

RAPID SOLUTION OF STEREOCHEMICAL PROBLEMS
WITH EUROPIUM-TRIS(TETRAMETHYLHEPTANEDIONE), $\text{Eu}(\text{thd})_3$

(Received in UK 24 March 1971; accepted for publication 1 April 1971)

The important discovery by C. C. Hinckley^[1] that proton nuclear magnetic resonance signals are dramatically shifted in a predictable manner in compounds which form a complex with $\text{Eu}(\text{thd})_3$ has opened a new field of study^[2].

We have isolated compounds 1^[3a] and 2^[4] in the course of our studies of bridged bis-homotropylum ions^[3]. Photolysis of compound 3, prepared by epoxidation^[5] of the cyclooctatetraene dimer which melts at 53^o^[6] forms oxa [17]annulene^[5]; thus, 3 is of considerable interest to us^[7].

The following stereochemical questions arise:

- are the methoxyl and hydroxyl groups in 1 and 2 exo or endo (relative to the butadiene bridge)?
- is the epoxide ring of 3 syn or anti to the proton at carbon atom 2?

Even though homonuclear double resonance experiments do not provide unequivocal results for answering these questions, the changes of the proton chemical shifts in the presence of $\text{Eu}(\text{thd})_3$ does permit an unambiguous assignment of the stereochemistry of each of these three molecules.

Syntheses of 1, 2 and 3

- 1 The preparation of 1 is reported in ref. [3]. 1 can also be synthesized via the procedure outlined for 2 but substituting methanol for water.
- 2 Bicyclo[4.2.2]decatetraene reacts with HBr in CH_2Cl_2 at -75° to form liquid 7-bromo-bicyclo[4.3.1]deca-2,4,8-triene (90%), which is purified by fractional vacuum distillation [8]. The NMR, UV and IR spectra are in agreement with the structure. The bromide is rapidly hydrolyzed in water-acetone- NaHCO_3 to 7-hydroxybicyclo[4.3.1]deca-2,4,8-triene (2) [8] (yield 90%; mp 67° (from pentane-ether)). The spectroscopic data are identical to those reported by Vogel, Roth and Fus [9].
- 3 Dimeric cyclooctatetraene, mp 53° [6], is epoxidized with 40% peracetic acid in CHCl_3 at 25°C ; 3 (mp $43 - 44^\circ$) was isolated from the reaction mixture in 40% yield by column chromatography (silica; pentane) [8]. UV spectrum (ether): 232 nm (sh, 6500).

NMR spectra in presence of $\text{Eu}(\text{thd})_3$

The three NMR spectra of 1 reproduced on figure 1 show the effect of adding $\text{Eu}(\text{thd})_3$ to the sample [10]. We observe that the magnitude of the resonance shifts is a function of $\text{Eu}(\text{thd})_3$

Figure 1: ^1H -NMR spectra of 7-methoxybicyclo[4.3.1]decatriene in CCl_4 in absence and in presence of $\text{Eu}(\text{thd})_3$ ($100\text{ MHz} = +25^\circ\text{C}$).

concentration and, for each proton, a function of its distance from europium [1, 2]. When the O...H_i distance r_i taken from a Dreiding model is used as an approximation to the Eu...H_i distance d_i then we expect the correct structure to be that in which the shifts ($\Delta\nu_i$ in Hz) of the proton signals are proportional to r_i^{-a} where the exponent $a = 2$ to 3 [1, 2c].

In the case of 7-methoxybicyclo[4.3.1]decatriene this condition ($\Delta\nu_i \propto r_i^{-2.2}$) is satisfied only by an *exo* methoxy group. Even so we can still discuss two conformations for the six-membered ring, the half-chair and the half-boat. A distinction between the two conformations is possible from the analysis of the shifts $\Delta\nu_i$ observed for the protons of the six-membered ring, but is more convincingly shown by the small coupling $J_{6,7} \leq 0.5$ Hz observed in the spectra of 1 in presence of Eu(thd)₃ (cf. Fig. 1). The dihedral angle H₆-C₆-C₇-H₇ is either ca. 70° (half-chair) or ca. 170° (half-boat); the small observed coupling is associated with the 70° conformation. Therefore the half-chair conformation is favoured even though it contains an axial methoxy group.

In the case of 7-hydroxybicyclo[4.3.1]decatriene the different protons show, in presence of Eu(thd)₃, paramagnetic shifts similar to those observed for 1 [10]. From these observed shifts it could be deduced that the C₇-hydroxy group is in the *exo* position, 2. Here again the relationship $\Delta\nu_i \propto r_i^{-2.2}$ is found to hold; however, at equal mole ratios of Eu(thd)₃ to substrate the paramagnetic shifts are greater for 2 than for 1. First-order fine structure of signals of proton 6 or 7 as observed in spectra of 2 in presence of Eu(thd)₃ also indicates that the half-chair conformation for the cyclohexene ring is again preferred.

The three NMR-spectra of the tetracyclic epoxide 3 (Fig. 2) show the effect of adding Eu(thd)₃ to the sample [10]. The upper spectrum, without Eu(thd)₃, exhibits a complex pattern between $\tau = 3.8$ to 4.7 for the ten olefinic protons. The signals of the aliphatic protons at $\tau = 6.56(m)$ and 7.78(m), in the intensity ratio 5 : 1, demonstrate that the epoxide ring is unsymmetrically placed on the COT dimer. In presence of Eu(thd)₃ the two epoxide protons 3 and 5 are more strongly shifted towards lower field than any other; the remaining protons undergoing a paramagnetic shift are, in the order of decreasing shift: 2, 6, 1, 10, 7, 17, 9, 8, 11, 12, 13 and 14. The individual shifts $\Delta\nu_i$ of all these protons correlate with the O...H_i distances r_i obtained from a Dreiding model of the *syn* isomer, 3 ($\Delta\nu_i \propto r_i^{-2.22}$); the same shifts can not be correlated with the O...H_i distances r_i in the *anti* compound. The protons 15 and 16 exhibit diamagnetic shifts; this observation is readily explained by the controlling features of the equation for the pseudocontact shift [2d] $\Delta\nu_i \propto (3\cos^2\chi_i - 1)d_i^{-3}$ where d_i is the distance between Europium and proton i and χ_i is the angle O...Eu...H_i. The angles χ_i for protons 15 and 16 are respectively 58° and 55°; they are thus greater than 54.7° (i. e. $3\cos^2\chi_i - 1 < 0$) and the shift are diamagnetic.

Acknowledgment

J. F. M. Oth likes to thank the Swiss Chemical Industries (Basel), J. Thio, G. Plinke and G. Schröder the Badische Anilin- and Soda-Fabrik AG (Ludwigshafen) and Fonds der Chemischen Industrie for generous support.

- [10] Spectra were obtained for ten different mole ratios (0.1 to 1.0) $\text{Eu}(\text{thd})_3$ /substrate. The shift effect $\Delta\nu_i$ for a particular proton is defined as the slope of the straight line which is obtained from a graph of the position of the resonance signal ν_i versus the mole ratio $\text{Eu}(\text{thd})_3$ /substrate.
