j^n}{2}.$$

The resulting system may be cast in an explicit form which handles the variable (^{t} denotes transposition)

$$U_j^n=\left(c_\infty B_{j+\frac12}^{n-\frac12},E_j^n,D_j^n/\varepsilon_0\varepsilon_\infty\right)^t,$$

and the amplification matrix G reads

$$\begin{pmatrix} 1 & -\lambda(e^{i\xi}-1) & 0\\ -\frac{(1+\delta)\lambda(1-e^{-i\xi})}{1+\delta\eta_\mathrm{s}} & \frac{(1-\delta\eta_\mathrm{s})+(1+\delta)\lambda^2(e^{i\xi}-2+e^{-i\xi})}{1+\delta\eta_\mathrm{s}} & \frac{2\delta}{1+\delta\eta_\mathrm{s}}\\ -\lambda(1-e^{-i\xi}) & \lambda^2(e^{i\xi}-2+e^{-i\xi}) & 1 \end{pmatrix},$$

where $\lambda = c_\infty k/h$ is the CFL constant, $\delta = k/2t_\mathrm{r} > 0$ is the normalized time step, and $\eta_\mathrm{s} = \varepsilon_\mathrm{s}/\varepsilon_\infty \geq 1$ denotes the normalized static permittivity. Moreover, we define $q = -\lambda^2(e^{i\xi}-2+e^{-i\xi}) = 4\lambda^2\sin^2(\xi/2)$. The characteristic polynomial is proportional to

$$\phi_0(Z) = [1+\delta\eta_\mathrm{s}]Z^3 - [3+\delta\eta_\mathrm{s}-(1+\delta)q]Z^2 + [3-\delta\eta_\mathrm{s}-(1-\delta)q]Z - [1-\delta\eta_\mathrm{s}].$$

The proof arguments are summed up in Table 3.1, and we deduce that the stability condition is $q \leq 4$ if $\varepsilon_\mathrm{s} > \varepsilon_\infty$ and $q < 4$ if $\varepsilon_\mathrm{s} = \varepsilon_\infty$.

TABLE 3.1
Proof arguments and results for the Debye B_ED and B_EP schemes.

q	ε_s	Argument	Result
$]0,4[$	$> \varepsilon_\infty$	Theorem 2.3	stable
$]0,4[$	$= \varepsilon_\infty$	Theorem 2.4	stable
0	$\geq \varepsilon_\infty$	G form	stable
4	$> \varepsilon_\infty$	Theorem 2.4	stable
4	$= \varepsilon_\infty$	eigenvectors	unstable

3.2. Debye B_EP scheme. In [5], Kashiwa, Yoshida, and Fukai close system (1.6)–(1.7b) by a discretization for (1.4b):

$$t_{\mathrm{r}}\frac{P_j^{n+1}-P_j^n}{k}=-\frac{P_j^{n+1}+P_j^n}{2}+\varepsilon_0(\varepsilon_{\mathrm{s}}-\varepsilon_\infty)\frac{E_j^{n+1}+E_j^n}{2}.$$

The system now handles the variable

$$U_j^n=\left(c_\infty B_{j+\frac{1}{2}}^{n-\frac{1}{2}},E_j^n,P_j^n/\varepsilon_0\varepsilon_\infty\right)^t,$$

the amplification matrix G reads

$$\begin{pmatrix} 1 & -\lambda(e^{i\xi}-1) & 0\\ -\frac{(1+\delta)\lambda(1-e^{-i\xi})}{1+\delta\eta_{\mathrm{s}}} & \frac{(1-\delta\eta_{\mathrm{s}})+(1+\delta)\lambda^2(e^{i\xi}-2+e^{-i\xi})+2\delta}{1+\delta\eta_{\mathrm{s}}} & \frac{2\delta}{1+\delta\eta_{\mathrm{s}}}\\ -\frac{\delta(\eta_s-1)\lambda(1-e^{-i\xi})}{1+\delta\eta_{\mathrm{s}}} & \frac{(\lambda^2(e^{i\xi}-2+e^{-i\xi})+2)(\eta_s-1)\delta}{1+\delta\eta_{\mathrm{s}}} & \frac{1+\eta_s\delta-2\delta}{1+\delta\eta_{\mathrm{s}}} \end{pmatrix},$$

and the characteristic polynomial is proportional to the same polynomial as for the B_ED scheme. All proofs are the same except those on matrix G directly, but even in these cases the conclusions are the same. Table 3.1 is also valid for the B_EP scheme.

3.3. Debye BP_E scheme. In [15], Young chooses to close system (1.6)–(1.7c) by two discretizations for (1.4b), namely

$$t_{\mathrm{r}}\frac{P_j^{n+\frac{1}{2}}-P_j^{n-\frac{1}{2}}}{k}=-\frac{P_j^{n+\frac{1}{2}}+P_j^{n-\frac{1}{2}}}{2}+\varepsilon_0(\varepsilon_{\mathrm{s}}-\varepsilon_\infty)E_j^n,$$

$$t_{\mathrm{r}}J_j^{n+\frac{1}{2}}=-P_j^{n+\frac{1}{2}}+\varepsilon_0(\varepsilon_{\mathrm{s}}-\varepsilon_\infty)\frac{E_j^{n+1}+E_j^n}{2}.$$

Although $J_j^{n+\frac{1}{2}}$ is used for the computations, this not a genuine variable for the full system which handles the variable

$$U_j^n=\left(c_\infty B_{j+\frac{1}{2}}^{n-\frac{1}{2}},E_j^n,P_j^{n-\frac{1}{2}}/\varepsilon_0\varepsilon_\infty\right)^t,$$

and the amplification matrix G reads

$$\begin{pmatrix} 1 & -\lambda(e^{i\xi}-1) & 0\\ -\frac{\lambda(1-e^{-i\xi})}{1+\delta\alpha} & \frac{1+\delta-\delta\alpha+3\delta^2\alpha-(1+\delta)q}{(1+\delta)(1+\delta\alpha)} & \frac{1-\delta}{1+\delta}\frac{2\delta}{1+\delta\alpha}\\ 0 & \frac{2\delta\alpha}{1+\delta} & \frac{1-\delta}{1+\delta} \end{pmatrix}$$

with the same notations as above and $\alpha=\eta_{\mathrm{s}}-1\geq 0$. The characteristic polynomial is proportional to

$$\phi_0(Z)=[(1+\delta\alpha)(1+\delta)]Z^3-[3+\delta+\delta\alpha+3\delta^2\alpha-(1+\delta)q]Z^2$$
$$+[3-\delta-\delta\alpha+3\delta^2\alpha-(1-\delta)q]Z-[(1-\delta\alpha)(1-\delta)].$$

Table 3.2 gathers the different arguments used. The stability condition is $q\leq 4$ and $\delta\leq 1$ if $\varepsilon_{\mathrm{s}}>\varepsilon_\infty$ and $q<4$ if $\varepsilon_{\mathrm{s}}=\varepsilon_\infty$.

TABLE 3.2
Proof arguments and results for the Debye BP_E scheme.

3.4. Conclusion for one-dimensional Debye schemes. If $\varepsilon_s > \varepsilon_\infty$, then the pure CFL condition $q \leq 4$ is the same for both models. It is exactly the condition for Maxwell equations. However, the BP_E scheme necessitates another condition, $\delta \leq 1$, which corresponds to a sufficient discretization of Debye equation (1.4b). Even if we are interested here in stability properties, such conditions are to be considered to ensure equations to be correctly taken into account. Results are given in physical variables in Table 3.3.

TABLE 3.3
Stability of Debye models for $\varepsilon_s > \varepsilon_\infty$ and $\varepsilon_s = \varepsilon_\infty$.

Scheme		Dimension 1		Dimension 1
	$\varepsilon_s > \varepsilon_\infty$		$\varepsilon_s = \varepsilon_\infty$	
B_ED or B_EP	$q \leq 4$	$k \leq h/c_\infty$	$q < 4$	$k < h/c_\infty$
BP_E	$q \leq 4$, $\delta \leq 1$	$k \leq \min(h/c_\infty, 2t_r)$	$q < 4$	$k < h/c_\infty$

To compare conditions on q and δ, let us consider a simple physical case. We assume that a matter with $\varepsilon_\infty = 1$ (and thus $c_\infty \simeq 3\times10^8\,\mathrm{m\,s^{-1}}$) is lighted by a wave of, say, wavelength 1 cm. The space step h has to be smaller than this wavelength, and therefore $q < 4$ reads at least $k < \frac{1}{3}\times10^{-10}\,\mathrm{s}$. In a Debye medium, relaxation times t_r are of the order of a picosecond (or even a nanosecond) which maybe of the same order than the previous bound. A typical example is water, for which $\varepsilon_\infty = 1.8$, $\varepsilon_s = 81.0$, and $t_r = 9.4\times10^{-12}\,\mathrm{s}$ [17]. Condition $k \leq 2t_r$ comes to $k \leq 1.88\times10^{-11}\,\mathrm{s}$. Condition $q \leq 4$ yields a similar condition if $h = 4.2\times10^{-3}\,\mathrm{m}$. For a very coarse space grid and with the BP_E scheme, the CFL condition comes from $k \leq 2t_r$; otherwise, for a fine grid and/or B_ED or B_EP schemes, it comes from $q \leq 4$.

A quite different material is, for example, the 0.25-dB loaded foam given in [8] for which $\varepsilon_\infty = 1.01$, $\varepsilon_s = 1.16$, and $t_r = 6.497\times10^{-10}\,\mathrm{s}$. Condition $k \leq 2t_r$ comes to $k \leq 1.3\times10^{-9}\,\mathrm{s}$ and $q \leq 4$ yields a similar condition if $h = 3.9\times10^{-1}\,\mathrm{m}$. In practice h has to be smaller to describe a wave with 1 cm wavelength, and the stability condition for this foam is $q < 4$ for both schemes.

In conclusion, the stability condition may depend on the material in classical applications, leading us to prefer the B_ED scheme, when t_r is small (picosecond). The result announced in [10] was $q \leq 4$ for the B_ED scheme and for water, which is consistent with our result.

4. Lorentz media. We now address the three discretizations of Maxwell–Lorentz equations mentioned in Table 1.1.

Each of these schemes reads the same in the undamped ($\nu = 0$) or damped ($\nu > 0$) cases. However, the analysis will differ greatly since $\phi_1 \equiv 0$ for all the schemes in the undamped case.

4.1. Lorentz B_ED scheme. In [4], system (1.6)–(1.7a) is closed by a discretization for (1.5a), namely

$$\varepsilon_0\varepsilon_\infty\frac{E_j^{n+1}-2E_j^n+E_j^{n-1}}{k^2}+\nu\varepsilon_0\varepsilon_\infty\frac{E_j^{n+1}-E_j^{n-1}}{2k}+\varepsilon_0\varepsilon_{\rm s}\omega_1^2\frac{E_j^{n+1}+E_j^{n-1}}{2}$$
$$=\frac{D_j^{n+1}-2D_j^n+D_j^{n-1}}{k^2}+\nu\frac{D_j^{n+1}-D_j^{n-1}}{2k}+\omega_1^2\frac{D_j^{n+1}+D_j^{n-1}}{2}.$$

The explicit version of the subsequent system does not explicitly use the value of D_j^{n-1}, and therefore this system handles the variable

$$U_j^n=\left(c_\infty B_{j+\frac12}^{n-\frac12},E_j^n,E_j^{n-1},D_j^n/\varepsilon_0\varepsilon_\infty\right)^t.$$

The amplification matrix G reads

$$\begin{pmatrix}1&-\lambda(e^{i\xi}-1)&0&0\\ -\frac{2\delta\lambda(1-e^{-i\xi})}{1+\delta+\omega\eta_{\rm s}}&\frac{2-q(1+\delta+\omega)}{1+\delta+\omega\eta_{\rm s}}&\frac{1-\delta+\omega\eta_{\rm s}}{1+\delta+\omega\eta_{\rm s}}&\frac{2\omega}{1+\delta+\omega\eta_{\rm s}}\\ 0&1&0&0\\ -\lambda(1-e^{-i\xi})&-q&0&1\end{pmatrix},$$

where $\delta=\nu k/2\geq 0$ is the new normalized time step, and $\omega=\omega_1^2k^2/2>0$ denotes the normalized squared frequency. The other notations used for the Debye model remain valid. The characteristic polynomial is proportional to

$$\phi_0(Z)=[1+\delta+\omega\eta_{\rm s}]Z^4-[4+2\delta+2\omega\eta_{\rm s}-(1+\delta+\omega)q]Z^3$$
$$+[6+2\omega\eta_{\rm s}-2q]Z^2-[4-2\delta+2\omega\eta_{\rm s}-(1-\delta+\omega)q]Z+[1-\delta+\omega\eta_{\rm s}].$$

The proofs are summed up in Table 4.1 for the damped and the undamped case.

TABLE 4.1
Proof arguments and results for the Lorentz B_ED scheme.

q	$\varepsilon_{\rm s}$	Argument	Result	Argument	Result
		damped: $\nu>0$		undamped: $\nu=0$	
$]0,2[$	$>\varepsilon_\infty$	Theorem 2.3	stable	Theorem 2.4	stable
$]0,2]$	$=\varepsilon_\infty$	Theorem 2.4	stable	subpolynomial	unstable
0	$\geq\varepsilon_\infty$	G form	stable	G form	stable
2	$\geq\varepsilon_\infty$	subpolynomial	stable	subpolynomial	stable

In the damped case the stability condition is $q\leq 2$ for all $\varepsilon_{\rm s}\geq\varepsilon_\infty$. The $\varepsilon_{\rm s}=\varepsilon_\infty$ undamped case needs some explanation. For $q\in]0,2]$, ϕ_0 may be cast as the product of two second order polynomials. The roots are two couples of conjugate complex roots of modulus 1. For the specific value $q=2\omega/(1+\omega)$, which always lies in the interval $]0,2]$, the two couples degenerate in one double couple with only two eigendirections, which is the unstable case. To avoid this instability one may think to bound q and say that the scheme is stable provided $q\in[0,2\omega/(1+\omega)[$. But if we come back to the original variables, we see that this is not an upper bound on k but rather a lower bound on h, which we surely do not want. It is therefore better to avoid using the B_ED scheme in this very specific case, $\varepsilon_{\rm s}=\varepsilon_\infty$ and $\nu=0$. A better scheme for this case is provided next.

4.2. Lorentz B_EPJ scheme. In [5], Kashiwa, Yoshida, and Fukai close system (1.6)–(1.7b) by a discretization for (1.5b), namely

$$\frac{P_j^{n+1}-P_j^n}{k}=\frac{J_j^{n+1}+J_j^n}{2},$$

$$\frac{J_j^{n+1}-J_j^n}{k}=-\nu\frac{J_j^{n+1}+J_j^n}{2}+\omega_1^2(\varepsilon_{\rm s}-\varepsilon_\infty)\varepsilon_0\frac{E_j^{n+1}+E_j^n}{2}-\omega_1^2\frac{P_j^{n+1}+P_j^n}{2}.$$

The explicit version of the system obtained handles the variable

$$U_j^n=\left(c_\infty B_{j+\frac12}^{n-\frac12},E_j^n,P_j^n/\varepsilon_0\varepsilon_\infty,kJ_j^n/\varepsilon_0\varepsilon_\infty\right)^t,$$

and the amplification matrix G reads

$$\begin{pmatrix} 1 & -\lambda(e^{i\xi}-1) & 0 & 0\\ \frac{-\lambda(1-e^{-i\xi})(\Delta-\frac12\omega\alpha)}{\Delta} & \frac{\Delta-q\Delta-(2-q)\frac12\omega\alpha}{\Delta} & \frac{\omega}{\Delta} & \frac{-1}{\Delta}\\ \frac{-\lambda(1-e^{-i\xi})\frac12\omega\alpha}{\Delta} & \frac{(2-q)\frac12\omega\alpha}{\Delta} & \frac{\Delta-\omega}{\Delta} & \frac{1}{\Delta}\\ \frac{-\lambda(1-e^{-i\xi})\omega\alpha}{\Delta} & \frac{(2-q)\omega\alpha}{\Delta} & \frac{-2\omega}{\Delta} & \frac{2-\Delta}{\Delta} \end{pmatrix},$$

where together with the previously defined notations, $\Delta=1+\delta+\omega\eta_{\rm s}/2$. The characteristic polynomial is proportional to

$$\phi_0(Z)=\left[1+\delta+\frac12\omega\eta_{\rm s}\right]Z^4-\left[4+2\delta-\left(1+\delta+\frac12\omega\right)q\right]Z^3$$
$$+[6-\omega\eta_{\rm s}+(\omega-2)q]Z^2-\left[4-2\delta-\left(1-\delta+\frac12\omega\right)q\right]Z+\left[1-\delta+\frac12\omega\eta_{\rm s}\right].$$

The proofs are summed up in Table 4.2. Both in the damped and undamped cases, the stability condition is $q<4$, which is much better than the previous scheme since we gain a factor 2 on k, and we have no problem when $\varepsilon_{\rm s}=\varepsilon_\infty$ and $\nu=0$ as for the previous model.

TABLE 4.2
Proof arguments and results for the Lorentz B_EPJ scheme.

q	$\varepsilon_{\rm s}$	Argument	Result	Argument	Result
		damped: $\nu>0$		undamped: $\nu=0$	
$]0,4[$	$>\varepsilon_\infty$	Theorem 2.3	stable	Theorem 2.4	stable
$]0,4[$	$=\varepsilon_\infty$	Theorem 2.4	stable	Theorem 2.4	stable
0	$\geq\varepsilon_\infty$	G form	stable	G form	stable
4	$\geq\varepsilon_\infty$	eigenvectors	unstable	eigenvectors	unstable

4.3. Lorentz BJ_EP scheme. In [15], system (1.6)–(1.7c) is closed by a discretization for (1.5b), namely

$$\frac{P_j^{n+1}-P_j^n}{k}=J^{n+\frac12},$$

$$\frac{J_j^{n+\frac12}-J_j^{n-\frac12}}{k}=-\nu\frac{J_j^{n+\frac12}+J_j^{n-\frac12}}{2}+\omega_1^2(\varepsilon_{\rm s}-\varepsilon_\infty)\varepsilon_0E_j^n-\omega_1^2P_j^n.$$

The explicit version of the system handles the variable

$$U_j^n = \left(c_\infty B_{j+\frac{1}{2}}^{n-\frac{1}{2}}, E_j^n, P_j^n/\varepsilon_0\varepsilon_\infty, kJ_j^{n-\frac{1}{2}}/\varepsilon_0\varepsilon_\infty\right)^t,$$

and the amplification matrix G reads

$$\begin{pmatrix} 1 & -\lambda(e^{i\xi}-1) & 0 & 0 \\ -\lambda(1-e^{-i\xi}) & \frac{(1-q)(1+\delta)-2\omega\alpha}{1+\delta} & \frac{2\omega}{1+\delta} & -\frac{1-\delta}{1+\delta} \\ 0 & \frac{2\omega\alpha}{1+\delta} & \frac{1+\delta-2\omega}{1+\delta} & \frac{1-\delta}{1+\delta} \\ 0 & \frac{2\omega\alpha}{1+\delta} & \frac{-2\omega}{1+\delta} & \frac{1-\delta}{1+\delta} \end{pmatrix}.$$

The characteristic polynomial is proportional to

$$\phi_0(Z) = [1+\delta]Z^4 - [4+2\delta-2\omega\eta_s-(1+\delta)q]Z^3 + 2[3-2\omega\eta_s+(\omega-1)q]Z^2 - [4-2\delta-2\omega\eta_s-(1-\delta)q]Z + [1-\delta].$$

TABLE 4.3

0	$= \varepsilon_\infty$	$= 2/(2\eta_s-1)$	eigenvectors	unstable

The proofs are summed up in Table 4.3. This scheme combines three drawbacks we have already encountered. First, as for the Debye model, there is an extra condition on the time step: $\omega < 2/(2\eta_s - 1)$. This will have to be compared to the condition on q for physical examples. Second, as for the Lorentz B_ED scheme, we need a twice smaller k than for raw Maxwell equations: $q \leq 2$ instead of $q \leq 4$. Last, and also as for the Lorentz B_ED scheme, the $\varepsilon_s = \varepsilon_\infty$ and $\nu = 0$ lead to an instability. This is exactly the same story. This time $q = 2\omega$ leads to double couples of conjugate complex roots of modulus 1, with only two eigendirections. If $\omega > 1$, then this value of q is, however, never reached. Else $q = 2\omega$ is rather a condition on h and therefore not a proper stability condition. As for the Lorentz B_ED, it seems better to avoid using this scheme if $\varepsilon_s = \varepsilon_\infty$ and $\nu = 0$.

4.4. Conclusion for one-dimensional Lorentz schemes. We summarize all our results for Lorentz schemes in Table 4.4. For the undamped BJ_EP scheme, if $\varepsilon_s > \varepsilon_\infty$, then the condition is slightly better since $q = 2$ and $\omega < 2/(2\eta_s - 1)$, or $q < 2$ and $\omega = 2/(2\eta_s - 1)$ also yield stable schemes.

Contrarily to Debye materials, for which all schemes compete, the B_EPJ scheme seems to overcome others for Lorentz material. First, there is a gain in CFL condition ($q < 4$ is twice better as $q \leq 2$), second, there are no instabilities for limiting values of the physical coefficients, and last, there is no extra condition on the time step. In practice, an extra condition is, however, needed to account for the dynamics of the Lorentz equation, but not for stability reasons.

However, we can compare the relative strength of the different conditions on k for the B_ED and BJ_EP schemes, and for optical waves of, say, wavelength $1\,\mu$m. The values used in [10] are $\varepsilon_\infty = 1$, $\varepsilon_s = 2.25$, $\omega_1 = 4 \times 10^{16}\,\mathrm{rad\,s^{-1}}$, and $\nu = 0.56 \times 10^{16}\,\mathrm{rad\,s^{-1}}$. Condition $\omega \leq 2/\sqrt{2\eta_s - 1}$ comes to $k \leq 2.7 \times 10^{-17}\,\mathrm{s}$, which is very small and corresponds to $h = 1.13 \times 10^{-8}\,\mathrm{m}$ in the $q < 2$ condition. This space step is more than sufficient to discretize optical waves. For such a material the extra condition imposed by the B_ED scheme is stronger than the basic CFL condition. The B_EPJ model is then more advisable.

TABLE 4.4
Stability of damped and undamped Lorentz models for $\varepsilon_s > \varepsilon_\infty$ and $\varepsilon_s = \varepsilon_\infty$.

Scheme		Dimension 1
damped: $\nu > 0$, and $\varepsilon_s \geq \varepsilon_\infty$		
B_ED	$q \leq 2$	$k \leq h/\sqrt{2}c_\infty$
B_EPJ	$q < 4$	$k < h/c_\infty$
BJ_EP	$q \leq 2$, $\omega \leq 2/(2\eta_s - 1)$	$k \leq \min(h/\sqrt{2}c_\infty, 2/\omega_1\sqrt{2\eta_s - 1})$
undamped: $\nu = 0$, and $\varepsilon_s > \varepsilon_\infty$		
B_ED	$q \leq 2$	$k \leq h/\sqrt{2}c_\infty$
B_EPJ	$q < 4$	$k < h/c_\infty$
BJ_EP	$q < 2$, $\omega < 2/(2\eta_s - 1)$	$k < \min(h/\sqrt{2}c_\infty, 2/\omega_1\sqrt{2\eta_s - 1})$
undamped: $\nu = 0$, and $\varepsilon_s = \varepsilon_\infty$		
B_ED	$q < 2\omega/(1+\omega)$	condition on h
B_EPJ	$q < 4$	$k < h/c_\infty$
BJ_EP	$q < 2$, $\omega < 2/(2\eta_s - 1)$	$k < \min(h/\sqrt{2}c_\infty, 2/\omega_1\sqrt{2\eta_s - 1})$ if $\omega > 1$; condition on h else

In [15] there is a totally different material for which $\varepsilon_\infty = 1.5$, $\varepsilon_s = 3$, $\omega_1 = 2\pi \times 5 \times 10^{10}\,\mathrm{rad\,s^{-1}}$, and $\nu = 10^{10}\,\mathrm{rad\,s^{-1}}$ (these round values certainly refer to a model material). In this case $\omega \leq 2/\sqrt{2\eta_s - 1}$ comes to $k \leq 3.6 \times 10^{-12}\,\mathrm{s}$, which corresponds to $h = 1.9 \times 10^{-3}\,\mathrm{m}$ in the $q < 2$ condition. For this material condition $q < 2$ is the strongest for optical waves. The B_EPJ scheme is, however, more advisable, since it allows $q < 4$ instead of $q \leq 2$.

The results obtained in [10] were obtained for our first cited material and for the B_ED and BJ_EP schemes. Petropoulos observed instabilities for $\xi > \frac{\pi}{2}$. We note that if $\xi \leq \frac{\pi}{2}$, then $\sin(\xi/2) \leq 1/\sqrt{2}$ and $q \leq 2$ instead of $q \leq 4$. This is exactly our result. He found also the B_EPJ scheme to be stable for $q \leq 4$.

5. Automation *via* computer algebra. For a three-dimensional Lorentz medium, ϕ_0 is typically a 12th degree polynomial with polynomial coefficients of

degree 6 in the different parameters. The previous procedure becomes awful if made by hand. A computer algebra environment based on MAPLE has been developed specifically to automate all the computational steps which may be the source of errors [2]. It is still dedicated only to electromagnetic models but could be extended in the future to other applications.

The schemes are defined by four parameters:

1. the space dimension `Dim` (1, 2 or 3),
2. the polarization `Polar` (TE or TM in dimension 2),
3. the physical model `Model` (e.g., Debye),
4. the variables used `Formula` (e.g., `B_EP`).

Maxwell equations have been written once and for all and just have to be "called":

```
> Faraday(Eq, Dim, Polar):
> Ampere(Eq, Dim, Polar, Formula):
```

For our applications, in the other equations space is only a parameter. Such equations are written once with no spatial dependence:

```
> NewEq := tr*(P[n+1]-P[n])/dt
         + 1/2*(P[n+1]+P[n])
         - eps0*(epss-epsinfini)*(E[n+1]+E[n])/2:
> CreateEq(Eq, NewEq, Dim, Polar):
```

and propagated to all the useful coordinates with the right indexes on the staggered grid, according to the space dimension and polarization.

Then changes of variables are automatically performed to have dimensionless variables (specific to the model), no redundant variables (specific to the scheme), and an explicit scheme in the frequency domain. This yields the amplification matrix G. The computation of polynomial ϕ_0 is then performed as well as the computational part of the von Neumann analysis: computation of the sequence of polynomials and factorizations. On these forms the user of the toolbox can easily see which are the specific cases to consider separately.

The comparisons $|\phi_m(0)| \leq |\phi_m^*(0)|$ are the real difficult points from the computer algebra point of view; therefore it is necessary to evaluate the sign of a polynomial in many variables (4 for a Lorentz medium) and of total degree of order say 6 for ϕ_0, about 10 for $\phi_1, \ldots$ knowing some variables are positive (like $\eta_s - 1$ or δ) and others lie within an interval (like q). This is also automated:

```
> SignCheck(phi, Z, [0 < delta, 1 < etas, 0 < q, q < 4]),
```

but sometimes MAPLE does not yield a totally explicit answer. This might lead us to migrate the whole toolbox in a C code to make use of some existing softwares specific for the solving of interval arithmetic problems.

Finally, tools are defined to compare the number of eigenvectors and the multiplicity of eigenvalues in the degenerate cases.

6. Two- and three-dimensional results.

6.1. Equation setting. In a two-dimensional context where unknowns depend only on space variables x and y, the Maxwell system may be split in two decoupled systems corresponding to the transverse electric (TE) (B_x, B_y, E_z) and the transverse magnetic (TM) (B_z, E_x, E_y) polarizations. In the one-dimensional case, Maxwell–Debye equations were represented by three equations and Maxwell–Lorentz by four equations. In the TE polarization, one more Faraday equation is added; therefore, we have four equations for Maxwell–Debye and five equations for Maxwell–Lorentz. In the TM polarization for the Maxwell–Debye model, one Ampère equation and one Debye equation have to be added, leading to five equation systems. For the

Maxwell–Lorentz model, there is one more Ampère equation and two more Lorentz equations, so the system consists of seven equations.

In the three-dimensional context, equations do not decouple any more, and systems consist of nine equations for the Maxwell–Debye schemes and twelve equations for the Maxwell–Lorentz schemes.

The principle of the stability analysis is exactly the same, but we now have larger polynomials to study. We, however, found out that the one-dimensional polynomials (which we denote by $\phi_0^{1D}(Z)$) are a factor in two- and three-dimensional polynomials, which reduces the formal calculations. More precisely we now denote by h_x, h_y, and h_z the space steps in the x-, y-, and z-directions, respectively, and by q the quantity

$$q = q_x + q_y = 4c_\infty^2 \left(\frac{k^2}{h_x^2} \sin^2(\xi_x/2) + \frac{k^2}{h_y^2} \sin^2(\xi_y/2) \right)$$

or

$$q = q_x + q_y + q_z = 4c_\infty^2 \left(\frac{k^2}{h_x^2} \sin^2(\xi_x/2) + \frac{k^2}{h_y^2} \sin^2(\xi_y/2) + \frac{k^2}{h_z^2} \sin^2(\xi_z/2) \right)$$

according to the space dimension (recall $q = 4c_\infty^2 \frac{k^2}{h_x^2} \sin^2(\xi_x/2)$ in one dimension).

6.2. Results. In the two-dimensional TE polarization, the characteristic polynomial reads

$$\phi_0^{2D,TE}(Z) = [Z-1]\phi_0^{1D}(Z)$$

for all the Maxwell–Debye and Maxwell–Lorentz schemes we study here. This could be a problem if 1 is already a root of $\phi_0^{1D}(Z)$, i.e., if $q = 0$, but it happens that it is never a problem: minimal stable subspaces are always one-dimensional.

In the TM polarization, the same factorization occurs but the remaining polynomial is slightly more complicated, namely

$$\phi_0^{2D,TM}(Z) = [Z-1]\psi_0(Z)\phi_0^{1D}(Z),$$

where $\psi_0(Z)$ is equal to:

- Debye B_ED and B_EP: $[(1+\delta\eta_s)Z - (1-\delta\eta_s)]$,
- Debye BP_E: $[(1+\alpha)(1+\delta\alpha)Z - (1-\alpha)(1-\delta\alpha)]$,
- Lorentz B_ED: $[(1+\delta+\omega\eta_s)Z^2 - 2Z + (1-\delta+\omega\eta_s)]$,
- Lorentz B_EPJ: $[(1+\delta+\frac{1}{2}\omega\eta_s)Z^2 - (2-\omega\eta_s)Z + (1-\delta+\frac{1}{2}\omega\eta_s)]$,
- Lorentz BJ_EP: $[(1+\delta)Z^2 - 2(1-\omega\eta_s)Z + (1-\delta)]$.

As for the TE polarization the extra eigenvalue 1 is never a source of instability. The other extra eigenvalues always lie inside or on the unit circle (conjugate complex roots). The only problem is when modulus 1 eigenvalues are also eigenvalues of the one-dimensional polynomial. This occurs only for the Lorentz B_ED scheme when $\varepsilon_s = \varepsilon_\infty$, and $q = 2\omega/(1+\omega)$, which is a resonant value we have already pointed out in the undamped case for this scheme.

In the three-dimensional context, the characteristic polynomial reads

$$\phi_0^{3D}(Z) = [Z-1]^2\psi_0(Z)\left(\phi_0^{1D}(Z)\right)^2$$

for all the schemes we have studied. In addition to extra eigenvalues 1, we have to check cases when we found out that $\phi_0^{1D}(Z)$ is a von Neumann polynomial but not a

Schur polynomial. If $\varepsilon_s = \varepsilon_\infty$, then we systematically have instabilities. Other extra instable cases depend on the scheme: $q = 4$ for the Debye B_ED and B_EP schemes, $\delta = 1$ for the Debye BP_E scheme; $q = 2$ for the Lorentz D_ED and BJ_EP schemes, $\nu = 0$ for all Lorentz schemes.

We do not have any explanation for these factorizations. This is a property of the characteristic polynomial and not necessarily of the amplification matrix, i.e., this may occur even if variables are not decoupled. However, there is probably some underlying block-triangular structure, which is still to be found.

We shall not duplicate Tables 3.3 and 4.4 for two- and three-dimensional schemes. In the two-dimensional case, if $h_x = h_y = h_z \equiv h$, condition $q \leq 4$ becomes $k \leq h/(\sqrt{2}c_\infty)$ and condition $q \leq 2$ becomes $k \leq h/(2c_\infty)$ in the physical variables. Besides, the Lorentz B_ED model, which was leading to a lower bound on h in the undamped case, leads also to such a bound in the damped case. These are the only differences with Tables 3.3 and 4.4.

In short, three-dimensional conditions are also essentially the same as one-dimensional conditions but inequalities always have to be strict and limiting (nonphysical) cases $\varepsilon_s = \varepsilon_\infty$ and $\nu = 0$ cannot be dealt with properly with a three-dimensional model.

7. Conclusion. We have studied a class of FD–TD schemes for dispersive materials based on the Yee scheme for Maxwell equations and compared them from the stability point of view. This study was inspired by Petropoulos [10] who performs the same analysis but uses specific values for the physical and numerical constants, and uses numeric routines to locate eigenvalues of the amplification matrix. Here we have general results which yield the constraint on numerical constants (k and h) for any Debye or Lorentz material. Our results confirm those of Petropoulos.

For usual Debye media, both studied schemes are stable under the same condition as the Yee scheme for nanosecond delay materials. The B_ED and B_EP schemes overcome the BP_E scheme in terms of stability condition for picosecond delay materials. Among the studied schemes for Lorentz media, the B_EPJ scheme clearly ranks first as far as stability is concerned. Its stability condition is also that of the Yee scheme. However, to properly take into account the Lorentz model, a smaller time step may have to be chosen, independently of stability issues. The two examples do not help us to deduce a general strategy to locate variables in time, in order to treat other physical models.

The computer algebra system that has been developed to handle the three-dimensional schemes has a much wider range of application. First, it can be extended with very small effort to other electromagnetic linear models such as cold plasmas, collisionless warm plasmas, or magnetic ferrites. With some more work (no computation skill but knowledge of dimensionless variables), it can be practically extended to the analysis of any linear finite-difference scheme occurring in areas other than electromagnetism.

Acknowledgments. The author thanks Françoise Jung and Jean-Guillaume Dumas for their assistance in mastering the tricks of MAPLE.

JACOBI CORRECTION EQUATION, LINE SEARCH, AND CONJUGATE GRADIENTS IN HERMITIAN EIGENVALUE COMPUTATION I: COMPUTING AN EXTREME EIGENVALUE*

E. E. OVTCHINNIKOV†

Abstract. This paper is concerned with the convergence properties of iterative algorithms of conjugate gradient type applied to the computation of an extreme eigenvalue of a Hermitian operator via the optimization of the Rayleigh quotient functional. The algorithms in focus employ the line search for the extremum of the Rayleigh quotient functional in the direction that is a linear combination of the gradient and the previous search direction. An asymptotically explicit equation for the reduction in the eigenvalue error after the line search step as a function of the search direction is derived and applied to the analysis of the local convergence properties (i.e., the error reduction after an iteration) of the algorithms in question. The local (stepwise) asymptotic equivalence of various conjugate gradient algorithms and the generalized Davidson method is proved, and a new convergence estimate for conjugate gradient iterations is derived, showing the reduction in the eigenvalue error after any two consecutive iterations. The paper's analysis extensively employs remarkable properties of the operator of the so-called Jacobi orthogonal complement correction equation.

Key words. Hermitian eigenvalue computation, convergence estimates, conjugate gradients, generalized Davidson method, Jacobi orthogonal complement correction equation

1. Introduction.

The conjugate gradient (CG) method was originally introduced as a method for solving linear systems [7]. It was later reinterpreted as a functional minimization method and is widely used as such in the smooth nonlinear optimization; see, e.g., [6, 28, 3, 21]. In its most familiar form, CG uses the following two-term recurrent formulas to generate a sequence of approximations x^i to the minimum point x of a functional $\phi(v)$:

$$x^{i+1} = x^i - \alpha_i y^i, \tag{1.1}$$

$$y^{i+1} = g^{i+1} + \beta_i y^i, \quad i = 0, 1, \ldots, \quad y^0 = g^0, \tag{1.2}$$

where g^i is the gradient of $\phi(v)$ at $v = x^i$. The parameter α_i in (1.1) minimizes $\phi(x^{i+1})$; the role of the parameter β_i is discussed below. We observe that (1.1) represents the line search for the minimum of $\phi(v)$ in the direction of $-y^i$; hence, we refer to the latter as the search direction (vector). Step (1.2) is referred to as the conjugation of g^{i+1} to y^i, or else as the conjugation of the search directions y^{i+1} and y^i.

For $\beta_i = 0$, the iterative scheme (1.1)–(1.2) becomes that of the steepest descent method, and the conjugation can be viewed as a way to improve the search direction. The case of the quadratic functional $\phi(v) = (Lv, v) - (f, v) - (v, f)$, where L is a Hermitian positive definite operator, is unique in that for each i there exists the optimal β_i, i.e., such that x^{i+2} is the minimum of $\phi(v)$ in the affine space $x^0 +$

$\mathrm{span}\{y^0,\dots,y^{i+1}\} = x^0 + \mathrm{span}\{g^0,\dots,g^{i+1}\} = x^0 + \mathrm{span}\{g^0, Lg^0,\dots,L^{i+1}g^0\}$ that contains all x^i, $i = 2,\dots,i+2$, that can be generated by (1.1)–(1.2) for arbitrary $\beta_1,\dots,\beta_i$. In the case of a general nonquadratic $\phi(v)$, no choice of β_i is known to deliver x^{i+2} that is optimal in this or a similar sense. Various ways to compute β_i considered in the literature (see, e.g., [6, 28, 3, 21, 20]) essentially reuse various mathematically equivalent expressions for β_i derived for the quadratic case, and the respective versions of CG are usually referred to as CG schemes.

The fact that the smallest and the largest eigenvalues of a Hermitian operator L acting in a Euclidean space are, respectively, the minimum and the maximum of the Rayleigh quotient functional $\lambda(v) = (Lv, v)/\|v\|^2$ opens the way to using CG for computing extreme eigenvalues. Since the case of the largest eigenvalue simply mirrors that of the smallest, in this paper we focus on the latter. Specific properties of the Rayleigh quotient functional allow certain modifications of the general CG scheme: the new vector iterate x^{i+1} is usually normalized, and the gradient g^i replaced by the residual vector $r^i = r(x^i) = Lx^i - \lambda(x^i)x^i$, which is collinear to g^i. The line search can be replaced with the minimization in the two-dimensional subspace $\mathrm{span}\{x^i,\ y^i\}$, for which the Rayleigh–Ritz procedure can be employed, or else with the minimization on the sphere $\|v\| = 1$ (see [4]). Certain precautions need to be taken with some CG schemes, however (cf. [2]), as the Hessian of $\lambda(v)$ is not positive definite.

It should be noted that a number of algorithms for computing eigenvalues employ an inner-outer iteration approach whereby CG is used for solving certain auxiliary linear systems (see, e.g., [24, 14, 26] or [1]). Such algorithms are not discussed in this paper, which is entirely focused on the one-level approach just described.

A number of CG schemes for eigenvalue computation are discussed in [5, 29] and [4]; the first two papers also present numerical comparisons between different schemes. A general conclusion at which the cited papers arrive is that most schemes are similar in convergence, one exception being the Perdon–Gambolati scheme that uses L-conjugation of search directions (cf. (3.4) in section 3) and is shown by [5] to be less efficient than the rest. A plausible explanation of the observed similarity of convergence behavior is the asymptotic closeness of the schemes in question pointed out by [5] (based on informal arguments) and, in the framework of the minimization on the sphere $\|v\| = 1$, by [4]. The present paper complements the comparative analysis of [5] and [4] by studying local convergence properties of CG schemes for eigenvalue computation and providing explicit upper bounds for the difference between new approximate eigenvalues $\lambda^{i+1} = \lambda(x^{i+1})$ computed by various CG schemes based on the same x^i and y^{i-1}.

In our local convergence analysis we use an approach based on the so-called *Jacobi orthogonal complement correction* equation of [27]. The operator of this equation maps the error vector into the residual vector, and, consequently, the associated energy norm of the former coincides with the respective dual energy norm of the latter; remarkably, for the normalized approximate eigenvector, both coincide with the eigenvalue error (see Lemma 2.5). In the paper we show how this and some other properties of the Jacobi correction operator can be used in the convergence analysis of methods employing the line search, in particular, the steepest descent and CG methods. We derive an equation that expresses the reduction in the eigenvalue error after the line search step as a function of the search direction vector, and we use this equation in our comparison of various CG schemes and the generalized Davidson method whereby the new vector iterate x^{i+1} minimizes the Rayleigh quotient in the subspace spanned by $x^0, g^0,\dots,g^i$. Further, we derive an asymptotic equation that relates the eigenvalue error reduction on two consecutive CG steps with that of the steepest descent step.

Based on this equation and available estimates for the steepest descent method, we derive a new convergence estimate for CG that explicitly shows the acceleration of convergence compared to the steepest descent method due to the conjugation of two consecutive search directions.

The sequel [19] to this paper shows how the Jacobi correction equation technique can be extended to the convergence analysis of a block version of the iterative scheme (1.1)–(1.2) that computes several eigenvalues simultaneously.

In this paper the eigenvalues λ_j of L are enumerated in increasing order, each one counted as many times as the multiplicity, and the eigenvectors are denoted by x_j. The first (leftmost) eigenvalue λ_1 is assumed to be simple. For a Hermitian positive definite A we denote by $(\cdot,\cdot)_A$ and $\|\cdot\|_A$ the associated energy scalar product and norm, i.e., $(u,v)_A = (Au,v)$ and $\|u\|_A^2 = (u,u)_A$. All of the results of this paper apply to the generalized eigenvalue problem after simple modifications (cf. the introduction in [18] for the relevant arguments; cf. also Remark 1 in section 2.1).

2. Jacobi correction operator.

2.1. Jacobi orthogonal complement correction equation and its operator. Correction equations, i.e., equations for the difference between an exact and an approximate eigenvector, have been employed by a number of authors in their design of algorithms for computing eigenvalues (see, e.g., [27, 14, 26]) or the comparative analysis of such algorithms (see, e.g., [30]). In the present paper we employ a particular kind of a correction equation that is solved approximately in the Jacobi–Davidson method of [27], and we start this section with the analysis of some elementary properties of the latter correction equation, or rather its operator, most of which do not appear to have been previously investigated to a comparable level of detail.

We recall that $\lambda(u)$ stands for the Rayleigh quotient of u, i.e., $\lambda(u) = (Lu,u)/\|u\|^2$. If u approximates an eigenvector, then $\lambda(u)$ is an approximation to the corresponding eigenvalue that is optimal in the sense that $\|Lu - \lambda(u)u\| \le \|Lu - \tilde{\lambda}u\|$ for any alternative approximate eigenvalue $\tilde{\lambda}$; i.e., $\lambda(u)$ minimizes the residual vector. In the paper we denote $r(u) = Lu - \lambda(u)u$ and refer to this minimal residual vector as simply the residual. We denote by P_u the orthogonal projector onto $\mathrm{span}\{u\}$, i.e., $P_u v = \|u\|^{-2}u(v,u)$, and we denote $R(u) = (I - P_u)LP_u$, where I is the identity operator. Owing to a simple relationship $P_u L P_u v = \|u\|^{-2}u(LP_u v,u) = \|u\|^{-4}u(v,u)(Lu,u) = \lambda(u)P_u$, the operator $R(u)$ is related to the residual vector $r(u)$ as follows: $R(u)v = LP_u v - \lambda(u)P_u v = \|u\|^{-2}(v,u)(Lu - \lambda(u)u) = \|u\|^{-2}(v,u)r(u)$, which implies $\|R(u)\| = \|r(u)\|$. It is referred to as the residual operator in this paper.

The correction equation in question can be derived in the following manner. Let $\tilde{x}_1$ be an approximation to an eigenvector x_1 corresponding to λ_1 and denote by e_1 the corresponding correction vector, i.e., $\tilde{x}_1 + e_1 = x_1$. Since $(L - \lambda_1 I)x_1 = 0$, we have

$$(L - \lambda_1 I)e_1 = -(L - \lambda_1 I)\tilde{x}_1.$$

Applying to both sides of the above equation the operator $\tilde{P}_1^{\perp} = I - P_{\tilde{x}_1}$, we obtain

$$\tilde{P}_1^{\perp}(L - \lambda_1 I)e_1 = -\tilde{P}_1^{\perp}(L - \lambda_1 I)\tilde{x}_1 = -\tilde{P}_1^{\perp}(L - \lambda(\tilde{x}_1)I)\tilde{x}_1 = -\tilde{P}_1^{\perp}r(\tilde{x}_1) = -r(\tilde{x}_1).$$

If $\tilde{x}_1$ is not orthogonal to x_1, we can normalize the latter so that $(\tilde{x}_1, x_1) = \|\tilde{x}_1\|^2$, in which case $(e_1, \tilde{x}_1) = 0$, i.e., $e_1 = \tilde{P}_1^{\perp}e_1$, and we arrive at what is called the *Jacobi orthogonal complement correction* (JOCC) equation in [27]:

$$J(\lambda_1, \tilde{x}_1)e_1 = -r(\tilde{x}_1). \tag{2.1}$$

Here and in what follows, we use the notation

$$J(\mu, u) = (I - P_u)(L - \mu)(I - P_u). \tag{2.2}$$

If we subtract $(\lambda(\tilde{x}_1) - \lambda_1 I)e_1$ from both sides (2.1), to arrive at

$$J(\lambda(\tilde{x}_1), \tilde{x}_1)e_1 = -r(\tilde{x}_1) - (\lambda(\tilde{x}_1) - \lambda_1)e_1, \tag{2.3}$$

and drop the second term in the right-hand side, we end up with the equation

$$J(\lambda(\tilde{x}_1), \tilde{x}_1)\tilde{e}_1 = -r(\tilde{x}_1) \tag{2.4}$$

that is solved approximately in the Jacobi–Davidson method of [27].

Remark 1. In the case of the generalized eigenvalue problem $Lx = \lambda Mx$ with Hermitian positive definite M, the definition of the operator $J(\mu, u)$ needs to be modified as follows:

$$J(\mu, u) = (I - P^*_{u,M})(L - \mu M)(I - P_{u,M}), \tag{2.5}$$

where $P_{u,M}$ is the orthogonal projector onto $\mathrm{span}\{u\}$ in the sense of the scalar product $(\cdot, \cdot)_M = (M\cdot, \cdot)$. To apply any of the results of this paper to the generalized case, one simply needs to replace the standard norm with $\|\cdot\|_M = \sqrt{(M\cdot, \cdot)}$ and use the Rayleigh quotient $\lambda(u) = (Lu, u)/(Mu, u)$ and the residual $r(u) = Lu - \lambda(u)Mu$.

Auxiliary results below reveal some elementary properties of the operator $J(\mu, y)$ that are used in the rest of the paper. Below we denote by $\mathrm{span}\{u\}^\perp$ the orthogonal complement to $\mathrm{span}\{u\}$, i.e., the subspace of vectors orthogonal to u. The orthogonal complement correction vector for a general nonzero u is denoted by $e(u)$, i.e.,

$$e(u) = \frac{\|u\|^2}{(x_1, u)} x_1 - u. \tag{2.6}$$

We start with a simple algebraic expression that relates $J(\mu, u)$ to the shifted operator $L - \mu$.

LEMMA 2.1. $J(\mu, u) = L - \mu I - R(u) - R(u)^* - (\lambda(u) - \mu)P_u$.

Proof. $L - \mu = (I - P_u + P_u)(L - \mu I)(I - P_u + P_u) = J(\mu, u) + (I - P_u)(L - \mu)P_u + P_u(L - \mu I)(I - P_u) + P_u(L - \mu I)P_u = J(\mu, u) + (I - P_u)LP_u + P_uL(I - P_u) + P_uLP_u - \mu P_u = L - \mu I - R(u) - R(u)^* - (\lambda(u) - \mu)P_u$. ∎

The second result shows that $J(\mu, u)$ is positive definite in the subspace $\mathrm{span}\{u\}^\perp$ provided that μ and $\lambda(u)$ are close enough to λ_1 (cf. Lemma 3.1 in [14]).

LEMMA 2.2. *For any* $v \in \mathrm{span}\{u\}^\perp$, $(J(\mu, u)v, v) \geq (\lambda_1 + \lambda_2 - \mu - \lambda(u))\|v\|^2$.

Proof. The scaling of u and v does not affect the inequality in question; hence, assume that $\|u\| = \|v\| = 1$. The Ritz values $\hat{\lambda}_1$ and $\hat{\lambda}_2$ of L in $\mathrm{span}\{u, v\}$ are the eigenvalues of the matrix

$$\hat{L} = \begin{bmatrix} (Lu, u) & (Lv, u) \\ (Lu, v) & (Lv, v) \end{bmatrix}. \tag{2.7}$$

We have $\hat{\lambda}_1 + \hat{\lambda}_2 = Tr(\hat{L}) = (Lu, u) + (Lv, v) = \lambda(u) + \lambda(v)$ and, by the minimax principle, $\hat{\lambda}_i \geq \lambda_i$. Hence, $\lambda(v) \geq \lambda_1 + \lambda_2 - \lambda(u)$. Since $(J(\mu, u)v, v) = (\lambda(v) - \mu)\|v\|^2$, we arrive at the inequality of the lemma. ∎

COROLLARY 2.3. $(J(\mu, u)v, v) \geq (\lambda_1 + \lambda_2 - \mu - \lambda(u))\|(I - P_u)v\|^2$.

The next result shows that the $J(\mu,u)$-energy seminorms are equivalent for various μ that are close enough to λ_1.

LEMMA 2.4. *For any* $\mu \le \nu < \lambda_1 + \lambda_2 - \lambda(u)$

$$\frac{\lambda_1+\lambda_2-\lambda(u)-\nu}{\lambda_1+\lambda_2-\lambda(u)-\mu}(J(\mu,u)v,v) \le (J(\nu,u)v,v) \le (J(\mu,u)v,v). \tag{2.8}$$

Proof. We have $J(\nu,u) = J(\mu,u) - (\nu-\mu)(I-P_u)$, and therefore $(J(\nu,u)v,v) = (J(\mu,u)v,v) - (\nu-\mu)\|(I-P_u)v\|^2$. Hence, using Corollary 2.3, we arrive at inequality (2.8). ∎

The last auxiliary result of this section relates to the operator $J(\lambda_1,u)$ that features in the JOCC equation (2.1); in what follows, we denote for brevity $J_1(u) = J(\lambda_1,u)$, and we call $J_1(u)$ the Jacobi correction operator. We observe that $J_1(u)$ is positive semidefinite; hence we can use the seminorm $\|\cdot\|_{J_1(u)} = \sqrt{(J_1(u)\cdot,\cdot)}$. We note also that the restriction of $J_1(u)$ to $\mathrm{span}\{u\}^\perp$ is equal to that of $L-\lambda_1$, and hence is positive definite if u is not orthogonal to x_1 since λ_1 is assumed to be simple.

LEMMA 2.5. *If* $(u,x_1) \ne 0$, *then* $(J_1(u)e(u),e(u)) = (J_1(u)^{-1}r(u),r(u)) = (\lambda(u)-\lambda_1)\|u\|^2$, *where* $J_1(u)^{-1}$ *is the inverse of the restriction of* $J_1(u)$ *to* $\mathrm{span}\{u\}^\perp$.

Proof. Denoting $\alpha = \|u\|^2/(x_1,u)$, we have

$$\begin{aligned}(J_1(u)e(u),e(u)) &= ((L-\lambda_1 I)(u-\alpha x_1),u-\alpha x_1)\\ &= ((L-\lambda_1 I)u,u) = (\lambda(u)-\lambda_1)\|u\|^2.\end{aligned}$$

To prove the second identity of the lemma, we observe that by (2.1) we have $J_1(u)e(u) = -r(u)$. As noted above, for u that is not orthogonal to x_1, $J_1(u)$ is positive definite, and hence invertible, in $\mathrm{span}\{u\}^\perp$. Thus, $e(u) = -J_1(u)^{-1}r(u)$, and we arrive at the identity in question. ∎

The remarkable simplicity of the relationship between the eigenvalue error and $J_1(u)$-based norms of the correction and residual vectors exposed by Lemma 2.5 suggests that these norms are "natural" ones in the a posteriori error analysis. The same can be said about the a priori error analysis. To give a simple illustration, let us obtain an estimate for the difference $\tilde e_1 - e_1$, where e_1 and $\tilde e_1$ are the solutions of the exact and approximate correction equations (2.3) and (2.4), respectively, assuming that $\lambda(\tilde x_1) < (\lambda_1+\lambda_2)/2$ and that $\|\tilde x_1\| = 1$ (cf. the related results in [15] that make use of a similar energy norm). Let us denote $J = J(\lambda_1,\tilde x_1)$ and $\tilde J = J(\lambda(\tilde x_1),\tilde x_1)$. From (2.3) and (2.4) we have $J(\tilde e_1 - e_1) = (\lambda(\tilde x_1)-\lambda_1)\tilde e_1$. By Lemma 2.2, the minimal eigenvalue of J restricted to the subspace $\mathrm{span}\{\tilde x_1\}^\perp$ (to which e_1, $\tilde e_1$ and their J- and $\tilde J$-images belong) is not less than $\lambda_2 - \lambda(\tilde x_1)$, which implies that

$$\|\tilde e_1 - e_1\|_J \le \frac{\lambda(\tilde x_1)-\lambda_1}{\lambda_2-\lambda(\tilde x_1)}\|\tilde e_1\|_J. \tag{2.9}$$

Using Lemma 2.4 and the relationship $(\tilde J\tilde e_1,\tilde e_1) = -(r(\tilde x_1),\tilde e_1) = (Je_1,\tilde e_1)$, we obtain

$$\|\tilde e_1\|_J^2 \le \frac{\lambda_2-\lambda(\tilde x_1)}{\lambda_1+\lambda_2-2\lambda(\tilde x_1)}\|\tilde e_1\|_{\tilde J}^2, \quad \|\tilde e_1\|_{\tilde J}^2 \le \|\tilde e_1\|_J\|e_1\|_J \le \frac{\lambda_2-\lambda(\tilde x_1)}{\lambda_1+\lambda_2-2\lambda(\tilde x_1)}\|e_1\|_J^2,$$

which, together with (2.9), yield a remarkably simple estimate

$$\|\tilde e_1 - e_1\|_J \le \frac{\lambda(\tilde x_1)-\lambda_1}{\lambda_1+\lambda_2-2\lambda(\tilde x_1)}\|e_1\|_J = \frac{\|e_1\|_J^3}{\lambda_1+\lambda_2-2\lambda(\tilde x_1)}. \tag{2.10}$$

In the remaining part of this section we demonstrate how the Jacobi correction operator can be used in the convergence analysis of methods employing the line search, in particular, the steepest descent and CG methods.

2.2. Jacobi correction operator and the line search. In this section we obtain some useful formulae for the reduction in the eigenvalue error achieved by the search for the local minimum of the Rayleigh quotient on a line.

Unlike in the case of a quadratic functional, the line search for the minimum of the Rayleigh quotient may fail in the sense that the minimum of $\lambda(w)$ on the line $w(\tau) = u + \tau v$ is not attained for any finite value of the parameter τ. It is not difficult to see that this happens if v is the Ritz vector of L in the subspace $\operatorname{span}\{u, v\}$ corresponding to the smaller Ritz value. Let us show first that the line search can be made fail-safe by orthogonalization of the search direction v to the current vector iterate u—provided that v is not orthogonal to the gradient of $\lambda(w)$ at $w = u$, i.e., not tangential to the level surface of the Rayleigh quotient.

Let u and v be two orthonormal vectors. The minimum of $\lambda(w)$ in $\operatorname{span}\{u, v\}$ is the leftmost Ritz value of L, i.e., the leftmost eigenvalue of the matrix $\hat{L}$ given by (2.7). Let $\tilde{x}_1 = \alpha u + \beta v$ be the corresponding normalized Ritz vector. We have $(Lv, u) = (v, Lu) = (v, Lu - \lambda(u)u) = (v, r(u))$. Hence, if v is not orthogonal to the gradient of $\lambda(w)$ at $w = u$, which is collinear to $r(u)$, then the off-diagonal element (Lv, u) of $\hat{L}$ is nonzero, and it is easy to see that neither α nor β can be zero. Thus, $\tilde{x}_1$ is collinear to $u + \tau_v v$, where $\tau_v = \beta/\alpha$.

We note that by the above calculation, the normalization of $u + \tau_v v$ produces $\tilde{x}_1$; i.e., the line search in the orthogonal direction with subsequent normalization (which is typically used in eigenvalue computation) is equivalent to the Rayleigh–Ritz procedure in $\operatorname{span}\{u, v\}$ as far as the leftmost Ritz value is concerned.

The next two results reveal an intimate link between the Jacobi correction operator and the line search technique for the Rayleigh quotient.

THEOREM 2.6. *Let u be a nonzero vector and let v be such that $(v, r(u)) \neq 0$. Let $u_v = u + \tau_v(I - P_u)v$, where P_u is the orthogonal projector onto* $\operatorname{span}\{u\}$ *and*

$$\tau_v \equiv \arg\min_{\tau} \lambda(u + \tau(I - P_u)v),$$

and denote $J_{u,v} = J(\lambda(u_v), u)$. The following relationships hold:

$$\tau_v = -\frac{(r(u), v)}{(J_{u,v}v, v)}, \tag{2.11}$$

$$\lambda(u_v) = \lambda(u) - \frac{|(r(u), v)|^2}{\|u\|^2 (J_{u,v}v, v)}, \tag{2.12}$$

$$(J_{u,v}(u - u_v), u - u_v) = (\lambda(u) - \lambda(u_v))\|u\|^2, \tag{2.13}$$

$$r(u_v) = r(u) + J_{u,v}(u_v - u). \tag{2.14}$$

If $\lambda(u) < (\lambda_1 + \lambda_2)/2$, then

$$\|r(u_v)\|^2_{J^{-1}_{u,v}} = \min_{\tau} \|r(u) + \tau J_{u,v}v\|^2_{J^{-1}_{u,v}} = \|r(u)\|^2_{J^{-1}_{u,v}} - (\lambda(u) - \lambda(u_v))\|u\|^2, \tag{2.15}$$

where $J^{-1}_{u,v}$ is the inverse of the restriction of $J_{u,v}$ to $\operatorname{span}\{u\}^{\perp}$.

Proof. Denote $v^\perp = (1 - P_u)v$. We have

$$r(u + \tau_v v^\perp) = r(u) + (\lambda(u) - \lambda(u + \tau_v v^\perp))u + (L - \lambda(u + \tau_v v^\perp)I)\tau_v v^\perp. \tag{2.16}$$

Since $\lambda(u + \tau_v v^\perp) = \min_\tau \lambda(u + \tau v^\perp)$, the gradient of $\lambda(w)$ at $w = u_v = u + \tau_v v^\perp$ is orthogonal to $v^\perp$; hence $(r(u_v), v^\perp) = 0$. Together with $(r(u_v), u_v) = 0$, this implies $(r(u_v), u) = 0$, i.e., $P_u r(u_v) = 0$. Applying $1 - P_u$ to both sides of (2.16), we obtain (2.14); multiplying (2.14) by v, we obtain (2.11). Multiplying $u_v = u + \tau_v v^\perp$ by $r(u)$, we obtain, on the one hand,

$$\begin{aligned}(u_v, r(u)) &= (u_v, Lu - \lambda(u)u) = (u_v, Lu - \lambda(u_v)u) + (\lambda(u_v) - \lambda(u))(u_v, u)\\ &= ((L - \lambda(u_v)I)u_v, u) + (\lambda(u_v) - \lambda(u))\|u\|^2 = (\lambda(u_v) - \lambda(u))\|u\|^2,\end{aligned}$$

and, on the other hand, $(u_v, r(u)) = (u + \tau_v v^\perp, r(u)) = \tau_v(v^\perp, r(u)) = \tau_v(v - P_u v, r(u)) = \tau_v(v, r(u))$, which, together with (2.11), yields (2.12) and (2.13). Turning to (2.15), we observe first that the assumption of the theorem made just before (2.15) implies that $J_{u,v}$ is positive definite in $\mathrm{span}\{u\}^\perp$ (see Lemma 2.2); hence it is invertible there. Owing to $0 = (r(u_v), v) = (r(u_v), J_{u,v}v)_{J_{u,v}^{-1}}$, we have $\|r(u) + \tau J_{u,v}v\|^2_{J_{u,v}^{-1}} = \|r(u_v)\|^2_{J_{u,v}^{-1}} + (\tau - \tau_v)^2\|v\|^2_{J_{u,v}}$, and we arrive at the first equation in (2.15). Setting $\tau = 0$ results in the second equation, owing to (2.13). ∎

We observe that the relationships of Theorem 2.6 are essentially the same as in the case of the standard line search minimization step for the quadratic functional $\phi(u) = (Lu, u) - (u, f) - (f, u)$, with L replaced by $J_{u,v}$ and ϕ with λ.

The next result provides an explicit (modulo asymptotically small term) expression for the relative reduction in the eigenvalue error as a function of the search direction.

THEOREM 2.7. *Let u be a nonzero vector nonorthogonal to x_1, and let v be such that $(v, r(u)) \neq 0$. Let u_v be the point of minimum of $\lambda(w)$ on the line $w(\tau) = u + \tau(I - P_u)v$. The following relationship is valid:*

$$\frac{\lambda(u_v) - \lambda_1}{\lambda(u) - \lambda_1} = \sin^2\theta(v) - \epsilon(v)\cos^2\theta(v), \tag{2.17}$$

where $\theta(v)$ is the angle between v and the correction vector $e(u)$ given by (2.6) *measured in the semiscalar product $(\cdot,\cdot)_{J_1(u)}$ associated with the Jacobi correction operator $J_1(u) = J(\lambda_1, u)$; i.e.,*

$$\cos\theta(v) = \frac{|(e(u), v)_{J_1(u)}|}{\|e(u)\|_{J_1(u)}\|v\|_{J_1(u)}}, \tag{2.18}$$

and

$$\epsilon(v) = \frac{\lambda(u_v) - \lambda_1}{\lambda(u) - \lambda(u_v)}\frac{\|u_v - u\|^2}{\|u\|^2}. \tag{2.19}$$

Proof. We start by noting that $(v, r(u)) \neq 0$ implies that v is not collinear to u; hence, $\|v\|_{J_1(u)} > 0$.

Using (2.12), (2.1), (2.18), and Lemma 2.5, we obtain

$$\begin{aligned}\lambda(u) - \lambda(u_v) &= \frac{|(r(u), v)|^2}{\|u\|^2(J_{u,v}v, v)} = \frac{\|v\|^2_{J_1(u)}}{(J_{u,v}v, v)}\frac{|(e(u), v)_{J_1(u)}|^2}{\|v\|^2_{J_1(u)}\|e(u)\|^2_{J_1(u)}}\frac{\|e(u)\|^2_{J_1(u)}}{\|u\|^2}\\ &= (1 + \epsilon(v))\cos^2\theta(v)(\lambda(u) - \lambda_1),\end{aligned}$$

where $\epsilon(v) = \|v\|^2_{J_1(u)}/(J_{u,v}v, v) - 1$. Hence, trivial calculation yields (2.17). To obtain (2.19), we observe that $J(\lambda_1, u) - J_{u,v} = (\lambda(u_v) - \lambda_1)(I - P_u)$ and hence $\|v\|^2_{J_1(u)} - (J_{u,v}v, v) = (\lambda(u_v) - \lambda_1)\|(I - P_u)v\|^2$. Therefore,

$$\epsilon(v) = \frac{(\lambda(u_v) - \lambda_1)\|(I - P_u)v\|^2}{(J_{u,v}v, v)} = \frac{(\lambda(u_v) - \lambda_1)\|u_v - u\|^2}{(J_{u,v}(u_v - u), u_v - u)},$$

and, taking into account (2.13), we obtain (2.19). □

We note that the second term in the right-hand side of (2.17) is asymptotically (as $u \to x_1$) smaller than the first in the following sense: if $\lambda(u) < (\lambda_1 + \lambda_2)/2$, then, applying Lemma 2.4 to the ratio $\|v\|^2_{J_1(u)}/(J_{u,v}v, v) = \epsilon(v) + 1$, one can estimate $\epsilon(v)$ as follows:

$$\epsilon(v) \le \frac{\lambda_1 + \lambda_2 - \lambda(u) - \lambda_1}{\lambda_1 + \lambda_2 - \lambda(u) - \lambda(u_v)} - 1 = \frac{\lambda(u_v) - \lambda_1}{\lambda_1 + \lambda_2 - \lambda(u) - \lambda(u_v)}$$

$$\le \frac{\lambda(u) - \lambda_1}{\lambda_1 + \lambda_2 - 2\lambda(u)} \frac{\lambda(u_v) - \lambda_1}{\lambda(u) - \lambda_1} \le \frac{\lambda(u) - \lambda_1}{\lambda_1 + \lambda_2 - 2\lambda(u)} \sin^2 \theta(v).$$

We observe that the factor in front of $\sin^2 \theta(v)$ is asymptotically close to the eigenvalue error ratio $(\lambda(u) - \lambda_1)/(\lambda_2 - \lambda_1)$.

2.3. Jacobi correction operator and the steepest descent. For the sake of illustration, in this section we apply Theorem 2.7 to the steepest descent method, and in the next to its preconditioned variant.[1]

The steepest descent method employs the line search in the direction that is opposite to that of the gradient of the Rayleigh quotient which, in turn, is collinear to the residual vector. Hence, by Theorem 2.7, the relative reduction in the eigenvalue error after a steepest descent step is asymptotically equal to the square of the sine of the $J_1(u)$-angle between the error $e(u)$ and $v = -r(u) = J_1(u)e(u)$ (cf. (2.1)). Applying Lemma A.1 from Appendix A to the operator $J_1(u)$ acting in the space $\mathrm{span}\{u\}^\perp$ endowed with the scalar product $(\cdot,\cdot)_{J_1(u)} = (J_1(u)\cdot, \cdot)$, we arrive at the estimate

$$\sin \angle_{J_1(u)}\{v, e(u)\} = \sin \angle_{J_1(u)}\{J_1(u)e(u), e(u)\} \le \frac{cond_\perp(J_1(u)) - 1}{cond_\perp(J_1(u)) + 1}, \tag{2.20}$$

where $\angle_{J_1(u)}\{v, w\}$ stands for the angle between v and w measured in $J_1(u)$-scalar product, and $cond_\perp(J_1(u))$ is the condition number of $J_1(u)$ restricted to $\mathrm{span}\{u\}^\perp$. Since the latter is the invariant subspace of $J_1(u)$ corresponding to positive eigenvalues, the said condition number is equal to the ratio $\iota_{-1}(u)/\iota_2(u)$ of the largest to the second eigenvalue of $J_1(u)$. As $u \to x_1$, $J_1(u) \to L - \lambda_1$ and $\iota_j(u) \to \lambda_j - \lambda_1$. Hence, the relative eigenvalue error reduction after a steepest descent step is asymptotically estimated by the square of the ratio

$$\gamma_1 = \frac{1 - \xi_1}{1 + \xi_1}, \quad \xi_1 = \frac{\lambda_2 - \lambda_1}{\lambda_{-1} - \lambda_1} \tag{2.21}$$

(cf. [9]), where λ_{-1} is the rightmost eigenvalue of L.

[1] These two sections may be skipped by a reader who is familiar with the preconditioned steepest descent and is not interested in its theoretical aspects.

2.4. Jacobi correction operator and preconditioning. In many applications, the spread of the spectrum of L, i.e., $\lambda_{-1} - \lambda_1$, is very large compared to $\lambda_2 - \lambda_1$. The estimate of the previous section (which is asymptotically sharp owing to the sharpness of (2.20); cf. also [18]) indicates that the convergence of steepest descent iterations for such problems may be very slow, and, indeed, this is the case in practical computation, the same being true for a closely related CG method. In this section we briefly discuss a technique, known as *preconditioning*, that can be employed to accelerate the convergence, and apply the results of section 2.2 to the convergence analysis of the *preconditioned* steepest descent.

Preconditioning is currently widely used for solving the linear system $Lx = f$ with a poorly conditioned Hermitian positive definite operator L. In the latter context, preconditioning is commonly conceived of as the multiplication of the system at hand by a Hermitian positive definite operator K such that the condition number of KL is considerably smaller than that of L. Since KL is Hermitian positive definite in energy scalar products $(L\cdot,\cdot)$ and $(K^{-1}\cdot,\cdot)$, the preconditioned system $KLx = Kf$ can be solved by any iterative algorithm for solving Hermitian positive definite systems, in particular, by the steepest descent iterations $x^{i+1} = x^i - \tau_i(KLx^i - Kf^i) = x^i - \tau_i Kr^i$.

Alternatively, preconditioning can be interpreted as the use of a different scalar product for computing the gradient, notably, $(K^{-1}\cdot,\cdot)$.

Yet another interpretation is that preconditioning is a way to reduce the angle between the search and the error direction, the latter being obviously the optimal search direction. If τ_i minimizes the quadratic functional $\phi(w) = (Lw, w) - (f, w) - (w, f)$ on the line $w(\tau) = x^i - \tau Kr^i$, then the gradient of $\phi(w)$ at $w = x^{i+1}$ is orthogonal to the search direction $y^i = Kr^i$, i.e., $(r^{i+1}, y^i) = 0$. Since $r^{i+1} = -Le^{i+1}$, where $e^{i+1} = x - x^{i+1}$ is the error vector, the two error vectors e^i, e^{i+1} and the search direction y^i form a triangle with the right L-angle between y^i and e^{i+1}. Hence, the ratio of the L-norms of the two errors is equal to the sine of the angle between $y^i = Kr^i = KLe^i$ and e^i measured in L-norm. On the intuitive level, one expects that if KL is close to a multiple of the identity, i.e., if $cond(KL)$ is close to 1, then the angle between y^i and e^i is small and the convergence is fast. Lemma A.1 supports such a conclusion by providing an explicit estimate for the sine of the L-angle between $y^i = Ae^i$, where $A = KL$, and e^i:

$$\sin \angle_L\{y^i, e^i\} = \sin \angle_L\{Ae^i, e^i\} \le \frac{cond(A) - 1}{cond(A) + 1}, \quad A = KL. \tag{2.22}$$

The same considerations apply to the steepest descent for the Rayleigh quotient minimization. Bearing in mind that the search direction v should preferably be orthogonal to u, let us use $v = -(I - P_u)Kr(u)$ in place of $v = -r(u)$ as the descent direction. We observe that $v = -(I - P_u)K(I - P_u)r(u) = -(I - P_u)K(I - P_u)J_1(u)e(u) = -A(u)e(u)$ and that in $\mathrm{span}\{u\}^\perp$ the operator $A(u) = (I - P_u)K(I - P_u)J_1(u)$ is Hermitian positive definite in the scalar product $(J_1(u)\cdot,\cdot)$. By Theorem 2.7, the reduction in the eigenvalue error is determined by the $J_1(u)$-angle between $A(u)e(u)$ and $e(u)$. Hence, the closer $A(u)$ is to a multiple of the identity, the greater the reduction, and one has one-step convergence if K is the inverse of $J_1(u)$ restricted to $\mathrm{span}\{u\}^\perp$; i.e., $v = Kr(u)$ solves the correction equation $J_1(u)v = r(u)$. For a general K, we have, by Lemma A.1, the estimate

$$\sin \angle_{J_1(u)}\{A(u)e(u), e(u)\} \le \frac{cond_\perp(A(u)) - 1}{cond_\perp(A(u)) + 1}, \tag{2.23}$$

where $cond_\perp(A(u))$ is the condition number of $A(u)$ restricted to $\mathrm{span}\{u\}^\perp$.

Together with Theorem 2.7, the estimate (2.23) yields the following estimate:

$$\frac{\min_\tau \lambda(u+\tau v)-\lambda_1}{\lambda(u)-\lambda_1} \le \left(\frac{cond_\perp(A(u))-1}{cond_\perp(A(u))+1}\right)^2. \tag{2.24}$$

The derivation of the above convergence result for the preconditioned steepest descent for the Rayleigh quotient minimization is remarkably simple, compared to much more complicated proofs of similar results that can be found in the literature; see, e.g., [8, 13, 12] and the relevant results in [16, 17, 18].[2] Admittedly, (2.24) is given in different terms. In order to reformulate this result in terms similar to, e.g., those used by the respective results in [8, 9], let us assume for simplicity of notation that L is positive definite.

We start by observing that $A(u) = ((I-P_u)K(I-P_u)+\kappa P_u)J_1(u) \equiv K_\kappa(u)J_1(u)$ for any scalar κ, and that $K_\kappa(u)$ is positive definite if κ is positive, which we assume from now on. Hence, the eigenvalues $\alpha_j(u)$ of $A(u)$ are the eigenvalues of the generalized problem $J_1(u)v = \alpha K_\kappa(u)^{-1}v$. As $u \to x_1$, $J_1(u) \to L - \lambda_1 I$ and $K_\kappa(u) \to K_\kappa \equiv (I-P_1)K(I-P_1)+\kappa P_1$, where $P_1 = P_{x_1}$. Denoting by κ_1 and κ_{-1} the minimal and maximal eigenvalues of KL, respectively, we have $\kappa_1 L^{-1} \le K \le \kappa_{-1}L^{-1}$, and, hence, assuming $\kappa_1 \le \kappa \le \kappa_{-1}$, $\kappa_1 L^{-1} \le K_\kappa \le \kappa_{-1}L^{-1}$. Thus, $\kappa_1(\lambda_j-\lambda_1)/\lambda_j \le \alpha_j(x_1) \le \kappa_{-1}(\lambda_j-\lambda_1)/\lambda_j$, and the relative error reduction is estimated by the square of γ_1 given by (2.21) with ξ_1 replaced by

$$\xi_1 = \frac{\kappa_1}{\kappa_{-1}}\frac{\lambda_2-\lambda_1}{\lambda_2}\frac{\lambda_{-1}}{\lambda_{-1}-\lambda_1} = \frac{1}{cond(KL)}\frac{\lambda_2-\lambda_1}{\lambda_2}\frac{\lambda_{-1}}{\lambda_{-1}-\lambda_1} \tag{2.25}$$

(cf. [9]), where $cond(KL)$ is the condition number of KL. We observe that a large λ_{-1} is no longer a problem and that we have a considerable improvement over the nonpreconditioned case if K is a good preconditioner for L; i.e., $cond(KL)$ is considerably smaller than $cond(L)$.

2.5. Jacobi correction operator and conjugate gradients. CG achieves significant acceleration of convergence compared to the steepest descent by making use of the previous search direction y^{i-1} alongside with the gradient direction (collinear to r^i or Kr^i). Here we show that the conjugation of search directions employed by CG can be viewed as another way of reducing the angle between the search direction $-y^i$ and the error direction e^i.

Turning to the quadratic functional $\phi(w) = (Lw,w)-(f,w)-(w,f)$ for guidance, we observe that the error $e^i = x - x^i$ is L-orthogonal to the previous search direction y^{i-1} owing to the fact that x^i is the minimum point of $\phi(w)$ on the line $w(\tau) = x^{i-1} - \tau y^{i-1}$ and hence $0 = (r^i, y^{i-1}) = -(Le^i, y^{i-1})$, where $r^i = Lx^i - f$. The L-orthogonalization of the gradient to y^{i-1} employed by CG projects the search direction onto the subspace L-orthogonal to y^{i-1}, where e^i belongs, and hence makes the L-angle between y^i and e^i as minimal as possible among all directions that can be formed by combining the gradient and y^{i-1}. It remains to note that the ratio of L-norms of e^{i+1} and e^i is equal to the sine of this angle, owing to L-orthogonality of e^{i+1} and y^i.

The same reasoning can be applied to CG in eigenvalue computation. Assume that x^i is not orthogonal to x_1 and $r^i = r(x^i) \ne 0$, and assume that the line search did not fail on the previous iteration; i.e., y^{i-1} is not collinear to x^i. Since x^i is the

[2] It should be noted, however, that [13, 12] and [18] present sharp estimates, whereas (2.24) is only asymptotically sharp.

minimum point of $\lambda(w)$ on the line $w(\tau) = x^{i-1} - \tau y^{i-1}$, we have $0 = (r^i, y^{i-1}) = (J_1(x^i)e(x^i), y^{i-1})$; i.e., $e(x^i)$ lies in the subspace that is $J_1(x^i)$-orthogonal to y^{i-1} (note that $J_1(x^i)y^{i-1}$ is nonzero since x^i is not orthogonal to x_1). We observe that y^i is not collinear to x^i for any β_{i-1}, owing to $(y^i, r^i) = (Kr^i, r^i) > 0$. Hence we are in a position to use the $J_1(x^i)$-seminorm for measuring the angle between y^i and $e(x^i)$, which, by Theorem 2.7, determines the reduction in the eigenvalue error. By simple geometrical arguments, this angle is minimal if y^i is $J_1(x^i)$-orthogonal to y^{i-1}; i.e.,

$$(J_1(x^i)y^i, y^{i-1}) = 0. \tag{2.26}$$

The analysis of section 3 suggests that in (2.26) the operator $J_1(x^i)$ can be replaced by $J(\mu^i, x^i)$ with $\mu^i \le \lambda(x^i)$ that is asymptotically close to λ_1, e.g., $\mu^i = \lambda^i$.

In the next section we compare the conjugation scheme just described, which we refer to as the *Jacobi* scheme, with other conjugation schemes that can be found in the literature, and show that most of them employ asymptotically equivalent conjugation.

3. Asymptotic equivalence of CG schemes.

3.1. CG schemes. We recall that the generic CG iterative scheme is given by (1.1)–(1.2), where g^i is the gradient of the minimized functional at $v = x^i$ and the line search parameter α_i minimizes this functional at x^{i+1}. In this section we analyze comparatively CG schemes for the minimization of the Rayleigh quotient functional that use the following formulas for the conjugation parameter β_i in (1.2):

$$\beta_i = \frac{(g^{i+1}, g^{i+1})}{(g^i, g^i)} \qquad \text{(Bradbury–Fletcher);} \tag{3.1}$$

$$\beta_i = \frac{(g^{i+1},\ g^{i+1} - g^i)}{(g^i, g^i)} \qquad \text{(Polak–Ribiére);} \tag{3.2}$$

$$\beta_i = -\frac{(H(x^{i+1})g^{i+1},\ y^i)}{(H(x^{i+1})y^i,\ y^i)} \qquad \text{(Daniel);} \tag{3.3}$$

$$\beta_i = -\frac{(Lg^{i+1},\ y^i)}{(Ly^i, y_i)} \qquad \text{(Perdon–Gambolati);} \tag{3.4}$$

$$\beta_i = -\frac{(J(\mu^{i+1}, x^{i+1})g^{i+1},\ y^i)}{(J(\mu^{i+1}, x^{i+1})y^i,\ y^i)} \qquad \text{(Jacobi)} \tag{3.5}$$

(cf., respectively, [2, 21, 3, 20] and section 2.5). In (3.3), $H(x^{i+1})$ is the Hessian of $\lambda(u)$ at $u = x^{i+1}$ or a multiple thereof, e.g.,

$$H(u) = (I - 2P_u)(L - \lambda(u))(I - 2P_u), \tag{3.6}$$

where P_u is the orthogonal projector onto $\operatorname{span}\{u\}$ (see, e.g., [30]). In (3.4), L is assumed to be positive definite. In (3.5), $\mu^{i+1} \le \lambda(x^{i+1})$ is any value that approximates λ_1, e.g., $\mu^{i+1} = \lambda(x^{i+1})$.

In yet another CG scheme suggested by Takahashi [28], β_i is chosen to minimize the functional at hand at $x^{i+2} = x^{i+1} - \alpha_{i+1}(g^{i+1} + \beta_i y^i)$. It is not difficult to see that in this case the new vector iterate x^{i+2} minimizes the functional in question in the two-dimensional affine space $x^{i+1} + \operatorname{span}\{y^i,\ y^{i+1}\} = x^{i+1} + \operatorname{span}\{y^i,\ g^{i+1}\}$, and, in the case of the Rayleigh quotient functional, in the three-dimensional subspace

$\mathrm{span}\{x^{i+1},\ g^{i+1},\ y^i\} = \mathrm{span}\{x^{i+1},\ g^{i+1},\ x^i\}$. The implied implementation of the Takahashi scheme is known as *locally optimal* CG ([23, 10, 11]).

In (3.3), (3.4), and (3.5), one can replace the gradients g^i with the residual vectors $r^i = r(x^i)$ or, if preconditioning is used, with preconditioned residuals Kr^i. The same can be done in (3.1) and (3.2), provided that the new vector iterate x^{i+1} is normalized after the line search step (1.1), in which case $g^i = 2r^i$ or $g^i = 2Kr^i$ (note, however, that unlike other schemes, these two are not scale-invariant because of the quadratic dependence of β_i on g^{i+1}; hence the normalization of x^{i+1} results in a nonequivalent scheme). In the preconditioned case, the K^{-1}-scalar product and norm must be used in (3.1) and (3.2), i.e., $\beta_i = (Kr^{i+1}, r^{i+1})/(Kr^i, r^i)$ and $\beta_i = (Kr^{i+1}, r^{i+1} - r^i)/(Kr^i, r^i)$, respectively. For the sake of generality, from now on we consider the preconditioned schemes.

In this section we compare the new approximate eigenvalues $\lambda^{i+2} = \lambda(x^{i+2})$ produced by the CG schemes in question based on given x^{i+1} and y^i assuming that these two vectors are not collinear, $r(x^{i+1})$ is nonzero, and $\lambda^i < (\lambda_1 + \lambda_2)/2$. To simplify the notation, we denote $u = x^{i+1}$, $\lambda = \lambda(x^{i+1})$, $\mu = \mu^{i+1}$, $r = r(x^{i+1})$, $v = y^{i+1}$, $\alpha = \alpha_i$, $u_p = x^i$, $v_p = y^i$, $r_p = r^i$, $\alpha_p = \alpha_{i-1}$. We observe that in all schemes $(r, v_p) = 0$, owing to the fact that u is the minimum point of $\lambda(w)$ in $\mathrm{span}\{u_p, v_p\}$, and hence $(r, v) = (r, Kr + \beta_i v_p) = (r, Kr) > 0$. Thus $(r, v) = (r, (1 - P_u)v) \neq 0$ for $r \neq 0$, and the line search in the direction $(1 - P_u)v$ never fails (cf. section 2.2). We observe also that u does not belong to $\mathrm{span}\{v, v_p\}$ (if $u = \sigma v + \tau v_p$, then the multiplication by $r(u)$ yields $0 = \sigma(Kr, r)$, and hence $u = x^{i+1}$ is collinear to $v_p = y^i$, which contradicts our assumption).

3.2. Locally optimal scheme. Let u_o and λ_o be the new eigenvector and eigenvalue iterates computed by the locally optimal (Takahashi) scheme; i.e., $\lambda_o = \lambda(u_o)$ is the minimum of $\lambda(w)$ in the subspace $\mathrm{span}\{u, Kr, v_p\}$. Since the new approximate eigenvector computed by any of the schemes discussed here belongs to this subspace, the corresponding approximate eigenvalue is not less than λ_o. In order to compare new approximate eigenvalues produced by different schemes, in this section we derive an upper bound for the difference $\lambda_v - \lambda_o$, where λ_v is the minimum of $\lambda(w)$ on the line $w(\tau) = u + \tau(1 - P_u)v$, for a general $v = Kr + \beta v_p$ as a function of v.

We start by showing that the locally optimal scheme implicitly employs a Jacobi conjugation scheme with $\mu = \lambda_o$, Since λ_o is not greater than the minimum of $\lambda(w)$ in $\mathrm{span}\{u, Kr\}$, which by (2.12) is strictly less than $\lambda = \lambda(u)$, we have $\lambda_o < \lambda$. This implies that $u_o = \sigma u + \tau Kr + \rho v_p$, where $\tau \neq 0$ (otherwise λ_o would be the minimum of $\lambda(w)$ in $\mathrm{span}\{u, v_p\}$, which is equal to λ). Let us show that $(u_o, u) \neq 0$. Multiplying u_o by r, we have, on the one hand, $(u_o, r) = \tau(r, Kr) \neq 0$, and, on the other hand, $(u_o, r) = (u_o, (L - \lambda)uI) = ((L - \lambda I)u_o, u) = (r(u_o), u) - (\lambda - \lambda_o)(u_o, u) = -(\lambda - \lambda_o)(u_o, u)$, owing to the fact that the gradient of $\lambda(w)$ at $w = u_o$ is orthogonal to the subspace $\mathrm{span}\{u, Kr, v_p\}$. Thus, u_o is not orthogonal to u and hence can be normalized so that $u_o - u$ is orthogonal to u. Assuming this normalization, we can write $u_o = u + (I - P_u)(-\alpha Kr - \gamma v_p) = u - \alpha(I - P_u)v_o, v_o = Kr + \beta_o v_p$. By (2.14), we have $r(u_o) = r(u) - \alpha J(\lambda_o, u)v_o$, and hence $(J(\lambda_o, u)v_o, v_p) = 0$. Thus, the locally optimal CG is a Jacobi scheme with $\mu = \lambda_o$, and it can be equivalently represented by the following two-term recurrent relationships for y^i and r^i:

$$y^{i+1} = Kr^i + \beta_i y^i, \qquad \beta_i :\ (J_i y^{i+1}, y^i) = 0, \tag{3.7}$$

$$r^{i+1} = r^i - \alpha_i J_i y^{i+1}, \quad \alpha_i :\ (r^{i+1}, y^i) = 0, \tag{3.8}$$

where $J_i = J(\lambda^{i+1}, x^i)$ and we shifted the superscript of y^i and subscript of β_i. We note that in (3.7), β_i minimizes the J_i-norm of the new search direction vector, and in (3.8), α_i minimizes the J_i^{-1}-norm of the new residual (see Theorem 2.6).

Remark 2. If in (3.7)–(3.8) we replace J_i with $J(\lambda^0, x^0)$, then (3.7)–(3.8) become the standard CG iterations with preconditioning (PCG) for solving the Jacobi correction equation $J(\lambda^0, x^0)h = -r^0$. If we replace J_i with $J_\infty = L - \lambda_1 I$, we arrive at PCG iterations for solving $(L - \lambda_1 I)h = 0$. (In both cases the meaning of r^i changes accordingly.)

Let us now estimate $\lambda_v - \lambda_o$, where λ_v is specified at the beginning of this subsection, assuming $\lambda < (\lambda_1 + \lambda_2)/2$. Denote $J_o = J(\lambda_o, u)$. We have observed at the beginning of this subsection that the new approximate eigenvector computed by any of the schemes discussed here belongs to the subspace $\mathcal{V} = \operatorname{span}\{u, Kr, v_p\}$. Let us denote by P the orthogonal projector onto $\mathcal{V}$ and by $\hat{L}$ the restriction of the operator PLP to $\mathcal{V}$. The leftmost eigenvalue of $\hat{L}$ is λ_o; hence, the Jacobi correction operator for $\hat{L}$ is $\hat{J}_1(u) = (I - P_u)(\hat{L} - \lambda_o)(I - P_u)$. Since $PP_u = P_u P = P_u$, this operator is related to J_o as $\hat{J}_1(u) = PJ_oP$. Hence, in $\mathcal{V}$ these two operators coincide. Applying Theorem 2.7, we have $(\lambda_v - \lambda_o)/(\lambda - \lambda_o) = \sin^2\theta_o(v) - \epsilon_o(v)\cos^2\theta_o(v)$, where

$$\cos\theta_o(v) = \frac{|(v_o, v)_{\hat{J}_1(u)}|}{\|v_o\|_{\hat{J}_1(u)}\|v\|_{\hat{J}_1(u)}} = \frac{|(v_o, v)_{J_o}|}{\|v_o\|_{J_o}\|v\|_{J_o}}, \quad \epsilon_o(v) = \frac{\lambda_v - \lambda_o}{\lambda - \lambda_v}\frac{\|u_v - u\|^2}{\|u\|^2}.$$

Since $\epsilon_o(v) \geq 0$ and v_o is J_o-orthogonal to v_p, the above relationship yields the desired estimate

$$\lambda_v - \lambda_o \leq (\lambda - \lambda_o)\cos^2\theta_p(v), \tag{3.9}$$

where $\theta_p(v)$ is the J_o-angle between v and v_p.

3.3. Jacobi scheme. Since the locally optimal scheme is a particular case of the Jacobi scheme, the comparative analysis of the two is relatively simple. Denoting by $v_{_J}$ the new search direction of the Jacobi scheme, we have $(J_o v_{_J}, v_p) = (J(\mu, u)v_{_J}, v_p) + (\mu - \lambda_o)((I - P_u)v_{_J}, v_p) = (\mu - \lambda_o)((I - P_u)v_{_J}, v_p)$. Hence, applying Corollary 2.3, we obtain

$$|(J_o v_{_J}, v_p)| \leq |\mu - \lambda_o|\|(I - P_u)v_{_J}\|\|(I - P_u)v_p\| \leq \frac{|\mu - \lambda_o|}{\lambda_1 + \lambda_2 - \lambda - \lambda_o}\|v_{_J}\|_{_{J_o}}\|v_p\|_{_{J_o}},$$

and thus

$$\lambda_{_J} - \lambda_o \leq \frac{(\lambda - \lambda_o)(\mu - \lambda_o)^2}{(\lambda_1 + \lambda_2 - \lambda - \lambda_o)^2} \leq \frac{(\lambda - \lambda_o)^3}{(\lambda_1 + \lambda_2 - \lambda - \lambda_o)^2}, \tag{3.10}$$

where $\lambda_{_J}$ is the new approximate eigenvalue produced by the Jacobi scheme.

3.4. Daniel scheme. The asymptotic closeness of the Daniel scheme to those just discussed is implied by the following simple relationship between $H(u)$ and J_o that is obtained in the same way as in Lemma 2.1:

$$H(u) = J(\lambda(u), u) - R(u) - R(u)^* = J_o - (\lambda - \lambda_o)(I - P_u) - R(u) - R(u)^*.$$

The search direction $v_{_D}$ of the Daniel scheme is $H(u)$-conjugate to v_p; i.e., $(H(u)v_{_D}, v_p) = 0$. Hence, $(J_o v_{_D}, v_p) = ((J(\lambda_o, u) - H(u))v_{_D}, v_p) = (\lambda - \lambda_o)((I - P_u)v_{_D}, v_p) + (R(u)v_{_D}, v_p) + (v_{_D}, R(u)v_p) = (\lambda - \lambda_o)((I - P_u)v_{_D}, v_p) + \|u\|^{-2}(u, v_p)(v_{_D}, r)$, where

we have used the fact that $R(u)v_{_D}$ is collinear to vector r that is orthogonal to v_p. Applying Corollary 2.3, we obtain

$$((I-P_u)v_{_D},v_p)| \le \|(I-P_u)v_{_D}\|\|(1-P_u)v_p\| \le \frac{\|v_{_D}\|_{J_o}\|v_p\|_{J_o}}{\lambda_1+\lambda_2-\lambda-\lambda_o}$$

and

$$|(u,v_p)| = \cos\{u;v_p\}\|u\|\|v_p\| = \frac{\cos\{u;v_p\}}{\sin\{u;v_p\}}\|u\|\|(I-P_u)v_p\| \le \frac{\cot\{u;v_p\}\|u\|\|v_p\|_{J_o}}{\sqrt{\lambda_1+\lambda_2-\lambda-\lambda_o}}.$$

Since $|(v_{_D},r)| \le \|v_{_D}\|_{J_o}\|r\|_{J_o^{-1}}$, it remains to estimate the J_o^{-1}-norm of r via the eigenvalue error, for which we employ first Lemma 2.4 and then Lemma 2.5 to arrive at

$$\|r\|^2_{J_o} \le \frac{\lambda_2-\lambda}{\lambda_1+\lambda_2-\lambda-\lambda_o}\|r\|^2_{J_1(u)} = \frac{(\lambda_2-\lambda)(\lambda-\lambda_1)}{\lambda_1+\lambda_2-\lambda-\lambda_o}\|u\|^2. \tag{3.11}$$

Put together, the above estimates provide an estimate for the J_o-cosine of the angle between $v_{_D}$ and v_p that, by (3.9), implies the following estimate for the difference between the new approximate eigenvalue $\lambda_{_D}$ produced by the Daniel scheme and λ_o:

$$\lambda_{_D}-\lambda_o \le (\lambda-\lambda_o)\left(\frac{\lambda-\lambda_o+\cot\{u;v_p\}\sqrt{(\lambda_2-\lambda)(\lambda-\lambda_1)}}{\lambda_1+\lambda_2-\lambda-\lambda_o}\right)^2. \tag{3.12}$$

The obtained upper bound is larger than that in (3.10) in the general case; however, if we modify the Daniel scheme by making v_p orthogonal to u, then (3.12) coincides with (3.10). The same is true for the Daniel scheme employed in the framework of the trace minimization CG of [4], whereby v_p is translated along the geodesics on the unit sphere and hence is made orthogonal to u. In fact, the Jacobi and Daniel schemes are identical in this framework because preconditioning is not used, and thus $v = Kr + \beta_i v_p = r + \beta_i v_p$ is also orthogonal to u; hence, $(H(u)v,v_p) = ((I-P_u)H(u)(I-P_u)v,v_p) = (J(u)v,v_p)$.

Yet another modification that makes the upper bound in (3.12) comparable to that in (3.10) is to orthogonalize v_p to u_p before the line search step (this modification has an additional benefit of making the line search step failsafe (see section 2.2), and we note also that it does not affect λ but generally affects $v_{_D}$). Indeed, estimating the standard norm of $u-u_p$ via the $J(\lambda,u_p)$-norm with the help of Corollary 2.3, and the latter norm via $\lambda_p-\lambda$ with the help of (2.13), we arrive at

$$\cot^2\{u;v_p\} = \cot^2\{u;u-u_p\} = \frac{\|u-u_p\|^2}{\|u_p\|^2} \le \frac{\lambda_p-\lambda}{\lambda_1+\lambda_2-\lambda-\lambda_p}. \tag{3.13}$$

We observe that the same estimate obviously holds in the case of yet another normalization that is commonly used in practical computation, notably, $\|u\| = \|u_p\| = 1$.

3.5. Polak–Ribiére scheme. The comparison with the Polak–Ribiére scheme is considerably more difficult. In order to simplify the calculations, let us employ one of the modifications of the standard CG scheme mentioned in the previous section, notably, the one where v_p is orthogonalized to u_p. In this case, by (2.14) we have

$$r = r_p - \alpha_p J_p v_p, \quad J_p = J(\lambda,u_p),$$

and we observed previously that $(v_p, r) = 0$ and $\|r_p\|_K^2 = (v_p, r_p)$. Hence $\|r_p\|_K^2 = (v_p, r_p - r)$, and we have for β_i computed by the Polak–Ribiére scheme the following relationship:

$$\beta_i = \frac{(r,\ r - r_p)_K}{\|r_p\|_K^2} = \frac{(Kr,\ r - r_p)}{(v_p, r_p - r)} = -\frac{(Kr, J_p v_p)}{(v_p, J_p v_p)}. \tag{3.14}$$

Thus, denoting by v_{PR} the new search direction, we have $(J_p v_{PR}, v_p) = 0$; i.e., in the scheme in question, the search directions are also conjugate with respect to a Jacobi correction operator, namely, $J_p = J(\lambda, u_p)$. The continuous dependence of the operator $J(\mu, u)$ on its arguments ensures that this scheme is also asymptotically close to the locally optimal scheme. In order to obtain an explicit estimate for the difference between the new approximate eigenvalue λ_{PR} computed by the Polak–Ribiére scheme and λ_o, we observe that

$$J_o - J_p = (\lambda - \lambda_o)I + R(u_p) - R(u) + R(u_p)^* - R(u)^* + (\lambda_p - \lambda)P_{u_p} - (\lambda - \lambda_o)P_u$$

(cf. Lemma 2.1). Since v_p is orthogonal to u_p, we have $P_{u_p} v_p = 0$ and $R(u_p)v_p = 0$, and since v_p is orthogonal to r, it is also orthogonal to $R(u)w = \|u\|^{-2}(w, u)r$ for any w. Hence, $((J_o - J_p)v_p, v_p) = (\lambda - \lambda_o)((I - P_u)v_p, v_p)$, and $(J_o v_p, v_p) = (\lambda - \lambda_o)\|(I - P_u)v_p\|^2 + (J_p v_p, v_p) \geq (J_p v_p, v_p)$. Since $(J_p v_{PR}, v_p) = 0$, we have $(J_o v_{PR}, v_p) = ((J_o - J_p)v_{PR}, v_p) = (\lambda - \lambda_o)((I - P_u)v_{PR}, v_p) + (R(u_p)v_{PR}, v_p) - (v_{PR}, R(u)v_p)$, where we have used the fact that $R(u_p)v_p = 0$ and $(R(u)v_{PR}, v_p) = 0$. The term $(\lambda - \lambda_o)((I - P_u)v_{PR}, v_p)$ has already been estimated in the previous section. For $(R(u_p)v_{PR}, v_p)$ we have

$$(R(u_p)v_{PR}, v_p) = \frac{(v_{PR}, u_p)(r_p, v_p)}{\|u_p\|^2} = \frac{(v_{PR}, (I - P_u)(u_p - u)) + (v_{PR}, P_u u_p)}{\|u_p\|^2}(r_p, v_p).$$

With the help of Corollary 2.3 and (3.13), the first term in the numerator is estimated by

$$\|(I - P_u)v_{PR}\|\|u_p - u\| \leq \frac{\|v_{PR}\|_{J_o}}{\sqrt{\lambda_1 + \lambda_2 - \lambda - \lambda_o}} \frac{\sqrt{\lambda_p - \lambda}\|u_p\|}{\sqrt{\lambda_1 + \lambda_2 - \lambda - \lambda_p}}.$$

The second term is estimated by

$$\|P_u v_{PR}\|\|u_p\| = \|(I - P_u)v_{PR}\|\|u_p\| \cot\{u; v_{PR}\} \leq \frac{\|v_{PR}\|_{J_o}\|u_p\| \cot\{u; v_{PR}\}}{\sqrt{\lambda_1 + \lambda_2 - \lambda - \lambda_o}},$$

and (r_p, v_p) is estimated as

$$|(r_p, v_p)| \leq \|r_p\|_{J_p^{-1}}\|v_p\|_{J_p} \leq \frac{\sqrt{(\lambda_2 - \lambda_p)(\lambda_p - \lambda_1)}\|u_p\|\|v_p\|_{J_o}}{\sqrt{\lambda_1 + \lambda_2 - \lambda - \lambda_p}},$$

where we have used the estimate for the J_p^{-1}-norm of r via $\lambda_p - \lambda_1$ similarly to (3.11). Finally $(v_{PR}, R(u)v_p) = \|u\|^{-2}(u, v_p)(v_{PR}, r)$, where (v_{PR}, r) is estimated in the same way as (v_D, r) in the previous section, and so is (u, v_p), with $\cot\{u; v_p\}$ estimated via (3.13), and we arrive at

$$\begin{aligned}\lambda_{PR} - \lambda_o \leq (\lambda - \lambda_o)\Bigg(&\frac{\lambda - \lambda_o}{\delta(\lambda + \lambda_o)} + \frac{\sqrt{(\lambda_2 - \lambda)(\lambda - \lambda_1)(\lambda_p - \lambda)}}{\delta(\lambda + \lambda_o)\sqrt{\delta(\lambda + \lambda_p)}} \\ &+ \frac{\sqrt{(\lambda_2 - \lambda_p)(\lambda_p - \lambda_1)}}{\sqrt{\delta(\lambda + \lambda_o)\delta(\lambda + \lambda_p)}}\left(\frac{\sqrt{\lambda_p - \lambda}}{\sqrt{\delta(\lambda + \lambda_p)}} + \cot\{u; v_{PR}\}\right)\Bigg)^2,\end{aligned} \tag{3.15}$$

where $\delta(\mu) = \lambda_1 + \lambda_2 - \mu$. The obtained upper bound is generally larger than that for the previous two schemes (assuming the orthogonality of v_p to u_p in the Daniel scheme) and cannot be reduced by orthogonalizing v_{PR} to u because this would generally destroy J_p-orthogonality of v_{PR} and v_p. We note, however, that if preconditioning is not used, then $(v_{PR}, u_p) = (r + \beta_i v_p, u_p) = 0$ and the third term in brackets in (3.15) disappears altogether, making this upper bound comparable to those for the other two schemes.

3.6. Bradbury–Fletcher scheme. Since u_o is the point of minimum of $\lambda(w)$ in the subspace $\operatorname{span}\{u, Kr, v_p\}$, we have $(r(u_o), Kr) = 0$. Hence, if v_p is the locally optimal search direction, then $(r, Kr_p) = 0$, and the Polak–Ribiére and Bradury–Fletcher schemes produce the same new search direction, which, as we have just shown, is asymptotically close to the new locally optimal one. Thus, in this particular sense, the estimate (3.15) applies to the Bradbury–Fletcher scheme as well.

We note that the asymptotic relationship between the Bradbury–Fletcher and Polak–Ribiére schemes without preconditioning has also been discussed in [4] based on the relationship $(r, r_p) = \mathcal{O}\left(\epsilon^3\right)$ assumed to be valid in the ϵ-vicinity of x_1. It is not difficult to show that for the scheme considered in the previous subsection and in the absence of preconditioning one actually has $(r, r_p) = \mathcal{O}\left(\epsilon^4\right)$. Indeed, by the calculations of section 3.5, the angle between the search directions of the locally optimal and Polak–Ribiére schemes is estimated by the expression inside the brackets in (3.15), which, in the absence of preconditioning, is of the order $\mathcal{O}\left(\lambda_p - \lambda_1\right) = \mathcal{O}\left(\epsilon^2\right)$. Hence, the difference between the new approximate eigenvectors u_o and u_{PR} computed by the locally optimal and Polak–Ribiére schemes is of the order $\mathcal{O}\left(\epsilon^2\right) \|u_o - u\| = \mathcal{O}\left(\epsilon^3\right)$, which implies $\|Pr(u_{PR})\| = \|Pr(u_o)\| + \mathcal{O}\left(\epsilon^3\right) = \mathcal{O}\left(\epsilon^3\right)$, where P is the orthogonal projector onto $\operatorname{span}\{v_p, r\}$. The J_p-orthogonality of $v_{PR} = r + \beta_i v_p$ to v_p implies that $\|\beta_i v_p\|_{J_p} \leq \|r\|_{J_p}$, and thus $\|\beta_i v_p\| = \mathcal{O}\left(\epsilon\right)$. Hence, $(r(u_{PR}), r) = (r(u_{PR}), v_{PR} - \beta_i v_p) = -(r(u_{PR}), \beta_i v_p) = -(Pr(u_{PR}), \beta_i v_p) = \mathcal{O}\left(\epsilon^4\right)$.

3.7. Perdon–Gambolati scheme. In the Perdon–Gambolati scheme, $(v, v_p)_L = 0$; i.e., the cosine of the L-angle between v and v_p (the angle measured via $\|\cdot\|_L$) is zero. In the general case, the cosine of the J_o-angle is not close to that of the L-angle, and hence the new search direction produced by the Pedon–Gambolati scheme may deviate significantly from the locally optimal one and therefore, by the calculations of this section, from those produced by other schemes in question. A similar comment is made by [4], and the numerical tests in [5] demonstrate that, indeed, the convergence of the Perdon–Gambolati CG is considerably slower than that of the Bradbury–Fletcher and Polak–Ribiére schemes.

4. New local convergence estimate for conjugate gradients. Owing to the inclusion $\operatorname{span}\{u, Kr, v_p\} \supset \operatorname{span}\{u, Kr\}$, the new approximate eigenvalue λ_o produced by the locally optimal CG step is not greater than that produced by the (preconditioned) steepest descent step for the same u. The calculations of the previous section imply that the same can be said, modulo asymptotically small terms, about the other schemes investigated there, save for the Perdon–Gambolati scheme. In practice, CG converges considerably faster than the steepest descent, but in eigenvalue computation this practical observation has not yet been supported by theoretical convergence estimates that would demonstrate convergence acceleration compared to the steepest descent. One way to obtain such estimates is to follow [4] in treating the Rayleigh quotient minimization as a minimization of a quadratic functional (Lv, v) constrained to the sphere $\|v\| = 1$. By introducing a suitable coordinate system on

this sphere, the latter minimization problem can be reformulated as a nonquadratic unconstrained problem in $(n-1)$-dimensional space, the main advantage over the original nonquadratic problem being the fact that the Hessian is positive definite, and hence the convergence results of, e.g., [3] or [22] are applicable. The described approach has a potential to produce convergence estimates for CG in eigenvalue computation similar to well-known estimates for linear systems and estimates of Kaniel and Saad for the Lanczos method. We note, however, that the mentioned results from nonquadratic CG minimization assume the initial vector x^0 to be close enough to the minimum point x and suggest upper bounds for the error reduction after i iterations of the form $q_i + c_i\|x^0 - x\|$, where $q_i < 1$ is related to the condition number of the Hessian at the minimum point in the same way as in the quadratic case and c_i grows rapidly with the iteration number i. Such results are meaningful only for the case where the iterations are frequently restarted, and after a sufficient number of restarts. We note also that the practical implementation of the approach of [4] to the generalized eigenvalue problem $Lx = \lambda Mx$ involves the application of M^{-1} to a vector (see section 4.5 of the cited paper), which hinders its application to generalized problems of large size, and it is not clear how to properly and efficiently employ preconditioning in the framework of this approach.

In this section we take a different approach that pursues a less ambitious goal of obtaining convergence results that would clearly demonstrate the advantages of conjugation—but would remain meaningful after any number of iterations. First, we derive an asymptotic equation that relates the reduction in the eigenvalue error achieved by the locally optimal CG to that which could be achieved by the locally optimal steepest descent for the same current eigenvector iterate x^i. Based on this equation, we then derive a convergence estimate for the general Jacobi scheme that explicitly shows the acceleration delivered by the conjugation of two consecutive search directions.

We start with a few simple observations regarding the equivalence of $J(\mu, u)$- and K^{-1}-energy norms. Below we assume that $\lambda_1 \le \mu \le \lambda(u) < (\lambda_1 + \lambda_2)/2$.

For any Hermitian positive definite K we have

$$(J(\mu, u)v, v) \le (J_1(u)v, v) \le \kappa_{-1}(u)(K^{-1}v, v), \tag{4.1}$$

where $J_1(u) = J(\lambda_1, u)$ and $\kappa_{-1}(u)$ is the rightmost eigenvalue of $KJ_1(u)$. By Lemma 2.2, the operator $J(u) = J(\lambda(u), u)$ is positive definite in $\mathrm{span}\{u\}^\perp$; hence for $\mu \le \lambda(u)$ and $v \in \mathrm{span}\{u\}^\perp$

$$(J(\mu, u)v, v) \ge (J(u)v, v) \ge \kappa_2(u)(K^{-1}v, v), \tag{4.2}$$

where $\kappa_2(u) > 0$ is second leftmost eigenvalue of $KJ(u)$. We note that as $u \to x_1$, $\kappa_2(u) \to \kappa_2$ and $\kappa_{-1}(u) \to \kappa_{-1}$, where κ_2 and κ_{-1} are the second leftmost and the rightmost eigenvalues of $K(L - \lambda_1)$.

Denoting $K(u) = (I - P_u)K(I - P_u) + \kappa P_u$, where $\kappa > 0$, and assuming $\mu + \lambda(u) < \lambda_1 + \lambda_2$, we observe that for $v \in \mathrm{span}\{u\}^\perp$

$$(J(\mu, u)v, v) \ge \kappa_2(\mu, u)(K(u)^{-1}v, v), \tag{4.3}$$

where $\kappa_2(\mu, u)$ is the second leftmost eigenvalue of $K(u)J(\mu, u)$. Lemma 2.2 implies that $\kappa_2(\mu, u) > 0$, and it is not difficult to see that $\kappa_2(\mu, u) \to \kappa_2$ as $\{\mu, u\} \to \{\lambda_1, x_1\}$, assuming $\kappa \ge \kappa_2$. Since $(J(\mu, u)Kr(u), Kr(u)) = (J(\mu, u)K(u)r(u), K(u)r(u))$ and $K(u)r(u) \in \mathrm{span}\{u\}^\perp$, by (4.3) we have

$$(J(\mu, u)Kr(u), Kr(u)) \ge \kappa_2(\mu, u)(r(u), K(u)r(u)) = \kappa_2(\mu, u)(r(u), Kr(u)). \tag{4.4}$$

Since $r(u) \in \operatorname{span}\{u\}^{\perp}$, we also have

$$(Kr(u), r(u)) = (K(u)r(u), r(u)) \le \kappa_{-1}(\mu, u)(J(\mu, u)^{-1}r(u), r(u)), \tag{4.5}$$

$$(Kr(u), r(u)) \ge \kappa_2(\mu, u)(J(\mu, u)^{-1}r(u), r(u)), \tag{4.6}$$

where $J(\mu, u)^{-1}$ is the inverse of the restriction of $J(\mu, u)$ to $\operatorname{span}\{u\}^{\perp}$ and $\kappa_{-1}(\mu, u)$ is the rightmost eigenvalue of $K(u)J(\mu, u)$.

We observe that $\kappa_{-1}(u)$, $\kappa_2(u)$, and $\kappa_2(\mu, u)$ continuously depend on u and μ. Hence, for $\lambda_1 \le \mu \le \lambda(u) \le \lambda^0 < (\lambda_1+\lambda_2)/2$ we have uniform (in μ and u) equivalence of the K^{-1}- and J-energy norms involved.

Below we return to the notation of section 3.1.

The first result of this section establishes an asymptotic relationship between the eigenvalue error reductions achieved on two consecutive locally optimal CG iterations and the error reduction achievable with the same data by the steepest descent.

THEOREM 4.1. *Assuming that $\lambda^{i-1} \le \nu < (\lambda_1 + \lambda_2)/2$ and $r^i \ne 0$, the following asymptotic relationship is valid:*

$$\frac{1}{\lambda^i - \lambda^{i+1}} + \frac{1}{\lambda^{i-1} - \lambda^i} = \frac{1 + \mathcal{O}(\epsilon_i)}{\lambda^i - \lambda_s^{i+1}}, \quad \epsilon_i = \sqrt{\lambda^{i-1} - \lambda_1}, \tag{4.7}$$

where $\lambda^k = \lambda(x^k)$ are computed by the locally optimal CG and λ_s^{i+1} by the steepest descent; i.e., λ_s^{i+1} minimizes $\lambda(w)$ in $\operatorname{span}\{x^i, g^i\}$.

Proof. Let us denote $J_i = J(\lambda^{i+1}, x^i)$ and $J_i^s = J(\lambda_s^{i+1}, x^i)$. In section 3.2 we have shown that the locally optimal scheme is a particular case of the Jacobi scheme with $\mu^i = \lambda^{i+1}$; i.e., the locally optimal scheme employs the line search in the direction $y^i = Kr^i + \beta_{i-1}y^{i-1}$, where β_{i-1} is such that $(J_i y^i, y^{i-1}) = 0$; i.e., $\beta_{i-1} = -(J_i Kr^i, y^{i-1})/(J_i y^{i-1}, y^{i-1})$. The scheme in question is scale-invariant; hence let us assume that $\|x^i\| = 1$ and $(x^{i+1} - x^i, x^i) = 0$.

By Theorem 2.6,

$$\lambda^i - \lambda^{i+1} = \frac{|(r^i, y^i)|^2}{\|y^i\|_{J_i}^2} = \frac{\|r^i\|_K^4}{\|y^i\|_{J_i}^2}, \quad \lambda^i - \lambda_s^{i+1} = \frac{\|r^i\|_K^4}{\|Kr^i\|_{J_i^s}^2}. \tag{4.8}$$

Thus,

$$\begin{aligned}\frac{\lambda^i - \lambda_s^{i+1}}{\lambda^i - \lambda^{i+1}} &= \frac{\|y^i\|_{J_i}^2}{\|Kr^i\|_{J_i^s}^2} = \frac{\|Kr^i\|_{J_i}^2 - |\beta_{i-1}|^2\|y^{i-1}\|_{J_i}^2}{\|Kr^i\|_{J_i^s}^2} \\ &= \frac{\|Kr^i\|_{J_i}^2}{\|Kr^i\|_{J_i^s}^2} - \frac{|(J_i Kr^i, y^{i-1})|^2}{\|Kr^i\|_{J_i^s}^2\|y^{i-1}\|_{J_i}^2} = \frac{\|Kr^i\|_{J_i}^2}{\|Kr^i\|_{J_i^s}^2} - \frac{|(J_i Kr^i, h^{i-1})|^2}{\|Kr^i\|_{J_i^s}^2\|h^{i-1}\|_{J_i}^2},\end{aligned} \tag{4.9}$$

where $h^{i-1} = x^i - x^{i-1}$. By Lemma 2.4, the ratio of the J_i- to the J_i^s- norm of any vector noncollinear to x^i is $1 + \mathcal{O}\left(\lambda_s^{i+1} - \lambda^{i+1}\right) = 1 + \mathcal{O}\left(\epsilon_i^2\right)$, and the continuity of $J(\mu, u)$ with respect to both arguments implies that in the last term in (4.9) J_i can be replaced with J_{i-1} at the cost of adding an $\mathcal{O}(\epsilon_i)$ term, leading to (cf. calculations in Appendix B)

$$\begin{aligned}\frac{|(J_i Kr^i, h^{i-1})|^2}{\|Kr^i\|_{J_i^s}^2\|h^{i-1}\|_{J_i}^2} &= \frac{|(J_{i-1} Kr^i, h^{i-1})|^2}{\|Kr^i\|_{J_i^s}^2\|h^{i-1}\|_{J_{i-1}}^2} + \mathcal{O}(\epsilon_i) \\ &= \frac{|(Kr^i, r^{i-1} - r^i)|^2}{\|Kr^i\|_{J_i^s}^2(\lambda^{i-1} - \lambda^i)} + \mathcal{O}(\epsilon_i),\end{aligned} \tag{4.10}$$

where we have used the relationships $r^i = r^{i-1} - J_{i-1}h^{i-1}$ and $\|h^{i-1}\|^2_{J_{i-1}} = (\lambda^{i-1} - \lambda^i)\|x^{i-1}\|^2$ (cf. (2.14) and (2.13)). A crucial observation is that $(Kr^i, r^{i-1}) = (r^i, Kr^{i-1}) = (r^i, y^{i-1} - \beta_{i-2}y^{i-2}) = 0$, and hence (4.8), (4.9), and (4.10) yield

$$\frac{\lambda^i - \lambda_s^{i+1}}{\lambda^i - \lambda^{i+1}} = 1 - \frac{\|r^i\|^4}{\|Kr^i\|^2_{J_i^s}(\lambda^{i-1} - \lambda^i)} + \mathcal{O}(\epsilon_i) = 1 - \frac{\lambda^i - \lambda_s^{i+1}}{\lambda^{i-1} - \lambda^i} + \mathcal{O}(\epsilon_i),$$

and we arrive at (4.7). ∎

We stress that in Theorem 4.1, $\mathcal{O}(\epsilon_i)$ stands for a quantity that is not greater than ϵ_i times a constant that does not depend on the iteration number.

The main merit of the result just obtained is that it explicitly and precisely (modulo an asymptotically small term) shows the convergence acceleration due to the conjugation of search direction. It strengthens considerably the trivial observation that the locally optimal CG is not worse than the steepest descent mentioned at the beginning of this section. Furthermore, (4.7) allows one to benefit from available convergence results for a relatively much better studied (as far as the eigenvalue computation is concerned) steepest descent method to arrive, in particular, at the following convergence estimate.

THEOREM 4.2. *Assuming $\lambda^{i-1} < (\lambda_1 + \lambda_2)/2$ and $\lambda_1 \le \mu^i \le \lambda^i$, the following asymptotic convergence estimate for Jacobi CG is valid:*

$$\lambda^{i+1} - \lambda_1 \le \left(\frac{q + \delta_i}{1 + \delta_i}\right)^2 (\lambda^{i-1} - \lambda_1), \quad q = T_2\left(\frac{\kappa + 1}{\kappa - 1}\right)^{-1}, \tag{4.11}$$

where $T_2(x) = 2x^2 - 1$, κ is the ratio of the rightmost to leftmost positive eigenvalue of $K(L - \lambda_1 I)$, and $\delta_i = \mathcal{O}\left(\sqrt{\lambda^{i-1} - \lambda_1}\right)$.

Proof. Consider first the locally optimal scheme, i.e., the particular case $\mu^i = \lambda^{i+1}$. Let us denote $q_i = (\lambda^{i+1} - \lambda_1)/(\lambda^i - \lambda_1)$ and $p_i = (\lambda_{sd}^{i+1} - \lambda_1)/(\lambda^i - \lambda_1)$. By the asymptotic estimate of [25] (cf. also section 2.4), $p_i \le p + \mathcal{O}\left(\lambda^{i-1} - \lambda_1\right)$, where $p = ((\kappa - 1)/(\kappa + 1))^2$. From (4.7) we have

$$\frac{1}{1 - q_i} + \frac{q_{i-1}}{1 - q_{i-1}} = \frac{1 + \mathcal{O}(\epsilon_i)}{1 - p_i} = \frac{1}{1 - p_i} + \varepsilon_i \le \frac{1}{1 - p} + \varepsilon_i,$$

where $\varepsilon_i = \mathcal{O}(\epsilon_i) = \mathcal{O}\left(\sqrt{\lambda^{i-1} - \lambda_1}\right)$. Subtracting 1 from both sides yields

$$\frac{q_i}{1 - q_i} + \frac{q_{i-1}}{1 - q_{i-1}} \le \frac{p}{1 - p} + \varepsilon_i, \tag{4.12}$$

or $u_i + u_{i-1} \le v_i$, where $u_i = q_i/(1 - q_i)$ and v_i is the right-hand side of (4.12). We have $q_i = u_i/(u_i + 1)$, and hence

$$q_i q_{i-1} = \frac{u_i u_{i-1}}{u_i u_{i-1} + v_i + 1} \le \frac{\frac{1}{4}v_i^2}{\frac{1}{4}v_i^2 + v_i + 1} = \frac{v_i^2}{(v_i + 2)^2}$$

$$= \frac{(p + (1 - p)\varepsilon_i)^2}{(2 - p + (1 - p)\varepsilon_i)^2} = \left(\frac{\frac{p}{2-p} + \delta_i}{1 + \delta_i}\right)^2.$$

Simple calculation shows that $(2-p)/p = T_2((\kappa+1)/(\kappa-1))$, and we arrive at (4.11).

To prove (4.11) in the general case, we need to revisit the proof of Theorem 4.1. Denoting $J_i^c = J(\mu^i, x^i)$, we observe that in the case at hand the search directions

are J_i^c-orthogonal, and hence $\beta_{i-1} = -(J_i^c Kr^i, y^{i-1})/(J_i^c y^{i-1}, y^{i-1})$, and in place of (4.9) we now have

$$\frac{\lambda^i - \lambda_s^{i+1}}{\lambda^i - \lambda^{i+1}} = \frac{\|y^i\|_{J_i}^2}{\|y^i\|_{J_i^c}^2} \frac{\|y^i\|_{J_i^c}^2}{\|Kr^i\|_{J_i^s}^2} = \frac{\|y^i\|_{J_i}^2}{\|y^i\|_{J_i^c}^2} \left(\frac{\|Kr^i\|_{J_i}^2}{\|Kr^i\|_{J_i^s}^2} - \frac{|(J_i^c Kr^i, h^{i-1})|^2}{\|Kr^i\|_{J_i^s}^2 \|h^{i-1}\|_{J_i^c}^2} \right).$$

The factor in front of the brackets and the first term inside them are of the order $1 + \mathcal{O}\left(|\mu^i - \lambda^{i+1}|\right)$. Regarding the second term in the brackets, it is not difficult to verify that in (4.10), J_i can be replaced with J_i^c. However, this time (Kr^i, r^{i-1}) is generally nonzero. Let us show that this scalar product is asymptotically insignificant.

We start by observing that the norm equivalencies noted at the beginning of this section together with the formula for $\lambda^i - \lambda_s^{i+1}$ in (4.8) imply $\lambda^i - \lambda_s^{i+1} \sim \|r\|_K^2 \sim \|Kr^i\|_{J_i^s}^2 \sim \lambda^i - \lambda_1 \sim \lambda^i - \lambda^{i+1}$. Next, we observe that

$$\begin{aligned}(r^i, Kr^{i-1}) &= (r^i, y^{i-1} - \beta_{i-2} y^{i-2}) = -(r^i, \beta_{i-2} y^{i-2}) \\ &= (-r^{i-1} + \alpha_{i-1} J(\lambda^i, x^{i-1}) y^{i-1}, \beta_{i-2} y^{i-2}) \\ &= (\mu^{i-1} - \lambda^i)((I - P_{x^{i-1}})\alpha_{i-1} y^{i-1}, (I - P_{x^{i-1}})\beta_{i-2} y^{i-2}),\end{aligned}$$

where we have used the $J(\mu^{i-1}, x^{i-1})$-orthogonality of y^{i-1} and y^{i-2}. By Corollary 2.3, the norms of $(I - P_{x^{i-1}})\alpha_{i-1} y^{i-1}$ and $(I - P_{x^{i-1}})\beta_{i-2} y^{i-2}$ are bounded by their $J(\lambda^i, x^{i-1})$-norms. By Theorem 2.6, the former norm is $\mathcal{O}(\sqrt{\lambda^{i-1} - \lambda^i})$, and the $J(\mu^{i-1}, x^{i-1})$-orthogonality of $y^{i-1} = Kr^{i-1} + \beta_{i-2} y^{i-2}$ and $\beta_{i-2} y^{i-2}$ implies that the latter norm is not greater than the same norm of Kr^{i-1}, which is equivalent to $\sqrt{\lambda^{i-1} - \lambda^i}$. Thus,

$$|(r^i, Kr^{i-1})| = \mathcal{O}\left(|\mu^{i-1} - \lambda^i|\right)(\lambda^{i-1} - \lambda^i) = \mathcal{O}\left((\lambda^i - \lambda_1)(\lambda^{i-1} - \lambda^i)\right).$$

Now, if $\|Kr^i\|_{J_i^s} < \lambda^{i-1} - \lambda_1$, then $\lambda^i - \lambda_1 = \mathcal{O}\left(\|r^i\|_K^2\right) = \mathcal{O}\left((\lambda^{i-1} - \lambda_1)^2\right)$, and we have (4.11); otherwise the ratio of $|(r^i, Kr^{i-1})|$ to $\|Kr^i\|_{J_i^s}\sqrt{\lambda^{i-1} - \lambda^i}$ is of the order $\mathcal{O}(\sqrt{\lambda^{i-1} - \lambda^i})$, and via (4.10) we again arrive at (4.7) and thus at (4.11). ∎

Remark 3. A similar result for the particular case $i = 1$ is reported in [10] (cf. also [16, 17]) under the assumption that the initial approximate eigenvalue λ^0 is close enough to λ_1, which makes it meaningful only for the first two iterations of the restarted CG after a sufficient number of restarts.

It is not difficult to verify that (4.7) applies to the case of CG-minimization of the quadratic functional $\phi(u) = (Lu, u) - (u, f) - (f, u)$, with λ^i replaced by $\phi(x^i)$ and $\epsilon_i = 0$, and hence so does (4.11) with $\delta_i = 0$ and κ standing for the condition number of KL. In the quadratic case, it can be shown that the number of CG iterations in (4.11) can be increased from 2 to arbitrary $k > 2$, with T_2 replaced with the Chebyshev polynomial of degree k (for $i = 1$ this is well known). It is plausible that a similar estimate is valid in the case at hand as well. Hence, one way to improve (4.11) is to try to extend the local convergence analysis of this section to more than two consecutive CG iterations.

An alternative way is to exploit the asymptotic stepwise closeness of the CG and the generalized Davidson method discussed in the next section.

5. Asymptotic local equivalence of CG and generalized Davidson methods. In the generalized Davidson method, the new eigenvector iterate x^{i+1} is defined as the minimum point of $\lambda(w)$ in the subspace $\mathcal{D}^i$ spanning the preconditioned residual (gradient) $g^i = Kr^i$ and all the previous iterates; i.e.,

$$x^{i+1} \in \mathcal{D}^i \ : \quad \lambda^{i+1} \equiv \lambda(x^{i+1}) = \min_{w \in \mathcal{D}^i} \lambda(w), \tag{5.1}$$

where $\mathcal{D}^i = \operatorname{span}\{x^0, \dots, x^i, g^i\} = \operatorname{span}\{g^0, \dots, g^i, x^i\}$. Since the computational expenses of the minimization in this $(i+2)$-dimensional subspace grow rapidly with i, in practical computation iterations are restarted when the dimension of $\mathcal{D}^i$ reaches a certain limit. In this section we show that after a sufficient number of restarts, the minimization in $\mathcal{D}^i$ becomes asymptotically equivalent to the line search employed by CG.

Our comparison of the generalized Davidson and CG below employs the same reasoning as that used earlier to compare the locally optimal CG with other CG schemes (cf. section 3.2). Let $P_{(i)}$ be the orthogonal projector onto $\mathcal{D}^i$, and let $\hat{L}_i$ be the restriction of the operator $P_{(i)}LP_{(i)}$ to $\mathcal{D}^i$. Since the leftmost eigenvalue of $\hat{L}_i$ is λ^{i+1}, the Jacobi correction operator for $\hat{L}_i$ is $\hat{J}_1(x^i) = (I - P_i)(\hat{L}_i - \lambda^{i+1}I)(I - P_i)$, where P_i is the orthogonal projector onto x^i. Since $P_iP = PP_i = P_i$, we have $\hat{J}_1(x^i) = P_{(i)}J_iP_{(i)}$, and thus $\hat{J}_1(x^i)$ and J_i coincide in $\mathcal{D}^i$. It remains to invoke Theorem 2.7 to arrive at the following estimate for the difference between λ^{i+1} and the approximate eigenvalue computed by the line search in an arbitrary direction y such that $(y, r^i) \neq 0$:

$$\lambda_y^{i+1} - \lambda^{i+1} \leq (\lambda^i - \lambda^{i+1}) \sin^2 \theta(y), \quad \lambda_y^{i+1} = \min_{\tau} \lambda(x^i - \tau y), \tag{5.2}$$

where $\theta(y)$ is the J_i-angle between y and h^i.

Let us now apply (5.2) to estimating $\lambda_o^{i+1} - \lambda^{i+1}$, where λ_o^{i+1} is computed by the locally optimal scheme based on x^i and x^{i-1}; i.e., λ_o^{i+1} is the minimum of $\lambda(w)$ in $\operatorname{span}\{x^{i-1}, x^i, Kr^i\}$. Below we assume that $\lambda^0 < (\lambda_1 + \lambda_2)/2$.

The generalized Davidson method is obviously scale-invariant, and, by the same arguments as with the locally optimal CG (see section 3.2), x^{i+1} is not orthogonal to x^i. Hence, we may assume $\|x^0\| = 1$ and assume the normalization of x^j for which $h^j = x^{j+1} - x^j$ is orthogonal to x^j. The vector x^{i+1} minimizes the Rayleigh quotient in $\mathcal{D}^i$ and hence on the line $x(\tau) = x^i + \tau h^i$ as well. By (2.14), this implies

$$r^{i+1} = r^i - J_i h^i, \quad J_i \equiv J(\lambda^{i+1}, x^i). \tag{5.3}$$

Since r^{i+1} is collinear to the gradient of the Rayleigh quotient at the point of minimum in $\mathcal{D}^i$, it is orthogonal to $x^0, \dots, x^{i+1}$ and hence to $h^0, \dots, h^i$. In view of (5.3), this implies

$$(J_i h^i, h^j) = 0, \quad j = 0, \dots, i-1. \tag{5.4}$$

The locally optimal search direction can be expressed as $y_o^i = Kr^i + \beta_o h^{i-1}$, where β_o is such that y_o^i and h^{i-1} are $J(\lambda_o^{i+1}, x^i)$-orthogonal (cf. section 3.2). We observe that $(y_o^i, r^i) = (Kr^i, r^i) > 0$; hence (5.2) applies. Let us denote $z^j = \|h^j\|_{J_j}^{-1} h^j$, $j = 0, \dots, i-1$. Employing $h^0, \dots, h^i, x^i$ as the basis of $\mathcal{D}^i$, we have

$$y_o^i = Kr^i + \beta_o h^{i-1} = \sum_{j=0}^{i-1} \alpha_j z^j + \alpha h^i + \gamma x^i = z_o^i + \alpha h^i + \gamma x^i, \tag{5.5}$$

and one observes that $\sin\theta(y_o^i) \le \|y_o^i - \alpha h^i\|_{J_i}/\|y_o^i\|_{J_i} = \|z_o^i\|_{J_i}/\|y_o^i\|_{J_i}$. In order to estimate the latter ratio, we multiply (5.5) by $J_i z^k$, $k = 0, \dots, i-1$, to arrive at the linear system $Au = v$, where A is an i-by-i matrix with entries $(J_i z^j, z^k)$ and the components of vectors u and v are α_k and $(J_i y_o^i, z^k) = (Kr^i + \beta_o h^{i-1}, J_i z^k)$, $k = 0, \dots, i-1$, respectively. Simple calculations (see section C) show that for $i > j \ge k$

$$|(J_i z^j, z^k) - (J_j z^j, z^k)| \le \sigma\sqrt{\epsilon_j}\sqrt{\epsilon_k}, \quad \epsilon_m = \frac{\lambda^m - \lambda_1}{\lambda_1 + \lambda_2 - 2\lambda^0}, \tag{5.6}$$

whereas calculations of section B adapted to the case at hand imply that for $j < i-1$

$$|(J_i K r^i, z^j)| \le \rho \|Kr^i\|_{J_i}\sqrt{\epsilon_j}, \tag{5.7}$$

where σ and ρ are constants independent of i. Together with (C.1), (5.6) implies $\|A - I\| = \mathcal{O}(\epsilon_0)$, where I is an i-by-i identity matrix, which implies $\|u\| = \|v\|(1 + \mathcal{O}(\epsilon_o))$. Since $\|z_o^i\|_{J_i}^2 = u^* A u = u^* v = \|v\|^2(1 + \mathcal{O}(\epsilon_0))$, it remains to estimate $\|v\|$ via $\|y_o^i\|_{J_i}$. For the v's first component $(J_i y_o^i, h^{i-1})$ we have an estimate similar to that in section 3.3:

$$|(J_i y_o^i, z^{i-1})| = |(\lambda_o^{i+1} - \lambda^{i+1})(y_o^i, z^{i-1})| \le (\lambda^i - \lambda_1)\|y_o^i\|\|(I - P_i)z^{i-1}\| \le \epsilon_i \|y_o^i\|_{J_i}.$$

For $j < i-1$ from (5.6) and (5.7) we obtain

$$|(J_i y_o^i, z^j)| = |(J_i K r^i, z^j) + \beta_o (J_i h^{i-1}, z^j)| \le (\rho\|Kr^i\|_{J_i} + \sigma|\beta_o| h^{i-1}\|_{J_i}\sqrt{\epsilon_{i-1}})\sqrt{\epsilon_j}.$$

Since $(Kr^i, h^{i-1})_{K^{-1}} = (r^i, h^{i-1}) = 0$, we have $\|Kr^i\|_{J_i} \sim \|Kr^i\|_{K^{-1}} \le \|y_o^i\|_{K^{-1}} \sim \|y_i^o\|_{J_i}$. Thus, the jth component of v is of the order $\mathcal{O}\left(\sqrt{\epsilon_j}\right)\|y_i^o\|_{J_i}$, and via (C.1) we arrive at $\sin\theta(y_o^i) = \mathcal{O}\left(\sqrt{\epsilon_0}\right)$, which by (5.2) implies

$$\lambda_o^{i+1} - \lambda^{i+1} = \mathcal{O}\left(\frac{\lambda^0 - \lambda_1}{\lambda_1 + \lambda_2 - 2\lambda^0}\right)(\lambda^i - \lambda^{i+1}). \tag{5.8}$$

The established asymptotic relationship between the CG and Davidson methods can be used as a starting point in the derivation of nonlocal convergence estimates for CG in eigenvalue computation. In [16, 17] the following convergence estimate for the restarted generalized Davidson method is obtained:

$$\lambda^k - \lambda^0 \le \left(T_k\left(\frac{\kappa_{-1} + \kappa_2}{\kappa_{-1} - \kappa_2}\right)^{-2} + c_k\sqrt{\lambda^0 - \lambda_1}\right)(\lambda^0 - \lambda_1), \tag{5.9}$$

where $T_k(x)$ is Chebyshev polynomial of degree k; i.e., $T_k(x) = \cos(k \arccos(x))$ for $x \in [-1, 1]$. We observe that for $k = 2$, (5.9) has the same asymptotics as (4.11) for $i = 1$. The calculations of this section suggest that it might be possible to obtain an estimate similar to (5.9) for the restarted CG. In this paper we refrain from using such an approach to the convergence analysis of CG because it is likely to produce an estimate of the form (5.9) with c_k rapidly growing in k (cf. convergence estimates of [3] and [22] and the discussion at the beginning of section 4).

6. Conclusion. The results of this paper amply demonstrate that the Jacobi correction operator is a useful and versatile tool for the analysis of iterative methods for eigenvalue computation employing the line search technique, in particular, steepest

descent and CG methods. It allows an analyst to relate the eigenvalue and eigenvector errors and residuals via identities rather than inequalities, and thus opens the way to establishing precise (modulo asymptotically small terms) relationships between different methods, such as (4.7) or the identity that yielded the estimate (3.9). It simplifies the convergence analysis of the line search methods and reveals inherent similarities between convergence acceleration techniques as different and mutually independent as preconditioning and conjugation. A challenging task is to extend the Jacobi correction operator technique to block iterative methods for computing eigenvalues; this task is faced by the second part [19] of the present paper. Yet another challenge, still to be faced, is to extend the two-step convergence analysis of the CG method presented here to several CG steps.

Appendix A. A sharp estimate for the angle between u and Au.

LEMMA A.1. *Let A be a Hermitian positive definite operator in a finite-dimensional linear space with the scalar product. The following inequality is valid for the angle $\angle\{u, Au\}$ between a nonzero u and Au:*

$$\sin\angle\{u, Au\} \le \frac{cond(A)-1}{cond(A)+1}, \tag{A.1}$$

where $cond(A)$ is the condition number of A, i.e., the ratio of the maximal to the minimal eigenvalue of A. The estimate (A.1) *is sharp; i.e., the right-hand side cannot be made smaller without additional assumptions on u.*

Proof. Denote by λ_1 and λ_{-1} the minimal and the maximal eigenvalue of A, respectively, and set $\tau_* = 2/(\lambda_1+\lambda_{-1})$. The norm of $1-\tau_* A$ is equal to the maximum of the absolute value of its eigenvalues, i.e., $(\lambda_{-1}-\lambda_1)/(\lambda_{-1}+\lambda_1)$, which coincides with the right-hand side of (A.1). Since

$$\sin\angle\{u, Au\} = \min_\tau \frac{\|u-\tau Au\|}{\|u\|} \le \frac{\|u-\tau_* Au\|}{\|u\|} \le \|1-\tau_* A\|,$$

we arrive at (A.1). Simple calculation shows that the minimum point of $\sigma(\tau) = \|u - \tau Au\|/\|u\|$ is $\tau_{min}(u) = (u, Au)/\|Au\|^2$ and that $\tau_{min}(u) = \tau_*$ for $u = \alpha_1 x_1 + \alpha_{-1} x_{-1}$, where x_1 and x_{-1} are normalized eigenvectors corresponding to λ_1 and λ_{-1} and $\alpha_1^2\lambda_1 = \alpha_{-1}^2\lambda_{-1}$. Since x_1 and x_{-1} are eigenvectors of $1-\tau_* A$ corresponding to eigenvalues $\pm\|1-\tau_* A\|$, $\|u - \tau_{min}(u)Au\| = \|u-\tau_* Au\| = \|1-\tau_* A\|\|u\|$, and both sides of (A.1) coincide. ∎

Appendix B. Auxiliary estimates for section 4. This section uses the notation of the proof of Theorem 4.1. Additionally, we denote $P_i = P_{x_i}$ and $R_i = R(x_i) = (1-P_i)LP_i$.

From Lemma 2.1 we have a relationship for $J_i - J_{i-1}$ that essentially coincides with that for $J_o - J_p$ in section 3.5:

$$\begin{aligned} J_i - J_{i-1} &= (\lambda^i - \lambda^{i+1})I + R_{i-1} - R_i + R_{i-1}^* - R_i^* \\ &\quad + (\lambda^{i-1} - \lambda^i)P_{i-1} - (\lambda^i - \lambda^{i+1})P_i. \end{aligned} \tag{B.1}$$

For exactly the same reasons as in section 3.5 we have $P_{i-1}h^{i-1} = 0$, $R_{i-1}h^{i-1} = 0$, and $(R_i w, h^{i-1}) = 0$ for any w. Hence, $\|h^{i-1}\|_{J_i}^2 = \|h^{i-1}\|_{J_{i-1}}^2 + (\lambda^i - \lambda^{i+1})\|(1-P_i)h^{i-1}\|^2$, and, employing Corollary 2.3, we obtain $\|h^{i-1}\|_{J_i}^2 = \|h^{i-1}\|_{J_{i-1}}^2(1+\mathcal{O}\left(\epsilon_i^2\right))$.

Further, by (2.13), $\|h^{i-1}\|^2_{J_{i-1}} = (\lambda^{i-1} - \lambda^i)\|x^{i-1}\|^2 = (\lambda^{i-1} - \lambda^i)(1 - \|h^{i-1}\|^2) = (\lambda^{i-1} - \lambda^i)(1 - \mathcal{O}\left(\lambda^{i-1} - \lambda^i\right))$.

Turning now to (4.10), we observe first that by Lemma 2.4, $\|Kr^i\|^2_{J_i^s} = \|Kr^i\|^2_{J_i}(1+\mathcal{O}\left(\epsilon_i^2\right)$. Hence, the left-hand side coincides with the cosine of the J_i-angle between Kr^i and h^{i-1} up to a quantity of the order $\mathcal{O}\left(\epsilon_i^2\right)$ and thus is not greater than $1+\mathcal{O}\left(\epsilon_i^2\right)$. Together with the relationships for the J_i- and J_{i-1}-norms of h^{i-1} just obtained, this implies that $\|h^{i-1}\|^2_{J_i}$ can be replaced with $\|h^{i-1}\|^2_{J_{i-1}}$ and, further, with $\lambda^{i-1} - \lambda^i$ at the cost of adding an asymptotic term of the order $\mathcal{O}\left(\epsilon_i^2\right)$.

Further, $(R_i Kr^i, h^{i-1}) = 0$, and hence (B.1) implies

$$((J_i - J_{i-1})Kr^i, h^{i-1}) = (\lambda^i - \lambda^{i+1})((I - P_i)Kr^i, h^{i-1}) + (R_{i-1}Kr^i, h^{i-1}) - (Kr^i, R_i h^{i-1}).$$

It is easy to see that the first term in the right-hand side of the above identity is of the order $\mathcal{O}\left(\lambda^i - \lambda^{i+1}\right)\|Kr^i\|_{J_i^s}\|h^{i-1}\|_{J_i}$. For the second term we have

$$|(R_{i-1}Kr^i, h^{i-1})| = \frac{|(Kr^i, x^{i-1})||(r^{i-1}, h^{i-1})|}{\|x^{i-1}\|^2} \le \frac{\|Kr^i\|\|r^{i-1}\|_{J_{i-1}^{-1}}\|h^{i-1}\|_{J_{i-1}}}{\|x^{i-1}\|}$$

$$\le \|K\|^{\frac{1}{2}}\|r^i\|_K\|r^{i-1}\|_{J_{i-1}^{-1}}\sqrt{\lambda^{i-1} - \lambda^i} \sim \|Kr^i\|_{J_i^s}\sqrt{\lambda^{i-1} - \lambda_1}\sqrt{\lambda^{i-1} - \lambda^i},$$

and for the third

$$(Kr^i, R_i h^{i-1}) = \frac{(Kr^i, r^i)(x^i, h^{i-1})}{\|x^{i-1}\|^2} = \frac{\|r^i\|^2_K\|h^{i-1}\|^2}{\|x^{i-1}\|^2}$$

$$= \mathcal{O}\left(\|r^i\|_K\right)\|Kr^i\|_{J_i^s}(\lambda^{i-1} - \lambda^i).$$

Thus, $|((J_i - J_{i-1})Kr^i, h^{i-1})| = \mathcal{O}\left(\epsilon_i\right)\|Kr^i\|_{J_i^s}\sqrt{\lambda^{i-1} - \lambda^i}$, which implies (4.10).

Appendix C. Auxiliary estimates for section 5. In this section we use the notation of section 5.

Since $\mathcal{D}^i \supset \operatorname{span}\{x^i, Kr^i\}$, on each iteration of the generalized Davidson method the error reduction is not worse than with the steepest descent method. The upper bound provided for the latter by (2.24) is given in terms of the condition number of the operator $(I-P_i)K(I-P_i)J_1(x^i)$, which is uniformly bounded for x^i in the vicinity of x_1 (cf. section 4). Hence, there exists $q < 1$ such that $\lambda^{i+1} - \lambda_1 \le q(\lambda^i - \lambda_1) \le \cdots \le q^{i+1}(\lambda^0 - \lambda_1)$, which implies that for any $p > 0$ we have

$$\sum_{i=j}^{k}(\lambda^i - \lambda_1)^p \le \frac{1}{1-q^p}(\lambda^j - \lambda_1)^p. \tag{C.1}$$

Since $(h^i, x^i) = 0$, the application of (2.13) yields

$$\|x^{i+1}\|^2 = \|x^i\|^2 + \|h^i\|^2 \le \|x^i\|^2 + \frac{\|h^i\|^2_{J_i}}{\delta(\lambda^i + \lambda^{i+1})} = \|x^i\|^2\left(1 + \frac{\lambda^i - \lambda^{i+1}}{\delta(\lambda^i + \lambda^{i+1})}\right),$$

where $\delta(\mu) = \lambda_1 + \lambda_2 - \mu$, which implies $\|x^i\| = 1 + \mathcal{O}\left(\lambda^0 - \lambda^{i+1}\right) = 1 + \mathcal{O}\left(\lambda^0 - \lambda_1\right)$.

By (5.4), $(J_j z^j, z^k) = 0$ for $k < j$, and by the definition of z^j, $(J_j z^j, z^j) = 1$. Employing Lemma 2.1, we obtain

$$\begin{aligned}(J_i z^j, z^k) &= ((J_i - J_j)z^j, z^k) = (\lambda^{j+1} - \lambda^{i+1})(z^j, z^k) + (R_j z^j, z^k) + (z^j, R_j z^k) \\ &\quad -(R_i z^j, z^k) - (z^j, R_i z^k) + (\lambda^j - \lambda^{j+1})(P_j z^j, z^k) - (\lambda^i - \lambda^{i+1})(P_i z^j, z^k) \\ &= (\lambda^{j+1} - \lambda^{i+1})(z^j, z^k) + (z^j, R_j z^k) - (\lambda^i - \lambda^{i+1})(P_i z^j, z^k),\end{aligned}$$

where $R_m = R(x^m)$, and we have used the fact that $P_j z^j = 0$ and $R_j z^j = 0$ and that for any z, $R_i z$ is collinear to r^i, which is orthogonal to z^j and z^k, and hence $(R_i z^j, z^k) = (R_i z^k, z^j) = 0$. With the help of Lemma 2.2, one finds that the first term in the right-hand side of the above identity is bounded by $\epsilon_{j+1} < \sqrt{\epsilon_j \epsilon_k}$, and the last term by a still smaller quantity ϵ_i. For the middle term we have $|(z^j, R_j z^k)| = |(z^j, r^j)(x^j, z^k)|$, and a calculation similar to (2.15) shows that $|(z^j, r^j)| \le \|r^j\|_{J_j^{-1}} \le \sqrt{\lambda_2 - \lambda_1}\sqrt{\epsilon_j}\|x^j\|$, whereas $(x^j, z^k) = (x^j - P_k x^j, z^k)| \le \|x^j - P_k x^j\|_{J_k}\|z^k\|_{J_k}/\delta(\lambda^k + \lambda^{k+1})$. Since x^j is the minimum point of $\lambda(v)$ in $\mathcal{D}^{j-1}$, it is also the minimum point on the line $v(\tau) = P_k x^j + \tau(x^j - P_k x^j)$. Hence, by (2.13), $\|x^j - P_k x^j\|_{J_k} = \sqrt{\lambda^k - \lambda^j}\|P_k x^j\| \le \sqrt{\lambda^k - \lambda^j}\|x^j\| \le \sqrt{\lambda^k - \lambda_1}\|x^j\|$, and we arrive at (5.6).

JACOBI CORRECTION EQUATION, LINE SEARCH, AND CONJUGATE GRADIENTS IN HERMITIAN EIGENVALUE COMPUTATION II: COMPUTING SEVERAL EXTREME EIGENVALUES*

E. E. OVTCHINNIKOV†

Abstract. This paper addresses the question of how to efficiently adapt the conjugate gradient (CG) method to the computation of several leftmost or rightmost eigenvalues and corresponding eigenvectors of Hermitian problems. A generic block CG algorithm instantiated by some available block CG algorithms is considered whereby the new approximate eigenpairs are computed by applying the Rayleigh–Ritz procedure in the trial subspace spanning current approximate eigenvectors and the search direction vectors, each of the latter being a linear combination of the respective gradient of the Rayleigh quotient and all search directions from the previous iteration. An approach related to the so-called *Jacobi orthogonal complement correction* equation is exploited in the local convergence analysis of this CG algorithm. Based on theoretical considerations, a new block conjugation scheme (a way to compute search directions) is suggested that enjoys a certain kind of optimality and has proved to be competitive in practical eigenvalue computation.

Key words. eigenvalue computation, convergence estimates, block conjugate gradients

1. Introduction.

This is the second part of a paper that addresses the computation of eigenvalues of Hermitian operators by iterative schemes based on the conjugate gradient (CG) method. The first part [17] is concerned with the computation of one extreme eigenvalue; here we tackle the case of several extreme eigenvalues. Just as in [17], we focus on the case of leftmost eigenvalues, to which the case of rightmost eigenvalues is totally symmetric, and consider, for simplicity of notation, the standard eigenvalue problem.

One way to compute several leftmost eigenvalues of a Hermitian problem by CG is to use it for computing the leftmost eigenvalue and corresponding eigenvector and then to apply CG in the subspace of vectors orthogonal to the computed eigenvector, which will produce the second leftmost eigenvalue, etc. (the computational scheme just described is a particular implementation of the technique known as *deflation*). The present paper deals with an alternative approach where eigenpairs are computed simultaneously rather than successively.

The CG method is a functional minimization method that employs, on each iteration, the line search for the minimum of the functional in question in the direction of a linear combination of the gradient and previous search direction. It can be used for computing the leftmost eigenvalue of a Hermitian operator L acting in a Euclidean space $\mathcal{E}$, owing to the fact that this eigenvalue is the minimum of the Rayleigh quotient functional $\lambda(v) = (Lv, v)/\|v\|^2$. Specific properties of the Rayleigh quotient allow the replacement of the line search step with the Rayleigh–Ritz procedure (see section A.1 for the summary of this procedure and related terminology) in the two-dimensional

trial subspace spanning the current approximate eigenvector and the search vector, with the Ritz vector corresponding to the left Ritz value taken as the new approximate eigenvector. A straightforward generalization of such a technique to simultaneous computation of several eigenvalues is to apply the Rayleigh–Ritz procedure in the subspace spanning all current approximate eigenvectors and search vectors and to take Ritz vectors corresponding to leftmost Ritz values as the new approximate eigenvectors. Here we refer to algorithms employing such a technique as *block* algorithms.

It should be stressed that block CG algorithms are generally not optimization algorithms in the standard sense, since most of them do not minimize a scalar function of several arguments, which prevents the direct use of convergence results and conjugation schemes available to date for CG for the function minimization.

What appears to be the first block CG algorithm was considered in [12]; however, it was discarded there, apparently for lack of justification for the way the search directions were defined and conjugated. (In the block CG algorithm in question, the jth search direction, where j enumerates approximate eigenpairs, was computed by conjugating the jth gradient to the jth previous search direction by the Bradbury–Fletcher scheme. An implicit assumption that can be seen behind this conjugation scheme is that on each iteration the jth Ritz vector represents an ever improving approximation of the same exact eigenvector, which is generally not true.) Another block CG scheme, where the search directions are computed in a similar way but using just one conjugation parameter for all pairs, can be found in section 4.4 of [5]. The motivation for such conjugation is transplanted from a totally different approach to the use of CG for simultaneous eigenvalue computation known as the trace minimization. We note that the latter approach was also considered and discarded by [12], and we refer the reader to [18] for further details and discussion of this and some other approaches not mentioned here.

Turning back to single-vector CG algorithms for instruction, one notices that the conjugation issue can be bypassed by adding previous search directions to the trial subspace, as done in the locally optimal CG (cf. part I of this paper [17]). It is not difficult to see that in the block CG described above, each search direction, however it is defined, that essentially participates in the computation of new eigenvector approximations (in the sense that discarding the former would affect the latter) is a linear combination of current and new approximate eigenvectors. Hence, if the current search directions are linear combinations of gradients and previous search directions, then the enlarged trial subspace can be defined as that spanning current approximate eigenvectors, respective gradients, and either previous approximate eigenvectors or some linear combinations of current and previous approximate eigenvectors. The resulting block CG, known as locally optimal block preconditioned conjugate gradient (LOBPCG) [8, 9], does not involve conjugation of the search direction—or else, one might say that the conjugation is implicit.

Bypassing the conjugation problem comes at a price: in LOBPCG one has to perform the Rayleigh–Ritz procedure in a larger trial subspace, and computationally expensive precautions must be taken to avoid problems caused by almost linearly dependent search directions (see [10]). In an apparent attempt to reduce the size of the trial subspace while preserving good convergence, [1] reinvented the block CG scheme suggested in [12], albeit in the framework of a somewhat different algorithm and with preconditioning, and showed that it works reasonably well. Judging by the numerical results of [1], this attempt has not been quite successful: the reinvented block CG scheme failed to outperform LOBPCG, despite being less computationally expensive,

because of a slower convergence. Numerical tests in [18] demonstrate that the convergence of the method in question could have been improved had the Bradbury–Fletcher conjugation scheme employed by [1] been replaced by the Polak–Ribiére scheme (cf. (2.3) and (2.4) in section 2). The resulting method outperforms LOBPCG in terms of the CPU time in the tests of [18], but the convergence of the former still lags considerably behind that of the latter. Still, the improvement brought about by the change of the conjugation scheme indicates that the potential of the approach reluctantly suggested by [12] and implemented by [1] has not yet been fully exploited, and more could be achieved if a "proper" conjugation were used.

The purpose of conjugation in the standard CG algorithm for the minimization of a quadratic functional with positive definite Hessian is to achieve optimal convergence. Outside the abovementioned particular optimization area, no results demonstrating optimality of any known CG algorithm are available at present. The Rayleigh quotient minimization has the additional difficulty of the Hessian not being positive definite, and the situation is still worse with block CG algorithms for simultaneous eigenvalue computation, where none of the known explicit conjugation schemes has any theoretical justification, save for the trace minimization scheme of [5] without preconditioning, which has certain practical limitations discussed in [18]. Thus, the question of "proper" conjugation in block CG algorithms remains wide open. In the present paper we tackle this question by studying the local convergence properties (the reduction in the error after an iteration) of a generic block CG algorithm instantiated by the abovementioned block CG algorithms. Based on the results of this investigation, we suggest a block conjugation scheme that is optimal in a certain sense. Numerical tests of [18] demonstrate that the convergence of the resulting block CG method is remarkably similar to that of LOBPCG, with lower computational cost per iteration. The two main ingredients of our analysis are (i) a technique, employed previously in [14], that reduces the convergence analysis of a block iterative method to that of the line search applied simultaneously to all approximate eigenpairs, and (ii) the so-called Jacobi correction equation [23] technique for the convergence analysis of methods employing the line search developed in part I [17], suitably generalized here based on the generalization of the Jacobi correction equation suggested in [4].

The plan of the paper is as follows.

In section 2 we formulate a generic block CG algorithm, of which the block CG algorithms of [12] and [1] and the block variant of the trace minimization scheme of [5] are particular cases. In section 3, we introduce a generalization of the Jacobi correction operator of part I [17]. We study the properties of this operator, the most important of which is the fact that for a given group of approximate eigenpairs, the total adjoint energy norm of the residuals coincides with the total eigenvalue error up to asymptotically insignificant terms (Theorem 3.2), a result of independent theoretical value. We emphasize that dealing with eigenpair groups rather than individual eigenpairs ensures that the results presented here are not adversely affected by eigenvalue clustering (cf. [14]). In section 3.4, we apply the results of section 3 to the simultaneous line search; in particular, we derive an asymptotic equation for the reduction in the total eigenvalue error of a group as a function of the respective search directions. In section 4 we apply the results of section 3.4 to the local convergence analysis of the block CG scheme of section 2 to arrive at a conjugation scheme that is locally optimal in the sense of the optimality of the related simultaneous line search. We derive a preliminary convergence estimate for this scheme similar to that derived for LOBPCG and some other block eigensolvers in [14].

Appendix A summarizes the Rayleigh–Ritz procedure and related results that are used in the paper. We note that some of the results of section A.2, notably, the formula (A.6) for the Lehmann optimal operator, the fact that Lehmann bounds are eigenvalues of matrices (A.8) or (A.9) (depending on the position of the Lehmann pole), and the residual bounds (A.10) and (A.11), do not appear to have been obtained elsewhere. Finally, Appendix B contains proofs that are too long and technical to be placed in the main text.

The convergence analysis of block iterative methods for simultaneous eigenvalue computation is often complicated and requires cumbersome and plentiful notation. The present paper is not exceptional in this respect; however, behind the sizeable amount of notation used here lie just a few principles. Capital calligraphic letters are used for linear spaces (except for $\mathcal{I}$ and $\mathcal{J}$, which are used for sets of indices in the appendices). Noncalligraphic capital letters are used for linear operators and matrices. Lowercase roman letters are used for vectors in $\mathcal{E}$, except for i, j, k, l, m, and n, used for indices and dimensions (cf. implicit integers in FORTRAN), and the letter c, traditionally used for coefficients. Small Greek letters are used for scalars; one exception to this rule is the notation for the Rayleigh quotient and residual functions $\lambda(\cdot)$ and $r(\cdot)$ whose values are determined by the argument (see section 2 for explicit formulae). The letter i always refers to the iteration number, and j, k, l to the exact or approximate eigenpair numbers. The eigenvalues λ_j of L are enumerated in increasing order, each one counted as many times as the multiplicity, and the eigenvectors are denoted by x_j. In sections dealing with CG iterations, we place the superscript i on approximate eigenvalues and eigenvectors and related quantities, and in sections not involving the iteration number, we put a tilde on top of them. The remaining more specific notation is introduced wherever it is needed.

All of the results of the paper apply to the generalized eigenvalue problem after simple modifications (see the introduction and Remark 1 in [17] for the modifications needed).

2. A block CG scheme for eigenvalue computation. In what follows, we denote by $\mathcal{R}R_m(\mathcal{V})$ the matrix whose columns are the Ritz vectors of L in the trial subspace $\mathcal{V}$ of dimension $\dim \mathcal{V} \geq m$ corresponding to the m leftmost Ritz values (see Appendix A for the summary of the Rayleigh–Ritz procedure), and we extend the notation for the Rayleigh quotient and residual to matrices with linear independent columns as follows:

$$\lambda(V) = (V^*V)^{-1}V^*LV, \quad r(V) = LV - V\lambda(V).$$

Consider the following iterative scheme for computing the n_l leftmost eigenpairs of L:

$$X^{i+1} = \mathcal{R}R_{n_b}(\operatorname{span}\{X^i, Y^i\}), \tag{2.1}$$

$$Y^{i+1} = KR^{i+1} + Y^iB_i, \tag{2.2}$$

where X^i and Y^i are matrices with $n_b \geq n_l$ columns, $R^i = r(X^i)$, K is a Hermitian positive definite operator that is used as the preconditioner (cf. part I [17]), KR^{i+1} stands for the matrix whose columns are K-images of the columns of R^{i+1}, and B_i is an n_b-by-n_b matrix.

We observe that the block CG scheme of [12] and [1] is a particular case of (2.1)–(2.2) with a diagonal B_i, the diagonal entries $\beta_j^{(i)}$, $j = 1, \ldots, n_b$, being computed by

the Bradbury–Fletcher conjugation scheme; i.e.,

$$\beta_j^{(i)} = \frac{(Kr_j^{i+1}, r_j^{i+1})}{(Kr_j^i, r_j^i)}, \tag{2.3}$$

where r_j^i are the columns of R^i, i.e., residual vectors (note that in [12], K is the identity; i.e., preconditioning is not used). A similar scheme, tested numerically in [18], uses Polak–Ribiére conjugation:

$$\beta_j^{(i)} = \frac{(Kr_j^{i+1}, r_j^{i+1} - r_j^i)}{(Kr_j^i, r_j^i)}. \tag{2.4}$$

We further observe that the Ritz vectors corresponding to the n_b leftmost Ritz values minimize the sum of the Rayleigh quotients over all sets of n_b orthogonal vectors in the trial subspace; i.e., X^{i+1} minimizes the trace of V^*LV over all V's with n_b orthonormal columns belonging to $\mathcal{V}$. Hence, (2.1)–(2.2) can be used as a trace minimization scheme, in which case $B_i = \beta^{(i)} I_{n_b}$, where I_{n_b} stands for the n_b-by-n_b identity and $\beta^{(i)}$ is a scalar that can be computed by a chosen conjugation scheme in $n_b n$-dimensional space, e.g.,

$$\beta^{(i)} = \frac{\langle KR^{i+1}, R^{i+1} - R^i \rangle}{\langle KR^i, R^i \rangle}, \tag{2.5}$$

where $\langle X, Y \rangle = \operatorname{Tr} Y^*X$ and $\operatorname{Tr} A$ stands for the trace of A (cf. [5]; note that here we have added preconditioning).

In this paper we investigate the local convergence properties of (2.1)–(2.2) (i.e., the reduction in eigenvalue error after an iteration) to come up with a suggestion for B_i that in practical computation delivers considerably better convergence than with any of B_i given above.

As mentioned in the introduction, the convergence analysis of the paper follows a technique employed by [14] for the convergence analysis of block preconditioned steepest descent and some related block methods. We observe that the trial subspace $\mathcal{V}^i = \operatorname{span}\{X^i, Y^i\}$ contains the following auxiliary subspace:

$$\mathcal{W}_m^i = \operatorname{span}\{x_j^i - \alpha_j^{(i)}(1 - P_i)y_j^i\}_{j=1}^m, \tag{2.6}$$

where $m \le n_b$ is such that $\lambda_m^i < \lambda_{m+1}$, P_i is the orthogonal projector onto $\mathcal{X}^i = \operatorname{span}\{X^i\}$, and $\alpha_j^{(i)}$ are scalar parameters. By the minimax principle, the m leftmost Ritz values in $\mathcal{V}^i$ are not greater than the respective Ritz values in $\mathcal{W}_m^i$. At the same time, it is not difficult to construct an example where the two coincide. We derive asymptotic equations for the Ritz values in $\mathcal{W}_m^i$ for a specific (locally optimal) $\alpha_j^{(i)}$, and, based on these equations, suggest a conjugation scheme that minimizes these Ritz values. According to [18], the convergence of the resulting two-term algorithm (2.1)–(2.2) is remarkably similar to that of LOBPCG, which suggests that the "core" subspace $\mathcal{W}_m^i$ contained in the trial subspaces of both methods might be the main component controlling their convergence, a hypothesis yet to be investigated.

We emphasize that the "core" subspace given by (2.6) is a purely theoretical object that is employed in this paper for the convergence analysis of the block CG scheme (2.1)–(2.2), and not a part of a new block algorithm suggested as an alternative to the latter.
