(Received in UK 11 April 1985)

Abstract. Reaction of various sulfoxides  $\underline{9}$ , with nitriles  $\underline{10}$  in presence of trifluoroacetic anhydride and trifluoroacetic acid gave the corresponding amides  $\underline{11}$  via a Ritter reaction on Pummerer intermediate derived from the sulfoxides.

Sulfoxides bearing atleast one  $\alpha$ -hydrogen undergo<sup>1</sup> a facile rearrangement, when treated with an electrophilic reagent, to give the corresponding  $\alpha$ -functionalised sulfides. This reaction has been studied<sup>2</sup> in detail and is known to proceed via the initial formation of the sulfonium salt  $\underline{2}$  (see scheme 1, where acetic anhydride is used as a typical electrophile) which is converted to an ylide  $\underline{3}$  followed by a rapid elimination of acetate ion to form the sulfenium ion  $\underline{4}$ . Reaction of  $\underline{4}$  with acetate ion gives the observed  $\alpha$ -acetoxy sulfide  $\underline{5}$ .

# Scheme 1

It is apparent that the intermediate  $\underline{4}$  is responsible in bringing out the functionalisation at  $\alpha$ -carbon. A variety of nucleophiles have been reported to trap  $\underline{4}$  in both inter and intramolecular fashion. However, there is no report where a Ritter reaction has been carried out on such an intermediate derived from a sulfoxide.

Recently we reported  $^4$  the synthesis of 2H-benzothiazine derivatives  $\underline{8}$  starting from chloromethyl aryl sulfide and nitrile in presence of SbCl<sub>5</sub> (see scheme  $\underline{2}$ ).

It was presumed that the reaction probably involved the formation of an intermediate <u>6</u> which is trapped by the nitrile to produce another intermediate <u>7</u> followed by its cyclization to give 8.

### Scheme 2

The structural similarity of <u>6</u> with that of Pummerer intermediate <u>4</u> prompted us to investigate the reaction of nitriles with sulfoxides in presence of an electrophile. In this paper we wish to report the trapping of a Pummerer intermediate, derived from sulfoxides <u>9</u>, by a variety of nitriles <u>10</u>, in presence of trifluoroacetic anhydride and trifluoroacetic acid to yield the corresponding amides <u>11</u> analogous to Ritter reaction (scheme <u>3</u>). Results are summarized in the

### Scheme 3

table. To our knowledge this is the first report of Ritter reaction on a Pummerer intermediate, derived from a sulfoxide. Use of approximately 4-5 equivalents of trifluoroacetic acid is necessary for the success of reaction or else only the trifluoroacetyl derivative  $\underline{14}$  is obtained (see path 'a', scheme  $\underline{4}$ ). A probable mechanism is shown in Scheme  $\underline{4}$ .

Unfortunately, the intermediate  $\underline{15}$ , unlike  $\underline{7}$  did not undergo any cyclization even in cases where the phenyl ring (if  $R_4$  phenyl ring) carried a methoxy group meta to the sulfoxide molety. It is likely that  $\underline{15}$  is easily trapped by the trifluoroacetate anion to yield  $\underline{16}$  which, under the reaction conditions, does not cyclize but undergoes hydrolysis, during work up, to give the amide.

## Scheme 4

Interestingly a reasonable amount of disulfide  $\underline{12}$  was obtained in every case examined (see table). This is possible only if free  $R_4SH$  is somehow produced in the reaction to react with  $\underline{13}$ . In view of the fact that the intermediate  $\underline{13}$  and the trifluoroacetyl derivative  $\underline{14}$  both react with water to produce formaldehyde and free  $R_4SH$  (scheme 5), it is likely that some water is produced in the reaction. Literature survey indicates that sulfoxides do ionise in strongly acidic medium to produce sulfonium salts of type 'A' (see scheme 4 and scheme 5) by eliminating  $H_2O$ . It is, therefore, not surprising that under the present reaction conditions some ionisation of sulfoxides of this type is possible which eventually results into the formation of disulfide  $\underline{12}$  (see scheme 5).

### EXPERIMENTAL

<sup>1</sup>H spectra were recorded at HA100, WP80 and EM90 spectrometer in CDCl<sub>3</sub> solution with TMS as internal standard. IR spectra were recorded at Perkin Elmer 580 instrument.

### General Procedure for the preparation of compounds 11 and 14

# (1) Corresponding to entries 1,2,4 and 5

To a stirred solution of a sulfoxide (2.5 mmol) in 5 ml freshly distilled nitrile at 0°C was added a mixture of trifluoroacetic anhydride (3.25 mmol) and trifluoroacetic acid (1.0 ml) in 2 ml of dry dichloromethane (dried over  $P_2O_5$ ) over a period of 30 minutes. It was allowed to stir at 0°C for 8 hrs. and then at room temperature for the time indicated in the table. At the end the reaction mixture was cooled to 0°C and a cold 8 aqueous solution of sodium hydroxide was slowly added to it till it was just basic to litmus. The reaction mixture was then diluted with water (10 ml) and extracted with dichloromethane (3x20 ml). The combined organic layers were washed with water (10 ml), then with brine (10 ml) and dried over anhydrous sodium sulfate. Evaporation of the solvent gave a crude product containing 11 and 14 which were separated by thick layer chromatography using silica gel (eluents benzene acetone, 80 20) and characterised by spectral means.

#### (11) Corresponding to entries 3 and 6

The reaction was carried out in the same manner as indicated above except that the excess of benzonitrile and trifluoroacetic acid were removed under vacuum prior to the treatment with base.

### (111) Corresponding to entries 7,8 and 9

The reaction was carried out in the same manner as above cf. (i). At the end excess of benzonitrile and trifluoroacetic acid were removed under vacuum and the residue treated with 8 aqueous cold NaOH solution until it was just basic to litmus. About 2 gms of solid sodium chloride was then added to it and extracted with ethyl acetate (3x15 ml). The combined organic layers were washed with brine (10 ml) and dried over anhydrous sodium sulfate. Evaporation of the solvent gave a crude product which was washed twice with pentane (5 ml). The pentane layer was discarded and the crude compound was purified by thick layer chromatography using silica gel (eluents benzene acetone, 80 20) and characterized by spectral means.
