The outlined approach requires the investigation of the efficiency of the line search in the direction of $(1 - P_i)y_j^i$ as a function of y_j^i. As mentioned in the introduction, the present paper employs for this task a technique based on the so-called Jacobi correction operator. In the next section we study the properties of a generalization of this operator to the case at hand.

3. Jacobi correction operator and simultaneous line search.

3.1. The Jacobi correction equation for invariant subspaces and related operators. Denote $X = [x_j]_{j=1}^m$, $\Lambda = \operatorname{diag}\{\lambda_j\}_{j=1}^m$, and $\mathcal{X} = \operatorname{span}\{X\}$. Let $\tilde{x}_j$ be linearly independent vectors approximating x_j, $j = 1, \dots, m$, and denote $\tilde{X} = [\tilde{x}_j]_{j=1}^m$, $\tilde{\mathcal{X}} = \operatorname{span}\{\tilde{X}\}$, and $R = r(\tilde{X})$. We assume that the angle between $\tilde{\mathcal{X}}$ and $\mathcal{X}$ is less than $\pi/2$; i.e., $\tilde{\mathcal{X}}$ does not contain vectors orthogonal to $\mathcal{X}$. Owing to this assumption, the m-by-m matrix $X^*\tilde{X}$ is nondegenerate. Denoting $X' = XS$, where $S = (\tilde{X}^*X)^{-1}\tilde{X}^*\tilde{X}$, we observe that $\tilde{X}^*(X' - \tilde{X}) = 0$, i.e., $X' = \tilde{X} + E$, where $\tilde{X}^*E = 0$.

Since $\mathcal{X}$ is an invariant subspace, and X' is the basis of $\mathcal{X}$, we have

$$LX' = X'\lambda(X'). \tag{3.1}$$

The substitution of $\tilde{X} + E$ for X' yields

$$LE - E\lambda(X') = -L\tilde{X} + \tilde{X}\lambda(X').$$

Let $\tilde{P}$ be the orthogonal projector onto $\tilde{\mathcal{X}}$. Applying $\tilde{P}_\perp = 1 - \tilde{P}$ to both sides of the above equation and noting that $\tilde{P}E$ and $\tilde{P}R$ vanish, we arrive at

$$\begin{aligned}\tilde{P}_\perp L\tilde{P}_\perp E - \tilde{P}_\perp E\lambda(X') &= -\tilde{P}_\perp(L\tilde{X} - \tilde{X}\lambda(X')) = -\tilde{P}_\perp(L\tilde{X} - \tilde{X}\lambda(\tilde{X}))\\ &= -\tilde{P}_\perp R = -R + \tilde{P}R = -R\end{aligned}$$

or

$$J(\lambda(X'), \tilde{\mathcal{X}})E = -R, \tag{3.2}$$

where

$$J(M, \mathcal{Y})V = (1 - P_{\mathcal{Y}})L(1 - P_{\mathcal{Y}})V - (1 - P_{\mathcal{Y}})VM \tag{3.3}$$

and $P_{\mathcal{Y}}$ is the orthogonal projector onto $\mathcal{Y}$. We observe that in the particular case $m = 1$, (3.2) becomes the Jacobi orthogonal complement correction equation of [23], and $J(M, \mathcal{Y})$ becomes what is for brevity called "Jacobi correction operator" in [17].

Assuming $\tilde{x}_i$ to be orthonormal, we observe that $\tilde{X}^*X'$ is the m-by-m identity matrix, and since $R^*\tilde{X} = 0$, we obtain

$$\begin{aligned}R^*E = R^*(X' - \tilde{X}) = R^*X' &= \tilde{X}^*LX' - \lambda(\tilde{X})\tilde{X}^*X'\\ &= \tilde{X}^*X'\lambda(X') - \lambda(\tilde{X})\tilde{X}^*X' = \lambda(X') - \lambda(\tilde{X}),\end{aligned}$$

i.e.,

$$\lambda(X') = \lambda(\tilde{X}) + R^*E, \tag{3.4}$$

and hence 3.2 can be rewritten as the following nonlinear Riccati equation for E derived in different terms in [4]:[1]

$$J(\tilde{X})E = -R + ER^*E, \tag{3.5}$$

where $J(Y) = J(\lambda(Y), \text{span}\{Y\})$. In [4], various algorithms for computing invariant subspaces via the solution of (3.5) are suggested; in the present paper we use this equation for purely theoretical purposes.

If $\tilde{x}_j$ are Ritz vectors, then $\lambda(\tilde{X})$ is a diagonal matrix with the corresponding Ritz values $\tilde{\lambda}_j$ on the diagonal, and we have

$$J(\tilde{X})E = [J(\tilde{\lambda}_j, \tilde{\mathcal{X}})e_j]_{j=1}^m, \tag{3.6}$$

where e_j is the jth column of E and $J(\mu,\mathcal{U})$ is given by

$$J(\mu,\mathcal{U}) = (1 - P_{\mathcal{U}})(L - \mu)(1 - P_{\mathcal{U}}). \tag{3.7}$$

3.2. Elementary properties of the operator $J(\mu,\mathcal{U})$. Some properties of the operator $J(\mu,\mathcal{U})$ in the case $\dim\mathcal{U} > 1$ are quite similar to its properties in the case $\dim\mathcal{U} = 1$ studied in part I [17]; e.g., the following analogue of Lemma 2.2 from [17] holds. Below $\mathcal{U}^\perp$ denotes the subspace of vectors orthogonal to $\mathcal{U}$.

LEMMA 3.1. *Let $\lambda_j^{\mathcal{U}}$, $j = 1,\dots,m$, be the Ritz values of L in the trial subspace $\mathcal{U}$ of dimension m. For any $v \in \mathcal{U}^\perp$*

$$(J(\mu,\mathcal{U})v, v) \geq \gamma(\mu,\mathcal{U})\|v\|^2, \tag{3.8}$$

where

$$\gamma(\mu,\mathcal{U}) = \lambda_{m+1} - \mu - \delta_\lambda(\mathcal{U}), \quad \delta_\lambda(\mathcal{U}) = \sum_{j=1}^m (\lambda_j^{\mathcal{U}} - \lambda_j). \tag{3.9}$$

Proof. Let $u_1,\dots,u_m$ be orthonormal vectors in $\mathcal{U}$, and denote $U = [u_1,\dots,u_m]$. The scaling of v does not affect 3.8; hence, assume that $\|v\| = 1$. The Ritz values $\hat{\lambda}_j$, $j = 1,\dots,m+1$, of L in $\text{span}\{u_1,\dots,u_m,v\}$ are the eigenvalues of the matrix

$$\hat{L} = \begin{bmatrix} U^*LU & U^*Lv \\ v^*LU & v^*Lv \end{bmatrix}.$$

We have $\hat{\lambda}_1 + \cdots + \hat{\lambda}_{m+1} = \text{Tr}(\hat{L}) = \text{Tr}(U^*LU) + v^*Lv = \lambda_1^{\mathcal{U}} + \cdots + \lambda_m^{\mathcal{U}} + \lambda(v)$ and, by the minimax principle, $\hat{\lambda}_i \geq \lambda_i$. Hence, $\lambda(v) \geq \lambda_1 + \cdots + \lambda_{m+1} - \lambda_1^{\mathcal{U}} - \cdots - \lambda_m^{\mathcal{U}}$. Since $(J(\mu,\mathcal{U})v, v) = (\lambda(v) - \mu)\|v\|^2$, we arrive at 3.8. ∎

Lemma 3.1 implies that $J(\mu,\mathcal{U})$ is positive definite in $\mathcal{U}^\perp$, provided that the total error of the Rayleigh–Ritz approximations to the first m eigenvalues, i.e., the sum of $\lambda_j^{\mathcal{U}} - \lambda_j$, is less than $\lambda_{m+1} - \mu$. One corollary of this fact is that, under the latter assumption on μ and $\mathcal{U}$, the operator $J(\mu,\mathcal{U})$ is invertible in $\mathcal{U}^\perp$ and the inverse of its restriction to $\mathcal{U}^\perp$, denoted here as $J(\mu,\mathcal{U})^{-1}$, satisfies

$$(J(\mu,\mathcal{U})^{-1}v, v) \leq \gamma(\mu,\mathcal{U})^{-1}\|v\|^2 \leq \gamma(\mu,\mathcal{U})^{-2}(J(\mu,\mathcal{U})v, v). \tag{3.10}$$

[1] We note that both derivations do not assume L to be Hermitian.

Another corollary is that the $J(\mu,\mathcal{U})$-energy seminorms for different μ's satisfying this assumption are equivalent; notably, if $\gamma(\nu,\mathcal{U}) > 0$, then for any $\mu < \nu$

$$(J(\nu,\mathcal{U})v,v) \le (J(\mu,\mathcal{U})v,v) \le \frac{\gamma(\mu,\mathcal{U})}{\gamma(\nu,\mathcal{U})}(J(\nu,\mathcal{U})v,v) \tag{3.11}$$

(cf. Lemma 2.4 of [17]), which implies

$$(J(\mu,\mathcal{U})^{-1}v,v) \le (J(\nu,\mathcal{U})^{-1}v,v) \le \frac{\gamma(\mu,\mathcal{U})}{\gamma(\nu,\mathcal{U})}(J(\mu,\mathcal{U})^{-1}v,v). \tag{3.12}$$

3.3. Asymptotic relationships between errors and residuals. It is not difficult to verify that the norm of E is the tangent of the angle between $\mathcal{X}$ and $\tilde{\mathcal{X}}$:

$$\tan\{\mathcal{X};\tilde{\mathcal{X}}\} = \max_{w\in\mathcal{X}} \frac{\|\tilde{P}_\perp w\|}{\|\tilde{P}w\|} = \max_{\hat{w}\in\mathcal{E}^m} \frac{\|\tilde{P}_\perp X'\hat{w}\|}{\|\tilde{P}X'\hat{w}\|} = \max_{\hat{w}\in\mathcal{E}^m} \frac{\|E\hat{w}\|}{\|\tilde{X}\hat{w}\|} = \max_{\hat{w}\in\mathcal{E}^m} \frac{\|E\hat{w}\|}{\|\hat{w}\|} = \|E\|,$$

where $\mathcal{E}^m$ stands for the m-dimensional Euclidean space of the column vector, and $\|E\|$ is the norm of E viewed as a linear operator acting from $\mathcal{E}^m$ to $\mathcal{E}$ (the above identity is valid for arbitrary orthonormal $\tilde{x}_j$). Furthermore, for the Ritz vectors $\tilde{x}_j$, the columns e_j of E are asymptotically (as $\|E\| \to 0$) close to the error vectors $x_j - \tilde{x}_j$ (see [7]). In this section we derive asymptotic relationships between norms of the "error vectors" e_j and the corresponding residual norms and eigenvalue errors. Below we assume that

$$\gamma(\tilde{\lambda}_m, \tilde{\mathcal{X}}) \ge \gamma > 0. \tag{3.13}$$

In order to eliminate possible adverse effects of eigenvalue clustering and to allow for multiple eigenvalues, the relationships in question are derived here for a group of leftmost Ritz values and vectors, assuming that the eigenvalues of L approximated by these Ritz values are well separated from the rest of the spectrum (cf. [15, 16]).

Owing to 3.13, the operators $J_j = J(\tilde{\lambda}_j, \tilde{\mathcal{X}})$ are positive definite in $\tilde{\mathcal{X}}^\perp$, and below we denote by J_j^{-1} the inverse of the restriction of J_j to $\tilde{\mathcal{X}}^\perp$. For any $v \in \tilde{\mathcal{X}}^\perp$ we denote $\|v\|_{J_j}^2 = (J_j v, v)$ and $\|v\|_{J_j^{-1}}^2 = (J_j^{-1} v, v)$. The result below, a generalization of Lemma 2.5 from [17], suggests that the two introduced energy norms are "natural" ones for the "error" and residual vectors, respectively.

THEOREM 3.2. *Assuming* 3.13, *for* $l \le m$ *such that* $\lambda_l < \lambda_{l+1}$ *the following inequalities are valid:*

$$\left| \sum_{j=1}^{l} \|e_j\|_{J_j}^2 - \sum_{j=1}^{l} (\tilde{\lambda}_j - \lambda_j) \right| \le c_e \frac{\delta_\lambda(\tilde{\mathcal{X}})}{\lambda_{m+1} - \lambda_m} \sum_{j=1}^{l} (\tilde{\lambda}_j - \lambda_j), \tag{3.14}$$

$$\left| \sum_{j=1}^{l} \|r_j\|_{J_j^{-1}}^2 - \sum_{j=1}^{l} (\tilde{\lambda}_j - \lambda_j) \right| \le c_r \frac{\delta_\lambda(\tilde{\mathcal{X}})}{\lambda_{m+1} - \lambda_m} \sum_{j=1}^{l} (\tilde{\lambda}_j - \lambda_j), \tag{3.15}$$

where $\delta_\lambda(\cdot)$ *is given in* 3.9 *and the coefficients* c_e *and* c_r *depend only on the ratios* $\rho_m = (\lambda_{m+1} - \lambda_m)/\gamma$, $\delta_m = (\lambda_{m+1} - \lambda_m)/(\lambda_{m+1} - \lambda_1)$ *and* $\delta_l = (\lambda_{l+1} - \lambda_l)/(\lambda_{m+1} - \lambda_1)$.

Proof. See section B.1. □

The inequalities of Theorem 3.2 reveal the asymptotic identity of J_j-based residual and error norms and eigenvalue errors:

$$\sum_{j=1}^{l} \|e_j\|_{J_j}^2 \simeq \sum_{j=1}^{l} \|r_j\|_{J_j^{-1}}^2 \simeq \sum_{j=1}^{l} (\tilde{\lambda}_j - \lambda_j), \tag{3.16}$$

where $a \simeq b$ stands for $a = (1 + \mathcal{O}(\delta_\lambda(\tilde{\mathcal{X}})))b$. In the paper we use these asymptotic relationships in order to obtain asymptotic identities related to the eigenvalue error reduction after a simultaneous line search applied to m vectors as a function of search directions, which, in turn, lead to a suggestion on a "proper" choice of the conjugation matrix B_i in (2.2).

3.4. Convergence properties of the simultaneous line search. In this section we study the properties of the simultaneous line search step whereby one starts with Ritz vectors $\tilde{x}_j$, $j = 1, \ldots, m$, and then applies the Rayleigh–Ritz procedure in the trial subspace

$$\mathcal{W} = \operatorname{span}\{w_j\}_{j=1}^m, \quad w_j = \tilde{x}_j - \alpha_j y_j, \quad \alpha_j = \arg\min_\alpha \lambda(\tilde{x}_j - \alpha y_j), \tag{3.17}$$

where y_j is orthogonal to $\tilde{\mathcal{X}}$ and nonorthogonal to $r_j = r(\tilde{x}_j)$. The orthogonality of y_j to $\tilde{x}_j$ ensures that the line searches in 3.17 do not fail (cf. [17, section 2.2]), and the orthogonality to $\tilde{\mathcal{X}}$ ensures that vectors w_j are linearly independent.

The first result of this section, a (partial) generalization of Theorem 2.6 of [17], expresses the difference between approximate eigenpairs before and after an individual line search step as a function of the search vector.

THEOREM 3.3. *Let u be a nonzero vector, let $\mathcal{U}$ be a subspace that contains u and is orthogonal to $r(u)$, and let v be orthogonal to $\mathcal{U}$ and such that $(v, r(u)) \neq 0$. Let $u_v = u + \tau_v v$, where $\tau_v \equiv \arg\min_\tau \lambda(u + \tau v)$, and denote $J_{u,v} = J(\lambda(u_v), \mathcal{U})$. The following relationships are valid:*

$$\tau_v = -\frac{(r(u), v)}{(J_{u,v} v, v)}, \tag{3.18}$$

$$\lambda(u) - \lambda(u_v) = \frac{|(r(u), v)|^2}{\|u\|^2 (J_{u,v} v, v)}, \tag{3.19}$$

$$(J_{u,v}(u - u_v), u - u_v) = (\lambda(u) - \lambda(u_v))\|u\|^2. \tag{3.20}$$

Proof. We observe that $(J_{u,v} w, w) = (J(\lambda(u_v), \mathcal{U})w, w) = (J(\lambda(u_v), \operatorname{span}\{u\})w, w)$ for any w that is orthogonal to $\mathcal{U}$. Hence, Theorem 2.6 of part I [17] implies (3.18)–(3.20). ∎

In the rest of this section we assume 3.13 to be satisfied.

In the case of the steepest descent line search, i.e., with $y_j = Kr_j$, (3.19) implies

$$\tilde{\lambda}_j - \mu_j = \frac{|(r_j, y_j)|^2}{(J(\mu_j, \tilde{\mathcal{X}}) y_j, y_j)} = \frac{|(r_j, Kr_j)|^2}{(J(\mu_j, \tilde{\mathcal{X}}) Kr_j, Kr_j)} \geq \frac{1}{\omega_j} \|r_j\|_K^2 \geq \frac{\alpha_j}{\omega_j} \|r_j\|_{J(\mu_j, \tilde{\mathcal{X}})^{-1}}^2,$$

where $\mu_j = \lambda(w_j)$, and α_j and ω_j are the minimal and maximal eigenvalues of the operator $A_j = J(\mu_j, \tilde{\mathcal{X}})K$, restricted to $\tilde{\mathcal{X}}^\perp$ (note that A_j is Hermitian positive definite in the scalar products $(\cdot, \cdot)_K$ and $(\cdot, \cdot)_{J(\mu_j, \tilde{\mathcal{X}})^{-1}}$). Below we assume that the

search directions y_j are "not much worse" than the steepest descent directions in the sense that a similar inequality is valid; notably, for some $\eta > 0$, we have

$$\|r_j\|^2_{J_j^{-1}} \le \eta(\tilde{\lambda}_j - \mu_j). \tag{3.21}$$

The second result demonstrates that the difference between the sum of the Ritz values in $\mathcal{W}$ approximating a well-separated group of $l \le m$ leftmost eigenvalues and the respective sum of the Rayleigh quotients $\lambda(w_j)$ is asymptotically insignificant compared to the total error reduction achieved by the line searches in (3.17).

THEOREM 3.4. *Denote $\mu_j = \lambda(w_j)$, and denote by ν_j the Ritz values of L in the trial subspace $\hat{\mathcal{X}}$ given by* (3.17). *Let $l \le m$ be such that $\tilde{\lambda}_l < \lambda_{l+1}$. Assuming* (3.13) *and* (3.21), *the following inequality is valid:*

$$\left|\sum_{j=1}^{l}(\nu_j - \mu_j)\right| \le c\frac{\delta_\lambda(\tilde{\mathcal{X}})}{\lambda_{m+1} - \lambda_m}\sum_{j=1}^{l}(\tilde{\lambda}_j - \mu_j), \tag{3.22}$$

where the coefficient c depends only on η and the ratios listed in Theorem 3.2, *with δ_l replaced by $\tilde{\delta}_l = (\lambda_{l+1} - \tilde{\lambda}_l)/(\lambda_{m+1} - \lambda_1)$.*

Proof. For the proof, see section B.2. ∎

Put together, the two results obtained in this subsection allow one to express the total error reduction for $\lambda_1, \dots, \lambda_l$, achieved by moving from $\tilde{X}$ to $\mathcal{W}$ as an explicit, modulo an asymptotically small term, function of the corresponding search directions. In the next section we use such an asymptotic expression in order to optimize search directions y_j in the framework of the iterative scheme (2.1)–(2.2).

4. Local convergence properties of the block CG. Let us now apply the results of the previous section to the investigation of local convergence properties of the block CG scheme (2.1)–(2.2) and the related issue of "proper" conjugation. Below we are using the notation of section 2. We assume that all residuals r_j^i are nonzero, and we assume that[2] (cf. (3.9) and (3.13))

$$\gamma(\lambda_m^i, \mathcal{X}_m^i) \ge \gamma > 0, \quad \mathcal{X}_m^i = \operatorname{span}\{x_j^i\}_{j=1}^m, \quad m \le n_b, \tag{4.1}$$

which, by Lemma 3.1, implies that the Jacobi operators $J(\lambda_j^i, \mathcal{X}_m^i)$ are positive definite in the orthogonal complement to $\mathcal{X}_m^i$. Since $(J(\lambda_j^i, \mathcal{X}_m^i)w, w) = (J(\lambda_j^i, \mathcal{X}^i)w, w)$ for any w that is orthogonal to $\mathcal{X}^i = \operatorname{span}\{X^i\}$, the operators $J(\lambda_j^i, \mathcal{X}^i)$, $j = 1, \dots, m$, are positive definite in the orthogonal complement to $\mathcal{X}^i$.

We remind that the new approximate eigenvalues λ_j^{i+1} produced by (2.1) are the Ritz values in the trial subspace $\mathcal{Y}^i = \operatorname{span}\{X^i, Y^i\}$. Since $(r_j^i, y_k^{i-1}) = 0$, owing to the fact that x_j^i are Ritz vectors in the trial subspace containing y_k^{i-1}, we have

[2] This assumption is somewhat stronger than $\lambda_{m+1} - \lambda_m^i > 0$, assumed in, e.g., [7, 14] (the weakest possible one, in terms of exact and approximate eigenvalues only, that ensures the convergence to the first m eigenpairs of L). The assumption we take here, that $\lambda_{m+1} - \lambda_m^i$ is greater than the total error in m leftmost eigenvalues, is actually not much stronger because (i) the spectrum of L typically consists of clusters of eigenvalues separated by lacunae of the size that is larger than the average distance between the eigenvalues at the margin of the spectrum in focus, and (ii) looking at the convergence curves for eigenvalues (see, e.g., [18]), one often finds that the convergence of a given group of approximate eigenvalues is rather erratic until the eigenvalue errors approach the level of the distance between the corresponding eigenvalues and the rest of the spectrum (hence useful theoretical estimates above this level do not seem to be likely) after which the convergence curves for the logarithm of the error become virtually straight.

$(r_j^i, y_j^i) = (r_j^i, Kr_j^i) = \|r_j^i\|_K^2$; hence, y_j^i does not belong to $\mathcal{X}^i$, and we can perform the line search in the direction $(1 - P_i)y_j^i$, where P_i is the orthogonal projector onto $\mathcal{X}^i$. Let us denote by ν_j^i the Ritz values in the subspace $\mathcal{W}_m^i$ given by (2.6) with $\alpha_j^{(i)}$ that minimize the Rayleigh quotients for $w_j^i = x_j^i - \alpha_j^{(i)}(1 - P_i)y_j^i$. By the minimax principle, $\lambda_j^{i+1} \le \nu_j^i$, and it is not difficult to show that these inequalities are sharp by considering the case where x_j^i and y_j^i belong to $\operatorname{span}\{x_j, x_{j+n_b}, x_{j+2n_b}, \ldots\}$. Indeed, in this case the triples w_j^i, x_j^i, y_j^i belong to different invariant subspaces of L for different j, and hence the residual $r(w_j^i)$ is orthogonal to x_k^i and y_k^i with $k \ne j$; it is also orthogonal to $(1 - P_i)y_j^i$, owing to the locally optimal $\alpha_j^{(i)}$, and hence to x_j^i. Thus, $r(w_j^i)$ is orthogonal to $\mathcal{V}^i$; i.e., w_j^i are Ritz vectors in $\mathcal{V}^i$, and the assumption (4.1) implies that the corresponding Ritz values are the leftmost ones. Hence $\lambda_j^{i+1} = \nu_j^i$.

The above considerations suggest that the search directions should be conjugated in such a way that ν_j^i are as minimal as possible. The results of the previous subsection imply the asymptotic identity

$$\sum_{j=1}^{l}(\lambda_j^i - \nu_j^i) = (1 + \varepsilon_{il})\sum_{j=1}^{l}\frac{\|r_j^i\|_K^4}{(J(\lambda_j^i, \mathcal{X}^i)y_j^i, y_j^i)}, \quad |\varepsilon_{il}| \le c\delta_\lambda(\mathcal{X}_m^i), \tag{4.2}$$

where we have used the fact that $(r_j^i, y_j^i) = (r_j^i, Kr_j^i)$, $(J(\lambda_j^i, \mathcal{X}_m^i)(1 - P_i)y_j^i, (1 - P_i)y_j^i) = (J(\lambda_j^i, \mathcal{X}^i)y_j^i, y_j^i)$, and the coefficient c has the same dependencies as that in Theorem 3.4. Thus, the conjugation scheme we are after should be aimed at minimizing $J(\lambda_j^i, \mathcal{X}^i)$-norms of y_j^i. Since y_j^i is the sum of Kr_j^i and a linear combination of the previous search directions, the $J(\lambda_j^i, \mathcal{X}^i)$-norm of y_j^i is minimal when y_j^i is $J(\lambda_j^i, \mathcal{X}^i)$-orthogonal to the previous search directions; i.e., B_i should be such that

$$(J(\lambda_j^i, \mathcal{X}^i)y_j^i, y_k^{i-1}) = 0. \tag{4.3}$$

The conjugation scheme just described is a generalization of the Jacobi scheme of [17], and here we refer to it as the block Jacobi scheme.[3] By construction, this scheme is "quasi-optimal" in the sense that it minimizes the Ritz values in the "core subspace" (2.6), which, as shown above, provide sharp upper bounds for the Ritz values in $\operatorname{span}\{X^i, Y^i\}$. One may also say that the search directions y_j^i are "individually locally optimal": by Theorem 3.3, the line search in the direction $(1 - P_i)y_j^i$ produces w_j^i such that

$$\delta_j^i = \lambda(x_j^i) - \lambda(w_j^i) = \frac{\|r_j^i\|_K^4}{\left(J(\lambda(w_j^i), \mathcal{X}^i)y_j^i, y_j^i\right)} = \frac{\|r_j^i\|_K^4}{(J(\lambda_j^i, \mathcal{X}^i)y_j^i, y_j^i)}\left(1 + \mathcal{O}\left(\delta_j^i\right)\right).$$

The Jacobi conjugation minimizes the denominator in the right-hand side, and thus $(1 - P_i)y_j^i$ is asymptotically the best possible line search direction for minimizing the Rayleigh quotient $\lambda(x_j^i - \alpha(1 - P_i)y_j^i)$ that can be expressed as a linear combination of Kr_j^i and $y_1^{i-1}, \ldots, y_{n_b}^{i-1}$.

In order to provide explicit expressions for the entries of the conjugation matrix B_i, let us consider an alternative formulation of the block Jacobi scheme. Denote for brevity[4] $J_j = J(\lambda_j^{i+1}, \mathcal{X}^{i+1})$. Since $0 = (J_j y_j^{i+1}, y_k^i) = (J_j y_j^{i+1}, (1 - P_{i+1})y_k^i)$,

[3] Just as in [17], λ_j^i may be replaced with asymptotically close values; here we stick to λ_j^i for simplicity.

[4] The iteration superscript is shifted for consistency with section 2.

the conjugation matrix B_i does not change if we replace y_k^i by $(1-P_{i+1})y_k^i$ in 2.2; neither does this orthogonalization affect the new trial subspace $\operatorname{span}\{X^{i+1}, Y^{i+1}\}$. Furthermore, vectors $(1-P_{i+1})y_k^i$ can obviously be replaced by the basis vectors in $\mathcal{Y}_\perp^i = \operatorname{span}\{(1-P_{i+1})Y^i\}$. Noting that $\mathcal{Y}_\perp^i$ is orthogonal to the n_b Ritz vectors in $\mathcal{V}^i = \operatorname{span}\{X^i, Y^i\}$ corresponding to the leftmost Ritz values, we observe that $\mathcal{Y}_\perp^i$ belongs to the linear span of the remaining Ritz vectors corresponding to the rightmost Ritz values. Hence, if $\dim \mathcal{Y}^\perp = \dim \mathcal{V}^i - n_b$, then we can equivalently use these Ritz vectors, denoted here by z_k^{i+1}, in place of y_k^i. If $\dim \mathcal{Y}^\perp < \dim \mathcal{V}^i - n_b$, then we can still do the same because the conjugation to a larger set of vectors reduces $(J_j y_j^{i+1}, y_j^{i+1})$ still further and thus improves the individual local optimality. Denoting $\mu_j^{i+1} = \lambda(z_j^{i+1})$, we observe that $(J_j z_k^{i+1}, z_l^{i+1}) = 0$ for $k \neq l$ and $(J_j z_k^{i+1}, z_k^{i+1}) = (\mu_k^{i+1} - \lambda_j^{i+1})\|z_k^{i+1}\|^2$. Finally, we note that $((L-\lambda_j^{i+1})x_l^{i+1}, z_k^{i+1}) = 0$, and therefore $(J_j K r_j^{i+1}, z_k^{i+1}) = ((L-\lambda_j^{i+1})K r_j^{i+1}, z_k^{i+1})$. Hence, multiplying

$$y_j^{i+1} = K r_j^{i+1} + \sum_{l=1}^{m_i} \beta_{lj}^{(i)} z_l^{i+1}$$

by $J_j z_k^{i+1}$, we obtain, assuming $\lambda_{n_b}^{i+1} < \mu_1^{i+1}$,

$$\beta_{kj}^{(i)} = -\frac{((L-\lambda_j^{i+1})K r_j^{i+1}, z_k^{i+1})}{(\mu_k^{i+1} - \lambda_j^{i+1})\|z_k^{i+1}\|^2}, \tag{4.4}$$

and if $\lambda_{n_b}^{i+1} = \mu_1^{i+1}$, then we set $\beta_{kj}^{(i)} = 0$ for any k such that $\mu_k^{i+1} - \lambda_j^{i+1} = 0$.

Thus, we arrive at the following iterative scheme:

$$[X^{i+1}, Z^{i+1}] = \mathcal{R} R_{\dim \mathcal{V}^i} \mathcal{V}^i, \quad \mathcal{V}^i = \operatorname{span}\{X^i, Y^i\}, \tag{4.5}$$

$$Y^{i+1} = K R^{i+1} + Z^{i+1} B_i, \tag{4.6}$$

where $Z^{i+1} = [z_1^{i+1}, \dots, z_{m_i}^{i+1}]$, $m_i = \dim \mathcal{V}^i - n_b$, and the entries $\beta_{kj}^{(i)}$ of the conjugation matrix B_i are given by (4.4) (practical considerations can be found in [19]).

Unlike in the case $m = 1$, there is apparently no asymptotical equivalence between this scheme and other schemes mentioned in section 2; however, the numerical test of [18] demonstrates remarkable similarity of the convergence behavior of the block Jacobi scheme and LOBPCG, a phenomenon yet to be explained.

A preliminary convergence result given below shows that the local convergence rate of the block CG (2.1)–(2.2) can be estimated in terms of the condition numbers κ_{ij} of operators $A_{ij} = J(\lambda_j^i, \mathcal{X}_m^i)K$, restricted to the subspace $(\mathcal{X}_m^i)^\perp$. We note that A_{ij} is Hermitian in K- and $J(\lambda_j^i, \mathcal{X}_m^i)^{-1}$-scalar products and that the following estimate for κ_{ij} is valid:

$$\kappa_{ij} \le \hat{\kappa}_{ij} = \kappa \left(1 + \lambda_{m+1} \sum_{k=1}^{m} \left(\frac{1}{\lambda_k} - \frac{1}{\lambda_k^i}\right)\right) \frac{\lambda_{m+1} - \delta_\lambda(\mathcal{X}_m^i)}{\lambda_{m+1} - \delta_\lambda(\mathcal{X}_m^i) - \lambda_j^i}, \tag{4.7}$$

where L is assumed to be positive definite for simplicity of notation[5] and κ is the condition number of KL (see section B.4 for the proof). As $\delta_\lambda(\mathcal{X}_m^i) \to 0$, the right-hand side of 4.7 decreases to $\kappa\lambda_{m+1}/(\lambda_{m+1} - \lambda_j)$; hence, $\kappa_{ij} \le \hat{\kappa}_{i_0 j} \le \hat{\kappa}_{i_0 l}$.

[5]To obtain an estimate for a nonpositive L, apply (4.7) to $L - \lambda_0$ with $\lambda_0 < \lambda_1$.

THEOREM 4.1. *Assume that* $\lambda_l^{i_0} < \lambda_{l+1}$ *for some* $l \le m$ *and iteration number* i_0, *and assume* (4.1) *for* $i = i_0$. *The following estimate is valid at each iteration* $i \ge i_0$ *of the block CG* (2.1)–(2.2) *with the search directions satisfying* (4.3)*:*

$$\sum_{j=1}^{l}(\lambda_j^{i+1} - \lambda_j) \le \frac{q_{il} + \epsilon_{il}}{1 + \epsilon_{il}} \sum_{j=1}^{l}(\lambda_j^i - \lambda_j), \tag{4.8}$$

where

$$q_{il} = \max_{1\le j\le l}\left(\frac{\kappa_{ij} - 1}{\kappa_{ij} + 1}\right)^2, \quad \epsilon_{il} \le c\frac{\delta_\lambda(\mathcal{X}_m^i)}{\lambda_{m+1} - \lambda_m}, \tag{4.9}$$

κ_{ij} *is the condition number of the operator* $A_{ij} = J(\lambda_j^i, \mathcal{X}_m^i)K$, *restricted to* $(\mathcal{X}_m^i)^\perp$, $\delta_\lambda(\cdot)$ *is given in* (3.9), *and the coefficient* c *depends on* $\kappa_l = \hat\kappa_{i_0 l}$, *where* $\hat\kappa_{ij}$ *is given in* (4.7), $\rho_m = (\lambda_{m+1} - \lambda_m)/\gamma$, $\delta_m = (\lambda_{m+1} - \lambda_m)/(\lambda_{m+1} - \lambda_1)$, *and* $\delta_l = (\lambda_{l+1} - \lambda_l^{i_0})/(\lambda_{m+1} - \lambda_1)$ *only.*

Proof. Let us first show that the search directions of the scheme in question satisfy (3.21). Below we denote by α_{ij} and ω_{ij} the minimal and maximal eigenvalues of A_{ij}, and $J_{ij} = J(\lambda_j^i, \mathcal{X}_m^i)$.

Let $\alpha_j^{(i)}$ be such that $\mu_j^i = \lambda(x_j^i - \alpha_j^{(i)}(1 - P_i)y_j^i) = \min_\alpha \lambda(x_j^i - \alpha(1 - P_i)y_j^i)$. By Theorem 3.3 we have (cf. (3.18))

$$|\alpha_j^{(i)}| = \frac{|(r_j^i, y_j^i)|}{(J'_{ij}y_j^i, y_j^i)} = \frac{\|r_j^i\|_K^2}{\|y_j^i\|_{J'_{ij}}^2}, \quad J'_{ij} = J(\mu_j^i, \mathcal{X}_m^i).$$

Denoting $\rho_1 = (\lambda_{m+1} - \lambda_1)/\gamma = \rho_m/\delta_m$, by (3.11) we have $\|y_j^i\|_{J'_{ij}}^2 \le \rho_1\|y_j^i\|_{J_{ij}}^2$. The conjugation condition (4.3) implies $\|y_j^i\|_{J_{ij}}^2 \le \|Kr_j^i\|_{J_{ij}}^2$. Since $P_i r_j^i = 0$, we have $\|Kr_j^i\|_{J_{ij}}^2 = (Kr_j^i, J_{ij}Kr_j^i) = (r_j^i, A_{ij}r_j^i)_K \le \omega_{ij}\|r_j^i\|_K^2$. Thus, $|\alpha_j^{(i)}|^{-1} \le \rho_1\omega_{ij}$. Finally, $\|r_j^i\|_{J_{ij}^{-1}}^2 = (J_{ij}^{-1}r_j^i, r_j^i) = (A_{ij}^{-1}r_j^i, r_j^i)_K \le \alpha_{ij}^{-1}\|r_j^i\|_K^2 = \alpha_{ij}^{-1}|\alpha_j^{(i)}|\|y_j^i\|_{J'_{ij}}^2 = \alpha_{ij}^{-1}|\alpha_j^{(i)}|^{-1}\|h_j^i\|_{J'_{ij}}^2 \le \rho_1^2\kappa_l\|h_j^i\|_{J_{ij}}^2 \le \rho_1^2\kappa_l\|h_j^i\|_{J'_{ij}}^2 = \rho_1^2\kappa_l(\lambda_j^i - \mu_j^i)$. Thus, (3.21) is satisfied, and Theorem 3.4 applies.

We have $\lambda_j^{i+1} - \lambda_j \le \nu_j^i - \lambda_j = \lambda_j^i - \lambda_j - (\lambda_j^i - \mu_j^i) - (\mu_j^i - \nu_j^i)$, where ν_j^i are the Ritz values in the trial subspace $\mathcal{W}_m^i = \operatorname{span}\{x_j^i - \alpha_j^{(i)}(1 - P_i)y_j^i\}$. By (3.22), the summation over $j = 1, \dots, l$ yields

$$\sum_{j=1}^{l}(\lambda_j^{i+1} - \lambda_j) \le \sum_{j=1}^{l}(\lambda_j^i - \lambda_j) - \left(1 - c\frac{\delta(\mathcal{X}_m^i)}{\lambda_{m+1} - \lambda_m}\right)\sum_{j=1}^{l}(\lambda_j^i - \mu_j^i).$$

In turn, for $\lambda_j^i - \mu_j^i$ we have, using (3.19) and then (3.11),

$$\lambda_j^i - \mu_j^i = \frac{|(r_j^i, Kr_j^i)|^2}{(J(\mu_j^i, \mathcal{X}^i)y_j^i, y_j^i)} \ge \frac{|(r_j^i, Kr_j^i)|^2}{\|y_j^i\|_{J_{ij}}^2}\left(1 - \frac{\lambda_j^i - \mu_j^i}{\gamma}\right).$$

The J_{ij}-orthogonality of y_j^i and z_k^{i-1} implies $\|y_j^i\|_{J_{ij}} \le \|Kr_j^i\|_{J_{ij}}$, and hence

$$\frac{|(r_j^i, Kr_j^i)|^2}{\|y_j^i\|_{J_{ij}}^2} \ge \frac{|(r_j^i, Kr_j^i)|^2}{\|K_i r_j^i\|_{J_{ij}}^2} = \frac{(r_j^i, A_{ij}r_j^i)_{J_{ij}^{-1}}^2}{\|A_{ij}r_j^i\|_{J_{ij}^{-1}}^2} = \|r_j^i\|_{J_{ij}^{-1}}^2 \cos^2_{J_{ij}^{-1}} \angle\{r_j^i, A_{ij}r_j^i\}.$$

By Lemma A.1 from part I [17] the sine of the angle between r_j^i and $A_{ij}r_j^i$ is bounded by $(\kappa_{ij}-1)/(\kappa_{ij}+1)$. As shown in the proof of Theorem 3.4, the sum of $\lambda_j^i - \mu_j^i$ is not greater than $8\rho_1^2\delta_\lambda(\mathcal{X}_m^i)$. Hence, simple manipulations with the three inequalities displayed just above yield

$$\sum_{j=1}^{l}(\lambda_j^{i+1}-\lambda_j) \le q_{il}\sum_{j=1}^{l}(\lambda_j^i-\lambda_j), + \frac{c_0\delta_\lambda(\mathcal{X}_m^i)}{\lambda_{m+1}-\lambda_m}\sum_{j=1}^{l}\|r_j^i\|^2_{J_{ij}^{-1}}, \tag{4.10}$$

where c_0 has the same dependencies as c in (4.8). Finally, $\|r_j^i\|^2_{J_{ij}^{-1}} \le \alpha_{ij}^{-1}\|r_j^i\|_K^2$ and (3.11) implies $(J(\lambda_1,\mathcal{X}_m^i)y_j^i,y_j^i) \le \rho_1(J_{ij}y_j^i,y_j^i)$, and thus $(J(\lambda_1,\mathcal{X}_m^i)y_j^i,y_j^i) \le \rho_1(J_{ij}Kr_j^i,Kr_j^i) \le \rho_1\omega_{ij}(Kr_j^i,r_j^i)$. Consulting Lemma B.1, we conclude that

$$\sum_{j=1}^{l}\|r_j^i\|^2_{J_{ij}^{-1}} \le \rho_1\kappa_{ij}\sum_{j=1}^{l}(\lambda_j^i-\lambda_j^{i+1}) = \rho_1\kappa_{ij}\left(\sum_{j=1}^{l}(\lambda_j^i-\lambda_j) - \sum_{j=1}^{l}(\lambda_j^{i+1}-\lambda_j),\right),$$

which, together with (4.10), yields (4.8). ∎

We stress that the above convergence result should be viewed as a preliminary one, being rather "pessimistic": it merely shows that the convergence of the block Jacobi CG is asymptotically not worse than that of the block steepest descent method (cf. convergence estimates for the block steepest descent of [13, 14], which, owing to the minimax principle, apply to LOBPCG—but not to (2.1)–(2.2)). In practice, the convergence of algorithms using this and other block CG schemes is considerably faster: the numerical tests of [18] suggest that in (4.9), κ_{ij} can be replaced with its square root (cf. a similar hypothesis in [9]). Still, the result in question adequately portrays the observed convergence behavior of the block Jacobi scheme in three important respects: (i) the convergence is not adversely affected by eigenvalue clustering, (ii) neither is it affected by the spread of the spectrum of L, provided that a good enough preconditioner K is used, and (iii) the convergence to leftmost eigenvalues is faster than to those deeper in the spectrum; hence the performance of the algorithm benefits substantially from the deflation technique (unlike with the trace minimization scheme (2.1), (2.2), (2.5); cf. [18]).

Appendix A. The Rayleigh–Ritz approximation. For the reader's convenience, section A.1 summarizes the Rayleigh–Ritz procedure; section A.2 presents new residual error bounds for the Rayleigh–Ritz approximation that are used in the proofs of Appendix B.

A.1. The Rayleigh–Ritz procedure. Denote by $P_{\mathcal{V}}$ the orthogonal projector onto a subspace $\mathcal{V}$. If $\mathcal{V}$ has a good approximation to x_j, then $\tilde{x}_j = P_{\mathcal{V}}x_j$ is close to x_j, and the norm of the residual $r_j = L\tilde{x}_j - \lambda(\tilde{x}_j)\tilde{x}_j$ is small, and hence so is the norm of $r_j^{\mathcal{V}} = P_{\mathcal{V}}r_j = P_{\mathcal{V}}L\tilde{x}_j - \lambda(\tilde{x}_j)\tilde{x}_j$. Denoting by $L_{\mathcal{V}}$ the restriction of the operator $P_{\mathcal{V}}LP_{\mathcal{V}}$ to $\mathcal{V}$, we observe that for $v \in \mathcal{V}$ the Rayleigh quotient $(L_{\mathcal{V}}v,v)/\|v\|^2$ coincides with $\lambda(v)$, and thus $r_j^{\mathcal{V}} = L_{\mathcal{V}}\tilde{x}_j - \lambda(\tilde{x}_j)\tilde{x}_j$ is the residual of $\tilde{x}_j$ viewed as an approximation to an eigenvector of $L_{\mathcal{V}}$. By the well-known results from eigenvalue approximation theory (see, e.g., [20]), the smallness of $r_j^{\mathcal{V}}$ implies that $\tilde{x}_j$ is close to an invariant subspace of $L_{\mathcal{V}}$. Thus, if some eigenvectors of L are close to $\mathcal{V}$, then one can find approximations to those eigenvectors in the invariant subspaces of $L_{\mathcal{V}}$.

The eigenvectors $x_j^{\mathcal{V}}$ of $L_{\mathcal{V}}$ are called *Ritz vectors* of L in the *trial subspace* $\mathcal{V}$, and the corresponding eigenvalues $\lambda_j^{\mathcal{V}} = \lambda(x_j^{\mathcal{V}})$ are called Ritz values. Since $0 =$

$L_{\mathcal{V}}x_j^{\mathcal{V}} - \lambda_j^{\mathcal{V}}x_j^{\mathcal{V}} = P_{\mathcal{V}}(Lx_j^{\mathcal{V}} - \lambda(x_j^{\mathcal{V}})x_j^{\mathcal{V}})$, the gradient of $\lambda(v)$ at $v = x_j^{\mathcal{V}}$ is orthogonal to $\mathcal{V}$. Conversely, if the gradient of $\lambda(v)$ is orthogonal to $\mathcal{V}$, then $L_{\mathcal{V}}v - \lambda(v)v = P_{\mathcal{V}}(Lv - \lambda(v)v) = 0$; i.e., v is a Ritz vector. Hence, Ritz vectors can be equivalently defined as the vectors on which the Rayleigh quotient restricted to $\mathcal{V}$ is stationary. Further, since $x_j^{\mathcal{V}}$ are eigenvectors of $L_{\mathcal{V}}$, $(x_j^{\mathcal{V}}, x_k^{\mathcal{V}}) = 0$ and $(Lx_j^{\mathcal{V}}, x_k^{\mathcal{V}}) = (L_{\mathcal{V}}x_j^{\mathcal{V}}, x_k^{\mathcal{V}}) = 0$; again, it is not difficult to verify that these two orthogonality properties, shared with the eigenvectors of L, represent yet another equivalent definition of Ritz vectors.

In practical terms, Ritz vectors and values are computed by what is known as the Rayleigh–Ritz procedure. A basis $\{v_1, \ldots, v_m\}$ is introduced in $\mathcal{V}$, and two m-by-m Gram matrices $\hat{A}$ and $\hat{B}$ with entries (Lv_j, v_k) and (v_j, v_k) are computed. Since $x_j^{\mathcal{V}} \in \mathcal{V}$, we have $x_j^{\mathcal{V}} = V\hat{x}_j$, where $V = [v_1, \ldots, v_m]$ and $\hat{x}_j$ is a column vector of dimension m. The orthogonality of $r(x_j^{\mathcal{V}})$ to $\mathcal{V}$ implies $0 = V^*(LV\hat{x}_j - \lambda(x_j^{\mathcal{V}})V\hat{x}_j) = \hat{A}\hat{x}_j - \lambda_j^{\mathcal{V}}\hat{B}\hat{x}_j$; i.e., the Ritz values $\lambda_j^{\mathcal{V}}$ are the eigenvalues of the generalized problem

$$\hat{A}\hat{x} = \lambda^{\mathcal{V}}\hat{B}\hat{x}, \tag{A.1}$$

and the Ritz vectors $x_j^{\mathcal{V}}$ are related to the eigenvectors $\hat{x}_j$ of this problem as $x_j^{\mathcal{V}} = V\hat{x}_j$.

It remains to note that the Rayleigh–Ritz procedure can also be applied to the generalized problem $Lx = \lambda Mx$ with Hermitian positive definite M, the only difference being the definition of the entries of the Gram matrix $\hat{B}$ as (Mv_j, v_k); we note that in this case Ritz vectors are M-orthogonal. Finally, we note that the scalar product that has been used in this section does not have to be the standard Euclidean one: any scalar product in which L and M are Hermitian can be used instead.

A.2. Lehmann intervals and related residual error bounds. By the minimax principle, Ritz values are not less than the leftmost eigenvalues with respective indices. Hence, one way to obtain estimates for the difference between the two is to find lower bounds for the eigenvalues of L, for which a method suggested by Lehmann can be employed (see, e.g., [11, 20, 2, 7]).

Lehmann's method produces, for a given subspace $\mathcal{V}$ and a given value α that is not a Ritz value in $\mathcal{V}$, a set of values

$$\cdots \le \lambda_{-2}^{\mathcal{V}}(\alpha) \le \lambda_{-1}^{\mathcal{V}}(\alpha) < \alpha < \lambda_1^{\mathcal{V}}(\alpha) \le \lambda_2^{\mathcal{V}}(\alpha) \le \cdots \tag{A.2}$$

such that each semiclosed interval $[\lambda_{-k}^{\mathcal{V}}(\alpha), \alpha)$ or $(\alpha, \lambda_k^{\mathcal{V}}(\alpha)]$ contains at least k eigenvalues of L; here we refer to α as the Lehmann pole and to $\lambda_k^{\mathcal{V}}(\alpha)$ as Lehmann values. The number of Lehmann values left and right of the pole coincides with the respective number of Ritz values, each Lehmann value being further away from the pole than the respective Ritz value. The described properties of Lehmann values imply that if $\lambda_m^{\mathcal{V}} < \alpha \le \lambda_{m+1}$, then $\lambda_{i-m-1}^{\mathcal{V}}(\alpha) \le \lambda_i \le \lambda_i^{\mathcal{V}}$, $i = 1, \ldots, m$.

Lehmann's method is a product of the following reasoning (cf. [11]). Let α be any value that is not a Ritz value of L in $\mathcal{V}$, and assume for a moment that neither is it an eigenvalue of L. The eigenvalues of the shifted operator $L - \alpha$ are $\lambda_j - \alpha$, and they coincide with those of the generalized eigenvalue problem

$$(L - \alpha)^2 y = \nu(L - \alpha)y, \tag{A.3}$$

which is equivalent to

$$(L - \alpha)y = \mu(L - \alpha)^2 y, \tag{A.4}$$

the eigenvalues of the latter being the inverses of those of the former. We observe that both problems are definite owing to the assumptions on α. Let us enumerate eigenvalues μ_j of (A.4) as follows: positive eigenvalues are $\mu_1 \geq \mu_2 \geq \cdots$ (starting from the rightmost) and negative are $\mu_{-1} \leq \mu_{-2} \leq \cdots$ (starting from the leftmost). Denote by $\mu_k^{\mathcal{V}}$ the Ritz values of (A.4) in $\mathcal{V}$ enumerated in the same way. By the minimax principle, $\mu_k^{\mathcal{V}} \leq \mu_k$ for positive k and $\mu_k^{\mathcal{V}} \geq \mu_k$ for negative k. Recalling that the eigenvalues of (A.4) are the inverses of the eigenvalues of (A.3), which in turn are the eigenvalues of L shifted by α, for $\lambda_k^{\mathcal{V}}(\alpha) = 1/\mu_k^{\mathcal{V}} + \alpha$ we have

$$\lambda_{(k)} \leq \lambda_k^{\mathcal{V}}(\alpha), \quad k > 0; \quad \lambda_{(k)} \geq \lambda_k^{\mathcal{V}}(\alpha), \quad k < 0, \tag{A.5}$$

where $\lambda_{(1)} \leq \lambda_{(2)} \leq \cdots$ are eigenvalues of L right of α and $\lambda_{(-1)} \geq \lambda_{(-2)} \geq \cdots$ are those left of α.

Observing that $\lambda_k^{\mathcal{V}}(\alpha)$ continuously depend on α in any interval not containing Ritz values of L in $\mathcal{V}$, we conclude that (A.5) is also valid when α is an eigenvalue of L (for as long as it is not a Ritz value at the same time, i.e., for as long as $\mathcal{V}$ does not contain the corresponding eigenvector).

Denote $X_{\mathcal{V}} = [x_1^{\mathcal{V}}, \ldots, x_m^{\mathcal{V}}]$, $R_{\mathcal{V}} = [r_1^{\mathcal{V}}, \ldots, r_m^{\mathcal{V}}]$, and $\Lambda_{\mathcal{V}} = \operatorname{diag}\{\lambda_1^{\mathcal{V}}, \ldots, \lambda_m^{\mathcal{V}}\}$, where $x_j^{\mathcal{V}}$ and $\lambda_j^{\mathcal{V}}$ are normalized Ritz vectors and Ritz values of L in $\mathcal{V}$, and $r_j^{\mathcal{V}} = Lx_j^{\mathcal{V}} - \lambda_j^{\mathcal{V}} x_j^{\mathcal{V}}$. Simple calculation shows that the eigenvalues of the operator

$$L(\alpha) = \alpha + [X_{\mathcal{V}}, R_{\mathcal{V}}] \begin{bmatrix} \Lambda_{\mathcal{V}} - \alpha & I \\ I & (\Lambda_{\mathcal{V}} - \alpha)^{-1} \end{bmatrix} \begin{bmatrix} X_{\mathcal{V}}^* \\ R_{\mathcal{V}}^* \end{bmatrix} \tag{A.6}$$

other than α coincide with its Lehmann values, and that $L(\alpha)w = Lw$ for any $w \in \mathcal{V}$. Hence, Lehmann bounds are sharp; i.e., they cannot be improved if the only information available is $\mathcal{V}$ and L-images of vectors from $\mathcal{V}$. We observe also that Lehmann values can be alternatively defined as eigenvalues of $L(\alpha)$ other than α.

It is not difficult to verify that $L(\alpha_1) \leq L(\alpha_2)$ for $\alpha_1 \leq \alpha_2$ (where $A \leq B$ means $B - A$ is positive semidefinite), which implies that Lehmann values are nondecreasing functions of α. For this reason, assuming $\lambda_m^{\mathcal{V}} < \lambda_{m+1}$, the optimal position of the pole, as far as the m leftmost eigenvalues are concerned, is $\alpha = \lambda_{m+1}$, as this is the rightmost value of α that provides guaranteed left bounds for $\lambda_1, \ldots, \lambda_m$.

From the practical point of view, Lehmann values can be computed using Ritz values and residuals. Indeed, applying to (A.4) the Rayleigh–Ritz procedure with Ritz vectors as the basis, ones gets, after simple calculation, the generalized eigenvalue problem (cf. [2])

$$(\Lambda_{\mathcal{V}} - \alpha)\hat{x} = \hat{\mu}\left((\Lambda_{\mathcal{V}} - \alpha)^2 + R_{\mathcal{V}}^* R_{\mathcal{V}}\right)\hat{x}. \tag{A.7}$$

Simple manipulations with (A.7) show that in the case $\alpha > \lambda_m^{\mathcal{V}}$, Lehmann values are the eigenvalues of the matrix

$$\hat{L}_{\alpha,-} = \Lambda_{\mathcal{V}} - S_{\mathcal{V},\alpha,-}^* S_{\mathcal{V},\alpha,-}, \quad S_{\mathcal{V},\alpha,-} = R_{\mathcal{V}}(\alpha - \Lambda_{\mathcal{V}})^{-1/2}, \tag{A.8}$$

and in the case $\alpha < \lambda_1^{\mathcal{V}}$, of the matrix

$$\hat{L}_{\alpha,+} = \Lambda_{\mathcal{V}} + S_{\mathcal{V},\alpha,+}^* S_{\mathcal{V},\alpha,+}, \quad S_{\mathcal{V},\alpha,+} = R_{\mathcal{V}}(\Lambda_{\mathcal{V}} - \alpha)^{-1/2}. \tag{A.9}$$

We observe that $\hat{L}_{+\infty,-} = \hat{L}_{-\infty,+} = \Lambda_{\mathcal{V}}$; i.e., $\lambda_{j-m-1}^{\mathcal{V}}(+\infty) = \lambda_j^{\mathcal{V}}(-\infty) = \lambda_j^{\mathcal{V}}$.

The established relationship between Lehmann values and (weighted) residuals facilitates the derivation of various residual error bounds for Ritz values. For example, assuming $\lambda_m^{\mathcal{V}} < \lambda_{m+1}$ and taking the trace of both sides of (A.8) for $\alpha = \lambda_{m+1}$, we arrive at the following total eigenvalue error estimate:

$$\sum_{j=1}^{m}(\lambda_j^{\mathcal{V}} - \lambda_j) \le \sum_{j=1}^{m}\lambda_j^{\mathcal{V}} - \sum_{j=-m}^{-1}\lambda_j^{\mathcal{V}}(\lambda_{m+1}) = \sum_{j=1}^{m}\frac{\|r_j^{\mathcal{V}}\|^2}{\lambda_{m+1} - \lambda_j^{\mathcal{V}}}. \tag{A.10}$$

The eigenvalues of the diagonal block of $\hat{L}_{\lambda_{m+1},-}$ on the intersection of several last rows and columns are not greater than the respective rightmost eigenvalues of this matrix, which implies that in (A.10) the summation can actually start at any value $1 \le k \le m$; i.e.,

$$\sum_{j=k}^{m}(\lambda_j^{\mathcal{V}} - \lambda_j) \le \sum_{j=k}^{m}\frac{\|r_j^{\mathcal{V}}\|^2}{\lambda_{m+1} - \lambda_j^{\mathcal{V}}}. \tag{A.11}$$

If α is placed to the right of the spectrum of L, then all eigenvalues of (A.4) are negative, with those closest to zero corresponding to the leftmost eigenvalues of L. The fact that the Ritz values for (A.4) do not exceed corresponding eigenvalues implies that the Lehmann values in this case are not smaller than the corresponding eigenvalues of L, whereas by (A.8) they are not greater than the corresponding Ritz values. Hence, taking the trace of both sides in (A.8), we arrive at the following estimate of [16]:

$$\sum_{j=1}^{m}\frac{\|r_j\|^2}{\alpha - \tilde{\lambda}_j} \le \sum_{j=1}^{m}(\tilde{\lambda}_j - \lambda_j) \tag{A.12}$$

that is valid for arbitrary α to the right of the spectrum of L; by continuity, it remains valid for α at the rightmost point of the spectrum as well. Just as with (A.10) and (A.11), the number of items in both sums in (A.12) can be simultaneously reduced, this time by lowering the upper summation limit.

It remains to note that the above residual bounds for eigenvalue errors can be applied to the generalized eigenvalue problem $Lx = \lambda Mx$ with Hermitian positive definite M as well. One just needs to consider an equivalent standard eigenvalue problem for the operator $A = M^{-1}L$ and use the scalar product $(\cdot,\cdot)_M = (M\cdot,\cdot)$, in which A is Hermitian. It is not difficult to verify that the Ritz values and vectors of A coincide with those of the generalized problem in question, and that the M-norm of the residual vector $A\tilde{x} - \tilde{\lambda}\tilde{x}$ is equal to the M^{-1}-norm of the residual vector $L\tilde{x} - \tilde{\lambda}M\tilde{x}$; hence, in the case at hand, we need to use M^{-1}-norms of residuals in the above estimates.

Appendix B. Proofs. Below, for any m-by-m matrix A and any $\mathcal{I}, \mathcal{J} \subset \{1, \dots, m\}$, we denote by $A_{\mathcal{I},\mathcal{J}}$ the block (submatrix) of A on the intersection of rows with indices from $\mathcal{I}$ and columns with indices from $\mathcal{J}$. For any matrix U with m columns, $U_{\mathcal{J}}$ stands for the matrix formed by columns of U with indices from $\mathcal{J}$.

In order to make the calculations more compact, we use the following notation. For any matrices U and V of the same size we denote $\langle U, V\rangle = \mathrm{Tr}V^*U$. We observe that the latter bilinear form is a scalar product (it is actually the standard Euclidean scalar product of two vectors formed by columns of U and V), and the corresponding norm $\langle U\rangle$ is just the Frobenius norm of U. Elementary calculation shows that for any matrices A and B for which the product AUB makes sense, one has $\langle AUB\rangle \le$

$\|A\|\langle U\rangle\|B\|$. Here and below, $\|A\|$ stands for the operator norm of A, i.e., $\|A\| = \sup_u \|Au\|/\|u\|$; we note that $\|A\| \le \langle A\rangle$. For any square matrix H of the same size as the height of U and V we denote $\langle U, V\rangle_H = \mathrm{Tr} V^* H U$. If H is Hermitian positive definite, then the latter is again a scalar product, and we denote by $\langle U\rangle_H$ the corresponding norm (often referred to as the energy norm). Since $\langle U\rangle_H = \langle H^{1/2}U\rangle$, we have $\langle UA\rangle_H \le \langle U\rangle_H \|A\|$ for any A that can be multiplied by U, and $|\langle U, V\rangle| \le \langle U\rangle_H \langle V\rangle_{H^{-1}}$.

For matrices U and V of the same size as E and columns orthogonal to $\tilde{\mathcal{X}}$, we denote

$$\langle U_{\mathcal{I}}, V_{\mathcal{I}}\rangle_J = \sum_{j\in\mathcal{I}} (J_j u_j, v_j), \quad \langle U_{\mathcal{I}}, V_{\mathcal{I}}\rangle_{J^{-1}} = \sum_{j\in\mathcal{I}} (J_j^{-1} u_j, v_j),$$

where $\mathcal{I} \subset \{1, \dots, m\}$ and J_j^{-1} is the inverse of the restriction of J_j to the subspace $\tilde{\mathcal{X}}^\perp$ (orthogonal complement to $\tilde{\mathcal{X}}$): here and below we assume (3.13) to hold. Again, the above are two scalar products in the latter subspace, and we denote by $\langle U\rangle_J$ and $\langle U\rangle_{J^{-1}}$ the corresponding norms. Owing to the equivalence of J_j-norms (cf. (3.11)), these norms are equivalent to J_j and J_j^{-1} norms of U, respectively, for any $1 \le j \le m$, and it is not difficult to verify that

$$\langle U\rangle_{J_j} \langle V\rangle_{J_j^{-1}} \le \sqrt{\rho_1} \langle U\rangle_J \langle V\rangle_{J^{-1}}, \tag{B.1}$$

where $\rho_1 = (\lambda_{m+1} - \lambda_1)/\gamma = \rho_m/\delta_m$. Finally, we observe that for any matrices U and V of the same height as E we have

$$\|V^*U\| \le \langle V^*U\rangle = \langle (J_1^{\frac12} V)^* J_1^{-\frac12} U\rangle \le \langle V\rangle_{J_1} \langle U\rangle_{J_1^{-1}} \le \sqrt{\rho_1} \langle V\rangle_J \langle U\rangle_{J^{-1}}. \tag{B.2}$$

Remark 1. It is not difficult to verify that (B.1) and (B.2) remain valid if we replace J_j with $J(\mu_j, \tilde{\mathcal{X}})$, where $\lambda_1 \le \mu_j \le \tilde{\lambda}_m$, everywhere.

B.1. Proof of Theorem 3.2. First we note that the assumptions of the theorem together with the inequality $\sin\{\mathcal{X}; \tilde{\mathcal{X}}\} \le (\tilde{\lambda}_m - \lambda_1)/(\lambda_{m+1} - \lambda_1)$ (cf., e.g., [7]) ensure that $\sin\{\mathcal{X}; \tilde{\mathcal{X}}\} < 1$, and hence we are in a position to use the notation and relationships of section 3.1.

The proof of inequalities (3.14) and (3.15) is based on the following two observations: (i) the eigenvalues of $\lambda(X')$ are $\lambda_1, \dots, \lambda_m$, and those of $\lambda(\tilde{X})$ are $\tilde{\lambda}_1, \dots, \tilde{\lambda}_m$, and hence (3.4) implies

$$\sum_{j=1}^m (\tilde{\lambda}_j - \lambda_j) = \mathrm{Tr}(\lambda(\tilde{X}) - \lambda(X')) = -\mathrm{Tr} R^* E = -\sum_{j=1}^m (e_j, r_j), \tag{B.3}$$

and (ii) the Riccati equation (3.5) is a set of m linear systems

$$(J_j - E R^*) e_j = -r_j, \tag{B.4}$$

linked by the asymptotically small operator perturbation ER^*; hence $J_j e_j \approx -r_j$, which leads, via calculations given below, to the asymptotic identities of the theorem.

Below we denote $\mathcal{I} = \{1, \dots, l\}$, $\delta_\lambda = \delta_\lambda(\tilde{\mathcal{X}})$, and $\delta_{\lambda,\mathcal{I}} = \sum_{j\in\mathcal{I}} (\tilde{\lambda}_j - \lambda_j)$.

To guide the reader through the rather long and technical proof below, we split it into several steps.

Step 1. *We show that* $\|R\|_{J^{-1}}^2 = \mathcal{O}(\delta_\lambda)$. In order to obtain the estimate in question, we apply the results of section A.2 to an auxiliary eigenvalue problem

$-L_0^{-1}x = \omega x$, where $L_0 = L - \lambda_0$ and $\lambda_0 < \lambda_1$ is specified later on. The reason for introducing this auxiliary problem rather than applying the estimates of section A.2 to the original problem is that in the latter case we would end up with coefficients that depend on the spread of L (cf. (A.12)), which is very large in many applications. Working the auxiliary problem just introduced allows us to eliminate this quantity from our calculation.

We observe that the eigenvectors of $-L_0^{-1}$ coincide with those of L and the corresponding eigenvalues are $\omega_j = 1/(\lambda_0 - \lambda_j)$. Replacing the standard scalar product with L_0-energy product $(\cdot,\cdot)_{L_0} = (L_0\cdot,\cdot)$, we observe that $-L_0^{-1}$ is Hermitian in the new product, the Ritz vectors of $-L_0^{-1}$ in $\tilde{\mathcal{X}}$ are $\tilde{x}_j$, and the corresponding Ritz values $\tilde{\omega}_j = 1/(\lambda_0 - \tilde{\lambda}_j)$. Hence, denoting $s_j = -L_0^{-1}\tilde{x}_j - \tilde{\omega}_j\tilde{x}_j$ (and bearing in mind that $\tilde{x}_j$ are not L_0-normalized), we derive from (A.12) with $\alpha = 0$ the inequality

$$-\sum_{j=1}^{m} \frac{\|s_j\|_{L_0}^2}{\tilde{\omega}_j \|\tilde{x}_j\|_{L_0}^2} = \sum_{j=1}^{m} \tilde{\omega}_j^2 \|r_j\|_{L_0^{-1}}^2 \le \sum_{j=1}^{m} (\tilde{\omega}_j - \omega_j), \tag{B.5}$$

which, after switching ω's to λ's, yields

$$\langle R\rangle_{L_0^{-1}} = \sum_{j=1}^{m} \|r_j\|_{L_0^{-1}}^2 \le \left(\frac{\lambda_{m+1} - \lambda_0}{\lambda_1 - \lambda_0}\right)^2 \sum_{j=1}^{m} (\tilde{\lambda}_j - \lambda_j). \tag{B.6}$$

Setting $\lambda_0 = \lambda_1 - (\lambda_{m+1} - \lambda_1)$, we arrive at the estimate $\langle R\rangle_{L_0^{-1}}^2 \le 4\delta_\lambda$. In order to obtain an estimate for the J^{-1}-norm of R, consider two auxiliary systems $L_0 u = r$ and $J_0 v = r$, where $J_0 = J(\lambda_0, \tilde{\mathcal{X}})$ and $v \in \tilde{\mathcal{X}}^\perp$, for an arbitrary $r \in \tilde{\mathcal{X}}^\perp$. Since $(J_0 v, v) = (L_0 v, v)$, we have $(L_0(v-u), v) = 0$, which implies $(L_0 v, v) \le (L_0 u, u)$. Recalling that $u = L_0^{-1} r$ and $v = J_0^{-1} r$, we arrive at $\|r\|_{J_0^{-1}} \le \|r\|_{L_0^{-1}}$, and, thus, via (3.12), at

$$\langle R\rangle_{J^{-1}}^2 \le 2\rho_1 \langle R\rangle_{J_0^{-1}}^2 \le 8\rho_1 \delta_\lambda. \tag{B.7}$$

Step 2. *We prove* (3.14) *and* (3.15) *for* $l = m$. Let us denote $\theta = \|(1-\tilde{P})P\|$ and $\theta_F = \langle (1-\tilde{P})P\rangle$, where P and $\tilde{P}$ are orthogonal projectors onto $\mathcal{X}$ and $\tilde{\mathcal{X}}$ respectively. We observe that θ is the sine of the (maximal) angle between $\mathcal{X}$ and $\tilde{\mathcal{X}}$, and we recall that in section 3.3 we have shown that $\|E\|$ is the tangent of this angle; i.e., $\|E\|^2 = \theta^2/(1-\theta^2)$, which implies $\|X'\|^2 = 1/(1-\theta^2)$. Lemma 4 of [15] implies

$$\theta_F^2 \le \frac{\delta_\lambda}{\lambda_{m+1} - \lambda_m}.$$

Owing to the assumption (3.13), $\delta_\lambda \le \lambda_{m+1} - \lambda_m - \gamma$, and, hence, $\theta^2 \le \theta_F^2 \le 1 - \gamma/(\lambda_{m+1} - \lambda_m)$. Thus,

$$\|E\|^2 \le \langle E\rangle^2 = \langle (1-\tilde{P})X'\rangle^2 = \langle (1-\tilde{P})PX'\rangle^2 \le \theta_F^2 \|X'\|^2 = \frac{\theta_F^2}{1-\theta^2} \le \frac{\delta_\lambda}{\gamma}.$$

From (3.5) we have $\langle E\rangle_J^2 = -\langle R, E\rangle + \langle ER^*E, E\rangle$. We have shown above (see (B.3)) that the first term in the right-hand side is equal to δ_λ. The second can be estimated as follows:

$$|\langle ER^*E, E\rangle| = |\operatorname{Tr} E^*ER^*E| = |\langle E, RE^*E\rangle| \le \langle E\rangle_{J_1} \langle RE^*E\rangle_{J_1}^{-1}$$

$$\le \langle E\rangle_{J_1} \langle R\rangle_{J_1}^{-1} \|E\|^2 \le \sqrt{\rho_1}\langle E\rangle_J \langle R\rangle_{J^{-1}} \frac{\delta_\lambda}{\gamma} \le \frac{1}{2}\langle E\rangle_J^2 + 4\rho_1^2 \frac{\delta_\lambda^3}{\gamma^2},$$

and thus,

$$\text{(B.8)}\quad \langle E\rangle_J^2 \le 2\left(1+4\rho_1^2\frac{\delta_\lambda^2}{\gamma^2}\right)\delta_\lambda \le 2\left(1+4\rho_1^2\rho_m^2\right)\delta_\lambda = 2\left(1+4\frac{\rho_m^4}{\delta_m^2}\right)\delta_\lambda \equiv c_1\delta_\lambda,$$

which implies

$$|\langle ER^*E,E\rangle| \le \sqrt{\rho_1}\langle E\rangle_J\langle R\rangle_{J^{-1}}\frac{\delta_\lambda}{\gamma} \le 2\rho_1\sqrt{2c_1}\frac{\delta_\lambda^2}{\gamma} = 2\frac{\rho_m^2}{\delta_m}\sqrt{2c_1}\frac{\delta_\lambda^2}{\lambda_{m+1}-\lambda_m},$$

and we arrive at (3.14) with $l=m$.

In order to obtain the respective estimate for $\langle R\rangle_{J^{-1}}$, we multiply (B.4) by $-J_j^{-1}r_j$ and take the sum over $j=1,\dots,m$ to arrive at the identity $-\langle E,R\rangle = \langle R\rangle_{J^{-1}} - \langle ER^*E,R\rangle_{J^{-1}}$. The left-hand side of the above identity is equal to δ_λ, and the second term in the right-hand side can be estimated, with the help of (3.10) and (B.2), as follows:

$$|\langle ER^*E,R\rangle_{J^{-1}}| \le \frac{1}{\gamma}\langle ER^*E\rangle\langle R\rangle_{J^{-1}} \le \frac{1}{\gamma}\langle E\rangle\|R^*E\|\langle R\rangle_{J^{-1}} \le \frac{\sqrt{\rho_1}}{\gamma}\langle E\rangle\langle E\rangle_J\langle R\rangle_{J^{-1}}^2,$$

and, via previously obtained estimates for $\langle E\rangle$, $\langle E\rangle_J$, and $\langle R\rangle_{J^{-1}}^2$, we arrive at (3.15) with $l=m$.

Step 3. *We show that* $\langle E_{\mathcal{I}}\rangle_J = \mathcal{O}(\delta_{\lambda,\mathcal{I}})$. In order to obtain such an estimate, we take advantage of the results of [15] applied to the auxiliary eigenvalue problem for the shifted operator L_0 introduced earlier (again, our motivation here is to avoid any dependency on the spread of L). Let us denote by $\tilde P_0$ the orthogonal projector onto $\tilde{\mathcal{X}}$ in the sense of the scalar product $(\cdot,\cdot)_{L_0}$. For $\theta_0 = \|(1-\tilde P_0)P\|_{L_0}$, where P is the same as above (note that P is orthogonal in both the standard and the L_0-product), we have

$$\theta_0^2 \le \frac{\tilde\omega_m-\omega_1}{\omega_{m+1}-\omega_1} < 1, \quad 1-\theta_0^2 \ge \frac{\omega_{m+1}-\tilde\omega_m}{\omega_{m+1}-\omega_1} = \frac{\lambda_{m+1}-\tilde\lambda_m}{\tilde\lambda_m-\lambda_0} \ge \frac{\gamma}{2(\lambda_{m+1}-\lambda_1)} = \frac{1}{2\rho_1}.$$

Observing that $\|\tilde P_0 x\|_{L_0}^2 \ge (1-\theta_0^2)\|x\|_{L_0}^2$ for any $x\in\mathcal{X}$, we conclude that the restriction of $\tilde P_0$ to $\mathcal{X}$ is invertible, and the norm of its inverse, which we denote by Q_0, is not greater than $1/\sqrt{1-\theta^2} \le \sqrt{2\rho_1}$. Denote $\mathcal{X}_{\mathcal{I}} = \operatorname{span}\{x_j\}_{j\in\mathcal{I}}$, $\tilde{\mathcal{X}}_{\mathcal{I}} = \operatorname{span}\{x_j\}_{j\in\mathcal{I}}$, and $\mathcal{Y}_{\mathcal{I}} = \operatorname{span}\{(1-\tilde P_0)x_j\}_{j\in\mathcal{I}}$, and denote by $P_{\mathcal{I}}$, $\tilde P_{\mathcal{I}}$, and S the L_0-orthogonal projectors onto these three subspaces. Lemma 4 of [15] implies the estimate

$$\text{(B.9)}\quad \langle(1-P_{\mathcal{I}})\tilde P_{\mathcal{I}}\rangle_{L_0}^2 = \langle(1-\tilde P_{\mathcal{I}})P_{\mathcal{I}}\rangle_{L_0}^2 \le \frac{1}{\omega_{l+1}-\omega_l}\sum_{j=1}^{l}(\tilde\omega_j-\omega_j) \le \frac{4\delta_{\lambda,\mathcal{I}}}{\lambda_{l+1}-\lambda_l}.$$

In order to take advantage of these estimates, we observe that

$$E_{0,\mathcal{I}} \equiv (Q_0-1)\tilde X_{\mathcal{I}} = (Q_0-1)S\tilde X_{\mathcal{I}} + (Q_0-1)(1-S)\tilde X_{\mathcal{I}}.$$

By the definition of Q_0, $Q_0-1 = (1-\tilde P_0)Q_0$, and since $\mathcal{Y}_{\mathcal{I}}$ is the projection of $\mathcal{X}_{\mathcal{I}}$, we have $Q_0S = P_{\mathcal{I}}Q_0S$. Thus, $(Q_0-1)S\tilde X_{\mathcal{I}} = (1-\tilde P_0)P_{\mathcal{I}}Q_0S\tilde X_{\mathcal{I}}$, and hence

$$\langle(Q_0-1)S\tilde X_{\mathcal{I}}\rangle_{L_0} \le \langle(1-\tilde P_0)P_{\mathcal{I}}\rangle_{L_0}\|Q_0\|_{L_0}\|S\|_{L_0}\|\tilde X_{\mathcal{I}}\|_{L_0} \le 4\frac{\sqrt{\rho_1(\lambda_{m+1}-\lambda_1)\delta_{\lambda,\mathcal{I}}}}{\sqrt{\lambda_{l+1}-\lambda_l}},$$

where we have used the fact that $\|u\|_{L_0}^2 \le (\tilde\lambda_m - \lambda_0)\|u\|^2 \le 2(\lambda_{m+1}-\lambda_1)$ for $u \in \tilde{\mathcal{X}}$. Further, $Q_0 - 1 = (1-\tilde P_0)Q_0 = (1-\tilde P_0)PQ_0$, and hence

$$\begin{aligned}\langle (Q_0-1)(1-S)\tilde X_{\mathcal I}\rangle_{L_0} &\le \|(1-\tilde P_0)P\|_{L_0}\|Q_0\|_{L_0}\langle (1-S)\tilde X_{\mathcal I}\rangle_{L_0}\\ &\le \sqrt{2\rho_1}\langle (1-S)\tilde X_{\mathcal I}\rangle_{L_0}.\end{aligned}$$

In order to estimate $\langle (1-S)\tilde X_{\mathcal I}\rangle_{L_0}$, we observe that for any $u, v \in \tilde{\mathcal X}_{\mathcal I}$, $\|(1-S)u\|_{L_0} \le \|u-v\|_{L_0}$, which implies $\|(1-S)u\|_{L_0} \le \|(1-SP_{\mathcal I})u\|_{L_0}$, and hence $\langle (1-S)\tilde X_{\mathcal I}\rangle_{L_0} \le \langle (1-SP_{\mathcal I})\tilde X_{\mathcal I}\rangle_{L_0}$. Recalling again that $\mathcal{Y}_{\mathcal I}$ is the projection of $\mathcal{X}_{\mathcal I}$, we observe that $SP_{\mathcal I} = \tilde P_0 P_{\mathcal I}$. Hence, $1 - SP_{\mathcal I} = 1 - P_{\mathcal I} + (1-S)P_{\mathcal I} = 1 - P_{\mathcal I} + (1-\tilde P_0)P_{\mathcal I}$, and thus $U = (1-SP_{\mathcal I})\tilde X_{\mathcal I} = (1-P_{\mathcal I})\tilde X_{\mathcal I} + (1-\tilde P_0)P_{\mathcal I}\tilde X_{\mathcal I} = (1-P_{\mathcal I})\tilde X_{\mathcal I} + V$. Observing that $V^* L_0 U = 0$, we conclude that $\langle (1-SP_{\mathcal I})\tilde X_{\mathcal I}\rangle_{L_0} \le \langle (1-P_{\mathcal I})\tilde X_{\mathcal I}\rangle_{L_0}$. Thus,

$$\langle (1-S)\tilde X_{\mathcal I}\rangle_{L_0} \le \langle (1-P_{\mathcal I})\tilde X_{\mathcal I}\rangle_{L_0} \le \langle (1-P_{\mathcal I})\tilde P_{\mathcal I}\rangle \|\tilde X_{\mathcal I}\|_{L_0} \le \sqrt{8\frac{\lambda_{m+1}-\lambda_1}{\lambda_{l+1}-\lambda_l}\delta_{\lambda,\mathcal I}},$$

and we arrive at the estimate

$$\langle E_{0,\mathcal I}\rangle_{L_0}^2 \le c_2 \delta_{\lambda,\mathcal I}, \tag{B.10}$$

where the coefficient c_2 depends on ρ_m, δ_m, and δ_l only. Let us now estimate $\langle E_{\mathcal I} - E_{0,\mathcal I}\rangle_{L_0}$. It is easy to see that $\tilde P = \tilde X \tilde X^*$ and $\tilde P_0 = \tilde X \tilde\Lambda_0^{-1}\tilde X^* L_0$, where $\tilde\Lambda_0$ is a diagonal matrix with $\tilde\lambda_j - \lambda_0$ on the diagonal. Since $L_0\tilde X - \tilde X\tilde\Lambda_0 = R$, we have $\tilde P_0 - \tilde P = \tilde X \tilde\Lambda_0^{-1} R^*$. Denoting by Q the inverse of the restriction of $\tilde P$ to $\mathcal{X}$, we observe that $X' = Q\tilde X$, and hence $E_{\mathcal I} - E_{0,\mathcal I} = (Q - Q_0)\tilde X_{\mathcal I} = Q(\tilde P_0 - \tilde P)Q_0\tilde X_{\mathcal I} = Q(\tilde P_0 - \tilde P)E_{0,\mathcal I} = Q\tilde X\tilde\Lambda_0^{-1}R^* E_{0,\mathcal I}$, and

$$\langle E_{\mathcal I} - E_{0,\mathcal I}\rangle_{L_0} \le \|X'\|_{L_0}\langle \tilde\Lambda_0^{-1}R\rangle_{L_0^{-1}}\langle E_{0,\mathcal I}\rangle_{L_0} \le \sqrt{\lambda_m - \lambda_0}\|X'\|\frac{\sqrt{\delta_\lambda}}{\lambda_1-\lambda_0}\langle E_{0,\mathcal I}\rangle_{L_0},$$

where we have used (B.5) for estimating $\langle \tilde\Lambda_0^{-1}R\rangle_{L_0^{-1}}$. Since $\|X'\| = 1/\sqrt{1-\theta^2} \le \sqrt{\rho_m}$ and $\delta_\lambda \le \lambda_{m+1} - \lambda_m \le \lambda_{m+1} - \lambda_1 = \lambda_1 - \lambda_0$, we end up with $\langle E_{\mathcal I} - E_{0,\mathcal I}\rangle_{L_0} \le \sqrt{2\rho_m}\langle E_{0,\mathcal I}\rangle_{L_0}$, which implies

$$\langle E_{\mathcal I}\rangle_J^2 \le 2\rho_1\langle E_{\mathcal I}\rangle_{L_0}^2 \le 2\rho_1\left(1+\sqrt{2\rho_m}\right)^2 c_2\delta_{\lambda,\mathcal I} \equiv c_3\delta_{\lambda,\mathcal I}. \tag{B.11}$$

Step 4. *We show that* $\langle R_{\mathcal I}\rangle_{J^{-1}} = \mathcal{O}(\delta_{\lambda,\mathcal I})$. We start by observing that (3.5) implies (cf. also (B.4))

$$\langle R_{\mathcal I}\rangle_{J^{-1}}^2 = -\langle E_{\mathcal I}, R_{\mathcal I}\rangle + \langle ER^*E_{\mathcal I}, R_{\mathcal I}\rangle_{J^{-1}} \le \langle E_{\mathcal I}\rangle_J\langle R_{\mathcal I}\rangle_{J^{-1}} + \langle ER^*E_{\mathcal I}\rangle_{J^{-1}}\langle R_{\mathcal I}\rangle_{J^{-1}},$$

and hence $\langle R_{\mathcal I}\rangle_{J^{-1}} \le \langle E_{\mathcal I}\rangle_J + \langle ER^*E_{\mathcal I}\rangle_{J^{-1}} \le \langle E_{\mathcal I}\rangle_J + \frac{1}{\sqrt{\gamma}}\langle ER^*E_{\mathcal I}\rangle$. With the help of (B.2), we have for $\langle ER^*E_{\mathcal I}\rangle$

$$\langle ER^*E_{\mathcal I}\rangle \le \langle E\rangle\|R^*E_{\mathcal I}\| \le \sqrt{\rho_1}\langle E\rangle\langle R\rangle_{J^{-1}}\langle E_{\mathcal I}\rangle_J \le \frac{\rho_1\sqrt{8}}{\sqrt{\gamma}}\delta_\lambda\langle E_{\mathcal I}\rangle_J, \tag{B.12}$$

and thus

$$\langle R_{\mathcal I}\rangle_{J^{-1}}^2 \le \left(1+\rho_1\sqrt{8}\frac{\delta_\lambda}{\gamma}\right)^2\langle E_{\mathcal I}\rangle_J^2 \le \left(1+\sqrt{8}\frac{\rho_m^2}{\delta_m}\right)^2 c_3\delta_{\lambda,\mathcal I} \equiv c_4\delta_{\lambda,\mathcal I}. \tag{B.13}$$

Step 5. *We show that* $\langle E_{\mathcal{I}}\rangle_J^2$, $\langle R_{\mathcal{I}}\rangle_{J^{-1}}^2$, *and* $-\langle E_{\mathcal{I}}, R_{\mathcal{I}}\rangle$ *are asymptotically identical.* From the correction equation (3.5) we have

$$\left|\langle E_{\mathcal{I}}\rangle_J^2 + \langle E_{\mathcal{I}}, R_{\mathcal{I}}\rangle\right| = |\langle ER^*E_{\mathcal{I}}, E_{\mathcal{I}}\rangle| \le \langle ER^*E_{\mathcal{I}}\rangle\langle E_{\mathcal{I}}\rangle \le \frac{1}{\sqrt{\gamma}}\langle ER^*E_{\mathcal{I}}\rangle\langle E_{\mathcal{I}}\rangle_J,$$

$$\left|\langle R_{\mathcal{I}}\rangle_{J^{-1}}^2 + \langle E_{\mathcal{I}}, R_{\mathcal{I}}\rangle\right| = |\langle ER^*E_{\mathcal{I}}, R_{\mathcal{I}}\rangle_{J^{-1}}| \le \frac{1}{\sqrt{\gamma}}\langle ER^*E_{\mathcal{I}}\rangle\langle R_{\mathcal{I}}\rangle_{J^{-1}}.$$

Hence, using (B.12) we obtain

$$\left|\langle E_{\mathcal{I}}\rangle_J^2 + \langle E_{\mathcal{I}}, R_{\mathcal{I}}\rangle\right| \le \sqrt{8}\frac{\rho_m^2}{\delta_m}c_3\frac{\delta_\lambda}{\lambda_{m+1}-\lambda_m}\delta_{\lambda,\mathcal{I}}, \tag{B.14}$$

$$\left|\langle R_{\mathcal{I}}\rangle_{J^{-1}}^2 + \langle E_{\mathcal{I}}, R_{\mathcal{I}}\rangle\right| \le \sqrt{8}\frac{\rho_m^2}{\delta_m}\sqrt{c_3c_4}\frac{\delta_\lambda}{\lambda_{m+1}-\lambda_m}\delta_{\lambda,\mathcal{I}}. \tag{B.15}$$

Step 6. *We show that* $-\langle E_{\mathcal{I}}, R_{\mathcal{I}}\rangle$ *and* $\delta_{\lambda,\mathcal{I}}$ *are asymptotically identical.* The identity in question has already been shown in the case $\mathcal{I} = \{1,\dots,m\}$ (see (B.3)). In what follows we assume the set $\mathcal{J} = \{1,\dots,m\}\setminus\mathcal{I}$ to be nonempty.

Denote $A = (X')^*LX'$, $B = (X')^*X'$, and $\Lambda' = \lambda(X')$. We observe that $B = I + E^*E \ge I$, where I is the m-by-m identity matrix; $\Lambda' = \tilde{\Lambda} + R^*E$, where $\tilde{\Lambda} = \lambda(\tilde{X})$ (see (3.4)); and $A = B\Lambda'$. Hence, $B_{\mathcal{I},\mathcal{J}} = E_{\mathcal{I}}^*R_{\mathcal{J}}$, $\Lambda'_{\mathcal{J},\mathcal{I}} = R_{\mathcal{J}}^*E_{\mathcal{I}}$, and

$$A_{\mathcal{I},\mathcal{I}} = B_{\mathcal{I},\mathcal{I}}\Lambda'_{\mathcal{I},\mathcal{I}} + B_{\mathcal{I},\mathcal{J}}\Lambda'_{\mathcal{J},\mathcal{I}} = B_{\mathcal{I},\mathcal{I}}\Lambda'_{\mathcal{I},\mathcal{I}} + E_{\mathcal{I}}^*E_{\mathcal{J}}R_{\mathcal{J}}^*E_{\mathcal{I}}. \tag{B.16}$$

Since $B_{\mathcal{I},\mathcal{I}} = I_{\mathcal{I},\mathcal{I}} + E_{\mathcal{I}}^*E_{\mathcal{I}} \ge I_{\mathcal{I},\mathcal{I}}$, we have $\|B_{\mathcal{I},\mathcal{I}}^{-1}\| \le 1$. Hence,

$$\begin{aligned}
\operatorname{Tr}(B_{\mathcal{I},\mathcal{I}}^{-1}A_{\mathcal{I},\mathcal{I}} - \Lambda'_{\mathcal{I},\mathcal{I}}) &= \operatorname{Tr}B_{\mathcal{I},\mathcal{I}}^{-1}E_{\mathcal{I}}^*E_{\mathcal{J}}R_{\mathcal{J}}^*E_{\mathcal{I}} = \left|\langle E_{\mathcal{I}}, R_{\mathcal{J}}E_{\mathcal{J}}^*E_{\mathcal{I}}B_{\mathcal{I},\mathcal{I}}^{-1}\rangle\right| \\
&\le \langle E_{\mathcal{I}}\rangle_{J_1}\langle E_{\mathcal{I}}, R_{\mathcal{J}}E_{\mathcal{J}}^*E_{\mathcal{I}}B_{\mathcal{I},\mathcal{I}}^{-1}\rangle_{J_1^{-1}} \le \langle E_{\mathcal{I}}\rangle_{J_1}\langle R_{\mathcal{J}}\rangle_{J_1^{-1}}\|E_{\mathcal{J}}^*E_{\mathcal{I}}B_{\mathcal{I},\mathcal{I}}^{-1}\| \\
&\le \sqrt{\rho_1}\langle E_{\mathcal{I}}\rangle_J\langle R_{\mathcal{J}}\rangle_{J^{-1}}\langle E_{\mathcal{J}}\rangle\langle E_{\mathcal{I}}\rangle \le \sqrt{\rho_1}\langle E_{\mathcal{I}}\rangle_J\langle R\rangle_{J^{-1}}\langle E\rangle\langle E_{\mathcal{I}}\rangle \le \hat{c}_1\frac{\delta_\lambda}{\lambda_{m+1}-\lambda_m}\delta_{\lambda,\mathcal{I}},
\end{aligned}$$

where $\hat{c}_1$ depends on ρ_m, δ_m, and δ_l only.

The rest of the proof employs the fact that the eigenvalues of $B_{\mathcal{I},\mathcal{I}}^{-1}A_{\mathcal{I},\mathcal{I}}$ are Ritz values of the generalized problem $Av = \lambda Bv$ in the trial subspace spanned by the columns of I with indices from $\mathcal{I}$. Denote by $\Lambda'_{\mathcal{I}}$ the diagonal matrix with the eigenvalues of $B_{\mathcal{I},\mathcal{I}}^{-1}A_{\mathcal{I},\mathcal{I}}$ on the diagonal and by $V_{\mathcal{I}}$ and $R'_{\mathcal{I}}$ the matrices whose columns are the corresponding Ritz and residual vectors, respectively. We have

$$\begin{aligned}
V_{\mathcal{I},\mathcal{I}}\Lambda'_{\mathcal{I}} = B_{\mathcal{I},\mathcal{I}}^{-1}A_{\mathcal{I},\mathcal{I}}V_{\mathcal{I}.\mathcal{I}} &= (\Lambda'_{\mathcal{I},\mathcal{I}} + B_{\mathcal{I},\mathcal{I}}^{-1}E_{\mathcal{I}}^*E_{\mathcal{J}}R_{\mathcal{J}}^*E_{\mathcal{I}})V_{\mathcal{I},\mathcal{I}} \\
&= (\tilde{\Lambda}_{\mathcal{I},\mathcal{I}} + R_{\mathcal{I}}^*E_{\mathcal{I}} + B_{\mathcal{I},\mathcal{I}}^{-1}E_{\mathcal{I}}^*E_{\mathcal{J}}R_{\mathcal{J}}^*E_{\mathcal{I}})V_{\mathcal{I},\mathcal{I}},
\end{aligned}$$

i.e., $\tilde{\Lambda}_{\mathcal{I},\mathcal{I}}V_{\mathcal{I},\mathcal{I}} - V_{\mathcal{I},\mathcal{I}}\Lambda'_{\mathcal{I}} = -(R_{\mathcal{I}}^*E_{\mathcal{I}} + B_{\mathcal{I},\mathcal{I}}^{-1}E_{\mathcal{I}}^*E_{\mathcal{J}}R_{\mathcal{J}}^*E_{\mathcal{I}})V_{\mathcal{I},\mathcal{I}}$. By Kahan's theorem (see, e.g., [20]), the eigenvalues of $\Lambda'_{\mathcal{I}}$ are not further away from respective eigenvalues of $\tilde{\Lambda}_{\mathcal{I},\mathcal{I}}$ than

$$\frac{1}{\sigma}\|\tilde{\Lambda}_{\mathcal{I},\mathcal{I}}V_{\mathcal{I},\mathcal{I}} - V_{\mathcal{I},\mathcal{I}}\Lambda'_{\mathcal{I}}\| \le \sqrt{\rho_m\rho_1}\left(\langle R_{\mathcal{I}}\rangle_{J^{-1}}\langle E_{\mathcal{I}}\rangle_J + \langle E_{\mathcal{I}}\rangle\langle E_{\mathcal{J}}\rangle\langle R_{\mathcal{J}}\rangle_{J^{-1}}\langle E_{\mathcal{I}}\rangle_J\right),$$

where σ is the minimal singular value of $V_{\mathcal{I},\mathcal{I}}$, for which we have, owing to $I_{\mathcal{I},\mathcal{I}} = V_{\mathcal{I},\mathcal{I}}^* B_{\mathcal{I},\mathcal{I}} V_{\mathcal{I},\mathcal{I}} \le (1 + \|E_{\mathcal{I}}\|^2) V_{\mathcal{I},\mathcal{I}}^* V_{\mathcal{I},\mathcal{I}}$, the lower bound $\sqrt{1-\theta^2} \ge 1/\sqrt{\rho_m}$. Since $\tilde{\lambda}_j - \lambda_j \le \delta_{\lambda,\mathcal{I}}$ for $j \in \mathcal{I}$, using previously obtained estimates for $\langle E_{\mathcal{I}}\rangle_J$ and $\langle R_{\mathcal{I}}\rangle_{J^{-1}}$ we conclude that the eigenvalues of $\Lambda'_{\mathcal{I}}$ are not further away from $\lambda_1, \dots, \lambda_l$ than $\hat{c}_2 \delta_{\lambda,\mathcal{I}}$, where $\hat{c}_2$ has the same dependencies as $\hat{c}_1$. Let us assume for a while that $\delta_{\lambda,\mathcal{I}} \le \delta_{\lambda,0} = \delta_{\mathcal{I},\mathcal{J}}/(2\hat{c}_2)$, where $\delta_{\mathcal{I},\mathcal{J}} = \lambda_{l+1} - \lambda_l$. Under this assumption, the Ritz values in question, i.e., the eigenvalues of $B_{\mathcal{I},\mathcal{I}}^{-1} A_{\mathcal{I},\mathcal{I}}$, lie in the interval that does not contain eigenvalues of L other than $\lambda_k, \dots, \lambda_l$, and we are in a position to apply residual bounds of section A.2.

Since the residual vectors are orthogonal to the trial subspace, the only nonzero rows of $R'_{\mathcal{I}}$ are those with indices from $\mathcal{J}$, and it is not difficult to see that these rows form the matrix $R'_{\mathcal{J},\mathcal{I}} = A_{\mathcal{J},\mathcal{I}} V_{\mathcal{I},\mathcal{I}} - B_{\mathcal{J},\mathcal{I}} V_{\mathcal{I},\mathcal{I}} \Lambda'_{\mathcal{I}}$, where $V_{\mathcal{I},\mathcal{I}}$ is the block of $V_{\mathcal{I}}$ formed by rows with indices from $\mathcal{I}$. Since

$$A = B\Lambda' = (I + E^*E)(\tilde{\Lambda} + R^*E) = \tilde{\Lambda} + R^*E + E^*E\tilde{\Lambda} + E^*ER^*E,$$

we have $A_{\mathcal{J},\mathcal{I}} = R_{\mathcal{J}}^* E_{\mathcal{I}} + E_{\mathcal{J}}^* E_{\mathcal{I}} \tilde{\Lambda}_{\mathcal{I},\mathcal{I}} + E_{\mathcal{J}}^* E R^* E_{\mathcal{I}}$, and hence

$$R'_{\mathcal{J},\mathcal{I}} = R_{\mathcal{J}}^* E_{\mathcal{I}} V_{\mathcal{I},\mathcal{I}} + E_{\mathcal{J}}^* E_{\mathcal{I}} \tilde{\Lambda}_{\mathcal{I},\mathcal{I}} + E_{\mathcal{J}}^* E R^* E_{\mathcal{I}} V_{\mathcal{I},\mathcal{I}} - E_{\mathcal{J}}^* E_{\mathcal{I}} V_{\mathcal{I},\mathcal{I}} \Lambda'_{\mathcal{I}}.$$

Assuming the Ritz vectors in question to be normalized by $V_{\mathcal{I}}^* B V_{\mathcal{I}} = V_{\mathcal{I},\mathcal{I}}^* B_{\mathcal{I},\mathcal{I}} V_{\mathcal{I},\mathcal{I}} = I_{\mathcal{I},\mathcal{I}}$, we have $V_{\mathcal{I},\mathcal{I}}^* V_{\mathcal{I},\mathcal{I}} \le V_{\mathcal{I},\mathcal{I}}^* B_{\mathcal{I},\mathcal{I}} V_{\mathcal{I},\mathcal{I}} = I_{\mathcal{I},\mathcal{I}}$, and hence $\|V_{\mathcal{I},\mathcal{I}}\| \le 1$. Therefore,

$$\begin{aligned}\langle R'_{\mathcal{I}}\rangle_{B^{-1}} \le \langle R'_{\mathcal{I}}\rangle = \langle R'_{\mathcal{J},\mathcal{I}}\rangle &\le \langle R_{\mathcal{J}}\rangle_{J_1^{-1}} \langle E_{\mathcal{I}}\rangle_{J_1} + \langle E_{\mathcal{J}}\rangle \langle E_{\mathcal{I}}\rangle \|\tilde{\Lambda}_{\mathcal{I},\mathcal{I}} V_{\mathcal{I},\mathcal{I}} - V_{\mathcal{I},\mathcal{I}} \Lambda'_{\mathcal{I}}\| \\ &+ \langle E_{\mathcal{J}}\rangle \langle E\rangle \langle R\rangle_{J_1^{-1}} \langle E_{\mathcal{I}}\rangle_{J_1} \le \sqrt{\rho_1}\,\big(\langle R_{\mathcal{J}}\rangle_{J^{-1}} \langle E_{\mathcal{I}}\rangle_J + \langle E_{\mathcal{J}}\rangle \langle E_{\mathcal{I}}\rangle \langle R_{\mathcal{I}}\rangle_{J^{-1}} \langle E_{\mathcal{I}}\rangle_J \\ &+ \langle E_{\mathcal{J}}\rangle^2 \langle E_{\mathcal{I}}\rangle^2 \langle R_{\mathcal{J}}\rangle_{J^{-1}} \langle E_{\mathcal{I}}\rangle_J + \langle E_{\mathcal{J}}\rangle \langle E\rangle_J \langle R\rangle_{J^{-1}} \langle E_{\mathcal{I}}\rangle_J\big) \le \sqrt{\rho_1 \hat{c}_3 \delta_\lambda \delta_{\lambda,\mathcal{I}}},\end{aligned}$$

where $\hat{c}_3$ depends on ρ_m, δ_m, δ_k (for $k > 1$), and δ_l only. Applying (A.11), we obtain

$$|\operatorname{Tr}\Lambda'_{\mathcal{I}} - \Lambda_{\mathcal{I},\mathcal{I}}| \le \frac{2}{\delta_{\mathcal{I},\mathcal{J}}} \langle R'_{\mathcal{I}}\rangle_{B^{-1}}^2 \le \frac{2\rho_1 \hat{c}_3}{\delta_{\mathcal{I},\mathcal{J}}} \delta_\lambda \delta_{\lambda,\mathcal{I}}.$$

Thus,

$$\begin{aligned}|\delta_{\lambda,\mathcal{I}} + \langle R_{\mathcal{I}}^* E_{\mathcal{I}}\rangle| &= \Big|\operatorname{Tr}\tilde{\Lambda}_{\mathcal{I},\mathcal{I}} + \operatorname{Tr} R_{\mathcal{I}}^* E_{\mathcal{I}} - \operatorname{Tr}\Lambda_{\mathcal{I},\mathcal{I}}\Big| = \big|\operatorname{Tr}\Lambda'_{\mathcal{I},\mathcal{I}} - \operatorname{Tr}\Lambda_{\mathcal{I},\mathcal{I}}\big| \\ &\le \big|\operatorname{Tr}\Lambda'_{\mathcal{I},\mathcal{I}} - \operatorname{Tr}\Lambda'_{\mathcal{I}}\big| + |\operatorname{Tr}\Lambda'_{\mathcal{I}} - \operatorname{Tr}\Lambda_{\mathcal{I},\mathcal{I}}| \le \left(\hat{c}_1 \frac{\delta_\lambda}{\lambda_{m+1} - \lambda_m} + 2\rho_1 \hat{c}_3 \frac{\delta_\lambda}{\delta_{\mathcal{I},\mathcal{J}}}\right) \delta_{\lambda,\mathcal{I}} \\ &\le \left(\hat{c}_1 + 2\hat{c}_3 \rho_m \frac{\lambda_{m+1} - \lambda_1}{\delta_{\mathcal{I},\mathcal{J}}}\right) \frac{\delta_\lambda \delta_{\lambda,\mathcal{I}}}{\lambda_{m+1} - \lambda_m} \le (\hat{c}_1 + 2\hat{c}_3 \rho_m \hat{c}_4) \frac{\delta_\lambda \delta_{\lambda,\mathcal{I}}}{\lambda_{m+1} - \lambda_m},\end{aligned}$$

where $\hat{c}_4 = 2\delta_l^{-1}$.

It remains to note that if $\delta_{\lambda,\mathcal{I}} > \delta_{\lambda,0}$, then a similar estimate holds, notably,

$$\begin{aligned}|\delta_{\lambda,\mathcal{I}} + \langle R_{\mathcal{I}}^* E_{\mathcal{I}}\rangle| &\le \delta_{\lambda,\mathcal{I}} + \langle R_{\mathcal{I}}\rangle_{J^{-1}} \langle E_{\mathcal{I}}\rangle_J \le (1 + \sqrt{c_3 c_4})\, \frac{\delta_\lambda}{\delta_{\lambda,0}} \delta_{\lambda,\mathcal{I}} \\ &\le 2\hat{c}_2\,(1 + \sqrt{c_3 c_4})\, \frac{\delta_\lambda}{\delta_{\mathcal{I},\mathcal{J}}} \delta_{\lambda,\mathcal{I}} \le 2\hat{c}_2 \hat{c}_4\,(1 + \sqrt{c_3 c_4})\, \frac{\delta_\lambda \delta_{\lambda,\mathcal{I}}}{\lambda_{m+1} - \lambda_m}.\end{aligned}$$

Together with (B.14) and (B.15), the estimates just obtained yield (3.14) and (3.15).

B.2. Proof of Theorem 3.4. The result in question is shift-invariant; hence below we assume L to be shifted so that $\lambda_1 = 0$.

In addition to the notation of section 3 and section B.1, let us denote $H = [h_1, \dots, h_m]$. The Ritz values ν_j are the eigenvalues of $B^{-1}A$, where $A = (\tilde{X} - H)^* L(\tilde{X} - H) = \tilde{\Lambda} - \tilde{X}^* L H - H^* L \tilde{X} - H^* L H = \tilde{\Lambda} - R^* H - H^* R - H^* L H$, $\tilde{\Lambda}$ is a diagonal matrix with $\tilde{\lambda}_j$ on the diagonal, $B = (\tilde{X} - H)^*(\tilde{X} - H) = I + H^* H$, and I is the m-by-m identity matrix. Let us denote $\delta A = A - \tilde{\Lambda}$ and $\delta B = B - I$. A direct calculation shows that (cf. Lemma 2 in Appendix A of [14])

$$\operatorname{Tr}(B^{-1}A) = \operatorname{Tr}(B_d^{-1}A_d) - \operatorname{Tr}A_1 + \operatorname{Tr}A_2 + \operatorname{Tr}A_3,$$

where $A_1 = B_d^{-1}\delta B B_d^{-1}\delta A$, $A_2 = B_d^{-1}\delta B_d B_d^{-1}\delta A_d$, $A_3 = B_d^{-1}B_o B^{-1} B_o B_d^{-1} A$, M_d stands for the diagonal matrix with the same diagonal as in M, and $M_o = M - M_d$. We observe that the diagonal entries of $B_d^{-1}A_d$ are μ_j; hence, to prove the theorem for $l = m$, it remains to estimate the traces of A_1, A_2, and A_3. Since $\operatorname{Tr}(ST) \le \operatorname{Tr}S\|T\|$ for any Hermitian positive definite S and Hermitian T (see Appendix A in [14]), we have $|\operatorname{Tr}(ST)| \le \operatorname{Tr}S\|T\| \le \operatorname{Tr}S\langle T\rangle$, and hence

$$|\operatorname{Tr}A_1| \le \operatorname{Tr}(B_d^{-1}\delta B B_d^{-1})\|\delta A\| \le \operatorname{Tr}(\delta B)\langle \delta A\rangle, \quad |\operatorname{Tr}A_2| \le \operatorname{Tr}(\delta B_d)\langle \delta A\rangle,$$

$$|\operatorname{Tr}A_3| \le \operatorname{Tr}(B_d^{-1}B_o B^{-1} B_o B_d^{-1})\|A\| = \langle B^{-\frac{1}{2}} B_o B_d^{-1}\rangle^2 \|A\| \le \langle \delta B\rangle^2 \|A\|,$$

where we have used the fact that $B \ge I$ and $\langle B_o\rangle = \langle \delta B_o\rangle \le \langle \delta B\rangle$. It is not difficult to see that $\operatorname{Tr}(\delta B) = \operatorname{Tr}(\delta B_d) = \langle H\rangle^2 \le \gamma^{-1}\langle H\rangle_J^2$, $\langle \delta A\rangle \le 2\langle R\rangle_{J_1^{-1}}\langle H\rangle_{J_1} + \langle H\rangle_L^2 \le 2\sqrt{\rho_1}\langle R\rangle_{J^{-1}}\langle H\rangle_J + \rho_1\langle H\rangle_J^2$, $\langle \delta B\rangle \le \langle H\rangle^2$, and $\|A\| \le \tilde{\lambda}_m - \lambda_1 + \|\delta A\| \le \lambda_{m+1} - \lambda_1 + \langle \delta A\rangle$. In view of (3.20) and (3.21), $\|h_j\|_{J_j}^2 \le \tilde{\lambda}_j - \mu_j$ and $\|r_j\|_{J_j^{-1}}^2 \le \eta(\tilde{\lambda}_j - \mu_j)$. Thus, for $l = m$ we have (3.22) with $c = c_0$, where c_0 depends on ρ_1, ρ_m, and η only.

Turning now to the general case, denote $\mathcal{W}_{\mathcal{I}} = \operatorname{span}\{w_j\}_{j\in\mathcal{I}}$, where $\mathcal{I} = \{1, \dots, l\}$, and denote by $\nu_j^{\mathcal{I}}$ the Ritz values of L in $\mathcal{W}_{\mathcal{I}}$. Repeating the above calculations with $A_{\mathcal{I},\mathcal{I}}$ and $B_{\mathcal{I},\mathcal{I}}$ substituted for A and B, we arrive at the estimate

$$\left|\sum_{j=1}^{l}(\nu_j^{\mathcal{I}} - \mu_j)\right| \le \frac{c_0\,(\delta_{\mu,\mathcal{I}})^2}{\lambda_{m+1} - \lambda_m}, \quad \delta_{\mu,\mathcal{I}} = \sum_{j=1}^{l}(\tilde{\lambda}_j - \mu_j). \tag{B.17}$$

We observe that $\tilde{\lambda}_j - \mu_j = (J(\mu_j, \tilde{\mathcal{X}})h_j, h_j) \le \rho_1\|h_j\|_{J_j}^2 \le \rho_1\|r_j\|_{J_j^{-1}}^2$, and hence $\delta_{\mu,\mathcal{I}} \le c_1\delta_{\lambda,\mathcal{I}} \le c_1\delta_\lambda \le c_1(\lambda_{m+1} - \lambda_m)$, where $\delta_{\lambda,\mathcal{I}}$ is the sum of $\tilde{\lambda}_j - \lambda_j$, $j = 1, \dots, l$, and $c_1 = 8\rho_1^2$ (cf. (B.7)). Further, (3.21) implies, via (A.10), $\delta_{\lambda,\mathcal{I}} \le c_2\delta_{\mu,\mathcal{I}}$, where c_2 depends on ρ_1, $\tilde{\delta}_l$, and η only. By the minimax principle, $\lambda_j \le \nu_j \le \nu_j^{\mathcal{I}}$. Thus,

$$\left|\sum_{j=1}^{l}(\nu_j - \mu_j)\right| \le \max\left\{\left|\sum_{j=1}^{l}(\lambda_j - \mu_j)\right|, \left|\sum_{j=1}^{l}(\nu_j^{\mathcal{I}} - \mu_j)\right|\right\}$$

$$\le \max\{\delta_{\lambda,\mathcal{I}} + \delta_{\mu,\mathcal{I}}, c_0c_1\delta_{\mu,\mathcal{I}}\} \le \max\{c_2 + 1, c_0c_1\}\delta_{\mu,\mathcal{I}},$$

which trivially implies (3.22) for $\delta_\lambda > \delta_0 = (\lambda_{m+1} - \lambda_m)/c_3$, where c_3 is an arbitrary positive value depending on the same parameters as c. It remains to prove (3.22) for $\delta_\lambda \le \delta_0$.

The estimate (B.17) suggests that in order to complete the proof, we need to estimate the difference between μ_j and $\nu_j^{\mathcal{I}}$. We observe that the latter are the eigenvalues

of $B_{\mathcal{I},\mathcal{I}}^{-1}A_{\mathcal{I},\mathcal{I}}$ and hence are the Ritz values of the generalized problem $Av = \lambda Bv$ in the subspace spanned by the columns of the m-by-m identity matrix with indices from $\mathcal{I}$. Denote by $V_{\mathcal{I}}$ and $R'_{\mathcal{I}}$ the matrices whose columns are the corresponding Ritz and residual vectors, respectively, and observe that the only nonzero rows of $R'_{\mathcal{I}}$ are those with indices from $\mathcal{J} = \{l+1, \dots, m\}$ and that they form the matrix

$$A_{\mathcal{J},\mathcal{I}}V_{\mathcal{I},\mathcal{I}} - B_{\mathcal{J},\mathcal{I}}V_{\mathcal{I},\mathcal{I}}\Lambda'_{\mathcal{I}} = (-R^*_{\mathcal{J}}H_{\mathcal{I}} - H^*_{\mathcal{J}}R_{\mathcal{I}} + H^*_{\mathcal{J}}LH_{\mathcal{I}})V_{\mathcal{I},\mathcal{I}} - H^*_{\mathcal{J}}H_{\mathcal{I}}V_{\mathcal{I},\mathcal{I}}\Lambda'_{\mathcal{I}},$$

where $V_{\mathcal{I},\mathcal{I}}$ is the block of $V_{\mathcal{I}}$ formed by rows with indices from $\mathcal{I}$, and $\Lambda'_{\mathcal{I}}$ is a diagonal matrix with $\lambda_j^{\mathcal{X}'_{\mathcal{I}}}$ on the diagonal. Assuming the Ritz vectors in question to be normalized by $V^*_{\mathcal{I},\mathcal{I}}B_{\mathcal{I},\mathcal{I}}V_{\mathcal{I},\mathcal{I}} = I_{\mathcal{I},\mathcal{I}}$, we have $\|V_{\mathcal{I},\mathcal{I}}\| \le 1$; owing to this and to (3.20) and (3.21) we have $\langle R'_{\mathcal{I}}\rangle \le c_4\delta_{\lambda,\mathcal{I}}\delta_{\lambda,\mathcal{J}}$, where c_4 has the same dependencies as c and $\delta_{\lambda,\mathcal{J}}$ is the sum of $\tilde{\lambda}_j - \lambda_j$, $j = l+1, \dots, m$. In order to apply the residual estimates of section A.2, let us find c_3 that ensures $\lambda_{l+1} - \nu_l^{\mathcal{I}} \ge (\lambda_{l+1} - \lambda_l)/2$. Since $\nu_l^{\mathcal{I}}$ is the largest eigenvalue of $B_{\mathcal{I},\mathcal{I}}^{-1}A_{\mathcal{I},\mathcal{I}}$, it is also the largest eigenvalue of $B_{\mathcal{I},\mathcal{I}}^{-1/2}A_{\mathcal{I},\mathcal{I}}B_{\mathcal{I},\mathcal{I}}^{-1/2}$ and hence is equal to $\|B_{\mathcal{I},\mathcal{I}}^{-1/2}A_{\mathcal{I},\mathcal{I}}B_{\mathcal{I},\mathcal{I}}^{-1/2}\| \le \|A_{\mathcal{I},\mathcal{I}}\| \le \|\tilde{\Lambda}_{\mathcal{I},\mathcal{I}}\| + \|\delta A_{\mathcal{I},\mathcal{I}}\| \le \tilde{\lambda}_l + \langle \delta A\rangle \le \tilde{\lambda}_l + c_5\delta_\lambda$. Therefore, $\lambda_{l+1} - \nu_l^{\mathcal{I}} = \lambda_{l+1} - \tilde{\lambda}_l + \tilde{\lambda}_l - \nu_l^{\mathcal{I}} \ge \lambda_{l+1} - \tilde{\lambda}_l - c_5\delta_\lambda \ge \lambda_{l+1} - \lambda_l - (1+c_5)\delta_\lambda$. Thus, c_3 should be set to $2(\lambda_{m+1} - \lambda_m)$ divided by $(\lambda_{l+1} - \lambda_l)/(1+c_5)$. It remains to apply (A.11) to arrive at

$$\left|\sum_{j=1}^{l}(\nu_j - \nu_j^{\mathcal{I}})\right| \le \frac{2c_4\delta_{\lambda,\mathcal{I}}\delta_{\lambda,\mathcal{J}}}{\lambda_{l+1} - \lambda_l} \le \frac{2c_4c_1\delta_\lambda}{\lambda_{l+1} - \lambda_l}\sum_{j=1}^{l}(\tilde{\lambda}_j - \mu_j),$$

which, together with (B.17), yields (3.22).

B.3. An auxiliary estimate for residuals.

LEMMA B.1. *Assuming that the search directions y_j^i employed by (2.1)–(2.2) satisfy $(J(\lambda_1, \mathcal{X}^i)y_j^i, y_j^i) \le \sigma(Kr_j^i, r_j^i)$ for some $\sigma > 0$, the following inequality is valid:*

$$\sum_{j=1}^{l}\|r\|_K^2 \le \sigma\sum_{j=1}^{l}(\lambda_j^i - \lambda_j^{i+1}). \tag{B.18}$$

Proof. The result in question is shift-invariant; hence we assume, in order to simplify the calculations, that $\lambda_1 = 0$. Denote $X_l^i = [x_j^i]_{j=1}^l$; $Y_l^i = [(1-P_i)y_j^i]_{j=1}^l$, where P_i is the orthogonal projector onto $\mathcal{X}^i$; $R_l^i = [r_j^i]_{j=1}^l$; $\Lambda_l^i = \operatorname{diag}\{\lambda_j^i\}_{j=1}^l$. Let ν_j^i be the Ritz values of L in $\mathcal{U}^i = \operatorname{span}\{X_l^i - \tau Y_l^i\}$, where $\tau = \sigma^{-1}$. Since $\mathcal{U}^i \subset \mathcal{V}^i = \operatorname{span}\{X^i, Y^i\}$, the minimax principle implies $\lambda_j^{i+1} \le \nu_j^i$. The Ritz values ν_j^i are the eigenvalues of the generalized problem $Au = \nu Bu$, where $A = (X_l^i)^*LX_l^i - \tau(X_l^i)^*LY_l^i - \tau(Y_l^i)^*LX_l^i + \tau^2(Y_l^i)^*LY_l^i = \Lambda_l^i - \tau(R_l^i)^*Y_l^i - \tau(Y_l^i)^*R_l^i + \tau^2(Y_l^i)^*LY_l^i = \Lambda_l^i - 2\tau(R_l^i)^*KR_l^i + \tau^2(Y_l^i)^*LY_l^i$; $B = I + \tau^2(Y_l^i)^*Y_l^i$; and I is l-by-l identity. Since $A \ge 0$ and $B \ge I$, the Ritz values ν_j^i are not greater than the eigenvalues of A. The assumption $(J(\lambda_1, \mathcal{X}^i)y_j^i, y_j^i) = (L(1-P_i)y_j^i, (1-P_i)y_j^i) \le \sigma(Kr_j^i, r_j^i)$ implies $\tau^2(Y_l^i)^*LY_l^i \le \tau(R_l^i)^*KR_l^i$, and hence the eigenvalues of A are not greater than the eigenvalues of $\hat{A} = \Lambda_l^i - \tau(R_l^i)^*KR_l^i$. Thus, λ_j^{i+1}, $j = 1, \dots, l$, are not greater than the eigenvalues of $\hat{A}$, and considering the trace of $\hat{A}$ results in (B.18). ∎

B.4. Proof of the estimate (4.7). The eigenvalue problem for A_{ij} is equivalent to the generalized eigenvalue problem $J_{ij}KJ_{ij}u = \xi J_{ij}u$, and the proof of (4.7) exploits this fact and the following energy norm equivalences: (i) the equivalence of the K- and L^{-1}-norms, responsible for the first factor in (4.7), (ii) the equivalence of the L^{-1}- and $J(0,\mathcal{X}^i)^{-1}$-norms, responsible for the second (bracketed) factor, and (iii) the equivalence of the $J(0,\mathcal{X}^i)^{-1}$ and J_{ij}^{-1}-norms, responsible for the last factor.

Denote by α and ω the minimal and the maximal eigenvalue of KL. We have $\alpha L^{-1} \le K \le \omega L^{-1}$, and hence for the eigenvalues ξ_k of A_{ij} we have $\alpha\eta_k \le \xi_k \le \omega\eta_k$, where η_k are the eigenvalues of the problem $J_{ij}L^{-1}J_{ij}v = \eta J_{ij}v$. As we have shown in section B.1, $\|r\|_{J_0^{-1}} \le \|r\|_{L^{-1}}$ for any $r \in (\mathcal{X}^i)^\perp$, where $J_0 = J(0,\mathcal{X}^i)$ (cf. the argument just above (B.7)). Thus, $(J_{ij}L^{-1}J_{ij}u,u) = \|J_{ij}u\|^2_{L^{-1}} \ge \|J_{ij}u\|^2_{J_0^{-1}} \ge (\gamma_{ij}/\gamma_i)\|J_{ij}u\|^2_{J_{ij}^{-1}} = (\gamma_{ij}/\gamma_i)\|u\|^2_{J_{ij}}$, where $\gamma_i = \lambda_{m+1} - \delta_\lambda(\mathcal{X}^i)$, $\gamma_{ij} = \lambda_{m+1} - \delta_\lambda(\mathcal{X}^i) - \lambda^i_j$, and we have used (3.12), which implies $\eta_k \ge \gamma_{ij}/\gamma_i$. In order to establish an upper bound for η_k, consider an auxiliary linear system $Lu = J_{ij}v$. We have $\|u\|^2_L = (J_{ij}v,u) \le \|v\|_{J_{ij}}\|u\|_{J_{ij}} \le \|v\|_{J_{ij}}\|u\|_{J_0}$. Denote by Q_i the $(\cdot,\cdot)_L$-orthogonal projector onto $\mathcal{X}^i$. As we have seen in section B.1 (Step 3), $Q_i = P_i + X^i\Lambda_i^{-1}(R^i)^*$, where Λ_i is an m-by-m diagonal matrix with λ^i_j on the diagonal. Since $((1-Q_i)u,(Q_i-P_i)u)_L = 0$, we have $\|u\|^2_{J_0} = \|(1-P_i)u\|_L = \|(1-Q_i)u\|^2_L + \|(Q_i-P_i)u\|^2_L \le \|u\|^2_L + \|X^i\Lambda_i^{-1}(R^i)^*u\|^2_L \le \|u\|^2_L + \tilde\lambda_m\|R_i\Lambda_i^{-1}\|^2_{L^{-1}}\|u\|^2_L \le (1+\lambda_{m+1}\|R_i\Lambda_i^{-1}\|^2_{L^{-1}})\|u\|^2_L \equiv \pi_m\|u\|^2_L$, and hence $\|u\|^2_L \le \pi_m\|v\|^2_{J_{ij}}$. Observing that $\|u\|_L = \|L^{-1}J_{ij}v\|_L = \|J_{ij}v\|_{L^{-1}}$, we conclude that $\|J_{ij}v\|^2_{L^{-1}} = (J_{ij}L^{-1}J_{ij}v,v) \le \pi_m(J_{ij}v,v)$. It remains to apply the estimate (B.5) for $\langle R^i\Lambda_i^{-1}\rangle_{L^{-1}} \ge \|R^i\Lambda_i^{-1}\|_{L^{-1}}$ to obtain an upper bound for π_m and hence for η_k. The obtained bounds for η_k yield the bounds for ξ_k that, in turn, yield (4.7).

RECOVERY OF EDGES FROM SPECTRAL DATA WITH NOISE—A NEW PERSPECTIVE*

SHLOMO ENGELBERG† AND EITAN TADMOR‡

Abstract. We consider the problem of detecting edges—jump discontinuities in piecewise smooth functions from their N-degree spectral content, which is assumed to be corrupted by noise. There are three scales involved: the "smoothness" scale of order $1/N$, the noise scale of order $\sqrt{\eta}$, and the $\mathcal{O}(1)$ scale of the jump discontinuities. We use concentration factors which are adjusted to the standard deviation of the noise $\sqrt{\eta} \gg 1/N$ in order to detect the underlying $\mathcal{O}(1)$-edges, which are separated from the noise scale $\sqrt{\eta} \ll 1$.

Key words. piecewise smoothness, edge detection, noisy data, concentration kernels, constrained optimization, separation of scales

AMS subject classifications. 42A10, 42A50, 65T10

DOI. 10.1137/070689899

1. Introduction and statement of main results.

We consider the detection of jump discontinuities in piecewise smooth data from its Fourier projection

$$S_N f(x) = \sum_{|k|\le N} \widehat{f}(k) e^{ikx}, \qquad \widehat{f}(k) := \frac{1}{2\pi}\int_{-\pi}^{\pi} f(\xi) e^{-i\xi x}.$$

Our approach for edge detection—we use the terminology of edges or jump discontinuities interchangeably—is based on the technique of *concentration kernels* advocated in [3, 4] and the closely related techniques described in [2]. The technique presented makes use of the fact that, if f is discontinuous, its Fourier coefficients contain a slowly decaying part associated with the jumps of f. This part decays much more slowly than the rapidly decaying smooth part of f. For example, if f is smooth except for a single jump discontinuity at $x = z$ of size $[f](z) := f(z+) - f(z-)$, the jump discontinuity is associated with slowly decaying Fourier coefficients (here and below we use $X \lesssim Y$ to denote the estimate $X \le CY$, where C is a constant which is independent of the variables $k, N, \dots$)

$$\widehat{f}(k) = [f](z)\frac{e^{-ikz}}{2\pi ik} + \widehat{s}(k), \qquad |\widehat{s}(k)| \lesssim \frac{1}{|k|^2}, \quad [f](x) := f(x+) - f(x-),$$

where $\widehat{s}(k)$ are the Fourier coefficients of s, the smooth part of f; the smoother s is, the faster is the decay of $\widehat{s}(k)$. Concentration kernels succeed in separating the two sets of coefficients. To this end one computes

$$\mathcal{K}_N^\sigma * (S_N f)(x) = \pi i \sum_{|k|\le N} \mathrm{sgn}(k)\sigma_N\left(\frac{|k|}{N}\right)\widehat{f}(k)e^{ikx}, \qquad \mathrm{sgn}(k) := \begin{cases} k/|k| & k \ne 0, \\ 0 & k = 0. \end{cases}$$

This author's research was supported in part by NSF grant 07-07949 and ONR grant N00014-91-J-1076.

Here, $\sigma_N(\xi)$ can be drawn from a large family of properly normalized concentration factors that is at our disposal. The resulting function tends to zero in regions in which f is smooth and tends to the amplitude of the jumps at points where the function has jump discontinuities, e.g., [8, section 4],

$$\mathcal{K}_N^\sigma * (S_N f)(x) = [f](x) + \mathcal{O}\left(\frac{\log N}{N}\right).$$

Thus, jump discontinuities, or edges, are detected by *separation of scales*: the quantity on the right is of a vanishing order $\lesssim (\log N)/N$, in regions of smoothness of f, and it is $\gg (\log N)/N$, in the neighborhood of jump discontinuities of f.

In this paper we utilize concentration kernels to detect edges from spectral information which is corrupted by *white noise*. In this context we observe that there are three scales involved—edges of order $\mathcal{O}(1)$, noise with variance $\mathcal{O}(\eta)$, and the smooth part of f which is resolved within order $\mathcal{O}(1/N)$ or smaller. Here, we can separate the noisy part $n(x)$ from the smooth part

$$s(x) \to s(x) + n(x), \qquad E(|\widehat{n}(k)|^2) = \eta;$$

if $\sqrt{\eta} \lesssim 1/N$, then the noisy part could be identified with (or below) the $\mathcal{O}(1/N)$-variation of the smooth part of f. In this case, there are essentially two scales, and edges can be detected using the usual framework of concentration kernels advocated in [3, 4]. Thus, our main focus in this paper is when the smoothness scale is dominated by the scale of the noise which is still well separated from the $\mathcal{O}(1)$-scale of the jumps,[1]

$$\frac{1}{N} \lesssim \sqrt{\eta} \ll 1.$$

The spectral information is now corrupted by white noise, affecting both low and high frequencies:

$$\widehat{f}(k) = [f](z)\frac{e^{-ikz}}{2\pi ik} + \widehat{s}(k) + \widehat{n}(k).$$

In order to separate edges from the noisy scale, the edge detector $K_N^\sigma f(x)$ must be properly adapted to the presence of white noise. We show how to design edge detectors that optimally compensate for noise and for the effects of the smooth part of the signal.

The paper is organized as follows. In section 2 we discuss the general framework of edge detection based on concentration kernels. We revisit the results of [4, 8], providing a simpler proof for the concentration property for a large family of concentration factors. In particular, we trace the precise dependence of the error on the regularity of the associated concentration factor. This will prove useful when we deal with noisy data in section 3. Here, we introduce our new perspective, where concentration factors are derived by a constrained minimization while taking into account the two main ingredients of our data—jump discontinuities and the noisy parts of the data. Numerical results are demonstrated in section 4. In section 5 we extend our construction of concentration factors to include the *three* ingredients of the data—taking into account the smooth part of the data in addition to the edges and noisy parts; numerical results are presented in section 6.

[1] Here and below, $X \ll Y$ indicates that X is an "order of magnitude smaller" than Y, so that $\lim_{N\to\infty} X/Y \to 0$, $X \sim Y$, indicates that X and Y are "of the same order of magnitude," namely, $X \lesssim Y \lesssim X$, and $X \approx Y$ indicates that $\lim_{N\to\infty} |X - Y| = 0$.

2. Detection of edges—concentration kernels. Consider an f which is *piecewise smooth* in the sense that it is sufficiently smooth except for finitely many jump discontinuities, say, at $z_1 < z_2, \dots < z_m$, where

$$[f](z_j) := f(z_j+) - f(z_j-) \neq 0, \quad j = 1, 2, \dots m.$$

Given the Fourier coefficients $\left\{\widehat{f}(k)\right\}_{k=-N}^{N}$, we are interested in detecting the edges of the underlying piecewise smooth f, namely, to detect their location $z_1, \dots, z_m$ and their amplitudes $[f](z_1), \dots, [f](z_m)$.

We utilize edge detection based on *concentration kernels*

$$\mathcal{K}_N^\sigma(y) := -\sum_{k=1}^{N} \sigma_N\left(\frac{k}{N}\right) \sin ky, \qquad \frac{\sigma_N(\xi)}{\xi} \in C^1[0,1]. \tag{2.1a}$$

We shall need the kernel $-\mathcal{K}_N^\sigma$ to have (approximately) unit mass

$$\int_0^\pi \mathcal{K}_N^\sigma(y)dy \approx -1.$$

To this end, we require that $\sigma(\xi) \equiv \sigma_N(\xi)$ be a properly normalized concentration factor so that $\sigma(\xi)$ satisfies

$$\int_0^1 \frac{\sigma(\xi)}{\xi} d\xi = 1. \tag{2.1b}$$

Indeed, the rectangular quadrature rule yields

$$\begin{aligned}\int_0^\pi \mathcal{K}_N^\sigma(y)dy &= \sum_{k=1}^{N} \sigma\left(\frac{k}{N}\right) \frac{(-1)^k - 1}{k} \\ &= -\sum_{k \text{ odd}\geq 1}^{N} \frac{\sigma(\xi_k)}{\xi_k} \frac{2}{N} = -\int_0^1 \frac{\sigma(\xi)}{\xi} d\xi + \delta_N, \quad \xi_k := \frac{k}{N},\end{aligned}$$

with an error estimate, e.g., [6, 1],

$$\left| \int_0^\pi \mathcal{K}_N^\sigma(y)dy + 1 \right| \lesssim \delta_N, \qquad \delta_N := \frac{1}{N} \left\| \frac{\sigma_N(\xi)}{\xi} \right\|_{BV}. \tag{2.2}$$

We set[2]

$$K_N^\sigma f(x) := \mathcal{K}_N^\sigma * f(x) = \pi i \sum_{|k|\leq N} \operatorname{sgn}(k) \sigma_N\left(\frac{|k|}{N}\right) \widehat{f}(k) e^{ikx}.$$

Our purpose is to choose the *concentration factors* $\sigma_N(|k|/N)$ such that $K_N^\sigma f(x) \approx [f](x)$. Thus, $K_N^\sigma f(x)$ will detect the edges $[f](z_j)$, $j = 1, \dots, m$, by concentrating near these $\mathcal{O}(1)$-edges, which are to be separated from a much smaller scale of order $K_N^\sigma f(x) \approx 0$ in regions of smoothness. In the following theorem we present a rather

[2]We observe that $K_N^\sigma f$ is the *operator* associated with, but otherwise different from, the concentration kernel $\mathcal{K}_N^\sigma(x)$.

general framework for edge detectors based on concentration factors. In particular, we track the precise dependence of the scale separation on the behavior of σ.

THEOREM 2.1 (concentration kernels). *Assume that $f(\cdot)$ is piecewise smooth such that the first variation of f is of locally bounded variation (BV)*

$$\omega_x(y) \equiv \omega_f(y,x) := \frac{f(x+y) - f(x-y) - [f](x)}{y} \in BV[-\pi,\pi]. \tag{2.3}$$

Let $\mathcal{K}_N^\sigma(x)$ be an admissible concentration kernel (2.1) *such that*

$$\delta_N := \frac{1}{N}\left\| \frac{\sigma_N(\xi)}{\xi} \right\|_{BV} \ll 1, \tag{2.4a}$$

$$\varepsilon_1(N) := \frac{1}{N}|\sigma_N(1)| \ll 1, \tag{2.4b}$$

$$\varepsilon_2(N) := \frac{1}{N}\int_{\xi\sim\frac{1}{N}}^{1} \frac{|\sigma_N'(\xi)|}{\xi} d\xi \ll 1, \tag{2.4c}$$

$$\varepsilon_3(N) := \left|\sigma_N\left(\frac{1}{N}\right)\right| \ll 1. \tag{2.4d}$$

Set

$$\varepsilon_N := \varepsilon_1(N) + \varepsilon_2(N) + \varepsilon_3(N). \tag{2.5}$$

Then, the conjugate sum

$$K_N^\sigma f(x) = \pi i \sum_{|k|\le N} \operatorname{sgn}(k)\sigma_N\left(\frac{|k|}{N}\right)\widehat{f}(k)e^{ikx} \tag{2.6}$$

satisfies the concentration property

$$|K_N^\sigma f(x) - [f](x)| \lesssim \delta_N + \varepsilon_N \|\omega_x(\cdot)\|_{BV}. \tag{2.7}$$

Proof. We simplify the proof in [4, 8]. The key to the proof is to observe that $\mathcal{K}_N^\sigma$ is an appropriately normalized *derivative* of the delta function; in particular, since $\mathcal{K}_N^\sigma(\cdot)$ is odd

$$\begin{aligned}\mathcal{K}_N^\sigma * f(x) &= -\int_0^\pi K_N^\sigma(y)\Big(f(x+y) - f(x-y)\Big)dy \\ &= -\int_0^\pi \mathcal{K}_N^\sigma(y)\Big(f(x+y) - f(x-y) - [f](x)\Big)dy - [f](x)\times\int_0^\pi \mathcal{K}_N^\sigma(y)dy.\end{aligned}$$

Since σ is assumed normalized, the error estimate (2.2) tells us[3] that

$$\int_0^\pi \mathcal{K}_N^\sigma(y)dy = -1 + \mathcal{O}(\delta_N), \qquad \delta_N = \frac{1}{N}\left\| \frac{\sigma_N(\xi)}{\xi} \right\|_{BV},$$

and we end up with the error estimate

$$\left|K_N^\sigma f(x) - [f](x)\right| \lesssim \left|\int_0^\pi \mathcal{K}_N^\sigma(y) y\omega_x(y)dy\right| + \mathcal{O}(\delta_N). \tag{2.8}$$

[3]In our case, the errors for the trapezoidal and rectangular rules provided, respectively, in [1] and [6] coincide modulo the $\mathcal{O}(\varepsilon_1(N) + \varepsilon_3(N))$ terms.

To upper bound the expression on the right, we use the following identity, which is derived by a straightforward summation by parts:

$$2\sin(y/2)\mathcal{K}_N^\sigma(y) \equiv \overbrace{\sigma_N(1)\cos\left(N+\frac{1}{2}\right)y}^{I_1(y)} + \sum_{k=1}^{N-1}\overbrace{\Big(\sigma_N(\xi_k)-\sigma_N(\xi_{k+1})\Big)\cos\left(k+\frac{1}{2}\right)y}^{I_{2k}(y)} - \overbrace{\sigma_N(\xi_1)\cos\left(\frac{y}{2}\right)}^{I_3(y)}.$$

The usual cancellation estimate $|\int_0^\pi \cos((k+\frac{1}{2})y)w(y)dy| \lesssim \|w\|_{BV}/|k+\frac{1}{2}|$ implies that

$$\left|\int_0^\pi I_1(y)\frac{y/2}{\sin(y/2)}\omega_x(y)dy\right| \lesssim |\sigma_N(1)|\cdot\frac{1}{N}\|\omega_x(\cdot)\|_{BV} \le \varepsilon_1(N)\|\omega_x(\cdot)\|_{BV},$$
$$\left|\int_0^\pi I_{2k}(y)\frac{y/2}{\sin(y/2)}\omega_x(y)dy\right| \lesssim |\sigma(\xi_{k+1})-\sigma(\xi_k)|\cdot\frac{1}{k+\frac{1}{2}}\|\omega_x(\cdot)\|_{BV},$$
$$\left|\int_0^\pi I_3(y)\frac{y/2}{\sin(y/2)}\omega_x(y)dy\right| \lesssim \varepsilon_3(N)\cdot\|\omega_x(\cdot)\|_{L^\infty}.$$

We conclude that

$$\begin{aligned}\left|\int_0^\pi \mathcal{K}_N^\sigma(y)y\omega_x(y)dy\right| &= \left|\int_0^\pi\left(I_1(y)+\sum_k I_{2k}(y)+I_3(y)\right)\frac{y/2}{\sin(y/2)}\omega_x(y)dy\right| \\ &\lesssim \left(\varepsilon_1(N)+\sum_{k=1}^{N-1}\frac{|\sigma(\xi_{k+1})-\sigma(\xi_k)|}{\xi_{k+\frac{1}{2}}}\frac{1}{N}+\varepsilon_3(N)\right)\left\|\frac{y/2}{\sin(y/2)}\omega_x(y)\right\|_{BV} \\ &\lesssim \Big(\varepsilon_1(N)+\varepsilon_2(N)+\varepsilon_3(N)\Big)\|\omega_x(\cdot)\|_{BV}.\end{aligned} \tag{2.9}$$

The result (2.7) follows from (2.8) and (2.9). ∎

As an example, we consider the noise-free case with a concentration factor for which

$$\frac{\sigma_N(\xi)}{\xi}\in C^1. \tag{2.10}$$

Clearly $\delta_N \lesssim 1/N$, and, since σ is bounded, $\varepsilon_1(N)\lesssim 1/N$. Moreover, since $\sigma_N'(\xi)$ is bounded,

$$\varepsilon_2(N)\lesssim\frac{1}{N}\int_{\xi\sim\frac{1}{N}}^1\frac{1}{\xi}d\xi\lesssim\frac{\log(N)}{N}.$$

Finally, since $|\sigma_N(\xi)|\lesssim\xi$, then $\varepsilon_3(N)\lesssim 1/N$. Thus, Theorem 2.1 applies with $\delta_N=1/N$ and $\varepsilon_N=\log(N)/N$, which we summarize in the following corollary.

COROLLARY 2.2 (see [8, Theorem 4.1]). *Assume that $f(\cdot)$ is a piecewise smooth function whose first variation is BV bounded, so that* (2.3) *holds. Let $\mathcal{K}_N^\sigma(x)$ be a*

normalized concentration kernel (2.1) *with* $\frac{\sigma(\xi)}{\xi} \in C^1$. *Then* $K_N^\sigma f(x)$ *satisfies the concentration property*

$$|K_N^\sigma f(x) - [f](x)| \lesssim \delta_N + \frac{\log N}{N}\|\omega_x(\cdot)\|_{BV}, \qquad \omega_x(\cdot) \equiv \omega_f(\cdot, x). \tag{2.11}$$

Corollary 2.2 tells us that if x is sufficiently close to z_j, then $K_N^\sigma f(x)$ is close to $[f](z_j)$; but how close should x be? This is determined by the behavior of $\omega_f(\cdot, x)$, which in turn depends on the behavior of $f(\cdot)$ in the neighborhood of x. Our next theorem converts (2.11) into a precise error statement which depends solely on the position of x relative to the jump discontinuities but otherwise *is independent of the behavior of* f *near* x.

THEOREM 2.3 (concentration kernels revisited). *Assume that* $f(\cdot) \in BV[-\pi, \pi]$ *is a piecewise* C^2*-smooth function so that*

$$M_2 := \|f\|_{C^2\left(\cup_j (z_j, z_{j+1})\right)} < \infty.$$

Let $\mathcal{K}_N^\sigma(x)$ *be a normalized concentration kernel* (2.1) *with* $\sigma(\xi)/\xi \in C^1$. *Then, there exist constants depending on* M_2 *but otherwise independent of* N *such that* $K_N^\sigma f(x)$ *satisfies the concentration property*

$$K_N^\sigma f(x) = \begin{cases} [f](z_j) + \mathcal{O}\left(\dfrac{\log(N)}{N}\right) & \text{if } |x - z_j| \lesssim \dfrac{\log(N)}{N}, \quad j = 1, \dots, m, \\ \mathcal{O}\left(\dfrac{\log(N)}{N d_x}\right) & \text{if } d_x := dist\Big\{x, \{z_1, \dots, z_m\}\Big\} \gg \dfrac{1}{N}. \end{cases} \tag{2.12}$$

Remark 2.4. Theorem 2.3 tells us that admissible kernels $\mathcal{K}_N^\sigma(x)$ tend to concentrate in the immediate $\mathcal{O}(1/N)$-neighborhood of the jump discontinuities z_j's, where they approach the amplitude of these jumps $[f](z_j)$, while they decay to zero away from these jumps, where $\log(N)/Nd_x \sim 0$ as $d_x \gg 1/N$. We note in passing that for the concentration property $K_N^\sigma f(x) \to [f](x)$ to hold, it suffices to require the integrability $\omega_f(\cdot, x) \in L^1 \ \forall x$, e.g., [3, 7, 5], and the references therein. The BV regularity of $\omega_f(\cdot, x)$ enables us to derive the first-order concentration rate stated in (2.11), and, when f satisfies the stronger assumption of piecewise C^2 smoothness, we have the improved first-order rate (2.12). In practice, the decay rate may be even *faster* than first order, depending on the fine properties of σ; consult [4, p. 1396].

The proof of Theorem 2.3 is based on the following sharp upper-bound:

$$\|\omega_x(\cdot)\|_{BV} \lesssim d_x \|f\|_{C^2(I_x)} + \frac{1}{d_x}\|f\|_{BV}, \tag{2.13}$$

here and below, I_x denotes the largest *punctured* interval of smoothness enclosing x, and d_x denotes the distance to the nearest jump, that is,[4]

$$\begin{aligned} &I_x = (x - d_x, x) \cup (x, x + d_x), \\ &d_x := \begin{cases} \min\limits_{0 \le j \le m+1} |x - z_j| > 0 & \text{if } x \notin \{z_1, \dots, z_m\}, \\ \min\limits_{\pm}\{|z_j - z_{j\pm 1}|\} > 0 & \text{if } x = z_j, \quad j = 1, 2, \dots m. \end{cases} \end{aligned} \tag{2.14}$$

[4]By periodicity, $z_0 := z_m - 2\pi$ and $z_{m+1} := z_1 + 2\pi$.

We postpone the proof of (2.13) to the end of this section (consult Lemma 2.5 below), and we turn to the proof of Theorem 2.3, where we distinguish between three cases.

• *Case* (i). If x is a discontinuity point, say, $x = z_j$, then (2.13) with $d_k := d_{z_k}$ states that

$$\|\omega_{z_j}(\cdot)\|_{BV} \lesssim C_{11} := \max_k \left\{ d_k \|f\|_{C^2(I_{z_k})} + \frac{1}{d_k}\|f\|_{BV} \right\}, \qquad j = 1, 2, \ldots, m,$$

and Corollary 2.2 implies that

$$|K_N^\sigma f(z_j) - [f](z_j)| \le C_{11}\frac{\log N}{N}, \qquad j = 1, 2, \ldots, m. \tag{2.15a}$$

• *Case* (ii). Assume that x is near a discontinuity $|x - z_j| \lesssim \log(N)/N$. We note that $\mathcal{K}_N^\sigma$ is uniformly bounded:

$$\|\mathcal{K}_N^\sigma\|_{L^\infty} \lesssim \sum_{|k|\le N} \sigma\left(\frac{|k|}{N}\right)|\widehat{f}(k)| \lesssim \sum_{k=1}^{N} \frac{\sigma(\xi_k)}{\xi_k}\frac{1}{N}\|f\|_{BV} \lesssim C_{12}, \qquad C_{12} = (1+\delta_N)\|f\|_{BV},$$

which in turn implies the Lipchitz continuity of $K_N^\sigma f(x)$:

$$|K_N^\sigma f(x_2) - K_N^\sigma f(x_1)| \le \|\mathcal{K}_N^\sigma\|_{L^\infty} \int |f(x_2 - y) - f(x_1 - y)|dy \lesssim C_{12}|x_2 - x_1| \cdot \|f\|_{BV}. \tag{2.15b}$$

Combining (2.15a) and (2.15b) yields the first half of (2.12)

$$\begin{aligned} |K_N^\sigma f(x) - [f](z_j)| &\le |K_N^\sigma f(x) - K_N^\sigma f(z_j)| + |K_N^\sigma f(z_j) - [f](z_j)| \\ &\le C_{12}|x - z_j| \cdot \|f\|_{BV} + C_{11}\frac{\log N}{N} \lesssim \frac{\log N}{N}, \qquad |x - z_j| \lesssim \frac{\log(N)}{N}. \end{aligned}$$

• *Case* (iii). Finally, we assume that x is bounded away from the discontinuities $d_x \gg 1/N$. Then (2.13) and (2.11) yield the second half of (2.12)

$$|K_N^\sigma f(x)| \lesssim \frac{\log(N)}{N}\left(d_x\|f\|_{C^2(I_x)} + \frac{1}{d_x}\|f\|_{BV}\right) \lesssim \frac{\log(N)}{N d_x}, \qquad d_x \gg \frac{\log(N)}{N}.$$

We close this section with the following BV bound, which is the heart of the matter.

LEMMA 2.5 (BV bound). *Assume that $f(\cdot)$ is piecewise C^2-smooth, and let $I_x = (x - d_x) \cup (x, x + d_x)$ in* (2.14) *be the largest punctured interval of smoothness enclosing x. Then*

$$\|\omega_x(\cdot)\|_{BV} \lesssim d_x\|f\|_{C^2(I_x)} + \frac{1}{d_x}\|f\|_{BV}.$$

Proof. We decompose $\omega_x(y)$ into two symmetric parts:

$$\omega_x(y) = \frac{f(x + y) - f(x+)}{y} - \frac{f(x-) - f(x - y)}{y} =: \omega_+(y) - \omega_-(y).$$

To upper bound the variation of $\omega_+(\cdot)$ we compute

$$\begin{aligned} \omega_+'(y) &= -\frac{f(x + y) - f(x+) - yf'(x + y)}{y^2} \\ &= \frac{-1}{y^2}\left(\int_{x+}^{x+y} f'(\xi)d\xi - yf'(x + y)\right) \\ &= \frac{1}{y^2}\int_{x+}^{x+y} (\xi - x)f''(\xi)d\xi, \qquad x < y < x + d_x. \end{aligned}$$

The variation of ω_+ to the right of x is therefore upper bounded by

$$\begin{aligned}\|\omega_+(\cdot)\|_{BV(x+,\pi)} &\le \int_{y=0}^{d_x}\left|\int_{\xi=x+}^{x+y}\frac{(\xi-x)}{y^2}f''(\xi)d\xi\right|dy\\ &\quad+\int_{y=d_x}^{\pi}\left|\frac{f'(x+y)}{y}\right|+\left|\frac{f(x+y)-f(x+)}{y^2}\right|dy\\ &\le \frac{1}{2}\int_{y=0}^{d_x}\max_{\xi\in(x,x+d_x)}|f''(\xi)|dy\\ &\quad+\frac{1}{d_x}\int_{y=d_x}^{\pi}|f'(x+y)|+\left|\frac{f(x+y)-f(x+)}{y}\right|dy\\ &\le \frac{d_x}{2}\|f\|_{C^2(x,x+d_x)}+\frac{2}{d_x}\|f\|_{BV}.\end{aligned}$$

Similarly, the variation of ω_+ to the left of x does not exceed $\|\omega_+(\cdot)\|_{BV(-\pi,x-)} \le \frac{d_x}{2}\|f\|_{C^2(x-d_x,x)}+\frac{2}{d_x}\|f\|_{BV}$. We then have

$$\|\omega_+(\cdot)\|_{BV}\le [f](x)+d_x\|f\|_{C^2(I_x)}+\frac{4}{d_x}\|f\|_{BV}\lesssim d_x\|f\|_{C^2(I_x)}+\frac{1}{d_x}\|f\|_{BV}.$$

A similar bound holds for $\|\omega_-(\cdot)\|_{BV}$, and the lemma follows. ∎

3. Noisy data—a new perspective based on constrained minimization. Assume that f experiences a single jump discontinuity at location z of height $[f](z)$. This dictates a first-order decay of the Fourier coefficients

$$\widehat{f}(k)=[f](z)\frac{e^{-ikz}}{2\pi ik}+\widehat{s}(k)+\widehat{n}(k). \tag{3.1}$$

Here, $\widehat{s}(k)$ are associated with the regular part of f after extracting the jumps $[f](z_j)$; their decay is of order $\sim |k|^{-2}$ or faster, depending on the smoothness of the regular part $s(\cdot)$. The new aspect of the problem enters through the $\widehat{n}(k)$'s, which are the Fourier coefficients of the noisy part corrupting the smooth part of the data. We assume $n(\cdot)$ to be white noise whose mean-square power at each frequency is $E(|\widehat{n}(k)|^2)=\eta$. With (3.1), the conjugate sum (2.6) becomes

$$\begin{aligned}K_N^\sigma f(x)=[f](z)\times 2\pi i\sum_{k=1}^{N}\frac{\sigma_N\left(\frac{k}{N}\right)}{k}\cos k(x-z)-2\pi\sum_{k=1}^{N}\sigma\left(\frac{k}{N}\right)\widehat{s}(k)\sin kx\\ -2\pi\sum_{k=1}^{N}\sigma\left(\frac{k}{N}\right)\widehat{n}(k)\sin kx.\end{aligned}$$

We quantify the "energy" of each of the three sums on the right. E_J and E_R are associated with the discontinuous and regular parts of f:

$$\sum_{k=1}^{N}\left(\frac{\sigma\left(\frac{k}{N}\right)}{k}\right)^2\approx\frac{1}{N}\int_0^1\left(\frac{\sigma(\xi)}{\xi}\right)^2d\xi=:E_J(\sigma), \tag{3.2a}$$

$$\sum_{k=1}^{N}\sigma^2\left(\frac{k}{N}\right)|\widehat{s}(k)|^2\sim\frac{1}{N^3}\int_0^1\frac{\sigma^2(\xi)}{\xi^4}d\xi=:E_R(\sigma), \tag{3.2b}$$

and $E_\eta(\sigma)$ is associated with the noisy part of f, which was assumed to have variance η:

$$\sum_{k=1}^{N} \sigma^2\left(\frac{k}{N}\right) E(|\widehat{n}(k)|^2) \approx \eta N \int_0^1 \sigma^2(\xi)d\xi =: E_\eta(\sigma). \tag{3.2c}$$

Our perspective for construction of edge detectors for such noisy data is to treat the problem as a *constrained minimization*. We seek a function $\sigma(\xi)$ which minimizes the total energy, thus making the conjugate sum $K_N^\sigma f$ as localized as possible, subject to prescribed normalization constraint (2.1b),

$$\min\left\{ a_J E_J(\sigma) + a_\eta E_\eta(\sigma) + a_R E_R(\sigma) \;\middle|\; \int_0^1 \frac{\sigma(\xi)}{\xi} d\xi = 1 \right\}. \tag{3.3}$$

This yields

$$\sigma(\xi) = C_\sigma \frac{\frac{1}{\xi}}{a_J \frac{1}{N\xi^2} + a_\eta \eta N + a_R \frac{1}{N^3\xi^4}} = \frac{C_\sigma N^3 \xi^3}{a_J N^2 \xi^2 + a_\eta \eta N^4 \xi^4 + a_R}.$$

We ignore the relatively negligible contribution of the regular part which becomes even smaller as $s(\cdot)$ becomes smoother. Setting $a_R = 0$ we end up with concentration factors of the form

$$\sigma(\xi) = \frac{C_\sigma}{a_J} \cdot \frac{N\xi}{1 + \eta\beta^2 N^2 \xi^2}, \quad \beta := \sqrt{\frac{a_\eta}{a_J}}. \tag{3.4}$$

The corresponding concentration kernel depends only on the *relative* size of the amplitudes $\beta^2 = a_\eta / a_J$. Indeed, the normalization of $\sigma(\xi)/\xi$ (2.1b) causes the constant C_σ to satisfy

$$\int_0^1 \frac{\sigma(\xi)}{\xi} d\xi = \frac{C_\sigma}{a_J \sqrt{\eta}\beta} \tan^{-1}\left(\sqrt{\eta}\beta N\right) = 1,$$

and we end up with the *normalized* concentration factor

$$\sigma(\xi) \equiv \sigma_\eta(\xi) = \frac{1}{\tan^{-1}\left(\sqrt{\eta}\beta N\right)} \cdot \frac{\sqrt{\eta}\beta N \xi}{1 + \eta\beta^2 N^2 \xi^2}, \qquad \beta = \sqrt{\frac{a_\eta}{a_J}}. \tag{3.5}$$

The corresponding edge detector then takes the form

$$K_N^{\sigma_\eta} f(x) = \frac{\pi\sqrt{\eta}\beta}{\tan^{-1}\left(\sqrt{\eta}\beta N\right)} \sum_{|k|\le N} \frac{ik}{1 + \eta\beta^2 k^2} \widehat{f}(k) e^{ikx}. \tag{3.6}$$

The concentration factor $\sigma = \sigma_\eta$ now involves three factors: the ratio β, the noise variance η, and the number of modes N. The concentration kernel (3.6) tends to de-emphasize both the low frequencies which are "corrupted" by the jump discontinuity(ies) and the high frequencies which are corrupted by the noise. Different procedures yield different policies for the choice of $\beta = \beta(\eta)$; one will be discussed in the next subsection. It is worth noting the essential dependence of $\sigma_\eta(\xi)$ on the variance of the noise η. There are three scales involved—the small "smoothness" of order $\sim 1/N$, the noise scale of order $\sim \sqrt{\eta}$, and the $\mathcal{O}(1)$-scale of jump discontinuities. We distinguish between two cases. If $\sqrt{\eta} \ll 1/N$ so that $\sqrt{\eta}\beta N \ll 1$, then the

noise can be considered part of the smooth variation of f and $\sigma_\eta(\xi) \approx \xi$ recovers the usual concentration factor for noise-free data. Indeed, $\sigma_\eta(\xi) = \xi$ at the limit of $\eta \downarrow 0$. Otherwise, when the $\mathcal{O}(1/N)$-smoothness scale is dominated by the $\mathcal{O}(\sqrt{\eta})$-noise scale in the sense that $\sqrt{\eta}\beta \gtrsim 1/N$ in which we assume the noise to be still well below the $\mathcal{O}(1)$-scale of the jumps,

$$\frac{1}{N} \lesssim \sqrt{\eta}\beta \ll \mathcal{O}(1).$$

In this case, we can ignore the bounded factor $1/\tan^{-1}(\sqrt{\eta}\beta N)$, and we compute the small scale dictated by Theorem 2.1. Setting $\zeta(\xi) := \sqrt{\eta}\beta N\xi$ we find

$$\begin{aligned}
\delta_N &= \frac{1}{N}\left\|\frac{\sigma_\eta(\xi)}{\xi}\right\|_{BV} \lesssim \frac{\sqrt{\eta}\beta N}{N}\int \frac{1}{(1+\zeta^2)^2}d\zeta \lesssim \sqrt{\eta}\beta,\\
\varepsilon_1(N) &= \frac{1}{N}|\sigma_\eta(1)| \lesssim \frac{1}{\sqrt{\eta}\beta N^2},\\
\varepsilon_2(N) &= \frac{1}{N}\int_{1/N}^1 \frac{1-\zeta^2}{\xi(1+\zeta^2(\xi))^2}d\xi \lesssim \sqrt{\eta}\beta\log\big(\sqrt{\eta}\beta\big),\\
\varepsilon_3(N) &= \left|\sigma_\eta\left(\frac{1}{N}\right)\right| \lesssim \sqrt{\eta}\beta.
\end{aligned}$$

Hence (2.4) holds with

$$\varepsilon_N \equiv \varepsilon_\eta := \sqrt{\eta}\beta\log\big(\sqrt{\eta}\beta\big).$$

It is remarkable to see how the small scale of smoothness in the noiseless case $\mathcal{O}(\log(N)/N)$ is now replaced by the small scale of noise $\varepsilon_\eta = \mathcal{O}(\sqrt{\eta}\beta\log(\sqrt{\eta}\beta))$. We now appeal to (2.7): since $\sqrt{\eta} \ll 1$, Theorem 2.1 implies that $K_N^{\sigma_\eta} f$ separates the $\mathcal{O}(1)$-scale of the edges from the noise scale of order $\varepsilon_\eta \ll 1$.

THEOREM 3.1 (edge detection in noisy data). *Assume that $f(\cdot)$ is piecewise smooth in the sense that* (2.3) *holds. Assume that its spectral data contain white noise with variance $\eta \ll 1$. Let $K_N^{\sigma_\eta} f(x)$ be a normalized concentration kernel* (3.6)

$$K_N^{\sigma_\eta} f(x) = \frac{\pi\sqrt{\eta}\beta}{\tan^{-1}(\sqrt{\eta}\beta N)} \sum_{|k|\le N} \frac{ik}{1+\eta\beta^2k^2}\widehat{f}(k)e^{ikx}$$

associated with the concentration factor

$$\sigma_\eta(\xi) = \frac{1}{\tan^{-1}(\sqrt{\eta}\beta N)} \cdot \frac{\sqrt{\eta}\beta N\xi}{1+\eta\beta^2N^2\xi^2}.$$

We distinguish between two cases:

(i) *if $\sqrt{\eta}\beta N \ll 1$, we set the small scale $\varepsilon = \varepsilon_N := \log(N)/N$;*

(ii) *if $1/N \lesssim \sqrt{\eta}\beta \ll 1$, we set the small scale $\varepsilon = \varepsilon_\eta := \sqrt{\eta}\beta\log\big(\sqrt{\eta}\beta\big)$. Then, $K_N^{\sigma_\eta} f(x)$ satisfies the following concentration property:*

$$K_N^{\sigma_\eta} f(x) = \begin{cases} [f](z_j) + \mathcal{O}\big(\varepsilon\big), & |x - z_j| \lesssim \varepsilon, \quad j = 1, \dots, m,\\ \mathcal{O}\left(\dfrac{\varepsilon}{d_x}\right), & d_x = dist\Big\{x, \{z_1, \dots, z_m\}\Big\} \gg \varepsilon. \end{cases} \tag{3.7}$$

Remark 3.2. We conclude that the concentration factor advocated in Theorem 3.1 is a rescaling of

$$\sigma(\xi) = \frac{\xi}{1+\xi^2}.$$

Thus, $\sigma_\eta(\xi) = C_\sigma \sigma(\sqrt{\eta}\beta N \xi)$, where C_σ is the proper normalization factor.

4. Numerical results. I.

4.1. Noiseless data. To illustrate the results of the previous section, we present two sets of numerical results. We begin with the case of *noiseless data* depicted in Figure 4.1—a standard periodic sawtooth function with a single jump continuity at $x = 1$. We still use the concentration factors advocated in Theorem 3.1, $C_\sigma \sigma(\sqrt{\eta}\beta N \xi)$. We set $\beta = 1$, corresponding to equal weights for the errors due to the noise and the discontinuous parts of the signal. The edge detector concentrates near the unit jump discontinuity at $x = 1$, and it decays to zero away from it. Since the data are noiseless, η is treated as an extra parameter. As η gets smaller, $K_N^{\sigma_\eta} f(x)$ tends to zero faster for x away from 1. The results of Figure 4.1 show that, by decreasing the value of η by a factor of 10, the decay of $K_N^{\sigma_\eta} f(x)$ away from $x = 1$ is accelerated by a factor of $0.00365/0.00137 = 2.66 \approx \sqrt{10}$; thus, the decay ratio in the smooth regime is of order $\sqrt{\eta}$, as it should be.

4.2. Noisy data—balancing the different types of errors. We now turn to the case of *noisy data*. In order to choose the free parameter β, it is important to know how β influences the error at the output of our edge detector (3.6). Let us

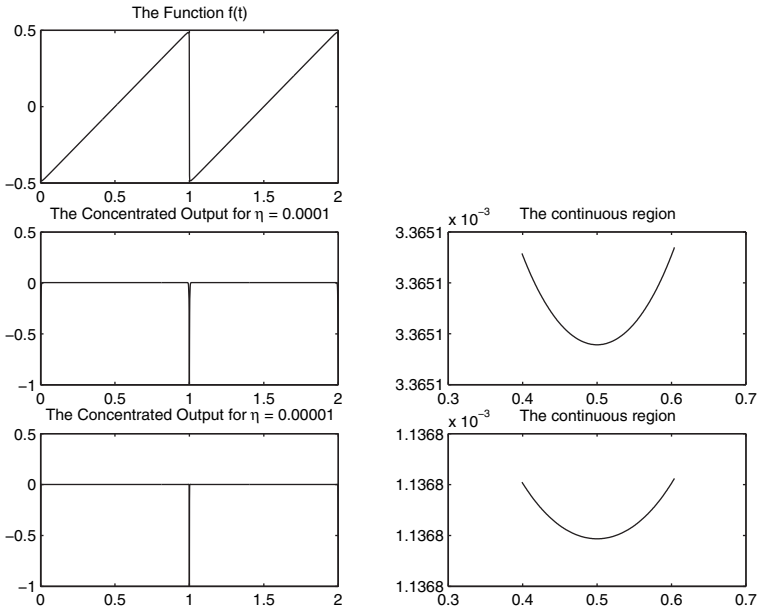

FIG. 4.1. *The output for various values of η when there is actually no noise at the input.*

consider E_η. We have seen that

$$\begin{aligned} E_\eta &= \eta N \int_0^1 \sigma^2(\xi)\, d\xi \\ &= \frac{\eta N}{(\tan^{-1}(\sqrt{\eta}\beta N))^2} \int_0^1 \frac{\eta\beta^2 N^2 \xi^2}{(1+\eta\beta^2 N^2\xi^2)^2}\, d\xi \\ &= \frac{\sqrt{\eta}}{\beta(\tan^{-1}(\sqrt{\eta}\beta N))^2} \int_0^{\sqrt{\eta}\beta N} \frac{\zeta^2}{(1+\zeta^2)^2}\, d\zeta \overset{\sqrt{\eta}\beta N \gtrsim 1}{\sim} \frac{\sqrt{\eta}}{\beta}. \end{aligned}$$

E_η is approximately the variance of the contribution due to noise to the edge detector. If we want to consider the *size* of the noise, we should consider the standard deviation of this contribution. It is customary to bound the noise by some constant multiple of the standard deviation—we will use the factor 2. We define the *effective size* of the noise's contribution to be

$$E_{\eta,eff} \equiv 2\sqrt{E_\eta} \sim \frac{\eta^{1/4}}{\sqrt{\beta}}.$$

By (3.2a), the effective contribution from the jump is of order

$$E_{J,eff} = E_J(\sigma_\eta) \sim \eta^{1/2}\beta.$$

Minimizing $E_{\eta,eff} + E_{J,eff}$ with respect to β yields $\beta \sim \eta^{-1/6}$. Figure 4.2 demonstrates the edge detected in noisy data using the concentration kernel (3.6) with the advocated $\beta = \pi\eta^{-1/6}$.

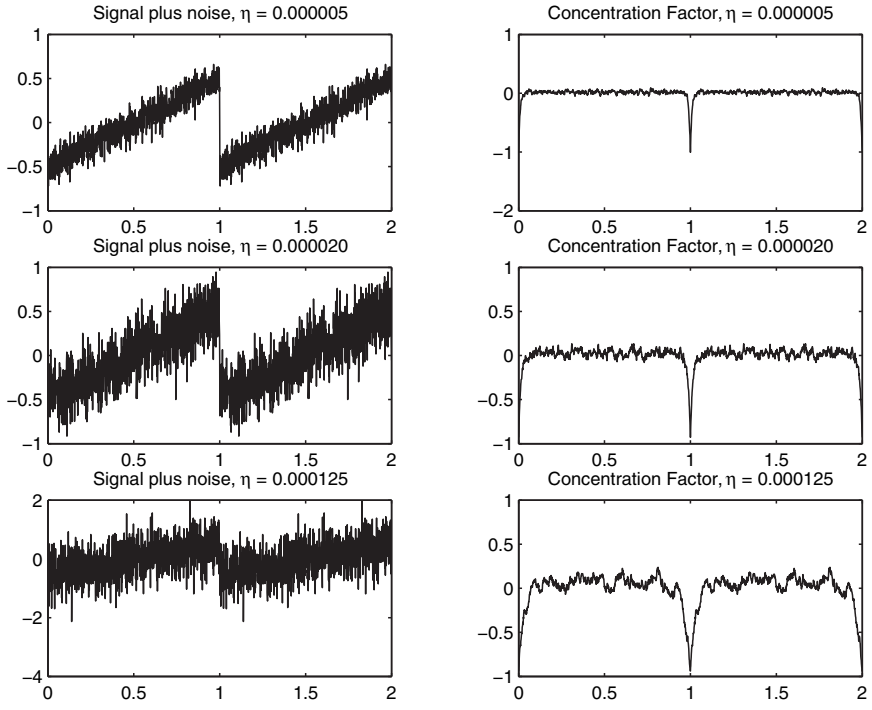

FIG. 4.2. *Detection of edges in a noisy sawtooth function corrupted with various values of* η *using the concentration kernel* (3.6) *with* $\beta = \pi\eta^{-1/6}$.

5. Noisy data and smoothness—concentration kernels revisited. As an alternative approach to the L^2-minimization offered in section 3, we now replace the L^2-"averaged" effect of the regular part taken in (3.2b) by the BV-like quantity

$$E_R(\sigma) \approx \sum_{k=1}^{N} \left| \sigma\left(\frac{k}{N}\right) \right| \cdot |\widehat{s}(k)|, \tag{5.1a}$$

where the regular part is sufficiently smooth that

$$|\hat{s}(k)| \sim \frac{1}{k^2}. \tag{5.1b}$$

As in (3.3), we consider the constrained minimization

$$\min \left\{ J(\sigma) \;\middle|\; \int_0^1 \frac{\sigma(\xi)}{\xi}\, d\xi = 1 \right\}, \tag{5.2a}$$

with $J(\sigma) = a_J E_J(\sigma) + a_\eta E_\eta(\sigma) + a_R E_R(\sigma)$, where $E_J(\sigma)$ and $E_\eta(\sigma)$ are given by (3.2a) and (3.2c), respectively, but with an alternative expression for the "energy" of the regular part motivated by (5.1): $E_R(\sigma) := \int_0^1 |\sigma(\xi)|\xi^{-2} d\xi/N$. We find that

$$J(\sigma) := \frac{a_J}{N} \int_0^1 \frac{\sigma^2(\xi)}{\xi^2}\, d\xi + a_\eta \eta N \int_0^1 \sigma^2(\xi)\, d\xi + \frac{a_R}{N} \int_0^1 \frac{|\sigma(\xi)|}{\xi^2}\, d\xi. \tag{5.2b}$$

Proceeding formally, the solution for the first variation of (5.2) leads to

$$\frac{2a_J\sigma(\xi)}{N\xi^2} + 2\eta a_\eta N\sigma(\xi) + \frac{a_R \cdot \operatorname{sgn}(\sigma(\xi))}{N\xi^2} = \frac{\lambda}{\xi}, \qquad \operatorname{sgn}(\sigma) = \begin{cases} 1, & \sigma > 0, \\ 0, & \sigma = 0, \\ -1, & \sigma < 0. \end{cases}$$

We will show that the resulting optimal concentration factor is given by

$$\sigma(\xi) = C_\sigma \frac{(N\xi - k_0)_+}{1 + \eta\beta^2 N^2 \xi^2}, \qquad k_0 := \frac{a_R}{\lambda}, \quad \beta = \sqrt{\frac{a_\eta}{a_J}}, \quad C_\sigma = \frac{\lambda}{2a_J}. \tag{5.3}$$

Indeed, to justify the passage to (5.3), one may consider a *regularized* version of the variational statement (5.2) $\min J_\varepsilon(\sigma)$, where

$$J_\varepsilon(\sigma) := \frac{a_J}{N} \int_0^1 \frac{\sigma^2(\xi)}{\xi^2}\, d\xi + a_\eta \eta N \int_0^1 \sigma^2(\xi)\, d\xi + \frac{a_R}{N} \int_0^1 \frac{|\sigma(\xi)|_\varepsilon}{\xi^2}\, d\xi$$

involves a *mollified* absolute value function

$$|\sigma|_\varepsilon := \begin{cases} |\sigma|, & |\sigma| \geq \epsilon, \\ \dfrac{\sigma^2}{2\epsilon} + \dfrac{\epsilon}{2}, & |\sigma| \leq \epsilon. \end{cases}$$

The solution of the corresponding regularized first variation yields the minimizer

$$\sigma(\xi) = C_\sigma \frac{N\xi - k_0 \cdot \operatorname{sgn}_\varepsilon(\sigma(\xi))}{\eta\beta^2 N^2 \xi^2 + 1}, \qquad \operatorname{sgn}_\varepsilon(\sigma) := \begin{cases} 1, & \sigma > \varepsilon, \\ \sigma/\varepsilon, & |\sigma| \leq \varepsilon, \\ -1, & \sigma < -\varepsilon. \end{cases}$$

Thus, we end up with the optimal concentration factor $\sigma(\xi) = \sigma_\varepsilon(\xi)$,

$$\sigma_\varepsilon(\xi) = \begin{cases} C_\sigma \dfrac{N\xi - k_0}{1 + \eta\beta^2 N^2 \xi^2}, & N\xi - k_0 > \varepsilon, \\ C_\sigma \dfrac{\varepsilon N \xi}{\varepsilon(1 + \eta\beta^2 N^2 \xi^2) + C_\sigma k_0}, & N\xi - k_0 \le \varepsilon, \end{cases}$$

and (5.3) is recovered by letting $\varepsilon \downarrow 0$. Clearly, the resulting optimal concentration factor is nonnegative.

It remains to calculate the normalization factor C_σ, for which

$$C_\sigma \int_{k_0/N}^1 \frac{1}{\xi} \frac{N\xi - k_0}{\eta\beta^2 N^2 \xi^2 + 1}\, d\xi = 1.$$

The integral on the left is found to be

$$\begin{aligned} &\int_{k_0/N}^1 \left(\frac{-k_0}{\xi} + \frac{k_0 \eta\beta^2 N^2 \xi + N}{\eta\beta^2 N^2 \xi^2 + 1} \right) d\xi \\ &\quad = k_0 \log\left(\frac{k_0}{N}\right) + \frac{k_0}{2} \log\left(\frac{\eta\beta^2 N^2 + 1}{\eta\beta^2 k_0^2 + 1}\right) + \frac{1}{\sqrt{\eta}\beta} \Big(\tan^{-1}(\sqrt{\eta}\beta N) - \tan^{-1}(\sqrt{\eta}\beta k_0) \Big). \end{aligned}$$

We focus our attention on the "noisy" case when $1/N \lesssim \sqrt{\eta}\beta \ll 1$ so that the fourth term on the right is negligible while the second term on the right is approximated by

$$\frac{k_0}{2} \log\left(\frac{\eta\beta^2 N^2 + 1}{\eta\beta^2 k_0^2 + 1}\right) \approx k_0 \log(\sqrt{\eta}\beta N).$$

We end up with an approximated integral

$$\int_{k_0/N}^1 \Big(\dots \Big) d\xi \approx k_0 \log(\sqrt{\eta}\beta N) + \frac{1}{\sqrt{\eta}\beta} \tan^{-1}(\sqrt{\eta}\beta N).$$

The balance between these two terms depends on the specific policy for β and the detailed balance between $\sqrt{\eta}\beta$ and N. Our normalized concentration factor takes the form

$$\sigma_\eta(\xi) = \frac{1}{\sqrt{\eta}\beta k_0 \log(\sqrt{\eta}\beta N) + \tan^{-1}(\sqrt{\eta}\beta N)} \cdot \frac{\sqrt{\eta}\beta (N\xi - k_0)_+}{1 + \eta\beta^2 N^2 \xi^2}. \tag{5.4a}$$

We can simplify this concentration factor in several ways; we mention two here.

(i) When N is large enough, we have $\tan^{-1}(\sqrt{\eta}\beta N) \approx \pi/2$ yielding

$$\sigma_\eta(\xi) = \frac{1}{k_0 \log(\sqrt{\eta}\beta N) + \pi/(2\sqrt{\eta}\beta)} \cdot \frac{(N\xi - k_0)_+}{1 + \eta\beta^2 N^2 \xi^2}. \tag{5.4b}$$

(ii) Observe that $\sigma_\eta(\xi)$ is rapidly decreasing at $\xi \approx 1$, with

$$\sigma_\eta(\xi) \sim \frac{1}{\eta\beta^2 N \log N}, \qquad \xi \approx 1,$$

so $\sigma_\eta(\xi)$ can be set to zero for $\xi \approx 1$ when N is large enough. In order to properly normalize the resulting concentration factor, N must be replaced by N_0. This leads us to the following:

$$\sigma_\eta\Big(\frac{k}{N}\Big) = \begin{cases} 0, & k < k_0, \\ \dfrac{1}{k_0 \log(\sqrt{\eta}\beta N_0) + \pi/(2\sqrt{\eta}\beta)} \cdot \dfrac{(k-k_0)_+}{1+\eta\beta^2 k^2}, & k_0 < k < N_0, \\ 0, & N_0 < k < N. \end{cases} \tag{5.4c}$$

6. Numerical results. II. We consider two examples depicted in Figure 6.1. In the first case, we have a noise of variance $\eta = 2\times 10^{-5}$ to be detected out of the first $N \gg 1000$ modes. The use of the edge detector (5.4) depends on three parameters, namely, β, k_0, and N_0. For β we use, as before, $\beta = \pi\eta^{-1/6} \sim 15$. The value of k_0 was chosen as $k_0 = 8\pi$: observe that, according to (5.3), $k_0 C_\sigma$ equals the ratio $a_R/2a_J$, and we found optimal results when the ratio of these amplitudes is set to be of order 10, yielding $k_0 = 10/0.3984 \sim 8\pi$. Finally, N_0 was taken as $N_0 = 1000$ since $\sigma_\eta(k/N) \le 0.1$ for $N \ge N_0$. With these parameters we find

$$\sigma_\eta\left(\frac{k}{N}\right) = \begin{cases} 0, & k = 1, \dots, 24, 1001, 1002, \dots, \\ 0.3985 \cdot \dfrac{(k-8\pi)_+}{1+\eta(15k)^2}, & 25 \le k \le 1000. \end{cases}$$

In the second case, the noise variance is $\eta = 4.5 \times 10^{-5}$. This led us to the choice of $\beta = \pi\eta^{-1/6} \sim 13$. Setting $k_0 = 6\pi$ (as before, $k_0 \sim 10/C_\sigma = 10/0.5070$) and $N_0 = 1000$, we have

$$\sigma_\eta\left(\frac{k}{N}\right) = \begin{cases} 0, & k = 1, \dots, 19, 1001, 1002, \dots, \\ 0.5070 \cdot \dfrac{(k-6\pi)_+}{1+\eta(13k)^2}, & 20 \le k \le 1000. \end{cases}$$

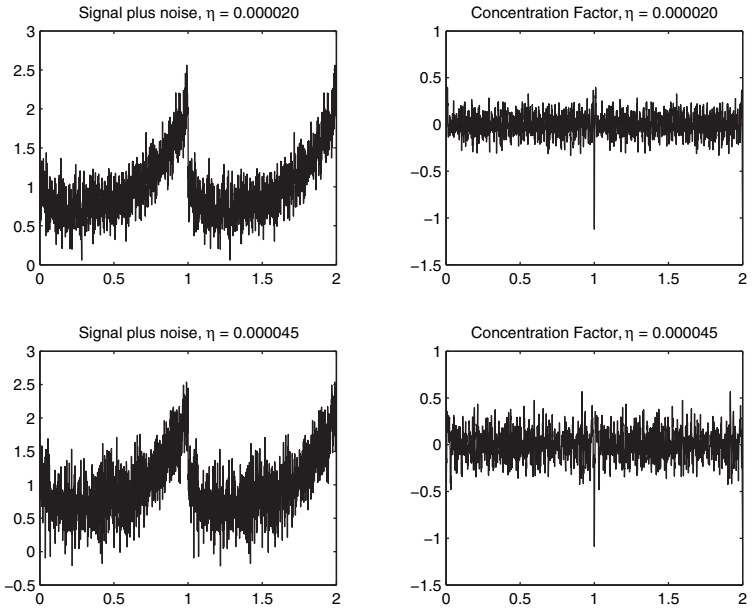

FIG. 6.1. *The output for various values of η when the input consists of a piecewise smooth function and noise (of the specified power spectral density).*

Note that in calculating the constants we made use of the *exact* normalization factor C_σ in (5.4b). $N_0 = 1000$ is not large enough to make the approximate normalization factor C_σ given in (5.4c) useful.

Note that, even with a large amount of white noise and a smooth signal, the location of the jump discontinuity is still clear. When considering jumps "corrupted" by low frequency data, we avoid low frequency signals by not using low frequency data. This helps keep the smooth signal from corrupting our results. On the other hand, because the jump discontinuity has most of its energy at low frequencies as well, our technique will increase the noise's effect. Comparing Figures 4.2 and 6.1, we find that the latter is not as clean as the former in the subfigure where the strength of the noise is the same.

Acknowledgment. Part of this research was carried out while the second author was visiting the Weizmann Institute, and he is grateful for their hospitality.

ON NUMERICAL APPROXIMATIONS OF FORWARD-BACKWARD STOCHASTIC DIFFERENTIAL EQUATIONS*

JIN MA†, JIE SHEN‡, AND YANHONG ZHAO‡

Abstract. A numerical method for a class of forward-backward stochastic differential equations (FBSDEs) is proposed and analyzed. The method is designed around the *four step scheme* [J. Douglas, Jr., J. Ma, and P. Protter, *Ann. Appl. Probab.*, 6 (1996), pp. 940–968] but with a Hermite-spectral method to approximate the solution to the decoupling quasi-linear PDE on the whole space. A rigorous synthetic error analysis is carried out for a fully discretized scheme, namely a first-order scheme in time and a Hermite-spectral scheme in space, of the FBSDEs. Equally important, a systematical numerical comparison is made between several schemes for the resulting decoupled forward SDE, including a stochastic version of the Adams–Bashforth scheme. It is shown that the stochastic version of the Adams–Bashforth scheme coupled with the Hermite-spectral method leads to a convergence rate of $\frac{3}{2}$ (in time) which is better than those in previously published work for the FBSDEs.

Key words. forward-backward stochastic differential equations, four step scheme, Hermite-spectral method, convergence rate

1. Introduction.

Since the seminal work of Pardoux and Peng [32] in early 1990s, the theory of backward stochastic differential equations (BSDEs) and forward-backward stochastic differential equations (FBSDEs) has grown into a ubiquitous tool in the fields of stochastic optimizations and mathematical finance (see, for example, the books of El Karoui and Mazliak [14] and Ma and Yong [28] and the survey of El Karoui, Peng, and Quenez [15] for a detailed account of both theory and applications of such SDEs). In the meantime, after the earlier works of Bally [1] and Douglas, Ma, and Protter [13], finding an efficient numerical scheme for both BSDEs and FBSDEs has also become an independent but integral part of the theory. Tremendous efforts have been made during the past decade to circumvent the fundamental difficulties caused by the combination of the "backward" nature of the SDEs and the associated decoupling techniques for FBSDEs. In the "pure backward" (or "decoupled" forward-backward) case, various methods have been proposed. These include the PDE method in the Markovian case (e.g., Chevance [8] and Zhang and Zheng [36]), random walk approximations (e.g., Briand, Delyon, and Mémin [6] and Ma et al. [26]), Malliavin calculus and Monte-Carlo method (e.g., Zhang [35], Ma and Zhang [29], and Bouchard and Touzi [5]), the quantization method (e.g., Bally and Pagès [2] and Bally, Pagès, and Printems [3]), and recently the regression-based Monte-Carlo method (Lemor, Gobet, and Warin [23] and [24]).

In the case of coupled FBSDEs, however, the results are very limited, largely due to the lack of a solution method itself in such cases. It has been well understood

that in order to solve an FBSDE in an arbitrary duration, a (numerically) tractable method is to utilize the "decoupling PDE," based on the so-called four step scheme initiated in Ma and Yong [28]. Such an idea has led directly to most of the existing numerical results for FBSDEs: from the early work [13] to the recent improvements by Milstein and Tretyakov [31] and Delarue and Menozzi [12]. Extending such a decoupling idea and combining it with an optimal control method as well as Monte-Carlo simulation, Cvitanić and Zhang [9] and Bender and Zhang [4] recently proposed a numerical scheme for FBSDEs without attacking the associated PDE directly. We should note that the Monte-Carlo method is most effective only when a single value of the solution is concerned at each computing cycle, which is quite different from the original problem where essentially the distribution of the solution at each time point was sought.

There are two main technical obstacles in developing numerical schemes for FBSDEs: the *dimensionality* and the *rate of convergence*. The former is a natural consequence of the close relation between the FBSDE and its decoupling quasi-linear PDE, where the notorious "curse of dimensionality" is still a formidable difficulty for any numerical method. In fact, to the best of our knowledge, there is still no efficient numerical method for high dimensional PDEs that is directly applicable to our case. We note that almost all the existing numerical schemes for FBSDEs are constructed with convergence rate $\frac{1}{2}$, except in [31], where the Euler scheme for the forward SDE is replaced by Milstein's first order scheme so the rate of convergence is improved to 1. We should mention that although higher order approximation is possible for forward SDEs (cf., e.g., [21]), it is by no means clear whether this can be extended to the coupled FBSDEs, even when all the coefficients are assumed to be *smooth*(!), given the intrinsic difficulties arising from the current numerical methods.

This then raises an interesting question: Is it possible to design a numerical scheme that has better than first-order convergence rate, and at the same time is applicable (in the practical sense) to high-dimensional cases? This paper is an effort towards this goal. We shall revisit the four step scheme again, but will replace the usual finite difference method for the PDE by a *Hermite-spectral method*. Several main features of the Hermite-spectral method are worth noting: (i) the PDE solution is approximated directly by Hermite functions as an orthonormal basis on the whole space, without using ad hoc artificial boundary conditions as in previous approaches using finite differences; (ii) the rate of convergence is related directly to the regularity of the coefficients; to wit, the higher regularity implies the higher convergence rate. We should remark that this last feature marks the main difference between a spectral method and traditional finite difference and finite element methods. In fact, as we pointed out before, even given smooth coefficients, none of the existing schemes for FBSDEs seems to be able to achieve higher than first-order convergence rate.

Given the aforementioned spectral accuracy in space, it seems hopeful that one can produce arbitrarily higher-order global error by applying a higher-order scheme in SDEs in, e.g., [21], at least when the coefficients are smooth. We shall carry out some numerical simulations to validate this point. To compare with the existing results, we shall use an example proposed in Milstein and Tretyakov [31], and we test several methods for the forward SDEs. These include the standard Euler scheme, the Milstein scheme, the Platen–Wagner scheme, and the *stochastic Adam–Bashforth* (SAB) scheme proposed in [16]. By the nature of these schemes, we expect the Euler scheme to be 1/2-order convergent, the Milstein first-order scheme to be first-order convergent, and the Platen–Wagner and SAB schemes to be 3/2-order convergent. Our simulation results give numerical evidence that this is exactly the case. Also, this

example shows that in the one-dimensional case our scheme has the best performance (in terms of computing time). Due to the apparent complexity of the error analysis and the length of the paper, in this paper we only give a rigorous proof of the rate of convergence with the Euler scheme for the forward SDE. A rigorous proof for higher order schemes would be quite similar, although conceivably much more tedious. We hope our numerical results are sufficiently convincing for this purpose.

As a final remark, we would like to point out that the numerical method in this paper, albeit technical, can be extended to higher-dimensional cases with a tensor-product approach. However, such a method quickly becomes nonfeasible for spatial dimensions higher than three, unless some non–tensor-product method, such as those based on sparse grid (cf. [7] and [34]) or lattice rules (cf. [25], [19], and [22]), is introduced. We plan to address the higher dimensional issue in a forthcoming work.

The rest of the paper is organized as follows. In section 2 we give the necessary preliminaries; in section 3 we introduce the Hermite-spectral method for the PDE and perform an error analysis. In section 4 we study the synthetic error analysis of the full numerical scheme, and in section 5 we carry out some numerical experiments.

2. Problem formulation and preliminaries. Throughout this paper we assume that $(\Omega, \mathcal{F}, P)$ is a complete probability space, on which is defined a d-dimensional Brownian motion $W = \{W(t) : t \geq 0\}$. We shall denote $\mathbf{F}^W = \{\mathcal{F}_t^W : t \geq 0\}$ to be the natural filtration generated by W, with usual P-augmentation so that it is right continuous and contains all the P-null sets in $\mathcal{F}$.

We consider the following FBSDE: for $t \in [0, T]$,

$$\begin{cases} X(t) = x + \displaystyle\int_0^t b(s, \Theta(s))ds + \int_0^t \sigma(s, X(s), Y(s))dW(s), \\ \\ Y(t) = \varphi(X(T)) + \displaystyle\int_t^T g(s, \Theta(s))ds - \int_t^T Z(s)dW(s), \end{cases} \tag{2.1}$$

where $\Theta \stackrel{\triangle}{=} (X, Y, Z)$. To simplify presentation, in what follows we shall assume that all processes involved are one dimensional. Moreover, we shall make use of the following *standing assumptions* in what follows.

(A1) The functions b, σ, g, and φ are continuously differentiable in all variables. Moreover, if we denote these functions by a generic one ψ, then there exists a constant $K > 0$ such that, for any $t \in [0, T]$, ψ satisfies the uniform Lipschitz condition:

$$|\psi(t, x, y, z) - \psi(t, x', y', z')| \leq K(|x - x'| + |y - y'| + |z - z'|).$$

(A2) The functions b, g, and φ satisfies the following growth conditions: for some $K > 0$,

$$|g(t, x, y, z)| \leq K(1 + |y| + |z|),$$

$$|\varphi(x)|, |b(t, x, y, z)| \leq K.$$

(A3) Function σ has bounded second derivatives, and there exist constants $0 < c < C$ such that

$$c \leq \sigma(t, x, y) \leq C \quad \forall\, (t, x, y) \in [0, T] \times \mathbb{R}^2. \tag{2.2}$$

Remark 2.1. We remark that assumptions (A1)–(A3) are stronger than is necessary for the well-posedness of FBSDE (2.1). In fact, in [10] it was shown that under (A1)–(A3) but without the differentiability assumption on the coefficients the FBSDE (2.1) already possesses a unique adapted solution over an arbitrarily prescribed time duration. The extra smoothness condition is needed only for our numerical scheme, and therefore is not essential, in principle. Note also, however, that even with the added differentiability conditions, our assumptions are still much weaker than that of [13].

Four step scheme. In [27] (see also [10]) it was shown that the *unique* adapted solution of FBSDE (2.1) can be obtained by the following steps:

Step 1. Define a function $z:\ [0,T]\times\mathbb{R}^3\ \to\ \mathbb{R}$ by

$$z(t,x,y,p) = p\,\sigma(t,x,y) \quad \forall\ (t,x,y,p).$$

Step 2. Using the function z above, solve the quasi-linear parabolic PDE :

$$\begin{cases} u_t + \dfrac{1}{2}\sigma^2(t,x,u)u_{xx} + b(t,x,u,z(t,x,u,u_x))u_x \\ \quad + g(t,x,u,z(t,x,u,u_x)) = 0, \qquad (t,x)\in(0,T)\times\mathbb{R}, \\ u(T,x) = \varphi(x), \quad x\in\mathbb{R}. \end{cases} \tag{2.3}$$

Step 3. Using the functions u and z, solve the forward SDE:

$$X(t) = x + \int_0^t \tilde{b}(s,X(s))ds + \int_0^t \tilde{\sigma}(s,X(s))dW(s), \tag{2.4}$$

where $\tilde{b} = b(t,x,u(t,x),z(t,x,u,u_x))$ and $\tilde{\sigma} = \sigma(t,x,u(t,x))$.

Step 4. Set

$$Y(t) = u(t,X(t)) \quad \text{and} \quad Z(t) = \sigma(t,X(t),u(t,X(t)))u_x(t,X(t)).$$

Then, (X,Y,Z) is the adapted solution to (2.1).

It is readily seen that if a numerical scheme is designed along the lines of four step scheme, then one essentially has to deal with two separate discretization schemes: one for the PDE (2.3) and the other for the (forward) SDE (2.4). We shall adopt a Hermite–Galerkin method with numerical integration. To do this we find it convenient to rewrite PDE (2.3) in a divergence form, mainly for the sake of numerical stability:

$$\begin{cases} u_t + \partial_x\left(\dfrac{1}{2}\sigma^2(t,x,u)u_x\right) + \hat{b}(t,x,u,u_x)u_x \\ \quad + g(t,x,u,\sigma(t,x,u)u_x) = 0, \qquad (t,x)\in(0,T)\times\mathbb{R}, \\ u(T,x) = \varphi(x), \quad x\in\mathbb{R}, \end{cases} \tag{2.5}$$

where

$$\hat{b}(t,x,y,z) = b(t,x,y,\sigma(t,x,y)z) - \sigma(t,x,y)(\sigma_x(t,x,y) + \sigma_y(t,x,y)z).$$

Remark 2.2. We note here that the main difference between b and $\hat{b}$ is that the latter now has a linear growth in the variable z, and thus it no longer satisfies assumptions (A1) and (A2). We shall make the following adjustment in what follows

to facilitate the error analysis. Note that under (A1)–(A3) it is known (cf. [11]) that the solution to the PDE (2.3), whence (2.5), has a globally bounded gradient u_x. Thus in light of the four step scheme, if we introduce the "cut-off" version of the coefficient function $\hat{b}$,

$$\hat{b}_K(t,x,y,z) = b(t,x,y,\sigma(t,x,y)z) - \sigma(t,x,y)(\sigma_x(t,x,y) + \sigma_y(t,x,y)\gamma_K(z)),$$

where $\gamma_K(z) \in C^\infty(\mathbb{R})$, $\gamma_K(z) = z$ for $|z| \le K$, and $|\gamma_K(z)| \le K+1$, $|\gamma_K'(z)| \le 1$, then for K large enough, the solution of the PDE (2.5) with coefficient $\hat{b}_K$ will coincide with the original solution. In other words, we can simply consider the "truncated" coefficients $\hat{b}_K$ for the purpose of approximation, which again satisfies (A1) and (A2). For the sake of simplicity, in what follows we shall still use $\hat{b}$ to denote $\hat{b}_K$.

Hermite polynomials, Hermite functions, and their properties. Throughout this paper we shall denote by $L^2(\mathbb{R})$ the space of all square integrable functions $u : \mathbb{R} \mapsto \mathbb{R}$, with the inner product

$$\langle u, v\rangle \;=\; \int_{\mathbb{R}} u(x)v(x)dx \qquad\qquad \forall\, u, v \in L^2(\mathbb{R})$$

and the norm $\|u\|^2 \triangleq \int_{\mathbb{R}} |u(x)|^2 dx$. For simplicity, in what follows, without further specification we shall always denote by $\|\cdot\|$ the $L^2(\mathbb{R})$ norm.

Next, for each integer $k \ge 1$, we denote the differential operator $\partial^k \triangleq \frac{d^k}{dx^k}$. Then the Sobolev space $H^m(\mathbb{R})$ is defined by

$$H^m(\mathbb{R}) = \{u \mid \partial^k u \in L^2(\mathbb{R}) \quad \forall\, 0 \le k \le m\},$$

with the seminorm $|u|_m \triangleq \|\partial^m u\|$, and the norm $\|u\|_m^2 \triangleq \sum_{k=0}^m \|\partial^k u\|^2$. We note that the operator ∂^k can be easily extended to the higher-dimensional case, namely, as a partial differential operator, in an obvious way. We define $H^{-1}(\mathbb{R})$ as the dual space of $H^1(\mathbb{R})$, and its norm will be denoted by $\|\cdot\|_{-1}$.

We recall that (cf., e.g., [17]) the *Hermite polynomials* $\{H_n(x)\}_{n\ge 0}$ are defined by

$$H_n(x) = (-1)^n \exp(x^2)\frac{d^n}{dx^n}\exp(-x^2), \qquad n = 0, 1, \ldots . \tag{2.6}$$

One can easily check that H_n is the solution to the recursive equations

$$\begin{cases} H_{n+1}(x) = 2xH_n(x) - 2nH_{n-1}(x), \\ H_n'(x) = 2nH_{n-1}(x), \\ H_0(x) = 1, \quad H_1(x) = 2x, \end{cases}$$

and the following orthogonality condition holds:

$$\int_{-\infty}^{\infty} H_m(x)H_n(x)e^{-x^2}dx = \gamma_n\delta_{mn}, \qquad m, n \ge 1, \tag{2.7}$$

where $\gamma_n = \sqrt{\pi}2^n n!$ and δ_{mn} is the Kronecker delta. For each $n \ge 1$, $H_n(x)$ is called the "Hermite polynomial of degree n," and the *Hermite function of degree* n is defined by

$$\widehat{H}_n(x) = \frac{1}{\sqrt{2^n n!}} e^{-x^2/2} H_n(x).$$

It follows immediately that the Hermite functions $\widehat{H}_n(x)$ enjoy the following recurrence and orthogonal relations:

$$\widehat{H}_{n+1}(x) = x\sqrt{\frac{2}{n+1}}\widehat{H}_n(x) - \sqrt{\frac{n}{n+1}}\widehat{H}_{n-1}(x), \quad n \geq 1, \tag{2.8}$$

$$\frac{d}{dx}\widehat{H}_n(x) = \sqrt{\frac{n}{2}}\widehat{H}_{n-1}(x) - \sqrt{\frac{n+1}{2}}\widehat{H}_{n+1}(x), \tag{2.9}$$

$$\int_{-\infty}^{\infty} \widehat{H}_m(x)\widehat{H}_n(x)dx = \sqrt{\pi}\delta_{mn}. \tag{2.10}$$

Moreover, we derive from $H_n' = 2nH_{n-1}$ that $\widehat{H}_n' + x\widehat{H}_n = \sqrt{2n}\widehat{H}_{n-1}$. Hence, by introducing a new operator $Du \stackrel{\triangle}{=} \partial_x u + xu$, we obtain the following recursive relation:

$$D\widehat{H}_n = \sqrt{2n}\widehat{H}_{n-1}. \tag{2.11}$$

Using the operator D we can define a Hilbert space similar to the Sobolev space $H^m(\mathbb{R})$, which will be important for our error analysis. To begin with, for any positive integer N, let $\mathcal{P}_N$ be the space of polynomials of degree less than or equal to N. We then define

$$\mathcal{H}_N = e^{-x^2/2}\mathcal{P}_N \stackrel{\triangle}{=} \{e^{-x^2/2}p(x) :\ p(x) \in \mathcal{P}_N\}. \tag{2.12}$$

Next, for each $N \in \mathbb{N}$ let us denote $\{x_i\}_{i=0}^N$ to be the roots of the polynomial $H_{N+1}(x)$ and define

$$w_j = \frac{\sqrt{\pi}2^N N!}{(N+1)[H_N(x_j)]^2}, \quad 0 \leq j \leq N. \tag{2.13}$$

The pairs $\{(x_i, \omega_i)\}_{i=0}^N$ are known as the *Hermite–Gauss quadrature points and weights*, respectively (cf., e.g., [33]). Using the Hermite–Gauss quadrature points and weights, we can then define a discrete scalar product defined on $C(\mathbb{R})$ by

$$\langle f, g\rangle_N \stackrel{\triangle}{=} \sum_{j=0}^{N} f(x_j)g(x_j)\hat{w}_j \qquad \forall f, g \in C(\mathbb{R}), \tag{2.14}$$

where $\hat{w}_j$'s are the normalized Hermite–Gauss quadrature weights defined by

$$\hat{w}_j \stackrel{\triangle}{=} w_j\ e^{x_j{}^2} = \frac{\sqrt{\pi}}{(N+1)\widehat{H}_N^2(x_j)}, \qquad 0 \leq j \leq N.$$

A direct consequence of the Hermite–Gauss quadrature is

$$\langle u, v\rangle\ =\ \langle u, v\rangle_N \qquad \forall\ u \in \mathcal{H}_m,\ v \in \mathcal{H}_n,\ n + m \leq 2N + 1. \tag{2.15}$$

For any integer $m \geq 0$, let us define

$$H_D^m(\mathbb{R}) \stackrel{\triangle}{=} \{u \mid D^m u \in L^2(\mathbb{R})\},$$

equipped with norm $\|D^m u\|$. Moreover, for any real number $r \geq 0$, the space $H_D^r(\mathbb{R})$ and its norm can be defined by the usual space interpolation.

In order to introduce our numerical approximation we need the following two operators:

- the "*orthogonal projection operator*" $P_N : L^2(\mathbb{R}) \to \mathcal{H}_N$, defined by
$$\langle u - P_N u, v\rangle = 0 \quad \forall u \in L^2(\mathbb{R}),\ v \in \mathcal{H}_N;$$
- the "*Hermite–Gauss interpolation operator*" $I_N : C(\mathbb{R}) \to \mathcal{H}_N$, defined by
$$I_N f \in \mathcal{H}_N \quad \text{such that} \quad I_N f(x_j) = f(x_j), \quad j = 0, 1, \ldots, N. \tag{2.16}$$

The following basic approximation results for P_N can be found in, e.g., [18].

LEMMA 2.3. *For any $u \in H^r_D(\mathbb{R})$, $N \in \mathbb{N}$, and $0 \le s \le r$, there exists a constant $C > 0$, independent of N and the function u, such that*

$$\|D^s(u - P_N u)\| \le C N^{\frac{s-r}{2}} \|D^r u\| \tag{2.17}$$

and

$$\|\partial_x(u - P_N u)\| \le C N^{\frac{1-r}{2}} \|D^r u\|. \tag{2.18}$$

3. Numerical schemes. In this section we present our numerical schemes, both for the PDE (2.5) and for the forward SDE (2.4). Although the scheme for the general quasi-linear PDE (2.5) can be treated the same way with more complicated notation, to simplify presentation we shall assume that the coefficients b and g are both independent of variable z. We note that under such a simplification the PDE (2.5) becomes, with a slight abuse of notation in light of Remark 2.2,

$$\begin{cases} u_t + \partial_x\left(\frac{1}{2}\sigma^2(t,x,u)u_x\right) + \hat{b}(t,x,u,u_x)u_x + g(t,x,u) = 0, \\ \qquad\qquad\qquad\qquad\qquad\qquad (t,x) \in (0,T)\times\mathbb{R}, \\ u(T,x) = \varphi(x), \quad x \in \mathbb{R}, \end{cases} \tag{3.1}$$

where $\hat{b}(t,x,y,z) = b(t,x,y) - \sigma(t,x,y)(\sigma_x(t,x,y) + \sigma_y(t,x,y)\gamma_{\bar{K}}(z))$, for some $\bar{K} > 0$. We shall design a numerical scheme for (3.1) based on a semi-implicit discretization in time and the Hermite-collocation method in space, and discuss three types of schemes for the corresponding forward SDE (2.4). The error analysis for the combined scheme will be carried out in the next two sections.

Before we proceed further, we should note that the constant $\bar{K} > 0$ above is determined by the *true* solution, which is independent of the numerical scheme, and is useful only for error analysis. In what follows we shall denote all the constants depending on K in (A1)–(A3) and $\bar{K}$ above by a generic one, and still denote it by K. Then, from (A1) we see that $|\sigma_x(t,x,y)| \le K$ and $|\sigma_y(t,x,y)| \le K$ for all $(t,x,y) \in [0,T]\times\mathbb{R}^2$ follow easily. Furthermore, by (A3) it implies that σ_y satisfies the Lipschitz condition as

$$|\sigma_y(t,x,y) - \sigma_y(t,x,y')| \le K\,|y - y'|.$$

Hence,

$$\begin{aligned} &|\sigma(t,x,y)\sigma_y(t,x,y)\gamma_{_K}(z) - \sigma(t,x,y')\sigma_y(t,x,y')\gamma_{_K}(z')| \\ &\le |\sigma(t,x,y)\sigma_y(t,x,y)\gamma_{_K}(z) - \sigma(t,x,y')\sigma_y(t,x,y)\gamma_{_K}(z)| \\ &\quad + |\sigma(t,x,y')\sigma_y(t,x,y)\gamma_{_K}(z) - \sigma(t,x,y')\sigma_y(t,x,y')\gamma_{_K}(z)| \\ &\quad + |\sigma(t,x,y')\sigma_y(t,x,y')\gamma_{_K}(z) - \sigma(t,x,y')\sigma_y(t,x,y')\gamma_{_K}(z')| \\ &\le K^2(K+1)|y-y'| + CK(1+K)|y-y'| + CK|z-z'|. \end{aligned}$$

Similarly, we have

$$|\sigma(t,x,y)\sigma_x(t,x,y) - \sigma(t,x,y')\sigma_x(t,x,y')| \le (K^2 + CK)|y - y'|.$$

For notational simplicity, we often allow the generic constant K to vary from line to line; then by the above arguments, the function $\hat{b}$ satisfies the Lipschitz condition

$$|\hat{b}(t,x,y,z) - \hat{b}(t,x,y',z')| \le K(|y - y'| + |z - z'|). \tag{3.2}$$

On the other hand, $\hat{b}$ satisfies the bounded property by boundedness of b and $\gamma_{_K}(z)$; i.e.,

$$|\hat{b}(t,x,y,z)| \le K. \tag{3.3}$$

3.1. Numerical scheme for the PDE (3.1). For any $M \in \mathbb{N}^*$, let $h = \frac{T}{M}$ be the length of the time step and set $t_k = kh$, $k = 0, 1, \ldots, M$.

We begin with a first-order semi-implicit time discretization: Let $u^M(x) = \varphi(x)$. For $k = M-1, \ldots, 0$, we compute u^k by solving the following discretized version of (3.1):

$$\begin{aligned} &\frac{u^{k+1} - u^k}{h} + \frac{1}{2}\partial_x\Big(\sigma^2(t_k, x, u^{k+1})u_x^k\Big) \\ &\quad + \hat{b}(t_k, x, u^{k+1}, u_x^{k+1})u_x^{k+1} + g(t_k, x, u^{k+1}) = 0. \end{aligned} \tag{3.4}$$

In other words, at each time step, the problem is reduced to solving the following elliptic equation:

$$u^k - \frac{h}{2}\partial_x\Big(\sigma^2(t_k, x, u^{k+1})u_x^k\Big) = f_h^{k+1}(x), \quad \lim_{x\to\pm\infty} u^k(x) = 0, \tag{3.5}$$

where

$$f_h^{k+1}(x) = u^{k+1} + h\Big\{\hat{b}(t_k, x, u^{k+1}, u_x^{k+1})u_x^{k+1} + g(t_k, x, u^{k+1})\Big\}.$$

Since the problem is set on the whole domain, it is natural to consider a *Hermite-spectral method*. To be more precise, let $\{x_j\}_{j=0}^N$ be the Hermite–Gauss quadrature points and let $\mathcal{H}_N$ be defined in (2.12). A Hermite-collocation method for (3.5) is as follows:

Let $u_N^M(x) = I_N\varphi$. For $k = M-1, \ldots, 0$, we compute $u_N^k \in \mathcal{H}_N$ such that

$$u_N^k(x_j) - \frac{h}{2}\partial_x\Big(I_N(\sigma^2(t_k, x, u_N^{k+1})\partial_x u_N^k)\Big)(x_j) = f_h^{k+1}(x_j), \quad j = 0, 1, \ldots, N. \tag{3.6}$$

Using the identity (2.15) and integration by parts, we can rewrite (3.6) in the following variational formulation: Find $u_N^k \in \mathcal{H}_N$ such that

$$\langle u_N^k,\, v_N\rangle_N + \frac{h}{2}\langle\sigma^2(t_k, x, u_N^{k+1})\partial_x u_N^k,\, \partial_x v_N\rangle_N = \langle f_{h,N}^{k+1},\, v_N\rangle_N \quad \forall v_N \in \mathcal{H}_N, \tag{3.7}$$

where $f_{h,N}^{k+1} \in \mathcal{H}_N$ and $f_{h,N}^{k+1}(x_j) = f^{k+1}(x_j)$, $j = 0, 1, \ldots, N$.

We remark here that while the first-order (time discretization) scheme is simple to use and analyze, in practice one often prefers higher-order schemes. These schemes could be easily constructed and often implemented in a straightforward manner, but

their error analysis becomes rather tedious. In fact, as we will see in the next sections, the error analysis for the first-order semi-implicit scheme presented in (3.7) is already unpleasantly lengthy. As an example, we present the following second-order backward difference formula (BDF) Adam–Bashforth scheme which will be used in our numerical experiments without theoretical error analysis.

The second-order BDF Adam–Bashforth scheme.

Let $u_N^M(x) = \varphi(x)$ and let $u_N^{M-1}(x)$ be computed from (3.4).

For $k = M-2, \dots, 1, 0$, we compute u^k from

$$\frac{-3u_N^{k+2} + 4u_N^{k+1} - u_N^k}{2h} + \partial_x\Big(\frac{\sigma^2}{2}\partial_x u_N^k\Big) + (2\partial_x u_N^{k+1} - \partial_x u_N^{k+2})\hat{b} + g = 0, \tag{3.8}$$

where

$$\sigma^2 \triangleq \sigma^2(t_k, x, 2u_N^{k+1} - u_N^{k+2}), \quad g \triangleq g(t_k, x, 2u_N^{k+1} - u_N^{k+2}),$$

$$\hat{b} \triangleq \hat{b}(t_k, x, 2u_N^{k+1} - u_N^{k+2}, 2\partial_x u_N^{k+1} - \partial_x u_N^{k+2}).$$

We note that this scheme still leads to an elliptic equation of the form (3.5) for u^k at each time step. In particular, this second-order scheme should be used together with the $\frac{3}{2}$-order SDE scheme presented below.

3.2. Numerical schemes for the SDE (2.4). We now turn our attention to the discretization of the forward SDE (2.4). We begin with the simplest one, known as the "*forward Euler scheme*." Assuming that for each $N \in \mathbb{N}$ we have obtained the approximating solution to the PDE (3.1), denoted by u_N^k, $k = 0, 1, \dots, M$, at each time $t_k = kh$ we define recursively the approximate solution to the SDE (2.4) by

$$\begin{cases} X_0^N = x, \\ X_{k+1}^N = X_k^N + b(t_k, X_k^N, u_N^k(X_k^N))h + \sigma(t_k, X_k^N, u_N^k(X_k^N))\Delta_k W, \ k = 0, 1, \dots, M, \end{cases} \tag{3.9}$$

where $\Delta_k W \triangleq W(t_k + h) - W(t_k)$. For notational simplicity in what follows we shall simply denote $X_k = X_k^N$ when the context is clear.

It is well understood that the Euler scheme is easy to implement and has the minimum requirements on the coefficients. Furthermore, if we denote the true solution to the PDE (3.1) by u, denote $u^k(x) \triangleq u(t_k, x)$, and define an intermediate approximation $\hat{X}$ by

$$\begin{cases} \hat{X}_0 = x, \\ \hat{X}_{k+1} = \hat{X}_k + b(t_k, \hat{X}_k, u^k(\hat{X}_k))h + \sigma(t_k, \hat{X}_k, u^k(\hat{X}_k))\Delta_k W, \quad k = 0, 1, \dots, M, \end{cases} \tag{3.10}$$

then by the *fundamental convergence theorem* (cf., e.g., [21]), the mean-square error of the Euler scheme is $E|X(t_k) - \hat{X}_k|^2 \sim h$, where X is the true solution of (2.4) (namely, the rate of convergence is $\frac{1}{2}$).

In order to obtain a higher-order rate of convergence, one has to use a higher order scheme for the forward SDE. However, we should note that while in theory arbitrarily high-order schemes for (2.4) can be constructed with Taylor–Itô-type expansions (see, e.g., [21]), the complexity of these schemes increases drastically. Consequently it often

becomes too "expensive" in computational terms to implement. We will consider the following higher-order schemes in our numerical experiments to test the numerical accuracy and to compare our method with existing results.

A. *Milstein scheme* (cf. [21], [31]).

This is a well-known scheme with a first-order convergence rate. The recursive relation, adapted to our case, is given as follows:

(3.11)
$$\begin{cases} X_0 = x, \\ X_{k+1} = X_k + b(t_k, X_k, u_N^k(X_k))h + \sigma(t_k, X_k, u_N^k(X_k))\Delta_k W \\ \qquad +\dfrac{1}{2}\sigma(t_k, X_k, u_N^k(X_k))\{\sigma_x(t_k, X_k, u_N^k(X_k)) + \sigma_u(t_k, X_k, u_N^k(X_k))\partial_x u_N^k(X_k)\} \\ \qquad \times(\Delta_k^2 W - h), \qquad k = 0, 1, \ldots, M-1, \end{cases}$$

where $\Delta_k^2 W \stackrel{\triangle}{=} (W(t_{k+1}) - W(t_k))^2$.

The next two schemes require higher-order regularity of the coefficients. We shall assume that all such requirements, whenever needed, are fulfilled without further specification.

B. *Platen–Wagner scheme* (cf. [21]).

Using the idea of Taylor–Itô expansion up to order $\frac{3}{2}$, and assuming that the coefficients are actually twice continuously differentiable, Platen and Wagner proposed the following scheme: for $k = 0, 1, \ldots, M-1$,

(3.12)
$$\begin{cases} X_0 = x, \\ X_{k+1} = X_k + bh + \sigma\Delta_k W + \dfrac{1}{2}\sigma\sigma'\{\Delta_k^2 W - h\} + b'\sigma\Delta_k\Psi + \dfrac{1}{2}\Big(bb' + \dfrac{1}{2}\sigma^2 b''\Big)h^2 \\ \qquad +\Big(b\sigma' + \dfrac{1}{2}\sigma^2\sigma''\Big)\{h\Delta_k W - \Delta_k W\} + \dfrac{1}{2}\sigma\Big(\sigma\sigma'' + (\sigma')^2\Big)\left\{\dfrac{1}{3}\Delta_k^2 W - h\right\}\Delta_k W, \end{cases}$$

where $\Delta_k^2 W \stackrel{\triangle}{=} (W(t_{k+1}) - W(t_k))^2$, $\Delta_k\Psi \stackrel{\triangle}{=} \int_{t_k}^{t_{k+1}}[W(t) - W(t_k)]dt$, $b = b(t_k, X_k, u_N^k(X_k))$, $\sigma = \sigma(t_k, X_k, u_N^k(X_k))$, and, for $\varphi = b$, σ,

$$\varphi' = \varphi_x + \varphi_u\partial_x u_N^k, \quad \varphi'' \stackrel{\triangle}{=} \varphi_{xx} + 2\varphi_{xu}\partial_x u_N^k + \varphi_{uu}(\partial_x u_N^k)^2 + \varphi_u\partial_x^2 u_N^k. \tag{3.13}$$

Here the partial derivatives of b and σ should be evaluated at $(t_k, X_k, u_N^k(X_k))$, and the approximate functions u_N^k, $\frac{du_N^k}{dx}$, and $\frac{d^2u_N^k}{dx^2}$ should be evaluated at point (X_k).

We should note that $\Delta_k\Psi = \int_{t_k}^{t_{k+1}} W(t) - W(t_k)dt \sim N(0, \frac{1}{3}h^3)$, and the covariance of $\Delta_k W$ and $\Delta_k\Psi$ is $\mathbb{E}\Big(\Delta_k W\Delta_k\Psi\Big) = \frac{1}{2}h^2$. The presence of the $\Delta_k\Psi$ obviously complicates the analysis of the scheme. This will be even more so when the order of expansion increases. Treating these terms effectively will become more important.

C. *The stochastic Adam–Bashforth (SAB) scheme* (cf. [16]).

It is easily seen from (3.13) that the Platen–Wagner $\frac{3}{2}$-order scheme requires that b and σ are both twice differentiable. Recently, Ewald and Temam [16] constructed a stochastic version of the Adam–Bashforth scheme which does not involve the second

derivatives of coefficient function b but still achieves the $\frac{3}{2}$-order convergence rate. This SAB scheme, adapted for a one-dimensional diffusion of the form

$$dX_t = b(t, X_t)dt + \sigma(t, X_t)dW(t),$$

can be rewritten as follows:

(3.14)
$$X_{k+2} = X_{k+1} + \frac{\Delta t}{2}[3b(t_{k+1}, X_{k+1}) - b(t_k, X_k)] - \frac{3}{2}\Delta t A_k(t_k, X_k) + B_k(t_k, X_k),$$

where

(3.15) $A_k(t, x) = [\sigma b_x](t, x)\Delta_k W,$

$$B_k(t, x) = \sigma(t, x)\Delta_k W + \left[\sigma_t + b\sigma_x + \frac{1}{2}\sigma^2\sigma_{xx}\right](t, x)I_{(0,1)} + [\sigma b_x](t, x)I_{(1,0)},$$

$$+ [\sigma\sigma_x](t, x)I_{(1,1)} + [\sigma((\sigma_x)^2 + \sigma\sigma_{xx})](t, x)I_{(1,1,1)},$$

with $\Delta_k W = W_{t_{k+1}} - W_{t_k}$ and $h = t_{k+1} - t_k$ as before, and the random coefficients I's are defined by

$$I_{(0,1)} = 2h\Delta_{k+1}W - \int_{t_{k+1}}^{t_{k+2}} [W(s) - W(t_{k+1})]ds,$$

(3.16)
$$I_{(1,0)} = h\Delta_k W + \int_{t_{k+1}}^{t_{k+2}} [W(s) - W(t_{k+1})]ds,$$

and $I(1,1)$, $I(1,1,1)$ are the iterated Itô integrals

(3.17)
$$I_{(1,1)} = \int_{t_k}^{t_{k+2}} \int_{t_k}^{t} dW(s)dW(t) - \int_{t_k}^{t_{k+1}} \int_{t_k}^{t} dW(s)dW(t),$$

$$I_{(1,1,1)} = \int_{t_k}^{t_{k+2}} \int_{t_k}^{t} \int_{t_k}^{s} dW(r)dW(s)dW(t) - \int_{t_k}^{t_{k+1}} \int_{t_k}^{t} \int_{t_k}^{s} dW(r)dW(s)dW(t).$$

To calculate the iterated Itô integrals $I_{(1,\dots,1)}$, the useful formula of Itô [20] is often employed. More precisely, recall the scaled Hermite polynomials h_n defined by

$$h_n(x) = (-1)^n e^{\frac{1}{2}x^2} \frac{d^n}{dx^n}(e^{-\frac{1}{2}x^2}), \quad n = 0, 1, 2, \dots .$$

Let $H_n^*(x, z) = z^{n/2}h_n(x/\sqrt{z})$. For any $g \in L^2([a, b])$, let $X_t = \int_a^t g(s)dW_s$. Applying Ito's formula repeatedly to $H_n^*(X_t, \langle X\rangle_t)$ from a to b and using the fact that $(\frac{\partial}{\partial_z} + 1/2\frac{\partial^2}{\partial_{x^2}})H_n^*(x, z) = 0$, we can derive

(3.18)
$$n! \int_a^b \int_a^{t_n} \cdots \int_a^{t_2} g(t_1)g(t_2)\cdots g(t_n)dW_{t_1}\cdots dW_{t_n} = \|g\|^n h_n\left(\frac{\theta}{\|g\|}\right),$$

where

$$\|g\| = \|g\|_{L^2([a,b])} \quad \text{and} \quad \theta = \int_a^b g(t)dW_t.$$

Thus the coefficients $I_{(1,1)}$ and $I_{(1,1,1)}$ in (3.17) can be calculated explicitly as

$$I_{(1,1)} = \frac{1}{2}\Big(\Delta_{k+1}^2 W + 2\Delta_{k+1}W\Delta_k W - h\Big), \tag{3.19}$$

$$I_{(1,1,1)} = \frac{1}{6}\Big((\Delta_{k+1}W + \Delta_k W)^3 - (\Delta_k W)^3 - 6h\Delta_{k+1}W - 3h\Delta_k W\Big).$$

Using the above relations, we can rewrite the $\frac{3}{2}$-order SAB scheme for the one-dimensional forward SDE (2.4) as

$$\begin{aligned}
&X_0 = x,\\
&X_{k+2} = X_{k+1} + \frac{h}{2}\Big[3b(t_{k+1}, X_{k+1}, u_N^{k+1}(X_{k+1})) - b\Big]\\
&\quad -\frac{3}{2}h\sigma b'\Delta_k W + \sigma\Delta_k W + \frac{1}{2}\sigma\sigma'\Big\{(\Delta_{k+1}W)^2 + 2(\Delta_{k+1}W)(\Delta_k W) - h\Big\}\\
&\quad +\Big(\sigma_t + b\sigma' + \frac{1}{2}\sigma^2\sigma''\Big)\{2h\Delta_{k+1}W - \Delta_{k+1}\Psi\} + \sigma b'\{h\Delta_k W + \Delta_{k+1}\Psi\}\\
&\quad +\frac{1}{6}\sigma\Big(\sigma\sigma'' + (\sigma')^2\Big)\Big\{(\Delta_{k+1}W + \Delta_k W)^3 - (\Delta_k W)^3 - 6h\Delta_{k+1}W - 3h\Delta_k W\Big\},
\end{aligned}$$

where $k = 0, 1, \ldots, M-1$. Similarly,

$$\begin{aligned}
b &= b(t_k, X_k, u_N^k(X_k)),\\
\sigma &= \sigma(t_k, X_k, u_N^k(X_k)),\\
b' &= \frac{\partial b}{\partial x} + \frac{\partial b}{\partial u}\frac{du_N^k}{dx},\\
\sigma' &= \frac{\partial \sigma}{\partial x} + \frac{\partial \sigma}{\partial u}\frac{du_N^k}{dx},\\
\sigma'' &= \frac{\partial^2\sigma}{\partial x^2} + 2\frac{\partial^2\sigma}{\partial x\partial u}\frac{du_N^k}{dx} + \frac{\partial^2\sigma}{\partial u^2}\left(\frac{du_N^k}{dx}\right)^2 + \frac{\partial\sigma}{\partial u}\frac{d^2u_N^k}{dx^2},
\end{aligned}$$

where the partial derivatives of b and σ are evaluated at $(t_k, X_k, u_N^k(X_k))$ and the approximate functions u_N^k, $\frac{du_N^k}{dx}$, and $\frac{d^2u_N^k}{dx^2}$ are evaluated at point (X_k).

Finally, the components Y and Z of the solution to (2.1) are approximated as

$$Y_k = u_N^k(X_k), \quad Z_k = \sigma(t_k, X_k, Y_k)\frac{\partial u_N^k}{\partial x}(X_k). \tag{3.20}$$

4. Error analysis for the PDE approximation. In this section we carry out an error analysis for the approximation of the PDE (3.1). In order to simplify the presentation, we shall consider only the following *Hermite–Galerkin scheme* for (3.4).

Let $u_N^M(x) = P_N\varphi$. For $k = M-1, \dots, 0$, we compute $u_N^k \in \mathcal{H}_N$ such that

$$\left\langle \frac{u_N^{k+1} - u_N^k}{h}, v_N \right\rangle + \frac{1}{2}\left\langle \partial_x\Big(\sigma^2(t_k, \cdot, u_N^{k+1})(u_N^k)_x\Big), v_N \right\rangle \tag{4.1}$$

$$+ \langle \hat{b}(t_k, \cdot, u_N^{k+1}, (u_N^{k+1})_x)\partial_x(u_N^{k+1}) + g(t_k, \cdot, u_N^{k+1}), v_N\rangle = 0 \qquad \forall v_N \in \mathcal{H}_N.$$

We note that the only difference between this Hermite–Galerkin scheme and the Hermite-collocation scheme (3.7) is that in the latter the continuous inner product is replaced by the discrete inner product. It is well known that for N sufficiently large, the differences between the two approaches are negligible (cf. [18]).

Hereafter, we shall use "$A \lesssim B$" to mean that there exists a constant $C > 0$ independent of N or h such that $A \le CB$.

Our main result in this section is the following theorem.

THEOREM 4.1. *Assume* (A1)–(A3). *Let u and u_N^k be the solutions of* (3.1) *and* (4.1), *respectively. Assume further that $u \in C([0,T]; H_D^m(\mathbb{R}))$, that $u_t \in L^2(0,T; H_D^m(\mathbb{R}))$ with some $m > 1$, and that $u_{tt} \in L^2(0,T; H^{-1}(\mathbb{R}))$. Then, there exists $h_0 > 0$ such that for $h \le h_0$ the scheme* (3.4) *is stable, and the following error estimates hold: for each $k = 0, 1, \dots, M$,*

$$\|u(t_k,\cdot) - u_N^k\| + \left(h\sum_{j=k}^{M}\|\partial_x(u(t_j,\cdot) - u_N^j)\|^2\right)^{\frac{1}{2}}$$

$$\lesssim h\Big(\|u_{tt}\|_{L^2(0,T;H^{-1}(\mathbb{R}))} + \|u_t\|_{L^2(0,T;H^1(\mathbb{R}))}\Big)$$

$$+ N^{\frac{1-m}{2}}\Big(\|u\|_{C([0,T];H_D^m)} + \|u_t\|_{L^2(0,T;H_D^m)}\Big).$$

Proof. Let E^k, $k = M-1, \dots, 1, 0$, be the consistency error defined by

$$E^k(\cdot) \triangleq \frac{1}{h}\Big(u(t_{k+1},\cdot) - u(t_k,\cdot)\Big) + \hat{b}(t_k,\cdot,u(t_{k+1},\cdot),\partial_x u(t_{k+1},\cdot))\,\partial_x u(t_{k+1},\cdot)$$

$$+ \partial_x\left(\frac{1}{2}\sigma^2(t_k,\cdot,u(t_{k+1},\cdot))\partial_x u(t_k,\cdot)\right) + g(t_k,\cdot,u(t_{k+1},\cdot)), \tag{4.2}$$

where $u(t_k,\cdot)$ is the exact solution to (3.1). First, we shall obtain the estimate for the consistency error E^k. By using the integral residue form of the Taylor series, and the fact that $u(t_k,\cdot)$ is the exact solution to (3.1), we can easily rewrite $E^k(\cdot)$ as

$$E^k(\cdot) = \frac{1}{h}\int_{t_k}^{t_{k+1}} u_{tt}(t,\cdot)(t-t_k)dt$$

$$+ g(t_k,\cdot,u(t_{k+1},\cdot)) - g(t_k,\cdot,u(t_k,\cdot))$$

$$+ \hat{b}(t_k,\cdot,u(t_{k+1},\cdot),\partial_x u(t_{k+1},\cdot))\,\partial_x u(t_{k+1},\cdot)$$

$$- \hat{b}(t_k,\cdot,u(t_{k+1},\cdot),\partial_x u(t_{k+1},\cdot))\,\partial_x u(t_k,\cdot)$$

$$+ \hat{b}(t_k,\cdot,u(t_{k+1},\cdot),\partial_x u(t_{k+1},\cdot))\,\partial_x u(t_k,\cdot) - \hat{b}(t_k,\cdot,u(t_k,\cdot),\partial_x u(t_k,\cdot))\,\partial_x u(t_k,\cdot)$$

$$+\partial_x\left(\frac{1}{2}(\sigma^2(t_k,\cdot,u(t_{k+1},\cdot))-\sigma^2(t_k,\cdot,u(t_k,\cdot)))\partial_x u(t_k,\cdot)\right).$$

Under assumptions (A1)–(A3) (see also Remark 2.2), it is known that the solution to (3.1) must have bounded first-order derivative $\partial_x u$; i.e., $\|\partial_x u\|_{L^\infty((0,T)\times\mathbb{R})}\le C$ (see, e.g., [10]). We can then derive from assumptions (A1)–(A3) (see also Remark 2.2) that

$$\begin{aligned}\|E^k(\cdot)\|_{-1}\lesssim{}&\frac{1}{h}\int_{t_k}^{t_{k+1}}\|u_{tt}(t,\cdot)\|_{-1}(t-t_k)dt+h^{\frac{1}{2}}\left(\int_{t_k}^{t_{k+1}}\|\partial_t u(t,\cdot)\|^2dt\right)^{\frac{1}{2}}\\&+h^{\frac{1}{2}}\left(\int_{t_k}^{t_{k+1}}\|\partial_{tx}u(t,\cdot)\|^2dt\right)^{\frac{1}{2}}\\&+\|(\sigma^2(t_k,\cdot,u(t_{k+1},\cdot))-\sigma^2(t_k,\cdot,u(t_k,\cdot)))\partial_x u(t_k,\cdot)\|.\end{aligned}$$

Applying the Schwarz inequality and using the boundedness of $\partial_x u$, we find

$$\|E^k(\cdot)\|_{-1}^2\lesssim h\int_{t_k}^{t_{k+1}}\|u_{tt}(t,\cdot)\|_{-1}^2dt+h\int_{t_k}^{t_{k+1}}\|u_t(t,\cdot)\|_1^2dt,$$

which implies that

$$h\sum_{k=0}^{M}\|E^k(\cdot)\|_{-1}^2\lesssim h^2\|u_{tt}\|^2_{L^2(0,T;H^{-1}(\mathbb{R}))}+h^2\|u_t\|^2_{L^2(0,T;H^1(\mathbb{R}))}.\tag{4.3}$$

In what follows we set $\hat{e}_N^k=P_Nu(t_k,\cdot)-u_N^k$, $\tilde{e}_N^k=u(t_k,\cdot)-P_Nu(t_k,\cdot)$, and thus we have $e_N^k=u(t_k,\cdot)-u_N^k=\hat{e}_N^k+\tilde{e}_N^k$.

Next, multiplying by $v_N\in\mathcal{H}_N$ on both sides of (4.2), using integration by parts, and then subtracting (4.1), we obtain that

$$\begin{aligned}\langle E^k,v_N\rangle=\frac{1}{h}\langle e_N^{k+1}-e_N^k\,,v_N\rangle&-\left\langle\frac{1}{2}\sigma^2(t_k,\cdot,u(t_{k+1},\cdot))\partial_x u(t_k,\cdot)\,,\partial_x v_N\right\rangle\\&+\left\langle\frac{1}{2}\sigma^2(t_k,\cdot,u_N^{k+1})\partial_x u_N^k\,,\partial_x v_N\right\rangle\\&+\langle\hat{b}(t_k,\cdot,u(t_{k+1},\cdot),\partial_x u(t_{k+1},\cdot)))\,\partial_x u(t_{k+1},\cdot)\\&\quad-\hat{b}(t_k,\cdot,u_N^{k+1},\partial_x u_N^{k+1})\partial_x u_N^{k+1}\,,v_N\rangle\\&+\langle g(t_k,\cdot,u(t_{k+1},\cdot))-g(t_k,\cdot,u_N^{k+1})\,,v_N\rangle.\end{aligned}$$

Or, equivalently,

$$\begin{aligned}\langle E^k,v_N\rangle=\frac{1}{h}\langle e_N^{k+1}-e_N^k\,,v_N\rangle&-\left\langle\frac{1}{2}\sigma^2(t_k,\cdot,u_N^{k+1})\partial_x e_N^k\,,\partial_x v_N\right\rangle\\&-\left\langle\partial_x u(t_k,\cdot)\,,\frac{1}{2}\sigma^2(t_k,\cdot,u(t_{k+1},\cdot))\partial_x v_N-\frac{1}{2}\sigma^2(t_k,\cdot,u_N^{k+1})\partial_x v_N\right\rangle\\&+\langle\hat{b}(t_k,\cdot,u(t_{k+1},\cdot),\partial_x u(t_{k+1},\cdot))\,\partial_x u(t_{k+1},\cdot)\\&\quad-\hat{b}(t_k,\cdot,u_N^{k+1},\partial_x u_N^{k+1})\partial_x u_N^{k+1}\,,v_N\rangle\\&+\langle g(t_k,\cdot,u(t_{k+1},\cdot))-g(t_k,\cdot,u_N^{k+1})\,,v_N\rangle.\end{aligned}$$

Since $e_N^k = \tilde{e}_N^k + \hat{e}_N^k$, we have

(4.4)
$$\begin{aligned}
&\frac{1}{h}\langle \hat{e}_N^{k+1} - \hat{e}_N^k, v_N\rangle - \left\langle \frac{1}{2}\sigma^2(t_k,\cdot,u_N^{k+1})\partial_x \hat{e}_N^k \,,\partial_x v_N \right\rangle \\
&\qquad = -\frac{1}{h}\langle \tilde{e}_N^{k+1} - \tilde{e}_N^k \,, v_N\rangle + \left\langle \frac{1}{2}\sigma^2(t_k,\cdot,u_N^{k+1})\partial_x \tilde{e}_N^k \,,\partial_x v_N \right\rangle \\
&\qquad + \left\langle \partial_x u(t_k,\cdot)\,, \frac{1}{2}\sigma^2(t_k,\cdot,u(t_{k+1},\cdot))\partial_x v_N - \frac{1}{2}\sigma^2(t_k,\cdot,u_N^{k+1})\partial_x v_N \right\rangle \\
&\qquad\quad - \langle \hat{b}(t_k,\cdot,u(t_{k+1},\cdot),\partial_x u(t_{k+1},\cdot))\ \partial_x u(t_{k+1},\cdot) \\
&\qquad - \hat{b}(t_k,\cdot,u_N^{k+1},\partial_x u_N^{k+1})\partial_x u_N^{k+1}\ , v_N\rangle \\
&\qquad - \langle g(t_k,\cdot,u(t_{k+1},\cdot)) - g(t_k,\cdot,u_N^{k+1})\ , v_N\rangle + \langle E^k(\cdot)\ , v_N\rangle.
\end{aligned}$$

Denote

$$I_1 = -\langle g(t_k,\cdot,u(t_{k+1},\cdot)) - g(t_k,\cdot,u_N^{k+1})\ , v_N\rangle,$$

$$I_2 = -\langle \hat{b}(t_k,\cdot,u(t_{k+1},\cdot),\partial_x u(t_{k+1},\cdot))\ \partial_x u(t_{k+1},\cdot) - \hat{b}(t_k,\cdot,u_N^{k+1},\partial_x u_N^{k+1})\partial_x u_N^{k+1}\ , v_N\rangle,$$

$$I_3 = \left\langle \partial_x u(t_k,\cdot)\,, \frac{1}{2}\sigma^2(t_k,\cdot,u(t_{k+1},\cdot))\partial_x v_N - \frac{1}{2}\sigma^2(t_k,\cdot,u_N^{k+1})\partial_x v_N \right\rangle,$$

$$I_4 = \left\langle \frac{1}{2}\sigma^2(t_k,\cdot,u_N^{k+1})\partial_x \tilde{e}_N^k \,,\partial_x v_N \right\rangle,$$

$$I_5 = -\frac{1}{h}\langle \tilde{e}_N^{k+1} - \tilde{e}_N^k \,, v_N\rangle,$$

$$I_6 = \langle E^k(\cdot)\ , v_N\rangle.$$

We shall estimate these terms separately under assumptions (A1)–(A3) (see also Remark 2.2). To begin with, noting the Lipschitz property of g and applying the Cauchy–Schwarz inequality, we have, for some constant $C_1 > 0$ and any $\varepsilon > 0$,

$$\begin{aligned}
(4.5)\quad |I_1| &\le C_1\langle |u(t_{k+1},\cdot) - u_N^{k+1}|\ , |v_N|\rangle = C_1\langle |e_N^{k+1}|\ , |v_N|\rangle \\
&\le \frac{C_1 h}{2\varepsilon}\|e_N^{k+1}\|^2 + \frac{C_1\varepsilon}{2h}\|v_N\|^2 \le \frac{C_1 h}{\varepsilon}\|\hat{e}_N^{k+1}\|^2 + \frac{C_1 h}{\varepsilon}\|\tilde{e}_N^{k+1}\|^2 + \frac{C_1\varepsilon}{2h}\|v_N\|^2.
\end{aligned}$$

Similarly, we have

$$(4.6)\qquad |I_4| \le C_4\langle |\partial_x \tilde{e}_N^k|\ , |\partial_x v_N|\rangle \le \frac{C_4 h}{2\varepsilon}\|\partial_x \tilde{e}_N^k\|^2 + \frac{C_4\varepsilon}{2h}\|\partial_x v_N\|^2;$$

$$
\begin{aligned}
|I_2| &\le |\langle \hat{b}(t_k,\cdot,u(t_{k+1},\cdot),\partial_x u(t_{k+1},\cdot))\ \partial_x u(t_{k+1},\cdot) \\
&\qquad - \hat{b}(t_k,\cdot,u_N^{k+1},\partial_x u_N^{k+1})\partial_x u(t_{k+1},\cdot)\ , v_N\rangle| \\
&\quad + |\langle \hat{b}(t_k,\cdot,u_N^{k+1},\partial_x u_N^{k+1}))(\partial_x u(t_{k+1},\cdot) - \partial_x u_N^{k+1})\ , v_N\rangle| \\
&\le |\langle \|\partial_x u\|_{L^\infty((0,T)\times\mathbb{R})} K(|e_N^{k+1}| + |\partial_x e_N^{k+1}|),\ |v_N|\rangle| + K|\langle |\partial_x e_N^{k+1}|, |v_N|\rangle| \\
&\le C_2\langle |e_N^{k+1}| + |\partial_x e_N^{k+1}|, |v_N|\rangle + C_2\langle |\partial_x e_N^{k+1}|, |v_N|\rangle \qquad (4.7)\\
&\le C_2\langle |\hat{e}_N^{k+1}| + |\partial_x \hat{e}_N^{k+1}| + |\tilde{e}_N^{k+1}| + |\partial_x \tilde{e}_N^{k+1}|\ , |v_N|\rangle \\
&\quad + C_2\langle |\partial_x \hat{e}_N^{k+1}| + |\partial_x \tilde{e}_N^{k+1}|\ , |v_N|\rangle \\
&\le \frac{C_2 h}{\varepsilon}(\|\hat{e}_N^{k+1}\|^2 + \|\tilde{e}_N^{k+1}\|^2 + \|\partial_x \tilde{e}_N^{k+1}\|^2) \\
&\quad + \frac{C_2\varepsilon}{h}\|v_N\|^2 + C_2\varepsilon_1 h\|\partial_x \hat{e}_N^{k+1}\|^2 + \frac{C_2}{\varepsilon_1 h}\|v_N\|^2,
\end{aligned}
$$

where C_2 depends only on $K, \|\partial_x u\|_{L^\infty((0,T)\times\mathbb{R})}$ and ε_1 is to be determined later;

$$
\begin{aligned}
|I_3| &\le CK\ \|\partial_x u\|_{L^\infty((0,T)\times\mathbb{R})}\ \langle |e_N^{k+1}|\ , |\partial_x v_N|\rangle \le \frac{C_3 h}{2\varepsilon}\|e_N^{k+1}\|^2 + \frac{C_3\varepsilon}{2h}\|\partial_x v_N\|^2 \qquad (4.8)\\
&\le \frac{C_3 h}{\varepsilon}(\|\hat{e}_N^{k+1}\|^2 + \|\tilde{e}_N^{k+1}\|^2) + \frac{C_3\varepsilon}{2h}\|\partial_x v_N\|^2,
\end{aligned}
$$

where $C_3 = CK\ \|\partial_x u\|_{L^\infty((0,T)\times\mathbb{R})}$. Finally, let $\tilde{E}_N^k = -\frac{1}{h}(\tilde{e}_N^{k+1} - \tilde{e}_N^k)$; then we have

$$
|I_5| \le \frac{h}{2\varepsilon}\|\tilde{E}_N^k\|^2 + \frac{\varepsilon}{2h}\|v_N\|^2 \quad \text{and} \quad |I_6| \le \frac{h}{2\varepsilon}\|E^k(\cdot)\|_{-1}^2 + \frac{\varepsilon}{2h}\|v_N\|_1^2. \qquad (4.9)
$$

To obtain the desired estimate, let us now look at the left-hand side of (4.4) with $v_N = -h\ \hat{e}_N^k$. Note that

$$
\begin{aligned}
&\frac{1}{h}\langle \hat{e}_N^{k+1} - \hat{e}_N^k\ , -h\ \hat{e}_N^k\rangle = \frac{1}{2}(\|\hat{e}_N^k\|^2 - \|\hat{e}_N^{k+1}\|^2 + \|\hat{e}_N^k - \hat{e}_N^{k+1}\|^2), \\
&-\left\langle \partial_x \hat{e}_N^k\ , \frac{1}{2}\sigma^2(t_k,\cdot,u_N^{k+1})\partial_x v_N \right\rangle \ge ch\|\partial_x \hat{e}_N^k\|^2, \qquad (4.10)
\end{aligned}
$$

where $c > 0$ is a lower bound of σ^2, with a slight abuse of notation (compare to the constant $c > 0$ in (A3)). Thanks to the Schwarz inequality, and denoting $C = 5\max_{1\le i\le 4}\{C_i\} + 1$, we derive from (4.5)–(4.10) that

$$
\begin{aligned}
\|\hat{e}_N^k\|^2 + ch\|\partial_x \hat{e}_N^k\|^2 &\le \left(\frac{Ch}{\varepsilon} + \frac{1}{2}\right)\|\hat{e}_N^{k+1}\|^2 + C\varepsilon_1 h\|\partial_x \hat{e}_N^{k+1}\|^2 \qquad (4.11)\\
&\quad + \left(\frac{Ch}{\varepsilon_1} + C\varepsilon h + \varepsilon h + \frac{1}{2}\right)\|\hat{e}_N^k\|^2 \\
&\quad + C\varepsilon h\|\partial_x \hat{e}_N^k\|^2 + \frac{Ch}{\varepsilon}(\|\tilde{e}_N^{k+1}\|^2 + \|\partial_x \tilde{e}_N^{k+1}\|^2) \\
&\quad + \frac{Ch}{\varepsilon}\|\partial_x \tilde{e}_N^k\|^2 + \frac{h}{\varepsilon}\|E^k(\cdot)\|_{-1}^2 + \frac{h}{\varepsilon}\|\tilde{E}_N^k\|^2.
\end{aligned}
$$

Therefore, (4.11) can now be rewritten as

$$\left(\frac{1}{2} - h\left(C\varepsilon + \varepsilon + \frac{C}{\varepsilon_1}\right)\right)\|\hat{e}_N^k\|^2 + (c - C\varepsilon)h\|\partial_x \hat{e}_N^k\|^2$$

$$\leq \left(\frac{Ch}{\varepsilon} + \frac{1}{2}\right)\|\hat{e}_N^{k+1}\|^2 + C\varepsilon_1 h\|\partial_x \hat{e}_N^{k+1}\|^2 \tag{4.12}$$

$$+ \frac{h}{\varepsilon}\Big(C\|\tilde{e}_N^{k+1}\|^2 + C\|\partial_x \tilde{e}_N^k\|^2 + C\|\partial_x \tilde{e}_N^{k+1}\|^2 + \|\tilde{E}_N^k\|^2 + \|E^k(\cdot)\|_{-1}^2\Big).$$

We choose ε small enough so that $c - C\varepsilon > 0$. Multiplying both sides of (4.12) by 2, choosing $\varepsilon_1 = \frac{c - C\varepsilon}{2C}$, setting $C_5 \triangleq C + 1$, $C_\varepsilon \triangleq 2(C\varepsilon + \varepsilon + \frac{C}{\varepsilon_1})$, and assuming that the time step h satisfies the conditions

$$h < h_0 = \min\left(\frac{1}{2C_\varepsilon}, \frac{\varepsilon}{2C}\right), \tag{4.13}$$

inequality (4.12) becomes

(4.14)

$$(1 - hC_\varepsilon)\|\hat{e}_N^k\|^2 + 2(c - C\varepsilon)h\|\partial_x \hat{e}_N^k\|^2 \leq \left(\frac{2Ch}{\varepsilon} + 1\right)\|\hat{e}_N^{k+1}\|^2 + (c - C\varepsilon)h\|\partial_x \hat{e}_N^{k+1}\|^2$$

$$+ \frac{hC_5}{\varepsilon}\Big(\|\tilde{e}_N^{k+1}\|^2 + \|\partial_x \tilde{e}_N^k\|^2 + \|\partial_x \tilde{e}_N^{k+1}\|^2 + \|\tilde{E}_N^k\|^2 + \|E^k(\cdot)\|_{-1}^2\Big).$$

We now apply a standard discrete backward Gronwall inequality and, noticing that $\hat{e}_N^M = 0$, we obtain

$$\|\hat{e}_N^k\|^2 + h\sum_{j=k}^{M}\|\partial_x \hat{e}_N^j\|^2 \lesssim h\sum_{j=k}^{M}\Big(\|\tilde{e}_N^j\|^2 + \|\partial_x \tilde{e}_N^j\|^2 + \|\tilde{E}_N^j\|^2 + \|E^j(\cdot)\|_{-1}^2\Big). \tag{4.15}$$

We now estimate the terms on the right-hand side. First, by virtue of Lemma 2.3 with $s = 0, 1$, respectively, and $r = m$, we have

$$\|\tilde{e}_N^{k+1}\|^2 + \|\tilde{e}_N^k\|^2 \leq C_6 N^{-m}(\|D^m u(t_{k+1}, .)\|^2 + \|D^m u(t_k, .)\|^2),$$

$$\|\partial_x \tilde{e}_N^{k+1}\|^2 \leq C_6 N^{1-m}\|D^m u(t_{k+1}, .)\|^2. \tag{4.16}$$

It remains to estimate $\|\tilde{E}_N^k\|$. Let $\tilde{e}_N(t, \cdot) = u(t, \cdot) - P_N u(t, \cdot)$. Then,

$$\tilde{E}_N^k = -\frac{1}{h}(\tilde{e}_N^{k+1} - \tilde{e}_N^k) = -\frac{1}{h}\int_{t_k}^{t_{k+1}} \partial_t \tilde{e}_N(t, \cdot)dt.$$

Applying the Schwarz inequality and (2.17) again, we obtain that

$$\|\tilde{E}_N^k\|^2 \leq \frac{1}{h}\int_{t_k}^{t_{k+1}} \|\partial_t \tilde{e}_N(t, \cdot)\|^2 \, dt. \tag{4.17}$$

We then derive from the above and (4.15) that

$$\|\hat{e}_N^k\|^2 + h\sum_{j=k}^{M}\|\partial_x \hat{e}_N^j\|^2 \lesssim h^2\Big(\|u_{tt}\|_{L^2(0,T;H^{-1}(\mathbb{R}))}^2 + \|u_t\|_{L^2(0,T;H^1(\mathbb{R}))}^2\Big)$$

$$+ N^{1-m}\Big(\|u\|_{C([0,T];H_D^m)}^2 + \|u_t\|_{L^2(0,T;H_D^m)}^2\Big),$$

proving the theorem. □

Remark 4.2. We would like to point out that one of the main purposes of Theorem 4.1 is to display a significant feature of the spectral method, that is, that the rate of convergence of the scheme increases as the smoothness of the solutions (i.e., m in the assumption of the above theorem) increases. Assumptions (A1)–(A3) are used only to guarantee the convergence of the numerical schemes proposed in this paper (in fact, all but the Platen–Wagner scheme where the second derivative of the drift b is required). The assumption on smoothness of the solution is used to prove the rate of convergence, which should always be true if the coefficients are sufficiently regular. We should note, however, that the explicit relation between the regularities of the coefficients and that of the solution seems to be a more subtle issue due to the quasi linearity of the PDE. We thus prefer making the exact smoothness requirement needed on the solution rather than on the coefficients.

We note also that by using a tensor product approach, the results in the above theorem can be directly extended to the high-dimensional case, although such a tensor product approach will become prohibitively expensive for space dimension ≥ 4.

5. The synthetic error analysis. In this section we present an error analysis for the synthesized numerical scheme. Our main result is the following.

THEOREM 5.1. *Assume that* (A1)–(A3) *and the assumptions in Theorem* 4.1 *hold. Let* (X, Y, Z) *be the adapted solution to the FBSDE* (2.1)*, and let* $\{X_k\}_{k=0}^M$ *be the solution to the Euler scheme* (3.9)*. Define*

$$Y_k \triangleq u_N^k(X_k), \qquad Z_k \triangleq \sigma(t_k, X_k, Y_k)\partial_x(u_N^k)(X_k), \qquad k = 0, 1, \ldots, M, \tag{5.1}$$

where $\{u_N^k\}_{k=0}^M$ *is the solution to* (4.1)*. Then, the following error estimate holds:*

$$\begin{aligned}\sup_{0\leq k\leq M} \mathbb{E}\Big[(X(t_k) - X_k)^2 + (Y(t_k) - Y_k)^2 + (Z(t_k) - Z_k)^2\Big]^{1/2} \\ \lesssim \sqrt{h} + h\Big(\|u_{tt}\|_{L^2(0,T;H^{-1}(\mathbb{R}))} + \|u_t\|_{L^2(0,T;L^2(\mathbb{R}))}\Big) \\ + N^{\frac{1-m}{2}}\Big(\|u\|_{C([0,T];H_D^m)} + \|u_t\|_{L^2(0,T;H_D^m)}\Big).\end{aligned} \tag{5.2}$$

Proof. Recall the intermediate Euler scheme (3.10):

$$\begin{cases} \hat{X}_0 = x, \\ \hat{X}_{k+1} = \hat{X}_k + b(t_k, \hat{X}_k, u^k(\hat{X}_k))h + \sigma(t_k, \hat{X}_k, u^k(\hat{X}_k))\Delta_k W, \end{cases} \tag{5.3}$$

where $u^k(x) = u(t_k, x)$ and $u(\cdot, \cdot)$ is the solution to the original PDE (3.1). Since the true solution u is at least uniformly Lipschitz under (A1)–(A3), we can apply the *fundamental convergence theorem* for SDEs (cf. [21] or [30]) to conclude that

$$\mathbb{E}|X(t_k) - \hat{X}_k|^2 \leq Ch \quad \forall\, k = 0, 1, \ldots, M. \tag{5.4}$$

Thus it remains to evaluate $\mathbb{E}|\hat{X}_k - X_k|^2$. To this end, note that

$$\begin{aligned}\hat{X}_{k+1} - X_{k+1} = \hat{X}_k - X_k + [b(t_k, \hat{X}_k, u(t_k, \hat{X}_k)) - b(t_k, X_k, u_N^k(X_k))]h \\ + [\sigma(t_k, \hat{X}_k, u(t_k, \hat{X}_k)) - \sigma(t_k, X_k, u_N^k(X_k))]\Delta_k W.\end{aligned} \tag{5.5}$$

Since $\Delta_k W = W(t_{k+1}) - W(t_k)$ is independent of $\mathcal{F}_{t_k}$ with $\mathbb{E}[\Delta_k W] = 0$ and $\mathbb{E}|\Delta_k W|^2 = h$, one has $\mathbb{E}[(\Delta_k W)F] = 0$ and $\mathbb{E}[(\Delta_k W)F]^2 = h\mathbb{E}[F]^2$ for all $F \in L^2(\mathcal{F}_{t_k};\mathbb{R})$. Therefore, squaring both sides of (5.5), applying the Cauchy–Schwartz inequality, and then using the Lipschitz assumption on the coefficients b and σ, we obtain that

$$\begin{aligned}
&\mathbb{E}|\hat{X}_{k+1} - X_{k+1}|^2 \\
&\quad \le (1+h)\mathbb{E}|\hat{X}_k - X_k|^2 + (h^2+h)\mathbb{E}|b(t_k,\hat{X}_k,u^k(\hat{X}_k)) - b(t_k,X_k,u_N^k(X_k))|^2 \\
&\quad\quad + h\,\mathbb{E}|\sigma(t_k,\hat{X}_k,u^k(\hat{X}_k)) - \sigma(t_k,X_k,u_N^k(X_k))|^2 \qquad (5.6)\\
&\quad \le (1+h+2K^2(h^2+h))\mathbb{E}|\hat{X}_k - X_k|^2 + 2K^2(h^2+h)\mathbb{E}|u^k(\hat{X}_k) - u_N^k(X_k)|^2.
\end{aligned}$$

Now, we write

$$u^k(\hat{X}_k) - u_N^k(X_k) = [u^k(\hat{X}_k) - u^k(X_k)] + [u^k(X_k) - u_N^k(X_k)] \qquad (5.7)$$

and note that

$$\mathbb{E}|u^k(\hat{X}_k) - u^k(X_k)|^2 \le K^2\mathbb{E}|\hat{X}_k - X_k|^2. \qquad (5.8)$$

We need only to estimate $\mathbb{E}|u^k(X_k) - u_N^k(X_k)|^2$. To this end, let us first establish the following simple inequality:

$$\|f\|_{L^\infty(\mathbb{R})} \le \|f\|_{L^2(\mathbb{R})} + \|f'\|_{L^2(\mathbb{R})} \qquad \forall\, f \in\ H^1(\mathbb{R}). \qquad (5.9)$$

Indeed, we first observe that $f \in H^1(\mathbb{R})$ implies that $f \in C(\mathbb{R})$. Then, for any unit interval $[n, n+1)$, $n \in \mathbb{Z}$, there must exist $x_n \in [n, n+1)$ such that $|f(x_n)| \le \|f\|_{L^2(n,n+1)} \le \|f\|_{L^2(\mathbb{R})}$. Hence, for any given $x \in [n, n+1)$, we have

$$|f(x)| \le |f(x) - f(x_n)| + |f(x_n)| = \left|\int_{x_n}^x f'(t)dt\right| + |f(x_n)| \le \|f\|_{L^2(\mathbb{R})} + \|f'\|_{L^2(\mathbb{R})}.$$

Thanks to (5.9), we obtain that

$$\begin{aligned}
\mathbb{E}|u^k(X_k) - u_N^k(X_k)|^2 &= \int_{-\infty}^{\infty} |u(t_k,x) - u_N^k(x)|^2 f_{X_k}(x)dx \\
&\le \|u(t_k,\cdot) - u_N^k(\cdot)\|^2_{L^\infty(\mathbb{R})} \int_{-\infty}^{\infty} f_{X_k}(x)dx \qquad (5.10)\\
&\le 2\|u(t_k,\cdot) - u_N^k\|^2 + 2\|\partial_x(u(t_k,\cdot) - u_N^k)\|^2,
\end{aligned}$$

where f_{X_k} is the probability density function of random variable X_k.

Combining (5.8)–(5.10), noting (5.7), and assuming without loss of generality that $h < 1$, it follows easily from (5.6) that, for $k = 1, 2, \ldots, M$,

$$\begin{aligned}
\mathbb{E}|\hat{X}_{k+1} - X_{k+1}|^2 &\le (1+Ch)\mathbb{E}|\hat{X}_k - X_k|^2 \\
&\quad + Ch\Big(\|u(t_k,\cdot) - u_N^k\|^2 + \|\partial_x(u(t_k,\cdot) - u_N^k)\|^2\Big).
\end{aligned}$$

We now apply a standard forward discrete Gronwall inequality and, noticing that $\hat{X}_0 = X_0 = x$ and using Theorem 4.1, we obtain, for $k = 1, 2, \ldots, M$,

$$\mathbb{E}|\hat{X}_k - X_k|^2 \lesssim \mathbb{E}|\hat{X}_0 - X_0|^2 + h\sum_{j=1}^{k}\Big(\|u(t_j,\cdot) - u_N^j\|^2 + \|\partial_x(u(t_j,\cdot) - u_N^j)\|^2\Big)$$

$$\lesssim h^2\Big(\|u_{tt}\|^2_{L^2(0,T;H^{-1}(\mathbb{R}))} + \|u_t\|^2_{L^2(0,T;L^2(\mathbb{R}))}\Big)$$

$$+ N^{1-m}\Big(\|u\|^2_{C([0,T];H_D^m)} + \|u_t\|^2_{L^2(0,T;H_D^m)}\Big).$$

This, together with (5.4), yields the final mean-square error estimate:

$$\mathbb{E}|X(t_k) - X_k|^2 \lesssim h + h^2\Big(\|u_{tt}\|^2_{L^2(0,T;H^{-1}(\mathbb{R}))} + \|u_t\|^2_{L^2(0,T;L^2(\mathbb{R}))}\Big)$$

$$+ N^{1-m}\Big(\|u\|^2_{C([0,T];H_D^m)} + \|u_t\|^2_{L^2(0,T;H_D^m)}\Big).$$

The error estimates for $\mathbb{E}|Y(t_k) - Y_k|^2$ and $\mathbb{E}|Z(t_k) - Z_k|^2$ then follow easily from the relation (3.20), (5.1), and the estimate (5.11). The proof is now complete. ∎

Remark 5.2. From the proof of Theorem 5.1 we see that if we combine the higher-order schemes for both PDE (2.5) and the resulting decoupled SDE (2.4), then we will obtain a higher-order rate of convergence. The proof would be completely similar, but conceivably much more lengthy and tedious. We shall discuss this issue with extensive numerical examples in the next section.

Unlike the results in Theorem 4.1, the results in the above theorem cannot be directly extended to the high-dimensional case due (only) to the fact that the embedding (5.9) is no longer valid in a high space dimension.

6. Numerical simulations and conclusions.

6.1. Implementation details. Let $\{h_j(x)\}_{j=0,1,\ldots,N}$ be the Lagrange interpolation polynomials in P_N associated with the Hermite–Gauss points $\{x_j\}_{j=0,1,\ldots,N}$, which are zeros of $H_{N+1}(x)$. We define $\hat{h}_j(x) = h_j(x)\frac{e^{-x^2/2}}{e^{-x_j^2/2}}$; then

$$\hat{h}_j(x_i) = \delta_{ij}, \quad \mathcal{H}_N = \text{span}\{\hat{h}_j : j = 0, 1, \ldots, N\},$$

so any function $g \in \mathcal{H}_N$ can be written as

$$g(x) = \sum_{j=0}^{N} g(x_j)\hat{h}_j(x).$$

We derive easily from $h_j^{'}(x_i)$ that

$$\hat{h}_j^{'}(x_i) = \frac{e^{-x_i^2/2}}{e^{-x_j^2/2}}(h_j^{'}(x_i) - x_i\delta_{ij}) = \begin{cases} \frac{\widehat{H}_N(x_i)}{(x_i - x_j)\widehat{H}_N(x_j)}, & i \neq j, \\ 0, & i = j. \end{cases}$$

Hence, $\hat{h}_j^{'}(x_i)$ can be computed in a stable way for N large.

Let us denote

$$\bar{u} = (u_N^k(x_0), u_N^k(x_1), \dots, u_N^k(x_N))^T, \quad \bar{f} = (f^{k+1}(x_0), f^{k+1}(x_1), \dots, f^{k+1}(x_N))^T$$

$$s_{ij} = (\alpha(x)\hat{h}_j^{'}, \hat{h}_i^{'})_N = \sum_{l=0}^{N} \alpha(x_l)\hat{h}_j^{'}(x_l)\hat{h}_i^{'}(x_l)\hat{w}_l$$

with $\alpha(x_i) = \frac{h}{2}\sigma^2(t_k, x_i, u_N^{k+1}(x_i))$. Then, (3.7) is reduced to the following linear system:

$$(S + W)\bar{u} = W\bar{f},$$

where

$$W = \mathrm{diag}(\hat{w}_0, \hat{w}_1, \dots, \hat{w}_N), \quad S = (s_{ij})_{i,j=0,1,\dots,N}.$$

6.2. Numerical results and discussions. In order to make sensible comparisons to the existing results, we shall consider an example proposed by Milstein and Tretyakov [31], use our spectral method to carry out the numerical approximation for $u(t, x)$, and then use different stochastic numerical schemes for the resulting decoupled SDE. In particular, we shall use the standard Euler scheme, first-order Milstein scheme, $\frac{3}{2}$-order Platen–Wagner strong scheme, as well as the $\frac{3}{2}$-order stochastic SAB scheme, respectively.

Example (Milstein–Tretyakov [31]). Consider the following FBSDE:

(6.1)
$$\begin{cases} dX = \dfrac{X(1+X^2)}{(2+X^2)^3}dt + \dfrac{1+X^2}{2+X^2}\sqrt{\dfrac{1+2Y^2}{1+Y^2+\exp(-\frac{2X^2}{t+1})}}dW(t), \quad X(0) = x, \\ \\ dY = -g(t,X,Y)dt - f(t,X,Y)Zdt + ZdW(t), \quad Y(T) = \exp\left(-\dfrac{X^2(T)}{T+1}\right), \end{cases}$$

where

$$g(t,x,u) = \frac{1}{t+1}\exp\left(-\frac{x^2}{t+1}\right)\left[\frac{4x^2(1+x^2)}{(2+x^2)^3} + \left(\frac{1+x^2}{2+x^2}\right)^2\left(1 - \frac{2x^2}{t+1}\right) - \frac{x^2}{t+1}\right],$$

$$f(t,x,u) = \frac{x}{(2+x^2)^2}\sqrt{\frac{1+u^2+\exp(-\frac{2x^2}{t+1})}{1+2u^2}}\,.$$

Then the corresponding Cauchy problem has the following form, for $t < T, x \in \mathbb{R}$:

(6.2)
$$\begin{cases} 0 = \dfrac{\partial u}{\partial t} + \dfrac{1}{2}\left(\dfrac{1+x^2}{2+x^2}\right)^2 \dfrac{1+2u^2}{1+u^2+\exp(-\frac{2x^2}{t+1})}\dfrac{\partial^2 u}{\partial x^2} + \dfrac{2x(1+x^2)}{(2+x^2)^3}\dfrac{\partial u}{\partial x} \\ \\ \qquad + \dfrac{1}{t+1}\exp\left(-\dfrac{x^2}{t+1}\right)\left[\dfrac{4x^2(1+x^2)}{(2+x^2)^3} + \left(\dfrac{1+x^2}{2+x^2}\right)^2\left(1 - \dfrac{2x^2}{t+1}\right) - \dfrac{x^2}{t+1}\right], \\ \\ u(T,x) = \exp(-\frac{x^2}{T+1}). \end{cases}$$

It is easy to verify that the solution to problem (6.2) is

$$u(t,x) = \exp\left(-\frac{x^2}{t+1}\right). \tag{6.3}$$

Since $Y(t) = u(t, X(t))$, plugging $Y(t)$ into the forward equation in (6.1), we get

$$dX = \frac{X(1+X^2)}{(2+X^2)^3}dt + \frac{1+X^2}{2+X^2}dW(t), \quad X(0) = x. \tag{6.4}$$

One can then easily check that the solution to this equation can be expressed as

$$X(t) = \Lambda(x + \arctan x + W(t)),$$

where the function $\Lambda(z)$ is defined by the equation

$$\Lambda(z) + \arctan \Lambda(z) = z. \tag{6.5}$$

Differentiating (6.5) with respect to z, we get

$$\Lambda'(z) = \frac{1+\Lambda^2(z)}{2+\Lambda^2(z)} > 0, \quad \forall\ z \in \mathbb{R}, \quad \text{and} \quad \Lambda''(z) = \frac{2\Lambda(1+\Lambda^2)}{(2+\Lambda^2)^3}, \tag{6.6}$$

which implies that $\Lambda(z)$ is a one-to-one function. Hence $X(0) = \Lambda(x + \arctan x) = x$. Furthermore, due to the Itô formula, we have

$$\begin{aligned} dX &= \Lambda'(x + \arctan x + W(t))dW(t) + \frac{1}{2}\Lambda''(x + \arctan x + W(t))dW(t) \\ &= \frac{X(1+X^2)}{(2+X^2)^3}dt + \frac{1+X^2}{2+X^2}dW(t). \end{aligned}$$

Hence, the solution to (6.1) is

$$\begin{aligned} X(t) &= \Lambda(x + \arctan x + W(t)), \\ Y(t) &= \exp\left(-\frac{X^2}{t+1}\right), \\ Z(t) &= -\frac{2X(1+X^2)}{(t+1)(2+X^2)} \exp\left(-\frac{X^2}{t+1}\right). \end{aligned}$$

We first carry out numerical tests on the parabolic equation (6.2) using the second-order (in time) scheme (3.8). In Tables 1–3, we tabulate the errors $\max_k \|u(t_k,x) - u_N^k(x)\|_{L^2(\mathbb{R})}$, $\max_k \|\frac{\partial u}{\partial x}(t_k,x) - \frac{d}{dx}u_N^k(x)\|_{L^2(\mathbb{R})}$, and $\max_k \|\frac{\partial^2 u}{\partial x^2}(t_k,x) - \frac{d^2}{dx^2}u_N^k(x)\|_{L^2(\mathbb{R})}$, respectively. We note that it is important to measure the errors of the approximation $u_N^k(x)$ to the first and second derivatives of $u(t_k,x)$ since the first-order Milstein scheme (3.11) and $\frac{3}{2}$-order Platen–Wagner scheme (3.12) need to use these derivatives. In the last column of these tables, the rates of convergence in time with $N = 150$ are reported. We observe that essentially second-order accuracy in time and exponential convergence in space are achieved for all three quantities.

Next, we examine the errors of the full simulation for the FBSDE with four different schemes presented in section 3 for the forward SDE and with the Hermite-collocation scheme (3.7). For the sake of comparison with the results in [31], we

also computed the same problem with a Monte Carlo simulation (with $S = 1000$ independent realizations of $X(T)$ and X_N) for the forward SDE. The results of the Euler scheme with Monte Carlo simulation are reported in Table 4. The averages presented in the table are computed as follows:

$$E(X(T) - X_N)^2 = \frac{1}{S}\sum_{k=1}^{S}\left(X^{(k)}(T) - X_N^{(k)}\right)^2 \pm 2\sqrt{\frac{D_S}{S}},$$

where

$$D_S = \frac{1}{S}\sum_{k=1}^{S}\left(X^{(k)}(T) - X_N^{(k)}\right)^4 - \left[\frac{1}{S}\sum_{k=1}^{S}\left(X^{(k)}(T) - X_N^{(k)}\right)^2\right]^2.$$

Hence,

$$\begin{aligned}\left[E(X(T) - X_N)^2\right]^{1/2} &= \sqrt{\frac{1}{S}\sum_{k=1}^{S}\left(X^{(k)}(T) - X_N^{(k)}\right)^2} \\ &\quad + \sqrt{\frac{1}{S}\sum_{k=1}^{S}\left(X^{(k)}(T) - X_N^{(k)}\right)^2 \pm 2\sqrt{\frac{D_S}{S}}} \\ &\quad - \sqrt{\frac{1}{S}\sum_{k=1}^{S}\left(X^{(k)}(T) - X_N^{(k)}\right)^2},\end{aligned}$$

where $X^{(k)}(T)$ and $X_N^{(k)}$ are independent realizations of $X(T)$ and X_N, respectively $(k = 1, 2, \ldots, S = 1000)$.

For conciseness, we now omit the Monte Carlo errors, which, as can be seen from Table 4, are significantly smaller than the approximation errors. In what follows, we denote $[E(X(T) - X_N)^2]^{1/2}$ by X, $[E(Y(T) - Y_N)^2]^{1/2}$ by Y, and $[E(Z(T) - Z_N)^2]^{1/2}$ by Z.

In the Tables 5–7, we report these errors by using the three schemes with 1000 independent realizations of $X(T)$ and X_N.

Observe that all three schemes produce expected convergence rates. The $\frac{3}{2}$-order SAB scheme is slightly less accurate than the $\frac{3}{2}$-order strong scheme, but the convergence rates of these two schemes are essentially the same.

7. Concluding remarks. We presented a numerical method for a class of forward-backward stochastic differential equations (FBSDEs). The method is based on the *four step scheme* with a Hermite-spectral method to approximate the solution to the decoupling quasi-linear PDE on the whole space. The use of the Hermite-spectral method not only avoids the use of artificial far field boundary conditions but also leads to spectrally accurate results in space. We carried out a rigorous error analysis for a fully discretized scheme for the FBSDEs with a first-order scheme in time and a Hermite-spectral scheme in space, and indicated that similar analysis can be extended to higher-order schemes in time. We presented detailed numerical comparisons between several schemes for the resulting decoupled forward SDE and showed that the stochastic version of the Adams–Bashforth scheme coupled with the Hermite-spectral method leads to a convergence rate of $\frac{3}{2}$ (in time).

Although the analysis and computation is performed for the one-dimensional case, the numerical scheme, and most of the analysis, can be extended to higher-dimensional cases. More precisely, the Hermite-spectral method for the PDE can be extended to high-dimensional cases in a straightforward matter using a tensor-product approach. Furthermore, the results in Theorem 4.1 still hold for high-dimensional cases; unfortunately, it appears to be very difficult to establish the results in Theorem 5.1 for high-dimensional cases due mainly to the fact that the Sobolev-type inequality (5.9) is no longer valid for higher-dimensional cases. On the other hand, the aforementioned tensor-product approach is feasible only for two- or three-dimensional problems, as the number of unknowns grows exponentially fast as the dimension increases, and the computational cost quickly becomes prohibitive for problems of four or more dimensions. In a forthcoming work, we plan to introduce new elliptic solvers based on lattice rules and sparse grids which would allow us to handle FBSDEs in relatively large space dimensions.

Acknowledgment. The authors would like to thank an anoymous referee whose comments and suggestions have led to numerous improvements to the paper.

CONVERGENCE OF IMPLICIT MONOTONE SCHEMES WITH APPLICATIONS IN MULTIPHASE FLOW IN POROUS MEDIA*

FELIX KWOK† AND HAMDI A. TCHELEPI‡

Abstract. Phase-based upstreaming, which is a commonly used spatial discretization for multiphase flow in reservoir simulation, naturally gives rise to implicit monotone schemes when implicit time-stepping is used. The nonlinear Gauss–Seidel and Jacobi algorithms are shown to converge to a unique bounded solution when applied to the resulting system of equations. Thus, for one-dimensional problems, we obtain an alternate, constructive proof that such schemes are well-defined and converge to the entropy solution of the conservation law for arbitrary CFL numbers. The accuracy of phase-based upstream solutions is studied for various spatial and temporal grids, revealing the importance of unconditional stability when nonuniform grids and/or variable porosity is involved.

Key words. conservation laws, multiphase flow, reservoir simulation, upstream weighting, implicit monotone schemes

1. Introduction.

In the simulation of multiphase flow in petroleum reservoirs, the most commonly used model consists of a system of n conservation laws, where n is the number of immiscible fluid phases. Each conservation law is defined for all $\mathbf{x} \in \Omega \subset \mathbb{R}^k$ $(1 \le k \le 3)$ and has the form

$$\frac{\partial(\phi \rho_j S_j)}{\partial t} + \nabla \cdot (\rho_j \mathbf{v}_j) = \rho_j q_j, \qquad j = 1, \ldots, n, \tag{1.1}$$

where $\phi = \phi(\mathbf{x})$ is the porosity of the medium (with $0 < \phi_{min} \le \phi \le 1$), $K = K(\mathbf{x}) \ge K_{min} > 0$ is the absolute permeability; for each phase j, $S_j = S_j(\mathbf{x}, t)$ is the saturation (i.e., the volume fraction occupied by phase j in the neighborhood of $\mathbf{x}$), $\rho_j > 0$ is the density, $q_j = q_j(\mathbf{x})$ is the source or sink term, and $\mathbf{v}_j$ is the phase velocity, which is given by generalized Darcy's law:

$$\mathbf{v}_j = -K\lambda_j \left[\nabla p_j - \rho_j \mathbf{g}\right]. \tag{1.2}$$

Here $\lambda_j = \lambda_j(S_1, \ldots, S_n)$ is the phase mobility, p_j is the phase pressure, and $\mathbf{g} \in \mathbb{R}^k$ is a constant vector representing the gravitational acceleration. In addition, we have the following algebraic relations:

$$\text{Saturation constraint:} \qquad \sum S_j = 1, \tag{1.3}$$

$$\text{Capillary pressure constraint:} \quad p_j - p_{j+1} = P_{cj}(S_1, \ldots, S_n), \quad j = 1, \ldots, n-1. \tag{1.4}$$

‡Energy Resources Engineering, Stanford University, Stanford, CA 94305 (tchelepi@stanford.edu).

In this paper we restrict our attention to incompressible flow with zero capillarity; i.e., we assume that the densities ρ_j are constant with respect to time and space, and that $p_1 = \cdots = p_n \equiv p$. The resulting system of PDEs exhibits a mixed hyperbolic-parabolic character, which becomes apparent when we consider the various limiting cases. If we multiply (1.1) by $1/\rho_j$ and sum over $j = 1, \ldots, N$, then we obtain $\sum_j \nabla \cdot \mathbf{v}_j = \sum_j q_j$, where the $\partial/\partial t$ terms cancel because of the saturation constraint. We have

$$-\nabla \cdot \left[K\lambda_T \nabla p - K\mathbf{g}\textstyle\sum_j \lambda_j \rho_j \right] = \sum_j q_j, \tag{1.5}$$

where $\lambda_T = \sum_j \lambda_j$ is the total mobility, which is assumed to be positive and uniformly bounded away from zero. Thus, for a given saturation distribution, the pressure field satisfies an elliptic PDE. On the other hand, if we define the total velocity $\mathbf{v}_T$ by $\mathbf{v}_T = \sum_j \mathbf{v}_j$, then we can rewrite $\mathbf{v}_j$ as

$$\mathbf{v}_j = \frac{\lambda_j}{\lambda_T} \left[\mathbf{v}_T - K\mathbf{g}\textstyle\sum_\ell \lambda_\ell (\rho_\ell - \rho_j) \right]. \tag{1.6}$$

This means when $\mathbf{v}_T$ is constant over time (which is the case for flow in a one-dimensional (1D) porous medium), the phase velocities $\mathbf{v}_j$ become functions of $\mathbf{x}$ and $S_1, \ldots, S_n$ only, so when we substitute (1.6) into (1.1), we get

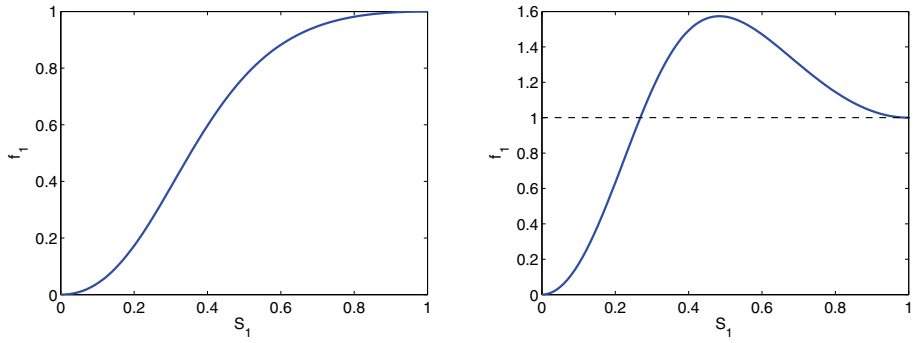
$$\phi \frac{\partial S_j}{\partial t} + \nabla \cdot \mathbf{v}_j(\mathbf{x}, S_1, \ldots, S_n) = 0, \qquad j = 1, \ldots, n-1. \tag{1.7}$$

As a result, saturation behaves like the solution to a system of first-order hyperbolic conservation laws, so one should expect discontinuous saturation profiles. In higher dimensions, $\mathbf{v}_T$ generally varies over time, and a strong coupling exists between pressure and saturation because of the saturation dependence of λ_j and λ_T in (1.5), as well as the dependence of $\mathbf{v}_T$ on the pressure field. However, one can still observe the same kind of discontinuities in the saturation profile in such cases.

The vastly different behavior between saturation and pressure means these variables need to be treated differently in a numerical method. The shock-forming nature of (1.7) requires the use of a finite-volume method, whereas the elliptic nature of (1.5) means pressure variables must be treated implicitly to avoid a time-step restriction of the form $\Delta t = \mathcal{O}(\Delta x^2)$. One can treat saturation variables either explicitly, for which a Courant–Friedrichs–Lewy (CFL) condition of the form $\Delta t = \mathcal{O}(\Delta x)$ applies, or implicitly, where no such time-step limit exists. In problems of practical interest, the porosity ϕ and permeability K are highly oscillatory, nonsmooth functions of $\mathbf{x}$, and $K(\mathbf{x})$ can vary by several orders of magnitude over the domain Ω. Thus, local CFL numbers can also exhibit large spatial variations. This means the time-step limit of an explicit method, which is determined by the maximum local CFL number, is often overly restrictive compared to the *average* CFL number. For this reason, the discretization of choice for most reservoir simulators is the *fully implicit method* (FIM), which uses finite volume in space and backward Euler in time. The numerical flux function $F_{j,il}$, which approximates the continuous flux $\int_{\partial V_{il}} \rho_j \mathbf{v}_j \cdot \mathbf{n}_{il}\, ds$, is given by

$$F_{j,il} = |\partial V_{il}| \rho_j K_{il} \lambda_j(S^*) \left(-\frac{(p_l - p_i)(\mathbf{x}_l - \mathbf{x}_i)}{|\mathbf{x}_l - \mathbf{x}_i|^2} + \rho_j \mathbf{g} \right) \cdot \mathbf{n}_{il}, \tag{1.8}$$

where $|\partial V_{il}|$ is the area of the interface between cells i and l, $\mathbf{x}_i$ and $\mathbf{x}_l$ are the locations of the centers of cells i and l, and $\mathbf{n}_{il}$ is the unit normal to the cell interface, pointing



(a) (b)

FIG. 1.1. *Flux functions for* 1*D incompressible two-phase flow:* (a) *Cocurrent flow (no buoyancy effects);* (b) *countercurrent flow due to gravity.*

from cell i to cell l. The mobility λ_j is evaluated at the *upstream* saturation:

$$S = \begin{cases} S(x_i) & \text{if } \left(-\dfrac{(p_l - p_i)(\mathbf{x}_l - \mathbf{x}_i)}{|\mathbf{x}_l - \mathbf{x}_i|^2} + \rho_j \mathbf{g}\right) \cdot \mathbf{n}_{il} \geq 0, \\ S(x_l) & \text{otherwise.} \end{cases} \tag{1.9}$$

As we will see in section 4, the resulting numerical flux functions are different from those used in classical CFD (e.g., the Godunov and Engquist–Osher schemes). Despite being only first-order accurate, phase-based upstreaming is the preferred upwind method in reservoir simulation because it is physically intuitive, and because it is generally easier to verify a consistency condition such as (1.9) than to locate potential sonic points, which vary over the domain and are strong functions of permeability and total velocity. This is especially true for the FIM because the total velocity at time t^{n+1} is usually unknown.

Notice that in (1.9) it is possible for each phase to have a different upstream direction when the densities ρ_j are different, i.e., when buoyancy forces are significant; this is known as *countercurrent flow* in reservoir engineering literature. In 1D porous media, countercurrent flow manifests itself through the presence of sonic points in the flux function v_j; thus, the flux function for a countercurrent flow problem would typically look like the one shown in Figure 1.1(b), whereas without countercurrent flow it would look more like Figure 1.1(a). A detailed treatment of phase-based upstreaming is given in [3], in which the authors show that, when explicit saturations are used on a two-phase flow problem, phase-based upstreaming leads to a monotone difference scheme, as long as the appropriate CFL condition is satisfied. This in turn implies that solutions obtained from an explicit scheme converge to the entropy solution of the two-phase equations

$$\frac{\partial S_1}{\partial t} + \frac{\partial f_1}{\partial x} = 0, \tag{1.10}$$

$$f_1(x, S_1) = v_1(x, S_1) = \frac{\lambda_1(S_1)}{\lambda_1(S_1) + \lambda_2(S_1)} \left[v_T + K(x) g \lambda_2(S_1)(\rho_1 - \rho_2)\right] \tag{1.11}$$

as $\Delta t, \Delta x \to 0$ while satisfying the CFL condition. The goal of this paper is to extend this result for the fully implicit case. This leads us to study the more general problem of implicit monotone schemes, of which the multiphase flow problem is a special case.

The use of implicit time stepping leads to a (typically large) system of nonlinear algebraic equations that must be solved for each time step. Moreover, the residual functions are generally nondifferentiable due to upstreaming criteria of the form (1.9); thus, the existence of a unique solution to these systems of equations is not immediately obvious. For implicit monotone schemes for 1D scalar conservation laws, Lucier [9] showed that a unique solution to the discrete problem exists whenever the initial data is bounded and has bounded total variation. The proof of existence, which relies heavily on Crandall–Liggett theory [5], proceeds along the following lines (see [6, Ch. 3] for more details). First, one shows that the residual function R for the numerical scheme defines an m-accretive operator in the L^1 norm. Then by the Crandall–Ligett theorem, the ODE

$$\frac{du}{dt} = -Ru, \quad u(0) = x \tag{1.12}$$

has a unique solution for $t \in [0, \infty)$ for any initial point x. Let $u(t; x)$ denote the solution of (1.12) with starting point x. Then one shows that the *Poincaré operator* P_ω, which maps the point x to the point $u(\omega, x)$, is strictly contractive. Then by Banach's fixed point theorem, P_ω has a unique fixed point x_0. One then proceeds to prove that $u(t; x_0) = x_0$ for all $0 \le t \le \omega$; thus, $du/dt = 0$, which implies $Rx_0 = 0$.

While this argument does prove the existence and uniqueness of a solution to the discretized problem, the proof does not suggest a practical algorithm for finding the solution. In section 3, we present an alternate constructive proof of existence by showing that the classical Gauss–Seidel and Jacobi iterations converge for this class of problems. In fact, we show that the iterative methods converge whenever the initial data for the discrete problem is bounded, so the implicit scheme is well-defined even when the initial data does not have bounded variation in $\mathbb{R}$. The well-definedness of the numerical scheme, together with the total variation diminishing (TVD) property and the existence of a discrete entropy inequality, imply that the numerical scheme converges to the entropy solution as the mesh is refined (i.e., as $\Delta x \to 0$). This result holds for any mesh ratio $\lambda = \Delta t/\Delta x$ (i.e., for any Courant number).

The remainder of this paper is organized as follows. Section 2 states the necessary assumptions of our framework. Section 3 contains the main result of this paper, which asserts that the nonlinear Gauss–Seidel and Jacobi processes converge when applied to implicit monotone schemes. This leads to a constructive proof of well-definedness of the numerical scheme, from which convergence of the numerical scheme under grid refinement follows [14]. In section 4, we derive the numerical flux functions for an implicit monotone scheme that is equivalent to the coupled problem (1.1) in the 1D case, which would allow us to establish the well-definedness and convergence of the coupled problem. We also discuss the applicability of the above analysis for multidimensional problems. Finally, we discuss the convergence behavior and accuracy issues for implicit schemes with phase-based upstreaming in section 5.

2. Implicit monotone schemes. We consider the following fully implicit, finite volume discretization

$$\phi_i(u_i^{n+1} - u_i^n) + \lambda(F_{i+1/2}^{n+1} - F_{i-1/2}^{n+1}) = 0, \qquad \lambda = \Delta t/\Delta x, \quad i \in \mathbb{Z}, \tag{2.1}$$

where $F_{i+1/2}$ denotes the numerical flux across the interface between cells i and $i+1$. The above scheme approximates the 1D nonlinear conservation law

$$\phi(x)u_t + f(x,u)_x = 0, \qquad (x,t) \in \mathbb{R} \times \mathbb{R}^+, \tag{2.2}$$

$$u(x,0) = u^0(x), \tag{2.3}$$

which generalizes the problem (1.10), (1.11) to the variable porosity and permeability case. For simplicity, we assume a three-point scheme $F^{n+1}_{i+1/2} = F_{i+1/2}(u^{n+1}_i, u^{n+1}_{i+1})$; thus, the implicit stencil at cell i contains the value at cell i at time t^n, as well as the values at cells $i-1$, i, and $i+1$ at the *future* time t^{n+1}. We also ignore the effects of boundary conditions by limiting ourselves to Cauchy problems for the moment; in section 4 we explain how certain boundary conditions can be incorporated. Assume that f and F are both locally Lipschitz continuous (but not necessarily differentiable), and that the numerical flux function $F_{i+1/2}$ is *consistent* with f in the sense that $F_{i+1/2}(u,u) = f(x_{i+1/2}, u)$. Given we are interested in handling flux functions of the type shown in Figure 1.1(b), we cannot assume that the flux function $f(x,u)$ is monotonic in u, so sonic points may be present. However, the numerical flux function is assumed to satisfy the following condition, which also appears in [14] and is central to all our arguments in this paper.

Assumption 1 (monotonic fluxes). For all $i \in \mathbb{Z}$, the numerical flux function $F_{i+1/2}$ is nondecreasing in the first argument and nonincreasing in the second argument; i.e., for any w, we have $F_{i+1/2}(u,w) \le F_{i+1/2}(v,w)$ and $F_{i+1/2}(w,u) \ge F_{i+1/2}(w,v)$ whenever $u \le v$.

For two-phase flow problems in one dimension, the numerical flux functions obtained by phase-based upstreaming have the form

$$F_{i+1/2}(S_{1,i}, S_{1,i+1}) = \frac{\lambda_1(S_{1,i})}{\lambda_1(S_{1,i}) + \lambda_2(S_1^*)}[v_T + K\lambda_2 g(\rho_1 - \rho_2)], \tag{2.4}$$

where $g(\rho_1 - \rho_2) \ge 0$ and

$$S_1^* = \begin{cases} S_{1,i} & \text{if } v_T - K\lambda_1(S_i)g(\rho_1-\rho_2) \ge 0, \\ S_{1,i+1} & \text{otherwise.} \end{cases} \tag{2.5}$$

The detailed derivation is deferred to section 4. The following theorem, which summarizes several results by Brenier and Jaffré [3] in the case of two-phase flow, guarantees that $F_{i+1/2}(S_i, S_{i+1})$ has the required properties.

THEOREM 2.1. *Assume that the mobility of phase j is increasing with S_j and decreasing with the saturation of the other phase for $j = 1, 2$ (e.g., water and oil). Then the numerical fluxes obtained from phase-based upstreaming defined by* (2.4), (2.5) *are consistent, are Lipschitz continuous, and satisfy Assumption* 1.

The hypothesis on phase mobilities is physically realistic [2]. Assumption 1 ensures that (2.1) is an implicit monotone scheme, in the sense that the resulting residual function defines an m-accretive operator in $\ell^1(\mathbb{Z})$ (see [7] for a proof). We do not use m-accretivity directly in this work. Instead, we show that Assumption 1 also implies that the residual function is an M-function in the sense of Rheinboldt [11]; this is generally not equivalent to m-accretivity [8] but nonetheless allows us to prove the existence and uniqueness of solutions. Once we establish that the implicit scheme is well-defined, we can apply the following theorem of Sanders [14, Theorem II] to conclude that the solutions of (2.1) converge to the unique entropy solution of (2.2)

when f does not depend explicitly on x, i.e., when $f = f(u)$. Note that Assumption 1 implies that (2.1) is an E-scheme [10], so it is at most first-order accurate.

THEOREM 2.2 (see Sanders [14]). *Let $\mathbb{R} = \cup \mathcal{I}_i^n$ with $\mathcal{I}_i^n = [x_i, x_{i+1}) \times [t^n, t^{n+1})$ and $\delta = \sup_{i,n} |x_{i+1} - x_i| + |t^{n+1} - t^n|$. Suppose the conservation law (2.2), (2.3) with $f = f(u)$ is discretized using (2.1), where $F_{i+1/2}(u_i, u_{i+1}) \equiv F(u_i, u_{i+1})$ for all i. Assume that F is locally Lipschitz continuous, consistent, and monotonic. Define the step function v_δ such that $v_\delta(x,t) = u_i^n$ when $(x,t) \in \mathcal{I}_i^n$, and suppose the initial data (2.3) is discretized via the averaging operator T_δ,*

$$T_\delta(u_0)(x) = \frac{1}{|x_{i+1} - x_i|} \int_{x_i}^{x_{i+1}} u_0(\xi) d\xi,$$

when $x \in [x_i, x_{i+1})$. Then $v_\delta(x,t)$ converges in $L^\infty(L^1(\mathbb{R}); [0,T])$ to the unique entropy solution of (2.2), (2.3) as δ tends to zero.

3. Existence and uniqueness of solutions for the discretized problem. In this section, we show that the nonlinear Jacobi and Gauss–Seidel processes, when applied to the infinite system of nonlinear equations (2.1), converge to a unique bounded solution. Thus, we obtain an alternate constructive proof of the well-definedness of implicit monotone schemes. In addition, we show that Jacobi and Gauss–Seidel converge for any starting point that is bounded by the initial data, leading to a practical algorithm for computing the solution. Finally, we show how to extend the analysis to deal with problems with spatially varying coefficients, as well as problems for which the flux function $f(u)$ is only defined over a finite interval rather than all of $\mathbb{R}$. An extension to multidimensional problems is considered in section 4.2. (Note: Throughout this section, x and t are generic variables and do not denote space or time.)

3.1. Nonlinear Jacobi and Gauss–Seidel processes. Suppose we want to solve a nonlinear system of algebraic equations $R(x) = 0$ for $x \in \ell^\infty(\mathbb{N})$, where $R = (r_1, r_2, \dots)^T : \ell^\infty(\mathbb{N}) \to \ell^\infty(\mathbb{N})$. Then we can consider the *nonlinear Gauss–Seidel process*:

$$\begin{aligned} &\text{solve} \quad r_i(x_1^{k+1}, \dots, x_{i-1}^{k+1}, x_i^*, x_{i+1}^k, x_{i+2}^k, \dots) = 0 \text{ for } x_i^*, \\ &\text{set} \qquad x_i^{k+1} = x_i^*, \quad i = 1, 2, \dots, \quad k = 0, 1, 2, \dots, \end{aligned} \tag{3.1}$$

as well as the *nonlinear Jacobi process*:

$$\begin{aligned} &\text{solve} \quad r_i(x_1^k, \dots, x_{i-1}^k, x_i^*, x_{i+1}^k, x_{i+2}^k, \dots) = 0 \text{ for } x_i^*, \\ &\text{set} \qquad x_i^{k+1} = x_i^*, \quad i = 1, 2, \dots, \quad k = 0, 1, 2, \dots . \end{aligned} \tag{3.2}$$

The only difference between (3.1)/(3.2) and classical Gauss–Seidel/Jacobi processes is that each Gauss–Seidel/Jacobi "sweep" now involves infinitely many variables and equations. To ensure that the iterations (3.1)/(3.2) make sense, we need the following assumptions on the residual function R.

Assumption 2 (preservation of bounded sets). $R : \ell^\infty(\mathbb{N}) \to \ell^\infty(\mathbb{N})$ is a mapping between bounded sequences for which there exists an increasing function $\zeta : [0, \infty) \to [0, \infty)$ such that $\|x\|_\infty \le B$ implies $\|R(x)\| \le \zeta(B)$.

Assumption 3 (finite number of dependencies). For each i, the residual function $r_i(x_1, x_2, \dots)$ is nonconstant with respect to at most a finite number of x_j.

In other words, the residual functions must come from a compact stencil and must preserve boundedness. Assumption 3 ensures that the iterative processes are

well-defined, since it guarantees that for any given $i, k \in \mathbb{N}$, the value of x_i^{k+1} can be calculated using a finite number of univariate solves. It also guarantees that whenever R is continuous and (3.1)/(3.2) converges, the limit point x^* must satisfy $R(x^*) = 0$. Assumption 2 then allows us to extend Rheinboldt's analysis [11] to the infinite-dimensional case and prove that (3.1)/(3.2) converges to a unique bounded solution when R is an M-function.

Remark. Even though the nonlinear iterations (3.1)/(3.2) is well-defined in theory, a practical implementation would require that we either solve a finite-dimensional problem by supplying appropriate boundary conditions, or that we use delayed evaluation [1] to compute only those values of x_i^k that are needed.

3.2. *M*-function theory. M-functions are essentially generalizations of M-matrices in linear algebra. In the linear setting, it is well known [13] that the Gauss–Seidel method applied to $Ax = b$ converges for any right-hand side b and starting point x_0 if A is a nonsingular M-matrix. M-functions have similar properties with respect to the nonlinear Gauss–Seidel process, which is the subject of investigation in [11]. Here we provide extensions to the relevant definitions and theorems in [11] that would allow us to prove the existence and uniqueness of bounded solutions to (2.1).

For the remainder of this section, the natural partial ordering on $\ell^\infty(\mathbb{N})$ is written as $x \le y$, i.e., $x \le y$ iff $x_i \le y_i$ for all $i \in \mathbb{N}$. We denote by e^i the unit basis vectors with the ith component one and all others zero. The following definitions are essentially identical to those in [11], except the domain of definition has been changed from $\mathbb{R}^n$ to $\ell^\infty(\mathbb{N})$ to handle vectors of infinite length.

DEFINITION 3.1. *Let $R : \ell^\infty(\mathbb{N}) \to \ell^\infty(\mathbb{N})$.*

1. *R is* isotone *(or* antitone*) if, for all $x, y \in \ell^\infty(\mathbb{N})$, $x \le y$ implies $R(x) \le R(y)$ (or $R(x) \ge R(y)$). It is* strictly isotone *(or antitone) if $x < y$ implies $R(x) < R(y)$ (or $R(x) > R(y)$).*
2. *R is* inverse isotone *if, for all $x, y \in \ell^\infty(\mathbb{N})$, $R(x) \le R(y)$ implies $x \le y$.*
3. *R is (strictly)* diagonally isotone *if, for all $x \in \ell^\infty(\mathbb{N})$, the functions*

$$\rho_{ii} : \mathbb{R} \to \mathbb{R}, \quad \rho_{ii}(t) = r_i(x + te^i), \quad i = 1, 2, \dots, \tag{3.3}$$

   are (strictly) isotone.
4. *R is* off-diagonally antitone *if, for any $x \in \ell^\infty(\mathbb{N})$ the functions*

$$\rho_{ij} : \mathbb{R} \to \mathbb{R}, \quad \rho_{ij}(t) = r_i(x + te^j), \quad i \ne j, \quad i, j = 1, 2, \dots, \tag{3.4}$$

   are antitone.
5. *R is an M-*function *if R is inverse isotone and off-diagonally antitone.*

One characterization of M-functions is given by the following theorem.

THEOREM 3.2. *Let $R : \ell^\infty(\mathbb{N}) \to \ell^\infty(\mathbb{N})$ be off-diagonally antitone and satisfy Assumptions 2 and 3. Then R is an M-function if, for each $B > 0$, there exists a positive sequence $\{w_i^B\}$ such that*

1. *$\sum_{i=1}^\infty w_i^B < \infty$,*
2. *for any $\|x\|_\infty < B$, the function $Q(t) = (q_1(t), q_2(t), \dots)$ defined by*

$$q_i(t) = \sum_{j=1}^\infty w_j^B r_j(x + te^i)$$

is strictly isotone over the interval $t \in (t_{min}, t_{max})$, where $t_{min} = -B - \inf_i x_i$ and $t_{max} = B - \sup_i x_i$.

Proof. The proof is based on [11, Theorem 5.1], suitably modified to handle the infinite-dimensional case. Suppose $R(x) \le R(y)$ for some $x, y \in \ell^\infty(\mathbb{N})$. Define the sets

$$N^- = \{i \in \mathbb{N} \mid y_i < x_i\}; \quad N^+ = \{i \in \mathbb{N} \mid y_i \ge x_i\}.$$

Suppose N^- is nonempty. For each $i \in N^-$, let $\gamma_i = (x_i - y_i)e^i$. We consider two cases:

1. If $|N^-| < \infty$, let $i_1 < i_2 < \cdots < i_m$ be the elements of N^-, and define

$$z^0 = y, \quad z^1 = y + \gamma_{i_1}, \dots, \quad z^m = y + \gamma_{i_1} + \cdots + \gamma_{i_m},$$

   and let $z^k = z^m = z$ for all $k > m$.
2. If $|N^-| = \infty$, let $i_1 < i_2 < \cdots$ be the elements of N^-, and define

$$z^0 = y, \quad z^1 = y + \gamma_{i_1}, \dots, \quad z^k = y + \gamma_{i_1} + \cdots + \gamma_{i_k}, \dots,$$

   and let $z = \{z_i\}$ be such that $z_i = \max\{x_i, y_i\}$.

Define $R^k := R(z^k)$ and $R^\infty = R(z)$. In either case, we have the following properties:

1. $\|z^k\|_\infty < B$ and $\|z\|_\infty < B$, where $B = \max\{\|x\|_\infty, \|y\|_\infty\}$. Hence, by Assumption 2, $\|R^k\|_\infty \le \zeta(B)$ for all k (similarly for R^∞).
2. For each i, $z_i^k = z_i$ for large enough k, so by Assumption 3, $R_j^k \to R_j^\infty$ *pointwise* for each j.

Thus, the sequence $R^k = (R_j^k)_{j=1}^\infty$ is dominated by $G = (\zeta(B), \zeta(B), \dots)$ for each $k \in \mathbb{N}$. Moreover, $\sum_{j=1}^\infty w_j^B G_j < \infty$, so by the dominated convergence theorem [12],

$$\sum_{j=1}^\infty w_j^B R_j^k \to \sum_{j=1}^\infty w_j^B R_j^\infty \quad \text{as } k \to \infty.$$

By the strict isotonicity of Q, we have

$$\sum_{j=1}^\infty w_j^B R_j^0 \le \sum_{j=1}^\infty w_j^B R_j^1 \le \cdots$$

with at least one strict inequality (since N^- is nonempty). Thus, we must have

$$\sum_{j=1}^\infty w_j^B r_j(y) = \sum_{j=1}^\infty w_j^B R_j^0 < \sum_{j=1}^\infty w_j^B R_j^\infty = \sum_{j=1}^\infty w_j^B r_j(z). \tag{3.5}$$

Now split the last sum into two parts

$$\sum_{j=1}^\infty w_j^B r_j(z) = \sum_{j \in N^-} w_j^B r_j(z) + \sum_{j \in N^+} w_j^B r_j(z), \tag{3.6}$$

where the summation over N^+ may be empty. Then by off-diagonal antitonicity of R (and invoking the dominated convergence theorem whenever necessary), we can show similarly that

$$\sum_{j \in N^-} w_j^B r_j(z) \le \sum_{j \in N^-} w_j^B r_j(x), \qquad \sum_{j \in N^+} w_j^B r_j(z) \le \sum_{j \in N^+} w_j^B r_j(y), \tag{3.7}$$

using the fact that $z - x$ and $z - y$ vanish on N^- and N^+, respectively. Combining (3.5)–(3.7) gives

$$\sum_{j=1}^{\infty} w_j^B r_j(y) < \sum_{j\in N^-} w_j^B r_j(x) + \sum_{j\in N^+} w_j^B r_j(y), \tag{3.8}$$

which implies $\sum_{j\in N^-} w_j^B r_j(y) < \sum_{j\in N^-} w_j^B r_j(x)$. Thus, we must have $r_j(y) < r_j(x)$ for some $j \in N^-$, which contradicts the hypothesis $R(x) \le R(y)$. Hence N^- must be empty, so $x \le y$. ∎

COROLLARY 3.3. *Let R satisfy the hypotheses of Theorem* 3.2. *Let $z \in \ell^\infty(\mathbb{N})$. Then there is at most one bounded solution to the equation $R(x) = z$.*

Remark. In the context of discretized PDEs one normally assumes tacitly that the solution of interest must be bounded; this can be regarded as a boundary condition "at infinity." However, since such boundary conditions are not explicitly stated in the definition of M-functions, one must be careful to exclude any parasitic unbounded solutions that may arise. In fact, the solution is not necessarily unique if we allow unbounded solutions. Consider the linear function $R = (r_1, r_2, \dots)$ defined by $r_i(x) = x_i - \alpha x_{i+1}$ for $|\alpha| < 1$. Then for any $\|x\|_\infty < \infty$, we have $\|R(x)\|_\infty \le (1+\alpha)\|x\|_\infty$, so that Assumption 2 is satisfied. Assumption 3 (finitely many dependencies) is also satisfied because each r_i is only nonconstant with respect to two components of x. Finally, if we let $w_j^B = \beta^j$ for any $|\alpha| < \beta < 1$, then $\sum_j \beta^j < \infty$ and

$$q_i(t) = \sum_{j=1}^{\infty} \beta^j \left[x_j + t\delta_{ij} - \alpha(x_{j+1} + t\delta_{i,j+1})\right] = (\beta-\alpha)\beta^{i-1}t + \beta x_1 + (\beta-\alpha)\sum_{j=2}^{\infty} \beta^{j-1} x_j,$$

so $q_i(t)$ is well-defined and is strictly increasing with respect to t whenever $\|x\|_\infty < \infty$. So the hypotheses of Theorem 3.2 are satisfied, and hence $x = 0$ is the only bounded solution of $R(x) = 0$. However, unbounded solutions of the form $y = \{K\alpha^{-i}\}$, $K \ne 0$ also satisfy $R(y) = 0$, so the theorem does not preclude these possibilities.

3.3. Convergence of nonlinear Jacobi and Gauss–Seidel. It turns out the hypotheses of Theorem 3.2 are enough to ensure convergence of nonlinear Jacobi and Gauss–Seidel for certain starting points, which will be described below. The following result is essentially Theorem 3.1 in [11], with modified hypotheses to accommodate ℓ^∞-bounded vectors with infinitely many components. The proof in [11] goes through verbatim but is reproduced here because similar arguments also appear in the proof of Theorem 3.7. Note that by Assumption 3, each r_i depends on only finitely many arguments, so the standard arguments on limits, continuity, and antitonicity hold without additional complications when they are used on individual components of R.

THEOREM 3.4 (see Rheinboldt [11]). *Let $R : \ell^\infty(\mathbb{N}) \to \ell^\infty(\mathbb{N})$ satisfy the hypotheses of Theorem* 3.2. *Suppose for some $z \in \ell^\infty(\mathbb{N})$ there exist $x^0, y^0 \in \ell^\infty(\mathbb{N})$ such that*

$$x^0 \le y^0, \qquad R(x^0) \le z \le R(y^0).$$

Then the nonlinear Gauss–Seidel and Jacobi iterates $\{y^k\}$ and $\{x^k\}$, given by (3.1) *and* (3.2), *and starting from y^0 and x^0, respectively, are uniquely defined and satisfy*

$$x^0 \le x^k \le x^{k+1} \le y^{k+1} \le y^k \le y^0, \qquad R(x^k) \le z \le R(y^k) \tag{3.9}$$

for $k = 0, 1, \dots$. In addition, the pointwise limits

$$\lim_{k\to\infty} x^k = \lim_{k\to\infty} y^k = x^* \tag{3.10}$$

exist, and $R(x^*) = z$.

First, we need the following lemma (which is part of Theorem 2.10 in [11]).

LEMMA 3.5. *Let* $R : \ell^\infty(\mathbb{N}) \to \ell^\infty(\mathbb{N})$ *be an M-function. Then* R *is strictly diagonally isotone.*

Proof. Suppose that for some $x \in \ell^\infty(\mathbb{N})$, $s, t \in \mathbb{R}$, $s > t$ and index i we have $r_i(x + se^i) \le r_i(x + te^i)$. Off-diagonal antitonicity then implies that

$$r_j(x + se^i) \le r_j(x + te^i), \qquad j \ne i,$$

or, altogether, that $R(x + se^i) \le R(x + te^i)$. By inverse isotonicity, this leads to the contradiction $s \le t$, which shows that R must be strictly diagonally isotone. ∎

Proof of Theorem 3.4. We present only the proof for convergence of Gauss–Seidel; the proof for Jacobi is similar. We proceed by induction and suppose that for some $k \ge 0$ and $i \ge 1$

$$x^0 \le x^k \le y^k \le y^0, \qquad R(x^k) \le z \le R(y^k), \tag{3.11a}$$

$$x_j^k \le x_j^{k+1} \le y_j^{k+1} \le y_j^k, \qquad j = 1, \dots, i-1, \tag{3.11b}$$

where for $i = 1$ the relation (3.11b) is vacuous. Clearly, (3.11) is valid for $k = 0$ and $i = 1$. Define the functions

$$\alpha(s) = r_i(x_1^{k+1}, \dots, x_{i-1}^{k+1}, s, x_{i+1}^k, x_{i+2}^k, \dots),$$

$$\beta(s) = r_i(y_1^{k+1}, \dots, y_{i-1}^{k+1}, s, y_{i+1}^k, x_{i+2}^k, \dots)$$

for $s \in [x_i^0, y_i^0]$. Then (3.11) and the off-diagonal antitonicity of R yield

$$\beta(s) \le \alpha(s), \qquad s \in [x_i^0, y_i^0], \tag{3.12}$$

$$\beta(x_i^k) \le \alpha(x_i^k) \le r_i(x^k) \le z_i \le r_i(y^k) \le \beta(y_i^k) \le \alpha(y_i^k). \tag{3.13}$$

Since R is strictly diagonally isotone, α and β are both continuous and strictly increasing, so (3.13) implies the existence of unique $\hat{y}_i^k$ and $\hat{x}_i^k$ for which

$$\beta(\hat{y}_i^k) = z_i = \alpha(\hat{x}_i^k), \qquad x_i^k \le \hat{x}_i^k \le \hat{y}_i^k \le y_i^k,$$

where the relation $\hat{x}_i^k \le \hat{y}_i^k$ is a consequence of (3.12). But $x_i^{k+1} = \hat{x}_i^k$ and $y_i^{k+1} = \hat{y}_i^k$ by definition, so we have proved (3.11b) for $j = 1, \dots, i$. Hence by induction (3.11b) holds for all $i \in \mathbb{N}$, and hence $x^k \le x^{k+1} \le y^{k+1} \le y^k$. From this it follows again from off-diagonal antitonicity that

$$r_i(y^{k+1}) \ge r_i(y_1^{k+1}, \dots, y_i^{k+1}, y_{i+1}^k, y_{i+2}^k \dots) = z_i$$

and similarly that

$$r_i(x^{k+1}) \le r_i(x_1^{k+1}, \dots, x_i^{k+1}, x_{i+1}^k, x_{i+2}^k \dots) = z_i.$$

This completes the induction on k and hence the proof of (3.9). Applying the monotone convergence theorem for sequences, we conclude that the *pointwise* limits

$$\lim_{k\to\infty} x_j^k = x_j^* \le y_j^* = \lim_{k\to\infty} y_j^k$$

exist for each j, which allows us to define $x^* = \{x_j^*\}$ and $y^* = \{y_j^*\}$. Since each r_i is continuous and depends on only finitely many arguments, the definition of the Gauss–Seidel process then implies $r_i(x^*) = r_i(y^*) = z_i$ for each i, and hence $R(x^*) = R(y^*) = z$. Since both x^* and y^* are bounded, Corollary 3.3 implies that they are equal, completing the proof. ∎

3.4. Well-definedness of implicit monotone schemes. Using the theory in the previous two sections, we can now prove that implicit monotone schemes (i.e., implicit schemes whose flux functions satisfy Assumption 1) are well-defined for bounded initial conditions. What we need to show is that the residual functions satisfy the hypotheses of Theorem 3.4. In the interest of clarity, in this section we show only convergence of the iterative schemes for problems whose coefficients do not vary in space (i.e., corresponding to the conservation law $u_t + f(u)_x = 0$, discretized on a uniform spatial grid). In the next section, we state the additional assumptions on ϕ_i and $F_{i+1/2}$ that are required for the spatially varying case.

THEOREM 3.6. *Consider the numerical scheme* (2.1) *with*

$$F_{i+1/2}^{n+1} = F(u_i^{n+1}, u_{i+1}^{n+1}),$$

where $F : \mathbb{R} \times \mathbb{R} \to \mathbb{R}$ *is locally Lipschitz continuous and satisfies Assumption* 1*, i.e., nondecreasing in the first argument and nonincreasing in the second. Assume that the initial condition* $\{u_i^0\}_{i=-\infty}^{\infty}$ *is bounded. Then* (2.1) *has a unique bounded solution* $\{u_i^{n+1}\}$ *for* $n = 0, 1, 2, \dots$*. Moreover, this bounded solution satisfies the estimate*

$$\inf_{j\in\mathbb{Z}} u_j^n \le u_i^{n+1} \le \sup_{j\in\mathbb{Z}} u_j^n \qquad \forall i \in \mathbb{Z}. \tag{3.14}$$

Proof. First, we need to define an ordering for the Gauss–Seidel sweeps, i.e., to permute the equations and variables so that the spatial indices go from 1 to ∞ rather than from $-\infty$ to ∞. After that, it suffices to check that all of the hypotheses of Theorem 3.4 are satisfied for this ordering.

1. For $j = 1, 2, \dots$, define $\sigma(j) = (-1)^j \lfloor j/2 \rfloor$, i.e., σ maps $\{1, 2, 3, 4, 5, \dots\}$ to $\{0, 1, -1, 2, -2, \dots\}$. Let τ be the inverse map, such that $\tau(\sigma(j)) = j$. Define $R : \ell^\infty(\mathbb{N}) \to \ell^\infty(\mathbb{N})$ to be the reordered (and rescaled) set of residual equations, i.e.,

$$r_j(v) = \frac{v_j - u_{\sigma(j)}^n}{\lambda} + F(v_j, v_{\tau(\sigma(j)+1)}) - F(v_{\tau(\sigma(j)-1)}, v_j), \tag{3.15}$$

where $v_j = u_{\sigma(j)}^{n+1}$.

2. Since F is locally Lipschitz continuous, it is Lipschitz continuous over any compact set, so for any $B > 0$ there exists K_B (which can be chosen to be increasing with B) such that for any $(x, y) \in [-B, B] \times [-B, B]$,

$$|F(x, y) - F(0, 0)| \le K_B(|x| + |y|) \le 2K_B \cdot B.$$

Thus, for any $\|v\|_\infty \le B$, we have $|r_j(v)| \le \zeta(B)$ for all j, where

$$\zeta(B) = \Big(\frac{1}{\lambda} + 4K_B\Big)B + \frac{1}{\lambda}\|u^n\|_\infty.$$

Hence Assumption 2 is satisfied. Moreover, since each r_j depends only on v_j, $v_{\tau(\sigma(j)-1)}$ and $v_{\tau(\sigma(j)+1)}$, Assumption 3 (finite number of dependencies) is also satisfied.

3. By Assumption 1 (monotonic fluxes), F is clearly off-diagonally antitone. To satisfy the remaining hypotheses of Theorem 3.2, let $\{w_j^B\}$ take the form $w_j^B = \beta^{|\sigma(j)|}$ for some $0 < \beta < 1$, so that $\sum_{j=1}^{\infty} w_j^B < \infty$. An easy calculation shows that

$$q_i(t) := \sum_{j=1}^{\infty} w_j^B r_j(v + te^i) = \tilde{q}_i(t) + \sum_{j=1}^{\infty} w_j^B r_j(v),$$

where

$$\tilde{q}_i(t) = w_i^B t/\lambda + (w_i^B - w^B_{\tau(\sigma(i)+1)})\big[F(v_i + t, v_{\tau(\sigma(i)+1)}) - F(v_i, v_{\tau(\sigma(i)+1)})\big] + (w^B_{\tau(\sigma(i)-1)} - w_i^B)\big[F(v_{\tau(\sigma(i)-1)}, v_i + t) - F(v_{\tau(\sigma(i)-1)}, v_i)\big].$$

By the definition of w_i^B, we see that

$$|w_i^B - w^B_{\tau(\sigma(i)\pm 1)}| \le \beta^{|\sigma(i)|-1}(1-\beta),$$

which, when combined with the local Lipschitz continuity of F, gives

$$\beta^{|\sigma(i)|-1}\big[\beta t/\lambda - 2(1-\beta)K_B|t|\big] \le \tilde{q}_i(t) \le \beta^{|\sigma(i)|-1}\big[\beta t/\lambda + 2(1-\beta)K_B|t|\big].$$

Hence, $\tilde{q}_i(t)$ is strictly isotone whenever $\beta/\lambda > 2(1-\beta)K_B$, so picking

$$\frac{2\lambda K_B}{1+2\lambda K_B} < \beta < 1 \tag{3.16}$$

ensures isotonicity for $\tilde{q}_i(t)$ (and hence $q_i(t)$) for all i, as required in Theorem 3.2. (Note that the choice of β depends on B.)

4. We need to choose starting points x^0 and y^0 that satisfy the requirements of Theorem 3.4. Let x^0 and y^0 both be constant sequences with

$$x_i^0 = \inf_{j\in\mathbb{Z}} u_j^n, \qquad y_i^0 = \sup_{j\in\mathbb{Z}} u_j^n \qquad \forall i \in \mathbb{N}.$$

Then clearly $x^0 \le y^0$, and for all $i \in \mathbb{N}$,

$$r_i(x^0) = \frac{1}{\lambda}\left(x_i^0 - u^n_{\sigma(i)}\right) = \frac{1}{\lambda}\left(\inf_{j\in\mathbb{Z}} u_j^n - u^n_{\sigma(i)}\right) \le 0,$$

$$r_i(y^0) = \frac{1}{\lambda}\left(y_i^0 - u^n_{\sigma(i)}\right) = \frac{1}{\lambda}\left(\sup_{j\in\mathbb{Z}} u_j^n - u^n_{\sigma(i)}\right) \ge 0,$$

so $R(x^0) \le 0 \le R(y^0)$. Thus, by Theorem 3.4, the nonlinear Gauss–Seidel iterates $\{y^k\}$ and $\{x^k\}$ both converge (pointwise) to the unique solution x^* with $R(x^*) = 0$; hence, a unique solution to (2.1) exists, i.e., $u_i^{n+1} = x^*_{\tau(i)}$. Moreover, we know that $x^0 \le x^* \le y^0$, which immediately implies (3.14). ∎

Remark. The initial condition $\{u_i^0\}_{i=-\infty}^{\infty}$ is not assumed to be in ℓ^1 nor in BV, so this result is somewhat more general than results that use Crandall–Liggett theory.

Remark. The definition of an M-function is invariant under symmetric permutations; i.e., $R(x)$ is an M-function if and only if $\sigma R(\sigma x)$ is also an M-function for any permutation $\sigma : \mathbb{N} \to \mathbb{N}$. Thus, the Gauss–Seidel process must converge regardless of the way the ordering is chosen in step 1 of the proof. However, the *rate* of convergence is sensitive to the ordering [8].

In fact, one can show that the nonlinear Jacobi and Gauss–Seidel processes converge for any starting point $\{z_i^{(0)}\}$ that is bounded by the initial data $\{u_i^n\}$. (In what follows, superscripts in brackets indicate iterates within the Gauss–Seidel process, and superscripts without brackets indicate the time level in the numerical scheme.)

THEOREM 3.7. *Assume the hypotheses of Theorem* 3.6. *Suppose the initial guess* $\{z_i^{(0)}\}$ *satisfies*

$$\inf_{j\in\mathbb{Z}} u_j^n \le z_i^{(0)} \le \sup_{j\in\mathbb{Z}} u_j^n \tag{3.17}$$

for all $i \in \mathbb{Z}$. Then the nonlinear Jacobi and Gauss–Seidel processes (3.1) *and* (3.2) *are well-defined and converge to the unique bounded solution of* (2.1).

Proof. Again we show only convergence for the Gauss–Seidel process, since the proof for Jacobi is similar. Denote $\underline{u} = \inf_{j\in\mathbb{Z}} u_j^n$ and $\overline{u} = \sup_{j\in\mathbb{Z}} u_j^n$. First, we show that the Gauss–Seidel iterates are well-defined and that $\underline{u} \le z_j^{(k)} \le \overline{u}$ for all j, k. At each step we need to solve

$$r_j(z_j^*) = \frac{1}{\lambda}\left(z_j^* - u_j^n\right) + F(z_j^*, z_{j+1}) - F(z_{j-1}, z_j^*) = 0, \tag{3.18}$$

where $z_{j\pm1} = z_{j\pm1}^{(k)}$ or $z_{j\pm1}^{(k+1)}$ depending on the ordering of the Gauss–Seidel sweep, which by induction must lie between $\underline{u}$ and $\overline{u}$. But

$$\begin{aligned} r_j(\underline{u}) &= \frac{1}{\lambda}\left(\underline{u} - u_j^n\right) + F(\underline{u}, z_{j+1}) - F(z_{j-1}, \underline{u}) \\ &\le 0 + F(\underline{u}, \underline{u}) - F(\underline{u}, \underline{u}) = 0, \end{aligned}$$

where the inequality follows from Assumption 1. Similarly one obtains $r_j(\overline{u}) \ge 0$, so by continuity of F (and hence r_j) there must exist a solution z_j^* to (3.18), which by Lemma 3.5 must be unique. Hence, by induction, the Gauss–Seidel iterates are well-defined and are bounded above and below by $\overline{u}$ and $\underline{u}$, respectively.

Now consider the Gauss–Seidel iterates $\{x_j^{(k)}\}$ and $\{y_j^{(k)}\}$ with initial guess $x_j^{(0)} = \underline{u}$ and $y_j^{(0)} = \overline{u}$ for all j. By Theorem 3.6 these iterates converge pointwise to the same solution $\{x_j^*\}$. We show inductively that $x^{(k)} \le z^{(k)} \le y^{(k)}$ for all k, which would imply that $z_j^{(k)} \to x_j^*$ pointwise. Using the same reordering as in Theorem 3.6, assume that for some $k \ge 0$ and $i \ge 1$ we have

$$y^{(k)} \ge z^{(k)} \ge x^{(k)}, \qquad y_j^{(k+1)} \ge z_j^{(k+1)} \ge x_j^{(k+1)}, \qquad j = 1, \dots, i-1,$$

which is valid for $k = 0$ and $i = 1$. Then by the same boundedness and antitonicity arguments as in Theorem 3.4, we have

$$\begin{aligned} r_i\left(y_1^{(k+1)}, \dots, y_{i-1}^{(k+1)}, y_i^{(k+1)}, y_{i+1}^{(k)}, \dots\right) = 0 = r_i\left(z_1^{(k+1)}, \dots, z_{i-1}^{(k+1)}, z_i^{(k+1)}, z_{i+1}^{(k)}, \dots\right) \\ \ge r_i\left(y_1^{(k+1)}, \dots, y_{i-1}^{(k+1)}, z_i^{(k+1)}, y_{i+1}^{(k)}, \dots\right), \end{aligned}$$

which, together with the strict diagonal isotonicity of r_i, implies that $y_i^{(k+1)} \ge z_i^{(k+1)}$. Similarly it follows that $z_i^{(k+1)} \le x_i^{(k+1)}$. This completes the induction, and hence $z_j^{(k)} \to x_j^*$ pointwise. ∎

In particular, the nonlinear Gauss–Seidel and Jacobi processes converge if we use $\{u_j^n\}$ (i.e., the solution from the previous time step) as an initial guess. For small to moderate time-step sizes, one generally expects the solutions between consecutive time steps to be close to each other, so using $\{u_j^n\}$ often results in much faster convergence than either $\underline{u}$ or $\overline{u}$ as an initial guess.

3.5. Extensions. In this section we show how to extend the results of Theorems 3.6 and 3.7 to deal with conservation laws with nonuniform spatial grids and/or spatially varying flux functions, as well as flux functions that are only defined over a closed interval $I \subset \mathbb{R}$.

3.5.1. Nonuniform grids and spatially varying flux functions. Consider again the fully implicit discretization (2.1):

$$\phi_i(u_i^{n+1} - u_i^n) + \lambda(F_{i+1/2}^{n+1} - F_{i-1/2}^{n+1}) = 0, \qquad \lambda = \Delta t/\Delta x, \;\; i \in \mathbb{Z},$$

where ϕ_i and $F_{i+1/2}$ can vary over the spatial index i. We assume that $0 < \phi_i \leq 1$. Note that the nonuniform grid case is automatically included: For any nonuniform discretization of the form

$$\frac{\tilde{\phi}_i(u_i^{n+1} - u_i^n)}{\Delta t} + \frac{F_{i+1/2}^{n+1} - F_{i-1/2}^{n+1}}{\Delta x_i} = 0, \tag{3.19}$$

we can multiply (3.19) by $\Delta t \Delta x_i/\Delta x_{max}$ to recover the form of (2.1) with

$$\phi_i = \tilde{\phi}_i \Delta x_i/\Delta x_{max}, \qquad \lambda = \Delta t/\Delta x_{max}.$$

To ensure convergence of the Jacobi and Gauss–Seidel processes, we need the following assumptions:

1. The family of flux functions $\{F_{i+1/2}\}_{i=-\infty}^{\infty}$ is equicontinuous (cf. [12]) with the same local Lipschitz constant K_B.
2. $\{\phi_i\}$ is uniformly bounded away from zero; i.e., there exists $\phi_{min} > 0$ such that $\phi_i \geq \phi_{min}$ for all $i \in \mathbb{Z}$.

While the equicontinuity condition may appear severe, it is usually satisfied in practice because the spatially varying coefficients (e.g., $K(x)$ in (1.11)) tend to be uniformly bounded, ensuring equicontinuity in the flux functions. With the above assumptions, we can mimic Theorem 3.6 exactly by replacing λ with λ/ϕ_i. Then the proof goes through verbatim, except for (3.16), which must be modified to

$$\frac{2\lambda K_B}{\phi_{min} + 2\lambda K_B} < \beta < 1. \tag{3.20}$$

3.5.2. Bounded admissible solutions. Formally, Theorem 3.6 requires the discrete flux function $F(u_i, u_{i+1})$ to be defined on $\mathbb{R} \times \mathbb{R}$. In practice one may want to solve problems for which the flux function f is defined only on an interval $[u_{min}, u_{max}]$ rather than on all of $\mathbb{R}$, because states outside these bounds are unphysical. For instance, in the two-phase flow problem, we must have $S_i \in [0, 1]$ for all i, and the flux function $f(S)$ in (1.11) is not even defined outside this range. Fortunately, the estimate (3.14) ensures that as long as the initial conditions are within physical bounds, so will the solution for subsequent time steps $n > 0$, as well as any intervening Jacobi or Gauss–Seidel iterate. Thus, to apply Theorem 3.6 to these problems, one can *formally extend* the domain of the flux function f to $\mathbb{R}$ by defining, for instance,

$$\tilde{f}(u) = \begin{cases} f(u_{min}), & u < u_{min}, \\ f(u), & u_{min} \leq u \leq u_{max}, \\ f(u_{max}), & u > u_{max}, \end{cases}$$

and similarly for the discrete flux $F(u, v)$. Since all Gauss–Seidel iterates $\{y^k\}$ and $\{x^k\}$ satisfy the bound $x^0 \leq x^k \leq y^k \leq y^0$, the exact manner in which the extension is defined is unimportant as long as Assumption 1 (monotonicity) is valid.

4. Applications to porous media flow.

4.1. 1D Buckley–Leverett problem with gravity. Consider a 1D incompressible two-phase flow problem with a constant-rate injection boundary condition on the left, a pressure boundary condition on the right, and no internal sources or sinks:

$$\phi(x)\frac{\partial S_j}{\partial t} + \frac{\partial v_j}{\partial x} = 0, \quad (x,t) \in (x_L, x_R) \times \mathbb{R}^+, \tag{4.1}$$

$$S_1(x,0) = S^0(x), \quad x \in (x_L, x_R), \tag{4.2}$$

$$v_j(x_L,t) = v_{j,L}, \quad p(x_R,t) = p_R, \quad t \in \mathbb{R}^+, \tag{4.3}$$

for $j = 1, 2$, where $v_j = -K(x)\lambda_j(S_1)(\frac{dp}{dx} - \rho_j \mathbf{g}\cdot\mathbf{i})$, $p \equiv p_1 = p_2$ (i.e., zero capillary pressure), and $\mathbf{i}$ is the unit vector along the x-direction. We assume that the injection velocities $v_{1,L}$ and $v_{2,L}$ are nonnegative, and that the total velocity $v_{T,L} := v_{1,L} + v_{2,L}$ is strictly positive. (These assumptions cover the most interesting cases, such as oil recovery by water flooding.) This formulation, which contains pressure variables, is known as the *parabolic form* of the problem, since it represents the incompressible limit of a parabolic problem. We can also derive the *hyperbolic* or "fractional flow" form of the problem by eliminating the pressure variables as follows. The discretized PDEs can be written as

$$\frac{\phi_i(S_{1,i} - S_{1,i}^{\text{old}})}{\Delta t} + \frac{F_{1,i+1/2} - F_{1,i-1/2}}{\Delta x} = 0, \tag{4.4a}$$

$$\frac{\phi_i(S_{1,i}^{\text{old}} - S_{1,i})}{\Delta t} + \frac{F_{2,i+1/2} - F_{2,i-1/2}}{\Delta x} = 0, \tag{4.4b}$$

where

$$F_{j,i+1/2} = K_{i+1/2}\lambda_{j,i+1/2}\left(\frac{p_i - p_{i+1}}{\Delta x} + \rho_j g\right) \tag{4.5}$$

for $j = 1, 2$, $i = 1, \ldots, N$, with $g = \mathbf{g}\cdot\mathbf{i}$. The numerical boundary conditions become

$$F_{j,1/2} = v_{j,L} \quad (j = 1, 2), \qquad p_{N+1} = 2p_R - p_N. \tag{4.6}$$

Assume, without loss of generality, that $g(\rho_1 - \rho_2) \geq 0$. To eliminate the pressure variables p_i, first note that summing (4.4a) and (4.4b) yields, after some manipulation,

$$F_{1,i+1/2} + F_{2,i+1/2} = F_{1,i-1/2} + F_{2,i-1/2} = v_1 + v_2 =: v_T.$$

In other words, the total flux v_T is constant across any interface, which must then be equal to $v_{T,L}$. We can express the pressure gradient $(p_i - p_{i+1})/\Delta x$ in terms of v_T by summing (4.5) through $j = 1, 2$:

$$v_T = K_{i+1/2}\left[\lambda_{T,i+1/2}\frac{p_i - p_{i+1}}{\Delta x} + (\lambda_{1,i+1/2}\,\rho_1 g + \lambda_{2,i+1/2}\,\rho_2 g)\right],$$

where $\lambda_{T,i+1/2} = \lambda_{1,i+1/2} + \lambda_{2,i+1/2}$. Thus,

$$\frac{p_i - p_{i+1}}{\Delta x} = \frac{v_T - K_{i+1/2}(\lambda_{1,i+1/2}\,\rho_1 g + \lambda_{2,i+1/2}\,\rho_2 g)}{K_{i+1/2}(\lambda_{1,i+1/2} + \lambda_{2,i+1/2})}. \tag{4.7}$$

Substituting into (4.5) for $j = 1$ gives

$$F_{1,i+1/2} = \frac{\lambda_{1,i+1/2}}{\lambda_{T,i+1/2}} \left[v_T + K_{i+1/2} \lambda_{2,i+1/2} (\rho_1 - \rho_2) g \right] \tag{4.8}$$
$$= F_{1,i+1/2}(S_{1,i}, S_{1,i+1}).$$

This, together with (4.4a), gives

$$\phi_i (S_{1,i} - S_{1,i}^{\text{old}}) + \frac{\Delta t}{\Delta x} \left(F_{1,i+1/2} - F_{1,i-1/2} \right) = 0, \tag{4.9}$$

leading to a numerical scheme that is identical to (2.1) except for the boundary conditions.Clearly, the treatment of boundary conditions will significantly affect the stability and accuracy of the numerical scheme. However, in order to understand the behavior of the numerical scheme at interior points, we will simply replace the initial-boundary value problem (4.1)–(4.3) with an initial value problem on an infinite domain with appropriate initial conditions. In particular, we replace the injection boundary condition with

$$S_1^0(x) = S_{1,L}, \qquad x < x_L, \tag{4.10}$$

where $S_{1,L}$ satisfies $f_1(x_L, S_{1,L}) = v_{1,L}/v_T$, with $f_1(x, S_1)$ given by (1.10). We also replace the pressure boundary condition with

$$S_1^0(x) = S_1^0(x_R), \qquad x > x_R. \tag{4.11}$$

The modified continuous problem will yield a solution identical to (4.1)–(4.3) for $0 < t < T_{BT}$, where T_{BT} is the breakthrough time (i.e., the time at which the shock front arrives at the pressure boundary). Note that f_1 is one-to-one over the interval $I = \{S : 0 \le f_1(S) < 1\}$ (see Figure 1.1), and $v_{1,L} \le v_T$ by assumption; thus, (4.10) is well-defined unless $v_{2,L} = 0$. (If $v_{2,L} = 0$, we define $S_1^0(x) = \inf f_1^{-1}(v_T)$, where f_1^{-1} denotes the inverse image.) For the remainder of this section, we will drop the phase subscript and denote $S_{1,i}$ and $F_{1,i+1/2}$ by S_i and $F_{i+1/2}$, respectively.

Phase-based upstreaming. Recall from section 1 (cf. (1.9)) that the mobilities $\lambda_{j,i+1/2}$ are evaluated using the upstream saturations with respect to the flow direction of phase j:

$$\lambda_{j,i+1/2} = \begin{cases} \lambda_j(S_i) & \text{if } \frac{1}{\Delta x}(p_i - p_{i+1}) + \rho_j g \ge 0, \\ \lambda_j(S_{i+1}) & \text{otherwise.} \end{cases} \tag{4.12}$$

In light of (4.7), we can rewrite the upstream conditions as

$$\lambda_{j,i+1/2} = \begin{cases} \lambda_j(S_i) & \text{if } v_T + K_{i+1/2} \lambda_{j',i+1/2} (\rho_j - \rho_{j'}) g \ge 0, \\ \lambda_j(S_{i+1}) & \text{otherwise,} \end{cases} \tag{4.13}$$

where the subscript $j' := 3 - j$ denotes the phase other than phase j. Even though pressure dependence has been eliminated, (4.13) still does not explicitly define the upstream direction for λ_j, since the latter is defined in terms of the (yet undetermined) mobility of the other phase $\lambda_{j',i+1/2}$. For explicit numerical schemes, Brenier and Jaffré have shown in [3] how to explicitly determine the upstream direction for each

phase for a given saturation profile $\{S_i^n\}$. In the special case of two-phase flow, they define the following quantities:

$$\theta_{1,i+1/2} = v_T + K_{i+1/2} g(\rho_1 - \rho_2)\lambda_2(S_{i+1}^n),$$
$$\theta_{2,i+1/2} = v_T - K_{i+1/2} g(\rho_1 - \rho_2)\lambda_1(S_i^n).$$

These quantities correspond precisely to the condition in (4.13), but the condition is evaluated at S_{i+1}^n for θ_1 and S_i^n for θ_2. Clearly $\theta_{1,i+1/2} > 0$, since $g(\rho_1 - \rho_2) \geq 0$. The correct upstream directions are then given by

$$\lambda_{1,i+1/2}^n = \lambda_1(S_i^n), \qquad \lambda_{2,i+1/2}^n = \lambda_2(S_i^n) \qquad \text{if } 0 \leq \theta_{2,i+1/2} \leq \theta_{1,i+1/2},$$
$$\lambda_{1,i+1/2}^n = \lambda_1(S_i^n), \qquad \lambda_{2,i+1/2}^n = \lambda_2(S_{i+1}^n) \qquad \text{if } \theta_{2,i+1/2} \leq 0 \leq \theta_{1,i+1/2}.$$

Thus, the numerical fluxes are well-defined if one uses an explicit method with respect to saturation. However, this analysis does not address implicit-saturation schemes (such as FIM), which require the upstream directions to be consistent with saturation values *at the end of the time step*, i.e., with the saturation profile $\{S_i^{n+1}\}$. Because of this consistency requirement, it is not clear a priori that a solution to the parabolic form of the problem (4.4) even exists. Our approach to proving existence is to rely on the hyperbolic form of the problem (4.8)–(4.11). From the above derivation, it is evident that if $\{(S_i, p_i)\}_{i=1}^N$ is any solution to the parabolic form (4.4)–(4.6), then $\{S_i\}_{i=1}^N$ must be a solution to the hyperbolic problem. Thus, the key idea is to first find the correct saturation profile $\{S_i\}$ using (4.8)–(4.11) with a numerical flux that automatically ensures consistency with the upstream directions; once the $\{S_i\}$ are known, we can easily solve for the pressure part because the pressure equation is linear. We distinguish two cases:

1. If $K_{i+1/2} g(\rho_1 - \rho_2)\lambda_{1,\max} \leq v_T$, then $\theta_{2,i+1/2} \geq 0$ always, so we revert to a single-point upstream scheme $F_{i+1/2} = F_{i+1/2}(S_i)$.

2. If $K_{i+1/2} g(\rho_1 - \rho_2)\lambda_{1,\max} > v_T$, then by the monotonicity of $\lambda_1(S)$, there exists a unique $0 < S_c < 1$ such that $K_{i+1/2} g(\rho_1 - \rho_2)\lambda_1(S_c) = v_T$. Then the numerical flux, which is to be evaluated at time t^{n+1}, is defined as

(4.14)
$$F_{i+1/2}(S_i, S_{i+1}) = \begin{cases} \dfrac{\lambda_1(S_i)\left[v_T + K_{i+1/2} g(\rho_1 - \rho_2)\lambda_2(S_i)\right]}{\lambda_1(S_i) + \lambda_2(S_i)} & \text{if } 0 \leq S_i \leq S_c, \\ \dfrac{\lambda_1(S_i)\left[v_T + K_{i+1/2} g(\rho_1 - \rho_2)\lambda_2(S_{i+1})\right]}{\lambda_1(S_i) + \lambda_2(S_{i+1})} & \text{if } S_c < S_i \leq 1. \end{cases}$$

Figure 4.1 shows a plot of $F(S_i, S_{i+1})$ in the latter case, which corresponds to the continuous flux function in Figure 1.1(b). Note that we are able to recover $f(S)$ from the numerical flux $F(S_i, S_{i+1})$ because consistency implies $F(S, S) = f(S)$. Even though $f(S)$ itself is nonmonotonic, the plot clearly shows that $F(S_i, S_{i+1})$ is an increasing function of S_i and a decreasing function of S_{i+1}, as predicted by Theorem 2.1. Also, the numerical flux is independent of the downstream saturation S_{i+1} inside the cocurrent region ($0 \leq S_i \leq S_c \approx 0.27$) but becomes a function of both variables when $S_i > S_c$. Finally, $F(S_i, S_{i+1})$ is Lipschitz continuous, but nondifferentiable, along the line $S_i = S_c$ due to the upstream condition (4.14). Since the numerical flux satisfies the monotonicity assumption, the analysis in the last two

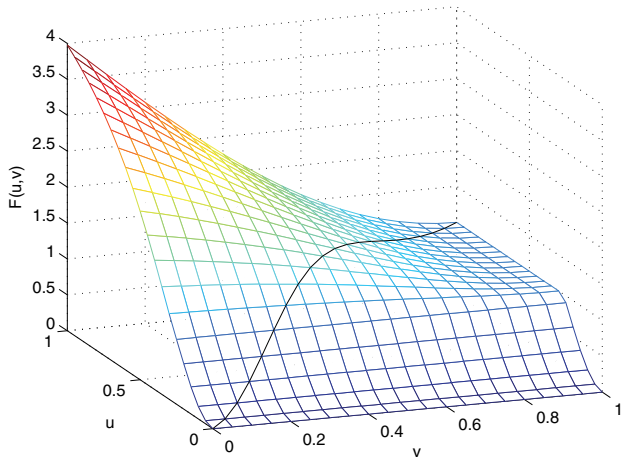


FIG. 4.1. *The numerical flux function $F(u,v)$ corresponding to the fractional flow in Figure* 1.1(b). *The black curve along the diagonal indicates the value of $F(u,u) = f(u)$.*

sections shows that the hyperbolic problem with implicit time-stepping has a unique solution $\{S_i^{n+1}\}$, which must also be the correct saturation profile for the parabolic problem. To solve for pressure, we use (4.7) and (4.6):

$$\frac{p_i - p_{i+1}}{\Delta x} = \frac{v_T - K_{i+1/2}(\lambda_{1,i+1/2}\, g\rho_1 + \lambda_{2,i+1/2}\, g\rho_2)}{K_{i+1/2}(\lambda_{1,i+1/2} + \lambda_{2,i+1/2})}, \qquad i = 1, \ldots, N, \tag{4.15}$$

$$p_{N+1} = 2p_R - p_N. \tag{4.16}$$

Since $\{S_i^{n+1}\}$ is now known, the right-hand side of (4.7) is also completely determined. Thus, the vector p of pressures satisfies $Ap = b$, where A is an $N \times N$ upper triangular matrix with a nonzero diagonal. So A is nonsingular, which means there is a unique pressure profile $\{p_i^{n+1}\}$ that satisfies (4.7) and (4.6). It is easy to see that this pressure profile is consistent with the upstream condition (4.12): because of (4.7), this upstream condition is equivalent to (4.13), and the conditions therein are precisely the ones we use to define the numerical flux function (4.14) for the hyperbolic problem. Hence, we have shown that the parabolic form (4.4)–(4.6) has a unique solution, given by the above $\{(S_i^{n+1}, p_i^{n+1})\}$.

4.2. Multidimensional considerations. In multiple dimensions, one can no longer eliminate pressure variables as shown above, because the total velocity $\mathbf{v}_T$ is generally a function of space and time. Thus, the system of PDEs (1.1), (1.2) does not reduce to a purely hyperbolic problem, which means we cannot directly apply our existence and uniqueness results to the FIM in this case. Nonetheless, our analysis does apply to a related numerical scheme known as the *sequential-implicit method* (SEQ). At each time step in SEQ, we first solve the discrete version of the (linear) elliptic equation (1.5), in which the saturation-dependent coefficients are taken at time t^n. In other words, we solve for p^{n+1} via

$$-\nabla \cdot \left[K\lambda_T(S^n)\nabla p^{n+1} - K\mathbf{g}\textstyle\sum_j \rho_j \lambda_j(S^n)\right] = \sum_j q_j. \tag{4.17}$$

Next, we compute the total velocity

$$\mathbf{v}_T^* = \textstyle\sum_j \mathbf{v}_j^* = -\sum_j K\lambda_j(S^n)(\nabla p^{n+1} - \rho_j \mathbf{g}). \tag{4.18}$$

Finally, we compute the saturations S_j^{n+1} $(j = 1, \ldots, n-1)$ by solving the discrete version of (1.6) and (1.7) with *implicit time-stepping*:

$$\phi \frac{\partial S_j}{\partial t} + \nabla \cdot \mathbf{v}_j(x, S_1, \ldots, S_n) = 0, \tag{4.19}$$

$$\mathbf{v}_j = \frac{\lambda_j}{\lambda_T}\left(\mathbf{v}_T^* - K\mathbf{g}\textstyle\sum_\ell \lambda_\ell(\rho_\ell - \rho_j)\right). \tag{4.20}$$

Essentially, the SEQ method decouples the system into an elliptic and a hyperbolic subproblem. For two-phase flow problems, one can readily extend the convergence results of Theorems 3.6 and 3.7 to the hyperbolic subproblem above, as long as the spatial grid satisfies certain shape and connectivity requirements. Discretizing (4.19) yields the multidimensional analogue of (2.1):

$$\phi_i(S_i^{n+1} - S_i^n) + \sum_{l \in \mathrm{adj}(i)} \lambda_{il} F_{il}(S_i^{n+1}, S_l^{n+1}) = 0. \tag{4.21}$$

Here, F_{il} is the flux (or velocity) from cell i to cell l, and $\lambda_{il} = \Delta t|\partial V_{il}|/|V_i|$, where $|\partial V_{il}|$ is the area of the surface separating cells i and l, $|V_i|$ is the volume of cell i, and Δt is the time step. For a conservative scheme we must have $F_{il}(S_i, S_l) = -F_{li}(S_l, S_i)$, and for monotonicity we require that F_{il} be nondecreasing with respect to the first argument and nonincreasing with respect to the second. This requirement is satisfied for two-phase flow problems, since we can reproduce the derivation in section 4.1 to obtain the flux function

$$F_{il} = \frac{\lambda_{1,il}}{\lambda_{T,il}}\left[v_{il} + K_{il}g_{il}(\rho_1 - \rho_2)\lambda_{2,il}\right]$$

and the upstream condition

$$\lambda_{j,il} = \begin{cases} \lambda_j(S_i) & \text{if } v_{il} + K_{il}g_{il}(\rho_j - \rho_{j'})\lambda_{j',il} \geq 0, \\ \lambda_j(S_l) & \text{otherwise,} \end{cases}$$

for $j = 1, 2$, where $v_{il} = \mathbf{v}_T^* \cdot \mathbf{n}_{il}$ and $g_{il} = \mathbf{g} \cdot \mathbf{n}_{il}$. In order to mimic the proof of Theorem 3.6, we need the following assumptions on the grid:

1. The number of cells (control volumes) adjacent to cell i is bounded for all i.
2. The ratio $|\partial V_{il}|/|V_i|$ is bounded for all pairs of adjacent cells (i, l).
3. The quantity $\phi_i|V_i|$ is uniformly bounded away from zero for all i.
4. For any cell i, the total number of cells reachable from i in k steps is $O(k^p)$ for some fixed $p > 0$ (i.e., grows at most polynomially in k).

The above assumptions are easily satisfied by regular Cartesian grids, and also by most unstructured grids of practical interest. We also need the following assumption on the numerical flux F_{il} (which is analogous to the assumption in section 3.5.1):

5. F_{il} is equicontinuous with the same Lipschitz constant for all pairs of adjacent cells (i, l).

These assumptions ensure that the residual functions are all bounded and have the same Lipschitz constant over the set $\{u \in \ell^\infty(N) \,|\, \|u\|_\infty < B\}$. The polynomial

growth assumption (4) allows us to assign the weights $\{w_i^B\}$ to each cell i in the following manner: pick any node i_0 and let $w_i^B = \beta^{d(i_0,i)}$, where $d(i,j)$ is the shortest distance between nodes i and j in the graph-theoretic sense. Since the number of cells within k steps of i_0 grows polynomially in k, the series $\sum_i w_i^B$ converges for any $0 < \beta < 1$, so β can be chosen the same way as in step 3 of the proof of Theorem 3.6 and the same argument will hold. Hence, we can conclude that the hyperbolic subproblem in the SEQ method is well-defined for any time-step size Δt, and the nonlinear Gauss–Seidel and Jacobi processes are guaranteed to converge for these problems.

5. Accuracy of phase-based upstreamed solutions. In this section, we investigate the accuracy of the numerical solution obtained from implicit phase-based upstreaming when we vary the spatial and temporal grid. Our 1D test case consists of a countercurrent flow problem inside the domain $\Omega = [0,1]$, and our two-dimensional (2D) example is a cocurrent flow problem in a heterogeneous reservoir. For the 1D problem, water is injected at the boundary $x = 0$ and a pressure boundary condition is maintained at $x = 1$. The hyperbolic form of the problem is described by (1.10), (1.11). The flux function $f_1(S)$, which is independent of x, is shown in Figure 1.1(b), with a sonic point at $S = 0.49$; countercurrent flow occurs whenever $S \geq S_c \approx 0.27$. The initial saturation profile is a step function with

$$S^0(x) = \begin{cases} 1, & 0 \leq x < 0.2, \\ 0, & 0.2 < x \leq 1. \end{cases}$$

The numerical solution is compared with the analytical solution at time $t = 0.15$. Because of the sonic point, the solution contains two shocks connected by a rarefaction; one shock moves to the right with a velocity of 3.9, and the other travels to the left with a velocity of -1.2. When considering the accuracy of a numerical solution, two error measures are shown:

- The L^1-*error*, which is the difference between the numerical and the analytical solution in the L^1-norm.
- The *front dispersion*, which is the distance between analytical shock front and the leftmost point for which the numerical solution becomes zero.

We also measure how difficult the nonlinear problem is by showing, for each test case, the average number of nonlinear Gauss–Seidel iterations required for convergence at each time step. We remark that this measure is only useful for problems with countercurrent flow; in the cocurrent case, the flux function $F_{i+1/2}$ is a function of S_i only, which means Gauss–Seidel will always converge in one iteration if we solve the single-cell equations in the order $1, 2, \ldots, N$ (i.e., from upstream to downstream). In the countercurrent case, convergence is generally linear, and the rate of convergence is a function of the time step [8].

5.1. Refinement under fixed mesh ratio. Here we refine the grid at a fixed mesh ratio $\Delta x/\Delta t$ to maintain a fixed CFL number of 4.10, which is above the CFL limit for explicit schemes. Figure 5.1 shows the plots for $N = 50, 100, 200, 400$, and Table 5.1 shows the L^1-error and front dispersion data. The plots show that the numerical solution converges to the analytical solution even though the CFL number is greater than 1, which confirms our analysis. Moreover, both the L^1-error and the front dispersion are decreasing to zero a bit worse than linearly, with a ratio of about 0.61 and about 0.58, respectively, for every refinement by a factor of two. Also note the poor resolution near the left boundary for $N = 50, 100$, where instead of approaching

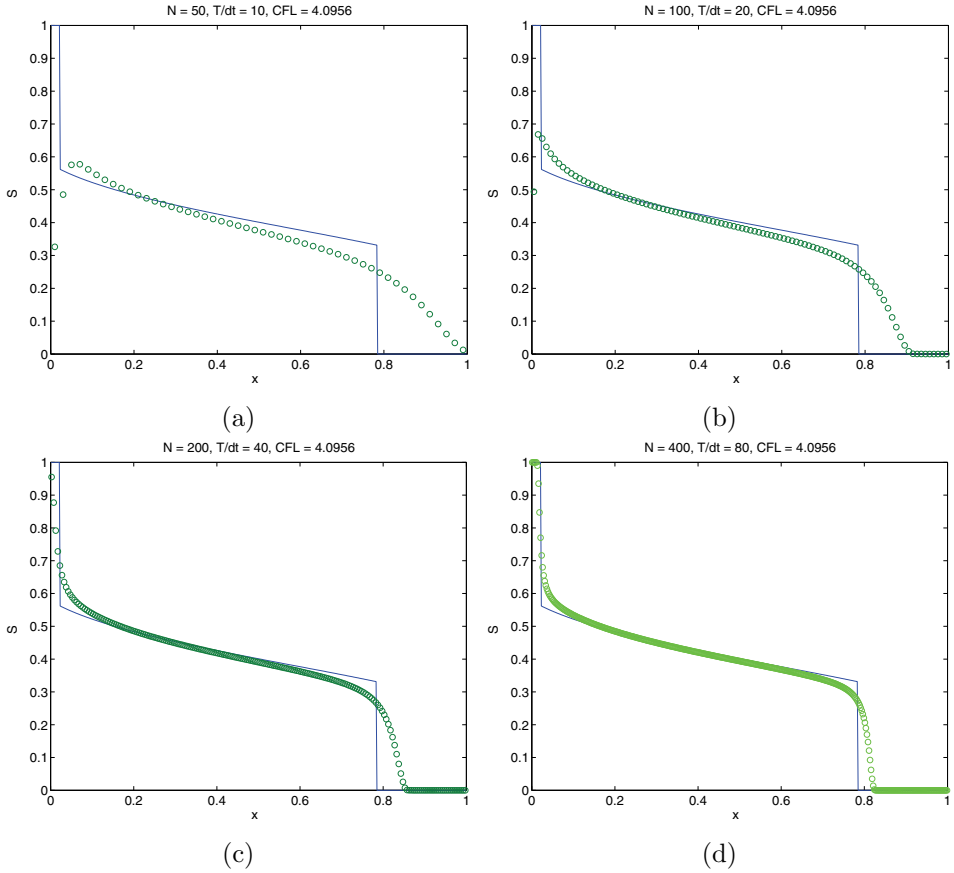

FIG. 5.1. *Numerical solution at different resolutions, CFL* $= 4.10$, $t = 0.15$.

$S = 1$, the solution is closer to $S_c \approx 0.27$ at the left boundary. For these coarser grids, the numerical solution cannot decide whether the left-moving wave has reached the boundary, which is maintained at $S(0,t) = S_c$ (see (4.10)). For higher resolutions ($N = 200, 400$), the artifact has disappeared and the numerical solution reproduces the back end of the saturation profile quite accurately. The average number of Gauss–Seidel iterations required for convergence are all similar, so refining the grid at a fixed mesh ratio does not increase the difficulty of the problem for the nonlinear solver.

5.2. Spatial refinement for fixed time steps. Here, we refine the spatial grid only while fixing the time-step size. Figure 5.2 and Table 5.2 show the results for $N = 25, 50, 100, 200, 400$ and a time-step size of $\Delta t = 0.0075$; i.e., we use 20 time steps to integrate up to $t = 0.15$. We see that even though the $N = 25$ case has a

TABLE 5.1

CFL number close to 1, the grid is clearly too coarse, and the shock fronts are very poorly resolved. The accuracy increases substantially when the spatial grid is refined to $N = 50, 100$, even though the CFL number becomes progressively larger; thus, the CFL number by itself is not a good measure of solution quality. However, the improvement due to spatial grid refinement becomes negligible for $N > 100$, since errors due to time discretization are now the dominant source of error. In addition, the average number of iterations required to attain convergence increases with each refinement: as we refine the grid, we are solving increasingly difficult problems, even though the improvement in solution accuracy will stagnate beyond a certain point. Thus, even though the FIM can tolerate arbitrarily large CFL numbers, one should not expect the solution accuracy to improve indefinitely simply by using a finer spatial grid, without making a corresponding reduction in time-step size.

5.3. Nonuniform grids. The real advantage of the FIM over an explicit scheme lies in its efficiency when applied to a heterogeneous problem, where the porosity $\phi(x)$ and permeability $K(x)$ can vary by orders of magnitude over the domain. In these problems, the CFL condition is determined by the minimum porosity in the domain, which can be much smaller than the average porosity. To illustrate this point, we show an example in which the spatial grid is nonuniform (which, from section 3.5.1,

is equivalent to the spatially varying porosity case). The nonuniform grid contains 50 gridblocks, with $\Delta x_{\max}/\Delta x_{\min} = 96$. Table 5.3 and Figure 5.3 compare the numerical solutions obtained from this grid to the uniform-grid solutions. We see that the solutions are qualitatively (from the plots) and quantitatively (from the L^1-error and front dispersion) not very different, even though the CFL number is 50 times larger in the nonuniform case. Thus, an explicit integrator would have to take unacceptably small time steps, whereas an implicit method allows time steps that are much more reasonable. In addition, the average number of iterations required for convergence is roughly the same for both cases, so the equations resulting from a nonuniform grid are not harder to solve, despite the large CFL numbers.

5.4. 2D example. The goal of this example is to compare the unconditionally stable SEQ method with the implicit-pressure-explicit-saturation (IMPES) method, which carries a time-step restriction $\Delta t = \mathcal{O}(\Delta x)$. We use a 110×30 grid to discretize a 2D horizontal reservoir (i.e., no gravity). The porosity ϕ is constant throughout the reservoir, whereas the permeability field $K(\mathbf{x})$ is taken from the SPE 10 test set [4] and ranges from a minimum of 0.0052 to a maximum of 1219 (see Figure 5.4(b)). The reservoir is initially saturated with oil. Starting from $t = 0$, water is injected at a constant rate into cell $(1, 1)$, and fluid is produced at constant pressure from cell $(110, 30)$. We simulate the reservoir until $t = 30$ (0.182 pore volumes injected), which is roughly when breakthrough occurs at the outlet boundary. For IMPES, we take the largest time step allowed by the CFL criterion, whereas for SEQ we use two time-stepping strategies:

- Small Δt: $t = 1, 2, 3, 4$; after $t = 4$, $\Delta t = 2$ until $t = 30$.
- Large Δt: $t = 1, 3, 6, 10$; after $t = 10$, $\Delta t = 5$ until $t = 30$.

Figures 5.4(a), (c), and (e) show the saturation profiles obtained from IMPES and SEQ for the two time-step sizes, and Table 5.4 shows the error and running times for each case. Note that all three solutions are very similar; the largest discrepancies occur near flood fronts, where the SEQ solutions are noticeably more diffuse than the IMPES solution. However, the IMPES profile is sharp only because the method is forced to take tiny time steps to satisfy a very severe CFL condition. As a result, IMPES runs 65 times slower than SEQ for the large Δt case, and 31 times slower for the small Δt case. Table 5.4 indicates that the maximum difference between the

Solution time (sec)	66017	1016	2130

IMPES and SEQ solutions remains nearly constant when the time step is reduced. This is not surprising, because the numerical solution cannot converge uniformly when discontinuities are present in the solution. However, we do observe a decrease in the L^1-error, as well as a later breakthrough time, when Δt is reduced. This is consistent with our 1D results, where refining the grid reduces the L^1 and front dispersion errors, but the L^∞-error does not go to zero because of smearing across the shock front. This example shows that, for problems of practical interest, an implicit method can produce solutions of comparable quality at much lower computational costs than an explicit

method.

6. Conclusion. We have shown that, for any residual function that arises from the implicit monotone discretization of a scalar hyperbolic conservation law, the nonlinear Gauss–Seidel and Jacobi processes converge to the unique bounded solution whenever the initial guess is bounded. This provides an alternate, constructive proof of the well-definedness of monotone implicit schemes, for which a solution algorithm is easily implementable. Convergence to the entropy solution for arbitrary CFL numbers follows immediately from the properties of the flux functions. These results are applicable to the fully coupled two-phase flow problem in one dimension, and to the hyperbolic subproblem in the sequential-implicit method in higher dimensions. Finally, we studied the accuracy of phase-based upstream solutions under different grid refinement schemes, and the importance of unconditional stability became evident when a nonuniform grid and/or a variable porosity field is used.

THE l^1-ERROR ESTIMATES FOR A HAMILTONIAN-PRESERVING SCHEME FOR THE LIOUVILLE EQUATION WITH PIECEWISE CONSTANT POTENTIALS*

XIN WEN† AND SHI JIN‡

Abstract. We study the l^1-error of a Hamiltonian-preserving scheme, developed in [S. Jin and X. Wen, *Commun. Math. Sci.*, 3 (2005), pp. 285–315], for the Liouville equation with a piecewise constant potential in one space dimension. This problem has important applications in computations of the semiclassical limit of the linear Schrödinger equation through barriers, and of the high frequency waves through interfaces. We use the l^1-error estimates established in [X. Wen and S. Jin, *J. Comput. Math.*, 26 (2008), pp. 1–22; X. Wen, *Convergence of an Immersed Interface Upwind Scheme for Linear Advection Equations with Piecewise Constant Coefficients* II: *Some Related Binomial Coefficient Inequalities*, preprint, 2008] for the immersed interface upwind scheme to the linear advection equations with piecewise constant coefficients. We prove that the scheme with the Dirichlet incoming boundary conditions is l^1-convergent for a class of bounded initial data and derive the half order l^1-error bounds with *explicit* coefficients. The initial conditions can be satisfied by applying the decomposition technique proposed in [S. Jin, H. L. Liu, S. Osher, and R. Tsai, *J. Comput. Phys.*, 205 (2005), pp. 222–241] for solving the Liouville equation with measure-valued initial data, which arises in the semiclassical limit of the linear Schrödinger equation.

1. Introduction.

In [11], we constructed a class of numerical schemes for the d-dimensional Liouville equation in classical mechanics:

$$f_t + \mathbf{v}\cdot\nabla_{\mathbf{x}} f - \nabla_{\mathbf{x}} V\cdot\nabla_{\mathbf{v}} f = 0\,, \quad t>0, \quad \mathbf{x},\mathbf{v}\in R^d\,, \tag{1.1}$$

where $f(t,\mathbf{x},\mathbf{v})$ is the density distribution of a classical particle at position $\mathbf{x}$ and time t and traveling with velocity $\mathbf{v}$. $V(\mathbf{x})$ is the potential. The main interest is in the case of a discontinuous potential $V(\mathbf{x})$, corresponding to a potential barrier. When V is discontinuous, the Liouville equation (1.1) is a linear hyperbolic equation with a measure-valued coefficient. Such a problem cannot be understood mathematically using the renormalized solution by DiPerna and Lions for linear advection equations with discontinuous coefficients [5] (see also [2]). Our approach in [11, 12] to such problems was to provide an interface condition to couple the Liouville equation (1.1) on both sides of the barrier or interface. The interface condition accounts for particle or wave transmission and reflection. Based on this notion of the solution, the so-called Hamiltonian-preserving schemes were constructed in [11, 12], which build this interface condition into the numerical flux. Schemes so constructed provide solutions that are physically relevant for particle or wave reflection and transmission through the barriers or interfaces.

The Liouville equation is the phase space representation of Newton's second law:

$$\frac{d\mathbf{x}}{dt} = \mathbf{v}\,, \quad \frac{d\mathbf{v}}{dt} = -\nabla_{\mathbf{x}} V\,,$$

which is a Hamiltonian system with the Hamiltonian

$$H = \frac{1}{2}|\mathbf{v}|^2 + V(\mathbf{x}).$$

It is known from classical mechanics that the Hamiltonian remains constant across a potential barrier. This is one of the main ingredients in the Hamiltonian-preserving schemes developed in [11, 12]. The two schemes developed in [11]—one based on a finite difference formulation (called Scheme I) and the other on a finite volume formulation (called Scheme II)—were proved, in one space dimension with a piecewise constant potential, to be positive and l^1- and l^∞-stable for suitable initial value problems and under a hyperbolic CFL condition (see also [29]).

The more sophisticated issue of the l^1-stability of Scheme I was studied in [29]. We proved in [29] that, in the case of a step function potential, Scheme I with the homogeneous Dirichlet incoming boundary conditions is l^1-stable under a certain condition on the initial data. In particular, we showed that such an initial condition is satisfied when choosing the numerical initial data as the cell averages of bounded analytical initial data. Since the exact solution, in the aforementioned notion using the interface condition, to the same problem is l^1-contracting, an l^1-convergent scheme should be l^1-stable. Thus the results established in [29] imply that Scheme I meets the necessary condition for the l^1-convergence in the case of the homogeneous Dirichlet boundary conditions and bounded initial data.

In this paper we will study the l^1-convergence of Scheme I in the case of a step function potential and the Dirichlet incoming boundary conditions. We will prove that in this case Scheme I is l^1-convergent for a class of bounded initial data. The initial conditions can be satisfied when applying the decomposition technique proposed in [10] for solving the Liouville equation with measure-valued initial data arising in the semiclassical limit of the linear Schrödinger equation.

The Liouville equation with a step function (or more generally piecewise constant) potential belongs to hyperbolic equations with singular (discontinuous or measure-valued) coefficients. For the discontinuous coefficient case, the convergence of numerical schemes was widely studied [6, 9, 14, 15, 4, 17, 25, 19, 21, 7, 26, 27, 16, 13, 1, 20]. However, in most cases the convergence rate estimates for numerical schemes were not studied. For the measure-valued coefficient case, recently we have obtained the half order l^1-error estimates for the immersed interface upwind scheme which builds the interface condition into the numerical flux; see [30, 28]. In this paper, we extend this result to the more interesting case of the Liouville equation with a step function potential. Since the Liouville equation is defined in the phase space, extra efforts are needed to deal with the discretization in the velocity space.

To derive the desired error estimates, we split the computational domain into several parts. In each subdomain, we will introduce a number of linear advection equations with step function coefficients. The immersed interface upwind schemes for these linear advection equations yield the same numerical solution as Scheme I for the Liouville equation with the step function potential. Then the l^1-error estimates for Scheme I can be achieved by applying the l^1-error estimates for the immersed interface upwind schemes and estimating the l^1-errors between the exact solutions of the linear

advection equations with step function coefficients and that of the Liouville equation with the step function potential. The first part of each error estimate is obtained by applying the results established in [30, 28] with the aid of the condition on the initial data. The second part of the error is analyzed also utilizing the condition on the initial data. With this approach, we can derive the half order l^1-error bound with *explicit* coefficients for Scheme I.

Our proof is based on the step function potential. This result clearly can be generated to piecewise constant potentials in a straightforward but tedious way. The same approach should also be applicable to analyzing the l^1-error estimates for the finite volume Scheme II developed in [11]. But we will not pursue this in this paper.

This paper is organized as follows. In section 2 we review the Hamiltonian-preserving scheme proposed in [11] for the Liouville equation with a discontinuous potential in one space dimension. In section 3 we recall the l^1-error estimates for the immersed interface upwind scheme established in [30, 28] for the linear advection equation with a step function wave speed. In section 4 we set up the problem and state the main theorem of this paper which is proved in section 5 using the results presented in section 3. We conclude the paper in section 6.

2. A Hamiltonian-preserving scheme. In this section we review the Hamiltonian-preserving scheme proposed in [11] for the Liouville equation in one space dimension

$$f_t + \xi f_x - V_x f_\xi = 0 \tag{2.1}$$

with a discontinuous potential $V(x)$.

Consider a uniform mesh with grid points at $x_{i+\frac{1}{2}}$, $i \in \mathbb{Z}$, in the x-direction and $\xi_{j+\frac{1}{2}}$, $j \in \mathbb{Z}$, in the ξ-direction. The cells are centered at $(x_i, \xi_j), (i,j) \in \mathbb{Z}^2$ with $x_i = \frac{1}{2}(x_{i+\frac{1}{2}} + x_{i-\frac{1}{2}})$ and $\xi_j = \frac{1}{2}(\xi_{j+\frac{1}{2}} + \xi_{j-\frac{1}{2}})$. The mesh size is denoted by $\Delta x = x_{i+\frac{1}{2}} - x_{i-\frac{1}{2}}, \Delta\xi = \xi_{j+\frac{1}{2}} - \xi_{j-\frac{1}{2}}$. We also assume a uniform time step Δt, and the discrete times are given by $t_n = n\Delta t$, $n \in \mathbb{N} \cup \{0\}$. We assume that the computation is performed in a bounded rectangular domain

$$\{(x,y) | x_{\frac{1}{2}} \le x \le x_{N+\frac{1}{2}},\ \xi_{\frac{1}{2}} \le \xi \le \xi_{M+\frac{1}{2}}\}. \tag{2.2}$$

Let the cell averages of f be

$$f_{ij} = \frac{1}{\Delta x \Delta\xi} \int_{x_{i-\frac{1}{2}}}^{x_{i+\frac{1}{2}}} \int_{\xi_{j-\frac{1}{2}}}^{\xi_{j+\frac{1}{2}}} f(x,\xi,t) d\xi dx.$$

The one-dimensional average quantity $f_{i+1/2,j}$ is defined as

$$f_{i+1/2,j} = \frac{1}{\Delta\xi} \int_{\xi_{j-\frac{1}{2}}}^{\xi_{j+\frac{1}{2}}} f(x_{i+1/2}, \xi, t) d\xi\,.$$

$f_{i,j+1/2}$ is defined similarly.

In classical mechanics, a particle will either cross a potential barrier with a changing momentum or be reflected, depending on its momentum and the strength of the potential barrier.

Figure 2.1 shows the typical situations when a particle moves from left to right at a potential barrier. If the potential is reduced, the particle will cross it with

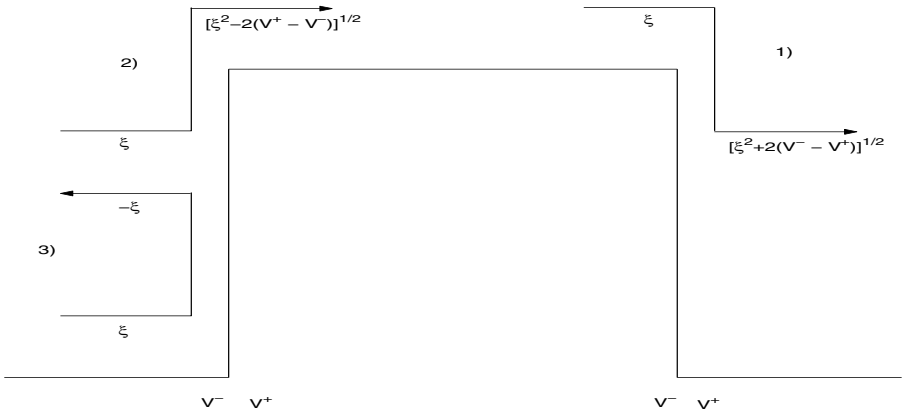

FIG. 2.1. *Transmission and reflection of a particle at a potential barrier.*

an accelerated speed. If the potential is increased, the particle is reflected if its momentum is not big enough to overcome the barrier or otherwise is transmitted with a reduced velocity. *The Hamiltonian* $H = \frac{1}{2}\xi^2 + V$ *is preserved across the potential barrier:*

$$\frac{1}{2}(\xi^+)^2 + V^+ = \frac{1}{2}(\xi^-)^2 + V^-, \tag{2.3}$$

where the superscripts $\pm$ indicate the right and left limits of the quantity at the potential barrier. This property was used in [11] to provide the interface condition for (2.1) at the barrier:

$$f(t, x^+, \xi^+) = f(t, x^-, \xi^-) \quad \text{for transmission,} \tag{2.4}$$

$$f(t, x^\pm, \xi^\pm) = f(t, x^\pm, -\xi^\pm) \quad \text{for reflection,} \tag{2.5}$$

where ξ^+ and ξ^- are related by the constant Hamiltonian condition (2.3) in the case of transmission. With such an interface condition, we established the well-posedness of the initial value problem to (1.1) with a piecewise constant potential in [12].

The main ingredient in the Hamiltonian-preserving schemes developed in [11], like the earlier work for shallow-water equations [22], was to build into the numerical flux the interface conditions (2.4), (2.5) at the barrier.

We now present the first Hamiltonian-preserving scheme, called *Scheme* I in [11].

Assume that the discontinuous points of the potential V are located at the grid points. Let the left and right limits of V at point $x_{i+1/2}$ be $V^-_{i+\frac{1}{2}}$ and $V^+_{i+\frac{1}{2}}$, respectively. Note that if V is continuous at $x_{j+1/2}$, then $V^-_{i+\frac{1}{2}} = V^+_{i+\frac{1}{2}}$. We approximate V by a piecewise linear function

$$V(x) \approx V^+_{i-1/2} + \frac{V^-_{i+1/2} - V^+_{i-1/2}}{\Delta x}(x - x_{i-1/2})\,.$$

The flux-splitting, semidiscrete scheme (with time continuous) reads

$$\partial_t f_{ij} + \xi_j \frac{f^-_{i+\frac{1}{2},j} - f^+_{i-\frac{1}{2},j}}{\Delta x} - \frac{V^-_{i+\frac{1}{2}} - V^+_{i-\frac{1}{2}}}{\Delta x}\frac{f_{i,j+\frac{1}{2}} - f_{i,j-\frac{1}{2}}}{\Delta \xi} = 0,$$

where the numerical fluxes $f_{i,j+\frac{1}{2}}$ are defined using the upwind discretization. Since the characteristics of the Liouville equation may be different on the two sides of a barrier, the corresponding numerical fluxes should also be different. The essential part of the algorithm is to define the split numerical fluxes $f^-_{i+\frac{1}{2},j}, f^+_{i-\frac{1}{2},j}$ at each cell interface. Conditions (2.4), (2.5) will be used to define these fluxes.

Assume V is discontinuous at $x_{i+1/2}$. Consider the case $\xi_j > 0$. Using upwind scheme, $f^-_{i+\frac{1}{2},j} = f_{ij}$. However,

$$f^+_{i+1/2,j} \equiv f(x^+_{i+1/2}, \xi^+) = f(x^-_{i+1/2}, \xi^-),$$

where ξ^- is obtained from $\xi^+ = \xi_j$ from (2.3). Since ξ^- may not be a grid point, we have to define it approximately. The first approach is to locate the two cell centers that bound this velocity and then use a linear interpolation to evaluate the needed numerical flux at ξ^-. The case of $\xi_j < 0$ is treated similarly. The algorithm to generate the numerical flux is given in [11]. Here we present the simplified algorithm for the case $V^-_{i+\frac{1}{2}} > V^+_{i+\frac{1}{2}}$ being discussed in this paper.

ALGORITHM I.

- $\xi_j > 0$

  $f^-_{i+\frac{1}{2},j} = f_{ij}$,

  ❑ if $\xi_j > \sqrt{2\left(V^-_{i+\frac{1}{2}} - V^+_{i+\frac{1}{2}}\right)}$,

  $\xi^- = \sqrt{\xi_j^2 + 2\left(V^+_{i+\frac{1}{2}} - V^-_{i+\frac{1}{2}}\right)}$

  if $\xi_k \le \xi^- < \xi_{k+1}$ for some k,

  then $f^+_{i+\frac{1}{2},j} = \frac{\xi_{k+1}-\xi^-}{\Delta\xi} f_{ik} + \frac{\xi^- - \xi_k}{\Delta\xi} f_{i,k+1}$

  ❑ else

  $f^+_{i+\frac{1}{2},j} = f_{i+1,k}$, where $\xi_k = -\xi_j$

  ❑ end

- $\xi_j < 0$

  $f^+_{i+\frac{1}{2},j} = f_{i+1,j}$,

  $\xi^+ = -\sqrt{\xi_j^2 + 2\left(V^-_{i+\frac{1}{2}} - V^+_{i+\frac{1}{2}}\right)}$

  if $\xi_k \le \xi^+ < \xi_{k+1}$ for some k,

  then $f^-_{i+\frac{1}{2},j} = \frac{\xi_{k+1}-\xi^+}{\Delta\xi} f_{i+1,k} + \frac{\xi^+ - \xi_k}{\Delta\xi} f_{i+1,k+1}$.

After the spatial discretization is specified, one can use any time discretization for the time derivative.

In [11] we proved that, when the first order upwind scheme is used spatially and the forward Euler method is used in time, and the potential V has a single jump, Scheme I is positive and l^∞-contracting under the CFL condition

$$\Delta t \left[\frac{\max_j |\xi_j|}{\Delta x} + \frac{\max_i \left| \frac{V^-_{i+\frac{1}{2}} - V^+_{i-\frac{1}{2}}}{\Delta x} \right|}{\Delta\xi} \right] < 1. \tag{2.6}$$

In [29] we proved that when the potential is a step function, the same scheme is l^1-stable under the CFL condition (2.6) and a suitable condition on the numerical initial data.

Note that the quantity $\left|\frac{V^-_{i+\frac{1}{2}} - V^+_{i-\frac{1}{2}}}{\Delta x}\right|$ represents the gradient of the potential at its

smooth point, which has a *finite* upper bound. Thus the scheme satisfies a hyperbolic CFL condition.

3. The l^1-error estimates for the immersed interface upwind scheme. In this section we present the l^1-error estimates for the immersed interface upwind scheme established in [30, 28] for the linear advection equation

$$\frac{\partial u}{\partial t} + c(x)\frac{\partial u}{\partial x} = 0, \qquad t > 0,\ x \in \mathbb{R}, \tag{3.1}$$

$$u|_{t=0} = u_0(x), \tag{3.2}$$

with a step function wave speed

$$c(x) = \begin{cases} c^-, & x < 0, \\ c^+, & x > 0. \end{cases} \tag{3.3}$$

We assume that $c(x)$ has a definite sign. This avoids the mathematical difficulties of dealing with nonuniqueness or measure-valued solutions; see, for example, [3, 23]. Without loss of generality we assume $c(x) > 0$.

We consider the following interface condition for (3.1)–(3.3) requiring u to be continuous across the interface:

$$u(0^+, t) = u(0^-, t). \tag{3.4}$$

In [30] we have considered a more general class of interface conditions including (3.4). In this paper we present only the results corresponding to the interface condition (3.4), which will be used to derive the l^1-error estimates for Scheme I.

The exact solution of (3.1)–(3.3) with the interface condition (3.4) can be constructed using the method of characteristics:

$$u(x,t) = \begin{cases} u_0(x - c^- t), & x < 0, \\ u_0\left(\frac{c^-}{c^+}x - c^- t\right), & 0 < x < c^+ t, \\ u_0(x - c^+ t), & x > c^+ t. \end{cases} \tag{3.5}$$

Consider the uniform mesh introduced in section 2 in the x- and t-directions. We assume that the interface $x = 0$ is located at a grid point. We introduce quantities $\lambda^- = c^-\frac{\Delta t}{\Delta x},\ \lambda^+ = c^+\frac{\Delta t}{\Delta x}$. The condition $0 < \lambda^-, \lambda^+ < 1$ is the CFL condition.

The immersed interface upwind scheme which builds the interface condition (3.4) into the upwind difference scheme (with the forward Euler time discretization) for (3.1)–(3.3) reads

$$v_i^{n+1} = (1 - \lambda^-)v_i^n + \lambda^- v_{i-1}^n \quad \text{if } x_i < 0, \tag{3.6}$$

$$v_i^{n+1} = (1 - \lambda^+)v_i^n + \lambda^+ v_{i-1}^n \quad \text{if } x_i > 0, \tag{3.7}$$

where

$$v_i^0 = \frac{1}{\Delta x}\int_{x_{i-\frac{1}{2}}}^{x_{i+\frac{1}{2}}} u_0(x)dx. \tag{3.8}$$

To compare the numerical solution computed from (3.6)–(3.8) with the exact solution (3.5), we introduce

$$v(x,t) = v_i^n \qquad \text{for } (x,t) \in [x_{i-\frac{1}{2}}, x_{i+\frac{1}{2}}) \times [t_n, t_{n+1}).$$

The following theorem was proved in [30].

THEOREM 3.1. *The upwind difference scheme* (3.6)–(3.8), *under the CFL condition* $0 < \lambda^-, \lambda^+ < 1$, *has the following* l^1*-error to the exact solution* (3.5)*:*

$$\|v(\cdot,t_n) - u(\cdot,t_n)\|_{l^1(\mathbb{R})} \le \|u_0\|_{BV(\mathbb{R})} \left[\gamma_m \frac{c^M}{c^m}\sqrt{\Delta x} + \left(1 + \frac{c^M}{c^m} + \max\left\{\frac{c^+}{c^-}, 1\right\}\right)\Delta x\right], \tag{3.9}$$

where

$$c^m = \min\{c^-, c^+\}, \quad c^M = \max\{c^-, c^+\}, \quad \gamma_m = \sqrt{\frac{2}{e}\, c^m \left(1 - c^m \frac{\Delta t}{\Delta x}\right) t_{n+1}},$$

and the definition of the BV norm on $\mathbb{R}$ *is given by*

$$\|u_0\|_{BV(\mathbb{R})} = \sup_{|h|\neq 0} \frac{1}{|h|} \|u_0(\cdot + h) - u_0(\cdot)\|_{l^1(\mathbb{R})}. \tag{3.10}$$

Remark 3.1. In the case of $c^- = c^+$, namely, a constant wave speed, the coefficient before Δx in (3.9) can be sharpened. In this paper we will also use (3.9) for the constant wave speed case since this will not affect the leading order coefficient in the l^1-error estimates for Scheme I.

4. Setup of the problem and the main result. In this section we establish the l^1-error estimates for Scheme I (with the first order numerical flux and the forward Euler method in time) under suitable conditions on the initial data. We consider the case when $V(x)$ is a step function, with a jump $-D, D > 0$ at $x = 0$. Namely,

$$V(0^-) - V(0^+) = D.$$

Let the computational domain be confined in the rectangular domain (2.2). We employ the uniform mesh introduced in section 2. Define mesh ratios $\lambda_x^t = \frac{\Delta t}{\Delta x}$, $\lambda_x^\xi = \frac{\Delta \xi}{\Delta x}$, assumed to be fixed. Let the potential barrier $x = 0$ be at a grid point $x_{m+\frac{1}{2}}$. Then the pointwise values of V satisfy

$$V^-_{m+\frac{1}{2}} - V^+_{m+\frac{1}{2}} = D, \quad V^\pm_{i+\frac{1}{2}} = V^-_{m+\frac{1}{2}},\ i < m, \quad V^\pm_{i+\frac{1}{2}} = V^+_{m+\frac{1}{2}},\ i > m,$$

where the superscripts $-, +$ represent the left and right limits at $x = 0$.

We consider the typical situation that $\xi_1 < -\sqrt{2D}$, $\xi_M > \sqrt{2D}$, so that all possible particle behaviors, including both transmission and reflection, are included. To simplify the discussion, we choose the mesh such that 0 and $\pm\sqrt{2D}$ are grid points in the ξ-direction. Define the indices I_0, I_+ satisfying

$$\xi_{I_0+\frac{1}{2}} = 0, \quad \xi_{I_++\frac{1}{2}} = \sqrt{2D}.$$

Define the domain

$$D_b = \left\{(x,y) | x < 0, \xi < -\sqrt{\left(\xi_{\frac{1}{2}}\right)^2 - 2D}\right\}.$$

Due to the velocity change across the barrier at $x = 0$, D_b represents the area where particles come from outside of the domain $[x_{\frac{1}{2}}, x_{N+\frac{1}{2}}] \times [\xi_{\frac{1}{2}}, \xi_{M+\frac{1}{2}}]$. In order to implement Scheme I conveniently, we need to exclude this domain from the computational domain. Define the index I_b satisfying

$$\xi_{I_b-\frac{3}{2}} < -\sqrt{\left(\xi_{\frac{1}{2}}\right)^2 - 2D} \le \xi_{I_b-\frac{1}{2}}$$

and the domain

$$\widehat{D}_b = \left\{(x,\xi) | x < 0, \xi < \xi_{I_b-\frac{1}{2}}\right\}.$$

Then we choose the computational domain as

$$D_C = \{(x,\xi) | x_{\frac{1}{2}} \le x \le x_{N+\frac{1}{2}},\ \xi_{\frac{1}{2}} \le \xi \le \xi_{M+\frac{1}{2}}\} \setminus \widehat{D}_b.$$

Figure 4.1 depicts D_C and $\widehat{D}_b$.

We consider the Dirichlet boundary conditions at the incoming boundaries and assume that the initial data satisfy these boundary conditions:

$$f(x_{\frac{1}{2}}, \xi, t) = f(x_{\frac{1}{2}}, \xi, 0), \quad 0 < \xi < \xi_{M+\frac{1}{2}}, \tag{4.1}$$

$$f(x_{N+\frac{1}{2}}, \xi, t) = f(x_{N+\frac{1}{2}}, \xi, 0), \quad \xi_{\frac{1}{2}} < \xi < 0. \tag{4.2}$$

Remark 4.1. When V is a step function, (2.1) becomes

$$f_t + \xi f_x = 0,$$

where ξ serves only as a parameter. However, when implementing the interface conditions (2.4), (2.5) numerically, the mesh in ξ is needed. This is the main new difficulty when comparing with the problem presented in section 3.

4.1. The initial data assumption. We now impose assumptions on the initial data. We assume that the initial data are given on the rectangular domain (2.2). We have the following assumption.

Assumption 4.1. The initial data $f(x,\xi,0)$ have bounded variation in the x-direction and are Lipschitz continuous in the ξ-direction. Namely,

$$\|f(.,\xi,0)\|_{BV([x_{\frac{1}{2}}, x_{N+\frac{1}{2}}])} \le A \quad \forall \xi \in [\xi_{\frac{1}{2}}, \xi_{M+\frac{1}{2}}], \tag{4.3}$$

$$|f(x,\xi',0) - f(x,\xi'',0)| \le B|\xi' - \xi''| \quad \forall x \in \left[x_{\frac{1}{2}}, x_{N+\frac{1}{2}}\right],\ \xi', \xi'' \in \left[\xi_{\frac{1}{2}}, \xi_{M+\frac{1}{2}}\right]. \tag{4.4}$$

Remark 4.2. When arising in the semiclassical limit of the linear Schrödinger equation, the Liouville equation is supplied with the measure-valued initial data [8, 18], which does not satisfy Assumption 4.1. However, in [10], a decomposition of the initial data was introduced, which allows one to solve the semiclassical limit problem with bounded initial data which do satisfy Assumption 4.1. Specifically, if one needs to solve the Liouville equation (2.1) with the measure-valued initial data

$$f(x,\xi,0) = \rho_0(x)\delta(\xi - v_0(x)), \tag{4.5}$$

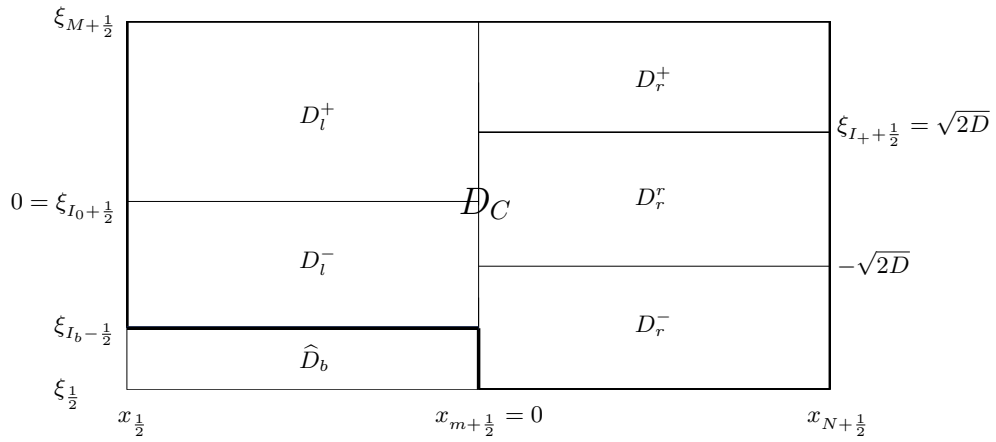

FIG. 4.1. *Sketch of partition of D_C and $\widehat{D}_b$.*

the decomposition technique proposed in [10] suggests that one just solves two functions satisfying the same Liouville equation with initial data

$$\phi(x,\xi,0) = \rho_0(x)\,, \quad \psi(x,\xi,0) = \xi - v_0(x)\,. \tag{4.6}$$

Then the measure-valued solution to the Liouville equation with the initial data (4.5) is simply

$$f(x,\xi,t) = \phi(x,\xi,t)\delta(\psi(x,\xi,t)).$$

The evaluations of the moments of f then resort to the numerical approximations to the delta function integrals.

In solving for ϕ, ψ, the initial data (4.6) satisfy Assumption 4.1 if the initial density and velocity $\rho_0(x), v_0(x)$ have bounded variations. For this situation we have established the l^1-error estimates for Scheme I.

Remark 4.3. It can be checked that the initial data satisfying Assumption 4.1 are bounded in both l^∞- and l^1-norms on D_C. When the numerical initial data are chosen to be cell averages of such initial data, the l^1-stability of Scheme I with homogeneous Dirichlet boundary conditions is established [29].

4.2. The exact solution. For our proof, we need to introduce the partition of D_C as

$$D_l^+ = \left\{(x,\xi) \;\middle|\; x_{\frac{1}{2}} < x < 0,\ 0 < \xi < \xi_{M+\frac{1}{2}}\right\},$$

$$D_l^- = \left\{(x,\xi) \;\middle|\; x_{\frac{1}{2}} < x < 0,\ \xi_{I_b-\frac{1}{2}} < \xi < 0\right\},$$

$$D_r^+ = \left\{(x,\xi) \;\middle|\; 0 < x < x_{N+\frac{1}{2}},\ \sqrt{2D} < \xi < \xi_{M+\frac{1}{2}}\right\},$$

$$D_r^- = \left\{(x,\xi) \;\middle|\; 0 < x < x_{N+\frac{1}{2}},\ \xi_{\frac{1}{2}} < \xi < -\sqrt{2D}\right\},$$

$$D_r^r = \left\{(x,\xi) \;\middle|\; 0 < x < x_{N+\frac{1}{2}},\ -\sqrt{2D} < \xi < \sqrt{2D}\right\}$$

and the extension of the initial data

(4.7)
$$\widehat{f}_0(x,\xi) = \begin{cases} f(x,\xi,0), & x_{\frac{1}{2}} \le x \le x_{N+\frac{1}{2}} \\ f(x_{\frac{1}{2}},\xi,0), & x < x_{\frac{1}{2}} \\ f(x_{N+\frac{1}{2}},\xi,0), & x > x_{N+\frac{1}{2}} \end{cases} \quad \text{for } x \in \mathbb{R},\ \xi_{\frac{1}{2}} \le \xi \le \xi_{M+\frac{1}{2}}.$$

Figure 4.1 shows a sketch of the partition of D_C.

The exact solution of (2.1) with the step function potential $V(x)$, when using the interface conditions (2.4), (2.5), can be obtained from the initial data $f(x,\xi,0)$ and boundary conditions (4.1), (4.2) by the method of characteristics:

(1) for $(x,\xi) \in D_l^+ \cup D_r^-$,

$$f(x,\xi,t_n) = \widehat{f}_0(x-\xi t_n,\xi)\,; \tag{4.8}$$

(2) for $(x,\xi) \in D_r^r$,

$$f(x,\xi,t_n) = \begin{cases} \widehat{f}_0(x-\xi t_n,\xi), & x > \xi t_n, \\ \widehat{f}_0(-x+\xi t_n,-\xi), & x < \xi t_n; \end{cases} \tag{4.9}$$

(3) for $(x,\xi) \in D_r^+$,

(4.10)
$$f(x,\xi,t_n) = \begin{cases} \widehat{f}_0\left(\frac{\sqrt{\xi^2-2D}}{\xi}\,x - \sqrt{\xi^2-2D}\,t_n, \sqrt{\xi^2-2D}\right), & 0 < x < \xi t_n, \\ \widehat{f}_0\left(x-\xi t_n,\xi\right), & x > \xi t_n; \end{cases}$$

(4) for $(x,\xi) \in D_l^-$,

(4.11)
$$f(x,\xi,t_n) = \begin{cases} \widehat{f}_0\left(-\frac{\sqrt{\xi^2+2D}}{\xi}\,x + \sqrt{\xi^2+2D}\,t_n, -\sqrt{\xi^2+2D}\right), & \xi t_n < x < 0, \\ \widehat{f}_0\left(x-\xi t_n,\xi\right), & x < \xi t_n. \end{cases}$$

4.3. The numerical solution. Denote

$$\mu_j = \lambda_x^t\,|\xi_j|\,, \qquad 1 \le j \le M. \tag{4.12}$$

Under the CFL condition (2.6), $\mu_j < 1$ for $1 \le j \le M$.

Since $V_x(x) = 0$ except at $x = x_{m+1/2}$, with the boundary conditions (4.1), (4.2), Scheme I on D_C is given by

(1) if $0 < \xi_j < \xi_{M+\frac{1}{2}}, i \ne m+1$,

$$g_{ij}^{n+1} = (1-\mu_j)g_{ij}^n + \mu_j g_{i-1,j}^n\,; \tag{4.13}$$

(2) if $\xi_{I_b-\frac{1}{2}} < \xi_j < 0,\ i < m$, or $\xi_{\frac{1}{2}} < \xi_j < 0,\ i > m$,

$$g_{ij}^{n+1} = (1-\mu_j)g_{ij}^n + \mu_j g_{i+1,j}^n\,; \tag{4.14}$$

(3) if $\sqrt{2D} < \xi_j < \xi_{M+\frac{1}{2}}$,

$$g^{n+1}_{m+1,j} = (1-\mu_j) g^n_{m+1,j} + \mu_j \left(c_{j,1} g^n_{m,d_j} + c_{j,2} g^n_{m,d_j+1} \right); \tag{4.15}$$

(4) if $0 < \xi_j < \sqrt{2D}$,

$$g^{n+1}_{m+1,j} = (1-\mu_j) g^n_{m+1,j} + \mu_j g^n_{m+1,d_j}; \tag{4.16}$$

(5) if $\xi_{I_b-\frac{1}{2}} < \xi_j < 0$,

$$g^{n+1}_{mj} = (1-\mu_j) g^n_{mj} + \mu_j \left(c_{j,1} g^n_{m+1,d_j} + c_{j,2} g^n_{m+1,d_j+1} \right), \tag{4.17}$$

where $0 \le c_{j,1}, c_{j,2} \le 1$ and $c_{j,1} + c_{j,2} = 1$. d_j's in (4.15)–(4.17) are determined according to Algorithm I by

$$\xi_{d_j} \le \sqrt{(\xi_j)^2 - 2D} < \xi_{d_j+1} \qquad \text{for } d_j \text{ in (4.15)}, \tag{4.18}$$

$$\xi_{d_j} = -\xi_j \qquad \text{for } d_j \text{ in (4.16)}, \tag{4.19}$$

$$\xi_{d_j} \le -\sqrt{(\xi_j)^2 + 2D} < \xi_{d_j+1} \qquad \text{for } d_j \text{ in (4.17)}. \tag{4.20}$$

The initial and incoming boundary values of the numerical solution are given by

$$g^0_{ij} = \frac{1}{\Delta x \Delta \xi} \int_{x_{i-\frac{1}{2}}}^{x_{i+\frac{1}{2}}} \int_{\xi_{j-\frac{1}{2}}}^{\xi_{j+\frac{1}{2}}} f(x,\xi,0) d\xi dx, \quad (x_i,\xi_j) \in D_C, \tag{4.21}$$

$$g^n_{0,j} = \frac{1}{\Delta \xi} \int_{\xi_{j-\frac{1}{2}}}^{\xi_{j+\frac{1}{2}}} f(x_{\frac{1}{2}},\xi,0) d\xi, \quad 0 < \xi_j < \xi_{M+\frac{1}{2}}, \tag{4.22}$$

$$g^n_{N+1,j} = \frac{1}{\Delta \xi} \int_{\xi_{j-\frac{1}{2}}}^{\xi_{j+\frac{1}{2}}} f(x_{N+\frac{1}{2}},\xi,0) d\xi, \quad \xi_{\frac{1}{2}} < \xi_j < 0. \tag{4.23}$$

To compare the numerical solution computed from (4.13)–(4.23) with the exact solution (4.8)–(4.11), we introduce

$$g(x,\xi,t) = g^n_{ij} \qquad \text{for } (x,\xi,t) \in [x_{i-\frac{1}{2}}, x_{i+\frac{1}{2}}) \times [\xi_{j-\frac{1}{2}}, \xi_{j+\frac{1}{2}}) \times [t_n, t_{n+1}), \quad (x_i,\xi_j) \in D_C.$$

We now state the main theorem of this paper.

THEOREM 4.1. *Under Assumption* 4.1 *on the initial data, the CFL condition* (2.6)*, and the mesh size restriction*

$$\Delta \xi \le \frac{3-2\sqrt{2}}{2} \sqrt{2D}, \tag{4.24}$$

Scheme I (4.13)–(4.23) *has the following* l^1*-error bound compared to the exact solution*

(4.8)–(4.11):

$$
\begin{aligned}
&\|g(\cdot,\cdot,t_n)-f(\cdot,\cdot,t_n)\|_{l^1(D_C)}\\
&\quad\le\left[\left(\xi_{M+\frac12}+\left|\xi_{\frac12}\right|+\sqrt{2D}\right)A+4DB\right]\sqrt{\frac{t_{n+1}}{2e\lambda_x^t}}\sqrt{\Delta x}\\
&\qquad+\left(4A+2\sqrt{2D}B\right)\sqrt{\frac{t_{n+1}}{2e}}\\
&\qquad\times\left(\frac{\xi_{M+\frac12}}{(2D)^{\frac14}}\sqrt{\frac{\xi_{M+\frac12}-\sqrt{2D}}{\lambda_x^t}}+2\left|\xi_{\frac12}\right|\left[\left(\xi_{\frac12}\right)^2-2D\right]^{\frac14}\right)\sqrt{\Delta x}\\
&\qquad+\left(2A+\sqrt{2D}B\right)\left[\frac{2\left(\xi_{M+\frac12}\right)^2t_n\lambda_x^\xi}{\sqrt{D}}+\left|\xi_{\frac12}\right|\right]\ln\left(\frac{1}{\Delta x}\right)\Delta x+O(\Delta x).
\end{aligned}
\tag{4.25}
$$

5. The proof of Theorem 4.1. This section is devoted to the proof of Theorem 4.1.

The l^1-error in (4.25) can be split according to the partition of D_C:

$$
\begin{aligned}
&\|g(\cdot,\cdot,t_n)-f(\cdot,\cdot,t_n)\|_{l^1(D_C)}\\
&=\|g(\cdot,\cdot,t_n)-f(\cdot,\cdot,t_n)\|_{l^1(D_l^+)}+\|g(\cdot,\cdot,t_n)-f(\cdot,\cdot,t_n)\|_{l^1(D_l^-)}\\
&\quad+\|g(\cdot,\cdot,t_n)-f(\cdot,\cdot,t_n)\|_{l^1(D_r^+)}+\|g(\cdot,\cdot,t_n)-f(\cdot,\cdot,t_n)\|_{l^1(D_r^r)}\\
&\quad+\|g(\cdot,\cdot,t_n)-f(\cdot,\cdot,t_n)\|_{l^1(D_r^-)}\\
&\equiv E_l^+ + E_l^- + E_r^+ + E_r^r + E_r^-.
\end{aligned}
\tag{5.1}
$$

We will estimate the five terms in (5.1). As stated in section 1, the strategy is to introduce a number of linear advection equations with step function coefficients in each partition whose immersed interface upwind schemes yield the same numerical solution as Scheme I. Then we apply the error estimates for the immersed interface upwind schemes given in section 3 and compare the exact solutions of the linear advection equations and that of the Liouville equation to derive the desired estimates.

5.1. The upper bounds for E_l^+ and E_r^-. For E_l^+ one has

$$
E_l^+=\sum_{j=I_0+1}^{M}\int_{\xi_{j-\frac12}}^{\xi_{j+\frac12}}\int_{x_{\frac12}}^{0}|g(x,\xi,t_n)-f(x,\xi,t_n)|\,dxd\xi.
\tag{5.2}
$$

For $I_0+1 \le j \le M$, consider the linear advection equation

$$\frac{\partial u^j_{l,+}}{\partial t} + \xi_j \frac{\partial u^j_{l,+}}{\partial x} = 0, \qquad t>0,\ x\in\mathbb{R}, \tag{5.3}$$

$$u^j_{l,+}|_{t=0} = \begin{cases} \frac{1}{\Delta\xi}\int_{\xi_{j-\frac12}}^{\xi_{j+\frac12}} \widehat{f}_0(x,\xi)d\xi, & x<0, \\ \frac{1}{\Delta\xi}\int_{\xi_{j-\frac12}}^{\xi_{j+\frac12}} \widehat{f}_0(0,\xi)d\xi, & x\ge 0. \end{cases} \tag{5.4}$$

The exact solution to (5.3), (5.4) is simply

$$u^j_{l,+}(x,t) = u^j_{l,+}(x-\xi_j t, 0). \tag{5.5}$$

Consider the upwind scheme for (5.3):

$$v_i^{n+1} = (1-\mu_j)v_i^n + \mu_j v_{i-1}^n, \tag{5.6}$$

$$v_i^0 = \frac{1}{\Delta x}\int_{x_{i-\frac12}}^{x_{i+\frac12}} u^j_{l,+}(x,0)dx, \tag{5.7}$$

where μ_j is defined in (4.12).

Define

$$v^j_{l,+}(x,t) = v_i^n \qquad \text{for } (x,t)\in[x_{i-\frac12}, x_{i+\frac12})\times[t_n, t_{n+1}).$$

Applying Theorem 3.1, the l^1-error between $v^j_{l,+}(x,t_n)$ and $u^j_{l,+}(x,t_n)$ is given by

$$\|v^j_{l,+}(\cdot,t_n) - u^j_{l,+}(\cdot,t_n)\|_{l^1(\mathbb{R})} \le \|u^j_{l,+}(\cdot,0)\|_{BV(\mathbb{R})}\left[\gamma_j\sqrt{\Delta x} + 3\Delta x\right], \tag{5.8}$$

where

$$\gamma_j = \sqrt{\frac{2}{e}\,\xi_j\left(1-\xi_j\frac{\Delta t}{\Delta x}\right)t_{n+1}}. \tag{5.9}$$

From definition (4.7) and condition (4.3) one has

$$\|\widehat{f}_0(\cdot,\xi)\|_{BV(\mathbb{R})} \le A, \quad \xi_{\frac12}\le\xi\le\xi_{M+\frac12}. \tag{5.10}$$

Definition (5.4) and condition (5.10) imply

$$\|u^j_{l,+}(\cdot,0)\|_{BV(\mathbb{R})} \le A. \tag{5.11}$$

γ_j in (5.9) satisfies

$$\gamma_j \le \sqrt{\frac{t_{n+1}}{2e}\frac{\Delta x}{\Delta t}} \equiv \gamma. \tag{5.12}$$

Substituting (5.11), (5.12) into (5.8) gives

$$\|v^j_{l,+}(\cdot,t_n) - u^j_{l,+}(\cdot,t_n)\|_{l^1(\mathbb{R})} \le A\left[\gamma\sqrt{\Delta x} + 3\Delta x\right]. \tag{5.13}$$

In comparison with schemes (4.13), (4.21), (4.22) and (5.6), (5.7), (5.4), (4.7), one can check that, for $I_0+1 \le j \le M$,

$$g(x,\xi,t_n) = v^j_{l,+}(x,t_n) \quad \text{for } \xi_{j-\frac12} < \xi < \xi_{j+\frac12},\ \ x_{\frac12} < x < 0. \tag{5.14}$$

From (5.2), (5.14), (5.13), (5.5), (5.4), and (4.8) one has, by the triangle inequality,

$$\begin{aligned} E^+_l \le & \sum_{j=I_0+1}^{M} \int_{\xi_{j-\frac12}}^{\xi_{j+\frac12}} \int_{x_{\frac12}}^{0} \left| v^j_{l,+}(x,t_n) - u^j_{l,+}(x,t_n) \right| dx d\xi \\ & + \sum_{j=I_0+1}^{M} \int_{\xi_{j-\frac12}}^{\xi_{j+\frac12}} \int_{x_{\frac12}}^{0} \left| u^j_{l,+}(x,t_n) - f(x,\xi,t_n) \right| dx d\xi \equiv E^{+,1}_l + E^{+,2}_l, \end{aligned} \tag{5.15}$$

where

$$E^{+,1}_l \le \xi_{M+\frac12} A \left[\gamma \sqrt{\Delta x} + 3\Delta x \right], \tag{5.16}$$

$$\begin{aligned} E^{+,2}_l &= \sum_{j=I_0+1}^{M} \int_{\xi_{j-\frac12}}^{\xi_{j+\frac12}} \int_{x_{\frac12}}^{0} \left| \frac{1}{\Delta\xi} \int_{\xi_{j-\frac12}}^{\xi_{j+\frac12}} \widehat{f}_0(x-\xi_j t_n, \xi') d\xi' - \widehat{f}_0(x-\xi t_n, \xi) \right| dx d\xi \\ &\le \sum_{j=I_0+1}^{M} \int_{\xi_{j-\frac12}}^{\xi_{j+\frac12}} \int_{x_{\frac12}}^{0} \left| \frac{1}{\Delta\xi} \int_{\xi_{j-\frac12}}^{\xi_{j+\frac12}} \left[\widehat{f}_0(x-\xi_j t_n, \xi') - \widehat{f}_0(x-\xi_j t_n, \xi) \right] d\xi' \right| dx d\xi \\ &\quad + \sum_{j=I_0+1}^{M} \int_{\xi_{j-\frac12}}^{\xi_{j+\frac12}} \int_{x_{\frac12}}^{0} \left| \widehat{f}_0(x-\xi_j t_n, \xi) - \widehat{f}_0(x-\xi t_n, \xi) \right| dx d\xi. \end{aligned} \tag{5.17}$$

According to the definition of the BV norm (3.10) and condition (5.10), one has

$$\int_{x_{\frac12}}^{0} \left| \widehat{f}_0(x-\xi_j t_n, \xi) - \widehat{f}_0(x-\xi t_n, \xi) \right| dx \le \| \widehat{f}_0(\cdot,\xi) \|_{BV(\mathbb{R})} |\xi - \xi_j| t_n \le A |\xi - \xi_j| t_n. \tag{5.18}$$

Applying the Lipschitz condition (4.4) and (5.18) to (5.17) yields

$$E^{+,2}_l \le \xi_{M+\frac12} \left| x_{\frac12} \right| B \Delta\xi + \sum_{j=I_0+1}^{M} \int_{\xi_{j-\frac12}}^{\xi_{j+\frac12}} |\xi - \xi_j|\, t_n A d\xi \le \xi_{M+\frac12} \left[\left| x_{\frac12} \right| B + \frac{t_n}{2} A \right] \Delta\xi. \tag{5.19}$$

Combining (5.15), (5.16), and (5.19) leads to

$$\begin{aligned} E^+_l &\le \xi_{M+\frac12} A \left[\gamma \sqrt{\Delta x} + 3\Delta x \right] + \xi_{M+\frac12} \left[\left| x_{\frac12} \right| B + \frac{t_n}{2} A \right] \Delta\xi \\ &= \xi_{M+\frac12} A \gamma \sqrt{\Delta x} + O(\Delta x). \end{aligned} \tag{5.20}$$

Similarly, for E_r^- one can deduce

$$E_r^- \le \left|\xi_{\frac{1}{2}} + \sqrt{2D}\right| A\left[\gamma\sqrt{\Delta x} + 3\Delta x\right] + \left|\xi_{\frac{1}{2}} + \sqrt{2D}\right|\left[x_{N+\frac{1}{2}}B + \frac{t_n}{2}A\right]\Delta\xi$$

$$= \left|\xi_{\frac{1}{2}} + \sqrt{2D}\right| A\gamma\sqrt{\Delta x} + O(\Delta x). \tag{5.21}$$

5.2. The upper bound for E_r^r. For E_r^r one has

$$E_r^r = \sum_{j=I_0+1}^{I_+} \int_0^{x_{N+\frac{1}{2}}} \left(\int_{\xi_{j-\frac{1}{2}}}^{\xi_{j+\frac{1}{2}}} |g(x,\xi,t_n) - f(x,\xi,t_n)|\, d\xi \right. \tag{5.22}$$

$$\left. + \int_{-\xi_{j+\frac{1}{2}}}^{-\xi_{j-\frac{1}{2}}} |g(x,\xi,t_n) - f(x,\xi,t_n)|\, d\xi \right) dx.$$

For $0 \le \xi \le \sqrt{2D}$, define the function

$$f_1(x,\xi) = \begin{cases} \widehat{f}_0(x,\xi), & x \ge 0 \\ \widehat{f}_0(-x,-\xi), & x < 0 \end{cases} \qquad \text{for } x \in \mathbb{R},\ 0 \le \xi \le \sqrt{2D}. \tag{5.23}$$

For $I_0 + 1 \le j \le I_+$, consider the linear advection equation

$$\frac{\partial u_{r,r}^j}{\partial t} + \xi_j \frac{\partial u_{r,r}^j}{\partial x} = 0, \qquad t > 0,\ x \in \mathbb{R}, \tag{5.24}$$

$$u_{r,r}^j|_{t=0} = \frac{1}{\Delta\xi} \int_{\xi_{j-\frac{1}{2}}}^{\xi_{j+\frac{1}{2}}} f_1(x,\xi) d\xi. \tag{5.25}$$

The exact solution to (5.24), (5.25) is simply

$$u_{r,r}^j(x,t) = u_{r,r}^j(x - \xi_j t, 0).$$

The upwind scheme for (5.24) is

$$v_i^{n+1} = (1-\mu_j)v_i^n + \mu_j v_{i-1}^n, \tag{5.26}$$

$$v_i^0 = \frac{1}{\Delta x} \int_{x_{i-\frac{1}{2}}}^{x_{i+\frac{1}{2}}} u_{r,r}^j(x,0) dx. \tag{5.27}$$

Define

$$v_{r,r}^j(x,t) = v_i^n \qquad \text{for } (x,t) \in [x_{i-\frac{1}{2}}, x_{i+\frac{1}{2}}) \times [t_n, t_{n+1}).$$

Applying Theorem 3.1, the l^1-error between $v_{r,r}^j(x,t_n)$ and $u_{r,r}^j(x,t_n)$ is given by

$$\|v_{r,r}^j(\cdot,t_n) - u_{r,r}^j(\cdot,t_n)\|_{l^1(\mathbb{R})} \le \|u_{r,r}^j(\cdot,0)\|_{BV(\mathbb{R})} \left[\gamma_j\sqrt{\Delta x} + \Delta x\right], \tag{5.28}$$

where γ_j is given by (5.9).

From definition (5.23) and conditions (4.3), (4.4) one has, for $0 \le \xi \le \sqrt{2D}$,

$$\begin{aligned}\|f_1(\cdot,\xi)\|_{BV(\mathbb{R})} &\le \|\widehat{f}_0(.,\xi)\|_{BV([0,x_{N+\frac{1}{2}}])} + \|\widehat{f}_0(.,-\xi)\|_{BV([0,x_{N+\frac{1}{2}}])} \\ &\quad + \left|\widehat{f}_0(0,-\xi) - \widehat{f}_0(0,\xi)\right| \\ &\le 2A + 2\sqrt{2D}B. \end{aligned} \tag{5.29}$$

Therefore

$$\|u^j_{r,r}(\cdot,0)\|_{BV(\mathbb{R})} \le 2A + 2\sqrt{2D}B. \tag{5.30}$$

Combining (5.28), (5.30), and (5.12) gives

$$\|v^j_{r,r}(\cdot,t_n) - u^j_{r,r}(\cdot,t_n)\|_{l^1(\mathbb{R})} \le \left(2A + 2\sqrt{2D}B\right)\left[\gamma\sqrt{\Delta x} + \Delta x\right] \tag{5.31}$$

with γ defined in (5.12).

In comparison with schemes (4.13), (4.14), (4.16), (4.19), (4.21), (4.23) and (5.26), (5.27), (5.25), (5.23), (4.7), one can check that, for $I_0 + 1 \le j \le I_+$,

(5.32)
$$g(x,\xi,t_n) = \begin{cases} v^j_{r,r}(x,t_n) & \text{for } 0 < x < x_{N+\frac{1}{2}},\ \xi_{j-\frac{1}{2}} < \xi < \xi_{j+\frac{1}{2}}, \\ v^j_{r,r}(-x,t_n) & \text{a.e. for } 0 < x < x_{N+\frac{1}{2}},\ -\xi_{j+\frac{1}{2}} < \xi < -\xi_{j-\frac{1}{2}}. \end{cases}$$

The second part of (5.32) holds except possibly at the cell interfaces.

From (5.22), (5.32), (4.9), and (5.23), one arrives at

$$\begin{aligned} E^r_r &= \sum_{j=I_0+1}^{I_+} \int_{\xi_{j-\frac{1}{2}}}^{\xi_{j+\frac{1}{2}}} \int_0^{x_{N+\frac{1}{2}}} \left|v^j_{r,r}(x,t_n) - f_1(x-\xi t_n,\xi)\right| dxd\xi \\ &\quad + \sum_{j=I_0+1}^{I_+} \int_{-\xi_{j+\frac{1}{2}}}^{-\xi_{j-\frac{1}{2}}} \int_0^{x_{N+\frac{1}{2}}} \left|v^j_{r,r}(-x,t_n) - f_1(-x+\xi t_n,-\xi)\right| dxd\xi \\ &= \sum_{j=I_0+1}^{I_+} \int_{\xi_{j-\frac{1}{2}}}^{\xi_{j+\frac{1}{2}}} \int_{-x_{N+\frac{1}{2}}}^{x_{N+\frac{1}{2}}} \left|v^j_{r,r}(x,t_n) - f_1(x-\xi t_n,\xi)\right| dxd\xi. \end{aligned}$$

From definition (5.23) and condition (4.4), $f_1(x,\xi)$ satisfies the Lipschitz condition in ξ with the Lipschitz constant B. Utilizing this and (5.29), (5.31), similarly to the deduction from (5.15) to (5.20), one obtains

$$\begin{aligned} E^r_r &\le \sqrt{2D}\left(2A + 2\sqrt{2D}B\right)\left[\gamma\sqrt{\Delta x} + \Delta x\right] \\ &\quad + \sqrt{2D}\left[2x_{N+\frac{1}{2}}B + t_n\left(A + \sqrt{2D}B\right)\right]\Delta\xi \\ &= \sqrt{2D}\left(2A + 2\sqrt{2D}B\right)\gamma\sqrt{\Delta x} + O(\Delta x). \end{aligned} \tag{5.33}$$

5.3. The upper bound for E_r^+. For E_r^+ one has

$$E_r^+ = \sum_{j=I_++1}^{M} \int_{\xi_{j-\frac{1}{2}}}^{\xi_{j+\frac{1}{2}}} \int_0^{x_{N+\frac{1}{2}}} |g(x,\xi,t_n) - f(x,\xi,t_n)|\, dx d\xi. \tag{5.34}$$

For $I_+ + 1 \le j \le M$, consider two linear advection equations

$$\frac{\partial u^j_{r,+,p}}{\partial t} + c_{+,p} \frac{\partial u^j_{r,+,p}}{\partial x} = 0, \qquad t > 0,\ x \in \mathbb{R}, \tag{5.35}$$

$$c_{+,p}(x) = \begin{cases} \xi_{J_{j,p}}, & x < 0, \\ \xi_j, & x > 0, \end{cases} \tag{5.36}$$

$$u^j_{r,+,p}|_{t=0} = \frac{1}{\Delta\xi} \int_{\xi_{j-\frac{1}{2}}}^{\xi_{j+\frac{1}{2}}} f^j_{r,+,p}(x,\xi) d\xi, \tag{5.37}$$

$$f^j_{r,+,p}(x,\xi) = \begin{cases} \widehat{f}_0(x, \xi - \xi_j + \xi_{J_{j,p}}), & x < 0, \\ \widehat{f}_0(x,\xi), & x \ge 0 \end{cases} \tag{5.38}$$

for $p = 1, 2$, where

$$J_{j,p} = d_j + p - 1, \quad p = 1, 2, \tag{5.39}$$

with d_j defined in (4.18).

The exact solutions to (5.35)–(5.38) are given by

$$u^j_{r,+,p}(x,t) = \begin{cases} u^j_{r,+,p}\left(x - \xi_{J_{j,p}} t, 0\right), & x < 0, \\ u^j_{r,+,p}\left(\frac{\xi_{J_{j,p}}}{\xi_j} x - \xi_{J_{j,p}} t, 0\right), & 0 \le x < \xi_j t, \quad p = 1, 2. \\ u^j_{r,+,p}\left(x - \xi_j t, 0\right), & x \ge \xi_j t, \end{cases} \tag{5.40}$$

The upwind schemes for (5.35) are

$$v_i^{n+1,j,p} = \begin{cases} (1 - \mu_{J_{j,p}}) v_i^{n,j,p} + \mu_{J_{j,p}} v_{i-1}^{n,j,p} & \text{if } x_i < 0, \\ (1 - \mu_j) v_i^{n,j,p} + \mu_j v_{i-1}^{n,j,p} & \text{if } x_i > 0, \end{cases} \tag{5.41}$$

$$v_i^{0,j,p} = \frac{1}{\Delta x} \int_{x_{i-\frac{1}{2}}}^{x_{i+\frac{1}{2}}} u^j_{r,+,p}(x,0) dx \tag{5.42}$$

for $p = 1, 2$.

Define

$$v^j_{r,+,p}(x,t) = v_i^{n,j,p} \qquad \text{for } (x,t) \in [x_{i-\frac{1}{2}}, x_{i+\frac{1}{2}}) \times [t_n, t_{n+1}),\ \ p = 1, 2.$$

We present some lemmas before giving estimates for E_r^+.

LEMMA 5.1. *If the mesh size satisfies* (4.24)*, then*

$$\frac{\xi_j}{\xi_{J_{j,p}}} \le \frac{\xi_{M+\frac{1}{2}}}{(2D)^{\frac{1}{4}} \sqrt{(j - I_+ - \frac{1}{2})\Delta\xi}}, \quad p = 1, 2, \tag{5.43}$$

$$\frac{\xi_j}{\sqrt{(\xi_j)^2 - 2D}} \le \frac{\xi_{M+\frac{1}{2}}}{\sqrt{2}(2D)^{\frac{1}{4}} \sqrt{(j - I_+ - \frac{1}{2})\Delta\xi}} \tag{5.44}$$

for $I_+ + 1 \le j \le M$.

Proof. We give the proof for (5.43); the proof for (5.44) is similar. One has for $I_+ + 1 \le j \le M$

$$\frac{\xi_j}{\xi_{J_{j,p}}} \le \frac{\sqrt{2D} + (j - I_+ - \frac{1}{2})\Delta\xi}{\sqrt{2\sqrt{2D}(j - I_+ - \frac{1}{2})\Delta\xi + \left[(j - I_+ - \frac{1}{2})\Delta\xi\right]^2} - \Delta\xi}$$

$$\le \frac{\xi_{M+\frac{1}{2}}}{\sqrt{2\sqrt{2D}(j - I_+ - \frac{1}{2})\Delta\xi} - \Delta\xi}.$$

Utilizing the mesh size condition (4.24), one then obtains (5.43). ∎

LEMMA 5.2.

(5.45)

$$\left|\sqrt{\xi^2 - 2D} - \xi'\right| \le \frac{\xi_j \Delta\xi}{\sqrt{(\xi_j)^2 - 2D}} + \frac{3}{2}\Delta\xi \quad \forall \xi_{j-\frac{1}{2}} \le \xi \le \xi_{j+\frac{1}{2}},\ \xi_{d_j-\frac{1}{2}} \le \xi' \le \xi_{d_j+\frac{3}{2}}$$

for $I_+ + 1 \le j \le M$.

Proof. Observe that, for all ξ, $\xi_{j-\frac{1}{2}} \le \xi \le \xi_{j+\frac{1}{2}}$,

$$\left|\sqrt{\xi^2 - 2D} - \sqrt{(\xi_j)^2 - 2D}\right| \le \sqrt{(\xi_j)^2 - 2D} - \sqrt{\left(\xi_{j-\frac{1}{2}}\right)^2 - 2D}$$

$$\le \frac{(\xi_j)^2 - \left(\xi_j - \frac{1}{2}\Delta\xi\right)^2}{\sqrt{(\xi_j)^2 - 2D}} \le \frac{\xi_j \Delta\xi}{\sqrt{(\xi_j)^2 - 2D}}.$$

Therefore

$$\left|\sqrt{\xi^2 - 2D} - \xi_{J_{j,p}}\right| \le \frac{\xi_j \Delta\xi}{\sqrt{(\xi_j)^2 - 2D}} + \Delta\xi, \quad p = 1, 2. \tag{5.46}$$

Thus (5.45) can be deduced. ∎

LEMMA 5.3. *Define functions*

$$H_\xi^{+,j,p}(x) = \begin{cases} \left(\frac{\sqrt{\xi^2 - 2D}}{\xi}\, x - \sqrt{\xi^2 - 2D}\, t_n + \xi_{J_{j,p}} t_n\right) \frac{\xi_j}{\xi_{J_{j,p}}}, & x < \xi t_n, \\ x - \xi t_n + \xi_j t_n, & x \ge \xi t_n. \end{cases}$$

Then

$$\left|H_\xi^{+,j,p}(x) - x\right| \le E_H^j \tag{5.47}$$

for $x \ge 0$, $\xi_{j-\frac{1}{2}} \le \xi \le \xi_{j+\frac{1}{2}}$, $I_+ + 1 \le j \le M$, $p = 1, 2$, *where*

$$E_H^j = \frac{5}{2}\frac{t_n \xi_{M+\frac{1}{2}}}{(2D)^{\frac{1}{4}}}\frac{\Delta\xi}{\sqrt{(j - I_+ - \frac{1}{2})\Delta\xi}} + \frac{\sqrt{2}\left(\xi_{M+\frac{1}{2}}\right)^2 t_n}{\sqrt{2D}}\frac{\Delta\xi}{(j - I_+ - \frac{1}{2})\Delta\xi}. \tag{5.48}$$

Proof. Clearly,

$$\left|H_\xi^{+,j,p}(x)-x\right| \le \frac{\Delta\xi}{2}t_n \quad \text{for } x \ge \xi t_n,\ \xi_{j-\frac{1}{2}} \le \xi \le \xi_{j+\frac{1}{2}}. \tag{5.49}$$

For $0 \le x < \xi t_n$,

$$\left|H_\xi^{+,j,p}(x)-x\right| = \left|\frac{\sqrt{\xi^2-2D}}{\xi}\,x - \frac{\xi_{J_{j,p}}}{\xi_j}\,x + \left(\xi_{J_{j,p}} - \sqrt{\xi^2-2D}\right)\,t_n\right| \frac{\xi_j}{\xi_{J_{j,p}}}$$

$$\le \left[\left(\frac{\xi_{J_{j,p}}\,|\xi-\xi_j|}{\xi\xi_j} + \frac{\left|\sqrt{\xi^2-2D}-\xi_{J_{j,p}}\right|}{\xi}\right)x + \left|\sqrt{\xi^2-2D}-\xi_{J_{j,p}}\right|\,t_n\right]\frac{\xi_j}{\xi_{J_{j,p}}}$$

$$\le \left(2\left|\sqrt{\xi^2-2D}-\xi_{J_{j,p}}\right| + |\xi-\xi_j|\right)t_n\frac{\xi_j}{\xi_{J_{j,p}}}. \tag{5.50}$$

Combining (5.49) and (5.50), applying (5.46) and Lemma 5.1 to (5.50) then leads to the estimates (5.47). ∎

LEMMA 5.4. *Define functions*

$$F_p^j(\xi) = \int_0^{x_{N+\frac{1}{2}}} \left|\widetilde{f}_{r,+,p}^{\,j}(x,\xi,t_n) - \widehat{f}_{r,+}(x,\xi,t_n)\right| dx \tag{5.51}$$

for $\xi_{j-\frac{1}{2}} \le \xi \le \xi_{j+\frac{1}{2}},\ I_+ + 1 \le j \le M,\ p = 1,2,$ *where*

$$\widetilde{f}_{r,+,p}^{\,j}(x,\xi,t) = \begin{cases} \widehat{f}_0\left(\frac{\xi_{J_{j,p}}}{\xi_j}x - \xi_{J_{j,p}}t, \sqrt{\xi^2-2D}\right), & x < \xi_j t, \\ \widehat{f}_0\left(x-\xi_j t,\xi\right), & x \ge \xi_j t, \end{cases} \tag{5.52}$$

$$\widehat{f}_{r,+}(x,\xi,t) = \begin{cases} \widehat{f}_0\left(\frac{\sqrt{\xi^2-2D}}{\xi}\,x - \sqrt{\xi^2-2D}\,t, \sqrt{\xi^2-2D}\right), & x < \xi t, \\ \widehat{f}_0\left(x-\xi t,\xi\right), & x \ge \xi t. \end{cases} \tag{5.53}$$

Then

$$F_p^j(\xi) \le 2\left(2A + \sqrt{2D}B\right)E_H^j \tag{5.54}$$

with E_H^j *defined in* (5.48).

Proof. From the definition (5.52) and the conditions (4.3), (4.4), one obtains

$$\|\widetilde{f}_{r,+,p}^{\,j}(\cdot,\xi,t)\|_{BV(\mathbb{R})} \le 2A + \sqrt{2D}B. \tag{5.55}$$

We use the fact that

$$\widehat{f}_{r,+}(x,\xi,t_n) = \widetilde{f}_{r,+,p}^{\,j}\left(H_\xi^{+,j,p}(x),\xi,t_n\right), \quad x \in \mathbb{R},\ p = 1,2. \tag{5.56}$$

From (5.51), (5.56), and (5.55), applying Lemma 5.3 and Lemma A.1 in the appendix then leads to (5.54). ∎

We now give estimates for E_r^+. In comparison with schemes (4.13), (4.15), (4.18), (4.21), (4.22) and (5.41), (5.42), (5.37), (5.38), (4.7), one can check that, for $I_+ + 1 \le j \le M$,

$$g(x,\xi,t_n) = \sum_{p=1}^{2} c_{j,p} v^j_{r,+,p}(x,t_n) \quad \text{for } \xi_{j-\frac{1}{2}} < \xi < \xi_{j+\frac{1}{2}},\ 0 < x < x_{N+\frac{1}{2}}. \tag{5.57}$$

Together with (5.34), (5.57) and the expression (4.10) of $f(x,\xi,t_n)$ in D_r^+, one obtains by triangle inequality

$$E_r^+ \le E_r^{+,1} + E_r^{+,2} + E_r^{+,3}, \tag{5.58}$$

where

$$E_r^{+,1} = \sum_{j=I_++1}^{M} \int_{\xi_{j-\frac{1}{2}}}^{\xi_{j+\frac{1}{2}}} \int_0^{x_{N+\frac{1}{2}}} \sum_{p=1}^{2} c_{j,p} \left| v^j_{r,+,p}(x,t_n) - u^j_{r,+,p}(x,t_n) \right| dx d\xi, \tag{5.59}$$

$$E_r^{+,2} = \sum_{j=I_++1}^{M} \int_{\xi_{j-\frac{1}{2}}}^{\xi_{j+\frac{1}{2}}} \int_0^{x_{N+\frac{1}{2}}} \sum_{p=1}^{2} c_{j,p} \left| u^j_{r,+,p}(x,t_n) - \widetilde{f}^j_{r,+,p}(x,\xi,t_n) \right| dx d\xi, \tag{5.60}$$

$$E_r^{+,3} = \sum_{j=I_++1}^{M} \int_{\xi_{j-\frac{1}{2}}}^{\xi_{j+\frac{1}{2}}} \int_0^{x_{N+\frac{1}{2}}} \sum_{p=1}^{2} c_{j,p} \left| \widetilde{f}^j_{r,+,p}(x,\xi,t_n) - \widehat{f}_{r,+}(x,\xi,t_n) \right| dx d\xi. \tag{5.61}$$

We then estimate these three terms.

Applying Theorem 3.1, the l^1-error between $v^j_{r,+,p}$ and $u^j_{r,+,p}$, $p = 1, 2$, is given by

$$\|v^j_{r,+,p}(\cdot,t_n) - u^j_{r,+,p}(\cdot,t_n)\|_{l^1(\mathbb{R})} \le \|u^j_{r,+,p}(\cdot,0)\|_{BV(\mathbb{R})} \left[\Delta x + \left(\gamma\sqrt{\Delta x} + 2\Delta x \right) \frac{\xi_j}{\xi_{J_{j,p}}} \right], \tag{5.62}$$

where γ is given by (5.12).

For $I_+ + 1 \le j \le M$, the index d_j defined in (4.18) satisfies

$$\xi_j - \sqrt{2D} \le \xi_{d_j} < \xi_{d_j+1} \le \xi_j. \tag{5.63}$$

From definitions (5.38) and conditions (4.3), (4.4), (5.63) one has, for $p = 1, 2$,

$$\|f^j_{r,+,p}(\cdot,\xi)\|_{BV(\mathbb{R})} \le 2A + \sqrt{2D}B, \qquad \xi_{j-\frac{1}{2}} \le \xi \le \xi_{j+\frac{1}{2}}.$$

Therefore

$$\|u^j_{r,+,p}(\cdot,0)\|_{BV(\mathbb{R})} \le 2A + \sqrt{2D}B. \tag{5.64}$$

Utilizing (5.62), (5.64), and (5.43) for (5.59), by summation of j and using the inequality

$$\sum_{j=I_++1}^{M} \frac{\Delta\xi}{\sqrt{(j - I_+ - \frac{1}{2})\Delta\xi}} \le 2\sqrt{\xi_{M+\frac{1}{2}} - \sqrt{2D}}, \tag{5.65}$$

one obtains

$$E_r^{+,1} \le \left(4A + 2\sqrt{2D}B\right) \frac{\xi_M}{(+\frac{1}{2}2D)^{\frac{1}{4}}} \sqrt{\xi_{M+\frac{1}{2}} - \sqrt{2D}}\gamma\sqrt{\Delta x} + O(\Delta x). \tag{5.66}$$

Using Lemma 5.2, the fact that

$$|\xi - \xi'| \le \Delta\xi \quad \forall\, \xi_{j-\frac{1}{2}} \le \xi,\ \xi' \le \xi_{j+\frac{1}{2}}, \tag{5.67}$$

and condition (4.4), from definitions (5.37), (5.38), (5.40), and (5.52) one has

$$\left|u^j_{r,+,p}(x,t_n) - \widetilde{f}^j_{r,+,p}(x,\xi,t_n)\right| \le B\left[\frac{\xi_j\Delta\xi}{\sqrt{(\xi_j)^2 - 2D}} + \frac{3}{2}\Delta\xi\right] \tag{5.68}$$

for $x \ge 0,\ \xi_{j-\frac{1}{2}} \le \xi \le \xi_{j+\frac{1}{2}}$.

Utilizing (5.68) and (5.44) for (5.60) and using the inequality (5.65), one obtains

$$E_r^{+,2} \le x_{N+\frac{1}{2}} B\left[\left(\xi_{M+\frac{1}{2}} - \sqrt{2D}\right)\frac{3}{2} + \frac{\xi_{M+\frac{1}{2}}}{\sqrt{2}(2D)^{\frac{1}{4}}} 2\sqrt{\xi_{M+\frac{1}{2}} - \sqrt{2D}}\right]\Delta\xi. \tag{5.69}$$

Applying Lemma 5.4 to (5.61), using the inequality (5.65) and

$$\sum_{j=I_++1}^{M} \frac{\Delta\xi}{(j - I_+ - \frac{1}{2})\Delta\xi} \le 2 + \ln\left(\xi_{M+\frac{1}{2}} - \sqrt{2D}\right) + \ln\left(\frac{1}{\Delta\xi}\right), \tag{5.70}$$

one obtains

$$E_r^{+,3} \le \left(4A + 2\sqrt{2D}B\right) \frac{\left(\xi_{M+\frac{1}{2}}\right)^2 t_n \lambda_x^{\xi}}{\sqrt{D}} \ln\left(\frac{1}{\Delta x}\right)\Delta x + O(\Delta x). \tag{5.71}$$

The inequalities (5.65) and (5.70) are obtained using the fact that the midpoint rule is less than the exact integral when the integrand is convex. The right-hand side of the inequality (5.70) contains the $\ln(\cdot)$ term which results in the $\ln(\cdot)$ term appearing in the estimate (4.25) in Theorem 4.1.

Combining (5.58), (5.66), (5.69), (5.71) gives

$$\begin{aligned} E_r^{+} \le{}& \left(4A + 2\sqrt{2D}B\right) \frac{\xi_{M+\frac{1}{2}}}{(2D)^{\frac{1}{4}}} \sqrt{\xi_{M+\frac{1}{2}} - \sqrt{2D}}\gamma\sqrt{\Delta x} \\ &+ \left(4A + 2\sqrt{2D}B\right) \frac{\left(\xi_{M+\frac{1}{2}}\right)^2 t_n \lambda_x^{\xi}}{\sqrt{D}} \ln\left(\frac{1}{\Delta x}\right)\Delta x + O(\Delta x). \end{aligned} \tag{5.72}$$

5.4. The upper bound for E_l^-. For E_l^- one has

$$E_l^- = \sum_{j=I_b}^{I_0} \int_{\xi_{j-\frac{1}{2}}}^{\xi_{j+\frac{1}{2}}} \int_{x_{\frac{1}{2}}}^{0} |g(x,\xi,t_n) - f(x,\xi,t_n)|\, dx d\xi. \tag{5.73}$$

For $I_b \le j \le I_0$, consider two linear advection equations

$$\frac{\partial u^j_{l,-,p}}{\partial t} + c_{-,p}\frac{\partial u^j_{l,-,p}}{\partial x} = 0, \qquad t>0,\ x\in\mathbb{R}, \tag{5.74}$$

$$c_{-,p}(x) = \begin{cases} \left|\xi_{J_{j,p}}\right|, & x<0,\\ |\xi_j|, & x>0, \end{cases} \tag{5.75}$$

$$u^j_{l,-,p}|_{t=0} = \frac{1}{\Delta\xi}\int_{\xi_{j-\frac12}}^{\xi_{j+\frac12}} f^j_{l,-,p}(x,\xi)d\xi, \tag{5.76}$$

$$f^j_{l,-,p}(x,\xi) = \begin{cases} \widehat{f_0}(-x,\xi-\xi_j+\xi_{J_{j,p}}), & x<0,\\ \widehat{f_0}(-x,\xi), & x\ge 0 \end{cases} \tag{5.77}$$

for $p=1,2$, where $J_{j,p}$ is defined in (5.39) with d_j defined in (4.20).

The exact solutions to (5.74)–(5.77) are given by

$$u^j_{l,-,p}(x,t) = \begin{cases} u^j_{l,-,p}\left(x-\left|\xi_{J_{j,p}}\right|t,0\right), & x<0,\\ u^j_{l,-,p}\left(\left|\frac{\xi_{J_{j,p}}}{\xi_j}\right|x-\left|\xi_{J_{j,p}}\right|t,0\right), & 0\le x<|\xi_j|\,t, \qquad p=1,2.\\ u^j_{l,-,p}\left(x-|\xi_j|\,t,0\right), & x\ge|\xi_j|\,t, \end{cases} \tag{5.78}$$

The upwind schemes for (5.74) are

$$v_i^{n+1,j,p} = \begin{cases} (1-\mu_{J_{j,p}})v_i^{n,j,p} + \mu_{J_{j,p}}v_{i-1}^{n,j,p} & \text{if } x_i<0,\\ (1-\mu_j)v_i^{n,j,p} + \mu_j v_{i-1}^{n,j,p} & \text{if } x_i>0, \end{cases} \tag{5.79}$$

$$v_i^{0,j,p} = \frac{1}{\Delta x}\int_{x_{i-\frac12}}^{x_{i+\frac12}} u^j_{l,-,p}(x,0)dx \tag{5.80}$$

for $p=1,2$.

Define

$$v^j_{l,-,p}(x,t) = v_i^{n,j,p} \qquad \text{for } (x,t)\in[x_{i-\frac12},x_{i+\frac12})\times[t_n,t_{n+1}),\ \ p=1,2.$$

We have the following lemmas.

LEMMA 5.5.

$$\left|\sqrt{\xi^2+2D}+\xi'\right| \le 2\Delta\xi \quad \forall \xi_{j-\frac12}\le\xi\le\xi_{j+\frac12},\ \ \xi_{d_j-\frac12}\le\xi'\le\xi_{d_j+\frac32} \tag{5.81}$$

for $I_b\le j\le I_0$.

This lemma can be directly checked, and the proof is omitted.

LEMMA 5.6. *Define functions*

$$H_\xi^{-,j,p}(x) = \begin{cases} -\left(\frac{\xi_{J_{j,p}}}{\xi_j}x-\xi_{J_{j,p}}t_n-\sqrt{\xi^2+2D}\,t_n\right)\frac{\xi}{\sqrt{\xi^2+2D}}, & x>\xi_j t_n,\\ x-\xi_j t_n+\xi t_n, & x\le\xi_j t_n. \end{cases}$$

Then

$$\left|H_{\xi}^{-,j,p}(x)-x\right| \le \frac{7}{2}\Delta\xi t_n \tag{5.82}$$

for $x \le 0,\ \xi_{j-\frac{1}{2}} \le \xi \le \xi_{j+\frac{1}{2}},\ I_b \le j \le I_0,\ p=1,2.$

This lemma can be proved using a technique similar to that used for proving Lemma 5.3, and we omit the detailed proof.

LEMMA 5.7. *Define functions*

$$G_p^j(\xi) = \int_{x_{\frac{1}{2}}}^{0} \left|\widetilde{f}_{l,-,p}^{j}(x,\xi,t_n) - \widehat{f}_{l,-}(x,\xi,t_n)\right| dx \tag{5.83}$$

for $\xi_{j-\frac{1}{2}} \le \xi \le \xi_{j+\frac{1}{2}},\ I_b \le j \le I_0,\ p=1,2,$ *where*

(5.84)

$$\widetilde{f}_{l,-,p}^{j}(x,\xi,t) = \begin{cases} \widehat{f}_0\left(\frac{\xi_{J_{j,p}}}{\xi_j}x - \xi_{J_{j,p}}t, -\sqrt{\xi^2+2D}\right), & x > \xi_j t, \\ \widehat{f}_0\left(x-\xi_j t,\xi\right), & x \le \xi_j t, \end{cases}$$

(5.85)

$$\widehat{f}_{l,-}(x,\xi,t) = \begin{cases} \widehat{f}_0\left(-\frac{\sqrt{\xi^2+2D}}{\xi}\,x + \sqrt{\xi^2+2D}\,t, -\sqrt{\xi^2+2D}\right), & x > \xi t, \\ \widehat{f}_0\left(x-\xi t,\xi\right), & x \le \xi t. \end{cases}$$

Then

$$G_p^j(\xi) \le \left(2A+\sqrt{2D}B\right) 7\Delta\xi t_n. \tag{5.86}$$

Proof. From definition (5.85) and conditions (4.3), (4.4) one obtains

$$\|\widehat{f}_{l,-}(\cdot,\xi,t)\|_{BV(\mathbb{R})} \le 2A+\sqrt{2D}B. \tag{5.87}$$

We use the fact that

$$\widetilde{f}_{l,-,p}^{j}(x,\xi,t_n) = \widehat{f}_{l,-}\left(H_{\xi}^{-,j,p}(x),\xi,t_n\right), \quad x\in\mathbb{R},\ p=1,2. \tag{5.88}$$

From (5.83), (5.88), and (5.87), applying Lemmas 5.6 and A.1 gives (5.86). ∎

We now give estimates for E_l^-. In comparison with schemes (4.14), (4.17), (4.20), (4.21), (4.23) and (5.79), (5.80), (5.76), (5.77), (4.7), one can check that, for $I_b \le j \le I_0$,

$$g(x,\xi,t_n) = \sum_{p=1}^{2} c_{j,p} v_{l,-,p}^{j}(-x,t_n) \quad \text{a.e. for } \xi_{j-\frac{1}{2}} < \xi < \xi_{j+\frac{1}{2}},\ x_{\frac{1}{2}} < x < 0. \tag{5.89}$$

Using (5.73), (5.89), and the expression (4.11) of $f(x,\xi,t_n)$ in D_l^-, one obtains

$$E_l^- \le E_l^{-,1} + E_l^{-,2} + E_l^{-,3}, \tag{5.90}$$

where

$$E_l^{-,1} = \sum_{j=I_b}^{I_0} \int_{\xi_{j-\frac{1}{2}}}^{\xi_{j+\frac{1}{2}}} \int_{x_{\frac{1}{2}}}^{0} \sum_{p=1}^{2} c_{j,p} \left| v_{l,-,p}^j(-x,t_n) - u_{l,-,p}^j(-x,t_n) \right| dx d\xi, \tag{5.91}$$

$$E_l^{-,2} = \sum_{j=I_b}^{I_0} \int_{\xi_{j-\frac{1}{2}}}^{\xi_{j+\frac{1}{2}}} \int_{x_{\frac{1}{2}}}^{0} \sum_{p=1}^{2} c_{j,p} \left| u_{l,-,p}^j(-x,t_n) - \widetilde{f}_{l,-,p}^j(x,\xi,t_n) \right| dx d\xi, \tag{5.92}$$

$$E_l^{-,3} = \sum_{j=I_b}^{I_0} \int_{\xi_{j-\frac{1}{2}}}^{\xi_{j+\frac{1}{2}}} \int_{x_{\frac{1}{2}}}^{0} \sum_{p=1}^{2} c_{j,p} \left| \widetilde{f}_{l,-,p}^j(x,\xi,t_n) - \widehat{f}_{l,-}(x,\xi,t_n) \right| dx d\xi. \tag{5.93}$$

Applying Theorem 3.1, the l^1-error between $v_{l,-,p}^j$ and $u_{l,-,p}^j$, $p = 1, 2$, is given by

$$\begin{aligned} &\|v_{l,-,p}^j(\cdot,t_n) - u_{l,-,p}^j(\cdot,t_n)\|_{l^1(\mathbb{R})} \\ &\quad \le \|u_{l,-,p}^j(\cdot,0)\|_{BV(\mathbb{R})} \left[\sqrt{\frac{2t_{n+1}}{e}} \frac{|\xi_{J_{j,p}}|}{\sqrt{|\xi_j|}} \sqrt{\Delta x} + \left(2 + \left| \frac{\xi_{J_{j,p}}}{\xi_j} \right| \right) \Delta x \right]. \end{aligned} \tag{5.94}$$

Similar to the derivation of (5.64), one has

$$\|u_{l,-,p}^j(\cdot,0)\|_{BV(\mathbb{R})} \le 2A + \sqrt{2D}B. \tag{5.95}$$

Applying (5.94) and (5.95) to (5.91), by summation of j and using the inequalities (5.65) and (5.70), one obtains

$$\begin{aligned} E_l^{-,1} \le &\left(4A + 2\sqrt{2D}B \right) \sqrt{\frac{2t_{n+1}}{e}} \left| \xi_{\frac{1}{2}} \right| \left[\left(\xi_{\frac{1}{2}} \right)^2 - 2D \right]^{\frac{1}{4}} \sqrt{\Delta x} \\ &+ \left(2A + \sqrt{2D}B \right) \left| \xi_{\frac{1}{2}} \right| \ln \left(\frac{1}{\Delta x} \right) \Delta x + O(\Delta x). \end{aligned} \tag{5.96}$$

Using Lemma 5.5, (5.67), and condition (4.4), from the definitions (5.76), (5.77), (5.78), and (5.84), one has

$$\left| u_{l,-,p}^j(-x,t_n) - \widetilde{f}_{l,-,p}^j(x,\xi,t_n) \right| \le 2B\Delta\xi$$

for $x \le 0$, $\xi_{j-\frac{1}{2}} \le \xi \le \xi_{j+\frac{1}{2}}$.

Thus one has

$$E_l^{-,2} \le \left| \xi_{I_b - \frac{1}{2}} \right| \left| x_{\frac{1}{2}} \right| 2B\Delta\xi. \tag{5.97}$$

Applying Lemma 5.7 to (5.93) yields

$$E_l^{-,3} \le 7 \left(2A + \sqrt{2D}B \right) \left| \xi_{I_b - \frac{1}{2}} \right| t_n \Delta\xi. \tag{5.98}$$

Combining (5.90), (5.96), (5.97), (5.98) leads to

$$\begin{aligned} E_l^{-} \le &\left(4A + 2\sqrt{2D}B \right) \sqrt{\frac{2t_{n+1}}{e}} \left| \xi_{\frac{1}{2}} \right| \left[\left(\xi_{\frac{1}{2}} \right)^2 - 2D \right]^{\frac{1}{4}} \sqrt{\Delta x} \\ &+ \left(2A + \sqrt{2D}B \right) \left| \xi_{\frac{1}{2}} \right| \ln \left(\frac{1}{\Delta x} \right) \Delta x + O(\Delta x). \end{aligned} \tag{5.99}$$

Finally, combining (5.1), (5.20), (5.21), (5.33), (5.72), (5.99), (5.12) completes the proof for Theorem 4.1.

Remark 5.1. The error terms derived in (4.25) include the half order terms and the $\ln\left(\frac{1}{\Delta x}\right)\Delta x$ terms. Thus the leading error terms are of half order, and Scheme I has a half order convergence rate. Note that this is sharp, since even for the discontinuous solution to linear hyperbolic equations with a smooth coefficient, one cannot expect a better convergence order in the l^1-norm [24].

6. Conclusion. In this paper we derived the l^1-error estimates for a Hamiltonian-preserving scheme, developed in [11], for the Liouville equation with a piecewise constant potential in one space dimension. The Hamiltonian-preserving scheme is designed by incorporating into the numerical fluxes the particle behavior—transmission and reflection—at the potential barrier. We proved that, with the Dirichlet incoming boundary conditions and for a class of bounded initial data, the numerical solution by the Hamiltonian-preserving scheme converges in the l^1-norm to the solution of the Liouville equation—defined by using the interface condition that accounts for particle transmission and reflection. The initial data conditions can be satisfied by applying the decomposition technique proposed in [10] for solving the Liouville equation with measure-valued initial data arising in the semiclassical limit of the linear Schrödinger equation.

The strategy for the error analysis in this paper is to apply the l^1-error estimates established in [30, 28] for the immersed interface upwind scheme to the linear advection equations with piecewise constant coefficients. This is a natural approach since the solution of the Liouville equation with a step function potential satisfies linear advection equations with piecewise constant coefficients on the bicharacteristics. To apply this strategy, we split the computational domain into several parts. In each subdomain, we introduced a number of linear advection equations with step function coefficients for which the immersed interface upwind schemes yield the same numerical solution as the Hamiltonian-preserving scheme for the Liouville equation with the step function potential. Then the l^1-error estimates for the Hamiltonian-preserving scheme were derived by applying the l^1-error estimates for the immersed interface upwind schemes and comparing the exact solutions of the linear advection equations and that of the Liouville equation in each of these subdomains. The conditions on the initial data were used in deriving these estimates. As a result, we obtained the half order l^1-error bound with explicit coefficients for the Hamiltonian-preserving scheme.

The problem under study has important applications in the computation of the semiclassical limit of the linear Schrödinger equation through barriers and, more generally, in the computation of high frequency waves through interfaces.

Appendix. In this appendix we prove a property of BV functions on $\mathbb{R}$.

LEMMA A.1. *Let $f(x)$ be a BV function on $\mathbb{R}$ and $H(x)$ be a function on $[a,b]$ satisfying*

$$|H(x)-x| \le H_C \quad \text{for } x \in [a,b],$$

where H_C is a positive constant. Then

$$\|f(\cdot)-f(H(\cdot))\|_{L^1([a,b])} \le 2H_C\|f\|_{BV(\mathbb{R})}. \tag{A.1}$$

Proof. For all $x \in [a,b]$, one has

$$|f(x)-f(H(x))| \le \|f\|_{BV([x-H_C,x+H_C])}.$$

Since $f(x)$ has a bounded variation on $\mathbb{R}$, $f'(x)$ exists a.e., and

$$\|f\|_{BV([x-H_C,x+H_C])} = \int_{x-H_C}^{x+H_C} |f'(y)|\,dy.$$

Thus

$$\|f(\cdot) - f(H(\cdot))\|_{L^1([a,b])} \le \int_a^b \int_{x-H_C}^{x+H_C} |f'(y)|\,dydx. \tag{A.2}$$

Introduce the function

$$g(x,y) = \begin{cases} |f'(y)| & \text{if } |x-y| \le H_C, \\ 0 & \text{else.} \end{cases}$$

Then $g(x,y) \in L^1([a,b] \times [a-H_C, b+H_C])$. Applying Fubini's theorem gives

$$\int_a^b \int_{x-H_C}^{x+H_C} |f'(y)|\,dydx = \int_a^b \int_{a-H_C}^{b+H_C} g(x,y)dydx$$

$$= \int_{a-H_C}^{b+H_C} \int_a^b g(x,y)dxdy \le \int_{a-H_C}^{b+H_C} \int_{y-H_C}^{y+H_C} |f'(y)|\,dxdy$$

$$= 2H_C \int_{a-H_C}^{b+H_C} |f'(y)|\,dy \le 2H_C \|f\|_{BV(\mathbb{R})}. \tag{A.3}$$

Combining (A.2) and (A.3) gives (A.1). ∎

AN ERROR ESTIMATE FOR A NEW SCHEME FOR MEAN CURVATURE MOTION*

N. FORCADEL†

Abstract. In this work, we propose a new numerical scheme for the anisotropic mean curvature equation. The solution of the scheme is not unique, but for all numerical solutions, we provide an error estimate between the continuous solution and the numerical approximation. Our scheme is also applicable to computing the solution to dislocation dynamics equations. We also provide some numerical simulations.

Key words. mean curvature motion, error estimate, numerical scheme, dislocation dynamics

1. Introduction.

Mean curvature motion has been largely studied in terms of both theory and computation, in particular due to the large number of applications such as front propagation, image processing, and fluid dynamics (see, for instance, Sethian [30] and Osher and Paragios [27]).

The level set framework has been used in both theoretical and numerical problems. Theoretically, the mean curvature equation has been well understood using the framework of viscosity solutions by Chen, Giga, and Goto [10] and Evans and Spruck [20]. However, this equation has serious problems for the question of numerical approximations. Nevertheless, there are several works on this question. First, let us mention the numerical method of Osher and Sethian [28]. This method is often used in practice, but, as far as we know, there is no convergence result. Another algorithm is the Merriman, Bence, and Osher scheme [25] in which motion by mean curvature is viewed as the singular limit of a diffusion equation with threshold. The convergence of this scheme has been proved by Barles and Georgelin [4] and by Evans [19] (see also Ishii [21]; Ishii, Pires, and Souganidis [22]; and Chambolle and Novaga [9]). A class of convergent schemes for nonlinear parabolic equations including mean curvature motion has been proposed by Crandall and Lions [12] (see also Deckelnick [14] for an error analysis of this scheme). Let us mention also the recent work of Oberman [26]. In the last two works, two different scales are used. The first is the space step Δx, and the second is the size of the stencil ε. As pointed out in [12], these two scales are very important in approximating degenerate equations such as the mean curvature equation. Some other approaches are also used to approximate the mean curvature motion. Let us mention the parametrization of surfaces used by Deckelnick and Dziuk [15, 16]. We also refer to the work of Walkington [33] in which the author used a finite element algorithm to approximate the level set solution of the mean curvature motion.

An overview of the above methods together with an extensive list of references can be found in the survey articles by Elliott [18] and Deckelnick, Dziuk, and Elliott [17].

The goal of our work is to propose a new scheme for mean curvature motion and to prove an error estimate between the continuous solution and its numerical approximation. This error estimate is not optimal, but as far as we know, it is the first one for a complete discretized scheme for mean curvature type motion.

The idea is to use a recent work of Da Lio, Forcadel, and Monneau [13] concerning the convergence of dislocation dynamics to mean curvature motion. Dislocations are linear defects which move in crystals. Their dynamics can be represented by a nonlocal first order Hamilton–Jacobi equation (see Alvarez et al. [3]). The first goal of this work is to prove an error estimate between the solution of dislocation dynamics and the solution of mean curvature motion. To do this, we will use in a more quantitative way the definition of viscosity solutions for mean curvature motion proposed by Barles and Georgelin [4] by considering a regularization with quartics.

The second goal of this work is to propose a numerical scheme for dislocation dynamics. The main properties of this scheme are that it is implicit (so there is no CFL condition) and that it uses two different scales. Moreover, this scheme is not monotone and does not admit a unique solution. It is only "almost monotone" (see Lemma 5.2). Nevertheless, the fact that it is implicit and the velocity is monotone allows us to "freeze" the velocity and to prove a Crandall–Lions-type [11] error estimate for any solutions (we refer to Alvarez et al. [1, 2] for error estimates for dislocation dynamics in the nonmonotone case). It is also possible to make the scheme explicit. In this case, we are able to prove the convergence of the scheme under a CFL condition, but error estimates in this case are still open. This comes from the fact that there is no consistency error for the scheme (see Proposition 5.6).

Finally, let us mention some works on error estimates for numerical schemes for Hamilton–Jacobi equations. For the first order case, we refer to Souganidis [32]. For the second order case, when the Hamiltonian is convex, we refer to Krylov [23, 24] and Barles and Jakobsen [5, 6]. When the Hamiltonian is uniformly elliptic, we refer to Caffarelli and Souganidis [8].

Let us now explain how this paper is organized. In section 2, we state the main results of this work. In section 3, we prove the main result concerning mean curvature-type motion. Section 4 is devoted to proving the error estimate between the solution of dislocation dynamics and that of mean curvature motion. In section 5, we study the numerical scheme for dislocation dynamics and we prove an error estimate between the continuous solution and its numerical approximation. Some numerical simulations are provided in section 6.

2. Main results.

2.1. Error estimate for mean curvature motion. In order to propose a numerical scheme for anisotropic mean curvature motion, we will use the work of Da Lio, Forcadel, and Monneau [13] that we briefly recall here. Given a function g defined on the unit sphere $\mathbf{S}^{N-1}$of $\mathbb{R}^N$ by

$$g \in \mathrm{Lip}(\mathbf{S}^{N-1}), \quad g(-\theta) = g(\theta) \geq 0 \quad \forall \theta \in \mathbf{S}^{N-1}, \tag{2.1}$$

we consider kernels $c_0 \in L^\infty(\mathbb{R}^N) \cap W^{1,1}(\mathbb{R}^N)$ satisfying

$$\begin{cases} c_0(x) = \dfrac{1}{|x|^{N+1}}\ g\left(\dfrac{x}{|x|}\right) & \text{if} \quad |x| \geq 1, \\ c_0(-x) = c_0(x) \geq 0 \quad \forall x \in \mathbb{R}^N, \end{cases} \tag{2.2}$$

and we use the following scaling for $0 < \varepsilon < \frac{1}{e}$:

$$c_0^\varepsilon(x) = \frac{1}{\varepsilon^{N+1}|\ln\varepsilon|}\ c_0\left(\frac{x}{\varepsilon}\right). \tag{2.3}$$

The term $|\ln\varepsilon|$ comes from the bad decay at infinity of the kernel c_0 (see [13, section 4.1]).

We then consider the auxiliary problem

$$\begin{cases} u_t^\varepsilon(x,t) = \left((c_0^\varepsilon \star 1_{\{u^\varepsilon(\cdot,t)\geq u^\varepsilon(x,t)\}})(x) - \dfrac{1}{2}\displaystyle\int_{\mathbb{R}^N} c_0^\varepsilon\right)|Du^\varepsilon(x,t)| & \text{in} \quad \mathbb{R}^N\times(0,T), \\ u^\varepsilon(\cdot,0) = u_0^\varepsilon & \text{in} \quad \mathbb{R}^N, \end{cases} \tag{2.4}$$

where u_t^ε denotes the derivative with respect to the time variable, Du^ε indicates the gradient of u^ε with respect to the space variables, the convolution is done in space only, and $1_{\{u^\varepsilon(\cdot,t)\geq u^\varepsilon(x,t)\}}$ is the characteristic function of the set $\{u^\varepsilon(\cdot,t)\geq u^\varepsilon(x,t)\}$ (which is equal to 1 on the set and 0 outside). This equation arises in the theory of dislocation dynamics (see Alvarez et al. [3]) and uses the Slepčev formulation [31] to consider the simultaneous evolutions of all the level sets of the function u^ε. We refer to Da Lio, Forcadel, and Monneau [13] for the study of this model and in particular to [13, Definition 2.1] for the definition of viscosity solutions for problem (2.4). In particular, we recall that we take the indicatrix of $\{u^\varepsilon(\cdot,t)\geq u^\varepsilon(x,t)\}$ for the subsolution and the indicatrix of $\{u^\varepsilon(\cdot,t) > u^\varepsilon(x,t)\}$ for the supersolution.

The main result of [13] is that, if $u_0^\varepsilon = u_0$, then the unique solution u^ε of (2.4) converges locally uniformly on compact sets to the solution u^0 of the limit equation

$$\begin{cases} u_t^0 - \text{trace}\ \left(D^2u^0\cdot A\left(\dfrac{Du^0}{|Du^0|}\right)\right) = 0 & \text{in} \quad \mathbb{R}^N\times(0,T), \\ u^0(\cdot,0) = u_0 & \text{in} \quad \mathbb{R}^N, \end{cases} \tag{2.5}$$

with

$$A\left(\frac{p}{|p|}\right) = \int_{\theta\in\mathbf{S}^{N-2}=\mathbf{S}^{N-1}\cap\left\{\langle x,\frac{p}{|p|}\rangle=0\right\}} \left(\frac{1}{2}g(\theta)\ \theta\otimes\theta\right)\ d\theta \tag{2.6}$$

and where $M\cdot A$ and $\langle\cdot,\cdot\rangle$ denote, respectively, the product between the two matrices and the usual scalar product.

Remark 2.1. In the particular case where $g\equiv 1$, we get $A = \frac{|\mathbf{S}^{N-2}|}{2(N-1)}Id_{\{x,\ <x,p>=0\}}$, where $|\mathbf{S}^{N-2}|$ is the Lebesgue measure of $\mathbf{S}^{N-2}$, and then

$$\text{trace}\left(M\cdot A\left(\frac{p}{|p|}\right)\right) = \frac{-|\mathbf{S}^{N-2}|}{2(N-1)}\ \text{trace}\left(\left(Id - \frac{p}{|p|}\otimes\frac{p}{|p|}\right)\cdot M\right).$$

We recover the classical mean curvature motion up to the factor $|\mathbf{S}^{N-2}|/2(N-1)$.

Our first main result is an error estimate between u^ε and u^0.

THEOREM 2.2 (error estimate for mean curvature motion). *Let $N\geq 1$ and $T\leq 1$. Assume that $u_0, u_0^\varepsilon\in \text{Lip}(\mathbb{R}^N)$, $g\in\text{Lip}(\mathbf{S}^{N-1})$, and that c_0 given in* (2.2) *satisfies $c_0\in W^{1,1}(\mathbb{R}^N)$. Then, there exists a constant K_1 depending on $N, \sup_{\mathbb{R}^N} c_0$,*

$|Dg|_{L^\infty(\mathbf{S}^{N-1})}$, and $|Du_0|_{L^\infty(\mathbb{R}^N)}$ such that the difference between the solution u^ε of (2.4) *and the solution u^0 of* (2.5) *is given by*

$$\sup_{\mathbb{R}^N\times(0,T)} |u^\varepsilon - u^0| \leq K_1 \left(\frac{T}{|\ln\varepsilon|}\right)^{\frac{1}{6}} + \sup_{\mathbb{R}^N} |u_0^\varepsilon - u_0|. \tag{2.7}$$

2.2. Discrete-continuous error estimate for dislocation dynamics. To approximate the solution u^0 of (2.5), we then have to approximate the solution u^ε of (2.4). Up to a change of variable (see Corollary 3.1), it suffices to approximate the solution u of

(2.8)
$$\begin{cases} u_t(x,t) = \left((c_0 \star 1_{\{u(\cdot,t)\geq u(x,t)\}})(x) - \dfrac{1}{2}\displaystyle\int c_0\right)|Du(x,t)| & \text{in} \quad \mathbb{R}^N\times(0,T), \\ u(\cdot,0) = \bar{u}_0 & \text{in} \quad \mathbb{R}^N. \end{cases}$$

Given a mesh size $\Delta x_1,\dots,\Delta x_N,\Delta t$ and a lattice $Q_T^\Delta = Q^\Delta\times\{0,\dots,(\Delta t)N_T\}$, where $Q^\Delta = \{(i_1\Delta x_1,\dots,i_N\Delta x_N),\, I=(i_1,\dots,i_N)\in\mathbb{Z}^N\}$ and N_T is the integer part of $T/\Delta t$, we will denote by $(x_1,\dots,x_N,t_n) = (x_I,t_n)$ the node $(i_1\Delta x_1,\dots,i_N\Delta x_N,$ $n\Delta t)$ and by v_I^n the value of a numerical approximation of the exact solution $u(x_I,t_n)$. We set $\Delta x = \sqrt{\Delta x_1^2+\cdots+\Delta x_N^2}$ the space mesh size. We shall assume throughout that $\Delta x + \Delta t \leq 1$.

The discrete solution v is computed iteratively by solving the implicit scheme

$$v_I^0 = \tilde{u}_0(x_I), \qquad \frac{v_I^{n+1}-v_I^n}{\Delta t} = c^\Delta[v]_I^{n+1} G(v^{n+1})_I, \tag{2.9}$$

where $\tilde{u}_0$ is an approximation of $\bar{u}_0$ and $G(v^{n+1})_I$ is a suitable approximation of the gradient of v^{n+1} taken at point x_I. The nonlocal velocity is the discrete convolution

$$c^\Delta[v]_I^{n+1} = c^\Delta[v](x_I,t_{n+1}) = \sum_{J\in\mathbb{Z}^N} \bar{c}^0_{I-J} 1_{\{v_J^{n+1}\geq v_I^{n+1}\}}\Delta x_1,\dots,\Delta x_N \tag{2.10}$$
$$-\frac{1}{2}\sum_{J\in\mathbb{Z}^N} \bar{c}^0_J \Delta x_1,\dots,\Delta x_N$$

with

$$\bar{c}^0_I = \frac{1}{|Q_I|}\int_{Q_I} c_0(x)\,dx, \tag{2.11}$$

where Q_I is the square cell centered in x_I,

$$Q_I = [x_{i_1} - \Delta x_1/2, x_{i_1} + \Delta x_1/2]\times\cdots\times[x_{i_N} - \Delta x_N/2, x_{i_N} + \Delta x_N/2]. \tag{2.12}$$

Finally, let us define

$$v_\#(y,t_n) = \sum_I v(x_I,t_n)\chi_{Q_I}(y), \tag{2.13}$$

where χ_{Q_I} is the indicator function of Q_I.

The approximation of the gradient is obtained using the Osher–Sethian scheme [28] (we can also use the one proposed by Rouy and Tourin [29]). It is monotone, consistent and depends on the sign of the nonlocal velocity. Its precise definition is recalled in section 5.

Since the velocity c^Δ is nonlocal and not continuous, we have to give a sense to the equality in the scheme (2.9). In fact, we will use the analogue of the Slepčev formulation [31] for discrete sub- and supersolutions (see Definition 5.1) and we will use a discrete version of Perron's method to construct a discrete solution. The solution of the scheme is not unique, but, for any solutions, we have the following Crandall–Lions-type [11] error estimate.

THEOREM 2.3 (discrete-continuous error estimate for (2.8)). *Let $N \geq 1$ and $T \leq 1$. Assume that $\bar{u}_0, \tilde{u}_0 \in W^{1,\infty}(\mathbb{R}^N)$ and that c_0 given in (2.2) satisfies $c_0 \in W^{1,1}(\mathbb{R}^N)$. Assume that $\Delta x + \Delta t \leq 1$. Then there exists a constant $K_2 > 0$ depending only on N, $|c_0|_{W^{1,1}(\mathbb{R}^N)}$, $|D\bar{u}_0|_{L^\infty(\mathbb{R}^N)}$, and $|D\tilde{u}_0|_{L^\infty(\mathbb{R}^N)}$ such that the error estimate between the continuous solution u of (2.8) and any discrete solution v of the finite difference scheme (2.9) is given by*

$$\sup_{\mathbb{R}^N \times \{0,\dots,t_{N_T}\}} |u - v_\#| \leq K_2 \sqrt{T}\,(\Delta x + \Delta t)^{1/2} + \sup_{\mathbb{R}^N} |\bar{u}_0 - (\tilde{u}_0)_\#|,$$

provided that $\Delta x + \Delta t \leq \frac{1}{K_2^2}$.

Remark 2.4. It is possible to make the computation of the gradient explicit, i.e., to replace the term $G(v^{n+1})_I$ by $G(v^n)_I$ in the scheme (2.9) and to consider the solution v of

$$v_I^0 = \tilde{u}_0(x_I), \qquad \frac{v_I^{n+1} - v_I^n}{\Delta t} = c^\Delta[v]_I^{n+1} G(v^n)_I. \tag{2.14}$$

In this case, as usual, we have to satisfy a CFL condition, for instance,

$$\Delta t \leq \frac{\Delta x}{2|c_0|_{L^1(\mathbb{R}^N)}},$$

for the Osher–Sethian discretization of the gradient. Under this additional assumption, Theorem 2.3 remains true with v the solution of the scheme (2.14).

2.3. Discrete-continuous error estimate for mean curvature motion. Using the above results, in section 3 we will prove the following theorem.

THEOREM 2.5 (discrete-continuous error estimate for the mean curvature motion). *Let $N \geq 1$ and $T \leq 1$. Let us denote by v^ε a solution of (2.9)–(2.11) with initial condition $\tilde{u}_0^\varepsilon$ (which is an approximation of u_0) and with c_0^ε in the place of c_0. Assume that $u_0, \tilde{u}_0^\varepsilon \in W^{1,\infty}(\mathbb{R}^N)$, $g \in \mathrm{Lip}(\mathbf{S}^{N-1})$, and that c_0 given in (2.2) satisfies $c_0 \in W^{1,1}(\mathbb{R}^N)$. Assume also that $\Delta x + \Delta t \leq 1$. Then there exists a constant $K_3 > 0$ depending only on N, $\sup_{\mathbb{R}^N} c_0$, $|Dg|_{L^\infty(\mathbf{S}^{N-1})}$, $|c_0|_{W^{1,1}(\mathbb{R}^N)}$, $|Du_0|_{L^\infty(\mathbb{R}^N)}$, and $|D\tilde{u}_0^\varepsilon|_{L^\infty(\mathbb{R}^N)}$ such that the error estimate between the continuous solution u^0 of (2.5) and its numerical approximation v^ε is given by*

$$\sup_{\mathbb{R}^N \times \{0,..,t_{N_T}\}} |u^0 - v_\#^\varepsilon| \leq K_3 \left(\frac{T}{|\ln \varepsilon|}\right)^{1/6} + \sup_{\mathbb{R}^N} |u_0 - (\tilde{u}_0^\varepsilon)_\#|,$$

where $\varepsilon \geq K_3(\Delta x + \sqrt{\Delta t})$.

Remark 2.6. If $T \geq 1$, since $|Du^0|_{L^\infty(\mathbb{R}^N\times(0,T))} \leq |Du_0|_{L^\infty(\mathbb{R}^N)}$ and "$|Dv^\varepsilon|_{L^\infty(\mathbb{R}^N)}$" $\leq |D\tilde{u}_0^\varepsilon|_{L^\infty(\mathbb{R}^N)}$ (see Proposition 5.4 for the exact setting), we can iterate the process and get a linear estimate in T, i.e.,

$$\sup_{\mathbb{R}^N\times\{0,..,t_{N_T}\}} |u^0 - v^\varepsilon_\#| \leq \frac{K_3}{|\ln\varepsilon|^{1/6}} T + \sup_{\mathbb{R}^N} |u_0 - (\tilde{u}_0^\varepsilon)_\#|.$$

Remark 2.7. We can truncate the kernel c_0 at infinity and consider

$$\tilde{c}_0^R(x) = \begin{cases} c_0(x) & \text{if } |x| \leq R, \\ 0 & \text{else.} \end{cases}$$

In this case, we make an error of order $\int_{\mathbb{R}^N\setminus B_R(0)} c_0 \leq \frac{K}{R}$ and we can make the computation on a finite stencil, even if Δx goes to zero. This is possible if we choose ε of the same order as Δx. The condition $\varepsilon \geq K(\Delta x + \sqrt{\Delta t})$ in Theorem 2.5 then implies that we need to impose a CFL condition $\Delta t \leq K\Delta x^2$ (which is classical for second order equations).

On the other hand, if we do not impose any CFL condition, we can choose Δt larger than Δx^2, but we have to choose ε of the same order of $\sqrt{\Delta t}$ and thus make the convolution on larger and larger stencils as Δx goes to zero.

As we mention in the introduction, it is also possible to make the computation of the velocity explicit in the scheme (2.9) and to consider

$$v_I^0 = \tilde{u}_0(x_I), \qquad \frac{v_I^{n+1} - v_I^n}{\Delta t} = c^\Delta[v]_I^n G(v^n)_I, \tag{2.15}$$

with c_0^ε in the place of c_0 in the definition of c^Δ.

We can prove the convergence of the scheme (see Theorem 2.8) under the CFL condition

$$\Delta t \leq \frac{\varepsilon|\ln\varepsilon|}{2|c_0|_{L^1(\mathbb{R}^N)}}\Delta x. \tag{2.16}$$

But, in this case, we are not able to prove an error estimate. The reason is that when we make the computation of the velocity implicit, it "freezes" it, and then we can use the consistency error on the scheme with given velocity. On the other hand, for the explicit scheme, we have to control the consistency error of the velocity, which is not possible, as we point out in Proposition 5.6.

We define

$$v^{\varepsilon,\delta}(x,t) = v^\varepsilon(x_I, t_n) \quad \text{if} \quad x \in Q_I,\ t \in [t_n, t_{n+1}),$$

where $\delta = (\Delta x, \Delta t)$ and v^ε is the solution of the scheme (2.15), (2.10), (2.11) with the kernel c_0^ε in the place of c_0. Then we have the following convergence result.

THEOREM 2.8 (convergence of the explicit scheme). *Assume* (2.16). *Under the assumptions of Theorem* 2.5, *the function $v^{\varepsilon,\delta}$ converges locally uniformly on compact sets as $\delta \to 0$ to the solution u^ε of* (2.4).

Remark 2.9. In Theorem 2.8, if we take the limit $\delta \to 0$ and $\varepsilon \to 0$ with $\delta \ll \varepsilon$, we will approach the solution of (2.5). The condition $\delta \ll \varepsilon$ implies that, in practice, we have to make the convolution in larger and larger stencils as $\delta \to 0$.

Remark 2.10. In the scheme (2.15), it is possible to make the computation of the gradient implicit and thus to withdraw the CFL condition (2.16) to get the same result as Theorem 2.8.

Notation. In what follows, we will denote by K a generic constant, which will then satisfy $K + K = K$, $K \cdot K = K$, and so on.

3. Numerical scheme for mean curvature motion.

3.1. Proof of Theorem 2.5. Using a rescaling argument, we will prove the following corollary of Theorem 2.3.

COROLLARY 3.1 (discrete-continuous error estimate for (2.4)). *Let us denote by v^ε a solution of* (2.9)–(2.11) *with initial condition $\tilde{u}_0^\varepsilon$ (which is an approximation of u_0^ε) and with c_0^ε in the place of c_0. Under the assumptions of Theorem* 2.3, *there exists a constant $K > 0$ depending only on $|c_0|_{W^{1,1}(\mathbb{R}^N)}$, $|Du_0^\varepsilon|_{L^\infty(\mathbb{R}^N)}$, and $|D\tilde{u}_0^\varepsilon|_{L^\infty(\mathbb{R}^N)}$ such that the error estimate between the continuous solution u^ε of* (2.4) *and its numerical approximation v^ε is given by*

$$\sup_{\mathbb{R}^N\times\{0,\dots,t_{N_T}\}} |u^\varepsilon - v_\#^\varepsilon| \le K\frac{1}{\varepsilon}\sqrt{\frac{T}{|\ln\varepsilon|}}\sqrt{\varepsilon\Delta x + \frac{\Delta t}{|\ln\varepsilon|}} + \sup_{\mathbb{R}^N}|u_0^\varepsilon - (\tilde{u}_0^\varepsilon)_\#|,$$

provided that $\varepsilon\Delta x + \dfrac{\Delta t}{|\ln\varepsilon|} \le \dfrac{\varepsilon^2}{K^2}$.

Proof of Corollary 3.1. First we remark that a simple change of variable gives (for u and v solutions of (2.8) and (2.9), respectively)

$$u^\varepsilon(y,\tau) = \varepsilon u\left(\frac{y}{\varepsilon}, \frac{\tau}{\varepsilon^2|\ln\varepsilon|}\right), \qquad u_0^\varepsilon(y) = \varepsilon\bar{u}_0\left(\frac{y}{\varepsilon}\right),$$

$$v^\varepsilon(y,\tau) = \varepsilon v\left(\frac{y}{\varepsilon}, \frac{\tau}{\varepsilon^2|\ln\varepsilon|}\right), \qquad \tilde{u}_0^\varepsilon(y) = \varepsilon\tilde{u}_0\left(\frac{y}{\varepsilon}\right).$$

Let us denote $x = \dfrac{y}{\varepsilon}$, $t = \dfrac{\tau}{\varepsilon^2|\ln\varepsilon|}$, $\Delta x = \dfrac{\Delta y}{\varepsilon}$, $\Delta t = \dfrac{\Delta\tau}{\varepsilon^2|\ln\varepsilon|}$, $T = \dfrac{\Gamma}{\varepsilon^2|\ln\varepsilon|}$, $s_n = n\Delta\tau$, and by N_Γ the integer part of $\Gamma/\Delta\tau$. Then, the following inequality holds:

$$\begin{aligned}\sup_{R^N\times\{0,\dots,s_{N_\Gamma}\}} |u^\varepsilon - v_\#^\varepsilon| &= \varepsilon \sup_{R^N\times\{0,\dots,t_{N_T}\}} |u - v_\#| \\ &\le K\frac{\sqrt{\Gamma}}{\sqrt{|\ln\varepsilon|}}\sqrt{\frac{\Delta y}{\varepsilon} + \frac{\Delta\tau}{\varepsilon^2|\ln\varepsilon|}} + \varepsilon\sup_{\mathbb{R}^N}|\bar{u}_0 - (\tilde{u}_0)_\#| \\ &\le K\frac{\sqrt{\Gamma}}{\varepsilon\sqrt{|\ln\varepsilon|}}\sqrt{\varepsilon\Delta y + \frac{\Delta\tau}{|\ln\varepsilon|}} + \sup_{\mathbb{R}^N}|u_0^\varepsilon - (\tilde{u}_0^\varepsilon)_\#|,\end{aligned}$$

provided that

$$\frac{\Delta y}{\varepsilon} + \frac{\Delta\tau}{\varepsilon^2|\ln\varepsilon|} \le \frac{1}{K^2},$$

i.e.,

$$\varepsilon\Delta y + \frac{\Delta\tau}{|\ln\varepsilon|} \le \frac{\varepsilon^2}{K^2}.$$

This ends the proof of the corollary. ∎

Proof of Theorem 2.5. The proof of Theorem 2.5 is now very easy. Indeed, using Theorem 2.2 and Corollary 3.1, we deduce that

$$|u^0 - v^\varepsilon| \le |u^0 - u^\varepsilon| + |u^\varepsilon - v^\varepsilon|$$
$$\le K\left(\frac{T}{|\ln\varepsilon|}\right)^{\frac{1}{6}} + \frac{K}{\varepsilon\sqrt{|\ln\varepsilon|}}\sqrt{T}\sqrt{\varepsilon\Delta x + \Delta t} + \sup_{\mathbb{R}^N}|u_0^\varepsilon - (\tilde{u}_0^\varepsilon)_\#| + \sup_{\mathbb{R}^N}|u_0^\varepsilon - u_0|.$$

Taking $\varepsilon \ge K(\Delta x + \sqrt{\Delta t})$ implies the prevalence of the first term with respect to the second, and so this implies the desired estimate for the choice of initial condition $u_0^\varepsilon = u_0$.

3.2. Proof of Theorem 2.8. The idea of the proof is borrowed from Barles and Souganidis [7]. Let us set

$$\overline{v}^\varepsilon = \limsup_{\delta\to 0}{}^*\, v^{\varepsilon,\delta}, \quad \underline{v}^\varepsilon = \liminf_{\delta\to 0}{}_*\, v^{\varepsilon,\delta}.$$

We now prove that $\overline{v}^\varepsilon$ and $\underline{v}^\varepsilon$ are, respectively, the sub- and the supersolution of (2.4). Let $\varphi \in C^\infty(\mathbb{R}^N \times [0,T))$ such that $\overline{v}^\varepsilon - \varphi$ reaches a strict maximum at the point (x_0,t_0) with $t_0 \in (0,T)$. Then, there exists $\delta \to 0$, $(x^\delta,t^\delta) \to (x_0,t_0)$ such that $v^{\varepsilon,\delta} - \varphi$ reaches a maximum at (x^δ,t^δ). We denote by $(x_I^\delta,t_n^\delta) \in Q_T^\Delta$ the node such that $v^{\varepsilon,\delta}(x^\delta,t^\delta) = v^{\varepsilon,\delta}(x_I^\delta,t_n^\delta)$. This implies that, for all (x,t),

$$v^{\varepsilon,\delta}(x,t) \le v^{\varepsilon,\delta}(x_I^\delta,t_n^\delta) - \varphi(x^\delta,t^\delta) + \varphi(x,t).$$

Using the monotony of the scheme for a given velocity and the fact that v is a solution of the scheme, we get

$$\frac{\varphi(x^\delta,t^\delta) - \varphi(x^\delta,t^\delta - \Delta t)}{\Delta t}$$
$$\le c^\varepsilon[v^{\varepsilon,\delta}](x_I^\delta,t^\delta - \Delta t)\begin{cases} G^+(D^+\varphi(x^\delta,t^\delta-\Delta t), D^-\varphi(x^\delta,t^\delta-\Delta t)) \\ \qquad \text{if} \quad c[v^{\varepsilon,\delta}](x_I^\delta,t^\delta-\Delta t) \ge 0, \\ G^-(D^+\varphi(x^\delta,t^\delta-\Delta t), D^-\varphi(x^\delta,t^\delta-\Delta t)) \\ \qquad \text{if} \quad c[v^{\varepsilon,\delta}](x_I^\delta,t^\delta-\Delta t) \le 0 \end{cases}$$

with

$$c^\varepsilon[u](x,t) = c_0^\varepsilon \star 1_{\{u(\cdot,t)\ge u(x,t)\}}(x) - \frac{1}{2}\int_{\mathbb{R}^N} c_0^\varepsilon,$$

where we have used Lemma 5.5 to obtain the velocity. Sending $\delta \to 0$, and using the Slepčev lemma [31, eq. (5)] and the consistency of the scheme for a given velocity, we get

$$\varphi_t(x_0,t_0) \le \left(c_0^\varepsilon \star 1_{\{\overline{v}^\varepsilon(\cdot,t_0)\ge \overline{v}^\varepsilon(x_0,t_0)\}}(x_0) - \frac{1}{2}\int_{\mathbb{R}^N} c_0^\varepsilon\right)|D\varphi(x_0,t_0)|.$$

This proves that $\overline{v}^\varepsilon$ is a subsolution of (2.4). The proof for $\underline{v}^\varepsilon$ is the same, and we skip it. Moreover, using a barrier argument (using the equivalent of Proposition 5.4), we get that $\overline{v}^\varepsilon(\cdot,0) = \underline{v}^\varepsilon(\cdot,0) = u_0^\varepsilon$. Then we have that $v^\varepsilon = \overline{v}^\varepsilon = \underline{v}^\varepsilon$ is solution of (2.4). This ends the proof of the theorem.

Remark 3.2. In the scheme (2.15), we have made the choice to take the velocity $c^{\Delta}[v]_I^n$. Another possibility is to take

$$\tilde{c}^{\Delta}[v]_I^{n+1} = \sum_{J\in\mathbb{Z}^N} \bar{c}^0_{I-J} 1_{\{v_J^{n+1} > v_I^{n+1}\}} \Delta x_1, \dots, \Delta x_N - \frac{1}{2} \sum_{J\in\mathbb{Z}^N} \bar{c}^0_J \Delta x_1, \dots, \Delta x_N.$$

This constructs two discrete solutions v and $\tilde{v}$. Thus, we can take any discrete function contained between $\tilde{v}$ and v. In fact, this is equivalent to defining a discrete solution as a sub- and a supersolution as in Definition 5.1. With this definition, v will be the greater subsolution and $\tilde{v}$ will be the lower supersolution and Theorem 2.8 will be true for every solution.

3.3. What happens if we change the kernel? A natural question is what happens if we change the kernel and if we take a kernel which decreases more quickly at infinity. For this kind of kernel K_0, the natural scaling is the following (see [13, section 4.1]):

$$K_0^{\varepsilon}(x) = \frac{1}{\varepsilon^{n+1}} K_0\left(\frac{x}{\varepsilon}\right).$$

In fact, using the same argument as the one we use for the proof of Theorem 2.2, we can prove the same kind of error estimate. For example, for $K_0(x) = \dfrac{1}{|x|^{n+p}}$ for $|x| \geq 1$ with $p \geq 3$, we get

$$|u^{\varepsilon} - u^0| \leq K\sqrt{\varepsilon} T^{1/4}.$$

This is the best estimate for ε small that we can obtain for a general kernel, as we can see in Step 3, Case 1 of the proof of Theorem 2.2.

The main difference is that the estimate of Corollary 3.1 is replaced by

$$\sup_{\mathbb{R}^N\times\{0,\dots,t_{N_T}\}} |u^{\varepsilon} - v^{\varepsilon}_{\#}| \leq K\frac{\sqrt{T}}{\varepsilon}\sqrt{\varepsilon\Delta x + \Delta t} + \sup_{\mathbb{R}^N} |u_0^{\varepsilon} - (\tilde{u}_0^{\varepsilon})_{\#}| \quad \text{for } \varepsilon\Delta x + \Delta t \leq \frac{\varepsilon^2}{K^2}.$$

Finally, we obtain for the choice $u_0^{\varepsilon} = u_0$

$$\sup_{\mathbb{R}^N\times\{0,\dots,t_{N_T}\}} |u^0 - (v^{\varepsilon})_{\#}| \leq K\sqrt{\varepsilon} T^{\frac{1}{4}} + \sup_{\mathbb{R}^N} |u_0 - \tilde{u}_0^{\varepsilon}|$$

if $\varepsilon \geq K(\sqrt{\Delta x} + (\Delta t)^{\frac{1}{3}})$. This implies that $\frac{\Delta x}{\varepsilon} \to 0$ as $\Delta x \to 0$. Thus, when $\Delta x \to 0$, we have to make the convolution on all the space, which can be very expensive in practice. This approach can also be used for the Gaussian kernel and should give the same estimates. In particular, this could give an error estimate for the equivalent version of the classical Bence–Merriman–Osher algorithm [25].

4. Proof of Theorem 2.2. Before proving Theorem 2.2, we need some notation. Let us define

$$F(M,p) = \operatorname{trace}\left(M \cdot A\left(\frac{p}{|p|}\right)\right) \quad \text{and} \quad G(M,p) = \frac{-1}{|p|} F(M,p),$$

where we recall that $A(p)\cdot p = 0$ for all $p \in \mathbf{S}^{N-1}$.

Then we have the following fundamental estimate for balls.

LEMMA 4.1 (error estimate for a ball). *Let $\varphi \in C^2(\mathbb{R}^N)$ with $D\varphi(x_0) \neq 0$ be such that the set $\{\varphi(x) \geq \varphi(x_0)\}$ is a ball of radius R. For $c_0^\varepsilon(\cdot) = \frac{1}{\varepsilon^{n+1}|\ln\varepsilon|}\ c_0\left(\frac{\cdot}{\varepsilon}\right)$, let us define*

$$c^\varepsilon = (c_0^\varepsilon \star 1_{\{\varphi(\cdot)>\varphi(x_0)\}})(x_0) - \frac{1}{2}\int_{\mathbb{R}^n} c_0^\varepsilon.$$

Then, there exists a constant $K = K(N, \sup_{\mathbb{R}^n} c_0, |Dg|_{L^\infty(\mathbf{S}^{N-1})}) > 0$ such that for $0 < \varepsilon < \delta$ with $0 < \delta \leq R/2$, we have

$$|c^\varepsilon + G(D^2\varphi(x_0), D\varphi(x_0))| \leq K \cdot e\,(\varepsilon, \delta, R)$$

with

$$e\,(\varepsilon, \delta, R) = \frac{1}{|\ln\varepsilon|}\left(\frac{1}{\delta} + \frac{1}{R}|\ln\delta|\right) + \frac{\delta}{R^2}.$$

This is a straightforward consequence of Da Lio, Forcadel, and Monneau [13, Proposition 4.1], where their Lemma 4.3 is replaced by a direct estimate for an explicit function $h(x') = R - \sqrt{R^2 - |x'|^2}$ with $x' \in \mathbb{R}^{N-1}$ and $|x'| \leq R$.

Proof of Theorem 2.2. Let u^0 be the solution of the mean curvature motion (2.5). The idea of the proof is to regularize the function u^0 by a kind of sup-convolution but using quartic penalization and then to plug the regularized function $u^{0,\alpha}$ into (2.4). This regularization allows us to control quantitatively the first and second space derivatives of $u^{0,\alpha}$. This is a quantitative version of the definition of Barles and Georgelin [4] for viscosity solutions of mean curvature motion, where they used this kind of regularization to prove that one can take test functions such that $D\varphi \neq 0$ or $D\varphi = 0$ and $D^2\varphi = 0$ in the definition of viscosity solutions. This kind of argument is also used to obtain the comparison principle for mean curvature-type equations.

The proof is decomposed into five steps:

Step 1. *Regularization of u^0.*

By classical estimates for mean curvature-type equations, we have

$$\|Du^0\|_{L^\infty(\mathbb{R}^N\times(0,T))} \leq \|Du_0\|_{L^\infty(\mathbb{R}^N)}. \tag{4.1}$$

We regularize u^0 by considering a spatial sup-convolution by quartics:

$$u^{0,\alpha}(x,t) = \sup_{y\in\mathbb{R}^N}\left\{u^0(x-y,t) - \frac{1}{4\alpha}|y|^4\right\} \tag{4.2}$$

$$= \sup_{z\in\mathbb{R}^N}\left\{u^0(z,t) - \frac{1}{4\alpha}|z-x|^4\right\}. \tag{4.3}$$

Since u^0 is Lipschitz continuous, the supremum is reached.

Step 2. *Estimate between u^0 and $u^{0,\alpha}$.*

For $x \in \mathbb{R}^N$ and $t \in (0,T)$, we denote by $\bar{x} = \bar{x}(x,t)$ a point where the maximum is reached in (4.3). Then

$$u^{0,\alpha}(x,t) = u^0(\bar{x},t) - \frac{1}{4\alpha}|\bar{x}-x|^4 \geq u^0(x,t). \tag{4.4}$$

Therefore

$$\frac{1}{4\alpha}|\bar{x}-x|^4 \le u^0(\bar{x},t)-u^0(x,t) \le K|\bar{x}-x|, \tag{4.5}$$

and so

$$|\bar{x}-x| \le K\alpha^{1/3}. \tag{4.6}$$

Moreover, by (4.4), we get

$$0 \le u^{0,\alpha}(x,t)-u^0(x,t) \le u^0(\bar{x},t)-u^0(x,t) \le K|\bar{x}-x|. \tag{4.7}$$

Using (4.6) and (4.7), we then deduce that, for $x \in \mathbb{R}^N$ and $t \in (0,T)$,

$$|u^{0,\alpha}(x,t)-u^0(x,t)| \le K\alpha^{1/3}. \tag{4.8}$$

Before continuing the proof, we need some notation. We now want to compare u^ε and $u^{0,\alpha}$. To do that, we will prove that $u^{0,\alpha} \pm (f(\varepsilon,\alpha)t + K\alpha^{\frac{1}{3}} + \sup_{\mathbb{R}^N}|u_0^\varepsilon - u_0|)$ are the super- and subsolutions, respectively, of problem (2.4) for

$$f(\varepsilon,\alpha) = K\left(\frac{1}{\sqrt{|\ln\varepsilon|}} + \frac{\ln|\ln\varepsilon|}{\alpha^{1/3}|\ln\varepsilon|} + \frac{1}{\alpha^{2/3}}\left(\frac{1}{\sqrt{|\ln\varepsilon|}}+\varepsilon\right)\right).$$

Let $\psi \in C^\infty(\mathbb{R}^N \times (0,T))$ such that $u^{0,\alpha}-\psi$ reaches a global strict maximum at $(x_0,t_0) \in \mathbb{R}^N \times (0,T)$. Since $u^{0,\alpha}$ is semiconvex in the space variable, the function $u^{0,\alpha}$ is derivable with respect to x at the point (x_0,t_0).

Let us denote

$$\varphi_z(x) = u^0(z,t_0) - \frac{1}{4\alpha}|z-x|^4.$$

Then

$$u^{0,\alpha}(x,t_0) = \sup_{z\in\mathbb{R}^N} \varphi_z(x).$$

We denote by $\bar{x}_0$ a point where the maximum is reached for $x = x_0$ and we also denote $\varphi = \varphi_{\bar{x}_0}$. We then deduce that

$$\psi(x,t_0) \ge u^{0,\alpha}(x,t_0) \ge \varphi(x) \tag{4.9}$$

with equality for $x = x_0$. This implies that

$$D\varphi(x_0) = Du^{0,\alpha}(x_0,t_0) = D\psi(x_0,t_0) \tag{4.10}$$

and

$$D^2\varphi(x_0) \le D^2\psi(x_0,t_0). \tag{4.11}$$

Moreover, with $h = |\bar{x}_0 - x_0|$, we have (by (4.6))

$$h \le K\alpha^{\frac{1}{3}}, \tag{4.12}$$

$$|D\varphi(x_0)| = \frac{h^3}{\alpha}, \tag{4.13}$$

and the set $\{\varphi(x) \geq \varphi(x_0)\}$ is a ball of radius $R = h$. Let us define the error

$$e(\varphi) = |c^\varepsilon[\varphi](x_0)|D\varphi(x_0)| - F(D^2\varphi(x_0), D\varphi(x_0))|,$$

where

$$c^\varepsilon[\varphi](x_0) = \left(c_0^\varepsilon \star 1_{\{\varphi(\cdot)\geq\varphi(x_0)\}}\right)(x_0) - \frac{1}{2}\int_{\mathbb{R}^N} c_0^\varepsilon.$$

Step 3. $e(\varphi) \leq f(\varepsilon, \alpha)$.

We distinguish three cases:

Case 1. $h \leq 2\varepsilon$. In this case, we directly have the estimate (using (4.13))

$$|c^\varepsilon[\varphi](x_0)|D\varphi(x_0)|| \leq |c_0^\varepsilon|_{L^1(\mathbb{R}^N)}\frac{h^3}{\alpha} \leq \frac{h^2|c_0|_{L^1(\mathbb{R}^N)}}{\varepsilon|\ln\varepsilon|}\frac{h}{\alpha} \leq \frac{K}{\alpha^{2/3}}\frac{\varepsilon}{|\ln\varepsilon|},$$

where we have also used (4.12). Using, moreover, the fact that

$$|F(D^2\varphi(x_0), D\varphi(x_0))| \leq \frac{K}{h}|D\varphi(x_0)| \leq K\frac{h^2}{\alpha},$$

we then deduce that

$$e(\varphi) \leq \frac{K}{\alpha^{2/3}}\varepsilon \leq f(\varepsilon, \alpha).$$

Case 2. $2\varepsilon < h \leq \frac{2}{\sqrt{|\ln\varepsilon|}}$. Using (4.13) and Lemma 4.1, with $\delta = h/2$, we then deduce that

$$\begin{aligned} e(\varphi) &\leq \frac{Kh^3}{\alpha}\left(\frac{1}{|\ln\varepsilon|}\left(\frac{1}{h} + \frac{1}{h}|\ln\delta|\right) + \frac{1}{h}\right) \\ &\leq \frac{Kh}{\alpha^{2/3}} \leq \frac{K}{\alpha^{2/3}}\frac{1}{\sqrt{|\ln\varepsilon|}} \leq f(\varepsilon, \alpha). \end{aligned}$$

Case 3. $h > \frac{2}{\sqrt{|\ln\varepsilon|}}$. We set $\delta = \frac{1}{\sqrt{|\ln\varepsilon|}}$. We then have $\varepsilon < \delta < \frac{h}{2}$. So by Lemma 4.1, we deduce that

$$\begin{aligned} e(\varphi) &\leq \frac{Kh^3}{\alpha}\left(\frac{1}{\sqrt{|\ln\varepsilon|}} + \frac{1}{h}\frac{\ln|\ln\varepsilon|}{|\ln\varepsilon|} + \frac{1}{h^2}\frac{1}{\sqrt{|\ln\varepsilon|}}\right) \\ &\leq K\left(\frac{1}{\sqrt{|\ln\varepsilon|}} + \frac{1}{\alpha^{1/3}}\frac{\ln|\ln\varepsilon|}{|\ln\varepsilon|} + \frac{1}{\alpha^{2/3}}\frac{1}{\sqrt{|\ln\varepsilon|}}\right) \\ &\leq f(\varepsilon, \alpha). \end{aligned}$$

Step 4. *Estimate between* $u^{0,\alpha}$ *and* u^ε.

By construction, we have, since $u^{0,\alpha}$ is a subsolution of (2.5) (but does not satisfy the initial condition),

$$\begin{aligned} \psi_t(x_0, t_0) &\leq F(D^2\psi(x_0, t_0), D\psi(x_0, t_0)) \\ &\leq c^\varepsilon[\varphi](x_0)|D\psi(x_0, t_0)| + F(D^2\varphi(x_0), D\varphi(x_0)) - c^\varepsilon[\varphi](x_0)|D\varphi(x_0)| \\ &\leq c^\varepsilon[u^{0,\alpha}(\cdot, t_0)](x_0)|D\psi(x_0, t_0)| + f(\varepsilon, \alpha), \end{aligned}$$

where we have used (4.9) for the last line. On the other hand, we have

$$u^{0,\alpha}(\cdot,0) - K\alpha^{1/3} - \sup_{\mathbb{R}^N} |u_0^\varepsilon - u_0| \le u_0^\varepsilon,$$

where we have used (4.8) at the limit $t = 0$. We then deduce that $\tilde{u}^{0,\alpha}(x,t) = u^{0,\alpha}(x,t) - f(\varepsilon,\alpha)t - K\alpha^{1/3} - \sup_{\mathbb{R}^N} |u_0^\varepsilon - u_0|$ is a subsolution of (2.4). This implies that $\tilde{u}^{0,\alpha} \le u^\varepsilon$ and so

$$u^{0,\alpha} - u^\varepsilon \le f(\varepsilon,\alpha)t + K\alpha^{1/3} + \sup_{\mathbb{R}^N} |u_0^\varepsilon - u_0|. \tag{4.14}$$

Step 5. *Estimate between* u^0 *and* u^ε.

Using (4.8) and (4.14), we then get

$$u^0 - u^\varepsilon = u^0 - u^{0,\alpha} + u^{0,\alpha} - u^\varepsilon \le f(\varepsilon,\alpha)t + K\alpha^{1/3} + \sup_{\mathbb{R}^N} |u_0^\varepsilon - u_0|.$$

But

$$\begin{aligned} &f(\varepsilon,\alpha)t + K\alpha^{1/3} \\ &\quad = K\left(\frac{1}{\sqrt{|\ln\varepsilon|}} + \frac{\ln|\ln\varepsilon|}{\alpha^{1/3}|\ln\varepsilon|} + \frac{1}{\alpha^{2/3}}\left(\frac{1}{\sqrt{|\ln\varepsilon|}} + \varepsilon\right)\right)t + K\alpha^{1/3} \\ &\quad \le K\left(\frac{T}{\sqrt{|\ln\varepsilon|}}\right)^{\frac{1}{3}} \end{aligned}$$

for $\alpha = \frac{Kt}{\sqrt{|\ln\varepsilon|}}$ and $t \le T \le 1$. We then get

$$u^0 - u^\varepsilon \le K\left(\frac{T}{\sqrt{|\ln\varepsilon|}}\right)^{\frac{1}{3}} + \sup_{\mathbb{R}^N} |u_0^\varepsilon - u_0|.$$

A lower bound is proved similarly (using the same result as Lemma 4.1, where the set $\{\varphi(x) \ge \varphi(x_0)\}$ is replaced by $\{\varphi(x) > \varphi(x_0)\}$). This implies (2.7) for $T \le 1$. This ends the proof of the theorem.

5. Numerical scheme for dislocation dynamics.

5.1. Definitions and preliminary results. We recall here the notation used in the scheme. The discrete solution v is computed iteratively by solving the implicit scheme

$$v_I^0 = \tilde{u}_0(x_I), \qquad \frac{v_I^{n+1} - v_I^n}{\Delta t} = c^\Delta[v]_I^{n+1} G(v^{n+1})_I, \tag{5.1}$$

where the nonlocal velocity is defined in (2.10). The approximation of the gradient of v^{n+1} at the point x_I is given by

$$G(v^{n+1})_I = \begin{cases} G^+(D^+v_I^{n+1}, D^-v_I^{n+1}) & \text{if} \quad c^\Delta[v]_I^{n+1} \ge 0, \\ G^-(D^+v_I^{n+1}, D^-v_I^{n+1}) & \text{if} \quad c^\Delta[v]_I^{n+1} < 0, \end{cases}$$

where $G^{\pm}$ is a suitable approximation of the Euclidean norm and $D^{\pm}v^n(x_I) = (D^{\pm}_{x_1}v^n(x_I), \dots, D^{\pm}_{x_N}v^n(x_I))$ are the discrete gradients. The terms $D^{\pm}_{x_i}v^n(x_I)$ are the standard forward and backward first order differences; i.e., for a general function $f(x_I)$

$$D^+_{x_i}f(x_I) = \frac{f(x_{I^{i,+}}) - f(x_I)}{\Delta x_i},$$

$$D^-_{x_i}f(x_I) = \frac{f(x_I) - f(x_{I^{i,-}})}{\Delta x_i},$$

where

$$I^{k,\pm} = (i_1, \dots, i_{k-1}, i_k \pm 1, i_{k+1}, \dots, i_N). \tag{5.2}$$

The approximations of the Euclidean norm $G^{\pm}$ are those proposed by Osher and Sethian [28] (we can also use the ones proposed by Rouy and Tourin [29]):

$$G^+(P,Q) = \left(\sum_{i=1,..,N} \max(P_i,0)^2 + \sum_{i=1,..,N} \min(Q_i,0)^2 \right)^{\frac{1}{2}}, \tag{5.3}$$

$$G^-(P,Q) = \left(\sum_{i=1,..,N} \min(P_i,0)^2 + \sum_{i=1,..,N} \max(Q_i,0)^2 \right)^{\frac{1}{2}}.$$

We recall that the functions $G^{\pm}$ are Lipschitz continuous with respect to the discrete gradients, i.e.,

$$|G^{\pm}(P_1,P_2) - G^{\pm}(P_1',P_2')| \le (|P_1 - P_1'| + |P_2 - P_2'|). \tag{5.4}$$

They are consistent with the Euclidean norm

$$G^{\pm}(P,P) = |P|, \tag{5.5}$$

and $G^{\pm} = G^{\pm}(P_1^+, \dots, P_N^+, P_1^-, \dots, P_N^-)$ enjoy suitable monotonicity with respect to each variable

$$\frac{\partial G^+}{\partial p_i^+} \ge 0, \quad \frac{\partial G^+}{\partial p_i^-} \ge 0, \quad \frac{\partial G^-}{\partial p_i^+} \ge 0, \quad \frac{\partial G^-}{\partial p_i^-} \ge 0. \tag{5.6}$$

To define discrete solution, we need the following notation:

$$\tilde{c}^{\Delta}[v]_I^{n+1} = \sum_{J \in \mathbb{Z}^N} \bar{c}^0_{I-J} 1_{\{v_J^{n+1} > v_I^{n+1}\}} \Delta x_1, \dots, \Delta x_N - \frac{1}{2} \sum_{J \in \mathbb{Z}^N} \bar{c}^0_J \Delta x_1, \dots, \Delta x_N, \tag{5.7}$$

$$\tilde{G}(v^{n+1})_I = \begin{cases} G^+(D^+v_I^{n+1}, D^-v_I^{n+1}) & \text{if} \quad \tilde{c}^{\Delta}[v]_I^{n+1} \ge 0, \\ G^-(D^+v_I^{n+1}, D^-v_I^{n+1}) & \text{if} \quad \tilde{c}^{\Delta}[v]_I^{n+1} < 0, \end{cases}$$

where $\bar{c}_0$ is defined in (2.11). Finally, for simplicity of presentation, let us denote

$$s[v]_I^{n+1} = \mathrm{Sign}(c^{\Delta}[v]_I^{n+1}), \quad \tilde{s}[v]_I^{n+1} = \mathrm{Sign}(\tilde{c}^{\Delta}[v]_I^{n+1}).$$

DEFINITION 5.1 (numerical subsolution, supersolution, and solution of the scheme). *We say that v is a discrete subsolution (resp., supersolution) of the scheme* (2.9) *if, for all $I \in \mathbb{Z}^N$, $n \in \mathbb{N}$, we have*

$$v_I^{n+1} \le v_I^n + \Delta t\, c^\Delta[v]_I^{n+1} G(v^{n+1})_I$$

$$\left(\text{resp., } v_I^{n+1} \ge v_I^n + \Delta t\, \tilde{c}^\Delta[v]_I^{n+1} \tilde{G}(v^{n+1})_I\right).$$

We say that v is a discrete solution if and only if it is a sub- and a supersolution.

LEMMA 5.2 (almost monotonicity of the scheme). *The scheme* (2.9) *is almost monotone in the following sense. Let v, w be two discrete functions and assume that there is I such that $w_I = v_I$ and $w_J \ge v_J$ for $J \ne I$. Then*

$$c^\Delta[v]_I G(v)_I \le c^\Delta[w]_I G(w)_I$$

and

$$\tilde{c}^\Delta[v]_I G(v)_I \le \tilde{c}^\Delta[w]_I G(w)_I.$$

Proof of Lemma 5.2. First, we remark that $c^\Delta[v]_I \le c^\Delta[w]_I$. Then, there are three cases:

1. $c^\Delta[v]_I \le 0 \le c^\Delta[w]_I$. In this case, the result is trivial.
2. $0 \le c^\Delta[v]_I \le c^\Delta[w]_I$. Using the monotonicity of G, we get that $G(v)_I \le G(w)_I$. This implies the result.
3. $c^\Delta[v]_I \le c^\Delta[w]_I \le 0$. Using the monotonicity of G, we get that $G(v)_I \ge G(w)_I$. This implies the result.

The proof for $\tilde{c}^\Delta$ is the same, and we skip it. This ends the proof of the lemma.

The existence of a solution for the scheme is not trivial (since it is implicit and nonlocal). This is the subject of the following proposition.

PROPOSITION 5.3 (existence of a solution for the scheme (2.9)). *There exists at least one discrete solution v of the scheme* (2.9) *in the sense of Definition* 5.1.

Proof of Proposition 5.3. We assume that there exists a solution v^n at step n, and we will construct a solution v^{n+1} at step $n+1$. First, we remark that if $(v^{n+1,i})_i$ is a family indexed by i of a discrete subsolution at step $n+1$, then $v^{n+1} = \max\, v^{n+1,i}$ is still a subsolution (it suffices to use Lemma 5.2). Moreover, $w^+ = \sup_{Q^\Delta} |v^n|$ and $w^- = -\sup_{Q^\Delta} |v^n|$ are, respectively, a discrete supersolution and a subsolution of the scheme (2.9). Then, let us define

$$v^{n+1} = \max\{w \text{ subsolution at step } n+1 \text{ such that } w \le w^+\}.$$

Then v^{n+1} is a discrete subsolution at step $n+1$. Now let us prove that v^{n+1} is a supersolution. By contradiction, assume that there is I such that

$$\frac{v_I^{n+1} - v_I^n}{\Delta t} < \tilde{c}[v]_I^{n+1} G^{\tilde{s}[v]_I^n}(D^+ v_I^{n+1}, D^- v_I^{n+1}).$$

This implies in particular that $v_I^{n+1} < w^+$. Now let us consider the solution w_I (in a sense similar to Definition 5.1) of

$$\frac{w_I - v_I^n}{\Delta t} = c^\Delta_{v^{n+1}}[w]_I \begin{cases} G^+(D^+_{v^{n+1}} w_I, D^-_{v^{n+1}} w_I) & \text{if} \quad c^\Delta_{v^{n+1}}[w]_I \ge 0, \\ G^-(D^+_{v^{n+1}} w_I, D^-_{v^{n+1}} w_I) & \text{if} \quad c^\Delta_{v^{n+1}}[w]_I < 0, \end{cases}$$

where

$$c^{\Delta}_{v^{n+1}}[w]_I = \sum_{J\in\mathbb{Z}^N} \bar{c}^0_{I-J} 1_{\{v^{n+1}_J \geq w_I\}} \Delta x_1,\dots,\Delta x_N - \frac{1}{2}\sum_{J\in\mathbb{Z}^N} \bar{c}^0_J \Delta x_1,\dots,\Delta x_N$$

and $D^{\pm}_{v^{n+1}} w_I = (D^{\pm}_{x_1,v^{n+1}} w_I,\dots,D^{\pm}_{x_N,v^{n+1}} w_I)$ with

$$D^{+}_{x_i,v^{n+1}} w_I = \frac{v^{n+1}_{I^{i,+}} - w_I}{\Delta x_i},$$

$$D^{-}_{x_i,v^{n+1}} w_I = \frac{w_I - v^{n+1}_{I^{i,-}}}{\Delta x_i},$$

where $I^{k,\pm}$ is defined in (5.2). The existence of such a solution comes from the fact that the left-hand side is nondecreasing in w_I and the right-hand side is nonincreasing. Then it is easy to prove (using Lemma 5.2) that $w_I > v^{n+1}_I$ and that w defined by

$$w_J = \begin{cases} w_I & \text{if } J = I, \\ v^{n+1}_J & \text{otherwise} \end{cases}$$

is a discrete subsolution of (2.9) at step $n+1$. This contradicts the definition of v^{n+1} and ends the proof of the proposition.

PROPOSITION 5.4 (properties of the discrete solutions). *Assume that* $\tilde{u}_0 \in W^{1,\infty}(\mathbb{R}^N)$. *Let us denote* $L = |D\tilde{u}_0|_{L^\infty(\mathbb{R}^N)}$ *and*

(5.8)
$$\overline{v} = \sup\{v \text{ subsolution of (2.9) with initial condition } v^0 = \tilde{u}_0, v \leq |\tilde{u}_0|_{L^\infty(\mathbb{R}^N)}\}.$$

For $k \in \mathbb{Z}^N$ *such that* $k\cdot\Delta X > 0$ *(with* $\Delta X = (\Delta x_1,\dots,\Delta x_N)$*), the following estimates hold:*

$$\frac{\overline{v}(x_I,t_n) - \overline{v}(x_I + k\cdot\Delta X, t_n)}{k\cdot\Delta X} \leq L, \tag{5.9}$$

$$\frac{\overline{v}(x_I,t_n) - \overline{v}(x_I + k\cdot\Delta X, t_n)}{k\cdot\Delta X} \geq -L, \tag{5.10}$$

$$\left|\frac{\overline{v}^{n+1}_I - \overline{v}^n_I}{\Delta t}\right| \leq \frac{\sqrt{N}}{2}|c_0|_{L^1(\mathbb{R}^N)}\, L. \tag{5.11}$$

The same estimates hold for

(5.12)
$$\underline{v} = \inf\{v \text{ supersolution of (2.9) with initial condition } v^0 = \tilde{u}_0, v \geq -|u_0|_{L^\infty(\mathbb{R}^N)}\}.$$

Proof of Proposition 5.4. For $k \in \mathbb{Z}^N$, let us denote by

$$\tilde{u}_{0,k}(x_I) = \tilde{u}_0(x_I + k\cdot\Delta X) + Lk\cdot\Delta X \geq \tilde{u}_0(x_I)$$

and by $\overline{v}_k$ the greater subsolution, with initial condition $\tilde{u}_{0,k}$, i.e.,

$$\overline{v}_k = \sup\{v_k \text{ subsolution of (2.9) with initial condition } v^0_k = \tilde{u}_{0,k}, v_k \leq |u_0|_{L^\infty(\mathbb{R}^N)}\}.$$

First, since the equation does not see the constants, we remark that $\overline{v} - Lk \cdot \Delta X$ is a subsolution of (2.9) with initial condition $\overline{v}^0 - Lk \cdot \Delta X \leq \tilde{u}_{0,k}$. Thus, by definition of $\overline{v}_k$, we have

$$\overline{v} - Lk \cdot \Delta X \leq \overline{v}_k.$$

Moreover, using the fact that the scheme is invariant by translation in space, we deduce that $\overline{v}(x_I + k \cdot \Delta X, t_n)$ is the greater subsolution with initial condition $\overline{v}(x_I + k \cdot \Delta X, 0) = \tilde{u}_{0,k}(x_I)$. We then deduce that

$$\overline{v}_k(x_I, t_n) = \overline{v}(x_I + k \cdot \Delta X, t_n).$$

This implies that for $k \cdot \Delta X > 0$

$$\frac{\overline{v}(x_I, t_n) - \overline{v}(x_I + k \cdot \Delta X, t_n)}{k \cdot \Delta X} \leq L.$$

The proof of (5.10) is similar, and we skip it.

To prove (5.11), we use the fact that $\overline{v}$ is a solution and the two previous estimates. This implies

$$-\frac{\sqrt{N}}{2}|c_0|_{L^1(\mathbb{R}^N)}L \leq \frac{\overline{v}_I^{n+1} - \overline{v}_I^n}{\Delta t} \leq \frac{\sqrt{N}}{2}|c_0|_{L^1(\mathbb{R}^N)}L,$$

which is the desired result.

Before proving Theorem 2.3, we need the following lemma.

LEMMA 5.5 (equivalent formulation for the discrete velocity). *The discrete velocity $c^\Delta[v]$ can be rewritten as*

$$c^\Delta[v]_I^n = \left(c_0 \star 1_{\{v_\#(.,t_n) \geq v_\#(x_I,t_n)\}}\right)(x_I) - \frac{1}{2}|c_0|_{L^1(\mathbb{R}^N)},$$

where $v_\#$ is defined in (2.13).

Proof of Lemma 5.5. The idea of the proof is borrowed from Alvarez et al. [2]. Using the definition of the discrete velocity and $\bar{c}^0$, we get

$$\begin{aligned}
c^\Delta[v]_I^n &= \sum_{J \in \mathbb{Z}^N} \bar{c}^0_{I-J} 1_{\{v_J^n \geq v_I^n\}} \Delta x_1, \ldots, \Delta x_N - \frac{1}{2} \sum_{J \in \mathbb{Z}^N} \bar{c}^0_J \Delta x_1, \ldots, \Delta x_N \\
&= \sum_{J \in \mathbb{Z}^N} \int_{Q_{J-I}} c_0(y)\, dy\, 1_{\{v_J^n \geq v_I^n\}} - \frac{1}{2} \sum_{J \in \mathbb{Z}^N} \int_{Q_J} c_0(y)\, dy \\
&= \sum_{J \in \mathbb{Z}^N} \int_{Q_J} c_0(x_I - y)\, 1_{\{v_J^n \geq v_I^n\}}\, dy\, - \frac{1}{2}|c_0|_{L^1(\mathbb{R}^N)} \\
&= \sum_{J \in \mathbb{Z}^N} \int_{Q_J} c_0(x_I - y)\, 1_{\{v_\#(y,t_n) \geq v_\#(x_I,t_n)\}}\, dy\, - \frac{1}{2}|c_0|_{L^1(\mathbb{R}^N)} \\
&= \left(c_0 \star 1_{\{v_\#(\cdot,t_n) \geq v_\#(x_I,t_n)\}}\right)(x_I) - \frac{1}{2}|c_0|_{L^1(\mathbb{R}^N)}.
\end{aligned}$$

This ends the proof of the lemma.

We now prove Theorem 2.3.

Proof of Theorem 2.3. The proof is an adaptation of the proof of Crandall and Lions [11], revisited by Alvarez et al. [1]. Nevertheless, for the reader's convenience, we give the main steps in order to show the new difficulties due to the nonlocal term. The main idea of the proof is the same as that of comparison principles, i.e., to consider the maximum of $u-v_{\#}$, to duplicate the variable, and to use the viscosity inequalities to get the result.

The proof splits into four steps.

We first assume that

$$\bar{u}_0(x_I) \geq (\tilde{u}_0(x_I))_{\#} \quad \forall I \in \mathbb{Z}^N, \tag{5.13}$$

and we set

$$\mu^0 = \sup_{\mathbb{R}^N}(\bar{u}_0 - (\tilde{u}_0)_{\#}) \geq 0. \tag{5.14}$$

We denote throughout by K various constants depending only on N, $|c_0|_{W^{1,1}(\mathbb{R}^N)}$, $|D\bar{u}_0|_{L^\infty(\mathbb{R}^N)}$, $|D\tilde{u}_0|_{L^\infty(\mathbb{R}^N)}$, and μ^0.

Step 1: *Estimate on* v.

We have the following estimate for the discrete solution:

$$-Kt_n \leq \bar{u}_0(x) - v_{\#}(x,t_n) \leq Kt_n + \mu^0. \tag{5.15}$$

To show this, it suffices to use the estimate (5.11) of Proposition 5.4. This implies that, for $x \in Q_I$ (with the notation $\overline{v}$ and $\underline{v}$ defined in Proposition 5.4),

$$\begin{aligned}(\tilde{u}_0)_{\#}(x) - Kt_n = v_I^0 - Kt_n \leq \underline{v}_I^n \leq v_I^n \\ = v_{\#}(x,t_n) \leq \overline{v}_I^n \leq Kt_n + v_I^0 = Kt_n + (\tilde{u}_0)_{\#}(x).\end{aligned}$$

This implies the desired estimate.

Before continuing the proof, we need some notation. We put

$$\mu = \sup_{\mathbb{R}^N}(u - v_{\#}).$$

We want to bound from above μ by μ^0 plus a constant. For every $0 < \alpha \leq 1$, $0 < \gamma \leq 1$, and $0 < \eta \leq 1$, we set

$$M_\eta^{\alpha,\gamma} = \sup_{\mathbb{R}^N \times \mathbb{R}^N \times (0,T) \times \{0,\dots,t_{N_T}\}} \Psi_\eta^{\alpha,\gamma}(x,y,t,t_n)$$

with

$$\Psi_\eta^{\alpha,\gamma}(x,y,t,t_n) = u(x,t) - v_{\#}(y,t_n) - \frac{|x-y|^2}{2\gamma} - \frac{|t-t_n|^2}{2\gamma} - \eta t - \alpha(|x|^2 + |y|^2).$$

We shall drop the super- and subscripts on Ψ when no ambiguity arises concerning the value of the parameter.

The main difference with the classical Crandall–Lions proof is to consider the function $v_{\#}$ in the place of v in the separation of variables. This allows us to treat the nonlocal velocity.

Since u is Lipschitz continuous and $T \leq 1$, we have

$$|u(x,t)| \leq K(1+|x|). \tag{5.16}$$

Moreover, by Step 1, we have

$$\begin{aligned}|v(x_i,t_n)| &\le |v(x_i,t_n)-\bar{u}_0(x_i)|+|\bar{u}_0(x_i)|\\ &\le Kt_n+K(1+|x_i|)\\ &\le K(1+|x_i|).\end{aligned}$$

We then deduce that Ψ achieves its maximum at some point that we denote by (x^*,y^*,t^*,t_n^*).

Step 2: *Estimates for the maximum point of* Ψ.

The maximum point of Ψ enjoys the following estimates:

$$\alpha|x^*|+\alpha|y^*|\le K \tag{5.17}$$

and

$$|x^*-y^*|\le K\gamma,\quad |t^*-t_n^*|\le (K+2\eta)\gamma. \tag{5.18}$$

Indeed, by inequality $\Psi(x^*,y^*,t^*,t_n^*)\ge\Psi(0,0,0,0)\ge 0$, we obtain

$$\begin{aligned}\alpha|x^*|^2+\alpha|y^*|^2 &\le u(x^*,t^*)-v_\#(y^*,t_n^*)\le K(1+|x^*|+|y^*|)\\ &\le K+\frac{K^2}{\alpha}+\frac{\alpha}{2}|x^*|^2+\frac{\alpha}{2}|y^*|^2.\end{aligned}$$

This implies (5.17), since $\alpha\le 1$.

The first bound of (5.18) follows from the Lipschitz regularity in space of u, from the inequality $\Psi(x^*,y^*,t^*,t_n^*)\ge\Psi(y^*,y^*,t^*,t_n^*)$, and from (5.17). The second bound of (5.18) is obtained in the same way, using the inequality $\Psi(x^*,y^*,t^*,t_n^*)\ge\Psi(x^*,y^*,t_n^*,t_n^*)$.

Step 3: *A better estimate for the maximum point of* Ψ.

Inequality (5.17) can be strengthened to

$$\alpha|x^*|^2+\alpha|y^*|^2\le K. \tag{5.19}$$

Indeed, using the Lipschitz regularity of u, the inequality $\Psi(x^*,y^*,t^*,t_n^*)\ge\Psi(0,0,0,0)$, Step 1, and (5.18), we have

$$\begin{aligned}\alpha|x^*|^2+\alpha|x_i^*|^2 &\le u(x^*,t^*)-v_\#(y^*,t_n^*)+u_0(y^*)-u_0(y^*)\\ &\le K(|x^*-y^*|+t^*)+Kt_n^*+\mu^0\le K.\end{aligned}$$

Step 4: *Upper bound of* μ.

We have the bound $\mu\le K\sqrt{T}\,(\Delta x+\Delta t)^{\frac{1}{2}}+\mu^0$ if $\Delta x+\Delta t\le\frac{1}{K^2}$.

First, we claim that for η large enough, we have either $t^*=0$ or $t_n^*=0$. We argue by contradiction. Then the function $(x,t)\mapsto\Psi(x,y^*,t,t_n^*)$ achieves its maximum at a point of $\mathbb{R}^N\times(0,T)$. Then, using the fact that u is a subsolution of (2.8), we deduce that

$$\eta+p_t^*\le c[u](x^*,t^*)|p_x^*+2\alpha x^*|, \tag{5.20}$$

where

$$c[u](x,t)=c_0\star 1_{\{u(\cdot,t)\ge u(x,t)\}}(x)-\frac{1}{2}\int_{\mathbb{R}^N}c_0$$

and

$$p_t^* = \frac{t^* - t_n^*}{\gamma}, \qquad p_x^* = \frac{x^* - y^*}{\gamma}.$$

Since $t_n^* > 0$, we also have $\Psi(x^*, y^*, t^*, t_n^*) \geq \Psi(x^*, y, t^*, t_n)$ for $t_n \geq t_n^* - \Delta t$. This implies that

$$v_\#(y^*, t_n^*) - v_\#(y, t_n) \leq \varphi(y^*, t_n^*) - \varphi(y, t_n) \quad \text{for } t_n \geq t_n^* - \Delta t \tag{5.21}$$

for $\varphi(y, t_n) = -(\frac{|x^*-y|^2}{2\gamma} + \frac{|t^*-t_n|^2}{2\gamma} + \alpha|y|^2)$. We denote by x_I^* the node such that $y^* \in Q_{I^*}$ (the unit cube centered in x_I^*). We then deduce

$$\begin{aligned}
&\frac{\varphi(y^*, t_n^*) - \varphi(y^*, t_n^* - \Delta t)}{\Delta t} \\
&\quad \geq \frac{v_\#(y^*, t_n^*) - v_\#(y^*, t_n^* - \Delta t)}{\Delta t} \\
&\quad = \frac{v(x_I^*, t_n^*) - v(x_I^*, t_n^* - \Delta t)}{\Delta t} \\
&\quad \geq \tilde{c}^\Delta[v](x_I^*, t_n^*) G^{s[v](x_I^*, t_n^*)}(D^+ v(x_I^*, t_n^*), D^- v(x_I^*, t_n^*)) \\
&\quad \geq \tilde{c}^\Delta[v](x_I^*, t_n^*) G^{s[v](x_I^*, t_n^*)}(D^+ \varphi(y^*, t_n^*), D^- \varphi(y^*, t_n^*)),
\end{aligned}$$

where we have used the monotonicity of $G^\pm$ and (5.21) with $t_n = t_n^*$ for the last line. We denote $s^* = s[v](x_I^*, t_n^*)$. Straightforward computations of the discrete derivative of φ yield

$$\begin{aligned}
&p_t^* + \frac{\Delta t}{2\gamma} \\
&\quad \geq \tilde{c}^\Delta[v](x_I^*, t_n^*) G^{s*}\left(p_x^* - \frac{\Delta x}{2\gamma} - \alpha(2y^* + \Delta x),\ p_x^* + \frac{\Delta x}{2\gamma} - \alpha(2y^* - \Delta x)\right).
\end{aligned} \tag{5.22}$$

Subtracting the above inequality from (5.20) yields

$$\begin{aligned}
\eta &\leq \frac{\Delta t}{2\gamma} + c[u](x^*, t^*)|p_x^* + 2\alpha x^*| \\
&\quad - \tilde{c}^\Delta[v](x_I^*, t_n^*) G^{s^*}\left(p_x^* - \frac{\Delta x}{2\gamma} - \alpha(2y^* + \Delta x),\ p_x^* + \frac{\Delta x}{2\gamma} - \alpha(2y^* - \Delta x)\right) \\
&\leq \frac{\Delta t}{2\gamma} + (c[u](x^*, t^*) - \tilde{c}^\Delta[v](x_I^*, t_n^*))|p_x^*| + \alpha K|x^*| + \tilde{c}^\Delta[v](x_I^*, t_n^*) \\
&\quad \times \left| G^{s^*}\left(p_x^* - \frac{\Delta x}{2\gamma} - \alpha(2y^* + \Delta x),\ p_x^* + \frac{\Delta x}{2\gamma} - \alpha(2y^* - \Delta x)\right) - G^{s^*}(p_x^*, p_x^*) \right| \\
&\leq \frac{\Delta t}{2\gamma} + (c[u](x^*, t^*) - \tilde{c}^\Delta[v](x_I^*, t_n^*))|p_x^*| + \alpha K|x^*| \\
&\quad + K\left(\frac{\Delta x}{\gamma} + 2\alpha|y^*| + 2\alpha\Delta x\right).
\end{aligned}$$

We now have to bound the term

$$\begin{aligned}\mathcal{I} &= (c[u](x^*,t^*) - \tilde{c}^{\Delta}[v](x_I^*,t_n^*))|p_x^*| \\ &= (c_0 \star 1_{\{u(\cdot,t^*)\geq u(x^*,t^*)\}}(x^*) - c_0 \star 1_{\{v_\#(\cdot,t_n^*)>v_\#(y^*,t_n^*)\}}(x_I^*))|p_x^*|.\end{aligned}$$

We have to distinguish two cases:

Case 1. Assume that for $\gamma > 0$ fixed $\frac{|x^*-y^*|^2}{\gamma} \geq C_\gamma^2$ for some constant $C_\gamma > 0$ and for all α small.

By inequality $\Psi(x^*,y^*,t^*,t_n^*) \geq \Psi(x,x,t^*,t_n^*)$, we deduce that

$$\begin{aligned}u(x,t^*) - u(x^*,t^*) \leq\ & v_\#(x,t_n^*) - v_\#(y^*,t_n^*) \\ & - \frac{|x^*-y^*|^2}{2\gamma} - \alpha(|x^*|^2+|y^*|^2) + 2\alpha|x|^2.\end{aligned}$$

We then get the inclusion

$$\{u(\cdot,t^*) \geq u(x^*,t^*)\} \cap \{v_\#(\cdot,t_n^*) \leq v_\#(y^*,t_n^*)\} \subset \{|x|^2 \geq R_{\alpha,\gamma}^2\},$$

where $R_{\alpha,\gamma}^2 = \frac{1}{2\alpha}(\frac{|x^*-y^*|^2}{2\gamma} + \alpha(|x^*|^2+|y^*|^2))$. We also have

$$\{|x-x^*| \geq R_{\alpha,\gamma}\} \subset \{|x| \geq \tilde{R}_{\alpha,\gamma}\},$$

where $\tilde{R}_{\alpha,\gamma} = R_{\alpha,\gamma} - |x^*| \to \infty$ as $\alpha \to 0$ (see Da Lio, Forcadel, and Monneau [13, Lemma 2.5]). We then obtain

$$\begin{aligned}\mathcal{I} &\leq (c_0 \star 1_{\{v_\#(\cdot,t_n^*)>v_\#(y^*,t_n^*)\}}(x^*) - c_0 \star 1_{\{v_\#(\cdot,t_n^*)>v_\#(y^*,t_n^*)\}}(x_I^*) \\ &\qquad + c_0 \star 1_{B^c(0,R_{\alpha,\gamma})}(x^*))|p_x^*| \\ &\leq K\left(|Dc_0|_{L^1(\mathbb{R}^N)}|x^*-x_I^*| + \int_{B^c(0,\tilde{R}_{\alpha,\gamma})} c_0(x)dx\right) \\ &< K(\gamma+\Delta x) + o_\alpha(1),\end{aligned}$$

where we have used (5.18) to bound $|p_x^*|$ in the second line.

Case 2. Assume that there exists a subsequence $\alpha_n > 0$ which we still denote by α such that

$$\frac{|x^*-y^*|^2}{\gamma} \to 0 \quad \text{as } \alpha \to 0.$$

We then get that $p_x^* \to 0$ as $\alpha \to 0$. Since the velocities are bounded, we get that $\mathcal{I} = o_\alpha(1)$.

To sum up, we have shown that

$$\mathcal{I} < K(\gamma+\Delta x) + o_\alpha(1).$$

We then get that

$$\eta < K\left(\frac{\Delta x + \Delta t}{\gamma} + \gamma\right) + o_\alpha(1).$$

Putting $\eta^* = K(\frac{\Delta x+\Delta t}{\gamma} + \gamma) + o_\alpha(1)$, we then conclude that either $t^* = 0$ or $t_n^* = 0$ for $\eta \geq \eta^*$.
Whenever $t^* = 0$, we get for $\eta^* \leq \eta \leq 1$

$$M = \Psi(x^*, y^*, 0, t_n^*) \leq u_0(x^*) - v_\#(y^*, t_n^*)$$

$$\leq K|x^* - y^*| + Kt_n^* + \mu^0$$

$$\leq K\gamma + \mu^0.$$

The same result holds whenever $t_n^* = 0$. We then deduce that for $\eta = \eta^*$ and $(x, t_n) \in \mathbb{R}^N \times \{0, \dots, t_{N_T}\}$

$$u(x, t_n) - v_\#(x, t_n) - \eta^* T - 2\alpha|x_I|^2 \leq M \leq K\gamma + \mu^0.$$

Sending $\alpha \to 0$, taking the supremum over (x, t_n), and choosing $\gamma = T^{1/2}(\Delta x + \Delta t)^{1/2}$, we get

$$\mu \leq K(\Delta x + \Delta t)^{1/2}\sqrt{T} + \mu^0,$$

provided that $\Delta x + \Delta t \leq \frac{1}{K^2}$. Using the same arguments of Alvarez et al. [1, Theorem 2], we easily deduce the result in the general case. This ends the proof of Theorem 2.3.

We now point out that there is no consistency error for the scheme (2.15). If there is a consistency error, then there will be a consistency error for the velocities. This means that, for all $\varphi \in C^1(\mathbb{R}^N \times (0, T))$ such that $\|\varphi\|_{C^1(\mathbb{R}^N \times (0,T))} \leq C$, we have

$$c^\Delta[\varphi_{|Q_T^\Delta}]_I^n - c[\varphi](x_I, t_n) \leq f(\Delta x, \Delta t) \tag{5.23}$$

with $f(\Delta x, \Delta t) \to 0$ as $(\Delta x, \Delta t) \to 0$.

PROPOSITION 5.6 (no consistency error). *There is no consistency error for the scheme* (2.15)*; i.e.,* (5.23) *does not hold.*

Proof of Proposition 5.6. We have to prove that there exists a constant $C_0 > 0$ such that for all $\Delta x, \Delta t > 0$ there exists a function φ such that

$$c^\Delta[\varphi_{|Q_T^\Delta}]_I^n - c[\varphi](x_I, t_n) \geq C_0 \quad \text{and} \quad |\varphi|_{C^1(\mathbb{R}^N \times (0,T))} \leq C.$$

To see this, it suffices to take a function φ which oscillates as shown in Figure 1.

Remark 5.7. There is no consistency error, but the scheme is consistent. Indeed, if we fix the function φ in the previous proof, then using the Slepčev lemma [31, eq. (5)], we get

$$\lim_{\Delta x \to 0} c^\Delta[\varphi_{|Q_T^\Delta}]_I^n - c[\varphi](x_I, t_n) = 0.$$

We now point out that the two schemes (2.9) and (2.15) are not monotone.

PROPOSITION 5.8 (nonmonotonicity of the scheme). *The two schemes* (2.9) *and* (2.15) *are not monotone for general* $\bar{c}^0$.

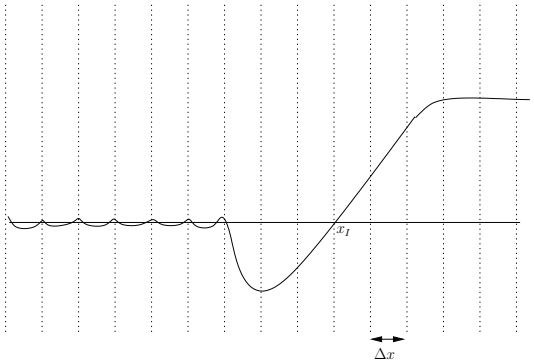

FIG. 1. *Graph of the function φ defined in $\mathbb{R}$.*

Proof of Proposition 5.8.

1. *The implicit scheme* (2.9).
   We give a simple counterexample in the one-dimensional case. We take $\tilde{u}_i^n = v_i^n = i\Delta x$. The goal is to construct a subsolution u^{n+1} and a supersolution v^{n+1} such that

$$u_i^{n+1} = i\Delta x + c_1,$$

$$v_i^{n+1} = i\Delta x + c_2.$$

   A simple computation gives

$$c_1 = \Delta t \sum_{j\geq 0} \bar{c}_j^0 \quad \text{and} \quad c_2 = \Delta t \sum_{j>0} \bar{c}_j^0.$$

   We then deduce that $c_1 - c_2 = \Delta t \bar{c}_0^0 > 0$ (if $\bar{c}_0^0 > 0$). This implies that we can construct two different solutions (the supremum of subsolutions and the infimum of supersolutions). This implies that the scheme (2.9) is not monotone.

2. *The explicit scheme* (2.15).
   We also give a counterexample in the one-dimensional case. We take

$$u_i^n = \begin{cases} -\delta & \text{if } i = 0, \\ 1-\delta & \text{if } i = -1, \\ 0 & \text{otherwise} \end{cases} \quad \text{and} \quad v_i^n = \begin{cases} \delta & \text{if } i = 0, \\ 1-\delta & \text{if } i = -1, \\ 0 & \text{otherwise.} \end{cases}$$

   We then have $u_i^n \leq v_i^n$ for all $i \in \mathbb{Z}$. We then prove that $u_0^{n+1} > v_0^{n+1}$ for δ small enough. First we remark that $c^{\Delta}[v^n]_0 \leq 0$ (if $\sum_{i\neq 0,-1} \bar{c}_j^0 \geq \bar{c}_0^0 + \bar{c}_{-1}^0$), so $v_0^{n+1} \leq \delta$. Moreover,

$$\begin{aligned} u_0^{n+1} &= -\delta + \frac{\Delta t}{\Delta x}\left(\sum_j \bar{c}_j^0 - \frac{1}{2}\sum_j \bar{c}_j^0\right)\sqrt{1+\delta^2} \\ &\geq -\delta + \frac{\Delta t}{\Delta x}\left(\frac{1}{2}|c_0|_{L^1(\mathbb{R})}\right) \\ &> \delta \end{aligned}$$

if

$$\delta < \frac{\Delta t}{2\Delta x}\left(\frac{1}{2}|c_0|_{L^1(\mathbb{R})}\right).$$

This contradicts the monotonicity of the scheme.
This ends the proof of the proposition.

6. Numerical simulations. In this section, we provide some numerical simulations. In subsection 6.1, we explain a method to solve numerically the implicit scheme (2.9)–(2.11). Then we provide a simple simulation concerning a collapsing circle, with the implicit scheme, and another simulation, to highlight the fattening phenomena, with the explicit scheme.

6.1. How do we solve the implicit scheme? To solve (2.9)–(2.11), we will use an iterative process. Assume that we have a solution v^n at step n. We now want to compute a solution v^{n+1} at step $n+1$. To do this, for $\tilde{w} \in \mathbb{R}^{Q^\Delta}$, we denote by $w = \Phi(\tilde{w})$ the solution of the following auxiliary scheme:

$$\frac{w_I - v_I^n}{\Delta t} = c_{\tilde{w}}^{\Delta}[w]_I \begin{cases} G^+(D_{\tilde{w}}^+ w_I, D_{\tilde{w}}^- w_I) & \text{if} \quad c_{\tilde{w}}^{\Delta}[w]_I \geq 0, \\ G^-(D_{\tilde{w}}^+ w_I, D_{\tilde{w}}^- w_I) & \text{if} \quad c_{\tilde{w}}^{\Delta}[w]_I < 0, \end{cases} \tag{6.1}$$

where

$$c_{\tilde{w}}^{\Delta}[w]_I = \sum_{J\in\mathbb{Z}^N} \bar{c}_{I-J}^0 1_{\{\tilde{w}_J \geq w_I\}} \Delta x_1, \ldots, \Delta x_N - \frac{1}{2} \sum_{J\in\mathbb{Z}^N} \bar{c}_J^0 \Delta x_1, \ldots, \Delta x_N$$

and $D_{\tilde{w}}^{\pm} w_I = (D_{x_1,\tilde{w}}^{\pm} w_I, \ldots, D_{x_N,\tilde{w}}^{\pm} w_I)$ with

$$D_{x_i,\tilde{w}}^+ w_I = \frac{\tilde{w}_{I^{i,+}} - w_I}{\Delta x_i},$$

$$D_{x_i,\tilde{w}}^- w_I = \frac{w_I - \tilde{w}_{I^{i,-}}}{\Delta x_i},$$

where $I^{k,\pm}$ is defined in (5.2). Since the left-hand side of (6.1) is nondecreasing in w_I and the right-hand side is nonincreasing, there exists a unique solution (in a sense similar to Definition 5.1) which can be computed using a dichotomy process.

The important point is that if $\tilde{w}$ is a subsolution (resp., supersolution), then $w = (w_I)_I$ is still a subsolution (resp., supersolution) and satisfies $w_I \geq \tilde{w}_I$ (resp., $w_I \leq \tilde{w}_I$) (see the proof of Proposition 5.3).

The idea is then to define $w^0 = v^n - C$, where the constant C is such that w^0 is a subsolution of (2.9), and then to construct iteratively $w^{k+1} = \Phi(w^k)$. Setting $v^{n+1} = \lim_{k\to\infty} w^k$, we have that v^{n+1} is a solution of (2.9).

Remark 6.1. In practice, the kernel $\bar{c}^0$ will be truncated at infinity, and the convolution term will be approximated by a finite sum (see also Remark 2.7).

6.2. A collapsing circle. In this subsection, we provide a simple test with the implicit scheme concerning the evolution of a circle. The goal of this simple simulation is just to check that the circle will disappear at the expected time. We take a circle of radius 1. The parameters are $\Delta x = 0,05$, $\Delta t = 0,01$, and $\varepsilon = 0,3$. Moreover, we take the kernel

$$c_0^\varepsilon = \begin{cases} 1 & \text{if} \quad |x| \leq 0,05, \\ \frac{1}{|\ln \varepsilon||x|^3} & \text{if} \quad 0,05 \leq |x| \leq 2, \\ 0 & \text{if} \quad |x| \geq 2. \end{cases}$$

The initial condition is the distance to the circle. The result is shown in Figure 2.

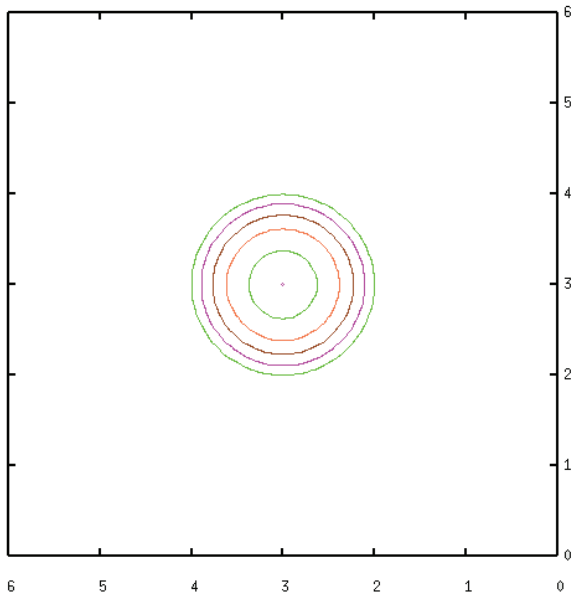

FIG. 2. *Evolution of a circle of radius* 1 *at time* 0, 0.1, 0.2, 0.3, 0.4, *and* 0.49.

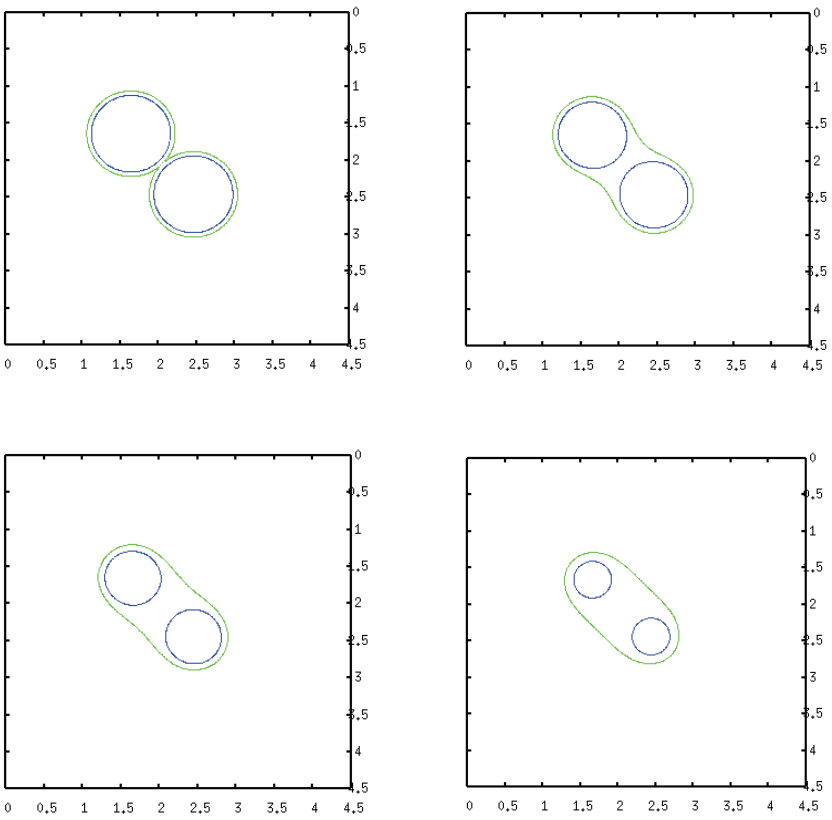

FIG. 3. *Evolution of the figure* 8 *shape at time* 0, 0.05, 0.1, *and* 0.15.

Numerically, the disappearing time is contained between 0.49 and 0.50, which corresponds to what we expect theoretically (the real time is 0.50).

6.3. Fattening phenomena. The second test is concerned with the evolution of the figure 8 shape to point out the fattening phenomena. This test has been made with the explicit scheme. We take two circles of radius $0,58$ such that they are tangent in one point and we look at the evolution of the level set 0 and $-0,06$. The parameters are $\Delta x_1 = \Delta x_2 = 0,01$, $\Delta t = 0,0001$, and $\varepsilon = 0,1$. Moreover, we take the kernel

$$c_0^\varepsilon(x) = \begin{cases} 0 & \text{if} \quad |x| \leq 0,3, \\ \frac{1}{|\ln \varepsilon||x|^3} & \text{if} \quad 0,05 \leq |x| \leq \frac{10}{3}, \\ 0 & \text{if} \quad |x| \geq \frac{10}{3}. \end{cases}$$

The results are provided in Figure 3.

Acknowledgments. The author would like to thank R. Monneau for proposing the problem and for fruitful discussions in the preparation of this paper, and E. Carlini for enlightening discussions about numerical simulations.

A MULTILEVEL PRECONDITIONER FOR THE INTERIOR PENALTY DISCONTINUOUS GALERKIN METHOD*

KOLJA BRIX†, MARTIN CAMPOS PINTO‡, AND WOLFGANG DAHMEN†

Abstract. In this article we present a multilevel preconditioner for interior penalty discontinuous Galerkin discretizations of second order elliptic boundary value problems that gives rise to uniformly bounded condition numbers without any additional regularity assumptions on the solution. The underlying triangulations are assumed only to be shape regular but may have hanging nodes subject to certain mild grading conditions. A key role is played by certain decompositions of the discontinuous trial space into a conforming subspace and a nonconforming subspace that is controlled by the jumps across the edges.

Key words. interior penalty method, energy-stable splittings, admissible averaging operators, frames, multilevel Schwarz preconditioners, discontinuous Galerkin methods

DOI. 10.1137/07069691X

1. Introduction.

An attractive feature of discontinuous Galerkin (DG) discretizations is their suitability for a variety of different problem types as well as the flexibility regarding local mesh refinement and even locally varying the order of the discretization. While initially the main focus has been on transport problems such as hyperbolic conservation laws, interest has shifted recently towards diffusion problems. One simple reason is that such problems naturally enter the picture in more complex applications such as the compressible or incompressible Navier–Stokes equations. By now numerous papers have been devoted to well-posedness and stability issues as well as to the derivation of (a priori and a posteriori) error estimation [2, 1, 13, 18, 19]. In comparison much less rigorous foundation of efficient solution methods for the resulting systems of equations seems to be currently available that covers the above-mentioned full scope of flexibility. An important step in this direction has been [11], which proposes a multigrid scheme (covering actually convection-diffusion problems as well) that does give rise to uniformly bounded condition numbers for diffusive problems provided that (i) the underlying hierarchy of meshes is *quasi-uniform* and (ii) the solution exhibits a certain (weak) extra regularity. Another successful approach, formulated as a two-level scheme in the sense of the auxiliary space method (see, e.g., [4, 17, 21]), was proposed in [10] and exhibits also mesh-independent convergence. However, its theoretical underpinning is also restricted only to quasi-uniform meshes with no hanging nodes.

On the other hand, the local nature of the method suggests a particular suitability for problems with singular behavior calling for inhomogeneous meshes and possibly

‡Institut de Recherche Mathématique Avancée, CNRS–Université Louis Pasteur, 67084 Strasbourg, France (campos@math.u-strasbg.fr, http://www.ann.jussieu.fr/~campos/).

weak regularity requirements. Therefore the main objective of this paper is to present a preconditioner that is optimal in the sense of providing uniformly bounded condition numbers even for meshes that are shape regular but only locally quasi-uniform and may have hanging nodes, arising, e.g., from local mesh refinements. Moreover, no extra regularity assumptions are needed. Our approach is quite different from [11] and uses stable splittings and concepts from the theory of multilevel Schwarz schemes. It can also be understood as a realization of the abstract setting in [17, 21].

In fact, one important by-product of our analysis, that could be reinterpreted in terms of the auxiliary space method, is that a simple splitting of any discontinuous, high order piecewise polynomial space $V_h := \mathbb{P}_k(\mathcal{T}_h)$ based on its first degree conforming subspace (the minimal conforming subspace) is stable with respect to the standard mesh-dependent norm $\|\!|\cdot|\!\|_h$ associated with the DG discretization of an H^1-elliptic boundary value problem (see (2.7)).

A special and somewhat simplified version of these findings can be formulated as follows.

THEOREM 1.1. *Let $\Phi_h := \{\phi_i : i \in \mathcal{I}_h\}$ be a standard local basis of V_h (i.e., each basis function is a piecewise polynomial supported in a single triangle), and let $V_{h,1}^{\mathrm{c}} := H_0^1(\Omega) \cap \mathbb{P}_1(\mathcal{T}_h) \subset V_h$ denote the space of continuous functions that are piecewise affine on $\mathcal{T}_h$. Then*

$$c\,|\!|\!| v |\!|\!|_h^2 \le \inf_{\substack{v^{\mathrm{c}} \in V_{h,1}^{\mathrm{c}},\ d_i \in \mathbb{R} \\ v = v^{\mathrm{c}} + \sum_{i \in \mathcal{I}_h} d_i \phi_i}} \|v^{\mathrm{c}}\|_1^2 + \sum_{i \in \mathcal{I}_h} |\!|\!| d_i \phi_i |\!|\!|_h^2 \le C\,|\!|\!| v |\!|\!|_h^2, \quad v \in V_h,$$

holds for constants c and C independent of $\mathcal{T}_h$, provided that the above-mentioned grading property holds.

However, when permitting hanging nodes due to local refinements, an essential (and necessary) requirement for the validity of such a result is that the triangulation $\mathcal{T}_h$ underlying V_h satisfies a certain mild *grading* property. Given such a grading property, one can prove a certain *local* Jackson-type estimate which is a crucial ingredient of the proof. In fact, a global version of such an estimate also appears in [10]. Thus, in summary, the primary goal of this paper is the rigorous foundation for mesh-independent iterative multilevel schemes for DG discretizations with local mesh refinements and hanging nodes. We are content here with additive schemes, although the quantitative performance of multiplicative versions is expected to be better; see [10, 11].

The layout of the paper is as follows. In section 2 we set notation, formulate the model problem, and recall some relevant facts about the *symmetric interior penalty discontinuous Galerkin method* (SIPG). In section 3 we briefly review the relevant aspects of additive Schwarz schemes that provide the framework for our preconditioners. Specifically, in section 3.1 we point out first that a certain naive attempt motivated by wavelet-type preconditioners does not work. This is unfortunate, since so-called multiwavelets would offer a simple tool in the present context. The explanation for why this fails is instructive in that it highlights the necessity of working with suitable splits of the trial spaces into a conforming part and a part that could be controlled solely by the jumps across element edges. Section 4 is devoted to the identification of suitable stable splittings that give rise to uniformly bounded condition numbers. There are essentially two crucial issues that are perhaps worth mentioning. First, the required grouping of stable splittings into conforming and nonconforming parts requires nontrivial conforming subspaces. When working with local mesh refinements with hanging vertices, this will be seen to boil down to certain mild *grading con-*

ditions on the meshes that are discussed in section 4.1. Second, given such graded meshes, suitable decompositions into conforming and nonconforming subspaces can be obtained through certain averaging projectors. Their essential qualifying property, namely, the *Jackson-type estimate* mentioned above, is developed in section 4.2. In fact, the main result of section 4 is that any split induced by such an admissible projector into a conforming subspace, which can be viewed as an auxiliary space in the sense of [21], gives rise to optimal Schwarz preconditioners by simply taking the union of two stable splittings for the respective subspaces; see Theorem 1.1. Section 5 is then devoted to the detailed concrete realization of a specific admissible averaging projector whose image is the space of continuous piecewise linear finite elements. In this case stable splittings for the conforming part can be invoked from the literature, while the discontinuous piecewise polynomial basis of the whole trial space turns out to be a stable splitting for the corresponding nonconforming subspace. In this case the conforming subspace is minimal. We emphasize though that this is only one possible realization among many other ones. In section 6 we present some first numerical experiments. We conclude with indicating alternatives, based on projectors onto a maximal conforming subspace, whose detailed analysis supported by more extensive numerical quantifications are deferred to a forthcoming paper; see [5].

We shall sometimes write $a \lesssim b$ to mean that a can be bounded by some constant multiple of b where the constant does not depend on any parameters on which a and b may depend. Likewise $a \sim b$ means that both $a \lesssim b$ and $b \lesssim a$ hold.

2. The symmetric interior penalty method—a model problem. Although the subsequent developments carry over to higher spatial dimensions, we shall confine the discussion for simplicity to the two-dimensional case. Thus, let Ω be a bounded polygonal domain in $\mathbb{R}^2$, and let

$$a(u,v) := \int_\Omega (A\nabla u)\cdot\nabla v + \int_\Omega buv, \tag{2.1}$$

where A is a uniformly positive definite 2×2 matrix and b is a nonnegative bounded function on Ω. To avoid quadrature issues, we shall always assume that both A and b are piecewise constant with respect to a fixed coarse *shape regular* conforming triangulation $\mathcal{T}^0 = \mathcal{T}^0(\Omega)$ of Ω. As usual this means that the ratio of the radii of the circumscribed and inscribed circles of all triangles remains uniformly bounded. It will be convenient to work with *closed* triangles; i.e., the triangles K will always be assumed to be closed.

We consider the following model problem: Given $f \in L_2(\Omega)$, find $u \in H_0^1(\Omega)$ (the usual Sobolev space of functions in $L_2(\Omega)$ whose first order weak derivatives belong also to $L_2(\Omega)$ and whose trace vanishes on $\partial\Omega$) such that

$$a(u,v) = \langle f, v\rangle, \quad v \in H_0^1(\Omega). \tag{2.2}$$

The Lax–Milgram theorem ensures the unique solvability of (2.2). In particular, we know that there exist positive constants c_a and C_a depending only on Ω, A, and b such that for $\|v\|_1^2 := \|v\|_{L_2(\Omega)}^2 + \|\nabla v\|_{L_2(\Omega)}^2$ one has

$$c_a\|v\|_1^2 \le a(v,v) \quad \text{and} \quad |a(v,w)| \le C_a\|v\|_1\|w\|_1, \quad v,w \in H_0^1(\Omega). \tag{2.3}$$

We shall discretize (2.2) with a discontinuous Galerkin scheme. To describe this it will be convenient to employ the following localized inner products. For any domain

$G \subseteq \Omega$ we set

$$\langle v, w\rangle_G := \int_G vw, \quad a(v,w)_G := \int_G (A\nabla u)\cdot\nabla v + \int_G buv.$$

2.1. The symmetric interior penalty method on locally refined triangulations. The DG discretization that we shall describe next will be based on triangulations $\mathcal{T}_h = \mathcal{T}_h(\Omega)$ that are generated from some initial shape regular conforming triangulation $\mathcal{T}^0$ through possibly local refinements. The subscript h therefore refers to a piecewise constant *mesh size function* given by $h(K) := \operatorname{diam}(K)$, $K \in \mathcal{T}_h$. In principle, any kind of local refinement is permitted that preserves shape regularity such as a partition based on "newest vertex insertion" or the standard partition of a triangle into four congruent subtriangles. One could think of closing the partitions arising from such local refinements to keep the triangulation conforming (which means that any two distinct closed triangles have an empty intersection or share a common face (edge or vertex)) while preserving shape regularity. We stress though that *nonconforming* triangulations are permitted as well; i.e., *hanging vertices* (sometimes called hanging nodes) may occur; see Figure 2.1. Since the occurrence of hanging vertices does complicate the construction of the preconditioner and its analysis somewhat and since conforming shape regular triangulations may be viewed as simpler special cases, we shall concentrate in the following on situations where hanging vertices occur. As usual we require the triangulations to be graded, meaning that an edge may contain at most one hanging vertex; see Figure 2.1.

Later we shall have to impose a slightly stronger grading property.

By denoting by $\mathbb{P}_k(G)$ the space of all polynomials of total degree at most k over the domain G, we associate with any (admissible) triangulation $\mathcal{T}_h$ the trial space

$$V_h := \mathbb{P}_k(\mathcal{T}_h) := \bigoplus_{K\in\mathcal{T}_h} \mathbb{P}_k(K) = \left\{ v = \sum_{K\in\mathcal{T}_h} \chi_K P_K : P_K \in \mathbb{P}_k(K) \right\}$$

of all (possibly discontinuous) piecewise polynomials of degree at most k on $\mathcal{T}_h$. Here χ_K is the standard indicator function, i.e., $\chi_K(x) = 1$ for $x \in K$ and $\chi_K(x) = 0$ otherwise. The subscript k is thus to be understood (in the same way as the mesh size function h) as a *degree function* taking a constant integer value $k = k(K)$ on each triangle $K \in \mathcal{T}_h$ that may vary for different K. However, we shall always assume that a fixed upper bound $\bar{k}$ is never exceeded, i.e., $k \le \bar{k}$ for all $K \in \mathcal{T}_h$.

For the derivation of the symmetric interior penalty method we refer, e.g., to [1, 2]. To formulate it in the present setting we need the following notation. Let $\mathcal{E}_h$ be the set of edges of the triangulation $\mathcal{T}_h$. Since hanging vertices are permitted we shall adopt the convention that whenever an edge has a hanging node it is replaced in $\mathcal{E}_h$ by its two halves. Moreover, $\mathcal{E}_{h,b}$ and $\mathcal{E}_{h,i}$ denote the subsets of boundary and interior edges, respectively. Since triangles are always assumed to be closed sets, for

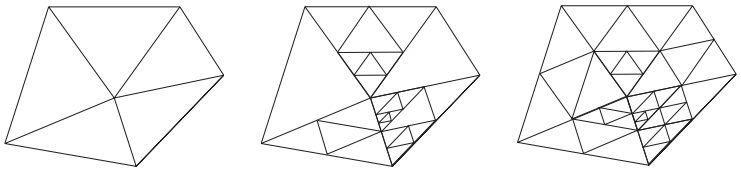

FIG. 2.1. *Coarse $\mathcal{T}^0$ (left), refinement (middle), and graded, shape regular $\mathcal{T}_h$ (right).*

any $e \in \mathcal{E}_{h,i}$ there exist $K, K' \in \mathcal{T}_h$ such that $e = K \cap K'$, and at least one of the two triangles has e as an edge. It will also be convenient to use the abbreviation

$$v^K := \chi_K v.$$

Thus for any $v \in V_h$ and $K \in \mathcal{T}_h$ it makes sense to denote by $v^K|_e$ the trace of the restriction of v to K on the subset e of ∂K. As usual the jump of v across e is then defined as

$$[v]_e := \mathbf{n}_{K,e}\, v^K|_e + \mathbf{n}_{K',e}\, v^{K'}|_e,$$

where $\mathbf{n}_{K,e} = -\mathbf{n}_{K',e}$ denotes the unit normal vector on e pointing to the exterior of K. When $e \in \mathcal{E}_{h,b}$ is a boundary edge we think of v being extended by zero outside Ω. Likewise, averages on e are defined as

$$\{v\}_e := \begin{cases} \frac{1}{2}(v^K|_e + v^{K'}|_e), & e \in \mathcal{E}_{h,i}, \\ v^K|_e, & e \in \mathcal{E}_{h,b} \end{cases}$$

(and we shall drop the subscript e when it is obvious from the context). Given $\mathcal{T}_h$, consider the bilinear form on V_h

(2.4)
$$a_h(v,w) := \sum_{K\in\mathcal{T}_h} a(v,w)_K - \sum_{e\in\mathcal{E}_h} \int_e \big(\{A\nabla w\}\cdot[v] + \{A\nabla v\}\cdot[w]\big) + \sum_{e\in\mathcal{E}_h} \frac{\gamma}{|e|}\int_e [w]\cdot[v].$$

Here γ is a positive (possibly piecewise) constant that has to be chosen appropriately to ensure stability of the method; see relation (2.7) below and, e.g., [19]. Its existence is usually argued under slightly different assumptions on the underlying meshes, but the argument easily carries over.

In fact, the only points to be addressed are perhaps the occurrence of a hanging vertex and a possible local variation of γ depending on the coefficients in (2.1). By applying a Cauchy–Schwarz inequality to (2.4), one gets

$$a_h(v,v) \geq \sum_{K\in\mathcal{T}_h} a(v,v)_K - 2\left(\sum_{e\in\mathcal{E}_h} \frac{|e|}{\sigma}\|\{A\nabla v\}\|^2_{L_2(e)}\right)^{1/2}\left(\sum_{e\in\mathcal{E}_h}\frac{\sigma}{|e|}\|[v]\|^2_{L_2(e)}\right)^{1/2} + \sum_{e\in\mathcal{E}_h}\frac{\gamma}{|e|}\|[v]\|^2_{L_2(e)}.$$

When $e = K \cap K'$ is an edge of K' but only half of an edge of K (see also Figure 4.1 in section 4), we can write for $v \in V_h$ the restriction v^K as $\sum_{J\in\boldsymbol{C}(K)} v^J$, where $\boldsymbol{C}(K)$ is the set of "children" triangles partitioning K; see section 4.1. Hence, by denoting by $\lambda_{\max\,/\,\min}(A)$ the maximal/minimal eigenvalue of A and defining for $\omega \subseteq \Omega$

$$\underline{\lambda}_\omega := \inf_{x\in\omega} \lambda_{\min}(A(x)), \quad \overline{\lambda}_\omega := \sup_{x\in\omega} \lambda_{\max}(A(x)), \tag{2.5}$$

the usual combination of a trace inequality with an inverse inequality yields

$$\begin{aligned} |e|\|\{A\nabla v\}\|^2_{L_2(e)} &\leq C(\|A\nabla v\|^2_{L_2(K')} + \|A\nabla v\|^2_{L_2(J)}) \\ &\leq C \max_{J'=K',J}\{\overline{\lambda}_{J'}\}\, a(v,v)_{K'\cup J}, \end{aligned} \tag{2.6}$$

where $J \subset K$ is the child of K adjacent to K' and the constant C depends on the shape properties of $\mathcal{T}^0$ and $\bar{k}$. Employing then Young's inequality in combination with (2.6) and a suitable choice of $\sigma > 0$ shows that there is indeed a positive γ (see Remark 2.1 below) such that

$$a_h(v,v) \geq \bar{c}\left(\sum_{K\in\mathcal{T}_h} a(v,v)_K + \sum_{e\in\mathcal{E}_h} \frac{\gamma}{|e|}\|[v]\|^2_{L_2(e)}\right) =: \bar{c}\,|\!|\!|v|\!|\!|_h^2\,, \quad v \in V_h, \tag{2.7}$$

for some uniform constant $\bar{c}$ that could actually be made $\bar{c} = \frac{1}{2}$, which yields the desired stability.

Remark 2.1. If we allow γ to vary, we should take $\gamma \geq 2\sigma$ where, for any edge of K, σ and hence γ should be of the order of $\overline{\lambda}_K$ up to constants depending on the shape properties of $\mathcal{T}^0$ and the degree k of the piecewise polynomials but not on h.

The same type of estimate establishes continuity

$$|a_h(v,w)| \leq \bar{C}\,|\!|\!|v|\!|\!|_h\,|\!|\!|w|\!|\!|_h\,, \quad v,w \in V_h, \tag{2.8}$$

for some uniform constant $\bar{C}$ that could actually be made $\bar{C} = \frac{3}{2}$ when taking γ sufficiently large but again of the order of $\overline{\lambda}_K$ locally. (In fact, continuity could be established even in a larger infinite-dimensional space; see, e.g., [13].) Hence, the problem

$$\text{find} \;\; u_h \in V_h \quad \text{such that} \;\; a_h(u_h,v) = \langle f, v\rangle \quad \forall v \in V_h \tag{2.9}$$

has a unique solution, where a_h is the symmetric bilinear form defined on V_h by (2.4).

Unfortunately, as in the case of conforming discretizations the corresponding linear systems of equations grow increasingly ill conditioned when the mesh size decreases. For instance, for quasi-uniform $\mathcal{T}_h$ the spectral condition numbers of stiffness matrices are known to grow like h^{-2}; see, e.g., [11].

3. Additive Schwarz schemes. It is now known that, for nonconforming discretizations, the abstract two-level method (see, e.g., [4, 17, 21]) allows us to reduce the task of preconditioning the resulting system to that of preconditioning an auxiliary system resulting from some auxiliary *conforming* discretization. In this section we shall explain why a "direct" classical multiwavelet approach fails to yield optimal preconditioners, and by following [16, 17] we shall formulate the more general framework for two-level methods and additive Schwarz schemes in the DG context that give rise to uniformly bounded condition numbers for the above type of discretizations under no additional regularity requirements on the solution u of (2.2).

3.1. A way that does not work. Schwarz-type preconditioners for conforming discretizations are closely related to change-of-basis preconditioners when energy space stable multiscale bases are available [7, 8]. To explain this, suppose that $\Psi = \{\psi_i : i \in \mathcal{I}\}$ is a basis of V_h, and recall that the spectral condition number $\kappa(\mathbf{L}_h^\Psi)$ of the stiffness matrix $\mathbf{L}_h^\Psi := (a_h(\psi_i,\psi_j))_{i,j\in\mathcal{I}}$ is given by

$$\kappa(\mathbf{L}_h^\Psi) = \left(\sup_{\mathbf{v}\neq\mathbf{0}} \frac{\mathbf{v}^T\mathbf{L}_h^\Psi\mathbf{v}}{\mathbf{v}^T\mathbf{v}}\right)\left(\inf_{\mathbf{v}\neq\mathbf{0}} \frac{\mathbf{v}^T\mathbf{L}_h^\Psi\mathbf{v}}{\mathbf{v}^T\mathbf{v}}\right)^{-1}.$$

Now according to (2.7) and (2.8), by writing $\mathbf{v} = (v_i)_{i\in\mathcal{I}} \neq \mathbf{0}$ we have, for $v = \sum_{i\in\mathcal{I}} v_i\psi_i$,

$$\frac{\mathbf{v}^T\mathbf{L}_h^\Psi\mathbf{v}}{\mathbf{v}^T\mathbf{v}} = \frac{a_h(v,v)}{\|\mathbf{v}\|^2_{\ell^2}} \sim \frac{|\!|\!|v|\!|\!|_h^2}{\|\mathbf{v}\|^2_{\ell^2}}.$$

This immediately yields the following fact.

Remark 3.1. If Ψ is stable in the sense that

$$\|\!|v|\!\|_h^2 \sim \sum_{i\in\mathcal{I}} |v_i|^2 \, \|\!|\psi_i|\!\|_h^2 \tag{3.1}$$

for any $v = \sum_{i\in\mathcal{I}} v_i\psi_i$ in V_h, then an optimal preconditioner is obtained by a symmetric diagonal scaling; namely, we have

$$\kappa(\mathbf{D}\mathbf{L}_h^{\Psi}\mathbf{D}) \sim 1, \quad \text{with} \quad \mathbf{D} = \operatorname{diag}\big(\, \|\!|\psi_i|\!\|_h^{-1} : i \in \mathcal{I}\big).$$

In the conforming case such energy space stable bases are typically derived from L_2-Riesz multilevel bases by rescaling. In the DG context it is very easy to construct L_2-stable multilevel bases for V_h by using the concept of multiwavelets. One might therefore be tempted to construct a change-of-basis preconditioner by suitably rescaling such a multiwavelet basis. For such a multilevel basis of V_h, a refinement $\mathcal{T}_{h'}$ of the mesh $\mathcal{T}_h$ entails expanding the current basis Ψ_h for V_h to the larger basis $\Psi_{h'}$ by adding a collection of new basis functions (on corresponding locally higher refinement levels) that span a complementary space W of V_h so that $V_{h'} = V_h \oplus W$. In the case of multiwavelets all basis functions would consist of globally discontinuous piecewise polynomials, and in the present context this turns out to cause a principal problem that we describe now.

Consider a *discontinuous* basis function ψ_i of Ψ, and assume that it belongs to some space V_h. Clearly there is at least one edge e in $\mathcal{E}_h$ for which $\|[\psi_i]\|_{L_2(e)}$ is positive. Now, if $\mathcal{T}_{h'}$ is a refinement of $\mathcal{T}_h$ where e is uniformly refined into 2^l pieces, we have

$$\|\!|\psi_i|\!\|_{h'}^2 \geq \sum_{e'\in\mathcal{E}_{h'}:e'\subset e} \frac{\gamma}{|e'|}\|[\psi_i]\|_{L_2(e')}^2 = 2^l\,\frac{\gamma}{|e|}\|[\psi_i]\|_{L_2(e)}^2.$$

Hence $\|\!|\psi_i|\!\|_{h'}$ tends to infinity as the edge e is further refined. As a first consequence, this shows that the ψ_i will not remain normalized when progressing to higher levels of refinements causing the mesh-dependent norm $\|\!|\cdot|\!\|_h$ to change.

This does not exclude yet stability in the sense of (3.1). On the other hand, the energy norm of a *continuous* $v \in V_h$ reduces to $a(v,v)^{1/2}$ and hence does not depend on the mesh. If ψ_i remains unchanged when expanding the basis of V_h to a basis of $V_{h'}$, the associated coordinate v_i does not change either. The desired stability of Ψ would thus yield

$$a(v,v) = a_h(v,v) = \|\!|v|\!\|_{h'}^2 \sim \sum_{i'\in\mathcal{I}_{h'}} |v_{i'}|^2 \, \|\!|\psi_{i'}|\!\|_{h'}^2 \geq |v_i|^2 \, \|\!|\psi_i|\!\|_{h'}^2 \,,$$

which clearly implies that $v_i = 0$, since otherwise the (constant) quantity $a(v,v)$ would have to tend to infinity with $h' \to 0$.

From this observation we infer that, when Ψ is a uniformly stable multilevel basis for the spaces V_h, it must have a subset Ψ^{c} that spans the conforming spaces $V_h^{\mathrm{c}} := V_h \cap H_0^1(\Omega)$. In particular, Ψ and V_h, respectively, decompose into

$$\Psi = \Psi^{\mathrm{c}} \cup \Psi^{\mathrm{nc}} \quad \text{and} \quad V_h = V_h^{\mathrm{c}} \oplus V_h^{\mathrm{nc}}$$

in such a way that subsets of Ψ^{c} and Ψ^{nc} are stable bases for V_h^{c} and V_h^{nc}, respectively, and that the splitting is stable with respect to the discrete energy norm $\|\!|\cdot|\!\|_h$.

This observation that appears to exclude standard multiwavelets will guide the subsequent developments.

3.2. Additive Schwarz preconditioners. It is of course not necessary to construct stable multilevel bases to produce efficient preconditioners for the problem (2.9) of finding $u_h \in V_h$ such that

$$a_h(u_h, v) = \langle f, v\rangle, \quad v \in V_h. \tag{3.2}$$

In fact, the theory of *two-level methods* and *additive Schwarz schemes* offers a more flexible framework based on so-called stable splittings for the respective energy space which in turn permit redundant systems, namely, frames. Such stable splittings for the DG setting will be constructed in section 4.3 below. First let us briefly recall the notion of such splittings and under which circumstances they give rise to good Schwarz preconditioners. The collection

$$\mathcal{S} = \{V_i\}_{i\in\mathcal{I}_h}, \qquad V_i \subset V_h,$$

is called a ($|||\cdot|||_h$-)stable splitting of V_h, uniformly with respect to all triangulations $\mathcal{T}_h$ of the specified type, if $\sum_{i\in\mathcal{I}_h} V_i = V_h$ and

$$c_S\,|||v|||_h^2 \le \inf_{\substack{v_i\in V_i\\ v=\sum_{i\in\mathcal{I}_h} v_i}} \left\{\sum_{i\in\mathcal{I}_h} |||v_i|||_h^2\right\} \le C_S\,|||v|||_h^2\,, \quad v \in V_h, \tag{3.3}$$

holds with constants c_S and C_S independent of $\mathcal{T}_h$.

With the aid of such stable splittings one can transform (3.2) into an equivalent problem which will be uniformly well conditioned.

To this end, the next ingredients are auxiliary inner products on the spaces V_i, namely,

$$b_i(\cdot,\cdot) : V_i \times V_i \to \mathbb{R}, \quad i \in \mathcal{I}_h,$$

yielding norms that are locally equivalent to $|||\cdot|||_h$, i.e., satisfy

$$c_b\,|||v_i|||_h^2 \le b_i(v_i, v_i) \le C_b\,|||v_i|||_h^2\,, \quad v_i \in V_i,\ i \in \mathcal{I}_h, \tag{3.4}$$

for constants c_b and C_b depending at most on the maximal degree $\bar{k}$, the shape properties of $\mathcal{T}^0$, and possibly the coefficients in the bilinear form $a(\cdot,\cdot)$ (see (4.37) below for concrete choices).

Finally, define the operators $P_i : V_h \to V_i$ and elements $f_i \in V_i$ by

$$b_i(P_i w, v_i) = a_h(w, v_i), \quad b_i(f_i, v_i) = \langle f, v_i\rangle, \quad v_i \in V_i,\ i \in \mathcal{I}_h. \tag{3.5}$$

Note that, whenever $V_i = \operatorname{span}(\theta_i)$ is a one-dimensional space, the application of P_i just amounts to solving a linear equation with a single unknown, namely,

$$P_i w = d_i\theta_i \quad\Longleftrightarrow\quad d_i = a_h(w,\theta_i)/b_i(\theta_i,\theta_i). \tag{3.6}$$

The central result we shall use reads then as follows; see, e.g., [16, 12].

THEOREM 3.1. *Define $P_h : V_h \to V_h$ and $\bar{f}_h \in V_h$ by*

$$P_h := \sum_{i\in\mathcal{I}_h} P_i, \qquad \bar{f}_h := \sum_{i\in\mathcal{I}_h} f_i. \tag{3.7}$$

Then the problem (3.2) *is equivalent to the operator equation*

$$P_h u_h = \bar{f}_h. \tag{3.8}$$

Moreover, if (3.3) *and* (3.4) *hold, then the spectral values of the symmetric positive definite (with respect to the inner product $a_h(\cdot,\cdot)$) operator P_h can be bounded by constants independent of $\mathcal{T}_h$, namely,*

(3.9)
$$\frac{\bar{c}}{C_b C_S} \leq \lambda_{\min}(P_h) := \inf_{\substack{v\in V_h\\ v\neq 0}} \frac{a_h(P_h v, v)}{a_h(v,v)}, \qquad \sup_{\substack{v\in V_h\\ v\neq 0}} \frac{a_h(P_h v, v)}{a_h(v,v)} =: \lambda_{\max}(P_h) \leq \frac{\bar{C}}{c_b c_S},$$

where $\bar{c} = \frac{1}{2}$ and $\bar{C} = \frac{3}{2}$ are the constants from (2.7) *and* (2.8)*, respectively. In particular, the spectral condition number of P_h is bounded independently of $\mathcal{T}_h$:*

$$\kappa(P_h) := \frac{\lambda_{\max}(P_h)}{\lambda_{\min}(P_h)} \leq \frac{\bar{C} C_b C_S}{\bar{c} c_b c_S}. \tag{3.10}$$

Obviously the complexity of applying the operator P_h in some iterative procedure has linear complexity when the dimension of the subspaces V_i is uniformly bounded. Such stable splittings will be constructed in sections 4.3 and 5 below; see in particular Corollary 5.3 for one specific realization.

Now, to interpret the above result, let us view (3.2) as the operator equation

$$L_h u_h = f_h, \quad \text{where } L_h \text{ is defined by } \quad \langle L_h w, v\rangle = a_h(w,v), \qquad w, v \in V_h,$$

and f_h is the L_2-orthogonal projection of f on V_h. Moreover, by defining $L_i : V_i \to V_i$ by $b_i(w_i, v_i) = \langle L_i w_i, v_i\rangle$ (i.e., L_i^{-1} is the approximate inverse of the restriction of L_h to V_i) and denoting by $Q_i : V_h \to V_i$ the V_i-orthogonal projection, we have by definition

$$P_i = L_i^{-1} Q_i L_h.$$

Therefore, we can write as usual

$$P_h u = \left(\sum_{i\in\mathcal{I}_h} L_i^{-1} Q_i\right) L_h u \quad \text{and} \quad \bar{f} = \left(\sum_{i\in\mathcal{I}_h} L_i^{-1} Q_i\right) f_h; \tag{3.11}$$

i.e., the operator

$$\mathcal{C}_h := \sum_{i\in\mathcal{I}_h} L_i^{-1} Q_i \tag{3.12}$$

can be viewed as a preconditioner.

4. Stable splittings for the DG method. This section is devoted to the construction and analysis of stable multilevel splittings for the DG method that can be used in Theorem 3.1. There are two ingredients that are perhaps worth emphasizing.

- The first one is that stable splittings for V_h can simply be assembled from stable splittings for an appropriate conforming and nonconforming part of V_h, respectively. The appropriateness will hinge on certain admissible averaging operators that are required to satisfy a Jackson estimate. In fact, this estimate would also allow one to conclude optimality of the preconditioners by utilizing the abstract framework of general two-level (also called "auxiliary space") methods in [4, 17, 21]. Indeed, this approach has been applied in [10] to a variety of DG schemes, including SIPG, but under the restriction that the meshes are quasi-uniform and have no hanging nodes.

- Second, the locality of such an estimate, however, turns out to impose a slightly stronger notion of gradedness (see Definition 4.1 below) for the underlying meshes (without actually inflating the complexity; see Remark 4.2 below) which we shall therefore address first.

4.1. Admissible triangulations—extended grading. We have already defined a standard grading requirement prohibiting an edge to have more than one hanging vertex. The grading that we shall have to impose on the triangulations will actually be slightly stronger but essentially keeps the complexity equivalent; see Remark 4.2 below.

To limit technicalities we shall consider only triangulations that are obtained by local subdivisions into four congruent subtriangles, starting from a conforming and shape regular coarse $\mathcal{T}^0$, as in Figure 2.1. As a consequence, every element of $\mathcal{T}_h$ has a *refinement level* $j(K)$, where $j(K) = 0$ means that $K \in \mathcal{T}^0$. From the shape regularity of $\mathcal{T}_h$ (inherited from that of $\mathcal{T}^0$), one then easily infers that

$$|K| := \operatorname{meas}(K) \sim (h|_K)^2 \sim 2^{-2j(K)} \quad \text{for any} \quad K \in \mathcal{T}_h, \tag{4.1}$$

with constants that depend only on the coarse $\mathcal{T}^0$.

DEFINITION 4.1 (graded triangulations). *A triangulation $\mathcal{T}_h$ obtained from refining a conforming coarse $\mathcal{T}^0$ as described above is called* graded *if every hanging vertex n is the midpoint of an edge spanned by two vertices, denoted by n' and n'' in Figure* 4.1 *(left) and if in such a case n' and n'' are never hanging vertices themselves.*

Note that this grading requirement implies the usual one; i.e., there is at most one hanging vertex per edge.

Remark 4.1 (necessity of the (extended) grading). The above grading requirement is necessary for Theorem 1.1 (and further similar splittings) to hold.

To see the validity of the above claim consider one triangulation $\mathcal{T}_h$ that has been obtained from one single coarse triangle $\mathcal{T}^0 = \{K_0\}$ by recursively refining the central child at each level up to some j_h, as shown in Figure 4.1 (right). Clearly, such a $\mathcal{T}_h$ satisfies the "classical" grading requirement permitting only one hanging vertex per edge but not the above stronger one. In particular, all of its vertices except those on $\partial\Omega$ are hanging, so that $H^1_0(\Omega) \cap \mathbb{P}_1(\mathcal{T}_h)$ contains only 0. Hence Theorem 1.1 would imply here that, for any basis $\{\phi_i : i \in \mathcal{I}_h\}$ of $V_h := \mathbb{P}_k(\mathcal{T}_h)$ consisting of local polynomial pieces normalized in L_∞, one has

$$\|\!|v|\!\|_h^2 \sim \sum_{i\in\mathcal{I}_h} |d_i|^2 \quad \text{for every} \quad v = \sum_{i\in\mathcal{I}_h} d_i\phi_i \in V_h, \tag{4.2}$$

with constants independent of the refinement level j_h. Consider now the piecewise constant function $v = \chi_K$, where K is the central triangle on level two. If the ϕ_i are

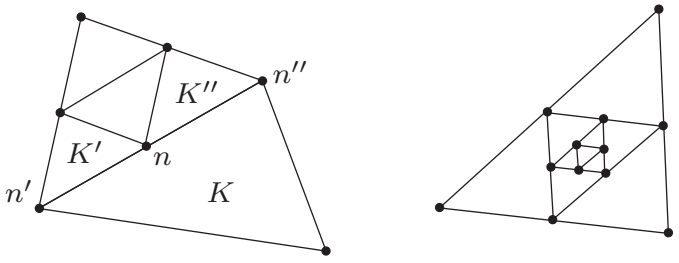

FIG. 4.1. *For $\mathcal{T}_h$ to be graded (the right one is not), n' and n'' must be regular vertices.*

interpolatory, such as in a local Lagrange basis, one has $d_i = 1$ for all but finitely many indices i and the right-hand side in (4.2) grows proportionally to j_h. On the other hand, since v is continuous inside K, it can be seen from the definition of the energy norm given in section 2.1 (see (2.7)) that $\|\!|v|\!\|_h$ does not depend on the further refinements of $\mathcal{T}_h$, which clearly contradicts (4.2).

We shall next give an algorithmic characterization of the grading property in Definition 4.1. Since the triangulations $\mathcal{T}_h$ of interest result from (possibly local) refinements, such a refinement history defines a tree $\widehat{\mathcal{T}}_h$, where $\mathcal{T}_h$ is the set of leaves (i.e., final nodes) of $\widehat{\mathcal{T}}_h$. We denote by $\boldsymbol{P}(K)$ and $\boldsymbol{C}(K)$ the *parent* and set of *children*, respectively, of a given triangle K. This means that any child $K' \in \boldsymbol{C}(K)$ is obtained by subdividing its parent $K = \boldsymbol{P}(K')$ once, according to the given rule. By $\boldsymbol{P}^2(K) = \boldsymbol{P}(\boldsymbol{P}(K))$ we denote the *grandfather* of K when $j(K) \geq 2$.

Also, by $\mathcal{T}^j$ we denote the jth uniform dyadic refinement of $\mathcal{T}^0$. Clearly, for any level j this is a partition of Ω. Given any triangle K in $\mathcal{T}_h$, we then let its *neighbors* $\boldsymbol{N}(K)$ be defined as the collection of triangles at level $j(K)$, i.e., belonging to $\mathcal{T}^{j(K)}$ (but not necessarily to $\widehat{\mathcal{T}}_h$) that share an edge with K. Finally, $\boldsymbol{N}^2(K) := \cup_{K' \in \boldsymbol{N}(K)} \boldsymbol{N}(K')$ consists of the neighbors of the neighbors of K. In these terms a constructive formulation of the grading property reads as follows.

Remark 4.2 (algorithmic formulation of the grading requirement). A triangle K in $\mathcal{T}_h$ is said to have the **G**-property if it is of level $j(K) \leq 1$ or if

- in the case that $\boldsymbol{P}(K)$ is not the central child of $\boldsymbol{P}^2(K)$, every triangle of $\boldsymbol{N}(\boldsymbol{P}(K))$ is in the tree $\widehat{\mathcal{T}}_h$, or
- in the case that $\boldsymbol{P}(K)$ is the central child of $\boldsymbol{P}^2(K)$, every triangle of $\boldsymbol{N}^2(\boldsymbol{P}(K))$ is in the tree $\widehat{\mathcal{T}}_h$.

Then the following properties hold, whose proofs are left to the reader:

1. A triangulation $\mathcal{T}_h$ is graded in the sense of Definition 4.1 if and only if all of its elements satisfy the **G**-property.
2. Given any multilevel triangulation $\mathcal{T}_h$, its smallest graded refinement is built by imposing recursively (starting from the highest levels) the **G**-property on all of its elements.

Therefore the **G**-property is a practical tool for constructing graded triangulations. Moreover, it can be checked that the set

$$\widehat{\mathcal{T}}_h^* := \widehat{\mathcal{T}}_h \cup \bigcup_{K \in \widehat{\mathcal{T}}_h} \boldsymbol{C}(\boldsymbol{N}^2(\boldsymbol{P}(K))) \tag{4.3}$$

is indeed a tree and that the corresponding set of leaves $\mathcal{T}_h^*$ is a refinement of $\mathcal{T}_h$ in which any triangle has the **G**-property. $\mathcal{T}_h^*$ is then a graded refinement of $\mathcal{T}_h$, and it is a standard exercise (see, for instance, Lemma 2.4 in [6]) to derive from (4.3) the following complexity estimates:

$$\#(\mathcal{T}_h^*) \sim \#(\widehat{\mathcal{T}}_h^*) \sim \#(\widehat{\mathcal{T}}_h) \sim \#(\mathcal{T}_h),$$

which hold with uniform constants. Thus, imposing our (extended) grading keeps the complexity of adaptive triangulations up to uniform constants.

We shall henceforth assume that $\mathcal{T}_h$ is graded in the sense of Definition 4.1.

4.2. Admissible conforming subspaces. Given a graded triangulation $\mathcal{T}_h$, it remains to construct energy-stable splittings to be used in Theorem 3.1. Motivated by the observations made in section 3.1, we shall first look at decomposing V_h into a conforming and a nonconforming part V_h^{c} and V_h^{nc}, respectively. However, it turns

out that, in the more general framework offered by Schwarz preconditioners, even the meaning of V_h^c can be relaxed in that it need not exhaust all of $V_h \cap H_0^1(\Omega)$. Different conforming subspaces will be seen to lead to different versions of preconditioners that are all asymptotically optimal in the sense of uniformly bounded condition numbers.

What matters is that the conforming part is the range of a suitable *averaging projector* $\mathcal{A}$ into some subspace of $V_h \cap H_0^1(\Omega)$. In this section we formulate the key property that qualifies the averaging projector as suitable, namely, a certain local Jackson-type estimate involving for each $K \in \mathcal{T}_h$ the localized energy norms

$$|\!|\!| v |\!|\!|_{h,\omega}^2 := \sum_{K \in \mathcal{T}_h : K \subset \omega} a(v,v)_K + \sum_{e \in \mathcal{E}_h : e \subset \omega} \frac{\gamma}{|e|} \|[v]\|_{L_2(e)}^2$$

for certain neighborhoods $\omega = \omega(K) \subset \Omega$ of any $K \in \mathcal{T}_h$.

To define $\omega(K)$ we need some further preparations and notational conventions. The set of vertices, viz., *first degree nodes*, will be denoted by

$$\mathcal{N}_1(K) := \{\text{vertices of } K\} \quad \text{and} \quad \mathcal{N}_{h,1} := \bigcup_{K \in \mathcal{T}_h} \mathcal{N}_1(K).$$

In connection with higher order elements we shall have to consider later corresponding sets of higher kth degree nodes that will be denoted by $\mathcal{N}_k(K)$; see section 4.3.

Moreover, it will be convenient to set for any closed domain D

$$\mathcal{T}_h(D) := \{K \in \mathcal{T}_h : K \cap D \neq \emptyset\}.$$

Similarly we define the sets $\mathcal{N}_{h,1}(D)$ and $\mathcal{E}_h(D)$ for mesh elements touching D. For instance, $\mathcal{T}_h(n)$ consists of the triangles that share the vertex n (including hanging vertices). Note that, when an edge of a triangle K contains a hanging vertex, the collections $\mathcal{N}_1(K)$ and $\mathcal{N}_{h,1}(K)$ differ by that hanging vertex. Unfortunately, due to hanging vertices, straightforward neighborhoods based on these notions do not suffice, and the construction of the domains $\omega(K)$ appearing in the announced Jackson estimate will actually rely on some *extended* sets of mesh quantities.

To this end, recall that for any vertex n there are two possibilities: Either it is hanging (i.e., there is one triangle K in $\mathcal{T}_h(n)$ for which n is not a vertex), and then n is the midpoint of one edge $e = [n', n'']$ of K (see Figure 4.1), or it is not. With these notations we first define

$$\mathcal{N}_{h,1}^*(n) := \begin{cases} \{n, n', n''\} & \text{if } n \text{ is hanging,} \\ \{n\} & \text{otherwise, i.e., if } n \text{ is regular.} \end{cases} \tag{4.4}$$

Recall that the grading we impose on $\mathcal{T}_h$ precisely means that both n' and n'' are regular; see Definition 4.1. For any triangle $K \in \mathcal{T}_h$ we then set

$$\mathcal{N}_{h,1}^*(K) := \bigcup_{n \in \mathcal{N}_1(K)} \mathcal{N}_{h,1}^*(n) \quad \subset \mathcal{N}_{h,1}, \tag{4.5}$$

$$\mathcal{E}_h^*(K) := \bigcup_{n \in \mathcal{N}_{h,1}^*(K)} \mathcal{E}_h(n) \quad \subset \mathcal{E}_h, \tag{4.6}$$

and

$$\mathcal{T}_h^*(K) := \bigcup_{n \in \mathcal{N}_{h,1}^*(K)} \mathcal{T}_h(n) \quad \subset \mathcal{T}_h \tag{4.7}$$

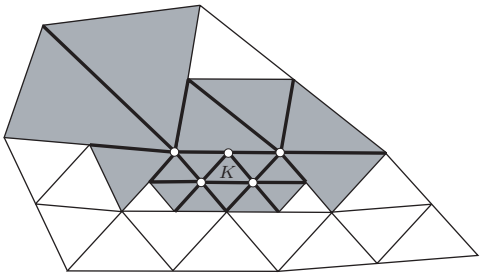

FIG. 4.2. *The neighborhood $\omega(K)$ consists of the union of the (gray) triangles in $\mathcal{T}_h^*(K)$.*

and finally define the domain

$$\omega(K) := \bigcup_{K' \in \mathcal{T}_h^*(K)} K' \quad \subset \Omega \tag{4.8}$$

as the union of triangles that are in contact with the extended set of vertices $\mathcal{N}_{h,1}^*(K)$. An illustration is presented in Figure 4.2, where the sets $\mathcal{N}_{h,1}^*(K)$, $\mathcal{E}_h^*(K)$, and $\mathcal{T}_h^*(K)$ are represented by white vertices, bold edges, and gray triangles, respectively.

Note in particular that the above definitions yield

$$\sum_{K' \in \mathcal{T}_h^*(K)} a(v,v)_{K'} + \sum_{e \in \mathcal{E}_h^*(K)} \frac{\gamma}{|e|} \|[v]\|_{L_2(e)}^2 \le |\!|\!| v |\!|\!|_{h,\omega(K)}^2 . \tag{4.9}$$

We are now prepared to formulate the key property of averaging projectors $\mathcal{A}$ that will be crucial for the subsequent developments.

PROPERTY 4.3. *A linear projector $\mathcal{A}$ that takes V_h into $V_h \cap H_0^1(\Omega)$ is called admissible if for any $v \in V_h$ one has the following Jackson estimate:*

$$\|(I - \mathcal{A})v\|_{L_2(K)} \le C^* 2^{-j(K)} |\!|\!| v |\!|\!|_{h,\omega(K)} , \qquad K \in \mathcal{T}_h, \tag{4.10}$$

with a constant C^* that may depend on the shape properties of $\mathcal{T}^0$ and on $\bar{k}$ (and on concrete realizations of γ). Note that the domains $\omega(K)$ defined by (4.8) *are local (closed) neighborhoods of the triangles $K \in \mathcal{T}_h$ satisfying a bounded overlapping property, i.e.,*

$$\sup_{K \in \mathcal{T}_h} \#\big(\{K' \in \mathcal{T}_h : \omega(K) \cap \omega(K') \neq \emptyset\}\big) \lesssim 1 \tag{4.11}$$

holds with a constant that depends only on $\mathcal{T}^0$.

We postpone the concrete construction of admissible $\mathcal{A}$ and the verification of Property 4.3 to section 4 and discuss first the consequences regarding stable splittings.

The significance of Property 4.3 lies in the following two consequences, summarized in Propositions 4.2 and 4.3. The first one concerns the energy stability of an admissible $\mathcal{A}$.

PROPOSITION 4.2. *Assume that $\mathcal{A}$ satisfies the Jackson estimate* (4.10). *Then one has*

$$|\!|\!| (I - \mathcal{A})v |\!|\!|_h \lesssim |\!|\!| v |\!|\!|_h , \quad |\!|\!| \mathcal{A}v |\!|\!|_h \lesssim |\!|\!| v |\!|\!|_h , \quad v \in V_h, \tag{4.12}$$

where the constants depend on $\bar{k}$ and the shape properties of $\mathcal{T}^0$ as well as on C^* and $\bar{C}_a$ defined in (4.14) *below.*

As a consequence we have

$$\|\!|v|\!\|_h \le \|\!|\mathcal{A}v|\!\|_h + \|\!|(I-\mathcal{A})v|\!\|_h \le C_{\mathcal{A}}\,\|\!|v|\!\|_h\,, \tag{4.13}$$

with the above dependence of the constant $C_{\mathcal{A}}$ in the upper bound.

Proof. Since the jumps of $(I-\mathcal{A})v$ equal the jumps of v we need only estimate $\sum_{K\in\mathcal{T}_h} a((I-\mathcal{A})v,(I-\mathcal{A})v)_K$. To keep track of the dependence of the various constants, recall that $\overline{\lambda}_K$ is defined by (2.5), and let

$$C_{a,K} := 2\max\{\overline{\lambda}_K, 2^{-2j(K)}\|b\|_{L_\infty(K)}\} \ \text{ and } \ \bar{C}_a := \max_{K\in\mathcal{T}_h} C_{a,K} \ \lesssim \ C_a; \tag{4.14}$$

see (2.3). Since $(I-\mathcal{A})v$ is a polynomial on K, a standard inverse estimate yields

$$a((I-\mathcal{A})v,(I-\mathcal{A})v)_K \le cC_{a,K}2^{2j(K)}\|(I-\mathcal{A})v\|^2_{L_2(K)} \ \lesssim \ C^*C_{a,K}\,\|\!|v|\!\|^2_{h,\omega(K)}\,,$$

where c depends on k and $\mathcal{T}^0$ and where we have used (4.10) again in the last step. On account of the bounded overlap of the $\omega(K), K\in\mathcal{T}_h$ (see (4.11)), and since $\|\!|\mathcal{A}v|\!\|_h \le \|\!|v|\!\|_h + \|\!|(I-\mathcal{A})v|\!\|_h$, this concludes the proof. ∎

Thus, by defining

$$V_h^{\rm c} := \mathcal{A}V_h \quad \text{and} \quad V_h^{\rm nc} := (I-\mathcal{A})V_h \tag{4.15}$$

as possible candidates for conforming and nonconforming parts of V_h, respectively, the above observation (4.13) already indicates that a stable splitting for all of V_h of the form (3.3) can be composed of stable splittings for the individual subspaces $V_h^{\rm c}$ and $V_h^{\rm nc}$, respectively. In fact, this would allow us to invoke known splittings for conforming spaces; see, e.g., [3, 7, 12, 16], and section 5.1.1.

Now the second consequence of Property 4.3 is a localization of $V_h^{\rm nc}$ that will simplify the identification of stable splittings for the nonconforming part. In what follows we shall make frequent use of the following simple consequences of standard trace inequalities, rescaling arguments, and the fact that all norms on a fixed finite-dimensional space are equivalent.

Remark 4.4. For any polynomial $P\in\mathbb{P}_k$, any $K\in\mathcal{T}_h$, and any edge e of K, the following relations hold:

(i) One has

$$\|P\|_{L_\infty(e)} \sim |e|^{-1/2}\|P\|_{L_2(e)}, \tag{4.16}$$

where the constants depend only on the degree k of P and on $\mathcal{T}_0$.

(ii) There exists a constant c depending only on the degree k of P and on $\mathcal{T}^0$ such that

$$\|\!|\chi_K P|\!\|_h \le c(C_{a,K}+\gamma)^{\frac12}\left\{\begin{array}{l} 2^{j(K)}\|P\|_{L_2(K)},\\ \|P\|_{L_\infty(K)},\end{array}\right. \tag{4.17}$$

where the constant c depends only on k and on the shape properties of $\mathcal{T}^0$ and $C_{a,K}$ is given by (4.14).

Observe then that splittings for $V_h^{\rm nc}$ will indeed take a simple form due to localization.

PROPOSITION 4.3. *Assume that $\mathcal{A}$ is admissible, i.e., satisfies* (4.10). *Then there exists a constant C_0, depending only on $\bar{k}$, on the shape properties of $\mathcal{T}^0$, on $\bar{C}_a$ defined in* (4.14), *and on the constant C^* in* (4.10) *such that for $w^K := \chi_K w$*

$$\|\!|w|\!\|_h^2 \le \sum_{K\in\mathcal{T}_h} \|\!|w^K|\!\|_h^2 \le C_0\,\|\!|w|\!\|_h^2\,, \quad w\in V_h^{\rm nc} := (I-\mathcal{A})V_h. \tag{4.18}$$

Proof. The lower inequality in (4.18) is due to the fact that for any edge $e \subset K \cap K'$ one has

$$\|[w]\|^2_{L_2(e)} \leq \|w^K\|^2_{L_2(e)} + \|w^{K'}\|^2_{L_2(e)}.$$

As for the upper inequality, since $w \in V_h^{\rm nc}$ and w^K is a polynomial on K, we infer from (4.17) and (4.10) (noticing that $(I-\mathcal{A})w = w$) that

$$\left|\!\left|\!\left| w^K \right|\!\right|\!\right|_h^2 \lesssim (C_{a,K}+\gamma)2^{2j(K)}\|w^K\|^2_{L_2(K)} \lesssim (C_{a,K}+\gamma)C^* \left|\!\left|\!\left| w \right|\!\right|\!\right|^2_{h(\omega(K))}, \tag{4.19}$$

where $C_{a,K}$ can be bounded by C_a from (2.3). The upper inequality follows now again from (4.11). ∎

4.3. Energy-stable splittings for V_h. As mentioned above, the stability of $\mathcal{A}$ asserted by Proposition 4.2 implies that stable splittings for the individual parts $V_h^{\rm c}$ and $V_h^{\rm nc}$ give rise to stable splittings for all of V_h. Moreover, the localization in $V_h^{\rm nc}$ given by Proposition 4.3 together with the fact that the frame for the nonconforming part need actually not be contained in $V_h^{\rm nc}$ greatly simplifies finding such a complementary frame as reflected by the following result (see [5] for placing this in the context of general two-level methods).

THEOREM 4.4. *Let $\{V_i^{\rm c}\}_{i\in\mathcal{I}_h^{\rm c}}$ be a stable splitting for $V_h^{\rm c}$, i.e.,*

$$c_1 a(v,v) \leq \inf_{\substack{v_i\in V_i^{\rm c}\\ v=\sum_{i\in\mathcal{I}_h^{\rm c}} v_i}} \left\{ \sum_{i\in\mathcal{I}_h^{\rm c}} a(v_i,v_i) \right\} \leq C_1 a(v,v), \quad v \in V_h^{\rm c}, \tag{4.20}$$

holds for some constants c_1 and C_1 independent of $\mathcal{T}_h$. Then one has for any $v \in V_h$

$$c_S \left|\!\left|\!\left| v \right|\!\right|\!\right|_h^2 \leq \inf_{\substack{v_K,\ v_i\\ v=\sum_{K\in\mathcal{T}_h} v_K+\sum_{i\in\mathcal{I}_h^{\rm c}} v_i}} \left\{ \sum_{K\in\mathcal{T}_h} \left|\!\left|\!\left| v_K \right|\!\right|\!\right|_h^2 + \sum_{i\in\mathcal{I}_h^{\rm c}} a(v_i,v_i) \right\} \leq C_S \left|\!\left|\!\left| v \right|\!\right|\!\right|_h^2, \tag{4.21}$$

where the v_K and v_i belong to $\chi_K\mathbb{P}_k(K)$ and $V_i^{\rm c}$, respectively, $c_S = \frac{1}{2}\min\{1,c_1\}$, and $C_S = C_{\mathcal{A}}\max\{C_0,C_1\}$ (C_0 being defined in Proposition 4.3).

Thus the collection

$$\mathcal{S} = \{\chi_K\mathbb{P}_k(K) : K \in \mathcal{T}_h\} \cup \{V_i^{\rm c} : i \in \mathcal{I}_h^{\rm c}\} \tag{4.22}$$

is a stable splitting for V_h in the sense of (3.3).

Proof. By definition of the infimum we have

$$\begin{aligned}
&\inf_{\substack{v_K,\ v_i\\ v=\sum_{K\in\mathcal{T}_h} v_K+\sum_{i\in\mathcal{I}_h^{\rm c}} v_i}} \left\{ \sum_{K\in\mathcal{T}_h} \left|\!\left|\!\left| v_K \right|\!\right|\!\right|_h^2 + \sum_{i\in\mathcal{I}_h^{\rm c}} a(v_i,v_i) \right\}\\
&\qquad \leq \inf_{\substack{v_K\\ (I-\mathcal{A})v=\sum_{K\in\mathcal{T}_h} v_K}} \left\{ \sum_{K\in\mathcal{T}_h} \left|\!\left|\!\left| v_K \right|\!\right|\!\right|_h^2 \right\} + \inf_{\substack{v_i\\ \mathcal{A}v=\sum_{i\in\mathcal{I}_h^{\rm c}} v_i}} \left\{ \sum_{i\in\mathcal{I}_h^{\rm c}} a(v_i,v_i) \right\}\\
&\qquad \leq C_0 \left|\!\left|\!\left| (I-\mathcal{A})v \right|\!\right|\!\right|_h^2 + C_1 \left|\!\left|\!\left| \mathcal{A}v \right|\!\right|\!\right|_h^2 \leq C_S \left|\!\left|\!\left| v \right|\!\right|\!\right|_h^2,
\end{aligned} \tag{4.23}$$

where we have used Proposition 4.3 and (4.20) in the second step (remember that $a(\cdot,\cdot)$ and $\left|\!\left|\!\left| \cdot \right|\!\right|\!\right|_h^2$ coincide on $V_h^{\rm c}$) and Proposition 4.2 in the last step. Thus $C_S = C_{\mathcal{A}}\max\{C_0,C_1\}$. This confirms the upper bound in (4.21).

In order to confirm the other direction consider any expansion

$$v = \sum_{K\in\mathcal{T}_h} \tilde{v}_K + \sum_{i\in\mathcal{I}_h^c} \tilde{v}_i =: v_1 + v_2,$$

with $\tilde{v}_K \in \chi_K \mathbb{P}_k(K)$ and $\tilde{v}_i \in V_i^c$. By writing first

$$\|\!|v|\!\|_h^2 \le 2(\|\!|v_1|\!\|_h^2 + \|\!|v_2|\!\|_h^2), \tag{4.24}$$

we note that by (4.20)

$$\|\!|v_2|\!\|_h^2 = a(v_2,v_2) \le c_1^{-1} \inf_{v_2=\sum_{i\in\mathcal{I}_h^c} v_i} \left\{ \sum_{i\in\mathcal{I}_h^c} a(v_i,v_i) \right\} \le c_1^{-1} \sum_{i\in\mathcal{I}_h^c} a(\tilde{v}_i,\tilde{v}_i), \tag{4.25}$$

while as in the proof of Proposition 4.3 one has for any $v_1 = \sum_{K\in\mathcal{T}-h} \tilde{v}_K \in V_h$

$$\|\!|v_1|\!\|_h^2 \le \sum_{K\in\mathcal{T}_h} \|\!|\tilde{v}_K|\!\|_h^2 . \tag{4.26}$$

Thus, we can combine (4.25) and (4.26) to conclude that

$$\|\!|v|\!\|_h^2 \le 2 \left(\sum_{K\in\mathcal{T}_h} \|\!|\tilde{v}_K|\!\|_h^2 + c_1^{-1} \sum_{i\in\mathcal{I}_h^c} a(\tilde{v}_i,\tilde{v}_i) \right).$$

Since the decomposition of v was arbitrary we have shown the lower inequality in (4.21) for $\frac{1}{2}\min\{1,c_1\}$. ∎

Theorem 4.4 covers various possible specifications of splittings which we shall begin to discuss now. Recall first that, in principle, energy-stable splittings for conforming finite element spaces are well understood. Of course, a concrete identification of collections $\{V_i^c\}_{i\in\mathcal{I}_h^c}$ depends on the concrete realization of an admissible projector $\mathcal{A}$, i.e., on the specific subspace $\mathcal{A}V_h$. We postpone this issue to section 5.

At this point we note first that the subspaces $V_K^{nc} := \chi_K \mathbb{P}_k(K)$ are of uniformly bounded finite dimension depending only on $\bar{k}$ and therefore could be further broken down. In fact, any (reasonable) basis for V_h will be seen to be an energy-stable frame for V_h^{nc}. To describe such a basis it is convenient to introduce the principal lattice of order k (also called the canonical k-mesh)

$$\mathcal{N}_k(K) := \left\{ p = p_\beta := \frac{1}{k} \sum_{j=0}^{2} \beta_j n_j : \beta \in \mathbb{Z}_+^3, \sum_{j=0}^{2} \beta_j = k \right\}, \tag{4.27}$$

induced on the triangle K; see Figure 4.3. Of course, for $k = 1$ we simply have

$$\mathcal{N}_1(K) = \{n_0, \ldots, n_2\},$$

the set of vertices of K itself, as used before. Note that the β/k are the barycentric coordinates of the mesh points $p = p_\beta$, a fact that will be used later again. Clearly we have $\dim(\mathbb{P}_k) = \#\mathcal{N}_k(K)$.

Now let $\{P_p : p \in \mathcal{N}_k(\hat{K})\}$ be a fixed basis for $\mathbb{P}_k$, where $\hat{K}$ is the standard triangle with vertices $(0,0)$, $(1,0)$, and $(0,1)$, and define for $K = F\hat{K} \in \mathcal{T}_h$, $F = F_K$ affine,

$$\phi_{K,p} := \chi_K P_p \circ F_K^{-1}, \quad p \in \mathcal{N}_k(K). \tag{4.28}$$

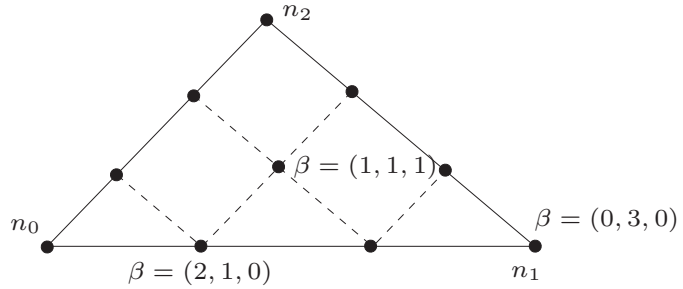

FIG. 4.3. *Principal lattice for $k = 3$, $\mathcal{N}_3(K)$.*

Obviously, $\Phi_h := \{\phi_{K,p} : p \in \mathcal{N}_k(K), K \in \mathcal{T}_h\}$ is a basis for V_h. Later, the reference polynomials P_p will be (essentially) normalized in L_∞ (or in H^1, which is equivalent in $\mathbb{R}^2$). Thus one has

$$\|P_p\|_{L_\infty(\hat{K})} \sim 1, \quad \|\{a_p\}_{p\in\mathcal{N}_k(\hat{K})}\|_{\ell_\infty} \sim \Big\| \sum_{p\in\mathcal{N}_k(\hat{K})} a_p P_p \Big\|_{L_\infty(\hat{K})}, \tag{4.29}$$

with constants depending only on k (and the specific choice of the polynomial basis).

Theorem 4.4 yields then the following general result, where it is seen that a complementary frame is simply given by a union of local polynomial basis functions that do not need to belong to the nonconforming part $V_h^{\rm nc}$ but only to span it.

COROLLARY 4.5. *Assume that $\mathcal{A}$ is admissible (i.e., satisfies the Jackson estimate* (4.10)*), and let $\{V_i^{\rm c} : i \in \mathcal{I}_h^{\rm c}\}$ be any energy-stable splitting for $V_h^{\rm c} := \mathcal{A}V_h$. Moreover, let the basis functions $\phi_{K,p}$ be constructed as above, i.e., satisfy* (4.28)*, and assume that the set of indices*

$$\mathcal{I}_h^{\rm nc} \subseteq \{i = (K,p) : p \in \mathcal{N}_k(K), K \in \mathcal{T}_h\} \tag{4.30}$$

satisfies

$$V_h^{\rm nc} := (I - \mathcal{A})V_h \subseteq \operatorname{span}\{\phi_i : i \in \mathcal{I}_h^{\rm nc}\} =: \operatorname{span}\Phi_h^{\rm nc}. \tag{4.31}$$

Then, by setting $V_i^{\rm nc} := \operatorname{span}\phi_i$, the collection

$$\mathcal{S} = \{V_i^{\rm nc} : i \in \mathcal{I}_h^{\rm nc}\} \cup \{V_i^{\rm c} : i \in \mathcal{I}_h^{\rm c}\} \tag{4.32}$$

is an energy-stable splitting for V_h in the sense of (3.3).

Proof. In view of Theorem 4.4, it suffices to estimate the local contributions $\|\!|w^K|\!\|_h$, $w^K = \chi_K w$, for $w \in V_h^{\rm nc}$. More precisely, we shall prove that

$$\sum_{K\in\mathcal{T}_h} \|\!|w^K|\!\|_h^2 \lesssim \sum_{(K,p)\in\mathcal{I}_h^{\rm nc}} \|\!|w_{K,p}\phi_{K,p}|\!\|_h^2 \lesssim \sum_{K\in\mathcal{T}_h} \|\!|w^K|\!\|_h^2 \tag{4.33}$$

holds with constants depending only on γ, $\bar{k}$, the shape properties of $\mathcal{T}^0$, and the constants C^*, c_a, and C_a in (4.10) and (2.3). Indeed by writing

$$w^K = \sum_{(K,p)\in\mathcal{I}_h^{\rm nc}} w_{K,p}\phi_{K,p},$$

we note from (4.28) and (4.29) that $\|\phi_{K,p}\|_{L_\infty(K)} \sim 1$. Hence, by (4.17) we have $\|\!|w_{K,p}\phi_{K,p}|\!\|_h^2 \lesssim (C_{a,K}+\gamma)|w_{K,p}|^2$ with a further constant factor depending on $\bar{k}$ and the shape properties of $\mathcal{T}^0$. By using the fact that only a fixed finite number (depending on $\bar{k}$) of basis functions are supported on each K, we conclude that

$$\begin{aligned}\|\!|w^K|\!\|_h^2 &\lesssim \sum_{(K,p)\in\mathcal{I}_h^{\mathrm{nc}}} \|\!|w_{K,p}\phi_{K,p}|\!\|_h^2 \lesssim \sum_{(K,p)\in\mathcal{I}_h^{\mathrm{nc}}} |w_{K,p}|^2 \lesssim \left\|\{w_{K,p}\}_{(K,p)\in\mathcal{I}_h^{\mathrm{nc}}}\right\|_{\ell_\infty}^2 \\ &\lesssim \left\|\sum_{(K,p)\in\mathcal{I}_h^{\mathrm{nc}}} w_{K,p}\phi_{K,p}\right\|_{L_\infty(K)}^2 = \|w\|_{L_\infty(K)}^2, \qquad (4.34)\end{aligned}$$

where the constants depend only on $\bar{k}$ as well as on $C_{a,K}$ and γ. Now we use again a scaling/norm equivalence argument and (4.10) to obtain

$$\|w\|_{L_\infty(K)} \lesssim 2^{j(K)}\|w\|_{L_2(K)} \lesssim C^* \|\!|w|\!\|_{h(\omega(K))}, \qquad (4.35)$$

where the remaining unspecified constant factor depends only on $\bar{k}$ and the shape properties of $\mathcal{T}^0$. Finally, we note again that for any edge $e \subset K' \cap K''$ one has $\|[w]\|_{L_2(e)}^2 \le \|w^{K'}\|_{L_2(e)}^2 + \|w^{K''}\|_{L_2(e)}^2$ and hence

$$\|\!|w|\!\|_{h(\omega(K))}^2 \le \sum_{J\in\mathcal{T}_h : J\subset\omega(K)} \|\!|w^J|\!\|_h^2. \qquad (4.36)$$

Combining now (4.34), (4.35), and (4.36) and using again (4.11) yields (4.33) and completes the proof. ∎

For the concrete realization of the preconditioned problem (3.8), it now remains to identify viable choices of the auxiliary bilinear forms $b_i(\cdot,\cdot)$ for $i \in \mathcal{I}_h := \mathcal{I}_h^{\mathrm{c}} \cup \mathcal{I}_h^{\mathrm{nc}}$. Here $\mathcal{I}_h^{\mathrm{c}}$ and $\mathcal{I}_h^{\mathrm{nc}}$ are the index sets for stable splittings $\{V_i^{\mathrm{c}}\}$ and $\{V_i^{\mathrm{nc}}\}$ of V_h^{c} and V_h^{nc}, respectively, as discussed above. Likewise, the conforming splitting typically contains the full coarse grid space. In general, let $\omega(i)$ denote the union of all of the supports of the nodal basis functions spanning the subspace V_i^{c} (which could be all of Ω when i refers to a full coarse level space).

Some admissible choices for the $b_i(v,w)$ are the following:

$$\begin{cases} a(v,w)_K + \sum_{e\in\mathcal{E}_h, e\subset\partial K} \frac{\gamma}{|e|}\int_e [v][w] & \text{or} \\ |K|^{-1}\langle v,w\rangle_K + \sum_{e\in\mathcal{E}_h, e\subset\partial K} \frac{\gamma}{|e|}\int_e [v][w] & \text{when } \ i=(K,p)\in\mathcal{I}_h^{\mathrm{nc}}, \\ a(v,w)_{\omega(i)} & \text{or} \\ |\omega(i)|^{-1}\langle v,w\rangle_{\omega(i)} & \text{when } \ i\in\mathcal{I}_h^{\mathrm{c}}. \end{cases} \qquad (4.37)$$

Remark 4.5. In all of the above cases in (4.37) there exist constants c_b and C_b depending only on the degree k, the shape properties of $\mathcal{T}^0$, and possibly the coefficients in the bilinear form $a(\cdot,\cdot)$ such that (3.4) holds.

Thus we can summarize these findings as follows.

THEOREM 4.6. *Assume that $\mathcal{A}$ is admissible. Then the additive Schwarz preconditioner based on the the above splittings (for the respective realizations of V_h^{c}; see section* 5.1.1*) and for any of the bilinear forms from* (4.37) *is asymptotically optimal in the sense of Theorem* 3.1.

The robustness of the scheme with respect to the diffusion coefficients in $a(\cdot,\cdot)$ will be discussed in more detail elsewhere.

5. Projecting onto the minimal conforming subspace. In principle the results of the previous section offer a general framework for a family of stable splittings and associated preconditioners. In this paper we are content with one specific realization of an admissible projector $\mathcal{A}$ and the identification of corresponding stable splittings for the conforming part. Specifically, we choose $\mathcal{A} = \mathcal{A}_1$ so as to map V_h into continuous *piecewise affine elements*—in this sense the smallest possible subspace of H^1_0-conforming trial functions, i.e.,

$$V^{\mathrm{c}}_{h,1} := \mathcal{A}_1 V_h = H^1_0(\Omega) \cap \mathbb{P}_1(\mathcal{T}_h). \tag{5.1}$$

In general it differs from $V_h \cap H^1_0(\Omega)$ whenever higher degrees are permitted.

An alternative would be to have $\mathcal{A} = \mathcal{A}_k$ produce globally continuous finite elements of the *same degree* as the original discontinuous elements and in that sense to split off the *maximal* conforming subspace in V_h, i.e.,

$$V^{\mathrm{c}}_{h,k} := \mathcal{A}_k V_h = V_h \cap H^1_0(\Omega). \tag{5.2}$$

This is elaborated on in [5].

In principle, such averaging operators are familiar in other contexts concerning DG discretizations; see, e.g., [13]. The form of such projectors in the presence of hanging vertices is to our knowledge less familiar. Since hanging vertices do appear to add some complication we shall give in what follows an explicit self-contained construction.

5.1. The construction of $\mathcal{A}_1$. The construction of $\mathcal{A}_1$ is inspired by the results in [13, 15] but has to cope with hanging nodes. For this reason, let us remember that we call *regular* those vertices that are not hanging. In particular, every vertex on the boundary $\partial\Omega$ is regular. Since boundary vertices are subject to a zero boundary condition in $H^1_0(\Omega)$, we can define $\mathcal{A}_1 v$ by prescribing its nodal values at every interior regular vertex n, following

$$(\mathcal{A}_1 v)(n) := \frac{1}{\#\big(\mathcal{T}_h(n)\big)} \sum_{K \in \mathcal{T}_h(n)} v^K(n). \tag{5.3}$$

Note that the same operator (denoted $\tilde{Q}_1$) is used in [10] to build a two-level method, but there the authors establish the Jackson estimate (4.10) only for piecewise affine DG spaces and in the case where the mesh is quasi-uniform and has no hanging nodes, as far as we understand.

Since $V^{\mathrm{c}}_{h,1}$ is always a subset of V_h (that is, for any degree distribution k), the space

$$V^{\mathrm{nc}}_{h,1} := (I - \mathcal{A}_1) V_h \tag{5.4}$$

stands as a possible candidate for complementing $V^{\mathrm{c}}_{h,1}$; i.e., we have

$$V_h = V^{\mathrm{c}}_{h,1} \oplus V^{\mathrm{nc}}_{h,1}.$$

5.1.1. Energy-stable splittings for $V^{\mathrm{c}}_{h,1}$. To describe an energy frame $\Phi^{\mathrm{c}}_{h,1}$ for $V^{\mathrm{c}}_{h,1}$ we can essentially resort to known results; see, e.g., [20, 22]. In fact $\Phi^{\mathrm{c}}_{h,1}$ has multilevel structure and is comprised by all nodal continuous basis functions associated with all predecessors of $\mathcal{T}_h$ within the tree $\widehat{\mathcal{T}}_h$. To describe this, let us denote again by $\mathcal{T}^j$ the jth uniform dyadic refinement of $\mathcal{T}^0$ and let

$$\mathcal{T}^j_h := \{K \in \mathcal{T}^j : \exists \;\; K' \in \mathcal{T}_h \;\; \text{such that} \;\; K' \subseteq K\} = \mathcal{T}^j \cap \widehat{\mathcal{T}}_h; \tag{5.5}$$

i.e. $\mathcal{T}_h^j$ is comprised of all level j triangles that appear in the refinement history leading to $\mathcal{T}_h$. Moreover, let

$$\Omega_h^j := \bigcup \{K : K \in \mathcal{T}_h^j\}$$

be the area covered by the elements in $\mathcal{T}_h^j$. The subspace $V_{h,1}^{\mathrm{c}} := \mathcal{A}_1 V_h$ consists of all continuous piecewise linear functions on $\mathcal{T}_h$. Consider now $\mathcal{N}_{h,1}^{j,\mathrm{c}}$ the set of those vertices that belong to a triangle in $\mathcal{T}_h^j$ and lie in the interior of Ω_h^j, i.e.,

$$\mathcal{N}_{h,1}^{j,\mathrm{c}} := \bigcup \{\mathcal{N}_1(K) \setminus \partial\Omega_h^j : K \in \mathcal{T}_h^j\}.$$

Note that, since hanging vertices are always located on some boundary $\partial\Omega_h^j$, the vertices in $\mathcal{N}_{h,1}^{j,\mathrm{c}}$ are neither hanging nor do they lie in the boundary of the corresponding domains.

Now define the multilevel index set

$$\mathcal{I}_{h,1}^{\mathrm{c}} := \bigcup \{i = (j,n) : j = 0, \dots, j_h,\ n \in \mathcal{N}_{h,1}^{j,\mathrm{c}}\}, \tag{5.6}$$

where j_h is the maximal level appearing in $\mathcal{T}_h$. With each $i = (j,n) \in \mathcal{I}_{h,1}^{\mathrm{c}}$ we associate now the standard nodal (piecewise affine) hat function φ_i^{c} at the vertex n supported on the star of triangles in $\mathcal{T}_h^j$ sharing n. Clearly φ_i^{c} is continuous, and it immediately follows from (4.17) that

$$\|\!|\varphi_i^{\mathrm{c}}|\!\|_h = a(\varphi_i^{\mathrm{c}}, \varphi_i^{\mathrm{c}})^{1/2} \sim 1, \quad i \in \mathcal{I}_{h,1}^{\mathrm{c}}, \tag{5.7}$$

holds with constants depending only on the constants in (2.3) and on the shape properties of $\mathcal{T}^0$. Now set

$$\Phi_{h,1}^{\mathrm{c}} := \{\varphi_i^{\mathrm{c}} : i \in \mathcal{I}_{h,1}^{\mathrm{c}}\}.$$

It is easy to see that $\Phi_{h,1}^{\mathrm{c}}$ spans $V_{h,1}^{\mathrm{c}}$, and it is known (see, e.g., [16, 12, 7]) that this collection is an energy-stable splitting, i.e.,

$$a(v,v) \sim \inf_{\substack{v_i \in \mathbb{R} \\ v = \sum_{i \in \mathcal{I}_{h,1}^{\mathrm{c}}} v_i \varphi_i^{\mathrm{c}}}} \left\{ \sum_{i \in \mathcal{I}_{h,1}^{\mathrm{c}}} v_i^2 a(\varphi_i^{\mathrm{c}}, \varphi_i^{\mathrm{c}}) \right\}, \quad v \in V_{h,1}^{\mathrm{c}}, \tag{5.8}$$

where the constants depend only on $\mathcal{T}^0$ and the constants c_a and C_a.

5.1.2. The Jackson estimate for $\mathcal{A}_1$. We shall confirm now the validity of Property 4.3 for $\mathcal{A} = \mathcal{A}_1$. To this end, let us first establish the following intermediate result that is valid only for *piecewise affine* functions. Remember that the different sets $\mathcal{E}_h(n)$, $\mathcal{N}_{h,1}^*(n)$, $\mathcal{T}_h(n), \dots$, which denote local neighborhoods made of mesh elements, are defined in section 4.2.

LEMMA 5.1. *If $v \in \mathbb{P}_1(\mathcal{T}_h)$ is a piecewise affine function, then we have for any node $n \in \mathcal{N}_{h,1}$*

$$\left|(v - \mathcal{A}_1 v)^K(n)\right| \le \sum_{n' \in \mathcal{N}_{h,1}^*(n)} \sum_{e \in \mathcal{E}_h(n')} \|[v]\|_{L_\infty(e)} \quad \forall K \in \mathcal{T}_h. \tag{5.9}$$

Proof. We begin with the following basic estimate, independent of the operator $\mathcal{A}_1$: At any vertex $n \in \mathcal{N}_{h,1}$, we have

$$|(v^K - v^{K'})(n)| \le \sum_{e \in \mathcal{E}_h(n)} \|[v]\|_{L_\infty(e)}, \quad K,\ K' \in \mathcal{T}_h(n), \tag{5.10}$$

for any $v \in V_h$. Indeed, since K and K' do not necessarily share an edge, write $\mathcal{T}_h(n) = \{K_1, \ \ldots, K_M\}$ the (closed) triangles containing n, in such a way that K_i and K_{i+1} have the edge $e_i \in \mathcal{E}_h(n)$ as their intersection, and assume that $K = K_M$ and $K' = K_m$, with $m < M$ (observe from the definition of the set $\mathcal{E}_h$ that this is possible even when n is a hanging vertex). It is then easily seen that

$$|(v^K - v^{K'})(n)| \le \sum_{i=m}^{M-1} |(v^{K_{i+1}} - v^{K_i})(n)| \le \sum_{i=m}^{M-1} \|[v]\|_{L_\infty(e_i)},$$

which clearly gives (5.10).

Actually, because the jumps over boundary edges are defined as if v was extended to 0 outside Ω, this argument yields the following estimate when n is on $\partial\Omega$:

$$|v^K(n)| \le \sum_{e \in \mathcal{E}_h(n)} \|[v]\|_{L_\infty(e)}, \qquad n \in \partial\Omega, \ K \in \mathcal{T}_h(n). \tag{5.11}$$

Now to prove the assertion of the lemma we consider $n \in K$ and distinguish three cases: (i) n is on the boundary $\partial\Omega$, (ii) n is a regular vertex in the interior of Ω, and finally (iii) n is hanging; i.e., there is (only) one triangle that contains n and for which n is not a vertex. Note that in the first two cases we have $\mathcal{N}^*_{h,1}(n) = \{n\}$.

In case (i), (5.11) readily yields Lemma 5.1 since then we have $\mathcal{A}_1 v = 0$.

In case (ii) where n is interior and regular, by definition (5.3) of $\mathcal{A}_1$, we have

$$\big|(v - \mathcal{A}_1 v)^K(n)\big| \le \frac{1}{\#(\mathcal{T}_h(n))} \sum_{K' \in \mathcal{T}_h(n)} \big|(v^K - v^{K'})(n)\big|, \tag{5.12}$$

so that Lemma 5.1 now follows from (5.10).

Finally, in case (iii), where n is hanging, denote by K' the unique triangle in $\mathcal{T}_h(n)$ for which n is not a vertex and by $[n', n'']$ the edge of K' for which n is the midpoint. Since both v and $\mathcal{A}_1 v$ are affine on K', we have

$$\big|(v - \mathcal{A}_1 v)^{K'}(n)\big| \le \frac{1}{2}\Big(\big|(v - \mathcal{A}_1 v)^{K'}(n')\big| + \big|(v - \mathcal{A}_1 v)^{K'}(n'')\big|\Big). \tag{5.13}$$

Now from the grading of $\mathcal{T}_h$, we know that n' and n'' are never hanging themselves, so that (5.12) applies, providing, on account of (5.10),

$$\big|(v - \mathcal{A}_1 v)^{K'}(\check{n})\big| \le \sum_{e \in \mathcal{E}_h(\check{n})} \|[v]\|_{L_\infty(e)}, \quad \check{n} = n' \text{ or } n''. \tag{5.14}$$

By writing then

$$\big|(v - \mathcal{A}_1 v)^K(n)\big| \le \big|v^K(n) - v^{K'}(n)\big| + \big|(v - \mathcal{A}_1 v)^{K'}(n)\big|,$$

we prove (5.9) in case (iii) by combining the estimates (5.13), (5.10), and (5.14), since then we have by definition $\mathcal{N}^*_{h,1}(n) = \{n, n', n''\}$; see (4.4). ∎

We are now ready to verify the validity of Property 4.3 for $\mathcal{A}_1$.

PROPOSITION 5.2. *The projector $\mathcal{A}_1$ has Property* 4.3 *where C^* in* (4.10) *depends only on the shape properties of $\mathcal{T}^0$, on $\bar{k}$, and on* $\max_{K' \subset \omega(K)} \underline{\lambda}_{K'}^{-1}$.

Proof. To estimate the projection error $(I - \mathcal{A}_1)v$ consider the interpolation operator $P_1 : V_h \to \mathbb{P}_1(\mathcal{T}_h)$ given by

$$\{P_1 v\}^K(n) := v^K(n), \qquad K \in \mathcal{T}_h, \ n \in \mathcal{N}_1(K), \tag{5.15}$$

for which the estimate

$$\|(I-P_1)v\|_{L_2(K)} \lesssim 2^{-j(K)}\|\nabla v\|_{L_2(K)} \tag{5.16}$$

is well known with a constant depending only on the shape properties of $\mathcal{T}^0$. In view of (5.3), it is readily seen that $\mathcal{A}_1 P_1 = \mathcal{A}_1$, so that the projection error reads

$$(I-\mathcal{A}_1)v = (I-P_1)v + (I-\mathcal{A}_1)P_1 v.$$

By writing $w := (I-\mathcal{A}_1)P_1 v \in \mathbb{P}_1(\mathcal{T}_h)$ it follows that

$$\|(I-\mathcal{A}_1)v\|_{L_2(K)} \lesssim 2^{-j(K)}\|\nabla v\|_{L_2(K)} + \|w\|_{L_2(K)}. \tag{5.17}$$

Now denote by $\{\phi^1_{(K,n)} : n \in \mathcal{N}_1(K)\}$ the discontinuous nodal basis of $\mathbb{P}_1(K)$. On any triangle $K \in \mathcal{T}_h$ we have

$$\|w\|_{L_2(K)} \le \sum_{n\in\mathcal{N}_1(K)} |w^K(n)|\, \|\phi^1_{(K,n)}\|_{L_2} \lesssim \sum_{n\in\mathcal{N}_1(K)} 2^{-j(K)}|w^K(n)|.$$

By applying then Lemma 5.1 to $P_1 v$ and recalling that the set $\mathcal{E}_h^*(K)$ is given by (4.6), we find

$$\|w\|_{L_2(K)} \lesssim 2^{-j(K)} \sum_{e\in\mathcal{E}_h^*(K)} \|[P_1 v]\|_{L_\infty(e)},$$

where the constant depends only on the shape properties of $\mathcal{T}^0$.

Now assume for the moment that for any edge $e \in \mathcal{E}_h$ there is one triangle K_e for which $e \subset \partial K_e$ and such that the inequality

$$\|[P_1 v]\|_{L_\infty(e)} \lesssim \|[v]\|_{L_\infty(e)} + \|\nabla v\|_{L_2(K_e)} \tag{5.18}$$

holds with a constant that depends only on the shape properties of $\mathcal{T}^0$. Since for every e in $\mathcal{E}_h^*(K)$, any such K_e is in $\mathcal{T}_h^*(K)$ (see (4.6) and (4.7)), this would yield

$$\|w\|_{L_2(K)} \lesssim 2^{-j(K)} \left(\sum_{e\in\mathcal{E}_h^*(K)} \|[v]\|_{L_\infty(e)} + \sum_{K'\in\mathcal{T}_h^*(K)} \|\nabla v\|_{L_2(K')} \right). \tag{5.19}$$

Now $[v]$ is polynomial on any e, so (4.16) reads $\|[v]\|_{L_\infty(e)} \sim |e|^{-1/2}\|[v]\|_{L_2(e)}$. Moreover, each term $\|\nabla v\|^2_{L_2(K')}$ can be bounded by $\underline{\lambda}_{K'}^{-1} a(v,v)_{K'}$, and indeed we have

$$a(v,v)_{K'} = \int_{K'} \left((A\nabla v)\cdot v + bv^2\right) \ge \|A^{1/2}\nabla v\|^2 \ge \underline{\lambda}_{K'}\|\nabla v\|^2_{L_2(K')}.$$

By using the fact that the sets $\mathcal{E}_h^*(K)$ and $\mathcal{T}_h^*(K)$ are of uniformly bounded cardinality (depending only on $\mathcal{T}^0$), we therefore find by combining (5.17), (5.19), and (4.9) that

$$\|(I-\mathcal{A}_1)v\|_{L_2(K)} \le C^* 2^{-j(K)} \,|\!|\!|v|\!|\!|_{h(\omega(K))},$$

where

$$C^* = C\Big(\max\big\{\{\gamma^{-1}\} \cup \{\underline{\lambda}_{K'}^{-1} : K' \in \mathcal{T}_h^*(K)\}\big\}\Big)^{1/2}$$

and where the unspecified C depends only on $\bar{k}$ and the shape properties of $\mathcal{T}^0$. This completes the proof of Lemma 4.3.

Thus, it remains only to prove (5.18). Here three situations may occur: Either (1) the edge e is on the boundary $\partial\Omega$, or this is not the case and we can write $e = K_e \cap K'_e$, with $K_e, K'_e \in \mathcal{T}_h$. Now either (2) e is an edge of both K_e and K'_e, or again (3) this is not the case. In the two first cases, we observe that $[P_1 v]_e = P_1([v]_e)$, so that

$$\|[P_1 v]\|_{L_\infty(e)} \le \|[v]\|_{L_\infty(e)}$$

is obvious. Now according to the structure of graded triangulations, the only possible configuration in case (3) is represented in Figure 4.1 with $e = [n', n]$. By setting then K_e and K'_e to be the coarser and finer triangles, respectively (i.e., K and K' in Figure 4.1), we observe that $P_1 v$ is affine on K_e. Therefore

$$\|[P_1 v]\|_{L_\infty(e)} = \max\left\{ |v^{K_e}(n') - v^{K'_e}(n')|, \left| \frac{1}{2}\big(v^{K_e}(n') + v^{K_e}(n'')\big) - v^{K'_e}(n) \right| \right\}.$$

By writing

$$\frac{1}{2}\big(v^{K_e}(n') + v^{K_e}(n'')\big) = \frac{1}{2}\big(v^{K_e}(n') - v^{K_e}(n)\big) + \frac{1}{2}\big(v^{K_e}(n) - v^{K_e}(n'')\big) + v^{K_e}(n),$$

we find (with an absolute constant)

$$\|[P_1 v]\|_{L_\infty(e)} \lesssim \|[v]\|_{L_\infty(e)} + |v^{K_e}(n') - v^{K_e}(n)| + |v^{K_e}(n) - v^{K_e}(n'')|.$$

By using a scaling argument together with the fact that v is polynomial on K_e, one finally verifies that

$$|v^{K_e}(n) - v^{K_e}(\check{n})| \lesssim \|\nabla v\|_{L_2(K_e)}, \quad \check{n} = n' \text{ or } n'',$$

holds with a constant that depends only on the shape properties of $\mathcal{T}^0$. By collecting the above estimates, one confirms (5.18) and completes the proof. ∎

Combining Corollary 4.5, (5.8), and Proposition 5.2 yields the following result.

COROLLARY 5.3. *Let $\mathcal{I}^c_{h,1}$ and φ^c_i be defined as in section* 5.1.1. *Then, for any basis $\{\phi_{K,p} : K \in \mathcal{T}_h,\ p \in \mathcal{N}_k(K)\}$ of V_h constructed as in* (4.28) *(such as a piecewise Lagrange basis), the collection*

$$\mathcal{S}_1 := \{\mathrm{span}(\varphi^c_i) : i \in \mathcal{I}^c_{h,1}\} \cup \{\mathrm{span}(\phi_{K,p}) : K \in \mathcal{T}_h,\ p \in \mathcal{N}_k(K)\}$$

is a stable splitting of V_h in the sense of (3.3). *In particular, the corresponding problem* (3.8) *is equivalent to the original equation* (3.2) *and has a condition number bounded by a constant independent of $\mathcal{T}_h$.*

Remark 5.1 (proof of Theorem 1.1). Theorem 1.1 is an immediate consequence of Corollary 4.5 and Proposition 5.2, observing that V^c_h can always be regarded as a splitting of itself. ∎

6. Numerical experiments. We now present some first numerical experiments for the simple model problem $a(u, v) = \int_\Omega \nabla u \cdot \nabla v$, where Ω is an L-shaped domain in $\mathbb{R}^2$ obtained by cutting out the upper right square $(1, 2]^2$ from $[0, 2]^2$. In the first two examples we consider only the first degree case $\bar{k} = 1$ on a uniformly refined grid. At this point we are mainly interested in the quantitative influence of the specific choice of the auxiliary bilinear forms $b_i(\cdot, \cdot)$, of the stabilization parameter γ, and of the low-dimensional subspaces V_i in the nonconforming part.

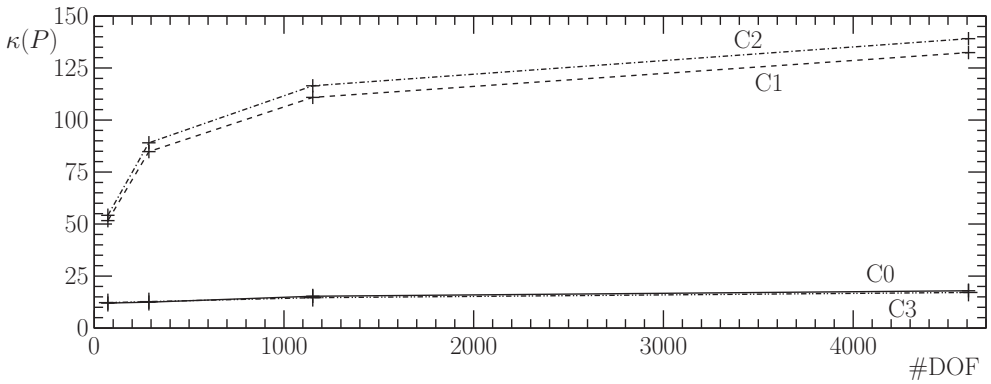

FIG. 6.1. *Condition numbers for the cases C0, C1, C2, and C3 for $\gamma = 10$ and $d_i = 1$.*

We shall use the following notation: $d_i := \dim V_i$ denotes the dimension of the subspaces in the nonconforming splitting; $d_i = 3$ refers to the case that V_i is spanned by the three nodal basis functions on each triangle in $\mathcal{T}_h$.

The case C0 refers to the choice

$$b_i(v,w) = \begin{cases} a(v,w)_K + \sum_{e\in\mathcal{E}_h, e\in\partial K} \frac{\gamma}{|e|}\int_e [v][w] & \text{for} \quad i = (K,p) \in \mathcal{I}_h^{\mathrm{nc}}, \\ a(v,w)_{\omega(i)} & \text{for} \quad i = (j,p) \in \mathcal{I}_h^{\mathrm{c}} \end{cases} \tag{6.1}$$

of the auxiliary inner products (see (4.37)), while C1 corresponds to

$$b_i(v,w) = \begin{cases} |K|^{-1}\langle v,w\rangle_K + \sum_{e\in\mathcal{E}_h, e\in\partial K} \frac{\gamma}{|e|}\int_e [v][w] & \text{for} \quad i = (K,p) \in \mathcal{I}_h^{\mathrm{nc}}, \\ 2^{2j}\,\langle v,w\rangle_{\omega(i)} & \text{for} \quad i = (j,p) \in \mathcal{I}_h^{\mathrm{c}}. \end{cases} \tag{6.2}$$

In order to test the preconditioning effect we have calculated the condition numbers. Figure 6.1 shows the dependence of the condition number of the preconditioned operator $\kappa(P_h)$ on the number of degrees of freedom for four selections of $b_i(\cdot,\cdot)$. For completeness, in addition to C0 and C1 we here also consider the cases C2 and C3, which are given by combining the first line of (6.1) with the second line of (6.2) and vice versa, respectively. Qualitatively for all choices of $b_i(\cdot,\cdot)$ the condition numbers of the preconditioned operator P_h show the same bounded behavior. The influence of the choice of the auxiliary bilinear form for the conforming part on the condition number dominates the choice for the nonconforming part. Selecting the bilinear form of the problem as the auxiliary bilinear form for the nonconforming part in cases C0 and C3 yields much smaller condition numbers than the scaled L_2 scalar product. The results in cases C0 and C3 show a very slight difference favoring the use of the scaled L_2 scalar product for the nonconforming part.

Recall that $\gamma = 10$ is usually considered as an appropriate choice. We consider first the moderate values $\gamma = 5$ and $\gamma = 7.5$ in the case $d_i = 1$.

Level	#DOF	κ for preconditioner (case/γ)					
		None/5	C0/5	C1/5	None/7.5	C0/7.5	C1/7.5
1	72	29.56	11.22	50.31	42.57	10.96	48.15
2	288	103.88	13.04	81.22	153.64	11.55	78.52
3	1152	403.17	16.31	105.98	601.26	14.50	102.56
4	4608	1602.08	18.98	126.37	2395.59	16.99	122.41

The results for $\gamma = 10$ and $\gamma = 15$ are shown in the next table.

Level	#DOF	κ for preconditioner (case/γ)					
		None/10	C0/10	C1/10	None/15	C0/15	C1/15
1	72	55.44	12.02	51.66	80.92	13.80	58.02
2	288	203.15	12.46	84.80	301.78	14.33	95.77
3	1152	799.07	15.28	110.87	1194.24	16.79	125.31
4	4608	3188.93	17.97	132.40	4775.39	19.84	149.72

The choice C0 is superior to C1 in both cases. We turn now to the case $d_i = 3$ for $\gamma = 5$ and $\gamma = 7.5$

Level	#DOF	κ for preconditioner (case/γ)					
		None/5	C0/5	C1/5	None/7.5	C0/7.5	C1/7.5
1	72	29.56	8.55	47.71	42.57	8.09	47.08
2	288	103.88	12.36	78.13	153.64	10.82	76.17
3	1152	403.17	15.60	101.91	601.26	13.76	99.48
4	4608	1602.08	18.24	121.52	2395.59	16.20	118.73

and further again for $\gamma = 10$ and $\gamma = 15$

Level	#DOF	κ for preconditioner (case/γ)					
		None/10	C0/10	C1/10	None/15	C0/15	C1/15
1	72	55.44	8.58	49.53	80.92	9.51	54.42
2	288	203.15	11.21	80.52	301.78	12.09	88.96
3	1152	799.07	14.35	105.24	1194.24	15.58	116.39
4	4608	3188.93	16.95	125.68	4775.39	18.47	139.06

which shows a similar effect as for $d_i = 1$ before, but the increase of d_i slightly decreases the condition numbers in all cases.

Next, for significantly larger problem sizes, we inspect the number of CG iterations needed to reduce the error below a certain tolerance. To derive an adequate stopping and accuracy criterion consider any basis $\Psi = \{\psi_i : i \in \mathcal{I}\}$ of V_h and the stiffness matrix $\mathbf{L}_h^\Psi := (a_h(\psi_i, \psi_j))_{i,j\in\mathcal{I}}$. Given u_h as in (3.2) and the kth CG iterate u_h^k with coefficient vectors $\mathbf{u}_h$ and $\mathbf{u}_h^k$ in Ψ, respectively, we define the residual vector $\mathbf{r}_h^k := \mathbf{f}_h - \mathbf{L}_h^\Psi \mathbf{u}_h^k$, where the ith entry of $\mathbf{f}_h$ is given by $\langle f, \psi_i\rangle$.

Consider the norm $\|\mathbf{v}\|_{\boldsymbol{\mathcal{C}}_h^\Psi} := \langle \mathbf{v}, \boldsymbol{\mathcal{C}}_h^\Psi \mathbf{v}\rangle^{\frac{1}{2}}$ for the coefficient arrays, induced by the preconditioner $\mathcal{C}_h$ with symmetric and positive definite matrix $\boldsymbol{\mathcal{C}}_h^\Psi := (\langle \psi_i, \mathcal{C}_h\psi_j\rangle)_{i,j\in\mathcal{I}}$. Because of (3.9) the eigenvalues of P_h are bounded independently of h. Therefore we can apply (2.7), (2.8), and Lemmas 8.23 and 8.25 from [9] to conclude that

$$\left|\!\left|\!\left| u_h^k - u_h \right|\!\right|\!\right|_h \sim a(u_h^k - u_h, u_h^k - u_h)_h^{\frac{1}{2}} = \left(\left(\mathbf{u}_h^k - \mathbf{u}_h\right)^T \mathbf{L}_h^\Psi \left(\mathbf{u}_h^k - \mathbf{u}_h\right) \right)^{\frac{1}{2}} \sim \|\mathbf{r}_h^k\|_{\boldsymbol{\mathcal{C}}_h^\Psi}.$$

Thus, in the following tests we stop the CG method when the residual $\|\mathbf{r}_h^k\|_{\boldsymbol{\mathcal{C}}_h^\Psi}$, controlling the error $\left|\!\left|\!\left| u_h^k - u_h \right|\!\right|\!\right|_h$, has been reduced by a factor of 10^{-5}.

Table 6.1 displays the corresponding number of iterations for $\gamma = 10$ and $f = 1$ on Ω as the right-hand side and zero as the initial guess for the conjugate gradient method, again for several choices of auxiliary bilinear forms.

We conclude with an example on an adaptive mesh. As trial functions we use Lagrange polynomials of degree $\bar{k} = 3$ corresponding to the principal lattice. Since the test case C0 with maximum d_i showed the best results in the previous examples, we now select this case with $d_i = 10$ and set $\gamma = 15$, which performed best in preliminary tests.

TABLE 6.1

Level	#DOF	Number of iterations for preconditioner (case/d_i)				
		None	C0/1	C0/3	C1/1	C1/3
1	72	26	19	15	20	18
2	288	55	19	17	33	29
3	1152	108	20	19	44	42
4	4608	208	21	20	46	45
5	18432	418	22	21	47	42
6	73728	849	23	22	48	44
7	294912	1718	24	22	48	42
8	1179648	3504	24	22	48	43
9	4718592	7137	24	23	47	41

Contrary to the last example, we now apply the preconditioner in a nested iteration scheme. In each loop we solve the linear system, apply the a posteriori error estimator [13], and capture a ϑ-fraction of the total estimated error by using a standard bulk chasing scheme, where $\vartheta = 0.6$ seems to be a good choice. The CG method stops in the initial loop on the coarsest level when the residual $\|\mathbf{r}_h^k\|_{\mathcal{C}_h^\Psi}$ reaches 10^{-15} and in the following loops when the the residual falls below $\frac{1}{1000}$ of the total estimated error.

Loop	#DOF	#its	Estimated error
0	240	78	1.70E-01
2	360	11	1.13E-01
4	480	10	8.16E-02

22	13110	13	7.20E-04
24	20010	12	4.09E-04
26	28230	14	2.28E-04
28	39960	14	1.29E-04
30	59820	13	7.53E-05
32	87330	13	4.43E-05
34	119280	14	2.58E-05
36	166440	14	1.53E-05

The quantitative performance of multiplicative schemes is known to be usually better than that of additive counterparts which is confirmed when comparing the above tests with [10, 14], whose analysis, however, is restricted to quasi-uniform meshes without hanging vertices. Nevertheless, the above comparisons show that the preconditioning effect is dominated by the treatment of the conforming subspace, namely, by the choice of the auxiliary bilinear forms in the above additive context, again supporting the favorable effect of employing a multiplicative version for this component.

7. Concluding remarks. We have reduced the problem of devising multilevel Schwarz preconditioners for the symmetric interior penalty DG formulation to the availability of admissible averaging projectors provided that the underlying meshes satisfy a certain grading property. We have specified one such projector for which uniformly bounded condition numbers are proved under no extra regularity conditions for

any graded triangulations and fixed highest polynomial degree. First numerical experiments illustrate the theoretical findings for a simple model problem and adaptive refinements. Alternative splittings for higher order discretizations will be explored in a forthcoming paper together with more extensive numerical experiments for variable coefficients.

A NEW APPROACH TO NUMERICAL SOLUTION OF DEFECTIVE BOUNDARY VALUE PROBLEMS IN INCOMPRESSIBLE FLUID DYNAMICS*

LUCA FORMAGGIA†, ALESSANDRO VENEZIANI‡, AND CHRISTIAN VERGARA†

Abstract. We consider the incompressible Navier–Stokes equations where on a part of the boundary flow rate and mean pressure boundary conditions are prescribed. There are basically two strategies for solving these defective boundary problems: the *variational approach* (see J. Heywood, R. Rannacher, and S. Turek, *Internat. J. Numer. Methods Fluids*, 22 (1996), pp. 325–352) and the *augmented formulation* (see L. Formaggia, J. F. Gerbeau, F. Nobile, and A. Quarteroni, *SIAM J. Numer. Anal.*, 40 (2002), pp. 376–401, and A. Veneziani and C. Vergara, *Internat. J. Numer. Methods Fluids*, 47 (2005), pp. 803–816). However, both of these approaches present some drawbacks. For the flow rate problem, the former resorts to nonstandard functional spaces, which are quite difficult to discretize. On the other hand, for the mean pressure problem, it yields exact solutions only in very special cases. The latter is applicable only to the flow rate problem, since for the mean pressure problem it provides unfeasible boundary conditions. In this paper, we propose a new strategy based on a reformulation of the problems at hand in terms of the minimization of an appropriate functional. This approach allows us to treat the two kinds of problems (flow rate and mean pressure) successfully within the same framework, which can be useful in view of a mixed problem where the two conditions are simultaneously prescribed on different artificial boundaries. Moreover, it is more versatile, being prone to be extended to other kinds of defective conditions. We analyze the problems obtained with this approach and propose some algorithms for their numerical solution. Several numerical results are presented supporting the effectiveness of our approach.

Key words. Navier–Stokes equations, flow rate boundary condition, mean pressure boundary condition, computational hemodynamics

1. Introduction.

In computational fluid dynamics the available boundary data are sometimes incomplete, in particular with reference to the *artificial boundaries*, i.e., the boundaries created just to limit the computational domain and not corresponding to a physical interface. On these boundaries, measurements or results coming from other computations (such as in the *geometrical multiscale approach*—see [5, 13]) typically provide mean or, more in general, incomplete data. This kind of problem has been addressed in [9] and in [4, 15, 16, 17]. In particular, by denoting with Γ an artificial portion of the boundary, two conditions have been considered on Γ, namely, *the mean pressure problem*

$$\frac{1}{|\Gamma|}\int_\Gamma p\, d\gamma = P(t), \tag{1.1}$$

where $p = p(t, \boldsymbol{x})$ is the fluid pressure and $P = P(t)$ is a given function of time, and the *flow rate problem*, where we have

$$\rho \int_\Gamma \boldsymbol{u} \cdot \boldsymbol{n} \, d\gamma = Q(t), \tag{1.2}$$

where $\boldsymbol{u} = \boldsymbol{u}(t, \boldsymbol{x})$ is the fluid velocity, $\boldsymbol{n}$ the outward unit vector, and ρ the constant fluid density and $Q = Q(t)$ is a given function.

In [9] a variational approach is proposed for finding an appropriate numerical solution of these problems. A well posedness analysis of the resulting boundary value problems is given, too. In [12] the same conditions on fluxes and pressures are considered as *asymptotic conditions* on infinite domains. In this approach, the artificial boundaries are replaced by far field conditions to be prescribed in an infinite domain. The analysis of this problem is by far not trivial; however, in [12] it is proved that flux and mean pressure conditions regarded as asymptotic conditions under appropriate assumptions yield well-posed problems. In practical problems, however, the computational domain needs to be truncated, so an appropriate method for prescribing such conditions in finite domains is needed.

The variational approach advocated in [9] for the mean pressure problem gives reliable results only in the case of special geometries. On the other hand, in the case of flow rate problems, the proposed variational formulation of [9] resorts to nonstandard functional spaces. The construction of finite-dimensional subspaces is actually quite problematic. For this reason, a different approach is proposed in [4], based on an augmented formulation, where condition (1.2) is regarded as a constraint for the solution to be forced by means of a Lagrange multiplier (see also [15]). Unfortunately, the technique cannot treat the mean pressure problem, as it yields inaccurate solutions for the velocity (see [4, 17]).

In this paper, we propose a new general approach for the defective boundary data problems, which does not suffer from the limitations of the previous ones, so that both mean pressure and flow rate problems can be solved successfully within the same framework. This approach relies on the introduction of an appropriate functional which quantifies the difference between the boundary solution and the prescribed data (see, in a different context, [1]). By resorting to a technique similar to that of a control problem, we introduce control variables related to the fluid velocity and pressure on the boundary. By acting on these control variables, we seek the minimum of the functional at hand. This approach is general and can be applied in principle to all kinds of defective boundary problems. The idea of using boundary data as control variables to force some properties of the solution has been already exploited: We quote, for instance, [7, 10, 2] and more recently [3]. In [6] it has been used for an effective splitting of velocity-pressure computation in standard unsteady Stokes problems. Boundary control variables were used here to force the incompressibility constraint. In general, in these papers the basic idea is to use pointwise velocity data on the boundary for driving the solution to some desired behavior. Here we still use boundary data (not necessarily the velocity) for forcing the "optimal" fulfillment of the incomplete boundary conditions. We consider both the flow rate and the mean pressure problem. We discuss the effectiveness of this approach in comparison with the variational approach proposed in [9] and with the augmented formulation addressed in [4, 15]. Numerical results presented here confirm the flexibility of our method.

The outline of the paper is as follows. Section 2 is devoted to the flow rate problem. The approach based on using normal stresses as control variables is first presented for the generalized Stokes problem and then extended to the nonlinear case.

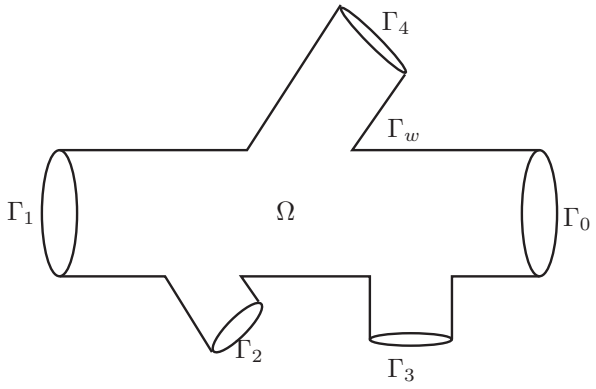

FIG. 1.1. *Reference domain* Ω.

For both cases a proof of well posedness is given. In section 3 we illustrate the approach for the mean pressure problem. We propose different formulations, featuring different sets of control variables. Well posedness analysis is in this case nontrivial and will be carried out in future work, yet the effectiveness of the methods is demonstrated here by numerical tests. Section 4 is devoted to the presentation of some algorithms for the solution of the proposed problems and to their convergence analysis. Finally, in section 5 we present and discuss some numerical results.

1.1. Basic notation. Let us denote by $\Omega \in \mathbb{R}^d$ a domain filled by an incompressible fluid, whose boundary can be split into two parts. The former is denoted by Γ_w and corresponds to a physical wall. The latter is given by the union of the artificial sections Γ_j $(j = 0, \ldots, m)$ which limit the domain of interest but do not have a direct physical significance. A possible domain of this sort is given in Figure 1.1. We assume that the walls are rigid, so that the velocity field is zero on Γ_w, and that the fluid is Newtonian. This domain is representative of incompressible flow problems in a network of pipes, such as in computational hemodynamics, which motivated the present study. The extension to the case of compliant vessels, which is of paramount interest for blood flow problems, requires a specific analysis still to be carried out. The Navier–Stokes equations for the problem at hand are

$$\begin{cases} \rho \dfrac{\partial \boldsymbol{u}}{\partial t} - \mu \triangle \boldsymbol{u} + \rho(\boldsymbol{u} \cdot \nabla)\boldsymbol{u} + \nabla p = \boldsymbol{f} & \text{in } (0,T) \times \Omega, \\ \nabla \cdot \boldsymbol{u} = 0 & \text{in } (0,T) \times \Omega, \end{cases} \tag{1.3}$$

where $\boldsymbol{f}(t, \boldsymbol{x})$ is a given forcing term and μ is the constant fluid viscosity. In what follows, for the sake of simplicity and without loss of generality we will set $\rho = 1$. Moreover, we have *no-slip* boundary conditions on Γ_w, i.e.,

$$\boldsymbol{u}|_{\Gamma_w} = \boldsymbol{0} \qquad \text{in } (0,T), \tag{1.4}$$

as well as the initial condition

$$\boldsymbol{u}|_{t=0} = \boldsymbol{u}_0 \qquad \text{in } \Omega, \tag{1.5}$$

where $\boldsymbol{u}_0 = \boldsymbol{u}_0(\boldsymbol{x})$ is a given function, regular enough. Boundary conditions still have to specified on Γ_j. On those boundaries, we will consider the two possibilities addressed in the introduction.

In what follows we will refer to the functional spaces

$$L^2(\Omega) = \Big\{ v : \Omega \to \mathbb{R} : \int_\Omega v^2 \, d\omega < \infty \Big\}, \qquad H^1(\Omega) = \{ v \in L^2(\Omega) : \nabla v \in L^2(\Omega) \},$$
$$\boldsymbol{V} = \{ \boldsymbol{v} \in \boldsymbol{H}^1(\Omega) : \boldsymbol{v}|_{\Gamma_w} = \boldsymbol{0} \},$$

where $\boldsymbol{H}^1(\Omega) = (H^1(\Omega))^d$, and use the following notation for scalar functions s, $q \in H^1(\Omega)$ and for vector functions $\boldsymbol{v}, \boldsymbol{w} \in \boldsymbol{H}^1(\Omega)$:

$$(s,q) = \int_\Omega s\, q \, d\omega, \quad (\boldsymbol{v}, \boldsymbol{w}) = \int_\Omega \boldsymbol{v} \cdot \boldsymbol{w} \, d\omega = \sum_{i=1}^d \int_\Omega v_i w_i \, d\omega,$$
$$(s,q)_{H^1} = (s,q) + (\nabla s, \nabla q),$$

$$(\nabla \boldsymbol{v}, \nabla \boldsymbol{w}) = \int_\Omega \nabla \boldsymbol{v} : \nabla \boldsymbol{w} \, d\omega = \sum_{i,j=1}^d \int_\Omega \frac{\partial v_i}{\partial x_j} \frac{\partial w_i}{\partial x_j} \, d\omega, \quad (\boldsymbol{v}, \boldsymbol{w})_{H^1} = (\boldsymbol{v}, \boldsymbol{w}) + (\nabla \boldsymbol{v}, \nabla \boldsymbol{w}),$$

$$a(\boldsymbol{v}, \boldsymbol{w}) = \alpha(\boldsymbol{v}, \boldsymbol{w}) + \mu(\nabla \boldsymbol{v}, \nabla \boldsymbol{w}), \qquad c(\boldsymbol{u}, \boldsymbol{v}, \boldsymbol{w}) = ((\boldsymbol{u} \cdot \nabla)\boldsymbol{v}, \boldsymbol{w}),$$

$\alpha \geq 0$ being a given parameter. We recall that $a(\cdot, \cdot)$ is coercive on the space $\boldsymbol{V}$ $\forall \alpha \geq 0$. Moreover, given a vector $\boldsymbol{q} \in \mathbb{R}^m$, we set

$$\|\boldsymbol{q}\|_p = \left(\sum_{j=1}^m |q_j|^p \right)^{1/p}.$$

Finally, given m Hilbert spaces $W_1, \ldots, W_m$, let $\boldsymbol{W} \equiv W_1 \times W_2 \times \cdots \times W_m$, $N : \boldsymbol{W} \to \mathbb{R}$, such that $(y_1, \ldots, y_m) \in \boldsymbol{W} \to N(y_1, \ldots, y_m) \in \mathbb{R}$ and $\langle \cdot, \cdot \rangle$ be the duality pairing between W' and $\boldsymbol{W}$. We denote

$$\langle dN_{y_j}[w_1, \ldots, w_m], z \rangle = \lim_{\varepsilon \to 0} \left(\frac{N(y_1, \ldots, y_j + \varepsilon z, \ldots, y_m) - N(y_1, \ldots, y_j, \ldots, y_m)}{\varepsilon} \right) \Bigg|_{\boldsymbol{y} = \boldsymbol{w}}$$

the Gateaux differential of N, with the respect of y_j computed in the point $\boldsymbol{w} = (w_1, \ldots, w_m) \in \boldsymbol{W}$ along the direction $z \in W_j$.

2. Flow rate boundary conditions. We start by considering the following boundary conditions applied to the artificial boundaries Γ_i:

$$\text{(2.1)} \qquad \begin{cases} (p\boldsymbol{n} - \mu \nabla \boldsymbol{u}\, \boldsymbol{n})|_{\Gamma_0} = \boldsymbol{0} & \text{in } (0,T), \\ \displaystyle\int_{\Gamma_i} \boldsymbol{u} \cdot \boldsymbol{n} \, d\gamma = Q_i, \qquad i = 1, 2, \ldots, m, & \text{in } (0,T), \end{cases}$$

where $Q_i = Q_i(t)$ are given functions of time. Since Γ_w is a rigid boundary, the incompressibility constraint implies that the flow rate on Γ_0 is $Q_0 = -\sum_{i=1}^m Q_i$. Conditions $(2.1)_2$ are not enough to make the problem at hand well-posed in the classical setting, since d "pointwise" boundary data should be prescribed. The approach proposed in [9] to overcome this lack of data is based on the introduction of a variational formulation in the "null fluxes" subspace of $\boldsymbol{V}$ and by lifting the solution by means of an appropriate set of functions called *flux carriers*. It is possible to prove (see, e.g., [14]) that

the boundary conditions implicitly prescribed on Γ_i by this formulation are constant-in-space Neumann boundary conditions. From the numerical viewpoint this has the drawback of dealing with a nonstandard functional space, whose finite-dimensional discretization is not easy to construct. For this reason, a different approach, based on Lagrange multipliers and on the reformulation of the problem in terms of a constraint minimization, has been investigated and numerically tested in [4] for the steady Stokes problem and then extended to the unsteady Navier–Stokes problem in [15, 16, 17]. The idea is to regard the flow rate boundary condition as a constraint to be forced by means of Lagrange multipliers. The *augmented variational formulation* associated with this approach leads to the following problem.

PROBLEM 1. *Given* $\boldsymbol{u}_0 \in \boldsymbol{V}$, *with* $\nabla \cdot \boldsymbol{u}_0 = 0$, $\boldsymbol{f} \in L^2(0,T;\boldsymbol{L}^2(\Omega))$, *and a vector of functions* $\boldsymbol{Q} \in (C^0([0,T]))^m$, *satisfying the conditions* $\int_{\Gamma_j} \boldsymbol{u}_0 \cdot \boldsymbol{n}\, d\gamma = Q_j(0)$ *for* $j = 1, \dots, m$, *find* $\boldsymbol{u} \in L^2(0,T;\boldsymbol{V}) \cap L^\infty(0,T;\boldsymbol{L}^2(\Omega))$, $p \in L^2(0,T;L^2(\Omega))$, *and* $\boldsymbol{\lambda} \in (L^2(0,T))^m$ *such that at any* $t \in (0,T)$

$$
\begin{cases}
\left(\dfrac{\partial \boldsymbol{u}}{\partial t}, \boldsymbol{v}\right) + \mu(\nabla \boldsymbol{u}, \nabla \boldsymbol{v}) + ((\boldsymbol{u}\cdot\nabla)\boldsymbol{u}, \boldsymbol{v}) - (p, \nabla\cdot\boldsymbol{v}) \\
\qquad\qquad + \displaystyle\sum_{j=1}^{m} \lambda_j \int_{\Gamma_j} \boldsymbol{v}\cdot\boldsymbol{n}\, d\gamma = (\boldsymbol{f}, \boldsymbol{v}) & \text{in } \Omega, \\
(q, \nabla\cdot\boldsymbol{u}) = 0 & \text{in } \Omega, \\
\displaystyle\int_{\Gamma_i} \boldsymbol{u}\cdot\boldsymbol{n}\, d\gamma = Q_i, & i = 1, \dots, m,
\end{cases}
$$

for all $\boldsymbol{v} \in \boldsymbol{V}$ *and* $q \in L^2(\Omega)$ *and with* $\boldsymbol{u} = \boldsymbol{u}_0$ *for* $t = 0$.

It has been proven in [4, 15] that this approach leads to the same natural boundary conditions on the artificial boundaries as the variational approach presented in [9]. However, in this case we deal with the standard functional space $\boldsymbol{V}$.

In the next section we show a different variational formulation, still prompt to numerical discretization. For the sake of simplicity we start considering the generalized Stokes problem. Then, in section 2, we extend the approach to the nonlinear case.

2.1. The generalized Stokes problem. In order to address conditions $(2.1)_2$, let us consider the following generalized Stokes problem with complete (i.e., nondefective) boundary conditions:

$$
\begin{cases}
\alpha\boldsymbol{u}(\boldsymbol{k}) - \mu\triangle\boldsymbol{u}(\boldsymbol{k}) + \nabla p(\boldsymbol{k}) = \boldsymbol{f} & \text{in } \Omega, \\
\nabla\cdot\boldsymbol{u}(\boldsymbol{k}) = 0 & \text{in } \Omega, \\
\boldsymbol{u}(\boldsymbol{k})|_{\Gamma_w} = \boldsymbol{0}, & \\
(-p(\boldsymbol{k})\boldsymbol{n} + \mu\nabla\boldsymbol{u}(\boldsymbol{k})\,\boldsymbol{n})|_{\Gamma_0} = \boldsymbol{0}, & \\
(-p(\boldsymbol{k})\boldsymbol{n} + \mu\nabla\boldsymbol{u}(\boldsymbol{k})\,\boldsymbol{n})|_{\Gamma_i} = -k_i\boldsymbol{n}, & i = 1, \dots, m,
\end{cases}
\tag{2.2}
$$

where $\boldsymbol{k} = (k_1, \dots, k_m) \in \mathbb{R}^m$ denotes the vector of the constant values of the normal stresses, $\boldsymbol{f} \in \boldsymbol{L}^2(\Omega)$ is given, and $\alpha \geq 0$ is a given parameter. For the solution of unsteady problems, α is related to the time step and to the time-advancing scheme (see section 2.1.1). As our notation suggests, we regard velocity and pressure fields as a function of the vector $\boldsymbol{k}$. More precisely, for any given $\boldsymbol{k} \in \mathbb{R}^m$, $\boldsymbol{u}(\boldsymbol{k})$ and $p(\boldsymbol{k})$ denote the velocity and the pressure field, respectively, obtained by solving (2.2). In this context, we consider $\boldsymbol{k}$ as a *control variable* to be set such that $\boldsymbol{u} = \boldsymbol{u}(\boldsymbol{k})$ fulfills

the constraint $(2.1)_2$ in some sense to be specified. To this aim we introduce the functional $J_Q : \boldsymbol{V} \to \mathbb{R}^+$:

$$J_Q(\boldsymbol{w}) = \frac{1}{2}\sum_{i=1}^{m}\Big(\int_{\Gamma_i} \boldsymbol{w}\cdot\boldsymbol{n}\, d\gamma - Q_i\Big)^2, \tag{2.3}$$

which is clearly minimal and equal to zero when $(2.1)_2$ is fulfilled. For each $\boldsymbol{w} \in \boldsymbol{V}$, $s \in L^2(\Omega)$, and $\boldsymbol{\eta} \in \mathbb{R}^m$, we build the following Lagrange functional, where (2.2) plays the role of *constraints* for the solution:

$$\begin{aligned}\mathcal{L}(\boldsymbol{w}, s; \boldsymbol{\lambda}_w, \lambda_s; \boldsymbol{\eta}) &= J_Q(\boldsymbol{w}) + a(\boldsymbol{w}, \boldsymbol{\lambda}_w) - (s, \nabla\cdot\boldsymbol{\lambda}_w)\\ &\quad + \sum_{i=1}^{m}\int_{\Gamma_i} \eta_i\boldsymbol{\lambda}_w\cdot\boldsymbol{n}\, d\gamma - (\boldsymbol{f}, \boldsymbol{\lambda}_w) - (\lambda_s, \nabla\cdot\boldsymbol{w}).\end{aligned} \tag{2.4}$$

Here $\boldsymbol{\lambda}_w \in \boldsymbol{V}$ and $\lambda_s \in L^2(\Omega)$ are the *adjoint* variables associated to $\boldsymbol{w}$ and s, respectively. In order to find the corresponding Euler equations, we force the Gateaux differentials of $\mathcal{L}$ evaluated for any test function to vanish in correspondence to the solution $\boldsymbol{\chi} = [\boldsymbol{u}, p; \boldsymbol{\lambda}_u, \lambda_p; \boldsymbol{k}]$. That is, we will consider the following problem, where for the sake of notation we omit to specify that the differentials are computed in $\boldsymbol{\chi}$.

PROBLEM 2. *Given $\boldsymbol{f} \in \boldsymbol{L}^2(\Omega)$ and $\boldsymbol{Q} \in \mathbb{R}^m$, find $\boldsymbol{k} \in \mathbb{R}^m$, $\boldsymbol{u}(\boldsymbol{k}) \in \boldsymbol{V}, p(\boldsymbol{k}) \in L^2(\Omega), \boldsymbol{\lambda}_u \in \boldsymbol{V}$, and $\lambda_p \in L^2(\Omega)$ such that, for all $\boldsymbol{v} \in \boldsymbol{V}$, $q \in L^2(\Omega)$, and $\nu \in \mathbb{R}$:*

$$\begin{cases}
\text{(P)} \begin{cases} \langle d\mathcal{L}_{\boldsymbol{\lambda}_w}, \boldsymbol{v}\rangle = a(\boldsymbol{u}, \boldsymbol{v}) - (p, \nabla\cdot\boldsymbol{v}) + \displaystyle\sum_{i=1}^{m}\int_{\Gamma_i} k_i\boldsymbol{v}\cdot\boldsymbol{n}\, d\gamma - (\boldsymbol{f}, \boldsymbol{v}) = 0, \\ \langle d\mathcal{L}_{\lambda_s}, q\rangle = -(q, \nabla\cdot\boldsymbol{u}) = 0, \end{cases} \\
\text{(A)} \begin{cases} \langle d\mathcal{L}_{\boldsymbol{w}}, \boldsymbol{v}\rangle = a(\boldsymbol{v}, \boldsymbol{\lambda}_u) + \displaystyle\sum_{i=1}^{m}\left(\int_{\Gamma_i} \boldsymbol{u}\cdot\boldsymbol{n}\, d\gamma - Q_i\right)\int_{\Gamma_i} \boldsymbol{v}\cdot\boldsymbol{n}\, d\gamma - (\lambda_p, \nabla\cdot\boldsymbol{v}) = 0, \\ \langle d\mathcal{L}_s, q\rangle = -(q, \nabla\cdot\boldsymbol{\lambda}_u) = 0, \end{cases} \\
\text{(C}_\text{j}\text{)} \quad \langle d\mathcal{L}_{\eta_j}, \nu\rangle = \nu\displaystyle\int_{\Gamma_j} \boldsymbol{\lambda}_u\cdot\boldsymbol{n}\, d\gamma = 0, \quad j = 1, \dots, m.
\end{cases} \tag{2.5}$$

This system couples a generalized Stokes problem (P) with its adjoint (A) and m scalar equations (*optimality conditions*), denoted by (C_j). Observe that the latter force the adjoint variable $\boldsymbol{\lambda}_u$ to have null flux on the artificial boundaries.

By exploiting the symmetry of the bilinear form $a(\cdot,\cdot)$, the strong formulation of the adjoint problem (A) can be readily deduced, yielding

$$\begin{cases}
\alpha\boldsymbol{\lambda}_u - \mu\triangle\boldsymbol{\lambda}_u + \nabla\lambda_p = \boldsymbol{0} & \text{in } \Omega, \\
\nabla\cdot\boldsymbol{\lambda}_u = 0 & \text{in } \Omega, \\
\boldsymbol{\lambda}_u|_{\Gamma_w} = \boldsymbol{0}, & \\
(-\lambda_p\boldsymbol{n} + \mu\nabla\boldsymbol{\lambda}_u\ \boldsymbol{n})|_{\Gamma_0} = \boldsymbol{0}, & \\
(-\lambda_p\boldsymbol{n} + \mu\nabla\boldsymbol{\lambda}_u\ \boldsymbol{n})|_{\Gamma_i} = -\left(\displaystyle\int_{\Gamma_i} \boldsymbol{u}\cdot\boldsymbol{n}\, d\gamma - Q_i\right)\boldsymbol{n}, & i = 1, \dots, m.
\end{cases} \tag{2.6}$$

Numerical solution of Problem 2 can be pursued by means of iterative techniques, as we will see in section 4. It is worth noting that, if the iterative process converges, at the limit (i.e., when $J_Q(\boldsymbol{u}) = 0$), the fulfillment of (A) and (C_j) implies that $\boldsymbol{\lambda}_u = \boldsymbol{0}$ and $\lambda_p = 0$. This is promptly verified by bearing in mind conditions (C_j) and by

selecting $\boldsymbol{v} = \boldsymbol{\lambda}_u$ in (A). The adjoint variables are, however, needed to drive the iterative scheme to the optimal solution, as will be illustrated in section 4.

A general theory of well posedness of problems arising in flow control is presented in [7, Chap. 6]. Here, we prove a well posedness results strongly based on the specific feature of the problems at hand.

PROPOSITION 2.1. *Problem* 2 *admits a unique solution* $[\boldsymbol{u}(\boldsymbol{k}), p(\boldsymbol{k}); \boldsymbol{\lambda}_u, \lambda_p; \boldsymbol{k}]$.

Proof. We introduce the following operators:

1. $\mathcal{P}_{\boldsymbol{f}} : \mathbb{R}^m \to \boldsymbol{V}$: Given a vector $\boldsymbol{h} \in \mathbb{R}^m$, it associates it with the function $\boldsymbol{w}$, where $[\boldsymbol{w}, s]$ is the solution of

$$\begin{cases} a(\boldsymbol{w}, \boldsymbol{v}) - (s, \nabla \cdot \boldsymbol{v}) = -\displaystyle\sum_{j=1}^{m} h_j \int_{\Gamma_j} \boldsymbol{v} \cdot \boldsymbol{n}\, d\gamma + (\boldsymbol{f}, \boldsymbol{v}) & \forall \boldsymbol{v} \in \boldsymbol{V}, \\ (q, \nabla \cdot \boldsymbol{w}) = 0 & \forall q \in L^2(\Omega). \end{cases} \tag{2.7}$$

   In particular, if $\boldsymbol{f} = \boldsymbol{0}$, we will write $\mathcal{P}_{\boldsymbol{0}}$. We point out that operator $\mathcal{P}_{\boldsymbol{f}}$ is well defined since, for a given $\boldsymbol{h}$, (2.7) admits an unique solution, being a generalized Stokes system with a constant mixed Neumann and Dirichlet boundary condition (see, e.g., [9]). By exploiting the linearity of the problem we have $\boldsymbol{w} = \mathcal{P}_{\boldsymbol{f}}(\boldsymbol{h}) = \boldsymbol{w}_1 + \boldsymbol{w}_2$, where

$$\boldsymbol{w}_1 = \mathcal{P}_{\boldsymbol{f}}(\boldsymbol{0}), \quad \boldsymbol{w}_2 = \mathcal{P}_{\boldsymbol{0}}(\boldsymbol{h}).$$

2. $\mathcal{A} : \boldsymbol{V} \to \mathbb{R}^m$ such that

$$\mathcal{A}\boldsymbol{w} = \left(\int_{\Gamma_1} \boldsymbol{w} \cdot \boldsymbol{n}\, d\gamma, \int_{\Gamma_2} \boldsymbol{w} \cdot \boldsymbol{n}\, d\gamma, \ldots, \int_{\Gamma_m} \boldsymbol{w} \cdot \boldsymbol{n}\, d\gamma \right). \tag{2.8}$$

3. We define $\mathcal{B}_{\boldsymbol{f}} = \mathcal{A} \circ \mathcal{P}_{\boldsymbol{f}}$ and $\mathcal{B}_{\boldsymbol{0}} = \mathcal{A} \circ \mathcal{P}_{\boldsymbol{0}}$, respectively. Operator $\mathcal{B}_{\boldsymbol{f}}$ is an affine operator from $\mathbb{R}^m$ to $\mathbb{R}^m$, while $\mathcal{B}_{\boldsymbol{0}}$ is linear. Observe that

$$\mathcal{B}_{\boldsymbol{f}}(\boldsymbol{h}) = \mathcal{A}\,(\boldsymbol{w}_1 + \boldsymbol{w}_2) = \mathcal{B}_{\boldsymbol{0}}\boldsymbol{h} + \mathcal{B}_{\boldsymbol{f}}(\boldsymbol{0}). \tag{2.9}$$

We point out that Problem 2 is equivalent to solving the following linear system for the unknown $\boldsymbol{k}$:

$$\mathcal{B}_{\boldsymbol{0}}[\mathcal{B}_{\boldsymbol{f}}(\boldsymbol{k}) - \boldsymbol{Q}] = \boldsymbol{0}. \tag{2.10}$$

Let us prove that $\mathcal{B}_{\boldsymbol{0}}$ is an invertible operator by providing its explicit representation. This is a linear operator from $\mathbb{R}^m$ to $\mathbb{R}^m$, so it can be represented by a matrix. Let us denote by $\boldsymbol{w}_j$ the solution of (2.7) for $\boldsymbol{f} = \boldsymbol{0}$ and $\boldsymbol{h} = \boldsymbol{e}_j$, $\boldsymbol{e}_j$ being the jth unit vector. For a generic vector $\boldsymbol{h} = \sum_{j=1}^m h_j \boldsymbol{e}_j$, we have $\mathcal{P}_{\boldsymbol{0}}(\boldsymbol{h}) = \sum_{j=1}^m h_j \boldsymbol{w}_j$.

Let us now exploit $(2.7)_2$ in $(2.7)_1$ by taking $\boldsymbol{v} = \boldsymbol{w}_j$ and $\boldsymbol{h} = \boldsymbol{e}_i$. We obtain

$$a(\boldsymbol{w}_i, \boldsymbol{w}_j) = -\int_{\Gamma_i} \boldsymbol{w}_j \cdot \boldsymbol{n} d\gamma.$$

This implies that

$$[\mathcal{B}_{\boldsymbol{0}}\boldsymbol{h}]_i = -\sum_{j=1}^{m} a(\boldsymbol{w}_i, \boldsymbol{w}_j) h_j,$$

so we finally have

$$[\mathcal{B}_{\boldsymbol{0}}]_{ij} = -a(\boldsymbol{w}_i, \boldsymbol{w}_j).$$

Since $a(\cdot,\cdot)$ is coercive, symmetric bilinear form, matrix $\mathcal{B}_{\mathbf{0}}$ is symmetric and negative definite. Therefore, it follows that (2.10) reduces to

$$\mathcal{B}_{\boldsymbol{f}}(\boldsymbol{k}) = \boldsymbol{Q}.$$

Thanks to the linearity, this in turn can be rewritten as

$$\mathcal{B}_{\mathbf{0}}\boldsymbol{k} = \boldsymbol{Q} - \mathcal{B}_{\boldsymbol{f}}(\mathbf{0}).$$

Again, thanks to the nonsingularity of $\mathcal{B}_{\mathbf{0}}$, we conclude that solution $\boldsymbol{k}$ exists and is unique. The corresponding $\boldsymbol{u}$ and p are obtained by solving (2.7) with $\boldsymbol{h} = \boldsymbol{k}$ and satisfy the constraints by construction. The associated adjoint variables $\boldsymbol{\lambda}_u$ and λ_p are zero. ∎

2.1.1. The unsteady case. When one wants to solve the unsteady Stokes problem

$$\text{(2.11)}\qquad \begin{cases} \dfrac{\partial \boldsymbol{u}(\boldsymbol{k})}{\partial t} - \mu\triangle\boldsymbol{u}(\boldsymbol{k}) + \nabla p(\boldsymbol{k}) = \boldsymbol{f} & \text{in } (0,T)\times\Omega, \\ \nabla\cdot\boldsymbol{u}(\boldsymbol{k}) = 0 & \text{in } (0,T)\times\Omega, \\ \boldsymbol{u}(\boldsymbol{k})|_{t=0} = \boldsymbol{u}_0 & \text{in } \Omega, \\ \boldsymbol{u}(\boldsymbol{k})|_{\Gamma_w} = \mathbf{0} & \text{in } (0,T), \\ (-p(\boldsymbol{k})\boldsymbol{n} + \mu\nabla\boldsymbol{u}(\boldsymbol{k})\,\boldsymbol{n})|_{\Gamma_0} = \mathbf{0} & \text{in } (0,T), \\ (-p(\boldsymbol{k})\boldsymbol{n} + \mu\nabla\boldsymbol{u}(\boldsymbol{k})\,\boldsymbol{n})|_{\Gamma_i} = -k_i(t)\boldsymbol{n}, \quad i=1,\dots,m, & \text{in } (0,T), \end{cases}$$

with $\boldsymbol{f} \in L^\infty(0,T;\boldsymbol{L}^2(\Omega))$, $\boldsymbol{u}_0 \in \boldsymbol{L}^2(\Omega)$, $\nabla\cdot\boldsymbol{u}_0 = 0$, and $k_i(t)$, $i = 1,\dots,m$, chosen such that (2.4) is minimal at each time step, a possible approach would rely on a Lagrangian functional for the time-dependent problem. However, this implies a time-dependent adjoint equation with a final time condition. The solution of the associated control problem in the time interval $(0,T)$ would lead to iteratively solving (and storing) the solution of the primal problem in order to find the time-reversed adjoint solution. A different, *discretize then optimize* approach consists of applying our control technique on the time discretization of (2.11). See, in different contexts, [2, 11]. In this way, we avoid the solution of the time adjoint problem, since we already know its exact solution, which is zero. In fact, here the adjoint problem is just a tool for enforcing the mean flux boundary conditions. In particular, by denoting $t^n = n\Delta t$, with Δt the time discretization step and referring to a backward difference formula (BDF) time-advancing scheme, we obtain, for each n, problem (2.2) and the Lagrangian (2.4) with $\alpha = \beta_0/\Delta t$ and a forcing term equal to $\boldsymbol{f}^n + \sum_{i=1}^r \beta_i/\Delta t\,\boldsymbol{u}^{n-i}$, where $\boldsymbol{k}^n = \boldsymbol{k}(t^n)$, $\boldsymbol{u}^n = \boldsymbol{u}^n(\boldsymbol{k}^n) = \boldsymbol{u}(t^n,\boldsymbol{x})$, $p^n = p^n(\boldsymbol{k}^n) = p(t^n,\boldsymbol{x})$, $\boldsymbol{f}^n = \boldsymbol{f}(t^n,\boldsymbol{x})$, $\boldsymbol{u}^{n-i}$ is the approximation of $\boldsymbol{u}(t^{n-i},\boldsymbol{x})$, and β_i $(i = 0,1,\dots,r \le n)$ are the coefficients of the time discretization. Therefore, with this notation, we can interpret Problem 2 as a technique for the solution of a *discrete-in-time* unsteady flow rate Stokes problem. In this case the strong formulation of the adjoint problem (A) is given by (2.6) with $\alpha = \beta_0/\Delta t$. It may be noted that in this case system (2.6) is exactly the BDF discretization at time $t = t^n$ of the backward-in-time adjoint problem when the exact solution $(\boldsymbol{\lambda}_u^{n+k} = \mathbf{0}, \lambda_p^{n+k} = 0)$ for $k = 1,2,\dots,r$ is used.

2.2. The nonlinear case. We focus now on the system arising when the nonlinear convective term is present in the fluid equations. More precisely, we consider the following Navier–Stokes problem:

$$\text{(2.12)}\qquad \alpha\boldsymbol{u}(\boldsymbol{k}) - \mu\triangle\boldsymbol{u}(\boldsymbol{k}) + (\boldsymbol{u}(\boldsymbol{k})\cdot\nabla)\boldsymbol{u}(\boldsymbol{k}) + \nabla p(\boldsymbol{k}) = \boldsymbol{f} \quad \text{in } \Omega$$

together with $(2.2)_{2-5}$. To minimize (2.3) with the constraint given by (2.12) together with $(2.2)_{2-5}$, we have to find the stationary point of the following Lagrangian functional:

$$\mathcal{L}(\boldsymbol{w}, s; \boldsymbol{\lambda}_w, \lambda_s; \boldsymbol{\eta}) = J_Q(\boldsymbol{w}) + a(\boldsymbol{w}, \boldsymbol{\lambda}_w) + c(\boldsymbol{w}, \boldsymbol{w}, \boldsymbol{\lambda}_w) - (s, \nabla \cdot \boldsymbol{\lambda}_w)$$

$$+\sum_{i=1}^{m} \int_{\Gamma_i} \eta_i \boldsymbol{\lambda}_w \cdot \boldsymbol{n}\, d\gamma - (\boldsymbol{f}, \boldsymbol{\lambda}_w) - (\lambda_p, \nabla \cdot \boldsymbol{w}).$$

This leads to the following.

PROBLEM 3. *Given $\boldsymbol{f} \in \boldsymbol{L}^2(\Omega)$ and $\boldsymbol{Q} \in \mathbb{R}^m$, find $\boldsymbol{k} \in \mathbb{R}^m$, $\boldsymbol{u}(\boldsymbol{k}) \in \boldsymbol{V}, p(\boldsymbol{k}) \in L^2(\Omega), \boldsymbol{\lambda}_u \in \boldsymbol{V}$, and $\lambda_p \in L^2(\Omega)$ such that, for all $\boldsymbol{v} \in \boldsymbol{V}$, $q \in L^2(\Omega)$, and $\nu \in \mathbb{R}$:*

$$\begin{cases} \text{(P)} \begin{cases} \langle d\mathcal{L}_{\boldsymbol{\lambda}_u}, \boldsymbol{v} \rangle = a(\boldsymbol{u}, \boldsymbol{v}) + c(\boldsymbol{u}, \boldsymbol{u}, \boldsymbol{v}) - (p, \nabla \cdot \boldsymbol{v}) + \displaystyle\sum_{i=i}^{m} \int_{\Gamma_i} k_i \boldsymbol{v} \cdot \boldsymbol{n}\, d\gamma - (\boldsymbol{f}, \boldsymbol{v}) = 0, \\ \langle d\mathcal{L}_{\lambda_p}, q \rangle = -(q, \nabla \cdot \boldsymbol{u}) = 0, \end{cases} \\ \text{(A)} \begin{cases} \langle d\mathcal{L}_{\boldsymbol{u}}, \boldsymbol{v} \rangle = a(\boldsymbol{v}, \boldsymbol{\lambda}_u) + c(\boldsymbol{u}, \boldsymbol{v}, \boldsymbol{\lambda}_u) + c(\boldsymbol{v}, \boldsymbol{u}, \boldsymbol{\lambda}_u) \\ \qquad\qquad -(\lambda_p, \nabla \cdot \boldsymbol{v}) + \displaystyle\sum_{i=1}^{m} \left(\int_{\Gamma_i} \boldsymbol{u} \cdot \boldsymbol{n}\, d\gamma - Q_i \right) \int_{\Gamma_i} \boldsymbol{v} \cdot \boldsymbol{n}\, d\gamma = 0, \\ \langle d\mathcal{L}_p, q \rangle = -(q, \nabla \cdot \boldsymbol{\lambda}_u) = 0, \end{cases} \\ \text{(C}_\text{j}\text{)} \quad \langle d\mathcal{L}_{k_j}, \nu \rangle = \displaystyle\int_{\Gamma_j} \nu \boldsymbol{\lambda}_u \cdot \boldsymbol{n}\, d\gamma = 0, \quad j = 1, \ldots, m. \end{cases}$$

In order to extend Proposition 2.1 to the nonlinear case, we introduce the following operators:

1. $\mathcal{F}_{\boldsymbol{f}} : \mathbb{R}^m \to \boldsymbol{V}$ associates to a vector $\boldsymbol{h} \in \mathbb{R}^m$ the function $\boldsymbol{w}$, where $[\boldsymbol{w}, s]$ is the solution of the Navier–Stokes problem:

(2.13)
$$\begin{cases} a(\boldsymbol{w}, \boldsymbol{v}) + c(\boldsymbol{w}, \boldsymbol{w}, \boldsymbol{v}) - (s, \nabla \cdot \boldsymbol{v}) = -\displaystyle\sum_{j=1}^{m} h_j \int_{\Gamma_j} \boldsymbol{v} \cdot \boldsymbol{n}\, d\gamma + (\boldsymbol{f}, \boldsymbol{v}) & \forall \boldsymbol{v} \in \boldsymbol{V}, \\ (q, \nabla \cdot \boldsymbol{w}) = 0 & \forall q \in L^2(\Omega). \end{cases}$$

2. Given $\boldsymbol{z} \in \boldsymbol{V}$, $\mathcal{M}[\boldsymbol{z}] : \mathbb{R}^m \to \boldsymbol{V}$ associates to a vector $\boldsymbol{h} \in \mathbb{R}^m$ the function $\boldsymbol{w}$, where $[\boldsymbol{w}, s]$ is the solution of the problem:

(2.14)
$$\begin{cases} a(\boldsymbol{w}, \boldsymbol{v}) + c(\boldsymbol{z}, \boldsymbol{v}, \boldsymbol{w}) + c(\boldsymbol{v}, \boldsymbol{z}, \boldsymbol{w}) - (s, \nabla \cdot \boldsymbol{v}) = -\displaystyle\sum_{j=1}^{m} h_j \int_{\Gamma_j} \boldsymbol{v} \cdot \boldsymbol{n}\, d\gamma & \forall \boldsymbol{v} \in \boldsymbol{V}, \\ (q, \nabla \cdot \boldsymbol{w}) = 0 & \forall q \in L^2(\Omega). \end{cases}$$

Let us denote with $\boldsymbol{Q}^0 = \mathcal{A} \circ \mathcal{F}_{\boldsymbol{f}}(\boldsymbol{0})$ the vector of flow rates (an entry for each artificial boundary) of the solution of the problem (2.13) with $h_j = 0$ for any j. $\mathcal{A}$ has been defined in (2.8).

PROPOSITION 2.2. *If the viscosity μ is large enough, and $\sum_i |Q_i - Q_i^0|$ and $\|\boldsymbol{f}\|$ are small enough, then Problem 3 admits a solution $[\boldsymbol{u}(\boldsymbol{k}), p(\boldsymbol{k}); \boldsymbol{\lambda}_u, \lambda_p; \boldsymbol{k}]$.*

Proof. Assume that the bilinear form $b_{\boldsymbol{z}}(\boldsymbol{w}, \boldsymbol{v}) := a(\boldsymbol{w}, \boldsymbol{v}) + c(\boldsymbol{z}, \boldsymbol{v}, \boldsymbol{w}) + c(\boldsymbol{v}, \boldsymbol{z}, \boldsymbol{w})$ is continuous and coercive for any $\boldsymbol{z} \in \boldsymbol{V}$. This is actually possible if the first term

dominates the other two, namely, if the viscosity μ is large enough. In this case, problem $\boldsymbol{w} = \mathcal{M}[\boldsymbol{z}](\boldsymbol{h})$ admits an unique solution for any $\boldsymbol{z} \in \boldsymbol{V}$. Let us introduce the following operators from $\mathbb{R}^m$ to $\mathbb{R}^m$: $\mathcal{C}[\boldsymbol{z}] = \mathcal{A} \circ \mathcal{M}[\boldsymbol{z}]$ and $\mathcal{D}_{\boldsymbol{f}} = \mathcal{A} \circ \mathcal{F}_{\boldsymbol{f}}$. Problem 3 is then equivalent to solving

$$\mathcal{C}[\mathcal{F}_{\boldsymbol{f}}(\boldsymbol{k})](\mathcal{D}_{\boldsymbol{f}}(\boldsymbol{k}) - \boldsymbol{Q}) = \boldsymbol{0}. \tag{2.15}$$

Now, for any $\boldsymbol{z} \in \boldsymbol{V}$, $\mathrm{Ker}(\mathcal{C}[\boldsymbol{z}]) = \{\boldsymbol{0}\}$. Indeed, $\mathcal{C}[\boldsymbol{z}](\boldsymbol{h})$ corresponds to computing the volume fluxes on Γ_i, $i = 1, \ldots, m$, of the velocity field solution of (2.14). $\mathcal{C}[\boldsymbol{z}]$ being a linear operator, it is in fact represented by matrix whose elements are $[\mathcal{C}[\boldsymbol{z}]]_{ij} = -b_{\boldsymbol{z}}(\boldsymbol{w}_j, \boldsymbol{w}_i)$ and where the velocity fields $\boldsymbol{w}_s$ are defined as in Proposition 2.1. Since $b_z(\cdot, \cdot)$ is coercive, we conclude that $\mathcal{C}[\boldsymbol{z}]$ is invertible. Therefore, system (2.15) is equivalent to the nonlinear problem

$$\mathcal{D}_{\boldsymbol{f}}(\boldsymbol{k}) = \boldsymbol{Q}, \tag{2.16}$$

that of finding suitably the k_j's such that the velocity field solution of system (P) in Problem 3 satisfies the flow rate condition $(2.1)_2$. This problem coincides with the augmented formulation proposed in [4, 15] with the difference that there the k_j were treated as Lagrange multipliers while here they act as control variables. In [15] it is shown that if $\sum_i |Q_i|$ is small enough, then an unique solution $[\boldsymbol{u}, p, \boldsymbol{k}]$ of the augmented problem exists in $[0, T]$, for a suitable $T > 0$, in the case $\boldsymbol{f} = \boldsymbol{0}$. By using similar arguments we can extend this result to the case $\boldsymbol{f} \neq \boldsymbol{0}$ by asking that $\sum_i |Q_i - Q_i^0|$ and $\|\boldsymbol{f}\|$ are small enough. Under these assumptions, problem (2.16) admits (at least) a solution $\boldsymbol{k}$ in $[0, T]$.

The corresponding $\boldsymbol{u}$ and p are obtained by solving system (P) in Problem 3 and satisfy the constraints by construction. The associated adjoint variables $\boldsymbol{\lambda}_u$ and λ_p are zero. ∎

The hypothesis on the smallness of $\sum_i |Q_i - Q_i^0|$ requires in fact that the prescribed fluxes are sufficiently close to the ones featured by the solution of the Navier–Stokes problem fulfilling homogeneous Neumann conditions in correspondence of the artificial boundaries.

3. Mean pressure boundary conditions. We consider now the mean pressure problem. Still referring to Figure 1.1, we consider (1.3) together with the boundary condition (1.4), the initial condition (1.5), and the following defective condition on the artificial sections Γ_j at any $t \in (0, T)$:

$$\frac{1}{|\Gamma_j|} \int_{\Gamma_j} p \, d\gamma = P_j, \quad j = 0, 1, \ldots, m, \tag{3.1}$$

where the $P_j = P_j(t)$ are given functions of time. We will specify later on the regularity of the data that we address. Conditions (3.1) are still not sufficient to make the problem at hand well-posed, too.

The variational approach for this type of problem advocated in [9] is based on the forcing of implicit natural homogeneous boundary conditions leading in this case to constant (in space) normal stresses and to zero tangential stresses on each Γ_i. Thus, this formulation is in fact just an approximation of the mean pressure problem and gives the expected results only for specific cases (see section 3.2). On the other hand, the Lagrange multiplier approach is not suited in this case. Its direct application indeed implies a constant normal velocity on each artificial section, which in general

not compatible with the conditions on Γ_w. Indeed, by referring, for the sake of simplicity, to the linear case, let us write the Lagrangian functional

$$\mathcal{M}(\boldsymbol{w}, s, \eta_0, \dots, \eta_m) = \frac{1}{2} a(\boldsymbol{w}, \boldsymbol{w}) + \sum_{j=0}^{m} \eta_j \int_{\Gamma_j} (s - P_j)\, d\gamma + (\nabla s, \boldsymbol{w}) - (\boldsymbol{f}, \boldsymbol{w}),$$

where $\boldsymbol{\eta} \in \mathbb{R}^{m+1}$ is the vector of the Lagrange multipliers related to the boundary conditions (3.1). By introducing the function

$$\Psi(\varepsilon, \varepsilon, \alpha_0, \dots, \alpha_m) = \mathcal{M}(\boldsymbol{w} + \varepsilon \boldsymbol{v}, s + \varepsilon q, \eta_0 + \alpha_0 \chi_0, \dots, \eta_m + \alpha_m \chi_m),$$

which takes into account variations of the velocity, of the pressure, and of the Lagrange multipliers along the directions $\boldsymbol{v}$, q, and χ_j, respectively, we impose $\frac{d\psi}{d\varepsilon}(0, 0, 0, \dots, 0) = 0$ and $\frac{d\psi}{d\alpha_j}(0, 0, 0, \dots, 0) = 0$, $j = 0, \dots, m$, and obtain the following augmented problem.

For all $\boldsymbol{v} \in \boldsymbol{V}$ and $q \in H^1(\Omega)$, find $\boldsymbol{u} \in V$, $p \in H^1(\Omega)$, and $\boldsymbol{\lambda} \in \mathbb{R}^{m+1}$ such that

$$\begin{cases} a(\boldsymbol{u}, \boldsymbol{v}) + (\nabla p, \boldsymbol{v}) = (\boldsymbol{f}, \boldsymbol{v}), \\ (\nabla q, \boldsymbol{u}) + \displaystyle\sum_{j=0}^{m} \lambda_j \int_{\Gamma_j} q\, d\gamma = 0, \\ \dfrac{1}{|\Gamma_j|} \displaystyle\int_{\Gamma_j} p\, d\gamma = P_j, \quad j = 0, 1, \dots, m. \end{cases}$$

The choice of the space $H^1(\Omega)$ for the pressures is done to guarantee the existence of their trace (see section 3.1). The second equation of the previous system gives

$$-(q, \nabla \cdot \boldsymbol{u}) + \int_{\partial\Omega} q\, \boldsymbol{u} \cdot \boldsymbol{n}\, d\gamma + \sum_{j=0}^{m} \lambda_j \int_{\Gamma_j} q\, d\gamma = 0,$$

that is, $(\boldsymbol{u} \cdot \boldsymbol{n})|_{\Gamma_j} = \lambda_j \, \forall j = 0, \dots, m$, meaning that the normal component of the velocity is constant on each Γ_j. These conditions are not in general compatible with the no-slip boundary condition (1.4) on Γ_w.

Here we propose as a possible alternative an extension of the approach introduced in the previous section. To this aim, it is crucial to select an appropriate control variable. For the moment, the (constant) normal stresses $\boldsymbol{k}$ will be retained as control variables.

3.1. Basic approach. Let us consider the generalized Stokes problem (2.2) where also at Γ_0 we prescribe a condition such as $(2.2)_5$. The control variables $\boldsymbol{k}$ are determined so that the following functional is minimized:

$$J_P(s) = \frac{1}{2} \left(\sum_{i=0}^{m} \frac{1}{|\Gamma_i|} \int_{\Gamma_i} s\, d\gamma - P_i \right)^2. \tag{3.2}$$

We refer to the following Lagrangian functional:

$$\begin{aligned} \mathcal{L}(\boldsymbol{w}, s; \boldsymbol{\lambda}_w, \lambda_s; \boldsymbol{\eta}) = J_P(s) + a(\boldsymbol{w}, \boldsymbol{\lambda}_w) - (s, \nabla \cdot \boldsymbol{\lambda}_w) \\ + \sum_{i=0}^{m} \int_{\Gamma_i} \eta_i \boldsymbol{\lambda}_w \cdot \boldsymbol{n}\, d\gamma - (\boldsymbol{f}, \boldsymbol{\lambda}_w) - (\lambda_s, \nabla \cdot \boldsymbol{w}) \end{aligned} \tag{3.3}$$

for all $\boldsymbol{w} \in \boldsymbol{V}$, $s \in H^1(\Omega)$, $\boldsymbol{\lambda}_w \in \boldsymbol{V}$, $\lambda_s \in H^1(\Omega)$, and $\boldsymbol{\eta} \in \mathbb{R}^{m+1}$. We point out that we take $s \in H^1(\Omega)$ so that its trace on Γ_i, $i = 0, \dots, m$, is meaningful. Of course, we assume that Ω is sufficiently regular. The stationary point of $\mathcal{L}$ fulfills the following.

PROBLEM 4. *Given $\boldsymbol{f} \in \boldsymbol{L}^2(\Omega)$ and $\boldsymbol{P} \in \mathbb{R}^{m+1}$, find $\boldsymbol{k} \in \mathbb{R}^{m+1}$, $\boldsymbol{u}(\boldsymbol{k}) \in \boldsymbol{V}, p(\boldsymbol{k}) \in H^1(\Omega), \boldsymbol{\lambda}_u \in \boldsymbol{V}$, and $\lambda_p \in H^1(\Omega)$ such that, for all $\boldsymbol{v} \in \boldsymbol{V}$, $q \in H^1(\Omega)$, and $\nu \in \mathbb{R}$,*

$$
\begin{cases}
\text{(P)} \begin{cases} \langle d\mathcal{L}_{\boldsymbol{\lambda}_u}, \boldsymbol{v} \rangle = a(\boldsymbol{u}, \boldsymbol{v}) - (p, \nabla \cdot \boldsymbol{v}) + \displaystyle\sum_{i=0}^{m} \int_{\Gamma_i} k_i \boldsymbol{v} \cdot \boldsymbol{n} \, d\gamma - (\boldsymbol{f}, \boldsymbol{v}) = 0, \\ \langle d\mathcal{L}_{\lambda_p}, q \rangle = -(q, \nabla \cdot \boldsymbol{u}) = 0, \end{cases} \\
\text{(A)} \begin{cases} \langle d\mathcal{L}_{\boldsymbol{u}}, \boldsymbol{v} \rangle = a(\boldsymbol{v}, \boldsymbol{\lambda}_u) - (\lambda_p, \nabla \cdot \boldsymbol{v}) = 0, \\ \langle d\mathcal{L}_p, q \rangle = \displaystyle\sum_{i=0}^{m} \left(\frac{1}{|\Gamma_i|} \int_{\Gamma_i} p \, d\gamma - P_i \right) \frac{1}{|\Gamma_i|} \int_{\Gamma_i} q \, d\gamma - (q, \nabla \cdot \boldsymbol{\lambda}_u) = 0, \end{cases} \\
\text{(C}_\text{j}\text{)} \quad \langle d\mathcal{L}_{k_i}, \nu \rangle = \displaystyle\int_{\Gamma_i} \nu \boldsymbol{\lambda}_u \cdot \boldsymbol{n} \, d\gamma = 0, \quad i = 0, \dots, m.
\end{cases}
$$

In this case, we obtain a system coupling a generalized Stokes (P) and a fluid problem featuring a nonzero divergence velocity (A). These two problems considered separately are well-posed in the spaces $[\boldsymbol{V}, H^1(\Omega)]$. Indeed, the inf-sup condition holds even if we restrict to the test functions $q \in H^1(\Omega)$, where $H^1(\Omega) \subset L^2(\Omega)$. Moreover, thanks to the density of $H^1(\Omega)$ in $L^2(\Omega)$, given $g \in L^2(\Omega)$, the equality $(q, \nabla \cdot \boldsymbol{v}) = (q, g) \, \forall q \in H^1(\Omega)$ implies that $\nabla \cdot \boldsymbol{v} = g$ in a weak sense.

The analysis of this control problem seems, however, more complex than that of Problem 2. The explicit definition of the operator mapping the given data to the control variables resorts to pseudodifferential operators involving the pressure. On the other hand, general theoretical results on the convergence of Lagrange multipliers, such as the ones reported in [7, Chap. 6], cannot be applied, since the functional at hand does not contain the control variables explicitly. The well posedness of this formulation is therefore still an open problem. Numerical results suggest, however, that the problem can in fact be solved (see section 4.2).

3.2. More complex functionals. In solving defective boundary problems, it is sometimes worthwhile to include into the formulation of the problem specific features of the solution that are not represented in terms of boundary conditions. However, the knowledge of these features can be useful in completing a defective boundary data set. The approach presented here is quite versatile and prone to include these features. In fact, the functional to be minimized can be properly designed for including these data. Consequently, the set of control variables for the optimization process can be driven by the definition of a modified functional. For the sake of clarity, let us consider a domain given by an almost rectilinear pipe, such as the one depicted in Figure 3.1, where we prescribe a mean value for the pressure on an artificial boundary not normal to the pipe axis. Geometrical considerations suggest that the flow is mainly directed along the axial direction **a**. On the contrary, a solution to Problem 4 would in general provide a significant transverse velocity component on the artificial boundary. Problem 4 indeed forces zero tangential stresses on Γ_i as a natural boundary condition. We can, however, modify the functional in such a way that the minimization process could include the transverse velocity component. This can be done, for instance, by assuming that

$$
J_P(\boldsymbol{w}, s) = \frac{1}{2} \sum_{i=0}^{m} \left(\frac{1}{|\Gamma_i|} \int_{\Gamma_i} s \, d\gamma - P_i \right)^2 + \mathcal{S}(\boldsymbol{w}, s, \Omega), \tag{3.4}
$$

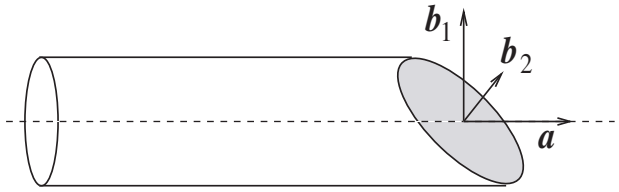

FIG. 3.1. *Artificial section Γ_i, axial direction $\boldsymbol{a}$, and orthogonal directions $\boldsymbol{b}_1$ and $\boldsymbol{b}_2$.*

where $\mathcal{S}$ depends also on the velocity field and on the domain. For example, for the case at hand a possible expression for $\mathcal{S}$ is

$$\mathcal{S} = \mathcal{S}_1(\boldsymbol{w}, \boldsymbol{b}_1, \dots, \boldsymbol{b}_{d-1}) = \frac{1}{2} \sum_{l=1}^{d-1} \sum_{i=0}^{m} \int_{\Gamma_i} |\boldsymbol{w} \cdot \boldsymbol{b}_l|^2 \, d\gamma, \tag{3.5}$$

where $\boldsymbol{b}_l$, $l = 1, \dots, d-1$, are, for each section Γ_i, the orthogonal unit vectors to the axial direction $\boldsymbol{a}$ (see Figure 3.1). In order to improve the effectiveness of the control procedure on the boundary velocity, we augment the set of control variables. For instance, we do not fix a specific direction for the normal stresses and set

$$(-p\boldsymbol{n} + \mu \nabla \boldsymbol{u}\, \boldsymbol{n})|_{\Gamma_j} = -\boldsymbol{K}_j(\boldsymbol{x}), \quad j = 0, \dots, m, \tag{3.6}$$

where, for instance, the $\boldsymbol{K}_j \in (L^2(\Gamma_j))^d$, $j = 0, \dots, m$, are the control variables. From the Lagrangian functional associated with (3.4) and (3.5), with the constraints $(2.2)_1$, $(2.2)_2$, $(2.2)_3$, and (3.6), we obtain the following.

PROBLEM 5. *Given $\boldsymbol{f} \in \boldsymbol{L}^2(\Omega)$ and $\boldsymbol{P} \in \mathbb{R}^{m+1}$, find $\boldsymbol{K}_j \in (L^2(\Gamma_j))^d$, $j = 0, \dots, m$, $\boldsymbol{u}(\boldsymbol{K}_0, \dots, \boldsymbol{K}_m) \in \boldsymbol{V}$, $p(\boldsymbol{K}_0, \dots, \boldsymbol{K}_m) \in H^1(\Omega)$, $\boldsymbol{\lambda}_u \in \boldsymbol{V}$, and $\lambda_p \in H^1(\Omega)$ such that, for all $\boldsymbol{v} \in \boldsymbol{V}$, $q \in H^1(\Omega)$, and $\boldsymbol{\nu} \in (L^2(\Gamma_i))^d$, $i = 0, \dots, m$:*

$$\begin{cases} \text{(P)} \begin{cases} \langle d\mathcal{L}_{\boldsymbol{\lambda}_u}, \boldsymbol{v} \rangle = a(\boldsymbol{u}, \boldsymbol{v}) - (p, \nabla \cdot \boldsymbol{v}) + \displaystyle\sum_{i=0}^{m} \int_{\Gamma_i} \boldsymbol{K}_i \cdot \boldsymbol{v} \, d\gamma - (\boldsymbol{f}, \boldsymbol{v}) = 0, \\ \langle d\mathcal{L}_{\lambda_p}, q \rangle = -(q, \nabla \cdot \boldsymbol{u}) = 0, \end{cases} \\ \text{(A)} \begin{cases} \langle d\mathcal{L}_{\boldsymbol{u}}, \boldsymbol{v} \rangle = \displaystyle\sum_{l=1}^{d-1} \sum_{i=0}^{m} \int_{\Gamma_i} (\boldsymbol{u} \cdot \boldsymbol{b}_l)(\boldsymbol{v} \cdot \boldsymbol{b}_l) \, d\gamma + a(\boldsymbol{v}, \boldsymbol{\lambda}_u) - (\lambda_p, \nabla \cdot \boldsymbol{v}) = 0, \\ \langle d\mathcal{L}_p, q \rangle = \displaystyle\sum_{i=0}^{m} \left(\frac{1}{|\Gamma_i|} \int_{\Gamma_i} p \, d\gamma - P_i \right) \frac{1}{|\Gamma_i|} \int_{\Gamma_i} q \, d\gamma - (q, \nabla \cdot \boldsymbol{\lambda}_u) = 0, \end{cases} \\ \text{(C}_\text{i}\text{)} \quad \langle d\mathcal{L}_{\boldsymbol{k}_i}, \boldsymbol{\nu} \rangle = \displaystyle\int_{\Gamma_i} \boldsymbol{\nu} \cdot \boldsymbol{\lambda}_u \, d\gamma = 0, \quad i = 0, \dots, m. \end{cases}$$

Observe that in this case the optimality conditions (C$_\text{i}$) imply that $\boldsymbol{\lambda}_u|_{\Gamma_i} = \boldsymbol{0}$, $i = 0, \dots, m$. The conditions of fulfillment of the optimal state are more restrictive than the ones in Problem 4 having a larger control variable set.

Other forms for the perturbing term $\mathcal{S}$ can be considered as well. For instance, we could minimize the functional

$$\mathcal{S}_2(\boldsymbol{w}, \boldsymbol{a}) = \frac{1}{2} \sum_{i=0}^{m} \int_{\Gamma_i} \|\nabla \boldsymbol{w}\, \boldsymbol{a}\|_2^2 \, d\gamma. \tag{3.7}$$

Here $\| \cdot \|_2$ is the Euclidean norm made on the components of the vector $\nabla \boldsymbol{w}\, \boldsymbol{a}$. In this way the variation of the velocity along $\boldsymbol{a}$ on the artificial boundary is minimized.

Due to the incompressibility constraint, a variation of the velocity along $\boldsymbol{a}$ will be compensated by variations of the components orthogonal to $\boldsymbol{a}$. For this reason, this form of $\mathcal{S}$ can be considered as an indirect way of forcing null tangential velocity. This leads to the following.

PROBLEM 6. *Given* $\boldsymbol{f} \in \boldsymbol{L}^2(\Omega)$ *and* $\boldsymbol{P} \in \mathbb{R}^{m+1}$, *find* $\boldsymbol{K}_j \in (L^2(\Gamma_j))^d$, $j = 0, \ldots, m$, $\boldsymbol{u}(\boldsymbol{K}_0, \ldots, \boldsymbol{K}_m) \in \boldsymbol{V}$, $p(\boldsymbol{K}_0, \ldots, \boldsymbol{K}_m) \in H^1(\Omega)$, $\boldsymbol{\lambda}_u \in \boldsymbol{V}$, *and* $\lambda_p \in H^1(\Omega)$ *such that, for all* $\boldsymbol{v} \in \boldsymbol{V}$, $q \in H^1(\Omega)$, *and* $\boldsymbol{\nu} \in (L^2(\Gamma_i))^d$, $i = 0, \ldots, m$:

$$
\begin{cases}
\text{(P)} \begin{cases} \langle d\mathcal{L}_{\boldsymbol{\lambda}_u}, \boldsymbol{v} \rangle = a(\boldsymbol{u}, \boldsymbol{v}) - (p, \nabla \cdot \boldsymbol{v}) + \displaystyle\sum_{i=0}^{m} \int_{\Gamma_i} \boldsymbol{K}_i \cdot \boldsymbol{v} \, d\gamma - (\boldsymbol{f}, \boldsymbol{v}) = 0, \\ \langle d\mathcal{L}_{\lambda_p}, q \rangle = -(q, \nabla \cdot \boldsymbol{u}) = 0, \end{cases} \\
\text{(A)} \begin{cases} \langle d\mathcal{L}_{\boldsymbol{u}}, \boldsymbol{v} \rangle = \displaystyle\sum_{i=0}^{m} \int_{\Gamma_i} (\nabla \boldsymbol{u}\, \boldsymbol{a}) \cdot (\nabla \boldsymbol{v}\ \boldsymbol{a}) \, d\gamma + a(\boldsymbol{v}, \boldsymbol{\lambda}_u) - (\lambda_p, \nabla \cdot \boldsymbol{v}) = 0, \\ \langle d\mathcal{L}_p, q \rangle = \displaystyle\sum_{i=0}^{m} \left(\frac{1}{|\Gamma_i|} \int_{\Gamma_i} p \, d\gamma - P_i \right) \frac{1}{|\Gamma_i|} \int_{\Gamma_i} q \, d\gamma - (q, \nabla \cdot \boldsymbol{\lambda}_u) = 0, \end{cases} \\
\text{(C}_\text{i}\text{)} \quad \langle d\mathcal{L}_{\boldsymbol{K}_i}, \boldsymbol{\nu} \rangle = \displaystyle\int_{\Gamma_i} \boldsymbol{\nu} \cdot \boldsymbol{\lambda}_u \, d\gamma = 0, \quad i = 0, \ldots, m.
\end{cases}
$$

We point out that it is possible to extend the previous control problems to the nonlinear case.

Remark 1. It is well known that the correct formulation of the diffusive term in the weak form of the momentum equation is $\int_\Omega \mu(\nabla \boldsymbol{u} + \nabla \boldsymbol{u}^T)\nabla \boldsymbol{v}$. This is crucial, for instance, in fluid structure interaction problems in correct computing of the stresses exchanged by the fluid and structure. On the other hand, in [9] it is observed that the complete diffusive term can have some drawbacks in applying the variational formulation for solving pressure drop problems due to boundary tangential velocity components induced by this approach. These drawbacks in the present framework can be dominated by resorting to functionals (3.4) and (3.5) or (3.4) and (3.7). This aspect will be investigated in a forthcoming paper in the case of problems in deformable domains.

3.3. Using the flow rates as control variables. For solving the mean pressure problem we can also pursue a sort of "dual" approach to the one proposed in section 2 for the flow rate problem. Here the control variables are given by the flow rates Q_j on Γ_j, $j = 1, \ldots, m$. More precisely, we consider the generalized Stokes problem

$$
\begin{cases}
\alpha \boldsymbol{u}(\boldsymbol{Q}) - \mu \triangle \boldsymbol{u}(\boldsymbol{Q}) + \nabla p(\boldsymbol{Q}) = \boldsymbol{f} & \text{in } \Omega, \\
\nabla \cdot \boldsymbol{u}(\boldsymbol{Q}) = 0 & \text{in } \Omega, \\
\boldsymbol{u}(\boldsymbol{Q})|_{\Gamma_w} = \boldsymbol{0}, & \\
(-p(\boldsymbol{Q})\boldsymbol{n} + \mu \nabla \boldsymbol{u}(\boldsymbol{Q})\, \boldsymbol{n})|_{\Gamma_0} = -P_0 \boldsymbol{n}, & \\
\displaystyle\int_{\Gamma_j} \boldsymbol{u}(\boldsymbol{Q}) \cdot \boldsymbol{n} \, d\gamma = Q_j, & j = 1, \ldots, m,
\end{cases} \tag{3.8}
$$

where P_0 is a given constant. Thanks to the Neumann condition on Γ_0, there is no need for compatibility conditions on the flow rate data. When we formulate the corresponding control problem where (3.2) (or its possible modifications) is the functional to be minimized, while (3.8) are the state equations, the latter can be solved according to the augmented Lagrangian approach (Problem 1). Therefore, we need to introduce

the following Lagrangian functional:

$$\begin{aligned}\mathcal{L}(\boldsymbol{w}, s, \boldsymbol{\xi}; \boldsymbol{\lambda}_w, \lambda_s, \boldsymbol{\lambda}_\xi; \boldsymbol{\eta}) = \quad & J_P(s) + a(\boldsymbol{w}, \boldsymbol{\lambda}_w) - (s, \nabla \cdot \boldsymbol{\lambda}_w) + \sum_{i=1}^{m} \xi_i \int_{\Gamma_i} \boldsymbol{\lambda}_w \cdot \boldsymbol{n}\, d\gamma \\ & -(\boldsymbol{f}, \boldsymbol{\lambda}_w) - (\lambda_s, \nabla \cdot \boldsymbol{w}) + \sum_{i=1}^{m} \lambda_{\xi_i} \left(\int_{\Gamma_i} \boldsymbol{w} \cdot \boldsymbol{n}\, d\gamma - \eta_i \right),\end{aligned}$$

where the $\boldsymbol{\xi} = (\xi_1, \ldots, \xi_m)$ are the Lagrange multipliers of the augmented formulation (see [4, 15]). The quantities $\boldsymbol{\lambda}_w, \lambda_s$, and $\lambda_{\xi_1}, \ldots, \lambda_{\xi_m}$ are the adjoint variables related to $\boldsymbol{w}, s$, and $\xi_1, \ldots, \xi_m$, respectively. By forcing the derivatives of $\mathcal{L}$ with respect to all of the variables in correspondence of the solution $[\boldsymbol{u}, p, \boldsymbol{\zeta}; \boldsymbol{\lambda}_u, \lambda_p, \boldsymbol{\lambda}_\zeta; \boldsymbol{Q}]$ to vanish, we obtain the following.

PROBLEM 7. *Given* $\boldsymbol{f} \in \boldsymbol{L}^2(\Omega)$ *and* $\boldsymbol{P} \in \mathbb{R}^m$, *find* $\boldsymbol{Q} \in \mathbb{R}^m$, $\boldsymbol{u}(\boldsymbol{Q}) \in \boldsymbol{V}, p(\boldsymbol{Q}) \in H^1(\Omega), \zeta_j(\boldsymbol{Q}) \in \mathbb{R}$, $j = 1, \ldots, m$, $\boldsymbol{\lambda}_u \in \boldsymbol{V}, \lambda_p \in H^1(\Omega)$, *and* $\lambda_{\zeta_j} \in \mathbb{R}$, $j = 1, \ldots, m$, *such that, for all* $\boldsymbol{v} \in \boldsymbol{V}$, $q \in H^1(\Omega)$, *and* $\nu \in \mathbb{R}$:

$$\begin{cases} \text{(P)} \begin{cases} \langle d\mathcal{L}_{\boldsymbol{\lambda}_u}, \boldsymbol{v} \rangle = a(\boldsymbol{u}, \boldsymbol{v}) - (p, \nabla \cdot \boldsymbol{v}) + \displaystyle\sum_{i=1}^{m} \zeta_i \int_{\Gamma_i} \boldsymbol{v} \cdot \boldsymbol{n}\, d\gamma - (\boldsymbol{f}, \boldsymbol{v}) = 0, \\ \langle d\mathcal{L}_{\lambda_p}, q \rangle = -(q, \nabla \cdot \boldsymbol{u}) = 0, \\ \langle d\mathcal{L}_{\lambda_{\zeta_i}}, \nu \rangle = \left(\displaystyle\int_{\Gamma_i} \boldsymbol{u} \cdot \boldsymbol{n}\, d\gamma - Q_i \right) \nu = 0, \end{cases} \\ \text{(A)} \begin{cases} \langle d\mathcal{L}_{\boldsymbol{u}}, \boldsymbol{v} \rangle = a(\boldsymbol{v}, \boldsymbol{\lambda}_u) - (\lambda_p, \nabla \cdot \boldsymbol{v}) + \displaystyle\sum_{i=1}^{m} \lambda_{\zeta_i} \int_{\Gamma_i} \boldsymbol{v} \cdot \boldsymbol{n}\, d\gamma = 0, \\ \langle d\mathcal{L}_p, q \rangle = \displaystyle\sum_{i=1}^{m} \left(\frac{1}{|\Gamma_i|} \int_{\Gamma_i} p\, d\gamma - P_i \right) \frac{1}{|\Gamma_i|} \int_{\Gamma_i} q\, d\gamma - (q, \nabla \cdot \boldsymbol{\lambda}_u) = 0, \\ \langle d\mathcal{L}_{\zeta_i}, \nu \rangle = \left(\displaystyle\int_{\Gamma_i} \boldsymbol{\lambda}_u \cdot \boldsymbol{n}\, d\gamma \right) \nu = 0, \end{cases} \\ \text{(C}_\text{i}\text{)} \quad \langle d\mathcal{L}_{Q_i}, \nu \rangle = -\lambda_{\zeta_i} \nu = 0, \quad i = 1, \ldots, m. \end{cases}$$

The compatibility conditions in this case yield $\lambda_{\zeta_i} = 0, i = 1, \ldots, m$, which amounts to forcing normal stress in the adjoint problem to be zero on each artificial section (see [4]). This is the dual situation to what we found for the flow rate problems of section 2, in which fluxes of the adjoint problem were zero. Also in this case, in correspondence to the solution of Problem 7, the adjoint problem features the (unique) zero solution.

The previous approach can be extended to the nonlinear case in analogy with section 2.

Also for solving Problem 7 we resort to an iterative scheme, where the optimality conditions (C$_\text{i}$) and $\lambda_{\zeta_i} = 0$ drive the convergence (see [7]).

4. Numerical algorithms. We present now some numerical procedures for the solution of the problems introduced in the previous sections. In particular, in section 4.1 we investigate the flow rate problem. We first introduce a general strategy applied to Problem 2; then we present a special algorithm for the prescription of just one flow rate condition. In section 4.2 we illustrate numerical algorithms for solving Problem 4 as well, as an example of mean pressure problem. Methods presented can be extended to different defective boundary problems.

4.1. Flow rate problems. Let us consider Problem 2. For its numerical solution, we can resort to an iterative method such that at each iteration we solve separately problems (P) and (A) and check condition (C$_\text{j}$) until convergence.

Let us notice that the adjoint problem (A) in Problem 2 depends linearly on the values of the natural boundary condition on Γ_j. Therefore, let $(\boldsymbol{\lambda}_{u,i}, \boldsymbol{\lambda}_{p,i})$ be the *reference solutions* of the problems featuring unit normal stresses:

$$\begin{cases} a(\boldsymbol{v}, \boldsymbol{\lambda}_{u,i}) - (\lambda_{p,i}, \nabla \cdot \boldsymbol{v}) + \displaystyle\int_{\Gamma_i} \boldsymbol{v} \cdot \boldsymbol{n}\, d\gamma = 0 & \forall \boldsymbol{v} \in \boldsymbol{V}, \\ (q, \nabla \cdot \boldsymbol{\lambda}_{u,i}) = 0 & \forall q \in L^2(\Omega) \end{cases} \tag{4.1}$$

for all $i = 1, \ldots, m$; then the solution of (A) in Problem 2 can be written as a linear combination of such reference solutions

$$\boldsymbol{\lambda}_u = \sum_{i=1}^{m} \left(\int_{\Gamma_i} \boldsymbol{u} \cdot \boldsymbol{n}\, d\gamma - Q_i \right) \boldsymbol{\lambda}_{u,i}, \qquad \lambda_p = \sum_{i=1}^{m} \left(\int_{\Gamma_i} \boldsymbol{u} \cdot \boldsymbol{n}\, d\gamma - Q_i \right) \lambda_{p,i}.$$

Hence, the computational cost of the adjoint problem reduces to the m problems (4.1), which can be computed preliminarily. Obviously, this is not true anymore for the nonlinear case.

Observe first of all that if we introduce the affine map $\mathcal{T}_\tau : \mathbb{R}^m \to \mathbb{R}^m$:

$$\mathcal{T}_\tau(\boldsymbol{k}) := \boldsymbol{k} + \tau \mathcal{B}_{\mathbf{0}}(\mathcal{B}_{\boldsymbol{f}}(\boldsymbol{k}) - \boldsymbol{Q}),$$

where $\mathcal{B}_{\boldsymbol{f}}$ and $\mathcal{B}_{\mathbf{0}}$ have been introduced in section 2.1 and τ is a given real coefficient, Problem 2 can be reformulated as the computation of a fixed point solution:

$$\hat{\boldsymbol{k}} = \mathcal{T}_\tau(\hat{\boldsymbol{k}}). \tag{4.2}$$

This naturally leads to the numerical method based on the fixed point iteration

$$\boldsymbol{k}^{l+1} = \mathcal{T}_\tau(\boldsymbol{k}^l),$$

where l denotes the iteration index. The following algorithm reflects this scheme.

ALGORITHM 1.

1. Solve for $j = 1, \ldots, m$ problems (4.1) discretized in space, giving solutions $\boldsymbol{\lambda}_{u,j,h}$ and $\lambda_{p,j,h}$ for $j = 1, \ldots, m$.
2. Loop: Given $k^1_{j,h}$, $j = 1, \ldots, m$, and ε, set $l = 1$ and do until convergence
   - Solve

$$\begin{cases} a(\boldsymbol{u}_h^l, \boldsymbol{v}_h) - (p_h^l, \nabla \cdot \boldsymbol{v}_h) + \displaystyle\sum_{i=1}^{m} \int_{\Gamma_i} k_{i,h}^l \boldsymbol{v}_h \cdot \boldsymbol{n}\, d\gamma - (\boldsymbol{f}, \boldsymbol{v}_h) = 0 & \forall \boldsymbol{v}_h \in \boldsymbol{V}_h, \\ (q_h, \nabla \cdot \boldsymbol{u}_h^l) = 0 & \forall q_h \in Q_h. \end{cases}$$

   - Compute the adjoint solutions

$$\boldsymbol{\lambda}_{u,h}^l = \sum_{i=1}^{m} \left(\int_{\Gamma_i} \boldsymbol{u}_h^l \cdot \boldsymbol{n}\, d\gamma - Q_i \right) \boldsymbol{\lambda}_{u,i,h},$$

$$\lambda_{p,h}^l = \sum_{i=1}^{m} \left(\int_{\Gamma_i} \boldsymbol{u}_h^l \cdot \boldsymbol{n}\, d\gamma - Q_i \right) \lambda_{p,i,h}.$$

   - Convergence test: If $|\int_{\Gamma_j} \boldsymbol{\lambda}_{u,h}^l \cdot \boldsymbol{n}\, d\gamma| < \varepsilon \, \forall j = 1, \ldots, m$, then break

`else` $k_{j,h}^{l+1} = k_{j,h}^{l} + \tau^l \int_{\Gamma_j} \boldsymbol{\lambda}_{u,h}^{l} \cdot \boldsymbol{n}\, d\gamma, \quad \forall j = 1, \dots, m,$ `and set` $l = l + 1$.

`end`

We have the following proposition.

PROPOSITION 4.1. *For an appropriate choice of* τ*, Algorithm* 1 *converges to the solution of Problem* 2.

Proof. Let us prove that $\mathcal{T}_\tau$ is a contraction for suitable values of τ. For a given increment $\delta\boldsymbol{k}$, thanks to the linearity of the involved operators, we obtain

$$\mathcal{T}_\tau(\boldsymbol{k} + \delta\boldsymbol{k}) - \mathcal{T}_\tau(\boldsymbol{k}) = (\mathcal{I} + \tau\mathcal{B}_{\mathbf{0}}^2)\delta\boldsymbol{k}, \tag{4.3}$$

where $\mathcal{I} + \tau\mathcal{B}_{\mathbf{0}}^2$ is a square matrix, $\mathcal{I}$ being the identity. $\mathcal{B}_{\mathbf{0}}$ being symmetric and negative definite (see Proposition 2.1), T_τ is a contraction for

$$-\frac{2}{\rho(\mathcal{B}_{\mathbf{0}}^2)} < \tau < 0,$$

where $\rho(\mathcal{B}_{\mathbf{0}})$ is the spectral radius of $\mathcal{B}_{\mathbf{0}}$. For any τ in this range, Algorithm 1 converges to the solution of Problem 2. The optimal value for the coefficient τ, which guarantees the highest convergence rate, is given by

$$\tau_{opt} = -\frac{2}{\rho(\mathcal{B}_0^2) + \mu_{min}},$$

where μ_{min} is the minimum eigenvalue of $\mathcal{B}_0^2$. ∎

The knowledge of the optimal value of τ is not exploitable in practice, as it is based on the knowledge of the spectrum of $\mathcal{B}_{\mathbf{0}}$, which is not in general available. Dynamic strategies for the selection of the parameter τ, regarded as a function of the iteration l, can be considered. In particular, by denoting by $\boldsymbol{\chi}_h^l$ the numerical solution obtained at iteration l, we can resort to the choice

$$\tau^l = \tau_N^l = -\frac{J_Q(\boldsymbol{u}_h^l)}{\|\mathcal{L}_{\boldsymbol{k}}(\boldsymbol{\chi}_h^l)\|_2^2} \tag{4.4}$$

that amounts to updating the k_j as follows:

$$k_{j,h}^{l+1} = k_{j,h}^{l} - \frac{\frac{1}{2}\sum_{j=1}^{m}\left(\int_{\Gamma_j} \boldsymbol{u}_h^l \cdot \boldsymbol{n}\, d\gamma - Q_j\right)^2 \int_{\Gamma_j} \boldsymbol{\lambda}_{u,h}^{l} \cdot \boldsymbol{n}\, d\gamma}{\sum_{j=1}^{m} |\int_{\Gamma_j} \boldsymbol{\lambda}_{u,h}^{l} \cdot \boldsymbol{n}\, d\gamma|^2}.$$

This choice stems from the application of the classical Newton method for the equation $J_Q(\boldsymbol{k}) = 0$. Indeed, it can be shown that $\langle J_Q'(\boldsymbol{k}), \boldsymbol{\nu}\rangle = \langle \mathcal{L}_{\boldsymbol{k}}(\boldsymbol{s}), \boldsymbol{\nu}\rangle \, \forall \boldsymbol{\nu} \in \mathbb{R}^m$. A further improvement can be yielded by observing that J_Q is a quadratic functional and the associate solution is supposed to be of multiplicity 2, so that we select $\tau^l = 2\tau_N^l$. As we will see in section 5 this is an affective choice.

Algorithm 1 can be suitably extended to nonlinear Problem 3.

4.1.1. Prescription of a single flow rate. In the particular case of only one prescribed flux, we can resort to a different algorithm based on the variational formulation of (2.2) (or (2.12) for the nonlinear case). For instance, considering (2.12) together with $(2.2)_{2-5}$ and $(2.1)_2$ and with $m = 1$, by setting $\boldsymbol{v} = \boldsymbol{u}$ we obtain:

$$a(\boldsymbol{u}, \boldsymbol{u}) + ((\boldsymbol{u} \cdot \nabla)\boldsymbol{u}, \boldsymbol{u}) + \int_\Gamma k\boldsymbol{u} \cdot \boldsymbol{n}\, d\gamma = (\boldsymbol{f}, \boldsymbol{u}),$$

and then, by exploiting the fact that k is constant, if $Q \neq 0$, we can calculate directly

$$k = \frac{(\boldsymbol{f}, \boldsymbol{u}(k)) - \|\boldsymbol{u}(k)\|_a^2 - ((\boldsymbol{u}(k)\cdot\nabla)\boldsymbol{u}(k), \boldsymbol{u}(k))}{Q} = \phi(k), \tag{4.5}$$

where we have set $\|\boldsymbol{v}\|_a^2 := a(\boldsymbol{v}, \boldsymbol{v})$. A fixed point iteration may then be set up as follows.

ALGORITHM 2. `Given` k_h^1, $\boldsymbol{u}_h^0$, `and` ε, `set` $l = 1$ `and do until convergence`

1. `Solve`

$$\begin{cases} a(\boldsymbol{u}_h^l, \boldsymbol{v}_h) + ((\boldsymbol{u}_h^{l-1}\cdot\nabla)\boldsymbol{u}_h^l, \boldsymbol{v}_h) - (p_h^l, \nabla\cdot\boldsymbol{v}_h) + \displaystyle\int_\Gamma k_h^l \boldsymbol{v}_h\cdot\boldsymbol{n}\, d\gamma = (\boldsymbol{f}, \boldsymbol{v}_h) & \forall \boldsymbol{v}_h \in \boldsymbol{V}_h, \\ (q_h, \nabla\cdot\boldsymbol{u}_h^l) = 0 & \forall q_h \in Q_h. \end{cases}$$

2. `Compute`

$$k_h^{l+1} = \frac{(\boldsymbol{f}, \boldsymbol{u}_h^l) - \|\boldsymbol{u}_h^l\|_a^2 - ((\boldsymbol{u}_h^{l-1}\cdot\nabla)\boldsymbol{u}_h^l, \boldsymbol{u}_h^l)}{Q}.$$

3. `Convergence test: if` $|k_h^{l+1} - k_h^l| < \varepsilon$, `then exit`
4. `else` $l = l + 1$

`end`

Remark 2. In the case of an unsteady problem, Algorithm 2 fails if there exists a $\widetilde{t}$ such that $Q(\widetilde{t})$=0.

In the particular case of a linear problem with $\boldsymbol{f} = \boldsymbol{0}$, we do not even need to resort to a fixed point iteration. Indeed, in this case the velocity $\boldsymbol{u}$ depends linearly on k. Therefore, by denoting with $\widetilde{\boldsymbol{u}}$ the solution obtained for $k = 1$, $\boldsymbol{u}$ is computed thanks to $\boldsymbol{u} = k\widetilde{\boldsymbol{u}}$. Therefore, from (4.5), we obtain $k = -k^2\|\widetilde{\boldsymbol{u}}\|_a^2/Q$, yielding the following explicit expression for k:

$$k = -\frac{Q}{\|\widetilde{\boldsymbol{u}}\|_a^2}.$$

4.2. Mean pressure problem. Algorithm 1 can be properly extended to the mean pressure problem presented in section 3. If the control variable is a vector of constants and the problem at hand is linear (like in Problems 4 and 7), the adjoint problem can be still solved effectively by solving a suitable problem out of the iterative loop. For instance, if we refer to Problem 4, and we denote by $(\widetilde{\boldsymbol{\lambda}}_{u,i}, \widetilde{\lambda}_{p,i})$ the solutions of

$$\begin{cases} a(\widetilde{\boldsymbol{\lambda}}_{u,i}, \boldsymbol{v}) - (\widetilde{\lambda}_{p,i}, \nabla\cdot\boldsymbol{v}) = 0 & \forall \boldsymbol{v} \in \boldsymbol{V}, \\ -(q, \nabla\cdot\widetilde{\boldsymbol{\lambda}}_{u,i}) = -\displaystyle\int_{\Gamma_i} q\, d\gamma & \forall q \in H^1(\Omega), \end{cases} \tag{4.6}$$

then we can obtain the solution to the adjoint problem (A) by setting

$$\boldsymbol{\lambda}_u = \sum_{i=0}^{m} \left(\frac{1}{|\Gamma_i|}\int_{\Gamma_i} p(\boldsymbol{k})\, d\gamma - P_i \right) \widetilde{\boldsymbol{\lambda}}_{u,i}, \qquad \lambda_p = \sum_{i=0}^{m} \left(\frac{1}{|\Gamma_i|}\int_{\Gamma_i} p(\boldsymbol{k})\, d\gamma - P_i \right) \widetilde{\lambda}_{p,i}.$$

Let $\boldsymbol{V}_h \subset \boldsymbol{V}$ and $Q_h^1 \subset H^1(\Omega)$, respectively, be a couple of inf-sup compatible finite-dimensional spaces. We denote by $\{\boldsymbol{\varphi}_i\}$ $(i = 1, \ldots, n_{vel})$ and $\{\psi_i\}$ $(i = 1, \ldots, n_p)$ the basis function set of $\boldsymbol{V}_h$ and Q_h^1, respectively, n_{vel} and n_p being their dimensions.

For solving Problem 4, we propose the following algorithm.

ALGORITHM 3.

1. `Solve, for` $i = 0, \dots, m$, `problems (4.6) discretized in space, giving the solutions` $\widetilde{\boldsymbol{\lambda}}_{u,i,h}$ `and` $\widetilde{\lambda}_{p,i,h}$.
2. `Loop: Given` $k^1_{j,h}$, $j = 0, \dots, m$, `and` ε, `set` $l = 1$ `and do until convergence`
   - `Solve`

$$\begin{cases} a(\boldsymbol{u}^l_h, \boldsymbol{v}_h) - (p^l_h, \nabla \cdot \boldsymbol{v}_h) + \displaystyle\sum_{i=0}^{m} \int_{\Gamma_i} k^l_{i,h} \boldsymbol{v}_h \cdot \boldsymbol{n}\, d\gamma - (\boldsymbol{f}, \boldsymbol{v}_h) = 0 & \forall \boldsymbol{v}_h \in \boldsymbol{V}_h \\ (q_h, \nabla \cdot \boldsymbol{u}^l_h) = 0 & \forall q_h \in Q^1_h. \end{cases}$$

   - `Compute the adjoint solutions`

$$\boldsymbol{\lambda}^l_{u,h} = \sum_{i=0}^{m} \left(\frac{1}{|\Gamma_i|} \int_{\Gamma_i} p^l_h \, d\gamma - P_i \right) \widetilde{\boldsymbol{\lambda}}_{u,i,h},$$

$$\lambda^l_{p,h} = \sum_{i=0}^{m} \left(\frac{1}{|\Gamma_i|} \int_{\Gamma_i} p^l_h \, d\gamma - P_i \right) \widetilde{\lambda}_{p,i,h}.$$

   - `Convergence test: If` $|\int_{\Gamma_j} \boldsymbol{\lambda}^l_{u,h} \cdot \boldsymbol{n}\, d\gamma| < \varepsilon \, \forall j = 0, \dots, m$, `then exit`
   - `else` $k^{l+1}_{j,h} = k^l_{j,h} + \tau^l \int_{\Gamma_j} \boldsymbol{\lambda}^l_{u,h} \cdot \boldsymbol{n}\, d\gamma \quad \forall j = 0, \dots, m$ `and set` $l = l + 1$
3. `end`

In order to investigate the properties of this algorithm, we introduce the following operators.

1. $\mathcal{N}_{\boldsymbol{f},h} : \mathbb{R}^{m+1} \to Q^1_h$. This operator maps a vector $\boldsymbol{h} \in \mathbb{R}^{m+1}$ to the function s_h, where $[\boldsymbol{w}_h, s_h]$ is the unique solution of

$$\begin{cases} a(\boldsymbol{w}_h, \boldsymbol{v}_h) - (s_h, \nabla \cdot \boldsymbol{v}_h) = -\displaystyle\sum_{j=0}^{m} h_j \int_{\Gamma_j} \boldsymbol{v}_h \cdot \boldsymbol{n}\, d\gamma + (\boldsymbol{f}, \boldsymbol{v}_h) & \forall \boldsymbol{v}_h \in \boldsymbol{V}_h, \\ (q_h, \nabla \cdot \boldsymbol{w}_h) = 0 & \forall q_h \in Q^1_h. \end{cases}$$

   Let A denote the $n_{vel} \times n_{vel}$ matrix with entries $a_{ij} = a(\boldsymbol{\varphi}_j, \boldsymbol{\varphi}_i)$, B the $n_{vel} \times n_p$ matrix $b_{ij} = -(\psi_j, \boldsymbol{\varphi}_i)$, G the matrix with entries $g_{ij} = \int_{\Gamma_i} \boldsymbol{\varphi}_j \cdot \boldsymbol{n}\, d\gamma$, and $\widetilde{\mathbf{f}}$ the vector whose components are $(\boldsymbol{f}, \boldsymbol{\varphi}_i)$. Then the algebraic counterpart of $\mathcal{N}_{\boldsymbol{f},h}$ reads:

$$\mathbf{s} = \left(BA^{-1}B^T\right)^{-1} \left(-BA^{-1}G^T\mathbf{h} + BA^{-1}\widetilde{\mathbf{f}}\right).$$

   We observe, by the way, that G is the algebraic representation of the finite-dimensional operator $\mathcal{A}_h$ obtained by taking the analogous of operator $\mathcal{A}$ defined in (2.8) from the subspace $\mathbf{V}_h$ to $\mathbb{R}^{m+1}$.
2. $\widetilde{\mathcal{G}}_h : Q^1_h \to \mathbb{R}^{m+1}$ such that $\widetilde{\mathcal{G}}_h(s_h) = (\frac{1}{|\Gamma_0|}\int_{\Gamma_0} s_h \, d\gamma, \frac{1}{|\Gamma_1|}\int_{\Gamma_1} s_h \, d\gamma, \dots, \frac{1}{|\Gamma_m|}\int_{\Gamma_m} s_h \, d\gamma)$. The algebraic counterpart of this operator is given by the matrix denoted by $\widetilde{G}$ with entries $\widetilde{g}_{ij} = \frac{1}{|\Gamma_i|}\int_{\Gamma_i} \psi_j \, d\gamma$.
3. $\mathcal{S}_h : \mathbb{R}^{m+1} \to \boldsymbol{V}_h$ maps a vector $\mathbf{r}$ in $\boldsymbol{w}_h$, where $[\boldsymbol{w}_h, s_h]$ is the unique solution of the generalized Stokes problem

$$\begin{cases} a(\boldsymbol{w}_h, \boldsymbol{v}_h) - (s_h, \nabla \cdot \boldsymbol{v}_h) = 0 & \forall \boldsymbol{v}_h \in \boldsymbol{V}_h, \\ -(q_h, \nabla \cdot \boldsymbol{w}_h) = -\displaystyle\sum_{i=0}^{m} r_i \frac{1}{|\Gamma_i|} \int_{\Gamma_i} q_h \, d\gamma & \forall q_h \in Q^1_h. \end{cases} \tag{4.7}$$

The algebraic formulation of this operator reads:

$$\mathbf{w} = A^{-1}B^T \left(BA^{-1}B^T\right)^{-1} \widetilde{G}^T \mathbf{r}.$$

Now set $\mathcal{H}_h = \mathcal{A}_h \circ \mathcal{S}_h$ and $\mathcal{E}_{\boldsymbol{f},h} = \widetilde{\mathcal{G}}_h \circ \mathcal{N}_{\boldsymbol{f},h}$. Then it is promptly verified that the discrete control problem at hand reads:

$$\mathcal{H} \circ (\mathcal{E}_{\boldsymbol{f},h}(\mathbf{k}) - \mathbf{P}) = 0. \tag{4.8}$$

Correspondingly, observe that the algorithm proposed above can be regarded as the Richardson iteration: Given $\mathbf{k}^l$, find $\mathbf{k}^{l+1}$ such that

$$\mathbf{k}^{l+1} = \mathbf{k}^l + \tau^l \mathcal{H}_h \circ \left(\mathbf{P} - \mathcal{E}_{\boldsymbol{f},h}(\mathbf{k}^l)\right).$$

Unfortunately, an analysis proving the definiteness of the residual operator on the right-hand side in this case, which would imply the convergence of the iterative scheme, is still missing.

We limit ourselves to point out that in algebraic terms if $\Sigma = BA^{-1}B^T$ is the Schur complement associated to the Stokes problem, (4.8) can be rewritten as:

$$GA^{-1}B^T\Sigma^{-1}\widetilde{G}^T \left(\widetilde{G}\Sigma^{-1}BA^{-1}\left(-G^T\mathbf{k} + \mathbf{f}\right) - \mathbf{P}\right) = 0.$$

We set $Z = \widetilde{G}\Sigma^{-1}BA^{-1}G^T$ so that, thanks to the symmetry of Σ and A, the matrix problem can be rewritten:

$$Z^T Z\mathbf{k} = Z^T \left(\widetilde{G}\Sigma^{-1}BA^{-1}\mathbf{f} - \mathbf{P}\right).$$

This formulation highlights that the matrix at hand is semidefinite positive. This excludes that the algorithm could yield divergent sequences, even if the convergence is still not ensured. This issue will be investigated in a future work. Numerical evidence suggests, however, that with a proper choice of the parameter τ the numerical solution converges.

Remark 3. A similar algorithm can be devised for Problem 7. In this case both the adjoint problem out of the iterative cycle and the problem in the iterative cycle are solved with the augmented formulation, in particular, by resorting to the *GMRES+Schur complement* scheme introduced in [15].

5. Numerical results. In this section we present several numerical results to validate the algorithms introduced in section 4. In particular, in section 5.1 we focus on the flow rate problem and in section 5.2 on the mean pressure problem.

5.1. Flow rate problems. All simulations of this section and of section 5.2 have been implemented by using the two-dimensional (2D) finite element library *Freefem++* (see [8]), with a discretization time step $\Delta t = 0.01$ s and using conforming $\mathbb{P}_2 - \mathbb{P}_1$ elements. In the first simulations we present, the computational domain is a rectangle R of 6×1 cm (see Figure 5.1, left), while the fluid kinematic viscosity is $\mu = 0.035$ cm^2/s. This is the usual value adopted for blood viscosity in computational hemodynamics. We prescribed both a steady ($Q = 0.1$ cm^2/s) and a pulsatile ($Q = 0.15 + 0.1\cos(2\pi t)$ cm^2/s) flow rate at the inlet Γ_{in} of R. We have used an almost uniform triangular grid with spacing $h = 0.05$ cm. We have considered in this first test case the Stokes problem.

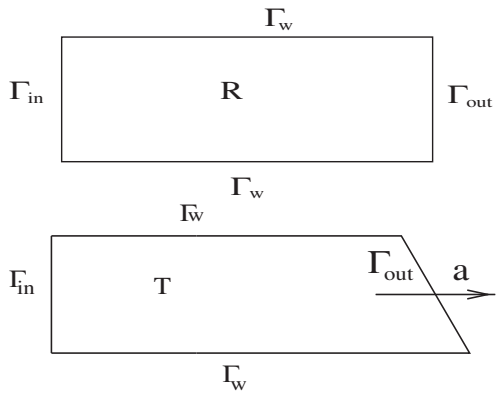

FIG. 5.1. *Computational domains R and T.*

TABLE 5.1
Relative errors of the numerical solutions obtained with Algorithms 1 *and* 2*, compared to the reference solution.*

	Time	D_{I}	D_{II}
Steady case		0.0000003	0.0000050
Unsteady case	$t = 1.25$ s	0.000230	0.000160
	$t = 1.30$ s	0.000154	0.000156
	$t = 1.60$ s	0.000348	0.000348

In order to verify the accuracy of the solutions obtained with the two algorithms, we provide comparisons with the analytical Poiseuille solution in the steady case (see Table 5.1, where $D_{\mathrm{I}} = \|\boldsymbol{u}_{pois} - \boldsymbol{u}_{\mathrm{I}}\|_{L^2(\Gamma_{in})}/\|\boldsymbol{u}_{pois}\|_{L^2(\Gamma_{in})}$ and $D_{\mathrm{II}} = \|\boldsymbol{u}_{pois} - \boldsymbol{u}_{\mathrm{II}}\|_{L^2(\Gamma_{in})}/\|\boldsymbol{u}_{pois}\|_{L^2(\Gamma_{in})}$, $\boldsymbol{u}_{pois}, \boldsymbol{u}_{\mathrm{I}}$ and $\boldsymbol{u}_{\mathrm{II}}$ are the Poiseuille solution and the numerical solutions obtained with Algorithms 1 and 2, respectively).

In the unsteady case we compare the results with the solution obtained by the augmented formulation (see [15, 17]). In particular, this formulation has been faced with the *GMRES+Schur complement* (GS) algorithm. In Table 5.1 we report $D_{\mathrm{I}} = \|\boldsymbol{u}_{augm} - \boldsymbol{u}_{\mathrm{I}}\|_{L^2(\Gamma_{in})}/\|\boldsymbol{u}_{augm}\|_{L^2(\Gamma_{in})}$ and $D_{\mathrm{II}} = \|\boldsymbol{u}_{augm} - \boldsymbol{u}_{\mathrm{II}}\|_{L^2(\Gamma_{in})}/\|\boldsymbol{u}_{augm}\|_{L^2(\Gamma_{in})}$, where $\boldsymbol{u}_{augm}$ is the numerical solutions obtained with the augmented formulation. In Figure 5.2, the axial velocity at the inlet Γ_{in}, computed with the two algorithms in the steady (top, left) and in the unsteady case, is compared with the reference solution. Differences among the different solutions are clearly small.

The number of iterations for the three algorithms is shown in Table 5.2. In the unsteady case, we give the mean values over the entire computation in time. For Algorithm 1 we compare different possible choices of τ. An Aitken acceleration procedure has been successfully implemented to speed up convergence. Algorithm 2 has been considered only in the case of Aitken procedure implementation.

In the steady case, as expected from section 4.1.1, Algorithm 2 is very fast. In the unsteady case, Algorithm 1 with $\tau = 2\tau_N^l$ gives the best performances. The number of iterations is in fact comparable with the one of the GMRES algorithm for the augmented problem. The latter is supposed (in exact arithmetic) to converge in $m + 1$ iterations per time step, where m is the number of prescribed flow rates (see [15]). In these two cases, we also compute the (mean) CPU time used to perform an iteration. These values are shown in Table 5.2 in the brackets, and they highlight

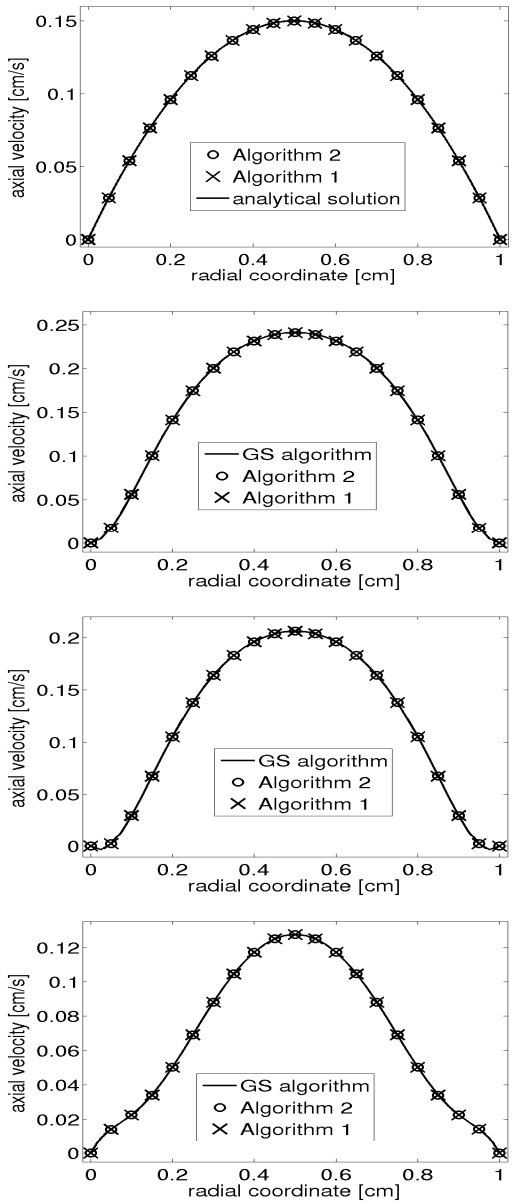

FIG. 5.2. *Axial velocity computed with Algorithms* 1 *and* 2 *and the reference solution—steady simulation (top, left) and unsteady simulation,* $t = 1.25\,s$ *(top, right),* $t = 1.30\,s$ *(bottom, left), and* $t = 1.60\,s$ *(bottom, right);* $toll = 10^{-7}$.

that also the computational costs of Algorithm 1 with $\tau = 2\tau_N^l$ and of the GMRES algorithm for the augmented problem are comparable.

In the second test case, we consider the computational domain depicted in Figure 5.3 representing a 2D simplified model of a bypass anastomosis (see, e.g., [17]). The space discretization step is of $h = 0.1$ cm. We solve the Navier–Stokes equations by extending Algorithm 1 to the nonlinear case. In this case the adjoint problem needs to be solved in the time-advancing loop. We prescribe the flow rates $Q_1 = \cos(2\pi t)$

TABLE 5.2

Unsteady case	-	5.08	3.81	1.98 (6.37 s)	4.50	2.00 (6.41 s)

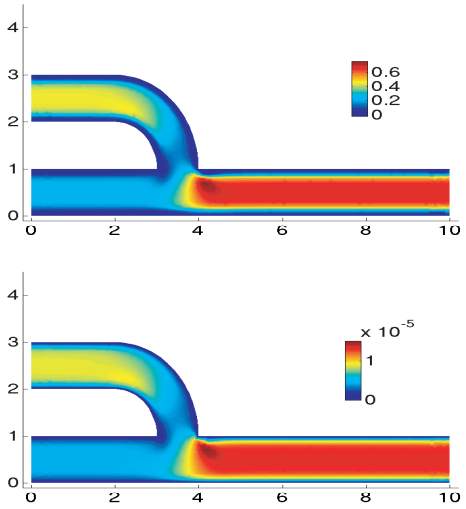

FIG. 5.3. *Anastomosis simulation—Algorithm* 1—$t = 1.2$ *s; on the left the axial velocity and on the right the difference with the GS algorithm; toll* $= 10^{-9}$.

cm^2/s on the upper inlet and $Q_2 = 0.5\cos(2\pi t)$ cm^2/s on the lower inlet. We show in Figure 5.3 the axial velocity on the left and the difference with the solution obtained by using the augmented formulation on the right. The two numerical results are in excellent agreement with the difference bounded by 10^{-5}. Moreover, we point out that this error is independent on the mesh size. The mean number of iterations per time step required in this case by Algorithm 1 with the choice $\tau = 2\tau_N^l$ is 18.22 versus the $m + 1 = 3$ iterations needed by the GS algorithm. The (mean) CPU times per iteration are 169.2 s and 16.1 s, respectively. The slow convergence of Algorithm 1 is due to the ill-conditioning of the problem when prescribing 2 flow rates. In this case it is well known that the convergence of the steepest descent method can be quite slow. One possibility that will be investigated in future work is to search for conjugate directions.

5.2. Mean pressure problems. In this section, we illustrate the performances of Algorithm 3 and its extensions to solve Problems 5, 6, and 7. In the first test case, we prescribe the mean pressure $P = \sin(2\pi t)$ $\text{g}/(\text{s}^2\ \text{cm})$ at the outlet Γ_{out} of the domain R (with $h = 0.1$ cm) of Figure 5.1 left. We compare the two strategies of using the normal component of the normal stress as a control variable (strategy PS; see Problem 4) and the one using flow rates (strategy PF; see Problem 7). Computations are performed for the Stokes problem.

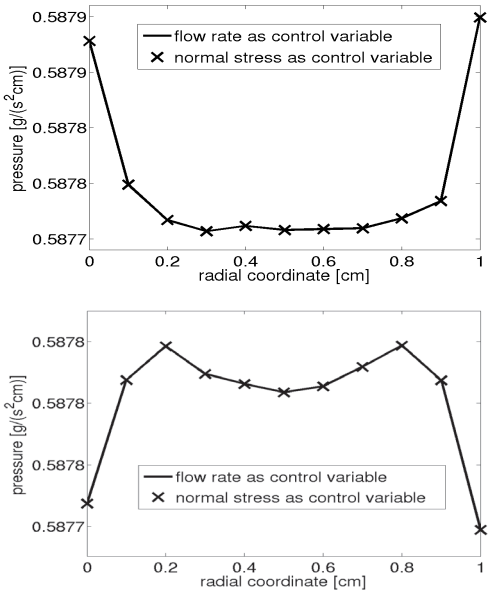

FIG. 5.4. *Mean pressure prescribed at the outlet at $t = 1.1$ s, $P = 0.5878\, g/(s^2\, cm)$ (left) and at $t = 1.4$ s, $P = 0.5878\, g/(s^2\, cm)$ (right); toll $= 10^{-7}$.*

TABLE 5.3
Relative errors in the $L^2(\Gamma)$ norm of the solutions obtained using the flow rate (PF) and the normal stress (PS), respectively, as a control variable.

Time	PF	PS
$t = 1.10\, s$	$9.327 \cdot 10^{-5}$	$9.329 \cdot 10^{-5}$
$t = 1.40\, s$	$3.569 \cdot 10^{-5}$	$3.578 \cdot 10^{-5}$

Figure 5.4 and Table 5.3 show that the two strategies give close results. However, the PF strategy is more problematic in terms of convergence of the numerical scheme. As a matter of fact, we observed that it diverges for the nonstationary choices of τ that we tested. Finally, we resorted to set a static value $\tau = -10^{-6}$. The average number of iterations in this case has been 31.31. It is worthwhile to observe that this strategy is more expensive also in terms of CPU times, since for each iteration it requires the solution of $m + 1 = 2$ generalized Stokes problems for solving the augmented formulation.

On the contrary, convergence with the PS strategy is obtained with an average of 2.00 iterations (with $\tau = 2\tau_N^l$). Each iteration requires the solution of only one generalized Stokes problem.

We conclude that, if the control variables can be chosen, strategy PS is definitely the best one.

In the second set of simulations, we prescribe the mean pressure $P = 1$ g/(s^2 cm) at the outlet Γ_{out} of the domain T (see Figure 5.1, right). We indicate with $\boldsymbol{a}$ the axial direction. By minimizing functional (3.2), an undesirable transverse velocity and, consequently, an incorrect axial velocity at the outlet occur (Figure 5.5, top). To avoid these effects, we solve Problems 5 and 6; i.e., we minimize functional (3.4) with (3.5) and (3.7), respectively. We consider the same iterative scheme of Algorithm

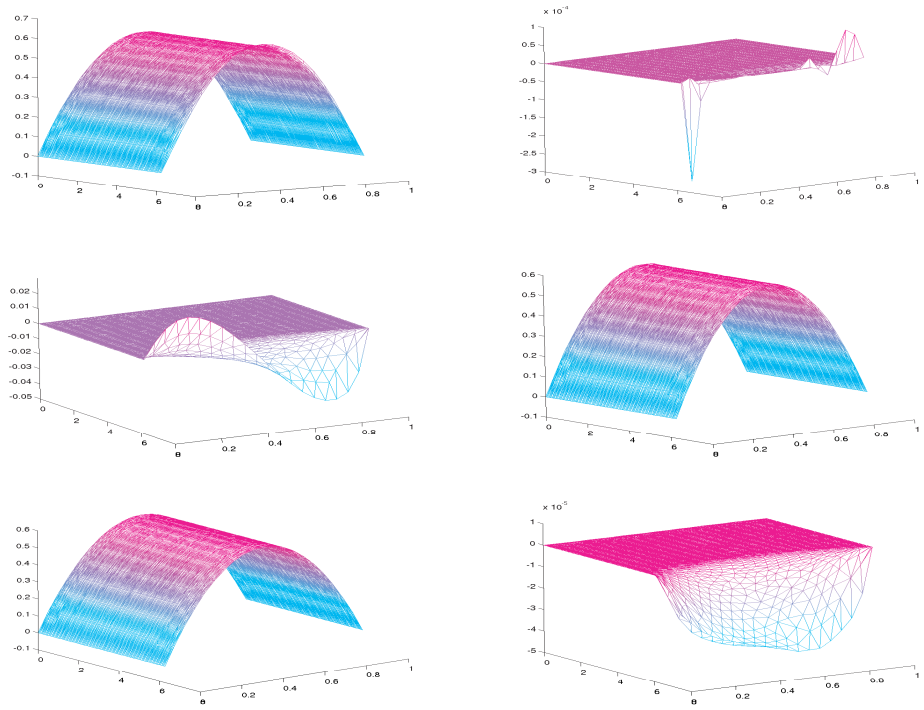

FIG. 5.5. *Axial (left) and tangential (right) velocity in* cm^2/s *obtained by prescribing* $P = 1\,g/(s^2\,cm)$ *at the outlet of* T *minimizing* (3.2) *(top),* (3.4) *with* (3.5) *(middle), and* (3.4) *with* (3.7) *(bottom); toll* $= 10^{-7}$.

3. Figure 5.5 illustrates the effectiveness of these strategies, yielding errors of about 3×10^{-4} in the former case and 5×10^{-5} in the latter one.

Acknowledgments. The authors thank Luca Dedè, Jean-Frederic Gerbeau, and Carlo D'Angelo for their useful comments and suggestions.

LEAPFROG FOR OPTIMAL CONTROL*

C. YALÇIN KAYA† AND J. LYLE NOAKES‡

Abstract. The leapfrog algorithm, so called because of its geometric nature, for solving a class of optimal control problems is proposed. Initially a feasible trajectory is given and subdivided into smaller pieces. In each subdivision, with the assumption that local optimal controls can easily be calculated, a piecewise-optimal trajectory is obtained. Then the junctions of these smaller pieces of optimal control trajectories are updated through a scheme of midpoint maps. Under some broad assumptions the sequence of trajectories is shown to converge to a trajectory that satisfies the maximum principle. The main advantages of the leapfrog algorithm are that (i) it does not need an initial guess for the costates and (ii) the piecewise-optimal trajectory generated in each iteration is feasible. These are illustrated through a numerical implementation of leapfrog on a problem involving the van der Pol system.

Key words. optimal control, two-point boundary-value problem, multiple shooting, geodesics, numerical methods, van der Pol system

1. Introduction.

Computational techniques for finding an optimal control solution of a nonlinear system can be classified into two major categories, namely, *direct* and *indirect* methods [37]. In a direct method, the problem is discretized and the resulting (usually large scale) finite-dimensional optimization problem is solved by using nonlinear programming techniques [4, 36, 6, 3, 19]. The solution obtained this way is an approximation of the true solution, unless the control function is of a special class, for example, of the bang-bang type [18, 14, 28]. On the other hand, in an indirect method, one tackles the two-point boundary-value problem (TPBVP) arising from the Pontryagin maximum principle (PMP). Accurate solutions can be obtained through indirect methods; however, available solution techniques for TPBVPs often face serious convergence difficulties, mainly because of the lack of a good initial guess. If the set of controls is bounded, the problem is even more difficult.

The leapfrog algorithm for optimal control, so called because of its geometric nature, is an extension of a similar iterative algorithm given by Noakes [30] for finding a geodesic joining two given points on a Riemannian manifold. The main advantages of leapfrog are that a good initial guess is not needed and the trajectories generated in each iteration are feasible. Under fairly general conditions, the algorithm is convergent to a trajectory that satisfies the PMP. The algorithm presented here, as well as that given in [30], can be viewed as a continuous-time analogue of the so-called two-stage approximation technique described by Zuo [39] for discrete-time optimal control.

Methods that are used for the solution of TPBVPs arising in optimal control usually incorporate some combination of (a) multiple shooting, (b) collocation methods,

and (c) continuation (homotopy) methods. Various expositions of multiple shooting can be found in [20, 32, 2, 35, 31, 11, 10, 26, 25, 23, 22]. Multiple shooting is a very accurate method but does still require good initial guesses in the subintervals taken. As the number of subdivisions is increased in order to exploit simple shooting more efficiently in each subinterval, the number of variables to be determined is substantially increased. With these problems in mind, multiple shooting is sometimes used in conjunction with some other method, for example, the method of collocation [38]. The method of collocation is used to obtain an approximate solution, in terms of cubic splines, for example, which is then fed into multiple shooting to achieve the required solution accurately. This twofold procedure may eventually need long computational times. The continuation method is also a method used in conjunction with multiple shooting [9, 7]. Usually, the nonlinear system is partitioned into its linear and nonlinear parts, and, by using the initial linear system solution and continuation techniques, the nonlinear system's solution is obtained. This method can also take long computational times depending on the nonlinearity of the system.

The leapfrog algorithm resembles multiple shooting in that the time interval is subdivided and local optimal controls are found separately over each subinterval. A significant difference is that leapfrog uses overlapping subintervals. Because of the use of subdivisions the algorithm is not expected to be troubled by the nonlinear dynamics. Three apparent advantages of the leapfrog algorithm over multiple shooting can be listed:

- Once a feasible trajectory is constructed, affine approximation of the subproblem in a subdivision (between nearby points) provides a good initial guess needed for simple shooting in that subdivision. So leapfrog does not depend critically on the supply of good initial guesses along the feasible trajectory.
- State trajectories generated by leapfrog are feasible at each step of the iteration, which is not in general the case in multiple shooting. Continuing improvements are obtained on the feasible trajectories, resulting in suboptimal trajectories. This may in particular be useful in real-time (online) applications, where time allowed to compute a solution is restricted.
- In each leapfrog iteration the number of subdivisions can be adjusted along the feasible trajectory. This allows one to eventually reduce the number of subdivisions as the solution is approached.

A drawback of leapfrog is that, as the solution is approached, convergence of leapfrog slows down; therefore the number of subdivisions q has to be progressively reduced to 2 (which is the case of simple shooting) so as to obtain a solution in a reasonable number of iterations. The effort to see, in each iteration, whether a reduction in q is possible or not incurs an additional computational cost.

Although leapfrog needs an initial feasible trajectory, in an implementation one can as well start with a set of nearby subdivision points through which concatenated local optimal solutions are obtained. Generally speaking, feasible trajectories can be established much more easily than optimal ones.

We list below some additional features of the leapfrog algorithm.

- Parallel computing is one of the efficiency concerns in the TPBVP literature (see [1, 29, 33]). Multiple shooting is particularly suited to doing computations in each subdivision independently, and for this reason it is sometimes referred to as *parallel shooting*. By using a slight variation of a leapfrog iteration, those subproblems whose time intervals are not overlapping can be solved independently. Therefore leapfrog is also suited to parallel computations.

- Suppose that an optimal control problem is given with n state equations, where the initial and terminal states are prescribed and the terminal time is fixed. For finding a local optimal control in a subdivision, the leapfrog algorithm updates only $2n$ real variables (states and costates) at a time. This amounts to a total of $[(2q-4)n]$ updates in one leapfrog iteration. With q subdivisions, multiple shooting updates $[(2q-1)n]$ variables at a time in one iteration.
- After a subproblem is solved, if two or more subdivision points (i.e., some of the junctions of the piecewise-optimal trajectories) become the same, they are referred to as *multiple points*. Multiple points occur rarely in practice. However, if they occur, leapfrog can eliminate them, yielding fewer subdivisions to deal with along a (piecewise-optimal) feasible trajectory. Elimination of multiple points does not have a clear advantage with multiple shooting.

In this paper, we show that the leapfrog algorithm converges under some general assumptions, such as the uniqueness of the local optimal control and costate variables in a given subdivision. In [15, 16], we gave some background and a survey of ideas leading to the development of leapfrog for solving the geodesic problem. We also reported an implementation of leapfrog (with fixed terminal time) for optimal control, without elaboration. In the present paper, we provide a careful and detailed account of a numerical implementation of leapfrog. We also gave some preliminaries of the theory in an earlier publication [17], which did not have the detailed setting and approach of the present article.

The present paper is organized as follows. In section 2 we state the optimal control problem and give definitions and assumptions, verifications of which are provided through example problems. In section 3 we describe the leapfrog algorithm. In section 4 we address multiple points and provide further definitions and facts. We prove convergence of the leapfrog algorithm in section 5. A computational illustration of the algorithm is given in section 6 by solving a problem involving the van der Pol system.

2. Preliminaries. Consider the control system

$$\dot{x}(t) = f(x(t), u(t)), \tag{1}$$

where the state $x(t) \in \mathbb{R}^n$ and the control $u : \mathbb{R} \longrightarrow \mathbb{R}^m$ is an arbitrary piecewise-continuous function, which, as described in [34], has discontinuity at finitely many points and has finite right- and left-hand limits at the points of discontinuity. The function $f : \mathbb{R}^n \times \mathbb{R}^m \longrightarrow \mathbb{R}^n$ is C^1 in x and u.

The following optimal control problem is considered:

$$\mathrm{P} : \begin{cases} \text{minimize} & \displaystyle\int_{t_0}^{t_f} f_0(x(t), u(t))\, dt \\ \text{subject to} & \dot{x}(t) = f(x(t), u(t)), \\ & x(t_0) = x_0 \quad \text{and} \quad x(t_f) = x_f, \end{cases}$$

where the function $f_0 : \mathbb{R}^n \times \mathbb{R}^m \to \mathbb{R}$ is C^1 and nonnegative and the final time $t_f > t_0$ is free. A *state trajectory* corresponding to a control $u(\cdot)$ is a continuous curve $x(\cdot)$ solving $\dot{x}(t) = f(x(t), u(t))$ for almost all t. An *optimal state trajectory* $x(\cdot)$ and a corresponding *optimal control* $u(\cdot)$ are those which solve problem (P).

The PMP gives necessary conditions of optimality [34] for large classes of problems including problem (P). In these problems the so-called Hamiltonian $H : \mathbb{R}^n \times \mathbb{R}^n \times$

$\mathbb{R}^m \longrightarrow \mathbb{R}$ is defined as

$$H(x, \psi, u) = \psi_0 \, f_0(x, u) + \langle \psi, f(x, u) \rangle,$$

where $\psi_0(t) \in \mathbb{R}$ and $\psi(t) \in \mathbb{R}^n$ are the adjoint or costate variables and $\langle \cdot, \cdot \rangle$ is the Euclidean inner product. The PMP states that if a state trajectory $x(\cdot)$ and a corresponding control $u(\cdot)$ are optimal, then there exists a nontrivial pair $(\psi_0, \psi) : [t_0, t_f] \longrightarrow \mathbb{R}^{n+1}$ such that, for almost every $t \in [t_0, t_f]$,

$$\dot{x} = \partial H / \partial \psi = f(x, u), \tag{2}$$

$$\dot{\psi} = -\partial H / \partial x, \tag{3}$$

$$H(x, \psi, u) = \min_{v \in \mathcal{U}} H(x, \psi, v), \tag{4}$$

$$H(x, \psi, u) \equiv 0, \tag{5}$$

with $x(t_0) = x_0$ and $x(t_f) = x_f$. Furthermore PMP requires that $\psi_0(t) \equiv c$, where c is some nonnegative constant. The costate variable ψ_0 accounts for the case when cost is treated as an additional state coordinate. Problems that yield $c = 0$ are referred to as *abnormal* in the literature, for which the necessary conditions in (2)–(5) are independent of the cost and therefore insufficiently informative. A discussion of the necessary conditions of optimality for abnormal trajectories can be found in [24] and the references therein.

ASSUMPTION 1. *Problem* (P) *is normal. Without loss we set* $\psi_0 = 1$.

We refer to the conditions given in (2)–(5) as the *optimality system*. A trajectory of the optimality system corresponding to a control $u(\cdot)$ is a continuous pair of curves $(x(\cdot), \psi(\cdot))$ which solve (2)–(5). If the trajectory pair $(x(\cdot), \psi(\cdot))$ corresponding to control $u(\cdot)$ satisfies the optimality system, then it is said to be a *critical trajectory* (*pair*). We will refer to the trajectory $(x(\cdot), \psi(\cdot))$ as optimal if the state trajectory $x(\cdot)$ along with a corresponding control $u(\cdot)$ is optimal. Note that a critical trajectory is not necessarily optimal.

Remark 2.1. Condition (5) stands because the terminal time t_f is free—t_f is an unknown of the problem. In the case when t_f is prescribed, however, condition (5) is not part of the optimality system anymore. In this case one has $H(x, \psi, u) \equiv a$, where a is any real constant, but this condition is usually not needed for computations, resulting in a simpler optimality system.

Remark 2.2. Although leapfrog is described for free terminal time problems, we can also tackle problems with a fixed terminal time. Given a problem with fixed t_f, say, $t_f = 1$, we can define a new state variable $x_{n+1}(t) = t$ such that $\dot{x}_{n+1}(t) = 1$, with the end points $x_{n+1}(0) = 0$ and $x_{n+1}(t_f) = 1$, where we now let t_f be free. The equation for x_{n+1} is trivial to solve. Therefore, in a practical implementation, there would be no need to augment the state equations in this way.

Next we describe the subproblems employed within leapfrog. Let $x(\cdot)$ be a continuous piecewise-C^1 trajectory such that $x(t_0) = x_0$ and $x(t_f) = x_f$. The point x_f is not necessarily close to x_0. The trajectory $x(\cdot)$ is simply a curve between x_0 and x_f. The aim is to find a critical trajectory between x_0 and x_f. We initially partition this feasible trajectory so as to obtain q pieces with roughly comparable costs. Let the corresponding partition times be $t_0 < t_1 < \cdots < t_{q-1} < t_q = t_f$. The number q of partitions is chosen so that the partition points $z_{i-1} := x(t_{i-1})$ and $z_i := x(t_i)$, $i = 1, \ldots, q$, are sufficiently close to each other that there exists a local optimal solution from z_{i-1} to z_{i+1}, $i = 1, \ldots, q-1$, which is easily computable. Namely, we

assume that local solutions to the following subproblems can be easily obtained:

$$\mathrm{P}_i : \begin{cases} \text{minimize} & \displaystyle\int_{t_{i-1}}^{t_{i+1}} f_0(x(t), u(t))\, dt \\ \text{subject to} & \dot{x}(t) = f(x(t), u(t)), \\ & x(t_{i-1}) = z_{i-1} \quad \text{and} \quad x(t_{i+1}) = z_{i+1}, \end{cases}$$

where t_{i-1} is fixed by the solution of problem (P_{i-1}) and t_{i+1} is free. Note that $z_0 = x_0$ and $z_q = x_f$. Through the PMP, the optimality system associated with problem (P_i) can be written as in (2)–(5) for $t \in [t_{i-1}, t_{i+1}]$, with end points $x(t_{i-1}) = z_{i-1}$ and $x(t_{i+1}) = z_{i+1}$. Solution of the optimality system provides an initial value of the costate variable, namely, $\psi(t_{i-1}) =: \lambda_{i-1}$, for problem (P_i).

Assumption 2. *There exists a.e. a (locally) unique optimal control* $u : [t_{i-1}, t_{i+1}] \longrightarrow \mathbb{R}^m$ *taking the system from* z_{i-1} *to* z_{i+1}.

Assumption 3. *The normalized costate vector* $\psi(t)$ *associated with problem* (P_i) *is determined uniquely by the locally optimal control* $u(t)$ *and the initial point* z_{i-1} *of the optimal trajectory.*

In what follows we discuss two example problems, albeit relatively simple, to illustrate Assumptions 1–3. In these problems the terminal time is fixed: As pointed out earlier they can easily be converted into an equivalent free terminal time form used for leapfrog.

Example 1 (geodesics). Let $\{g_{ij} : 1 \le i, j \le n\}$ define a Riemannian metric on an open subset U of $\mathbb{R}^n$, namely, the matrix $[g_{ij}(x)]$ is symmetric positive definite, and C^∞ in x. The problem of finding geodesics between two given points can be formulated as an optimal control problem as follows:

$$\mathrm{P}_g : \begin{cases} \text{minimize} & \displaystyle\int_0^1 \sum_{i,j} g_{ij}(x) u_i u_j \, dt \\ \text{subject to} & \dot{x} = u, \\ & x(0) = x_0 \quad \text{and} \quad x(1) = x_f \ , \end{cases}$$

where the initial and terminal points x_0 and x_f are in $\mathbb{R}^n$. The control $u(t)$ is also in $\mathbb{R}^n$. The Hamiltonian for the problem is

$$H(x, u, \psi) = \psi_0 \sum_{i,j} g_{ij}(x)\, u_i u_j + \langle \psi, u \rangle.$$

Condition (4) in this case implies that $\partial H / \partial u_i = 0$, $i = 1, \ldots, n$, which gives

$$\psi_i = -2\, \psi_0 \sum_j g_{ij}(x)\, u_j \ . \tag{6}$$

Suppose that $\psi_0 = 0$. Then $\psi_i = 0$, $i = 1, \ldots, n$, i.e., (ψ_0, ψ) is trivial, which is a contradiction. This verifies Assumption 1. Set $\psi_0 = 1$ from this point onwards.

Given u_i, $i = 1, \ldots, n$, ψ_i are determined uniquely from (6). By differentiating ψ_i one gets

$$\dot{\psi}_i = -2 \left(\sum_{j,k} \frac{\partial g_{ij}}{\partial x_k} u_j u_k + \sum_j g_{ij}(x)\, \dot{u}_j \right) \ .$$

On the other hand, another condition (3) of PMP yields

$$\dot{\psi}_i = -\sum_{j,k} \frac{\partial g_{jk}}{\partial x_i} u_j u_k.$$

By equating the two expressions for $\dot{\psi}_i$ and rearranging,

$$\dot{u}_i = -\sum_{j,k} \Gamma^i_{jk}(x)\, u_j u_k, \tag{7}$$

where

$$\Gamma^i_{jk}(x) = \frac{1}{2} \sum_s g^{is}(x) \left(2\frac{\partial g_{sj}}{\partial x_k} - \frac{\partial g_{jk}}{\partial x_s} \right).$$

In the above equations Γ^i_{jk} are the so-called Christoffel symbols [5], and g^{is} is the isth entry of the inverse of the matrix $[g_{is}]$. A direct substitution from the state equations give the so-called geodesic equation which has a unique solution for x_f sufficiently close to x_0:

$$\ddot{x}_i = -\sum_{j,k} \Gamma^i_{jk}(x)\, \dot{x}_j \dot{x}_k \ . \tag{8}$$

Then locally the control u has a unique solution, which verifies Assumption 2; in turn, Assumption 3 is verified by (6).

Example 2 (LTI systems). Consider the minimum energy control of a linear time-invariant (LTI) system:

$$\mathrm{P}_{LTI} : \begin{cases} \text{minimize} & \dfrac{1}{2}\displaystyle\int_0^1 u^T R u \, dt \\ \text{subject to} & \dot{x}(t) = Ax(t) + Bu(t), \\ & x(0) = x_0 \quad \text{and} \quad x(1) = x_f \ , \end{cases}$$

where $x(t) \in \mathbb{R}^n$, $u : \mathbb{R} \longrightarrow \mathbb{R}^m$, and the constant matrices A and B have appropriate dimensions. The constant matrix R is symmetric and positive definite. The system is assumed to be controllable. The Hamiltonian is

$$H(x, \psi, u) = \frac{1}{2}\, \psi_0\, u^T R u + \psi^T (Ax + Bu) \ .$$

The condition $\partial H / \partial u = 0$ gives

$$\psi_0\, Ru = -B^T \psi. \tag{9}$$

Furthermore (3) of PMP yields

$$\dot{\psi}^T = -\psi^T A \ . \tag{10}$$

By differentiating (9) up to $(n-1)$ times and using (10) one gets

$$\begin{aligned} \psi^T B &= \psi_0\, Ru, \\ \psi^T AB &= \psi_0\, R\dot{u}, \\ &\cdots \\ \psi^T A^{n-1} B &= \psi_0\, Ru^{(n-1)}, \end{aligned} \tag{11}$$

where $u^{(i)} = d^i u / dt^i$, $i = 1, \ldots, n-1$, with $\dot{u} = u^{(1)}$.

Suppose that $\psi_0 = 0$. Since the system is controllable, the controllability matrix $[B|AB|\dots|A^{n-1}B]$ is of rank n, so $\psi = \mathbf{0}$, which contradicts the nontriviality of (ψ_0, ψ) in PMP. This verifies Assumption 1.

We set $\psi_0 = 1$. Again because the system is controllable, ψ can be expressed uniquely from (11) in terms of u and its derivatives. This verifies Assumption 3.

It can be shown (by using $R = R^{1/2}R^{1/2}$ and by considering a generalization of the controllability Gramian in Exercise 9.2-11 of [13]) that the optimal control $u(t)$ is given by the expression

$$u(t) = -R^{-1}B^T e^{-A^T t} M^{-1} \left(x(0) - e^{-A}x(1)\right), \tag{12}$$

where

$$M = \int_0^1 e^{-sA} B R^{-1} B^T e^{-sA^T} ds \ ,$$

and the nonsingularity of M is furnished by the controllability of the system. As can be seen, the optimal control $u(t)$ is unique by the choice of $x(0)$ and $x(1)$, which verifies Assumption 2.

A point $\widetilde{x}$ is said to be *reachable* from a point x_0 with cost less than $\Delta > 0$ if and only if, for some admissible control, there exists a trajectory $x(\cdot)$ defined on an interval $[t_0, t]$, $t > t_0$, such that $x(t_0) = x_0$, $x(t) = \widetilde{x}$, and $\int_{t_0}^{t_f} f_0(x(t), u(t))\, dt < \Delta$. The trajectory $x(\cdot)$ of concern here does not necessarily satisfy PMP; namely, it is not necessarily critical. The set of all such points $\widetilde{x}$ is denoted by $\mathcal{R}(x_0, < \Delta)$. The reachable set $\mathcal{R}(x_0, < \Delta)$ is said to be a *small-cost reachable set* when Δ is sufficiently small.

Let D denote the set of all ordered pairs (z_{i-1}, z_{i+1}) such that z_{i+1} can be reached from z_{i-1} with a cost less than 2δ, namely,

$$D = \{(z_{i-1}, z_{i+1}) \in \mathbb{R}^n \times \mathbb{R}^n : z_{i+1} \in \mathcal{R}(z_{i-1}, < 2\delta)\} \ , \tag{13}$$

where $\delta > 0$ is so chosen that there exists a local optimal control from z_{i-1} to z_{i+1}, which is easily computable. Namely, the choice of δ ensures that the points z_{i-1} and z_{i+1} are nearby so that affine approximations and the simple shooting method can be used to get a local solution for problem (P_i) efficiently.

Let $\tau : D \longrightarrow \mathbb{R}$ denote the *local cost function* such that, given $(z_{i-1},\ z_{i+1})$ in D, $\tau(z_{i-1}, z_{i+1})$ is the infimum of the cost to get from z_{i-1} to z_{i+1}. Note that $\tau(z_{i-1}, z_{i+1}) < 2\delta$.

Clearly both D and τ depend on δ; however, for brevity, we will not show this dependence explicitly. The associated value of δ should be clear from the context.

3. Leapfrog algorithm. In this section we give a description of the leapfrog algorithm. Suppose that a feasible trajectory $\mu_z : [t_0, t_f] \longrightarrow \mathbb{R}^n$ is given between the initial and terminal states $z_0 = \mu_z(t_0)$ and $z_q = \mu_z(t_f)$, which is divided into q trajectory segments, such that $z_i = \mu_z(t_i)$, $i = 1, \dots, q-1$. The junction points of μ_z are represented by the $(q+1)$-tuple $z = (z_0, z_1, z_2, \dots, z_q)$. Through the leapfrog scheme, while the initial and terminal states z_0 and z_q, and t_0, are kept fixed, each z_i, $i = 1, \dots, q-1$, and t_i, $i = 1, \dots, q$, are adjusted in the following fashion.

For $(z_{i-1}, z_{i+1}) \in D$, let $\gamma_{z_{i-1}, z_{i+1}} : [t_{i-1}, t_{i+1}] \longrightarrow \mathbb{R}^n$ be the unique *local optimal trajectory* (by Assumption 2) such that $\gamma_{z_{i-1}, z_{i+1}}(t_{i-1}) = z_{i-1}$ and $\gamma_{z_{i-1}, z_{i+1}}(t_{i+1}) = z_{i+1}$. The *midpoint* $\widehat{z}_i := \gamma_{z_{i-1}, z_{i+1}}(\widehat{t}_i)$, $t_{i-1} \le \widehat{t}_i \le t_{i+1}$, between z_{i-1} and z_{i+1} is

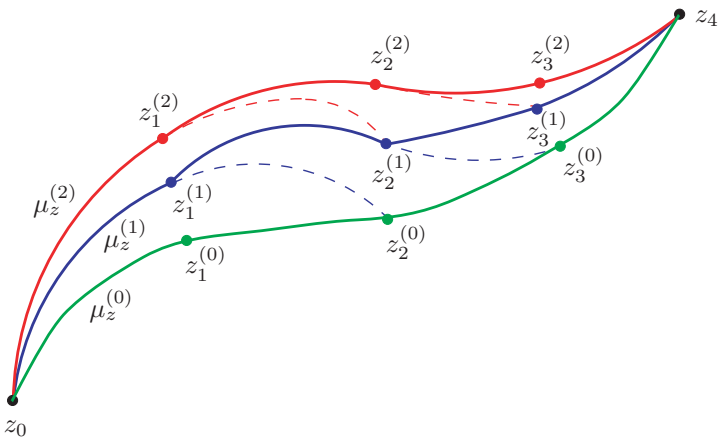

FIG. 1. *An illustration of the leapfrog algorithm in state space.*

defined by $\tau(z_{i-1},\widehat{z}_i) = \tau(\widehat{z}_i, z_{i+1}) = \tau(z_{i-1}, z_{i+1})/2$. For convenience, we also set $\widehat{t}_0 := t_0$ and $\widehat{t}_q := t_q$. The point z_i is moved to the midpoint $\widehat{z}_i$, while the time t_i is updated as $\widehat{t}_i$.

Moving z_i onto an optimal trajectory from z_{i-1} to z_{i+1} (obtained by solving problem (P_i)) achieves locally the largest possible decrease in cost while keeping other junction points fixed. The point where z_i goes in the optimal trajectory segment is taken to be the point such that the cost of getting from z_{i-1} to that point is half the cost of getting from z_{i-1} to z_{i+1}. However, somewhat different positioning of z_i is also permissible.

The leapfrog algorithm consists of updating z_i and t_i in this way infinitely often where i cycles through $1,\ldots,q-1$. This generates a sequence

$$\mathcal{M}_z = \{\mu_z^{(k)} : [t_0, t_f^{(k)}] \longrightarrow \mathbb{R}^n : k > 0\}$$

of piecewise-optimal (state) trajectories. Along each consecutive trajectory $\mu_z^{(k)}$ the cost decreases. This decrease precludes convergence to a global maximum. A schematic illustration of the leapfrog algorithm is given in state space in Figure 1. The initial set of points $z_i^{(0)}$, $i = 1, 2, 3$, are the junctions chosen on an initial feasible trajectory. Two leapfrog iterations are depicted. The piecewise-optimal trajectory $\mu_z^{(1)}$ is obtained after the first iteration from the initial feasible trajectory. The second iteration yields the piecewise-optimal trajectory $\mu_z^{(2)}$.

Let us outline the leapfrog algorithm by using the definitions we have just given.

Step 0. Choose the number of subdivisions $q > 0$ and final time $t_f > t_0$.

Take an initial feasible trajectory $\mu_z^{(0)}$ given between $z_0 = x_0$ and $z_q = x_f$.

Subdivide $\mu_z^{(0)}$ into q segments with subdivision points

$$z_0^{(0)},\ z_1^{(0)}, \ldots, z_{q-1}^{(0)},\ z_q^{(0)}\ .$$

Set $t_0^{(0)} = t_0$ and $k = 0$.

Step k. Perform Steps $k.1$ and $k.2$ below for $i = 1, 2, \ldots, q-1$.

Step $k.1$. Given $z_{i-1}^{(k)}$, $z_{i+1}^{(k)}$ and $t_{i-1}^{(k)}$: Solve problem (P_i) with $x(t_{i-1}) = z_{i-1}^{(k)}$, $x(t_{i+1}) = z_{i+1}^{(k)}$, and $t_{i-1} = t_{i-1}^{(k)}$.

Step k.2. Let $z_i^{k+1} = x(t_i)$ and $t_i^{k+1} = t_i$ such that

$$\tau(x(t_{i-1}), x(t_i)) = \frac{1}{2}\,\tau(x(t_{i-1}), x(t_{i+1}))\ .$$

Set $k = k + 1$ and repeat Step k.

For proving convergence to a critical trajectory, it is necessary to consider the local critical trajectory pairs $(x(\cdot), \psi(\cdot))$ obtained by solving the subproblems (P_i). For each update of z_i, an update is also obtained for $\lambda_{i-1} := \psi(t_{i-1})$ and t_i, $i = 1, \ldots, q-1$, through the solution of (P_i) and the associated optimality system. The updates for λ_{q-1}, λ_q, and $t_q = t_f$ are given by the trajectories of the optimality system associated with problem (P_{q-1}).

Now let $y_i = (z_i, \lambda_i) = (x(t_i), \psi(t_i))$, and consider the $(q+1)$-tuple $y = (y_0, y_1, y_2, \ldots, y_q)$ and the sequence

$$\mathcal{M} = \{\mu^{(k)} : [t_0, t_f^{(k)}] \longrightarrow \mathbb{R}^{2n} : k > 0\}\ ,$$

where $\mu^{(k)}(\cdot) = (x^{(k)}(\cdot), \psi^{(k)}(\cdot))$, with $\mu^{(k)}(t_0) = (z_0, \lambda_0^{(k)})$ and $\mu^{(k)}(t_q) = (z_q, \lambda_q^{(k)})$. In each iteration of leapfrog the states $x(t_0) = z_0$ and $x(t_f) = z_q$ at the end points of $\mu^{(k)}$ are fixed, but the costates $\psi(t_0) = \lambda_0$ and $\psi(t_f) = \lambda_q$, as well as the terminal time t_f, are updated when the new local optimal controls are found and concatenated. Under the assumptions we pose, notably under the uniqueness of the local optimal control and costates, the sequence $\{\mu^{(k)} : k > 0\}$ will be shown to converge to a critical trajectory.

4. Further definitions and facts.

4.1. Elimination of multiple points. If two or more of z_i become the same point, then they are referred to as *multiple points*. Clearly there are no multiple points along the initial trajectory, because the trajectory is not self-intersecting and along each trajectory segment the cost is positive. Multiple points may occur, albeit rarely, in leapfrog, but they can be eliminated through a relabeling procedure described below.

Suppose that there are $\tilde{q}$ subdivisions. Fix i, $0 < i < \tilde{q}$. Let $z_i^{(k+1)}$ be the midpoint along the local optimal trajectory from $z_{i-1}^{(k+1)}$ to $z_{i+1}^{(k)}$.

(M1) If $z_i^{(k+1)} = z_\ell^{(k+1)}$ for some ℓ where $0 \le \ell < i$, then relabel $z_r^{(k)}$, $r = i+1, \ldots, \tilde{q}$, such that

$$z_{i+s}^{(k)} = z_{\ell+s}^{(k)}, \quad s = 1, \ldots, \tilde{q} - i.$$

(M2) If $z_i^{(k+1)} = z_\ell^{(k)}$ for some ℓ where $i < \ell \le \tilde{q}$, then relabel $z_r^{(k)}$, $r = \ell, \ldots, \tilde{q}$, such that

$$z_{\ell+s}^{(k)} = z_{i+s}^{(k)}, \quad s = 0, 1, \ldots, \tilde{q} - \ell.$$

Note that if (M1) applies, the earlier piecewise-optimal trajectory from $z_\ell^{(k+1)}$ to $z_{i+1}^{(k)}$ is replaced by the new local optimal trajectory from $z_i^{(k+1)}$ to $z_{i+1}^{(k)}$. If (M2) applies, the earlier piecewise-optimal trajectory from $z_{i-1}^{(k+1)}$ to $z_\ell^{(k)}$ is replaced by the new local optimal trajectory from $z_{i-1}^{(k+1)}$ to $z_i^{(k)}$. In either case the number of subdivisions $\tilde{q}$ is reduced by $|\ell - i|$. The removal of trajectory segments also reduces total cost.

Either (M1) or (M2) is repeated as often as there are multiple points. Because $\tilde{q}$ is finite, the elimination procedure is applied only a finite number of times, until no more multiple points occur in the remaining leapfrog iterations, yielding a constant number of subdivisions q such that $1 \leq q \leq \tilde{q}$.

It can be shown as a special case that in steps (M1) and (M2) one cannot have $\ell = i - 1$ or $i + 1$. We state this observation as a lemma below.

LEMMA 4.1. *$z_i^{(k+1)} \neq z_{i-1}^{(k+1)}$ and $z_i^{(k+1)} \neq z_{i+1}^{(k)}$.*

Proof. Suppose that $z_i^{(k+1)} = z_{i-1}^{(k+1)}$. Then there exist two local optimal trajectories from $z_{i-1}^{(k+1)}$ to $z_{i+1}^{(k)}$: the local optimal trajectory emanating from $z_{i-1}^{(k+1)}$, revisiting $z_{i-1}^{(k+1)} = z_i^{(k+1)}$, and terminating at $z_{i+1}^{(k)}$ and the segment of the same trajectory after revisiting $z_{i-1}^{(k+1)}$. This contradicts the uniqueness assumption of the local optimal trajectories. Therefore $z_i^{(k+1)} \neq z_{i-1}^{(k+1)}$. Suppose that $z_i^{(k+1)} = z_{i+1}^{(k)}$. A similar argument leads to a similar contradiction. Hence $z_i^{(k+1)} \neq z_{i+1}^{(k)}$. ∎

It should be noted that, in practice, sufficiently nearby z_i may be treated as multiple points. This is highly desirable because it would result in a reduction in both $\tilde{q}$ and cost along the current leapfrog trajectory.

In the sections to follow we give more tools and assumptions for the convergence analysis of leapfrog with constant q after the elimination process described above is completed.

4.2. Continuity of the local cost function. The following assumption will be used in proving the continuity of τ stated in Lemma 4.2, which will in turn be useful in the convergence analysis.

ASSUMPTION 4. *Given $\epsilon > 0$, there exists $\kappa > 0$ such that, for any $z_i, \widetilde{z}_i \in \mathbb{R}^n$,*

$$\|z_i - \widetilde{z}_i\| < \kappa \implies \tau(z_i, \widetilde{z}_i) < \epsilon \ .$$

Example 3. Recall the optimal control problem with the LTI system in Example 2. With $x_0 = z_i$ and $x(1) = \widetilde{z}_i$, it can be shown that

$$\tau(z_i, \widetilde{z}_i) = \frac{1}{2} \left(z_i - e^{-A}\widetilde{z}_i\right)^T M^{-1} \left(z_i - e^{-A}\widetilde{z}_i\right) \ ,$$

where

$$M = \int_0^1 e^{-sA} B R^{-1} B^T e^{-sA^T} ds \ .$$

Because the LTI system is controllable, the Gramian M is positive definite. Therefore $\tau(z_i, \widetilde{z}_i) < \epsilon$ defines a region enclosed by an ellipsoid containing z_i, and thus some $\kappa > 0$ can be found to enclose an open ball of radius $\kappa > 0$ centered at z_i within the ellipsoid. This justifies Assumption 4. In fact, one can conclude from the above expression that the local cost function τ is continuous.

LEMMA 4.2. *The local cost function τ is continuous.*

Proof. Consider the set D given in (13) with some $\delta > 0$ and the open ball $B_\kappa(z_{i-1}, z_{i+1})$ with radius $\kappa > 0$ centered at $(z_{i-1}, z_{i+1}) \in D$, namely,

$$B_\kappa(z_{i-1}, z_{i+1}) = \{(\widetilde{z}_{i-1}, \widetilde{z}_{i+1}) \in D : \|(z_{i-1}, z_{i+1}) - (\widetilde{z}_{i-1}, \widetilde{z}_{i+1})\| < \kappa\}, \tag{14}$$

where $\|\cdot\|$ is the Euclidean norm. The inequality in (14) implies that

$$\|z_{i-1} - \widetilde{z}_{i-1}\| < \kappa \qquad \text{and} \qquad \|z_{i+1} - \widetilde{z}_{i+1}\| < \kappa \ .$$

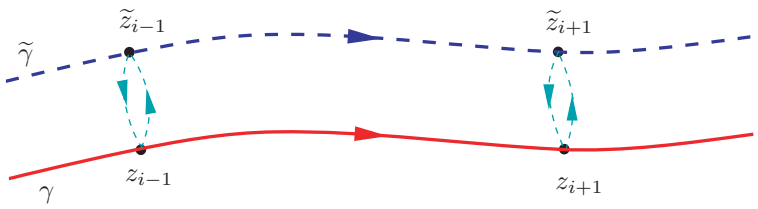

FIG. 2. *Two neighboring optimal trajectories γ and $\widetilde{\gamma}$.*

Because $(z_{i-1}, z_{i+1}) \in D$, there is a local optimal trajectory γ passing through z_{i-1} and z_{i+1}. Similarly because $(\widetilde{z}_{i-1}, \widetilde{z}_{i+1}) \in D$, one has a local optimal trajectory $\widetilde{\gamma}$ passing through $\widetilde{z}_{i-1}$ and $\widetilde{z}_{i+1}$. The trajectories γ and $\widetilde{\gamma}$ are illustrated in Figure 2.

By Assumption 4, for any $\epsilon > 0$, there exist $\kappa_1 > 0$ and $\kappa_2 > 0$ such that

$$\|z_i - \widetilde{z}_i\| < \kappa_1 \implies \tau(z_i, \widetilde{z}_i) < \epsilon/2$$

and

$$\|\widetilde{z}_i - z_i\| < \kappa_2 \implies \tau(\widetilde{z}_i, z_i) < \epsilon/2 \ .$$

Let $\kappa = \min\{\kappa_1, \kappa_2\}$. Then, for any $\epsilon > 0$,

$$\|z_i - \widetilde{z}_i\| < \kappa \implies \tau(z_i, \widetilde{z}_i) < \epsilon/2 \quad \text{and} \quad \tau(\widetilde{z}_i, z_i) < \epsilon/2 \ .$$

This statement is depicted in Figure 2 for the pairs $(z_{i-1}, \widetilde{z}_{i-1})$ and $(z_{i+1}, \widetilde{z}_{i+1})$. Because γ is optimal,

$$\begin{aligned} \tau(z_{i-1}, z_{i+1}) &\le \tau(z_{i-1}, \widetilde{z}_{i-1}) + \tau(\widetilde{z}_{i-1}, \widetilde{z}_{i+1}) + \tau(\widetilde{z}_{i+1}, z_{i+1}) \\ &\le \tau(\widetilde{z}_{i-1}, \widetilde{z}_{i+1}) + \epsilon \ . \end{aligned} \tag{15}$$

Similarly, because $\widetilde{\gamma}$ is optimal,

$$\begin{aligned} \tau(\widetilde{z}_{i-1}, \widetilde{z}_{i+1}) &\le \tau(\widetilde{z}_{i-1}, z_{i-1}) + \tau(z_{i-1}, z_{i+1}) + \tau(z_{i+1}, \widetilde{z}_{i+1}) \\ &\le \tau(z_{i-1}, z_{i+1}) + \epsilon \ . \end{aligned} \tag{16}$$

Inequalities (15)–(16) furnish continuity of τ. ∎

4.3. Midpoint maps and total cost. Consider $(z_{i-1}, z_{i+1}) \in D$, where D is as in (13). We define a *midpoint map* to be any $M : \mathbb{R}^n \times \mathbb{R}^n \longrightarrow \mathbb{R}^n$ such that $M(z_{i-1}, z_{i+1}) = \widehat{z}_i$, where $\widehat{z}_i$ is the midpoint between z_{i-1} and z_{i+1}.

Let $X \subseteq \mathbb{R}^{2n}$ and Y be the set of all $(q+1)$-tuples $y = (y_0, y_1, \ldots, y_q) \in X^{q+1}$ such that $y_i = (z_i, \lambda_i)$ and $\tau(z_i, z_{i+1}) \le \delta$ for all $i = 0, 1, \ldots, q-1$.

For $1 \le p < q$ define $G_p : Y \longrightarrow X^{q+1}$ by

$$G_p(y) = (y_0, \ldots, y_{p-1}, \widehat{y}_p, y_{p+1}, \ldots, y_q),$$

where $\widehat{y}_p = (\widehat{z}_p, \widehat{\lambda}_p)$, $\widehat{z}_p = M(z_{p-1}, z_{p+1})$, and $\widehat{\lambda}_p$ is given by one of the two cases below.

(i) For $p = 0, 1, \ldots, (q-3)$, $\widehat{\lambda}_p = \psi(\widehat{t}_p)$, the initial costate associated with problem (P_{p+1}).

(ii) For $p = (q-2), (q-1), q$, $\widehat{\lambda}_p = \psi(\widehat{t}_p)$, costates associated with problem (P_{q-1}). It should be noted that the update $\widehat{y}_p$, $p = 0, 1, \ldots, (q-3)$, is obtained by solving two subproblems; namely, problem (P_p) is solved to get $\widehat{z}_p$, and problem (P_{p+1}) is solved to get $\widehat{\lambda}_p$.

LEMMA 4.3. *$G_p(y) \in Y$.*

Proof. $\tau(z_{p-1}, \widehat{z}_p) = \tau(z_{p-1}, z_{p+1})/2 \leq (\tau(z_{p-1}, z_p) + \tau(z_p, z_{p+1}))/2 \leq (2\delta)/2$. ∎

So $G_p : Y \longrightarrow Y$, where $1 \leq p < q$. Define $F : Y \longrightarrow Y$ as the composite

$$F = G_{q-1} \circ G_{q-2} \circ \cdots \circ G_1 \ .$$

The $(q+1)$-tuple $\widehat{y} = (\widehat{y}_0, \widehat{y}_1, \ldots, \widehat{y}_q) = F(y) \in Y$ can be defined alternatively by

(i) $\widehat{y}_0 = (\widehat{z}_0, \widehat{\lambda}_0)$, where $\widehat{z}_0 = z_0$ and $\widehat{\lambda}_0 = \psi(t_0)$ is given by the optimal control from z_0 to z_2;

(ii) $\widehat{y}_i = (\widehat{z}_i, \widehat{\lambda}_i)$, where $\widehat{z}_i = M(\widehat{z}_{i-1}, z_{i+1})$ and $\widehat{\lambda}_i = \psi(\widehat{t}_i)$ is given by the optimal control from $\widehat{z}_i$ to z_{i+2} for $1 \leq i \leq q-2$;

(iii) $\widehat{y}_{q-1} = (\widehat{z}_{q-1}, \widehat{\lambda}_{q-1})$, where $\widehat{z}_{q-1} = M(\widehat{z}_{q-2}, z_q)$ and $\widehat{\lambda}_{q-1} = \psi(\widehat{t}_{q-1})$ is given by the optimal control from $\widehat{z}_{q-2}$ to z_q;

(iv) $\widehat{y}_q = (\widehat{z}_q, \widehat{\psi}_q)$, where $\widehat{z}_q = z_q$ and $\widehat{\psi}_q = \psi(\widehat{t}_q)$ is given by the optimal control from $\widehat{z}_{q-2}$ to z_q.

Let Z be the set of all $(q+1)$-tuples $z = (z_0, z_1, \ldots, z_q)$. The $(q+1)$-tuple z is said to have cost $\alpha(z)$, where $\alpha : Z \longrightarrow \mathbb{R}$ is defined by

$$\alpha(z) = \sum_{i=1}^{q} \tau(z_{i-1}, z_i) \ .$$

Note that $\alpha(z) = \int_{t_0}^{t_f} f_0(x, u)\, dt$ is the cost incurred along the piecewise-optimal trajectory defined by the $(q+1)$-tuple z. The function α is continuous, because τ is continuous.

Let the local cost function $\tau : D \longrightarrow \mathbb{R}$ be extended as $\widetilde{\tau} : \widetilde{D} \longrightarrow \mathbb{R}$, where

$$\widetilde{D} = \{(x, \widetilde{x}) \in \mathbb{R}^n \times \mathbb{R}^n : \widetilde{x} \in \mathcal{R}(x, < \Delta)\}$$

and Δ is not necessarily small, such that $\widetilde{\tau}(x, \widetilde{x})$ is the infimum of the cost to get from x to $\widetilde{x}$. Then

$$\widetilde{\tau}(z_0, z_q) \leq \alpha(y) \ .$$

Define the state-space projection map $\pi_1 : Y \longrightarrow Z$ such that

$$\pi_1 \circ G_p(y) = (z_0, z_1, \ldots, \widehat{z}_p, \ldots, z_q)$$

and that $\pi_1 \circ F(y) = (\widehat{z}_0, \widehat{z}_1, \ldots, \widehat{z}_q) =: \widehat{z}$.

LEMMA 4.4. *For $1 \leq p < q$ and all $y \in Y$*

$$\alpha(\pi_1 \circ G_p(y)) \leq \alpha(z) \ .$$

Proof.

$$\begin{aligned} \alpha(z) - \alpha(\pi_1 \circ G_p(y)) &= \tau(z_{p-1}, z_p) + \tau(z_p, z_{p+1}) - \tau(z_{p-1}, \widehat{z}_p) - \tau(\widehat{z}_p, z_{p+1}) \\ &= \tau(z_{p-1}, z_p) + \tau(z_p, z_{p+1}) - \tau(z_{p-1}, z_{p+1}) \\ &\geq 0. \end{aligned}$$ ∎

If one considers the composite $F = G_{q-1} \circ G_{q-2} \circ \cdots \circ G_1$ in Lemma 4.4 instead of G_p, then the following lemma is obtained.

LEMMA 4.5. *For all* $y \in Y$

$$\alpha(\pi_1 \circ F(y)) \leq \alpha(z) \ .$$

5. Convergence analysis.

5.1. Compactness of the state-costate space. Define the set $C(x_0, r)$ of all final states $x_f = x(t_f)$ and costates $\psi_f = \psi(t_f)$ such that the states x_f can be reached from $x_0 = x(t_0)$ over $[t_0, t_f]$ with a minimum cost less than or equal to $r \geq 0$; namely,

$$C(x_0, r) = \{(x_f, \psi_f) \in \mathbb{R}^{2n} : \widetilde{\tau}(x_0, x_f) \leq r\} \ .$$

For each (x_0, x_f, ψ_f) above, the optimal trajectory pair $(x(t), \psi(t))$ and a corresponding control trajectory $u(t)$ satisfy conditions (2)–(5) with $x(t_0) = x_0$, $x(t_f) = x_f$, and $\psi(t_f) = \psi_f$.

Let α_0 be the cost incurred along the initial feasible trajectory.

ASSUMPTION 5. *The set* $C(x_0, \alpha_0)$ *is bounded.*

ASSUMPTION 6. *The optimal terminal time* t_f *is finite.*

The following two examples verify Assumptions 5 and 6.

Example 4. On a Riemannian manifold N, minimal geodesics between two sufficiently nearby given points in a compact subset S of N are contained within a bounded set $W \supset S$. The costates associated with the geodesic problem are also bounded by virtue of (6) because the controls $u_i = \dot{x}_i$ are bounded. Furthermore $t_f = 1$ is fixed.

Example 5. In the case of linear time-varying control systems the right-hand side of (1) is not bounded. However, suppose that the optimal control can be expressed as a linear state feedback and that it is substituted into the system equation to get a system dependent only on the state. It is a well-known fact that there is no *finite-escape time* for linear time-varying systems [21]. So the states are bounded. The associated costates are bounded likewise. The simple case of a fixed time horizon is an example to Assumption 6.

Let $y \in Y$, and define $y^{(k)} = F^k(y)$ for $k \geq 1$.

LEMMA 5.1. Y *is compact.*

Proof. Since $C(x_0, \alpha_0)$ is bounded (by Assumption 5), the set Y is also bounded. Now one needs to show that Y is closed as well. Consider $y = (y_0, y_1, \ldots, y_q) \in Y$. Note that $z_i^{(k)} \in \mathcal{R}(z_{i-1}^{(k)}, \leq \delta)$ for the kth iterate $y^{(k)} = F(y^{(k-1)})$. Since the closure $\overline{C}(x_0, \alpha_0)$ is compact, one can take a convergent subsequence $\{y^{(k_j)} : j \geq 1\}$ of the sequence $\{y^{(k)} : k \geq 0\} \subset Y$. Write

$$\lim_{j \longrightarrow \infty} y^{(k_j)} = y^{(\infty)} \ , \tag{17}$$

and so

$$\lim_{j \longrightarrow \infty} z^{(k_j)} = z^{(\infty)} \ ,$$

where

$$y^{(\infty)} = \left(y_0^{(\infty)}, y_1^{(\infty)}, \ldots, y_q^{(\infty)}\right)$$

and

$$z^{(\infty)} = \left(z_0^{(\infty)}, z_1^{(\infty)}, \ldots, z_q^{(\infty)}\right) \ .$$

Recall that for $1 \leq i \leq q$

$$\tau(z_{i-1}^{(k)}, z_i^{(k)}) \leq \delta \ .$$

By taking limits and using the continuity of τ, we get

$$\tau(z_{i-1}^{(\infty)}, z_i^{(\infty)}) \leq \delta,$$

which implies that $y^{(\infty)} \in Y$. ∎

LEMMA 5.2. *Each sequence* $\{t_i^{(k)} : k \geq 0\}$, $i = 1, \ldots, q$, *has a convergent subsequence with the same index set as that of* $\{y^{(k_j)} : j \geq 1\}$ *such that* $\lim_{j \longrightarrow \infty} y^{(k_j)} = y^{(\infty)}$.

Proof. The conclusion follows from Assumption 6 and the limit expression in (17). ∎

LEMMA 5.3. *The sequence* $\{\alpha(z^{(k)}) : k \geq 1\}$ *converges to its infimum* $\alpha^{(\infty)}$. *In particular*

$$0 < \alpha(z^{(\infty)}) = \alpha^{(\infty)} \in [\widetilde{\tau}(z_0, z_q), q\delta].$$

Proof. The result follows from the continuity of α and Lemmas 5.1 and 4.5. ∎

5.2. Extreme points and leapfrog splicing. Recall that by Assumption 2 the curve $\gamma_{z_{i-1}, z_{i+1}} : [t_{i-1}, t_{i+1}] \longrightarrow \mathbb{R}^n$ is the unique optimal trajectory from z_{i-1} to z_{i+1}. The point $y_i = (z_i, \lambda_i)$ is said to be *between* y_{i-1} and y_{i+1} if z_i lies in the image of $\gamma_{z_{i-1}, z_{i+1}}$. Note that, trivially, y_{i-1} and y_{i+1} are between y_{i-1} and y_{i+1}.

The $(q+1)$-tuple $y \in Y$ is said to be *extreme* when y_i is between y_{i-1} and y_{i+1} for all $1 < i < q$.

Let $\mu_i : [t_i, t_{i+1}] \longrightarrow \mathbb{R}^{2n}$ be the optimal trajectory pair $(\gamma_{z_{i-1}, z_i}(\cdot), \psi(\cdot))$ solving the optimality system associated with problem (P_i) from z_{i-1} to z_i, $i = 1, \ldots, q$. Then $\mu_y : [t_0, t_f] \longrightarrow \mathbb{R}^{2n}$ is defined as the concatenation (or track sum) of $\mu_1, \mu_2, \ldots, \mu_q$ in the given order such that $\mu_y(t_0) = \mu_1(t_0)$, $\mu_y(t_i) = \mu_i(t_i) = \mu_{i+1}(t_i)$, $i = 1, \ldots, q-1$, and $\mu_y(t_f) = \mu_q(t_q)$. It is convenient to use a special symbol, for example, $\smile$, for this kind of concatenation. The trajectory μ_y can then be expressed by

$$\mu_y := \mu_1 \smile \mu_2 \smile \cdots \smile \mu_q \ .$$

LEMMA 5.4. *If* y *is extreme, then* μ_y *is a critical trajectory.*

Proof. Suppose that $y \in Y$ is extreme. We will use induction on what we call the *leapfrog splicing* of trajectories, which is illustrated in Figure 3, to prove the lemma. We define

$$\mu_y^{(p)} := \mu_1 \smile \mu_2 \smile \cdots \smile \mu_p$$

and aim to prove the following: $\mu_y^{(p)}$ is critical with the fixed end points $x(t_0) = z_0$ and $x(t_p) = z_p$ for $2 \leq p \leq q$, where q is provided.

Suppose that $p = 2$. Then $\mu_y^{(2)} = \mu_1 \smile \mu_2$. Because y_1 is between y_0 and y_2, z_1 is in the image of the optimal trajectory γ_{z_0, z_2}. Therefore there exists some nontrivial $\psi(\cdot)$ such that $\mu_y^{(2)} = (\gamma_{z_0, z_2}(\cdot), \psi(\cdot))$ solves the associated optimality system. So $\mu_y^{(2)}$ is critical.

Assume that $\mu_y^{(k)} = \mu_1 \smile \mu_2 \smile \cdots \smile \mu_k$ is critical. The next leapfrog step from z_{k-1} to z_{k+1} gives the local optimal trajectory segment $\gamma_{z_{k-1}, z_{k+1}}(\cdot)$ and the associated

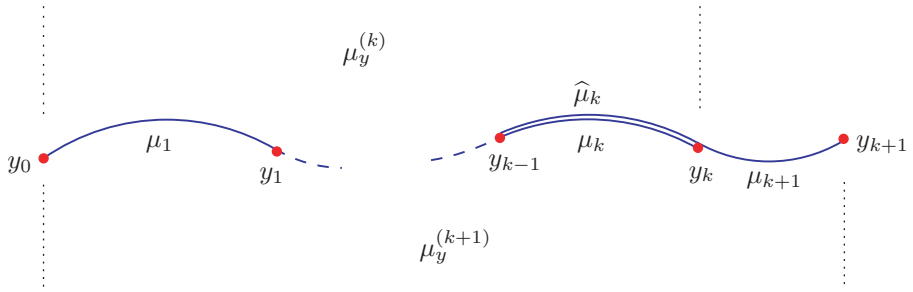

FIG. 3. *Concatenation of the local optimal trajectories μ_i and the leapfrog splicing.*

costate trajectory $\widehat{\psi}(\cdot)$. So $(\widehat{\gamma}_{z_{k-1},z_{k+1}}(\cdot), \widehat{\psi}(\cdot)) = \widehat{\mu}_k \smile \mu_{k+1}$. By the induction hypothesis, $\mu_k = (\gamma_{z_{k-1},z_k}(\cdot), \psi(\cdot))$ is optimal. Because y_k is between y_{k-1} and y_{k+1}, $\widehat{\mu}_k = (\widehat{\gamma}_{z_{k-1},z_k}(\cdot), \widehat{\psi}(\cdot))$ is also optimal. By the local uniqueness of the controls and costates posed in Assumptions 2 and 3, $\gamma_{z_{k-1},z_k}(\cdot) = \widehat{\gamma}_{z_{k-1},z_k}(\cdot)$ and $\psi(\cdot) = \widehat{\psi}(\cdot)$. Therefore $\mu_k = \widehat{\mu}_k$. By "splicing" the trajectory segments $\mu_1 \smile \mu_2 \smile \cdots \smile \mu_k$ and $\widehat{\mu}_k \smile \mu_{k+1}$, by means of the overlap $\widehat{\mu}_k = \mu_k$ between y_{k-1} and y_k (see Figure 3), we obtain the trajectory

$$\mu_y^{(k+1)} = \mu_1 \smile \mu_2 \smile \cdots \smile \mu_k \smile \mu_{k+1},$$

which satisfies the optimality system associated with the optimal control problem with the end conditions $x(t_0) = z_0$ and $x(t_{k+1}) = z_{k+1}$. So $\mu_y^{(k+1)}$ is critical. ∎

Remark 5.1. The converse of Lemma 5.4 holds if μ_y is not only critical but also (locally) optimal.

LEMMA 5.5. (a) *If y is extreme and all z_i, $i = 1, \ldots, q-1$, are midpoints, then $F(y) = y$.*

(b) *If $F(y) = y$, then y is extreme.*

Proof. (a) Suppose that y is extreme and all z_p, $p = 1, \ldots, q-1$, are midpoints, that is, $z_p = \widehat{z}_p = M(z_{p-1}, z_{p+1})$. One further has $\lambda_p = \widehat{\lambda}_p$, because, by using the notation of the proof of Lemma 5.4, $\widehat{\mu}_{p-1} \smile \widehat{\mu}_p = \mu_{p-1} \smile \mu_p$ by the local uniqueness of optimal trajectories. Therefore $y_p = \widehat{y}_p = G_p(y)$, $p = 1, \ldots, q-1$. The composition $F = G_{q-1} \circ G_{q-2} \circ \cdots \circ G_1$ then gives $F(y) = \widehat{y} = y$.

(b) Suppose that $F(y) = y$. Recall that $\widehat{z}_0 = y_0$, $\widehat{z}_p = M(\widehat{z}_{p-1}, z_{p+1})$ for $p = 1, \ldots, q-1$, and $\widehat{z}_q = z_q$, where M is the midpoint map. Now since $F(y) = y$,

$$z_p = \widehat{z}_p = M(z_{p-1}, z_{p+1}) \ .$$

So y_p is between y_{p-1} and y_{p+1}, $p = 1, \ldots, q-1$. ∎

LEMMA 5.6. *y is extreme if and only if $\mu_{F(y)} = \mu_y$.*

Proof. Suppose that y is extreme. Because y_p is between y_{p-1} and y_{p+1}, $\widehat{y}_p = G_p(y)$ is also between y_{p-1} and y_{p+1}. So $\mu_{G_p(y)} = \mu_y$, by the uniqueness of $\gamma_{z_{i-1},z_{i+1}}$. The composition $F = G_{q-1} \circ G_{q-2} \circ \cdots \circ G_1$ gives $\mu_{F(y)} = \mu_y$.

Suppose that $\mu_{F(y)} = \mu_y$. Then $\mu_{G_1(y)} = \mu_y$. By using the notation of the proof of Lemma 5.4, $\widehat{\mu}_1 \smile \widehat{\mu}_2 = \mu_1 \smile \mu_2$. So $\widehat{y}_1$ is between y_0 and y_1. The composition $F = G_{q-1} \circ G_{q-2} \circ \cdots \circ G_1$ yields that y is extreme. ∎

LEMMA 5.7. *y is extreme if and only if $\alpha(\pi_1 \circ F(y)) = \alpha(z)$.*

Proof. Suppose that y is extreme. Then $\alpha(\pi_1 \circ F(y)) = \alpha(z)$ by Lemma 5.6. Suppose that $\alpha(\pi_1 \circ F(y)) = \alpha(z)$. Recall that

$$\alpha(z) = \tau(z_0, z_1) + \cdots + \tau(z_{p-1}, z_p) + \tau(z_p, z_{p+1}) + \cdots + \tau(z_{q-1}, z_q) \ .$$

For $0 < p < q$,

$$\alpha(\pi_1 \circ G_p(y)) = \tau(z_0, z_1) + \cdots + \tau(z_{p-1}, \widehat{z}_p) + \tau(\widehat{z}_p, z_{p+1}) + \cdots + \tau(z_{q-1}, z_q) \ .$$

Then

$$\tau(z_{p-1}, \widehat{z}_p) + \tau(\widehat{z}_p, z_{p+1}) = \tau(z_{p-1}, z_p) + \tau(z_p, z_{p+1}) \ . \tag{18}$$

By the definition of the midpoint map, $\widehat{z}_p$ lies in the image of $\gamma_{z_{p-1}, z_{p+1}}$. Equation (18) implies that z_p lies in a trajectory of equal cost, and this trajectory can only be $\gamma_{z_{p-1}, z_{p+1}}(\cdot)$, by uniqueness. Therefore y_p is between y_{p-1} and y_{p+1}. The composition $F = G_{q-1} \circ G_{q-2} \circ \cdots \circ G_1$ then provides that y is extreme. ∎

5.3. Convergence to a critical trajectory.

LEMMA 5.8. *$y^{(\infty)}$ is extreme.*

Proof. By Lemmas 4.5 and 5.3, $\alpha(\pi_1 \circ F(y^{(\infty)})) = \alpha^{(\infty)} = \alpha(\pi_1(y^{(\infty)}))$. Then the result follows by Lemma 5.7. ∎

LEMMA 5.9. *$\mu_{y^{(\infty)}}$ is a critical trajectory.*

Proof. Lemmas 5.8 and 5.4 furnish the lemma. ∎

THEOREM 5.1. *The leapfrog iterations converge to a critical trajectory $\mu_{y^{(\infty)}}$.*

Proof. Lemmas 5.8 and 5.6 imply that $\mu_{F(y^{(\infty)})} = \mu_{y^{(\infty)}}$, which together with Lemma 5.9 proves the theorem. ∎

Although Theorem 5.1 guarantees convergence of the trajectory iterates $\mu_{y^{(k)}}$, no assertion has yet been made about convergence of the iterates $y^{(k)}$. Convergence of $y^{(k)}$ is particularly important in a numerical implementation. If it is known that $y^{(k)}$ is convergent, too, then, instead of using an infinite-dimensional norm (for example, the L^∞ norm) to measure the change from the trajectory iterate $\mu_{y^{(k)}}$ to $\mu_{y^{(k+1)}}$, a finite-dimensional norm (for example, the Euclidean norm) can be used to measure the change from the iterate $y^{(k)}$ to $y^{(k+1)}$, which is much less demanding computationally. In what follows, we will give a lemma and Theorem 5.2, which guarantees convergence of the iterates $y^{(k)}$.

LEMMA 5.10. *If y is extreme, then all $z_i^{(\infty)}$, $i = 1, \ldots, q-1$, are uniformly distributed with respect to cost, namely,*

$$\tau(z_{i-1}^{(\infty)}, z_i^{(\infty)}) = \tau(z_i^{(\infty)}, z_{i+1}^{(\infty)}) \ ,$$

$i = 1, \ldots, q-1$.

Proof. Let y be extreme. Then by Lemma 5.4, μ_y is critical. Suppose that μ_y is parameterized proportionally to the cost so that $\mu_y : [0,1] \longrightarrow \mathbb{R}^{2n}$, with $\mu_y(0) = y_0$ and $\mu_y(1) = y_q$. Note that, by Lemma 5.6, $\mu_{F(y)} = \mu_y$. Then it suffices to show that the sequence $\{F^k(y) : k \geq 1\}$ converges to the uniformly distributed $(q+1)$-tuple

$$(y_0, \mu_y(1/q), \mu_y(2/q), \ldots, \mu_y(i/q), \ldots, y_q) \ .$$

The rest of the proof follows similar lines as those given by [30, Lemma 3.2], which we adapt here by using our notation and definitions.

If $q = 2$, the result is clear since $F(y)$ is independent of y_1 and the limit is achieved immediately as $F(y)$. For $q > 2$ we give some definitions first and then prove the convergence to the required $(q+1)$-tuple.

Let $y^{(0)} = y$ and $y^{(k)} = F^k(y)$ for $k = 1, 2, \ldots$. Since $\mu_{y^{(k)}} = \mu_{y^{(0)}}$ by Lemma 5.6,

$$y^{(k)} = (\mu(0), \mu(t_1^{(k)}), \mu(t_2^{(k)}), \ldots, \mu(t_{q-1}^{(k)}), \mu(t_q^{(k)}))$$

for $k = 0, 1, 2, \ldots$, where $t_i^{(k)}$, $i = 1, \ldots, q-1$, are the junction times. Since μ_y is parameterized proportionally to the cost, application of F gives the recursion

$$t_i^{(k)} = (t_{i-1}^{(k)} + t_{i+1}^{(k-1)})/2$$

for $i = 1, \ldots, q-1$, where $t_0^{(k)} = 0$, $t_q^{(k)} = 1$. Write

$$t^{(k)} = [t_2^{(k)}, t_3^{(k)}, \ldots, t_{q-1}^{(k)}]^T \in \mathbb{R}^{q-2} \ .$$

Then $t^{(k)} = A\, t^{(k-1)} + b$, where

$$A = \begin{bmatrix} 1/2^2 & 1/2 & 0 & \cdots & 0 \\ 1/2^3 & 1/2^2 & 1/2 & \cdots & 0 \\ \vdots & \vdots & \vdots & \vdots & \vdots \\ 1/2^{q-1} & 1/2^{q-2} & 1/2^{q-3} & \cdots & 1/2^2 \end{bmatrix}$$

and $b = [0, 0, \ldots, 0, 1/2]^T \in \mathbb{R}^{q-2}$. It is straightforward to obtain

$$t^{(k)} = b + Ab + A^2 b + \cdots + A^{k-1} b + A^k t^0 \ ,$$

which converges since $\|A\| < 1$. So the limit $t^{(\infty)}$ satisfies $t^{(\infty)} = A\, t^{(\infty)} + b$. It is seen that

$$t^{(\infty)} = [2, 3, \ldots, q-1]^T / q$$

is the unique solution, which completes the proof. □

THEOREM 5.2. *$\{F(y^{(k)}) : k \geq 0\}$ has a unique accumulation point.*

Proof. By Lemmas 5.8, 5.10, and 5.5(a), $F(y^{(\infty)}) = y^{(\infty)}$. □

6. Numerical implementation. We will illustrate a numerical implementation of leapfrog on an optimal control problem with a fixed terminal time. Recall Remark 2.2. For a fixed terminal time problem, one solves the subproblems (P_i) with both t_{i-1} and t_{i+1} fixed. At the start of the algorithm, the values $t_{i-1}^{(0)}$ and $t_{i+1}^{(0)}$ are given by a partition between $x_{n+1}(0) = 0$ and $x_{n+1}(t_f) = 1$: One typically takes a regular partition of the time interval $[0, 1]$. Then, given $t_{i-1}^{(k+1)}$ and $t_{i+1}^{(k)}$, the time iterate $t_i^{(k+1)}$ is determined through the solution of (P_i) as the time at which the midpoint $z_i^{(k+1)}$ is placed.

6.1. The van der Pol system. The van der Pol system has been used in earlier control applications, including time-optimal control problems where the control regime is bang–bang [18, 27]. Here we consider the van der Pol system with unbounded control

$$\dot{x}_1(t) = x_2(t) \ , \tag{19}$$

$$\dot{x}_2(t) = -x_1(t) - (x_1^2(t) - 1)\, x_2(t) + u(t) \ , \tag{20}$$

where the problem is to get from $x(0) = (-2, -3)$ to $x(1) = (5, 0)$, minimizing the quadratic cost

$$\frac{1}{2} \int_0^1 (x_1^2(t) + x_2^2(t) + u^2(t)) dt \ .$$

The Hamiltonian is

$$H(x,\psi,u) = (x_1^2 + x_2^2 + u^2)/2 + \psi_1 x_2 + \psi_2[-x_1 - (x_1^2 - 1)x_2 + u] \ .$$

The maximum principle yields, in addition to the system equations (19)–(20), the following costate equations:

$$\dot{\psi}_1(t) = -x_1(t) + (1 + 2x_1(t)x_2(t))\,\psi_2(t) \ , \tag{21}$$

$$\dot{\psi}_2(t) = -x_2(t) - \psi_1(t) + (x_1^2(t) - 1)\,\psi_2(t) \ . \tag{22}$$

Furthermore optimal control has to satisfy

$$u(t) = -\psi_2(t) \ . \tag{23}$$

Substitution of (23) gives rise to the following TPBVP:

$$\dot{x}_1 = x_2 \ , \tag{24}$$

$$\dot{x}_2 = -x_1 - (x_1^2 - 1)\,x_2 - \psi_2 \ , \tag{25}$$

$$\dot{\psi}_1 = -x_1 + (1 + 2x_1x_2)\,\psi_2 \ , \tag{26}$$

$$\dot{\psi}_2 = -x_2 - \psi_1 + (x_1^2 - 1)\,\psi_2 \ , \tag{27}$$

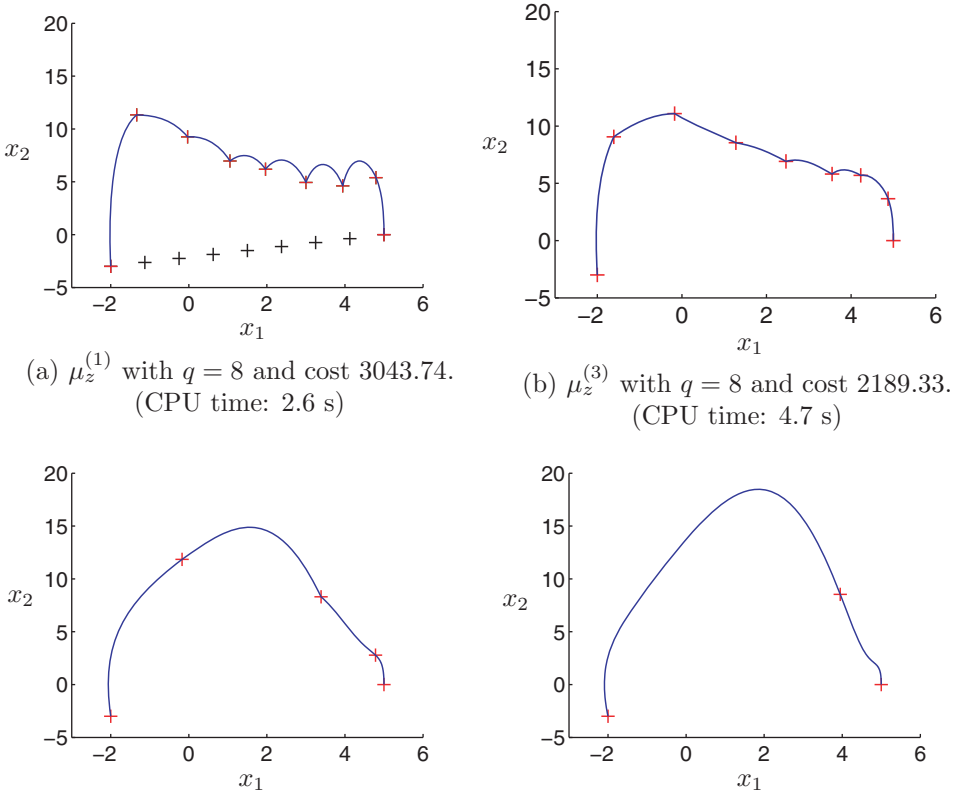
$$\text{with } x(0) = (-2,-3) \quad \text{and} \quad x(1) = (5,0) \ .$$

6.1.1. Solution with leapfrog. The leapfrog algorithm owes its working largely to the solutions of subproblems (P_i). These subproblems for the van der Pol problem have been reduced to (24)–(27) with the accompanying boundary conditions. A solution to these equations can be found by using simple shooting, because the leapfrog partition points are initially chosen close enough to one another so that affine approximations provide good initial guesses for simple shooting.

A MATLAB code has been written to implement the leapfrog algorithm. For solving the ODEs (24)–(27), the MATLAB function `ode45` is utilized with the absolute and relative tolerances of 10^{-8}. The simple shooting technique that we have programmed incorporates Newton's method with backtracking [8]. This increases the chances of simple shooting to converge; however, if the number of iterations within simple shooting exceeds 10, then we regard simple shooting to have failed. In the final iteration of leapfrog the relative and absolute tolerances for `ode45` are sharpened to 10^{-10}.

Iterations of the leapfrog algorithm in the state space are shown in Figure 4. Figure 4(a) displays both the initial partition with which we start and the concatenation of the locally optimal trajectories $\mu_z^{(1)}$ obtained as a result of the first leapfrog iteration. The initial points $z_i^{(0)}$ have been chosen to be equally spaced along the straight line between x_0 and x_T. For ease of bookkeeping in the code we consider powers of 2 for the number of subdivisions; i.e., we use $q = 2, 4, 8$, etc. In each iteration we use the smallest possible q with which each subproblem (P_i) is solved successfully. This eventually leads to a final iteration where $q = 2$, and simple shooting is used to achieve the solution.

With leapfrog, different positioning of the midpoints is permissible, as long as the subintervals of the consequent subproblems overlap. So, in the implementation, the midpoint $z_i^{(k+1)}$ is chosen as the point which is reached in roughly half the time along the optimal trajectory from $z_{i-1}^{(k+1)}$ to $z_{i+1}^{(k)}$. This choice of midpoints is computationally more economical than the choice of midpoint where *exactly* half the cost is incurred.



(a) $\mu_z^{(1)}$ with $q = 8$ and cost 3043.74. (CPU time: 2.6 s)

(b) $\mu_z^{(3)}$ with $q = 8$ and cost 2189.33. (CPU time: 4.7 s)

(c) $\mu_z^{(6)}$ with $q = 4$ and cost 1151.34. (CPU time: 8.0 s)

(d) $\mu_z^{(10)}$ with $q = 2$ and cost 993.67. (CPU time: 14.2 s)

FIG. 4. *Locally optimal state trajectories $\mu_z^{(k)}$ during leapfrog iterations for the van der Pol system. Crosses in iteration k represent partition points $z_i^{(k)}$, $i = 0, 1, \ldots, q$.*

The first to fifth iterations could all be successfully completed by taking at least eight subdivisions. The sixth to ninth iterations could be carried out with a minimum of four subdivisions, where the new partition is formed in the sixth iteration by taking the points $z_2^{(5)}$, $z_4^{(5)}$, and $z_6^{(5)}$ from iteration 5. The trajectory $\mu_z^{(3)}$ and the updated partition points $z_i^{(3)}$, $i = 1, 2, 3$, are illustrated in Figure 4(c). The tenth iteration, after reducing the number of partitions to two, or simply applying simple shooting between x_0 and x_T with the initial guess value $\psi(0) = \lambda_0^{(9)}$, yields the solution trajectory for the problem, which is depicted in Figure 4(d). The costs along each of the leapfrog trajectory iterates $\mu_z^{(k)}$, $k = 1, 3, 6, 10$, are reported in Figures 4(a)–(d), respectively. We also report the CPU times, cumulatively at each iteration, as measured within MATLAB, running on the (single user) Windows XP Professional (Version 5.1) operating system with a 2.00 GHz Intel Pentium M processor and 1 GB of RAM.

The first leapfrog iteration can also be viewed as one where a trajectory is constructed in a simple way and verified to be feasible. Because of the Newton backtracking, this iteration takes more than twice longer than each of the rest of the iterations except the last one. The last iteration, where we reduce the whole process to simple shooting, also takes longer because of the Newton backtracking and because we require a higher accuracy.

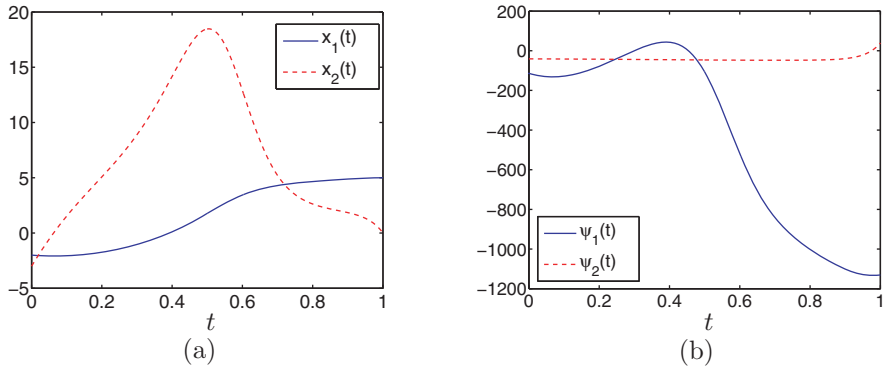


FIG. 5. *The solution state and costate trajectories for the van der Pol system.*

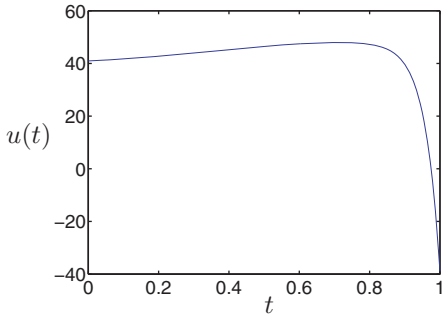

FIG. 6. *The solution control trajectory for the van der Pol system.*

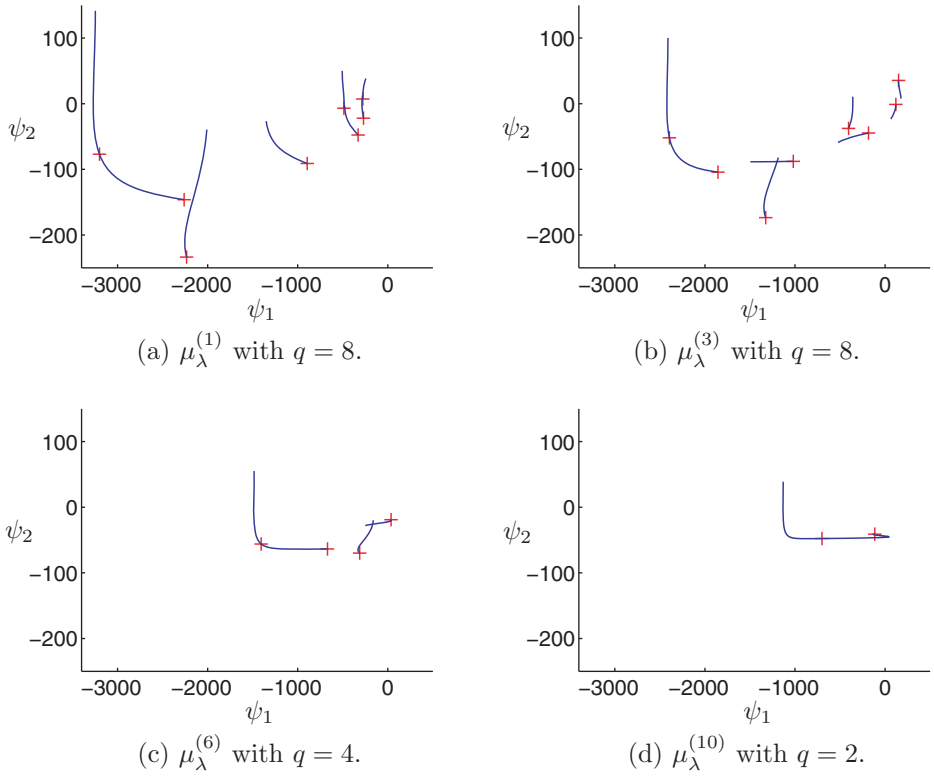
The solution trajectories of the state, costate, and control variables as functions of time can be seen in Figures 5(a)–(b) and 6. In Figure 6, simply $u(t) = -\psi_2(t)$. The initial costate vector $\psi(0) = (-113.817881, -40.950820)$ generates an accurate solution.

Some of the locally optimal costate trajectories obtained in the leapfrog iterations are shown in Figure 7.

Overall it appears that there are pros and cons with using leapfrog. Numerical evidence arising from our application of leapfrog to the van der Pol problem point to certain advantages and disadvantages of leapfrog.

ADVANTAGE 1. With leapfrog, one has only to choose the starting values of the states. These values can usually be chosen in a practical manner (for example, along a straight line joining x_0 and x_T), which could then generate a feasible trajectory. In the leapfrog scheme, it is not necessary to guess the starting values of costates. For solving the subproblems in leapfrog, affine approximations usually give reasonable starting values for the costates.

ADVANTAGE 2. At each iteration, leapfrog generates a locally optimal trajectory $\mu_z^{(k)}$, which is feasible. Suppose that the time allowed to design an optimal control for the system is not long enough to compute a solution. Then leapfrog may provide at least a suboptimal control. For example, if it is necessary to obtain a solution in less than 10 seconds, then, within the computational means we have in this article, we may offer the suboptimal solution depicted in Figure 4(c), which is far better than the feasible solution given in Figure 4(a).



(a) $\mu_\lambda^{(1)}$ with $q = 8$. (b) $\mu_\lambda^{(3)}$ with $q = 8$.

(c) $\mu_\lambda^{(6)}$ with $q = 4$. (d) $\mu_\lambda^{(10)}$ with $q = 2$.

FIG. 7. *Locally optimal costate trajectories during leapfrog iterations for the van der Pol system. Crosses in iteration k represent partition points $\lambda_i^{(k)}$, $i = 0, 1, \ldots, q-1$.*

One restriction on the applicability of the suboptimal solution found by leapfrog is that the control $u(t) = -\psi(t)$ is discontinuous, because the piecewise optimal $\psi(t)$ obtained in the third iteration is discontinuous, as can be seen in Figure 7(c). However, many dynamical systems allow discontinuous controls; so the suboptimal control generated by leapfrog can possibly be implemented.

An apparent drawback of leapfrog is that, as the solution is approached, it is observed from the numerical experiments that, with a fixed number of partitions $q > 2$, the leapfrog updates get sluggish. Therefore, q needs to be reduced progressively (eventually down to $q = 2$) for convergence in a reasonable number of iterations. This effort may in general incur an additional computational cost.

6.2. Further comments on implementation of leapfrog. We observe that the solution for the problem in the previous subsection is obtained in ten iterations. It is worthwhile to note that the same problem with different initial and target states may require a different number of subdivisions at the start, and reducing the number of subdivisions may take a lot longer than what is presented here. The performance of the algorithm would depend not only on the difficulty of the problem but also on the way the algorithm is implemented. Two particular issues seem to be of main concern in any implementation of leapfrog, namely, (i) the efficiency of the simple shooting technique employed in subproblems (P_i) and (ii) a dynamic way of doing the partitioning along a leapfrog trajectory iterate.

Because we were concerned only with providing an illustration of the leapfrog algorithm in this particular study, we have coded a rather straightforward simple shooting scheme. A more sophisticated simple shooting scheme may be necessary for more difficult problems. In particular, one should note that `ode45` is not necessarily the method of choice for the integration of the state-costate equations; it merely serves to illustrate an implementation of leapfrog. Otherwise, in a more elaborate implementation, a certain approximation order for both the states and the costates can be achieved only if certain conditions are satisfied [12].

In the case when $q > 2$ is fixed, convergence can usually not be obtained in a finite number of iterations. Furthermore if q is large, then the numerical experiments show that convergence becomes rather slow. So it is important to employ some kind of *dynamic* partitioning. A simple dynamic partitioning scheme was prescribed in the example application in section 6.1. However, more sophisticated schemes can also be employed. One can increase or decrease the number of partitions *locally* in a smaller segment of the leapfrog trajectory, as the need arises. Given a trajectory, it may be appropriate to increase the number of subdivisions in one segment of the trajectory, while it is appropriate to decrease the number in some other segment. The ultimate aim would still remain to reduce the number of iterations to just two, in which case simple shooting, if successful, would deliver the required solution.

PRIMAL AND DUAL INTERFACE CONCENTRATED ITERATIVE SUBSTRUCTURING METHODS*

SVEN BEUCHLER†, TINO EIBNER‡, AND ULRICH LANGER§

Abstract. This paper is devoted to the fast solution of interface concentrated finite element equations. The interface concentrated finite element schemes are constructed on the basis of a nonoverlapping domain decomposition where a conforming boundary concentrated finite element approximation is used in every subdomain. Similar to boundary element domain decomposition methods, the total number of unknowns per subdomain behaves like $O((H/h)^{(d-1)})$, where H, h, and d denote the usual scaling parameter of the subdomains, the average discretization parameter of the subdomain boundaries, and the spatial dimension, respectively. We propose and analyze primal and dual substructuring iterative methods which asymptotically exhibit the same or at least almost the same complexity as the number of unknowns. In particular, the so-called all-floating finite element tearing and interconnecting solvers are highly parallel and very robust with respect to large coefficient jumps.

Key words. solution of discretized equations, domain decomposition, finite elements

1. Introduction.

Boundary concentrated finite element methods (BC-FEM), introduced and investigated by Khoromskij and Melenk in [22], allow us to solve potential problems with smooth coefficients and right-hand sides as accurately as the corresponding standard finite element methods (FEMs) but with a significantly smaller number of unknowns. Indeed, the total number of unknowns in the BC-FEM is proportional to $O(h^{-(d-1)})$, whereas the total number of unknowns in the standard FEM behaves like $O(h^{-d})$, where h and d denote the average discretization parameter of the boundary and the spatial dimension, respectively. This idea has also been used in the related boundary element method (BEM); see the recent paper [20]. Another advantage is the lower condition number of the corresponding finite element stiffness matrices in comparison to the usual FEM, at least, for the Dirichlet problem. This property was already discovered by Yserentant [48].

Efficient solution methods for the BC-FEM have been designed in [22, 23, 10, 11]. In [23] it is shown how the Cholesky factorization of the stiffness matrix for two-dimensional problems can be performed with the complexity $O(h^{-1}\log^8 h^{-1})$. The paper [22] briefly suggests a preconditioner based on the fast realization of $H^{1/2}(\partial\Omega)$-like norms on the space of piecewise linear functions. Moreover, the paper [22] also

points out the case of Dirichlet boundary conditions as being special, since the condition number of the diagonally scaled stiffness matrix is shown to be bounded by $O(\log^{\beta} N)$ for some $\beta \geq 0$ depending on the choice of shape functions. However, these preconditioners lead to condition numbers that grow polylogarithmically in the problem size instead of the desirable optimal $O(1)$. The first preconditioners for BC-FEM that achieve optimal condition numbers are presented in [10, 11]. These preconditioners are based on the additive Schwarz framework; see, e.g., [38, 41, 47]. They are dimension independent and applicable to a wide range of boundary conditions.

Interface concentrated finite element methods (IC-FEM) are a combination of nonoverlapping domain decomposition (DD) methods with the BC-FEM that is used in the subdomains Ω_k in which the initial domain Ω is decomposed. Now we can admit piecewise smooth coefficients in the PDE that we are going to solve. An efficient method for the solution of symmetric and positive definite (SPD) systems of linear algebraic equations arising from the finite element discretization of elliptic boundary value problems is the preconditioned conjugate gradient (PCG) method with DD preconditioners. The nonoverlapping Dirichlet–Dirichlet DD preconditioning technique and the finite-element-tearing and interconnecting (FETI) method are typical representatives of primal and dual nonoverlapping DD approaches, respectively. The Dirichlet–Dirichlet DD preconditioner requires preconditioners for the local Dirichlet problems on the subdomains, a Schur complement preconditioner related to the interfaces and approximate discrete harmonic extension operators, or, more precisely, bounded discrete extension operators acting from the subdomain boundaries into the interior; see, e.g., [34, 38, 17, 18, 29] and the references therein.

Today, for preconditioning the local Dirichlet problems, a lot of very efficient techniques are available from preconditioning standard h, p, or hp finite element equations; see, e.g., [29]. The first preconditioners for the Schur complement were proposed by Dryja for some special cases in [8] and [9]. The BPS preconditioners proposed and developed by Bramble, Pasciak, and Schatz in a series of papers can be seen as a generalization to more general decompositions and discretizations [3]. During the last 20 years many alternative Schur complement preconditioners have been proposed in the literature. Here let us mention only the Bramble–Pasciak–Xu (BPX) Schur complement preconditioner [44], techniques borrowed from the BEM [32], and $\mathcal{H}$-matrix techniques [21]. In the case of uniformly refined meshes, two basic techniques for the fast evaluation of the approximate discrete harmonic extension of a finite element function on the boundary to the interior exist, namely, an averaging technique [38], [35] and hierarchical decomposition techniques [18, 15, 19].

The FETI technology introduced by Farhat and Roux in [14] has been developed to a very efficient and robust parallel solver technique for large-scale finite element equations. There are a lot of modifications and new versions of the classical one-level FETI method like the FETI-DP (dual-primal) [13] and BDDC (balanced domain decomposition by constraints) methods [6, 33]. The main building blocks of the FETI methods are solvers or preconditioners for the local Dirichlet and the local Neumann problems in the subdomains and a component managing the global information exchange. Preconditioners of Neumann–Neumann-type and FETI preconditioners for hp-FEM tensor product discretizations of elliptic boundary value problems have been proposed in [45, 46]. We again refer the reader to the monograph [47] for more information on and references to FETI methods.

In this paper, we propose and investigate fast, robust, and highly parallel DD solvers for large-scale interface concentrated finite element equations. The polynomials

of high order are removed by an overlapping preconditioner with inexact subproblem solvers which was proposed by Pavarino [42]; see also [36, 11]. This preconditioner requires

- a solver for each patch corresponding to a node, and
- a coarse space solver for $p = 1$ on the computational domain.

The first problem is treated by a direct solver, whereas the second problem is treated by two different types of DD preconditioners. The first preconditioner is a nonoverlapping DD preconditioner of Dirichlet–Dirichlet type with inexact subproblem solvers. The second type of preconditioners are all-floating (AF)-FETI preconditioners. The AF or total tearing and interconnecting techniques have independently been introduced by Of [40] and by Dostál, Horák, and Kučera [7]. We will prove that the design of both preconditioners leads to an almost optimal solver for the corresponding system of algebraic finite element equations. The complexity is almost proportional to the number of unknowns corresponding to the skeleton of the DD. Moreover, we show that the FETI preconditioners are robust with respect to jumps in the coefficients of the PDE. The preconditioners also work in the three-dimensional case. For the sake of simplicity, we restrict ourselves to the two-dimensional case. A brief discussion of the three-dimensional case is presented at the end of this paper.

The rest of the paper is organized as follows: In section 2, we formulate the boundary value problem and describe its discretization with the help of the IC-FEM. Section 3 is devoted to the primal DD preconditioners. In section 4, we investigate the FETI preconditioners. Several numerical experiments are presented in section 5.

2. Model problem and finite element discretization.

2.1. Model problem. For a polygonal Lipschitz domain Ω with

$$\overline{\Omega} = \bigcup_{i=1}^{s} \overline{\Omega}_i \subset \mathbb{R}^2, \qquad \Omega_i \cap \Omega_j = \emptyset \ \text{ with } i \neq j, \tag{2.1}$$

an SPD matrix function $\mathcal{D} \in \mathbb{R}^{2,2}$ which is piecewise constant on Ω_j and a right-hand side $f \in L^2(\Omega)$ analytic on $\overline{\Omega}_j$, we consider the following Dirichlet problem, given in weak formulation.

PROBLEM 2.1 (model problem). *Find $u \in H_0^1(\Omega)$ such that*

$$a(u,v) := \int_\Omega \nabla u(x) \cdot \mathcal{D}(x) \nabla v(x)\, dx = \int_\Omega f(x) v(x)\, dx =: l(v) \qquad \forall\, v \in H_0^1(\Omega). \tag{2.2}$$

For simplicity, throughout this paper, the subdomains Ω_j are assumed to be polygonal Lipschitz domains. Of course, weaker assumptions are possible (e.g., piecewise smooth Lipschitz domains).

2.2. Discretization: The geometric mesh, the linear degree vector, and the finite element space. We will restrict our considerations to γ-shape-regular triangulations τ of Ω consisting of affine triangles; i.e., each element $K \in \tau$ is the image $F_K(\hat{K})$ of the reference triangle $\hat{K}$, where the mapping F_K satisfies the inequality

$$h_K^{-1} \|F_K'\|_{L^\infty(K)} + h_K \|(F_K')^{-1}\|_{L^\infty(K)} \leq \gamma \qquad \forall\, K \in \tau.$$

Here h_K denotes the diameter of the element K. Moreover, we assume $\tau = \cup_{j=1}^{s} \tau^{(j)}$ with $\tau^{(j)} := \{K \in \tau \mid K \subset \Omega_j\}$ to be a geometric mesh with boundary mesh size h (see also Figure 5.1). The precise description is given in the following definition.

DEFINITION 2.2 (geometric mesh). *There exist $c_1, c_2 > 0$ s.t. for all $K \in \tau^{(j)}$:*
1. *if $\overline{K} \cap \partial\Omega_j \neq \emptyset$, then $h \leq h_K \leq c_2 h$, and*
2. *if $\overline{K} \cap \partial\Omega_j = \emptyset$, then $c_1 \inf_{x\in K} \operatorname{dist}(x, \partial\Omega_j) \leq h_K \leq c_2 \sup_{x\in K} \operatorname{dist}(x, \partial\Omega_j)$.*

In order to define *hp*-FEM spaces on the mesh τ, we associate a polynomial degree $p_K \in \mathbb{N}$ with each element $K \in \tau$ and collect these p_K in the polynomial degree vector $\mathbf{p} := (p_K)_{K\in\tau}$. Furthermore, we associate a polynomial degree

$$p_e := \min\{p_K \mid \text{e is an edge of element } K\} \tag{2.3}$$

with each edge e of the triangulation. We denote the vector containing the polynomial distribution of the triangle $K \in \tau$ with edges $\{e_i \mid i = 1, 2, 3\}$ by

$$\mathbf{p}(K) := (p_{e1}, p_{e2}, p_{e3}, p_K). \tag{2.4}$$

In conjunction with geometric meshes, a particularly useful polynomial degree distribution is the linear degree vector.

DEFINITION 2.3 (linear degree vector). *Let $\overline{\Omega} = \cup_{j=1}^s \overline{\Omega}_j$. For all $j = 1, \ldots, s$, let $\tau^{(j)}$ be a geometric mesh on Ω_j with boundary mesh size h, and let $\tau = \cup_{j=1}^s \tau^{(j)}$ be a mesh on Ω. A polynomial degree vector $\mathbf{p} = (p_K)_{K\in\tau}$ is said to be a linear degree vector with slope $\alpha > 0$ if*

$$1 + \alpha c_1 \log\frac{h_K}{h} \leq p_K \leq 1 + \alpha c_2 \log\frac{h_K}{h} \tag{2.5}$$

for some $c_1, c_2 > 0$.

Now we are in a position to define our *hp*-FEM spaces.

DEFINITION 2.4 (FEM spaces). *Let $\overline{\Omega} = \cup_{j=1}^s \overline{\Omega}_j$. For all $j = 1, \ldots, s$, let $\tau^{(j)}$ be a geometric mesh on Ω_j with boundary mesh size h, and let $\tau = \cup_{j=1}^s \tau^{(j)}$ be a mesh on Ω. Let $\mathbf{p}$ be a linear degree vector. Furthermore, for all edges e, let p_e be given by* (2.3) *and for all $K \in \tau$ let $\mathbf{p}(K)$ be given by* (2.4)*. Then we set*

$$\begin{aligned}
\mathbb{S}_j^{\mathbf{p}} = \mathbb{S}^{\mathbf{p}}(\Omega_j, \tau^{(j)}) &:= \{u \in H^1(\Omega_j) \mid u \circ F_K \in \mathcal{P}_{\mathbf{p}(K)}(\hat{K}) \quad \forall K \in \tau^{(j)}\},\\
\mathbb{S}_{j,0}^{\mathbf{p}} = \mathbb{S}_0^{\mathbf{p}}(\Omega_j, \tau^{(j)}) &:= \mathbb{S}_j^{\mathbf{p}} \cap H_0^1(\Omega_j),\\
\mathbb{V}^{\mathbf{p}} = \mathbb{V}^{\mathbf{p}}(\Omega, \tau) &:= \{u \in H^1(\Omega_j) \mid u|_{\Omega_j} \in \mathbb{S}_j^{\mathbf{p}} \quad \forall j = 1, \ldots, s\},\\
\mathbb{V}_0^{\mathbf{p}} &:= \mathbb{V}^{\mathbf{p}} \cap H_0^1(\Omega),
\end{aligned}$$

where

$$\mathcal{P}_{\mathbf{p}(K)}(\hat{K}) := \{u \in \mathcal{P}_{p_K}(\hat{K}) \mid u|_{e_i} \in \mathcal{P}_{p_{e_i}},\ i = 1, 2, 3\}.$$

The finite element discretization of Problem 2.1 then reads as follows.

PROBLEM 2.5 (finite element approximation). *Find $u_h \in \mathbb{V}_0^{\mathbf{p}}$ such that*

$$a(u_h, v_h) = l(v_h) \qquad \forall\, v_h \in \mathbb{V}_0^{\mathbf{p}}.$$

Considering the approximation properties of the BC-*hp*-FEM, the optimality of the convergence order can be proved in the two-dimensional case.

THEOREM 2.6. *Let $\Omega_i \subset \mathbb{R}^2$ and τ_i be a geometric mesh with boundary mesh size h on Ω_i. Let $\mathbf{p}$ be a linear degree vector with slope α sufficiently large. Then for $u \in H^{1+\delta}(\Omega_i)$, $\delta \in (0, 1)$, we have*

$$\inf_{v_h\in\mathbb{S}_i^{\mathbf{p}}} \|u - v_h\|_{H^1(\Omega_i)} \leq Ch^{\delta}.$$

Proof. See [22]. ∎

2.3. The system of finite element equations. To solve Problem 2.5 numerically, we equip the space $\mathbb{V}_0^{\mathbf{p}}$ with a basis

$$\Phi = \{\Phi_B, \Phi_L, \Phi_H\} = \{\phi_i \mid i = 1, \dots, N\} \tag{2.6}$$

in the following way.

The functions $\phi_1, \dots, \phi_{N_B}$ are the usual nodal hat functions with $\operatorname{supp}\phi_i \not\subset \overline{\Omega}_j$ for all $j = 1, \dots, s$, for all $i = 1, \dots, N_B$; i.e., the support is not contained in one subdomain $\overline{\Omega}_j$ only. The functions $\phi_{N_B+1}, \dots, \phi_{N_L}$ are the usual nodal hat functions with $\operatorname{supp}\phi_i \subset \overline{\Omega}_j$ for some j, for all $i = N_B + 1, \dots, N_L$. The remaining functions $\phi_{N_L+1}, \dots, \phi_{N_H}$ are all polynomials of degree $p > 1$. Since $h_K \sim h$ for all elements with $\overline{K} \cap \partial\Omega_j \neq \emptyset$, we can assume that $p = 1$ for all these boundary elements by (2.5). With this definition, the basis functions ϕ_i can be divided into three groups:

- the boundary functions $\Phi_B = \{\phi_i \mid i = 1, \dots, N_B\}$,
- the interior functions of low order $\Phi_L = \{\phi_i \mid i = N_B + 1, \dots, N_L\}$, and
- the interior functions of high order $\Phi_H = \{\phi_i \mid i = N_L + 1, \dots, N_H\}$.

In the same way, the basis $\Phi_i = \{\phi_{j,i}\}_j$ on the subdomains Ω_i, $i = 1, \dots, s$, are introduced. Analogously, this basis can be partitioned into $\Phi_{B,i}$, $\Phi_{L,i}$, and $\Phi_{H,i}$, i.e., boundary functions (B), interior functions of low order (L), and interior functions of high order (H). More precisely, let

$$\Phi_i = \Phi\,|_{\Omega_i}\, R_i \quad \text{and} \quad \Phi_{B,i} = \Phi_B\,|_{\Omega_i}\, R_{B,i} \tag{2.7}$$

with the corresponding restriction matrices R_i and $R_{B,i}$. Now, the solution of Problem 2.5 is equivalent to solving the system of linear equations

$$\mathcal{K}\underline{u} = \underline{f}, \quad \text{where} \quad \mathcal{K} = [a(\phi_j, \phi_k)]_{k,j=1}^N, \qquad \underline{f} = [l(\phi_j)]_{j=1}^N, \qquad \underline{u} = [u_k]_{k=1}^N. \tag{2.8}$$

Then, $u_h = \sum_{k=1}^N u_k \phi_k$ provides the solution of Problem 2.5. Moreover, let $\mathcal{K}_i$ be the stiffness matrix restricted to Φ_i, $i = 1, \dots, s$, i.e.,

$$\mathcal{K}_i = [a(\phi_{j,i}, \phi_{k,i})]_{k,j=1}^{N_i}. \tag{2.9}$$

Then, a consequence of (2.7)–(2.9) is the formula

$$\mathcal{K} = \sum_{i=1}^{s} R_i \mathcal{K}_i R_i^\top \tag{2.10}$$

with the restriction matrix introduced in (2.7). In the following, we are interested in constructing a fast solver for the system of linear algebraic equations (2.8).

3. Primal iterative substructuring methods.

3.1. Block partitioning of the stiffness matrix. We partition the stiffness matrix into three-by-three blocks, which corresponds to the partition of the shape functions into Φ_B, Φ_L, and Φ_H (see (2.6)),

$$\mathcal{K} = \begin{bmatrix} \mathcal{K}_B & \mathcal{K}_{B,L} & \mathcal{K}_{B,H} \\ \mathcal{K}_{L,B} & \mathcal{K}_L & \mathcal{K}_{L,H} \\ \mathcal{K}_{H,B} & \mathcal{K}_{H,L} & \mathcal{K}_H \end{bmatrix} = \begin{bmatrix} \mathcal{K}_B & \mathcal{K}_{B,D} \\ \mathcal{K}_{D,B} & \mathcal{K}_D \end{bmatrix},$$

with $D = L \cup H$. This two-by-two block matrix can be factorized into

$$\mathcal{K} = \begin{bmatrix} I & \mathcal{K}_{B,D}\mathcal{K}_D^{-1} \\ \mathbf{0} & I \end{bmatrix} \begin{bmatrix} \mathcal{S}_B & \mathbf{0} \\ \mathbf{0} & \mathcal{K}_D \end{bmatrix} \begin{bmatrix} I & \mathbf{0} \\ \mathcal{K}_D^{-1}\mathcal{K}_{D,B} & I \end{bmatrix} \tag{3.1}$$

with the Schur complement

$$\mathcal{S}_B = \mathcal{K}_B - \mathcal{K}_{B,D}\mathcal{K}_D^{-1}\mathcal{K}_{D,B}. \tag{3.2}$$

In this section, we will investigate preconditioners of the type

$$\mathcal{C} = \begin{bmatrix} I & -\mathcal{E}_{DB}^\top \\ \mathbf{0} & I \end{bmatrix} \begin{bmatrix} \mathcal{C}_S & \mathbf{0} \\ \mathbf{0} & \mathcal{C}_D \end{bmatrix} \begin{bmatrix} I & \mathbf{0} \\ -\mathcal{E}_{DB} & I \end{bmatrix}, \tag{3.3}$$

where $\mathcal{C}_D$ is a preconditioner for $\mathcal{K}_D$, $\mathcal{E}_{DB}$ is the matrix representation of the extension operators E_j acting from the interface $\Gamma = \cup_{i=1}^s \partial\Omega_i \backslash \partial\Omega$ into the interior of the domains Ω_j, and $\mathcal{C}_S$ is a preconditioner for the Schur complement $\mathcal{S}_B$ or the inexact Schur complement

$$\mathcal{S}_B + \mathcal{T}_B := \mathcal{S}_B + (\mathcal{E}_{DB}^\top - \mathcal{H}_{DB}^\top)\mathcal{K}_D(\mathcal{E}_{DB} - \mathcal{H}_{DB}) \tag{3.4}$$

with $\mathcal{H}_{DB} = \mathcal{K}_D^{-1}\mathcal{K}_{DB}$.

The following result is the key in analyzing the preconditioner $\mathcal{C}$, which generalizes previous estimates given in [16, 39].

LEMMA 3.1. *Let $\mathcal{C}_S$ and $\mathcal{C}_D$ be SPD preconditioners for $\mathcal{S}_B$ and $\mathcal{K}_D$, i.e.,*

$$c_S\,(\mathcal{C}_S\underline{v},\underline{v}) \le (\mathcal{S}_B\underline{v},\underline{v}) \quad \forall \underline{v} \in \mathbb{R}^{M_c}, \tag{3.5}$$

$$c_I\,(\mathcal{C}_D\underline{v},\underline{v}) \le (\mathcal{K}_D\underline{v},\underline{v}) \le C_I\,(\mathcal{C}_D\underline{v},\underline{v}) \quad \forall \underline{v} \in \mathbb{R}^{M_i}. \tag{3.6}$$

Moreover, let

$$\left(\mathcal{K}\begin{bmatrix} I \\ \mathcal{E}_{DB} \end{bmatrix}\underline{g}, \begin{bmatrix} I \\ \mathcal{E}_{DB} \end{bmatrix}\underline{g}\right) \le c_E^2\left(\mathcal{C}_S\underline{g},\underline{g}\right) \quad \forall \underline{g} \in \mathbb{R}^{M_c}. \tag{3.7}$$

Then, $c_E^2 \ge c_S$ and the inequalities

$$c\,(\mathcal{C}\underline{v},\underline{v}) \le (\mathcal{K}\underline{v},\underline{v}) \le C\,(\mathcal{C}\underline{v},\underline{v}) \quad \forall \underline{v} \in \mathbb{R}^M$$

hold with $c = 0.5\,c_I \min\{1, c_S/(c_I + c_E^2 - c_S)\}$ and $C = 2\max\{c_E^2, C_I\}$.

Proof. The proof has been given in the report [2]. ∎

Remark 3.2. A direct consequence of (3.7) is the spectral equivalence of the Schur complement $\mathcal{S}_B$ and the perturbed Schur complement $\mathcal{S}_B + \mathcal{T}_B$; see [16].

Summarizing, we have to find the preconditioners $\mathcal{C}_D$ and $\mathcal{C}_S$ as well as the extension $\mathrm{E} \leftrightarrow \mathcal{E}_{BD}$ in order to derive a good preconditioner $\mathcal{C}$.

For the AF-FETI2 and AF-FETI3 preconditioners (see section 4), a preconditioner $\mathcal{C}_i$ for $\mathcal{K}_i$ (cf. (2.9)), i.e., for the Neumann problem on domain Ω_i, is required. Due to (2.7), the block partitioning for $\mathcal{K}$ in (3.1) can be done for the subdomain stiffness matrices, too. A simple computation shows

$$\mathcal{K}_i = \begin{bmatrix} I & \mathcal{K}_{B,D,i}\mathcal{K}_{D,i}^{-1} \\ \mathbf{0} & I \end{bmatrix} \begin{bmatrix} \mathcal{S}_{B,i} & \mathbf{0} \\ \mathbf{0} & \mathcal{K}_{D,i} \end{bmatrix} \begin{bmatrix} I & \mathbf{0} \\ \mathcal{K}_{D,i}^{-1}\mathcal{K}_{D,B,i} & I \end{bmatrix} \tag{3.8}$$

with the local Schur complement

$$\mathcal{S}_{B,i} = \mathcal{K}_{B,i} - \mathcal{K}_{B,D,i}\mathcal{K}_{D,i}^{-1}\mathcal{K}_{D,B,i}. \tag{3.9}$$

The global Schur complement can be computed via the local Schur complements, i.e.,

$$\mathcal{S}_B = \sum_{i=1}^{s} R_{B,i}\mathcal{S}_{B,i}R_{B,i}^\top \tag{3.10}$$

with the assembling matrices $R_{B,i}$. The DD approach can also be applied to $\mathcal{K}_i$ instead of $\mathcal{K}$. In the following subsections, we will develop the preconditioners for the subproblems.

3.2. An overlapping preconditioner for the Dirichlet subproblems. In this subsection, we present the preconditioner for the matrix $\mathcal{K}_D$. Since $\mathcal{K}_D = \text{blockdiag}\,[\mathcal{K}_{D,j}]_j$, we restrict ourselves to the case of one subdomain Ω_j.

Here, we use an overlapping preconditioner which has been developed in [36]; see also [11, 42]. The preconditioner is based on the additive Schwarz framework (see, e.g., [47]). We decompose the *hp*-FEM space $\mathbb{S}^{\mathbf{p}}_{j,0} = \sum_{i=0}^{\#K} \mathbb{V}_i$ into subspaces $\mathbb{V}_i$ that will be specified below. This splitting defines an additive Schwarz method (ASM) preconditioner. This eliminates all high order degrees of freedom. Moreover, the properties of this preconditioner can be characterized by the two numbers C_0 and $\rho(\epsilon)$ defined below. As a well-known fact from ASM theory, the condition number of the preconditioned system is bounded by $C_0^2(1+\rho(\epsilon))$.

In order to keep the notation simple, we skip the index j for the subdomain j.

LEMMA 3.3 (Clement interpolation). *Let τ be a γ-shape-regular affine triangulation. For $K \in \tau$ define the patch*

$$\omega_K := \cup\{K' \in \tau \mid \overline{K} \cap \overline{K'} \neq \emptyset\}.$$

Then there exist $C > 0$ depending solely on γ and a linear operator $I^C : H^1(\Omega) \mapsto \mathbb{S}^{\mathbf{1}}(\tau)$ such that

$$\|u - I^C u\|_{L^2(K)} \leq C h_K \|\nabla u\|_{L^2(\omega_K)} \quad \text{and} \quad \|\nabla I^C u\|_{L^2(K)} \leq C \|\nabla u\|_{L^2(\omega_K)}.$$

Proof. The proof can be found in several papers; see, e.g., [12]. ∎

LEMMA 3.4. *Let $\hat{K}$ be the reference triangle and $\mathbf{p}(K) = (p_{e_1}, p_{e_2}, p_{e_3}, p_K)$ with $p_{e_i} \leq p_K$, $i = 1, \ldots, 3$, a polynomial degree distribution. Let $\mathcal{J}_p$ be the one-dimensional Gauss–Lobatto interpolation operator. Then there exist a constant $C > 0$ and a linear operator*

$$I_{\mathbf{p}(\mathbf{K})} : \mathcal{P}_{2p_K}(\hat{K}) \mapsto \mathcal{P}_{\mathbf{p}}(\hat{K}) \tag{3.11}$$

such that

- $I_{\mathbf{p}(\mathbf{K})} u = u$ *for all* $u \in \mathcal{P}_{\mathbf{p}}(\hat{K})$,
- $\|I_{\mathbf{p}(\mathbf{K})} u\|_{H^1(\hat{K})} \leq C \|u\|_{H^1(\hat{K})}$ *for all* $u \in \mathcal{P}_{2p_K}(\hat{K})$, *and*
- $(I_{\mathbf{p}(\mathbf{K})} u)|_{\Gamma_i} = \mathcal{J}_{p_{e_i},\Gamma_i} u$ *for* $i = 1, \ldots, 3$.

Proof. The proof is given in [12, Theorem 4.4]. ∎

DEFINITION 3.5. *Let τ be a γ-shape-regular triangulation with polynomial degree distribution $\mathbf{p} = (p_K)_{K\in\tau}$. For each $K \in \tau$ let the operator $I_{\mathbf{p}(\mathbf{K})}$ be given by* (3.11). *Then we define*

$$I_{\mathbf{p}} : \mathbb{S}^{2\mathbf{p}}(\tau) \mapsto \mathbb{S}^{\mathbf{p}}(\tau) \qquad \text{by} \qquad (I_{\mathbf{p}} u)|_K = (I_{\mathbf{p}}(u|_K \circ F_K)) \circ F_K^{-1}.$$

For a finite element mesh τ, we denote the set of its vertices by $V(\tau)$ and the polynomial degree vector by $\mathbf{p} = (p_K)_{K\in\tau}$. In order to define our ASM preconditioner, we associate with each vertex v_j a patch

$$\omega_j := \cup\{K \in \tau \mid v_j \text{ is a vertex of } K\}$$

and decompose the space $\mathbb{S}^{\mathbf{p}}(\tau)$ into the following subspaces:

1. the space of piecewise linear polynomials $\mathbb{V}_0 := \mathbb{S}^{\mathbf{1}}(\tau)$, and
2. local higher dimensional spaces $\mathbb{V}_j := \{u \in \mathbb{S}^{\mathbf{p}}(\tau) \mid \text{supp}\, u \subset \overline{\omega}_j\}$.

To analyze the properties of the decomposition of $\mathbb{S}^{\mathbf{p}}(\tau)$, let C_0 be a constant such that

$$\min\left\{\sum_{j=0}^{\#V(\tau)}\|u_j\|_A^2 \;\middle|\; u=u_0+\sum_{j=1}^{\#V(\tau)}u_j,\;\; u_j\in\mathbb{V}_j\right\}\le C_0^2\|u\|_A^2 \tag{3.12}$$

holds, where $\|u\|_A^2 = a(u,u)$ denotes the energetic norm. Moreover, we define a symmetric matrix $\epsilon\in\mathbb{R}^{(\#V(\tau))\times(\#V(\tau))}$ with entries $\epsilon_{ik}=0$ if ω_i and ω_k are disjoint and $\epsilon_{ik}=1$ otherwise. Let $\rho(\epsilon)$ be the spectral radius of ϵ. Thus

$$|a(u_i,u_k)|\le\epsilon_{ik}\|u_i\|_A\|v_k\|_A \qquad \forall u_i\in\mathbb{V}_i,\ \forall u_k\in\mathbb{V}_k. \tag{3.13}$$

THEOREM 3.6. *Let τ be a γ-shape-regular triangulation and $\mathbf{p}$ a corresponding polynomial degree distribution. Let $\mathbb{S}^{\mathbf{p}}(\tau)=\mathbb{V}_0+\sum_{j=1}^{\#V(\tau)}\mathbb{V}_j$, and let $a(\cdot,\cdot):H^1\times H^1\mapsto\mathbb{R}$ be an SPD bilinear form. Then there exists a constant $C>0$ depending solely on the bilinear form $a(\cdot,\cdot)$ and γ such that $C_0\le C$ and $\rho(\epsilon)\le C$, where C_0 and ϵ are from* (3.12) *and* (3.13)*, respectively.*

Proof. Since there exists $M>0$, depending only on γ, such that

$$\#\{v'\in V\mid\overline{\omega}_v\cap\overline{\omega}_{v'}\neq\emptyset\}\le M \qquad \forall v\in V,$$

we have $\rho(\epsilon)\le\|\epsilon\|_\infty\le M$. In order to bound C_0, we exploit the properties of the operators I^C and $I_{\mathbf{p}}$ and decompose $u\in\mathbb{S}^{\mathbf{p}}(\tau)$ as

$$u=I^Cu+I_{\mathbf{p}}(u-I^Cu) \;=\; I^Cu+I_{\mathbf{p}}\left(\sum_{j=1}^{\#V(\tau)}\phi_j(u-I^Cu)\right),$$

where ϕ_j denotes the usual nodal hat function corresponding to the vertex $v_j\in V(\tau)$. Thus we have

$$u=u_0+\sum_{j=1}^{\#V(\tau)}u_j \qquad \text{with } u_0:=I^C(u)\in\mathbb{V}_0,\quad u_j:=I_{\mathbf{p}}(\phi_j(u-I^Cu))\in\mathbb{V}_j.$$

Now we want to bound $\|u_0\|_A^2+\sum_{j=1}^{\#V(\tau)}\|u_j\|_A^2$. Lemma 3.3 and the Poincaré–Friedrichs inequality $\|\cdot\|_A\sim\|\cdot\|_{H^1}$ imply the estimate

$$\|u_0\|_A^2=\left\|I^C(u)\right\|_A^2\le C\|u\|_A^2.$$

Next we consider a fixed $j\in1,\dots,\#V(\tau)$ and a fixed $K\subset\omega_j$ such that

$$\|u_j|_K\|_A^2\le C\|u_j\|_{H^1(K)}^2=\left\|I_{\mathbf{p}}(\phi_j(u-I^Cu))\right\|_{H^1(K)}^2.$$

Denoting $\tilde{u}:=(u-I^Cu)$, $\hat{u}:=\tilde{u}|_K\circ F_K$, and $\hat{\phi}:=\phi_j|_K\circ F_K$ and applying Lemmas 3.4 and 3.3, we get the estimates

$$\begin{aligned}
\|u_j\|_{H^1(K)}^2 &\le C\left(h_K^2\|I_{\mathbf{p}}(\hat{\phi}\hat{u})\|_{L^2(\hat{K})}^2+\|\nabla I_{\mathbf{p}}(\hat{\phi}\hat{u})\|_{L^2(\hat{K})}^2\right)\\
&\le C\|I_{\mathbf{p}}(\hat{\phi}\hat{u})\|_{H^1(\hat{K})}^2\\
&\le C\|\hat{\phi}\hat{u}\|_{H^1(\hat{K})}^2\\
&\le C\|\hat{u}\|_{H^1(\hat{K})}^2\\
&\le C\left(h_K^{-2}\|u-I^Cu\|_{L^2(K)}^2+\|\nabla(u-I^Cu)\|_{L^2(K)}^2\right)\\
&\le C\|\nabla u\|_{L^2(\omega_j)}^2.
\end{aligned}$$

Thus, the inequalities

$$\|u_j\|^2_{H^1(\omega_j)} \le C \sum_{K\subset\omega_j} \|\nabla u\|^2_{L^2(\omega_j)} \text{ and } \sum_{j=1}^{\#V(\tau)} \|u_j\|^2_{H^1(\omega_j)} \le C\|\nabla u\|^2_{L^2(\Omega)} \le C\|u\|^2_A$$

follow immediately. ∎

Now we are able to define the following preconditioner for $\mathcal{K}_{D,i}$. Let

$$\mathcal{C}_D^{-1} = \sum_{j=1}^{\#V(\tau)} Q_j^\top \mathcal{K}_{P,j}^{-1} Q_j + Q_0^\top (\mathcal{D}_L)^{-1} Q_0, \tag{3.14}$$

where

- $\mathcal{K}_{P,j}$ denotes the stiffness matrix restricted to $\mathbb{V}_j$, $j = 1, \dots, \#V(\tau)$,
- Q_j, $j = 0, \dots, \#V(\tau)$, is the corresponding finite element restriction matrix onto $\mathbb{V}_j$, and
- $\mathcal{D}_L$ is the diagonal part of the matrix $\mathcal{K}_L$.

THEOREM 3.7. *Let $\mathcal{C}_D$ be defined via* (3.14). *Then, we have $\mathcal{C}_D \sim \mathcal{K}_D$.*

Proof. Due to [48] and [22], the condition number of $\mathcal{K}_L$ does not depend on the discretization parameter. This gives $\mathcal{D}_L \sim \mathcal{K}_L$. Now, the result is a consequence of Theorem 3.6. ∎

3.3. Schur complement preconditioner and extension operator. Next, we consider the preconditioner $\mathcal{C}_S$ for $\mathcal{S}_B$ (3.2). We will prove that the norm induced by the Schur complement $\mathcal{S}_B$ (3.2) is equivalent to a suitable seminorm. Therefore, the extension operators E for the nearly discrete harmonic extension of a function $g \in H^{1/2}(\partial\tilde{\Omega})$ to a function $u = \mathrm{E}g \in H^1(\tilde{\Omega})$ have to be investigated. We follow the approach of Haase and Nepomnyaschikh [19].

In a first step, we describe the extension of Haase and Nepomnyaschikh. Then, we prove that this type of extension can also be used for boundary concentrated meshes with $p = 1$ or $p > 1$ defined via Definition 2.3. Finally, the equivalence of the Schur complement is shown.

The technique of Haase and Nepomnyaschikh was originally derived for the h-version of the FEM with $p = 1$, using uniform refined meshes and the hierarchy of the nested finite element spaces. Let $\tau_0 \subset \tau_1 \subset \tau_2 \subset \cdots \subset \tau_L := \tau$ be a sequence of nested triangular ($d = 2$) or tetrahedral ($d = 3$) finite element meshes with nodes $x_i^{(l)}$, $i = 1, \dots, N_l$, $l = 0, \dots, L$, on a domain $\tilde{\Omega}$. Here τ_0 is the coarse mesh and τ_l is obtained from τ_{l-1} by subdividing each element of τ_{l-1} into 2^d new congruent elements.

Due to Definition 2.4, $\mathbb{S}_l^{\mathbf{1}}$ denotes the space of all functions which are linear on each element of τ_l and belong to $H^1(\tilde{\Omega})$. The corresponding trace space is denoted by $\mathbb{B}_l$, i.e., $\mathbb{B}_l = \mathbb{S}_l^{\mathbf{1}}\,|_{\partial\tilde{\Omega}}$. This space is spanned by nodal basis functions $\psi_{i,l}$, i.e.,

$$\mathbb{B}_l = \operatorname{span}\{\psi_{i,l}\}_{i=1}^{N_l} = \operatorname{span}\Psi_l. \tag{3.15}$$

Moreover, let $\mathbb{W}_l^{(i)} = \operatorname{span}\{\psi_{i,l}\}$ be the one-dimensional subspace corresponding to the node $x_i^{(l)}$. Let $g \in \mathbb{B}_l \subset H^{1/2}(\partial\tilde{\Omega})$. In order to define a function $u = \mathrm{E}g$ such that

$$\| u \|_{H^1(\tilde{\Omega})} \le c \, \| g \|_{H^{1/2}(\partial\tilde{\Omega})}, \quad u\,|_{\partial\tilde{\Omega}} = g, \tag{3.16}$$

Haase and Nepomnyaschikh used a BPX-like decomposition of the function g. Let $Q_{i,l} : L_2(\partial\tilde{\Omega}) \mapsto \mathbb{W}_l^{(i)}$ be the L_2-like projection from $L_2(\partial\tilde{\Omega})$ onto $\mathbb{W}_l^{(i)}$, i.e.,

$$Q_{i,l}g = d_{i,l}(g)\psi_{i,l} \quad \forall g \in \mathbb{B}_l.$$

Possible choices of $d_{i,l}$ are $d_{i,l}(g) = \frac{(g,\psi_{i,l})_{L_2(\partial\tilde{\Omega})}}{(\psi_{i,l},\mathbf{1})_{L_2(\partial\tilde{\Omega})}}$ or $d_{i,l}(g) = \frac{(g,\mathbf{1})_{L_2(\operatorname{supp}\psi_{i,l})}}{(\mathbf{1},\mathbf{1})_{L_2(\operatorname{supp}\psi_{i,l})}}$. Moreover, let

$$Q_l = \sum_{i=1}^{N_l} Q_{i,l}, \quad l = 0, \ldots, L, \quad \text{and} \quad Q_{-1} = \mathbf{0}.$$

Now, the extension of a function $g \in \mathbb{B}_L$ into $\tilde{\Omega}$ can be defined.

ALGORITHM 3.8.

1. *Let* $\psi_l = (Q_l - Q_{l-1})g \in \mathbb{B}_l$, $l = 0, \ldots, L$.
2. *Define the function* $u_l \in \mathbb{S}_l^{\mathbf{1}}$ *via*

$$u_l(x_i^{(0)}) = \begin{cases} \psi_l(x_i^{(0)}) & \text{if} \quad x_i^{(0)} \in \partial\tilde{\Omega}, \\ \overline{g} & \text{if} \quad x_i^{(0)} \notin \partial\tilde{\Omega}, \end{cases} \tag{3.17}$$

$$u_l(x_i^{(l)}) = \begin{cases} \psi_l(x_i^{(l)}) & \text{if} \quad x_i^{(l)} \in \partial\tilde{\Omega}, \\ 0 & \text{if} \quad x_i^{(l)} \notin \partial\tilde{\Omega}, \end{cases} \tag{3.18}$$

   where $\overline{g}$ *is defined in Remark* 3.9.
3. *Set* $u = \mathrm{E}g = u_0 + u_1 + \cdots + u_L$.

Remark 3.9. Note that the function u_l in (3.17) and (3.18) is uniquely defined by setting the function values in the nodes $x_i^{(l)}$ of the mesh τ_l. For $\overline{g}$, a coarse grid problem on the mesh τ_0 has to be solved. Alternatively, the mean value of g over $\partial\tilde{\Omega}$ can be taken.

Now, the following result has been shown.

THEOREM 3.10. *Let* $\tau_0 \subset \cdots \subset \tau_L = \tau$ *be a family of uniformly refined meshes, and let* $\mathbb{S}_l^{\mathbf{1}}$, $l = 0, \ldots, L$, *be the space of the piecewise linear nodal basis functions on* τ_l. *Let* $\mathrm{E} : \mathbb{B}_L \mapsto \mathbb{S}^{\mathbf{1}} = \mathbb{S}_L^{\mathbf{1}}$ *be the extension of Algorithm* 3.8. *Then, we have* $\mathrm{E}g \mid_{\partial\tilde{\Omega}} = g$. *Moreover, there is a constant* c_2 *which is independent of* L *such that*

$$\| \mathrm{E}g \|_{H^1(\tilde{\Omega})} \leq c_2 \| g \|_{H^{1/2}(\partial\tilde{\Omega})} \quad \forall g \in \mathbb{B}_L.$$

Proof. The proof is given in [19]. ∎

Next, we consider a family of boundary concentrated finite element meshes and the corresponding finite element spaces $\mathbb{S}_l^{\mathbf{p}}$.

THEOREM 3.11. *Let* $\tau_0 \subset \cdots \subset \tau_L = \tau$ *be a family of meshes on a domain* $\tilde{\Omega}$ *which are geometrically refined to the boundary. Let* $\mathbb{S}_l^{\mathbf{p}}$, $l = 0, \ldots, L$, *be the finite element space of Definition* 2.4 *for the mesh* τ_l. *Then,* $\mathbb{S}^{\mathbf{p}} \mid_{\partial\tilde{\Omega}} = \mathbb{B}_L$. *Moreover, let* $\mathrm{E} : \mathbb{B}_L \mapsto \mathbb{S}^{\mathbf{p}}$ *be the extension operator of Algorithm* 3.8. *Then, there exists a constant* c_2 *which is independent of* L *(and* N*) such that*

$$\| \mathrm{E}g \|_{H^1(\tilde{\Omega})} \leq c_2 \| g \|_{H^{1/2}(\partial\tilde{\Omega})} \quad \forall g \in \mathbb{B}_L. \tag{3.19}$$

Proof. Due to (2.5), the polynomial degree on the elements which touch $\partial\tilde{\Omega}$ can be assumed to be 1. Thus, $\mathbb{S}^{\mathbf{p}} \mid_{\partial\tilde{\Omega}} = \mathbb{B}_L$. This proves the first assertion.

Due to (3.17) and (3.18), the image of the extension operator described in Algorithm 3.8 for uniformly refined meshes belongs to the space $\mathbb{S}^{\mathbf{1}}$, i.e., $\mathrm{E}g \in \mathbb{S}^{\mathbf{1}}$. Theorem 3.10 implies the estimate

$$\| \mathrm{E}g \|_{H^1(\tilde{\Omega})} \leq c_2 \| g \|_{H^{1/2}(\partial\tilde{\Omega})} \quad \forall g \in \mathbb{B}_L$$

with the constant of Theorem 3.10. Since $\mathbb{S}^{\mathbf{1}} \subset \mathbb{S}^{\mathbf{p}}$, the second assertion follows. ∎

Remark 3.12. If $\int_{\partial\tilde{\Omega}} g = 0$, or $g\,|_{\tilde{\Gamma}} = 0$ for $\tilde{\Gamma} \subset \partial\tilde{\Omega}$ with $\mathrm{meas}(\tilde{\Gamma}) > 0$, relation (3.19) remains valid if the seminorms are used instead of the norms in (3.19). This is a consequence of the Poincaré–Friedrichs-type inequalities; see [47, Lemma A17] or [37].

Hence, we have shown that the extension of Haase and Nepomnyaschikh for uniformly refined meshes can also be used for geometrically refined meshes with grading factor 0.5.

In the next theorem, we show that the norm induced by the Schur complement $\mathcal{S}_{B,i}$ (3.9) is equivalent to the $H^{1/2}(\partial\Omega_i)$ norm and that the norm induced by the Schur complement $\mathcal{S}_B$ (3.2) is equivalent to the following norm on the interface $\Gamma = \cup_{i=1}^{s} \partial\Omega_i \backslash \partial\Omega$:

$$\| g \|^2_{H^{1/2}(\Gamma)} := \| g \|^2_{L^2(\Gamma)} + |g|^2_{H^{1/2}(\Gamma)}, \quad \text{where} \quad |g|^2_{H^{1/2}(\Gamma)} = \inf_{\substack{u|_\Gamma = g \\ u|_{\partial\Omega} = 0}} |u|^2_{H^1(\Omega)}.$$

THEOREM 3.13. *Let $\tau_0^{(i)} \subset \cdots \subset \tau_L^{(i)} = \tau^{(i)}$ be a family of geometrically refined meshes on the domains Ω_i, $i = 1, \ldots, s$, and let $\mathbb{B}_i$ and $\mathbb{B}_\Gamma$ be the trace spaces of $\mathbb{S}^{\mathbf{p}}$ and $\mathbb{V}_0$ onto $\partial\Omega_i$ and the interface $\Gamma = \cup_{i=1}^{s} \partial\Omega_i \backslash \partial\Omega$, respectively. Let $\Phi_{B,i}$ and Φ_B be defined via* (2.6) *and* (2.7)*, respectively.*

Moreover, let $\mathcal{S}_{B,i}$ be defined via (3.9)*. If $\partial\Omega \cap \partial\Omega_i \neq \emptyset$, we have*

(3.20)
$$c_4 \, |g_i|^2_{H^{1/2}(\partial\Omega_i \cap \Gamma)} \leq (\mathcal{S}_{B,i} \underline{g}_i, \underline{g}_i) \leq c_5 \, |g_i|^2_{H^{1/2}(\partial\Omega_i \cap \Gamma)} \quad \forall g_i = \Phi_{B,i} \underline{g}_i \in \mathbb{B}_i, g\,|_{\partial\Omega} = 0.$$

If $\partial\Omega \cap \partial\Omega_i = \emptyset$, we have

$$c_4 \, |g_i|^2_{H^{1/2}(\partial\Omega_i \cap \Gamma)} \leq (\mathcal{S}_{B,i} \underline{g}_i, \underline{g}_i) \leq c_5 \, |g_i|^2_{H^{1/2}(\partial\Omega_i \cap \Gamma)} \quad \forall g_i = \Phi_{B,i} \underline{g}_i \in \mathbb{B}_i. \tag{3.21}$$

Moreover, the relation

$$c_6 \| g \|^2_{H^{1/2}(\Gamma)} \leq (\mathcal{S}_B \underline{g}, \underline{g}) \leq c_7 \| g \|^2_{H^{1/2}(\Gamma)} \quad \forall g = \Phi_B \underline{g} \in \mathbb{B}_\Gamma \tag{3.22}$$

holds. The constants c_4, c_5, c_6, and c_7 are independent of L and N.

Proof. The proof of (3.20) is adapted from [47]; see also [1]. By the trace theorem and the Poincaré–Friedrichs inequality, one can conclude that

$$c_{14} c_T^{-2} |g_i|^2_{H^{1/2}(\partial\Omega_i)} \leq c_{14} \| u \|^2_{H^1(\Omega_i)} \leq c_{15} |u|^2_{H^1(\Omega_i)} \leq \min_{\underline{u}_D} (\mathcal{K}_i \underline{u}, \underline{u}) = (\mathcal{S}_{B,i} \underline{g}_i, \underline{g}_i),$$

with $\underline{u}^\top = \left[\begin{array}{cc} \underline{g}_i^\top & \underline{u}_D^\top \end{array} \right]$ and $u = \Phi_i \underline{u}$. Due to Theorem 3.11 and Remark 3.12, there exists a function $u \in H^1(\Omega_i)$, $u\,|_{\partial\Omega_i} = g$, such that $|u|_{H^1(\Omega_i)} \leq c_2 |g|_{H^{1/2}(\partial\Omega_i)}$. Thus, we can conclude that

$$(\mathcal{S}_{B,i} \underline{g}_i, \underline{g}_i) \leq (\mathcal{K}_i \underline{u}, \underline{u}) \leq c_{12} |u|^2_{H^1(\Omega_i)} \leq c_{12} c_2^2 |g_i|^2_{H^{1/2}(\partial\Omega_i)}.$$

This proves (3.20).

To prove (3.21), we have

(3.23)
$$c_4\,|g_i|^2_{H^{1/2}(\partial\Omega_i\cap\Gamma)} \le (\mathcal{S}_{B,i}\underline{g}_i,\underline{g}_i) \le c_5\,|g_i|^2_{H^{1/2}(\partial\Omega_i\cap\Gamma)} \quad \forall g_i=\Phi_{B,i}\underline{g}_i\in\mathbb{B}_i, \int_{\partial\Omega_i} g_i = 0$$

by the same arguments.

Let $g_i\in\mathbb{B}_i$ with $\overline{g}=\int_{\partial\Omega} g_i$. Thus, one obtains $g_i=\overline{g}\cdot\mathbf{1}+g_{i,0}$ with $\int_{\partial\Omega} g_{i,0}=0$. Since $|g_i|_{H^{1/2}(\partial\Omega_i)}=|g_{i,0}|_{H^{1/2}(\partial\Omega_i)}$ and $(\mathcal{S}_{B,i}\underline{g}_i,\underline{g}_i)=(\mathcal{S}_{B,i}\underline{g}_{0,i},\underline{g}_{0,i})$ for $g_{i,0}=\Phi_{B,i}\underline{g}_i$, relation (3.21) is a consequence of (3.23).

To prove (3.22), we have

$$\| g \|^2_{H^{1/2}(\Gamma)} = \sum_{i=1}^{s} \| g \|^2_{H^{1/2}(\partial\Omega_i\cap\Gamma)}\,. \tag{3.24}$$

Since we have homogeneous Dirichlet boundary conditions on $\partial\Omega$, i.e., $\partial\Omega=\Gamma_D$, the $H^{1/2}(\Gamma)$ seminorm is equivalent to the $H^{1/2}(\Gamma)$ norm. This is implied by the Poincaré–Friedrichs inequality. Using (3.24), (3.10), (3.21), and (3.20), the assertion follows. ∎

3.4. Final condition number estimates. Now, we are in a position to summarize the results of subsections 3.2 and 3.3. In a first step, we propose the primal DD preconditioner for $\mathcal{K}_i$ (3.8). Let

$$\mathcal{C}_i = \begin{bmatrix} I & -\mathcal{E}^\top_{DB,i} \\ \mathbf{0} & I \end{bmatrix} \begin{bmatrix} \mathcal{C}_{S,i} & \mathbf{0} \\ \mathbf{0} & \mathcal{C}_{D,i} \end{bmatrix} \begin{bmatrix} I & \mathbf{0} \\ -\mathcal{E}_{DB,i} & I \end{bmatrix}, \tag{3.25}$$

where

- $\mathcal{C}_{D,i}$ is the preconditioner (3.14) for $\mathcal{K}_{D,i}$,
- $\mathcal{C}_{S,i}$ is a preconditioner for $\mathcal{S}_{B,i}$ with $\mathcal{C}_{S,i}\sim\mathcal{S}_{B,i}$, and
- $\mathcal{E}_{DB,i}$ is the matrix representation of the extension operator $\mathrm{E}_i:\partial\Omega_i\mapsto\Omega_i$ in Algorithm 3.8.

Note that the matrix $\mathcal{C}_i$ is positive definite if $\partial\Omega\cap\partial\Omega_i\neq\emptyset$. If $\partial\Omega\cap\partial\Omega_i=\emptyset$, this matrix is positive semidefinite with $\ker\mathcal{C}_i=\ker\mathcal{K}_i=[\underline{u}_B,\underline{u}_L,\underline{u}_H]^\top=\left[\underline{1}^\top_{i,B},\underline{1}^\top_{i,L},\underline{0}^\top_{i,H}\right]^\top$. The choice of the preconditioners $\mathcal{C}_{S,i}$ is specified in the next subsection.

THEOREM 3.14. *Let $\mathcal{C}_i$ be defined via* (3.25). *Then, the spectral inequalities*

$$c_8\,(\mathcal{C}_i\underline{v},\underline{v}) \le (\mathcal{K}_i\underline{v},\underline{v}) \le c_9\,(\mathcal{C}_i\underline{v},\underline{v}) \quad \forall\underline{v}\in\mathbb{R}^{N_i} \tag{3.26}$$

are valid, where the spectral constants c_8 and c_9 do not depend on N_i.

Proof. We show that the assumptions of Lemma 3.1 are satisfied. Due to Theorem 3.7, we have $\mathcal{C}_{D,i}\sim\mathcal{K}_{D,i}$. Our assumptions imply the estimate $\mathcal{C}_{S,i}\sim\mathcal{S}_{B,i}$. Using Theorem 3.13, Theorem 3.11, and $|u|^2_{H^1(\Omega_i)}\sim(\mathcal{K}_i\underline{u},\underline{u})$ for all $u=\Phi_i\underline{u}\in\mathbb{S}^{\mathbf{1}}_{L,i}$, the relation

$$\left(\mathcal{K}_i\begin{bmatrix} I \\ \mathcal{E}_{BD,i}\end{bmatrix}\underline{g},\begin{bmatrix} I \\ \mathcal{E}_{BD,i}\end{bmatrix}\underline{g}\right) \le c_E^2\,(\mathcal{C}_{S,i}\underline{g},\underline{g}) \quad \forall\underline{g}\in\mathbb{R}^{M_i}$$

holds with a constant which is independent of N_i for the matrix representation of the extension operator in Algorithm 3.8. ∎

Now, we will present the preconditioner for the global stiffness matrix $\mathcal{K}$. Let

$$\mathcal{C} = \begin{bmatrix} I & -\mathcal{E}^\top_{DB} \\ \mathbf{0} & I \end{bmatrix} \begin{bmatrix} \mathcal{C}_S & \mathbf{0} \\ \mathbf{0} & \mathcal{C}_D \end{bmatrix} \begin{bmatrix} I & \mathbf{0} \\ -\mathcal{E}_{DB} & I \end{bmatrix}, \tag{3.27}$$

where $\mathcal{C}_D = \mathrm{diag}(\mathcal{C}_{D,i})_{i=1,\dots,s}$, $\mathcal{C}_S$ is a preconditioner for $\mathcal{S}_B$ which satisfies $\mathcal{C}_S \sim \mathcal{S}_B$, and $\mathcal{E}_{DB}$ is the matrix representation of the extension operators $\mathrm{E}_{L,i} : \partial\Omega_i \mapsto \Omega_i$ in Algorithm 3.8.

THEOREM 3.15. *Let $\mathcal{C}$ be defined via* (3.27). *Then,*

$$c_{10}\,(\mathcal{C}\underline{v},\underline{v}) \le (\mathcal{K}\underline{v},\underline{v}) \le c_{11}\,(\mathcal{C}\underline{v},\underline{v}) \quad \forall \underline{v} \in \mathbb{R}^N.$$

The constants do not depend on N.

Proof. The proof is similar to the proof of Theorem 3.14. ∎

3.5. Computational aspects. In the previous subsection, we have proved the optimality of the condition number of $\mathcal{C}^{-1}\mathcal{K}$. The purpose of this subsection is to show that the operation $\mathcal{C}^{-1}\underline{r}$ can be performed in optimal arithmetical complexity.

The preconditioner $\mathcal{C}$ (3.27) consists of three ingredients, namely, the preconditioner $\mathcal{C}_D$ for $\mathcal{K}_D$, the Schur complement preconditioner $\mathcal{C}_S$, and the extension operator $\mathcal{E}_{DB}$.

For the preconditioning operation $\mathcal{C}_D^{-1}\underline{r}_D$ (3.14), we have to solve subproblems in the high order subspaces $\mathbb{V}_j$, $j = 1,\dots,n$. Those problems can be treated by direct solvers since $\dim(\mathbb{V}_j) \preceq (1 + \log \frac{h_K}{h})^2$; see (2.5). On the subspace $\mathbb{V}_0$, we have to multiply with a diagonal matrix. Hence, the cost for $\mathcal{C}_D^{-1}\underline{r}_D$ is $\mathcal{O}(N)$.

Furthermore, we need a good preconditioner C_S for $\mathcal{S}_B$. Due to Theorem 3.13, the norm induced by the Schur complement is equivalent to the $H^{1/2}$ norm on the interface. Hence, any preconditioner which is known from the h-version of the FEM using uniformly refined meshes can be used as a preconditioner for the Schur complements $\mathcal{S}_{B,i}$ or the assembled Schur complement $\mathcal{S}_B$ (see, e.g., [29] or [47]). Indeed, today many preconditioners $\mathcal{C}_{S,i}$ for $\mathcal{S}_{B,i}$ are available such that $\kappa({\mathcal{C}_{S,i}}^{-\frac{1}{2}}\mathcal{S}_{B,i}{\mathcal{C}_{S,i}}^{-\frac{1}{2}}) = \mathcal{O}(1)$ and the solution of a system $\mathcal{C}_{S,i}\underline{w} = \underline{r}$ requires $\mathcal{O}(N_i)$ floating point operations. Similar results are valid for the assembled Schur complement $\mathcal{S}_B$. In our numerical experiments presented in section 5, we use the so-called Schur complement BPX preconditioner proposed in [44].

The last ingredient is the matrix representation of the extension operator $\mathcal{E}_{DB}$. Due to Algorithm 3.8, the operations $\mathcal{E}_{DB}\underline{w}_B$ and $\mathcal{E}_{DB}^T\underline{w}_D$ involve only BPX-like basis transformations on the boundary or the interface and in the interior, which are proportional to the numbers of unknowns in the interface or the interior. Therefore, both operations require $\mathcal{O}(N)$ floating point operations.

Summarizing, the total cost for the evaluation of $\mathcal{C}^{-1}\underline{r}$ is $\mathcal{O}(N)$ flops.

4. All-floating interface concentrated finite element tearing and interconnecting methods.

4.1. AF-FETI formulations. In order to avoid assembled matrices and vectors, we tear the global potential vector $\underline{u}$ on the subdomain boundaries $\Gamma_i = \partial\Omega_i$ by introducing the individual local unknowns $\underline{u}_i = R_i\underline{u}$; cf. also (2.7).

In contrast to the preceding sections, the vector $\underline{u}$ of nodal parameters now also contains those nodal parameters belonging to the Dirichlet boundary Γ_D that coincides with $\partial\Omega$ for our model problem (2.1). The global continuity of the potentials and the Dirichlet boundary conditions are now enforced by the constraints

$$\sum_{i=1}^{s} \mathcal{B}_i\underline{u}_i = \underline{0} \tag{4.1}$$

interconnecting the local potential vectors across the subdomain boundaries and the nodal parameters on the boundary Γ_D with the corresponding Dirichlet data,

which are zero for our model problem. Each row of the matrix $\mathcal{B} = (\mathcal{B}_1, \ldots, \mathcal{B}_s) = ((\mathcal{B}_{1,B}, \mathbf{0}), \ldots, (\mathcal{B}_{s,B}, \mathbf{0}))$ is connected with a pair of matching nodes across the subdomain boundaries or with a Dirichlet node. The entries of the former rows are 1 and -1 for the indices corresponding to the matching nodes on the interface (coupling boundaries) $\Gamma = \Gamma_S \setminus \Gamma_D$ and 0 otherwise, whereas an entry corresponding to a Dirichlet node on Γ_D is 1 and again 0 otherwise, where $\Gamma_S = \cup_{i=1}^{s} \Gamma_i$ denotes the skeleton. This method is called all floating (AF)-FETI. Therefore, (4.1) implies that the corresponding finite element functions $u_{i,h}$ are continuous across the interface Γ, i.e., $u_{i,h} = u_{j,h}$ on $\Gamma_i \cap \Gamma_j \neq \emptyset$, and are vanishing on $\Gamma_i \cap \Gamma_D$. We assume here that the number of constraints at some matching node is equal to the number of matching subdomains minus one. This method resulting in a minimal number of multipliers is called nonredundant; see, e.g., [28] for the use of redundant constraints.

By introducing Lagrange multipliers $\underline{\lambda} \in \mathbb{R}^L$, the linear system (2.8) is equivalent to the extended system

$$\begin{pmatrix} \mathcal{K}_1 & & & \mathcal{B}_1^\top \\ & \ddots & & \vdots \\ & & \mathcal{K}_s & \mathcal{B}_s^\top \\ \mathcal{B}_1 & \ldots & \mathcal{B}_s & \mathbf{0} \end{pmatrix} \begin{pmatrix} \underline{u}_1 \\ \vdots \\ \underline{u}_s \\ \underline{\lambda} \end{pmatrix} = \begin{pmatrix} \underline{f}_1 \\ \vdots \\ \underline{f}_s \\ \underline{0} \end{pmatrix}, \tag{4.2}$$

where now all matrices $\mathcal{K}_i$ correspond to local Neumann problems given by the Neumann bilinear form $\int_{\Omega_i} \nabla u \cdot \mathcal{D} \nabla v \, \mathrm{d}x$ on $H^1(\Omega_i)$. Due to the choice of the Lagrange multipliers, all matrices $\mathcal{K}_i$ are singular with kernels spanned by the vector $\left[\underline{1}_{i,B}^\top, \underline{1}_{i,L}^\top, \underline{0}_{i,H}^\top\right]^\top$, as was already mentioned in subsection 3.4.

Eliminating all interior unknowns $\underline{u}_{i,D}$, $i = 1, \ldots, s$, from system (4.2), we arrive at the equivalent reduced system

$$\begin{pmatrix} \mathcal{S}_{B,1} & & & \mathcal{B}_{B,1}^\top \\ & \ddots & & \vdots \\ & & \mathcal{S}_{B,s} & \mathcal{B}_{B,s}^\top \\ \mathcal{B}_{B,1} & \ldots & \mathcal{B}_{B,s} & \mathbf{0} \end{pmatrix} \begin{pmatrix} \underline{u}_{B,1} \\ \vdots \\ \underline{u}_{B,s} \\ \underline{\lambda} \end{pmatrix} = \begin{pmatrix} \underline{g}_{B,1} \\ \vdots \\ \underline{g}_{B,s} \\ \underline{0} \end{pmatrix}, \tag{4.3}$$

with the singular Schur complements

$$\mathcal{S}_{B,i} = \mathcal{K}_{B,i} - \mathcal{K}_{BD,i} \mathcal{K}_{D,i}^{-1} \mathcal{K}_{DB,i}, \quad i = 1, \ldots, s, \tag{4.4}$$

and the corresponding right-hand sides

$$\underline{g}_{B,i} = \underline{f}_{B,i} - \mathcal{K}_{BD,i} \mathcal{K}_{D,i}^{-1} \underline{f}_{D,i}, \quad i = 1, \ldots, s. \tag{4.5}$$

The kernels of the matrices $\mathcal{S}_{B,i}$ are spanned by the vector $\underline{1}_{B,i}$. We now replace the singular Neumann–Schur complements $\mathcal{S}_{B,i}$ by the regularized matrices

$$\widetilde{\mathcal{S}}_{B,i} = \mathcal{S}_{B,i} + \alpha_i \underline{1}_{B,i} \underline{1}_{B,i}^\top, \quad i = 1, \ldots, s. \tag{4.6}$$

This corresponds to the regularized Neumann bilinear form

$$\int_{\Omega_i} \nabla u(x) \cdot \mathcal{D}(x) \nabla v(x) \, \mathrm{d}x + \left(\int_{\Gamma_i} u(x) \, \mathrm{d}s \right) \left(\int_{\Gamma_i} v(x) \, \mathrm{d}s \right) \tag{4.7}$$

on $H^1(\Omega_i)\times H^1(\Omega_i)$ with a positive regularization parameter α_i, e.g., $\alpha_i = h_i^2$. Taking into account the solvability conditions for local Neumann problems

$$(\underline{g}_{B,i} - \mathcal{B}_{B,i}^\top \underline{\lambda}, \underline{1}_{B,i}) = 0 \tag{4.8}$$

and the representation of the vectors $\underline{u}_{B,i}$ as

$$\underline{u}_{B,i} = \underline{v}_{B,i} + \gamma_i \underline{1}_{B,i} \quad \text{with} \quad (\underline{v}_{B,i}, \underline{1}_{B,i}) = 0, \tag{4.9}$$

we get the two-fold saddle point problem

$$\begin{pmatrix} \widetilde{\mathcal{S}}_{B,1} & & & \mathcal{B}_{B,1}^\top & \mathbf{0} \\ & \ddots & & \vdots & \\ & & \widetilde{\mathcal{S}}_{B,s} & \mathcal{B}_{B,s}^\top & \mathbf{0} \\ \mathcal{B}_{B,1} & \dots & \mathcal{B}_{B,s} & \mathbf{0} & \mathcal{G} \\ \mathbf{0} & \dots & \mathbf{0} & \mathcal{G}^\top & \mathbf{0} \end{pmatrix} \begin{pmatrix} \underline{v}_{B,1} \\ \vdots \\ \underline{v}_{B,s} \\ \underline{\lambda} \\ \underline{\gamma} \end{pmatrix} = \begin{pmatrix} \underline{g}_{B,1} \\ \vdots \\ \underline{g}_{B,s} \\ \underline{0} \\ \underline{e} \end{pmatrix} \tag{4.10}$$

with the notation $\underline{\gamma} = (\gamma_i)_{i=1,\dots,s} \in \mathbb{R}^s$, $\mathcal{G} = (\mathcal{B}_{B,1}\underline{1}_{B,1}, \dots, \mathcal{B}_{B,s}\underline{1}_{B,s})$, and $\underline{e} = (e_i)_{i=1,\dots,s} = ((\underline{g}_{B,i}, \underline{1}_{B,i}))_{i=1,\dots,s} \in \mathbb{R}^s$. The solution $\underline{u}_{B,i}$ can be recovered via formula (4.9).

Applying the orthogonal projection

$$\mathcal{P} = \mathcal{I} - \mathcal{G}(\mathcal{G}^\top\mathcal{G})^{-1}\mathcal{G}^\top \tag{4.11}$$

from the space $\mathbf{\Lambda} := \mathbb{R}^L$ onto the subspace $\mathbf{\Lambda}_0 = \ker \mathcal{G}^\top = (\operatorname{range}\mathcal{G})^\perp$ with respect to the scalar product $(\cdot,\cdot) = (\cdot,\cdot)_{\mathbf{\Lambda}} = (\cdot,\cdot)_{\mathbb{R}^L}$ to the penultimate equation of system (4.10), we can exclude $\underline{\gamma}$ from the first $s+1$ block equations of (4.10). Moreover, let us represent $\underline{\lambda}$ in the form

$$\underline{\lambda} = \mathcal{L}_0\underline{\lambda}_0 + \underline{\lambda}_e \tag{4.12}$$

with known $\underline{\lambda}_e = \mathcal{G}(\mathcal{G}^\top\mathcal{G})^{-1}\underline{e} \in (\ker\mathcal{G}^\top)^\perp = \operatorname{range}\mathcal{G}$, fulfilling the constraints $\mathcal{G}^\top\underline{\lambda}_e = \underline{e}$, and unknown $\mathcal{L}_0\underline{\lambda}_0 \in \ker\mathcal{G}^\top$, i.e., $\mathcal{G}^\top\mathcal{L}_0\underline{\lambda}_0 = \underline{0}$, where $\underline{\lambda}_0 \in \mathbb{R}^{L_0}$ and $L_0 = \dim\Lambda_0$. It is clear that the columns of $\mathcal{L}_0$ span a basis of Λ_0. Let

$$\widetilde{\mathcal{B}}_i = \begin{pmatrix} \mathcal{L}_0^\top\mathcal{P}^\top\mathcal{B}_{B,i} & \mathbf{0} \end{pmatrix}. \tag{4.13}$$

Now we can define $\underline{v}_{B,1}, \dots, \underline{v}_{B,s}$ and $\underline{\lambda}_0$ from the one-fold saddle point problem

$$\begin{pmatrix} \widetilde{\mathcal{S}}_{B,1} & & & \widetilde{\mathcal{B}}_1^\top \\ & \ddots & & \vdots \\ & & \widetilde{\mathcal{S}}_{B,s} & \widetilde{\mathcal{B}}_s^\top \\ \widetilde{\mathcal{B}}_1 & \dots & \widetilde{\mathcal{B}}_s & \mathbf{0} \end{pmatrix} \begin{pmatrix} \underline{v}_{B,1} \\ \vdots \\ \underline{v}_{B,s} \\ \underline{\lambda}_0 \end{pmatrix} = \begin{pmatrix} \underline{d}_{B,1} \\ \vdots \\ \underline{d}_{B,s} \\ \underline{0} \end{pmatrix}, \tag{4.14}$$

where $\underline{d}_{B,i} = \underline{g}_{B,i} - \mathcal{B}_{1,B}^\top\underline{\lambda}_e$. Once the vectors $\underline{v}_{B,1}, \dots, \underline{v}_{B,s}$ and $\underline{\lambda}_0$ are defined from (4.14), we get $\underline{\lambda}$ from (4.12), $\underline{\gamma}$ from the penultimate equation of (4.10), i.e.,

$$\underline{\gamma} = -(\mathcal{G}^\top\mathcal{G})^{-1}\mathcal{G}^\top(\mathcal{B}_{B,1}\underline{v}_{B,1} + \dots + \mathcal{B}_{B,s}\underline{v}_{B,s}), \tag{4.15}$$

and, finally, $\underline{u}_{B,1}, \dots, \underline{u}_{B,s}$ from (4.9). We will call the one-fold saddle point problem (4.14) an AF-FETI2 system.

Remark 4.1. We mention that the iteration updates for $\underline{\lambda}$ completely live in the subspace $\mathbf{\Lambda}_0$ if the initial guess is chosen as $\underline{\lambda}_e$. Therefore, a basis of $\mathbf{\Lambda}_0$, forming the columns of $\mathcal{L}_0$, is not explicitly required in the computation. We further mention that in the case of large jumps in the coefficients of the PDE the scalar product in $\mathbf{\Lambda}$ has to be changed from $(\cdot,\cdot)_{\mathbb{R}^L}$ to $(\mathcal{Q}\cdot,\cdot)_{\mathbb{R}^L}$ with some SPD matrix $\mathcal{Q}$ according to the proposals made in [28]; see also [5] and [47]. Of course, the change of the scalar product changes the orthogonal projection $\mathcal{P}$ from (4.11) to $\mathcal{P} = \mathcal{I} - \mathcal{Q}\mathcal{G}(\mathcal{G}^\top \mathcal{Q}\mathcal{G})^{-1}\mathcal{G}^\top$.

Eliminating the unknowns $\underline{v}_{B,1}, \ldots, \underline{v}_{B,s}$ from the AF-FETI2 system (4.14), we get the FETI Schur complement problem

$$\hat{\mathcal{F}}\underline{\lambda}_0 = \hat{\underline{d}}_0 \tag{4.16}$$

with the FETI Schur complement

$$\hat{\mathcal{F}} = \mathcal{L}_0^\top \mathcal{P}^\top \mathcal{F}\mathcal{P}\mathcal{L}_0 \quad \text{with} \quad \mathcal{F} = \sum_{i=1}^{s} \mathcal{B}_{B,i}\widetilde{\mathcal{S}}_{B,i}^{-1}\mathcal{B}_{B,i}^\top \tag{4.17}$$

and the corresponding right-hand side

$$\hat{\underline{d}}_0 = \mathcal{L}_0^\top \mathcal{P}^\top \underline{d}_0 - \mathcal{L}_0^\top \mathcal{P}^\top \sum_{i=1}^{s} \mathcal{B}_{B,i}\widetilde{\mathcal{S}}_{B,i}^{-1}\underline{d}_{B,i}. \tag{4.18}$$

The SPD system (4.16) is called the AF-FETI1 system.

On the other hand, we can again unfold the AF-FETI2 system (4.14), arriving at a saddle point system that is similar to the saddle point system (4.2), but now with regular diagonal blocks

$$\widetilde{\mathcal{K}}_i = \begin{bmatrix} \widetilde{\mathcal{K}}_{B,i} & \mathcal{K}_{BD,i} \\ \mathcal{K}_{DB,i} & \mathcal{K}_{D,i} \end{bmatrix} \tag{4.19}$$

with the regularized matrices $\widetilde{\mathcal{K}}_{B,i} = \mathcal{K}_{B,i} + \alpha_i \underline{1}_{B,i}\underline{1}_{B,i}^\top$. Then, the resulting system, called the AF-FETI3 system, can be written in the form

$$\begin{pmatrix} \widetilde{\mathcal{K}}_1 & \mathbf{0} & \ldots & \mathbf{0} & \widetilde{\mathcal{B}}_1^\top \\ \mathbf{0} & \widetilde{\mathcal{K}}_2 & & \vdots & \widetilde{\mathcal{B}}_2^\top \\ \vdots & & \ddots & \mathbf{0} & \vdots \\ \mathbf{0} & \ldots & \mathbf{0} & \widetilde{\mathcal{K}}_s & \widetilde{\mathcal{B}}_s^\top \\ \widetilde{\mathcal{B}}_1 & \ldots & & \widetilde{\mathcal{B}}_s & \mathbf{0} \end{pmatrix} \begin{pmatrix} \underline{\widetilde{u}}_1 \\ \vdots \\ \vdots \\ \underline{\widetilde{u}}_s \\ \underline{\lambda}_0 \end{pmatrix} = \begin{pmatrix} \underline{\widetilde{f}}_1 \\ \vdots \\ \vdots \\ \underline{\widetilde{f}}_s \\ \underline{0} \end{pmatrix}, \tag{4.20}$$

where

$$\underline{\widetilde{u}}_i = \begin{pmatrix} \underline{v}_{B,i} \\ \underline{u}_{D,i} \end{pmatrix}, \quad \underline{\widetilde{f}}_i = \begin{pmatrix} \underline{f}_{B,i} - \mathcal{B}_{B,i}^\top \underline{\lambda}_e \\ \underline{f}_{D,i} \end{pmatrix}, \quad \text{and} \quad \tilde{B}_i$$

are defined via (4.13).

Let us mention that all AF-FETI systems derived in this subsection are equivalent. In the following subsection we propose and analyze fast and robust solvers for the AF-FETI1–AF-FETI3 systems (4.16), (4.14), and (4.20).

4.2. AF-FETI solvers and preconditioners. Throughout this subsection, we assume that $\mathcal{D}(x) = a_i\mathcal{I}$ on Ω_i. We are interested in the robustness of our FETI preconditioners with respect to large jumps of these coefficients across the interfaces. We note that all results remain valid if the spectral condition number $\kappa(\mathcal{D}) = \lambda_{max}(\mathcal{D})/\lambda_{min}(\mathcal{D})$ of the diffusion matrix is uniformly small on Ω_i.

4.2.1. AF-FETI1 solvers. Since the system matrix $\hat{\mathcal{F}}$ of the AF-FETI1 system (4.16) is SPD, it can be efficiently solved with the help of the PCG method with an appropriate FETI preconditioner $\hat{\mathcal{C}}_F$. It is clear that we have only to construct a preconditioner $\mathcal{C}_F$ for $\mathcal{F}$ on the subspace $\mathbf{\Lambda}_0 = \ker \mathcal{G}^\top = (\operatorname{range} \mathcal{G})^\perp$. Candidates for $\mathcal{C}_F$ are the following preconditioners:

- Scaled exact Dirichlet FETI preconditioner (see, e.g., [47]):

$$\mathcal{C}_F^{-1} = \mathcal{A}\mathcal{S}_B\mathcal{A}^\top, \quad \mathcal{S}_B = \operatorname{diag}(\widetilde{\mathcal{S}}_{B,i}). \tag{4.21}$$

- Scaled inexact Dirichlet FETI preconditioner:

$$\mathcal{C}_F^{-1} = \mathcal{A}(\mathcal{S}_B + \mathcal{T}_B)\mathcal{A}^\top, \quad \mathcal{S}_B + \mathcal{T}_B = \operatorname{diag}(\widetilde{\mathcal{S}}_{B,i} + \mathcal{T}_{B,i}), \tag{4.22}$$

  where the exact Schur complement $\mathcal{S}_B$ is replaced by the perturbed Schur complement $\mathcal{S}_B + \mathcal{T}_B$; see (3.4).

- Scaled data-sparse hypersingular BETI preconditioner:

$$\mathcal{C}_F^{-1} = \mathcal{A}\mathcal{W}\mathcal{A}^\top, \quad \mathcal{W} = \operatorname{diag}(\widetilde{\mathcal{W}}_{B,i}), \tag{4.23}$$

  with the matrices $\widetilde{\mathcal{W}}_{B,i}$ arising from an appropriate data-sparse approximation of the hypersingular operator on $\partial\Omega_i$ [31].

The matrix $\mathcal{A} = (\mathcal{B}\tilde{\mathcal{D}}^{-1}\mathcal{B}^\top)^{-1}\mathcal{B}\tilde{\mathcal{D}}^{-1}$ is defined by the interconnecting matrix $\mathcal{B} = \operatorname{diag}(\mathcal{B}_{B,i})$ and by the scaling matrix $\tilde{\mathcal{D}} = \operatorname{diag}(\tilde{\mathcal{D}}_{B,i})$ with appropriate diagonal matrices $\tilde{\mathcal{D}}_{B,i}$. The diagonal entries depend on the coefficients a_i; see [28, 5, 47] for further details.

THEOREM 4.2. *Let $\mathcal{C}_F$ be one of the FETI preconditioners defined by* (4.21), (4.22), *or* (4.23). *Then, there exist positive constants $\underline{c}_F$ and $\overline{c}_F$ such that the spectral inequalities*

$$\underline{c}_F\,(\mathcal{C}_F\underline{\lambda},\underline{\lambda}) \le (\mathcal{F}\underline{\lambda},\underline{\lambda}) \le \overline{c}_F\,(1+\log(H/h))^2\,(\mathcal{C}_F\underline{\lambda},\underline{\lambda}) \tag{4.24}$$

hold for all $\underline{\lambda} \in \mathbf{\Lambda}_0 = \ker \mathcal{G}^\top$, where the constants $\underline{c}_F$ *and* $\overline{c}_F$ are *independent of h_i, H_i, and the a_i's (coefficient jumps), $H/h = \max H_i/h_i$.*

Proof. By Theorem 3.13, the matrices $\widetilde{\mathcal{S}}_{B,i}$, $\widetilde{\mathcal{S}}_{B,i} + \mathcal{T}_{B,i}$, and $\widetilde{\mathcal{W}}_{B,i}$ are spectrally equivalent to an auxiliary Schur complement $\widetilde{\mathcal{S}}_{B,i}^{FEM}$ arising from a standard finite element discretization with linear triangular elements on an auxiliary quasi-uniform triangular mesh generated from the given quasi-uniform boundary mesh on $\partial\Omega_i$ with the average mesh size h [31]. Since the spectral inequalities (4.24) were proved for $\widetilde{\mathcal{S}}_{B,i}^{FEM}$ (see [28], [5], or [47]), they are also valid if we replace $\widetilde{\mathcal{S}}_{B,i}^{FEM}$ in $\mathcal{F}$ and $\mathcal{C}_F^{-1}$ by the matrices $\widetilde{\mathcal{S}}_{B,i}$, $\widetilde{\mathcal{S}}_{B,i}+\mathcal{T}_{B,i}$, or $\widetilde{\mathcal{W}}_{B,i}$. This completes the proof of the theorem. ∎

Now we can solve the SPD system (4.16) via the PCG method, which can be efficiently performed on the subspace $\mathbf{\Lambda}_0$ with one of the preconditioners $\mathcal{C}_F^{-1}$ proposed above. Theorem 4.2 immediately implies that we need at most $I(\varepsilon) = O((1+\log(H/h))\log\varepsilon^{-1})$ iterations in order to reduce the initial error by the factor $\varepsilon \in (0,1)$ in a parallel regime. The matrix-vector product $\mathcal{F}\underline{\lambda}$, or $\widehat{\mathcal{F}}\underline{\lambda}_0$, requires the (parallel) solution of the systems

$$\widetilde{\mathcal{S}}_{B,i}\underline{w}_{B,i} = \underline{r}_{B,i}, \tag{4.25}$$

which are equivalent to the solution of the regularized finite element Neumann problems

$$\begin{pmatrix} \widetilde{\mathcal{K}}_{B,i} & \mathcal{K}_{BD,i} \\ \mathcal{K}_{DB,i} & \mathcal{K}_{D,i} \end{pmatrix} \begin{pmatrix} \underline{w}_{B,i} \\ \underline{w}_{D,i} \end{pmatrix} = \begin{pmatrix} \underline{r}_{B,1} \\ \underline{0}_{D,1} \end{pmatrix}, \quad i = 1, \ldots, s. \tag{4.26}$$

The discrete Neumann problem (4.26) can now be solved either by means of a sparse direct method with the matrix factorization in a preprocessing step or with the help of the PCG method with the Neumann preconditioner (3.25) proposed in subsection 3.4. The preconditioning step $\mathcal{C}_F^{-1}\underline{\rho}$ requires

- the (parallel) solution of local discrete Dirichlet problems with the system matrices $\mathcal{K}_{D,i}$,
- the (parallel) matrix-vector multiplications $(\widetilde{\mathcal{S}}_{B,i} + \mathcal{T}_{B,i})\underline{w}_{B,i}$ with a cost of $O((H_i/h_i))$ arithmetical operations, or
- the (parallel) multiplications $\widetilde{\mathcal{W}}_{B,i}\underline{w}_{B,i}$ with a cost of $O((H_i/h_i)(\log(H_i/h_i))^2)$ arithmetical operations

for the preconditioners (4.21), (4.22), or (4.23), respectively. Thus, the scaled inexact Dirichlet FETI preconditioner (4.22) is the cheapest FETI preconditioner.

4.2.2. AF-FETI2 solvers. The saddle point problem (4.14) can be solved by the Bramble–Pasciak PCG [4] or by any other suitable Krylov subspace iterative solver [43], e.g., the preconditioned conjugate residual method [27]; see also [25] and [26] for inexact FETI-DP as possible alternative. In any case, we need

- efficient preconditioners $\mathcal{C}_{B,i}$ for the regularized local Schur complements $\widetilde{\mathcal{S}}_{B,i}$ and
- a FETI preconditioner $\mathcal{C}_F$,

which are available from section 3 (cf. (3.25)) and (4.21)–(4.23), respectively. It follows from Theorem 4.2, Theorem 3.7, and the results of [4] and [49] that the number $I(\varepsilon)$ of iterations of the Bramble–Pasciak PCG behaves like $O((1+\log(H/h))\log\varepsilon^{-1})$.

The matrix-vector multiplication $\widetilde{\mathcal{S}}_{B,i}\underline{v}_{B,i}$ requires the solution of the local Dirichlet systems

$$\mathcal{K}_{D,i}\underline{w}_{D,i} = \underline{r}_{D,i}, \tag{4.27}$$

which can be done in parallel and which can be performed by means of a sparse direct method with the matrix factorization in a preprocessing step or with the help of the PCG method with the Dirichlet preconditioner $\mathcal{C}_{D,i}$ proposed by relation (3.14) in subsection 3.2.

4.2.3. AF-FETI3 solvers. The AF-FETI3 system (4.20) is again a one-fold saddle point problem which can be solved by the solvers mentioned above. In any case, we need

- efficient preconditioners $\mathcal{C}_i$ for the regularized local Neumann matrices $\tilde{K}_i$ (4.19) and
- a FETI preconditioner $\mathcal{C}_F$,

which are available from section 3 and (4.21)–(4.23), respectively.

THEOREM 4.3. *Assume that the AF-FETI3 system* (4.20) *is solved by means of the Bramble–Pasciak PCG method with the scaled inexact Dirichlet FETI preconditioner* (4.22) *and an appropriately scaled local Neumann preconditioner* (3.25) *composed of the optimal components* $\mathcal{C}_{D,i}$, $\mathcal{C}_{S,i}$, *and* $\mathcal{E}_{DB,i}$ *given in section* 3. *Then not more than* $I(\varepsilon) = O((1+\log(H/h))\log\varepsilon^{-1})$ *iterations and ops*$(\varepsilon) = O((H/h)(1+$

$\log(H/h))\log\varepsilon^{-1})$ *arithmetical operations are required in order to reduce the initial error by the factor* $\varepsilon \in (0,1)$ *in a parallel regime, where* $H/h = \max H_i/h_i$. *The number of iterations* $I(\varepsilon)$ *is robust with respect to the jumps in the coefficients across the interfaces. Moreover, at most* $O(H/h)$ *storage units are needed per processor.*

Proof. The estimate for the number $I(\varepsilon)$ of iterations is a direct consequence of results given in [4] (see [49] for improved estimates) and of the spectral estimates (3.14) and (4.24). The complexity estimates for the arithmetical costs and the memory demand follow from the corresponding complexity estimates for the block matrices involved in the matrix-vector multiplications and in the preconditioning. ∎

We emphasize that we can solve the interface concentrated finite element equations with the same complexity (even with a slightly better complexity) as data-sparse boundary element DD equations (cf. [30]). In contrast to boundary element technology, we can easily include source terms $f(\cdot)$ and we can even admit nonconstant but smooth coefficients $a_i(\cdot)$ in the subdomains Ω_i.

5. Numerical experiments. In this section, we first present some numerical experiments for the primal DD solver proposed in section 3. Finally, we investigate the behavior of the FETI preconditioner studied in section 4.

We consider problem (2.2) in $\Omega = (-1,1)^2$ using a piecewise constant coefficient matrix $\mathcal{D}(x,y)$ with coefficients $a_i\mathcal{I}$, $i = 1,2,3,4$, and a right-hand side $f(x,y) = 1$; see Figure 5.1. The problem is discretized by an IC-FEM with $p = 1$ in all elements. The interfaces are at the lines $x = 0$ and $y = 0$, whereas the boundaries are situated at $x = \pm 1$ and $y = \pm 1$. Here, we choose homogeneous Dirichlet boundary conditions.

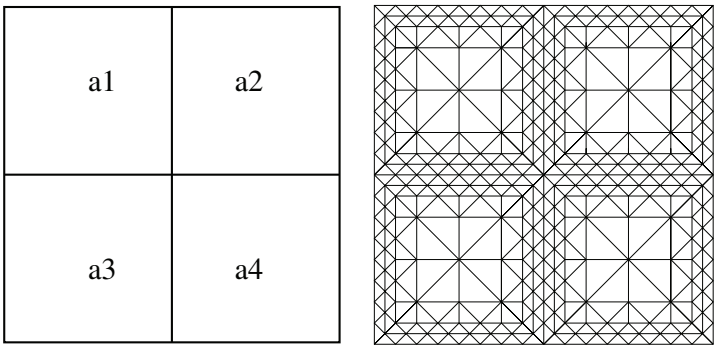

FIG. 5.1. *Coefficient matrix (left) and IC-concentrated mesh (right).*

In all experiments, we use the preconditioner $\mathcal{C}$ (3.27), where $\mathcal{E}_{DB}$ is the matrix representation of the extension operator of Algorithm 3.8 and $\mathcal{C}_S = \{\mathcal{S}_B, \mathcal{C}_{B,BPX}\}$ and $\mathcal{C}_D = \{\mathcal{K}_L, \mathcal{D}_L, \mathcal{C}_{D,BPX}, RR^T\}$ are the preconditioners for the Schur complement and the interior block, respectively, where

- $\mathcal{C}_{B,BPX}$ and $\mathcal{C}_{D,BPX}$ denote the BPX preconditioners for $\mathcal{S}_B$ and $\mathcal{K}_D$, respectively,
- R denotes the Cholesky factor of the incomplete Cholesky factorization for $\mathcal{K}_D$, i.e., $\mathcal{C}_{ichol} = RR^T$, and
- $\mathcal{D}_L$ denotes the diagonal part of $\mathcal{K}_L$.

Since $p = 1$ on all elements, the block $\mathcal{K}_H$ does not exist. The block $\mathcal{K}_H$ has been removed by the arguments of the overlapping preconditioner $\mathcal{C}_D$ which is defined via (3.14). This preconditioner is adapted from [12]; see also [36] for the three-dimensional

case. In both papers, the performance of the preconditioners is checked numerically for different applications. The experiments show the efficiency of this preconditioner. The aim of our experiments is to present efficiency of our preconditioner, which corresponds to a solver for the low order part in (3.14). Nevertheless, we present some numerical experiments for the AF-FETI1 preconditioner with $p > 1$.

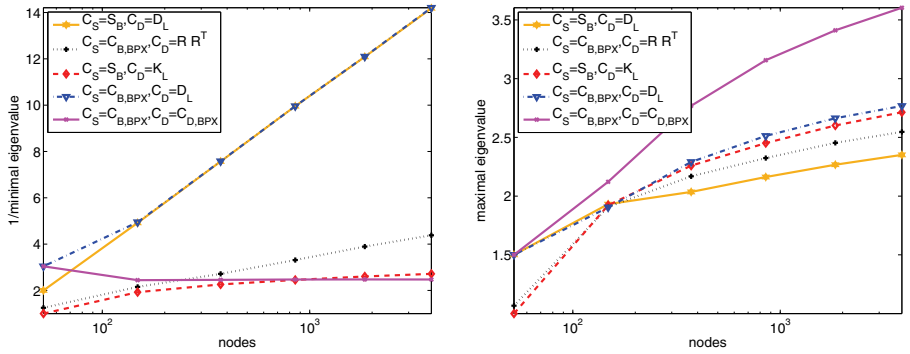

FIG. 5.2. *Eigenvalues of $\mathcal{C}^{-1}\mathcal{K}$ for moderate jumping coefficients: Minimal eigenvalue left; maximal eigenvalue right.*

Figure 5.2 displays the maximal and minimal eigenvalues of $\mathcal{C}^{-1}\mathcal{K}$ for several variants of $\mathcal{C}_S$ and $\mathcal{C}_D$ in the case of moderate jumping coefficients $a_i = i$, $i = 1, 2, 3, 4$. The optimality of the condition number can be seen in all cases. The usage of $\mathcal{C}_D = C_{D,BPX}$ or $\mathcal{C}_D = RR^T$ reduces the constants in comparison to $\mathcal{C}_D = \mathcal{D}_L$.

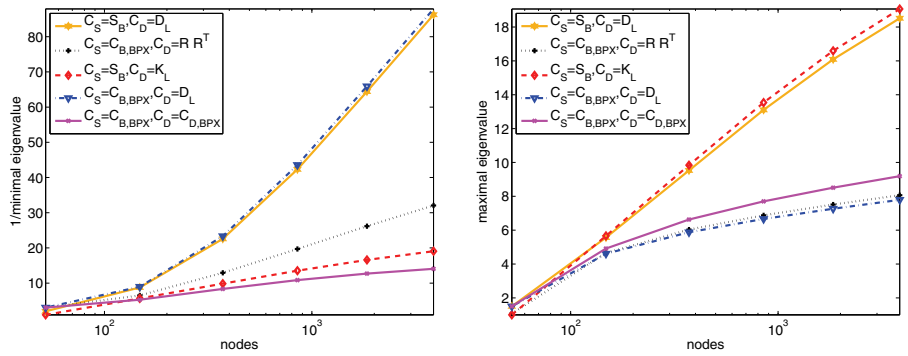

FIG. 5.3. *Eigenvalues of $\mathcal{C}^{-1}\mathcal{K}$ for strongly jumping coefficients: Minimal eigenvalue left; maximal eigenvalue right.*

In a second experiment, we have chosen $a_i = 10^i$, $i = 1, 2, 3, 4$. From the experiments, it can seen that the primal DD preconditioner is asymptotically optimal with respect to the number of unknowns. However, it is not robust with respect to the jumps of the diffusion coefficient; see Figure 5.3.

Moreover, we determine the numbers of iterations of the PCG method for the solution of $\mathcal{K}\underline{u} = \underline{f}$ using the preconditioner $\mathcal{C}$ (3.27) with $\mathcal{C}_S = \mathcal{C}_{B,BPX}$ and $\mathcal{C}_D = \mathcal{C}_{D,BPX}$ and a relative accuracy of 10^{-5}. Table 5.1 displays the numbers of iterations for the diffusion coefficients $a_i = i$ and $a_i = 10^i$, $i = 1, 2, 3, 4$, respectively.

In both cases, the numbers of PCG iterations are bounded in accordance with

TABLE 5.1
Numbers of PCG iterations for the solution of $\mathcal{K}\underline{u} = \underline{f}$ with the preconditioner $\mathcal{C}$.

$a_i = 10^i$	5	23	35	41	53	57	57	55	56	56

our theory.

In the next experiment, we investigate the FETI preconditioner $\mathcal{C}_F$ (4.21) for $\mathcal{F}$ (4.16). Again, the finite element mesh of Figure 5.1 with $p = 1$ is used. We consider five different distributions for the coefficients $\underline{mat} = [a_i]_{i=1}^4$ in the subdomains Ω_i, $i = 1, 2, 3, 4$. The maximal eigenvalue of $\mathcal{C}_F^{-1}\mathcal{F}$ is displayed in Figure 5.4, whereas the minimal eigenvalue is 1 in all experiments. Both eigenvalues are robust with respect to material jumps. Moreover, a polynomial logarithmic growth of the condition number can be seen.

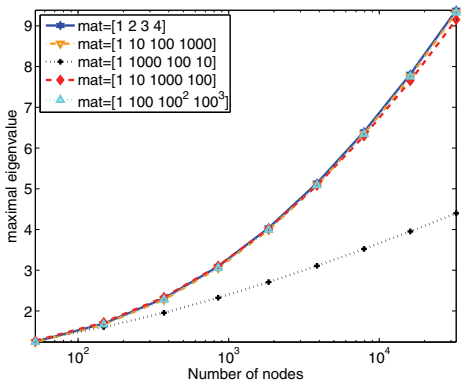

FIG. 5.4. *Maximal eigenvalue of the FETI preconditioner.*

In a last experiment, the solution of (4.16) with the FETI preconditioner $\mathcal{C}_F$ (4.21) is studied for more complex DDs. We consider problem (2.2) in $\Omega = (-1, 1)^2$ using a piecewise constant coefficient matrix $\mathcal{D}(x, y)$ with coefficients a_i, $i = 1, 2, 3, 4$, and a right-hand side $f(x, y) = 1$; see Figure 5.1. This problem is discretized by the IC-*hp*-FEM with $p > 1$, where Ω is decomposed into $s = 4^k$ congruent squares, $k = 1, 2, 3, 4$; see Figure 5.5 for $k = 2$. As in the previous examples, we compare moderate and highly jumping coefficients, i.e., $a_i = i$ and $a_i = 10^i$, $i = 1, 2, 3, 4$, respectively. Note that each coefficient a_i is chosen in 4^{k-1} subdomains. Figure 5.6 displays the condition number of $\mathcal{C}_F^{-1}\hat{\mathcal{F}}$ which is estimated by the Lanzcos method for the maximal eigenvalue and by one for the minimal eigenvalue.

In the case of highly jumping coefficients $a_i = 10^i$, the AF-FETI1 system (4.16) has been solved by the PCG method using the FETI preconditioner $\mathcal{C}_F^{-1}$ (4.21). Table 5.2 displays the PCG iteration number using a relative accuracy of 10^{-8}. The largest problem corresponding to level 12 and $s = 256$ subdomains has 36330497 unknowns. We mention that a uniformly refined grid would yield about 4.3 billions unknowns. The solution of the problem with 36330497 unknowns requires less than 40 minutes using the 8 processors of our 4 × Dualcore Intel Xeon computer (CPU 3.40GHz, 16MB processor cache, 64GB RAM in total). We also determined the number of

PCG iterations for the case of an interface concentrated finite element discretization with polynomial degree $p = 1$ on all elements. The number of iterations for $p > 1$ and $p = 1$ differs only for the cases $l = 5, s = 16$ (17 instead of 16) and $l = 12, s = 64$ (30 instead of 31) by one iteration!

Remark 5.1. In real applications, the numbers of unknowns on the subdomains Ω_i can be quite different. Thus, a mesh partitioning where each processor obtains one

domain Ω_i is not suitable in the sense of a good load balancing. In order to obtain a good load balancing, a mesh partitioner is used in order to decompose the mesh into subdomains $\tilde{\Omega}_j$ such that $\cup_j \overline{\tilde{\Omega}}_j = \overline{\Omega}_i$ or $\cup_i \overline{\Omega}_i = \overline{\tilde{\Omega}}_j$ if the number of unknowns on Ω_i is too large or too small, respectively. Material or source interfaces are not cut with this strategy. The preconditioners are not changed, but the data structures have to be adapted. We mention that the component $\mathcal{D}_L$ of the overlapping preconditioner (3.14) is a diagonal matrix. However, the component $\mathcal{K}_{P,j}$ of the preconditioner (3.14) requires data exchanges of the unknowns on elements between different processors.

6. Conclusions and possible generalizations. The solution of potential problems with piecewise smooth coefficients can be approximated by the IC-FEM with the same asymptotical accuracy as the standard FEM but with a considerably smaller number of unknowns. We have proposed primal and dual DD preconditioners resulting in asymptotically optimal or almost optimal solvers for the interface concentrated finite element equations. The first class of preconditioners is based on inexact Dirichlet–Dirichlet preconditioning techniques. The second class of preconditioners is constructed on the basis of the so-called all-floating finite element tearing and interconnecting (AF-FETI) technology. The latter class of preconditioners is very robust with respect to jumps in the coefficients of the PDE and highly efficient in parallel computing. It is clear that instead of AF-FETI technology, the FETI-DP technique can also be used. The number of unknowns involved in the IC-FEM is comparable to the number of unknowns living on the skeleton of the DD. Thus, the coupling of IC-FEM with data-sparse boundary element methods (BEM) seems to be very attractive for many applications. This coupling has also been suggested for exterior boundary value problems in [22] based on the results in [24]. In contrast to the standard FEM, the IC-FEM will not perturb the complexity of data-sparse BEM. We refer the reader to the survey paper [32] for the standard symmetric BEM-FEM coupling.

Our results have been presented for the two-dimensional case. The results for the development of the preconditioners can also be applied to the three-dimensional case. The key ingredients, the overlapping preconditioner of subsection 3.2 (see [36]) and the Haase–Nepomnyaschikh extension are available. However, an approximation theorem such as Theorem 2.6 is still missing in the literature. It might be possible to prove such a result as in [22], but the proof seems to be very technical.

Acknowledgments. The authors thank Clemens Pechstein (Linz) for the numerical experiments with the FETI preconditioner and the anonymous referees for improving the paper.

ANALYSIS OF FINITE ELEMENT DOMAIN EMBEDDING METHODS FOR CURVED DOMAINS USING UNIFORM GRIDS*

SHENG ZHANG†

Abstract. We analyze the error of a finite element domain embedding method for elliptic equations on a domain ω with curved boundary. The domain is embedded in a rectangle R on which uniform mesh and linear continuous elements are employed. The numerical scheme is based on an extension of the differential equation from ω to R by regularization with a small parameter ϵ (for Neumann and Robin problems), or penalty with a large parameter ϵ^{-1} (for the Dirichlet problem), or a mixture of these (for a mixed boundary value problem). For Neumann and Robin problems, we prove that when $\epsilon \leq h$ (the mesh size), the error in the $H^1(\omega)$ norm is of the optimal order $\mathcal{O}(h)$. For the Dirichlet problem, when $\epsilon \leq h^{1/2}$, the error is $\mathcal{O}(h^{1/2})$ that is not optimal. If the mesh is adjusted around $\partial\omega$ to fit it, then the optimal convergence rate $\mathcal{O}(h)$ holds for the Dirichlet problem if ω is convex and $\epsilon \leq h$. If ω is not convex, then the convergence rate can only be improved to $\mathcal{O}(h^{2/3})$ by such mesh adjustment, with the parameter being $\epsilon = h^{2/3}$. In this latter case, a parameter smaller than $h^{2/3}$ thwarts the convergence rate, which is verified by a numerical result.

1. Introduction.

In recent years, domain embedding, or fictitious domain, methods have developed into a general methodology of the numerical computations of partial differential equations that has the advantage of efficiently dealing with complex domain boundaries by using uniform, or slightly adjusted, grids on a larger rectangular domain [11]. For a second order elliptic boundary value problem on a complicated domain, the ultimate goal of domain embedding methods is to quickly obtain an accurate numerical solution by mainly solving the Poisson equation on uniform meshes on a rectangle by fast solvers, through, say, preconditioned iterations. A first step in these methods is to extend the boundary value problem to a larger rectangle. There are many ways to do this, one of which is using regularization for Neumann or Robin problem, or penalty for Dirichlet problem, or a combination of these for a mixed boundary value problem [14, 15, 17, 23]. A more general approach, including some additional treatments on the original domain boundary, can be found in [2]. This step results in an extended boundary value problem on the rectangle with large jumps in the coefficients of the differential equation. A finite element domain embedding method then is obtained as a straightforward discretization of the extended equation on a uniform mesh on the rectangle. The error of the finite domain embedding method has two sources. One is due to the replacement of the original problem by the one on the larger rectangular domain. This has been analyzed by many authors, and in [23, 24] the sharp estimates on the regularization/penalty error can be found. The other is due to the discretization of the extended equation, which seems not to have been completely understood. In the literature, there are numerous

†Department of Mathematics, Wayne State University, Detroit, MI 48202 (sheng@math.wayne.edu).

works devoted to this subject. In [17], a thorough analysis is presented under the assumption that the original domain boundary aligns with the uniform mesh. This assumption seems to be a stringent restriction on the arbitrariness of the domain. For example, the domain boundary cannot be smoothly curved. The regularity of the solution and the alignment of the domain boundary with the uniform mesh required in this analysis are often not compatible. Furthermore, the results of [17] are actually not valid for general curved domains for Dirichlet problems. In [14, 15], an analysis for the Neumann problem can be found, which did not impose such restriction on the domain. But the error estimates established there are not sharp enough. A difficulty in this kind of error analysis for curved and complex domains is that the solution of the extended equation is not globally smooth. It has jumps in its normal derivative across the original domain boundary that inevitably cuts through some element if the mesh is uniform. In this paper, we present an analysis on such discretization errors for various boundary value problems. We first establish the estimates under the mere assumption that the original domain is Lipschitz. We then assume the domain boundary is smoothly curved, and we establish sharp estimates and use the aforementioned regularization/penalty error estimate to determine the balance between the mesh size and the regularization/penalty parameter such that the overall accuracy of the finite element domain embedding method is optimized [20, 19]. We shall see that the balance is rather delicate in some cases.

While the primary objective of this paper is analyzing the accuracy of the finite element domain embedding methods, there is, however, an important question that must be addressed before the methods can be claimed competitive. A domain embedding finite element method results in a discrete system that involves large or small parameters. The question is whether the fast Poisson solver can effectively precondition such a system so that a preconditioned iterative method could converge uniformly with respect to both the finite element mesh sizes and the large/small parameters. While the uniformity of such convergence with respect to the mesh sizes is obvious, the uniformity with respect to the parameters is by no means trivial. We shall not go into details with this issue, but refer to [5] for a strategy to resolve this. This strategy suggests to start the preconditioned iteration with some special initial vectors such that the whole process of the iteration is confined in a subspace in which the parameters have no effect. In our case, we need to choose initial vectors that are zero on the finite element nodes outside the original domain.

In view of the preconditioning, a slight distortion of the uniform mesh is acceptable, as long as the discrete Laplacian on the distorted mesh is spectrally equivalent to that on the uniform mesh. It turns out that no such adjustment is needed for Neumann or Robin problems, since the full accuracy is already achieved by uniform meshes. But for the Dirichlet problem, due to a locking phenomena, the accuracy offered by uniform meshes is rather poor. A slight adjustment of the uniform mesh around the original domain boundary by moving the nearby nodes onto the boundary efficiently reduces the locking effect and renders the full accuracy to the domain embedding finite element method when the domain is convex, or significantly improves the accuracy when the domain is not convex around the concave portion of accuracy.

For simplicity, we only present the results for the Poisson equation defined on a two-dimensional domain and for linear continuous finite elements. The results of this paper are, however, valid for general self-adjoint second order elliptic equations. Similar results can be derived for finite elements of higher orders. The theory is also possible to extend to some higher order equations like those of clamped and free (but not simply supported) plates. In the remainder of this introduction, we briefly

summarize our results and compare them with existing results in the literature.

Let $\omega \subset \mathbb{R}^2$ be a bounded connected domain such that its boundary Γ is of C^2 class [13]. For a given function $f \in L^2(\omega)$, we consider the boundary value problem

$$-\Delta u = f \quad \text{in} \quad \omega$$

subject to the homogeneous Dirichlet boundary condition $u = 0$ on Γ; or the homogeneous Neumann condition $\partial u/\partial n = 0$, with n being the unit outward normal of Γ; or a Robin condition $ku + \partial u/\partial n = 0$, with k being a smooth, bounded, and a strictly positive function on Γ; or a mixed boundary condition. The homogeneity is not a real restriction for Neumann and Robin conditions. A nonhomogeneous Dirichlet condition could be reduced to a homogeneous one by defining a function satisfying the boundary condition and subtracting it from u.

The finite element domain embedding method is based on an approximation to u obtained by solving an ϵ-dependent boundary value problem on a larger rectangular domain $R \subset \mathbb{R}^2$ such that $\omega \subset R$. The formulation of the problem on R depends on the boundary condition in the original problem. The finite element domain embedding method is then a straightforward discretization of the extended one on R with mesh size h. We shall assume that $\omega \subset\subset R$. Then the boundary condition on ∂R is at one's disposal. We impose the homogeneous Dirichlet condition. However, Neumann, Robin, mixed, or a periodical boundary condition on ∂R works equally well. (If $\partial R \cap \Gamma \neq \emptyset$, the condition on ∂R must be subject to some restrictions [24].) We let $\Omega = R \setminus \overline{\omega}$ be the fictitious domain, and we extend the function f to a function $\bar{f}$ on R by defining $\bar{f} = 0$ on Ω. Henceforth, we shall use the notation $\mathcal{P} \lesssim \mathcal{Q}$, which means that there exists a constant C independent of $\mathcal{P}$, $\mathcal{Q}$, ϵ, and h such that $\mathcal{P} \leq C\mathcal{Q}$. The notation $\mathcal{P} \simeq \mathcal{Q}$ means $\mathcal{P} \lesssim \mathcal{Q}$ and $\mathcal{Q} \lesssim \mathcal{P}$. We use $H^s(D)$ to denote the L^2-based Sobolev space of order s on a domain D, in which the norm and semi-norm are denoted by $\|\cdot\|_{s,D}$ and $|\cdot|_{s,D}$, respectively. In particular, the L^2 norm is denoted by $\|\cdot\|_{0,D}$ or $|\cdot|_{0,D}$.

We start with the Neumann problem of which the weak formulation seeks $u \in H^1(\omega)/\mathbb{R}$ such that

$$(\nabla u, \nabla v)_{[L^2(\omega)]^2} = \int_\omega f v dx \quad \forall\ v \in H^1(\omega). \tag{1.1}$$

Here ∇ is the gradient operator, and the parentheses stand for the inner products in Hilbert spaces indicated by the subscripts. This problem is well posed under the assumption that $\int_\omega f dx = 0$. For $\epsilon > 0$, we determine that $u^\epsilon \in H_0^1(R)$ by a regularization such that

$$(\nabla u^\epsilon, \nabla v)_{[L^2(\omega)]^2} + \epsilon(\nabla u^\epsilon, \nabla v)_{[L^2(\Omega)]^2} = \int_R \bar{f} v dx \quad \forall\ v \in H_0^1(R). \tag{1.2}$$

This is an elliptic problem that yields a unique $u^\epsilon \in H_0^1(R)$. As $\epsilon \to 0$, u^ϵ converges to a limit $u^0 \in H_0^1(R)$ at the sharp rate of ϵ as long as ω is a Lipschitz domain (which is assured by our assumption on Γ). The limit u^0 is harmonic on Ω, and $u^0|_\omega$ solves the Neumann problem (1.1). The equivalent estimate [24]

$$\|u^\epsilon - u^0\|_{1,R} \simeq |u^\epsilon - u^0|_{1,\omega} \simeq \epsilon$$

holds with the rare exception that $u^\epsilon \equiv u^0$, which occurs if and only if $u^0 = 0$ on Γ, i.e., a solution of the homogeneous Neumann problem also satisfies the homogeneous

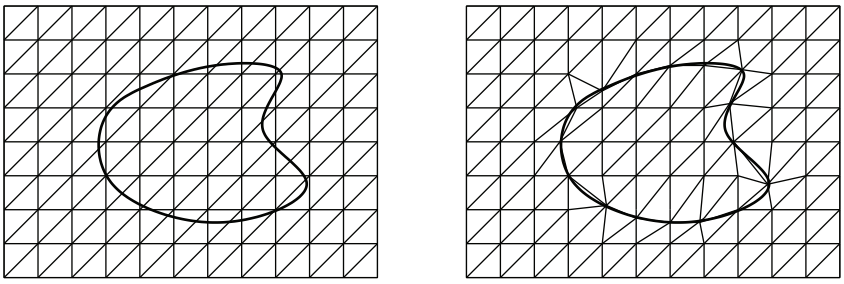

FIG. 1. *A domain ω embedded in a rectangle R with a uniform triangulation (left), and a triangulation adjusted around Γ (right).*

Dirichlet condition on Γ. Incidentally, this is also equivalent to $u^0 \in H^2(R)$. In this case, we can take $\epsilon = 1$ in (1.2), and the Poisson equation on R produces the exact solution of the original equation on ω. Except for this special case, we do not have $u^0 \in H^2(R)$, since there is a jump in its normal derivative across Γ.

We introduce a uniform triangulation of mesh size h on R; see Figure 1 (left), and let $H_h \subset H_0^1(R)$ be the subspace of piecewise linear continuous functions subordinate to this triangulation. The finite element domain embedding method is a straightforward discretization of (1.2). It determines $u_h^\epsilon \in H_h$ such that

$$(\nabla u_h^\epsilon, \nabla v_h)_{[L^2(\omega)]^2} + \epsilon(\nabla u_h^\epsilon, \nabla v_h)_{[L^2(\Omega)]^2} = \int_R \bar{f} v_h dx \quad \forall\ v \in H_h. \tag{1.3}$$

Then the restriction of u_h^ϵ on ω is the numerical solution offered by the finite domain embedding method. We prove that

$$|u_h^\epsilon - u^0|_{1,\omega} \lesssim \epsilon + \inf_{v_h \in H_h} \left(|u^0 - v_h|_{1,\omega} + \sqrt{\epsilon}|u^0 - v_h|_{1,\Omega} \right).$$

This estimate is valid as long as ω is a Lipschitz domain. When $\Gamma \in C^2$, we have the piecewise smoothness property of u^0 such that $u^0|_\omega \in H^2(\omega)$ and $u^0|_\Omega \in H^2(\Omega)$. Using this regularity, we construct an interpolation v_h of u^0 such that $|u^0 - v_h|_{1,\omega} \lesssim h$ and $|u^0 - v_h|_{1,\Omega} \lesssim \sqrt{h}$; thus to prove that

$$|u_h^\epsilon - u^0|_{1,\omega} \lesssim \epsilon + h + \sqrt{\epsilon\, h}. \tag{1.4}$$

From this we see that when $\epsilon \lesssim h$, we have a domain embedding finite element method that achieves the full accuracy of linear continuous finite elements with an error of $\mathcal{O}(h)$. This result is better than that of [14, 15], in which an estimate of the form $\sqrt{\epsilon} + h + \sqrt{\epsilon}$, instead of that in (1.4), was established. They, therefore, require $\epsilon = Ch^2$ to achieve the full accuracy. Taking smaller ϵ does not hurt the accuracy of the finite element domain embedding methods. From a computational point of view, one would like to avoid very small ϵ. In this sense, $\epsilon = Ch$ seems the best choice.

The piecewise smoothness of u^0 is a consequence of the assumption that $\Gamma \in C^2$ and $f \in L^2(\omega)$ [13]. It is not valid when ω is a polygon, since either $u^0|_\omega \in H^2(\omega)$ or $u^0|_\Omega \in H^2(\Omega)$ will be broken, depending on the convexity of ω. However, when ω is convex and Γ aligns with the mesh line, as assumed in [17], the result (1.4) remains valid, which needs a different argument.

If we fix h and let $\epsilon \to 0$, we have $u_h^\epsilon \to u_h^0 \in H_h$. The restriction of the limit u_h^0 on ω is identical to the solution given by a method proposed by Friedrichs and Keller

in 1966 [12], of which an analogue for the Robin problem (see below) was used in the 1980s by the Boeing program `tranair` to circumvent the mesh generation problem around a complete aircraft and was also included in the software `freefem3d` [11]. The positive value of ϵ renders to the equation (1.3) the advantages of better data structure and faster resolution by using fast Poisson solvers on the rectangle R as preconditioners. This method also offers an alternative of dealing with the singularity of a discretized Neumann problem. See [6], where a survey of such various techniques can be found.

The weak formulation of the Robin problem seeks $u \in H^1(\omega)$ such that

$$(\nabla u, \nabla v)_{[L^2(\omega)]^2} + (ku, v)_{L^2(\Gamma)} = \int_\omega f v dx \quad \forall\ v \in H^1(\omega). \tag{1.5}$$

This equation can be extended to R in the following way. We determine $u^\epsilon \in H_0^1(R)$ such that

$$(\nabla u^\epsilon, \nabla v)_{[L^2(\omega)]^2} + (ku^\epsilon, v)_{L^2(\Gamma)} + \epsilon(\nabla u^\epsilon, \nabla v)_{[L^2(\Omega)]^2} = \int_R \bar{f} v dx \quad \forall\ v \in H_0^1(R). \tag{1.6}$$

This, once again, is a well-defined problem on R, and $\lim_{\epsilon \to 0} u^\epsilon = u^0 \in H_0^1(R)$. The limit u^0 is harmonic on Ω, and $u^0|_\omega$ solves the Robin problem (1.5). The equivalent estimate

$$\|u^\epsilon - u^0\|_{1,R} \simeq \|u^\epsilon - u^0\|_{1,\omega} + \|u^\epsilon - u^0\|_{0,\Gamma} \simeq \epsilon \tag{1.7}$$

holds as long as ω is Lipschitz [24]. There is an exception to the equivalent estimate (1.7) in which $u^\epsilon \equiv u^0$. This happens if and only if $u^0 = 0$ on Γ. This is the only case in which $u^0 \in H^2(R)$. Otherwise, u^0 has only the piecewise smoothness as for the Neumann problem. The finite element domain embedding method that determines $u_h^\epsilon \in H_h$ is a straightforward discretization of (1.6) on a uniform mesh. Using the very same argument as for Neumann problem, we obtain that

$$\|u_h^\epsilon - u^0\|_{1,\omega} \lesssim \epsilon + h + \sqrt{\epsilon\, h}.$$

The weak formulation of the Dirichlet problem seeks $u \in H_0^1(\omega)$ such that

$$(\nabla u, \nabla v)_{[L^2(\omega)]^2} = \int_\omega f v dx \quad \forall\ v \in H_0^1(\omega).$$

If ω is simply connected, then, on the continuous level, the domain embedding method determines $u^\epsilon \in H_0^1(R)$ such that

$$(\nabla u^\epsilon, \nabla v)_{[L^2(\omega)]^2} + \epsilon^{-1}(\nabla u^\epsilon, \nabla v)_{[L^2(\Omega)]^2} = \int_R \bar{f} v dx \quad \forall\ v \in H_0^1(R). \tag{1.8}$$

We have that $\lim_{\epsilon \to 0} u^\epsilon = u^0 \in H_0^1(R)$, that the limit is characterized by $u^0|_\omega = u$ and $u^0|_\Omega = 0$, and that the equivalent estimate

$$\|u^\epsilon - u^0\|_{1,R} \simeq \|u^\epsilon\|_{1,\Omega} \simeq \epsilon \tag{1.9}$$

holds, under the assumption that Ω is Lipschitz [24]. (This is true since we have assumed $\Gamma \in C^2$ and $\omega \subset\subset R$; it is also true when, for example, a L-shaped polygon is tightly embedded in a rectangle. It, however, is not true when a circular domain

is tightly embedded in a square.) Furthermore, if we let $u^1 \in H_0^1(R)$ be the unique function determined by $\Delta u^1 = 0$ in ω, and let

$$(\nabla u^1, \nabla v)_{[L^2(\Omega)]^2} = \int_\omega f v dx - (\nabla u^0, \nabla v)_{[L^2(\omega)]^2} \quad \forall\ v \in H_0^1(R). \tag{1.10}$$

Then we have

$$\|u^\epsilon - u^0 - \epsilon\, u^1\|_{1,R} \simeq \epsilon^2\,. \tag{1.11}$$

An exception to (1.9) and (1.11) is that $u^\epsilon \equiv u^0$ and $u^1 = 0$. This occurs if and only if u also satisfies the homogeneous Neumann condition on Γ. This is equivalent to, say, $u^0 \in H^2(R)$. Except for this special case, we do not have $u^0 \in H^2(R)$, since the normal derivative of u^0 is not continuous across Γ.

The finite element domain embedding method determines $u_h^\epsilon \in H_h$ such that

$$(\nabla u_h^\epsilon, \nabla v_h)_{[L^2(\omega)]^2} + \epsilon^{-1}(\nabla u_h^\epsilon, \nabla v_h)_{[L^2(\Omega)]^2} = \int_R \bar{f} v_h dx \quad \forall\ v \in H_h. \tag{1.12}$$

We prove that

$$\begin{aligned}\|u_h^\epsilon - u\|_{1,\omega} \lesssim \epsilon + \inf_{v_h^1 \in H_h} \left(\epsilon\, \|u^1 - v_h^1\|_{1,\omega} + \sqrt{\epsilon}\|u^1 - v_h^1\|_{1,\Omega}\right) \\ + \inf_{v_h^0 \in H_h} \left(\|u^0 - v_h^0\|_{1,\omega} + \frac{1}{\sqrt{\epsilon}}\|v_h^0\|_{1,\Omega}\right).\end{aligned} \tag{1.13}$$

We construct a v_h^1 to interpolate u^1 in the same way as interpolating u^0 in a Neumann problem and bound the above second term by $\epsilon\sqrt{h} + h\sqrt{\epsilon}$. Our assumption of $\Gamma \in C^2$ and $f \in L^2(\omega)$ assures us that $u = u^0|_\omega \in H^2(\omega) \cap H_0^1(\omega)$. We construct an interpolation v_h^0 in such a way that it is zero on any open triangular element that is not entirely contained in ω. This makes $\|v_h^0\|_{1,\Omega} = 0$ and $\|u^0 - v_h^0\|_{1,\omega} \lesssim \sqrt{h}$. The above third term is then bounded by $\sqrt{h}$, which is a sharp estimate. We thus have

$$\|u_h^\epsilon - u\|_{1,\omega} \lesssim \epsilon + \epsilon\sqrt{h} + h\sqrt{\epsilon} + \sqrt{h}. \tag{1.14}$$

So the accuracy of the finite element domain embedding method is limited by $\mathcal{O}(\sqrt{h})$, which is assured when $\epsilon \lesssim \sqrt{h}$. The rather low order of accuracy is a kind of locking phenomena that is not unusual in the numerical computation of equations involving large parameters, like the Reissner–Mindlin plate and nearly incompressible elasticity [3].

The accuracy of the finite element domain embedding method for Dirichlet problem can be significantly improved by a slight adjustment of the nodes around Γ. One can move the nearby nodes onto Γ and reconnect some of the affected nodes such that no mesh-line segment has one end in ω and the other in Ω. This way, a polygonal interpolation of Γ will be formed in the mesh; see Figure 1 (right). This can be done by using Börger's algorithm [7] that results in a triangulation that is quasi uniform and shape regular, on which the discrete Laplacian is spectrally equivalent to that on the uniform mesh. On the adjusted triangulation, we then construct v_h^0 by simply interpolating u^0 at all of the nodes. When ω is convex, we have $\|u^0 - v_h^0\|_{1,\omega} \lesssim h$; see [10], and $\|v_h^0\|_{1,\Omega} = 0$ in (1.13). Thus, to obtain the estimate

$$\|u_h^\epsilon - u\|_{1,\omega} \lesssim \epsilon + \epsilon\sqrt{h} + h\sqrt{\epsilon} + h. \tag{1.15}$$

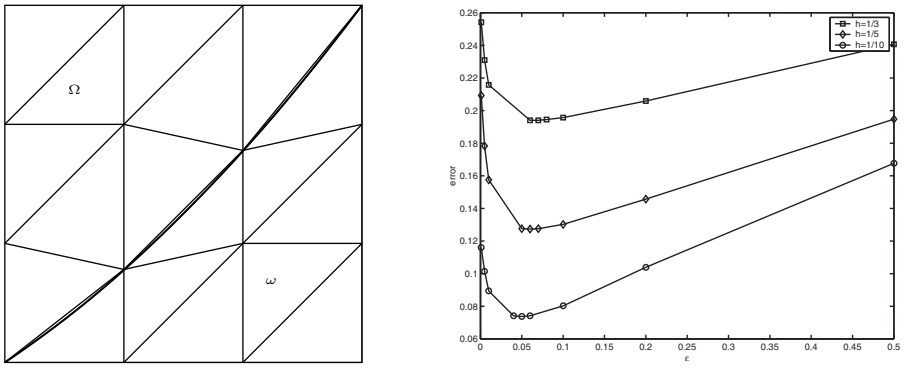

FIG. 2. *A nonconvex ω embedded in the unit square with adjusted mesh around its boundary (left), and the dependence of the error on ϵ and h (right).*

So when $\epsilon \lesssim h$ the error of the finite element domain embedding method in the $H^1(\omega)$ norm is of the optimal order $\mathcal{O}(h)$. If ω is not convex, we still have $\|u^0 - v_h^0\|_{1,\omega} \lesssim h$. However, $\|v_h^0\|_{1,\Omega}$ is no longer zero, but it is bounded by $\mathcal{O}(h)$. The error estimate becomes

$$\|u_h^\epsilon - u\|_{1,\omega} \lesssim \epsilon + \epsilon\sqrt{h} + h\sqrt{\epsilon} + h + \frac{h}{\sqrt{\epsilon}}. \tag{1.16}$$

This estimate is also sharp. The dependence of the error of a finite element domain embedding method on h and ϵ is rather complicated. From the above estimate we see that if we take $\epsilon = Ch^{2/3}$, the domain embedding finite element method has the error estimate $\mathcal{O}(h^{2/3})$ in $H^1(\omega)$ norm. It is interesting to note that, in this case, a smaller ϵ thwarts the convergence rate. This should be compared with the Neumann problem and the Dirichlet problem on convex domains, in which smaller ϵ does not improve but does not hurt the convergence rate of the finite element domain embedding method either. To confirm this observation, we include a numerical example here. We choose R to be the unit square $(0,1) \times (0,1)$ on the xy-plane, in which ω is the curvilinear triangle under the curved diagonal $y = x(x+2)/3$, which is not convex. The exact solution of the Dirichlet problem with a homogeneous boundary condition is $u(x,y) = [3y - x(x+2)]y(x-1)$. We first divide R by a uniform mesh of mesh size h, and then we move some nodes near the curved boundary of ω onto it to form the adjusted mesh; see Figure 2 (left), in which $h = 1/3$. On this mesh, we perform the computation with the method (1.12). Figure 2 (right) shows the dependence of $|u - u_h^\epsilon|_{1,\omega}$ on ϵ for $h = 1/3$, $1/5$, and $1/10$, respectively. It clearly shows that there is an optimal value of ϵ for each h, which decreases with h, and smaller ϵ thwarts the accuracy.

In conclusion, a slight adjustment of the finite element mesh to accommodate Γ appears to be worthwhile for the Dirichlet problem, which enhances the convergence rate from $\sqrt{h}$ to h if ω is convex, and from $\sqrt{h}$ to $h^{2/3}$ if ω is not convex.

It is important to note that the discrete system (1.12) based on such adjusted mesh can be efficiently preconditioned by using the discrete Laplacian on the uniform mesh with the preconditioned iteration initiated with a vector of zero entries corresponding to nodes in $R \setminus \omega$ [7, 5]. If one wishes to achieve full accuracy for nonconvex ω, then the mesh could be refined around the concave portion of Γ. A local mesh size $\mathcal{O}(h^{1.5})$ would lead to the full accuracy of the order $\mathcal{O}(h)$ of the domain embedding finite

element method in which $\epsilon = Ch$. This refinement is needed only around the concave portion of the boundary of ω. See [18] for such an example.

If ω is polygonal and Γ aligns with the finite element mesh, then if $u^0|_\omega \in H^2(\omega)$ (which is true when ω is a convex polygon, but is only an assumption otherwise), we construct v_h^0 and v_h^1 by nodal interpolation to u^0 and u^1 in (1.13) to obtain the estimate

$$\|u_h^\epsilon - u\|_{1,\omega} \lesssim \epsilon + \epsilon\sqrt{h} + \sqrt{\epsilon\, h} + h. \tag{1.17}$$

Here we have used the fact that $u^1|_\omega \in H^{1.5}(\omega)$ and $u^1|_\Omega \in H^{1.5}(\Omega)$ [16]. Thus when $\epsilon \lesssim h$, one has a domain embedding finite element method that has the optimal accuracy of $\mathcal{O}(h)$. This was mentioned in [17], where a rigorous analysis was presented for the Neumann problem under this alignment assumption.

If ω is not simply connected, a term like $\epsilon^{-1}(u^\epsilon, v)_{L^2(\Omega)}$ needs to be added to the left-hand side of (1.8). Then the estimate (1.9) holds, and $u^0|_\omega = u$ regardless of the connectivity of ω. Actually, in case that ω is multiply connected, adding a term of the form $\epsilon^{-1}(u^\epsilon, v)_{L^2(\Omega^0)}$ in the left-hand side of (1.8) is sufficient to guarantee the validity of the domain embedding method on the continuous level. Here Ω^0 is the union of the isolated components of Ω. The finite element domain embedding methods should then be based on such a modification of (1.8).

Finally, we make some remarks on the mixed boundary value problem. To make the presentation sufficiently general, we assume that Γ is split into three parts such that $\Gamma = \overline{\Gamma}_D \cup \overline{\Gamma}_N \cup \overline{\Gamma}_R$, and on Γ_D, Γ_N, and Γ_R, homogeneous Dirichlet, Neumann, and Robin conditions are imposed, respectively. Corresponding to this splitting, we divide Ω into three parts such that $\overline{\Omega} = \overline{\Omega}_D \cup \overline{\Omega}_N \cup \overline{\Omega}_R$, and $\partial\Omega_D \cap \Gamma = \overline{\Gamma}_D$, $\partial\Omega_N \cap \Gamma = \overline{\Gamma}_N$, and $\partial\Omega_R \cap \Gamma = \overline{\Gamma}_R$. The weak formulation of the mixed problem determines $u \in H_D^1(\omega)$ (that is, the space of $H^1(\omega)$ functions that vanish on Γ_D) such that

$$(\nabla u, \nabla v)_{[L^2(\omega)]^2} + (ku, v)_{L^2(\Gamma_R)} = \int_\omega f v dx \quad \forall\ v \in H_D^1(\omega). \tag{1.18}$$

On the continuous level, the domain embedding method determines that $u^\epsilon \in H_0^1(R)$ such that

$$\begin{aligned}(\nabla u^\epsilon, \nabla v)_{[L^2(\omega)]^2} &+ (ku^\epsilon, v)_{L^2(\Gamma_R)} \\ &+ \epsilon^{-1}(\nabla u^\epsilon, \nabla v)_{[L^2(\Omega_D)]^2} + \epsilon(\nabla u^\epsilon, \nabla v)_{[L^2(\Omega\setminus\overline{\Omega}_D)]^2} = \int_R \bar{f} v dx \quad \forall\ v \in H_0^1(R).\end{aligned} \tag{1.19}$$

When $\epsilon \to 0$, u^ϵ converges to a limit $u^0 \in H_0^1(R)$. The limit satisfies (1) $u^0|_\omega$ solves (1.18) (assuming ω is simply connected), (2) $u^0 = 0$ on Ω_D, and (3) u^0 is harmonic on Ω_N and Ω_R. Under the assumption that *both* Ω_D *and* $\omega \cup \Gamma_D \cup \Omega_D$ *are Lipschitz domains*, the equivalent estimate

$$\|u^\epsilon - u^0\|_{1,R} \simeq \|u^\epsilon - u^0\|_{1,\omega} + \|u^\epsilon\|_{1,\Omega_D} \simeq \epsilon \tag{1.20}$$

holds, with the exception that $u^\epsilon \equiv u^0$, which occurs when and only when $u^0 \in H^2(R)$ [23]. The finite element domain embedding method then is again a straightforward discretization of (1.18) that determines $u_h^\epsilon \in H_h$ such that

$$\begin{aligned}(\nabla u_h^\epsilon, \nabla v_h)_{[L^2(\omega)]^2} &+ (ku_h^\epsilon, v_h)_{L^2(\Gamma_R)} \\ &+ \epsilon^{-1}(\nabla u_h^\epsilon, \nabla v_h)_{[L^2(\Omega_D)]^2} + \epsilon(\nabla u_h^\epsilon, \nabla v_h)_{[L^2(\Omega\setminus\overline{\Omega}_D)]^2} = \int_R \bar{f} v_h dx \quad \forall\ v_h \in H_h.\end{aligned} \tag{1.21}$$

The convergence rate estimates on $\|u^0 - u_h^\epsilon\|_{1,\omega}$ can be obtained under some regularity assumption on the solution of the original problem (1.18), which is not guaranteed by our assumptions on Γ and f. For uniform meshes, Γ_D generally cuts through some elements, and the ends of Γ_D lie in the interior of some elements; the rate is only bounded by $\sqrt{h}$. By moving nearby nodes onto Γ_D and its ends, and reconnecting some mesh lines, as for the Dirichlet problem, we can improve the convergence rate to $\mathcal{O}(h)$ or $\mathcal{O}(h^{2/3})$, depending on the convexity of Γ_D with respect to ω. As for Neumann and Robin problems, no treatment is needed to accommodate Γ_N or Γ_R.

The paper is organized as follows. In section 2, as a preparation, we derive some estimates on the finite element interpolation error on a strip around Γ that cuts through some elements. We also include a result about the ϵ-dependent variational problem, which is a cornerstone in estimating the regularization/penalty error. This result is also needed in the discretization error estimate for the Dirichlet problem. In section 3, we estimate the error of the finite element domain embedding methods for Neumann and Dirichlet problems, and we determine the balance between the value of the regularization/penalty parameter and the finite element mesh size. Since no new technique is needed for the Robin problem and the mixed problem, we shall not go into details to prove the results mentioned above.

2. Technical preliminaries. We need to estimate the error of piecewise linear interpolation to functions whose restriction on both ω and Ω are in H^2, but the functions themselves do not belong to $H^2(R)$. Their normal derivatives are not continuous across the curve Γ, and Γ cuts through some of the triangular elements. For this purpose we need to estimate the H^1 norms on thin strips of piecewise H^2 functions and their finite element interpolations. The following lemmas will be used in the next section.

Let $y = \gamma(x)$ be a C^2 function on $[0, L]$. We consider a strip domain γ_δ that is bounded by $x = 0$, $x = L$, $y = \gamma(x)$, and $y = \gamma(x) + \delta$; see Figure 3. We assume that D is a given domain such that $\gamma_\delta \subset\subset D$. We have the following estimates on functions restricted on γ_δ.

LEMMA 2.1. *Let $w \in H^1(D)$. Then we have that*

$$\|w\|^2_{L^2(\gamma_\delta)} \le C\delta \|w\|^2_{1,D}.$$

Here, C is a constant independent of δ and w.

Proof. In terms of the curvilinear coordinates $X = x, Y = y - \gamma(x)$, we have that $\|w\|^2_{0,\gamma_\delta} \simeq \int_0^\delta \int_0^L w^2 dX dY$. For each $Y \in (0, \delta)$, by a trace theorem [1], we have that $\int_0^L w^2 dX \le C\|w\|^2_{1,D}$. The constant C can be chosen to be independent of Y. Integrating this estimate, with respect to Y from 0 to δ, gives the desired estimate. ∎

From this result, the following lemma easily follows.

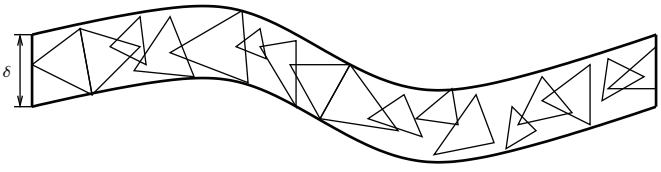

FIG. 3. *A strip γ_δ with a cluster of shape regular triangles.*

LEMMA 2.2. *Let $w \in H^2(D)$. Then we have that*

$$\|w\|^2_{1,\gamma_\delta} \le C\delta \|w\|^2_{2,D}.$$

Here, C is independent of δ and w.

LEMMA 2.3. *Let $\mathcal{T}_\delta$ be the set of a cluster of shape regular, but not necessarily quasi uniform, open triangles contained in γ_δ, and suppose that any point in γ_δ can only be covered by at most a certain number of triangles in $\mathcal{T}_\delta$. Let $w \in H^2(D)$. For each $\tau \in \mathcal{T}_\delta$, we let $I_\tau w$ be the linear interpolation of w on the vertices of τ. Then we have that*

$$\sum_{\tau \in \mathcal{T}_\delta} |I_\tau w|^2_{1,\tau} \le C\delta \|w\|^2_{2,D}.$$

Here, C is a constant independent of δ and w.

Proof. Let $\tau \in \mathcal{T}_\delta$ be one such triangle. We affine map it onto a standard reference triangle T of unit size through the mapping F_τ. The restriction on τ of a function $w \in H^2(D)$ is mapped to a function $\hat{w}$ on T such that $\hat{w} \circ F_\tau = w$. Let I be the linear interpolation operator on the vertices of T. For any constant p_0, we have that

$$|I_\tau w|^2_{1,\tau} = |I_\tau(w - p_0)|^2_{1,\tau} \le C|I(\hat{w} - p_0)|^2_{1,T} \le C\|\hat{w} - p_0\|^2_{L^\infty(T)} \le C\|\hat{w} - p_0\|^2_{2,T}.$$

Thus, by the Bramble–Hilbert Lemma

$$|I_\tau w|^2_{1,\tau} \le C(|\hat{w}|^2_{1,T} + |\hat{w}|^2_{2,T}).$$

Scaling the right-hand side back from T to τ, we get that

$$|I_\tau w|^2_{1,\tau} \le C(|w|^2_{1,\tau} + h^2_\tau |w|^2_{2,\tau}).$$

Here h_τ is the diameter of τ, which does not exceed δ. Summing up the above inequality for all triangles in the cluster $\mathcal{T}_\delta$, we get that

$$\sum_{\tau \in \mathcal{T}_\delta} |I_\tau w|^2_{1,\tau} \le C \sum_{\tau \in \mathcal{T}_\delta} |w|^2_{1,\tau} + C\delta^2 \sum_{\tau \in \mathcal{T}_\delta} |w|^2_{2,\tau} \le C|w|^2_{1,\gamma_\delta} + C\delta^2 |w|^2_{2,\gamma_\delta}.$$

In the last step, we used the assumption that any point in γ_δ can only be covered by at most a certain number of triangles in $\mathcal{T}_\delta$. The desired result follows from Lemma 2.2. ∎

We shall apply these estimates to strips that can be covered by a finite number of (translated and rotated) strips as defined here. The strips of width δ referred to in the later sections are understood in this sense.

As we mentioned in the introduction, there are two sources of errors in the finite element domain embedding methods. The first one is due to the extension of the original boundary value problem from ω to R. The sharp estimates on this kind of error can be obtained by using the following equivalent estimates on an abstract ϵ-dependent equation. This estimate will also be directly used in estimating the finite element interpolation error for the Dirichlet problem in the next section.

Let H, U, and V be Hilbert spaces, $A : H \to U$ be a bounded linear operator, and let $B : H \to V$ be a bounded linear operator *with closed range*. We assume that

$$\|A\boldsymbol{v}\|_U + \|B\boldsymbol{v}\|_V \simeq \|\boldsymbol{v}\|_H \quad \forall\ \boldsymbol{v} \in H. \tag{2.1}$$

Thus the bilinear form

$$(\boldsymbol{u},\boldsymbol{v})_{\mathcal{H}} := (A\boldsymbol{u},A\boldsymbol{v})_U + (B\boldsymbol{u},B\boldsymbol{v})_V$$

defines an equivalent inner product on H. Furnished with this new inner product, the space H will be denoted by $\mathcal{H}$. Let $\ker B \subset H$ be the kernel of the operator B. Let $\boldsymbol{f}$ be a linear continuous functional on H such that $\boldsymbol{f}|_{\ker B} = 0$. There is a unique $\boldsymbol{u}^\epsilon \in H$ such that

$$\epsilon(A\boldsymbol{u}^\epsilon, A\boldsymbol{v})_U + (B\boldsymbol{u}^\epsilon, B\boldsymbol{v})_V = \langle \boldsymbol{f},\boldsymbol{v}\rangle \ \forall \boldsymbol{v} \in H. \tag{2.2}$$

Without loss of generality, we assume that the operator B maps H onto V. (If necessary, we replace V by the range of B in it.) Then B is an isomorphism between $(\ker B)^\perp_{\mathcal{H}}$ (the orthogonal complement of $\ker B$ with respect to the $\mathcal{H}$-norm) and V. Since we have assumed that $\boldsymbol{f}|_{\ker B} = 0$, according the the closed range theorem and the Riesz representation theorem, there exists a unique $\boldsymbol{u}^0 \in (\ker B)^\perp_{\mathcal{H}}$ such that

$$(B\boldsymbol{u}^0, B\boldsymbol{v})_V = \langle \boldsymbol{f},\boldsymbol{v}\rangle \ \ \forall\ \boldsymbol{v} \in H. \tag{2.3}$$

LEMMA 2.4. *Under the assumptions that $\boldsymbol{f}|_{\ker B} = 0$ and B has a closed range in V as $\epsilon \to 0$, $\boldsymbol{u}^\epsilon$, the solution of (2.2) converges to the limit $\boldsymbol{u}^0 \in (\ker B)^\perp_{\mathcal{H}}$ defined by (2.3), and we have the equivalence estimate*

$$\|\boldsymbol{u}^\epsilon - \boldsymbol{u}^0\|_H \simeq \|B(\boldsymbol{u}^\epsilon - \boldsymbol{u}^0)\|_V \simeq \epsilon\,\|A\boldsymbol{u}^0\|_U. \tag{2.4}$$

Therefore, if $A\boldsymbol{u}^0 = 0$, then $\boldsymbol{u}^\epsilon \equiv \boldsymbol{u}^0$. Otherwise $\boldsymbol{u}^\epsilon$ converges to $\boldsymbol{u}^0$ at the sharp rate of ϵ.

Proof. From (2.2) and (2.3), we see that

$$\epsilon(A(\boldsymbol{u}^\epsilon - \boldsymbol{u}^0), A\boldsymbol{v})_U + (B(\boldsymbol{u}^\epsilon - \boldsymbol{u}^0), B\boldsymbol{v})_V = -\,\epsilon(A\boldsymbol{u}^0, A\boldsymbol{v})_U \ \forall \boldsymbol{v} \in H. \tag{2.5}$$

Taking $\boldsymbol{v} = \boldsymbol{u}^\epsilon - \boldsymbol{u}^0$, we get that

$$\epsilon\,\|A(\boldsymbol{u}^\epsilon - \boldsymbol{u}^0)\|_U^2 + \|B(\boldsymbol{u}^\epsilon - \boldsymbol{u}^0)\|_V^2 = -\,\epsilon(A\boldsymbol{u}^0, A(\boldsymbol{u}^\epsilon - \boldsymbol{u}^0))_U. \tag{2.6}$$

It is easy to see that $\boldsymbol{u}^\epsilon$ lies in the subspace $(\ker B)^\perp_{\mathcal{H}}$. So does $\boldsymbol{u}^\epsilon - \boldsymbol{u}^0$. Because B is an isomorphism between $(\ker B)^\perp_{\mathcal{H}}$ and V, we have that

$$\|A(\boldsymbol{u}^\epsilon - \boldsymbol{u}^0)\|_U \lesssim \|\boldsymbol{u}^\epsilon - \boldsymbol{u}^0\|_H \simeq \|B(\boldsymbol{u}^\epsilon - \boldsymbol{u}^0)\|_V. \tag{2.7}$$

By the Cauchy–Schwarz inequality, there exists a constant C such that

$$|\,\epsilon(A\boldsymbol{u}^0, A(\boldsymbol{u}^\epsilon - \boldsymbol{u}^0))_U| \le C\,\epsilon^2\,\|A\boldsymbol{u}^0\|_U^2 + \frac{1}{2}\|B(\boldsymbol{u}^\epsilon - \boldsymbol{u}^0)\|_V^2.$$

This estimate and the equation (2.6) show that

$$\|B(\boldsymbol{u}^\epsilon - \boldsymbol{u}^0)\|_V \lesssim \epsilon\,\|A\boldsymbol{u}^0\|. \tag{2.8}$$

The equivalence (2.1) and (2.7) then lead to $\|\boldsymbol{u}^\epsilon - \boldsymbol{u}^0\|_H \lesssim \epsilon\,\|A\boldsymbol{u}^0\|_U$.

To see the lower bound, in (2.5) we take $\boldsymbol{v} = \boldsymbol{u}^0$ to get

$$\epsilon(A(\boldsymbol{u}^\epsilon - \boldsymbol{u}^0), A\boldsymbol{u}^0)_U + (B(\boldsymbol{u}^\epsilon - \boldsymbol{u}^0), B\boldsymbol{u}^0)_V = -\,\epsilon\,\|A\boldsymbol{u}^0\|_U^2.$$

If $A\boldsymbol{u}^0 \neq 0$, then

$$\epsilon\,\|A\boldsymbol{u}^0\|_U \lesssim \epsilon\,\|A(\boldsymbol{u}^\epsilon - \boldsymbol{u}^0)\|_U + \frac{\|B\boldsymbol{u}^0\|_V}{\|A\boldsymbol{u}^0\|_U}\|B(\boldsymbol{u}^\epsilon - \boldsymbol{u}^0)\|_V \lesssim \|B(\boldsymbol{u}^\epsilon - \boldsymbol{u}^0)\|_V.$$

The equivalence (2.4) then follows. ∎

3. Analysis of domain embedding methods. In this section, we derive the error estimates for the finite element domain embedding methods for various boundary conditions, as described in the Introduction. The main issues appear in Neumann and Dirichlet boundary value problems. In subsection 3.1, we analyze the Neumann problem and assume that the grid on R is uniform. However, all of the results hold for shape regular triangulations. We analyze the Dirichlet problem with uniform mesh in subsection 3.2. The results of this subsection motivate mesh adjustment around Γ for the Dirichlet problem, to which we devote subsection 3.4.

3.1. Neumann boundary condition. We first consider the Neumann problem. Let $\omega \subset \mathbb{R}^2$ be a bounded domain whose boundary Γ is in the C^2 class. Let $f \in L^2(\omega)$. We seek a function u on ω solving the homogeneous Neumann problem whose weak formulation seeks $u \in H^1(\omega)/\mathbb{R}$ such that

$$(\nabla u, \nabla v)_{[L^2(\omega)]^2} = \int_\omega f v dx \quad \forall\ v \in H^1(\omega). \tag{3.1}$$

We assume that $\int_\omega f(x)dx = 0$, so that this is well posed in the quotient space $H^1(\omega)/\mathbb{R}$.

Let $R \subset \mathbb{R}^2$ be a larger rectangular domain such that $\omega \subset\subset R$. Let $\Omega = R \setminus \overline{\omega}$ be the fictitious domain. We extend the function f to a function $\bar{f}$ on R by defining $\bar{f} = 0$ on Ω. The first step in the finite element domain embedding method is replacing (3.1) by the following problem defined on the rectangle R. For $\epsilon > 0$, one determines $u^\epsilon \in H_0^1(R)$ such that

$$(\nabla u^\epsilon, \nabla v)_{[L^2(\omega)]^2} + \epsilon(\nabla u^\epsilon, \nabla v)_{[L^2(\Omega)]^2} = \int_R \bar{f} v dx \ \forall\ v \in H_0^1(R). \tag{3.2}$$

This equation fits in the form of (2.2) in an obvious manner. The condition that B has closed range is assured as long as ω is a Lipschitz domain. All of the other conditions of Lemma 2.4 are also satisfied; see [24] for details. We have that $\lim_{\epsilon\to 0} u^\epsilon = u^0$. The limit $u^0 \in H_0^1(R)$ is characterized by the following two equations:

$$(\nabla u^0, \nabla v)_{[L^2(\omega)]^2} = \int_\omega f v dx \quad \forall\ v \in H^1(\omega), \tag{3.3}$$

i.e., the restriction of u^0 on ω solves the Neumann problem (3.1), and

$$\Delta u^0 = 0 \text{ in } \Omega, \quad \left\langle \frac{\partial u^0}{\partial n^-}, 1 \right\rangle_{H^{-1/2}(\Gamma)\times H^{1/2}(\Gamma)} = 0. \tag{3.4}$$

Here n^- is the outward normal to Γ viewed as a boundary of Ω. By Lemma 2.4 we have that

$$\|u^\epsilon - u^0\|_{1,R} \simeq |u^\epsilon - u^0|_{1,\omega} \simeq \epsilon\, |u^0|_{1,\Omega}. \tag{3.5}$$

It is easy to see that $|u^0|_{1,\Omega} = 0$ if and only if $u^0 = 0$ on Γ, in which case $u^\epsilon \equiv u^0$. This is the exceptional case in which $u^0 \in H^2(R)$. Generally, u^0 is only piecewise smooth, with a normal derivative jump across Γ.

We introduce a uniform triangulation of mesh size h on R; see Figure 1 (left), and let $H_h \subset H_0^1(R)$ be the subspace of piecewise linear continuous functions subordinate to this triangulation. The finite element domain embedding method is a straightforward discretization of (1.2). It determines $u_h^\epsilon \in H_h$ such that

$$(\nabla u_h^\epsilon, \nabla v_h)_{[L^2(\omega)]^2} + \epsilon(\nabla u_h^\epsilon, \nabla v_h)_{[L^2(\Omega)]^2} = \int_R \bar{f} v_h dx \quad \forall\ v \in H_h. \tag{3.6}$$

The numerical approximation of the solution of (3.1) offered by the finite element domain embedding method is the restriction of u_h^ϵ on ω. We have the following theorem.

THEOREM 3.1. *Let $u^0 \in H_0^1(R)$ be the limit of u^ϵ that is determined by the domain embedding equation* (3.2). *Then $u^0|_\omega$ solves the Neumann problem* (3.1). *Let $u_h^\epsilon \in H_h$ be the solution of the finite element domain embedding equation* (3.6). *We have the following estimate on the difference between $u_h^\epsilon|_\omega$ and $u^0|_\omega$:*

$$|u_h^\epsilon - u^0|_{1,\omega} \le C\,\epsilon\,|u^0|_{1,\Omega} + C \inf_{v_h \in H_h} \left(|u^0 - v_h|_{1,\omega} + \sqrt{\epsilon}|u^0 - v_h|_{1,\Omega}\right). \tag{3.7}$$

Here, C is a constant independent of h, ϵ, and f.

Proof. Since u_h^ϵ is the projection of u^ϵ in the subspace H_h with respect to the inner product defined by the bilinear form in the left-hand side of the domain embedding equation (3.2), we have that

$$|u^\epsilon - u_h^\epsilon|_{1,\omega} + \sqrt{\epsilon}|u^\epsilon - u_h^\epsilon|_{1,\Omega} \le |u^\epsilon - v_h|_{1,\omega} + \sqrt{\epsilon}|u^\epsilon - v_h|_{1,\Omega} \quad \forall\, v_h \in H_h.$$

Thus by (3.5)

$$\begin{aligned}
|u^0 - u_h^\epsilon|_{1,\omega} &\le |u^0 - u^\epsilon|_{1,\omega} + |u^\epsilon - u_h^\epsilon|_{1,\omega} \\
&\le \epsilon\,|u^0|_{1,\Omega} + |u^\epsilon - v_h|_{1,\omega} + \sqrt{\epsilon}|u^\epsilon - v_h|_{1,\Omega} \\
&\le \epsilon\,|u^0|_{1,\Omega} + |u^0 - v_h|_{1,\omega} + |u^\epsilon - u^0|_{1,\omega} + \sqrt{\epsilon}|u^0 - v_h|_{1,\Omega} + \sqrt{\epsilon}|u^\epsilon - u^0|_{1,\Omega} \\
&\le (2\,\epsilon + \epsilon^{3/2})|u^0|_{1,\Omega} + |u^0 - v_h|_{1,\omega} + \sqrt{\epsilon}|u^0 - v_h|_{1,\Omega} \quad \forall\, v_h \in H_h.
\end{aligned}$$

The estimate thus follows. ∎

This theorem is valid as long as ω is Lipschitz. Based on this result, we can establish the following error estimate on the finite element domain embedding method for the Neumann problem under our assumptions that $\Gamma \in C^2$ and $f \in L^2(\omega)$. Under these assumptions, by the regularity of elliptic differential equation [13], we have that $u^0|_\omega \in H^2(\omega)$ and $\|u^0\|_{2,\omega} \lesssim \|f\|_{0,\omega}$. Since $u^0|_\Omega$ is harmonic and it shares the value with $u^0|_\omega$ on Γ, we have that $\|u^0\|_{2,\Omega} \lesssim \|u^0\|_{1.5,\Gamma} \lesssim \|u^0\|_{2,\omega} \lesssim \|f\|_{0,\omega}$. We can extend $u^0|_\omega$ to R; see [21], to obtain a function $\bar{u}^0 \in H^2(R)$ such that $\bar{u}^0|_\omega = u^0|_\omega$ and $\|\bar{u}^0\|_{2,R} \lesssim \|u^0\|_{2,\omega}$. Similarly, we extend $u^0|_\Omega$ to R to obtain a function $\underline{u}^0 \in H^2(R)$ such that $\underline{u}^0|_\Omega = u^0|_\Omega$ and $\|\underline{u}^0\|_{2,R} \lesssim \|u^0\|_{2,\Omega}$. Note that $\bar{u}^0|_\Omega \ne u^0|_\Omega$, $\underline{u}^0|_\omega \ne u^0|_\omega$, and $\bar{u}^0 = \underline{u}^0 = u^0$ on Γ.

THEOREM 3.2. *Under the assumption that $\Gamma \in C^2$ and $f \in L^2(\omega)$, there is a positive constant C that is independent of ϵ, h, and f such that the following error estimate of the finite element domain embedding method for the Neumann problems holds:*

$$|u_h^\epsilon - u^0|_{1,\omega} \le C\left(\epsilon + h + \sqrt{\epsilon\,h}\right)\|f\|_{0,\omega}. \tag{3.8}$$

Before proving this theorem, we introduce some notations to describe triangles, vertices, and their relative relations with Γ. Let $\mathcal{T}$ be the set of all the open triangular elements of the finite element partition of R. We divide $\mathcal{T}$ into three distinctive subsets such that $\mathcal{T} = \mathcal{T}_\omega \cup \mathcal{T}_\Gamma \cup \mathcal{T}_\Omega$, and

$$\mathcal{T}_\Gamma = \{\tau \in \mathcal{T}; \tau \cap \Gamma \ne \emptyset\},\ \mathcal{T}_\omega = \{\tau \in \mathcal{T}; \tau \subset \omega\},\ \text{and}\ \mathcal{T}_\Omega = \{\tau \in \mathcal{T}; \tau \subset \Omega\}.$$

Among the triangles of $\mathcal{T}_\omega$, we let $\mathcal{T}_\omega^0$ be the subset of those that share a vertex with some triangle in $\mathcal{T}_\Gamma$, and we define $\mathcal{T}_\Omega^1$ as a subset of $\mathcal{T}_\Omega$ similarly. See Figure 4 in

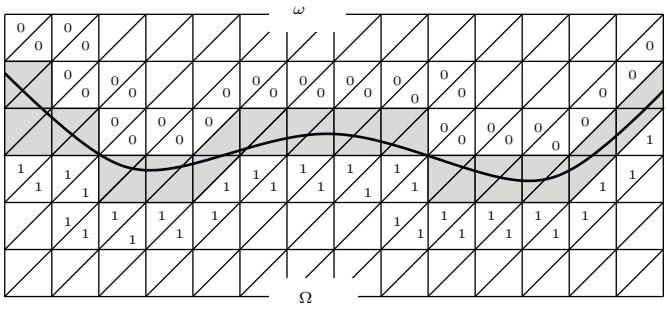

FIG. 4. *A portion of uniform mesh around* Γ.

which triangles in $\mathcal{T}_\Gamma$ are shaded, those in $\mathcal{T}_\omega^0$ are marked by 0, and those in $\mathcal{T}_\Omega^1$ are marked by 1.

With a slight abuse of notations, we shall also use $\mathcal{T}_\Gamma$ to denote the domain formed by the union of all triangles in $\mathcal{T}_\Gamma$, which is the interior of $\cup_{\tau\in\mathcal{T}_\Gamma}\bar{\tau}$. We use $\mathcal{T}$, $\mathcal{T}_\omega$, $\mathcal{T}_\Omega$, $\mathcal{T}_\omega^0$, and $\mathcal{T}_\Omega^1$ in the same way. Thus $\mathcal{T} = R$, and $\omega \subset \overline{\mathcal{T}}_\omega \cup \mathcal{T}_\Gamma$, etc.

Let $\mathcal{V}$ be the set of all the vertices in R of the triangulation. We divide $\mathcal{V}$ into three distinctive subsets such that $\mathcal{V} = \mathcal{V}_\omega \cup \mathcal{V}_\Gamma \cup \mathcal{V}_\Omega$, in which

$$\begin{aligned}\mathcal{V}_\Gamma &= \{\nu \in \mathcal{V}; \nu \text{ is a vertex of a triangle of } \mathcal{T}_\Gamma, \text{ or } \nu \in \Gamma\},\\ \mathcal{V}_\omega &= \{\nu \in \mathcal{V}; \nu \in \omega, \text{ and } \nu \text{ is not a vertex in } \mathcal{V}_\Gamma\},\\ \mathcal{V}_\Omega &= \{\nu \in \mathcal{V}; \nu \in \Omega, \text{ and } \nu \text{ is not a vertex in } \mathcal{V}_\Gamma\}.\end{aligned}$$

Note that $\mathcal{T}_\Gamma$ could be empty, for example, when Γ is straight and aligns with the triangulation, in which case $\mathcal{V}_\Gamma$ is composed of nodes on Γ. We let

$$\begin{aligned}\mathcal{V}_\omega^0 &= \{\nu \in \mathcal{V}_\omega;\ \nu \text{ is a vertex of a triangle in } \mathcal{T}_\omega^0\},\\ \mathcal{V}_\Omega^1 &= \{\nu \in \mathcal{V}_\Omega;\ \nu \text{ is a vertex of a triangle in } \mathcal{T}_\Omega^1\}.\end{aligned}$$

Proof of Theorem 3.2. What we need to do is to construct a finite element interpolation $v_h \in H_h$ to u^0 such that $|u^0 - v_h|_{1,\omega} \lesssim h$ and $|u^0 - v_h|_{1,\Omega} \lesssim \sqrt{h}$. We define v_h by requiring $v_h(\nu) = \bar{u}^0(\nu)$ for $\nu \in \mathcal{V}_\omega \cup \mathcal{V}_\Gamma$, and $v_h(\nu) = u^0(\nu)$ for $\nu \in \mathcal{V}_\Omega$. Note that the defined interpolation interpolates u^0 on all of the vertices except those in $\mathcal{V}_\Gamma \cap \Omega$. By the standard argument of finite element interpolation, we have that

$$|v_h - \bar{u}^0|_{1,\tau}^2 \le Ch^2 |\bar{u}^0|_{2,\tau}^2 \quad \forall\ \tau \in \mathcal{T}_\omega \cup \mathcal{T}_\Gamma.$$

Summing up these estimates, we get that

$$|v_h - \bar{u}^0|_{1,\omega\cup\mathcal{T}_\Gamma}^2 \le Ch^2 |\bar{u}^0|_{2,\omega\cup\mathcal{T}_\Gamma}^2 \le Ch^2 |\bar{u}^0|_{2,R}^2 \le Ch^2 |u^0|_{2,\omega}^2 \le Ch^2 \|f\|_{0,\omega}^2.$$

Thus

$$|v_h - u^0|_{1,\omega}^2 = |v_h - \bar{u}^0|_{1,\omega}^2 \le Ch^2 \|f\|_{0,\omega}^2. \tag{3.9}$$

By the standard argument of finite element interpolation, we have that

$$|v_h - u^0|_{1,\tau}^2 \le Ch^2 |u^0|_{2,\tau}^2 \quad \forall\ \tau \in \mathcal{T}_\Omega \setminus \mathcal{T}_\Omega^1.$$

Summing up, we get that

$$|v_h - u^0|^2_{1,\mathcal{T}_\Omega \setminus \overline{\mathcal{T}}^1_\Omega} \le Ch^2 |u^0|^2_{2,\Omega} \le Ch^2 \|f\|^2_{0,\omega}. \tag{3.10}$$

The remaining part of Ω, i.e., $\mathcal{T}^1_\Omega \cup (\Omega \cap \mathcal{T}_\Gamma)$, is covered by a strip of width $\mathcal{O}(h)$, which meets the definition of a γ_δ of section 2, with $\delta = \mathcal{O}(h)$. Thus, according to Lemma 2.2, we have that

$$|u^0|^2_{1,\mathcal{T}^1_\Omega \cup (\Omega \cap \mathcal{T}_\Gamma)} \le Ch \|\underline{u}^0\|^2_{2,R} \le Ch \|f\|^2_{0,\omega}. \tag{3.11}$$

We are left with estimating $|v_h|^2_{1,\mathcal{T}^1_\Omega \cup (\Omega \cap \mathcal{T}_\Gamma)}$. We consider this separately on $\Omega \cap \mathcal{T}_\Gamma$ and $\mathcal{T}^1_\Omega$. We see that $|v_h|^2_{1,\Omega \cap \mathcal{T}_\Gamma} \le |v_h|^2_{1,\mathcal{T}_\Gamma}$. Since v_h interpolates $\bar{u}^0$ at every vertex of triangles in $\mathcal{T}_\Gamma$, which itself is a cluster of shape regular triangles contained in a strip of width $\mathcal{O}(h)$, by Lemma 2.3, we have that $|v_h|^2_{1,\mathcal{T}_\Gamma} \le Ch \|\bar{u}^0\|^2_{2,R}$. Thus

$$|v_h|^2_{1,\Omega \cap \mathcal{T}_\Gamma} \le Ch \|\bar{u}^0\|^2_{2,R} \le Ch \|f\|^2_{0,\omega}. \tag{3.12}$$

To estimate $|v_h|^2_{1,\mathcal{T}^1_\Omega}$, we introduce an auxiliary interpolation $I_{\mathcal{T}^1_\Omega} u^0$ that interpolates u^0 on every vertex of triangles in $\mathcal{T}^1_\Omega$. Since $\mathcal{T}^1_\Omega$ is composed of a cluster of shape regular triangles covered by a strip of width h, by Lemma 2.3, we have that

$$|I_{\mathcal{T}^1_\Omega} u^0|^2_{1,\mathcal{T}^1_\Omega} \le Ch \|\underline{u}^0\|^2_{2,R} \le Ch \|f\|^2_{0,\omega}. \tag{3.13}$$

From the definition we see that $v_h(\nu) - I_{\mathcal{T}^1_\Omega} u^0(\nu) = 0$ for all $\nu \in \mathcal{V}^1_\Omega$, and $v_h(\nu) - I_{\mathcal{T}^1_\Omega} u^0(\nu) = \bar{u}^0(\nu) - u^0(\nu)$ for all $\nu \in \mathcal{V}_\Gamma \cap \Omega$. Thus we have that

$$|v_h - I_{\mathcal{T}^1_\Omega} u^0|^2_{1,\mathcal{T}^1_\Omega} \le C \sum_{\nu \in \mathcal{V}_\Gamma \cap \Omega} (v_h(\nu) - I_{\mathcal{T}^1_\Omega} u^0(\nu))^2 = C \sum_{\nu \in \mathcal{V}_\Gamma \cap \Omega} (\bar{u}^0(\nu) - u^0(\nu))^2.$$

For each $\nu \in \mathcal{V}_\Gamma \cap \Omega$, we construct a shape regular triangle τ_ν, with ν being one of its vertices, and the other two vertices sitting on Γ. Let $I_{\tau_\nu}(\bar{u}^0 - \underline{u}^0)$ be the linear interpolation of $\bar{u}^0 - \underline{u}^0$ on τ_ν. Since $\bar{u}^0 = \underline{u}^0$ on Γ, we have that

$$|I_{\tau_\nu}(\bar{u}^0 - \underline{u}^0)|^2_{1,\tau_\nu} \simeq (\bar{u}^0(\nu) - u^0(\nu))^2.$$

Thus

$$\sum_{\nu \in \mathcal{V}_\Gamma \cap \Omega} (\bar{u}^0(\nu) - u^0(\nu))^2 \le C \sum_{\nu \in \mathcal{V}_\Gamma \cap \Omega} |I_{\tau_\nu}(\bar{u}^0 - \underline{u}^0)|^2_{1,\tau_\nu}.$$

The cluster of triangles $\{\tau_\nu; \nu \in \mathcal{V}_\Gamma \cap \Omega\}$ satisfies the condition of Lemma 2.3, with $\delta = h$. We therefore have that

$$\sum_{\nu \in \mathcal{V}_\Gamma \cap \Omega} |I_{\tau_\nu}(\bar{u}^0 - \underline{u}^0)|^2_{1,\tau_\nu} \le Ch \|\bar{u}^0 - \underline{u}^0\|^2_{2,R}.$$

From these estimates, we see that

$$|v_h - I_{\mathcal{T}^1_\Omega} u^0|^2_{1,\mathcal{T}^1_\Omega} \le Ch \|\bar{u}^0 - \underline{u}^0\|^2_{2,R} \le Ch \|f\|^2_{0,\omega}. \tag{3.14}$$

Therefore, by (3.13) and (3.14),

$$|v_h|^2_{1,\mathcal{T}^1_\Omega} \le |I_{\mathcal{T}^1_\Omega} u^0|^2_{1,\mathcal{T}^1_\Omega} + |v_h - I_{\mathcal{T}^1_\Omega} u^0|^2_{1,\mathcal{T}^1_\Omega} \le Ch(\|\underline{u}^0\|^2_{2,R} + \|\bar{u}^0 - \underline{u}^0\|^2_{2,R}) \le Ch \|f\|^2_{0,\omega}.$$

Combining this and (3.12), we get that

$$|v_h|^2_{1,\mathcal{T}^1_\Omega \cup (\Omega \cap \mathcal{T}_\Gamma)} \leq Ch\|f\|^2_{0,\omega}. \tag{3.15}$$

The theorem now follows from (3.9), (3.10), (3.11), and (3.15). ∎

From this theorem we see that, when $\Gamma \in C^2$ and $f \in L^2(\omega)$ and if we take $\epsilon = Ch$, we have a domain embedding finite element method on uniform mesh that achieves the full accuracy with an error of $\mathcal{O}(h)$. Although the triangulation was assumed to be uniform, it is clear that Theorem 3.2 holds for any triangulation that is shape regular, (but not necessarily quasi uniform,) with a maximum mesh size h. The result of Theorem 3.1 is valid as long as ω is a Lipschitz domain, which does not guarantee the piecewise regularity of u^0. For example, when ω is a convex polygon, then $u^0|_\omega \in H^2(\omega)$, but $u^0|_\Omega$ cannot be expected to have the H^2 regularity. If ω is a convex polygon and Γ aligns with the mesh, one can define v_h by simply requiring it to interpolate u^0 at every node in $\mathcal{V}$. Then one uses the regularity $u^0|_\omega \in H^2(\omega)$ and $u^0|_\Omega \in H^{1.5}(\Omega)$ [16] to show the validity of the estimate in Theorem 3.2. If ω is a nonconvex polygon, then $u^0|_\omega \in H^2(\omega)$ may not hold, in which case, a local refinement may be needed at reentrant corners of ω to make $|u^0 - v_h|_{1,\omega} \lesssim h$. This can be done by taking a small rectangle around a corner, which conforms to the uniform mesh, and on which one uses a fine uniform mesh. Thus doing, fast Fourier transforms on the global uniform mesh and local uniform fine mesh can be combined in preconditioning the discrete system, in view of the additive multilevel Schwarz method or the Chimera method [9].

For a Robin boundary condition, the theory is similar to that of the Neumann problem, so we will be very brief. We seek a function u on ω solving the homogeneous Robin problem

$$-\Delta u = f \text{ on } \omega, \quad \frac{\partial u}{\partial n} + ku = 0 \text{ on } \Gamma. \tag{3.16}$$

Here k is a smooth, bounded, and positively valued function on Γ. The weak formulation is

$$\begin{gathered}(\nabla u, \nabla v)_{[L^2(\omega)]^2} + \int_\Gamma kuvds = \int_\omega fvdx \ \ \forall\ v \in H^1(\omega), \\ u \in H^1(\omega).\end{gathered} \tag{3.17}$$

On the continuous level, the domain embedding method determines $u^\epsilon \in H^1_0(R)$ such that

$$(\nabla u^\epsilon, \nabla v)_{[L^2(\omega)]^2} + \int_\Gamma kuvds + \epsilon(\nabla u^\epsilon, \nabla v)_{[L^2(\Omega)]^2} = \int_R \bar{f}vdx \ \forall\ v \in H^1_0(R). \tag{3.18}$$

This equation also fits in the form of (2.2), in which the B operator has closed range in V if ω is Lipschitz. Therefore, as $\epsilon \to 0$, u^ϵ converges to a limit $u^0 \in H^1_0(R)$. The limit is harmonic on Ω, and $u^0|_\omega$ solves the Robin problem (3.17). By Lemma 2.4 we have that

$$\|u^\epsilon - u^0\|_{1,R} \simeq |u^\epsilon - u^0|_{1,\omega} + \|u^\epsilon - u^0\|_{0,\Gamma} \simeq \epsilon\,|u^0|_{1,\Omega}. \tag{3.19}$$

The finite element domain embedding method is a straightforward discretization of (3.18) on a uniform mesh on R. The same results of Theorems 3.1 and 3.2 hold for the Robin problem, and the argument is exactly the same.

The Robin problem provides an alternative approach to designing domain embedding for the Dirichlet problem, other than the one we analyze below. In the equation (3.18), we can fix ϵ and take k as a parameter. When $k \to \infty$, the solution of (3.18) then converges to a function (at a rate much lower than $1/k$ [22]) whose restriction on ω solves the homogeneous Dirichlet problem. This method is essentially that of [4]. But the above theory of the domain embedding method for the Robin problem does not extend to this approach for the Dirichlet problem.

3.2. Dirichlet boundary condition. We seek a function u on ω solving the homogeneous Dirichlet problem whose weak formulation is

$$(\nabla u, \nabla v)_{[L^2(\omega)]^2} = \int_\omega f v dx \quad \forall\ v \in H_0^1(\omega), \qquad u \in H_0^1(\omega). \tag{3.20}$$

Under the assumption that ω is simply connected, on the continuous level, the domain embedding method determines $u^\epsilon \in H_0^1(R)$ such that

$$(\nabla u^\epsilon, \nabla v)_{[L^2(\omega)]^2} + \epsilon^{-1}(\nabla u^\epsilon, \nabla v)_{[L^2(\Omega)]^2} = \int_R \bar{f} v dx \quad \forall\ v \in H_0^1(R). \tag{3.21}$$

This is a penalty formulation. We extend u to a function u^0 on R such that $u^0|_\omega = u$ and $u^0|_\Omega = 0$. It is easy to see that, for all $v \in H_0^1(R)$,

$$\epsilon(\nabla(u^\epsilon - u^0), \nabla v)_{[L^2(\omega)]^2} + (\nabla(u^\epsilon - u^0), \nabla v)_{[L^2(\Omega)]^2} = \epsilon \left[\int_R \bar{f} v dx - (\nabla u^0, \nabla v)_{[L^2(\omega)]^2} \right]. \tag{3.22}$$

This equation fits in the form of (2.2) by properly defining the operators and spaces. We see that

$$\ker B = \{v \in H_0^1(R); v = 0 \text{ on } \Omega\},$$

and, more importantly, the right-hand side of (3.22), as a functional, annihilates this subspace. Thus there is a unique $u^1 \in H_0^1(R)$ such that $\Delta u^1 = 0$ on ω (since $u^1 \in (\ker B)^\perp_{\mathcal{H}}$), and

$$(\nabla u^1, \nabla v)_{[L^2(\Omega)]^2} = \left[\int_R \bar{f} v dx - (\nabla u^0, \nabla v)_{[L^2(\omega)]^2} \right] \quad \forall\ v \in H_0^1(R). \tag{3.23}$$

In strong form, this function satisfies

$$-\Delta u^1 = 0 \text{ in } \Omega, \quad \frac{\partial u^1}{\partial n^-} = \frac{\partial u^0}{\partial n} \text{ on } \Gamma, \quad \text{and } u^1 = 0 \text{ on } \partial R. \tag{3.24}$$

Here n is the unit outward normal to Γ viewed as a boundary of ω, and n^- is the outward normal of Ω, which is opposite to n. When Ω is a Lipschitz domain, the operator B arising from fitting (3.22) into (2.2) has closed range. By Lemma 2.4 we have that

$$\|u^\epsilon - u^0 - \epsilon\, u^1\|_{1,R} \simeq |u^\epsilon - u^0 - \epsilon\, u^1|_{1,\Omega} \simeq \epsilon^2\, |u^1|_{1,\omega}. \tag{3.25}$$

From (3.24) we see that $|u^1|_{1,\omega} = 0$, which is equivalent to $|u^1|_{1,\Omega} = 0$ if and only if u^0 satisfies the homogeneous Neumann condition on Γ, or equivalently, $u^0 \in H^2(R)$. In this case $u^\epsilon \equiv u^0$, otherwise u^ϵ converges to u^0 at the sharp rate of ϵ.

Remark. If ω is not simply connected, then Ω could have isolated components whose union is, say, Ω_0. In this case, the limit u^0 of u^ϵ does not satisfy the homogeneous Dirichlet condition on Γ, and the domain embedding method (3.21) fails. A remedy is adding, for example, the term $\epsilon^{-1}(u^\epsilon, v)_{L^2(\Omega_0)}$ or $\epsilon^{-1}(u^\epsilon, v)_{L^2(\Gamma)}$ (or something else as long as $\ker B$ can be identified with $H_0^1(\omega)$) to the left-hand side of the domain embedding equation (3.21). Then the method would be convergent, and the convergence rate would be retained.

The finite element domain embedding method is a straightforward discretization of (3.21) in the finite element space $H_h \subset H_0^1(R)$. In this subsection, as for the Neumann and Robin problems, we assume the triangulation is uniform. The numerical method determines $u_h^\epsilon \in H_h$ such that

$$(\nabla u_h^\epsilon, \nabla v_h)_{[L^2(\omega)]^2} + \epsilon^{-1}(\nabla u_h^\epsilon, \nabla v_h)_{[L^2(\Omega)]^2} = \int_R \bar{f} v_h dx \quad \forall\ v \in H_h. \tag{3.26}$$

We have the following estimate on the error of this method.

THEOREM 3.3. *Let $u^0 \in H_0^1(R)$ be the limit of u^ϵ determined by the domain embedding equation* (3.21)*. Then $u^0|_\omega$ solves the Dirichlet problem* (3.20)*, and $u^0|_\Omega = 0$. Let $u_h^\epsilon \in H_h$ be the solution of the finite element domain embedding equation* (3.26)*. We have that*

$$\begin{aligned}\|u_h^\epsilon - u^0\|_{1,\omega} \le C\,\epsilon\,|u^1|_{1,R} + C\sqrt{\epsilon} \inf_{v_h^1 \in H_h} \left(\sqrt{\epsilon}|u^1 - v_h^1|_{1,\omega} + |u^1 - v_h^1|_{1,\Omega}\right) \\ + C \inf_{v_h^0 \in H_h} \left(|u^0 - v_h^0|_{1,\omega} + \frac{1}{\sqrt{\epsilon}}|v_h^0|_{1,\Omega}\right).\end{aligned} \tag{3.27}$$

Here u^1 is defined by (3.23)*, and C is a constant independent of h, ϵ, and f.*

Proof. Since u_h^ϵ is the projection of u^ϵ in the subspace H_h with respect to the inner product defined by the bilinear form in (3.21), we have that

$$|u^\epsilon - u_h^\epsilon|_{1,\omega} + \frac{1}{\sqrt{\epsilon}}|u^\epsilon - u_h^\epsilon|_{1,\Omega} \le |u^\epsilon - v_h|_{1,\omega} + \frac{1}{\sqrt{\epsilon}}|u^\epsilon - v_h|_{1,\Omega} \quad \forall\ v_h \in H_h.$$

Thus, by using (3.25), we see that

$$\begin{aligned}\|u^0 - u_h^\epsilon\|_{1,\omega} le\ C|u^0 - u_h^\epsilon|_{1,R} &\le C\Big(|u^0 - u^\epsilon|_{1,R} + |u^\epsilon - u_h^\epsilon|_{1,R}\Big) \\ &\le C\left(\epsilon\,|u^1|_{1,R} + |u^\epsilon - v_h|_{1,\omega} + \frac{1}{\sqrt{\epsilon}}|u^\epsilon - v_h|_{1,\Omega}\right) \\ &\le C\Bigg(\epsilon\,|u^1|_{1,R} + |u^\epsilon - u^0 - \epsilon\,u^1|_{1,\omega} + |u^0 + \epsilon\,u^1 - v_h|_{1,\omega} \\ &\quad + \frac{1}{\sqrt{\epsilon}}(|u^\epsilon - u^0 - \epsilon\,u^1|_{1,\Omega} + |\,\epsilon\,u^1 - v_h|_{1,\Omega})\Bigg) \quad \forall\ v_h \in H_h.\end{aligned}$$

We write any $v_h \in H_h$ as $v_h = v_h^0 + \epsilon\,v_h^1$ and use (3.25) again to obtain that

$$\begin{aligned}\|u^0 - u_h^\epsilon\|_{1,\omega} \le C[(\epsilon + \epsilon^{1.5} + \epsilon^2)|u^1|_{1,R} + \epsilon\,|u^1 - v_h^1|_{1,\omega} + \sqrt{\epsilon}|u^1 - v_h^1|_{1,\Omega} \\ + |u^0 - v_h^0|_{1,\omega} + \frac{1}{\sqrt{\epsilon}}|v_h^0|_{1,\Omega}].\end{aligned}$$

The desired estimate then follows. ∎

This result is valid as long as Ω is a Lipschitz domain. In the following, we assume that $\omega \subset\subset R$, $\Gamma \in C^2$, and $f \in L^2(\omega)$. Under this assumption, we have the regularity that $u^0|_\omega \in H^2(\omega) \cap H_0^1(\omega)$. Thus $\partial u^0/\partial n \in H^{1/2}(\Gamma)$. This in turn means that $\partial u^1/\partial n^- \in H^{1/2}(\Gamma)$; cf. (3.24). Therefore, $u^1|_\Omega \in H^2(\Omega)$. Since $u^1|_\omega$ is harmonic and shares values with $u^1|_\Omega$ on Γ, so $u^1|_\omega \in H^2(\omega)$. Furthermore, we have that the estimates $\|u^0\|_{2,\omega} \le C\|f\|_{0,\omega}$, $\|u^1\|_{2,\omega} \le C\|f\|_{0,\omega}$, and $\|u^1\|_{2,\Omega} \le C\|f\|_{0,\omega}$. We shall also use the fact that $u^0|_\omega$ has a H^2 extension onto R [21], denoted by $\bar{u}^0$, such that $\|\bar{u}^0\|_{2,R} \le C\|u^0\|_{2,\omega} \le C\|f\|_{0,\omega}$.

THEOREM 3.4. *Under the assumption that $\omega \subset\subset R$, $\Gamma \in C^2$, and $f \in L^2(\omega)$, for the Dirichlet problem, the following error estimate of the finite element domain embedding method based on uniform mesh holds:*

$$\|u^0 - u_h^\epsilon\|_{1,\omega} \le C(\epsilon + \epsilon\sqrt{h} + h\sqrt{\epsilon} + \sqrt{h})\|f\|_{0,\omega}.$$

Here, C is a constant independent of ϵ, h, and f.

Proof. We need to estimate the three terms in the right-hand side of (3.27). The first one is trivial. For the other two, we need to construct finite element interpolation v_h^1 to u^1 and v_h^0 to u^0, respectively. The construction of v_h^1 aims to estimate the infimum

$$\inf_{v_h^1 \in H_h} \left(\sqrt{\epsilon}|u^1 - v_h^1|_{1,\omega} + |u^1 - v_h^1|_{1,\Omega}\right).$$

We observe that this is in the same form as the second term in the right-hand side of the estimate for the Neumann problem; c.f. (3.7), except that the roles of Ω and ω are switched. We use exactly the same technique of proving Theorem 3.2 to estimate this term. We define $v_h^1 \in H_h$ such that $v_h^1(\nu) = \underline{u}^1(\nu)$ for all $\nu \in \mathcal{V}_\Omega \cup \mathcal{V}_\Gamma$, and $v_h^1(\nu) = u^1(\nu)$ for all $\nu \in \mathcal{V}_\omega$. Here $\underline{u}^1 \in H^2(R)$ is an extension of $u^1|_\Omega$ to R such that $\underline{u}^1|_\Omega = u^1|_\Omega$. With such defined interpolation, we have that

$$|u^1 - v_h^1|_{1,\Omega} \le Ch\|f\|_{0,\omega} \text{ and } |u^1 - v_h^1|_{1,\omega} \le C\sqrt{h}\|f\|_{0,\omega}.$$

Thus

$$\inf_{v_h^1 \in H_h} \left(\sqrt{\epsilon}|u^1 - v_h^1|_{1,\omega} + |u^1 - v_h^1|_{1,\Omega}\right) \le C(\sqrt{\epsilon\, h} + h)\|f\|_{0,\omega}. \tag{3.28}$$

We now turn to the last term in (3.27); i.e.,

$$\inf_{v_h^0 \in H_h} \left(|u^0 - v_h^0|_{1,\omega} + \frac{1}{\sqrt{\epsilon}}|v_h^0|_{1,\Omega}\right). \tag{3.29}$$

The best choice of the interpolation to estimate this one is taking $v_h^0 \in H_h$ such that

$$v_h^0(\nu) = u^0(\nu) \ \ \forall\ \nu \in \mathcal{V}_\omega, \quad v_h^0(\nu) = 0 \ \ \forall\ \nu \in \mathcal{V}_\Gamma \cup \mathcal{V}_\Omega.$$

(See the remark below for the reason why this is the best.) This choice makes $|v_h^0|_{1,\Omega} = 0$. To estimate the other term in (3.29), we observe that

$$|u^0 - v_h^0|_{1,\omega}^2 = |u^0 - v_h^0|_{1,\mathcal{T}_\omega \setminus \mathcal{T}_\omega^0}^2 + |u^0 - v_h^0|_{1,\mathcal{T}_\omega^0}^2 + |u^0|_{1,\omega \cap \mathcal{T}_\Gamma}^2. \tag{3.30}$$

Note that v_h^0 interpolates u^0 at all of the vertices of triangles in $\mathcal{T}_\omega \setminus \mathcal{T}_\omega^0$. On each of the triangle $\tau \in \mathcal{T}_\omega \setminus \mathcal{T}_\omega^0$, we have that $|u^0 - v_h^0|_{1,\tau}^2 \le Ch^2|u^0|_{2,\tau}^2$. Summing up, we get that

$$|u^0 - v_h^0|_{1,\mathcal{T}_\omega \setminus \mathcal{T}_\omega^0}^2 \le Ch^2|u^0|_{2,\mathcal{T}_\omega \setminus \mathcal{T}_\omega^0}^2 \le Ch^2|u^0|_{2,\omega}^2. \tag{3.31}$$

Since $\mathcal{T}_\omega^0$ is covered by a strip of width $\mathcal{O}(h)$ that satisfies the condition of Lemma 2.2, so we have that

$$|u^0|^2_{1,\mathcal{T}_\omega^0} \le Ch\|\bar{u}^0\|^2_{2,R}. \tag{3.32}$$

Here $\bar{u}^0$ is an H^2 extension of $u^0|_\omega$ to R such that $\|\bar{u}^0\|_{2,R} \le C\|u^0\|_{2,\omega}$. Note that a vertex of any triangle in $\mathcal{T}_\omega^0$ either belongs to $\mathcal{V}_\omega^0$ or belongs to $\omega \cap \mathcal{V}_\Gamma$. Since $v_h^0(\nu) = u^0(\nu)$ for all $\nu \in \mathcal{V}_\omega^0$ and $v_h^0(\nu) = 0$ for all $\nu \in \omega \cap \mathcal{V}_\Gamma$, we have that $|v_h^0|^2_{1,\mathcal{T}_\omega^0} \le C\sum_{\nu\in\mathcal{V}_\omega^0}(u^0(\nu))^2$. For each $\nu \in \mathcal{V}_\omega^0$, we construct a shape regular triangle τ_ν with ν being a vertex, and the other two vertices sitting on Γ. Let $I_{\tau_\nu}\bar{u}^0$ be the linear interpolation of $\bar{u}^0$ on this triangle. We have that $(u^0(\nu))^2 \simeq |I_{\tau_\nu}\bar{u}^0|^2_{1,\tau_\nu}$. Thus

$$|v_h^0|^2_{1,\mathcal{T}_\omega^0} \le C\sum_{\nu\in\mathcal{V}_\omega^0} |I_{\tau_\nu}\bar{u}^0|^2_{1,\tau_\nu} \le Ch\|\bar{u}^0\|^2_{2,R}. \tag{3.33}$$

In the last step, we used Lemma 2.3. Finally, according to Lemma 2.2, we have that

$$|u^0|^2_{1,\omega\cap\mathcal{T}_\Gamma} \le Ch\|\bar{u}^0\|^2_{2,R}. \tag{3.34}$$

The estimates (3.32), (3.33), and (3.34) together lead to

$$|u^0 - v_h^0|^2_{1,\mathcal{T}_\omega^0} + |u^0|^2_{1,\omega\cap\mathcal{T}_\Gamma} \le Ch\|\bar{u}^0\|^2_{2,R}. \tag{3.35}$$

This and (3.31) show that $|u^0 - v_h^0|_{1,\omega} \le C\sqrt{h}\|\bar{u}^0\|_{2,R}$, which together with (3.27) and (3.28) complete the proof. ∎

3.3. Remark on the sharpness of the estimate on (3.29). The estimated upper bound $C\sqrt{h}$ on (3.29) is rather big. This estimate was established by taking the interpolation v_h^0 to u^0. One of the reasons for the estimate to be so big is that the chosen v_h^0 does not offer any approximation to u^0 on $\omega \cap \mathcal{T}_\Gamma$, where v_h^0 is identically equal to zero. Even so, the estimate is sharp. To see this, we consider an example of a homogeneous Dirichlet boundary value problem in which ω is the unit circle, $f = 1$, and the solution is $u^0|_\omega = (1 - x^2 - y^2)/2$. We embed ω in a larger rectangle R, on which we introduce a uniform triangulation of mesh size h. The unit circle inevitably cuts through Ch triangles. The area of $\omega \cap \mathcal{T}_\Gamma$ is of the magnitude h. We have that $|u^0|_{1,\omega\cap\mathcal{T}_\Gamma} \simeq \sqrt{h}$. The interpolation v_h^0, defined in the proof, is zero on $\omega \cap \mathcal{T}_\Gamma$, which makes the error bound to be at least $C\sqrt{h}$. But the estimate $C\sqrt{h}$ is sharp. One may try to construct a "better" piecewise linear approximation to u^0 to make $|u^0 - v_h^0|_{1,\omega\cap\mathcal{T}_\Gamma}$ smaller. However, if the v_h^0 were to offer any approximation to u^0, one would at least have that $|v_h^0|_{1,\omega\cap\mathcal{T}_\Gamma} \simeq |u^0|_{1,\omega\cap\mathcal{T}_\Gamma}$. Since v_h^0 is piecewise linear on $\mathcal{T}_\Gamma$, we have that $|v_h^0|_{1,\Omega\cap\mathcal{T}_\Gamma} \simeq |v_h^0|_{1,\omega\cap\mathcal{T}_\Gamma} \simeq |u^0|_{1,\omega\cap\mathcal{T}_\Gamma} \simeq \sqrt{h}$. The bound for (3.29) thus obtained would exceed $\sqrt{h}/\sqrt{\epsilon}$, which is much bigger than $\sqrt{h}$.

This argument shows that the estimate of Theorem 3.4 on the error of the finite element domain embedding method for the Dirichlet problem is sharp. The optimal convergence rate $\mathcal{O}(\sqrt{h})$ can be achieved by taking the penalty parameter as $\epsilon = \mathcal{O}(\sqrt{h})$. Smaller ϵ does not help in improving the accuracy, but it does not hurt the accuracy either. From a computational point of view, the best value of ϵ should be $\epsilon = C\sqrt{h}$. Since this accuracy is rather poor, it seems desirable to find ways to enhance it.

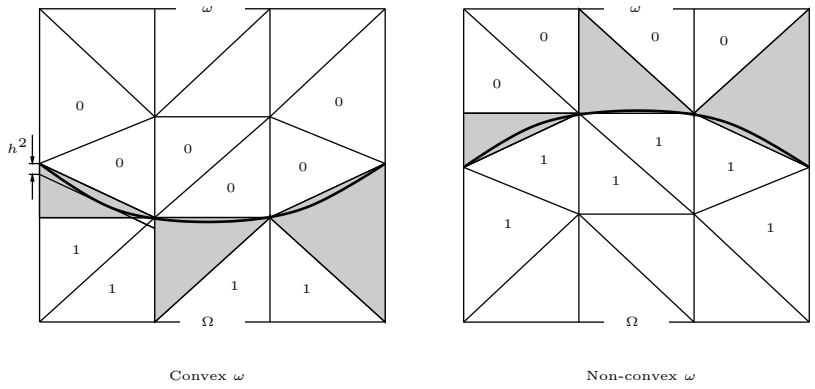

FIG. 5. *A portion of the adjusted mesh around* Γ.

3.4. Dirichlet boundary condition with adjusted mesh. One way to reduce the magnitude of (3.29) is to adjust the uniform mesh around Γ by moving the nearby nodes onto Γ and reconnecting some mesh lines to form a polygonal interpolation to Γ in the mesh; see Figure 1. The adjusted mesh must fulfill the following requirements: (1) The total number of nodes keeps unchanged. (2) No mesh-line segment has one end in ω and the other in Ω. (3) The adjusted triangulation is shape regular and quasi uniform. Fulfilling these requirements ensures, on one hand, that the discrete Laplacian on the adjusted mesh is spectrally equivalent to the one on the uniform triangulation thus retains the effectiveness of preconditioning the discrete system by fast Poisson solvers. On the other hand, the magnitude of (3.29) is significantly reduced, and thus the accuracy of the finite element domain embedding method is accordingly enhanced. The Börgers's algorithm [7] exactly carries out such adjustment. It is interesting to note that the algorithm was proposed in a context of solving a Neumann problem by domain embedding methods [8]. Our above analysis shows that the mesh adjustment is actually not necessary for Neumann problems, while it has a significant effect for the Dirichlet problem.

It turns out that the effect of this mesh adjustment is different whether ω is convex. For convex ω, we prove that the full accuracy of $\mathcal{O}(h)$ is achieved by the domain embedding finite element method on such adjusted mesh if one takes $\epsilon = \mathcal{O}(h)$. Smaller ϵ does not hurt the accuracy. If ω is not convex, then the accuracy can only be improved to $\mathcal{O}(h^{2/3})$ by taking $\epsilon = Ch^{2/3}$. But in this case, smaller ϵ could diminish the improvement and sets the accuracy back to that of the uniform mesh. This is a case in which the balance between ϵ and h is delicate.

We keep the notations of triangles and vertices introduced for uniform triangulation. For example, $\mathcal{T}_\Gamma$ still comprises those triangles that intersect Γ, which are shaded in Figure 5. In addition, we shall use $\mathcal{P}$ to denote the set of all triangles enclosed by the polygonal interpolation of Γ. In consistence to our earlier convention, $\mathcal{P}$ also stands for the enclosed polygonal domain.

THEOREM 3.5. *We assume that* $\omega \subset\subset R$, $\Gamma \in C^2$, *and* $f \in L^2(\omega)$. *The triangulation* $\mathcal{T}$ *of* R *is obtained by adjusting a uniform mesh around* Γ *in the way described above. The finite element domain embedding method* (3.26) *is a straightforward discretization of the penalty formulation* (3.21) *on the adjusted mesh. Then if* ω *is convex, we have that*

$$\|u^0 - u_h^\epsilon\|_{1,\omega} \le C(\epsilon + \epsilon\sqrt{h} + h\sqrt{\epsilon} + h)\|f\|_{0,\omega}. \tag{3.36}$$

If ω is not convex, we have that

$$\|u^0 - u_h^\epsilon\|_{1,\omega} \le C\left(\epsilon + \epsilon\sqrt{h} + h\sqrt{\epsilon} + h + \frac{h}{\sqrt{\epsilon}}\right)\|f\|_{0,\omega}. \tag{3.37}$$

Here, C is a constant independent of ϵ, h, and f.

Proof. The proof is based on the estimate (3.27) that was established in Theorem 3.3, which is still valid even when $\mathcal{T}$ is not uniform. There is nothing new in estimating the first two terms in the right-hand side of (3.27); i.e., we have $\epsilon\,|u^1|_{1,R} \le C\,\epsilon\,\|f\|_{0,R}$ and $\sqrt{\epsilon}\inf_{v_h^1\in H_h}\left(\sqrt{\epsilon}|u^1 - v_h^1|_{1,\omega} + |u^1 - v_h^1|_{1,\Omega}\right) \le C(\epsilon\sqrt{h} + h\sqrt{\epsilon})\|f\|_{0,R}$. We need only to analyze the third term

$$\inf_{v_h^0\in H_h}\left(|u^0 - v_h^0|_{1,\omega} + \frac{1}{\sqrt{\epsilon}}|v_h^0|_{1,\Omega}\right). \tag{3.38}$$

We let $v_h^0 \in H_h$ be such a piecewise linear function that interpolates u^0 for all the vertices $\nu \in \mathcal{V}$. When ω is convex, this interpolation is consistent with that defined in the proof of Theorem 3.4. It is, however, different if ω is not convex, since the latter was required to be zero on the shaded $\mathcal{T}_\Gamma$; see Figure 5.

When ω is convex, we have $\mathcal{P} \subset \omega$, and

$$|u^0 - v_h^0|_{1,\omega}^2 = |u^0|_{1,\omega\setminus\overline{\mathcal{P}}}^2 + |u^0 - v_h^0|_{1,\mathcal{P}}^2.$$

Since $\omega \setminus \overline{\mathcal{P}}$ is covered by a strip γ_δ, with $\delta = Ch^2$; see Figure 5 (left), by Lemma 2.2, we have that $|u^0|_{1,\omega\setminus\overline{\mathcal{P}}}^2 \le Ch^2\|\bar{u}^0\|_{2,R}^2$. Here $\bar{u}^0 \in H^2(R)$ is a H^2 extension of $u^0|_\omega$ such that $\|\bar{u}^0\|_{2,R} \le C\|u^0\|_{2,\omega}$. Since v_h^0 interpolates u^0 at the vertices of every triangle $\tau \in \mathcal{P}$, by the standard argument, we see that $|u^0 - v_h^0|_{1,\mathcal{P}}^2 \le Ch^2|u^0|_{2,\mathcal{P}}^2$. Therefore, $|u^0 - v_h^0|_{1,\omega} \le Ch\|f\|_{0,\omega}$. Since $v_h^0 = 0$ on Ω, we get that

$$|u^0 - v_h^0|_{1,\omega} + \frac{1}{\sqrt{\epsilon}}|v_h^0|_{1,\Omega} \le Ch\|f\|_{0,\omega}.$$

The estimate (3.36) then follows from this and Theorem 3.3.

When ω is not convex, we have that

$$|u^0 - v_h^0|_{1,\omega}^2 = |u^0|_{1,\omega\cap\mathcal{P}^c}^2 + |u^0 - v_h^0|_{1,\omega\cap\mathcal{P}}^2.$$

Here $\mathcal{P}^c = R\setminus\overline{\mathcal{P}}$. Since $\omega\cap\mathcal{P}^c$ is contained in a strip of width $\mathcal{O}(h^2)$, by Lemma 2.2, we have that $|u^0|_{1,\omega\cap\mathcal{P}^c}^2 \le Ch^2\|\bar{u}^0\|_{2,R}^2$. We see that $|u^0 - v_h^0|_{1,\omega\cap\mathcal{P}}^2 \le |\bar{u}^0 - v_h^0|_{1,\mathcal{P}}^2$. Since v_h^0 interpolates $\bar{u}^0$ on the vertices of every triangle in $\mathcal{P}$, by the standard argument of finite element interpolation, we have that $|\bar{u}^0 - v_h^0|_{1,\mathcal{P}}^2 \le Ch^2\|\bar{u}^0\|_{2,\mathcal{P}}^2$. Therefore,

$$|u^0 - v_h^0|_{1,\omega} \le Ch\|f\|_{0,\omega}. \tag{3.39}$$

Now, we consider $|v_h^0|_{1,\Omega}$. Since v_h^0 is zero on $\Omega\cap\mathcal{P}^c$, we have that $|v_h^0|_{1,\Omega}^2 = |v_h^0|_{1,\Omega\cap\mathcal{P}}^2$. Let $\mathcal{P}_\Omega = \{\tau \in \mathcal{P}; \tau\cap\Omega \ne \emptyset\}$, which is a cluster of triangles contained in a strip of width $\mathcal{O}(h)$ around Γ. On every $\tau \in \mathcal{P}_\Omega$, v_h^0 interpolates $\bar{u}^0$. According to Lemma 2.3, we have that $\sum_{\tau\in\mathcal{P}_\Omega}|v_h^0|_{1,\tau}^2 \le Ch\|\bar{u}^0\|_{2,R}^2$. For each $\tau \in \mathcal{P}_\Omega$, the portion $\tau\cap\Omega$ is either contained in a trapezoid of height $\mathcal{O}(h^2)$ by one side of τ, or a smaller triangle of diameter $\mathcal{O}(h^2)$ at a vertex of τ. In any case, we have that $|v_h^0|_{1,\tau\cap\Omega}^2 \le Ch|v_h^0|_{1,\tau}^2$. We thus have that

$$|v_h^0|_{1,\Omega\cap\mathcal{P}}^2 = \sum_{\tau\in\mathcal{P}_\Omega}|v_h^0|_{1,\tau\cap\Omega}^2 \le Ch\sum_{\tau\in\mathcal{P}_\Omega}|v_h^0|_{1,\tau}^2 \le Ch^2\|\bar{u}^0\|_{2,R}^2.$$

Therefore, $|v_h^0|_{1,\Omega} \le Ch\|\bar{u}^0\|_{2,R}$. This together with (3.39) shows that

$$\inf_{v_h^0 \in H_h} \left(|u^0 - v_h^0|_{1,\omega} + \frac{1}{\sqrt{\epsilon}} |v_h^0|_{1,\Omega} \right) \le C \left(h + \frac{h}{\sqrt{\epsilon}} \right) \|\bar{u}^0\|_{2,R}.$$

The proof of (3.37) is complete. □

The estimates of this theorem are sharp. The sharpness argument is similar to that which follows Theorem 3.4.

From (3.36) we see that when ω is convex, the finite element domain embedding method (3.26) with the adjusted mesh achieves the full accuracy $\mathcal{O}(h)$ in the H^1 norm by taking $\epsilon = \mathcal{O}(h)$. From a computational point of view, the best value then is $\epsilon = Ch$. But smaller ϵ won't hurt the accuracy.

From (3.37) we see that if ω is not convex, then the full accuracy of $\mathcal{O}(h)$ cannot be achieved by the mesh adjustment. In this case, there is an optimal value for ϵ. It is $\epsilon = Ch^{2/3}$, which leads to an overall accuracy of order $h^{2/3}$ in the H^1 norm. Unlike the Neumann problem with a uniform mesh or the Dirichlet problem on a convex domain with adjusted mesh, for this case, a smaller ϵ thwarts the accuracy of the finite element domain embedding. It could reduce the order back to $h^{1/2}$, that is, the order of accuracy achieved by the uniform mesh.

REDUCED-ORDER OPTIMAL CONTROL BASED ON APPROXIMATE INERTIAL MANIFOLDS FOR NONLINEAR DYNAMICAL SYSTEMS*

KAZUFUMI ITO† AND KARL KUNISCH‡

Abstract. A reduced-order method for optimal control problems in infinite dimensions based on approximate inertial manifolds is developed. Convergence of the cost, optimal controls, and optimal states of the finite dimensional, reduced-order, optimal control problems to the original optimal control problem is analyzed. Special attention is given to the particular case when the dynamics are described by the Navier–Stokes equations in dimension two.

Key words. reduced-order methods, approximate inertial manifold, nonlinear Galerkin, decomposition of state space, infinite dimensional system

1. Introduction.

In this research we consider optimal control problems governed by partial differential equations. For such problems there has recently been an increased interest in developing reduced-order control methods. This is motivated by computational needs and by systems science considerations as well. For nonlinear distributed parameter control systems, let us specifically mention model reduction based on proper orthogonal decomposition approach [1, 15, 16, 24] and the reduced-basis method [11, 12, 13, 17]. The key issue for the reduction consists in selecting basis elements which are rich in information in the sense that they capture well the essential dynamical properties of the original control system. After the basis elements are selected by these methods the standard Galerkin approach is applied to obtain a reduced-order control system. For linear control systems many alternative reduction methods were proposed and analyzed, including the Hankel-norm approximation [7] and the LQG-balanced truncation realization [2]. The LQG-balanced truncation method was introduced in the finite dimensional literature by [14] and other interpretations followed in [19, 20]. For the infinite dimensional theory we refer to [3]. For linear systems, model reduction based on specific versions of proper orthogonal decomposition and of balanced truncation coincide [22]. The selection of references here is by no means complete and we refer to the citations in the quoted papers for references.

In this paper we discuss an order-reduction method based on the concept of inertial manifolds. Let us recall that an important feature of inertial manifolds consists in the description of the small-scale dynamics as a graph of the large-scale dynamics. The inertial manifold is a finite dimensional invariant manifold that attracts all orbits exponentially. Thus it is natural to expect that controlling the inertial manifold dynamics results in the ability to control the full underlying control system. However,

there are some technical difficulties associated with this approach: (1) the existence of the inertial manifold can only be proved for a limited class of systems, (2) the construction of the inertial manifold is highly involved and technical, and (3) the analysis of the behavior of the closed-loop system has not been fully addressed.

Here we therefore consider approximate inertial manifolds which are not necessarily invariant under the dynamics but which approximate all orbits starting from a bounded set with any desired accuracy. We use nonlinear Galerkin approximations as proposed, e.g., in [5, 18], and the manifold is represented by a stationary graph determined by the residual dynamics. If one would simply truncate the residual dynamics (the flat manifold), then this approach coincides with the standard Galerkin approximation. In [10] we demonstrated the effectiveness of the approximate inertial manifold approach for the linear quadratic regulator problem.

Error estimates for the uncontrolled solution based on the approximate inertial manifold method were investigated extensively. We refer, e.g., to [5, 18], where the estimates are obtained for $t \geq t^* > 0$ for some sufficiently large t^*. In this paper we establish error estimates for control systems based on the reduced-order systems governed by approximate inertial manifolds. Such estimates are obtained by the necessary optimality condition for the optimal control problem, a second order sufficient optimality condition, and the gap estimate for the approximate inertial manifold.

The outline of this paper is as follows. In section 2 we describe the general inertial manifold approach. An upper bound for the performance of the reduced-order control as well as an error estimate for the reduced-order control to the infinite dimensional control in terms of the gap estimate of the approximate inertial manifold are established. In section 3 we discuss error estimates for the two-dimensional Navier–Stokes equations in $L^2(0,T;X)$, where X denotes the state space. Section 4 is devoted to the necessary optimality condition, a second order sufficient optimality condition as well as a first concrete estimate for the finite dimensional optimal controls to the infinite dimensional one. In section 5 a sharper estimate of the convergence rate of the reduced-order control is established on the basis of a sensitivity analysis for the necessary optimality condition.

2. Approximate inertial manifold and reduced-order control system. In this section we describe a general strategy for the approximation of nonlinear control systems by nonlinear Galerkin schemes. Throughout this paper, X and U denote separable Hilbert spaces. We consider the optimal control problem

$$\min_{u \in L^2(0,T;U)} \quad J(x,u) = \int_0^T \ell(x(t)) + h(u(t))\, dt, \tag{2.1}$$

subject to

$$\frac{d}{dt}x(t) = A_0 x(t) + F(x(t)) + Bu(t), \quad x(0) = x_0 \in X, \tag{2.2}$$

where $T > 0$, $F : X \to X^*$ is a nonlinear mapping, A_0 is a linear self-adjoint negative definite operator in X with dense domain denoted by $dom(A_0)$, and B is a bounded linear operator from U to X. We further set $V = dom(-A_0)^{\frac{1}{2}}$ endowed with $|v|_V = \sqrt{\langle -A_0 v\,, v\rangle}$ as norm. We assume that (2.2) is a well-posed control system, i.e., given any $x_0 \in X$ and $u \in L^2(0,T;U)$, there exists a unique weak solution $x = x(t;x_0,u) \in C(0,T;X) \cap L^2(0,T;V)$ to (2.2) which depends continuously on $(x_0,u) \in X \times L^2(0,T;U)$. For example, we can formulate the control problem (2.1)–(2.2) in a

Gelfand triple formulation or as semilinear control systems; see, e.g., [9, 21]. Further, $\ell : X \to \mathbb{R}$ and $h : U \to \mathbb{R}$ are C^1 mappings, ℓ is supposed to be uniformly Lipschitz continuous on bounded sets of X, and h is such that the associated substitution operator from $L^2(0,T;U)$ to $\mathbb{R}$ is well-defined.

We assume that $-A_0$ has eigenpairs (λ_i, ϕ_i) in ascending order and that $\{\phi_i\}_{i=1}^{\infty}$ forms an orthonormal basis of X. Let P_1 be the orthogonal projection of X onto

$$X_1 = \text{ span } \{\phi_i : 1 \le i \le N\}.$$

Further we set $X_2 = (I - P_1)X$. Expressing x as

$$x = p + q, \quad \text{with } p(t) = P_1 x(t) \text{ and } q(t) = P_2 x(t),$$

where $P_2 = I - P_1$, we have from (2.2)

$$\begin{aligned} \frac{d}{dt} p(t) &= A_0 p(t) + P_1 F(p(t) + q(t)) + P_1 B u(t), \\ \frac{d}{dt} q(t) &= A_0 q(t) + P_2 F(p(t) + q(t)) + P_2 B u(t). \end{aligned} \tag{2.3}$$

In the linear Galerkin approach, the higher order modes q are neglected. This results in the control system

$$\frac{d}{dt} \hat{x}_1(t) = A_0 \hat{x}_1(t) + P_1 F(\hat{x}_1(t)) + P_1 B u(t).$$

In the nonlinear Galerkin approach, $\frac{d}{dt}\, q(t)$ is assumed to be negligible compared to $A_0\, q(t)$ in (2.3). This suggests considering the control system

$$\begin{aligned} \frac{d}{dt} \hat{x}_1(t) &= A_0 \hat{x}_1(t) + P_1 F(\hat{x}_1(t) + \hat{x}_2(t)) + P_1 B u(t), \\ 0 &= A_0 \hat{x}_2(t) + P_2 F(\hat{x}_1(t) + \hat{x}_2(t)) + P_2 B u(t). \end{aligned} \tag{2.4}$$

We set

$$\hat{x} = \hat{x}_1 + \hat{x}_2.$$

and the first equation in (2.4) can be expressed as

$$\frac{d}{dt} P_1 \hat{x}(t) = A_0 \hat{x}(t) + P_1 F(\hat{x}(t)) + P_1 B u(t).$$

The second equation in (2.4) is nonlinear and is replaced in the approach that follows by the linear equation

$$A_0 \hat{x}_2(t) + P_2 F(\hat{x}_1) = 0,$$

where the coupling in the nonlinearity and $P_2 B u(t)$ are neglected. An alternative to this may be to consider

$$A_0 \hat{x}_2 + P_2(F(\hat{x_1}) + F'(\hat{x_1})\hat{x}_2) = 0,$$

which should lead to better approximation properties. The reduced-order system that we consider in this paper is given by

$$\frac{d}{dt}\hat{x}_1(t) = A_0\hat{x}_1(t) + P_1F(\hat{x}_1(t)+\hat{x}_2(t)) + P_1Bu(t), \tag{2.5}$$

$$0 = A_0\hat{x}_2(t) + P_2F(\hat{x}_1(t)).$$

Given $\hat{x}_1 \in X_1 = P_1X$, we denote the unique solution to the second equation in (2.5) by

$$\hat{x}_2 = \Phi(\hat{x}_1), \quad \text{where} \quad \Phi(\phi) = -A_0^{-1}P_2F(\phi). \tag{2.6}$$

In this way we obtain the finite dimensional reduced-order control system in X_1:

$$\min_{u\in L^2(0,T;U)} \quad \int_0^T \ell\big(z(t)+\Phi(z(t))\big) + h(u(t))\,dt \tag{2.7}$$

subject to

$$\frac{d}{dt}z(t) = A_0z(t) + P_1F(z(t)+\Phi(z(t))) + P_1Bu(t), \quad z(0) = P_1x_0; \tag{2.8}$$

i.e., we set $z = \hat{x}_1$ with $\hat{x}_1$ as in (2.5). Here we assume the existence of an optimal control u to (2.7) as well as u^* to (2.1). To obtain error estimates for $u-u^*$, we first establish an error estimate for the reduced-order equation. This involves an estimate of the gap

$$\Delta(t) = |q(t) - \Phi(p(t))|,$$

where $p(t)$ and $q(t)$ are defined in (2.3); see, e.g., [5] and section 3. Then, we can argue that under appropriate conditions

$$|z(t)-p(t)|^2 \le M\int_0^t |q(s)-\Phi(p(s))|^2\,ds \text{ for } t\in[0,T] \tag{2.9}$$

for some $M>0$. In fact, for $S=\{v\in V : |v|\le K\}$, with $K\ge 0$, let us assume the properties

$$\langle F(x)-F(y),\phi\rangle \le c\,|x-y||\phi|_V \quad \text{for all} \quad x,y,\phi\in S\subset V, \tag{2.10}$$

and

$$x(t)\in S \text{ and } z(t)+\Phi(z(t))\in S \text{ for a.e. } t\in(0,T).$$

From (2.3) and (2.8) we have

(2.11)

$$\tfrac{d}{dt}(z(t)-p(t)) = A_0(z(t)-p(t)) + P_1\,F(z(t)+\Phi(z(t))) - P_1\,F(p(t)+q(t)),$$

$$z(0)-p(0) = 0.$$

By (2.10) we find for $x(t)\in S$ and $z(t)+\Phi(z(t))\in S$ that

$$\begin{aligned}&\langle P_1\,F\big(z(t)+\Phi(z(t))\big) - P_1\,F\big(p(t)+q(t)\big), z(t)-p(t)\rangle\\ &\le c\big(|z(t)-p(t)| + |\Phi(z(t))-\Phi(p(t))| + |q(t)-\Phi(p(t))|\,\big)|z(t)-p(t)|_V\\ &\le c\big((1+\|\Phi\|)|z(t)-p(t)| + |q(t)-\Phi(p(t))|\big)|z(t)-p(t)|_V,\end{aligned} \tag{2.12}$$

where $\|\Phi\|$ is the Lipschitz constant of Φ on S. Taking the inner product of (2.11) with $z(t) - p(t)$ and using (2.12) results in

$$\frac{1}{2}\frac{d}{dt}|z(t) - p(t)|^2 \le -|z(t) - p(t)|_V^2 + c\big((1 + \|\Phi\|)\,|z(t) - p(t)| + |q(t) - \Phi(p(t))|\big)\,|z(t) - p(t)|_V,$$

which implies, using $ab \le a^2 + \frac{1}{4}b^2$, that

$$\frac{1}{2}\frac{d}{dt}|z(t) - p(t)|^2 \le \frac{c^2}{2}\big((1 + \|\Phi\|)^2|z(t) - p(t)|^2 + |q(t) - \Phi(p(t))|^2\big).$$

Estimate (2.9) with $M = c^2 exp\big(c^2(1 + \|\Phi\|)^2 T\big)$ follows from Gronwall's inequality since $z(0) = p(0)$.

Once (2.9) is established, it implies the error estimate

$$\begin{aligned} |\hat{x}(t) - x(t)| &= |z(t) + \Phi(z(t)) - x(t)| \\ &\le |z(t) - p(t)| + |\Phi(z(t)) - \Phi(p(t))| + |q(t) - \Phi(p(t))| \\ &\le (1 + \|\Phi\|)\,|z(t) - p(t)| + |q(t) - \Phi(p(t))|, \end{aligned} \tag{2.13}$$

for $t \in [0, T]$.

To demonstrate the use of the a priori estimate (2.13) in the context of the optimal control problem, let us assume the existence of optimal controls u and u^* to (2.7)–(2.8) and (2.1)–(2.2), respectively. Moreover, let x and x^* in $C(0, T; X) \cap L^2(0, T; V)$ be the solutions to (2.2) with u and u^*, respectively. Thus x^* is the optimal trajectory to (2.1)–(2.2), whereas x is the trajectory of the infinite dynamical system controlled by the optimal control computed on the bases of the reduced-order system. Let

$$\hat{x} = z + \Phi(z) \ \text{ and } \hat{x}^* = z^* + \Phi(z^*),$$

where z and z^* are the solutions in $C(0, T; X) \cap L^2(0, T; V)$ to (2.8), corresponding to u and u^*, respectively. Then, for the finite horizon control on $[0, T]$ we have

$$\begin{aligned} 0 &\le J(x, u) - J(x^*, u^*) \\ &= J(x, u) - J(\hat{x}, u) + J(\hat{x}, u) - J(\hat{x}^*, u^*) + J(\hat{x}^*, u^*) - J(x^*, u^*) \\ &\le J(x, u) - J(\hat{x}, u) + J(\hat{x}^*, u^*) - J(x^*, u^*), \end{aligned}$$

where we used that $J(\hat{x}, u) - J(\hat{x}^*, u^*) \le 0$. Thus

$$0 \le J(x, u) - J(x^*, u^*) \le C\,(|x^* - \hat{x}^*|_{L^2(0,T;X)} + |x - \hat{x}|_{L^2(0,T;X)}), \tag{2.14}$$

with C the Lipschitz constant of $\ell : X \to R$ on the ball determined by the $C(0, T; X)$ norm of $x, \hat{x}, x^*$, and $\hat{x}^*$. The error estimate (2.9) now provides an upper bound for the performance of the suboptimal control u based on the reduced-order control problem (2.7)–(2.8) imposed onto the original control problem (2.1)–(2.2). In fact, if

$$x(t),\ \hat{x}(t),\ x^*(t),\ \hat{x}^*(t) \ \text{ are in } S \text{ for a.e. } t \in (0, T)$$

with $\hat{x} = z + \Phi(z)$ and $\hat{x}^* = z^* + \Phi(z^*)$, then by (2.9) and (2.13)–(2.14)

$$0 \le J(x, u) - J(x^*, u^*) \le \hat{C}(|q - \Phi(p)|_{L^2(0,T;X)} + |q^* - \Phi(p^*)|_{L^2(0,T;X)}), \tag{2.15}$$

where $\hat{C} = \hat{C}(\|\Phi\|, c, C)$ and (p, q), (p^*, q^*) are the orthogonal projections of x and x^* according to (2.3).

Suppose, moreover, that for some $\sigma > 0$ the second order sufficient optimality condition

$$J(x(v), v) - J(x^*, u^*) \geq \sigma \, |v - u^*|^2_{L^2(0,T;U)} \tag{2.16}$$

holds for all $v \in L(0, T; U)$ in a neighborhood of u^*, where $x(v)$ denotes the solution to (2.2) with u replaced by v. Then, if u is contained in this neighborhood for second order sufficient optimality, we have the estimate

$$\begin{aligned} |u - u^*|^2_{L^2(0,T;U)} &\leq \tfrac{C}{\sigma} \left(|x - \hat{x}|_{L^2(0,T;X)} + |x^* - \hat{x}^*|_{L^2(0,T;X)} \right) \\ &\leq \tfrac{\hat{C}}{\sigma} (|q - \Phi(p)|_{L^2(0,T;X)} + |q^* - \Phi(p^*)|_{L^2(0,T;X)}), \end{aligned} \tag{2.17}$$

and thus the optimal controls for the finite and the original optimal control systems are estimated in terms of the gap $q - \Phi(p)$ and $q^* - \Phi(p^*)$.

3. Basic estimates for two-dimensional Navier–Stokes systems. In this section we analyze the case where the dynamical system (2.2) is given by the Navier–Stokes equations in dimension two. We establish estimates for q and the gap $\Delta = q - \Phi(p)$ following [5]. Our estimate here, however, differs from those in [5] in that we consider the transient situation on the time horizon $[0, T]$, as opposed to the case where t is sufficiently large as in [5]. We then turn to analyzing properties of the mapping Φ and derive error estimates for the reduced-order system.

Let us consider the two-dimensional incompressible Navier–Stokes equations:

$$\begin{aligned} &v_t + (v \cdot \nabla)v + \nabla \rho = \nu \, \Delta v + Bu && \text{for } (t, x) \in (0, T] \times \Omega, \\ &\nabla \cdot v = 0 && \text{in } (0, T] \times \Omega, \\ &v(x, 0) = v_0(x) \text{ in } \Omega, \quad v(t, x) = 0 && \text{for } (t, x) \in (0, T] \times \Gamma, \end{aligned} \tag{3.1}$$

where Ω is a bounded open domain in $\mathbb{R}^2$ with sufficiently smooth boundary Γ, $v = v(t, x) \in \mathbb{R}^2$ is the velocity field, $\rho = \rho(t, x) \in \mathbb{R}$ is the pressure, and $\nu > 0$ is the normalized viscosity. For convenience, in order to exclude special cases in the estimate we also assume that $\nu \leq 1$. Let

$$V = \{\phi \in H^1_0(\Omega)^2 : \nabla \cdot \phi = 0\},$$

and let

$$X = \{\phi \in L^2(\Omega) : \nabla \cdot \phi = 0, \;\; n \cdot \phi = 0 \text{ on } \partial\Omega\}$$

denote the closure of $\{\phi \in \mathcal{D}(\Omega) : \nabla \cdot \phi = 0\}$ in $H^1_0(\Omega)^2$ and $L^2(\Omega)^2$, respectively. Let P stand for the orthogonal projection of $L^2(\Omega)^2$ onto the closed subspace X, and let $A = P\Delta$ in X denote the Stokes operator defined by

$$(A\phi, \psi) = -(\nabla\phi, \nabla\psi)_{L^2} \text{ for } \phi, \; \psi \in V.$$

It is a closed self-adjoint operator with $dom(A) = H^2(\Omega)^2 \cap V$ and $dom((-A)^{\frac{1}{2}}) = V$. The operator $(A)^{-1}$ is compact from X to $dom(A)$ and hence the eigenvalue-eigenvector pairs of $-A$ define a complete orthonormal basis of X.

Let $B \in \mathcal{L}(U, X)$, and define $A_0 = \nu A$, and $F : X \to X^*$

$$-F(\phi) = b(\phi, \phi) = P(\phi \cdot \nabla \phi).$$

Then (3.1) can equivalently be expressed in abstract form as (2.2). For results on the Navier–Stokes equations that we utilize here, we refer to [23]. Note that we chose to endow V with $\sqrt{\langle -A_0 v\,, v\rangle}$ as norm in section 2, whereas $\sqrt{\langle -Av\,, v\rangle}$ is the norm for V in this and the following sections in order to specify the dependency of our estimates on $\nu > 0$ as in [5]. We use the following properties [5, 23] of the bilinear form $b(\phi, \psi) = P(\phi \cdot \nabla \psi)$: There exist constants c_i such that for all ϕ, ψ, w in $dom\, A$

$$
\begin{aligned}
&|b(\phi,\psi)|_{L^2} \le c_1 \begin{cases} |\phi|^{\frac{1}{2}} |\phi|_V^{\frac{1}{2}} |\psi|_V^{\frac{1}{2}} |A\psi|^{\frac{1}{2}}, \\ |\phi|^{\frac{1}{2}} |A\phi|^{\frac{1}{2}} |\psi|_V, \end{cases} \\
&|(b(\phi,\psi), w)| \le c_2\, |\phi|^{\frac{1}{2}} |\phi|_V^{\frac{1}{2}} |\psi|_V |w|^{\frac{1}{2}} |w|_V^{\frac{1}{2}}, \\
&|\phi|_{L^\infty(\Omega)} \le c_3\, |\phi|_V \left(1 + \log\left(\frac{|A\phi|^2}{\lambda_1 |\phi|_V^2}\right)\right)^{\frac{1}{2}}, \\
&|b(\phi,\psi)|_{L^2} \le c_4 \begin{cases} |\phi|_V |\psi|_V \left(1 + \log\left(\frac{|A\phi|^2}{\lambda_1 |\phi|_V^2}\right)\right)^{\frac{1}{2}}, \\ |\phi|\, |A\psi| \left(1 + \log\left(\frac{|A^{\frac{3}{2}}\psi|^2}{\lambda_1 |A\psi|^2}\right)\right)^{\frac{1}{2}}, \end{cases}
\end{aligned}
\tag{3.2}
$$

and satisfies

$$(b(\phi, \psi), \psi) = 0 \quad \text{for } \phi, \psi \in V. \tag{3.3}$$

It follows from [23, proof of Theorem III.3.10], that for $x_0 \in V$ and $u \in L^2(0, T; U)$ there exists a unique solution to (2.2),

$$x(t) \in C(0, T; V) \cap L^2(0, T; dom\,(A)),$$

and

$$|x|_{C(0,T;V)\cap L^2(0,T;dom\,(A))} \le C(|x_0|_V, |u|_{L^2(0,T;U)}),$$

for a constant C depending continuously on its arguments. We let

$$M_0 = \sup_{t\in[0,T]} |x(t)| \text{ and } M_1 = \sup_{t\in[0,T]} |x(t)|_V.$$

Throughout the remainder of this paper we assume that the cut off for the subspace X_1 is such that

$$\lambda_{N+1} \ge \left(\frac{4c_2 M_1}{\nu}\right)^2. \tag{3.4}$$

Note that

$$|A\phi|^2 \le \lambda_N\, |\phi|_V^2 \text{ for } \phi \in X_1, \text{ and } |\phi|_V^2 \ge \lambda_{N+1} |\phi|^2 \text{ for } \phi \in X_2. \tag{3.5}$$

Taking the inner product of (2.2) with $q(t) \in X_2$ we obtain

$$\frac{1}{2}\frac{d}{dt}|q|^2 + \nu\, |q|_V^2 = -(b(p+q, p+q), q) + (P_2 B u, q) \text{ for a.e. } t \in (0, T).$$

From (3.3)

$$(b(p+q,p+q),q) = (b(p,p),q) + (b(q,p),q).$$

Together with (3.2)–(3.5) it follows that

$$|(b(p+q,p+q),q)| \le |(b(p,p),q)| + |(b(q,p),q)| \le c_4 L^{\frac{1}{2}} |p|_V^2 |q| + c_2 |q||q|_V |p|_V,$$

at a.e. $t \in (0,T)$, where

$$L = 1 + \log \frac{\lambda_{N+1}}{\lambda_1}. \tag{3.6}$$

Referring to (3.5) once again we obtain

$$\begin{aligned}\frac{d}{dt}|q|^2 + (2\nu - 2c_2\lambda_{N+1}^{-\frac{1}{2}} M_1|)\,|q|_V^2 &\le 2|P_2Bu||q| + 2c_4 M_1 L^{\frac{1}{2}}\,|p|_V|q| \\ &\le \tfrac{4}{\nu\lambda_{N+1}}(c_4^2 L M_1^2 |p|_V^2 + |P_2Bu|^2) + \tfrac{\nu}{2}|q|_V^2.\end{aligned}$$

By (3.4) the above inequality implies that

$$\frac{d}{dt}|q|^2 + \frac{3\nu}{2}\,|q|_V^2 \le \frac{\nu}{2}|q|_V^2 + \frac{4}{\nu\lambda_{N+1}}(|P_2Bu|^2 + c_4^2 M_1^2 L|p|_V^2)$$

and

$$\frac{d}{dt}|q|^2 + \nu\lambda_{N+1}\,|q|^2 \le \frac{4}{\nu\lambda_{N+1}}(|P_2Bu|^2 + c_4^2 M_1^2 L|x|_V^2).$$

Multiplying this inequality with $e^{\nu\lambda_{N+1}t}$ and integrating over $(0,t)$ implies that

$$|q(t)|^2 \le e^{-\nu\lambda_{N+1}t}|q(0)|^2 + \frac{4}{\nu\lambda_{N+1}}\int_0^t e^{\nu\lambda_{N+1}(s-t)}(|P_2Bu(s)|^2 + c_4^2 M_1^4 L)\,ds, \tag{3.7}$$

for every $t \in [0,T]$. Consequently,

$$\int_0^T |q|^2\,dt \le \frac{1}{\nu\lambda_{N+1}}|q(0)|^2 + \frac{4}{\nu^2\lambda_{N+1}^2}\int_0^T (|P_2Bu|^2 + c_4^2 M_1^4 L)\,dt$$

and this implies the existence of a constant $k_1 = k_1(M_1, c_4, T)$ such that

$$\int_0^T |q|^2\,dt \le \frac{1}{\nu^2\lambda_{N+1}^2}(|q(0)|_V^2 + 4|P_2Bu|^2_{L^2(0,T;X)} + k_1\,L). \tag{3.8}$$

Taking the inner product of (2.2) with Aq we find that

$$\frac{1}{2}\frac{d}{dt}|q|_V^2 + \nu\,|Aq|^2 = -(b(p+q,p+q),Aq) + (P_2Bu,Aq).$$

From (3.2)–(3.5)

$$\begin{aligned}&|(b(p+q,p+q),Aq)| + (P_2Bu,Aq) \\ &\le c_4 L^{\frac{1}{2}}|p|_V|Aq|(|p|_V + |q|_V) + c_1\,|q|^{\frac{1}{2}}|Aq|^{\frac{3}{2}}(|p|_V + |q|_V) + (P_2Bu,Aq).\end{aligned}$$

Expressing $|Aq|^{\frac{3}{2}}(|p|_V + |q|_V)$ as $\nu^{\frac{3}{4}}|Aq|^{\frac{3}{2}}\frac{1}{\nu^{\frac{3}{4}}}(|p|_V + |q|_V)$ and analogously for the remaining terms which contain $A(q)$, we have

$$\begin{aligned}&|(b(p+q,p+q),Aq)| + (P_2Bu,Aq)\\ &\quad\le \frac{\nu}{2}|Aq|^2 + \frac{1}{\nu}|P_2Bu| + \frac{\tilde{c}_3M_1^2L\,|x|_V^2}{\nu} + \frac{\tilde{c}_1M_0^2|x|_V^4}{\nu^3},\end{aligned}$$

where $\tilde{c}_1, \tilde{c}_3$ are independent of ν, L, x, and u. Hence

$$\frac{d}{dt}|q|_V^2 + \nu\,|A\,q|^2 \le \frac{2}{\nu}|P_2Bu|^2 + \frac{2\tilde{c}_3M_1^2L\,|x|_V^2}{\nu} + \frac{2\tilde{c}_1M_0^2|x|_V^4}{\nu^3},$$

and

$$|q(t)|_V^2 \le e^{-\nu\lambda_{N+1}t}|q_0|_V^2 + \int_0^t e^{\nu\lambda_{N+1}(s-t)}\left(\frac{2}{\nu}|P_2Bu(s)| + \frac{2\tilde{c}_3M_1^4L}{\nu} + \frac{2\tilde{c}_1M_0^2M_1^4}{\nu^3}\right).$$

Thus there exists a constant $k_2 = k_2(M_1)$ such that

$$\int_0^T |q(t)|_V^2\,dt \le \frac{1}{\nu\lambda_{N+1}}\left(|q(0)|_V^2 + \frac{2}{\nu}|P_2Bu|_{L^2}^2 + \frac{k_2L}{\nu} + \frac{k_2}{\nu^3}\right). \tag{3.9}$$

For this estimate the assumption $\lambda_{N+1} \ge (\frac{4c_2M_1}{\nu})^2$ is not needed. We now summarize these results.

THEOREM 3.1. *Assume that $x_0 \in V$, $u \in L^2(0,T;U)$, and that $|x|_{C(0,T;V)} \le M_1$ and $\lambda_{N+1} \ge (\frac{4c_2M_1}{\nu})^2$. Then there exist constants $k_1 = k_1(M_1)$ and $k_2 = k_2(M_1)$ such that*

$$\int_0^T |q(t)|^2\,dt \le \delta^2(|q(0)|_V^2 + 4|P_2Bu|_{L^2(0,T;X)}^2 + k_1L)$$

and

$$\int_0^T |q(t)|_V^2\,dt \le \delta\left(|q(0)|_V^2 + \frac{2}{\nu}|P_2Bu|_{L^2(0,T;X)}^2 + \frac{k_2L}{\nu} + \frac{k_2}{\nu^3}\right),$$

where $\delta = \frac{1}{\nu\lambda_{N+1}}$ and $L = 1 + \log\frac{\lambda_{N+1}}{\lambda 1}$.

If, moreover, $u \in L^\infty(0,T;U)$ and $x_0 \in dom(A_0)$, then for constants $k_3 = k_3(M_1)$ and $k_4 = k_4(M_1)$

$$|q(t)|^2 \le \delta^2(|A_0q(0)|^2 + 4|P_2Bu|_{L^\infty(0,T;X)}^2 + k_3L),$$

and

$$|q(t)|_V^2 \le \delta\left(|A_0q(0)|^2 + \frac{2}{\nu}|P_2Bu|_{L^\infty(0,T;X)}^2 + \frac{k_4L}{\nu} + \frac{k_4}{\nu^3}\right),$$

for all $t \in [0,T]$.

The second part of the theorem follows from (3.7) and the equation above (3.9). For the optimal solution u to (2.1)–(2.2), the assumption that $u \in L^\infty(0,T;U)$ is not restrictive as can be seen from the associated optimality system which will be given below.

3.1. Gap estimate. In this subsection we prove an estimate for the gap

$$\Delta(t) = q(t) - \Phi(p(t)) \text{ for } t \in [0,T].$$

Throughout we assume that $x(t) \in C(0,T;V) \cap L^2(0,T;dom\,(A_0))$, and we again set $M_1 = \sup_{t\in[0,T]} |x(t)|_V$. By (2.3) and (2.6) we have

$$-A_0\Delta + b(p,q) + b(q,p) + b(q,q) + \frac{d}{dt}\, q - P_2Bu = 0 \text{ for a.e. } t \in (0,T). \tag{3.10}$$

Using (3.2), (3.3), and (3.6) we find that

$$\begin{aligned} &|b(p,q) + b(q,p) + b(q,q)| \\ &\le (c_4 L^{\frac12} + c_1)|p|_V|q|_V + \tfrac{c_1}{\sqrt{\lambda_{N+1}}}|q|_V|Aq| \quad \text{for a.e. } t \in (0,T). \end{aligned} \tag{3.11}$$

Taking the inner product of (2.2) with $\frac{d}{dt}q$,

$$\frac{\nu}{2}\frac{d}{dt}|q|_V^2 + |\frac{d}{dt}q|^2 = -\left(b(p+q,p+q)\,,\frac{d}{dt}q\right) + \left(P_2Bu, \frac{d}{dt}q\right),$$

and therefore

$$\begin{aligned} &\tfrac{\nu}{2}\tfrac{d}{dt}|q|_V^2 + |\tfrac{d}{dt}q|^2 \\ &\le |b(p,q) + b(q,p) + b(q,q)|^2 + |P_2(b(p,p) + Bu)|^2 + \tfrac12|\tfrac{d}{dt}q|^2. \end{aligned}$$

This implies that

$$\begin{aligned} &\nu|q(T)|_V^2 + \textstyle\int_0^T |\frac{d}{dt}q|^2\,dt \le \nu|q(0)|_V^2 \\ &+2\textstyle\int_0^T |b(p,q) + b(q,p) + b(q,q)|^2\,dt + 2\int_0^T |P_2(b(p,p) + Bu)|^2\,dt \\ &\le \nu|q(0)|_V^2 + 4\textstyle\int_0^T \left((c_4L^{\frac12} + c_1)^2M_1^2|q|_V^2 + \frac{c_1^2}{\lambda_{N+1}}M_1^2|Aq|^2\right)dt \\ &+2\textstyle\int_0^T |P_2(b(p,p) + Bu)|^2\,dt. \end{aligned} \tag{3.12}$$

From (3.10)–(3.12) there exists a constant $\hat{k}$ such that

$$\begin{aligned} \textstyle\int_0^T |A_0\Delta|^2\,dt \le \hat{k}\big[\textstyle\int_0^T [(c_4L^{\frac12} + c_1)^2M_1^2|q|_V^2 + \frac{c_1^2}{\lambda_{N+1}}M_1^2|A\,q|^2]\,dt \\ +\nu|q(0)|_V^2 + \textstyle\int_0^T |P_2(b(p,p))|^2\,dt + \int_0^T |P_2Bu|^2\,dt\big]. \end{aligned}$$

Hence using (3.5) and $L \ge 1$ there exists a constant k_5 independent of ν such that

$$\begin{aligned} &\textstyle\int_0^T |A_0\Delta|^2\,dt \le k_5\frac{L}{\lambda_{N+1}}[|Aq|^2_{L^2(0,T;X)} \\ &\quad +\nu|Aq(0)|^2 + |P_2Bu|^2_{L^2(0,T;V)}] + k_5|P_2b(p,p)|^2_{L^2(0,T;X)}. \end{aligned} \tag{3.13}$$

We consider the term $P_2b(p,p)$. Recall that $b(p,p) = P\,(p\cdot\nabla)p$. Since $p \in X_1$ and hence, in particular, $p \in dom(A)$, then we have

$$g := (p\cdot\nabla)p \;\in\; H_0^1(\Omega).$$

Then Pg satisfies

$$P\,g = g - \nabla\tilde{p} \in X,$$

where $\tilde{p} \in H^1(\Omega)/\mathbb{R}$ is given by

$$\begin{cases} \Delta\tilde{p} = \nabla \cdot g, \\ \frac{\partial\tilde{p}}{\partial n} = 0. \end{cases}$$

Note that $\tilde{p} \in H^2(\Omega)$ and $|\nabla\tilde{p}|_{H^1} \le c\,|g|_{H^1}$. Hence

$$|Pg|_{H^1} = |g - \nabla\tilde{p}|_{H^1} \le c\,|g|_{H^1}$$

and $Pg \in H^1(\Omega)\cap X$, with $Pg\cdot n = 0$. (But Pg is not in V since $\tau\cdot Pg \neq 0$, in general.) Recall from [6] that $dom((-A)^\alpha) = dom((-\Delta)^\alpha)\cap X$ for $\alpha \in (0,1)$, where Δ denotes the vector Laplacian. We further refer to [4, Chapter 8], for characterizations and properties of the domains of $(-\Delta)^\alpha$. It follows from [4] that for $\epsilon > 0$ there exists C_ϵ such that

$$|Pg|_{dom((-A)^{\frac{1}{4}-\epsilon})} \le C_\epsilon |Pg|_{H^1(\Omega)}$$

and hence we have

$$|P_2 b(p,p)|_X = |P_2 P(p\cdot\nabla)p|_X \le \frac{1}{\lambda_{N+1}^{\frac{1}{4}-\epsilon}} |(-A)^{\frac{1}{4}-\epsilon} P((p\cdot\nabla)p)| \le \frac{cC_\epsilon}{\lambda_{N+1}^{\frac{1}{4}-\epsilon}} |(p\cdot\nabla)p|_{H^1}.$$

Here and below C_ϵ is a constant independent of N and p. By (3.2) we have

$$|(p\cdot\nabla)p|_{H^1}^2 \le |(p\cdot\nabla)p|^2 + |\nabla(p\cdot\nabla)p|^2 \le |(p\cdot\nabla)p|^2 + 2\big(|(p\cdot\nabla)p_{x_1}|^2$$
$$+|(p\cdot\nabla)p_{x_2}|^2 + |(p_{x_1}\cdot\nabla)p|^2 + |(p_{x_2}\cdot\nabla)p|^2\big) \le C|p|_V^2 |Ap|^2 L.$$

Combining these estimates, we find

$$|P_2\, b(p,p)|_X \le \frac{C_\epsilon\, L^{1/2}}{\lambda_{N+1}^{\frac{1}{4}-\epsilon}} |p|_V |Ap| \le \frac{C_\epsilon\, L^{1/2}}{\lambda_{N+1}^{\frac{1}{4}-\epsilon}} M_1 |Ap|.$$

This estimate can now be used for the last term in (3.13).

For Neumann boundary conditions $V = \{\phi \in H^1(\Omega)^2 : \nabla\cdot\phi = 0\}$. Since $p \in H^2(\Omega) \subset L^\infty(\Omega)$ $g = (p\cdot\nabla)p \in H^1(\Omega)$ and $Pg = g - \nabla\tilde{p}$, where $\tilde{p} \in H^1(\Omega)/\mathbb{R}$ with

$$\begin{cases} \Delta\tilde{p} = \nabla \cdot g, \\ \frac{\partial\tilde{p}}{\partial n} = n\cdot g. \end{cases}$$

Hence $\tilde{p} \in H^2(\Omega)$, $Pg \in H^1(\Omega)$, and $Pg \in V$. In this case, as well as for periodic boundary conditions, $\lambda_{N+1}^{\frac{1}{4}-\epsilon}$ and the above estimates can be replaced by $\lambda_{N+1}^{\frac{1}{2}}$.

We summarize these estimates in the following theorem.

THEOREM 3.2. *If $x_0 \in dom\,(A_0), P_2 Bu \in L^2(0,T;V)$, and $\epsilon > 0$, then there exists a constant k_7 such that*

$$\int_0^T |A_0(q - \Phi(p))|^2\, dt \le k_7\, \frac{L}{(\lambda_{N+1})^\alpha},$$

where $\alpha = 1/2 - \epsilon$ in the case of Dirichlet boundary conditions and $\alpha = 1$ for Neumann or periodic boundary conditions. Here k_7 depends on ϵ and also on $k_5, |Aq|_{L^2(0,T;X)}$, $|Aq(0)|_X, |P_2 Bu|_{L^2(0,T;V)}, \nu$.

3.2. Lipschitz continuity of Φ. We derive Lipschitz estimates for

$$e = \Phi(p_1) - \Phi(p_2),$$

in X and V, where $p_1 \in X_1$ and $p_2 \in X_1$ satisfy $|p_1|_V,\ |p_2|_V \le M_1$. From (2.6) and (3.2), (3.5) we have

$$\nu(Ae, e) = -\big(b(p_1, p_1 - p_2) + b(p_1 - p_2, p_2), e\big) \le c_4(|p_1|_V + |p_2|_V)|p_1 - p_2|L^{\frac{1}{2}}|e|_V$$

and hence

$$|\Phi(p_1) - \Phi(p_2)|_X \le k_8\,|p_1 - p_2|_X, \quad \text{where } k_8 = \frac{2c_4 L^{\frac{1}{2}} M_1}{\nu\sqrt{\lambda_{N+1}}}. \tag{3.14}$$

Note that $k_8 = k_8(N) \to 0$ for $N \to \infty$. We also find

$$\begin{aligned}\nu|e|_V^2 &\le -\big(b(p_1, p_1 - p_2) + b(p_1 - p_2, p_2), e\big)\\ &\le c_4\,(|p_1|_V + |p_2|_V)\,|p_1 - p_2|_V L^{\frac{1}{2}}|e| \le \tfrac{2}{\sqrt{\lambda_{N+1}}} c_4 M_1 L^{\frac{1}{2}}\ |p_1 - p_2|_V |e|_V,\end{aligned}$$

and hence

$$|\Phi(p_1) - \Phi(p_2)|_V \le k_8\,|p_1 - p_2|_V. \tag{3.15}$$

LEMMA 3.1. *Let $|p_1|_V \le M_1, |p_2|_V \le M_1$ and set $k_8 = \frac{2c_4 L^{\frac{1}{2}} M_1}{\nu\sqrt{\lambda_{N+1}}}$. Then*

$$|\Phi(p_1) - \Phi(p_2)|_V \le k_8|p_1 - p_2|_V,\ \textit{and}\ |\Phi(p_1) - \Phi(p_2)|_X \le k_8|p_1 - p_2|_X.$$

3.3. Error analysis for reduced-order system. We derive error estimates for $z - p$, where z and p are the components of the reduced systems given by (2.8) and the first equation in (2.3). The following a priori estimates will be needed.

LEMMA 3.2. *Let $u \in L^2(0,T;U)$ and $x_0 \in V$, and let x denote the solution to (2.2). Then for all N sufficiently large, the solution $\hat{x}$ to (2.5) exists. Moreover, there exists a constant M_1, such that $|x(t)|_V \le M_1$ and $|\hat{x}(t)|_V \le M_1$ for all $t \in [0,T]$, and this constant is uniform with respect to (u, x_0) in bounded sets of $L^2(0,T;U) \times V$ and all N sufficiently large.*

An outline for the proof is given in the appendix.

From (2.8) we have

$$\begin{aligned}&\tfrac{d}{dt}(z(t) - p(t)) - \nu\, A(z(t) - p(t))\\ &\quad + P_1 b(\hat{x}(t), \hat{x}(t) - x(t)) + P_1 b(\hat{x}(t) - x(t), x(t)) = 0, \quad z(0) - p(0) = 0,\end{aligned}$$

where

$$x(t) = p(t) + q(t), \quad \hat{x} = z(t) + \Phi(z(t)).$$

Taking the inner product with $z(t) - p(t)$,

$$\begin{aligned}&\tfrac{1}{2}\tfrac{d}{dt}|z(t) - p(t)|^2 + \nu|z(t) - p(t)|_V^2\\ &\le |(b(\hat{x}, \hat{x} - x), z - p)| + |(b(\hat{x} - x, x), z - p)|\\ &\le |(b(\hat{x}, \Phi(z) - q), z - p)| + |(b(z - p, x), z - p)| + |(b(\Phi(z) - q, x), z - p)|,\end{aligned}$$

where we suppressed the dependence on t on the right-hand side and used

$$(b(\hat{x}(t),\hat{x}(t)-x(t)),z(t)-p(t)) = (b(\hat{x}(t),\Phi(z(t))-q(t)),z(t)-p(t)).$$

From (3.2) and the fact that $\big(b(\hat{x},\hat{x}-x),z-p\big) = -\big(b(\hat{x},\hat{x}-x),z-p\big)$, we find that

$$\begin{aligned}
&\tfrac{1}{2}\tfrac{d}{dt}|z(t)-p(t)|^2+\nu|z(t)-p(t)|_V^2\\
&\quad\le |\hat{x}|_{L^\infty}|z(t)-p(t)|_V\big(|z(t)-p(t)|_X+|q(t)-\Phi(p(t))|_X\big)\\
&\quad+M_1\big(c_2|z(t)-p(t)|_X+c_3L^{\frac{1}{2}}(k_8|z(t)-p(t)|_X+|q(t)-\Phi(p(t))|_X)\big)|z(t)-p(t)|_V.
\end{aligned}$$

Concerning the term $|\hat{x}(t)|_{L^\infty}$, note that for $z\in V$

$$|A_0\Phi(z)|\le c_4L^{\frac{1}{2}}|z|_V^2,$$

and hence

$$\nu|A\Phi(z)|\le c_4\,L^{\frac{1}{2}}|z|_V^2.$$

Moreover, for every $\epsilon>0$ there exists $c>0$ such that

$$|\phi|_{L^\infty}\le c|A^{\frac{1}{2}+\epsilon}\phi| \text{ for all } \phi\in dom(A).$$

Consequently,

$$|\Phi(z(t))|_{L^\infty}\le c\frac{c_4}{\nu}\lambda_{N+1}^{-\frac{1}{2}+\epsilon}L^{\frac{1}{2}}|z(t)|_V^2 \quad\text{and}\quad |z(t)|_{L^\infty}\le c_3L^{\frac{1}{2}}|z(t)|_V,$$

where (3.2) was used for the second estimate. Since $L=L(N)\sim\log\lambda_{N+1}$, we can assume without loss of generality that

$$|\hat{x}(t)|_{L^\infty}=|z(t)+\Phi(z(t))|_{L^\infty}\le\bar{c}L^{\frac{1}{2}}M_1^2 \quad \text{for } t\in[0,T],$$

where $\bar{c}=\max(c_3,\frac{c_4}{\nu})$. Without loss of generality we also assume that $M_1\ge 1$ and, as before, that $\nu\le 1$. Combining these estimates we find that

$$\begin{aligned}
&\tfrac{1}{2}\tfrac{d}{dt}|z(t)-p(t)|^2+\nu|z(t)-p(t)|_V^2\\
&\quad\le M_1^2(c_2+2k_8\bar{c}L^{\frac{1}{2}})\,|z(t)-p(t)|\,|z(t)-p(t)|_V+2M_1^2\bar{c}L^{\frac{1}{2}}\,|q(t)\\
&\qquad-\Phi(p(t))|\,|z(t)-p(t)|_V
\end{aligned}$$

and thus

$$\begin{aligned}
&\tfrac{d}{dt}|z(t)-p(t)|^2+\nu\,|z(t)-p(t)|_V^2\\
&\quad\le 2\frac{(c_2M_1^2+2k_8M_1^2\bar{c}L^{\frac{1}{2}})^2}{\nu}|z(t)-p(t)|^2+\frac{8\bar{c}^2LM_1^4}{\nu}|q(t)-\Phi(p(t)|^2.
\end{aligned}$$

Gronwall's lemma now implies the following theorem.

THEOREM 3.3. *Let z and p denote the solutions to* (2.8) *and the first equation in* (2.2)*, with $x_0\in V$. Then for all N sufficiently large*

$$|z(t)-p(t)|^2+\nu\int_0^t|z(s)-p(s)|_V^2\,dt\le\frac{8\bar{c}^2LM_1^4}{\nu}\int_0^t e^{c(t-s)}\,|q(s)-\Phi(p(s))|^2\,ds,$$

where $\bar{c} = \max(c_3, \frac{c_4}{\nu})$ *and* $c = 2\frac{(c_2 M_1^2 + 2k_8 M_1^2 \bar{c} L^{\frac{1}{2}})^2}{\nu}$, *and* $t \in [0, T]$.

Considering the definitions of k_8 and $\bar{c}$, we deduce that c behaves like $\frac{L^2}{\lambda_{N+1}}$, where $L(N) = 1 + \log\frac{\lambda_{N+1}}{\lambda_1}$, for $N \to \infty$ and, in particular, is bounded with respect to N for $N \to \infty$.

At the end of section 2 we addressed the question of the performance of the finite dimensional controller applied to the infinite dimensional optimal control problem, measured in term of the difference of the control-costs. For the two-dimensional Navier–Stokes equations we obtain, using the results of this section, the following performance indicator in terms of the cost.

COROLLARY 3.1. *Let* $x_0 \in V$, J *as in section* 2, *and let* u^* *denote an optimal solution to* (2.1)–(2.2) *and* u *an optimal solution to* (2.7)–(2.8), *with dynamics given by the Navier–Stokes equations. Then there exists a constant* $k_9 = k_9(C, \nu, \bar{c}, M_1, c, k_7, k_8)$ *independent of* N, *such that*

$$0 \le J(x,u) - J(x^*,u^*) \le k_9 \, \frac{L}{(\lambda_{N+1})^{1+\frac{\alpha}{2}}},$$

where x *denotes the solution to the infinite dimensional system* (2.2) *controlled by* u.

Proof. Let $x^* = x(u^*)$ and $x = x(u)$ denote the solutions to (2.2) with controls u and u^*, respectively. Then by Lemma 3.2 there exists M_1 such that $x^*, x, \hat{x}(u^*)$, and $\hat{x}(u)$ are all bounded in $C([0,T];V)$ by M_1. By (2.14)

$$0 \le J(x,u) - J(x^*,u^*) \le C\big(|x^* - \hat{x}^*|_{L^2(0,T;X)} + |x - \hat{x}|_{L^2(0,T;X)}\big).$$

From (2.13) and Lemma 3.1 we have with $\hat{C} = C(1 + k_8)$ that

$$\begin{aligned} J(x,u) - J(x^*,u^*) \le \hat{C}\big(&|p(u_N) - z(u_N)|_{L^2(0,T;X)} + |q(u_N) - \Phi(z(u_N))|_{L^2(0,T;X)} \\ &+ |p(u^*) - z(u^*)|_{L^2(0,T;X)} + |q(u^*) - \Phi(z(u^*))|_{L^2(0,T;X)}\big). \end{aligned}$$

In the following estimates k denotes a generic constant depending continuously on the indicated arguments but independent of N. From Theorem 3.3, (3.5), and Theorem 3.2, we have

$$\begin{aligned} &J(x,u) - J(x^*,u^*) \\ &\quad \le k(\hat{C}, \nu, \bar{c}, M_1, c)\sqrt{L}\big(|q(u) - \Phi(z(u))|_{L^2(0,T;X)} + |q(u^*) - \Phi(z(u^*))|_{L^2(0,T;X)}\big) \\ &\quad \le k(\hat{C}, \nu, \bar{c}, M_1, c)\tfrac{\sqrt{L}}{\nu\lambda_{N+1}} \\ &\qquad \big(|A_0(q(u) - \Phi(z(u)))|_{L^2(0,T;X)} + |A_0(q(u^*) - \Phi(z(u^*)))|_{L^2(0,T;X)}\big) \\ &\quad \le k(\hat{C}, \nu, \bar{c}, M_1, c, k_7)\frac{L}{(\lambda_{N+1})^{1+\frac{\alpha}{2}}}. \qquad \square \end{aligned}$$

In section 4 these estimates will be carried further to obtain estimates on $u_N - u^*$, where u_N is the solution to (2.7)–(2.8), as $N \to \infty$.

4. Optimality condition. In this section we discuss a direct approach to obtain necessary and sufficient optimality conditions for (2.1)–(2.2), with the dynamical system given by (3.1). As above, let $V = dom\,((-A)^{\frac{1}{2}})$ and $-\langle A\phi, \phi\rangle = |\phi|_V^2$ for $\phi \in V$. Let (x^*, u^*) be an optimal solution to (2.1)–(2.2) with

$$J(x,u) = \frac{1}{2}\int_0^T (Q(x(t) - \bar{x}(t)), x(t) - \bar{x}(t))\,dt + \frac{\beta}{2}\int_0^T |u(t)|_U^2, \tag{4.1}$$

where Q is symmetric and positive definite on X, $\bar{x} \in L^2(0,T;X)$, and $\beta > 0$. We shall use the following properties:

- Given $(x_0, u) \in X \times L^2(0,T;U)$, there exists a unique weak solution x to (2.2) in $W = L^2(0,T;V) \times H^1(0,T;V^*)$ satisfying $x(0) = x_0$ and

$$\left\langle \frac{d}{dt}x(t), \psi \right\rangle = \langle A_0 x(t) + F(x(t)) + Bu(t), \psi \rangle \text{ for all } \psi \in V.$$

- $F : V \to V^*$ is continuously differentiable and there exists a $c > 0$ such that

$$\begin{aligned} &\langle F(y) - F(x), y - x \rangle \le c\,|y-x||y-x|_V|x|_V \\ &\langle F'(x)y, y \rangle \le c\,|y||y|_V|x|_V \\ &|F(y) - F(x) - F'(x)(y-x)|_{V^*} \le c\,|y-x||y-x|_V \end{aligned}$$

for all $x, y \in V$.

The second item follows from (3.2).

4.1. Necessary optimality condition. Since the bilinear form a on $V \times V$ defined by

$$t \to a(t,\phi,\psi) = -\langle A_0\phi, \psi\rangle - \langle \phi, F'(x^*(t))\psi\rangle$$

satisfies

$$a(t,\phi,\phi) \ge \nu|\phi|_V^2 - c|x^*(t)|_V|\phi||\phi|_V \ge \frac{\nu}{2}|\phi|_V^2 - \frac{c^2\,|x^*(t)|_V^2}{2\nu}|\phi|^2,$$

with $t \to |x^*(t)|_V^2 \in L^1(0,T)$, there exists a unique solution $\chi^* \in H^1(0,T;V^*) \cap L^2(0,T;V)$ to the adjoint equation

$$-\frac{d}{dt}\chi^*(t) = A_0\chi^*(t) + F'(x^*(t))^*\chi^*(t) + Q(x^*(t) - \bar{x}(t)), \quad \chi^*(T) = 0. \tag{4.2}$$

Recall that for $x \in W$, we have $x \in C(0,T;X)$, and for $x,\ \chi \in W$ it follows that

$$\frac{d}{dt}(x(t), \chi(t))_X = \left\langle \frac{d}{dt}x(t), \chi(t) \right\rangle + \left\langle x(t), \frac{d}{dt}\chi(t) \right\rangle$$

for a.e. $t \in (0,T)$. Denoting by $x \in W$ the weak solution corresponding to $u \in L^2(0,T;X)$, and using $a\,b \le \frac{1}{4}a^2 + b^2$ we have

$$\begin{aligned} \frac{1}{2}\frac{d}{dt}|x(t) - x^*(t)|^2 + \nu|x - x^*|_V^2 &= \langle F(x) - F(x^*), x - x^*\rangle + \langle B(u-u^*), x - x^*\rangle \\ &\le c\,|x^*|_V|x-x^*|\,|x-x^*|_V + \|B\|_{\mathcal{L}(U,V^*)}|x-x^*|_V|u-u^*| \\ &\le \frac{\nu}{2}|x-x^*|_V^2 + \frac{c^2}{\nu}|x^*|_V^2|x-x^*|^2 + \frac{1}{\nu}\|B\|_{\mathcal{L}(U,V^*)}^2|u-u^*|^2. \end{aligned}$$

By Gronwall's inequality

$$|x(t) - x^*(t)|^2 \le \frac{2}{\nu^2}\|B\|_{\mathcal{L}(U,V^*)}^2\, exp\left(\frac{2}{\nu}c^2\int_0^t |x^*(s)|_V^2\,ds\right)\int_0^t |u(s) - u^*(s)|^2\,ds \tag{4.3}$$

and

$$\int_0^T |x(t)-x(t)|_V^2\,dt \le M\int_0^T |u(t)-u^*(t)|^2\,dt \tag{4.4}$$

with

$$M=\frac{2}{\nu^2}\|B\|^2_{\mathcal{L}(U,V^*)}\left(1+\frac{2}{\nu}c^2\left(\int_0^T |x^*(t)|_V^2\,dt\right)e^{\frac{2}{\nu}c^2\int_0^T |x^*(t)|_V^2\,dt}\right).$$

Note that

$$\begin{aligned}J(u)-J(u^*)&=\beta(u-u^*,u^*)_{L^2(0,T;U)}+(Q(x^*-\bar x),x-x^*)_{L^2(0,T;X)}\\&\quad+\frac{1}{2}\left(\beta|u-u^*|^2_{L^2(0,T;U)}+(Q(x-x^*),(x-x^*))_{L^2(0,T;X)}\right),\end{aligned} \tag{4.5}$$

and

$$\begin{aligned}&\tfrac{d}{dt}(x(t)-x^*(t),\chi^*(t))=\langle F(x)-F(x^*)-F'(x^*)(x-x^*),\chi^*\rangle\\&\quad-(Q(x^*-\bar x),x-x^*)+\langle B(u-u^*),\chi^*\rangle.\end{aligned}$$

Integrating this expression on $[0,T]$,

$$\int_0^T (Q(x^*-\bar x),x-x^*)\,dt=\int_0^T (B^*\chi^*,u-u^*)+(H(x-x^*,x-x^*),\chi^*)\,dt,$$

where

$$H(x-x^*,x-x^*)=F(x)-F(x^*)-F'(x^*)(x-x^*).$$

Then, from (4.5)

(4.6)

$$\begin{aligned}J(u)-J(u^*)&=(\beta u^*+B^*\chi^*,u-u^*)_{L^2(0,T;U)}+\int_0^T (H(x-x^*,x-x^*),\chi^*)\,dt\\&\quad+\frac{1}{2}\left(\beta|u-u^*|^2_{L^2(0,T;U)}+(Q(x-x^*),(x-x^*))_{L^2(0,T;X)}\right),\end{aligned}$$

where

$$\begin{aligned}&\left|\int_0^T (H(x-x^*,x-x^*),\chi^*)\,dt\right|\\&\quad\le c\left(\int_0^T |x-x^*|^2|x-x^*|_V^2\,dt\right)^{\frac12}\left(\int_0^T |\chi^*|_V^2\,dt\right)^{\frac12}.\end{aligned} \tag{4.7}$$

Let $u=u^*+\tau v,\ v\in L^2(0,T;U)$. Then

$$0\le J(u^*+\tau v)-J(u^*)=(\beta u^*+B^*\chi^*,\tau v)_{L^2(0,T;U)}+o(\tau).$$

Dividing by τ and letting τ tend to 0^+ implies that $(\beta u^*+B^*\chi^*,v)\le 0$ for all $v\in L^2(0,T;X)$. Hence the necessary optimality condition is given by

$$\beta u^*+B^*\chi^*=0\quad\text{in } L^2(0,T;U), \tag{4.8}$$

and the optimality system consists of the primal equation (2.2), the adjoint equation (4.2), and the optimality condition (4.8).

4.2. Second order sufficient optimality. Suppose that there exists a constant $\sigma > 0$ such that

$$\begin{aligned}(4.9)\qquad &\frac{1}{2}\left(|u-u^*|^2_{L^2(0,T;U)} + (Q(x-x^*),(x-x^*))_{L^2(0,T;X)}\right)\\ &\quad + \int_0^T (H(x-x^*,x-x^*),\chi^*)\,dt \geq \sigma\,|u-u^*|^2_{L^2(0,T;U)}\end{aligned}$$

in a neighborhood of u^*, where $x = x(u)$ denote the solution to (2.2). Then the second order sufficient optimality condition (2.16) follows. This follows from (4.6) and (4.8) above.

Turning to (4.9), we first note that

$$-\frac{1}{2}\frac{d}{dt}|\chi^*(t)|^2 \leq -\nu|\chi^*(t)|^2_V + c\,|x^*(t)|_V|\chi^*(t)|\,|\chi^*(t)|_V + (Q(x^*(t)-\bar{x}(t)),\chi^*(t)),$$

and hence

$$-\frac{1}{2}\frac{d}{dt}|\chi^*(t)|^2 + \frac{\nu}{2}|\chi^*(t)|^2_V \leq \frac{c^2}{\nu}\,|x^*(t)|^2_V\,|\chi^*(t)|^2 + \frac{1}{\nu}|Q(x^*(t)-\bar{x}(t))|^2_{V^*}.$$

By Gronwall's inequality applied backwards with respect to time and terminal condition $\chi^*(T) = 0$, we find that

$$\int_0^T |\chi^*(t)|^2 \leq \frac{2}{\nu}\int_0^T |Q(x^*-\bar{x})|^2_{V^*}\exp\left(\int_0^T \frac{2c^2}{\nu}|x^*(s)|^2_V\right).$$

Hence there exists a constant $M = M(c, \frac{1}{\nu})$ such that

$$(4.10)\qquad \int_0^T |\chi^*|^2_V \leq M^2\int_0^T |Q(x^*-\bar{x})|^2_{V^*}\,dt.$$

By (4.7) and (4.10)

$$\begin{aligned}&\frac{1}{2}\left(|u-u^*|^2_{L^2(U)} + (Q(x-x^*),(x-x^*))_{L^2(X)}\right) + \int_0^T (H(x-x^*,x-x^*),\chi^*)\,dt\\ &\quad \geq \tfrac{1}{2}\left(|u-u^*|^2_{L^2(U)} + (Q(x-x^*),(x-x^*))_{L^2(X)}\right)\\ &\qquad -cM|x-x^*|_{C(X)}\,|x-x^*|_{L^2(V)}\,|Q(\bar{x}-x^*)|_{L^2(V^*)},\end{aligned}$$

where $L^2(U)$ stands for $L^2(0,T;U)$. Let $B(r)$ denote the ball with center 0 and radius r in $L^2(0,T;U)$. Let $r > 0$ and $x_0 \in V$. Then by Lemma 3.2 estimate (4.9) holds for all $u \in B$, provided that

$$(4.11)\qquad |Q(\bar{x}-x^*)|_{L^2(V^*)}$$

is sufficiently small.

These results can now be utilized to argue convergence of the reduced optimal controls u to an optimal control u^* of (2.1)–(2.2).

THEOREM 4.1. *Let $x_0 \in V$, J as in* (4.1)*, and let u^* denote an optimal solution to* (2.1)–(2.2) *and u_N an optimal solution to* (2.7)–(2.8)*, with dynamics given by the Navier–Stokes equations. Then, if $|Q(\bar{x}-x^*)|_{L^2(V^*)}$ is sufficiently small, there exists*

a constant $k_{11} = k_{11}(C, \sigma, \nu, \bar{c}, M_1, c, k_7, k_8)$*, independent of* N*, such that for all* N *sufficiently large*

$$|u_N - u^*|^2_{L^2(0,T;U)} \le k_{11}\ \frac{L}{(\lambda_{N+1})^{1+\frac{\sigma}{2}}}.$$

Proof. Following the notation already used at the end of section 2, we denote by

$$x(u) \text{ the solution to (2.2) with } u,$$

$$z(u) \text{ the solution to (2.8) with } u.$$

Note that $J(z(u_N) + \Phi(z(u_N)), u_N) \le J(z(0) + \Phi(z(0)), 0)$. By Lemma 3.2 the right-hand side is bounded and hence there exists $r \in \mathbb{R}$ such that $u_N \in B(r)$ for all N. Thus, if (4.11) is chosen such that the second order sufficient optimality condition (4.9) is satisfied, then from (2.16), (2.14), (2.13), and Lemma 3.1 we have with $\hat{C} = \frac{C}{\sigma}(1 + k_8)$ that

$$\begin{aligned}|u_N - u^*|^2_{L^2(0,T;U)} &\le \hat{C}\big(|p(u_N) - z(u_N)|_{L^2(X)} \\ &+|q(u_N) - \Phi(z(u_N))|_{L^2(X)} + |p(u^*) - z(u^*)|_{L^2(X)} + |q(u^*) - \Phi(z(u^*))|_{L^2(X)}\big),\end{aligned}$$

where again $L^2(X)$ is short for $L^2(0, T; X)$. The proof can now be completed by Theorem 3.3, (3.5), and Theorem 3.2 in the same manner as that of Corollary 3.1. ∎

5. Convergence rate analysis. In the previous section convergence and a first rate of convergence estimate were obtained on the basis of the second order sufficient optimality condition. In this section a rate estimate for the solutions of the reduced problem to the original problem is derived by means of the optimality systems. For the sake of simplicity we assume throughout this section that J is of the form given in (4.1) with $Q = I$ and that

$$\text{range}\,(B) \subset X_1. \tag{5.1}$$

Further let (x^*, u^*) denote a solution to (2.1)–(2.2). Then, (x^*, u^*) with $x^*(t) = p(t) + q(t)$ satisfies

$$\frac{d}{dt}p(t) = A_0 p(t) + P_1\, F\big(p(t) + \Phi(p(t)) + \Delta(t)\big) + Bu^*(t), \tag{5.2}$$

where

$$\Delta(t) = q(t) - \Phi(p(t)) \in X_2.$$

Let

$$\tilde{F}(z) = P_1 F(z + \Phi(z)) \text{ for } z \in X_1$$

and recall that $\Phi : X_1 \to X_2$ is C_1 regular.

The first order necessary optimality condition for (2.7), (2.8) is given by

$$\begin{cases} \dfrac{d}{dt}z(t) = A_0 z(t) + \tilde{F}(z(t)) + Bu(t), \\ -\dfrac{d}{dt}\xi(t) = A_0\xi(t) + \tilde{F}'(z(t))^*\xi(t) + (z(t) - P_1\bar{x}) + \Phi'(z(t))^*(\Phi(z(t)) - P_2\bar{x}), \\ \beta\, u(t) + B^*\xi(t) = 0, \end{cases} \tag{5.3}$$

where $z(0) = P_1 x_0$, $\xi(T) = 0$, and $\hat{x}(t) = z(t) + \Phi(z(t))$. Observe that $\beta u(t) + B^* P_1 \xi(t) = 0$, and

$$\begin{aligned} \tilde{F}'(z)h &= P_1 F'(\hat{x})(h + \Phi'(z)h) = F'_{11}(\hat{x})h + F'_{12}(\hat{x})\Phi'(z)h, \\ \tilde{F}'(z)^* h &= F'_{11}(\hat{x})^* h + \Phi'(z)^* F'_{12}(\hat{x})^* h, \end{aligned} \tag{5.4}$$

for $h \in X_1$. Here $F_{ij} = P_i F P_j$. The adjoint equation split into the X_1 and X_2 components and the necessary optimality condition for (2.1)–(2.2) are given by

$$\begin{aligned} -\tfrac{d}{dt}\eta &= A_0\eta + F'_{11}(x^*)^*\eta + F'_{21}(x^*)^*\zeta + p(t) - P_1\bar{x}, \\ -\tfrac{d}{dt}\zeta &= A_0\zeta + F'_{12}(x^*)^*\eta + F'_{22}(x^*)^*\zeta + q(t) - P_2\bar{x}, \\ \beta u^*(t) &+ B^*\eta(t) = 0, \end{aligned} \tag{5.5}$$

where $\eta(T) = 0$, $\zeta(T) = 0$. Note that for $\hat{x} = z + \Phi(z) \in X_1 + X_2$ we have

$$\begin{aligned} \Phi'(z)h_1 &= -A_0^{-1}F'_{21}(z)h_1, \quad h_1 \in X_1, \\ \Phi'(z)^* h_2 &= -F'_{21}(\hat{x})^* A_0^{-1} h_2, \quad h_2 \in X_2. \end{aligned} \tag{5.6}$$

From the second equation of (5.5)

$$\zeta(t) = -A_0^{-1}(F'_{12}(x^*)^*\eta + q(t) - P_2\bar{x}) - E(t)$$

with

$$E(t) = A_0^{-1}\left(\frac{d}{dt}\zeta + F'_{22}(x^*)^*\zeta\right). \tag{5.7}$$

This quantity E will appear in the final estimate. So let us discuss the effect of the terms which enter into the second equation in (5.5), which is the equation for the fast modes in the adjoint system. The input to the system is $F'_{12}(x^*)^*\eta + q(t) - P_2\bar{x}$ which is small if the effect of the X_2-component of the primal equation and the target state $\bar{x}$, as well as the coupling of the nonlinearity from X_1 to X_2 are small. This results in smallness of the term $\int_0^T |\frac{d}{dt}\zeta + F'_{22}(x^*)^*\zeta|_X^2\, dt$ is small. Further A_0 acts on the fast components ζ of the adjoint state and thus

$$|E(t)|_X \le \frac{1}{\lambda_{N+1}}\left|\frac{d}{dt}\zeta + F'_{22}(x^*)^*\zeta\right|_X.$$

Inserting E into the first equation of (5.5) we find that

$$-\frac{d}{dt}\eta = A_0\eta + F'_{11}(x^*)^*\eta - F'_{21}(x^*)^*\big(A_0^{-1}(F'_{12}(x^*)^*\eta + q(t) - P_2\bar{x}) + E\big) + p(t) - P_1\bar{x},$$

and thus by the second equations of (5.4) and (5.6)

(5.8)
$$
\begin{aligned}
-\frac{d}{dt}(\xi-\eta) &= A_0(\xi-\eta)+\tilde F'(z)^*(\xi)-F_{11}'(x^*)^*\eta+z-p+\Phi'(z)^*(\Phi(z)-P_2\bar x)\\
&\quad +(F_{21}'(x^*)^*A_0^{-1})(F_{12}'(x^*)^*\eta+q-P_2\bar x)+F_{21}'(x^*)^*E\\
&= A_0(\xi-\eta)+\tilde F'(z)^*(\xi-\eta)+(\tilde F'(z)^*-\tilde F'(p)^*)\eta+\tilde F'(x^*)^*\eta-F_{11}'(x^*)^*\eta+z-p\\
&\quad +\Phi'(z)^*\Phi(z)+F_{21}'(\hat x)^*A_0^{-1}(q-P_2\bar x)+(F_{21}'(x^*)^*-F_{21}'(\hat x)^*)A_0^{-1}(q-P_2\bar x)\\
&\quad +F_{21}'(x^*)^*A_0^{-1}F_{12}(x^*)^*\eta-\Phi'(z)^*P_2\bar x+F_{21}'(x^*)^*E\\
&= A_0(\xi-\eta)+\tilde F'(z)^*(\xi-\eta)+(\tilde F'(z)^*-\tilde F'(p)^*)\eta+z-p\\
&\quad +\Phi'(z)^*(\Phi(z)-\Phi(p)-\Delta)+(F_{21}'(x^*)^*-F_{21}'(\hat x)^*)A_0^{-1}(q-P_2\bar x)+F_{21}'(x^*)^*E.
\end{aligned}
$$

Similarly we find

(5.9)
$$
\begin{aligned}
\frac{d}{dt}(z-p) &= A_0(z-p)+\tilde F'(z)(z-p)+B(u-u^*)\\
&\quad +P_1F(\hat x)-P_1F(x^*)-P_1F'(\hat x)(\hat x-x^*)\\
&\quad +F_{12}'(\hat x)\big(\Phi(z)-\Phi(p)-\Phi'(\hat x)(z-p)-\Delta\big).
\end{aligned}
$$

Here we used that

$$
\begin{aligned}
P_1F'(\hat x)(\hat x-x^*) &= F_{11}'(\hat x)(z-p)+F_{12}'(\hat x)(\Phi(z)-q)\\
&= F_{11}'(\hat x)(z-p)+F_{12}'(\hat x)(\Phi(z)-\Phi(p)-\Delta),
\end{aligned}
$$

$$
\tilde F'(z)(z-p)=F_{11}'(\hat x)(z-p)+F_{12}'(\hat x)(\Phi'(\hat x)(z-p)).
$$

For the following discussion let $f : L^2(0,T;U)\times L^2(0,T;X_2)\times L^2(0,T;X_2)\to L^2(0,T;U)$ be defined by the forward integration of the control dynamics for $p(t)$, then the backward integration of the adjoint equation for $\xi(t)$, followed by the application of B^*, where $(u,(\Delta,E))\in L^2(0,T;U)\times L^2(0,T;X_2)\times L^2(0,T;X_2)$ are given. Thus f is the composite $u\to p(u)\to\xi(p)\to B^*\xi=B^*P_1\xi$. Then the optimality system for (2.1)–(2.2) can be expressed as

$$
\beta\, u^*+f(u^*,\Delta,E)=0,
$$

and, using (5.8), (5.9) the optimality system for (2.7), (2.8) is

$$
\beta\, u+f(u,0,0)=0.
$$

Now, if f is C^1 and

$$
\beta\, I+H,\quad H=f_u(u,0,0)
$$

is an isomorphism on $L^2(0,T;U)$, then an argument based on the implicit function theorem implies that

$$
|u^*-u|_{L^2(0,T;U)}\le k_{12}\,(|\Delta|_{L^2(0,T;X_2)}+|E|_{L^2(0,T;X_2)}),
$$

provided that $u = u_N$ is sufficiently close to u^*. Sufficient conditions for convergence of u_N to u^* were already given in Theorem 4.1. We prove such an estimate directly. First, observe that

$$\beta\,(u-u^*, u-u^*) + (B^*(\xi-\eta), u-u^*) = 0. \tag{5.10}$$

From (5.8), (5.9), and (5.4) we find that

$$\begin{aligned}\frac{d}{dt}(z-p,\xi-\eta) &= \langle F(\hat{x}) - F(x^*) - F'(\hat{x})(\hat{x}-x^*), \xi(t)-\eta(t)\rangle \\ &\quad -\langle \tilde{F}'(z) - \tilde{F}'(p)(z-p), \eta\rangle - |z-p|^2 - (\Phi'(z)^*(\Phi(z)-\Phi(p)-\Delta), z-p) \\ &\quad +((\Phi'(z)^* - \Phi'(p)^*)(q-P_2\bar{x}), z-p) - \langle F_{21}'(x^*)^*E, z-p\rangle + (B^*(\xi-\eta), u-u^*) \\ &\quad +\langle F_{12}'(x)(\Phi(z)-\Phi(p)-\Phi'(\hat{x})(z-p)-\Delta), \xi-\eta\rangle.\end{aligned}$$

Integrating this expression onto $[0,T]$,

$$\begin{aligned}&\int_0^T (B^*(\xi-\eta), u-u^*)\,dt \\ &= \int_0^T \big[|z-p|^2 + \Phi'(z)^*(\Phi(z)-\Phi(p)-\Delta, z-p) \\ &\qquad +(\Phi'(z)^* - (\Phi'(p)^*)(q-P_2\bar{x}), z-p)\big]\,dt \\ &\quad -\int_0^T [\langle F(\hat{x}) - F(x^*) - F'(\hat{x})(\hat{x}-x^*), \xi-\eta\rangle + \langle(\tilde{F}'(z) - \tilde{F}'(p)(z-p), \eta\rangle \\ &\quad +\langle F_{21}'(x^*)^*E, z-p\rangle]\,dt - \textstyle\int_0^T \langle F_{12}'(x)(\Phi(z)-\Phi(p)-\Phi'(z)(z-p)-\Delta), \xi-\eta\rangle\,dt.\end{aligned} \tag{5.11}$$

Let us now assume that the assumptions of Theorem 4.1 are satisfied, and let U denote a neighborhood of u^* in $L^2(0,T;U)$. Let M_1 be a bound for $|\hat{x}|_{C(0,T;V)}$ with $u \in U$, and let N be sufficiently large such that $u = u_N \in U$. Using the properties of F specified at the beginning of section 4, we verify from (5.9) with techniques as in the proof of Theorem 3.3 that for some constant k_1,

$$|z(t)-p(t)|^2 + \int_0^T |z(s)-p(s)|_V^2\,ds \le k_1 \int_0^T (|u(s)-u^*(s)|^2 + L\,|\Delta(s)|^2)\,ds \tag{5.12}$$

for all $t \in [0,T]$ and N sufficiently large. Similarly by (5.8), if $x^* \in L^2(0,T;dom(-A))$, then there exists a constant k_2 such that for all N sufficiently large so that $u \in U$,

$$\begin{aligned}&|\xi(t)-\eta(t)|^2 + \int_0^T |\xi(s)-\eta(s)|_V^2\,ds \\ &\qquad \le k_2 \textstyle\int_0^T \big(|u(s)-u^*(s)|_U^2 + L\,|\Delta(s)|_V^2 + |E(s)|^2\big)\,ds.\end{aligned} \tag{5.13}$$

Applying the last two estimates to (5.11) we find with Lemma 3.1 and (3.2) the existence of a constant k_3 such that

$$\begin{aligned}\int_0^T (B^*(\xi-\eta), u-u^*)\,dt \le k_3 \int_0^T \big(&|u(s)-u^*(s)|_U^2 \\ &+ L\,|\Delta(s)|^2 + |E(s)|^2\big)\,ds,\end{aligned} \tag{5.14}$$

for u sufficiently close to u^*. The detailed estimates are quite similar to those necessary for proving (5.12) and (5.13). Together with (5.10) we obtain the following result.

THEOREM 5.1. *Under the assumptions of Theorem* 4.1, *if β is sufficiently large, then there exists a constant k_4 such that*

$$|u_N - u^*|_{L^2(0,T;U)} \le \frac{k_4}{\beta}(L^{\frac{1}{2}} |\Delta|_{L^2(0,T;X_2)} + |E|_{L^2(0,T;X_2)}),$$

where Δ defines the gap and E is defined by (5.7).

Referring to (5.11) let us discuss qualitatively which terms enter into the assumption that β is sufficiently large. These are clearly the first and second terms, without Δ, on the right-hand side of (5.11). The third term is quadratic in $|z-p|_{L^2(0,T;V)}$ multiplied by $|q - P_2\bar{x}|_{L^2(0,T;V)}$, which is small for small residue problems. Similarly, the fifth term is a quadratic multiplied by $|\eta|_{L^2(0,T;V)}$, which in view of (5.5) is again small for small residue problems when p is close to $P_1\bar{x}$. The fourth and seventh terms are of cubic nature. The remaining terms involving Δ and E imply no assumption on size of β.

6. Appendix. Here we sketch the proof for Lemma 3.2. The estimate for x is well known [23]. We turn to the estimate for $\hat{x}$. Let $f = Bu$ and $r = \Phi(z)$. Then $\hat{x} = z + r$ satisfies

$$\left(\frac{d}{dt}z, \psi_1\right) - \nu(Az, \psi_1) + (b(z+r, z+r), \psi_1) = (f, \psi_1),$$
$$\nu\,(Ar, \psi_2) - (b(z,z), \psi_2) = 0$$

for all $\psi_1 \in X_1$ and $\psi_2 \in X_2$. Letting $\psi_1 = z$ and $\psi_2 = r$, we have

$$\frac{1}{2}\frac{d}{dt}|z|^2 + \nu\,(|z|_V^2 + |r|_V^2) + b(r, r, z) = (f, z), \tag{6.1}$$

where we used

$$(b(z+r, z+r), z) + (b(z,z), r) = (b(r,r), z).$$

Assume that $|z(t)|_V \le M$ on $[0,T]$. The definition of M will be given at the end of the proof. From (3.2)

(6.2)
$$|r|_V \le c_4 L^{\frac{1}{2}} M \frac{1}{\nu\sqrt{\lambda_{N+1}}}|z|_V, \quad |r|_X \le \frac{1}{\sqrt{\lambda_{N+1}}}|r|_V, \quad |r|_X \le c_4 L^{\frac{1}{2}} M \frac{1}{\nu\sqrt{\lambda_{N+1}}}|z|_X.$$

Since $|(b(r,r), z)| \le c_2 |r||r|_V |z|_V$,

$$|b(r,r,z)| \le c_2 c_4^2 L M^3 \frac{1}{\nu^2(\lambda_{N+1})^{3/2}}|z|_V^2.$$

We select N so that $c_2 c_4^2 L M^3 \dfrac{1}{\nu^2(\lambda_{N+1})^{3/2}} \le \dfrac{\nu}{2}$. Then from (6.1)

$$|z(t)|^2 + \nu\int_0^t |z|_V^2\, ds \le e^t |z(0)|^2 + \int_0^t e^{t-s}|f(s)|^2\, dx \le C, \tag{6.3}$$

for $t \in [0,T]$, where

$$C = e^T |z(0)|^2 + \int_0^T e^{T-s} |f(s)|^2 \, dx. \tag{6.4}$$

Next, letting $\psi_1 = -Az$ and $\psi_2 = -Ar$,

$$\begin{aligned} &\frac{1}{2}\frac{d}{dt}|z|_V^2 + \nu\,|Az|^2 - (b(z+r, z+r), Az) = (f, Az), \\ &\nu\,|Ar|^2 - (b(z,z), Ar) = 0. \end{aligned} \tag{6.5}$$

From the second equation

$$\nu\,|Ar| \le c_4 L^{\frac{1}{2}} |z|_V^2.$$

Thus,

$$|(b(z+r, r), Az)| \le |z+r|_{L^\infty} |r|_V |Az| \le \bar{c} c_4 L M^3 \frac{1}{\nu\sqrt{\lambda_{N+1}}} |z|_V |Az|,$$

where, as shown in section 3, we can assume that $\bar{c} = \max c_3, \frac{c_4}{\nu}$ is chosen such that

$$|z(t) + r(t)|_{L^\infty} \le \bar{c} M^2 L^{\frac{1}{2}}.$$

From (3.2) and (6.2) we deduce that

$$|(b(z+r, z), Az)| \le 2c_1 |z|^{\frac{1}{2}} |z|_V |Az|^{\frac{3}{2}},$$

where we assumed

$$c_4 L^{\frac{1}{2}} M \frac{1}{\nu\sqrt{\lambda_{N+1}}} \le 1.$$

From the first equation in (6.5) we obtain

$$\frac{1}{2}\frac{d}{dt}|z|_V^2 + \frac{\nu}{2}|Az|^2 \le \left(\frac{2}{\nu} d^2 + \frac{108}{\nu^3} c_1^4 |z|^2 |z|_V^2\right) |z|_V^2 + \frac{2}{\nu}|f|^2,$$

where

$$d = c_4^2 L M^3 \frac{1}{\nu^2\sqrt{\lambda_{N+1}}}.$$

We select N such that $d^2 = d(N)^2 \le \frac{\nu}{4}$. Then

$$\frac{1}{2}\frac{d}{dt}|z|_V^2 + \frac{\nu}{2}|Az|^2 \le \left(1 + \frac{216}{\nu^3} c_1^4 C |z|_V^2\right) |z|_V^2 + \frac{4}{\nu}|f|^2.$$

By Gronwall's lemma we obtain

$$|z(t)|_V^2 + \nu \int_0^t |Az|^2 \, ds \le exp\left(\int_0^T \left(1 + \frac{216}{\nu^3} c_1^4 C |z|_V^2\right) ds\right) \left(|z(0)|_V^2 + \frac{4}{\nu}\int_0^T |f|^2 \, ds\right),$$

and hence

(6.6)
$$|z(t)|_V^2 + \nu \int_0^t |Az|^2 \, ds \leq \exp\left(T + \frac{216}{\nu^4} c_1^4 C^2\right) \left(|z(0)|_V^2 + \frac{4}{\nu} \int_0^T |f|^2 \, ds\right) =: M.$$

Note that the estimate for $|z(t)|_X$ by C in (6.3) involves $|z(0)|$ and $|f|_{L^2(0,T;X)} = |B(u)|_{L^2(0,T;X)}$ but is independent of M for all N sufficiently large. Similarly, the estimate for $|z(t)|_V$ in (6.6) involves C, $|z(0)|$, and $|B(u)|_{L^2(0,T;X)}$, but is independent of M for all N sufficiently large. Hence, the theory of ordinary differential equations on the ball with radius M in $V \cap X_1$ allows one to construct a solution to (2.5) with a priori bound for the $z(t)$ component given by M. The uniform bound for the $\Phi(z(t))$ component follows immediately from (6.2).

EFFICIENT STRONG INTEGRATORS FOR LINEAR STOCHASTIC SYSTEMS*

GABRIEL LORD†, SIMON J. A. MALHAM†, AND ANKE WIESE†

SJAM would like to dedicate this paper to the memory of Nairo Aparicio, a friend and collaborator who passed away on 20th June 2005

Abstract. We present numerical schemes for the strong solution of linear stochastic differential equations driven by an arbitrary number of Wiener processes. These schemes are based on the Neumann (stochastic Taylor) and Magnus expansions. First, we consider the case when the governing linear diffusion vector fields commute with each other, but not with the linear drift vector field. We prove that numerical methods based on the Magnus expansion are more accurate in the mean-square sense than corresponding stochastic Taylor integration schemes. Second, we derive the maximal rate of convergence for arbitrary multidimensional stochastic integrals approximated by their conditional expectations. Consequently, for general nonlinear stochastic differential equations with noncommuting vector fields, we deduce explicit formulae for the relation between error and computational costs for methods of arbitrary order. Third, we consider the consequences in two numerical studies, one of which is an application arising in stochastic linear-quadratic optimal control.

Key words. linear stochastic differential equations, strong numerical methods, Magnus expansion, stochastic linear-quadratic control

1. Introduction.

We are interested in designing efficient numerical schemes for the strong approximation of linear Stratonovich stochastic differential equations of the form

$$y_t = y_0 + \sum_{i=0}^{d} \int_0^t a_i(\tau)\, y_\tau \,\mathrm{d}W_\tau^i, \tag{1.1}$$

where $y \in \mathbb{R}^p$, $W^0 \equiv t$, $(W^1, \dots, W^d)$ is a d-dimensional Wiener process and $a_0(t)$ and $a_i(t)$ are given $p \times p$ coefficient matrices. We call $a_0(t)\, y$ the linear *drift* vector field and $a_i(t)\, y$ for $i = 1, \dots, d$ the linear *diffusion* vector fields. We can express the stochastic differential equation (1.1) more succinctly in the form

$$y = y_0 + \mathsf{K} \circ y, \tag{1.2}$$

where $\mathsf{K} \equiv \mathsf{K}_0 + \mathsf{K}_1 + \cdots + \mathsf{K}_d$ and $(\mathsf{K}_i \circ y)_t \equiv \int_0^t a_i(\tau)\, y_\tau \,\mathrm{d}W_\tau^i$. The solution of the integral equation for y is known as the *Neumann series*, *Peano–Baker series*, *Feynman–Dyson path ordered exponential*, or *Chen–Fleiss series*

$$y_t = (\mathsf{I} - \mathsf{K})^{-1} \circ y_0 \equiv (\mathsf{I} + \mathsf{K} + \mathsf{K}^2 + \mathsf{K}^3 + \cdots) \circ y_0.$$

A significant portion of this paper was completed while SJAM was visiting the Isaac Newton Institute in the spring of 2007.

The flow-map, or fundamental solution matrix, S_t maps the initial data y_0 to the solution $y_t = S_t\, y_0$ at time $t > 0$. It satisfies an analogous matrix valued stochastic differential equation to (1.2) with the $p \times p$ identity matrix as initial data. The logarithm of the Neumann expansion for the flow-map is the *Magnus expansion*. We can thus write the solution to the stochastic differential equation (1.1) in the form

$$y_t = (\exp \sigma_t)\, y_0,$$

where

$$\sigma_t = \ln\big((\mathsf{I} - \mathsf{K})^{-1} \circ I\big) \equiv \mathsf{K} \circ I + \mathsf{K}^2 \circ I - \tfrac{1}{2}(\mathsf{K} \circ I)^2 + \cdots . \tag{1.3}$$

See Magnus [41], Yamato [60], Kunita [35], Azencott [3], Ben Arous [5], Strichartz [54], Castell [12], Burrage [9], Burrage and Burrage [7], and Baudoin [4] for the derivation and convergence of the original and also stochastic Magnus expansion; Iserles et al. [30] for a deterministic review; Lyons [38] and Sipiläinen [53] for extensions to rough signals; Lyons and Victoir [40] for a recent application to probabilistic methods for solving partial differential equations; and Sussmann [56] for a related product expansion.

In the case when the coefficient matrices $a_i(t) = a_i$, $i = 0, \ldots, d$ are constant and noncommutative, the solution to the linear problem (1.1) is nontrivial and given by the Neumann series or stochastic Taylor expansion (see Kloeden and Platen [33])

$$y_t^{\text{neu}} = \sum_{\ell=0}^{\infty} \sum_{\alpha \in \mathbb{P}_\ell} J_{\alpha_\ell \cdots \alpha_1}(t)\, a_{\alpha_1} \cdots a_{\alpha_\ell}\, y_0, \tag{1.4}$$

where

$$J_{\alpha_\ell \cdots \alpha_1}(t) \equiv \int_0^t \int_0^{\xi_1} \cdots \int_0^{\xi_{\ell-1}} \mathrm{d}W_{\xi_\ell}^{\alpha_\ell} \cdots \mathrm{d}W_{\xi_2}^{\alpha_2}\, \mathrm{d}W_{\xi_1}^{\alpha_1}.$$

Here $\mathbb{P}_\ell$ is the set of all combinations of multi-indices $\alpha = \{\alpha_1, \ldots, \alpha_\ell\}$ of length ℓ with $\alpha_k \in \{0, 1, \ldots, d\}$ for $k = 1, \ldots, \ell$. There are some special noncommutative cases where we can write down an explicit analytical solution. For example the stochastic differential equation $\mathrm{d}y_t = a_1 y_t\, \mathrm{d}W_t^1 + y_t a_2\, \mathrm{d}W_t^2$ with the identity matrix as initial data has the explicit analytical solution $y_t = \exp(a_1 W_t^1) \cdot \exp(a_2 W_t^2)$. However, in general we cannot express the Neumann solution series (1.4) in such a closed form.

Classical numerical schemes such as the Euler–Maruyama and Milstein methods correspond to truncating the stochastic Taylor expansion to generate global strong order 1/2 and order 1 schemes, respectively. Stochastic Runge–Kutta numerical methods have also been derived—see Kloeden and Platen [33] and Talay [57]. At the linear level, the Neumann, stochastic Taylor, and Runge–Kutta type methods are equivalent. In the stochastic context, Magnus integrators have been considered by Castell and Gaines [13], Burrage [9], Burrage and Burrage [7], and Misawa [46].

We present numerical schemes based on truncated Neumann and Magnus expansions. Higher order multiple Stratonovich integrals are approximated across each time-step by their expectations conditioned on the increments of the Wiener processes on suitable subdivisions (see Newton [49] and Gaines and Lyons [22]). What is new in this paper is that we:

1. Prove the strong convergence of the truncated stochastic Magnus expansion for small stepsize.

2. Derive uniformly accurate higher order stochastic integrators based on the Magnus expansion in the case of commuting linear diffusion vector fields.
3. Prove the maximal rate of convergence for arbitrary multidimensional stochastic integrals approximated by their conditional expectations.
4. Derive explicit formulae for the relation between error and computational costs for methods of arbitrary order in the case of general nonlinear, noncommuting governing vector fields.

Our results can be extended to nonlinear stochastic differential equations with analogous conditions on the governing nonlinear vector fields, where the exponential Lie series (replacing the Magnus expansion) can be evaluated using the Castell–Gaines approach.

In the first half of this paper, sections 2–5, we focus on proving the convergence of the truncated Magnus expansion and establishing Magnus integrators that are more accurate than Neumann (stochastic Taylor) schemes of the same order. The numerical schemes we present belong to the important class of *asymptotically efficient* schemes introduced by Newton [49]. Such schemes have the optimal minimum leading error coefficient among all schemes that depend on increments of the underlying Wiener process only. Castell and Gaines [13, 14] prove that the order $1/2$ Magnus integrator driven by a d-dimensional Wiener process and a modified order 1 Magnus integrator driven by a 1-dimensional Wiener process are asymptotically efficient. We extend this result of Castell and Gaines to an arbitrary number of driving Wiener processes. We prove that if we assume the linear diffusion vector fields commute, then an analogously modified order 1 Magnus integrator and a new order $3/2$ Magnus integrator are globally more accurate than their corresponding Neumann integrators.

There are several potential sources of cost contributing to the overall computational effort of a stochastic numerical integration scheme. The main ones are the efforts associated with:

- Evaluation: computing (and combining) the individual terms and special functions such as the matrix exponential.
- Quadrature: the accurate representation of multiple Stratonovich integrals.

There are usually fewer terms in the Magnus expansion compared to the Neumann expansion to the same order, but there is the additional computational expense of computing the matrix exponential. When the cost of computing the matrix exponential is not significant, due to their superior accuracy we expect Magnus integrators to be preferable to classical stochastic numerical integrators. This will be the case for systems that are small (see Moler and Van Loan [47] and Iserles and Zanna [31]) or for large systems when we have only to compute the exponential of a large sparse matrix times given vector data for which we can use Krylov subspace methods (see Moler and Van Loan [47] and Sidje [52]). Magnus integrators are also preferable when using higher order integrators (applied to nonsparse systems of any size) when high accuracies are required. This is because, in this scenario, quadrature computational cost dominates integrator effort.

In the second half of this paper, sections 6–8, we focus on the quadrature cost associated with approximating multiple Stratonovich integrals to a degree of accuracy commensurate with the order of the numerical method implemented. Our conclusions apply generally to the case of nonlinear, noncommuting governing vector fields. The governing set of vector fields and driving path process $(W^1, \dots, W^d)$ generate the unique solution process $y \in \mathbb{R}^p$ to the stochastic differential equation (1.1). For a scalar driving Wiener process W the Itô map $W \mapsto y$ is continuous in the topology of uniform

convergence. For a d-dimensional driving process with $d \geq 2$ the universal limit theorem implies that the Itô map $(W^1, \ldots, W^d) \mapsto y$ is continuous in the p-variation topology, in particular for $2 \leq p < 3$ (see Lyons [38], Lyons and Qian [39], and Malliavin [43]). Since Wiener paths with $d \geq 2$ have finite p-variation for $p > 2$, approximations to y constructed using successively refined approximations to the driving path will converge only to the correct solution y if we include information about the Lévy chordal areas of the driving path (the L^2-norm of the 2-variation of a Wiener process is finite though). Hence if we want to implement a scheme using adaptive stepsize we should consider order 1 or higher pathwise stochastic numerical methods (see Gaines and Lyons [22]).

However, simulating multiple Stratonovich integrals accurately is costly! For classical accounts of this limitation on applying higher order pathwise stochastic numerical schemes, see Kloeden and Platen [33, p. 367], Milstein [44, p. 92], and Schurz [51, p. 58], and for more recent results, see Gaines and Lyons [21, 22], Wiktorsson [58], Cruzeiro, Malliavin, and Thalmaier [17], Stump and Hill [55], Gilseng and Shardlow [26], and Giles [24, 25].

Taking a leaf from Gaines and Lyons [22], we consider whether it is computationally cheaper to collect a set of sample data over a given time interval and then evaluate the solution (conditioned on that sample data) than it is to evaluate the solution frequently, say at every sample time. The resounding result here is that of Clark and Cameron [16] who prove that when the multiple Stratonovich integral J_{12} is approximated by its expectation conditioned on intervening sample points, the maximal rate of L^2-convergence is of order $h/Q^{1/2}$, where h is the integration steplength and Q is the sampling rate. We extend this result to multiple Stratonovich integrals $J_{\alpha_1,\ldots,\alpha_\ell}$ of arbitrary order approximated by their expectation conditioned on intervening information sampled at the rate Q. Indeed we prove that the maximal rate of convergence is $h^{\ell/2}/Q^{1/2}$ when $\alpha_1, \ldots, \alpha_\ell$ are nonzero indices (and an improved rate of convergence if some of them are zero). In practice the key information is how the accuracy achieved scales with the effort required to produce it on the global interval of integration say $[0, T]$, where $T = Nh$. We derive an explicit formula for the relation between the global error and the computational effort required to achieve it for a multiple Stratonovich integral of arbitrary order when the indices $\alpha_1, \ldots, \alpha_\ell$ are distinct. This allows us to infer the effectiveness of strong methods of arbitrary order for systems with noncommuting vector fields. For a given computational effort which method delivers the best accuracy? The answer not only relies on methods that are more accurate at a given order, it is also influenced by three regimes for the stepsize that are distinguished as follows. In the first large stepsize regime the evaluation effort is greater than the quadrature effort; higher order methods produce superior performance for given effort. Quadrature effort exceeds evaluation effort in the second smaller stepsize regime. We show that in this regime when $d = 2$, or when $d \geq 3$ and the order of the method $M \leq 3/2$, then the global error scales with the computational effort with an exponent of $-1/2$. Here more accurate higher order methods still produce superior performance for given effort; but not at an increasing rate as the stepsize is decreased. However, when $d \geq 3$ for strong methods with $M \geq 2$ the global error verses computational effort exponent is worse than $-1/2$ and this distinguishes the third very small stepsize regime. The greater exponent means that eventually lower order methods will deliver greater accuracy for a given effort.

We have chosen to approximate higher order integrals over a given time step by their expectations conditioned on the increments of the Wiener processes on suitable

subdivisions. This is important for adaptive time-step schemes (Gaines and Lyons [22]) and filtering problems where the driving processes (say W^1 and W^2) are observed signals. However, it should be noted that Wiktorsson [58] has provided a practical method for efficiently sampling the set of multiple Stratonovich integrals $\{J_{ij} : i, j = 1, \dots, d\}$ across a given time-step associated with a d-dimensional driving process (see Gilsing and Shardlow [23] for a practical implementation). Wiktorsson simulates the tail distribution in a truncated Karhunen–Loève Fourier series approximation of these integrals which produces a convergence rate of order $hd^{3/2}/Q$, where Q is analogously the number of required independent normally distributed samples.

Other potential sources of computational effort might be path generation and memory access. Path generation effort depends on the application context. This cost is at worst proportional to the quadrature effort where we could subsume it. Memory access efforts depend on the processing and access memory environment. To reveal higher order methods (which typically require more path information) in the best light possible, we have ignored this effect.

Our paper is outlined as follows. We start in section 2 by proving that the exponential of every truncation of the Magnus series converges to the solution of our linear stochastic differential equation (1.1). In section 3 we define the strong error measures we use and how to compute them. Using these, we explicitly compare the local and then global errors for the Magnus and Neumann integrators in section 4 and thus establish our stated results for uniformly accurate Magnus integrators. In section 5 we show that when the linear diffusion vector fields do not commute we cannot expect the corresponding order 1 Magnus integrator to in general be globally more accurate than the order 1 Neumann integrator. We then turn our attention in section 6 to the method of approximating multiple Stratonovich integrals by their conditional expectations. We prove the maximal rate of convergence for an arbitrary multiple Stratonovich integral in section 6. We then use this result in section 7 to show how the global error scales with the computational effort for numerical schemes of arbitrary order. The shuffle algebra of multiple Stratonovich integrals generated by integration by parts allows for different representations and therefore bases for the solution of a stochastic differential equation. Some choices of basis representation are more efficiently approximated than others and in section 8 we investigate the impact of this choice. In section 9 we present numerical experiments that reflect our theoretical results. To illustrate the superior accuracy of the uniformly accurate Magnus methods we apply them to a stochastic Riccati differential system that can be reformulated as a linear system which has commuting diffusion vector fields. Since for the linear system expensive matrix-matrix multiplications can be achieved independent of the path, the Neumann method performs better than an explicit Runge–Kutta type method applied directly to the nonlinear Riccati system. We also numerically solve an explicit linear system with governing linear vector fields that do not commute for two and also three driving Wiener processes—Magnus integrators also exhibit superior accuracy in practice in these cases also. Last, in section 10 we outline how to extend our results to nonlinear stochastic differential equations and propose further extensions and applications.

2. Strong convergence of truncated Magnus series. We consider here the case when the stochastic differential equation (1.1) is driven by d Wiener processes with constant coefficient matrices $a_i(t) = a_i$, $i = 0, 1, \dots, d$. The Neumann expansion has the form shown in (1.4). We construct the Magnus expansion by taking the logarithm of this Neumann series as in (1.3). In the appendix we explicitly give the

Neumann and Magnus expansions up to terms with L^2-norm of order 3/2. Let $\hat{\sigma}_t$ denote the truncated Magnus series

$$\hat{\sigma}_t = \sum_{\alpha \in \mathbb{Q}_m} J_\alpha(t)\, c_\alpha, \tag{2.1}$$

where $\mathbb{Q}_m$ denotes the finite set of multi-indices α for which $\|J_\alpha\|_{L^2}$ is of order up to and including t^m. Note that here m is a half-integer index, $m = 1/2, 1, 3/2, \ldots$. The terms c_α are linear combinations of finitely many (more precisely exactly length α) products of the a_i, $i = 0, 1, \ldots, d$. Let $|\mathbb{Q}_m|$ denote the cardinality of $\mathbb{Q}_m$.

THEOREM 2.1 (convergence). *For any $t \le 1$, the exponential of the truncated Magnus series, $\exp \hat{\sigma}_t$, is square-integrable. Further, if y_t is the solution of the stochastic differential equation* (1.1)*, there exists a constant $C(m)$ such that*

$$\left\| y_t - \exp \hat{\sigma}_t \cdot y_0 \right\|_{L^2} \le C(m)\, t^{m+1/2}. \tag{2.2}$$

Proof. First, we show that $\exp \hat{\sigma}_t \in L^2$. Using the expression (2.1) for $\hat{\sigma}_t$, we see that for any number k, $(\hat{\sigma}_t)^k$ is a sum of $|\mathbb{Q}_m|^k$ terms, each of which is a k-multiple product of terms $J_\alpha c_\alpha$. It follows that

$$\left\| (\hat{\sigma}_t)^k \right\|_{L^2} \le \Big(\max_{\alpha \in \mathbb{Q}_m} \|c_\alpha\|_{\mathrm{op}} \Big)^k \cdot \sum_{\substack{\alpha_i \in \mathbb{Q}_m \\ i = 1, \ldots, k}} \|J_{\alpha(1)} J_{\alpha(2)} \cdots J_{\alpha(k)}\|_{L^2}. \tag{2.3}$$

Note that the maximum of the operator norm $\|\cdot\|_{\mathrm{op}}$ of the coefficient matrices is taken over a finite set. Repeated application of the product rule reveals that the product $J_{\alpha(i)} J_{\alpha(j)}$, where $\alpha(i)$ and $\alpha(j)$ are multi-indices of length $\ell(\alpha(i))$ and $\ell(\alpha(j))$, is a linear combination of $2^{\ell(\alpha(i)) + \ell(\alpha(j)) - 1}$ multiple Stratonovich integrals. Since $\ell(\alpha(i)) \le 2m$ for $i = 1, \ldots, k$, each term $J_{\alpha(1)} J_{\alpha(2)} \cdots J_{\alpha(k)}$ in (2.3) is thus the sum of at most 2^{2mk-1} Stratonovich integrals J_β. We also note that $k \le \ell(\beta) \le 2mk$.

From equation (5.2.34) in Kloeden and Platen [33], every multiple Stratonovich integral J_β can be expressed as a finite sum of at most $2^{\ell(\beta)-1}$ multiple Itô integrals I_γ with $\ell(\gamma) \le \ell(\beta)$. Further, from Remark 5.2.8 in Kloeden and Platen [33], $\ell(\gamma) + \mathrm{n}(\gamma) \ge \ell(\beta) + \mathrm{n}(\beta)$, where $\mathrm{n}(\beta)$ and $\mathrm{n}(\gamma)$ denote the number of zeros in β and γ, respectively. From Lemma 5.7.3 in Kloeden and Platen [33],

$$\|I_\gamma\|_{L^2} \le 2^{\ell(\gamma) - \mathrm{n}(\gamma)}\, t^{(\ell(\gamma) + \mathrm{n}(\gamma))/2}.$$

Noting that $\ell(\gamma) \le \ell(\beta) \le 2mk$ and $\ell(\gamma) + \mathrm{n}(\gamma) \ge k$, it follows that for $t \le 1$, we have $\|J_\beta\|_{L^2} \le 2^{4mk-1}\, t^{k/2}$. Since the right-hand side of (2.3) consists of $|\mathbb{Q}_m|^k\, 2^{2mk-1}$ Stratonovich integrals J_β, we conclude that

$$\left\| \left(\hat{\sigma}_t\right)^k \right\|_{L^2} \le \Big(\max_{\alpha \in \mathbb{Q}_m} \|c_\alpha\|_{\mathrm{op}} \cdot |\mathbb{Q}_m| \cdot 2^{6m} \cdot t^{1/2} \Big)^k.$$

Hence $\exp \hat{\sigma}_t$ is square-integrable.

Second, we prove (2.2). Let $\hat{y}_t$ denote Neumann series solution (1.4) truncated to include terms of order up to and including t^m. We have

$$\left\| y_t - \exp \hat{\sigma}_t \cdot y_0 \right\|_{L^2} \le \left\| y_t - \hat{y}_t \right\|_{L^2} + \left\| \hat{y}_t - \exp \hat{\sigma}_t \cdot y_0 \right\|_{L^2}. \tag{2.4}$$

We know $y_t \in L^2$ (see Gihman and Skorohod [23] or Arnold [2]). Furthermore, for any order m, $\hat{y}_t$ corresponds to the truncated Taylor expansion involving terms of order

up to and including t^m. Hence $\hat{y}_t$ is a strong approximation to y_t to that order with the remainder consisting of $\mathcal{O}(t^{m+1/2})$ terms (see Proposition 5.9.1 in Kloeden and Platen [33]). It follows from the definition of the Magnus series as the logarithm of the flow-map Neumann series that the terms of order up to and including t^m in $\exp\hat{\sigma}_t \cdot y_0$ correspond with $\hat{y}_t$; the error consists of $\mathcal{O}(t^{m+1/2})$ terms. □

Convergence of approximations based on truncations of the stochastic Taylor expansion has been studied in Kloeden and Platen [33]; see Propositions 5.10.1, 5.10.2, and 10.6.3. Ben Arous [5] and Castell [12] prove the remainder of the exponential of any truncation of the Magnus series is bounded in probability as $t \to 0$ (in the full nonlinear case). Burrage [9] shows that the first terms up to and including order 3/2 Magnus expansion coincide with the terms in the Taylor expansion of the same order. Our result holds for any order in L^2 for sufficiently small t. A more detailed analysis is needed to establish results concerning the convergence radius. Similar arguments can be used to study the nonconstant coefficient case with suitable conditions on the coefficient matrices (see Proposition 5.10.1 in Kloeden and Platen [33] for the corresponding result for the Taylor expansion).

Note that above and in subsequent sections, one may equally consider a stochastic differential equation starting at time $t_0 > 0$ with square-integrable $\mathcal{F}_{t_0}$-measurable initial data y_0. Here $(\mathcal{F}_t)_{t\geq 0}$ denotes the underlying filtration.

3. Global and local error. Suppose $S_{t_n,t_{n+1}}$ and $\hat{S}_{t_n,t_{n+1}}$ are the exact and approximate flow-maps across the interval $[t_n, t_{n+1}]$, respectively; both satisfying the usual flow-map semigroup property: composition of flow-maps across successive intervals generates the flow-map across the union of those intervals. We call the difference between the exact and approximate flow-maps

$$R_{t_n,t_{n+1}} \equiv S_{t_n,t_{n+1}} - \hat{S}_{t_n,t_{n+1}} \tag{3.1}$$

the *local flow remainder*. For an approximation $\hat{y}_{t_{n+1}}$ across the interval $[t_n, t_{n+1}]$ the local remainder is thus $R_{t_n,t_{n+1}} y_{t_n}$. Our goal here is to see how the leading order terms in the local remainders accumulate and contribute to the global error.

Definition 3.1 (strong global error). *We define the* strong global error *associated with an approximate solution $\hat{y}_T$ to the stochastic differential equation* (1.1) *over the global interval of integration $[0,T]$ as $\mathcal{E} \equiv \|y_T - \hat{y}_T\|_{L^2}$.*

The global error can be decomposed additively into two components, the global truncation error due to truncation of higher order terms, and the global quadrature error due to the approximation of multiple Stratonovich integrals retained in the approximation. If $[0,T] = \cup_{n=0}^{N-1}[t_n, t_{n+1}]$, where $t_n = nh$, then for small stepsize $h = T/N$ we have

$$\begin{aligned}\mathcal{E} &= \left\| \left(\prod_{n=N-1}^{0} S_{t_n,t_{n+1}} - \prod_{n=N-1}^{0} \hat{S}_{t_n,t_{n+1}} \right) y_0 \right\|_{L^2} \\ &= \left\| \left(\sum_{n=0}^{N-1} \hat{S}_{t_{n+1},t_N} R_{t_n,t_{n+1}} \hat{S}_{t_0,t_n} \right) y_0 \right\|_{L^2} + \mathcal{O}\big(\max_n \|R_{t_n,t_{n+1}}\|_{L^2}^{3/2}\, h^{-3/2}\big). \end{aligned} \tag{3.2}$$

The local flow remainder has the following form in the case of constant coefficients a_i, $i = 1, \ldots, d$, (see, for example, the integrators in the appendix):

$$R_{t_n,t_{n+1}} = \sum_{\alpha} J_\alpha(t_n, t_{n+1})\, c_\alpha.$$

Here α is a multi-index and the terms c_α represent products or commutations of the constant matrices a_i. The J_α represent Stratonovich integrals or linear combinations, of the same order, of products of integrals including permutations of α. The global error $\mathcal{E}^2$ at leading order in the stepsize is thus

$$y_0^{\mathrm{T}} \sum_{\alpha,\beta} \Bigg(\sum_n \mathbb{E}\big(J_\alpha(t_n,t_{n+1})\, J_\beta(t_n,t_{n+1})\big) \mathbb{E}\Big(\big(\hat{S}_{t_{n+1},t_N} c_\alpha \hat{S}_{t_0,t_n}\big)^{\mathrm{T}} \big(\hat{S}_{t_{n+1},t_N} c_\beta \hat{S}_{t_0,t_n}\big) \Big)$$

$$+ \sum_{n\neq m} \mathbb{E}\big(J_\alpha(t_n,t_{n+1})\big)\, \mathbb{E}\big(J_\beta(t_m,t_{m+1})\big) \mathbb{E}\Big(\big(\hat{S}_{t_{n+1},t_N} c_\alpha \hat{S}_{t_0,t_n}\big)^{\mathrm{T}} \big(\hat{S}_{t_{m+1},t_N} c_\beta \hat{S}_{t_0,t_m}\big) \Big) \Bigg) y_0.$$

Hence in the global truncation error we distinguish between the *diagonal sum* consisting of the first sum on the right-hand side above, and the *off-diagonal sum* consisting of the second sum above with $n \neq m$.

Suppose we include in our integrator all terms with local L^2-norm up to and including $\mathcal{O}(h^M)$. The leading terms $J_\alpha c_\alpha$ in $R_{t_n,t_{n+1}}$ thus have L^2-norm $\mathcal{O}(h^{M+1/2})$. Those with zero expectation will contribute to the diagonal sum, generating $\mathcal{O}(h^M)$ terms in the global error, consistent with a global order M integrator. However, those with nonzero expectation contribute to the off-diagonal double sum. They will generate $\mathcal{O}(h^{M-1/2})$ terms in the global error. We must thus either include them in the integrator, or more cheaply, include only their expectations—the corresponding terms $\big(J_\alpha - \mathbb{E}(J_\alpha)\big)c_\alpha$ of order $h^{M+1/2}$ in $R_{t_n,t_{n+1}}$ will then have zero expectation and contribute only through the diagonal sum—see, for example, Milstein [44, p. 12]. This also guarantees that the next order term in the global error estimate (3.2), whose largest term has the upper bound $\max_n \|R_{t_n,t_{n+1}}\|_{L^2}^{3/2} h^{-3/2}$, involves only higher order contributions to the leading $\mathcal{O}(h^M)$ error.

Note that high order integrators may include multiple Stratonovich integral terms. We approximate these multiple integrals by their conditional expectations to the local order of approximation $h^{M+1/2}$ of the numerical method. Hence terms in the *integrator* of the form $J_\alpha c_\alpha$ are in fact approximated by $\mathbb{E}(J_\alpha|\mathcal{F}_Q)c_\alpha$, their expectation conditioned on intervening path information $\mathcal{F}_Q$ (see section 6 for more details). This generates terms of the form $\big(J_\alpha - \mathbb{E}(J_\alpha|\mathcal{F}_Q)\big)c_\alpha$ in the local flow remainder, which have zero expectation and hence contribute to the global error through the diagonal sum generating $\mathcal{O}(h^M)$ terms.

4. Uniformly accurate Magnus integrators. Our goal is to identify a class of Magnus integrators that are more accurate than Neumann (stochastic Taylor) integrators of the same order for any governing set of linear vector fields (for the integrators of order 1 and 3/2, we assume the diffusion vector fields commute). We thus compare the local accuracy of the Neumann and Magnus integrators through the leading terms of their remainders. We consider the case of constant coefficient matrices a_i, $i = 0, 1, \ldots, d$.

The local flow remainder of a Neumann integrator R^{neu} is simply given by the terms not included in the flow-map Neumann approximation. Suppose $\hat{\sigma}$ is the truncated Magnus expansion and that ρ is the corresponding remainder, i.e., $\sigma = \hat{\sigma} + \rho$.

Then the local flow remainder R^{mag} associated with the Magnus approximation is

$$\begin{aligned} R^{\mathrm{mag}} &= \exp\sigma - \exp\hat{\sigma} \\ &= \exp\bigl(\hat{\sigma}+\rho\bigr) - \exp\hat{\sigma} \\ &= \rho + \tfrac{1}{2}(\hat{\sigma}\rho + \rho\hat{\sigma}) + \mathcal{O}(\hat{\sigma}^2\rho). \end{aligned} \tag{4.1}$$

Hence the local flow remainder of a Magnus integrator R^{mag} is the truncated Magnus expansion remainder ρ and higher order terms $\frac{1}{2}(\hat{\sigma}\rho+\rho\hat{\sigma})$ that can contribute to the global error at leading order through their expectations. For the integrators considered in this section, these higher order terms do not contribute in this way; however, for the order 1 integrator we consider in the next section that they do.

DEFINITION 4.1 (uniformly accurate Magnus integrators). *When the linear diffusion vector fields commute so that* $[a_i,a_j]=0$ *for all* $i,j\neq 0$*, we define the order* 1 *and order* $3/2$ uniformly accurate Magnus integrators *by*

$$\hat{\sigma}^{(1)}_{t_n,t_{n+1}} = J_0a_0 + \sum_{i=1}^{d}\bigl(J_ia_i + \tfrac{h^2}{12}[a_i,[a_i,a_0]]\bigr),$$

and

$$\hat{\sigma}^{(3/2)}_{t_n,t_{n+1}} = J_0a_0 + \sum_{i=1}^{d}\bigl(J_ia_i + \tfrac{1}{2}(J_{i0}-J_{0i})[a_0,a_i] + \tfrac{h^2}{12}[a_i,[a_i,a_0]]\bigr).$$

By *uniformly* we mean for any given set of governing linear vector fields (or equivalently coefficient matrices a_i, $i=0,1,\ldots,d$) for which the diffusion vector fields commute, and for any initial data y_0.

THEOREM 4.2 (global error comparison). *For any initial condition* y_0 *and sufficiently small fixed stepsize* $h=t_{n+1}-t_n$*, the order* $1/2$ *Magnus integrator is globally more accurate in* L^2 *than the order* $1/2$ *Neumann integrator. If, in addition, we assume the linear diffusion vector fields commute so that* $[a_i,a_j]=0$ *for all* $i,j\neq 0$*, then the order* 1 *and* $3/2$ uniformly accurate Magnus integrators *are globally more accurate in* L^2 *than the corresponding Neumann integrators. In other words, if* $\mathcal{E}^{\mathrm{mag}}$ *denotes the global error of the order* $1/2$ *Magnus integrator or the uniformly accurate Magnus integrators of order* 1 *or order* $3/2$*, respectively, and* $\mathcal{E}^{\mathrm{neu}}$ *is the global error of the Neumann integrators of the corresponding order, then at each of those orders*

$$\mathcal{E}^{\mathrm{mag}} \leq \mathcal{E}^{\mathrm{neu}}. \tag{4.2}$$

Proof. Let R^{mag} and R^{neu} denote the local flow remainders corresponding to the Magnus and Neumann approximations across the interval $[t_n,t_{n+1}]$ with $t_n=nh$. A direct calculation reveals that

$$\mathbb{E}\bigl((R^{\mathrm{neu}})^{\mathrm{T}}R^{\mathrm{neu}}\bigr) = \mathbb{E}\bigl((R^{\mathrm{mag}})^{\mathrm{T}}R^{\mathrm{mag}}\bigr) + D_M + \mathcal{O}\bigl(h^{2M+1/2}\bigr),$$

where if we set $\hat{R}\equiv R^{\mathrm{neu}}-R^{\mathrm{mag}}$, then

$$D_M \equiv \mathbb{E}\bigl(\hat{R}^{\mathrm{T}}R^{\mathrm{mag}}\bigr) + \mathbb{E}\bigl((R^{\mathrm{mag}})^{\mathrm{T}}\hat{R}\bigr) + \mathbb{E}\bigl(\hat{R}^{\mathrm{T}}\hat{R}\bigr). \tag{4.3}$$

We now show explicitly in each of the three cases of the theorem that at leading order R^{mag} and $\hat{R}$ are uncorrelated and hence D_M is positive semidefinite. This implies that

the local remainder for the Neumann expansion is larger than that of the Magnus expansion. Hereafter assume the indices $i, j, k, l \in \{1, \dots, d\}$.

For the *order* $1/2$ *integrators* we have to leading order (see the form of the expansions in the appendix)

$$R^{\mathrm{mag}} = \sum_{i<j} \tfrac{1}{2}(J_{ij} - J_{ji})[a_j, a_i],$$

and

$$\hat{R} = \sum_i \big(J_{ii} - \tfrac{1}{2}h\big)a_i^2 + \sum_{i<j} \tfrac{1}{2}(J_{ij} + J_{ji})(a_j a_i + a_i a_j),$$

which are uncorrelated by direct inspection.

We henceforth assume $[a_i, a_j] = 0$ for all i, j. For the *uniformly accurate order* 1 *integrator* we have to leading order (again see the appendix)

$$R^{\mathrm{mag}} = \sum_i \tfrac{1}{2}(J_{i0} - J_{0i})[a_0, a_i],$$

and

$$\hat{R} = \tfrac{1}{2}h^2 a_0^2 + \sum_i \tfrac{1}{2}\big(J_{i0} + J_{0i}\big)(a_0 a_i + a_i a_0) + \tfrac{1}{4}h^2(a_i^2 a_0 + a_0 a_i^2)$$

$$+ \sum_{i,j,k} \big(J_{ijk} - \mathbb{E}(J_{ijk})\big)a_k a_j a_i,$$

which again by direct inspection are uncorrelated.

For the *uniformly accurate order* $3/2$ *integrator* the local flow remainders are

$$R^{\mathrm{neu}} = \sum_i (J_{ii0} - \tfrac{1}{4}h^2)a_0 a_i^2 + J_{i0i}a_i a_0 a_i + (J_{0ii} - \tfrac{1}{4}h^2)a_i^2 a_0$$

$$+ \sum_{i<j} \Big((J_{0ji} + J_{0ij})a_i a_j a_0 + J_{j0i}a_i a_0 a_j$$

$$+ J_{i0j}a_j a_0 a_i + (J_{ji0} + J_{ij0})a_0 a_i a_j \Big)$$

$$+ \sum_{i,j,k,l} \big(J_{ijkl} - \mathbb{E}(J_{ijkl})\big)a_l a_k a_j a_i,$$

and

$$R^{\mathrm{mag}} = \sum_i \tfrac{1}{12}(J_i^2 J_0 - h^2 - 6J_{i0i})[a_i, [a_i, a_0]]$$

$$+ \sum_{i<j} \tfrac{1}{6}\big(J_0 J_i J_j - 3(J_{i0j} + J_{j0i})\big)[a_j, [a_i, a_0]].$$

Consequently, we have

$$\begin{aligned}\hat{R} = \tfrac{1}{12}\sum_i \Big(&(6J_{i0}J_i - J_i^2J_0 - 2h^2)a_0a_i^2 + 2(J_i^2J_0 - h^2)a_ia_0a_i \\ &+ (6J_{0i}J_i - J_i^2J_0 - 2h^2)a_i^2a_0\Big) \\ + \tfrac{1}{6}\sum_{i<j}\Big(&\big(3(J_iJ_{0j} + J_jJ_{0i}) - J_0J_iJ_j\big)a_ia_ja_0 \\ &+ \big(J_0J_iJ_j + 3(J_{i0j} - J_{j0i})\big)a_ja_0a_i \\ &+ \big(J_0J_iJ_j + 3(J_{j0i} - J_{i0j})\big)a_ia_0a_j \\ &+ \big(3(J_iJ_{j0} + J_jJ_{i0}) - J_0J_iJ_j\big)a_0a_ia_j\Big) \\ + \sum_{i,j,k,l} &\big(J_{ijkl} - \mathbb{E}(J_{ijkl})\big)a_la_ka_ja_i.\end{aligned}$$

First, we note that the terms in $\hat{R}$ of the form $J_{ijkl}a_la_ka_ja_i$, for which at least three of the distinct indices, are uncorrelated with any terms in R^{mag}. We thus focus on the terms of this form with at most two distinct indices, namely

$$\sum_{i<j}(J_{ii}J_{jj} - \tfrac{1}{4}h^2)a_j^2a_i^2 + \sum_{i\neq j}J_{iii}J_ja_ja_i^3 + \sum_i(J_{iiii} - \tfrac{1}{8}h^2)a_i^4$$

and other remaining terms in $\hat{R}$. Since $\mathbb{E}\big[J_{i0i}|J_i\big] \equiv h(J_i^2 - h)/6$ and $\mathbb{E}\big[J_{i0j}|J_i,J_j\big] \equiv hJ_iJ_j/6$ for $i \neq j$, the following conditional expectations are immediate:

$$\begin{aligned}\mathbb{E}\big[(J_i^2J_0 - h^2)(J_i^2J_0 - h^2 - 6J_{i0i})|J_i\big] &= 0,\\ \mathbb{E}\big[(J_{iiii} - \tfrac{1}{8}h^2)(J_i^2J_0 - h^2 - 6J_{i0i})|J_i\big] &= 0,\\ \mathbb{E}\big[(J_{ii}J_{jj} - \tfrac{1}{4}h^2)(J_i^2J_0 - h^2 - 6J_{i0i})|J_i,J_j\big] &= 0,\\ \mathbb{E}\big[\big(J_0J_iJ_j + 3(J_{i0j} - J_{j0i})\big)\big(J_0J_iJ_j - 3(J_{i0j} + J_{j0i})\big)|J_i,J_j\big] &= 0,\\ \mathbb{E}\big[(J_{ii}J_{jj} - \tfrac{1}{4}h^2)\big(J_0J_iJ_j - 3(J_{i0j} + J_{j0i})\big)|J_i,J_j\big] &= 0,\\ \mathbb{E}\big[J_{iii}J_j\big(J_0J_iJ_j - 3(J_{i0j} + J_{j0i})\big)|J_i,J_j\big] &= 0.\end{aligned}$$

Hence the expectations of the terms shown are also zero. Second, direct computation of the following expectations reveals

$$\begin{aligned}\mathbb{E}\big((6J_{0i}J_i - J_i^2J_0 - 2h^2)(J_i^2J_0 - h^2 - 6J_{i0i})\big) &= 0,\\ \mathbb{E}\Big(\big(3(J_iJ_{0j} + J_jJ_{0i}) - J_0J_iJ_j\big)\big(J_0J_iJ_j - 3(J_{i0j} + J_{j0i})\big)\Big) &= 0.\end{aligned}$$

Hence R^{mag} and $\hat{R}$ are uncorrelated.

The corresponding global comparison results (4.2) now follow directly in each of the three cases above using that the local errors accumulate and contribute to the

global error as diagonal terms in the standard manner described in detail at the end of section 3. Note that we include the terms $\frac{1}{12}h^2[a_i,[a_i,a_0]]$ in the order 1 uniformly accurate Magnus integrator. These terms appear at leading order in the global remainder where they would otherwise generate a nonpositive definite contribution to D_M in (4.3). ∎

Note that the Magnus integrator $\hat{\sigma}^{(1)}$ is an order 1 integrator without the terms $\frac{1}{12}h^2[a_i,[a_i,a_0]]$. However, they are cheap to compute and including them in the integrator guarantees global superior accuracy independent of the set of governing coefficient matrices.

5. Noncommuting linear diffusion vector fields. What happens when the linear diffusion vector fields do not commute, i.e., we have $[a_i,a_j]\neq 0$ for nonzero indices $i\neq j$? Hereafter, assume $i,j,k\in\{1,\dots,d\}$. Consider the case of order 1 integrators. The local flow remainders are

$$R^{\mathrm{neu}}=\sum_i (J_{i0}a_0a_i+J_{0i}a_ia_0)+\sum_{i,j,k}J_{kji}a_ia_ja_k$$

and

$$\begin{aligned}R^{\mathrm{mag}}=&\sum_i \tfrac{1}{2}(J_{i0}-J_{0i})[a_0,a_i]+\sum_{i\neq j}\big(J_{iij}-\tfrac{1}{2}J_iJ_{ij}+\tfrac{1}{12}J_i^2J_j\big)[a_i,[a_i,a_j]]\\&+\sum_{i<j<k}\big((J_{ijk}+\tfrac{1}{2}J_jJ_{ki}+\tfrac{1}{2}J_kJ_{ij}-\tfrac{2}{3}J_iJ_jJ_k)[a_i,[a_j,a_k]]\\&\qquad+(J_{jik}+\tfrac{1}{2}J_iJ_{kj}+\tfrac{1}{2}J_kJ_{ji}-\tfrac{2}{3}J_iJ_jJ_k)[a_j,[a_i,a_k]]\big).\end{aligned}$$

Computing D_M in (4.3) gives

$$D_M=h^2\sum_{i\neq j}U_{iij}^{\mathrm{T}}BU_{iij}+h^2\sum_{i\neq j\neq k}U_{ijk}^{\mathrm{T}}CU_{ijk},$$

where $U_{iij}=(a_ja_i^2,a_ia_ja_i,a_i^2a_j,a_j^3,a_0a_j,a_ja_0)^{\mathrm{T}}\in\mathbb{R}^{6p\times p}$ and, in addition, we have that $U_{ijk}=(a_ka_ja_i,a_ja_ka_i,a_ka_ia_j,a_ia_ka_j,a_ja_ia_k,a_ia_ja_k)^{\mathrm{T}}\in\mathbb{R}^{6p\times p}$. Here $B,C\in\mathbb{R}^{6p\times 6p}$ consist of $p\times p$ diagonal blocks of the form $b_{k\ell}I_p$ and $c_{k\ell}I_p$, where

$$b=\tfrac{1}{144}\begin{pmatrix}31&10&1&18&12&24\\10&4&10&0&0&0\\1&10&31&18&24&12\\18&0&18&60&36&36\\12&0&24&36&36&36\\24&0&12&36&36&36\end{pmatrix},$$

and

$$c=\tfrac{1}{36}\begin{pmatrix}4&1&1&1&1&-2\\1&4&1&-2&1&1\\1&1&4&1&-2&1\\1&-2&1&4&1&1\\1&1&-2&1&4&1\\-2&1&1&1&1&4\end{pmatrix}.$$

Again, c is positive semidefinite with eigenvalues $\{\frac{1}{6},\frac{1}{6},\frac{1}{6},\frac{1}{6},0,0\}$. However, b has eigenvalues $\{\frac{1}{6},\frac{1}{48}(5+\sqrt{41}),\frac{1}{48}(5-\sqrt{41}),0.94465,0.0943205,-0.03897\}$, where the final three values are approximations to the roots of $288x^3-2888x^2+14x+1$.

The eigenvalues of b and c, respectively, are multiple eigenvalues for the matrices B and C, respectively. This implies that there are certain matrix combinations and initial conditions, for which the order 1 Taylor approximation is more accurate in the mean-square sense than the Magnus approximation. However, the two negative values are small in absolute value compared to the positive eigenvalues. For the majority of systems, one can thus expect the Magnus aproximation to be more accurate (as already observed by Sipiläinen [53], Burrage [9], and Burrage and Burrage [7]). For any given linear system of stochastic differential equations, the scheme that is more accurate can be identified using the results above.

In this case there are terms from $\frac{1}{2}(\hat{\sigma}\rho+\rho\hat{\sigma})$ in the Magnus remainder expression (4.1) that appear at leading order in the local flow remainder. These terms are of the form $\frac{1}{12}\big(a_i[a_j,[a_j,a_i]]+a_j[a_i,[a_i,a_j]]\big)h^2$. They make a negative definite contribution to global error, though this can be negated by including them as cheaply computable terms in the Magnus integrator (indeed we recommend doing so).

6. Quadrature. We start by emphasizing that there are two inherent scales:

- *Quadrature scale* Δt on which the discrete Wiener paths are generated.
- *Evaluation scale* h on which the stochastic differential equation is advanced.

The idea is to approximate multiple Stratonovich integrals by their corresponding expectations conditioned on the σ-algebra representing intervening knowledge of the Wiener paths (Clark and Cameron [16], Newton [49], and Gaines and Lyons [22]). Hence we approximate $J_\alpha(t_n,t_{n+1})$ by $\mathbb{E}\big(J_\alpha(t_n,t_{n+1})|\,\mathcal{F}_Q\big)$, where

$$\mathcal{F}_Q=\{\Delta W^i_{t_n+q\,\Delta t}\colon i=1,\dots,d;\,q=0,\dots,Q-1;\,n=0,\dots,N-1\},$$

with $\Delta W^i_{t_n+q\,\Delta t}\equiv W^i_{t_n+(q+1)\,\Delta t}-W^i_{t_n+q\,\Delta t}$, and $Q\Delta t\equiv h$, i.e., Q is the number of Wiener increments. We extend the result of Clark and Cameron [16] on the maximum rate of convergence to arbitrary order multiple Stratonovich integrals.

LEMMA 6.1 (quadrature error). *Suppose at least two of the indices in the multi-index* $\alpha=\{\alpha_1,\dots,\alpha_\ell\}$ *are distinct. Define*

$$j^*\equiv\min\{j\le\ell-1\colon\alpha_i=\alpha_l\;\forall\,i,l>j\}.$$

Let $\mathrm{n}(\alpha)$ *denote the number of zeros in* α, *and* $\mathrm{n}^*(\alpha)=\mathrm{n}(\{\alpha_{j^*},\dots,\alpha_\ell\})$. *Then the* L^2 *error in the multiple Stratonovich integral approximation* $\mathbb{E}\big(J_\alpha(t_n,t_{n+1})|\,\mathcal{F}_Q\big)$ *is*

$$\big\|J_\alpha(t_n,t_{n+1})-\mathbb{E}\big(J_\alpha(t_n,t_{n+1})|\,\mathcal{F}_Q\big)\big\|_{L^2}=\mathcal{O}\bigg(\frac{h^{(\ell+\mathrm{n}(\alpha))/2}}{Q^{(\mathrm{n}^*(\alpha)+1)/2}}\bigg).\tag{6.1}$$

Proof. For any s,t, we write for brevity

$$\widehat{J}_\alpha(s,t)=\mathbb{E}\big(J_\alpha(s,t)\,|\mathcal{F}_Q\big).$$

We define α^{-k} as the multi-index obtained by deleting the last k indices, that is, $\alpha^{-k} = \{\alpha_1, \ldots, \alpha_{\ell-k}\}$. We set $\tau_q \equiv t_n + q\Delta t$, where $q = 0, \ldots, Q-1$. Then

$$\begin{aligned} J_\alpha(t_n, t_{n+1}) &= \sum_{q=0}^{Q-1} \int_{\tau_q}^{\tau_{q+1}} J_{\alpha^{-1}}(t_n, \tau)\, \mathrm{d}W_\tau^{\alpha_\ell} \\ &= \sum_{q=0}^{Q-1} \left(\sum_{k=1}^{\ell-1} J_{\alpha^{-k}}(t_n, \tau_q) J_{\alpha_{\ell-k+1},\ldots,\alpha_\ell}(\tau_q, \tau_{q+1}) + J_\alpha(\tau_q, \tau_{q+1}) \right). \end{aligned}$$

Thus we have

$$\begin{aligned} &J_\alpha(t_n, t_{n+1}) - \widehat{J}_\alpha(t_n, t_{n+1}) \\ &\quad = \sum_{q=0}^{Q-1} \left(\sum_{k=1}^{\ell-1} \big(J_{\alpha^{-k}}(t_n, \tau_q) - \widehat{J}_{\alpha^{-k}}(t_n, \tau_q)\big) J_{\alpha_{\ell-k+1},\ldots,\alpha_\ell}(\tau_q, \tau_{q+1}) \right. \\ &\qquad\qquad + \widehat{J}_{\alpha^{-k}}(t_n, \tau_q) \left(J_{\alpha_{\ell-k+1},\ldots,\alpha_\ell}(\tau_q, \tau_{q+1}) - \widehat{J}_{\alpha_{\ell-k+1},\ldots,\alpha_\ell}(\tau_q, \tau_{q+1})\right) \\ &\qquad\qquad \left. + J_\alpha(\tau_q, \tau_{q+1}) - \widehat{J}_\alpha(\tau_q, \tau_{q+1}) \right). \end{aligned} \tag{6.2}$$

We prove the assertion by induction over ℓ. For $\ell = 2$, the first two terms in the sum (6.2) are zero and

$$\begin{aligned} \Big\| \sum_{q=0}^{Q-1} \big(J_\alpha(\tau_q, \tau_{q+1}) - \widehat{J}_\alpha(\tau_q, \tau_{q+1})\big) \Big\|_2^2 &= \mathcal{O}\big(Q(\Delta t)^{\ell+\mathrm{n}(\alpha)}\big) \\ &= \mathcal{O}\left(\frac{h^{\ell+\mathrm{n}(\alpha)}}{Q^{\ell+\mathrm{n}(\alpha)-1}} \right) \\ &= \mathcal{O}\left(\frac{h^{\ell+\mathrm{n}(\alpha)}}{Q^{\mathrm{n}^*(\alpha)+1}} \right). \end{aligned}$$

Here we have used that fact that $\ell = 2$, $j^* = 1$ and thus $\mathrm{n}(\alpha) = \mathrm{n}^*(\alpha)$.

Assume now that $\ell > 2$. We will investigate the order of each of the three types of terms in (6.2) separately. If at least two indices in α^{-k} are distinct, then by induction hypothesis

$$\big\| J_{\alpha^{-k}}(t_n, \tau_q) - \widehat{J}_{\alpha^{-k}}(t_n, \tau_q) \big\|_2^2 = \mathcal{O}\left(\frac{(\tau_q - t_n)^{\ell-k+\mathrm{n}(\alpha^{-k})}}{q^{\mathrm{n}^*(\alpha^{-k})+1}} \right),$$

and since $\tau_q - t_n = q\Delta t$ and $Q\,\Delta t = h$, we have for each $k = 1, \ldots, \ell-1$,

$$\begin{aligned} &\sum_{q=0}^{Q-1} \big\| \big(J_{\alpha^{-k}}(t_n, \tau_q) - \widehat{J}_{\alpha^{-k}}(t_n, \tau_q)\big)\, J_{\alpha_{\ell-k+1},\ldots,\alpha_\ell)}(\tau_q, \tau_{q+1}) \big\|_2^2 \\ &\qquad = \mathcal{O}\left(\frac{h^{\ell+\mathrm{n}(\alpha)}}{Q^{\mathrm{n}^*(\alpha^{-k})+\mathrm{n}(\alpha)-\mathrm{n}(\alpha^{-k})+k}} \right). \end{aligned}$$

Note that we have

$$\mathrm{n}^*(\alpha^{-k}) + \mathrm{n}(\alpha) - \mathrm{n}(\alpha^{-k}) + k \geq \mathrm{n}^*(\alpha) + k \geq \mathrm{n}^*(\alpha) + 1. \tag{6.3}$$

If all indices in α^{-k} are equal, then $\big\|J_{\alpha^{-k}}(t_n,\tau_q) - \widehat{J}_{\alpha^{-k}}(t_n,\tau_q)\big\|_2^2 = 0$.

For the second term in (6.2) we have for each $k = 1,\dots,\ell-1$,

$$\sum_{q=0}^{Q-1} \big\|\widehat{J}_{\alpha^{-k}}(t_n,\tau_q)\left(J_{\alpha_{\ell-k+1},\dots,\alpha_\ell}(\tau_q,\tau_{q+1}) - \widehat{J}_{\alpha_{\ell-k+1},\dots,\alpha_\ell}(\tau_q,\tau_{q+1})\right)\big\|_2^2$$

$$= \begin{cases} 0 & \text{if } \alpha_\ell = \cdots = \alpha_{\ell-k+1}, \\ \mathcal{O}\Big(\frac{h^{\ell+\mathrm{n}(\alpha)}}{Q^{\mathrm{n}(\alpha)-\mathrm{n}(\alpha^{-k})+k-1}}\Big) & \text{otherwise.} \end{cases}$$

Note that in the second of these cases

$$\mathrm{n}(\alpha) - \mathrm{n}(\alpha^{-k}) + k - 1 \geq \mathrm{n}^*(\alpha) + 1. \tag{6.4}$$

For the third term we have

$$\sum_{q=0}^{Q-1} \big\|J_\alpha(\tau_q,\tau_{q+1}) - \widehat{J}_\alpha(\tau_q,\tau_{q+1})\big\|_2^2 = \mathcal{O}\Big(\frac{h^{\ell+\mathrm{n}(\alpha)}}{Q^{\ell+\mathrm{n}(\alpha)-1}}\Big).$$

Again, note that we have

$$\ell + \mathrm{n}(\alpha) - 1 \geq \mathrm{n}^*(\alpha) + 1. \tag{6.5}$$

Equality holds in at least one of (6.3) to (6.5). To see this we distinguish the case when the last two indices are equal, $\alpha_{\ell-1} = \alpha_\ell$, and the case when the last two indices are distinct, $\alpha_{\ell-1} \neq \alpha_\ell$. If $\alpha_{\ell-1} = \alpha_\ell$, then

$$\mathrm{n}^*(\alpha^{-1}) + \mathrm{n}(\alpha) - \mathrm{n}(\alpha^{-1}) = \mathrm{n}^*(\alpha).$$

Since in this case at least two indices in α^{-1} are distinct, equality holds for $k = 1$ in (6.3). If $\alpha_{\ell-1} \neq \alpha_\ell$, then

$$\mathrm{n}^*(\alpha) = \mathrm{n}(\alpha) - \mathrm{n}(\alpha^{-2}),$$

and thus equality holds for $k = 2$ in (6.4). Hence the lemma follows. □

Note that each multiple Stratonovich integral $J_\alpha(t_n,t_{n+1})$ can be thought of as an ℓ-dimensional topologically conical volume in $(W^1,\dots,W^\ell)$-space. The surface of the conical volume is *panelled* with each panel distinguished by a double Stratonovich integral term involving two consecutive indices from α. The edges between the panels are distinguished by a triple integral and so forth. The conditional expectation approximation $\mathbb{E}\big(J_\alpha(t_n,t_{n+1})\big|\,\mathcal{F}_Q\big)$ can also be decomposed in this way. In the L^2-error estimate for this approximation, the leading terms are given by sums over the panels which also confirm the estimate (6.1).

Approximations of multiple Stratonovich integrals constructed using their conditional expectations are intimately linked to those constructed using paths W_t^i that are approximated by piecewise linear interpolations of the intervening sample points. The difference between the two approaches are asymptotically smaller terms. For more details, see Wong and Zakai [59], Kloeden and Platen [33], Hofmann and Müller-Gronbach [29], and Gyöngy and Michaletzky [27].

TABLE 7.1

Slopes of the logarithm of the global error $\mathcal{E}$ verses the logarithm of the quadrature effort $\mathcal{U}$, i.e., the exponent $-M/\beta(M,\ell)$, for different values of ℓ and M when $J_{\alpha_1\cdots\alpha_\ell}$ has distinct nonzero indices.

	$\ell=2$	$\ell=3$	$\ell=4$	$\ell=5$	$\ell=6$
No zero index					
$M=1$	$-1/2$	$\cdots$	$\cdots$	$\cdots$	$\cdots$
$M=3/2$	$-1/2$	$-1/2$	$\cdots$	$\cdots$	$\cdots$
$M=2$	$-1/2$	$-2/5$	$-1/2$	$\cdots$	$\cdots$
$M=5/2$	$-1/2$	$-5/14$	$-5/14$	$-1/2$	$\cdots$
$M=3$	$-1/2$	$-1/3$	$-3/10$	$-1/3$	$-1/2$

7. Global error vs computational effort. We examine in detail the step-size/accuracy regimes for which higher order stochastic integrators are feasible and also when they become less efficient than lower order schemes. In any strong simulation there are two principle sources of computational effort. First, there is evaluation effort $\mathcal{U}^{\text{eval}}$ associated with evaluating the vector fields, their compositions, and any functions such as the matrix exponential. Second, there is the quadrature effort $\mathcal{U}^{\text{quad}}$ associated with approximating multiple stochastic integrals to an accuracy commensurate with the order of the method. For a numerical approximation of order M the computational evaluation effort measured in flops over $N = Th^{-1}$ evaluation steps is

$$\mathcal{U}^{\text{eval}} = (c_M p^2 + c_E)\, Th^{-1}.$$

Here p is the size of the system, c_M represents the number of scalar-matrix multiplications and matrix-matrix additions for the order M truncated Magnus expansion, and c_E is the effort required to compute the matrix exponential. Note that if we implement an order $1/2$ method there is no quadrature effort. Hence since $\mathcal{E} = \mathcal{O}(h^{1/2})$, we have $\mathcal{E} = \mathcal{O}\big((\mathcal{U}^{\text{eval}})^{-1/2}\big)$.

Suppose we are required to simulate $J_{\alpha_1\cdots\alpha_\ell}(t_n, t_{n+1})$ with all of the indices distinct with a global error of order h^M; naturally $\ell \geq 2$ and $M \geq \ell/2$.

LEMMA 7.1. *The quadrature effort $\mathcal{U}$ measured in flops required to approximate $J_{\alpha_1\cdots\alpha_\ell}(t_n, t_{n+1})$ with a global error of order h^M when all of the indices are distinct and nonzero, is to leading order in h*

$$\mathcal{U} = \mathcal{O}\big(h^{-\beta(M,\ell)}\big),$$

where

$$\beta(M,\ell) = (\ell-1)(2M+1-\ell)+1.$$

Since we stipulate the global error associated with the multiple integral approximation to be $\mathcal{E} = \mathcal{O}(h^M)$, we have

$$\mathcal{E} = \mathcal{O}\big(\mathcal{U}^{-M/\beta(M,\ell)}\big).$$

Proof. The quadrature effort required to construct $\mathbb{E}\big(J_{\alpha_1\cdots\alpha_\ell}(t_n, t_{n+1})\,|\,\mathcal{F}_Q\big)$, which is an $(\ell-1)$-multiple sum, over $[0,T]$ is $\mathcal{U} = \mathcal{O}(Q^{\ell-1}N)$ with $N = Th^{-1}$. Using Lemma 6.1 to achieve a global accuracy of order h^M and therefore local L^2-norm of order $h^{M+1/2}$ for this integral, requires that $Q = h^{\ell-1-2M}$. ∎

In Table 7.1 we quote values for the exponent $-M/\beta(M,\ell)$ for different values of M and ℓ in the case when all of the distinct indices $\alpha_1, \ldots, \alpha_\ell$ are nonzero.

Suppose we are given a stochastic differential equation driven by a d-dimensional Wiener process with noncommuting governing vector fields. To successfully implement a strong numerical method of order M we must guarantee that the global error associated with each multiple integral present in the integrator that is approximated by its conditional expectation is also of order M. If we implement a numerical method of order $M \leq d/2$, we will *in general* be required to simulate multiple Stratonovich integrals with distinct indices of length ℓ with $2 \leq \ell \leq 2M \leq d$. We will also have to simulate multiple integrals with repeated indices of length $\ell_r \leq 2M$. These integrals will require the same or fewer quadrature points than those with distinct indices as we can take advantage of the repeated indices—see section 8 for more details. Such integrals therefore represent lower order corrections to the quadrature effort. Similarly multiple integrals with distinct indices that involve a zero index have index length that is one less than similar order multiple integrals with distinct nonzero indices. Hence they will also represent lower order corrections to the quadrature effort.

To examine the scaling exponent in the relation between the global error $\mathcal{E}$ and the quadrature effort $\mathcal{U}^{\text{quad}}$, which is the sum total of the efforts required to approximate all of the required multiple integrals to order h^M, we use Table 7.1 as a guide for the dominant scalings. For methods of order $M \leq d/2$, if $d = 2$ and we implement a method of order $M = 1$, then the dominant exponent is $-1/2$. Similarly if $d = 3$, then order 1 and $3/2$ methods also invoke a dominant scaling exponent of $-1/2$ for the integrals of length $\ell = 2$ and $\ell = 3$. If $d = 4$, then methods of order 1 and $3/2$ have the same scaling exponent of $-1/2$; however, the method of order 2 involves multiple integrals with three indices which are all distinct and the dominant scaling exponent for them is $-2/5$.

If we implement a method of order $M > d/2$, then we will be required to simulate multiple Stratonovich integrals with distinct indices of length ℓ with $2 \leq \ell \leq d$. We must also simulate higher order multiple integrals with indices of length ℓ_r involving repetitions with $d \leq \ell_r \leq 2M$; these may be cheaper to simulate than multiple integrals of the same length with distinct indices (again see section 8). When $d = 2$ the dominant scaling exponent is $-1/2$ for all orders. For $d \geq 3$ the dominant scaling exponent is *at best* $-1/2$, and so forth.

Last, we give an estimate for the critical stepsize h_{cr} below which the quadrature effort dominates the evaluation effort. Since $\ell = M + 1$ minimizes $\beta(M, \ell)$, we have the following estimate.

COROLLARY 7.2. *For the case of general noncommuting governing vector fields and a numerical approximation of order M, we have $\mathcal{U}^{\text{eval}} \geq \mathcal{U}^{\text{quad}}$ if and only if $h \geq h_{\text{cr}}$, where the critical stepsize*

$$h_{\text{cr}} = \mathcal{O}\Big(\big(T(c_M p^2 + c_E)\big)^{-1/(1-\beta(M,\ell_{\max}))} \Big),$$

where $\ell_{\max} = \max\{d, M + 1\}$.

In practice when we implement numerical methods for stochastic differential equations driven by a d-dimensional Wiener process, we expect that for $h \geq h_{\text{cr}}$ the evaluation effort dominates the compuational cost. In this scenario integrators of order M scale like their deterministic counterparts. Consider what we might expect to see in a log-log plot of global error versus computational cost. As a function of increasing computational cost, we expect the global error for each method to fan out with slope $-M$, with higher order methods providing superior accuracy for a given effort. However, once the quadrature effort starts to dominate, the scaling exponents described above take over. When $d = 2$, for example, and all methods dress themselves with the

scaling exponent $-1/2$, we then expect to see parallel graphs with higher order methods still providing superior accuracy for a given cost. However, higher order methods that assume a scaling exponent worse than $-1/2$ will eventually reintersect the graphs of their lower order counterparts, and past that regime they should not be used.

Note that in the case when all of the diffusion vector fields commute, methods of order 1 do not involve any quadrature effort and hence $\mathcal{E} = \mathcal{O}\big((\mathcal{U}^{\text{eval}})^{-1}\big)$. Using Lemma 6.1, we can, by analogy with the arguments in the proof of Lemma 7.1, determine the dominant scaling exponents for methods of order $M \geq 3/2$. For example, the L^2-error associated with approximating J_{0i} by its expectation conditioned on intervening information is of order $h^{3/2}/Q$. Hence we need only choose $Q = h^{-1/2}$ to achieve a global error of order $3/2$. In this case the dominant scaling exponent is -1. However, the L^2-error associated with approximating J_{0ij} for $i \neq j$ is of order $h^2/Q^{1/2}$, whereas for J_{i0j} and J_{ij0} it is of order h^2/Q. For the case of diffusing vector fields, we do not need to simulate J_{0ij}, and so for a method of order 2 the dominant scaling exponent is still -1. However, more generally the effort associated with approximating J_{0ij} dominates the effort associated with the other two integrals.

8. Efficient quadrature bases. When multiple Stratonovich integrals contain repeated indices, are they as cheap to compute as the corresponding lower dimensional integrals with an equal number of distinct indices (none of them repeated)?

Let $i \cdots i_p$ denote the multi-index with p copies of the index i. Repeated integration by parts yields the formulae

$$J_{i\cdots i_p j i\cdots i_q} = \sum_{k=1}^{q} (-1)^{k+1} J_{i\cdots i_k} J_{i\cdots i_p j i\cdots i_{q-k}} + (-1)^{q+2} \int J_{i\cdots i_p} J_{i\cdots i_q} \mathrm{d}J_j, \tag{8.1a}$$

$$J_{i\cdots i_p j\cdots j_q} = \sum_{k=1}^{q-1} (-1)^{k+1} J_{j\cdots j_k} J_{i\cdots i_p j\cdots j_{q-k}} + (-1)^{q+1} \int J_{i\cdots i_p} \mathrm{d}J_{j\cdots j_q}. \tag{8.1b}$$

The first relation (8.1a) suggests that any integral of the form $J_{i\cdots i_p j i\cdots i_q}$ can always be approximated by a single sum. This last statement is true for $q = 1$. If we assume it is true for $q-1$ and apply the relation (8.1a), then we establish by induction that $J_{i\cdots i_p j i\cdots i_q}$ can be approximated by a single sum. A similar induction argument using (8.1b) then also establishes that any integral of the form $J_{i\cdots i_p j\cdots j_q}$ can also be approximated by a single sum. Hence in both cases the quadrature effort is proportional to QN.

Implicit in the relations (8.1a) and (8.1b) is the natural underlying shuffle algebra created by integration by parts (see Gaines [20, 19], Kawksi [32], and Munthe–Kaas and Wright [48]). Two further results are of interest. First, we remark that by integration by parts we have the following two shuffle product results:

$$J_{i_1 i_2 i_3} J_{i_4} = J_{i_1 i_2 i_3 i_4} + J_{i_1 i_2 i_4 i_3} + J_{i_1 i_4 i_2 i_3} + J_{i_4 i_1 i_2 i_3}, \tag{8.2a}$$

$$J_{i_1 i_2} J_{i_3 i_4} = J_{i_1 i_2 i_3 i_4} + J_{i_1 i_3 i_2 i_4} + J_{i_3 i_1 i_2 i_4} + J_{i_3 i_4 i_1 i_2} + J_{i_3 i_1 i_4 i_2} + J_{i_1 i_3 i_4 i_2}. \tag{8.2b}$$

If we replace $\{i_1, i_2, i_3, i_4\}$ by $\{i, i, j, j\}$ in (8.2b) and (8.2a) and then by $\{i, j, i, j\}$ in (8.2a) and (8.2b), respectively, we obtain the linear system of equations

$$\begin{pmatrix} 1 & 1 & 1 & 1 \\ 0 & 2 & 0 & 1 \\ 0 & 0 & 1 & 1 \\ 0 & 0 & 0 & 2 \end{pmatrix} \begin{pmatrix} J_{jiji} \\ J_{ijji} \\ J_{jiij} \\ J_{ijij} \end{pmatrix} = \begin{pmatrix} J_{ii} J_{jj} - J_{iijj} - J_{jjii} \\ J_{iji} J_j - J_{jjii} \\ J_{iij} J_j - 2 J_{iijj} \\ J_{ij} J_{ij} - 4 J_{iijj} \end{pmatrix}. \tag{8.3}$$

By direct inspection the coefficient matrix on the left-hand side has rank 4 and so all of the multiple Stratonovich integrals J_{jiji}, J_{ijji}, J_{jiij}, and J_{ijij} can be expressed in terms of J_{iijj} and J_{jjii} and products of lower order integrals, all of which can be approximated by single sums (note that $J_{iji} \equiv J_{ij}J_i - 2J_{iij}$).

Now consider the set of multiple Stratonovich integrals

$$\mathfrak{J} = \big\{J_{i_1i_2i_3i_4i_5} : \{i_1,i_2,i_3,i_4,i_5\} \in \text{perms}\{i,i,i,j,j\}\big\} \backslash \big\{J_{iiijj}, J_{jjiii}\big\},$$

where we exclude the elements J_{iiijj} and J_{jjiii} which we know can be approximated by single sums from (8.1b). By considering the shuffle relations generated by products of the form $J_{i_1i_2i_3i_4}J_{i_5}$, $J_{i_1i_2i_3}J_{i_4i_5}$, $J_{i_1i_2}J_{i_3i_4i_5}J_{i_5}$ and $J_{i_1}J_{i_2}J_{i_3}J_{i_4}J_{i_5}$ and substituting in the ten elements with indices from perms$\{i,i,i,j,j\}$ we obtain a linear system of equations analogous to (8.3) with 50 equations for the 8 unknowns in $\mathfrak{J}$. However, direct calculation shows that the corresponding coefficient matrix has rank 7. In particular, all of the multiple integrals in $\mathfrak{J}$ can be expressed in terms of J_{iiijj}, J_{jjiii}, and J_{jiji}. Hence the set of multiple integrals with indices from perms$\{i,i,i,j,j\}$ cannot all be approximated by single sums, but in fact require a double sum to approximate J_{jiji}.

For simplicity, assume $d = 1$. Consider numerical schemes of increasing order M. If $3/2 \le M \le 3$, then all of the necessary multiple integrals can be approximated by single sums—at the highest order in this range indices involving permutations of $\{1,1,1,1,0\}$ and $\{1,1,0,0\}$ are included for which the corresponding integrals can be approximated by single sums. For methods of order $M \ge 7/2$, we require at least double sums to approximate the necessary multiple integrals.

When $d = 2$, for methods of order $M = 1, 3/2$ the integrals involved can be approximated by single sums, but for $M = 2$ integrals involving indices with permutations of $\{2,1,0\}$ are included which can be approximated only by double sums. If there were no drift vector field, then for $1 \le M \le 2$ the necessary multiple integrals can all be approximated by single sums, but for $M = 5/2$ we need to include multiple integrals involving indices with permutations of $\{2,2,1,1,1\}$ which require approximation by double sums. We can in principle extend these results to higher values M; however, methods of order $M \ge d/2$ for $d \ge 3$ are not commonly implemented!

9. Numerical simulations.

9.1. Riccati system. Our first application is for stochastic Riccati differential systems—some classes of which can be reformulated as linear systems (see Freiling [18] and Schiff and Shnider [50]). Such systems arise in stochastic linear-quadratic optimal control problems, for example, mean-variance hedging in finance (see Bobrovnytska and Schweizer [6] and Kohlmann and Tang [34])—though often these are backward problems (which we intend to investigate in a separate study). Consider, for example, Riccati equations of the form

$$u_t = u_0 + \sum_{i=0}^{d} \int_0^t \big(u_\tau A_i(\tau) u_\tau + B_i(\tau) u_\tau + u_\tau C_i(\tau) + D_i(\tau)\big)\, \mathrm{d}W_\tau^i.$$

If $y = (U\ V)^{\mathrm{T}}$ satisfies the linear stochastic differential system (1.1), with

$$a_i(t) \equiv \begin{pmatrix} B_i(t) & D_i(t) \\ -A_i(t) & -C_i(t) \end{pmatrix},$$

then $u = UV^{-1}$ solves the previous Riccati equation.

We consider here a Riccati problem with two additive Wiener processes, W^1 and W^2, and coefficient matrices

$$D_0 = \begin{pmatrix} \frac{1}{2} & \frac{1}{2} \\ 0 & 1 \end{pmatrix}, \qquad D_1 = \begin{pmatrix} 0 & 1 \\ -\frac{1}{2} & -\frac{51}{200} \end{pmatrix}, \qquad \text{and} \qquad D_2 = \begin{pmatrix} 1 & 1 \\ 1 & \frac{1}{2} \end{pmatrix}, \tag{9.1}$$

and

$$A_0 = \begin{pmatrix} -1 & 1 \\ -\frac{1}{2} & -1 \end{pmatrix} \qquad \text{and} \qquad C_0 = \begin{pmatrix} -\frac{1}{2} & 0 \\ -1 & -1 \end{pmatrix}.$$

All other coefficient matrices are zero. The initial data is the 2×2 identity matrix, i.e., $u_0 = I_2$ and therefore $U_0 = I_2$ and $V_0 = I_2$ also. We found the paper by Higham [28] a very useful starting point for our MATLAB simulations.

Note that for this example the coefficient matrices a_1 and a_2 are upper right block triangular and therefore nilpotent of degree 2, and also that $a_1 a_2$ and $a_2 a_1$ are identically zero so that, in particular, $[a_1, a_2] = 0$. The number of terms in each integrator at either order 1 or 3/2 is roughly equal, and so for a given stepsize the uniformly accurate Magnus integrators should be more expensive to compute due to the cost of computing the 4×4 matrix exponential—we used a $(6, 6)$ Padé approximation with scaling to compute the matrix exponential; see Moler and Van Loan [47] and also Iserles and Zanna [31] (the computational cost is roughly 6 times the system size cubed). Also note that the order 1 integrators do not involve quadrature effort whilst the order 3/2 integrators involve the quadrature effort associated with approximating J_{10} and J_{20}. For comparison, we use a nonlinear Runge–Kutta type order 3/2 scheme for the case of two additive noise terms (from Kloeden and Platen [33, p. 383]) applied directly to the original Riccati equation:

$$\begin{aligned} S_{t_n,t_{n+1}} &= S_{t_n} + f\big(S_{t_n}\big)h + D_1 J_1 + D_2 J_2 \\ &\quad + \tfrac{h}{4}\big(f(Y_1^+) + f(Y_1^-) + f(Y_2^+) + f(Y_2^-) - 4f\big(S_{t_n}\big)\big) \\ &\quad + \tfrac{1}{2\sqrt{h}}\big(\big(f(Y_1^+) - f(Y_1^-)\big)J_{10} + \big(f(Y_2^+) - f(Y_2^-)\big)J_{20}\big), \end{aligned} \tag{9.2}$$

where $Y_j^{\pm} = S_{t_n} + \frac{h}{2} f\big(S_{t_n}\big) \pm D_j \sqrt{h}$ and $f(S) = SA_0S + B_0S + SC_0 + D_0$.

In Figure 9.1 we show how the global error scales with stepsize and also CPU clocktime for this Riccati problem. Note that, as anticipated, for the same stepsize (compare respective plot points starting from the left), the order 1 Magnus integrator is more expensive to compute and more accurate than the order 1 Neumann integrator. Now compare the order 3/2 integrators. For the nonlinear scheme (9.2), we must evaluate $f(S)$ five times per step per path costing $20p^3 + 54p^2$ flops—here $p = 2$ refers to the size of the original Riccati system. For the Neumann and Magnus integrators the evaluation costs are $16(2p \times p) = 32p^2$ and $6(2p)^3 + 11(2p)^2 = 48p^3 + 44p^2$ flops, respectively (directly counting from the schemes). Hence for large stepsize we expect the Neumann integrator to be cheapest and the Magnus and nonlinear Runge–Kutta integrators to be more expensive. However, for much smaller stepsizes the quadrature effort should start to dominate. The efforts of all the order 3/2 integrators will not be much different and the Magnus integrator then outperforms the other two due to its superior accuracy.

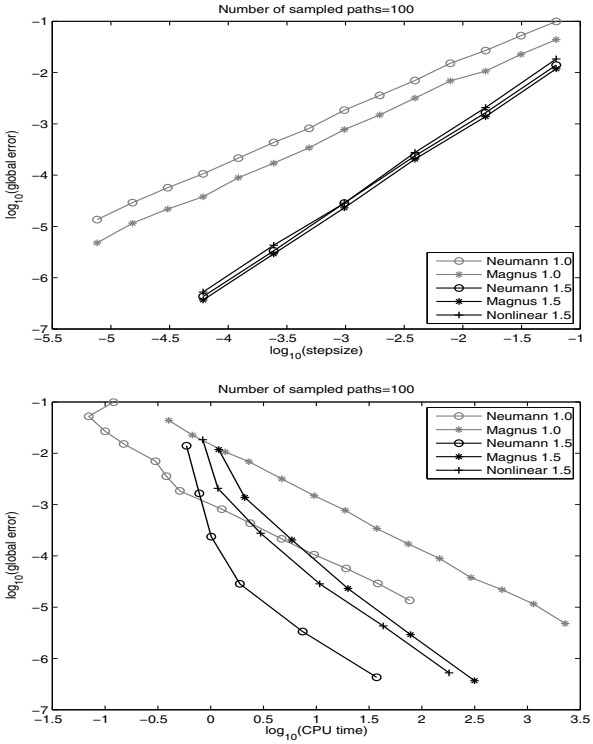

FIG. 9.1. *Global error vs stepsize (top) and vs CPU clocktime (bottom) for the Riccati problem at time* $t = 1$. *The Magnus integrators of order* 1 *and* 3/2 *shown are the uniformly accurate Magnus integrators from section* 4.

9.2. Linear system. Our second numerical example is for a homogeneous and constant coefficient linear problem involving two Wiener processes with coefficient matrices $a_i \equiv D_i$, where the D_i, $i = 0, 1, 2$ are given in (9.1) and do *not commute*, and initial data $y_0 = (\frac{1}{2}\ 1)^T$. In Figure 9.2 we show how the error scales with stepsize and CPU clocktime. We see that the superior accuracy of the Magnus integrators is achieved for the same computational cost. Note that in the case $M = 1$ we have $d = \ell = 2$. For the case when $h \leq h_{\rm cr}$, when computational cost is dominated by quadrature effort, the relation between the global error $\mathcal{E}_1$ and computational cost $\mathcal{U}$ is, ignoring $\mathcal{U}^{\rm eval}$ and taking the logarithm,

$$\log \mathcal{E}_1 \approx \log K_1 - \tfrac{1}{2} \log \mathcal{U}.$$

For the order 1/2 Magnus method the computational cost $\mathcal{U}$ is given solely by the evaluation effort and therefore we have

$$\log \mathcal{E}_{1/2} = \log K_{1/2} + \tfrac{1}{2} \log T(c_{1/2} p^2 + c_E) - \tfrac{1}{2} \log \mathcal{U}.$$

Further note that $K_{1/2}$ and K_1 are strictly order 1, and that $T = 1$, $p = 2$, $c_{1/2} = 5$, and $c_1 = 7$ (counting directly from the integration scheme). In addition, $c_E \approx 6p^3 = 48$ flops using the $(6, 6)$ Padé approximation with scaling. Substituting these values into the difference of these last two estimates reveals that

$$\log \mathcal{E}_1 - \log \mathcal{E}_{1/2} \approx -\tfrac{1}{2} \log 68 \approx -0.9,$$

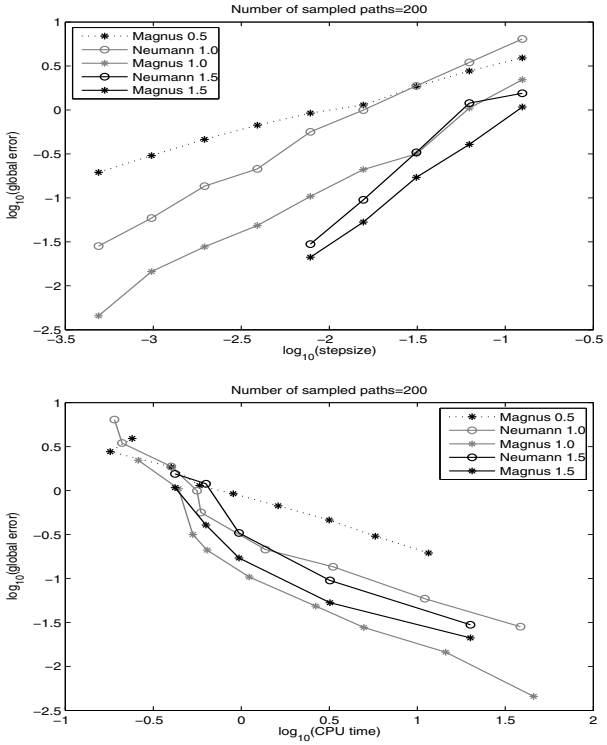

FIG. 9.2. *Global error vs stepsize (top) and vs CPU clocktime (bottom) for the model problem at time* $t = 1$ *with* 2 *driving Wiener processes. The error corresponding to the largest stepsize takes the shortest time to compute.*

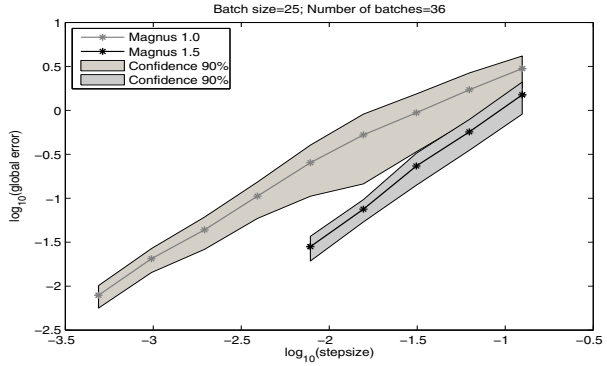

FIG. 9.3. *Confidence intervals for the global errors of the uniformly accurate Magnus integrators for the model problem at time* $t = 1$ *with* 2 *driving Wiener processes.*

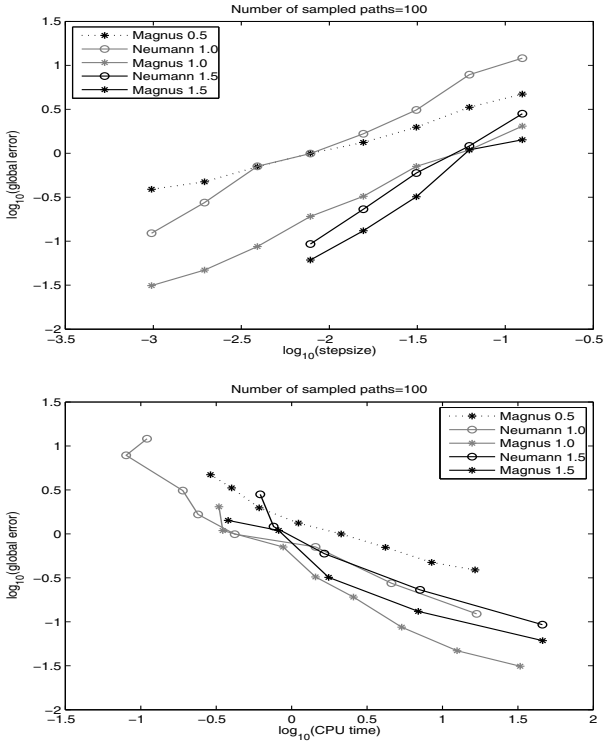

FIG. 9.4. *Global error vs stepsize (top) and vs CPU clocktime (bottom) for the model problem at time* $t = 1$ *with* 3 *driving Wiener processes. The error corresponding to the largest step size takes the shortest time to compute.*

which is in good agreement with the difference shown in Figure 9.2.

Also for this example, we have shown 90% confidence intervals in Figure 9.3 for the global errors of the uniformly accurate Magnus integrators of orders 1 and 3/2. The confidence intervals become narrower as the stepsize decreases and order of the method increases, as expected—see Kloeden and Platen [33, pp. 312–316].

In Figure 9.4 we consider a linear stochastic differential system driven by *three* independent scalar Wiener processes, with the same vector fields as in the linear system with two Wiener processes just considered but with an additional linear diffusion vector field characterized by the coefficient matrix

$$a_3 = \begin{pmatrix} \frac{1}{4} & \frac{2}{5} \\ \frac{1}{6} & \frac{1}{7} \end{pmatrix},$$

which does not commute with a_0, a_1, or a_2. Using Table 7.1 we would expect to see for small stepsizes for the order 1 and 3/2 Magnus and Neumann methods, that the global error scales with the computational effort with exponent $-1/2$. This can be seen in Figure 9.4.

10. Concluding remarks. Our results can be extended to nonlinear stochastic differential equations. Consider a stochastic differential system governed by $(d+1)$ nonlinear autonomous vector fields $V_i(y)$—instead of the linear vector fields $a_i(t)y$ in (1.1)—and driven by a d-dimensional Wiener process $(W^1, \ldots, W^d)$. If we take

the logarithm of the stochastic Taylor series for the flow-map, then we obtain the exponential Lie series (see Chen [15] and Strichartz [54])

$$\sigma_t = \sum_{i=0}^{d} J_i(t) V_i + \sum_{j>i=0}^{d} \tfrac{1}{2}(J_{ij} - J_{ji})(t)[V_i, V_j] + \cdots .$$

Here $[\cdot\,,\cdot]$ is the Lie–Jacobi bracket on the Lie algebra of vector fields defined on $\mathbb{R}^p$. The solution y_t of the system at time $t > 0$ is given by $y_t = \exp \sigma_t \circ y_0$ (see, for example, Ben Arous [5] or Castell and Gaines [13, 14]). Across the interval $[t_n, t_{n+1}]$, let $\hat{\sigma}_{t_n,t_{n+1}}$ denote the exponential Lie series truncated to a given order, with multiple integrals approximated by their expectations conditioned on intervening sample points. Then

$$\hat{y}_{t_{n+1}} = \exp\bigl(\hat{\sigma}_{t_n,t_{n+1}}\bigr) \circ y_{t_n}$$

is an approximation to the exact solution $y_{t_{n+1}}$ at the endpoint of the interval. The truncated and conditioned exponential Lie series $\hat{\sigma}_{t_n,t_{n+1}}$ is itself an ordinary vector field. Hence to compute $\hat{y}_{t_{n+1}}$, we solve the ordinary differential system

$$u'(\tau) = \hat{\sigma}_{t_n,t_{n+1}} \circ u(\tau)$$

with $u(0) = y_{t_n}$ across the interval $\tau \in [0, 1]$ (see Castell and Gaines [13, 14]). If we use a sufficiently accurate ordinary differential integrator commensurate with the order of the truncation of the exponential Lie series, then $u(1) \approx \hat{y}_{t_{n+1}}$ to that order.

Hence the order 1/2 exponential Lie series integrator is more accurate than the Euler–Maruyama method. Further in the case of commuting diffusion vector fields, the uniformly accurate exponential Lie series integrators of order 1 and 3/2 are more accurate than the stochastic Taylor approximations of the corresponding order. This generalization is discussed in Malham and Wiese [42]. An important future investigation to justify the viability of these schemes would be the relation between global error and computational cost, which must take into account the additional computational effort associated with the ordinary differential solver.

An important application for our results that we have in mind for the future are large order problems driven by a large number of Wiener processes. High-dimensional problems occur in many financial applications, for example in portfolio optimization or risk management and in the context of option pricing when high-dimensional models are used, for example for the pricing of interest rate options or rainbow options. Large order problems also arise when numerically solving stochastic parabolic partial differential equations driven by a multiplicative noise term which is white noise in time and spatially smooth (see, for example, Lord and Shardlow [37]). Here we think of projecting the system onto a finite spatial basis set which results in a large system of coupled ordinary stochastic differential equations each driven by a multiplicative noise term. The high dimension d of the driving Wiener process will now be an important factor in the computational cost for order $M \geq 1$ as, for example, we will need to simulate $\frac{1}{2}d(d-1)$ multiple integrals J_{ij}; though the results of Wiktorsson [58] suggest this can be improved upon. Krylov subspace methods for computing large matrix exponentials would be important for efficient implementation of our methods for this case (see Moler and Van Loan [47] and Sidje [52]).

Last, extensions of our work that we also intend to investigate further are: (1) implementing a variable step scheme following Gaines and Lyons [22], Lamba, Mattingly and Stuart [36], Burrage and Burrage [10], and Burrage, Burrage, and Tian [8]—by

using analytic expressions for the local truncation errors (see Aparicio, Malham, and Oliver [1]); (2) pricing path-dependent options; (3) deriving strong symplectic numerical methods (see Milstein, Repin, and Tretyakov [45]); and (4) constructing numerical methods based on the nonlinear Magnus expansions of Casas and Iserles [11].

11. Appendix. Neumann and Magnus integrators. We present Neumann and Magnus integrators up to global order $3/2$ in the case of a d-dimensional Wiener process $(W^1,\dots,W^d)$, and with constant coefficient matrices a_0 and a_i, $i=1,\dots,d$. The Neumann expansion for the solution of the stochastic differential equation (1.1) over an interval $[t_n,t_{n+1}]$, where $t_n=nh$, is

$$y^{\text{neu}}_{t_n,t_{n+1}} \approx \big(I+S_{1/2}+S_1+S_{3/2}\big)\,y_{t_n},$$

where (the indices i,j,k run over the values $1,\dots,d$)

$$\begin{aligned}
S_{1/2} &= J_0a_0+\sum_i J_ia_i+\sum_i J_{ii}a_i^2,\\
S_1 &= \sum_{i\neq j} J_{ij}a_ia_j,\\
S_{3/2} &= \sum_i (J_{i0}a_0a_i+J_{0i}a_ia_0)+\sum_{i,j,k} J_{kji}a_ia_ja_k\\
&\quad+\sum_i (J_{0ii}a_i^2a_0+J_{ii0}a_0a_i^2)+\sum_{i,j} J_{iijj}a_i^2a_j^2+J_{00}a_0^2.
\end{aligned}$$

The corresponding approximation using the Magnus expansion is

$$y^{\text{mag}}_{t_n,t_{n+1}} \approx \exp\big(s_{1/2}+s_1+s_{3/2}\big)\,y_{t_n},$$

where, with $[\cdot,\cdot]$ as the matrix commutator,

$$\begin{aligned}
s_{1/2} &= J_0a_0+\sum_i J_ia_i,\\
s_1 &= \sum_{i<j} \tfrac{1}{2}(J_{ji}-J_{ij})[a_i,a_j],\\
s_{3/2} &= \sum_i \tfrac{1}{2}(J_{i0}-J_{0i})[a_0,a_i]+\sum_{i\neq j}(J_{iij}-\tfrac{1}{2}J_iJ_{ij}+\tfrac{1}{12}J_i^2J_j)[a_i,[a_i,a_j]]\\
&\quad+\sum_{i<j<k}\big((J_{ijk}+\tfrac{1}{2}J_jJ_{ki}+\tfrac{1}{2}J_kJ_{ij}-\tfrac{2}{3}J_iJ_jJ_k)[a_i,[a_j,a_k]]\\
&\qquad+(J_{jik}+\tfrac{1}{2}J_iJ_{kj}+\tfrac{1}{2}J_kJ_{ji}-\tfrac{2}{3}J_iJ_jJ_k)[a_j,[a_i,a_k]]\big)\\
&\quad+\sum_i (J_{ii0}-\tfrac{1}{2}J_iJ_{i0}+\tfrac{1}{12}J_i^2J_0)[a_i,[a_i,a_0]].
\end{aligned}$$

To obtain a numerical scheme of global order M using the Neumann or Magnus expansion, we must use all of the terms up to and including S_M or s_M, respectively. Leading order terms of order $M+1/2$ with nonzero expectation can be replaced by their expectations (as detailed at the end of section 3). Further, extending these solution series to the nonhomogeneous and/or the nonconstant coefficient case is straightforward.

Acknowledgments. We thank Kevin and Pamela Burrage, Sandy Davie, Terry Lyons, Per-Christian Moan, Nigel Newton, Tony Shardlow, Josef Teichmann, and Michael Tretyakov for stimulating discussions. We would also like to thank the anonymous referees for their very helpful comments and suggestions.

CONVERGENCE OF A GENERALIZED FAST-MARCHING METHOD FOR AN EIKONAL EQUATION WITH A VELOCITY-CHANGING SIGN*

E. CARLINI†, M. FALCONE†, N. FORCADEL‡, AND R. MONNEAU‡

Abstract. We present a new fast-marching algorithm for an eikonal equation with a velocity-changing sign. This first order equation models a front propagation in the normal direction. The algorithm is an extension of the fast-marching method in two respects. The first is that the new scheme can deal with a *time-dependent* velocity, and the second is that there is *no restriction on its change in sign*. We analyze the properties of the algorithm, and we prove its convergence in the class of discontinuous viscosity solutions. Finally, we present some numerical simulations of fronts propagating in $\mathbb{R}^2$.

Key words. Hamilton–Jacobi equations, fast-marching scheme, convergence, viscosity solutions

1. Introduction.

The goal of this paper is to propose and analyze a numerical scheme to compute the evolution of a front driven by its normal velocity $c(x,t)$ under very general assumptions on c. In particular, we will remove the usual assumption which assigns to c a constant sign during the evolution. This means that the front can oscillate and pass several times over the same point. The initial front is the boundary of an open set Ω_0, which is represented by a characteristic function $1_{\Omega_0} - 1_{\Omega_0^c}$, defined equal to 1 on Ω_0 and -1 on its complementary set. The use of characteristic functions instead of continuous functions has the advantage to avoid the situation when the representation function of the front has a very low derivative around its 0-level set. In fact, in that situation it can be very difficult to compute the front by the level set due to numerical errors, and this is why some (rather expensive) reinitialization techniques have been proposed (see, e.g., [18, 26]) particularly in the framework of fluid dynamics. However, it has been observed [14] that such reinitialization is obviously a disagreement between the theory of the level set method and its implementation and in many cases moves the front from its exact location. On the contrary the representation of the front by characteristics functions has always a jump at the front, and no reinitialization is needed; naturally, we pay a price in terms of accuracy (we will come back on this point in section 6). The above considerations explain why we are interested in the discontinuous viscosity solution $\theta(x,t)$ of the following equation:

$$\begin{cases} \theta_t(x,t) = c(x,t)|D\theta(x,t)| & \text{on} \quad \mathbb{R}^N \times (0,T), \\ \theta(\cdot,0) = 1_{\Omega_0} - 1_{\Omega_0^c}. \end{cases} \tag{1.1}$$

Here the support of the discontinuities of the function θ localizes the front in which we are interested. This work is motivated by the applications to dislocations dynamics

where the velocity of the front depends on an integral term and can change sign (see Alvarez et al. [3] and Rodney et al. [19]).

A very popular method to describe the evolution of a front is the level sets method (see the seminal papers by Osher and Sethian [17] and Barles et al. [6] as well as the books [21, 22, 13]), where the discontinuous solution θ is replaced by a continuous function, and the equation is discretized by using a finite difference method with a CFL condition of the type $\Delta t\|c\|_\infty \leq \Delta x$ for explicit schemes, where Δx is the space step and Δt is the time step. In the case when the normal velocity c depends on t and can change its sign, it is absolutely necessary to solve the evolutive problem like (1.1) and track the front by its 0-level set. On the other hand, when the velocity c depends only on x and it is constant in sign (positive or negative), the evolution of the front is monotone (increasing or decreasing, respectively), and the problem can be solved via an associated stationary problem corresponding to a generalized eikonal equation (see [12] for more details and for the relations with the minimum time problem). Once the problem is reduced to the stationay eikonal equation we can use the fast-marching method (FMM) (see Sethian [23, 20]), where the unknown of the problem is the time $T(x)$ the front reaches the point x. This method works for nonnegative (nonpositive) velocities and provides a very efficient scheme which concentrates the computational effort on a neighborhood of the front. To be more precise, keeping in mind the viewpoint of discontinuous solutions, in the usual FMM we define the accepted region (A_+) as the discretization of the region $\{\theta = 1\}$ and the narrow band (NB_-) as the discretization of the boundary $\partial\{\theta = 1\}$, which is at the discrete level contained in the region $\{\theta = -1\}$. The algorithm computes the new values only at the nodes belonging to the narrow band and accepts just one of them, the one corresponding to the minimum value (see Kim [15] for a faster implementation). If c cannot change sign, we have a monotone (increasing or decreasing) evolution, and the front passes just one time on every point of the computational domain. The corresponding arrival time of the front is univalued so that the evolutive problem reduces to a stationary problem (the eikonal equation). Note that in this method there is no time step, because the time is itself the unknown of the problem so that the original evolutive problem (1.1) reduces to a stationary problem as remarked in [12, 16], i.e.,

$$|\nabla T| = \frac{1}{c(x)}. \tag{1.2}$$

To set this paper into perspective, let us recall that the FMM was initially developed for (1.2) with time-independent velocities $c(x) > 0$ (see Sethian [20] and Tsitsiklis [27]). This FMM scheme has been proved to be convergent, using a relation between the FMM solution and the numerical solution to finite difference schemes for the level sets formulation, for which it is known that these schemes are convergent (see Sethian and Vladimirsky [24] and Cristiani and Falcone [11]). More recently, the method has been extended to a more general Hamilton–Jacobi equation by Sethian and Vladimirsky [24, 25], and it has also been adapted to the case of time-dependent nonnegative velocities $c(x,t) \geq 0$ by Vladimirsky [28]. We also refer to Chopp [9] for some results for nonmonotone propagation but with time-independent velocity. However, to our knowledge, no proof of convergence has been given for the variable sign velocity case.

As we said, the goal of this paper is to propose a generalized fast-marching method (GFMM) which works for general velocities $c(x,t)$ without sign restrictions. This implies that the evolution is not necessarily monotone and that the time of arrival of the front can be multivalued. Then in our GFMM it is natural to introduce two

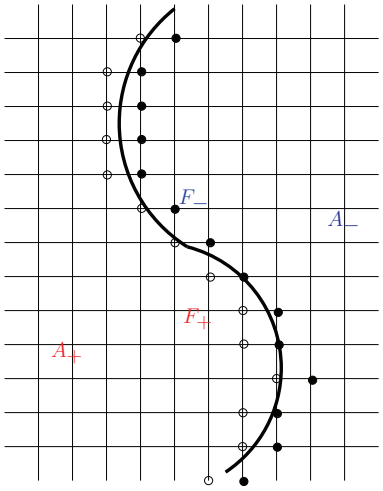

FIG. 1. *The narrow bands F_+ and F_-.*

accepted regions (A_+) and (A_-) and two narrow bands (F_+) and (F_-) in order to be able to take into account the changes of sign of the velocity. The typical picture is Figure 1. We track two fronts: one moving with positive velocity and one moving with negative velocity. A preliminary version of this new scheme has been proposed in [8]; however, in that first version no proof was given, and some small but very important details, which make the scheme work in the general case, were missing.

Our GFMM has a great potential for several future developments. Let us mention the application to dislocations dynamics where the velocity depends on the front itself via a convolution term. The corresponding level set model leads to a nonlocal Hamilton–Jacobi equation which has been analyzed in [3], a numerical approximation has been proposed in [2].

Let us underline some differences between the classical FMM method and our algorithm. One feature of the classical FMM algorithm is to generate a sequence of times t_n. Let us observe that there are several subtilities that do not appear in the usual FMM for $c(x) > 0$. These new features seem necessary to make the scheme work for general $c(x,t)$. Let us list a few of them. First, where the velocity changes sign in space, we need somehow to regularize it (see Definition 2.2) to avoid instabilities (in time) of the front. Second, because the time step is the difference $\Delta t_n = t_{n+1} - t_n$ between two computed times, we need our algorithm to ensure that this time step remains bounded from above by a given time step Δt, i.e.,

$$\Delta t_n \leq \Delta t. \tag{1.3}$$

Indeed, this is not a CFL condition. Here Δt can be much bigger than Δx divided by the maximum of the velocity. Condition (1.3) is necessary only to ensure the convergence of the scheme when Δt and Δx go to 0 (especially in the region where the velocity is very close to zero). If bound (1.3) is not respected, the algorithm may generate a sequence of time steps Δt_n nonconvergent to zero as Δx goes to zero. Third, in the classical FMM, the computed time $\tilde{t}_{n+1}$ associated to an accepted point satisfies $\tilde{t}_{n+1} > t_n$, and then we can choose as useful time $t_{n+1} = \tilde{t}_{n+1}$. One of the difficulties that we have to face in our GFMM is that it may happen that $\tilde{t}_{n+1} < t_n$ (if, for instance, the velocity is always equal to zero except at time t_n). In that case,

we cannot choose $t_{n+1} = \tilde{t}_{n+1}$, but we choose $t_{n+1} = t_n$ (see Step 8 of the algorithm). Fourth, when the front is close to a given point we have to choose carefully if we update or not the value of the time at this given point. This really depends on the position of the discrete front at time t_n and at time t_{n+1} and on the definition of the new accepted points (see Step 12 of the algorithm).

The main result of this paper is Theorem 2.5, which shows the convergence of our GFMM algorithm. When the discontinuous solution is unique, this result states that the numerical solution converges to the discontinuous viscosity solution as $\Delta x, \Delta t$ go to zero. In the case where the discontinuous viscosity solution is not unique, the result claims only that the upper semicontinuous envelope (obtained by a limsup*; see (2.7) for a definition) of the numerical solution is a discontinuous viscosity subsolution and, conversely, that the lower semicontinuous envelope (obtained by the liminf$_*$) is a supersolution.

Another novelty is the proof of convergence of this GFMM algorithm. In fact, we cannot use the relation with the usual schemes for the eikonal equation as in the case of nonnegative velocities $c(x) > 0$, and we need a *direct proof*. It is interesting to remark that, even in the case of nonnegative velocity, our proof is new. However, the idea of our proof is inspired by the paper by Barles and Georgelin [5] on fronts driven by mean curvature, where they prove convergence for a scheme in the framework of discontinuous viscosity solutions (we also refer to Barles and Souganidis [7] for convergence in the framework of continuous viscosity solutions). Basically, it is sufficient to consider a test function touching the upper semicontinuous envelope of the numerical solution (obtained as $\Delta x, \Delta t$ go to zero) which violates the subsolution property and to derive from this some properties of the discrete solution for nonzero $\Delta x, \Delta t$. This corresponds to considering test functions touching the discrete analogue of the discontinuous function θ in order to get a contradiction with the basic properties of the algorithm.

The paper is organized as follows. In section 2 we introduce our notation and present our GFMM algorithm and the main result of this paper, i.e., the convergence of the algorithm (Theorem 2.5). Section 3 is devoted to proving comparison principles and symmetry for GFMM. In section 4, several preliminary results are presented, focusing on properties of discrete times and on the geometry of the level sets of test functions. In section 5, we use the results of section 4 to prove the subsolution property of the limsup* envelope of the numerical solution, while the comparison principle of section 3 is used to prove this subsolution property at the initial time. The main result of section 5 is the proof of our main theorem (Theorem 2.5). In section 6 we present some numerical simulations and comment about these results in connection with our theoretical results.

2. The GFMM algorithm and the main result. In this section we give details for our GFMM algorithm for unsigned velocity. Let us start by introducing our definitions and notation.

Let us consider a lattice $Q \equiv \{x_I = (x_{i_1}, \dots, x_{i_N}) = (i_1 \Delta x, \dots, i_N \Delta x),\ I = (i_1, \dots, i_N) \in \mathbb{Z}^N\}$, with space step $\Delta x > 0$. We will also use a time step $\Delta t > 0$ (which does not satisfy any CFL condition).

The following definitions will be useful in what follows.

DEFINITION 2.1. *The* neighborhood of the node $I \in \mathbb{Z}^N$ *is the set*

$$V(I) \equiv \{J \in \mathbb{Z}^N : |J - I| \leq 1\}.$$

DEFINITION 2.2. *Given the speed $c_I^n \equiv c(x_I, t_n)$, we define the function*

$$\widehat{c}_I^n \equiv \begin{cases} 0 & \text{if there exists } J \in V(I) \text{ such that } (c_I^n c_J^n < 0 \text{ and } |c_I^n| \le |c_J^n|), \\ c_I^n & \text{otherwise.} \end{cases}$$

DEFINITION 2.3. *The* numerical boundary *∂E of a set $E \subset \mathbb{Z}^N$ is*

$$\partial E \equiv V(E) \backslash E,$$

with

$$V(E) = \left\{ J \in \mathbb{Z}^N, \quad \exists I \in E, \quad J \in V(I) \right\}.$$

DEFINITION 2.4. *Given a field θ_I^n with values $+1$ and -1, we define the two phases*

$$\Theta_\pm^n \equiv \{ I : \theta_I^n = \pm 1 \}$$

and the fronts $F_\pm^n \equiv \partial \Theta_\mp^n$ and $F^n \equiv F_+^n \cup F_-^n$.

In the description of the algorithm we will use the following notations:

$$\pm g \ge 0 \ \text{ for } I \in F_\pm \tag{2.1}$$

means

$$+g \ge 0 \ \text{ for } I \in F_+ \quad \text{and} \quad -g \ge 0 \text{ for } I \in F_-. \tag{2.2}$$

Moreover,

$$\min_\pm \{0, g_\pm\} \equiv \min\{0, g_+, g_-\} \quad \text{and} \quad \max_\pm \{0, g_\pm\} \equiv \max\{0, g_+, g_-\}. \tag{2.3}$$

2.1. The algorithm step by step. We describe now our GFMM algorithm for unsigned velocity. As in the classical FMM, our GFMM will generate a nondecreasing sequence of times $(t_n)_{n\in\mathbb{N}}$, with $t_0 = 0$. Contrary to the FMM, we will need a phase parameter θ_I^n with values $+1$ or -1 defined at each step n of the algorithm and for any $I \in \mathbb{Z}^N$. This θ_I^n should be thought of as a discretization of the solution θ of (1.1) at time t_n and at point x_I.

Similarly to the classical FMM, we will need to introduce a time u_I^n defined for I in the whole front F^n at the nth iteration of the algorithm. In the FMM, this time u_I^n can be interpreted as the time when the front F^n reaches the point I (this interpretation is essentially true for our GFMM algorithm except in the more delicate case where the velocity vanishes).

To write the details of the algorithm, we will need to introduce further variables:

- $\hat{u}_I^n$ corresponds to the time u_I^n at which the front passes through I, or ∞ if I is not an "upwind" point; this information is needed to compute the candidate time.
- $\tilde{u}_I^n$ is the candidate time the front may reach the point I.
- $\tilde{t}_n$ is simply the minimum of such $\tilde{u}_I^n$ for I in the front F^n. It is not a nondecreasing sequence. In general we accept $\tilde{t}_n$ as the time the front passes through at least one grid point; i.e., we have $t_n = \tilde{t}_n$, except if $\tilde{t}_n < t_{n-1}$ (nonincreasing sequence) or if $\tilde{t}_n$ is too large (speed close to zero), i.e., $\tilde{t}_n > t_{n-1} + \Delta t$ for some arbitrary (but given) time step $\Delta t > 0$.
- $\hat{t}_n$ is an intermediate time to ensure that $t_{n-1} - t_n < \Delta t$.

Initialization

1. Set $n = 1$.
2. *Initialize the field* θ^0 as
$$\theta_I^0 = \begin{cases} 1 & \text{for } x_I \in \Omega_0, \\ -1 & \text{elsewhere.} \end{cases}$$
3. *Initialize the time on* F^0
$u_I^0 = 0$ for all $I \in F^0$, $t_0 = 0$.

Main cycle

4. *Initialize* $\widehat{u}^{n-1}$ *everywhere on the grid*
$$\widehat{u}_{\pm,J}^{n-1} = \begin{cases} u_J^{n-1} & \text{for } J \in F_\pm^{n-1}, \\ \infty & \text{elsewhere.} \end{cases}$$

5. *Compute* $\tilde{u}^{n-1}$ *on* F^{n-1} *as follows:*
Let $I \in F_\pm^{n-1}$, and then
   1. if $\pm\widehat{c}_I^{n-1} \geq 0$, $\tilde{u}_I^{n-1} = \infty$;
   2. if $\pm\widehat{c}_I^{n-1} < 0$, we compute $\tilde{u}_I^{n-1}$ as the solution of the following second order equation:

$$\begin{aligned} &\sum_{k=1}^{N} \left(\max_{\pm} \left(0, \tilde{u}_I^{n-1} - \widehat{u}_{+,I^{k,\pm}}^{n-1} \right) \right)^2 = \frac{(\Delta x)^2}{|\widehat{c}_I^{n-1}|^2} \quad \text{if } I \in F_-^{n-1}, \\ &\sum_{k=1}^{N} \left(\max_{\pm} \left(0, \tilde{u}_I^{n-1} - \widehat{u}_{-,I^{k,\pm}}^{n-1} \right) \right)^2 = \frac{(\Delta x)^2}{|\widehat{c}_I^{n-1}|^2} \quad \text{if } I \in F_+^{n-1}, \end{aligned} \tag{2.4}$$

   where $I^{k,\pm} = (i_1, \ldots, i_{k-1}, i_k \pm 1, i_{k+1}, \ldots, i_N)$.
6. $\tilde{t}_n = \min\left\{ \tilde{u}_I^{n-1},\ I \in F^{n-1} \right\}$.
7. $\widehat{t}_n = \min\{\tilde{t}_n, t_{n-1} + \Delta t\}$.
8. $t_n = \max(t_{n-1}, \widehat{t}_n)$.
9. If $t_n = t_{n-1} + \Delta t$ and $t_n < \tilde{t}_n$, go to Step 4 with $n := n + 1$ and
$$\begin{cases} u_I^n = u_I^{n-1} \text{ for all } I \in F^n := F^{n-1}, \\ \theta_I^n = \theta_I^{n-1} \text{ for all } I \in \mathbb{Z}^N. \end{cases}$$

10. *Initialize the new accepted point*
$NA_\pm^n = \{I \in F_\pm^{n-1},\ \tilde{u}_I^{n-1} = \tilde{t}_n\}$, $NA^n = NA_+^n \cup NA_-^n$.
11. *Reinitialize* θ^n
$$\theta_I^n = \begin{cases} -1 & \text{for} \quad I \in NA_+^n, \\ 1 & \text{for} \quad I \in NA_-^n, \\ \theta_I^{n-1} & \text{elsewhere.} \end{cases}$$

12. *Reinitialize* u^n *on* F^n:
   1. If $I \in F^n \backslash V(NA^n)$, then $u_I^n = u_I^{n-1}$.
   2. If $I \in NA^n$, then $u_I^n = t_n$.
   3. If $I \in (F^{n-1} \cap V(NA^n)) \backslash NA^n$, then $u_I^n = u_I^{n-1}$.
   4. If $I \in V(NA^n) \backslash F^{n-1}$, then $u_I^n = t_n$.
13. Set $n := n + 1$ and go to Step 4.

Let us describe a few features of this new algorithm:

1. We know, at each time step, the time u_I^{n-1} on the fronts, i.e., on both sides of the front. This is necessary to allow the changes of the velocity sign in time.

2. In Step 5, we use the regularized velocity $\hat{c}$ and not c in order to stabilize the front. Indeed, if we do not do that, this typically leads to a duplication of the front.
3. Step 7 avoids large jumps in time and guarantees that $t_n - t_{n-1} \leq \Delta t$ with Δt small enough. Notice that this restriction on Δt is not a CFL condition but is here only to ensure that $t_n - t_{n-1} \to 0$ when we refine the mesh (i.e., decrease Δt). In particular, Δt can be chosen completely independently of Δx.
4. Step 9 allows us to increase the time. For example, if at time step n, we have $\widehat{c}_I^{n-1} = 0$ for all $I \in F^{n-1}$, then there will be no new accepted points, the time will not change, and the algorithm will be blocked without Steps 7 and 9.
5. The sequence of time $(\tilde{t}_n)$ is not necessarily nondecreasing in time. Indeed, if the velocity increases in time, we can have $\tilde{t}_n < \tilde{t}_{n-1}$, and so we have to do something to have an increasing sequence of time. In fact, Step 8 guarantees that the physical time t_n does not decrease.
6. In Step 12, for the reinitialization of u_I^n, we change its value only if a point of the neighborhood of the point I has been accepted. Moreover when u_I^n is updated, we use the physical time t_n and not $\tilde{t}_n$ or $\hat{t}_n$.

These choices, which can appear strange with respect to the classical FMM scheme, seem necessary to guarantee the convergence of our algorithm.

2.2. The main result. The scheme approximates the evolution of the fronts by a double *narrow band* and the physical time by the sequence $\{t_k, k \in \mathbb{N}\}$, defined at Step 8 in the algorithm. Such a sequence is nondecreasing, and we can extract a subsequence $\{t_{k_n}, n \in \mathbb{N}\}$ strictly increasing such that

$$t_{k_n} = t_{k_n+1} = \cdots = t_{k_{n+1}-1} < t_{k_{n+1}}.$$

We denote by S_I^n the square cell $S_I^n = [x_I, x_I + \Delta x[\times[t_{k_n}, t_{k_{n+1}}[$, with

$$[x_I, x_I + \Delta x[= \Pi_{\alpha=1}^N [x_{i_\alpha}, x_{i_\alpha} + \Delta x[,$$

and by ε the couple

$$\varepsilon = (\Delta x, \Delta t).$$

Let us define the following functions:

(2.5)
$$\theta^\varepsilon(x,t) = \begin{cases} \sup\{\theta_I^m : k_n \leq m \leq k_{n+1}-1\} & \text{if } (x,t) \in S_I^n \text{ and } c(x_I, t_{k_n}) > 0, \\ \inf\{\theta_I^m : k_n \leq m \leq k_{n+1}-1\} & \text{if } (x,t) \in S_I^n \text{ and } c(x_I, t_{k_n}) < 0, \\ \theta_I^m \ \forall m : \ k_n \leq m \leq k_{n+1}-1 & \text{if } (x,t) \in S_I^n \text{ and } c(x_I, t_{k_n}) = 0. \end{cases}$$

This definition will be useful in the proof but is indeed equivalent to the following:

$$\theta^\varepsilon(x,t) = \theta_I^{k_{n+1}-1} \text{ if } (x,t) \in S_I^n. \tag{2.6}$$

We define the half-relaxed limits

$$\overline{\theta}^0(x,t) = \text{limsup}_{\varepsilon \to 0, y \to x, s \to t} \theta^\varepsilon(y,s), \quad \underline{\theta}^0(x,t) = \text{liminf}_{\varepsilon \to 0, y \to x, s \to t} \theta^\varepsilon(y,s). \tag{2.7}$$

We make the following assumption:

(A) The velocity $c \in W^{1,\infty}(\mathbb{R}^N \times [0,T])$; for some constant $L > 0$ we have $|c(x',t') - c(x,t)| \leq L(|x'-x| + |t'-t|)$; and Ω_0 is a C^2 open set, with bounded boundary $\partial\Omega_0$.

THEOREM 2.5 (convergence result). *Under assumption* (A), $\overline{\theta}^0$ *(resp.,* $\underline{\theta}^0$*) is a viscosity subsolution (resp., supersolution) of* (1.1). *In particular, if* (1.1) *satisfies a comparison principle, then* $\overline{\theta}^0 = (\underline{\theta}^0)^*$ *and* $(\overline{\theta}^0)_* = \underline{\theta}^0$ *is the unique viscosity solution of* (1.1).

Remark 2.6. When the uniqueness holds, this is up to the upper and lower semicontinuous envelopes.

Remark 2.7. Note that when $c > 0$ our GFMM algorithm is a modified FMM algorithm where the time on the narrow band is computed by using *only* the accepted points. In this monotone case the viscosity solution of (1.1) is unique, and our result provides a convergence result (see also Test 3 in the last section).

Remark 2.8. The Lipschitz continuity in time of the velocity could be relaxed to continuity but is assumed here to simplify the presentation of the proofs, which are already quite complicated.

2.3. Computational complexity and remarks on the implementation. In this subsection, we give some rough asymptotic bounds on the computational complexity of our GFMM algorithm. Let us assume that the velocity is constant on each time interval $[k\Delta T, (k+1)\Delta T)$ for some ΔT. Of course, the velocity is not Lipschitz in time but can always be seen as the discretization of some Lipschitz velocity. We work on a (spatial) grid box of width $M^{\frac{1}{N}}$ in dimension N and therefore with a total number of grid points equal to M. We assume that the velocity is normalized $|c| \simeq 1$, and then the time T for the front to pass one time on the whole grid box is roughly $T \simeq 1$. Moreover, we normalize the space step with $\Delta x = 1$. The typical size (as a number of grid points) of the front is $M^{\frac{N-1}{N}}$ in the box. We can distinguish several cases depending on the value of ΔT.

Case 1 (constant in time velocity (i.e., $\Delta T = +\infty$)). Here the situation is very similar to the one of the classical FMM, and we can use a binary heap. Because the velocity is independent on time, we need only to recompute the value of the time at the points I whose neighbors have been accepted (i.e., $I \in V(NA^n)$). This means in practice to slightly modify point 5b of our algorithm GFMM. This implies that our GFMM is equivalent to two FMM algorithms, and so we recover the complexity in $O(M \log M)$.

Case 2 ($O(\frac{1}{M^{\frac{1}{N}}}) \leq \Delta T < +\infty$). In spirit, it is equivalent to Case 1 (indeed on the time interval $[k\Delta T, (k+1)\Delta T)$). Since the time T for the front to pass one time on the whole grid box is roughly $T \simeq 1$, we deduce that the number of time interval $[k\Delta T, (k+1)\Delta T)$ is $\frac{T}{\Delta T} = \frac{1}{\Delta T}$. On each interval $[k\Delta T, (k+1)\Delta T)$, the complexity is $M_k \log M_k$ (as in Case 1), where M_k is the number of points crossed by the front during this interval of time (with $\sum_k M_k = M$). This gives a complexity

$$\sum_{k=1}^{\frac{1}{\Delta T}} M_k \log M_k.$$

Moreover, at each $k\Delta T$, we have to recompute the candidate times and the binary heap (since the velocity changes). The complexity for these operations is

$O(M^{\frac{N-1}{N}} \log M)$. Therefore, the total complexity is then

$$\sum_{k=1}^{\frac{1}{\Delta T}} M_k \log M_k + \sum_{k=1}^{\frac{1}{\Delta T}} M^{\frac{N-1}{N}} \log M \leq M \log M + \frac{1}{\Delta T} M^{\frac{N-1}{N}} \log M.$$

If $\Delta T \geq \frac{1}{M^{\frac{1}{N}}}$, we then get a complexity in $O(M \log M)$ (as in the classical case).

Case 3 (variable velocity (i.e., $\Delta T = 0$) or $0 < \Delta T < O(\frac{1}{M^{\frac{1}{N}}})$). From a complexity point of view, it is not interesting to use a binary heap to sort the time of the points on the front. Because the velocity changes at each step n of the algorithm, it is much more efficient to recompute all of the times on the front and extract the minimum of these times at each iteration. The complexity for these operations is $O(M^{\frac{N-1}{N}})$. On the time necessary for the front to pass one time on the whole grid box, we need to do this computation $O(M)$ times. Therefore, the total complexity is $O(M^{\frac{2N-1}{N}})$.

In this case, it seems that the narrow band level set method can be more interesting from the complexity point of view (see [1]) although it is rather difficult to make a precise statement on this point.

We can then implement our algorithm depending on the variability of the velocity in time (see Cases 1, 2, and 3 above). Finally, we want to point out that Case 2, where ΔT is not so small, is acceptable in practice if the velocity is Lipschitz in time with a reasonable Lipschitz constant (and this is what we assume theoretically in our convergence theorem).

3. Comparison principles for the GFMM algorithm. As we said in the introduction, our convergence result will be proved in the framework of discontinuous viscosity solutions. To this end the role of comparison principles is crucial.

In this section, we first present a property of symmetry of the algorithm and then present some comparison principles in some special cases.

3.1. Symmetry of the algorithm. The following lemma claims that if we change the sign of the velocity and the sign of the two phases at the initial time, then the GFMM algorithm computes the same front.

LEMMA 3.1 (symmetry of the GFMM algorithm). *We denote by* $\overline{\theta}^0[\theta^0, c]$ *and* $\underline{\theta}^0[\theta^0, c]$ *the functions constructed by the GFMM algorithm with initial condition* θ^0 *and velocity* c. *Then we have*

$$\underline{\theta}^0[\theta^0, c] = -\overline{\theta}^0[-\theta^0, -c].$$

Proof of Lemma 3.1. With the same kind of notation, we remark that $\theta_I^n[-\theta^0, -c] = -\theta_I^n[\theta^0, c]$. We then have, for $x \in [x_I, x_I + \Delta x[$, $t \in [t_{k_n}, t_{k_{n+1}}[$, and $c(x_I, t_{k_n}) > 0$,

$$\begin{aligned}\theta^\varepsilon[\theta^0, c](x,t) &= \sup\{\theta_I^k[\theta^0, c],\ k_n \leq k \leq k_{n+1} - 1\} \\ &= -\inf\{-\theta_I^k[\theta^0, c],\ k_n \leq k \leq k_{n+1} - 1\} \\ &= -\inf\{\theta_I^k[-\theta^0, -c],\ k_n \leq k \leq k_{n+1} - 1\} = -\theta^\varepsilon[-\theta^0, -c].\end{aligned}$$

The result is similar for $c(x_I, t_{k_n}) \leq 0$. Therefore, $\underline{\theta}^0[\theta^0, c] = -\overline{\theta}^0[-\theta^0, -c]$. ∎

3.2. Comparison principles.

PROPOSITION 3.2 (comparison principle for the time). *We denote by* u_I^n *(resp.,* v_I^n*) the numerical solution at the point* (x_I, t_n) *of the GFMM algorithm with velocity*

c_u (resp., c_v). We assume that there exists $T > 0$ such that for all $(x,t) \in \mathbb{R}^N \times [0,T]$

$$\inf_{s\in[t-\Delta t,t],\ s\geq 0} c_v(x,s) \geq \sup_{s\in[t-\Delta t,t],\ s\geq 0} (c_u(x,s))^+,$$

where $(f)^+$ is the positive part of f. We assume that

$$\{\theta_u^0 = 1\} \subset \{\theta_v^0 = 1\} \quad \text{and} \quad v^0 = u^0 = 0.$$

We define $\bar{m}$ and $\bar{k}$ such that

$$\begin{cases} t_{\bar{m}} \leq T < t_{\bar{m}+1}, \\ s_{\bar{k}} \leq T < s_{\bar{k}+1}, \end{cases}$$

where $(t_m)_m$ and $(s_m)_m$ are the sequence of time constructed by the GFMM algorithm with velocity c_u and c_v, respectively. We then consider

$$v_I = \begin{cases} v_I^0 & \text{if} \quad \theta_{v,I}^0 = 1, \\ v_I^k & \text{if} \quad I \in NA_v^k \quad \text{for some} \quad k \leq \bar{k}+1, \\ s_{\bar{k}+1} & \text{if} \quad \theta_{v,I}^{\bar{k}} = -1. \end{cases}$$

Then, $\forall l \leq \bar{m}$, $\forall I \in NA_u^l$, we have $v_I \leq u_I^l$.

Remark 3.3. Here the notations for $\theta_u, \theta_v, NA_u^l$, and further notation in what follows are obvious and are not explained. Moreover we also remark that the front for v passes at most one time at a given point because $c_v \geq 0$.

Proof of Proposition 3.2. We argue by contradiction. We denote by $m(u)$ the first index such that there exists $I \in NA_u^{m(u)}$ such that

$$u_I^{m(u)} < v_I. \tag{3.1}$$

We define $k(v)$ such that $I \in NA_v^{k(v)}$ with the convention that $k(v) = \bar{k}+1$ if $\theta_{v,I}^{\bar{k}} = -1$. This implies that $t_{m(u)} = u_I^{m(u)} < v_I = s_{k(v)}$. The proof distinguishes two cases:

1. $I \in NA_{-,u}^{m(u)} \subset F_{-,u}^{m(u)-1}$. We claim that, for all $J \in V(I)\setminus\{I\}$, we have

$$\widehat{u}_{+,J}^{m(u)-1} \geq \widehat{v}_{+,J}^{k(v)-1}. \tag{3.2}$$

Indeed assume that $\widehat{u}_{+,J}^{m(u)-1} < \infty$ (if $\widehat{u}_{+,J}^{m(u)-1} = \infty$, then (3.2) holds); then $J \in F_{+,u}^{m(u)-1}$, and we have

$$t_{m(u)} \geq \widehat{u}_{+,J}^{m(u)-1} \geq v_J.$$

It just remains to show that $v_J = \widehat{v}_{+,J}^{k(v)-1}$. We argue by contradiction. Assume that $\widehat{v}_{+,J}^{k(v)-1} = \infty$, i.e., $J \in \{\theta_v^{k(v)-1} = -1\}$. Then $v_J \geq s_{k(v)}$. This contradicts the fact that $v_J \leq t_{m(u)} < s_{k(v)}$ and proves (3.2).

We define

$$k^* := \sup\{k, s_k \leq t_{m(u)}\} < k(v).$$

In particular, we have $t_{m(u)} - \Delta t \leq s_{k^*} \leq t_{m(u)}$. Since for all $J \in V(I) \cap F_{+,u}^{m(u)-1}$

$$t_{m(u)} \geq \widehat{u}_{+,J}^{m(u)-1} \geq \widehat{v}_{+,J}^{k(v)-1},$$

we deduce that

$$s_{k^*} \geq \widehat{v}_{+,J}^{k(v)-1}. \tag{3.3}$$

Indeed, $+\infty > \widehat{v}_{+,J}^{k(v)-1} > s_{k^*}$ would imply that there exists $k' > k^*$ such that $t_{m(u)} \geq \widehat{v}_{+,J}^{k(v)-1} = s_{k'}$, which contradicts the definition of k^*.

Then we claim that for all $J \in V(I) \cap F_{+,u}^{m(u)-1}$

$$\widehat{v}_{+,J}^{k(v)-1} = \widehat{v}_{+,J}^{k^*}. \tag{3.4}$$

We now prove the claim (3.4). First, because we have $\widehat{v}_{+,J}^{k(v)-1} < +\infty$, we deduce that $\theta_{v,J}^{k(v)-1} = 1$; then there exists $k \leq k(v)-1$ such that, if $k \geq 1$, then $J \in NA_v^k$ and $\widehat{v}_{+,J}^{k(v)-1} = v_J^k = s_k$, and, if $k = 0$, then $\theta_{v,J}^0 = 1$ and $\widehat{v}_{+,J}^{k(v)-1} = v_J^0 = 0$.

Assume by contradiction that $k > k^*$. Then

$$\widehat{v}_{+,J}^{k(v)-1} = v_J^k = s_k \geq s_{k^*+1} > s_{k^*}$$

in contradiction with (3.3). Therefore $k \leq k^*$. Now we have $\theta_{v,I}^{k(v)} = 1$ and $\theta_{v,I}^m = -1$ for $m \leq k(v)-1$. Therefore $J \in F_{+,v}^{k^*}$ and

$$\widehat{v}_{+,J}^{k(v)-1} = v_J^k = \widehat{v}_{+,J}^{k^*},$$

which ends the proof of the claim (3.4). We deduce that

$$\widehat{v}_{+,J}^{k(v)-1} = \widehat{v}_{+,J}^{k^*} \leq \widehat{u}_{+,J}^{m(u)-1},$$

where we have used (3.2). We define the following function:

$$f_{\widehat{u}^m}^2(t) = \sum_{k=1}^{N} \left(\max_{\pm} \left(0, t - \widehat{u}_{+,I^{k,\pm}}^m \right) \right)^2.$$

We then have, by using the fact that $\tilde{v}_I^{k^*} \geq s_{k^*+1} > s_{k^*}$,

$$f_{\widehat{v}^{k^*}}(s_{k^*+1}) \leq f_{\widehat{v}^{k^*}}(\tilde{v}_I^{k^*}) = \left| \frac{\Delta x}{\widehat{c}_{I,v}^{k^*}} \right| \leq \left| \frac{\Delta x}{\widehat{c}_{I,u}^{m(u)-1}} \right| = f_{\widehat{u}^{m(u)-1}}(\tilde{u}_I^{m(u)-1}) \leq f_{\widehat{v}^{k^*}}(\tilde{u}_I^{m(u)-1}).$$

We then deduce that $s_{k^*+1} \leq \tilde{u}_I^{m(u)-1} \leq u_I^{m(u)} = t_{m(u)}$. This is absurd.

2. $I \in NA_{+,u}^{m(u)} \subset F_{+,u}^{m(u)-1}$. We consider the following subcases:
   1. $I \in \{\theta_v^0 = 1\}$. Then $v_I = v_I^0 = 0 = u_I^0 \leq u_I^{m(u)}$. This is absurd.
   2. $I \in \{\theta_v^0 = -1\}$. Then $\theta_{u,I}^0 = -1$, and so there exists $n < m(u)$ such that

$$\theta_{u,I}^{n-1} = -1 \quad \text{and} \quad \theta_{u,I}^n = 1.$$

This implies that $u_I^n \geq v_I > u_I^{m(u)} \geq u_I^n$. This is absurd. ∎

Remark 3.4. If we imply the computation of the gradient, i.e., the computation of $\tilde{u}$ in step 5, the situation seems better, and one could expect to prove a general comparison principle without restriction on the velocity.

We now rephrase this comparison principle for the functions θ^ε and prove it.

COROLLARY 3.5 (comparison principle with a nonnegative velocity). *Under the assumptions of Proposition* 3.2*, we have for all* $(x,t) \in \mathbb{R}^N \times [0,T]$

$$\theta_u^\varepsilon(x,t) \le \theta_v^\varepsilon(x,t).$$

Proof of Corollary 3.5. By contradiction, assume that there exist x_I and t such that

$$\theta_u^\varepsilon(x_I,t) = 1 \quad \text{and} \quad \theta_v^\varepsilon(x_I,t) = -1. \tag{3.5}$$

We denote by t the first time such that (3.5) holds. We then have, since $c_v \ge 0$,

$$\theta_u^\varepsilon(x_I,s) = -1 \quad \text{if} \quad s < t.$$

We then deduce that there exists $m(u)$ such that $t = t_{m(u)}$, $I \in NA_u^{m(u)}$, and $u_I^{m(u)} = t_{m(u)} = t$. Moreover, since the index I has not been already accepted for v, we have $v_I > t = u_I^{m(u)}$. This is absurd. ∎

COROLLARY 3.6 (comparison principle for a nonpositive velocity). *We denote by* u_I^n *(resp.,* v_I^n*) the numerical solution at the point* (x_I,t_n) *of the GFMM algorithm with velocity* c_u *(resp.,* c_v*). We assume that there exists* $T > 0$ *such that for all* $(x,t) \in \mathbb{R}^N \times [0,T]$

$$\sup_{s\in[t-\Delta t,t],\ s\ge 0} c_u(x,s) \le \inf_{s\in[t-\Delta t,t],\ s\ge 0} -(c_v(x,s))^-,$$

where $(f)^- \ge 0$ *is the negative part of* f*. We assume that*

$$\{\theta_v^0 = -1\} \subset \{\theta_u^0 = -1\} \quad \text{and} \quad v^0 = u^0 = 0.$$

Then, for all $(x,t) \in \mathbb{R}^N \times [0,T]$*, we have*

$$\theta_u^\varepsilon(x,t) \le \theta_v^\varepsilon(x,t).$$

Proof of Corollary 3.6. This is a straightforward consequence of Corollary 3.5 and the fact that $\theta^\varepsilon[-\theta^0,-c] = -\theta^\varepsilon[\theta^0,c]$ (with the notation of Lemma 3.1). ∎

4. Preliminary results on the discrete time and on the level sets of test functions. The GFMM algorithm described in section 2 has several properties which fit the physics of the problem that we want to solve. We present in this section several results that will be used in the proof of Proposition 5.1, which is crucial for the proof of our main result of convergence.

In a first subsection, we present some properties of the various times $\hat{u}, t, \tilde{t}$ appearing in our algorithm, and in a second subsection we give some geometrical consequences of the existence of test functions tangent from above to our function θ^ε.

4.1. Preliminary results on the discrete time.

LEMMA 4.1 (time character of the $\widehat{u}$). *Assume that there exists* $\delta > 0$ *and* $(I,n) \in \mathbb{Z}^N \times \mathbb{N}$ *such that* $c(x_I,t_n) \ge \delta > 0$*,* $\theta_I^{n-1} = -1$*, and* $\theta_I^n = 1$ *(resp.,* $c(x_I,t_n) \le -\delta < 0$*,* $\theta_I^{n-1} = 1$*; and* $\theta_I^n = -1$*) then for any* $J \in V(I) \cap F_+^{n-1}$ *(resp.,* $J \in V(I) \cap F_-^{n-1}$*), we have for* $\Delta x \le \frac{\delta^2}{16L}$

$$\widehat{u}_{+,J}^{n-1} = \sup\{t_m \le t_{n-1},\ \theta_J^{m-1} = -1, \theta_J^p = 1 \quad \textit{for} \quad m \le p \le n-1\} > t_n - \frac{4\Delta x}{\delta},$$

with the convention that $\widehat{u}^{n-1}_{+,J} = 0$ *if* $\theta^p_J = 1$ *for* $0 \le p \le n-1$

(*resp.,* $\widehat{u}^{n-1}_{-,J} = \sup\{t_m \le t_{n-1},\ \theta^{m-1}_J = 1, \theta^p_J = -1 \quad for \quad m \le p \le n-1\} > t_n - \dfrac{4\Delta x}{\delta}$,

with the convention that $\widehat{u}^{n-1}_{+,J} = 0$ *if* $\theta^p_J = -1$ *for* $0 \le p \le n-1$*).*

This lemma claims in fact that the $\widehat{u}^{n-1}_{+,J}$ is defined as the last time at which the front passed through J. Intuitively, this comes from the fact that, since the velocity is locally nonnegative and since the front has crossed the node x_I at time t_n, it has crossed the node x_J at a time closed to t_n.

Proof of Lemma 4.1. We do only the proof in the case $c > 0$ (the case $c < 0$ is similar). By assumption, c is Lipschitz-continuous with constant L, and there exists $\delta_0 \le \delta/(4L)$ such that, for all $(x_J, t_m) \in B_{\delta_0}(x_I) \times [t_n - \delta_0, t_n + \delta_0]$, we have

$$\widehat{c}^m_J \ge \frac{\delta}{2}.$$

This implies that

$$\theta^m_I = -1 \text{ for all } m \text{ such that } \ t_n - \delta_0 \le t_m \le t_{n-1}. \tag{4.1}$$

Let $J \in V(I) \cap F^{n-1}_+$. We define $m_J = \sup\{m \le n-1,\ \theta^{m-1}_J = -1, \theta^m_J = 1\}$. We claim that, for all $J \in V(I) \cap F^{n-1}_+$, we have $t_{m_J} > t_n - \delta_0$ for Δx small enough. Indeed, by contradiction, assume that there exists $J \in V(I) \cap F^{n-1}_+$ such that $t_{m_J} \le t_n - \delta_0$. Let us define $p \ge 0$ such that $t_n = \cdots = t_{n-p} > t_{n-p-1}$. We then have $\widehat{u}^{n-p-1}_{+,J} \le t_n - \delta_0$ and $\tilde{u}^{n-p-1}_I \ge t_{n-p} = t_n$. By using the fact that

$$\sum_{k=1}^{N} \left(\max_{\pm} \left(0, \tilde{u}^{n-p-1}_I - \widehat{u}^{n-p-1}_{+,I^{k,\pm}}\right)\right)^2 = \left(\frac{\Delta x}{\widehat{c}^{n-p-1}_I}\right)^2,$$

we then deduce that

$$\delta_0 = t_{n-p} - (t_n - \delta_0) \le \tilde{u}^{n-p-1}_I - \widehat{u}^{n-p-1}_J \le \frac{2\Delta x}{\delta}.$$

This is absurd for the choice $\delta_0 = \frac{4\Delta x}{\delta} \le \frac{\delta}{4L}$ which is valid for Δx small enough. Moreover, by using (4.1), we deduce that $J \in F^m$ for all $m_J \le m \le n-1$. This implies that $\widehat{u}^{n-1}_{+,J} = u^{n-1}_J = u^{m_J}_J = t_{m_J}$. ∎

The following lemma is concerned with the fact that we can control the decay of the time $\tilde{t}_n$ given by the GFMM algorithm, by the variations in time of the velocity.

LEMMA 4.2 (error estimate between t_n and $\tilde{t}_n$). *Assume that there exists* $I \in NA^n$ *such that* $|\widehat{c}^{n-1}_I| \ge \delta > 0$. *Then the following estimate holds:*

$$\left(t_n - \tilde{t}_n\right)^+ \le \frac{2L}{\delta^2}\Delta x \Delta t \quad \textit{if} \quad \Delta t \le \frac{\delta}{2L}.$$

Proof of Lemma 4.2. We treat only the case $c^{n-1}_I \ge \delta > 0$ (the other case is similar). Assume that $\tilde{t}_n < t_n$, and then necessarily $t_n = t_{n-1}$. We define $p > 0$ such that $t_{n-p-1} < t_{n-p} = \cdots = t_{n-1} = t_n$. In particular, we have

$$t_{n-p} \le \tilde{t}_{n-p} \le \tilde{u}^{n-p-1}_J \quad \forall J \in F^{n-p-1}$$

and

$$\tilde{t}_n = \tilde{u}_I^{n-1} \le \tilde{u}_J^{n-1} \quad \forall J \in F^{n-1}.$$

We claim that $I \in F_-^{n-p-1}$. Indeed, assume that $I \notin F_-^{n-p-1}$. By using the fact that $\theta_I^{n-p-1} = -1$ (since $\widehat{c}_I > 0$), we deduce that, for all $J \in V(I) \cap F_+^{n-1}$, we have $\theta_J^{n-p-1} = -1$ and so $\widehat{u}_{+,J}^{n-1} = t_n$; this means that also the node J has been accepted at the physical time t_n . This implies that $\tilde{u}_I^{n-1} > t_n$, and this is absurd.

Moreover, because $t_{n-p} - t_{n-p-1} \le \Delta t$, we have $\widehat{c}_I^{n-p-1} \ge \frac{\delta}{2}$ for $\Delta t \le \frac{\delta}{2L}$. We then have

$$\sum_{k=1}^{N} \left(\max_{\pm} \left(0, \tilde{u}_I^{n-p-1} - \widehat{u}_{+,I^{k,\pm}}^{n-p-1} \right) \right)^2 = \left(\frac{\Delta x}{\widehat{c}_I^{n-p-1}} \right)^2 \tag{4.2}$$

and

$$\sum_{k=1}^{N} \left(\max_{\pm} \left(0, \tilde{u}_I^{n-1} - \widehat{u}_{+,I^{k,\pm}}^{n-1} \right) \right)^2 = \left(\frac{\Delta x}{\widehat{c}_I^{n-1}} \right)^2. \tag{4.3}$$

Let us compare $\widehat{u}_{+,J}^{n-1}$ and $\widehat{u}_{+,J}^{n-p-1}$ for $J \in V(I) \cap F_+^{n-1}$. If $J \notin F_+^{n-p-1}$, then u_J changes values during the iterations $n-p \le m \le n-1$, and for such m we have $\widehat{u}_{+,J}^{n-1} = u_J^m = t_m = t_n$. Since $\tilde{t}_n < t_n$, then this node $J \in V(I)$ does not contribute to the evaluation of (4.3) and

$$\sum_{k=1}^{N} \left(\max_{\pm} \left(0, \tilde{t}_n - \widehat{u}_{+,I^{k,\pm}}^{n-p-1} \right) \right)^2 = \sum_{k=1}^{N} \left(\max_{\pm} \left(0, \tilde{t}_n - \widehat{u}_{+,I^{k,\pm}}^{n-1} \right) \right)^2. \tag{4.4}$$

Let us denote that

$$f_q(v) = \left\{ \sum_{k=1}^{N} \left(\max_{\pm} \left(0, v - \widehat{u}_{+,I^{k,\pm}}^{q} \right) \right)^2 \right\}^{1/2}.$$

The function f_q verifies for any $q \in \mathbb{N}$ such that $I \in F_-^q$:

$$f_q(\tilde{u}_I^q) = \frac{\Delta x}{|\widehat{c}_I^q|}, \quad f_q'(v) \ge 1.$$

Then

$$\begin{aligned} t_n - \tilde{t}_n &\le \tilde{u}_I^{n-p-1} - \tilde{t}_n \le f_{n-p-1}(\tilde{u}_I^{n-p-1}) - f_{n-p-1}(\tilde{t}_n) \\ &= f_{n-p-1}(\tilde{u}_I^{n-p-1}) - f_{n-1}(\tilde{t}_n) = \Delta x \left(\frac{1}{|\widehat{c}_I^{n-p-1}|} - \frac{1}{|\widehat{c}_I^{n-1}|} \right) \\ &\le \Delta x \frac{|\widehat{c}_I^{n-p-1} - \widehat{c}_I^{n-p}|}{|\widehat{c}_I^{n-p-1}||\widehat{c}_I^{n-p}|} \le \frac{\Delta x |\partial_t c|_{L^\infty} |t_{n-p} - t_{n-p-1}|}{|\widehat{c}_I^{n-p-1}||\widehat{c}_I^{n-p}|} \le \frac{2\Delta x |\partial_t c|_{L^\infty} \Delta t}{\delta^2}. \end{aligned}$$

∎

4.2. Preliminary results on the level sets of test functions. In this subsection, we give some geometric results concerning the test function for θ^ε (see Figures 2 and 3).

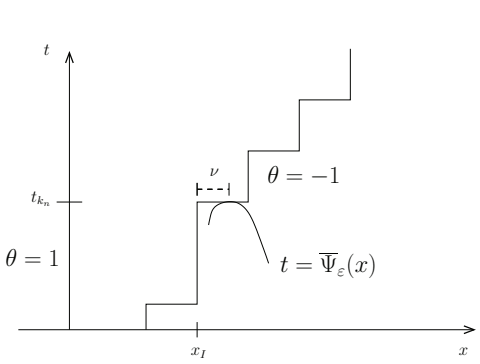

FIG. 2. *Test function from below.*

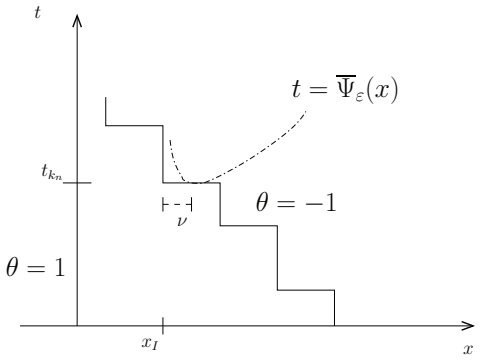

FIG. 3. *Test function from above.*

LEMMA 4.3 (separation of the phases of θ^ε by the level set of a test function). *Let $\varphi \in C^2$ in a neighborhood V of (x_0, t_0) such that $\varphi_t(x_0, t_0) > 0$ (resp., $\varphi_t(x_0, t_0) < 0$). There exist $\delta_0 > 0$, $r > 0$, $\tau > 0$ such that, if $\max_{\overline{V}}((\theta^\varepsilon)^* - \varphi)$ is reached at $(x_\varepsilon, t_\varepsilon) \in B_{\delta_0}(x_0, t_0) \subset V$ with $(\theta^\varepsilon)^*(x_\varepsilon, t_\varepsilon) = 1$, then there exists $\Psi_\varepsilon \in C^2(B_r(x_0), (t_0 - \tau, t_0 + \tau))$ such that*

(i) *for all $(x_J, t_m) \in Q_{r,\tau}(x_0, t_0) = B_r(x_0) \times (t_0 - \tau, t_0 + \tau)$*

$$\theta^\varepsilon(x_J, t_m) = 1 \quad \Longrightarrow \quad t_m \geq \Psi_\varepsilon(x_J) \text{ (resp., } t_m \leq \Psi_\varepsilon(x_J)).$$

(ii) *There exists $(I, n) \in \mathbb{Z}^N \times \mathbb{N}$ such that*

$$(x_\varepsilon, t_\varepsilon) \in \bar{Q}_I^n = [x_I, x_I + \Delta x] \times [t_{k_n}, t_{k_{n+1}}], \quad (\theta^\varepsilon)^*(x_I, t_{k_n}) = 1, \quad t_{k_n} = \Psi_\varepsilon(x_I),$$

and $\theta_I^{\overline{n}} = 1$, $\theta_I^m = -1$, $m_0 \leq m \leq \overline{n} - 1$ (resp., $\theta_I^{\overline{n}} = -1$, $\theta_I^m = 1$, $m_0 \leq m \leq \overline{n} - 1$), where $\overline{n} = \inf\{k, k_n \leq k \leq k_{n+1} - 1, \theta_I^k = 1$ (resp., $\theta_I^k = -1)\}$ and $m_0 = \inf\{m,\ t_m \geq t_0 - \tau\}$.

(iii) *The following Taylor expansion holds:*

$$\Psi_\varepsilon(x_J) = \Psi_\varepsilon(x_I) - \frac{D\varphi(x_0, t_0)}{\varphi_t(x_0, t_0)}(x_J - x_I) + (\Delta x)\, O\left(\Delta x + |x_I - x_0| + |t_{k_n} - t_0|\right).$$

(iv) *If $\varphi_t(x_0, t_0) < 0$, then for all $(x_J, t_{k_n}) \in Q_{r,\tau}(x_0, t_0) = B_r(x_0) \times (t_0 - \tau, t_0 + \tau)$*

$$\theta^\varepsilon(x_J, t_{k_{n-1}}) = 1 \quad \text{and} \quad \theta^\varepsilon(x_J, t_{k_n}) = -1 \quad \Longrightarrow \quad t_{k_n} \leq \Psi_\varepsilon(x_J).$$

Proof of Lemma 4.3. We consider the case $\varphi_t(x_0, t_0) > 0$. The other case can be treated in a similar way. We define $\varphi_\varepsilon = \varphi + ((\theta^\varepsilon)^* - \varphi)(x_\varepsilon, t_\varepsilon)$. In particular, we have $(\theta^\varepsilon)^* \leq \varphi_\varepsilon$ and $(\theta^\varepsilon)^*(x_\varepsilon, t_\varepsilon) = \varphi_\varepsilon(x_\varepsilon, t_\varepsilon) = 1$. We start by proving (i) and (ii). The proof is decomposed in several steps.

Step 1. We have $t_\varepsilon = t_{k_n}$.

Indeed, assume that $t_\varepsilon \in (t_{k_n}, t_{k_{n+1}})$. By using the fact that $(\theta^\varepsilon)^*(x_\varepsilon, t_\varepsilon) = 1$, we deduce that $(\theta^\varepsilon)^*(x_\varepsilon, t) = 1$ for $t_{k_n} \leq t \leq t_{k_{n+1}}$ and so $\varphi_t(x_\varepsilon, t_\varepsilon) = 0$. This is absurd for δ_0 small enough since $\varphi_t(x_0, t_0) > 0$.

Step 2. We have $(\theta^\varepsilon)^* = -1$ on all $Q_J^{n-1} =]x_J, x_J + \Delta x[\times]t_{k_{n-1}}, t_{k_n}[$ such that $(x_\varepsilon, t_{k_n}) \in \bar{Q}_J^{n-1}$.

Indeed, since $\varphi_\varepsilon(x_\varepsilon, t_{k_n}) = 1$ and $(\varphi_\varepsilon)_t > 0$, we deduce that $\varphi_\varepsilon(x_\varepsilon, t) < 1$ if $t < t_{k_n}$. Using the fact that $(\theta^\varepsilon)^* - \varphi_\varepsilon$ reaches a maximum in (x_ε, t_{k_n}) yields

$$(\theta^\varepsilon)^*(x_\varepsilon, t) \leq \varphi_\varepsilon(x_\varepsilon, t) < 1 \quad \text{if } t < t_{k_n}$$

and so

$$(\theta^\varepsilon)^*(x_\varepsilon, t) = -1 \quad \text{if } t < t_{k_n}.$$

By using the semicontinuity of $(\theta^\varepsilon)^*$, one deduce that

$$(\theta^\varepsilon)^* = -1 \quad \text{on all } Q_J^{n-1} \text{ such that } (x_\varepsilon, t_{k_n}) \in \bar{Q}_J^{n-1}.$$

Step 3. There exists $I \in \mathbb{Z}^N$ such that $(x_\varepsilon, t_{k_n}) \in \bar{Q}_I^n$ and $(\theta^\varepsilon)^* = 1$ on Q_I^n.

By contradiction, assume that, on all cubes Q_J^n such that $(x_\varepsilon, t_{k_n}) \in \bar{Q}_J^n$, we have $(\theta^\varepsilon)^* = -1$. Then, by using Step 2, we deduce that $(\theta^\varepsilon)^* = -1$ in a neighborhood of (x_ε, t_{k_n}). This is absurd since $(\theta^\varepsilon)^*(x_\varepsilon, t_{k_n}) = 1$.

Before continuing the proof, we need a few notations. We set

$$\overline{n} = \inf\{k, \quad k_n \le k \le k_{n+1} - 1,\ \theta_I^k = 1\}.$$

In particular, we have $\theta_I^{\overline{n}} = 1$ and $\theta_I^{\overline{n}-1} = -1$.

Since $(\varphi_\varepsilon)_t(x_\varepsilon, t_{k_n}) > 0$ for ε small enough, by the implicit function theorem, there exists a neighborhood V_ε of $(x_\varepsilon, t_\varepsilon)$ and a function $\bar{\Psi}_\varepsilon$ such that

$$\{\varphi_\varepsilon(x,t) < 1\} \Leftrightarrow \{t < \bar{\Psi}_\varepsilon(x)\}$$

in V_ε. Using the fact that $(\theta^\varepsilon)^* \le \varphi_\varepsilon$ yields

$$\{(\theta^\varepsilon)^* = 1\} \subset \{t \ge \bar{\Psi}_\varepsilon(x)\}. \tag{4.5}$$

Moreover, for δ_0 small enough, i.e., for $(x_\varepsilon, t_\varepsilon)$ closed enough to (x_0, t_0), we can assume that $V_\varepsilon \supset Q_{r,\tau}(x_0, t_0) = B_r(x_0) \times (t_0 - \tau, t_0 + \tau)$. We define $\nu = x_\varepsilon - x_I \in [0, \Delta x)^N$ and $\Psi_\varepsilon(x) = \bar{\Psi}_\varepsilon(x + \nu)$. In particular, we have $\Psi_\varepsilon(x_I) = t_{k_n}$.

Step 4. For all $(x_J, t_{k_m}) \in Q_{r,\tau}(x_0, t_0) = B_r(x_0) \times (t_0 - \tau, t_0 + \tau)$

$$\theta^\varepsilon(x_J, t_{k_m}) = 1 \quad \Longrightarrow \quad t_{k_m} \ge \Psi_\varepsilon(x_J).$$

To prove this, we consider the collection of nodes

$$\mathcal{C} = \{(x_J, t_{k_m}) \in Q_{r,\tau}(x_0, t_0) \cap \{\theta^\varepsilon = 1\}\}.$$

By inclusion (4.5), we then have $t_{k_m} \ge \bar{\Psi}_\varepsilon(x_J)\ \forall (x_J, t_{k_m}) \in \mathcal{C}$. We deduce $\forall (x_J, t_{k_m}) \in \mathcal{C}$ that

$$\bar{Q}_J^m = [x_J, x_J + \Delta x] \times [t_{k_m}, t_{k_{m+1}}] \subset \{t \ge \bar{\Psi}_\varepsilon(x)\}.$$

This implies that

$$(x_J + (x_\varepsilon - x_I), t_{k_m}) \in \{t \ge \bar{\Psi}_\varepsilon(x)\}$$

and so

$$(x_J, t_{k_m}) \in \{t \ge \Psi_\varepsilon(x)\},$$

which implies (i) because any $t_{m'}$ can be written t_{k_m} for a suitable m.

Step 5. We have $\theta_I^m = -1$ for $m_0 \le m \le \overline{n} - 1$, where $m_0 = \inf\{m,\ t_m \ge t_0 - \tau\}$.

By contradiction, suppose that there exists $m_0 \le m \le \overline{n} - 1$ such that $\theta_I^m = 1$. We then define m_1 as

$$m_1 = \sup\{m \le \overline{n} - 1,\ \theta_I^m = 1\}.$$

In particular, we have $\theta_I^{m_1+1} = -1$ (since $\theta_I^{\overline{n}-1} = -1$). Two cases may occur:

1. $t_{m_1} = t_{k_n} = t_{\overline{n}}$. In this case, we have $\widehat{c}_I^{m_1} = \widehat{c}_I^{\overline{n}-1} > 0$ (since $\theta_I^{\overline{n}-1} = -1$ and $\theta_I^{\overline{n}} = 1$). This contradicts the fact that $\theta_I^{m_1} = 1$ and $\theta_I^{m_1+1} = -1$.
2. $t_{m_1} < t_{k_n} = t_{\overline{n}}$. In this case, we have $\theta^\varepsilon(x_I, t_{m_1}) = 1$ and $t_{m_1} < t_{k_n} = \Psi_\varepsilon(x_I)$. This contradicts Step 4.

We now prove (iii).

By the implicit functions theorem, we have $\varphi_\varepsilon(x, \bar{\Psi}_\varepsilon(x)) = 1$. Deriving yields

$$\varphi_t(x, \bar{\Psi}_\varepsilon(x)) D\bar{\Psi}_\varepsilon(x) + D\varphi(x, \bar{\Psi}(x)) = 0.$$

Taking $x = x_\varepsilon$ yields

$$D\Psi_\varepsilon(x_I) = -\frac{D\varphi(x_\varepsilon, \bar{\Psi}_\varepsilon(x_\varepsilon))}{\varphi_t(x_\varepsilon, \bar{\Psi}_\varepsilon(x_\varepsilon))} = -\frac{D\varphi(x_I, t_{k_n})}{\varphi_t(x_I, t_{k_n})} + O(\Delta x)$$

and so

$$D\Psi_\varepsilon(x_I) = -\frac{D\varphi(x_0, t_0)}{\varphi_t(x_0, t_0)} + O(|x_I - x_0| + |t_{k_n} - t_0| + \Delta x).$$

Moreover, by Taylor expansion, we get, if $|\varphi(x_\varepsilon, t_\varepsilon) - 1|$ is small enough, for all $J \in V(I)$

$$\begin{aligned}\Psi_\varepsilon(x_J) =& \Psi_\varepsilon(x_I) + (x_J - x_I) \cdot D\Psi_\varepsilon(x_I) + O(|\Delta x|^2) \\ =& \Psi_\varepsilon(x_I) - \frac{D\varphi(x_0, t_0)}{\varphi_t(x_0, t_0)} \cdot (x_J - x_I) + (\Delta x)\ O\left(\Delta x + |x_I - x_0| + |t_{k_n} - t_0|\right),\end{aligned}$$

where "the O is uniform in ε." This ends the proof of (iii).

It just remains to show that, if $\varphi_t(x_0, t_0) < 0$, then for all $(x_J, t_{k_n}) \in Q_{r,\tau}(x_0, t_0) = B_r(x_0) \times (t_0 - \tau, t_0 + \tau)$

$$\theta^\varepsilon(x_J, t_{k_{n-1}}) = 1 \quad \text{and} \quad \theta^\varepsilon(x_J, t_{k_n}) = -1 \quad \Longrightarrow \quad t_{k_n} \le \Psi_\varepsilon(x_J).$$

In this case, inclusion (4.5) is replaced by

$$\{(\theta^\varepsilon)^* = 1\} \subset \{t \le \bar{\Psi}_\varepsilon(x)\}.$$

By the definition of θ^ε, for all $y \in [x_J, x_J + \Delta x]$, we have $(\theta^\varepsilon)^*(y, t_{k_n}) = 1$. By taking $y = x_J + \nu$, we then deduce that

$$t_{k_n} \le \bar{\Psi}_\varepsilon(y) = \bar{\Psi}_\varepsilon(x_J + \nu) = \Psi_\varepsilon(x_J). \qquad \square$$

LEMMA 4.4 (approximate horizontal level set in the i-direction for negative velocity). *Under the notation and assumptions of Lemma 4.3 with $\varphi_t(x_0, t_0) < 0$, let us suppose that there exists $\delta_0 > 0$ such that $c < -\delta < 0$ on $B_{\delta_0}(x_0, t_0)$.*

Let us assume moreover that $(x_I, t_{\overline{n}}) \in B_{\delta_0}(x_0, t_0)$, $\theta_I^{\overline{n}-1} = 1$, and $\theta_I^{\overline{n}} = -1$. If for some fixed $i \in \{1, \dots, N\}$ we have

$$\tilde{u}_I^{\overline{n}-1} - \widehat{u}_{-,I^{i,+}}^{\overline{n}-1} < 0 \quad \text{and} \quad \tilde{u}_I^{\overline{n}-1} - \widehat{u}_{-,I^{i,-}}^{\overline{n}-1} < 0,$$

then

$$\left| \frac{D\varphi(x_0, t_0)}{\varphi_t(x_0, t_0)} \cdot e_i \right| \le o(1).$$

Proof. We first prove that if $\tilde{u}_I^{\overline{n}-1} - \widehat{u}_{-,J}^{\overline{n}-1} < 0$ for some $J \in V(I)\backslash\{I\}$, then

$$\Psi_\varepsilon(x_I) - \Psi_\varepsilon(x_J) \leq o(\Delta x).$$

There are two cases: $\widehat{u}_{-,J}^{\overline{n}-1} = \infty$ or $\widehat{u}_{-,J}^{\overline{n}-1} < \infty$.

If $\widehat{u}_{-,J}^{\overline{n}-1} < \infty$, then $J \in F_-^{\overline{n}-1}$. By Lemma 4.1 it results that

$$\widehat{u}_{-,J}^{\overline{n}-1} = \sup\{t_m \leq t_{\overline{n}-1},\ \theta_J^{m-1} = 1, \theta_J^p = -1 \quad \text{for} \quad m \leq p \leq \overline{n}-1\},$$

and by Lemma 4.3(iv) we have $\widehat{u}_{-,J}^{\overline{n}-1} \leq \Psi_\varepsilon(x_J)$.

We then deduce that

$$0 > \tilde{u}_I^{\overline{n}-1} - \widehat{u}_{-,J}^{\overline{n}-1} \geq \tilde{t}_{\overline{n}} - \Psi_\varepsilon(x_J) = \Psi_\varepsilon(x_I) - \Psi_\varepsilon(x_J) - (t_{\overline{n}} - \tilde{t}_{\overline{n}}).$$

We apply Lemma 4.2, and we obtain

$$\Psi_\varepsilon(x_I) - \Psi_\varepsilon(x_J) \leq o(\Delta x).$$

If $\widehat{u}_{-,J}^{\overline{n}-1} = \infty$, then necessarily $\theta_J^{\overline{n}-1} = 1$, and now either $\theta_J^{\overline{n}} = 1$ or $\theta_J^{\overline{n}} = -1$. Then we can apply Lemma 4.3(i), (resp., (iv)), and we get $t_{\overline{n}} \leq \Psi_\varepsilon(x_J)$. We deduce then that

$$\Psi_\varepsilon(x_I) - \Psi_\varepsilon(x_J) \leq t_{\overline{n}} - t_{\overline{n}} \leq 0.$$

By using Lemma 4.3(iii) for $J = I^{i,\pm}$, we deduce that

$$\pm\Delta x \frac{D\varphi(x_0,t_0)}{\varphi_t(x_0,t_0)} \cdot e_i \leq o(\Delta x). \qquad \square$$

LEMMA 4.5 (decay of θ^ε in the gradient direction of a test function). *Let φ be C^2 in a neighborhood V of (x_0,t_0), and let us suppose that there exist $\delta_0 > 0$ such that $\max_{\overline{V}}((\theta^\varepsilon)^* - \varphi) = (\theta^\varepsilon)^*(x_\varepsilon,t_\varepsilon) - \varphi(x_\varepsilon,t_\varepsilon)$, with $(x_\varepsilon,t_\varepsilon) \in B_{\delta_0}(x_0,t_0) \subset V$ and $(\theta^\varepsilon)^*(x_\varepsilon,t_\varepsilon) = 1$. Then there exists a node $(I,n) \in \mathbb{Z}^N \times \mathbb{N}$ such that $\theta_I^{k_{n+1}-1} = 1$ with $(x_\varepsilon,t_\varepsilon) \in \partial Q_I^n = \partial(]x_I, x_I + \Delta x[\times]t_{k_n}, t_{k_{n+1}}[)$ such that if $\mp e_i \cdot D\varphi(x_0,t_0) > 0$, then*

$$\theta^\varepsilon(x,t) = -1 \qquad \text{in } Q_{I^{i,\pm}}^n =]x_{I^{i,\pm}}, x_{I^{i,\pm}} + \Delta x[\times]t_{k_n}, t_{k_{n+1}}[.$$

Proof of Lemma 4.5. Since $(\theta^\varepsilon)^*(x_\varepsilon,t_\varepsilon) = 1$, there exists a node $(I,n) \in \mathbb{Z}^N \times \mathbb{N}$ such that $\theta_I^{k_{n+1}-1} = 1$ with $(x_\varepsilon,t_\varepsilon) \in \partial Q_I^n = \partial(]x_I, x_I + \Delta x[\times]t_{k_n}, t_{k_{n+1}}[)$.

Assume, for example, that

$$e_i \cdot D\varphi(x_0,t_0) < 0,$$

and let us suppose by contradiction that $\theta^\varepsilon = 1$ in $Q_{I^{i,+}}^n =]x_{I^{i,+}}, x_{I^{i,+}} + \Delta x[\times]t_{k_n}, t_{k_{n+1}}[$.

We define $\varphi_\varepsilon = \varphi + ((\theta^\varepsilon)^* - \varphi)(x_\varepsilon,t_\varepsilon)$. In particular, we have $(\theta^\varepsilon)^* \leq \varphi_\varepsilon$ and $(\theta^\varepsilon)^*(x_\varepsilon,t_\varepsilon) = \varphi_\varepsilon(x_\varepsilon,t_\varepsilon) = 1$. Since $(\theta^\varepsilon)^* \leq \varphi_\varepsilon$, the following inclusion holds:

$$\{(\theta^\varepsilon)^* = 1\} \subset \{\varphi_\varepsilon \geq 1\}.$$

We define $x_\varepsilon^{i,\lambda} = x_\varepsilon + \lambda e_i$, with $0 \leq \lambda \leq \Delta x$ such that $(\theta^\varepsilon)^*(x_\varepsilon^{i,\lambda}, t_\varepsilon) = 1$. Then $\varphi_\varepsilon(x_\varepsilon^{i,\lambda}, t_\varepsilon) \geq 1$ and

$$\frac{\varphi_\varepsilon(x_\varepsilon^{i,\lambda}, t_\varepsilon) - \varphi_\varepsilon(x_\varepsilon, t_\varepsilon)}{\lambda} \geq 0.$$

By taking the limit for $\lambda \to 0$, we obtain

$$e_i \cdot D\varphi(x_\varepsilon, t_\varepsilon) = e_i \cdot D\varphi_\varepsilon(x_\varepsilon, t_\varepsilon) \geq 0.$$

This ends the proof, since it contradicts the assumption. ∎

LEMMA 4.6 (bound on $|t_\varepsilon - t_{\overline{m}_0}|$ for negative velocity). *Under the notation and assumptions of Lemma* 4.5*, if we suppose that there exist* $\delta > 0$ *and* $\delta_0 > 0$ *such that* $c(x,t) < -\delta < 0$ *in* $(x,t) \in B_{2\delta_0}(x_0,t_0) \subset V$*, then the following estimate holds:*

$$|t_\varepsilon - t_{\overline{m}_0}| \leq \frac{\Delta x}{\delta},$$

with

$$t_{\overline{m}_0} = \sup\{t_m \leq t_{k_n} \ : \ \theta^{m-1}_{I^{i,+}} = 1,\ \theta^m_{I^{i,+}} = -1\} \quad \textit{if we assume} \quad -e_i \cdot D\varphi(x_0,t_0) > 0$$

(*resp.,* $t_{\overline{m}_0} = \sup\{t_m \leq t_{k_n} : \theta^{m-1}_{I^{i,-}} = 1,\ \theta^m_{I^{i,-}} = -1\}$ *if we assume* $+e_i \cdot D\varphi(x_0,t_0) > 0$),

where I *is defined in Lemma* 4.5.

Proof of Lemma 4.6. Let us define

$$\overline{m}_0 = \sup\{\ m \leq k_{n+1} - 1,\ \theta^{m-1}_{I^{i,\pm}} = 1, \theta^m_{I^{i,\pm}} = -1\}.$$

For $\Delta x, \Delta t$ small enough, we can assume that $(x_K, t_m) \in B_{2\delta_0}(x_0,t_0)$ for $K = I, I^{i,\pm}$ and $\overline{m}_0 \leq m \leq k_{n+1}$. Since $c < 0$ in $B_{2\delta_0}(x_0,t_0)$, $\theta^{k_{n+1}-1}_I = 1$ implies $\theta^m_I = 1$ for all $\overline{m}_0 \leq m \leq k_{n+1}-1$ and, by the definition of $\overline{m}_0$, $\theta^m_{I^{i,\pm}} = -1$ for all $\overline{m}_0 \leq m \leq k_{n+1}-1$.

This means that $I^{i,\pm} \in F^m_-$ for all $\overline{m}_0 \leq m \leq k_{n+1} - 1$ and so

$$\widehat{u}^m_{-,I^{i,\pm}} = t_{\overline{m}_0} \text{ for } \overline{m}_0 \leq m \leq k_{n+1} - 1. \tag{4.6}$$

In particular, $\widehat{u}^{k_{n+1}-1}_{-,I^{i,\pm}} = t_{\overline{m}_0}$, and by the definition of the $\widehat{t}_{k_{n+1}}$ it results that $\tilde{u}^{k_{n+1}-1}_I \geq \widehat{t}_{k_{n+1}}$, with $\widehat{t}_{k_{n+1}} = t_{k_{n+1}}$, since $t_{k_{n+1}} > t_{k_n}$.

By the equation

$$\sum_{k=1}^{N} \left(\max_{\pm} \left(0, \tilde{u}^{k_{n+1}-1}_I - \widehat{u}^{k_{n+1}-1}_{-,I^{k,\pm}}\right)\right)^2 = \left(\frac{\Delta x}{\widehat{c}^{k_{n+1}-1}_I}\right)^2,$$

we conclude that

$$t_\varepsilon - t_{\overline{m}_0} \leq t_{k_{n+1}} - t_{\overline{m}_0} \leq \tilde{u}^{k_{n+1}-1}_I - \widehat{u}^{k_{n+1}-1}_{-,I^{i,\pm}} \leq \frac{(\Delta x)}{|\widehat{c}^{k_{n+1}-1}_I|} \leq \frac{\Delta x}{\delta}. \qquad \blacksquare$$

5. Proof of Theorem 2.5. This section is dedicated to the proof of the main theorem, which is preceded by two important propositions.

The first proposition will show that the limit function $\overline{\theta}^0$ is a subsolution in all of the domain excepted for the initial time, whereas the second proposition will show that the limit function $\overline{\theta}^0$ is a subsolution at the initial time. The reason why we need to treat apart the initial condition is that the proof of the first proposition is based on the definition of a discontinuous viscosity subsolution (see Barles [4] and Crandall, Ishii, and Lions [10]) consisting in testing the equation by smooth functions, but this definition does not hold at the initial time. Then we treat the initial condition by using the technique of barriers.

At the end of this section, we give the main proof using both results.

PROPOSITION 5.1 (subsolution property of the limit). *The function* $\overline{\theta}^0$ *is a subsolution of the equation*

$$\theta_t(x,t) = c(x,t)|D\theta(x,t)|$$

on $\mathbb{R}^N \times (0,T)$.

Proof of Proposition 5.1. By contradiction, assume that there are (x_0,t_0) and $\varphi \in C^2$ such that $\overline{\theta}^0 - \varphi$ reaches a strict maximum at (x_0,t_0), with $\overline{\theta}^0(x_0,t_0) = \varphi(x_0,t_0)$ and

$$\varphi_t(x_0,t_0) = \alpha + c(x_0,t_0)|D\varphi(x_0,t_0)|, \tag{5.1}$$

with $\alpha > 0$. Since the maximum of $\overline{\theta}^0 - \varphi$ is strict, there exists $(x_\varepsilon,t_\varepsilon) \to (x_0,t_0)$ as $\Delta x \to 0$ such that

$$\max((\theta^\varepsilon)^* - \varphi) = ((\theta^\varepsilon)^* - \varphi)(x_\varepsilon,t_\varepsilon).$$

In particular, we have $(\theta^\varepsilon)^*(x_\varepsilon,t_\varepsilon) = 1$ for $\Delta x, \Delta t$ small enough. Indeed, by contradiction, suppose that $(\theta^\varepsilon)^*(x_\varepsilon,t_\varepsilon) = -1$. By using the fact that $(\theta^\varepsilon)^*$ is upper semi-continuous, we obtain $(\theta^\varepsilon)^* = -1$ a neighborhood of $(x_\varepsilon,t_\varepsilon)$. We then deduce that $\varphi_t(x_\varepsilon,t_\varepsilon) = D\varphi(x_\varepsilon,t_\varepsilon) = 0$ and so

$$0 = \varphi_t(x_\varepsilon,t_\varepsilon) - c(x_\varepsilon,t_\varepsilon)|D\varphi(x_\varepsilon,t_\varepsilon)| \to \varphi_t(x_0,t_0) - c(x_0,t_0)|D\varphi(x_0,t_0)| = \alpha.$$

This is absurd.

If $|D\varphi(x_0,t_0)| \neq 0$, we note that we can rewrite inequality (5.1) as

$$\varphi_t(x_0,t_0) = \bar{c}|D\varphi(x_0,t_0)|, \quad \text{with } \bar{c} > c(x_0,t_0). \tag{5.2}$$

We denote that

$$\vec{n}_0 = \frac{D\varphi(x_0,t_0)}{|D\varphi(x_0,t_0)|}. \tag{5.3}$$

To continue the proof, we have to distinguish several cases:

1. $c(x_0,t_0) > 0$. In this case, we have in particular $\varphi_t(x_0,t_0) > 0$. Then we can apply Lemma 4.3, and we deduce that there exist $\Psi_\varepsilon \in C^2$ and $(I,n) \in \mathbb{Z}^N \times \mathbb{N}$ such that $(x_I,t_{k_n}) \to (x_0,t_0)$ as $\varepsilon = (\Delta x, \Delta t) \to 0$,

$$(\theta^\varepsilon)^*(x_I,t_{k_n}) = 1, \quad t_{k_n} = \Psi_\varepsilon(x_I),$$

and $\theta_I^{\overline{n}} = 1, \quad \theta_I^{\overline{n}-1} = -1$, where $\bar{n}$ is defined in Lemma 4.3. By using Lemmas 4.1 and 4.3(i), we deduce also that, for all $J \in V(I)\setminus\{I\}$ such that $\theta_J^{\overline{n}-1} = 1$, we have

$$\widehat{u}_{+,J}^{\overline{n}-1} \geq \Psi_\varepsilon(x_J).$$

This implies for all $J \in V(I) \cap F_+^{\overline{n}-1}$, using also the (general) fact that $\tilde{u}_I^{\overline{n}-1} \leq t_{\overline{n}} = t_{k_n}$, that

$$\tilde{u}_I^{\overline{n}-1} - \widehat{u}_{+,J}^{\overline{n}-1} \leq t_{\overline{n}} - \widehat{u}_{+,J}^{\overline{n}-1} = \Psi_\varepsilon(x_I) - \widehat{u}_{+,J}^{\overline{n}-1} \leq \Psi_\varepsilon(x_I) - \Psi_\varepsilon(x_J). \tag{5.4}$$

By the GFMM algorithm (Step 5), $\tilde{u}_I^{\overline{n}-1}$ is a solution of the equation

$$\left(\frac{\Delta x}{c(x_I, t_{\overline{n}-1})}\right)^2 = \sum_{i=1}^{N} \left(\max_{\pm}\left(0, \tilde{u}_I^{\overline{n}-1} - \widehat{u}_{+,I^{i,\pm}}^{\overline{n}-1}\right)\right)^2.$$

If $|D\varphi(x_0,t_0)| \neq 0$, by adding (5.4) for $J = I^{i,\pm}$ on all directions $i \in \mathcal{C} \subset \{1,\dots,N\}$ such that

$$\tilde{u}_I^{\overline{n}-1} - \widehat{u}_{+,I^{i,+}}^{\overline{n}-1} \geq 0 \ \text{ or } \ \tilde{u}_I^{\overline{n}-1} - \widehat{u}_{+,I^{i,-}}^{\overline{n}-1} \geq 0$$

and by using Lemma 4.3(iii), we can estimate

$$\begin{aligned}\left(\frac{\Delta x}{c(x_I, t_{\overline{n}-1})}\right)^2 &= \sum_{i\in\mathcal{C}} \left(\max_{\pm}\left(\tilde{u}_I^{\overline{n}-1} - \widehat{u}_{+,I^{i,\pm}}^{\overline{n}-1}\right)\right)^2 \leq \sum_{i\in\mathcal{C}} \max_{\pm}\left(\Psi_\varepsilon(x_I) - \Psi_\varepsilon(x_{I^{i,\pm}})\right)^2 \\ &\leq \frac{(\Delta x)^2}{\bar{c}^2} \sum_{i\in\mathcal{C}} (\vec{n_0}\cdot e_i)^2 + (\Delta x)^2 O(\Delta x + |x_I - x_0| + |t_{k_n} - t_0|) \\ &\leq \frac{(\Delta x)^2}{\bar{c}^2} + (\Delta x)^2 O(\Delta x + |x_I - x_0| + |t_{k_n} - t_0|),\end{aligned}$$

where $\bar{c}$ and $\vec{n}_0$ are defined in (5.2) and (5.3), respectively.

It follows that

$$\frac{1}{c^2(x_I, t_{\overline{n}-1})} - \frac{1}{\bar{c}^2} \leq O(\Delta x + |x_I - x_0| + |t_{k_n} - t_0|).$$

By taking the limit $\varepsilon = (\Delta x, \Delta t) \to 0$, we obtain a contradiction.

If $D\varphi(x_0,t_0) = 0$, we get in the same way

$$\frac{1}{c^2(x_I, t_{\overline{n}-1})} \leq O(\Delta x + |x_I - x_0| + |t_{k_n} - t_0|).$$

By taking the limit $\varepsilon \to 0$, since we have assumed that $c(x_0,t_0) > 0$, we obtain a contradiction.

2. $c(x_0,t_0) < 0$. In this case, we have no information on the sign of φ_t, so we have to distinguish several cases:

1. $\varphi_t(x_0,t_0) < 0$. Note that, in this case, $|D\varphi(x_0,t_0)| \neq 0$ and (5.2) holds with $0 > \bar{c} > c(x_0,t_0)$.
   Then we can apply Lemma 4.3 and we deduce that there exist $\Psi_\varepsilon \in C^2$ and $(I,n) \in \mathbb{Z}^N \times \mathbb{N}$ such that

   $$(\theta^\varepsilon)^*(x_I, t_{k_n}) = 1, \quad t_{k_n} = \Psi_\varepsilon(x_I),$$

   and

   $$\theta_I^{\overline{n}} = -1, \quad \theta_I^{\overline{n}-1} = 1,$$

   where $\bar{n}$ is defined in Lemma 4.3. By using Lemmas 4.1 and 4.3(iv), we deduce also that, for all $J \in V(I)\setminus\{I\}$ such that $\theta_J^{\overline{n}-1} = -1$, we have

   $$\widehat{u}_{-,J}^{\overline{n}-1} \leq \Psi_\varepsilon(x_J).$$

This implies that for all $J \in V(I) \cap F_-^{\overline{n}-1}$

$$\tilde{u}_I^{\overline{n}-1} - \widehat{u}_{-,J}^{\overline{n}-1} \geq \tilde{t}_{\overline{n}} - \Psi_\varepsilon(x_J) = t_{\overline{n}} - \Psi_\varepsilon(x_J) + (\tilde{t}_{\overline{n}} - t_{\overline{n}}) = \Psi_\varepsilon(x_I) - \Psi_\varepsilon(x_J) + (\tilde{t}_{\overline{n}} - t_{\overline{n}}).$$

Since $c(x_0, t_0) \neq 0$, there exist $\delta,\ \delta_0 > 0$ such that $|c| \geq \delta > 0$ on $B_{\delta_0}(x_0, t_0)$, and we can apply Lemma 4.2 to get

$$\tilde{u}_I^{\overline{n}-1} - \widehat{u}_{-,J}^{\overline{n}-1} \geq \Psi_\varepsilon(x_I) - \Psi_\varepsilon(x_J) + o(\Delta x).$$

Using Lemma 4.3(iii) yields

$$\tilde{u}_I^{\overline{n}-1} - \widehat{u}_{-,J}^{\overline{n}-1} \geq \frac{1}{\bar{c}} \vec{n_0} \cdot (x_J - x_I) + (\Delta x)\ O(\Delta x + |x_I - x_0| + |t_{k_n} - t_0|) + o(\Delta x).$$

By adding the previous equation for $J = I^{i,\pm}$ on all directions $i \in \mathcal{C} \subset \{1, \ldots, N\}$ such that

$$\tilde{u}_I^{\overline{n}-1} - \widehat{u}_{-,I^{i,+}}^{\overline{n}-1} \geq 0 \ \text{ or } \ \tilde{u}_I^{\overline{n}-1} - \widehat{u}_{-,I^{i,-}}^{\overline{n}-1} \geq 0,$$

we obtain, since $|D\varphi(x_0, t_0)| \neq 0$,

$$\begin{aligned} \left(\frac{\Delta x}{c(x_I, t_{\overline{n}-1})}\right)^2 &= \sum_{i=1}^{N} \left(\max_{\pm}\left(0, \tilde{u}_I^{\overline{n}-1} - \widehat{u}_{-,I^{i,\pm}}^{\overline{n}-1}\right)\right)^2 \\ &= \sum_{i \in \mathcal{C}} \left(\tilde{u}_I^{\overline{n}-1} - \widehat{u}_{-,I^{i,\pm}}^{\overline{n}-1}\right)^2 \\ &\geq \frac{(\Delta x)^2}{\bar{c}^2} \sum_{i \in \mathcal{C}} (\vec{n_0} \cdot e_i)^2 + (\Delta x)^2\ O(\Delta x + |x_I - x_0| \\ &\qquad + |t_{k_n} - t_0|) + o(\Delta x)^2. \end{aligned} \tag{5.5}$$

If $i \notin \mathcal{C}$ (i.e., $\tilde{u}_I^{\overline{n}-1} - \widehat{u}_{-,I^{i,+}}^{\overline{n}-1} < 0$ and $\tilde{u}_I^{\overline{n}-1} - \widehat{u}_{-,I^{i,-}}^{\overline{n}-1} < 0$), then by Lemma 4.4 we deduce that

$$\left|\frac{1}{\bar{c}} \Delta x\ \vec{n_0} \cdot e_i\right| = o(\Delta x). \tag{5.6}$$

By combining (5.5) and (5.6), we get

$$\begin{aligned} \left(\frac{\Delta x}{c(x_I, t_{\overline{n}-1})}\right)^2 &\geq \frac{(\Delta x)^2}{\bar{c}^2} \sum_{i=1}^{N} (\vec{n_0} \cdot e_i)^2 + (\Delta x)^2\ O(\Delta x + |x_I - x_0| \\ &\qquad + |t_{k_n} - t_0|) + o(\Delta x^2) \\ &= \frac{(\Delta x)^2}{\bar{c}^2} + (\Delta x)^2\ O(\Delta x + |x_I - x_0| + |t_{k_n} - t_0|) + o(\Delta x^2). \end{aligned}$$

This implies that

$$\frac{1}{c^2(x_I, t_{\overline{n}-1})} - \frac{1}{\bar{c}^2} \geq O(\Delta x + |x_I - x_0| + |t_{k_n} - t_0|) + o(1).$$

By taking the limit $\varepsilon = (\Delta x, \Delta t) \to 0$, we get the contradiction since $|c(x_0, t_0)| > |\bar{c}|$.

2. $\varphi_t(x_0,t_0) > 0$. Since $c(x_0,t_0) < 0$, we have by the algorithm that $\frac{\partial(\theta^\varepsilon)^*}{\partial t} \le 0$. We define $\varphi_\varepsilon = \varphi + ((\theta^\varepsilon)^* - \varphi)(x_\varepsilon, t_\varepsilon)$. In particular, we have $(\theta^\varepsilon)^* \le \varphi_\varepsilon$ and
$$(\theta^\varepsilon)^*(x_\varepsilon,t_\varepsilon) = \varphi_\varepsilon(x_\varepsilon,t_\varepsilon) = 1.$$
We have $t_\varepsilon = t_{k_n}$. Indeed, assume that $t_\varepsilon \in (t_{k_n}, t_{k_{n+1}})$. Bu using the fact that $(\theta^\varepsilon)^*(x_\varepsilon,t_\varepsilon) = 1$, we deduce that $(\theta^\varepsilon)^*(x_\varepsilon,t) = 1$ for $t_{k_n} \le t \le t_{k_{n+1}}$ and so $\varphi_t(x_\varepsilon,t_\varepsilon) = 0$. This is absurd for ε small enough since $\varphi_t(x_0,t_0) > 0$.
By using the fact that $(\varphi_\varepsilon)_t > 0$, we deduce that $(\theta^\varepsilon)^*(x_\varepsilon,t) \le \varphi_\varepsilon(x_\varepsilon,t) < 1$ for $t < t_{k_n}$. This is absurd since $\frac{\partial(\theta^\varepsilon)^*}{\partial t} \le 0$.
3. $\varphi_t(x_0,t_0) = 0$. Since (5.1) holds with $\alpha > 0$, we have, in particular, $|D\varphi(x_0,t_0)| \neq 0$. Then there exists a direction $\pm e_i$ such that $\mp e_i \cdot D\varphi(x_0,t_0) > 0$. By using Lemma 4.5, we deduce that there exists $(I,n) \in \mathbb{Z}^N \times \mathbb{N}$ such that $\theta_I^{k_{n+1}-1} = 1$ and $\theta^\varepsilon = -1$ on $Q^n_{I^{i,\pm}} =]x_{I^{i,\pm}}, x_{I^{i,\pm}} + \Delta x[\times]t_{k_n}, t_{k_{n+1}}[$. We define $t_{\overline{m}_0}$ such that
$$\overline{m}_0 = \sup\{m \,:\, t_m \le t_{k_n},\ \theta^{m-1}_{I^{i,\pm}} = 1,\ \theta^m_{I^{i,\pm}} = -1\}.$$
In particular, $(\theta^\varepsilon)^*(x, t_{\overline{m}_0}) = 1$ for all $x \in [x_{I^{i,\pm}}, x_{I^{i,\pm}} + \Delta x]$.
We define $\varphi_\varepsilon = \varphi + ((\theta^\varepsilon)^* - \varphi)(x_\varepsilon,t_\varepsilon)$. In particular, we have $(\theta^\varepsilon)^* \le \varphi_\varepsilon$ and
$$(\theta^\varepsilon)^*(x_\varepsilon,t_\varepsilon) = \varphi_\varepsilon(x_\varepsilon,t_\varepsilon) = 1.$$
Since the following inclusion $\{(\theta^\varepsilon)^* = 1\} \subset \{\varphi_\varepsilon \ge 1\}$ holds, $\varphi_\varepsilon(x, t_{\overline{m}_0}) \ge 1$ for all $x \in [x_{I^{i,\pm}}, x_{I^{i,\pm}} + \Delta x]$.
Let $\nu \in [0,\Delta x]^N$ be such that $x_\varepsilon = x_I + \nu$, and let us define $y \equiv x_{I^{i,\pm}} + \nu$ and $\overline{\varphi}(\cdot,\cdot) \equiv \varphi_\varepsilon(\cdot + \nu, \cdot)$. Then it yields $\overline{\varphi}(x_I,t_\varepsilon) = \varphi_\varepsilon(x_\varepsilon,t_\varepsilon) = 1$, and $\overline{\varphi}(x_{I^{i,\pm}}, t_{\overline{m}_0}) = \varphi_\varepsilon(y, t_{\overline{m}_0}) \ge 1$.
To obtain the contradiction, we consider the expansion of $\overline{\varphi}$ up to the first order
$$\begin{aligned} 0 &\le \overline{\varphi}(x_{I^{i,\pm}}, t_{\overline{m}_0}) - \overline{\varphi}(x_I,t_\varepsilon) \\ &\le (x_{I^{i,\pm}} - x_I)\cdot D\overline{\varphi}(x_I,t_\varepsilon) + (t_{\overline{m}_0} - t_\varepsilon)\partial_t\overline{\varphi}(x_I,t_\varepsilon) + O((\Delta x)^2 + |t_\varepsilon - t_{\overline{m}_0}|^2). \end{aligned}$$
Now by Lemma 4.6 and using the fact that $\partial_t\varphi(x_0,t_0) = 0$ we obtain
$$\pm e_i \cdot D\overline{\varphi}(x_I,t_\varepsilon)\Delta x + o(\Delta x) \ge 0,$$
which is absurd, since by assumption $\pm e_i \cdot D\varphi(x_0,t_0) < 0$.
3. $c(x_0,t_0) = 0$. In this case, we have
$$\varphi_t = \alpha > 0,$$
and we can apply Lemma 4.3. Hence, there exist $r,\ \tau > 0$, a function $\Psi_\varepsilon \in C^2(B_r(x_0),(t_0-\tau,t_0+\tau))$, and a node $(I,n) \in \mathbb{Z}^N \times \mathbb{N}$ such that
$$(\theta^\varepsilon)^*(x_I,t_{k_n}) = 1, \quad t_{k_n} = \Psi_\varepsilon(x_I),$$
and for all $J \in V(I),\ t_m \in (t_0-\tau, t_0+\tau)$, we have
$$\theta^\varepsilon(x_J,t_m) = 1 \implies t_m \ge \Psi_\varepsilon(x_J). \tag{5.7}$$
We define m_0 such that $t_{m_0-1} < t_0 - \tau \le t_{m_0}$.
For all $J \in (V(I)\setminus\{I\}) \cap \{\theta^{\overline{n}-1} = 1\}$ (with $\bar{n}$ defined in Lemma 4.3), we define
$$m_J = \sup\{k \le \overline{n},\ \theta^{k-1}_J = -1\}.$$
We distinguish two cases:

1. There exists $J \in (V(I)\setminus\{I\}) \cap \{\theta^{\overline{n}-1} = 1\}$ such that $m_J < m_0$.
   By using the fact that $\theta_I^k = -1$ for $m_0 \le k \le \overline{n}-1$ (see Lemma 4.3(ii)), we have that $J \in F_+^k \ \forall\, m_0 \le k \le \overline{n}-1$, and we deduce that

$$\widehat{u}_{+,J}^{\overline{n}-1} = u_J^{\overline{n}-1} \le t_{m_0} \quad \text{and} \quad \theta^\varepsilon(x_J, t_{m_0}) = 1.$$

   By (5.7), we then have $t_{m_0} \ge \Psi_\varepsilon(x_J)$.
   We now assume that $|D\varphi| \neq 0$ (the case $|D\varphi| = 0$ can be treated in a similar way). By using Lemma 4.3, we deduce that

$$t_{m_0} \ge \Psi_\varepsilon(x_J) = t_{k_n} - \frac{1}{\bar{c}}\,\vec{n}_0 \cdot (x_J - x_I) + (\Delta x)\ O(\Delta x + |x_I - x_0| + |t_{k_n} - t_0|),$$

   and so

$$\begin{aligned} t_{k_n} - t_{m_0} \le & \frac{1}{\bar{c}}\,\vec{n}_0 \cdot (x_J - x_I) + (\Delta x)\ O(\Delta x + |x_I - x_0| + |t_{k_n} - t_0|) \\ \le & \frac{\Delta x}{\bar{c}} + (\Delta x)\ O(\Delta x + |x_I - x_0| + |t_{k_n} - t_0|). \end{aligned}$$

   Sending $\Delta x, \Delta t$ to 0 yields $t_0 - (t_0 - \tau) = \tau \le 0$. This is absurd.
2. For all $J \in (V(I)\setminus\{I\}) \cap \{\theta^{\overline{n}-1} = 1\}$, $m_J \ge m_0$.
   We then have $\theta^\varepsilon(x_J, t_{m_J}) = 1$, and so by (5.7) we have $\widehat{u}_{+,J}^{\overline{n}-1} = t_{m_J} \ge \Psi(x_J)$.
   We now assume that $|D\varphi| \neq 0$ (the case $|D\varphi| = 0$ can be treated in a similar way). By using Lemma 4.3, we deduce that

$$\widehat{u}_{+,J}^{\overline{n}-1} \ge \Psi(x_J) = t_{k_n} - \frac{1}{\bar{c}}\vec{n}_0 \cdot (x_J - x_I) + (\Delta x)\ O(\Delta x + |x_I - x_0| + |t_{k_n} - t_0|),$$

   and so

$$\begin{aligned} \tilde{u}_I^{\overline{n}-1} - \widehat{u}_{+,J}^{\overline{n}-1} \le & \ t_{k_n} - \widehat{u}_{+,J}^{\overline{n}-1} \\ \le & \ \frac{1}{\bar{c}}\vec{n}_0 \cdot (x_J - x_I) + (\Delta x)\ O(\Delta x + |x_I - x_0| + |t_{k_n} - t_0|). \end{aligned}$$

   By adding for $J = I^{i,\pm}$ on all directions $i \in \mathcal{C} \subset \{1, \dots, N\}$ such that

$$\tilde{u}_I^{\overline{n}-1} - \widehat{u}_{+,I^i}^{\overline{n}-1} = \max(\tilde{u}_I^{\overline{n}-1} - \widehat{u}_{+,I^{i,+}}^{\overline{n}-1}, \tilde{u}_I^{\overline{n}-1} - \widehat{u}_{+,I^{i,-}}^{\overline{n}-1}) \ge 0,$$

   we deduce that

$$\left(\frac{\Delta x}{\widehat{c}_I^{\overline{n}-1}}\right)^2 = \sum_{i\in\mathcal{C}} \left(\tilde{u}_I^n - \widehat{u}_{+,I^i}^{n-1}\right)^2 \le \left(\frac{\Delta x}{\bar{c}}\right)^2 + (\Delta x)^2\, O(\Delta x + |x_I - x_0| + |t_{k_n} - t_0|),$$

   i.e.,

$$\frac{1}{|\widehat{c}_I^{\overline{n}-1}|^2} \le \frac{1}{\bar{c}^2} + O(\Delta x + |x_I - x_0| + |t_{k_n} - t_0|).$$

   Sending $\Delta x, \Delta t$ to 0 yields a contradiction since $\bar{c} > c(x_0, t_0) = 0$. ∎

We construct a barrier subsolution, and we prove that $\overline{\theta}^0$ defined by (2.7) satisfies the initial condition of (1.1).

PROPOSITION 5.2 (initial condition). *We have the following inequality:*

$$\overline{\theta}^0(\cdot, 0) \le \left(1_{\Omega_0} - 1_{\Omega_0^c}\right)^*. \tag{5.8}$$

Proof of Proposition 5.2. For $\alpha > 0$ which will be made precise later, we consider the following function:

$$v(x) = \alpha \operatorname{dist}(x, \Omega_0), \tag{5.9}$$

and we define for all $I \in \mathbb{Z}^N$

$$v_I = v(x_I).$$

We then define for $x_I \in \Omega_0^c$ a velocity $\infty > c_{v,I} > 0$ by solving

$$\sum_{k=1}^{N} (\max_{\pm}(0, v_I - \widehat{v}_{I^{k,\pm}}))^2 = \left(\frac{\Delta x}{c_{v,I}}\right)^2,$$

where

$$\widehat{v}_J = \begin{cases} v_J & \text{if} \quad v_J \le v_I, \\ \infty & \text{if} \quad v_J > v_I. \end{cases}$$

This define a GFMM with velocity $c_{v,I}$ and whose solution is v_I. On the one hand, using the fact that $|v_I - v_J| \le \alpha \Delta x$ yields for $J \in V(I)$

$$c_{v,I} \ge \frac{1}{\alpha\sqrt{N}}. \tag{5.10}$$

On the other hand, the C^2 regularity of $\partial\Omega_0$ implies that $c_{v,I}$ is uniformly bounded as $\Delta x \to 0$ in a neighborhood of $\partial\Omega_0$.

Moreover, we can define θ_v^ε in the following way:

$$\theta_v^\varepsilon(x,t) = \begin{cases} 1 & \text{if} \quad x \in [x_I, x_I + \Delta x[\text{ and } t \ge v_I, \\ -1 & \text{if} \quad x \in [x_I, x_I + \Delta x[\text{ and } t < v_I. \end{cases}$$

We denote by u the solution of the GFMM algorithm with velocity $c(x,t)$. We then have

$$\theta_{u,I}^0 = 1 \Rightarrow x_I \in \Omega_0 \Rightarrow v_I = 0 \Rightarrow \theta_{v,I}^0 = 1,$$

and so $\{\theta_u^0 = 1\} \subset \{\theta_v^0 = 1\}$. Moreover, by using (5.10), we deduce that, for α small enough, we have, for all $t \ge 0$, $c_{v,I} \ge (c(x_I,t))^+$. By using the comparison principle Corollary 3.5, we deduce that $\theta_v^\varepsilon(x,t) \ge \theta^\varepsilon(x,t)$. We denote that $v^\varepsilon(x) = \sup_{y \in [x-\Delta x, x]} v(y)$ and $\theta_{v^\varepsilon}(x,t) = 1_{\{v^\varepsilon(x) \ge t\}} - 1_{\{v^\varepsilon(x) < t\}}$. It is easy to check that

$$(\theta_{v^\varepsilon})^*(x,t) \ge (\theta_v^\varepsilon)^*(x,t) \ge (\theta^\varepsilon)^*(x,t).$$

By passing to the limit $\varepsilon \to 0$, we then obtain for $t > 0$

$$1_{\{v(x) \ge t\}} - 1_{\{v(x) < t\}} = \theta_v(x,t) \ge \overline{\theta}^0(x,t)$$

and so $(1_{\Omega_0} - 1_{\Omega_0^c})^* \ge \overline{\theta}^0(x,0)$. This implies that $\overline{\theta}^0$ satisfies the initial condition (5.8). □

Proof of Theorem 2.5. The proof of Theorem 2.5 is now quite simple. Indeed, by using Theorem 5.1 and Proposition 5.2, we get that $\overline{\theta}^0$ is a viscosity subsolution of (1.1).

For the supersolution property of $\underline{\theta}^0$, it suffices to use the symmetry of $\overline{\theta}^0$ and $\underline{\theta}^0$ (see Lemma 3.1). Indeed, by contradiction, assume that there are (x_0, t_0) and $\varphi \in C^2$ such that $\underline{\theta}^0 - \varphi$ reaches a strict minimum at (x_0, t_0), with

$$\varphi_t(x_0, t_0) = -\alpha + c(x_0, t_0)|D\varphi(x_0, t_0)|,$$

with $\alpha > 0$ and $t_0 > 0$. Let us define $c_1 = -c$, $\varphi_1 = -\varphi$, and $\overline{\theta}_1^0 = \overline{\theta}^0[-\theta^0, -c]$. Then, by using Lemma 3.1, we get that $\overline{\theta}_1^0 - \varphi_1$ reaches a strict maximum at (x_0, t_0) with $\overline{\theta}_1^0(x_0, t_0) = \varphi_1(x_0, t_0)$ and

$$(\varphi_1)_t(x_0, t_0) = \alpha + c_1(x_0, t_0)|D\varphi(x_0, t_0)|.$$

This contradicts the subsolution property of $\overline{\theta}_1^0$. For the initial condition, we use the same arguments as those of Proposition 5.2.

Moreover, if (1.1) satisfies a comparison principle, then $\overline{\theta}^0 \leq (\underline{\theta}^0)^*$ and $(\overline{\theta}^0)_* \leq \underline{\theta}^0$. Since, by definition, $\overline{\theta}^0 \geq \underline{\theta}^0$, we get that $\overline{\theta}^0 = (\underline{\theta}^0)^*$ and $(\overline{\theta}^0)_* = \underline{\theta}^0$ is a solution of (1.1). This exactly means that $\overline{\theta}^0$ and $\underline{\theta}^0$ are solutions, which are then unique (when the comparison principle holds for a special choice of the initial data), up to the upper and the lower semicontinuous envelopes. ∎

6. Numerical tests. We are going to verify our algorithm by some numerical tests in dimension $N = 2$.

First we will give in two cases the representation formula of the solution so that we will be able to obtain numerical errors comparing it with the numerical solution obtained by the GFMM algorithm.

Representation formulas for hyperplanes and spheres propagating with linear speed. We verify that hyperplanes and spheres in $\mathbb{R}^N$, which propagate with a linear speed along the normal direction, keep their shapes during the evolution remaining, respectively, hyperplanes and spheres.

These manifolds can be characterized by the level set of a polynomial $P(x) : \mathbb{R}^N \to \mathbb{R}$ of degree 1 and 2. We denote by $P(x, t)$ the polynomials with coefficients depending on t.

Each point x such that (s.t.) $P(x, t_0) = 0$ verifies the following dynamics:

$$\begin{cases} \dot{y}(t) &= -c(y(t), t)\frac{DP(y(t),t)}{|DP(y(t),t)|}, \\ y(t_0) &= x, \end{cases}$$

since they propagate with speed c along the unit normal to the manifold. These trajectories are known as *characteristics*. Then we just need to check that the evolution of each point of the manifold verifies the equation $P(y(t), t) = 0$, i.e., derive with respect to t

$$P_t(y(t), t) - |DP(y(t), t)|c(y(t), t) = 0 \tag{6.1}$$

for any linear speed $c(x, t) = a(t)x + b(t)$ and for any $P(x, t)$ representing hyperplanes or spheres.

Hyperplanes: $P(x, t) = \alpha(t)x + \beta(t)$. It results that $P_t(x, t) = \dot{\alpha}(t)x + \dot{\beta}(t)$ and $|DP(x(t), t)| = |\alpha(t)|$, and then $P(x, t)$ verifies (6.1) with coefficients such that:

$$\begin{cases} \dot{\alpha}(t) = |\alpha(t)|a(t), \\ \dot{\beta}(t) = |\alpha(t)|b(t). \end{cases}$$

Spheres: $P(x,t) = R(t)^2 - |x - x_0(t)|^2$. It results that $P_t(x,t) = 2(x - x_0(t))\dot{x}_0(t) + 2R(t)\dot{R}(t)$ and $|DP(x(t),t)| = 2|x - x_0(t)|$, and then $P(x,t)$ verifies (6.1) with coefficients such that:

$$\begin{cases} \dot{x}_0(t) = a(t)R(t), \\ \dot{R}(t) = x_0(t)a(t) + b(t). \end{cases}$$

Test 1: *A rotating line.* We choose as initial data a line $P(x,0) = x_2 + 1.5x_1$ and then as representing function:

$$\theta(x,0) = \begin{cases} 1 & \text{if } x_2 + 1.5x_1 > 0, \\ -1 & \text{otherwise.} \end{cases} \tag{6.2}$$

We choose as velocity $c(x,t) = x_1$. We have proved that a line propagating with linear speed stays a line. By applying the result of the previous section, we obtain that $P(x,t) = \alpha(t)x + \beta(t)$ has coefficients solving the following ODE:

$$\begin{cases} \dot{\alpha}_1(t) = \sqrt{1 + \alpha_1(t)^2}, \\ \alpha_1(0) = 1.5, \end{cases} \qquad \begin{cases} \dot{\alpha}_2(t) = 0, \\ \alpha_2(0) = 1, \end{cases}$$

and then we get $P(x,t) = \sinh(t + \operatorname{arcsinh}(\alpha_1(0)))x_1 + x_2$.

We compute the discrete solution in the numerical domain $D = [-1,1] \times [-1,1]$. The evaluation of the error is a delicate point. We decided to evaluate the error at the final time $T = 1$ in terms of the difference between the area $\mathcal{A}(\cdot)$ of the set $\Omega_T^+ = \{x \in \mathbb{R}^2 : P(x,T) > 0\}$ and its numerical approximation $\Omega_m^+ = \{x \in \mathbb{R}^2 : I[\theta^m](x) > 0\}$, where m is the number of iterations to reach the final time T and $I[\theta^m]$ is the linear interpolation of the discrete numerical solution $(\theta_I^m)_I$. In both cases we were able to compute the area exactly.

Note that a priori a small error on the areas does not guarantee that the two fronts (exact and approximated) are close each other since, for example, positive errors in the area on one piece of the boundary can be compensated by negative errors on another piece of the boundary. Naturally, the more accurate way to evaluate the error at $T = 1$ is to compute the Hausdorff distance $\mathcal{H}(\cdot,\cdot)$ between the exact front $\mathcal{C} = \{x \in \mathbb{R}^2 : P(x,T) = 0\}$ and the approximated front $\tilde{\mathcal{C}} = \{x \in \mathbb{R}^2 : I[\theta^m](x) = 0\}$. Although that distance cannot be computed exactly, a good approximation can be obtained by computing it on only a finite number of points belonging to the fronts.

We measure the amount of inhomogeneity of the speed by the ratio

$$\max_{I \in F_+^n} |\widehat{c}_I^n| / \min_{I \in F_-^n} |\widehat{c}_I^n|.$$

Since in this test there are points in the front with speed 0, the coefficient results to be infinity.

The speed is constant in time; then we are in the situation described in Case 1 in section 2.3, and we can implement the algorithm without updating the values of $\tilde{u}$ on each node of the front at each iteration. We need only to recompute the value of $\tilde{u}$ at the node I whose neighbors have been accepted ($I \in V(NA^n)$); i.e., after one iteration the algorithm should be modified in Step 5 as follows:

for $n \geq 2$

5. *Compute* $\tilde{u}^{n-1}$ *on* $F_\pm^{n-1}$ *as follows*:
   1. If $I \notin V(NA^{n-1})$, then $\tilde{u}_I^{n-1} = \tilde{u}_I^{n-2}$;

TABLE 1
Area and Hausdorff distances: GFMM-Case 1 *versus FD, for Test* 1 *with constant time speed.*

	GFMM			FD		
Δx	$\lvert\mathcal{A}(\Omega_T^+) - \mathcal{A}(\Omega_m^+)\rvert$	$\mathcal{H}(\mathcal{C}, \tilde{\mathcal{C}})$	CPU	$\lvert\mathcal{A}(\Omega_T^+) - \mathcal{A}(\Omega_n^+)\rvert$	$\mathcal{H}(\mathcal{C}, \tilde{\mathcal{C}})$	CPU
0.04	$1.62 \cdot 10^{-1}$	$5.08 \cdot 10^{-2}$	0.19 s	$1.15 \cdot 10^{-1}$	$4.10 \cdot 10^{-2}$	1.82 s

0.01	$4.05 \cdot 10^{-2}$	$1.35 \cdot 10^{-2}$	3.98 s	$2.80 \cdot 10^{-2}$	$1.03 \cdot 10^{-2}$	102 s
0.005	$2.05 \cdot 10^{-2}$	$6.80 \cdot 10^{-3}$	76 s	$9.00 \cdot 10^{-3}$	$2.60 \cdot 10^{-3}$	810 s

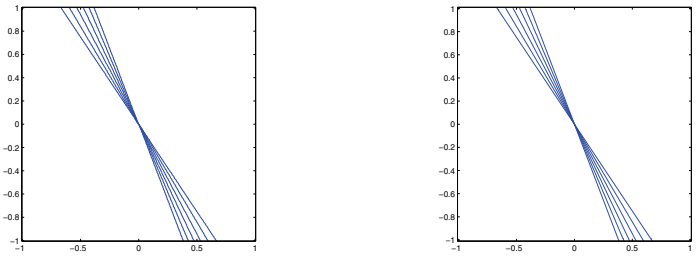

FIG. 4. *A rotating line by the GFMM algorithm (left) and by the FD algorithm (right).*

2. if $I \in V(NA^{n-1})$, then
   (a) if $\pm\widehat{c}_I^{n-1} \geq 0$, $\tilde{u}_I^{n-1} = \infty$;
   (b) if $\pm\widehat{c}_I^{n-1} < 0$, compute $\tilde{u}_I^{n-1}$ as the solution of (2.4).

We compare the GFMM method with the iterative finite difference (FD) scheme described in [17], in terms of complexity and accuracy. In this case the approximated set is $\Omega_n^+ = \{x \in \mathbb{R}^2 : I[v^n](x) > 0\}$, where $(v_I^n)_I$ is the solution of the FD scheme approximating the continuous solution $P(x,T)$, $I[v^n]$ its linear interpolation, and $\tilde{\mathcal{C}} = \{x \in \mathbb{R}^2 : I[v^n](x) = 0\}$ the approximated front.

Table 1 shows the error for the tests run with 50, 100, 200, 400 and the number of nodes for each side of the square domain.

Table 1 shows a better performance in terms of accuracy for the FD scheme; this can be explained by observing that in the scheme the front is represented by the zero level set of a continuous function and this convergence is uniform. On the other hand, the GFMM algorithm represents the front by the interface of a discontinuous function (i.e., the front is where there is a jump between -1 and 1). The advantage here to use the GFMM scheme is in terms of CPU time; the GFMM results are approximately 10 times faster than the full matrix approach.

Figure 4 (left) shows the interface between $\{\theta^\varepsilon = 1\}$ and $\{\theta^\varepsilon = -1\}$ at each time interval 0.1. The line is rotating clockwise, and it will reach in infinite time the x_2 axis. Figure 4 (right) shows the same test computed by the FD scheme; here the lines are the 0-level set of the discrete function $(v_I^n)_{I,n}$. In both cases the test has computed with $\Delta x = 0.01$, and the line has been plotted at times $t_n = n0.1$, $n = 1, 2, 3 \ldots$.

Now let us consider a speed depending on time and changing sign during the evolution $c(x,t) = \sin(2\pi t)x_1$. This means that we are in Case 2 of section 2.3. We obtain the exact solution by solving (6.1). The line is rotating around the origin, changing its direction of rotation after every time interval of length 1/2. We compute the discrete solution in the numerical domain $D = [-1,1] \times [-1,1]$, we evaluate the error at final time $T = 1$, and we choose $\Delta T = 4\Delta x > \frac{1}{\sqrt{M}}$ as the time step to update

TABLE 2
Area and Hausdorff distances: GFMM-Case 2 versus FD for Test 1 with time-dependent speed.

	GFMM			FD		
Δx	$\lvert\mathcal{A}(\Omega_T^+) - \mathcal{A}(\Omega_m^+)\rvert$	$\mathcal{H}(\mathcal{C}, \tilde{\mathcal{C}})$	CPU	$\lvert\mathcal{A}(\Omega_T^+) - \mathcal{A}(\Omega_n^+)\rvert$	$\mathcal{H}(\mathcal{C}, \tilde{\mathcal{C}})$	CPU
0.04	$1.60 \cdot 10^{-1}$	$5.21 \cdot 10^{-2}$	0.52 s	$9.76 \cdot 10^{-2}$	$4.82 \cdot 10^{-2}$	1.82 s
0.02	$8.66 \cdot 10^{-2}$	$3.07 \cdot 10^{-2}$	1.71s	$4.76 \cdot 10^{-2}$	$2.46 \cdot 10^{-2}$	13.3 s
0.01	$4.27 \cdot 10^{-2}$	$1.54 \cdot 10^{-2}$	10.5 s	$2.37 \cdot 10^{-2}$	$1.35 \cdot 10^{-2}$	102 s
0.005	$2.14 \cdot 10^{-2}$	$9.00 \cdot 10^{-3}$	130 s	$6.88 \cdot 10^{-3}$	$7.00 \cdot 10^{-3}$	842 s

the speed and the values of the time on the front; i.e., Step 5 in the algorithm is computed only on $F^n \cap V(NA^n)$ and each ΔT time step on all of the nodes of F^n.

By measuring the amount of inhomogeneity as before, we still get infinity for the coefficient, since also in this test there are points in the front with zero speed.

Table 2 shows an increase of the CPU time for the GFMM method with respect to the previous test. This was expected since we update all of the values of $\tilde{u}$ on the fronts after every time interval ΔT. The FD scheme is still more accurate, but in terms of CPU time the GFMM method wins since it is 6 times faster (in the last test) than the FD scheme. All tables show that for smooth speed the GFMM algorithm has approximately order of convergence 1.

All of the tests have been computed on a laptop with a Intel Centrino Duo processor.

Test 2: *Propagation of a circle.* We choose as initial data a circle $P(x, 0) = x_1^2 + x_2^2 - 1$ and then as representing function:

$$\theta(x,0) = \begin{cases} 1 & x_1^2 + x_2^2 - 1 < 0, \\ -1 & \text{otherwise.} \end{cases} \tag{6.3}$$

We choose as velocity $c(x,t) = 0.1t - x_1$. We have proved that a circle propagating with linear speed stays a circle. By applying the result of the previous section, we obtain that $P(x,t) = (x_1 - x_{0,1}(t))^2 + (x_2 - x_{0,2}(t))^2 - R(t)^2$ has coefficients solving the following ODE:

$$\begin{cases} \dot{x}_{0,1}(t) = -R(t), \\ x_{0,1}(0) = 0, \end{cases} \quad \begin{cases} \dot{x}_{0,2}(t) = 0, \\ x_{0,2}(0) = 0, \end{cases} \quad \begin{cases} \dot{R}(t) = -x_{0,1}(t) + 0.1t, \\ R(0) = 1. \end{cases}$$

By solving, we obtain $x_{0,1}(t) = 1/20(2t + 11(\exp(-t) - \exp(t))$ and $R(t) = 1/20(-2 + 11(\exp(t) + \exp(-t)))$.

We compute the discrete solution in the numerical domain $D = [-2, 2] \times [-2, 2]$. The amount of inhomogeneity as in the previous test is infinity, because again in this test there are points in the front with zero speed.

We evaluate the error at the final time $T = 0.5$ by comparing the areas $\mathcal{A}(\cdot)$ of the sets Ω_T^+ and Ω_m^+ and computing the approximated Hausdorff distance between the exact and approximated fronts, as defined in the previous test.

Table 3 shows the error for the tests run with 50, 100, 200, 400 and the number of nodes for each side of the square domain. As can be seen in the table, the order of convergence is approximately 1, which seems to be a very good result for an algorithm which adopts a discontinuous representation of the front.

TABLE 3
Area and Hausdorff distances for Test 2 with GFMM.

Δx	$\lvert\mathcal{A}(\Omega_T^+) - \mathcal{A}(\Omega_m^+)\rvert$	$\mathcal{H}(\mathcal{C}, \tilde{\mathcal{C}})$
0.08	$1.26 \cdot 10^{-1}$	$8.52 \cdot 10^{-1}$
0.04	$6.56 \cdot 10^{-2}$	$4.42 \cdot 10^{-2}$
0.02	$3.34 \cdot 10^{-2}$	$2.41 \cdot 10^{-2}$
0.01	$1.41 \cdot 10^{-2}$	$1.24 \cdot 10^{-2}$

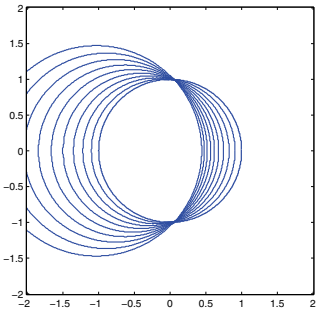

FIG. 5. *A propagating circle.*

Figure 5 shows the interface between $\{\theta^\varepsilon = 1\}$ and $\{\theta^\varepsilon = -1\}$ at each time interval 0.1 obtained with space step 0.01; the circle is expanding, and its center is propagating on the left.

Test 3: *Comparison between the FMM and GFMM algorithms.* When the evolution is monotone (with time-independent velocity), i.e., $c(x) > 0$, there exists a link between the evolutive and the stationary equation (see [12, 16]):

$$\begin{cases} c(x)|DT(x)| = 1 & x \in \Omega, \\ T(x) = 0 & x \in \partial\Omega. \end{cases}$$

In this case the discrete function u_I^n, computed by the GFMM algorithm, approximates the solution $T(x)$ outside the set Ω.

The two schemes, the FMM and the GFMM, are run in the case where the speed is $c(x,t) = 1$ with initial set Ω a circle centered in the origin with radius 0.5. The amount of inhomogeneity is obviously one, because in this test the speed is a constant.

For this choice of speed, the solution $T(x)$ corresponds to the distance function of the point x from the set Ω (see Figure 6).

We compare the two schemes by computing the errors in the $||\cdot||_\infty$ discrete norm:

$$\|T(x_I) - u_I\|_\infty \equiv \sup_{\{I:x_I \in D\}} |T(x_I) - u_I|.$$

As one can see in Table 4, the GFMM scheme produces in this particular case almost the same results as the FMM scheme (as implemented in the HJpack library [29]). The results are slightly different in particular because the time computed in the narrow band in the classical FMM uses not only the accepted points but also the points of the narrow band.

TABLE 4
Numerical errors for Test 3.

Δx	FMM	GFMM
0.08	$6.5 \cdot 10^{-2}$	$7.8 \cdot 10^{-2}$
0.04	$3.3 \cdot 10^{-2}$	$3.9 \cdot 10^{-2}$
0.02	$2.0 \cdot 10^{-2}$	$1.8 \cdot 10^{-2}$
0.01	$1.0 \cdot 10^{-2}$	$1.0 \cdot 10^{-2}$

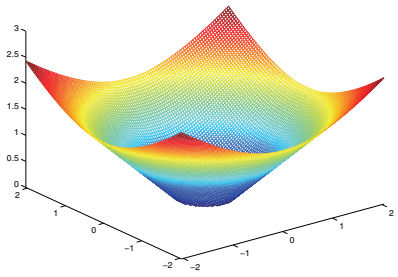

FIG. 6. *The discrete time u of a propagating circle with positive constant speed.*

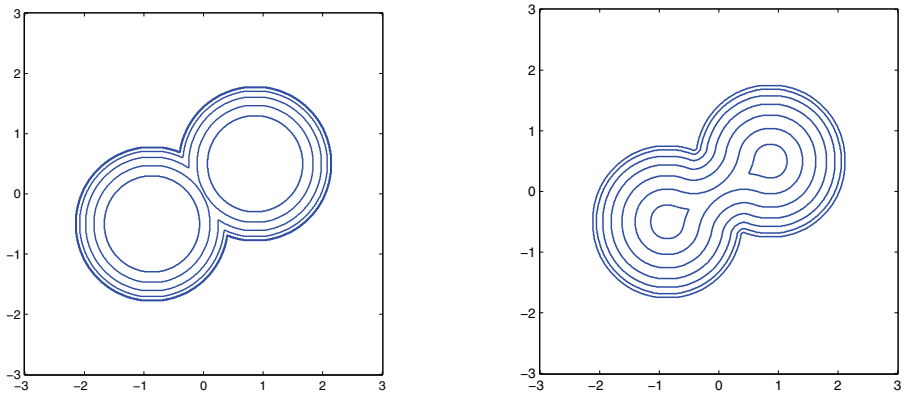

FIG. 7. *Two propagating circles.*

Test 4: *Two collapsing circles.* We choose as initial data two circles and as velocity $c(x,t) = 1 - t$. The amount of inhomogeneity is one, since the speed is not depending on space variables.

The two circles grow as far as the speed is positive. At $t = 1$, when the velocity changes sign, they start to decrease. Figure 7 on the left shows the interface between $\{\theta^\varepsilon = 1\}$ and $\{\theta^\varepsilon = -1\}$ obtained with $\Delta x = 0.01$ at each time interval 0.2 until $t = 1$, and Figure 7 on the right shows the interface between $\{\theta^\varepsilon = 1\}$ and $\{\theta^\varepsilon = -1\}$ at each time interval 0.2 for the time interval $[1.2, 2.4]$.

ENO MULTIRESOLUTION SCHEMES WITH GENERAL DISCRETIZATIONS*

PASCAL GETREUER† AND FRANÇOIS G. MEYER‡

Abstract. Harten's framework is a nonlinear generalization of the wavelet framework. Previously, the choice of discretization (scaling function) in Harten multiresolution schemes has been limited to point-value, cell-average, and hat-based discretization. This paper shows how to construct multiresolution schemes consistent with Harten's framework for a variety of discretizations. The construction here begins with the discrete operators and deduces the corresponding continuous operators, reversing the order of the usual approach. This construction yields as a special case essentially nonoscillatory (ENO) multiresolution schemes for any order of spline discretization and also has the flexibility to define multiresolution schemes with nonspline discretizations. An error-control strategy is also developed.

Key words. ENO interpolation, multiscale decomposition, wavelets

DOI. 10.1137/060663763

1. Introduction.

Harten's multiresolution framework [5] generalizes wavelet transforms. Harten's framework requires that the decimation (coarsening) operator be linear, but the prediction (refining) operator may be nonlinear.

One effective choice for this prediction operator is essentially nonoscillatory (ENO) interpolation, an edge-adaptive interpolation technique originating in the numerical methods of hyperbolic conservation laws [12]. ENO multiresolution schemes based on ENO interpolation achieve efficient, edge-adaptive decompositions and are especially successful on piecewise-smooth functions, as shown by the numerical experiments in [2].

1.1. Earlier work.

Much work on nonlinear multiresolution in the wavelet literature has been inspired by Sweldens's wavelet lifting scheme [19]. In [8], Claypoole et al. used a nonlinear prediction stage to create an edge-adaptive transform. Heijmans and Goutsias [15] developed the general morphological wavelets framework for constructing nonlinear wavelets.

Many have worked to develop Harten multiresolution, including:

- Harten [13, 14] developed the foundation of Harten's framework and ENO multiresolution schemes.
- Cohen, Dyn, and Mateï [10] studied the convergence of ENO prediction schemes and other properties of recursive prediction using the machinery of subdivision refinement schemes.
- Sonar, Iske, Cecil, Qian, and Osher [7, 16, 18] proposed the extensions of ENO beyond one dimension using radial basis functions. Cohen and Mateï [9] extended ENO to two dimensions with rotating step functions.

- Aràndiga, Donat, and Harten [6] constructed an ENO transform satisfying Harten's framework using hat-based discretization.

1.2. This paper's contribution. Harten's framework is in principle more general than the wavelet framework, yet most development so far has focused on the point-value and cell-average discretizations (analogous to the lazy and Haar wavelets). Aràndiga, Donat, and Harten [6] developed a third, the hat-based discretization. In wavelet nomenclature, only three possible scaling functions have been thoroughly considered.

The goal of this paper is to extend these constructions to all discretizations where the decimation filter is finite impulse response (FIR). This class of discretizations includes those induced by FIR wavelets as well as the three previously developed discretizations. Previously, Harten constructions start in the continuous domain by defining a discretization operator $\mathcal{D}_k$ and a reconstruction operator $\mathcal{R}_k$. Approaching the construction from the discrete domain, however, many operators can be defined without $\mathcal{D}_k$ and $\mathcal{R}_k$. We construct the decimation and prediction operators first and then deduce $\mathcal{D}_k$ and a choice of $\mathcal{R}_k$.

1.3. Outline. Section 2 reviews the construction of Harten's framework. Section 3 describes ENO interpolation (section 3.1), point-value discretization ENO schemes (section 3.2), and cell-average and hat-based discretization ENO schemes (section 3.3). Sections 4 and 5 develop for any FIR decimation filter h,

- a valid prediction operator (section 4.3),
- detail operators for a nonredundant scheme (section 4.1),
- $\mathcal{D}_k$ and $\mathcal{R}_k$ (section 4.4),
- an error-control strategy (section 5).

Section 6 develops two examples of this construction: Schemes with any spline discretization (section 6.1) and an example of nonspline discretization (section 6.2). Section 7 is the conclusion.

1.4. Notation. Define a *discrete signal* as any real or complex-valued sequence $v = (v_n)_{n\in\mathbb{Z}}$. An FIR filter is a discrete signal that is nonzero for finitely many n. Define its bilateral Z-transform $v(z)$,

$$v(z) \stackrel{\text{def}}{=} \mathcal{Z}\{v\}(z) = \sum_{n\in\mathbb{Z}} v_n z^{-n}. \tag{1.1}$$

Define dyadic downsampling and upsampling on v as

$$(\downarrow v)_n = v_{2n}, \qquad (\uparrow v)_n = \begin{cases} v_{n/2} & \text{if } n \text{ even}, \\ 0 & \text{if } n \text{ odd}. \end{cases}$$

The Z-transform of $\uparrow\downarrow v$ is

$$\tfrac{1}{2}\big(v(z) + v(-z)\big). \tag{1.2}$$

Denote by $\hat{\cdot}$ the Fourier transform,

$$\hat{f}(\omega) \stackrel{\text{def}}{=} \int_{-\infty}^{+\infty} f(x)\, \mathrm{e}^{-i\omega x}\, dx.$$

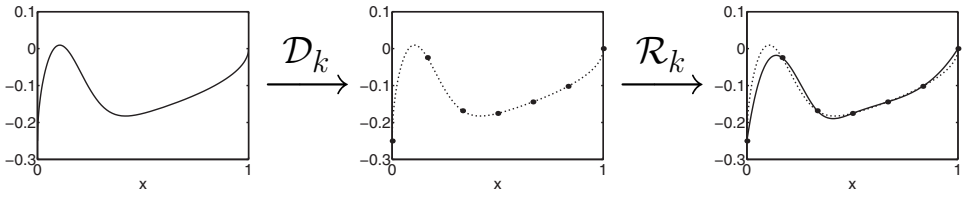

FIG. 2.1. *Left:* $f(x) = \mathrm{e}^{-25x^2}\sqrt{x} - \frac{1}{4}\sqrt{1-x}$. *Center:* $\mathcal{D}_k f$ *with point-value discretization,* $(\mathcal{D}_k f)_n = f(n/6)$. *Right:* $\mathcal{R}_k \mathcal{D}_k f$, *where* $\mathcal{R}_k$ *is cubic spline interpolation.*

2. Harten's framework. Harten's framework [5] builds from two operators: *Discretization* $\mathcal{D}_k$ and *reconstruction* $\mathcal{R}_k$. These operators map between functions and discrete signals at resolution k. The index k denotes the resolution level, where increasing k implies finer resolution.

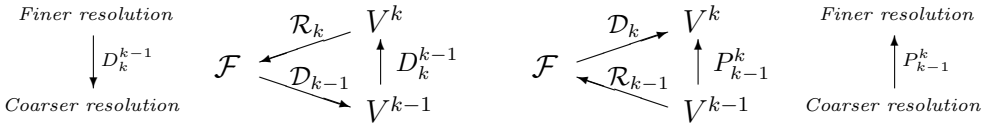
Let $\mathcal{F}$ be space of functions, and let V^k be a vector space of discrete signals. Discretization $\mathcal{D}_k : \mathcal{F} \to V^k$ is a *linear* operator mapping $f \in \mathcal{F}$ to a discrete signal $v^k = \mathcal{D}_k f$. Reconstruction $\mathcal{R}_k : V^k \to \mathcal{F}$ is a (generally) *nonlinear* operator mapping discrete signals to functions. This nonlinearity is where Harten's framework is more general than the wavelet framework. Figure 2.1 shows an example of discretization and reconstruction, where $\mathcal{D}_k$ is point-value discretization and $\mathcal{R}_k$ is cubic spline interpolation.

Harten's framework requires that the discretization and reconstruction operators satisfy a consistency relationship

$$\mathcal{D}_k \mathcal{R}_k = I_{V^k}, \tag{2.1}$$

where I_{V^K} denotes identity on V^k. The reconstruction $\mathcal{R}_k v^k$ must be consistent with the discrete information in v^k.

To construct a multiresolution scheme, define a decimation operator $D_k^{k-1} = \mathcal{D}_{k-1}\mathcal{R}_k$ and a prediction operator $P_{k-1}^k = \mathcal{D}_k \mathcal{R}_{k-1}$ as follows:



Decimation reduces the discrete signal v^k to v^{k-1}; $v^{k-1} = D_k^{k-1} v^k$. The prediction operator predicts v^k from v^{k-1}; $P_{k-1}^k v^{k-1}$ is an approximation of v^k. Define the prediction error as

$$e^k = v^k - P_{k-1}^k v^{k-1}.$$

The operators D_k^{k-1} and P_{k-1}^k can be used to construct a multiresolution pyramid (see Figure 2.2). If v^k is the input, then one stage of decomposition outputs the

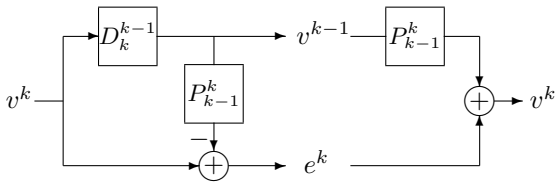


FIG. 2.2. *Pyramid decomposition under Harten's framework.*

decimated signal v^{k-1} and the prediction error e^k. Because e^k is at the same sample rate as v^k, the decomposition is 50% oversampled, that is, (v^{k-1}, e^k) redundantly represents v^k. This single decomposition stage is iterated on the decimated signal for a multiresolution representation $(v^{k-L}, e^{k-L+1}, \dots, e^k)$.

The discretization sequence $(\mathcal{D}_k)$ is *nested* if

$$\mathcal{D}_k f = 0 \;\Rightarrow\; \mathcal{D}_{k-1} f = 0 \qquad \text{for all } f \in \mathcal{F},\ k \in \mathbb{Z}. \tag{2.2}$$

If $(\mathcal{D}_k)$ is nested, then D^k_{k-1} has no dependence on $\mathcal{R}_k$ despite its definition, and it must be a linear operator [5]. This property, along with the consistency requirement (2.1), implies that $\mathcal{D}_m \mathcal{R}_k \mathcal{D}_k = \mathcal{D}_m$ for $m \le k$ and a discrete analogy of the consistency relationship

$$D^{k-1}_k P^k_{k-1} = \mathcal{D}_{k-1}\mathcal{R}_k\mathcal{D}_k\mathcal{R}_{k-1} = \mathcal{D}_{k-1}\mathcal{R}_{k-1} = I_{V^{k-1}}. \tag{2.3}$$

Consequently, e^k is in the nullspace of D^{k-1}_k:

$$\begin{aligned} D^{k-1}_k e^k &= D^{k-1}_k \left(I_{V^k} - P^k_{k-1} D^{k-1}_k\right) v^k \\ &= \left(D^{k-1}_k - D^{k-1}_k (P^k_{k-1} D^{k-1}_k)\right) v^k \;=\; 0. \end{aligned} \tag{2.4}$$

By (2.4), it is possible to design a nonredundant (critically sampled) multiresolution decomposition. Let G_k be a detail encoder such that $d^k = G_k e^k$ is at half the sample rate of e^k, and let $\tilde{G}_k$ be the corresponding decoder such that $\tilde{G}_k G_k e^k = e^k$ for any e^k in the nullspace of D^{k-1}_k. Then (v^{k-1}, d^k) is a nonredundant representation of v^k. This single stage is iterated on the decimated signal for a multiresolution representation $(v^{k-L}, d^{k-L+1}, \dots, d^k)$.

In summary, a multiresolution scheme within Harten's framework is characterized by six operators: The fundamental discretization and reconstruction operators $\mathcal{D}_k$ and $\mathcal{R}_k$, the decimation operator D^{k-1}_k, the prediction operator P^k_{k-1}, and the detail operators G_k and $\tilde{G}_k$. The next section shows how ENO multiresolution schemes fit into the Harten framework.

3. ENO multiresolution schemes. ENO multiresolution schemes are Harten multiresolution schemes where the reconstruction operator is ENO interpolation. ENO interpolation is an effective edge-adaptive strategy for piecewise polynomial interpolation (essentially) without oscillatory artifacts (see Figure 3.1).

3.1. ENO interpolation. Let $v_n = f(x_n)$ be samples from an underlying function f. ENO interpolation approximates f from the point-values v by a piecewise polynomial model.

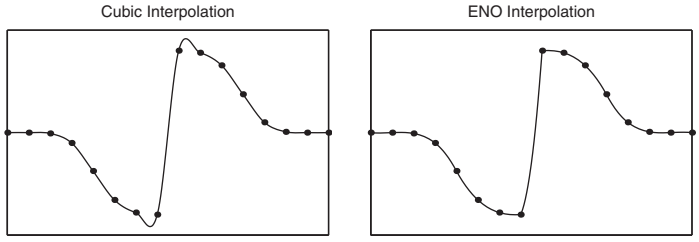

FIG. 3.1. *An interpolation of piecewise-smooth data. Cubic interpolation produces oscillations around the discontinuity, but ENO interpolation does not.*

On each subinterval $[x_{n-1}, x_n]$, a polynomial interpolant $q_n(x)$ is constructed based on a stencil $\mathcal{S}_n$ such that $q_n(x) = f(x)$ for all $x \in \mathcal{S}_n$. For example, cubic interpolation finds the cubic polynomial q_n satisfying the point-values at $\mathcal{S}_n = \{x_{n-2}, x_{n-1}, x_n, x_{n+1}\}$ to interpolate $[x_{n-1}, x_n]$. In ENO interpolation, the $\mathcal{S}_n$ are selected to adapt to the v^k.

The accuracy of such an interpolant depends heavily on the stencil. Let $\mathcal{S}$ be a stencil, and denote by $\widehat{\mathcal{S}}$ its convex hull. If $\mathcal{S}$ has $M+1$ points and $f \in C^{M+1}(\widehat{\mathcal{S}})$, the interpolation error is

$$f(x) - q(x) = \frac{f^{(M+1)}\big(\xi(x)\big)}{(M+1)!} \prod_{x_j \in \mathcal{S}} (x - x_j) \quad \text{for some } \xi(x) \in \widehat{\mathcal{S}}. \tag{3.1}$$

If f is locally smooth, the interpolation error is small. However, if f has a jump or derivative singularity in $\widehat{\mathcal{S}}$, the error can be much greater [5].

ENO interpolation attempts to choose stencils that do not cross jumps or derivative discontinuities. To construct an interpolant $q_n(x)$ of degree M, consider the stencils $\mathcal{S}_n = \{x_{k_n-1}, \ldots, x_{k_n+M-1}\}$, $n - M + 1 \le k_n \le n$. Each stencil has $M+1$ points and includes x_{n-1} and x_n. The interpolation error associated with a particular stencil is estimated with the Mth-order divided difference of the stencil samples $f[\mathcal{S}]$:

$$|f[\mathcal{S}]| = \begin{cases} 0, & f \text{ is locally polynomial,} \\ O([f^{(p)}])/h^{M-p}, & \text{the stencil crosses a discontinuity in } f^{(p)}, \\ O(\|f^{(M)}\|), & \text{otherwise,} \end{cases} \tag{3.2}$$

where $[f^{(p)}]$ is the size of the jump and $\|f^{(M)}\|$ is the max-norm of $f^{(M)}$ over $\widehat{\mathcal{S}}$. For example, if $M = 2$, (3.2) has the form

$$|f[\mathcal{S}_i]| = \frac{1}{2h^2} \left| f(x_{k-1}) - 2f(x_k) + f(x_{k+1}) \right|, \quad k = i-1 \text{ or } i.$$

This estimate distinguishes between intervals where f is locally linear and intervals containing jumps or first derivative discontinuities. In general, the Mth-order error estimate can detect discontinuities in up to the $M-1$ derivative.

In [12], Harten et al. consider two methods for choosing the stencil shifts k_n:

Hierarchical stencil selection

For each n
  $k_n := n$
  for $j = 0, \ldots, M-2$
    if $|f[x_{k_n-2}, \ldots, x_{k_n+j}]| < |f[x_{k_n-1}, \ldots, x_{k_n+j+1}]|$, **then** $k_n := k_n - 1$
  end.

Nonhierarchical stencil selection

For each n, choose k_n such that
$$|f[x_{k_n-1}, \ldots, x_{k_n+M-1}]| = \min_{n-M+1 \le k \le n} |f[x_{k-1}, \ldots, x_{k+M-1}]|.$$

The hierarchical method has the disadvantage that it can produce singularity-crossing stencils for discontinuities in f'' or higher derivatives regardless of M. The nonhierarchical method avoids this problem, but it is biased by $f^{(M)}$ [5, 12]. The hierarchical method is usually preferred; however, for the multiresolution constructions

FIG. 3.2. *An example of point-value ENO decomposition using cubic ENO interpolation. The largest error* $e^k_7 = 0.7146$ *occurs in the interval containing the discontinuity.*

developed in this paper, the nonhierarchical method is often the better choice. This will be discussed further in section 6.1.

Define $\mathcal{I}^{\mathrm{ENO}}_k : V^k \to \mathcal{F}$ as ENO interpolation. For uniformly spaced x_n, define

$$(P^{\mathrm{ENO}}v)_n = (\mathcal{I}^{\mathrm{ENO}}_k v)(x_n/2).$$

P^{ENO} has the property $\downarrow P^{\mathrm{ENO}} = I$. We call an operator with this property an *interpolatory* operator.

3.2. Point-value discretization. ENO interpolation is the reconstruction operator in point-value ENO multiresolution. Define $\mathcal{D}_k$ as sampling point values:

$$v^k_n = (\mathcal{D}_k f)_n = f(x^k_n), \quad x^k_n = 2^{-k}n.$$

The interpolant $\mathcal{R}_k v^k = \mathcal{I}^{\mathrm{ENO}}_k v^k$ is equal to f at the point-values $f(x^k_n)$, so the consistency relationship $\mathcal{D}_k\mathcal{R}_k = I_{V^k}$ is trivially satisfied. The decimation operator is downsampling, $v^{k-1} = D^k_{k-1}v^k = \downarrow v^k$. The prediction operator $P^k_{k-1} = \mathcal{D}_k\mathcal{R}_{k-1}$ is ENO interpolatory prediction,

$$(P^k_{k-1}v^{k-1})_n = (\mathcal{I}^{\mathrm{ENO}}_k v^{k-1})(x^k_n) = (P^{\mathrm{ENO}}v^{k-1})_n.$$

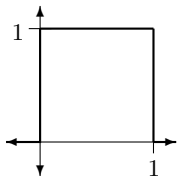
The prediction error $e^k = v^k - P^k_{k-1}v^{k-1}$ is nonzero only for odd n. For a nonredundant representation, the detail is encoded by keeping samples at odd n; $d^k_n = e^k_{2n+1}$ (see Figure 3.2).

3.3. Cell-average and hat-based discretizations. In most multiresolution schemes, smoothing is applied before downsampling to avoid aliasing in the coarser subbands. The cell-average and hat-based discretizations use local averages to achieve this smoothing. Suppose $f \in L^1_{\mathrm{loc}}$ is discretized by computing weighted averages

$$(\mathcal{D}_k f)_n = \int 2^k \phi(n - 2^k x)\, f(x)\, dx,$$

where ϕ is a compactly supported weighting function. Equivalently, $(\mathcal{D}_k f)_n = (\phi_k * f)(x_n^k)$, with $\phi_k(x) = 2^k\phi(2^k x)$. For cell-average discretization, ϕ is the Haar scaling function

$$\phi(x) = \begin{cases} 1, & 0 \le x < 1, \\ 0, & \text{otherwise.} \end{cases}$$



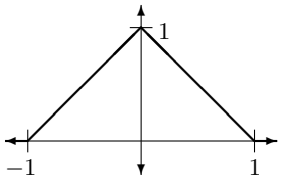
The discretization $(\mathcal{D}_k f)_n$ is the average over the cell $c_n^k = (\,2^{-k}(n-1), 2^{-k}n\,)$,

$$(\mathcal{D}_k f)_n = 2^k \int_{c_n^k} f(x)\,dx,$$

hence the name "cell-average." The dilation equation of the Haar scaling function $\phi(x) = \phi(2x)+\phi(2x-1)$ implies that $v_n^{k-1} = \frac{1}{2}v_{2n}^k + \frac{1}{2}v_{2n-1}^k$. Therefore, the decimation operator is $(D_k^{k-1}v^k)_n = \frac{1}{2}v_{2n}^k + \frac{1}{2}v_{2n-1}^k$.

For hat-based discretization, ϕ is the hat function

$$\phi(x) = \begin{cases} 1+x, & -1 \le x \le 0, \\ 1-x, & 0 \le x \le 1, \\ 0, & \text{otherwise.} \end{cases}$$



As with cell-average discretization, the dilation equation of ϕ determines D_k^{k-1}:

$$\begin{aligned} \phi(x) &= \tfrac{1}{2}\phi(2x-1) + \phi(2x) + \tfrac{1}{2}\phi(2x+1), \\ (D_k^{k-1}v^k)_n &= \tfrac{1}{4}v_{2n-1}^k + \tfrac{1}{2}v_{2n}^k + \tfrac{1}{4}v_{2n+1}^k. \end{aligned}$$

Consider the reconstruction operators for these discretization operators. To satisfy the consistency requirement $\mathcal{D}_k\mathcal{R}_k = I_{V^k}$, one approach is to modify the point-value ENO interpolation described in section 3.1 such that the reconstruction function attains averages rather than point-values [1].

Harten's approach to constructing $\mathcal{R}_k$ is *reconstruction via primitive function* [6, 14]. The idea is to reduce reconstruction to interpolation (that is, to point-value reconstruction). For cell-average discretization, the relationship between f and its primitive $\mathring{f}$ is

$$\mathring{f}(x) = \int_0^x f(y)\,dy, \qquad f(x) = \frac{d}{dx}\mathring{f}(x).$$

Set $\mathring{v}_{-1}^k = 0$, then the relationship between v^k and $\mathring{v}^k$ is

$$\mathring{v}_n^k = 2^{-k}\sum_{m=0}^{n} v_m^k, \quad v_n^k = 2^k(\mathring{v}_n^k - \mathring{v}_{n-1}^k), \quad n = 0, \ldots J_k - 1. \tag{3.3}$$

Let $\mathcal{I}_k$ be any interpolatory operator, for example, ENO interpolation. Define the reconstruction operator as

$$(\mathcal{R}_k v^k)(x) = \frac{d}{dx}\mathcal{I}_k\mathring{v}^k(x). \tag{3.4}$$

This $\mathcal{R}_k$ satisfies the consistency relationship (2.1): For any $v^k \in V^k$,

$$(\mathcal{D}_k \mathcal{R}_k v^k)_n = 2^k \int_{x^k_{n-1}}^{x^k_n} \frac{d}{dx}(\mathcal{I}_k \mathring{v}^k)\, dx = 2^k(\mathring{v}^k_n - \mathring{v}^k_{n-1}) = v^k_n.$$

The derivative in (3.4) should be interpreted in the weak sense. When $\mathcal{I}_k$ is ENO interpolation, $\mathcal{I}_k \mathring{v}^k$ is piecewise differentiable, so $\mathcal{R}_k v^k$ is piecewise continuous.

Using (3.3) to obtain $\mathring{v}^k$ from v^k, the prediction operator $P^k_{k-1} = \mathcal{D}_k \mathcal{R}_{k-1}$ is

$$(P^k_{k-1} v^{k-1})_n = 2^k \left[(\mathcal{I}_{k-1}\mathring{v}^{k-1})(x^k_n) - (\mathcal{I}_{k-1}\mathring{v}^{k-1})(x^k_{n-1})\right]. \tag{3.5}$$

The approach is similar for hat-based discretization. As developed in [6], the relationship between f and its primitive is

$$\mathring{f}(x) = \int_0^x \int_0^y f(z)\, dz\, dy, \qquad f(x) = \frac{d^2}{dx^2}\mathring{f}(x).$$

Setting $\mathring{v}^k_n = 0$ for $n < 0$, there is a bijection between v^k and $\mathring{v}^k$:

$$\mathring{v}^k_n = 4^{-k} \sum_{m=0}^{n} \sum_{j=0}^{m} v^k_j, \quad v^k_n = 4^k(\mathring{v}^k_{n+1} - 2\mathring{v}^k_n + \mathring{v}^k_{n-1}), \quad n = 0, \dots J_k - 1.$$

Define the reconstruction operator analogously to (3.4),

$$(\mathcal{R}_k v^k)(x) = \frac{d^2}{dx^2}\mathcal{I}_k \mathring{v}^k(x). \tag{3.6}$$

The second derivative should be interpreted in the weak sense. While the first derivative in (3.4) can produce jump discontinuities, (3.6) can produce Dirac measures.

It is true that (3.6) satisfies $\mathcal{D}_k \mathcal{R}_k = I_{V^k}$, but verifying this is more cumbersome than in the cell-average case; see [6]. The prediction operator $P^k_{k-1} = \mathcal{D}_k \mathcal{R}_{k-1}$ is

$$\begin{aligned}(P^k_{k-1} v^{k-1})_n = 4^k \big[&(\mathcal{I}_{k-1}\mathring{v}^{k-1})(x^k_{n+1}) \\ &-2(\mathcal{I}_{k-1}\mathring{v}^{k-1})(x^k_n) + (\mathcal{I}_{k-1}\mathring{v}^{k-1})(x^k_{n-1})\big].\end{aligned} \tag{3.7}$$

Detail encoder and decoder operators can be found using the property that $D^{k-1}_k e^k = 0$. For cell-average discretization, this is $e^k_{2n} = -e^k_{2n-1}$; thus a choice of detail encoder and decoder operators is

$$d^k_n = (G_k e^k)_n = e^k_{2n-1}, \qquad \begin{cases} e^k_{2n-1} = (\tilde{G}_k d^k)_{2n-1} = d^k_n, \\ e^k_{2n} = (\tilde{G}_k d^k)_{2n} = -d^k_n. \end{cases}$$

For hat-based discretization, $e^k_{2n} = -\frac{1}{2}(e^k_{2n-1} + e^k_{2n+1})$. As proposed in [6], the detail operators can be

$$d^k_n = (G_k e^k)_n = e^k_{2n-1}, \qquad \begin{cases} e^k_{2n-1} = (\tilde{G}_k d^k)_{2n-1} = d^k_n, \\ e^k_{2n} = (\tilde{G}_k d^k)_{2n} = -\frac{1}{2}(d^k_n + d^k_{n+1}). \end{cases}$$

Cell-average and hat-based discretizations are two members of a family of spline-based discretizations. Denote the order of a spline discretization by N, with cell-average discretization as $N = 1$ and hat-based discretization as $N = 2$. Point-value discretization fits into this classification as $N = 0$.

For general N, the weight function ϕ is the B-spline of order $N-1$, and $\mathring{f}$ is related to f through an Nth-order integral. The next sections develop the construction of the framework operators for a variety of discretizations, including spline-based discretization of any order (section 6.1).

4. Construction with general discretizations. Harten's framework is defined starting with a discretization operator $\mathcal{D}_k$ and a reconstruction operator $\mathcal{R}_k$ in the continuous domain. These operators are then used to define the decimation and prediction operators in the discrete domain. In this section, the reverse is done: Construction begins with the discrete operators.

Through this section, let h be an FIR filter, and define the decimation operator $D_k^{k-1}v^k = \downarrow(h * v^k)$.

4.1. Detail encoding. Considering h as a wavelet lowpass filter, let $\tilde{h}$, g, and $\tilde{g}$ be corresponding dual lowpass, highpass, and dual highpass wavelet filters, and define $H_k v = D_k^{k-1} v$, $G_k v = \downarrow(g * v)$, $\tilde{H}_k v = \tilde{h} *\uparrow v$, $\tilde{G}_k = \tilde{g} *\uparrow v$.

Suppose this wavelet transform is applied to e^k. Since $H_k e^k = D_k^{k-1} e^k = 0$ by (2.4), the lowpass component is zero (see Figure 4.1). Therefore, G_k and $\tilde{G}_k$ from this wavelet transform are a choice of detail operators for nonredundant decomposition.

Since G_k and $\tilde{G}_k$ are linear, the nonredundant decomposition shown in Figure 4.2 is equivalent to a one-stage lifting scheme (see Figure 4.3).

Remark 1. More generally, any linear operators G_k from V^k to V^{k-1} and $\tilde{H}_k$ and $\tilde{G}_k$ from V^{k-1} to V^k satisfying $\tilde{H}_k D_k^{k-1} + \tilde{G}_k G_k = I_{V^k}$ constitute a lifting scheme as shown in Figure 4.3.

To construct the detail operators for a given decimation filter h, a wavelet must be constructed with this same filter h as its lowpass filter. The perfect reconstruction of the wavelet scheme implies the conditions

$$h(z)\,\tilde{h}(z) \;+\; g(z)\,\tilde{g}(z) = 2,$$
$$h(z)\,\tilde{h}(-z) \;+\; g(z)\,\tilde{g}(-z) = 0.$$

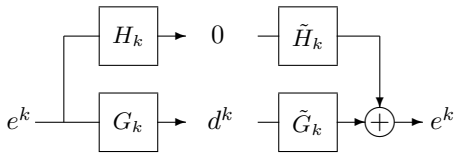


FIG. 4.1. *A wavelet transform of* e^k.

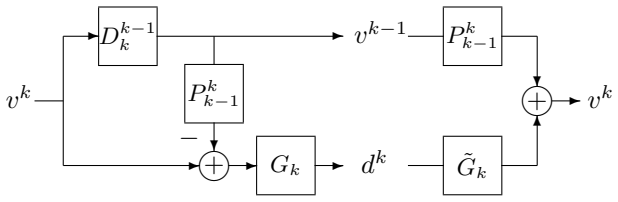

FIG. 4.2. *Nonredundant decomposition using detail encoding.*

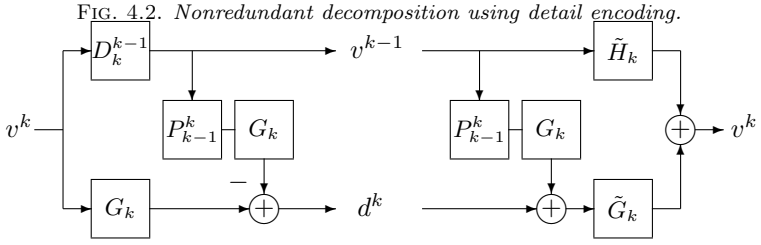

FIG. 4.3. *Nonredundant decomposition as a one-stage lifting scheme.*

If $g(z) = z^{-1}\,\tilde{h}(-z)$ and $\tilde{g}(z) = z\,h(-z)$, the second condition is satisfied. The first condition then reduces to $h(z)\,\tilde{h}(z) + h(-z)\,\tilde{h}(-z) = 2$, which is true if $(h * \tilde{h})_0 = 1$ and $(h * \tilde{h})_n = 0$ for nonzero even n. Thus $\tilde{h}$ must satisfy the linear system

$$\sum_j \tilde{h}_j\, h_{2n-j} = \begin{cases} 1 & \text{if } n = 0, \\ 0 & \text{if } n \neq 0 \end{cases} \qquad \text{for all } n. \tag{4.1}$$

For example, consider $h(z) = az^2 + bz + c + dz^{-1} + ez^{-2}$. If $\tilde{h}$ is assumed to have the form $\tilde{h}(z) = \tilde{h}_{-1}\,z + \tilde{h}_0 + \tilde{h}_1\,z^{-1}$, (4.1) becomes the matrix equation

$$\begin{bmatrix} b & a & 0 \\ d & c & b \\ 0 & e & d \end{bmatrix} \begin{bmatrix} \tilde{h}_{-1} \\ \tilde{h}_0 \\ \tilde{h}_1 \end{bmatrix} = \begin{bmatrix} 0 \\ 1 \\ 0 \end{bmatrix}.$$

Provided a nonzero determinant $\kappa = bcd - ad^2 - b^2e \neq 0$, the solution is $\tilde{h}(z) = \frac{1}{\kappa}(-adz + bd - bez^{-1})$ and

$$\begin{aligned} h(z) &= az^2 + bz + c + dz^{-1} + ez^{-2}, \quad & g(z) &= \frac{1}{\kappa}\left(ad + bdz^{-1} + bez^{-2}\right), \\ \tilde{h}(z) &= \frac{1}{\kappa}\left(-adz + bd - bez^{-1}\right), & \tilde{g}(z) &= az^3 - bz^2 + cz - d + ez^{-1}. \end{aligned} \tag{4.2}$$

It is also possible to select filters from existing wavelet families. Given a number of reconstruction vanishing moments N and decomposition vanishing moments $\tilde{N}$ where $N + \tilde{N}$ is even, the spline wavelet filters are

$$h(z) = z^{\lfloor N/2 \rfloor} \left(\frac{1 + z^{-1}}{2}\right)^N, \tag{4.3}$$

$$\tilde{h}(z) = 2z^{\lceil \tilde{N}/2 \rceil} \left(\frac{1 + z^{-1}}{2}\right)^{\tilde{N}} \sum_{n=0}^{M} \binom{M+n}{n} (-4)^{-n} (z - 2 + z^{-1})^n, \tag{4.4}$$

where $M = \frac{1}{2}(N + \tilde{N}) - 1$, $\lfloor \cdot \rfloor$ denotes the floor function, and $\lceil \cdot \rceil$ denotes the ceiling function [11]. The corresponding highpass filters are $g(z) = \frac{1}{2}z^{-1}\tilde{h}(-z)$ and $\tilde{g}(z) = 2zh(-z)$. The lowpass filter h is the decimation filter corresponding to the spline discretization of order N. If the prediction operator can predict locally polynomial signals, then vanishing moments in g are unnecessary, and $\tilde{N}$ should be 0 (or 1, if N is odd) to minimize the support of g.

Setting $N = 2$, $\tilde{N} = 0$ yields the hat filters

$$h(z) = z\left(\frac{1 + z^{-1}}{2}\right)^2 = \tfrac{1}{4}z + \tfrac{1}{2} + \tfrac{1}{4}z^{-1}, \qquad g(z) = z^{-1},$$

$$\tilde{h}(z) = 2\sum_{n=0}^{0} (-4)^{-n}(z - 2 + z^{-1})^n = 2, \qquad \tilde{g}(z) = -\tfrac{1}{2}z^2 + z - \tfrac{1}{2}.$$

These lead to the same encoding and decoding operators as before in section 3.3:

$$\begin{aligned} &\textit{Encoding} \qquad d^k = \downarrow(e^k * g) \quad \Leftrightarrow \quad d^k_n = e^k_{2n-1}, \\ &\textit{Decoding} \qquad e^k = (\uparrow d^k) * \tilde{g} \quad \Leftrightarrow \quad \begin{cases} e^k_{2n-1} = d^k_n, \\ e^k_{2n} = -\frac{1}{2}(d^k_n + d^k_{n+1}). \end{cases} \end{aligned}$$

Section 6.1 will expand upon this example to construct spline schemes for $N > 2$.

Remark 2. If h, $\tilde{h}$, g, and $\tilde{g}$ satisfy the perfect reconstruction conditions, then so do the scaled and shifted filters

$$h'(z) = \alpha z^{2j} h(z), \qquad g'(z) = \beta z^{2k} g(z),$$
$$\tilde{h}'(z) = \frac{1}{\alpha} z^{-2j} \tilde{h}(z), \qquad \tilde{g}'(z) = \frac{1}{\beta} z^{-2k} \tilde{g}(z).$$

Notice that the detail encoding and decoding operators are not uniquely determined by h. Consider the filter $h(z) = \frac{1}{8}z + \frac{3}{8} + \frac{3}{8}z^{-1} + \frac{1}{8}z^{-2}$. With the spline wavelet approach with $N = 3$ and $\tilde{N} = 1$, the filters g and $\tilde{g}$ are

$$g(z) = \tfrac{1}{4}z + \tfrac{3}{4} - \tfrac{3}{4}z^{-1} - \tfrac{1}{4}z^{-2}, \qquad \tilde{g}(z) = \tfrac{1}{4}z^2 - \tfrac{3}{4}z + \tfrac{3}{4} - \tfrac{1}{4}z^{-1}.$$

Using (4.2), the filters are

$$g(z) = 3z^{-1} + z^{-2}, \qquad \tilde{g}(z) = -\tfrac{1}{8}z^2 + \tfrac{3}{8}z - \tfrac{3}{8} + \tfrac{1}{8}z^{-1}.$$

There is a lot of flexibility in designing the detail operators. Harten's framework does not even require that they are linear, only that $\tilde{G}_k G_k e^k = e^k$ for all $e^k \in \mathcal{N}(D_k^{k-1})$.

4.2. Diagonalizing the decimation operator. Following the "via primitive" technique (section 3.3), our next step is to choose maps under which D_k^{k-1} becomes pure downsampling.

THEOREM 4.1. *Suppose $D_k^{k-1} : V^k \to V^{k-1}$ is any linear and surjective operator, then there exists bijections T_k on V^k and $\tilde{T}_{k-1}$ on V^{k-1} such that*

$$\tilde{T}_{k-1}^{-1} D_k^{k-1} T_k = \downarrow . \tag{4.5}$$

For any such maps $\tilde{T}_{k-1}$ and T_k, P_{k-1}^k is a consistent prediction operator if and only if $T_k^{-1} P_{k-1}^k \tilde{T}_{k-1}$ is an interpolatory operator.

Proof. One way to construct T_k and $\tilde{T}_{k-1}$ is to interpret D_k^{k-1} as a $J_{k-1} \times J_k$ matrix, and let $D_k^{k-1} = U\Sigma V^*$ be a singular value decomposition (SVD). Since D_k^{k-1} is surjective, the singular values $\sigma_1, \ldots, \sigma_{J_{k-1}}$ are all positive. Let S be the $J_{k-1} \times J_{k-1}$ diagonal matrix $S_{ii} = \sigma_i$, and let P be the $J_k \times J_k$ permutation matrix such that $S^{-1}\Sigma P = \left[I \,\middle|\, 0 \right] P = \downarrow$. Then

$$D_k^{k-1} \;=\; US(S^{-1}\Sigma P)P^* V^* = US \downarrow (VP)^*.$$

So a choice for the maps is $T_k = VP$ and $\tilde{T}_{k-1} = US$.

For any interpolatory operator Q_{k-1}^k, the prediction operator

$$P_{k-1}^k = T_k Q_{k-1}^k \tilde{T}_{k-1}^{-1} \tag{4.6}$$

is consistent: $D_{k-1}^k T_k Q_{k-1}^k \tilde{T}_{k-1}^{-1} = \tilde{T}_{k-1} \downarrow Q_{k-1}^k \tilde{T}_{k-1}^{-1} = I_{V^{k-1}}$. Conversely, if P_{k-1}^k is consistent, $\downarrow T_k^{-1} P_{k-1}^k \tilde{T}_{k-1} = \tilde{T}_{k-1}^{-1} D_k^{k-1} P_{k-1}^k \tilde{T}_{k-1} = I_{V^{k-1}}$. Thus P_{k-1}^k is a consistent prediction operator if and only if $T_k^{-1} P_{k-1}^k \tilde{T}_{k-1}$ is interpolatory. ∎

Remark 3. Furthermore, if an SVD of D_k^{k-1} is available, then $E_k v = [0 | I_{J_{k-1} \times J_{k-1}}] V^* v$, and $F_k d = E_k^* d$ are valid detail operators.

Given $\tilde{H}_k$, G_k, and $\tilde{G}_k$ such that $\tilde{H}_k D_k^{k-1} + \tilde{G}_k G_k = I_{V^k}$, a practical choice for the diagonalization maps is

$$T_k = \left[\tilde{H}_k \; \tilde{G}_k \right] P^*, \qquad \tilde{T}_{k-1} = I_{V^{k-1}}, \tag{4.7}$$

where P is the permutation matrix in the proof of Theorem 4.1. Then prediction takes the form $P_{k-1}^k v^{k-1} = \tilde{H}_k v^{k-1} + \tilde{G}_k w$, where w may be any element of V^{k-1}.

Moreover, (4.7) yields a strategy for correcting the consistency of a nonconsistent prediction operator. Let $\hat{P}_{k-1}^k : V^{k-1} \to V^k$ be any operator, then

$$P_{k-1}^k v^{k-1} = \tilde{H}_k v^{k-1} + \tilde{G}_k G_k \hat{P}_{k-1}^k v^{k-1} \tag{4.8}$$

is consistent and if $\hat{P}_{k-1}^k$ is already consistent, then $P_{k-1}^k = \hat{P}_{k-1}^k$. Such a prediction operator may be efficiently implemented in lifting scheme form as in Figure 4.3:

$$\textit{Encoding} \begin{cases} v^{k-1} = D_k^{k-1} v^k, \\ d^k = G_k v^k - G_k \hat{P}_{k-1}^k v^{k-1}, \end{cases} \qquad \textit{Decoding} \begin{cases} \tilde{d}^k = d^k + G_k \hat{P}_{k-1}^k v^{k-1}, \\ v^k = \tilde{H}_k v^{k-1} + \tilde{G}_k \tilde{d}^k. \end{cases}$$

The maps T_k and $\tilde{T}_{k-1}$ diagonalize D_k^{k-1} to the operation of pure downsampling. In the cell-average and hat-based constructions, these maps are seen as a relationship between the original signal v^{k-1} and its primitive $\mathring{v}^{k-1}$:

$$v^{k-1} \xrightarrow{\tilde{T}_{k-1}^{-1}} \mathring{v}^{k-1}, \qquad \mathring{v}^k \xrightarrow{T_k} v^k.$$

At least for spline discretizations, there are diagonalization maps such that $\tilde{T}_k = T_k$. However, $\tilde{T}_k$ and T_k need not be equal in general.

4.3. Prediction for convolution-based decimation. The preceding discussion applies to constructions with any linear and surjective D_{k-1}^k. In the rest of our construction we restrict to decimation of the form $D_{k-1}^k v^k = \downarrow(h * v^k)$, where h is an FIR filter.

In both the cell-average and hat-based constructions, the relationship between v^k and $\mathring{v}^k$ is linear shift-invariant, which suggests diagonalization maps of the form

$$T_k \mathring{v}^k = a * \mathring{v}^k, \quad \tilde{T}_{k-1}^{-1} v^{k-1} = b * v^{k-1}.$$

Moreover, from a design point of view, this is a convenient choice of maps since if Q_{k-1}^k is shift-invariant, then so is P_{k-1}^k.

Ignoring boundary issues for the moment, consider the scheme on the infinite grid. Discrete consistency $D_k^{k-1} P_{k-1}^k = I_{V^{k-1}}$ can be written using (1.2) as

$$\tfrac{1}{2}\left[h(z)\mathcal{Z}\{P_{k-1}^k v^{k-1}\}(z) + h(-z)\mathcal{Z}\{P_{k-1}^k v^{k-1}\}(-z)\right] = v^{k-1}(z^2).$$

Consider $P_{k-1}^k v^{k-1} = a * Q_{k-1}^k (b * v^{k-1})$, with $a(z) = h(-z)$. Then

$$\begin{aligned} \tfrac{1}{2}\left[h(z)h(-z)\mathcal{Z}\{Q_{k-1}^k(b * v^{k-1})\}(z) + h(-z)h(z)\mathcal{Z}\{Q_{k-1}^k(b * v^{k-1})\}(-z)\right] &= v^{k-1}(z^2) \\ h(z)h(-z)\tfrac{1}{2}\left[\mathcal{Z}\{Q_{k-1}^k(b * v^{k-1})\}(z) + \mathcal{Z}\{Q_{k-1}^k(b * v^{k-1})\}(-z)\right] &= v^{k-1}(z^2). \end{aligned}$$

Let $\mathring{v}^{k-1} = b * v^{k-1}$, then since Q_{k-1}^k is interpolatory,

$$\tfrac{1}{2}\left[\mathcal{Z}\{Q_{k-1}^k \mathring{v}^{k-1}\}(z) + \mathcal{Z}\{Q_{k-1}^k \mathring{v}^{k-1}\}(-z)\right] = \mathcal{Z}\{\uparrow\downarrow(Q_{k-1}^k \mathring{v}^{k-1})\}(z) = \mathring{v}^{k-1}(z^2).$$

Thus

$$h(z)h(-z)\left[b(z^2)v^{k-1}(z^2)\right] = v^{k-1}(z^2) \quad \Rightarrow \quad b(z^2) = \frac{1}{h(z)h(-z)}.$$

Since $h(z)h(-z)$ is even, $b(z)$ is well defined by this expression. Therefore, for any interpolatory operator Q^k_{k-1},

$$P^k_{k-1}v^{k-1} = a * Q^k_{k-1}(b * v^{k-1}) \tag{4.9}$$

is a consistent prediction operator with

$$a(z) = h(-z), \quad b(z^2) = \frac{1}{h(z)h(-z)}.$$

For finite-length signals, the consistency of the prediction operator (4.9) does not hold near the boundaries. The boundaries can be corrected using (4.8).

Remark 4. If c satisfies $c(z) = c(-z)$, the prediction operator $P^k_{k-1}v^{k-1} = a * Q^k_{k-1}(b * v^{k-1})$ with filters

$$b(z^2) = \frac{1}{c(z)h(z)h(-z)}, \qquad a(z) = c(z)h(-z)$$

is also consistent. In particular, b and a may be rescaled with $c(z) = \kappa$.

Beware that b is typically an unstable filter. If $h(z)$ has a zero at r, then $b(z)$ has a pole at r^2. Depending on the rate of unstable growth and the signal length, a direct implementation of (4.9) may yet be numerically tractable. Otherwise, (4.9) should be considered conceptually and then implemented using other diagonalization maps (for example, (4.7)).

This construction reproduces the cell-average and hat-based discretization strategies in section 3.3. Let $\mathcal{I}_k$ be an interpolatory operator, and define Q^k_{k-1} by $(Q^k_{k-1}v^{k-1})_n = (\mathcal{I}_{k-1}v^{k-1})(x^k_n)$. If h is the cell-average decimation filter $h(z) = \frac{1}{2} + \frac{1}{2}z^{-1}$ and $\kappa = 2^{k+1}$,

$$\begin{aligned} b(z^2) = \frac{1}{\kappa\, h(z)h(-z)} &= \frac{2^{1-k}}{1-z^{-2}} \qquad \Rightarrow \qquad b(z) = \frac{2^{1-k}}{1-z^{-1}}, \\ a(z) = \kappa\, h(-z) &= 2^k(1-z^{-1}). \end{aligned}$$

Convolution with b is cumulative summation, and convolution with a is backward differencing. Define

$$\tilde{v}^{k-1}_n = (b * v^{k-1})_n = 2^{1-k}\sum_{m=1}^{n} v^{k-1}_m,$$

then the prediction operator is

$$\begin{aligned} (P^k_{k-1}v^{k-1})_n = (a * Q^k_{k-1}\tilde{v}^{k-1})_n &= 2^k\left[(Q^k_{k-1}\tilde{v}^{k-1})_n - (Q^k_{k-1}\tilde{v}^{k-1})_{n-1}\right] \\ &= 2^k\left[(\mathcal{I}_{k-1}\tilde{v}^{k-1})(x^k_n) - (\mathcal{I}_{k-1}\tilde{v}^{k-1})(x^k_{n-1})\right]. \end{aligned}$$

Compare this to the cell-average prediction described in section 3.3, which is

$$(P^k_{k-1}v^{k-1})_n = 2^k\left[(\mathcal{I}_{k-1}\mathring{v}^{k-1})(x^k_n) - (\mathcal{I}_{k-1}\mathring{v}^{k-1})(x^k_{n-1})\right], \quad \mathring{v}^{k-1}_n = 2^{1-k}\sum_{m=1}^{n} v^{k-1}_m.$$

Notice that $\tilde{v}^{k-1} = b*v^{k-1}$ has the same role as the primitive samples $\mathring{v}^{k-1}_n = \mathring{f}(x^{k-1}_n)$. Section 4.4 generalizes the notion of primitive through this connection.

For the hat-based prediction as in section 3.3, set $h(z) = \frac{1}{4}z + \frac{1}{2} + \frac{1}{4}z^{-1}$ and $\kappa = -4^{k+1}$:

$$b(z^2) = \frac{1}{\kappa\, h(z)h(-z)} = \frac{4^{1-k}z^{-2}}{(1-z^{-2})^2} \qquad \Rightarrow \qquad b(z) = \frac{4^{1-k}z^{-1}}{(1-z^{-1})^2},$$
$$a(z) = \kappa\, h(-z) = 4^k(z - 2 + z^{-1}).$$

The interpolatory operator Q^k_{k-1} must be sufficiently regular to compensate for applying the highpass filter a. For hat-based prediction, $a * Q^k_{k-1}\mathring{v}^{k-1}$ is the second difference of $Q^k_{k-1}\mathring{v}^{k-1}$, which has Dirac measures if Q^k_{k-1} is not smooth. One way to make a smoother version of Q^k_{k-1} is by defining

$$\tilde{Q}^k_{k-1}\mathring{v}^{k-1} = \operatorname*{arg\,min}_{q:\downarrow q = \mathring{v}^{k-1}} \left\|Q^k_{k-1}\mathring{v}^{k-1} - q\right\|_2^2 + \|\lambda \cdot (d * q)\|_2^2, \tag{4.10}$$

where d is a finite difference filter and λ_n weights the amount of regularization around point n. The minimization is equivalent to solving a sparse linear system.

Remark 5. There is no restriction that a prediction must be formulated in the same way for all scales k. The filters a and b may depend on k.

4.4. Operators $\mathcal{D}_k$ and $\mathcal{R}_k$. Knowing only the discrete operators D^{k-1}_k, P^k_{k-1}, G_k, and $\tilde{G}_k$ is sufficient for implementation. However, to complete Harten's framework, this section finds operators $\mathcal{D}_k$ and $\mathcal{R}_k$ consistent with the discrete operators. In this section, complications at the boundaries are ignored by working on the infinite grid.

Given a discrete signal g, define its delta sequence at resolution level k as

$$g_{\delta_k}(x) \stackrel{\text{def}}{=} \sum_{n\in\mathbb{Z}} g_n\, \delta(x - x^k_n), \quad x^k_n = 2^{-k}n.$$

Suppose that $h(z)$ has at least one root at $z = -1$ and is normalized as $h(1) = 1$. Analogous to the scaling function in wavelet theory, define

$$\phi(x) = 2\sum_n h_n\, \phi(2x - n). \tag{4.11}$$

This determines $\hat{\phi}$ up to a scale factor [17], which is chosen such that $\hat{\phi}(0) = 1$. Define the discretization operator

$$(\mathcal{D}_k f)_n = (\phi_k * f)(x^k_n), \qquad \phi_k(x) = 2^k\phi(2^k x). \tag{4.12}$$

Now consider the reconstruction operator $\mathcal{R}_k$. Let $\mathcal{I}_k$ be any interpolatory operator. Define the corresponding interpolatory operator $(Q^k_{k-1}v^{k-1})_n = (\mathcal{I}_{k-1}v^{k-1})(x^k_n)$. Section 4.3 defines the prediction operator as

$$\begin{aligned}(P^k_{k-1}v^{k-1})_n &= \big(a * Q^k_{k-1}(b * v^{k-1})\big)_n \\ &= \big(a_{\delta_k} * \mathcal{I}_{k-1}(b * v^{k-1})\big)(x^k_n),\end{aligned} \tag{4.13}$$

where $b(z^2) = 1/\big(h(z)h(-z)\big)$ and $a(z) = h(-z)$. Suppose that the reconstruction operator has the form $\mathcal{R}_k v^k = \xi_k * \mathcal{I}_k(b * v^k)$, where ξ_k is a distribution. Then the prediction operator is defined by the framework to be

$$\begin{aligned}(P^k_{k-1}v^{k-1})_n &= (\mathcal{D}_k\mathcal{R}_{k-1}v^{k-1})_n \\ &= \big(\phi_k * \xi_{k-1} * \mathcal{I}_{k-1}(p * v^{k-1})\big)(x^k_n).\end{aligned}$$

In order to agree with the construction of P_{k-1}^k in (4.13), ξ_{k-1} is defined implicitly by $\phi_k * \xi_{k-1} = a_{\delta_k}$. Since h is FIR, ϕ_k has a finite degree of continuity, and hence $\left|\hat{\xi}_{k-1}(\omega)\right| = |\hat{a}_{\delta_k}(\omega)| / |\hat{\phi}_k(\omega)| \le \|a\|_{\ell^1} / |\hat{\phi}_k(\omega)| = O(|\omega|^p)$ for some finite p. Therefore, ξ_{k-1} is a tempered distribution.

Let $w(z) = 1/b(z)$, then since $w = \downarrow(h * a)$ and $\phi_{k-1} = h_{\delta_k} * \phi_k$,

$$\phi_k * \xi_{k-1} = a_{\delta_k} \quad \Rightarrow \quad h_{\delta_k} * \phi_k * \xi_{k-1} = (h * a)_{\delta_k} \quad \Rightarrow \quad \phi_{k-1} * \xi_{k-1} = w_{\delta_{k-1}}.$$

So ξ_k is also given by $\phi_k * \xi_k = w_{\delta_k}$. Define the reconstruction operator as

$$\mathcal{R}_k v^k = \xi_k * \mathcal{I}_k(b * v^k), \qquad \phi_k * \xi_{k-1} = a_{\delta_k}. \tag{4.14}$$

For example, in the cell-average case, $\mathcal{R}_k$ should be $\mathcal{R}_k v^k = \frac{d}{dx}\mathcal{I}_k(b * v^k)$, with $b(z) = 2^{-k}(1 - z^{-1})^{-1}$ and $\xi_k = -\delta'$ (such that $\xi_k * (\cdot) = \frac{d}{dx}(\cdot)$).

This approach to the reconstruction operator provides a general notion of primitive. If the primitive samples are $\mathring{v}^k = b * v^k$, then

$$\begin{aligned} \mathring{f}^k(x_n^k) = \mathring{v}_n^k = (b * v^k)_n = (b_{\delta_k} * \phi_k * f)(x_n^k), \\ (\xi_k * \mathring{f}^k)(x_n^k) = (\xi_k * b_{\delta_k} * \phi_k * f)(x_n^k) = (b_{\delta_k} * w_{\delta_k} * f)(x_n^k) = f(x_n^k), \end{aligned}$$

which suggests defining a "generalized primitive" $\mathring{f}^k$ (see Figure 4.4) by

$$\mathring{f}^k = b_{\delta_k} * \phi_k * f, \qquad f = \xi_k * \mathring{f}^k.$$

In contrast to the primitive in the cell-average and hat-based formulations (section 3.3), the generalized primitive $\mathring{f}^k$ is a different function for each scale k. However, for spline discretizations, section 6.1 will show that there is a single primitive independent of k.

THEOREM 4.2. *The discretization and reconstruction operators defined in* (4.12) *and* (4.14) *satisfy the consistency relationship, and* $(\mathcal{D}_k)$ *is nested. Furthermore, the decimation operator* $D_k^{k-1} = \mathcal{D}_{k-1}\mathcal{R}_k$ *and the prediction operator* $P_{k-1}^k = \mathcal{D}_k\mathcal{R}_{k-1}$ *are*

$$D_k^{k-1} v^k = \downarrow(h * v^k), \qquad P_{k-1}^k v^{k-1} = a * Q_{k-1}^k(b * v^{k-1}),$$

where $(Q_{k-1}^k v^{k-1})_n = (\mathcal{I}_{k-1} v^{k-1})(x_n^k)$.

Proof. For any v^k, $(\mathcal{D}_k\mathcal{R}_k v^k)_n = (\phi_k * \xi_k * \mathcal{I}_k \mathring{v}^k)(x_n^k) = (w_{\delta_k} * \mathcal{I}_k \mathring{v}^k)(x_n^k)$. Because $\mathcal{I}_k$ is an interpolatory operator, $(\mathcal{I}_k \mathring{v}^k)(x_n^k) = \mathring{v}_n^k$. Also noting that w_{δ_k} is a delta sequence, the convolution is equivalently written as the discrete convolution $(w * \mathring{v}^k)_n$. Thus,

$$(\mathcal{D}_k\mathcal{R}_k v^k)_n \;=\; (w * \mathring{v}^k)_n \;=\; v_n^k.$$

So the consistency relationship is satisfied. Because $\phi_{k-1} = h_{\delta_k} * \phi_k$,

$$v_n^{k-1} \;=\; (\phi_{k-1} * f)(x_n^{k-1}) \;=\; (h_{\delta_k} * \phi_k * f)(x_{2n}^k) \;=\; \downarrow(h * v^k)_n.$$

If $\mathcal{D}_k f = v^k = 0$, then $\mathcal{D}_{k-1} f = v^{k-1} = \downarrow(h * v^k) = 0$. Therefore, $(\mathcal{D}_k)$ is nested. Furthermore, consistency and nestedness imply that

$$D_k^{k-1} v^k \;=\; \mathcal{D}_{k-1}\mathcal{R}_k\mathcal{D}_k f \;=\; \mathcal{D}_{k-1} f \;=\; v^{k-1} \;=\; \downarrow(h * v^k).$$

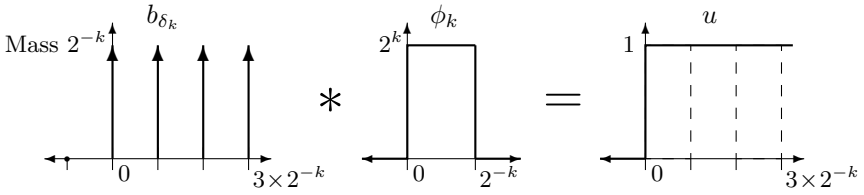

FIG. 4.4. *The cell-average primitive $\mathring{f}$ is related to f by convolution with the unit step $\mathring{f} = b_{\delta_k} * \phi_k * f = u * f$.*

The prediction operator is

$$\begin{aligned}(\mathcal{D}_k \mathcal{R}_{k-1} v^{k-1})_n &= (\phi_k * \xi_{k-1} * \mathcal{I}_{k-1} \mathring{v}^{k-1})(x_n^k) \\ &= \big(a_{\delta_k} * \mathcal{I}_{k-1}(b * v^{k-1})\big)(x_n^k) \\ &= \big(a * Q_{k-1}^k (b * v^{k-1})\big)_n. \qquad \square\end{aligned}$$

Remark 6. If c satisfies $c(z) = c(-z)$, Theorem 4.2 also holds for filters

$$b(z^2) = \frac{1}{c(z)h(z)h(-z)}, \qquad a(z) = c(z)h(-z).$$

Remark 7. Suppose that the interpolation $\mathcal{I}_k$ is linear, shift-invariant, and scale-independent, then

$$(\mathcal{I}_k \mathring{v}^k)(x) = \sum_n 2^k \theta(2^k x - n)\, \mathring{v}_n^k = (\theta_k * \mathring{v}_{\delta_k}^k)(x), \qquad \theta_k(x) = 2^k \theta(2^k x),$$

where the associated function θ satisfies $\theta(0) = 1$ and $\theta(n) = 0$ for all nonzero integers $n \in \mathbb{Z}\backslash\{0\}$. The reconstruction operator becomes $\mathcal{R}_k v^k = \xi_k * \theta_k * b_{\delta_k} * v_{\delta_k}^k$. Let $\tilde{\phi}_k = \xi_k * \theta_k * b_{\delta_k}$ such that $\mathcal{R}_k v^k = \tilde{\phi}_k * v^k$. Since $\phi_k * \xi_k = w_{\delta_k}$ and $w(z) = 1/b(z)$,

$$\phi_k * \tilde{\phi}_k = (\phi_k * \xi_k) * \theta_k * b_{\delta_k} = (w_{\delta_k} * b_{\delta_k}) * \theta_k = \theta_k,$$

so $\tilde{\phi}_k$ satisfies $\phi_k * \tilde{\phi}_k = \theta_k$. Reconstruction reduces to the wavelet reconstruction

$$(\mathcal{R}_k v^k)(x) = \sum_n 2^k \tilde{\phi}(2^k x - n)\, v_n^k,$$

where the dual scaling function $\tilde{\phi}$ satisfies $\phi * \tilde{\phi} = \theta$.

As an example of Theorem 4.2, consider a cell-average ENO with $h(z) = (1+z^{-1})$. Then if $\kappa = 2^k$, $a(z) = 2^{k-1}(1 - z^{-1})$ and $b(z) = 2^{-k}(1 - z^{-1})^{-1}$. The discretization operator is

$$(\mathcal{D}_k f)_n = (\phi_k * f)(x_n^k) = \int_{x_{n-1}^k}^{x_n^k} f(x)\, dx, \qquad \phi(x) = \begin{cases} 1 & \text{if } 0 \le x < 1, \\ 0 & \text{otherwise.} \end{cases}$$

The primitive $\mathring{f}$ is related to f by

$$\mathring{f}(x) = (b_{\delta_k} * \phi_k * f)(x) = (u * f)(x) = \int_0^x f(y)\, dy.$$

Since $\phi_{k+1} * \xi_k = a_{\delta_{k+1}}$,

$$\hat{\xi}_k(\omega) \;=\; \frac{\hat{a}_{\delta_{k+1}}(\omega)}{\hat{\phi}_{k+1}(\omega)} \;=\; \frac{1-\exp(-i\omega 2^{-k-1})}{\frac{1}{i\omega}\left(1-\exp(-i\omega 2^{-k-1})\right)} \;=\; i\omega.$$

That is, convolution with ξ_k is differentiation. Consistent with (3.4) in section 3.3, the reconstruction operator is $(\mathcal{R}_k v^k)(x) = (\xi_k * \mathcal{I}_k \mathring{v}^k)(x) = \frac{d}{dx}(\mathcal{I}_k \mathring{v}^k)(x)$, where $\mathring{v}^k_n = (b * v^k)_n = \mathring{f}(x^k_n)$.

5. Error control. An application of multiresolution decompositions is signal approximation. When the multiresolution transform is linear and orthogonal (or nearly orthogonal), an effective strategy is retaining the M largest transform coefficients and setting the rest to zero. This "M-term approximation" works, since the ℓ^2 error incurred by truncating a coefficient is proportional to its magnitude. However, for nonorthogonal or nonlinear schemes, another strategy is necessary.

Rather than fixing the number of nonzero coefficients, Harten proposed [13] a modified encoding procedure that produces a sparse representation $\hat{m}$ with approximation error less than a specified maximum error.

Define the (hard) thresholding operator

$$\mathrm{tr}(x,\epsilon) = \begin{cases} 0 & \text{if } |x| \le \epsilon, \\ x & \text{if } |x| > \epsilon. \end{cases}$$

Given v^L and a sequence of tolerances (ϵ_k), the modified encoding algorithm is

(5.1)
$$\begin{aligned}
&\textbf{for } k = L, \ldots, 1 \\
&\quad v^{k-1} = D^k_{k-1} v^k \\
&\textbf{end} \\
&\hat{v}^0 = v^0 \\
&\textbf{for } k = 1, \ldots, L \\
&\quad \tilde{d}^k = G_k(v^k - P^k_{k-1}\hat{v}^{k-1}) \\
&\quad \hat{d}^k = \mathrm{tr}(\tilde{d}^k, \epsilon_k) \\
&\quad \hat{v}^k = P^k_{k-1}\hat{v}^{k-1} + \tilde{G}_k \hat{d}^k \\
&\textbf{end} \\
&\hat{m} = (\hat{v}^0, \hat{d}^1, \ldots, \hat{d}^L).
\end{aligned}$$

The thresholds (ϵ_k) control the error of the approximation. Larger values of ϵ_k lead to sparser decompositions, but also larger error. Given a tolerance ϵ, thresholds (ϵ_k) can be selected such that the error is bounded:

$$J_L^{-1/p} \left\| v^L - \hat{v}^L \right\|_p \le \epsilon,$$

where J_k is the length of v^k and $\|\cdot\|_p$ denotes the usual ℓ^p norm.

Such error control has been developed for point-value, cell-average, and hat-based discretizations with zero-padded boundary handling [5, 6]. For point-value discretization, if $\epsilon_k = \epsilon$, then

$$J_L^{-1/p} \left\| v^L - \hat{v}^L \right\|_p \le \epsilon \qquad \text{for } p = 1, 2, \infty. \tag{5.2}$$

For cell-average discretization, if $\epsilon_k = \epsilon\, q^{L-k}$ with $0 < q < 1$, then

$$J_L^{-1/p} \left\| v^L - \hat{v}^L \right\|_p \le \begin{cases} \dfrac{\epsilon}{1-q} & \text{for } p = 1, \infty, \\ \dfrac{\epsilon}{\sqrt{1-q^2}} & \text{for } p = 2. \end{cases} \tag{5.3}$$

For hat-based discretization, if $\epsilon_k = \epsilon\, q^{L-k}$ with $0 < q \le \frac{1}{2}$, then

$$J_L^{-1/p} \left\| v^L - \hat{v}^L \right\|_p \le \begin{cases} \dfrac{\epsilon}{1-2q} & \text{if } 0 < q < \frac{1}{2}, \\ L\epsilon & \text{if } q = \frac{1}{2}, \end{cases} \qquad \text{for } p = 1, 2, \infty. \tag{5.4}$$

See [5, 6] for proofs. Theorem 5.1 provides error control for general discretizations.

THEOREM 5.1. *Let D_k^{k-1} and G_k be linear operators from V^k to V^{k-1}, and $\tilde{H}_k$ and $\tilde{G}_k$ be linear operators from V^{k-1} to V^k satisfying $\tilde{H}_k D_k^{k-1} + \tilde{G}_k G_k = I_{V^k}$, and let P_{k-1}^k be any operator from V^{k-1} to V^k satisfying $D_k^{k-1} P_{k-1}^k = I^{V_{k-1}}$.*

Let $\|\cdot\|$ be a norm, and let α, β be such that

$$\|\tilde{H}_k v\| \le \alpha \|v\| \quad \text{and} \quad \|\tilde{G}_k v\| \le \beta \|v\|_\infty \qquad \text{for all } v \in V^{k-1}, k \le L.$$

If the thresholds (ϵ_k) in the modified encoding algorithm (5.1) satisfy $\epsilon_k = \epsilon\, q^{L-k}$ for some $q \in (0, \alpha^{-1})$, then the reconstruction error is bounded:

$$\left\| v^L - \hat{v}^L \right\| \;<\; \frac{\beta\epsilon}{1-\alpha q}.$$

Proof. First, observe that

$$v^k - \hat{v}^k = (P_{k-1}^k v^{k-1} - P_{k-1}^k \hat{v}^{k-1}) + \tilde{G}_k (d^k - \hat{d}^k).$$

The detail term expands to $d^k - \hat{d}^k = (d^k - \tilde{d}^k) + (\tilde{d}^k - \hat{d}^k) = -G_k(P_{k-1}^k v^k - P_{k-1}^k \hat{v}^{k-1}) + (\tilde{d}^k - \hat{d}^k)$. Therefore,

$$\begin{aligned} v^k - \hat{v}^k &= (I_{V^k} - \tilde{G}_k G_k)(P_{k-1}^k v^{k-1} - P_{k-1}^k \hat{v}^{k-1}) + \tilde{G}_k(\tilde{d}^k - \hat{d}^k) \\ &= \tilde{H}_k D_k^{k-1} (P_{k-1}^k v^{k-1} - P_{k-1}^k \hat{v}^{k-1}) + \tilde{G}_k(\tilde{d}^k - \hat{d}^k) \\ &= \tilde{H}_k (D_k^{k-1} P_{k-1}^k v^{k-1} - D_k^{k-1} P_{k-1}^k \hat{v}^{k-1}) + \tilde{G}_k(\tilde{d}^k - \hat{d}^k) \\ &= \tilde{H}_k (v^{k-1} - \hat{v}^{k-1}) + \tilde{G}_k(\tilde{d}^k - \hat{d}^k). \end{aligned}$$

Now by definitions of α, β, and $\hat{d}^k = \mathrm{tr}(\tilde{d}^k, \epsilon_k)$, it follows that

$$\begin{aligned} \left\| v^k - \hat{v}^k \right\| &\le \left\| \tilde{H}_k (v^{k-1} - \hat{v}^{k-1}) \right\| + \left\| \tilde{G}_k (\tilde{d}^k - \hat{d}^k) \right\| \\ &\le \alpha \left\| v^{k-1} - \hat{v}^{k-1} \right\| + \beta\epsilon_k. \end{aligned}$$

Applying this bound recursively,

$$\left\| v^L - \hat{v}^L \right\| \;\le\; \beta \sum_{k=1}^{L} \alpha^{L-k} \epsilon_k \;=\; \beta\epsilon \frac{1 - (\alpha q)^L}{1 - \alpha q} \;<\; \frac{\beta\epsilon}{1-\alpha q}. \qquad \square$$

COROLLARY 5.2. *Let $\|v\|$ be the scaled ℓ^p norm $J_k^{-1/p} \|v\|_p$. Let $\tilde{h}$ and $\tilde{g}$ be wavelet filters as in section 4.1, and let $\tilde{h}_n^e = \tilde{h}_{2n}$ and $\tilde{h}_n^o = \tilde{h}_{2n+1}$ be the even and odd components of $\tilde{h}$, and similarly $\tilde{g}^e$ and $\tilde{g}^o$ be the even and odd components of $\tilde{g}$.*

Suppose that $\circledast$ is periodic convolution or, for convolution with other boundary handling, suppose that the wavelet filters have the form $h(z) = h_0 + zh^o(z^2)$ and $g(z) = z^{-1}$. Then $\tilde{H}_k v = \tilde{h} \circledast \uparrow v$ and $\tilde{G}_k v = \tilde{g} \circledast \uparrow v$.

(i) *If $\circledast$ is periodic convolution, then Theorem* 5.1 *applies with*

(5.5)
$$\alpha = \left(\frac{\|\tilde{h}^e\|_1^p + \|\tilde{h}^o\|_1^p}{2} \right)^{1/p}, \quad \beta = \left(\frac{\|\tilde{g}^e\|_1^p + \|\tilde{g}^o\|_1^p}{2} \right)^{1/p} \quad \text{if } 1 \le p < \infty,$$
$$\alpha = \|\tilde{h}^e\|_1 \vee \|\tilde{h}^o\|_1, \qquad \beta = \|\tilde{g}^e\|_1 \vee \|\tilde{g}^o\|_1 \qquad \text{if } p = \infty.$$

(ii) *If $\circledast$ is zero-padded convolution and $h(z) = h_0 + zh^o(z^2)$, $g(z) = z^{-1}$, then Theorem* 5.1 *applies with* (5.5).

(iii) *If $\circledast$ is convolution with symmetric or constant boundary extension and $h(z) = h_0 + zh^o(z^2)$, $g(z) = z^{-1}$, then Theorem* 5.1 *applies with* (5.5) *for $p = \infty$.*

Proof. (i) By Young's inequality on the periodic grid,

$$\begin{aligned} J_k^{-1/p} \left\| \tilde{h} \circledast \uparrow v \right\|_p &= J_k^{-1/p} \left[\left\| \tilde{h}^e \circledast v \right\|_p^p + \left\| \tilde{h}^o \circledast v \right\|_p^p \right]^{1/p} \\ &\le J_k^{-1/p} \left[\left(\left\| \tilde{h}^e \right\|_1^p + \left\| \tilde{h}^o \right\|_1^p \right) \|v\|_p^p \right]^{1/p} = \alpha J_{k-1}^{-1/p} \|v\|_p . \end{aligned}$$

(ii) and (iii) Let $v \in V^k$, and let v^{ext} be its extension to the infinite grid, as determined by the boundary-handling method, but with $v_n^{\text{ext}} = 0$ for $|n| > \operatorname{supp} \tilde{h} + \operatorname{supp} v$. Then $(\tilde{h} \circledast \uparrow v)_n = (\tilde{h} * \uparrow \tilde{v})_n$ for $n = 0, \dots J_k - 1$ and $\|v\|_p = \|v^{\text{ext}}\|_p$. By Young's inequality on the infinite grid,

$$\begin{aligned} J_k^{-1/p} \left\| \tilde{h} \circledast \uparrow v \right\|_p &\le J_k^{-1/p} \left\| \tilde{h} * \uparrow v^{\text{ext}} \right\|_p \\ &= J_k^{-1/p} \left[\left\| \tilde{h}^e * v^{\text{ext}} \right\|_p^p + \left\| \tilde{h}^o * v^{\text{ext}} \right\|_p^p \right]^{1/p} \\ &\le J_k^{-1/p} \left[\left(\left\| \tilde{h}^e \right\|_1^p + \left\| \tilde{h}^o \right\|_1^p \right) \left\| v^{\text{ext}} \right\|_p^p \right]^{1/p} = \alpha J_{k-1}^{-1/p} \|v\|_p . \end{aligned}$$

Similarly, β is such that $\left\| \tilde{g} \circledast v \right\| \le \beta \|v\| \le \beta \|v\|_\infty$. ∎

Remark 8. For nonperiodic boundary handling, the requirement $h(z) = h_0 + zh^o(z^2)$ and $g(z) = z^{-1}$ ensures a wavelet transform implementation with a single update lifting step. For wavelets with more than one lifting step, it is generally not true that $\tilde{H}_k v = \tilde{h} \circledast \uparrow v$ and $\tilde{G}_k v = \tilde{g} \circledast \uparrow v$, though these formulas do hold for points sufficient far from the boundaries.

However, presuming these boundary effects are small, the conclusions of Theorem 5.1 with (5.5) hold approximately for any wavelet and boundary handling.

For the point-value, cell-average, and hat-based discretizations, the wavelet filters have the form $h(z) = h_0 + zh^o(z^2)$ and $g(z) = z^{-1}$. For both the cell-average and hat-based discretizations with periodic or zero-padded boundary handling, $\alpha = 2^{1-1/p}$ and $\beta = 1$, and Theorem 5.1 yields

$$J_L^{-1/p} \left\| v^L - \hat{v}^L \right\|_p \le \frac{\epsilon}{1 - 2^{1-1/p} q} = \begin{cases} \dfrac{\epsilon}{1-q} & \text{for } p = 1, \\ \dfrac{\epsilon}{1-\sqrt{2}q} & \text{for } p = 2, \\ \dfrac{\epsilon}{1-2q} & \text{for } p = \infty. \end{cases}$$

For cell-average discretization, this bound agrees with (5.3) for $p = 1$ and is worse for $p = 2, \infty$. For hat-based discretization, it agrees with (5.4) for $p = \infty$ and is better for $p < \infty$.

For point-value discretization, Theorem 5.1 is overly conservative with error bound $\epsilon/(2^{1/p-1} - q)$, which is much worse than (5.2). However, this case is extreme, as all involved filters are one-tap.

6. Example constructions. In this section, two examples of Harten multiresolution schemes are constructed using the approach proposed in the previous sections. The first is a family of spline discretization schemes, where cell-average discretization is order $N = 1$ and hat-based discretization is $N = 2$. The second is a simple example with nonspline decimation filters.

6.1. Spline discretizations. This section develops Harten schemes with spline discretization. Let $h(z)$ be the Nth-order spline decimation filter

$$h(z) = z^{\lfloor N/2 \rfloor} \left(\frac{1 + z^{-1}}{2} \right)^N,$$

and define $D_k^{k-1} v^k = {\downarrow}(h * v^k)$. As in section 4.3, the prediction operator is $P_{k-1}^k v^{k-1} = a * Q_{k-1}^k (b * v^{k-1})$ for any interpolatory operator Q_{k-1}^k, with

$$b(z) = \frac{1}{z^{\lfloor N/2 \rfloor} (1 - z^{-1})^N}, \qquad a(z) = z^{\lfloor N/2 \rfloor} (1 - z^{-1})^N.$$

Choose $\tilde{N}$ such that $M = \frac{1}{2}(N + \tilde{N}) - 1$ is integer, and define $\tilde{h}$, g, and $\tilde{g}$ as in (4.4),

$$\tilde{h}(z) = 2 z^{\lceil \tilde{N}/2 \rceil} \left(\frac{1 + z^{-1}}{2} \right)^{\tilde{N}} \sum_{n=0}^{M} \binom{M+n}{n} (-4)^{-n} (z - 2 + z^{-1})^n,$$
$$g(z) = \tfrac{1}{2} z^{-1} \tilde{h}(-z), \qquad \tilde{g}(z) = 2 z h(-z).$$

The detail encoder operator is $G_k e^k = {\downarrow}(g * e^k)$, and the decoder is $\tilde{G}_k d^k = \tilde{g} * ({\uparrow} d^k)$. At this point, all of the necessary operators for a discrete implementation of the scheme are established.

Now consider the continuous operators $\mathcal{D}_k$ and $\mathcal{R}_k$. The function $\phi(x)$ satisfying dilation equation (4.11) is the B-spline

$$\phi(x) = \frac{1}{(N-1)!} \sum_{n=0}^{N} \binom{N}{n} (-1)^n \left[(x + \left\lfloor \frac{N}{2} \right\rfloor - n)^+ \right]^{N-1}. \tag{6.1}$$

The B-spline ϕ can be shown to satisfy the dilation equation in the Fourier domain. Let $\tau = 0$ if N is even and $\tau = 1$ if N is odd. Its Fourier transform is $\hat{\phi}(\omega) = \mathrm{e}^{-i\omega\tau/2} (\frac{\sin(\omega/2)}{\omega/2})^N$, so that

$$\begin{aligned}
2 \sum_n h_n \tfrac{1}{2} \hat{\phi}(\omega/2) \mathrm{e}^{-in\omega/2} &= 2 \sum_{n=-\lfloor N/2 \rfloor}^{\lceil N/2 \rceil} 2^{-N} \binom{N}{n + \lfloor \frac{N}{2} \rfloor} \tfrac{1}{2} \mathrm{e}^{-i\omega(\tau+2n)/4} \left(\frac{\sin(\omega/4)}{\omega/4} \right)^N \\
&= \mathrm{e}^{-i\omega(\tau - 2\lfloor N/2 \rfloor)/4} \left(\sum_{n=0}^{N} \binom{N}{n} \mathrm{e}^{-i\omega n/2} \right) \left(\frac{\sin(\omega/4)}{\omega/2} \right)^N \\
&= \mathrm{e}^{-i\omega\tau/2} \left(\frac{\sin(\omega/2)}{\omega/2} \right)^N = \hat{\phi}(\omega).
\end{aligned}$$

As in section 4.4, define the discretization operator as $(\mathcal{D}_k f)_n = (\phi_k * f)(x_n^k)$. The primitive $\mathring{f}^k$ is related to f by $\mathring{f}^k = b_{\delta_k} * \phi_k * f$. In the Fourier domain,

$$\hat{b}_{\delta_k}(\omega)\hat{\phi}_k(\omega) \;=\; \frac{\mathrm{e}^{-i\omega\tau/2^{k+1}}\left(\frac{\sin(\omega/2^{k+1})}{\omega/2^{k+1}}\right)^N}{\mathrm{e}^{i\omega(2\lfloor N/2\rfloor - N)/2^{k+1}}(2i\sin(\omega/2^{k+1}))^N} \;=\; 2^{kN}(i\omega)^{-N}. \tag{6.2}$$

Thus the primitive $\mathring{f}^k$ is related to f by an Nth-order integral with scale factor 2^{kN},

$$\mathring{f}^k(x) = 2^{kN}\int_0^x\int_0^{y_1}\cdots\int_0^{y_{N-1}} f(y_N)\,dy_N\cdots dy_2\,dy_1.$$

Let $\mathring{v}_n^k = \mathring{f}^k(x_n^k)$ be samples of $\mathring{f}^k$. In the Fourier domain, ξ_k is

$$\frac{\hat{a}_{\delta_{k+1}}(\omega)}{\hat{\phi}_{k+1}(\omega)} \;=\; \frac{\mathrm{e}^{i\omega(2\lfloor N/2\rfloor - N)/2^{k+2}}(2i\sin(\omega/2^{k+2}))^N}{\mathrm{e}^{-i\omega\tau/2^{k+2}}\left(\frac{\sin(\omega/2^{k+2})}{\omega/2^{k+2}}\right)^N} \;=\; 2^{-kN}(i\omega)^N. \tag{6.3}$$

Convolution with ξ_k is Nth-order differentiation, with a scale factor 2^{-kN}. Given an interpolatory operator $\mathcal{I}_k$, the reconstruction operator is

$$(\mathcal{R}_k v^k)(x) = \big(\xi_k * \mathcal{I}_k(b * v^k)\big)(x) = 2^{-kN}\frac{d^N}{dx^N}(\mathcal{I}_k\mathring{v}^k)(x).$$

If b is scaled by 2^{kN} and a by 2^{-kN}, then the 2^{kN} scale factor in (6.2) and (6.3) cancels, yielding a primitive independent of k:

$$\mathring{f}(x) = \int_0^x\int_0^{y_1}\cdots\int_0^{y_{N-1}} f(y_N)\,dy_N\cdots dy_2\,dy_1,$$
$$(\mathcal{R}_k v^k)(x) = \frac{d^N}{dx^N}(\mathcal{I}_k\mathring{v}^k)(x), \qquad \mathring{v}_n^k = \mathring{f}(x_n^k).$$

Since the primitive $\mathring{f}$ is related to f by Nth-order integration, predicting a polynomial of degree K requires interpolation, with an order of at least $K+N$.

To control regularity, $\mathcal{I}_k\mathring{v}^{k-1}$ should be at least N times weakly differentiable. An ENO interpolant has a weak first derivative, so $\mathcal{I}_k = \mathcal{I}_k^{\mathrm{ENO}}$ works directly for the point-value $N=0$ and the cell-average $N=1$ cases. In the hat-based case $N=2$, the second derivative of an ENO interpolant contains Dirac measures. Aràndiga, Donat, and Harten [6] control the manifestation of Dirac measures in their hat-based scheme using a careful subcell-resolution scheme.

Another solution is to follow P^{ENO} with a smoothing step (4.10). This modification controls the regularity without losing the prediction's edge-adaptive behavior, as demonstrated in Figure 6.1.

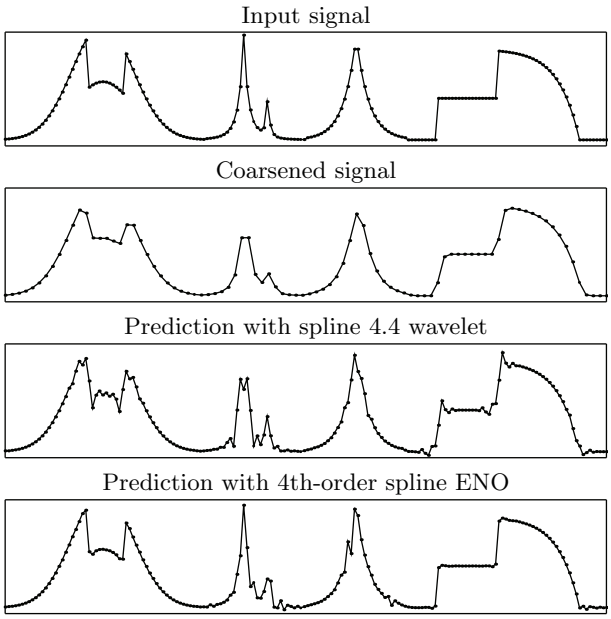

FIG. 6.1. *A piecewise-regular signal is first coarsened with 4th-order spline decimation, and then prediction with the spline 4.4 wavelet and 4th-order spline ENO both attempt to recover the original. ENO interpolation is followed by* (4.10) *to control regularity.*

The hierarchical stencil selection method (described in section 3.1) has the problem that it may select singularity-crossing stencils for discontinuities in $\mathring{f}''$ and higher derivatives [5]. Since a jump becomes a discontinuity in $\mathring{f}^{(N)}$, jump discontinuity in f is not correctly handled for $N \geq 2$. Nonhierarchical selection does not have this problem, so it is the better method for $N \geq 2$.

6.2. A nonspline scheme. Harten's multiresolution framework generalizes wavelets, including those with nonspline lowpass filters. This section constructs a simple Harten multiresolution scheme based on piecewise polyharmonic (PPH) interpolation and the Cohen–Daubechies–Feauveau 9/7 (CDF 9/7) wavelet.

Define the linear/cubic PPH interpolatory operator

$$(P^{\mathrm{PPH}} v)_{2n+1} = \frac{v_{n+1} + v_n}{2} - \frac{1}{4} \frac{(\Delta^2 v_{n+1} \Delta^2 v_n)^+}{\Delta^2 v_{n+1} + \Delta^2 v_n},$$

where $\Delta^2 v_n = v_{n+1} - 2v_n + v_{n-1}$. Amat et al. [3, 4] considered it as the prediction operator in point-value discretization schemes and have shown its nice properties and potential in nonlinear approximation.

Let H, G, $\tilde{H}$, and $\tilde{G}$ be the decomposition and reconstruction operators for the CDF 9/7 wavelet, and let $D_k^{k-1} = H$ be the decimation operator. As in (4.8), a consistent prediction based on P^{PPH} is

$$P_{k-1}^k v^{k-1} = \tilde{H} v^{k-1} + \tilde{G} G P^{\mathrm{PPH}} v^{k-1}. \tag{6.4}$$

The CDF 9/7 PPH scheme is applied to nonlinear approximation in Figure 6.2. An image is sparsely decomposed with 3% nonzero coefficients using the modified encoding algorithm (section 5) and then reconstructed. The same is done with the

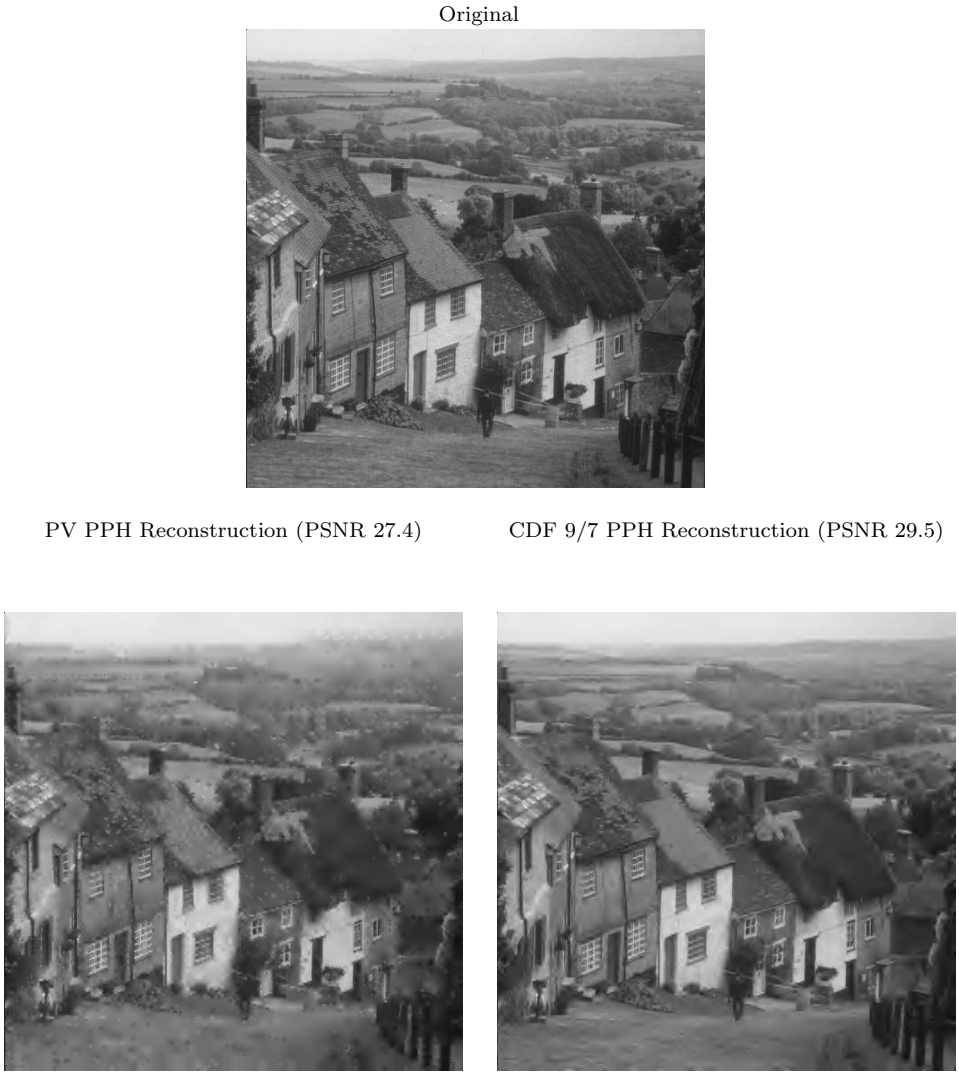

FIG. 6.2. *A nonlinear approximation of Goldhill using* 3% *nonzero coefficients. Left: Reconstruction using point-value discretization and PPH interpolation. Right: Reconstruction using CDF* 9/7 *wavelet discretization and* (6.4).

PPH scheme based on point-value discretization (PV PPH). Reconstruction quality is measured in terms of peak signal-to-noise (PSNR). Since the CDF 9/7 PPH scheme applies a smoothing filter before decimating, it can suppress aliasing artifacts and handle texture better.

7. Conclusion. This paper develops a new approach to the construction of Harten multiresolution schemes, where the decimation operator is based on an arbitrary FIR decimation filter h.

- It is possible to design all of the operators (D_k^{k-1}, P_{k-1}^k, G_k, $\tilde{G}_k$) necessary for implementing a nonredundant decomposition from h without ever defining $\mathcal{D}_k$ or $\mathcal{R}_k$ (section 4.3, section 4.1).

- $\mathcal{D}_k$ and $\mathcal{R}_k$ can be constructed (section 4.4) such that they are consistent with the decimation and prediction operators defined in section 4.3.
- The construction of $\mathcal{R}_k$ "via primitive function" [6, 14], and the notion of primitive generalizes to discretizations with any h (section 4.4).
- Schemes under this construction may be applied to nonlinear approximation using the error-control strategy developed in section 5.
- As a special case, the construction yields a family of Harten schemes with spline discretizations (section 6.1), where the point-value, cell-average, and hat-based discretizations are the first three members.
- It is also possible to construct Harten schemes with nonspline discretizations, as demonstrated by the example in section 6.2.

The presented construction expands the choice of discretization to any discretization with an FIR decimation filter. New Harten multiresolution schemes are possible using smoother and nonspline decimation filters.

Acknowledgments. We are grateful to the reviewers for their comments which helped improve the paper. We also thank Dr. James Curry and Dr. Anne Dougherty, who provided advice and guidance that focused the direction and ensured the quality of this work.

NUMERICAL APPROXIMATION OF RELATIVE EQUILIBRIA FOR EQUIVARIANT PDES*

VERA THÜMMLER†

Abstract. We prove convergence results for the numerical approximation of relative equilibria of parabolic systems in one space dimension. These systems are special examples of equivariant evolution equations. We use finite differences on a large interval with appropriately chosen boundary conditions. Moreover, we consider the approximation of isolated eigenvalues of finite multiplicity of the linear operator which arises from linearization at the equilibrium as well as the approximation of the corresponding invariant subspace. The results in this paper which are a generalization of the results in [V. Thümmler, *Numerical Analysis of the Method of Freezing Traveling Waves*, Ph.D. thesis, Bielefeld University, 2005] are illustrated by numerical computations for the cubic quintic Ginzburg–Landau equation.

Key words. equivariance, Lie groups, partial differential algebraic equations, unbounded domains, finite differences

1. Introduction and basic setting.

Relative equilibria, i.e., solutions of partial differential equations which are equilibria in an appropriately comoving frame, frequently occur in systems with underlying symmetry [8], [16]. A basic class is formed by traveling waves which are stationary in a frame which moves with the velocity of the wave. The purpose of this paper is to analyze numerical methods for the approximation of relative equilibria of parabolic systems in one space dimension which are equivariant w.r.t. the action of a finite-dimensional Lie group [16], [18]. The numerical computation of the relative equilibrium amounts to solving a boundary value problem on the real line and to computing extra parameters (from the Lie algebra). These determine the motion of the comoving frame in the original coordinates. We analyze the combined effect of discretization with finite differences and the truncation of the infinite boundary value problem to a finite but large interval. This is achieved by using exponential dichotomies for the continous system which are inherited by the discretized equations. The truncation of the finite interval can then be handled via approximations of invariant subspaces. We prove the rate of convergence to the exact solution as well as error estimates for invariant subspaces corresponding to isolated eigenvalues of finite multiplicity of the linearization at the relative equilibrium.

A similar task has been accomplished for Galerkin approximations for traveling waves on cylindrical domains in [14]. In [17] a different approach for approximating homoclinic and heteroclinic orbits using Laguerre approximations has been proposed. In this paper we deal with the simplest numerical method—finite differences—and with a rather general set of problems—relative equilibria on the real line. The key difficulty is the simultaneous truncation of the real line to a finite interval together with the approximation of differential operators by finite differences. This is different

from well-known results for boundary value problems on finite intervals as presented, e.g., in [1].

In this section we review the basic setting of the freezing approach which realizes the comoving frame and which has been developed in [5]. We fix the notations and provide an example. Moreover, we state the main spectral conditions on the linearization of a continuous system at the relative equilibrium. In section 2 we introduce the discretization and boundary conditions and state the main nonlinear approximation results Theorems 2.5 (approximation of relative equilibria) and 2.6 (approximation of isolated eigenvalues and invariant subspaces of the linearization). These are based on corresponding estimates for a linearized problem which are proven in section 3. In section 5 we illustrate the main results from section 2 by numerical computations for rotating pulses of the cubic quintic Ginzburg–Landau equation.

1.1. Equivariant evolution equations. We begin with a rather abstract setting for equivariant equations on Banach manifolds that covers the approaches in [5], [8], [23], [25] (see also [6]). Thereby the general structure of the boundary value problem to be solved becomes apparent. We show the necessary computations for a general relative equilibrium and in this way avoid repeating the calculation for different symmetries anew.

It will be applied later in Examples 1.3 and 1.4 with affine Banach spaces.

Let M be a manifold modeled over some Banach space X, and let N be a submanifold modeled over some dense subspace $Y \subset X$. Consider an evolutionary equation

$$u_t = F(u), \quad u(0) = u^0, \tag{1.1}$$

with a vector field $F : N \to TM$, where TM denotes the tangent bundle of M. In our applications (see section 1.2) we will have either Banach spaces $X = M,\ Y = N$ or affine spaces $M = \tilde{v} + X,\ N = \tilde{v} + Y$ such that the tangent spaces always satisfy $T_u M = X,\ T_v N = Y$ for all $u \in M, v \in N$.

Further we assume that the system is equivariant w.r.t. a finite-dimensional (possibly noncompact) Lie group G acting on M via

$$a : G \times M \to M,\ (\gamma, u) \mapsto a(\gamma)u,$$

where

$$a(\gamma_1 \circ \gamma_2)v = a(\gamma_1)[a(\gamma_2)v], \quad a(1)v = v, \quad 1 = \text{unit element in } G,$$

which has a tangent action Ta in TM, i.e., $Ta(\gamma) : T_v M \to T_{a(\gamma)v} M$. By equivariance we mean that the following relation holds:

$$\begin{aligned} a(\gamma)(N) &\subset N \quad \forall \gamma \in G, \\ F(a(\gamma)u) &= Ta(\gamma)F(u) \quad \forall u \in N, \gamma \in G. \end{aligned}$$

We assume that for any $v \in M$ the map $a(\cdot)v :\ G \to M, \quad \gamma \mapsto a(\gamma)v$ is continuous and is continuously differentiable for any $v \in N$ with its derivative denoted by

$$da(\gamma)v : T_\gamma G \to T_{a(\gamma)v} M, \quad \lambda \mapsto [da(\gamma)v]\lambda.$$

Finally, we denote the left translation by $L_\gamma :\ G \to G,\ g \mapsto \gamma \circ g$ and its derivative at g by $dL_\gamma(g) : T_g G \to T_{\gamma \circ g} G$.

In the following we give a constructive definition of relative equilibria which is appropriate from a numerical point of view [5].

DEFINITION 1.1. *A solution $\bar{u}$ of (1.1) is called a relative equilibrium if it has the form $\bar{u}(t) = a(\bar{\gamma}(t))\bar{v}$, where $\bar{\gamma} : [0, \infty) \to G$ is a smooth curve satisfying $\bar{\gamma}(0) = 1$ and $\bar{v} \in N$ does not depend on time.*

In general one calls the whole group orbit $\mathcal{O}(\bar{v}) = \{a(\gamma)\bar{v},\ \gamma \in G\}$ a relative equilibrium if it is invariant under the semiflow [8], [16]. For our purpose it is more convenient to select a special time orbit within this group orbit, since $\mathcal{O}(\bar{v})$ can always be generated by applying the group action a to the selected time orbit.

By using the ansatz $u(t) = a(\gamma(t))v(t)$, (1.1) can be transformed into a system for the unknowns $v(t) \in M,\ \gamma(t) \in G$, and $\mu(t) \in T_1G$ as follows (cf. [5], [22], [25]):

$$v_t = F(v) - [da(1)v]\mu, \qquad v(0) = u^0, \tag{1.2a}$$

$$\gamma_t = dL_\gamma(1)\mu, \qquad \gamma(0) = 1. \tag{1.2b}$$

If a relative equilibrium $\bar{u}(t) = a(\bar{\gamma}(t))\bar{v}$ is given such that $da(1)\bar{v}\mu \in T_{\bar{v}}M$ for all $\mu \in T_1G$ and $da(1)\bar{v} : T_1G \to T_{\bar{v}}M$ has full rank, then it can be shown that there exists $\bar{\mu} \in T_1G$ such that $(\bar{v}, \bar{\mu})$ is a stationary solution of (1.2), i.e.,

$$0 = F(\bar{v}) - [da(1)\bar{v}]\bar{\mu} \tag{1.3}$$

and $\bar{\gamma}_t = dL_\gamma(1)\bar{\mu} = \exp(t\bar{\mu})$. Conversely, if (1.3) holds for $(\bar{v}, \bar{\mu})$, then $a(\bar{\gamma}(t))\bar{v}$ is a relative equilibrium, where $\bar{\gamma}$ solves $\gamma_t = dL_\gamma(1)\bar{\mu} = \exp(t\bar{\mu})$.

Note that one can recover the relative equilibrium $\bar{u}(t) = a(\bar{\gamma}(t))\bar{v}$ exactly from a stationary solution $(\bar{v}, \bar{\mu})$ of (1.2a) by using the reconstruction equation (1.2b): For a solution $(\bar{v}, \bar{\mu})$ of (1.3), (1.2b) is an ODE which in many cases can be solved analytically (e.g., $\bar{\gamma}(t) = t\bar{\mu}$ in the traveling wave case; cf. Example 1.3). In this paper we are interested only in the approximation of $(\bar{v}, \bar{\mu})$ under discretization. However, the stability in time of $(\bar{v}, \bar{\mu})$ as an equilibrium of (1.2a) and the convergence towards the stationary solution is another interesting issue which has been dealt with in [26].

1.2. Parabolic equations. In the rest of the paper we are concerned with the special case of a parabolic PDE

$$u_t = Au_{xx} + f(u, u_x), \quad x \in \mathbb{R}, t > 0, u(x, t) \in \mathbb{R}^m, \tag{1.4}$$

where $A \in \mathbb{R}^{m,m}$ is positive definite and $f \in \mathcal{C}^1(\mathbb{R}^m \times \mathbb{R}^m, \mathbb{R}^m)$ is of the form

$$f(u, v) = f_1(u)v + f_2(u), \quad f_1 \in \mathcal{C}^1(\mathbb{R}^m, \mathbb{R}^{m,m}), \qquad f_2 \in \mathcal{C}^1(\mathbb{R}^m, \mathbb{R}^m), \tag{1.5}$$

and f_1, f_2, f_1', f_2' are globally Lipschitz.

Remark 1.2. The above conditions on f are also satisfied for "conservation laws" with special flux functions (e.g., Burgers equation). They imply that f_1' and f_2' are globally bounded, and with

$$D_1 f(u, w) = f_1'(u)(w, \cdot) + f_2'(u), \quad D_2 f(u, w) = f_1(u),$$

we obtain for $u, w, \delta_u, \delta_w \in \mathbb{R}^m$

$$\begin{aligned} &\|D_1 f(u + \delta_u, w + \delta_w) - D_1 f(u, w)\| \le \text{const}(\|\delta_u\| + \|\delta_w\|), \\ &\|D_2 f(u + \delta_u, w + \delta_w) - D_2 f(u, w)\| \le \text{const}\, \|\delta_u\|. \end{aligned} \tag{1.6}$$

In this case F in (1.1) reads

$$F(u) = Au'' + \bar{f}(u, u'),$$

where $\bar{f}(u,u')(x) = f(u(x),u'(x))$. Let a function $\tilde{v}:\mathbb{R}\to\mathbb{R}^m$ be given with

$$F(\tilde{v}) = A\tilde{v}'' + f(\tilde{v},\tilde{v}') \in \mathcal{L}_2. \tag{1.7}$$

Then we define $M = \tilde{v} + \mathcal{L}_2$ and $N = \tilde{v} + \mathcal{H}^2$, and with the properties of f we obtain that the condition $F : \tilde{v} + \mathcal{H}^2 \to \mathcal{L}_2$ is satisfied.

We choose a basis $\{e^1,\dots,e^p\}$ in the Lie algebra T_1G, where p is the dimension of G, write $\mu = \sum_{i=1}^p \mu_i e^i$, and define $S^i(v) = -\,da(1)ve^i$. Then the stationary equation reads

$$0 = Av'' + S(v)\mu + \bar{f}(v,v'), \quad x\in\mathbb{R},\ v(x)\in\mathbb{R}^m, \mu\in\mathbb{R}^p, \tag{1.8}$$

where we use the short notation $S(v)\mu = \sum_{i=1}^p S^i(v)\mu_i$.

Throughout the paper we need two additional assumptions:

A1. The operators S^i are linear differential operators of order ≤ 1 which can be written as

$$S^i(v)(x) = S^i_0 v(x) + S^i_1 v'(x), \quad S^i_{0,1}\in\mathbb{R}^{m,m} \tag{1.9}$$

and for which $S^i(\bar{v})\in\mathcal{L}_2$ for $i=1,\dots,p$. The last condition is necessary for the existence of a solution $\bar{v}\in\tilde{v}+\mathcal{H}^2$ of (1.8).

A2. There exist $\bar{v}_\pm\in\mathbb{R}^m$ such that

$$\lim_{x\to\pm\infty}\bar{v}(x) = \bar{v}_\pm. \tag{1.10}$$

In order to compensate for the additional p degrees of freedom which are obtained by introducing the parameter μ, we add a phase condition of the form

$$0 = \langle S^i(\hat{v}), v-\hat{v}\rangle_{\mathcal{L}_2}, \quad i=1,\dots,p, \tag{1.11}$$

to (1.8). Here $\hat{v}\neq 0$ is a given template function which satisfies $\hat{v}-\bar{v}\in\mathcal{H}^1$. The use of this phase condition is also called the method of slices [22]. In numerical calculations one can use the initial approximation of $\bar{v}$ as a template function.

In the following we present two characteristic examples, namely, traveling waves and rotating and traveling waves.

Example 1.3 (traveling waves). Consider (1.4), and let $\tilde{v}$ be a function with $\|\tilde{v}(x)-v_\pm\|\le \text{const}\,\mathrm{e}^{\pm\varrho x}$, where $f(v_\pm,0)=0$. Consider the shift action of $G=\mathbb{R}$, i.e., $[a(\gamma)u](x) = u(x-\gamma)$ on $M=\tilde{v}+\mathcal{L}_2 \supset N = \tilde{v}+\mathcal{H}^2$. Then we have $[da(1)v]e^1 = -v_x$, i.e., $S^1_1 = I$, $S^1_0 = 0$ and (1.2a), (1.11) read

$$\begin{aligned} v_t &= Av_{xx} + \lambda v_x + f(v,v_x),\\ 0 &= \langle \hat{v}', v-\hat{v}\rangle_{\mathcal{L}_2}. \end{aligned}$$

The relative equilibria are traveling waves $\bar{u}(x,t) = \bar{v}(x-\bar{\lambda}t)$ with stationary points $\lim_{x\to\pm\infty}\bar{v}(x) = v_\pm$.

Example 1.4 (rotating and traveling waves). Consider (1.4) for $\tilde{v}=0$, i.e., for $M=\mathcal{L}_2$ and $N=\mathcal{H}^2$. Let the Lie group be $G = S^1\times\mathbb{R}$ with $(\rho,\tau)=\gamma\in G$ and $(\rho,\tau)\circ(\tilde{\rho},\tilde{\tau}) = (\rho+\tilde{\rho},\tau+\tilde{\tau})$. Let the action $a: G\times\mathcal{L}_2\to\mathcal{L}_2$ be given for $u:\mathbb{R}\to\mathbb{R}^2$ by

$$[a(\gamma)u](x) = R_{-\rho}u(x-\tau), \quad R_\rho = \begin{pmatrix}\cos\rho & -\sin\rho\\ \sin\rho & \cos\rho\end{pmatrix}.$$

Then we have $[da(1)v]e^1 = -v_x$, $[da(1)v]e^2 = -R_{\frac{\pi}{2}}v$, i.e., $S_1^1 = I$, $S_0^2 = R_{\frac{\pi}{2}}$, $S_0^1 = S_1^2 = 0$ and (1.2a), (1.11) read with $\mu_\tau = \tau_t$, $\mu_\rho = \rho_t$,

$$\begin{aligned} v_t &= Av_{xx} + \mu_\tau v_x + \mu_\rho R_{\frac{\pi}{2}}v + f(v, v_x), \\ 0 &= \langle \hat{v}', v - \hat{v}\rangle_{\mathcal{L}_2}, \quad 0 = \langle R_{\frac{\pi}{2}}v, v - \hat{v}\rangle_{\mathcal{L}_2}. \end{aligned} \tag{1.12}$$

The relative equilibria are rotating and traveling waves

$$\bar{u}(x,t) = R_{-\bar{\mu}_\rho t}\bar{v}(x - \bar{\mu}_\tau t). \tag{1.13}$$

In the previous example our theory will apply only to pulses $\bar{v}$ ($\bar{v}_- = \bar{v}_+$) with arbitrary $\bar{\mu}_\rho$ and to fronts ($\bar{v}_- \neq \bar{v}_+$) with $\bar{\mu}_\rho = 0$. However, in the case of a front with $\bar{\mu}_\rho \neq 0$ we cannot expect (1.12) to be a well-posed problem in $\mathcal{L}_2$. On a formal level the condition $S^2(\bar{v}) = R_{\frac{\pi}{2}}\bar{v} \in \mathcal{L}_2$ of Assumption A1 is violated. On an intuitive level we expect that any $\mathcal{L}_2$ perturbation of the right-hand side of (1.12) will lead to an angular shift (in direction $R_{\frac{\pi}{2}}$) that does not decay at infinity and hence is not in $\mathcal{L}_2$.

1.3. Spectral properties of the continuous system. In order to deal with the truncation to a finite interval, we need some information of the behavior at $x \to \pm\infty$. More specifically we need to ensure the existence of exponential dichotomies for the linear operators obtained by linearizing the continuous equation (1.8) about the relative equilibrium $(\bar{v}, \bar{\mu})$. These dichotomies are then inherited by the discretized equations and allow us to deal with the influence of the boundary conditions.

The linearization of (1.8) w.r.t. v at $(\bar{v}, \bar{\mu})$ is given by

$$\Lambda v = Av'' + Bv' + Cv, \tag{1.14}$$

where

$$B(x) = D_2 f(\bar{v}(x), \bar{v}'(x)) + \sum_{i=1}^{p} \bar{\mu}_i S_1^i, \quad C(x) = D_1 f(\bar{v}(x), \bar{v}'(x)) + \sum_{i=1}^{p} \bar{\mu}_i S_0^i.$$

Assumption (1.10) implies with the invertibility of A that $\lim_{x\to\pm\infty} \bar{v}'(x) = 0$. Thus Λ converges for $x \to \pm\infty$ to constant coefficient operators

$$\Lambda_\pm v = Av'' + B_\pm v' + C_\pm v, \qquad B_\pm = \lim_{x\pm\infty} B(x), \qquad C_\pm = \lim_{x\pm\infty} C(x). \tag{1.15}$$

The main spectral assumption on Λ is the following.

Hypothesis 1.5.

1. *Eigenvalue condition*: The functions $S^i(\bar{v}) \in \mathcal{L}_2$, $i = 1, \dots, p$, are linearly independent and span the null space of $\Lambda : \mathcal{H}^2 \to \mathcal{L}_2$, i.e.,

$$\mathcal{N}(\Lambda) = \operatorname{span}\{S^1(\bar{v}), \dots, S^p(\bar{v})\}.$$

   Moreover, the algebraic and the geometric multiplicity of zero both equal p.
2. *Spectral condition*: The eigenvalue 0 lies in the connected component of $\mathbb{C} \setminus \{\Sigma_+ \cup \Sigma_-\}$ that contains a right half plane, where

$$\Sigma_\pm = \{s \in \mathbb{C} : \det(-\kappa^2 A + i\kappa B_\pm + C_\pm - sI) = 0 \text{ for some } \kappa \in \mathbb{R}\}.$$

Note that spectral properties of Λ determine asymptotic stability with an asymptotic phase of relative equilibria [11]. However, the spectral conditions given above are weaker than the standard stability conditions and allow us to discuss the approximation of unstable equilibria as well.

Example 1.6. For Example 1.4 the operator Λ reads

$$\Lambda v = Av'' + (\mu_\tau I + D_2 f(\bar v, \bar v'))v' + (\mu_\rho R_{\frac{\pi}{2}} + D_1 f(\bar v, \bar v'))v,$$

and its null space is spanned by $\bar v'$ and $R_{\frac{\pi}{2}}\bar v$.

The condition that zero is semisimple cannot be concluded from properties of the Lie group G. For the cubic Ginzburg–Landau equation which has the symmetry properties of Example 1.4 and is a special case of the system considered in section 5, a principal vector exists for a special parameter combination [2]; i.e., the algebraic multiplicity is 3 and the geometric multiplicity is 2.

2. Discretization. In this section we first introduce the discretization and the relevant notions for the double limit process of increasing the interval and decreasing the step size. Then we state the main nonlinear approximation theorems for the approximation of relative equilibria and the approximation of isolated eigenvalues and corresponding invariant subspaces.

2.1. Problem formulation. In order to compute numerical approximations of $(\bar v, \bar\mu)$ we define a discrete interval

$$J = [n_-, n_+] = \{n \in \mathbb{Z} :\ n_- \le n \le n_+,\ \text{where } n_\pm \in \mathbb{Z} \cup \{\pm\infty\}\ \}$$

and a corresponding equidistant grid with grid size $h > 0$

$$J_h = \{x_n :\ x_n = nh,\ n \in J\}.$$

We write $J_h \to \mathbb{R}$ if $h \to 0$ and simultaneously $h \cdot \min\{-n_-, n_+\} \to \infty$, i.e., $\pm n_\pm$ grows faster than h decreases, so that $[hn_-, hn_+] \to \mathbb{R}$.

We denote the Banach space of sequences in $\mathbb{R}^m$ which are indexed by J provided with the supremum norm $\|z\|_\infty = \sup_{n\in J}\|z_n\|$ by $\ell^J_\infty(\mathbb{R}^m)$ and write $\ell_\infty(\mathbb{R}^m)$ for $\ell^{\mathbb{Z}}_\infty(\mathbb{R}^m)$. If no confusion is possible, we drop the argument $\mathbb{R}^m$ and write just ℓ^J_∞ and ℓ_∞.

Let the standard finite difference operators on the extended grid

$$\hat J_h = \Big\{x_n :\ x_n = nh,\ n \in \hat J = [n_- - 1, n_+ + 1]\Big\}$$

be given by

$$\begin{aligned}
&\delta_0 : \ell^{\hat J}_\infty \to \ell^J_\infty, && (\delta_0 v)_n = \frac{1}{2h}(v_{n+1} - v_{n-1}),\\
&\delta_+ : \ell^{[n_-, n_+ + 1]}_\infty \to \ell^J_\infty, && (\delta_+ v)_n = \frac{1}{h}(v_{n+1} - v_n),\\
&\delta_- : \ell^{[n_- - 1, n_+]}_\infty \to \ell^J_\infty, && (\delta_- v)_n = \frac{1}{h}(v_n - v_{n-1}).
\end{aligned}$$

For sequences $u, v \in \ell^J_\infty$, $J = [n_-, n_+]$ we define the inner product and discrete Sobolev norms by

$$\begin{aligned}
&\langle u, v\rangle_{J_h} = \sum_{n=n_-}^{n_+} h u_n^T v_n, && \|u\|_{\mathcal{L}_{2,h}} = \sqrt{\langle u, u\rangle_{J_h}},\\
&\|u\|_{\mathcal{H}^1_h} = \|u\|_{\mathcal{L}_{2,h}} + \|\delta_+ u\|_{\mathcal{L}_{2,h}}, && \|u\|_{\mathcal{H}^2_h} = \|u\|_{\mathcal{H}^1_h} + \|\delta_+\delta_- u\|_{\mathcal{L}_{2,h}}.
\end{aligned}$$

One has to keep in mind that the summation is done on different sets for the different difference operators. If necessary, we embed each $u \in \ell_\infty^J$ in ℓ_∞ by setting $u_n = 0$ for $n \in \mathbb{Z} \setminus J$ without further notice. For matrices $U = [U^1, \dots, U^p]$ and $V = [V^1, \dots, V^p] \in (\ell_\infty^J(\mathbb{R}^m))^p$ we use the notation $\langle U, V \rangle_{J_h} = [\langle U^i, V^j \rangle_{J_h}]_{i=1,\dots,p}^{j=1,\dots,p} \in \mathbb{R}^{p,p}$. This notation is also adopted for the $\mathcal{L}_2$ inner product $\langle \cdot, \cdot \rangle_{\mathcal{L}_2}$ in an analogous fashion.

We discretize (1.8) and (1.11) and add linear boundary conditions

$$\mathcal{B}v = P_- v_{n_-} + Q_-(\delta_0 v)_{n_-} + P_+ v_{n_+} + Q_+(\delta_0 v)_{n_+}, \quad P_\pm, Q_\pm \in \mathbb{R}^{2m,m}. \tag{2.1}$$

This leads to the discrete boundary value problem

$$A(\delta_+\delta_- v)_n + \hat{S}_n(v)\mu + f(v_n, (\delta_0 v)_n) = 0, \quad n \in J, \tag{2.2a}$$

$$\mathcal{B}v = \eta, \tag{2.2b}$$

$$\langle \hat{S}^i(\hat{v}_{|_{J_h}}), v - \hat{v}_{|_{J_h}} \rangle_{J_h} = 0, \quad i = 1, \dots, p, \tag{2.2c}$$

where $\hat{S}_n^i(v) = S_0^i v_n + S_1^i(\delta_0 v)_n \in \mathbb{R}^m$ and $\hat{S}_n(v)\mu = \sum_{i=1}^p \mu_i \hat{S}_n^i(v)$. For the approximation theorem to hold, we need boundary conditions which are consistent with the behavior of the exact solution at $\pm\infty$; i.e., we will require $\eta = P_-\bar{v}_- + P_+\bar{v}_+$ in Hypothesis 2.4.

Linearizing the left-hand side of (2.2a) at a solution $(\tilde{v}, \tilde{\mu}) \in \ell_\infty^{\hat{J}} \times \mathbb{R}^p$ of (2.2) leads to the following discrete approximation of Λ:

$$\left(\tilde{\Lambda} v\right)_n = A(\delta_+\delta_- v)_n + \tilde{B}_n(\delta_0 v)_n + \tilde{C}_n v_n, \quad n \in J, \tag{2.3}$$

where

$$\tilde{B}_n = D_2 f(\tilde{v}_n, (\delta_0 \tilde{v})_n) + \sum_{i=1}^p \tilde{\mu}_i S_1^i, \quad \tilde{C}_n = D_1 f(\tilde{v}_n, (\delta_0 \tilde{v})_n) + \sum_{i=1}^p \tilde{\mu}_i S_0^i.$$

It is well known that a multiple eigenvalue will split into several eigenvalues under perturbations [12]. Therefore we approximate the whole invariant subspace which corresponds to zero instead of dealing with each eigenfunction separately. The spatial discretization of the invariant subspace equation together with boundary conditions and a normalizing condition leads for the unknowns (V, Σ) to the system

$$\left(\tilde{\Lambda} V\right)_n - V_n \Sigma = 0, \quad n \in J, \tag{2.4a}$$

$$\mathcal{B}V = 0, \tag{2.4b}$$

$$\left\langle \hat{X}_{|_{J_h}}, V \right\rangle_{J_h} = I. \tag{2.4c}$$

Here $\hat{X} = [\hat{X}^1, \dots, \hat{X}^p] : \mathbb{R} \to \mathbb{R}^{m,p}$ is a given normalizing function for which $\langle \hat{X}, S(\bar{v}) \rangle_{\mathcal{L}_2} = I$. The columns of $V \in (\ell_\infty^{\hat{J}})^p$ span the invariant subspace which corresponds to the eigenvalues of $\Sigma \in \mathbb{R}^{p,p}$. Thus for V to be a good approximation of the null space of Λ, the norm of Σ has to be small.

2.2. Main results. Before we can state the main approximation results, we have to collect the necessary hypotheses on the boundary conditions and the phase condition. The template function $\hat{v}$ and the normalizing function $\hat{X}$ are assumed to be in the following class of functions.

DEFINITION 2.1. *We define a function* $g : I \to \mathbb{R}^{m,p},\ I \subset \mathbb{R}$, *to be in* $\mathcal{E}_\varrho(I, \mathbb{R}^{m,p})$ *if there exists* $K > 0$ *such that* $\forall x \in I$*:*

$$\|g(x)\| \le K\mathrm{e}^{-\varrho|x|} \quad \textit{and} \quad \|g'(x)\| \le K\mathrm{e}^{-\varrho|x|}.$$

Similar to [29] we have the following lemma.

LEMMA 2.2. *Let* $g \in \mathcal{E}_\varrho(\mathbb{R}^+, \mathbb{R}^{m,p})$ *and* $\tilde{g} \in (\ell_\infty)^p$ *be given with*

$$\|g(x_n) - \tilde{g}_n\| \le \mathrm{const}\, h\mathrm{e}^{-\varrho x_n} \quad \forall n \in \mathbb{N}.$$

Then the following estimate holds:

$$\left\| \int_0^\infty g(x)\, dx - h \sum_{n=0}^{n_+-1} \tilde{g}_n \right\| \le \mathrm{const}(h + \mathrm{e}^{-\varrho x_{n_+}}). \tag{2.5}$$

A well-known determinant condition [3], which ensures the existence of the resolvent on finite intervals in the continuous case, uses the following determinant.

DEFINITION 2.3. *Define*

$$\mathcal{D} = \det\left(\begin{pmatrix} P_- & Q_- \end{pmatrix} \begin{pmatrix} Y_-^s \\ Y_-^s \Sigma_-^s \end{pmatrix} \quad \begin{pmatrix} P_+ & Q_+ \end{pmatrix} \begin{pmatrix} Y_+^u \\ Y_+^u \Sigma_+^u \end{pmatrix} \right), \tag{2.6}$$

where $(\Sigma_-^s, Y_-^s),\ (\Sigma_+^u, Y_+^u) \in \mathbb{R}^{m,m} \times \mathbb{R}^{m,m}$ *solve the quadratic eigenvalue problems*

$$AY\Sigma^2 + B_\pm Y\Sigma + C_\pm Y = 0 \tag{2.7}$$

with $\operatorname{Re}\sigma(\Sigma_-^s) < 0$ *and* $\operatorname{Re}\sigma(\Sigma_+^u) > 0$.

Then we can formulate the determinant condition and a consistency assumption for the boundary conditions as well as a regularity assumption for the phase condition.

Hypothesis 2.4.

1. *Boundary conditions*: The boundary condition (2.2b) is satisfied at the stationary points $\bar{v}_\pm$, i.e.,

   $$\eta = P_-\bar{v}_- + P_+\bar{v}_+,$$

   and the determinant $\mathcal{D}$ defined in (2.6) is nonzero.
2. *Phase condition*: The phase condition is satisfied by $\bar{v}$, i.e.,

   $$\langle S(\hat{v}), \bar{v} - \hat{v} \rangle_{\mathcal{L}_2} = 0, \tag{2.8}$$

   $\bar{v} - \hat{v} \in \mathcal{H}^1$, $S(\hat{v}) \in \mathcal{E}_\varrho(\mathbb{R}, \mathbb{R}^{m,p})$, and the $p \times p$ matrix

   $$\langle S(\hat{v}), S(\bar{v}) \rangle_{\mathcal{L}_2} = \int_{\mathbb{R}} [S(\hat{v})](x)^T [S(\bar{v})](x)\, dx \tag{2.9}$$

   is nonsingular.

The determinant condition on the boundary conditions may seem hard to check but is satisfied for Dirichlet, Neumann, and periodic boundary conditions (see the discussion in [3]). Condition (2.8) is a technical assumption that prevents the approximate solution from converging to a shifted version of $\bar{v}$, which can be dropped. Then one has to deal with an additional phase shift, which can be estimated in terms of $\bar{v}$ and $\hat{v}$, but we do not pursue this here.

Now we can formulate the main approximation results of the paper.

THEOREM 2.5 (approximation of the relative equilibrium). *Assume Hypotheses* 1.5 *and* 2.4. *Then there exist* $\varrho > 0$, $T > 0$, *and* $h_0 > 0$ *such that for* $h < h_0$ *and* $\pm h n_\pm > T$ *the boundary value problem* (2.2) *has a unique solution* $(\tilde{v}, \tilde{\mu})$ *in a neighborhood* $B_\varrho(\bar{v}, \bar{\mu}) = \{(v, \mu) \in \ell^{\hat{J}}_\infty \times \mathbb{R}^p : \|\bar{v}_{|J_h} - v\|_{\mathcal{H}^2_h} + \|\bar{\mu} - \mu\| < \varrho\}$. *This solution obeys the following estimate for some* $\alpha > 0$*:*

$$\|\bar{v}_{|J_h} - \tilde{v}\|_{\mathcal{H}^2_h} + \|\bar{\mu} - \tilde{\mu}\| \le \mathrm{const}(h^2 + \mathrm{e}^{-\alpha h \min\{-n_-, n_+\}}). \tag{2.10}$$

The second result is an approximation theorem for the zero eigenvalue of Λ and the corresponding invariant subspace.

THEOREM 2.6 (approximation of the zero eigenvalue). *Assume Hypothesis* 1.5 *and* $\hat{X} \in \mathcal{E}_\beta(\mathbb{R}, \mathbb{R}^{m,p})$ *for some* $\beta > 0$. *Then there exist* $\varrho > 0$, $T > 0$, *and* $h_0 > 0$ *such that for* $h < h_0$ *and* $\pm h n_\pm > T$ *the eigenvalue problem* (2.4) *has a unique solution* (X, Σ) *in a neighborhood* $B_\varrho(S(\bar{v})_{|J_h}, 0) := \{(X, \Sigma) \in ((\ell^{\hat{J}}_\infty)^p \times \mathbb{R}^{p,p} : \|S(\bar{v})_{|J_h} - X\|_{\mathcal{H}^2_h} + \|\Sigma\| < \varrho\}$. *This solution obeys the following estimate for some* $\alpha > 0$*:*

$$\|S(\bar{v})_{|J_h} - X\|_{\mathcal{H}^2_h} + \|\Sigma\| \le \mathrm{const}(h^2 + \mathrm{e}^{-\alpha \min\{-n_-, n_+\}}). \tag{2.11}$$

Remark 2.7.

- The above result can be easily generalized to invariant subspaces which are related to other isolated eigenvalues of finite multiplicity.
- The stated results hold for $\|\cdot\|_\infty$ as well, and estimates similar to (2.10) and (2.11) can be shown [25].
- Estimate (2.11) implies with standard perturbation results for eigenvalues [12] the convergence of the eigenvalues as $J_h \to \mathbb{R}$.

3. The linear equation. Before we can state the main linear theorem in this section, we have to collect some results from the theory of exponential dichotomies [19], [20]. First we transfer exponential dichotomies for the continous system to the discretized system. Particular attention is paid to the dichotomy constants, which should be uniform for both large intervals and small step sizes. This is relevant for constructing solutions of the linearized problem in section 3.2 and deriving estimates for them.

3.1. Exponential dichotomies and auxiliary results. Consider the linear differential operator

$$Lz = z' - M(\cdot)z, \quad x \in J \subset \mathbb{R},\ M(\cdot) : J \to \mathbb{R}^{k,k} \tag{3.1}$$

with solution operator $\mathcal{S}(x, \xi)$.

DEFINITION 3.1 (exponential dichotomy, continuous case). *The operator* L *defined in* (3.1) *has an exponential dichotomy in the interval* $J = [x_-, x_+]$, $x_\pm \in \mathbb{R} \cup \{\pm\infty\}$, *with data* (K, α, π) *if there exist a bound* $K > 0$, *a rate* $\alpha > 0$, *and a function* $\pi : J \ni x \mapsto \pi(x)$, $\pi(x)$ *a projector, such that the following holds:*

$$\mathcal{S}(x, \xi)\pi(\xi) = \pi(x)S(x, \xi), \tag{3.2}$$

and the Green's function

$$\mathcal{G}(x, \xi) = \begin{cases} \mathcal{S}(x, \xi)\pi(\xi), & x \ge \xi, \\ -\mathcal{S}(x, \xi)(I - \pi(\xi)), & x < \xi, \end{cases}$$

satisfies the exponential estimate

$$\|\mathcal{G}(x,\xi)\| \le K\mathrm{e}^{-\alpha|x-\xi|}, \quad x,\xi \in J. \tag{3.3}$$

In the following remarks we recall some well known facts about exponential dichotomies (see [19], [7]).

Remark 3.2. If L has an exponential dichotomy on $\mathbb{R}^- = (-\infty, 0]$ and $\mathbb{R}^+ = [0,\infty)$ with data (K_-, α_-, π_-) and (K_+, α_+, π_+), respectively, then the kernel of L is given by

$$\mathcal{N}(L) = \{\mathcal{S}(\cdot,0)z_0 : \ z_0 \in \mathcal{N}(\pi_-(0)) \cap \mathcal{R}(\pi_+(0))\}.$$

Remark 3.3. We transform Λ via $z = (v, v')$ into a first order operator

$$Lz = z' - M(\cdot)z, \qquad M(x) = \begin{pmatrix} 0 & I \\ -A^{-1}C(x) & -A^{-1}B(x) \end{pmatrix}. \tag{3.4}$$

Hypothesis 1.5 ensures together with the positive definiteness of A that L possesses exponential dichotomies on $\mathbb{R}^\pm$ with data $(K^\pm, \alpha^\pm, \pi^\pm)$. Moreover, the null space of L is given by

$$\mathcal{N}(L) = \operatorname{span}\{\phi^1, \dots, \phi^p\}, \quad \phi^i = (S^i(\bar v), S^i(\bar v'))^T. \tag{3.5}$$

Note that the columns of $X^s_- = \left(\begin{smallmatrix} Y^s_- \\ Y^s_-\Sigma^s_- \end{smallmatrix}\right)$ and $X^u_+ = \left(\begin{smallmatrix} Y^u_+ \\ Y^u_+\Sigma^u_+ \end{smallmatrix}\right)$, where (Y^s_-, Σ^s_-) and $(Y^u_+\Sigma^u_+)$ are the solutions of the characteristic equation (2.7) in Definition 2.3, span the stable invariant subspace of $M_- = \lim_{x\to-\infty} M(x)$ and the unstable invariant subspace of $M_+ = \lim_{x\to+\infty} M(x)$, respectively.

Remark 3.4. The fact that L defined in (3.4) has exponential dichotomies on $\mathbb{R}^-, \mathbb{R}^+$ implies that $(\bar v', \bar v'')$ is actually exponentially decaying for $x \to \pm\infty$, i.e.,

$$\|\bar v(x) - v_\pm\| \le \text{const}\,\mathrm{e}^{\mp\varrho x} \quad \text{as well as} \quad \|\bar v^{(k)}(x)\| \le \text{const}\,\mathrm{e}^{-\varrho|x|}, \ k = 1, 2,$$

for some $\varrho > 0$. Thus we have $\bar v' \in \mathcal{E}_\varrho(\mathbb{R}, \mathbb{R}^m)$ and $\lim_{x\to\infty}[S^i(\bar v')](x) = 0$ for $i = 1, \dots, p$. Moreover, from the eigenvalue condition we obtain $S^i(\bar v) \in \mathcal{H}^2$ and thus $\lim_{x\to\infty}[S^i(\bar v)](x) = 0$, $i = 1, \dots, p$.

Exponential dichotomies can be defined for a linear difference operator

$$(\hat L z)_n = z_{n+1} - \hat M_n z_n, \quad n \in J, \ \hat M_n \in \mathbb{R}^{k,k}, \tag{3.6}$$

in the following way. If the matrices $\hat M_n$ are invertible for all $n \in J$, then the map $\hat{\mathcal{S}} : J \times J \to \mathbb{R}^{k,k}$ given by

$$\hat{\mathcal{S}}(n,m) = \begin{cases} \hat M_{n-1} \cdot \ldots \cdot \hat M_m & \text{for } n > m, \\ I & \text{for } n = m, \\ \hat M_n^{-1} \cdot \ldots \cdot \hat M_{m-1}^{-1} & \text{for } n < m \end{cases}$$

is a solution operator for (3.6), which has the cocycle property

$$\hat{\mathcal{S}}(n,l)\hat{\mathcal{S}}(l,m) = \hat{\mathcal{S}}(n,m) \quad \forall\, l, m, n \in J.$$

Definition 3.5 (exponential dichotomy, discrete case). *The linear difference operator $\hat L$ defined in* (3.6) *has an exponential dichotomy with data (K, α, P) on $J \subset \mathbb{Z}$*

if $\hat{M}_n$ is invertible for all $n \in J$ and there exist a bound $K > 0$, a rate $\alpha > 0$, and projectors P_n such that the following holds:

$$\hat{\mathcal{S}}(n,m)P_m = P_n\hat{\mathcal{S}}(n,m), \tag{3.7}$$

and the Green's function

$$\hat{\mathcal{G}}(n,m) = \begin{cases} \hat{\mathcal{S}}(n,m)P_m & \text{for } n \geq m, \\ -\hat{\mathcal{S}}(n,m)(I-P_m) & \text{for } n < m \end{cases} \tag{3.8}$$

satisfies the exponential estimate

$$\|\hat{\mathcal{G}}(n,m)\| \leq K\mathrm{e}^{-\alpha|n-m|}, \quad n,m \in J. \tag{3.9}$$

A connection between an exponential dichotomy for an ODE and the corresponding difference equation is given via the time h-map of the flow [29].

LEMMA 3.6. *Let the linear differential operator L given by*

$$Lz = z' - Mz, \quad x \in J = \mathbb{R}^{\pm}, \quad M : J \to \mathbb{R}^{k,k}$$

have an exponential dichotomy with data (K,α,π) on $J = \mathbb{R}^{\pm}$ and define

$$\hat{\mathcal{S}}(n,m) = \mathcal{S}(x_n, x_m).$$

Then the difference operator

$$\hat{L}z = (z_{n+1} - \hat{\mathcal{S}}(n+1,n)z_n)_{n\in\hat{J}}$$

has an exponential dichotomy on $\hat{J} = \mathbb{Z}^{\pm}$ with data $(K, \alpha h, P)$, where $P_n = \pi(x_n)$.

3.2. The linear difference equation. The main result in this section deals with the existence of solutions $(Z,\Upsilon) \in (\ell_\infty^{[n_-,n_+ +1]}(\mathbb{R}^{2m}))^q \times \mathbb{R}^{p,q}$, $1 \leq q \leq p$, of the following linear inhomogeneous boundary value problem:

$$Z_{n+1} - \hat{M}_n Z_n - \hat{V}_n\Upsilon = R^{de}, \quad n \in J = [n_-, n_+], \tag{3.10a}$$

$$(P_-Q_-)Z_{n_-} + (P_+Q_+)Z_{n_+} = R^{bc} \in \mathbb{R}^{2m,q}, \tag{3.10b}$$

$$\langle\hat{\Psi}, Z\rangle_{J_h} = R^{pc} \in \mathbb{R}^{p,q}, \tag{3.10c}$$

where

$$\hat{M}_n = \mathcal{S}(x_{n+1}, x_n) \in \mathbb{R}^{2m,2m}, \tag{3.11}$$

$\mathcal{S}$ denotes the solution operator corresponding to L defined in (3.4), and $\hat{\Psi} \in \ell_\infty^J(\mathbb{R}^{2m,p})$ and $\hat{V}_n \in \mathbb{R}^p$ satisfy the following hypothesis.

Hypothesis 3.7.

1. *Phase condition*: There exists a continuous template function $\Psi \in \mathcal{E}_\varrho(\mathbb{R}, \mathbb{R}^{2m,p})$ such that $\|\hat{\Psi} - \Psi_{|_{J_h}}\|_{\mathcal{L}_{2,h}} \to 0$ as $J_h \to \mathbb{R}$ and $\langle\Psi,\Phi\rangle_{\mathcal{L}_{2,h}} \in \mathbb{R}^{p,p}$ is nonsingular, where

   $$\Phi = [\phi^1, \ldots, \phi^p] \tag{3.12}$$

   and ϕ^i, $i = 1, \ldots, p$, are the functions which span the null space of L, which have been defined in (3.5).

2. *Nondegeneracy condition*: The matrices $\hat{V}_n$ have the form

$$\hat{V}_n = hV(x_n) + \mathcal{O}(h^2) \in \mathbb{R}^{2m,p}, \tag{3.13}$$

where $V \in \mathcal{L}_2(\mathbb{R}, \mathbb{R}^{2m,p})$, $\|V\|_\infty < \infty$, $\operatorname{rank}(V) = p$, and $\mathcal{R}(L) \cap \mathcal{R}(V) = \{0\}$.

Remark 3.8. Define $\Xi = [\xi_1, \dots, \xi_p]$, where ξ_i, $i = 1, \dots, p$, span the null space of the adjoint operator

$$L^* : z \mapsto -z' - M^T(\cdot)z.$$

Then the eigenvalue condition in Hypothesis 1.5 implies that the Melnikov integral

$$\langle \Xi, V \rangle = \int_{\mathbb{R}} [\xi_1, \dots, \xi_p](x)^T V(x)\, dx \ \in \mathbb{R}^{p,p}$$

is nonsingular.

It can be shown that Hypothesis 3.7 implies the invertibility of the operator $\left(\begin{smallmatrix} L & -V \\ \Psi & 0 \end{smallmatrix}\right)$ by the bordering lemma [13].

Now we can formulate the main linear existence result from which we obtain the existence of solutions of (3.10) as well as corresponding estimates.

THEOREM 3.9. *Consider* (3.10)*, and let Hypothesis* 3.7 *be satisfied.*

Then there exist $h_0 > 0$ *and* $T > 0$ *such that for* $h < h_0$ *and* $\pm h n_\pm > T$ (3.10) *has a unique solution* $(\tilde{Z}, \tilde{\Upsilon}) \in (\ell_\infty^{[n_-, n_+ + 1]}(\mathbb{R}^{2m}))^q \times \mathbb{R}^{p,q}$ *for any* $R^{de} \in (\ell_\infty^J(\mathbb{R}^{2m}))^q$, $R^{bc} \in \mathbb{R}^{2m,q}$, $R^{pc} \in \mathbb{R}^{p,q}$. *Furthermore, the following estimate holds:*

$$\|\tilde{Z}\|_{\mathcal{H}_h^1} + \|\tilde{\Upsilon}\| \le \text{const} \left(\frac{1}{h} \|R^{de}\|_{\mathcal{L}_{2,h}} + \|R^{bc}\| + \|R^{pc}\| \right). \tag{3.14}$$

Note that in the traveling wave case we have $p = 1$ and $q = 1$, whereas for the approximation of general equilibria we have $p = \dim G$, and $q = 1$, and for the approximation of the null space we have $p = q = \dim G$.

The existence of exponential dichotomies ensures that certain boundary value problems can be solved that arise later in the construction of solutions of (3.10). We use a slightly adapted version of Lemma 1.1.6 in [4] or Lemma 2.7 in [20] in which the dependency on h is addressed.

LEMMA 3.10. *Let the linear difference operator*

$$\hat{L} : \ell_\infty^{[n_-, n_+ + 1]} \to \ell_\infty^J, z \mapsto \left(z_{n+1} - \hat{M}_n z_n \right)_{n \in J}$$

have an exponential dichotomy with data (K, β, P) *on* $J = [n_-, n_+] \subset \mathbb{Z}$, *where* $n_\pm = \pm\infty$ *is allowed.*

For each $r \in \ell_\infty^J$ *there exists a unique solution* $\tilde{z} \in \ell_\infty^{[n_-, n_+ + 1]}$ *of the inhomogeneous equation*

$$\begin{aligned} \left(\hat{L} z\right)_n &= r_n \quad n \in J, \\ P_{n_-} z_{n_-} &= \varrho_- \in \mathcal{R}(P_{n_-}) \qquad \text{if } n_- \in \mathbb{Z}, \\ (I - P_{n_+}) z_{n_+} &= \varrho_+ \in \mathcal{R}(I - P_{n_+}) \quad \text{if } n_+ \in \mathbb{Z}. \end{aligned}$$

It is given by

$$\tilde{z}_n = b_n^-(\varrho_-) + b_n^+(\varrho_+) + \hat{s}_n(r), \quad n \in J,$$
$$\tilde{z}_{n_+ +1} = \hat{M}_{n_+}\tilde{z}_{n_+} + r_{n_+},$$

where $\hat{s}$ is defined with the Green's function $\hat{\mathcal{G}}$ from (3.8) *as follows:*

$$\hat{s}_n(r) = \sum_{m=n_-}^{n_+-1} \hat{\mathcal{G}}(n, m+1)\ r_m, \quad n \in J, \tag{3.15}$$

and

$$b_n^\pm(\varrho) = \begin{cases} \hat{\mathcal{S}}(n, n_\pm)\varrho & \text{in case } \pm n_\pm < \infty, \\ 0 & \text{otherwise.} \end{cases}$$

Furthermore, the following estimate holds for $n \in J$:

$$\|\hat{s}_n(r)\| \le K\ C_\beta \|r\|_\infty, \quad \text{where } C_\beta = \frac{1+\mathrm{e}^{-\beta}}{1-\mathrm{e}^{-\beta}}. \tag{3.16}$$

In addition, if $r \in \mathcal{L}_{2,h}(J)$, then

$$\|\hat{s}_n(r)\| \le K\sqrt{\frac{C_{2\beta}}{h}}\ \|r\|_{\mathcal{L}_{2,h}} \quad \forall n \in J \quad \text{and} \quad \|\hat{s}(r)\|_{\mathcal{L}_{2,h}} \le KC_\beta\ \|r\|_{\mathcal{L}_{2,h}}. \tag{3.17}$$

In case $\pm n_\pm < \infty$ we obtain for the boundary terms the estimates

$$\|b_n^\pm(\varrho_\pm)\| \le K\mathrm{e}^{-\beta|n-n_\pm|}\|\varrho_\pm\|,\ n \in J, \quad \text{and} \quad \|b^\pm(\varrho_\pm)\|_{\mathcal{L}_{2,h}} \le K\sqrt{hC_{2\beta}}\|\varrho_\pm\|.$$

Note that C_β does not depend on the interval J but only on the dichotomy data and that $C_{h\alpha}$ is of order $\mathcal{O}(\frac{1}{h})$ for small h. Thus we can estimate the solutions $\tilde{z}$ for $\beta = \alpha h$ as follows.

COROLLARY 3.11. *If $\beta = \alpha h$, then the partial solutions $\tilde{z}$ defined in Lemma* 3.10 *obey the estimate*

$$\|\tilde{z}\|_{\mathcal{L}_{2,h}} \le \text{const}\left(\frac{1}{h}\|r\|_{\mathcal{L}_{2,h}} + \|\varrho_-\| + \|\varrho_+\|\right). \tag{3.18}$$

In the following we transfer the proof in [4] to the discrete case along the lines of the method used in [29] and [30].

Proof of Theorem 3.9. From the properties of L (see Remark 3.3) one obtains that L has exponential dichotomies on $\mathbb{R}^\pm$ with data $(K_\pm, \alpha_\pm, \pi^\pm)$. Then Lemma 3.6 implies that the operator $\hat{L} : \ell_\infty \to \ell_\infty$ defined by

$$\hat{L}z = \left(z_{n+1} - \hat{M}_n z_n\right)_{n\in\mathbb{Z}}$$

possesses exponential dichotomies on $\mathbb{Z}^\pm$ with data $(K_\pm, \alpha_\pm h, P^\pm)$ and

$$\mathcal{N}\left(\hat{L}\right) = \text{span}\{\hat{\phi}^1, \dots, \hat{\phi}^p\}, \quad \text{where } \hat{\phi}^i = \phi^i{}_{|_{J_h}} = \begin{pmatrix} S^i(\bar{v}) \\ S^i(\bar{v}') \end{pmatrix},\ i = 1, \dots, p. \tag{3.19}$$

We use Lemma 3.10 to define solutions of the boundary value problems

$$\begin{aligned}\left(\hat{L}Z\right)_n &= R^{de}_n, \quad n \in [n_-, -1],\\ P^-_{n_-} Z_{n_-} &= \rho_- \in (\mathcal{R}(P^-_{n_-}))^q,\\ (I - P^-_0)Z_0 &= Z^-_0 \in (\mathcal{N}(P^-_0))^q\end{aligned}$$

and

$$\begin{aligned}\left(\hat{L}Z\right)_n &= R^{de}_n, \quad n \in [0, n_+],\\ P^+_0 Z_0 &= Z^+_0 \in \left(\mathcal{R}\left(P^+_0\right)\right)^q,\\ (I - P^+_{n_+})Z_{n_+} &= \rho_+ \in \left(\mathcal{N}\left(P^+_{n_+}\right)\right)^q,\end{aligned}$$

where we use the notation $(\hat{L}Z)_n := [(\hat{L}Z^1)_n, \dots, (\hat{L}Z^q)_n] \in \mathbb{R}^{m,q}$. These are for each $R^{de} \in (\ell^J_\infty)^q$ defined by

$$\begin{aligned}\tilde{Z}^-_n &= \hat{s}^-_n \left(R^{de} + \hat{V}^\Upsilon\right) + \hat{\mathcal{S}}(n,0)Z^-_0 + \hat{\mathcal{S}}(n,n_-)\rho_-, \quad n \in [n_-, 0],\\ \tilde{Z}^+_n &= \hat{s}^+_n \left(R^{de} + \hat{V}^\Upsilon\right) + \hat{\mathcal{S}}(n,0)Z^+_0 + \hat{\mathcal{S}}(n,n_+)\rho_+, \quad n \in [0, n_+],\\ \tilde{Z}^+_{n_++1} &= \hat{M}_{n_+}\tilde{Z}^+_{n_+} + R^{de}_{n_+} \in \mathbb{R}^{2m,q},\end{aligned}$$

where $\hat{V}^\Upsilon_n = \hat{V}_n\Upsilon \in \mathbb{R}^{2m,q}$.

Then $\tilde{Z} \in (\ell^{[n_-,n_++1]}_\infty)^q$ defined by

$$\tilde{Z}_n = \begin{cases}\tilde{Z}^-_n & \text{for } n \in J^- := [n_-, -1],\\ \tilde{Z}^+_n & \text{for } n \in J^+ := [0, n_+ + 1]\end{cases} \tag{3.20}$$

is a solution of (3.10) if it solves the following system:

$$\tilde{Z}^-_0 = \tilde{Z}^+_0 \quad \in \mathbb{R}^{2m,q}, \tag{3.21a}$$

$$(P_-Q_-)\tilde{Z}_{n_-} + (P_+Q_+)\tilde{Z}_{n_+} = R^{bc} \quad \in \mathbb{R}^{2m,q}, \tag{3.21b}$$

$$\left\langle \hat{\Psi}, \tilde{Z} \right\rangle_{J_h} = R^{pc} \quad \in \mathbb{R}^{p,q}. \tag{3.21c}$$

Note that the dependency on $\Upsilon \in \mathbb{R}^{p,q}$ is hidden in the definition of $\tilde{Z}^\pm_n$ and is yet to be determined.

We decompose $\mathbb{R}^{2m}$ as follows: Let $\mathcal{W}_1 = \mathcal{R}(P^+_0) \cap \mathcal{N}(P^-_0)$. From (3.19) we obtain $\dim(\mathcal{W}_1) = p$, and thus we can complement $\mathcal{W}_1$ by subspaces $\mathcal{W}_2$ and $\mathcal{W}_3$ such that

$$\mathcal{R}\left(P^+_0\right) = \mathcal{W}_1 \oplus \mathcal{W}_2, \quad \mathcal{N}\left(P^-_0\right) = \mathcal{W}_1 \oplus \mathcal{W}_3.$$

Since $\dim(\mathcal{W}_1 \oplus \mathcal{W}_2 \oplus \mathcal{W}_3) = 2m - p$, there exists a subspace $\mathcal{W}_4$ with $\dim \mathcal{W}_4 = p$ such that $\mathcal{W}_1 \oplus \mathcal{W}_2 \oplus \mathcal{W}_3 \oplus \mathcal{W}_4 = \mathbb{R}^{2m}$ is a complete decomposition of $\mathbb{R}^{2m}$.

We can change the projectors $P^\pm_0$ in such a way that (see [20, Proposition 2.3])

$$\mathcal{N}\left(P^+_0\right) = \mathcal{W}_3 \oplus \mathcal{W}_4, \quad \mathcal{R}\left(P^-_0\right) = \mathcal{W}_2 \oplus \mathcal{W}_4,$$

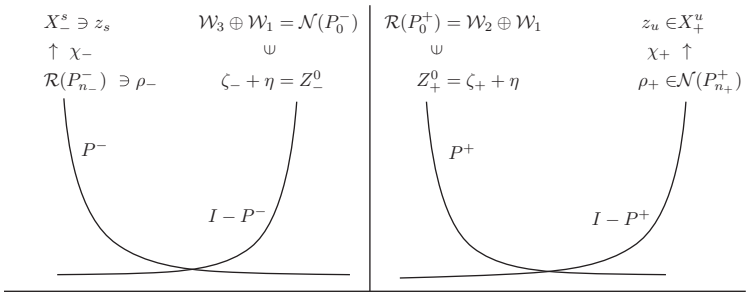

FIG. 3.1. *Overview over dichotomy estimates.*

increasing the dichotomy constants $K_\pm$ to $2K_\pm(1+K_\pm)$ and without changing $\mathcal{N}(P_0^-)$, $\mathcal{R}(P_0^+)$ or the dichotomy exponents $\alpha_\pm$. From the choice of Z_0^- and Z_0^+ follows

$$\begin{aligned} \left(I - P_0^-\right)\tilde{Z}_0^- = Z_0^- \quad &\in \left(\mathcal{N}\left(P_0^-\right)\right)^q = \mathcal{W}_3^q \oplus \mathcal{W}_1^q, \\ P_0^+ \tilde{Z}_0^+ = Z_0^+ \quad &\in \left(\mathcal{R}\left(P_0^+\right)\right)^q = \mathcal{W}_2^q \oplus \mathcal{W}_1^q \end{aligned}$$

(for an overview of the decomposition according to the different dichotomy data see Figure 3.1). We use the ansatz $Z_0^- = \zeta_- + \eta_-$, $Z_0^+ = \zeta_+ + \eta_+$, where $\zeta_- \in \mathcal{W}_3^q$, $\zeta_+ \in \mathcal{W}_2^q$, and $\eta_\pm \in \mathcal{W}_1$, and from (3.21a) we obtain $\eta_+ = \eta_- =: \eta$. Equation (3.21a) now reads

$$\zeta_- - \zeta_+ + \hat{\mathcal{S}}(0, n_-)\rho_- - \hat{\mathcal{S}}(0, n_+)\rho_+ + \left(\hat{s}_0^-\left(\hat{V}\right) - \hat{s}_0^+\left(\hat{V}\right)\right)\Upsilon = \hat{s}_0^+\left(R^{de}\right) - \hat{s}_0^-\left(R^{de}\right).$$

We transform the boundary values ρ_- and ρ_+ to coordinates (z_s, z_u) which are independent of J as follows: Denote by E_-^s the projector onto X_-^s along X_-^u and by E_+^u the projector onto X_+^u along X_+^s, where $X_\pm^s$ are the stable subspaces and $X_\pm^u$ are the unstable subspaces of $M_\pm$ (cf. Definition (2.3)).

We define the transformations

$$\chi_- : \mathcal{R}\left(P_{n_-}^-\right) \to X_-^s,\ \varrho_- \mapsto z_s, \qquad \chi_+ : \mathcal{N}\left(P_{n_+}^+\right) \to X_+^u,\ \varrho_+ \mapsto z_u$$

by

$$\chi_- = I + E_-^s - P_{n_-}^-, \qquad \chi_+ = I - E_+^s + P_{n_+}^+.$$

Now we apply $\chi_\pm$ columnwise. From the roughness theorem for exponential dichotomies [19] we have $\lim_{x\to\pm\infty} \pi^\pm(x) = E_\pm^s$. With $P_n^\pm = \pi^\pm(x_n)$ the invertibility of χ_- and χ_+ follows for $J_h \to \mathbb{R}$ together with the estimates

$$\left\|\chi_\pm^{-1}\right\| \le \frac{1}{1 - \left\|P_{n_\pm}^\pm - E_\pm^s\right\|} \le 2. \tag{3.22}$$

This implies for all $(z_s, z_u) \in X_-^s \times X_+^u$ that

$$\left\|(I - E_-^s)\chi_-^{-1} z_s\right\| \le \frac{\|P_{n_-}^- - E_-^s\|\|z_s\|}{1 - \|P_{n_-}^- - E_-^s\|}, \qquad \left\|E_+^s \chi_+^{-1} z_u\right\| \le \frac{\|P_{n_+}^+ - E_+^s\|\|z_u\|}{1 - \|P_{n_+}^+ - E_+^s\|}. \tag{3.23}$$

Define $\hat{\Phi} \in \ell_\infty(\mathbb{R}^{2m,p})$ by $\hat{\Phi}_n = \Phi(hn)$, where Φ has been defined in (3.12). Since the columns $\hat{\phi}_0^i$, $i = 1, \ldots, p$, of $\hat{\Phi}_0 = \Phi(0)$ span a basis of $\mathcal{N}(P_0^-) \cap \mathcal{R}(P_0^+)$ (see Remark 3.2), we can write $\eta \in \mathcal{W}_1^q$ as $\eta = \hat{\Phi}_0 \kappa$ for some $\kappa \in \mathbb{R}^{p,q}$.

Equation (3.21) can now be written as

$$T\begin{pmatrix}(\zeta_-,\zeta_+,\Upsilon)\\(z_s,z_u)\\\kappa\end{pmatrix}=\begin{pmatrix}\hat{s}_0^+(R^{de})-\hat{s}_0^-\left(R^{de}\right)\\R^{bc}-\left((P_+Q_+)\hat{s}_{n_+}^+\left(R^{de}\right)-(P_-Q_-)\hat{s}_{n_-}^-\left(R^{de}\right)\right)\\R^{pc}-\left\langle\hat{\Psi}_{|_{J^-}},\hat{s}^-\left(R^{de}\right)\right\rangle_{J_h}-\left\langle\hat{\Psi}_{|_{J^+}},\hat{s}^+\left(R^{de}\right)\right\rangle_{J_h}\end{pmatrix},\tag{3.24}$$

where $T:\ (\mathcal{W}_2^q\times\mathcal{W}_3^q\times\mathbb{R}^{p,q})\times(X_-^s)^q\times(X_+^u)^q\times\mathbb{R}^{p,q}\to(\mathcal{W}_2\oplus\mathcal{W}_3\oplus\mathcal{W}_4)^q\times\mathbb{R}^{2m,q}\times\mathbb{R}^{p,q}$ has the following structure:

$$T=\begin{pmatrix}\mathcal{X}&\sigma&0\\\Delta&\mathcal{Y}&\varrho\\\Theta&\Pi&\mathcal{Z}\end{pmatrix},$$

where

$$\begin{aligned}
\mathcal{X}(\zeta_-,\zeta_+,\lambda)&=\zeta_--\zeta_++\left(\hat{s}_0^-\left(\hat{V}\right)-\hat{s}_0^+\left(\hat{V}\right)\right)\Upsilon,\\
\sigma(z_s,z_u)&=\hat{\mathcal{S}}(0,n_-)\left[\chi_-^{-1}z_s^1,\dots,\chi_-^{-1}z_s^q\right]-\hat{\mathcal{S}}(0,n_+)\left[\chi_+^{-1}z_u^1,\dots,\chi_+^{-1}z_u^q\right],\\
\Delta(\zeta_-,\zeta_+,\Upsilon)&=(P_-Q_-)\left(\hat{\mathcal{S}}(n_-,0)\zeta_-+\hat{s}_{n_-}^-\left(\hat{V}\right)\Upsilon\right)\\
&\quad+(P_+Q_+)\left(\hat{\mathcal{S}}(n_+,0)\zeta_++\hat{s}_{n_+}^+\left(\hat{V}\right)\Upsilon\right),\\
\mathcal{Y}(z_s,z_u)&=(P_-Q_-)\left[\chi_-^{-1}z_s^1,\dots,\chi_-^{-1}z_s^q\right]+(P_+Q_+)\left[\chi_+^{-1}z_u^1,\dots,\chi_+^{-1}z_u^q\right],\\
\varrho(\kappa)&=\left((P_-Q_-)\hat{\mathcal{S}}(n_-,0)+(P_+Q_+)\hat{\mathcal{S}}(n_+,0)\right)\hat{\Phi}_0\kappa,\\
\Theta(\zeta_-,\zeta_+,\Upsilon)&=\left\langle\hat{\Psi}_{|_{J^-}},\hat{\mathcal{S}}(\cdot,0)\zeta_-+\hat{s}^-\left(\hat{V}\right)\Upsilon\right\rangle_{J_h}+\left\langle\hat{\Psi}_{|_{J^+}},\hat{\mathcal{S}}(\cdot,0)\zeta_++\hat{s}^+\left(\hat{V}\right)\Upsilon\right\rangle_{J_h},\\
\Pi(z_s,z_u)&=\left\langle\hat{\Psi}_{|_{J^-}},\hat{\mathcal{S}}(\cdot,n_-)\chi_-^{-1}\left[z_s^1,\dots,z_s^q\right]\right\rangle_{J_h}\\
&\quad+\left\langle\hat{\Psi}_{|_{J^+}},\hat{\mathcal{S}}(\cdot,n_+)\chi_+^{-1}\left[z_u^1,\dots,z_u^q\right]\right\rangle_{J_h},\\
\mathcal{Z}(\kappa)&=\left\langle\hat{\Psi},\hat{\Phi}\right\rangle_{J_h}\kappa.
\end{aligned}$$

We have to show the invertibility of T as well as an estimate of the inverse of T. The terms σ and ϱ can be estimated by using (3.22), the exponential dichotomy of $\hat{L}$ and $\mathcal{R}(\hat{\Phi}_0)=\mathcal{R}(P_0^+)\cap\mathcal{N}(P_0^-)$ by

$$\|\sigma\|,\|\varrho\|\le\text{const}\,\mathrm{e}^{-\alpha h\min(-n_-,n_+)}\quad\to 0\quad\text{as } J_h\to\mathbb{R}.$$

The boundedness of the operators Δ,Π, and Θ follows from the dichotomy estimates (3.9) and the properties of $\hat{V}$. The properties of $\hat{\Psi}$ in Hypothesis 3.7 ensure that the map $(\mathcal{L}_{2,h}(\mathbb{R}^{2m}))^q\to\mathbb{R}^{p,q},\ Z\mapsto\langle\hat{\Psi},Z\rangle_{J_h}$ is uniformly bounded.

Hypothesis 2.4 and (3.23) imply that $\mathcal{Y}$ has a uniformly bounded inverse. Lemma 2.2 and the properties of $\hat{V}$ imply that the other operators on the diagonal $\mathcal{X}$ and $\mathcal{Z}$ converge for $J_h\to\mathbb{R}$ to asymptotic operators $\bar{\mathcal{X}}$ and $\bar{\mathcal{Z}}$. These are defined as follows: Let $\mathcal{S}$ be the solution operator corresponding to L, and $\pi^\pm$ the stable and unstable dichotomy projectors. We define

$$\bar{\mathcal{X}}(\zeta_-,\zeta_+,\Upsilon)=\zeta_--\zeta_++(s^-(V)(0)-s^+(V)(0))\Upsilon,$$

where

$$s^-(V)(x) = \int_{-\infty}^{x} \mathcal{S}(x,\xi)\pi^-(\xi)V(\xi)\,d\xi - \int_{x}^{0} \mathcal{S}(x,\xi)(I-\pi^-(\xi))V(\xi)\,d\xi \quad \text{for } x \le 0,$$
$$s^+(V)(x) = \int_{0}^{x} \mathcal{S}(x,\xi)\pi^+(\xi)V(\xi)\,d\xi - \int_{x}^{\infty} \mathcal{S}(x,\xi)(I-\pi^+(\xi))V(\xi)\,d\xi \quad \text{for } x \ge 0,$$

and

$$\bar{\mathcal{Z}}(\kappa) = \langle \Psi, \Phi\rangle \kappa.$$

The invertibility of $\bar{\mathcal{Z}}$ is ensured by Hypothesis 3.7. Similarly the invertibility of $\bar{\mathcal{X}}$ follows from the nondegeneracy condition in Hypothesis 3.7 similar to [7], by multiplying the equation

$$0 = \zeta_- - \zeta_+ + (s^-(V)(0) - s^+(V)(0))\Upsilon$$

from the left by $\Xi(0)^T$ and using Remark 3.8.

Then we obtain that $\mathcal{X}$ and $\mathcal{Z}$ are invertible for h small enough and $\mp h n_\pm$ large enough with a uniform bound for the inverse.

By summing up the estimates for the right-hand side in (3.24) and using estimate (3.16) for $\hat{s}^\pm$ in Lemma 3.10 as well as the properties of $\hat{\Psi}$, one obtains for $J_h \to \mathbb{R}$

$$\|\zeta_-\| + \|\zeta_+\| + \|\Upsilon\| + \|z_s\| + \|z_u\| + \|\kappa\| \le \text{const}\left(\frac{1}{h}\|R^{de}\|_{\mathcal{L}_{2,h}} + \|R^{bc}\| + \|R^{pc}\|\right).$$

This implies with Corollary 3.11 and (3.22) for $\tilde{Z}^- \in (\ell_\infty^{J^-})^q$ and $\tilde{Z}^+ \in (\ell_\infty^{J^+})^q$ that

$$\|\tilde{Z}^\pm\|_{\mathcal{L}_{2,h}} \le \text{const}\left(\frac{1}{h}\|R^{de}\|_{\mathcal{L}_{2,h}} + \|R^{bc}\| + \|R^{pc}\|\right).$$

A similar estimate for the contribution of $\tilde{Z}_{n_++1}$ at $n_+ + 1$ leads to

$$\left\|\tilde{Z}\right\|_{\mathcal{L}_{2,h}} + \|\Upsilon\| \le \text{const}\left(\frac{1}{h}\|R^{de}\|_{\mathcal{L}_{2,h}} + \|R^{bc}\| + \|R^{pc}\|\right).$$

This can be improved for h small enough to the $\|\cdot\|_{\mathcal{H}_h^1}$ estimate (3.14) by using the difference equation (3.10a) and the following properties of $\hat{V}$ and $\hat{M}$:

$$\hat{V}_n = hV(x_n) + \mathcal{O}(h^2), \quad \hat{M}_n = I + \mathcal{O}(h),$$

which follow from (3.13) and (3.11). ∎

4. Proof of the main results. In the following section we use the following fixed point theorem (see [27] or [7, Lemma 3.1]) to prove the main approximation results.

THEOREM 4.1. *Let $F : \mathcal{Y} \supset B_\varrho(\bar{y}) \to \mathcal{Z}$ be a C^1 mapping between two Banach spaces $\mathcal{Y}$ and $\mathcal{Z}$, and let $(DF(\bar{y}))^{-1} \in L[\mathcal{Z},\mathcal{Y}]$ exist. Assume the following estimates for $\kappa, \sigma > 0$:*

$$\|DF(y) - DF(\bar{y})\|_{\mathcal{Y}\to\mathcal{Z}} \le \kappa < \sigma \le \frac{1}{\|DF(\bar{y})^{-1}\|_{\mathcal{Z}\to\mathcal{Y}}} \quad \forall y \in B_\varrho(\bar{y}), \tag{4.1}$$

$$\|F(\bar{y})\|_Z \le (\sigma - \kappa)\varrho. \tag{4.2}$$

Then F has a unique zero y_0 in $B_\varrho(\bar y) = \{y : \|y-\bar y\|_{\mathcal Y} \le \varrho\}$, and the following estimates hold:

$$\|y_0-\bar y\|_{\mathcal Y} \le \frac{1}{(\sigma-\kappa)}\|F(\bar y)\|_{\mathcal Z}, \tag{4.3}$$

$$\|y_1-y_2\|_{\mathcal Y} \le \frac{1}{(\sigma-\kappa)}\|F(y_1)-F(y_2)\|_{\mathcal Z} \quad \forall y_1,y_2 \in B_\varrho(\bar y). \tag{4.4}$$

The linear Theorem 3.9 is used to derive estimates of the inverse of the linearization $DF(\bar y)^{-1}$.

4.1. Approximation of relative equilibria.

Proof of Theorem 2.5. Set $w = v-\bar v$ and $\lambda = \mu - \bar\mu$. Then a solution of (2.2) is given by $(\bar w+\bar v, \bar\lambda+\bar\mu)$, where $(\bar w,\bar\lambda)$ is a zero of the operator $F : \ell^{\hat J}_\infty \times \mathbb{R}^p \to \ell^J_\infty \times \mathbb{R}^{2m}\times\mathbb{R}^p$, given by

$$F(w,\lambda) = \begin{pmatrix} \left(\left(\bar\Lambda w\right)_n + \hat S_n\left(\bar v_{|_{J_h}}\right)\lambda + g_n(w,\lambda) + \left(R^{de}_{J_h}\right)_n\right)_{n\in J} \\ \mathcal B w + R^{bc}_{J_h} \\ \left\langle \hat S\left(\hat v_{|_{J_h}}\right), w\right\rangle_{J_h} + R^{pc}_{J_h} \end{pmatrix},$$

where

$$\begin{aligned} \left(\bar\Lambda w\right)_n &= A(\delta_+\delta_- w)_n + B_n(\delta_0 w)_n + C_n w_n, \qquad B_n = B(x_n),\ C_n = C(x_n),\\ g_n(w,\lambda) &= f(\bar v_n + w_n, \delta_0(\bar v+w)_n) - f(\bar v_n,\delta_0\bar v_n)\\ &\quad - D_1 f(\bar v_n,\bar v_n')w_n - D_2 f(\bar v_n,\bar v_n')\delta_0 w_n + \hat S_n(w)\lambda, \quad n\in J, \end{aligned}$$

and

$$\begin{aligned} R^{de}_{J_h} &= A\delta_+\delta_-\bar v + \hat S(\bar v)\bar\mu + f(\bar v,\delta_0\bar v), \qquad R^{bc}_{J_h} = \mathcal B\bar v_{|_{J_h}} - (P_-\bar v_- + P_+\bar v_+),\\ R^{pc}_{J_h} &= \left\langle \hat S(\hat v_{|_{J_h}}), (\bar v-\hat v)_{|_{J_h}}\right\rangle_{J_h}. \end{aligned}$$

We will apply Theorem 4.1 to F with $\mathcal Y = (\ell^{\hat J}_\infty)\times\mathbb{R}^p$ and $\mathcal Z = (\ell^J_\infty)\times\mathbb{R}^{2m}\times\mathbb{R}^p$, at the approximative zero $\bar y = 0$ with norms

$$\|(v,\mu)\|_{\mathcal Y} = \|v\|_{\mathcal H^2_h} + \|\mu\|, \qquad \|(R^{de},R^{bc},R^{pc})\|_{\mathcal Z} = \|R^{de}\|_{\mathcal L_{2,h}} + \|R^{bc}\| + \|R^{pc}\|.$$

We have with the properties of $\bar v$ (see Remark 3.4)

$$\begin{aligned} \|R^{de}_{J_h}\|_{\mathcal L_{2,h}} &\le \|A\|\,\|\delta_+\delta_-\bar v - \bar v''\|_{\mathcal L_{2,h}} + \|f(\bar v,\delta_0\bar v) - f(\bar v,\bar v')\|_{\mathcal L_{2,h}}\\ &\qquad + \|\hat S(\bar v_{|_{J_h}}) - S(\bar v)\|_{\mathcal L_{2,h}}\|\bar\mu\|\\ &\le \operatorname{const} h^2. \end{aligned}$$

Similarly, we obtain with the assumptions on the phase condition in Hypothesis 2.4 and Lemma 2.2

$$\begin{aligned} \|R^{pc}_{J_h}\| &\le \left\|\left\langle S(\hat v)_{|_{J_h}}, (\bar v-\hat v)_{|_{J_h}}\right\rangle_{J_h}\right\| + \left\|\left\langle \hat S(\hat v_{|_{J_h}}) - S(\hat v)_{|_{J_h}}, (\bar v-\hat v)_{|_{J_h}}\right\rangle_{J_h}\right\|\\ &\le \operatorname{const}\left(h^2 + \mathrm{e}^{-\alpha h\min\{n_-,n_+\}}\right). \end{aligned}$$

By using the consistency of the boundary conditions in Hypothesis 2.4 we have

$$\begin{aligned}\|R^{bc}_{J_h}\| &\le \|P_-\|\|\bar v_{n_-} - \bar v_-\| + \|Q_-\|(\|\delta_0 \bar v_{n_-} - \bar v'(x_{n_-})\| + \|\bar v'(x_{n_-})\|)\\ &\quad + \|P_+\|\|\bar v_{n_+} - \bar v_+\| + \|Q_+\|(\|\delta_0 \bar v_{n_+} - \bar v'(x_{n_+})\| + \|\bar v'(x_{n_+})\|)\\ &\le \text{const}\left(h^2 + \mathrm{e}^{-\alpha h \min\{n_-, n_+\}}\right).\end{aligned}$$

These estimates together with $g(0,0) = 0$ imply the consistency estimate

$$\|F(0,0)\|_Z \le \|R^{de}\|_{\mathcal{L}_{2,h}} + \|R^{bc}\| + \|R^{pc}\| \le \text{const}\left(h^2 + \mathrm{e}^{-\alpha h \min\{-n_-, n_+\}}\right).$$

With

$$DF\left(\tilde w, \tilde\lambda\right)(w,\lambda) = \begin{pmatrix} (\bar\Lambda w)_n + \hat S_n\left(\bar v_{|_{J_h}}\right)\lambda + Dg_n\left(\tilde w, \tilde\lambda\right)(w,\lambda) \\ \mathcal{B}w \\ \left\langle \hat S\left(\hat v_{|_{J_h}}\right), w\right\rangle_{J_h}\end{pmatrix},$$

$Dg(0,0) = 0$, the properties of f (see Remark 1.2), and the discrete Sobolev embedding $\|v\|_\infty \le \text{const}\,\|v\|_{\mathcal{H}^1_h}$, we arrive at

$$\begin{aligned}\left\|\left(DF\left(\tilde w, \tilde\lambda\right) - DF(0,0)\right)(w,\lambda)\right\|_{\mathcal{Z}} &= \left\|Dg\left(\tilde w, \tilde\lambda\right)(w,\lambda)\right\|_{\mathcal{L}_{2,h}}\\ &\le \text{const}\left(\|\tilde w\|_{\mathcal{H}^2_h} + \|\tilde\lambda\|\right)\left(\|w\|_{\mathcal{H}^2_h} + \|\lambda\|\right).\end{aligned}$$

It remains to estimate the inverse of $DF(0,0)$. With the definitions

$$z_n = (v_n, w_n), \qquad w_n = (\delta_- v)_n, \qquad \text{and} \qquad \hat R^{de}_n = \begin{pmatrix} 0 \\ hR^{de}_n\end{pmatrix}, \tag{4.5}$$

the equation

$$DF(0,0)(w,\lambda) = (R^{de}, R^{bc}, R^{pc})^T \tag{4.6}$$

is transformed into

$$\tilde T(z,\lambda) = \left(\hat R^{de}, R^{bc}, R^{pc}\right)^T, \tag{4.7}$$

where $\tilde T : \ell^{[n_-, n_+ + 1]}_\infty(\mathbb{R}^{2m}) \times \mathbb{R}^p \to \ell^J_\infty(\mathbb{R}^{2m}) \times \mathbb{R}^{2m} \times \mathbb{R}^p$ is given by

(4.8)
$$\tilde T(z,\lambda) = \begin{pmatrix} \left(\tilde N_n z_{n+1} - \tilde K_n z_n - \tilde U_n \lambda\right)_{n\in J} \\ P_- v_{n_-} + Q_-\left(w_{n_-} + \frac{h}{2}\delta_+ w_{n_-}\right) + P_+ v_{n_+} + Q_+\left(w_{n_+} + \frac{h}{2}\delta_+ w_{n_+}\right) \\ \left\langle \tilde\Psi, z\right\rangle_{J_h}\end{pmatrix},$$

with

$$\tilde N_n = \begin{pmatrix} I & -hI \\ 0 & A + \frac{h}{2}B_n\end{pmatrix}, \quad \tilde K_n = \begin{pmatrix} I & 0 \\ -hC_n & A - \frac{h}{2}B_n\end{pmatrix}, \quad \tilde U_n = -\begin{pmatrix} 0 \\ h\hat S\left(\bar v_{|_{J_h}}\right)_n\end{pmatrix},$$

and

$$\tilde{\Psi} = \begin{pmatrix} \hat{S}\left(\hat{v}_{|_{J_h}}\right) \\ 0 \end{pmatrix}.$$

In order to use the properties of the continuous operator L, we consider the following approximation of $\tilde{T}$:

$$T(z,\lambda) = \begin{pmatrix} \left(N z_{n+1} - N\hat{M}_n z_n - U_n \lambda\right)_{n\in J} \\ (P_- \; Q_-) z_{n_-} + (P_+ \; Q_+) z_{n_+} \\ \left\langle \Psi_{|_{J_h}}, z \right\rangle_{J_h} \end{pmatrix},$$

where

$$N = \begin{pmatrix} I & 0 \\ 0 & A \end{pmatrix}, \qquad U_n = -\begin{pmatrix} 0 \\ h[S(\bar{v})](x_n) \end{pmatrix}, \qquad \Psi(x) = \begin{pmatrix} [S(\hat{v})](x) \\ 0 \end{pmatrix}. \tag{4.9}$$

From the definition of $\hat{M}_n$ we get

$$\hat{M} = \mathcal{S}(x_{n+1}, x_n) = I + hM(x_n) + \mathcal{O}(h^2)$$

as well as the estimates

$$\begin{aligned} \|\tilde{N}_n - N\| &\le \text{const}\, h, \\ \|N\hat{M}_n - \tilde{K}_n + \tilde{N}_n - N\| &\le \text{const}\, h^2, \\ \|\tilde{U} - U\|_{\mathcal{L}_{2,h}} &\le \text{const}\, h^2. \end{aligned}$$

These estimates imply that T is a perturbation of $\tilde{T}$ of order h w.r.t. the norms $\|(\hat{R}^{de}, R^{bc}, R^{pc})\|_h^* = \frac{1}{h}\|\hat{R}^{de}\|_{\mathcal{L}_{2,h}} + \|R^{bc}\| + \|R^{pc}\|$ and $\|(z,\lambda)\|_{\mathcal{H}_h^1}^* = \|z\|_{\mathcal{H}_h^1} + \|\lambda\|$ as follows. We have

$$\begin{aligned} &\left\| \left(\left(\tilde{N}_n - N\right) z_{n+1} - \left(\tilde{K}_n - N\hat{M}_n\right) z_n + \left(\tilde{U}_n - U_n\right)\lambda \right)_{n\in J} \right\|_{\mathcal{L}_{2,h}}^2 \\ &\quad \le \text{const} \sum_{n=n_-}^{n_+} h \left(h^2 \|\tilde{N}_n - N\|^2 \|\delta_+ z_n\|^2 + \|N\hat{M}_n - \tilde{K}_n + \tilde{N}_n - N\|^2 \|z_n\|^2 \right. \\ &\qquad\qquad \left. + \|\tilde{U}_n - U_n\|^2 \|\lambda\|^2 \right) \\ &\quad \le \text{const}\, h^4 \|\delta_+ z\|_{\mathcal{L}_{2,h}}^2 + h^4 \|z\|_{\mathcal{L}_{2,h}}^2 + \|\tilde{U} - U\|_{\mathcal{L}_{2,h}}^2 \|\lambda\|^2 \le \text{const}\, h^4 (\|z\|_{\mathcal{H}_h^1} + \|\lambda\|)^2 \end{aligned}$$

and with Lemma 2.2

$$\|\Psi_{|_{J_h}} - \tilde{\Psi}\|_{J_h} \le \left\| \hat{S}\left(\hat{v}_{|_{J_h}}\right) - S\left(\hat{v}\right)_{|_{J_h}} \right\|_{J_h} \le \text{const} \left(h^2 + \mathrm{e}^{-\alpha h \min\{-n_-, n_+}} \right).$$

Thus we obtain

$$\begin{aligned}\left\|\left(\tilde{T}-T\right)(z,\lambda)\right\|_h^* &= \frac{1}{h}\left\|\left(\left(\tilde{N}_n-N\right)z_{n+1}-\left(\tilde{K}_n-N\hat{M}_n\right)z_n+\left(\tilde{U}_n-U_n\right)\lambda\right)_{n\in J}\right\|_{\mathcal{L}_{2,h}}\\ &\quad+\left\|Q_-\left(\frac{h}{2}\delta_+ w_{n_-}\right)+Q_+\left(\frac{h}{2}\delta_+ w_{n_+}\right)\right\|+\left\|\left\langle\Psi_{|_{J_h}}-\tilde{\Psi},z\right\rangle_{J_h}\right\|\\ &\le \text{const}\,h(\|z\|_{\mathcal{H}_h^1}+\|\lambda\|)\\ &\quad+\frac{h}{2}(\|Q_-\|\|\delta_+ w_{n_-}\|+\|Q_+\|\|\delta_+ w_{n_+}\|)+\text{const}\,h^2\|z\|_{\mathcal{L}_{2,h}}\\ &\le \text{const}\left(h+\mathrm{e}^{-\alpha h\min\{-n_-,n_+\}}\right)\left(\|z\|_{\mathcal{H}_h^1}+\|\lambda\|\right).\end{aligned}$$

Define

$$V(x)=\begin{pmatrix}0\\ -A^{-1}[S(\bar{v})](x)\end{pmatrix}, \tag{4.10}$$

and set $\hat{V}_n=N^{-1}U_n=hV(x_n)$. Then the equation

$$T(z,\lambda)=\left(\hat{R}^{de},R^{bc},R^{pc}\right)^T \tag{4.11}$$

can be equivalently written as

$$\begin{aligned}z_{n+1}-\hat{M}_n z_n-\hat{V}_n\lambda &= N^{-1}\hat{R}_n^{de},\\ (P_-\ Q_-)z_{n_-}+(P_+\ Q_+)z_{n_+} &= R^{bc},\\ \left\langle\Psi_{|_{J_h}},z\right\rangle_{J_h} &= R^{pc}.\end{aligned} \tag{4.12}$$

In order to apply the linear Theorem 3.9 to (4.12), we show that Hypothesis 3.7 is satisfied. The nondegeneracy condition in Hypothesis 3.7 follows from the fact that the null space of Λ is spanned by $S^i(\bar{v})$, $i=1,\dots,p$, and (4.10).

The assumptions on the phase condition in Hypothesis 3.7 follow with the definition of Ψ in (4.9) directly from the corresponding assumptions in Hypothesis 2.4.

By applying Theorem 3.9 to (4.12) and multiplying with the bounded matrix N, we obtain the invertibility of T as well as an uniform bound for the inverse

$$\left\|T^{-1}\left(R^{de},R^{bc},R^{pc}\right)\right\|_{\mathcal{H}_h^1}^*\le\text{const}\left(\frac{1}{h}\|\hat{R}^{de}\|_{\mathcal{L}_{2,h}}+\|R^{bc}\|+\|R^{pc}\|\right).$$

By perturbation arguments the invertibility of $\tilde{T}$ follows with the same bound for a possibly different constant. These estimates can be transformed back into (2.10) by using the structure of the matrices $\tilde{N}_n,\tilde{K}_n$, and $\tilde{U}_n$ (see (4.9)) as well as the structure of the right-hand side $\hat{R}^{de}$ (see (4.5)) together with the estimate $\|z\|_{\mathcal{H}_h^1}\le\text{const}\,\|v\|_{\mathcal{H}_h^2}$. ∎

4.2. Approximation of the spectrum. The proof of Theorem 2.6 follows the same lines as the proof of Theorem 2.5.

Proof of Theorem 2.6. As in the previous proof we insert $X = V - S(\bar{v})_{|_{J_h}}$ into (2.4) and obtain $F(X,\Sigma) = 0$, where

$$F(X,\Sigma) = \begin{pmatrix} \left(\left(\tilde{\Lambda}X\right)_n - [S(\bar{v})](x_n)\Sigma - X_n\Sigma + \left(R^{de}_{J_h}\right)_n\right)_{n\in J} \\ \mathcal{B}X + R^{bc}_{J_h} \\ \left\langle \hat{X}_{|_{J_h}}, X\right\rangle_{J_h} + R^{pc}_{J_h} \end{pmatrix},$$

with $R^{de}_{J_h} = \tilde{\Lambda}S(\bar{v})_{|_{J_h}}$, $R^{bc}_{J_h} = \mathcal{B}S(\bar{v})_{|_{J_h}}$, and $R^{pc}_{J_h} = \langle \hat{X}_{|_{J_h}}, S(\bar{v})_{|_{J_h}}\rangle_{J_h} - I$.

We will apply Theorem 4.1 to F with $\mathcal{Y} = (\ell^{\hat{J}}_\infty)^p \times \mathbb{R}^{p,p}$ and $\mathcal{Z} = (\ell^J_\infty)^p \times \mathbb{R}^{2m,p} \times \mathbb{R}^{p,p}$, at the approximative zero $\bar{y} = 0$ with norms

$$\|(X,\Sigma)\|_{\mathcal{Y}} = \|X\|_{\mathcal{H}^2_h} + \|\Sigma\|, \qquad \|(R^{de},R^{bc},R^{pc})\|_{\mathcal{Z}} = \|R^{de}\|_{\mathcal{L}_{2,h}} + \|R^{bc}\| + \|R^{pc}\|.$$

In the same way as in the proof of Theorem 2.5 we have

$$\left\|R^{bc}_{J_h}\right\| + \left\|R^{pc}_{J_h}\right\| \le \text{const}\left(h^2 + \mathrm{e}^{-\alpha h \min\{-n_-,n_+\}}\right)$$

and

$$\begin{aligned}\left\|R^{de}_{J_h}\right\|_{\mathcal{L}_{2,h}} &\le \left\|\tilde{\Lambda}S(\bar{v})_{|_{J_h}} - (\Lambda S(\bar{v}))_{|_{J_h}}\right\|_{\mathcal{L}_{2,h}} + \left\|(\Lambda S(\bar{v}))_{|_{J_h}}\right\|_{\mathcal{L}_{2,h}} \\ &\le \text{const}\left(h^2 + \mathrm{e}^{-\alpha h \min\{-n_-,n_+\}}\right).\end{aligned}$$

The properties of $S(\bar{v})$ (see Remark 3.4) imply that $P_-S(\bar{v}_-) + P_+S(\bar{v}_+) = 0$ as well as $\lim_{x\to\infty}[S(\bar{v}')](x) = 0$. These estimates lead to

$$\begin{aligned}\|F(0,0)\|_Z &\le \left\|\tilde{\Lambda}S(\bar{v})_{|_{J_h}}\right\|_{\mathcal{L}_{2,h}} + \left\|\mathcal{B}S(\bar{v})_{|_{J_h}}\right\| + \left\|\left\langle \hat{X}_{|_{J_h}}, S(\bar{v})_{|_{J_h}}\right\rangle_{J_h} - I\right\| \\ &\le \text{const}\left(h^2 + \mathrm{e}^{-\alpha h \min\{-n_-,n_+\}}\right).\end{aligned}$$

With

$$DF\left(\tilde{X},\tilde{\Sigma}\right)(X,\Sigma) = \begin{pmatrix} \left(\left(\tilde{\Lambda}X\right)_n - [S(\bar{v})](x_n)\Sigma - \tilde{X}_n\Sigma - X_n\tilde{\Sigma}\right)_{n\in J} \\ \mathcal{B}X \\ \left\langle \hat{X}_{|_{J_h}}, X\right\rangle_{J_h} \end{pmatrix},$$

we obtain

$$\begin{aligned}\left\|\left(DF\left(\tilde{X},\tilde{\Sigma}\right) - DF(0,0)\right)(X,\Sigma)\right\|_{\mathcal{Z}} &= \left\|\left(\tilde{X}_n\Sigma + X_n\tilde{\Sigma}\right)_{n\in J}\right\|_{\mathcal{L}_{2,h}} \\ &\le \text{const}\left(\left\|\tilde{X}\right\|_{\mathcal{H}^2_h} + \left\|\tilde{\Sigma}\right\|\right)\left(\|X\|_{\mathcal{H}^2_h} + \|\Sigma\|\right).\end{aligned}$$

It remains to estimate the inverse of $DF(0,0)$. In the same way as before, we transform (4.6) into (4.7), where $\tilde{T} : (\ell^{[n_-,n_++1]}_\infty(\mathbb{R}^{2m}))^p \times \mathbb{R}^{p,p} \to (\ell^J_\infty(\mathbb{R}^{2m}))^p \times \mathbb{R}^{2m,p} \times \mathbb{R}^{p,p}$ is given by (4.8) with

$$\tilde{N}_n = \begin{pmatrix} I & -hI \\ 0 & A + \frac{h}{2}\tilde{B}_n \end{pmatrix}, \quad \tilde{K}_n = \begin{pmatrix} I & 0 \\ -h\tilde{C}_n & A - \frac{h}{2}\tilde{B}_n \end{pmatrix}, \quad \tilde{U}_n = -\begin{pmatrix} 0 \\ h[S(\bar{v})](x_n) \end{pmatrix},$$

$$\tilde{\Psi} = \begin{pmatrix} \hat{X} \\ 0 \end{pmatrix}.$$

Again we solve (4.11) in order to solve (4.7), where $U_n = \tilde{U}_n$ and $\Psi = \tilde{\Psi}$. With the properties of f (see (1.6)) and (2.10) we obtain

$$\begin{aligned}\left\|\tilde{B}_n - B(x_n)\right\| &\le \|D_2 f(\tilde{v}_n, (\delta_0 \tilde{v})_n) - D_2 f(\bar{v}_n, \bar{v}'_n)\| + \sum_{i=1}^{p} |\tilde{\mu}_i - \bar{\mu}_i| \|S_1^i\| \\ &\le \text{const}\left(h^2 + \mathrm{e}^{-\alpha h \min\{n_-, n_+\}}\right),\end{aligned}$$

and similarly

$$\left\|\tilde{C}_n - C(x_n)\right\| \le \text{const}\left(h^2 + \mathrm{e}^{-\alpha h \min\{-n_-, n_+\}}\right).$$

This implies that T is a perturbation of $\tilde{T}$ of order h. As in the previous proof, the assumptions on the phase condition in Hypothesis 3.7 follow with the definition of Ψ directly from the assumptions on $\hat{X}$. The rest of the arguments is the same as in the proof of Theorem 2.5. ∎

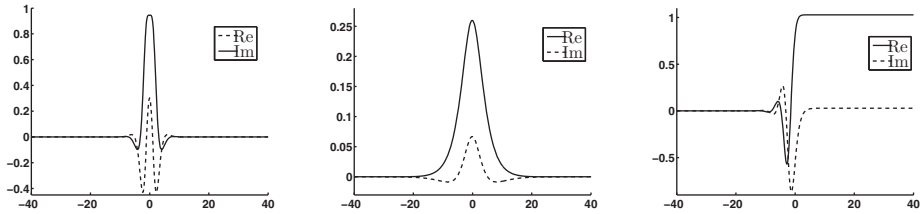
5. Numerical results. We illustrate the approximation results on the cubic quintic Ginzburg–Landau equation, a reaction-diffusion equation for which exact solutions are known. We compare the order of approximation for different grid sizes h and intervals J with the expected behavior from Theorems 2.5 and 2.6. Similar experiments have been conducted for traveling wave solutions of the Nagumo equation in [25]. The cubic quintic Ginzburg–Landau equation [24], [28], [9] reads

$$u_t = a u_{xx} + \delta u + g(u), \quad g(u) = \beta |u|^2 u + \gamma |u|^4 u, \ \delta \in \mathbb{R}, \ a, \beta, \gamma \in \mathbb{C}. \tag{5.1}$$

It shows a variety of coherent structures, such as stable pulse solutions, fronts, sources, sinks, etc.

For numerical computations we write (5.1) in real variables; then (5.1) has the equivariance properties given in Example 1.4. For the parameter set $a = 1$, $\delta = -0.1$, $\beta = 3 + i$, $\gamma = -2.75 + i$, which has been used in [24], this equation possesses a stable rotating pulse (Figure 5.1(a)), an unstable rotating pulse [24] (Figure 5.1(b)), and a rotating and traveling front (Figure 5.1(c)). All of these solutions can (in real notation) be written in the form (1.13) where $\bar{\mu}_\tau = 0$ in the case of the rotating pulse. Thus these solutions are relative equilibria in the sense of Definition 1.1 (cf. Example 1.4). Depending on the choice of initial conditions, a different type of solution is selected.

To solve the boundary value problem (2.2) we use Newton's method with initial data that in the stable cases 5.1(a) and 5.1(c) has been generated by using the method



(a) stable pulse (b) unstable pulse (c) front

FIG. 5.1. *Cubic quintic Ginzburg–Landau system: stable/unstable pulse and stable front.*

of freezing described in [5], [25], [6]. For the unstable case 5.1(b) there is an explicit formula that has been derived in [15] by using Painlevé methods, which reads (in complex notation)

$$u(x,t) = \mathrm{e}^{-i\bar{\mu}_\rho t}\ \bar{v}(x), \tag{5.2}$$

where

$$\bar{v}(\xi) = u_0 \mathrm{e}^{ia_0\theta_0\xi}(\cosh(k\xi) - \cosh(\rho))^{ia_0}\sqrt{\frac{k\sinh(\rho)}{\cosh(k\xi)+\cosh(\rho)}}\ .$$

The parameters $u_0, a_0, \theta_0, \rho, \bar{\mu}_\rho$, and k can be computed explicitly from a, δ, β, and γ by the formulas given in [15].

Figure 5.1 shows the numerical solutions on the interval $[-40, 40]$ with mesh size $h = 0.1$ using Dirichlet and Neumann boundary conditions.

In case 5.1(b) we can illustrate the results of Theorems 2.5 and 2.6 in sections 5.1 and 5.2. While the numerics seems to work in every case, Theorems 2.5 and 2.6 apply to cases 5.1(a) and 5.1(b) but not to 5.1(c). To some surprise the method seems to work as well, but it is hard to derive a numerical test to check the validity of the estimates of Theorems 2.5 and 2.6 in this case.

5.1. Approximation of the unstable pulse. We compare the approximation error of the solution of the boundary value problem (2.2) with the estimates (2.10) in Theorem 2.5. For the unstable pulse the exact solution is explicitly given by (5.2). Figure 5.2 shows the approximation error of the pulse for Dirichlet boundary

conditions. Here the interplay between the discretization error, which varies with the step size h, and the truncation error, which varies with the interval length T, is clearly visible. The grid size h is varied exponentially in $[10^{-4}, 10^{-1}]$ and the size T of the symmetric interval J linearly in $[20, 80]$.

As shown in Figure 5.2 the rate of convergence of μ_ρ to $\bar{\mu}_\rho \approx 0.0573$ is of order 2 in h and the exponential rate in T is $\alpha \approx 0.15$ (cf. Table 5.1). In contrast, μ_τ reaches quickly the range of machine precision where rounding errors dominate and the bad conditioning of the equations in the Newton iteration becomes prominent. The wave $\tilde{v}$ itself converges also as predicted with order 2 in h (cf. Table 5.1 and Figure 5.3(a)) and with $\alpha \approx 0.16$ in T (cf. Table 5.1 and Figure 5.3(b)). This behavior can be observed in $\|\cdot\|_{\mathcal{H}_h^2}$ as well as in $\|\cdot\|_\infty$ (see Figures 5.2(c) and 5.2(d)). Note that the exponent α of convergence w.r.t. the interval length T depends on the asymptotics of the exact solution for $x \to \pm\infty$. In all cases the overall behavior matches estimate (2.10) in Theorem 2.5.

5.2. Approximation of discrete eigenvalues. In this section we compare the approximation error of the solution of the eigenvalue problem (2.4) for the unstable pulse with the estimates (2.11) in Theorem 2.6. In order to solve the eigenvalue problem (2.4) we use a Newton iteration, starting from $\hat{X} = [\bar{v}'_{|J_h}, R_{\frac{\pi}{2}} \bar{v}_{|J_h}]$. Alternatively one can use an Arnoldi iteration to compute the two eigenvalues of smallest magnitude of the corresponding generalized eigenvalue problem. This leads to similar results.

The angle between the approximating subspace X and $\hat{X}$ (see [10]) and the absolute values of the two eigenvalues near zero are shown in Figure 5.4. Here σ_τ denotes the eigenvalue which belongs to the approximation of the translational eigenfunction $\bar{v}'$, and σ_ρ is the eigenvalue which belongs to the approximation of the eigenfunction $R_{\frac{\pi}{2}}\bar{v}$. It can be seen that the eigenvalue σ_τ is in the range of machine precision; thus the errors increase for decreasing h, since the condition of the eigenvalue problem gets worse. The error in the rotational eigenvalue σ_ρ is nearly constant for different h but decreases for increasing T, as expected (cf. Table 5.2). For very small h and large T the increase in error due to the conditioning becomes visible as well. The angle between the invariant subspace which belongs to σ_τ and σ_ρ and the span of the exact

FIG. 5.5. *Approximation error* $\epsilon_v = \angle(X, [\bar{v}'|_{J_h}, R_{\frac{\pi}{2}}\bar{v}|_{J_h}])$ *for the invariant subspace for fixed* h *and fixed* T*, respectively.*

eigenfunctions $\bar{v}'$ and $R_{\frac{\pi}{2}}\bar{v}$ of Λ restricted to the grid shows the expected behavior. It decreases quadratically in h and exponentially in T with a rate of $\alpha \approx -0.32$ (cf. Table 5.2 and Figure 5.5) until the range of machine precision is reached.

6. Conclusions. This paper gives a detailed study of the numerical approximation of relative equilibria of parabolic equations on the real line. These can be obtained as a stationary solution of a suitable boundary value problem. This is derived in an abstract setting, which reveals their underlying structure and makes it possible to deal with different symmetry groups in a general fashion. The discretization of this boundary value problem with a widely used numerical discretization and rather general boundary conditions is analyzed in detail. In particular, error estimates are given that are uniform in the step size and in the length of the finite interval. Although the use of dynamical systems tools such as exponential dichotomies restricts the analysis to one space dimension, the general methodology described in section 1.1 also works in higer space dimensions [5], [6]. Moreover, many one-dimensional phenomena such as traveling and rotating waves have relevant applications to systems from biology, chemistry, and physics. We expect that the results of this paper as well as some of the techniques can be generalized to higher space dimensions and to more refined structures such as wave trains or modulated waves. This corresponds to point-to-periodic or periodic-to-periodic connecting orbits, for which approximation results for the truncation to finite intervals have been derived in [21].

Acknowledgments. We wish to thank the referees for their valuable comments, which helped improve the exposition of this paper.

POLYNOMIAL EXTENSION OPERATORS. PART I*

LESZEK DEMKOWICZ†, JAYADEEP GOPALAKRISHNAN‡, AND JOACHIM SCHÖBERL§

Abstract. In this series of papers, we construct operators that extend certain given functions on the boundary of a tetrahedron into the interior of the tetrahedron, with continuity properties in appropriate Sobolev norms. These extensions are novel in that they have certain polynomial preservation properties important in the analysis of high order finite elements. This part of the series is devoted to introducing our new technique for constructing the extensions, and its application to the case of polynomial extensions from $H^{1/2}(\partial K)$ into $H^1(K)$, for any tetrahedron K.

Key words. Sobolev, polynomial, extension, tangential, normal, trace

DOI. 10.1137/070698786

1. Introduction.

This paper is the first in a series of papers that construct extension operators with certain polynomial preservation properties for the three basic first-order Sobolev spaces

$$H^1(D) = \{u \in L^2(D) : \ \mathbf{grad}\, u \in \boldsymbol{L}^2(D)\} \tag{1.1}$$

$$\boldsymbol{H}(\mathbf{curl}, D) = \{\boldsymbol{u} \in \boldsymbol{L}^2(D) : \ \mathbf{curl}\, \boldsymbol{u} \in \boldsymbol{L}^2(D)\} \tag{1.2}$$

$$\boldsymbol{H}(\mathrm{div}, D) = \{\boldsymbol{u} \in \boldsymbol{L}^2(D) : \ \mathrm{div}\, \boldsymbol{u} \in L^2(D)\}. \tag{1.3}$$

Here the derivatives are understood in the distributional sense, $L^2(D)$ denotes the set of square integrable functions (with respect to the Lebesgue measure) on an open subset D of the three-dimensional Euclidean space, and $\boldsymbol{L}^2(D)$ denotes the set of vector functions whose components are in $L^2(D)$. The domain into which our extensions are performed is a tetrahedron K.

Extension operators are right inverses of trace maps. To describe the traces of the spaces in (1.1)–(1.3), let ϕ be a smooth scalar function and $\boldsymbol{\phi}$ is a smooth vector function on K. Then three standard trace operators are

$$\begin{aligned}
&\mathrm{trc}\, \phi = \phi|_{\partial K}, && \text{(scalar trace)},\\
&\mathrm{trc}_\tau\, \boldsymbol{\phi} = \big(\boldsymbol{\phi} - (\boldsymbol{\phi}\cdot\boldsymbol{n})\boldsymbol{n}\big)\big|_{\partial K}, && \text{(tangential trace)},\\
&\mathrm{trc}_n\, \boldsymbol{\phi} = (\boldsymbol{\phi}\cdot\boldsymbol{n})\big|_{\partial K}, && \text{(normal trace)}.
\end{aligned}$$

where $\boldsymbol{n}$ denotes the outward unit normal on ∂K. It is well known that trc extends to a continuous operator (which we continue to call trc) from $H^1(K)$ onto $H^{1/2}(\partial K)$ [17]. Similarly, the tangential trace trc_τ is well defined on $\boldsymbol{H}(\mathbf{curl}, K)$ and its range is a

subspace of $\boldsymbol{H}^{-1/2}(\partial K)$, and the normal trace trc_n is well defined on $\boldsymbol{H}(\mathrm{div}, K)$ [6] with its range equal to $H^{-1/2}(\partial K)$. We want to construct continuous extension operators that map functions on the boundary of a tetrahedron lying in the range of $\mathrm{trc}, \mathrm{trc}_\tau$, and trc_n into $H^1(K), \boldsymbol{H}(\mathbf{curl}, K)$, and $\boldsymbol{H}(\mathrm{div}, K)$, respectively.

A *polynomial extension operator* is an extension operator with the additional property that whenever the function on ∂K to be extended is the trace of a polynomial on K, the extended function is also a polynomial.

1.1. Goal. Our aim in this series of papers is to construct three polynomial extension operators $\mathcal{E}_K^{\mathrm{grad}}, \mathcal{E}_K^{\mathrm{curl}}$, and $\mathcal{E}_K^{\mathrm{div}}$ on any tetrahedron K such that the following diagram commutes:

$$\begin{array}{ccccc} H^{1/2}(\partial K) & \xrightarrow{\mathbf{grad}_\tau} & \mathrm{trc}_\tau(\boldsymbol{H}(\mathbf{curl}, K)) & \xrightarrow{\mathrm{curl}_\tau} & \mathrm{trc}_n(\boldsymbol{H}(\mathrm{div}, K)) \\ \downarrow \mathcal{E}_K^{\mathrm{grad}} & & \downarrow \mathcal{E}_K^{\mathrm{curl}} & & \downarrow \mathcal{E}_K^{\mathrm{div}} \\ H^1(K) & \xrightarrow{\mathbf{grad}} & \boldsymbol{H}(\mathbf{curl}, K) & \xrightarrow{\mathbf{curl}} & \boldsymbol{H}(\mathrm{div}, K) \end{array} \tag{1.4}$$

The goal of this part of the series is to construct the first in the sequence of these operators, namely, $\mathcal{E}_K^{\mathrm{grad}}$. In the forthcoming parts [11, 12], we will construct the other two polynomial extension operators. Next, we state precisely the properties we require for $\mathcal{E}_K^{\mathrm{grad}}$.

1.2. The $H^1(K)$ polynomial extension problem. The problem we occupy ourselves with in this paper is that of constructing a linear operator $\mathcal{E}_K^{\mathrm{grad}} : H^{1/2}(\partial K) \mapsto H^1(K)$ with the following properties:

(1.5)

The trace of $\mathcal{E}_K^{\mathrm{grad}} u$ on ∂K coincides with u; i.e., $\mathrm{trc}\left(\mathcal{E}_K^{\mathrm{grad}} u\right) = u$.

(1.6)

$\mathcal{E}_K^{\mathrm{grad}}$ is a continuous map from $H^{1/2}(\partial K)$ into $H^1(K)$; i.e., there is a constant C_{grad} independent of u such that

$$\|\mathcal{E}_K^{\mathrm{grad}} u\|_{H^1(K)} \leq C_{\mathrm{grad}} \|u\|_{H^{1/2}(\partial K)} \qquad \text{for all } u \in H^{1/2}(\partial K).$$

(1.7)

If u is a polynomial of degree at most p on each face of K and continuous on ∂K, then $\mathcal{E}_K^{\mathrm{grad}} u$ is a polynomial of degree at most p on K.

The main result of this paper is Theorem 6.1, which solves the problem as stated above.

1.3. Existing work. The concept of extension operators is intimately related with the idea of the trace operators and it has been present in the vast literature on Sobolev spaces for a long time. For instance, the proof of subjectivity of trace operator for standard Sobolev spaces $H^s(\Omega)$ is based on the Lion's construction of a corresponding extension operator; see, e.g., [23, Lemma 3.36]. It is perhaps worth mentioning that, contrary to this trace operator, the extension operator does not break down at half-integers and that the same construction serves the whole Sobolev scale for $s \in \mathbb{R}$.

The subject of polynomial preserving extension operators originates from the convergence analysis for the *p*- and *hp*-versions of the Finite Element Method (FEM).

The first construction of such an operator is for the H^1-space on a two-dimensional region and is due to Babuška and Suri [3]. It contains the origins of many ideas that have been generalized and developed in subsequent contributions. Those include the definition of the primary extension operator (cf. section 2 of this contribution), the solution of a 'two-edge extension problem' using a system of two integral equations, and the analysis of continuity properties of 'edge-to-edge operators' necessary for the solution of an ultimate 'three edge extension' problem. The analysis was carried out first for a triangle and then extended to the case of a square element by using a bilinear map collapsing a square into a triangle. The construction from [3] appears again in a later paper [2] by Babuška, Craig, Mandel, and Pitkäranta, in the context of preconditioning for the p version of the FEM.

The two-dimensional polynomial preserving extension operator was subsequently utilized by Maday [21, 22] to demonstrate that interpolation between polynomial spaces equipped with Sobolev integer norms yields norms equivalent to the standard fractional Sobolev norms. A recent exposition of this subject is contained in [5]. Maday [22] also studied the continuity properties of the Babuška–Suri operator in weighted Sobolev spaces.

The first construction of a polynomial preserving extension operator in three space dimensions from $H^{1/2}(\partial U)$ into $H^1(U)$ was done for a cube U by Ben Belgacem in [4]. The construction utilized the earlier results of Maday mentioned above. The second construction was done for a tetrahedron by Muñoz-Sola [24]. The idea of Muñoz-Sola is rooted in the construction of "face bubble" shape functions for tetrahedral FEM. If ζ is the product of barycentric coordinates of the vertices of a face, then the face bubble functions have ζ as a factor. Muñoz-Sola applies a three-dimensional analogue of the Babuška–Suri extension to the quotient ϕ/ζ, and multiplies the factor ζ back into the extension. The resulting lift vanishes on the remaining faces and displays appropriate continuity properties. The Muñoz-Sola's construction was recently analyzed in [18] in the context of boundary elements, wherein it is shown that the norm of the extension as an operator from L^2 into $\tilde{H}^{1/2}$ grows with polynomial order p as $\log^{1/2} p$. (Here $\tilde{H}^{1/2}$ is the stronger intrinsic norm on the subspace of $H^{1/2}$ with weakly vanishing traces—see [18] for its definition.) Although the tetrahedral H^1 polynomial extension problem, as stated in (1.2), was solved by Muñoz-Sola [24], in this paper we want to present an alternate solution to the same problem. The main reason for presenting our new construction is that our techniques can be generalized to give polynomial extensions in the other two Sobolev spaces in (1.2) and (1.3), as will be amply evident from the subsequent parts of this series [11, 12]. Furthermore, with our techniques, we are able to provide polynomial extensions with the commutativity properties shown in (1.4), which we find aesthetic as well as useful. It is not clear to us if the technique in [24] can yield such extensions, but we do recognize the importance of [24], and indeed some of our arguments are motivated by it.

The need for polynomial preserving extension operators, at least in the analysis of p methods in H^1, is well known, as attested by the above-mentioned works. In fact, they are important also in other areas, such as in the theory of spectral methods even on one element as shown in [15], and for preconditioning as shown in [25]. The importance of polynomial extensions in the context of p and hp approximation theory for Maxwell equations was first recognized by Demkowicz and Babuška in [9], who considered the two-dimensional triangular case. For a triangle T, the construction of a polynomial preserving extension operator from $H^{-1/2}(\partial T)$ into $H(\mathrm{curl}, T)$ follows directly from the corresponding construction for the H^1-case, and presents no essential technical difficulties. The utility of the polynomial extension operators in $H^1(T)$ and

$H(\mathrm{curl}, T)$, forming a commuting de Rham diagram in developing approximations using "projection-based interpolation operators," is evident from [9]. The projection-based interpolation theory was generalized to three space dimensions (tetrahedra) by Demkowicz and Buffa in [10], under the conjecture of existence of commuting, polynomial preserving extension operators for the three spaces $H^1(K)$, $\boldsymbol{H}(\mathbf{curl}, K)$, and $\boldsymbol{H}(\mathrm{div}, K)$ (for a refined version of the theory in context of both tetrahedral and hexahedral elements, see [13]). The extensions we construct in this series of papers establish the truth of this conjecture, thus providing the missing link in the approximation theory of [10].

An alternate technique for constructing commuting $H^1(T)$ and $H(\mathrm{curl}, T)$ polynomial extensions deserves special mention. In two space dimensions, for any triangle T, Ainsworth and Demkowicz [1] constructed polynomial extensions explicitly by solving a system of three integral equations in the spirit of the system of two integral equations analyzed in [3]. The $H^1(T)$ extension operator has smaller norm than the two-dimensional version of the Muñoz-Sola's operator [24] and can be used for constructing optimal shape functions for a triangular element. The Ainsworth–Demkowicz operator was also shown to map $L^2(\partial K)$ into $H^{1/2}(K)$, with a constant independent of polynomial order p (cf. this result with that of [18] mentioned above). Unfortunately, our attempts to extend the Ainsworth–Demkowicz technique to three dimensions failed as the analysis reached prohibitive levels of complexity.

To the best of our knowledge, our commuting polynomial extensions for a tetrahedron is the first result of this kind. To compare with the most recent other work in this direction that we know of, the contribution of Costabel, Dauge, and Demkowicz [8] presents an analogous family of commuting extension operators defined on polynomial spaces on a cube. The construction mimics separation of variables for polynomial spaces and is based on the Maday's spectral equivalence results for fractional spaces mentioned earlier. However, these extension operators defined on polynomial spaces change with the polynomial degree, although their norms are shown to be independent of polynomial degree p. In contrast, the expressions defining our extensions do not vary with degree.

1.4. Overview of our techniques. Our approach to solve the problem stated above starts with a study of the simpler case of extending a given function from just one face. Then we will analyze how to modify this extension process to solve the case when data is given on more faces. We highlight the main new techniques in the construction of our extension operators:

1. *Primary extensions:* We start with processes that extend functions given on the plane $\mathbb{R}^2$, which we call "primary extensions". In constructing the final extension from ∂K, the first step is to pick a face of ∂K and apply the primary extension from that face. Of course, such an extended function in general will not have the needed traces in the remaining faces.
2. *Corrections:* The next step is to "correct" the above-mentioned incorrect traces on the remaining faces. This step is divided into the construction of "face correction operators," "edge correction operators," and a "vertex correction operator." Most of the technical aspects of the presented construction are in the design of these corrections.
3. *Commutativity:* Once we construct the first operator appearing in the commuting diagram (1.4), namely $\mathcal{E}_K^{\mathrm{grad}}$, then the construction of the succeeding operators is motivated by the commutativity properties in (1.4). Indeed, to obtain $\mathcal{E}_K^{\mathrm{curl}}$, we consider each of the primary and correction operators that

went into the design of the preceding operator $\mathcal{E}_K^{\text{grad}}$, and find corresponding $\boldsymbol{H}(\mathbf{curl})$ operators that commute with it. Similarly, the construction of the $\boldsymbol{H}(\text{div})$ extension will proceed by examining the steps in the construction of the $\boldsymbol{H}(\mathbf{curl})$ extension and finding their commuting $\boldsymbol{H}(\text{div})$ analogues. This will be clear from Parts II [11] and III [12] of this series.

4. *Regular decomposition of traces:* In the $\boldsymbol{H}(\mathbf{curl})$ and $\boldsymbol{H}(\text{div})$ cases where traces are in Sobolev spaces of negative index, we will characterize the trace space using a decomposition involving Sobolev spaces of positive indices only. This will feature in Parts II [11] and III [12] only, as the trace space of $H^1(K)$ is $H^{1/2}(\partial K)$, a Sobolev space of positive index.
5. *Weighted norm estimates:* The extension operators we construct are all integral operators with polynomial kernels. To establish their continuity properties in appropriate fractional Sobolev norms, we use weighted norm estimates. We are able to do this even when traces are in Sobolev spaces of negative index, because of the above-mentioned regular decomposition of the trace space. A number of weighted norm estimates used throughout this series are given in Appendix A of this part.

1.5. Notations. For ready reference, we quickly list here some notations that we will use throughout this series.

The "reference tetrahedron" $\hat{K}$ is defined by

$$\hat{K} = \{(x, y, z) : x \geq 0,\ y \geq 0,\ x + y + z \leq 1\},$$

with the following enumeration of vertices:

$$\hat{\boldsymbol{a}}_0 = (0, 0, 0),\ \hat{\boldsymbol{a}}_1 = (1, 0, 0),\ \hat{\boldsymbol{a}}_2 = (0, 1, 0),\ \text{and } \hat{\boldsymbol{a}}_3 = (0, 0, 1).$$

The face of $\hat{K}$ opposite to vertex $\hat{\boldsymbol{a}}_i$ is denoted by $\hat{F}_i$. The face $\hat{F}_3$ is distinguished in that the data for the primary extensions is given there, so we shall also denote it simply by $\hat{F}$. The edge connecting $\hat{\boldsymbol{a}}_i$ and $\hat{\boldsymbol{a}}_j$ is denoted by $\hat{E}_{ij}$.

We denote by K a generic tetrahedron (of positive volume). When the notations defined for $\hat{K}$ above are employed without the superscript (hat), they denote the corresponding geometrical objects on a general tetrahedron K; e.g., $\boldsymbol{a}_i$ denotes the vertices of K, and F_i is the face of K opposite to the vertex $\boldsymbol{a}_i$.

Let $\lambda_i(\boldsymbol{x})$, for $i = 0, \ldots 3$ be the linear function on K satisfying $\lambda_i(\boldsymbol{a}_j) = \delta_{ij}$. The *affine coordinates* (or barycentric coordinates) of a point in K are the values of λ_i at that point arranged into a 4-tuple $(\lambda_i, \lambda_j, \lambda_k, \lambda_l)$, where the order is not significant. Throughout this series, the indices i, j, k, l are a permutation of $0, 1, 2, 3$.

Many integral operators we consider will require us to integrate over subtriangles of a face F_l of K. We now express these subtriangles using the affine coordinates of F_l, namely $\lambda_m^{F_l} = \lambda_m|_{F_l}$ for $m = i, j$, or k. For any permutation $\{i, j, k, l\}$ of $\{0, 1, 2, 3\}$, we define

$$T_l(r_i, r_j, r_k) = \left\{\boldsymbol{x} \in F_l :\ \lambda_i^{F_l}(\boldsymbol{x}) \geq r_i,\ \lambda_j^{F_l}(\boldsymbol{x}) \geq r_j,\ \text{and } \lambda_k^{F_l}(\boldsymbol{x}) \geq r_k\right\}. \tag{1.8}$$

Note that the order of the arguments r_i, r_j, r_k in the notation $T_l(r_i, r_j, r_k)$ is not significant, but the subscripts of these arguments indicate to which affine coordinate it corresponds. This region is illustrated in Figure 1. Also, define

$$T_l(0, r_j, r_k) = \left\{\boldsymbol{x} \in F_l :\ \lambda_j^{F_l}(\boldsymbol{x}) \geq r_j,\ \text{and } \lambda_k^{F_l}(\boldsymbol{x}) \geq r_k\right\}, \tag{1.9}$$

$$T_l(0, 0, r_i) = \left\{\boldsymbol{x} \in F_l :\ \lambda_i^{F_l}(\boldsymbol{x}) \geq r_i\right\}. \tag{1.10}$$

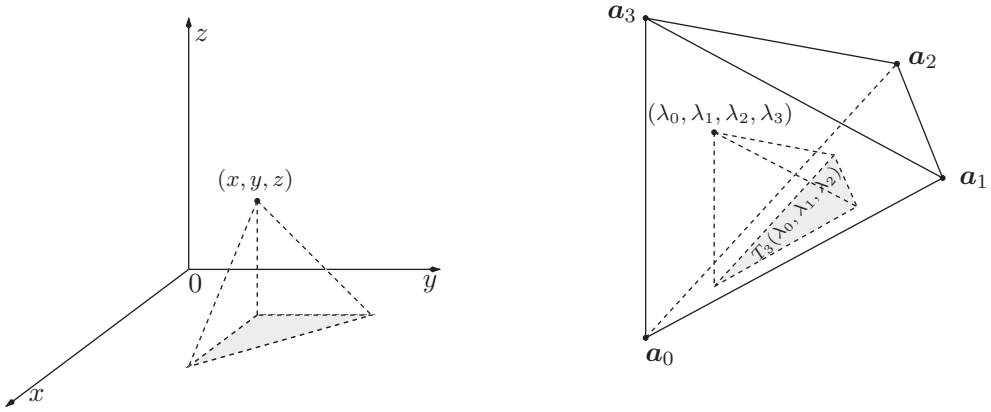

FIG. 1. *The regions of integration that define* $\mathcal{E}^{\mathrm{grad}}u$. *The left figure shows the integration region in gray for the extension from the x-y plane. The right figure shows the integration region for the mapped extension from a face of a general tetrahedron.*

Note that the definition of $T_l(0, r_j, r_k)$ is consistent with (1.8) when $r_i = 0$. Similarly the definition of $T_l(0, 0, r_i)$ is consistent with (1.8) when $r_j = r_k = 0$. In particular, from the indices of the arguments, we judge which barycentric coordinates are zero; e.g., in $T_l(0, r_k, 0)$, since l and k have already appeared, and since $\{i, j, k, l\}$ is a permutation of $\{0, 1, 2, 3\}$, we understand that the affine coordinates with indices that have not appeared, namely $\lambda_i^{F_l}$ and $\lambda_j^{F_l}$, are simply greater than or equal to zero: $T_l(0, r_k, 0) = \{\boldsymbol{x} \in F_l : \ \lambda_k^{F_l}(\boldsymbol{x}) \geq r_k, \ \lambda_i^{F_l}(\boldsymbol{x}) \geq 0, \ \lambda_j^{F_l}(\boldsymbol{x}) \geq 0\}$, which is consistent with (1.8). See Figures 1, 3, and 4 for illustrations of these subtriangles.

Our notation for Sobolev spaces is standard: Let $H^s(D)$ denote the standard Sobolev space of order s on domain D; e.g., when $s = 1$ the definition is as in (1.1). See, e.g., [14, 19, 23] for the more complex definitions in the case when s is fractional. The definitions of $\boldsymbol{H}(\mathbf{curl}, D)$ and $\boldsymbol{H}(\mathrm{div}, D)$ are already given in (1.2)–(1.3). To shorten the notation, when the domain is K, we often simply write $\boldsymbol{H}(\mathbf{curl})$ for $\boldsymbol{H}(\mathbf{curl}, K)$ (and similarly $\boldsymbol{H}(\mathrm{div})$).

In inequalities bounding function norms, we denote by C (or C with some subscript) a generic constant whose value at different occurrences may differ but is independent of the functions involved.

2. The primary extension operator. The primary extension operator for the $H^1(K)$ case follows from the well-known, two-dimensional polynomial extension from a line [2], as generalized to three space dimensions in [24]. Suppose $u(x, y)$ is a smooth function given on the face $\hat{F}$ of $\hat{K}$ (see section 1.5 for notation). The primary extension maps u to a function $\mathcal{E}^{\mathrm{grad}}u$ defined on $\hat{K}$ as follows:

$$\mathcal{E}^{\mathrm{grad}}u\,(x, y, z) = \frac{2}{z^2}\int_x^{x+z}\int_y^{x+y+z-\widetilde{x}} u(\widetilde{x}, \widetilde{y})\, d\widetilde{y}\, d\widetilde{x}. \tag{2.1}$$

Clearly, the value of the extension at the point (x, y, z) is determined by integrating u over the triangle with vertices $(x, y, 0), (x + z, y, 0)$, and $(x, y + z, 0)$, as shown in the first illustration of Figure 1. Note that $\mathcal{E}^{\mathrm{grad}}$ can be thought of either as an extension from the plane $\mathbb{R}^2$ into the adjacent infinite slab $\mathbb{R}^2 \times (0, 1) \equiv \{(x, y, z) : 0 < z < 1\}$, or as an extension from the face $\hat{F}$ into $\hat{K}$.

THEOREM 2.1. *The following statements apply to* $\mathcal{E}^{\mathrm{grad}}$*:*

(1) *The operator* $\mathcal{E}^{\mathrm{grad}}$ *defined for smooth functions* u *by* (2.1) *extends as a continuous operator from* $H^{1/2}(\hat{F})$ *to* $H^1(\hat{K})$*; i.e., there is a constant* $C > 0$ *such that*

$$\|\mathcal{E}^{\mathrm{grad}}u\|_{H^1(\hat{K})} \leq C\|u\|_{H^{1/2}(\hat{F})},$$

for all u *in* $H^{1/2}(\hat{F})$.

(2) *The trace of* $\mathcal{E}^{\mathrm{grad}}u$ *on* $\hat{F}$ *equals* u *for all* u *in* $H^{1/2}(\hat{F})$.

(3) *If* u *is a polynomial of degree at most* p*, then* $\mathcal{E}^{\mathrm{grad}}u$ *is also a polynomial of degree at most* p.

Proof. The proof of the continuity estimate in the first item proceeds by a standard technique involving the Fourier transform. We have included this proof in Appendix B. (In Part II [11], we will develop an alternate technique.)

The second statement of the theorem is immediately verified for smooth u, once we rewrite (2.1) by a change of variable as

$$\mathcal{E}^{\mathrm{grad}}u\,(x,y,z) = 2\int_0^1\int_0^{1-s} u(x+sz, y+tz)\,dt\,ds. \tag{2.2}$$

So, by the standard density argument, it follows for all $u \in H^{1/2}(\hat{F})$.

To prove the last statement of the theorem, observe that if u is a polynomial of degree at most p, then the integrand $u(x+sz, y+tz)$ in (2.2) is a polynomial of degree at most p in x, y, and z, with coefficients depending on s and t. After integrating over s and t, we continue to have a polynomial of degree at most p in x, y, and z. ∎

Since any tetrahedron can be mapped one-one onto $\hat{K}$ using an affine map, the above definition of $\mathcal{E}^{\mathrm{grad}}$ automatically defines an extension from a face for any tetrahedron. The expressions for such mapped extensions are greatly simplified by the use of affine coordinates (or barycentric coordinates) of the tetrahedron. Let K be any tetrahedron. Suppose u is a smooth function defined on a face F_l of K and we want to extend it to K. The extension operator on K now involves integration of u over a subtriangle of F_l. We express such subtriangles using the notations established in section 1.5. The extension from F_l into K is defined by

$$\mathcal{E}_l^{\mathrm{grad}}u\,(\lambda_i,\lambda_j,\lambda_k,\lambda_l) = \frac{2}{\lambda_l^2}\iint_{T_l(\lambda_i,\lambda_j,\lambda_k)} u(\boldsymbol{s})\,d\boldsymbol{s}, \tag{2.3}$$

where $\boldsymbol{s}$ is the two-dimensional variable of integration running over the subtriangle $T_l(\lambda_i,\lambda_j,\lambda_k)$ defined in (1.8) and $d\boldsymbol{s}$ is the standard (two-dimensional) Lebesgue measure on this subtriangle. (The region of integration is illustrated in Figure 1.) Clearly, the definition in (2.3) reduces to (2.1) if we choose $l = 3$ and $K = \hat{K}$. An analogue of Theorem 2.1 obviously holds for the operator in (2.3) by mapping.

3. Face corrections. From the definition of $\mathcal{E}_l^{\mathrm{grad}}u$, it is clear that when u is a smooth function on F_l which vanishes on the boundary ∂F_l, the extended function $\mathcal{E}_l^{\mathrm{grad}}u$, in general, does not have zero trace on $\partial K \setminus F_l$. Now we show how to add a correction to $\mathcal{E}_l^{\mathrm{grad}}u$ so that the corrected result will have zero trace on a face other than F_l.

For definiteness, we first consider the situation on the face $\hat{F}_1$ of the reference tetrahedron $\hat{K}$ after the extension $\mathcal{E}^{\mathrm{grad}}u$ has been performed. The correction term

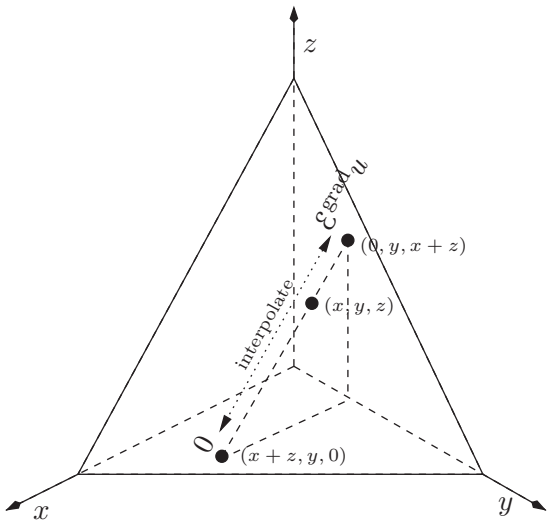

FIG. 2. *Illustration of the face correction process.*

for $\hat{F}_1$, namely, $\mathcal{E}^{\text{grad}}_{\hat{F}_1}u$, must be so that the corrected result $\mathcal{E}^{\text{grad}}u - \mathcal{E}^{\text{grad}}_{\hat{F}_1}u$ achieves zero trace on $\hat{F}_1$ without altering the trace on the original face $\hat{F}$. Therefore, we design the correction term by linear interpolation between the value of $\mathcal{E}^{\text{grad}}u$ on $\hat{F}_1$ and 0 along the lines where $x+z$ and y are constant (see Figure 2); i.e., we define

$$\mathcal{E}^{\text{grad}}_{\hat{F}_1}u\,(x,y,z) = \frac{z}{x+z}\,\mathcal{E}^{\text{grad}}u(0,y,x+z). \tag{3.1}$$

The interpolation process that we employed here has the following interesting continuity property in weighted spaces (whose proof appears in Appendix A). Our notation for weighted spaces is as follows: Let $L^2_w(D)$ denote the weighted space of all Lebesgue measurable functions f on a domain D (in $\mathbb{R}^n$ – in this paper $n = 1, 2$, or 3) such that $\|f\|^2_{L^2_w(D)} \equiv \int_D w\,|f|^2\,dx < \infty$. Here $w(x)$ is a nonnegative weight function on D and dx is the standard Lebesgue measure on D. Similarly, the weighted Sobolev space $H^1_w(D)$ consists of all functions in $L^2_w(D)$ whose first-order distributional derivatives are also in $L^2_w(D)$.

LEMMA 3.1. *The map $\mathcal{B}_{\hat{F}_1}$ defined by*

$$\phi(y,z) \;\mapsto\; \mathcal{B}_{\hat{F}_1}\phi := \frac{z}{x+z}\phi(y,x+z)$$

is continuous from $L^2_{1/z}(\hat{F}_1) \cap H^1_z(\hat{F}_1)$ into $H^1(\hat{K})$.

To study the face correction operator in (3.1), in addition to the above lemma, we shall need some more properties of the primary extension $\mathcal{E}^{\text{grad}}u$ involving weighted spaces.

LEMMA 3.2.

(1) *Let $\mathcal{R}^{\text{grad}}$ map smooth functions u on face $\hat{F}_3$ to functions on face $\hat{F}_1$ by*

$$u(x,y) \;\mapsto\; \mathcal{R}^{\text{grad}}u\,(y,z) := \mathcal{E}^{\text{grad}}u(0,y,z).$$

$\mathcal{R}^{\text{grad}}$ extends to a continuous map from $L^2_{1/x}(\hat{F}_3)$ into $L^2_{1/z}(\hat{F}_1) \cap H^1_z(\hat{F}_1)$.

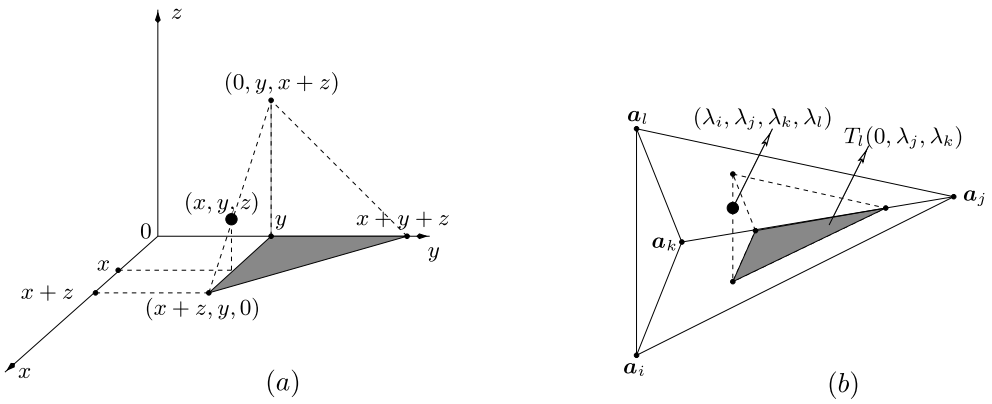

FIG. 3. *Domain of integration for face corrections* (*a*) *in the reference domain and* (*b*) *in a general tetrahedron.*

(2) *Let* $\mathcal{L}^{\mathrm{grad}}$ *map smooth functions* u *on face* $\hat{F}_3$ *to functions on edge* $\hat{E}_{03}$ *by*

$$u(x,y) \;\mapsto\; \mathcal{L}^{\mathrm{grad}}u\,(z) := \mathcal{E}^{\mathrm{grad}}u(0,0,z).$$

$\mathcal{L}^{\mathrm{grad}}$ extends to a continuous map from $L^2_{1/x}(\hat{F}_3)\cap L^2_{1/y}(\hat{F}_3)$ into $L^2(\hat{E}_{03})\cap H^1_{z^2}(\hat{E}_{03})$.

Proofs of this and all other lemmas appear in Appendix A. Note that although Theorem 2.1 needs u to be in $H^{1/2}(\hat{F})$ for $\mathcal{E}^{\mathrm{grad}}u$ to be in $H^1(\hat{K})$, the above lemma shows that the traces of $\mathcal{E}^{\mathrm{grad}}u$ on a face and an edge are well defined even when u is only in a weighted L^2 space.

Before stating the properties of $\mathcal{E}^{\mathrm{grad}}_{\hat{F}}$, let us extend its definition for any face of a general tetrahedron K, using the affine coordinate notation established in section 1.5. The face correction operator for a face F_i to correct the primary extension from face F_l is defined in affine coordinates by

$$\mathcal{E}^{\mathrm{grad}}_{F_i,l}u\,(\lambda_0,\lambda_1,\lambda_2,\lambda_3) = \frac{2\lambda_l}{(\lambda_i+\lambda_l)^3}\iint\limits_{T_l(0,\lambda_j,\lambda_k)} u(\boldsymbol{s})\,d\boldsymbol{s}, \tag{3.2}$$

where $T_l(0,r_j,r_k)$ is as defined in (1.9). The region of integration is illustrated in Figure 3.

Now suppose u is a smooth function on F_l which vanishes on one of its edges, say the edge connecting vertices $\boldsymbol{a}_j$ and $\boldsymbol{a}_k$, which we denote by E_{jk}. This edge is shared by F_i and F_l. The *two-face problem* is the problem of finding a polynomial extension of u from F_l that is zero on F_i. With the above-defined face correction, we are now able to solve the two-face problem. The extension operator that solves the F_i-F_l two-face problem is defined by

$$\mathcal{E}^{\mathrm{grad}}_{i,l}u = \mathcal{E}^{\mathrm{grad}}_{l}u - \mathcal{E}^{\mathrm{grad}}_{F_i,l}u. \tag{3.3}$$

It can be extended to an operator on

$$H^{1/2}_{0,i}(F_l) = H^{1/2}(F_l)\cap L^2_{1/\lambda_i}(F_l) \tag{3.4}$$

with the following properties:

PROPOSITION 3.1. *The two-face extension* $\mathcal{E}^{\mathrm{grad}}_{i,l}$ *satisfies the following:*

(1) $\mathcal{E}^{\mathrm{grad}}_{i,l}$ *is a continuous operator from* $H^{1/2}_{0,i}(F_l)$ *into* $H^1(K)$.
(2) *For all* $u \in H^{1/2}_{0,i}(F_l)$, *the trace of* $\mathcal{E}^{\mathrm{grad}}_{i,l}u$ *on* F_i *is zero, while its trace on* F_l *equals* u.
(3) *If* u *is a polynomial of degree at most* p *that vanishes on* E_{jk}, *then* $\mathcal{E}^{\mathrm{grad}}_{i,l}u$ *is a polynomial of degree at most* p.

Proof. To prove item (3.1), observe that since Theorem 2.1 yields

$$\|\mathcal{E}^{\mathrm{grad}}_{l}u\|_{H^1(K)} \le C\|u\|_{H^{1/2}(F_l)} \le C\|u\|_{H^{1/2}_{0,i}(F_l)},$$

it suffices to prove that $\mathcal{E}^{\mathrm{grad}}_{F_i,l}$ is a continuous map from $H^{1/2}_{0,i}(F_l)$ into $H^1(K)$. In fact, $\mathcal{E}^{\mathrm{grad}}_{F_i,l}$ is continuous on the larger space $L^2_{1/\lambda_i}(F_l)$, as we show now. Because $\mathcal{E}^{\mathrm{grad}}_{F_i,l}$ for any i is obtained by mapping $\mathcal{E}^{\mathrm{grad}}_{\hat{F}_1}$ from $\hat{K}$, it suffices to prove that $\mathcal{E}^{\mathrm{grad}}_{\hat{F}_1} : L^2_{1/x}(\hat{F}_3) \mapsto H^1(\hat{K})$ is continuous. By definition, $\mathcal{E}^{\mathrm{grad}}_{\hat{F}_1}$ is the composition

$$\mathcal{E}^{\mathrm{grad}}_{\hat{F}_1} = \mathcal{B}_{\hat{F}_1} \circ \mathcal{R}^{\mathrm{grad}}.$$

By Lemma 3.2, $\mathcal{R}^{\mathrm{grad}} : L^2_{1/x}(\hat{F}_3) \mapsto L^2_{1/z}(\hat{F}_1) \cap H^1_z(\hat{F}_1)$ is continuous, and by Lemma 3.1, $\mathcal{B}_{\hat{F}_1} : L^2_{1/z}(\hat{F}_1) \cap H^1_z(\hat{F}_1) \mapsto H^1(\hat{K})$ is continuous, hence the continuity of their composition follows.

Proof of (3.1): By (2.3) and (3.2),

$$\mathcal{E}^{\mathrm{grad}}_{i,l}u = \frac{2}{\lambda_l^2} \iint\limits_{T_l(\lambda_i,\lambda_j,\lambda_k)} u(\boldsymbol{s})\, d\boldsymbol{s} \;-\; \frac{2\lambda_l}{(\lambda_i+\lambda_l)^3} \iint\limits_{T_l(0,\lambda_j,\lambda_k)} u(\boldsymbol{s})\, d\boldsymbol{s}.$$

Since $\lambda_i = 0$ on face F_i, we immediately see after setting $\lambda_i = 0$ above, that the trace on F_i vanishes. The trace on F_l is u because the the last term above vanishes upon setting $\lambda_l = 0$, while the trace of $\mathcal{E}^{\mathrm{grad}}_{l}u$ on F_l is u (by Theorem 2.1).

Proof of (3.1): Going back to the reference tetrahedron, observe that if u vanishes on edge along the y-axis, then

$$u(x,y) = \, x\, u_{p-1}(x,y)$$

for some polynomial u_{p-1} of degree at most $p-1$. Using this in the face correction expression in (3.1), we have

$$\begin{aligned}
\left(\mathcal{E}^{\mathrm{grad}}_{\hat{F}_1}u\right)(x,y,z) &= \frac{z}{x+z}\int_0^1\int_0^{1-t} u(s(x+z), y+t(x+z))\, ds\, dt \\
&= \frac{z}{x+z}\int_0^1\int_0^{1-t} s(x+z)u_{p-1}(s(x+z), y+t(x+z))\, ds\, dt \\
&= z\int_0^1\int_0^{1-t} s u_{p-1}(s(x+z), y+t(x+z))\, ds\, dt.
\end{aligned}$$

The integral above is a polynomial of degree at most $p-1$ by the same arguments as in the proof of Theorem 2.1 (3.1); hence, the result follows. ∎

4. Edge corrections. If the function u (to be extended from face F_l) vanishes on ∂F_l, then we want the extended function to vanish on all faces other than F_l. After an application of the face correction operator for face F_i, the extension has zero trace on F_i. To obtain zero trace on another face, say F_j, we can consider applying the face correction operator for F_j. Unfortunately, after this second correction the resulting total trace on F_i will no longer be zero, in general. This necessitates the use of further correction operators which we discuss now.

Let us first consider the case of the reference tetrahedron $\hat{K}$ after the application of the face correction $\mathcal{E}^{\mathrm{grad}}_{\hat{F}_1}$. This operator alters the traces on face $\hat{F}_2$. In order to return this trace to its original setting, we use an additional correction operator whose trace coincides with that of $\mathcal{E}^{\mathrm{grad}}_{\hat{F}_1}u$ on $\hat{F}_2$. It is defined by linearly interpolating the value of $\mathcal{E}^{\mathrm{grad}}_{\hat{F}_1}u$ on this face down to zero along the lines where $y+z$ and x are constant:

$$\begin{aligned}\mathcal{E}^{\mathrm{grad}}_{\hat{E}_{03}}u(x,y,z) &= \frac{z}{y+z}\mathcal{E}^{\mathrm{grad}}_{\hat{F}_1}u(x,0,y+z),\\ &= \frac{z}{x+y+z}\mathcal{E}^{\mathrm{grad}}u(0,0,x+y+z), && \text{by (3.1)} \qquad (4.1)\\ &= \frac{2z}{(x+y+z)^3}\int_0^{x+y+z}\int_0^{x+y+z-\widetilde{x}} u(\widetilde{x},\widetilde{y})\,d\widetilde{y}\,d\widetilde{x}, && \text{by (2.1).} \qquad (4.2)\end{aligned}$$

We call this operator the "edge correction operator" for the $\hat{E}_{03}$ edge, because as is clear from (4.1), its action depends only on the value of $\mathcal{E}^{\mathrm{grad}}u$ along $\hat{E}_{03}$. The interpolation process from this edge to the tetrahedron implicit in (4.1) has the following continuity property:

LEMMA 4.1. *The map* $\mathcal{B}_{\hat{E}_{03}}$ *defined by*

$$\phi(z) \;\mapsto\; \mathcal{B}_{\hat{E}_{03}}\phi := \frac{z}{x+y+z}\phi(x+y+z)$$

is continuous from $L^2(\hat{E}_{03})\cap H^1_{z^2}(\hat{E}_{03})$ *into* $H^1(\hat{K})$.

Next, we generalize the expression in (4.2) to one in affine coordinates on a general tetrahedron. Let K be a general tetrahedron with the function to be extended given on face F_l. Let E_{il} denote the edge connecting the vertex $\boldsymbol{a}_i$ to $\boldsymbol{a}_l$. Then, the correction operator associated to the edge E_{il} is

$$\mathcal{E}^{\mathrm{grad}}_{E_{il},l}u\,(\lambda_0,\lambda_1,\lambda_2,\lambda_3) = \frac{2\lambda_l}{(1-\lambda_i)^3}\iint\limits_{T_l(0,0,\lambda_i)} u(\boldsymbol{s})\,d\boldsymbol{s}, \qquad (4.3)$$

where $T_l(0,0,r_i)$ is as defined in (1.10). The integration domain is illustrated in Figure 4.

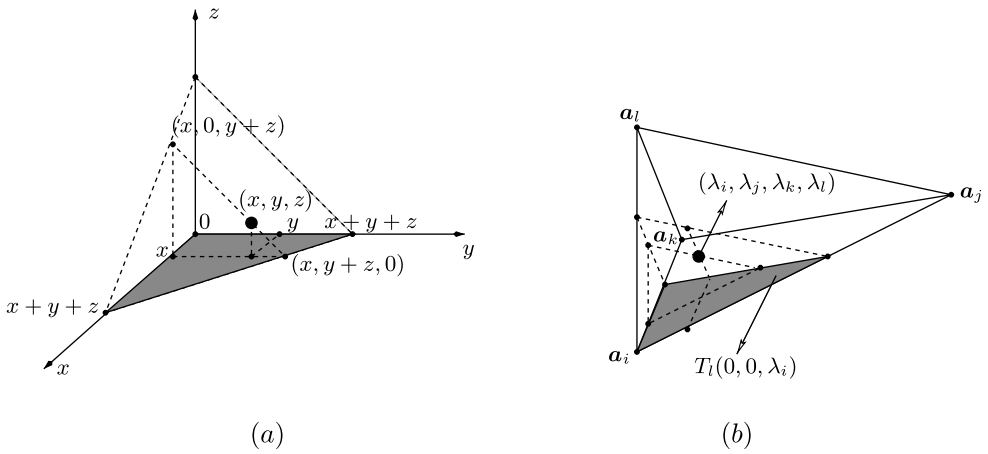
We can now solve the *three-face problem* of finding an extension of u from F_l that is zero on F_i and F_j whenever u is a smooth function that vanishes on edges E_{jk} and E_{ik}. The F_i-F_j-F_l three-face problem is solved by the extension operator

$$\mathcal{E}^{\mathrm{grad}}_{ij,l} = \mathcal{E}^{\mathrm{grad}}_{l} - \mathcal{E}^{\mathrm{grad}}_{F_i,l} - \mathcal{E}^{\mathrm{grad}}_{F_j,l} + \mathcal{E}^{\mathrm{grad}}_{E_{kl},l}, \qquad (4.4)$$

whose properties appear in the next proposition. The space to which $\mathcal{E}^{\mathrm{grad}}_{ij,l}$ can be extended continuously is

$$H^{1/2}_{0,ij}(F_l) = H^{1/2}(F_l)\;\cap\; L^2_{1/\lambda_i}(F_l)\;\cap\; L^2_{1/\lambda_j}(F_l) \qquad (4.5)$$

as seen below.



(a) (b)

FIG. 4. *Domain of integration for the edge correction operators in* (a) *reference domain, and* (b) *general tetrahedron.*

PROPOSITION 4.1. *The three-face extension* $\mathcal{E}^{\mathrm{grad}}_{ij,l}$ *satisfies the following:*

(1) $\mathcal{E}^{\mathrm{grad}}_{ij,l}$ *is a continuous operator from* $H^{1/2}_{0,ij}(F_l)$ *into* $H^1(K)$.

(2) *For all* $u \in H^{1/2}_{0,ij}(F_l)$ *the traces of the edge and face corrections satisfy*

$$\mathcal{E}^{\mathrm{grad}}_{F_i,l} u\big|_{F_k} = \mathcal{E}^{\mathrm{grad}}_{E_{jl},l} u, \tag{4.6}$$

$$\left(\mathcal{E}^{\mathrm{grad}}_{E_{jl},l} u\right)\big|_{F_j} = 2\lambda_l \iint_{F_l} u(\boldsymbol{s})\, d\boldsymbol{s}, \tag{4.7}$$

$$\left(\mathcal{E}^{\mathrm{grad}}_{E_{jl},l} u\right)\big|_{F_l} = 0, \tag{4.8}$$

$$\mathcal{E}^{\mathrm{grad}}_{ij,l} u\big|_{F_i \cup F_j} = 0. \tag{4.9}$$

(3) *If* u *is a polynomial of degree at most* p *that vanishes on* $E_{ij} \cup E_{jk}$, *then* $\mathcal{E}^{\mathrm{grad}}_{E_{jl},l} u$ *is a polynomial of degree at most* p *for all* $j = 0, 1, 2$.

Proof. To prove the first item, in view of Theorem 2.1(1) and Proposition 3.1(1), it suffices to prove that the last term in (4.4), namely, $\mathcal{E}^{\mathrm{grad}}_{E_{kl},l}$, is a continuous operator from $H^{1/2}_{0,ij}$ into $H^1(K)$. Since $\mathcal{E}^{\mathrm{grad}}_{E_{kl},l}$ is obtained by mapping $\mathcal{E}^{\mathrm{grad}}_{\hat{E}_{03}}$ from $\hat{K}$, it suffices to prove the continuity of $\mathcal{E}^{\mathrm{grad}}_{\hat{E}_{03}}$. But $\mathcal{E}^{\mathrm{grad}}_{\hat{E}_{03}} = \mathcal{B}_{\hat{E}_{03}} \circ \mathcal{L}^{\mathrm{grad}}$, so by Lemmas 3.2 and 4.1, we conclude that $\mathcal{E}^{\mathrm{grad}}_{\hat{E}_{03}}$ is continuous from $L^2_{1/x}(\hat{F}_3) \cap L^2_{1/y}(\hat{F}_3)$ into $H^1(\hat{K})$. Thus $\mathcal{E}^{\mathrm{grad}}_{E_{kl},l}$ is continuous from $H^{1/2}_{0,ij}$ into $H^1(K)$.

To prove (4.6), we start with

$$\mathcal{E}^{\mathrm{grad}}_{F_i,l} u - \mathcal{E}^{\mathrm{grad}}_{E_{jl},l} u = \frac{2\lambda_l}{(\lambda_i + \lambda_l)^3} \iint_{T_l(0,\lambda_j,\lambda_k)} u(\boldsymbol{s})\, d\boldsymbol{s} \;-\; \frac{2\lambda_l}{(1-\lambda_j)^3} \iint_{T_l(0,\lambda_j,0)} u(\boldsymbol{s})\, d\boldsymbol{s}.$$

Since $\lambda_k = 0$ on face F_k, by setting $\lambda_k = 0$ in the first integral above, and observing that $1 - \lambda_j = \lambda_i + \lambda_l$, we see that the right-hand side above is zero, thus proving (4.6). Proofs of (4.7) and (4.8) follow immediately by setting $\lambda_i = 0$ and $\lambda_l = 0$, respectively,

in (4.3). To prove (4.9), observe that

$$\mathcal{E}^{\mathrm{grad}}_{ij,l}u\big|_{F_i} = \mathcal{E}^{\mathrm{grad}}_{i,l}u\big|_{F_i} - (\mathcal{E}^{\mathrm{grad}}_{F_j,l}u - \mathcal{E}^{\mathrm{grad}}_{E_{kl},l}u)\big|_{F_i}.$$

We see that this trace is zero by using Proposition 3.1(2) and (4.6). By symmetry of $\mathcal{E}^{\mathrm{grad}}_{ij,l}$, the trace on F_j must also vanish.

Proof of (4.1): This is best seen using the reference tetrahedron expression (4.1). Since u vanishes on the edges of $\hat{K}$ along the x and y axes, we can write, for instance, $u(x,y) = xu_{p-1}(x,y)$ for some polynomials u_{p-1} of degree at most $p-1$. Then

$$\begin{aligned}\mathcal{E}^{\mathrm{grad}}_{\hat{E}_{03}}u &= \frac{2z}{x+y+z}\int_0^1\int_0^{1-s} u(s(x+y+z),t(x+y+z))\,dt\,ds \\ &= 2z\int_0^1\int_0^{1-s} s\,u_{p-1}(s(x+y+z),t(x+y+z))\,dt\,ds,\end{aligned}$$

so the polynomial preservation property follows. ∎

5. Extension of a face bubble. In this section, we consider the problem of extending functions in

$$H^{1/2}_{0,ijk}(F_l) = H^{1/2}(F_l)\cap L^2_{1/\lambda_i}(F_l)\cap L^2_{1/\lambda_j}(F_l)\cap L^2_{1/\lambda_k}(F_l) \tag{5.1}$$

in such a way that the extension is polynomial preserving and has zero traces on all faces other than F_l. Such extensions have applications in the design of optimal face shape functions for high order finite elements. Note that smooth functions that vanish on the boundary edges of F_l (the so called "face bubble" functions) are in $H^{1/2}_{0,ijk}(F_l)$.

The extension operator from $H^{1/2}_{0,ijk}(F_l)$ into $H^1(K)$ is given by

$$\mathcal{E}^{\mathrm{grad}}_{ijk,l}u = \mathcal{E}^{\mathrm{grad}}_{l}u \;-\; \mathcal{E}^{\mathrm{grad}}_{V_l}u \;-\; \sum_{m\in\{i,j,k\}}\big(\mathcal{E}^{\mathrm{grad}}_{F_m,l}u - \mathcal{E}^{\mathrm{grad}}_{E_{ml},l}u\big), \tag{5.2}$$

where $\mathcal{E}^{\mathrm{grad}}_{l}$ is the primary extension operator defined in (2.3), $\mathcal{E}^{\mathrm{grad}}_{F_i,l}$ is the face correction operator defined in (3.2), $\mathcal{E}^{\mathrm{grad}}_{E_{il},l}$ is the edge correction operator defined in (4.3), and

$$\mathcal{E}^{\mathrm{grad}}_{V_l}u\,(\lambda_0,\lambda_1,\lambda_2,\lambda_3) = 2\lambda_l\iint_{F_l} u(\boldsymbol{s})\,d\boldsymbol{s}.$$

This last operator may be thought of as a *vertex correction*, because the right-hand side above equals $\lambda_l\mathcal{E}^{\mathrm{grad}}_{l}u(\boldsymbol{a}_l)$; i.e., it depends only on the value of $\mathcal{E}^{\mathrm{grad}}_{l}u$ at a vertex. It is needed because the edge corrections alter the traces zeroed by the face corrections.

PROPOSITION 5.1. *The operator $\mathcal{E}^{\mathrm{grad}}_{ijk,l}$ satisfies the following:*

1. *$\mathcal{E}^{\mathrm{grad}}_{ijk,l}$ is a continuous map from $H^{1/2}_{0,ijk}(F_l)$ into $H^1(K)$.*
2. *The traces of $\mathcal{E}^{\mathrm{grad}}_{ijk,l}u$ on all faces of the tetrahedron are zero except for the face F_l, where the trace equals u.*
3. *If u is a polynomial of degree at most p, then $\mathcal{E}^{\mathrm{grad}}_{ijk,l}u$ is a polynomial of degree at most p.*

Proof. The continuity property of $\mathcal{E}^{\mathrm{grad}}_{ijk,l}$ follows immediately by the results established in Propositions 3.1(1) and 4.1(1), since the continuity of the vertex correction is obvious.

Let us now prove that the trace of $\mathcal{E}^{\mathrm{grad}}_{ijk,l}u$ on F_i is zero. Observe that by a rearrangement of the terms in (5.2),

$$\begin{aligned}\mathcal{E}^{\mathrm{grad}}_{ijk,l}u|_{F_i} = &\left(\mathcal{E}^{\mathrm{grad}}_{l}u - \mathcal{E}^{\mathrm{grad}}_{F_i,l}u\right)|_{F_i}\\ &- \left(\mathcal{E}^{\mathrm{grad}}_{F_j,l}u - \mathcal{E}^{\mathrm{grad}}_{E_{kl},l}u\right)|_{F_i} - \left(\mathcal{E}^{\mathrm{grad}}_{F_k,l}u - \mathcal{E}^{\mathrm{grad}}_{E_{jl},l}u\right)|_{F_i}\\ &+ \left(\mathcal{E}^{\mathrm{grad}}_{E_{il},l}u - \mathcal{E}^{\mathrm{grad}}_{V_l}u\right)|_{F_i}.\end{aligned}$$

The first term on the right-hand side is zero by Proposition 3.1(2). The second and third are also zero by Proposition 4.1—see (4.6). Furthermore, the last term also vanishes by (4.7). Thus the trace of $\mathcal{E}^{\mathrm{grad}}_{ijk,l}u$ on F_i is zero. The traces on F_j and F_k must also be zero because the expression for $\mathcal{E}^{\mathrm{grad}}_{ijk,l}u$ is symmetric in i,j,k. That the trace on F_l is u, as well as the polynomial preservation property, follows by collecting the results in Propositions 3.1 and 4.1. ∎

6. The total extension operator. We are now in a position to solve the extension problem as posed in the beginning of this paper in (1.5)–(1.7) by combining the primary extension $\mathcal{E}^{\mathrm{grad}}$ with the face, edge, and vertex corrections.

Let u be any function in $H^{1/2}(\partial K)$. We extend this function into K by selecting the faces of K in some order, say F_i, F_j, F_k, and F_l, and defining the following extensions from these faces:

$$\begin{aligned}U_i &= \mathcal{E}^{\mathrm{grad}}_{i}u,\\ U_j &= \mathcal{E}^{\mathrm{grad}}_{i,j}w_j, && \text{where } w_j = (u-U_i)|_{F_j},\\ U_k &= \mathcal{E}^{\mathrm{grad}}_{ij,k}w_k, && \text{where } w_k = (u-U_i-U_j)|_{F_k},\\ U_l &= \mathcal{E}^{\mathrm{grad}}_{ijk,l}w_l, && \text{where } w_l = (u-U_i-U_j-U_k)|_{F_l}.\end{aligned}$$

Here, the operators $\mathcal{E}^{\mathrm{grad}}_{i}$, $\mathcal{E}^{\mathrm{grad}}_{i,j}$, $\mathcal{E}^{\mathrm{grad}}_{ij,k}$, and $\mathcal{E}^{\mathrm{grad}}_{ijk,l}$ are as defined in (2.3), (3.3), (4.4), and (5.2), respectively. The total extension operator is then defined by

$$\mathcal{E}^{\mathrm{grad}}_{K}u = U_i + U_j + U_k + U_l. \tag{6.1}$$

This operator is well defined provided w_j, w_k, and w_l are in the domains of the operators $\mathcal{E}^{\mathrm{grad}}_{i,j}$, $\mathcal{E}^{\mathrm{grad}}_{ij,k}$, and $\mathcal{E}^{\mathrm{grad}}_{ijk,l}$, respectively, which is indeed the case as asserted by the following lemma:

LEMMA 6.1. *There is a constant $C>0$ independent of u such that the functions w_j, w_k, and w_l defined above satisfy*

$$\begin{aligned}\|w_j\|_{H^{1/2}_{0,i}(F_j)} &\le C\|u\|_{H^{1/2}(\partial K)},\\ \|w_k\|_{H^{1/2}_{0,ij}(F_k)} &\le C\|u\|_{H^{1/2}(\partial K)},\\ \|w_l\|_{H^{1/2}_{0,ijk}(F_l)} &\le C\|u\|_{H^{1/2}(\partial K)}.\end{aligned}$$

Collecting all the results we have established in the course of the construction of $\mathcal{E}^{\mathrm{grad}}_{K}$, we have the following theorem:

THEOREM 6.1. *The operator $\mathcal{E}^{\mathrm{grad}}_{K}$ defined by* (6.1) *satisfies*

(1) *the extension property* (1.5),
(2) *the continuity property* (1.6), *and*
(3) *the polynomial preservation property* (1.7).

Proof. All three properties follow from the previous propositions. For example, to prove the continuity property, we use the previously proved inequalities

$$\begin{aligned}
\|\mathcal{E}^{\mathrm{grad}}_{ijk,l} w_l\|_{H^1(K)} &\le C\|w_l\|_{H^{1/2}_{0,ijk}(F_l)}, && \text{by Proposition 5.1(1)},\\
\|\mathcal{E}^{\mathrm{grad}}_{ij,k} w_k\|_{H^1(K)} &\le C\|w_k\|_{H^{1/2}_{0,ij}(F_k)}, && \text{by Proposition 4.1(1)},\\
\|\mathcal{E}^{\mathrm{grad}}_{i,j} w_j\|_{H^1(K)} &\le C\|w_j\|_{H^{1/2}_{0,i}(F_j)}, && \text{by Proposition 3.1(1)},\\
\|\mathcal{E}^{\mathrm{grad}}_{i} u\|_{H^1(K)} &\le C\|u\|_{H^{1/2}(F_l)}, && \text{by Theorem 2.1(1)},
\end{aligned}$$

in

$$\|\mathcal{E}^{\mathrm{grad}}_{K} u\|_{H^1(K)} \le \|\mathcal{E}^{\mathrm{grad}}_{i} u\|_{H^1(K)} + \|\mathcal{E}^{\mathrm{grad}}_{i,j} w_j\|_{H^1(K)} + \|\mathcal{E}^{\mathrm{grad}}_{ij,k} w_k\|_{H^1(K)} + \|\mathcal{E}^{\mathrm{grad}}_{ijk,l} w_l\|_{H^1(K)},$$

and complete the estimate using Lemma 6.1. ∎

Appendix A. Proofs of the lemmas.

In this section, we prove all the previously stated lemmas in the order in which they appeared in sections 2–5. Before we start proving these lemmas, let us begin with some preliminary results which will turn useful in the proofs. These results are often stated in more generality than we need them in this paper, because we will need the general forms in later parts of this series.

There are two kind of operators that pervade the proofs, namely, the averaging type and the interpolating type. We first collect the continuity properties of some averaging type operators in Lemmas A.1 and A.2. The interpolatory operators are considered next in Lemmas A.3 and A.4, after which we begin proving the lemmas of the previous sections. We start with operators that map functions on the x-y face to functions on the y-z face.

LEMMA A.1 (Face-to-face maps). *Let $\theta(s,t)$ be a function in $C(\bar{\hat{F}})$. Define the the following maps for smooth $u(x,y)$:*

$$\begin{aligned}
u(x,y) &\longmapsto A^\theta_1 u\,(y,z) := \int_0^1 \theta(s,0)\; u(sz,y)\; ds,\\
u(x,y) &\longmapsto A^\theta_2 u\,(y,z) := \int_0^1 \theta(s,1-s)\; u(sz,y+(1-s)z)\; ds,\\
u(x,y) &\longmapsto A^\theta_3 u\,(y,z) := 2\int_0^1\int_0^{1-s} \theta(s,t)\; u(sz,y+tz)\; dt\, ds.
\end{aligned}$$

Then the following continuity properties hold:

1. *The maps A^θ_1, A^θ_2, and A^θ_3 extend to continuous operators from $L^2_{1/x}(\hat{F}_3)$ into $L^2_{1/z}(\hat{F}_1)$.*
2. *If, in addition, $\theta(s,t)$ is in $C^1(\bar{\hat{F}})$, then A^θ_3 is continuous under the a stronger norm, namely,*

$$\|A^\theta_3 u\|_{L^2_{1/z}(\hat{F}_1)\cap H^1_z(\hat{F}_1)} \le C\|u\|_{L^2_{1/x}(\hat{F}_3)}. \tag{A.1}$$

Proof. Because of the well-known [20] density of $C^\infty(\bar{\hat{F}}_3)\cap L^2_{1/x}(\hat{F}_3)$ in $L^2_{1/x}(\hat{F}_3)$, to prove item (1), it suffices to prove that there is a constant $C>0$ such that

$$\|A^\theta_i u\|_{L^2_{1/z}(\hat{F}_3)} \le C\|u\|_{L^2_{1/x}(\hat{F}_1)}$$

for all smooth functions $u(x,y)$.

Let us consider the operator A_1^θ acting on a smooth function u. We start with an application of Cauchy–Schwarz inequality to bound the required norm:

$$\begin{aligned}\|A_1^\theta u\|^2_{L^2_{1/z}(\hat{F}_1)} &= \int_0^1\int_0^{1-y} \frac{1}{z}\left|\int_0^1 \theta(s,0)\ u(sz,y)\ ds\right|^2 dz\ dy\\ &\le \int_0^1\int_0^{1-y} \frac{1}{z}\left(\int_0^1 |\theta(s,0)|^2 ds\right)\left(\int_0^1 |u(sz,y)|^2 ds\right) dz\ dy,\end{aligned}$$

by Cauchy–Schwarz inequality. Setting $C_\theta = \int_0^1 |\theta(s,0)|^2 ds$, we continue, and apply Fubini's theorem on a tetrahedral region, as follows.

$$\begin{aligned}\|A_1^\theta u\|^2_{L^2_{1/z}(\hat{F}_1)} &= C_\theta^2 \int_0^1\int_0^{1-y} \frac{1}{z}\int_0^z |u(x,y)|^2\ \frac{dx}{z}\ dz\ dy,\\ &= C_\theta^2 \int_0^1\int_0^{1-y} \left(\int_x^{1-y} \frac{1}{z^2}\ dz\right)|u(x,y)|^2\ dx\ dy,\\ &= C_\theta^2 \int_0^1\int_0^{1-y} \left(\frac{1}{x} - \frac{1}{1-y}\right)|u(x,y)|^2\ dx\ dy,\\ &\le C_\theta^2\ \|u\|^2_{L^2_{1/x}(\hat{F})}.\end{aligned}$$

This establishes the continuity of A_1^θ.

To prove the continuity of the next map,

$$\begin{aligned}\|A_2^\theta u\|^2_{L^2_{1/z}(\hat{F}_1)} &= \int_0^1\int_0^{1-y} \frac{1}{z}\left|\int_0^1 \theta(s,1-s)u(sz,y+(1-s)z)\ ds\right|^2 dz\,dy\\ &= \left(\int_0^1 |\theta(s,1-s)|^2 ds\right)\int_0^1\int_0^{1-y} \frac{1}{z}\int_0^1 |u(sz,y+(1-s)z)|^2 ds\,dz\,dy\\ &= C_\theta^2 \int_0^1\int_0^{1-y}\int_0^z \frac{1}{z}|u(x,y+z-x)|^2 \frac{dx}{z} dz\,dy,\end{aligned}$$

by the substitution $x = zs$. Here $C_\theta = \int_0^1 |\theta(s,1-s)|^2 ds$. Continuing,

$$\begin{aligned}\|A_2^\theta u\|^2_{L^2_{1/z}(\hat{F}_1)} &= C_\theta^2 \int_0^1\int_x^1\int_0^{1-z} \frac{1}{z^2}|u(x,y+z-x)|^2\ dy\,dz\,dx,\\ &\qquad\qquad \text{by Fubini's theorem,}\\ &= C_\theta^2 \int_0^1\int_x^1\int_{z-x}^{1-x} \frac{1}{z^2}|u(x,y')|^2 dy'\,dz\,dx,\\ &\qquad\qquad \text{by substitution } y' = y+z-x,\\ &\le C_\theta^2 \int_0^1\int_x^1\int_0^{1-x} |u(x,y')|^2 dy'\,dz\,dx\\ &= C_\theta^2 \int_0^1\int_0^{1-x} \left(\frac{1}{x} - 1\right)|u(x,y')|^2 dy'\,dx\\ &\le\ C_\theta^2\ \|u\|^2_{L^2_{1/x}(\hat{F})}.\end{aligned}$$

To prove the continuity of A_3^θ,

$$\left\|\frac{1}{2}A_3^1 u\right\|^2_{L^2_{1/z}(\hat{F}_1)} = \int_0^1\int_0^{1-y}\frac{1}{z}\left(\int_0^1\int_0^{1-s}\theta(s,t)\ u(sz,y+tz)\ \ dt\,ds\right)^2 dz\,dy$$
$$\leq \|\theta\|^2_{L^2(\hat{F})}\int_0^1\int_0^{1-y}\frac{1}{z}\left(\int_0^1\int_0^{1-s}|u(sz,y+tz)|^2\ dt\,ds\right)dz\,dy,$$

where we have applied the Cauchy–Schwarz inequality. Next, we change variables, and then interchange the order of integration, carefully considering the variable integration limits:

$$\left\|\frac{1}{2}A_3^1 u\right\|^2_{L^2_{1/z}(\hat{F}_1)} \leq \int_0^1\int_0^{1-y}\frac{1}{z^3}\int_0^z\int_y^{y+z-x'}|u(x',y')|^2\ \ dy'dx'\ \ dz\,dy$$
$$= \int_0^1\int_0^{1-y'}|u(x',y')|^2\int_0^{y'}\int_{x'+y'-y}^{1-y} z^{-3}\,dz\,dy\ \ dx'\,dy',$$

(In the last step we have applied Fubini's theorem to a four-dimensional region.) Now the inner z and y integrals can be evaluated and estimated by

$$2\int_0^{y'}\int_{x'+y'-y}^{1-y} z^{-3}\,dz\,dy = \int_0^{y'}\left((x'+y'-y)^{-2}-(1-y)^{-2}\right)dy$$
$$= -\frac{1}{1-y'}+\frac{1}{x'}+1-\frac{1}{x'+y'}$$
$$\leq \frac{1}{x'}.$$

Hence the continuity of A_3^θ from $L^2_{1/x}(\hat{F}_3)$ into $L^2_{1/z}(\hat{F}_1)$ follows.

It now only remains to prove (A.1) under the stronger assumption on θ. This is a consequence of the following two identities.

$$\partial_y\left(A_3^\theta u\right) = -\frac{1}{z}A_3^{\partial_t\theta}u+\frac{2}{z}\left(A_1^\theta u - A_2^\theta u\right), \tag{A.2}$$

$$\partial_z\left(A_3^\theta u\right) = -\frac{1}{z}A_3^{(s\partial_s\theta+t\partial_t\theta)}u+\frac{2}{z}\left(A_2^\theta u - A_3^\theta u\right). \tag{A.3}$$

These identities follow by variable changes and differentiation; e.g., to prove the first one,

$$\partial_y A_3^\theta v = \frac{2}{z^2}\frac{\partial}{\partial y}\left(\int_0^x\int_y^{y+z-x'}\theta\left(\frac{x'}{z},\frac{y'-y}{z}\right)\ u(x',y')\ dy'\,dx'\right)$$
$$= -\frac{1}{z}\int_0^x\int_y^{y+z-x'}\frac{\partial\theta}{\partial t}\left(\frac{x'}{z},\frac{y'-y}{z}\right)\ u(x',y')\ dy'\,dx'$$
$$+\frac{2}{z^2}\int_0^x\theta\left(\frac{x'}{z},\frac{y'-y}{z}\right)\ u(x',y+z-x')\,dx' - \frac{2}{z^2}\int_0^x\theta\left(\frac{x'}{z},0\right)\ v(x',y)\,dx'$$
$$= -\frac{1}{z}A_3^{\partial_t\theta}u+\frac{2}{z}\int_0^1\theta(s,1-s)\,u(sz,y+(1-s)z)\,ds-\frac{2}{z}\int_0^1\theta(s,0)\,u(sz,y)\,ds,$$

which is (A.2). Equation (A.3) is proved similarly. From (A.2) and (A.3), it is clear that if θ satisfies the additional smoothness assumptions, then we can apply continuity results already proved above to obtain (A.1). ∎

LEMMA A.2 (Face-to-edge maps). *Let $\theta(s,t)$ be a function in $C(\bar{\hat{F}})$. Define the the following maps for smooth $u(x,y)$.*

$$\begin{aligned} u(x,y) &\longmapsto \quad B_1^\theta u\,(z) := \int_0^1 \theta(s,1-s)\; u(sz,(1-s)z)\; ds, \\ u(x,y) &\longmapsto \quad B_2^\theta u\,(z) := 2\int_0^1\int_0^{1-s} \theta(s,t) u(sz,tz)\; dt\, ds. \end{aligned}$$

Then the following continuity properties hold:

1. *B_1^θ and B_2^θ extend to continuous operators from $L^2_{1/x}(\hat{F}_3)\cap L^2_{1/y}(\hat{F}_3)$ into $L^2(\hat{E}_{03})$.*
2. *If, in addition, $\theta(s,t)$ is in $C^1(\bar{\hat{F}})$, then B_2^θ is continuous in a stronger norm:*

$$\|B_2^\theta u\|_{H^2_{z^2}(\hat{E}_{03}\cap L^2(\hat{E}_{03})} \le C\|u\|_{L^2_{1/x}(\hat{F}_3)\cap L^2_{1/y}(\hat{F}_3)}. \tag{A.4}$$

Proof. As in Lemma A.1, it suffices to consider smooth $u(x,y)$ because of density. To prove the continuity of B_1^θ, set $C_\theta = \int_0^1 |\theta(s,1-s)|^2 ds$ and observe that

$$\begin{aligned} \left\|B_1^\theta u\right\|^2_{L^2(\hat{E}_{03})} &= \int_0^1 \left| \int_0^1 \theta(s,1-s)\; u(sz,(1-s)z)\; ds\right|^2 dz, \\ &\le C_\theta^2 \int_0^1\int_0^1 |u(sz,(1-s)z)|^2\, ds\, dz, \\ &= C_\theta^2 \int_0^1\int_0^z \frac{1}{z}|u(x',z-x')|^2\, dx'\, dz, \\ &= C_\theta^2 \int_0^1\int_0^{1-x} \frac{1}{x+y}|u(x,y)|^2\, dy\, dx. \end{aligned}$$

The result now follows from

$$\frac{1}{x+y} \le \frac{1}{2}\left(\frac{1}{x}+\frac{1}{y}\right).$$

The continuity of B_2 is proved as follows:

$$\begin{aligned} \left\|\frac{1}{2}B_2^\theta u\right\|^2_{L^2(\hat{E}_{03})} &= \int_0^1 \left| \int_0^1\int_0^{1-s} \theta(s,t)\; u(sz,tz)\; dt\, ds\right|^2 dz \\ &\le \|\theta\|^2_{L^2(\hat{F})} \int_0^1\int_0^1\int_0^{1-s} |u(sz,tz)|^2\; dt\, ds\, dz \\ &= \|\theta\|^2_{L^2(\hat{F})} \int_0^1\int_0^z\int_0^{z-x'} \frac{1}{z^2}|u(x',y')|^2\; dy'\, dx'\, dz. \end{aligned}$$

Now we apply Fubini's theorem over a tetrahedron to get

$$\begin{aligned} \left\|\frac{1}{2}B_2^\theta u\right\|^2_{L^2(\hat{E}_{03})} &= \int_0^1\int_0^{1-x'} |u(x',y')|^2 \int_{x'+y'}^1 \frac{1}{z^2}\; dz\;\; dy'\, dx' \\ &= \int_0^1\int_0^{1-x'} \left(\frac{1}{x'+y'}-1\right)|u(x',y')|^2\; dz\, dy'\, dx', \end{aligned}$$

from which the result follows since $\frac{1}{x'+y'}-1 \le \frac{1}{2}(\frac{1}{x'}+\frac{1}{y'})$.

It now only remains to prove (A.4). Differentiating,

$$\frac{d}{dz}B_2^\theta u = \frac{d}{dz}\left(\frac{2}{z^2}\int_0^z\int_0^{z-x'} u(x',y')\ dy'\,dx'\right)$$
$$= -\frac{2}{z}B_2^\theta u - \frac{1}{z}B_2^{s\partial_s\theta+t\partial_t\theta}u + \frac{2}{z^2}\int_0^z \left(\frac{x'}{z}, z-x'z\right)\ u(x',z-x')\,dx'.$$

In other words,

$$\frac{d}{dz}B_2^\theta u = -\frac{1}{z}B_2^{s\partial_s\theta+t\partial_t\theta}u + \frac{2}{z}\left(B_1^\theta u - B_2^\theta u\right). \tag{A.5}$$

Hence (A.4) follows from the already proved item (1). ∎

LEMMA A.3 (Face-to-tetrahedron maps). *Let $\theta(x,y,z)$ be a function in $L^\infty(\hat{K})$. The following map, defined for smooth $\phi(y,z)$,*

$$\phi(y,z) \longmapsto J_\theta\phi\,(x,y,z) := \theta(x,y,z)\,\phi(y,x+z)$$

extends to a continuous operator from $L^2_z(\hat{F}_1)$ into $L^2(\hat{K})$.

Proof. The proof is immediate once we make the change of variable $(x',y',z') = (x,y,x+z)$. Indeed,

$$\|J_\theta\phi\|^2_{L^2(\hat{K})} = \int_0^1\int_0^{1-x}\int_0^{1-x-z} |\theta(x,y,z)\,\phi(y,x+z)|^2\ dy\,dz\,dx$$
$$= \int_0^1\int_0^{1-y'}\int_0^{z'} \left|\theta(x',y',z'-x')|^2\,|\phi(y',z')\right|^2\ dx'\,dz'dy'$$
$$\le \int_0^1\int_0^{1-y'}\left(\int_0^{z'}\|\theta\|^2_{L^\infty(\hat{K})}dx'\right)|\phi(y',z')|^2\,dz'dy'$$
$$\le \|\theta\|^2_{L^\infty(\hat{K})}\|\phi\|^2_{L_z(\hat{F}_1)}. \qquad ∎$$

LEMMA A.4 (Edge-to-tetrahedron maps). *Let $\theta(x,y,z)$ be a function in $L^\infty(\hat{K})$. The following map, defined for smooth $\psi(z)$,*

$$\psi(z) \longmapsto L_\theta\psi\,(x,y,z) := \theta(x,y,z)\,\psi(x+y+z)$$

extends to continuous operators from $L^2_{z^2}(\hat{E}_{03})$ into $L^2(\hat{K})$.

Proof. Making the variable change $(x',y',z') = (x+y,y,x+y+z)$, we find that

$$\|L_\theta\psi\|^2_{L^2(\hat{K})} = \int_0^1\int_0^{z'}\int_0^{y'} |\theta(x'-y',y',z-x')\,\psi(z')|^2\ dx'\,dy'\,dz'$$
$$\le \int_0^1 \|\theta\|^2_{L^\infty(\hat{K})}\frac{(z')^2}{2}\,|\psi(z')|^2\ dz',$$

thus proving the continuity of L_θ. ∎

With the help of the above results, we now start proving all the lemmas that appeared in the previous sections.

Proof of Lemma 3.2. First, we need to prove that

$$\mathcal{R}^{\text{grad}}:\ L^2_{1/x}\left(\hat{F}_3\right) \longmapsto L^2_{1/z}\left(\hat{F}_1\right)\cap H^1_z\left(\hat{F}_1\right)$$

is continuous. But

$$\mathcal{R}^{\mathrm{grad}} u = A_3^\theta u,$$

with $\theta(s,t) \equiv 1$. Hence, we obtain the required continuity properties from Lemma A.1, specifically the estimate in (A.1).

Similarly, the continuity of $\mathcal{L}^{\mathrm{grad}} : L^2_{1/x}(\hat{F}_3) \cap L^2_{1/y}(\hat{F}_3) \longmapsto L^2(\hat{E}_{03}) \cap H^1_{z^2}(\hat{E}_{03})$ follows from Lemma A.2 because

$$\mathcal{L}^{\mathrm{grad}} u = B_2^\theta u,$$

with $\theta(s,t) \equiv 1$ (see (A.4)). ∎

Proof of Lemma 3.1. It suffices to prove that

$$\|\mathcal{B}_{\hat{F}_1}\phi\|_{H^1(\hat{K})} \le C\left(\|\phi\|_{L^2_{1/z}(\hat{F}_1)} + \|\phi\|_{H^1_z(\hat{F}_1)}\right) \tag{A.6}$$

for all $\phi(y,z)$ in $C^\infty(\bar{\hat{F}}_1)$ that vanish in a neighborhood of the y-axis, because it is proven in [16, Lemma 3.1] that such functions are dense in $L^2_{1/z}(\hat{F}_1) \cap H^1_z(\hat{F}_1)$. For such a ϕ, the function $\mathcal{B}_{\hat{F}_1}\phi$ is obviously in $H^1(\hat{K})$ and vanishes on $\hat{F}_3$. Hence, the Poincaré inequality gives a constant $\hat{C}$ depending only on $\hat{K}$ such that

$$\|\mathcal{B}_{\hat{F}_1}\phi\|_{L^2(\hat{K})} \le \hat{C}\|\,\mathbf{grad}\left(\mathcal{B}_{\hat{F}_1}\phi\right)\|_{L^2(\hat{K})}.$$

Moreover,

$$\begin{aligned}
\mathbf{grad}(\mathcal{B}_{\hat{F}_1}\phi) &= \frac{z}{x+z}\,\mathbf{grad}\Big(\phi(y,x+z)\Big) + \phi(y,x+z)\,\mathbf{grad}\left(\frac{z}{x+z}\right)\\
&= \frac{z}{x+z}\begin{pmatrix}\partial_z\phi(y,x+z)\\ \partial_y\phi(y,x+z)\\ \partial_z\phi(y,x+z)\end{pmatrix} + \frac{1}{(x+z)^2}\begin{pmatrix}-z\\ 0\\ x\end{pmatrix}\phi(y,x+z)\\
&= \begin{pmatrix}J_{\theta_2}(\partial_z\phi)\\ J_{\theta_2}(\partial_y\phi)\\ J_{\theta_2}(\partial_z\phi)\end{pmatrix} + \begin{pmatrix}-J_{\theta_2}(\phi/z)\\ 0\\ J_{\theta_1}(\phi/z)\end{pmatrix},
\end{aligned}$$

with

$$\theta_1 = \frac{x}{x+z} \quad \text{and} \quad \theta_2 = \frac{z}{x+z}.$$

Thus (A.6) follows from the continuity properties of J_θ established in Lemma A.3 (noting that both θ_1 and θ_2 take only values between 0 and 1). ∎

Proof of Lemma 4.1. Since $\mathcal{B}_{\hat{E}_{03}}\psi = L_{\theta_2}\psi$ with

$$\theta_2 = \frac{z}{x+y+z},$$

and since

$$\begin{aligned}
\mathbf{grad}(\mathcal{B}_{\hat{E}_{03}}\psi) &= \frac{1}{(x+y+z)^2}\begin{pmatrix}-z\\ -z\\ x+y\end{pmatrix}\psi(x+y+z) + \frac{z}{x+y+z}\begin{pmatrix}1\\ 1\\ 1\end{pmatrix}\psi'(x+y+z)\\
&= \begin{pmatrix}-L_{\theta_2}(\psi/z)\\ -L_{\theta_2}(\psi/z)\\ L_{\theta_1}(\psi/z)\end{pmatrix} + \begin{pmatrix}L_{\theta_2}(\psi')\\ L_{\theta_2}(\psi')\\ L_{\theta_2}(\psi')\end{pmatrix},
\end{aligned}$$

with

$$\theta_1 = \frac{x+y}{x+y+z},$$

the required estimate follows immediately from the continuity properties of L_θ established in Lemma A.4. ∎

Proof of Lemma 6.1. By a well-known characterization of $H^{1/2}$ norms on polyhedral surfaces (see [6, Theorem 2.5], [17, Lemma 1.3.2.6], or [24, Lemma 1]), there is a constant $C > 0$ such that for all v in $H^{1/2}(\partial K)$,

$$\|v\|^2_{L^2_{1/\lambda_i}(F_j)} \le C\|v\|^2_{H^{1/2}(F_i\cup F_j)} \qquad \text{if } v|_{F_i} = 0, \tag{A.7}$$

$$\|v\|^2_{L^2_{1/\lambda_i}(F_k)} + \|v\|^2_{L^2_{1/\lambda_j}(F_k)} \le C\|v\|^2_{H^{1/2}(F_i\cup F_j\cup F_k)} \qquad \text{if } v|_{F_i\cup F_j} = 0, \tag{A.8}$$

$$\|v\|^2_{L^2_{1/\lambda_i}(F_l)} + \|v\|^2_{L^2_{1/\lambda_j}(F_l)} + \|v\|^2_{L^2_{1/\lambda_k}(F_l)} \le C\|v\|^2_{H^{1/2}(\partial K)} \qquad \text{if } v|_{F_i\cup F_j\cup F_k} = 0. \tag{A.9}$$

Applying the first inequality above to the function $v = u - \mathcal{E}_i^{\mathrm{grad}} u|_{\partial K}$, which vanishes on F_i (by Theorem 2.1(2)), and coincides with the given function w_j on F_j, we find that

$$\begin{aligned}
\|w_j\|^2_{H^{1/2}_{0,i}(F_j)} &= \|w_j\|^2_{H^{1/2}(F_j)} + \|w_j\|^2_{L^2_{1/\lambda_i}(F_j)} \le C\|v\|^2_{H^{1/2}(F_i\cup F_j)} \\
&\le C\|u\|^2_{H^{1/2}(F_i\cup F_j)} + C\|\mathcal{E}_i^{\mathrm{grad}} u\|^2_{H^{1/2}(F_i\cup F_j)} \\
&\le C\|u\|^2_{H^{1/2}(F_i\cup F_j)} + C\|\mathcal{E}_i^{\mathrm{grad}} u\|^2_{H^1(K)} \qquad \text{(by trace theorem)} \\
&\le C\|u\|^2_{H^{1/2}(F_i\cup F_j)} + C\|u\|^2_{H^{1/2}(F_i)} \qquad \text{(by Theorem 2.1(1))},
\end{aligned}$$

which proves the first inequality of the lemma.

To prove the bound for $w_k = (u - U_i - U_j)|_{F_k}$, we apply (A.8) to the function

$$v = (I - \mathcal{E}_{i,j}^{\mathrm{grad}} R_j)(I - \mathcal{E}_i^{\mathrm{grad}})u,$$

where R_j denotes the restriction to face F_j (and I is the identity). Clearly, $w_k = R_k v$, and by Proposition 3.1(2), v vanishes on $F_i \cup F_j$, so (A.8) gives

$$\|w_k\|_{H^{1/2}_{0,ij}(F_k)} \le C\|v\|_{H^{1/2}(F_i\cup F_j\cup F_k)}.$$

The required bound for w_k follows as in the w_j case by using the trace theorem and the continuity of the operators $\mathcal{E}_{i,j}^{\mathrm{grad}}$ and $\mathcal{E}_i^{\mathrm{grad}}$. The final estimate for w_l is proved similarly, but using

$$v = \left(I - \mathcal{E}_{ij,k}^{\mathrm{grad}} R_k\right)\left(I - \mathcal{E}_{i,j}^{\mathrm{grad}} R_j\right)\left(I - \mathcal{E}_i^{\mathrm{grad}}\right)u$$

and (A.9). ∎

Appendix B. Two techniques to study the primary extension.

The starting point for constructing the tetrahedral extensions in any of the $H^1(K)$, $\boldsymbol{H}(\mathbf{curl})$, or $\boldsymbol{H}(\mathrm{div})$ case is the study of "primary extensions," i.e., extensions

into $H^1(\hat{K})$, $\boldsymbol{H}(\mathbf{curl}\,,\hat{K})$, and $\boldsymbol{H}(\mathrm{div},\hat{K})$ from one face:

$$\mathcal{E}^{\mathrm{grad}}u\,(x,y,z) = \frac{2}{z^2}\int_x^{x+z}\int_y^{x+y+z-\widetilde{x}} u(\widetilde{x},\widetilde{y})\,d\widetilde{y}\,d\widetilde{x}, \tag{B.1}$$

$$\mathcal{E}^{\mathrm{curl}}\boldsymbol{v}\,(x,y,z) = \frac{2}{z^3}\int_x^{x+z}\int_y^{x+y+z-\widetilde{x}} \begin{pmatrix} z & 0 \\ 0 & z \\ \widetilde{x}-x & \widetilde{y}-y \end{pmatrix} \boldsymbol{v}(\widetilde{x},\widetilde{y})\,d\widetilde{y}\,d\widetilde{x}, \tag{B.2}$$

$$\mathcal{E}^{\mathrm{div}}w\,(x,y,z) = \frac{2}{z^3}\int_x^{x+z}\int_y^{x+y+z-\widetilde{x}} \begin{pmatrix} \widetilde{x}-x \\ \widetilde{y}-y \\ -z \end{pmatrix} w(\widetilde{x},\widetilde{y})\,d\widetilde{y}\,d\widetilde{x}. \tag{B.3}$$

We have already seen the primary extension appearing in (B.1) in the previous sections. The other two operators above are the primary extensions for the $\boldsymbol{H}(\mathbf{curl}\,)$ and $\boldsymbol{H}(\mathrm{div})$ case (which will be discussed in more detail in Parts II [11] and III [12]).

The purpose of this appendix is to establish the continuity property of $\mathcal{E}^{\mathrm{grad}}$ stated in Theorem 2.1. But since the arguments required to prove the continuity of the other two operators $\mathcal{E}^{\mathrm{curl}}$ and $\mathcal{E}^{\mathrm{div}}$ are very similar, we establish the continuity of all of these primary extensions together here. We can exhibit two techniques to establish such continuity properties, one using the Fourier transform, and the other using Peetre's K-functional. The latter approach will be shown in Part II. In this appendix, we outline the more standard Fourier transform technique.

The Fourier transform technique proceeds by viewing the above operators as extending functions given on $\mathbb{R}^2$ (the entire x-y plane) into the infinite slab $\mathbb{R}^2 \times (0,1) \equiv \{(x,y,z) : 0 < z < 1\}$. Define the Fourier transform on $\mathbb{R}^2$ as usual by

$$\mathcal{F}u\,(\boldsymbol{\omega}) \equiv \widehat{u}(\boldsymbol{\omega}) := \iint_{\mathbb{R}^2} e^{-i2\pi\boldsymbol{\omega}\cdot\boldsymbol{x}}u(\boldsymbol{x})\,d\boldsymbol{x}. \tag{B.4}$$

We begin by noting some properties of the Fourier transform of an indicator function.

LEMMA B.1. *Let $\chi_{\triangle}$ denote the characteristic function of the unit triangle $\triangle = \{(x,y)\in\mathbb{R}^2 : x>0, y>0, x+y<1\}$, and $\eta(x,y)$ be a linear function. Then, for all $t>0$ and all unit vectors $\boldsymbol{\omega}$,*

(1) *$\widehat{\chi_{\triangle}\eta}\,(t\boldsymbol{\omega})$ is bounded uniformly in t and $\boldsymbol{\omega}$, and*

(2) *the integral $\displaystyle\int_0^\infty |\widehat{\chi_{\triangle}\eta}\,(t\boldsymbol{\omega})|^2\,dt$ is finite and bounded uniformly in $\boldsymbol{\omega}$.*

Proof. We begin with the case of a constant function $\eta\equiv 1$. For this case the first assertion is immediate as the exponential in (B.4) is uniformly bounded by one:

$$|\widehat{\chi_{\triangle}\eta}(\boldsymbol{\omega})| = |\widehat{\chi}_{\triangle}(\boldsymbol{\omega})| \le \iint_{\triangle} \left|e^{-i2\pi t\boldsymbol{\omega}\cdot\boldsymbol{x}}\right| d\boldsymbol{x} \le \frac{1}{2}. \tag{B.5}$$

To prove the second assertion, it will be convenient to work with a rotated system of coordinates $\widetilde{x},\widetilde{y}$ in such a way that the $\widetilde{x}$-axis passes through the point $\boldsymbol{\omega}$ (see Figure 5). We consider only the case when $\boldsymbol{\omega}$ is in the first quadrant as the other cases are similar. Then

$$\widehat{\chi_{\triangle}\eta}(\boldsymbol{\omega}) = \int_{\mathbb{R}}\int_{\mathbb{R}} e^{-i2\pi|\boldsymbol{\omega}|\widetilde{x}}\chi_{\triangle}(\widetilde{x},\widetilde{y})\,d\widetilde{x}\,d\widetilde{y} = \int_{\widetilde{y}_1}^{\widetilde{y}_2}\left[\frac{e^{-i2\pi|\boldsymbol{\omega}|\widetilde{x}}}{-i2\pi|\boldsymbol{\omega}|}\right]_{\widetilde{x}=a(\widetilde{y})}^{\widetilde{x}=b(\widetilde{y})} d\widetilde{y}\,,$$

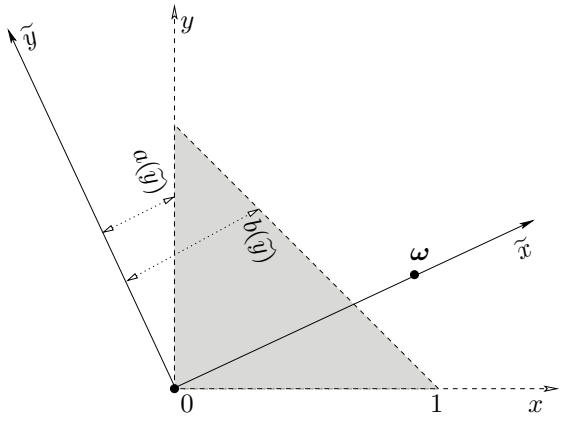


FIG. 5. *Rotated system of coordinates* $(\widetilde{x}, \widetilde{y})$ *in Lemma* B.1.

where $a(\widetilde{y})$ and $b(\widetilde{y})$ are as in Figure 5, $\widetilde{y}_1$ and $\widetilde{y}_2$ are such that the interval $[\widetilde{y}_1, \widetilde{y}_2]$ is the projection of $\triangle$ on the $\widetilde{y}$-axis, and the notation $[g(x)]_{x=p}^{x=q}$ denotes the difference $g(q) - g(p)$. Now, for $|\boldsymbol{\omega}| = 1$ and $t > 0$, the second assertion follows from

$$\int_1^\infty |\widehat{\chi}_\triangle(t\boldsymbol{\omega})|^2 \, dt = \int_1^\infty \left| \int_{\widetilde{y}_1}^{\widetilde{y}_2} \left[\frac{e^{-i2\pi t\widetilde{x}}}{-i2\pi t} \right]_{\widetilde{x}=a(\widetilde{y})}^{\widetilde{x}=b(\widetilde{y})} d\widetilde{y} \right|^2 dt$$
$$\leq \int_1^\infty \frac{1}{4\pi^2} \left| \frac{1}{t} \int_{-1}^1 \left[e^{-i2\pi t\widetilde{x}} \right]_{\widetilde{x}=a(\widetilde{y})}^{\widetilde{x}=b(\widetilde{y})} d\widetilde{y} \right|^2 dt$$

and the fact that the inner integral is bounded uniformly in t. Notice that integrability from 0 to 1 follows from the first assertion.

The proofs for $\eta(x, y) = x$ and $\eta(x, y) = y$ are similar. For instance, for $\eta(x, y) = x = (\widetilde{x}, -\widetilde{y})^t \cdot \boldsymbol{\omega}$, we have

$$\widehat{\chi_\triangle x}(t\boldsymbol{\omega}) = \int_{\widetilde{y}_1}^{\widetilde{y}_2} \left(\int_{a(\widetilde{y})}^{b(\widetilde{y})} e^{-i2\pi t\widetilde{x}} \begin{pmatrix} \widetilde{x} \\ -\widetilde{y} \end{pmatrix} \cdot \boldsymbol{\omega} \; d\widetilde{x} \right) d\widetilde{y},$$

so the first assertion follows because the integrand is uniformly bounded. The second assertion also follows because once the inner integral is evaluated, it is immediate that it can be bounded as before by C/t as $t \to \infty$. ∎

Remark B.1. In fact, Lemma B.1 extends to a large class of functions $\eta(x, y)$, including polynomials of arbitrary degree.

LEMMA B.2. *Let* $\eta(s, t)$ *be a linear polynomial. Then the map defined for smooth functions* $u(x, y)$ *on* $\mathbb{R}^2$ *by*

$$u(x, y) \;\longmapsto\; \mathcal{K}_\eta u\,(x, y, z) := \int_0^1 \int_0^{1-s} \eta(s, t)\, u(x + sz, y + tz)\, dt\, ds$$

extends to a continuous operator from $H^{-1/2}(\mathbb{R}^2)$ *into* $L^2\big(\mathbb{R}^2 \times (0, 1)\big)$.

Proof. We shall consider the case $\eta \equiv 1$ first. Notice that for each fixed z, the operator is in the form of a convolution in x and y variables:

$$\mathcal{K}_\eta u(x, y, z) = \frac{1}{z^2} \int_{-z}^0 \int_{-z-s'}^0 u(x - s', y - t')\, dt'\, ds' = \frac{1}{z^2} (\chi_{z\triangledown} * u),$$

where $\chi_{z\nabla}$ is the characteristic function of $\{(x,y) : x<0, y<0, x+y>-z\}$ (the unit triangle scaled by $-z$). In what follows, we assume that $u(x,y)$ is a test function from the Schwartz space (see, e.g., [19, 23]) and, upon establishing the continuity estimate, tacitly complete the proof using the standard density argument.

Applying the Fourier transform (on the x-y plane) and using its standard properties [19]

$$\widehat{\mathcal{K}_\eta u}\,(\boldsymbol{\omega},z) \;=\; \frac{1}{z^2}\,\widehat{\chi}_{z\nabla}(\boldsymbol{\omega})\,\widehat{u}(\boldsymbol{\omega}) \;=\; \widehat{\chi}_{\triangle}(-z\boldsymbol{\omega})\,\widehat{u}(\boldsymbol{\omega}).$$

By Parseval's identity,

$$\begin{aligned}\int_0^1 \iint\limits_{\mathbb{R}^2} |\mathcal{K}_\eta u(x,y,z)|^2\,dx\,dy\,dz &= \int_0^1 \iint\limits_{\mathbb{R}^2} |\widehat{\mathcal{K}_\eta u}(\boldsymbol{\omega},z)|^2\,d\boldsymbol{\omega}\,dz\\ &= \iint\limits_{\mathbb{R}^2}\left(\int_0^1 |\widehat{\chi}_{\triangle}(z\boldsymbol{\omega})|^2\,dz\right)|\widehat{u}(\boldsymbol{\omega})|^2\,d\boldsymbol{\omega}. \qquad \text{(B.6)}\end{aligned}$$

Now we split the integral over $\mathbb{R}^2$ into two integrals, one over the unit disk $D=\{\boldsymbol{\omega}\in\mathbb{R}^2:\ |\boldsymbol{\omega}|<1\}$ and the other over $\mathbb{R}^2\setminus D$, and analyze each separately.

Substituting $z|\boldsymbol{\omega}|=t$ and denoting $\widehat{\boldsymbol{\omega}}=\boldsymbol{\omega}/|\boldsymbol{\omega}|$,

$$\int_0^1 |\widehat{\chi}_{\triangle}(z\boldsymbol{\omega})|^2\,dz = \frac{1}{|\boldsymbol{\omega}|}\int_0^{|\boldsymbol{\omega}|} |\widehat{\chi}_{\triangle}(t\widehat{\boldsymbol{\omega}})|^2\,dt \le \frac{1}{2} \qquad \text{(B.7)}$$

by the first assertion of Lemma B.1 (see (B.5)). By the second assertion of Lemma B.1, we can get another bound for the same term:

$$\int_0^1 |\widehat{\chi}_{\triangle}(z\boldsymbol{\omega})|^2\,dz = \frac{1}{|\boldsymbol{\omega}|}\int_0^{|\boldsymbol{\omega}|} |\widehat{\chi}_{\triangle}(t\widehat{\boldsymbol{\omega}})|^2\,dt \le \frac{1}{|\boldsymbol{\omega}|}\int_0^{\infty} |\widehat{\chi}_{\triangle}(t\widehat{\boldsymbol{\omega}})|^2\,dt \le \frac{c}{|\boldsymbol{\omega}|}. \qquad \text{(B.8)}$$

Using these estimates in (B.6), specifically (B.7) in D and (B.8) in $\mathbb{R}^2\setminus D$,

$$\begin{aligned}\int_0^1 \iint\limits_{\mathbb{R}^2} |\mathcal{K}_\eta u(x,y,z)|^2\,dx\,dy\,dz &\le \iint\limits_{D} \frac{1}{2}|\widehat{u}(\boldsymbol{\omega})|^2\,d\boldsymbol{\omega} + \iint\limits_{\mathbb{R}^2\setminus D} \frac{c}{|\boldsymbol{\omega}|}|\widehat{u}(\boldsymbol{\omega})|^2\,d\boldsymbol{\omega}\\ &\le C\iint\limits_{\mathbb{R}^2}\left(1+|\boldsymbol{\omega}|^2\right)^{-1/2}|\widehat{u}(\boldsymbol{\omega})|^2\,d\boldsymbol{\omega}.\end{aligned}$$

Because of a well-known characterization of Sobolev norms via the Fourier transform [19, 23], the right-hand side above is the square of a norm equivalent to the $H^{-1/2}(\mathbb{R}^2)$ norm, so the proof for the $\eta\equiv 1$ case is finished.

The reasoning for cases $\eta(x,y)=x$ and $\eta(x,y)=y$ is fully analogous. For instance, for the former, we have

$$\mathcal{K}_\eta\,(x,y,z) = \frac{1}{z^2}\left(\frac{x}{z}\chi_{z\nabla} * u\right),$$

so

$$\widehat{\mathcal{K}_\eta u}(\boldsymbol{\omega},z) \;\; = \frac{1}{z^2}\,\widehat{\chi_{z\nabla}x}(\boldsymbol{\omega})\,\widehat{u}(\boldsymbol{\omega}) = \widehat{\chi_{\triangle}x}(z\boldsymbol{\omega})\widehat{u}(\boldsymbol{\omega}).$$

The rest of the estimation is fully analogous utilizing the boundedness properties for the Fourier transform of factor $x\chi_{\triangle}$ proved in Lemma B.1. ∎

THEOREM B.1. *The polynomial extension operators in* (B.1)–(B.3) *extend to continuous operators on the spaces below:*

$$\begin{aligned} \mathcal{E}^{\mathrm{grad}}: &\quad H^{1/2}(\hat{F}) &&\longmapsto &&H^1(\hat{K}) \\ \mathcal{E}^{\mathrm{curl}}: &\quad \boldsymbol{H}^{-1/2}(\mathrm{curl}_\tau, \hat{F}) &&\longmapsto &&\boldsymbol{H}(\mathbf{curl}, \hat{K}) \\ \mathcal{E}^{\mathrm{div}}: &\quad H^{-1/2}(\hat{F}) &&\longmapsto &&\boldsymbol{H}(\mathrm{div}, \hat{K}). \end{aligned}$$

Proof. We quickly sketch the arguments, considering the last operator first.

The $\boldsymbol{H}(\mathrm{div})$ primary extension: According to Lemma B.2, each of the three components of $\mathcal{E}^{\mathrm{div}}$ is a continuous map from $H^{-1/2}(\mathbb{R}^2)$ into $L^2(\mathbb{R}^2 \times (0,1))$. Moreover, $\mathrm{div}(\mathcal{E}^{\mathrm{div}} w) = 0$. Consequently, $\mathcal{E}^{\mathrm{div}}$ maps $H^{-1/2}(\mathbb{R}^2)$ into $\boldsymbol{H}(\mathrm{div}, \mathbb{R}^2 \times (0,1))$. Since there is a continuous extension operator [7] from $H^{-1/2}(\hat{F})$ into $H^{-1/2}(\mathbb{R}^2)$, and since the restriction operator from $\boldsymbol{H}(\mathrm{div}, \mathbb{R}^2 \times (0,1))$ into $\boldsymbol{H}(\mathrm{div}, \hat{K})$ is obviously continuous, the proof of this case is finished.

The $\boldsymbol{H}(\mathbf{curl})$ primary extension: By the same arguments as above, the three components of $\mathcal{E}^{\mathrm{curl}}$ are continuous maps from $H^{-1/2}(\hat{F})$ into $L^2(\hat{K})$. Moreover, by the readily established commutativity property

$$\mathbf{curl}\,(\mathcal{E}^{\mathrm{curl}} \boldsymbol{v}) = \mathcal{E}^{\mathrm{div}}(\mathrm{curl}_\tau\, \boldsymbol{v})$$

and the continuity of $\mathcal{E}^{\mathrm{div}}$ on $H^{-1/2}(\hat{F})$, we find that $\mathcal{E}^{\mathrm{curl}}$ is a continuous map from $\boldsymbol{H}^{-1/2}(\mathbf{curl}, \hat{F})$ into $\boldsymbol{H}(\mathbf{curl}, T)$.

The H^1 primary extension: The surface gradient $\mathbf{grad}_\tau$ is a continuous map [6] from $H^{1/2}(\hat{F})$ into $\boldsymbol{H}^{-1/2}(\hat{F})$. Combining this with the easily established commutativity property

$$\mathbf{grad}(\mathcal{E}^{\mathrm{grad}} u) = \mathcal{E}^{\mathrm{curl}}(\mathbf{grad}_\tau\, u),$$

and the continuity of $\mathcal{E}^{\mathrm{curl}}$, we find that the left-hand side above has its $L^2(\hat{K})$ norm bounded by the $H^{1/2}(\hat{F})$ norm of u. Since square integrability of the gradient $\mathbf{grad}(\mathcal{E}^{\mathrm{grad}} u)$ implies the square integrability of the function $\mathcal{E}^{\mathrm{grad}} u$ (by, e.g., a generalization of Stokes theorem [14, Theorem I.2.9]), and since constants are preserved by $\mathcal{E}^{\mathrm{grad}}$, the H^1 extension operator $\mathcal{E}^{\mathrm{grad}}$ is continuous from $H^{1/2}(\hat{F})$ into $H^1(\hat{K})$. ∎

FINITE VOLUME METHOD FOR 2D LINEAR AND NONLINEAR ELLIPTIC PROBLEMS WITH DISCONTINUITIES*

FRANCK BOYER† AND FLORENCE HUBERT†

Abstract. In this paper we study the approximation of solutions to linear and nonlinear elliptic problems with discontinuous coefficients in the discrete duality finite volume (DDFV) framework. This family of schemes allows very general meshes and inherits the main properties of the continuous problem. In order to take into account the discontinuities and to prevent consistency defect in the scheme, we propose to modify the definition of the numerical fluxes on the edges of the mesh where the discontinuity occurs. We first illustrate our approach by the study of the 1D situation. Then, we show how to design our new scheme, called m-DDFV, and we propose its analysis. We also describe an iterative solver, whose convergence is proved, which can be used to solve the nonlinear discrete equations defining the finite volume scheme. Finally, we provide numerical results which confirm that the m-DDFV scheme significantly improves the convergence rate of the usual DDFV method for both linear and nonlinear problems.

Key words. finite volume schemes, discontinuous coefficients, nonlinear elliptic problems

DOI. 10.1137/060666196

1. Introduction.

In this paper, we are concerned with the finite volume approximation of solutions to the following nonlinear diffusion problem with homogeneous Dirichlet boundary conditions:

$$\begin{cases} -\mathrm{div}(\varphi(z,\nabla u_e(z))) = f(z), & \text{in } \Omega, \\ u_e = 0, & \text{on } \partial\Omega, \end{cases} \tag{1.1}$$

where Ω is a given bounded polygonal domain in $\mathbb{R}^2$. We first recall the classical functional framework ensuring that the problem above is well-posed (see [16]). Let $p \in]1,\infty[$ and $p' = \frac{p}{p-1}$. The flux $\varphi : \Omega \times \mathbb{R}^2 \to \mathbb{R}^2$ in (1.1) is supposed to be a Caratheodory function, which is strictly monotonic with respect to $\xi \in \mathbb{R}^2$:

$$(\mathcal{H}_1) \qquad (\varphi(z,\xi) - \varphi(z,\eta), \xi - \eta) > 0, \text{ for all } \xi \neq \eta, \text{ for } a.e.\ z \in \Omega\,.$$

We also assume that there exists $C_\varphi > 0$ such that

$$(\mathcal{H}_2) \qquad (\varphi(z,\xi),\xi) \geq \frac{1}{C_\varphi}|\xi|^p - C_\varphi, \text{ for all } \xi \in \mathbb{R}^2, \text{ for } a.e.\ z \in \Omega,$$

$$(\mathcal{H}_3) \qquad |\varphi(z,\xi)| \leq C_\varphi \left(1 + |\xi|^{p-1}\right), \text{ for all } \xi \in \mathbb{R}^2, \text{ for } a.e.\ z \in \Omega.$$

These assumptions ensure that $u \mapsto -\mathrm{div}(\varphi(\,\cdot\,,\nabla u))$ is a Leray–Lions operator, and hence that Problem (1.1) has a unique solution in $W_0^{1,p}(\Omega)$ for any $f \in W^{-1,p'}(\Omega)$. Nevertheless, since we are particularly interested in proving error estimates for (piecewise) smooth enough solutions, we restrict our attention here to source terms f in $L^{p'}(\Omega)$.

In the present work, we concentrate on the case where the flux φ defining the equation admits discontinuities with respect to the space variable z. This kind of transmission (or bimaterial) problems were, for instance, studied in the finite element framework in [11, 20] for $p = 2$ and in [17, 18] for $p \neq 2$. A typical physical situation where one can face such problems is the computation of an incompressible flow in an heterogeneous porous medium (with various layers of different kinds, for instance). In a linear regime (for small or moderate pressure gradients), the situation is modeled by a Darcy low whose permeability tensor is anisotropic and possibly discontinuous across interfaces between different material layers. In a nonlinear regime, the Darcy law may not be relevant anymore, and we may use a nonlinear Darcy law (like the Darcy–Forchheimer law, for instance) in each of the layers of the porous medium. In that situation, we exactly have to deal with Leray–Lions-type operators with discontinuous coefficients. Note that the general situation where the operator is linear in some subdomains and nonlinear in others does not exactly enter the scope of the present paper. Nevertheless, the schemes we propose here can easily be extended to this case and the analysis (which is much more intricate) can also be performed (see some details in [5]).

A key concept in this work is the notion of transmission condition. Indeed, suppose, for instance, that Ω is divided into two disjoint domains Ω_1 and Ω_2 and that φ is smooth with respect to the space variable z on each subdomain Ω_i, $i = 1, 2$. A function $u_e \in W_0^{1,p}(\Omega)$ solves (1.1) if and only if:

1. It solves the equation $-\mathrm{div}(\varphi(z, \nabla u_e(z))) = f(z)$ in the two domains Ω_1 and Ω_2.
2. The normal flux $\varphi(z, \nabla u_e(z)) \cdot \boldsymbol{\nu}$ is *continuous* accross $\Gamma = \partial\Omega_1 \cap \partial\Omega_2$, which means that the two traces of this flux (in the sense of $W^{-\frac{1}{p'},p'}(\Gamma)$) computed from the two domains Ω_1 and Ω_2 are the same.

In the context of flows in heterogeneous porous media briefly described above, the transmission condition is nothing but the mass conservation property across the interfaces between the different layers.

Our analysis mainly consists in taking into account such a transmission condition in a finite volume scheme accross each edge in the mesh.

Finite volume approximation of such nonlinear elliptic problems is a current research topic. We refer to [3, 4, 9] for the description and the analysis of the main available schemes up to now. More precisely, we proposed in [3] to approach the solution to (1.1) by using a discrete duality finite volume method (DDFV). This method (previously studied in the linear case in [8, 14, 15]) can be applied to a wide class of 2D meshes (note that 3D cases can also be treated, see [6, 19]) and inherits the main qualitative properties of the continuous problem: monotonicity, coercivity, variational formulation, etc... (see Lemmas 4.7, 4.8, 4.9). Hence, we succeeded in showing the convergence of such schemes and error estimates in the case where the flux φ and the exact solution u_e are assumed to be smooth enough. In the case where φ has discontinuous coefficients, our results in [3] show that the scheme is still convergent but the error analysis is no more valid.

Actually, it is known (even for a 1D linear equation) that such discontinuities in the coefficients imply a consistency defect in the numerical fluxes of usual finite volume schemes. In the linear case, this leads to a $\frac{1}{2}$ convergence rate in the discrete H^1 norm instead of the first order we may expect. The situation is the same for DDFV schemes, and it is needed to modify the scheme in order to take into account the jumps of the coefficients of the problem and then to recover a better convergence rate.

The aim of this work is to present a modified DDFV scheme in this framework—that we called m-DDFV—which enjoys a better convergence rate than the usual DDFV method. Then we provide the error analysis of this scheme. In particular, in the linear case, we prove the first-order convergence of the m-DDFV scheme. Hence, our analysis provides a theoretical confirmation of the behavior numerically observed in a particular case in [15].

Outline. In section 2, we propose to study a simple 1D problem where the flux φ has only one point of discontinuity. This section will let us introduce the main ideas of the method we propose and illustrate the way one can obtain the consistency estimate for the scheme under study.

In section 3, we recall the DDFV framework for the finite volume approximation of nonlinear elliptic problems on unstructured grids. We also recall the scheme introduced and analyzed in [3]. In section 4, we describe the m-DDFV scheme and its first properties.

Section 5 is devoted to the error analysis of this method in the case where the exact solution is assumed to be piecewise smooth enough. The main new difficulty in the analysis, compared to the ones already encountered in [3], is contained in the consistency estimate of the new discrete gradient operator introduced in section 4. As an illustration, we give some explicit examples of the schemes under study in section 6. Nevertheless, in general, the method is not explicit and then seems to be difficult to solve. That is the reason why in section 7 we propose an iterative explicit algorithm to compute the approximate solution for any given data and we prove its convergence.

Notice that we also introduce a so-called *hybrid* DDFV scheme, called h-DDFV, for which a better error estimate can be obtained in the very common case where the flux is, in fact, smooth enough on a finite number of subdomains covering the whole domain Ω.

We finally conclude this paper by showing, in section 8, some numerical results illustrating both the efficiency of the finite volume scheme and of the iterative solver.

2. A 1D finite volume method for a model problem.

2.1. The toy system. Let us consider in this section a model problem in 1D of the form (1.1) in order to illustrate the main steps we will follow in the sequel of this paper for 2D problems. We take $\Omega =]-1,1[$ (denoting here by x the space variable) and we define $\varphi(x,\xi) = \varphi_-(\xi)$ for $x < 0$ and $\varphi(x,\xi) = \varphi_+(\xi)$ for $x > 0$. We suppose that φ_- and φ_+ are two increasing maps from $\mathbb{R}$ to $\mathbb{R}$ such that $(\mathcal{H}_2)$ and $(\mathcal{H}_3)$ hold.

Problem (1.1) reads in this setting

$$\begin{cases} -\partial_x\big(\varphi_-(\partial_x u_e)\big) = f(x), \text{ for } x < 0, \\ -\partial_x\big(\varphi_+(\partial_x u_e)\big) = f(x), \text{ for } x > 0, \\ u_e(-1) = u_e(1) = 0, \\ \varphi_-(\partial_x u_e(0^-)) = \varphi_+(\partial_x u_e(0^+)), \end{cases} \tag{2.1}$$

the last equation being, in this simplified case, the transmission condition described in the introduction.

2.2. The 1D finite volume scheme. Suppose now that we are given a finite volume mesh $\mathcal{T}$ of the domain Ω compatible with the discontinuity point. More precisely, let $x_0 = -1 < \ldots < x_N = 0 < \ldots < x_{N+M} = 1$ a subdivision of $[-1,1]$. We denote by $\kappa_{i+\frac{1}{2}} = [x_i, x_{i+1}]$, $i \in \{0,\ldots,N+M-1\}$ the control volumes of this discretization and by $x_{i+\frac{1}{2}}$ their centers. The finite volume method associates to each

center $x_{i+\frac{1}{2}}$ an unknown value $u_{i+\frac{1}{2}}$. We denote by $u^{\mathcal{T}} = (u_{i+\frac{1}{2}})_{0\le i\le N+M-1}$ the whole approximate solution, and we define the usual difference quotients

$$\nabla_i u^{\mathcal{T}} = \frac{u_{i+\frac{1}{2}} - u_{i-\frac{1}{2}}}{x_{i+\frac{1}{2}} - x_{i-\frac{1}{2}}},\ i \in \{0,\dots,N+M\},$$

where, conventionally, we set $x_{-\frac{1}{2}} = x_0 = -1$, $x_{N+M+\frac{1}{2}} = x_{N+M} = 1$, and $u_{-\frac{1}{2}} = u_{N+M+\frac{1}{2}} = 0$. To obtain the finite volume scheme, we integrate the problem (2.1) on each control volume

$$-\int_{\mathcal{K}_{i+\frac{1}{2}}} \partial_x\big(\varphi(x,\partial_x u_e)\big)\,dx = \int_{\mathcal{K}_{i+\frac{1}{2}}} f(x)\,dx,\quad \forall i \in \{1,\dots,N+M-1\}.$$

Integrating the first term by parts, the scheme reads

$$-F_{i+1} + F_i = \int_{\mathcal{K}_{i+\frac{1}{2}}} f(x)\,dx,\quad \forall i \in \{0,\dots,N+M-1\}, \tag{2.2}$$

where F_i, $i \in \{0, N+M\}$ is an approximation of the flux $\varphi(x_i, \partial_x u_e(x_i))$. This approximation can easily be obtained away from the discontinuity in the usual way:

$$\begin{cases} F_i = \varphi_-\left(\nabla_i u^{\mathcal{T}}\right),\quad \forall i \in \{0,\dots,N-1\},\\ F_i = \varphi_+\left(\nabla_i u^{\mathcal{T}}\right),\quad \forall i \in \{N+1,\dots,N+M\}. \end{cases} \tag{2.3}$$

The problem is: how do we choose the numerical flux F_N at the point $x_N = 0$ where the discontinuity occurs? One may imagine many naive ways to treat this problem. For instance, one can define F_N by

$$F_N = \varphi_-\left(\nabla_N u^{\mathcal{T}}\right),\ \text{or } F_N = \varphi_+\left(\nabla_N u^{\mathcal{T}}\right),\ \text{or } F_N = \frac{1}{2}\left(\varphi_-\left(\nabla_N u^{\mathcal{T}}\right) + \varphi_+\left(\nabla_N u^{\mathcal{T}}\right)\right).$$

In fact, it can be shown that all these choices lead, in general, to a nonconsistent approximation of the flux at x_N. This fact is well known even in the linear case (see, e.g., [10]). A good way to find out a consistent approximation of the flux is to introduce a new artificial unknown $\tilde{u}$ at the point of the discontinuity x_N so that we can define two different approximate gradients on both sides of the discontinuity

$$\nabla_N^+ u^{\mathcal{T}} = \frac{u_{N+\frac{1}{2}} - \tilde{u}}{h_N^+},\quad \text{and } \nabla_N^- u^{\mathcal{T}} = \frac{\tilde{u} - u_{N-\frac{1}{2}}}{h_N^-}, \tag{2.4}$$

where we set $h_N^+ = x_{N+\frac{1}{2}} - x_N$ and $h_N^- = x_N - x_{N-\frac{1}{2}}$. In fact, it is convenient (see Figure 2.1 and the discussion below) to look for $\tilde{u}$ under the form

$$\tilde{u} = \bar{u} + \delta,\quad \text{with } \bar{u} = \frac{h_N^- u_{N+\frac{1}{2}} + h_N^+ u_{N-\frac{1}{2}}}{h_N^- + h_N^+}.$$

The value $\bar{u}$ is the value at the point 0 of the affine interpolation between $(x_{N-\frac{1}{2}}, u_{N-\frac{1}{2}})$ and $(x_{N+\frac{1}{2}}, u_{N+\frac{1}{2}})$. From now on, δ is the new artificial unknown to be determined. It follows that

$$\nabla_N^+ u^{\mathcal{T}} = \nabla_N u^{\mathcal{T}} - \frac{\delta}{h_N^+},\quad \text{and } \nabla_N^- u^{\mathcal{T}} = \nabla_N u^{\mathcal{T}} + \frac{\delta}{h_N^-}.$$

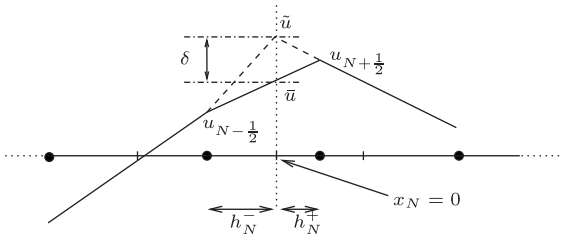

FIG. 2.1. *Illustration of the* 1*D case.*

Notice that we have

$$\nabla_N u^{\mathcal{T}} = \frac{1}{h_N^- + h_N^+} \left(h_N^- \nabla_N^- u^{\mathcal{T}} + h_N^+ \nabla_N^+ u^{\mathcal{T}} \right). \tag{2.5}$$

It is now necessary to eliminate the new unknown δ. This is done by imposing a discrete equivalent of the transmission condition in (2.1) which reads

$$\varphi_-(\nabla_N^- u^{\mathcal{T}}) = \varphi_+(\nabla_N^+ u^{\mathcal{T}}). \tag{2.6}$$

This equation uniquely defines δ as a function $\delta = \delta_N(\nabla_N u^{\mathcal{T}})$ of the usual difference quotient $\nabla_N u^{\mathcal{T}}$ since the map $\delta \mapsto \varphi_-(\nabla_N^- u^{\mathcal{T}}) - \varphi_+(\nabla_N^+ u^{\mathcal{T}})$ is strictly monotonic and tends to infinity at infinity. In the particular case where $\varphi_- = \varphi_+$, δ_N is then identically zero and $\nabla_N^+ u^{\mathcal{T}} = \nabla_N^- u^{\mathcal{T}} = \nabla_N u^{\mathcal{T}}$. Hence, we recover the generic situation without discontinuities in the coefficients of the equation. We can eventually define the approximate flux at the discontinuity by

$$F_N = \varphi_- \left(\nabla_N u^{\mathcal{T}} + \frac{\delta_N(\nabla_N u^{\mathcal{T}})}{h_N^-} \right) = \varphi_+ \left(\nabla_N u^{\mathcal{T}} - \frac{\delta_N(\nabla_N u^{\mathcal{T}})}{h_N^+} \right),$$

the last equality being true by definition of $\delta_N(\nabla_N u^{\mathcal{T}})$. In a more symmetric way we also have

$$F_N = \frac{h_N^- \varphi_- \left(\nabla_N u^{\mathcal{T}} + \frac{\delta_N(\nabla_N u^{\mathcal{T}})}{h_N^-} \right) + h_N^+ \varphi_+ \left(\nabla_N u^{\mathcal{T}} - \frac{\delta_N(\nabla_N u^{\mathcal{T}})}{h_N^+} \right)}{h_N^- + h_N^+}. \tag{2.7}$$

Example 2.1. *Let us consider the case where φ_- and φ_+ are two p-Laplacian-like fluxes given by*

$$\varphi_-(\xi) = k_- |\xi + G_-|^{p-2}(\xi + G_-), \ \forall \xi \in \mathbb{R},$$
$$\varphi_+(\xi) = k_+ |\xi + G_+|^{p-2}(\xi + G_+), \ \forall \xi \in \mathbb{R},$$

where $k_-, k_+ \in \mathbb{R}^+$ and $G_-, G_+ \in \mathbb{R}$. In this situation, all the computations can be made by hand. In particular, (2.6) *can be solved and we find*

$$\delta_N(\xi) = h_N^- h_N^+ \frac{\left[(k_+)^{\frac{1}{p-1}} - (k_-)^{\frac{1}{p-1}} \right] \xi + \left[(k_+)^{\frac{1}{p-1}} G_+ - (k_-)^{\frac{1}{p-1}} G_- \right]}{h_N^+ (k_-)^{\frac{1}{p-1}} + h_N^- (k_+)^{\frac{1}{p-1}}}.$$

Finally, the numerical flux at the discontinuity is found to be

$$F_N = \left(\frac{k_-^{\frac{1}{p-1}} k_+^{\frac{1}{p-1}} (h_N^- + h_N^+)}{h_N^+ k_-^{\frac{1}{p-1}} + h_N^- k_+^{\frac{1}{p-1}}} \right)^{p-1} \left| \nabla_N u^{\mathcal{T}} + \overline{G} \right|^{p-2} \left(\nabla_N u^{\mathcal{T}} + \overline{G} \right),$$

where $\overline{G}$ *is the arithmetic mean-value between* G_- *and* G_+ *defined by*

$$\overline{G} = \frac{h_N^- G_- + h_N^+ G_+}{h_N^- + h_N^+}.$$

Notice that the map $\nabla_N u^{\mathcal{T}} \mapsto F_N$ *is increasing and coercive. In the linear case (i.e.,* $p = 2$*) we recover the well-known harmonic mean-value formula between the two diffusion coefficients* k_- *and* k_+ *(see, for instance,* [10]*):*

$$F_N = \frac{k_- k_+ (h_N^- + h_N^+)}{h_N^+ k_- + h_N^- k_+} \left(\nabla_N u^{\mathcal{T}} + \overline{G} \right).$$

Let us sum up the previous study: we defined a monotonic map $\nabla_N u^{\mathcal{T}} \mapsto \delta_N(\nabla_N u^{\mathcal{T}})$ and a numerical flux F_N at the discontinuity, which is also a monotonic map with respect to $\nabla_N u^{\mathcal{T}}$. The finite volume scheme is then given by (2.2) with (2.3) and (2.7).

A very important remark is that the map δ_N is defined through the implicit relation (2.6) and hence, in general, cannot be computed explicitly like in Example 2.1. At first sight, it can be considered as a major drawback of our approach. Nevertheless, we will propose in section 7 a fully practical solver for this nonlinear scheme whose convergence is proved and whose computational cost is of the same order as in the case of continuous coefficient equations.

2.3. Consistency analysis. Let us analyze the consistency property of the flux F_N defined above. The following computations give the main ideas used in the analysis of the 2D scheme presented in the sequel of this paper. For simplicity we assume in this section that $p > 2$ and we suppose that φ_- and φ_+ satisfy the strong monotonicity assumption ($\mathcal{H}_{1'b}$) and the Hölder regularity assumption ($\mathcal{H}_{4b}$) described in section 4.1. Finally we suppose that the exact solution u_e of (2.1) is continuous on Ω and smooth on the two sides of the discontinuity point $x_N = 0$. In order to simplify the notations, assume that $h_N^- = h_N^+$ and denote this common value by h.

The error analysis for such a finite volume scheme basically relies on the estimate of the consistency error on the discrete gradient just defined above. This consistency error measures the distance between the gradient $\partial_x u_e$ of the exact solution and the discrete gradient applied to the projection $\mathbb{P}^{\mathcal{T}} u_e = (u_e(x_{i+\frac{1}{2}}))_{0 \le i \le N+M-1}$ of the exact solution on the mesh. More precisely, one has typically to estimate quantities like

$$R = \frac{1}{h} \int_{-h}^{0} |\partial_x u_e - \nabla_N^- \mathbb{P}^{\mathcal{T}} u_e|^p \, dx. \tag{2.8}$$

The corresponding result in the DDFV framework will be given in Proposition 5.7. It will imply the estimate of the consistency error on the fluxes (Proposition 5.8) and finally the *a priori* error estimates for the finite volume (Theorems 5.1 and 5.3).

Returning to our 1D example, let us derive an estimate for the term R defined in (2.8). Since u_e is smooth on $[-h, 0]$ we have

$$\begin{aligned} R &\le C \|\partial_x^2 u_e\|_\infty h^p + \frac{1}{h} \int_{-h}^{0} \left| \frac{u_e(x_N) - u_e(x_{N-\frac{1}{2}})}{h} - \frac{\tilde{u} - u_e(x_{N-\frac{1}{2}})}{h} \right|^p dx \\ &= C \|\partial_x^2 u_e\|_\infty h^p + \left| \frac{u_e(x_N) - \tilde{u}}{h} \right|^p, \end{aligned} \tag{2.9}$$

where $\tilde{u}$ is the artifical unknown (associated to $u^{\mathcal{T}} = \mathbb{P}^{\mathcal{T}} u_e$) defined in (2.6), that is, through the equation

$$\varphi_- \left(\frac{\tilde{u} - u_e(x_{N-\frac{1}{2}})}{h} \right) = \varphi_+ \left(\frac{u_e(x_{N+\frac{1}{2}}) - \tilde{u}}{h} \right). \tag{2.10}$$

Furthermore, since u_e is piecewise smooth, Taylor expansions yield

$$\frac{u_e(x_N) - u_e(x_{N-\frac{1}{2}})}{h} = \partial_x u_e(0^-) + T_1 h, \tag{2.11}$$

$$\frac{u_e(x_{N+\frac{1}{2}}) - u_e(x_N)}{h} = \partial_x u_e(0^+) + T_2 h, \tag{2.12}$$

where T_1 and T_2 are bounded with respect to h. Hence, using (2.11) and (2.12), the transmission condition in (2.1) reads

$$\varphi_- \left(\frac{u_e(x_N) - u_e(x_{N-\frac{1}{2}})}{h} - T_1 h \right) = \varphi_+ \left(\frac{u_e(x_{N+\frac{1}{2}}) - u_e(x_N)}{h} - T_2 h \right). \tag{2.13}$$

Finally, we estimate the second term in the right-hand side of (2.9) by using (2.10) and (2.13). To this end, we subtract (2.13) from (2.10) and we multiply by $\frac{u_e(x_N) - \tilde{u}}{h}$. It follows

$$\begin{aligned} &\left(\varphi_- \left(\frac{u_e(x_N) - u_e(x_{N-\frac{1}{2}})}{h} - T_1 h \right) - \varphi_- \left(\frac{\tilde{u} - u_e(x_{N-\frac{1}{2}})}{h} \right) \right) \frac{u_e(x_N) - \tilde{u}}{h} \\ &\quad + \left(\varphi_+ \left(\frac{u_e(x_{N+\frac{1}{2}}) - \tilde{u}}{h} \right) - \varphi_+ \left(\frac{u_e(x_{N+\frac{1}{2}}) - u_e(x_N)}{h} - T_2 h \right) \right) \frac{u_e(x_N) - \tilde{u}}{h} = 0. \end{aligned}$$

We add and subtract now the terms $T_1 h$ and $T_2 h$ in order to make appear expressions under the form $(\varphi_\pm(\xi) - \varphi_\pm(\eta))(\xi - \eta)$. We get

$$\begin{aligned} &\left(\varphi_- \left(\frac{u_e(x_N) - u_e(x_{N-\frac{1}{2}})}{h} - T_1 h \right) - \varphi_- \left(\frac{\tilde{u} - u_e(x_{N-\frac{1}{2}})}{h} \right) \right) \left(\frac{u_e(x_N) - \tilde{u}}{h} - T_1 h \right) \\ &+ \left(\varphi_+ \left(\frac{u_e(x_{N+\frac{1}{2}}) - \tilde{u}}{h} \right) - \varphi_+ \left(\frac{u_e(x_{N+\frac{1}{2}}) - u_e(x_N)}{h} - T_2 h \right) \right) \left(\frac{u_e(x_N) - \tilde{u}}{h} + T_2 h \right) \\ &\quad = -T_1 h \left(\varphi_- \left(\frac{u_e(x_N) - u_e(x_{N-\frac{1}{2}})}{h} - T_1 h \right) - \varphi_- \left(\frac{\tilde{u} - u_e(x_{N-\frac{1}{2}})}{h} \right) \right) \\ &\qquad + T_2 h \left(\varphi_+ \left(\frac{u_e(x_{N+\frac{1}{2}}) - \tilde{u}}{h} \right) - \varphi_+ \left(\frac{u_e(x_{N+\frac{1}{2}}) - u_e(x_N)}{h} - T_2 h \right) \right). \end{aligned}$$

Hence, using assumptions $(\mathcal{H}_{1'b})$ and $(\mathcal{H}_{4b})$ we deduce that

$$\begin{aligned} &\left| \frac{u_e(x_N) - \tilde{u}}{h} - T_1 h \right|^p + \left| \frac{u_e(x_N) - \tilde{u}}{h} + T_2 h \right|^p \\ &\qquad \leq Ch \left(1 + \left| \frac{u_e(x_N) - \tilde{u}}{h} \right|^{p-2} \right) \left(Ch + \left| \frac{u_e(x_N) - \tilde{u}}{h} \right| \right), \end{aligned}$$

and finally we have

$$\left|\frac{u_e(x_N)-\tilde{u}}{h}\right|^p \leq Ch^{\frac{p}{p-1}},$$

so that the consistency term R is finally bounded by

$$R \leq Ch^{\frac{p}{p-1}}.$$

When $p \to 2$ we recover the usual first-order estimate (that is, $R = O(h^2)$), whereas when p increases, this consistency order decreases.

3. The discrete duality finite volume framework.

3.1. Definition of the mesh. We recall the notations used in [3]. Let $\mathcal{T}$ be a triple $(\mathfrak{M}, \mathfrak{M}^*, \mathfrak{D})$ of meshes on Ω as follows (see Figure 3.1). The set $\mathfrak{M}$ is a set of disjoint open polygonal convex control volumes $\kappa \in \Omega$ such that $\cup\bar{\kappa} = \bar{\Omega}$. For all adjacent volume κ and $\mathcal{L}$, we assume that $\partial\kappa \cap \partial\mathcal{L}$ is a segment that we call *an edge of the mesh* and that we denote by $\sigma = \kappa|\mathcal{L}$. Let $\mathcal{E}_{int}$ denote the set of such edges, $\mathcal{E}_{ext}$ denotes the set of edges $\sigma = \partial\kappa \cap \partial\Omega$, and finally $\mathcal{E} = \mathcal{E}_{int} \cup \mathcal{E}_{ext}$. We associate to $\mathfrak{M}$ a family $\mathfrak{P}_{int}$ of points x_κ such that $x_\kappa \in \kappa$ and to the set $\mathcal{E}_{ext}$ a family $\mathfrak{P}_{ext}$ of points x_σ where x_σ is a point of $\sigma \in \mathcal{E}_{ext}$. Let $\mathfrak{P}^*$ be the set of vertices of the mesh $\mathfrak{M}$. The set $\mathfrak{P}^*$ can be decomposed into $\mathfrak{P}^* = \mathfrak{P}^*_{int} \cup \mathfrak{P}^*_{ext}$, where $\mathfrak{P}^*_{ext} \subset \partial\Omega$ and $\mathfrak{P}^*_{int} \cap \partial\Omega = \emptyset$. To any point $x_{\kappa^*} \in \mathfrak{P}^*_{int}$, we associate a polygon $\kappa^* \in \mathfrak{M}^*$ whose vertices are $\{x_\kappa \in \mathfrak{P}/x_{\kappa^*} \in \bar{\kappa},\ \kappa \in \mathfrak{M}\}$ sorted with respect to the clockwise order of the corresponding primal control volumes. Moreover $\mathcal{E}^*$ denotes the set of the edges of the mesh $\mathfrak{M}^*$.

For each $\sigma = \kappa|\mathcal{L} \in \mathcal{E}_{int}$, we can associate a diamond cell $\mathcal{D}$ where $\mathcal{D}$ is the quadrangle whose diagonals are $\sigma = (x_{\mathcal{K}^*}, x_{\mathcal{L}^*})$ and $\sigma^* = \kappa^*|\mathcal{L}^* = (x_\kappa, x_\mathcal{L})$ if $\sigma \in \mathcal{E}_{int}$, and if $\sigma = (x_{\mathcal{K}^*}, x_{\mathcal{L}^*}) \in \mathcal{E}_{ext} \cap \partial\bar{\kappa}$, $\mathcal{D}$ is the triangle defined by the points $x_\kappa, x_{\kappa^*}, x_{\mathcal{L}^*}$. The set of all diamond cells is noted $\mathfrak{D} = \mathfrak{D}_{\rm int} \cup \mathfrak{D}_{\rm ext}$. Note that $\mathfrak{D}$ forms a partition of Ω.

In this work, we assume that the diamond cells are all convex. Notice that this assumption is not necessary, in general, in order to define and analyze DDFV methods (see [3] and [8]).

3.2. Notations. For any one- (resp. two-) dimensional set $\mathcal{V}$, we denote by $|\mathcal{V}|$ its one-dimensional (resp. two-dimensional) Lebesgue measure.

For any control volume $\kappa \in \mathfrak{M}$, we define

- $\mathfrak{D}_\kappa = \{\mathcal{D} \in \mathfrak{D}/\kappa \cap \mathcal{D} \neq \emptyset\}$.

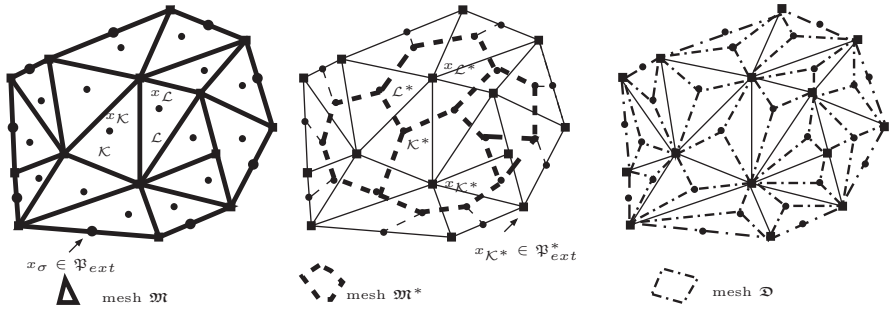

FIG. 3.1. *Example of a DDFV mesh.*

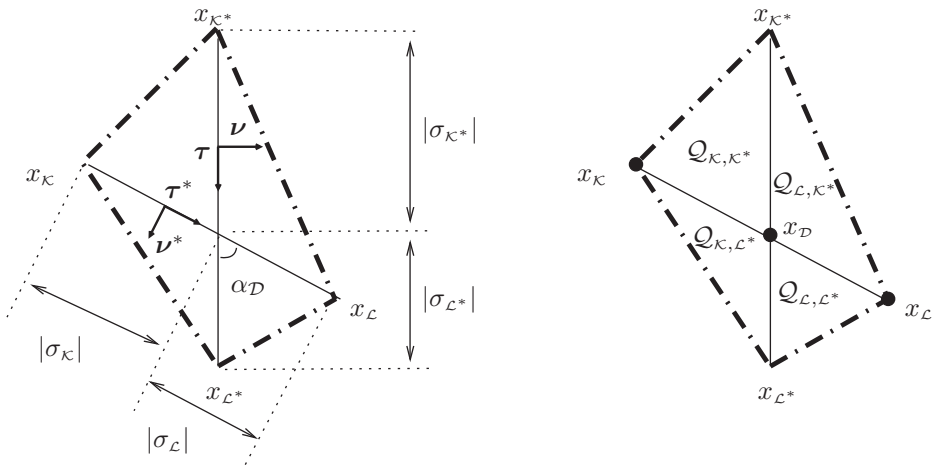

FIG. 3.2. *Notations in a diamond cell; quarter diamonds.*

- $\boldsymbol{\nu}_{\mathcal{K}}$, the outward unit normal vector to $\partial\mathcal{K}$.
- $\mathrm{d}_{\mathcal{K}}$, the diameter of $\mathcal{K}$.

In the same way, for a dual control volume $\mathcal{K}^* \in \mathfrak{M}^*$, we set

- $\mathfrak{D}_{\mathcal{K}^*} = \{\mathcal{D} \in \mathfrak{D} / \mathcal{K}^* \cap \mathcal{D} \neq \emptyset\}$.
- $\boldsymbol{\nu}_{\mathcal{K}^*}$, the outward unit normal vector to $\partial\mathcal{K}^*$.
- $\mathrm{d}_{\mathcal{K}^*}$, the diameter of $\mathcal{K}^*$.

For a diamond cell $\mathcal{D} \in \mathfrak{D}_{\mathrm{int}}$ (resp. $\mathcal{D} \in \mathfrak{D}_{\mathrm{ext}}$), recall that $(x_{\mathcal{K}}, x_{\mathcal{K}^*}, x_{\mathcal{L}}, x_{\mathcal{L}^*})$ are the vertices of $\mathcal{D}$ (resp. $(x_{\mathcal{K}}, x_{\mathcal{K}^*}, x_{\mathcal{L}^*})$ are vertices of $\mathcal{D}$ and $x_\sigma \in \partial\mathcal{D}$) and note:

- $\boldsymbol{\tau}$, the unit vector parallel to σ, oriented from $x_{\mathcal{K}^*}$ to $x_{\mathcal{L}^*}$.
- $\boldsymbol{\nu}$, the unit vector normal to σ, oriented from $x_{\mathcal{K}}$ to $x_{\mathcal{L}}$ (resp. from $x_{\mathcal{K}}$ to x_σ).
- $\boldsymbol{\tau}^*$, the unit vector parallel to σ^*, oriented from $x_{\mathcal{K}}$ to $x_{\mathcal{L}}$ (resp. from $x_{\mathcal{K}}$ to x_σ).
- $\boldsymbol{\nu}^*$, the unit vector normal to σ^*, oriented from $x_{\mathcal{K}^*}$ to $x_{\mathcal{L}^*}$.
- $\alpha_{\mathcal{D}}$, the angle between $\boldsymbol{\tau}$ and $\boldsymbol{\tau}^*$.
- $\mathrm{d}_{\mathcal{D}}$, the diameter of $\mathcal{D}$.
- $x_{\mathcal{D}}$ the intersection of $(x_{\mathcal{K}}, x_{\mathcal{L}})$ and $(x_{\mathcal{K}^*}, x_{\mathcal{L}^*})$ (resp. $x_{\mathcal{D}} = x_\sigma$).

As shown in Figure 3.2, each diamond cell $\mathcal{D} \in \mathfrak{D}_{\mathrm{int}}$ (resp. $\mathcal{D} \in \mathfrak{D}_{\mathrm{ext}}$) is naturally split along its diagonals into a set $\mathfrak{Q}_{\mathcal{D}}$ of four triangles (resp. two triangles), denoted by $\mathcal{Q}_{\mathcal{K},\mathcal{K}^*}$, $Q_{\mathcal{K},\mathcal{L}^*}$, $Q_{\mathcal{L},\mathcal{K}^*}$, and $Q_{\mathcal{L},\mathcal{L}^*}$ and satisfying $Q_{\mathcal{K},\mathcal{K}^*} \subset \overline{\mathcal{K}} \cap \overline{\mathcal{K}^*}$, etc ... The set of all the quarter diamonds in the domain is denoted by $\mathfrak{Q} = \cup_{\mathcal{D}\in\mathfrak{D}} \mathfrak{Q}_{\mathcal{D}}$, and $\mathrm{d}_{\mathcal{Q}}$ denotes the diameter of any $\mathcal{Q} \in \mathfrak{Q}$.

We denote by $\sigma_{\mathcal{K}}, \sigma_{\mathcal{L}}, \sigma_{\mathcal{K}^*}$, and $\sigma_{\mathcal{L}^*}$ the segments $(x_{\mathcal{K}}, x_{\mathcal{D}})$, $(x_{\mathcal{L}}, x_{\mathcal{D}})$, $(x_{\mathcal{K}^*}, x_{\mathcal{D}})$, and $(x_{\mathcal{L}^*}, x_{\mathcal{D}})$, so that $\sigma = \sigma_{\mathcal{K}^*} \cup \sigma_{\mathcal{L}^*}$ and $\sigma^* = \sigma_{\mathcal{K}} \cup \sigma_{\mathcal{L}}$ for $\mathcal{D} \in \mathfrak{D}_{\mathrm{int}}$. For $\mathcal{D} \in \mathfrak{D}_{\mathrm{ext}}$ we note abusively $\sigma^* = \sigma_{\mathcal{K}}$.We note $\mathcal{E}_{\mathcal{Q}}$ the set of such segments included in $\partial\mathcal{Q}$.

3.3. Regularity assumptions for the meshes. We note size$(\mathcal{T})$ as the maximum of the diameters of the diamond cells in $\mathfrak{D}$. The bounds follow:

$$
\begin{aligned}
&|\sigma| \leq \mathrm{size}(\mathcal{T}),\ \forall \sigma \in \mathcal{E}; \quad |\sigma^*| \leq \mathrm{size}(\mathcal{T}),\ \forall \sigma^* \in \mathcal{E}^*;\\
&|\mathcal{K}| \leq \pi\, \mathrm{size}(\mathcal{T})^2,\ \forall \mathcal{K} \in \mathfrak{M}; \quad |\mathcal{K}^*| \leq \pi\, \mathrm{size}(\mathcal{T})^2,\ \forall \mathcal{K}^* \in \mathfrak{M}^*;\\
&|\mathcal{Q}| \leq \frac{1}{2}\mathrm{size}(\mathcal{T})^2,\ \forall \mathcal{Q} \in \mathfrak{Q}.
\end{aligned}
$$

To measure how flat the diamond cells are, we introduce $\alpha_{\mathcal{T}}$ the unique real in $]0, \frac{\pi}{2}]$ such that $\sin\alpha_{\mathcal{T}} \stackrel{\text{def}}{=} \min_{\mathcal{D}\in\mathfrak{D}} |\sin\alpha_{\mathcal{D}}|$. We also need to control the ratio between the sizes of the quarter diamond cells inside each diamond $\mathcal{D}$. As a consequence, we will measure the regularity of the DDFV mesh by the following quantity:

$$\mathrm{reg}(\mathcal{T}) \stackrel{\text{def}}{=} \max\left(\frac{1}{\alpha_{\mathcal{T}}}, \max_{\mathcal{D}\in\mathfrak{D}} \max_{\mathcal{Q}\in\mathfrak{Q}_{\mathcal{D}}} \frac{\mathrm{d}_{\mathcal{D}}}{\sqrt{|\mathcal{Q}|}}, \max_{\substack{\mathcal{K}\in\mathfrak{M}\\ \mathcal{D}\in\mathfrak{D}_{\mathcal{K}}}} \frac{\mathrm{d}_{\mathcal{K}}}{\mathrm{d}_{\mathcal{D}}}, \max_{\substack{\mathcal{K}^*\in\mathfrak{M}^*\\ \mathcal{D}\in\mathfrak{D}_{\mathcal{K}^*}}} \frac{\mathrm{d}_{\mathcal{K}^*}}{\mathrm{d}_{\mathcal{D}}}\right).$$

In particular, there exists two constants C_1 and C_2 depending on $\mathrm{reg}(\mathcal{T})$ such that for any $\kappa \in \mathfrak{M}$, $\kappa^* \in \mathfrak{M}^*$, and $\mathcal{D} \in \mathfrak{D}$ such that $\mathcal{D} \cap \kappa \neq \emptyset$ and $\mathcal{D} \cap \kappa^* \neq \emptyset$ we have

$$C_1|\kappa| \leq |\mathcal{D}| \leq C_2|\kappa|, \quad C_1|\kappa^*| \leq |\mathcal{D}| \leq C_2|\kappa^*|.$$

3.4. Original DDFV approach for linear problems. The DDFV finite volume method associates to all primal control volume $\kappa \in \mathfrak{M}$ an unknown value $u_{\mathcal{K}}$ and to all dual control volume $\kappa^* \in \mathfrak{M}^*$ an unknown value $u_{\mathcal{K}^*}$. The approximate solution $u^{\mathcal{T}}$ is denoted by

$$u^{\mathcal{T}} = \left((u_{\mathcal{K}})_{\mathcal{K}\in\mathfrak{M}}, (u_{\mathcal{K}^*})_{\mathcal{K}^*\in\mathfrak{M}^*}\right).$$

The set of such unknowns $u^{\mathcal{T}}$ is denoted by $\mathbb{R}^{\mathcal{T}}$.

The method consists in introducing a discrete gradient operator $\nabla^{\mathcal{T}}$ (see [7, 8]) defined to be constant on each diamond cell

$$\nabla^{\mathcal{T}}_{\mathcal{D}} u^{\mathcal{T}} = \frac{1}{\sin\alpha_{\mathcal{D}}}\left(\frac{u_{\mathcal{L}} - u_{\mathcal{K}}}{|\sigma^*|}\boldsymbol{\nu} + \frac{u_{\mathcal{L}^*} - u_{\mathcal{K}^*}}{|\sigma|}\boldsymbol{\nu}^*\right), \tag{3.1}$$

where $u_{\mathcal{K}^*} = 0$ (resp. $u_{\mathcal{L}^*} = 0$) if $x_{\mathcal{K}^*} \in \mathfrak{P}^*_{ext}$ (resp. if $x_{\mathcal{L}^*} \in \mathfrak{P}^*_{ext}$) and $u_{\mathcal{L}} = 0$ if $\mathcal{D} \in \mathfrak{D}_{\mathrm{ext}}$. By elementary geometric arguments, we also have the useful equivalent formula given in [8]:

$$\nabla^{\mathcal{T}}_{\mathcal{D}} u^{\mathcal{T}} = \frac{1}{2|\mathcal{D}|}\Big(|\sigma|(u_{\mathcal{L}} - u_{\mathcal{K}})\boldsymbol{\nu} + |\sigma^*|(u_{\mathcal{L}^*} - u_{\mathcal{K}^*})\Big). \tag{3.2}$$

Then the discrete divergence operator is defined to be the adjoint of $\nabla^{\mathcal{T}}$, so that for linear equations (in particular the Laplace equation), we obtain a well-posed finite volume scheme which is, for instance, studied in [8, 14]. Notice that the discrete gradient operator $\nabla^{\mathcal{T}}$ was already used, e.g., in [1, 2, 7], but in these references the values $u_{\mathcal{K}^*}$ and $u_{\mathcal{L}^*}$ on the dual mesh were not considered as unknowns of the problem but were built *via* interpolation formulas between the values of the solution on the primal mesh. In this last approach, there are less unknowns, but the structure of the original equation (in particular, the symmetry) is lost. The main advantage of the DDFV method is that the discrete equations inherit from the properties of the continuous one, which is crucial in particular in the nonlinear setting.

3.5. The DDFV method for nonlinear elliptic problems. In [3], we have studied the generalization of the DDFV method to the nonlinear equation (1.1). We proved that all the tools used in the study of this equation (monotonicity, compactness, etc...) can be translated to the discrete level. The scheme we proposed consists in integrating the equation (1.1) on each $\kappa \in \mathfrak{M}$ and each $\kappa^* \in \mathfrak{M}^*$ and then to approximate fluxes $\int_\sigma (\varphi(s, \nabla u_e(s)), \boldsymbol{\nu})\, ds$ or $\int_{\sigma^*} (\varphi(s, \nabla u_e(s)), \boldsymbol{\nu}^*)\, ds$ by using the

discrete gradient $\nabla^{\mathcal{T}}$ operator defined above. The scheme now writes:

$$\left\{\begin{array}{l} -\displaystyle\sum_{\mathcal{D}\in\mathfrak{D}_{\mathcal{K}}} |\sigma|\left(\varphi_{\mathcal{D}}(\nabla^{\mathcal{T}}_{\mathcal{D}}u^{\mathcal{T}}),\boldsymbol{\nu}_{\mathcal{K}}\right) = |\mathcal{K}| f_{\mathcal{K}},\ \forall \mathcal{K}\in\mathfrak{M}, \\ -\displaystyle\sum_{\mathcal{D}\in\mathfrak{D}_{\mathcal{K}^*}} |\sigma^*|\left(\varphi_{\mathcal{D}}(\nabla^{\mathcal{T}}_{\mathcal{D}}u^{\mathcal{T}}),\boldsymbol{\nu}_{\mathcal{K}^*}\right) = |\mathcal{K}^*| f_{\mathcal{K}^*},\ \forall \mathcal{K}^*\in\mathfrak{M}^*, \end{array}\right. \tag{3.3}$$

where $f_{\mathcal{K}}$ and $f_{\mathcal{K}^*}$ denote the mean value of f over κ and κ^*, respectively, and $\varphi_{\mathcal{D}}$ is the mean value of φ over $\mathcal{D}$; that is:

$$\varphi_{\mathcal{D}}(\xi) = \frac{1}{|\mathcal{D}|}\int_{\mathcal{D}} \varphi(z,\xi)\,dz. \tag{3.4}$$

We proved in [3] that this scheme is convergent for any φ satisfying assumptions $(\mathcal{H}_1)$–$(\mathcal{H}_3)$ and any source term $f \in L^{p'}(\Omega)$, and that we can adapt the scheme for source terms in $W^{-1,p'}(\Omega)$, which is the natural space in which source terms can be taken.

We also proved error estimates for the scheme above in the case where the flux φ is assumed to be smooth enough with respect to ξ and to z on the whole domain Ω, and u_e is assumed to belong to $W^{2,p}(\Omega)$.

4. Taking into account discontinuities in the DDFV framework. The point we are concerned with in this paper is that the scheme (3.3) (even though we know that it is convergent) suffers from a lost of consistency in the case where φ presents discontinuities in the space variable z. This behavior is illustrated in section 8 in comparison with the one of the new scheme we propose in the present section. More precisely, we present a way to recover the consistency of the fluxes even when φ presents jumps. The method essentially follows the line described for the very simple toy 1D problem studied in section 2.

4.1. Assumptions on the flux $\boldsymbol{\varphi}$. We first give the precise assumptions we need on the flux φ. First of all, we reinforce the monotonicity assumption $(\mathcal{H}_1)$ in the following way:

- If $1 < p \le 2$: for all $(\xi,\eta)\in\mathbb{R}^2\times\mathbb{R}^2$ and almost every $z\in\Omega$,

$$(\varphi(z,\xi)-\varphi(z,\eta),\xi-\eta) \ge \frac{1}{C_\varphi}|\xi-\eta|^2(1+|\xi|^p+|\eta|^p)^{\frac{p-2}{p}}. \tag{$\mathcal{H}_{1'a}$}$$

- If $p > 2$: for all $(\xi,\eta)\in\mathbb{R}^2\times\mathbb{R}^2$ and almost every $z\in\Omega$,

$$(\varphi(z,\xi)-\varphi(z,\eta),\xi-\eta) \ge \frac{1}{C_\varphi}|\xi-\eta|^p. \tag{$\mathcal{H}_{1'b}$}$$

We also assume that the flux φ is Hölder continuous with respect to ξ:

- If $1 < p \le 2$: for all $(\xi,\eta)\in\mathbb{R}^2\times\mathbb{R}^2$ and almost every $z\in\Omega$,

$$|\varphi(z,\xi)-\varphi(z,\eta)| \le C_\varphi|\xi-\eta|^{p-1}. \tag{$\mathcal{H}_{4a}$}$$

- If $p > 2$: for all $(\xi,\eta)\in\mathbb{R}^2\times\mathbb{R}^2$, and almost every $z\in\Omega$,

$$|\varphi(z,\xi)-\varphi(z,\eta)| \le C_\varphi\left(1+|\xi|^{p-2}+|\eta|^{p-2}\right)|\xi-\eta|. \tag{$\mathcal{H}_{4b}$}$$

The four assumptions above are classical in the error analysis of numerical methods for nonlinear problems and are satisfied by many usual nonlinear operators. We can think, for instance, to p-Laplacian-like operators $\varphi(z,\xi) = k(z)(A(z)\xi,\xi)^{\frac{p-2}{2}}A(z)\xi$, where k (resp. A) is a real-valued (resp. symmetric matrix-valued) bounded map satisfying a uniform coercivity assumption. We also refer to [3] for other examples.

Finally, as we have seen above we want to consider a flux φ which is piecewise smooth with respect to the space variable. The precise meaning of this statement is the following:

- If $1 < p \leq 2$: for all $\xi \in \mathbb{R}^2$, for all $\mathcal{Q} \in \mathfrak{Q}$ and almost every $(z,z') \in \mathcal{Q}^2$,

$$(\mathcal{H}_{5a}) \qquad |\varphi(z,\xi) - \varphi(z',\xi)| \leq C_\varphi(1+|\xi|^{p-1})|z-z'|^{p-1}.$$

- If $p > 2$: φ is Lipschitz on any $\mathcal{Q} \in \mathfrak{Q}$, and for all $\xi \in \mathbb{R}^2$ and almost every $z \in \mathcal{Q}$ we have

$$(\mathcal{H}_{5b}) \qquad \left|\frac{\partial\varphi}{\partial z}(z,\xi)\right| \leq C_\varphi\left(1+|\xi|^{p-1}\right).$$

Contrary to the assumptions we considered in [3], the above hypotheses are localized on each quarter diamond. From a practical point of view, this means that the mesh is built in such a way that the discontinuities with respect to the space variable z of the flux φ are allowed only across edges of the primal mesh and edges of the dual mesh.

4.2. Approximate fluxes on the quarter diamond. From now on, we assume that φ is a given flux satisfying $(\mathcal{H}_2)$,$(\mathcal{H}_3)$ and either $(\mathcal{H}_{1'a})$, $(\mathcal{H}_{4a})$, and $(\mathcal{H}_{5a})$ if $p \leq 2$, or $(\mathcal{H}_{1'b})$, $(\mathcal{H}_{4b})$, and $(\mathcal{H}_{5b})$ if $p > 2$.

Then, we define for each quarter diamond $\mathcal{Q} \in \mathfrak{Q}$, an approximation $\varphi_\mathcal{Q}$ of φ defined as the mean value of φ on $\mathcal{Q}$, that is,

$$\varphi_\mathcal{Q}(\xi) = \frac{1}{|\mathcal{Q}|}\int_\mathcal{Q} \varphi(z,\xi)\,dz. \tag{4.1}$$

Such a map $\varphi_\mathcal{Q}$ inherits the monotonicity, coercivity, and regularity properties of the initial flux φ, that is, for any $\mathcal{Q} \in \mathfrak{Q}$:

$$(\mathcal{P}_2^\mathcal{T}) \qquad (\varphi_\mathcal{Q}(\xi),\xi) \geq \frac{1}{C_\varphi}|\xi|^p - C_\varphi, \quad \forall \xi \in \mathbb{R}^2,$$

$$(\mathcal{P}_3^\mathcal{T}) \qquad |\varphi_\mathcal{Q}(\xi)| \leq C_\varphi(1+|\xi|^{p-1}), \quad \forall \xi \in \mathbb{R}^2.$$

- If $1 < p \leq 2$:

$$(\mathcal{P}_{1'a}^\mathcal{T}) \quad (\varphi_\mathcal{Q}(\xi) - \varphi_\mathcal{Q}(\eta), \xi-\eta) \geq \frac{1}{C_\varphi}|\xi-\eta|^2(1+|\xi|^p+|\eta|^p)^{\frac{p-2}{p}}, \quad \forall \xi,\eta \in \mathbb{R}^2,$$

$$(\mathcal{P}_{4a}^\mathcal{T}) \qquad |\varphi_\mathcal{Q}(\xi) - \varphi_\mathcal{Q}(\eta)| \leq C_\varphi|\xi-\eta|^{p-1}, \quad \forall \xi,\eta \in \mathbb{R}^2.$$

- If $p > 2$:

$$(\mathcal{P}_{1'b}^\mathcal{T}) \qquad (\varphi_\mathcal{Q}(\xi) - \varphi_\mathcal{Q}(\eta), \xi-\eta) \geq \frac{1}{C_\varphi}|\xi-\eta|^p, \quad \forall \xi,\eta \in \mathbb{R}^2,$$

$$(\mathcal{P}_{4b}^\mathcal{T}) \qquad |\varphi_\mathcal{Q}(\xi) - \varphi_\mathcal{Q}(\eta)| \leq C_\varphi\left(1+|\xi|^{p-2}+|\eta|^{p-2}\right)|\xi-\eta|, \quad \forall \xi,\eta \in \mathbb{R}^2.$$

Remark 4.1. It is possible to consider more general definitions of $\varphi_{\mathcal{Q}}$ under the form

$$\varphi_{\mathcal{Q}}(\,\cdot\,) = \int_{\overline{\mathcal{Q}}} \varphi(z,\,\cdot\,)\, d\mu_{\overline{\mathcal{Q}}}(z),$$

where $d\mu_{\overline{\mathcal{Q}}}$ is any probability measure on $\overline{\mathcal{Q}}$. This makes sense since φ is supposed to be Hölder continuous on $\mathcal{Q}$ (see assumptions $(\mathcal{H}_{5a})$–$(\mathcal{H}_{5b})$ above) and hence can be extended to a continuous map on $\overline{\mathcal{Q}}$. This quite general framework includes the case where $\varphi_{\mathcal{Q}}$ is defined by (4.1) but also the case where $\varphi_{\mathcal{Q}}$ is chosen to be the value of φ at a given point in $\overline{\mathcal{Q}}$ or more generally an approximation of the mean value of φ through a quadrature formula with nonnegative coefficients. These three situations are the usual ones that we may use in practice.

For such choices, properties $(\mathcal{P}_2^{\mathcal{T}})$–$(\mathcal{P}_{4b}^{\mathcal{T}})$ still hold and the analysis performed in the remainder of this paper is still valid. The only difference is that a supplementary term $R_{\mathcal{Q}}^z$ appears in the definition 5.5 of the consistency error of the gradient. This term writes

$$R_{\mathcal{Q}}^z = \frac{1}{|\mathcal{Q}|}\int_{\mathcal{Q}} \varphi(z', \nabla_{\mathcal{Q}}^{\mathcal{N}}\mathbb{P}^{\mathcal{T}} u_e)\, dz' - \int_{\overline{\mathcal{Q}}} \varphi(z', \nabla_{\mathcal{Q}}^{\mathcal{N}}\mathbb{P}^{\mathcal{T}} u_e) d\mu_{\overline{\mathcal{Q}}}(z'),$$

and can be estimated by writing

$$|R_{\mathcal{Q}}^z| \le \frac{1}{|\mathcal{Q}|}\int_{\mathcal{Q}}\int_{\overline{\mathcal{Q}}} |\varphi(z, \nabla_{\mathcal{Q}}^{\mathcal{N}}\mathbb{P}^{\mathcal{T}} u_e) - \varphi(z', \nabla_{\mathcal{Q}}^{\mathcal{N}}\mathbb{P}^{\mathcal{T}} u_e)|\, dz\, d\mu_{\overline{\mathcal{Q}}}(z')$$

and using assumptions $(\mathcal{H}_{5a})$ or $(\mathcal{H}_{5b})$.

4.3. Local modification of the discrete gradient operator. As we saw in the 1D case (see section 2), we need to introduce new gradient operators near the discontinuities of the flux and finally define a new approximate flux $\varphi_{\mathcal{D}}^{\mathcal{N}}$ on each diamond cell.

The new gradient operator $\nabla^{\mathcal{N}}$ we propose to consider is built upon the usual DDFV gradient $\nabla^{\mathcal{T}}$. It is chosen to be constant on all the quarter diamonds $\mathcal{Q} \in \mathfrak{Q}$. This new operator has to be thought as the 2D generalization of the definitions of ∇_{N}^{+} and ∇_{N}^{-} in (2.4). In this 1D situation, the place where the artificial unknown $\tilde{u}$ (or $\delta = \tilde{u} - \bar{u}$) must be chosen is clear: it is the point of the mesh where the discontinuity takes place, that is, $x_N = 0$ in the framework of section 2.

In the 2D setting the situation is less straightforward. In order to make a good choice it is useful to remember that the usual DDFV gradient $\nabla_{\mathcal{D}}^{\mathcal{T}} u^{\mathcal{T}}$ on a diamond cell $\mathcal{D}$ can be understood (it is an easy computation) as the gradient of the unique affine function $\Pi_{\mathcal{D}} u^{\mathcal{T}}$ whose value at the middle of each side of the diamond $\mathcal{D}$ is the mean value between the two unknowns associated to the two extremities of this segment. This situation is summed up in Figure 4.1 for a given interior diamond cell $\mathcal{D} \in \mathfrak{D}_{\text{int}}$. In this figure, we introduce x_σ to be the middle of the segment σ for each $\sigma \in \{\sigma_{\mathcal{K}}, \sigma_{\mathcal{L}}, \sigma_{\mathcal{K}^*}, \sigma_{\mathcal{L}^*}\}$.

It seems now natural to define the new discrete gradient operator $\nabla_{\mathcal{Q}}^{\mathcal{N}} u^{\mathcal{T}}$ on each quarter diamond as the gradient of a function $\widetilde{\Pi}_{\mathcal{D}} u^{\mathcal{T}}$ which coincides with $\Pi_{\mathcal{D}} u^{\mathcal{T}}$ in the middle of each side of $\mathcal{D}$ and which is continuous at each point $x_{\sigma_{\mathcal{K}}}$, $x_{\sigma_{\mathcal{L}}}$, $x_{\sigma_{\mathcal{K}^*}}$, and $x_{\sigma_{\mathcal{L}^*}}$, but which is not necessarily continuous on the whole diamond $\mathcal{D}$.

This new function $\widetilde{\Pi}_{\mathcal{D}} u^{\mathcal{T}}$ is then entirely defined, for a given $u^{\mathcal{T}}$, by its four values $\widetilde{\Pi}_{\mathcal{D}} u^{\mathcal{T}}(x_\sigma)$ at each of these four points x_σ. These four values are the artificial unknowns

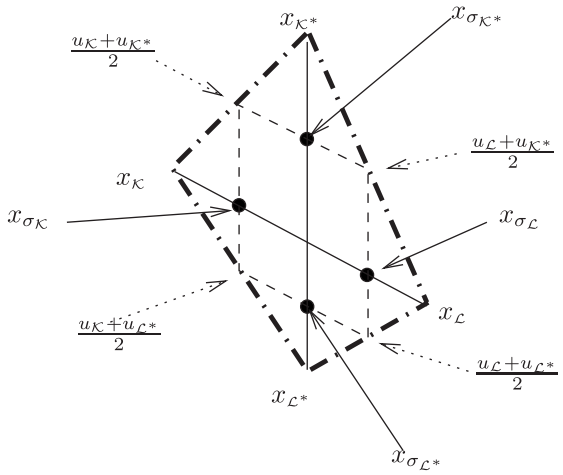

FIG. 4.1. *Affine function whose gradient is* $\nabla_{\mathcal{D}}^{\mathcal{T}} u^{\mathcal{T}}$.

in our problem. Like in the 1D case, it is equivalent and more suitable to work with the new unknowns $\delta_{\mathcal{K}}^{\mathcal{D}}, \delta_{\mathcal{L}}^{\mathcal{D}}, \delta_{\mathcal{K}^*}^{\mathcal{D}}, \delta_{\mathcal{L}^*}^{\mathcal{D}}$ defined to be the differences $\widetilde{\Pi}_{\mathcal{D}} u^{\mathcal{T}}(x_\sigma) - \Pi_{\mathcal{D}} u^{\mathcal{T}}(x_\sigma)$ for each $\sigma \in \{\sigma_{\mathcal{K}}, \sigma_{\mathcal{L}}, \sigma_{\mathcal{K}^*}, \sigma_{\mathcal{L}^*}\}$. Notice that each $\Pi_{\mathcal{D}} u^{\mathcal{T}}(x_\sigma)$ can be computed as an explicit function of $u_{\mathcal{K}}, u_{\mathcal{L}}, u_{\mathcal{K}^*}$, and $u_{\mathcal{L}^*}$.

The situation is simpler in the case of exterior diamond cells $\mathcal{D} \in \mathfrak{D}_{\text{ext}}$, in which case we only need one artificial unknown, $\delta_{\mathcal{K}}^{\mathcal{D}}$. Hence, we define $n_{\mathcal{D}}$ to be the number of artificial unknowns needed on the diamond cell $\mathcal{D}$. From the discussion above we have $n_{\mathcal{D}} = 4$ if $\mathcal{D} \in \mathfrak{D}_{\text{int}}$ and $n_{\mathcal{D}} = 1$ if $\mathcal{D} \in \mathfrak{D}_{\text{ext}}$.

By straightforward computations, the above discussion can be summed up as follows: we define the new discrete gradient operator on each quarter diamond $\mathcal{Q} \in \mathfrak{Q}_{\mathcal{D}}$, to be the gradient of $\widetilde{\Pi}_{\mathcal{D}} u^{\mathcal{T}}$, which reads

$$\nabla_{\mathcal{Q}}^{\mathcal{N}} u^{\mathcal{T}} = \nabla_{\mathcal{D}}^{\mathcal{T}} u^{\mathcal{T}} + B_{\mathcal{Q}} \delta^{\mathcal{D}}, \tag{4.2}$$

where $\delta^{\mathcal{D}} \in \mathbb{R}^{n_{\mathcal{D}}}$ is an artificial $n_{\mathcal{D}}$-tuple of unknowns introduced above and $(B_{\mathcal{Q}})_{\mathcal{Q} \in \mathfrak{Q}_{\mathcal{D}}}$ is a family of matrices whose size is $2 \times n_{\mathcal{D}}$. Existence of such matrices $B_{\mathcal{Q}}$ is clear since $\nabla \widetilde{\Pi}_{\mathcal{D}} u^{\mathcal{T}} - \nabla \Pi_{\mathcal{D}} u^{\mathcal{T}}$ depends linearly on $\delta^{\mathcal{D}}$ on each quarter diamond $\mathcal{Q}$.

In order to implement and to analyze the scheme we need to compute explicitly the matrices $B_{\mathcal{Q}}$. This can be done by integrating (4.2) on $\mathcal{Q}$ and by using the Stokes formula. For instance, for an interior diamond cell, and considering $\mathcal{Q} = \mathcal{Q}_{\mathcal{K},\mathcal{K}^*}$, we find that for any $\delta^{\mathcal{D}}$

$$|\mathcal{Q}_{\mathcal{K},\mathcal{K}^*}| B_{\mathcal{Q}_{\mathcal{K},\mathcal{K}^*}} \delta^{\mathcal{D}} = \int_{\partial \mathcal{Q}_{\mathcal{K},\mathcal{K}^*}} \left(\widetilde{\Pi}_{\mathcal{D}} u^{\mathcal{T}} - \Pi_{\mathcal{D}} u^{\mathcal{T}} \right) \cdot \boldsymbol{\nu}_{\mathcal{Q}} \, ds.$$

We use now the fact that the integral of an affine function over a segment is equal to the value of the function in the middle of the segment multiplied by its length. In particular, since $\widetilde{\Pi}_{\mathcal{D}} u^{\mathcal{T}}$ and $\Pi_{\mathcal{D}} u^{\mathcal{T}}$ are equal in the middle of the sides of $\mathcal{D}$, it only remains the contributions on $\sigma_{\mathcal{K}}$ and $\sigma_{\mathcal{K}^*}$ which reads, by definition of $\delta^{\mathcal{D}}$

$$|\mathcal{Q}_{\mathcal{K},\mathcal{K}^*}| B_{\mathcal{Q}_{\mathcal{K},\mathcal{K}^*}} \delta^{\mathcal{D}} = \delta_{\mathcal{K}}^{\mathcal{D}} |\sigma_{\mathcal{K}}| \boldsymbol{\nu}^* + \delta_{\mathcal{K}^*}^{\mathcal{D}} |\sigma_{\mathcal{K}^*}| \boldsymbol{\nu}.$$

Doing the same computations in the other quarter diamonds we find that, for $\mathcal{D} \in \mathfrak{D}_{\text{int}}$, the four matrices $B_{\mathcal{Q}}$ writes:

$$B_{\mathcal{Q}_{\mathcal{K},\mathcal{K}^*}} = \frac{1}{|\mathcal{Q}_{\mathcal{K},\mathcal{K}^*}|}\left(|\sigma_{\mathcal{K}}|\boldsymbol{\nu}^*, 0, |\sigma_{\mathcal{K}^*}|\boldsymbol{\nu}, 0\right) = \frac{2}{\sin\alpha_{\mathcal{D}}}\left(\frac{\boldsymbol{\nu}^*}{|\sigma_{\mathcal{K}^*}|}, 0, \frac{\boldsymbol{\nu}}{|\sigma_{\mathcal{K}}|}, 0\right), \tag{4.3}$$

$$B_{\mathcal{Q}_{\mathcal{K},\mathcal{L}^*}} = \frac{1}{|\mathcal{Q}_{\mathcal{K},\mathcal{L}^*}|}\left(-|\sigma_{\mathcal{K}}|\boldsymbol{\nu}^*, 0, 0, |\sigma_{\mathcal{L}^*}|\boldsymbol{\nu}\right) = \frac{2}{\sin\alpha_{\mathcal{D}}}\left(-\frac{\boldsymbol{\nu}^*}{|\sigma_{\mathcal{L}^*}|}, 0, 0, \frac{\boldsymbol{\nu}}{|\sigma_{\mathcal{K}}|}\right), \tag{4.4}$$

$$B_{\mathcal{Q}_{\mathcal{L},\mathcal{L}^*}} = \frac{1}{|\mathcal{Q}_{\mathcal{L},\mathcal{L}^*}|}\left(0, -|\sigma_{\mathcal{L}}|\boldsymbol{\nu}^*, 0, -|\sigma_{\mathcal{L}^*}|\boldsymbol{\nu}\right) = \frac{2}{\sin\alpha_{\mathcal{D}}}\left(0, -\frac{\boldsymbol{\nu}^*}{|\sigma_{\mathcal{L}^*}|}, 0, -\frac{\boldsymbol{\nu}}{|\sigma_{\mathcal{L}}|}\right), \tag{4.5}$$

$$B_{\mathcal{Q}_{\mathcal{L},\mathcal{K}^*}} = \frac{1}{|\mathcal{Q}_{\mathcal{L},\mathcal{K}^*}|}\left(0, |\sigma_{\mathcal{L}}|\boldsymbol{\nu}^*, -|\sigma_{\mathcal{K}^*}|\boldsymbol{\nu}, 0\right) = \frac{2}{\sin\alpha_{\mathcal{D}}}\left(0, \frac{\boldsymbol{\nu}^*}{|\sigma_{\mathcal{K}^*}|}, -\frac{\boldsymbol{\nu}}{|\sigma_{\mathcal{L}}|}, 0\right). \tag{4.6}$$

In the case where $\mathcal{D} \in \mathfrak{D}_{\text{ext}}$, there are only two nondegenerate quarter diamonds in $\mathfrak{Q}_{\mathcal{D}}$ and the two corresponding matrices $B_{\mathcal{Q}}$ are given by

$$B_{\mathcal{Q}_{\mathcal{K},\mathcal{K}^*}} = \frac{1}{|\mathcal{Q}_{\mathcal{K},\mathcal{K}^*}|}\left(|\sigma_{\mathcal{K}}|\boldsymbol{\nu}^*\right) = \frac{2}{\sin\alpha_{\mathcal{D}}}\left(\frac{\boldsymbol{\nu}^*}{|\sigma_{\mathcal{K}^*}|}\right), \tag{4.7}$$

$$B_{\mathcal{Q}_{\mathcal{K},\mathcal{L}^*}} = \frac{1}{|\mathcal{Q}_{\mathcal{K},\mathcal{L}^*}|}\left(-|\sigma_{\mathcal{K}}|\boldsymbol{\nu}^*\right) = \frac{2}{\sin\alpha_{\mathcal{D}}}\left(-\frac{\boldsymbol{\nu}^*}{|\sigma_{\mathcal{L}^*}|}\right). \tag{4.8}$$

Notice that these matrices depend only on the geometry of the diamond cell $\mathcal{D}$. Furthermore we easily see from formulas (4.3)–(4.8) above that $\sum_{\mathcal{Q}\in\mathfrak{Q}_{\mathcal{D}}} |\mathcal{Q}| B_{\mathcal{Q}} = 0$ for any diamond cell $\mathcal{D}$. Hence, the following straightforward result holds:

LEMMA 4.2. *For all $\xi \in \mathbb{R}^2$, for all $\mathcal{D} \in \mathfrak{D}$, for all $\delta \in \mathbb{R}^{n_{\mathcal{D}}}$, we have*

$$\xi = \frac{1}{|\mathcal{D}|}\sum_{\mathcal{Q}\in\mathfrak{Q}_{\mathcal{D}}} |\mathcal{Q}|\left(\xi + B_{\mathcal{Q}}\delta\right). \tag{4.9}$$

This Lemma implies that the new gradient has a mean value over $\mathcal{D}$ which equals the usual DDFV gradient $\nabla^{\mathcal{T}}_{\mathcal{D}} u^{\mathcal{T}}$, that is,

$$\nabla^{\mathcal{T}}_{\mathcal{D}} u^{\mathcal{T}} = \frac{1}{|\mathcal{D}|}\sum_{\mathcal{Q}\in\mathfrak{Q}_{\mathcal{D}}} |\mathcal{Q}| \nabla^{\mathcal{N}}_{\mathcal{Q}} u^{\mathcal{T}},$$

which is the 2D equivalent to formula (2.5).

Like in the monodimensional case presented in section 2, we want to eliminate the additional unknowns $\delta^{\mathcal{D}}$ on each $\mathcal{D}$ in such a way that the conservativity of the numerical fluxes on all edges $\sigma \in \mathcal{E}_{\mathcal{D}}$ (the transmission condition) is ensured. More precisely, we want to choose $\delta^{\mathcal{D}}$ such that, setting $\xi = \nabla^{\mathcal{T}}_{\mathcal{D}} u^{\mathcal{T}}$, we have

$$\begin{cases} \left(\varphi_{\mathcal{Q}_{\mathcal{K},\mathcal{K}^*}}(\xi + B_{\mathcal{Q}_{\mathcal{K},\mathcal{K}^*}}\delta^{\mathcal{D}}), \boldsymbol{\nu}^*\right) = \left(\varphi_{\mathcal{Q}_{\mathcal{K},\mathcal{L}^*}}(\xi + B_{\mathcal{Q}_{\mathcal{K},\mathcal{L}^*}}\delta^{\mathcal{D}}), \boldsymbol{\nu}^*\right), \\ \left(\varphi_{\mathcal{Q}_{\mathcal{L},\mathcal{K}^*}}(\xi + B_{\mathcal{Q}_{\mathcal{L},\mathcal{K}^*}}\delta^{\mathcal{D}}), \boldsymbol{\nu}^*\right) = \left(\varphi_{\mathcal{Q}_{\mathcal{L},\mathcal{L}^*}}(\xi + B_{\mathcal{Q}_{\mathcal{L},\mathcal{L}^*}}\delta^{\mathcal{D}}), \boldsymbol{\nu}^*\right), \\ \left(\varphi_{\mathcal{Q}_{\mathcal{K},\mathcal{K}^*}}(\xi + B_{\mathcal{Q}_{\mathcal{K},\mathcal{K}^*}}\delta^{\mathcal{D}}), \boldsymbol{\nu}\right) = \left(\varphi_{\mathcal{Q}_{\mathcal{L},\mathcal{K}^*}}(\xi + B_{\mathcal{Q}_{\mathcal{L},\mathcal{K}^*}}\delta^{\mathcal{D}}), \boldsymbol{\nu}\right), \\ \left(\varphi_{\mathcal{Q}_{\mathcal{K},\mathcal{L}^*}}(\xi + B_{\mathcal{Q}_{\mathcal{K},\mathcal{L}^*}}\delta^{\mathcal{D}}), \boldsymbol{\nu}\right) = \left(\varphi_{\mathcal{Q}_{\mathcal{L},\mathcal{L}^*}}(\xi + B_{\mathcal{Q}_{\mathcal{L},\mathcal{L}^*}}\delta^{\mathcal{D}}), \boldsymbol{\nu}\right), \end{cases} \tag{4.10}$$

in the case where $\mathcal{D} \in \mathfrak{D}_{\text{int}}$. If $\mathcal{D} \in \mathfrak{D}_{\text{ext}}$, the conditions on $\delta^{\mathcal{D}}$ take the simpler form

$$\left(\varphi_{\mathcal{Q}_{\mathcal{K},\mathcal{K}^*}}(\xi + B_{\mathcal{Q}_{\mathcal{K},\mathcal{K}^*}}\delta^{\mathcal{D}}), \boldsymbol{\nu}^*\right) = \left(\varphi_{\mathcal{Q}_{\mathcal{K},\mathcal{L}^*}}(\xi + B_{\mathcal{Q}_{\mathcal{K},\mathcal{L}^*}}\delta^{\mathcal{D}}), \boldsymbol{\nu}^*\right). \tag{4.11}$$

We are now going to show that (4.10) or (4.11) uniquely define $\delta^{\mathcal{D}} \in \mathbb{R}^{n_{\mathcal{D}}}$ as a function of ξ.

PROPOSITION 4.3. *For all $\mathcal{D} \in \mathfrak{D}$ and all $\xi \in \mathbb{R}^2$, there exists a unique $\delta^{\mathcal{D}}(\xi) \in \mathbb{R}^{n_{\mathcal{D}}}$ such that* (4.10) *(resp.* (4.11)*) holds if $\mathcal{D} \in \mathfrak{D}_{\rm int}$ (resp. if $\mathcal{D} \in \mathfrak{D}_{\rm ext}$).*

Proof. We only give the proof for $\mathcal{D} \in \mathfrak{D}_{\rm int}$ (so that $n_{\mathcal{D}} = 4$), since the case of boundary diamond cells can be treated in the same way. Let $\xi \in \mathbb{R}^2$ given and define $F_\xi : \mathbb{R}^4 \mapsto \mathbb{R}^4$ by

$$F_\xi(\delta) = \sum_{\mathcal{Q} \in \mathfrak{Q}_{\mathcal{D}}} |\mathcal{Q}|^t B_{\mathcal{Q}}.\varphi_{\mathcal{Q}}(\xi + B_{\mathcal{Q}}\delta).$$

By using (4.3)–(4.6), we easily see that the conditions (4.10) are equivalent to the equation $F_\xi(\delta^{\mathcal{D}}) = 0$. Hence, the claim will be proved if we show that this nonlinear equation has a unique solution. To this end, we remark that for any $\widetilde{\delta} \in \mathbb{R}^4$, we have

$$\left(F_\xi(\delta), \tilde{\delta}\right) = \sum_{\mathcal{Q} \in \mathfrak{Q}_{\mathcal{D}}} |\mathcal{Q}| \left(\varphi_{\mathcal{Q}}(\xi + B_{\mathcal{Q}}\delta), B_{\mathcal{Q}}\widetilde{\delta}\right). \tag{4.12}$$

Hence, we deduce using properties $(\mathcal{P}_2^{\mathcal{T}})$ and $(\mathcal{P}_3^{\mathcal{T}})$ that there exists C depending only on p and C_φ such that

$$(F_\xi(\delta), \delta) \geq \frac{1}{C} \left(\sum_{\mathcal{Q} \in \mathfrak{Q}_{\mathcal{D}}} |\mathcal{Q}| \, |\xi + B_{\mathcal{Q}}\delta|^p \right) - C|\mathcal{D}|(1 + |\xi|^p). \tag{4.13}$$

Finally, we deduce

$$(F_\xi(\delta), \delta) \geq \frac{1}{C} \left(\sum_{\mathcal{Q} \in \mathfrak{Q}_{\mathcal{D}}} |\mathcal{Q}| \, |B_{\mathcal{Q}}\delta|^p \right) - C|\mathcal{D}|(1 + |\xi|^p),$$

for another constant C. Since $\sum_{\mathcal{Q} \in \mathfrak{Q}_{\mathcal{D}}} |\mathcal{Q}||B_{\mathcal{Q}}\delta|^p \underset{|\delta| \to \infty}{\longrightarrow} \infty$, we deduce that F_ξ is coercive. By the Brouwer theorem (F_ξ is continuous since each $\varphi_{\mathcal{Q}}$ is continuous) we obtain the existence of at least one solution to the problem $F_\xi(\delta) = 0$.

Notice now that if $B_{\mathcal{Q}}\delta = B_{\mathcal{Q}}\widetilde{\delta}, \forall \mathcal{Q} \in \mathfrak{Q}_{\mathcal{D}}$, then $\delta = \widetilde{\delta}$. Hence, we deduce from (4.12) that for all $\delta \neq \widetilde{\delta}$

$$\left(F_\xi(\delta) - F_\xi(\widetilde{\delta}), \delta - \widetilde{\delta}\right) = \sum_{\mathcal{Q} \in \mathfrak{Q}_{\mathcal{D}}} |\mathcal{Q}| \left(\varphi_{\mathcal{Q}}(\xi + B_{\mathcal{Q}}\delta) - \varphi_{\mathcal{Q}}(\xi + B_{\mathcal{Q}}\widetilde{\delta}), B_{\mathcal{Q}}\delta - B_{\mathcal{Q}}\widetilde{\delta}\right) > 0,$$

using property $(\mathcal{P}_{1'a}^{\mathcal{T}})$ or $(\mathcal{P}_{1'b}^{\mathcal{T}})$. This gives the uniqueness of the solution to $F_\xi(\delta) = 0$ and the claim is proved. ∎

Example 4.4. In many situations, it can happen that φ is smooth, for instance, in each primal control volume. In that case, it is possible (see Remark 4.1) to choose the approximations $\varphi_{\mathcal{Q}}$ in such a way that for each $\mathcal{D} \in \mathfrak{D}_{\rm int}$ we have

$$\varphi_{\mathcal{Q}_{\mathcal{K},\mathcal{K}^*}} = \varphi_{\mathcal{Q}_{\mathcal{K},\mathcal{L}^*}}, \quad \text{and } \varphi_{\mathcal{Q}_{\mathcal{L},\mathcal{K}^*}} = \varphi_{\mathcal{Q}_{\mathcal{L},\mathcal{L}^*}}.$$

Then, one can easily show that the solution $\delta^{\mathcal{D}}(\xi)$ of (4.10) appears to satisfy

$$\delta_{\mathcal{K}}^{\mathcal{D}} = 0, \quad \delta_{\mathcal{L}}^{\mathcal{D}} = 0, \quad \text{and } \delta_{\mathcal{K}^*}^{\mathcal{D}} = \delta_{\mathcal{L}^*}^{\mathcal{D}}.$$

Hence, everything happens like in the 1D case and there is in fact only one artificial unknown ($\delta_{\mathcal{K}^*}^{\mathcal{D}}$, for instance) to determine.

A symmetric situation holds if we assume that φ is smooth in each dual control volume and that $\varphi_{\mathfrak{Q}_{\mathcal{K},\mathcal{K}^*}} = \varphi_{\mathfrak{Q}_{\mathcal{L},\mathcal{K}^*}}$, $\varphi_{\mathfrak{Q}_{\mathcal{K},\mathcal{L}^*}} = \varphi_{\mathfrak{Q}_{\mathcal{L},\mathcal{L}^*}}$.

Finally, notice that if we only assume that $\varphi_{\mathfrak{Q}_{\mathcal{K},\mathcal{K}^*}} = \varphi_{\mathfrak{Q}_{\mathcal{K},\mathcal{L}^*}}$, for instance, then in the general nonlinear case there is no reason why $\delta^{\mathcal{D}}_{\mathcal{K}}$ should be 0.

From now on, the new discrete gradient operator $\nabla^{\mathcal{N}}$ is completely determined by

$$\nabla^{\mathcal{N}}_{\mathcal{Q}} u^{\mathcal{T}} = \nabla^{\mathcal{T}}_{\mathcal{D}} u^{\mathcal{T}} + B_{\mathcal{Q}} \delta^{\mathcal{D}}(\nabla^{\mathcal{T}}_{\mathcal{D}} u^{\mathcal{T}}), \text{ for any } \mathcal{D} \in \mathfrak{D} \text{ and } \mathcal{Q} \in \mathfrak{Q}_{\mathcal{D}}, \tag{4.14}$$

where the map $\xi \mapsto \delta^{\mathcal{D}}(\xi)$ is defined in Proposition 4.3. Notice that, in general, this new gradient operator $\nabla^{\mathcal{N}}_{\mathcal{Q}}$ is *nonlinear* contrarily to the operator $\nabla^{\mathcal{T}}_{\mathcal{D}}$ and depends on the flux φ defining the problem (1.1) under study (and more precisely to its approximations $\varphi_{\mathcal{Q}}$).

Furthermore, let us emphasize the fact that the nonlinear map $\xi \mapsto \delta^{\mathcal{D}}(\xi)$ is only defined implicitly through (4.10) or (4.11) (see also the 1D discussion in section 2), which seems to make the new discrete gradient $\nabla^{\mathcal{N}}$ quite difficult to compute. We postpone to section 7 the important discussion on practical ways to solve the scheme we will propose in the sequel.

4.4. Some useful inequalities. The usual DDFV discrete gradient and the modified one can be compared as follows.

LEMMA 4.5. *There exists a constant C that depends only on C_φ and p such that for all $\mathcal{D} \in \mathfrak{D}$, and all $u^{\mathcal{T}} \in \mathbb{R}^{\mathcal{T}}$, we have*

$$\int_{\mathcal{D}} |\nabla^{\mathcal{T}} u^{\mathcal{T}}(z)|^p \, dz \le \int_{\mathcal{D}} |\nabla^{\mathcal{N}} u^{\mathcal{T}}(z)|^p \, dz \le C \int_{\mathcal{D}} (1 + |\nabla^{\mathcal{T}} u^{\mathcal{T}}(z)|^p) \, dz.$$

Proof. Thanks to Lemma 4.2, we have

$$|\mathcal{D}||\nabla^{\mathcal{T}}_{\mathcal{D}} u^{\mathcal{T}}|^p = |\mathcal{D}| \left| \frac{1}{|\mathcal{D}|} \sum_{\mathcal{Q} \in \mathfrak{Q}_{\mathcal{D}}} |\mathcal{Q}| \nabla^{\mathcal{N}}_{\mathcal{Q}} u^{\mathcal{T}} \right|^p = |\mathcal{D}| \left| \frac{1}{|\mathcal{D}|} \int_{\mathcal{D}} \nabla^{\mathcal{N}} u^{\mathcal{T}}(z) \, dz \right|^p.$$

Using the Jensen inequality, we deduce the first inequality.

The second one is a consequence of (4.13) applied to $\xi = \nabla^{\mathcal{T}}_{\mathcal{D}} u^{\mathcal{T}}$, $\delta = \delta^{\mathcal{D}}(\nabla^{\mathcal{T}}_{\mathcal{D}} u^{\mathcal{T}})$ using that $F_{\nabla^{\mathcal{T}}_{\mathcal{D}} u^{\mathcal{T}}}(\delta^{\mathcal{D}}(\nabla^{\mathcal{T}}_{\mathcal{D}} u^{\mathcal{T}})) = 0$ by definition of $\delta^{\mathcal{D}}$. ∎

Finally we can state the following discrete Poincaré inequality. Its proof is sketched in [3] and uses an argument given in [4] (see also [10]).

PROPOSITION 4.6 (discrete Poincaré inequality). *Let $\mathcal{T}$ be a DDFV mesh on Ω. There exists a constant C depending on p, Ω, and $\mathrm{reg}(\mathcal{T})$ such that*

$$\|u^{\mathfrak{M}}\|_{L^p} + \|u^{\mathfrak{M}^*}\|_{L^p} \le C \|\nabla^{\mathcal{T}} u^{\mathcal{T}}\|_{L^p} \le C \|\nabla^{\mathcal{N}} u^{\mathcal{T}}\|_{L^p}, \quad \forall u^{\mathcal{T}} \in \mathbb{R}^{\mathcal{T}}.$$

In particular, if $\nabla^{\mathcal{N}}_{\mathcal{Q}} u^{\mathcal{T}} = 0$ for all $\mathcal{Q} \in \mathfrak{Q}$, then $u^{\mathcal{T}} = 0$.

4.5. The m-DDFV scheme for discontinuous fluxes. We can finally introduce the new approximate flux $\varphi^{\mathcal{N}}_{\mathcal{D}}$ on each diamond cell to be used in the finite volume scheme instead of (3.4). For any diamond cell $\mathcal{D} \in \mathfrak{D}$, we set

$$\varphi^{\mathcal{N}}_{\mathcal{D}}(\xi) = \frac{1}{|\mathcal{D}|} \sum_{\mathcal{Q} \in \mathfrak{Q}_{\mathcal{D}}} |\mathcal{Q}| \varphi_{\mathcal{Q}}(\xi + B_{\mathcal{Q}} \delta^{\mathcal{D}}(\xi)), \quad \forall \xi \in \mathbb{R}^2. \tag{4.15}$$

This definition is nothing but the adaptation to the 2D case of the corresponding formula in the 1D case (see (2.7)).

Applying definition (4.15) to $\xi = \nabla_{\mathcal{D}}^{\mathcal{T}} u^{\mathcal{T}}$ for a given $u^{\mathcal{T}} \in \mathbb{R}^{\mathcal{T}}$, we find that

$$\varphi_{\mathcal{D}}^{\mathcal{N}}(\nabla_{\mathcal{D}}^{\mathcal{T}} u^{\mathcal{T}}) = \frac{1}{|\mathcal{D}|} \sum_{\mathcal{Q} \in \mathfrak{Q}_{\mathcal{D}}} |\mathcal{Q}| \varphi_{\mathcal{Q}}(\nabla_{\mathcal{Q}}^{\mathcal{N}} u^{\mathcal{T}}). \tag{4.16}$$

The m-DDFV scheme that we will study in the sequel of the paper can now be defined by the set of equations

$$\begin{cases} \mathfrak{a}_{\mathcal{K}}^{\mathcal{N}}(u^{\mathcal{T}}) \stackrel{\text{def}}{=} - \displaystyle\sum_{\mathcal{D} \in \mathfrak{D}_{\mathcal{K}}} |\sigma| \left(\varphi_{\mathcal{D}}^{\mathcal{N}}(\nabla_{\mathcal{D}}^{\mathcal{T}} u^{\mathcal{T}}), \boldsymbol{\nu}_{\mathcal{K}}\right) = |\mathcal{K}| f_{\mathcal{K}}, \ \forall \mathcal{K} \in \mathfrak{M}, \\ \mathfrak{a}_{\mathcal{K}^*}^{\mathcal{N}}(u^{\mathcal{T}}) \stackrel{\text{def}}{=} - \displaystyle\sum_{\mathcal{D} \in \mathfrak{D}_{\mathcal{K}^*}} |\sigma^*| \left(\varphi_{\mathcal{D}}^{\mathcal{N}}(\nabla_{\mathcal{D}}^{\mathcal{T}} u^{\mathcal{T}}), \boldsymbol{\nu}_{\mathcal{K}^*}\right) = |\mathcal{K}^*| f_{\mathcal{K}^*}, \ \forall \mathcal{K}^* \in \mathfrak{M}^*, \end{cases} \tag{4.17}$$

that we write under the short form $\mathfrak{a}^{\mathcal{N}}(u^{\mathcal{T}}) = f^{\mathcal{T}}$, with $\mathfrak{a}^{\mathcal{N}}(\,\cdot\,) \stackrel{\text{def}}{=} ((\mathfrak{a}_{\mathcal{K}}^{\mathcal{N}}(\,\cdot\,))_{\mathcal{K}}, (\mathfrak{a}_{\mathcal{K}^*}^{\mathcal{N}}(\,\cdot\,))_{\mathcal{K}^*})$ and $f^{\mathcal{T}} = ((|\mathcal{K}| f_{\mathcal{K}})_{\mathcal{K}}, (|\mathcal{K}^*| f_{\mathcal{K}^*})_{\mathcal{K}^*})$. Note that the only difference between this scheme (4.17) and the previous one (3.3) is the fact that we replaced the previous mean-value approximation $\varphi_{\mathcal{D}}$ of φ over $\mathcal{D}$ by the map $\varphi_{\mathcal{D}}^{\mathcal{N}}$ defined by (4.15).

4.6. Basic properties of the scheme. Before proving existence and uniqueness of the solution for the nonlinear system (4.17), we first give some properties of the map $\mathfrak{a}^{\mathcal{N}}$. The first result is a *summation by parts* result showing that the m-DDFV scheme we propose enjoys the same discrete duality property than the original DDFV scheme.

LEMMA 4.7. *For any $u^{\mathcal{T}}$, $v^{\mathcal{T}}$ in $\mathbb{R}^{\mathcal{T}}$ we have*

$$\begin{aligned} (\mathfrak{a}^{\mathcal{N}}(u^{\mathcal{T}}), v^{\mathcal{T}}) &= 2 \sum_{\mathcal{D} \in \mathfrak{D}} |\mathcal{D}| \left(\varphi_{\mathcal{D}}^{\mathcal{N}}(\nabla_{\mathcal{D}}^{\mathcal{T}} u^{\mathcal{T}}), \nabla_{\mathcal{D}}^{\mathcal{T}} v^{\mathcal{T}}\right) \\ &= 2 \sum_{\mathcal{Q} \in \mathfrak{Q}} |\mathcal{Q}| \left(\varphi_{\mathcal{Q}}(\nabla_{\mathcal{Q}}^{\mathcal{N}} u^{\mathcal{T}}), \nabla_{\mathcal{Q}}^{\mathcal{N}} v^{\mathcal{T}}\right). \end{aligned}$$

Proof. The first equality can be proved in the same way than in [3] by reordering the summation on the primal and dual control volumes as a summation over the diamond set

$$\begin{aligned} &\sum_{\mathcal{K} \in \mathfrak{M}} \mathfrak{a}_{\mathcal{K}}^{\mathcal{N}}(u^{\mathcal{T}}) v_{\mathcal{K}} + \sum_{\mathcal{K}^* \in \mathfrak{M}^*} \mathfrak{a}_{\mathcal{K}^*}^{\mathcal{N}}(u^{\mathcal{T}}) v_{\mathcal{K}^*} \\ &\quad = - \sum_{\mathcal{K} \in \mathfrak{M}} \sum_{\mathcal{D} \in \mathfrak{D}_{\mathcal{K}}} |\sigma| (\varphi_{\mathcal{D}}^{\mathcal{N}}(\nabla_{\mathcal{D}}^{\mathcal{T}} u^{\mathcal{T}}), \boldsymbol{\nu}) v_{\mathcal{K}} - \sum_{\mathcal{K}^* \in \mathfrak{M}^*} \sum_{\mathcal{D} \in \mathfrak{D}_{\mathcal{K}^*}} |\sigma^*| (\varphi_{\mathcal{D}}^{\mathcal{N}}(\nabla_{\mathcal{D}}^{\mathcal{T}} u^{\mathcal{T}}), \boldsymbol{\nu}^*) v_{\mathcal{K}^*} \\ &\quad = \sum_{\mathcal{D} \in \mathfrak{D}_{\text{int}}} |\mathcal{D}| \left(\varphi_{\mathcal{D}}^{\mathcal{N}}(\nabla_{\mathcal{D}}^{\mathcal{T}} u^{\mathcal{T}}), \frac{2}{\sin \alpha_{\mathcal{D}}} \left(\frac{v_{\mathcal{K}} - v_{\mathcal{L}}}{|\sigma^*|} \boldsymbol{\nu} + \frac{v_{\mathcal{K}^*} - v_{\mathcal{L}^*}}{|\sigma|} \boldsymbol{\nu}^* \right) \right) \\ &\qquad + \sum_{\mathcal{D} \in \mathfrak{D}_{\text{ext}}} |\mathcal{D}| \left(\varphi_{\mathcal{D}}^{\mathcal{N}}(\nabla_{\mathcal{D}}^{\mathcal{T}} u^{\mathcal{T}}), \frac{2}{\sin \alpha_{\mathcal{D}}} \frac{v_{\mathcal{K}}}{|\sigma^*|} \boldsymbol{\nu} \right) \\ &\quad = 2 \sum_{\mathcal{D} \in \mathfrak{D}} |\mathcal{D}| \left(\varphi_{\mathcal{D}}^{\mathcal{N}}(\nabla_{\mathcal{D}}^{\mathcal{T}} u^{\mathcal{T}}), \nabla_{\mathcal{D}}^{\mathcal{T}} v^{\mathcal{T}}\right). \end{aligned}$$

To prove the second equality, we use (4.16) and (4.14) to write on each diamond cell $\mathcal{D} \in \mathfrak{D}$

$$\begin{aligned}
|\mathcal{D}|\,(\varphi_{\mathcal{D}}^{\mathcal{N}}(\nabla_{\mathcal{D}}^{\mathcal{T}} u^{\mathcal{T}}), \nabla_{\mathcal{D}}^{\mathcal{T}} v^{\mathcal{T}}) &= \sum_{\mathcal{Q} \in \mathfrak{Q}_{\mathcal{D}}} |\mathcal{Q}|\,(\varphi_{\mathcal{Q}}(\nabla_{\mathcal{Q}}^{\mathcal{N}} u^{\mathcal{T}}), \nabla_{\mathcal{D}}^{\mathcal{T}} v^{\mathcal{T}}) \\
&= \sum_{\mathcal{Q} \in \mathfrak{Q}_{\mathcal{D}}} |\mathcal{Q}|\,(\varphi_{\mathcal{Q}}(\nabla_{\mathcal{Q}}^{\mathcal{N}} u^{\mathcal{T}}), \nabla_{\mathcal{Q}}^{\mathcal{N}} v^{\mathcal{T}} - B_{\mathcal{Q}} \delta^{\mathcal{D}}(\nabla_{\mathcal{D}}^{\mathcal{T}} v^{\mathcal{T}})) \\
&= \sum_{\mathcal{Q} \in \mathfrak{Q}_{\mathcal{D}}} |\mathcal{Q}|\,(\varphi_{\mathcal{Q}}(\nabla_{\mathcal{Q}}^{\mathcal{N}} u^{\mathcal{T}}), \nabla_{\mathcal{Q}}^{\mathcal{N}} v^{\mathcal{T}}) \\
&\qquad - \sum_{\mathcal{Q} \in \mathfrak{Q}_{\mathcal{D}}} |\mathcal{Q}|^t B_{\mathcal{Q}} \varphi_{\mathcal{Q}}(\nabla_{\mathcal{Q}}^{\mathcal{N}} u^{\mathcal{T}}) \cdot \delta^{\mathcal{D}}(\nabla_{\mathcal{D}}^{\mathcal{T}} v^{\mathcal{T}}),
\end{aligned}$$

and this last term vanishes by definition of the map $\delta^{\mathcal{D}}$ (see proposition 4.3). Indeed, we have

$$\sum_{\mathcal{Q} \in \mathfrak{Q}_{\mathcal{D}}} |\mathcal{Q}|^t B_{\mathcal{Q}} \varphi_{\mathcal{Q}}(\nabla_{\mathcal{Q}}^{\mathcal{N}} u^{\mathcal{T}}) \cdot \delta^{\mathcal{D}}(\nabla_{\mathcal{D}}^{\mathcal{T}} v^{\mathcal{T}}) = (F_{\nabla_{\mathcal{D}}^{\mathcal{T}} u^{\mathcal{T}}}(\delta^{\mathcal{D}}(\nabla_{\mathcal{D}}^{\mathcal{T}} u^{\mathcal{T}})), \delta^{\mathcal{D}}(v^{\mathcal{T}})) = 0. \qquad \square$$

LEMMA 4.8. *For any $u^{\mathcal{T}} \in \mathbb{R}^{\mathcal{T}}$ we have*

$$(\mathfrak{a}^{\mathcal{N}}(u^{\mathcal{T}}), u^{\mathcal{T}}) \geq \frac{2}{C_\varphi} \|\nabla^{\mathcal{N}} u^{\mathcal{T}}\|_{L^p}^p - 2C_\varphi |\Omega| \geq \frac{2}{C_\varphi} \|\nabla^{\mathcal{T}} u^{\mathcal{T}}\|_{L^p}^p - 2C_\varphi |\Omega|.$$

Proof. We derive from Lemma 4.7 and property $(\mathcal{P}_2^{\mathcal{T}})$ that

$$\begin{aligned}
(\mathfrak{a}^{\mathcal{N}}(u^{\mathcal{T}}), u^{\mathcal{T}}) &= 2 \sum_{\mathcal{D} \in \mathfrak{D}} \sum_{\mathcal{Q} \in \mathfrak{Q}_{\mathcal{D}}} |\mathcal{Q}|\,(\varphi_{\mathcal{Q}}(\nabla_{\mathcal{Q}}^{\mathcal{N}} u^{\mathcal{T}}), \nabla_{\mathcal{Q}}^{\mathcal{N}} u^{\mathcal{T}}) \\
&\geq 2 \sum_{\mathcal{D} \in \mathfrak{D}} \left(\int_{\mathcal{D}} \frac{1}{C_\varphi} |\nabla^{\mathcal{N}} u^{\mathcal{T}}(z)|^p \, dz - C_\varphi |\mathcal{D}| \right).
\end{aligned}$$

We conclude using Lemma 4.5. $\square$

LEMMA 4.9. *We have*

$$(\mathfrak{a}^{\mathcal{N}}(u^{\mathcal{T}}) - \mathfrak{a}^{\mathcal{N}}(v^{\mathcal{T}}), u^{\mathcal{T}} - v^{\mathcal{T}}) > 0, \quad \forall u^{\mathcal{T}}, v^{\mathcal{T}} \in \mathbb{R}^{\mathcal{T}}, \ u^{\mathcal{T}} \neq v^{\mathcal{T}}.$$

Proof. From Lemma 4.7, we have

$$\begin{aligned}
&(\mathfrak{a}^{\mathcal{N}}(u^{\mathcal{T}}) - \mathfrak{a}^{\mathcal{N}}(v^{\mathcal{T}}), u^{\mathcal{T}} - v^{\mathcal{T}}) \\
&\qquad = 2 \sum_{\mathcal{Q} \in \mathfrak{Q}} |\mathcal{Q}|\,(\varphi_{\mathcal{Q}}(\nabla_{\mathcal{Q}}^{\mathcal{N}} u^{\mathcal{T}}) - \varphi_{\mathcal{Q}}(\nabla_{\mathcal{Q}}^{\mathcal{N}} v^{\mathcal{T}}), \nabla_{\mathcal{Q}}^{\mathcal{N}} u^{\mathcal{T}} - \nabla_{\mathcal{Q}}^{\mathcal{N}} v^{\mathcal{T}}).
\end{aligned} \tag{4.18}$$

By using the monotonicity properties of the nonlinearity $\varphi_{\mathcal{Q}}$, that is, properties $(\mathcal{P}_{1'a}^{\mathcal{T}})$ and $(\mathcal{P}_{1'b}^{\mathcal{T}})$, we deduce that the left-hand side of (4.18) is nonnegative and vanishes if and only if $u^{\mathcal{T}} = v^{\mathcal{T}}$ (by Proposition 4.6). $\square$

THEOREM 4.10. *The scheme* (4.17) *admits a unique solution $u^{\mathcal{T}} \in \mathbb{R}^{\mathcal{T}}$. Furthermore, there exists a constant C depending only on C_φ,* $\mathrm{reg}(\mathcal{T})$*, and p such that this solution $u^{\mathcal{T}}$ satisfies*

$$\|\nabla^{\mathcal{T}} u^{\mathcal{T}}\|_{L^p} + \|\nabla^{\mathcal{N}} u^{\mathcal{T}}\|_{L^p} \leq C \left(1 + \|f\|_{L^{p'}}^{\frac{1}{p-1}} \right). \tag{4.19}$$

Proof. The map $u^{\mathcal{T}} \mapsto \mathfrak{a}^{\mathcal{N}}(u^{\mathcal{T}}) - f^{\mathcal{T}}$ is continuous and coercive thanks to Lemma 4.8. We deduce from the Brouwer theorem the existence of a solution to (4.17). Uniqueness is a consequence of the monotonicity Lemma 4.9.

Estimate (4.19) comes directly from Lemmas 4.5 and 4.8. ∎

We finally show that the numerical solution of the scheme (4.17) depends continuously on the source term f.

THEOREM 4.11 (stability). *There exists a constant $C > 0$ depending only on C_φ, $\mathrm{reg}(\mathcal{T})$, and p such that for any $f, g \in L^{p'}(\Omega)$, we have*

$$\|\nabla^{\mathcal{N}} u^{\mathcal{T}} - \nabla^{\mathcal{N}} v^{\mathcal{T}}\|_{L^p} \leq \begin{cases} C\left(1 + \|f\|_{L^{p'}} + \|g\|_{L^{p'}}\right)^{\frac{2-p}{p-1}} \|f - g\|_{L^{p'}}, & \text{if } 1 < p \leq 2 \\ C\|f - g\|_{L^{p'}}^{\frac{1}{p-1}}, & \text{if } p > 2, \end{cases}$$

where $u^{\mathcal{T}}$ (resp. $v^{\mathcal{T}}$) is the solution of the m-DDFV scheme (4.17) *associated to the data f (resp. g).*

Proof. We apply estimate (4.18) and obtain thanks to property $(\mathcal{P}^{\mathcal{T}}_{1'b})$ for $p > 2$

$$(\mathfrak{a}^{\mathcal{N}}(u^{\mathcal{T}}) - \mathfrak{a}^{\mathcal{N}}(v^{\mathcal{T}}), u^{\mathcal{T}} - v^{\mathcal{T}}) \geq \frac{1}{C} \sum_{\mathcal{D} \in \mathfrak{D}} \sum_{\mathcal{Q} \in \mathfrak{Q}_{\mathcal{D}}} |\mathcal{Q}| |\nabla^{\mathcal{N}}_{\mathcal{Q}} u^{\mathcal{T}} - \nabla^{\mathcal{N}}_{\mathcal{Q}} v^{\mathcal{T}}|^p.$$

For $1 < p \leq 2$, property $(\mathcal{P}^{\mathcal{T}}_{1'a})$ implies

$$(\mathfrak{a}^{\mathcal{N}}(u^{\mathcal{T}}) - \mathfrak{a}^{\mathcal{N}}(v^{\mathcal{T}}), u^{\mathcal{T}} - v^{\mathcal{T}}) \geq \frac{1}{C} \sum_{\mathcal{D} \in \mathfrak{D}} \sum_{\mathcal{Q} \in \mathfrak{Q}_{\mathcal{D}}} |\mathcal{Q}| \left(1 + |\nabla^{\mathcal{N}}_{\mathcal{Q}} u^{\mathcal{T}}|^p + |\nabla^{\mathcal{N}}_{\mathcal{Q}} v^{\mathcal{T}}|^p\right)^{\frac{p-2}{p}} |\nabla^{\mathcal{N}}_{\mathcal{Q}} u^{\mathcal{T}} - \nabla^{\mathcal{N}}_{\mathcal{Q}} v^{\mathcal{T}}|^2.$$

Hence, if $1 < p \leq 2$ we have

$$\|\nabla^{\mathcal{N}} u^{\mathcal{T}} - \nabla^{\mathcal{N}} v^{\mathcal{T}}\|^2_{L^p} \leq C\left(1 + \|\nabla^{\mathcal{N}} u^{\mathcal{T}}\|^{2-p} + \|\nabla^{\mathcal{N}} v^{\mathcal{T}}\|^{2-p}\right) \times \left(\mathfrak{a}^{\mathcal{N}}(u^{\mathcal{T}}) - \mathfrak{a}^{\mathcal{N}}(v^{\mathcal{T}}), u^{\mathcal{T}} - v^{\mathcal{T}}\right).$$

We conclude using the definition of $f^{\mathcal{T}}$ and $g^{\mathcal{T}}$, the discrete Poincaré inequality (Proposition 4.6) and the *a priori* estimate (4.19). ∎

5. Error estimates. We first give some error estimates for the scheme (4.17) in the case where the exact solution u_e of the problem (1.1) is piecewise smooth. More precisely let us introduce for any $q \in [1, +\infty]$ the space

$$W^{2,q}(\mathfrak{Q}) = \left\{ u \in W^{1,p}_0(\Omega), \quad u_{|\mathcal{Q}} \in W^{2,q}(\mathcal{Q}), \ \forall \mathcal{Q} \in \mathfrak{Q} \right\},$$

endowed with the norm

$$\|u\|_{W^{2,q}(\mathfrak{Q})} = \|u\|_{W^{1,p}_0(\Omega)} + \left(\sum_{\mathcal{Q} \in \mathfrak{Q}} \|D^2 u\|^q_{L^q(\mathcal{Q})} \right)^{\frac{1}{q}}.$$

Our first result gives an error estimate for the solution of the m-DDFV scheme. In this result the flux φ is allowed to have discontinuities across all the edges of the primal and the dual meshes.

THEOREM 5.1. *Let $\mathcal{T}$ be a mesh on Ω. Let $f \in L^{p'}(\Omega)$ and assume that the solution u_e to* (1.1) *belongs to $W^{2,p}(\mathfrak{Q})$.*

There exists $C > 0$ depending on $\|u_e\|_{W^{2,p}(\mathfrak{Q})}$, $\mathrm{reg}(\mathcal{T})$, $\|f\|_{L^{p'}}$, C_φ, and p such that the solution $u^{\mathcal{T}} \in \mathbb{R}^{\mathcal{T}}$ of the m-DDFV scheme (4.17) *satisfies*

$$\|u_e - u^{\mathfrak{M}}\|_{L^p} + \|u_e - u^{\mathfrak{M}^*}\|_{L^p} + \|\nabla u_e - \nabla^{\mathcal{N}} u^{\mathcal{T}}\|_{L^p} \leq \begin{cases} C\,\mathrm{size}(\mathcal{T})^{(p-1)^2}, & \text{if } 1 < p \leq 2, \\ C\,\mathrm{size}(\mathcal{T})^{\frac{1}{(p-1)^2}}, & \text{if } p > 2. \end{cases}$$

A typical case for which our method can be applied is the one where the domain Ω can be divided into N disjoint subdomains $(\Omega_i)_{1\leq i\leq N}$ such that

$$\varphi \text{ is smooth over each subdomain } \Omega_i. \tag{5.1}$$

We assume that each domain Ω_i is polygonal and that the mesh is compatible with the subdomains in the sense that, for any i there exists a subset $\mathcal{E}_i$ of $\mathcal{E}$ such that $\partial\Omega_i = \cup_{\sigma\in\mathcal{E}_i}\sigma$. More generally, we may assume that the discontinuities of the flux φ occur only along a finite number of curves in Ω.

In that situation, the diamond cells naturally divide into two subsets defined by

$$\mathfrak{D}_{\mathrm{cont}} = \{\mathcal{D} \in \mathfrak{D},\ \ \exists i \in \{1,\dots,N\},\ \mathcal{D} \subset \Omega_i\},\ \text{ and }\ \mathfrak{D}_{\mathrm{disc}} = \mathfrak{D} \setminus \mathfrak{D}_{\mathrm{cont}}.$$

We propose to use in that case a hybrid DDFV scheme defined as follows:

DEFINITION 5.2. *Under assumption* (5.1)*, we call h-DDFV scheme for the problem* (1.1) *the DDFV scheme still under the form* (4.17)*, but where $\varphi_{\mathcal{D}}^{\mathcal{N}}$ is defined as follows:*

- *For the diamond cells $\mathcal{D} \in \mathfrak{D}_{\mathrm{disc}}$, that is, the ones where the discontinuities of the flux occur, we take $\varphi_{\mathcal{D}}^{\mathcal{N}}$ as defined in* (4.16).
- *For the diamond cells $\mathcal{D} \in \mathfrak{D}_{\mathrm{cont}}$, that is, away from the discontinuities, we take $\varphi_{\mathcal{D}}^{\mathcal{N}}$ to be the usual mean-value $\varphi_{\mathcal{D}}$ of φ over $\mathcal{D}$ defined in* (3.4).

Assuming that u_e is slightly more regular than in the previous result, this approach let us recover the same convergence rate than in the usual continuous flux case (see [3]).

THEOREM 5.3. *Consider the same assumptions than in Theorem* 5.1 *with the additional assumption* (5.1)*. Assume furthermore that the solution u_e of* (1.1) *lies in $W^{2,q}(\mathfrak{Q})$ for $q = p(p-1)^2$ if $p \geq 2$ and $q = \frac{p}{(p-1)^2}$ if $p < 2$. Then, there exists a constant $C > 0$ like in Theorem* 5.1 *such that the solution $u^{\mathcal{T}}$ to the h-DDFV scheme satisfies*

$$\|u_e - u^{\mathfrak{M}}\|_{L^p} + \|u_e - u^{\mathfrak{M}^*}\|_{L^p} + \|\nabla u_e - \nabla^{\mathcal{N}} u^{\mathcal{T}}\|_{L^p} \leq \begin{cases} C\,\mathrm{size}(\mathcal{T})^{p-1}, & \text{if } 1 < p \leq 2, \\ C\,\mathrm{size}(\mathcal{T})^{\frac{1}{p-1}}, & \text{if } p > 2. \end{cases}$$

We are now going to prove these two results. The key ingredients in this analysis are the consistency error estimates on the numerical fluxes across edges of the primal and the dual control volumes.

5.1. Consistency error. In order to evaluate the error between u_e and $u^{\mathcal{T}}$ we need to introduce a projection of the exact solution u_e onto the space of discrete functions $\mathbb{R}^{\mathcal{T}}$. Notice that any function v in $W^{2,p}(\mathfrak{Q})$ is continuous over $\overline{\Omega}$. Hence, it makes sense to consider the center-value projection $\mathbb{P}^{\mathcal{T}}$ defined as follows:

DEFINITION 5.4. *For any $v \in \mathcal{C}^0(\overline{\Omega})$, we define its center-value projection $\mathbb{P}^{\mathcal{T}} v \in \mathbb{R}^{\mathcal{T}}$ as the vector*

$$\mathbb{P}^{\mathcal{T}} v = \Big((v(x_{\mathcal{K}}))_{\mathcal{K}\in\mathfrak{M}}, (v(x_{\mathcal{K}^*}))_{\mathcal{K}^*\in\mathfrak{M}^*} \Big).$$

We refer to [3] for the proofs of the main properties of this projection operator.

As usual in finite volume methods, the error analysis is mainly based on estimates of consistency errors for the fluxes as defined below.

DEFINITION 5.5. *Assume that* $u_e \in W^{2,p}(\mathfrak{D})$. *For any* $\mathcal{Q} \in \mathfrak{D}$, $z \in \overline{\mathcal{Q}}$ *we define*

$$\begin{aligned} R_{\mathcal{Q}}(z) &= \varphi_{\big|\overline{\mathcal{Q}}}(z, \nabla u_e{\big|}_{\overline{\mathcal{Q}}}(z)) - \varphi_{\mathcal{Q}}(\nabla_{\mathcal{Q}}^{\mathcal{N}} \mathbb{P}^{\mathcal{T}} u_e) \\ &= R_{\mathcal{Q}}^{\varphi}(z) + R_{\mathcal{Q}}^{\mathrm{grad}}, \end{aligned}$$

with

$$\begin{aligned} R_{\mathcal{Q}}^{\varphi}(z) &\overset{\mathrm{def}}{=} \varphi_{\big|\overline{\mathcal{Q}}}(z, \nabla u_e{\big|}_{\overline{\mathcal{Q}}}(z)) - \frac{1}{|\mathcal{Q}|} \int_{\mathcal{Q}} \varphi(z', \nabla u_e(z'))\, dz' \\ R_{\mathcal{Q}}^{\mathrm{grad}} &\overset{\mathrm{def}}{=} \frac{1}{|\mathcal{Q}|} \int_{\mathcal{Q}} \left(\varphi(z', \nabla u_e(z')) - \varphi(z', \nabla_{\mathcal{Q}}^{\mathcal{N}} \mathbb{P}^{\mathcal{T}} u_e)\right)\, dz'. \end{aligned}$$

Finally, for any $\mathcal{Q} \in \mathfrak{D}$ *and* $\sigma \in \mathcal{E}_{\mathcal{Q}}$, *we note*

$$R_{\mathcal{Q},\sigma}^{\varphi} = \frac{1}{|\sigma|} \int_{\sigma} (R_{\mathcal{Q}}^{\varphi}(z), \boldsymbol{\nu}_{\mathcal{Q},\sigma})\, dz, \quad R_{\mathcal{Q},\sigma}^{\mathrm{grad}} = \left(R_{\mathcal{Q}}^{\mathrm{grad}}, \boldsymbol{\nu}_{\mathcal{Q},\sigma}\right),$$

and $R_{\mathcal{Q},\sigma} = R_{\mathcal{Q},\sigma}^{\mathrm{grad}} + R_{\mathcal{Q},\sigma}^{\varphi}$, *where* $\boldsymbol{\nu}_{\mathcal{Q},\sigma}$ *is the unit normal to* σ *pointing outward* $\mathcal{Q}$.

It is fundamental to notice that, by definition of the new discrete gradient operator $\nabla^{\mathcal{N}}$ and since $u_e \in W^{2,p}(\mathfrak{D})$, we have the conservativity property

$$R_{\mathcal{Q},\sigma} = -R_{\mathcal{Q}',\sigma}, \text{ if } \sigma = \mathcal{Q}|\mathcal{Q}'. \tag{5.2}$$

The goal is now to estimate each of the two terms involved in this consistency error. The term $R_{\mathcal{Q}}^{\varphi}$ can be controlled by using exactly the same techniques as in [3, Proposition 7.10]. With the present notations, and thanks to assumptions $(\mathcal{H}_{4a})$–$(\mathcal{H}_{4b})$ and $(\mathcal{H}_{5a})$–$(\mathcal{H}_{5b})$, the result reads:

PROPOSITION 5.6. *Let* $\mathcal{T}$ *be a mesh on* Ω *and assume that the solution* u_e *to problem* (1.1) *lies in* $W^{2,p}(\mathfrak{D})$. *There exists a constant* $C > 0$ *depending on* p, $\mathrm{reg}(\mathcal{T})$, *and* C_{φ} *such that*

$$|\mathcal{Q}|\, |R_{\mathcal{Q},\sigma}^{\varphi}|^{\frac{p}{p-1}} \leq C \mathrm{d}_{\mathcal{Q}}^{p\alpha_p} \int_{\mathcal{Q}} (1 + |\nabla u_e|^p + |D^2 u_e|^p)\, dz, \quad \forall \mathcal{Q} \in \mathfrak{D}, \forall \sigma \in \mathcal{E}_{\mathcal{Q}},$$

where $\alpha_p = \max(1, \frac{1}{p-1})$.

The estimate of the term $R_{\mathcal{Q},\sigma}^{\mathrm{grad}}$ will follow from a consistency estimate for the new gradient operator $\nabla^{\mathcal{N}}$ that we have introduced. This is the main difference between the present study and our previous works since the definition of the new discrete gradient depends on the jumps of φ in each diamond cell. Hence, the consistency estimate for this operator cannot be obtained as in the usual way, that is, only by applying well-chosen Taylor formulas. The proof of the estimate is much more involved and makes use of the bound obtained in Proposition 5.6.

We also want to point out the fact that, when $p \neq 2$, we do not obtain the usual first-order consistency estimate as we obtained in [3] for the operator $\nabla_{\mathcal{D}}^{\mathcal{T}}$. Indeed, due to the degeneracy/singularity of the nonlinear operator near the origin, we only recover a consistency property of order less than one.

PROPOSITION 5.7. *Let* $\mathcal{T}$ *be a mesh on* Ω *and assume that the solution* u_e *to problem* (1.1) *lies in* $W^{2,p}(\mathfrak{D})$. *There exists a constant* $C > 0$ *depending on* $p, \mathrm{reg}(\mathcal{T})$,

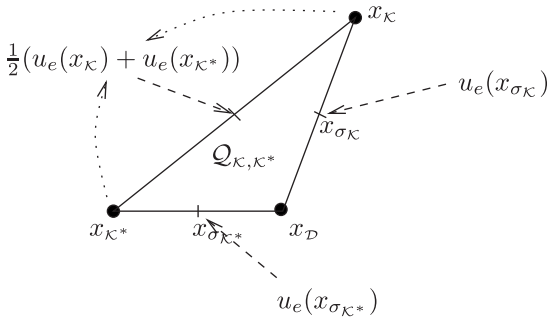

FIG. 5.1. *The affine interpolation* $\mathbb{P}^{\mathfrak{Q}}_{\mathcal{Q}_{\mathcal{K},\mathcal{K}^*}}$ *on the quarter diamond* $\mathcal{Q}_{\mathcal{K},\mathcal{K}^*}$.

and C_φ *such that for any* $\mathcal{D} \in \mathfrak{D}$ *we have*

$$\int_{\mathcal{D}} |\nabla u_e(z) - \nabla^{\mathcal{N}} \mathbb{P}^{\mathcal{T}} u_e(z)|^p \, dz \leq C \mathrm{d}_{\mathcal{D}}^{p(p-1)\alpha_p^2} \sum_{\mathcal{Q} \in \mathfrak{Q}_{\mathcal{D}}} \int_{\mathcal{Q}} \left(1 + |\nabla u_e|^p + |D^2 u_e|^p\right) \, dz,$$

where α_p *is given in Proposition* 5.6.

Proof. Let us give the proof in the case where $\mathcal{D}$ is an interior diamond cell. The case $\mathcal{D} \in \mathfrak{D}_{\mathrm{ext}}$ can be treated in a similar, and in fact, simpler way.

Let us define the projection $\mathbb{P}^{\mathfrak{Q}} u_e$ of u_e on the set of quarter diamonds as follows. For each quarter diamond $\mathcal{Q} \in \mathfrak{Q}$, the restriction of $\mathbb{P}^{\mathfrak{Q}} u_e$ to the triangle $\mathcal{Q}$ is the unique affine function $\mathbb{P}^{\mathfrak{Q}}_{\mathcal{Q}} u_e$ which coincides with u_e at the middle of the semi-edges $\sigma \in \mathcal{E}_{\mathcal{Q}}$ and whose value at the middle of the third side of $\mathcal{Q}$ is the mean value of the values of u_e at the extremities of this side. Notice that this definition makes sense since $u_e\big|_{\overline{\mathcal{Q}}} \in W^{2,p}(\mathcal{Q}) \subset \mathcal{C}^0(\overline{\mathcal{Q}})$. As an example, in the case of the quarter diamond $\mathcal{Q} = \mathcal{Q}_{\mathcal{K},\mathcal{K}^*}$ (see Figure 5.1), this definition reads

$$\begin{aligned}
\mathbb{P}^{\mathfrak{Q}}_{\mathcal{Q}_{\mathcal{K},\mathcal{K}^*}} u_e(x_{\sigma_{\mathcal{K}}}) &= u_e(x_{\sigma_{\mathcal{K}}}), \\
\mathbb{P}^{\mathfrak{Q}}_{\mathcal{Q}_{\mathcal{K},\mathcal{K}^*}} u_e(x_{\sigma_{\mathcal{K}^*}}) &= u_e(x_{\sigma_{\mathcal{K}^*}}), \\
\mathbb{P}^{\mathfrak{Q}}_{\mathcal{Q}_{\mathcal{K},\mathcal{K}^*}} u_e\left(\frac{x_{\mathcal{K}} + x_{\mathcal{K}^*}}{2}\right) &= \frac{u_e(x_{\mathcal{K}}) + u_e(x_{\mathcal{K}^*})}{2}.
\end{aligned}$$

The gradient of $\mathbb{P}^{\mathfrak{Q}}_{\mathcal{Q}_{\mathcal{K},\mathcal{K}^*}} u_e$ is then given by

$$\nabla \mathbb{P}^{\mathfrak{Q}}_{\mathcal{Q}_{\mathcal{K},\mathcal{K}^*}} u_e = \frac{2}{\sin \alpha_{\mathcal{D}}} \left(\frac{u_e(x_{\sigma_{\mathcal{K}^*}}) - \frac{u_e(x_{\mathcal{K}}) + u_e(x_{\mathcal{K}^*})}{2}}{|\sigma_{\mathcal{K}}|} \boldsymbol{\nu} + \frac{u_e(x_{\sigma_{\mathcal{K}}}) - \frac{u_e(x_{\mathcal{K}}) + u_e(x_{\mathcal{K}^*})}{2}}{|\sigma_{\mathcal{K}^*}|} \boldsymbol{\nu}^* \right).$$

Let us now define the consistency error for this projection $\mathbb{P}^{\mathfrak{Q}}$ as follows:

$$T_{\overline{\mathcal{Q}}}(z) = \nabla u_e(z) - \nabla \mathbb{P}^{\mathfrak{Q}}_{\mathcal{Q}} u_e, \quad \forall z \in \mathcal{Q}, \quad \forall \mathcal{Q} \in \mathfrak{Q}. \tag{5.3}$$

By usual Taylor expansions inside each quarter diamond $\mathcal{Q}$ (see [3], for instance), we can easily show that there exists a constant $C > 0$ as in the claim on the proposition such that

$$\int_{\mathcal{Q}} |T_{\overline{\mathcal{Q}}}(z)|^p \, dz \leq C \mathrm{d}_{\mathcal{Q}}^p \int_{\mathcal{Q}} |D^2 u_e(z)|^p \, dz, \quad \forall \mathcal{Q} \in \mathfrak{Q}. \tag{5.4}$$

By the discussion of section 4.3 we remark that, $\mathcal{D}$ being an interior diamond cell, there exists $\widetilde{\delta}_{\mathcal{D}} \in \mathbb{R}^4$ such that

$$\nabla \mathbb{P}^{\mathfrak{Q}}_{\mathcal{Q}} u_e - \nabla^{\mathcal{T}}_{\mathcal{D}} \mathbb{P}^{\mathcal{T}} u_e = B_{\mathcal{Q}} \widetilde{\delta}_{\mathcal{D}}, \, \forall \mathcal{Q} \in \mathfrak{Q}_{\mathcal{D}},$$

and then, by the definition (4.14) of $\nabla^{\mathcal{N}}_{\mathcal{Q}}$, we deduce that there exists $\overline{\delta^{\mathcal{D}}} \in \mathbb{R}^4$ such that

$$\nabla \mathbb{P}^{\mathfrak{Q}}_{\mathcal{Q}} u_e - \nabla^{\mathcal{N}}_{\mathcal{Q}} \mathbb{P}^{\mathcal{T}} u_e = B_{\mathcal{Q}} \overline{\delta^{\mathcal{D}}}, \, \forall \mathcal{Q} \in \mathfrak{Q}_{\mathcal{D}}. \tag{5.5}$$

Since u_e solves (1.1) with $f \in L^{p'}(\Omega)$, we know that the following transmission property holds (just like the fourth equation in (2.1)):

$$\int_{\sigma_{\mathcal{K}}} \varphi|_{\overline{\mathcal{Q}_{\mathcal{K},\mathcal{K}^*}}}(z, \nabla u_e|_{\overline{\mathcal{Q}_{\mathcal{K},\mathcal{K}^*}}}(s)) \cdot \boldsymbol{\nu}^* \, ds = \int_{\sigma_{\mathcal{K}}} \varphi|_{\overline{\mathcal{Q}_{\mathcal{K},\mathcal{L}^*}}}(z, \nabla u_e|_{\overline{\mathcal{Q}_{\mathcal{K},\mathcal{L}^*}}}(s)) \cdot \boldsymbol{\nu}^* \, ds. \tag{5.6}$$

Recall that the gradient operator $\nabla^{\mathcal{N}}$ is built to ensure that the discrete equivalent of this property, that is, the first equation of (4.10), holds. It follows that

$$\begin{aligned}
&\left(\frac{1}{|\sigma_{\mathcal{K}}|} \int_{\sigma_{\mathcal{K}}} \varphi|_{\overline{\mathcal{Q}_{\mathcal{K},\mathcal{K}^*}}}(s, \nabla u_e|_{\overline{\mathcal{Q}_{\mathcal{K},\mathcal{K}^*}}}(s)) \, ds - \varphi_{\mathcal{Q}_{\mathcal{K},\mathcal{K}^*}}(\nabla^{\mathcal{N}}_{\mathcal{Q}_{\mathcal{K},\mathcal{K}^*}} \mathbb{P}^{\mathcal{T}} u_e), \boldsymbol{\nu}^* \right) \\
&\qquad - \left(\frac{1}{|\sigma_{\mathcal{K}}|} \int_{\sigma_{\mathcal{K}}} \varphi|_{\overline{\mathcal{Q}_{\mathcal{K},\mathcal{L}^*}}}(s, \nabla u_e|_{\overline{\mathcal{Q}_{\mathcal{K},\mathcal{L}^*}}}(s)) \, ds - \varphi_{\mathcal{Q}_{\mathcal{K},\mathcal{L}^*}}(\nabla^{\mathcal{N}}_{\mathcal{Q}_{\mathcal{K},\mathcal{L}^*}} \mathbb{P}^{\mathcal{T}} u_e), \boldsymbol{\nu}^* \right) = 0.
\end{aligned}$$

By using Definition 5.5, we get

$$\begin{aligned}
&\left(\frac{1}{|\mathcal{Q}_{\mathcal{K},\mathcal{K}^*}|} \int_{\mathcal{Q}_{\mathcal{K},\mathcal{K}^*}} \Big(\varphi(z, \nabla u_e(z)) - \varphi(z, \nabla^{\mathcal{N}}_{\mathcal{Q}_{\mathcal{K},\mathcal{K}^*}} \mathbb{P}^{\mathcal{T}} u_e) \Big) \, dz, \boldsymbol{\nu}^* \right) \\
&- \left(\frac{1}{|\mathcal{Q}_{\mathcal{K},\mathcal{L}^*}|} \int_{\mathcal{Q}_{\mathcal{K},\mathcal{L}^*}} \Big(\varphi(z, \nabla u_e(z)) - \varphi(z, \nabla^{\mathcal{N}}_{\mathcal{Q}_{\mathcal{K},\mathcal{L}^*}} \mathbb{P}^{\mathcal{T}} u_e) \Big) \, dz, \boldsymbol{\nu}^* \right) = R^{\varphi}_{\mathcal{Q}_{\mathcal{K},\mathcal{K}^*},\sigma_{\mathcal{K}}} - R^{\varphi}_{\mathcal{Q}_{\mathcal{K},\mathcal{L}^*},\sigma_{\mathcal{K}}}.
\end{aligned}$$

Similarly we obtain for the other three semi-edges in the diamond under study the following relations

$$\begin{aligned}
&\left(\frac{1}{|\mathcal{Q}_{\mathcal{L},\mathcal{K}^*}|} \int_{\mathcal{Q}_{\mathcal{L},\mathcal{K}^*}} \Big(\varphi(z, \nabla u_e(z)) - \varphi(z, \nabla^{\mathcal{N}}_{\mathcal{Q}_{\mathcal{L},\mathcal{K}^*}} \mathbb{P}^{\mathcal{T}} u_e) \Big) \, dz, \boldsymbol{\nu}^* \right) \\
&- \left(\frac{1}{|\mathcal{Q}_{\mathcal{L},\mathcal{L}^*}|} \int_{\mathcal{Q}_{\mathcal{L},\mathcal{L}^*}} \Big(\varphi(z, \nabla u_e(z)) \, dz - \varphi(z, \nabla^{\mathcal{N}}_{\mathcal{Q}_{\mathcal{L},\mathcal{L}^*}} \mathbb{P}^{\mathcal{T}} u_e) \Big) \, dz, \boldsymbol{\nu}^* \right) = R^{\varphi}_{\mathcal{Q}_{\mathcal{L},\mathcal{K}^*},\sigma_{\mathcal{L}}} - R^{\varphi}_{\mathcal{Q}_{\mathcal{L},\mathcal{L}^*},\sigma_{\mathcal{L}}}.
\end{aligned}$$

$$\begin{aligned}
&\left(\frac{1}{|\mathcal{Q}_{\mathcal{K},\mathcal{K}^*}|} \int_{\mathcal{Q}_{\mathcal{K},\mathcal{K}^*}} \Big(\varphi(z, \nabla u_e(z)) - \varphi(z, \nabla^{\mathcal{N}}_{\mathcal{Q}_{\mathcal{K},\mathcal{K}^*}} \mathbb{P}^{\mathcal{T}} u_e) \Big) \, dz, \boldsymbol{\nu} \right) \\
&- \left(\frac{1}{|\mathcal{Q}_{\mathcal{L},\mathcal{K}^*}|} \int_{\mathcal{Q}_{\mathcal{L},\mathcal{K}^*}} \Big(\varphi(z, \nabla u_e(z)) - \varphi(z, \nabla^{\mathcal{N}}_{\mathcal{Q}_{\mathcal{L},\mathcal{K}^*}} \mathbb{P}^{\mathcal{T}} u_e) \Big) \, dz, \boldsymbol{\nu} \right) = R^{\varphi}_{\mathcal{Q}_{\mathcal{K},\mathcal{K}^*},\sigma_{\mathcal{K}^*}} - R^{\varphi}_{\mathcal{Q}_{\mathcal{L},\mathcal{K}^*},\sigma_{\mathcal{K}^*}}.
\end{aligned}$$

$$\begin{aligned}
&\left(\frac{1}{|\mathcal{Q}_{\mathcal{K},\mathcal{L}^*}|} \int_{\mathcal{Q}_{\mathcal{K},\mathcal{L}^*}} \Big(\varphi(z, \nabla u_e(z)) - \varphi(z, \nabla^{\mathcal{N}}_{\mathcal{Q}_{\mathcal{K},\mathcal{L}^*}} \mathbb{P}^{\mathcal{T}} u_e) \Big) \, dz, \boldsymbol{\nu} \right) \\
&- \left(\frac{1}{|\mathcal{Q}_{\mathcal{L},\mathcal{L}^*}|} \int_{\mathcal{Q}_{\mathcal{L},\mathcal{L}^*}} \Big(\varphi(z, \nabla u_e(z)) - \varphi(z, \nabla^{\mathcal{N}}_{\mathcal{Q}_{\mathcal{L},\mathcal{L}^*}} \mathbb{P}^{\mathcal{T}} u_e) \Big) \, dz, \boldsymbol{\nu} \right) = R^{\varphi}_{\mathcal{Q}_{\mathcal{K},\mathcal{L}^*},\sigma_{\mathcal{L}^*}} - R^{\varphi}_{\mathcal{Q}_{\mathcal{L},\mathcal{L}^*},\sigma_{\mathcal{L}^*}}.
\end{aligned}$$

Multiplying these equations, respectively, by $|\sigma_{\mathcal{K}}|\overline{\delta_{\mathcal{K}}}$, $|\sigma_{\mathcal{L}}|\overline{\delta_{\mathcal{L}}}$, $|\sigma_{\mathcal{K}^*}|\overline{\delta_{\mathcal{K}^*}}$, and $|\sigma_{\mathcal{L}^*}|\overline{\delta_{\mathcal{L}^*}}$ and summing, we obtain

$$\sum_{\mathcal{Q}\in\mathfrak{Q}_{\mathcal{D}}}\int_{\mathcal{Q}}\left(\varphi(z,\nabla u_e(z))-\varphi(z,\nabla_{\mathcal{Q}}^{\mathcal{N}}\mathbb{P}^{\mathcal{T}}u_e),B_{\mathcal{Q}}\overline{\delta^{\mathcal{D}}}\right)\,dz\le\sum_{\mathcal{Q}\in\mathfrak{Q}_{\mathcal{D}}}|\mathcal{Q}||B_{\mathcal{Q}}\overline{\delta^{\mathcal{D}}}|\sum_{\sigma\in\mathcal{E}_{\mathcal{Q}}}|R^{\varphi}_{\mathcal{Q},\sigma}|,$$

where we used the definitions (4.3)–(4.6). Using (5.3) and (5.5) we finally deduce

$$\begin{aligned}(5.7)\qquad &\sum_{\mathcal{Q}\in\mathfrak{Q}_{\mathcal{D}}}\int_{\mathcal{Q}}(\varphi(z,\nabla u_e(z))-\varphi(z,\nabla_{\mathcal{Q}}^{\mathcal{N}}\mathbb{P}^{\mathcal{T}}u_e),\nabla u_e(z)-\nabla_{\mathcal{Q}}^{\mathcal{N}}\mathbb{P}^{\mathcal{T}}u_e)\,dz\\&\le\sum_{\mathcal{Q}\in\mathfrak{Q}_{\mathcal{D}}}\left(\int_{\mathcal{Q}}|\nabla u_e(z)-\nabla_{\mathcal{Q}}^{\mathcal{N}}\mathbb{P}^{\mathcal{T}}u_e(z)|\,dz+\int_{\mathcal{Q}}|T_{\overline{\mathcal{Q}}}(z)|\,dz\right)\sum_{\sigma\in\mathcal{E}_{\mathcal{Q}}}|R^{\varphi}_{\mathcal{Q},\sigma}|\\&\qquad+\sum_{\mathcal{Q}\in\mathfrak{Q}_{\mathcal{D}}}\int_{\mathcal{Q}}(\varphi(z,\nabla u_e(z))-\varphi(z,\nabla_{\mathcal{Q}}^{\mathcal{N}}\mathbb{P}^{\mathcal{T}}u_e),T_{\overline{\mathcal{Q}}}(z))\,dz.\end{aligned}$$

In the case $p>2$, using assumptions $(\mathcal{H}_{1'b})$ and $(\mathcal{H}_{4b})$ and Young's inequality, we deduce from formula (5.7) that

$$\begin{aligned}\sum_{\mathcal{Q}\in\mathfrak{Q}_{\mathcal{D}}}\int_{\mathcal{Q}}|\nabla u_e(z)-\nabla_{\mathcal{Q}}^{\mathcal{N}}\mathbb{P}^{\mathcal{T}}u_e|^p\,dz&\le C\sum_{\mathcal{Q}\in\mathfrak{Q}_{\mathcal{D}}}\sum_{\sigma\in\mathcal{E}_{\mathcal{Q}}}|\mathcal{Q}||R^{\varphi}_{\mathcal{Q},\sigma}|^{\frac{p}{p-1}}+C\sum_{\mathcal{Q}\in\mathfrak{Q}_{\mathcal{D}}}\int_{\mathcal{Q}}|T_{\overline{\mathcal{Q}}}(z)|^p\,dz\\&\quad+C\left(\sum_{\mathcal{Q}\in\mathfrak{Q}_{\mathcal{D}}}\int_{\mathcal{Q}}|T_{\overline{\mathcal{Q}}}(z)|^p\,dz\right)^{\frac{1}{p-1}}\left(\int_{\mathcal{D}}(1+|\nabla u_e(z)|^p)\,dz\right)^{\frac{p-2}{p-1}}.\end{aligned}$$

From (5.4) and the estimates in Proposition 5.6, it follows that

$$\sum_{\mathcal{Q}\in\mathfrak{Q}_{\mathcal{D}}}\int_{\mathcal{Q}}|\nabla u_e(z)-\nabla_{\mathcal{Q}}^{\mathcal{N}}\mathbb{P}^{\mathcal{T}}u_e|^p\,dz\le C\mathrm{d}_{\mathcal{D}}^{\frac{p}{p-1}}\sum_{\mathcal{Q}\in\mathfrak{Q}_{\mathcal{D}}}\int_{\mathcal{Q}}(1+|\nabla u_e|^p+|D^2u_e|^p)\,dz,$$

and the claim is proved.

In the case $1 < p \le 2$, using assumptions $(\mathcal{H}_{1'a})$ and $(\mathcal{H}_{4a})$, we deduce from formula (5.7) that

$$\begin{aligned}
&\sum_{\mathcal{Q}\in\mathfrak{Q}_\mathcal{D}} \int_\mathcal{Q} |\nabla u_e(z) - \nabla_\mathcal{Q}^\mathcal{N} \mathbb{P}^\mathcal{T} u_e|^p \, dz \\
&\le \Bigg[\sum_{\mathcal{Q}\in\mathfrak{Q}_\mathcal{D}} \left(\int_\mathcal{Q} |\nabla u_e(z) - \nabla_\mathcal{Q}^\mathcal{N} \mathbb{P}^\mathcal{T} u_e(z)| \, dz + \int_\mathcal{Q} |T_{\overline{\mathcal{Q}}}(z)| \, dz \right) \sum_{\sigma\in\mathcal{E}_\mathcal{Q}} |R_{\mathcal{Q},\sigma}^\varphi| \\
&\qquad\qquad + \sum_{\mathcal{Q}\in\mathfrak{Q}_\mathcal{D}} \int_\mathcal{Q} \left(\varphi(z, \nabla u_e(z)) - \varphi(z, \nabla_\mathcal{Q}^\mathcal{N} \mathbb{P}^\mathcal{T} u_e), T_{\overline{\mathcal{Q}}}(z)\right) dz \Bigg]^{\frac{p}{2}} \\
&\times \left(\sum_{\mathcal{Q}\in\mathfrak{Q}_\mathcal{D}} \int_\mathcal{Q} (1 + |\nabla u_e(z)|^p + |\nabla_\mathcal{Q}^\mathcal{N} \mathbb{P}^\mathcal{T} u_e|^p) \, dz \right)^{\frac{2-p}{2}} \\
&\le C \Bigg[\left(\left(\sum_{\mathcal{Q}\in\mathfrak{Q}_\mathcal{D}} \int_\mathcal{Q} |\nabla u_e(z) - \nabla_\mathcal{Q}^\mathcal{N} \mathbb{P}^\mathcal{T} u_e(z)|^p \, dz \right)^{\frac{1}{2}} + \left(\sum_{\mathcal{Q}\in\mathfrak{Q}_\mathcal{D}} \int_\mathcal{Q} |T_{\overline{\mathcal{Q}}}(z)|^p \, dz \right)^{\frac{1}{2}} \right) \\
&\qquad\qquad \times \left(\sum_{\mathcal{Q}\in\mathfrak{Q}_\mathcal{D}} |\mathcal{Q}| \sum_{\sigma\in\mathcal{E}_\mathcal{Q}} |R_{\mathcal{Q},\sigma}^\varphi|^{\frac{p}{p-1}} \right)^{\frac{p-1}{2}} \\
&+ \left(\sum_{\mathcal{Q}\in\mathfrak{Q}_\mathcal{D}} \int_\mathcal{Q} |\nabla u_e(z) - \nabla_\mathcal{Q}^\mathcal{N} \mathbb{P}^\mathcal{T} u_e|^p \right)^{\frac{p-1}{2}} \left(\sum_{\mathcal{Q}\in\mathfrak{Q}_\mathcal{D}} \int_\mathcal{Q} |T_{\overline{\mathcal{Q}}}(z)|^p \, dz \right)^{\frac{1}{2}} \Bigg] \\
&\qquad \times \left(\sum_{\mathcal{Q}\in\mathfrak{Q}_\mathcal{D}} \int_\mathcal{Q} (1 + |\nabla u_e(z)|^p + |\nabla_\mathcal{Q}^\mathcal{N} \mathbb{P}^\mathcal{T} u_e|^p) \, dz \right)^{\frac{2-p}{2}}.
\end{aligned}$$

Using Young's inequality, the bound (5.4) and the estimates in Proposition 5.6, the claim follows. ∎

We can now estimate the consistency error of the scheme due to the approximation of the gradient as follows.

PROPOSITION 5.8. *Let $\mathcal{T}$ be a mesh on Ω and assume that u_e lies in $W^{2,p}(\mathfrak{Q})$. There exists a constant $C > 0$ depending on $p, \mathrm{reg}(\mathcal{T})$, and C_φ such that for any $\mathcal{D} \in \mathfrak{D}$ we have*

$$\sum_{\mathcal{Q}\in\mathfrak{Q}_\mathcal{D}} |\mathcal{Q}| |R_\mathcal{Q}^{\mathrm{grad}}|^{\frac{p}{p-1}} \le C \mathrm{d}_\mathcal{D}^{p(p-1)\alpha_p^3} \sum_{\mathcal{Q}\in\mathfrak{Q}_\mathcal{D}} \int_\mathcal{Q} \left(1 + |\nabla u_e|^p + |D^2 u_e|^p\right) dz.$$

Proof. In the case $1 < p \le 2$, using assumption $(\mathcal{H}_{4a})$ and the consistency estimate of Proposition 5.7, we deduce that

$$\begin{aligned}
\sum_{\mathcal{Q}\in\mathfrak{Q}_\mathcal{D}} |\mathcal{Q}| |R_\mathcal{Q}^{\mathrm{grad}}|^{\frac{p}{p-1}} &\le C_\varphi^{\frac{p}{p-1}} \sum_{\mathcal{Q}\in\mathfrak{Q}_\mathcal{D}} |\mathcal{Q}| \left(\frac{1}{|\mathcal{Q}|} \int_\mathcal{Q} |\nabla u_e(z) - \nabla_\mathcal{Q}^\mathcal{N} \mathbb{P}^\mathcal{T} u_e|^{p-1} \, dz \right)^{\frac{p}{p-1}} \\
&\le C_\varphi^{\frac{p}{p-1}} \sum_{\mathcal{Q}\in\mathfrak{Q}_\mathcal{D}} \int_\mathcal{Q} |\nabla u_e(z) - \nabla_\mathcal{Q}^\mathcal{N} \mathbb{P}^\mathcal{T} u_e|^p \, dz \\
&\le C \mathrm{d}_\mathcal{D}^{p(p-1)\alpha_p^2} \sum_{\mathcal{Q}\in\mathfrak{Q}_\mathcal{D}} \int_\mathcal{Q} \left(1 + |\nabla u_e|^p + |D^2 u_e|^p\right) dz,
\end{aligned}$$

which gives the claim since $\alpha_p = 1$ as soon as $1 < p \le 2$.

When $p > 2$, by Jensen's and Hölder's inequality, we have

$$
\begin{aligned}
&\sum_{\mathcal{Q}\in\mathfrak{Q}_{\mathcal{D}}} |\mathcal{Q}||R_{\mathcal{Q}}^{\mathrm{grad}}|^{\frac{p}{p-1}} \\
&\quad\le C_{\varphi}^{\frac{p}{p-1}} \sum_{\mathcal{Q}\in\mathfrak{Q}_{\mathcal{D}}} |\mathcal{Q}| \Bigg(\frac{1}{|\mathcal{Q}|} \int_{\mathcal{Q}} \left(1 + |\nabla u_e(z)|^{p-2} + |\nabla_{\mathcal{Q}}^{\mathcal{N}} \mathbb{P}^{\mathcal{T}} u_e|^{p-2}\right) \\
&\qquad\qquad \times |\nabla u_e(z) - \nabla_{\mathcal{Q}}^{\mathcal{N}} \mathbb{P}^{\mathcal{T}} u_e| \, dz \Bigg)^{\frac{p}{p-1}} \\
&\quad\le C \left(\sum_{\mathcal{Q}\in\mathfrak{Q}_{\mathcal{D}}} \int_{\mathcal{Q}} \left(1 + |\nabla u_e(z)|^p + |\nabla_{\mathcal{Q}}^{\mathcal{N}} \mathbb{P}^{\mathcal{T}} u_e|^p\right) \, dz \right)^{\frac{p-2}{p-1}} \\
&\qquad\qquad \times \left(\sum_{\mathcal{Q}\in\mathfrak{Q}_{\mathcal{D}}} \int_{\mathcal{Q}} |\nabla u_e(z) - \nabla_{\mathcal{Q}}^{\mathcal{N}} \mathbb{P}^{\mathcal{T}} u_e|^p \, dz \right)^{\frac{1}{p-1}} \\
&\quad\le C \mathrm{d}_{\mathcal{D}}^{p\alpha_p^2} \sum_{\mathcal{Q}\in\mathfrak{Q}_{\mathcal{D}}} \int_{\mathcal{Q}} \left(1 + |\nabla u_e|^p + |D^2 u_e|^p\right) \, dz,
\end{aligned}
\tag{5.8}
$$

and we conclude by noting that $p\alpha_p^2 = p(p-1)\alpha_p^3$ when $p > 2$. ∎

5.2. Proof of Theorem 5.1. We have

$$
\|\nabla u_e - \nabla^{\mathcal{N}} u^{\mathcal{T}}\|_{L^p} \le \|\nabla u_e - \nabla^{\mathcal{N}} \mathbb{P}^{\mathcal{T}} u_e\|_{L^p} + \|\nabla^{\mathcal{N}} \mathbb{P}^{\mathcal{T}} u_e - \nabla^{\mathcal{N}} u^{\mathcal{T}}\|_{L^p}.
$$

Proposition 5.7 gives a bound for the first term. We come back to the proof of the stability Theorem 4.11 to evaluate the second one. That proof shows that the estimate of $\|\nabla^{\mathcal{N}} \mathbb{P}^{\mathcal{T}} u_e - \nabla^{\mathcal{N}} u^{\mathcal{T}}\|_{L^p}$ requires the control of

$$
I \overset{\mathrm{def}}{=} \left(\mathfrak{a}^{\mathcal{N}}(\mathbb{P}^{\mathcal{T}} u_e) - \mathfrak{a}^{\mathcal{N}}(u^{\mathcal{T}}), \mathbb{P}^{\mathcal{T}} u_e - u^{\mathcal{T}}\right).
$$

By classical manipulations (using the conservativity of numerical fluxes) we express I through the consistency errors thanks to

$$
\begin{aligned}
\mathfrak{a}_{\mathcal{K}}^{\mathcal{N}}(u^{\mathcal{T}}) - \mathfrak{a}_{\mathcal{K}}^{\mathcal{N}}(\mathbb{P}^{\mathcal{T}} u_e) &= \sum_{\mathcal{Q}\subset\mathcal{K}} \sum_{\sigma\in\mathcal{E}_{\mathcal{Q}}\cap\partial\mathcal{K}} |\sigma| R_{\mathcal{Q},\sigma}, \ \forall \mathcal{K} \in \mathfrak{M} \\
\mathfrak{a}_{\mathcal{K}^*}^{\mathcal{N}}(u^{\mathcal{T}}) - \mathfrak{a}_{\mathcal{K}^*}^{\mathcal{N}}(\mathbb{P}^{\mathcal{T}} u_e) &= \sum_{\mathcal{Q}\subset\mathcal{K}^*} \sum_{\sigma\in\mathcal{E}_{\mathcal{Q}}\cap\partial\mathcal{K}^*} |\sigma| R_{\mathcal{Q},\sigma}, \ \forall \mathcal{K}^* \in \mathfrak{M}^*.
\end{aligned}
$$

If we define the error $e^{\mathcal{T}} = u^{\mathcal{T}} - \mathbb{P}^{\mathcal{T}} u_e$, whose components are denoted by $((e_{\mathcal{K}})_{\mathcal{K}}, (e_{\mathcal{K}^*})_{\mathcal{K}^*})$, the formulas above yield

$$
I = \sum_{\mathcal{K}\in\mathfrak{M}} \sum_{\mathcal{Q}\subset\mathcal{K}} \sum_{\sigma\in\mathcal{E}_{\mathcal{Q}}\cap\partial\mathcal{K}} |\sigma| R_{\mathcal{Q},\sigma} e_{\mathcal{K}} + \sum_{\mathcal{K}^*\in\mathfrak{M}^*} \sum_{\mathcal{Q}\subset\mathcal{K}^*} \sum_{\sigma\in\mathcal{E}_{\mathcal{Q}}\cap\partial\mathcal{K}^*} |\sigma| R_{\mathcal{Q},\sigma} e_{\mathcal{K}^*}.
$$

Reordering the sum over the diamond cells, we find that

$$
\begin{aligned}
I = \sum_{\mathcal{D}\in\mathfrak{D}} \Big(&|\sigma_{\mathcal{K}^*}| (R_{\mathcal{Q}_{\mathcal{K},\mathcal{K}^*,\sigma_{\mathcal{K}^*}}} e_{\mathcal{K}} + R_{\mathcal{Q}_{\mathcal{L},\mathcal{K}^*,\sigma_{\mathcal{K}^*}}} e_{\mathcal{L}}) \\
&+ |\sigma_{\mathcal{L}^*}| (R_{\mathcal{Q}_{\mathcal{K},\mathcal{L}^*,\sigma_{\mathcal{L}^*}}} e_{\mathcal{K}} + R_{\mathcal{Q}_{\mathcal{L},\mathcal{L}^*,\sigma_{\mathcal{L}^*}}} e_{\mathcal{L}}) \\
&+ |\sigma_{\mathcal{K}}| (R_{\mathcal{Q}_{\mathcal{K},\mathcal{K}^*,\sigma_{\mathcal{K}}}} e_{\mathcal{K}^*} + R_{\mathcal{Q}_{\mathcal{K},\mathcal{L}^*,\sigma_{\mathcal{K}}}} e_{\mathcal{L}^*}) \\
&+ |\sigma_{\mathcal{L}}| (R_{\mathcal{Q}_{\mathcal{L},\mathcal{K}^*,\sigma_{\mathcal{K}}}} e_{\mathcal{K}^*} + R_{\mathcal{Q}_{\mathcal{L},\mathcal{L}^*,\sigma_{\mathcal{K}}}} e_{\mathcal{L}^*}) \Big).
\end{aligned}
\tag{5.9}
$$

Using the conservativity property (5.2), the first term in the sum above reads

$$
\begin{aligned}
(5.10)\quad & |\sigma_{\mathcal{K}^*}|(R_{\mathcal{Q}_{\mathcal{K},\mathcal{K}^*,\sigma_{\mathcal{K}^*}}} e_{\mathcal{K}} + R_{\mathcal{Q}_{\mathcal{L},\mathcal{K}^*,\sigma_{\mathcal{K}^*}}} e_{\mathcal{L}}) \\
&= -|\mathcal{Q}_{\mathcal{K},\mathcal{K}^*}| R_{\mathcal{Q}_{\mathcal{K},\mathcal{K}^*,\sigma_{\mathcal{K}^*}}} \frac{2}{\sin\alpha_{\mathcal{D}}} \frac{e_{\mathcal{L}} - e_{\mathcal{K}}}{|\sigma_{\mathcal{K}}| + |\sigma_{\mathcal{L}}|} + |\mathcal{Q}_{\mathcal{L},\mathcal{K}^*}| R_{\mathcal{Q}_{\mathcal{L},\mathcal{K}^*,\sigma_{\mathcal{K}^*}}} \frac{2}{\sin\alpha_{\mathcal{D}}} \frac{e_{\mathcal{L}} - e_{\mathcal{K}}}{|\sigma_{\mathcal{K}}| + |\sigma_{\mathcal{L}}|} \\
&= -|\mathcal{Q}_{\mathcal{K},\mathcal{K}^*}| R_{\mathcal{Q}_{\mathcal{K},\mathcal{K}^*,\sigma_{\mathcal{K}^*}}} (\nabla_{\mathcal{D}}^{\mathcal{T}} e^{\mathcal{T}}, \boldsymbol{\tau}^*) + |\mathcal{Q}_{\mathcal{L},\mathcal{K}^*}| R_{\mathcal{Q}_{\mathcal{L},\mathcal{K}^*,\sigma_{\mathcal{K}^*}}} (\nabla_{\mathcal{D}}^{\mathcal{T}} e^{\mathcal{T}}, \boldsymbol{\tau}^*).
\end{aligned}
$$

We remark now, by using (4.3) and (4.6), that for any $\delta \in \mathbb{R}^4$ we have

$$
|\mathcal{Q}_{\mathcal{K},\mathcal{K}^*}| \left(B_{\mathcal{Q}_{\mathcal{K},\mathcal{K}^*}} \delta, \boldsymbol{\tau}^*\right) = |\sigma_{\mathcal{K}^*}| \sin\alpha_{\mathcal{D}} \delta_{\mathcal{K}^*} = -|\mathcal{Q}_{\mathcal{L},\mathcal{K}^*}| \left(B_{\mathcal{Q}_{\mathcal{L},\mathcal{K}^*}} \delta, \boldsymbol{\tau}^*\right).
$$

Hence by using once more the conservativity property and the definition (4.14), we can replace $\nabla_{\mathcal{D}}^{\mathcal{T}} e^{\mathcal{T}}$ by the corresponding $\nabla_{\mathcal{Q}}^{\mathcal{N}} e^{\mathcal{T}}$ in the right-hand side of (5.10). It follows

$$
\begin{aligned}
&|\sigma_{\mathcal{K}^*}|(R_{\mathcal{Q}_{\mathcal{K},\mathcal{K}^*,\sigma_{\mathcal{K}^*}}} e_{\mathcal{K}} + R_{\mathcal{Q}_{\mathcal{L},\mathcal{K}^*,\sigma_{\mathcal{K}^*}}} e_{\mathcal{L}}) \\
&\qquad = -|\mathcal{Q}_{\mathcal{K},\mathcal{K}^*}| R_{\mathcal{Q}_{\mathcal{K},\mathcal{K}^*,\sigma_{\mathcal{K}^*}}} (\nabla_{\mathcal{Q}_{\mathcal{K},\mathcal{K}^*}}^{\mathcal{N}} e^{\mathcal{T}}, \boldsymbol{\tau}^*) + |\mathcal{Q}_{\mathcal{L},\mathcal{K}^*}| R_{\mathcal{Q}_{\mathcal{L},\mathcal{K}^*,\sigma_{\mathcal{K}^*}}} (\nabla_{\mathcal{Q}_{\mathcal{L},\mathcal{K}^*}}^{\mathcal{N}} e^{\mathcal{T}}, \boldsymbol{\tau}^*).
\end{aligned}
$$

The other terms in (5.9) being treated in the same way, it follows that

$$
\begin{aligned}
I &\le C \sum_{\mathcal{Q}\in\mathfrak{Q}} \sum_{\sigma\in\mathcal{E}_{\mathcal{Q}}} |\mathcal{Q}| |R_{\mathcal{Q},\sigma}| |\nabla_{\mathcal{Q}}^{\mathcal{N}} e^{\mathcal{T}}| \\
&\le C \left(\sum_{\mathcal{Q}\in\mathfrak{Q}} \sum_{\sigma\in\mathcal{E}_{\mathcal{Q}}} |\mathcal{Q}| |R_{\mathcal{Q},\sigma}|^{\frac{p}{p-1}} \right)^{\frac{p-1}{p}} \|\nabla^{\mathcal{N}} e^{\mathcal{T}}\|_{L^p}.
\end{aligned}
$$

Using properties $(\mathcal{P}_{1'a}^{\mathcal{T}})$ and $(\mathcal{P}_{1'b}^{\mathcal{T}})$, we derive that

$$
\begin{aligned}
\|\nabla^{\mathcal{N}} e^{\mathcal{T}}\|_{L^p}^2 &\le C(1 + \|\nabla^{\mathcal{N}} u^{\mathcal{T}}\|_{L^p}^{2-p} + \|\nabla^{\mathcal{N}} \mathbb{P}^{\mathcal{T}} u_e\|_{L^p}^{2-p}) \\
&\quad \times \left(\sum_{\mathcal{Q}\in\mathfrak{Q}} \sum_{\sigma\in\mathcal{E}_{\mathcal{Q}}} |\mathcal{Q}| |R_{\mathcal{Q},\sigma}|^{\frac{p}{p-1}} \right)^{\frac{p-1}{p}} \|\nabla^{\mathcal{N}} e^{\mathcal{T}}\|_{L^p}, \quad \text{if } 1 < p \le 2,
\end{aligned}
$$

and

$$
(5.11)\qquad \|\nabla^{\mathcal{N}} e^{\mathcal{T}}\|_{L^p}^p \le C \left(\sum_{\mathcal{Q}\in\mathfrak{Q}} \sum_{\sigma\in\mathcal{E}_{\mathcal{Q}}} |\mathcal{Q}| |R_{\mathcal{Q},\sigma}|^{\frac{p}{p-1}} \right)^{\frac{p-1}{p}} \|\nabla^{\mathcal{N}} e^{\mathcal{T}}\|_{L^p}, \quad \text{if } p > 2.
$$

The claim follows by using the estimate (4.19) and Propositions 5.6, 5.7, and 5.8.

5.3. Proof of Theorem 5.3. We give only the proof in the case $p > 2$ since the other case can be treated in the same way. We come back to (5.11) which is still valid for the h-DDFV scheme. It follows

$$
\|\nabla^{\mathcal{N}} e^{\mathcal{T}}\|_{L^p} \le C \left(\sum_{\mathcal{Q}\in\mathfrak{Q}} \sum_{\sigma\in\mathcal{E}_{\mathcal{Q}}} |\mathcal{Q}| |R_{\mathcal{Q},\sigma}|^{\frac{p}{p-1}} \right)^{\frac{1}{p}}.
$$

The terms $R_{\mathcal{Q},\sigma}$ contain the respective contributions of $R^{\varphi}_{\mathcal{Q},\sigma}$ and $R^{\mathrm{grad}}_{\mathcal{Q}}$. As far as $R^{\varphi}_{\mathcal{Q},\sigma}$ is concerned, the estimate of Proposition 5.6 is still valid for the hybrid scheme so that

$$\left(\sum_{\mathcal{Q}\in\mathfrak{Q}}\sum_{\sigma\in\mathcal{E}_{\mathcal{Q}}}|\mathcal{Q}||R^{\varphi}_{\mathcal{Q},\sigma}|^{\frac{p}{p-1}}\right)^{\frac{1}{p}}\leq C\mathrm{size}(\mathcal{T})^{\frac{1}{p-1}}\|u_e\|_{W^{2,p}(\mathfrak{Q})}.$$

We split now the contribution of $R^{\mathrm{grad}}_{\mathcal{Q}}$ into two parts: the one coming from diamond cells in $\mathfrak{D}_{\mathrm{cont}}$ where the usual DDFV approximate flux is used and the one coming from the diamond cells in $\mathfrak{D}_{\mathrm{disc}}$ where we used our new discrete gradient and flux. It follows

$$\left(\sum_{\mathcal{Q}\in\mathfrak{Q}}|\mathcal{Q}||R^{\mathrm{grad}}_{\mathcal{Q}}|^{\frac{p}{p-1}}\right)^{\frac{1}{p}}\leq C\left(\sum_{\mathcal{D}\in\mathfrak{D}_{\mathrm{cont}}}\sum_{\mathcal{Q}\in\mathfrak{Q}_{\mathcal{D}}}|\mathcal{Q}||R^{\mathrm{grad}}_{\mathcal{Q}}|^{\frac{p}{p-1}}\right)^{\frac{1}{p}}+C\left(\sum_{\mathcal{D}\in\mathfrak{D}_{\mathrm{disc}}}\sum_{\mathcal{Q}\in\mathfrak{Q}_{\mathcal{D}}}|\mathcal{Q}||R^{\mathrm{grad}}_{\mathcal{Q}}|^{\frac{p}{p-1}}\right)^{\frac{1}{p}}. \tag{5.12}$$

Near the discontinuities of the flux, that is for each diamond cell $\mathcal{D}\in\mathfrak{D}_{\mathrm{disc}}$, we use the estimate (5.8). Away from the discontinuities, i.e., for $\mathcal{D}\in\mathfrak{D}_{\mathrm{cont}}$ we used the usual DDFV scheme (that is $\nabla^{\mathcal{N}}=\nabla^{\mathcal{T}}$), so that the gradient consistency estimate given by (5.7) reads, since $u_e\in W^{2,p}(\mathcal{D})$:

$$\int_{\mathcal{D}}|\nabla u_e(z)-\nabla^{\mathcal{T}}\mathbb{P}^{\mathcal{T}}u_e(z)|^p\,dz\leq C\mathrm{d}_{\mathcal{D}}^p\int_{\mathcal{D}}\left(1+|\nabla u_e|^p+|D^2u_e|^p\right)\,dz.$$

This estimate is proved, for instance, in [3, Lemma 7.5]. Hence, (5.12) now gives

$$\left(\sum_{\mathcal{Q}\in\mathfrak{Q}}|\mathcal{Q}||R^{\mathrm{grad}}_{\mathcal{Q}}|^{\frac{p}{p-1}}\right)^{\frac{1}{p}}\leq C\mathrm{size}(\mathcal{T})^{\frac{1}{p-1}}\|u_e\|_{W^{2,p}(\mathfrak{Q})}+C\mathrm{size}(\mathcal{T})^{\frac{1}{(p-1)^2}}\left(\int_{\Omega_{\mathrm{disc}}}(1+|\nabla u_e|+|D^2u_e|)^p\,dz\right)^{\frac{1}{p}},$$

where we introduced $\Omega_{\mathrm{disc}}=\bigcup_{\mathcal{D}\in\mathfrak{D}_{\mathrm{disc}}}\mathcal{D}$. Since we assumed that φ is smooth on each subdomain Ω_i, we see that the set Ω_{disc} is a size$(\mathcal{T})$-neighborhood of the union of the boundaries of the Ω_i's. Hence, there exists $C>0$ such that $|\Omega_{\mathrm{disc}}|\leq C\mathrm{size}(\mathcal{T})$. It follows by the Hölder inequality and using the assumption $u_e\in W^{2,q}(\mathfrak{Q})$ that

$$\left(\sum_{\mathcal{Q}\in\mathfrak{Q}}|\mathcal{Q}||R^{\mathrm{grad}}_{\mathcal{Q}}|^{\frac{p}{p-1}}\right)^{\frac{1}{p}}\leq C\mathrm{size}(\mathcal{T})^{\frac{1}{p-1}}\|u_e\|_{W^{2,p}(\mathfrak{Q})}+C\mathrm{size}(\mathcal{T})^{\left(\frac{1}{(p-1)^2}+\frac{q-p}{pq}\right)}\|u_e\|_{W^{2,q}(\mathfrak{Q})},$$

and the claim is proved since $\frac{1}{(p-1)^2}+\frac{q-p}{pq}\geq\frac{1}{p-1}$ as soon as $q\geq p(p-1)^2$.

6. Examples. In the case of a linear problem where $\varphi(z,\xi) = A(z)\xi$, it is easily seen that for any $\mathcal{D} \in \mathfrak{D}$ the numerical flux $\varphi^{\mathcal{N}}_{\mathcal{D}}$ is a linear map of the DDFV gradient $\nabla^{\mathcal{T}}_{\mathcal{D}} u^{\mathcal{T}}$. More precisely, there exists a unique definite positive matrix $\overline{A}_{\mathcal{D}}$ such that $\varphi^{\mathcal{N}}_{\mathcal{D}}(\nabla^{\mathcal{T}}_{\mathcal{D}} u^{\mathcal{T}}) = \overline{A}_{\mathcal{D}} \nabla^{\mathcal{T}}_{\mathcal{D}} u^{\mathcal{T}}$.

In general, it is difficult to give an explicit formula for the matrix $\overline{A}_{\mathcal{D}}$, but it can be evaluated by computing the map $\delta^{\mathcal{D}}$, that is, following Proposition 4.3 and its proof, by computing the inverse of the $n_{\mathcal{D}} \times n_{\mathcal{D}}$ matrix $\sum_{\mathcal{D} \in \mathfrak{Q}_{\mathcal{D}}} |\mathcal{Q}|^t B_{\mathcal{Q}} A_{\mathcal{Q}} B_{\mathcal{Q}}$. This operation has a very low computational cost and has to be made only once.

In some particular cases, it is possible to find an explicit form for $\overline{A}_{\mathcal{D}}$ which is interesting in order to illustrate our approach and to compare the results with the 1D case. Let us consider a given diamond cell $\mathcal{D} \in \mathfrak{D}_{\text{int}}$ whose diagonals are $\sigma = \kappa|\mathcal{L}$ and $\sigma^* = \kappa^*|\mathcal{L}^*$.

- *First example:* We assume that $A(z)$ is constant on each control volume of the primal mesh. We denote by A_κ the value of $A(z)$ on the control volume κ. The matrix $\overline{A}_{\mathcal{D}}$ is then defined by

$$(\overline{A}_{\mathcal{D}}\boldsymbol{\nu}, \boldsymbol{\nu}) = \frac{(|\sigma_\kappa| + |\sigma_\mathcal{L}|)(A_\kappa \boldsymbol{\nu}, \boldsymbol{\nu})(A_\mathcal{L}\boldsymbol{\nu}, \boldsymbol{\nu})}{|\sigma_\mathcal{L}|(A_\kappa \boldsymbol{\nu}, \boldsymbol{\nu}) + |\sigma_\kappa|(A_\mathcal{L}\boldsymbol{\nu}, \boldsymbol{\nu})}, \tag{6.1}$$

$$(\overline{A}_{\mathcal{D}}\boldsymbol{\nu}^*, \boldsymbol{\nu}^*) = \frac{|\sigma_\mathcal{L}|(A_\mathcal{L}\boldsymbol{\nu}^*, \boldsymbol{\nu}^*) + |\sigma_\kappa|(A_\kappa \boldsymbol{\nu}^*, \boldsymbol{\nu}^*)}{|\sigma_\kappa| + |\sigma_\mathcal{L}|} - \frac{|\sigma_\kappa||\sigma_\mathcal{L}|}{|\sigma_\kappa| + |\sigma_\mathcal{L}|} \frac{((A_\kappa \boldsymbol{\nu}, \boldsymbol{\nu}^*) - (A_\mathcal{L}\boldsymbol{\nu}, \boldsymbol{\nu}^*))^2}{|\sigma_\mathcal{L}|(A_\kappa \boldsymbol{\nu}, \boldsymbol{\nu}) + |\sigma_\kappa|(A_\mathcal{L}\boldsymbol{\nu}, \boldsymbol{\nu})}, \tag{6.2}$$

$$(\overline{A}_{\mathcal{D}}\boldsymbol{\nu}, \boldsymbol{\nu}^*) = \frac{|\sigma_\mathcal{L}|(A_\mathcal{L}\boldsymbol{\nu}, \boldsymbol{\nu}^*)(A_\kappa \boldsymbol{\nu}, \boldsymbol{\nu}) + |\sigma_\kappa|(A_\kappa \boldsymbol{\nu}, \boldsymbol{\nu}^*)(A_\mathcal{L}\boldsymbol{\nu}, \boldsymbol{\nu})}{|\sigma_\mathcal{L}|(A_\kappa \boldsymbol{\nu}, \boldsymbol{\nu}) + |\sigma_\kappa|(A_\mathcal{L}\boldsymbol{\nu}, \boldsymbol{\nu})}. \tag{6.3}$$

  We recognize in (6.1) the weighted harmonic mean value of $(A_\kappa \boldsymbol{\nu}, \boldsymbol{\nu})$ and $(A_\mathcal{L}\boldsymbol{\nu}, \boldsymbol{\nu})$ and in the first term of (6.2) the weighted arithmetic mean value of $(A_\kappa \boldsymbol{\nu}^*, \boldsymbol{\nu}^*)$ and $(A_\mathcal{L}\boldsymbol{\nu}^*, \boldsymbol{\nu}^*)$.
- *Second example:* We assume that $A(z) = \lambda(z)\mathrm{Id}$ is isotropic, continuous on each quarter diamond, and we assume that the mesh is orthogonal, that is, $\sigma \perp \sigma^*$ or equivalently $\sin \alpha_{\mathcal{D}} = 1$. Introducing $\lambda_{\mathcal{Q}} = \frac{1}{|\mathcal{Q}|} \int_{\mathcal{Q}} \lambda(z)\, dz$, the mean value of λ over $\mathcal{Q}$, the equivalent matrix $\overline{A}_{\mathcal{D}}$ satisfies in that case:

$$(\overline{A}_{\mathcal{D}}\boldsymbol{\nu}, \boldsymbol{\nu}) = \frac{|\sigma_\kappa| + |\sigma_\mathcal{L}|}{|\sigma_{\kappa^*}| + |\sigma_{\mathcal{L}^*}|} \left(\frac{|\sigma_{\kappa^*}| \lambda_{\mathcal{Q}_{\mathcal{L},\kappa^*}} \lambda_{\mathcal{Q}_{\kappa,\kappa^*}}}{|\sigma_\kappa| \lambda_{\mathcal{Q}_{\mathcal{L},\kappa^*}} + |\sigma_\mathcal{L}| \lambda_{\mathcal{Q}_{\kappa,\kappa^*}}} + \frac{|\sigma_{\mathcal{L}^*}| \lambda_{\mathcal{Q}_{\mathcal{L},\mathcal{L}^*}} \lambda_{\mathcal{Q}_{\kappa,\mathcal{L}^*}}}{|\sigma_\kappa| \lambda_{\mathcal{Q}_{\mathcal{L},\mathcal{L}^*}} + |\sigma_\mathcal{L}| \lambda_{\mathcal{Q}_{\kappa,\mathcal{L}^*}}} \right), \tag{6.4}$$

$$(\overline{A}_{\mathcal{D}}\boldsymbol{\nu}^*, \boldsymbol{\nu}^*) = \frac{|\sigma_{\kappa^*}| + |\sigma_{\mathcal{L}^*}|}{|\sigma_\kappa| + |\sigma_\mathcal{L}|} \left(\frac{|\sigma_\kappa| \lambda_{\mathcal{Q}_{\kappa,\mathcal{L}^*}} \lambda_{\mathcal{Q}_{\kappa,\kappa^*}}}{|\sigma_{\kappa^*}| \lambda_{\mathcal{Q}_{\kappa,\mathcal{L}^*}} + |\sigma_{\mathcal{L}^*}| \lambda_{\mathcal{Q}_{\kappa,\kappa^*}}} + \frac{|\sigma_\mathcal{L}| \lambda_{\mathcal{Q}_{\mathcal{L},\mathcal{L}^*}} \lambda_{\mathcal{Q}_{\mathcal{L},\kappa^*}}}{|\sigma_{\kappa^*}| \lambda_{\mathcal{Q}_{\mathcal{L},\mathcal{L}^*}} + |\sigma_{\mathcal{L}^*}| \lambda_{\mathcal{Q}_{\mathcal{L},\kappa^*}}} \right), \tag{6.5}$$

$$(\overline{A}_{\mathcal{D}}\boldsymbol{\nu}, \boldsymbol{\nu}^*) = 0. \tag{6.6}$$

  Notice that even though $A(z)$ is isotropic, the matrix $\overline{A}_{\mathcal{D}}$ is only diagonal (in the orthogonal frame $(\boldsymbol{\nu}, \boldsymbol{\nu}^*)$) and not isotropic in general. Furthermore, we

see that (6.4) and (6.5) combine the arithmetic mean value of the coefficients in the transverse direction and harmonic mean value of the coefficients along the direction in which we are looking.

Unfortunately, in the nonlinear case there are very few cases where all the computations can be performed explicitly (see, for instance, the 1D Example 2.1). That is the reason why we propose in the following section a fully practical method to solve the m-DDFV and h-DDFV schemes in any situation.

7. Numerical implementation of the scheme. In this section we present a fully explicit algorithm to solve the finite volume scheme under study and we prove its convergence. From now on, we suppose given a DDFV mesh $\mathcal{T}$ on Ω and a source term f.

7.1. Some remarks on the potential case. We assume, only in this paragraph, that φ derives from a potential Φ, that is

$$\left\{ \begin{array}{rcl} \varphi(z,\xi) & = & \nabla_\xi \Phi(z,\xi), \quad \text{for all } \xi \in \mathbb{R}^2 \ \text{ and a.e. } z \in \Omega, \\ \Phi(z,0) & = & 0, \quad \text{for a.e. } z \in \Omega. \end{array} \right. \tag{7.1}$$

We can now define an approximation of Φ on each quarter diamond by $\Phi_{\mathcal{Q}}(\cdot) = \frac{1}{|\mathcal{Q}|}\int_{\mathcal{Q}} \Phi(z,\cdot)\,dz$ that satisfies $\nabla\Phi_{\mathcal{Q}} = \varphi_{\mathcal{Q}}$. Since φ is strictly monotonic, the function Φ is strictly convex.

PROPOSITION 7.1. *The solution $u^{\mathcal{T}}$ of the scheme* (4.17) *is the unique minimizer of the functional defined by*

$$J^{\mathcal{T}}(v^{\mathcal{T}}) = 2\sum_{\mathcal{D}\in\mathfrak{D}} \sum_{\mathcal{Q}\in\mathfrak{Q}_{\mathcal{D}}} |\mathcal{Q}|\Phi_{\mathcal{Q}}(\nabla^{\mathcal{N}}_{\mathcal{Q}} v^{\mathcal{T}}) - \sum_{\mathcal{K}} |\mathcal{K}| f_{\mathcal{K}} v_{\mathcal{K}} - \sum_{\mathcal{K}^*} |\mathcal{K}^*| f_{\mathcal{K}^*} v_{\mathcal{K}^*}, \quad \forall v^{\mathcal{T}} \in \mathbb{R}^{\mathcal{T}}.$$

Proof. By using assumptions $(\mathcal{H}_1)$, $(\mathcal{H}_2)$, and $(\mathcal{H}_3)$, the definition (7.1) and the Poincaré inequality, it is easily seen that $J^{\mathcal{T}}$ is strictly convex and coercive on $\mathbb{R}^{\mathcal{T}}$ and thus has a unique minimizer that we call $u^{\mathcal{T}}$.

Let us now write the Euler–Lagrange equation for this minimization problem. The equation corresponding to the unknown $u_{\mathcal{K}}$ reads

$$2\sum_{\mathcal{D}\in\mathfrak{D}_{\mathcal{K}}} \sum_{\mathcal{Q}\in\mathfrak{Q}_{\mathcal{D}}} |\mathcal{Q}| \left(\varphi_{\mathcal{Q}}(\nabla^{\mathcal{N}}_{\mathcal{Q}} u^{\mathcal{T}}), (\mathrm{Id} + \mathrm{B}_{\mathcal{Q}}.\mathrm{D}\delta^{\mathcal{D}}) \frac{\partial \nabla^{\mathcal{T}}_{\mathcal{D}} \mathrm{u}^{\mathcal{T}}}{\partial \mathrm{u}_{\mathcal{K}}} \right) = |\mathcal{K}| f_{\mathcal{K}}.$$

By definition of $\delta^{\mathcal{D}}$, for any $\mathcal{D}$ we have $\sum_{\mathcal{Q}\in\mathfrak{Q}_{\mathcal{D}}} |\mathcal{Q}|^t B_{\mathcal{Q}} \varphi_{\mathcal{Q}}(\nabla^{\mathcal{N}}_{\mathcal{Q}} u^{\mathcal{T}}) = 0$ so that the term containing the derivative $D\delta^{\mathcal{D}}$ of $\delta^{\mathcal{D}}$ vanishes. Furthermore, by definition of $\nabla^{\mathcal{T}}_{\mathcal{D}} u^{\mathcal{T}}$ (see (3.2)) we have

$$\frac{\partial \nabla^{\mathcal{T}}_{\mathcal{D}} u^{\mathcal{T}}}{\partial u_{\mathcal{K}}} = -\frac{|\sigma|}{2|\mathcal{D}|} \boldsymbol{\nu}_{\mathcal{K}}.$$

Hence it follows, using (4.16),

$$\begin{aligned} |\mathcal{K}| f_{\mathcal{K}} &= -2 \sum_{\mathcal{D}\in\mathfrak{D}_{\mathcal{K}}} \left(\sum_{\mathcal{Q}\in\mathfrak{Q}_{\mathcal{D}}} |\mathcal{Q}| \varphi_{\mathcal{Q}}(\nabla^{\mathcal{N}}_{\mathcal{Q}} u^{\mathcal{T}}), \frac{|\sigma|}{2|\mathcal{D}|} \boldsymbol{\nu}_{\mathcal{K}} \right) \\ &= -2 \sum_{\mathcal{D}\in\mathfrak{D}_{\mathcal{K}}} |\mathcal{D}| \left(\varphi^{\mathcal{N}}_{\mathcal{D}}(\nabla^{\mathcal{T}}_{\mathcal{D}} u^{\mathcal{T}}), \frac{|\sigma|}{2|\mathcal{D}|} \boldsymbol{\nu}_{\mathcal{K}} \right) = - \sum_{\mathcal{D}\in\mathfrak{D}_{\mathcal{K}}} |\sigma| \left(\varphi^{\mathcal{N}}_{\mathcal{D}}(\nabla^{\mathcal{T}}_{\mathcal{D}} u^{\mathcal{T}}), \boldsymbol{\nu}_{\mathcal{K}} \right), \end{aligned}$$

and the claim is proved. ∎

From now on, we denote by $\Delta = \bigoplus_{\mathcal{D}\in\mathfrak{D}} \mathbb{R}^{n_\mathcal{D}}$ the space in which the artificial unknowns $(\delta^\mathcal{D})_\mathcal{D}$ are lying. We introduce the following new functional defined on $\mathbb{R}^\mathcal{T} \times \Delta$

$$J^{\mathcal{T},\Delta}(v^\mathcal{T},\tilde{\delta}) = 2\sum_{\mathcal{D}\in\mathfrak{D}}\sum_{\mathcal{Q}\in\mathfrak{Q}_\mathcal{D}} |\mathcal{Q}|\Phi_\mathcal{Q}\left(\nabla^\mathcal{T}_\mathcal{D} v^\mathcal{T} + B_\mathcal{Q}\tilde{\delta}^\mathcal{D}\right) - \sum_{\mathcal{K}} |\mathcal{K}| f_\mathcal{K} v_\mathcal{K} - \sum_{\mathcal{K}^*} |\mathcal{K}^*| f_{\mathcal{K}^*} v_{\mathcal{K}^*}, \quad \forall v^\mathcal{T}\in\mathbb{R}^\mathcal{T},\ \forall\tilde{\delta}\in\Delta.$$

PROPOSITION 7.2. *The functional $J^{\mathcal{T},\Delta}$ has a unique minimizer which is given by $(u^\mathcal{T}, (\delta^\mathcal{D}(\nabla^\mathcal{T}_\mathcal{D} u^\mathcal{T}))_\mathcal{D})$.*

Proof. It is easily seen that, for any $v^\mathcal{T}\in\mathbb{R}^\mathcal{T}$ fixed, the functional $\tilde{\delta}\in\Delta \mapsto J^{\mathcal{T},\Delta}(v^\mathcal{T},\tilde{\delta})$ decouples into a sum over $\mathfrak{D}$ of independant maps depending only on $\tilde{\delta}^\mathcal{D}$ for a given $\mathcal{D}\in\mathfrak{D}$. Following the proof of Proposition 4.3, each of these maps has a unique minimum exactly given by $\delta^\mathcal{D}(\nabla^\mathcal{T}_\mathcal{D} v^\mathcal{T})$. Hence we proved

$$J^\mathcal{T}(v^\mathcal{T}) = J^{\mathcal{T},\Delta}\left(v^\mathcal{T}, (\delta^\mathcal{D}(\nabla^\mathcal{T}_\mathcal{D} v^\mathcal{T}))_\mathcal{D}\right) \le J^{\mathcal{T},\Delta}(v^\mathcal{T},\tilde{\delta}), \quad \forall\tilde{\delta}\in\Delta,$$

with equality if and only if $\tilde{\delta} = (\delta^\mathcal{D}(\nabla^\mathcal{T}_\mathcal{D} v^\mathcal{T}))_\mathcal{D}$, which gives the claim. ∎

7.2. Derivation of the decomposition-coordination method. In the case of a potential flux φ, we proved in Proposition 7.2 that the solution of the scheme can be obtained by minimizing a functional which can be computed explicitly but depending on much more unknowns than the cardinality of $\mathbb{R}^\mathcal{T}$ in which we look for the approximate solution.

We propose, for this nonquadratic minimization problem, a saddle-point formulation (in the very spirit of [12, 13]). Let us define the set $(\mathbb{R}^2)^\mathfrak{Q}$ of families of vectors of $\mathbb{R}^2$ indexed by the set of quarter diamonds. We suppose given a family $\mathcal{A} = (A_\mathcal{Q})_{\mathcal{Q}\in\mathfrak{Q}}$ of definite positive 2×2 matrices, which is aimed to play the role of heterogeneous and isotropic augmentation parameters. More precisely, we introduce now the augmented lagrangian

$$\begin{aligned} L^{\mathcal{T},\Delta}_\mathcal{A}(v^\mathcal{T},\tilde{\delta},g,\lambda) &= 2\sum_{\mathcal{Q}\in\mathfrak{Q}} |\mathcal{Q}|\Phi_\mathcal{Q}(g_\mathcal{Q}) + 2\sum_{\mathcal{Q}\in\mathfrak{Q}} |\mathcal{Q}|(\lambda_\mathcal{Q}, g_\mathcal{Q} - \nabla^\mathcal{T}_\mathcal{D} v^\mathcal{T} - B_\mathcal{Q}\tilde{\delta}^\mathcal{D}) \\ &\quad + \sum_{\mathcal{Q}\in\mathfrak{Q}} |\mathcal{Q}|\left(A_\mathcal{Q}(g_\mathcal{Q} - \nabla^\mathcal{T}_\mathcal{D} v^\mathcal{T} - B_\mathcal{Q}\tilde{\delta}^\mathcal{D}), (g_\mathcal{Q} - \nabla^\mathcal{T}_\mathcal{D} v^\mathcal{T} - B_\mathcal{Q}\tilde{\delta}^\mathcal{D})\right) \\ &\quad - \sum_{\mathcal{K}} |\mathcal{K}| f_\mathcal{K} v_\mathcal{K} - \sum_{\mathcal{K}^*} |\mathcal{K}^*| f_{\mathcal{K}^*} v_{\mathcal{K}^*}, \quad \forall v^\mathcal{T}\in\mathbb{R}^\mathcal{T}, \forall\tilde{\delta}\in\Delta, \forall g,\lambda\in(\mathbb{R}^2)^\mathfrak{Q}. \end{aligned}$$

If, for any $\mathcal{Q}\in\mathfrak{Q}$, we take $A_\mathcal{Q} = r\mathrm{Id}$ for a given parameter $r>0$ we recover the augmented lagrangian algorithm proposed in [12, 13]. It is easily seen that this lagrangian has a unique saddle-point $(u^\mathcal{T}, \delta^\mathcal{D}, p, \lambda)$ satisfying the equilibrium equations

$$\left\{\begin{array}{l} \varphi_\mathcal{Q}(g_\mathcal{Q}) + \lambda_\mathcal{Q} + A_\mathcal{Q}(g_\mathcal{Q} - \nabla^\mathcal{T}_\mathcal{D} u^\mathcal{T} - B_\mathcal{Q}\delta^\mathcal{D}) = 0, \quad \forall\mathcal{Q}\in\mathfrak{Q}, \\ \displaystyle\sum_{\mathcal{Q}\in\mathfrak{Q}_\mathcal{D}} |\mathcal{Q}|{}^t B_\mathcal{Q} A_\mathcal{Q}(B_\mathcal{Q}\delta^\mathcal{D} + \nabla^\mathcal{T}_\mathcal{D} u^\mathcal{T} - g_\mathcal{Q}) - \sum_{\mathcal{Q}\in\mathfrak{Q}_\mathcal{D}} |\mathcal{Q}|{}^t B_\mathcal{Q}\lambda_\mathcal{Q} = 0, \quad \forall\mathcal{D}\in\mathfrak{D}, \\ g_\mathcal{Q} - \nabla^\mathcal{T}_\mathcal{D} u^\mathcal{T} - B_\mathcal{Q}\delta^\mathcal{D} = 0, \quad \forall\mathcal{Q}\in\mathfrak{Q}, \\ \displaystyle 2\sum_{\mathcal{Q}\in\mathfrak{Q}} |\mathcal{Q}|\left(A_\mathcal{Q}(\nabla^\mathcal{T}_\mathcal{D} u^\mathcal{T} + B_\mathcal{Q}\delta^\mathcal{D} - g_\mathcal{Q}), \nabla^\mathcal{T}_\mathcal{D} v^\mathcal{T}\right) = \sum_{\mathcal{K}} |\mathcal{K}| f_\mathcal{K} v_\mathcal{K} + \sum_{\mathcal{K}^*} |\mathcal{K}^*| f_{\mathcal{K}^*} v_{\mathcal{K}^*} \\ \qquad \displaystyle + 2\sum_{\mathcal{Q}\in\mathfrak{Q}} |\mathcal{Q}|(\lambda_\mathcal{Q}, \nabla^\mathcal{T}_\mathcal{D} v^\mathcal{T}), \quad \forall v^\mathcal{T}\in\mathbb{R}^\mathcal{T}. \end{array}\right. \tag{7.2}$$

These equations are clearly equivalent to

$$
\text{(7.3)}\qquad \begin{cases} \lambda_{\mathcal{Q}} = -\varphi_{\mathcal{Q}}(g_{\mathcal{Q}}), \quad \forall \mathcal{Q} \in \mathfrak{\mathbf{Q}}, \\ \displaystyle\sum_{\mathcal{Q}\in\mathfrak{\mathbf{Q}}_{\mathcal{D}}} |\mathcal{Q}|{}^t B_{\mathcal{Q}} \lambda_{\mathcal{Q}} = 0, \quad \forall \mathcal{D} \in \mathfrak{\mathbf{D}}, \\ g_{\mathcal{Q}} = \nabla_{\mathcal{D}}^{\mathcal{T}} u^{\mathcal{T}} + B_{\mathcal{Q}} \delta^{\mathcal{D}}, \quad \forall \mathcal{Q} \in \mathfrak{\mathbf{Q}}, \\ \displaystyle -2 \sum_{\mathcal{Q}\in\mathfrak{\mathbf{Q}}} |\mathcal{Q}|(\lambda_{\mathcal{Q}}, \nabla_{\mathcal{D}}^{\mathcal{T}} v^{\mathcal{T}}) = \sum_{\mathcal{K}} |\mathcal{K}| f_{\mathcal{K}} v_{\mathcal{K}} + \sum_{\mathcal{K}^*} |\mathcal{K}^*| f_{\mathcal{K}^*} v_{\mathcal{K}^*}, \quad \forall v^{\mathcal{T}} \in \mathbb{R}^{\mathcal{T}}. \end{cases}
$$

The first three equations imply that $\delta^{\mathcal{D}} = \delta^{\mathcal{D}}(\nabla_{\mathcal{D}}^{\mathcal{T}} u^{\mathcal{T}})$, and then the fourth equation is nothing but a different way to write (4.17). As a consequence, the saddle point of $L_{\mathcal{A}}^{\mathcal{T},\Delta}$ gives the unique solution to the finite volume scheme.

From (7.2), we deduce an iterative method to solve our problem following the same idea as [13, ALG 2, p. 170]. In our setting, the algorithm reads as follows: we suppose given $\lambda^0 \in (\mathbb{R}^2)^{\mathfrak{Q}}$, $g^0 \in (\mathbb{R}^2)^{\mathfrak{Q}}$, then for any $n \geq 1$:

1. Find $(u^{\mathcal{T},n}, \delta_{\mathcal{D}}^n) \in \mathbb{R}^{\mathcal{T}} \times \Delta$ solution to the linear problem

$$
\text{(7.4)}\qquad \begin{aligned} &2 \sum_{\mathcal{Q}\in\mathfrak{\mathbf{Q}}} |\mathcal{Q}| \Big(A_{\mathcal{Q}}(\nabla_{\mathcal{D}}^{\mathcal{T}} u^{\mathcal{T},n} + B_{\mathcal{Q}} \delta_{\mathcal{D}}^n - g_{\mathcal{Q}}^{n-1}), \nabla_{\mathcal{D}}^{\mathcal{T}} v^{\mathcal{T}} \Big) \\ &\qquad = \sum_{\mathcal{K}} |\mathcal{K}| f_{\mathcal{K}} v_{\mathcal{K}} + \sum_{\mathcal{K}^*} |\mathcal{K}^*| f_{\mathcal{K}^*} v_{\mathcal{K}^*} + 2 \sum_{\mathcal{Q}\in\mathfrak{\mathbf{Q}}} |\mathcal{Q}| (\lambda_{\mathcal{Q}}^{n-1}, \nabla_{\mathcal{D}}^{\mathcal{T}} v), \quad \forall v^{\mathcal{T}} \in \mathbb{R}^{\mathcal{T}}. \\ &\sum_{\mathcal{Q}\in\mathfrak{\mathbf{Q}}_{\mathcal{D}}} |\mathcal{Q}|{}^t B_{\mathcal{Q}} A_{\mathcal{Q}} (B_{\mathcal{Q}} \delta_{\mathcal{D}}^n + \nabla_{\mathcal{D}}^{\mathcal{T}} u^{\mathcal{T},n} - g_{\mathcal{Q}}^{n-1}) - \sum_{\mathcal{Q}\in\mathfrak{\mathbf{Q}}_{\mathcal{D}}} |\mathcal{Q}|{}^t B_{\mathcal{Q}} \lambda_{\mathcal{Q}}^{n-1} = 0, \, \forall \mathcal{D} \in \mathfrak{\mathbf{D}}. \end{aligned}
$$

   Notice that the second equation explicitly gives, locally on each diamond cell $\mathcal{D}$, the expression of $\delta_{\mathcal{D}}^n$ as an affine function of $\nabla_{\mathcal{D}}^{\mathcal{T}} u^{\mathcal{T},n}$. It is only needed to compute, one time at the beginning of the algorithm, the inverse of all the definite positive symmetric matrices $\sum_{\mathcal{Q}\in\mathfrak{\mathbf{Q}}_{\mathcal{D}}} |\mathcal{Q}|{}^t B_{\mathcal{Q}} \, A_{\mathcal{Q}} \, B_{\mathcal{Q}}$ whose size is $n_{\mathcal{D}} \times n_{\mathcal{D}}$ (which is low since $n_{\mathcal{D}} = 1$ for boundary diamond cells and $n_{\mathcal{D}} = 4$ for interior diamond cells).
   Finally, once the second equation in (7.4) is solved, we can introduce the expression of $\delta_{\mathcal{D}}^n$ as a function of $\nabla_{\mathcal{D}}^{\mathcal{T}} u^{\mathcal{T},n}$ in the first equation of (7.4). This first equation is now an explicit large linear system in the variables $u^{\mathcal{T},n}$. Notice that the matrix of this large sparse linear system is the same at each iteration, which is very important if one wants to use direct linear solvers, for instance. Finally, notice that the size and the stencil of this system is exactly the same as the one of the DDFV matrix for the Laplace equation, for instance.
2. For any $\mathcal{Q} \in \mathfrak{\mathbf{Q}}$, find $g_{\mathcal{Q}}^n$ satisfying

$$
\text{(7.5)}\qquad \varphi_{\mathcal{Q}}(g_{\mathcal{Q}}^n) + \lambda_{\mathcal{Q}}^{n-1} + A_{\mathcal{Q}}(g_{\mathcal{Q}}^n - \nabla_{\mathcal{D}}^{\mathcal{T}} u^{\mathcal{T},n} - B_{\mathcal{Q}} \delta_{\mathcal{D}}^n) = 0.
$$

   This is the unique nonlinear part of the algorithm. The equation is localized on each quarter diamond and consists in solving a nonlinear equation in $\mathbb{R}^2$ defined by the explicit map $\varphi_{\mathcal{Q}} + A_{\mathcal{Q}}$. Notice that $\varphi_{\mathcal{Q}} + A_{\mathcal{Q}}$ is strictly monotonic and coercive on $\mathbb{R}^2$ so that the solution $g_{\mathcal{Q}}^n$ to (7.5) exists and is unique.
   From a practical point of view, one can use here a Newton method to solve all these equations simultaneously (this step can be massively parallelized).

3. Finally compute $\lambda_{\mathcal{Q}}^n$ through

$$\lambda_{\mathcal{Q}}^n = \lambda_{\mathcal{Q}}^{n-1} + A_{\mathcal{Q}}(g_{\mathcal{Q}}^n - \nabla_{\mathcal{D}}^{\mathcal{T}} u^{\mathcal{T},n} - B_{\mathcal{Q}}\delta_{\mathcal{D}}^n), \quad \forall \mathcal{Q} \in \mathfrak{\mathbf{Q}}. \tag{7.6}$$

The choice of the *best* augmentation matrices $\mathcal{A}$ is a complex problem (see the discussion in [13], for instance). We will give some examples of such choices in section 8.

7.3. General fluxes. Convergence of the iterative solver. The above algorithm is deduced from the lagrangian formulation of the scheme which is available only in the variational case (7.1). Nevertheless, the iterative algorithm (7.4)–(7.6) can be used in the general case of any monotonic flux φ. We can now prove the convergence of this algorithm in the non-variational setting.

THEOREM 7.3. *Let $\mathcal{T}$ be a DDFV mesh on Ω and $(\varphi_{\mathcal{Q}})_{\mathcal{Q}}$ a family of strictly monotonic continuous maps from $\mathbb{R}^2$ onto itself. Then for any augmentation matrices family $\mathcal{A}$, the algorithm given by* (7.4)–(7.6) *converges, when n goes to infinity, towards the unique solution to* (7.3)*, that is, the unique solution to the m-DDFV scheme* (4.17)*.*

Remark 7.4. This result still holds if one replaces (7.6) by

$$\lambda_{\mathcal{Q}}^n = \lambda_{\mathcal{Q}}^{n-1} + \gamma A_{\mathcal{Q}}(g_{\mathcal{Q}}^n - \nabla_{\mathcal{D}}^{\mathcal{T}} u^{\mathcal{T},n} - B_{\mathcal{Q}}\delta_{\mathcal{D}}^n), \quad \forall \mathcal{Q} \in \mathfrak{\mathbf{Q}}.$$

for any $\gamma \in \left]0, \frac{1+\sqrt{5}}{2}\right[$. It is possible in some cases to improve the convergence rate of the algorithm by choosing values of $\gamma \neq 1$.

The proof we present here is an adaptation to our framework of the arguments given in [13]. Furthermore, a similar algorithm and result is available for the hybrid h-DDFV scheme.

Proof. For any real-valued or vector-valued families $f = (f_{\mathcal{Q}})_{\mathcal{Q}\in\mathfrak{\mathbf{Q}}}$, $g = (g_{\mathcal{Q}})_{\mathcal{Q}\in\mathfrak{\mathbf{Q}}}$, and any $\alpha \in \{-1, 0, 1\}$, we introduce the following inner products and associated norms:

$$(f,g)_{\alpha,\mathcal{A}} = \sum_{\mathcal{Q}\in\mathfrak{\mathbf{Q}}} |\mathcal{Q}|(A_{\mathcal{Q}}^{\alpha} f_{\mathcal{Q}}, g_{\mathcal{Q}}), \quad \|f\|_{\alpha,\mathcal{A}} = (f,f)_{\alpha,\mathcal{A}}^{\frac{1}{2}}.$$

Let us define the error terms $v^{\mathcal{T},n} = u^{\mathcal{T},n} - u^{\mathcal{T}}$, $h^n = (h_{\mathcal{Q}}^n)_{\mathcal{Q}} \in (\mathbb{R}^2)^{\mathfrak{Q}}$ with $h_{\mathcal{Q}}^n = g_{\mathcal{Q}}^n - g_{\mathcal{Q}}$, $\mu^n = (\mu_{\mathcal{Q}}^n)_{\mathcal{Q}} \in (\mathbb{R}^2)^{\mathfrak{Q}}$ with $\mu_{\mathcal{Q}}^n = \lambda_{\mathcal{Q}}^n - \lambda_{\mathcal{Q}}$, and $\beta^n = (\beta_{\mathcal{D}}^n)_{\mathcal{D}} \in \Delta$ with $\beta_{\mathcal{D}}^n = \delta_{\mathcal{D}}^n - \delta^{\mathcal{D}}$. Finally, we introduce the nonlinear map $\varphi_{\mathfrak{Q}} : (\mathbb{R}^2)^{\mathfrak{Q}} \mapsto (\mathbb{R}^2)^{\mathfrak{Q}}$ defined by $(\varphi_{\mathfrak{Q}}(g))_{\mathcal{Q}} = \varphi_{\mathcal{Q}}(g_{\mathcal{Q}})$ and the linear map $\mathcal{B} : \Delta \mapsto (\mathbb{R}^2)^{\mathfrak{Q}}$ defined by $(\mathcal{B}\beta)_{\mathcal{Q}} = B_{\mathcal{Q}}\beta_{\mathcal{D}}$, where $\mathcal{D}$ is the diamond cell such that $\mathcal{Q} \in \mathfrak{\mathbf{Q}}_{\mathcal{D}}$.

Using those notations, we see from (7.4)–(7.6) that these quantities solve the following equations:

1. Equation for $v^{\mathcal{T},n}$:

$$\begin{aligned}(\nabla^{\mathcal{T}} v^{\mathcal{T},n} + \mathcal{B}\beta^n - h^n, \nabla_{\mathcal{D}}^{\mathcal{T}} w^{\mathcal{T}})_{1,\mathcal{A}} + \left(h^n - h^{n-1}, \nabla^{\mathcal{T}} w^{\mathcal{T}}\right)_{1,\mathcal{A}} \\ = \left(\mu^{n-1}, \nabla^{\mathcal{T}} w^{\mathcal{T}}\right)_{0,\mathcal{A}}, \quad \forall w^{\mathcal{T}} \in \mathbb{R}^{\mathcal{T}}.\end{aligned} \tag{7.7}$$

2. Equation for $\beta_{\mathcal{D}}^n$:

$$\begin{aligned}\sum_{\mathcal{Q}\in\mathfrak{\mathbf{Q}}_{\mathcal{D}}} |\mathcal{Q}|^t B_{\mathcal{Q}} A_{\mathcal{Q}}(B_{\mathcal{Q}}\beta_{\mathcal{D}}^n + \nabla_{\mathcal{D}}^{\mathcal{T}} v^{\mathcal{T},n} - h_{\mathcal{Q}}^n) + \sum_{\mathcal{Q}\in\mathfrak{\mathbf{Q}}_{\mathcal{D}}} |\mathcal{Q}|^t B_{\mathcal{Q}} A_{\mathcal{Q}} \left(h_{\mathcal{Q}}^n - h_{\mathcal{Q}}^{n-1}\right) \\ - \sum_{\mathcal{Q}\in\mathfrak{\mathbf{Q}}_{\mathcal{D}}} |\mathcal{Q}|^t B_{\mathcal{Q}} \mu_{\mathcal{Q}}^{n-1} = 0, \quad \forall \mathcal{D} \in \mathfrak{\mathbf{D}}.\end{aligned} \tag{7.8}$$

3. Equation for $h^n_{\mathcal{Q}}$:

$$\varphi_{\mathcal{Q}}(g^n_{\mathcal{Q}}) - \varphi_{\mathcal{Q}}(g_{\mathcal{Q}}) + \mu^{n-1}_{\mathcal{Q}} + A_{\mathcal{Q}}(h^n_{\mathcal{Q}} - \nabla^{\mathcal{T}}_{\mathcal{D}} v^{\mathcal{T},n} - B_{\mathcal{Q}}\beta^n_{\mathcal{D}}) = 0, \quad \forall \mathcal{Q} \in \mathfrak{Q}. \tag{7.9}$$

4. Equation for $\mu^n_{\mathcal{Q}}$:

$$\mu^n_{\mathcal{Q}} = \mu^{n-1}_{\mathcal{Q}} + A_{\mathcal{Q}}(h^n_{\mathcal{Q}} - \nabla^{\mathcal{T}}_{\mathcal{D}} v^{\mathcal{T},n} - B_{\mathcal{Q}}\beta^n_{\mathcal{D}}), \quad \forall \mathcal{Q} \in \mathfrak{Q}. \tag{7.10}$$

We take $w^{\mathcal{T}} = v^{\mathcal{T},n}$ in (7.7) and get

$$(\nabla^{\mathcal{T}} v^{\mathcal{T},n} + \mathcal{B}\beta^n - h^n, \nabla^{\mathcal{T}} v^{\mathcal{T},n})_{1,\mathcal{A}} + \left(h^n - h^{n-1}, \nabla^{\mathcal{T}} v^{\mathcal{T},n}\right)_{1,\mathcal{A}} = \left(\mu^{n-1}, \nabla^{\mathcal{T}} v^{\mathcal{T},n}\right)_{0,\mathcal{A}}. \tag{7.11}$$

From (7.10), we deduce

$$\frac{1}{2}\|\mu^n\|^2_{-1,\mathcal{A}} - \frac{1}{2}\left\|\mu^{n-1}\right\|^2_{-1,\mathcal{A}} - \left(\mu^{n-1}, h^n - \nabla^{\mathcal{T}} v^{\mathcal{T},n} - \mathcal{B}\beta^n\right)_{0,\mathcal{A}} - \frac{1}{2}\|h^n - \nabla^{\mathcal{T}} v^{\mathcal{T},n} - \mathcal{B}\beta^n\|^2_{1,\mathcal{A}} = 0. \tag{7.12}$$

Taking the $(\cdot,\cdot)_{0,\mathcal{A}}$ inner product of (7.9) with $h^n = g^n - g$, we get

$$(\varphi_{\mathfrak{Q}}(g^n) - \varphi_{\mathfrak{Q}}(g), g^n - g)_{0,\mathcal{A}} + (h^n - \nabla^{\mathcal{T}} v^{\mathcal{T},n} - \mathcal{B}\beta^n, h^n)_{1,\mathcal{A}} + \left(\mu^{n-1}, h^n\right)_{0,\mathcal{A}} = 0.$$

Multiplying (7.8) by $\beta^n_{\mathcal{D}}$, summing over $\mathfrak{D}$ and using (7.11), it follows

$$(\varphi_{\mathfrak{Q}}(g^n) - \varphi_{\mathfrak{Q}}(g), g^n - g)_{0,\mathcal{A}} + \|h^n - \nabla^{\mathcal{T}} v^{\mathcal{T},n} - \mathcal{B}\beta^n\|^2_{1,\mathcal{A}} + \left(\mu^{n-1}, h^n - \nabla^{\mathcal{T}} v^{\mathcal{T},n} - \mathcal{B}\beta^n\right)_{0,\mathcal{A}} + \left(h^n - h^{n-1}, \nabla^{\mathcal{T}} v^{\mathcal{T},n} + \mathcal{B}\beta^n\right)_{1,\mathcal{A}} = 0.$$

Adding this equation to (7.12), we get rid of the term containing $\mu^{n-1}_{\mathcal{Q}}$. We obtain

$$\frac{1}{2}\|\mu^n\|^2_{-1,\mathcal{A}} - \frac{1}{2}\left\|\mu^{n-1}\right\|^2_{-1,\mathcal{A}} + (\varphi_{\mathfrak{Q}}(g^n) - \varphi_{\mathfrak{Q}}(g), g^n - g)_{0,\mathcal{A}} + \frac{1}{2}\|h^n - \nabla^{\mathcal{T}} v^{\mathcal{T},n} - \mathcal{B}\beta^n\|^2_{1,\mathcal{A}} + \left(h^n - h^{n-1}, \nabla^{\mathcal{T}} v^{\mathcal{T},n} + \mathcal{B}\beta^n\right)_{1,\mathcal{A}} = 0. \tag{7.13}$$

From (7.5) we get, for any $\mathcal{Q} \in \mathfrak{Q}$,

$$\varphi_{\mathcal{Q}}(g^n_{\mathcal{Q}}) - \varphi_{\mathcal{Q}}(g^{n-1}_{\mathcal{Q}}) + \left(\mu^{n-1}_{\mathcal{Q}} - \mu^{n-2}_{\mathcal{Q}}\right) + A_{\mathcal{Q}}\left(\left(h^n_{\mathcal{Q}} - h^{n-1}_{\mathcal{Q}}\right) - \left(\nabla^{\mathcal{T}}_{\mathcal{D}} v^{\mathcal{T},n} - \nabla^{\mathcal{T}}_{\mathcal{D}} v^{\mathcal{T},n-1}\right) - B_{\mathcal{Q}}\left(\beta^n_{\mathcal{D}} - \beta^{n-1}_{\mathcal{D}}\right)\right) = 0,$$

so that, using (7.10) it follows

$$\varphi_{\mathcal{Q}}\left(g^n_{\mathcal{Q}}\right) - \varphi_{\mathcal{Q}}\left(g^{n-1}_{\mathcal{Q}}\right) + A_{\mathcal{Q}}\left(h^n_{\mathcal{Q}} - h^{n-1}_{\mathcal{Q}}\right) + A_{\mathcal{Q}} h^{n-1}_{\mathcal{Q}} - A_{\mathcal{Q}}\left(\nabla^{\mathcal{T}}_{\mathcal{D}} v^{\mathcal{T},n} + B_{\mathcal{Q}}\beta^n_{\mathcal{D}}\right) = 0.$$

Taking the inner product $(\cdot,\cdot)_{0,\mathcal{A}}$ of these equations by $g^n - g^{n-1} = h^n - h^{n-1}$ we get

$$\left(\varphi_{\mathfrak{Q}}(g^n) - \varphi_{\mathfrak{Q}}\left(g^{n-1}\right), g^n - g^{n-1}\right)_{0,\mathcal{A}} + \left\|h^n - h^{n-1}\right\|^2_{1,\mathcal{A}} + \left(h^{n-1}, h^n - h^{n-1}\right)_{1,\mathcal{A}} - \left(\nabla^{\mathcal{T}} v^{\mathcal{T},n} + \mathcal{B}\beta^n, h^n - h^{n-1}\right)_{1,\mathcal{A}} = 0.$$

If we add to this equation the following algebraic relation

$$\frac{1}{2}\left\|h^n\right\|_{1,\mathcal{A}}^2-\frac{1}{2}\left\|h^{n-1}\right\|_{1,\mathcal{A}}^2-\frac{1}{2}\left\|h^n-h^{n-1}\right\|_{1,\mathcal{A}}^2=\left(h^{n-1},h^n-h^{n-1}\right)_{1,\mathcal{A}},$$

we get

$$\begin{aligned}&\frac{1}{2}\left\|h^n\right\|_{1,\mathcal{A}}^2-\frac{1}{2}\left\|h^{n-1}\right\|_{1,\mathcal{A}}^2+\frac{1}{2}\left\|h^n-h^{n-1}\right\|_{1,\mathcal{A}}^2\\&\quad+\left(\varphi_{\mathfrak{D}}(g^n)-\varphi_{\mathfrak{D}}(g^{n-1}),g^n-g^{n-1}\right)_{0,\mathcal{A}}-\left(\nabla^{\mathcal{T}}v^{\mathcal{T},n}+\mathcal{B}\beta^n,h^n-h^{n-1}\right)_{1,\mathcal{A}}=0.\end{aligned}$$

Summing this equation with (7.13), it follows:

$$\begin{aligned}(7.14)\quad&\frac{1}{2}\left(\left\|\mu^n\right\|_{-1,\mathcal{A}}^2+\left\|h^n\right\|_{1,\mathcal{A}}^2\right)-\frac{1}{2}\left(\left\|\mu^{n-1}\right\|_{-1,\mathcal{A}}^2+\left\|h^{n-1}\right\|_{1,\mathcal{A}}^2\right)\\&+\left(\varphi_{\mathfrak{D}}(g^n)-\varphi_{\mathfrak{D}}\left(g^{n-1}\right),g^n-g^{n-1}\right)_{0,\mathcal{A}}+\left(\varphi_{\mathfrak{D}}(g^n)-\varphi_{\mathfrak{D}}(g),g^n-g\right)_{0,\mathcal{A}}\\&+\frac{1}{2}\left\|h^n-h^{n-1}\right\|_{1,\mathcal{A}}^2+\frac{1}{2}\left\|h^n-\nabla^{\mathcal{T}}v^{\mathcal{T},n}-\mathcal{B}\beta^n\right\|_{1,\mathcal{A}}^2=0.\end{aligned}$$

Since each map $\varphi_{\mathcal{Q}}$ is monotonic as is $\varphi_{\mathfrak{D}}$, we deduce that the sequence

$$\left(\left\|\mu^n\right\|_{-1,\mathcal{A}}^2+\left\|h^n\right\|_{1,\mathcal{A}}^2\right)_n$$

of nonnegative numbers is nonincreasing and then converges. Coming back to (7.14), we deduce that $(g_{\mathcal{Q}}^n)_n$ converges toward $g_{\mathcal{Q}}$ for any $\mathcal{Q}\in\mathfrak{Q}$, that is $h_{\mathcal{Q}}^n\to 0$, and that

$$h_{\mathcal{Q}}^n-\nabla_{\mathcal{D}}^{\mathcal{T}}v^{\mathcal{T},n}-B_{\mathcal{Q}}\beta_{\mathcal{D}}^n\xrightarrow{n\to\infty}0,\quad\forall\mathcal{Q}\in\mathfrak{Q}.$$

It follows that $\nabla_{\mathcal{D}}^{\mathcal{T}}v^{\mathcal{T},n}+B_{\mathcal{Q}}\beta_{\mathcal{D}}^n$ goes to 0 for any $\mathcal{Q}\in\mathfrak{Q}$. Then we get that $\mu_{\mathcal{Q}}^n\to 0$ by (7.9). Using now (4.9), we find that for any $\mathcal{D}\in\mathfrak{D}$ we have $\nabla_{\mathcal{D}}^{\mathcal{T}}v^{\mathcal{T},n}\to 0$ and then finally $\beta_{\mathcal{D}}^n\to 0$. □

8. Numerical results. We present here some numerical results in the following situation: we consider the domain $\Omega=]0,1[\times]0,1[$, and the flux φ defined by

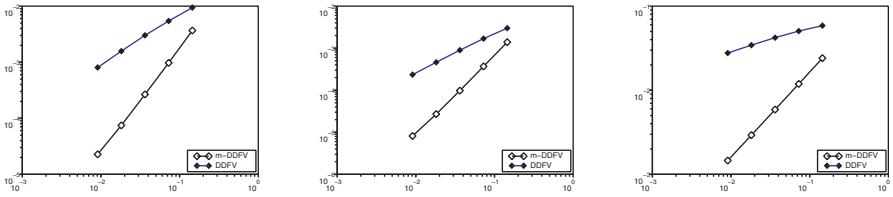
$$(8.1)\qquad\varphi(z,\xi)=\begin{cases}|\xi|^{p-2}\xi, & \text{if } z_1<0.5,\\ (A\xi,\xi)^{\frac{p-2}{2}}A\xi, & \text{if } z_1>0.5,\end{cases}$$

where A is the matrix $A=\left(\begin{smallmatrix}\alpha & 0\\ 0 & \beta\end{smallmatrix}\right)$, $\alpha,\beta\in]1,+\infty[$. Then we construct the source term f, and the boundary data in such a way that the solution of (1.1) is given by

$$u_e(z)=\begin{cases}(\alpha z_1+\gamma z_2)^2, & \text{if } z_1<0.5,\\ \left(z_1+\gamma z_2+\dfrac{\alpha-1}{2}\right)^2, & \text{if } z_1>0.5,\end{cases}$$

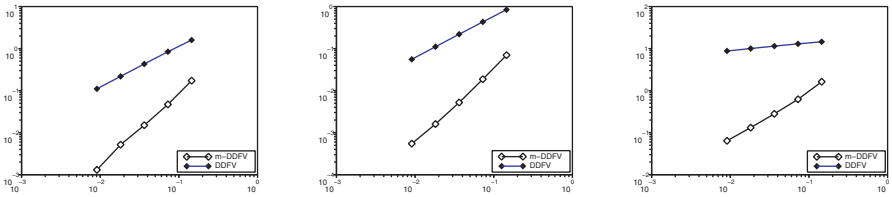
where $\gamma=\sqrt{\alpha\frac{1-\alpha}{1-\beta}}$. It is easily seen that this function u_e satisfies the transmission condition described in the introduction along the line $\{z_1=\frac{1}{2}\}$. This is true for any value of p.

In a first test case, we choose $p=3.0$ and $(\alpha,\beta)=(5.0,2.0)$ so that the problem we consider has discontinuities and is anisotropic. We show in Figure 8.1 the errors in three different norms as a function of the mesh size, in a logarithmic scale, for the



L^∞ error slopes 1.71 and 0.97 | L^p error slopes 1.73 and 0.97 | $W^{1,p}$ error slopes 1.0 and 0.31

FIG. 8.1. *Test case* 1*:* $p = 3.0$*,* $\alpha = 5$*,* $\beta = 2$*.*



L^∞ error slopes 1.98 and 0.98 | L^p error slopes 1.54 and 0.99 | $W^{1,p}$ error slopes 1.04 and 0.19

FIG. 8.2. *Test case* 2*:* $p = 5.0$*,* $\alpha = \beta = 10.0$*.*

original DDFV scheme (3.3)–(3.4) (marked by ⧫) and for the m-DDFV scheme (4.16)–(4.17) (marked by ◇). Notice that, since the operator defined by (8.1) is piecewise constant, the h-DDFV scheme of Definition 5.2 is exactly the same as the m-DDFV scheme.

As predicted by the theory, the m-DDFV scheme provides a much better convergence rate than the original DDFV scheme. Furthermore, and it is an important point, the error (in any of the three norms we consider) obtained by the m-DDFV scheme is better even in the case of coarse meshes.

As a second test case we assume that $p = 5.0$ and $(\alpha, \beta) = (10.0, 10.0)$. In this situation the operator is isotropic, but the jump of the diffusion coefficient is of order $10^{2.5}$. We observe (see Figure 8.2) the same overall behavior of the two schemes.

Finally, we want to illustrate the behavior of the decomposition-coordination algorithm proposed in section 7. First of all, it is shown in [13], for instance, that such algorithms can be applied, in suitable infinite dimensional functional spaces, directly to the continuous problem (1.1). This fact let us hope that the convergence rate of the present method may not depend too much on the size of the mesh we consider. Actually, in our numerical computations, we observed that the number of iterations needed to achieve a given residual norm was essentially the same in each level of refinement of the mesh we considered.

Let us now illustrate the fact that one can take advantage of using the heterogeneous and isotropic augmentation matrices family $\mathcal{A}$. To this end, we consider the first example given above (Figure 8.1) and we plot in Figure 8.3 the evolution during the iterations of the L^p, $W^{1,p}$ errors and the residual norm of the algorithm. The left plot is the one obtained with the classical augmentation term when $A_{\mathcal{Q}} = r\mathrm{Id}$ for any $\mathcal{Q} \in \mathfrak{Q}$, with $r = 1.5$. In the right plot, we have chosen $A_{\mathcal{Q}} = r\mathrm{Id}$ if $\mathcal{Q} \subset \{z_1 < \frac{1}{2}\}$ and $A_{\mathcal{Q}} = rA$ if $\mathcal{Q} \subset \{z_1 > \frac{1}{2}\}$.

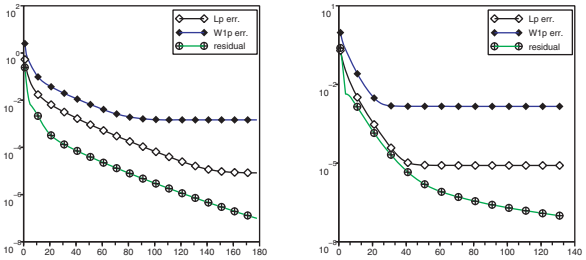


FIG. 8.3. *Convergence of the iterative solver. Isotropic (left) and anisotropic augmentation (right).*

We see that the use of anisotropic and heterogeneous augmention terms lets us achieve the tolerance 10^{-7} on the residual norm in ~ 130 iterations instead of ~ 180 in the isotropic case. Furthermore, we see that the error due to the scheme is achieved after ~ 40 iterations, that is, when the residual norm is $\sim 5.10^{-6}$ in the anisotropic augmentation case, whereas it is only achieved in ~ 150 iterations, for a residual norm of 5.10^{-7} in the isotropic case. This illustrates the fact that the choice of suitable augmentation matrices $\mathcal{A}$ may let us save a significant amount of computational time to solve our scheme.

9. Conclusions. In this paper we provide a modification of the DDFV finite volume scheme for nonlinear elliptic problems on general 2D grids in order to take into account discontinuities in the coefficients. The m-DDFV scheme we obtained is proven to present a better consistency of the fluxes at the discontinuities. The performance of the scheme is illustrated by numerical results on heterogeneous and anisotropic p-Laplacian equations. Moreover, we proposed a generalization of the decomposition-coordination method of Glowinski in order to solve our scheme. We show that the use of heterogeneous and anisotropic augmentation terms in this approach may lead to much better performance of the algorithm.

Finally, some extensions of this work are given in [5] where we analyze the m-DDFV method in the case of the coupling, through transmission conditions, of a linear and a nonlinear elliptic Leray–Lions operators.

Acknowledgments. The authors want to thank the referees whose remarks have improved this paper.

We dedicate this paper to the memory of H. B. Keller

Abstract. We propose and analyze a pseudotransient continuation algorithm for dynamics on subsets of R^N. Examples include certain flows on manifolds and the dynamic formulation of bound-constrained optimization problems. The method gets its global convergence properties from the dynamics and inherits its local convergence properties from any fast locally convergent iteration.

Key words. pseudotransient continuation, constrained dynamics, gradient flow, bound-constrained optimization, quasi-Newton method

1. Introduction. In this paper we extend algorithms and convergence results [9, 12, 13, 15, 24] for the method of pseudotransient continuation (Ψtc) to a class of constrained problems in which projections onto the feasible set are easy to compute. Such constraints arise in inverse eigenvalue and singular value problems [7, 8], where Ψtc is an efficient alternative to a fully time-accurate geometric integration [14], for which theory is only available for fixed time-step methods. The objective of Ψtc is not to stay on the manifold with high precision but rather to move rapidly to the steady state.

The algorithms we propose use the projection and can hence be applied to other classes of problems. Bound-constrained optimization is one example [22] and we explore that in this paper as well. The results in this paper may also be applicable to more general problems on manifolds [1] if the relevant projections can be approximated efficiently, and this will be the subject of future work.

Ψtc was originally designed as a method for finding steady-state solutions to time-dependent differential equations. The idea is to mimic integration to the steady state while managing the "time step" to move the iteration as rapidly as possible to Newton's method. This is different from the standard approach in an algorithm for initial value problems [2], where the time step is controlled with stability and accuracy in mind. Ψtc also differs from traditional continuation methods in that

the objective is to find a steady-state solution, not, as is the case for pseudoarclength continuation [20], to track that solution as a function of another parameter. Homotopy methods [31] also introduce an artificial parameter to solve nonlinear equations but not in a way that is intended to capture dynamic properties, such as stability, of the solution.

In the remainder of this section, we will briefly review Ψtc. We refer the reader to [9, 12, 13, 15, 24] for the existing convergence results and references to applications.

In section 2 we will describe an algorithm for constrained Ψtc and prove a convergence theorem which not only allows for constraints but has a weaker stability assumption than was used in [9, 13, 24] and includes more general assumptions on the iteration itself. We close section 2 with some remarks on applications of the theory. In section 3, we will show how the new form of Ψtc can be applied to bound-constrained optimization in a way that maintains superlinear convergence in the terminal phase of the iteration. In section 4 we apply the methods to two example problems.

1.1. Ψtc for nonlinear equations. The formulation for ODE dynamics is the easiest to understand and is sufficient for this paper. Suppose $F : R^N \to R^N$ is Lipschitz continuously differentiable and

$$u^* = \lim_{t\to\infty} u(t), \tag{1.1}$$

where u is the solution of the initial value problem

$$\frac{du}{dt} = -F(u), \qquad u(0) = u_0. \tag{1.2}$$

We will refer to (1.1) as a stability condition in what follows, and it is a property of both F and the initial point u_0. The objective of the algorithms we discuss in this paper is to find u^*.

One might try to find u^* by solving the nonlinear equation $F(u) = 0$ with a globalized version of Newton's method [21, 23]. The danger is that one may find a solution other than u^* and even a solution that is dynamically unstable. One could also use an ODE code to accurately integrate the initial value problem (1.2) to the steady state. The problem with this latter approach is that one is accurately computing transient behavior of u that is not necessarily needed to compute u^*.

The most common form of Ψtc is the iteration

$$u_+ = u_c - \left(\delta_c^{-1} I + F'(u_c)\right)^{-1} F(u_c), \tag{1.3}$$

where, as is standard, u_c is the current iteration, δ_c the current time step, and u_+ the new iteration. The "time step" δ is managed in a way that captures important transients early in the iteration but grows near u^* so that (1.3) becomes Newton's method. One common way to control δ is "switched evolution relaxation" (SER) [29]. In SER the new time step is

$$\delta_+ = \min(\delta_c \|F(u_c)\|/\|F(u_+)\|, \delta_{max}). \tag{1.4}$$

Using $\delta_{max} = \infty$ is common, in which case $\delta_+ = \delta_0 \|F(u_0)\|/\|F(u_+)\|$. We will refer to the updated formula (1.4) as SER-A, to distinguish it from (1.5).

The existing convergence theory applies only to SER-A, but there are other approaches, and we will discuss two. A variation of SER, which we call SER-B, was proposed in [19]. The formula for the time step is

$$\delta_+ = \max(\delta_c / \|u_+ - u_c\|, \delta_{max}). \tag{1.5}$$

In section 2.1.1, we show how SER-B can be modified so that the convergence theory applies in the case of certain gradient flows.

The temporal truncation error approach (TTE) [25] estimates the local truncation error of $(u)_i(t_n)$, the ith component of $u(t_n) \in R^N$, by $\tau_i \equiv \frac{\delta_n^2 (u)_i''(t_n)}{2}$, approximates $(u)_i''$ by

$$\frac{2}{\delta_{n-1}+\delta_{n-2}}\left[\frac{((u)_i)_n - ((u)_i)_{n-1}}{\delta_{n-1}} - \frac{((u)_i)_{n-1} - ((u)_i)_{n-2}}{\delta_{n-2}}\right], \tag{1.6}$$

and computes δ_n by setting $\tau_i = 3/4$ for all i. In section 4 we will compare the three methods for time-step management. The good performance of SER-B and TTE raises interesting research questions.

One way to see how Ψtc and temporal integration are related is to derive Ψtc from the implicit Euler method. The formula for an implicit Euler step is $u^{n+1} = u^n - \delta_n F(u^{n+1})$, where u^n is the approximation to u at t_n and $\delta_n = t_{n+1} - t_n$ is the nth time step. If we determine u^{n+1} by taking a single Newton step for the nonlinear equation $G(u) \equiv u - u^n + \delta_n F(u) = 0$, with u^n as the initial iterate, then we obtain (1.3).

2. Constrained Ψtc . Let F be Lipschitz continuous, and assume that $u(t) \in \Omega$ for all $t \geq 0$, where $\Omega \subset R^N$. Examples of such constrained dynamics are flows where F is the projected gradient onto the tangent space of Ω at u, and our two examples are such flows. One should not expect a general purpose integrator to keep the solutions in Ω, and we use a projection to correct after each step to keep the iterations in Ω.

Let $\mathcal{P}$ be a Lipschitz continuous projection onto Ω. Our assumptions on $\mathcal{P}$ are as follows.

Assumption 2.1.

1. $\mathcal{P}(u) = u$ for all $u \in \Omega$.
2. There are $M_{\mathcal{P}}$ and $\epsilon_{\mathcal{P}}$ such that for all $u \in \Omega$ and v such that $\|v - u\| \leq \epsilon_{\mathcal{P}}$

$$\|\mathcal{P}(v) - u\| \leq \|v - u\| + M_{\mathcal{P}}\|v - u\|^2. \tag{2.1}$$

Assumption 2.1 is trivially true if Ω is convex and $\mathcal{P}$ is the projection onto Ω, for then $\mathcal{P}$ is Lipschitz continuous with Lipschitz constant 1, so $M_{\mathcal{P}} = 0$. If Ω is a smooth manifold of the form $\Omega = \{u \,|\, \mathcal{F}(u) = 0\}$ where $\mathcal{F} : R^N \to R^M$ with $M < N$, and $\mathcal{P}$ is smooth, then $\|\mathcal{P}'(u)\| = 1$, which will imply (2.1). Note that we are making no explicit assumptions on Ω, only assumptions on the existence of $\mathcal{P}$ and its properties.

We will consider a Ψtc iteration of the form

$$u_+ = \mathcal{P}\left[u_c - \left(\delta_c^{-1} I + H(u_c)\right)^{-1} F(u_c)\right], \tag{2.2}$$

where H is an $N \times N$ matrix-valued function of u. We will assume that H is a sufficiently good approximation to F' (or, in the semismooth case, sufficiently close to ∂F) to make the iteration locally convergent. The theory we will develop applies equally well to the inexact formulation $u_+ = u_c + s$, where

$$\|(\delta_c^{-1} I + H(u_c))s + F(u_c)\| \leq \eta_c \|F(u_c)\|. \tag{2.3}$$

The "forcing term" η_c could be, for example, the termination tolerance in a linear iterative method for computing the step [10, 21]. The forcing term has a well-known effect on convergence analysis, which is reflected in (2.11).

Assumption 2.2.

1. There are $M_H, \epsilon_H > 0$ such that

$$\|H(u)\| \le M_H \text{ for all } u \in S(\epsilon_H) = \left\{ z \mid \inf_{t \ge 0} \|z - u(t)\| \le \epsilon_H \right\}. \tag{2.4}$$

   For all $\epsilon > 0$ there is $\bar{\epsilon} > 0$ such that if $u \in S(\epsilon_H)$ and $\|u - u^*\| > \epsilon$, then

$$\|F(u)\| > \bar{\epsilon}. \tag{2.5}$$

2. There is ϵ_L so that if $\|u_c - u^*\| \le \epsilon_L$, then $H(u_c)$ is nonsingular,

$$\|(I + \delta H(u_c))^{-1}\| \le (1 + \beta\delta)^{-1}, \text{ for some } \beta > 0 \text{ and all } \delta \ge 0, \tag{2.6}$$

   and the local Newton iteration

$$u_+^{NL} = u_c - H(u_c)^{-1} F(u_c) \tag{2.7}$$

   reduces the error by a factor $r \in [0, 1)$ for all $u_c \in \Omega$ sufficiently near u^*, i.e.,

$$\|e_+^{NL}\| \le r \|e_c\|. \tag{2.8}$$

One new feature in Assumption 2.2 is the local nonlinear iteration, which is general enough to allow for Gauss–Newton methods (and quasi-Newton methods, see section 2.1.3). Note that the convergence rate for the local iteration is expressed in terms of the underlying unprojected Newton-like method (2.7). The assumption we must make (2.8) on the unprojected iteration can be verified in the examples we consider in section 4.

Theorem 2.1 extends previous work in several ways. The smoothness assumptions on F are relaxed, the projection is introduced to handle constrained dynamics, H is constrained only by the local convergence behavior of the Newton-like iteration (2.7), so superlinear convergence is not required, and (2.6) need only hold in a neighborhood of u^*.

THEOREM 2.1. *Let F be locally Lipschitz continuous, and assume that*

$$\lim_{t \to \infty} u(t) = u^*$$

and that Assumptions 2.1 *and* 2.2 *hold. Let the sequence $\{\delta_n\}$ be updated with* (1.4). *Assume that there is $\delta^* > 0$ such that*

$$M_{\mathcal{P}} \epsilon_L / \beta < \delta^* \le \delta_n \tag{2.9}$$

for all n. Assume that the q-factor r in (2.8) *satisfies*

$$r < ((1 + M_{\mathcal{P}} \epsilon_L) - (1 + \beta\delta^*)^{-1})/2, \tag{2.10}$$

where β is the constant in (2.6). *Then if δ_0 and the sequence $\{\eta_n\}$ are sufficiently small, the inexact Ψtc iteration $u_{n+1} = \mathcal{P}(u_n + s_n)$, where $\|(\delta_n^{-1} I + H(u_n))s_n + F(u_n)\| \le \eta_n \|F(u_n)\|$ converges to u^*. Moreover, there is $K > 0$ such that for n sufficiently large*

$$\|e_{n+1}\| \le \|e_{n+1}^{NL}\| + K \|e_n\| \left(\eta_n + \delta_n^{-1}\right). \tag{2.11}$$

Proof. We will prove the result for the exact ($\eta_n = 0$) iteration with $\delta_{max} = \infty$ in (1.4). The complete proof is based on the same ideas but requires more bookkeeping. The outline of the proof follows those in [9, 13, 24].

We begin with the global phase. We wish to prove that, while u is out of the local convergence region for the iteration (2.7), the iteration remains close to the solution of the differential equation, i.e., in $S(\epsilon)$ for a sufficiently small ϵ. Only (1.1), the lower bound $\delta_n \geq \delta^*$, Lipschitz continuity of F, and Part 2.2 of Assumption 2.2 are needed for this stage of the analysis. Having done this, we address the local phase, where δ is small and u is near u^*. We will use the rest of Assumption 2.2 to prove the local convergence estimate (2.11).

Let $\epsilon < \min(\epsilon_L, \epsilon_H)$. We may reduce ϵ as the proof of the local convergence progresses. The first step is to show that if δ_0 is sufficiently small, then

$$\|u_n - u^*\| < \epsilon \tag{2.12}$$

for sufficiently large n. To do this we need only verify that, for δ sufficiently small,

$$\left(\delta^{-1} I + H(u_n)\right)^{-1} = \delta I + O\left(\delta^2\right), \tag{2.13}$$

and obtain upper and lower bounds on δ_n/δ_0 while (2.12) fails to hold.

The estimate (2.13) follows from (2.4) if $\delta < 1/(2M_H)$. To obtain bounds for δ_n, we can apply the update formula (1.4) and (2.5) to show that while $u_n \in S(\epsilon_H)$ and $\|u_n - u^*\| > \epsilon/2$, then

$$\begin{aligned} \delta^* &\equiv \delta_0 \|F(u_0)\| / \max_{u \in S(\epsilon_H)} \|F(u)\| \\ &\leq \delta_n = \delta_0 \|F(u_0)\| / \|F(u_n)\| \leq 2\delta_0 \|F(u_0)\| / C_F \epsilon. \end{aligned} \tag{2.14}$$

Equation (1.4) with $\delta_{max} = \infty$ and our lower bound on δ imply that

$$\delta^* \leq \delta_n \leq \frac{\|F(u_0)\|\delta_0}{\|F(u_n)\|} \leq \frac{2\delta_0 \|F(u_0)\|}{C_F \epsilon}. \tag{2.15}$$

Hence, for δ_0 sufficiently small, (2.13) holds if (2.12) does not.

With (2.13) in hand, we see that either (2.12) holds or

$$u_{n+1} = \mathcal{P}(u_n - \delta F(u_n)) + O\left(\delta^2\right), \tag{2.16}$$

where the constant in the O-term is independent of n. Now, if $u \in \Omega$, then Lipschitz continuity of $\mathcal{P}$ implies that

$$\mathcal{P}\left(u - \left(\delta^{-1} I + H(u)\right)^{-1}\right) F(u) = \mathcal{P}(u - \delta F(u)) + O\left(\delta^2\right).$$

Euler's method, $u_{n+1} = u_n - \delta F(u)$, has the same local truncation error as $u_{n+1} = \mathcal{P}(u_n - \delta F(u))$, because $u(t) \in \Omega$ for all t [26]. To see this, we note that

$$\mathcal{P}(u(t) - \delta F(u(t))) = \mathcal{P}\left(u(t+\delta) + O\left(\delta^2\right)\right) = u(t+\delta) + O\left(\delta^2\right).$$

Now let T be such that $\|u(t) - u^*\| < \epsilon/2$ for all $t \geq T$, and let N^* be the least integer $\geq T/\delta^*$. The standard analysis for the forward Euler method [2] implies that there is C_E such that

$$\|u_n - u(t_n)\| \leq C_E \max_{1 \leq k \leq n} \delta_k \leq \frac{2C_E \delta_0 \|F(u_0)\|}{C_F \epsilon}$$

for all $n \leq N^*$. In particular, $\|u_n - u^*\| \leq \epsilon$ for all $n \geq N^*$ if $\delta_0 \leq (C_F \epsilon^2)/(4C_E \|F(u_0)\|)$.

For the local phase, assume that $n \geq N^*$. Hence, (2.12) holds. We need to show that $\|e_{n+1}\| < \|e_n\|$ and that $\delta_{n+1} > \delta_n$. Once those things are done, we can complete the proof with a simple calculation.

Define $v_{n+1} = u_n - (\delta_n^{-1} I + H(u_n))^{-1} F(u_n)$, and note that $(H(u_n)^{-1} - (\delta_n^{-1} I + H(u_n))^{-1}) = (I + \delta_n H(u_n))^{-1} H(u_n)^{-1}$. Hence

$$\begin{aligned} v_{n+1} &= u_n - H(u_n)^{-1} F(u_n) + (H(u_n)^{-1} - (\delta_n^{-1} I + H(u_n))^{-1}) F(u_n) \\ &= u_{n+1}^{NL} + (I + \delta_n H(u_n))^{-1} H(u_n)^{-1} F(u_n) \\ &= u_{n+1}^{NL} - (I + \delta_n H(u_n))^{-1} \left(u_{n+1}^{NL} - u_n \right), \end{aligned}$$

and therefore $u_{n+1} = \mathcal{P}(v_{n+1}) = \mathcal{P}(u_{n+1}^{NL} - (I + \delta_n H(u_n))^{-1} (e_{n+1}^{NL} - e_n))$.

We use (2.1) to conclude that

$$\begin{aligned} e_{n+1} &= \mathcal{P}(v_{n+1}) - u^* = \mathcal{P}\left(u_{n+1}^{NL} - (I + \delta_n H(u_n))^{-1} \left(e_{n+1}^{NL} - e_n \right) \right) - u^* \\ &= \mathcal{P}\left(u_{n+1}^{NL} - (I + \delta_n H(u_n))^{-1} \left(e_{n+1}^{NL} - e_n \right) \right) - \mathcal{P}(u^*). \end{aligned}$$

So, since $\epsilon < \epsilon_L$,

$$\begin{aligned} \|e_{n+1}\| &\leq (1 + M_{\mathcal{P}} \epsilon_L) \left(\|e_{n+1}^N\| + \|(I + \delta_n H(u_n))^{-1}\| \left(\|e_{n+1}^{NL}\| + \|e_n\| \right) \right) \\ &\leq (1 + M_{\mathcal{P}} \epsilon_L) \left(2r + (1 + \beta \delta^*)^{-1} \right) \|e_n\|. \end{aligned}$$

This completes the proof since $(1 + M_{\mathcal{P}} \epsilon_L)(2r + (1 + \beta \delta^*)^{-1}) < 1$ by (2.9). Hence, the iteration converges at least locally q-linearly. Formula (1.4) then will imply (2.11). ∎

2.1. Remarks. Even in the unconstrained case (where $\mathcal{P}(u) = u$ for all $u \in R^N$) Theorem 2.1 extends the results from [9, 13, 24] by replacing the semismoothness and the inexact Newton condition with a general condition on the convergence of the local iteration. If the stability condition (1.1) holds, then Ψtc with SER is a convergent iteration for unconstrained optimization, even if one does not use exact Hessians.

2.1.1. Control of δ with f for gradient flows. The key parts to the proof of Theorem 2.1 are showing that the time step remains small until u_n is near the solution and that the step will grow at that time. The way this is done in the case of SER-A is to note that (1.4) implies that if u_n is not close to u^*, then δ_n is bounded from above and below by constant multiples of δ_0, and hence the method is an accurate temporal integration. Then, once near u^*, (2.6) drives u_n to u^* and δ_n to δ_{max}.

One can augment the time-step control method in several ways without affecting the theory. If the dynamics are a gradient flow, then one can reject the step if f is increased, reduce δ, and try again. As long as δ is bounded from above and below by constant multiples of δ_0 and the number of reductions is bounded, the global convergence assertion $u_n \to u^*$ will hold. If one accepts the SER-A formula only when f decreases, then the local theory will be unchanged and Theorem 2.1 will hold. One can also apply this idea to SER-B and TTE but must take care that increases in δ are not too large to maintain the resolution of the dynamics while $u(t)$ is far from u^*. One way to do this is to accept the SER-B or TTE step only if f decreases and limit the size of the increases in δ to factors of two at each iteration.

Another approach is the trust-region method from [15], and the proof of Theorem 2.1 extends to that method. Here $\delta_{max} = \infty$ and the increase in δ at each iteration is limited.

2.1.2. Semismooth nonlinearities. If F is semismooth, which is the case considered in [13], and $H(u_n) \in \partial F(u_n)$, then the local iteration (2.7) is superlinearly convergent, if all matrices in $\partial F(u^*)$ are nonsingular. Hence, we may recover the results from [13] from Theorem 2.1, the extension to DAE dynamics being the same as that in [13] and not relevant to this paper.

2.1.3. Quasi-Newton methods. The proof of Theorem 2.1 can be modified to allow a quasi-Newton [11, 22] model Hessian. This modification simply replaces the dependence of H on u_n with one on the history of the iteration and makes the assumptions of boundedness of H_n and convergence of the local iteration. The resulting modified proof would be somewhat longer, and, since our examples are not quasi-Newton iterations, we used the shorter and simpler proof in this paper.

Unlike Newton or Gauss–Newton iterations, one must assume (rather than verify) the convergence of the local iteration. The reason for this is that local convergence of quasi-Newton methods requires that both the initial iterate and the initial model Hessian be good approximations to the solution and the Hessian at the solution. The global theory [5] requires a line search and convex level sets, neither of which is a part of the Ψtc methods we propose.

2.1.4. Gauss–Newton iteration. If $F(u) = \nabla f(u) = R'(u)^T R(u)$ is the gradient of a nonlinear least squares functional $f(u) = R(u)^T R(u)/2$, where $R : R^N \to R^M$, with $M > N$, we may let H be the Gauss–Newton model Hessian $H(u) = R'(u)^T R'(u)$ and apply Theorem 2.1 if R' has full column rank at the minimizer. Moreover, many of the assumptions can be verified with ease in this case. If $u(t) \to u^*$, which we still must assume, then $H(u^*)$ is symmetric and positive definite, so (2.6) holds. Moreover $\delta^{-1} I + H(u)$ is nonsingular for all $\delta > 0$ and all u, because $H(u)$ is always nonnegative definite. For a zero-residual problem, the estimate (2.10) will hold because the local iteration converges q-quadratically if R is Lipschitz continuously differentiable. In this case, Ψtc is a version of the Levenberg–Marquardt method, where the parameter is selected based on the norm of the gradient rather than with a trust region scheme. Similar ideas for selection of the parameter have been made [22].

3. Bound-constrained optimization. The bound-constrained optimization problem is

$$\min_{\Omega} f(u), \tag{3.1}$$

where $\Omega = \{u \,|\, L \le u \le U\}$, and the inequalities are componentwise.

In order to describe necessary conditions and formulate the algorithms, we must recall some notation from [4, 22, 27].

The l^2 projection onto Ω is $\mathcal{P}$, where

$$\mathcal{P}(u)_i = \max(L_i, \min(U_i, (u)_i)). \tag{3.2}$$

Here $(u)_i$ denotes the ith component of the vector $u \in R^N$. $\mathcal{P}$ trivially satisfies Assumption 2.1 because Ω is convex.

We will assume that f is Lipschitz continuously differentiable. In that case, the first-order necessary conditions for optimality are [4, 22]

$$F(u) = u - \mathcal{P}(u - \nabla f(u)) = 0. \tag{3.3}$$

Equation (3.3) is a semismooth nonlinear equation. Fast locally convergent methods include the semismooth Newton, methods of [30], and the projected Newton or scaled gradient projection methods [4, 22, 27].

Consistent with the unconstrained case, the gradient flow equations are [26]

$$\frac{du}{dt} = -F(u), \qquad u(0) = u_0, \tag{3.4}$$

where in this case, F is defined by (3.3). If we let $u_0 \in \Omega$, then the solution of (3.4) satisfies

$$\lim_{t\to\infty} F(u(t)) = 0. \tag{3.5}$$

We will also assume that (1.1) holds. Since dynamics [26] force $u(t) \in \Omega$ for all t and Ω is bounded, then if there are only finitely many solutions of $F(u) = 0$ in Ω, (1.1) will hold for all $u_0 \in \Omega$ in this case.

We may apply Theorem 2.1 directly, once we describe the maps $H(u)$ and show that (2.8) holds. We use known results [4, 22, 27] from optimization to do this.

One choice of $H(u)$ is the reduced Hessian. Letting $u \in \Omega$ and $0 \le \sigma < \min(U_i - L_i)/2$, we define the set of σ-binding constraints as

$$\begin{aligned}\mathcal{B}^\sigma(u) \quad = \{i \,|\quad & U_i - (u)_i \le \sigma \text{ and } (\nabla f(u))_i < -\sqrt{\sigma} \text{ or} \\ & (u)_i - L_i \le \sigma \text{ and } (\nabla f(u))_i > \sqrt{\sigma}\}.\end{aligned}$$

For $\mathcal{N} \subset \{1, 2, \ldots N\}$ we define $D(\mathcal{N})$ as the diagonal matrix with entries

$$D(\mathcal{N})_{ii} = \begin{cases} 1 & i \in \mathcal{N}, \\ 0 & i \notin \mathcal{N} \end{cases}$$

and define the reduced Hessian as

$$\bar{\mathcal{R}} f(u) = I - D(\mathcal{B}^0(u))(I - \nabla^2 f(u))D(\mathcal{B}^0(u)). \tag{3.6}$$

The second-order sufficiency conditions for a point u^* to be a local minimizer are [27] that $F(u^*) = 0$ and $\bar{\mathcal{R}} f(u^*)$ is positive definite. We will assume that u^* satisfies the second-order sufficiency conditions in what follows.

One must approximate the bounding constraints carefully in order to obtain a superlinearly convergent iteration. One way to do this [22, 27] is to let

$$H(u) = I - D(\mathcal{B}^\sigma(u)) \left(I - \nabla^2 f(u)\right) D(\mathcal{B}^\sigma(u)), \tag{3.7}$$

where $\sigma(u) = \|u - \mathcal{P}(u - \nabla f(u))\|$. With this choice the local iteration satisfies (2.8). In the case of a small residual bound-constrained nonlinear least squares problem, we may replace $\nabla^2 f(u)$ with the Gauss–Newton model Hessian.

4. Examples. In this section we present two examples. The first is a nonlinear equation on a manifold, which is a gradient flow of an inverse singular value problem. The projection is more subtle in this case, and we describe it in detail in section 4.1.1.

The second is a nonlinear bound-constrained least squares problem for which we compare the three variants of Ψtc (SER-A, SER-B, and TTE) with the trust-region method (`lmtr`) from [15], which in the nonlinear least squares case is a classic trust-region method [11, 22], and the damped Levenberg–Marquardt algorithm (`lmls`) from [22]. The projection in this case is trivial to compute, and we use the reduced Gauss–Newton model Hessian instead of $\nabla^2 f$ in (3.7). This example is a small artificial problem, which enables us to consider the cases where the minimizer is in the interior

of the feasible set, on the boundary (and hence degenerate in the sense that the binding constraints are a proper subset of the active constraints), and outside of the feasible set (and therefore a nonzero residual problem). In this example we do not increase δ unless f decreases, and we manage δ with the approach in section 2.1.1. All of the Ψtc methods, and especially SER-B and TTE, work much better if we do that.

In all of the examples, SER-B performs very well.

4.1. Inverse singular value problem. The inverse singular value problem [7] is to find $c \in R^N$ so that the $M \times N$ matrix

$$B(c) = B_0 + \sum_{k=1}^{N} c_k B_k$$

has prescribed singular values $\{\sigma_i\}_{i=1}^N$. This is one example of a wide class of inverse eigenvalue and singular value problems for which a dynamic formulation is useful [8].

One can assume without loss of generality that the matrices $\{B_i\}_{i=1}^N$ are orthonormal with respect to the Frobenius inner product and then formulate the problem as a constrained nonlinear least squares problem

$$\min \Psi(U,V) \equiv \|R(U,V)\|_F^2 \tag{4.1}$$

for $M \times M$ and $N \times N$ matrices U and V, subject to the constraint that U and V be orthogonal. If one finds a solution with a zero residual, then one has solved the original problem. This is not always possible, as the original problem may not have a solution [6]. In (4.1) the residual is

$$R(U,V) = U\Sigma V^T - B_0 - \sum_{k=1}^{N} \langle U\Sigma V^T, B_k\rangle B_k,$$

where $\langle\cdot,\cdot\rangle$ is the Frobenius inner product.

If we let Ω denote the manifold of pairs of $M \times M$ and $N \times N$ orthogonal matrices, then the projection of $\nabla\Psi$ onto the tangent space of Ω at $(U,V) \in \Omega$ is

$$g(U,V) = \frac{1}{2} \begin{pmatrix} \left(R(U,V)V\Sigma^T U^T - U\Sigma V^T R(U,V)^T\right) U \\ \left(R(U,V)^T U\Sigma V^T - V\Sigma^T U^T R(U,V)\right) V \end{pmatrix}.$$

The gradient flow equations for the problem are of the form (1.2) with

$$F(u) = g(U,V), \text{ where } u = \begin{pmatrix} U \\ V \end{pmatrix}. \tag{4.2}$$

Since $F(u)$ is in the tangent space of Ω at u [7], the solution of (1.2) is in Ω if $u_0 \in \Omega$. Since g is analytic in u, the results of [28] will apply, and so (1.1) holds for all initial vectors $u_0 \in \Omega$.

4.1.1. The projection onto Ω. The projection of an $N \times N$ matrix A onto the manifold of orthogonal matrices [17, 18] $A \to U_P$. Here $A = U_P H_P$, with U_P orthogonal and H_P symmetric positive semidefinite, is a polar decomposition of A. H_P is unique. U_P is unique if A is nonsingular. In this case (2.1) will hold. Since $S(\epsilon)$ is near a curve of orthogonal matrices, which have full rank, the possible singularity

of A is not an issue for us. One can compute U_P directly from the singular value decomposition $A = U\Sigma V^T$ of A as $U_P = UV^T$. This is efficient when A is small. For large A, there are several efficient iterative methods [16, 18].

So, in the context of this paper, given a pair of $N \times N$ matrices $w = (A, B)^T$,

$$\mathcal{P}(w) = \begin{pmatrix} U_P^A \\ U_P^B \end{pmatrix},$$

where U_P^A and U_P^B are the orthogonal parts of the polar decompositions of A and B.

4.1.2. Convergence of the local method. In this section we will verify that (2.8) holds. The local method uses the reduced Gauss–Newton model Hessian, which requires the projection $P_T(u)$ onto the tangent space at a point $u \in \Omega$. One can compute that projection by noting that if $w(t)$ is a differentiable orthogonal matrix-valued function, then differentiating $w^T(t)w(t) = I$,

$$\frac{dw(t)^T w(t)}{dt} = \dot{w}(t)^T w(t) + w(t)^T \dot{w}(t) = 0,$$

and hence $w^T\dot{w}$ is skew-symmetric. This implies that the tangent space for the manifold of orthogonal matrices at a point U is the space of matrices W for which U^TW is skew-symmetric. The projection onto the tangent space can then be computed as follows. If $\{S_i\}$ is a Frobenius-orthonormal basis for the skew-symmetric matrices, then a Frobenius-orthonormal basis for the tangent space is $\{US_i\}$, which we can use to compute the projection. If we do this for each component of $u = (U, V)^T$, we obtain $P_T(u)$. Alternatively we could use

$$P_T(u) = \mathcal{P}'(u) \text{ for all } u \in \Omega\ , \tag{4.3}$$

which follows from the fact that $\mathcal{P}$ is a map-to-nearest.

The local method for $F(u) = 0$ uses $H(u) = (I - P_T(u)) + P_T(u)F'(u)P_T(u)$, and we will show that $u_+^{NL} = u_c - H(u_c)^{-1}F(u_c)$ satisfies $\|e_+^{NL}\| = O(\|e_c\|^2)$, which implies (2.8) and will allow us to apply Theorem 2.1. We do this by noting that for all $u \in \Omega$

$$\begin{aligned} F(u) &= P_T(u)F(u) = P_T(u)F'(u)e + O\left(\|e\|^2\right) \\ &= H(u)e - (I - P_T(u))e + P_T(u)F'(u)(I - P_T(u))e + O\left(\|e\|^2\right) \\ &= H(u)e + O\left(\|(I - P_T(u))e\| + \|e\|^2\right). \end{aligned} \tag{4.4}$$

If $u \in \Omega$ is near u^*, then we can use (4.3) and the Lipschitz continuity of $\mathcal{P}$ to conclude that

$$u = \mathcal{P}(u) = \mathcal{P}(u^*) + \mathcal{P}'(u)e + O\left(\|e\|^2\right) = P_T(u)e + O\left(\|e\|^2\right),$$

and so $(I - P_T(u))e = O(\|e\|^2)$. Hence $u_+^{NL} - u^* = u_c - u^* - H(u_c)^{-1}F(u_c) = O(\|e_c\|^2)$.

4.1.3. Computations. We take the example from [7], having orthonormalized the matrices $\{B_j\}_{j=0}^4$ with classical Gram–Schmidt and the Frobenius inner product. In Figure 4.1 we compare the relative performance of the three time-step management strategies SER-A, SER-B, and TTE. While TTE does poorly, it is interesting to see that both versions of SER do well.

We did not reduce δ to respond to increases in $\|\Psi\|$ in this example, and the SER-A and SER-B iterations still converged well.

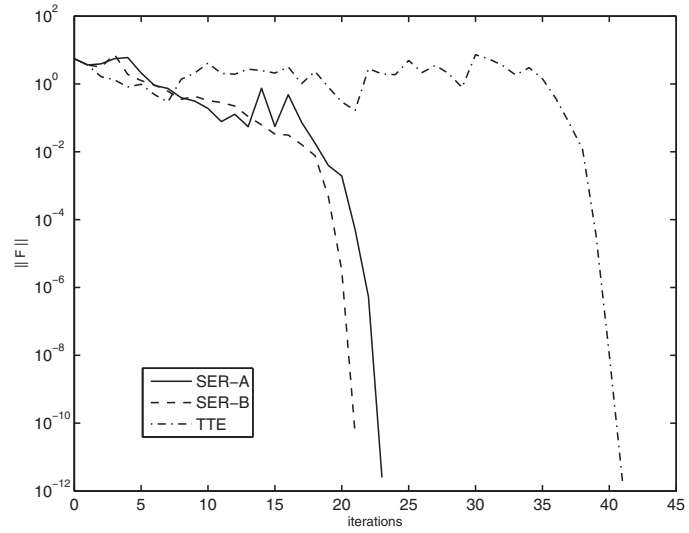

FIG. 4.1. *Inverse singular value problem.*

4.2. Inverse problem. This small ($N = 2$) example is taken from [3, 22]. We seek to identify the damping coefficient c and spring constant k for a simple harmonic oscillator. The governing differential equation is

$$w'' + cw' + kw = 0; \qquad w(0) = w_0, w'(0) = 0 \tag{4.5}$$

on the interval $[0, 1]$. We let $u = (c, k)^T$ and fit samples of the exact solution at 100 equally spaced points. We let $c = k = 1$ be the parameter values for the true solution and use `ode15s` from MATLAB to integrate (4.5) with the approximate parameters. The relative and absolute error tolerances were 10^{-6}.

The function to be minimized is

$$f(u) = \frac{1}{2} R(u)^T R(u) = \frac{1}{2} \sum_{i=1}^{100} (w^{exact}(t_i) - w_i(u))^2,$$

where $t_i = i/100$, $w_i(u)$ is the solution returned by `ode15s` with $u = (c, k)^T$, and w^{exact} is the solution of (4.5) with $(c, k) = (1, 1)$. The upper bounds are $[10, 10]$, and we consider three cases for the lower bounds: $[0, 0]$, placing the global minimizer in the interior of the feasible region, $[1, 0]$, placing the global minimizer on the boundary, and $[2, 0]$, placing the global minimizer outside. In the last case the solution of the unconstrained zero-residual problem does not satisfy the bound constraints. The residual at the optimal point for the constrained problem is 21.5.

The initial iterate in all cases was $(c, k) = (10, 10)$. In this computation we set $\delta_0 = 1/100$ and terminate the continuation when either the norm of the projected gradient $\|F\|$ has been reduced by a factor of 10^3 or $f < 10^{-6}$.

In Figure 4.2 we plot the values of f and $\|F\|$ as functions of the iteration count for several variations of Ψtc : SER-A (`ser-a`), SER-B (`ser-b`), TTE (`tte`), and the trust-region Levenberg–Marquardt method `lmtr` from [15]. We also compare them with the Levenberg–Marquardt line search method (`lmls`) from [22]. For SER-A, SER-B, and TTE, we rejected any step that increased the residual and decreased the time step by factors of 2 until either the residual decreased or $dt = 10^{-4}$. In the latter case we terminated the iteration.

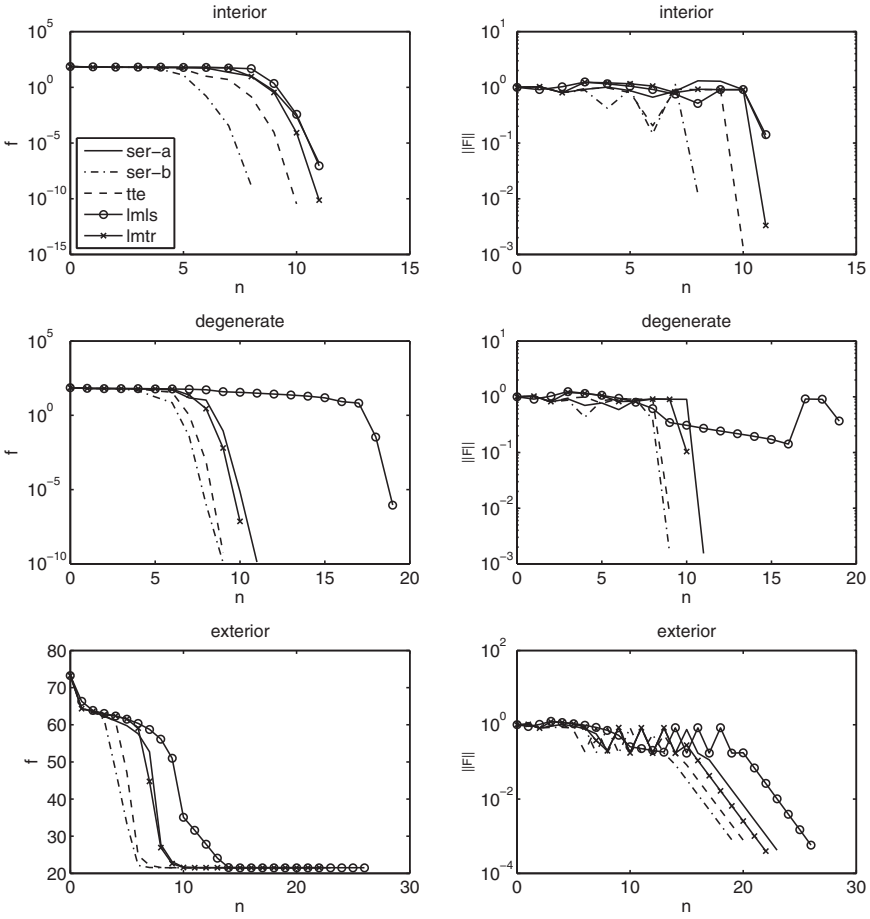

FIG. 4.2. *Parameter ID example.*

The damped Levenberg–Marquardt method from [22] is not as effective as the other four approaches, and SER-B is consistently better than the others.

5. Conclusions. We have described and analyzed a generalization of the pseudo-transient continuation algorithm which can be applied to a class of constrained nonlinear equations. The new approach can be applied to bound-constrained problems and to certain inverse eigenvalue and singular value problems.

We have reported on numerical testing which illustrates the performance of the method.

CONVERGENCE OF FOURIER-WAVELET MODELS FOR GAUSSIAN RANDOM PROCESSES*

O. KURBANMURADOV† AND K. SABELFELD‡

Abstract. Mean square convergence and convergence in probability of Fourier-wavelet models (FWM) of stationary Gaussian random processes in the metric of Banach space of continuously differentiable functions and in Sobolev space are studied. Sufficient conditions for the convergence formulated in the frame of spectral functions are given. It is shown that the given rates of convergence of FWM in the mean square obtained in the Nikolskiĭ–Besov classes cannot be improved.

Key words. Fourier-wavelet model, stationary Gaussian random process, Meyer's wavelets, Nikolskiĭ–Besov space, convergence in probability, convergence in mean square

AMS subject classifications. 65C05, 68U20, 62M40

1. Introduction.

Random processes and fields provide a convenient tool for a quantitative description of highly inhomogeneous and multiscale media such as, for instance, atmosphere, ocean, and soil (e.g., see [5], [17], [26], [29]).

The random fields are defined by all of their finite-dimensional distributions (e.g., see [12]). Fortunately, the most often used distributions in practice are Gaussian. The Gaussian random fields are defined uniquely by their expectations and covariances which greatly simplifies the measurement design. Along with the Gaussian random fields, one often exploits random fields which are obtained by some transformations of the Gaussian fields either through an explicit transform or implicitly through differential or integral equations where the Gaussian random fields are entered as random coefficients, random source terms, or boundary functions. As an important example we mention the hydraulic conductivity which is often modeled as a lognormal random field; e.g., see [5]. The Darcy flow itself is obtained as a random field which solves the Darcy equation with the lognormal hydraulic conductivity.

Another question about the structure of the random field which in practice is of extremely high importance is whether or not the random field is homogeneous. Unlike gaussianity, the most practically interesting random fields are nonhomogeneous. However, the homogeneous Gaussian random fields can be treated as perfect approximations in many cases, and they are indeed the most frequently used models in all branches of science and technology since the simulation technique based on the spectral representation is well developed.

Simulation of nonhomogeneous random fields is a much more difficult problem. The most completely developed are the Cholesky (singular) decomposition (e.g., see, [8], [32]) and Karhunen–Loeve expansion techniques (e.g., see, [40]). We also mention the wavelet decomposition method, which is applied to many interesting multiscale resolution problems; e.g., see [35], [41].

There is a very extensive literature on simulation of homogeneous random fields, and even for a short discussion of recent publications in this field we would need to write a large review article. So we mention here only some publications, and the reader can search further leading by the references inside these publications: [7], [8], [10], [11], [21], [23], [25], [28], [29], [30], [31], [32], [33], [34].

It should be mentioned that there are also a lot of publications devoted to a comparative analysis of the cost of the simulation algorithms, but as we have concluded in [18], the most competitive simulation method for multiscale random fields are the randomized spectral methods, Fourier-wavelet methods, and the wavelet decomposition technique (e.g., see, [2], [10], [11], [22]).

Having an approximate model u_N for our random field $u(x)$ (say, the parameter N is integer), we have to estimate the error between the statistical characteristics of u_N and $u(x)$. The convergence $u_N \to u$ as $N \to \infty$ can be defined differently: (i) convergence of the relevant finite-difference distributions and (ii) convergence in a relevant functional space. The convergence in function spaces is important for practical applications, and they were considered in many publications (e.g., for the spectral models, see [1], [19], [20], [39]). In [3], [4], the convergence of wavelet decomposition models is studied. As to the Fourier-wavelet models (FWM), the first convergence results were obtained in [21], where the convergence of the correlation function of the model process FWM $u_N(x)$, $B_N(x,r) = E(u_N(x+r)u_N(x))$, to the correlation function $B(r) = E(u(x+r)u(x))$ of the original Gaussian process $u(x)$ has been established. In the language of the spectral function $F(k)$, we have obtained an estimation of $\sup_{x,r\in\mathbb{R}} |B(r) - B_N(x,r)|$ which shows that this quantity can be made arbitrarily small as $N \to \infty$.

In this paper we study the convergence of FWM $u_N \to u$ as $N \to \infty$ in Sobolev spaces $W_2^n[a,b]$ and in the space of n-times continuously differentiable functions $C^n[a,b]$, where n is a nonnegative integer. We study conditions on the spectral function F which are sufficient for $E||\mathcal{E}_N||^2_{W_2^n[a,b]} \to 0$ and $||\mathcal{E}_N||_{C^n[a,b]} \xrightarrow{P} 0$ as $N \to \infty$. Here $[a,b] \subset \mathbf{R}$ is an arbitrary fixed finite interval, and $\mathcal{E}_N(x) = u(x) - u_N(x)$. To make the presentation clear, we first consider the case of a scalar random process $u(x)$ and give sufficient conditions for the convergence $E||\mathcal{E}_N||^2_{L_2[a,b]} \to 0$ and $||\mathcal{E}_N||_{C[a,b]} \xrightarrow{P} 0$ as $N \to \infty$. Then we give a relevant generalization of the results to vector processes and extend the study for some stronger metrics.

The paper is organized as follows. The definition of the FWM for Gaussian random processes is given in section 2. Convergence of FWM in $L_2[0,1]$ and an analysis of the quality of the derived estimates are presented in section 3. Convergence of FWM in the space $C[0,1]$ is given in section 4. In section 5 we study the convergence FWM in some stronger metrics (in spaces $W_p^n[0,1]$ and $C^n[0,1]$) and for vector processes. Conclusions are made in section 6. Finally, in the Appendix we give the proofs of Lemmas 4.1 and 4.2 and present some known results from the theory of Besov's space that we used in our work in the Appendix.

2. Fourier-wavelet models of Gaussian random processes.

2.1. Fourier-wavelet expansions of Gaussian random processes. Let us introduce the notation $\mathbf{u}(x) = (u_1(x), \dots, u_l(x))^T$, $x \in \mathbf{R} = (-\infty, \infty)$, for an l-dimensional real-valued Gaussian stationary (homogeneous) random process with zero mean and a given correlation tensor $B(r)$:

$$B_{ij}(r) = E[u_i(x+r)\, u_j(x)], \quad i,j = 1, \dots, l, \tag{2.1}$$

or the corresponding spectral tensor F:

(2.2)
$$F_{ij}(k) = \int_{-\infty}^{\infty} e^{-\mathrm{i}\,2\pi\,k\cdot r} B_{ij}(r)\,dr, \quad B_{ij}(r) = \int_{-\infty}^{\infty} e^{\mathrm{i}\,2\pi\,r\cdot k} F_{ij}(k)\,dk, \quad i,j = 1,\dots,l.$$

Here and throughout the paper E stands for mathematical expectation. Furthermore, we will assume that $\int_{-\infty}^{\infty} \sum_{j=1}^{l} B_{jj}^2(r)\,dr < \infty$, which ensures the existence of the spectral tensor F_{ij} in the space $L_2(\mathbb{R})$ [26]. Moreover, $B_{ii}(0) = Eu_i^2(x) < \infty$ implies $B_{ii}(0) = \int_{-\infty}^{\infty} F_{ii}(k)\,dk < \infty$, that is, $F \in L_1(\mathbb{R})$. Hence $F \in L_1(\mathbb{R}) \cap L_2(\mathbb{R})$.

For some positive integer n let $Q(k)$ be an $l \times n$-matrix satisfying the condition

$$Q(k)Q^*(k) = F(k), \quad Q(-k) = \bar{Q}(k). \tag{2.3}$$

Here the star stands for the complex conjugate transpose which is equivalent to taking two operations: the transpose ^{T} and the complex conjugation of each entry.

Let $\phi(x)$ and $\psi(x)$, $x \in \mathbb{R}$, be orthonormal scaling and wavelet functions (for the definitions see, e.g., [10], [24], [13]), respectively, and $\hat{\phi}(k)$ and $\hat{\psi}(k)$ are Fourier transformations of these functions:

$$\hat{\phi}(k) = \int_{-\infty}^{\infty} e^{-\mathrm{i}\,2\pi\,kx}\phi(x)dx, \quad \hat{\psi}(k) = \int_{-\infty}^{\infty} e^{-\mathrm{i}\,2\pi\,kx}\psi(x)dx.$$

Assume that $\hat{\phi}(k)$ and $\hat{\psi}(k)$ are even functions

$$\hat{\phi}(-k) = \bar{\hat{\phi}}(k), \quad \hat{\psi}(-k) = \bar{\hat{\psi}}(k). \tag{2.4}$$

Then the Fourier-wavelet expansion of the random process $\mathbf{u}(x)$ reads [10], [21]:

$$\mathbf{u}(x) = \sum_{j=-\infty}^{\infty} \mathcal{F}_{m_0}^{(\phi)}(2^{m_0}x + j)\,\boldsymbol{\xi}_j + \sum_{m=m_0}^{\infty}\sum_{j=-\infty}^{\infty} \mathcal{F}_{m}^{(\psi)}(2^{m}x + j)\,\boldsymbol{\xi}_{mj}, \tag{2.5}$$

where m_0 is an arbitrary (but fixed) integer, $\boldsymbol{\xi}_j$, $\boldsymbol{\xi}_{mj}$ $(j \in \mathbb{Z},\, m \geq m_0)$ is a family of mutually independent standard real-valued Gaussian random vectors of dimension n, and $\mathcal{F}^{(\phi)}(\cdot)$, $\mathcal{F}^{(\psi)}(\cdot)$ are $l \times n$-dimensional matrix functions defined by

$$\begin{aligned} \mathcal{F}_{m}^{(\phi)}(y) &= \int_{-\infty}^{\infty} e^{-\mathrm{i}\,2\pi\,ky}\,2^{m/2}\bar{Q}(2^m k)\hat{\phi}(k)\,dk, \\ \mathcal{F}_{m}^{(\psi)}(y) &= \int_{-\infty}^{\infty} e^{-\mathrm{i}\,2\pi\,ky}\,2^{m/2}\bar{Q}(2^m k)\hat{\psi}(k)\,dk. \end{aligned} \tag{2.6}$$

Since $B(0) = \int F(k)dk < \infty$, and $QQ^* = F$, we conclude that all of the entries of the matrix Q belong to $L_2(\mathbb{R})$. Therefore, the functions given by (2.6) are well-defined.

Let us give a comment concerning some difference between the Fourier-wavelet and wavelet decompositions. In both methods, the random process is represented as a series of deterministic functions weighted by a random Gaussian coefficient. The crucial difference is that, unlike the wavelet decomposition, in the Fourier-wavelet method these random coefficients are independent, which might be quite convenient in practical simulations; see, for instance, [18]. The wavelet decomposition is more general and can be used also to simulate inhomogeneous random fields [41].

Further, in Fourier-wavelet expansion (2.5) we will use Meyer's wavelet functions $\phi(x)$ and $\psi(x)$, which are defined by their Fourier transforms (e.g., see [6]):

$$\phi(x) = \int_{-\infty}^{\infty} e^{\mathrm{i}\,2\pi\,kx}\hat{\phi}(k)\,dk, \quad \psi(x) = \int_{-\infty}^{\infty} e^{\mathrm{i}\,2\pi\,kx}\hat{\psi}(k)\,dk, \tag{2.7}$$

where

$$\hat{\phi}(k)=\begin{cases}1, & |k|\le 1/3,\\ \cos\theta_{1k}, & 1/3\le|k|\le 2/3,\\ 0, & \text{otherwise},\end{cases}\qquad \hat{\psi}(k)=\begin{cases}e^{-\mathrm{i}\,\pi\,k}\sin\theta_{1k}, & 1/3\le|k|\le 2/3,\\ e^{-\mathrm{i}\,\pi\,k}\cos\theta_{2k}, & 2/3x\le|k|\le 4/3,\\ 0, & \text{otherwise},\end{cases}$$

where $\theta_{1k}=\frac{\pi}{2}\nu(3|k|-1)$ and $\theta_{2k}=\frac{\pi}{2}\nu(\frac{3}{2}|k|-1)$. Here $\nu(x)$ is a smooth function satisfying the following conditions: $\nu(x)\equiv 0$ for $x\le 0$, $\nu(x)\equiv 1$ for $x\ge 1$, and $\nu(x)+\nu(1-x)=1$ for $0<x<1$. As an example of such a function, we mention a function $\nu(x)=\nu_p(x)$ depending on a positive parameter p (see [10]):

$$\nu_p(x)=\frac{4^{p-1}}{p}\left\{[x-x_0]_+^p+[x-x_p]_+^p+2\sum_{j=1}^{p-1}(-1)^j\,[x-x_j]_+^p\right\},$$

where $x_j=(1/2)[\cos(((p-j)/p)\pi)+1]$ and $[a]_+=\max(a,0)$. The function ν_p is $p-1$ times continuously differentiable; therefore, by choosing p sufficiently large, we can make the functions $\hat{\phi}$ and $\hat{\psi}$ smooth enough.

2.2. Fourier-wavelet models. In the numerical implementation of (2.5) we have to find a reasonable choice of the cutoff parameters m_1 and b_0, b_m ($m=m_0,\dots,m_1$) in the approximations:

$$\sum_{j=-\infty}^{\infty}\mathcal{F}_{m_0}^{(\phi)}(2^{m_0}x+j)\,\boldsymbol{\xi}_j\simeq\sum_{j=-b-\lfloor 2^{m_0}x\rfloor}^{b-\lfloor 2^{m_0}x\rfloor}\mathcal{F}_{m_0}^{(\phi)}(2^{m_0}x+j)\,\boldsymbol{\xi}_j, \tag{2.8}$$

$$\sum_{m=m_0}^{\infty}\sum_{j=-\infty}^{\infty}\mathcal{F}_{m}^{(\psi)}(2^{m}x+j)\,\boldsymbol{\xi}_{mj}\simeq\sum_{m=m_0}^{m_1}\sum_{j=-b_m-\lfloor 2^{m}x\rfloor}^{b_m-\lfloor 2^{m}x\rfloor}\mathcal{F}_{m}^{(\psi)}(2^{m}x+j)\,\boldsymbol{\xi}_{mj}, \tag{2.9}$$

where $\lfloor a\rfloor$ stands for the integer part of a. The general idea is that b and b_m should be chosen so that supports of the functions $\mathcal{F}_{m_0}^{(\phi)}$ and $\mathcal{F}_{m}^{(\psi)}$ belong essentially to the intervals $[-b,b]$ and $[-b_m,b_m]$, respectively.

In previous papers on Fourier-wavelet models [2], [10], [18], [21], the authors use approximations of type (2.8)–(2.9). Unfortunately, functions staying in the right-hand sides of (2.8)–(2.9) are discontinuous in x (with the jump discontinuity). Therefore, to ensure that the samples of the approximation process are continuous, we have to modify the model. So let us define the following modification of the FWM of the random field $\mathbf{u}(x)$. Let $\{\mu_N\}_{N=1}^{\infty}$ be a sequence of positive integers, $\mu_N\ge m_0$, $N=1,2,\dots$, and $\{b_N\}_{N=1}^{\infty}$, $\{b_{mN}\}_{N=1}^{\infty}$, $m=0,\dots,\mu_N$ be sequences of positive real numbers depending on a positive integer N so that

$$\lim_{N\to\infty}\mu_N=\infty,\quad \lim_{N\to\infty}b_N=\infty,\quad \lim_{N\to\infty}b_{mN}=\infty,\quad m=0,1,\dots,\mu_N. \tag{2.10}$$

For fixed positive number A denote by $\eta_A(\cdot)$ a cutoff function $\eta_A:[0,\infty)\to[0,1]$ defined by

$$\eta_A(x)=\begin{cases}0, & 0\le x\le A,\\ 1, & x\ge A+1,\\ x-A, & A<x<A+1.\end{cases} \tag{2.11}$$

Define functions $\chi_N : \mathbb{R} \to [0,1]$ and $\chi_{mN} : \mathbb{R} \to [0,1]$, $m = 0, 1, \dots, \mu_N$, by assuming that

$$\chi_N(x) = \eta_{b_N}(|x|), \qquad \chi_{mN}(x) = \eta_{b_{mN}}(|x|),$$
$$\chi'_N(x) = 1 - \chi_N(x), \quad \chi'_{mN}(x) = 1 - \chi_{mN}(x).$$

Under FWM of the random process $\mathbf{u}(x)$ we understand the following sequence of random functions:

$$\mathbf{u}_N(x) = \sum_{j\in\mathbb{Z}} \chi'_N(2^{m_0}x + j) \cdot \mathcal{F}^{(\phi)}_{m_0}(2^{m_0}x + j)\, \boldsymbol{\xi}_j + \sum_{m=m_0}^{\mu_N} \sum_{j\in\mathbb{Z}} \chi'_{mN}(2^m x + j) \cdot \mathcal{F}^{(\psi)}_m(2^m x + j)\, \boldsymbol{\xi}_{mj}, \quad N = 1, 2, \dots . \tag{2.12}$$

Our aim is to study the convergence $\mathbf{u}_N \to \mathbf{u}$ as $N \to \infty$ in functional spaces $W_2^n[a,b]$ and $C^n[a,b]$, where n is a nonnegative integer. Here we suggest sufficient conditions on the spectral tensor F which ensure $E||\mathcal{E}_N||^2_{W_2^n[a,b]} \to 0$ and $||\mathcal{E}_N||_{C^n[a,b]} \xrightarrow{P} 0$ as $N \to \infty$. Here $[a,b] \subset \mathbf{R}$ is an arbitrary fixed finite interval, and $\mathcal{E}_N(x) = u(x) - u_N(x)$. Further, not losing in generality, we can take $[a,b] = [0,1]$, and $m_0 = 0$. Moreover, for the simplicity of presentation we first consider the case of a scalar random process $u(x)$ (i.e., $l = 1$) and give sufficient conditions for the convergence $E||\mathcal{E}_N||^2_{L_2[a,b]} \to 0$ and $||\mathcal{E}_N||_{C[a,b]} \xrightarrow{P} 0$ as $N \to \infty$. In section 5 we give relevant generalizations of results for vector processes and stronger metrics.

3. Convergence of FWM in the L_2 metric. Let $u(x)$, $x \in \mathbb{R}$, be a real-valued scalar stationary zero mean Gaussian random process with a spectral function $F(k)$, and let $\phi(x)$ and $\psi(x)$ be orthonormal Meyer's scaling and wavelet functions, respectively. It is clear that their Fourier transforms $\hat{\phi}(k)$ and $\hat{\psi}(k)$ are even functions. In this case the FWM of $u(x)$ is (see (2.12) and recall that $m_0 = 0$):

$$u_N(x) = \sum_{j\in\mathbb{Z}} \chi'_N(x + j) \cdot \mathcal{F}^{(\phi)}_0(x + j)\, \xi_j + \sum_{m=0}^{\mu_N} \sum_{j\in\mathbb{Z}} \chi'_{mN}(2^m x + j) \cdot \mathcal{F}^{(\psi)}_m(2^m x + j)\, \xi_{mj}, \tag{3.1}$$

where ξ_j, ξ_{mj}, $m = 0, 1, \dots$; $j \in \mathbb{Z}$ is a set of mutually independent standard Gaussian random variables.

Let us introduce some notation: $\Delta = [-4/3,\, 4/3]$, $\Delta_m = [-4 \cdot 2^m/3,\, -2^m/3] \cup [2^m/3,\, 4 \cdot 2^m/3]$, $m = 0, 1, 2, \dots$, and $\Delta' = \cup_{m=0}^{\infty} \Delta_m$. For a function $f : \mathbb{R} \to \mathbb{R}$ and $D \subset \mathbb{R}$ we denote by $f|_D$ the restriction of the function f in D. For a measurable $D \subset \mathbb{R}$ we write $|D| = \int_D dx$.

In this paper we use some results from the theory of Nikolskiĭ–Besov spaces (e.g., see [27], [37]). For $r > 0$, a triple (r, j, l) is called admissible if $j \in \mathbb{N}$, $l \in \mathbb{N}_0$, and $j > r - l > 0$. Here $\mathbb{N}_0 = \{0, 1, 2, \dots\}$ and $\mathbb{N} = \{1, 2, \dots\}$. Let us denote by $\Delta_h^{(j)} g$ the jth difference of g:

$$\Delta_h g(\cdot) = g(\cdot + h) - g(\cdot), \dots, \Delta_h^{(j)} g(\cdot) = \Delta_h \Delta_h^{(j-1)} g(\cdot).$$

For $1 \le p, q \le \infty$, and $r > 0$, the Nikolskiĭ–Besov space $B^r_{pq}(\mathbb{R})$ is defined as the set of all functions $f \in L_p$ such that the norm

$$||f||_{B^r_{pq}} = ||f||_{L_p} + ||f||_{b^r_{pq}},$$

where

$$||f||_{b^r_{pq}} = \left(\int_{-1}^{1} \left(\frac{||\Delta_h^{(j)} f^{(l)}||_{L_p}}{|h|^{r-l}} \right)^q \frac{dh}{|h|} \right)^{\frac{1}{q}} \quad (1 \le q < \infty), \quad \text{and}$$

$$||f||_{b^r_{p\infty}} = \sup_{0<|h|\le 1} |h|^{\,l-r}\, ||\Delta_h^{(j)} f^{(l)}||_{L_p}$$

makes sense and is finite for some admissible triple (r, j, l). Here $f^{(l)}(x) = D^l f(x)$ is the lth derivative of the function f. The ambiguity in the choice of triple (r, j, l) is not essential: Different admissible triples correspond to equivalent norms. For a measurable subset $D \subset \mathbb{R}$, the space $B^r_{pq}(D)$ is defined as above but by changing $||\cdot||_{L_p}$ with $||\cdot||_{L_p(D_{jh})}$, where $D_h = \{x \in D : x + \lambda h \in D \text{ for all } \lambda \in [0,1]\}$. For a function $f : \mathbb{R} \to \mathbb{R}$ such that $f|_D \in B^r_{pq}(D)$ we will simply write $||f||_{B^r_{pq}(D)}$ instead of the more exact but complex notation $||(f|_D)||_{B^r_{pq}(D)}$.

We will exploit the following imbeddings (e.g., see [27], [37]):

$$B^r_{pq}(\mathbb{R}) \hookrightarrow B^{\rho}_{p_1 q}(\mathbb{R}), \quad \rho = r\left(1 - \frac{1}{r} \cdot \left[\frac{1}{p} - \frac{1}{p_1}\right]\right), \quad 1 \le p < p_1 < \infty, \tag{3.2}$$

$$B^{r+\varepsilon}_{p\infty}(\mathbb{R}) \hookrightarrow B^r_{pq}(\mathbb{R}) \hookrightarrow B^r_{pq_1}(\mathbb{R}), \quad 1 \le q < q_1 \le \infty, \quad \varepsilon > 0, \tag{3.3}$$

where $X \hookrightarrow Y$ means that $X \subset Y$ for seminormed spaces X and Y and there exists a constant $c > 0$ such that the inequality $||x||_Y \le c||x||_X$ is fulfilled.

3.1. Main results on convergence of FWM in the mean square. Let us formulate two assumptions on the functions $F(k)$ and $Q(k) = (F(k))^{1/2}$.

(H0): For some $s > 0$

$$I_s \stackrel{def}{=} \int_{-\infty}^{\infty} F(k)(1 + |k|^2)^s dk < \infty; \tag{3.4}$$

(H1): there exist positive constants c_0, ε, $\rho_0 > 1/2$, and $\rho_1 > 1/2$ and positive integer m_0 such that

$$\begin{aligned} &\text{(i) } Q|_\Delta \in B^{\rho_0}_{1\infty}(\Delta),\ Q|_{\Delta_0} \in B^{\rho_0}_{1\infty}(\Delta_0),\ \ldots,\ Q|_{\Delta_{m_0-1}} \in B^{\rho_0}_{1\infty}(\Delta_{m_0-1});\\ &\text{(ii) } Q|_{\Delta_m} \in B^{\rho_1}_{1\infty}(\Delta_m), \quad m \ge m_0;\\ &\text{(iii) } ||Q||_{b^{\rho_1}_{1\infty}(\Delta_m)} \le c_0 \cdot 2^{-m(\rho_1 - 1/2 + \varepsilon)}, \quad m \ge m_0. \end{aligned} \tag{3.5}$$

THEOREM 3.1. *Assume that the spectral function $F(k)$ satisfies the condition* (H0). *Let $\{\rho_m\}_{m=0}^{\mu_N}$ be a finite sequence of positive numbers such that* $\min_m \rho_m > 1/2$. *Suppose that $Q|_\Delta \in B^{\rho_0}_{1\infty}(\Delta)$ and $Q|_{\Delta_m} \in B^{\rho_m}_{1\infty}(\Delta_m)$ for $1 \le m \le \mu_N$, and assume that the Meyer wavelet functions ϕ and ψ belong to the class $C^{\nu+1}$ for $\nu =$* $\max\{\lfloor\rho\rfloor, \lfloor s\rfloor\}$, *where $\rho = \max_{0\le m\le\mu_N} \rho_m$. Then*

$$\begin{aligned} E(u(x) - u_N(x))^2 &\le \frac{C_1(s,\psi)}{4^{s(\mu_N+1)}} \cdot I_s + \frac{C_2(\rho_0,\phi)}{b_N^{2\rho_0-1}} ||Q||^2_{B^{\rho_0}_{1\infty}(\Delta)}\\ &+ \sum_{m=0}^{\mu_N} \frac{C_3(\rho_m,\psi)}{b_{mN}^{2\rho_m-1}} \cdot \left(2^{-m}||Q||^2_{L_1(\Delta_m)} + 2^{2m(\rho_m-1/2)}||Q||^2_{b^{\rho_m}_{1\infty}(\Delta_m)}\right), \end{aligned} \tag{3.6}$$

where constants C_i, $i = 1, 2, 3$, depend only on the shown arguments.

Proof. From the definition (3.1) we have

$$u(x) = u_N(x) + v^{(1)}(x) + \sum_{m=0}^{\mu_N} v_m^{(2)}(x) + v^{(3)}(x), \tag{3.7}$$

where

$$\begin{aligned} v^{(1)}(x) &= \sum_{j\in\mathbb{Z}} \chi_N(x+j)\cdot \mathcal{F}_0^{(\phi)}(x+j)\,\xi_j\,, \\ v_m^{(2)}(x) &= \sum_{j\in\mathbb{Z}} \chi_{mN}(2^m x+j)\cdot \mathcal{F}_m^{(\psi)}(2^m x+j)\,\xi_{mj}\,, \\ v^{(3)}(x) &= \sum_{m=\mu_N+1}^{\infty}\ \sum_{j=-\infty}^{\infty} \mathcal{F}_m^{(\psi)}(2^m x+j)\,\xi_{mj}\,. \end{aligned}$$

The random variables ξ_j and ξ_{mj} are mutually independent; hence the terms in the right-hand side of (3.7) are also independent, and therefore

$$E(u(x)-u_N(x))^2 = E(v^{(1)}(x))^2 + \sum_{m=0}^{\mu_N} E(v_m^{(2)}(x))^2 + E(v^{(3)}(x))^2. \tag{3.8}$$

Let us estimate the terms in the right-hand side. First, we have for the last term

$$E(v^{(3)}(x))^2 = \sum_{m=\mu_N+1}^{\infty}\ \sum_{j=-\infty}^{\infty} |\mathcal{F}_m^{(\psi)}(2^m x+j)|^2. \tag{3.9}$$

Further, from the definition (2.6) of the function $\mathcal{F}$, and since the functions $Q(k)$ and $\psi(k)$ are even, we have

$$\mathcal{F}_m^{(\psi)}(y) = \int_{-\infty}^{\infty} e^{-\mathrm{i}2\pi k y} 2^{m/2}\bar{Q}(2^m k)\hat{\psi}(k)dk = \int_{-\infty}^{\infty} e^{\mathrm{i}2\pi k y} 2^{m/2} Q(2^m k)\bar{\hat{\psi}}(k)dk.$$

Therefore,

$$\begin{aligned} \mathcal{F}_m^{(\psi)}(2^m x+j) &= \int_{-\infty}^{\infty} e^{\mathrm{i}2\pi k(2^m x+j)} 2^{m/2} Q(2^m k)\bar{\hat{\psi}}(k)dk \\ &= \int_{-\infty}^{\infty} e^{\mathrm{i}2\pi k x} Q(k)\bar{\hat{\psi}}_{mj}(k)\,dk \\ &= \int_{-\infty}^{\infty} G(x+y)\psi_{mj}(y)dy, \end{aligned} \tag{3.10}$$

where $G(x) = \int_{-\infty}^{\infty} e^{\mathrm{i}2\pi k x} Q(k)\,dk$, and

$$\psi_{mj}(x) = 2^{m/2}\psi(2^m x - j), \quad \hat{\psi}_{mj}(k) = 2^{-m/2}\, e^{-\mathrm{i}\,2\pi\, k\, j\, 2^{-m}}\, \hat{\psi}(2^{-m} k).$$

Consequently for fixed x, the quantities $\mathcal{F}_m^{(\psi)}(2^m x+j)$ $(m,j\in\mathbb{Z})$ are Fourier coefficients in the expansion of $G(x+\cdot)$ with respect to the orthonormal system ψ_{mj} $(m,j\in\mathbb{Z})$.

Notice that the condition (3.4) is equivalent to the fact that the function G belongs to the Sobolev space $H_2^s(\mathbb{R})$. This is because $G\in H_2^s(\mathbb{R})$ means that the function

$Q(k)(1+|k|^2)^{s/2}$ is in $L_2(\mathbb{R})$ and $||G||_{H_2^s} = I_s^{1/2}$ (more details in [37]). Furthermore, we use the fact that $H_2^s(\mathbb{R})$ coincides with the Besov space $B_{22}^s(\mathbb{R})$, and the norms in these spaces are equivalent (see [37, section 2.3.9]). Since $G \in B_{22}^s$, we conclude by virtue of Corollary A.3 that

$$\sum_{j=-\infty}^{\infty} |\mathcal{F}_m^{(\psi)}(2^m x + j)|^2 \le B_s^2\, 4^{-ms} \cdot ||G(x+\cdot)||_{H_2^s}^2 \tag{3.11}$$

for some $B_s = B_s(\psi)$ depending only on s and ψ. From this we get by $||G(x+\cdot)||_{H_2^s}^2 = ||G||_{H_2^s}^2 = I_s$ that

$$E(v^{(3)}(x))^2 = \sum_{m=\mu_N+1}^{\infty} \sum_{j=-\infty}^{\infty} |\mathcal{F}_m^{(\psi)}(2^m x + j)|^2 \le \frac{B_s^2}{4^{(\mu_N+1)s}}\, I_s. \tag{3.12}$$

Now we turn to the estimation of the first two terms of the right-hand side (r.h.s.) of (3.8). It is obvious, due to the independence of random variables $\xi_j,\ j \in \mathbb{Z}$, that

$$E(v^{(1)}(x))^2 = \sum_{j\in\mathbb{Z}} |\chi_N(x+j)|^2 \cdot |\mathcal{F}_0^{(\phi)}(x+j)|^2 \le \sum_{j\in\mathbb{Z}:\, |x+j|\ge b_N} |\mathcal{F}_0^{(\phi)}(x+j)|^2. \tag{3.13}$$

We first estimate each term of this sum. The function $\mathcal{F}_0^{(\phi)}(y)$ has the Fourier transform $\hat{\mathcal{F}}(k) = Q(-k)\hat{\phi}(-k) = Q(k)\hat{\phi}(-k)$ (see (2.6)). Due to the conditions $\phi \in C^{\nu+1}$ and $Q|_\Delta \in B_{1\infty}^{\rho_0}(\Delta)$ it follows from Corollary A.2 that $||\hat{\mathcal{F}}||_{B_{1\infty}^{\rho_0}(\mathbb{R})} \le C(\rho_0,\phi)||Q||_{B_{1\infty}^{\rho_0}(\Delta)}$. Then from Lemma A.1 we get

$$|\mathcal{F}_0^{(\phi)}(y)| \le \frac{C(\rho_0,\phi)}{|y|^{\rho_0}} \cdot ||\hat{\mathcal{F}}||_{B_{1\infty}^{\rho_0}(\mathbb{R})} \le \frac{C(\rho_0,\phi)}{|y|^{\rho_0}} \cdot ||Q||_{B_{1\infty}^{\rho_0}(\Delta)}. \tag{3.14}$$

Note that from (3.13) and (3.14) we get

$$E(v^{(1)}(x))^2 \le \frac{C(\rho_0,\phi)}{b_N^{2\rho_0-1}} \cdot ||Q||_{B_{1\infty}^{\rho_0}(\Delta)}^2. \tag{3.15}$$

Let us turn to estimating the terms $E(v_m^{(2)}(x))^2$, $m = 0,\dots,\mu_N$. Denote by Q_m the function $Q_m : \Delta_0 \to \mathbb{R}$ defined as $Q_m(k) = Q(2^m k)$. Then by the same arguments as we used in the derivation of estimate (3.15), we obtain

$$\begin{aligned} E(v_m^{(2)}(x))^2 &\le \sum_{j\in\mathbb{Z}:\, |2^m x+j|\ge b_{mN}} |\mathcal{F}_m^{(\psi)}(2^m x + j)|^2 \le \frac{C(\rho_m,\psi)}{b_{mN}^{2\rho_m-1}} \cdot 2^m ||Q_m||_{B_{1\infty}^{\rho_m}(\Delta_0)}^2 \\ &\le \frac{C(\rho_m,\psi)}{b_{mN}^{2\rho_m-1}} \cdot 2^m \cdot \left(2||Q_m||_{L_1(\Delta_0)}^2 + ||Q_m||_{b_{1\infty}^{\rho_m}(\Delta_0)}^2\right). \end{aligned} \tag{3.16}$$

Put $l = \lfloor \rho_m \rfloor - 1$. Then

$$||Q_m||_{b_{1\infty}^{\rho_m}(\Delta_0)} = \sup_{|h|\le 1} \frac{1}{|h|^{\rho_m - l}} \int_{\Delta_{0,2h}} |\Delta_h^{(2)} Q_m^{(l)}(k)|\, dk. \tag{3.17}$$

Define a function $g_h : \Delta_m \to \mathbb{R}$ by $g_h(k) = \Delta_h^{(2)} Q^{(l)}(k)$. Then $\Delta_h^{(2)} Q_m^{(l)}(k) = 2^{ml} g_{2^m h}(2^m k)$. Therefore,

$$\begin{aligned} ||Q_m||_{b_{1\infty}^{\rho_m}(\Delta_0)} &= \sup_{|h|\le 1} \frac{1}{|h|^{\rho_m - l}} \int_{\Delta_{0,2h}} 2^{ml} |g_{2^m h}(2^m k)|\, dk \\ &= \sup_{|h|\le 1} \frac{2^{-m}}{|h|^{\rho_m - l}} \int_{\Delta_{m,2^{m+1}h}} 2^{ml} |g_{2^m h}(k)|\, dk\,. \end{aligned} \tag{3.18}$$

By the definition we have

$$\int_{\Delta_{m,2h}} |g_h(k)|\,dk = \int_{\Delta_{m,2h}} |\Delta_h^{(2)} Q^{(l)}(k)| \le ||Q||_{b_{1\infty}^{\rho_m}(\Delta_m)} |h|^{\rho_m - l}, \quad h \in \mathbb{R}. \tag{3.19}$$

Therefore it follows from (3.18) and (3.19) that

$$||Q_m||_{b_{1\infty}^{\rho_m}(\Delta_0)} \le 2^{m(\rho_m-1)} ||Q||_{b_{1\infty}^{\rho_m}(\Delta_m)}. \tag{3.20}$$

Now by taking into account that $||Q_m||_{L_1(\Delta_0)} \le 2^{-m} \cdot ||Q||_{L_1(\Delta_m)}$ and using the estimates (3.16) and (3.20), we obtain

$$E(v_m^{(2)}(x))^2 \le \frac{2C(\rho_m,\psi)}{b_{mN}^{2\rho_m-1}} \cdot \left(2^{-m}||Q||_{L_1(\Delta_m)}^2 + 2^{m(2\rho_m-1)}||Q||_{b_{1\infty}^{\rho_m}(\Delta_m)}^2\right) \tag{3.21}$$

for $m = 0, 1, \ldots, \mu_N$. This completes the proof of Theorem 3.1. □

PROPOSITION 3.1. *Assume that*

$$\lim_{N\to\infty} \mu_N = \infty, \quad \lim_{N\to\infty} b_N = \infty, \quad \lim_{N\to\infty} \min_{0\le m\le \mu_N} \{b_{mN}\} = \infty. \tag{3.22}$$

Then under the assumptions (H0)–(H1)*,*

$$\sup_{x\in[0,1]} E\mathcal{E}_N^2(x) \to 0 \quad as \quad N \to \infty. \tag{3.23}$$

Proof. Indeed, as a simple consequence of Theorem 3.1 we have

$$\begin{aligned}\sup_{x\in[0,1]} E\mathcal{E}_N^2(x) \le{}& \frac{C_1(s,\psi)}{4^{s(\mu_N+1)}} \cdot I_s + \frac{C_2(\rho_0,\phi)}{b_N^{2\rho_0-1}} ||Q||_{B_{1\infty}^{\rho_0}(\Delta)}^2 \\ &+ \sum_{m=0}^{m_0-1} \frac{C_3(\rho_0,\psi)}{b_{mN}^{2\rho_0-1}} \cdot \left(2^{-m}||Q||_{L_1(\Delta_m)}^2 + 2^{2m(\rho_0-1/2)}||Q||_{b_{1\infty}^{\rho_0}(\Delta_m)}^2\right) \\ &+ \sum_{m=m_0}^{\mu_N} \frac{C_3(\rho_1,\psi)}{b_{mN}^{2\rho_1-1}} \cdot \left(2^{-m}||Q||_{L_1(\Delta_m)}^2 + 2^{2m(\rho_1-1/2)}||Q||_{b_{1\infty}^{\rho_1}(\Delta_m)}^2\right). \end{aligned} \tag{3.24}$$

To show (3.23), it is sufficient to check that the last sum in the r.h.s. of this inequality converges to zero as $N \to \infty$. For this sake, for given $\delta > 0$, let us choose $N_0 = N_0(\delta)$ so that

$$\min_{0\le m\le \mu_N} \frac{1}{b_{mN}^{2\rho_1-1}} \le \delta, \quad N \ge N_0.$$

Denote by S_N the last sum in the r.h.s. of (3.24). Then due to the condition (3.5) we get for $N \ge N_0$

$$S_N \le C_3(\rho_1,\psi) \cdot \delta \cdot \left(\sum_{m=0}^{\infty} 2^{-m}||Q||_{L_1(\Delta_m)}^2 + c_0 \cdot \sum_{m=0}^{\infty} 2^{-2\varepsilon m}\right).$$

From

$$||Q||_{L_1(\Delta_m)}^2 \le |\Delta_m| \cdot \int_{\Delta_m} F(k)\,dk$$

and due to the assumption (H0), we get

$$||Q||^2_{L_1(\Delta_m)} \le |\Delta_m|(3\cdot 2^{-m})^{2s}\cdot I_s = 2\cdot 2^m(3\cdot 2^{-m})^{2s}\cdot I_s.$$

This implies that $S_N \le C\cdot\delta$ for $N \ge N_0(\delta)$ with a constant C which is not dependent on N. Since the parameter δ can be chosen arbitrarily small, $S_N \to 0$ as $N \to \infty$. The proof of Proposition 3.1 is complete. □

A straightforward consequence of Theorem 3.1 is the following assertion on the rate of the mean square convergence of FWM (3.1).

COROLLARY 3.1. *Assume that the hypotheses* (H0)–(H1) *are valid. Choose in the model* (3.1)

$$\mu_N = \left\lfloor \frac{(2\rho_0-1)}{2s}\cdot\log_2 N\right\rfloor + 1, \quad b_N = N, \quad b_{mN} = N,\ 0 \le m \le m_0 - 1;$$

$$b_{mN} = N^{\frac{2\rho_0-1}{2\rho_1-1}},\ m_0 \le m \le \mu_N. \tag{3.25}$$

Assume that $\phi,\ \psi \in C^{\nu+1}$, *where* $\nu = \max\{\lfloor s\rfloor,\ \lfloor\rho_0\rfloor,\ \lfloor\rho_1\rfloor\}$. *Then for each positive integer* N *the following estimation is valid:*

$$\sup_{x\in[0,1]} E\mathcal{E}_N^2(x) \le C\cdot N^{-(2\rho_0-1)}, \tag{3.26}$$

where C *is a constant not depending on* N.

3.2. Sufficient conditions for validity of (3.5). From the results given above it follows that the condition (3.5) is crucial in the analysis of the mean square convergence of FWM.

PROPOSITION 3.2. *For a nonnegative* k_0 *and a nonnegative integer* l, *assume that* $Q \in W_1^l(k_0,\infty)$ *and*

$$|\Delta_h^{(2)}Q^{(l)}(k)| \le \frac{C|h|^\gamma}{k^{l+1/2+\gamma+\varepsilon}} \quad \forall h\in[-1,1] \quad \text{and} \quad \forall k \ge k_0 \tag{3.27}$$

for some positive numbers C, ε *and* $\gamma \in (0,2)$. *Then the following estimate is true:*

$$||Q||_{b^{\rho_1}_{1\infty}(\Delta_m)} \le c_0\cdot 2^{-m(\rho_1-1/2+\varepsilon)} \quad \forall\ m \ge \log_2(3k_0), \tag{3.28}$$

where $\rho_1 = l+\gamma$ *and* $c_0 = c_0(\rho_1,\varepsilon)$.

Proof. Since the triple $(l+\gamma, 2, l)$ is admissible,

$$||Q||_{b^{\rho_1}_{1\infty}(\Delta_m)} \le C(\rho_1)\sup_{|h|\le 1}\frac{1}{|h|^\gamma}\int_{\Delta_m}|\Delta_h^{(2)}Q^{(l)}(k)|\,dk.$$

Therefore, for $2^m > 3k_0$ we have

$$||Q||_{b^{\rho_1}_{1\infty}(\Delta_m)} \le C(\rho_1)\sup_{|h|\le 1}\frac{1}{|h|^\gamma}\int_{\Delta_m}\frac{C|h|^\gamma}{k^{l+1/2+\gamma+\varepsilon}}\,dk \le c_0(\rho_1,\varepsilon)\cdot 2^{-m(\rho_1-1/2+\varepsilon)}. \qquad \square$$

COROLLARY 3.2. *Assume that for a nonnegative* k_0 *and positive integer* n, $Q \in W_1^n(k_0,\infty)$ *and*

$$|Q^{(n)}(k)| \le \frac{C}{k^{n+1/2+\varepsilon}} \quad \forall k \ge k_0 \tag{3.29}$$

for some positive numbers C and ε. Then the following estimate is valid:

$$||Q||_{b^n_{1\infty}(\Delta_m)} \le c_0 \cdot 2^{-m(n-1/2+\varepsilon)} \quad \forall\ m \ge \log_2(3(k_0+2)) \tag{3.30}$$

for some positive $c_0 = c_0(n,\varepsilon)$.

Proof. Indeed,

$$\begin{aligned}|\Delta_h^{(2)} Q^{(n-1)}(k)| &\le |\Delta_h Q^{(n-1)}(k+h)| + |\Delta_h Q^{(n-1)}(k+h)| \\ &\le h \cdot |Q^{(n)}(k+\beta h)| + h \cdot |Q^{(n)}(k+\alpha h)|\end{aligned}$$

for some $\alpha \in [0,1]$ and $\beta \in [1,2]$. Hence, by virtue of (3.29)

$$|\Delta_h^{(2)} Q^{(n-1)}(k)| \le \frac{C_1 h}{k^{n+1/2+\varepsilon}} \quad \forall k \ge k_0 + 2\,.$$

Therefore for $l = n-1$ and $\gamma = 1$ all of the conditions of Proposition 3.2 are fulfilled. □

Remark 3.1. Conditions (3.27) and (3.29) can be replaced with the following weaker conditions:

$$\int_{k_0}^{\infty} k^{l+\gamma-1/2+\varepsilon} \cdot \frac{|\Delta_h^{(2)} Q^{(l)}(k)|}{|h|^\gamma} \cdot dk < \infty \text{ and } \int_{k_0}^{\infty} k^{n-1/2+\varepsilon} |Q^{(n)}(k)|\, dk < \infty,$$

respectively.

3.3. Cost estimations for FWM. Now let us discuss the efficiency of FWM. Let us denote by T_N the number of arithmetic operations for calculation of the value of FWM (3.1) in one point $x \in \mathbb{R}$. It is obvious that $T_N \sim b_N + \sum_{m=0}^{\mu_N} b_{mN}$. Here $T_N \sim a_N$ means that there exist constants $0 < C_1 \le C_2$ not depending on N such that $C_1 a_N \le T_N \le C_2 \cdot a_N$. Therefore, if we choose the parameters of the FWM in accordance with (3.25), then under the conditions of Corollary 3.1 it follows that

$$\begin{aligned} T_N &\sim N \quad \text{if} \quad \rho_1 > \rho_0; \\ T_N &\sim N \ln N \quad \text{if} \quad \rho_1 = \rho_0; \\ T_N &\sim N^{(2\rho_0-1)/(2\rho_1-1)} \ln N \quad \text{if} \quad \rho_1 < \rho_0. \end{aligned} \tag{3.31}$$

Let us denote

$$\varepsilon_N = \left(\int_0^1 E(u(x) - u_N(x))^2 dx \right)^{1/2} = \left(E||\mathcal{E}_N||^2_{L_2[0,1]} \right)^{1/2}$$

the root mean square discrepancy of FWM (3.1) in the $L_2[0,1]$ metric. Then under the conditions of Corollary 3.1 the following estimate holds:

$$\varepsilon_N \le C \cdot N^{-(\rho_0 - 1/2)}, \qquad N = 1, 2, \ldots, \tag{3.32}$$

where C is some positive constant not depending on N. Hence under the conditions of Corollary 3.1 the number of operations T_ε required to achieve a given value of the r.m.s. error $\varepsilon_N = \varepsilon$ satisfies the estimates

$$\begin{aligned} T_\varepsilon &\lesssim \varepsilon^{-1/(\rho_0-1/2)} \quad \text{if} \quad \rho_1 > \rho_0; \\ T_\varepsilon &\lesssim \varepsilon^{-1/(\rho_0-1/2)} \ln \varepsilon \quad \text{if} \quad \rho_1 = \rho_0; \\ T_\varepsilon &\lesssim \varepsilon^{-1/(\rho_1-1/2)} \ln \varepsilon \quad \text{if} \quad \rho_1 < \rho_0. \end{aligned} \tag{3.33}$$

Here $T_\varepsilon \lesssim a(\varepsilon)$ means that there exists a constant C not depending on ε such that $T_\varepsilon \le C \cdot a(\varepsilon)$.

3.4. Analysis of the estimates (3.15)–(3.16). In this section we show that the exponents $2\rho_0 - 1$ and $2\rho_m - 1$ appearing in the estimates (3.15)–(3.16) cannot be improved in the Nikolskiĭ–Besov spaces $B^{\rho_0}_{1\infty}$ and $B^{\rho_m}_{1\infty}$, respectively. This will be done by the construction of a function Q which makes it possible to write $E(v^{(1)}(x))^2 \sim b_N^{-(2\rho_0-1)}$ and $E(v^{(2)}(x))^2 \sim b_{mN}^{-(2\rho_m-1)}$.

Let us consider the following example.

Example 3.1. Let $k_0 \geq 0$ and $\rho > 0$. Define

$$Q_0(k) = \begin{cases} 0, & 0 \leq k \leq k_0, \\ (k-k_0)^{\rho-1}, & k > k_0, \end{cases} \tag{3.34}$$

$$Q_0(k) = Q_0(-k) \quad \text{if} \quad k < 0.$$

Let $q : \mathbb{R} \to [0, \infty)$ be an arbitrary $(l+1)$-times differentiable even function with compact support satisfying the condition $q(k_0) \neq 0$. Within this section we denote $l = \lfloor \rho \rfloor$. Define $Q(k) = q(k)Q_0(k)$. From the definitions it follows that $Q \in B^{\rho}_{1\infty}$.

Now let us consider the asymptotic behavior of functions $\mathcal{F}_0^{(\phi)}(y)$, $\mathcal{F}_m^{(\psi)}(y)$ as $y \to \infty$. We will separately consider two cases: (i) ρ is noninteger and (ii) ρ is integer.

3.4.1. Asymptotics of $\mathcal{F}_0^{(\phi)}$ and $\mathcal{F}_m^{(\psi)}$ for noninteger ρ. Let us first assume that $k_0 < 2/3$ and $\hat{\phi} \in C^l$ and consider the function $\mathcal{F}_0^{(\phi)}(y)$. If we denote $g = q\hat{\phi}$, then

$$\begin{aligned} \mathcal{F}_0^{(\phi)}(y) &= \int_{-\infty}^{\infty} e^{-\mathrm{i}\,2\pi\,ky} \cdot Q(k)\hat{\phi}(k)\,dk = \int_{-\infty}^{\infty} e^{-\mathrm{i}\,2\pi\,ky} \cdot Q_0(k)g(k)\,dk \\ &= \frac{1}{(-\mathrm{i}2\pi y)^l} \int_{-\infty}^{\infty} e^{-\mathrm{i}\,2\pi\,ky} \cdot (Q_0 g)^{(l)}(k)\,dk \\ &= \frac{1}{(-\mathrm{i}2\pi y)^l} \int_{-\infty}^{\infty} e^{-\mathrm{i}\,2\pi\,ky} \cdot [Q_0^{(l)}(k)g(k) + \mathcal{R}(k)]\,dk, \end{aligned}$$

where $\mathcal{R}(k) = \sum_{j=0}^{l-1} C_l^j Q_0^{(j)}(k) g^{(l-j)}(k)$. It is obvious that $\mathcal{R}$ is a function from $B^1_{1\infty}$. Therefore, due to Lemma A.1 the integral

$$R(y) = \int_{-\infty}^{\infty} e^{-\mathrm{i}\,2\pi\,ky} \cdot \mathcal{R}(k)\,dk$$

satisfies the following estimate: $|R(y)| \leq \frac{A_1}{1+|y|}, y \in \mathbb{R}$.

Now let us consider the integral

$$\begin{aligned} F_0(y) &= \int_{-\infty}^{\infty} e^{-\mathrm{i}\,2\pi\,ky} \cdot Q_0^{(l)}(k)g(k)\,dk \\ &= \begin{cases} 2 \cdot \int_0^{\infty} \cos(2\pi\,ky) \cdot Q_0^{(l)}(k) \cdot g(k)\,dk, & l \text{ even}, \\ -2\mathrm{i} \cdot \int_0^{\infty} \sin(2\pi\,ky) \cdot Q_0^{(l)}(k) \cdot g(k)\,dk, & l \text{ odd}. \end{cases} \end{aligned}$$

Let us assume that l is even. Then

$$F_0(y) = 2C_1 \cos(2\pi k_0 y) F_c(2\pi y) - 2C_1 \sin(2\pi k_0 y) F_s(2\pi y),$$

where $C_1 = C_1(\rho) = (l-\alpha) \cdot (l-1-\alpha) \cdot \cdots \cdot (1-\alpha)$, $\alpha = 1 - \rho + l$, and

$$F_c(x) = \int_0^{\infty} \cos(kx) \cdot f(k)\,dk, \quad F_s(x) = \int_0^{\infty} \sin(kx) \cdot f(k)\,dk \tag{3.35}$$

are the respective Fourier cosine and sine transformations of the function $f(k) = g(k+k_0)k^{-\alpha}$. Now we will use the following assertion.

THEOREM 3.2 (see [36, Theorem 126]). *Let $f(k) = k^{-\alpha}\varphi(k)$, where $0 < \alpha < 1$ and $\varphi(k)$ is of bounded variation in $(0,\infty)$. Let F_c and F_s be Fourier sine and cosine transformations of f, respectively. Then*

$$F_c(x) = \varphi(+0)\cdot\left(\frac{2}{\pi}\right)^{1/2}\Gamma(1-\alpha)\sin(\pi\alpha/2)\cdot x^{\alpha-1}\cdot(1+o(1)) \quad as \quad x\to\infty$$

and

$$F_c(x) = \varphi(\infty)\cdot\left(\frac{2}{\pi}\right)^{1/2}\Gamma(1-\alpha)\sin(\pi\alpha/2)\cdot x^{\alpha-1}\cdot(1+o(1)) \quad as \quad x\to 0.$$

$F_s(x)$ satisfies similar conditions with $\sin(\pi\alpha/2)$ replaced by $\cos(\pi\alpha/2)$.

For even l it follows from this theorem that

$$F_0(y) = C_2(\rho)g(k_0)\cdot\frac{\sin(\pi\alpha/2 - 2\pi k_0 y)}{y^{1-\alpha}}\cdot(1+o(1)) \quad \text{as} \quad y\to\infty. \tag{3.36}$$

For odd l one can obtain a similar asymptotic:

$$F_0(y) = -\mathrm{i}\cdot C_2(\rho)g(k_0)\cdot\frac{\cos(\pi\alpha/2 + 2\pi k_0 y)}{y^{1-\alpha}}\cdot(1+o(1)) \quad \text{as} \quad y\to\infty. \tag{3.37}$$

Thus we have obtained the following asymptotic result for $\mathcal{F}_0^{(\phi)}$:

$$\mathcal{F}_0^{(\phi)}(y) = C_3(\rho)\cdot\Phi(k_0 y)\cdot\frac{q(k_0)\cdot\hat{\phi}(k_0)}{y^{\rho}}\cdot(1+o(1)) \quad \text{as} \quad y\to\infty, \tag{3.38}$$

where $\Phi(x) = \sin(\pi\alpha/2 - 2\pi x)$ if $l = \lfloor\rho\rfloor$ is even and $\Phi(x) = \cos(\pi\alpha/2 + 2\pi x)$ if l is odd.

Recall that we have assumed that $k_0 \in [0, 2/3]$. If $k_0 \geq 2/3$, then $\mathcal{F}_0^{(\phi)} \equiv 0$. By the same arguments it can be shown that for m such that $2^m < 3k_0 < 2^{m+2}$ the following asymptotic is valid:

$$\mathcal{F}_m^{(\psi)}(y) = C_3(\rho)\cdot 2^{m(\rho-1/2)}\Phi(2^{-m}k_0 y)\cdot\frac{q(2^{-m}k_0)\cdot\hat{\psi}(2^{-m}k_0)}{y^{\rho}}\cdot(1+o(1)) \tag{3.39}$$

as $y\to\infty$, provided $q(2^{-m}k_0)\neq 0$.

3.4.2. Asymptotics of $\mathcal{F}_0^{(\phi)}$ and $\mathcal{F}_m^{(\psi)}$ for integer ρ. Let $l = \rho = 1$. Then

$$\begin{aligned}\mathcal{F}_0^{(\phi)}(y) &= 2\int_{k_0}^{\infty}\cos(2\pi k y)g(k)\,dk = \frac{1}{\pi y}\int_{k_0}^{\infty} g(y)\cdot d(\sin(2\pi k y))\\ &= -\frac{g(k_0)}{\pi y}\cdot(1+O(1/|y|)) \quad \text{as} \quad y\to\infty.\end{aligned} \tag{3.40}$$

If $l \geq 2$, then

$$\mathcal{F}_0^{(\phi)}(y) = \frac{1}{(-\mathrm{i}2\pi y)^{l-1}}\int_{-\infty}^{\infty} e^{-\mathrm{i}\,2\pi\,k y}\cdot[Q_0^{(l-1)}(k)g(k) + \mathcal{R}(k)]\,dk,$$

where $\mathcal{R} \in B^2_{1\infty}$. Therefore

$$\mathcal{F}_0^{(\phi)}(y) = \frac{1}{(-\mathrm{i}2\pi y)^{l-1}} \cdot (F_0(y) + O(1/|y|^2) \quad \text{as} \quad y \to \infty,$$

where

$$F_0(y) = \int_{-\infty}^{\infty} e^{-\mathrm{i}\,2\pi\,ky} \cdot Q_0^{(l-1)}(k) g(k)\,dk = \begin{cases} 2 \cdot \int_{k_0}^{\infty} \cos(2\pi\,ky) \cdot g(k)\,dk, & l \text{ odd}, \\ -2\mathrm{i} \cdot \int_{k_0}^{\infty} \sin(2\pi\,ky) \cdot g(k)\,dk, & l \text{ even}. \end{cases}$$

By using integration by parts and Lemma A.1 we can easily show that

$$\mathcal{F}_0^{(\phi)}(y) = C(\rho) \cdot \Phi(k_0 y) \cdot \frac{q(k_0) \cdot \hat{\phi}(k_0)}{y^l} \cdot (1 + o(1)) \quad \text{as} \quad y \to \infty, \tag{3.41}$$

where $\Phi(x) = \cos(2\pi x)$ if $l = \rho$ is even and $\Phi(x) = \sin(2\pi x)$ if l is odd.

By the same arguments we can establish that (3.39) is valid for integer ρ with $\Phi(x) = \cos(2\pi x)$ if $l = \rho$ is even and $\Phi(x) = \sin(2\pi x)$ if l is odd.

3.4.3. Lower bounds for the estimates (3.15)–(3.16). Now let us come back to the estimates (3.15)–(3.16). Assume that ρ is not integer and $l = \lfloor \rho \rfloor$ is even. Let $k_0 = 1/2$. Then by virtue of (3.38) we get for some positive integer N_0 and for each $N \geq N_0$

$$\begin{aligned} E(v^{(1)}(x))^2 &\geq \sum_{j \in \mathbb{Z}:\, |x+j| \geq b_N + 1} |\mathcal{F}_0^{(\phi)}(x+j)|^2 \\ &\geq C(\rho) \cdot \sum_{j \in \mathbb{Z}:\, |x+j| \geq b_N + 1} \sin^2(\pi\alpha/2 - \pi \cdot (x+j)) \cdot \frac{1}{|x+j|^{2\rho}} \\ &\geq C_1(\rho) \sin^2(\pi\alpha/2 - \pi x) \frac{1}{b_N^{2\rho-1}}, \end{aligned}$$

where $C_1(\rho) > 0$; in the same way the estimate can be established for odd l and noninteger ρ. For integer ρ, one can use (3.41) and establish the analogous result.

If, for nonnegative m_0, one puts $k_0 = 2^{m_0 - 1}$, then by (3.39)

$$E(v_{m_0}^{(2)}(x))^2 \geq C(\rho) \sin^2(\pi\alpha/2 - \pi 2^{m_0} x) 2^{2m_0(\rho - 1/2)} \sum_{j \in \mathbb{Z}:\, |2^{m_0} x + j| \geq b_{m_0 N} + 1} \frac{1}{|2^{m_0} x + j|^{2\rho}}$$

$$\geq C_1(\rho) \sin^2(\pi\alpha/2 - \pi 2^{m_0} x) 2^{2m_0(\rho - 1/2)} \frac{1}{b_{m_0 N}^{2\rho-1}}, \quad N \geq N_0, \tag{3.42}$$

for noninteger ρ with even $l = \lfloor \rho \rfloor$. For other values of ρ ($\lfloor \rho \rfloor$ is odd or ρ is integer) similar estimates can be obtained in an analogous way.

Hence in Nikolskiĭ–Besov classes $B^{\rho_m}_{1\infty}$, $m = 0, 1, \ldots, \mu_N$, the exponents $2\rho_m - 1$, $m = 0, \ldots, \mu_N$, on the r.h.s. of the estimate (3.6) are best possible values. In this connection it should be pointed out that, for Sobolev spaces $W_1^{\rho_m}$, this is not the case. More precisely, if for positive integers $l_0, \ldots, l_{\mu_N}$ we replace the conditions $Q|_\Delta \in B^{\rho_0}_{1\infty}(\Delta)$ and $Q|_{\Delta_m} \in B^{\rho_m}_{1\infty}(\Delta_m)$ in Theorem 3.1 with the conditions $Q|_\Delta \in W_1^{l_0}(\Delta)$ and $Q|_{\Delta_m} \in W_1^{l_m}(\Delta_m)$, then the following estimate holds true:

$$\begin{aligned} E(u(x) - u_N(x))^2 &\leq \frac{C_1(s,\psi)}{4^{s(\mu_N+1)}} \cdot I_s + \frac{C_2(l_0,\phi)}{b_N^{2l_0-1}} ||Q||^2_{W_1^{l_0}(\Delta)} \\ &+ \sum_{m=0}^{\mu_N} \frac{C_3(l_m,\psi)}{b_{mN}^{2l_m-1}} \cdot \left(2^{-m} ||Q||^2_{L_1(\Delta_m)} + 2^{2m(l_m - 1/2)} ||Q||^2_{W_1^{l_m}(\Delta_m)} \right). \end{aligned} \tag{3.43}$$

But exponents $2l_m - 1$, $m = 0, 1, \ldots, \mu_N$ in this estimate might be not best possible. To illustrate this idea let us consider the following example.

Example 3.2. For $\rho \in (1, 2)$ let us consider the function $Q(k)$ constructed as above in Example 3.1 with $k_0 = 1/2$ and $q \in C^2(\mathbb{R})$ such that $\mathrm{supp}(q) \subset (-\frac{2}{3}, \frac{2}{3})$. Then the maximum possible value of an integer l_0 in the condition $Q|_\Delta \in W_1^{l_0}(\Delta)$ is $l_0 = 1$. Therefore by taking into account that $Q|_{\Delta_m} = 0$, $m = 1, 2, \ldots$, we get by (3.43) $E(u(x) - u_N(x))^2 \le C \cdot (1/b_N + 1/b_{0N})$, while the estimate (3.6) ensures more exact inequality is true: $E(u(x) - u_N(x))^2 \le C \cdot (1/b_N^{2\rho-1} + 1/b_{0N}^{2\rho-1})$.

4. Convergence of FWM in the C metric. Now let us turn to the problem of convergence of FWM (3.1) in probability, in the metric $C[0, 1]$. Recall that $\mathcal{E}_N(x) = u(x) - u_N(x)$. Denote by $D = [0, 1]$ the unit interval, and $C(D)$ is the space of continuous scalar functions on D with the uniform norm $||f||_{C(D)} = \max_{x\in D} |f(x)|$. Let us mention that the functional convergence $u_N \xrightarrow{P} u$ in $C(D)$ as $N \to \infty$ means $||\mathcal{E}_N||_{C(D)} \xrightarrow{P} 0$ as $N \to \infty$; that is, for each nonnegative ε and δ there exists $N_0 = N_0(\varepsilon, \delta)$ such that $\mathcal{P}\{||\mathcal{E}_N||_{C(D)} > \varepsilon\} < \delta$ for each $N \ge N_0$. Thus to study the convergence in probability $u_N \xrightarrow{P} u$ in $C(D)$ as $N \to \infty$, we need to estimate the probability $\mathcal{P}\{||\mathcal{E}_N||_{C(D)} > \varepsilon\}$.

Let $\xi(x)$, $x \in D = [0, 1]$, be a Gaussian random process with zero mean. Let

$$\varphi_\xi(h) = \sup_{\substack{x,y\in D \\ |x-y|\le h}} (E|\xi(x) - \xi(y)|^2)^{1/2}, \quad h \in [0, 1].$$

The following assertion is a one-dimensional variant of the well-known Fernique's inequality.

THEOREM 4.1 (see [9]). *If $\int_1^\infty \varphi_\xi(e^{-x^2})dx < \infty$, then almost all samples of the random process $\xi(x)$ are continuous. Moreover, for each $t \ge \sqrt{5}$ the following estimate is valid:*

$$\mathcal{P}\{\sup_{x\in D} |\xi(x)| \ge qt\} \le 10 \cdot \int_t^\infty e^{-x^2/2}\, dx, \tag{4.1}$$

where

$$q = \sup_{x\in D} (E|\xi(x)|^2)^{1/2} + (2 + \sqrt{2}) \cdot \int_1^\infty \varphi_\xi(2^{-x^2})dx.$$

By taking into account the inequality $\int_t^\infty e^{-x^2/2}\, dx \le \frac{e^{-t^2/2}}{t} \le \frac{e^{-t^2/2}}{\sqrt{5}}$ for $t \ge \sqrt{5}$ and the estimate (4.1), one can derive the following estimation:

$$\mathcal{P}\{\sup_{x\in D} |\xi(x)| \ge qt\} \le 2\sqrt{5} \cdot e^{-t^2/2}, \qquad t \ge \sqrt{5}. \tag{4.2}$$

Thus, in order to use this estimate for $\xi(x) = \mathcal{E}_N(x)$ we have to analyze the function

$$\varphi_{\mathcal{E}_N}(h) = \sup_{\substack{x,y\in D \\ |x-y|\le h}} (E|\mathcal{E}_N(x) - \mathcal{E}_N(y)|^2)^{1/2}, \quad h \in [0, 1].$$

Let us turn to estimating this function.

For a fixed positive integer N we denote $\epsilon_N^{(1)} = \frac{||Q||^2_{B^{\rho_0}_{1\infty}(\Delta)}}{b_N^{2\rho_0-1}}$, $\epsilon_N^{(3)} = \frac{I_s}{4^{(\mu_N+1)s}}$, and

$$\epsilon_{mN}^{(2)} = \frac{1}{b_{mN}^{2\rho_m-1}} \cdot \left(2^{-m}||Q||^2_{L_1(\Delta_m)} + 2^{2m(\rho_m-1/2)}||Q||^2_{b^{\rho_m}_{1\infty}(\Delta_m)}\right), \quad m = 0, 1, \dots, \mu_N.$$

THEOREM 4.2. *Assume that all of the conditions of Theorem* 3.1 *are satisfied. Then for each* $\alpha \in (0,1)$ *and* $h \in [0,1]$ *the following inequality is valid:*

$$E|\mathcal{E}_N(x+h) - \mathcal{E}_N(x)|^2 \le C(s) \cdot \left(I_s \cdot |h|^{s\wedge 1}\right)^{\alpha} \cdot \epsilon_N^{1-\alpha}, \quad N = 1, 2, \dots, \tag{4.3}$$

where $s \wedge 1 = \min\{s, 1\}$,

$$\epsilon_N = C_1(\rho_0, \phi) \cdot \epsilon_N^{(1)} + \sum_{m=0}^{\mu_N} C_2(\rho_m, \psi) \cdot \epsilon_{mN}^{(2)} + C_3(s, \psi) \cdot \epsilon_N^{(3)},$$

and C *and* C_i, $i = 1, 2, 3$, *are some constants depending only on the shown arguments.*

Proof. From independence of the random variables ξ_j, ξ_{mj}, $j \in \mathbb{Z}$, $m \ge 0$ it follows that (see (3.7))

$$\begin{aligned} E[\mathcal{E}_N(x+h) - \mathcal{E}_N(x)]^2 &= E[v^{(1)}(x+h) - v^{(1)}(x)]^2 \\ &+ \sum_{m=0}^{\mu_N} E[v_m^{(2)}(x+h) - v_m^{(2)}(x)]^2 + E[v^{(3)}(x+h) - v^{(3)}(x)]^2. \end{aligned} \tag{4.4}$$

The first and second terms in r.h.s. of the last equality are estimated in the following statements. The proof is given in the Appendix.

LEMMA 4.1. *For each* $\alpha \in (0,1)$ *the following estimate holds:*

$$E[v^{(1)}(x+h) - v^{(1)}(x)]^2 \le \left(C(s) I_s \cdot |h|^{(s\wedge 1)}\right)^{\alpha} \cdot (C_1(\rho_0, \phi) \cdot \epsilon_N^{(1)})^{1-\alpha}. \tag{4.5}$$

LEMMA 4.2. *For each* $\alpha \in (0,1)$ *the following estimate is valid for* $N = 1, 2, \dots$:

$$\sum_{m=0}^{\mu_N} E[v_m^{(2)}(x+h) - v_m^{(2)}(x)]^2 \le \left(C(s) \cdot I_s \cdot |h|^{s\wedge 1}\right)^{\alpha} \cdot \left(\sum_{m=0}^{\mu_N} C_2(\rho_m, \psi) \cdot \epsilon_{mN}^{(2)}\right)^{1-\alpha}. \tag{4.6}$$

It is easy to see that

$$E(v^{(3)}(x+h) - v^{(3)}(x))^2 = \sum_{m=\mu_N+1}^{\infty} \sum_{j\in\mathbb{Z}} |a_{mj} - b_{mj}|^2,$$

where $a_{mj} = \mathcal{F}_m^{(\psi)}(2^m \cdot (x+h) + j)$ and $b_{mj} = \mathcal{F}_m^{(\psi)}(2^m \cdot x + j)$. Therefore by using

$$\sum_{j\in\mathbb{Z}} |a_{mj} - b_{mj}|^2 \le ||\Delta_h G||^2_{L_2}$$

for each integer m

$$\sum_{m=\mu_N+1}^{\infty} \sum_{j\in\mathbb{Z}} (|a_{mj}| + |b_{mj}|)^2 \le 2 \cdot [E(v^{(3)}(x+h))^2 + E(v^{(3)}(x))^2],$$

and taking into account (3.12) and (A.7), we get

$$E(v^{(3)}(x+h)-v^{(3)}(x))^2 \le \left(C(s)\cdot I_s\cdot |h|^{s\wedge 1}\right)^{\alpha}\cdot\left(C_3(s,\psi)\cdot\epsilon_N^{(3)}\right)^{1-\alpha}. \tag{4.7}$$

Finally, by using (4.4), (4.5), (4.6), and the last inequality we obtain

$$\begin{aligned} &E|\mathcal{E}_N(x+h)-\mathcal{E}_N(x)|^2 \\ &\le \left(C(s)\cdot I_s\cdot |h|^{s\wedge 1}\right)^{\alpha}\cdot\left[(C_1\cdot\epsilon_N^{(1)})^{1-\alpha}+\left(\sum_{m=0}^{\mu_N} C_{2m}\cdot\epsilon_{mN}^{(2)}\right)^{1-\alpha}+(C_3\cdot\epsilon_N^{(3)})^{1-\alpha}\right] \\ &\le 3^{\alpha}\left(C(s)\cdot I_s\cdot |h|^{s\wedge 1}\right)^{\alpha}\cdot\left[C_1\cdot\epsilon_N^{(1)}+\sum_{m=0}^{\mu_N} C_{2m}\cdot\epsilon_{mN}^{(2)}+C_3\cdot\epsilon_N^{(3)}\right]^{1-\alpha}. \end{aligned} \tag{4.8}$$

Theorem 4.2 is proven. □

Now we are in a position to formulate an assertion on the convergence of FWM in probability.

THEOREM 4.3. *Assume that all of the conditions of the Corollary* 3.1 *are fulfilled. Then for each* $\alpha\in(0,1)$ *and* $t>\sqrt{5}$

$$\mathcal{P}\left\{\sup_{x\in[0,1]}|\mathcal{E}_N(x)|>C\cdot\varepsilon_N(\alpha)\cdot t\right\}\le 2\sqrt{5}\cdot e^{-t^2/2}, \tag{4.9}$$

where C *is some positive constant not depending on* α *and* N *and*

$$\varepsilon_N(\alpha)=\frac{1}{\sqrt{\alpha}}\cdot N^{-\frac{(2\rho_0-1)\cdot(1-\alpha)}{2}}.$$

Proof. From the estimate in (4.3), by taking into account (3.5) and (3.25) we get

$$\sup_{x,y\in[0,1],\,|x-y|\le h} E(\mathcal{E}_N(x)-\mathcal{E}_N(y))^2\le C_1|h|^{\alpha(s\wedge 1)}N^{-(2\rho_0-1)\cdot(1-\alpha)}$$

for each $\alpha\in(0,1)$ and $|h|\le 1$, where C_1 is some positive constant not depending on α, h, and N. Now let $\xi(x)=\mathcal{E}_N(x)$. Then

$$\varphi_\xi(h)=\sup_{\substack{x,y\in D\\ |x-y|\le h}} E^{1/2}(|\xi(x)-\xi(y)|^2)\le C_2\cdot|h|^{\alpha(s\wedge 1)/2}N^{-(2\rho_0-1)\cdot(1-\alpha)/2}.$$

Therefore, by (3.26)

$$\begin{aligned} q=\sup_{x\in D}E^{1/2}|\xi(x)|^2+(2+\sqrt{2})\cdot\int_1^{\infty}\varphi_\xi(2^{-x^2})dx &\le C_3\cdot N^{-\frac{(2\rho_0-1)}{2}} \\ &+C_4\cdot N^{-\frac{(2\rho_0-1)\cdot(1-\alpha)}{2}}\cdot\int_1^{\infty}2^{-x^2\alpha(s\wedge 1)/2)}dx\le C\varepsilon_N(\alpha). \end{aligned}$$

Now (4.9) is a direct consequence of estimation (4.2). Theorem 4.3 is proven. □

COROLLARY 4.1. *Under the conditions of Theorem* 4.3, $u_N\xrightarrow{P}u$ *in the metric of* $C[0,1]$ *as* $N\to\infty$.

Proof. By (4.9), for each $\varepsilon>0$ and $\delta>0$ it can be found a positive integer N_0 such that

$$\mathcal{P}\left\{\sup_{x\in[0,1]}|\mathcal{E}_N(x)|>\varepsilon\right\}\le\delta,\qquad N\ge N_0.$$ □

5. Generalization of results to vector processes and some stronger metrics.

5.1. Convergence in the L_p metric. Recall the well-known relation between different moments of zero mean Gaussian random variables. Let ξ be a zero mean real-valued Gaussian random variable. Then (e.g., see, [16])

$$E|\xi|^p = c_p(E\xi^2)^{p/2}, \quad p \geq 1, \quad c_p = \frac{2^{p/2}}{\sqrt{\pi}}. \tag{5.1}$$

Therefore, under the conditions of Theorem 3.1, by using the estimate in (3.6) for $E\mathcal{E}_N^2(x) = E(u(x) - u_N(x))^2$ it is easy to obtain an estimate for the convergence rate $E||\mathcal{E}_N||^p_{L_p[0,1]} = \int_0^1 E(\mathcal{E}_N(x))^p\,dx$ in the metric of $L_p[0,1]$, $p \geq 1$.

5.2. Convergence in the metric of the Sobolev space W_p^n. For a positive integer n and $p \geq 1$, let $W_p^n[0,1]$ be a Sobolev space with the norm

$$||f||_{W_p^n[0,1]} = ||f||_{L_p[0,1]} + ||f^{(n)}||_{L_p[0,1]}.$$

In the study of convergence $E||\mathcal{E}_N||^p_{W_p^n[0,1]} \to 0$, due to the relation (5.1), we can restrict ourselves to the case $p = 2$. Therefore let us consider the convergence of the FWM (3.1) in the Sobolev space W_2^n. In order to analyze the convergence of FWM, $u_N(x)$ to $u(x)$ as $N \to \infty$ in $W_2^n[0,1]$, it is sufficient to study: (i) convergence $u_N \to u$ in $L_2[0,1]$ and (ii) convergence $u_N^{(n)} \to u^{(n)}$ in $L_2[0,1]$. The first question was already studied in section 3. Therefore we will concentrate on the second question: $u_N^{(n)} \to u^{(n)}$ in $L_2[0,1]$. Recall that for a function $f : \mathbb{R} \to \mathbb{R}$ we denote by $f^{(n)}$ the nth derivative $D^n f$ (if it exists).

First of all note that a necessary and sufficient condition that samples of a random process $u(x)$ belong to $W_2^n[0,1]$ (with probability 1) is (e.g., see, [15])

$$\int_{-\infty}^{\infty} |k|^{2n} F(k)\,dk < \infty. \tag{5.2}$$

If this condition is satisfied, then $D^n u(x) = u^{(n)}$ have the spectral function $k^{2n}F(k)$. In order to ensure that u_N is n-times differentiable we have to choose the cutoff function η_A n-times differentiable. Therefore we will assume that $\eta_A \in C^n$ and

$$\eta_A(x) = \begin{cases} 0, & 0 \leq x \leq A, \\ 1, & x \geq A+1. \end{cases} \tag{5.3}$$

Thus, by using results of section 3 one can formulate sufficient conditions for $u_N^{(n)} \to u^{(n)}$ as $N \to \infty$ in $L_2[0,1]$. Denote by Q_n the function $Q_n(k) = |k|^n Q(k) = |k|^n F^{1/2}(k)$. Then the following assertion is valid.

THEOREM 5.1. *Assume that the spectral function $F(k)$ satisfies the condition*

$$I_{n+s} \stackrel{def}{=} \int_{-\infty}^{\infty} F(k)(1+|k|^2)^{n+s}dk < \infty \tag{5.4}$$

for some $s > 0$. Let $\{\rho_m\}_{m=0}^{\mu_N}$ be a finite sequence of positive numbers such that $\min_m \rho_m > 1/2$. Assume that $Q_n|_\Delta \in B_{1\infty}^{\rho_0}(\Delta)$ and $Q|_{\Delta_m} \in B_{1\infty}^{\rho_m}(\Delta_m)$ for $1 \leq m \leq$

μ_N. Assume that the Meyer wavelet functions ϕ and ψ belong to the class $C^{\nu+1}$ for $\nu = \max\{\lfloor\rho\rfloor, \lfloor s\rfloor\}$, where $\rho = \max_{0\le m\le\mu_N}\rho_m$. Then

$$E(u^{(n)}(x) - u_N^{(n)}(x))^2 \le \frac{C_1(s,\psi)}{4^{s(\mu_N+1)}}\cdot I_{n+s} + \frac{C_2(\rho_0,\phi)}{b_N^{2\rho_0-1}}||Q_n||^2_{B^{\rho_0}_{1\infty}(\Delta)}$$

$$+\sum_{m=0}^{\mu_N}\frac{C_3(\rho_m,\psi)}{b_{mN}^{2\rho_m-1}}\cdot\left(2^{-2ms}\cdot I_{n+s} + 2^{2m(\rho_m-1/2)}||Q_n||^2_{b^{\rho_m}_{1\infty}(\Delta_m)}\right), \tag{5.5}$$

where C_i, $i = 1,2,3$, are some positive constants depending only on the shown arguments.

Proof. Indeed, this assertion is a direct consequence of Theorem 3.1 applied to the random process $u^{(n)}(x)$ with the spectral function $|k|^{2n}F(k)$. Then the estimate (5.5) is a consequence of (3.6) and the following simple inequality:

$$||Q_n||_{L_1(\Delta_m)} = \int_{\Delta_m}|k|^n Q(k)dk \le |\Delta_m|^{1/2}\left(\int_{\Delta_m}|k|^{2n}F(k)dk\right)^{1/2}$$
$$\le 2^{(m+1)/2-ms}I^{1/2}_{n+s}. \qquad \square$$

PROPOSITION 5.1. *Assume that, for a nonnegative k_0 and positive integer l, $Q \in W_1^l(k_0,\infty)$ and, for each nonnegative integer j such that $0 \le j \le n\wedge l$, the following condition is valid:*

$$|Q^{(l-j)}(k)| \le \frac{A_\varepsilon}{k^{n+l-j+1/2+\varepsilon}} \quad \forall k \ge k_0 \tag{5.6}$$

for some positive numbers A_ε and ε. Then

$$||Q_n||_{b^l_{1\infty}(\Delta_m)} \le A_\varepsilon\cdot c_0\cdot 2^{-m(l-1/2+\varepsilon)} \quad \forall\ m \ge \log_2(3(k_0+2)) \tag{5.7}$$

for some positive $c_0 = c_0(n,l,\varepsilon)$.

Proof. Indeed,

$$|\Delta_h^{(2)}Q_n^{(l-1)}(k)| \le |\Delta_h Q_n^{(l-1)}(k+h)| + |\Delta_h Q_n^{(l-1)}(k+h)|$$
$$\le h\cdot|Q_n^{(l)}(k+\beta h)| + h\cdot|Q_n^{(l)}(k+\alpha h)|$$

for some $\alpha\in[0,1]$ and $\beta\in[1,2]$. Since

$$Q_n^{(l)}(k) = \sum_{j=0}^{n\wedge l}C_l^j\cdot n\cdot(n-1)\cdot\cdots\cdot(n-j+1)\cdot k^{n-j}Q^{(l-j)}(k),$$

we find for each $k\in\Delta_m$ and $m\ge\log_2(3(k_0+2))$ that $|Q_n^{(l)}(k)| \le C(n,l)2^{-m(l+1/2+\varepsilon)}$ by virtue of condition (5.6). Therefore,

$$\int_{\Delta_m}|\Delta_h^{(2)}Q^{(l-1)}(k)| \le C(n,l)2^{-m(l+1/2+\varepsilon)}\cdot h\cdot|\Delta_m| \le C_1(n,l)\cdot h\cdot 2^{-m(l-1/2+\varepsilon)}.$$

This completes the proof of (5.7). $\square$

COROLLARY 5.1. *Assume that the spectral function $F(k)$ satisfies the condition (5.4) for some $s>0$ and a positive integer n and that the function $Q_n(k) = |k|^n\cdot F^{1/2}(k) = |k|^n\cdot Q(k)$ satisfies the conditions*

$$Q_n|_\Delta \in B^{\rho_0}_{1\infty}(\Delta), \quad Q|_{\Delta'}\in W_1^l(\Delta') \tag{5.8}$$

for some positive $\rho_0 > 1/2$ and positive integer l. Assume that for each nonnegative integer $j \in [0, n \wedge l]$ the function Q satisfies the condition (5.6)*, and suppose that $\phi, \psi \in C^{\nu+1}$, where $\nu = \max\{\lfloor s \rfloor, \lfloor \rho_0 \rfloor, l\}$. Let us choose in FWM* (3.1)

$$\mu_N = \left\lfloor \frac{(2\rho_0 - 1)}{s \ln 4} \cdot \ln N \right\rfloor, \quad b_N = N, \quad b_{mN} = N^{\frac{2\rho_0 - 1}{2l-1}},\ m = 0, 1, \ldots, \mu_N. \tag{5.9}$$

Then for each positive integer N and $x \in \mathbb{R}$ the following estimate is valid:

$$\begin{aligned} &E(u^{(n)}(x) - u_N^{(n)}(x))^2 \le N^{-(2\rho_0 - 1)} \\ &\quad \times \left[C_1(s, \psi) I_{n+s} + C_2(\rho_0, \phi) \cdot ||Q_n||^2_{B^{\rho_0}_{1\infty}(\Delta)} + C_3(n, \rho_1, \varepsilon, \psi) \cdot C_\varepsilon^2 \right], \end{aligned} \tag{5.10}$$

where C_i, $i = 1, 2, 3$, are some positive constants depending only on the shown arguments.

Thus if the spectral function $F(\cdot)$ satisfies all of the conditions of the last corollary and $Q|_\Delta \in B^{\rho_0}_{1\infty}(\Delta)$, then the estimates (3.32) and (5.10) imply the following result on convergence of FWM in W_2^n.

COROLLARY 5.2. *Let all of the conditions of Corollary* 5.1 *be fulfilled and $Q|_\Delta \in B^{\rho_0}_{1\infty}(\Delta)$. Then*

$$E||\mathcal{E}_N||^2_{W_2^n[0,1]} \le \frac{C}{N^{2\rho_0 - 1}}, \quad N = 1, 2, \ldots,$$

for some positive C not depending on N.

5.3. Convergence in $C^n[0, 1]$. For positive integer n, let $C^n[0, 1]$ be the space of all n-times continuously differentiable real-valued scalar functions $f : [0, 1] \to \mathbb{R}$ with the norm

$$||f||_{C^n[0,1]} = \sup_{x \in [0,1]} |f(x)| + \sup_{x \in [0,1]} |f^{(n)}(x)|.$$

By the definition of this norm it follows that $\{u_N(x)\}_{N=1}^\infty$, $x \in [0, 1]$ converges in the metric of $C^n[0, 1]$ to a random field $u(x)$, $x \in [0, 1]$, as $N \to \infty$ iff: (i) $u_N \to u$ in $C[0, 1]$ as $N \to \infty$ and (ii) $u_N^{(n)} \to u^{(n)}$ in $C[0, 1]$ as $N \to \infty$. Since the first question was studied in section 4, we concentrate on the second one. To ensure that the samples of FWM (3.1) are of $C^n[0, 1]$, we assume below that $\eta_A \in C^n(\mathbb{R})$ and the condition (5.3) is satisfied.

The following assertion is an analog of Theorem 4.3 and can be proved in a similar way.

THEOREM 5.2. *Let all of the conditions of Corollary* 5.1 *be fulfilled. Then for each $\alpha \in (0, 1)$ and $t > \sqrt{5}$,*

$$\mathcal{P}\left\{ \sup_{x \in [0,1]} |\mathcal{E}_N^{(n)}(x)| > C\varepsilon_N(\alpha) \cdot t \right\} \le 2\sqrt{5} \cdot e^{-t^2/2}, \tag{5.11}$$

where C is a positive constant not depending on α and N and

$$\varepsilon_N(\alpha) = \frac{1}{\sqrt{\alpha}} \cdot N^{-\frac{(2\rho_0 - 1) \cdot (1 - \alpha)}{2}}.$$

Now let all of the conditions of Corollary 5.2 be valid. Then by using the simple

inequality $\mathcal{P}\{\xi+\eta>x+y\}\le\mathcal{P}\{\xi>x\}+\mathcal{P}\{\eta>y\}$ and the results of Theorems 4.3 and 5.2 we arrive at the following.

COROLLARY 5.3. *Let all of the conditions of Corollary* 5.2 *be satisfied. Then for each* $\alpha\in(0,1)$ *and* $t>\sqrt{5}$

$$\mathcal{P}\left\{||\mathcal{E}_N||_{C^n[0,1]}>\frac{C\cdot t}{\sqrt{\alpha}}\cdot N^{-\frac{(2\rho_0-1)\cdot(1-\alpha)}{2}}\right\}\le 4\sqrt{5}\cdot e^{-t^2/2},$$

where C *is some positive constant not depending on* α.

Under the conditions of this corollary it follows immediately that $u_N\xrightarrow{P}u$ in the metric of $C^n[0,1]$ as $N\to\infty$.

5.4. Generalizations for vector processes. Let $\mathbf{u}(x)=(u_1(x),\dots,u_l(x))^T$, $x\in\mathbf{R}$, be an l-dimensional real-valued stationary Gaussian random process with mean zero and spectral tensor $F(k)=(F_{ij}(k))$, $i=1,\dots,l$, $j=1,\dots,l$, and $\mathbf{u}_N(x)$ is its FWM given by (2.12). Denote by $|\mathbf{a}|=(\sum_{i=1}^l a_i^2)^{1/2}$ the Euclidean norm of an l-dimensional real-valued vector $\mathbf{a}$ and by $|A|=(\sum_{i=1}^l\sum_{j=1}^n a_{ij}^2)^{1/2}$ the Euclidean norm of a matrix $A=(a_{ij})$, $i=1,\dots l$, $j=1,\dots,n$, which can be realized as the Euclidean norm of the $l\times n$-vector A. For an $l\times n$-dimensional function $Q(k)=(q_{ij}(k))$, $i=1,\dots l$, $j=1,\dots,n$, and $D\subset\mathbb{R}$, denote (if it makes a sense)

$$|||Q|||_{L_1(D)}=\left(\sum_{i=1}^l\sum_{j=1}^n||q_{ij}||^2_{L_1(D)}\right)^{1/2},\quad |||Q|||_{b^\rho_{1\infty}(D)}=\left(\sum_{i=1}^l\sum_{j=1}^n||q_{ij}||^2_{b^\rho_{1\infty}(D)}\right)^{1/2}.$$

Finally, denote by $SpF(k)$ the trace $\sum_{i=1}^l F_{ii}(k)$ of the spectral tensor F. Then by the same arguments as in the scalar case one can establish the following result.

THEOREM 5.3. *Assume that the spectral tensor* $F(k)$ *satisfies the condition*

$$I_s\stackrel{def}{=}\int_{-\infty}^{\infty}SpF(k)(1+|k|^2)^s dk<\infty \tag{5.12}$$

for some $s>0$. *Let* $\{\rho_m\}_{m=0}^{\mu_N}$ *be a finite sequence of positive numbers such that* $\min_m\rho_m>1/2$. *Assume that* $|||Q|||_{L_1(\Delta)}<\infty$, $|||Q|||_{b^{\rho_0}_{1\infty}(\Delta)}<\infty$, *and*

$$|||Q|||_{L_1(\Delta_m)}<\infty,\quad |||Q|||_{b^{\rho_m}_{1\infty}(\Delta_m)}<\infty,\quad m=0,1,\dots,\mu_N.$$

Assume that the Meyer wavelet functions ϕ *and* ψ *belong to the class* $C^{\nu+1}$ *for* $\nu=\max\{\lfloor\rho\rfloor,\lfloor s\rfloor\}$, *where* $\rho=\max_{0\le m\le\mu_N}\rho_m$. *Then*

$$\begin{aligned}E|u(x)-u_N(x)|^2\le{}&\frac{C_1(s,\psi)}{4^{s(\mu_N+1)}}\cdot I_s+\frac{C_2(\rho_0,\phi)}{b_N^{2\rho_0-1}}\cdot\left\{|||Q|||^2_{L_1(\Delta)}+|||Q|||^2_{b^{\rho_0}_{1\infty}(\Delta)}\right\}\\ &+\sum_{m=0}^{\mu_N}\frac{C_3(\rho_m,\psi)}{b_{mN}^{2\rho_m-1}}\cdot\left(2^{-m}|||Q|||^2_{L_1(\Delta_m)}+2^{2m(\rho_m-1/2)}|||Q|||^2_{b^{\rho_m}_{1\infty}(\Delta_m)}\right),\end{aligned} \tag{5.13}$$

where C_i, $i=1,2,3$, *are some constants depending only on the shown arguments.*

Analogous convergence results can be obtained in stronger metrics.

6. Conclusion and discussion. Functional convergence of FWM for stationary Gaussian random processes was studied in Sobolev spaces $W_p^n[0,1]$ and in the space of n-times continuously differentiable functions $C^n[0,1]$. Conditions sufficient for the

convergence of FWM are formulated in terms of spectral functions F (spectral tensors, in the case of vector random processes). Two kinds of assumptions on the behavior of the spectral functions are made: (i) the finiteness of certain spectral moments and (ii) a generalized smoothness of the function $Q = F^{1/2}$ in different wave bands. This is formulated in terms of smoothness in Besov's space $B^{\rho}_{1\infty}$.

Condition (i) is related to the behavior of the high-frequency part of the spectrum which is standard in the convergence studies. Condition (ii) is related to the rate of convergence of the tails of the wavelet function $\mathcal{F}^{\psi}_{m}$ for a given spectral band. For these tails, we obtained upper estimations which are improvable in the sense that for some functions these estimations are exact to within a constant factor.

This analysis is new and provides a constructive algorithm for choosing the cutoff parameters for all spectral bands to ensure a uniform behavior of the error on the whole spectral interval.

We give also estimates of the cost needed to guarantee the desired root mean square error ε in $L_2[0,1]$ depending on the smoothness parameter of the relevant Besov space. The typical behavior of the cost has the form $T_{\varepsilon} \lesssim \frac{\ln \varepsilon}{\varepsilon^{1/(\rho_{min}-0.5)}}$, where ρ_{min} is the minimal smoothness parameter.

The Fourier-wavelet models are well suited for simulation of random processes with smooth spectral functions as is clearly seen from our presentation. However, in case the spectral function is not smooth in an isolated point, it is reasonable to use a hybrid method as follows. The spectral function is decomposed into two parts, the first being smooth, and the second is nonsmooth, and has a compact support in the neighborhood of the isolated point. Then the random process is represented respectively as a sum of two independent processes, the first having the smooth spectral function and the second with the nonsmooth spectral function. The smooth part is simulated by FWM and the second part by a standard deterministic spectral method which takes into account the singularity.

Appendix A. Some technical details. We present here some technical results which we use in the main part of this paper.

Proof of Lemma 4.1. For each $\alpha \in (0,1)$ one has

$$\begin{aligned} &E[v^{(1)}(x+h) - v^{(1)}(x)]^2 \\ &\quad = \sum_{j\in\mathbb{Z}} [\chi_N(x+h+j)\cdot \mathcal{F}^{(\phi)}(x+h+j) - \chi_N(x+j)\cdot \mathcal{F}^{(\phi)}(x+j)]^2 \\ &\quad = \sum_{j\in\mathbb{Z}} |a_j - b_j|^2 \le \left(\sum_{j\in\mathbb{Z}} |a_j-b_j|^2\right)^{\alpha} \cdot \left(\sum_{j\in\mathbb{Z}} (|a_j|+|b_j|)^2\right)^{1-\alpha}. \end{aligned} \tag{A.1}$$

Here we denote $a_j = \chi_N(x+h+j)\cdot \mathcal{F}^{(\phi)}_0(x+h+j)$ and $b_j = \chi_N(x+j)\cdot \mathcal{F}^{(\phi)}_0(x+j)$, and in the second line of (A.1) we use Hölder's inequality:

$$\begin{aligned} \sum_{j\in\mathbb{Z}} |a_j-b_j|^2 &\le \sum_{j\in\mathbb{Z}} \left\{ |a_j-b_j|^{2\alpha} \cdot (|a_j|+|b_j|)^{2\cdot(1-\alpha)} \right\} \\ &\le \left(\sum_{j\in\mathbb{Z}} |a_j-b_j|^{2\alpha p}\right)^{1/p} \cdot \left(\sum_{j\in\mathbb{Z}} (|a_j|+|b_j|)^{2\cdot(1-\alpha)q}\right)^{1/q}, \end{aligned} \tag{A.2}$$

with parameters $p = 1/\alpha$ and $q = 1/(1-\alpha)$. Let us estimate each multiplier in the

right-hand side of (A.1). First note that

$$\begin{aligned}|a_j - b_j| &= |\chi_N(x+h+j)\cdot \mathcal{F}_0^{(\phi)}(x+h+j) - \chi_N(x+j)\cdot \mathcal{F}_0^{(\phi)}(x+j)| \\ &\le |\chi_N(x+h+j)\cdot \mathcal{F}_0^{(\phi)}(x+h+j) - \chi_N(x+h+j)\cdot \mathcal{F}_0^{(\phi)}(x+j)| \\ &\quad + |\chi_N(x+h+j)\cdot \mathcal{F}_0^{(\phi)}(x+j) - \chi_N(x+j)\cdot \mathcal{F}_0^{(\phi)}(x+j)| \\ &\le |\mathcal{F}_0^{(\phi)}(x+h+j) - \mathcal{F}_0^{(\phi)}(x+j)| \\ &\quad + |\mathcal{F}_0^{(\phi)}(x+j)|\cdot|\chi_N(x+h+j) - \chi_N(x+j)|. \end{aligned} \tag{A.3}$$

Therefore,

$$\begin{aligned}\sum_{j\in\mathbb{Z}} |a_j - b_j|^2 &\le 2\cdot \sum_{j\in\mathbb{Z}} [\mathcal{F}_0^{(\phi)}(x+h+j) - \mathcal{F}_0^{(\phi)}(x+j)]^2 \\ &\quad + 2\cdot \sum_{j\in\mathbb{Z}} |\mathcal{F}_0^{(\phi)}(x+j)|^2 \cdot |\chi_N(x+h+j) - \chi_N(x+j)|^2. \end{aligned} \tag{A.4}$$

Note that $\{\mathcal{F}_0^{(\phi)}(x+h+j) - \mathcal{F}_0^{(\phi)}(x+j)\}_{j\in\mathbb{Z}}$ and $\{\mathcal{F}_0^{(\phi)}(x+j)\}_{j\in\mathbb{Z}}$ are the Fourier coefficients of $\Delta_h G(x+\cdot)$ and $G(x+\cdot)$, respectively, in the orthonormal system $\{\phi(\cdot+j)\}_{j\in\mathbb{Z}}$. Therefore

$$\sum_{j\in\mathbb{Z}} |\mathcal{F}_0^{(\phi)}(x+j)|^2 \le ||G(x+\cdot)||_{L_2}^2 = ||G(\cdot)||_{L_2}^2 \le I_s \tag{A.5}$$

and

$$\sum_{j\in\mathbb{Z}} [\mathcal{F}_0^{(\phi)}(x+h+j) - \mathcal{F}_0^{(\phi)}(x+j)]^2 \le ||\Delta_h G(x+\cdot)||_{L_2}^2 = ||\Delta_h G(\cdot)||_{L_2}^2. \tag{A.6}$$

Note that $G \in B_{22}^s \hookrightarrow B_{2\infty}^s \hookrightarrow B_{2\infty}^\gamma$ for each $0 < \gamma \le s$. Therefore, by taking $\gamma = \min\{1/2, s/2\}$ we have

$$\begin{aligned}||\Delta_h G(\cdot)||_{L_2} \le C_1(s)\cdot|h|^\gamma \cdot ||\Delta_h G(\cdot)||_{B_{2\infty}^\gamma} &\le C_2(s)\cdot|h|^\gamma\cdot||\Delta_h G(\cdot)||_{B_{22}^s} \\ &\le C_3(s)\cdot|h|^\gamma\cdot I_s^{1/2} \end{aligned} \tag{A.7}$$

for each $h \in [-1, 1]$. From (A.4)–(A.7), by taking into account that $|\chi_N(x+h+j) - \chi_N(x+j)| \le |h|$, we obtain

$$\sum_{j\in\mathbb{Z}} |a_j - b_j|^2 \le C(s)\, I_s \cdot |h|^{s\wedge 1}, \tag{A.8}$$

where $s \wedge 1 = \min\{1, s\}$.

Now let us estimate the second factor on the r.h.s. of (A.1). From

$$\sum_{j\in\mathbb{Z}} (|a_j| + |b_j|)^2 \le 2\cdot\sum_{j\in\mathbb{Z}} |a_j|^2 + 2\cdot\sum_{j\in\mathbb{Z}} |b_j|^2 = 2\cdot E(v^{(1)}(x+h))^2 + 2\cdot E(v^{(1)}(x))^2$$

and (3.15), we obtain

$$\sum_{j\in\mathbb{Z}} (|a_j| + |b_j|)^2 \le \frac{4\cdot C(\rho_0,\phi)}{b_N^{2\rho_0-1}} \cdot ||Q||_{B_{1\infty}^{\rho_0}(\Delta)}^2. \tag{A.9}$$

Thus by virtue of (A.1) and (A.8)–(A.9) the estimate (4.5) follows. The proof of Lemma 4.1 is complete. □

Proof of Lemma 4.2. For each $\alpha \in (0,1)$, by the same arguments as we used in proof of Lemma 4.1, we arrive at

(A.10)
$$E[v_m^{(2)}(x+h)-v_m^{(2)}(x)]^2 \le \left(\sum_{j\in\mathbb{Z}} |a_{mj}-b_{mj}|^2\right)^{\alpha} \cdot \left(\sum_{j\in\mathbb{Z}} (|a_{mj}|+|b_{mj}|)^2\right)^{1-\alpha},$$

where

$$a_{mj} = \chi_{mN}(2^m\cdot(x+h)+j)\cdot\mathcal{F}_m^{(\psi)}(2^m\cdot(x+h)+j), \quad b_{mj} = \chi_{mN}(2^m\cdot x+j)\cdot\mathcal{F}_m^{(\psi)}(2^m\cdot x+j).$$

From (A.10) it follows that

$$\sum_{m=0}^{\mu_N} E[v_m^{(2)}(x+h)-v_m^{(2)}(x)]^2 \le \left(\sum_{m=0}^{\mu_N}\sum_{j\in\mathbb{Z}} |a_{mj}-b_{mj}|^2\right)^{\alpha}\left(\sum_{m=0}^{\mu_N}\sum_{j\in\mathbb{Z}} (|a_{mj}|+|b_{mj}|)^2\right)^{1-\alpha}.$$

Now obviously

$$\begin{aligned} |a_{mj}-b_{mj}| &\le |\mathcal{F}_m^{(\psi)}(2^m\cdot(x+h)+j)-\mathcal{F}_m^{(\psi)}(2^m\cdot x+j)| \\ &\quad +|\mathcal{F}_m^{(\psi)}(2^m\cdot x+j)|\cdot|\chi_{mN}(2^m\cdot(x+h)+j)-\chi_{mN}(2^m\cdot x+j)|. \end{aligned} \tag{A.11}$$

Since $\{\mathcal{F}_m^{(\psi)}(2^m\cdot(x+h)+j)-\mathcal{F}_m^{(\psi)}(2^m\cdot x+j)\}_{j\in\mathbb{Z}}$, $m=0,\dots,\mu_N$, are Fourier coefficients in the expansion of $\Delta_h G(x+\cdot)$ with respect to the orthonormal system $\{\psi_{mj}\}_{j\in\mathbb{Z}}$, $m=0,\dots,\mu_N$, then (see (A.7)–(A.8))

(A.12)
$$\sum_{m=0}^{\mu_N}\sum_{j\in\mathbb{Z}} |\mathcal{F}_m^{(\psi)}(2^m(x+h)+j)-\mathcal{F}_m^{(\psi)}(2^m x+j)|^2 \le ||\Delta_h G||_{L_2} \le C(s)\, I_s |h|^{s\wedge 1}.$$

When we estimate the second term in the r.h.s. of (A.11) we consider two cases: (i) $2^m|h| \le 1$ and (ii) $2^m|h| > 1$. In the first case, by taking into account that $|\chi_{mN}(2^m\cdot(x+h)+j)-\chi_{mN}(2^m\cdot x+j)|^2 \le (2^m|h|)^2$ (see (A.7) and (3.11)), we have

$$\begin{aligned} &\sum_{m=0}^{\mu_N}\sum_{j\in\mathbb{Z}} |\mathcal{F}_m^{(\psi)}(2^m\cdot x+j)|^2\cdot|\chi_{mN}(2^m\cdot(x+h)+j)-\chi_{mN}(2^m\cdot x+j)|^2 \\ &\quad \le (2^m|h|)^2\cdot\sum_{m=0}^{\mu_N}\sum_{j\in\mathbb{Z}} |\mathcal{F}_m^{(\psi)}(2^m\cdot x+j)|^2 \le (2^m|h|)^{s\wedge 1}\cdot\sum_{m=0}^{\mu_N}\sum_{j\in\mathbb{Z}} |\mathcal{F}_m^{(\psi)}(2^m\cdot x+j)|^2 \\ &\quad \le B_s^2\cdot I_s\cdot|h|^{s\wedge 1} \qquad \text{if} \quad 2^m|h|\le 1. \end{aligned}$$

In the second case (i.e., $2^m|h|>1$) it is obvious that $(2^m|h|)^s > 1$ and $|\chi_{mN}(2^m\cdot(x+h)+j)-\chi_{mN}(2^m\cdot x+j)|^2 \le 1$. Therefore, in this case

$$\begin{aligned} &\sum_{m=0}^{\mu_N}\sum_{j\in\mathbb{Z}} |\mathcal{F}_m^{(\psi)}(2^m\cdot x+j)|^2\cdot|\chi_{mN}(2^m\cdot(x+h)+j)-\chi_{mN}(2^m\cdot x+j)|^2 \\ &\quad \le \sum_{m=0}^{\mu_N}\sum_{j\in\mathbb{Z}} |\mathcal{F}_m^{(\psi)}(2^m\cdot x+j)|^2 \le (2^m|h|)^{2s}\cdot\sum_{m=0}^{\mu_N}\sum_{j\in\mathbb{Z}} |\mathcal{F}_m^{(\psi)}(2^m\cdot x+j)|^2 \\ &\quad \le B_s 2\cdot I_s\cdot|h|^{2s} \qquad \text{if} \quad 2^m|h|>1. \end{aligned} \tag{A.13}$$

Thus in the general case we have

$$\sum_{m=0}^{\mu_N}\sum_{j\in\mathbb{Z}}|\mathcal{F}_m^{(\psi)}(2^m\cdot x+j)|^2\cdot|\chi_{mN}(2^m\cdot(x+h)+j)-\chi_{mN}(2^m\cdot x+j)|^2$$

$$\le B_s^2\cdot I_s\cdot|h|^{s\wedge 1}\qquad\text{if}\quad |h|\le 1. \tag{A.14}$$

By using (A.12) and (A.14) and taking into account (A.11) we obtain

$$\sum_{m=0}^{\mu_N}\sum_{j\in\mathbb{Z}}|a_j-b_j|^2\le C(s)\cdot I_s\cdot|h|^{s\wedge 1}\qquad\text{if}\quad |h|\le 1. \tag{A.15}$$

To estimate the second factor on the r.h.s. of inequality (A.10) we first notice that

$$\sum_{j\in\mathbb{Z}}(|a_j|+|b_j|)^2\le 2\cdot E(v_m^{(2)}(x+h))^2\ +\ 2\cdot E(v_m^{(2)}(x))^2.$$

Then by using the inequality (3.21) we get

$$\sum_{j\in\mathbb{Z}}(|a_j|+|b_j|)^2\le\frac{C(\rho_m,\psi)}{b_{mN}^{2\rho_m-1}}\cdot 2^{-m}||Q||^2_{L_1(\Delta_m)}+\frac{C(\rho_m,\psi)}{b_{mN}^{2\rho_m-1}}\cdot 2^{m(2\rho_m-1)}||Q||^2_{b^{\rho_m}_{1\infty}(\Delta_m)} \tag{A.16}$$

for $m=0,1,\dots,\mu_N$.

From (A.10), (A.15), and (A.16) we get (4.6). The proof of Lemma 4.2 is complete. □

LEMMA A.1. *Let $\hat f\in B^r_{1\infty}(\mathbb{R})$, $r>1/2$. Then f is uniformly continuous, $f\in L_2(\mathbb{R})$, and there exists a positive constant C_r depending only on r such that for all $x\in\mathbb{R}$*

$$|x|^r\,|f(x)|\le C_r||\hat f||_{b^r_{1\infty}}. \tag{A.17}$$

Proof. The uniform continuity of f follows from the fact that $\hat f\in L_1(\mathbb{R})$, since $B^r_{1\infty}(\mathbb{R})\subset L_1(\mathbb{R})$. Then, for a positive $\varepsilon\in(0,r-1/2)$ by (3.2) and (3.3),

$$B^r_{1\infty}(\mathbb{R})\hookrightarrow B^{r-1/2}_{2\infty}(\mathbb{R})\hookrightarrow B^{r-1/2-\varepsilon}_{22}(\mathbb{R}). \tag{A.18}$$

From this we get that $\hat f\in L_2(\mathbb{R})$, and hence $f\in L_2(\mathbb{R})$. Let $l=\lfloor r\rfloor$ be the integer part of r. From

$$\Delta_h^{(l+2)}\hat f(k)=\int_{-\infty}^{\infty}e^{-\mathrm{i}\,2\pi\,kx}(e^{-\mathrm{i}\,2\pi\,hx}-1)^{l+2}f(x)\,dx \tag{A.19}$$

and $f\in L_2(\mathbb{R})$, it follows by the inverse Fourier transform that

$$f(x)(e^{-\mathrm{i}\,2\pi\,hx}-1)^{l+2}=\int_{-\infty}^{\infty}e^{\mathrm{i}\,2\pi\,kx}\Delta_h^{(l+2)}\hat f(k)\,dk. \tag{A.20}$$

By taking the absolute values and dividing this equation by $|h|^r$ we then take the supremum over $h\in\mathbb{R}$. This yields

$$|x|^r\,|f(x)|C'_r\le\sup_{h\in\mathbb{R}}|h|^{-r}\,||\Delta_h^{(l+2)}\hat f||_{L_1},\quad C'_r=\sup_{t\in\mathbb{R}}\left\{\frac{|e^{-\mathrm{i}\,2\pi\,t}-1|^{l+2}}{|t|^r}\right\}.$$

Since the triple $(r, l+2, 0)$ is admissible, we have $\sup_{h\in\mathbb{R}} |h|^{-r} ||\Delta_h^{(l+2)} \hat{f}||_{L_1} \le C_r'' ||\hat{f}||_{b_{1\infty}^r}$ for some C_r'' depending only on r, which completes the proof of Lemma A.1. □

LEMMA A.2. *Assume that $\phi \in C^2(\mathbb{R})$ is chosen so that ϕ, $\phi' = D^1\phi$, $\phi'' = D^2\phi \in L_\infty(\mathbb{R})$. Then for $\varepsilon \in [0,1)$ and $Q \in B_{1\infty}^{1+\varepsilon}(\mathbb{R})$ the product $\phi \cdot Q \in B_{1\infty}^{1+\varepsilon}(\mathbb{R})$ and $||\phi Q||_{b_{1\infty}^{1+\varepsilon}} \le C||Q||_{B_{1\infty}^{1+\varepsilon}}$ for some constant $C = C(\varepsilon, \phi)$ depending only on ε and ϕ.*

Proof. From the obvious equalities

$$\phi(x+h) = \phi(x) + h\phi'(x) + h^2\phi''(x+\alpha\cdot h)/2, \quad \alpha \in [0,1],$$
$$\phi(x+2h) = \phi(x) + 2h\phi'(x) + 2h^2\phi''(x+\beta\cdot 2h), \quad \beta \in [0,1],$$

it follows that

$$\Delta_h^{(2)}(\phi Q)(x) = \phi(x)\cdot\Delta_h^{(2)}Q(x) + 2h\cdot\phi'(x)\Delta_h Q(x+h) + 2h^2\phi''(x+\beta\cdot 2h)Q(x+2h) - h^2\phi''(x+\alpha\cdot h)Q(x+h).$$

Therefore

$$||\Delta_h^{(2)}(\phi Q)||_{L_1} \le ||\phi||_{L_\infty}\cdot||\Delta_h^{(2)}Q||_{L_1} + 2|h|\cdot||\phi'||_{L_\infty}\cdot||\Delta_h Q||_{L_1} + 3h^2||\phi''||_{L_\infty}\cdot||Q||_{L_1}.$$

Since

$$||\Delta_h^{(2)}Q||_{L_1} \le ||Q||_{B_{1\infty}^{1+\varepsilon}}|h|^{1+\varepsilon}, \quad ||\Delta_h Q||_{L_1} \le ||Q||_{B_{1\infty}^{\varepsilon}}\cdot|h|^{\varepsilon} \le C(\varepsilon)||Q||_{B_{1\infty}^{1+\varepsilon}}\cdot|h|^{\varepsilon},$$

then for $|h| \le 1$ we have

$$||\Delta_h^{(2)}(\phi Q)||_{L_1} \le (||\phi||_{L_\infty} + 2C(\varepsilon)||\phi'||_{L_\infty} + 3||\phi''||_{L_\infty})\cdot||Q||_{B_{1\infty}^{1+\varepsilon}}|h|^{1+\varepsilon}.$$

This completes the proof. □

COROLLARY A.1. *For $r > 0$, let $\psi \in C^{\lfloor r\rfloor+1}$ be chosen so that*

$$\max_{n=0,1,\ldots,\lfloor r\rfloor+1} ||D^n\psi||_{L_\infty} < \infty.$$

Then there exists a constant $C = C(r,\psi)$ such that $||\psi F||_{b_{1\infty}^r} \le C||F||_{B_{1\infty}^r}$ for each $F \in B_{1\infty}^r(\mathbb{R})$.

Proof. Since $||\psi F||_{b_{1\infty}^r} = \sup_{h:\,|h|\le 1}\frac{1}{|h|^{1+\varepsilon}}\cdot||\Delta_h^{(2)}(\psi F)^{(l)}||_{L_1}$, where $l = \lfloor r\rfloor - 1$, and $\varepsilon = r - \lfloor r\rfloor$, it is sufficient to show that $||\Delta_h^{(2)}(\psi F)^{(l)}||_{L_1} \le C(r,\psi)||F||_{B_{1\infty}^r}\cdot|h|^{1+\varepsilon}$. Indeed, $\Delta_h^{(2)}(\psi F)^{(l)} = \sum_{n=0}^{l} C_l^n \Delta_h^{(2)}(\psi^{(n)}F^{(l-n)})$. For all n $(0 \le n \le l)$, the functions $\phi = \psi^{(n)}$ and $Q = F^{(l-n)}$ satisfy all of the conditions of Lemma A.2. Therefore, by taking into account that $||\Delta_h^{(2)}Q||_{B_{1\infty}^{1+\varepsilon}} \le c(r)h^{1+\varepsilon}||Q||_{B_{1\infty}^r}$ and using the result of Lemma A.2, one completes the proof of the corollary. □

COROLLARY A.2. *Let $r > 0$ and $\psi \in C^{\lfloor r\rfloor+1}$ be a function with a compact support $\Delta = \mathrm{supp}\{\psi\}$. Then there exists a constant $C = C(r,\psi)$ such that $||\psi f||_{B_{1\infty}^r(\mathbb{R})} \le C||f||_{B_{1\infty}^r(\Delta)}$ for each $f \in B_{1\infty}^r(\Delta)$.*

Proof. Indeed, let us denote by A the extension operator $A : B_{1\infty}^r(\Delta) \to B_{1\infty}^r(\mathbb{R})$, i.e., $(Af)(x) = f(x)$ for $x \in \Delta$ and $f \in B_{1\infty}^r(\Delta)$. The existence of a bounded linear extension operator is well known (e.g., see [27]). The corollary then follows from

$$||\psi f||_{B_{1\infty}^r(\mathbb{R})} = ||\psi\cdot Af||_{B_{1\infty}^r(\mathbb{R})} \le C(r,\psi)||Af||_{B_{1\infty}^r(\mathbb{R})} \le C(r,\psi)\cdot||A||\cdot||f||_{B_{1\infty}^r(\Delta)}.$$ □

Below, we give a result about characterization of the Besov space norms through wavelet coefficients.

For a nonnegative integer L we denote by $\mathcal{R}^L$ the class of $(L+1)$-times continuously differentiable functions $f : \mathbb{R} \to \mathbb{R}$ satisfying the following conditions:

$$\int_{\mathbb{R}} x^n f(x)dx = 0 \quad \text{for} \quad n = 0, 1, 2, \ldots, L;$$

$$\exists \gamma > 0,\, C > 0 \quad \text{such that} \quad |f(x)| \le \frac{C}{(1+|x|)^{2+L+\gamma}} \quad \forall x \in \mathbb{R};$$

$$\exists \varepsilon > 0,\, C_1 > 0 \quad \text{such that} \quad \max_{1 \le n \le L+1} |D^n f(x)| \le \frac{C}{(1+|x|)^{1+\varepsilon}} \quad \forall x \in \mathbb{R}. \tag{A.21}$$

It is known (e.g., see [24], [14], [38]) that, under the assumption $\psi \in \mathcal{R}^{\lfloor s \rfloor}$ on a wavelet function ψ, the norm $||f||_{B^s_{pq}}$ in Besov's space $B^s_{pq}(\mathbb{R})$, $1 \le p, q \le \infty$, $s > 0$, can be equivalently defined through the wavelet coefficients $\beta_{mj}(f) = \int_{\mathbb{R}} f(x)\, \psi_{mj}(x)dx$, m, $j \in \mathbb{Z}$, where $\psi_{mj}(x) = 2^{m/2}\psi(2^m\, x - j)$. Namely, let us introduce the norm $||\cdot||^{(\psi)}_{B^s_{pq}}$ by

$$||f||^{(\psi)}_{B^s_{pq}} = ||f||_{L_p} + \left\{ \sum_{m=-\infty}^{\infty} \left[\sum_{j=-\infty}^{\infty} \left(|\beta_{mj}(f)| \cdot 2^{m(s+\frac{1}{2}-\frac{1}{p})} \right)^p \right]^{q/p} \right\}^{1/q} \qquad (1 \le q < \infty),$$

$$||f||^{(\psi)}_{B^s_{p\infty}} = ||f||_{L_\infty} + \sup_{m \in \mathbb{Z}} \left[\sum_{j=-\infty}^{\infty} \left(|\beta_{mj}(f)| \cdot 2^{m(s+\frac{1}{2}-\frac{1}{p})} \right)^p \right]^{1/p}.$$

Then there exist constants $C_1 = C_1(p, q, s, \psi) > 0$ and $C_2 = C_2(p, q, s, \psi) > 0$ such that

$$C_1 \cdot ||f||^{(\psi)}_{B^s_{pq}} \le ||f||_{B^s_{pq}} \le C_2 \cdot ||f||^{(\psi)}_{B^s_{pq}} \qquad \forall f \in B^s_{pq}(\mathbb{R}). \tag{A.22}$$

As an immediate consequence of the last inequality we arrive at the following.

COROLLARY A.3. *For $s > 0$, let ψ be an orthonormal wavelet function satisfying the condition $\psi \in \mathcal{R}^{\lfloor s \rfloor}$. Then there exists a constant $C = C(p, q, s, \psi)$ such that for each $f \in B^s_{pq}(\mathbb{R})$*

$$\left\{ \sum_{j=-\infty}^{\infty} |\beta_{mj}(f)|^p \right\}^{1/p} \le C \cdot 2^{-m(s+\frac{1}{2}-\frac{1}{p})} \cdot ||f||_{B^s_{pq}}. \tag{A.23}$$

OPERATOR SPLITTING FOR AN IMMUNOLOGY MODEL USING REACTION-DIFFUSION EQUATIONS WITH STOCHASTIC SOURCE TERMS*

TIMOTHY A. LUCAS†

Abstract. When immune cells detect foreign molecules, they secrete soluble factors that attract other immune cells to the site of the infection. In this paper, I study numerical solutions to a model of this behavior proposed by Kepler. In this model the soluble factors are governed by a system of reaction-diffusion equations with sources that are centered on the cells. The motion of the model cells is a Langevin process that is biased toward the gradient of the soluble factors. I have shown that the solution to this system exists for all time and remains positive, the supremum is a priori bounded, and the derivatives are bounded for finite time. I have also developed a first order split scheme for solving the reaction-diffusion stochastic system. This allows us to make use of known first order schemes for solving the diffusion, the reaction, and the stochastic differential equations separately.

Key words. operator splitting, reaction-diffusion, stochastic differential equations

DOI. 10.1137/070701595

1. Introduction.

The immune system in higher organisms is composed of individual cells called leukocytes which work together to combat pathogens such as bacteria and viruses. These cells are unique because they move throughout the body and signal to each other in order to organize a response to an infection. Upon detecting pathogens in the body, an immune cell will secrete cytokines which are proteins that mediate communication among leukocytes and coordinate their response. Some cytokines called chemokines direct the motion of immune cells along their concentration gradient by a process known as chemotaxis. Other cytokines, such as tumor necrosis factor (TNF), recruit cells to the site of inflammation and activate immune cells. One process by which inflamation is regulated is the shedding of cytokine receptors, such as those for TNF (sTNFr). Those soluble receptors bind to the respective cytokines and limit their activity. Based on these signals, the cells will group together to respond to an infection. The ability of these cells to organize spatially in a timely manner is vital to an effective immune response.

The following sections describe a mathematical model of soluble factors and immune cell motion proposed in [7] and [6]. The cytokines are modeled continuously as soluble factors governed by reaction-diffusion equations with source terms that are centered on activated leukocytes. The motion of the immune cells is inherently stochastic but is biased toward the chemical gradients of the chemokines. We will show that solutions to this system exist and describe a numerical simulation of the model based on operator splitting. Although operator splitting is a well-known technique for solving reaction-diffusion systems; see [4], there is an added degree of difficulty due to the stochastic source terms.

1.1. Soluble factors. Suppose $U_i(x,t)$ is the local concentration of soluble factor i at the position x and time t. Let x_μ be the position of the center of cell μ in the bounded domain $\Omega \in \mathbb{R}^3$. Then, for $x \in \Omega$, the reaction-diffusion equations that describe the behavior of the soluble factors from [6] are

$$\frac{\partial U_i}{\partial t}(x,t) = \left\{ D_i \Delta - \sum_{j=1}^{N} r_{ij} U_j(x,t) - \lambda_i \right\} U_i(x,t) + \sum_{\mu=1}^{M} J_{i\mu} g_\mu(x - x_\mu(t)). \tag{1.1}$$

Here D_i denotes the diffusion coefficient for soluble factor U_i, r_{ij} is the rate at which U_i is removed by interaction with U_j, and λ_i is the rate of the removal of U_i by other factors. The secretion of soluble factor U_i by cell μ is a smoothly cutoff Gaussian source centered at the cell position x_μ, with support over the volume of the cell. The source term in (1.1) is a sum over the M individual cells indexed by μ, with secretion rates $J_{i\mu}$. The constants D_i, r_{ij}, and $J_{i\mu}$ are all nonnegative.

In this paper we consider a smooth source term with compact support as opposed to the point sources in [6] for two reasons. Point sources do not take into account the volume of the cells which can vary in size and shape. Also, the point sources in [6] are delta functions, and we are currently unaware of any rigorous mathematical treatment of (1.1) with this type of source. We will make use of the smoothness of the source terms in order to show the existence of a solution. In the simulation, there is no qualitative difference between the use of smooth sources versus point sources.

1.2. Cell motion. The system (1.1) is coupled with M systems of stochastic differential equations that describe the motion of each individual cell. For each cell, indexed by μ, we let $x_t \in \mathbb{R}^3$ be the position and $v_t \in \mathbb{R}$ be the velocity. The motion of each cell is a Langevin process

$$dx_t = v_t dt, \quad dv_t = [h(U(x_t)) - \gamma v]\, dt + \sigma\sqrt{\gamma} dW_t, \tag{1.2}$$

where dW_t is standard Brownian motion in $\mathbb{R}^3$. The direction of motion is random, but it is biased toward the direction of the vector $h(U)$, which depends on the local concentration of one or more of the soluble factors by the relation

$$h(U) = \sum_{i=1}^{N} \frac{\chi_i \nabla U_i}{h_0 + |\nabla U_i|}. \tag{1.3}$$

Here χ_i is the chemotactic constant that controls how much the drift is influenced by the gradient of soluble factor U_i, and h_0 is the length of the gradient of U_i at which h attains half of its maximum value. The constants γ, h_0, and χ_i are nonnegative.

In this model we track the motion of each cell to better understand their individual behavior and collective immune response. This is a departure from the mathematical models of pattern formation which are based on the work of Turing in [18], e.g., Othmer and Scriven [14] or Palsson and Othmer [15]. Early models of chemotaxis, such as Keller and Segel in [5], describe the density of immune cells by reaction-diffusion equations but not the motion of individual cells.

1.3. Notation. Throughout we will refer to $C_f(x_1, x_2, \ldots, x_n)$ as a constant that depends on the function f and the values of $x_1, x_2, \ldots, x_n$. We also refer to $L_f(x_1, x_2, \ldots, x_n)$ as a Lipschitz constant for the function f that depends on $x_1, x_2, \ldots, x_n$. We define $B_r(x)$ to be a ball of radius r centered at $x \in \mathbb{R}^n$. For $a, b \in \mathbb{R}$ we define $a \vee b = \max(a, b)$ and $a \wedge b = \min(a, b)$.

Let X and Y be sets and suppose that $f_i : X \to Y$, $i = 1, \ldots, n$. Then $(f_1, \ldots, f_n)$ is an n-tuple whose components are in Y^X. We shall also let $(f_1, \ldots, f_n)$ denote the function from X to Y^n which assigns $(f_1(x), f_2(x), \ldots f_n(x))$ to $x \in X$, i.e.,

$$(f_1, f_2, \ldots, f_n)(x) = (f_1(x), f_2(x), \ldots f_n(x)).$$

1.4. Overview and main results. In the following sections we consider the case where Ω is a cube and the reaction-diffusion equations for the soluble factors have periodic boundary conditions. Section 2 contains a proof that the reaction-diffusion-stochastic system (1.1), (1.2) has a solution for a short time. The contraction defined in section 2 is used in the convergence proofs in the following sections. We consider a first order split scheme in section 3 to make use of known numerical schemes for solving the diffusion, reaction, and stochastic differential equations for the cell motion. In section 4, we carefully add up the local truncation error due to the splitting using a method similar to the convergence proof of higher order numerical schemes for stochastic differential equations by Milstein in [11]. We also show that the solution to the reaction-diffusion system with a nonnegative initial condition is positive. We find in section 5 that the the supremum of the solution to the reaction-diffusion system is a priori bounded, and that derivatives are bounded for finite time. In addition, solutions to the reaction–diffusion-stochastic system exist for all time. The analysis in sections 2–5 is carried out using a single immune cell. The proofs for multiple cells are similar, and section 6 contains a sample simulation with three chemokine sources and multiple cells.

2. Short time existence. The definitions and estimates that follow allow us to define a contraction on the appropriate spaces in order to prove existence of a solution to the model (1.1), (1.2) for a short time.

2.1. Preliminaries. Suppose that the domain Ω is an open cube in $\mathbb{R}^n$, with side length Λ. Let $\mathbb{Z}^n$ be the set of integer frequencies $\omega = (\omega_1, \ldots, \omega_n)$, and define $|\omega|_\infty = \max_{1 \le i \le n} |\omega_i|$. Let $A(k, n)$ be the set of multi-indices $\alpha = (\alpha_1, \alpha_2, \ldots \alpha_n)$, with weight $w(\alpha) = \sum_{i=1}^n |\alpha_i| \le k$. Let $\mathcal{E}$ be the vector space of smooth Λ-periodic complex valued functions on $\mathbb{R}^n$. For each $\omega \in \mathbb{Z}^n$, define $E_\omega(x) \in \mathcal{E}$ by

$$E_\omega(x) = \Lambda^{-\frac{n}{2}} e^{\frac{i2\omega \cdot x}{\Lambda}}, \quad x \in \Omega. \tag{2.1}$$

For a locally integrable function f, define the Fourier coefficient

$$c_\omega(f) = \int_\Omega f(x) E_\omega(x) dx. \tag{2.2}$$

For $s \in \mathbb{R}$ and a locally integrable function f, let $\|f\|_s \in [0, \infty]$ be such that

$$\|f\|_s^2 = \sum_{\omega \in \mathbb{Z}^n} (1 + |\omega|_\infty^2)^s |c_\omega(f)|^2. \tag{2.3}$$

DEFINITION 2.1. *For $s \ge 0$, define $\mathbb{H}_s$ to be the space of measurable, Λ-periodic, complex valued functions f on $\Omega \subset \mathbb{R}^n$ such that $\|f\|_s < \infty$.*

The following facts from [3] about Sobolev spaces are useful throughout.

Remark 2.2. If $k > \frac{n}{2}$, then corresponding to any element $f \in \mathbb{H}_k$ is a continuous function $g \in \mathbb{H}_k$ such that $f = g$ a.e. We may therefore assume when $k > \frac{n}{2}$ that

the elements of $\mathbb{H}_k$ are continuous. Moreover, the set $\{f \in \mathbb{H}_k : f \text{ is continuous}\}$ is a Hilbert space with respect to $\|\cdot\|_k$. For $g_\alpha = \partial_\alpha f$ in the sense of distributions,

$$\|f\|_k^2 = \sum_{w(\alpha)\le k} \|g_\alpha\|_0^2 . \tag{2.4}$$

LEMMA 2.3 (Sobolev's lemma). *Let $k > \frac{n}{2} + l$. Then*

$$\sup_{w(\alpha)\le l} |\partial^\alpha f(x)| \le C(k,l)\, \|f\|_k . \tag{2.5}$$

Remark 2.4. Note that $f \in \mathbb{H}_{k+l}$ if and only if $\partial^\alpha f \in \mathbb{H}_k$ for $w(\alpha) \le l$.

Define the linear map $\Delta : \mathbb{H}_4 \to \mathbb{H}_2$ by $\Delta f = \sum_{i=1}^n \partial_{x_i}^2 f$. Then, for $s \ge 2$,

$$\|\Delta f\|_s \le \|(1-\Delta)(f)\|_s = \|f\|_{s+2} . \tag{2.6}$$

Let $\mathbb{H}_k^N$ be the space of N-tuples $u = (u_1, u_2, \dots, u_N)$ such that $u_i \in \mathbb{H}_k$ for $i = 1, 2 \dots, N$, and set

$$\|u\|_k = \left(\sum_{i=1}^N \|u_i\|_k^2 \right)^{\frac{1}{2}} . \tag{2.7}$$

By our convention $(u_1, \dots, u_N)(x) = (u_1(x), \dots, u_N(x))$. Define $\mathcal{D} : \mathbb{H}_4^N \to \mathbb{H}_2^N$ by

$$\mathcal{D}u = (D_1 \Delta u_1, D_2 \Delta u_2, \dots, D_N \Delta u_N), \tag{2.8}$$

where $D_i > 0$ for $i = 1, 2 \dots, N$ as in (1.1).

We now define the fundamental solution of the diffusion equation. For $t > 0$, define the linear map $K_t : \mathbb{H}_k^N \to \mathcal{E}^N$ by requiring that

$$(K_t(u))_i = \sum_{\omega \in \mathbb{Z}^n} e^{-\frac{2D_i |w|^2 t}{\Lambda}} c_\alpha(u_i) E_\omega . \tag{2.9}$$

Note that

$$\frac{d}{dt} K_t(u) = \mathcal{D}(K_t(u)) = K_t(\mathcal{D}(u)). \tag{2.10}$$

It also follows that

$$\|K_t u\|_s \le \|u\|_s . \tag{2.11}$$

Below we define the space of solutions to the reaction-diffusion equations (1.1).

DEFINITION 2.5. *For any integer $k > \frac{n}{2}$, let $\mathbf{B}_k^N(m_1, m_2)$ be the set of N-tuples $u \in \mathbb{H}_k^N$ such that $\sup|u| \le m_1$ and $\|u\|_k \le m_2$. Note that*

$$\mathbb{H}_k^N = \bigcup_{0 \le m_1, m_2 < \infty} \mathbf{B}_k^N(m_1, m_2).$$

Remark 2.6. If $u \in \mathbf{B}_k^N(m_1, m_2)$ and $t > 0$, then $\sup|K_t(u)| \le \sup|u|$.

DEFINITION 2.7. *For any integer $k > \frac{n}{2}$, let $\mathbf{C}_{k,T}^N(m_1, m_2)$ be the set of functions $U : [0, T] \to \mathbf{B}_k^N(m_1, m_2)$ that are continuous with respect to $\|\cdot\|_k$. Then define*

$$\|U\|_{k,T} = \sup_{0 \le t \le T} \|U(t)\|_k . \tag{2.12}$$

Also, let

$$\mathbf{C}^N_{k,T} = \bigcup_{0\le m_1,m_2<\infty} \mathbf{C}^N_{k,T}(m_1,m_2).$$

Below we define the space of solutions to the stochastic differential equations (1.2).

DEFINITION 2.8. *Suppose $T>0$ and $m>0$. Define $\mathcal{S}_T(m)$ to be the space of continuous stochastic processes on $\mathbb{R}^n$ such that the norm*

$$\|X_t\|_{\mathcal{S}_T} = \left(\mathbb{E}\left[\sup_{0\le t\le T}|X_t|^2\right]\right)^{\frac{1}{2}} \le m. \tag{2.13}$$

We now define the space of functions which will contain the solutions to the reaction–diffusion-stochastic system (1.1), (1.2).

DEFINITION 2.9. *For any integer $k>\frac{n}{2}$, let $\mathcal{B}^N_k(m_1,m_2,m_3)$ be the space of ordered pairs $\phi=(u,\xi)$, where $u\in\mathbf{B}^N_k(m_1,m_2)$ and ξ is a random variable with values in $\mathbb{R}^n$ such that $\mathbb{E}\left[|\xi|^2\right]^{\frac{1}{2}}\le m_3$. Then, for $\psi=(v,\zeta)\in\mathcal{B}^N_k(m_1,m_2,m_3)$, define*

$$(\phi,\psi)_k = (u,v)_k + \xi\cdot\zeta, \tag{2.14}$$

$$|||\phi|||_k = \mathbb{E}\left[(\phi,\phi)_k\right]^{\frac{1}{2}} = \mathbb{E}\left[\|u\|^2_k+|\xi|^2\right]^{\frac{1}{2}}. \tag{2.15}$$

DEFINITION 2.10. *For any integer $k>\frac{n}{2}$ and $T>0$, let $\mathcal{C}^N_{k,T}(M_1,M_2,M_3)$ be the Cartesian product of $\mathbf{C}^N_{k,T}(M_1,M_2)$ and $\mathcal{S}_T(M_3)$. Define the norm $|||\cdot|||_{k,T}$ by*

$$|||(U,X)|||_{k,T} = \mathbb{E}\left[\sup_{0\le t\le T}\left(\|U(t)\|^2_k+|X_t|^2\right)\right]^{\frac{1}{2}}. \tag{2.16}$$

Since our space of solutions is periodic, we must define the Gaussian source terms to be periodic as well. Let $g_\mu:\mathbb{R}^n\to\mathbb{R}$ be a mean zero Gaussian, with standard deviation μ. Define $g_{\mu,i}$ to be the periodification of g_μ, i.e., $g_{\mu,i}(x)=\sum_{j\in\mathbb{Z}} g_\mu\left(x-\frac{2\pi j}{\Lambda}\right)$. Let $\bar{J}_i>0$ for $i=1,2,\dots,N$ and $J=\max\{\bar{J}_i : i=1,2,\dots,N\}$. Then let $\epsilon>0$ and $J_i:\mathbb{R}^n\to\mathbb{R}$ be a smooth cutoff defined by

$$J(X)=\begin{cases}\bar{J}_i & X\in\left(-\frac{\Lambda}{2}+\epsilon,\frac{\Lambda}{2}-\epsilon\right)^3,\\ 0 & X\notin\left(-\frac{\Lambda}{2},\frac{\Lambda}{2}\right)^3.\end{cases}$$

Then define $g_\mu:\mathbb{R}^n\times\mathbb{R}^n\to\mathbb{R}^N$ by $g_\mu(X,x)=(J_1(X)g_{\mu,1}(x),\dots,J_N(X)g_{\mu,N}(x))$.

Let $T>0$, $(U,X)\in\mathcal{C}^N_{k,T}$, and $\mathcal{T}_x$ be translation by $x\in\mathbb{R}^n$. Throughout we will consider the reaction–diffusion-stochastic system with one cell:

$$\begin{aligned}\frac{dU}{dt} &= \mathcal{D}U(t)+f(U)(t)+g(X_t)\circ\mathcal{T}_{X_t},\quad 0<t<T,\\ dX_t &= a(U(X_t),X_t)dt+b(X_t)dW_t,\quad 0<t<T,\\ (U,X)(0) &= (u,\xi),\end{aligned} \tag{2.17}$$

where $u\in\mathbb{H}^N_k$ and $\xi\in\mathbb{R}^n$. We will usually consider the case where $n=3$.

Remark 2.11. We choose to work with a single cell in order to make the proofs more clear. For multiple cells, the definition of g and the estimates that follow would include a sum over all cells indexed by μ.

Remark 2.12. We compose g with $\mathcal{T}_{X_t}$ so that the Gaussian source term is centered on the position of the cell. If the cell leaves the domain, then the cutoff J restricts the source term g from contributing to the reaction-diffusion equation. Since J_i is a function of X, g is still periodic in x.

2.2. Estimates for the reaction-diffusion equations. The following theorem provides estimates for the reaction terms $f(u)$.

THEOREM 2.13. *Let N be a positive integer and $f : \mathbb{R}^N \to \mathbb{R}^N$ be a smooth function such that $f(0) = 0$. Suppose that $0 \le m_1, m_2 < \infty$, k is a nonnegative integer, and $u, v \in \mathbf{B}_k^N(m_1, m_2)$. Then*

$$|f(u)| \le c_{f,1}(m_1)\,|u|\,, \tag{2.18}$$

$$\|f(u)\|_k \le C_{f,k}(m_1)\,\|u\|_k\,, \tag{2.19}$$

where

$$c_{f,k}(m_1) = \sup\left\{\left|\left(\frac{\partial}{\partial u}\right)^{\alpha} f(u)\right| : w(\alpha) \le k, u \in \mathbb{R}^N \text{ and } |u| \le m_1\right\}, \tag{2.20}$$

$$C_{f,k}(m_1) = C(k,N)c_{f,\max\{1,k\}}(m_1)(1+m_1)^{\max\{0,k-1\})}. \tag{2.21}$$

Let $k = 0$ or $k > \frac{n}{2}$. Then we also have

$$\|f(u) - f(v)\|_k \le L_{f,k}(m_1, m_2)\,\|u - v\|_k\,, \tag{2.22}$$

where

$$\begin{aligned} L_{f,0}(m_1) &= c_{f,1}(m_1), \\ L_{f,k}(m_1, m_2) &= C(k,N)c_{f,k+1}(m_1)(1+m_1)^{k-1}m_2. \end{aligned} \tag{2.23}$$

Proof. We can rewrite

$$\begin{aligned} f(u) - f(v) &= \int_0^1 \frac{d}{dt} f((1-t)v + tu)dt \\ &= \left(\int_0^1 \partial f\big((1-t)v + tu\big)\frac{d}{dt}((1-t)v + tu)dt\right) \\ &= \left(\int_0^1 \partial f\big((1-t)v + tu\big)dt\right)(u - v). \end{aligned}$$

It immediately follows from the Cauchy–Schwarz inequality that

$$\|f(u) - f(v)\|_0 \le c_{f,1}(m_1)\,\|u - v\|_0\,,$$

and, for $v = 0$, we have $|f(u)| \le c_{f,1}(m_1)\,|u|$ and $\|f(u)\|_0 \le c_{f,1}(m_1)\,\|u\|_0$.

Let k be a positive integer. Using well-known arguments found in [16, section 13.3], there exist constants $C(k,N)$ and $C(k)$ such that

$$\|f(u)\|_k \le C(k,N)c_{f,k}(m_1)(1+m_1)^{k-1}\,\|u\|_k\,, \tag{2.24}$$

$$\|u_1 u_2\|_k \le C(k)\left(\|u_1\|_k\,\|u_2\|_\infty + \|u_1\|_\infty\,\|u_2\|_k\right). \tag{2.25}$$

Then (2.19) immediately follows from (2.24).

Now consider $k > \frac{n}{2}$. Rewrite $f(u) - f(v) = u_1 u_2$, where $u_1 = \int_0^1 \partial f\big((1-t)v + tu\big)dt$ and $u_2 = u - v$. Then by (2.24),

$$\|u_1\|_k \le C(k+1, N) c_{f,k+1}(m_1)(1+m_1)^k (\|u\|_k \vee \|v\|_k). \tag{2.26}$$

The result (2.22) follows from substituting (2.20) and (2.26) into (2.25) and applying the Sobolev inequality. □

The following estimates on the source terms g can be easily obtained.

LEMMA 2.14. *For $k \ge 0$, there exist constants C_g, $C_{g,k}$, and $L_{g,k}$ such that*

$$|g| \le C_g, \quad \|g\|_k \le C_{g,k}, \quad \text{and} \quad \|g \circ \mathcal{T}_y - g \circ \mathcal{T}_z\|_k \le L_{g,k}|y - z|. \tag{2.27}$$

2.3. Estimates for the cell motion. Let $X_t = (x_t, v_t)$,

$$a(u, X_t) = \begin{pmatrix} v_t \\ h(u) - \gamma v_t \end{pmatrix}, \quad \text{and} \quad b(X_t) = \begin{pmatrix} 0 & 0 \\ 0 & \sigma\sqrt{\gamma} \end{pmatrix}. \tag{2.28}$$

It is immediately clear that b is Lipschitz in X and bounded. We also have

$$|a(u(X), X)| \le C_a(m), \quad X \in \mathcal{S}_T(m), \tag{2.29}$$

since h is bounded by $N(\max_{1\le i\le N} \chi_i)$. Recall from (1.3) that h depends on $\nabla u(X_t)$. Using the Sobolev lemma we can show that a is Lipschitz in both u and X.

LEMMA 2.15. *The drift $a(u(X), X)$ is Lipschitz in u and X, i.e., there exist constants $L_{a,1}(M_2)$ and $L_{a,2}(M_2)$ such that if $u, v \in \mathbf{B}_4^N(M_1, M_2)$, then*

$$|a(u(X), X) - a(v(Y), Y)| \le L_{a,1}(M_2)\,\|u - v\|_3 + L_{a,2}(M_2)\,|X - Y|\,. \tag{2.30}$$

The proof of this lemma depends on the fact that the supremum is bounded by the $\mathbb{H}_k$ norm for $k > \frac{3}{2}$ in three dimensions. Therefore, the supremum of the difference between u and $v \in \mathbf{B}_4^N$ is bounded by the $\mathbb{H}_3$ norm and a Lipschitz constant for ∇u is $\|u\|_4$. Also ∇u is Lipschitz in x, with a constant depending on $\|u\|_4$.

The facts below about Itô integrals from [10] and [13] are useful throughout.

PROPOSITION 2.16 (Itô isometry). *Let $X_t \in \mathcal{S}_T(m)$ and $0 \le t_1 \le t_2 \le T$. Then*

$$\mathbb{E}\left[\left|\int_{t_1}^{t_2} X_t dW_t\right|^2\right] = \mathbb{E}\left[\int_{t_1}^{t_2} |X_t|^2 dt\right]. \tag{2.31}$$

PROPOSITION 2.17 (Doob's martingale inequality for stochastic integrals). *Let $X_t \in \mathcal{S}_T(m)$. Then $\int_0^t X_\tau dW_\tau$ is a martingale, and*

$$\mathbb{E}\left[\sup_{0\le t\le T}\left|\int_0^t X_\tau dW_\tau\right|^p\right] \le \frac{p}{p-1}\mathbb{E}\left[\left|\int_0^T X_\tau dW_\tau\right|^p\right]. \tag{2.32}$$

2.4. Short-time existence. We now set up a contraction to show the existence of a solution to (2.17) for a short time. Define $F : \mathbf{C}_{k,T}^N \times \mathbb{R}^n \times \mathbb{H}_k^N \to \mathbf{C}_{k,T}^N$ by

$$F(U, X, u)(t) = K_t(u) + \int_0^t K_{t-\tau}(f(U) + g \circ \mathcal{T}_{X_\tau})d\tau, \tag{2.33}$$

and $G : \mathbf{C}_{k,t} \times \mathbb{R}^n \to \mathbb{R}^n$ by

$$G(U, X, \xi)(t) = \xi + \int_0^t a(U(X_\tau, \tau), X_\tau)d\tau + \int_0^t b(X_\tau)dW_\tau. \tag{2.34}$$

Then for $X, \xi \in \mathbb{R}^n$, $U \in \mathbf{C}^N_{k,T}$, and $u \in \mathbb{H}^N_k$, define

$$H(U,X,u,\xi)(t) = \big(F(U,X,u)(t), G(U,X,\xi)(t)\big). \tag{2.35}$$

To show H is a contraction, we first let $0 \le m_1 \le M_1 < \infty$, $0 \le m_2 \le M_2 < \infty$, and $0 \le m_3 \le M_3 < \infty$. For an integer $k \ge 4$, assume that $u \in \mathbf{B}^N_k(m_1, m_2)$, $|\xi| \le m_3$, and $(U,X), (V,Y) \in \mathcal{C}^N_{k,T}(M_1, M_2, M_3)$. Then by (2.20) and (2.27),

$$\begin{aligned}
\sup_{0\le t\le T} |F(U,X,u)| &= \sup_{0\le t\le T} \left| K_t(u) + \int_0^t K_{t-\tau}(f(U))d\tau + \int_0^t K_{t-\tau}(g)d\tau \right| \\
&\le m_1 + \sup_{0\le t\le T} \int_0^t |K_{t-\tau}(f(U))|\, d\tau + \sup_{0\le t\le T} \int_0^t |K_{t-\tau}(g)|\, d\tau \\
&\le m_1 + \int_0^T |f(U)|\, d\tau + \int_0^T |g|\, d\tau \le m_1 + T[c_{f,1}(M_1)M_1 + C_g].
\end{aligned}$$

Similarly by (2.21) and (2.27),

$$\|F(U,X,u)\|_{k,T} \le m_2 + T[C_{f,k}(M_1)M_2 + C_{g,k}].$$

Finally, by the Cauchy–Schwarz inequality and Doob's martingale inequality,

$$\begin{aligned}
\|G(U,X,\xi)\|^2_{\mathcal{S}_T} &= \mathbb{E}\left[\sup_{0\le t\le T} \left| \xi + \int_0^t a(U(X_s,s),X_s)ds + \int_0^t b(X_s)dW_s \right|^2 \right] \\
&\le 3|\xi|^2 + 3\mathbb{E}\left[\sup_{0\le t\le T} \left(\left| \int_0^t a(U(X_s,s),X_s)ds \right|^2 + \left| \int_0^t b(X_s)dW_s \right|^2 \right) \right] \\
&\le 3m_3^2 + 3\mathbb{E}\left[T\int_0^T |a(U(X_s,s),X_s)ds|^2 + 4\left| \int_0^t b(X_s)dW_s \right|^2 \right].
\end{aligned}$$

Then by Itô isometry,

$$\|G(U,X,\xi)(t)\|^2_{\mathcal{S}_T} \le 3(m_3 + C_a(M_3)T^2 + 4C_bT).$$

Therefore, we can choose T such that

$$\sup_{0\le t\le T} |F(U,X,u)| \le M_1, \quad \|F(U,X,u)\|_{k,T} \le M_2, \quad \text{and} \quad \|G(U,X,\xi)\|_{\mathcal{S}_T} \le M_3.$$

Thus, H takes $\mathcal{C}^N_{k,T}(M_1,M_2,M_3) \times \mathbf{B}^N_k(m_1,m_2) \times B_{m_3}(0)$ into $\mathcal{C}^N_{k,T}(M_1,M_2,M_3)$. Next we show that H is Lipschitz with respect to the norm $|||\cdot|||_{k,T}$. By (2.22),

$$\begin{aligned}
&\|F(U,X,u)(t) - F(V,Y,u)(t)\|_k \\
&\quad = \left\| \int_0^t K_{t-\tau}(f(U(\tau)) - f(V(\tau)))d\tau + \int_0^t (g\circ\mathcal{T}_{X_\tau} - g\circ\mathcal{T}_{Y_\tau})\, d\tau \right\|_k \\
&\quad \le \int_0^t \|f(U(\tau)) - f(V(\tau))\|_k\, d\tau + \int_0^t \|g\circ\mathcal{T}_{X_\tau} - g\circ\mathcal{T}_{Y_\tau}\|_k\, d\tau \\
&\quad \le L_{f,k}(M_1,M_2)\int_0^t \|U(\tau) - V(\tau)\|_k\, d\tau + L_{g,k}\int_0^t |X_\tau - Y_\tau|\, d\tau.
\end{aligned}$$

By the Cauchy–Schwarz inequality,

$$
\begin{aligned}
&\mathbb{E}\big[\|F(U,X,u)-F(V,Y,u)\|_{k,T}^2\big]\\
&\quad=\mathbb{E}\left[\sup_{0\le t\le T}\left(L_{f,k}(M_1,M_2)\int_0^t\|U(\tau)-V(\tau)\|_k\,d\tau+L_{g,k}\int_0^t|X_\tau-Y_\tau|\,d\tau\right)^2\right]\\
&\quad\le 2\,\mathbb{E}\left[L_{f,k}(M_1,M_2)^2\left(\int_0^T\|U(\tau)-V(\tau)\|_k\,d\tau\right)^2+L_{g,k}^2\left(\int_0^T|X_\tau-Y_\tau|\,d\tau\right)^2\right]\\
&\quad\le 2T\,\mathbb{E}\left[L_{f,k}(M_1,M_2)^2\int_0^T\|U(\tau)-V(\tau)\|_k^2\,d\tau+L_{g,k}^2\int_0^T|X_\tau-Y_\tau|^2\,d\tau\right]\\
&\quad\le 2T^2\,\mathbb{E}\left[L_{f,k}(M_1,M_2)^2\sup_{0\le t\le T}\|U(\tau)-V(\tau)\|_k^2+L_{g,k}^2\sup_{0\le t\le T}|X_\tau-Y_\tau|^2\right]\\
&\quad\le T^2L_{F,k}(M_1,M_2)^2\,|||(U,X)-(V,Y)|||_{k,T}^2\,,
\end{aligned}
$$

where $L_F(M_2)^2=2\max\{L_{f,k}^2(M_2),L_{g,k}\}$.

Define $\tilde a(U(t),X_t,V(t),Y_t)=a(U(X_t,t),X_t)-a(V(Y_t,t),Y_t)$, and $\tilde b(X_t,Y_t)=b(X_t)-b(Y_t)$. By Lemma 2.15, the Cauchy–Schwarz inequality, and the Doob martingale inequality,

$$
\begin{aligned}
\|G(U,X,\xi)(t)-G(V,Y,\xi)(t)\|_{\mathcal{S}_T}^2&=\mathbb{E}\left[\sup_{0\le t\le T}|G(U,X,\xi)(t)-G(V,Y,\xi)(t)|^2\right]\\
&=\mathbb{E}\left[\sup_{0\le t\le T}\left|\int_0^t\tilde a(U(\tau),X_\tau,V(\tau),Y_\tau)d\tau+\int_0^t\tilde b(X_\tau,Y_\tau)dW_\tau\right|^2\right]\\
&\le 2\mathbb{E}\left[\sup_{0\le t\le T}\left|\int_0^t\tilde a(U(\tau),X_\tau,V(\tau),Y_\tau)d\tau\right|^2+\sup_{0\le t\le T}\left|\int_0^t\tilde b(X_\tau,Y_\tau)dW_\tau\right|^2\right]\\
&\le 2\mathbb{E}\left[\sup_{0\le t\le T}t\int_0^t|\tilde a(U(\tau),X_\tau,V(\tau),Y_\tau)|^2\,d\tau+4\left|\int_0^T\tilde b(X_\tau,Y_\tau)dW_\tau\right|^2\right]\\
&\le 2\mathbb{E}\left[T\int_0^T|\tilde a(U(\tau),X_\tau,V(\tau),Y_\tau)|^2\,d\tau+4\int_0^T\left|\tilde b(X_\tau,Y_\tau)\right|^2d\tau\right]\\
&\le 2T\mathbb{E}\left[TL_{a,1}(M_2)^2\|U(t)-V(t)\|_k^2+\big(TL_{a,2}(M_2)^2+4L_b^2\big)\sup_{0\le t\le T}|X_t-Y_t|^2\right]\\
&\le TL_{G,k}(M_2,M_3)^2\,|||(U,X)-(V,Y)|||_{k,T}^2\,,
\end{aligned}
$$

where $L_{G,k}(M_2,M_3)^2=2\max\{TL_{a,1}(M_2),TL_{a,2}(M_2)^2+4L_b^2)\}$. Therefore,

$$
|||H(U,X,u,\xi)-H(V,Y,u,\xi)|||_{k,T}^2\le L_{H,k}^2\,|||(U,X)-(V,Y)|||_{k,T}^2\,, \tag{2.36}
$$

where $L_{H,k}^2=L_{H,k}(M_1,M_2,M_3)^2=T\max\{TL_{F,k}(M_1,M_2)^2,L_{G,k}(M_2,M_3)^2\}$. Thus, H is a contraction for $T<L_{H,k}(M_1,M_2,M_3)^{-1}$. Given $(U,X)(0)=(u,\xi)$, it follows that there is a unique $(U,X)\in\mathcal{C}_{k,T}^N(M_1,M_2,M_3)$ such that $H(U,X,u,\xi)=(U,X)$.

Remark 2.18. Let $k\ge 0$, $(U,X),(V,Y)\in\mathcal{C}_{4,T}^N(M_1,M_2,M_3)$, and $(u,\xi)\in\mathcal{B}_4^N(M_1,M_2,M_3)$. Using the same argument as above, we also have the estimate

$$
|||H(U,X,u,\xi)-H(V,Y,u,\xi)|||_{k,T}^2\le L_{H,k\vee 3}\,|||(U,X)-(V,Y)|||_{k\vee 3,T}\,. \tag{2.37}
$$

The next lemma is the basis of the error estimates that follow.

LEMMA 2.19. *Let k be a nonnegative integer, $(U,X),(V,Y) \in \mathcal{C}^N_{4,T}(M_1,M_2,M_3)$, and $H(U,X,u,\xi) = (U,X)$. Then*

$$|||(U,X)-(V,Y)|||_{k,T} \le \frac{1}{1-L_{H,k}} \, |||H(V,Y,u,\xi)-(V,Y)|||_{k\vee 3,T}\,, \tag{2.38}$$

provided that $L_{H,k} = L_{H,k}(M_1,M_2,M_3) < 1$.

Proof. Since $H(U,X,u,\xi) = (U,X)$,

$$\begin{aligned}
|||(U,X)-(V,Y)|||_{k,T} &= |||H(U,X,u,\xi) - H(V,Y,u,\xi) + H(V,Y,u,\xi) - (V,Y)|||_{k,T} \\
&\le |||H(U,X,u,\xi) - H(V,Y,u,\xi)|||_{k,T} + |||H(V,Y,u,\xi)-(V,Y)|||_{k,T} \\
&\le L_{H,k}(M_1,M_2,M_3)\, |||(U,X)-(V,Y)|||_{k\vee 3,T} + |||H(V,Y,u,\xi)-(V,Y)|||_{k\vee 3,T}\,,
\end{aligned}$$

from which (2.38) immediately follows. ∎

3. Operator splitting. In this section we will apply operator splitting to the reaction–diffusion-stochastic system (2.17). This will aid in both proving the existence of long-time solutions and solving the system numerically.

3.1. Taylor expansions. In order to analyze the error due to operator splitting, we introduce some notation. Suppose X and Y are normed vector spaces. Let f be a J times continuously differentiable function mapping an open convex subset A of X into Y. For each $j = 0,1,\dots,J$, we let $f^{[j]}$ be the jth differential of f. Thus, for each $a \in A$, $f^{(j)}(a)$ is a jth degree polynomial function on X whose value at $v \in X$ is

$$\left(\frac{d}{dt}\right)^j f(a+tv)|_{t=0}.$$

Let $f^{\{J\}}$ be the function on $A \times A$ whose value at $(a,b) \in A \times A$ is the Jth degree polynomial function on X whose value at $v \in X$ is

$$\int_0^1 f^{[j]}(a+\lambda(b-a)(v)d(1-\lambda)^N.$$

Taylor's theorem implies that

$$f(b) = \sum_{j=0}^{J-1} f^{[j]}(a)(b-a) + \frac{1}{J!} f^{\{J\}}(a,b)(b-a), \quad (a,b) \in A \times A.$$

Suppose B is an open subset of $X \times [0,\infty)$, with the property that if $b \in B$, then $\{t : (b,t) \in B\}$ is an interval containing 0. Let f be a J times continuously differentiable function mapping B into Y. For each $j = 0,1,\dots,J$ and $b \in B$, let

$$f^{(j)}(b) = \left(\frac{d}{dt}\right)^j f(b,t)\big|_{t=0} \quad \text{and} \quad f^{<J>}(b,t) = \int_0^1 \left(\frac{d}{d\lambda}\right)^J f(\lambda b) d(1-\lambda)^N.$$

Then Taylor's theorem implies that

$$f(b,t) = \sum_{j=0}^{J-1} \frac{t^j}{j!} f^{(j)}(b) + \frac{t^J}{J!} f^{<J>}(b,t).$$

3.2. Ordinary differential equations. Let $f : \mathbb{R}^N \to \mathbb{R}^N$ be smooth. Suppose R is the flow of f, i.e., the set of $((t, u_0), u_1) \in \mathbb{R} \times \mathbb{R}^N$ such that either $t = 0$ and $u_0 = u_1$ or $t \neq 0$ and there is a continuously differentiable function R carrying an open interval I, with $[0, t] \subset I$ into $\mathbb{R} \times \mathbb{R}^N$ such that

$$\frac{d}{d\tau} R(\tau) = f(R(\tau)) \quad \text{for } \tau \in I.$$

Note that R is a function; the domain of R is an open subset of $\mathbb{R} \times \mathbb{R}^N$ which contains $\{0\} \times \mathbb{R}^N$; and that R is smooth. It follows that

$$R(0, u) = u, \quad \frac{\partial}{\partial t} R(t, u) = f(R(t, u)) \quad \text{whenever } (t, u) \in \mathbb{R} \times \mathbb{R}^N. \tag{3.1}$$

It is easy to show that

$$R^{(0)}(u) = u, \quad R^{(1)}(u) = f(u), \quad R^{(2)}(u) = f^{[1]}(u)(f(u)), \quad u \in \mathbb{R}^N. \tag{3.2}$$

We shall abbreviate $R(t, u)$ by $R_t(u)$.

3.3. A first order split scheme. We can decouple the system (2.17) into three separate systems for the diffusion, reaction, and motion of the cells, respectively, i.e.,

$$\frac{dU}{dt} = \mathcal{D}(U) + g \circ \mathcal{T}_\xi, \qquad U(0) = u, \tag{3.3}$$

$$\frac{dU}{dt} = f(U), \qquad U(0) = u, \tag{3.4}$$

$$dX_t = a(u, X_t)dt + b(X_t)dW_t, \qquad X(0) = \xi. \tag{3.5}$$

Let F, G, and H be defined by (2.33), (2.34), and (2.35), respectively. Let K_t be defined by (2.9), and define

$$L_t(u, \xi) = K_t(u) + \int_0^t K_{t-\tau}(g \circ \mathcal{T}_\xi) d\tau. \tag{3.6}$$

It follows from (2.10) that $L_t(u, \xi)$ solves the inhomogeneous diffusion equation (3.3). Let R_t be the flow of (3.4) as defined by (3.1) and $Y_t(u, \xi)$ be the solution of (3.5) given by

$$Y_t(u, \xi) = \xi + \int_0^t a(u, Y_\tau) d\tau + \int_0^t b(Y_\tau) dW_\tau. \tag{3.7}$$

Then a split-step method to approximate (2.17) is given by the following three steps:

1. Solve the diffusion, (3.3), for one time step T using the initial data u and ξ.
2. Solve the reaction, (3.4), for one time step T using $L_t(u)$ and ξ as initial data.
3. Move the cells according to (3.5) for time T using $R_t(L_t(u))$ and ξ as initial data.

We express this split-step method as

$$\Psi_t(u, \xi) = \begin{pmatrix} R_t(L_t(u, \xi)) \\ Y_t(R_t(L_t(u, \xi)), \xi) \end{pmatrix}. \tag{3.8}$$

The next theorem shows that the local truncation error for the split scheme Ψ_t is $\mathcal{O}(t^{\frac{3}{2}})$. In section 4 we will show that the global error is $\mathcal{O}(t)$.

THEOREM 3.1. *Let (U,X) be the solution of (2.17) on $[0,T)$, where $(U,X)(0) = (u,\xi) \in \mathbb{H}_k^N \times \mathbb{R}^n$. Let the error due to the split scheme (3.8) be given by*

$$\mathbf{e}(t) = (U,X)(t) - \Psi_t(u,\xi).$$

Then, for a nonnegative integer k,

$$|||\mathbb{E}[\mathbf{e}]|||_{k,T} \le C(\sup|u|, \|u\|_{(k+2)\vee 3})T^2, \tag{3.9}$$

$$|||\mathbf{e}|||_{k,T} \le C(\sup|u|, \|u\|_{(k+2)\vee 3})T^{\frac{3}{2}}. \tag{3.10}$$

Proof. Using Lemma 2.19, we estimate the error for the splitting Ψ by estimating the difference between $H(\Psi_t(u,\xi),u,\xi)$ and $\Psi_t(u,\xi)$, i.e.,

$$\begin{aligned}|||\mathbf{e}(t)|||_{k,T} &\le |||H(\Psi_t(u,\xi),u,\xi) - \Psi_t(u,\xi)|||_{k\vee 3,T} \\ &= \mathbb{E}\left[\sup_{0\le t\le T}\left\{\|\mathbf{e}_1(t)\|_{k\vee 3}^2 + |\mathbf{e}_2(t)|^2\right\}\right]^{\frac{1}{2}},\end{aligned}$$

where

$$\begin{aligned}\mathbf{e}_1(t) &= F\left(\Psi_t\begin{pmatrix}u\\ \xi\end{pmatrix}, u\right) - R_t(L_t(u,\xi)), \\ \mathbf{e}_2(t) &= G\left(\Psi_t\begin{pmatrix}u\\ \xi\end{pmatrix}, \xi\right) - Y_t(R_t(L_t(u,\xi)),\xi).\end{aligned}$$

We immediately see from the definitions of G and Y_t that $\mathbf{e}_2(t) = 0$.

We shall now examine $\mathbf{e}_1(t)$. By the definition of F,

$$\begin{aligned}\mathbf{e}_1(t) &= K_t(u) + \int_0^t K_{t-\tau} f(R_\tau(L_\tau(u,\xi)))d\tau \\ &\quad + \int_0^t K_{t-\tau}\left(g\circ\mathcal{T}_{Y_\tau(R_\tau(L_\tau(u,\xi)),\xi)}\right)d\tau - R_t(L_t(u,\xi)).\end{aligned}$$

We proceed using Taylor expansions. A second order expansion of R_t is

$$\begin{aligned}R_t(L_t(u,\xi)) &= L_t(u,\xi) + tR_t^{(1)}(L_t(u,\xi)) + \frac{t^2}{2}R^{<2>}(t,L_t(u,\xi)) \\ &= K_t(u) + \int_0^t K_{t-\tau}\left(g\circ\mathcal{T}_\xi\right)d\tau + tf(L_t(u,\xi)) + \frac{t^2}{2}R^{<2>}(t,L_t(u,\xi)).\end{aligned}$$

Substituting the above expansion,

$$\mathbf{e}_1(t) = \mathbf{e}_{11}(t) + \mathbf{e}_{12}(t) - \frac{t^2}{2}R^{<2>}(t,L_t(u,\xi)),$$

where

$$\begin{aligned}\mathbf{e}_{11}(t) &= \int_0^t K_{t-\tau} f(R_\tau(L_\tau(u,\xi)))d\tau - tf(L_t(u,\xi)), \\ \mathbf{e}_{12}(t) &= \int_0^t K_{t-\tau}\left(g\circ\mathcal{T}_{Y_\tau(R_\tau(L_\tau(u,\xi)),\xi)}\right)d\tau - \int_0^t K_{t-\tau}\left(g\circ\mathcal{T}_\xi\right)d\tau.\end{aligned}$$

A first order Taylor expansion of f is given by

$$f(x+h) = f(x) + f^{\{1\}}(x, x+h)(h).$$

If we substitute a first order Taylor expansion of R_τ in $f(R_\tau(L_\tau(u,\xi)))$, then

$$f(R_\tau(L_\tau(u,\xi))) = f\big(L_\tau(u,\xi)\big) + f^{\{1\}}\big(L_\tau(u,\xi), R_\tau(L_\tau(u,\xi))\big)\big(\tau R^{<1>}(\tau, L_\tau(u,\xi))\big)$$

Thus,

$$\mathbf{e}_{11}(t) = \int_0^t K_{t-\tau} f(L_\tau(u,\xi))d\tau - tf(L_t(u,\xi)) + \mathcal{O}(t^2),$$

where the remainder term is

$$\int_0^t K_{t-\tau} f^{\{1\}}\big(L_\tau(u,\xi), R_\tau(L_\tau(u,\xi))\big)\big(\tau R^{<1>}(\tau, L_\tau(u,\xi))\big)d\tau.$$

Let $\eta(\tau) = K_{t-\tau} f(L_\tau(u,\xi))$. Then

$$\begin{aligned}\|\mathbf{e}_{11}(t)\|_k &= \left\| \int_0^t \eta(\tau)d\tau - t\eta(t) \right\|_k \le \int_0^t \|\eta(\tau) - \eta(t)\|_k \, d\tau \\ &\le \int_0^t \|\eta'(\tau)\|_k \, |t-\tau| d\tau = \sup_{0\le\tau\le t} \|\eta'(\tau)\|_k \, \frac{t^2}{2}.\end{aligned}$$

Then by Theorem 2.13 and Lemma 2.14,

$$\begin{aligned}\|\eta'(\tau)\|_k &= \left\| \frac{\partial}{\partial\tau} K_{t-\tau} f(L_\tau(u,\xi)) \right\|_k = \|\mathcal{D} K_{t-\tau} f(L_\tau(u,\xi))\|_k \le \|f(L_\tau(u,\xi))\|_{k+2} \\ &\le C_{f,k}(\sup|u|) \, \|L_\tau(u,\xi)\|_{k+2} \\ &\le C_{f,k}(\sup|u|) \left\| K_\tau(u) + \int_0^\tau K_{\tau-s} \, (g \circ \mathcal{T}_\xi) \, ds \right\|_{k+2} \\ &\le C_{f,k}(\sup|u|) \, \left(\|u\|_{k+2} + C_{g,k+2} \, \tau \right).\end{aligned}$$

Therefore,

$$\|\mathbf{e}_{11}\|_k \le C_{f,k}(\sup|u|, \|u\|_{k+2}) t^2. \tag{3.11}$$

To find the appropriate bounds on $\mathbf{e}_{12}$ consider a second order Taylor expansion of g;

$$g(x+h) - g(x) = g^{[1]}(x)(h) + \frac{1}{2} g^{\{2\}}(x, x+h)(h).$$

Using (3.7), we can rewrite

$$\begin{aligned}\mathbf{e}_{12}(t) &= \int_0^t K_{t-\tau} \left(g \circ \mathcal{T}_{Y_\tau(R_\tau(L_\tau(u,\xi)),\xi)} - g \circ \mathcal{T}_\xi \right) d\tau \\ &= \int_0^t K_{t-\tau} \left[g^{[1]}(x-\xi) \left(\int_0^\tau a(R_s(L_s(u,\xi)),\xi) ds + \int_0^\tau b(\xi) dW_s \right) \right] d\tau + \mathcal{O}(t^2),\end{aligned}$$

where the remainder term is

$$\frac{1}{2} \int_0^t K_{t-\tau} \left(g^{\{2\}}(x-\xi, x-Y_\tau) \, (Y_\tau - \xi) \right) d\tau.$$

Since the expectation of the Itô integral is zero,

$$\begin{aligned}\|\mathbb{E}\left[\mathbf{e}_{12}(t)\right]\|_k &\le \left\|\mathbb{E}\left[\int_0^t K_{t-\tau}\left(g^{[1]}(x-\xi)\left(\int_0^\tau a(R_s(L_s(u,\xi)),\xi)ds\right)\right)d\tau\right]\right\|_k \\ &\le \int_0^t \left\|\mathbb{E}\left[g^{[1]}(x-\xi)\left(\int_0^\tau a(R_s(L_s(u,\xi)),\xi)ds\right)\right]\right\|_k d\tau \\ &\le C_g C_a(\xi)t^2. \qquad (3.12)\end{aligned}$$

Recall from Lemma 2.14 that g is Lipschitz. It follows that

$$\begin{aligned}\|\mathbf{e}_{12}(t)\|_k &\le \int_0^t \left\|K_{t-\tau}\left(g\circ\mathcal{T}_{Y_\tau(R_\tau(L_\tau(u,\xi)),\xi)} - g\circ\mathcal{T}_{Y_\tau(u,\xi)}\right)\right\|_k d\tau \\ &\le \int_0^t \left\|g\circ\mathcal{T}_{Y_\tau(R_\tau(L_\tau(u,\xi)),\xi)} - g\circ\mathcal{T}_{\xi}\right\|_k d\tau \\ &\le L_{g,k}\int_0^t \left|Y_\tau(R_\tau(L_\tau(u,\xi)),\xi) - \xi\right| d\tau \\ &\le L_{g,k}\int_0^t\int_0^\tau \left|a(R_s(L_s(u,\xi)),\xi)\right| ds d\tau + L_{g,k}\int_0^t \left|\int_0^\tau b(\xi)dW_s\right| d\tau.\end{aligned}$$

By the Cauchy–Schwarz inequality, Doob's martingale inequality, and the Itô isometry,

$$\begin{aligned}\mathbb{E}\left[\sup_{0\le t\le T}\|\mathbf{e}_{12}(t)\|_k^2\right] &\le 2L_{g,k}\mathbb{E}\left[\sup_{0\le t\le T}\left(\int_0^t\int_0^\tau |a(R_s(L_s(u,\xi)),\xi)dsd\tau|\right)^2\right] \\ &\quad + 2L_{g,k}\mathbb{E}\left[\sup_{0\le t\le T}\left(\int_0^t\left|\int_0^\tau b(\xi)dW_s\right|d\tau\right)^2\right] \\ &\le 2L_{g,k}\left(\frac{1}{4}C_a^2(\xi)T^4 + 4T\mathbb{E}\left[\sup_{0\le t\le T}\int_0^t\int_0^\tau |b(\xi)|^2 dsd\tau\right]\right) \\ &\le 2L_{g,k}\left(\frac{1}{4}C_a^2(\xi)T^4 + 2C_b^2T^3\right). \qquad (3.13)\end{aligned}$$

Combining (3.11) and (3.12),

$$\sup_{0\le t\le T}\|\mathbb{E}\left[\mathbf{e}_1(t)\right]\|_k \le C(\sup|u|,\|u\|_{(k+2)})T^2. \qquad (3.14)$$

From (3.11) and (3.13) we have

$$\mathbb{E}\left[\sup_{0\le t\le T}\|\mathbf{e}_1(t)\|_k^2\right]^{\frac{1}{2}} \le C(\sup|u|,\|u\|_{(k+2)})T^{\frac{3}{2}}. \qquad (3.15)$$

Equations (3.9) and (3.10) follow from (3.14), (3.15), and the fact that $\mathbf{e}_2(t)=0$. ∎

4. Convergence. In this section we will show that the splitting outlined in section 3 is a first order method. These ideas can be extended to show the convergence rates of other numerical methods as well.

4.1. Preliminaries. Suppose $k \geq 4$, $t \in [0,T)$, and $\phi = (u,\xi) \in \mathcal{B}_k^N(m_1,m_2,m_3)$ for $0 \leq m_1, m_2, m_3 < \infty$. Let

$$\Phi(t,\phi,\delta) = (U(t,\phi,\delta), X(t,\phi,\delta)) \tag{4.1}$$

be the flow of the reaction–diffusion-stochastic system (2.17), i.e., the set of $((t,\phi,\tau),\eta)$ such that there exists a solution $\mathcal{U}$ of (2.17) whose domain is an interval containing t and $t+\tau$, $\mathcal{U}(t) = \phi$, and $\mathcal{U}(t+\tau) = \eta$. It is a consequence of uniqueness that Φ is a function. By local existence, for any $(t,\phi) \in [0,T) \times \mathcal{B}_k^N(m_1,m_2,m_3)$, there exists $\tau > 0$ such that $(t,\phi,\tau) \in \operatorname{domain}\Phi$. It follows from uniqueness that if δ_1,$\delta_2 > 0$, then

$$\Phi(t,\phi,\delta_1+\delta_2) = \Phi\big(t,\Phi(t,\phi,\delta_1),\delta_2\big). \tag{4.2}$$

Suppose $\Psi(t,\phi,\delta) = (V(t,\phi,\delta), Y(t,\phi,\delta))$ is a *one step method* for solving (2.17) such that $\Psi(t,\phi,0) = \phi$. Then the *local truncation error* for the method Ψ is given by

$$T(t,\phi,\delta) = \Phi(t,\phi,\delta) - \Psi(t,\phi,\delta) = (T_U(t,\phi,\delta), T_X(t,\phi,\delta)), \tag{4.3}$$

where

$$T_U(t,\phi,\delta) = U(t,\phi,\delta) - V(t,\phi,\delta) \ \text{ and } \ T_X(t,\phi,\delta) = X(t,\phi,\delta) - Y(t,\phi,\delta). \tag{4.4}$$

Suppose $t_0, T \in [0,\infty)$ such that $t_0 < T$. Let J be a positive integer such that $\delta = \frac{T}{J} < 1$. Then, for each $j = 1,\dots,J$, let

$$\begin{aligned}
&t_j = t_{j-1} + \delta, && \Phi_j = \Phi(t_0,\Phi_0,t_j - t_0), && \Psi_j = \Psi(t_{j-1},\Psi_{j-1},\delta),\\
&U_j = U(t_0,U_0,t_j - t_0), && X_j = X(t_0,X_0,t_j - t_0),\\
&V_j = V(t_{j-1},V_{j-1},\delta), && Y_j = Y(t_{j-1},Y_{j-1},\delta),\\
&e_j = \Phi_j - \Psi_j, && T_j = T(t_{j-1},\Psi_{j-1},\delta).
\end{aligned}$$

Finally, define

$$\Phi_{t,\phi}(x,\delta) = \Phi(t,\phi,\delta)(x) \quad \text{and} \quad \Psi_{t,\psi}(x,\delta) = \Psi(t,\psi,\delta)(x). \tag{4.5}$$

The next theorem, which gives the error due to the difference in initial conditions, is based on a lemma from [11].

THEOREM 4.1. *Let $Z_t = (Z_U, Z_X)$ be defined by*

$$\Phi(t,\phi,\delta) - \Phi(t,\psi,\delta) = \begin{pmatrix} K_\delta(u-v) \\ \xi - \zeta \end{pmatrix} + \begin{pmatrix} Z_U \\ Z_X \end{pmatrix}, \tag{4.6}$$

where $\phi = (u,\xi)$, $\psi = (v,\zeta)$. Then, for any integer $k \geq 4$, there exists a constant $C_{\Phi,k} = C(\sup|U|, \|U\|_k, \|X\|_{\mathcal{S}_T})$ which is independent of δ, for $\delta < 1$, such that

$$\|\!|\Phi_{t,\phi} - \Phi_{t,\psi}|\!\|_{k,\delta}^2 \leq \|\!|\phi - \psi|\!\|_k^2 \,(1 + C_{\Phi,k}\delta), \tag{4.7}$$

$$\|\!|Z_t|\!\|_{k,\delta}^2 \leq C_{\Phi,k}\, \|\!|\phi - \psi|\!\|_k^2 \,\delta. \tag{4.8}$$

Before we prove this theorem, we must first state several lemmas.

LEMMA 4.2. *Let $\alpha \in \mathbb{B}$, a Banach space with norm $\|\cdot\|$, and β be a function $\beta : [0,T) \to \mathbb{B}$ which is continuous with respect to the norm $\|\cdot\|$. Then*

$$\left\| \alpha + \int_t^{t+\delta} \beta(\tau) d\tau \right\|^2 \leq (1+\delta)\,\|\alpha\|^2 + (1+\delta)\int_t^{t+\delta} \|\beta(\tau)\|^2 \, d\tau. \tag{4.9}$$

The lemma above is proven by squaring the left-hand side and applying the Cauchy–Schwarz inequality. The next lemma from [11] is proven using induction.

LEMMA 4.3. *Let $A, B, \delta > 0$ and $p \geq 1$. If*

$$\mu_{j+1} \leq (1 + A\delta)\mu_j + B\delta^p, \tag{4.10}$$

then

$$\mu_j \leq e^{AT}\mu_0 + \frac{B}{A}\left(e^{AT} - 1\right)\delta^{p-1}. \tag{4.11}$$

Proof of Theorem 4.1. Consider the two components of $\Phi = (U, X)$ separately. In the context of Lemma 4.2, let $\alpha = K_\delta(u - v)$ and $\int_t^{t+\delta} \beta(\tau)d\tau = Z_U$. Then

$$\begin{aligned}
&\|U(t,\phi,\delta) - U(t,\psi,\delta)\|_k^2 \\
&\leq (1+\delta)\left\|K_\delta(u-v)\right\|_k^2 + 2(1+\delta)\int_t^{t+\delta} \left\|K_{t-\tau}\left[f(U(t,\phi,\tau)) - f(U(t,\psi,\tau))\right]\right\|_k^2 d\tau \\
&\quad + 2(1+\delta)\int_t^{t+\delta} \left\|K_{t-\tau}\left[g(X(t,\phi,\tau)) - g(X(t,\psi,\tau))\right]\right\|_k^2 d\tau \\
&\leq (1+\delta)\left\|u-v\right\|_k^2 + 2(1+\delta)L_{f,k}(\sup|U|, \|U\|_k)^2 \int_t^{t+\delta} \|U(t,\phi,\tau) - U(t,\psi,\tau)\|_k^2 d\tau \\
&\quad + 2(1+\delta)L_{g,k}^2 \int_t^{t+\delta} |X(t,\phi,\tau) - X(t,\psi,\tau)|^2 d\tau.
\end{aligned}$$

Define $\tilde{a}(\tau) = a(U(t,\phi,\tau), X(t,\phi,\tau)) - a(U(t,\psi,\tau), X(t,\psi,\tau))$ and $\tilde{b}(\tau) = b(X(t,\phi,\tau)) - b(X(t,\psi,\tau))$. Since the expected value of the Itô integral is zero,

$$\begin{aligned}
&\mathbb{E}\left[\sup_{0\leq s\leq\delta} |X(t,\phi,s) - X(t,\psi,s)|^2\right] \\
&\quad = \mathbb{E}\left[\sup_{0\leq s\leq\delta}\left|\xi - \zeta + \int_t^{t+s} \tilde{a}(\tau)d\tau\right|^2\right] + \mathbb{E}\left[\sup_{0\leq s\leq\delta}\left|\int_t^{t+s} \tilde{b}(\tau)dW_\tau\right|^2\right].
\end{aligned}$$

In the context of Lemma 4.2, let $\alpha = \xi - \zeta$ and $\beta = \tilde{a}$. Then

$$\begin{aligned}
&\mathbb{E}\left[\sup_{0\leq s\leq\delta} |X(t,\phi,s) - X(t,\psi,s)|^2\right] \\
&\quad \leq (1+\delta)\mathbb{E}\left[|\xi-\zeta|^2\right] + (1+\delta)\mathbb{E}\left[\int_t^{t+\delta} \left|\tilde{a}(\tau)\right|^2 d\tau\right] + 4\mathbb{E}\left[\int_t^{t+\delta} \left|\tilde{b}(\tau)\right|^2 d\tau\right] \\
&\quad \leq (1+\delta)\mathbb{E}\left[|\xi-\zeta|^2\right] \\
&\qquad + (1+\delta)L_{a,1}(\|U\|_k)^2 \int_t^{t+\delta} \mathbb{E}\left[\sup_{0\leq\sigma\leq\tau} \|U(t,\phi,\sigma) - U(t,\psi,\sigma)\|_k^2\right] d\tau \\
&\qquad + (1+\delta)L_{a,2}(\|U\|_k, \|X\|_{\mathcal{S}_T})^2 \int_t^{t+\delta} \mathbb{E}\left[\sup_{0\leq\sigma\leq\tau} |X(t,\phi,\sigma) - X(t,\psi,\sigma)|^2\right] d\tau \\
&\qquad + L_b^2 \int_t^{t+\delta} \mathbb{E}\left[\sup_{0\leq\sigma\leq\tau} |X(t,\phi,\sigma) - X(t,\psi,\sigma)|^2\right] d\tau
\end{aligned} \tag{4.12}$$

by the Doob martingale inequality and Itô isometry. Therefore,

$$\begin{aligned}\left|\left|\left|\Phi(t,\phi,s)-\Phi(t,\psi,s)\right|\right|\right|_{k,\delta}^2 &\le (1+\delta)\left|\left|\left|\phi-\psi\right|\right|\right|_k^2 \\ &+ C_{\Phi,k}(\sup|U|,\|U\|_k,\|X\|_{\mathcal{S}_T})\int_t^{t+\delta}\left|\left|\left|\Phi(t,\phi,\tau)-\Phi(t,\psi,\tau)\right|\right|\right|_{k,\delta}^2 d\tau,\end{aligned} \tag{4.13}$$

where

$$\begin{aligned}C_{\Phi,k}(\sup|U|,\|U\|_k,\|X\|_{\mathcal{S}_T}) = \max\{&(1+\delta)\delta(2L_{f,k}(\sup|U|,\|U\|_k)^2+L_{a,1}(\|U\|_k)^2),\\ &(1+\delta)(2L_{g,k}^2+L_{a,2}(\|U\|_k,\|X\|_{\mathcal{S}_T})^2)+L_b^2\}.\end{aligned}$$

Then by the Gronwall inequality,

$$\left|\left|\left|\Phi_{t,\phi}-\Phi_{t,\psi}\right|\right|\right|_{k,\delta}^2 \le \left|\left|\left|\phi-\psi\right|\right|\right|_k^2(1+\delta)e^{C_{\Phi,k}\delta}. \tag{4.14}$$

Equation (4.7) immediately follows, and (4.8) is the result of subtracting $\mathbb{E}\left[|\xi-\zeta|^2\right]$ from (4.12) and (4.14). ∎

Remark 4.4. The proof of this lemma can be modified to yield the same estimate with the $\left|\left|\left|\cdot\right|\right|\right|_k$ norm instead of the $\left|\left|\left|\cdot\right|\right|\right|_{k,\delta}$ norm.

4.2. Positivity and local bounds. It is well known; see [2], that if the initial condition is nonnegative, i.e., $u_i \ge 0$ for $i = 1, 2, \ldots, N$, the solution to the diffusion (3.3) is positive, i.e., for $t > 0$, $U_i(t) > 0$ for all i. The following lemma shows that if the initial condition is positive, the solution to the reaction (3.4) is also positive.

LEMMA 4.5. *Let I be an open interval. Suppose $U : I \to \mathbb{R}^n$ satisfies* (3.4) *and for some $t_0 \in I$, $U_i(t_0) > 0$ for all i. Then, for all $t \in I$, $U_i(t) > 0$ for all i.*

Proof. Note that if $u_i = 0$ for some i, then there exists a solution of (3.4) such that $U_i(t) = 0$ for all $t > 0$. Let $t_0 \in I$ and $U : I \to \mathbb{R}^n$ be a trajectory for (3.4) such that $U_i(t_0) = 0$ for some i. Then $f(U(t_0)) = 0$, and it follows by uniqueness that $U_i(t) = 0$ for all $t \in I$. Thus, if $U_i(t_0) > 0$ for all i, for all $t \in I$, $U_i(t) > 0$ for all i. ∎

Since the split-step method for the reaction-diffusion equation converges to the true solution, the solution to the reaction-diffusion equation is positive if the initial condition is nonnegative.

Before estimating the global error of the split-step method, we must show that the splitting $\Psi_t(u,\xi)$ from (3.8) is bounded in the appropriate norms. Define L_t as in (3.6), and let R_t be the flow of (3.4) where the reaction terms are given by

$$f(U) = -\lambda U - q(U), \tag{4.15}$$

where $\lambda = \mathrm{diag}(\lambda_1, \lambda_2, \ldots, \lambda_N)$ and $q = (q_1, q_2, \ldots, q_N)$ is given by

$$q_i(U) = \left(\textstyle\sum_{j\ne i} r_{ij}U_j\right)U_i. \tag{4.16}$$

Recall that $\lambda_i \ge 0$ and $r_{ij} \ge 0$ for all i and j. Define $\lambda_{\min} = \min\{\lambda_i : i = 1, 2, \ldots, N\}$.

LEMMA 4.6. *Suppose k is a nonnegative integer, $t \in [0, T)$, and $u \in \mathbb{H}_k^N$ such that $u_i \ge 0$ for $i = 1, 2, \ldots N$. Then*

$$|R_t(L_t(u,\xi))| \le (\sup|u| + C_g t)e^{-\lambda_{\min}t}, \tag{4.17}$$

$$\|R_t(L_t(u,\xi))\|_k^2 \le (\|u\|_k^2 + C_{g,k}t)e^{C_{f,k}(\sup|u|)t}. \tag{4.18}$$

Proof. By Lemma 2.14,

$$|L_t(u,\xi)| \le |K_t(u)| + \int_0^t |K_{t-\tau}(g \circ \mathcal{T}_\xi)|\, d\tau \le \sup|u| + C_g T, \tag{4.19}$$

$$\text{and} \quad \|L_t(u,\xi)\|_k \le \|K_t(u)\|_k + \int_0^t \|K_{t-\tau}(g \circ \mathcal{T}_\xi)\|_k\, d\tau \le \|u\|_k + C_{g,k} T. \tag{4.20}$$

Assume that $u_i > 0$ for all i. It follows from Lemma 4.5 that, for $t > 0$, $R_t(u_i) > 0$ and $q_i(R_t(u)) > 0$ for all i. Thus,

$$\frac{d}{dt} R_t(u) \le -\lambda R_t(u) \quad \text{and} \quad R_t(u) \le u e^{-t\lambda}.$$

Recall that, if $u_i \ge 0$ for all i, the diffusion $L_t(u_i) > 0$ for all $t > 0$. Then by (4.19),

$$|R_t(L_t(u))| \le |L_t(u)| e^{-\lambda_{\min} t} \le (\sup|u| + C_g t) e^{-\lambda_{\min} t}.$$

From Theorem 2.13 we have

$$\begin{aligned} \frac{1}{2}\frac{d}{dt}\|\partial^\alpha R_t(u)\|_0^2 &= \left(\partial^\alpha \left(\frac{d}{dt} R_t(u)(t)\right), \partial^\alpha R_t(u)\right) = (\partial^\alpha f(R_t(u)), \partial^\alpha R_t(u)) \\ &\le \|\partial^\alpha f(R_t(u))\|_0 \, \|\partial^\alpha R_t(u)\|_0 . \end{aligned}$$

Summing over $|\alpha| \le k$,

$$\frac{1}{2}\frac{d}{dt}\|R_t(u)\|_k^2 \le C_{f,k}(\sup|u|)\, \|R_t(u)\|_k^2 .$$

The solution of the differential equation above is

$$\|R_t(u)\|_k^2 \le \|u\|_k^2 \, e^{C_{f,k}(\sup|u|)t}. \tag{4.21}$$

Equation (4.18) follows from substituting $L_t(u)$ for u and applying (4.20). ∎

COROLLARY 4.7. *Let $j = 1, 2, \ldots, J$ and C_1 and C_2 be constants that are independent of δ for $\delta < 1$. Under the assumptions of Lemma* 4.6*,*

$$|V_j| \le \sup|u| e^{-\lambda_{\min} T} + C_1, \tag{4.22}$$

$$\|V_j\|_k^2 \le (\|u\|_k + C_2) e^{C_{f,k}(\sup|u|)T}. \tag{4.23}$$

Proof. Equations (4.22) and (4.23) follow from repeatedly applying (4.17) and (4.18), respectively. ∎

LEMMA 4.8. *If $Y_t(u,\xi)$ is a solution to* (3.5)*, then*

$$\mathbb{E}\left[\sup_{0\le t\le T} |Y_t(u,\xi)|^2\right] \le C_X(\xi, T). \tag{4.24}$$

Proof. Using an integrating factor $e^{\gamma t}$, the solution to the velocity equation in (1.2) is

$$v_t = e^{-\gamma t}\nu + \int_0^t e^{-\gamma(t-\tau)} h(U(x_t)) d\tau + \sigma\sqrt{\gamma}\int_0^t e^{\gamma(t-\tau)} dW_\tau.$$

By the Cauchy–Schwarz inequality, Doob's martingale inequality, and Itô isometry,

$$\begin{aligned}\mathbb{E}\left[\sup_{0\le t\le T}|v_t|^2\right] &\le 3e^{-2\gamma T}\nu + 3\mathbb{E}\left[\sup_{0\le t\le T}\left|\int_0^t e^{-\gamma(t-\tau)}h(U(x_t))d\tau\right|^2\right]\\ &\quad + 3\sigma^2\gamma\mathbb{E}\left[\sup_{0\le t\le T}\left|\int_0^t e^{-\gamma(t-\tau)}dW_\tau\right|^2\right]\\ &\le 3e^{-2\gamma T}\nu + 3T\mathbb{E}\left[\sup_{0\le t\le T}\int_0^t e^{-2\gamma(t-\tau)}|h(U(x_t))|^2d\tau\right]\\ &\quad + 12\sigma^2\gamma\mathbb{E}\left[\sup_{0\le t\le T}\left|\int_0^t e^{-\gamma(t-\tau)}d\tau\right|^2\right]\\ &\le 3e^{-2\gamma T}\nu + \frac{3T}{2\gamma}\left(1-e^{-2\gamma T}\right) + 6\sigma\left(1-e^{-2\gamma T}\right).\end{aligned}$$

The bound on Y_t (4.24) immediately follows. ∎

4.3. Error estimates for numerical methods. The following theorem gives the convergence rate of a general numerical scheme to approximate (2.17). The proof builds on an argument by Milstein in [11].

THEOREM 4.9. *Let $p_2 \ge \frac{1}{2}$ and $p_1 \ge p_2 + \frac{1}{2}$ and $k \ge 3$ be an integer. Assume that there exist constants $C_1, C_2 > 0$ such that*

$$\left|\!\left|\!\left|\mathbb{E}\left[\Phi(t,\xi,\delta) - \Psi(t,\xi,\delta)\right]\right|\!\right|\!\right|_k \le C_1\delta^{p_1}, \tag{4.25}$$

$$\left|\!\left|\!\left|\Phi(t,\xi,\delta) - \Psi(t,\xi,\delta)\right|\!\right|\!\right|_k \le C_2\delta^{p_2}. \tag{4.26}$$

Then, for $j = 0, 1 \ldots, J$, there exists a constant C such that

$$\left|\!\left|\!\left|\Phi(t_0,\Phi_0,t_j) - \Psi(t_0,\Phi_0,t_j)\right|\!\right|\!\right|_k \le C\delta^{p_2-\frac{1}{2}}. \tag{4.27}$$

Proof. To make use of Theorem 4.1, (4.25), and (4.26), we rewrite $\Phi_{j+1} - \Psi_{j+1}$ as the sum of the difference in initial conditions and the local trucnation error, i.e.,

$$\begin{aligned}\Phi_{j+1} - \Psi_{j+1} &= \Phi(t_j,\Phi_j,\delta) - \Psi(t_j,\Psi_j,\delta)\\ &= \Phi(t_j,\Phi_j,\delta) - \Phi(t_j,\Psi_j,\delta) + T(t_j,\Psi_j,\delta).\end{aligned}$$

Then

$$\left|\!\left|\!\left|\Phi_{j+1} - \Psi_{j+1}\right|\!\right|\!\right|_k^2 = A_1 + 2A_2 + A_3, \tag{4.28}$$

where

$$\begin{aligned}&A_1 = \left|\!\left|\!\left|\Phi(t_j,\Phi_j,\delta) - \Phi(t_j,\Psi_j,\delta)\right|\!\right|\!\right|_k^2,\\ &A_2 = \mathbb{E}[(\Phi(t_j,\Phi_j,\delta) - \Phi(t_j,\Psi_j,\delta), T(t_j,\Psi_j,\delta))_k], \quad A_3 = \left|\!\left|\!\left|T(t_j,\Psi_j,\delta)\right|\!\right|\!\right|_k^2.\end{aligned}$$

By Theorem 4.1 and (4.26), we have

$$A_1 \le \left|\!\left|\!\left|\Phi_j - \Psi_j\right|\!\right|\!\right|_k^2 (1 + C_{\Phi,k}\delta) = \left|\!\left|\!\left|e_j\right|\!\right|\!\right|_k^2 (1 + C_{\Phi,k}\delta), \tag{4.29}$$

$$A_3 \le C_2\delta^{2p_2}, \tag{4.30}$$

respectively. Using Theorem 4.1, we write $A_2 = B_1 + B_2$, where

$$B_1 = \mathbb{E}\left[\left(\binom{K_\delta(U_j - V_j)}{X_j - Y_j}, T(t_j, \Psi_j\delta)\right)\right] \text{ and } B_2 = \mathbb{E}\left[(Z_\delta, T(t_j, \Psi_j\delta))\right].$$

Then by the Cauchy–Schwarz inequality and condition (4.25),

$$\begin{aligned} B_1 &= \mathbb{E}\left[\mathbb{E}\left[\left(\binom{K_\delta(U_j - V_j)}{X_j - Y_j}, T(t_j, \Psi_j\delta)\right)\middle|\mathcal{F}_j\right]\right] = \mathbb{E}\left[\left(\binom{K_\delta(U_j - V_j)}{X_j - Y_j}, \mathbb{E}\left[T(t_j, \Psi_j\delta)|\mathcal{F}_j\right]\right)\right] \\ &\le \left|\left|\left|\binom{K_\delta(U_j - V_j)}{X_j - Y_j}\right|\right|\right|_k |||\mathbb{E}\left[T(t_j, \Psi_j\delta)|\mathcal{F}_j\right]|||_k \le |||\Phi_j - \Psi_j|||_k \, |||\mathbb{E}\left[T(t_j, \Psi_j\delta)|\mathcal{F}_j\right]|||_k \\ &\le |||e_j|||_k \left(\sqrt{2}C_1\delta^{p_1}\right). \end{aligned}$$

Using the Cauchy–Schwarz inequality, (4.8), and (4.26), we estimate the second term

$$B_2 \le |||Z_\delta|||_k \, |||T(t_j, \Psi_j, \delta)|||_k \le C_{\Phi,k} \, |||e_j|||_k \, \delta^{\frac{1}{2}}(C_2\delta^{p_2}).$$

Since $p_1 \ge p_2 + 1$, $\delta^{p_1} \le \delta^{p_2+\frac{1}{2}}$ for $\delta < 1$. Thus,

$$A_2 \le C \, |||e_j|||_k \, \delta^{p_2+\frac{1}{2}} \le \frac{1}{2}\delta \, |||e_j|||_k^2 + \frac{1}{2}C^2\delta^{2p_2}. \tag{4.31}$$

Putting the estimates for (4.29), (4.30), and (4.31) together,

$$|||e_{j+1}|||_k^2 \le |||e_j|||_k^2 \left(1 + C_{\Phi,k}\delta\right) + C\delta^{2p_2}. \tag{4.32}$$

The main result (4.27) follows from Lemma 4.3, with $e_0 = 0$. ∎

Remark 4.10. The split scheme Ψ from section 3 satisfies Theorem (4.9), with $p_1 = 2$ and $p_2 = \frac{3}{2}$ and is therefore a first order method.

5. Long-time existence. In the previous section we showed that the splitting outlined in section 3 converges to the true solution, and that the reaction-diffusion equations preserve positivity. In this section we will show that the supremum of the solution is a priori bounded, and its derivatives are bounded for finite time. Assuming the solutions to (2.17) exist for $t \in [0, T)$, the limit as t approaches T also exists, allowing us to solve (2.17) for further time. We begin by showing the solution to (2.17) is bounded in the appropriate norms for $t \in [0, T)$.

THEOREM 5.1. *Let $\Phi(t) = (U(t), X_t)$ be a solution of the reaction–diffusion-stochastic system* (2.17) *on $[0, T)$. Then, for any nonnegative integer k, there exist constants C_U and $C_{U,k}$ such that*

$$\sup|U(t)| \le C_U(\sup|u|), \tag{5.1}$$

$$\|U(t)\|_k \le C_{U,k}(\sup|u|, \|u\|_k, T). \tag{5.2}$$

Proof. Using (4.15) and (4.16), we can rewrite the first equation in (2.17) as

$$\frac{dU}{dt} = (\mathcal{D} - \lambda)U(t) - q(U(t)) + g \circ \mathcal{T}_{X_t}, \quad U(0) = u, \tag{5.3}$$

where we assume that $u \ge 0$. Define $\mathcal{K}_t = e^{-t\lambda}K_t$. Then

$$\frac{d}{dt}\mathcal{K}_t(u) = e^{-t\lambda}\left(\frac{d}{dt}K_t(u) - \lambda K_t(u)\right) = e^{-t\lambda}(\mathcal{D}K_t(u) - \lambda K_t(u)) = \mathcal{K}_t[(\mathcal{D} - \lambda)u].$$

Therefore,

$$U(t) = \mathcal{K}_t(u) + \int_0^t \mathcal{K}_{t-\tau}(-q(U) + g \circ \mathcal{T}_{X_\tau})d\tau. \tag{5.4}$$

Clearly $q_i(U) > 0$ for all i, and thus

$$U(t) \le \mathcal{K}_t(u) + \int_0^t \mathcal{K}_{t-\tau}(g \circ \mathcal{T}_{X_\tau})d\tau.$$

Then (5.1) follows from the fact that

$$|U(t)| \le |\mathcal{K}_t u| + \int_0^t e^{-(t-\tau)\lambda}|K_t(g \circ \mathcal{T}_{X_\tau})|d\tau \le |u| + \frac{1}{\lambda}C_g.$$

Let $u, v \in \mathbb{H}_k^N$, and $|\alpha| \le k$ for a nonnegative integer k. Then,

$$(\partial^\alpha u, \partial^\alpha v) = \sum_{i=1}^N (\partial^\alpha u_i, \partial^\alpha v_i) \le \sum_{i=1}^N \frac{\|\partial^\alpha u_i\|_k^2 + \|\partial^\alpha v_i\|_k^2}{2} = \frac{\|\partial^\alpha u\|_k^2 + \|\partial^\alpha v\|_k^2}{2}.$$

Thus, using Theorem 2.13 and Lemma 2.14,

$$\begin{aligned}\frac{1}{2}\frac{d}{dt}\|\partial^\alpha U(t)\|_0^2 &= \left(\partial^\alpha \dot{U}(t), \partial^\alpha U(t)\right) \\ &= (\mathcal{D}\partial^\alpha U(t), \partial^\alpha U(t)) + (\partial^\alpha f(U(t)), \partial^\alpha U(t)) + (\partial^\alpha g, \partial^\alpha U(t)) \\ &\le \|\partial^\alpha f(U(t))\|_0 \|\partial^\alpha U(t)\|_0 + \frac{1}{2}\left(\|\partial^\alpha g\|_0^2 + \|\partial^\alpha U(t)\|_0^2\right).\end{aligned}$$

Summing over $|\alpha| \le k$,

$$\frac{1}{2}\frac{d}{dt}\|U(t)\|_k^2 \le C_{f,k}(C_U(\sup|u|))\|U(t)\|_k^2 + \frac{1}{2}C_{g,k}^2.$$

Then (5.2) follows from the fact that the solution of the differential equation above is

$$\|U(t)\|_k^2 \le \left(\|u\|_k^2 + \frac{C_{g,k}^2}{C_{f,k}(C_U(\sup|u|))}\right)e^{C_{f,k}(C_U(\sup|u|))t} - \frac{C_{g,k}^2}{C_{f,k}(C_U(\sup|u|))}. \tag{5.5}$$

∎

THEOREM 5.2. *The solution of the reaction–diffusion-stochastic system* (2.17) *exists for all* $t \ge 0$.

Proof. Suppose that $[0, T)$ is the largest interval on which $\Phi(t)$ is a solution of the reaction–diffusion-stochastic system (2.17). If $\lim_{t\uparrow T}\Phi(t)$ exists in $\mathcal{C}_k^N$, then there exists a solution on the interval $[0, T+\delta)$ for some $\delta > 0$ that depends on the appropriate bounds on $\Phi(t)$. But this contradicts the assumption that $[0, T)$ is the largest interval of existence, and therefore the solution of (2.17) exists for all time.

In order to show that $\lim_{t\uparrow T}\Phi(t)$ exists, we obtain the Hölder estimate

$$\|\Phi(t+\delta) - \Phi(t)\|_k \le C\delta^{\frac{1}{2}} \tag{5.6}$$

for a constant C. Suppose $U(0) = u$. By Theorem 2.13 and Theorem 5.1,

$$\begin{aligned}\|U(t+\delta) - U(t)\|_k &\le \|(K_\delta - 1)K_t(u)\|_k + \int_t^{t+\delta} \|f(U(\tau))\|_k + \|g \circ \mathcal{T}_{X_\tau}\|_k \, d\tau \\ &\le \delta^{\frac{1}{2}}\|u\|_{k+1} + [C_{f,k}(C_U(\sup|u|), C_{U,k}(\sup|u|, \|u\|_k, T)) + C_{g,k}]\,\delta.\end{aligned}$$

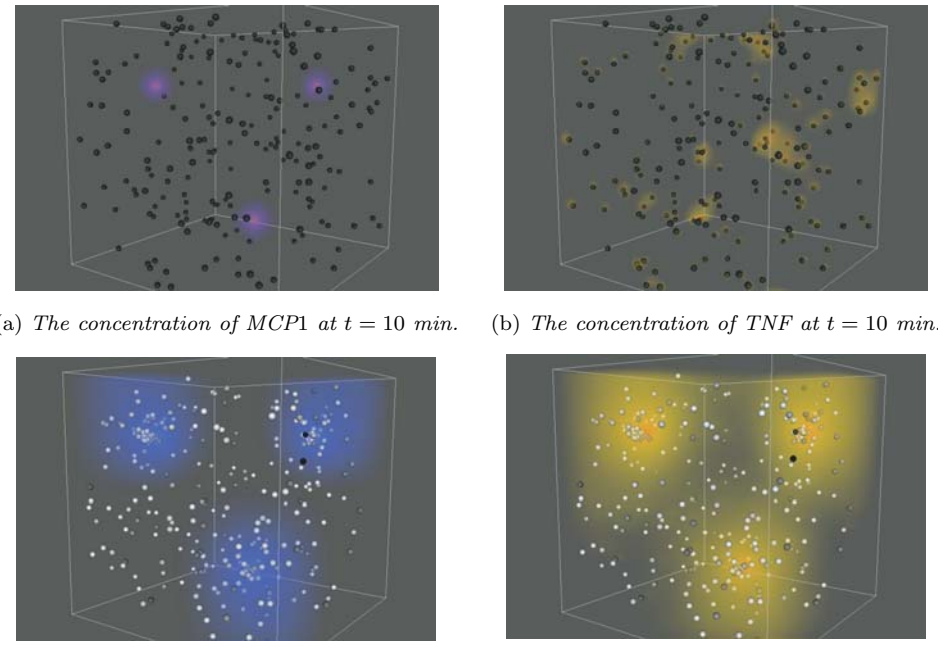
By (2.29) and (4.24), we have

$$\begin{aligned}\mathbb{E}\left[|X_{t+\delta} - X_t|^2\right] &\leq \mathbb{E}\left[2\left|\int_t^{t+\delta} a(U(X_\tau), X_\tau)d\tau\right|^2 + 2\left|\int_t^{t+\delta} b(X_\tau)dW_\tau\right|^2\right] \\ &\leq \mathbb{E}\left[2\delta\int_t^{t+\delta} |a(U(X_\tau), X_\tau)|^2 \, d\tau + 2\int_t^{t+\delta} |b(X_\tau)|^2 \, d\tau\right] \\ &\leq 2\delta^2 C_a(\xi, T) + 2\sigma^2\gamma\delta.\end{aligned}$$

Therefore, (5.6) holds, with $C = C(\sup|u|, \|u\|_k, \xi, T)$. ∎

6. Conclusions. The use of a first order splitting for the reaction–diffusion-stochastic system allows us to make use of known first order numerical methods for the diffusion, reaction, and stochastic differential equations. In particular, the diffusion can be discretized spatially using finite elements. From [1], we know that the resulting error is $\mathcal{O}(h^2)$, where h is the grid spacing. The resulting problem can be discretized in time using a first order backward Euler scheme as described in [17]. From [4], we know that the backward Euler scheme preserves positivity. The reaction can be approximated by a semi-implicit scheme that preserves positivity. General numerical methods for stochastic differential equations are outlined in [8]. In our case the cell motion (1.2) is a Langevin process that can be simulated exactly using ideas from [9]. By combining the numerical methods outlined above, we obtain a numerical simulation that is first order in time and preserves the positivity of the soluble factors.

The numerical methods outlined above have been implemented in a three-dimensional immune simulation with a large number of cells as described in [12]. Figure 6.1 shows a simulation of the immune response to three fixed sources of MCP1



(a) *The concentration of MCP*1 *at* $t = 10$ *min.* (b) *The concentration of TNF at* $t = 10$ *min.*

(c) *The concentration of MCP*1 *at* $t = 120$ *min.* (d) *The concentration of TNF at* $t = 120$ *min.*

FIG. 6.1. *A simulation of an immune response to three sources of MCP*1.

which is known to attract immune cells called macrophages. The macrophages secrete the cytokines TNF and sTNFr depending on their internal state, e.g., in Figure 6.1 the color of each macrophage from black to white represents the rate of secretion on TNF. The domain is a cube with side length 400μm and grid spacing 6.25μm. The radius of each macrophage is 5μm, and the cube initially contains 100 cells, with more cells entering the domain according to a Poisson distribution. The time step is 0.1 min. and in Figure 6.1 you can see the cells clustering around the sources of MCP1 after 120 min. The diffusion of MCP1 and TNF is also apparent in Figure 6.1.

Acknowledgments. The author thanks William K. Allard and Thomas B. Kepler who have served as mentors on this project. The author also thanks Cliburn Chan for his contributions to the simulation code and Eric Monson for his contributions to the vizualization of the simulation.

AN A POSTERIORI CONDITION ON THE NUMERICAL APPROXIMATIONS OF THE NAVIER–STOKES EQUATIONS FOR THE EXISTENCE OF A STRONG SOLUTION*

MASOUMEH DASHTI† AND JAMES C. ROBINSON†

Abstract. In their 2006 paper, Chernyshenko et al. [*J. Math. Phys.*, 48 (2007), 065204, 15 pp]. prove that a sufficiently smooth strong solution of the 3D Navier–Stokes equations is robust with respect to small enough changes in initial conditions and forcing function. They also show that if a regular enough strong solution exists, then Galerkin approximations converge to it. They then use these results to conclude that the existence of a sufficiently regular strong solution can be verified using sufficiently refined numerical computations. In this paper we study the strong solutions with less regularity than those considered in Chernyshenko et al. [*J. Math. Phys.*, 48 (2007), 065204, 15 pp]. We prove a similar robustness result and show the validity of the results relating convergent numerical computations and the existence of the strong solutions.

Key words. Navier–Stokes equations, regularity of solutions, rigorous numerics

AMS subject classifications. 76D05, 74H30

DOI. 10.1137/060677537

1. Introduction. For the three-dimensional (3D) Navier–Stokes equations the existence of strong solutions over an arbitrary time interval is not known. Therefore, the validity of the results of the numerical solutions of 3D Navier–Stokes equations is not obvious. This problem is addressed in [2] where a rigorous relationship between numerical and sufficiently regular exact solutions is given. It is shown there for sufficiently smooth initial conditions and forcing functions (data) that although a priori there is no guarantee of the validity of the numerical solutions, there is an a posteriori condition that if satisfied by the numerical results guarantees the existence of a strong solution. In this paper we show the validity of the results proved in [2] for less regular strong solutions than are covered there.

We will study the Navier–Stokes equations in their functional form. For a bounded domain Ω we let $\mathcal{H}$ be the space of divergence-free smooth vector-valued functions on Ω with compact support and define

$$H = \text{closure of } \mathcal{H} \text{ in } [L^2(\Omega)]^3,$$
$$V = \text{closure of } \mathcal{H} \text{ in } [H^1(\Omega)]^3.$$

In the case of a periodic domain Q, we consider $\mathcal{H}_p$ to be the space of periodic, divergence-free, and smooth vector-valued functions on Q with zero average and use the same notation H and V for the closure of $\mathcal{H}_p$ in $[L^2(Q)]^3$ and $[H^1(Q)]^3$, respectively. The Navier–Stokes equations in their functional form are written as [3, 11]

$$\frac{\mathrm{d}u}{\mathrm{d}t} + \nu Au + B(u,u) = f, \quad \text{with} \quad u(0) = u_0, \tag{1.1}$$

where $Au = -\Pi\Delta$, $B(u,u) = \Pi(u.\nabla)u$ with Π the orthogonal projection from L^2 into H. We will consider this equation with the following cases for the data:

(a) "first-order regularity" when $u_0 \in V$ and $f \in L^2(0,T;H) \cap L^1(0,T;V)$

(b) "second-order regularity" when $u_0 \in V^2$ and $f \in L^2(0,T;V) \cap L^1(0,T;V^2)$,

where $V^m = H^m \cap V$. For the periodic case we know that $D(A^{m/2}) = H^m \cap V$ for all m, and therefore we define the norm on V^m as $\|u\|_m = |A^{m/2}u|$. We denote by $(\cdot,\cdot)$ and $|\cdot|$ the inner product and norm on H.

We will show that the strong solution of (1.1) with the data introduced in (a) or (b), if it exists, remains strong if the changes in the initial condition and forcing function are small enough. The exact conditions required for these changes to be "small" are given in Theorems 4.1 and 4.2. For example, in case (a) we require

$$|D(u_0 - v_0)| + \int_0^T |Df(s) - Dg(s)|\,\mathrm{d}s < \frac{1}{k}\left(\frac{\nu^3}{27T}\right)^{1/4} \exp\left(-\frac{k^2}{2}\int_0^T \frac{27k^2}{2}\frac{1}{\nu^3}|Du(s)|^4 + \frac{1}{\nu}|Du(s)|\,|Au(s)|\,\mathrm{d}s\right),$$

where v_0 and g are the nearby initial condition and forcing function and k is a constant. In Theorems 6.1 and 6.2, we use these robustness results to find an a posteriori condition that if satisfied by sufficiently refined numerical approximations, implies the existence of a strong solution.

We then show that if a strong solution exists the Galerkin approximations converge to it. This implies that assuming that the Navier–Stokes equations are a meaningful model of fluid flow, the numerical experiments based on the Galerkin method can be justified mathematically.

Combining the above two results, we prove that the existence of a strong solution can be verified by the Galerkin approximations. In the last section we consider a channel flow as a physical example that can be described by the Navier–Stokes equations with the conditions introduced above. For this example we will show how the results of this paper can be applied to the Galerkin approximations to verify the existence of a strong solution.

The results we prove here for a strong solution with first-order regularity hold in a general bounded domain as well as in the absence of boundaries unlike the results for more regular solutions which are proved only for the equations in a periodic domain or the whole space.

2. General ODE lemma. We first prove an ODE lemma which will be used in dealing with the differential inequalities that appear in the proofs. We consider the differential inequality

$$\frac{\mathrm{d}y}{\mathrm{d}t} \le \delta(t) + \alpha y^n \qquad \text{with} \quad y(0) = y_0 > 0$$

and find the conditions on y_0, $\delta(t)$ and α that ensure that $y(t)$ exists on a finite time interval $[0,T]$. This lemma is a generalization of the result obtained for $n = 2$ in [2].

LEMMA 2.1. *Let $T > 0$, $\alpha > 0$, and $n > 1$ be constants and let $\delta(t)$ be a nonnegative continuous function on $[0,T]$. Let y satisfy the differential inequality*

$$\frac{\mathrm{d}y}{\mathrm{d}t} \le \delta(t) + \alpha y^n \qquad \textit{with} \quad y(0) = y_0 > 0 \tag{2.1}$$

and define

$$\eta = y_0 + \int_0^T \delta(s)\,\mathrm{d}s.$$

(i) *If*

$$\eta < \frac{1}{[(n-1)\alpha T]^{1/(n-1)}}, \tag{2.2}$$

then $y(t)$ remains bounded on $[0,T]$.

(ii) *$y(t) \to 0$ uniformly on $[0,T]$ as $\eta \to 0$.*

Proof. We first consider the following differential inequality

$$\dot{z} \le \alpha z^n \quad \text{with} \quad z(0) = \eta \tag{2.3}$$

and show that

$$\sup_{S_1} y(T) \le \sup_{S_2} z(T), \tag{2.4}$$

where S_1 and S_2 are the sets of all possible solutions of inequalities (2.1) and (2.3), respectively.

Since $\dot{y}$, $\dot{z}$, $y(0)$, and $z(0)$ are nonnegative, the suprema of $y(T)$ and $z(T)$ happen when

$$\begin{aligned}\dot{y} &= \delta(t) + \alpha y^n,\\ \dot{z} &= \alpha z^n\end{aligned}$$

for all $t \in [0,T]$. In this case, for the difference $w = y - z$ we have

$$\dot{w} = \delta(t) + \alpha w \sum_{k=0}^{n-1} \binom{n-1}{k} y^{n-1-k}\, z^k \quad \text{with} \quad w(0) = -\int_0^t \delta(s)\,\mathrm{d}s.$$

Since $y(t)$ and $z(t)$ are greater than zero and assuming they remain finite over $[0,T]$, there exists some $M > 0$ such that

$$\dot{w} \le \alpha M w + \delta(t)$$

and therefore by Gronwall's inequality

$$\begin{aligned} w(t) &\le w(0)\mathrm{e}^{\alpha M t} + \int_0^t \delta(s)\,\mathrm{d}s\\ &= (1 - \mathrm{e}^{\alpha M t}) \int_0^t \delta(s)\,\mathrm{d}s. \end{aligned}$$

This implies $w(t) \le 0$ for any $t \in [0,T]$ and (2.4) follows.

The inequality (2.3) can be written as

$$\frac{\dot{z}}{z^n} \le \alpha.$$

Integrating both sides from 0 to t yields

$$z(T) \le \frac{\eta}{(-\alpha T(n-1)(\eta)^{n-1} + 1)^{1/n-1}}. \tag{2.5}$$

Since $y(t) \le y(T) \le z(T)$, $y(t)$ remains finite on $[0,T]$ provided that

$$\alpha T(n-1)(\eta)^{n-1} < 1,$$

which yields (2.2).

Furthermore, it is clear from (2.5) that $z(T) \to 0$ as $\eta \to 0$, from which it follows that $y(t) \to 0$ uniformly on $[0,T]$. □

3. The inequalities for the nonlinear term. For the nonlinear operator, we will use the following inequalities in this paper:

$$|(B(u,v),Aw)| \le k|Du|\,|Dv|^{1/2}|Av|^{1/2}|Aw| \tag{3.1}$$

$$|(B(w,u),A^2w)| \le c\|u\|_3\|w\|_2^2 \tag{3.2}$$

$$|(B(u,w),A^2w)| \le c'\|u\|_3\|w\|_2^2, \tag{3.3}$$

The last two inequalities only hold in $\mathbb{R}^3$ [9] and the periodic domain [3]. In the latter case where $\Omega = (0,L)^3$, c and c' depend on L [3]. The first inequality holds for both Dirichlet and periodic boundary conditions [3]. The constant k depends on the geometric properties and size of the domain. We show this here for a cubic domain which we will use in Section 7.

Using Hölder inequality, one can write

$$|(B(u,v),Aw)| \le \sum_{i,j=1}^{3} \|u_i\|_{L^6}\|D_iv_j\|_{L^3}|Aw_j|.$$

By the Sobolev embedding theorem and the Poincaré inequality, we have

$$\|u\|_{L^6} \le c_s\|u\|_{H^1} \le c_s(|u| + |Du|) \le c_s(1+c_p)\,|Du|.$$

Also, we can write

$$\begin{aligned}
\|Dv\|_{L^3} &\le \|Dv\|_{L^6}^{1/2}\,|Dv|^{1/2} \\
&\le c_s^{1/2}\,\|Dv\|_{H^1}^{1/2}\,|Dv|^{1/2} \\
&\le c_s^{1/2}\,(1+c_p)^{1/2}\,|D^2v|^{1/2}\,|Dv|^{1/2} \\
&\le c_s^{1/2}\,(1+c_p)^{1/2}\,c_e^{1/2}\,|Av|^{1/2}\,|Dv|^{1/2}.
\end{aligned}$$

Since

$$|(B(u,v),Aw)| \le \sum_{i,j=1}^{3} \|u_i\|_{L^6}\,\|D_iv_j\|_{L^3}\,|Aw_j| \le 9\,\|u\|_{L^6}\,\|Dv\|_{L^3}\,|Aw|,$$

we have

$$k = 9\,c_s^{3/2}\,c_e^{1/2}\,(1+c_p)^{3/2}. \tag{3.4}$$

Now for $\Omega = (0,L_1)\times(0,L_3)\times(0,L_3)$, along the lines of the proof of Theorem (5.10) of [1], one can show that

$$c_s = \sqrt{2}\,(1 + 2\max\{L_1,L_2,L_3\}).$$

Since for a function in a convex domain with zero average, the constant of the Poincaré inequality is d_D/π, where d_D is the diameter of the domain [10], $c_p = (L_1^2 + L_2^2 +$

$L_3^2)^{1/2}/\pi$. The constant c_e also depends on the geometric properties and size of the domain (see [7] or [11] for example)."

In obtaining the robustness conditions in the next section, we keep track of the constants k, c, and c' when they appear, so that the value of the constant coefficients in the robustness conditions could be computed if desired.

The inequalities (3.1)–(3.3) are not as elegant as the inequalities available for the more regular solutions considered in [2], and this is why different proofs are needed in the less regular cases we are studying here.

We note here that assuming a strong solution $u \in L^\infty(0,T;V) \cap L^2(0,T;V^2)$ exists, from (3.1) we have $B(u,u) \in L^2(0,T;H)$ and therefore (1.1) implies that $\mathrm{d}u/\mathrm{d}t \in L^2(0,T;H)$. Having $u_0 \in V^2$ and $f \in L^2(0,T;V)$ in case (b), from the regularity result for periodic domains proved in [3] we know that the strong solution u is, in fact, more regular and an element of $L^\infty(0,T;V^2) \cap L^2(0,T;V^3)$.

4. Robustness of strong solutions. Here we show that as long as a strong solution exists for some specific initial data and forcing function, the equations with sufficiently close data also have a strong solution. A similar result about the robustness of strong solutions with respect to changes in the forcing function is proved by Fursikov [6] in his 1980 paper. For the 3D Navier–Stokes equations with initial condition $u_0 \in V^m$ where $m \geq 1/2$, he shows that the set of forcing functions for which a strong solution exists is open in $L^q(0,T;V^{m-1})$ with $q \geq 2$.

For both the first-order regular solutions of case (a) and the more regular case (b), the condition we obtain here for the data depends explicitly on the viscosity coefficient unlike the more regular cases considered in [2]. The robustness result we prove for the strong solutions with $u_0 \in V$ holds in a general bounded domain. For the second-order regular solutions, however, we need to restrict the domain to be periodic or the whole of $\mathbb{R}^3$ since the inequalities (3.2) and (3.3) hold only in a periodic domain [3] or the whole of $\mathbb{R}^3$ [9].

(a) Strong solutions with first-order regularity. To prove the robustness with respect to the data, we write the governing equation for the difference between the solution of the equations with nearby data and the strong solution and find a bound on the norm of this difference.

THEOREM 4.1. *Consider $f, g \in L^1(0,T,V) \cap L^2(0,T;H)$, $u_0, v_0 \in V$ and let $u \in L^\infty(0,T;V) \cap L^2(0,T;V^2)$ be a strong solution of*

$$\frac{\mathrm{d}u}{\mathrm{d}t} + Au + B(u,u) = f \quad \textit{with} \quad u(0) = u_0.$$

If

$$\begin{aligned} &|D(u_0 - v_0)| + \int_0^T |Df(s) - Dg(s)|\,\mathrm{d}s \\ &< \frac{1}{k}\left(\frac{\nu^3}{27T}\right)^{1/4} \exp\left(-\frac{k^2}{2}\int_0^T \frac{27k^2}{2}\frac{1}{\nu^3}|Du(s)|^4 + \frac{1}{\nu}|Du(s)|\,|Au(s)|\,\mathrm{d}s\right), \end{aligned} \tag{4.1}$$

then the solution of

$$\frac{\mathrm{d}v}{\mathrm{d}t} + \nu Av + B(v,v) = g \quad \textit{with} \quad v(0) = v_0$$

is also a strong solution on $[0,T]$ with the same regularity as u.

Proof. By the local existence of strong solutions ([3], [12]), we know that there exists $T^* > 0$ such that $v \in L^\infty(0,T';V) \cap L^2(0,T';V^2)$ for any $T' < T^*$. We consider T^* the maximal time of existence of the strong solution v, meaning that $\limsup_{t\to T^*} |Dv| = \infty$. In the following argument we assume $T^* \le T$ and deduce a contradiction.

We consider $w = u - v$ which satisfies

$$\frac{\mathrm{d}w}{\mathrm{d}t} + \nu Aw + B(u,w) + B(w,u) - B(w,w) = f - g.$$

Over the time interval $t \in [0,T')$ for any $T' < T^*$, we have $\mathrm{d}v/\mathrm{d}t \in L^2(0,T';H)$ and since $T^* \le T$, $\mathrm{d}u/\mathrm{d}t \in L^2(0,T';H)$. Therefore, taking the inner product of the above equation with Aw and using (3.1) we can write

$$\begin{aligned}\frac{1}{2}\frac{\mathrm{d}}{\mathrm{d}t}|Dw|^2 + \nu|Aw|^2 \le k|Du||Dw|^{1/2}|Aw|^{3/2} + k|Dw||Du|^{1/2}|Au|^{1/2}|Aw| \\ + k|Dw|^{3/2}|Aw|^{3/2} + |D(f-g)|\,|Dw|.\end{aligned}$$

We then use Young's inequality to remove $|Aw|$ (which causes the appearence of ν in the coefficients) and obtain

$$\frac{1}{2}\frac{\mathrm{d}}{\mathrm{d}t}|Dw|^2 \le \left(\frac{27k^4}{4\nu^3}|Du|^4 + \frac{k^2}{2\nu}|Du||Au|\right)|Dw|^2 + \frac{27k^4}{4\nu^3}|Dw|^6 + |D(f-g)|\,|Dw|.$$

Dividing by $|Dw|$ (assuming $|Dw|$ is nonzero; if not, replacing $|Dw|$ by $|Dw|+e_0$ with $e_0 > 0$ will lead us to the same result after tending e_0 to zero at the end) we get

$$\frac{\mathrm{d}}{\mathrm{d}t}|Dw| \le \left(\frac{27k^4}{4\nu^3}|Du|^4 + \frac{k^2}{2\nu}|Du||Au|\right)|Dw| + \frac{27k^4}{4\nu^3}|Dw|^5 + |D(f-g)|.$$

Now letting

$$\beta(t) = \frac{k^2}{2}\int_0^t \left(\frac{27k^2}{2}\frac{1}{\nu^3}|Du|^4 + \frac{1}{\nu}|Du|\,|Au|\right)\,\mathrm{d}s$$

and setting $y(t) = |Dw(t)|\mathrm{e}^{-\beta(t)}$ the above inequality can be written as

$$\frac{\mathrm{d}y}{\mathrm{d}t} \le \alpha y^5 + \delta(t),$$

where $\alpha = \frac{27k^4}{4\nu^3}\mathrm{e}^{4\beta(T)}$ and $\delta(t) = |Df(t) - Dg(t)|$.

By Lemma 2.1, if the condition (4.1) is satisfied, $|Dw(t)|$ is uniformly bounded on $[0,T^*)$. This implies that $|Dv(T^*)| < \infty$, which contradicts the maximality of T^*. It follows that $v(t)$ is a strong solution on $[0,T]$. ∎

(b) Strong solutions with second-order regularity. We follow the same approach as in the previous case to show the robustness for a strong solution with second-order regularity. Here also the inequalities we need to use for the nonlinear operator to find a bound on the V^2-norm of the difference between nearby solutions depend on the V^3-norm of this difference, and therefore the robustness condition on the data depends explicitly on the viscosity coefficient. However, its dependence is weaker in this case.

THEOREM 4.2. *Let $f \in L^1(0,T,V^2) \cap L^2(0,T;V)$, $u_0 \in V^2$ and $u \in L^\infty(0,T;V^2) \cap L^2(0,T;V^3)$ be a strong solution of*

$$\frac{\mathrm{d}u}{\mathrm{d}t} + Au + B(u,u) = f \quad \textit{with} \quad u(0) = u_0.$$

If

$$|A(u_0 - v_0)| + \int_0^T |A(f-g)|\,\mathrm{d}t \;<\; \frac{1}{c}\sqrt{\frac{2\nu}{T}} \exp\left(-\int_0^T (c+c')\|u\|_3\,\mathrm{d}t\right), \tag{4.2}$$

then the solution of

$$\frac{\mathrm{d}v}{\mathrm{d}t} + Av + B(v,v) = g \quad \textit{with} \quad v(0) = v_0$$

is also a strong solution on $[0,T]$ with the same regularity as u.

Proof. As before, the difference $w = u - v$ satisfies

$$\frac{\mathrm{d}w}{\mathrm{d}t} + \nu Aw + B(u,w) + B(w,u) + B(w,w) = f - g.$$

Taking the inner product of the above equation with $A^2 w$ and using (3.2) and (3.3) we obtain

$$\frac{1}{2}\frac{\mathrm{d}}{\mathrm{d}t}\|w\|_2 + \nu\|w\|_3^2 \le (c+c')\|u\|_3^2\|w\|_2^2 + c\|w\|_3\|w\|_2^2 + \|f-g\|_2\|w\|_2.$$

We apply Young's inequality to the second term on the right-hand side and get

$$\frac{1}{2}\frac{\mathrm{d}}{\mathrm{d}t}\|w\|_2^2 \le (c+c')\|u\|_3\|w\|_2^2 + \frac{c^2}{4\nu}\|w\|_2^4 + \|f-g\|_2\|w\|_2.$$

Dividing the above inequality by $\|w\|_2$ yields

$$\frac{\mathrm{d}}{\mathrm{d}t}\|w\|_2 \le (c+c')\|u\|_3\,\|w\|_2 + \frac{c^2}{4\nu}\|w\|_2^3 + \|f-g\|_2.$$

Now we consider

$$y(t) = \|w\|_2 e^{-\beta(t)}$$

with $\beta(t) = \int_0^t (c+c')\|u\|_3\,\mathrm{d}t$. The equation with this new variable becomes

$$\frac{\mathrm{d}y}{\mathrm{d}t} \le \delta(t) + \alpha y^3,$$

where $\alpha = \frac{c^2}{4\nu} e^{2\beta(T)}$ and $\delta = \|f-g\|_2$. Using Lemma 2.1 $\|w\|_2$ is bounded if the condition (4.2) is satisfied. ∎

5. Convergence of Galerkin approximations. Here we show that if a strong solution with first- or second-order regularity exists, Galerkin approximations converge to it. Similar results about convergence of various numerical methods, assuming the existence of a strong solution, are given for finite element methods by Heywood and Rannacher [8], for a Fourier collocation method by E [5] and for a nonlinear

Galerkin method by Devulder, Marion, and Titi [4]. Here, as in [2], we make no assumption on the regularity of the Galerkin approximations.

For the first-order regular case the result we prove here holds for the solution of the equations over a general bounded domain. For the second-order regular solutions we need to use inequality (3.3) which is valid only in a periodic domain or the whole of $\mathbb{R}^3$.

In the following theorems we let P_n be the orthogonal projection in H onto the space spanned by the first n eigenfunctions of the Stokes operator A, $\{w_j\}_{j=1}^n$, ordered so that their corresponding eigenvalues satisfy $0 < \lambda_1 \le \lambda_2 \le \dots$. Since the eigenfunctions of A are smooth [3], for any $u \in V^m$, $m \ge 0$ (with $V^0 = H$) we have $u_n = P_n u = \sum_{j=1}^n (u, w_j) w_j \in V^m$.

We note that what we obtain here about the convergence of Galerkin approximations would be useful even if the existence of regular solutions was known.

(a) First-order regularity. The following theorem, like the robustness theorem in the first-order regularity case, holds in sufficiently smooth bounded domains as well as in the absence of boundaries.

THEOREM 5.1. *Let $u_0 \in V$, $f \in L^2(0,T;H)$ and $u \in L^\infty(0,T;V) \cap L^2(0,T;V^2)$ be a strong solution of the Navier–Stokes equations*

$$\frac{\mathrm{d}u}{\mathrm{d}t} + \nu A u + B(u,u) = f(t) \quad \textit{with} \quad u(0) = u_0.$$

Then u_n, the solution of Galerkin system

$$\frac{\mathrm{d}u_n}{\mathrm{d}t} + \nu A u_n + P_n B(u_n, u_n) = P_n f(t) \quad \textit{with} \quad u_n(0) = P_n u_0, \tag{5.1}$$

converges strongly to u in both $L^\infty(0,T;V)$ and $L^2(0,T;V^2)$ as $n \to \infty$.

Proof. We consider $w_n = u - u_n$ which satisfies

$$\frac{\mathrm{d}w_n}{\mathrm{d}t} + \nu A w_n + P_n B(u, w_n) + P_n B(w_n, u) - P_n B(w_n, w_n) = Q_n f(t) - Q_n B(u,u),$$

with $Q_n = I - P_n$. Let $q_n = u - P_n u$, noting that u_n the solution of the Galerkin system (5.1) is different from $P_n u$, the image of u under orthogonal projection P_n. Taking the inner product of the above equation with Aw_n while noting that $(P_n B(u,v), Aw_n) = (B(u,v), P_n A w_n)$, we obtain

$$\begin{aligned}\frac{1}{2}\frac{\mathrm{d}}{\mathrm{d}t}|Dw_n|^2 + \nu |Aw_n|^2 \le k \Big(& |Du|\,|Dw_n|^{1/2}|Aw_n|^{3/2} \\ & + |Dw_n|\,|Du|^{1/2}\,|Au|^{1/2}|Aw_n| + |Dw_n|^{3/2}|Aw_n|^{3/2} \\ & + |Du|^{3/2}|Au|^{1/2}|Aq_n| \Big) + |f|\,|Aq_n|.\end{aligned}$$

Applying Young's inequality and redefining the constant k gives

$$\begin{aligned}\frac{\mathrm{d}}{\mathrm{d}t}|Dw_n|^2 \le k \Bigg\{ & \left(\frac{1}{\nu^3}|Du|^4 + \frac{1}{\nu}|Du|\,|Au| \right) |Dw_n|^2 + \frac{1}{\nu^3}|Dw_n|^6 \\ & + |Du|^{3/2}|Au|^{1/2}|Aq_n| \Bigg\} + |f|\,|Aq_n|.\end{aligned}$$

Now letting

$$\beta(t) = k \int_0^t \left(\frac{1}{\nu^3}|Du|^4 + \frac{1}{\nu}|Du|\,|Au| \right) \mathrm{d}s$$

and

$$y_n(t) = \mathrm{e}^{-\beta(t)}|Dw_n|^2,$$

the above inequality can be written as

$$\frac{\mathrm{d}y_n}{\mathrm{d}t} \le \alpha y_n^3 + \delta_n(t),$$

with $\alpha = \frac{k}{\nu^3}\mathrm{e}^{2\beta(T)}$ and $\delta_n(t) = |f|\,|Aq_n| + k|Du|^{3/2}|Au|^{1/2}|Aq_n|$.

Using the Hölder inequality we have

$$\int_0^T \delta_n(s)\,\mathrm{d}s \le \left[\left(\int_0^T |f|^2\mathrm{d}s\right)^{1/2} + k\left(\int_0^T |Du|^3|Au|\mathrm{d}s\right)^{1/2}\right]\left(\int_0^T |Aq_n|^2\mathrm{d}s\right)^{1/2}.$$

Since $u \in L^2(0,T;V^2)$, $u(s) \in V^2$ for almost every $s \in [0,T]$ and therefore $q_n(s) = Q_n u(s) \to 0$ in V^2 as $n \to \infty$ and $|Aq_n(s)|^2 \le |Au(s)|^2$ for a.e. $s \in [0,T]$. Hence the Lebesgue dominated convergence theorem for each s implies that $\int_0^T |Aq_n|^2\mathrm{d}s$ tends to zero as $n \to \infty$ and therefore

$$\int_0^T \delta_n(s)\,\mathrm{d}s \to 0$$

as $n \to \infty$. Since $y_n(0) \to 0$ as $n \to \infty$, Lemma 2.1 shows that y_n, and hence $|Dw_n|^2$, converges to zero uniformly on $[0,T]$ as $n \to \infty$. □

(b) Second-order regularity. Here also, in a similar way to the previous case, we try to find a bound on the V^2-norm of the difference between a second-order regular strong solution and Galerkin approximations. However, here the more regular solution space makes the proof easier.

THEOREM 5.2. *Let $u_0 \in V^2$, $f \in L^2(0,T;V) \cap L^1(0,T;V^2)$ and $u \in L^\infty(0,T;V^2) \cap L^2(0,T;V^3)$ be a strong solution of the Navier–Stokes equations*

$$\frac{\mathrm{d}u}{\mathrm{d}t} + \nu Au + B(u,u) = f(t) \quad \textit{with} \quad u(0) = u_0.$$

Then u_n, the solution of Galerkin system

$$\frac{\mathrm{d}u_n}{\mathrm{d}t} + \nu Au_n + P_nB(u_n,u_n) = P_nf(t) \quad \textit{with} \quad u_n(0) = P_nu_0, \tag{5.2}$$

converges strongly to u in both $L^\infty(0,T;V^2)$ and $L^2(0,T;V^3)$ as $n \to \infty$.

Proof. Let $w_n = u - u_n$. Then w_n satisfies

$$\frac{\mathrm{d}w_n}{\mathrm{d}t} + \nu Aw_n + P_nB(u,w_n) + P_nB(w_n,u) + P_nB(w_n,w_n) = Q_nf - Q_nB(u,u).$$

Taking the inner product of the above equation with A^2w_n and using (3.2) and (3.3) we obtain

$$\begin{aligned}\frac{1}{2}\frac{\mathrm{d}}{\mathrm{d}t}\|w_n\|_2^2 + \nu\|w_n\|_3^2 \le (c+c')\|u\|_3\|w_n\|_2^2 + c\|w_n\|_3\|w_n\|_2^2 \\ + \|Q_nf - Q_nB(u,u)\|_2\|w_n\|_2\end{aligned}$$

Now we use Young's inequality to remove the dependence on $\|w_n\|_3$ and then divide by $\|w\|_2$ to obtain

$$\frac{\mathrm{d}}{\mathrm{d}t}\|w_n\|_2 \le (c+c')\|u\|_3\|w_n\|_2 + \frac{c^2}{4\nu}\|w_n\|_2^3 + \|Q_nf - Q_nB(u,u)\|_2,$$

in which the coefficient of $\|w_n\|_2$ does not depend on n.

Letting

$$y_n = \|w_n\|_2 e^{-\beta(t)},$$

with $\beta(t) = \exp\left(\int_0^t (c+c')\|u(s)\|_3 \, \mathrm{d}s\right)$ yields

$$\dot{y}_n \le \delta(t) + \alpha y_n^3,$$

where $\alpha = \frac{c^2}{4\nu} e^{2\beta(T)}$ and $\delta(t) = \|Q_n f - Q_n B(u,u)\|_2$. So by Lemma 2.1 if

$$\eta = \|Q_n u_0\|_m + \int_0^T \|Q_n f - Q_n B(u,u)\|_2 \, \mathrm{d}s \to 0 \quad \text{as} \quad n \to \infty,$$

then $y_n(t) \to 0$ uniformly on $[0,T]$ as $n \to \infty$.

By (5.2) $\|Q_n u_0\|_m \to 0$ as $n \to \infty$. We know that

$$\|B(u,u)\|_2 \le c\|u\|_2 \|u\|_3 \tag{5.3}$$

([9], [3]), and therefore $f(s) - B(u(s),u(s)) \in V^2$ for almost every $s \in [0,T]$. So since $\{w_j\}_{j=1}^n$ forms a basis for V^2 as well as H, $\|Q_n\left(f(s) - B(u(s),u(s))\right)\|_2 \to 0$ and

$$\|Q_n\left(f(s) - B(u(s),u(s))\right)\|_2 \le \|f(s) - B(u(s),u(s))\|_2$$

for almost every $s \in [0,T]$. Therefore, by the Lebesgue dominated convergence theorem it follows that

$$\int_0^T \|Q_n\left(f(s) - B(u(s),u(s))\right)\|_2 \to 0$$

and the result follows. □

6. Numerical verification of the existence of a strong solution. Here we show that the existence of first- and second-order regular strong solutions can be verified via computations using sufficiently refined Galerkin approximations.

THEOREM 6.1. (i) *Consider the Navier–Stokes equations*

$$\frac{\mathrm{d}u}{\mathrm{d}t} + \nu A u + B(u,u) = f \quad \textit{with} \quad u(0) = u_0 \tag{6.1}$$

with $u_0 \in V$, $f \in L^2(0,T;H) \cap L^1(0,T;V)$, that hold in a bounded domain Ω with sufficiently smooth boundary or in a periodic domain.

Let $v \in L^\infty(0,T;V) \cap L^2(0,T;V^2)$ be a numerical approximation of u satisfying

$$\frac{\mathrm{d}v}{\mathrm{d}t} + \nu A v + B(v,v) \in L^1(0,T;V) \cap L^2(0,T;H)$$

and

$$\begin{aligned} &|Dv(0) - Du_0| + \int_0^T \left\| \frac{dv(s)}{ds} + \nu A v(s) + B(v(s),v(s)) - f(s) \right\|_1 \mathrm{d}s \\ &< \frac{1}{k}\left(\frac{\nu^3}{27T}\right)^{1/4} \exp\left(-\frac{k^2}{2}\int_0^T \frac{27k^2}{2}\frac{1}{\nu^3}|Dv(s)|^4 + \frac{1}{\nu}|Dv(s)||Av(s)|\,\mathrm{d}s\right). \end{aligned} \tag{6.2}$$

Then the Navier–Stokes equations (6.1) *have a strong solution* $u \in L^\infty(0,T;V) \cap L^2(0,T;V^2)$.

(ii) *Let* u *be a strong solution of* (6.1). *Then there exists an* N *such that the Galerkin approximations* u_n *satisfy the inequality* (6.2) *for all* $n > N$. *Therefore in view of part* (i), u *passes the a posteriori test as a solution approximated by* u_n; *i.e., the existence of a strong solution with first-order regularity can be verified by the Galerkin approximations.*

Proof.

(i) Considering

$$g = \frac{\mathrm{d}v}{\mathrm{d}t} + \nu Av + B(v,v),$$

v is a strong solution of

$$\frac{\mathrm{d}z}{\mathrm{d}t} + \nu Az + B(z,z) = g, \quad \text{with } z(0) = v(0).$$

So by Theorem 4.1, if the inequality (6.2) holds, the solution of the equations with nearby data (u_0, f) is a strong solution.

(ii) The strong convergence of u_n to u in $L^\infty(0,T;V)$ and $L^2(0,T;V^2)$ is guaranteed by Theorem 5.1. Therefore, the right-hand side of (6.2) is bounded below for every n. It follows from (5.1) that $|Du_n(0) - Du_0| \to 0$ as $n \to 0$ and

$$\frac{du_n}{dt} + \nu Au_n + B(u_n,u_n) - f = Q_n[B(u_n,u_n) - f].$$

Therefore it only remains to show $\|Q_n[B(u_n(s),u_n(s)) - f]\|_1$ converges to zero as $n \to \infty$ for a.e. $s \in [0,T]$; it is then clear that (6.2) will be satisfied for all n sufficiently large.

For the nonlinear operator we have

$$\begin{aligned}\|B(u_n,u_n)\|_1 &= \sqrt{(D(u_n\cdot\nabla)u_n, D(u_n\cdot\nabla)u_n)} \\ &\le c\left(\|Du_n\|^4_{L^4(\Omega)} + \|u_n\|^2_{L^\infty(\Omega)}|Au_n|^2\right)^{1/2}.\end{aligned}$$

Using the Sobolev inequalities we can write

$$\|Du_n\|_{L^4(\Omega)} \le c\|Du_n\|_{L^6(\Omega)} \le c|Au_n|$$

and

$$\|u_n\|_{L^\infty} \le c|Au_n|.$$

Therefore $\|B(u_n,u_n)\|_1 \le c|Au_n|^2$ which implies

$$f(s) - B(u_n(s),u_n(s)) \in V \quad \text{for a.e. } s \in [0,T]$$

and we will have

$$\|Q_n(B(u_n(s),u_n(s)) - f(s))\|_1 \to 0 \quad \text{as } n \to \infty \text{ and for a.e. } s \in [0,T]$$

and

$$\|Q_n(B(u_n(s),u_n(s)) - f(s))\|_1 \le \|B(u_n(s),u_n(s)) - f(s)\| \quad \text{for a.e. } s \in [0,T].$$

By the Lebesgue-dominated convergence theorem we conclude that

$$\int_0^T \|Q_n(B(u_n(s),u_n(s))-f(s))\|_1 \mathrm{d}s \to 0 \quad \text{as } n\to\infty. \qquad \square$$

A similar result holds for the strong solutions with second-order regularity in a periodic domain.

THEOREM 6.2. (i) *Consider the Navier–Stokes equations*

$$\frac{\mathrm{d}u}{\mathrm{d}t}+\nu Au+B(u,u)=f \quad \textit{with} \quad u(0)=u_0 \tag{6.3}$$

with $u_0\in V^2$, $f\in L^2(0,T;V^1)\cap L^1(0,T;V^2)$, that hold in a periodic domain.

Let $v\in L^\infty(0,T;V^2)\cap L^2(0,T;V^3)$ be a numerical approximation of u satisfying

$$\frac{\mathrm{d}v}{\mathrm{d}t}+\nu Av+B(v,v)\in L^1(0,T;V^2)\cap L^2(0,T;V)$$

and

$$\begin{aligned}\|v(0)-u_0\|_2+\int_0^T \left\|\frac{dv(s)}{ds}(s)+\nu Av(s)+B(v(s),v(s))-f(s)\right\|_2 \mathrm{d}s \\ < \frac{1}{c}\sqrt{\frac{2\nu}{T}}\exp\left(-\int_0^T (c+c')\|u_n\|_3\,\mathrm{d}t\right).\end{aligned} \tag{6.4}$$

Then the Navier–Stokes equations (6.3) *have a strong solution $u\in L^\infty(0,T;V^2)\cap L^2(0,T;V^3)$.*

(ii) *Let u be a strong solution of* (6.3). *Then there exists an N such that the Galerkin approximations u_n satisfy the inequality* (6.4) *for all $n>N$. Therefore in view of part* (i), *u passes a posteriori test as a solution approximated by u_n which means that the existence of the strong solution u can be verified using the Galerkin approximations.*

Using the robustness result for the strong solutions with second-order regularity, Theorem 4.2, the proof of the above theorem closely parallels that of Theorem 6.1.

7. A physical application: channel flow. We considered the Navier–Stokes equations for flow in a domain with nonmoving boundary and with the forcing function in the form of a body force. A physical situation for which the results of this paper and in particular the a posteriori test of Theorem 6.1 can be applied is a channel flow in the domain $0<x<L_x$, $0<y<1$, $0<z<L_z$ with the velocity field $u(x,y,z,t)$ considered to be periodic in x and z with periods L_x and L_z, respectively, and zero at $y=0$ and $y=1$. The body force g is assumed constant and equal to $(1,1,1)$. Here we show how to write the inequality (6.2) for the Galerkin approximations, u_n, of the solution u of this problem.

By Theorem 6.1 we know that if for some n the Galerkin approximation, u_n, satisfies

$$\begin{aligned}|Du_n(0)-Du_0|+\int_0^T \left\|\frac{du_n(s)}{ds}+\nu Au_n(s)+B(u_n(s),u_n(s))-f(s)\right\|_1 \mathrm{d}s \\ < \frac{1}{k}\left(\frac{\nu^3}{27T}\right)^{1/4}\exp\left(-\frac{k^2}{2}\int_0^T \frac{27k^2}{2}\frac{1}{\nu^3}|Du_n(s)|^4+\frac{1}{\nu}|Du_n(s)||Au_n(s)|\,\mathrm{d}s\right),\end{aligned}$$

then a strong solution u exists and the Galerkin approximations converge to it. To check this inequality for a Galerkin approximation of the above channel flow example, we need to compute Au_n, $B(u_n, u_n)$, and $f = \Pi g$.

The functions

$$w_{\mathbf{k}} = \mathrm{e}^{2\pi i(\frac{k_1}{L_x}x + \frac{k_3}{L_z}z)} \sin(\pi k_2 y)$$

with $\mathbf{k} = (k_1, k_2, k_3)$, form an orthogonal basis for the space of L^2-functions on the cubic domain introduced above, which have periodic bounday values in x and z directions and are zero on $y = 0$ and $y = 1$. We can therefore define the Galerkin approximation u_n in terms of $w_{\mathbf{k}}$ as

$$u_n = \sum_{\mathbf{k}=\mathbf{n}_0}^{\mathbf{n}} \alpha_{\mathbf{k}} w_{\mathbf{k}}, \quad \text{with} \quad \nabla \cdot u_n = 0 \tag{7.1}$$

where $\alpha_{\mathbf{k}} = (\alpha_{1\mathbf{k}}(t), \alpha_{2\mathbf{k}}(t), \alpha_{3\mathbf{k}}(t))$, $\alpha_{(-k_1,k_2,-k_3)} = \bar{\alpha}_{(k_1,k_2,k_3)}$ (with $\bar{\alpha}_{\mathbf{k}}$ the complex conjugate of $\alpha_{\mathbf{k}}$), $\mathbf{n}_0 = (-n, 0, -n)$, and $\mathbf{n} = (n, n, n)$. Since u_n is divergence-free we have

$$\sum_{\mathbf{k}=\mathbf{n}_0}^{\mathbf{n}} 2\pi i \left(\frac{k_1}{L_x}\alpha_{1\mathbf{k}} + \frac{k_3}{L_z}\alpha_{3\mathbf{k}}\right) \sin(\pi k_2 y) + \pi k_2\, \alpha_{2\mathbf{k}} \cos(\pi k_2 y) = 0.$$

After expanding $\cos(\pi k_2 y)$ in terms of sine functions we obtain

$$\pi i \left(\frac{k_1}{L_x}\alpha_{1\mathbf{k}} + \frac{k_3}{L_z}\alpha_{3\mathbf{k}}\right) + \sum_{l=\lfloor \frac{k_2}{2} \rfloor}^{\lfloor \frac{k_2+n}{2} \rfloor} (2l + 1 - k_2) \left(\frac{1}{2k_2 - 2l - 1} + \frac{1}{2l+1}\right) \alpha_{2\mathbf{k}} = 0.$$

Defining

$$\hat{\mathbf{k}} = \left(\frac{\pi i k_1}{L_x}, \sum_{l=\lfloor \frac{k_2}{2} \rfloor}^{\lfloor \frac{k_2+n}{2} \rfloor} (2l + 1 - k_2) \left(\frac{1}{2k_2 - 2l - 1} + \frac{1}{2l+1}\right), \frac{\pi i k_3}{L_z} \right)$$

and having (7.1) we obtain

$$Au_n = 4\pi^2 \sum_{\mathbf{k}=\mathbf{n}_0}^{\mathbf{n}} \left(\frac{k_1^2}{L_x^2} + \frac{k_2^2}{4} + \frac{k_3^2}{L_z^2}\right) \alpha_{\mathbf{k}}\, w_{\mathbf{k}}$$

and

$$B(u_n, u_n) = 2 \sum_{\mathbf{k}=2\mathbf{n}_0}^{2\mathbf{n}} \sum_{\mathbf{j}=\mathbf{k}_-}^{\mathbf{k}_+} \sum_{m=\lfloor \frac{k_2+1}{2} \rfloor}^{\lfloor \frac{k_2+2n}{2} \rfloor} \left\{ (\alpha_{\mathbf{k}_m - \mathbf{j}} \cdot \mathbf{j}) \left(\alpha_{\mathbf{j}} - \frac{\hat{\mathbf{k}}}{|\hat{\mathbf{k}}|^2} (\alpha_{\mathbf{j}} \cdot \hat{\mathbf{k}}) \right) \right.$$
$$\left. \frac{1}{\pi} \left(\frac{1}{2m - 2j_2 + 1} + \frac{1}{2m - 2j_2 - 2k_2 + 1} - \frac{1}{2m+1} - \frac{1}{2m - 2k_2 + 1} \right) w_{\mathbf{k}} \right\},$$

where $\mathbf{k}_m = (k_1, 2m + 1 - k_2, k_3)$, $\mathbf{k}_- = (\min\{k_1, 0\}, \min\{k_2, 0\}, \min\{k_3, 0\})$, and $\mathbf{k}_+ = (\max\{k_1, 0\}, \max\{k_2, 0\}, \max\{k_3, 0\})$.

Now we note that $f = (1,0,1)$, since $f - g = (0,1,0)$ is perpendicular (with respect to L^2-norm) to all functions in H. Therefore, using the expansion of u_n and Au_n with respect to $\{w_{\mathbf{k}}\}_{\mathbf{k}=\mathbf{n}_0}^{\mathbf{n}}$ and $B(u_n,u_n)$ with respect to $\{w_{\mathbf{k}}\}_{\mathbf{k}=2\mathbf{n}_0}^{2\mathbf{n}}$, we can write (noting that the coefficients of $w_{\mathbf{k}}$ when k_1, k_2, or k_3 are less than $-n$ or bigger than n are zero for u_n and Au_n)

$$E_n = \frac{\mathrm{d}u_n}{\mathrm{d}t} + \nu A u_n + B(u_n,u_n) - f = \sum_{\mathbf{k}=2\mathbf{n}_0}^{2\mathbf{n}} \beta_{\mathbf{k}} w_{\mathbf{k}} - (1,0,1)$$

and therefore

$$DE_n = \frac{\partial E_n}{\partial x} + \frac{\partial E_n}{\partial y} + \frac{\partial E_n}{\partial z} = 2 \sum_{\mathbf{k}=2\mathbf{n}_0}^{2\mathbf{n}} \beta_{\mathbf{k}} \left(\hat{k}_1 + \hat{k}_2 + \hat{k}_3\right) w_{\mathbf{k}}$$

and

$$\left\| \frac{\mathrm{d}u_n}{\mathrm{d}t} + \nu A u_n + B(u_n,u_n) - f \right\|_1^2 = 2L_xL_z \sum_{\mathbf{k}=2\mathbf{n}_0}^{2\mathbf{n}} \left(\beta_{1\mathbf{k}}^2 + \beta_{2\mathbf{k}}^2 + \beta_{3\mathbf{k}}^2\right) \left(\hat{k}_1 + \hat{k}_2 + \hat{k}_3\right)^2.$$

The norms of Du_n and Au_n are computed as

$$|Du_n|^2 = 2L_xL_z \sum_{\mathbf{k}=\mathbf{n}_0}^{\mathbf{n}} \left(\alpha_{1\mathbf{k}}^2 + \alpha_{2\mathbf{k}}^2 + \alpha_{3\mathbf{k}}^2\right) \left(\hat{k}_1 + \hat{k}_2 + \hat{k}_3\right)^2,$$

$$|Au_n|^2 = 2\pi^2 L_xL_z \sum_{\mathbf{k}=\mathbf{n}_0}^{\mathbf{n}} \left(\alpha_{1\mathbf{k}}^2 + \alpha_{2\mathbf{k}}^2 + \alpha_{3\mathbf{k}}^2\right) \left(\frac{k_1^2}{L_x^2} + \frac{k_2^2}{4} + \frac{k_3^2}{L_z^2}\right)^2.$$

The remaining term on the left-hand side of (6.2), $|Du_n(0) - Du_0|$, is obtained in a similar way to $|Du_n|$.

We note that for the spatial domain and the boundary values of this example, the constant k is obtained from (3.4) by letting $c_s = \sqrt{2}\,(1 + 2\max\{L_x, L_y, 1\})$, $c_p = (L_x^2 + L_z^2 + 1)^{1/2}/\pi$ as explained in Section 3, and $c_e = (\max\{L_x, L_z, 2\})^2/4\pi^2$ [11, Theorem 6.5].

8. Conclusion. We extended the results of [2] to the less regular strong solutions not considered in their paper. Unlike their results, the robustness conditions on the data that we obtained for the first- and second-order regular strong solutions in Theorems 4.1 and 4.2 depended explicitly on the viscosity coefficient in a way that as the viscosity coefficient became smaller, the conditions (4.1) and (4.2) became more restrictive which obviously is not desirable. Moreover, since this is due to the less elegant inequalities available for the trilinear form in the less regular spaces considered here, it does not seem that we can remove the viscosity coefficient from the robustness conditions.

On the other hand, the results proved here for the first-order regular strong solutions are valid in a sufficiently smooth bounded domain as well as in the absence of boundaries, while in the case of the second-order regular solutions considered also here and the more regular ones studied in the above-mentioned paper, the results are restricted to a periodic domain or the whole of $\mathbb{R}^3$. The reason is that the inequalities we need to use in these cases for $|(B(u,v),v)_m|$ when $m \geq 2$ are valid in the absence of boundaries where we know that swapping the action of Π, the orthogonal projection from L^2 onto H, and the Laplacian operator is possible.

It would be interesting to see if there exists a big enough m for which it is possible to swap the action of the Laplacian operator and Π in $D(A^{m/2})$ over a bounded domain. If such a finite m exists we can extend the robustness results for regular enough solutions to the more physically relevant bounded domains. Furthermore, for two-dimensional bounded domains, equality of the Stokes and Laplacian operators in $D(A^{m/2})$ can be used in obtaining a better bound on the attractor dimension in L^2.

TAMING THE CFL NUMBER FOR DISCONTINUOUS GALERKIN METHODS ON STRUCTURED MESHES*

T. WARBURTON† AND T. HAGSTROM‡

Abstract. The upwind discontinuous Galerkin method is an attractive method for solving time-dependent hyperbolic conservation laws. It is possible to use high-order explicit time-stepping methods and high-order spatial approximations without incurring heavy numerical linear algebra overheads. However, the Courant–Friedrichs–Lewy (CFL) condition for these methods depends on the polynomial order used, and there is a somewhat excessive cost for using very high order spatial approximation. We discuss the impact of a covolume mesh based filter on the CFL number for these methods and present an algorithm which has a CFL number independent of the spatial order of approximation. We present computational results for the advection equation and the wave equation on one-dimensional meshes using up to tenth order in space and time.

1. Introduction.

A significant numerical hurdle for wave propagation is the generic need for preservation of phase and amplitude information as rapidly varying wave profiles travel over long distances. The upwind discontinuous Galerkin (DG) method has emerged as a competitive numerical modeling technique for achieving this goal. This method was originally proposed for neutron transport by Reed and Hill [27] and analyzed by many, including Lesaint and Raviart [24], Johnson and Pitkäranta [19], Richter [28], and Peterson [25]. The DG method was revisited for time-dependent conservation laws in a sequence of papers by Cockburn, Shu, et al. (see [9, 8, 7, 11]). The method is particularly attractive for wave propagation because of the ability to use high-order, piecewise polynomial approximations for the solution, which provides an efficient mechanism to manage phase and dissipation errors (see, for example, Ainsworth [1]). The method has been shown to be effective on quadrilateral meshes by Kopriva, Woodruff, and Hussaini [20, 21], on unstructured meshes of triangles with high-order approximation for Maxwell's equations by Warburton [31] and Hesthaven and Warburton [15, 16], and on overlapping triangular meshes by Chung and Engquist [5]. Furthermore, this method automatically controls spurious solutions through selective dissipation of nonphysical solutions (see, for example, Hesthaven and Warburton [17] and Warburton and Embree [32]). In addition, the structure of the numerical method results in computational algorithms which scale efficiently for large scale SIMD computations (see Biswas, Devine, and Flaherty [2]).

The positive aspects of the upwind DG method are accompanied by a particular sour note. As the order of the polynomial approximation n is increased on a fixed mesh of elements, with mesh size h, the spatial differential operator discretized with

the DG method typically has a spectral radius which grows as n^2/h. This is in contrast to typical finite difference discretized spatial differential operators which have spectral radii which grow as n/h. This translates into the reality that the DG method requires smaller time steps, dt, to scale its spatial derivative operator's spectrum into the stability region of a standard Runge–Kutta (RK) time-stepping method. Thus, the advantages of the DG method are tempered by the extra number of time steps compared with finite difference methods.

In this paper we present a simple modification to the upwind DG method which reduces the spectral radius of a modified version of the discrete DG derivative operator to a more competitive n/h. By way of motivation we note the Hermite–Taylor method analyzed by Goodrich, Hagstrom, and Lorenz [13]. There it is shown that a combination of staggered Hermite interpolation and Taylor expansion based time stepping leads to a method with degree-independent time-step stability constraints. Similarly, we find that for the case of an autonomous system of linear partial differential equations, when combining the modified upwind DG spatial discretization with an $(n+1)$-stage, explicit, RK time-stepping method it is possible to choose a stable time step size, dt, independent of the spatial polynomial order n. In the more general case of partial differential equations with nonlinear terms or time-dependent forcing, we can expect a factor proportional to n increase in the allowable time step size. In the conclusion we discuss the limitations of this approach.

2. Formulation. In this section we describe a standard upwind DG formulation for the one-dimensional, unidirectional, advection equation. We then describe how to introduce a covolume-based filter which allows for larger steps when time stepping the discretized equations.

2.1. Notation. The spatial interval $\Omega = [a, b]$ is divided into a primal grid of K^1 elements, $T_h^1 = \bigcup_{k=1}^{k=K^1} I^{1,k}$, with $I^{1,k} = \left[x^{1,k}, x^{1,k+1}\right]$. We associate the following broken Sobolev spaces with the primal grid:

$$H^m\left(\Omega, T_h^1\right) = \left\{q \in L^2(\Omega) : q|_{I^{1,k}} \in H^m\left(I^{1,k}\right) \text{ for } k = 1, \ldots, K^1\right\}, \tag{2.1}$$

where

$$H^m\left(I^{1,k}\right) = \left\{q \in L^2\left(I^{1,k}\right) : \sum_{\alpha=0}^{\alpha=m} \left\| \frac{\partial^\alpha q}{\partial x^\alpha} \right\|^2_{L^2(I^{1,k})} < \infty \right\}. \tag{2.2}$$

In each element the solution will be represented by polynomials of maximum degree n. The numerical solution on the primal grid is chosen from

$$V^{1,h} = \bigcup_{k=1}^{k=K^1} P^n\left(I^{1,k}\right), \tag{2.3}$$

with no a priori assumption about the continuity of the solution. We also require a covolume mesh whose elements are formed with endpoints in the interior of the primal grid. For definiteness we consider here the special case where these are chosen to be the midpoints of the subintervals of the primal grid, but as seen below such a precise choice is unnecessary. The covolume mesh then consists of K^2 elements, $\left\{I^{2,k}\right\}_{k=1}^{k=K^2}$, with elements $I^{2,k} = [\frac{x^{1,k-1}+x^{1,k}}{2}, \frac{x^{1,k}+x^{1,k+1}}{2}]$ for elements not on the boundary. We will discuss how the covolume mesh is formed at the boundary in section 7.

2.2. Upwind DG derivative operator for advection. We are interested in solving advection and wave type phenomena and consequently consider the prototype one-way advection equation

$$\frac{\partial u}{\partial t} + \frac{\partial u}{\partial x} = 0 \quad \text{for } (x,t) \in [0,2) \times [0,1]\,, \tag{2.4}$$

with periodic boundary conditions $u(2,t) = u(0,t)$.

In this paper we consider the upwind DG discretization of this equation, because of its weighted residual formulation which has guaranteed stability, a block diagonal mass matrix, and potentially high-order accuracy. The upwind DG variational statement involves finding $u \in V^{1,h}$ such that

$$\left(\phi, \frac{\partial u}{\partial t}\right)_{I^{1,k}} + \left(\phi, \frac{\partial u}{\partial x}\right)_{I^{1,k}} + \left(\phi, \frac{n_x - |n_x|}{2}\,[u]\right)_{\partial I^{1,k}} = 0 \tag{2.5}$$

for all $\phi \in V^{1,h}$ and $k = 1, \ldots, K^1$, where the notation $[u]$ denotes the trace of u from inside element k subtracted from the trace of u taken from within the element sharing a boundary vertex with element k. In familiar notation $[u] = u^+ - u^-$, where u^- is the internal trace of u in element k and u^+ is the external trace. Here n_x is the outward facing normal at the element boundary, and the boundary inner product is defined by

$$(f,g)_{\partial I^{1,k}} = f\left(x^{1,k}\right) g\left(x^{1,k}\right) + f\left(x^{1,k-1}\right) g\left(x^{1,k-1}\right). \tag{2.6}$$

We introduce a slightly more general notation which allows us to choose between an upwind boundary treatment and a central treatment via the operator D^1_α, where $\alpha \in [0,1]$ is a parameter which interpolates between each type of treatment. Formally D^1_α is the operator which satisfies for any $u \in V^{1,h}$

$$\left(\phi, D^1_\alpha u\right)_{I^{1,k}} = \left(\phi, \frac{\partial u}{\partial x}\right)_{I^{1,k}} + \left(\phi, \frac{n_x - \alpha|n_x|}{2}\,[u]\right)_{\partial I^{1,k}} \tag{2.7}$$

for $k = 1, \ldots, K^1$ and $\phi \in V^{1,h}$. Now we succinctly represent the upwind DG variational statement by

$$\left(\phi, \frac{\partial u}{\partial t}\right)_{I^{1,k}} + \left(\phi, D^1_\alpha u\right)_{I^{1,k}} = 0. \tag{2.8}$$

This notation highlights the significant fact that despite its apparent complexity, the DG operator is actually just the result of encoding a distributional derivative to account for boundary conditions introduced at the endpoints of each element.

After discretization of the $V^{1,h}$ variational space of functions defined with respect to the primal grid, the advection equation is reduced from a partial differential equation to an ordinary differential equation:

$$\frac{d\mathbf{u}^1}{dt} = -\mathbf{D}^1_\alpha \mathbf{u}^1, \tag{2.9}$$

where $\mathbf{D}^1_\alpha$ is the upwind DG derivative matrix defined on the primal grid by

$$\left(\mathbf{D}^1_\alpha\right)_{ij} = \sum_k \left(\mathbf{M}^{1,k}\right)^{-1}_{in} \left(\left(\phi_n, \frac{\partial \phi_j}{\partial x}\right)_{I^{1,k}} + \left(\phi_n, \frac{n_x - \alpha|n_x|}{2}\,[\phi_j]\right)_{\partial I^{1,k}}\right), \tag{2.10}$$

where $\mathbf{M}^{1,k}_{nm} = (\phi_n, \phi_m)_{I^{1,k}}$. It is useful to view the $\mathbf{D}^1_\alpha$ matrix as representing a discrete distributional derivative operator, and thus later on it will be transparent that modifying this operator by filtering matrices is not a complicated process. Once we establish the method, then we will appeal to the variational statement to establish stability, but in terms of implementation it is most instructive to think in terms of the action of matrices on the solution.

We can immediately establish L^2 stability with the following result:

$$\frac{1}{2}\frac{d}{dt}\sum_k \left(\mathbf{u}^1\right)^t \mathbf{M}^{1,k}\mathbf{u}^1 = -\frac{1}{2}\sum_k \left(\alpha|n_x|\left[u^1\right],\left[u^1\right]\right)_{\partial I^{1,k}} \leq 0, \tag{2.11}$$

which states succinctly that the choice of upwinding the solution at the endpoints of the elements before taking the DG distributional derivatives acts to reduce the L^2 energy of the numerical solution whenever there is a jump in the solution between elements.

We next introduce the discretized form of the transfer operators. These are the matrices $\mathbf{\Pi}^2$, $\mathbf{\Pi}^1$ defined by

$$\left(\phi^2_i, \phi^2_n\right)_{T^2_h} \mathbf{\Pi}^2_{nj} = \sum_k \left(\left(\phi^2_i, \phi^1_j\right)_{I^{1,k}\cap I^{2,k}} + \left(\phi^2_i, \phi^1_j\right)_{I^{1,k-1}\cap I^{2,k}}\right), \tag{2.12}$$

$$\left(\phi^1_i, \phi^1_n\right)_{T^1_h} \mathbf{\Pi}^1_{nj} = \sum_k \left(\left(\phi^1_i, \phi^2_j\right)_{I^{1,k}\cap I^{2,k}} + \left(\phi^1_i, \phi^2_j\right)_{I^{1,k+1}\cap I^{2,k}}\right) \tag{2.13}$$

for all basis members $\left\{\phi^2_i\right\}_{i=1}^{i=N_p}$ on the K covolume mesh elements and all basis members $\left\{\phi^1_i\right\}_{i=1}^{i=N_p}$ on the K primal grid elements. It is immediately observed that these transfer matrices are related by

$$\mathbf{M}^2\mathbf{\Pi}^2 = \left(\mathbf{M}^1\mathbf{\Pi}^1\right)^t. \tag{2.14}$$

2.3. Modified upwind DG method. We now have sufficient notation to propose a new type of DG method which we write in pseudocode.

1. Evaluate initial condition on primal grid.
2. Start time stepping, with an s-stage RK scheme.
3. For each RK stage do the following:
   (a) L^2 project the solution from primal grid to covolume mesh.
   (b) Compute DG distributional derivative on covolume mesh, using upwind fluxes suitable for the advection equation.
   (c) L^2 project the DG distributional derivative to original grid.
   (d) Update solution for RK stage using L^2 projected DG distributional derivative.
4. Continue time stepping until final time reached.

We have added two projection stages. The first stage is designed to project the original piecewise polynomial solution on the primal grid onto the covolume mesh. The purpose of this projection is to diminish the maximum gradients achieved on the covolume mesh elements. We then evaluate the DG distributional gradient on the covolume mesh and project it back on to the primal grid, and again our aim is to reduce the potential for large near boundary gradients.

In matrix notation we are solving the following ordinary differential equation:

$$\frac{d\mathbf{u}}{dt} = -\mathbf{\Pi}^1\mathbf{D}^2_\alpha\mathbf{\Pi}^2\mathbf{u}, \tag{2.15}$$

where the DG derivative matrix $\mathbf{D}_\alpha^2$ is defined on the covolume mesh. We can also relax the stabilization by averaging the stabilized DG derivative with the unstabilized DG derivative:

$$\frac{d\mathbf{u}}{dt} = -\beta \mathbf{\Pi}^1 \mathbf{D}_\alpha^2 \mathbf{\Pi}^2 \mathbf{u} - (1-\beta)\mathbf{D}_\alpha^1 \mathbf{u}, \tag{2.16}$$

where $\beta = 1 - O\left(\frac{1}{n}\right)$. It is straightforward to perform the L^2 stability analysis for this modified DG scheme, with the L^2 energy equation given by

$$\begin{aligned} \frac{d}{dt}\left\|u^1\right\|^2_{L^2(T_h^1)} \leq & -\frac{\beta}{2}\sum_k \left(\alpha|n_x|\left[\Pi^2 u^1\right],\left[\Pi^2 u^1\right]\right)_{\partial I^{2,k}} \\ & -\frac{(1-\beta)}{2}\sum_k \alpha\left(|n_x|\left[u^1\right],\left[u^1\right]\right)_{\partial I^{1,k}}. \end{aligned} \tag{2.17}$$

Thus the numerical energy decreases if there are jumps in u^1 between elements on the primal grid and if there are jumps in $\Pi^2 u^1$ between elements on the covolume mesh. (We will subsequently observe that the filtering process creates an intermediate field with much reduced jumps.)

We discuss further minor variations on this idea in section 6 to address the computational overhead of the additional operations required to compute the filtered solution.

2.4. Motivation for using a covolume mesh based filter. The traditional DG discretization of a first-order distributional derivative has a maximum eigenvalue which asymptotically grows as $O(\frac{n^2}{h})$ when the order of polynomials used, n, is increased or h is decreased (see, e.g., [14, 12]). In the particular case of *hp* type methods, where it is considered desirable to use a high-order polynomial approximation when possible, the derivative operators become artificially stiff. This artificial stiffness is the result of the nature of the piecewise polynomial discretization spaces used. In this section we detail the causes behind the scaling and present a revealing observation that we use to build the modified DG methods.

We first recall the following polynomial inequalities (see, for example, Borwein and Erdélyi [3] for details and generalizations).

THEOREM 2.1 (Bernstein's inequality). *The inequality*

$$\left|\frac{dq}{dx}(x)\right| \leq \frac{n}{\sqrt{1-x^2}}\left\|q\right\|_\infty, \quad -1 < x < 1,$$

holds for every $q \in P^n([-1,1])$.

THEOREM 2.2 (Markov's inequality). *The inequality*

$$\left\|\frac{dq}{dx}\right\|_\infty \leq n^2 \left\|q\right\|_\infty$$

holds for every $q \in P^n([-1,1])$.

We put these together and observe that

$$\left|\frac{dq}{dx}(x)\right| \leq \min\left(n^2, \frac{n}{\sqrt{1-x^2}}\right)\left\|q\right\|_\infty, \quad -1 \leq x \leq 1, \tag{2.18}$$

and since these estimates are sharp, the gradients of normalized nth-order polynomials may be up to $O(\frac{n^2}{h})$ at the near boundary portion of the element and $O\left(\frac{n}{h}\right)$

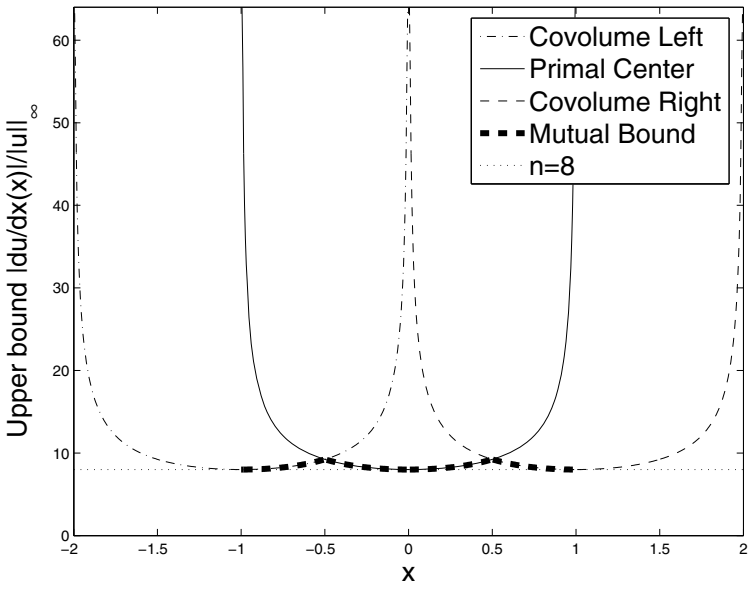

FIG. 2.1. *Combining upper bounds on the relative maximal gradient of polynomials in P^8 for primal and covolume mesh yields a more uniform bound.*

near the center of the element. These inequalities explain the difference between the Courant–Friedrichs–Lewy (CFL) conditions of a typical finite difference method, where a moving interpolation stencil is used and slope information is generally extracted at element centers, and the DG method, where slope information is used throughout.

In this paper we will show how it is possible to achieve CFL numbers within a modified upwind DG method comparable with typical finite difference discretizations, even when high-order polynomial approximations are used. In Figure 2.1, we plot the upper bound (2.18) for three biunit one-dimensional elements which each overlap by half their lengths with their neighbors. This upper bound on the scaled gradient of polynomials grows dramatically near each of the element boundaries. However, we have also highlighted the minimum upper bound of all three in the central element, and this curve is almost constant throughout this element. This observation yields the possibility that we may be able to overcome the artificial stiffness induced in the DG scheme by the nonuniform gradients of polynomial approximations to fields. In the next sections we prove that the covolume derivative operator, $\mathbf{\Pi}^1\mathbf{D}_\alpha^2\mathbf{\Pi}^2$, motivated by these inequalities, in fact satisfies the desired bound.

It is also necessary to study the properties of the projection-based filter that is implicit in our formulation. We note that these projection operators are both contractions, i.e., $\|\Pi^2 u\| \leq \|u\|$ and $\|\Pi^1 u\| \leq \|u\|$. Furthermore, we consider the action of the operator defined by $\Pi^2\Pi^1$. This operator is a filter, and in subsequent sections we establish its properties by deriving bounds on $\|u - \Pi^2\Pi^1 u\|$.

It is instructive to see the consequence of projecting the polynomial lift of the Dirac delta used in the distributional derivative at the center of the DG formulation from the primal grid to the covolume mesh and back again. In Figure 2.2, we show the $n = 8$ polynomial lift of the Dirac delta before and after being filtered by the operator $\beta\Pi^1\Pi^2 + (1 - \beta)$ with $\beta = 1 - \frac{2}{n+1}$ used as a relaxation parameter for the

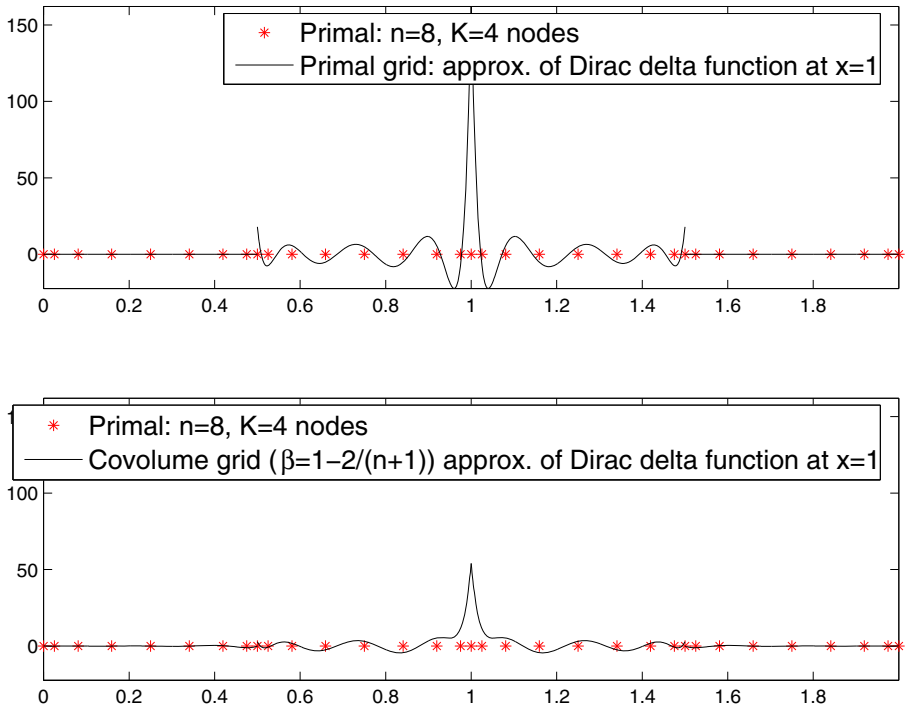

FIG. 2.2. *The polynomial approximation of the Dirac delta used to lift jump data at element boundaries into their interior for* $n = 8$. *Top: without filtering. Bottom: with filtering* $(\beta = 1 - (2/(n+1))$.

amount of filtering to be applied. It is clear that this type of filtering will reduce the contribution to the DG gradient from the jump terms besides de-emphasizing gradients at and near the element boundaries. Taken together, these effects of the filtering are our motivation for using the filtering process to reduce the artificially stiff DG operators and hopefully increase the allowable time step size.

3. Bounds on the covolume derivative operator. Here we prove our main result on the n-dependence of the covolume derivative operator. We work in the framework described above, periodically extending functions beyond $[0, 2)$.

THEOREM 3.1. *Let* q *be a degree* n *piecewise polynomial function relative to the primal grid,* $q \in V^{1,h}$, *and set, for* $\alpha \in [0, 1]$,

$$\mathcal{D}_{S,\alpha} q = \Pi^1 \mathbf{D}^2_\alpha \Pi^2 q. \tag{3.1}$$

Then there exists a universal constant, C, *such that*

$$\|\mathcal{D}_{S,\alpha} q\|_{L^2(\Omega)} \leq C \frac{n}{h} \|q\|_{L^2(\Omega)}. \tag{3.2}$$

Before proving Theorem 3.1 we note that as an immediate corollary we have

$$\| \left(\beta \mathcal{D}_{S,\alpha} + (1-\beta)\mathbf{D}^1_\alpha\right) q\|_{L^2(\Omega)} \leq C \left(\beta \frac{n}{h} + (1-\beta)\frac{n^2}{h}\right) \|q\|_{L^2(\Omega)}, \tag{3.3}$$

so that the desired bound for the matrix appearing in (2.16) is obtained if we take $\beta = 1 - O\left(\frac{1}{n}\right)$.

3.1. Proof of Theorem 3.1. We proceed by proving a number of lemmas. We begin with an L^2 version of Bernstein's inequality.

LEMMA 3.2 (L^2 version of Bernstein's inequality). *The inequality*

$$\left\| \frac{dq}{dx} \right\|_{L^2([-a,a])} \leq C_a n \left\| q \right\|_{L^2([-1,1])}, \tag{3.4}$$

where $C_a = \frac{\sqrt{3}+a}{1-a^2}$, *holds for every* $q \in P^n([-1,1])$.

Proof. Without loss of generality we assume $\left\| q \right\|_{L^2([-1,1])} = 1$. We next represent q using Legendre polynomials:

$$q(x) = \sum_{j=0}^{j=n} c_j P_j(x), \tag{3.5}$$

where we are assuming the standard definition of P_j (see, for example, Sansone [29, Chapter III]). With this normalization, the Legendre polynomials satisfy the following recurrence relationship:

$$\frac{1}{n}\frac{dP_j}{dx}(x) = \frac{1}{1-x^2}P_{j-1}(x) - \frac{x}{1-x^2}P_j(x), \quad j \geq 1. \tag{3.6}$$

Thus

$$\frac{1}{n}\frac{dq}{dx}(x) = \frac{1}{1-x^2}w_1(x) - \frac{x}{1-x^2}w_2(x), \tag{3.7}$$

where

$$w_1(x) = \sum_{j=1}^{j=n} c_j P_{j-1}(x), \quad w_2(x) = \sum_{j=1}^{j=n} c_j P_j(x). \tag{3.8}$$

We then use the triangle inequality and the fact that $(2j+1)/(2j-1) \leq 3$ for $j \geq 1$:

$$\begin{aligned}
\frac{1}{n}\left\| \frac{dq}{dx} \right\|_{L^2([-a,a])} &\leq \max_{|x|\leq a}\left(\frac{1}{1-x^2}\right)\left\| w_1 \right\|_{L^2([-a,a])} + \max_{|x|\leq a}\left(\frac{|x|}{1-x^2}\right)\left\| w_2 \right\|_{L^2([-a,a])} \\
&\leq \frac{1}{1-a^2}\left\| w_1 \right\|_{L^2([-1,1])} + \frac{a}{1-a^2}\left\| w_2 \right\|_{L^2([-1,1])} \\
&\leq \frac{1}{1-a^2}\left(\sum_{j=1}^{j=n}\left(j-\frac{1}{2}\right)^{-1}c_j^2\right)^{\frac{1}{2}} + \frac{a}{1-a^2}\left(\sum_{j=1}^{j=n}\left(j+\frac{1}{2}\right)^{-1}c_j^2\right)^{\frac{1}{2}} \\
&\leq \frac{\sqrt{3}+a}{1-a^2}.
\end{aligned}$$

Noting the normalization of q completes the proof. ∎

Just as with Bernstein's lemma we see the upper bound degenerates when considering the whole interval. We have made no effort to optimize the coefficient C_a, and numerical computations of the bound for $1 \leq n \leq 512$ with $a = 1/2$ reveal that in this case the constant is only suboptimal by approximately a factor of 2.43.

Later on we will also require a polynomial inverse inequality, which is an L^2 analogue of Markov's theorem.

LEMMA 3.3 (inverse inequality). *Assume* $u \in P^n\left(I^{1,k}\right)$*; then*

$$\left\|\frac{\partial u}{\partial x}\right\|_{L^2([-1,1])} \leq \sqrt{3}n^2 \left\|u\right\|_{L^2([-1,1])}.$$

Proof. See, for example, Ciarlet [6] or Schwab [30]. □

In addition to Lemma 3.2 we will need bounds on the pointwise values of degree n polynomials. Precisely we prove the following lemma.

LEMMA 3.4. *The inequality*

$$|q(a)| \leq M_a \sqrt{n} \left\|q\right\|_{L^2([-1,1])}, \tag{3.9}$$

where $M_a = \frac{12}{\sqrt{\pi}}(1-a^2)^{-1/4}$*, holds for every* $q \in P^n([-1,1])$ *with* $n \geq 1$.

(We note that if we apply the result on an interval of width h, the right-hand side scales like $h^{-\frac{1}{2}}$.)

Proof. We again employ the Legendre expansion (3.5) and recall Stieltjes' bound [29, Section III.10]:

$$|P_j(a)| \leq 4\sqrt{\frac{2}{\pi}}(1-a^2)^{-1/4} j^{-1/2}, \tag{3.10}$$

which can obviously be improved by setting the right-hand side to 1 if $j = 0$. We then have using the Cauchy–Schwarz inequality

$$\begin{aligned}
|q(a)| &\leq \sum_{j=0}^{n} |c_j||P_j(a)| \\
&\leq 6\sqrt{\frac{2}{\pi}}(1-a^2)^{-1/4} \sum_{j=0}^{n} \left(j+\frac{1}{2}\right)^{-1/2} |c_j| \\
&\leq 6\sqrt{\frac{2}{\pi}}(1-a^2)^{-1/4} \sqrt{n+1} \left(\sum_{j=0}^{n} \left(j+\frac{1}{2}\right)^{-1} c_j^2\right)^{1/2} \\
&\leq M_a \sqrt{n} \left\|q\right\|_{L^2([-1,1])}. \qquad \square
\end{aligned}$$

Finally, we will make use of the following explicit expression for the lift polynomial, $L(x)$.

LEMMA 3.5. *The polynomial*

$$\begin{aligned}
L^{(k,2)}(x) = (-1)^n \frac{d}{dx}\left(\left(\frac{2(x-x^{1,k})-h}{2h}\right) P_n\left(\frac{2}{h}(x-x^{1,k})\right)\right) \\
+ (-1)^n \frac{4n+1}{2h} P_n\left(\frac{2}{h}(x-x^{1,k})\right)
\end{aligned} \tag{3.11}$$

satisfies

$$\int_{I^{2,k}} L^{(k,2)}(x) Q(x) dx = Q\left(x^{1,k} - \frac{h}{2}\right) \tag{3.12}$$

for all polynomials, Q*, of degree* n*.*

Proof. With the change of variables $z = \frac{2}{h}(x - x^{1,k})$ the statement becomes

$$\int_{-1}^{1} \tilde{L}(z)\tilde{Q}(z)dz = \tilde{Q}(-1) \tag{3.13}$$

for all degree-n polynomials $\tilde{Q}(z)$, where

$$\tilde{L}(z) = (-1)^n \left(\frac{d}{dz} \left(\left(\frac{z-1}{2} \right) P_n(z) \right) + \frac{4n+1}{4} P_n(z) \right). \tag{3.14}$$

To prove it we note that using integration by parts the statement is equivalent to

$$\int_{-1}^{1} P_n(z) \left(\frac{1-z}{2} \frac{d\tilde{Q}}{dz}(z) + \frac{4n+1}{4} \tilde{Q}(z) \right) dz = 0. \tag{3.15}$$

Now we can write $\tilde{Q}(z) = R(z) + \gamma P_n(z)$, where the degree of R is $n-1$. By the orthogonality properties of P_n the integrals involving R and $\frac{dR}{dz}$ are zero. Then integrating by parts once more

$$\begin{aligned} \int_{-1}^{1} \frac{1-z}{2} P_n(z) P_n'(z) dz &= -\frac{1}{2} + \frac{1}{4} \int_{-1}^{1} P_n^2(z) dz \\ &= -\frac{4n+1}{4(2n+1)} \\ &= -\frac{4n+1}{4} \int_{-1}^{1} P_n^2(z) dz. \end{aligned}$$

This completes the proof. ∎

With these results we can prove Theorem 3.1. As the proof involves separate estimates of a number of terms we will avoid keeping close track of the constants. Thus C will be used to denote any absolute constant independent of n and h.

Proof of Theorem 3.1. As $\mathcal{D}_S$ is obviously linear we can consider the special case of q nonzero only on $I^{1,k}$ and denote by q_k the degree n polynomial which is the restriction of q to $I^{1,k}$. Now $\tilde{q} = \Pi_n^2 q$ is supported on $I^{2,k} \cup I^{2,k+1}$, and let $\tilde{q}_j$ denote its restriction to $I^{2,j}$. Last, let $Q = \Pi_n^1 \mathbf{D}^2 \tilde{q}$. We will estimate Q in two parts: Q_d, the contribution of the derivatives, $\tilde{q}_j'$, and Q_l, the contribution of the lifts.

Let $Q_{d,j}$ denote the restriction of Q_d to $I^{1,j}$. Now $Q_{d,j}$ is nonzero only for $j = k$, $k \pm 1$. We begin by estimating the contribution of $\tilde{q}_k'$ to $Q_{d,k}$, which we label $Q_{d,k,k}$. Using the properties of L^2 projection we have

$$\begin{aligned} \int_{I^{1,k}} Q_{d,k,k}^2(x) dx &= \int_{x^{1,k}}^{\frac{x^{1,k}+x^{1,k+1}}{2}} Q_{d,k,k}(x) \tilde{q}_k'(x) dx \\ &= \int_{x^{1,k}}^{x^{1,k}+\frac{h}{4}} Q_{d,k,k}(x) \tilde{q}_k'(x) dx - \int_{x^{1,k}+\frac{h}{4}}^{\frac{x^{1,k}+x^{1,k+1}}{2}} Q_{d,k,k}'(x) \tilde{q}_k(x) dx \\ &\quad + Q_{d,k,k} \left(\frac{x^{1,k}+x^{1,k+1}}{2} \right) \cdot \tilde{q}_k \left(\frac{x^{1,k}+x^{1,k+1}}{2} \right) \\ &\quad - Q_{d,k,k} \left(x^{1,k} + \frac{h}{4} \right) \cdot \tilde{q}_k \left(x^{1,k} + \frac{h}{4} \right). \end{aligned}$$

Proceeding to estimate the four terms on the right-hand side above, we see that the first two can be handled by means of Lemma 3.2. That is, each of the derivative terms is integrated in the strict interior of the domain over which the norm of the polynomial can be bounded. Thus, noting that $\tilde{q}_k$ was computed by an L^2 projection and employing the Cauchy–Schwarz inequality we conclude that these terms are bounded by

$$\text{Term}_1 + \text{Term}_2 \leq C\frac{n}{h}\|Q_{k,k}\|_{L^2(I^{1,k})}\|q_k\|_{L^2(I^{1,k})}. \tag{3.16}$$

Similarly, favorable bounds on the fourth term follow from Lemma 3.4 and the fact that $\frac{x^{1,k}+x^{1,k+1}}{4}$ lies in the interior of both $I^{1,k}$ and $I^{2,k}$. Thus

$$\text{Term}_4 \leq C\frac{n}{h}\|Q_{d,k,k}\|_{L^2(I^{1,k})}\|q_k\|_{L^2(I^{1,k})}. \tag{3.17}$$

The third term is more difficult to estimate, as it involves the evaluation of $\tilde{q}_k$ on the boundary of $I^{2,k}$. (The bound $|Q_{d,k,k}(\frac{x^{1,k}+x^{1,k+1}}{2})| \leq C\sqrt{\frac{n}{h}}\|Q_{d,k,k}\|_{L^2(I^{1,k})}$ is a direct consequence of Lemma 3.4.) To complete the argument we rely on the fact that $\tilde{q}_k$ was computed by projecting q_k, which itself is well behaved at the midpoint of $I^{1,k}$. By Christoffel's formula [29, Section III.5] we have

$$\tilde{q}_k\left(\frac{x^{1,k}+x^{1,k+1}}{2}\right) = \int_0^1 \left(P'_{n+1}(y) + P'_n(y)\right) q_k\left(x^{1,k} + \frac{h}{2}y\right) dy.$$

We again break this integral into two pieces and integrate by parts:

$$\begin{aligned}\tilde{q}_k\left(\frac{x^{1,k}+x^{1,k+1}}{2}\right) = &\int_0^{\frac{1}{2}} \left(P'_{n+1}(y) + P'_n(y)\right) q_k\left(x^{1,k} + \frac{h}{2}y\right) dy \\ &- \frac{h}{2}\int_{\frac{1}{2}}^1 \left(P_{n+1}(y) + P_n(y)\right) q'_k\left(x^{1,k} + \frac{h}{2}y\right) dy \\ &+ 2q_k\left(\frac{x^{1,k}+x^{1,k+1}}{2}\right) \\ &- \left(P_{n+1}\left(\frac{1}{2}\right) + P_n\left(\frac{1}{2}\right)\right) q_k\left(x^{1,k} + \frac{h}{4}\right).\end{aligned}$$

Using Lemma 3.2 and the normalization of the Legendre polynomials we bound the first two terms:

$$\text{Term}'_1 + \text{Term}'_2 \leq C\sqrt{\frac{n}{h}}\|q_k\|_{L^2(I^{1,k})}. \tag{3.18}$$

Similarly, by Stieltjes' bound and Lemma 3.4 we bound the second two terms:

$$\text{Term}'_3 + \text{Term}'_4 \leq C\sqrt{\frac{n}{h}}\|q_k\|_{L^2(I^{1,k})}. \tag{3.19}$$

Combining (3.18) and (3.19) we have

$$\text{Term}_3 \leq C\frac{n}{h}\|Q_{d,k,k}\|_{L^2(I^{1,k})}\|q_k\|_{L^2(I^{1,k})}, \tag{3.20}$$

which combined with (3.16) and (3.17) yields

$$\|Q_{d,k,k}\|_{L^2(I^{1,k})} \leq C\frac{n}{h}\|q_k\|_{L^2(I^{1,k})}, \tag{3.21}$$

with an analogous bound obviously valid for the contribution of $\tilde{q}'_{k+1}$.

Finally, we must estimate $\|Q_{d,k\pm1}\|_{L^2(I^{1,k\pm1})}$. These follow along the same lines as the estimates above. For example,

$$\begin{aligned}\int_{I^{1,k+1}} Q^2_{d,k+1}(x)dx &= \int_{x^{1,k+1}}^{\frac{x^{1,k+1}+x^{1,k+2}}{2}} Q_{d,k+1}(x)\tilde{q}'_{k+1}(x)dx \\ &= \int_{x^{1,k+1}}^{x^{1,k+1}+\frac{h}{4}} Q_{d,k+1}(x)\tilde{q}'_{k+1}(x)dx \\ &\quad - \int_{x^{1,k+1}+\frac{h}{4}}^{\frac{x^{1,k+1}+x^{1,k+2}}{2}} Q'_{d,k+1}(x)\tilde{q}_{k+1}(x)dx \\ &\quad + Q_{d,k+1}\left(\frac{x^{1,k+1}+x^{1,k+2}}{2}\right)\cdot\tilde{q}_{k+1}\left(\frac{x^{1,k+1}+x^{1,k+2}}{2}\right) \\ &\quad - Q_{d,k+1}\left(x^{1,k+1}+\frac{h}{4}\right)\cdot\tilde{q}_{k+1}\left(x^{1,k+1}+\frac{h}{4}\right).\end{aligned}$$

Estimates of the first, second, and fourth terms are exactly analogous to (3.16) and (3.17). For the third term we now still have $|Q_{d,k+1}(\frac{x^{1,k+1}+x^{1,k+2}}{2})| \le C\sqrt{\frac{n}{h}}$ $\|Q_{d,k+1}\|_{L^2(I^{1,k+1})}$ by Lemma 3.4. In this case Christoffel's formula yields

$$\begin{aligned}\tilde{q}_{k+1}\left(\frac{x^{1,k+1}+x^{1,k+2}}{2}\right) &= \int_{-1}^{0}\left(P'_{n+1}(y)+P'_n(y)\right)q_k\left(x^{1,k+1}+\frac{h}{2}y\right)dy \\ &= \int_{-\frac{1}{2}}^{0}\left(P'_{n+1}(y)+P'_n(y)\right)q_k\left(x^{1,k+1}+\frac{h}{2}y\right)dy \\ &\quad - \frac{h}{2}\int_{-1}^{-\frac{1}{2}}\left(P_{n+1}(y)+P_n(y)\right)q'_k\left(x^{1,k+1}+\frac{h}{2}y\right)dy \\ &\quad + \left(P_{n+1}\left(-\frac{1}{2}\right)+P_n\left(-\frac{1}{2}\right)\right)q_k\left(x^{1,k+1}-\frac{h}{4}\right).\end{aligned}$$

Again all of these terms can be estimated as above. With the analogous estimate for $Q_{d,k-1}$ we finally conclude that

$$\sum_{j=k-1}^{j=k+1}\|Q_{d,j}\|^2_{L^2(I^{1,k-1})} \le C^2\frac{n^2}{h^2}\|q_k\|^2_{L^2(I^{1,k})}. \tag{3.22}$$

Summing (3.22) over k and taking the square root shows that the contribution of Q_d satisfies the desired inequality.

We now consider Q_l. We note first that the jumps themselves are bounded by $C\sqrt{\frac{n}{h}}\|q_k\|_{L^2(I^{1,k})}$ following (3.18) and (3.19). Thus we need only estimate projections of the lift polynomials, $L^{(k,2)}(x)$. Now the undifferentiated (second) term in (3.11) has L^2 norm $O(\sqrt{\frac{n}{h}})$, and thus so does its projection. The projection of the differentiated term is then estimated in precisely the same method as the derivatives above. In particular, we estimate the projection of the derivative term of $L^{(k,2)}$ on $I^{(1,k)}$ and $I^{(1,k+1)}$, which repeating the arguments given above yield bounds of the form

$$O\left(\frac{n}{h}\right)\|P_n\left(\frac{2}{h}(x-x^{1,k})\right)\|_{I^{2,k}} + O\left(\sqrt{\frac{n}{h}}\right) = O\left(\sqrt{\frac{n}{h}}\right). \tag{3.23}$$

Therefore the contributions of the lift terms are also bounded by $C\frac{n}{h}\|q_k\|_{L^2(I^{1,k})}$, completing the proof of the theorem. ∎

3.2. Implications for time stepping. In the numerical experiments which follow we employ an nth-order RK–Taylor method suitable for linear autonomous systems such as Maxwell's equations in piecewise uniform media. We find experimentally that with this time-stepping procedure we can use a time step independent of n. However, we as yet lack a complete proof of this fact, which would require a detailed analysis of the stability regions of the RK–Taylor methods. Instead we state more general results which hold for a large class of standard RK methods applicable to a less restrictive class of systems.

Consider now the symmetric-hyperbolic system with smooth, uniformly bounded, 2-periodic coefficients, initial data, and forcing:

$$\frac{\partial u}{\partial t} = \frac{\partial}{\partial x}\left(A(x,t)u\right) + B(x,t)u + F(x,t), \quad u(x,0) = u_0(x). \tag{3.24}$$

We recall the results of Kreiss and Wu [23]. An RK method is called locally stable if there exists $R > 0$ such that the open half circle $\{z||z| < R, \Re z < 0\}$ is contained within its stability domain. Note that the standard third- and fourth-order RK methods as well as certain higher-order Dormand–Prince pairs are locally stable [22]. We then have the following theorem:

THEOREM 3.6. *Semidiscretize* (3.24) *on* $V^{1,h}$ *using the covolume differentiation operator* $\mathcal{D}_{S,\alpha}$ *and discretize in time using a locally stable RK method. Then there exists a constant* C *independent of* h *and* n *such that the fully discrete method is stable for time steps,* dt*, satisfying*

$$dt \le C\frac{h}{n}. \tag{3.25}$$

Proof. The result is a direct consequence of [23], the L^2 stability of the semidiscrete approximation, and Theorem 3.1. In particular for $F = 0$ the solution of the semidiscrete problem will satisfy

$$\|u_h\|_{L^2(T_h^1)} \le Ce^{\eta t}\|u_0^h\|_{L^2(T_h^1)}, \tag{3.26}$$

which is all that is needed to apply the Kreiss–Wu theory. ∎

Note that the RK–Taylor methods used below are locally stable only for $n = 4k$ and $n = 4k - 1$.

4. Semidiscrete convergence analysis. In this section we prove a suboptimal error bound for the proposed covolume method. We note that, in comparison with error estimates for the standard approach, our estimates are $O(h^{1/2})$ worse. We suspect that, in fact, the proposed method is as accurate as the standard one. We show below that this is true in the constant coefficient case on uniform grids; then we can use Fourier methods as in [18] to show that the error is $O(h^{n+1})$. Our numerical experiments indicate that the modified method is also as accurate as the standard method for nonuniform grids. However, direct application of the method of proof from, e.g., [10] fails. We plan to consider alternative analyses in the future.

To simplify the presentation we consider the $\beta = 1$ fully filtered case, as the extension to the partially filtered case is straightforward. We also consider only the semidiscrete scheme.

THEOREM 4.1. *Suppose u satisfies (2.4) with $u(x,0) = u_0(x) \in H^{r+1}$. Then for all $0 \le s \le \min(n,r)$ there exist constants $C_{n,s}$ such that the solution, u_h, of the semidiscrete problem satisfies the following error estimate:*

$$\begin{aligned}\|u-u_h\|_{L^2(\Omega)} \le C_{n,s} &\sum_{k=1}^{k=K^1} \left(h^{1,k}\right)^{s+1} \|u\|_{H^{s+1}(I^{1,k})} \\ &+ C_{n,s} \sum_{k=1}^{k=K^1} \left(h^{1,k}\right)^{s} T \max_{t\in[0,T]} \left(\|u\|_{H^{s+1}(I^{1,k})}\right) \\ &+ C_{n,s} \sum_{k=1}^{k=K^2} \left(h^{2,k}\right)^{s+1} \|u\|_{H^{s+1}(I^{2,k})} \\ &+ C_{n,s} \sum_{k=1}^{k=K^2} \left(h^{2,k}\right)^{s} T \max_{t\in[0,T]} \left(\|u\|_{H^{s+1}(I^{2,k})}\right).\end{aligned}$$

We begin with a sequence of lemmas estimating the errors induced by the filter. We recall the basic polynomial approximation results on the reference interval, $D = [-1,1]$ (see, for example, Schwab [30] for a comprehensive summary). The first result bounds the L^2 projection error incurred by nth-order polynomial approximation of a function.

LEMMA 4.2 (L^2 polynomial approximation). *Assume that $u \in H^{r+1}\left(I^{1,k}\right)$, $r \ge 0$; then, for every integer s such that $0 \le s \le \min(n+1, r+1)$, the following estimate holds:*

$$\left\|u - \Pi_n^1 u\right\|_{L^2(I^{1,k})} \le C_s \frac{h^s}{(n+1)^s} \left\|\frac{\partial^s u}{\partial x^s}\right\|_{L^2(I^{1,k})}. \tag{4.1}$$

Proof. See Ciarlet [6]. □

Using Lemma 4.2, we are able to establish the following result.

LEMMA 4.3 (bound on filter induced error). *Assume that*

$$u \in H^{r+1}\left(\Omega, T_h^1\right) \bigcap H^{r+1}\left(\Omega, T_h^2\right);$$

then, for every integer s such that $0 \le s \le \min(n+1, r+1)$, the following inequality holds:

$$\left\|u - \Pi^2\Pi^1 u\right\|_{L^2(\Omega)} \le C_{n,s} \sum_{k=1}^{k=K^1} \left(h^{1,k}\right)^s \|u\|_{H^s(I^{1,k})} + C_{n,s} \sum_{k=1}^{k=K^2} \left(h^{2,k}\right)^s \|u\|_{H^s(I^{2,k})}.$$

Proof. Starting from the definition of $\Pi^2\Pi^1$

$$\begin{aligned}\left\|u - \Pi^2\Pi^1 u\right\|_{L^2(\Omega)} &= \left\|u - \Pi^2 u + \Pi^2 u - \Pi^2\Pi^1 u\right\|_{L^2(\Omega)}, \\ &\le \left\|u - \Pi^2 u\right\|_{L^2(\Omega)} + \left\|\Pi^2 u - \Pi^2\Pi^1 u\right\|_{L^2(\Omega)}, \\ &\le \left\|u - \Pi^2 u\right\|_{L^2(\Omega)} + \left\|\Pi^2\left(u - \Pi^1 u\right)\right\|_{L^2(\Omega)}, \\ &\le \left\|u - \Pi^2 u\right\|_{L^2(\Omega)} + \left\|u - \Pi^1 u\right\|_{L^2(\Omega)},\end{aligned}$$

where the last result follows from the contraction property of Π^1. Finally, we observe that each of the two terms on the right-hand side are the remainder terms from

performing an L^2 projection mapping u to piecewise polynomial spaces and apply Lemma 4.2. ∎

We now bound the L^2 norm of the derivative of the error induced by the filter. Recall the following bound for the first derivative of the error incurred in the L^2 projection of a function in terms of its derivatives.

LEMMA 4.4. *Assume that* $u \in H^{r+1}\left(I^{1,k}\right)$, $r \geq 0$; *then, for* $n \geq 1$, *and* $0 \leq s \leq \min(n, r)$, *the following estimate holds:*

$$\left\| \frac{\partial}{\partial x}\left(u - \Pi_n^1 u\right) \right\|_{L^2(I^{1,k})} \leq C_{n,s}\left(h^{1,k}\right)^s \left\| \frac{\partial^{s+1} u}{\partial x^{s+1}} \right\|_{L^2(I^{1,k})}. \tag{4.2}$$

Proof. See Ciarlet [6]. ∎

We use this bound to establish the following minor variation of Lemma 4.3, which bounds the derivative of the filtered component of a function.

LEMMA 4.5 (bound on the derivative of filter induced error). *The inequality*

$$\begin{aligned}\left\| \frac{\partial}{\partial x}\left(u - \Pi^2\Pi^1 u\right) \right\|_{L^2\left(T_h^2\right)} \leq\ & C_{n,s} \sum_{k=1}^{k=K^1} \left(h^{1,k}\right)^s \|u\|_{H^{s+1}(I^{1,k})} \\ & + C_{n,s} \sum_{k=1}^{k=K^2} \left(h^{2,k}\right)^s \|u\|_{H^{s+1}(I^{2,k})}\end{aligned}$$

holds for all $u \in H^{s+1}\left(\Omega, T_h^1\right) \bigcap H^{s+1}\left(\Omega, T_h^2\right)$ *when* $0 \leq s \leq \min(n, r)$.

Proof. Starting from the definition of $\Pi^2\Pi^1$

$$\begin{aligned}\left\| \frac{\partial}{\partial x}\left(u - \Pi^2\Pi^1 u\right) \right\|_{L^2\left(T_h^2\right)} &= \left\| \frac{\partial}{\partial x}\left(u - \Pi^2 u\right) + \frac{\partial}{\partial x}\left(\Pi^2 u - \Pi^2\Pi^1 u\right) \right\|_{L^2\left(T_h^2\right)}, \\ &\leq \left\| \frac{\partial}{\partial x}\left(u - \Pi^2 u\right) \right\|_{L^2\left(T_h^2\right)} + \left\| \frac{\partial}{\partial x}\left(\Pi^2 u - \Pi^2\Pi^1 u\right) \right\|_{L^2\left(T_h^2\right)}, \\ &\leq \left\| \frac{\partial}{\partial x}\left(u - \Pi^2 u\right) \right\|_{L^2\left(T_h^2\right)} + \frac{n^2\sqrt{3}}{h} \left\| \Pi^2 u - \Pi^2\Pi^1 u \right\|_{L^2\left(T_h^2\right)}, \\ &\leq \left\| \frac{\partial}{\partial x}\left(u - \Pi^2 u\right) \right\|_{L^2\left(T_h^2\right)} + \frac{n^2\sqrt{3}}{h} \left\| u - \Pi^1 u \right\|_{L^2\left(T_h^1\right)},\end{aligned}$$

where we have used the the inverse inequality (3.3) and the contraction property of Π^2. The approximation bound follows from Lemmas 4.4 and 4.2. ∎

Next we bound the polynomial lift of the interelement jumps of functions filtered through the covolume mesh. Recall the definition of the lift operator on the reference element as the linear operator $\mathcal{L}$ which satisfies, given $u \in L^2(\partial I)$,

$$(\phi, \mathcal{L}u)_I = (\phi, u)_{\partial I} \quad \forall \phi \in L^2(I). \tag{4.3}$$

We first note the multiplicative trace inequality.

LEMMA 4.6 (multiplicative trace inequality). *There exists a constant* C *independent of* q, h, *and* D *such that*

$$\|q\|^2_{L^2(\partial I^{1,k})} \leq C\left(\|q\|_{L^2(I^{1,k})} \left\| \frac{\partial q}{\partial x} \right\|_{L^2(I^{1,k})} + \frac{1}{h^{1,k}} \|q\|^2_{L^2(I^{1,k})} \right), \quad q \in H^1\left(I^{1,k}\right). \tag{4.4}$$

Proof. See Prudhomme et al. [26] for a succinct derivation of this result. ∎

Also we note the polynomial trace inequality.

LEMMA 4.7 (polynomial trace inequality). *Assume* $u \in P^n\left(I^{1,k}\right)$*; then*

$$\|u\|_{L^2(\partial I^{1,k})} \leq \frac{(n+1)}{\sqrt{h^{1,k}}} \|u\|_{L^2(I^{1,k})}. \tag{4.5}$$

Proof. See Warburton and Hesthaven [33] for a constant free derivation for the d-simplex. ∎

These results allow us to prove the following bound on the polynomial lift of the L^2 norm of the jump in a filtered solution u which is sufficiently smooth.

LEMMA 4.8 (bound on the polynomial lift of filter induced jumps). *The inequality*

$$\sum_{k=1}^{k=K^2} \left\|\mathcal{L}\left[\Pi^2\Pi^1 u\right]\right\|_{L^2\left(I_h^{2,k}\right)} \leq C_{n,s} \sum_{k=1}^{k=K^1} \left(h^{1,k}\right)^s \|u\|_{H^{s+1}(I^{1,k})} + C_{n,s} \sum_{k=1}^{k=K^2} \left(h^{2,k}\right)^s \|u\|_{H^{s+1}(I^{2,k})}$$

holds for all $u \in H^{r+1}\left(\Omega, T_h^1\right) \bigcap H^{r+1}\left(\Omega, T_h^2\right)$ *when* $0 \leq s \leq \min(n, r)$.

Proof. By this definition of the lift operator $\mathcal{L}$,

$$\left(\mathcal{L}\left[\Pi^2\Pi^1 u\right], \mathcal{L}\left[\Pi^2\Pi^1 u\right]\right)_{I^{2,k}} = \left(\mathcal{L}\left[\Pi^2\Pi^1 u\right], \left[\Pi^2\Pi^1 u\right]\right)_{\partial I^{2,k}}; \tag{4.6}$$

thus by the Cauchy–Schwarz inequality and the polynomial trace inequality (Lemma 4.7)

$$\left\|\mathcal{L}\left[\Pi^2\Pi^1 u\right]\right\|_{L^2(I^{2,k})} \leq C\frac{n}{\sqrt{h^{2,k}}} \left\|\left[\Pi^2\Pi^1 u\right]\right\|_{L^2(\partial I^{2,k})}. \tag{4.7}$$

Next, we rely on the solution being in $H^r\left(\Omega, T_h^1\right)$ to guarantee that u is continuous at the midpoints of the elements of the primal grid and therefore continuous at the endpoints of the dual grid. We thus add $[u]$ to the argument of the norm and then break the jump term into two parts:

$$\begin{aligned}\left\|\left[\Pi^2\Pi^1 u\right]\right\|_{L^2(\partial I^{2,k})} &= \left\|\left[\Pi^2\Pi^1 u - u\right]\right\|_{\partial I^{2,k}} \\ &\leq \left\|\Pi^2\Pi^1 u^- - u^-\right\|_{\partial I^{2,k}} + \left\|\Pi^2\Pi^1 u^+ - u^+\right\|_{\partial I^{2,k}}.\end{aligned}$$

Applying the multiplicative trace inequality from Lemma 4.6, summing over both negative and positive traces, for all boundaries of all elements then recalling (4.7), and finally using the filter approximation results from Lemmas 4.3 and 4.5 the result is complete. ∎

We are now in a position to complete the proof of the main theorem of this section.

Proof of Theorem 4.1. We directly establish consistency using the previous lemmas. First, we consider the original advection equation as a residual, projected into $V^{1,h}$:

$$\frac{\partial \Pi^1 u}{\partial t} = -\Pi^1 \frac{\partial u}{\partial x}. \tag{4.8}$$

Next we consider the local truncation error, T_h, which is the residual when the solution is L^2 projected onto V^h and acted on by the numerical operator:

$$\frac{\partial \Pi^1 u}{\partial t} = -\Pi^1 \left(\frac{\partial \Pi^2\Pi^1 u}{\partial x} + \frac{1}{2}\mathcal{L}\left(\tau\left[\Pi^2\Pi^1 u\right]\right)\right) + T_h. \tag{4.9}$$

Finally, we consider the numerical operator acting on the numerical solution

$$\frac{\partial u_h}{\partial t} = -\Pi^1 \left(\frac{\partial \Pi^2 u_h}{\partial x} + \frac{1}{2} \mathcal{L} \left(\tau \left[\Pi^2 u_h \right] \right) \right). \tag{4.10}$$

Combining the first two equations

$$T_h = \Pi^1 \frac{\partial u}{\partial x} - \Pi^1 \left(\frac{\partial \Pi^2 \Pi^1 u}{\partial x} + \frac{1}{2} \mathcal{L} \left(\tau \left[\Pi^2 \Pi^1 u \right] \right) \right), \tag{4.11}$$

we deduce that

$$\|T_h\|_{L^2(\Omega)} \leq \left\| \Pi^1 \left(\frac{\partial u}{\partial x} - \frac{\partial \Pi^2 \Pi^1 u}{\partial x} \right) \right\|_{L^2\left(T_h^1\right)} + \frac{1}{2} \left\| \Pi^1 \mathcal{L} \left(\tau \left[\Pi^2 \Pi^1 u \right] \right) \right\|_{L^2\left(T_h^1\right)}, \tag{4.12}$$

and then recalling the contraction property of Π^1

$$\|T_h\|_{L^2(\Omega)} \leq \left\| \frac{\partial u}{\partial x} - \frac{\partial \Pi^2 \Pi^1 u}{\partial x} \right\|_{L^2\left(T_h^2\right)} + \frac{1}{2} \left\| \mathcal{L} \left(\tau \left[\Pi^2 \Pi^1 u \right] \right) \right\|_{L^2\left(T_h^2\right)}. \tag{4.13}$$

Applying Lemmas 4.3, 4.5, and 4.8 we obtain

$$\|T_h\|_{L^2(\Omega)} \leq C_{n,s} \sum_{k=1}^{k=K^1} \left(h^{1,k}\right)^s \|u\|_{H^{s+1}(I^{1,k})} + C_{n,s} \sum_{k=1}^{k=K^2} \left(h^{2,k}\right)^s \|u\|_{H^{s+1}(I^{2,k})}, \tag{4.14}$$

which requires that the solution u is bounded in a broken Sobolev norm both on the covolume and primal meshes.

To continue the convergence analysis we take the difference between (4.9) and (4.10) to form a local error equation, and using the stability of the upwind DG derivative operator we obtain

$$\frac{d}{dt} \left\| \Pi^1 u - u_h \right\|_{L^2(\Omega)} \leq \|T_h\|_{L^2(\Omega)}. \tag{4.15}$$

Following the approach in Hesthaven and Warburton [15] we now obtain

$$\begin{aligned}
\|u - u_h\|_{L^2(\Omega)} &\leq \left\| u - \Pi^1 u \right\|_{L^2(\Omega)} + \left\| (u - u_h)|_{t=0} \right\|_{L^2(\Omega)} + T \max_{t \in [0,T]} \|T_h\| \\
&\leq C_{n,s} \sum_{k=1}^{k=K^1} \left(h^{1,k}\right)^{s+1} \|u\|_{H^{s+1}(I^{1,k})} \\
&\quad + C_{n,s} \sum_{k=1}^{k=K^1} \left(h^{1,k}\right)^s T \max_{t \in [0,T]} \left(\|u\|_{H^{s+1}(I^{1,k})} \right) \\
&\quad + C_{n,s} \sum_{k=1}^{k=K^2} \left(h^{2,k}\right)^{s+1} \|u\|_{H^{s+1}(I^{2,k})} \\
&\quad + C_{n,s} \sum_{k=1}^{k=K^2} \left(h^{2,k}\right)^s T \max_{t \in [0,T]} \left(\|u\|_{H^{s+1}(I^{2,k})} \right),
\end{aligned}$$

completing the proof. ∎

These estimates can be improved in the specific case when the domain is periodic and the mesh consists of equal sized elements. In section 5 we provide a dispersion analysis of the overlapping DG method and attain optimal order convergence in the limit of small kh for wave numbers k which are small in comparison with the element size h.

5. Fourier analysis for uniform element sizes. In the special case of uniform meshes we can directly analyze the covolume filtered approximation using discrete Fourier series. We recall the results of applying this analysis to the standard DG method, as completed first via symbolic computations by Hu and Atkins [18] and subsequently proven by Ainsworth [1]. Namely, the DG derivative operator admits a discrete eigenfunction, $\hat{u}^{DG}(x)$, which agrees with e^{ikx} within an error of $O(h^{n+1})$, and an eigenvalue, $i\lambda(k)$, which agrees with ik within an error of $O(h^{2n+2})$; precisely, the error has a real part of $O(h^{2n+2})$, corresponding to dissipation, and an imaginary part of $O(h^{2n+3})$, corresponding to a dispersion error.

Our symbolic calculations, carried out for $1 \leq n \leq 14$, show that the covolume filtered DG operator in fact has the same properties. As shown in Table 5.1, the leading-order dissipation error is precisely the same as for the standard DG derivative operator. The constant in the dispersion error is different, however, though of somewhat comparable magnitude.

TABLE 5.1
Errors in the dispersion relation as a function of n and $\zeta = kh$.

n	Standard upwind DG	Covolume filtered upwind DG
1	$1.4 \times 10^{-2}\zeta^4 + i \cdot 3.7 \times 10^{-3}\zeta^5$	$1.4 \times 10^{-2}\zeta^4 + i \cdot 5.4 \times 10^{-3}\zeta^5$
2	$1.4 \times 10^{-4}\zeta^6 + i \cdot 2.4 \times 10^{-5}\zeta^7$	$1.4 \times 10^{-4}\zeta^6 + i \cdot 2.0 \times 10^{-6}\zeta^7$
3	$7.1 \times 10^{-7}\zeta^8 + i \cdot 9.0 \times 10^{-8}\zeta^9$	$7.1 \times 10^{-7}\zeta^8 + i \cdot 9.9 \times 10^{-7}\zeta^9$
4	$2.2 \times 10^{-9}\zeta^{10} + i \cdot 2.2 \times 10^{-10}\zeta^{11}$	$2.2 \times 10^{-9}\zeta^{10} - i \cdot 2.5 \times 10^{-10}\zeta^{11}$
5	$4.5 \times 10^{-12}\zeta^{12} + i \cdot 3.8 \times 10^{-13}\zeta^{13}$	$4.5 \times 10^{-12}\zeta^{12} + i \cdot 2,2 \times 10^{-11}\zeta^{13}$
6	$6.7 \times 10^{-15}\zeta^{14} + i \cdot 4.8 \times 10^{-16}\zeta^{15}$	$6.7 \times 10^{-15}\zeta^{14} - i \cdot 5.7 \times 10^{-16}\zeta^{15}$
7	$7.4 \times 10^{-18}\zeta^{16} + i \cdot 4.7 \times 10^{-19}\zeta^{17}$	$7.4 \times 10^{-18}\zeta^{16} + i \cdot 1.6 \times 10^{-16}\zeta^{17}$
8	$6.4 \times 10^{-21}\zeta^{18} + i \cdot 3.6 \times 10^{-22}\zeta^{19}$	$6.4 \times 10^{-21}\zeta^{18} + i \cdot 1.9 \times 10^{-21}\zeta^{19}$
9	$4.4 \times 10^{-24}\zeta^{20} + i \cdot 2.2 \times 10^{-25}\zeta^{21}$	$4.4 \times 10^{-24}\zeta^{20} + i \cdot 4.5 \times 10^{-22}\zeta^{21}$
10	$2.5 \times 10^{-27}\zeta^{22} + i \cdot 1.1 \times 10^{-28}\zeta^{23}$	$2.5 \times 10^{-27}\zeta^{22} + i \cdot 8.0 \times 10^{-27}\zeta^{23}$
11	$1.2 \times 10^{-30}\zeta^{24} + i \cdot 5.0 \times 10^{-32}\zeta^{25}$	$1.2 \times 10^{-30}\zeta^{24} + i \cdot 6.3 \times 10^{-28}\zeta^{25}$
12	$4.8 \times 10^{-34}\zeta^{26} + i \cdot 1.8 \times 10^{-35}\zeta^{27}$	$4.8 \times 10^{-34}\zeta^{26} + i \cdot 9.4 \times 10^{-33}\zeta^{27}$
13	$1.6 \times 10^{-37}\zeta^{28} + i \cdot 5.8 \times 10^{-39}\zeta^{29}$	$1.6 \times 10^{-37}\zeta^{28} + i \cdot 4.7 \times 10^{-34}\zeta^{29}$
14	$4.9 \times 10^{-41}\zeta^{30} + i \cdot 1.6 \times 10^{-42}\zeta^{31}$	$4.9 \times 10^{-41}\zeta^{30} + i \cdot 5.3 \times 10^{-39}\zeta^{31}$

We note that this result has a number of important consequences for applications on uniform meshes. First, one expects the error to be far less sensitive to the time of integration than other approximations of the same order, as the time dependence of the error is manifested only through the error in the dispersion relation. Second, in terms of formal order of accuracy, one now expects convergence at order $n + 1$. The point again is that the order $n + 1$ error incurred by projecting the initial data onto the piecewise polynomial approximation space is propagated with far more accuracy. Thus we do not experience the usual order reduction over time.

We note that eigenanalysis is straightforward. Without loss of generality we scale x so that the element widths are 1, and as in [13] we represent the solution in the ith element by the coefficients of its Taylor expansion about the element center, P_i. We now simply view the DG method (covolume filtered or standard) as a difference method applied to this vector function. For the covolume filtered derivative operator the difference stencil is seen to involve four elements,

$$(\mathcal{D}P)_i = D_{-2}P_{i-2} + D_{-1}P_{i-1} + D_0P_i + D_1P_{i+1}, \tag{5.1}$$

leading to the following symbol:

$$\hat{\mathcal{D}} = e^{-2ikh} D_{-2} + e^{-ikh} D_{-1} + D_0 + e^{ikh} D_1. \tag{5.2}$$

For $|\zeta| = |kh| \ll 1$ we find that the Taylor coefficients of the exponential function $e^{i\zeta}$,

$$\hat{P}^{(e)} = \begin{pmatrix} 1 \\ i\zeta \\ -\frac{\zeta^2}{2} \\ \vdots \\ i^n \frac{\zeta^n}{n!} \end{pmatrix}, \tag{5.3}$$

satisfy

$$\hat{\mathcal{D}}\hat{P}^{(e)} = i\zeta \hat{P}^{(e)} + O(|\zeta|^{n+1}). \tag{5.4}$$

Moreover, expansion of the coefficients of the characteristic polynomial of $\hat{\mathcal{D}}$ for ζ small reveals that there is a single small eigenvalue, $i\lambda$, which satisfies

$$i\lambda = i\zeta + c_{2n+2}\zeta^{2n+2} + ic_{2n+3}\zeta^{2n+3} + O(|\zeta|^{2n+4}). \tag{5.5}$$

The constants are displayed in Table 5.1.

Of course it would be desirable to prove these results in general using, for example, the techniques in [1]. We will consider this in a later work. Also there will be spurious modes which we have not computed.

6. Algorithmic cost and variations on the method. It is natural to discuss the algorithmic overhead of using the covolume mesh based filtering. For the advection equation example the filter requires approximately two grid transfers as well as two evaluations of the upwind DG derivative per stage in the RK time-stepping scheme, and this approximately triples the cost of each time step. Thus, the minimum n required for breaking even is quite high. We can, however, reduce the computational cost with the following version:

$$\frac{\partial u^1}{\partial t} = -D_1^1 F^\beta u^1, \tag{6.1}$$

where $F^\beta = \beta \Pi^1 \Pi^2 + (1-\beta)$. This formulation requires only one upwind DG derivative evaluation, and the action of the transfers can be consolidated into one operator which uses a three element stencil to filter the upwind DG gradient in each element. This approach requires less than double the operations of the unfiltered method, and the break even n is lower.

The L^2 stability equation for this method is

$$\beta \frac{d}{dt} \left\| \Pi^2 u_h^1 \right\|^2_{L^2(T_h^2)} + (1-\beta) \frac{d}{dt} \left\| u_h^1 \right\|^2_{L^2(T_h^1)} = -\frac{1}{2} \sum_k \left(|n_x| \left[F^\beta u_h^1 \right], \left[F^\beta u_h^1 \right] \right)_{\partial I^{1,k}}.$$

Proceeding as before, we compute a bound on the local truncation error for this

method:

$$\begin{aligned}
\|T_h\|_{L^2(T_h^1)} &\leq \left\| \Pi^1 \frac{\partial u}{\partial x} - \frac{\partial}{\partial x}\left(\beta \Pi^1\Pi^2\Pi^1 u + (1-\beta)\right) u \right\|_{L^2(T_h^1)} \\
&\quad + \left\| \mathcal{L}\left(\tau\left[\beta\Pi^1\Pi^2\Pi^1 u + (1-\beta)\Pi^1 u\right]\right)\right\|_{L^2(T_h^1)} \\
&\leq \left\| \frac{\partial}{\partial x}\left(u - \Pi^1\Pi^2 u\right)\right\|_{L^2(T_h^1)} \\
&\quad + \left\| \frac{\partial}{\partial x}\left((1-\beta)\Pi^1\left(\Pi^2 - 1\right) u\right)\right\|_{L^2(T_h^1)} \\
&\quad + \left\| \mathcal{L}\left(\tau\left[\beta\Pi^1\Pi^2\Pi^1 u + (1-\beta)\Pi^1 u\right]\right)\right\|_{L^2(T_h^1)} \\
&\leq \left\| \frac{\partial}{\partial x}\left(u - \Pi^1\Pi^2 u\right)\right\|_{L^2(T_h^1)} + (1-\beta)\frac{n^2}{h}\left\|\left(\Pi^2 - 1\right) u\right\|_{L^2(T_h^1)} \\
&\quad + \left\| \mathcal{L}\left(\tau\left[\beta\Pi^1\Pi^2\Pi^1 u + (1-\beta)\Pi^1 u\right]\right)\right\|_{L^2(T_h^1)}.
\end{aligned}$$

Following the same strategies as before we obtain the same form for the local truncation error as in (4.14), albeit with different constants; i.e., as one would expect with this type of analysis we lose one order of accuracy for the local truncation error. The global error analysis follows as before, again yielding error bounds with the same form but different constants.

We can also interchange the order of differentiation and filtering to obtain

$$\frac{\partial u^1}{\partial t} = -F^\beta D_1^1 u^1. \tag{6.2}$$

We note that when the right-hand side spatial operator is spectrally equivalent to the filter-then-differentiate operator, from (6.1), and all approximation results follow. This observation is based on operating on both sides of (6.1) and replacing $F^\beta u \to u$.

Finally, an important property of DG methods is that they are locally conservative. As presented none of the modified methods preserves this property, as they do not conserve the mean of the solution or gradients. However, local conservation can be easily restored. For instance, we can restore local conservation of the method in (6.2) by changing the operator F^β so that it filters only functions orthogonal to $\bigcup_{k=1}^{k=K^1} P^0\left(I^{1,k}\right)$. In fact to maintain the spectral scaling of the filtered operator it is sufficient to filter only functions orthogonal to the polynomial space $\bigcup_{k=1}^{k=K^1} P^m\left(I^{1,k}\right)$ with $m \leq \sqrt{n}$.

7. Modified upwind DG method for one-dimensional Maxwell's equations. In this section we consider the transverse mode Maxwell's equations in one dimension, which are a first-order version of the two-way wave equation. The equations are

$$\frac{\partial H_y}{\partial t} = \frac{\partial E_z}{\partial x}, \tag{7.1}$$

$$\frac{\partial E_z}{\partial t} = \frac{\partial H_y}{\partial x}, \tag{7.2}$$

where H_y is the magnetic field and E_z is the electric field. We assume perfectly electrically conducting boundary conditions at $x = 0$ and $x = 2$:

$$0 = \frac{\partial H_y}{\partial x}(0,t) = \frac{\partial H_y}{\partial x}(2,t), \tag{7.3}$$

$$0 = E_z(0,t) = E_z(2,t). \tag{7.4}$$

The appearance of these boundary conditions is in contrast to the previous examples, where the domain is periodic. We are now faced with the question of how to treat these Dirichlet and natural Neumann conditions because we are using a covolume mesh, and thus we require the solution to extend beyond the domain boundary. In the specific circumstance of Maxwell's equations with homogeneous boundary data, we are able to use the method of images. For both cases we extend the primal mesh by two elements at each end which are constructed by reflecting the mesh about each end vertex. We can then extend the primal solution by reflection for the zero Neumann condition and by antireflection for the zero Dirichlet condition. At this point we have extended the primal mesh, and a covolume mesh which encompasses the original domain may be constructed. The last modification of note is that the DG operator is applied on the covolume mesh, and since we have extended the primal grid by two elements at each end we are able to apply arbitrary boundary condition states for the DG derivative on the covolume mesh without affecting the result after projection back onto the primal mesh. With this approach we can recycle the solvers from the modified DG approach for advection.

8. Numerical results. In this section we investigate the sharpness of the analytical prediction of order of accuracy, and in fact we go further and experimentally test the spectral correctness of the discrete modified upwind DG operators. This latter test is an important indicator of potential solution quality and robustness in practical situations. Admittedly, the method as presented is rather limited in geometric flexibility and in representing solutions of low regularity, but it is important to establish the potential for the method before we should even consider further development.

8.1. Test 1: Advection on regular grid. In our first test we chose to discretize the periodic interval $[0, 2]$ with 20 elements using seventh-order polynomials in each element. In Figure 8.1 we show the full spectra of the discretized upwind DG differentiation operator for $\beta = 0, 0.2, 0.4, 0.6, 0.8, 1.0$. It is immediately apparent that the modified operator has a much reduced spectral radius as β increases.

However, it is also apparent that the filtering process is wrapping the spectrum tightly near the imaginary axis, so we must be concerned about the possibility of spurious eigenvalues for the discrete operator. In Figure 8.2 we show the same spectral plots but each zoomed to the limits of the $\beta = 1$ case.

We see that with $\beta = 1$ the normally highly dissipated DG eigenmodes have reduced dissipation and are now in close proximity to the imaginary axis, in particular near the origin, and may present in time-domain simulations as parasitic solutions. This effect can be mitigated in this specific case by choosing $\beta = 0.8$, say. Then there is a clear separation between the spurious and nonspurious eigenvalues. There is clearly a need for a subtle balance between decreasing the spectral radius of the original DG operator and confusing the spectrum near the imaginary axis. The well-represented Fourier modes evident on the imaginary axis are in danger of being inundated with the collapsing modified spurious DG modes.

In Table 8.1 we show the spectral radius for each β value tried. It is clear that this simple modification yields significant reduction in the spectral radius and corre-

sponding increase in the maximum size of dt. We may deduce that using $\beta = 0.8$ is a reasonable compromise between spectral radius deduction and maintaining separation of the spurious modes from the imaginary axis.

The decrease in spectral radius is an attractive property of this approach, but it is also necessary to examine the impact of the use of the covolume meshes on the accuracy of the solution. We performed h-convergence tests for $K = 32, 64, 128, 256$, $n = 1, 2, \ldots, 9$ with $\beta = 0$ (i.e., unfiltered upwind DG discretization) with $dt = h/(2(n+1))$ and then with $\beta = 1 - 2/(n+1)$ and $dt = h/4$ using an initial condition:

$$u = \exp\left(-40 \sin\left((2\pi x)^2\right)\right). \tag{8.1}$$

We integrated in time using the $(n+1)$-order RK–Taylor method, sometimes referred to as the Jameson–Schmidt–Turkel scheme (see, e.g., [4]), which for a linear autonomous system is simply a recursive evaluation of the Taylor series for the matrix

TABLE 8.1

Dependence of the spectral radius of the partially stabilized operator on the β parameter for the $K = 20$, $n = 7$ upwind DG operator on the $[0, 2]$ periodic interval.

β	0	0.2	0.4	0.6	0.8	1.0

exponential. We estimated the rate of convergence by assuming the error has form $\epsilon = C_n h^n$ and using the MATLAB function polyfit to compute a linear fit to the log of the error values: coeffs = polyfit(log([1 .5 .25 .125]),log(errors)); order = coeffs(1).

The results for the unfiltered upwind DG solution of the advection equation are shown in Table 8.2. We clearly see that for $2 \leq n \leq 7$ the order of convergence measured at time $t = 1$ is between n and $n + 1$. It is clear that the $n = 1$ results are preasymptotic for this case, and the $n = 9$ and $n = 10$ cases show convergence rates diminished because the finest resolution error is near finite precision. Here we used a time step $dt = h/(2(n + 1))$ which was experimentally found to be stable for all test cases and close to the maximum dt while retaining stability. The $\beta = 1 - 2/(n + 1)$ results are shown in Table 8.3. Again, the solution includes relatively narrow exponential pulses, which are not well resolved by the linear elements even with $K = 512$ elements, and this is reflected by the preasymptotic order of accuracy obtained for the $n = 1$ test. With the exception of the $n = 1$ and $n = 5$ cases we see that the convergence rates are close to optimal with rates of nearly $n + 1$ reported. The $n = 9$ reported rate may be slightly lower than expected because the errors found on the finest mesh are close to machine precision. The filtered upwind DG results are comparable with the unfiltered upwind DG results shown in Table 8.2 despite the time steps being used for the former being much larger than those used for the latter. To examine if the $n = 5$ slow convergence is caused by an overly aggressive choice of dt we repeated this experiment with $dt = h/5$ instead of $dt = h/4$ and show the results in Table 8.4. It is clear that the near optimal rates of convergence are attained in this case. We can explain this weak dependence on n by considering the stability regions of the higher-order RK–Taylor schemes as shown in Figure 8.3. It is apparent that these regions do not grow homogeneously with increasing order, and we know that the fifth- and sixth-order schemes are not locally stable. This may result in very weak instability for marginally stable time steps and possibly explains

the issue with the $n = 6$ convergence for $dt = h/4$ which disappears for $dt = h/5$. In Figure 8.4 we show the discrete eigenspectra of the fourth- to ninth-order DG operators scaled by $dt = h/4$ and superimposed on their corresponding RK stability regions. Close examination shows that for this choice of dt the $n = 5$ scheme has eigenvalues just outside the stability region of the RK scheme near the ends of the RK stability boundary along the imaginary axis. The spectra, excluding the $n = 5$ case, are more comfortably contained within their RK stability regions, although as usual the limited inclusion of the imaginary axis within these stability regions, for $n > 4$, raises concerns for long time stability. In Figure 8.5 we show results for $dt = h/5$; this more conservative time step comfortably accommodates the discrete spectra within the RK stability regions. Some weak growth in the spectral radius of the scaled operators may be associated with the β weighted sum of filtered and unfiltered gradients.

8.1.1. Filtering and then differentiating. In this section we briefly compare the discrete spectra for an upwind DG discretization of the advection equation where we differentiate on the covolume mesh compared (see (6.1)) with a case where we filter and then differentiate on the primal grid (see (2.15)). In Figure 8.6, we compare these two approaches for a primal grid of $n = 9$, $\beta = 1 - 2/(n+1)$, and $K = 16$. It is immediately apparent that the filter-then-differentiate approach is prone to spurious eigenvalues impinging on the imaginary axis, in contrast to the original approach of differentiating on the primal grid. Furthermore, the filter-then-differentiate approach has a slightly larger spectral radius. These observations may well limit the desirability

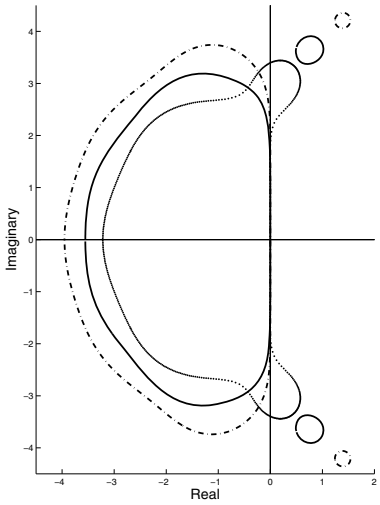

FIG. 8.3. *Margins of absolute stability for the fifth- (points), sixth- (solid line), and seventh-order (dot-dash line) RK–Taylor schemes.*

of the filter-then-differentiate approach, despite its lower algorithmic cost.

8.1.2. Long time integration: Testing the truncation error estimate. To test the sharpness of the L^2 error estimate resulting from the convergence analysis in section 4, we solved the same problem as above to a more challenging final time $T = 100$. We used discretization parameters $n = 4, 5, 6, 7$ and $K = 16, 32, 64, 128$ and set $dt = 0.15h$ and $\beta = 1 - 2/(n + 1)$.

For each simulation, we estimated the slope of the L^2 error, sampled every 10 time steps and fit to a linear function in time. For each order we then fit these slopes as a function of element width h. In Table 8.5 we report estimates for the local truncation error, which range approximately between n and $n+1$ and are in agreement with our estimate.

8.2. Test 2: Advection on variable width elements. Given the above positive results for advection on meshes with equally spaced vertices, we repeated the eigenspectra computations of section 8.1 for advection in a periodic interval with period two. For this experiment we used $K = 32$ elements and $n = 7$ polynomials on a mesh with randomly chosen vertex spacing with element lengths in the range $4.7312e - 02 \leq h \leq 7.7361e - 02$. In Figure 8.7, we show the discrete eigenspectra of the upwind DG discretized derivative operator with $\beta = 1-2/(n+1)$ and with $\beta = 1$. As with the equispaced grid, it is apparent that the $\beta = 1$ pure covolume mesh based filtering introduces spurious solutions onto the imaginary axis. However, relaxing the filter to $\beta = 1 - 2/(n + 1)$ we see that there is convincing separation between the spurious modes and the imaginary axis for all but two of the spurious eigenvalues in this case. Finally, although the filtering is relaxed we see that the spectral radius in this case is not dramatically larger than for the fully filtered case.

8.3. Numerical results: One-dimensional Maxwell's equations. In this section we will present experimental results for the accuracy of the modified DG

method for Maxwell's equations in section 7.

We first present estimates of the order of accuracy of the method based on simulations run to time $t = 100.23$. The model solution was constructed from a random coefficient linear combination of the first 200 standing wave solutions to the Maxwell's equations which satisfy the boundary conditions

$$H_y = \sum_{m=1}^{m=200} r_m \cos(m\pi x)\cos(m\pi t), \tag{8.2}$$

$$E_z = -\sum_{m=1}^{m=200} r_m \sin(m\pi x)\sin(m\pi t), \tag{8.3}$$

where the r_m are random numbers generated by the MATLAB function rand as $r_m = \text{rand}(1) * 2^{-.2m}$ which decay with increasing mode number to guarantee smoothness. We deliberately chose a relatively long integration time to allow for the truncation error to accumulate to a measurable degree. The time step size dt was chosen according to

$$dt = 0.15h.$$

The results in Table 8.6 show that for $n \geq 4$ we see the expected order of accuracy. The $n = 1$ and $n = 2$ results are likely preasymptotic, and no conclusions are drawn. It should be noted that two different ranges of h were used to estimate the order of the method for $1 \leq n \leq 6$ and $7 \leq n \leq 9$ since the solutions converged to machine precision for the latter range of n before the end of the range of h used for the former

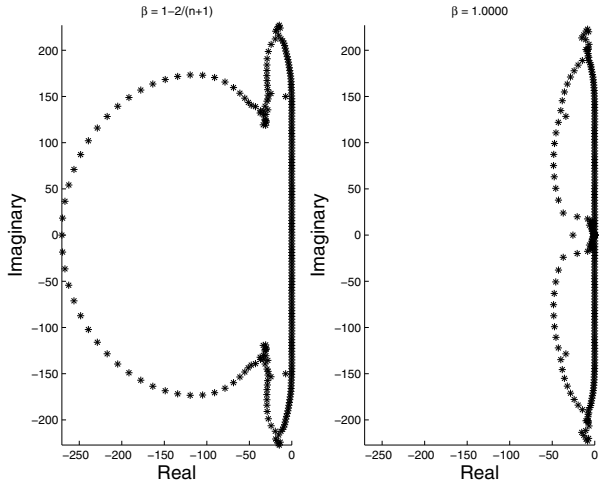

FIG. 8.7. *Full spectra for (left) $\beta = 1 - 2/(n+1)$ and (right) $\beta = 1.0$ versions of the discrete upwind DG operator on a randomly created mesh of $K = 32$ and $n = 7$. Notice the spurious eigenvalues apparent on the imaginary axis for the $\beta = 1$ case.*

tests. Finally, we note that the $n = 1$ case with our choice of $\beta = 1 - 2/(n+1)$ is actually the unmodified upwind DG method.

9. Summary. We have introduced a minor modification to the upwind DG method which increases the allowable time step by a factor proportional to the polynomial order of the spatial discretization, n. Both a basic local truncation error type analysis and Fourier-based dispersion analysis reveal that the modified method yields convergence rates comparable to the unmodified method in L^2. The method was tested for the advection equation and Maxwell's equations on one-dimensional meshes.

The increase in maximum time step was achieved at the expense of additional projection operations between the primal and covolume meshes and additional evaluations of DG derivatives. The break-even point is application dependent and requires further investigation. In addition, the use of approximation on primal and covolume meshes induces extra complexity in handling boundary conditions. This approach also has an impact on the efficiency of the method for parallel computations, but the local

nature of the extra projections will have a relatively minor impact on communication overheads.

In summary, the goal of reducing the spectral radius of the upwind DG spatial operator has been demonstrated and the method analyzed.

Acknowledgments. The authors express their appreciation to Professors David Gottlieb and Jan Hesthaven, Brown University, for many fruitful discussions on this topic.

THE COMPOSITE MINI ELEMENT—COARSE MESH COMPUTATION OF STOKES FLOWS ON COMPLICATED DOMAINS*

DANIEL PETERSEIM† AND STEFAN A. SAUTER†

Abstract. We introduce a new finite element method, the *composite mini element*, for the mixed discretization of the Stokes equations on two- and three-dimensional domains that may contain a huge number of geometric details. In standard finite element discretizations of the Stokes problem, such as the classical *mini element*, the approximation quality is determined by the maximal mesh size of the underlying triangulation, while the computational effort is determined by its number of elements. If the physical domain is very complicated, then the minimal number of simplices, which are necessary to resolve the domain, can be very large and distributed in a nonoptimal way with respect to the approximation quality. In contrast to that, the minimal dimension of the composite mini element space is independent of the number of geometric details. Instead of a geometric resolution of the domain and the boundary condition by the finite element mesh the *shape* of the finite element functions is adapted to the geometric details. This approach allows low-dimensional approximations even for problems with complicated geometric details such as holes or rough boundaries. We prove its linear (optimal order) approximability and its inf-sup stability. Further, we will be able to control the nonconformity in the space without increasing the space dimension in such a way that the a priori error estimate $\|\mathbf{u}-\mathbf{u}^{\mathrm{CME}}\|_{1,\Omega}+\|p-p^{\mathrm{CME}}\|_{0,\Omega}\lesssim h\|\mathbf{f}\|_{0,\Omega}$ holds. Thereby, in contrast to the classical methods, the choice of the mesh size parameter h is *not* constrained by the size of geometric details. In addition, it turns out that the method can be viewed as a coarse-scale generalization of the classical mini element approach; i.e., it reduces the computational effort, while the approximation quality depends on the (coarse) mesh size in the usual way.

Key words. finite elements, mixed methods, Stokes equation, nonconforming finite elements, space coarsening, complicated domain

1. Introduction.

The motion of a viscous incompressible fluid in a bounded, connected Lipschitz domain $\Omega\subseteq\mathbb{R}^d$, $d\in\{2,3\}$, can be described by a velocity field $\mathbf{u}:\Omega\to\mathbb{R}^d$ and a pressure distribution $p:\Omega\to\mathbb{R}^d$ which fulfill the Stokes equations under the standard Dirichlet boundary condition

$$\left.\begin{aligned}-\Delta\mathbf{u}+\nabla p &= \mathbf{f}\\ \operatorname{div}\mathbf{u} &= 0\end{aligned}\right\}\quad\text{in }\Omega,\qquad \mathbf{u}=\mathbf{0}\quad\text{on }\partial\Omega, \tag{1.1}$$

where $\mathbf{f}:\Omega\to\mathbb{R}^d$ is a given force density. Problem (1.1) has been studied in detail, both analytically and numerically, in the literature. A wide range of finite element methods for the numerical approximation of (1.1) has been developed. In principle, these methods can also be applied to flow problems on very complicated domains Ω that arise, e.g., in environmental modeling or life sciences. However, the standard requirement that the underlying finite element mesh has to resolve the domain couples the minimal dimension of the finite element space with the number and size of geometric details, e.g., rough boundaries or holes. Such a complicated domain Ω is

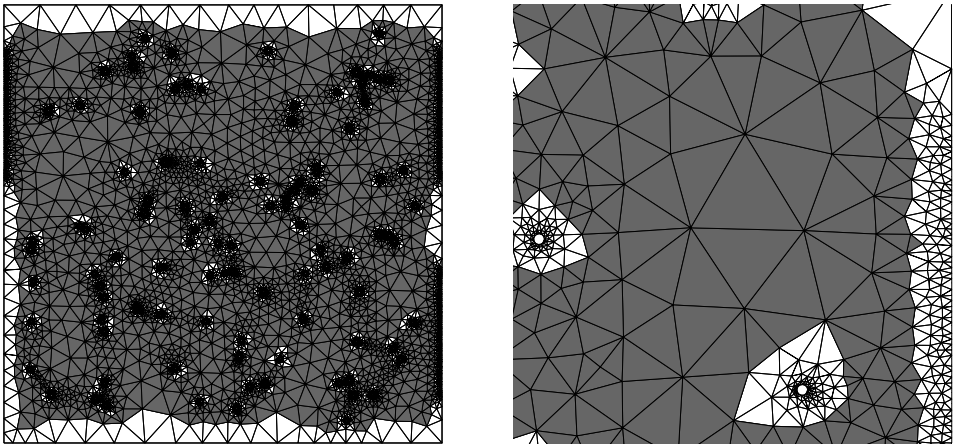
FIG. 1.1. *A model problem: Stokes flow on the unit square with* 100 *randomly distributed circular holes (*$r = 0.005$*), an Dirichlet-inflow boundary (cf. Figure* 1.3(a)*), and two Neumann-outflow boundaries,* $\mathbf{f} = \mathbf{0}$.

depicted in Figure 1.1(a), and a coarse triangulation of Ω is depicted in Figure 1.2(a). This triangulation is a minimal subdivision in the sense that further coarsening can be performed only by violating the shape regularity condition (cf. (2.6)). The application of standard finite elements (cf. section 2) with respect to the depicted triangulation leads to a satisfactory approximation of the corresponding Stokes flow depicted in Figure 1.1(b). However, the gain of putting a huge amount of freedom into the boundary region might be only small since the error is still mainly determined by the maximal mesh size. The use of coarser unfitted meshes is *not* satisfying either since the solution of the model problem behaves critically on perturbations of the model domain, as can be seen in Figure 1.3. That means that a simplification of Ω (allowing coarser subdivisions) typically will lead to poor approximations. In this paper, we will define a method that allows the low-dimensional discretization of such types of problems, while the convergence rates (with respect to the mesh size) are preserved. The main idea is to adapt the *shape* of the finite element functions instead of resolving the geometric details by the finite element mesh. This composite mini element belongs to the class of *composite finite element methods* which have been introduced to Poisson-type problems and to problems in linear elasticity [12], [17]. Here we will generalize composite finite elements to the Stokes problem. Thereby the following difficulties have to be overcome:

(a) the definition of the composite mini element based on new extension operators of finite element functions for Dirichlet, Neumann, or slip-type boundary conditions,
(b) analysis: proof of convergence and discrete stability,
(c) complexity analysis.

Related approaches in the literature can be found, for instance, in [2], where unfitted meshes are used to approximate elliptic equations with Neumann boundary data.



(a) Triangulation $\mathcal{T}$ with dark-shaded inner zone $\mathcal{T}^{\mathrm{dof}}$ ($\sharp\mathcal{T}^{\mathrm{dof}} \approx 1000$).

(b) $(0.8, 1) \times (0.25, 0.45)$-section of Figure 1.2(a).

FIG. 1.2. *Shape regular triangulation $\mathcal{T}$ of the model domain Ω from Figure* 1.1(a) *resolving the holes as well as the in- and outflow boundaries: max. mesh size $\approx 10^{-1}$, min. mesh size $\approx 10^{-3}$, regularity constant ≈ 2, number of triangles ≈ 9000.*

FIG. 1.3. *Consequences of simplification or perturbation of the model problem introduced in Figure* 1.1 *on the outflow behavior: Velocity components (x_1 solid, x_2 dotted) on $\{0\} \times (0, 1)$ and on $\{1\} \times (0, 1)$ for different domain modifications.*

Alternative approaches in [13], [24], and [1] are not restricted to Neumann conditions. However, the coarse spaces introduced are still coupled with the geometry, and the major goal lies in the efficient solution of fine-scale discretization (see, e.g., [24] and [1]). In contrast to our approach, the asymptotic convergence order of the underlying discretization is *not* preserved on coarser meshes. In cases where the geometric details are distributed periodically over the domain, homogenization-based approaches used to solve Stokes problems on complicated domains provide a powerful machinery

to construct problem-adapted finite element spaces (see, e.g., [8], [6]). In contrast, composite finite elements do *not* require any periodicity assumptions on the geometry.

The paper is organized as follows. In section 2 we recall the classical mini element for the weak formulation of the Stokes problem. Then, in section 3, we define the composite mini element space. Its convergence analysis is the topic of section 4, while the final section is devoted to numerical experiments.

2. The weak Stokes problem and the classical mini element. We first introduce some basic notation. By $\mathrm{W}^m_p(\Omega)$ we denote the Sobolev space of L^p-functions with weak derivatives up to order $m \in \mathbb{N} \cup \{0\}$ in $\mathrm{L}^p(\Omega)$, $p \in \mathbb{N} \cup \{\infty\}$. In the special case $p = 2$, these spaces are Hilbert spaces and are denoted by $\mathrm{H}^m(\Omega)$. We will write

$$\begin{array}{lll} & \|\cdot\|_{m,p,\Omega} \quad (|\cdot|_{m,p,\Omega}) & \text{for the norm (seminorm) in } \mathrm{W}^m_p(\Omega), \\ & \|\cdot\|_{m,\Omega} \quad (|\cdot|_{m,\Omega}) & \text{for the norm (seminorm) in } \mathrm{H}^m(\Omega), \\ \text{and} & \langle\cdot,\cdot\rangle_{m,\Omega} & \text{for the scalar product in } \mathrm{H}^m(\Omega). \end{array}$$

We will use bold letters for the function spaces if their elements are vector valued.

The Sobolev space that contains the velocity fields of Stokes flows with a homogeneous Dirichlet boundary condition is denoted by

$$\mathbf{H}^1_{\mathbf{0}}(\Omega) := \left\{ \mathbf{u} \in \mathbf{H}^1(\Omega) : \mathbf{u}|_{\partial\Omega} = \mathbf{0} \quad \text{in the sense of traces} \right\}.$$

The associated pressure space is $\mathrm{L}^2_0(\Omega) := \left\{ p \in \mathrm{L}^2(\Omega) : \int_\Omega p = 0 \right\}$. For a given right-hand side $\mathbf{f} \in \mathbf{H}^{-1}(\Omega) := (\mathbf{H}^1_{\mathbf{0}}(\Omega))'$, the weak formulation of (1.1) reads as follows: *Find a pair* $(\mathbf{u}, p) \in \mathbf{H}^1_{\mathbf{0}}(\Omega) \times L^2_0(\Omega)$ *such that*

$$\begin{array}{lll} \mathfrak{a}(\mathbf{u},\mathbf{v}) + \mathfrak{b}(\mathbf{v},p) = \langle \mathbf{f}, \mathbf{v} \rangle_{0,\Omega} & \forall \mathbf{v} \in \mathbf{H}^1_{\mathbf{0}}(\Omega), \\ \mathfrak{b}(\mathbf{u},q) = 0 & \forall q \in \mathrm{L}^2_0(\Omega). \end{array} \tag{2.1}$$

The bilinear forms $\mathfrak{a} : \mathbf{H}^1(\Omega) \times \mathbf{H}^1(\Omega) \to \mathbb{R}$ and $\mathfrak{b} : \mathbf{H}^1(\Omega) \times \mathrm{L}^2(\Omega) \to \mathbb{R}$ are defined by

$$\mathfrak{a}(\mathbf{u},\mathbf{v}) := 2\int_\Omega \mathbf{Du} : \mathbf{Dv}, \quad \mathbf{Du} := \tfrac{1}{2}\left(\nabla\mathbf{u} + (\nabla\mathbf{u})^\intercal\right), \quad \mathfrak{b}(\mathbf{v},q) := -\int_\Omega q \operatorname{div}\mathbf{v}. \tag{2.2}$$

Both bilinear forms are continuous, and, due to Korn's inequality (cf. [9] and [14]), the bilinear form $\mathfrak{a}$ is coercive with respect to $\mathbf{H}^1_{\mathbf{0}}(\Omega)$; i.e., there exists $\alpha > 0$ such that

$$\mathfrak{a}(\mathbf{u},\mathbf{u}) \geq \alpha \|\mathbf{u}\|^2_{1,\Omega} \quad \forall \mathbf{u} \in \mathbf{H}^1_{\mathbf{0}}(\Omega). \tag{2.3}$$

The coercivity constant α depends only on the diameter of Ω. The bilinear form $\mathfrak{b}$ fulfills the inf-sup condition [10, Lemma 3.2]

$$\inf_{0\neq p\in \mathrm{L}^2_0(\Omega)} \sup_{0\neq \mathbf{u}\in \mathbf{H}^1_{\mathbf{0}}(\Omega)} \frac{\mathfrak{b}(\mathbf{u},p)}{\|\mathbf{u}\|_{1,\Omega}\,\|p\|_{0,\Omega}} \geq \beta > 0. \tag{2.4}$$

It is well known from the framework of mixed variational problems (cf. [10]) that coercivity (2.3) and stability (2.4) are sufficient conditions for the unique solvability of problem (2.1). If the solution has additional smoothness properties, i.e., $(\mathbf{u}, p) \in$

$\big(\mathbf{H}^1_{\mathbf{0}}(\Omega) \times \mathrm{L}^2_0(\Omega)\big) \cap \big(\mathbf{H}^2(\Omega) \times \mathrm{H}^1(\Omega)\big)$, then (cf. [21]) there exists a constant C_{reg} such that

$$\big\|\mathbf{u}\big\|_{2,\Omega} + \big\|p\big\|_{1,\Omega} \leq C_{\mathrm{reg}} \big\|\mathbf{f}\big\|_{0,\Omega}. \tag{2.5}$$

We recall the approximation of the weak solution by the classical mini element (see, e.g., [4]). Its basis is the subdivision of the physical domain Ω into simplices, which can be performed in an exact way only if Ω is a polyhedron. In the general case, Ω needs to be approximated by a polyhedral domain $\Omega_{\mathcal{T}}$. Let $\mathcal{T} := \{T_i : 1 \leq i \leq N\}$ be a subdivision of $\Omega_{\mathcal{T}}$ consisting of (closed) simplices. The mesh size of $\mathcal{T}$ is denoted by $h := \max_{T \in \mathcal{T}} \mathrm{diam}\big(T\big)$. Any two different simplices are supposed to either be disjoint or to share exactly either one face or one side or one vertex. We will refer to Θ as the set of vertices of $\mathcal{T}$ and to $\partial\Theta := \Theta \cap \partial\Omega_{\mathcal{T}}$ as the set of boundary vertices. Furthermore, $\mathcal{T}$ is assumed to be shape regular; i.e., there exists $\rho > 0$ such that

$$\rho_T := \frac{\mathrm{diam}\big(B_T\big)}{\mathrm{diam}\big(T\big)} \geq \rho \quad \forall T \in \mathcal{T}, \tag{2.6}$$

where B_T denotes the largest ball contained in T. Based on the triangulation $\mathcal{T}$ we define the space of continuous piecewise affine functions

$$S_{\mathcal{T}} := \big\{ v \in C^0\big(\overline{\Omega_{\mathcal{T}}}\big) \mid \forall T \in \mathcal{T} : v|_T \in \mathbb{P}_1 \big\}. \tag{2.7}$$

In order to fulfill the discrete analogue of the inf-sup condition (2.4) the velocity space has to be enriched by simplex bubble functions, i.e.,

$$B_{\mathcal{T}} := \mathrm{span}\,\{\psi_T : T \in \mathcal{T}\}, \quad \psi_T := (d+1)^{d+1} \prod_{\mathbf{y} \in V(T)} \lambda_{\mathbf{y}}, \tag{2.8}$$

where $V(T)$ denotes the set of vertices of a simplex T and $\lambda_{\mathbf{y}}$, $\mathbf{y} \in V(T)$, its barycentric coordinates. The unconstrained mini element space on $\mathcal{T}$ is given by

$$\mathbf{X}_{\mathcal{T}} \times \mathrm{M}_{\mathcal{T}} := \big(\mathbf{S}_{\mathcal{T}} \oplus \mathbf{B}_{\mathcal{T}}\big) \times S_{\mathcal{T}}, \tag{2.9}$$

where bold letters mark vector-valued spaces. For problems with a homogeneous Dirichlet boundary condition, the mini element space is given by

$$\mathbf{X}^{\mathbf{0}}_{\mathcal{T}} \times \mathrm{M}_{\mathcal{T}} := \big(\underbrace{\{\mathbf{v} \in \mathbf{S}_{\mathcal{T}} \mid \mathbf{v}|_{\partial\Theta} = \mathbf{0}\}}_{\{\mathbf{v} \in \mathbf{S}_{\mathcal{T}} \,|\, \mathbf{v}|_{\partial\Omega_{\mathcal{T}}} = 0\}} \oplus \mathbf{B}_{\mathcal{T}}\big) \times S_{\mathcal{T}}. \tag{2.10}$$

If $\Omega = \Omega_{\mathcal{T}}$, then the mini element space $\mathbf{X}^{\mathbf{0}}_{\mathcal{T}} \times \mathrm{M}_{\mathcal{T}}$ is conforming, i.e., $\mathbf{X}^{\mathbf{0}}_{\mathcal{T}} \subseteq \mathbf{H}^1_{\mathbf{0}}(\Omega)$. A pair $(\mathbf{u}, p) \in \mathbf{X}^{\mathbf{0}}_{\mathcal{T}} \times \big(\mathrm{M}_{\mathcal{T}} \cap \mathrm{L}^2_0(\Omega)\big)$ is called the mini element approximation if it fulfills the discrete variational system

$$\begin{aligned} \mathfrak{a}(\mathbf{u}, \mathbf{v}) + \mathfrak{b}(\mathbf{v}, p) &= \langle \mathbf{f}, \mathbf{v} \rangle_{0,\Omega} \quad && \forall \mathbf{v} \in \mathbf{X}^{\mathbf{0}}_{\mathcal{T}}, \\ \mathfrak{b}(\mathbf{u}, q) &= 0 && \forall q \in \mathrm{M}_{\mathcal{T}} \cap \mathrm{L}^2_0(\Omega). \end{aligned} \tag{2.11}$$

It is well known that, if the continuous solution satisfies $(\mathbf{u}^*, p^*) \in \mathbf{H}^{1+r}(\Omega) \times \mathrm{H}^r(\Omega)$ for some $r \in (\frac{1}{2}, 1]$, the resulting method fulfills the following a priori error estimate:

$$\big\|\mathbf{u}^* - \mathbf{u}\big\|_{1,\Omega} + \big\|p^* - p\big\|_{0,\Omega} \leq C h^r \big\|\mathbf{f}\big\|_{1-r,\Omega}, \tag{2.12}$$

where $C > 0$ is a constant that is independent of h, $\mathbf{u}^*$, and p^*. As already mentioned in the introduction, estimate (2.12) indeed reflects the error but not necessarily the computational effort, namely the dimension of the finite element space. Our focus is on problems with different scales in the geometry; i.e., the domain contains parts that can be resolved by coarse meshes and (a huge number of) small geometric details. The standard (domain resolving) mini element has two disadvantages for problems of this type:

1. In practice, one is often interested in a moderate accuracy that cannot be achieved at a moderate effort if the mesh has very fine parts in order to resolve the geometry.
2. The mesh density of coarse shape regular triangulations of complicated domains is determined by the geometry and *not* by the smoothness properties of the solution.

The composite mini element allows a flexible handling of multiple scales in the geometry and coarse mesh computations even on very complicated domains.

3. The composite mini element. In this section we define a new mixed finite element for the Stokes equations, the composite mini element (CME). It decouples the minimal space dimension of the approximation space from the domain geometry. In the classical finite element methods this coupling is due to the fact that the boundary condition has to be incorporated into the space, which usually leads to boundary concentrated meshes. The simple idea is now *not* to use every vertex of the mesh as a degree of freedom, as is usually done, but to assign degrees of freedom only to nodal points at a proper distance to the boundary and "smear" the shape functions to the boundary by taking the Dirichlet condition into account. To increase flexibility we will use an overlapping triangulation $\mathcal{T}$, i.e., the condition[1]

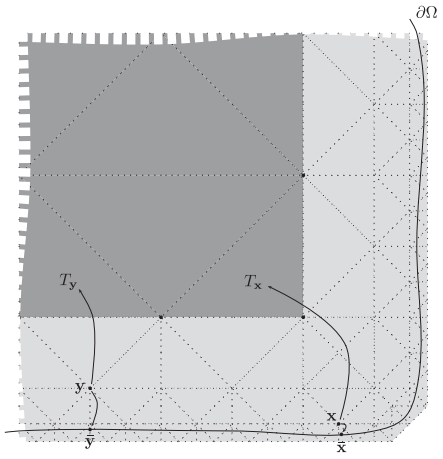
$$\Omega \subseteq \Omega_{\mathcal{T}} := \operatorname{int}\Big(\bigcup_{\tau\in\mathcal{T}} \tau\Big).$$

We define shape functions depending only on a subset of nodes of $\mathcal{T}$; the remaining nodes are *slave nodes*. The latter are used to adapt the shape of the CME functions to the complicated zero boundary. We split the triangulation into two disjoint submeshes, a coarse (inner) part $\mathcal{T}^{\mathrm{dof}}$ and a possibly refined (boundary) part $\mathcal{T}^{\mathrm{slave}}$ (see Figure 1.2):

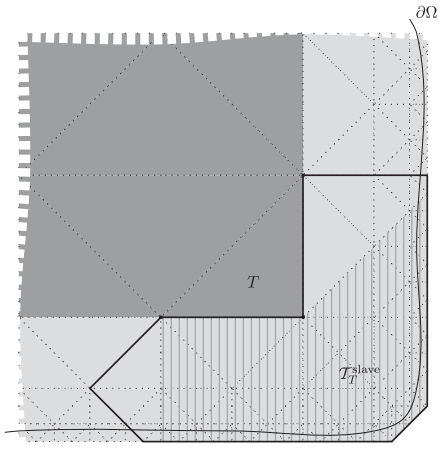
$$\mathcal{T} = \mathcal{T}^{\mathrm{dof}} \cup \mathcal{T}^{\mathrm{slave}}, \quad \emptyset \neq \Omega_{\mathcal{T}^{\mathrm{dof}}} := \bigcup_{T\in\mathcal{T}^{\mathrm{dof}}} T \subseteq \Omega.$$

Accordingly, the set of vertices Θ is decomposed into $\Theta = \Theta^{\mathrm{dof}} \cup \Theta^{\mathrm{slave}}$, where Θ^{dof} is the set of vertices of $\mathcal{T}^{\mathrm{dof}}$ and $\Theta^{\mathrm{slave}} := \Theta \setminus \Theta^{\mathrm{dof}}$. The common vertices of $\mathcal{T}^{\mathrm{dof}}$ and $\mathcal{T}^{\mathrm{slave}}$ have been put into Θ^{dof}, and the degrees of freedom will be associated with Θ^{dof}. We refer to the vertices in Θ^{slave} as slave nodes since later the values therein are defined via extension from the inner degrees of freedom toward the boundary conditions. This approach reduces the number of unknowns in the finite element discretization of the problem to the order $\sharp\mathcal{T}^{\mathrm{dof}}$ compared to $\sharp\mathcal{T}$. Thus, the local mesh refinements located in the slave part of the mesh do not affect the space dimension. This technique will turn out to be very efficient for problems on domains with rough outer boundaries

[1] This inclusion condition can be relaxed in the sense that triangulations are allowed if the errors arising from the domain approximation are negligible.



(a) The choice of closest boundary point and closest inner simplex.



(b) Inner simplex T with its domain of influence $\mathcal{T}_T^{\text{slave}}$ (black bordered). The hatched subset depicts $\hat{\mathcal{T}}_T^{\text{slave}}$.

FIG. 3.1. *Illustration of a part of a composite mesh $\mathcal{T}$ with dark-shaded inner part $\mathcal{T}^{\text{dof}}$.*

and (or) a moderate number of holes. The crucial point in the definition of the CME space is the choice of suitable extension operators for the pressure and for the velocity.

3.1. Construction of extension operators for finite elements. First, we assign a closest boundary point $\bar{\mathbf{x}} \in \partial\Omega$ and a closest inner simplex $T_{\mathbf{x}} \in \mathcal{T}^{\text{dof}}$ to every slave node $\mathbf{x} \in \Theta^{\text{slave}}$ by

$$\mathbf{x} \mapsto \bar{\mathbf{x}} \in \arg\inf_{\mathbf{y}\in\partial\Omega} \operatorname{dist}(\mathbf{x},\mathbf{y}), \quad \mathbf{x} \mapsto T_{\mathbf{x}} \in \arg\min_{T\in\mathcal{T}^{\text{dof}}} \operatorname{dist}(\mathbf{x},T). \tag{3.1}$$

Both mappings are illustrated in Figure 3.1. They can easily be computed in a preprocessing step, for instance, during the assembling of the triangulation (cf. [11], [16]).

3.1.1. Pressure extension. Pressure test functions $q \in S_{\mathcal{T}^{\text{dof}}}$, defined on the inner mesh $\mathcal{T}^{\text{dof}}$, are extended to $\Omega_{\mathcal{T}}$ by

$$\mathcal{E}^{\text{p}} : S_{\mathcal{T}^{\text{dof}}} \to S_{\mathcal{T}}, \quad \big(\mathcal{E}^{\text{p}} q\big)(\mathbf{x}) := \begin{cases} q(\mathbf{x}), & \mathbf{x} \in \Theta^{\text{dof}}, \\ q_{T_{\mathbf{x}}}(\mathbf{x}), & \mathbf{x} \in \Theta^{\text{slave}}, \end{cases} \tag{3.2}$$

where q_T denotes the affine extension (extension by itself) of $q|_T$ to $\mathbb{R}^d$. The operator $\mathcal{E}^{\text{p}}$ is well defined since its image is supposed to be a subspace of $S_{\mathcal{T}}$.

3.1.2. Velocity extension. We will use a modification of $\mathcal{E}^{\text{p}}$ for the extension of the velocity which takes into account the homogeneous Dirichlet boundary condition (cf. [17])

$$\boldsymbol{\mathcal{E}}^{\mathbf{0}} : \mathbf{S}_{\mathcal{T}^{\text{dof}}} \to \mathbf{S}_{\mathcal{T}}, \quad \boldsymbol{\mathcal{E}}^{\mathbf{0}}\mathbf{u}(\mathbf{x}) := \begin{cases} \mathbf{u}(\mathbf{x}) & \forall \mathbf{x} \in \Theta^{\text{dof}}, \\ \mathbf{u}_{T_{\mathbf{x}}}(\mathbf{x}) - \mathbf{u}_{T_{\mathbf{x}}}(\bar{\mathbf{x}}) & \forall \mathbf{x} \in \Theta^{\text{slave}}. \end{cases} \tag{3.3}$$

Note that $\big(\boldsymbol{\mathcal{E}}^{\mathbf{0}}\mathbf{u}\big)(\mathbf{x}) = 0$ if $\mathbf{x} \in \partial\Omega$ and that only the linear part of a mini element velocity field is extended. Using the mean value theorem, $\big(\boldsymbol{\mathcal{E}}^{\mathbf{0}}\mathbf{u}\big)(\mathbf{x})$ can be rewritten in the following form:

$$\big(\boldsymbol{\mathcal{E}}^{\mathbf{0}}\mathbf{u}\big)(\mathbf{x}) = (\nabla \mathbf{u}_{T_{\mathbf{x}}})(\mathbf{x} - \bar{\mathbf{x}}) \quad \forall \mathbf{x} \in \Theta^{\mathrm{slave}}, \tag{3.4}$$

where $\mathbf{u} = (u^1, \dots, u^d)^T$ and $\nabla \mathbf{u}_{T_{\mathbf{x}}}$ is the (constant) Jacobian matrix of $\mathbf{u}$ on $T_{\mathbf{x}}$.

3.2. Space definition. The CME space is defined as the image of the mini element space on $\mathcal{T}^{\mathrm{dof}}$ under the linear mapping $\boldsymbol{\mathcal{E}}^{\mathrm{CME}}$ that is composed of the previous extensions:

$$\boldsymbol{\mathcal{E}}^{\mathrm{CME}} : \mathbf{X}_{\mathcal{T}^{\mathrm{dof}}} \times \mathrm{M}_{\mathcal{T}^{\mathrm{dof}}} \to \mathbf{X}_{\mathcal{T}} \times \mathrm{M}_{\mathcal{T}}, \quad \big(\mathbf{u}^S + \mathbf{u}^B, p\big) \mapsto \big(\boldsymbol{\mathcal{E}}^{\mathbf{0}}\mathbf{u}^S + \mathbf{u}^B, \mathcal{E}^{\mathrm{p}} p\big). \tag{3.5}$$

Thereby, the bubble part $\mathbf{u}^B \in \mathbf{B}_{\mathcal{T}^{\mathrm{dof}}}$ of a velocity field $\mathbf{u} = \mathbf{u}^S + \mathbf{u}^B$, $\mathbf{u}^S \in \mathbf{S}_{\mathcal{T}^{\mathrm{dof}}}$, is simply extended by zero. The operator $\boldsymbol{\mathcal{E}}^{\mathrm{CME}}$ is injective, since functions are not changed on $\mathcal{T}^{\mathrm{dof}}$. If any two elements of $\mathbf{X}_{\mathcal{T}^{\mathrm{dof}}} \times \mathrm{M}_{\mathcal{T}^{\mathrm{dof}}}$ are different, so are their images. Finally, the CME space is defined by

$$\mathbf{X}_{\mathcal{T}}^{\mathrm{CME}} \times \mathrm{M}_{\mathcal{T}}^{\mathrm{CME}} := \boldsymbol{\mathcal{E}}^{\mathrm{CME}}\big(\mathbf{X}_{\mathcal{T}^{\mathrm{dof}}} \times \mathrm{M}_{\mathcal{T}^{\mathrm{dof}}}\big) \subseteq \mathbf{X}_{\mathcal{T}} \times \mathrm{M}_{\mathcal{T}}.$$

Note that, in general, the CME is nonconforming because the Dirichlet boundary condition is satisfied only in an approximate way. This nonconformity can be controlled in an a priori or, respectively, in an a posteriori way by the local mesh size in the near boundary zone $\mathcal{T}^{\mathrm{slave}}$. Note that there is no nonconformity arising from the pressure part of the space. A pair $(\mathbf{u}, p) \in \mathbf{X}_{\mathcal{T}}^{\mathrm{CME}} \times \big(\mathrm{M}_{\mathcal{T}}^{\mathrm{CME}} \cap \mathrm{L}_0^2(\Omega)\big)$ defines the CME approximation if it fulfills the discrete variational system

$$\begin{aligned} \mathfrak{a}(\mathbf{u}, \mathbf{v}) + \mathfrak{b}(\mathbf{v}, p) &= \langle \mathbf{f}, \mathbf{v} \rangle_{0,\Omega} && \forall \mathbf{v} \in \mathbf{X}_{\mathcal{T}}^{\mathrm{CME}}, \\ \mathfrak{b}(\mathbf{u}, q) &= 0 && \forall q \in \mathrm{M}_{\mathcal{T}}^{\mathrm{CME}} \cap \mathrm{L}_0^2(\Omega). \end{aligned} \tag{3.6}$$

4. A priori error analysis. In this section we will present the main theorem on the convergence of the CME method. Our results are based on the general mixed theory presented in [10] and [4]. The main steps are the investigation of the approximation properties as well as discrete coercivity and inf-sup stability.

4.1. Approximability. First, we show that $\mathbf{H}_{\mathbf{0}}^1(\Omega)$-functions can be approximated by the velocity part of the CME space. Usually, a piecewise affine interpolant $\mathcal{I}_{\mathcal{T}}$ with respect to the mesh $\mathcal{T}$ is used to prove this property. However, this is not possible in our situation because the simplices in $\mathcal{T}^{\mathrm{slave}}$ do not contain degrees of freedom. We will use the extensions of the affine interpolants $\mathcal{I}_{\mathcal{T}^{\mathrm{dof}}}$ on the inner mesh $\mathcal{T}^{\mathrm{dof}}$ instead. Therefore we may apply standard interpolation results on $\mathcal{T}^{\mathrm{dof}}$. The approximation quality of the proposed method will depend on the choice of $\mathcal{T}^{\mathrm{dof}}$ and the following two constants:

$$C_1^{\mathcal{T}} := \max_{t \in \mathcal{T}^{\mathrm{slave}}} \frac{\mathrm{dist}(t, \partial\Omega)}{\mathrm{diam}(t)} \quad \text{and} \quad C_2^{\mathcal{T}} := \max_{\mathbf{x} \in \Theta^{\mathrm{slave}}} \frac{\mathrm{dist}(\mathbf{x}, T_{\mathbf{x}})}{\mathrm{diam}(T_{\mathbf{x}})} \tag{4.1}$$

will enter the convergence estimates. We suppose them to be moderately bounded. An algorithm for the generation of meshes such that (4.1) holds with constants of moderate size is presented in [16]. It is well known (cf. [5, Theorem 16.1]) that, for

an arbitrary simplex $T \subseteq \mathbb{R}^d$, $d = 2, 3$, with regularity constant ρ_T, there exists a constant $C_{\mathrm{int}} = C_{\mathrm{int}}(m, p, d)$ such that

$$\big|u - \mathcal{I}_{\mathrm{T}} u\big|_{m,p,T} \leq \frac{C_{\mathrm{int}}}{\rho_T^m} \operatorname{diam}\big(T\big)^{\left(2-\frac{d}{2}+\frac{d}{p}-m\right)} \big|u\big|_{2,T} \quad \forall u \in \mathrm{H}^2(T), \tag{4.2}$$

where $m \in \{0, 1\}$ and $1 \leq p \leq \infty$, provided $\mathrm{W}_p^m(\Omega) \subseteq \mathrm{H}^2(\Omega)$.[2] $\mathcal{I}_{\mathrm{T}} u \in \mathbb{P}_1(\mathbb{R}^d)$ denotes the linear interpolant of u in the vertices of T. The subsequent lemma analyzes the approximation quality of $\mathcal{I}_{\mathrm{T}} u$ in a neighborhood of T. A basic tool of the proof is an inverse estimate of the form

$$\big|q\big|_{m,p,T} \leq \left(\frac{2}{\rho_T}\right)^m h_T^{\left(\frac{d}{p}-m\right)} \big\|q\big\|_{0,\infty,T} \quad \forall q \in \mathbb{P}_1(\mathbb{R}^d), \tag{4.3}$$

where $m \in \{0, 1\}$ and $p \in \mathbb{N} \cup \{\infty\}$.

LEMMA 4.1 (neighborhood property).[3] *Let T be an arbitrary simplex with regularity constant ρ_T, and let t be an arbitrary simplex with regularity constant ρ_t. Let the ratio of the diameters of t and T be denoted by C_{size} and the distance between T and t relative to the size of T by C_{dist}, i.e.,*

$$C_{\mathrm{size}} := \frac{\operatorname{diam}\big(t\big)}{\operatorname{diam}\big(T\big)} \quad \textit{and} \quad C_{\mathrm{dist}} := \frac{\operatorname{dist}(t, T)}{\operatorname{diam}\big(T\big)}.$$

Furthermore, let $u \in H^2(\operatorname{conv}\big(T \cup t\big))$, and let $\mathcal{I}_{\mathrm{T}} u \in \mathbb{P}_1(\mathbb{R}^d)$ denote the affine interpolation of u at the vertices of T. Then, for $m \in \{0, 1\}$ and $1 \leq p \leq \infty$, provided $W_p^m(\Omega) \subseteq H^2(\Omega)$, there exists a constant $C_{\mathrm{np}} = C_{\mathrm{np}}(C_{\mathrm{int}}, d, C_{\mathrm{size}}, C_{\mathrm{dist}}, \rho_t, \rho_T) > 0$ such that

$$\big|u - \mathcal{I}_{\mathrm{T}} u\big|_{m,p,t} \leq C_{\mathrm{np}} \operatorname{diam}\big(T\big)^{\left(2-\frac{d}{2}\right)} \operatorname{diam}\big(t\big)^{\left(\frac{d}{p}-m\right)} \big|u\big|_{2,\operatorname{conv}\left(T\cup t\right)}.$$

Proof. Let $\mathcal{I}_{\mathrm{t}} u \in \mathbb{P}_1(\mathbb{R}^d)$ denote the affine interpolation of u at the vertices of t. We define $h_t := \operatorname{diam}\big(t\big)$ and $h_T := \operatorname{diam}\big(T\big)$. The use of the triangle inequality, (4.2), and (4.3) leads to

$$\begin{aligned} \big|u - \mathcal{I}_{\mathrm{T}} u\big|_{m,p,t} &\leq \big|u - \mathcal{I}_{\mathrm{t}} u\big|_{m,p,t} + \big|\mathcal{I}_{\mathrm{t}} u - \mathcal{I}_{\mathrm{T}} u\big|_{m,p,t} \\ &\leq \frac{C_{\mathrm{int}}}{\rho_t^m} h_t^{\left(2-\frac{d}{2}+\frac{d}{p}-m\right)} \big|u\big|_{2,t} + \left(\frac{2}{\rho_t}\right)^m h_t^{\left(\frac{d}{p}-m\right)} \big\|\mathcal{I}_{\mathrm{t}} u - \mathcal{I}_{\mathrm{T}} u\big\|_{0,\infty,t}. \end{aligned} \tag{4.4}$$

Note that $\big\|\mathcal{I}_{\mathrm{t}} u - \mathcal{I}_{\mathrm{T}} u\big\|_{0,\infty,t} = \max_{\mathbf{x}\in V(t)} \big|\mathcal{I}_{\mathrm{t}} u(\mathbf{x}) - \mathcal{I}_{\mathrm{T}} u(\mathbf{x})\big|$. We will relate the interpolates with respect to T and t by constructing a simplex τ that contains an arbitrary but fixed $\mathbf{x} \in V(t)$ as a vertex, while the other vertices are taken from $V(T)$. More precisely, we chose τ out of the $d + 1$ simplices collected in the set

$$\Lambda := \big\{\tau \mid \tau \text{ is a simplex, } \mathbf{x} \in V(\tau),\ V(\tau) \setminus \{\mathbf{x}\} \subseteq V(T)\big\}.$$

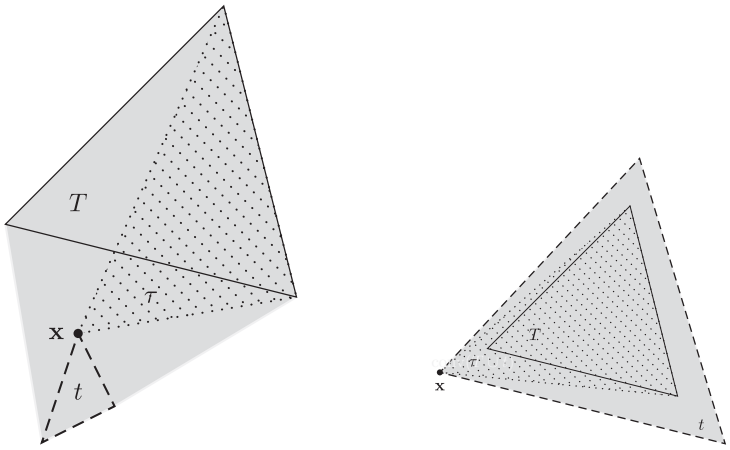
There is at least one $\tau \in \Lambda$ (cf. Figure 4.1) that fulfills the inequality[4]

$$\big|\tau \cap T\big| \geq \frac{1}{d+1} \big|T\big|. \tag{4.5}$$

[2] The condition $\mathrm{W}_p^m(\Omega) \subseteq \mathrm{H}^2(\Omega)$ restricts the choices of m and p depending on the dimension d. The combinations of m and p that will be useful later ($(m, p) \in \{(0, 2), (0, \infty), (1, 2)\}$) are allowed in two as well as three dimensions.

[3] A less general two-dimensional version of this lemma has already been given in [17].

[4] Inequality (4.5) is sharp if T is a regular simplex and $\mathbf{x}$ its midpoint.



(a) $t \cap T = \emptyset$, $C_{\mathrm{dist}} \approx C_{\mathrm{size}} \approx \frac{1}{3}$, $t, T \subsetneq \mathrm{conv}(T \cup t)$.

(b) $T \subseteq t$, $C_{\mathrm{dist}} = 0$, $C_{\mathrm{size}} \approx \frac{3}{2}$, $\mathrm{conv}(T \cup t) = t$.

FIG. 4.1. *Two typical situations for the simplices t and T from Lemma 4.1.*

Since $\tau \cap T$ is again a simplex, we can use Heron's formula to derive

$$\operatorname{diam}\big(B_\tau\big) \geq \operatorname{diam}\big(B_{\tau\cap T}\big) = \frac{d\big|\tau \cap T\big|}{\big|\partial(\tau \cap T)\big|} \geq \frac{1}{d+1}\frac{d\big|T\big|}{\big|\partial T\big|} = \frac{1}{d+1}\operatorname{diam}\big(B_T\big),$$

where, again, B_τ (resp., $B_{\tau\cap T}$) is the maximal ball contained in τ (resp., $\tau \cap T$). For this choice of τ we get

$$\operatorname{diam}\big(\tau\big) \leq (1 + C_{\mathrm{dist}} + C_{\mathrm{size}})h_T, \quad \rho_\tau \geq \frac{\rho_T}{(d+1)(1 + C_{\mathrm{dist}} + C_{\mathrm{size}})}. \tag{4.6}$$

For $\mathbf{y} \in V(\tau) \setminus \{\mathbf{x}\} = (V(\tau) \cap V(T))$ and a Taylor expansion argument, we get

$$\begin{aligned}
\big|\mathcal{I}_{\mathrm{t}}u(\mathbf{x}) - \mathcal{I}_{\mathrm{T}}u(\mathbf{x})\big| &= \big|\mathcal{I}_\tau u(\mathbf{x}) - \mathcal{I}_{\mathrm{T}}u(\mathbf{x})\big| \\
&= \big|\mathcal{I}_\tau u(\mathbf{y}) - \mathcal{I}_{\mathrm{T}}u(\mathbf{y}) + \nabla\left(\mathcal{I}_\tau u - \mathcal{I}_{\mathrm{T}}u\right)\cdot(\mathbf{x}-\mathbf{y})\big| \\
&\leq \big|\nabla\left(\mathcal{I}_\tau u - \mathcal{I}_{\mathrm{T}}u\right)\big|\operatorname{diam}\big(\tau\big) \overset{(4.6)}{\lesssim} \big|\nabla\left(\mathcal{I}_\tau u - \mathcal{I}_{\mathrm{T}}u\right)\big|\big|T\big|^{\frac{1}{2}}h_T^{\left(1-\frac{d}{2}\right)} \\
&\overset{(4.6),(4.5)}{\lesssim} h_T^{\left(1-\frac{d}{2}\right)}\big|\mathcal{I}_\tau u - \mathcal{I}_{\mathrm{T}}u\big|_{1,T\cap\tau} \lesssim h_T^{\left(1-\frac{d}{2}\right)}\left(\big|\mathcal{I}_\tau u - u\big|_{1,\tau} + \big|u - \mathcal{I}_{\mathrm{T}}u\big|_{1,T}\right) \\
&\overset{(4.2)}{\lesssim} h_T^{\left(1-\frac{d}{2}\right)}\left(\operatorname{diam}\big(\tau\big) + h_T\right)\big|u\big|_{2,\mathrm{conv}\left(T\cup\tau\right)} \overset{(4.6)}{\lesssim} h_T^{\left(2-\frac{d}{2}\right)}\big|u\big|_{2,\mathrm{conv}\left(T\cup t\right)}.
\end{aligned} \tag{4.7}$$

Plugging (4.7) into (4.4) finishes the proof. Devoting more effort to the estimation of the constants (see [15]) leads to

$$C_{\mathrm{np}} \leq \frac{4(d+1)^{\frac{3}{2}}C_{\mathrm{int}}}{\rho_t^m \rho_T^{\left(1+\frac{d}{2}\right)}}\left(C_{\mathrm{size}}^{\left(2-\frac{d}{2}\right)} + (1 + C_{\mathrm{dist}} + C_{\mathrm{size}})^3\right). \qquad \square$$

Next, we will show that an arbitrary $\mathbf{H}^2 \cap \mathbf{H}^1_{\mathbf{0}}(\Omega)$-function $\mathbf{u}$, which will be fixed throughout this section, can be approximated sufficiently well by $\boldsymbol{\mathcal{E}}^{\mathbf{0}}\left(\mathcal{I}_{\mathcal{T}^{\mathrm{dof}}}\mathbf{u}\right) \in \mathbf{X}_{\mathcal{T}}^{\mathrm{CME}}$, i.e., by the extension of the piecewise affine interpolation with respect to $\mathcal{T}^{\mathrm{dof}}$. Since in general $\Omega \subseteq \Omega_{\mathcal{T}}$, it will be useful to extend $\mathbf{u}$ to the larger domain Ω_T. It is known that, if Ω is bounded and Lipschitz, there exists a continuous, linear extension operator $\mathfrak{E} : \mathrm{H}^k(\Omega) \to \mathrm{H}^k(\mathbb{R}^d)$, $k \in \mathbb{N}_0$, such that

$$\forall u \in \mathrm{H}^k(\Omega): \quad \mathfrak{E}u|_{\Omega} = u \quad \text{and} \quad \left\|\mathfrak{E}u\right\|_{\mathrm{H}^k(\mathbb{R}^d)} \leq C_{\mathrm{ext}}\left\|u\right\|_{\mathrm{H}^k(\Omega)}, \tag{4.8}$$

with a constant C_{ext} depending only on k and Ω (cf. [20]). It is worth noting that, for domains containing a large number of holes and a possibly rough outer boundary, there exists an extension operator with moderately small norm C_{ext} under mild assumptions on the geometry. For all details, including the characterization of the class of domain geometries, we refer the reader to [18]. In the following we always identify $\mathbf{u}$ with its minimal extension $\mathfrak{E}\mathbf{u}$ without mentioning this explicitly. For $T \in \mathcal{T}^{\mathrm{dof}}$ the approximation results are obvious corollaries of the classical interpolation estimate (4.2). We will concentrate on the boundary region $\mathcal{T}^{\mathrm{slave}}$. Its elements can be grouped according to their closest inner simplices. For $T \in \mathcal{T}^{\mathrm{dof}}$ we define the set of slave simplices by

$$\mathcal{T}_T^{\mathrm{slave}} := \{t \in \mathcal{T}^{\mathrm{slave}} \mid \exists \mathbf{x} \in V(t) \ : \ T_{\mathbf{x}} = T\} \subseteq \mathcal{T}^{\mathrm{slave}}.$$

$\mathcal{T}_T^{\mathrm{slave}}$ is empty for all simplices that do not intersect $\partial\Omega_{\mathcal{T}^{\mathrm{dof}}}$. A simplex $T \in \mathcal{T}^{\mathrm{dof}}$ with $\mathcal{T}_T^{\mathrm{slave}} \neq \emptyset$ is called an *extrapolation simplex* and $\mathcal{T}_T^{\mathrm{slave}}$ its mesh of influence. Additionally, we fix the subsets of $\mathcal{T}^{\mathrm{slave}}$ which are exclusively influenced by a single element $T \in \mathcal{T}^{\mathrm{dof}}$ by

$$\hat{\mathcal{T}}_T^{\mathrm{slave}} := \left\{t \in \mathcal{T}_T^{\mathrm{slave}} \mid \forall \mathbf{x} \in V(t) \ : \ T_{\mathbf{x}} = T\right\} \subseteq \mathcal{T}_T^{\mathrm{slave}}.$$

An example is depicted in Figure 3.1(b). As a first step for the $\mathbf{H}^1$ approximation result we prove a local $\mathbf{L}^\infty$-estimate. Due to the extension $\boldsymbol{\mathcal{E}}^{\mathbf{0}}$ the estimate with respect to a slave simplex t cannot be local in the sense that it depends only on the $\mathbf{H}^2$-norm of $\mathbf{u}$ on t. Therefore we introduce neighborhoods of slave simplices

$$\omega_t := \bigcup_{T \in \mathcal{T}^{\mathrm{dof}} \,:\, t \in \mathcal{T}_T^{\mathrm{slave}}} \left(T \cup \bigcup_{\tau \in \mathcal{T}_T^{\mathrm{slave}}} \tau\right), \quad t \in \mathcal{T}^{\mathrm{slave}},$$

and neighborhoods of extrapolation simplices

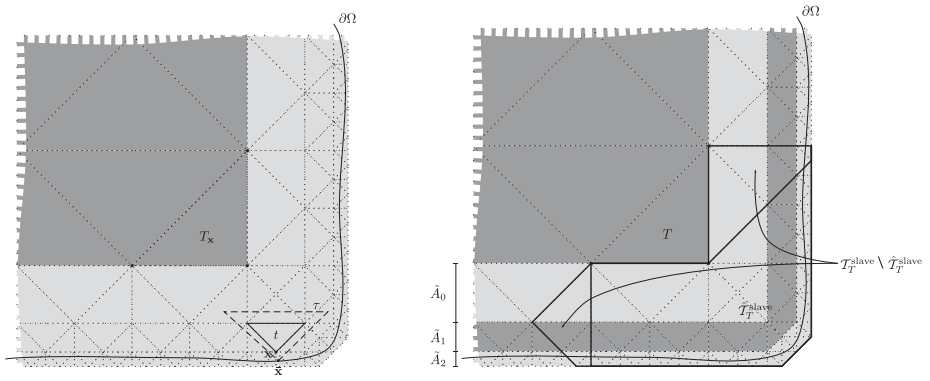
$$\omega_T := \bigcup_{t \in \mathcal{T}_T^{\mathrm{slave}}} \omega_t, \quad T \in \mathcal{T}^{\mathrm{dof}}.$$

LEMMA 4.2. *There is a constant $C = C(C_{\mathrm{int}}, \rho, C_1^{\mathcal{T}}, C_2^{\mathcal{T}}, d) > 0$ that does not depend on $\mathbf{u}$ such that*

$$\left\|\mathbf{u} - \boldsymbol{\mathcal{E}}^{\mathbf{0}}\mathcal{I}_{\mathcal{T}^{\mathrm{dof}}}\mathbf{u}\right\|_{0,\infty,t} \leq C\left[\left(\mathrm{diam}(t)^{(d-1)}h\right)^{\frac{1}{d}}\right]^{\left(2-\frac{d}{2}\right)} \left|\mathbf{u}\right|_{2,\omega_T} \quad \forall t \in \mathcal{T}^{\mathrm{slave}}.$$

Proof. For $t \in \mathcal{T}^{\mathrm{slave}}$ let $h_t := \mathrm{diam}(t)$ and $\mathcal{I}_{\mathrm{t}}\mathbf{u}$ denote the affine interpolant of $\mathbf{u}$ at the vertices of t. Then

$$\left\|\mathbf{u} - \boldsymbol{\mathcal{E}}^{\mathbf{0}}\mathcal{I}_{\mathcal{T}^{\mathrm{dof}}}\mathbf{u}\right\|_{\infty,t} \leq \left\|\mathbf{u} - \mathcal{I}_{\mathrm{t}}\mathbf{u}\right\|_{\infty,t} + \left\|\mathcal{I}_{\mathrm{t}}\mathbf{u} - \boldsymbol{\mathcal{E}}^{\mathbf{0}}\mathcal{I}_{\mathcal{T}^{\mathrm{dof}}}\mathbf{u}\right\|_{\infty,t}. \tag{4.9}$$



(a) Illustration of a slave node $\mathbf{x}$ and the simplex $\tau = \tau_{\mathbf{x}}$ from the proof of Lemma 4.2 in $\mathbb{R}^2$.

(b) The boundary regions $\tilde{A}_i$.

FIG. 4.2. *Some illustrations for the proofs of Lemma* 4.2 *and Theorem* 4.4.

A bound of the first term in (4.9) is given by (4.2). It remains to bound the second term in (4.9) or, equivalently, $\big|\mathbf{u}(\mathbf{x}) - \boldsymbol{\mathcal{E}}^{\mathbf{0}}\mathcal{I}_{\mathcal{T}^{\mathrm{dof}}}\mathbf{u}(\mathbf{x})\big|$ for $\mathbf{x} \in V(t)$. We construct a simplex τ (that does not necessarily belong to $\mathcal{T}$ (see also Figure 4.2(a))) with the following properties:

1. $\mathbf{x} \in \tau$;
2. $\bar{\mathbf{x}}$ is a vertex of τ;
3. $h_\tau := \operatorname{diam}(\tau) \in \mathcal{O}(h_t(\frac{h}{h_t})^{\frac{1}{d}})$, $\rho_\tau \geq \rho$, and $\tau \subseteq \omega_t$.

Due to (2.6) and (4.1) such a simplex always exists. The choice $h_\tau \approx h_t(\frac{h}{h_t})^{\frac{1}{d}}$ is made in order to minimize the bound of the pointwise error (see (4.11) in this proof). Let the closest inner simplex according to $\mathbf{x}$ be denoted by $T_{\mathbf{x}}$, and let its diameter be denoted by $h_{T_{\mathbf{x}}} := \operatorname{diam}(T_{\mathbf{x}})$. Let $\mathcal{I}_\tau$ and $\mathcal{I}_{\mathrm{T}_{\mathbf{x}}}$ denote the affine interpolation operators corresponding to τ and $T_{\mathbf{x}}$. Then we get

$$
\begin{aligned}
\big|\boldsymbol{\mathcal{E}}^{\mathbf{0}}\mathcal{I}_{\mathcal{T}^{\mathrm{dof}}}\mathbf{u}(\mathbf{x}) - \mathbf{u}(\mathbf{x})\big| &\overset{(3.3)}{=} \big|\nabla\mathcal{I}_{\mathrm{T}_{\mathbf{x}}}\mathbf{u}\cdot(\mathbf{x}-\bar{\mathbf{x}}) \underbrace{-\overbrace{(\mathcal{I}_\tau\mathbf{u}(\mathbf{x}) - \mathcal{I}_\tau\mathbf{u}(\bar{\mathbf{x}}))}^{=\nabla(\mathcal{I}_\tau\mathbf{u})\cdot(\mathbf{x}-\bar{\mathbf{x}})} + \mathcal{I}_\tau\mathbf{u}(\mathbf{x})}_{=0} - \mathbf{u}(\mathbf{x})\big| \\
&\leq \big|\nabla\left(\mathcal{I}_{\mathrm{T}_{\mathbf{x}}}\mathbf{u} - \mathcal{I}_\tau\mathbf{u}\right)\cdot(\mathbf{x}-\bar{\mathbf{x}})\big| + \big|\mathbf{u}(\mathbf{x}) - \mathcal{I}_\tau\mathbf{u}(\mathbf{x})\big| \qquad (4.10)\\
&\overset{(4.1),(4.2)}{\lesssim} h_t\big\|\mathcal{I}_{\mathrm{T}_{\mathbf{x}}}\mathbf{u} - \mathcal{I}_\tau\mathbf{u}\big\|_{1,\infty,\tau} + h_\tau^{\left(2-\frac{d}{2}\right)}\big|\mathbf{u}\big|_{2,\tau} \\
&\overset{(4.3)}{\lesssim} \frac{h_t}{h_\tau}\big\|\mathcal{I}_{\mathrm{T}_{\mathbf{x}}}\mathbf{u} - \mathcal{I}_\tau\mathbf{u}\big\|_{0,\infty,\tau} + h_\tau^{\left(2-\frac{d}{2}\right)}\big|\mathbf{u}\big|_{2,\tau} \\
&\lesssim \frac{h_t}{h_\tau}\left(\big\|\mathcal{I}_{\mathrm{T}_{\mathbf{x}}}\mathbf{u} - \mathbf{u}\big\|_{0,\infty,\tau} + \big\|\mathbf{u} - \mathcal{I}_\tau\mathbf{u}\big\|_{0,\infty,\tau}\right) + h_\tau^{\left(2-\frac{d}{2}\right)}\big|\mathbf{u}\big|_{2,\tau} \\
&\overset{L4.1,(4.2)}{\lesssim} \left[\frac{h_t h_{T_{\mathbf{x}}}^{\left(2-\frac{d}{2}\right)}}{h_\tau} + h_t h_\tau^{\left(1-\frac{d}{2}\right)} + h_\tau^{\left(2-\frac{d}{2}\right)}\right]\big|\mathbf{u}\big|_{2,\mathrm{conv}\left(T\cup\tau\right)}. \qquad (4.11)
\end{aligned}
$$

The choice of the diameter of τ as in property 3 leads to the assertion. ∎

LEMMA 4.3. *Let $m \in \{0,1\}$. There is a constant $C = C(C_{\mathrm{int}}, \rho, C_1^{\mathcal{T}}, C_2^{\mathcal{T}}, d) > 0$ such that*

$$\left\|\mathbf{u} - \boldsymbol{\mathcal{E}}^{\mathbf{0}}\mathcal{I}_{\mathcal{T}^{\mathrm{dof}}}\mathbf{u}\right\|_{m,t} \leq Ch^{\left(\frac{2}{d}-\frac{1}{2}\right)}\operatorname{diam}(t)^{\left(\frac{5}{2}-m-\frac{2}{d}\right)}\left|\mathbf{u}\right|_{2,\omega_t} \quad \forall t \in \mathcal{T}^{\mathrm{slave}}.$$

Proof. We separate the linear part of the error by the triangle inequality to estimate

$$\begin{aligned}\left|\mathbf{u} - \boldsymbol{\mathcal{E}}^{\mathbf{0}}\mathcal{I}_{\mathcal{T}^{\mathrm{dof}}}\mathbf{u}\right|_{m,t} &\leq \left|\boldsymbol{\mathcal{E}}^{\mathbf{0}}\mathcal{I}_{\mathcal{T}^{\mathrm{dof}}}\mathbf{u} - \mathcal{I}_{\mathrm{t}}(\mathbf{u})\right|_{m,t} + \left|\mathcal{I}_{\mathrm{t}}(\mathbf{u}) - \mathbf{u}\right|_{m,t}\\ &\overset{(4.3),(4.2)}{\lesssim} \operatorname{diam}(t)^{\left(\frac{d}{2}-m\right)}\left\|\boldsymbol{\mathcal{E}}^{\mathbf{0}}\mathcal{I}_{\mathcal{T}^{\mathrm{dof}}}\mathbf{u} - \mathcal{I}_{\mathrm{t}}(\mathbf{u})\right\|_{\infty,t} + \operatorname{diam}(t)^{(2-m)}\left|\mathbf{u}\right|_{2,t}.\end{aligned}$$

We apply Lemma 4.2 to estimate the first summand and obtain the assertion. The resulting constant C equals $\left(\frac{2}{\rho}\right)^m$ times the constant of Lemma 4.2. ∎

The error estimates in Lemmas 4.2 and 4.3 contain positive powers of $\operatorname{diam}(t)$. Hence, it is possible to localize the approximation error with respect to the elements of $\mathcal{T}^{\mathrm{slave}}$. Unfortunately, the dependence on the $\mathbf{H}^2$-norm of $\mathbf{u}$ is not local with respect to the fine-scale mesh. Thus it is not possible to sum up the local errors to get an optimal global estimate. A deeper analysis is needed to prove the following global approximation property of the velocity space.

THEOREM 4.4 (approximation property of $\mathbf{X}_{\mathcal{T}}^{\mathrm{CME}}$). *Let $m \in \{0,1\}$. There is a constant $C = C(C_{\mathrm{int}}, \rho, C_1^{\mathcal{T}}, C_2^{\mathcal{T}}, d, C_{\mathrm{ext}}) > 0$ which does not depend on h such that*

$$\left\|\mathbf{u} - \boldsymbol{\mathcal{E}}^{\mathbf{0}}\mathcal{I}_{\mathcal{T}^{\mathrm{dof}}}\mathbf{u}\right\|_{m,\Omega} \leq Ch^{(2-m)}\left|\mathbf{u}\right|_{2,\Omega}.$$

Proof. We start with a splitting of the error:

$$\left|\mathbf{u} - \boldsymbol{\mathcal{E}}^{\mathbf{0}}\mathcal{I}_{\mathcal{T}^{\mathrm{dof}}}\mathbf{u}\right|_{m,\Omega}^2 \leq \left|\mathbf{u} - \mathcal{I}_{\mathcal{T}}\mathbf{u}\right|_{m,\Omega}^2 + \sum_{T\in\mathcal{T}^{\mathrm{dof}}}\sum_{t\in\mathcal{T}_T^{\mathrm{slave}}}\left|\mathcal{I}_{\mathcal{T}}\mathbf{u} - \boldsymbol{\mathcal{E}}^{\mathbf{0}}\mathcal{I}_{\mathcal{T}^{\mathrm{dof}}}\mathbf{u}\right|_{m,t}^2. \tag{4.12}$$

As indicated before, the direct application of Lemma 4.3 leads to a suboptimal error bound in the $\mathbf{H}^1$-case. In fact, we use Lemma 4.3 only on those (few) simplices whose nodes are assigned to different inner simplices; i.e., there does not exist a $T \in \mathcal{T}^{\mathrm{dof}}$ such that $t \in \hat{\mathcal{T}}_T^{\mathrm{slave}}$. For all other simplices we will use a more local bound. Let $T \in \mathcal{T}^{\mathrm{dof}}$ and $t \in \hat{\mathcal{T}}_T^{\mathrm{slave}}$. By $\mathcal{I}_{\mathrm{t}}\mathbf{u} \subseteq \mathbb{P}_1(\mathbb{R}^d)$ we denote the affine interpolation of $\mathbf{u}$ at the vertices of t, $h_t := \operatorname{diam}(t)$. Then

$$\begin{aligned}\left|\boldsymbol{\mathcal{E}}^{\mathbf{0}}\mathcal{I}_{\mathcal{T}^{\mathrm{dof}}}\mathbf{u} - \mathcal{I}_{\mathcal{T}}\mathbf{u}\right|_{m,t} &= \left|\boldsymbol{\mathcal{E}}^{\mathbf{0}}\mathcal{I}_{\mathcal{T}^{\mathrm{dof}}}\mathbf{u} - \mathcal{I}_{\mathrm{t}}\mathbf{u}\right|_{m,t} \overset{(4.3)}{\lesssim} h_t^{\left(\frac{d}{2}-m\right)}\left\|\boldsymbol{\mathcal{E}}^{\mathbf{0}}\mathcal{I}_{\mathcal{T}^{\mathrm{dof}}}\mathbf{u} - \mathcal{I}_{\mathrm{t}}\mathbf{u}\right\|_{0,\infty,t}\\ &\overset{(3.3)}{=} h_t^{\left(\frac{d}{2}-m\right)}\max_{\mathbf{x}\in V(t)}\Big|\nabla\mathcal{I}_{\mathrm{T}_{\mathbf{x}}}\mathbf{u}\cdot(\mathbf{x}-\bar{\mathbf{x}}) - \underbrace{\left(\mathcal{I}_{\mathrm{t}}\mathbf{u}(\bar{\mathbf{x}}) + \nabla\mathcal{I}_{\mathrm{t}}\mathbf{u}\cdot(\mathbf{x}-\bar{\mathbf{x}})\right)}_{=\mathcal{I}_{\mathrm{t}}\mathbf{u}(\mathbf{x})}\Big|\\ &\overset{(4.1)}{\lesssim} h_t^{\left(1+\frac{d}{2}-m\right)}\left\|\nabla\left(\mathcal{I}_{\mathrm{T}_{\mathbf{x}}}\mathbf{u} - \mathcal{I}_{\mathrm{t}}\mathbf{u}\right)\right\|_{0,\infty,t} + h_t^{\left(\frac{d}{2}-m\right)}\max_{\mathbf{x}\in V(t)}\left|\mathcal{I}_{\mathrm{t}}\mathbf{u}(\bar{\mathbf{x}}) - \underbrace{\mathbf{u}(\bar{\mathbf{x}})}_{=0}\right|\\ &\overset{L4.1,(4.7)}{\lesssim} h_t^{(1-m)}\left|\mathcal{I}_{\mathrm{T}}\mathbf{u} - \mathcal{I}_{\mathrm{t}}\mathbf{u}\right|_{1,t} + h_t^{(2-m)}\left|\mathbf{u}\right|_{2,\tilde{t}},\end{aligned} \tag{4.13}$$

where $\tilde{t} := \operatorname{conv}\big(t \cup \{\bar{\mathbf{x}} \mid \mathbf{x} \in V(t)\}\big)$. We insert (4.13) into (4.12) and get

$$\begin{aligned}
&\sum_{t\in\mathcal{T}_T^{\mathrm{slave}}} \big|\mathcal{I}_{\mathcal{T}}\mathbf{u} - \boldsymbol{\mathcal{E}}^{\mathbf{0}}\mathcal{I}_{\mathcal{T}^{\mathrm{dof}}}\mathbf{u}\big|_{m,t}^2 \\
&\le \sum_{t\in\hat{\mathcal{T}}_T^{\mathrm{slave}}} \big|\mathcal{I}_{\mathcal{T}}\mathbf{u} - \boldsymbol{\mathcal{E}}^{\mathbf{0}}\mathcal{I}_{\mathcal{T}^{\mathrm{dof}}}\mathbf{u}\big|_{m,t}^2 + \sum_{t\in\mathcal{T}_T^{\mathrm{slave}}\setminus\hat{\mathcal{T}}_T^{\mathrm{slave}}} \big|\mathcal{I}_{\mathcal{T}}\mathbf{u} - \boldsymbol{\mathcal{E}}^{\mathbf{0}}\mathcal{I}_{\mathcal{T}^{\mathrm{dof}}}\mathbf{u}\big|_{m,t}^2 \\
&\overset{\substack{(4.13),\\ L4.3}}{\lesssim} \sum_{t\in\hat{\mathcal{T}}_T^{\mathrm{slave}}} h_t^{(2-2m)}\big|\mathcal{I}_{\mathrm{T}}\mathbf{u} - \mathcal{I}_{\mathrm{t}}\mathbf{u}\big|_{1,t}^2 + h_t^{(4-2m)}\big|\mathbf{u}\big|_{2,\tilde{t}}^2 + \sum_{t\in\mathcal{T}_T^{\mathrm{slave}}\setminus\hat{\mathcal{T}}_T^{\mathrm{slave}}} h^{\left(\frac{4}{d}-1\right)} h_t^{\left(5-2m-\frac{4}{d}\right)}\big|\mathbf{u}\big|_{2,\omega_t}^2 \\
&\le h^{2-2m}\Bigg(\underbrace{\big|\mathcal{I}_{\mathrm{T}}\mathbf{u} - \mathcal{I}_{\mathcal{T}}\mathbf{u}\big|_{1,\hat{\mathcal{T}}_T^{\mathrm{slave}}}^2}_{=:M_{1,T}} + \underbrace{\sum_{t\in\hat{\mathcal{T}}_T^{\mathrm{slave}}} h_t^2\big|\mathbf{u}\big|_{2,\tilde{t}}^2}_{=:M_{2,T}} + \underbrace{\Bigg(\sum_{t\in\mathcal{T}_T^{\mathrm{slave}}\setminus\hat{\mathcal{T}}_T^{\mathrm{slave}}} h_t^2\Bigg)\big|\mathbf{u}\big|_{2,\omega_T}^2}_{=:M_{3,T}} \Bigg).
\end{aligned}$$

If we could show the existence of constants $C_i > 0$, such that $M_{i,T} \le C_i h^2\big|\mathbf{u}\big|_{2,\omega_T}^2$ for all $i \in \{1,2,3\}$, then the proof is finished since

$$\sum_{T\in\mathcal{T}^{\mathrm{dof}}} \big|\mathbf{u}\big|_{2,\omega_T}^2 \le C(\rho, C_{\mathrm{ext}})\big|\mathbf{u}\big|_{2,\Omega}^2.$$

In case of $M_{1,T}$ this can be done in the following way:

$$M_{1,T} \le \big|\mathcal{I}_{\mathrm{T}}\mathbf{u} - \mathbf{u}\big|_{1,\hat{\mathcal{T}}_T^{\mathrm{slave}}}^2 + \big|\mathbf{u} - \mathcal{I}_{\mathcal{T}}\mathbf{u}\big|_{1,\hat{\mathcal{T}}_T^{\mathrm{slave}}}^2 \overset{L4.1,(4.2)}{\lesssim} h^2\big|\mathbf{u}\big|_{2,\operatorname{conv}\left(\hat{\mathcal{T}}_T^{\mathrm{slave}}\right)}^2.$$

For the estimation of $M_{2,T}$ we group simplices from $\mathcal{T}^{\mathrm{slave}}$ not only according to their extrapolation simplices but also according to their boundary distance. We define the sets

$$A_0 := \mathcal{T}^{\mathrm{slave}}, \quad A_k := \big\{t \in \mathcal{T}^{\mathrm{slave}} \mid \max_{\mathbf{x}\in t} \operatorname{dist}(\mathbf{x}, \partial\Omega) < 2^{-k}h\big\}, \quad k \in \mathbb{N},$$

and choose K such that $A_k = \emptyset$ for all $k > K$. Their disjoint versions are given by (cf. Figure 4.2(b))

$$\tilde{A}_k := A_k \setminus A_{k+1}, \quad 0 \le k \le K-1, \quad \tilde{A}_K := A_K. \tag{4.14}$$

The summation in $M_{2,T}$ can be resorted using (4.14):

$$\begin{aligned}
M_{2,T} = \sum_{t\in\hat{\mathcal{T}}_T^{\mathrm{slave}}} h_t^2\big|\mathbf{u}\big|_{2,\tilde{t}}^2 &\overset{(4.1)}{\lesssim} \sum_{k=0}^{K} \sum_{t\in\hat{\mathcal{T}}_T^{\mathrm{slave}}\cap\tilde{A}_k} 2^{-2k}h^2 \Bigg(\sum_{j=0}^{K}\sum_{\tau\in\tilde{A}_j} \big|\mathbf{u}\big|_{2,\tau\cap\tilde{t}}^2\Bigg) \\
&\le h^2\sum_{k=0}^{K} 2^{-2k}\Bigg(\sum_{j=0}^{K}\sum_{\tau\in\tilde{A}_j}\sum_{t\in\hat{\mathcal{T}}_T^{\mathrm{slave}}\cap\tilde{A}_k} 2^{-2k}\big|\mathbf{u}\big|_{2,\tau\cap\tilde{t}}^2\Bigg) \\
&\le h^2\sum_{k=0}^{K} 2^{-2k}\Bigg(\sum_{j=0}^{K}\sum_{\tau\in\tilde{A}_j} \sharp\tilde{A}_{k,\tau}\big|\mathbf{u}\big|_{2,\tau}^2\Bigg).
\end{aligned}$$

Here $\tilde{A}_{k,\tau} := \{t \in \hat{\mathcal{T}}_T^{\text{slave}} \cap \tilde{A}_k \mid \tau \cap \tilde{t} \neq \emptyset\}$. For $\tau \in \tilde{A}_j$ and $j > k$, $\tilde{A}_{k,\tau}$ is an empty set. In the other cases, $j \leq k$, its number of elements is bounded by a constant $C(C_1^{\mathcal{T}}, \rho, d)$ since

$$\operatorname{dist}(t_1, t_2) \leq 2 \cdot 2^{-k} h \quad \forall t_1, t_2 \in \tilde{A}_{k,\tau} \quad \text{and} \quad \big|t_1\big| \geq C(C_1^{\mathcal{T}}, \rho)(2^{-k}h)^d \quad \forall t_1 \in \tilde{A}_{k,\tau}.$$

Furthermore, $\tilde{A}_{k,\tau}$ is an empty set if $\tau \not\subseteq \omega_t$. This leads to

$$M_{2,T} \lesssim h^2 \sum_{k=0}^{K} 2^{-2k} \sum_{j=0}^{k} \big|\mathbf{u}\big|_{2,\omega_t}^2 = h^2 \Big(\underbrace{\sum_{k=0}^{K} 2^{-2k} k}_{\leq 2} \Big) \big|\mathbf{u}\big|_{2,\omega_T}^2.$$

It remains to estimate $M_{3,T}$. Let $N(T)$ denote the set of neighbors of $T \in \mathcal{T}^{\text{dof}}$ in $\mathcal{T}^{\text{dof}}$, i.e., $N(T) := \{\tau \in \mathcal{T}^{\text{dof}} : \bar{\tau} \cap \bar{T} \neq \emptyset\}$. Since $\mathcal{T}_T^{\text{slave}} \setminus \hat{\mathcal{T}}_T^{\text{slave}} \subseteq \bigcup_{\tau \in N(T)} \mathcal{T}_\tau^{\text{slave}}$ we get

(4.15)

$$\begin{aligned} M_{3,T} &\overset{(4.14)}{=} \Big(\sum_{t \in \mathcal{T}_T^{\text{slave}} \setminus \mathcal{T}_\tau^{\text{slave}}} h_t^2 \Big) \big|\mathbf{u}\big|_{2,\omega_t}^2 \leq \Big(\sum_{k=0}^{K} \sum_{\tau \in N(T)} \sum_{t \in \mathcal{T}_T^{\text{slave}} \cap \mathcal{T}_\tau^{\text{slave}} \cap \tilde{A}_k} 2^{-2k} h^2 \Big) \big|\mathbf{u}\big|_{2,\omega_T}^2 \\ &\leq h^2 \big|\mathbf{u}\big|_{2,\omega_T}^2 \Big(\sum_{\tau \in N(T)} \sum_{k=0}^{K} \#\big(\mathcal{T}_T^{\text{slave}} \cap \mathcal{T}_\tau^{\text{slave}} \cap \tilde{A}_k\big) 2^{-2k} \Big). \end{aligned}$$

A simplex t belongs to the set $\mathcal{T}_T^{\text{slave}} \cap \mathcal{T}_\tau^{\text{slave}}$, $\tau \in N(T)$, if it intersects the $(d-1)$-dimensional manifold on which the mapping

$$\mathbb{R}^d \ni \mathbf{x} \mapsto T_{\mathbf{x}} \in \operatorname{argmin}\{\operatorname{dist}(\mathbf{x}, T), \operatorname{dist}(\mathbf{x}, \tau)\}$$

has a jump (see also (3.1)). Therefore and due to (4.1) and shape regularity (2.6) the cardinality of $\mathcal{T}_T^{\text{slave}} \cap \mathcal{T}_\tau^{\text{slave}} \cap \tilde{A}_k$ satisfies

$$\#\big(\mathcal{T}_T^{\text{slave}} \cap \mathcal{T}_\tau^{\text{slave}} \cap \tilde{A}_k\big) \leq C(C_1^{\mathcal{T}}, C_2^{\mathcal{T}}, \rho, d)(2^k)^{d-2} \quad \forall k = 1, \ldots, K. \tag{4.16}$$

In two dimensions, the bounded number of simplices belonging to $\mathcal{T}_T^{\text{slave}} \cap \mathcal{T}^\tau \cap \tilde{A}_k$ is $\mathcal{O}(1)$. This is not true for $d = 3$; however, the growth in k is sufficiently slow to preserve the final estimate:

$$M_{3,T} \overset{(4.15),(4.16)}{\lesssim} \Big(\sum_{k=0}^{K} 2^{-k} \Big) h^2 \big|\mathbf{u}\big|_{2,\omega_t}^2 \leq 2h^2 \big|\mathbf{u}\big|_{2,\omega_T}^2. \qquad \square$$

The derivation of corresponding approximation results for an appropriate pressure function $p \in \mathrm{H}^1(\Omega)$ is less technical. However, the pointwise interpolation operator $\mathcal{I}_{\mathcal{T}^{\text{dof}}}$ which we used up to now is not well defined for H^1-functions and has to be replaced by a quasi-interpolation operator $\Pi_{\mathcal{T}} : \mathrm{H}^1(\Omega_{\mathcal{T}}) \to S_{\mathcal{T}}$ of Scott and Zhang[5] (see, e.g., [19]). Following [19, Theorem 4.1 and Corollary 4.1], the operator $\Pi_{\mathcal{T}}$ is bounded, and there exists a constant C_{qint} that depends only on ρ such that

$$\big\|p - \Pi_{\mathcal{T}} p\big\|_{m,t} \leq C_{\text{qint}} \operatorname{diam}(t)^{1-m} \big\|p\big\|_{1,\omega_t} \quad \forall t \in \mathcal{T}, \quad m \in \{0, 1\}. \tag{4.17}$$

[5]Since we use only the approximation property of this operator and not its special structure it is also possible to use the quasi-interpolation operator as introduced by Clément [7] or its modifications as described in [22] and [23].

As before we let $p \in \mathrm{H}^1(\Omega)$ be fixed and identify it with its extension $\mathfrak{E}p$ (cf. (4.8)). The error estimates with respect to the inner mesh $\mathcal{T}^{\mathrm{dof}}$ are given in (4.17), and we concentrate on the boundary part of the mesh.

THEOREM 4.5 (approximation property of $\mathrm{M}_{\mathcal{T}}^{\mathrm{CME}}$). *There is a constant* $C = C(C_{\mathrm{qint}}, \rho, C_1^{\mathcal{T}}, C_2^{\mathcal{T}}, d)$ *such that*

$$\|p - \mathcal{E}^{\mathrm{p}}\Pi_{\mathcal{T}^{\mathrm{dof}}} p\|_{0,t} \le Ch\|p\|_{1,\omega_t} \quad \forall t \in \mathcal{T}^{\mathrm{slave}}. \tag{4.18}$$

Furthermore, we have the global estimate

$$\|p - \mathcal{E}^{\mathrm{p}}\Pi_{\mathcal{T}^{\mathrm{dof}}} p\|_{0,\Omega} \le Ch\|p\|_{1,\Omega},$$

where the constant C *depends only on* C_{ext}, ρ, *and the constant of the local estimate.*

Proof. We start by estimating the local error. Let $t \in \mathcal{T}^{\mathrm{slave}}$. Then

$$\begin{aligned}\|p - \mathcal{E}^{\mathrm{p}}\Pi_{\mathcal{T}^{\mathrm{dof}}} p\|_{0,t} &\le \|p - \Pi_{\mathcal{T}} p\|_{0,t} + \|\Pi_{\mathcal{T}} p - \mathcal{E}^{\mathrm{p}}\Pi_{\mathcal{T}^{\mathrm{dof}}} p\|_{0,t} \\ &\overset{(4.17),(4.3)}{\lesssim} \operatorname{diam}(t)\|p\|_{1,\omega_t} + |t|^{\frac{1}{2}}\|\mathcal{I}_{\mathcal{T}} p - \mathcal{E}^{\mathrm{p}}\mathcal{I}_{\mathcal{T}^{\mathrm{dof}}} p\|_{\infty,t}.\end{aligned}$$

The infinity norm of the affine function equals the absolute value of $\big(\Pi_{\mathcal{T}} p - \mathcal{E}^{\mathrm{p}}\Pi_{\mathcal{T}^{\mathrm{dof}}} p\big)$ in some vertex $\mathbf{x} \in V(t)$, which can be estimated as follows:

$$\begin{aligned}\big|\Pi_{\mathcal{T}} p(\mathbf{x}) - \mathcal{E}^{\mathrm{p}}\Pi_{\mathcal{T}^{\mathrm{dof}}} p(\mathbf{x})\big| &= \big|\Pi_{\mathcal{T}} p(\mathbf{x}) - \Pi_{\mathrm{T}_{\mathbf{x}}} p(\mathbf{x})\big| \le \|\Pi_{\mathcal{T}} p - \Pi_{\mathrm{T}_{\mathbf{x}}} p\|_{\infty,t} \\ &\lesssim |t|^{-\frac{1}{2}}\|\Pi_{\mathcal{T}} p - \Pi_{\mathrm{T}_{\mathbf{x}}} p\|_{0,t} \overset{L4.1}{\lesssim} \operatorname{diam}(T_{\mathbf{x}})\,|t|^{-\frac{1}{2}}\|p\|_{1,\omega_t}.\end{aligned}$$

Hence, (4.18) is proved. The global estimate follows immediately, since the overlap of ω_t can be controlled in terms of ρ. ∎

The preceding approximation result is one basic ingredient of the error analysis in the next section. Note that there was no restriction concerning the *minimal* mesh size in $\mathcal{T}^{\mathrm{slave}}$, which will allow us to control the nonconformity in the space by adapting the local mesh size in $\mathcal{T}^{\mathrm{slave}}$ and without increasing the space dimension. Furthermore, it is straightforward to generalize Theorems 4.4 and 4.5 to the case of less regular solutions, say $\mathbf{u} \in \mathbf{H}^{1+r}(\Omega)$ and $p \in \mathrm{H}^r(\Omega)$ for $r \in (0,1]$, by using the interpolation theory of Sobolev spaces (cf. [3]).

4.2. Discrete stability and coercivity. In this section, we will investigate the unique solvability of the discrete CME systems. The stability proof makes use of the boundedness of the pressure extension $\mathcal{E}^{\mathrm{p}}$.

LEMMA 4.6. *There is a constant* $C_{\mathcal{E}^{\mathrm{p}}} = C_{\mathcal{E}^{\mathrm{p}}}(\rho, d)$ *such that*

$$\|\mathcal{E}^{\mathrm{p}} p\|_{0,\Omega} \le C_{\mathcal{E}^{\mathrm{p}}}\|p\|_{0,\Omega_{\mathcal{T}^{\mathrm{dof}}}} \quad \forall p \in M_{\mathcal{T}^{\mathrm{dof}}}.$$

Proof. For $p \in \mathrm{M}_{\mathcal{T}^{\mathrm{dof}}}$ there holds

$$\|\mathcal{E}^{\mathrm{p}} p\|_{0,\Omega}^2 \le \sum_{T\in\mathcal{T}^{\mathrm{dof}}} \|\mathcal{E}^{\mathrm{p}} p\|_{0,T}^2 + \sum_{t\in\mathcal{T}^{\mathrm{slave}}} \|\mathcal{E}^{\mathrm{p}} p\|_{0,t}^2 \overset{(4.3)}{\lesssim} \sum_{T\in\mathcal{T}^{\mathrm{dof}}} \|p\|_{0,T}^2 + \sum_{T\in\mathcal{T}^{\mathrm{slave}}} |t|\,\|\mathcal{E}^{\mathrm{p}} p\|_{\infty,t}^2. \tag{4.19}$$

Since $\mathcal{E}^{\mathrm{p}} p|_t$ takes its maximum in a vertex $\mathbf{x} \in V(t)$, there holds

$$\|\mathcal{E}^{\mathrm{p}} p\|_{\infty,t} \le \|p_{T_{\mathbf{x}}}\|_{\infty,t} \overset{L4.1}{\le} \left(1 + \frac{\operatorname{diam}(T_{\mathbf{x}})}{\operatorname{diam}(t)}\right)\|p_{T_{\mathbf{x}}}\|_{\infty,T_{\mathbf{x}}} \lesssim |T_{\mathbf{x}}|^{-\frac{1}{2}}\|p\|_{0,\omega_t\cap\Omega_{\mathcal{T}^{\mathrm{dof}}}},$$

where $p_{T_\mathbf{x}}$ denotes the extension of $p|_{T_\mathbf{x}}$ (by itself) to $\mathbb{R}^d$. We plug this into (4.19), which finishes the proof, since the resulting overlap is bounded by the maximal number of neighbors in $\mathcal{T}^{\mathrm{dof}}$ and therefore in terms of ρ. ∎

Now we can show that the CME is stable for the boundary conditions under consideration.

THEOREM 4.7 (stability). *$\mathbf{X}_{\mathcal{T}}^{\mathrm{CME}} \times M_{\mathcal{T}}^{\mathrm{CME}}$ is a stable pairing; i.e., there is a constant β^{CME} which depends only on d, ρ, and the discrete inf-sup constant of the mini element such that*

$$\inf_{p \in \mathrm{M}_{\mathcal{T}}^{\mathrm{CME}} \cap \mathrm{L}_0^2(\Omega)} \sup_{\mathbf{0} \neq \mathbf{u} \in \mathbf{X}_{\mathcal{T}}^{\mathrm{CME}}} \frac{\mathfrak{b}(\mathbf{u}, p)}{\|\mathbf{u}\|_{1,\Omega} \|p\|_{0,\Omega}} \geq \beta^{\mathrm{CME}}.$$

Proof. We start with the stability of the CME $\mathbf{X}_{\mathcal{T}^{\mathrm{dof}}} \times \mathrm{M}_{\mathcal{T}^{\mathrm{dof}}}$ with respect to the inner mesh $\mathcal{T}^{\mathrm{dof}}$, which is known from [4]:

$$\inf_{0 \neq p \in \mathrm{M}_{\mathcal{T}^{\mathrm{dof}}} \cap \mathrm{L}_0^2(\Omega_{\mathcal{T}^{\mathrm{dof}}})} \sup_{\mathbf{0} \neq \mathbf{u} \in \mathbf{X}_{\mathcal{T}^{\mathrm{dof}}}} \frac{\int_{\Omega_{\mathcal{T}^{\mathrm{dof}}}} p \operatorname{div} \mathbf{u}}{\|p\|_{0,\Omega_{\mathcal{T}^{\mathrm{dof}}}} \|\mathbf{u}\|_{1,\Omega_{\mathcal{T}^{\mathrm{dof}}}}} \geq \beta > 0. \tag{4.20}$$

Thereby β does not depend on the mesh size. We define two mappings to transport this result to the CME space. The first one is just a slight modification of $\mathcal{E}^{\mathrm{p}}$ in order to handle the L_0^2 intersection:

$$\tilde{\mathcal{E}}^{\mathrm{p}} : \mathrm{M}_{\mathcal{T}^{\mathrm{dof}}} \cap \mathrm{L}_0^2(\Omega_{\mathcal{T}^{\mathrm{dof}}}) \to \mathrm{M}_{\mathcal{T}}^{\mathrm{CME}} \cap \mathrm{L}_0^2(\Omega), \quad q \mapsto \mathcal{E}^{\mathrm{p}} q - \frac{1}{|\Omega|} \int_\Omega \mathcal{E}^{\mathrm{p}} q.$$

Due to Lemma 4.6, $\tilde{\mathcal{E}}^{\mathrm{p}}$ is bounded and $\|\tilde{\mathcal{E}}^{\mathrm{p}} q\|_{0,\Omega} \leq 2 C_{\mathcal{E}^{\mathrm{p}}} \|p\|_{0,\Omega_{\mathcal{T}^{\mathrm{dof}}}}$. Furthermore, $\tilde{\mathcal{E}}^{\mathrm{p}}$ is a bijection since $\mathcal{E}^{\mathrm{p}}$ maps constants on constants and the preimage of a constant function is constant. In a second step we construct a bounded mapping $\pi : \mathbf{X}_{\mathcal{T}^{\mathrm{dof}}} \to \mathbf{X}_{\mathcal{T}}^{\mathrm{CME}}$ that satisfies

$$\int_\Omega \tilde{\mathcal{E}}^{\mathrm{p}} q \operatorname{div} \pi \mathbf{u} = \int_{\Omega_{\mathcal{T}^{\mathrm{dof}}}} q \operatorname{div} \mathbf{u} \quad \forall q \in \mathrm{M}_{\mathcal{T}^{\mathrm{dof}}}. \tag{4.21}$$

This step is similar to Fortin's lemma (cf. [4, Proposition II.2.9]), where such a mapping is employed to deduce the discrete stability from the continuous one. Let us suppose for the moment that π exists. From (4.20) we know that

$$\forall q \in \mathrm{M}_{\mathcal{T}^{\mathrm{dof}}} \cap \mathrm{L}_0^2(\Omega_{\mathcal{T}^{\mathrm{dof}}}) \ \exists \mathbf{u}_q \in \mathbf{X}_{\mathcal{T}^{\mathrm{dof}}} : \int_{\Omega_{\mathcal{T}^{\mathrm{dof}}}} q \operatorname{div} \mathbf{u}_q \geq \frac{\beta}{2} \|q\|_{0,\Omega_{\mathcal{T}^{\mathrm{dof}}}} \|\mathbf{u}_q\|_{1,\Omega_{\mathcal{T}^{\mathrm{dof}}}}.$$

The left-hand side can be replaced using (4.21) and the bijectivity of $\tilde{\mathcal{E}}^{\mathrm{p}}$ which leads to

$$\forall p \in \mathrm{M}_{\mathcal{T}}^{\mathrm{CME}} \cap \mathrm{L}_0^2(\Omega) \ \exists q \in \mathrm{M}_{\mathcal{T}^{\mathrm{dof}}} \cap \mathrm{L}_0^2(\Omega_{\mathcal{T}^{\mathrm{dof}}}), \ \mathbf{u}_q \in \mathbf{X}_{\mathcal{T}^{\mathrm{dof}}} : p = \tilde{\mathcal{E}}^{\mathrm{p}} q \quad \text{and}$$
$$\int_\Omega p \operatorname{div} \pi \mathbf{u}_q = \int_{\Omega_{\mathcal{T}^{\mathrm{dof}}}} q \operatorname{div} \mathbf{u}_q \geq \frac{\beta}{2} \|q\|_{0,\Omega_{\mathcal{T}^{\mathrm{dof}}}} \|\mathbf{u}_q\|_{1,\Omega_{\mathcal{T}^{\mathrm{dof}}}}.$$

Let C_π denote the operator norm of π. Recalling $C_{\mathcal{E}^{\mathrm{p}}}$ as in Lemma 4.6 we get

$$\inf_{p \in \mathrm{M}_{\mathcal{T}}^{\mathrm{CME}} \cap \mathrm{L}_0^2(\Omega)} \sup_{\mathbf{0} \neq \mathbf{u} \in \mathbf{X}_{\mathcal{T}}^{\mathrm{CME}}} \frac{\mathfrak{b}(\mathbf{u}, p)}{\|\mathbf{u}\|_{1,\Omega} \|p\|_{0,\Omega}} \geq \frac{\beta}{4 C_{\mathcal{E}^{\mathrm{p}}} C_\pi}.$$

It remains to define π: Let $\mathbf{u} \in \mathbf{X}_{\mathcal{T}^{\mathrm{dof}}}$. The extension of $\mathbf{u} \in \mathbf{X}_{\mathcal{T}^{\mathrm{dof}}}$ by zero (again denoted by $\mathbf{u}$) is mapped onto $\mathbf{X}_{\mathcal{T}}^{\mathrm{CME}}$ by using the $\mathbf{H}^1$-orthogonal projection (denoted by $\mathcal{P}_{\mathbf{X}_{\mathcal{T}}^{\mathrm{CME}}}$). Due to (4.20) and the coercivity of $\mathfrak{a}$ on $\mathbf{H}_{\mathbf{0}}^1(\Omega_{\mathcal{T}^{\mathrm{dof}}})$ there is a unique $\mathbf{u}^* \in \mathbf{X}_{\mathcal{T}^{\mathrm{dof}}}^{\mathbf{0}}$ satisfying the following discrete Stokes problem of Dirichlet type in $\Omega_{\mathcal{T}^{\mathrm{dof}}}$:

$$\begin{aligned}
\int_{\Omega_{\mathcal{T}^{\mathrm{dof}}}} \mathrm{D}(\mathbf{u}^*) : \mathrm{D}(\mathbf{v}) - \int_{\Omega_{\mathcal{T}^{\mathrm{dof}}}} p \ \mathrm{div}\, \mathbf{v} &= \mathbf{0} \qquad \forall \mathbf{v} \in \mathbf{X}_{\mathcal{T}^{\mathrm{dof}}}^{\mathbf{0}}, \\
\int_{\Omega_{\mathcal{T}^{\mathrm{dof}}}} q \ \mathrm{div}\, \mathbf{u}^* &= g(q) \quad \forall q \in \mathrm{M}_{\mathcal{T}^{\mathrm{dof}}} \cap \mathrm{L}_0^2(\Omega_{\mathcal{T}^{\mathrm{dof}}}),
\end{aligned}$$

where the linear form $g : \mathrm{M}_{\mathcal{T}^{\mathrm{dof}}} \cap \mathrm{L}_0^2(\Omega_{\mathcal{T}^{\mathrm{dof}}}) \to \mathbb{R}$ is given by $g(q) := \int_\Omega \tilde{\mathcal{E}}^{\mathrm{p}} q \ \mathrm{div}(\mathbf{u} - \mathcal{P}_{\mathbf{X}_{\mathcal{T}}^{\mathrm{CME}}} \mathbf{u})$. Defining $\pi\mathbf{u} := \mathcal{P}_{\mathbf{X}_{\mathcal{T}}^{\mathrm{CME}}} \mathbf{u} + \mathcal{E}^{\mathbf{0}} \mathbf{u}^*$ condition (4.21) is obviously fulfilled. The operator π is bounded because of the boundedness of the orthogonal projection and Lemma 4.6:

$$\begin{aligned}
\big\|\pi\mathbf{u}\big\|_{1,\Omega} &\le \big\|\mathbf{u}\big\|_{1,\Omega_{\mathcal{T}^{\mathrm{dof}}}} + C^* \Big(\sup_{0 \neq q \in \mathrm{M}_{\mathcal{T}^{\mathrm{dof}}} \cap \mathrm{L}_0^2(\Omega_{\mathcal{T}^{\mathrm{dof}}})} \frac{\big|g(q)\big|}{\big\|q\big\|_{0,\Omega_{\mathcal{T}^{\mathrm{dof}}}}} \Big) \\
&\le \underbrace{\big(1 + C^*(1 + 3C_{\mathcal{E}^{\mathrm{p}}})\big)}_{=C_\pi} \big\|\mathbf{u}\big\|_{1,\Omega_{\mathcal{T}^{\mathrm{dof}}}}. \qquad \square
\end{aligned}$$

It is remarkable that we deduced stability from the mini element with respect to the triangulation $\mathcal{T}^{\mathrm{dof}}$ and not from the continuous result on the complicated domain Ω.

Next, we have to investigate the coercivity of the bilinear form $\mathfrak{a}$ with respect to the discrete space $\mathbf{X}_{\mathcal{T}}^{\mathrm{CME}}$. We know from (2.3) that $\mathfrak{a}$ is coercive on $\mathbf{H}_{\mathbf{0}}^1(\Omega)$. Since $\mathbf{X}_{\mathcal{T}}^{\mathrm{CME}} \not\subseteq \mathbf{H}_{\mathbf{0}}^1(\Omega)$ this result needs to be extended to a certain neighborhood of $\mathbf{H}_{\mathbf{0}}^1(\Omega)$. This neighborhood can be measured in terms of the $\mathbf{L}^2$-norm of the trace, as can be seen in the following lemma, the proof of which (see [15]) is analogous to the proof for the Poincaré inequality.

LEMMA 4.8 (equivalent norms in $\mathbf{H}^1(\Omega)$). *For all* $\mathbf{u} \in \mathbf{H}^1(\Omega)$ *there holds* $\|\mathbf{u}\|_{1,\Omega}^2 \lesssim \mathfrak{a}(\mathbf{u},\mathbf{u}) + \|\mathbf{u}\|_{0,\partial\Omega}^2$.

Lemma 4.8 implies that $\mathfrak{a}$ is coercive on the composite space $\mathbf{X}_{\mathcal{T}}^{\mathrm{CME}}$ if the violation of the zero boundary condition is not too large. We will make this fact precise in the subsequent lemma by showing that the nonconformity in the space can be controlled by the local mesh refinement in the slave part $\mathcal{T}^{\mathrm{slave}}$ of the mesh $\mathcal{T}$, more precisely, by the ratio

$$\mathrm{R}(T) := \max_{t \in \mathcal{T}_T^{\mathrm{slave}} : t \cap \partial\Omega \neq \emptyset} \frac{\mathrm{diam}(t)}{\mathrm{diam}(T)}, \quad T \in \mathcal{T}^{\mathrm{dof}},$$

which can be assigned to every extrapolation simplex.

LEMMA 4.9 (nonconformity). *There is a constant* $C = C(\rho, C_3^{\mathcal{T}}) > 0$ *such that*

$$\big\|\mathbf{u}\big\|_{0,\partial\Omega} \le C\big(\max_{T \in \mathcal{T}^{\mathrm{dof}}} \mathrm{R}(T)\big) h^{\frac{1}{2}} \big|\mathbf{u}\big|_{1,\Omega} \quad \forall \mathbf{u} \in \mathbf{X}_{\mathcal{T}}^{\mathrm{CME}}.$$

Proof. Let $t \in \mathcal{T}^{\text{slave}}$ such that $t \cap \partial\Omega \neq \emptyset$. We start by estimating the value of $\mathbf{u} \in \mathbf{X}_{\mathcal{T}}^{\text{CME}}$ at a vertex $\mathbf{x}$ of t:

$$\big|\mathbf{u}(\mathbf{x})\big| \overset{(3.4)}{\leq} \operatorname{diam}(t)\big|\nabla(\mathbf{u}|_{T_{\mathbf{x}}})\big| = \frac{\operatorname{diam}(t)}{\big|T_{\mathbf{x}}\big|^{\frac{1}{2}}}\big|\mathbf{u}\big|_{1,T_{\mathbf{x}}}. \tag{4.22}$$

Now we can estimate the $\mathbf{L}^2$-norm of $\mathbf{u}$ on $\partial\Omega$:

$$\begin{aligned}
\big\|\mathbf{u}\big\|_{0,\partial\Omega}^2 &\leq \sum_{T\in\mathcal{T}^{\text{dof}}} \sum_{t\in\mathcal{T}_T^{\text{slave}}:t\cap\partial\Omega\neq\emptyset} \big|\partial\Omega\cap t\big|\big|\mathbf{u}\big|_{\infty,t}^2 \\
&\overset{(4.22),(2.6)}{\lesssim} \sum_{T\in\mathcal{T}^{\text{dof}}} \sum_{t\in\mathcal{T}_T^{\text{slave}}:t\cap\partial\Omega\neq\emptyset} \frac{\big|\partial\Omega\cap t\big|\operatorname{diam}(t)^2}{\operatorname{diam}(T)^d}\big|\mathbf{u}\big|_{1,T}^2 \\
&\overset{(2.6)}{\lesssim} \sum_{T\in\mathcal{T}^{\text{dof}}} \big|\partial\Omega\cap\mathcal{T}_T^{\text{slave}}\big|\frac{\operatorname{diam}(t)^2}{\operatorname{diam}(T)^d}\big|\mathbf{u}\big|_{1,T}^2 \\
&\overset{(2.6)}{\lesssim} \underbrace{\left(\max_{T\in\mathcal{T}^{\text{dof}}} \frac{\big|\partial\Omega\cap\mathcal{T}_T^{\text{slave}}\big|}{\operatorname{diam}(T)^{(d-1)}}\right)}_{=:C_3^{\mathcal{T}}} \frac{\operatorname{diam}(t)^2}{\operatorname{diam}(T)}\big|\mathbf{u}\big|_{1,\Omega}^2. \qquad \square
\end{aligned}$$

In Lemma 4.9 we have seen that the nonconformity in the velocity space can be controlled by the ratios $\mathrm{R}(T)$ independent from the mesh size h. This fact will be important for the error estimate in the subsequent section. For the unique solvability we want to avoid constraints on $\mathrm{R}(T)$. The right-hand side in Lemma 4.9 always contains at least a factor $\sqrt{h}$. So, in view of Lemma 4.8, there is an h_0 such that the bilinear form is coercive for all triangulations with mesh size $h \leq h_0$. The case $h > h_0$ is discussed in what follows. The bilinear $\mathfrak{a}$ has a nontrivial kernel given by the set of rigid body motions

$$\mathcal{R} := \{\mathbf{A}\cdot + \mathbf{b} \mid \mathbf{A} \in \mathbb{R}^{d\times d} \text{ skew symmetric}, \mathbf{b} \in \mathbb{R}^d\}, \tag{4.23}$$

and it is therefore coercive on a subspace $\mathbf{U} \subseteq \mathbf{H}^1(\Omega)$ if and only if $\mathbf{U} \cap \mathcal{R} = \{\mathbf{0}\}$. This is the key to prove discrete coercivity.

LEMMA 4.10 (discrete coercivity). *There is a constant α^{CME} that does not depend on h such that $\mathfrak{a}(\mathbf{u},\mathbf{u}) \geq \alpha^{\text{CME}}\big\|\mathbf{u}\big\|_{1,\Omega}^2$ for all $\mathbf{u} \in \mathbf{X}_{\mathcal{T}}^{\text{CME}}$.*

Proof. Let $\mathbf{u} \in \mathbf{X}_{\mathcal{T}}^{\text{CME}}$, $\mathbf{A} \in \mathbb{R}^{d\times d}$ be skew symmetric and $\mathbf{b} \in \mathbb{R}^d$ such that $\mathbf{u}(\mathbf{x}) = \mathbf{A}\mathbf{x} + \mathbf{b}$. Then, by definition, $\mathbf{u}(\mathbf{x}) = \mathbf{A}\mathbf{x} + \mathbf{b} = \mathbf{A}(\mathbf{x} - \bar{\mathbf{x}})$ in a slave node $\mathbf{x}$, and we get $\mathbf{A}\bar{\mathbf{x}} = -\mathbf{b}$ for all $\bar{\mathbf{x}} \in \{\bar{\mathbf{x}}_i \mid \mathbf{x}_i \in \Theta^{\text{slave}}\}$. Since $\operatorname{span}\{\bar{\mathbf{x}}_i \mid \mathbf{x}_i \in \Theta^{\text{slave}}\} = \mathbb{R}^d$ this can be true only if $\mathbf{A} = \mathbf{0}$ and $\mathbf{b} = \mathbf{0}$. $\square$

4.3. A priori error estimate. This section provides the main result on the convergence of the CME method.

THEOREM 4.11. *The discrete problem* (3.6) *always has a unique solution. Furthermore, if $(\mathbf{u}^*, p^*) \in \big(\mathbf{H}_{\mathbf{0}}^1 \cap \mathbf{H}^{1+r}(\Omega)\big) \times \big(L_0^2(\Omega) \cap H^r(\Omega)\big)$, $r \in (\frac{1}{2}, 1]$, is the solution of* (2.1)*, then we have the following a priori error estimate:*

$$\big\|\mathbf{u}^* - \mathbf{u}\big\|_{1,\Omega} + \big\|p^* - p\big\|_{0,\Omega} \leq C\left(C_{\text{appr}}h^r + \sup_{\mathbf{0}\neq\mathbf{v}\in\mathbf{X}_{\mathcal{T}}^{\text{CME}}} \frac{\big\|\mathbf{v}\big\|_{0,\partial\Omega}}{\big\|\mathbf{v}\big\|_{1,\Omega}}\right)\big\|\mathbf{f}\big\|_{r-1,\Omega},$$

where the constant C depends on α^{CME}, β^{CME}, while C_{appr} depends on the constants in Theorems 4.4 *and* 4.5.

Furthermore, if $\Omega = \Omega_{\mathcal{T}}$ or $\mathrm{R}(T) \lesssim h^r$ for all $T \in \mathcal{T}^{\mathrm{dof}}$, then

$$\|\mathbf{u}^* - \mathbf{u}\|_{1,\Omega} + \|p^* - p\|_{0,\Omega} \lesssim h^r \|\mathbf{f}\|_{r-1,\Omega}.$$

Proof. The unique solvability is a consequence of Theorem 4.7 and Lemma 4.10. Following the abstract mixed theory presented in [4], especially Proposition 2.16, we additionally get the following error bound:

$$\|\mathbf{u}^* - \mathbf{u}\|_{1,\Omega} + \|p^* - p\|_{0,\Omega} \overset{T4.10,T4.7}{\lesssim} \inf_{\mathbf{v}\in\mathbf{X}_{\mathcal{T}}^{\mathrm{CME}}} \|\mathbf{u}^* - \mathbf{v}\|_{1,\Omega} + \inf_{q\in\mathrm{M}_{\mathcal{T}}^{\mathrm{CME}}} \|p^* - q\|_{0,\Omega} + \underbrace{\sup_{\mathbf{0}\neq\mathbf{v}\in\mathbf{X}_{\mathcal{T}}^{\mathrm{CME}}} \frac{\left|\mathfrak{a}(\mathbf{u}^*,\mathbf{v}) + \mathfrak{b}(\mathbf{v},p^*) - \langle \mathbf{f},\mathbf{v}\rangle_{0,\Omega}\right|}{\|\mathbf{v}\|_{1,\Omega}}}_{=:K}.$$

The infima have been estimated in section 4. The supremum which reflects the error due to nonconformity in the space can be estimated by using the identity

$$\int_\Omega \mathbf{D}\mathbf{u}^* : \mathbf{D}\mathbf{v} + \int_\Omega p^* \operatorname{div}\mathbf{v} - \langle \mathbf{f},\mathbf{v}\rangle_{0,\Omega} = \int_{\partial\Omega} \langle (\mathbf{D}\mathbf{u}^* - p^*\mathbf{I_d})\boldsymbol{\nu},\mathbf{v}\rangle\,, \tag{4.24}$$

which holds for the solution $(\mathbf{u}^*, p^*)$ and an arbitrary $\mathbf{v} \in \mathbf{H}^1(\Omega)$, and the trace theorem

$$\|\mathbf{D}\mathbf{u}^*\|_{0,\partial\Omega}^2 + \|p^*\|_{0,\partial\Omega}^2 \lesssim \|\mathbf{u}^*\|_{\frac{3}{2},\Omega}^2 + \|p^*\|_{\frac{1}{2},\Omega}^2. \tag{4.25}$$

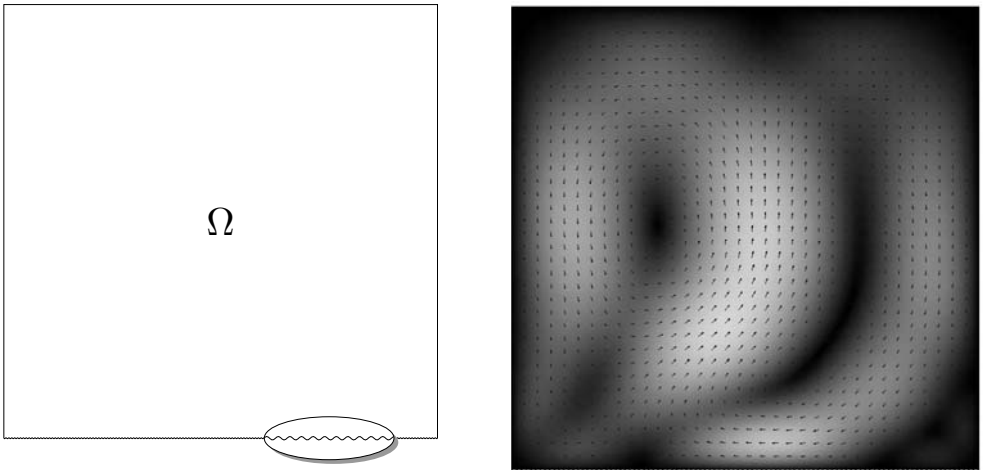
Therefore the nonconformity error K can be estimated as follows:

$$K \overset{(4.24),(4.25)}{\lesssim} \left(\|\mathbf{u}^*\|_{\frac{3}{2},\Omega}^2 + \|p^*\|_{\frac{1}{2},\Omega}^2\right)^{\frac{1}{2}} \sup_{\mathbf{0}\neq\mathbf{v}\in\mathbf{X}_{\mathcal{T}}^{\mathrm{CME}}} \frac{\|\mathbf{v}\|_{0,\partial\Omega}}{\|\mathbf{v}\|_{1,\Omega}}.$$

Finally, the assertion follows from the regularity estimate (2.5) and the interpolation theory of Sobolev spaces (cf. [3]). ∎

5. Numerical experiments. Typical applications of the CME are flow problems on domains with rough outer boundaries which arise, for instance, in the modeling of rivers, lakes, and oceans where the shorelines are rarely smooth. Model problems of this type have been investigated in [15]. The results show that the theoretical estimates of the previous section are sharp for the test problems. Performance tests for composite finite elements for the Poisson equations and elasticity problems can be found in [17] and [16], where especially the use of overlapping meshes has been investigated. The subsequent experiments are addressed to flow problems on complicated domains with mixed boundary conditions. Our first model problem on the unit square with 100 randomly distributes circular holes of diameter 0.005 is depicted in Figure 1.1:

$$\begin{aligned}
-\Delta\mathbf{u} + \nabla p &= \mathbf{0} && \text{in } \Omega,\\
\operatorname{div}\mathbf{u} &= 0 && \text{in } \Omega,\\
\mathbf{u}(\mathbf{x}) &= 0.5\,(1+\cos(8\pi(\mathbf{x}_2 - 0.75))) && \forall \mathbf{x}\in\Gamma^{\mathrm{in}},\\
2(\mathbf{D}\mathbf{u}(\mathbf{x}))\boldsymbol{\nu}(\mathbf{x}) &= p(\mathbf{x})\boldsymbol{\nu}(\mathbf{x}) && \forall \mathbf{x}\in\Gamma^{N},\\
\mathbf{u}(\mathbf{x}) &= \mathbf{0} && \forall \mathbf{x}\in\partial\Omega\setminus(\Gamma^{\mathrm{in}}\cup\Gamma^{N}),
\end{aligned} \tag{5.1}$$



(a) Model domain $\Omega := \{\mathbf{x} \in \mathbb{R}^2 \mid 0 < \mathbf{x}_1 < 1,\ g(\mathbf{x}_1) < \mathbf{x}_2 < 1\}$, $g(\mathbf{x}_1) := a\sin(\omega\pi\mathbf{x}_1)$, $a := 0.001$, $\omega := 199$.

(b) Solution velocity (black = 0, white = 0.5).

FIG. 5.1. *A model problem: Force-driven Stokes flow in a domain with a rough slip bottom boundary.*

where $\Gamma^{\text{in}} := \{0\} \times (\frac{5}{8}, \frac{7}{8})$ and $\Gamma^N := \{1\} \times (\frac{1}{8}, \frac{3}{8}) \cup (\frac{5}{8}, \frac{7}{8})$. The difficulties of problem (5.1) not only stem from the holes but are also related to the mixed boundary conditions. The second test problem (see Figure 5.1) models a force-driven flow in a perturbed unit square (rough bottom boundary) with mixed Dirichlet and slip boundary conditions:

$$
\begin{aligned}
-\Delta\mathbf{u} + \nabla p &= \mathbf{f} && \text{in } \Omega,\\
\operatorname{div}\mathbf{u} &= 0 && \text{in } \Omega,\\
\mathbf{u}(\mathbf{x}) &= \mathbf{0} && \forall \mathbf{x} \in \Gamma^D,\\
\langle \mathbf{u}(\mathbf{x}), \boldsymbol{\nu}(\mathbf{x})\rangle &= 0 && \forall \mathbf{x} \in \partial\Omega \setminus \Gamma^D,\\
(\mathbf{D}\mathbf{u}(\mathbf{x}))\boldsymbol{\nu}(\mathbf{x}) &= \big(\boldsymbol{\nu}(\mathbf{x})^T(\mathbf{D}\mathbf{u}(\mathbf{x}))\boldsymbol{\nu}(\mathbf{x})\big)\,\boldsymbol{\nu}(\mathbf{x}) && \forall \mathbf{x} \in \partial\Omega \setminus \Gamma^D,
\end{aligned}
\tag{5.2}
$$

where $\mathbf{f}(\mathbf{x}) := (\cos(2\pi\mathbf{x}_2)\sin(2\pi\mathbf{x}_1), (\frac{3}{2} - \frac{3}{2}\mathbf{x}_2)^5\sin(\pi\mathbf{x}_2)\cos(2\pi\mathbf{x}_1))^T$, and $\Gamma^D := \{0\} \times [0,1] \cup [0,1] \times \{1\} \cup \{1\} \times [0,1]$. Analytical solutions of (5.1) or (5.2) are not known; approximations on very fine meshes will be used for the error indication instead. We will investigate the mini element spaces with respect to coarse shape-regular meshes (see, e.g., Figures 1.2 and 5.4) for the domains of (5.1) and (5.2). They resolve the geometric details of the domain, i.e., the rough boundaries and holes, as well as the inflow and outflow boundaries. The definition of the method in section 3 has left some freedom in the choice of the inner mesh $\mathcal{T}^{\text{dof}}$ determining the CME space. We will use the simplest possible rule:

$$t \in \mathcal{T}^{\text{dof}} \quad \Leftrightarrow \quad \operatorname{dist}(t, \partial\Omega) > \tfrac{1}{2}h^{\text{slave}}.$$

In the case of boundary concentrated meshes as depicted in Figures 1.2 and 5.4 this choice leads to moderate constants in condition (4.1), at least for $h^{\text{slave}} \in (0, h)$. Note that this choice does not take any special properties of the model problems into

account. The sparse linear system $\mathbf{S}^{\mathrm{CME}}\mathbf{w}^{\mathrm{CME}} = \mathbf{g}$, which arises from the CME discretization of (5.1) and (5.2), can be assembled locally in the usual way (see [11], [16], and [15]). The resulting system matrix is $\mathbf{S}^{\mathrm{CME}}$ fulfills

$$\mathbf{S}^{\mathrm{CME}} = (\mathbf{E}^{\mathrm{CME}})^T \mathbf{S} \mathbf{E}^{\mathrm{CME}},$$

where $\mathbf{E}^{\mathrm{CME}}$ is the matrix representation of the linear operator $\boldsymbol{\mathcal{E}}^{\mathrm{CME}}$ presented in (3.5). $\mathbf{E}^{\mathrm{CME}}$ is a sparse rectangular matrix with order $\sharp\mathcal{T}$ number of rows but only order $\sharp\mathcal{T}^{\mathrm{dof}}$ number of columns. It is obvious that the composite system matrix $\mathbf{S}^{\mathrm{CME}}$ is (much) smaller than the classical mini element matrix $\mathbf{S}$. Sparsity can thereby be preserved since the support of the CME basis functions remains local. As a consequence the storage requirements are reduced, and a (possibly) much smaller system has to be solved.

Before we present numerical results we will comment on the handling of the boundary conditions that are not covered by the theory presented before. The inhomogeneous Dirichlet boundary condition can be handled in the standard way. By introducing a discrete vector field $\mathbf{u}_0 : \Omega \to \mathbb{R}^2$ that approximates the inflow condition sufficiently well the problem can be reduced to a homogeneous problem with a modified right-hand side. Note that $\mathbf{u}_0$ can be chosen in the full mini element space based on a possibly fine mesh close to the inhomogeneous Dirichlet boundary which allows us to handle even complicated Dirichlet data. It is therefore independent from the choice of h^{slave}. From the pressure part of the CME space we know how to deal with functions that are unconstrained on the domain boundary. We simply use $\mathcal{E}^{\mathrm{p}}$ componentwise to define the values of the velocity test functions close to the Neumann boundary. For the slip boundary condition in (5.2) we use $\mathcal{E}^{\mathrm{p}}$ in the tangential direction and $\boldsymbol{\mathcal{E}}^{\mathbf{0}}$ in the normal direction. A theoretical justification of this procedure has been presented in [15], where the use of the slip boundary condition is discussed in detail. The question of which extension has to be used in a slave node $\mathbf{x}$ is decided by its closest boundary point $\bar{\mathbf{x}}$ that belongs to either the Dirichlet, Neumann, or slip boundary.

We will use problem (5.1) to investigate the behavior of the error and the system dimension on two coarse triangulations for varying choices of the parameter h^{slave}. Figure 5.2 summarizes the results: In both plots the lower curves ($\square$) represent the compression rates, that is, the quotients between the dimensions of the composite spaces for varying values of h^{slave} and the classical mini element space. The upper curves ($\circ$) show the relative errors (left: velocity, right: pressure), more precisely, the quotient of the errors of the composite approximations and the full mini element approximation. In between, the dotted curves ($\times$) are the product of compression rate and relative error. It can be seen that the errors stay almost constant as h^{slave} tends to h. Since the space dimension rapidly decreases at the same time, the efficiency of the composite method increases. Only for values of $h^{\mathrm{slave}} > h$ does the pressure error become large, which indicates that the pressure extension depends more critically on the choice of h^{slave}. This is not surprising, since information from the boundary conditions is not available. However, the velocity error in Figure 5.2(a) is not affected from the worse pressure approximation, and the behavior is fine if $h^{\mathrm{slave}} < h$. In Figure 5.3 it can be observed that the generalization of the composite method to Neumann boundaries works well for the model problem under consideration. Due to the extension there is an expected loss in smoothness, but the general outflow behavior can be captured without placing additional degrees of freedom. This indicates a certain potential of the method not only for problems with complicated boundaries

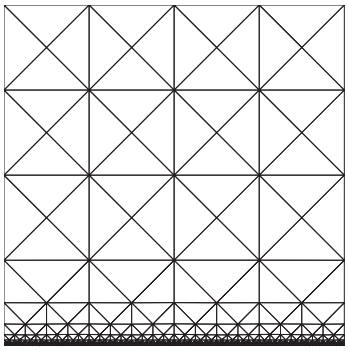
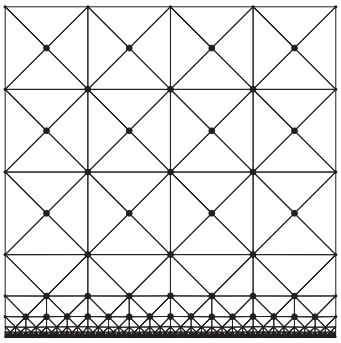
but also with complicated boundary conditions, i.e., complicated Dirichlet data or complicated distribution of mixed Dirichlet–Neumann boundary conditions.

Finally, we use the second model problem (5.2) to investigate the convergence rates as the mesh size h decreases. Thereby we compare the classical mini element on a resolving triangulation (Mini), its composite version (CME) for $h^{\text{slave}} = 0.1h$, and a classical mini element with respect to nonmatching, quasi-uniform triangulations (uniformMini). All approaches and the according parameter choices are summarized in Figure 5.4.

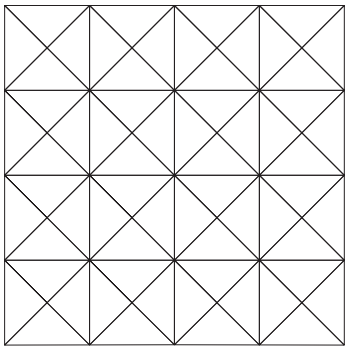
The results of the slip model computations are depicted in Figure 5.5, where the dependence of the velocity and pressure errors on the mesh size and the system



(a) Classical mini element (Mini) on a resolving mesh (minimal mesh size 2^{-10}).



(b) Composite mini element (CME) on a resolving mesh with marked degrees of freedom (•) (minimal mesh size 2^{-10}, $h^{\text{slave}} = h$).



(c) Nonconforming classical mini element (uniformMini) on quasi-uniform mesh.

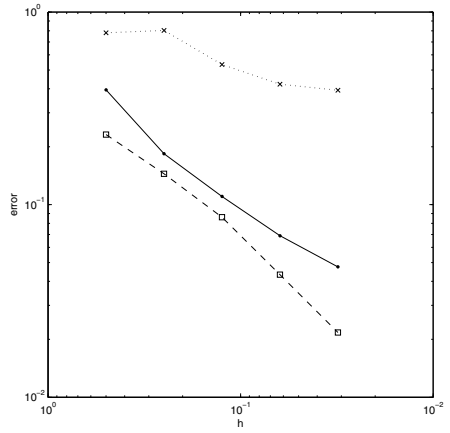
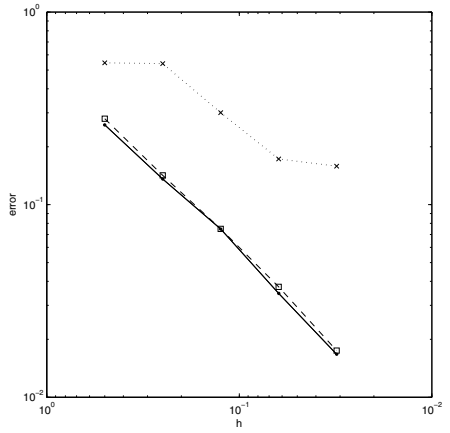
FIG. 5.4. *The grids with degrees of freedom of the different approaches for the solution of the model problem* (5.2).

dimension are depicted. We make the following observations:

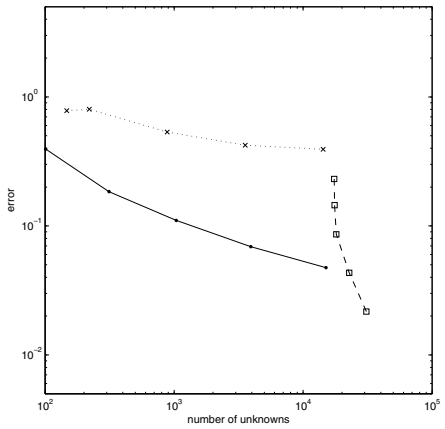
1. The (conforming) mini element and its composite version converge at the predicted optimal (linear) rate (cf. Figure 5.5(a)). The compressed method CME is only slightly worse than the full version (cf. Figure 5.5(a)). Note that the error of the composite method is larger than full mini error only in a near boundary zone. Away from the rough boundary the errors are almost equal; i.e., pollution effects cannot be observed for this test case (cf. Figures 5.5(b)).
2. The quasi-uniform approach is not competitive (cf. Figures 5.5(a)–(b)). The reason is that the very crude approximation of the boundary conditions spoils the overall discretization too significantly. That means that our choice of minimal mesh size for the boundary resolution cannot be weakened without increasing the errors.



(a) Error on Ω as a function of h.



(b) Error on $(0,1)\times(0.1,1)$ as a function of h.



(c) Error on Ω as a function of the system dimension.

FIG. 5.5. *Convergence of the methods applied to model problem* (5.2). *The errors (sum of H^1-velocity and L^2-pressure error) are plotted versus the maximal mesh size h and the system dimension: Mini* (dashed, $\square$), CME (solid, $\circ$), uniformMini (dotted, $\times$).

3. The dimension of the CME space behaves like h^{-d} (cf. Figure 5.4(d)). That means that the CME preserves the accuracy of the full mini element space on the coarser levels, while the cost is comparable with the quasi-uniform approach. This underpins the efficiency of our "fuzzy" treatment of the boundary conditions.
4. The composite method is the most efficient method in this test case. Though the full mini element produces slightly smaller errors than the composite element, the resulting system dimension is up to 100 times bigger than for CME on the coarsest level (see Figure 5.5(c)). In contrast to the CME the less costly quasi-uniform method produces unsatisfying approximations.

The gain of the composite method depends on the maximal mesh size h. If h is small enough to resolve the domain, the composite and the full method are almost equal in cost and accuracy. If one is satisfied with only moderate errors, or one is restricted to smaller dimensions, then the composite method is the better choice. Refinements in the triangulation which are due to geometric issues do not need to be treated by degrees of freedom.

FULLY COMPUTABLE BOUNDS FOR THE ERROR IN NONCONFORMING FINITE ELEMENT APPROXIMATIONS OF ARBITRARY ORDER ON TRIANGULAR ELEMENTS*

MARK AINSWORTH† AND RICHARD RANKIN†

Abstract. We obtain a fully computable a posteriori error bound on the broken energy norm of the error in the nonconforming finite element approximation on triangles of arbitrary order of a linear second order elliptic problem with variable permeability. The estimator is completely free of unknown constants and provides a guaranteed numerical bound on the broken energy norm of the error. This estimator is shown to be efficient in the sense that it also provides a lower bound for the broken energy norm of the error up to a constant and higher order data oscillation terms.

Key words. robust a posteriori error estimation, nonconforming finite element

AMS subject classifications. 65N15, 65N30

DOI. 10.1137/07070838X

1. Introduction.

A posteriori error estimation is important for determining the accuracy of finite element approximations and implementing adaptive refinement strategies. The papers referenced in [10] provide a recent survey of the state of the art in a posteriori error estimation for nonconforming finite element approximations. However, none of the a posteriori error estimators found in [10] provide actual *computable* upper bounds on the error, apart from those described in [4, 6]. While such error indicators have a role to play, if one really wants to estimate the *value* of the error, then a fresh approach is required.

In [5] computable bounds were obtained for the broken energy norm of the error in the lowest order nonconforming Crouzeix–Raviart finite element approximation on triangles [13] of a linear second order elliptic problem with variable permeability. In this estimator only the constants in front of the oscillation of the data were not specified explicitly but could be obtained using techniques described in [3]. Subsequently, this approach was extended to the nonconforming Fortin–Soulie triangular element of second order [16] with the resulting estimator being completely free of unknown constants [3]. Unfortunately, the approach of [5] could not be applied directly to the Fortin–Soulie elements since, as noted in [16], nonconforming triangular elements of *even* order have a very different structure from the nonconforming triangular elements of *odd* order. The estimators in both [5] and [3] also provided, up to a positive constant independent of the size of any of the elements in the mesh and higher order data oscillation terms, local lower bounds on the broken energy norm of the error.

The objective of the present work is to obtain computable estimators, which are completely free of all unknown constants, for nonconforming triangular elements of arbitrary order [9, 19]. The estimators and techniques used in [3, 5] are not readily generalized to the case of elements of arbitrary order, and a different approach is required. The robustness of the new estimators with respect to jumps in the perme-

The second author was partially supported through a research studentship.

ability coefficient is achieved under the same conditions as in [3, 5], and the estimators provide a local lower bound up to a constant on the broken energy norm of the error plus higher order data oscillation terms.

One advantage of treating elements of arbitrary order together at the same time is that the basic underlying structure of the approach is highlighted. In particular, the fundamental difference in the structure of the odd and even order nonconforming elements also manifests itself in the structure of the estimators. More specifically, in the lowest order case considered in [5] the jumps in the normal derivative of the finite element approximation did not appear, whereas these were found to be necessary in the case of second order elements considered in [3]. Rather surprisingly the relationship between the need to include normal jump terms and the parity of the order extends to the case of arbitrary order nonconforming finite element approximations. This phenomenon is reminiscent of what was witnessed in [8] in the context of biquadratic elements and [1] for higher order elements although in both these cases it was the estimators for the even order elements that were free of terms involving jumps in the normal derivative in contrast to what we find here. The absence of jumps in normal fluxes in the estimator in the case of elements of odd order makes the use of such elements more attractive since the calculation of the jumps in the normal derivative is relatively computationally expensive.

The only other fully computable a posteriori error estimators for nonconforming finite element approximations on triangular elements of which we are aware are those in [3, 5]. The estimators we obtain in this paper for the lowest order odd and even nonconforming finite element approximations differ slightly from those obtained previously in [5], [3]. In particular, in the case of the Crouzeix–Raviart element the treatment of the data oscillation differs from that in [5], although if the data are piecewise constant on the mesh, then the estimators are identical. Similarly, the treatment of the data oscillation for the Fortin–Soulie element differs from that in [3], and in addition the estimator is constructed using a modified projection operator which is more naturally extended to the higher order elements. In practice both estimators gave virtually identical results for smooth data.

The remainder of the paper is organized as follows. In section 2, we describe the finite element schemes and introduce the notation. Following [14] we decompose the broken energy norm of the error into conforming and nonconforming components. Fully computable upper bounds, as well as lower bounds, for each of these components are derived in sections 3 and 4. Finally, in section 5 we summarize the main results and present a numerical example illustrating the theory. An appendix is provided where we give a key result concerning the existence of polynomial solutions of a local boundary value problem with polynomial data.

2. Preliminaries.

2.1. Model problem.

Consider the model problem

$$-\operatorname{div}(a\,\mathbf{grad}\,u) = f \text{ in } \Omega$$

subject to $u = q$ on Γ_D and $a\partial u/\partial \boldsymbol{n} = g$ on Γ_N, where Ω is a simple plane polygonal domain, the disjoint sets Γ_D (nonempty) and Γ_N form a partitioning of the boundary $\Gamma = \partial\Omega$ of the domain, and $\boldsymbol{n}$ is the outward unit normal vector to Γ_N. The data satisfy $f \in L_2(\Omega)$, $g \in L_2(\Gamma_N)$, and $q \in H^1(\Gamma_D)$, and $a \in L_\infty(\Omega)$ is piecewise constant. We will assume that a is positive and that the value of a across the boundary of a subdomain of Ω may undergo a jump of many orders of magnitude, corresponding to a transition between regions of widely differing permeability.

The variational form of the problem consists of finding $u \in H^1(\Omega)$ such that $u = q$ on Γ_D and

$$(a\,\mathbf{grad}\,u, \mathbf{grad}\,v) = (f,v) + (g,v)_{\Gamma_N} \;\; \forall v \in H^1_D(\Omega), \tag{2.1}$$

where $H^1_D(\Omega) = \{v \in H^1(\Omega) : v = 0 \text{ on } \Gamma_D\}$. We shall use the notation $(\cdot,\cdot)_\omega$ to denote the integral inner product over a region or line segment ω and omit the subscript in the case where ω is the physical domain Ω.

Consider a family of partitions $\{\mathcal{P}\}$ of the domain Ω into the union of nonoverlapping, shape-regular triangular elements such that the nonempty intersection of a distinct pair of elements is a single common node or single common edge. Consequently, the family of partitions is locally quasi-uniform in the sense that the ratio of the diameters of any pair of neighboring elements is uniformly bounded above and below over the whole family.

2.2. Nonconforming finite element approximation. Let K denote an individual element in $\mathcal{P}$, let $\partial\mathcal{P}$ denote the set of element edges, and let γ denote an individual edge in $\partial\mathcal{P}$. Let $\mathbb{P}_m(K)$ denote the space of polynomials on $K \in \mathcal{P}$ of total degree at most m, and let $\mathbb{P}_m(\gamma)$ denote the space of polynomials on $\gamma \subset \partial\mathcal{P}$ of total degree at most m (with respect to the arc length parameter).

Henceforth, fix the order $n \geq 1$ of approximation. The order n nonconforming finite element space on triangles is defined by

$$X^n = \Big\{ v : \Omega \to \mathbb{R} : v_{|K} \in \mathbb{P}_n(K) \;\; \forall K \in \mathcal{P}, \\ \Big([v]_\gamma, p \Big)_\gamma = 0 \;\; \forall p \in \mathbb{P}_{n-1}(\gamma) \;\; \text{for } \gamma \subset \partial\mathcal{P}\backslash\Gamma \Big\}$$

with the subspace X^n_D defined by

$$X^n_D = \Big\{ v \in X^n : (v,p)_\gamma = 0 \;\; \forall p \in \mathbb{P}_{n-1}(\gamma) \;\; \text{for } \gamma \subset \Gamma_D \Big\}, \tag{2.2}$$

where, for $v \in X^n$, we define the jump of v on an edge γ by $[v]_\gamma$. The spaces defined above are exactly the same spaces as those defined in [13] for $n = 1$, [16] for $n = 2$, [12] for $n = 3$, [11] for $n = 4, 6$, and more generally [9, 19] for all integer $n \geq 1$. The equivalence of the above definition with the conventional one follows easily by noting that for all $\gamma \subset \partial\mathcal{P}\backslash\Gamma$, if $v \in X^n_D$, then $[v]_\gamma \in \mathbb{P}_n(\gamma)$ is orthogonal to $\mathbb{P}_{n-1}(\gamma)$, and hence v is continuous at the mapped Gauss–Legendre points on γ. Also, for all $\gamma \subset \partial\mathcal{P} \cap \Gamma_D$, if $v \in X^n_D$, then $v_{|\gamma} \in \mathbb{P}_n(\gamma)$ is orthogonal to $\mathbb{P}_{n-1}(\gamma)$, meaning that v is zero at the mapped Gauss–Legendre points on $\gamma \subset \Gamma_D$.

Let $\mathcal{N}$ index a set of points $\{\boldsymbol{x}_m\}_{m\in\mathcal{N}}$ on $\overline{\Omega}$ associated with a Lagrange basis for the conforming finite element space of order n, and let $\mathcal{N}(\omega)$ denote the subset of $\mathcal{N}$ corresponding to points located on $\overline{\omega}$ for $\omega \subset \Omega$.

The nonconforming finite element approximation of order n of problem (2.1) consists of finding $u_{nc} \in X^n$ such that

$$(a\,\mathbf{grad_{nc}}\,u_{nc}, \mathbf{grad_{nc}}\,v) = (f,v) + (g,v)_{\Gamma_N} \;\; \forall v \in X^n_D, \\ (u_{nc},p)_\gamma = (q_I,p)_\gamma \;\; \forall p \in \mathbb{P}_{n-1}(\gamma) \;\; \text{for } \gamma \subset \Gamma_D, \tag{2.3}$$

where $\mathbf{grad_{nc}}$ denotes the operator defined by $(\mathbf{grad_{nc}}\,v)_{|K} = \mathbf{grad}(v_{|K})$ for $K \in \mathcal{P}$. Here, the Dirichlet datum q has been approximated by the piecewise $\mathbb{P}_n$ interpolant q_I which satisfies $q_{I|\gamma} \in \mathbb{P}_n(\gamma)$ and $q_I(\boldsymbol{x}_m) = q(\boldsymbol{x}_m)$ for $m \in \mathcal{N}(\Gamma_D)$.

For convenience, we shall adopt the convention that $\sum_i^j$ indicates a null sum in the case when $i > j$. Likewise, if $i > j$, then $i, \ldots, j$ and $\mathbb{P}_{j-i}$ are taken to be void. For $K \in \mathcal{P}$ let $\{P_{i,K}\}_{i=1}^{\dim \mathbb{P}_{n-3}(K)}$ form a basis for $\mathbb{P}_{n-3}(K)$ such that the value taken by $P_{i,K}$ at all points on K is independent of the size of element K, and for $\gamma \subset \partial\mathcal{P}$ let $L_{i,\gamma}$ denote the Legendre polynomial of degree i mapped onto the edge γ. Let $\beta_K \in \mathbb{P}_3(K)$ denote the function which equals zero on all edges of element K and satisfies $(\beta_K, 1)_K = |K|$. Likewise, for $\gamma \subset \partial K$ let $\beta_\gamma \in \mathbb{P}_2(K)$ denote the function which equals zero on all edges of element K except edge γ and satisfies $(\beta_\gamma, 1)_\gamma = |\gamma|$. Also, if n is a positive even number, let $\tilde{\beta}_K \in \mathbb{P}_n(K)$ be the nonconforming bubble function defined in [19], which we recall is supported on element K and vanishes at the n mapped Gauss–Legendre points on each edge on the boundary of element K.

The next result gives a characterization of the degrees of freedom associated with X^n when n is odd.

LEMMA 2.1. *Suppose that n is a positive odd number. Then the set of degrees of freedom on X^n defined by*

$$v \to \int_K v P_{j,K} \text{ for } j = 1, \ldots, \dim \mathbb{P}_{n-3}\left(\mathbb{R}^2\right) \text{ for all } K \in \mathcal{P} \tag{2.4}$$

and

$$v \to \int_\gamma v L_{j,\gamma} \text{ for } j = 0, \ldots, n-1 \text{ for all } \gamma \in \partial\mathcal{P} \tag{2.5}$$

is unisolvent.

Proof. Let $\sharp\mathcal{P}$ and $\sharp\partial\mathcal{P}$ denote the cardinality of $\mathcal{P}$ and $\partial\mathcal{P}$, respectively. The dimension of the space X^n is $\sharp\mathcal{P}.\dim \mathbb{P}_{n-3}(\mathbb{R}^2) + \sharp\partial\mathcal{P}.\dim \mathbb{P}_{n-1}(\mathbb{R})$ which agrees with the number of degrees of freedom. It therefore suffices to show that if $\rho \in X^n$ satisfies

$$(p, \rho)_K = 0 \ \forall p \in \mathbb{P}_{n-3}(K) \text{ for all } K \in \mathcal{P} \tag{2.6}$$

and

$$(p, \rho)_\gamma = 0 \ \forall p \in \mathbb{P}_{n-1}(\gamma) \text{ for all } \gamma \in \partial\mathcal{P}, \tag{2.7}$$

then $\rho = 0$.

First observe that (2.7) implies that ρ vanishes at the mapped Gauss–Legendre points on all edges $\gamma \in \partial\mathcal{P}$. Since n is odd, it follows that ρ vanishes on all edges $\gamma \in \partial\mathcal{P}$. Consequently, $\rho_{|K}$ must be of the form $\beta_K v$, $v \in \mathbb{P}_{n-3}(K)$. Letting $p = v$ in (2.6) then implies that v must be zero. Repeating this argument for all $K \in \mathcal{P}$ we conclude that the only solution $\rho \in X^n$ to (2.6) and (2.7) is $\rho = 0$. ∎

For n odd we define the functions $\theta_{i,K} \in X^n$ and $\theta_{i,\gamma} \in X^n$ to be such that

$$\int_{K'} \theta_{i,K} P_{j,K'} = \delta_{KK'}\delta_{ij}, \quad \int_{K'} \theta_{i,\gamma} P_{j,K'} = 0,$$

for $j = 1, \ldots, \dim \mathbb{P}_{n-3}(\mathbb{R}^2)$ for all $K' \in \mathcal{P}$, and

$$\int_{\gamma'} \theta_{i,K} L_{j,\gamma'} = 0, \quad \int_{\gamma'} \theta_{i,\gamma} L_{j,\gamma'} = \delta_{\gamma\gamma'}\delta_{ij},$$

for $j = 0, \ldots, n-1$ for all $\gamma' \in \partial\mathcal{P}$. Then, for n odd,

$$X^n = \operatorname{span}\left\{ \{\theta_{i,K}\}_{i=1}^{\dim \mathbb{P}_{n-3}(K)} \text{ for all } K \in \mathcal{P}, \ \{\theta_{i,\gamma}\}_{i=0}^{n-1} \text{ for all } \gamma \in \partial\mathcal{P} \right\}.$$

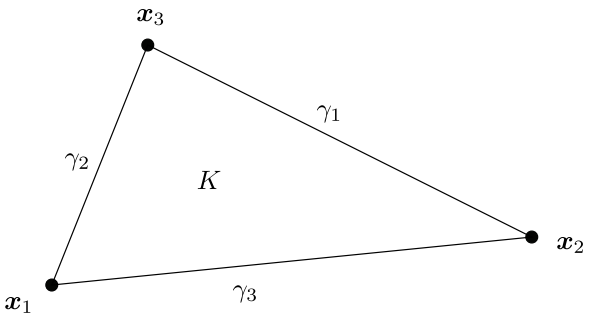

FIG. 2.1. *Enumeration of the vertices and edges of element K.*

The next result is the analogue of Lemma 2.1 in the case of even order elements.

LEMMA 2.2. *Suppose that n is a positive even number. Then the set of degrees of freedom on X^n defined by*

$$v \to \int_K v P_{j,K} \text{ for } j = 1, \ldots, \dim \mathbb{P}_{n-3}\left(\mathbb{R}^2\right) \text{ for all } K \in \mathcal{P}, \tag{2.8}$$

$$v \to \int_\gamma v L_{j,\gamma} \text{ for } j = 0, \ldots, n-1 \text{ for all } \gamma \in \partial\mathcal{P}, \tag{2.9}$$

and

$$v \to \int_{\partial K} v \tilde{\beta}_K \text{ for all } K \in \mathcal{P} \tag{2.10}$$

is unisolvent if and only if the datum v satisfies the compatibility condition

$$\sum_{\gamma \in \partial K} \int_\gamma v \sum_{\substack{1 \le j \le n-1: \\ j \text{ odd}}} \frac{L_{j,\gamma}}{\|L_{j,\gamma}\|^2_{L_2(\gamma)}} = 0 \text{ for all } K \in \mathcal{P}. \tag{2.11}$$

Proof. The dimension of the space X^n is $\sharp\mathcal{P}.\dim \mathbb{P}_{n-3}(\mathbb{R}^2) + \sharp\partial\mathcal{P}.\dim \mathbb{P}_{n-1}(\mathbb{R})$ which is $\sharp\mathcal{P}$ less than the number of degrees of freedom. We shall first show that if $v \in X^n$, then the compatibility condition holds. Now, making use of the fact that if $v \in X^n$, then $v_{|K} \in \mathbb{P}_n(K)$, we can write

$$v_{|\gamma} = \sum_{0 \le j \le n} c_{j,\gamma} L_{j,\gamma} \text{ on } K$$

for some $c_{j,\gamma} \in \mathbb{R}$. We then have

$$\sum_{\gamma \in \partial K} \int_\gamma v \sum_{\substack{1 \le j \le n-1: \\ j \text{ odd}}} \frac{L_{j,\gamma}}{\|L_{j,\gamma}\|^2_{L_2(\gamma)}} = \sum_{\substack{1 \le j \le n-1: \\ j \text{ odd}}} \left(c_{j,\gamma_1} + c_{j,\gamma_2} + c_{j,\gamma_3}\right), \tag{2.12}$$

where the edges and vertices of element K are oriented as shown in Figure 2.1.

Now, since $v_{|K}$ must be continuous at the vertices of element K, we have

$$\left(v_{|\gamma_1}(\boldsymbol{x}_3) - v_{|\gamma_1}(\boldsymbol{x}_2)\right) + \left(v_{|\gamma_2}(\boldsymbol{x}_1) - v_{|\gamma_2}(\boldsymbol{x}_3)\right) + \left(v_{|\gamma_3}(\boldsymbol{x}_2) - v_{|\gamma_3}(\boldsymbol{x}_1)\right) = 0,$$

which implies that

$$\sum_{\substack{1\le j\le n-1:\\ j \text{ odd}}} c_{j,\gamma_1} + \sum_{\substack{1\le j\le n-1:\\ j \text{ odd}}} c_{j,\gamma_2} + \sum_{\substack{1\le j\le n-1:\\ j \text{ odd}}} c_{j,\gamma_3} = 0,$$

which we can insert into (2.12) to give the compatibility condition for element K. Repeating this argument for all elements in $\mathcal{P}$ gives us the $\sharp\mathcal{P}$ linearly independent conditions which make up (2.11).

Now if the compatibility condition holds, then $\sharp\mathcal{P}$ of these degrees of freedom are linearly dependent, and so the dimension of the space X^n is the same as the number of degrees of freedom. We can therefore deduce unisolvency, if the compatibility condition holds, by showing that if $\rho \in X^n$ satisfies

$$(p,\rho)_K = 0 \ \forall p \in \mathbb{P}_{n-3}(K) \text{ for all } K \in \mathcal{P}, \tag{2.13}$$

$$(p,\rho)_\gamma = 0 \ \forall p \in \mathbb{P}_{n-1}(\gamma) \text{ for all } \gamma \in \partial\mathcal{P}, \tag{2.14}$$

and

$$\int_{\partial K} \rho\tilde{\beta}_K = 0 \text{ for all } K \in \mathcal{P}, \tag{2.15}$$

then $\rho = 0$.

As with the odd case we first observe that (2.14) implies that ρ vanishes at the mapped Gauss–Legendre points on all edges $\gamma \in \partial\mathcal{P}$. Since n is even, $\rho_{|K}$ must be of the form $\beta_K v + c\tilde{\beta}_K$, $v \in \mathbb{P}_{n-3}(K)$ for $K \in \mathcal{P}$ and some $c \in \mathbb{R}$. Now, (2.15) then implies that $c = 0$ which allows us to conclude that v must be zero by letting $p = v$ in (2.13). Hence, the only solution $\rho \in X^n$ to (2.13), (2.14), and (2.15) is $\rho = 0$. ∎

The following result gives an alternative formulation of the degrees of freedom in the case of even order elements that will be found more suitable for present purposes.

COROLLARY 2.3. *Suppose that n is a positive even number, and let*

$$X^n_* = \left\{ v \in X^n : \int_\gamma v \sum_{\substack{1\le j\le n-1:\\ j \text{ odd}}} \frac{L_{j,\gamma}}{\|L_{j,\gamma}\|^2_{L_2(\gamma)}} = 0 \text{ for all } \gamma \in \partial\mathcal{P} \right\}. \tag{2.16}$$

Then the set of degrees of freedom defined by (2.8), (2.10), *and*

$$v \to \int_\gamma v L_{j,\gamma} \text{ for } j = 0,\dots,n-2 \text{ for all } \gamma \in \partial\mathcal{P} \tag{2.17}$$

is unisolvent on X^n_*.

Proof. Observe that the degrees of freedom for X^n_* are related to the degrees of freedom for X^n described in Lemma 2.2 with the difference that the edge moment with respect to $L_{n-1,\gamma}$ for all $\gamma \subset \partial\mathcal{P}$ is missing from (2.17). The definition of the space X^n_* (2.16) imposes this missing degree of freedom on every edge $\gamma \subset \partial\mathcal{P}$ while respecting the compatibility condition (2.11). Hence, since X^n_* is a subspace of X^n we can apply Lemma 2.2 to deduce that the degrees of freedom described in Corollary 2.3 are unisolvent on X^n_*. ∎

For n even we define the functions $\theta_{i,K} \in X^n_*$, $\theta_{i,\gamma} \in X^n_*$, and $\theta_{\tilde{\beta},K} \in X^n_*$ to be such that

$$\int_{K'} \theta_{i,K} P_{j,K'} = \delta_{KK'}\delta_{ij}, \quad \int_{K'} \theta_{i,\gamma} P_{j,K'} = 0, \quad \int_{K'} \theta_{\tilde{\beta},K} P_{j,K'} = 0,$$

for $j = 1, \ldots, \dim \mathbb{P}_{n-3}(\mathbb{R}^2)$ for all $K' \in \mathcal{P}$,

$$\int_{\gamma'} \theta_{i,K} L_{j,\gamma'} = 0, \quad \int_{\gamma'} \theta_{i,\gamma} L_{j,\gamma'} = \delta_{\gamma\gamma'}\delta_{ij}, \quad \int_{\gamma'} \theta_{\tilde{\beta},K} L_{j,\gamma'} = 0,$$

for $j = 0, \ldots, n-1$ for all $\gamma' \in \partial\mathcal{P}$, and

$$\int_{\partial K'} \theta_{i,K} \tilde{\beta}_{K'} = 0, \quad \int_{\partial K'} \theta_{i,\gamma} \tilde{\beta}_{K'} = 0, \quad \int_{\partial K'} \theta_{\tilde{\beta},K} \tilde{\beta}_{K'} = \delta_{KK'},$$

for all $K' \in \mathcal{P}$. Then, for n even,

$$X_*^n = \operatorname{span}\left\{ \{\theta_{i,K}\}_{i=1}^{\dim \mathbb{P}_{n-3}(K)},\ \theta_{\tilde{\beta},K} \text{ for all } K \in \mathcal{P},\ \{\theta_{i,\gamma}\}_{i=0}^{n-2} \text{ for all } \gamma \in \partial\mathcal{P} \right\}.$$

We also define the subspace of X_*^n

$$X_{*D}^n = \left\{ v \in X_D^n : \int_\gamma v \sum_{\substack{1 \le j \le n-1: \\ j \text{ odd}}} \frac{L_{j,\gamma}}{\|L_{j,\gamma}\|_{L_2(\gamma)}^2} = 0 \text{ for all } \gamma \in \partial\mathcal{P} \right\}.$$

From the above definitions it follows that in both the odd and even order cases the functions $\theta_{i,K}$ and $\theta_{\tilde{\beta},K}$ are supported on element K with the functions $\theta_{i,\gamma}$ being supported on the two elements having γ as one of their edges.

The essential difference in the structures of the degrees of freedom in the case of odd versus even order elements is well known for nonconforming finite elements. This phenomenon will manifest itself throughout the subsequent analysis.

For further details of the implementation of these nonconforming finite element methods we refer the reader to [19], where the bases defined in [11, 12, 13, 16] for the full spaces X^n are generalized to arbitrary order.

2.3. Projection operators. As seen previously the structure of nonconforming finite elements is different depending on the parity of n. This fact means that we are obliged to consider the cases where n is odd or even separately when constructing the projection operators. We wish to construct operators that project functions from the space $H_D^1(\Omega)$ into the spaces X_D^n for odd $n \ge 1$ and X_{*D}^n for even $n \ge 2$.

LEMMA 2.4. *Suppose that n is a positive odd number. There exists a unique operator $\Pi : H^1(\Omega) \to X^n$ such that, for all $K \in \mathcal{P}$,*

$$(v - \Pi v, p)_K = 0 \ \forall p \in \mathbb{P}_{n-3}(K), \tag{2.18}$$

and, for all $\gamma \subset \partial\mathcal{P}$,

$$(v - \Pi v, p)_\gamma = 0 \ \forall p \in \mathbb{P}_{n-1}(\gamma). \tag{2.19}$$

Moreover, $\Pi : H_D^1(\Omega) \to X_D^n$ and, for all $K \in \mathcal{P}$,

$$\Pi p_{|K} = p_{|K} \text{ for all } p \in H^1(\Omega) \text{ such that } p_{|K} \in \mathbb{P}_n(K). \tag{2.20}$$

Also, there exists a positive constant C independent of the size of any of the elements in the mesh such that for all $K \in \mathcal{P}$

$$\|\Pi v\|_{L_2(K)} \le C \left(\|v\|_{L_2(K)} + h_K^{1/2} \sum_{\gamma \subset \partial K} \|v\|_{L_2(\gamma)} \right), \tag{2.21}$$

$$\sum_{\gamma\subset\partial K}\|\Pi v\|_{L_2(\gamma)}\leq C\sum_{\gamma\subset\partial K}\|v\|_{L_2(\gamma)}\,, \tag{2.22}$$

and

$$\|v-\Pi v\|_{L_2(K)}+h_K^{1/2}\sum_{\gamma\subset\partial K}\|v-\Pi v\|_{L_2(\gamma)}\leq Ch_K\,\|\mathbf{grad}\,v\|_{L_2(K)}\,, \tag{2.23}$$

where h_K is the length of the longest edge of element K.

Proof. The existence of such an operator Π follows from Lemma 2.1. Now, (2.19) implies that, for $v\in H_D^1(\Omega)$ and all $\gamma\subset\partial\mathcal{P}\cap\Gamma_D$, $(\Pi v,p)_\gamma=0$ for all $p\in\mathbb{P}_{n-1}(\gamma)$ and so $\Pi: H_D^1(\Omega)\to X_D^n$. Also, for all $K\in\mathcal{P}$, (2.18) for K and (2.19) for $\gamma\subset\partial K$ uniquely determine $\Pi v_{|K}$. This means that since, for all $p\in H^1(\Omega)$ such that $p_{|K}\in\mathbb{P}_n(K)$, letting $v=p$ and $\Pi p_{|K}=p_{|K}$ satisfies (2.18) for K and (2.19) for $\gamma\subset\partial K$, then (2.20) must hold. Finally, we can write

$$\Pi v_{|K}=\sum_{i=1}^{\dim\mathbb{P}_{n-3}(K)}\theta_{i,K|K}\left(P_{i,K},v\right)_K+\sum_{\gamma\subset\partial K}\sum_{i=0}^{n-1}\theta_{i,\gamma|K}\left(L_{i,\gamma},v\right)_\gamma \tag{2.24}$$

to which we can apply standard scaling arguments to obtain inequalities (2.21), (2.22), and (2.23) upon also noting that the $\theta_{i,K}$ vanish on and outside the boundary of K. ∎

Note that when $n=1$ the projection operator given in Lemma 2.4 reduces to the same projection operator that was defined by (2.7) in [5].

We turn to the case of even order elements.

LEMMA 2.5. *Suppose that n is a positive even number. There exists a unique operator $\Pi: H^1(\Omega)\to X_*^n$ such that, for all $K\in\mathcal{P}$,*

$$\left(v-\Pi v,p\right)_K=0\ \forall p\in\mathbb{P}_{n-3}\left(K\right) \tag{2.25}$$

and

$$\sum_{\gamma'\subset\partial K}\left(v-\Pi v,\tilde{\beta}_K\right)_{\gamma'}=0 \tag{2.26}$$

and, for all $\gamma\subset\partial\mathcal{P}$,

$$\left(v-\Pi v,p\right)_\gamma=0\ \forall p\in\mathbb{P}_{n-2}\left(\gamma\right) \tag{2.27}$$

and

$$\left(\Pi v,\sum_{\substack{1\leq j\leq n-1;\\ j\ odd}}\frac{L_{j,\gamma}}{\|L_{j,\gamma}\|_{L_2(\gamma)}^2}\right)_\gamma=0. \tag{2.28}$$

Moreover, $\Pi: H_D^1\left(\Omega\right)\to X_{*D}^n$ and, for all $K\in\mathcal{P}$,

$$\Pi p_{|K}=p_{|K}\ \textit{for all}\ p\in H^1\left(\Omega\right)\ \textit{such that}\ p_{|K}\in\mathbb{P}_0\left(K\right). \tag{2.29}$$

Also, inequalities (2.21), (2.22), *and* (2.23) *are satisfied.*

Proof. The existence of such an operator Π follows from Corollary 2.3. The same arguments that were used in the proof of Lemma 2.4 can be used to show that the remainder of this lemma is true by noting that we can write

$$\Pi v_{|K} = \sum_{i=1}^{\dim \mathbb{P}_{n-3}(K)} \theta_{i,K|K} \left(P_{i,K}, v\right)_K + \sum_{\gamma \subset \partial K} \left(\theta_{\tilde{\beta},K|K} \left(\tilde{\beta}_K, v\right)_\gamma + \sum_{i=0}^{n-2} \theta_{i,\gamma|K} \left(L_{i,\gamma}, v\right)_\gamma \right). \tag{2.30}$$

∎

While the projection operators that we have defined in Lemma 2.4 are natural extensions of the projection operator defined in [5], it is worth noting that when $n = 2$ the projection operator defined in Lemma 2.5 does not reduce to the projection operator defined in [3].

2.4. Data oscillation. Let $|K|$ denote the area of the element K, and let $|\gamma|$ denote the length of edge γ.

The oscillation of the data f on an element $K \in \mathcal{P}$ is defined to be

$$\operatorname{osc}(f, K) = |K|^{1/2} \inf_{p \in \mathbb{P}_n(K)} \|f - p\|_{L_2(K)}.$$

Since $\mathbb{P}_n(K)$ is finite-dimensional and the norm is strictly convex, it follows that there exists a unique minimizer of the right-hand side, which we shall denote by $P_K f$. Likewise, the oscillation of the Neumann data g on an edge $\gamma \subset \Gamma_N$ is defined to be

$$\operatorname{osc}(g, \gamma) = |\gamma|^{1/2} \inf_{p \in \mathbb{P}_n(\gamma)} \|g - p\|_{L_2(\gamma)},$$

and again we denote the minimizer by $P_\gamma g$. For $K \in \mathcal{P}$ and $\gamma \subset \partial K \cap \Gamma_D$, let the space $H^1_\gamma(K) = \{v : v \in H^1(K) : v = 0 \text{ on } \partial K \setminus \gamma\}$. The oscillation of the Dirichlet data q on an edge $\gamma \subset \partial K \cap \Gamma_D$ is defined to be

$$\operatorname{osc}(q, \gamma) = \inf_{\substack{v \in H^1_\gamma(K): \\ v_{|\gamma} = q - q_I}} \|\mathbf{grad}\, v\|_{L_2(K)}.$$

This definition of oscillation differs from that used in [5], [3]. However, it will transpire that the definition given here is more natural for the general case considered here.

LEMMA 2.6. *Let* $C_K = \frac{h_K}{\pi}$ *and let* $C^K_\gamma = (\frac{|\gamma|}{|K|} \frac{h_K}{\pi} (\frac{h_K}{\pi} + \max_{\gamma' \subset \partial K} |\gamma'|))^{1/2}$ *for* γ, γ' *distinct edges. Then, for* $v \in H^1_D(\Omega)$,

$$(f - P_K f, v - \Pi v)_K \le C_K \|f - P_K f\|_{L_2(K)} \|\mathbf{grad}\, v\|_{L_2(K)} \tag{2.31}$$

for $K \in \mathcal{P}$ *and*

$$(g - P_\gamma g, v - \Pi v)_\gamma \le C^K_\gamma \|g - P_\gamma g\|_{L_2(\gamma)} \|\mathbf{grad}\, v\|_{L_2(K)} \tag{2.32}$$

for $\gamma \subset \partial K \cap \Gamma_N$.

Proof. Since $\Pi v_{|K} \in \mathbb{P}_n(K)$, from the definition of $P_K f$ it follows that

$$(f - P_K f, v - \Pi v)_K = (f - P_K f, v)_K = (f - P_K f, v - c)_K$$

for any $c \in \mathbb{R}$. Now, by [18] there exists a $c \in \mathbb{R}$ such that $\|v - c\|_{L_2(K)} \le C_K \|\mathbf{grad}\, v\|_{L_2(K)}$ from which we can obtain (2.31) after applying the Cauchy–Schwarz inequality to the above. By a similar argument we can also obtain inequality (2.32) by making use of the inequality $\inf_{c \in \mathbb{R}} \|v - c\|_{L_2(\gamma)} \le C^K_\gamma \|\mathbf{grad}\, v\|_{L_2(K)}$, which is proved in [7]. ∎

2.5. Path permeability. Let a_K denote the value taken by the permeability a on element K. For $m \in \mathcal{N}$ let Ω_m denote the patch composed from those elements whose closure contains the point $\boldsymbol{x}_m$, and let $K, K' \subset \Omega_m$ be distinct elements. To define the permeability $a_{KK'}$ between a pair of elements, first observe that there is always at least one connected path $\wp(K, K') \subset \mathcal{P}$ passing from K to K' through adjacent elements belonging to the patch Ω_m. The smallest permeability of all of the elements in the path $\wp(K, K')$ is given by $\min\{a_M : M \in \wp(K, K')\}$. We take $\wp^\star(K, K')$ to be the path which maximizes the value of this quantity and define

$$a_{KK'} = \min\{a_M : M \in \wp^\star(K, K')\}. \tag{2.33}$$

If $m \in \mathcal{N}(\Gamma_D)$, then the element may be linked to $\gamma \subset \Gamma_D$ such that $\boldsymbol{x}_m \subset \overline{\gamma}$ by a connected path $\wp(K, \Gamma_D, m)$ passing through adjacent elements as before. Choosing $\wp^\star(K, \Gamma_D, m)$ to be the path which maximizes the value of $\min\{a_M : M \in \wp(K, \Gamma_D, m)\}$, the permeability between element K and the Dirichlet boundary is then defined by $a_{K\Gamma_D,m} = \min\{a_M : M \in \wp^\star(K, \Gamma_D, m)\}$. We also define

$$\Upsilon_K = \max\left(\max_{\substack{m\in\mathcal{N}(K):\\ m\in\mathcal{N}(\Gamma_D)}} \frac{a_K}{a_{K\Gamma_D,m}}, \max_{\substack{m\in\mathcal{N}(K):\\ m\notin\mathcal{N}(\Gamma_D)}} \left(\sum_{K'\subset\Omega_m\setminus K} \frac{\min(a_K, a_{K'})}{a_{KK'}}\right)\right). \tag{2.34}$$

For more details and examples on path permeability we refer the reader to [5].

2.6. A posteriori error estimation. Let the broken energy norm over a region ω be denoted by $\|\!|\cdot|\!\|_\omega = (a\,\mathbf{grad_{nc}}\,\cdot, \mathbf{grad_{nc}}\,\cdot)_\omega^{1/2}$ where again we shall omit the subscript in the case where $\omega = \Omega$. Our objective is to obtain a computable estimator for the broken energy norm of the error $e = u - u_{nc}$. To achieve this we shall make use of the following lemma, the proof of which can be found in [14].

LEMMA 2.7. *Let $\mathcal{H} = \{w \in H^1(\Omega) : (w, 1)_\Omega = 0$ and $\partial w/\partial \boldsymbol{t} = 0$ on $\Gamma_N\}$, where $\boldsymbol{t}$ is a tangent vector to Γ_N. The error $e = u - u_{nc}$ may be decomposed into the form*

$$a\,\mathbf{grad_{nc}}\,e = a\,\mathbf{grad}\,\phi + \mathbf{curl}\,\psi, \tag{2.35}$$

where the conforming error $\phi \in H^1_D(\Omega)$ satisfies

$$(a\,\mathbf{grad}\,\phi, \mathbf{grad}\,v) = (a\,\mathbf{grad_{nc}}\,e, \mathbf{grad}\,v)\ \forall v \in H^1_D(\Omega) \tag{2.36}$$

and the nonconforming error $\psi \in \mathcal{H}$ satisfies

$$(a^{-1}\,\mathbf{curl}\,\psi, \mathbf{curl}\,w) = (\mathbf{grad_{nc}}\,e, \mathbf{curl}\,w)\ \forall w \in \mathcal{H}. \tag{2.37}$$

Moreover,

$$\|\!|e|\!\|^2 = \|\!|\phi|\!\|^2 + (a^{-1}\,\mathbf{curl}\,\psi, \mathbf{curl}\,\psi). \tag{2.38}$$

The importance of this lemma is that it allows us to write $\|\!|e|\!\|^2$ as the sum of a conforming part $\|\!|\phi|\!\|^2$ and a nonconforming part $(a^{-1}\,\mathbf{curl}\,\psi, \mathbf{curl}\,\psi)$ which reduces the task of obtaining an estimator for $\|\!|e|\!\|$ to that of obtaining separate estimators for each of the two terms in this decomposition.

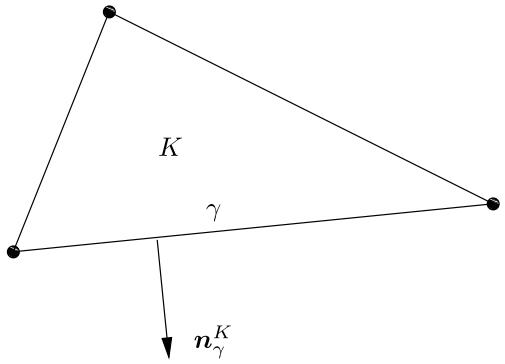

FIG. 3.1. *Orientation of the unit normal vector to an edge γ of element K.*

3. Estimation of the conforming error.

3.1. Upper bound. Let the unit normal vector $\boldsymbol{n}_\gamma^K$ to edge γ of element K be oriented as shown in Figure 3.1.

Our aim is to find a fully computable upper bound for $|||\phi|||^2$. Let $v \in H_D^1(\Omega)$. Then, by (2.36), the definition of e and (2.1),

$$\begin{aligned}(a\,\mathbf{grad}\,\phi, \mathbf{grad}\,v) &= (a\,\mathbf{grad_{nc}}\,e, \mathbf{grad}\,v)\\ &= (a\,\mathbf{grad}\,u, \mathbf{grad}\,v) - (a\,\mathbf{grad_{nc}}\,u_{nc}, \mathbf{grad}\,v)\\ &= (f,v) + (g,v)_{\Gamma_N} - (a\,\mathbf{grad_{nc}}\,u_{nc}, \mathbf{grad}\,v)\\ &= \sum_{K\in\mathcal{P}} \left((f,v)_K - (a_K\,\mathbf{grad}\,u_{nc}, \mathbf{grad}\,v)_K + \sum_{\gamma\subset\partial K} (g,v)_{\gamma\cap\Gamma_N} \right).\end{aligned}$$

Observing that $\Pi v \in X_D^n$, we find

$$0 = (a\,\mathbf{grad_{nc}}\,u_{nc}, \mathbf{grad_{nc}}\,\Pi v) - (f, \Pi v) - (g, \Pi v)_{\Gamma_N}$$

from (2.3), and so

$$\begin{aligned}(a\,\mathbf{grad}\,\phi, \mathbf{grad}\,v) = \sum_{K\in\mathcal{P}} \Bigg(&- (a_K\,\mathbf{grad}\,u_{nc}, \mathbf{grad}\,(v-\Pi v))_K\\ &+ (f, v-\Pi v)_K + \sum_{\gamma\subset\partial K} (g, v-\Pi v)_{\gamma\cap\Gamma_N} \Bigg).\end{aligned}$$

We can then use integration by parts to obtain

$$\begin{aligned}&(a\,\mathbf{grad}\,\phi, \mathbf{grad}\,v)\\ &= \sum_{K\in\mathcal{P}} \Bigg((P_K f + a_K\,\mathrm{div}\,(\mathbf{grad}\,u_{nc}), v-\Pi v)_K + (f - P_K f, v-\Pi v)_K\\ &\quad + \sum_{\gamma\subset\partial K} \Bigg((P_\gamma g, v-\Pi v)_{\gamma\cap\Gamma_N} + (g - P_\gamma g, v-\Pi v)_{\gamma\cap\Gamma_N}\\ &\quad - \left(a_K \frac{\partial u_{nc|K}}{\partial \boldsymbol{n}_\gamma^K}, v-\Pi v \right)_\gamma \Bigg) \Bigg).\end{aligned} \tag{3.1}$$

We shall now consider the two cases n odd and n even separately. For n odd, applying property (2.19) gives

$$
\begin{aligned}
(3.2)\qquad & (a\,\mathbf{grad}\,\phi, \mathbf{grad}\,v) \\
&= \sum_{K\in\mathcal{P}} \left(P_K f + a_K \operatorname{div}\left(\mathbf{grad}\,u_{nc}\right), v-\Pi v\right)_K + \sum_{\gamma\subset\partial\mathcal{P}\cap\Gamma_N} \left(P_\gamma g, v-\Pi v\right)_\gamma \\
&\quad + \sum_{K\in\mathcal{P}} \left(f-P_K f, v-\Pi v\right)_K + \sum_{\gamma\subset\partial\mathcal{P}\cap\Gamma_N} \left(g-P_\gamma g, v-\Pi v\right)_\gamma
\end{aligned}
$$

since $a_K \partial u_{nc|K}/\partial \boldsymbol{n}_\gamma^K \in \mathbb{P}_{n-1}(\gamma)$. We can then rewrite this using the definition of Πv (2.24) and the fact that the $\theta_{i,K}$ vanish on the boundary of element K as

$$
\begin{aligned}
(3.3)\qquad (a\,\mathbf{grad}\,\phi, \mathbf{grad}\,v) = \sum_{K\in\mathcal{P}} \Big(& \left(r_K, v\right)_K + \left(f-P_K f, v-\Pi v\right)_K \\
& + \sum_{\gamma\subset\partial K} \Big(\left(g-P_\gamma g, v-\Pi v\right)_{\gamma\cap\Gamma_N} + \left(R_{\gamma,K}, v\right)_\gamma \Big)\Big),
\end{aligned}
$$

where

$$
r_K = P_K f + a_K \operatorname{div}\left(\mathbf{grad}\,u_{nc}\right) - \sum_{i=1}^{\dim \mathbb{P}_{n-3}(K)} \left(\theta_{i,K}, P_K f + a_K \operatorname{div}\left(\mathbf{grad}\,u_{nc}\right)\right)_K P_{i,K}
$$

and, defining $P_\gamma g$ and $P_{\gamma'} g$ to vanish if $\gamma \cap \Gamma_N$ or $\gamma' \cap \Gamma_N$, respectively, are empty

$$
R_{\gamma,K} = P_\gamma g - \sum_{i=0}^{n-1} \left(\sum_{\gamma'\subset\partial K\cap\Gamma_N} \left(\theta_{i,\gamma}, P_{\gamma'} g\right)_{\gamma'} + \left(\theta_{i,\gamma}, P_K f + a_K \operatorname{div}\left(\mathbf{grad}\,u_{nc}\right)\right)_K \right) L_{i,\gamma}.
$$

We now turn to the case when n is even. Unlike the odd order case we cannot eliminate the term involving the normal derivative of u_{nc} from (3.2). This was possible in the case of odd order elements because of the property that $v - \Pi v$ was orthogonal to $\mathbb{P}_{n-1}(\gamma)$. The corresponding property fails to hold in the case of even order elements owing to the compatibility condition in Lemma 2.2. We shall therefore require the following definitions in order to deal with this term in a way that allows us to prove that the estimator is efficient and robust with respect to the permeability coefficient a. For each $K \in \mathcal{P}$ and each edge $\gamma \subset \partial K$, define

$$
\alpha_\gamma^K = \begin{cases} \dfrac{a_{K'}^{-1/2}}{a_K^{-1/2} + a_{K'}^{-1/2}} & \text{if } \gamma = \partial K \cap \partial K', \\ 1 & \text{if } \gamma \subset \Gamma_N, \\ 0 & \text{if } \gamma \subset \Gamma_D \end{cases}
$$

and

$$
\left[a\frac{\partial u_{nc}}{\partial \boldsymbol{n}}\right]_\gamma = \begin{cases} a_K \dfrac{\partial u_{nc|K}}{\partial \boldsymbol{n}_\gamma^K} + a_{K'} \dfrac{\partial u_{nc|K'}}{\partial \boldsymbol{n}_\gamma^{K'}} & \text{if } \gamma = \partial K \cap \partial K', \\ a_K \dfrac{\partial u_{nc|K}}{\partial \boldsymbol{n}_\gamma^K} & \text{if } \gamma \subset \Gamma. \end{cases}
$$

Now, for n even, since $\alpha_\gamma^K + \alpha_\gamma^{K'} = 1$ for $\gamma = \partial K \cap \partial K'$, we can make use of the properties of the space X_D^n to which Πv belongs and the fact that $v = 0$ on Γ_D to

obtain

$$
\begin{aligned}
&(a\,\mathbf{grad}\,\phi, \mathbf{grad}\,v)\\
&= \sum_{K\in\mathcal{P}} \Bigg((P_K f + a_K \operatorname{div}(\mathbf{grad}\,u_{nc}), v-\Pi v)_K + (f - P_K f, v-\Pi v)_K\\
&+ \sum_{\gamma\subset\partial K} \Bigg((P_\gamma g, v-\Pi v)_{\gamma\cap\Gamma_N} + (g-P_\gamma g, v-\Pi v)_{\gamma\cap\Gamma_N}\\
&- \left(\alpha_\gamma^K \left[a\frac{\partial u_{nc}}{\partial \boldsymbol{n}}\right]_\gamma, v-\Pi v\right)_\gamma\Bigg)\Bigg).
\end{aligned}
$$

In the same way that we did for the odd case we can rewrite this equation using the definition of Πv (2.30) as (3.3) where r_K is defined in the same way that it was for the odd case but

$$
\begin{aligned}
R_{\gamma,K} = P_\gamma g - \alpha_\gamma^K \left[a\frac{\partial u_{nc}}{\partial \boldsymbol{n}}\right]_\gamma + \sum_{i=0}^{n-2} \Bigg(&\left(\theta_{i,\gamma}, \alpha_\gamma^K \left[a\frac{\partial u_{nc}}{\partial \boldsymbol{n}}\right]_\gamma\right)_\gamma\\
&- \sum_{\gamma'\subset\partial K\cap\Gamma_N} (\theta_{i,\gamma}, P_{\gamma'} g)_{\gamma'} - (\theta_{i,\gamma}, P_K f + a_K \operatorname{div}(\mathbf{grad}\,u_{nc}))_K \Bigg) L_{i,\gamma}\\
&- \left(\sum_{\gamma'\subset\partial K\cap\Gamma_N} \left(\theta_{\tilde\beta,K}, P_{\gamma'} g\right)_{\gamma'} + \left(\theta_{\tilde\beta,K}, P_K f + a_K \operatorname{div}(\mathbf{grad}\,u_{nc})\right)_K \right) \tilde\beta_{K|\gamma}
\end{aligned}
$$

when n is even. To arrive at this we have made use of the fact that, for all $p\in\mathbb{P}_{n-1}(\gamma)$, $(\theta_{\tilde\beta,K}, p)_\gamma$ and $(\theta_{i,\gamma'}, p)_\gamma$ vanish for all edges $\gamma\neq\gamma'$.

Note that evaluation of our estimator will require calculation of r_K and $R_{\gamma,K}$. This means that the evaluation of our estimator is simpler when n is odd since in that case we need not calculate $\alpha_\gamma^K \left[a\frac{\partial u_{nc}}{\partial \boldsymbol{n}}\right]_\gamma$. The functions r_K and $R_{\gamma,K}$ are used to calculate an auxiliary function $\boldsymbol{\sigma}_K$ as follows.

THEOREM 3.1. *Consider the problem of minimizing $\|\boldsymbol{\sigma}_K\|^2_{L_2(K)}$ subject to*

$$
(\boldsymbol{\sigma}_K, \mathbf{grad}\,v)_K = (r_K, v)_K + \sum_{\gamma\subset\partial K} (R_{\gamma,K}, v)_\gamma \quad \forall v\in\mathbb{P}_{n+3}(K). \tag{3.4}
$$

A unique solution $\boldsymbol{\sigma}_K\in\mathbb{P}_{n+1}(K)\times\mathbb{P}_{n+1}(K)$ to this problem exists. Moreover, the solution $\boldsymbol{\sigma}_K$ of this problem satisfies

$$
(\boldsymbol{\sigma}_K, \mathbf{grad}\,v)_K = (r_K, v)_K + \sum_{\gamma\subset\partial K} (R_{\gamma,K}, v)_\gamma \quad \forall v\in H^1(K). \tag{3.5}
$$

Also, there exists a positive constant C, independent of the size of any of the elements in the mesh, such that

$$
\|\boldsymbol{\sigma}_K\|_{L_2(K)} \le C\left(|K|^{1/2}\|r_K\|_{L_2(K)} + \sum_{\gamma\subset\partial K} |\gamma|^{1/2}\|R_{\gamma,K}\|_{L_2(\gamma)}\right). \tag{3.6}
$$

Proof. We shall first show that (3.4) is equivalent to

$$
\boldsymbol{n}_\gamma^K\cdot\boldsymbol{\sigma}_K = R_{\gamma,K}\in\mathbb{P}_n(\gamma) \text{ on } \gamma\subset\partial K \text{ for all } \gamma\subset\partial K \tag{3.7}
$$

and

$$-\operatorname{div}\boldsymbol{\sigma}_K = r_K \in \mathbb{P}_n(K) \text{ on } K. \tag{3.8}$$

Now, integration by parts shows that (3.4) is equivalent to

$$\sum_{\gamma\subset\partial K}\left(R_{\gamma,K}-\boldsymbol{n}_\gamma^K\cdot\boldsymbol{\sigma}_K,v\right)_\gamma+\left(r_K+\operatorname{div}\boldsymbol{\sigma}_K,v\right)_K=0\ \forall v\in\mathbb{P}_{n+3}(K), \tag{3.9}$$

which obviously holds when (3.7) and (3.8) are satisfied. Conversely, we first let $v=\beta_K(r_K+\operatorname{div}\boldsymbol{\sigma}_K)\in\mathbb{P}_{n+3}(K)$ in (3.9), where $\beta_K\geq 0$ is the cubic bubble, to see that (3.8) must hold. Furthermore, extending $R_{\gamma,K}$ onto K as a polynomial in $\mathbb{P}_n(K)$ and letting $v=\beta_\gamma(R_{\gamma,K}-\boldsymbol{n}_\gamma^K\cdot\boldsymbol{\sigma}_K)\in\mathbb{P}_{n+3}(K)$ in (3.9) for each $\gamma\subset\partial K$, where $\beta_\gamma\geq 0$ is the quadratic edge bubble, shows that (3.7) is satisfied.

In Theorem 6.1 in the appendix, the existence of a function in $\mathbb{P}_{n+1}(\hat{K})\times\mathbb{P}_{n+1}(\hat{K})$ satisfying (3.7) and (3.8) for a reference element $\hat{K}$ is proven provided that the data satisfy the usual compatibility condition

$$(r_K,1)_K+\sum_{\gamma\subset\partial K}(R_{\gamma,K},1)_\gamma=0. \tag{3.10}$$

To see that this condition does hold we observe that, for all $v\in H^1(K)$,

$$\begin{aligned}&(r_K,v)_K+\sum_{\gamma\subset\partial K}(R_{\gamma,K},v)_\gamma\\&=\left(P_Kf+a_K\operatorname{div}(\mathbf{grad}\,u_{nc}),v-\Pi v\right)_K+\sum_{\gamma\subset\partial K\cap\Gamma_N}(P_\gamma g,v-\Pi v)_\gamma\end{aligned}$$

if n is odd, while for n even

$$\begin{aligned}&(r_K,v)_K+\sum_{\gamma\subset\partial K}(R_{\gamma,K},v)_\gamma\\&=\left(P_Kf+a_K\operatorname{div}(\mathbf{grad}\,u_{nc}),v-\Pi v\right)_K+\sum_{\gamma\subset\partial K}\left(P_\gamma g-\alpha_\gamma^K\left[a\frac{\partial u_{nc}}{\partial\boldsymbol{n}}\right]_\gamma,v-\Pi v\right)_\gamma\end{aligned}$$

from which condition (3.10) then follows since Π preserves constants. Moreover, the strict convexity of the norm implies that $\boldsymbol{\sigma}_K$ exists and is unique. Assertion (3.5) is then a trivial consequence of (3.7) and (3.8). Finally, we can apply standard scaling arguments to inequality (6.5) in the appendix to arrive at inequality (3.6) on recalling $\boldsymbol{\sigma}_K$ has minimal norm. □

Theorem 3.1 shows that, despite the fact that condition (3.4) is enforced with respect to a *finite*-dimensional space of test functions, the condition actually holds over an *infinite*-dimensional space.

We are now in a position to obtain a computable upper bound for $|\!|\!|\phi|\!|\!|$.

LEMMA 3.2. *Define*

(3.11)
$$\Phi_K = a_K^{-1/2}\left(\|\boldsymbol{\sigma}_K\|_{L_2(K)} + C_K\,\|f - P_K f\|_{L_2(K)} + \sum_{\gamma\subset\partial K\cap\Gamma_N} C_\gamma^K\,\|g - P_\gamma g\|_{L_2(\gamma)}\right),$$

where C_K and C_γ^K are the fully computable constants defined in Lemma 2.6. *Then*

$$\|\!|\phi|\!\|^2 \le \sum_{K\in\mathcal{P}} \Phi_K^2. \tag{3.12}$$

Proof. Returning to (3.3) and using Theorem 3.1 we obtain

$$(a\,\mathbf{grad}\,\phi, \mathbf{grad}\,v) = \sum_{K\in\mathcal{P}}\Big((\boldsymbol{\sigma}_K, \mathbf{grad}\,v)_K + (f - P_K f, v - \Pi v)_K + \sum_{\gamma\subset\partial K\cap\Gamma_N} (g - P_\gamma g, v - \Pi v)_\gamma\Big).$$

Inserting (2.31) and (2.32) and then applying the Cauchy–Schwarz inequality yields

$$(a\,\mathbf{grad}\,\phi, \mathbf{grad}\,v) \le \sum_{K\in\mathcal{P}} \Phi_K\,\|\!|v|\!\|_K \le \left(\sum_{K\in\mathcal{P}}\Phi_K^2\right)^{1/2} \|\!|v|\!\|$$

from which we can obtain the result by letting $v = \phi$ and dividing both sides of the inequality by $\|\!|\phi|\!\|$. ∎

3.2. Local lower bounds. We now show that Φ_K also provides a local lower bound for the conforming component of the error plus data oscillation up to a generic constant.

LEMMA 3.3. *Let K^* be the union of those elements, including element K, that share an edge with element K. Then there exists a positive constant c, independent of the size of any of the elements in the mesh and the permeability coefficient a, such that*

(3.13)
$$c\Phi_K \le \begin{cases} \|\!|\phi|\!\|_K + a_K^{-1/2}\,\mathrm{osc}\,(f,K) + a_K^{-1/2}\displaystyle\sum_{\gamma\subset\partial K\cap\Gamma_N} \mathrm{osc}\,(g,\gamma) & \text{if } n \text{ is odd,} \\ \displaystyle\sum_{K'\subset K^*}\Big(\|\!|\phi|\!\|_{K'} + a_K^{-1/2}\,\mathrm{osc}\,(f,K')\Big) + a_K^{-1/2}\sum_{\gamma\subset\partial K\cap\Gamma_N} \mathrm{osc}\,(g,\gamma) & \text{if } n \text{ is even.}\end{cases}$$

Proof. Applying the estimates $C_K \le C|K|^{1/2}$ and $C_\gamma^K \le C|\gamma|^{1/2}$ to the expression for Φ_K allows us to say that

$$\Phi_K \le C a_K^{-1/2}\left(\|\boldsymbol{\sigma}_K\|_{L_2(K)} + \mathrm{osc}\,(f,K) + \sum_{\gamma\subset\partial K\cap\Gamma_N}\mathrm{osc}\,(g,\gamma)\right),$$

and by (3.6) and the equivalence of norms in finite dimensions we can say that

$$\|\boldsymbol{\sigma}_K\|_{L_2(K)} \le C\left(|K|^{1/2}\left\|\beta_K^{1/2} r_K\right\|_{L_2(K)} + \sum_{\gamma\subset\partial K}|\gamma|^{1/2}\left\|\beta_\gamma^{1/2} R_{\gamma,K}\right\|_{L_2(\gamma)}\right).$$

Let $J_{i,\gamma}$ denote the mapped Jacobi polynomial of order i with weight β_γ on edge γ. Then, when n is odd, by property (2.19) of Πv we can write

$$(P_\gamma g, v - \Pi v)_\gamma = \frac{(P_\gamma g, \beta_\gamma J_{n,\gamma})_\gamma}{(J_{n,\gamma}, \beta_\gamma J_{n,\gamma})_\gamma} (J_{n,\gamma}, v - \Pi v)_\gamma .$$

Hence, for all $v \in H^1(K)$, for n odd

$$\begin{aligned} &(P_K f + a_K \operatorname{div}(\mathbf{grad}\, u_{nc}), v - \Pi v)_K \\ &+ \sum_{\gamma \subset \partial K \cap \Gamma_N} \frac{(P_\gamma g, \beta_\gamma J_{n,\gamma})_\gamma}{(J_{n,\gamma}, \beta_\gamma J_{n,\gamma})_\gamma} (J_{n,\gamma}, v - \Pi v)_\gamma \\ &= (r_K, v)_K + \sum_{\gamma \subset \partial K} (R_{\gamma,K}, v)_\gamma , \end{aligned}$$

and for n even

$$\begin{aligned} &(P_K f + a_K \operatorname{div}(\mathbf{grad}\, u_{nc}), v - \Pi v)_K + \sum_{\gamma \subset \partial K} \alpha_\gamma^K \left(P_\gamma g - \left[a \frac{\partial u_{nc}}{\partial \boldsymbol{n}} \right]_\gamma , v - \Pi v \right)_\gamma \\ &= (r_K, v)_K + \sum_{\gamma \subset \partial K} (R_{\gamma,K}, v)_\gamma . \end{aligned}$$

Applying techniques used in [2, 20] to these equations allows us to say, with the aid of inequalities (2.21) and (2.22), that

$$|K|^{1/2} \left\| \beta_K^{1/2} r_K \right\|_{L_2(K)} \le C |K|^{1/2} \left\| \beta_K^{1/2} (P_K f + a_K \operatorname{div}(\mathbf{grad}\, u_{nc})) \right\|_{L_2(K)}$$

with, for n odd and $\gamma \subset \partial \mathcal{P} \cap \partial K$,

$$\begin{aligned} &|\gamma|^{1/2} \left\| \beta_\gamma^{1/2} R_{\gamma,K} \right\|_{L_2(\gamma)} \\ &\le C \Big(|K|^{1/2} \left\| \beta_K^{1/2} (P_K f + a_K \operatorname{div}(\mathbf{grad}\, u_{nc})) \right\|_{L_2(K)} \\ &\quad + \sum_{\gamma' \subset \partial K \cap \Gamma_N} \left| (P_{\gamma'} g, \beta_{\gamma'} J_{n,\gamma'})_{\gamma'} \right| \Big) \end{aligned}$$

and, for n even and all $\gamma \subset \partial \mathcal{P} \cap \partial K$,

$$\begin{aligned} |\gamma|^{1/2} \left\| \beta_\gamma^{1/2} R_{\gamma,K} \right\|_{L_2(\gamma)} \le C \Bigg(&\sum_{\gamma' \subset \partial K} \alpha_{\gamma'}^K |\gamma'|^{1/2} \left\| \beta_{\gamma'}^{1/2} \left(P_{\gamma'} g - \left[a \frac{\partial u_{nc}}{\partial \boldsymbol{n}} \right]_{\gamma'} \right) \right\|_{L_2(\gamma')} \\ &+ |K|^{1/2} \left\| \beta_K^{1/2} (P_K f + a_K \operatorname{div}(\mathbf{grad}\, u_{nc})) \right\|_{L_2(K)} \Bigg). \end{aligned}$$

We can also apply these techniques to (3.1) to obtain, for all $K \in \mathcal{P}$,

$$|K|^{1/2} \left\| \beta_K^{1/2} (P_K f + a_K \operatorname{div}(\mathbf{grad}\, u_{nc})) \right\|_{L_2(K)} \le C \left(a_K^{1/2} |\!|\!| \phi |\!|\!|_K + \operatorname{osc}(f, K) \right)$$

as well as, for n odd and all $\gamma' \subset \partial \mathcal{P} \cap \partial K \cap \Gamma_N$,

$$\left| (P_{\gamma'} g, \beta_{\gamma'} J_{n,\gamma'})_{\gamma'} \right| \le C \left(a_K^{1/2} |\!|\!| \phi |\!|\!|_K + \operatorname{osc}(f, K) + \operatorname{osc}(g, \gamma') \right)$$

and, for n even and all $\gamma' \subset \partial\mathcal{P}$,

$$|\gamma'|^{1/2} \left\| \beta_{\gamma'}^{1/2} \left(P_{\gamma'} g - \left[a \frac{\partial u_{nc}}{\partial \boldsymbol{n}} \right]_{\gamma'} \right) \right\|_{L_2(\gamma')}$$

$$\leq C \left(\sum_{\substack{K' \in \mathcal{P}_i \\ \gamma' \subset \partial K'}} \left(a_{K'}^{1/2} \left\| \phi \right\|_{K'} + \operatorname{osc}(f, K') \right) + \operatorname{osc}(g, \gamma' \cap \Gamma_N) \right),$$

which we can then combine with the above to obtain the result claimed upon noting that

$$\alpha_{\gamma'}^{K} \sum_{\substack{K' \in \mathcal{P}_i \\ \gamma' \subset \partial K'}} a_{K'}^{1/2} = a_K^{1/2}. \qquad \square$$

4. Estimation of the nonconforming error.

4.1. Upper bound. The upper bound for $(a^{-1}\,\mathbf{curl}\,\psi, \mathbf{curl}\,\psi)$ is defined analogously to [3, 5] using the continuous piecewise $\mathbb{P}_n$ interpolant of u_{nc} on $\mathcal{P}$ whose values at the conforming nodes are given by

$$\mathcal{S}(u_{nc})(\boldsymbol{x}_m) = \begin{cases} q(\boldsymbol{x}_m) & \text{if } m \in \mathcal{N}(\Gamma_D), \\ \displaystyle\sum_{K \in \Omega_m} \omega_{K,m} u_{nc|K}(\boldsymbol{x}_m) & \text{if } m \notin \mathcal{N}(\Gamma_D) \end{cases} \tag{4.1}$$

for $m \in \mathcal{N}$ with the weights $\omega_{K,m}$ defined by

$$\omega_{K,m} = \frac{a_K^{1/2}}{\sum_{K' \subset \Omega_m} a_{K'}^{1/2}}.$$

As in [3, 5], it is also essential here that a weighted average be used in order that robustness of the estimator with respect to the permeability coefficient is maintained. Note that these weights satisfy the condition

$$\sum_{K \subset \Omega_m} \omega_{K,m} = 1.$$

LEMMA 4.1. *Let*

$$\Psi_K = \left\| u_{nc} - \mathcal{S}(u_{nc}) \right\|_K + \sum_{\gamma \subset \partial K \cap \Gamma_D} a_K^{1/2} \operatorname{osc}(q, \gamma). \tag{4.2}$$

Then

$$\left(a^{-1}\,\mathbf{curl}\,\psi, \mathbf{curl}\,\psi\right) \leq \sum_{K \in \mathcal{P}} \Psi_K^2. \tag{4.3}$$

Proof. The above result can easily be obtained from the upper bound proven in [5]. $\square$

The $\mathcal{S}(u_{nc})$ defined in (4.1) says that, for $\boldsymbol{x}_m \notin \partial\mathcal{P}$, $\mathcal{S}(u_{nc})(\boldsymbol{x}_m) = u_{nc}(\boldsymbol{x}_m)$, but any choice of $\mathcal{S}(u_{nc})$ at these points will provide an upper bound for the nonconforming component of the broken energy norm of the error when used in the evaluation of $\sum_{K \in \mathcal{P}} \Psi_K^2$. We therefore propose that at these points on the interior of the triangles the values taken by $\mathcal{S}(u_{nc})$ are chosen so that they minimize Ψ_K. Note that the local lower bound proved in the next section will still hold if this is done. Also, the choice of the points $\boldsymbol{x}_m$ on the edge interiors is not unique. In our numerical examples uniformly spaced points were used.

4.2. Local lower bounds. It can also be shown that Ψ_K provides a local lower bound for the nonconforming component of the error plus data oscillation up to a generic constant.

LEMMA 4.2. *Let $\tilde{K}$ denote the patch formed from element K and those elements sharing a common vertex with element K. Then there exists a positive constant c, independent of the size of any of the elements in the mesh and the permeability coefficient a, such that*

$$c\Psi_K^2 \leq \Upsilon_K \left(a^{-1}\,\mathbf{curl}\,\psi, \mathbf{curl}\,\psi\right)_{\tilde{K}} + a_K \sum_{\gamma \subset \partial\tilde{K} \cap \Gamma_D} \operatorname{osc}^2(q,\gamma)\,. \tag{4.4}$$

Proof. This result can be proved using the techniques used to prove its analogue in [3, 5]. ∎

5. Summary and numerical examples.

5.1. Summary of main results. Our fully computable upper bound and local lower bound on the broken energy norm of the error e in the nonconforming finite element approximation are summarized in the following theorem.

THEOREM 5.1. *Let Φ_K and Ψ_K be defined as in Lemmas* 3.2 *and* 4.1*, respectively. Then the broken energy norm of the total error e can be estimated as*

$$|\!|\!|e|\!|\!|^2 \leq \sum_{K\in\mathcal{P}} \left(\Phi_K^2 + \Psi_K^2\right). \tag{5.1}$$

Also, there exists a positive constant c, which is independent of the size of any of the elements in the mesh and the permeability coefficient a, such that

$$\begin{aligned} c\left(\Phi_K^2 + \Psi_K^2\right) \leq \Upsilon_K\, |\!|\!|e|\!|\!|_{\tilde{K}}^2 &+ a_K \sum_{\gamma \subset \partial\tilde{K}\cap\Gamma_D} \operatorname{osc}^2(q,\gamma) \\ &+ a_K^{-1} \sum_{K'\subset\tilde{K}} \operatorname{osc}^2(f,K') + a_K^{-1} \sum_{\gamma\subset\partial K\cap\Gamma_N} \operatorname{osc}^2(g,\gamma)\,, \end{aligned} \tag{5.2}$$

where $\tilde{K}$ denotes the patch formed from element K and those elements sharing a common vertex with element K and Υ_K is defined in (2.34).

Proof. The proof follows from Lemmas 2.7, 3.2, 3.3, 4.1, and 4.2 on observing that $K \subset K^* \subset \tilde{K}$. ∎

5.2. Example. For our example we look at the performance of the estimator for the problem of finding u^* such that $-\operatorname{div}(a\,\mathbf{grad}\,u^*) = f$ in the region $\Omega = (0,1)^2$ with homogeneous Dirichlet data on $\Gamma_D = \partial\Omega$. The function f has been chosen so that the exact solution to this problem is $u^* = (1-x^2)(1-y^2)u$, where u is the solution to the Kellogg problem described in [17], where a is also defined to take the value $161.4\ldots$ in the first and third quadrants and 1 in the second and fourth quadrants. The gradient of the true solution displays highly singular behavior at the origin since $\mathbf{grad}\,u^* = O(r^{-9/10})$. The initial mesh used for this example is shown in Figure 5.1.

Two refinement strategies were implemented.

Strategy 1 (results shown in Figures 5.2(a), 5.3(a), and 5.4(a)): The mesh was uniformly refined whereby each triangle is subdivided into four subtriangles at each step.

Strategy 2 (results shown in Figures 5.2(b), 5.3(b), and 5.4(b)): The mesh was adaptively refined whereby a bulk criterion [15] was used to refine the mesh on the

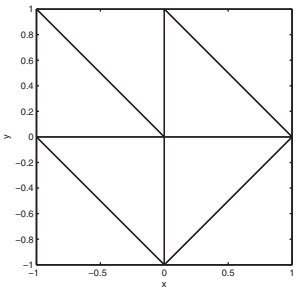

FIG. 5.1. *Initial mesh for Example* 5.2.

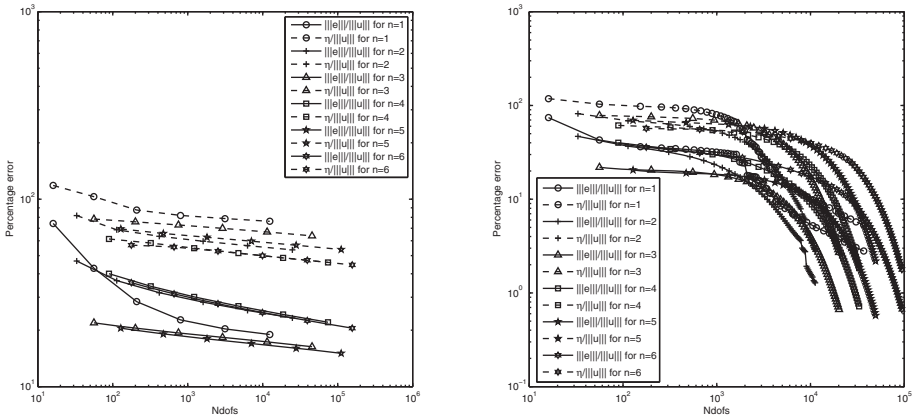


(a) (b)

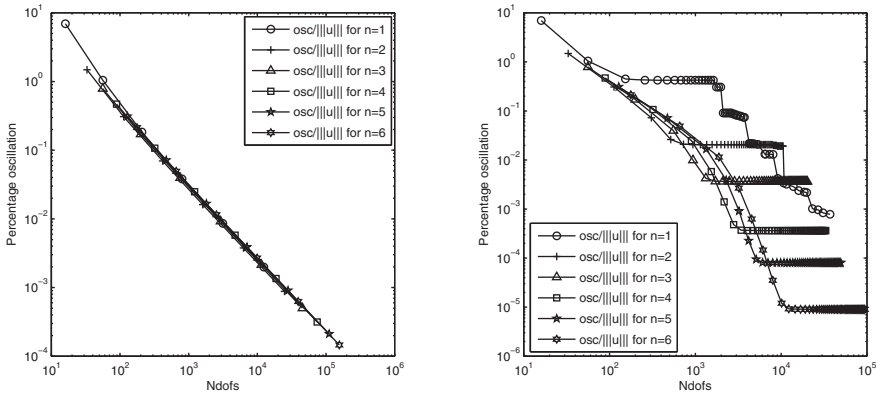
FIG. 5.2. *Performance of estimators for Example* 5.2 *with* (a) *the uniform refinement strategy and* (b) *the adaptive refinement strategy.*

smallest number of elements such that the sum of the contributions toward the estimator from these elements exceeded 50% of the value of the estimator.

When reporting numerical results we let Ndofs denote the number of degrees of freedom, let $\eta^2 = \sum_{K\in\mathcal{P}}(\Phi_K^2 + \Psi_K^2)$, $\mathrm{osc}^2 = \sum_{K\in\mathcal{P}} a_K^{-1} C_K^2 \|f - P_K f\|_{L_2(K)}^2$, and let the effectivity index of the estimator be denoted by $\vartheta = \eta / |||e|||$.

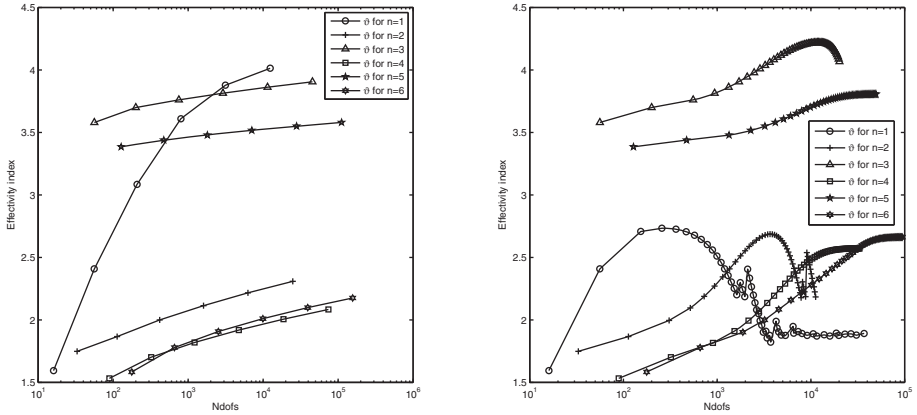
From the graphs in Figure 5.2 it can be seen that, as expected from Theorem 5.1, the estimators provide a numerical upper bound on the broken energy norm of the error. It can also be seen from Figure 5.4 that for this example, which was the one where we witnessed the most overestimation, the estimator overestimates the broken energy norm of the error by a factor less than 4.3 and that the estimator does not appear to be becoming less efficient as n increases. When uniform refinement is used it appears that the nonconforming finite element approximations of odd order outperform those of even order. It is also worth mentioning that in our example the use of an adaptive refinement strategy leads to faster reduction of the broken energy norm of the error than if uniform refinement is used.

In the cases $n = 1$ and $n = 2$ the way we have defined the oscillation, and consequently the estimator, does not reduce to how it was defined in [5] and [3],



(a) (b)

FIG. 5.3. *Data oscillation for Example* 5.2 *with* (a) *the uniform refinement strategy and* (b) *the adaptive refinement strategy.*



(a) (b)

FIG. 5.4. *Effectivity index for Example* 5.2 *with* (a) *the uniform refinement strategy and* (b) *the adaptive refinement strategy.*

respectively. This change was made since when generalized to higher orders the techniques employed in [3] to obtain the constants C_K and C_γ^K in Lemma 2.6 resulted in vast overestimation of the broken energy norm of the error being witnessed since the size of these constants would increase as n did. With the oscillation now defined as it is in Lemma 2.6 these constants are the same for all n.

6. Appendix. Let $\hat{K}$ be the element with vertices, edges, tangents, and normals as shown in Figure 6.1.

We prove the following theorem used in the proof of Theorem 3.1.

THEOREM 6.1. *Suppose* $\boldsymbol{\sigma}^\star \in H(\mathrm{div}; \hat{K})$ *is given such that*

$$\hat{\boldsymbol{n}}_i \cdot \boldsymbol{\sigma}^\star \in \mathbb{P}_n(\hat{\gamma}_i) \quad \text{on } \hat{\gamma}_i \text{ for } i = 1, 2, 3 \tag{6.1}$$

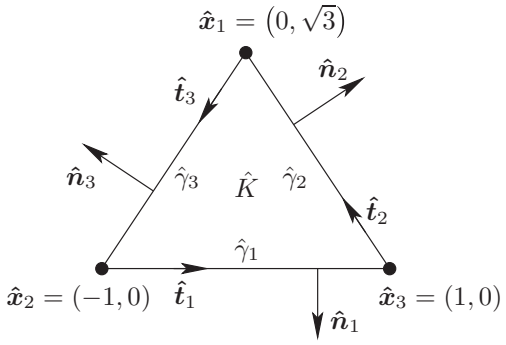


FIG. 6.1. *Direction and enumeration of the vertices, edges, unit tangent, and unit normal vectors of element* $\hat{K}$.

and

$$-\operatorname{div}\boldsymbol{\sigma}^\star \in \mathbb{P}_n\left(\hat{K}\right) \text{ on } \hat{K}. \tag{6.2}$$

Then there exists $\hat{\boldsymbol{\sigma}} \in \mathbb{P}_{n+1}(\hat{K}) \times \mathbb{P}_{n+1}(\hat{K})$ *such that*

$$\hat{\boldsymbol{n}}_i \cdot \hat{\boldsymbol{\sigma}} = \hat{\boldsymbol{n}}_i \cdot \boldsymbol{\sigma}^\star \text{ on } \hat{\gamma}_i \text{ for } i = 1, 2, 3, \tag{6.3}$$

$$-\operatorname{div}\hat{\boldsymbol{\sigma}} = -\operatorname{div}\boldsymbol{\sigma}^\star \text{ on } \hat{K}, \tag{6.4}$$

and there exists a constant C, *independent of* $\boldsymbol{\sigma}^\star$, *such that*

$$\|\hat{\boldsymbol{\sigma}}\|_{H(\operatorname{div};\hat{K})} \leq C\left(\sum_{i=1}^{3} \|\hat{\boldsymbol{n}}_i \cdot \boldsymbol{\sigma}^\star\|_{L_2(\hat{\gamma}_i)} + \|\operatorname{div}\boldsymbol{\sigma}^\star\|_{L_2(\hat{K})}\right). \tag{6.5}$$

The proof of this result will require some preparation. Let $\lambda_i \in \mathbb{P}_1(\hat{K})$ be the usual barycentric coordinates satisfying $\lambda_i(\hat{\boldsymbol{x}}_j) = \delta_{ij}$ for $j = 1, 2, 3$. For ease of exposition, it is convenient to use the convention whereby $\lambda_4 \equiv \lambda_1$, $\hat{\boldsymbol{x}}_4 \equiv \hat{\boldsymbol{x}}_1$, $\hat{\boldsymbol{t}}_4 \equiv \hat{\boldsymbol{t}}_1$, $\lambda_5 \equiv \lambda_2$, $\hat{\boldsymbol{x}}_5 \equiv \hat{\boldsymbol{x}}_2$, and $\hat{\boldsymbol{t}}_5 \equiv \hat{\boldsymbol{t}}_2$. We may parametrize an edge $\hat{\gamma}_i \subset \partial\hat{K}$ by $\boldsymbol{x}(s_i) = \hat{\boldsymbol{x}}_{i+1} + (s_i + 1)\hat{\boldsymbol{t}}_i$, where

$$s_i = \lambda_{i+2} - \lambda_{i+1} \in (-1, 1). \tag{6.6}$$

The following identities will prove useful. For $i = 1, 2, 3$,

$$\left(\hat{\boldsymbol{t}}_i \cdot \hat{\boldsymbol{n}}_i\right) = \lambda_{1|\hat{\gamma}_1} = \lambda_{2|\hat{\gamma}_2} = \lambda_{3|\hat{\gamma}_3} = 0, \tag{6.7}$$

$$\left(\hat{\boldsymbol{t}}_1 \cdot \hat{\boldsymbol{n}}_2\right) = \left(\hat{\boldsymbol{t}}_2 \cdot \hat{\boldsymbol{n}}_3\right) = \left(\hat{\boldsymbol{t}}_3 \cdot \hat{\boldsymbol{n}}_1\right) = -\left(\hat{\boldsymbol{t}}_1 \cdot \hat{\boldsymbol{n}}_3\right) = -\left(\hat{\boldsymbol{t}}_2 \cdot \hat{\boldsymbol{n}}_1\right) = -\left(\hat{\boldsymbol{t}}_3 \cdot \hat{\boldsymbol{n}}_2\right) = \frac{\sqrt{3}}{2}, \tag{6.8}$$

$$\lambda_1 + \lambda_2 + \lambda_3 = (\lambda_2 + \lambda_3)_{|\hat{\gamma}_1} = (\lambda_3 + \lambda_1)_{|\hat{\gamma}_2} = (\lambda_1 + \lambda_2)_{|\hat{\gamma}_3} = 1, \tag{6.9}$$

$$\mathbf{grad}\,\lambda_i = -\frac{1}{\sqrt{3}}\hat{\boldsymbol{n}}_i, \tag{6.10}$$

and

$$\mathbf{curl}\,\lambda_i = \frac{1}{\sqrt{3}}\hat{\boldsymbol{t}}_i. \tag{6.11}$$

LEMMA 6.2. *For $i = 1, 2, 3$, let*

$$\boldsymbol{\theta}_i^{(0)} = \frac{2}{\sqrt{3}} \left(\lambda_{i+1} \hat{\boldsymbol{t}}_{i+2} - \lambda_{i+2} \hat{\boldsymbol{t}}_{i+1} \right). \tag{6.12}$$

Then, for $i, j = 1, 2, 3$,

$$\left(\hat{\boldsymbol{n}}_i \cdot \boldsymbol{\theta}_j^{(0)} \right)_{|\hat{\gamma}_i} = \delta_{ij} \tag{6.13}$$

and

$$-\operatorname{div} \boldsymbol{\theta}_i^{(0)} = -\frac{2}{\sqrt{3}} \text{ in } K. \tag{6.14}$$

Proof. We shall prove this result for $\boldsymbol{\theta}_1^{(0)}$ since the other cases then follow by rotation. The fact that $(\hat{\boldsymbol{n}}_i \cdot \boldsymbol{\theta}_1^{(0)})_{|\hat{\gamma}_i} = 0$ when $i = 2$ or $i = 3$ is easily seen using identity (6.7). Applying identities (6.8) and (6.9) allows us to see that $(\hat{\boldsymbol{n}}_1 \cdot \boldsymbol{\theta}_1^{(0)})_{|\hat{\gamma}_1} = 1$, and making use of the identity (6.10) and simplifying using (6.8) yields (6.14). ∎

LEMMA 6.3. *For integer $m \geq 1$ and $i = 1, 2, 3$, let*

$$\boldsymbol{\theta}_i^{(m)} = \begin{cases} -\dfrac{1}{C_i^{(m,m)}} \left(4\, \mathbf{curl} \left((\lambda_{i+1}\lambda_{i+2})^{(m+1)/2} \right) + \displaystyle\sum_{l=1}^{m-2} C_i^{(l,m)} \boldsymbol{\theta}_i^{(l)} \right) & \text{if } m \text{ is odd,} \\ \dfrac{1}{C_i^{(m,m)}} \left(2\, \mathbf{curl} \left(\lambda_{i+1}\lambda_{i+2}^m - \lambda_{i+1}^m \lambda_{i+2} \right) - \displaystyle\sum_{l=2}^{m-2} C_i^{(l,m)} \boldsymbol{\theta}_i^{(l)} \right) & \text{if } m \text{ is even} \end{cases} \tag{6.15}$$

and

$$C_i^{(l,m)} = \begin{cases} \dfrac{(-1)^{(l-1)/2}\,(m+1)}{2^{m-1}} \begin{pmatrix} \dfrac{m-1}{2} \\ \dfrac{l-1}{2} \end{pmatrix} & \text{if } l \text{ and } m \text{ are both odd,} \\ \dfrac{m-2l-1}{2^{m-1}} \begin{pmatrix} m \\ l \end{pmatrix} & \text{if } l \text{ and } m \text{ are both even and } l \neq m, \\ -\dfrac{m+1}{2^{m-1}} & \text{if } l \text{ and } m \text{ are both even and } l = m, \\ 0 & \text{otherwise.} \end{cases} \tag{6.16}$$

Then, for $i, j = 1, 2, 3$ and integer $m \geq 1$,

$$\left(\hat{\boldsymbol{n}}_i \cdot \boldsymbol{\theta}_j^{(m)} \right)_{|\hat{\gamma}_i} = \begin{cases} \left(s_i^m - \dfrac{1}{2} (1, s_i^m)_{\hat{\gamma}_i} \right) \delta_{ij} = s_i^m \delta_{ij} & \text{if } m \text{ is odd,} \\ \left(s_i^m - \dfrac{1}{2} (1, s_i^m)_{\hat{\gamma}_i} \right) \delta_{ij} = \left(s_i^m - \dfrac{1}{m+1} \right) \delta_{ij} & \text{if } m \text{ is even} \end{cases} \tag{6.17}$$

and

$$-\operatorname{div} \boldsymbol{\theta}_i^{(m)} = 0 \text{ in } K. \tag{6.18}$$

Proof. If we can prove this result for the $\boldsymbol{\theta}_1^{(m)}$, then it shall hold for the $\boldsymbol{\theta}_2^{(m)}$ and $\boldsymbol{\theta}_3^{(m)}$ by rotation. The fact that the $\boldsymbol{\theta}_1^{(m)}$ are the sums of the **curl** of functions which are zero on edges $\hat{\gamma}_2$ and $\hat{\gamma}_3$ implies that $(\hat{\boldsymbol{n}}_2 \cdot \boldsymbol{\theta}_1^{(m)})_{|\hat{\gamma}_2} = (\hat{\boldsymbol{n}}_3 \cdot \boldsymbol{\theta}_1^{(m)})_{|\hat{\gamma}_3} = 0$ and $\operatorname{div} \boldsymbol{\theta}_1^{(m)} = 0$ in K. To prove that $(\hat{\boldsymbol{n}}_1 \cdot \boldsymbol{\theta}_1^{(m)})_{|\hat{\gamma}_1} = s_1^m - \frac{1}{2}(1, s_1^m)_{\hat{\gamma}_1}$ we shall first consider the case that m is an odd number. When $m = 1$, we can apply identity (6.11) to find that

$$\boldsymbol{\theta}_1^{(1)} = -\frac{2}{\sqrt{3}} \left(\lambda_3 \hat{\boldsymbol{t}}_2 + \lambda_2 \hat{\boldsymbol{t}}_3 \right)$$

to which we can apply identity (6.8) along with the definition of s_1 (6.6) to yield $(\hat{\boldsymbol{n}}_1 \cdot \boldsymbol{\theta}_1^{(1)})_{|\hat{\gamma}_1} = s_1$. We shall now assume that the result holds for all odd m up to $m = k$ and complete the proof by induction by showing that the result holds for $m = k + 2$. As with $m = 1$ we can apply identity (6.8) to give

$$-4 \left(\hat{\boldsymbol{n}}_1 \cdot \mathbf{curl} \left((\lambda_2 \lambda_3)^{(k+3)/2} \right) \right)_{|\hat{\gamma}_1} = (k+3) (\lambda_2 \lambda_3)^{(k+1)/2} (\lambda_3 - \lambda_2).$$

By combining the definition of s_1 (6.6) with identity (6.9) we see that $\lambda_{2|\hat{\gamma}_1} = \frac{1}{2} - \frac{1}{2} s_1$ and $\lambda_{3|\hat{\gamma}_1} = \frac{1}{2} + \frac{1}{2} s_1$, which we can use to obtain

$$\begin{aligned}
-4 \left(\hat{\boldsymbol{n}}_1 \cdot \mathbf{curl} \left((\lambda_2 \lambda_3)^{(k+3)/2} \right) \right)_{|\hat{\gamma}_1} &= (k+3) \left(\frac{1}{4} - \frac{1}{4} s_1^2 \right)^{(k+1)/2} s_1 \\
&= (k+3) \sum_{l=0}^{(k+1)/2} \left(\begin{array}{c} \frac{k+1}{2} \\ l \end{array} \right) \frac{(-1)^l}{2^{k+1}} s_1^{2l+1} \\
&= (k+3) \sum_{\substack{\text{odd } l: \\ 1 \le l \le k+2}} \left(\begin{array}{c} \frac{k+1}{2} \\ \frac{l-1}{2} \end{array} \right) \frac{(-1)^{(l-1)/2}}{2^{k+1}} s_1^l \\
&= \sum_{l=1}^{k+2} C_1^{(l,k+2)} s_1^l
\end{aligned}$$

upon applying the binomial theorem and definition (6.16). It then follows that $(\hat{\boldsymbol{n}}_1 \cdot \boldsymbol{\theta}_1^{(k+2)})_{|\hat{\gamma}_1} = s_1^{k+2}$ since $(\hat{\boldsymbol{n}}_1 \cdot \boldsymbol{\theta}_1^{(l)})_{|\hat{\gamma}_1} = s_1^l$ for odd l between 1 and k inclusive.

By applying the same method that we used for the odd case, we can obtain that $(\hat{\boldsymbol{n}}_1 \cdot \boldsymbol{\theta}_1^{(2)})_{|\hat{\gamma}_1} = s_1^2 - \frac{1}{3}$ and

$$2 \left(\hat{\boldsymbol{n}}_1 \cdot \mathbf{curl} \left(\lambda_2 \lambda_3^{k+2} - \lambda_2^{k+2} \lambda_3 \right) \right)_{|\hat{\gamma}_1} = \frac{k+1}{2^{k+1}} + \sum_{l=2}^{k+2} C_1^{(l,k+2)} s_1^l,$$

and so using induction as before we observe that

$$\left(\hat{\boldsymbol{n}}_1 \cdot \boldsymbol{\theta}_1^{(k+2)} \right)_{|\hat{\gamma}_1} = s_1^{k+2} + \nu,$$

where ν is a constant which must take the value $-\frac{1}{2} \left(s_1^{k+2}, 1 \right)_{\hat{\gamma}_1}$ since

$$\left(\hat{\boldsymbol{n}}_1 \cdot \boldsymbol{\theta}_1^{(k+2)}, 1 \right)_{\hat{\gamma}_1} = \sum_{j=1}^{3} \left(\hat{\boldsymbol{n}}_j \cdot \boldsymbol{\theta}_1^{(k+2)}, 1 \right)_{\hat{\gamma}_j} = \left(\operatorname{div} \boldsymbol{\theta}_1^{(k+2)}, 1 \right)_{\hat{K}} = 0. \qquad \square$$

LEMMA 6.4. *For integer $m_1, m_2, m_3 \geq 1$, let $\boldsymbol{\theta}_{\hat{K}}^{(0,0,0)} = 0$,*

$$\boldsymbol{\theta}_{\hat{K}}^{(m_1,0,0)} = \frac{1}{m_1+2}\left(m_1\boldsymbol{\theta}_{\hat{K}}^{(m_1-1,0,0)} + 2\lambda_1^{m_1}\left(\lambda_3\hat{\boldsymbol{t}}_2 - \lambda_2\hat{\boldsymbol{t}}_3\right)\right), \tag{6.19}$$

$$\boldsymbol{\theta}_{\hat{K}}^{(0,m_2,0)} = \frac{1}{m_2+2}\left(m_2\boldsymbol{\theta}_{\hat{K}}^{(0,m_2-1,0)} + 2\lambda_2^{m_2}\left(\lambda_1\hat{\boldsymbol{t}}_3 - \lambda_3\hat{\boldsymbol{t}}_1\right)\right), \tag{6.20}$$

$$\boldsymbol{\theta}_{\hat{K}}^{(0,0,m_3)} = \frac{1}{m_3+2}\left(m_3\boldsymbol{\theta}_{\hat{K}}^{(0,0,m_3-1)} + 2\lambda_3^{m_3}\left(\lambda_2\hat{\boldsymbol{t}}_1 - \lambda_1\hat{\boldsymbol{t}}_2\right)\right), \tag{6.21}$$

$$\begin{aligned}\boldsymbol{\theta}_{\hat{K}}^{(m_1,m_2,0)} = \frac{1}{2\left(m_1+m_2+2\right)}\Big(&m_1\boldsymbol{\theta}_{\hat{K}}^{(m_1-1,m_2,0)} + m_2\boldsymbol{\theta}_{\hat{K}}^{(m_1,m_2-1,0)} \\ &+ 2\lambda_1^{m_1}\lambda_2^{m_2}\left(\lambda_1\hat{\boldsymbol{t}}_3 - \lambda_2\hat{\boldsymbol{t}}_3 + \lambda_3\left(\hat{\boldsymbol{t}}_2 - \hat{\boldsymbol{t}}_1\right)\right)\Big),\end{aligned} \tag{6.22}$$

$$\begin{aligned}\boldsymbol{\theta}_{\hat{K}}^{(0,m_2,m_3)} = \frac{1}{2\left(m_2+m_3+2\right)}\Big(&m_2\boldsymbol{\theta}_{\hat{K}}^{(0,m_2-1,m_3)} + m_3\boldsymbol{\theta}_{\hat{K}}^{(0,m_2,m_3-1)} \\ &+ 2\lambda_2^{m_2}\lambda_3^{m_3}\left(\lambda_2\hat{\boldsymbol{t}}_1 - \lambda_3\hat{\boldsymbol{t}}_1 + \lambda_1\left(\hat{\boldsymbol{t}}_3 - \hat{\boldsymbol{t}}_2\right)\right)\Big),\end{aligned} \tag{6.23}$$

$$\begin{aligned}\boldsymbol{\theta}_{\hat{K}}^{(m_1,0,m_3)} = \frac{1}{2\left(m_3+m_1+2\right)}\Big(&m_3\boldsymbol{\theta}_{\hat{K}}^{(m_1,0,m_3-1)} + m_1\boldsymbol{\theta}_{\hat{K}}^{(m_1-1,0,m_3)} \\ &+ 2\lambda_3^{m_3}\lambda_1^{m_1}\left(\lambda_3\hat{\boldsymbol{t}}_2 - \lambda_1\hat{\boldsymbol{t}}_2 + \lambda_2\left(\hat{\boldsymbol{t}}_1 - \hat{\boldsymbol{t}}_3\right)\right)\Big),\end{aligned} \tag{6.24}$$

$$\begin{aligned}\boldsymbol{\theta}_{\hat{K}}^{(m_1,m_2,m_3)} = \frac{1}{3\left(m_1+m_2+m_3+2\right)}\Big(&m_1\boldsymbol{\theta}_{\hat{K}}^{(m_1-1,m_2,m_3)} \\ &+ m_2\boldsymbol{\theta}_{\hat{K}}^{(m_1,m_2-1,m_3)} + m_3\boldsymbol{\theta}_{\hat{K}}^{(m_1,m_2,m_3-1)} \\ &+ 2\lambda_1^{m_1}\lambda_2^{m_2}\lambda_3^{m_3}\left(\lambda_1\left(\hat{\boldsymbol{t}}_3 - \hat{\boldsymbol{t}}_2\right) + \lambda_2\left(\hat{\boldsymbol{t}}_1 - \hat{\boldsymbol{t}}_3\right) + \lambda_3\left(\hat{\boldsymbol{t}}_2 - \hat{\boldsymbol{t}}_1\right)\right)\Big).\end{aligned} \tag{6.25}$$

Then, for $i = 1, 2, 3$ and integer $m_1, m_2, m_3 \geq 0$,

$$\left(\hat{\boldsymbol{n}}_i \cdot \boldsymbol{\theta}_{\hat{K}}^{(m_1,m_2,m_3)}\right)_{|\hat{\gamma}_i} = 0 \tag{6.26}$$

and

$$-\operatorname{div}\boldsymbol{\theta}_{\hat{K}}^{(m_1,m_2,m_3)} = \lambda_1^{m_1}\lambda_2^{m_2}\lambda_3^{m_3} - \frac{1}{\sqrt{3}}\left(\lambda_1^{m_1}\lambda_2^{m_2}\lambda_3^{m_3}, 1\right)_{\hat{K}} \ \text{in } \hat{K}. \tag{6.27}$$

Proof. By making use of the identity (6.7) it can be seen that (6.26) holds. Now, using the product rule and identity (6.10) yields, for $m_1 \geq 1$,

$$-\operatorname{div}\left(2\lambda_1^{m_1}\left(\lambda_3\hat{\boldsymbol{t}}_2 - \lambda_2\hat{\boldsymbol{t}}_3\right)\right) = \left(m_1+2\right)\lambda_1^{m_1} - m_1\lambda_1^{m_1-1} \text{ in } \hat{K} \tag{6.28}$$

after simplifying with the help of identity (6.9). Now this implies that

$$-\operatorname{div}\boldsymbol{\theta}_{\hat{K}}^{(1,0,0)} = -\frac{1}{3}\operatorname{div}\left(2\lambda_1\left(\lambda_3\hat{\boldsymbol{t}}_2 - \lambda_2\hat{\boldsymbol{t}}_3\right)\right) = \lambda_1 - \frac{1}{3} \text{ in } \hat{K},$$

and so (6.27) is true for $m_2 = m_3 = 0$ and $m_1 = 1$. Now assume that (6.27) holds for $m_2 = m_3 = 0$ and $1 \leq m_1 \leq k$. Hence, from (6.28) and the definition of $\boldsymbol{\theta}_{\hat{K}}^{(m_1,0,0)}$ (6.19) we have

$$-\operatorname{div}\boldsymbol{\theta}_{\hat{K}}^{(k+1,0,0)} = \lambda_1^{k+1} + \nu \text{ in } \hat{K},$$

where ν is a constant. Now since

$$\left(\operatorname{div}\boldsymbol{\theta}_{\hat{K}}^{(k+1,0,0)},1\right)_{\hat{K}}=\sum_{j=1}^{3}\left(\hat{\boldsymbol{n}}_j\cdot\boldsymbol{\theta}_{\hat{K}}^{(k+1,0,0)},1\right)_{\hat{\gamma}_j}=0,$$

the constant ν must be equal to $-\frac{1}{\sqrt{3}}(\lambda_1^{k+1},1)_{\hat{K}}$, and hence (6.27) is true in the case $m_1\geq 1$ and $m_2=m_3=0$ by induction. This means that (6.27) then also holds for the functions defined in (6.20) and (6.21) by rotation. Likewise, for $m_1,m_2\geq 1$, we have

$$\begin{aligned}&-\operatorname{div}\left(2\lambda_1^{m_1}\lambda_2^{m_2}\left(\lambda_1\hat{\boldsymbol{t}}_3-\lambda_2\hat{\boldsymbol{t}}_3+\lambda_3\left(\hat{\boldsymbol{t}}_2-\hat{\boldsymbol{t}}_1\right)\right)\right)\\&=2\left(2+m_1+m_2\right)\lambda_1^{m_1}\lambda_2^{m_2}-m_1\lambda_1^{m_1-1}\lambda_2^{m_2}-m_2\lambda_1^{m_1}\lambda_2^{m_2-1}\text{ in }\hat{K},\end{aligned}$$

from which (6.27) can be proved by induction for the functions defined in (6.22) (and therefore, by rotation, those defined in (6.23) and (6.24)) by also making use of the fact that (6.27) holds for the functions defined in (6.19), (6.20), and (6.21). Finally, the fact that (6.27) is true for all of the other cases allows us to show that (6.27) holds for the functions defined in (6.25) in the same way. ∎

Let $\{P^{(i)}\}_{i=1}^{\dim\mathbb{P}_n(\hat{K})}$ be an orthonormal basis for $\mathbb{P}_n(\hat{K})$ such that $P^{(1)}=3^{-1/4}$. Likewise, for $j=1,2,3$, let $\{P_j^{(i)}\}_{i=0}^{n}$ be an orthonormal basis for $\mathbb{P}_n(\hat{\gamma}_j)$ such that $P_j^{(0)}=2^{-1/2}$.

Corollary 6.5. *For $i=0,\ldots,n$ and $k=1,2,3$ there exist functions $\boldsymbol{\vartheta}_k^{(i)}\in\mathbb{P}_{n+1}(\hat{K})\times\mathbb{P}_{n+1}(\hat{K})$ such that, for $j=1,2,3$,*

$$\left(\hat{\boldsymbol{n}}_j\cdot\boldsymbol{\vartheta}_k^{(i)}\right)_{|\hat{\gamma}_j}=\delta_{jk}P_j^{(i)}\ \text{ and }\ -\operatorname{div}\boldsymbol{\vartheta}_k^{(i)}=-\frac{\sqrt{2}}{\sqrt{3}}\delta_{i0}\ \text{ in }\hat{K}.\tag{6.29}$$

Also, for $i=2,\ldots,\dim\mathbb{P}_n(\hat{K})$ there exist functions $\boldsymbol{\vartheta}_{\hat{K}}^{(i)}\in\mathbb{P}_{n+1}(\hat{K})\times\mathbb{P}_{n+1}(\hat{K})$ such that, for $j=1,2,3$,

$$\left(\hat{\boldsymbol{n}}_j\cdot\boldsymbol{\vartheta}_{\hat{K}}^{(i)}\right)_{|\hat{\gamma}_j}=0\ \text{ and }\ -\operatorname{div}\boldsymbol{\vartheta}_{\hat{K}}^{(i)}=P^{(i)}\ \text{ in }\hat{K}.\tag{6.30}$$

Proof. This follows from Lemmas 6.2, 6.3, and 6.4 upon noting that, for $j=1,2,3$, $\{(\hat{\boldsymbol{n}}_j\cdot\boldsymbol{\theta}_j^{(i)})_{|\hat{\gamma}_j}\}_{i=1}^{n}$ forms a basis for $\{v:v\in\mathbb{P}_n(\hat{\gamma}_j),(v,P_j^{(0)})_{\hat{\gamma}_j}=0\}$ and that, for integer $m_1,m_2,m_3\geq 0$, $\{-\operatorname{div}\boldsymbol{\theta}_{\hat{K}}^{(m_1,m_2,m_3)}\}_{m_1+m_2+m_3=n}$ forms a basis for $\{v:v\in\mathbb{P}_n(\hat{K}),(v,P^{(1)})_{\hat{K}}=0\}$. ∎

Finally, we are in a position to provide the proof of Theorem 6.1.

Proof. Let

$$\hat{\boldsymbol{\sigma}}=\sum_{j=1}^{3}\sum_{i=0}^{n}\left(\hat{\boldsymbol{n}}_j\cdot\boldsymbol{\sigma}^\star,P_j^{(i)}\right)_{\hat{\gamma}_j}\boldsymbol{\vartheta}_j^{(i)}-\sum_{i=2}^{\dim\mathbb{P}_n(\hat{K})}\left(\operatorname{div}\boldsymbol{\sigma}^\star,P^{(i)}\right)_{\hat{K}}\boldsymbol{\vartheta}_{\hat{K}}^{(i)}.\tag{6.31}$$

Then, by Corollary 6.5, we have

$$\hat{\boldsymbol{n}}_j\cdot\hat{\boldsymbol{\sigma}}=\sum_{i=0}^{n}\left(\hat{\boldsymbol{n}}_j\cdot\boldsymbol{\sigma}^\star,P_j^{(i)}\right)_{\hat{\gamma}_j}P_j^{(i)}=\hat{\boldsymbol{n}}_j\cdot\boldsymbol{\sigma}^\star\text{ on }\hat{\gamma}_j\text{ for }j=1,2,3$$

and

$$-\operatorname{div}\hat{\boldsymbol{\sigma}}=-\frac{\sqrt{2}}{\sqrt{3}}\sum_{j=1}^{3}\left(\hat{\boldsymbol{n}}_j\cdot\boldsymbol{\sigma}^\star,P_j^{(0)}\right)_{\hat{\gamma}_j}-\sum_{i=2}^{\dim\mathbb{P}_n(\hat{K})}\left(\operatorname{div}\boldsymbol{\sigma}^\star,P^{(i)}\right)_{\hat{K}}P^{(i)}\text{ in }\hat{K}.\tag{6.32}$$

To see that the right-hand side of (6.32) is equal to $-\operatorname{div}\boldsymbol{\sigma}^\star$, observe that, since $\boldsymbol{\sigma}^\star \in H(\operatorname{div};\hat{K})$,

$$\sum_{j=1}^{3} (\hat{\boldsymbol{n}}_j \cdot \boldsymbol{\sigma}^\star, 1)_{\hat{\gamma}_j} = (\operatorname{div}\boldsymbol{\sigma}^\star, 1)_{\hat{K}}$$

and so

$$-\frac{\sqrt{2}}{\sqrt{3}} \sum_{j=1}^{3} \left(\hat{\boldsymbol{n}}_j \cdot \boldsymbol{\sigma}^\star, P_j^{(0)}\right)_{\hat{\gamma}_j} = -\left(\operatorname{div}\boldsymbol{\sigma}^\star, P^{(1)}\right)_{\hat{K}} P^{(1)}.$$

Finally, we can arrive at inequality (6.5), by applying Cauchy–Schwarz inequalities to the expression obtained for $\|\hat{\boldsymbol{\sigma}}\|_{L_2(\hat{K})}$ using (6.31). ∎

CONVERGENCE OF A SEMIDISCRETE TWO-GRID ALGORITHM FOR THE CONTROLLABILITY OF THE $1-d$ WAVE EQUATION*

MIHAELA NEGREANU†

Abstract. The problem of exact controllability of elastic strings has been extensively studied during the last years. We consider the problem of computing numerically the boundary control for a finite-dimensional system obtained by discretizing in space the $1-d$ wave equation. More precisely, we analyze whether the controls of numerical approximation schemes converge to the control of the continuous wave equation as the mesh size tends to zero. It is by now well known that, due to high-frequency spurious oscillations, numerical instabilities occur and may lead to the failure of convergence of some apparently natural numerical algorithms. In other words, the classical convergence property of numerical schemes does not guarantee a stable and convergent approximation of controls. Several remedies have been proposed in the literature to compensate for this fact: Tychonoff regularization, Fourier filtering, and mixed finite elements. In this paper we prove that the two-grid method proposed by Glowinski in [*J. Comput. Phys.*, 103 (1992), pp. 189–221] to numerically approximate the control of the wave equation converges in $1-d$. We prove this result in the context of the finite-element space semidiscretization. Our method of proof relies essentially on the particular properties of the Fourier representation of the initial data of the coarse mesh when projected into the fine one. The explicit representation formula of the solutions shows that the high-frequency components are modulated by some weights that diminish the effect of these spurious components. This fact, combined with discrete multipliers techniques, allows us to prove uniform observability inequalities. Classical arguments then allow proving the uniform boundedness of the controls and passing to the limit as the mesh size tends to zero. In this way we prove the convergence of the controls of the finite-element semidiscrete approximation of the $1-d$ wave equation with a boundary control on one extreme. It is important to underline that the controls obtained by this two-grid algorithm are not exact in the sense that they only guarantee the controllability of the projection of the solutions into the coarse mesh.

Key words. wave equation, boundary controllability, uniform observability, two-grid algorithm, finite-element discretization

1. Introduction.

Consider the $1-d$ wave equation, with constant coefficients and control on one extreme:

$$\begin{cases} u_{tt} - u_{xx} = 0, & 0 < x < 1, \quad 0 < t < T, \\ u(0,t) = 0, \quad u(1,t) = v(t), & 0 < t < T, \\ u(x,0) = u^0(x), \qquad u_t(x,0) = u^1(x), & 0 < x < 1. \end{cases} \tag{1.1}$$

Here (u^0, u^1) are the initial state and v is the control function that acts on the system through the extreme $x = 1$ of the space interval $(0,1)$. System (1.1) describes the vibrations of a controlled string, and it is well posed in appropriate functional spaces.

When no control acts on the boundary $x = 1$ of the string, i.e., when $v = 0$, the energy:

$$E(t) = \frac{1}{2} \int_0^1 \left(\mid u_x(x,t) \mid^2 + \mid u_t(x,t) \mid^2 \right) dx \tag{1.2}$$

of the solutions is conserved in time

$$\frac{dE(t)}{dt} = E'(t) = 0 \quad \forall t \in [0,T].$$

The starting point of our study is the following well-known exact controllability result for (1.1) (see [6]): *Given $T \geq 2$ and $(u^0, u^1) \in L^2(0,1) \times H^{-1}(0,1)$, there exists a control function $v \in L^2(0,T)$ such that the solution $u = u(x,t)$ of* (1.1) *satisfies*

$$u(T) = u_t(T) = 0, \qquad 0 < x < 1. \tag{1.3}$$

The goal in this control problem is to drive solutions to equilibrium at time $t = T$. Once the equilibrium configuration is reached at time $t = T$, by taking null control for $t \geq T$, i.e., $v = 0$ for $t \geq T$, the solution remains at rest for all $t \geq T$.

For (u^0, u^1) and $T \geq 2$ as above, there may exist infinitely many controls v with (1.3). The *Hilbert uniqueness method* (HUM) introduced by Lions in 1986 (see [6]) furnishes the one of minimal $L^2(0,T)$-norm, the so-called HUM control. Note that (1.3) makes sense, since in these conditions, (1.1) admits a unique solution $u \in \mathcal{C}([0,T]; L^2(0,1)) \cap \mathcal{C}^1([0,T]; H^{-1}(0,1))$.

Let us now introduce the homogeneous system (the adjoint of (1.1))

$$\begin{cases} \phi_{tt} - \phi_{xx} = 0, & 0 < x < 1, \quad 0 < t < T, \\ \phi(0,t) = \phi(1,t) = 0, & 0 < t < T, \\ \phi(x,T) = \phi^0(x), \qquad \phi_t(x,T) = \phi^1(x), & 0 < x < 1. \end{cases} \tag{1.4}$$

When $(\phi^0, \phi^1) \in H_0^1(0,1) \times L^2(0,1)$, (1.4) admits a unique solution $\phi = \phi(x,t) \in \mathcal{C}^0\left([0,T], H_0^1(0,1)\right) \cap \mathcal{C}^1\left([0,T], L^2(0,1)\right)$.

With the aid of the HUM, the property of the exact controllability of (1.1) is shown to be equivalent to the following observability inequality of the adjoint system (1.4): *Given $T \geq 2$, there exists a positive constant $C(T) > 0$ such that*

$$E(0) \leq C(T) \int_0^T |\, \phi_x(1,t)\,|^2 \, dt \tag{1.5}$$

holds for every solution $\phi = \phi(x,t)$ of the adjoint problem (1.4).

Inequality (1.5), when it holds, guarantees that the total energy of solutions can be observed or estimated from the energy concentrated or measured on the extreme x = 1 of the string during the time interval $(0,T)$, uniformly in the whole class of solutions of (1.4). Here and in what follows, the best constant $C(T)$ in inequality (1.5) will be referred to as the *observability constant*.

It is well known that the problems of observability and controllability are equivalent provided one chooses an appropriate functional setting, which depends on the equation.

When (1.5) holds, the quadratic functional

$$J\left(\phi^0, \phi^1\right) = \frac{1}{2} \int_0^T |\phi_x(1,t)|^2 \, dt + \int_0^1 u^0(x)\phi_t(0)dx - \left\langle u^1(x), \phi(0)\right\rangle_{H^{-1} \times H_0^1} \tag{1.6}$$

is coercive in the space $H_0^1(0,1) \times L^2(0,1)$. Therefore, *when the observability inequality* (1.5) *holds, the functional J has an unique minimizer $(\hat{\phi}^0, \hat{\phi}^1)$ in $H_0^1(0,1) \times L^2(0,1)$. The control $v = -\hat{\phi}_x(1,t)$, with $\hat{\phi} = \hat{\phi}(x,t)$ the solution of* (1.4) *corresponding to $(\hat{\phi}^0, \hat{\phi}^1)$ is such that the solution of* (1.1) *satisfies* (1.3).

Consequently, in this way, the exact controllability problem (1.3) is reduced to the analysis of the so-called *inverse observability inequality* (1.5). Furthermore, the minimization of the functional J provides a useful way of constructing the control of minimal $L^2(0,T)$-norm. Once we know that such a control exists, it is natural to try to construct this control numerically.

The goal of this paper is to obtain a convergent numerical approximation of the exact control.

A possible procedure is to approximate the wave operator by some sequence of discrete or semidiscrete operators and to try to obtain the control of system (1.1) as the limit of the sequence of the controls of the approximating equations.

However, it is well known that the interaction of waves with the numerical mesh produces dispersion phenomena and spurious high-frequency oscillations [14, 15]. In particular, the velocity of propagation of waves, more precisely, the so-called *group velocity*, may converge to zero when the wavelength of solutions is of the order of the size of the mesh and the latter tends to zero. As a consequence of this fact, the time needed to uniformly (with respect to the mesh size) observe (or control) the numerical waves from the boundary tends to infinity as the mesh becomes finer and finer. This is the reason for the unstable behavior of the control and observation properties of most numerical approximation schemes as the mesh size tends to zero. Due to this, the observation and control properties of the discrete model may eventually disappear as the mesh size tends to zero. This occurs for the standard space semidiscrete approximation by finite-differences and finite-elements, and it has some impact when computing the control for the continuous model.

The main reason for the lack of uniform observability/controllability of the numerical high-frequency spurious solutions is that they generate high-frequency wave packets for which the group velocity is of the order of the mesh size (see [17]). Thus, as the mesh size tends to zero, since the velocity becomes smaller and smaller, the time for observability/controllability is increasing in a divergent way. This fact is related with the dispersion diagram associated to the numerical approximation scheme, since, roughly, the slope of the dispersion diagram is the group velocity of the propagation of wave packets and also coincides with the spectral gap.

Several remedies have been proposed in the literature to compensate for this fact: Tychonoff regularization, Fourier filtering, and mixed finite elements. (see [17]).

One way of restoring the uniform observability inequality for the homogeneous adjoint system consists in filtering the high-frequency modes of the solution by truncating the Fourier series. This is equivalent with the uniform controllability of the projection of the solution of the semidiscrete controlled system over the subspaces generated by the remaining eigenmodes, where the high frequencies have been filtered (see [5, 6, 7, 8, 9, 10, 11, 12, 13, 14, 15, 16]). However, in practice, it is not a very efficient result to compute these projections of the solutions and can be hard to implement in numerical simulations. Indeed, solving the semidiscrete system provides the nodal values of the solution. Then, one needs to compute its Fourier coefficients and, once these are done, to recalculate the nodal values of the filtered/truncated solution. Therefore, it is convenient to explore other ways of avoiding these high-frequency pathologies that do not require going back and forth from the physical space to the frequency one. In addition, the uniform time T needed for this algorithm to converge as the mesh size tends to zero depends strongly on the value of the filtering parameter, since the latter determines the minimal velocity of the propagation of the remaining numerical waves.

In [13] the authors proposed and analyzed a wavelet-based numerical method for exact controllability of the $1-d$ wave equation, concentrating on the particular case

of *Dirichlet* controls in the context of the finite-element space semidiscretization with spline wavelet basis functions.

The algorithm for the numerical construction of the controls is based on a conjugate gradient method proposed by Glowinski [2] and a two-grid filtering technique in the wavelet basis. The wavelet filtering yields numerical exact controllability in the optimal time of the continuous problem and the convergence of the numerical controls using a multilevel discretization filtering technique. Classical arguments then allow proving the uniform boundedness of the numerical controls and passing to the limit as the mesh size tends to zero. Numerical experiments show that wavelet filtering yields numerical controls with the same control time T as in the continuous case.

Glowinski in [2] proposed an alternative method for efficiently computing the controls. It is a two-grid algorithm based on the use of two numerical meshes: the coarse one G_C^{2h}, with step size $2h$ and the finer one G_F^h, corresponding to h. The bigrid strategy allows us to eliminate the highly oscillating parts of the solution of the uncontrolled semidiscrete system without filtering and performs a part of the computation of the algorithm on a coarse grid. Briefly, this algorithm consists in computing the numerical controls on the fine grid by minimizing a discrete version of the functional J only over the slowly data subspace projected from the coarse grid.

There are numerical evidences of the efficiency of this method introduced at the beginning of the nineties, but the proof of convergence was given only recently in [10] in the case of finite-difference semidiscretizations. The numerical efficiency of the method was illustrated in several experiments in [3] and [1].

This method is closely related to the filtering technique considered in [5]. In fact, it is about replacing a filtered solutions subclass by another one where we consider only the slowly oscillating initial data in the *fine grid* G_F^h, coming from a *coarse grid* G_C^{2h}, with mesh size $2h$. The multigrid method's advantage consists in that it is possible to work directly and completely in the physical space, without the necessity of using the Fourier transform and its inverse, permanently, opposite the filtering method.

The main objective of this paper is to prove that this two-grid method does indeed provide a convergent algorithm. This is done in the context of the finite-element semidiscrete approximation of the $1-d$ wave equation (1.1). It is worth noting that the two-grid technique was introduced by Glowinski in [2] precisely in the context of finite elements in which it can be applied with more flexibility.

The key ingredient of the proof is the uniform observability inequality for any solution of the semidiscrete uncontrolled wave equation defined on the fine grid with slowly oscillating initial data. The proof of the uniform observability combines two ingredients: (a) the Fourier representation of slow data on the fine grid; (b) the multiplier technique.

The paper is organized as follows: in section 2 we present some known properties of the solutions of the finite-element semidiscretization of the adjoint system (1.4), which are used in the proof of the main result. In section 3 we introduce the two-grid method, which permits its application in the finite-element semidiscrete approximation and in other circumstances as finite-difference approximations (see [10]). Section 4 is devoted to the proof of one of our main results, namely, the uniform discrete version of (1.5) for the solutions of the finite-element semidiscretization of (1.4) using the two-grid method. This is precisely the context in which this method was introduced and used (see [2]).

We discuss the consequences of this result concerning the controllability of the discrete controlled system (2.6) in section 5. Moreover, we prove the convergence of

the sequence of controls for system (2.6) that the two-grid algorithm provides as the mesh size h tends to zero.

The convergence results we present in this paper have been announced in [10] for the finite-difference semidiscretization of the $1-d$ wave equation. The same proof is done in that case, and we choose to present the complete proof for the finite-element approximation because it is more complete and it can be applied with more flexibility.

2. The semidiscrete problem: Notations and preliminary results. Take $N \in \mathbb{N}$, set $h = 1/(N+1)$. The finite-element semidiscrete version of system (1.4) (and (1.1), respectively) is obtained by a Galerkin approximation of the solution

$$\phi = \sum_{j=1}^{N} \phi_j(t)\psi_j(x), \tag{2.1}$$

when the basis $(\psi_j(x))_{j=1,\dots,N}$ of $H_0^1(0,1)$ is built by means of P_1 finite elements

$$S_h = \left\{ (\psi_j(x))_{j=1,\dots,N} : \quad \psi_j(x) = \left[1 - \frac{|x-x_j|}{h}\right]^+, \quad j = 1,\dots,N,\ x_j = jh \right\}.$$

The variational formulation of (1.4) in S_h is given by

$$-\int_0^1 \phi'' \psi_k dx = \int_0^1 \phi_x \psi_{k,x} dx, \qquad 0 < t < T \qquad \forall\, k = 1,\dots,N.$$

Taking into account that

$$\int_0^1 \psi_j(x)\psi_k(x) = \frac{h}{6}, \quad \text{if} \quad k = j-1, j+1, \quad \int_0^1 \psi_j(x)\psi_k(x) = 0, \quad \text{if} \quad |k-j| > 2, \tag{2.2}$$

$$\int_0^1 |\ \psi_j(x)\ |^2 = \frac{2h}{3} \quad \forall j = 1,\dots,N, \tag{2.3}$$

$$\int_0^1 \psi_{j,x}(x)\psi_{k,x}(x) = -\frac{1}{h}, \quad \text{if} \quad k = j-1, j+1, \quad \int_0^1 \psi_{j,x}(x)\psi_{k,x}(x) = 0, \quad \text{if} \quad |k-j| > 2, \tag{2.4}$$

$$\int_0^1 |\ \psi_{j,x}(x)\ |^2 = \frac{2}{h} \quad \forall\, j = 1,\dots,N, \tag{2.5}$$

the following simplest finite-element space semidiscretization of (1.1) can be easily derived:

$$\begin{cases} \dfrac{2}{3}u_j''(t) + \dfrac{1}{6}u_{j+1}''(t) + \dfrac{1}{6}u_{j-1}''(t) = \dfrac{u_{j+1}(t) + u_{j-1}(t) - 2u_j(t)}{h^2}, & 0 < t < T,\ j = 1,\dots,N, \\ u_0(t) = 0, \quad u_{N+1}(t) = v_h(t), & 0 < t < T, \\ u_j(0) = u_j^0, \quad u_j'(0) = u_j^1, & j = 1,\dots,N. \end{cases} \tag{2.6}$$

By $'$ we denote the time derivative, and by $\bar{u}(t) = (u_1(t),\dots,u_N(t))$ the vector-valued solution at the time t.

The problem of boundary controllability for (2.6) consists in finding a control $v_h \in L^2(0,T)$ such that the solution of system (2.6) satisfies

$$\bar{u}_h(T) = \bar{u}_h'(T) = \bar{0}.$$

Following the HUM method, for a given h, the existence of a control v_h for (2.6) is equivalent to the existence of an *observability constant* $C_h(T) > 0$ such that

$$E_h(t) \le C_h(T) \int_0^T \left| \frac{\phi_N(t)}{h} \right|^2 dt, \tag{2.7}$$

where $\bar{\phi}(t)$ is the solution of the homogeneous adjoint semidiscrete system

$$\begin{cases} \dfrac{2}{3}\phi_j''(t) + \dfrac{1}{6}\phi_{j+1}''(t) + \dfrac{1}{6}\phi_{j-1}''(t) = \dfrac{\phi_{j+1}(t) + \phi_{j-1}(t) - 2\phi_j(t)}{h^2}, & 0 < t < T,\ j = 1, \dots, N, \\ \phi_0(t) = \phi_{N+1}(t) = 0, & 0 < t < T, \\ \phi_j(T) = \phi_j^0, \quad \phi_j'(T) = \phi_j^1, & j = 1, \dots, N. \end{cases} \tag{2.8}$$

The energy E_h of this system is given by

$$E_h(t) = \frac{h}{6} \sum_{j=1}^{N} | \phi_j'(t) |^2 + \frac{h}{12} \sum_{j=0}^{N} | \phi_j'(t) + \phi_{j+1}'(t) |^2 + \frac{h}{2} \sum_{j=0}^{N} \left| \frac{\phi_{j+1}(t) - \phi_j(t)}{h} \right|^2. \tag{2.9}$$

Observe that the energy E_h represents a natural discretization of the continuous one (1.2).

Now, we rewrite system (2.8) in the following equivalent form:

$$\begin{cases} M_h \bar{\phi}'' = -A_h \bar{\phi}, \\ \phi_0(t) = \phi_{N+1}(t) = 0, \qquad 0 < t < T, \end{cases} \tag{2.10}$$

where $\bar{\phi} = (\phi_1, \dots, \phi_N)$, M_h and A_h are tridiagonal symmetric matrices, the so-called mass and rigidity or stiffness matrices, respectively:

$$M_h = h \begin{bmatrix} 2/3 & 1/6 & 0 & \cdots & 0 & 0 & 0 \\ 1/6 & 2/3 & 1/6 & \cdots & 0 & 0 & 0 \\ 0 & 1/6 & 2/3 & \cdots & 0 & 0 & 0 \\ \vdots & \vdots & \vdots & \ddots & \vdots & & \\ 0 & 0 & 0 & \cdots & 2/3 & 1/6 & 0 \\ 0 & 0 & 0 & \cdots & 1/6 & 2/3 & 1/6 \\ 0 & 0 & 0 & \cdots & 0 & 1/6 & 2/3 \end{bmatrix},$$

$$A_h = \tfrac{1}{h} \begin{bmatrix} 2 & -1 & 0 & \cdots & 0 & 0 & 0 \\ -1 & 2 & -1 & \cdots & 0 & 0 & 0 \\ 0 & -1 & 2 & \cdots & 0 & 0 & 0 \\ \vdots & \vdots & \vdots & \ddots & \vdots & & \\ 0 & 0 & 0 & \cdots & 2 & -1 & 0 \\ 0 & 0 & 0 & \cdots & -1 & 2 & -1 \\ 0 & 0 & 0 & \cdots & 0 & -1 & 2 \end{bmatrix}. \tag{2.11}$$

We denote by M and A the symmetric matrices

$$M = \frac{1}{h} M_h, \qquad A = \frac{1}{h} A_h.$$

System (2.10) is now

$$M\bar{\phi}'' = -A\bar{\phi}. \tag{2.12}$$

Let us define the Hilbert spaces sequences ℓ^2, $\hbar^1$, and $\hbar^{-1}$ as follows:

$$\ell^2 = \left\{ \{c_k\} \ : \ \|c_k\|_{\ell^2}^2 = \sum_{k\in\mathbb{N}} |\ c_k\ |^2 < \infty \right\}, \tag{2.13}$$

$$\hbar^1 = \left\{ \{c_k\} \in \ell^2 \ : \ \|c_k\|_{\hbar^1}^2 = \sum_{k\in\mathbb{N}} k^2\pi^2 \left|c_k\right|^2 < \infty \right\}, \tag{2.14}$$

$$\hbar^{-1} = \left\{ \{c_k\} \in \ell^2 \ : \ \|c_k\|_{\hbar^{-1}}^2 = \sum_{k\in\mathbb{N}} \left|\frac{c_k}{k\pi}\right|^2 < \infty \right\}. \tag{2.15}$$

DEFINITION 2.1. *Let $\delta = 1/(J+1)$, $J \in \mathbb{N}$, and $(U,V) \in \mathbb{R}^{J+1} \times \mathbb{R}^{J+1}$. We define the following scalar products:*

$$(U,V) := \sum_{j=0}^{J} U_j V_j, \quad \langle U,V\rangle := \delta\,(U,V)\,. \tag{2.16}$$

Taking into account the definitions in Fourier of the discrete norms ℓ^2 and $\hbar^1$, for every function $\bar{\phi} = (\phi_1, \ldots, \phi_N)$, $\phi_0 = 0$, we have

$$|\bar{\phi}|_{\ell^2}^2 = \langle \bar{\phi}, \bar{\phi}\rangle = h\sum_{j=0}^{N} |\phi_j|^2\,, \tag{2.17}$$

$$\|\bar{\phi}\|_{\hbar^1}^2 = \left(A_h^{1/2}\bar{\phi}, A_h^{1/2}\bar{\phi}\right) = \left\langle A^{1/2}\bar{\phi}, A^{1/2}\bar{\phi}\right\rangle = h\sum_{j=0}^{N} \left|\frac{\phi_{j+1}-\phi_j}{h}\right|^2. \tag{2.18}$$

Therefore, the energy (2.9) of the solution of the semidiscrete system (2.8) is given by

$$\begin{aligned} E_h(t) &= \frac{1}{2}\left[\left\langle M^{1/2}\bar{\phi}', M^{1/2}\bar{\phi}'\right\rangle + \left\langle A^{1/2}\bar{\phi}, A^{1/2}\bar{\phi}\right\rangle\right] \\ &= \frac{1}{2}\left[\left|M^{1/2}\bar{\phi}'\right|_{\ell^2}^2 + \left\|\bar{\phi}\right\|_{\hbar^1}^2\right], \end{aligned} \tag{2.19}$$

with the discrete norms $|\cdot|_{\ell^2}$ and $\|\cdot\|_{\hbar^1}$ given by (2.17) and (2.18), respectively.

The following result is well known.

LEMMA 2.2. *The energy E_h of the solution $\bar{\phi}$ of system* (2.8) *is conserved along the time, i.e.,*

$$E_h(t) = E_h(0) \qquad \forall t \in [0,T].$$

Proof. Multiplying equation (2.12) by $\bar{\phi}'$ and integrating in time variable, we have

$$\frac{1}{2}\frac{d}{dt}\left[\left\langle M^{1/2}\bar{\phi}', M^{1/2}\bar{\phi}'\right\rangle + \left\langle A^{1/2}\bar{\phi}, A^{1/2}\bar{\phi}\right\rangle\right] = 0.$$

This is equivalent to $d(E_h(t))/dt = 0$, and therefore $E_h(t)$ is constant in time for all $t \in [0,T]$. ∎

The eigenvalue problem corresponding to (2.8) is of the form

$$\begin{cases} -\dfrac{\varphi_{k+1}+\varphi_{k-1}-2\varphi_k}{h^2} = \mu\left[\dfrac{2}{3}\varphi_k + \dfrac{1}{6}\varphi_{k+1} + \dfrac{1}{6}\varphi_{k-1}\right], \quad k=1,\dots,N, \ (A\bar{\varphi} = \mu M\bar{\varphi}), \\ \varphi_0 = \varphi_{N+1} = 0. \end{cases} \tag{2.20}$$

The eigenvalues and eigenvectors of (2.20) may be computed explicitly. One has

$$\mu_k := \mu_k\left(M^{-1}A\right) = \frac{\lambda_k(h)}{1-\frac{h^2}{6}\lambda_k(h)} = \frac{6}{h^2}\left[\frac{\sin^2(k\pi h/2)}{\frac{3}{2}-\sin^2(k\pi h/2)}\right] = \frac{6}{h^2}\left[\frac{1-\cos(k\pi h)}{2+\cos(k\pi h)}\right] \tag{2.21}$$

and $\{\bar{\varphi}^k\}_k$, $\bar{\varphi}^k = (\varphi_{k,1},\dots,\varphi_{k,N})$, $\varphi_{k,j} = \sin(jk\pi h)$, with the eigenvalues of matrix A

$$\lambda_k(h) = \frac{4}{h^2}\sin^2\left(\frac{k\pi h}{2}\right) \tag{2.22}$$

(see [4], p. 456). The discrete eigenvalues μ_k approximate the eigenvalues of the continuous model $\lambda_k = k^2\pi^2$ for k fixed, when the size of the mesh h tends to zero and its corresponding eigenvectors $\bar{\varphi}^k$ coincide with the eigenfunctions $\varphi^k(x) = \sin(k\pi x)$ of the continuous model on the mesh points.

We have the following orthogonality properties of the eigenvectors of the matrix A in the discrete space:

$$\left\langle \bar{\varphi}^k, \bar{\varphi}^l \right\rangle := h\sum_{j=1}^{N}\varphi_{k,j}\varphi_{l,j} = \delta_{k,l}\frac{(N+1)h}{2} = \frac{1}{2}\delta_{k,l}, \quad k,l = 1,\dots,N, \tag{2.23}$$

where $\delta_{k,l}$ is *Kronecker's delta* (for more details, see [5, 6, 7, 8, 9, 10, 11, 12]). Moreover, for any eigenvectors of the matrix A with corresponding eigenvalues λ, the following identities hold (see (2.5) in [5]):

$$\sum_{j=0}^{N}\left|\frac{\varphi_{j+1}-\varphi_j}{h}\right|^2 = \lambda\sum_{j=1}^{N}|\varphi_j|^2 \tag{2.24}$$

and

$$\sum_{j=1}^{N}\left[\varphi_{k,j+1}\varphi_{l,j} + \varphi_{k,j}\varphi_{l,j+1}\right] = 0, \quad k \neq l. \tag{2.25}$$

The Fourier representation of the solution of (2.8) is as follows:

$$\bar{\phi}(t) = \sum_{k=1}^{N}\left(a_k\sin(\sqrt{\mu_k}t) + b_k\cos(\sqrt{\mu_k}t)\right)\bar{\varphi}^k = \sum_{k=-N}^{N} m_k e^{i\sqrt{\mu_k}t}\bar{\varphi}^k \tag{2.26}$$

for suitable Fourier coefficients a_k, b_k, and m_k depending on the initial data.

The *observability inequality* (2.7) is said to be *uniform* if the constants $C_h(T)$ are bounded uniformly in h as $h \to 0$. However, in [5] it was proved that, for all $T > 0$, the best constant C_h in (2.7) blows-up, i.e., $C_h \to \infty$ as $h \to 0$. As a consequence of this fact, there exist initial data for the wave equation (1.1) such that the controls v_h

of (2.6) are unbounded in $L^2(0,T)$ as $h \to 0$. Thus, computing v_h is not necessarily an efficient way to approximate the control of (1.1).

This nonuniformity turns out to be due to the highly oscillating components of the solutions. In fact, a positive result can be obtained when filtering appropriately the eigenvector components of the solutions. Indeed, as is pointed in [5], we introduce the class $\mathcal{C}_\delta(h)$ of filtered solutions

$$\mathcal{C}_\delta(h) = \left\{ \bar{\phi} \text{ solution of (2.8)} : \bar{\phi} = \sum_{|\mu_k| h \le \sqrt{\delta}} a_k e^{i\sqrt{\mu_k}t} \bar{\varphi}_k \right\}, \tag{2.27}$$

where $\mu_{-k} = -\mu_k$, $k > 0$, and $0 < \delta < 12$. The class $\mathcal{C}_\delta(h)$ consists only of solutions of (2.8) generated by the eigenvectors associated to eigenvalues $\mu_k \le \delta/h^2$, $0 < \delta < 12$, or equivalently, the solutions of the class $\mathcal{C}_\delta(h)$ contain only the eigenvectors corresponding to the $N\varepsilon(\delta)$ smallest eigenvalues for a suitable $0 < \varepsilon(\delta) < 1$. When restricting the solutions to this class, there exists $T(\gamma) > 0$

$$T(\gamma) = \frac{2\sqrt{1 + \dfrac{\gamma}{16}\left(\dfrac{3}{\lambda_1} - \dfrac{h^2}{3}\right)}}{1 - \gamma/12}$$

such that the uniform observability inequality (2.7) holds for all $T > T(\delta)$, with a constant $C(T,\delta)$ independent of h. Moreover, $T(\gamma) \nearrow \infty$ as $\gamma \nearrow 12$, and $T(\gamma) \searrow 2$ as $\gamma \searrow 0$ (see [5]).

Another possible cure is to use the two-grid algorithm introduced by Glowinski [2] to avoid the high-frequency pathologies producing the blow-up phenomena described above. In order to restore the uniformity of the observability inequality with respect to h, we consider and study the convergence of this algorithm.

Our aim is to obtain an uniform observability inequality of type (2.7) for a subclass of solutions $\bar{\phi}$ of (2.8) without filtering.

As we said above, this method is closely related to the presented filtering method. In fact, here we substitute the subclass $\mathcal{C}_\delta(h)$ of solutions for another one where we consider only the slowly oscillating initial data coming from a *coarse grid* G_C^{2h}, with mesh size $2h$. Recall that the multigrid method's advantage consists in that it is possible to work directly and completely in the physical space without the necessity of using the Fourier transform and its inverse, permanently, opposite the filtering method.

3. A two-grid method. Let $N \in \mathbb{N}$ be an odd number. With $h = 1/(N+1)$ we introduce the *coarse grid* G_C^{2h}, an equidistant partition of the interval $(0,1)$, $x_0 = 0 < x_1 = 2h < \cdots < x_{(N+1)/2} = 1$, with $x_j = 2jh$, $j = 0, \ldots, (N+1)/2$ and the *fine grid* G_F^h, $y_0 = 0 < y_1 = h < \cdots < y_N = Nh < y_{N+1} = 1$, with $y_j = jh$, $j = 0, \ldots, N+1$.

Let us introduce the space V_h:

$$V_h = \Bigg\{ \bar{\phi}_h = (\phi_1, \ldots, \phi_N) \in \mathbb{R}^N : \phi_{2j+1} = \frac{\phi_{2j} + \phi_{2j+2}}{2}, \ j = 0, \ldots, \frac{N-1}{2}, \ \phi_0 = \phi_{N+1} = 0 \Bigg\}. \tag{3.1}$$

Note that V_h is constituted by discrete functions defined on the fine grid G_F^h obtained by the interpolation of discrete functions defined on the coarse one G_C^{2h}. Thus, V_h contains only slowly oscillatory functions.

Next, we shall study some general properties of the discrete functions of V_h and the restriction of the matrix A as in (2.11) to this subspace.

PROPOSITION 3.1. *For every function $\bar{\phi}_h \in V_h$, we have*

$$\left(A\bar{\phi}_h\right)_{2j+1} = 0, \qquad j = 0, \dots, \frac{N-1}{2}. \tag{3.2}$$

Proof. By Definition (3.1) of the space V_h, for any function $\bar{\phi}_h \in V_h$, we have

$$\phi_{2j+1} = \frac{\phi_{2j+2} + \phi_{2j}}{2}, \qquad j = 0, \dots, \frac{N-1}{2}, \tag{3.3}$$

which is equivalent to

$$2\phi_{2j+1} - \phi_{2j+2} - \phi_{2j} = 0, \qquad j = 0, \dots, \frac{N-1}{2}.$$

This last identity is exactly (3.2), since

$$\left(A\bar{\phi}_h\right)_j = \frac{2\phi_j - \phi_{j-1} - \phi_{j+1}}{h^2} \qquad \forall j = 1, \dots, N. \tag{3.4}$$

□

DEFINITION 3.2. *Let $\bar{U} \in G_F^h$, $\bar{U} = (U_1, \dots, U_N)$ be a discrete function defined on the fine grid. We define the following orthogonal projection $\Pi_{odd} : G_F^h \to G_F^h$, with*

$$\Pi_{odd}(\bar{U}) = (U_1, 0, \dots, U_{N-1}, 0).$$

Remark 3.3. Note that, as consequence of Proposition 3.1, if $\bar{\phi}_h \in V_h$, one has

$$\Pi_{odd}(A\bar{\phi}_h) = \bar{0}, \tag{3.5}$$

and, that is, $A\bar{\phi}_h$ is orthogonal in the scalar product (2.16) to all of the vectors $v \in \mathbb{R}^N$ for which all of the components corresponding to the even points of the fine grid G_F^h vanish (these are precisely the points of the coarse grid, G_C^{2h}).

Let us denote by $c_k \in \mathbb{R}$ the coefficients of $\bar{\phi}_h \in G_F^h$ in the orthogonal bases $\{\bar{\varphi}^k\}$ of the eigenvectors of the system (2.20), with $\bar{\varphi}^k = (\varphi_{k,1}, \dots, \varphi_{k,N})$, $\varphi_{k,j} = \sin(jk\pi h)$. That is,

$$\bar{\phi}_h = \sum_{k=1}^{N} c_k \bar{\varphi}^k. \tag{3.6}$$

The following holds.

PROPOSITION 3.4. *For every discrete function $\bar{\phi}_h \in V_h$, the coefficients $(c_k)_k$ satisfy*

$$c_{N+1-k} = -c_k \frac{\lambda_k(h)}{\lambda_{N+1-k}(h)}, \qquad k = 1, \dots, N, \tag{3.7}$$

$$c_{\frac{N+1}{2}} = 0, \tag{3.8}$$

where $\lambda_k(h)$ are the eigenvalues given by (2.22) of the symmetric matrix A.

Proof. Recall that $\varphi_{k,j} = \sin(jk\pi h)$. We have

$$\varphi_{N+1-k,j} = \sin\left((N+1-k)\pi jh\right) = (-1)^{j+1} \sin(jk\pi h), \tag{3.9}$$

and then the eigenvectors $\bar{\varphi}^k$ satisfy the symmetry property:

$$\varphi_{k,j} = (-1)^{j+1}\varphi_{N+1-k,j} \quad \forall\, k, j = 1, \dots, N. \tag{3.10}$$

We have

$$\begin{aligned}\left\langle A\bar{\phi}_h, \bar{\varphi}^l \right\rangle &:= h \sum_{j=1}^{N} \left(A\bar{\phi}_h\right)_j \varphi_{l,j} \\ &= \sum_{k=1}^{N} c_k \lambda_k(h) \left\langle \bar{\varphi}^k, \bar{\varphi}^l \right\rangle = h \sum_{j=1}^{N}\sum_{k=1}^{N} c_k \lambda_k(h) \varphi_{k,j}\varphi_{l,j},\end{aligned} \tag{3.11}$$

with the scalar product $\langle \cdot, \cdot \rangle$ defined in (2.16) (recall that $\lambda_k(h)$ are the eigenvalues of the symmetric matrix A, i.e., $A\bar{\varphi}_k = \lambda_k(h)\bar{\varphi}_k$). By Proposition 3.1, relation (3.11) is reduced to

$$\left\langle A\bar{\phi}_h, \bar{\varphi}^l \right\rangle = h \sum_{j=1}^{\frac{N-1}{2}} \sum_{k=1}^{N} c_k \lambda_k(h) \varphi_{k,2j}\varphi_{l,2j}, \qquad l = 1, \dots, N. \tag{3.12}$$

We have

$$\begin{aligned}\left\langle A\bar{\phi}_h, \bar{\varphi}^l \right\rangle &= \sum_{k=1}^{N} c_k \lambda_k(h) \left\langle \bar{\varphi}^k, \bar{\varphi}^l \right\rangle = \sum_{k=1}^{N} c_{N+1-k} \lambda_{N+1-k}(h) \left\langle \bar{\varphi}^{N+1-k}, \bar{\varphi}^l \right\rangle \\ &= h \sum_{j=1}^{N}\sum_{k=1}^{N} c_{N+1-k} \lambda_{N+1-k}(h) \varphi_{N+1-k,j}\varphi_{l,j}.\end{aligned} \tag{3.13}$$

Moreover, due to the symmetry property (3.10), it follows that

$$\begin{aligned}\left\langle A\bar{\phi}_h, \bar{\varphi}^l \right\rangle &= h \sum_{j=1}^{N}\sum_{k=1}^{N} c_{N+1-k} \lambda_{N+1-k}(h) (-1)^{j+1} \varphi_{k,j}\varphi_{l,j} \\ &= h \sum_{j=1}^{\frac{N-1}{2}}\sum_{k=1}^{N} c_{N+1-k} \lambda_{N+1-k}(h) (-1)^{2j+1} \varphi_{k,2j}\varphi_{l,2j} \\ &= -\sum_{k=1}^{N} c_{N+1-k} \lambda_{N+1-k}(h) \left(\langle \bar{\varphi}_k, \bar{\varphi}_l \rangle\right)_{2j} \\ &= -h \sum_{j=1}^{\frac{N-1}{2}}\sum_{k=1}^{N} c_{N+1-k} \lambda_{N+1-k}(h) \varphi_{k,2j}\varphi_{l,2j}, \\ &\qquad\qquad l = 1, \dots, N, \;\; j = 1, \dots, (N-1)/2.\end{aligned} \tag{3.14}$$

Finally, by (3.12) and (3.14), we have

$$h \sum_{j=1}^{\frac{N-1}{2}} \sum_{k=1}^{N} c_k \lambda_k(h) \varphi_{k,2j}\varphi_{l,2j} = -h \sum_{j=1}^{\frac{N-1}{2}} \sum_{k=1}^{N} c_{N+1-k} \lambda_{N+1-k}(h) \varphi_{k,2j}\varphi_{l,2j}.$$

Taking into account the orthogonality properties (2.23) of the eigenvectors of the matrix A, it is immediate to see that the identities (3.7) and (3.8) hold. This concludes the proof. ∎

We consider the following decomposition in low and high frequencies of an arbitrary function $\bar{\phi}_h \in G_F^h$:

$$\bar{\phi}_h = \bar{\phi}_L + \bar{\phi}_H, \quad \bar{\phi}_L = \sum_{k=1}^{\frac{N-1}{2}} c_k \bar{\varphi}^k, \quad \bar{\phi}_H = \sum_{\frac{N+1}{2}}^{N} c_k \bar{\varphi}^k. \tag{3.15}$$

THEOREM 3.5. *For any discrete function $\bar{\phi}_h \in V_h$, we have*

$$\bar{\phi}_h = \bar{\phi}_L + \bar{\phi}_H, \quad \bar{\phi}_L = \sum_{k=1}^{\frac{N-1}{2}} c_k \bar{\varphi}^k, \quad \bar{\phi}_H = -\sum_{k=1}^{\frac{N-1}{2}} c_k \tan^2\left(\frac{k\pi h}{2}\right) \bar{\varphi}^{N+1-k}. \tag{3.16}$$

Proof. Taking into account that

$$\frac{\lambda_k(h)}{\lambda_{N+1-k}(h)} = \frac{\sin^2\left(\frac{k\pi h}{2}\right)}{\sin^2\left(\frac{(N+1-k)\pi h}{2}\right)} = \tan^2\left(\frac{k\pi h}{2}\right),$$

the proof is an immediate consequence of Proposition 3.4 and relations (3.15). ∎

We also deduce the following additional properties.

PROPOSITION 3.6. *For every function $\bar{\phi}_h \in V_h$ as in* (3.6)*, with $\bar{\phi}_h = \bar{\phi}_L + \bar{\phi}_H$ given by* (3.16)*, the following inequalities hold:*

$$\left\|\bar{\phi}_L\right\|_{\hbar^1}^2 \geq \left\|\bar{\phi}_H\right\|_{\hbar^1}^2, \tag{3.17}$$

$$\left|A\bar{\phi}_L\right|_{\ell^2}^2 \geq \left|A\bar{\phi}_H\right|_{\ell^2}^2, \tag{3.18}$$

where $|\cdot|_{\ell^2}$ and $\|\cdot\|_{\hbar^1}$ are the ℓ^2 and $\hbar^1$ discrete norms defined by (2.17) *and* (2.18)*, respectively.*

Proof. By the orthogonality property (2.23) and relation (2.24) of the eigenvectors $\{\bar{\varphi}^k\}_k$, for every function $\bar{\phi}_h \in \mathbb{R}^N$, we have

$$\begin{aligned} \left|A\bar{\phi}_h\right|_{\ell^2}^2 &= \left\langle A\bar{\phi}_h, A\bar{\phi}_h\right\rangle = \sum_{k,l=1}^{N} \lambda_k(h)\lambda_l(h) c_k c_l \left\langle \bar{\varphi}^k, \bar{\varphi}^l\right\rangle \\ &= h\sum_{j=1}^{N}\left|\sum_{k=1}^{N} c_k \lambda_k(h)\bar{\varphi}^k\right|^2 = \frac{1}{2}\sum_{k=1}^{N}\lambda_k^2(h)c_k^2, \end{aligned} \tag{3.19}$$

$$\begin{aligned} \left\|\bar{\phi}_h\right\|_{\hbar^1}^2 &= \left\langle A^{1/2}\bar{\phi}_h, A^{1/2}\bar{\phi}_h\right\rangle = \sum_{k,l=1}^{N} \sqrt{\lambda_k(h)\lambda_l(h)} c_k c_l \left\langle \bar{\varphi}^k, \bar{\varphi}^l\right\rangle \\ &= h\sum_{j=1}^{N}\left|\sum_{k=1}^{N} \sqrt{\lambda_k(h)} c_k \bar{\varphi}^k\right|^2 = \frac{1}{2}\sum_{k=1}^{N}\lambda_k(h)c_k^2. \end{aligned} \tag{3.20}$$

For the component $\bar{\phi}_L$, corresponding to the low frequencies, we obtain

$$\left\|\bar{\phi}_L\right\|_{\hbar^1}^2 = \frac{1}{2}\sum_{k=1}^{\frac{N-1}{2}}\lambda_k(h)c_k^2, \tag{3.21}$$

$$\left|A\bar{\phi}_L\right|_{\ell^2}^2 = \frac{1}{2}\sum_{k=1}^{\frac{N-1}{2}}\lambda_k^2(h)c_k^2, \tag{3.22}$$

and for the component $\bar{\phi}_H$, corresponding to the high frequencies, taking into account Proposition 3.4, we have

$$\|\bar{\phi}_H\|^2_{\hbar^1} = \frac{1}{2}\sum_{k=\frac{N+1}{2}}^{N-1}\left|\frac{\lambda_k(h)}{\lambda_{N+1-k}(h)}\right|^2 c_k^2\lambda_k(h) = \frac{1}{2}\sum_{k=\frac{N+1}{2}}^{N-1}\left|\tan^2\left(\frac{k\pi h}{2}\right)\right|^2 \lambda_k(h)c_k^2, \tag{3.23}$$

$$\left|A\bar{\phi}_H\right|^2_{\ell^2} = \frac{1}{2}\sum_{k=1}^{\frac{N-1}{2}}\left|\frac{\lambda_k(h)}{\lambda_{N+1-k}(h)}\right|^2 \lambda_k^2(h)c_k^2 = \frac{1}{2}\sum_{k=1}^{\frac{N-1}{2}}\left|\tan^2\left(\frac{k\pi h}{2}\right)\right|^2 \lambda_k^2(h)c_k^2. \tag{3.24}$$

Relations (3.17) and (3.18) are obtained immediately taking into account that

$$\frac{\lambda_k^2(h)}{\lambda_{N+1-k}^2(h)} = \frac{\sin^4\left(\frac{k\pi h}{2}\right)}{\sin^4\left(\frac{(N+1-k)\pi h}{2}\right)} = \tan^4\left(\frac{k\pi h}{2}\right) \le 1 \quad \forall\, k = 1,\dots,\frac{N-1}{2}. \tag{3.25}$$

Then, we have (3.17) and (3.18). The proof of Proposition 3.6 is now complete. ∎

4. Two-grid finite-element semidiscrete scheme. In this section we shall see that the two-grid technique for the finite-element semidiscretization of the wave equation allows us to eliminate the highly oscillating components of the control without filtering and to guarantee its convergence. This method is closely related to the filtering mentioned above.

We are able to get a uniform observability inequality for every solution of the wave equation (2.8) defined on the fine grid G_F^h, with initial data in V_h.

A very direct way to eliminate the high frequencies is as follows: take any initial data $(\bar{\phi}^0, \bar{\phi}^1)$ in $V_h \times V_h$ and denote by $\bar{\phi}$ the corresponding solution of system (2.8). We develop the functions $(\bar{\phi}^0, \bar{\phi}^1)$ in high and low frequencies as in (3.15):

$$\bar{\phi}^0 = \bar{\phi}_L^0 + \bar{\phi}_H^0, \qquad \bar{\phi}^1 = \bar{\phi}_L^1 + \bar{\phi}_H^1.$$

First we prove some basic identities.

PROPOSITION 4.1. *Let $\bar{\phi} = \bar{\phi}_L + \bar{\phi}_H$ be the solution of* (2.8)*, with given data $(\bar{\phi}^0, \bar{\phi}^1)$ in time $t = T$ contained in $V_h \times V_h$. For every $t \in [0,T]$, we have*

$$E_{\bar{\phi}}(t) = E_{\bar{\phi}_L}(t) + E_{\bar{\phi}_H}(t) \qquad \text{and} \qquad E_{\bar{\phi}_L}(t) \ge E_{\bar{\phi}_H}(t). \tag{4.1}$$

Proof. The first identity is immediate due to the orthogonality properties of eigenvectors.

Taking into account that $\bar{\phi}_L$ and $\bar{\phi}_H$ are solutions of the semidiscrete wave equation (2.8) in the fine grid G_F^h, where $\bar{\phi} = \bar{\phi}_L + \bar{\phi}_H$ is the development (3.15) of the solution $\bar{\phi}$ in low and high frequencies, the corresponding energies $E_{\bar{\phi}_L}$ and $E_{\bar{\phi}_\hbar}$ are conserved in time, and therefore, to obtain (4.1) for every $t \in [0,T]$, it is sufficient to prove it for $t = T$. That is, we prove

$$\left|M^{1/2}\bar{\phi}_L^1\right|^2_{\ell^2} + \left\|\bar{\phi}_L^0\right\|^2_{\hbar^1} \ge \left|M^{1/2}\bar{\phi}_H^1\right|^2_{\ell^2} + \left\|\bar{\phi}_H^0\right\|^2_{\hbar^1}. \tag{4.2}$$

We have

$$\begin{aligned}\frac{1}{2}|M^{1/2}\bar{\phi}^1|^2_{\ell^2} &= \frac{h}{6}\sum_{j=1}^{N}|\phi_j^1|^2 + \frac{h}{12}\sum_{j=0}^{N}|\phi_j^1 + \phi_{j+1}^1\,|^2 \\ &= \frac{1}{6}|\bar{\phi}^1|^2_{\ell^2} + \frac{h}{12}\sum_{j=0}^{N}|\phi_j^1 + \phi_{j+1}^1\,|^2\,.\end{aligned} \tag{4.3}$$

By the orthogonality properties (2.23), (2.24), and (2.25) of the eigenvectors $\{\bar{\varphi}^k\}_k$ and taking into account that $(\bar{\phi}^0, \bar{\phi}^1) \in V_h \times V_h$, combining (3.17), (4.3), and the property of the conservation of the energy, we deduce that (4.2) holds. The proof of Proposition 4.1 is now complete. ∎

4.1. Uniform observability. This section is devoted to the proof of the uniform observability property, one of the main results of this paper. Our first result guarantees that the observability inequality for (2.8) is uniform within the class $V_h \times V_h$.

THEOREM 4.2. *Let $h > 0$ and $T > 4$. Then, there exist positive constants $C_j(T,h) > 0$, $j = 1, 2$, uniformly bounded in h such that*

$$C_1(T,h)\int_0^T \left[\left|\frac{\phi_N(t)}{h}\right|^2 + \frac{|\phi_N'(t)|^2}{6}\right] dt \le E_h(0) \le C_2(T,h)\int_0^T \left[\left|\frac{\phi_N(t)}{h}\right|^2 + \frac{|\phi_N'(t)|^2}{6}\right] dt \tag{4.4}$$

for the solution of (2.8)*, with initial data in the space $V_h \times V_h$ and all $h > 0$.*

Remark 4.3. An extra term $\int_0^T |\phi_N'(t)|^2/6dt$ appears in the observability inequality (4.4). This is not the case in the context of the finite-difference semidiscretization (see [5, 9, 10]). Filtering the high frequencies by truncating the Fourier series of the solution and using Ingham's inequality, this extra term can be absorbed by the term $\int_0^T |\phi_N(t)|^2 dt$ by increasing the observability constant $C_1(T)$ (see [5]).

We shall see that the uniform inequality (4.4) is sufficient to guarantee the convergence of the sequence of discrete controls v_h.

Proof. (Sketch of the proof of Theorem 4.2.) The proof of this theorem uses discrete multiplier techniques similar to those in [5]. For simplicity, we divide the proof into several steps.

Step 1. Multiplying (2.8) by $j\,(\phi_{j+1} - \phi_{j-1}/2)$, which is a discrete version of the discrete multiplier $x\phi_x$ for the wave equation (1.4), integrating in time $[0,T]$, and adding for $j = 1, \dots, N$, the following identity holds for all the solutions of system (2.8) (see formula (3.26) in [5]):

$$TE_h(0) + X_h(t)\Big|_0^T = \frac{1}{2}\int_0^T \left[\left|\frac{\phi_N(t)}{h}\right|^2 + \frac{|\phi_N'(t)|^2}{6}\right] dt + \frac{h}{12}\sum_{j=1}^N \int_0^T \left|\phi_j'(t) - \phi_{j+1}'(t)\right|^2, \tag{4.5}$$

with

$$X_h(t) = h\sum_{j=1}^N j(\phi_{j+1} - \phi_{j-1})\left(\frac{1}{3}\phi_j' + \frac{1}{12}\phi_{j+1}' + \frac{1}{12}\phi_{j-1}'\right). \tag{4.6}$$

Remark 4.4. Observe that this discrete identity (4.5) is very close to the well-known identity for the $1-d$ wave equation (1.4) (see [6]):

$$TE(0) + X(t)\Big|_0^T = \frac{1}{2}\int_0^T |\phi_x(1,t)|^2 dt, \tag{4.7}$$

with

$$X(t) = \int_0^1 x\phi_x\phi_t dx.$$

Note, however, that in (4.5) in addition to the discrete analogue of the terms entering in the identity (4.7), we also have the extra term

$$\frac{h}{12}\sum_{j=1}^{N}\int_0^T \left|\phi_j'(t)-\phi_{j+1}'(t)\right|^2. \tag{4.8}$$

As indicated in [5], when estimating this term one loses completely the observability inequality if the class of solutions under consideration is not restricted and precisely filtering the high frequencies makes possible its boundary with respect to h.

Step 2. We have the following.

PROPOSITION 4.5 (Equipartition of energy). *For any $h>0$ and $\bar\phi$ solution of system* (2.8)*, the following identity holds:*

$$\frac{h}{12}\int_0^T\sum_{j=0}^{N}\left|\frac{\phi_{j+1}(t)-\phi_j(t)}{h}\right|^2=\frac{1}{12}TE_h-\frac{1}{24}Y_h(t)\Big|_0^T, \tag{4.9}$$

or

$$\begin{aligned} h\int_0^T\sum_{j=0}^{N}&\left|\frac{\phi_{j+1}(t)-\phi_j(t)}{h}\right|^2 \\ &=h\int_0^T\sum_{j=0}^{N}\left[\frac{1}{3}|\phi_j'(t)|^2+\frac{1}{6}|\phi_{j+1}'(t)+\phi_j'(t)|^2\right]dt-Y_h(t)\Big|_0^T, \end{aligned} \tag{4.10}$$

where

$$Y_h(t)=h\sum_{j=1}^{N}\left(\frac{2}{3}\phi_j'+\frac{1}{6}\phi_{j+1}'+\frac{1}{6}\phi_{j-1}'\right)\phi_j. \tag{4.11}$$

Proof. This identity is verified by every solution $\bar\phi$ of system (2.8) (see the formula (3.33) in [5]). It is obtained by multiplying equation (2.8) by $\bar\phi$, taking into account the expression of the energy (2.19). ∎

Taking into account that the equipartition of energy (4.9) holds for every solution $\bar\phi$ of (2.8), we have the following identity for the time derivative $\bar\phi'$ of $\bar\phi$:

$$\frac{h}{12}\int_0^T\sum_{j=0}^{N}\left|\phi_{j+1}'(t)-\phi_j'(t)\right|^2=\frac{h^2}{12}TE_{\bar\phi'}-\frac{h^2}{24}\tilde Y_h(t)\Big|_0^T, \tag{4.12}$$

where

$$\tilde Y_h(t)=h\sum_{j=1}^{N}\left(\frac{2}{3}\phi_j''+\frac{1}{6}\phi_{j+1}''+\frac{1}{6}\phi_{j-1}''\right)\phi_j' \tag{4.13}$$

and $E_{\bar\phi'}$ is the conservative energy of the derivative $\bar\phi'$ of the solution $\bar\phi$.

Step 3. (Some key estimations). The following holds.

PROPOSITION 4.6. *For any $h>0$ and any solution $\bar\phi$ of* (2.8)*, with initial data in the space $V_h\times V_h$, the following relation holds:*

$$\frac{h^2}{12}E_{\bar\phi'}\le\frac{1}{2}E_{\bar\phi_L}\le\frac{1}{2}E_h(t), \tag{4.14}$$

where $E_{\bar\phi_L}$ and $E_h(t)$ are the conservative energies (4.1) *and* (2.9)*, respectively.*

Proof. The time derivative of every solution ϕ of (2.8) is a solution of (2.8), too, with given state $\bar{\phi}'(T) = \bar{\phi}^1$ and $\bar{\phi}''(T) = M^{-1}A\bar{\phi}^0$, A and M being as in (2.11). In virtue of Proposition 4.1, we have

$$\frac{h^2}{12}E_{\bar{\phi}'} = \frac{h^2}{12}\left(E_{\bar{\phi}'_L} + E_{\bar{\phi}'_H}\right) \leq \frac{h^2}{6}E_{\bar{\phi}'_L} \leq \frac{h^2}{6}\Lambda E_{\bar{\phi}_L}, \tag{4.15}$$

where Λ is the largest eigenvalue entering in the Fourier development of the solution $\bar{\phi}_L$ of (2.8), corresponding to the low frequencies, i.e.,

$$\bar{\phi}_L(t) = \sum_{k=1}^{\frac{N-1}{2}} c_k \bar{\varphi}^k. \tag{4.16}$$

That is,

$$\Lambda = \max_{1\leq k\leq (N-1)/2} \mu_k(M^{-1}A) = \max_{1\leq k\leq (N-1)/2} \frac{6}{h^2}\left[\frac{\sin^2\left(\frac{k\pi h}{2}\right)}{\frac{3}{2} - \sin^2\left(\frac{k\pi h}{2}\right)}\right] = \frac{3}{h^2}. \tag{4.17}$$

Thus, using estimation (4.17) of Λ in (4.15), we find exactly inequality (4.14), and the proof is complete. □

Step 4. Now we are able to estimate the extra term (4.8) entering in the identity (4.7).

In view of (4.14) in (4.12), we obtain the following sharp estimate for the solutions of (2.8) in the class $V_h \times V_h$ of slowly varying initial data:

$$\frac{h}{12}\int_0^T \sum_{j=0}^{N} \left|\phi'_{j+1}(t) - \phi'_j(t)\right|^2 \leq \frac{T}{2}E_h(t) - \frac{h^2}{24}\tilde{Y}_h(t)\Big|_0^T. \tag{4.18}$$

In view of this relation, combining (4.5), (4.9), and (4.18) we deduce that

$$\frac{T}{2}E_h(0) + Z_h(t)\Big|_0^T \leq \frac{1}{2}\int_0^T \left[\left|\frac{\phi_N(t)}{h}\right|^2 + \frac{|\phi'_N(t)|^2}{6}\right] dt, \tag{4.19}$$

with

$$Z_h(t) = X_h(t) + \frac{h^2}{24}\tilde{Y}_h(t). \tag{4.20}$$

Recall that the Fourier development of the solution $\bar{\phi}$ is

$$\bar{\phi}(t) = \sum_{|k|\leq N} a_k e^{i\mu_k t}\bar{\varphi}^k, \tag{4.21}$$

with $\mu_k = \sqrt{\mu_k}$ for $k \geq 1$ and $\mu_{-k} = -\mu_k$. Hence, by (4.13),

$$\begin{aligned}\frac{h^2}{24}\tilde{Y}_h(t) &= \frac{h^3}{24}\sum_{j=1}^{N}\left(\frac{2}{3}\phi''_j + \frac{1}{6}\phi''_{j+1} + \frac{1}{6}\phi''_{j-1}\right)\phi'_j \\ &\asymp \frac{h}{2}\sum_{j=1}^{N}\left(\frac{2}{3}\phi'_j + \frac{1}{6}\phi'_{j+1} + \frac{1}{6}\phi'_{j-1}\right)\phi_j = \frac{1}{2}Y_h(t).\end{aligned} \tag{4.22}$$

Equation (4.22) is equivalent to the existence of positive constants K_1, K_2, such that

$$K_1 Y_h(t) \leq \frac{h^2}{24}\tilde{Y}_h(t) \leq K_2 Y_h(t). \tag{4.23}$$

The following provides an estimate on the reminder term Z_h given by (4.20).

PROPOSITION 4.7. *For any $h > 0$ and any solution $\bar{\phi}$ of (2.8), it follows that*

$$|Z_h(t)| \leq \sqrt{1 + \frac{Kh^2}{4} + \frac{3h}{4\mu_1}(-2K + K^2)}E_h(0) \;\; \forall\, 0 < t < T, \tag{4.24}$$

where K is a positive constant.

Proof. Taking into account identity (4.20), with X_h and Y_h given by (4.6) and (4.11), respectively, we obtain

$$\begin{aligned} Z_h(t) &\asymp h\sum_{j=1}^{N} j\,(\phi_{j+1} - \phi_{j-1})\left(\frac{1}{3}\phi'_j + \frac{1}{12}\phi'_{j-1} + \frac{1}{12}\phi'_{j+1}\right) \\ &\quad + \frac{Kh}{2}\sum_{j=1}^{N}\left(\frac{2}{3}\phi'_j + \frac{1}{6}\phi'_{j+1} + \frac{1}{6}\phi'_{j-1}\right)\phi_j \\ &= h\sum_{j=1}^{N}\left[\frac{2}{3}\phi'_j + \frac{1}{6}\phi'_{j+1} + \frac{1}{6}\phi'_{j-1}\right]\left(\frac{j}{2}(\phi_{j+1} - \phi_{j-1}) + \frac{K}{2}\phi_j\right) \\ &= h\sum_{i,j=1}^{N} m_{ij}a_i b_j = \left\langle M\bar{a}, \bar{b}\right\rangle, \end{aligned} \tag{4.25}$$

with

$$a_i = \frac{i}{2}(\phi_{i+1} - \phi_{i-1}) + \frac{K}{2}\phi_i; \;\; b_i = \phi'_i$$

and m_{ij} are the entries of matrix M. Therefore

$$|Z_h(t)| \leq \left|h\sum_{i,j=1}^{N} m_{ij}a_i a_j\right|^{1/2}\left|h\sum_{i,j=1}^{N} m_{ij}b_i b_j\right|^{1/2} = |M^{1/2}\bar{a}|_{\ell^2}\cdot|M^{1/2}\bar{b}|_{\ell^2}. \tag{4.26}$$

On the other hand,

$$\begin{aligned} |M^{1/2}\bar{b}|_{\ell^2} &= h\sum_{j=1}^{N}\left[\frac{2}{3}\mid\phi'_j\mid^2 + \frac{1}{6}(\phi'_{j+1} + \phi'_{j-1})\phi'_j\right] \\ &= h\sum_{j=1}^{N}\left[\frac{1}{3}\mid\phi'_j\mid^2 + \frac{1}{6}\left|\phi'_{j+1} + \phi'_j\right|^2\right] \end{aligned} \tag{4.27}$$

and

(4.28)

$$
\begin{aligned}
|M^{1/2}\bar{a}|_{\ell^2} &\le h\sum_{i=1}^{N} a_i^2 = \frac{h}{4}\sum_{i=1}^{N}[i(\phi_{i+1}-\phi_{i-1})+K\phi_i]^2\\
&= \frac{h}{4}\sum_{i=1}^{N}\big[i^2(\phi_{i+1}-\phi_i)^2+i^2(\phi_i-\phi_{i-1})^2+2i^2(\phi_{i+1}-\phi_i)(\phi_i-\phi_{i-1})\\
&\quad + K^2\phi_i^2+2Ki\phi_{i+1}\phi_i-2Ki\phi_{i-1}\phi_i\big]\\
&\le \frac{h}{4}\sum_{i=1}^{N}\big[2i^2\mid\phi_{i+1}-\phi_i\mid^2+2i^2\mid\phi_i-\phi_{i-1}\mid^2\\
&\quad + 2Ki\phi_i(\phi_{i+1}-\phi_{i-1})+K^2\mid\phi_i\mid^2\big]\\
&\le h(N+1)^2\sum_{i=0}^{N}|\phi_{i+1}-\phi_i|^2+\frac{Kh}{2}\sum_{i=1}^{N}i\phi_i\phi_{i+1}\\
&\quad -\frac{Kh}{2}\sum_{i=1}^{N}i\phi_{i-1}\phi_i+\frac{K^2h}{4}\sum_{i=0}^{N}|\phi_i|^2\\
&= h\sum_{i=0}^{N}\left|\frac{\phi_{i+1}-\phi_i}{h}\right|^2+\frac{Kh}{2}\sum_{i=0}^{N}[i\phi_i\phi_{i+1}-(i+1)\phi_i\phi_{i+1}]+\frac{K^2h}{4}\sum_{i=0}^{N}|\phi_i|^2\\
&= h\sum_{i=0}^{N}\left|\frac{\phi_{i+1}-\phi_i}{h}\right|^2-\frac{Kh}{2}\sum_{i=0}^{N}\phi_i\phi_{i+1}+\frac{K^2h}{4}\sum_{i=0}^{N}|\phi_i|^2\\
&= h\sum_{i=0}^{N}\left|\frac{\phi_{i+1}-\phi_i}{h}\right|^2-\frac{Kh^3}{4}\sum_{i=0}^{N}\left|\frac{\phi_{i+1}-\phi_i}{h}\right|^2+\left(-\frac{Kh}{2}+\frac{K^2h}{4}\right)\sum_{i=0}^{N}|\phi_i|^2\\
&\le \left(1+\frac{Kh^2}{4}+\frac{3h}{4\mu_1}(-2K+K^2)\right)h\sum_{i=0}^{N}\left|\frac{\phi_{i+1}-\phi_i}{h}\right|^2.
\end{aligned}
$$

To obtain the last relation, we have used the inequality

$$
\sum_{j=0}^{N}\left|\frac{\phi_{j+1}(t)-\phi_j(t)}{h}\right|^2 \ge \frac{\mu_1}{3}\sum_{j=0}^{N}\mid\phi_j(t)\mid^2, \tag{4.29}
$$

which is a consequence of the following identity (see [5] for a detailed proof) which holds for any eigenvectors φ, with eigenvalues μ of (2.20):

$$
\sum_{j=0}^{N}\left|\frac{\varphi_{j+1}-\varphi_j}{h}\right|^2=\mu\sum_{j=0}^{N}\left[\frac{1}{3}|\varphi_j|^2+\frac{1}{6}|\varphi_j+\varphi_{j+1}|^2\right]. \tag{4.30}
$$

We deduce that

$$
\begin{aligned}
|Z_h(t)| &\le \left[h\sum_{j=0}^{N}\left(\frac{1}{3}\mid\phi_j'\mid^2+\frac{1}{6}\mid\phi_j'+\phi_{j+1}'\mid^2\right)\right]^{1/2}\\
&\quad \left[\left(1+\frac{Kh^2}{4}+\frac{3h}{4\mu_1}\left(-2K+K^2\right)\right)h\sum_{i=0}^{N}\left|\frac{\phi_{i+1}-\phi_i}{h}\right|^2\right]^{1/2} \qquad (4.31)\\
&\le \sqrt{1+\frac{Kh^2}{4}+\frac{3h}{4\mu_1}(-2K+K^2)}E_h(0). \qquad \square
\end{aligned}
$$

Now, by (4.19) and (4.24), we have

$$\left(T-4\sqrt{1+\frac{Kh^2}{4}+\frac{3h}{4\mu_1}(-2K+K^2)}\right)E_h(0)\le\int_0^T\left[\left|\frac{\phi_N}{h}\right|^2+\frac{|\,\phi'_N\,|^2}{6}\right]dt, \tag{4.32}$$

and (4.4) holds, with

$$C_2(T,h)=1\Big/\left(T-4\sqrt{1+\frac{Kh^2}{4}+\frac{3h}{4\mu_1}(-2K+K^2)}\right)$$

for every

$$T>T(h):=4\sqrt{1+\frac{Kh^2}{4}+\frac{3h}{4\mu_1}(-2K+K^2)}. \tag{4.33}$$

The minimal observability time $T(h)$ obtained in (4.33) is suboptimal.

However, the term $\left(1-h^2/4+3h(1+K^2)/4\mu_1\right)^{1/2}E_h$ is of the order of the discrete L^2-norm of the solutions. Therefore, it is a lower term when compared to the energy. A compactness-uniqueness argument may allow us to get rid of it (see [16]). This compactness-uniqueness principle guarantees that, if an observability inequality holds up to a compact additive remainder, then the remainder may be removed provided a suitable uniqueness or unique-continuation result holds (see [6]). Therefore, we can recover the uniform observability inequality for any $T>4$ with a not explicit constant $C_2(T,h)>0$, uniformly bounded with respect to h.

This concludes the proof of the second (so-called *inverse*) inequality in (4.4).

Let us prove now the first inequality (so-called *direct*) in (4.4). By (4.30), we have (see [5, 6, 7, 8, 9])

$$\begin{aligned}
&\frac{h}{12}\sum_{j=0}^{N}\int_0^T|\phi'_{j+1}-\phi'_j|^2\\
&\qquad\ge\frac{h^3}{6}\mu_1(M^{-1}A)\int_0^T\left[\sum_{j=0}^{N}\frac{|\,\phi'_j\,|^2}{6}+\frac{|\,\phi'_{j+1}+\phi'_j\,|^2}{12}\right]dt\\
&\qquad\ge\frac{h^3}{6}\left(\frac{6}{h^2}\frac{2}{3}\sin^2\left(\frac{\pi h}{2}\right)\right)\int_0^T\left[\sum_{j=0}^{N}\frac{|\,\phi'_j\,|^2}{6}+\frac{|\,\phi'_{j+1}+\phi'_j\,|^2}{12}\right]dt\\
&\qquad\ge\frac{2h^3}{3}\int_0^T\left[\sum_{j=0}^{N}\frac{|\,\phi'_j\,|^2}{6}+\frac{|\,\phi'_{j+1}+\phi'_j\,|^2}{12}\right]dt.
\end{aligned} \tag{4.34}$$

Hence, in (4.5)

$$\begin{aligned}
&\int_0^T\left[\left|\frac{\phi_N}{h}\right|^2+\frac{h^2}{6}\left|\frac{\phi'_N}{h}\right|^2\right]dt\\
&\qquad\le 2TE_h(0)-\frac{2h^3}{3}\sum_{j=0}^{N}\int_0^T\left[\frac{\left|\phi'_j\right|^2}{3}+\frac{\left|\phi'_{j+1}+\phi'_j\right|^2}{6}\right]dt+2X_h(t)\,|_0^T,
\end{aligned} \tag{4.35}$$

with X_h given by (4.6).

Moreover, in (4.9) we obtain

$$2TE_h(0) + Y_h(t)\,|_0^T = 2h\sum_{j=1}^{N}\int_0^T \left(\frac{1}{3}\left|\phi_j'\right|^2 dt + \frac{1}{6}\left|\phi_j' + \phi_{j+1}'\right|^2\right) dt,$$

with Y_h as in (4.13).

Therefore,

(4.36)
$$\begin{aligned}\frac{1}{2}\int_0^T \left[\left|\frac{\phi_N}{h}\right|^2 + \frac{h^2}{6}\left|\frac{\phi_N'}{h}\right|^2\right] dt &\le TE_h(0) - \frac{h^2}{3}\left(TE_h(0) + \frac{1}{2}Y_h(t)\,|_0^T\right) + X_h(t)\,|_0^T \\ &= TE_h(0) - \frac{h^2}{3}TE_h(0) - \frac{h^2}{6}Y_h(t)\,|_0^T + X_h(t)\,|_0^T \\ &= TE_h(0)\left[1 - \frac{h^2}{3}\right] - \frac{h^2}{6}Y_h(t)\,|_0^T + X_h(t)\,|_0^T \\ &= TE_h(0)\left[1 - \frac{h^2}{3}\right] + Z_h(t)\,|_0^T,\end{aligned}$$

where

$$Z_h(t) = X_h(t) - \frac{h^2}{6}Y_h(t). \tag{4.37}$$

The following provides an estimate of the term Z_h.

PROPOSITION 4.8. *For any $h > 0$ and any solution ϕ of* (2.8)*, it follows that*

$$|Z_h(t)| \le \sqrt{1 - \frac{h^4}{12} + \frac{h^4}{2\mu_1}\left(1 + \frac{h^2}{6}\right)}E_h(0) \;\; \forall 0 < t < T. \tag{4.38}$$

The proof of this relation is similar to the proof of (4.24), and it is given in detail in [5] and [9].

Using (4.36) and (4.38), we deduce that

$$\begin{aligned}\frac{1}{2}\int_0^T \left[\left|\frac{\phi_N}{h}\right|^2 + \frac{h^2}{6}\left|\frac{\phi_N'}{h}\right|^2\right] dt \\ \le \left[T\left[1 - \frac{h^2}{3}\right] + 2\sqrt{\left(1 - \frac{h^4}{12} + \frac{h^4}{2\mu_1}\left(1 + \frac{h^2}{6}\right)\right)}\right]E_h(0),\end{aligned} \tag{4.39}$$

with

$$C_1(T,h) = 1 \Big/ \left[T\left(1 - \frac{h^2}{3}\right) + 2\sqrt{\left(1 - \frac{h^4}{12} + \frac{h^4}{2\mu_1}\left(1 + \frac{h^2}{6}\right)\right)}\right].$$

Therefore, we can obtain a constant $C_1(T,h) > 0$ uniformly bounded, with respect to h such that the first inequality in (4.4) holds. The proof of Theorem 4.2 is now complete. □

Remark 4.9. It is important to underline that the inequality in (4.32) is uniform in h precisely because of considering slowly oscillating initial data in the fine grid. Relation (4.14) plays a fundamental role in the above proof.

The time $T > 4$ is twice the observability time for the continuous case. The analysis of the dispersion diagram of filtered solutions predicts a propagation velocity equal to $1/2$ in the class of solutions under consideration and confirms the observability time $T = 4$.

Any time-dependent scalar, linear partial differential equation with constant coefficients admits plane wave solutions

$$\phi(x,t) = e^{i(\omega t - \xi x)}, \quad \xi \in \mathbb{R},\ \omega \in \mathbb{C}, \tag{4.40}$$

where ξ is the *wave number* and ω is the *frequency*. The relationship

$$\omega = \omega(\xi) \tag{4.41}$$

is known as the *dispersion relation* for the equation. By dispersion, one understands the property of a dynamical continuous or discrete (in time) system to propagate, with different velocities, the components of the solution.

Any individual *"monochromatic wave"* of (4.40) moves at the *phase velocity*

$$c(\xi,\omega) = \frac{\omega(\xi)}{\xi}. \tag{4.42}$$

When one superimposes two waves with nearby propagation velocities, there appear wave packets which can propagate with different velocities. The energy of wave packets propagates at the so-called *group velocity*

$$C(\xi,\omega) = \frac{d\omega(\xi)}{d\xi}. \tag{4.43}$$

At the numerical level it is important to distinguish the notions of phase and group velocity. Phase velocity refers to the velocity of the propagation of individual monochromatic waves, while group velocity corresponds to the velocity of the propagation of wave packets, that may significantly differ from the phase velocity when waves of similar frequencies are combined.

• For the continuous wave equation (1.4), we have $\omega(\xi) = \xi$, and therefore $c(\xi) = C(\xi) = 1$.

• For the semidiscrete scheme (2.6), the dispersion relation is

$$\omega(\xi) = \frac{\sqrt{6}}{h}\sqrt{\frac{1-\cos(\xi h)}{2+\cos(\xi h)}}. \tag{4.44}$$

The phase velocity is in this case

$$c(\xi,\omega) = \frac{\sqrt{6}}{\xi h}\sqrt{\frac{1-\cos(\xi h)}{2+\cos(\xi h)}}. \tag{4.45}$$

The corresponding group velocity is

$$C(\xi,\omega) = \frac{\sqrt{6}}{2}\sqrt{\frac{2+\cos(\xi h)}{1-\cos(\xi h)}}\frac{3\sin(\xi h)}{(2+\cos(\xi h))^2} = 3\sqrt{\frac{3}{2}}\sqrt{\frac{1+\cos(\xi h)}{(2+\cos(\xi h))^3}}. \tag{4.46}$$

Note that, as $h \to 0$, for all ξ we have

$$C(\xi,\omega) \le \frac{3\sqrt{3}}{4}\sqrt{1+\cos(\xi h)} \to 0,$$

when $\xi = \pi/h$.

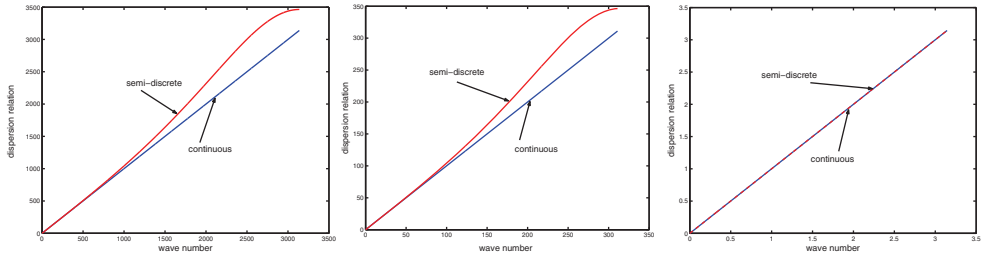

FIG. 1. *Dispersion relation for the continuous and finite-element semidiscrete cases with* $h = 0.001$ *(left),* $h = 0.1$ *(middle),* $h = 0.99999$ *(right).*

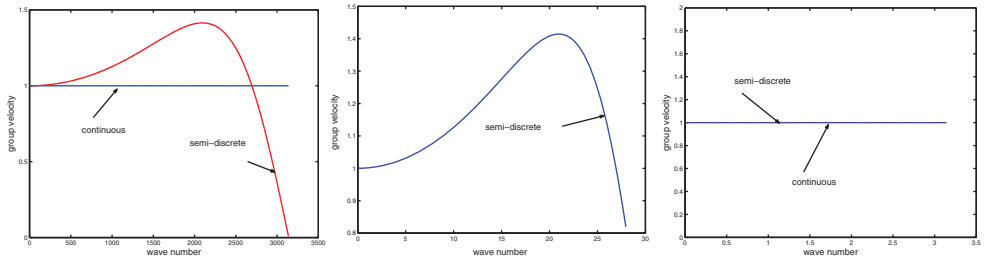

FIG. 2. *Group velocity for the continuous and the finite-element semidiscrete cases with* $h = 0.001$ *(left),* $h = 0.1$ *(middle),* $h = 0.99999$ *(right).*

The group velocity is the derivative of the eigenfrequencies μ_k, and the spectral gap is $\mu_{k+1} - \mu_k$. Both magnitudes are similar, and they become closer as $h \to 0$.

Thus, to efficiently observe at the point $x = 1$ a wave packet (or an initial disturbance concentrated near the extreme $x = 1$) that moves to the left (in the space variable) as t increases, starting at a point sufficiently close to $x = 1$, the time needed is

$$T \geq \frac{2}{\min\limits_{\xi}\{C(\xi,\omega)\}}. \tag{4.47}$$

This is the time that the wave packet needs to, after bouncing at the left extreme $x = 0$, reach the point $x = 1$ (time of going and return or observation time).

In fact, drawing the graph of the group velocity above, one can immediately visualize that it corresponds to a wave propagation of the order of h in space-time. These facts confirm that a suitable filtering of the spurious numerical high frequencies is a good cure for these pathologies.

In Figures 1 and 2 we describe the evolution of the dispersion relation and group velocity diagrams for the semidiscrete case starting with $h = 0.001$ up to $h = 0.99999$.

5. Uniform controllability of the two-grid solutions. In this section, we apply the uniform observability results obtained above to analyze the controllability properties of the semidiscrete system (2.6).

Let us denote by $\mathcal{F}_h$ the subspace of $\mathbb{R}^N \times \mathbb{R}^N$, $\mathcal{F}_h = V_h \times V_h$, with V_h defined by (3.1) endowed with the norm

$$\|(U,V)\|^2_{\mathcal{F}_h} := \|U\|^2_{\hbar^1} + |M^{1/2}V|^2_{\ell^2}, \quad U,\ V \in V_h,$$

and by $\mathcal{F}_h^*$ we denote the dual space of $\mathcal{F}_h$, considered as a subspace of the Euclidian space $\hbar^{-1} \times \ell^2$.

DEFINITION 5.1. *Let $(U,V) \in \mathcal{F}_h^* \subset \hbar^{-1} \times \ell^2$ and $(U',V') \in \mathcal{F}_h$. We define the symmetric products in $\mathcal{F}_h^* \times \mathcal{F}_h$*

$$\big((U,V), (U',V') \big)_{\mathcal{F}_h^* \times \mathcal{F}_h} = \big(MV, U'\big) + \big(- MU, V'\big), \tag{5.1}$$

where M is given by (2.11) *and $\big(\cdot,\cdot\big)$ is the scalar product in $\mathbb{R}^N$,*

$$\big(MV, U'\big) := \frac{1}{6} \sum_{j=1}^{N} (V_{j-1} + V_{j+1} + 4V_j) U'. \tag{5.2}$$

DEFINITION 5.2. *Let $(u',u) \in \hbar^{-1} \times \ell^2$ be discrete functions defined on the fine grid G_F^h. We define a suitable projection $(\bar{U}'_{2h}, \bar{U}_{2h})$ of $(\bar{u}'_h, \bar{u}_h)$ on the coarse grid as follows:*

$$U'_j = \frac{1}{12} \left(\frac{1}{2} u'_{2j-2} + 3u'_{2j-1} + 5u'_{2j} + 3u'_{2j+1} + \frac{1}{2} u'_{2j+2} \right) \tag{5.3}$$

and

$$U_j = \frac{1}{12} \left(\frac{1}{2} u_{2j-2} + 3u_{2j-1} + 5u_{2j} + 3u_{2j+1} + \frac{1}{2} u_{2j+2} \right) \tag{5.4}$$

for any $j = 1, \ldots, (N-1)/2$.

PROPOSITION 5.3. *Set $(\bar{\phi}_h^0, \bar{\phi}_h^1) \in \mathcal{F}_h$ and $(\bar{u}'_h, \bar{u}_h) \in \mathcal{F}_h^* \subset \hbar^{-1} \times \ell^2$. Hence*

$$\big((\bar{u}'_h, \bar{u}_h), (\bar{\phi}_h^0, \bar{\phi}_h^1) \big)_{\mathcal{F}_h^* \times \mathcal{F}_h} = 0 \tag{5.5}$$

if and only if

$$\bar{U}_{2h} = \bar{0}, \quad \text{and} \quad \bar{U}'_{2h} = \bar{0} \qquad \forall\, h > 0, \tag{5.6}$$

where $\bar{U}_{2h}$, $\bar{U}'_{2h}$ are defined by (5.4) *and* (5.3)*, respectively.*

Proof. Let us consider the $\mathbb{R}^N$-vectors in the fine grid

$$\bar{\phi}_h^0 = \left(0, 0, \ldots, \frac{1}{2}, 1, \frac{1}{2}, \ldots, 0, 0 \right), \quad \phi_{2j}^0 = \delta_{2j}(i),$$

$$\phi_{2j+1}^0 = \frac{\phi_{2j}^0 + \phi_{2j+2}^0}{2}, \quad j = 1, \ldots, \frac{N-1}{2},$$

where $\phi_0 = \phi_{N+1} = 0$, $\delta_j(i)$ is the Kronecker's delta, $1 \le i \le N$, i is arbitrarily fixed, and

$$\bar{\phi}_h^1 = (0, 0, \ldots, 0, \ldots, 0, 0).$$

Taking into account Definition (5.1) of the symmetric products in $\mathcal{F}_h^* \times \mathcal{F}_h$, we deduce that (5.5) is equivalent to

$$\big(M\bar{u}'_h, \bar{\phi}_h^0\big) + \big(-M\bar{u}_h, \bar{\phi}_h^1\big) = 0, \tag{5.7}$$

and by (5.2), (5.21) is

(5.8)

$$\left(M\bar{u}_h', \bar{\phi}_h^0\right) + \left(-M\bar{u}_h, \bar{\phi}_h^1\right) := \frac{1}{6}\sum_{j=1}^{N}\left[(u_{j-1}' + u_{j+1}' + 4u_j')\phi_j^0 - (u_{j-1} + u_{j+1} + 4u_j)\,\phi_j^1\right]$$

for all $(\bar{\phi}_h^0, \bar{\phi}_h^1) \in \mathcal{F}_h$. If (5.7) holds for all $(\bar{\phi}_h^0, \bar{\phi}_h^1) \in \mathcal{F}_h$, it follows that it also holds for every $\bar{\phi}_h^0$, $\bar{\phi}_h^1$, defined previously. Therefore,

$$\left(M\bar{u}_h', \bar{\phi}_h^0\right) = \frac{1}{6}\sum_{j=1}^{N}\left(u_{j-1}' + u_{j+1}' + 4u_j'\right)\phi_j^0 = 0. \tag{5.9}$$

We have

$$\sum_{j=1}^{N} u_{j-1}'\phi_j^0 = \sum_{j=1}^{\frac{N-1}{2}}\left[u_{2j-1}'\phi_{2j}^0 + u_{2j}'\phi_{2j+1}^0\right], \tag{5.10}$$

$$\sum_{j=1}^{N} u_{j+1}'\phi_j^0 = \sum_{j=1}^{\frac{N-1}{2}}\left[u_{2j+2}'\phi_{2j+1}^0 + u_{2j+1}'\phi_{2j}^0\right], \tag{5.11}$$

and

$$\sum_{j=1}^{N} u_j'\phi_j^0 = \sum_{j=1}^{\frac{N-1}{2}}\left[u_{2j+1}'\phi_{2j+1}^0 + u_{2j}'\phi_{2j}^0\right]. \tag{5.12}$$

Adding these relations we obtain

$$\sum_{j=1}^{\frac{N-1}{2}}\phi_{2j}^0\left[\frac{1}{2}u_{2j-2}' + 3u_{2j-1}' + 5u_{2j}' + 3u_{2j+1}' + \frac{1}{2}u_{2j+2}'\right] = 0. \tag{5.13}$$

This relation does not imply that $u_j' = 0$ for every $j = 1, \ldots, N$, but, if we consider U_{2h}' as in (5.3), we conclude

$$\bar{U}_{2h}' = \bar{0} \quad \forall\, h \in (0,1).$$

Analogously, we can prove that (5.7) holds if and only if $\bar{U}_{2h} = \bar{0}$, with $\bar{U}_{2h}$ defined as in (5.4). □

5.1. Partial controllability. Set $T > 0$. The partial controllability problem of system (2.6) in the space $\ell^2 \times \hbar^{-1}$ consists in finding a control $v_h \in L^2(0,T)$ such that the solution $\bar{u}_h$ of (2.6) satisfies

$$\mathcal{R}\left(\bar{u}_h'(T), \bar{u}_h(T)\right) = (\bar{0}, \bar{0}). \tag{5.14}$$

Operator $\mathcal{R}$ is the projection from $\hbar^{-1} \times \ell^2$ into $\mathcal{F}_h^*$, with

$$\mathcal{R}\left(\bar{u}_h'(T), \bar{u}_h(T)\right) = \left(\bar{U}'(T), \bar{U}(T)\right),$$

where $\bar{U}(T)$ and $\bar{U}'(T)$ are given by

$$U_j(T) = \frac{1}{12}\left(\frac{1}{2}u_{2j-2}(T) + 3u_{2j-1}(T) + 5u_{2j}(T) + 3u_{2j+1}(T) + \frac{1}{2}u_{2j+2}(T)\right) \tag{5.15}$$

and

(5.16)
$$U_j'(T) = \frac{1}{12}\left(\frac{1}{2}u_{2j-2}'(T) + 3u_{2j-1}'(T) + 5u_{2j}'(T) + 3u_{2j+1}'(T) + \frac{1}{2}u_{2j+2}'(T)\right),$$

for any $j = 1, \dots, (N-1)/2$, where $\bar{u}_h$ is the solution of (2.6).

To simplify the notations, we define

(5.17)
$$\begin{aligned} f(\bar{u}_h, \bar{\phi}_h) &:= \left(M\bar{u}_h^1, \bar{\phi}_h(0)\right) + \left(-M\bar{u}_h^0, \bar{\phi}_h'(0)\right) \\ &= \frac{1}{6}\sum_{j=1}^{N}\left[(u_{j-1}^1 + u_{j+1}^1 + 4u_j^1)\phi_j(0) - (u_{j-1}^0 + u_{j+1}^0 + 4u_j^0)\phi_j'(0)\right], \end{aligned}$$

where $\bar{u}_h$ and $\bar{\phi}_h$ are the solutions of systems (2.6) and (2.8), respectively, and $(\cdot,\cdot)$ is the scalar product (5.2).

Multiplying the first equation in (2.6) by $\{\bar{\phi}_h\}$, integrating by parts in $[0,T]$ and adding in j, $1 \le j \le N$, we deduce that

(5.18)
$$\begin{aligned} &\left(M\bar{u}_h'(T), \bar{\phi}_h^0\right) + \left(-M\bar{u}_h(T), \bar{\phi}_h^1\right) - f\left(\bar{u}_h, \bar{\phi}_h\right) + \int_0^T \sum_{j=1}^{N} u_j(t)\left(M\phi''(t) + A\phi(t)\right)_j \\ &\quad = \frac{1}{h^2}\int_0^T v_h(t)\phi_N(t)dt - \frac{1}{6}\int_0^T v_h(t)\phi_N''(t)dt, \end{aligned}$$

with $f(\bar{u}_h, \bar{\phi}_h)$ defined as in (5.17).

Therefore, it is immediate to see that, for all solution $\bar{\phi}_h$ of the semidiscrete system (2.8), we have

(5.19)
$$\begin{aligned} &\left(M\bar{u}_h'(T), \bar{\phi}_h^0\right) + \left(-M\bar{u}_h(T), \bar{\phi}_h^1\right) - f(\bar{u}_h, \bar{\phi}_h) \\ &\qquad + \frac{1}{6}\int_0^T v_h(t)\phi_N''(t)dt = \frac{1}{h^2}\int_0^T v_h(t)\phi_N(t)dt. \end{aligned}$$

The solution of system (2.6) may be characterized through a transposition argument based on the identity above. Indeed, $\{\bar{u}_h\}_h$ solves (2.6) if for every $s \in [0,T]$, it holds

$$L_s(\bar{\phi}^0, \bar{\phi}^1) = \left(M\bar{u}_h'(s), \bar{\phi}_h(s)\right) + \left(-M\bar{u}_h(s), \bar{\phi}_h'(s)\right)$$

for every solution $\{\bar{\phi}_h\}$ of the discrete problem (2.8), where the functional $L_s : \mathbb{R}^N \times \mathbb{R}^N \to \mathbb{R}$ is such that

$$L_s(\bar{\phi}^0, \bar{\phi}^1) = f(\bar{u}_h, \bar{\phi}_h) - \frac{1}{6}\int_0^s v_h(t)\phi_N''(t)dt + \frac{1}{h^2}\int_0^s v_h(t)\phi_N(t)dt.$$

Now, let us consider the functional $L_T : \mathbb{R}^{\mathbb{N}} \times \mathbb{R}^N \to \mathbb{R}$:

$$L_T(\bar{u}_h^0, \bar{u}_h^1) = f(\bar{u}_h, \bar{\phi}_h) - \frac{1}{6}\int_0^T v_h(t)\phi_N''(t)dt + \frac{1}{h^2}\int_0^T v_h(t)\phi_N(t)dt.$$

Proposition 5.4 provides a characterization of the partial controllability property of semidiscrete system (2.6).

PROPOSITION 5.4. *Set $T > 0$. Problem (2.6) is partially controllable in $\ell^2 \times \hbar^{-1}$ if and only if, for each initial state $(\bar{u}_h^0, \bar{u}_h^1) \in \ell^2 \times \hbar^{-1}$, there exists a function $v_h \in L^2(0,T)$ such that*

$$f\left(\bar{u}_h, \bar{\phi}_h\right) = \frac{1}{6}\int_0^T v_h(t)\phi_N''(t)dt - \frac{1}{h^2}\int_0^T v_h(t)\phi_N(t)dt \tag{5.20}$$

for any initial data $(\bar{\phi}_h^0, \bar{\phi}_h^1) \in \mathcal{F}_h$ associated to the solution $\bar{\phi}_h$ of (2.8).

Proof. In view of identity (5.19), it is immediate to see that the control v_h such that (5.21) holds is characterized by the property (5.20). □

Remark 5.5. In the continuous case we have the following characterization of the property of exact controllability: the control v steers the initial data (u^0, u^1) of problem (1.1) to $(0,0)$ if and only if

$$\int_0^T v(t)\phi_x(1,t)dt = \int_0^1 (u^1\phi^0 - u^0\phi^1)dx$$

for every solution ϕ of the homogeneous problem (1.4), with initial data (ϕ^0, ϕ^1).

Set $(\bar{\phi}_h^0, \bar{\phi}_h^1) \in \mathcal{F}_h$. As we said above, (5.20) is equivalent to

$$\left(M\bar{u}_h'(T), \bar{\phi}_h^0\right) + \left(-M\bar{u}_h(T), \bar{\phi}_h^1\right) = 0 \tag{5.21}$$

for all $(\bar{\phi}_h^0, \bar{\phi}_h^1) \in \mathcal{F}_h$.

Note that (5.21) does not imply that the solution of (2.6) vanishes at time $t = T$. Rather the projection (5.14) of the state (u', u) on the coarse grid vanishes. More precisely, $\bar{U}(T), \bar{U}'(T)$ vanish.

5.2. Construction of the two-grid controls. We now briefly describe the algorithm for building an efficient approximation of the control v of (1.1), which is inspired in Glowinski [2]. We apply the uniform observability results obtained in the previous section to analyze the controllability properties of the semidiscrete system (2.6). We can prove now the existence of a bounded sequence of HUM controls for the semidiscrete problem (2.6).

The following uniform (with respect to $h \to 0$) partial controllability property holds in the space $\mathcal{F}_h$.

THEOREM 5.6. *For any $T > 4$, system (2.6) is partially controllable on $\ell^2 \times \hbar^{-1}$ for all $0 < h < 1$. Moreover, the controls $\{v_h\}_h$ of minimal norm are uniformly bounded, more precisely, there exists a positive constant $C = C(T)$, independent of $h \in (0,1)$, such that*

$$\|v_h\|_{L^2(0,T)} \le C\|\mathcal{R}(u_h^1, -u_h^0)\|^2_{\mathcal{F}_h^*} \qquad \forall\, 0 < h < 1. \tag{5.22}$$

Proof. Given $T > 4$ and $\varepsilon > 0$ small enough ($T - 4 > 2\varepsilon$), we consider $\rho_\varepsilon(t) \in \mathcal{C}^\infty(\mathbb{R})$, so that $0 \le \rho_\varepsilon \le 1$, $\rho_\varepsilon = 1$ in $(\varepsilon, T-\varepsilon)$, and the support of ρ_ε is compact in $(0,T)$. We define the functional $J_h : \mathbb{R}^N \times \mathbb{R}^N \to \mathbb{R}$ by

$$J_h\left((\bar{\phi}_h^0, \bar{\phi}_h^1)\right) = \frac{1}{2}\int_0^T \left|\frac{\phi_N(t)}{h}\right|^2 dt + \frac{h^2}{12}\int_0^T \rho_\varepsilon(t)\left|\frac{\phi_N'(t)}{h}\right|^2 dt + hf(\bar{u}_h, \bar{\phi}_h), \tag{5.23}$$

where $\bar{\phi}_h$ is the solution of the adjoint problem (2.8), with initial data $(\bar{\phi}_h^0,\ \bar{\phi}_h^1) \in \mathcal{F}_h$, $(\bar{u}_h^0, \bar{u}_h^1)$ are the initial data of system (2.6) to be controlled.

The conservative energy of system (2.8) is

$$E_h(0) = \frac{1}{2} \left\| \left(\bar{\phi}_h^0, \bar{\phi}_h^1 \right) \right\|_{\mathcal{F}_h}^2 . \tag{5.24}$$

We have

$$\left| hf(\bar{u}_h, \bar{\phi}_h) \right| = \left| \left((M\bar{u}_h^1, \bar{\phi}_h(0)), (-M\bar{u}_h^0, \bar{\phi}_h'(0)) \right) \right| \leq \| \mathcal{R} \left(\bar{u}_h^1, -\bar{u}_h^0 \right) \|_{\mathcal{F}_h^*} \| \left(\bar{\phi}_h^0, \bar{\phi}_h^1 \right) \|_{\mathcal{F}_h}. \tag{5.25}$$

The functional J_h is continuous according to (5.25) and the direct observability inequality in (4.4). Moreover, J_h is convex. On the other hand, in view of inequality (4.4), it is uniformly (with respect to $0 < h < 1$) coercive in $\mathcal{F}_h$ provided $T - 2\varepsilon > 4$. Thus, for each $0 < h < 1$ and for any $T - 2\varepsilon > 4$, there is a unique minimizer $(\hat{\phi}_h^0, \hat{\phi}_h^1) \in \mathcal{F}_h$ of the functional J_h:

$$I_h = J_h \left(\hat{\phi}_h^0, \hat{\phi}_h^1 \right) = \min_{\left(\bar{\phi}_h^0, \bar{\phi}_h^1 \right) \in \mathcal{F}_h} J_h \left(\bar{\phi}_h^0, \bar{\phi}_h^1 \right). \tag{5.26}$$

The corresponding Euler equation reads

$$\left(\hat{\phi}_h^0, \hat{\phi}_h^1 \right) \in \mathcal{F}_h : \quad J_h' \left(\left(\hat{\phi}_h^0, \hat{\phi}_h^1 \right) \right) \left(\phi_h^0, \phi_h^1 \right) = 0 \quad \forall \ \left(\phi_h^0, \phi_h^1 \right) \in \mathcal{F}_h.$$

Calculating the Gateaux derivative of J_h in $(\hat{\phi}_h^0, \hat{\phi}_h^1)$, we get that this equality is equivalent to

$$\int_0^T \frac{\hat{\phi}_N(t)}{h} \left[\frac{\phi_N(t)}{h} - \frac{h^2}{6} \left(\rho_\varepsilon(t) \frac{\phi_N'(t)}{h} \right)' \right] dt + hf \left(\bar{u}_h, \bar{\phi}_h \right) = 0 \tag{5.27}$$

for every solution $\bar{\phi}_h$ of the adjoint problem (2.8).

Now, we define

$$v_h(t) = \frac{\hat{\phi}_N(t)}{h}, \tag{5.28}$$

hence, in (5.27) we obtain

$$\int_0^T v_h(t) \left[\frac{\phi_N(t)}{h} - \frac{h^2}{6} \left(\rho_\varepsilon(t) \frac{\phi_N'(t)}{h} \right)' \right] dt + hf \left(\bar{u}_h, \bar{\phi}_h \right) = 0. \tag{5.29}$$

Thus, when $\varepsilon \to 0$, we obtain the partial controllability property (5.20) for every $T > 4$.

We have $I_h \leq J_h(\bar{0}, \bar{0}) = 0$, which is equivalent to

$$\frac{1}{2} \int_0^T \left[\left| \frac{\hat{\phi}_N(t)}{h} \right|^2 dt + \frac{h^2}{6} \int_0^T \rho_\varepsilon(t) \left| \frac{\hat{\phi}_N'(t)}{h} \right|^2 dt \right] \leq \| \mathcal{R} \left(u_h^1, -u_h^0 \right) \|_{\mathcal{F}_h^*} \| \left(\hat{\phi}_h^1, \hat{\phi}_h^1 \right) \|_{\mathcal{F}_h}. \tag{5.30}$$

Combining (5.30) with the uniform observability inequality (4.4) yields

$$\begin{aligned} &\int_0^T \left[\left| \frac{\hat{\phi}_N(t)}{h} \right|^2 dt + \frac{h^2}{6} \int_0^T \left| \frac{\hat{\phi}_N'(t)}{h} \right|^2 dt \right] \\ &\qquad \leq C \| \mathcal{R} \left(u_h^1, -u_h^0 \right) \|_{\mathcal{F}_h^*} \left(\int_0^T \left[\left| \frac{\hat{\phi}_N(t)}{h} \right|^2 dt + \frac{h^2}{6} \int_0^T \left| \frac{\hat{\phi}_N'(t)}{h} \right|^2 dt \right] \right)^{\frac{1}{2}}, \end{aligned} \tag{5.31}$$

or, equivalently,

$$\|v_h\|_{L^2(0,T)} = \int_0^T \left|\frac{\hat\phi_N(t)}{h}\right|^2 dt \le \int_0^T \left[\left|\frac{\hat\phi_N(t)}{h}\right|^2 dt + \frac{h^2}{6}\int_0^T \left|\frac{\hat\phi_N'(t)}{h}\right|^2 dt\right] \le C\|\mathcal{R}\left(u_h^1, -u_h^0\right)\|^2_{\mathcal{F}_h^*}, \tag{5.32}$$

where $C = C(T)$ is independent of h.

In view of (5.32), the sequence of controls we have obtained v_h is bounded in $L^2(0,T)$ when $h \to 0$ as we wanted to prove. □

Remark 5.7. Observe that, in this method, the functional J_h is minimized on $\mathcal{F}_h$, in contrast with the direct application of the minimization method of the functional J_h (that leads to divergent controls as $h \to 0$ for some pathological initial data; see [5] and [17]). The uniform observability inequality (4.4) guarantees the uniform coercivity of J_h when restricted to $\mathcal{F}_h$ and, consequently, the boundedness of the controls.

Note that (5.27) does not imply that the solution of (2.6) vanishes at time $t = T$. Rather a suitable projection of the state (u, u') on the coarse grid vanishes. More precisely, if we define the restriction (5.15)–(5.16), we have

$$\mathcal{R}(\bar u(T), \bar u'(T)) = \left(\bar U_h(T), \bar U_h'(T)\right) = (\bar 0, \bar 0).$$

5.3. Convergence of the controls. The aim of this section is to obtain controls for the continuous system (1.1) as limits as $h \to 0$ of the sequences of controls for the corresponding semidiscrete problems (2.6). We proceed as follows.

Given an initial state $(u^0, u^1) \in L^2(0,1) \times H^{-1}(0,1)$ of the continuous system (1.1), we develop it in Fourier series

$$\left(u^0, u^1\right) = \sum_{k=1}^{\infty} \left(c_k^0, c_k^1\right) \varphi_k(x), \tag{5.33}$$

with $(c_k^0, c_k^1) \in \ell^2 \times \hbar^{-1}$, $\varphi_k(x) = \sin(k\pi x)$. Further, we construct the sequence of discrete initial states:

$$\left(\bar u_h^0, \bar u_h^1\right) = \sum_{k=1}^{N} \left(c_k^0, c_k^1\right) \bar\varphi_k, \tag{5.34}$$

with $\bar\varphi_k = (\varphi_{k,1}, \dots, \varphi_{k,N})$, $\varphi_{k,j} = \sin(k\pi j \Delta x)$, $j, k = 1, \dots, N$.

In view of Theorem 5.6, for every $h \in (0,1)$ there exists a HUM control (v_h) for semidiscrete system (2.6), with initial data (5.34). Then, we prove in Theorem 5.8 that the sequence (v_h) converges (in a sense defined below) to a function $v \in L^2(0,T)$, which is the HUM control for system (1.1), with initial data (5.33).

As the solution u of (1.1), with initial data $(u^0, u^1) \in L^2(0,1) \times H^{-1}(0,1)$ and control $v \in L^2(0,T)$ satisfies $u \in \mathcal{C}([0,T]; L^2(0,1)) \cap \mathcal{C}^1([0,T]; H^{-1}(0,1))$, then there exist functions $c_k(t)$, $k \in \mathbb{N}$ such that

$$u(x,t) = \sum_{k\in\mathbb{N}} c_k(t)\varphi_k(x), \tag{5.35}$$

with

$$\sup_{t\in[0,T]} \left[\| c_k(t) \|_{\ell^2} + \| c_k'(t) \|_{\hbar^{-1}}\right] < \infty. \tag{5.36}$$

The solution of (2.6) may be written in a similar form as $\bar{u}_h(t) = \sum_k c_{k,h}(t)\bar{\varphi}_k$ by putting $c_{k,h}(t) = 0$ for $k > N$.

The control $v \in L^2(0,T)$ of minimal L^2-norm (HUM control) verifies

$$v(t) = -\partial_x \hat{\phi}(1,t), \tag{5.37}$$

where $\hat{\phi}$ is the solution of the adjoint problem (1.4), with initial data $(\hat{\phi}^0, \hat{\phi}^1) \in H_0^1(0,1) \times L^2(0,1)$, the unique minimizer of the functional

$$J\left(\phi^0, \phi^1\right) = \frac{1}{2}\int_0^T \mid \partial_x \phi(1,t) \mid^2 dt - \int_0^1 u^0\phi^1 - < u^1, \phi^0 >_{-1,1}$$

in that space $H_0^1(0,1) \times L^2(0,1)$.

The following convergence result holds.

THEOREM 5.8. *Let $T > 4$. Let $\bar{u}_h$ and u be the solutions of* (2.6) *and* (1.1) *as above. Then*

$$\{c_{k,h}(\cdot)\}_{k\in\mathbb{N}} \to \{c_k(\cdot)\}_{k\in\mathbb{N}} \text{ strongly in } L^p(0,T;\ell^2) \cap W^{1,p}(0,T;\hbar^{-1}) \text{ as } h \to 0, \text{ with } 1 \le p < \infty \tag{5.38}$$

$$v_h(\cdot) \to v(\cdot) \quad \text{strongly in } L^2(0,T) \text{ as } h \to 0, \tag{5.39}$$

where $v_h = v_h(t)$ is the control of (2.6) *constructed by the multigrid algorithm above and $v = v(t)$ is the HUM control for the continuous wave equation which drives the initial data (u^0, u^1) to rest in time T.*

Proof. (Sketch of the proof.) In view of (5.22), it is easy to see that

$$\int_0^T |v_h|^2 \, dt \le C. \tag{5.40}$$

Then, up to the extraction of a subsequence that we still denote by $\{v_h\}_h$, we have

$$v_h(t) \rightharpoonup v(t) \text{ in } L^2(0,T) \text{ as } h \to 0. \tag{5.41}$$

By a Γ-convergence argument, it can also be seen that the limit v is given by

$$v(t) = -\partial_x \hat{\phi}(1,t), \tag{5.42}$$

where $\hat{\phi}$ is the solution of the adjoint problem (1.4), with initial data $(\hat{\phi}^0, \hat{\phi}^1) \in H_0^1(0,1) \times L^2(0,1)$, the unique minimizer of the functional

$$J\left(\phi^0, \phi^1\right) = \frac{1}{2}\int_0^T \mid \partial_x \phi(1,t) \mid^2 dt - \int_0^1 u^0\phi^1 - < u^1, \phi^0 >_{-1,1} \tag{5.43}$$

in the energy space $H_0^1(0,1) \times L^2(0,1)$. By taking limits in (5.29) and thanks to the construction of the initial data to be controlled for the discrete system, we obtain

$$0 = \int_0^1 \left[u^1(x)\phi^0(x) - u^0(x)\phi^1(x)dx\right] + \int_0^T v(t)\partial_x\phi(1,t)dt, \tag{5.44}$$

and this latter condition is equivalent to the fact that v, the limit in (5.41), is a control for system (1.1), driving the initial data (u^0, u^1) to rest , i.e., $v \in L^2(0,T)$ is the control of minimal L^2-norm.

The limit v being identified in a unique way, we deduce that the whole sequence v_h converges.

Moreover, by the hypotheses of Theorem 5.8, the linear term of the discrete functional J_h in (5.23) converges to the linear term of the functional defined in (5.43). Therefore, proving (5.39) is equivalent to proving that

$$J_h\left(\hat{\phi}_h^0, \hat{\phi}_h^1\right) \to J\left(\hat{\phi}^0, \hat{\phi}^1\right) \text{ as } h \to 0,$$

where $(\hat{\phi}_h^0, \hat{\phi}_h^1) \in \mathcal{F}_h$ minimizes (5.23) and $(\hat{\phi}^0, \hat{\phi}^1) \in H_0^1(0,1) \times L^2(0,1)$ minimizes (5.43). Indeed, taking into account the convergence of the linear terms in this functional and the structure of the functionals (5.23) and (5.43), we deduce the convergence of the norms of the controls that, together with the weak convergence, ensure strong convergence.

Thus, the controls v_h and the controlled discrete solutions u_h converge to the control and the controlled solution of the wave equation (1.1). It is important to note that the projections of the solutions of the controlled system end up covering the whole range of frequencies so that, in the limit, we recover the exact controllability property (1.3) of the continuous wave equation. The details of the several steps of the proof are given in [9], and it is similar to the proof of the convergence of the solution of the semidiscrete $1-d$ beam equation (see [7] for more details), and we omit them for brevity. □

Remark 5.9. Equation (5.32) implies that a subsequence of (v_h) can be chosen so that it is weak-convergent to a function $v \in L^2(0,T)$. By taking limits in (5.29) and thanks to the convergence assumptions of the initial data, we obtain

$$0 = \int_0^1 \left[u^1(x)\phi^0(x) - u^0(x)\phi^1(x)dx\right] + \int_0^T v(t)\partial_x\phi(1,t)dt, \tag{5.45}$$

and this condition is equivalent to the fact that v is control for the system (1.1) driving initial data (u^0, u^1) to rest. One can also show by a Γ-convergence argument that v is in fact the HUM control.

Remark 5.10. Similar results can be obtained for the finite-difference semidiscretization of the $1-d$ wave equation (see [9, 10], [17]).

The numerical efficiency of the multigrid algorithm which illustrate our theoretical results was proved in [2] and in [8] by various numerical experiments in the multidimensional and one-dimensional cases, respectively.

Acknowledgment. The author would like to thank Enrique Zuazua for fruitful discussions and his help in making this work possible.

SOLVING ELLIPTIC FINITE ELEMENT SYSTEMS IN NEAR-LINEAR TIME WITH SUPPORT PRECONDITIONERS*

ERIK G. BOMAN†, BRUCE HENDRICKSON‡, AND STEPHEN VAVASIS§

Abstract. We consider linear systems arising from the use of the finite element method for solving scalar linear elliptic problems. Our main result is that these linear systems, which are symmetric and positive semidefinite, are well approximated by symmetric diagonally dominant matrices. Our framework for defining matrix approximation is support theory. Significant graph theoretic work has already been developed in the support framework for preconditioners in the diagonally dominant case, and, in particular, it is known that such systems can be solved with iterative methods in nearly linear time. Thus, our approximation result implies that these graph theoretic techniques can also solve a class of finite element problems in nearly linear time. We show that the support number bounds, which control the number of iterations in the preconditioned iterative solver, depend on mesh quality measures but not on the problem size or shape of the domain.

Key words. finite elements, preconditioning, matrix algorithm, support graph, diagonal dominance

1. Introduction.

Finite element discretizations of elliptic partial differential equations (PDEs) give rise to large sparse linear systems of equations. A topic of great interest is preconditioners for the iterative solution of such systems. We focus on scalar boundary value problems of the form $\nabla \cdot (\theta \nabla u) = -f$, in which θ is a scalar conductivity field. See (3.1) below for a more detailed statement of the PDE under consideration. Such PDEs arise in a variety of physical applications listed in section 3. We prove that the stiffness matrix K of this PDE, which is defined precisely by (3.7) below, can be well approximated by a diagonally dominant matrix $\bar{K}$. "Well approximated" means that $\kappa(\bar{K}, K)$ has an upper bound in terms of mesh quality measures only; the notation $\kappa(\cdot, \cdot)$ is defined below. Since significant theory has been developed for diagonally dominant matrices, our result shows that the same theory extends to this class of stiffness matrices. In particular, our approximation result means that the system $K\mathbf{x} = \mathbf{f}$ arising from the finite element method (FEM) can be

solved in nearly linear time by preconditioned iterative methods.

Our analysis uses the *support theory* framework described in [5] for analyzing condition numbers and (generalized) eigenvalues for preconditioned systems. Our analysis is as follows. In sections 5–7, we state and prove our theorem that K may be factored as $K = A^T \bar{D}^{1/2} H \bar{D}^{1/2} A$. A preliminary general-purpose result in section 2 shows that a matrix of this form can be approximated by $\bar{K} = A^T \bar{D} A$ (a diagonally dominant matrix), with the quality of approximation depending on $\kappa(H)$. The analysis of $\kappa(H)$ in section 7 establishes that this quantity depends on the space dimension d and degree p of the FEM, the quadrature rule, and various mesh quality measures but does not depend on the number of nodes or elements or on the shape of the domain or the size of elements. It also does not depend on the conductivity field θ under certain assumptions to be made below.

The idea of approximating FEM systems by diagonally dominant matrices is not new; see, for example, Gustafsson [13]. In fact, our approach is similar to Gustafsson's in that we approximate each element matrix by a diagonally dominant matrix. In contrast to [13], we are able to rigorously prove bounds on the spectral properties of our approximation (and thus also the preconditioner).

An approach in [3, section 7.3] proposes to precondition general FEM problems with a diagonally dominant preconditioner obtained by using a lower-order method. Again, our result is a departure from theirs because we get precise and rigorous bounds on the quality of the approximation.

In section 10, we specialize the theory to four common cases of the finite element method and report on computational tests for these cases. The computational tests are intended to illustrate the size of the constants in our main theorem and do not measure the practical performance of our solution strategy versus competitors. See further remarks on the practical efficiency of our preconditioning approach in section 9.

2. Support theory. Let A, B be symmetric positive semidefinite matrices of the same size, and let $N(A)$ and $N(B)$ denote their null spaces. We define the *support number* of A with respect to B to be

$$\sigma(A,B) = \sup_{\mathbf{x} \in \mathbb{R}^n - N(B)} \frac{\mathbf{x}^T A \mathbf{x}}{\mathbf{x}^T B \mathbf{x}}. \tag{2.1}$$

Note that this quantity is finite only if $N(B) \subset N(A)$. We follow the convention established in the previous literature of using $\sigma(\cdot,\cdot)$ to denote support numbers. Unfortunately, σ is also commonly used to denote singular values. In this paper, σ with one argument is a singular value, and σ with two arguments is a support number.

The results in this section can be partially generalized to indefinite symmetric matrices. This generalization requires a more general definition of a support number than (2.1) and requires the use of the symmetric product support theorem from [5]. Since this paper focuses on the positive semidefinite case, we omit this generalization.

If A and B are symmetric positive definite (SPD), then $\sigma(A,B) = \lambda_{\max}(A,B)$, the largest generalized eigenvalue. When B is a preconditioner for A in the preconditioned conjugate gradient iterative method [10], the condition number of the preconditioned system is given by $\sigma(A,B)\sigma(B,A)$, which we denote as $\kappa(A,B)$. When A, B are SPD, then $\kappa(A,B) = \kappa(B^{-1}A)$, where κ denotes the standard spectral condition number.

A principal goal of this paper is to propose the construction of a symmetric diagonally dominant matrix $\bar{K}$ that approximates the finite element stiffness matrix K in the sense that $\kappa(K,\bar{K})$ is not too large. The following two lemmas and subsequent theorem define our framework for defining $\bar{K}$ and bounding $\kappa(K,\bar{K})$.

LEMMA 2.1. *Suppose $V \in \mathbb{R}^{n\times p}$, and suppose $H \in \mathbb{R}^{p\times p}$ is SPD. Then*

$$\sigma(VHV^T, VV^T) \le \lambda_{\max}(H),$$

where $\lambda_{\max}$ denotes the largest eigenvalue.

Proof.

$$\begin{aligned}\sigma(VHV^T, VV^T) &= \sup_{\mathbf{x}\in\mathbb{R}^n - N(V^T)} \frac{\mathbf{x}^T VHV^T\mathbf{x}}{\mathbf{x}^T VV^T\mathbf{x}} \\ &= \sup_{\mathbf{y}\in R(V^T)} \frac{\mathbf{y}^T H\mathbf{y}}{\mathbf{y}^T\mathbf{y}} \\ &\le \lambda_{\max}(H).\end{aligned}$$

The second line follows from the first by substituting $\mathbf{y} = V^T\mathbf{x}$ and the third from the Courant–Fischer minimax theorem [10, section 8.1.1]. Here, $R(V^T)$ denotes the range space of V^T. ∎

LEMMA 2.2. *Suppose $V \in \mathbb{R}^{n\times p}$, and suppose $H \in \mathbb{R}^{p\times p}$ is SPD. Then*

$$\sigma(VV^T, VHV^T) \le 1/\lambda_{\min}(H),$$

where $\lambda_{\min}$ denotes the smallest eigenvalue.

Proof. Using the same idea in the previous proof leads to a supremum over the Rayleigh quotient $\mathbf{y}^T\mathbf{y}/(\mathbf{y}^T H\mathbf{y})$, which is bounded above by $1/\lambda_{\min}(H)$. ∎

Combining these two lemmas yields a result for the condition number.

THEOREM 2.3. *Suppose $V \in \mathbb{R}^{n\times p}$, and suppose $H \in \mathbb{R}^{p\times p}$ is SPD. Then*

$$\kappa(VHV^T, VV^T) \le \kappa(H).$$

Proof. The result follows from Lemma 2.1 and 2.2 and by using the fact $\kappa(H) = \lambda_{\max}(H)/\lambda_{\min}(H)$ when H is SPD. ∎

The way we will apply this theorem is to let $V = A^T\bar{D}^{1/2}$, where A is the node-arc incidence matrix of a graph and $\bar{D}$ is a diagonal weight matrix. Then $\bar{K} = VV^T = A^T\bar{D}A$ is diagonally dominant, while $K = VHV^T = A^T\bar{D}^{1/2}H\bar{D}^{1/2}A$ is not (in general). Therefore, we now have a tool to approximate more general positive definite matrices.

3. Finite element analysis. In this section we provide a brief summary of isoparametric finite element approximation as well as an introduction to notation that is crucial for our main theorem. The material in this section is standard [15] in textbooks, except that our description herein uses notation for indexing that is more detailed than usual. This section concludes with a summary of our notation.

The class of problems under consideration consists of finite element discretizations of the following second-order elliptic boundary value problem. Find $u : \Omega \to \mathbb{R}$ satisfying

$$\begin{aligned}\nabla\cdot(\theta\nabla u) &= -f \quad \text{on } \Omega, \\ u &= u_0 \quad \text{on } \Gamma_1, \\ \theta\partial u/\partial n &= g \quad \text{on } \Gamma_2.\end{aligned} \tag{3.1}$$

Here, Ω is a bounded open subset of $\mathbb{R}^d$ (typically $d = 2$ or $d = 3$), Γ_1 and Γ_2 form a partition of $\partial\Omega$, θ is a given scalar field on Ω that is positive-valued everywhere

and is sometimes called the *conductivity*, $f : \Omega \to \mathbb{R}$ is a given function called the *forcing function*, u_0 is a given function called the *Dirichlet boundary condition*, and g is another given function called the *Neumann boundary condition.*

This problem has applications to many problems in mathematical physics. For example, u can represent voltage in a conducting medium, in which case θ stands for electrical conductivity. The two types of boundary conditions stand for, respectively, a boundary point held at fixed voltage or a boundary point electrically insulated (or with prespecified nonzero current). Another application is thermodynamics, in which u stands for the temperature of the body, θ for thermal conductivity, Γ_1 for a boundary held at fixed temperature, and Γ_2 for a boundary insulated (or with prespecified heat flow). Problem (3.1) is also used to model membrane deflection and gravity. It arises as a subproblem in fluid flow modeling.

For clarity, we keep track of our assumptions by explicitly numbering them. One assumption has already been made.

ASSUMPTION 1. *For all* $x \in \Omega$, $\theta(x) > 0$.

Without this assumption, the problem may be ill-posed.

The first step in the isoparametric FEM is to produce a mesh of this domain. For the remainder of the paper, we assume isoparametric elements are defined with respect to the usual polynomial basis on a simplicial reference element, although the results can be generalized to other reference elements and basis families.

In more detail, let T_0 denote the standard unit d-simplex: for $d = 2$, this simplex is the triangle with vertices $(0,0)$, $(1,0)$, $(0,1)$, and for $d = 3$ this simplex is the tetrahedron with vertices $(0,0,0)$, $(1,0,0)$, $(0,1,0)$, $(0,0,1)$. Let p denote the polynomial order of the FEM. In the reference element, position an evenly spaced array of $l = (p+1)(p+2)/2$ *reference nodes* when $d = 2$ or of $l = (p+1)(p+2)(p+3)/6$ nodes when $d = 3$. These nodes have coordinates of the form $(i/p, j/p)$ (in two dimensions) or $(i/p, j/p, k/p)$ (in three dimensions), where i, j (and, in three dimensions, k) are nonnegative integers whose sum is at most p. Let these nodes be enumerated $z_1, \ldots, z_l$.

One generates a *mesh* of Ω composed of m elements to be defined via mapping functions. For each element $t = 1, \ldots, m$, there is a *mapping function* ϕ_t that maps T_0 to $\mathbb{R}^d$. Let $\nabla\phi_t$ denote the derivative (Jacobian) of ϕ_t. The following assumption is nearly universal in the literature.

ASSUMPTION 2. *Mapping function* $\phi_t : T_0 \to \mathbb{R}^d$ *is injective, and* $\det(\nabla\phi_t(z)) > 0$ *for all* $z \in T_0$, $t = 1, \ldots, m$.

The tth *element* is defined to be $\phi_t(T_0)$ and hence has a shape of a curved simplex. The function ϕ_t carries the l reference nodes $z_1, \ldots, z_l$ to l *real-space nodes* $\phi_t(z_1), \ldots, \phi_t(z_l)$, which are often just called *nodes*. These may be denoted $\zeta_{t,1}, \ldots, \zeta_{t,l}$. The nodes are chosen so that the nodes on the boundary of the tth element coincide with the corresponding nodes on the boundaries of its neighbors.

We restrict ϕ_t to be a polynomial of degree p, in which case it is uniquely determined by the positions of its real-space nodes. In more detail, let N_μ, $\mu = 1, \ldots, l$, be a real-valued degree-p polynomial function on T_0 with the property that

$$N_\mu(z_\nu) = \left\{ \begin{array}{ll} 1 & \text{if } \mu = \nu, \\ 0 & \text{if } \mu \neq \nu, \end{array} \right\} \text{ for all } \nu = 1, \ldots, l. \tag{3.2}$$

It is not hard to write down an explicit formula for N_μ and to prove that (3.2) uniquely determines N_μ among degree-p polynomials. These functions $N_1, \ldots, N_l$ are called *shape functions*. For each t, ϕ_t necessarily has the formula $\phi_t = \zeta_{t,1}N_1 + \cdots + \zeta_{t,l}N_l$.

There are many duplicate entries in the list $\zeta_{1,1}, \ldots, \zeta_{m,l}$ because of common nodes at the boundaries of the elements. Let $w_1, \ldots, w_{n'}$ be a listing of the real-space nodes with all duplicates removed. This renumbering is specified by an index mapping function, the *local-to-global* numbering map, denoted LG and carrying an index pair (t, μ) to an index $i \in 1, \ldots, n'$ so that $w_i \equiv \zeta_{t,\mu}$.

Finally, the *mesh* $\mathcal{T}$ is specified by listing the nodes $w_1, \ldots, w_{n'}$ and the local-global mapping defined by LG. From this data, one can deduce all of the ϕ_t's.

Let $\tilde{\Omega}$ be the union of the elements, which may be slightly different from Ω. This is because at the boundary of Ω, the elements may either protrude a bit outside Ω or may fail to cover a small part of the boundary. Let the boundary of $\tilde{\Omega}$ be partitioned into $\tilde{\Gamma}_1$ and $\tilde{\Gamma}_2$ in correspondence with the partition Γ_1, Γ_2 of the boundary of Ω. It is necessary to transfer θ (and several other fields) from Ω to $\tilde{\Omega}$ and to transfer the boundary conditions to $\tilde{\Gamma}_1$ and $\tilde{\Gamma}_2$. We omit the details.

The next step in the isoparametric FEM is to define *basis functions* $\pi_1, \ldots, \pi_{n'}$, which are functions from $\tilde{\Omega}$ to $\mathbb{R}$ satisfying

$$\pi_i(w_k) = \left\{ \begin{array}{ll} 1 & \text{if } i = k, \\ 0 & \text{if } i \neq k, \end{array} \right\} \text{for } k = 1, \ldots, n'. \tag{3.3}$$

We require that π_i, when restricted to an element t, must be of the form $N_\mu \circ \phi_t^{-1}$, where $LG(t, \mu) = i$, or else must be identically 0 if i does not occur among $LG(t, 1), \ldots, LG(t, l)$. This requirement uniquely determines the π_i's. It can be shown that π_i is continuous but fails to be differentiable at interelement boundaries.

Let the global numbering be chosen so that $w_1, \ldots, w_n$, the first n real-space nodes, are the nodes with no Dirichlet boundary condition imposed, and let the final $n' - n$ nodes have Dirichlet boundary conditions. Now we can define the *exact assembled stiffness matrix* K^{exact} of the FEM to be the $n \times n$ matrix whose (i, j) entry is given by

$$K^{\text{exact}}(i, j) = \int_{\tilde{\Omega}} \nabla \pi_i(x) \cdot \theta(x) \nabla \pi_j(x)\, dx, \tag{3.4}$$

where ∇, as usual, denotes the gradient.

Matrix K^{exact} is sparse, symmetric, and positive semidefinite. Symmetry is obvious; semidefiniteness follows from a fairly straightforward argument that we omit, and sparsity follows because $K^{\text{exact}}(i, j)$ is nonzero only if there is an element t that contains both nodes w_i and w_j.

Integral (3.4) is difficult to compute directly because evaluating π_i requires the evaluation of ϕ_t^{-1}. Fortunately, this difficulty is avoided by breaking the integral into a sum over elements, and then carrying out the integral over the reference domain following a change of variables as follows:

$$K^{\text{exact}}(i, j) = \sum_{t=1}^{m} \int_{T_0} \nabla_x \pi_i(\phi_t(z)) \cdot \theta(\phi_t(z)) \nabla_x \pi_j(\phi_t(z)) \det(\nabla \phi_t(z))\, dz, \tag{3.5}$$

where the notation ∇_x means derivative with respect to the coordinates of element t (as opposed to derivative with respect to z, the coordinates of T_0).

The integrand of (3.5) is evaluated using the chain rule for derivatives. Assume w_i is a node of element t (else the above integral is 0). Let μ be the index such that $LG(t, \mu) = i$, so that $\pi_i = N_\mu \circ \phi_t^{-1}$ on element t. Then

$$\begin{aligned} \nabla_x \pi_i(\phi_t(z)) &= \nabla_x N_\mu(z) \\ &= \nabla \phi_t(z)^{-T} \cdot \nabla_z N_\mu(z) \end{aligned} \tag{3.6}$$

and similarly for π_j. Here, $\nabla\phi_t(z)^{-T}$ denotes the transposed inverse of the $d\times d$ matrix $\nabla\phi_t(z)$, which exists by Assumption 2. The '$\cdot$' notation in the previous formula indicates matrix-vector multiplication. Gradients are regarded as length-d column vectors.

We assume that the entries of K are not the exact value of the integral (3.5) but are obtained by a quadrature rule that we now discuss. Let $r_1,\dots,r_q$ be points in the interior of the reference element T_0 called the *Gauss points*. (As is common practice, we use this terminology even if the quadrature rule is not derived from Gaussian quadrature.) Let $\omega_1,\dots,\omega_q$ be corresponding *Gauss weights*. We denote this quadrature rule, i.e., the set of ordered pairs $(r_1,\omega_1),\dots,(r_q,\omega_q)$, by the symbol $\mathcal{Q}$. Then in place of (3.5) we take

$$K(i,j)=\sum_{t=1}^{m}\sum_{k=1}^{q}\nabla_x\pi_i(\phi_t(r_k))\cdot\theta(\phi_t(r_k))\nabla_x\pi_j(\phi_t(r_k))\det(\nabla\phi_t(r_k))\omega_k, \tag{3.7}$$

in which $\nabla_x\pi_i(\phi_t(r_k))$ is evaluated by substituting $z=r_k$ into the right-hand side of (3.6) and similarly for $\nabla_x\pi_j(\phi_t(r_k))$. The symmetry and sparsity of K follow for the same reason as for K^{exact}; positive semidefiniteness will follow from results in the next two sections (under some additional assumptions to be made).

We close this section with a summary of the notation introduced thus far. Integers that define the size of the computation are as follows:

$$\begin{aligned}
d &= \text{the space dimension of (3.1)},\\
p &= \text{the polynomial order of the FEM},\\
l &= \text{the number of reference nodes} = \begin{cases}(p+1)(p+2)/2 & \text{if } d=2,\\ (p+1)(p+2)(p+3)/6 & \text{if } d=3,\end{cases}\\
m &= \text{the number of elements},\\
n &= \text{the number of non-Dirichlet real-space nodes},\\
n' &= \text{the total number of real-space nodes},\\
q &= \text{the number of Gauss points in the quadrature rule } \mathcal{Q}.
\end{aligned}$$

The sets of points in $\mathbb{R}^d$ include

$$\begin{aligned}
z_1,\dots,z_l &= \text{reference nodes},\\
\zeta_{1,1},\dots,\zeta_{m,l} &= \text{real-space nodes (local numbering)},\\
w_1,\dots,w_{n'} &= \text{real-space nodes (global numbering)}.
\end{aligned}$$

The quadrature rule $\mathcal{Q}$ is defined by

$$\begin{aligned}
r_1,\dots,r_q &= \text{Gauss points},\\
\omega_1,\dots,\omega_q &= \text{Gauss weights}.
\end{aligned}$$

Important domains are

$$\begin{aligned}
T_0 &= \text{the reference element},\\
\Omega &= \text{the domain of (3.1)},\\
\phi_1(T_0),\dots,\phi_m(T_0) &= \text{the elements},\\
\tilde{\Omega} &= \text{the approximation to } \Omega \text{ given by } \phi_1(T_0)\cup\cdots\cup\phi_m(T_0).
\end{aligned}$$

Important functions are

$$\begin{aligned}
\phi_1, \ldots, \phi_m &= \text{element mapping functions } (T_0 \to \tilde{\Omega}),\\
N_1, \ldots, N_l &= \text{shape functions } (T_0 \to \mathbb{R}),\\
\theta &= \text{conductivity } (\tilde{\Omega} \to \mathbb{R}),\\
LG &= \text{local-to-global index mapping } \{1, \ldots, m\} \times \{1, \ldots, l\} \to \{1, \ldots, n'\},\\
\pi_1, \ldots, \pi_{n'} &= \text{basis functions } (\tilde{\Omega} \to \mathbb{R}).
\end{aligned}$$

Finally, scalar quantities to be introduced in the next section, but which are included here for completeness, include

$$\begin{aligned}
m_{\mathcal{Q}}, M_{\mathcal{Q}} &= \text{min and max quadrature weights},\\
\hat{\theta}(\mathcal{T}) &= \text{intraelement conductivity variation},\\
\alpha_1, \ldots, \alpha_m &= \text{maximum compression in elements},\\
\beta_1, \ldots, \beta_m &= \text{maximum stretch in elements},\\
\kappa_1(\mathcal{T}), \kappa_2(\mathcal{T}) &= \text{mesh quality measures},\\
\sigma_{\mathcal{Q},p}, \tau_{\mathcal{Q},p} &= \text{the max and min singular values of } S_{\mathcal{Q},p}.
\end{aligned}$$

This section presented in detail the construction of the finite element stiffness matrix K, but it omitted the construction of $\mathbf{f}$, the right-hand side of the linear system $K\mathbf{x} = \mathbf{f}$ under consideration. The construction of $\mathbf{f}$ is not relevant to the main result of this paper, but for the sake of completeness, we give a very brief overview and refer the reader to [15] for the details. The steps involved in obtaining a formula for the ith entry $\mathbf{f}$ are as follows. Multiply the PDE on both sides by π_i, integrate over Ω, and apply integration by parts. Applying integration by parts causes a boundary term involving Neumann data g to enter the equation. Write u as a linear combination of π_j's for $j = 1, \ldots, n'$. The coefficients of this linear combination are the entries of $\mathbf{x}$ for $j = 1, \ldots, n$ and are known from the Dirichlet boundary condition for $j = n+1, \ldots, n'$. Finally, gather terms not involving entries of $\mathbf{x}$ together on the right-hand side and apply quadrature rules to obtain the ith entry of $\mathbf{f}$. Once the linear system $K\mathbf{x} = \mathbf{f}$ is solved, the approximation of the unknown function u of (3.1) is recovered as a linear combination of the π_j's using the entries of $\mathbf{x}$ and the Dirichlet conditions as coefficients.

4. Condition numbers and assumptions. Our main theorem about matrix approximation, which is Theorem 5.1 below, depends on several scalars associated with the FEM and the problem at hand that we define in this section. In addition, this section states further assumptions about the problem and method.

Two constants appearing in our bound are $m_{\mathcal{Q}}$ and $M_{\mathcal{Q}}$, which we define to be the minimum and maximum weights in the quadrature rule, respectively, i.e.,

$$m_{\mathcal{Q}} = \min(\omega_1, \ldots \omega_q);\ M_{\mathcal{Q}} = \max(\omega_1, \ldots, \omega_q). \tag{4.1}$$

Assumption 3. *The quadrature weights are positive, i.e., $m_{\mathcal{Q}} > 0$.*

There is some loss of generality with this assumption because a few popular finite element quadrature schemes (but certainly not all) use negative weights [8].

Assumption 4. *The quadrature scheme is exact for all polynomials of degree up to $2p-2$, i.e., if $\psi : T_0 \to \mathbb{R}$ is a polynomial of degree $2p-2$ or less in the d coordinates of T_0, then*

$$\sum_{k=1}^{q} \psi(r_k)\omega_k = \int_{T_0} \psi(z)\, dz.$$

This assumption is quite reasonable, since it is usually required anyway for an accurate solution by finite element analysis: one wants accurate quadrature of $\nabla\pi_i \cdot \nabla\pi_j$.

We now define a $dq \times (l-1)$ matrix $S_{\mathcal{Q},p}$ according to the following formula:

$$S_{\mathcal{Q},p} = \begin{pmatrix} \nabla N_2(r_1) & \nabla N_3(r_1) & \cdots & \nabla N_l(r_1) \\ \vdots & & & \vdots \\ \nabla N_2(r_q) & \nabla N_3(r_q) & \cdots & \nabla N_l(r_q) \end{pmatrix}. \tag{4.2}$$

Although we introduce this matrix in this section in order to define two associated scalars, the motivation for this definition will be postponed until section 6. Before defining these scalars, we require the following lemma.

LEMMA 4.1. *Under Assumption* 4, *matrix* $S_{\mathcal{Q},p}$ *has full column rank.*

Proof. Let $v \in \mathbb{R}^{l-1}$ be chosen so that $S_{\mathcal{Q},p}v = \mathbf{0}$. Define the function $U : \mathcal{T}_0 \to \mathbb{R}$ according to the formula $U = v_1N_2 + v_2N_3 + \cdots + v_{l-1}N_l$. Observe that, by the definition of $S_{\mathcal{Q},p}$, the first d entries of $S_{\mathcal{Q},p}v$ are precisely $\nabla U(r_1)$, and the next d entries are $\nabla U(r_2)$, etc. Therefore, ∇U vanishes identically at $r_1, \ldots, r_q$. Let $\psi : T_0 \to \mathbb{R}$ be defined by $\psi = \nabla U \cdot \nabla U$. Then ψ has degree at most $2p-2$, is a nonnegative function, and also vanishes identically at $r_1, \ldots, r_q$. By Assumption 4, this means that $\int_{T_0} \psi = 0$. But since ψ is nonnegative-valued, we conclude that $\psi \equiv 0$. Therefore, $\nabla U \equiv 0$ also, and thus U must be a constant function on T_0. But the definition of U omits the N_1 term, and therefore $U(z_1) = 0$. Since U is constant, this means that $U \equiv 0$ on all of T_0, and in particular, $U(z_2) = \cdots = U(z_l) = 0$. But $U(z_2) = v_1$, $U(z_3) = v_2, \ldots, U(z_l) = v_{l-1}$ by the construction of U. Therefore, the entries of v are all zeros. Since v was an arbitrary vector in $N(S_{\mathcal{Q},p})$, this argument proves that this nullspace contains only the $\mathbf{0}$ vector, hence $S_{\mathcal{Q},p}$ has full column rank. ∎

The next constants that appear in our theorem are $\sigma_{\mathcal{Q},p}$ and $\tau_{\mathcal{Q},p}$, defined as follows:

$$\sigma_{\mathcal{Q},p} = \sigma_{\max}(S_{\mathcal{Q},p});\ \tau_{\mathcal{Q},p} = \sigma_{\min}(S_{\mathcal{Q},p}). \tag{4.3}$$

These constants depend only on p and the quadrature scheme. It follows from the lemma that both are positive.

The remaining scalars and assumptions in this section pertain to the mesh. Define for $t = 1, \ldots, m$,

$$\alpha_t = \max\{\|\nabla\phi_t(r_1)^{-1}\|, \ldots, \|\nabla\phi_t(r_q)^{-1}\|\}, \tag{4.4}$$

$$\beta_t = \max\{\|\nabla\phi_t(r_1)\|, \ldots, \|\nabla\phi_t(r_q)\|\}. \tag{4.5}$$

The norms in these equations are matrix 2-norms: $\|B\| \equiv \sigma_{\max}(B)$. Finally, for the whole mesh, a quality measure is

$$\kappa_1(\mathcal{T}) = \max_{t=1,\ldots,m} \alpha_t\beta_t. \tag{4.6}$$

Although the α's and β's are subscripted only by t, it is clear from the definition that they also depend on $\mathcal{Q}$. On the other hand, it is possible to get a $\mathcal{Q}$-independent definition of these by simply taking the upper bounds similar to (4.4), (4.5) over all $z \in T_0$ instead of just $r_1, \ldots, r_q$. Unfortunately, for higher-order elements ($p > 1$), there is no simple method to compute $\max_{z\in T_0} \|\nabla\phi_t(z)^{-1}\|$; a technique for obtaining an upper bound appears in [21].

It should be noted that $\kappa_1(\mathcal{T}) \geq 1$, since for any z, $\|\nabla\phi_t(z)^{-1}\| \cdot \|\nabla\phi_t(z)\| \geq 1$. If all of the elements are well shaped, i.e., not too distorted when compared to the reference element, then $\kappa_1(\mathcal{T})$ will not be much larger than 1.

The second mesh quality measure is

$$\kappa_2(\mathcal{T}) = \max_{t=1,\ldots,m} \frac{\max_{k=1,\ldots,q} \det(\nabla \phi_t(r_k))}{\min_{k=1,\ldots,q} \det(\nabla \phi_t(r_k))}. \tag{4.7}$$

This quantity measures the maximum over elements of the variation in volumetric distortion over the element. This may be regarded as a measure of how much elements depart from linearity (flatness). Measure κ_2 is not completely independent from κ_1 as the following argument shows. It follows from Hadamard's inequality that

$$\alpha_t^{-d} \leq \det(\nabla \phi_t(r_k)) \leq \beta_t^d,$$

and therefore

$$\frac{\max_{k=1,\ldots,q} \det(\nabla \phi_t(r_k))}{\min_{k=1,\ldots,q} \det(\nabla \phi_t(r_k))} \leq (\alpha_t \beta_t)^d,$$

hence $\kappa_2(\mathcal{T}) \leq \kappa_1(\mathcal{T})^d$. This bound is not likely to be tight in practice (see our computation results in Table 10.3), so we prefer to distinguish the roles of κ_1 and κ_2.

The final two assumptions are qualitative in nature and are meant to indicate cases in which our method is expected to work well. The violation of these assumptions does not invalidate our theorem but merely indicates that our bound on $\kappa(K, \bar{K})$ may grow large.

ASSUMPTION 5. *Mesh quality measures $\kappa_1(\mathcal{T}), \kappa_2(\mathcal{T})$ are not too large.*

In the case of linear elements ($p = 1$), $\kappa_1(\mathcal{T})$ is proportional to the reciprocal of the minimum angle (in two dimensions) or the solid angle (in three dimensions) of the mesh, and $\kappa_2(\mathcal{T}) \equiv 1$.

Assumption 5 does not imply that the elements are of a uniform size: A uniform rescaling of element t does not affect the product $\alpha_t \beta_t$.

The final constant and assumption pertain to the conductivity field. Define

$$\hat{\theta}(\mathcal{T}) = \max_{t=1,\ldots,m} \frac{\max_{k=1,\ldots,q} \theta(\phi_t(r_k))}{\min_{k=1,\ldots,q} \theta(\phi_t(r_k))}. \tag{4.8}$$

In other words, $\hat{\theta}(\mathcal{T})$ measures the maximum intraelement variation of the conductivity field θ.

ASSUMPTION 6. *Intraelement conductivity variation $\hat{\theta}(\mathcal{T})$ is not too large.*

This assumption implies that if there are huge jumps in θ in the domain (e.g., because one is modeling a domain composed of two materials with vastly different conductivities), then the mesh boundaries should be aligned with the conductivity jumps. If the mesh boundaries are aligned with the conductivity jumps, then no element will have large variation in θ among its Gauss points, and thus $\hat{\theta}(\mathcal{T})$ will not be large.

Note that, as in the case of $\kappa_1(\mathcal{T})$ and $\kappa_2(\mathcal{T})$, scalar $\hat{\theta}(\mathcal{T})$ also depends on the quadrature rule, but this dependence can be eliminated by overestimating $\hat{\theta}(\mathcal{T})$ as

$$\max_{t=1,\ldots,m} \frac{\max_{z \in T_0} \theta(\phi_t(z))}{\min_{z \in T_0} \theta(\phi_t(z))}.$$

5. The matrix approximation. Our main matrix factorization result is summarized by the following theorem whose proof is explained in upcoming sections.

THEOREM 5.1. *Let K be defined by* (3.7) *above, and let Assumptions* 1–4 *hold. Then K may be factored as $A^T J^T D J A$, where*

- *A is an $(l-1)m \times n$ reduced node-arc incidence matrix of a certain multigraph,*
- *J is a $dqm \times (l-1)m$ matrix that is well conditioned in the sense that*

$$\sigma_{\max}(J) \leq \sigma_{\mathcal{Q},p}, \tag{5.1}$$

and

$$\sigma_{\min}(J) \geq \tau_{\mathcal{Q},p}/\kappa_1(\mathcal{T}). \tag{5.2}$$

- *D is a $dqm \times dqm$ positive definite diagonal matrix.*

Further, $J^T D J$ may be refactored as $\bar{D}^{1/2} H \bar{D}^{1/2}$, where $\bar{D}$ is a $(l-1)m \times (l-1)m$ SPD diagonal matrix and H is a $(l-1)m \times (l-1)m$ SPD matrix whose condition number is bounded as follows:

$$\kappa(H) \leq \hat{\theta}(\mathcal{T})\kappa_1(\mathcal{T})^2\kappa_2(\mathcal{T}) \cdot \frac{M_{\mathcal{Q}}\sigma_{\mathcal{Q},p}^2}{m_{\mathcal{Q}}\tau_{\mathcal{Q},p}^2}. \tag{5.3}$$

This theorem can now be combined with Theorem 2.3 to obtain a good approximation $\bar{K}$ to the stiffness matrix K. In particular, we take $\bar{K} = A^T \bar{D} A$. Note that this matrix, being a weighted graph Laplacian, is symmetric and diagonally dominant. Then in the context of Theorem 2.3, $V = A^T \bar{D}^{1/2}$. The theorem thus implies that the condition number of $\bar{K}$ with respect to K depends only on the condition number of H for which we have a good bound (5.3). Then $\bar{K}$ can be preconditioned using techniques in the previous literature. The complete description of the algorithm is given below in section 8.

The approximation bound clearly depends on the quadrature rule, mesh quality, and the intraelement variation of θ. It is also informative to make a list of quantities on which $\kappa(\bar{K}, K)$ does *not* depend:

- The number of nodes or elements,
- The size of the elements,
- Variation in the size of elements (i.e., the gradation of the mesh),
- The shape of Ω,
- The conductivity field θ (provided that the mesh respects internal boundaries where large conductivity jumps occur).

Although the shape of Ω does not directly affect $\kappa(\bar{K}, K)$, naturally, it affects the mesh generation procedure, which in turn affects mesh quality. A particular case that requires further consideration is when Ω has a sharp corner; a sharp corner of Ω forces the mesh to contain at least one element with a sharp corner, thus causing $\kappa_1(\mathcal{T})$ to be large. Even in this case, however, it may be possible to obtain an upper bound on $\kappa(\bar{K}, K)$ independent of this sharp angle using the analysis of Phillips and Miller (see section 9).

6. The first factorization. In this section we develop the first factorization of K stated in Theorem 5.1. This factorization is related to one proposed in [22]. We state the main result of this section as a lemma.

LEMMA 6.1. *Matrix K defined by* (3.7) *can be factored as $K = A^T S^T R^T D R S A$, where the factors are as follows.*

- *Define matrix $A \in \mathbb{R}^{(l-1)m \times n}$ to be a sparse matrix all of whose entries are -1, 0, or 1. In more detail, A is written in block form*

$$A = \begin{pmatrix} A_1 \\ \vdots \\ A_m \end{pmatrix},$$

where A_t is $(l-1) \times n$ for each element $t = 1, \ldots, m$. The columns are indexed $1, \ldots, n$ in correspondence with nodes $w_1, \ldots, w_n$. Row $\mu - 1$ of A_t has a "1" in column $LG(t, \mu)$ for $\mu = 2, \ldots, l$ and a "-1" in column $LG(t, 1)$. Thus, most rows of A have exactly two nonzero entries. If $LG(t, \mu) > n$ (i.e., node $\zeta_{t,\mu}$ lies in the Dirichlet boundary $\tilde{\Gamma}_1$), then the "1" entry is omitted. Similarly, if $LG(t, 1) > n$, then the "-1" entry is omitted. For this reason, a few rows of A have just one nonzero entry or none at all.

- *Define $S \in \mathbb{R}^{dqm \times (l-1)m}$ by*

$$S = \left(\begin{array}{ccc} S_{\mathcal{Q},p} & & \\ & \ddots & \\ & & S_{\mathcal{Q},p} \end{array} \right) \Bigg\} m \text{ times}, \tag{6.1}$$

where $S_{\mathcal{Q},p}$ was defined by (4.2).

- *Define block diagonal $R \in \mathbb{R}^{dqm \times dqm}$ by*

$$R = \left(\begin{array}{ccc} R_1 & & \\ & \ddots & \\ & & R_m \end{array} \right), \tag{6.2}$$

where each of $R_1, \ldots, R_m \in \mathbb{R}^{qd \times qd}$ is itself block diagonal and given by

$$R_t = \alpha_t^{-1} \left(\begin{array}{ccc} \nabla \phi_t(r_1)^{-T} & & \\ & \ddots & \\ & & \nabla \phi_t(r_q)^{-T} \end{array} \right). \tag{6.3}$$

The scalar α_t used here was defined by (4.4).

- *Finally, $D \in \mathbb{R}^{qdm \times qdm}$ is positive definite diagonal and given by*

$$D = \left(\begin{array}{ccc} D_1 & & \\ & \ddots & \\ & & D_m \end{array} \right), \tag{6.4}$$

where $D_t \in \mathbb{R}^{qd \times qd}$, $t = 1, \ldots, m$, is given by

$$D_t = \alpha_t^2 \left(\begin{array}{ccc} \theta(\phi_t(r_1)) \det(\nabla \phi_t(r_1)) \omega_1 I & & \\ & \ddots & \\ & & \theta(\phi_t(r_q)) \det(\nabla \phi_t(r_q)) \omega_q I \end{array} \right), \tag{6.5}$$

in which I denotes the $d \times d$ identity matrix.

Remarks. Intuitively, this factorization of K decomposes finite element analysis into natural ingredients: A encodes the combinatorial connectivity of the mesh, R encodes the geometry of the mesh, S encodes the quadrature points, and D encodes the quadrature weights and conductivity. The scaling factor α_t, which is necessary for our analysis, cancels out between D_t and R_t.

Note that the positive definiteness of D follows from Assumptions 1, 2, and 3. Note also that A is a reduced node-arc incidence matrix of a multigraph defined on the nodes of $\mathcal{T}$. (*Multi*graph indicates that more than one edge may connect a particular pair of vertices.) Each element gives rise to $l - 1$ arcs in the graph. In particular, for

each element $t = 1, \ldots, m$, there is an arc joining each of its nodes $2, \ldots, l$ to node 1. Columns corresponding to nodes of $\tilde{\Gamma}_1$ are omitted. (This is what is meant by "reduced.")

Proof. Let $\boldsymbol{\xi}$ be an arbitary vector in $\mathbb{R}^n$, and let $u : \tilde{\Omega} \to \mathbb{R}$ be defined by

$$u = \sum_{i=1}^{n} \xi_i \pi_i.$$

For an element t, define function $U_t : T_0 \to \mathbb{R}$ by

$$U_t = \sum_{\mu=1}^{l} \xi_{LG(t,\mu)} N_\mu. \tag{6.6}$$

With these definitions, it is clear that $u \circ \phi_t = U_t$. In (6.6), we follow the convention that $\xi_i \equiv 0$ in the case that $i \in \{n+1, \ldots, n'\}$.

The assembled stiffness matrix is defined by (3.7) so that

$$\begin{aligned}
\boldsymbol{\xi}^T K \boldsymbol{\xi} &= \sum_{i=1}^{n}\sum_{j=1}^{n} \xi_i \xi_j K(i,j) \\
&= \sum_{i=1}^{n}\sum_{j=1}^{n} \xi_i \xi_j \sum_{t=1}^{m}\sum_{k=1}^{q} \nabla_x \pi_i(\phi_t(r_k)) \cdot \theta(\phi_t(r_k)) \nabla_x \pi_j(\phi_t(r_k)) \det(\nabla \phi_t(r_k)) \omega_k \\
&= \sum_{t=1}^{m}\sum_{k=1}^{q}\sum_{i=1}^{n} \xi_i \nabla_x \pi_i(\phi_t(r_k)) \cdot \theta(\phi_t(r_k)) \sum_{j=1}^{n} \xi_j \nabla_x \pi_j(\phi_t(r_k)) \det(\nabla \phi_t(r_k)) \omega_k \\
&= \sum_{t=1}^{m}\sum_{k=1}^{q} \nabla_x u(\phi_t(r_k)) \cdot \theta(\phi_t(r_k)) \nabla_x u(\phi_t(r_k)) \det(\nabla \phi_t(r_k)) \omega_k \\
&= \sum_{t=1}^{m}\sum_{k=1}^{q} \nabla_x U_t(r_k) \cdot \theta(\phi_t(r_k)) \nabla_x U_t(r_k) \det(\nabla \phi_t(r_k)) \omega_k \\
&= \sum_{t=1}^{m}\sum_{i=1}^{q} (\nabla \phi_t(r_k)^{-T} \nabla_z U_t(r_k)) \cdot \theta(\phi_t(r_k)) \\
&\qquad (\nabla \phi_t(r_k)^{-T} \nabla_z U_t(r_k)) \det(\nabla \phi_t(r_k)) \omega_k \qquad (6.7) \\
&= \mathbf{v}^T D \mathbf{v}. \qquad (6.8)
\end{aligned}$$

In (6.8), we have used the matrix D defined by (6.4). We have also introduced the vector $\mathbf{v} \in \mathbb{R}^{dqm}$ defined in block fashion as follows. Write $\mathbf{v} = [v_1; \cdots; v_m]$, where $v_t \in \mathbb{R}^{dq}$ is itself composed of blocks $v_t = [v_{t,1}; \cdots; v_{t,q}]$. Here $v_{t,k} \in \mathbb{R}^d$ is defined to be

$$v_{t,k} = (\nabla \phi_t(r_k))^{-T} \nabla_z U_t(r_k) / \alpha_t. \tag{6.9}$$

It is clear by the construction of D and $\mathbf{v}$ that $\mathbf{v}^T D \mathbf{v}$ is equal to the expression in (6.7).

Next, we claim that $\mathbf{v} = RSA\boldsymbol{\xi}$. Focus on the block corresponding to a particular element $t \in \{1, \ldots, m\}$, in which case we must show that $v_t = R_t S_{\mathcal{Q},p} A_t \boldsymbol{\xi}$. The product $A_t \boldsymbol{\xi}$ yields a vector with $(l-1)$ entries that contains finite differences of the entries of $\boldsymbol{\xi}$. Specifically, the $\mu - 1$ entry is $\xi_{LG(t,\mu)} - \xi_{LG(t,1)}$ for $\mu = 2, \ldots, l$.

By the definition of $S_{\mathcal{Q},p}$ in (4.2), it follows that the k-block of entries ($k = 1, \ldots, q$) of $S_{\mathcal{Q},p} A_t \boldsymbol{\xi}$ is the d-vector $\nabla_z \bar{U}_t(r_k)$, where

$$\bar{U}_t = (\xi_{LG(t,2)} - \xi_{LG(t,1)})N_2 + \cdots + (\xi_{LG(t,l)} - \xi_{LG(t,1)})N_l.$$

Comparing this equation to (6.6) indicates that $\bar{U}_t$ and U_t differ by

$$\xi_{LG(t,1)}(N_1 + \cdots + N_l).$$

This latter quantity, however, is a constant function (because $N_1 + \cdots + N_l$ is identically 1, a property that follows from (3.2) and the fact that 1 is a polynomial of degree at most p and hence must be expressable as a sum of N_μ's). Therefore, U_t and $\bar{U}_t$ have the same gradient. We conclude that the k block of $S_{\mathcal{Q},p} A_t \boldsymbol{\xi}$ must equal $\nabla_z U_t(r_k)$.

Combining this equation with (6.3) shows that

$$R_t S_{\mathcal{Q},p} A_t \boldsymbol{\xi} = (\nabla \phi_t(r_k))^{-T} \nabla_z U_t(r_k)/\alpha_t$$

and hence is equal to $v_{t,k}$ as defined by (6.9). This concludes the proof that $\mathbf{v} = RSA\boldsymbol{\xi}$.

Since $\mathbf{v}^T D \mathbf{v} = \boldsymbol{\xi}^T K \boldsymbol{\xi}$, this means that $\boldsymbol{\xi}^T A^T S^T R^T D R S A \boldsymbol{\xi} = \boldsymbol{\xi}^T K \boldsymbol{\xi}$. Since this holds for all $\boldsymbol{\xi} \in \mathbb{R}^n$ and since a symmetric matrix C is uniquely determined by the mapping $\boldsymbol{\xi} \mapsto \boldsymbol{\xi}^T C \boldsymbol{\xi}$, this means that $K = A^T S^T R^T D R S A$, which concludes the proof of the lemma. ∎

Now we analyze the singular values of J to finish the first part of Theorem 5.1. Let us define $J = RS$ so that $K = A^T J^T D J A$ as claimed. The block structures of R and S induce a corresponding block structure on J:

$$J = \begin{pmatrix} J_1 & & \\ & \ddots & \\ & & J_m \end{pmatrix},$$

where

$$J_t = R_t S_{\mathcal{Q},p} \tag{6.10}$$

for all $t = 1, \ldots, m$. Because of this structure, the maximum singular value of J is the maximum singular value among any of its blocks and similarly for its minimum singular value. Since in general $\sigma_{\max}(AB) \le \sigma_{\max}(A)\sigma_{\max}(B)$,

$$\begin{aligned} \sigma_{\max}(J_t) &\le \sigma_{\max}(R_t)\sigma_{\max}(S_{\mathcal{Q},p}) \\ &= \sigma_{\max}(\operatorname{diag}(\nabla \phi_t(r_1)^{-T}, \ldots, \nabla \phi_t(r_q)^{-T}))\sigma_{\mathcal{Q},p}/\alpha_t \\ &= \max_{k=1,\ldots,q} \sigma_{\max}(\nabla \phi_t(r_k)^{-1})\sigma_{\mathcal{Q},p}/\alpha_t \\ &= \sigma_{\mathcal{Q},p}. \end{aligned} \tag{6.11}$$

The last line follows from (4.4) and establishes (5.1).

Since $\sigma_{\min}(AB) \ge \sigma_{\min}(A)\sigma_{\min}(B)$ for two matrices A, B with full column rank,

$$\begin{aligned} \sigma_{\min}(J_t) &\ge \sigma_{\min}(R_t)\sigma_{\min}(S_{\mathcal{Q},p}) \\ &= \sigma_{\min}(\operatorname{diag}(\nabla \phi_t(r_1)^{-T}, \ldots, \nabla \phi_t(r_q)^{-T}))\tau_{\mathcal{Q},p}/\alpha_t \\ &= \min_{k=1,\ldots,q} \sigma_{\min}(\nabla \phi_t(r_k)^{-1})\tau_{\mathcal{Q},p}/\alpha_t \\ &= \min_{k=1,\ldots,q} (1/\sigma_{\max}(\nabla \phi_t(r_k)))\tau_{\mathcal{Q},p}/\alpha_t \\ &= (1/\beta_t) \cdot \tau_{\mathcal{Q},p}/\alpha_t \\ &\ge \tau_{\mathcal{Q},p}/\kappa_1(\mathcal{T}). \end{aligned} \tag{6.12}$$

For the last line, we used the fact that $\alpha_t \beta_t \leq \kappa_1(\mathcal{T})$, which follows from (4.6). This establishes (5.2) and concludes the proof of the first factorization in Theorem 5.1.

Our factorization $K = A^T J^T D J A$ is reminiscent of one proposed by Argyris [1] of the form $K = \tilde{A} P \tilde{A}^T$, which he calls the "natural factorization." In Argyris's factorization, however, the matrix $\tilde{A}$ has all $+1$ and 0 entries and therefore is not a node-arc incidence matrix. The purpose of Argyris's matrix $\tilde{A}$ is to assemble the element stiffness matrices, which constitute the blocks of the block-diagonal matrix P.

7. The second factorization. In this section we prove the second part of Theorem 5.1. We state the existence of the second factorization in the form of a lemma.

LEMMA 7.1. *Let J and D be defined as in Lemma 6.1. Then $J^T D J$ can be refactored as $\bar{D}^{1/2} \bar{J}^T \bar{J} \bar{D}^{1/2}$, where*

- *Matrix $\bar{D} \in \mathbb{R}^{m(l-1) \times m(l-1)}$ is positive definite diagonal and is written in block form*

$$\bar{D} = m_{\mathcal{Q}} \begin{pmatrix} f_1 g_1 \alpha_1^2 I & & \\ & \ddots & \\ & & f_m g_m \alpha_m^2 I \end{pmatrix}, \tag{7.1}$$

where I is the $(l-1) \times (l-1)$ identity matrix. In this formula, f_t is the minimum value of θ over the Gauss points of element t:

$$f_t = \min_{k=1,\ldots,q} \theta(\phi_t(r_k)), \tag{7.2}$$

and similarly, g_t is the minimum value of $\det(\nabla \phi_t)$*:*

$$g_t = \min_{k=1,\ldots,q} \det(\nabla \phi_t(r_k)). \tag{7.3}$$

- *Matrix $\bar{J} \in \mathbb{R}^{dqm \times (l-1)m}$ is defined by*

$$\bar{J} = D^{1/2} J \bar{D}^{-1/2}. \tag{7.4}$$

Proof. The fact that $\bar{D}^{1/2} \bar{J}^T \bar{J} \bar{D}^{1/2} = J^T D J$ follows as an immediate consequence of (7.4) regardless of how we have defined $\bar{D}$. ∎

Next we analyze the condition number of H to finish proving the second part of Theorem 5.1. We define $H = \bar{J}^T \bar{J}$ so that $J^T D J = \bar{D}^{1/2} H \bar{D}^{1/2}$. We must estimate the singular values of $\bar{J}$, which are the square roots of the eigenvalues of H.

Let the diagonal block of $\bar{J}$ associated with element t be denoted $\bar{J}_t$ for $t = 1, \ldots, m$. Because of the block structure, the maximum and minimum singular values for $\bar{J}$ are the maximum and minimum singular values among the blocks $\bar{J}_t$, which may be written as

$$\begin{aligned} \bar{J}_t &= D_t^{1/2} J_t f_t^{-1/2} g_t^{-1/2} m_{\mathcal{Q}}^{-1/2} \alpha_t^{-1} \\ &= \hat{D}_t J_t, \end{aligned}$$

where

$$\hat{D}_t = f_t^{-1/2} g_t^{-1/2} m_{\mathcal{Q}}^{-1/2} \alpha_t^{-1} D_t^{1/2}.$$

Examining the constituent parts of D_t given by (6.5), observing that the α_t^2 in (6.5) is cancelled by the α_t^{-1} in the preceding equation, and applying the inequalities

$$1 \leq \omega_k / m_{\mathcal{Q}} \leq M_{\mathcal{Q}} / m_{\mathcal{Q}}$$

for $k = 1, \ldots, q$ (see (4.1)),

$$1 \le \theta(\phi_t(r_k)) f_t^{-1} \le \frac{\max_{k=1,\ldots,q} \theta(\phi_t(r_k))}{\min_{k=1,\ldots,q} \theta(\phi_t(r_k))}$$

(see (7.2)), and

$$1 \le \det(\nabla \phi_t(r_k)) g_t^{-1} \le \frac{\max_{k=1,\ldots,q} \det(\nabla \phi_t(r_k))}{\min_{k=1,\ldots,q} \det(\nabla \phi_t(r_k))}$$

(see (7.3)), we conclude that the diagonal entries of $\hat{D}_t$ satisfy

$$1 \le \hat{D}_t(i,i) \le \left(\frac{\max_k \theta(\phi_t(r_k))}{\min_k \theta(\phi_t(r_k))} \right)^{1/2} \left(\frac{\max_k \det(\nabla \phi_t(r_k))}{\min_k \det(\nabla \phi_t(r_k))} \right)^{1/2} \left(\frac{M_{\mathcal{Q}}}{m_{\mathcal{Q}}} \right)^{1/2}.$$

By (4.7) and (4.8), the first two quantities on the right-hand side of the preceding equation are bounded by $\hat{\theta}(\mathcal{T})^{1/2}$ and $\kappa_2(\mathcal{T})^{1/2}$, respectively. Thus, it is apparent that, for each i,

$$1 \le D_t(i,i) \le (\hat{\theta}(\mathcal{T}) \kappa_2(\mathcal{T}) M_{\mathcal{Q}} / m_{\mathcal{Q}})^{1/2}.$$

Since $\bar{J}_t = \hat{D}_t J_t$, we can combine the inequalities in the previous line with (6.11) and (6.12) to obtain the following:

$$\sigma_{\max}(\bar{J}_t) \le \hat{\theta}(\mathcal{T})^{1/2} \kappa_2(\mathcal{T})^{1/2} M_{\mathcal{Q}}^{1/2} \sigma_{\mathcal{Q},p} / m_{\mathcal{Q}}^{1/2} \tag{7.5}$$

and

$$\sigma_{\min}(\bar{J}_t) \ge \tau_{\mathcal{Q},p} / \kappa_1(\mathcal{T}). \tag{7.6}$$

Since $H = \bar{J}^T \bar{J}$ and $\bar{J}$ has full column rank, (7.5) and (7.6) prove (5.3), which concludes the proof of Theorem 5.1.

8. Preconditioning strategy summary. The main result of this paper is that the stiffness matrix K of (3.1) can be approximated by a symmetric diagonally dominant matrix $\bar{K}$. In this section we discuss several approaches for using this approximation to efficiently solve the linear system $K\mathbf{x} = \mathbf{f}$ by iteration.

The first step in using the approximation is to construct $\bar{K}$. Recall that $\bar{K} = A^T \bar{D} A$, and thus A and $\bar{D}$ must be formed. Forming A means the construction of the multigraph consisting of $l - 1$ edges (a star-tree) per element of $\mathcal{T}$. Matrix A is then the reduced node-arc incidence matrix of this multigraph as specified by Lemma 6.1. The construction of $\bar{D}$ is given by (7.1). Notice that computing A and $\bar{D}$ requires information about the mesh and the original boundary value problem. In other words, our method is not applicable (at least not in a straightforward manner) if the only information about the original problem is the stiffness matrix K.

Once $\bar{K}$ is on hand, there are several ways to proceed. The most straightforward is to suppose that one has an efficient preconditioned conjugate gradient solver for systems of the form $\bar{K}\mathbf{x} = \mathbf{f}$. Efficient preconditioners for symmetric diagonally dominant systems were proposed and analyzed in a graph-theoretic framework by Vaidya. Vaidya's work is described and extended by [4, 6], and [11] contains a related analysis. One of the most recent improvements is due to Spielman and Teng [20], who propose a graph-based preconditioner whose running time is $O(n^{5/4})$. (Spielman and Teng

improve this bound to $O(n^{1+\epsilon})$ for any $\epsilon > 0$, but the algorithm corresponding to the improved bound is no longer preconditioned conjugate gradients.) Other techniques proposed in the literature for symmetric diagonally dominant matrices such as algebraic multigrid could also be used.

If one has a good preconditioner M for $\bar{K}$, then one could also use M as a preconditioner directly for K. This is because of the "triangle inequality" (see [5]), which states that

$$\sigma(K, M) \leq \sigma(K, \bar{K})\sigma(\bar{K}, M). \tag{8.1}$$

This shows that the the overall support number is bounded by the product of the support numbers in each step of the approximation $K \approx \bar{K} \approx M$. In particular. $\kappa(M, K) \leq \kappa(H)\kappa(M, \bar{K})$. Since the number of iterations of preconditioned conjugate gradients is bounded by the square root of the condition number, our analysis shows that the increase in the number of iterations for solving $K\mathbf{x} = \mathbf{f}$ (compared to solving $\bar{K}\mathbf{x} = \mathbf{f}$) is at most a factor of $\sqrt{\kappa(H)}$, which in turn is bounded by

$$\hat{\theta}(\mathcal{T})^{1/2}\kappa_1(\mathcal{T})\kappa_2(\mathcal{T})^{1/2}M_{\mathcal{Q}}\sigma_{\mathcal{Q},p}/(m_{\mathcal{Q}}\tau_{\mathcal{Q},p}).$$

The asymptotically fastest known iterative algorithm for solving symmetric diagonally dominant matrices is due to Elkin et al. [9]. This algorithm, which we denote EEST, extends Spielman and Teng [20] and requires $O(n_e(\log n)^s)$ time to solve any diagonally dominant $\bar{K}\mathbf{x} = \mathbf{f}$, where n_e is the number of nonzero entries in $\bar{K}$ and s is some constant. Our preconditioner $\bar{K}$ is the Laplacian of a graph with ml edges, where m is the number of elements and l is the number of nodes in the reference element (refer to Lemma 6.1), hence $n_e = ml$. We may assume that $m = O(n)$ for the following reasons. First, this relationship holds for all automatic finite element mesh generators of which we are aware. Second, a violation of the relationship $m = O(n)$ implies that the mesh has elements of unbounded aspect ratio, which in turn means $\kappa_1(\mathcal{T})$ tends to infinity so that our results are not as useful anyway. Thus, it is safe to assume that $n_e \leq \text{const} \cdot nl$, and we are regarding l (which depends on p, the polynomial degree, and d, the space dimension) as a constant.

The EEST iteration is more complicated than preconditioned conjugate gradients, and hence it is unclear whether it is possible to simply replace the diagonally dominant coefficient matrix $\bar{K}$ by our stiffness matrix K and expect the algorithm to converge in $O(n(\log n)^s\kappa(H)^{1/2})$ time.

On the other hand, one could obtain this running time $O(n(\log n)^s\kappa(H)^{1/2})$ by using a nested iteration: The outer iteration is preconditioned conjugate gradients in which $\bar{K}$ preconditions K. Thus, $O(\kappa(H)^{1/2})$ outer iterations are required. The inner loop is the EEST algorithm to apply the preconditioner, i.e., to solve $\bar{K}\mathbf{x} = \mathbf{f}$ in $O(n(\log n)^s)$ iterations. The EEST algorithm is fairly complex, and using it in a two-level manner would raise a number of difficulties associated with termination tests, so it is unlikely to be practical currently.

This bound of $O(n(\log n)^s\kappa(H)^{1/2})$ on the number of operations is independent of the condition number of the underlying system because, as noted above, $\kappa(H)$ depends on factors associated with the FEM and on mesh quality measures but not on the conditioning of K.

Our approximation scheme can be rewritten on an element-by-element basis as follows. For some element index $t \in \{1, \ldots, m\}$, consider its element stiffness matrix $K_t = A_t^T J_t^T D_t J_t A_t$, where A_t is defined in Lemma 6.1, J_t is defined by (6.10), and D_t is defined by (6.5). The above proof shows that $\bar{D}_t$, which is the tth block of

(7.1), is a good approximation to $J_t^T D_t J_t$. Thus, we let $\bar{K}_t = A_t^T \bar{D}_t A_t$. The overall approximation is $\bar{K} = \sum_{t=1}^m \bar{K}_i$. Note that the so-called splitting lemma frequently used in support-graph theory (see, e.g., [5]) shows that

$$\sigma(K, \bar{K}) \leq \max(\sigma(K_1, \bar{K}_1), \ldots, \sigma(K_m, \bar{K}_m)),$$

so it suffices to analyze the quality of the approximation of $\bar{K}_t$ to K_t.

Alternatively, we can take a global view as in the above analysis and write $\bar{K} = A^T \bar{D} A$, where $A = (A_1; A_2; \ldots; A_m)$ and $\bar{D} = \mathrm{diag}(\bar{D}_1, \bar{D}_2, \ldots, \bar{D}_m)$. To simplify notation, we have adopted the global view in this paper, but the reader should keep in mind that our approximation can take place element by element, which may be important in an implementation.

9. Notes added in revision. Since the first version of this paper, there have been three related developments of interest. First, R. Gupta's Master's thesis [12] gave a geometric method to approximate element stiffness matrices by diagonally dominant matrices in the $p = 1$, $d = 2$ case. In follow-up work, Wang and Sarin [23] showed how to parallelize the algorithm. Computational experiments are presented. For this particular case $p = 1, d = 2$, their result is essentially equivalent to ours.

Second, Phillips and Miller [18] have shown that, in the $p = 1$, $d = 2$ case, $\kappa(H)$ is still small even if some elements have very small angles, provided that no element has large angles (close to π). In our preceding analysis, the right-hand side of (5.3) would grow large in the presence of small angles, since the factor $\kappa_1(\mathcal{T})$ would be large. Wang and Sarin make a similar observation.

In a third development, Avron et al. [2] have shown how to get an approximation to element stiffness matrices that is optimal up to a constant factor. In other words, for an element stiffness matrix K_t, they find a diagonally dominant matrix $\tilde{K}_t$ such that $\kappa(K_t, \tilde{K}_t) \leq c_1 \kappa(K_t, K_t')$, where K_t' is any other symmetric diagonally dominant matrix of the correct size and c_1 depends only on p, d. Thus, their preconditioner could lead to a faster algorithm than ours, since ours is not optimal in this sense. Their theory, however, does not subsume ours, since they do not obtain any new bounds on $\kappa(K, \tilde{K})$ comparable to (5.3). Their results are competitive and in some cases better than an algebraic multgrid method.

10. Computational tests. There are at least two possible ways to test the effectiveness of our result: Calculate the quality of matrix approximation or measure the speed of an iterative method. Since our theory is primarily about the former issue and since Avron et al. conduct extensive testing on the latter question, we focus on the first question.

We try out four specific commonly occurring cases: $(d, p) = (2, 1), (2, 2), (3, 1)$, and $(3, 2)$, i.e., linear and quadratic triangles and linear and quadratic tetrahedra. Six test meshes were tried, which we denote $\mathbf{T}_1, \ldots, \mathbf{T}_6$; the first two are two-dimensional and the last four are three-dimensional. For quadrature in the $p = 1$ cases, we use the midpoint rule. For the $p = 2$ cases, we use the symmetric $d + 1$-point rule, which is accurate for polynomials up to degree 2. Table 10.1 gives the quadrature rules used.

Table 10.2 gives the values of relevant scalars for these test cases. It should be noted that $\sigma_{\mathcal{Q},p} = \tau_{\mathcal{Q},p} = 1$ for the $p = 1$ cases under the midpoint rule because, in these cases, $S_{\mathcal{Q},p}$ given by (4.2) turns out to be the identity matrix.

Finally, we can tabulate element stiffness approximation bounds. (As mentioned in section 8, it suffices to measure element stiffness approximation, which is much easier to compute than global stiffness approximation.) There are at least three relevant

TABLE 10.1
Quadrature rules used for the six test cases. The rules are written in the form $(r_1, \omega_1), \ldots, (r_q, \omega_q)$*, where* r_k *is a Gauss point in the reference simplex and* ω_k *is its weight. In this table* $\xi_1 = (10 - \sqrt{20})/40$ *and* $\xi_2 = 1 - 3\xi_1$.

Test	$\mathcal{Q}$
$\mathbf{T}_1$	$((1/3, 1/3), 1/2)$
$\mathbf{T}_2$	$((1/6, 1/6), 1/6), ((1/6, 2/3), 1/6), ((2/3, 1/6), 1/6)$
$\mathbf{T}_3, \mathbf{T}_5$	$((1/4, 1/4, 1/4), 1/6)$
$\mathbf{T}_4, \mathbf{T}_6$	$((\xi_1, \xi_1, \xi_1), 1/24), ((\xi_1, \xi_1, \xi_2), 1/24), ((\xi_1, \xi_2, \xi_1), 1/24), ((\xi_2, \xi_1, \xi_1), 1/24)$

TABLE 10.2
Scalars relevant for test cases.

Test	d	p	q	$\sigma_{\mathcal{Q},p}$	$\tau_{\mathcal{Q},p}$	$M_{\mathcal{Q}}/m_q$
$\mathbf{T}_1$	2	1	1	1.00	1.00	1.0
$\mathbf{T}_2$	2	2	3	5.26	0.83	1.0
$\mathbf{T}_3, \mathbf{T}_5$	3	1	1	1.00	1.00	1.0
$\mathbf{T}_4, \mathbf{T}_6$	3	2	4	6.47	0.63	1.0

quantities to tabulate: $\chi_1 = \kappa(K_t, \bar{K}_t)$, $\chi_2 = \kappa(H)$, and $\chi_3 = \hat{\theta}(\mathcal{T})\kappa_1(\mathcal{T})^2\kappa_2(\mathcal{T}) \cdot \frac{M_{\mathcal{Q}}\sigma^2_{\mathcal{Q},p}}{m_{\mathcal{Q}}\tau^2_{\mathcal{Q},p}}$, which is the right-hand side of (5.3). Here, K_t is the stiffness matrix of element t ($t = 1, \ldots, m$), and $\bar{K}_t$ is the diagonally dominant preconditioner given by $A_t^T \bar{D}_t A_t$. It follows from Theorem 2.3 and (5.3) that $\chi_1 \le \chi_2 \le \chi_3$.

We generate six meshes and take the max of χ_1, χ_2, χ_3 over all of the elements of the mesh. For conductivity, we use $\theta \equiv 1$ so that the factor $\hat{\theta}(\mathcal{T})$ does not enter the bound. The meshes are generated as follows. In two dimensions, we use the Triangle mesh generator [19] to generate a mesh of an annulus, which is $\mathbf{T}_1$ and consists of linear ($p = 1$) elements. To generate $\mathbf{T}_2$, a quadratic mesh, we insert midpoint nodes in every element of $\mathbf{T}_1$, and for the edges on the boundaries, we moved the midpoint nodes onto the boundary.

The remaining four meshes are three-dimensional. For $\mathbf{T}_3$, we used the QMG mesh generator [17] to generate a mesh of a unit ball in $\mathbb{R}^3$. QMG's meshes are intended for the $p = 1$ case. For $\mathbf{T}_4$, we use midpoint insertion on the $\mathbf{T}_3$ mesh to obtain a $p = 2$ mesh. Again, the midpoint nodes of edges whose endpoints were on the boundary were displaced outward onto the boundary. For $\mathbf{T}_5$ and $\mathbf{T}_6$, we again mesh a unit ball (actually, one octant of the ball) using a mesh generator tailored for that domain only. The mesh generator for $\mathbf{T}_5$ first generates a highly regular mesh of a unit tetrahedron, and then it projects the mesh nodes radially outward toward one facet so that an octant of the unit ball is covered. Finally, $\mathbf{T}_6$ is obtained from $\mathbf{T}_5$ using midpoint insertion and displacement at the boundary.

Then, for every element in each mesh, we compute the three quantities χ_1, χ_2, and χ_3. We have tabulated the maximum values in Table 10.3. The undesirably large values of χ_1 for $\mathbf{T}_3$ and $\mathbf{T}_4$ appear to be due primarily to poorly shaped elements, i.e., a large value of $\kappa_1(\mathcal{T})$. This is evident from comparing $\mathbf{T}_3$ and $\mathbf{T}_4$ against $\mathbf{T}_5$ and $\mathbf{T}_6$, two meshes for the same domain but with much better shaped tetrahedra.

The value of $\kappa_2(\mathcal{T})$ was quite small in all of the tests; as mentioned earlier, it is identically 1 for the $p = 1$ cases. For the $p = 2$ cases, interior elements are still linear, and elements adjacent to the boundary are fairly close to linear. It is interesting to note that $\chi_1 = \chi_2$ in all cases. This implies that the invariant subspaces of H corresponding to its extremal eigenvalues meet the range space of $\bar{D}^{1/2}A$. We do not have a deeper explanation for this observation.

TABLE 10.3
An approximation of the element stiffness matrix by a diagonally dominant matrix.

Test	m	n	$\kappa_1(\mathcal{T})$	$\kappa_2(\mathcal{T})$	χ_1	χ_2	χ_3
$\mathbf{T}_1$	234	143	4.1	1.0	16.6	16.6	16.6
$\mathbf{T}_2$	234	520	4.7	1.3	185.1	185.1	1117.2
$\mathbf{T}_3$	9078	1913	59.6	1.0	3549.5	3549.5	3549.5
$\mathbf{T}_4$	9078	13608	90.2	2.7	$5.96 \cdot 10^4$	$5.96 \cdot 10^4$	$2.32 \cdot 10^6$
$\mathbf{T}_5$	729	220	5.0	1.0	24.9	24.9	24.9
$\mathbf{T}_6$	729	1330	5.0	1.2	396.6	396.6	2644.5

Although an iterative method was not tested, some conclusions can still be drawn from Table 10.3. For example, if our approximation were used on $\mathbf{T}_6$ in an iterative setting, then the slowdown would be at most a factor of $\sqrt{\kappa(\bar{K}_t, K_t)}$, i.e., a slowdown of at most a factor of 20. In practice, the method seems to work better than that according to Avron et al.

11. Open questions. This work is the first to extend support-tree methods, which previously have been shown to be good preconditioners for diagonally dominant matrices with negative off-diagonal entries, to the class of finite element matrices. We have shown that the scope of the method includes a standard scalar elliptic boundary value problem, but perhaps the scope of finite element problems that can be tackled with this method could be expanded further.

One generalization would be the class of problems $\nabla \cdot (\Theta(x) \nabla u) = -f$, where $\Theta(x)$ is a spatially varying $d \times d$ SPD matrix. This generalization would present problems for our current analysis in the case that $\Theta(x)$ is highly ill conditioned. It would still be straightforward to write $K = A^T J^T D J A$, where D is now block diagonal, but our analysis of the introduction of $\bar{J}$ would run into trouble because the $dq \times dq$ diagonal blocks of D are no longer individually well conditioned.

It would also be interesting to tackle vector problems such as linear elasticity or Stokes' flow, or higher-order equations like the biharmonic equation. It seems likely that our techniques can extend to at least some of these problems, since they all have a SPD weak form. On the other hand, a recent result [7] suggests that the extension of our results to linear elasticity will not be straightforward because of the higher nullity of element stiffness matrices in the case of linear elasticity. A further generalization would be to unsymmetric problems like the convection-diffusion equation. The latter class of problems would require a substantial rethinking of the whole approach, since condition number reduction, which is very relevant for the application of conjugate gradients to SPD systems, is less relevant to the application of GMRES to unsymmetric systems.

Our analysis is based on condition numbers (support numbers). One drawback of this approach is that the convergence and work estimates may be too pessimistic. For instance, the condition number of the preconditioned linear systems depends on $\kappa_1(\mathcal{T})$, the worst aspect ratio of any element in the mesh. If there is only one poorly shaped element in the mesh, we expect iterative solvers will take only a few extra iterations since changing a single element implies a low-rank correction to the assembled stiffness matrix. Any analysis based on condition numbers will be unable to capture this effect. A related open issue is whether we can exploit recent work in mesh quality metrics [16] to show that "good meshes" both have small error in the FEM approximation and also produce linear systems that can be well approximated by diagonally dominant systems.

Another point to make about our method is that, although the condition number of the preconditioned system has an upper bound independent of

$$R_\theta = \max_{x\in\Omega} \theta(x) / \min_{x\in\Omega} \theta(x),$$

there will still be a loss of significant digits due to roundoff error when using our method in the case where R_θ is large. This is because the system matrix and the preconditioner separately are ill-conditioned operators. A special case of (3.1), in which R_θ is extremely large and in which $f = 0$, was considered in [22]. That paper proposed a method based on Gaussian elimination in which the loss of significant digits is avoided. Some of the ideas behind [22] were also extended to solution via conjugate gradient using support preconditioners by [14]. The methodology in [14], however, was for node-arc incidence matrices and for a particular kind of support preconditioner called a *support tree* [11], and it is not clear whether that method would apply to the present setting.

Finally, there is greater effort to couple automatic finite element mesh generation to a detailed analysis of the solver and its error bounds. Our approximation result adds another ingredient to this mix; it would be interesting if an automatic finite element mesh generator could be tailored to reduce specifically the quantity $\kappa(K, \bar{K})$.

Acknowledgments. The authors wish to thank the four anonymous referees of this paper for their very helpful comments.

EFFECTIVE LAGUERRE ASYMPTOTICS*

DAVID BORWEIN†, JONATHAN M. BORWEIN‡, AND RICHARD E. CRANDALL§

Abstract. It is known that the generalized Laguerre polynomials can enjoy subexponential growth for large primary index. In particular, for certain fixed parameter pairs (a, z) one has the large-n asymptotic behavior

$$L_n^{(-a)}(-z) \sim C(a,z) n^{-a/2-1/4} e^{2\sqrt{nz}}.$$

We introduce a computationally motivated contour integral that allows efficient numerical Laguerre evaluations yet also leads to the complete asymptotic series over the full parameter domain of subexponential behavior. We present a fast algorithm for symbolic generation of the rather formidable expansion coefficients. Along the way we address the difficult problem of establishing effective (i.e., rigorous and explicit) error bounds on the general expansion. A primary tool for these developments is an "exp-arc" method giving a natural bridge between converging series and effective asymptotics.

Key words. Laguerre polynomials, effective asymptotic expansions, contour integrals

AMS subject classifications. 34E05, 33C65

DOI. 10.1137/07068031X

1. The challenge of "effectiveness." For primary integer indices $n = 0, 1, 2, \ldots$, we define the Laguerre polynomial thus:

$$L_n^{(-a)}(-z) := \sum_{k=0}^{n} \binom{n-a}{n-k} \frac{z^k}{k!}. \tag{1}$$

Our use of negated parameters $-a, -z$ is intentional, for convenience in our analysis and in connection with related research, as we later explain. We shall work on the difficult problem of establishing asymptotics *with* effective error bounds for the two-parameter domain

$$\mathbb{D} := \{(a,z) \in \mathbb{C} \times \mathbb{C} : z \notin (-\infty, 0]\}.$$

That is, a is any complex number, while z is a complex number not on the negative-closed cut $(-\infty, 0]$.

Herein, we say a function $f(n)$ is of *subexponential* growth if $\log f(n) \sim Cn^D$ as $n \to \infty$ for positive constants C, D, with $D < 1$. It will turn out that $\mathbb{D}$ is the precise domain of subexponential growth of $L_n^{(-a)}(-z)$ as $n \to \infty$, with (a, z) fixed. The reason for the negative-cut exclusion on z is simple: For z negative real, the Laguerre polynomial exhibits oscillatory behavior in large n and is not of subexponential growth. Note also, from the definition (1), that

$$L_n^{(-a)}(0) = \binom{n-a}{n}, \tag{2}$$

which covers the case $z = 0$; again, not subexponential growth.

For fixed $(a,z) \in \mathbb{D}$, we shall have the large-n behavior (here and beyond we define $m := n+1$ which will turn out to be a natural reassignment):

$$L_n^{(-a)}(-z) \;\sim\; S_n(a,z)\left(1 + O\left(\frac{1}{m^{1/2}}\right)\right), \tag{3}$$

where the subexponential term S_n is

$$S_n(a,z) \;:=\; \frac{e^{-z/2}}{2\sqrt{\pi}}\,\frac{e^{2\sqrt{mz}}}{z^{1/4-a/2}\;m^{1/4+a/2}}. \tag{4}$$

In such expressions, $\Re\,(\sqrt{mz})$ denotes $\sqrt{m|z|}\cos(\theta/2)$, where $\theta := \arg(z) \in (-\pi,\pi]$ (we hereby impose $\arg(-1) := \pi$), and so for $(a,z) \in \mathbb{D}$, the expression (4) involves genuinely diverging growth in n.

1.1. Research motives. There are many interdisciplinary applications of Laguerre asymptotics. The Laguerre functions appear standardly in the quantum theory of the hydrogen atom [46, Chapter 4] and in certain exactly solvable three-body problems of chemical physics [13], [14]. The so-called WKB phase of a quantum eigenstate can, in such cases and for high quantum numbers, be calculated via Laguerre asymptotics. The Hermite polynomials $H_n(x)$—closely related to the Laguerre polynomials $L_n^{(\pm 1/2)}(x^2)$—also figure in quantum analyses; e.g., one may derive Hermite asymptotics from Laguerre asymptotics. In this context there is the fascinating López–Temme representation of *any* $L_n^{(-a)}(-z)$ as a finite superposition of Hermite evaluations [23].

Our own research motive for providing effective asymptotics involves not the Laguerre–Hermite connection, rather it begins with a beautiful link to the incomplete gamma function, namely, [19]

$$\Gamma(a,z) \;=\; z^a e^{-z}\cfrac{1}{z+\cfrac{1-a}{1+\cfrac{1}{z+\cfrac{2-a}{1+\cdots}}}} \;=\; z^a e^{-z}\sum_{n=0}^{\infty}\frac{(1-a)_n}{(n+1)!}\,\frac{1}{L_n^{(-a)}(-z)\,L_{n+1}^{(-a)}(-z)}, \tag{5}$$

where $(c)_n := c(c+1)\cdots(c+n-1)$ is the *Pochhammer symbol*. This series is valid whenever none of the Laguerre denominators has a zero. Thus an interesting sidelight is the research problem of establishing zero-free regions for Laguerre polynomials (see our Open problems section). We note that convergence of the continued-fraction can be highly problematic, especially when the full complex parameter space is allowed. One might encounter smooth convergence, or steady divergence, or even chaotic divergence, all of which possibilities are exemplified in [7, 8, 9, 22].

The problem, then, of general Laguerre asymptotics arises because there is a way to write Riemann zeta-function evaluations $\zeta(s)$ in terms of the incomplete gamma function, as was known to Riemann himself [40, p. 22]. But when s has large imaginary height, one becomes interested in the incomplete gamma's corresponding complex parameters (a,z) also of possibly large imaginary height [11], [12]. For example, in the art of prime-number counting, say, for primes $< 10^{20}$, one might need to know, for example, $\Gamma\left(3/4 + 10^{10}\,i, z\right)$ for various z also of large imaginary height, to good precision, in order to evaluate $\zeta(s)$ high up on the line $\Re(s) = 3/2$. The point is,

exact computations on prime numbers must, of course, employ rigor—hence the need for effective error bounds.

Independent of Riemann-ζ considerations is the following issue: Continued-fraction theory is to this very day incomplete in a distinct sense. The vast majority of available convergence theorems are for Stieltjes, or S-fractions. Now the continued fraction in (5) is an S-fraction only when the a parameter is real [24, p. 138]. Due to the relative paucity of convergence theorems outside the S-fraction class, one encounters great difficulty in estimating the convergence rate for arbitrary $\Gamma(a,z)$; this is what led to our focus on the Laguerre asymptotics. Incidentally, we are aware that subexponential convergence results *might* be attainable via the complicated and profound work of Jacobsen and Thron [21] on oval convergence regions. In any case, our effective-Laguerre approach proves the subexponential convergence of $\Gamma(a,z)$ for any complex pairs $(a,z) \in \mathbb{D}$; moreover, this is done with effective constant factors. Separate research on these superexponential convergence issues for continued fractions is underway.

1.2. Historical results on Laguerre asymptotics. Laguerre asymptotics have long been established for certain restricted domains and usually with noneffective asymptotics.[1] For example, in 1909 Fejér established that, for z on the open cut $(-\infty, 0)$ and any real a, one has [36, Theorem 8.22.1]:

$$L_n^{(-a)}(-z) = \frac{e^{-z/2}}{\sqrt{\pi}(-z)^{1/4-a/2}\ m^{1/4+a/2}} \cos\left(2\sqrt{-mz} + a\pi/2 - \pi/4\right) + O\left(m^{-a/2-3/4}\right), \tag{6}$$

where we again use index $m := n+1$, which slightly alters the coefficients in such classical expansions, said coefficients being for powers $n^{-k/2}$, but we are now using powers $m^{-k/2}$. By 1921 Perron [35] had generalized the Fejér series to arbitrary orders, then, for $z \notin (-\infty, 0]$, established a series consistent with (3) and (4), in essentially the form [36, Theorem 8.22.3]:

$$L_n^{(-a)}(-z) = S_n(a,z)\left(\sum_{k=0}^{N-1} \frac{C_k}{m^{k/2}} + O\left(m^{-N/2}\right)\right), \tag{7}$$

although this was for *real* a and so not for our general parameter domain $\mathbb{D}$. Note that $C_0 = 1$, consistent with our (3) and (4); however, one should take care that because we are using index $m := n+1$, the coefficients C_k in the above formula differ slightly from the historical ones.

A modern literature treatment that is again consistent with the heuristic (3)–(4) is given by Winitzki in [45], where one invokes a formal generating function to yield a contour integral for $L_n^{(-a)}(-z)$. Then a stationary-phase approach yields the correct first-asymptotic term, at least for certain subregions of $\mathbb{D}$. Winitzki's treatment is both elegant and nonrigorous; there is no explicit estimate given on the $O(1/\sqrt{m})$ correction in (3).

There is an interesting anecdote that reveals the difficulty inherent in Laguerre asymptotics. Namely, W. Van Assche in a fine 1985 paper [41] used the expansion

[1] Some researchers use the term "realistic error bound" for big-O terms that have explicit structure. We prefer "effective bound," and when an expansion is bestowed with such a bound, we may say "effective expansion."

(7) for work on zero-distributions, only to find by 2001 that the C_1 term in that 1985 paper had been calculated incorrectly. The amended series is given in his correction note [42] as

$$L_n^{(-a)}(-z) = \frac{e^{-z/2}}{2\sqrt{\pi}} \frac{e^{2\sqrt{nz}}}{z^{1/4-a/2}\, n^{1/4+a/2}} \cdot \left(1 + \left(\frac{3 - 12a^2 + 24(1-a)z + 4z^2}{48\sqrt{z}}\right) \frac{1}{\sqrt{n}} + O\left(\frac{1}{n}\right)\right),$$

or in our own notation with $m := n + 1$,

$$= S_n(a,z) \left(1 + \left(\frac{3 - 12a^2 - 24(1+a)z + 4z^2}{48\sqrt{z}}\right) \frac{1}{\sqrt{m}} + O\left(\frac{1}{m}\right)\right). \tag{8}$$

Note the slight alteration used to obtain our $C_1/\sqrt{m}$ term. Van Assche credits T. Müller and F. Olver for aid in working out the correct $O(1/\sqrt{n})$ component.[2] This story suggests that even a low-order asymptotic development is nontrivial.

The great classical analysts certainly knew in principle how to establish effective error bounds. The excellent treatment of effectiveness for Laplace's method of steepest descent in [27] is a shining example. Also illuminating is Olver's paper [26], which explains effective bounding and shows how unwieldy rigorous bounds can be obtained. However, efficient algorithms for generating *explicit* effective big-O constants have only become practicable in recent times, when computational machinery is prevalent.

2. Contour representation. In this section we develop an efficient—both numerically and analytically—contour-integral representation for $L_n^{(-a)}(-z)$.

2.1. Development of a "keyhole" contour. A well-known integral [36, section 5.4] has contour Γ encircling $s = 1$ and avoiding the branch cut $(-\infty, 0]$:

$$L_n^{(-a)}(-z) = \frac{e^{-z}}{2\pi i} \oint_\Gamma s^{-1-a} \left(1 - \frac{1}{s}\right)^{-n-1} e^{zs}\, ds. \tag{9}$$

This representation holds for all pairs $(a, z) \in \mathbb{C} \times \mathbb{C}$, with n a nonnegative integer.[3]

However—and this is important—we found via experimental mathematical techniques, e.g., extreme-precision evaluations, that a specific kind of contour allows very accurate, efficient, and well-behaved *numerical* Laguerre evaluations. It is not completely understood why the "keyhole" contour we are about to define does so well in numerical Laguerre evaluations; we do know that this new contour consistently provides better numerics than, say, a simple circle surrounding $s = 1$. It may be simply the internal quirks of various modern numerical integrators at work, or it may be the smooth phase behavior along our keyhole's perimeter.

For the desired contour, take $z \neq 0$, $m := n + 1$ and assume $r := \sqrt{m/z}$ has $|r| > 1/2$. Then, use a circular contour centered at $s = 1/2$ with radius $|r|$. This contour will encompass $s = 1$, so the remaining requirement is to avoid the cut $s \in (-\infty, 0]$ as can be done by cutting out a "wedge" from the negative-real arc of the circle, with apex at $s = 1/2$. We tried such schemes with high-precision integration, to

[2] Accordingly, we hereby name the polynomial $C_1(a, z)$ the Perron–van Assche–Müller–Olver (PAMO) coefficient.

[3] The contour representation (9) can easily be continued to noninteger n, with care taken on the $(-n-1)$th power, but our present treatment will only use nonnegative integer n.

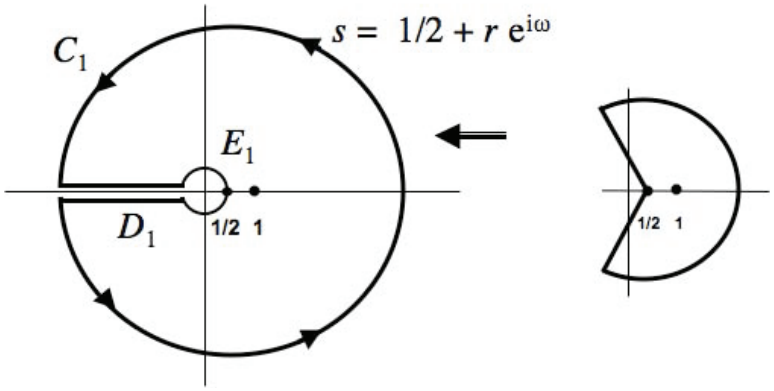

FIG. 1. *A numerically efficient "keyhole contour" for Laguerre evaluations $L_n^{(-a)}(-z)$, valid for all complex a, z, with $z \neq 0$ and $n+1 > |z|/4$. Wedges with center-1/2—as pictured at right—are experimentally accurate, leading to a "keyhole" deformation avoiding the cut $s \in (-\infty, 0]$. It turns that, for any $(a, z) \in \mathbb{D}$, the main arc C_1 gives the predominant contribution for large n, the D_1, E_1 components being subexponentially minuscule.*

settle finally on the contour of Figure 1, where the aforementioned wedge has evolved to a "keyhole" pattern consisting of cut-run D_1 and small, origin-centered circle E_1 of radius $1/2$.

So, adopting constraints and nomenclature

$$z \neq 0, \quad \theta := \arg(z), \quad \omega_\pm := \pm\pi + \theta/2,$$
$$m := n + 1, \quad r := \sqrt{m/z} := \sqrt{m/|z|}e^{-i\theta/2}, \quad R := |r| > 1/2,$$

but no other constraints, we have the following representation:

$$L_n^{(-a)}(-z) = c_1 + d_1 + e_1, \tag{10}$$

where c_1, d_1, e_1 are the respective contributions from contour C_1, cut-discontinuity D_1, and contour E_1 from Figure 1. Exact formulae for said contributions are

$$c_1 = \frac{1}{2\pi} r^{-a} e^{-z/2} \int_{\omega_-}^{\omega_+} \mathcal{H}_m(a, z, e^{-i\omega}) e^{2\sqrt{mz}\cos\omega}\, d\omega, \tag{11}$$

$$d_1 = \frac{e^{-z}}{\pi} \sin(\pi a) \int_{1/2}^{R-1/2} T^{-1-a} \left(1 + \frac{1}{T}\right)^{-m} e^{-zT}\, dT, \tag{12}$$

$$e_1 = -\frac{e^{-z}}{4\pi} \int_{-\pi}^{\pi} \left(2e^{-i\omega}\right)^{1+a} \left(1 - 2e^{-i\omega}\right)^{-m} e^{i\omega + \frac{z}{2}e^{i\omega}}\, d\omega, \tag{13}$$

and when $m > \Re(a)$, we may write this last contribution, by shrinking down the radius-$1/2$ contour segment to embrace the cut $(-1/2, 0]$, as

$$e_1 = \frac{e^{-z}}{\pi} \sin(\pi a) \int_0^{1/2} T^{-1-a} \left(1 + \frac{1}{T}\right)^{-m} e^{-zT}\, dT. \tag{14}$$

For the c_1 contribution above, we have used the function $\mathcal{H}_m$ defined by

$$\mathcal{H}_m(a, z, v) := v^a \left(1 + \frac{v}{2r}\right)^{-1-a} \left[F\left(\frac{v}{r}\right)\right]^m, \tag{15}$$

$$F(t) := \left(\frac{1 + t/2}{1 - t/2}\right) e^{-t}, \tag{16}$$

which for small t can be written $F(t) = 1 + t^3/12 + t^5/80 + \cdots = 1 + O(t^3)$.

In any event, e_1, like d_1, is subexponentially small relative to c_1 for large n and $(a,z) \in \mathbb{D}$. It is to be stressed that decomposition (10) holds for all $(a,z) \in \mathbb{C} \times \mathbb{C}, z \neq 0$, as long as $m := n + 1 > |z|/4$. We remind ourselves of (2) for $z = 0$. This means that such contour calculus applies to both oscillatory (Fejér) cases, where z is negative real, and subexponential (Perron) cases for the stated parameters.

2.2. Numerical success on the keyhole contour. The triumvirate c_1, d_1, e_1 of integrals is suitable for accurate Laguerre computations, which computations do show that *integrals d_1, e_1 tend to be subexponentially small* relative to c_1. This, of course, is our motive for so identifying the contour terms. An example, using the defining series (1) with $(a,z) := (-i, -1-i)$ is

$$L_8^{(i)}(1+i) \;=\; -\frac{137}{288} + \frac{53}{45} i \;\approx\; -0.475694444444444444 + 1.177777777777777777 i,$$

while the contributions from the C_1, D_1, E_1 segments of the contour of Figure 1 are

$$\begin{aligned} c_1 &\approx -0.44406762576110996056 + 0.81722282272705891241 i, \\ d_1 &\approx -0.03169598827425878852 + 0.36065591639721657587 i, \\ e_1 &\approx 0.00006916959092430464 - 0.00010096134649771051 i, \end{aligned}$$

with the sum $c_1 + d_1 + e_1$ giving $L_8^{(i)}(1+i)$ to the implied precision.

Remarkably, this "keyhole-contour" approach has the additional, unexpected feature that, for some parameter regions, the contour evaluation of $L_n^{(a)}(-z)$ is actually *faster* than direct summation of the defining series (1). A typical example is as follows: For the 13-digit evaluation

$$L_{50000}^{(25i/2)}(-30+3i) \approx (0.9275136583293 + 1.7406691595239 i) \times 10^{1056},$$

the defining series (1) was, in our trials, slower than the integral c_1.[4]

3. Effective bounds on the contour components.

3.1. Theta-calculus. We now introduce a notation useful in effective-error analysis. When two functions enjoy

$$|f(z)| \leq |g(z)|$$

over some relevant domain of z values, we shall say that

$$f(z) = \Theta(g(z)), \quad \text{or} \quad f(z) = \Theta : g(z)$$

on said domain. Thus, the Θ-notation is an effective replacement for big-O notation. The reason for allowing the notation $\Theta : \ldots$ is that a long formula g can run arbitrarily to the right of the colon.

Incidentally, there is a literature precedent for such a "theta-calculus." Namely, in computational number theory treatments such as [10], one encounters terms such as, say, $\theta x/\log^2 x$, with a stated constraint $\theta \in [-10, 10]$. This means the term is $O(x/\log^2 x)$ but with effective big-O constant bounded in magnitude by 10. In our nomenclature we would use $\Theta : 10x/\log^2 x$.

[4] Of course, series acceleration as in [5] would give the direct series a "leg up." Still, it is remarkable that contour integration is competitive. For the record, we compared *Mathematica*'s numerical integration to its own `LaguerreL[ ]` function.

3.2. Effective bound for e_1. First we address the integral e_1 as given in relation (13). We need some preliminary lemmas, starting with a collection of polynomial estimates to transcendental functions.

LEMMA 1. *The following inequalities hold for the respective conditions on ω:*

$$\log(5-4\cos\omega) \geq \frac{\log 9}{\pi^2}\omega^2, \quad \omega \in [-\pi,\pi];$$
$$\log(1+\omega) \geq \frac{4}{5}\omega, \quad \omega \in [0,1/2];$$
$$\arcsin\omega \leq \frac{\pi}{\sqrt{8}}\omega, \quad \omega \in [0,1/\sqrt{2}];$$
$$\cos\omega \leq 1-\frac{4}{\pi^2}\omega^2, \quad \omega \in [-\pi/2,\pi/2].$$

Proof. All four are straightforward calculus exercises. □

LEMMA 2. *Consider integrals of error-function class, specifically, for nonnegative real parameter μ,*

$$V_\mu(\alpha,\beta,\gamma) := \int_\gamma^\infty (x^2)^\mu e^{2\alpha x-\beta x^2}\, dx,$$

where each of α,β,γ is real, with $\alpha,\beta>0$. Then we always have the bound

$$V_0(\alpha,\beta,\gamma) = \Theta : \sqrt{\frac{\pi}{\beta}}\; e^{\frac{\alpha^2}{\beta}}.$$

If in addition $\gamma > 2\alpha/\beta$, we also have

$$V_\mu(\alpha,\beta,\gamma) = \Theta : \frac{1}{2}\; \frac{\Gamma(\mu+1/2)}{(\beta-2\alpha/\gamma)^{\mu+1/2}};$$

finally, if $\gamma > 4\alpha/\beta$, we have

$$V_\mu(\alpha,\beta,\gamma) = \Theta :\; 2^{\mu-1/2}\; \frac{\Gamma(\mu+1/2)}{\beta^{\mu+1/2}}.$$

Remark. We use the double-exponential $(x^2)^\mu$ because the first case of the theorem allows $\gamma<0$.

Proof. Completing the exponent's square gives the first bound easily, since

$$V_0 = e^{\alpha^2/\beta}\int_\gamma^\infty e^{-\beta(x-\alpha/\beta)^2}\, dx \;=\; \Theta : \sqrt{\pi/\beta}.$$

For the second bound, it is elementary that, for $x\geq\gamma$, one has $2\alpha x-\beta x^2 \leq x^2(2\alpha/\gamma-\beta)$ so that

$$V_\mu \leq \int_0^\infty x^{2\mu} e^{-(\beta-2\alpha/\gamma)x^2}\, dx,$$

and the resulting bound follows. The final bound follows immediately from the previous bound, because $\gamma > 4\alpha/\beta$ implies $\beta-2\alpha/\gamma > \beta/2$. □

THEOREM 1. *The contour contribution e_1 defined by* (13)*, under conditions $(a,z) \in \mathbb{D}$ and m sufficiently large in the explicit sense $m := n+1 > m_0 := |z|/4,\ \ m > m_1 := 5\left(|\Re(z)| + (|\Im(a)| + |\Im(z)|/2)^2\right)$, is bounded as*

$$e_1 = \Theta : e^{-z/2} 2^{\Re(a)+3} \frac{1}{\sqrt{m}}.$$

Moreover, under alternative conditions $(a,z) \in \mathbb{D}$ and $m > m_0, \quad m > m_2 := \Re(a), \quad m > m_3 := -\frac{5}{4}|z|\cos\theta$ we have a bound

$$e_1 = \Theta : \frac{e^{-z}}{\pi} \sin(\pi a) \frac{2^{\Re(a)-m}}{m - \Re(a)}.$$

Proof. The proof involves careful application of Lemmas 1 and 2 to the integral forms (13), (14); for brevity we omit these details. ∎

3.3. Effective bound for d_1. Again we need an opening lemma.

LEMMA 3. *Consider integrals of the incomplete-Bessel class, specifically*

$$W(\alpha,\beta) := \int_0^1 e^{-\alpha x - \frac{\beta}{x}}\ \frac{dx}{x},$$

where each of α, β is real, with $\beta > 0$. If $\beta > \alpha$, we have a bound

$$W = \Theta : \frac{1}{2} e^{-\beta-\alpha} \sqrt{\frac{\pi}{\beta}}.$$

Proof. We write

$$W(\alpha,\beta) = \int_0^1 e^{\beta x - \alpha x}\, e^{-\beta x - \frac{\beta}{x}}\ \frac{dx}{x} \le e^{\beta-\alpha} \int_0^1 e^{-\beta x - \frac{\beta}{x}}\ \frac{dx}{x}.$$

This last integral is a modified-Bessel term $K_0(2\beta)$ and has the required bound [2, Lemma 1]. ∎

THEOREM 2. *The contour contribution d_1 defined by* (12) *can be bounded, under conditions $(a,z) \in \mathbb{D}$ and $m > m_4 := 4|z|$, as*

$$d_1 = \Theta : \frac{e^{-z/2}}{\sqrt{\pi}} m^{|\Re(a)|/2 - 1/4} |z|^{-|\Re(a)|/2 - 1/4} \sin(\pi a) e^{-2\sqrt{m|z|}\cos^2\frac{\theta}{2}}.$$

Proof. Starting from (12) one applies Lemma 3; again for brevity we omit the details. ∎

3.4. Rigorous estimates on c_1. Having dispensed with d_1, e_1, we next show the integration limits ω_-, ω_+ on the c_1 contribution can be changed—with a subexponentially small error penalty—to $-\pi/2, \pi/2$, respectively.

LEMMA 4. *For any v on the unit circle $\{e^{i\phi} : \phi \in (-\pi, \pi]\}$, any complex a, and any real $R > (1+|a|)/2$ we have*

$$\left| \left(1 + \frac{v}{2R}\right)^{-1-a} \right| \le \frac{1}{1 - \frac{1+|a|}{2R}}.$$

Proof. Via the binomial theorem,

$$\left| \left(1 + \frac{v}{2R}\right)^{-1-a} \right| \le 1 + (1+|a|)\frac{1}{2R} + (1+|a|)^2 \left(\frac{1}{2R}\right)^2 + \cdots = \frac{1}{1 - \frac{1+|a|}{2R}}. \qquad ∎$$

LEMMA 5. *Let v be on the unit circle as in Lemma 4, let $R > 1$ be real, and let m be a positive integer. For the function F appearing in* (16)*, we have the bound*

$$\left| F\left(\frac{v}{R}\right)^m \right| \leq e^{\frac{1}{6}\frac{m}{R^3}}.$$

Proof. From the definition (16) we have

$$F(v/R)^m = e^{\frac{1}{12}\frac{m}{R^3}(1+(3/5)/(2R)^2+(3/7)/(2R)^4+\cdots)}.$$

For $R := 1$, the infinite sum is no larger than 1.18 and is monotonic decreasing in R. □

LEMMA 6. *Let v be on the unit circle as in Lemma 4 and define for nonnegative integer m*

$$K := \left(1+\frac{v}{2R}\right)^{-1-a} F\left(\frac{v}{R}\right)^m.$$

For the assignments $(a, z) \in \mathbb{C} \times \mathbb{C}, z \neq 0, R := \sqrt{m/|z|} > 1, m > m_5 := |z|(1 + |a| + |z|/2)^2$, we have

$$K = \Theta : 2.$$

Proof. From Lemmas 4 and 5 we have

$$|K| \leq \frac{1}{1-\frac{1+|a|}{2(1+|a|+|z|/2)}} e^{\frac{1}{6}\frac{|z|}{1+|a|+|z|/2}}.$$

The fact that the right-hand side is $\Theta(2)$ follows from the observation that the function

$$\frac{1}{1-\frac{Q}{2Q+x}} e^{\frac{1}{3}\frac{x}{2Q+x}}$$

for $Q \geq 1, x \in [0, \infty)$ is itself $\Theta(2)$. This in turn follows easily on substituting $y := x/(2Q + x)$. Now the function to be bounded is $g(y) := (2/(1 + y))e^{y/3}$ on $y \in [0, 1/2]$—as differentiation settles. □

These lemmas in turn allow us to contract the range on the c_1 contour integral.

THEOREM 3. *Decompose c_1 as defined by* (11) *into two terms,*

$$c_1 := c_0 + c_2,$$

with c_0 involving the integral's range contracted to $[-\pi/2, \pi/2]$, namely,

$$c_0 := \frac{1}{2\pi} r^{-a} e^{-z/2} \int_{-\pi/2}^{\pi/2} \mathcal{H}_m(a, z, e^{-i\omega}) e^{2\sqrt{mz}\cos\omega}\, d\omega.$$

Then, under conditions $(a, z) \in \mathbb{D}$ and $m > m_5 := |z|(1 + |a| + |z|/2)^2$, we have a bound

$$c_2 = \Theta : r^{-a} e^{-z/2} e^{\frac{3}{2}\pi|\Im(a)|}.$$

Proof. It is evident that c_2 is obtained from the definition (11) but with the integral replaced via

$$\int_{\omega_-}^{\omega_+} \to \left\{ \int_{\omega_-}^{-\pi/2} + \int_{\pi/2}^{\omega_+} \right\}.$$

Over these domains of integration, we have $e^{2\sqrt{mz}\cos\omega} = \Theta(1)$. Thus, Lemmas 4, 5, and 6 show

$$c_2 = \Theta : \frac{1}{2\pi} r^{-a} e^{-z/2} \left\{ \int_{\omega_-}^{-\pi/2} + \int_{\pi/2}^{\omega_+} \right\} 2 \left| e^{-i\omega a} \right| \, d\omega.$$

As the total support of the integrals cannot exceed π, the desired c_2 bound follows. □

3.5. Summary of the contour decomposition for $L_n^{(-a)}(-z)$. The above manipulations lead to the main result of the present section, namely, a formula that decomposes the Laguerre evaluation, as in the following.

THEOREM 4 (contour decomposition). *Let $(a, z) \in \mathbb{C} \times \mathbb{C}$ be an arbitrary parameter pair, with $z \neq 0$ (with $z = 0$ cases resolved exactly by (2)). If $m := n + 1 = m_0 > |z|/4$, then the contour decomposition*

$$L_n^{(-a)}(-z) = c_0 + \mathcal{E}$$

holds, with c_0, c_2 as defined in Theorem 3 and $\mathcal{E} := c_2 + d_1 + e_1$. If an appropriate set of conditions on m across Theorems 1, 2, and 3 *holds, then we can write*

$$L_n^{(-a)}(-z) = c_0 + S_n(a, z)\mathcal{E}_1,$$

where $\mathcal{E}_1$ is subexponentially small, in the sense that, for any fixed positive ϵ, the large-n behavior is

$$\mathcal{E}_1 = O\left(e^{-(2-\epsilon)\sqrt{m|z|}\cos\frac{\theta}{2}} \right).$$

Moreover, an effective big-O constant is available (the proof exhibits explicit forms).

Proof. The contour calculus holds for all complex pairs (a, z), with $z \neq 0, R := \sqrt{m/|z|} > 1/2$, which assures that the point 1 is contained in the contour. It remains to analyze $\mathcal{E}_1$. Consider, then, an appropriate union of conditions from the cited theorems, say, $(a, z) \in \mathbb{D}$ and $m > \max(m_0, m_1, m_2, m_3, m_4, m_5)$, in which case we have, from Theorems 1, 2, and 3 (in that respective order of Θ terms):

$$\mathcal{E}_1 = \Theta : \frac{e^{-z/2}}{\sqrt{\pi}} \sin(\pi a) \frac{2^{1+\Re(a)-m}}{m - \Re(a)} z^{1/4-a/2} m^{1/4+a/2} e^{-2\sqrt{m|z|}\cos\frac{\theta}{2}}$$

$$+\Theta : 2 \left(\frac{m}{|z|} \right)^{(\Re(a)+|\Re(a)|)/2} e^{\frac{3}{2}\pi|\Im(a)|} e^{-2\sqrt{m|z|}\left(\cos^2\frac{\theta}{2} + \cos\frac{\theta}{2}\right)}$$

$$+\Theta : 2\sqrt{\pi}\, |mz|^{1/4} e^{\frac{3}{2}\pi|\Im(a)|} e^{-2\sqrt{m|z|}\cos\frac{\theta}{2}}.$$

This explicit bounding of the error term $\mathcal{E}_1$ proves the big-O statement of the theorem, while for any choice of ε, an effective big-O constant can be read off at will. □

4. Effective expansion for the $\mathcal{H}$-kernel. Theorem 4 shows the main contribution to $L_n^{(a)}(-z)$, for $(a, z) \in \mathbb{D}$, with $r := \sqrt{m/z}, |r| > 1/2$, is

$$c_0 := \frac{1}{2\pi} r^{-a} e^{-z/2} \int_{-\pi/2}^{\pi/2} \mathcal{H}_m\left(a, z, e^{-i\omega}\right) e^{2\sqrt{mz}\cos\omega} \, d\omega, \tag{17}$$

with the integration kernel $\mathcal{H}_m$ defined, see (15) and (16), as

$$\mathcal{H}_m(a,z,v) := v^a \left(1+\frac{v}{2r}\right)^{-1-a} \left(\frac{1+\frac{v}{2r}}{1-\frac{v}{2r}}\right)^m e^{-mv/r}, \tag{18}$$

where in the integral we assign $v := e^{-i\omega}$. We need to obtain the growth properties of $\mathcal{H}_m$.

4.1. Exponential form for $\mathcal{H}_m$.

LEMMA 7. *For $|v|=1$ and $m > |z|/4$, the $\mathcal{H}$-kernel can be cast in the exponential form*

$$\mathcal{H}_m := v^a \exp\left\{\sum_{k\geq 1} \frac{a_k}{k}\frac{1}{m^{k/2}}\right\}, \tag{19}$$

where

$$a_k := (1+a)(-1)^k \left(\frac{v\sqrt{z}}{2}\right)^k + \left(1-(-1)^k\right)\frac{k}{k+2}\left(\frac{v\sqrt{z}}{2}\right)^{k+2}. \tag{20}$$

Moreover, we have the general coefficient bound

$$|a_k| \leq \left(\frac{\sqrt{z}}{2}\right)^k (1+|a|+|z|/2). \tag{21}$$

Proof. (18) can be recast, with $\rho := v/(2r)$, as

$$\mathcal{H}_m := v^a \exp\left\{-(1+a)\log(1+\rho) - 2m\rho + m\left(\log(1+\rho)-\log(1-\rho)\right)\right\}. \tag{22}$$

Since $|r|>1/2$ and $|v|=1$, the logarithmic series converge absolutely and we have

$$\mathcal{H}_m := v^a \exp\left\{\sum_{k\geq 1}\left[\frac{(1+a)(-1)^k}{k}\left(\frac{v\sqrt{z}}{2}\right)^k g^k + \frac{2}{2k+1}\left(\frac{v\sqrt{z}}{2}\right)^{2k+1} g^{2k-2}\right]\right\}, \tag{23}$$

where $g := 1/\sqrt{m}$, and the precise form (20) for the a_k follows immediately. The given bound on $|a_k|$ is also immediate from (20). ∎

4.2. Exponentiation of series. Though Lemma 7 is progress, we still need to exponentiate a series, in the sense that we want to know, for the following expansion, given the sequence (a_k),

$$\exp\left\{\sum_{k\geq 1}\frac{a_k}{k}x^k\right\} =: \sum_{h\geq 0} A_h x^h,$$

how the A_h depend on the a_k. The combinatorial answer is

$$A_h = \sum_{j=0}^{h}\frac{1}{j!}\,G_h(j;\vec{a}), \qquad G_h(j;\vec{a}) := \sum_{h_1+\cdots+h_j=h}\frac{a_{h_1}\cdots a_{h_j}}{h_1\cdots h_j},$$

with the understanding that $G_h(0,\vec{a}) := \delta_{0h}$ and that such combinatorial sums involve positive integer indices h_i. One useful result is the following.

LEMMA 8. *If all coefficients $a_k = 1$, then, for $j > 0$,*

$$G_h(j;\vec{1}) \;=\; \sum_{h_1+\cdots+h_j=h} \frac{1}{h_1\cdots h_j} \;=\; \Theta : \frac{1}{h}\,(2H_{h-j+1})^{j-1} \;=\; \Theta : \frac{1}{h}\,(2\gamma + 2\log h)^{j-1}\,.$$

Here, $H_p := 1 + 1/2 + \cdots + 1/p$ is the pth harmonic number, $H_0 := 0$, and γ is the Euler constant.

Remark. It turns out that G here enjoys a closed form of sorts, namely,

$$G_h(j;\vec{1}) = \frac{j!}{h!}(-1)^{h-j}\mathcal{S}_h^{(j)},$$

where $\mathcal{S}$ denotes the Stirling number of the first kind, normalized via $x(x-1)\cdots(x-h+1) =: \sum_{j=0}^{h} \mathcal{S}_h^{(j)} x^j$. So one byproduct of our lemma is a rigorous bound on the growth of Stirling numbers; see [1, 24.1.3,III] and [37] for research on Stirling asymptotics.

Proof. The first Θ-estimate arises by induction. For notational convenience we omit the vector $\vec{1}$ and just use the symbol $G_h(j)$. Note that $G_N(1) = 1/N$ and $G_N(2) = \frac{2}{N}H_{N-1}$. Generally we have

$$G_N(J) = \sum_{j=1}^{N-J+1} \frac{1}{j} G_{N-j}(J-1).$$

Now, assume by induction that $G_h(j) = \Theta : \frac{1}{h}(2H_{h-j+1})^{j-1}$ holds for all $j < J$. Then

$$G(N,J) \;\le\; \sum_{j=1}^{N-j+1} \frac{2^{J-2}H_{N-J-j+2}^{J-2}}{j(N-J)} \;\le\; \frac{2^{J-2}}{N} H_{N-J+1}^{J-2} \sum_{j=1}^{N-J+1} \left(\frac{1}{j} + \frac{1}{N-j}\right).$$

Now this last parenthetical term is $H_{N-J+1} + H_{N-1} - H_J$ which, because $H_a - H_b \le H_{a-b}$ for any positive integer indices $a > b$, is bounded above by $2H_{N-J+1}$, which proves the first Θ-bound of the theorem. For the second Θ-bound it suffices, since H_j is increasing, to show that $H_{n-1} > \gamma + \log(n)$, which is an elementary calculus problem. ∎

Though we do not use Lemma 8 directly in what follows, it is useful in proving convergence for various sums $\sum A_h x^h$ and may well matter in future research along our lines.

LEMMA 9. *Let $y \ge 1$ and $x \in (-1,1)$ be real. Then in the expansion*

$$\exp\left\{ y \sum_{k\ge 1} \frac{x^k}{k} \right\} =: \sum_{h\ge 0} Y_h x^h$$

the coefficients Y_h enjoy the bound $Y_h = \Theta : y^h$.

Proof. First, $Y_0 = 1 \le 1$. The left-hand side is $\exp(-y\log(1-x)) = (1-x)^{-y}$ whose binomial expansion has hth coefficient ($h \ge 1$) equal to

$$\frac{y(y+1)\cdots(y+h-1)}{h!} \le y^h\, \frac{1}{1}\frac{1+1/y}{2}\cdots\frac{1+(h-1)/y}{h} \le y^h. \qquad ∎$$

4.3. Effective expansions of exponentiated series. We are now in a position to derive an effective expansion for an exponentiated series, starting with the following.

LEMMA 10. *Assume complex vector $\vec{b}$ of defining coefficients b_k bounded as $|b_k| \leq cd^k$ for positive real c, d with $c \geq 1$. Assume also $|x| < 1/(2cd)$. Then, for any order $N \geq 0$, we have an effective expansion*

$$\exp\left\{\sum_{k\geq 1} \frac{b_k}{k} x^k\right\} = \sum_{h=0}^{N-1} B_h x^h + \Theta : 2c^N d^N x^N,$$

where

$$B_h = \sum_{j=0}^{h} \frac{G_h(j;\vec{b})}{j!}$$

are the usual coefficients of the full formal exponentiation.

Proof. Denoting $f(x) := \exp\left\{\sum_{k\geq 1} \frac{b_k}{k} x^k\right\}$, we have

$$f(x) = \sum_{h=0}^{N-1} B_h x^h + T_N,$$

with remainder $T_N = \sum_{h\geq N} B_h x^h$, having B_h coefficients given by a G-sum as in Lemma 10. Now,

$$|B_h| \leq \sum_{j=0}^{h} \frac{|G_h(j;\vec{b})|}{j!} \leq \sum_{j=0}^{h} \frac{|G_h(j;\vec{f})|}{j!},$$

where $\vec{f} = (cd^k : k \geq 0)$. By Lemma 9 we know that $|B_h| \leq (cd)^h$. Therefore

$$|T_N| \leq \sum_{h\geq N} (cd)^h x^h = \frac{c^N d^N x^N}{1 - cdx} = \Theta : 2(cdx)^N. \qquad \square$$

Finally we arrive at a general expansion—with effective remainder—for the $\mathcal{H}$-kernel.

THEOREM 5 (effective expansion for $\mathcal{H}_m$). *For general complex $(a, z) \in \mathbb{C} \times \mathbb{C}$, assume that $m > m_5 := |z|(1 + |a| + |z|/2)^2$ and $|v| = 1$. Then, for any expansion order $N \geq 0$, we have*

$$\mathcal{H}_m(a, z, v) = v^a \left(\sum_{h=0}^{N-1} \frac{A_h}{m^{h/2}} \; + \; \Theta : 2\left(\frac{m_5}{4m}\right)^{N/2} \right),$$

where, on the basis of the defining coefficients a_k given in (20),

$$A_h := \sum_{j=0}^{h} \frac{G_h(j;\vec{a})}{j!}, \qquad G_h(j;\vec{a}) := \sum_{h_1+\cdots+h_j=h} \frac{a_{h_1} \cdots a_{h_j}}{h_1 \cdots h_j}.$$

Proof. The result follows immediately from Lemma 10, on assigning $\vec{b} = \vec{a}$, with $x := 1/\sqrt{m}$, $c := 1 + |a| + |z|/2$, $d := (1/2)\sqrt{|z|}$. $\square$

Note that Theorem 5 in the instance $N = 0$ implies our previous Lemma 6. It is interesting and suggestive that the threshold $m_5 := |z|(1 + |a| + |z|/2)^2$ appears in these results rather naturally.

4.4. Effective integral form for c_0. To obtain a useful form for c_0, the dominant component of $L_n^{(-a)}(-z)$, we use Theorem 5 to obtain the following.

THEOREM 6. *For $(a,z) \in \mathbb{D}$ and $m > m_5$, the dominant component of Theorems 3 and 4, namely,*

$$c_0 := \frac{1}{2\pi} r^{-a} e^{-z/2} \int_{-\pi/2}^{\pi/2} \mathcal{H}_m(a,z,e^{-i\omega}) e^{2\sqrt{mz}\cos\omega}\, d\omega,$$

can be given an effective form for any order $N \geq 0$, as

$$c_0 = \frac{1}{2\pi} r^{-a} e^{-z/2} \sum_{h=0}^{N-1} \frac{1}{m^{h/2}} \int_{-\pi/2}^{\pi/2} e^{-i\omega a} A_h e^{2\sqrt{mz}\cos\omega}\, d\omega + \; S_n(a,z)\; \mathcal{E}_{2,N},$$

where the error term is bounded as

$$\mathcal{E}_{2,N} = \Theta : \frac{\pi}{\sqrt{2}} \left(\frac{m_5}{4m}\right)^{N/2} \exp\left(\frac{\pi^2 \Im(a)^2 \sec\frac{\theta}{2}}{32\sqrt{m|z|}}\right) \sec^{1/2}\frac{\theta}{2}$$

and the A_h are to be calculated as the first N coefficients of

$$\sum_{h=0}^{\infty} A_h x^h := \exp\left\{ \sum_{k\geq 1} \frac{a_k}{k} x^k \right\},$$

via (20)*, with $v := e^{-i\omega}$.*

Proof. Inserting the effective $\mathcal{H}$-kernel expansion from Theorem 5 directly into the c_0 integral gives the indicated sum over $h \in [0, N-1]$ plus an error term

$$\Theta : \frac{1}{2\pi} r^{-a} e^{-z/2} 2 \left(\frac{m_5}{4m}\right)^{N/2} \int_{-\pi/2}^{\pi/2} e^{\omega\Im(a)} e^{-2\sqrt{m|z|}\cos(\theta/2)\cos\omega}\, d\omega.$$

Using Lemma 1 on $\cos\omega$ and the V_0-part of Lemma 2, we obtain the $\mathcal{E}_{2,N}$ bound of the theorem. ∎

With Theorem 6 we have come far enough to see that a Laguerre evaluation can be obtained—up to a subexponentially small relative error—via the A_h terms in said theorem. To this end, an inspection of the defining relations reveals that, in general, we can decompose an A_h coefficient in terms of powers of $v := e^{-i\omega}$, namely, we define $\alpha_{h,\mu}$ terms via

$$A_h =: \sum_{u=0}^{h} \alpha_{h,u}(a,z) v^{h+2u}. \tag{24}$$

For example,

$$\alpha_{00} = 1, \quad \alpha_{10} = -\frac{1+a}{2} z^{1/2}, \quad \alpha_{11} = \frac{z^{3/2}}{12}, \quad \alpha_{31} = \frac{1}{480}\left(5a^2 + 15a + 16\right) z^{5/2}.$$

The point being, we now have special formulae for the dominant contribution c_0, namely,

$$c_0 = \frac{1}{2\pi} r^{-a} e^{-z/2} \sum_{h=0}^{N-1} \frac{1}{m^{h/2}} \sum_{u=0}^{h} \alpha_{h,u}(a,z)\; \mathcal{I}(2\sqrt{mz}, a+h+2u) \; + \quad S_n(a,z)\; \mathcal{E}_{2,N}, \tag{25}$$

where the integral

$$\mathcal{I}(p,q) := \int_{-\pi/2}^{\pi/2} e^{-iq\omega} e^{p\cos\omega}\, d\omega \tag{26}$$

thus emerges as a fundamental entity for the research at hand.

5. $\mathcal{I}$-integrals and an "exp-arc" method. Having reduced the problem of subexponential Laguerre growth to a study of the $\mathcal{I}$-integrals (26), we next develop a method that is effective for both their numerical and theoretical estimation. This method amounts to the avoidance of stationary-phase techniques, employing instead various forms of *exponential-arcsine* (exp-arc) series, as we see shortly.

Let us first define, for any complex pair (p,q) and $\alpha,\beta \in (-\pi,\pi)$,

$$I(p,q,\alpha,\beta) := \int_{\alpha}^{\beta} e^{-iq\omega} e^{p\cos\omega}\, d\omega \tag{27}$$

so that our special case (26) is simply $\mathcal{I}(p,q) := I(p,q,-\pi/2,\pi/2)$.

Importantly, one may write the Bessel functions J_n of integer order n in terms of $\mathcal{I}$-integrals:

$$J_n(z) = \frac{1}{2\pi}\left(e^{-i\pi n/2}\mathcal{I}(iz,n) + e^{i\pi n/2}\mathcal{I}(-iz,n)\right), \tag{28}$$

and the modified Bessel function, again of integer order n:

$$I_n(z) = \frac{1}{2\pi}\left(\mathcal{I}(z,n) + (-1)^n\mathcal{I}(-z,n)\right), \tag{29}$$

about which representations we shall have more to say in a later section.[5]

5.1. Essentials of the exp-arc method. Now we investigate what we call exp-arc series. First, for any complex τ and $x \in [-1,1]$, one has a remarkable, absolutely convergent expansion (see [6]):

$$e^{\tau \arcsin x} = \sum_{k=0}^{\infty} r_k(\tau)\,\frac{x^k}{k!}, \tag{30}$$

where the coefficients depend on the parity of the index

$$r_{2m+1}(\tau) := \tau \prod_{j=1}^{m}\left(\tau^2 + (2j-1)^2\right), \qquad r_{2m}(\tau) := \prod_{j=1}^{m}\left(\tau^2 + (2j-2)^2\right).$$

By differentiating with respect to x, we obtain

$$\frac{e^{\tau \arcsin x}}{\sqrt{1-x^2}} = \frac{1}{\tau}\sum_{k=0}^{\infty} r_{k+1}(\tau)\,\frac{x^k}{k!},$$

valid for $x \in (-1,1)$. In particular, we have the important expansion (using a function G, in passing)

$$G(\tau,x) := \frac{\cosh(\tau \arcsin x)}{\sqrt{1-x^2}} = \sum_{k=0}^{\infty} g_k(\tau)\frac{x^{2k}}{(2k)!}, \tag{31}$$

[5]The $\mathcal{I}$-integral can also be written in compact terms of an *Anger function* **J** and *Weber function* **E**; see [1].

where

$$g_k(\tau) := \prod_{j=1}^{k} \left((2j-1)^2 + \tau^2\right).$$

These exp-arc expansions may be applied to the $I(p,q,\alpha,\beta)$ integrals as follows.[6] From (27) and its subsequent manipulations we have

$$I(p,q,\alpha,\beta) = e^p \int_\alpha^\beta e^{-iq\omega} e^{-2p\sin^2(\omega/2)}\, d\omega = 2e^p \int_{\sin\frac{\alpha}{2}}^{\sin\frac{\beta}{2}} \frac{e^{-2iq\arcsin x}}{\sqrt{1-x^2}} e^{-2px^2}\, dx$$

$$= i\frac{e^p}{q} \sum_{k=0}^{\infty} \frac{r_{k+1}(-2iq)}{k!} \int_{\sin\frac{\alpha}{2}}^{\sin\frac{\beta}{2}} x^k e^{-2px^2}\, dx. \tag{32}$$

Even though we eventually consider asymptotic expansions, the convergence of such an I-series is the rule.

LEMMA 11. *For $\alpha,\beta \in (-\pi,\pi)$ and any complex pair (p,q), the series* (32) *converges absolutely.*

Proof. Define $\delta := \max(|\sin(\alpha/2)|, |\sin(\beta)/2|)$ so that the integral in (32) is bounded in magnitude by $2\exp(2\Re(p))\delta^{k+1}/(k+1)$. But this means the kth summand in (32) is, up to a k-independent multiplier, bounded in magnitude by $r_{k+1}(2|q|)\delta^{k+1}/(k+1)!$. This summand is of the same form as that in the defining series (30), so absolute convergence is assured. ∎

Likewise, from (31) and (32) we have an absolutely convergent expansion for the special-case $\mathcal{I}$ integral:

$$\mathcal{I}(p,q) = 4e^p \int_0^{1/\sqrt{2}} G(-2iq,x) e^{-2px^2} = 4e^p \sum_{k=0}^{\infty} \frac{g_k(-2iq)}{(2k)!} B_k(p), \tag{33}$$

where B_k is an error–function-class integral

$$B_k(p) := \int_0^{1/\sqrt{2}} x^{2k} e^{-2px^2}\, dx = \frac{1}{2}\frac{1}{(2p)^{k+1/2}} \left\{\Gamma(k+1/2) - \Gamma(k+1/2,p)\right\}. \tag{34}$$

A computationally key recurrence relation accrues: with $B_0(p) = \sqrt{\frac{\pi}{8p}}\,\mathrm{erf}\left(\sqrt{p}\right)$ and $k > 0$, we have

$$B_k(p) := \frac{2k-1}{4p} B_{k-1} - \frac{2^{-k-3/2}}{p} e^{-p}. \tag{35}$$

5.2. Effective expansion for the cosh-arc *G*-series. Our asymptotic analysis of representation (33) begins with a lemma that reveals how the G function (31) has an attractive self-similarity property. Namely, the function appears naturally in modified form within its own error terms.

LEMMA 12. *For any complex τ, the G function* (31) *can be given an effective expansion to any integer order $N \geq 0$, as*

$$G(\tau,x) := \frac{\cosh(\tau\arcsin x)}{\sqrt{1-x^2}} = \sum_{k=0}^{N-1} g_k(\tau)\frac{x^{2k}}{(2k)!} + g_N(\tau)\frac{x^{2N}}{(2N)!}\left(1 + T_N(\tau,x)\right), \tag{36}$$

[6] An equivalent approach to expanding I uses a series for $e^{iq\omega}\sec(\omega/2)$ in terms of $x := \sin(\omega/2)$, as in [20, p. 276].

with the error term T_N conditionally bounded over real $x \in [0, 1/\sqrt{2}]$ in the form

$$\begin{aligned} T_N &= \Theta : 1 && \text{if } N \geq 2x^2|\tau|^2 - 1; \\ &= \Theta : (\sqrt{2}\ x^2 + x|\tau|)e^{|\tau| \arcsin x} && \text{otherwise.} \end{aligned}$$

Proof. The error term is, by the definition of the $g_k(\tau)$, given by the absolutely convergent sum

$$T_N = h_N + h_N h_{N+1} + h_N h_{N+1} h_{N+2} + \cdots,$$

where

$$h_k := \frac{(2k+1)^2 + \tau^2}{(2k+1)(2k+2)} x^2.$$

When $|\tau|^2 x^2 \leq (N+1)/2$ and since $x^2 \leq 1/2$, it is immediate that, for $k \geq N$, we have a bound:

$$|h_k| \leq \frac{(4k^2+4k+1)/2 + (N+1)/2}{4k^2+5k+2} \leq 1/2,$$

whence $T_N = \Theta : 1/2 + 1/4 + 1/8 + \ldots$, settling the first conditional bound of the theorem. In any case, i.e., any complex τ and any $x \in [0, 1/\sqrt{2}]$, we have for $j \geq 0$:

$$\begin{aligned} h_N h_{N+1} \cdots h_{N+j} &= x^{2j} \prod_{k=0}^{j} \frac{(2N+2k+1)^2 \left((2k+1)^2 + \tau^2 \frac{(2k+1)^2}{(2N+2k+1)^2} \right)}{(2N+2k+1)(2N+2k+2)(2k+1)^2} \\ &= \Theta : \frac{g_{j+1}(|\tau|)}{(2j+1)!!^2}. \end{aligned}$$

However, it is elementary that $(2j+1)!!^2 \geq (2j+1)!$ by simple factor-tallying, so

$$|T_N| \leq \frac{\left(1^2 + |\tau|^2\right) \cdot 2}{2!} x^2 + \frac{\left(1^2 + |\tau|^2\right)\left(3^2 + |\tau|^2\right) \cdot 4}{4!} x^4 + \ldots = x \frac{\partial}{\partial x} G(|\tau|, x),$$

where we have noticed that the right-hand series here is itself a differentiated "cosh-arc" series. Thus

$$T_N = \Theta : x \frac{\partial}{\partial x} \frac{\cosh(|\tau| \arcsin x)}{\sqrt{1-x^2}} = \Theta : \frac{x^2}{2\left(1-x^2\right)^{3/2}} \left(e^u + e^{-u}\right) + \frac{x|\tau|}{2\left(1-x^2\right)} \left(e^u - e^{-u}\right),$$

where $u := |\tau| \arcsin x$. Now by excluding $2x^2|\tau|^2 \leq N+1$ for the second conditional bound of the lemma, we have $|\tau| \geq 1$, whence the e^{-u} terms can be ignored over $x \in [0, 1/\sqrt{2}]$, and the second conditional bound follows. ∎

5.3. Effective expansion of the $\mathcal{I}$-integral. We first invoke a classical lemma that bounds the incomplete gamma function for certain parameters.

LEMMA 13. *For integer $M \geq 0$, $\Re(z) \geq 0, z \neq 0$ and $|z| \geq 2M - 1$, we have*

$$\Gamma(M + 1/2, z) = \Theta : 2z^{M-1/2} e^{-z}.$$

Proof. Proofs of results such as these on incomplete-gamma bounds appear in various texts on special functions, e.g., [27, section 2.2, p. 110]. ∎

The results of the present section may now be applied to a general, effective expansion of the $\mathcal{I}$-integral whenever $\Re(p)$ is sufficiently positive.

THEOREM 7 (effective $\mathcal{I}$ expansion). *For the integral*

$$\mathcal{I}(p,q) := I(p,q,-\pi/2,\pi/2) = \int_{-\pi/2}^{\pi/2} e^{-iq\omega} e^{p\cos\omega}\, d\omega,$$

assume an integer expansion order $N \geq 1$. Assume $\phi := \arg(p) \in (-\pi/2, \pi/2)$ and conditions

$$\Re(p) \geq 2N+1, \quad \Re(p) \geq 2\pi|q|^2.$$

Then we have an effective expansion

$$\mathcal{I}(p,q) = \sqrt{\frac{2\pi}{p}}\; e^p \left\{ \sum_{k=0}^{N-1} \frac{g_k(-2iq)}{k!\; 8^k} \frac{1}{p^k} + \Theta : \sqrt{\frac{8}{\pi p}}\; e^{-p} \cosh\left(\frac{\pi}{2}|q|\right) + \frac{g_N(-2iq)}{N!\; 8^N} \frac{1}{p^N} \left(1 + \Theta : u_N \sec^{N+1/2}\phi\right) \right\}, \tag{37}$$

where the g_k are as in the cosh-arc expansion (31)*, and we may take*

$$u_N := 1 + 2^N + \frac{2^{3N+1}}{\pi \binom{2N}{N}}\ ; \tag{38}$$

however, on the extra condition $N \geq 4|q|^2 - 1$, taking $u_N := 1$ suffices.

Proof. The insertion of the series of Lemma 12 into representation (33) results in

$$\mathcal{I}(p,q) = 4e^p \left\{ \sum_{k=0}^{N} \frac{g_k(-2iq)}{(2k)!} B_k(p) + \frac{g_N(-2iq)}{(2N)!} \int_0^{1/\sqrt{2}} x^{2N} T_N(-2iq, x) e^{-2px^2}\, dx \right\},$$

where the $B_k(p)$ are given by (34). The sum over $k \in [0, N]$ here is thus

$$\frac{1}{2} \sum_{k=0}^{N} \frac{g_k(-2iq)}{(2k)!} \frac{\Gamma(k+1/2)}{(2p)^{k+1/2}} + \Theta : e^{-p} \sum_{k=0}^{N} \frac{|g_k(-2iq)|}{(2k)!} \frac{1}{2^{k+1/2} p},$$

where the Θ-term here follows from Lemma 13 on our condition $\Re(p) \geq 2N+1$. But this very Θ-term is bounded above by

$$\frac{e^{-p}}{p\sqrt{2}} \sum_{k=0}^{\infty} \frac{g_k(2|q|)}{(2k)!} \frac{1}{2^k} = \frac{e^{-p}}{p} \cosh\left(2|q| \arcsin\left(1/\sqrt{2}\right)\right),$$

so we have settled the summation and the $\cosh(\pi|q|/2)$ term in (37). Now consider the integral term

$$I_0 := \int_0^{1/\sqrt{2}} x^{2N} T_N(-2iq, x) e^{-2px^2}\, dx.$$

Define $\gamma := |q|^{-1}\sqrt{(N+1)/8}$. If $\gamma \geq 1/\sqrt{2}$, then by Lemma 12, we know that $T_N = \Theta(1)$, and our theorem follows in the $u_N := 1$ case. Otherwise, $\gamma < 1/\sqrt{2}$, and

we bound I_0 using two integrals

$$|I_0| \le \int_0^{1/\sqrt{2}} x^{2N} e^{-2\Re(p)x^2}\, dx + \int_\gamma^{1/\sqrt{2}} \left(\sqrt{2}\, x^{2N+2} + 2|q|\, x^{2N+1}\right) e^{2|q|\arcsin x - 2\Re(p)x^2}\, dx.$$

From Lemma 1 we know that the exponent here can be taken to be $\pi|q|x/\sqrt{2} - 2\Re(p)x^2$. For the assignments $\alpha := \pi|q|/\sqrt{8},\ \beta := 2\Re(p)$, we have $\beta > 4\alpha/\gamma$ so that by Lemma 2 there is a bound

$$\begin{aligned} I_0 &\le \frac{1}{2}\frac{\Gamma(N+1/2)}{(2\Re(p))^{N+1/2}} + \sqrt{2}\, V_{N+1}(\alpha,\beta,\gamma) + 2|q|\, V_{N+1/2}(\alpha,\beta,\gamma) \\ &\le \frac{1}{2}\frac{\Gamma(N+1/2)}{(2\Re(p))^{N+1/2}} + 2^N \frac{\Gamma(N+3/2)}{(2\Re(p))^{N+3/2}} + 2^{N+1}|q|\frac{\Gamma(N+1)}{(2\Re(p))^{N+1}}. \end{aligned}$$

Using $|q|^2 \le \Re(p)/(2\pi)$, $\Re(p) \ge 2N+1$ with $\Re(p) = |p|\cos\phi$ yields the N-dependent u_N form of the theorem. □

6. Effective asymptotics for $L_n^{(-a)}(-z)$. At last we may provide explicit terms for Laguerre expansions in the subexponential-growth regime, which regime turns out to be precisely characterized by the parameter-pair requirement: $(a,z) \in \mathbb{D}$.

First, for convenience, we recapitulate the thresholds for sufficiently large $m := n+1$ from our previous theorems:

$$m_0 := |z|/4, \quad m_1 := 5\left(|\Re(z)| + (|\Im(a)| + |\Im(z)|/2)^2\right),$$
$$m_2 := \Re(a), \quad m_3 := -(5/4)|z|\cos\theta, \quad m_4 = 4|z|, \quad m_5 := |z|(1+|a|+|z|/2)^2,$$
$$m_6 := (2N+1)^2\, \frac{\sec^2(\theta/2)}{|z|}, \quad m_7 := 4\pi^2\, \frac{\sec^2(\theta/2)}{|z|}(|a|+3N-3)^4.$$

Here, $\theta := \arg(z)$ as before, while m_6, m_7 involve an asymptotic expansion order $N \ge 1$. We are aware that the m_i bounds here are interdependent, and some are masked by others (e.g., m_0 is masked by m_4). The important quantity in our central result (Theorem 8, below) is simply $\max_{i\in[0,7]} m_i$.

Before delving into the central result, let us remind ourselves of previous nomenclature:

$$g_k(\tau) := \prod_{j=1}^{k} \left((2j-1)^2 + \tau^2\right), \tag{39}$$

$$a_k := (1+a)(-1)^k \left(\frac{v\sqrt{z}}{2}\right)^k + \left(1-(-1)^k\right)\frac{k}{k+2}\left(\frac{v\sqrt{z}}{2}\right)^{k+2}, \tag{40}$$

$$\sum_{h=0}^{\infty} A_h x^h := \exp\left\{\sum_{k\ge1} \frac{a_k}{k} x^k\right\}, \tag{41}$$

$$A_h := \sum_{u=0}^{h} \alpha_{h,u}(a,z) v^{h+2u}. \tag{42}$$

Note that the $\alpha_{h,u}$ coefficients are thus implicitly defined in terms of the original a_k functions.

6.1. The general subexponential expansion. Using Theorem 7 with $p := 2\sqrt{mz}$ and inserting this into formula (25), we arrive at our desired effective Laguerre expansion.

THEOREM 8 (effective Laguerre expansion). *Assume $(a, z) \in \mathbb{D}$. For asymptotic expansion order $N \geq 1$ and $m := n + 1$ sufficiently large in the sense $m > \max_{i\in[0,7]} m_i$, we have the expansion*

$$L_n^{(-a)}(-z) = \frac{1}{2\sqrt{\pi}} \frac{e^{-z/2} e^{2\sqrt{mz}}}{z^{1/4-a/2}\ m^{1/4+a/2}} \left\{ \sum_{j=0}^{N-1} \frac{C_j}{m^{j/2}} + \frac{\overline{C}_N}{m^{N/2}} + \mathcal{E}_1 + \mathcal{E}_{3,N} \right\}, \tag{43}$$

where the expansion coefficients C_j are given in finite form:

$$C_j := \sum_{k=0}^{j} \frac{1}{16^k\ k!} \frac{1}{z^{k/2}} \sum_{u=0}^{j-k} \alpha_{j-k,u}(a, z)\, g_k(-2i(a + j - k + 2u)), \tag{44}$$

while the error term $\overline{C}_N$ is bounded as

$$\begin{aligned} \overline{C}_N = \Theta : \sum_{v=1}^{N} \frac{1}{|z|^{v/2} 16^v v!} \left(1 + u_v \sec^{v+1/2} \frac{\theta}{2}\right) \\ \sum_{u=0}^{N-v} |\alpha_{N-v,u}(a, z)\, g_v(-2i(a + N - v + 2u))| \\ + \Theta : 4(m_5/4)^{N/2} \sec^{1/2} \tfrac{\theta}{2}, \end{aligned}$$

with u_v taking the v-dependent form of (38) *in Theorem* 7 *(with $q := a$ there). Finally, the term $\mathcal{E}_1$ is subexponentially small (from Theorem* 4*), as is*

$$\mathcal{E}_{3,N} = \Theta : \sqrt{\frac{4}{\pi\sqrt{mz}}} e^{-2\sqrt{mz}} \sum_{h=0}^{N-1} \frac{1}{m^{h/2}} \sum_{u=0}^{h} |\alpha_{h,u}(a, z)| \cosh\left(\frac{\pi}{2}|a + h + 2u|\right).$$

Proof. For brevity we leave out the details—all of which are straightforward, if tedious, applications of the previous theorems and formulae. ∎

We now have a resolution of the domain of subexponential growth as follows.

COROLLARY 1. *For $(a, z) \in \mathbb{D}$, the Laguerre polynomial grows subexponentially in the sense that, for order $N \geq 1$ and any $\varepsilon > 0$,*

$$L_n^{(-a)}(-z) = S_n(a, z) \left\{ \sum_{j=0}^{N-1} \frac{C_j}{m^{j/2}} + O\left(\frac{1}{m^{N/2}}\right) + O\left(e^{-(2-\varepsilon)\sqrt{m|z|}\cos(\theta/2)}\right) \right\},$$

with all coefficients and the implied big-O constant effectively bounded via our previous theorems. Moreover, for $(a, z) \notin \mathbb{D}$, the large-n growth is not subexponential. Thus, the precise domain of subexponential growth is characterized by $(a, z) \in \mathbb{D}$.

Proof. The given subexponential formula is a paraphrase of Theorem 8. Now assume that $z \in (-\infty, 0]$. We already know that $z = 0$ does not yield such growth (see (2)). Now, for z negative real, note that the integrals in (12, 14) are both decaying in large m. Finally, the integral in (11) has phase factor $|\exp(2\sqrt{mz}\cos\omega)| \leq 1$, and Lemma 6 show that c_1 also cannot grow subexponentially in m. ∎

This corollary echoes, of course, the classical Perron result (7), and we again admit that historical efforts derived the C_j coefficients in principle. The new aspects are (a) we have asymptotic coefficients and effective bounds for general $(a, z) \in \mathbb{D}$ parameters, and (b) we can develop in a natural way an algorithm for symbolic generation of said coefficients.

6.2. Algorithm for explicit asymptotic coefficients. Theorem 8 indicates that, to obtain actual C_j coefficients, we need the cosh-arc numbers $g_k(\tau)$ and the $\alpha_{h,u}(a, z)$ coefficients. Observe that the chain of relations starting with (39) is a prescription for the generation of the C_k. All of this can proceed via symbolic processing, noting that v is simply a placeholder throughout.

Remarkably, there is a fast algorithm that bypasses much of the symbolic tedium. First, we have an explicit recursion for A_h, with $A_0 := 1$, as

$$A_k = \frac{1}{k} \sum_{j=0}^{k-1} A_j \, a_{k-j} \tag{45}$$

as follows from differentiating (41) logarithmically and then comparing terms. Second, when we use (42) together with (45), we obtain a recursion *devoid* of the symbolic placeholder v, as

$$\alpha_{k,u} = \frac{1}{k} \sum_{j=0}^{k-1} \left(\alpha_{j,u} b_{k-j} + \alpha_{j,u-1} d_{k-j} \right), \tag{46}$$

where these new recursion coefficients are

$$b_h := (-1)^h (1 + a) \left(\frac{\sqrt{z}}{2} \right)^h, \quad d_h := \left(1 - (-1)^h \right) \frac{h}{h+2} \left(\frac{\sqrt{z}}{2} \right)^{h+2}.$$

In practice we define $\alpha_{0,0} := 1$ and force any $\alpha_{j,u}$, with $u > j$ or $u < 0$ to vanish. In this sense, the collection of $\alpha_{k,u}$ make up a *lower-triangular matrix*, e.g., the entries for $k \le 3$ appear thus:

$$\begin{pmatrix} 1 & 0 & 0 & 0 \\ -\frac{(a+1)}{2} z^{1/2} & \frac{1}{12} z^{3/2} & 0 & 0 \\ \frac{a^2+3a+2}{8} z & -\frac{(a+1)}{24} z^2 & \frac{1}{288} z^3 & 0 \\ -\frac{a^3+6a^2+11a+6}{48} z^{3/2} & \frac{5a^2+15a+16}{480} z^{5/2} & -\frac{a+1}{576} z^{7/2} & \frac{1}{10368} z^{9/2} \end{pmatrix},$$

where $\alpha_{3,3}$ is the lower-right element here.

These observations lead to a fast algorithm for the computation of the asymptotic coefficients.

ALGORITHM 1 (fast computation of Laguerre asymptotic coefficients).
For given $(a, z) \in \mathbb{D}$ and desired expansion order N, this algorithm returns the asymptotic coefficients $(C_k : k \in [0, N])$ of relation (44), Theorem 8.

1. Set $\alpha_{0,0} := 1$ and, for desired order N, calculate the lower-triangular matrix elements
$(\alpha_{k,u} : 0 \le u \le k \le N)$ via a recursion such as
$\alpha(k, u)$ {

if($k == 0$) return $\delta_{0,u}$;
return $\frac{1}{k}\sum_{j=0}^{k-1}\left(\alpha_{j,u}b_{k-j} + \alpha_{j,u-1}d_{k-j}\right)$;
}
or use an unrolled, equivalent loop (i.e., one may generate the left-hand column of the α-matrix, then fill in one row at a time, lexicographically).
2. Use the recursion $g_k(\tau) = \left((2k+1)^2 + \tau^2\right) g_{k-1}(\tau)$ and the lower-triangular matrix of α values to generate the C coefficients via (44). □

We observe that the expensive sums in this algorithm are all *acyclic convolutions*. Thus, for numerical input (a, z), the algorithm complexity turns out to be $O\left(N^{2+\epsilon}\right)$ arithmetic operations, with the "2" part of the complexity power arising from the area of the lower-triangular sector.[7]

We employed the algorithm to generate exact asymptotic coefficients as follows:

$$C_0 = 1, \qquad C_1 = \frac{1}{48\sqrt{z}}\left(-12a^2 - 24za + 4z^2 - 24z + 3\right),$$
$$C_2 = \frac{1}{4608z}\left(144a^4 + 576za^3 + 480z^2a^2 + 1728za^2 - 360a^2 - 192z^3a \right.$$
$$\left. + 1152z^2a + 1584za + 16z^4 - 192z^3 + 312z^2 + 432z + 81\right),$$

and so on. Note that the C_1 form here agrees with the PAMO coefficient in (8). We were able to generate the full, symbolic $C_{64}(a, z)$ in about one minute of CPU on a typical desktop computer. To aid future researchers, we report that the numerator of C_{64} has degree 128 in both a, z, while the denominator is an integer divisible by every prime not exceeding 64, namely,

$$2^{319} \cdot 3^{94} \cdot 5^{25} \cdot 7^{13} \cdot 11^7 \cdot 13^5 \cdot 17^4 \cdot 19^3 \cdot 23^3 \cdot 29^2 \cdot 31^2 \cdot 37 \cdot 41 \cdot 43 \cdot 47 \cdot 53 \cdot 59 \cdot 61.$$

While formidable, the bivariate $C_k(a, z)$ coefficients evidently have intricate structure and patterning. Future research into said structure would be of interest.

6.3. Generating and verifying effective bounds. For the first nontrivial effective bound, we can employ the rigorous bound $\overline{C}_1$ in Theorem 8, with $N = 1$, to get an effective version of the original asymptotic (3) as

$$L_n^{(-a)}(-z) = S_n(a, z)\left(1 + \frac{\overline{C}_1}{\sqrt{m}} + \ \mathcal{E}_1 + \mathcal{E}_{3,1}\right),$$

with

$$\overline{C}_1 = \Theta : \frac{\left|1 - 4a^2\right|}{16|z|^{1/2}}\left(1 + 6\sec^{3/2}\frac{\theta}{2}\right) + 2|z|^{1/2}(1 + |a| + |z|/2)\sec^{1/2}\frac{\theta}{2},$$

and we remind ourselves that $\mathcal{E}_{3,1}$ (Theorem 8) and $\mathcal{E}_1$ (Theorem 4) are both subexponentially small.

At last we have an effective numerator, then, for the $1/\sqrt{m}$ asymptotic term. Though this effective numerator is almost surely nonoptimal, we are evidently on the right track, because the exact C_1 asymptotic coefficient above (see (8)) has very much the same form as does the Θ-expression for $\overline{C}_1$ here (i.e., the same degrees

[7]For example, floating-point FFT-based convolutions of length L require $O(L \log L)$ operations, of complexity less than $O\left(L^{1+\epsilon}\right)$.

TABLE 1

Examples of rigorous accuracy versus asymptotic order. For the indices n and parameters $(a, z) \in \mathbb{D}$, numbers $\mathcal{L}_{n,N}$ are computed via the asymptotic series through term $C_{N-1}/(n+1)^{(N-1)/2}$ as in Theorem 8. The relative error (RE) and rigorous upper bound (RRE) on the relative errors in taking these terms is reported. All decimal values are reported as correct to ± 1 in the last displayed digit of $\Re, \Im$ parts. Such rigorous bounds can be used to establish indisputable accuracies for various other functions.

n	a, z	N	Approximation $\mathcal{L}_{n,N}$ to $L_n^{(-a)}(-z)$	RE	RRE
1300	$0, -1 + 4i$	1	$(7 - i) \cdot 10^{37}$	0.0038	0.43
10^7	$0, 1$	1	$1.59 \cdot 10^{2744}$	0.00011	0.00099
		2	$1.595190 \cdot 10^{2744}$	$1.4 \cdot 10^{-9}$	$2.8 \cdot 10^{-7}$
		3	$1.5951907764 \cdot 10^{2744}$	$5.4 \cdot 10^{-13}$	$9.2 \cdot 10^{-11}$
10^6	$\frac{1}{2} + i, \frac{1}{2} + 4i$	1	$(-1.5 - 2.0i) \cdot 10^{1303}$	0.0016	0.021
		2	$(-1.565 - 2.041i) \cdot 10^{1303}$	$1.6 \cdot 10^{-6}$	$9.8 \cdot 10^{-5}$
		3	$(-1.562555 - 2.041423i) \cdot 10^{1303}$	$1.4 \cdot 10^{-9}$	$4.2 \cdot 10^{-7}$
		4	$(-1.56255567 - 2.041423269i) \cdot 10^{1303}$	$1.3 \cdot 10^{-12}$	$1.4 \cdot 10^{-9}$
		5	$(-1.56255567881 - 2.04142326969i) \cdot 10^{1303}$	$1.3 \cdot 10^{-15}$	$5.9 \cdot 10^{-12}$
10^7	$-\frac{3}{2}, 1 - 100i$	1	$(2 + i) \cdot 10^{19520}$	0.027	0.41
		2	$(1.8 + 0.9i) \cdot 10^{19520}$	0.00035	0.034
		3	$(-1.85 + 0.95i) \cdot 10^{19520}$	$3.1 \cdot 10^{-6}$	0.0028
		4	$(-1.851 + 0.957i) \cdot 10^{19520}$	$2.1 \cdot 10^{-8}$	0.00023
		5	$(-1.8510 + 0.9575i) \cdot 10^{19520}$	$1.1 \cdot 10^{-10}$	$2.0 \cdot 10^{-5}$
		10	$(-1.8509993203 + 0.9575616603i) \cdot 10^{19520}$	$7.1 \cdot 10^{-23}$	$7.6 \cdot 10^{-11}$

of appearance for a, z, and similar coefficients). And, it is easy to see that the Θ-expression here is an upper bound on $|C_1|$ itself, as must of course be true; it is necessary that $\overline{C}_N \geq |C_N|$ for every asymptotic order N.

Table 1 shows the numerical instances of our asymptotic series from Theorem 8. It displays various indices n and parameters a, z, together with corresponding asymptotic orders N from the theorem, using the following nomenclature. Denote, for asymptotic order N,

$$T_{n,N} \;:=\; 1 + \frac{C_1}{m^{1/2}} + \cdots + \frac{C_{N-1}}{m^{(N-1)/2}},$$

so, for S_n being the assignment (4), we have an approximation $\mathcal{L}_{n,N}$ defined by

$$\mathcal{L}_{n,N} \;:=\; S_n T_{n,M} \;\approx\; L_n^{(-a)}(-z).$$

Thus, $\mathcal{L}_{n,1}$ is simply S_n, as $T_{n,1} = 1$ always. How good are these $\mathcal{L}_{n,N}$ approximations? The important right-most columns of Table 1 report relative error (call it RE), with

$$\text{RE} := \left| \frac{\mathcal{L}_{n,N} - L_n^{(-a)}(-z)}{L_n^{(-a)}(-z)} \right|,$$

and a *rigorous* upper bound on relative error (call it RRE), expressed in terms of Theorem 8's various error bounds, with

$$\text{RRE} := \left| \frac{\epsilon}{T_{n,N}} \right|,$$

where $\epsilon > 0$ can be taken to be any number not exceeding $\left|\overline{C}_N/m^{N/2} + \mathcal{E}_1 + \mathcal{E}_{3,N}\right|$. Note that the three error components in this last expression are all magnitude-bounded via Theorem 8; this is how the RRE table entry was constructed.

A convenient way to view RRE is to realize that $L_n^{(-a)}(-z)$ is rigorously known to lie in the interval $\mathcal{L}_{n,N} \cdot (1 - \mathrm{RRE}, 1 + \mathrm{RRE})$. The decimal representations in Table 1 are reflexive; i.e., there is ambiguity only in the respective final digits. (When a reported value is $(a + ib) \cdot 10^c$, then both a and b are correct to within ± 1 in their respective last digits.)

One might ask about the "first-missing" asymptotic term $C_N/m^{N/2}$—a term of interest in many asymptotic theories. This term is typically close to, but often greater than, the RE. As is common to many asymptotic developments, rules about the behavior of these first-missing terms are hard to establish when parameters (in our case a, z) roam over the complex plane. In any case, the first-missing term is often an order of magnitude or more greater than the RRE. Yet this discrepancy between first-missing and RRE terms is not as harmful as might appear, as we discuss next.

6.4. Example application of effective bounds: Rigor for incomplete gamma. We have mentioned research motives in section 1.1. A worked example of *rigorous* incomplete gamma evaluations is the following. Let us use our very first entry from Table 1, namely,

$$L_{1300}^{(0)}(1 - 4i) \;\approx\; (7 - i) \cdot 10^{37},$$

with a rather large RRE = 0.43. Though this is an order of magnitude larger than the relative error, the penalty paid is only a few digits of precision for the relevant incomplete gamma. Indeed, from (5),

$$\Gamma(0, -1 + 4i) = e^{1-4i} \sum_{n=0}^{1299} \frac{1}{n+1} \frac{1}{L_n^{(0)}(1 - 4i) L_{n+1}^{(0)}(1 - 4i)} \;+\; \delta,$$

where the error δ is bounded, using RRE = 0.43 and (4), by

$$|\delta| \;<\; \frac{\left|e^{1-4i}\right|}{(1 - \mathrm{RE})^2} \sum_{n \geq 1300} \frac{1}{n+1} \frac{1}{|S_n S_{n+1}|} \;<\; 10^{-76}, \tag{47}$$

the last bound using (4) and careful estimates on the summation over $n \geq 1300$. Thence the sum for $n \in [1, 1299]$ gives a rigorous, 76–digit-accurate value for $\Gamma(0, -1 + 4i)$, $(\approx 0.497 \,+\, 0.415\, i)$. Correspondingly, the actual absolute error in using the sum over $n \in [0, 1299]$ is about 10^{-78}, so the apparently poor RRE bound brings only a 2-digit penalty.

An additional application of Theorem 8 would be to use effective bounds to rule out zeros of L_n in the crossed (a, z)-plane, that is, to establish an m_0 such that the term $1 + \overline{C}_1/\sqrt{m}$ must be positive for all $m > m_0$ (see our Open problems section).

7. Brief remarks on oscillatory regimes. The exp-arc method has led to rigorous asymptotics for subexponential growth but not for the Fejér form (6) for $z \neq 0$ on the cut $(-\infty, 0]$. Such oscillatory behavior can be dealt with, but other techniques come into play. For one thing, contour integrals must be handled differently.

7.1. When z is on the negative real cut. Even on $z \in (-\infty, 0)$ the contour prescription of Figure 1 is valid, and the Laguerre polynomial is exactly the sum

$c_1+d_1+e_1$, with $R := \sqrt{m/|z|} > 1/2$ being the only requirement for contour validity. However—and this is important—the dominant contribution (17) has to change to involve an expanded integration interval; in fact, now we must use the contour integral c_1 itself as the main contribution. For reasons of brevity, we simply state the complete asymptotic result stemming from contour integral c_1 as

$$L_n^{(-a)}(-z) \;\sim\; \frac{e^{-z/2}}{\sqrt{\pi}(-z)^{1/4-a/2}\; m^{1/4+a/2}} \times \left\{ \left(\sum_{k=0}^{\infty} \frac{A_k}{m^k} \right) \cos\left(2\sqrt{-mz} + a\pi/2 - \pi/4\right) + \left(\sum_{k=0}^{\infty} \frac{B_k}{m^{k+1/2}} \right) \sin\left(2\sqrt{-mz} + a\pi/2 - \pi/4\right) \right\}, \tag{48}$$

where these oscillatory-series coefficients are directly related to the coefficients in Theorem 8 by

$$A_k := C_{2k}(a,z), \quad B_k := iC_{2k+1}(a,z).$$

It transpires that, for a real, every A_k, B_k is real, whence the asymptotic has all real terms. The Fejér–Perron–Szegö expansion in [36, Theorem 8.22.2] for the oscillatory Laguerre mode is stated there in a fashion structurally different from our asymptotic (48); notwithstanding this Szegö's own $A_{\text{odd}}, B_{\text{even}}$—also not defined quite like ours—vanish.[8]

7.2. Brief remarks on Bessel functions I_n, J_n. There is vast literature on Bessel asymptotics [44], [39], resulting in the *Hankel asymptotic series* [1, section 9.2.5] and effective bounds on error terms (for certain parameter domains). In many cases these restricted error bounds are nevertheless optimal [44]. It is instructive to explore, at least briefly, the application of our exp-arc method to Bessel expansions. We recall (29) which leads to

$$I_n(z) = \frac{2}{\pi} \sum_{k\geq 0} \frac{g_k(-2in)}{(2k)!} \left\{ e^z B_k(z) + (-1)^n e^{-z} B_k(-z) \right\} \;\sim\; \frac{e^z}{\sqrt{2\pi z}} \sum_{k=0}^{\infty} \frac{g_k(-2in)}{k!\; 8^k} \frac{1}{z^k}, \tag{49}$$

(again we omit proofs) where the first sum is convergent, exact, and the second sum agrees with the classical Hankel asymptotic [44], [1]. For $\arg(z) \in (-\pi/2, \pi/2)$, at least, one may derive effective bounds on I_n error terms using the exp-arc techniques.

Computationalists have known for decades that one way to evaluate Bessel functions uniformly in the argument z is to use the standard ascending series for small $|z|$, but an asymptotic series for large $|z|$. However, via the exp-arc method one can establish a converging series whose evaluation only involves *a single error-function evaluation*, followed by recursion and elementary algebra. In fact, the relations (34), (35) can be used to calculate $J_n(z)$ from relation (28) via the sum

$$J_n(z) = \frac{2}{\pi} \sum_{k=0}^{\infty} g_k(-2in) \left(b_k \cos\chi - c_k \sin\chi \right), \tag{50}$$

[8] Our oscillatory asymptotic (48) has been verified to several terms by Temme; also he verifies our claim that the classical Szegö coefficients do vanish for the parities indicated [38].

with

$$\chi := z - \pi n/2 - \pi/4, \quad b_k := B_k(iz)e^{i\pi/4} + B_k(-iz)e^{-i\pi/4}, \quad ic_k := B_k(iz)e^{i\pi/4} - B_k(-iz)e^{-i\pi/4}.$$

Note that if z is real, then each b_k, c_k is real, whence our series here has all real terms. Note that our recursion (35) likewise ignites a recursion amongst the b_k, c_k.

Note that (50) is actually the Hankel asymptotic if we replace B_k by its first term in (34), namely, $(1/2)(2iz)^{-k-1/2}\Gamma(k+1/2)$; however, we already know that the sum (50) is always convergent. It is remarkable that we are using the same structure as the classical asymptotic, yet convergence for all complex z is guaranteed. Moreover, the $B_k(iz)$ are independent of the order n and so can be reused if multiple $J_n(z)$ are desired for fixed z.

Those acquainted with the intricacies of Bessel theory may observe that our convergent expansion (49) is at least reminiscent of the convergent *Hadamard expansion* found in [44, p. 204] for the modified Bessel function I_ν. Though both expansions are absolutely convergent, there are some important differences between this Hadamard expansion and our exp-arc forms (49, 50). For example, we have given our convergent sum only for integer ν. Moreover, the exp-arc expansion is geometrically convergent, while the Hadamard expansion is genuinely slower.

The research area of convergent expansions related to classical, asymptotic ones has been pioneered in large part by Paris, whose works cover real and complex domains, saddle points, and the like [29], [30], [31], [32], [33], [34]. We should point out that Paris was able to develop within the last decade some similar, linearly convergent Bessel series by modifying the "tails" of Hadamard-class series. Finally,we note that the problem of generalizing such unconditionally convergent series as our (50) to noninteger indices—and with comparison to the recent work of Paris—is analyzed in a new work [3].

8. Open problems.

- How might one proceed with the exp-arc theory to obtain effective error bounds for oscillatory Laguerre modes and-or oscillatory Bessel modes? We know that previous researchers have described how to give effective bounds in these cases (e.g., to our asymptotic (48), as in [36, section 8.72]), but once again we stress, How can this be done explicitly and for full parameter ranges?
- Where are the zeros in the complex z-plane—for fixed a—of $L_n^{(-a)}(-z)$? Are "most of" the zeros along some a-dependent ray, in some sense? There is a considerable literature on this zero–free-region topic, especially for polynomials in real variables. For example, with $a := 0$ the Laguerre zeros are all real and negative; see [24, Chapter X] and references therein. There is also an interesting connection between Laguerre zeros and eigenvalues of certain (large) matrices [15]. Certainly the theorems of the Saff–Varga type are relevant in this context [24, Theorem 11].
- How can Laguerre asymptotics be gleaned from standard recurrence relations amongst the $L_n^{(-a)}(-z)$? One may ask the same question for the Laguerre differential equation as starting point. A promising research avenue for a discrete-iterative approach to asymptotics is [43]; see also [4] for the asymptotic analysis of certain complex continued fractions. As for differential-equation approaches, there is the classical work of Erdélyi and Olver, plus modern work on the combinations of differential, discrete, and saddle-point theory [16], [18].

- The efficient "keyhole" contour of Figure 1 was discovered experimentally. What other analytical problems might be approached in this fashion? For that matter, how might one properly use the celebrated Watson loop-integral lemma with error term [27, Theorem 5.1] on our keyhole contour to obtain similar effective asymptotics?
- Here is a scenario suggested by Temme [38]. When n is small (in some sense not made rigorous here), and, say, $|z| \ll |a|$, one should expect an asymptotic behavior

$$L_n^{(-a)}(-z) \sim \binom{n-a}{n} \left(1 + \frac{z}{1-a}\right)^n.$$

The problem is, How does one make this rigorous, with effective error bounds?

Acknowledgments. We are indebted to J. Buhler, R. Mayer, O-Yeat Chan, R. Paris, and N. Temme for the generous lending of expertise, ideas, and suggestions. We are equally grateful to two referees for their insightful remarks.

EFFECTIVE LAGUERRE ASYMPTOTICS*

DAVID BORWEIN†, JONATHAN M. BORWEIN‡, AND RICHARD E. CRANDALL§

Abstract. It is known that the generalized Laguerre polynomials can enjoy subexponential growth for large primary index. In particular, for certain fixed parameter pairs (a, z) one has the large-n asymptotic behavior

$$L_n^{(-a)}(-z) \sim C(a,z) n^{-a/2-1/4} e^{2\sqrt{nz}}.$$

We introduce a computationally motivated contour integral that allows efficient numerical Laguerre evaluations yet also leads to the complete asymptotic series over the full parameter domain of subexponential behavior. We present a fast algorithm for symbolic generation of the rather formidable expansion coefficients. Along the way we address the difficult problem of establishing effective (i.e., rigorous and explicit) error bounds on the general expansion. A primary tool for these developments is an "exp-arc" method giving a natural bridge between converging series and effective asymptotics.

Key words. Laguerre polynomials, effective asymptotic expansions, contour integrals

1. The challenge of "effectiveness." For primary integer indices $n = 0, 1, 2, \ldots$, we define the Laguerre polynomial thus:

$$L_n^{(-a)}(-z) := \sum_{k=0}^{n} \binom{n-a}{n-k} \frac{z^k}{k!}. \tag{1}$$

Our use of negated parameters $-a, -z$ is intentional, for convenience in our analysis and in connection with related research, as we later explain. We shall work on the difficult problem of establishing asymptotics *with* effective error bounds for the two-parameter domain

$$\mathbb{D} := \{(a,z) \in \mathbb{C} \times \mathbb{C} : z \notin (-\infty, 0]\}.$$

That is, a is any complex number, while z is a complex number not on the negative-closed cut $(-\infty, 0]$.

Herein, we say a function $f(n)$ is of *subexponential* growth if $\log f(n) \sim Cn^D$ as $n \to \infty$ for positive constants C, D, with $D < 1$. It will turn out that $\mathbb{D}$ is the precise domain of subexponential growth of $L_n^{(-a)}(-z)$ as $n \to \infty$, with (a, z) fixed. The reason for the negative-cut exclusion on z is simple: For z negative real, the Laguerre polynomial exhibits oscillatory behavior in large n and is not of subexponential growth. Note also, from the definition (1), that

$$L_n^{(-a)}(0) = \binom{n-a}{n}, \tag{2}$$

which covers the case $z = 0$; again, not subexponential growth.

For fixed $(a,z) \in \mathbb{D}$, we shall have the large-n behavior (here and beyond we define $m := n+1$ which will turn out to be a natural reassignment):

$$L_n^{(-a)}(-z) \;\sim\; S_n(a,z)\left(1 + O\left(\frac{1}{m^{1/2}}\right)\right), \tag{3}$$

where the subexponential term S_n is

$$S_n(a,z) \;:=\; \frac{e^{-z/2}}{2\sqrt{\pi}}\,\frac{e^{2\sqrt{mz}}}{z^{1/4-a/2}\;m^{1/4+a/2}}. \tag{4}$$

In such expressions, $\Re\,(\sqrt{mz})$ denotes $\sqrt{m|z|}\cos(\theta/2)$, where $\theta := \arg(z) \in (-\pi,\pi]$ (we hereby impose $\arg(-1) := \pi$), and so for $(a,z) \in \mathbb{D}$, the expression (4) involves genuinely diverging growth in n.

1.1. Research motives. There are many interdisciplinary applications of Laguerre asymptotics. The Laguerre functions appear standardly in the quantum theory of the hydrogen atom [46, Chapter 4] and in certain exactly solvable three-body problems of chemical physics [13], [14]. The so-called WKB phase of a quantum eigenstate can, in such cases and for high quantum numbers, be calculated via Laguerre asymptotics. The Hermite polynomials $H_n(x)$—closely related to the Laguerre polynomials $L_n^{(\pm 1/2)}(x^2)$—also figure in quantum analyses; e.g., one may derive Hermite asymptotics from Laguerre asymptotics. In this context there is the fascinating López–Temme representation of *any* $L_n^{(-a)}(-z)$ as a finite superposition of Hermite evaluations [23].

Our own research motive for providing effective asymptotics involves not the Laguerre–Hermite connection, rather it begins with a beautiful link to the incomplete gamma function, namely, [19]

$$\Gamma(a,z) \;=\; z^a e^{-z}\cfrac{1}{z+\cfrac{1-a}{1+\cfrac{1}{z+\cfrac{2-a}{1+\cdots}}}} \;=\; z^a e^{-z}\sum_{n=0}^{\infty}\frac{(1-a)_n}{(n+1)!}\,\frac{1}{L_n^{(-a)}(-z)\,L_{n+1}^{(-a)}(-z)}, \tag{5}$$

where $(c)_n := c(c+1)\cdots(c+n-1)$ is the *Pochhammer symbol*. This series is valid whenever none of the Laguerre denominators has a zero. Thus an interesting sidelight is the research problem of establishing zero-free regions for Laguerre polynomials (see our Open problems section). We note that convergence of the continued-fraction can be highly problematic, especially when the full complex parameter space is allowed. One might encounter smooth convergence, or steady divergence, or even chaotic divergence, all of which possibilities are exemplified in [7, 8, 9, 22].

The problem, then, of general Laguerre asymptotics arises because there is a way to write Riemann zeta-function evaluations $\zeta(s)$ in terms of the incomplete gamma function, as was known to Riemann himself [40, p. 22]. But when s has large imaginary height, one becomes interested in the incomplete gamma's corresponding complex parameters (a,z) also of possibly large imaginary height [11], [12]. For example, in the art of prime-number counting, say, for primes $< 10^{20}$, one might need to know, for example, $\Gamma\left(3/4 + 10^{10}\,i, z\right)$ for various z also of large imaginary height, to good precision, in order to evaluate $\zeta(s)$ high up on the line $\Re(s) = 3/2$. The point is,

exact computations on prime numbers must, of course, employ rigor—hence the need for effective error bounds.

Independent of Riemann-ζ considerations is the following issue: Continued-fraction theory is to this very day incomplete in a distinct sense. The vast majority of available convergence theorems are for Stieltjes, or S-fractions. Now the continued fraction in (5) is an S-fraction only when the a parameter is real [24, p. 138]. Due to the relative paucity of convergence theorems outside the S-fraction class, one encounters great difficulty in estimating the convergence rate for arbitrary $\Gamma(a,z)$; this is what led to our focus on the Laguerre asymptotics. Incidentally, we are aware that subexponential convergence results *might* be attainable via the complicated and profound work of Jacobsen and Thron [21] on oval convergence regions. In any case, our effective-Laguerre approach proves the subexponential convergence of $\Gamma(a,z)$ for any complex pairs $(a,z)\in\mathbb{D}$; moreover, this is done with effective constant factors. Separate research on these superexponential convergence issues for continued fractions is underway.

1.2. Historical results on Laguerre asymptotics. Laguerre asymptotics have long been established for certain restricted domains and usually with noneffective asymptotics.[1] For example, in 1909 Fejér established that, for z on the open cut $(-\infty,0)$ and any real a, one has [36, Theorem 8.22.1]:

$$L_n^{(-a)}(-z)=\frac{e^{-z/2}}{\sqrt{\pi}(-z)^{1/4-a/2}\ m^{1/4+a/2}}\cos\left(2\sqrt{-mz}+a\pi/2-\pi/4\right)+O\left(m^{-a/2-3/4}\right), \tag{6}$$

where we again use index $m:=n+1$, which slightly alters the coefficients in such classical expansions, said coefficients being for powers $n^{-k/2}$, but we are now using powers $m^{-k/2}$. By 1921 Perron [35] had generalized the Fejér series to arbitrary orders, then, for $z\notin(-\infty,0]$, established a series consistent with (3) and (4), in essentially the form [36, Theorem 8.22.3]:

$$L_n^{(-a)}(-z)=S_n(a,z)\left(\sum_{k=0}^{N-1}\frac{C_k}{m^{k/2}}+O\left(m^{-N/2}\right)\right), \tag{7}$$

although this was for *real* a and so not for our general parameter domain $\mathbb{D}$. Note that $C_0=1$, consistent with our (3) and (4); however, one should take care that because we are using index $m:=n+1$, the coefficients C_k in the above formula differ slightly from the historical ones.

A modern literature treatment that is again consistent with the heuristic (3)–(4) is given by Winitzki in [45], where one invokes a formal generating function to yield a contour integral for $L_n^{(-a)}(-z)$. Then a stationary-phase approach yields the correct first-asymptotic term, at least for certain subregions of $\mathbb{D}$. Winitzki's treatment is both elegant and nonrigorous; there is no explicit estimate given on the $O(1/\sqrt{m})$ correction in (3).

There is an interesting anecdote that reveals the difficulty inherent in Laguerre asymptotics. Namely, W. Van Assche in a fine 1985 paper [41] used the expansion

[1] Some researchers use the term "realistic error bound" for big-O terms that have explicit structure. We prefer "effective bound," and when an expansion is bestowed with such a bound, we may say "effective expansion."

(7) for work on zero-distributions, only to find by 2001 that the C_1 term in that 1985 paper had been calculated incorrectly. The amended series is given in his correction note [42] as

$$L_n^{(-a)}(-z) = \frac{e^{-z/2}}{2\sqrt{\pi}} \frac{e^{2\sqrt{nz}}}{z^{1/4-a/2}\, n^{1/4+a/2}} \cdot \left(1 + \left(\frac{3 - 12a^2 + 24(1-a)z + 4z^2}{48\sqrt{z}}\right) \frac{1}{\sqrt{n}} + O\left(\frac{1}{n}\right)\right),$$

or in our own notation with $m := n + 1$,

$$= S_n(a,z) \left(1 + \left(\frac{3 - 12a^2 - 24(1+a)z + 4z^2}{48\sqrt{z}}\right) \frac{1}{\sqrt{m}} + O\left(\frac{1}{m}\right)\right). \tag{8}$$

Note the slight alteration used to obtain our $C_1/\sqrt{m}$ term. Van Assche credits T. Müller and F. Olver for aid in working out the correct $O(1/\sqrt{n})$ component.[2] This story suggests that even a low-order asymptotic development is nontrivial.

The great classical analysts certainly knew in principle how to establish effective error bounds. The excellent treatment of effectiveness for Laplace's method of steepest descent in [27] is a shining example. Also illuminating is Olver's paper [26], which explains effective bounding and shows how unwieldy rigorous bounds can be obtained. However, efficient algorithms for generating *explicit* effective big-O constants have only become practicable in recent times, when computational machinery is prevalent.

2. Contour representation. In this section we develop an efficient—both numerically and analytically—contour-integral representation for $L_n^{(-a)}(-z)$.

2.1. Development of a "keyhole" contour. A well-known integral [36, section 5.4] has contour Γ encircling $s = 1$ and avoiding the branch cut $(-\infty, 0]$:

$$L_n^{(-a)}(-z) = \frac{e^{-z}}{2\pi i} \oint_\Gamma s^{-1-a} \left(1 - \frac{1}{s}\right)^{-n-1} e^{zs}\, ds. \tag{9}$$

This representation holds for all pairs $(a, z) \in \mathbb{C} \times \mathbb{C}$, with n a nonnegative integer.[3]

However—and this is important—we found via experimental mathematical techniques, e.g., extreme-precision evaluations, that a specific kind of contour allows very accurate, efficient, and well-behaved *numerical* Laguerre evaluations. It is not completely understood why the "keyhole" contour we are about to define does so well in numerical Laguerre evaluations; we do know that this new contour consistently provides better numerics than, say, a simple circle surrounding $s = 1$. It may be simply the internal quirks of various modern numerical integrators at work, or it may be the smooth phase behavior along our keyhole's perimeter.

For the desired contour, take $z \neq 0$, $m := n + 1$ and assume $r := \sqrt{m/z}$ has $|r| > 1/2$. Then, use a circular contour centered at $s = 1/2$ with radius $|r|$. This contour will encompass $s = 1$, so the remaining requirement is to avoid the cut $s \in (-\infty, 0]$ as can be done by cutting out a "wedge" from the negative-real arc of the circle, with apex at $s = 1/2$. We tried such schemes with high-precision integration, to

[2] Accordingly, we hereby name the polynomial $C_1(a, z)$ the Perron–van Assche–Müller–Olver (PAMO) coefficient.

[3] The contour representation (9) can easily be continued to noninteger n, with care taken on the $(-n-1)$th power, but our present treatment will only use nonnegative integer n.

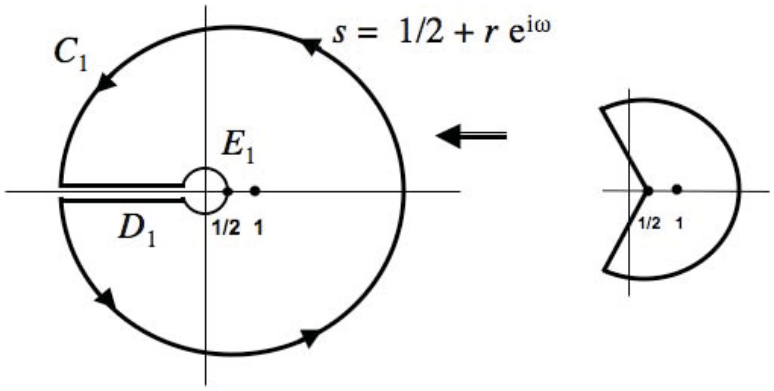

FIG. 1. *A numerically efficient "keyhole contour" for Laguerre evaluations $L_n^{(-a)}(-z)$, valid for all complex a, z, with $z \neq 0$ and $n+1 > |z|/4$. Wedges with center-1/2—as pictured at right—are experimentally accurate, leading to a "keyhole" deformation avoiding the cut $s \in (-\infty, 0]$. It turns that, for any $(a, z) \in \mathbb{D}$, the main arc C_1 gives the predominant contribution for large n, the D_1, E_1 components being subexponentially minuscule.*

settle finally on the contour of Figure 1, where the aforementioned wedge has evolved to a "keyhole" pattern consisting of cut-run D_1 and small, origin-centered circle E_1 of radius 1/2.

So, adopting constraints and nomenclature

$$z \neq 0, \quad \theta := \arg(z), \quad \omega_\pm := \pm\pi + \theta/2,$$
$$m := n + 1, \quad r := \sqrt{m/z} := \sqrt{m/|z|}e^{-i\theta/2}, \quad R := |r| > 1/2,$$

but no other constraints, we have the following representation:

$$L_n^{(-a)}(-z) = c_1 + d_1 + e_1, \tag{10}$$

where c_1, d_1, e_1 are the respective contributions from contour C_1, cut-discontinuity D_1, and contour E_1 from Figure 1. Exact formulae for said contributions are

$$c_1 = \frac{1}{2\pi} r^{-a} e^{-z/2} \int_{\omega_-}^{\omega_+} \mathcal{H}_m(a, z, e^{-i\omega}) e^{2\sqrt{mz}\cos\omega}\, d\omega, \tag{11}$$

$$d_1 = \frac{e^{-z}}{\pi} \sin(\pi a) \int_{1/2}^{R-1/2} T^{-1-a} \left(1 + \frac{1}{T}\right)^{-m} e^{-zT}\, dT, \tag{12}$$

$$e_1 = -\frac{e^{-z}}{4\pi} \int_{-\pi}^{\pi} \left(2e^{-i\omega}\right)^{1+a} \left(1 - 2e^{-i\omega}\right)^{-m} e^{i\omega + \frac{z}{2}e^{i\omega}}\, d\omega, \tag{13}$$

and when $m > \Re(a)$, we may write this last contribution, by shrinking down the radius-1/2 contour segment to embrace the cut $(-1/2, 0]$, as

$$e_1 = \frac{e^{-z}}{\pi} \sin(\pi a) \int_0^{1/2} T^{-1-a} \left(1 + \frac{1}{T}\right)^{-m} e^{-zT}\, dT. \tag{14}$$

For the c_1 contribution above, we have used the function $\mathcal{H}_m$ defined by

$$\mathcal{H}_m(a, z, v) := v^a \left(1 + \frac{v}{2r}\right)^{-1-a} \left[F\left(\frac{v}{r}\right)\right]^m, \tag{15}$$

$$F(t) := \left(\frac{1 + t/2}{1 - t/2}\right) e^{-t}, \tag{16}$$

which for small t can be written $F(t) = 1 + t^3/12 + t^5/80 + \cdots = 1 + O(t^3)$.

In any event, e_1, like d_1, is subexponentially small relative to c_1 for large n and $(a,z) \in \mathbb{D}$. It is to be stressed that decomposition (10) holds for all $(a,z) \in \mathbb{C} \times \mathbb{C}, z \neq 0$, as long as $m := n + 1 > |z|/4$. We remind ourselves of (2) for $z = 0$. This means that such contour calculus applies to both oscillatory (Fejér) cases, where z is negative real, and subexponential (Perron) cases for the stated parameters.

2.2. Numerical success on the keyhole contour. The triumvirate c_1, d_1, e_1 of integrals is suitable for accurate Laguerre computations, which computations do show that *integrals d_1, e_1 tend to be subexponentially small* relative to c_1. This, of course, is our motive for so identifying the contour terms. An example, using the defining series (1) with $(a,z) := (-i, -1-i)$ is

$$L_8^{(i)}(1+i) \;=\; -\frac{137}{288} + \frac{53}{45} i \;\approx\; -0.475694444444444444 + 1.177777777777777777 i,$$

while the contributions from the C_1, D_1, E_1 segments of the contour of Figure 1 are

$$\begin{aligned} c_1 &\approx -0.44406762576110996056 + 0.81722282272705891241 i, \\ d_1 &\approx -0.03169598827425878852 + 0.36065591639721657587 i, \\ e_1 &\approx 0.00006916959092430464 - 0.00010096134649771051 i, \end{aligned}$$

with the sum $c_1 + d_1 + e_1$ giving $L_8^{(i)}(1+i)$ to the implied precision.

Remarkably, this "keyhole-contour" approach has the additional, unexpected feature that, for some parameter regions, the contour evaluation of $L_n^{(a)}(-z)$ is actually *faster* than direct summation of the defining series (1). A typical example is as follows: For the 13-digit evaluation

$$L_{50000}^{(25i/2)}(-30+3i) \approx (0.9275136583293 + 1.7406691595239 i) \times 10^{1056},$$

the defining series (1) was, in our trials, slower than the integral c_1.[4]

3. Effective bounds on the contour components.

3.1. Theta-calculus. We now introduce a notation useful in effective-error analysis. When two functions enjoy

$$|f(z)| \leq |g(z)|$$

over some relevant domain of z values, we shall say that

$$f(z) = \Theta(g(z)), \quad \text{or} \quad f(z) = \Theta : g(z)$$

on said domain. Thus, the Θ-notation is an effective replacement for big-O notation. The reason for allowing the notation $\Theta : \ldots$ is that a long formula g can run arbitrarily to the right of the colon.

Incidentally, there is a literature precedent for such a "theta-calculus." Namely, in computational number theory treatments such as [10], one encounters terms such as, say, $\theta x/\log^2 x$, with a stated constraint $\theta \in [-10, 10]$. This means the term is $O(x/\log^2 x)$ but with effective big-O constant bounded in magnitude by 10. In our nomenclature we would use $\Theta : 10x/\log^2 x$.

[4] Of course, series acceleration as in [5] would give the direct series a "leg up." Still, it is remarkable that contour integration is competitive. For the record, we compared *Mathematica*'s numerical integration to its own `LaguerreL[ ]` function.

3.2. Effective bound for e_1. First we address the integral e_1 as given in relation (13). We need some preliminary lemmas, starting with a collection of polynomial estimates to transcendental functions.

LEMMA 1. *The following inequalities hold for the respective conditions on ω:*

$$\log(5-4\cos\omega) \geq \frac{\log 9}{\pi^2}\omega^2, \quad \omega \in [-\pi,\pi];$$
$$\log(1+\omega) \geq \frac{4}{5}\omega, \quad \omega \in [0,1/2];$$
$$\arcsin\omega \leq \frac{\pi}{\sqrt{8}}\omega, \quad \omega \in [0,1/\sqrt{2}];$$
$$\cos\omega \leq 1-\frac{4}{\pi^2}\omega^2, \quad \omega \in [-\pi/2,\pi/2].$$

Proof. All four are straightforward calculus exercises. □

LEMMA 2. *Consider integrals of error-function class, specifically, for nonnegative real parameter μ,*

$$V_\mu(\alpha,\beta,\gamma) := \int_\gamma^\infty (x^2)^\mu e^{2\alpha x-\beta x^2}\, dx,$$

where each of α,β,γ is real, with $\alpha,\beta>0$. Then we always have the bound

$$V_0(\alpha,\beta,\gamma) = \Theta : \sqrt{\frac{\pi}{\beta}}\; e^{\frac{\alpha^2}{\beta}}.$$

If in addition $\gamma > 2\alpha/\beta$, we also have

$$V_\mu(\alpha,\beta,\gamma) = \Theta : \frac{1}{2}\; \frac{\Gamma(\mu+1/2)}{(\beta-2\alpha/\gamma)^{\mu+1/2}};$$

finally, if $\gamma > 4\alpha/\beta$, we have

$$V_\mu(\alpha,\beta,\gamma) = \Theta : \; 2^{\mu-1/2}\; \frac{\Gamma(\mu+1/2)}{\beta^{\mu+1/2}}.$$

Remark. We use the double-exponential $(x^2)^\mu$ because the first case of the theorem allows $\gamma<0$.

Proof. Completing the exponent's square gives the first bound easily, since

$$V_0 = e^{\alpha^2/\beta}\int_\gamma^\infty e^{-\beta(x-\alpha/\beta)^2}\, dx \;=\; \Theta : \sqrt{\pi/\beta}.$$

For the second bound, it is elementary that, for $x\geq\gamma$, one has $2\alpha x-\beta x^2 \leq x^2(2\alpha/\gamma-\beta)$ so that

$$V_\mu \leq \int_0^\infty x^{2\mu} e^{-(\beta-2\alpha/\gamma)x^2}\, dx,$$

and the resulting bound follows. The final bound follows immediately from the previous bound, because $\gamma > 4\alpha/\beta$ implies $\beta-2\alpha/\gamma > \beta/2$. □

THEOREM 1. *The contour contribution e_1 defined by* (13)*, under conditions $(a,z) \in \mathbb{D}$ and m sufficiently large in the explicit sense $m := n+1 > m_0 := |z|/4,\ \ m > m_1 := 5\left(|\Re(z)| + (|\Im(a)| + |\Im(z)|/2)^2\right)$, is bounded as*

$$e_1 = \Theta : e^{-z/2} 2^{\Re(a)+3} \frac{1}{\sqrt{m}}.$$

Moreover, under alternative conditions $(a,z) \in \mathbb{D}$ and $m > m_0, \quad m > m_2 := \Re(a), \quad m > m_3 := -\frac{5}{4}|z|\cos\theta$ we have a bound

$$e_1 = \Theta : \frac{e^{-z}}{\pi} \sin(\pi a) \frac{2^{\Re(a)-m}}{m - \Re(a)}.$$

Proof. The proof involves careful application of Lemmas 1 and 2 to the integral forms (13), (14); for brevity we omit these details. □

3.3. Effective bound for d_1. Again we need an opening lemma.

LEMMA 3. *Consider integrals of the incomplete-Bessel class, specifically*

$$W(\alpha,\beta) := \int_0^1 e^{-\alpha x - \frac{\beta}{x}}\ \frac{dx}{x},$$

where each of α, β is real, with $\beta > 0$. If $\beta > \alpha$, we have a bound

$$W = \Theta : \frac{1}{2} e^{-\beta-\alpha} \sqrt{\frac{\pi}{\beta}}.$$

Proof. We write

$$W(\alpha,\beta) = \int_0^1 e^{\beta x - \alpha x}\, e^{-\beta x - \frac{\beta}{x}}\ \frac{dx}{x} \le e^{\beta-\alpha} \int_0^1 e^{-\beta x - \frac{\beta}{x}}\ \frac{dx}{x}.$$

This last integral is a modified-Bessel term $K_0(2\beta)$ and has the required bound [2, Lemma 1]. □

THEOREM 2. *The contour contribution d_1 defined by* (12) *can be bounded, under conditions $(a,z) \in \mathbb{D}$ and $m > m_4 := 4|z|$, as*

$$d_1 = \Theta : \frac{e^{-z/2}}{\sqrt{\pi}} m^{|\Re(a)|/2 - 1/4} |z|^{-|\Re(a)|/2 - 1/4} \sin(\pi a) e^{-2\sqrt{m|z|}\cos^2\frac{\theta}{2}}.$$

Proof. Starting from (12) one applies Lemma 3; again for brevity we omit the details. □

3.4. Rigorous estimates on c_1. Having dispensed with d_1, e_1, we next show the integration limits ω_-, ω_+ on the c_1 contribution can be changed—with a subexponentially small error penalty—to $-\pi/2, \pi/2$, respectively.

LEMMA 4. *For any v on the unit circle $\{e^{i\phi} : \phi \in (-\pi, \pi]\}$, any complex a, and any real $R > (1+|a|)/2$ we have*

$$\left| \left(1 + \frac{v}{2R}\right)^{-1-a} \right| \le \frac{1}{1 - \frac{1+|a|}{2R}}.$$

Proof. Via the binomial theorem,

$$\left| \left(1 + \frac{v}{2R}\right)^{-1-a} \right| \le 1 + (1+|a|)\frac{1}{2R} + (1+|a|)^2 \left(\frac{1}{2R}\right)^2 + \cdots = \frac{1}{1 - \frac{1+|a|}{2R}}. \qquad \square$$

LEMMA 5. *Let v be on the unit circle as in Lemma 4, let $R > 1$ be real, and let m be a positive integer. For the function F appearing in* (16)*, we have the bound*

$$\left| F\left(\frac{v}{R}\right)^m \right| \leq e^{\frac{1}{6}\frac{m}{R^3}}.$$

Proof. From the definition (16) we have

$$F(v/R)^m = e^{\frac{1}{12}\frac{m}{R^3}(1+(3/5)/(2R)^2+(3/7)/(2R)^4+\cdots)}.$$

For $R := 1$, the infinite sum is no larger than 1.18 and is monotonic decreasing in R. □

LEMMA 6. *Let v be on the unit circle as in Lemma 4 and define for nonnegative integer m*

$$K := \left(1+\frac{v}{2R}\right)^{-1-a} F\left(\frac{v}{R}\right)^m.$$

For the assignments $(a, z) \in \mathbb{C} \times \mathbb{C}, z \neq 0, R := \sqrt{m/|z|} > 1, m > m_5 := |z|(1 + |a| + |z|/2)^2$, we have

$$K = \Theta : 2.$$

Proof. From Lemmas 4 and 5 we have

$$|K| \leq \frac{1}{1-\frac{1+|a|}{2(1+|a|+|z|/2)}} e^{\frac{1}{6}\frac{|z|}{1+|a|+|z|/2}}.$$

The fact that the right-hand side is $\Theta(2)$ follows from the observation that the function

$$\frac{1}{1-\frac{Q}{2Q+x}} e^{\frac{1}{3}\frac{x}{2Q+x}}$$

for $Q \geq 1, x \in [0, \infty)$ is itself $\Theta(2)$. This in turn follows easily on substituting $y := x/(2Q + x)$. Now the function to be bounded is $g(y) := (2/(1 + y))e^{y/3}$ on $y \in [0, 1/2]$—as differentiation settles. □

These lemmas in turn allow us to contract the range on the c_1 contour integral.

THEOREM 3. *Decompose c_1 as defined by* (11) *into two terms,*

$$c_1 := c_0 + c_2,$$

with c_0 involving the integral's range contracted to $[-\pi/2, \pi/2]$, namely,

$$c_0 := \frac{1}{2\pi} r^{-a} e^{-z/2} \int_{-\pi/2}^{\pi/2} \mathcal{H}_m(a, z, e^{-i\omega}) e^{2\sqrt{mz}\cos\omega}\, d\omega.$$

Then, under conditions $(a, z) \in \mathbb{D}$ and $m > m_5 := |z|(1 + |a| + |z|/2)^2$, we have a bound

$$c_2 = \Theta : r^{-a} e^{-z/2} e^{\frac{3}{2}\pi|\Im(a)|}.$$

Proof. It is evident that c_2 is obtained from the definition (11) but with the integral replaced via

$$\int_{\omega_-}^{\omega_+} \to \left\{ \int_{\omega_-}^{-\pi/2} + \int_{\pi/2}^{\omega_+} \right\}.$$

Over these domains of integration, we have $e^{2\sqrt{mz}\cos\omega} = \Theta(1)$. Thus, Lemmas 4, 5, and 6 show

$$c_2 = \Theta : \frac{1}{2\pi} r^{-a} e^{-z/2} \left\{ \int_{\omega_-}^{-\pi/2} + \int_{\pi/2}^{\omega_+} \right\} 2 \left| e^{-i\omega a} \right| \, d\omega.$$

As the total support of the integrals cannot exceed π, the desired c_2 bound follows. □

3.5. Summary of the contour decomposition for $L_n^{(-a)}(-z)$. The above manipulations lead to the main result of the present section, namely, a formula that decomposes the Laguerre evaluation, as in the following.

THEOREM 4 (contour decomposition). *Let $(a, z) \in \mathbb{C} \times \mathbb{C}$ be an arbitrary parameter pair, with $z \neq 0$ (with $z = 0$ cases resolved exactly by (2)). If $m := n + 1 = m_0 > |z|/4$, then the contour decomposition*

$$L_n^{(-a)}(-z) = c_0 + \mathcal{E}$$

holds, with c_0, c_2 as defined in Theorem 3 and $\mathcal{E} := c_2 + d_1 + e_1$. If an appropriate set of conditions on m across Theorems 1, 2, and 3 *holds, then we can write*

$$L_n^{(-a)}(-z) = c_0 + S_n(a, z)\mathcal{E}_1,$$

where $\mathcal{E}_1$ is subexponentially small, in the sense that, for any fixed positive ϵ, the large-n behavior is

$$\mathcal{E}_1 = O\left(e^{-(2-\epsilon)\sqrt{m|z|}\cos\frac{\theta}{2}} \right).$$

Moreover, an effective big-O constant is available (the proof exhibits explicit forms).

Proof. The contour calculus holds for all complex pairs (a, z), with $z \neq 0, R := \sqrt{m/|z|} > 1/2$, which assures that the point 1 is contained in the contour. It remains to analyze $\mathcal{E}_1$. Consider, then, an appropriate union of conditions from the cited theorems, say, $(a, z) \in \mathbb{D}$ and $m > \max(m_0, m_1, m_2, m_3, m_4, m_5)$, in which case we have, from Theorems 1, 2, and 3 (in that respective order of Θ terms):

$$\mathcal{E}_1 = \Theta : \frac{e^{-z/2}}{\sqrt{\pi}} \sin(\pi a) \frac{2^{1+\Re(a)-m}}{m - \Re(a)} z^{1/4-a/2} m^{1/4+a/2} e^{-2\sqrt{m|z|}\cos\frac{\theta}{2}}$$

$$+\Theta : 2 \left(\frac{m}{|z|} \right)^{(\Re(a)+|\Re(a)|)/2} e^{\frac{3}{2}\pi|\Im(a)|} e^{-2\sqrt{m|z|}\left(\cos^2\frac{\theta}{2} + \cos\frac{\theta}{2}\right)}$$

$$+\Theta : 2\sqrt{\pi}\, |mz|^{1/4} e^{\frac{3}{2}\pi|\Im(a)|} e^{-2\sqrt{m|z|}\cos\frac{\theta}{2}}.$$

This explicit bounding of the error term $\mathcal{E}_1$ proves the big-O statement of the theorem, while for any choice of ε, an effective big-O constant can be read off at will. □

4. Effective expansion for the $\mathcal{H}$-kernel. Theorem 4 shows the main contribution to $L_n^{(a)}(-z)$, for $(a, z) \in \mathbb{D}$, with $r := \sqrt{m/z}, |r| > 1/2$, is

$$c_0 := \frac{1}{2\pi} r^{-a} e^{-z/2} \int_{-\pi/2}^{\pi/2} \mathcal{H}_m\left(a, z, e^{-i\omega}\right) e^{2\sqrt{mz}\cos\omega} \, d\omega, \tag{17}$$

with the integration kernel $\mathcal{H}_m$ defined, see (15) and (16), as

$$\mathcal{H}_m(a,z,v) := v^a \left(1+\frac{v}{2r}\right)^{-1-a} \left(\frac{1+\frac{v}{2r}}{1-\frac{v}{2r}}\right)^m e^{-mv/r}, \tag{18}$$

where in the integral we assign $v := e^{-i\omega}$. We need to obtain the growth properties of $\mathcal{H}_m$.

4.1. Exponential form for $\mathcal{H}_m$.

LEMMA 7. *For $|v|=1$ and $m > |z|/4$, the $\mathcal{H}$-kernel can be cast in the exponential form*

$$\mathcal{H}_m := v^a \exp\left\{\sum_{k\geq 1} \frac{a_k}{k}\frac{1}{m^{k/2}}\right\}, \tag{19}$$

where

$$a_k := (1+a)(-1)^k \left(\frac{v\sqrt{z}}{2}\right)^k + \left(1-(-1)^k\right)\frac{k}{k+2}\left(\frac{v\sqrt{z}}{2}\right)^{k+2}. \tag{20}$$

Moreover, we have the general coefficient bound

$$|a_k| \leq \left(\frac{\sqrt{z}}{2}\right)^k (1+|a|+|z|/2). \tag{21}$$

Proof. (18) can be recast, with $\rho := v/(2r)$, as

$$\mathcal{H}_m := v^a \exp\left\{-(1+a)\log(1+\rho) - 2m\rho + m\left(\log(1+\rho)-\log(1-\rho)\right)\right\}. \tag{22}$$

Since $|r|>1/2$ and $|v|=1$, the logarithmic series converge absolutely and we have

$$\mathcal{H}_m := v^a \exp\left\{\sum_{k\geq 1}\left[\frac{(1+a)(-1)^k}{k}\left(\frac{v\sqrt{z}}{2}\right)^k g^k + \frac{2}{2k+1}\left(\frac{v\sqrt{z}}{2}\right)^{2k+1} g^{2k-2}\right]\right\}, \tag{23}$$

where $g := 1/\sqrt{m}$, and the precise form (20) for the a_k follows immediately. The given bound on $|a_k|$ is also immediate from (20). ∎

4.2. Exponentiation of series. Though Lemma 7 is progress, we still need to exponentiate a series, in the sense that we want to know, for the following expansion, given the sequence (a_k),

$$\exp\left\{\sum_{k\geq 1}\frac{a_k}{k}x^k\right\} =: \sum_{h\geq 0} A_h x^h,$$

how the A_h depend on the a_k. The combinatorial answer is

$$A_h = \sum_{j=0}^{h}\frac{1}{j!}\,G_h(j;\vec{a}), \qquad G_h(j;\vec{a}) := \sum_{h_1+\cdots+h_j=h}\frac{a_{h_1}\cdots a_{h_j}}{h_1\cdots h_j},$$

with the understanding that $G_h(0,\vec{a}) := \delta_{0h}$ and that such combinatorial sums involve positive integer indices h_i. One useful result is the following.

LEMMA 8. *If all coefficients $a_k = 1$, then, for $j > 0$,*

$$G_h(j;\vec{1}) \;=\; \sum_{h_1+\cdots+h_j=h} \frac{1}{h_1\cdots h_j} \;=\; \Theta : \frac{1}{h}\,(2H_{h-j+1})^{j-1} \;=\; \Theta : \frac{1}{h}\,(2\gamma + 2\log h)^{j-1}\,.$$

Here, $H_p := 1 + 1/2 + \cdots + 1/p$ is the pth harmonic number, $H_0 := 0$, and γ is the Euler constant.

Remark. It turns out that G here enjoys a closed form of sorts, namely,

$$G_h(j;\vec{1}) = \frac{j!}{h!}(-1)^{h-j}\mathcal{S}_h^{(j)},$$

where $\mathcal{S}$ denotes the Stirling number of the first kind, normalized via $x(x-1)\cdots(x-h+1) =: \sum_{j=0}^{h} \mathcal{S}_h^{(j)} x^j$. So one byproduct of our lemma is a rigorous bound on the growth of Stirling numbers; see [1, 24.1.3,III] and [37] for research on Stirling asymptotics.

Proof. The first Θ-estimate arises by induction. For notational convenience we omit the vector $\vec{1}$ and just use the symbol $G_h(j)$. Note that $G_N(1) = 1/N$ and $G_N(2) = \frac{2}{N}H_{N-1}$. Generally we have

$$G_N(J) = \sum_{j=1}^{N-J+1} \frac{1}{j} G_{N-j}(J-1).$$

Now, assume by induction that $G_h(j) = \Theta : \frac{1}{h}(2H_{h-j+1})^{j-1}$ holds for all $j < J$. Then

$$G(N,J) \;\le\; \sum_{j=1}^{N-j+1} \frac{2^{J-2}H_{N-J-j+2}^{J-2}}{j(N-J)} \;\le\; \frac{2^{J-2}}{N} H_{N-J+1}^{J-2} \sum_{j=1}^{N-J+1} \left(\frac{1}{j} + \frac{1}{N-j}\right).$$

Now this last parenthetical term is $H_{N-J+1} + H_{N-1} - H_J$ which, because $H_a - H_b \le H_{a-b}$ for any positive integer indices $a > b$, is bounded above by $2H_{N-J+1}$, which proves the first Θ-bound of the theorem. For the second Θ-bound it suffices, since H_j is increasing, to show that $H_{n-1} > \gamma + \log(n)$, which is an elementary calculus problem. □

Though we do not use Lemma 8 directly in what follows, it is useful in proving convergence for various sums $\sum A_h x^h$ and may well matter in future research along our lines.

LEMMA 9. *Let $y \ge 1$ and $x \in (-1,1)$ be real. Then in the expansion*

$$\exp\left\{ y \sum_{k\ge 1} \frac{x^k}{k} \right\} =: \sum_{h\ge 0} Y_h x^h$$

the coefficients Y_h enjoy the bound $Y_h = \Theta : y^h$.

Proof. First, $Y_0 = 1 \le 1$. The left-hand side is $\exp(-y\log(1-x)) = (1-x)^{-y}$ whose binomial expansion has hth coefficient ($h \ge 1$) equal to

$$\frac{y(y+1)\cdots(y+h-1)}{h!} \le y^h\, \frac{1}{1}\frac{1+1/y}{2}\cdots\frac{1+(h-1)/y}{h} \le y^h. \qquad \square$$

4.3. Effective expansions of exponentiated series. We are now in a position to derive an effective expansion for an exponentiated series, starting with the following.

LEMMA 10. *Assume complex vector $\vec{b}$ of defining coefficients b_k bounded as $|b_k| \leq cd^k$ for positive real c, d with $c \geq 1$. Assume also $|x| < 1/(2cd)$. Then, for any order $N \geq 0$, we have an effective expansion*

$$\exp\left\{\sum_{k\geq 1} \frac{b_k}{k} x^k\right\} = \sum_{h=0}^{N-1} B_h x^h + \Theta : 2c^N d^N x^N,$$

where

$$B_h = \sum_{j=0}^{h} \frac{G_h(j;\vec{b})}{j!}$$

are the usual coefficients of the full formal exponentiation.

Proof. Denoting $f(x) := \exp\left\{\sum_{k\geq 1} \frac{b_k}{k} x^k\right\}$, we have

$$f(x) = \sum_{h=0}^{N-1} B_h x^h + T_N,$$

with remainder $T_N = \sum_{h\geq N} B_h x^h$, having B_h coefficients given by a G-sum as in Lemma 10. Now,

$$|B_h| \leq \sum_{j=0}^{h} \frac{|G_h(j;\vec{b})|}{j!} \leq \sum_{j=0}^{h} \frac{|G_h(j;\vec{f})|}{j!},$$

where $\vec{f} = (cd^k : k \geq 0)$. By Lemma 9 we know that $|B_h| \leq (cd)^h$. Therefore

$$|T_N| \leq \sum_{h\geq N} (cd)^h x^h = \frac{c^N d^N x^N}{1 - cdx} = \Theta : 2(cdx)^N. \qquad \square$$

Finally we arrive at a general expansion—with effective remainder—for the $\mathcal{H}$-kernel.

THEOREM 5 (effective expansion for $\mathcal{H}_m$). *For general complex $(a, z) \in \mathbb{C} \times \mathbb{C}$, assume that $m > m_5 := |z|(1 + |a| + |z|/2)^2$ and $|v| = 1$. Then, for any expansion order $N \geq 0$, we have*

$$\mathcal{H}_m(a, z, v) = v^a \left(\sum_{h=0}^{N-1} \frac{A_h}{m^{h/2}} \; + \; \Theta : 2\left(\frac{m_5}{4m}\right)^{N/2} \right),$$

where, on the basis of the defining coefficients a_k given in (20),

$$A_h := \sum_{j=0}^{h} \frac{G_h(j;\vec{a})}{j!}, \qquad G_h(j;\vec{a}) := \sum_{h_1+\cdots+h_j=h} \frac{a_{h_1} \cdots a_{h_j}}{h_1 \cdots h_j}.$$

Proof. The result follows immediately from Lemma 10, on assigning $\vec{b} = \vec{a}$, with $x := 1/\sqrt{m}$, $c := 1 + |a| + |z|/2$, $d := (1/2)\sqrt{|z|}$. $\square$

Note that Theorem 5 in the instance $N = 0$ implies our previous Lemma 6. It is interesting and suggestive that the threshold $m_5 := |z|(1 + |a| + |z|/2)^2$ appears in these results rather naturally.

4.4. Effective integral form for c_0. To obtain a useful form for c_0, the dominant component of $L_n^{(-a)}(-z)$, we use Theorem 5 to obtain the following.

THEOREM 6. *For $(a,z) \in \mathbb{D}$ and $m > m_5$, the dominant component of Theorems 3 and 4, namely,*

$$c_0 := \frac{1}{2\pi} r^{-a} e^{-z/2} \int_{-\pi/2}^{\pi/2} \mathcal{H}_m(a,z,e^{-i\omega}) e^{2\sqrt{mz}\cos\omega}\, d\omega,$$

can be given an effective form for any order $N \geq 0$, as

$$c_0 = \frac{1}{2\pi} r^{-a} e^{-z/2} \sum_{h=0}^{N-1} \frac{1}{m^{h/2}} \int_{-\pi/2}^{\pi/2} e^{-i\omega a} A_h e^{2\sqrt{mz}\cos\omega}\, d\omega + \; S_n(a,z)\; \mathcal{E}_{2,N},$$

where the error term is bounded as

$$\mathcal{E}_{2,N} = \Theta : \frac{\pi}{\sqrt{2}} \left(\frac{m_5}{4m}\right)^{N/2} \exp\left(\frac{\pi^2 \Im(a)^2 \sec\frac{\theta}{2}}{32\sqrt{m|z|}}\right) \sec^{1/2}\frac{\theta}{2}$$

and the A_h are to be calculated as the first N coefficients of

$$\sum_{h=0}^{\infty} A_h x^h := \exp\left\{ \sum_{k\geq 1} \frac{a_k}{k} x^k \right\},$$

via (20)*, with $v := e^{-i\omega}$.*

Proof. Inserting the effective $\mathcal{H}$-kernel expansion from Theorem 5 directly into the c_0 integral gives the indicated sum over $h \in [0, N-1]$ plus an error term

$$\Theta : \frac{1}{2\pi} r^{-a} e^{-z/2} 2 \left(\frac{m_5}{4m}\right)^{N/2} \int_{-\pi/2}^{\pi/2} e^{\omega\Im(a)} e^{-2\sqrt{m|z|}\cos(\theta/2)\cos\omega}\, d\omega.$$

Using Lemma 1 on $\cos\omega$ and the V_0-part of Lemma 2, we obtain the $\mathcal{E}_{2,N}$ bound of the theorem. ∎

With Theorem 6 we have come far enough to see that a Laguerre evaluation can be obtained—up to a subexponentially small relative error—via the A_h terms in said theorem. To this end, an inspection of the defining relations reveals that, in general, we can decompose an A_h coefficient in terms of powers of $v := e^{-i\omega}$, namely, we define $\alpha_{h,\mu}$ terms via

$$A_h =: \sum_{u=0}^{h} \alpha_{h,u}(a,z) v^{h+2u}. \tag{24}$$

For example,

$$\alpha_{00} = 1, \quad \alpha_{10} = -\frac{1+a}{2} z^{1/2}, \quad \alpha_{11} = \frac{z^{3/2}}{12}, \quad \alpha_{31} = \frac{1}{480}\left(5a^2 + 15a + 16\right) z^{5/2}.$$

The point being, we now have special formulae for the dominant contribution c_0, namely,

$$c_0 = \frac{1}{2\pi} r^{-a} e^{-z/2} \sum_{h=0}^{N-1} \frac{1}{m^{h/2}} \sum_{u=0}^{h} \alpha_{h,u}(a,z)\; \mathcal{I}(2\sqrt{mz}, a+h+2u) \; + \quad S_n(a,z)\; \mathcal{E}_{2,N}, \tag{25}$$

where the integral

$$\mathcal{I}(p,q) := \int_{-\pi/2}^{\pi/2} e^{-iq\omega} e^{p\cos\omega}\, d\omega \tag{26}$$

thus emerges as a fundamental entity for the research at hand.

5. $\mathcal{I}$-integrals and an "exp-arc" method. Having reduced the problem of subexponential Laguerre growth to a study of the $\mathcal{I}$-integrals (26), we next develop a method that is effective for both their numerical and theoretical estimation. This method amounts to the avoidance of stationary-phase techniques, employing instead various forms of *exponential-arcsine* (exp-arc) series, as we see shortly.

Let us first define, for any complex pair (p,q) and $\alpha,\beta \in (-\pi,\pi)$,

$$I(p,q,\alpha,\beta) := \int_{\alpha}^{\beta} e^{-iq\omega} e^{p\cos\omega}\, d\omega \tag{27}$$

so that our special case (26) is simply $\mathcal{I}(p,q) := I(p,q,-\pi/2,\pi/2)$.

Importantly, one may write the Bessel functions J_n of integer order n in terms of $\mathcal{I}$-integrals:

$$J_n(z) = \frac{1}{2\pi}\left(e^{-i\pi n/2}\mathcal{I}(iz,n) + e^{i\pi n/2}\mathcal{I}(-iz,n)\right), \tag{28}$$

and the modified Bessel function, again of integer order n:

$$I_n(z) = \frac{1}{2\pi}\left(\mathcal{I}(z,n) + (-1)^n\mathcal{I}(-z,n)\right), \tag{29}$$

about which representations we shall have more to say in a later section.[5]

5.1. Essentials of the exp-arc method. Now we investigate what we call exp-arc series. First, for any complex τ and $x \in [-1,1]$, one has a remarkable, absolutely convergent expansion (see [6]):

$$e^{\tau \arcsin x} = \sum_{k=0}^{\infty} r_k(\tau)\,\frac{x^k}{k!}, \tag{30}$$

where the coefficients depend on the parity of the index

$$r_{2m+1}(\tau) := \tau \prod_{j=1}^{m}\left(\tau^2 + (2j-1)^2\right), \qquad r_{2m}(\tau) := \prod_{j=1}^{m}\left(\tau^2 + (2j-2)^2\right).$$

By differentiating with respect to x, we obtain

$$\frac{e^{\tau \arcsin x}}{\sqrt{1-x^2}} = \frac{1}{\tau}\sum_{k=0}^{\infty} r_{k+1}(\tau)\,\frac{x^k}{k!},$$

valid for $x \in (-1,1)$. In particular, we have the important expansion (using a function G, in passing)

$$G(\tau,x) := \frac{\cosh(\tau \arcsin x)}{\sqrt{1-x^2}} = \sum_{k=0}^{\infty} g_k(\tau)\frac{x^{2k}}{(2k)!}, \tag{31}$$

[5]The $\mathcal{I}$-integral can also be written in compact terms of an *Anger function* **J** and *Weber function* **E**; see [1].

where

$$g_k(\tau) := \prod_{j=1}^{k} \left((2j-1)^2 + \tau^2\right).$$

These exp-arc expansions may be applied to the $I(p,q,\alpha,\beta)$ integrals as follows.[6] From (27) and its subsequent manipulations we have

$$I(p,q,\alpha,\beta) = e^p \int_\alpha^\beta e^{-iq\omega} e^{-2p\sin^2(\omega/2)}\, d\omega = 2e^p \int_{\sin\frac{\alpha}{2}}^{\sin\frac{\beta}{2}} \frac{e^{-2iq\arcsin x}}{\sqrt{1-x^2}} e^{-2px^2}\, dx$$

$$= i\frac{e^p}{q} \sum_{k=0}^{\infty} \frac{r_{k+1}(-2iq)}{k!} \int_{\sin\frac{\alpha}{2}}^{\sin\frac{\beta}{2}} x^k e^{-2px^2}\, dx. \tag{32}$$

Even though we eventually consider asymptotic expansions, the convergence of such an I-series is the rule.

LEMMA 11. *For $\alpha, \beta \in (-\pi, \pi)$ and any complex pair (p,q), the series* (32) *converges absolutely.*

Proof. Define $\delta := \max(|\sin(\alpha/2)|, |\sin(\beta)/2|)$ so that the integral in (32) is bounded in magnitude by $2\exp(2\Re(p))\delta^{k+1}/(k+1)$. But this means the kth summand in (32) is, up to a k-independent multiplier, bounded in magnitude by $r_{k+1}(2|q|)\delta^{k+1}/(k+1)!$. This summand is of the same form as that in the defining series (30), so absolute convergence is assured. ∎

Likewise, from (31) and (32) we have an absolutely convergent expansion for the special-case $\mathcal{I}$ integral:

$$\mathcal{I}(p,q) = 4e^p \int_0^{1/\sqrt{2}} G(-2iq,x) e^{-2px^2} = 4e^p \sum_{k=0}^{\infty} \frac{g_k(-2iq)}{(2k)!} B_k(p), \tag{33}$$

where B_k is an error–function-class integral

$$B_k(p) := \int_0^{1/\sqrt{2}} x^{2k} e^{-2px^2}\, dx = \frac{1}{2}\frac{1}{(2p)^{k+1/2}} \left\{\Gamma(k+1/2) - \Gamma(k+1/2, p)\right\}. \tag{34}$$

A computationally key recurrence relation accrues: with $B_0(p) = \sqrt{\frac{\pi}{8p}}\,\mathrm{erf}\left(\sqrt{p}\right)$ and $k > 0$, we have

$$B_k(p) := \frac{2k-1}{4p} B_{k-1} - \frac{2^{-k-3/2}}{p} e^{-p}. \tag{35}$$

5.2. Effective expansion for the cosh-arc *G*-series. Our asymptotic analysis of representation (33) begins with a lemma that reveals how the G function (31) has an attractive self-similarity property. Namely, the function appears naturally in modified form within its own error terms.

LEMMA 12. *For any complex τ, the G function* (31) *can be given an effective expansion to any integer order $N \geq 0$, as*

$$G(\tau,x) := \frac{\cosh(\tau \arcsin x)}{\sqrt{1-x^2}} = \sum_{k=0}^{N-1} g_k(\tau)\frac{x^{2k}}{(2k)!} + g_N(\tau)\frac{x^{2N}}{(2N)!}\left(1 + T_N(\tau,x)\right), \tag{36}$$

[6] An equivalent approach to expanding I uses a series for $e^{iq\omega}\sec(\omega/2)$ in terms of $x := \sin(\omega/2)$, as in [20, p. 276].

with the error term T_N conditionally bounded over real $x \in [0, 1/\sqrt{2}]$ in the form

$$\begin{aligned} T_N &= \Theta : 1 && \text{if } N \geq 2x^2|\tau|^2 - 1; \\ &= \Theta : (\sqrt{2}\ x^2 + x|\tau|)e^{|\tau| \arcsin x} && \text{otherwise.} \end{aligned}$$

Proof. The error term is, by the definition of the $g_k(\tau)$, given by the absolutely convergent sum

$$T_N = h_N + h_N h_{N+1} + h_N h_{N+1} h_{N+2} + \cdots,$$

where

$$h_k := \frac{(2k+1)^2 + \tau^2}{(2k+1)(2k+2)} x^2.$$

When $|\tau|^2 x^2 \leq (N+1)/2$ and since $x^2 \leq 1/2$, it is immediate that, for $k \geq N$, we have a bound:

$$|h_k| \leq \frac{(4k^2 + 4k + 1)/2 + (N+1)/2}{4k^2 + 5k + 2} \leq 1/2,$$

whence $T_N = \Theta : 1/2 + 1/4 + 1/8 + \ldots$, settling the first conditional bound of the theorem. In any case, i.e., any complex τ and any $x \in [0, 1/\sqrt{2}]$, we have for $j \geq 0$:

$$\begin{aligned} h_N h_{N+1} \cdots h_{N+j} &= x^{2j} \prod_{k=0}^{j} \frac{(2N+2k+1)^2 \left((2k+1)^2 + \tau^2 \frac{(2k+1)^2}{(2N+2k+1)^2} \right)}{(2N+2k+1)(2N+2k+2)(2k+1)^2} \\ &= \Theta : \frac{g_{j+1}(|\tau|)}{(2j+1)!!^2}. \end{aligned}$$

However, it is elementary that $(2j+1)!!^2 \geq (2j+1)!$ by simple factor-tallying, so

$$|T_N| \leq \frac{\left(1^2 + |\tau|^2\right) \cdot 2}{2!} x^2 + \frac{\left(1^2 + |\tau|^2\right)\left(3^2 + |\tau|^2\right) \cdot 4}{4!} x^4 + \ldots = x \frac{\partial}{\partial x} G(|\tau|, x),$$

where we have noticed that the right-hand series here is itself a differentiated "cosh-arc" series. Thus

$$T_N = \Theta : x \frac{\partial}{\partial x} \frac{\cosh(|\tau| \arcsin x)}{\sqrt{1-x^2}} = \Theta : \frac{x^2}{2\left(1-x^2\right)^{3/2}} \left(e^u + e^{-u}\right) + \frac{x|\tau|}{2\left(1-x^2\right)} \left(e^u - e^{-u}\right),$$

where $u := |\tau| \arcsin x$. Now by excluding $2x^2|\tau|^2 \leq N+1$ for the second conditional bound of the lemma, we have $|\tau| \geq 1$, whence the e^{-u} terms can be ignored over $x \in [0, 1/\sqrt{2}]$, and the second conditional bound follows. ∎

5.3. Effective expansion of the $\mathcal{I}$-integral. We first invoke a classical lemma that bounds the incomplete gamma function for certain parameters.

LEMMA 13. *For integer $M \geq 0$, $\Re(z) \geq 0, z \neq 0$ and $|z| \geq 2M - 1$, we have*

$$\Gamma(M + 1/2, z) = \Theta : 2z^{M-1/2} e^{-z}.$$

Proof. Proofs of results such as these on incomplete-gamma bounds appear in various texts on special functions, e.g., [27, section 2.2, p. 110]. ∎

The results of the present section may now be applied to a general, effective expansion of the $\mathcal{I}$-integral whenever $\Re(p)$ is sufficiently positive.

THEOREM 7 (effective $\mathcal{I}$ expansion). *For the integral*

$$\mathcal{I}(p,q) := I(p,q,-\pi/2,\pi/2) = \int_{-\pi/2}^{\pi/2} e^{-iq\omega} e^{p\cos\omega}\, d\omega,$$

assume an integer expansion order $N \geq 1$. Assume $\phi := \arg(p) \in (-\pi/2, \pi/2)$ and conditions

$$\Re(p) \geq 2N+1, \quad \Re(p) \geq 2\pi|q|^2.$$

Then we have an effective expansion

$$\mathcal{I}(p,q) = \sqrt{\frac{2\pi}{p}}\; e^p \left\{ \sum_{k=0}^{N-1} \frac{g_k(-2iq)}{k!\; 8^k} \frac{1}{p^k} + \Theta : \sqrt{\frac{8}{\pi p}}\; e^{-p} \cosh\left(\frac{\pi}{2}|q|\right) + \frac{g_N(-2iq)}{N!\; 8^N} \frac{1}{p^N} \left(1 + \Theta : u_N \sec^{N+1/2}\phi\right) \right\}, \tag{37}$$

where the g_k are as in the cosh-arc expansion (31)*, and we may take*

$$u_N := 1 + 2^N + \frac{2^{3N+1}}{\pi \binom{2N}{N}}\ ; \tag{38}$$

however, on the extra condition $N \geq 4|q|^2 - 1$, taking $u_N := 1$ suffices.

Proof. The insertion of the series of Lemma 12 into representation (33) results in

$$\mathcal{I}(p,q) = 4e^p \left\{ \sum_{k=0}^{N} \frac{g_k(-2iq)}{(2k)!} B_k(p) + \frac{g_N(-2iq)}{(2N)!} \int_0^{1/\sqrt{2}} x^{2N} T_N(-2iq,x) e^{-2px^2}\, dx \right\},$$

where the $B_k(p)$ are given by (34). The sum over $k \in [0,N]$ here is thus

$$\frac{1}{2} \sum_{k=0}^{N} \frac{g_k(-2iq)}{(2k)!} \frac{\Gamma(k+1/2)}{(2p)^{k+1/2}} + \Theta : e^{-p} \sum_{k=0}^{N} \frac{|g_k(-2iq)|}{(2k)!} \frac{1}{2^{k+1/2} p},$$

where the Θ-term here follows from Lemma 13 on our condition $\Re(p) \geq 2N+1$. But this very Θ-term is bounded above by

$$\frac{e^{-p}}{p\sqrt{2}} \sum_{k=0}^{\infty} \frac{g_k(2|q|)}{(2k)!} \frac{1}{2^k} = \frac{e^{-p}}{p} \cosh\left(2|q| \arcsin\left(1/\sqrt{2}\right)\right),$$

so we have settled the summation and the $\cosh(\pi|q|/2)$ term in (37). Now consider the integral term

$$I_0 := \int_0^{1/\sqrt{2}} x^{2N} T_N(-2iq,x) e^{-2px^2}\, dx.$$

Define $\gamma := |q|^{-1}\sqrt{(N+1)/8}$. If $\gamma \geq 1/\sqrt{2}$, then by Lemma 12, we know that $T_N = \Theta(1)$, and our theorem follows in the $u_N := 1$ case. Otherwise, $\gamma < 1/\sqrt{2}$, and

we bound I_0 using two integrals

$$|I_0| \le \int_0^{1/\sqrt{2}} x^{2N} e^{-2\Re(p)x^2}\, dx + \int_\gamma^{1/\sqrt{2}} \left(\sqrt{2}\, x^{2N+2} + 2|q|\, x^{2N+1}\right) e^{2|q|\arcsin x - 2\Re(p)x^2}\, dx.$$

From Lemma 1 we know that the exponent here can be taken to be $\pi|q|x/\sqrt{2} - 2\Re(p)x^2$. For the assignments $\alpha := \pi|q|/\sqrt{8},\ \beta := 2\Re(p)$, we have $\beta > 4\alpha/\gamma$ so that by Lemma 2 there is a bound

$$\begin{aligned} I_0 &\le \frac{1}{2}\frac{\Gamma(N+1/2)}{(2\Re(p))^{N+1/2}} + \sqrt{2}\, V_{N+1}(\alpha,\beta,\gamma) + 2|q|\, V_{N+1/2}(\alpha,\beta,\gamma) \\ &\le \frac{1}{2}\frac{\Gamma(N+1/2)}{(2\Re(p))^{N+1/2}} + 2^N \frac{\Gamma(N+3/2)}{(2\Re(p))^{N+3/2}} + 2^{N+1}|q|\frac{\Gamma(N+1)}{(2\Re(p))^{N+1}}. \end{aligned}$$

Using $|q|^2 \le \Re(p)/(2\pi)$, $\Re(p) \ge 2N+1$ with $\Re(p) = |p|\cos\phi$ yields the N-dependent u_N form of the theorem. □

6. Effective asymptotics for $L_n^{(-a)}(-z)$. At last we may provide explicit terms for Laguerre expansions in the subexponential-growth regime, which regime turns out to be precisely characterized by the parameter-pair requirement: $(a,z) \in \mathbb{D}$.

First, for convenience, we recapitulate the thresholds for sufficiently large $m := n+1$ from our previous theorems:

$$m_0 := |z|/4, \quad m_1 := 5\left(|\Re(z)| + (|\Im(a)| + |\Im(z)|/2)^2\right),$$
$$m_2 := \Re(a), \quad m_3 := -(5/4)|z|\cos\theta, \quad m_4 = 4|z|, \quad m_5 := |z|(1+|a|+|z|/2)^2,$$
$$m_6 := (2N+1)^2\, \frac{\sec^2(\theta/2)}{|z|}, \quad m_7 := 4\pi^2\, \frac{\sec^2(\theta/2)}{|z|}(|a|+3N-3)^4.$$

Here, $\theta := \arg(z)$ as before, while m_6, m_7 involve an asymptotic expansion order $N \ge 1$. We are aware that the m_i bounds here are interdependent, and some are masked by others (e.g., m_0 is masked by m_4). The important quantity in our central result (Theorem 8, below) is simply $\max_{i\in[0,7]} m_i$.

Before delving into the central result, let us remind ourselves of previous nomenclature:

$$g_k(\tau) := \prod_{j=1}^{k} \left((2j-1)^2 + \tau^2\right), \tag{39}$$

$$a_k := (1+a)(-1)^k \left(\frac{v\sqrt{z}}{2}\right)^k + \left(1-(-1)^k\right)\frac{k}{k+2}\left(\frac{v\sqrt{z}}{2}\right)^{k+2}, \tag{40}$$

$$\sum_{h=0}^{\infty} A_h x^h := \exp\left\{\sum_{k\ge1} \frac{a_k}{k} x^k\right\}, \tag{41}$$

$$A_h := \sum_{u=0}^{h} \alpha_{h,u}(a,z) v^{h+2u}. \tag{42}$$

Note that the $\alpha_{h,u}$ coefficients are thus implicitly defined in terms of the original a_k functions.

6.1. The general subexponential expansion. Using Theorem 7 with $p := 2\sqrt{mz}$ and inserting this into formula (25), we arrive at our desired effective Laguerre expansion.

THEOREM 8 (effective Laguerre expansion). *Assume $(a, z) \in \mathbb{D}$. For asymptotic expansion order $N \geq 1$ and $m := n + 1$ sufficiently large in the sense $m > \max_{i\in[0,7]} m_i$, we have the expansion*

$$L_n^{(-a)}(-z) = \frac{1}{2\sqrt{\pi}} \frac{e^{-z/2} e^{2\sqrt{mz}}}{z^{1/4-a/2}\ m^{1/4+a/2}} \left\{ \sum_{j=0}^{N-1} \frac{C_j}{m^{j/2}} + \frac{\overline{C}_N}{m^{N/2}} + \mathcal{E}_1 + \mathcal{E}_{3,N} \right\}, \tag{43}$$

where the expansion coefficients C_j are given in finite form:

$$C_j := \sum_{k=0}^{j} \frac{1}{16^k\ k!} \frac{1}{z^{k/2}} \sum_{u=0}^{j-k} \alpha_{j-k,u}(a, z)\, g_k(-2i(a + j - k + 2u)), \tag{44}$$

while the error term $\overline{C}_N$ is bounded as

$$\begin{aligned} \overline{C}_N = \Theta : \sum_{v=1}^{N} \frac{1}{|z|^{v/2} 16^v v!} \left(1 + u_v \sec^{v+1/2} \frac{\theta}{2}\right) \\ \sum_{u=0}^{N-v} |\alpha_{N-v,u}(a, z)\, g_v(-2i(a + N - v + 2u))| \\ + \Theta : 4(m_5/4)^{N/2} \sec^{1/2} \tfrac{\theta}{2}, \end{aligned}$$

with u_v taking the v-dependent form of (38) *in Theorem* 7 *(with $q := a$ there). Finally, the term $\mathcal{E}_1$ is subexponentially small (from Theorem* 4*), as is*

$$\mathcal{E}_{3,N} = \Theta : \sqrt{\frac{4}{\pi\sqrt{mz}}} e^{-2\sqrt{mz}} \sum_{h=0}^{N-1} \frac{1}{m^{h/2}} \sum_{u=0}^{h} |\alpha_{h,u}(a, z)| \cosh\left(\frac{\pi}{2}|a + h + 2u|\right).$$

Proof. For brevity we leave out the details—all of which are straightforward, if tedious, applications of the previous theorems and formulae. ∎

We now have a resolution of the domain of subexponential growth as follows.

COROLLARY 1. *For $(a, z) \in \mathbb{D}$, the Laguerre polynomial grows subexponentially in the sense that, for order $N \geq 1$ and any $\varepsilon > 0$,*

$$L_n^{(-a)}(-z) = S_n(a, z) \left\{ \sum_{j=0}^{N-1} \frac{C_j}{m^{j/2}} + O\left(\frac{1}{m^{N/2}}\right) + O\left(e^{-(2-\varepsilon)\sqrt{m|z|}\cos(\theta/2)}\right) \right\},$$

with all coefficients and the implied big-O constant effectively bounded via our previous theorems. Moreover, for $(a, z) \notin \mathbb{D}$, the large-n growth is not subexponential. Thus, the precise domain of subexponential growth is characterized by $(a, z) \in \mathbb{D}$.

Proof. The given subexponential formula is a paraphrase of Theorem 8. Now assume that $z \in (-\infty, 0]$. We already know that $z = 0$ does not yield such growth (see (2)). Now, for z negative real, note that the integrals in (12, 14) are both decaying in large m. Finally, the integral in (11) has phase factor $|\exp(2\sqrt{mz}\cos\omega)| \leq 1$, and Lemma 6 show that c_1 also cannot grow subexponentially in m. ∎

This corollary echoes, of course, the classical Perron result (7), and we again admit that historical efforts derived the C_j coefficients in principle. The new aspects are (a) we have asymptotic coefficients and effective bounds for general $(a, z) \in \mathbb{D}$ parameters, and (b) we can develop in a natural way an algorithm for symbolic generation of said coefficients.

6.2. Algorithm for explicit asymptotic coefficients. Theorem 8 indicates that, to obtain actual C_j coefficients, we need the cosh-arc numbers $g_k(\tau)$ and the $\alpha_{h,u}(a, z)$ coefficients. Observe that the chain of relations starting with (39) is a prescription for the generation of the C_k. All of this can proceed via symbolic processing, noting that v is simply a placeholder throughout.

Remarkably, there is a fast algorithm that bypasses much of the symbolic tedium. First, we have an explicit recursion for A_h, with $A_0 := 1$, as

$$A_k = \frac{1}{k} \sum_{j=0}^{k-1} A_j \, a_{k-j} \tag{45}$$

as follows from differentiating (41) logarithmically and then comparing terms. Second, when we use (42) together with (45), we obtain a recursion *devoid* of the symbolic placeholder v, as

$$\alpha_{k,u} = \frac{1}{k} \sum_{j=0}^{k-1} \left(\alpha_{j,u} b_{k-j} + \alpha_{j,u-1} d_{k-j} \right), \tag{46}$$

where these new recursion coefficients are

$$b_h := (-1)^h (1 + a) \left(\frac{\sqrt{z}}{2} \right)^h, \quad d_h := \left(1 - (-1)^h \right) \frac{h}{h+2} \left(\frac{\sqrt{z}}{2} \right)^{h+2}.$$

In practice we define $\alpha_{0,0} := 1$ and force any $\alpha_{j,u}$, with $u > j$ or $u < 0$ to vanish. In this sense, the collection of $\alpha_{k,u}$ make up a *lower-triangular matrix*, e.g., the entries for $k \le 3$ appear thus:

$$\begin{pmatrix} 1 & 0 & 0 & 0 \\ -\frac{(a+1)}{2} z^{1/2} & \frac{1}{12} z^{3/2} & 0 & 0 \\ \frac{a^2+3a+2}{8} z & -\frac{(a+1)}{24} z^2 & \frac{1}{288} z^3 & 0 \\ -\frac{a^3+6a^2+11a+6}{48} z^{3/2} & \frac{5a^2+15a+16}{480} z^{5/2} & -\frac{a+1}{576} z^{7/2} & \frac{1}{10368} z^{9/2} \end{pmatrix},$$

where $\alpha_{3,3}$ is the lower-right element here.

These observations lead to a fast algorithm for the computation of the asymptotic coefficients.

ALGORITHM 1 (fast computation of Laguerre asymptotic coefficients).
For given $(a, z) \in \mathbb{D}$ and desired expansion order N, this algorithm returns the asymptotic coefficients $(C_k : k \in [0, N])$ of relation (44), Theorem 8.

1. Set $\alpha_{0,0} := 1$ and, for desired order N, calculate the lower-triangular matrix elements
$(\alpha_{k,u} : 0 \le u \le k \le N)$ via a recursion such as
$\alpha(k, u)$ {

if($k == 0$) return $\delta_{0,u}$;
return $\frac{1}{k}\sum_{j=0}^{k-1}\left(\alpha_{j,u}b_{k-j} + \alpha_{j,u-1}d_{k-j}\right)$;
}
or use an unrolled, equivalent loop (i.e., one may generate the left-hand column of the α-matrix, then fill in one row at a time, lexicographically).
2. Use the recursion $g_k(\tau) = \left((2k+1)^2 + \tau^2\right) g_{k-1}(\tau)$ and the lower-triangular matrix of α values to generate the C coefficients via (44). □

We observe that the expensive sums in this algorithm are all *acyclic convolutions*. Thus, for numerical input (a, z), the algorithm complexity turns out to be $O\left(N^{2+\epsilon}\right)$ arithmetic operations, with the "2" part of the complexity power arising from the area of the lower-triangular sector.[7]

We employed the algorithm to generate exact asymptotic coefficients as follows:

$$C_0 = 1, \qquad C_1 = \frac{1}{48\sqrt{z}}\left(-12a^2 - 24za + 4z^2 - 24z + 3\right),$$
$$C_2 = \frac{1}{4608z}\left(144a^4 + 576za^3 + 480z^2a^2 + 1728za^2 - 360a^2 - 192z^3a \right.$$
$$\left. + 1152z^2a + 1584za + 16z^4 - 192z^3 + 312z^2 + 432z + 81\right),$$

and so on. Note that the C_1 form here agrees with the PAMO coefficient in (8). We were able to generate the full, symbolic $C_{64}(a, z)$ in about one minute of CPU on a typical desktop computer. To aid future researchers, we report that the numerator of C_{64} has degree 128 in both a, z, while the denominator is an integer divisible by every prime not exceeding 64, namely,

$$2^{319} \cdot 3^{94} \cdot 5^{25} \cdot 7^{13} \cdot 11^7 \cdot 13^5 \cdot 17^4 \cdot 19^3 \cdot 23^3 \cdot 29^2 \cdot 31^2 \cdot 37 \cdot 41 \cdot 43 \cdot 47 \cdot 53 \cdot 59 \cdot 61.$$

While formidable, the bivariate $C_k(a, z)$ coefficients evidently have intricate structure and patterning. Future research into said structure would be of interest.

6.3. Generating and verifying effective bounds. For the first nontrivial effective bound, we can employ the rigorous bound $\overline{C}_1$ in Theorem 8, with $N = 1$, to get an effective version of the original asymptotic (3) as

$$L_n^{(-a)}(-z) = S_n(a, z)\left(1 + \frac{\overline{C}_1}{\sqrt{m}} + \ \mathcal{E}_1 + \mathcal{E}_{3,1}\right),$$

with

$$\overline{C}_1 = \Theta : \frac{\left|1 - 4a^2\right|}{16|z|^{1/2}}\left(1 + 6\sec^{3/2}\frac{\theta}{2}\right) + 2|z|^{1/2}(1 + |a| + |z|/2)\sec^{1/2}\frac{\theta}{2},$$

and we remind ourselves that $\mathcal{E}_{3,1}$ (Theorem 8) and $\mathcal{E}_1$ (Theorem 4) are both subexponentially small.

At last we have an effective numerator, then, for the $1/\sqrt{m}$ asymptotic term. Though this effective numerator is almost surely nonoptimal, we are evidently on the right track, because the exact C_1 asymptotic coefficient above (see (8)) has very much the same form as does the Θ-expression for $\overline{C}_1$ here (i.e., the same degrees

[7]For example, floating-point FFT-based convolutions of length L require $O(L \log L)$ operations, of complexity less than $O\left(L^{1+\epsilon}\right)$.

TABLE 1

Examples of rigorous accuracy versus asymptotic order. For the indices n and parameters $(a, z) \in \mathbb{D}$, numbers $\mathcal{L}_{n,N}$ are computed via the asymptotic series through term $C_{N-1}/(n+1)^{(N-1)/2}$ as in Theorem 8. The relative error (RE) and rigorous upper bound (RRE) on the relative errors in taking these terms is reported. All decimal values are reported as correct to ± 1 in the last displayed digit of $\Re, \Im$ parts. Such rigorous bounds can be used to establish indisputable accuracies for various other functions.

n	a, z	N	Approximation $\mathcal{L}_{n,N}$ to $L_n^{(-a)}(-z)$	RE	RRE
1300	$0, -1 + 4i$	1	$(7 - i) \cdot 10^{37}$	0.0038	0.43
10^7	$0, 1$	1	$1.59 \cdot 10^{2744}$	0.00011	0.00099
		2	$1.595190 \cdot 10^{2744}$	$1.4 \cdot 10^{-9}$	$2.8 \cdot 10^{-7}$
		3	$1.5951907764 \cdot 10^{2744}$	$5.4 \cdot 10^{-13}$	$9.2 \cdot 10^{-11}$
10^6	$\frac{1}{2} + i, \frac{1}{2} + 4i$	1	$(-1.5 - 2.0i) \cdot 10^{1303}$	0.0016	0.021
		2	$(-1.565 - 2.041i) \cdot 10^{1303}$	$1.6 \cdot 10^{-6}$	$9.8 \cdot 10^{-5}$
		3	$(-1.562555 - 2.041423i) \cdot 10^{1303}$	$1.4 \cdot 10^{-9}$	$4.2 \cdot 10^{-7}$
		4	$(-1.56255567 - 2.041423269i) \cdot 10^{1303}$	$1.3 \cdot 10^{-12}$	$1.4 \cdot 10^{-9}$
		5	$(-1.56255567881 - 2.04142326969i) \cdot 10^{1303}$	$1.3 \cdot 10^{-15}$	$5.9 \cdot 10^{-12}$
10^7	$-\frac{3}{2}, 1 - 100i$	1	$(2 + i) \cdot 10^{19520}$	0.027	0.41
		2	$(1.8 + 0.9i) \cdot 10^{19520}$	0.00035	0.034
		3	$(-1.85 + 0.95i) \cdot 10^{19520}$	$3.1 \cdot 10^{-6}$	0.0028
		4	$(-1.851 + 0.957i) \cdot 10^{19520}$	$2.1 \cdot 10^{-8}$	0.00023
		5	$(-1.8510 + 0.9575i) \cdot 10^{19520}$	$1.1 \cdot 10^{-10}$	$2.0 \cdot 10^{-5}$
		10	$(-1.8509993203 + 0.9575616603i) \cdot 10^{19520}$	$7.1 \cdot 10^{-23}$	$7.6 \cdot 10^{-11}$

of appearance for a, z, and similar coefficients). And, it is easy to see that the Θ-expression here is an upper bound on $|C_1|$ itself, as must of course be true; it is necessary that $\overline{C}_N \geq |C_N|$ for every asymptotic order N.

Table 1 shows the numerical instances of our asymptotic series from Theorem 8. It displays various indices n and parameters a, z, together with corresponding asymptotic orders N from the theorem, using the following nomenclature. Denote, for asymptotic order N,

$$T_{n,N} \;:=\; 1 + \frac{C_1}{m^{1/2}} + \cdots + \frac{C_{N-1}}{m^{(N-1)/2}},$$

so, for S_n being the assignment (4), we have an approximation $\mathcal{L}_{n,N}$ defined by

$$\mathcal{L}_{n,N} \;:=\; S_n T_{n,M} \;\approx\; L_n^{(-a)}(-z).$$

Thus, $\mathcal{L}_{n,1}$ is simply S_n, as $T_{n,1} = 1$ always. How good are these $\mathcal{L}_{n,N}$ approximations? The important right-most columns of Table 1 report relative error (call it RE), with

$$\text{RE} := \left| \frac{\mathcal{L}_{n,N} - L_n^{(-a)}(-z)}{L_n^{(-a)}(-z)} \right|,$$

and a *rigorous* upper bound on relative error (call it RRE), expressed in terms of Theorem 8's various error bounds, with

$$\text{RRE} := \left| \frac{\epsilon}{T_{n,N}} \right|,$$

where $\epsilon > 0$ can be taken to be any number not exceeding $\left|\overline{C}_N/m^{N/2} + \mathcal{E}_1 + \mathcal{E}_{3,N}\right|$. Note that the three error components in this last expression are all magnitude-bounded via Theorem 8; this is how the RRE table entry was constructed.

A convenient way to view RRE is to realize that $L_n^{(-a)}(-z)$ is rigorously known to lie in the interval $\mathcal{L}_{n,N} \cdot (1 - \mathrm{RRE}, 1 + \mathrm{RRE})$. The decimal representations in Table 1 are reflexive; i.e., there is ambiguity only in the respective final digits. (When a reported value is $(a + ib) \cdot 10^c$, then both a and b are correct to within ± 1 in their respective last digits.)

One might ask about the "first-missing" asymptotic term $C_N/m^{N/2}$—a term of interest in many asymptotic theories. This term is typically close to, but often greater than, the RE. As is common to many asymptotic developments, rules about the behavior of these first-missing terms are hard to establish when parameters (in our case a, z) roam over the complex plane. In any case, the first-missing term is often an order of magnitude or more greater than the RRE. Yet this discrepancy between first-missing and RRE terms is not as harmful as might appear, as we discuss next.

6.4. Example application of effective bounds: Rigor for incomplete gamma. We have mentioned research motives in section 1.1. A worked example of *rigorous* incomplete gamma evaluations is the following. Let us use our very first entry from Table 1, namely,

$$L_{1300}^{(0)}(1 - 4i) \;\approx\; (7 - i) \cdot 10^{37},$$

with a rather large RRE = 0.43. Though this is an order of magnitude larger than the relative error, the penalty paid is only a few digits of precision for the relevant incomplete gamma. Indeed, from (5),

$$\Gamma(0, -1 + 4i) = e^{1-4i} \sum_{n=0}^{1299} \frac{1}{n+1} \frac{1}{L_n^{(0)}(1 - 4i) L_{n+1}^{(0)}(1 - 4i)} \;+\; \delta,$$

where the error δ is bounded, using RRE = 0.43 and (4), by

$$|\delta| \;<\; \frac{\left|e^{1-4i}\right|}{(1 - \mathrm{RE})^2} \sum_{n \geq 1300} \frac{1}{n+1} \frac{1}{|S_n S_{n+1}|} \;<\; 10^{-76}, \tag{47}$$

the last bound using (4) and careful estimates on the summation over $n \geq 1300$. Thence the sum for $n \in [1, 1299]$ gives a rigorous, 76–digit-accurate value for $\Gamma(0, -1 + 4i)$, $(\approx 0.497 \,+\, 0.415\, i)$. Correspondingly, the actual absolute error in using the sum over $n \in [0, 1299]$ is about 10^{-78}, so the apparently poor RRE bound brings only a 2-digit penalty.

An additional application of Theorem 8 would be to use effective bounds to rule out zeros of L_n in the crossed (a, z)-plane, that is, to establish an m_0 such that the term $1 + \overline{C}_1/\sqrt{m}$ must be positive for all $m > m_0$ (see our Open problems section).

7. Brief remarks on oscillatory regimes. The exp-arc method has led to rigorous asymptotics for subexponential growth but not for the Fejér form (6) for $z \neq 0$ on the cut $(-\infty, 0]$. Such oscillatory behavior can be dealt with, but other techniques come into play. For one thing, contour integrals must be handled differently.

7.1. When z is on the negative real cut. Even on $z \in (-\infty, 0)$ the contour prescription of Figure 1 is valid, and the Laguerre polynomial is exactly the sum

$c_1+d_1+e_1$, with $R := \sqrt{m/|z|} > 1/2$ being the only requirement for contour validity. However—and this is important—the dominant contribution (17) has to change to involve an expanded integration interval; in fact, now we must use the contour integral c_1 itself as the main contribution. For reasons of brevity, we simply state the complete asymptotic result stemming from contour integral c_1 as

$$L_n^{(-a)}(-z) \;\sim\; \frac{e^{-z/2}}{\sqrt{\pi}(-z)^{1/4-a/2}\; m^{1/4+a/2}} \times \left\{ \left(\sum_{k=0}^{\infty} \frac{A_k}{m^k} \right) \cos\left(2\sqrt{-mz} + a\pi/2 - \pi/4\right) + \left(\sum_{k=0}^{\infty} \frac{B_k}{m^{k+1/2}} \right) \sin\left(2\sqrt{-mz} + a\pi/2 - \pi/4\right) \right\}, \tag{48}$$

where these oscillatory-series coefficients are directly related to the coefficients in Theorem 8 by

$$A_k := C_{2k}(a,z), \quad B_k := iC_{2k+1}(a,z).$$

It transpires that, for a real, every A_k, B_k is real, whence the asymptotic has all real terms. The Fejér–Perron–Szegö expansion in [36, Theorem 8.22.2] for the oscillatory Laguerre mode is stated there in a fashion structurally different from our asymptotic (48); notwithstanding this Szegö's own $A_{\text{odd}}, B_{\text{even}}$—also not defined quite like ours—vanish.[8]

7.2. Brief remarks on Bessel functions I_n, J_n. There is vast literature on Bessel asymptotics [44], [39], resulting in the *Hankel asymptotic series* [1, section 9.2.5] and effective bounds on error terms (for certain parameter domains). In many cases these restricted error bounds are nevertheless optimal [44]. It is instructive to explore, at least briefly, the application of our exp-arc method to Bessel expansions. We recall (29) which leads to

$$I_n(z) = \frac{2}{\pi} \sum_{k\geq 0} \frac{g_k(-2in)}{(2k)!} \left\{ e^z B_k(z) + (-1)^n e^{-z} B_k(-z) \right\} \;\sim\; \frac{e^z}{\sqrt{2\pi z}} \sum_{k=0}^{\infty} \frac{g_k(-2in)}{k!\; 8^k} \frac{1}{z^k}, \tag{49}$$

(again we omit proofs) where the first sum is convergent, exact, and the second sum agrees with the classical Hankel asymptotic [44], [1]. For $\arg(z) \in (-\pi/2, \pi/2)$, at least, one may derive effective bounds on I_n error terms using the exp-arc techniques.

Computationalists have known for decades that one way to evaluate Bessel functions uniformly in the argument z is to use the standard ascending series for small $|z|$, but an asymptotic series for large $|z|$. However, via the exp-arc method one can establish a converging series whose evaluation only involves *a single error-function evaluation*, followed by recursion and elementary algebra. In fact, the relations (34), (35) can be used to calculate $J_n(z)$ from relation (28) via the sum

$$J_n(z) = \frac{2}{\pi} \sum_{k=0}^{\infty} g_k(-2in) \left(b_k \cos\chi - c_k \sin\chi \right), \tag{50}$$

[8] Our oscillatory asymptotic (48) has been verified to several terms by Temme; also he verifies our claim that the classical Szegö coefficients do vanish for the parities indicated [38].

with

$$\chi := z - \pi n/2 - \pi/4, \quad b_k := B_k(iz)e^{i\pi/4} + B_k(-iz)e^{-i\pi/4}, \quad ic_k := B_k(iz)e^{i\pi/4} - B_k(-iz)e^{-i\pi/4}.$$

Note that if z is real, then each b_k, c_k is real, whence our series here has all real terms. Note that our recursion (35) likewise ignites a recursion amongst the b_k, c_k.

Note that (50) is actually the Hankel asymptotic if we replace B_k by its first term in (34), namely, $(1/2)(2iz)^{-k-1/2}\Gamma(k+1/2)$; however, we already know that the sum (50) is always convergent. It is remarkable that we are using the same structure as the classical asymptotic, yet convergence for all complex z is guaranteed. Moreover, the $B_k(iz)$ are independent of the order n and so can be reused if multiple $J_n(z)$ are desired for fixed z.

Those acquainted with the intricacies of Bessel theory may observe that our convergent expansion (49) is at least reminiscent of the convergent *Hadamard expansion* found in [44, p. 204] for the modified Bessel function I_ν. Though both expansions are absolutely convergent, there are some important differences between this Hadamard expansion and our exp-arc forms (49, 50). For example, we have given our convergent sum only for integer ν. Moreover, the exp-arc expansion is geometrically convergent, while the Hadamard expansion is genuinely slower.

The research area of convergent expansions related to classical, asymptotic ones has been pioneered in large part by Paris, whose works cover real and complex domains, saddle points, and the like [29], [30], [31], [32], [33], [34]. We should point out that Paris was able to develop within the last decade some similar, linearly convergent Bessel series by modifying the "tails" of Hadamard-class series. Finally,we note that the problem of generalizing such unconditionally convergent series as our (50) to noninteger indices—and with comparison to the recent work of Paris—is analyzed in a new work [3].

8. Open problems.

- How might one proceed with the exp-arc theory to obtain effective error bounds for oscillatory Laguerre modes and-or oscillatory Bessel modes? We know that previous researchers have described how to give effective bounds in these cases (e.g., to our asymptotic (48), as in [36, section 8.72]), but once again we stress, How can this be done explicitly and for full parameter ranges?
- Where are the zeros in the complex z-plane—for fixed a—of $L_n^{(-a)}(-z)$? Are "most of" the zeros along some a-dependent ray, in some sense? There is a considerable literature on this zero–free-region topic, especially for polynomials in real variables. For example, with $a := 0$ the Laguerre zeros are all real and negative; see [24, Chapter X] and references therein. There is also an interesting connection between Laguerre zeros and eigenvalues of certain (large) matrices [15]. Certainly the theorems of the Saff–Varga type are relevant in this context [24, Theorem 11].
- How can Laguerre asymptotics be gleaned from standard recurrence relations amongst the $L_n^{(-a)}(-z)$? One may ask the same question for the Laguerre differential equation as starting point. A promising research avenue for a discrete-iterative approach to asymptotics is [43]; see also [4] for the asymptotic analysis of certain complex continued fractions. As for differential-equation approaches, there is the classical work of Erdélyi and Olver, plus modern work on the combinations of differential, discrete, and saddle-point theory [16], [18].

- The efficient "keyhole" contour of Figure 1 was discovered experimentally. What other analytical problems might be approached in this fashion? For that matter, how might one properly use the celebrated Watson loop-integral lemma with error term [27, Theorem 5.1] on our keyhole contour to obtain similar effective asymptotics?
- Here is a scenario suggested by Temme [38]. When n is small (in some sense not made rigorous here), and, say, $|z| \ll |a|$, one should expect an asymptotic behavior

$$L_n^{(-a)}(-z) \sim \binom{n-a}{n} \left(1 + \frac{z}{1-a}\right)^n.$$

The problem is, How does one make this rigorous, with effective error bounds?

Acknowledgments. We are indebted to J. Buhler, R. Mayer, O-Yeat Chan, R. Paris, and N. Temme for the generous lending of expertise, ideas, and suggestions. We are equally grateful to two referees for their insightful remarks.
