(Received in UK 27 July 1973; Accepted for publication 17 August 1973)

Abstract—A new synthetic sequence of phosphorus heterocycles was developed using RPX₂·AlX₃ complex addition to 1,4-dienes. For example, the reactions of PhPX₂ (X=Cl, Br), CH₃PCl₂ and PCl₃—AlCl₃ complexes with 1-allyl-cyclohex-1-ene to give two isomeric 2-phosphatricyclo [4.4.0.0^{4.6}] decanes (i.e. 2 and 4) accompanied by a phosphorus acid chloride (3) are described. Several transformations of 2 into other ring systems, namely phosphadecaline and perhydrophosphindoline are mentioned.

Olefins are known to react with RPX₂-AlX₃ complexes to give C-P bonds, a reaction which has already been utilized by Jungermann, McBride² and others in the preparation of phosphetanes using olefins such as 2,4,4-trimethyl-2-pentene as starting materials. Olefins in which a methyl group vicinal to the double bond is available, after the initial pattack, for a 1,2-shift, thereby yield the more stable tertiary carbonium ion which can then undergo ring closure with the phosphorus to give the phosphetane.

It was interesting to check the possibility of preparing other phosphorus heterocycles by this type of reaction in which instead of methyl or hydrogen 1,2-shifts, a double bond should migrate. 1,4-dienes were chosen as substrates for this synthesis for which a priori several routes of cyclization could be described, each leading to different heterocycles (cf Scheme 1).

Various phosphorus heterocycles were indeed obtained by the use of different 1,4-dienes as substrates; the results of the reaction with 1-allyl-cyclohex-1-ene (1)⁴ are reported herewith.

Addition of 1 to a preformed complex from phenylphosphonous dichloride and aluminium chloride in CH₂Cl₂ at 0° gave, after 5 hr, and following quenching in water, two main compounds which could be separated by chromatography: compound 2 m.p. 153-155°, C₁₅H₁₉PO, and compound 3, an oil, C₁₅H₂₀ClPO; IR, ν_{max} 2950, 2900, 2840, 1220 (P=O), 910 (C=CH₂) 690 cm⁻¹, mass spectrum: m/e 282 (25%, M⁺), 247 (2%, M—Cl), 241 (9%,

M—CH₂CH=CH₂), 161, 163 (20% and 7%, PhPH(OH)Cl), 160, 162 (17% and 6%, PhP(OH)Cl), 125 (15%, PhP(OH)), 122 (65%, M—PhP(OH)Cl), 81 (100%, 122—CH₂CH=CH₂) and 77 (60%, Ph), NMR (CDCl₃): δ 5·66–5·84 m and 6·46–6·87 m (—CH=CH₂), 3·22 m (J_{PH} = 27 Hz, two allylic protons). Compound 3 was thought to be the hydrolyzed addition product of PhPCl₂ to the trisubstituted double bond of 1, obtained from the initial at-

tack of PhPCl AlCl at C-2 (to give g) which is believed to be the first step in the synthesis of 2. However, the NMR spectrum of 3 pointed to a linkage of the phosphorus to C-1, as the two C-1', allylic protons were coupled with the P-atom to the extent of 27 Hz in accordance with a ³J_{PR} coupling constant and excluding a 1/3 one (known to be 1-4 Hz)³. Furthermore, the mass spectrum pointed to a P(O)PhCl group which could be confirmed by the exchange of the chlorine atom by OMe, using NaOMe in MeOH (the NMR was identical with that of 3 except for an additional doublet at δ 3.64 J = 10.5 Hz); the mechanism for obtaining 3 is now being investigated. Compound 2 on the other hand did not contain chlorine or double bonds and according to the elemental analysis and mass spectra had to be a phosphatricyclic compound, one of four possible structures obtained from the intermediates m-p (Scheme 1). A priori, intermediates m and n should be preferred to o and p since they are obtained from a tertiary homoallylic carbonium ion, however, the distinction between the two is not clear cut. Although in the NMR spectrum of 2, two protons which resonate at high field (δ 0.4–0.8) could be best attributed to a cyclopropanic ring supporting structure m, the presence of this moiety required further evidence as the influence of the phenyl and P=O groups' anisotropy on the various skeleton protons could only be estimated with diffi-

[†]Compound g, which was not isolated by itself, could in principle undergo ring closure by a second internal attack of a possible newly formed R₂PX AlX₁ complex. Although in this case such a product could not be isolated from the mixture, it was the main product obtained from other 1,4-dienic systems.

SCHEME 1.

culty. It was thus essential to determine the number of protons vicinal to the P-atom in order to distinguish between structures m-p. For this task, compound 2 was reduced by HSiCl₃⁶ to 5 and, following addition of methyliodide, the corresponding phosphonium salt 6 was obtained. As expected, the protons vicinal to the P-atom were paramagnetically shifted, emerging from the methylenic envelope, and it turned out that three such protons existed, thereby cancelling out all other possible structures for 2 except the one including the cyclopropanic ring obtained from m.

An interesting similarity was found between the above reaction and the cycloaddition of CH₃PCl₂ to norbornadiene,⁷ both resulting in similar products. However, although both dienes were 1,4-situated, compound 1 failed to react under the mild cycloaddition conditions, most probably because of the unfavored geometry causing less overlap between the two double bonds.

Performing the reaction on 1 with PhPBr₂ instead of PhPCl₂ and AlCl₃ (or AlBr₃) resulted in an additional compound (4), which accompanied compounds 2 and 3 and was isolated in the former case only in minute quantities. In this compound the presence of the cyclopropanic ring was obvious according to the NMR spectrum as the corresponding protons resonated at δ 0·1–0·3, a much higher field

as compared to 2; compound 4 therefore seems to be the P-epimer of 2. The fact that 4 was obtained in higher yields using PhPBr₂ instead of PhPCl₂ can be best explained by the smaller difference in size between the phenyl and bromine groups as compared with the phenyl and chlorine which makes the bromine competitive to the phenyl in the intermediate.

Although 4 was only obtained in small quantities, it was important for the stereochemistry study; we assume the β -direction (the same direction as the cyclopropanic ring towards the perhydrophosphindoline) for the P=O group in compound 2 and the α -direction for it in 4, on the basis of the following reasons:

a. The C-5-protons in 2 resonate at δ 0.9-1.2 in comparison to 0.1-0.3 found for 4, due to the paramagnetic shift of the β (P=O) group in the former.

b. The 3α -proton which can unequivocally be identified in 2 at δ 2.7 giving a double doublet (J=15, and 4.5 Hz) after P-irradiation, in a heterodecoupling experiment, is shifted upfield in the P-cyclohexanic analog (8) derived from 2 (vide infra), due to cancelling of the phenyl paramagnetic shift which had a greater influence in 2.

 c. Complexation of 2 (and 12) by Eu(fod), causes the downfield shift of several protons among which the 5β -proton showed a $\Delta\delta$ value of 3.9 ppm similar to 4.5 ppm found for 3β -H (for a substrate/Eu(fod)₃ ratio of ca 1).

In this complexed spectra a third broad signal was found to be shifted by the same order of magnitude ($\Delta\delta$ 4.5 ppm) as 3β -H and 5β -H, pointing at first glance to a cis (1β -H) ring junction of the perhydrophosphindoline system in which the 1β -proton is the corresponding one, but further consideration could not exclude the trans (1α -H) configuration in which the above broad signal could be attributed to the 10β -proton, thus leaving this problem open until further evidence will be available.

With the purpose of checking the possibilities of changing 2 into other phosphorus heterocycles, several reactions directed to open the cyclopropanic ring were performed on 2 (Scheme 2).

Acidic treatment (boiling conc. HCl) gave compound 7 in which, according to the NMR spectrum (δ 1.22d (J = 6 Hz); CH—CH₃, and no other low

SCHEME 2.

field signals) the C₅—C₆ bond was cleaved to give a tetrasubstituted double bond and a secondary Me group. Opening of the 3-membered ring, on the other hand, by hydrogenation at room temperature and atmospheric pressure or even 60-100 psi failed, the only site which was reduced was the phenyl group (comp 8). This tendency to undergo easy saturation was already found by us in several cases.⁸

Among other conditions which were studied in order to open the cyclopropanic ring, Hg(OAc)₂ in acetic acid was found to be efficient in opening, this time, the C₄—C₆ bond to give the phosphadecalinic system 9. The NMR of 9 showed clearly the disappearance of the cyclopropanic ring and the entering of a tertiary acetoxy group; hydrolysis of the acetate gave the alcohol 10 which then by elimination with SOCl₂ gave the unsaturated phosphine oxide 11 (Scheme 2). The above reactions clearly show the use of the synthesis for the preparation of several P-heterocycles. Similar to the synthesis of 2, compounds 12 and 13 were obtained, starting with PCl₃·AlCl₃ or CH₃PCl₂·AlCl₃ respectively. The P=O orientation in these compounds seems to be as in 2, according to the similar 5β -proton shift by Eu(fod), in the NMR spectrum.

EXPERIMENTAL

M.ps were taken on a Unimelt Thomas & Hoover's capillary m.p. apparatus and are uncorrected. IR spectra were recorded on a Perkin-Elmer Infracord model 337 spectrophotometer. NMR spectra were taken either on a Varian HA-100 spectrometer or a JEOL JNM-C-6OHL spectrometer on 5-10% solns. in CDCl₃ (unless otherwise indicated), containing TMS as an internal standard. Mass spectra were taken with a Hitachi-Perkin-Elmer RMU-6 instrument.

Reaction of phenylphosphonous dichloride (or dibromiae) with 1-allylcyclohex-1-ene4. (1). To a stirred soln of AlCl₃ (1.0 g) and PhPCl₂ (1.36 g) in dry CH₂Cl₂ (20 ml) a soln of 1 (0.9 g) in CH₂Cl₂ (10 ml) was slowly added at 0°. The mixture was stirred under N₂ at room temp for 5 hr, then ice water was slowly added, the two phases separated, and the aqueous soln extracted several times with CH₂Cl₂. The combined CH₂Cl₂ soln was washed with small portions of 5% NaHCO, aq, then water, dried (Na₂SO₄) and evaporated yielding a viscous oil (1.54 g) which was then chromatographed on silicagel column; elution with EtOAc gave 2 (0.5 g), whereas 3 (0.8 g) and 4 (0.05 g) needed 5% MeOH-EtOAc to be eluted. 2-phenyl-2-oxo-2-phosphatricyclo [4.4.0.0^{4.6}] decane (2); m.p. 153°-155° (CH₂Cl₂-cyclohexane), $\nu_{\text{max}}^{\text{KBr}}$ 2950, 1440, 1180, 1130, 1100, 1020, 820, 740, 690 cm⁻¹. NMR (CDCl₃), after P-irradiation at 24.286.820 Hz, δ 0.4-0.6 m (C-4-H), $1\cdot0-1\cdot9$ m (10 H, C₅, C₇—C₁₀ protons), $2\cdot2$ d $(C-3\beta-H, J_{H_{10}H_{30}}=15 \text{ Hz}, J_{H_{4}H_{30}}=0 \text{ Hz}), 2.7 \text{ dd}$ $(C-3\alpha-H, J_{H_{4}H_{30}}=4.5 \text{ Hz}), 2.1 \text{ dd} (C-1-H, J=12 \text{ and}$ 4.5 Hz (estimated)), 7.4-7.9 m (Ph, 5H). Mass spectrum m/e: 246 (100%, M⁺), 231 (7%, [M-CH₃]⁺), 218 (11%,

[M—Et]⁺), 205 (15%, [M—C,H,]⁺), 125 (17%, PhP(OH)), 121 (20%), 93 (25%), 91 (21%), 81 (37%) and 79 (50%). (Found: C, 72·97; H, 7·77; P, 12·56; $C_{15}H_{19}PO$ requires: C, 73·15; H, 7·77 and P, 12·57%).

Compound 3, an oil $\nu_{\text{max}}^{\text{neat}}$ 2950, 2900, 2840, 1450, 1430,

1220, 1100, 915, 690 cm⁻¹; NMR (CDCl₃) δ 1·6 brs (10 H), 3·22 m (2H, J_{PH} = 27 Hz), 5·66–6·84 m (2H) and 6·46–6·87 m (1H, —CH=CH₂), 7·6 m (3H) and 7·8 m (2H, Ph). (Found: m/e 282 (15%); C₁₅H₂₀ ClPO requires: M⁺ m/e 282).

Compound 4, m.p. $94^{\circ}-95^{\circ}$ (CH₂Cl₂-cyclohexane). Very hygroscopic crystals, C₁₅H₁₀PO, $\nu_{\rm max}^{\rm max}$ 2910, 2850, 1450, 1200, 1170, 1140, 1125, 1100, 1000, 900, 870, 810 cm⁻¹, mass spectrum m/e: 246 (80%, M⁺), 231 (14%, [M—CH₃]⁺), 231 (14%, [M—CH₃]⁺), 18 (14%, [M—Et]]⁺), 217 (14%), 204 (11%, [M—C₃H₆)⁺), 153 (11%), 149 (14%), 140 (17%), 125 (35%, PhPOH), 121 (25%); NMR (CDCl₃) δ 0·1–0·3 m (two cyclopropanic protons), 0·8–2·2 m (9H, C₇—C₁₀+ one cyclopropanic proton), 2·3–2·8 m (3H, C—3—H and C—1—H), 7·3–7·9 m (5H, Ph). Performing the reaction with PhPBr₂ yielded compounds 2 and 4 in ratio of ~2:4 respectively.

2-Phenyl-2-methyl-2-phosphonium-tricyclo [4,4,0,0^{4,6}] decane iodide (6). To a stirred soln of 2 (100 mg) in dry benzene (10 ml) an excess of HSiCl₃ (1.5 ml) was added in one portion. The mixture was stirred under N₂ at r.t. for 1/2 hr and then refluxed for 2 hr. After cooling, N2-purged water (5 ml) were added, causing the precipitation of a white solid. The mixture was filtered under N2, yielding a turbide benzene soln. The white solid was washed twice with 10 ml portions benzene. The combined benzenic soln was washed with 5% NaHCO3 aq, then water, dried (Na₂SO₄) and evaporated yielding a viscous oil. This oil was immediately dissolved in acetone (3 ml) and MeI (0.5 ml) added. The phosphonium salt precipitated out immediately as a white ppt m.p. $192^{\circ}-193^{\circ}$ (acetone), $\nu_{\text{max}}^{\text{KBr}}$ 2900, 2860, 2830, 1450, 1440, 1230, 1150, 1105, 1095, 1035, 1020, 960, 900, 820, 750 cm⁻¹.

NMR(CDCl₃), after P-irradiation at 24.286.470 Hz, δ 0·7-0·9 m (two cyclopropanic protons), 1·1-1·2 m (one cycloproponic proton), 1·3-2·2 m (8H), 3·15 d (C-3 β -H, J_{H3,H3 β} = 15 Hz), 3·4-3·9 m (C-3 α -H and C-1-H), 2·60 d (J_{P-CH3} = 14 Hz), 7·6-8·4 m (5H, Ph). (Found: C, 51·60; H, 6·00; C₁₆H₂₂ IP requires: C, 51·55 and H, 5·96%).

Acidic opening of compound 2 to 7. A soln of 2 (500 mg) in conc HCl (30 ml) was refluxed for 5 hr. After cooling the aqueous soln was extracted with CHCl₃ the organic soln was washed with 5%-NaHCO₃-aq, then water, dried (Na₂SO₄) and evaporated yielding an oil (400 mg). Upon chromatography on a silica gel column 7 (300 mg) eluted with 5%-MeOH-EtOAc was obtained. C₁₅H₁₉PO, an oil, $\nu_{\text{max}}^{\text{neat}}$ 2990, 2900, 2850, 1620, 1450, 1440, 1150, 1120, 1050 cm⁻¹; NMR (CDCl₃) δ 1·22 d (C-CH₃, J = 6 Hz), 1·4-2·9 m (all other protons) and 7·7-8·3 m (5H, Ph); mass spectrum m/e: 246 (100%, M⁺), 245 (47%), 231 (55%, [M—CH₃)⁺), 218 (8%, [m—Et]⁺), 125 (14%, PhPOH), 121 (8%) 107 (10%), 105 (7%), 93 (10%) and 91 (20%).

Hydrogenation of compound 2 to 8. Compound 2 (250 mg) in EtOH (20 ml) was hydrogenated over 10%-PtO₂ on charcoal at atm press or 100 PSI at r.t., for 48 hr. The product obtained following evaporation of the solvent was crystallized from CH₂Cl₂-cyclohexane; C₁₅H₂₇PO, m.p. 201°, $\nu_{\text{mir}}^{\text{mir}}$ 2900, 2850, 1450, 1190, 1130, 910, 850, 820, 775, 745 cm⁻¹. Mass spectrum m/e: 252 (50%, M⁻¹), 237 (5%, [M—CH₃]⁺, 224 (5%, [M-Et]⁺), 211 (9%, [M—C₂H₃]⁺), 210 (7%, [M—C₃H₃]⁺), 171 (24%, [M—C₄H₃]⁺) 170 (100%, [M—C₆H₁₀]⁺). NMR (CDCl₃) δ 0·3–0·6 m (1H, cyclopropanic), 0·8–2·3 m (all other protons).

Opening of the cyclopropanic ring in 2 to give 9. A soln of 2 (500 mg) and Hg(OAc)₂ (1 g) in glacial AcOH (25 ml) was heated on an oil bath at 75° for 72 hr. After cooling

ice-water (50 ml) was added, and the aqueous soln extracted several times with CHCl₃. The combined organic soln was washed with 5%-NaHCO₃ aq, then water dried (Na₂SO₄) and evaporated to give the product (400 mg) which was cleaned by chromatography on a silica gel column, eluted with 5%-MeOH-EtOAc. $C_{17}H_{23}PO_{3}$; m.p. 213°-214° (CH₂Cl₂-cyclohexane), ν_{\max}^{KBP} 2920, 2850, 1710, 1230, 1150, 1110, 940, 830, 730, 690 cm⁻¹; mass spectrum m/e: 306 (100%, M⁻¹), 263 (31%, M-COCH₃), 246 (72%, M-HOAc), 245 (80%, 246-H), 244 (23%), 231 (14%, M-HOAc-CH₃); NMR (CDCl₃) δ 1·0-1·9 m (7H), 2·28 s (OCOCH₃), 2·14 m (1H) 2·4-3·0 m (5H), 3·2-4·0 m (2H α to P=O) and 7·4-8·0 m (5H, Ph).

Hydrolysis of compound 9 to 10. Compound 9 (100 mg) was left overnight in the presence of methanolic KOH (1%, 10 ml). The soln was neutralized by the dropwise addition of 5% HCl aq and most of the solvent was removed under reduced press. The residue was diluted with CHCl₃, washed with water, dried and the solvent removed. $C_{15}H_{21}PO_2$, m.p. $264^\circ-265^\circ$ (CH₂Cl₂-cyclohexane), ν_{max}^{KB} , 3260, 2900, 2850, 2800, 1460, 1450, 1245, 1220, 1140, 1100, 1050, 960, 920, 835, 740, 690, 610 cm⁻¹. Mass spectrum m/e: 264 (20%, M⁺), 263 (100%, M-H, 262 (9%, M-H₂), 225 (10%), 221 (12%), 165 (28%), 141 (20%), 125 (43%, PhPOH).

Elimination of compound 10 to 11. To a soln of 10 (300 mg) in dry pyridine (10 ml), a soln of SOCl₂ (0·5 ml) in pyridine (3 ml) was added slowly at 0°. After the usual workup, 11 was obtained as a very hygroscopic oil, $C_{15}H_{19}PO$; $\nu_{\text{max}}^{\text{max}}$ 3050, 2950, 2860, 1610, 1450, 1205, 1170, 1150, 1105, 1060, 1020, 905, 800 cm⁻¹. Mass spectrum m/e: 246 (50%, M⁺), 244 (24%, M-H₂), 231 (6%, M—CH₃), 218

(7%, M–Et), 217 (9%, 218-H), 125 (19%, PhPOH), 121 (17%), 93 (23%), 91 (36%), 85 (100%, C_6H_{13}); NMR (CDCl₃) NMR (CDCl₃) δ 0·8–2·9 m (13H), 3·5 m (1H) and 7·3–8·0 (5H, Ph).

2-Methyl-2-oxo-2-phosphatricyclo [4.4.0.0^{4.6}] decane (12). Compound 12 was obtained from 1 by following the procedure as described for the prep of 3 and 4 using CH₃PCl₂ (instead of PhPCl₂). C₁₀H₁₇PO, m.p. 153° (CH₂Cl₂-cyclo-hexane), $\nu_{\text{max}}^{\text{KB}}$ 2900, 2850, 1450, 1190, 1130, 910, 870, 850, 820, 775, 740 cm⁻¹. Mass spectrum m/e: 184 (100%, M⁺), 169 (12%, M—C₃H₃), 156 (16%, M—Et), 155 (22%, 156-H, 143 (20%, M—C₃H₃), 142 (25%, M—C₃H₆), 93 (26%), 91 (20%), 81 (47%) and 79 (50%); NMR (CDCl₃) δ 0·3-0·7 m (one cyclopropanic protone), 0·8-2·3 m (13H), 1·46 d (J = 15 Hz, P—CH₃).

2-Methoxy-2-oxo-2-phosphatricyclo [4.4.0.0^{4.6}] octane 13. Compound 13 was obtained from 1 by following a procedure as described for the prep of 3 using PCI₃ or PBr, (instead of PhPCI₃) followed by quenching of the reaction with MeOH in the presence of NEt₃ (10 mI₃) (1.61₁₋₁PO₃, an oil, ν_m^{meal} 2900, 2850, 1450, 1400, 1240, 1200, 1130, 970, 890, 830, 810, 780, 770, 730 cm⁻¹. Mass spectrum m/e: 200 (53%, M*), 185 (17%, M—CH₃), 172 (19%, M—Et), 171 (9%, 172—H), 159 (7%, M—C₃H₃), 158 (5%, M—C,H₆), 122 (14%, M—P(O)OCH₃), 107 (21%), 94 (17%), 93 (25%), 91 (20%), 85 (70%, C₆H₁₃), 83 (100%, C₆H₁₁); NMR (CDCI₃) δ 0·2-0·5 m (one cyclopropanic proton), 0·6-0·9 m (two cyclopropanic protons) 1·0-2·3 m (11H), 3·65 d ($J_{\text{POCH}} = 10 \text{ Hz}$, POCH).
