

THE PERIODIC BEHAVIOR OF MORSE-SMALE DIFFEOMORPHISMS ON COMPACT SURFACES

BY

CAROLYN C. NARASIMHAN

ABSTRACT. Necessary and sufficient conditions are given for the existence of Morse-Smale diffeomorphisms homotopic to the identity with prescribed periodic characteristics on any compact 2-manifold.

An important class of dynamical systems on smooth compact manifolds consists of the Morse-Smale diffeomorphisms. These have a relatively simple orbit structure and this structure is preserved under small C^1 perturbations. If f is a Morse-Smale diffeomorphism, then the nonwandering set of f consists of a finite number of periodic orbits γ_i and each such γ_i has the following invariants: p_i , the period of $x \in \gamma_i$; u_i , the dimension of E_x^u for $x \in \gamma_i$; and Δ_i , the orientation type of $x \in \gamma_i$ (see §1 for definitions). If we define the periodic data of a diffeomorphism to be the collection of triples (p_i, u_i, Δ_i) , then it would be interesting to know when there exists a diffeomorphism with given periodic data.

Clearly, the topology of a manifold M imposes certain restrictions on the orbit structure of a diffeomorphism of M . For example, if M is compact, then a Morse-Smale diffeomorphism of M has at least one source and one sink; that is, $u_i = 0$ and $u_j = \dim M$ for some i and j .

Smale defines in [9] the homology zeta function $\eta(f)$ of a diffeomorphism f of a compact manifold M by

$$\eta(t) = \exp\left(\sum_{m=1}^{\infty} \frac{1}{m} L(f^m) t^m\right),$$

where $L(f^m)$, the Lefschetz number of f^m , counts the fixed points of f^m algebraically. This function is always rational and is a homotopy invariant of f . In fact, as shown in [9], if f is homotopic to the identity of M , then $\eta(f) = (1 - t)^{-\chi(M)}$, where $\chi(M)$ is the Euler characteristic of M . Franks has shown in [3] that if f is a C^1 map with only n periodic orbits, all hyperbolic,

then $\eta(f)$ has the simple form

$$\eta(t) = \prod_{i=1}^n (1 - \Delta_i t^{p_i})^{(-1)^{u_i+1}},$$

where $\{(p_i, u_i, \Delta_i)\}_{i=1}^n$ is the periodic data of f . Therefore, the periodic data of a Morse-Smale diffeomorphism f which is homotopic to the identity must satisfy the equation

$$\prod_{i=1}^n (1 - \Delta_i t^{p_i})^{(-1)^{u_i}} = (1 - t)^{\chi(M)}.$$

The purpose of this paper is to show that when M is a compact, connected 2-manifold, these two conditions are sufficient for the existence of a Morse-Smale diffeomorphism homotopic to the identity. Thus, we have the following theorem.

THEOREM. *Let M be a compact, connected 2-manifold. There exists a Morse-Smale diffeomorphism f of M homotopic to the identity with periodic data $\{(p_i, u_i, \Delta_i)\}_{i=1}^n$ if and only if*

- (a) $u_i = 0$ and $u_j = 2$ for some i and j ;
- (b) $\prod_{i=1}^n (1 - \Delta_i t^{p_i})^{(-1)^{u_i}} = (1 - t)^{\chi(M)}$.

In §1, we give definitions and background. Two general references for this are [9] and [5]. In §2, we consider the equation

$$\prod_{i=1}^n (1 - \Delta_i t^{p_i})^{(-1)^{u_i}} = (1 - t)^{\chi(M)}$$

and, using combinatorial arguments, rewrite it in a canonical form which is useful in proving the theorem. In §3, we construct several basic diffeomorphisms on discs and annuli in the plane and indicate how these can be pieced together to produce the desired diffeomorphism on the given 2-manifold. Some additional results derived from the canonical form are proved in §4.

I wish to thank my advisor, John Franks, for suggesting the problem and for the help he has given me with this work, and R. Narasimhan, for helpful conversations.

1. Preliminaries. Let M be a compact C^∞ manifold and $\text{Diff}(M)$ the group of C^r diffeomorphisms of M , $1 \leq r \leq \infty$. A point $x \in M$ is called a *nonwandering point* of $f \in \text{Diff}(M)$ if for every neighborhood U of x , there exists $m > 0$ such that $f^m(U) \cap U \neq \emptyset$. The set of nonwandering points is a closed, invariant set of f and is denoted by $\Omega(f)$, or Ω .

A *hyperbolic periodic point* of f is a point $x \in M$ with $f^n(x) = x$ for some $n \geq 1$ and such that the derivative map $Df_x^n: T_x M \rightarrow T_x M$ has no eigenvalues of absolute value one. If all eigenvalues of Df_x^n are less than one in absolute

value, x is called a *sink*, and if all eigenvalues of Df_x^n are greater than one in absolute value, x is called a *source*. Otherwise, x is called a *saddle*. Let E_x^u be the subspace of $T_x M$ spanned by eigenspaces of Df_x^n corresponding to eigenvalues greater than one in absolute value, and E_x^s the subspace of $T_x M$ spanned by the remaining eigenspaces. Then $T_x M = E_x^u \oplus E_x^s$, and this splitting is invariant under Df_x^n .

Suppose γ is a hyperbolic periodic orbit of f with least period p . Let $x, y \in \gamma$, $f^m(x) = y$. Then $Df_x^m: E_x^u \rightarrow E_y^u$ is an isomorphism, so $\dim E_x^u = \dim E_y^u$. Also, $Df_x^p: E_x^u \rightarrow E_x^u$ preserves orientation if and only if $Df_y^p: E_y^u \rightarrow E_y^u$ preserves orientation, since

$$Df_y^p = (Df_x^m)(Df_x^p)(Df_x^m)^{-1}.$$

Define the *orientation type* Δ of γ to be $+1$ if $Df_x^p: E_x^u \rightarrow E_x^u$ preserves orientation and -1 if it reverses orientation.

Thus, each hyperbolic periodic orbit γ_i of f has three integer invariants: p_i , the least period of γ_i ; $u_i = \dim E_x^u$ for $x \in \gamma_i$; and Δ_i , the orientation type of $x \in \gamma_i$.

DEFINITION. If f is a diffeomorphism whose nonwandering set consists of n hyperbolic periodic orbits, we define the *periodic data* of f to be the collection $\{(p_i, u_i, \Delta_i)\}_{i=1}^n$.

The *stable manifold* of a hyperbolic fixed point x of f is defined by

$$W^s(x) = W^s(x, f) = \{y \in M \mid d(f^n(x), f^n(y)) \rightarrow 0 \text{ as } n \rightarrow \infty\},$$

where d is a metric on M , and the *unstable manifold* of x is $W^u(x) = W^u(x, f) = W^s(x, f^{-1})$. These are one-to-one immersed submanifolds of M and $T_x(W^s(x)) = E_x^s$, $T_x(W^u(x)) = E_x^u$ (see [8]). If x is a hyperbolic periodic point of period p , the stable and unstable manifolds of x are defined by

$$W^s(x) = W^s(x, f^p), \quad W^u(x) = W^u(x, f^p).$$

DEFINITION. A *Morse-Smale diffeomorphism* is a diffeomorphism f of M satisfying the following conditions:

- (1) $\Omega(f)$ is finite;
 - (2) the periodic points of f are hyperbolic;
 - (3) for each $x, y \in \Omega(f)$, $W^s(x)$ and $W^u(y)$ have transversal intersection.
- Condition (1) implies that $\Omega(f)$ consists of periodic points. Palis and Smale proved in [6] that for $f \in \text{Diff}(M)$ with $\Omega(f)$ finite, f is a Morse-Smale diffeomorphism if and only if f is structurally stable.

For a Morse-Smale diffeomorphism, $M = \bigcup W^s(x_i) = \bigcup W^u(x_i)$ for $x_i \in \Omega(f)$. Therefore, a Morse-Smale diffeomorphism has at least one source and one sink.

If $f \in \text{Diff}(M)$ has a finite nonwandering set consisting of periodic orbits $\{\gamma_i\}_{i=1}^k$, then a *filtration* for f is a finite sequence $\{M_i\}_{i=1}^k$ of manifolds with

boundary, of the same dimension as M , such that $M = M_k \supset \cdots \supset M_1 \supset M_0 = \emptyset$, $f(M_i) \subset \text{int}(M_i)$, and $\bigcap_{m \in \mathbb{Z}} f^m(M_i - M_{i-1}) = \gamma_i$.

In proving the theorem, we shall construct a diffeomorphism f of M whose nonwandering set is a finite number of hyperbolic periodic orbits and such that f has a filtration. In this case, by the Ω -stability theorem (see [10]), and the Kupka-Smale theorem (see [1] or [7]), we can find in a neighborhood of f a Morse-Smale diffeomorphism of M which has the same periodic data as f .

2. Canonical form. To prove that a diffeomorphism f whose periodic data satisfy the equation

$$\prod_{i=1}^n (1 - \Delta_i t^{p_i})^{(-1)^{u_i+1}} = \eta(f) = (1 - t)^{-\chi(M)}$$

can actually be constructed, it is necessary to study this equation more closely. First, note that in the case of a 2-dimensional manifold M , u_i is 0, 1, or 2. Furthermore, since f is homotopic to the identity, it is orientation preserving. Thus, $\Delta_i = +1$ when $u_i = 0$ or $u_i = 2$, and Δ_i may be $+1$ or -1 when $u_i = 1$. Therefore, we are interested in equations of the form

$$\frac{\prod_{i=1}^m (1 \pm t^{q_i})}{\prod_{j=1}^l (1 - t^{p_j})} = 1.$$

We shall show that such an equation imposes restrictions on the integers m , l , q_i , and p_j (which are part of the given periodic data).

LEMMA 2.1. *If*

$$\frac{\prod_{i=1}^m (1 - t^{q_i}) \prod_{k=1}^n (1 + t^{r_k})}{\prod_{j=1}^l (1 - t^{p_j})} = 1,$$

then

(a) $m = l$;

(b) *there exist integers* $a_1 \geq 0, \dots, a_m \geq 0$ *such that*

(i) *the set* $\{p_1, p_2, \dots, p_m\}$ *equals the set* $\{2^{a_1} q_1, 2^{a_2} q_2, \dots, 2^{a_m} q_m\}$;

(ii) *the set* $\{r_1, r_2, \dots, r_n\}$ *equals the set*

$$\{q_1, 2q_1, \dots, 2^{a_1-1} q_1; q_2, 2q_2, \dots, 2^{a_2-1} q_2; \dots; q_m, \dots, 2^{a_m-1} q_m\}.$$

(If $a_i = 0$ for some i , i.e., if $p_i = q_i$, then the set of numbers $q_i, \dots, 2^{a_i-1} q_i$ in (ii) stands for the empty set, i.e., there are no corresponding r_j .)

Thus, such an equation has the canonical form

$$\prod_{i=1}^m \left[\frac{(1 - t^{q_i})(1 + t^{q_i})(1 + t^{2q_i}) \cdots (1 + t^{2^{a_i-1} q_i})}{(1 - t^{2^{a_i} q_i})} \right] = 1.$$

PROOF. Let $P(t) = \prod_{i=1}^m (1 - t^{q_i}) \prod_{k=1}^n (1 + t^{r_k})$ and $Q(t) = \prod_{j=1}^l (1 - t^{p_j})$. Then $P(t)$ has a zero of order m at $t = 1$ and $Q(t)$ has a zero of order l at $t = 1$. Since $P(t) = Q(t)$, $m = l$.

We shall prove (b) by induction on $m + n$. Suppose $m + n = 1$. Then either $m = 0$ or $n = 0$. In the first case, $\prod_{k=1}^n (1 + t^{r_k}) = 1$, so $n = 0$. In the second case, we have $(1 - t^{q_1}) = (1 - t^{p_1})$. Therefore, $q_1 = p_1$ and the statement is true in this case.

Now assume that the statement is true for $s < m + n$, and that we have

$$\prod_{i=1}^m (1 - t^{q_i}) \prod_{k=1}^n (1 + t^{r_k}) = \prod_{j=1}^m (1 - t^{p_j}).$$

Reorder the q 's and p 's so that

$$q_1 \leq q_2 \leq \cdots \leq q_m \quad \text{and} \quad p_1 \leq p_2 \leq \cdots \leq p_m.$$

We shall show that either $p_m = q_m$ or $p_m = 2r_j$ for some j .

Let

$$P_1(t) = \prod_{i=1}^m (1 - t^{q_i}), \quad P_2(t) = \prod_{k=1}^n (1 + t^{r_k}).$$

Then $P_1(t)P_2(t) = Q(t)$. Since $e^{2\pi i/q_m}$ is a root of $P_1(t)$, it is a root of $Q(t)$. Thus, there exists j such that $e^{2\pi i p_j/q_m} = 1$. Therefore, q_m divides p_j , so $q_m \leq p_j \leq p_m$. Now $e^{2\pi i/p_m}$ is a root of $Q(t)$, so there are two possibilities to consider:

(i) Suppose $e^{2\pi i/p_m}$ is a root of $P_1(t)$. Then, by the same reasoning as above, $p_m \leq q_m$, so $p_m = q_m = 2^0 q_m$. In this case, we have

$$\prod_{i=1}^{m-1} (1 - t^{q_i}) \prod_{k=1}^n (1 + t^{r_k}) = \prod_{j=1}^{m-1} (1 - t^{p_j}),$$

and the result follows by induction,

(ii) Suppose $e^{2\pi i/p_m}$ is a root of $P_2(t)$. Then there exists j such that $e^{2\pi i r_j/p_m} = -1$, so $2r_j/p_m = l$ for some odd integer l . On the other hand, $e^{\pi i/r_j}$ is a root of $P_2(t)$, so it is a root of $Q(t)$ and $e^{\pi i p_s/r_j} = 1$ for some s . Therefore, $p_s/r_j = 2l'$ for some integer l' . Thus, $p_s = ll'p_m$. But $p_s \leq p_m$, so $l = 1$ and $p_m = 2r_j$. In this case, we have

$$\prod_{i=1}^m (1 - t^{q_i}) \prod_{k=1}^{j-1} (1 + t^{r_k}) \prod_{k=j+1}^n (1 + t^{r_k}) = (1 - t^{r_j}) \prod_{j=1}^{m-1} (1 - t^{p_j}),$$

or, after a change of notation,

$$\prod_{i=1}^m (1 - t^{q_i}) \prod_{k=1}^{n-1} (1 + t^{r_k}) = \prod_{j=1}^m (1 - t^{p_j}),$$

and, again, the result follows by induction. Q.E.D.

3. Construction of diffeomorphisms. The technique used in proving the sufficiency of the conditions in the theorem is to write the given 2-manifold M as a union of 2-dimensional annuli, or annuli and discs, and to construct a diffeomorphism of M which agrees with certain basic diffeomorphisms in these regions. Below, we prove the existence of three mappings of regions in the plane which, together with their inverses, will constitute these basic diffeomorphisms. These mappings are constructed so that they agree in a neighborhood of the boundaries of their domains, and therefore may be easily pieced together to define a mapping of the manifold M .

In the rest of this chapter, when we say that a diffeomorphism f has periodic data $\{(p_i, u_i, \Delta_i)\}$, we shall mean that the nonwandering set of f consists only of the hyperbolic orbits described by this data.

We construct first a diffeomorphism of a disc whose periodic points all have periods a power of 2. This example is due to Dennis Pixton.

LEMMA 3.1. *For any $n \geq 0$, there exists a diffeomorphism f of the 2-dimensional unit disc onto its image with periodic data*

$$\{(2^{n+1}, 0, +1), (1, 1, -1), (2, 1, -1), (2^2, 1, -1), \dots, (2^n, 1, -1)\}.$$

Furthermore, for some $R > 0, \varepsilon > 0$, f maps the annulus $\{x \in \mathbb{R}^2 | 1 - R \leq |x| \leq 1\}$ inward along radii a fixed distance ε , and there exists a filtration of the disc for f .

PROOF. Let D_0^1 denote the unit disc and let D_1^1, D_1^2 denote the two discs with radius $r_1 = \frac{1}{4}$ and centers $a_1^1 = (-\frac{1}{2}, 0), a_1^2 = (\frac{1}{2}, 0)$; i.e., D_1^1 and D_1^2 are discs contained in D_0^1 with radii $\frac{1}{4}$ that of D_0^1 and centers on the x -axis at the midpoints of the two radii of D_0^1 .

In general, for $2 \leq k \leq n+1$, let $D_k^1, D_k^2, \dots, D_k^{2^k}$ denote the 2^k discs with radii $r_k = \frac{1}{4} r_{k-1}$ such that $D_k^1, D_k^2 \subset D_{k-1}^1$; $D_k^3, D_k^4 \subset D_{k-1}^2$; $\dots$; $D_k^{2^{k-1}}, D_k^{2^k} \subset D_{k-1}^{2^{k-1}}$, and such that the centers $a_k^{2^i-1}, a_k^{2^i}$ of $D_k^{2^i-1}, D_k^{2^i}$ respectively are the midpoints of the radii of D_{k-1}^i on the x -axis. Choose $R > 0$ small ($R < \frac{1}{16} r_{n+1}$) and let A_0^1 be the annulus $\{x \in D_0^1 | r_0 - R \leq |x| \leq r_0\}$ and for $1 \leq k \leq n+1, A_k^i = \{x \in D_0^1 | r_k - R \leq |x - a_k^i| \leq r_k + R\}$ (see Figure 1).

For $0 \leq k \leq n+1$, choose a C^∞ function $\alpha_k: R \rightarrow [0, 1]$ such that

$$\alpha_k(t) = \begin{cases} 1, & t \leq (7/8)r_k \\ 0, & (15/16)r_k \leq t. \end{cases}$$

Now define $h_k: D_k^1 \rightarrow D_k^1$ in polar coordinates centered at a_k^1 to be

$$h_k(r, \theta) = (r, \theta + \pi \alpha_k(r)).$$

Then h_k is a diffeomorphism of D_k^1 which is the identity on the annulus $A_k^1 \cap D_k^1$ and is a rotation on the inner disc $\{x \in D_k^1 | |x - a_k^1| \leq \frac{7}{8} r_k\}$ by π .

FIGURE 1

FIGURE 2

Note that the center of D_k^1 is a fixed point of h_k and that h_k reverses the two discs D_{k+1}^1 and D_{k+1}^2 . In particular, h_k interchanges the centers of these two discs. For $1 \leq k \leq n+1$, extend h_k to the entire disc D_0^1 by the identity.

Define $h: D_0^1 \rightarrow D_0^1$ by $h(x) = h_0 \circ h_1 \circ \dots \circ h_{n+1}(x)$. Then h is a diffeomorphism of D_0^1 with the following property: for each k , $0 \leq k \leq n+1$, the centers of the 2^k discs D_k^i form a periodic orbit of period 2^k .

Let $B_k^i = D_k^i \cup A_k^i - \{(D_{k+1}^{2i-1} - A_{k+1}^{2i-1}) \cup (D_{k+1}^{2i} - A_{k+1}^{2i})\}$, for $k = 0, 1, \dots, n$. Let ρ_k be a flow on $\bigcup_{i=1}^{2^k} B_k^i$ with the following properties (Figure 2):

- (a) ρ_k maps the annuli A_k^i , A_{k+1}^{2i-1} , and A_{k+1}^{2i} inward along radii a distance ε at time 1;
- (b) ρ_k has exactly one saddle point at the center of each B_k^i ;
- (c) ρ_k is symmetric in B_k^i with respect to the center of B_k^i .

On the union of discs $\bigcup_{i=1}^{2^{n+1}} (D_{n+1}^i \cup A_{n+1}^i)$, define a flow ρ_{n+1} with the properties:

- (a) ρ_{n+1} maps the annuli A_{n+1}^i inward along radii a distance ε at time 1;
- (b) ρ_{n+1} has exactly one sink at the center of each D_{n+1}^i ;
- (c) ρ_{n+1} is symmetric in each D_{n+1}^i with respect to the center of D_{n+1}^i .

The flows ρ_k have been defined so that ρ_k and ρ_{k+1} agree where they are both defined, namely, on the annuli A_{k+1}^i . Therefore, we can define a flow ρ on all of D_0^1 by setting $\rho(x) = \rho_k(x)$ for $x \in B_k^i$. Let g be the time-one map of ρ . Then g is a diffeomorphism of D_0^1 with $\sum_{i=0}^n 2^i$ saddle points of period 1 (the centers of the D_k^i for $0 \leq k \leq n$) and 2^{n+1} sinks of period 1 (the centers of the D_{n+1}^i). All other points of D_0^1 are wandering under g .

Let $f = g \circ h$. Then f is a diffeomorphism of D_0^1 . For any k , $0 \leq k \leq n+1$, the centers of the 2^k discs D_k^i form a periodic orbit of period 2^k under h and are left fixed by g . Thus, they form a periodic orbit of period 2^k under f .

For each k , $0 \leq k \leq n+1$, let $C_k^i = \{x \in D_k^i \mid |x - a_k^i| < \frac{1}{8} r_k\}$. Then h permutes these 2^k discs, so for $x \in C_k^i$, $h(x) \in C_k^j$ for some j . Suppose $x = (r, \theta)$ in polar coordinates centered at a_k^i . Then $h(x)$ is either (r, θ) or $(r, \theta + \pi)$ in polar coordinates centered at a_k^i . But ρ is symmetric with respect to the centers of the D_k^i . Hence $(g \circ h)(x) = (h \circ g)(x)$. Therefore, $\bigcup_{i=1}^{2^k} C_k^i$ is a neighborhood of the points a_k^i in which g and h commute. Thus, in this neighborhood, $f^{2^k} = g^{2^k} \circ h^{2^k}$. Now, h^{2^k} maps C_k^i to itself (since $h^{2^k}(a_k^i) = a_k^i$), but h^{2^k} interchanges the centers of the discs $D_{k+1}^{2^i-1}$ and $D_{k+1}^{2^i}$ (since they are points of period 2^{k+1}). Therefore, $h^{2^k}|_{C_k^i}$ is just rotation by π , and $Df^{2^k} = Dg^{2^k} \circ h$. Hence, the $n+1$ orbits consisting of the points a_k^i , for $0 \leq k \leq n$, are hyperbolic saddles and the orbit consisting of the a_{n+1}^i is a hyperbolic sink. All other points are wandering under f .

Let $0 \leq k \leq n$, and let $W^u(a_k^i)$ denote the unstable manifold of a_k^i . We must show that f^{2^k} reverses the orientation of $W^u(a_k^i)$. But in the neighborhood C_k^i of a_k^i , $W^u(a_k^i)$ is on the x -axis, so its orientation is left fixed by g^{2^k} and reversed by h^{2^k} , which rotates C_k^i by π . Therefore, f^{2^k} reverses the orientation of $W^u(a_k^i)$.

Note that f maps the annulus A_0^1 inward along radii a distance ϵ , since this is the effect of g and h leaves A_0^1 fixed.

Finally, f has the filtration

$$D_0^1 \supset D_1^1 \cup D_1^2 \supset \cdots \supset \bigcup_{i=1}^{2^k} D_k^i \supset \cdots \supset \bigcup_{i=1}^{2^{n+1}} D_{n+1}^i \supset \emptyset. \quad \text{Q.E.D.}$$

LEMMA 3.2. Let $A = \{x \in \mathbf{R}^2 \mid 1 \leq |x| \leq 3\}$. For any $n \geq 1$, $m \geq 0$, there exists a diffeomorphism f of A onto its image with periodic data

$$\{(2^m n, 0, +1), (n, 1, +1), (n, 1, -1), (2n, 1, -1), \dots, (2^{m-1}n, 1, -1)\}.$$

Furthermore, for some $R > 0$, $\epsilon > 0$, f maps the annuli

$$A_1 = \{x \in A \mid 1 \leq |x| \leq 1 + R\} \quad \text{and} \quad A_2 = \{x \in A \mid 3 - R \leq |x| \leq 3\}$$

into A along radii a distance ϵ , and f has a filtration on A .

PROOF. Choose $R > 0$, $\delta > 0$ small, $0 < R < \delta < 1/3$ and let $\alpha: \mathbf{R} \rightarrow [0, 1]$ be a C^∞ function such that

$$\alpha(t) = \begin{cases} 0, & t \leq 1 + R, \\ 1, & 2 - \delta - R \leq t \leq 2 + \delta + R, \\ 0, & 3 - R \leq t. \end{cases}$$

Define $h: A \rightarrow A$ in polar coordinates to be

$$h(r, \theta) = \left(r, \theta + \frac{2\pi}{n} \alpha(r)\right).$$

Then h is a diffeomorphism of A which is the identity on the annuli A_1 and

A_2 and which rotates the annulus $\{x \in A \mid 2 - \delta - R < |x| < 2 + \delta + R\}$ by $2\pi/n$.

Let $a_k = (2, 2(k-1)\pi/n)$ for $k = 1, \dots, n$ and define sets

$D_k = \{x \in A \mid |x - a_k| < \delta\}$ and $B_k = \{x \in A \mid \delta - R \leq |x - a_k| \leq \delta + R\}$ (see Figure 3).

FIGURE 3

FIGURE 4

Let $B = A - \bigcup_{k=1}^n (D_k - B_k)$ and define a flow ρ on B with the following properties (Figure 4):

(a) ρ maps the annuli A_1 and A_2 into A along radii a distance of ϵ at time 1;

- (b) ρ maps the n annuli B_k inward along radii a distance of ε at time 1;
 (c) ρ has n saddle points at $b_k = (2, (2k - 1)\pi/n)$, $k = 1, \dots, n$ and all other points are wandering;
 (d) ρ commutes with rotation through $2\pi/n$.

Let φ be the time-one map of ρ . Then φ has n saddles of orientation type $+1$.

We shall now define diffeomorphisms $g_1, \dots, g_n$ on the discs $D_1 \cup B_1, \dots, D_n \cup B_n$. In each disc $D_k \cup B_k$, choose the diametral axis which makes an angle of $2(k - 1)\pi/n$ with the positive x -axis. By Lemma 3.1, there exists a diffeomorphism g_1 of $D_1 \cup B_1$ with m saddles of periods $1, 2, \dots, 2^{m-1}$ respectively and each of orientation type -1 , and one sink of period 2^m , and such that the annulus B_1 is mapped inward along radii a distance ε . Let c_1^i denote a point of period 2^i . Then, as is clear from the proof of Lemma 3.1, we can choose these $\sum_{i=0}^m 2^i$ points so that they all lie on the given axis of $D_1 \cup B_1$. Now for $2 \leq k \leq n$, define a flow ρ_k on $D_k \cup B_k$ with the following properties (Figure 5):

FIGURE 5

- (a) ρ_k maps the annulus B_k inward along radii a distance ε at time 1;
 (b) at each of the $\sum_{i=0}^{m-1} 2^i$ points c_k^i on the given axis such that $|c_k^i - a_k| = |c_1^i - a_1|$, ρ_k has a saddle point;
 (c) at each of the 2^m points c_k^m such that $|c_k^m - a_k| = |c_1^m - a_1|$, ρ_k has a sink;
 (d) all other points are wandering under ρ_k .

Let g_k be the time-one map of ρ_k , $k = 2, \dots, n$. Now define a diffeomorphism g of A by

$$g(x) = \begin{cases} \varphi(x), & x \in B, \\ g_i(x), & x \in D_i \cup B_i. \end{cases}$$

Then g is well defined, since φ and g_i agree on $B \cap (D_i \cup B_i) = B_i$.

Let $f = g \circ h$. The points $b_1, \dots, b_n$ are saddle points of g and are permuted by h . Also, in the neighborhood $\bigcup_{i=1}^n D'_i$, $D'_i = \{x \in A \mid |x - b_i| < \delta\}$, g and h commute and $h|_{\bigcup D'_i}$ is just rotation by $2\pi/n$. Therefore, $Df^n = Dg^n \circ h$, so the points $b_1, \dots, b_n$ form a hyperbolic saddle of period n . Furthermore, both h and g leave the orientation of $W^u(b_i)$ fixed for all i , so this saddle has orientation type $+1$.

Now consider the points c_j^i . Under g , the $\sum_{i=0}^m 2^i$ points c_1^i form $m+1$ hyperbolic orbits: m saddles of periods $1, 2, \dots, 2^{m-1}$ respectively and orientation type -1 , and 1 sink of period 2^m . For $j > 1$, the c_j^i are left fixed by g . For each i , $h^k(c_1^i) = c_{k+1}^i$, $1 \leq k \leq n-1$, and $h^n(c_1^i) = c_1^i$. Therefore, f has the following periodic orbits: m saddles of periods $n, 2n, \dots, 2^{m-1}n$ respectively, and one sink of period $2^m n$. As in the proof of Lemma 3.1, there exists a small disc C_1^i about each c_1^i such that on $\bigcup_i C_1^i$, the mappings g and h commute. Furthermore, these C_1^i may be chosen so that $h^k|_{C_1^i}$ is just rotation in coordinates centered at 0 by $2k\pi/n$. Therefore, in the neighborhood

$$\bigcup_i C_1^i \cup \bigcup_{k,i} h^k(C_1^i)$$

of the c_j^i , g and h commute, and $Df^k = Dg^k \circ h$, $1 \leq k \leq 2^m n$. Hence, these orbits are hyperbolic orbits. Finally, it is clear that the orientation type of the saddles formed this way is -1 , since rotation of A by h does not change the orientation of their unstable manifolds.

That f acts as desired in a neighborhood of the boundary of A is clear from the construction.

Let $D_k \supset M_k^1 \supset M_k^2 \supset \dots \supset M_k^{p_k} \supset \emptyset$ be the filtration for $f|_{D_k}$ as described in Lemma 3.1. Then a filtration for f is given by

$$A \supset \bigcup_{k=1}^n D_k \supset \bigcup_{k=1}^n M_k^1 \supset \dots \supset \bigcup_{k=1}^n M_k^{p_k} \supset \emptyset. \quad \text{Q.E.D.}$$

LEMMA 3.3. Let A , A_1 , and A_2 be as in Lemma 3.2. For any $n \geq 1$, $m \geq 0$, there exists a diffeomorphism f of A onto its image with periodic data

$$\{(2^m n, 0, +1), (n, 1, +1), (n, 1, -1), (2n, 1, -1), \dots, (2^{m-1}n, 1, -1)\}$$

and such that f maps the annulus A_1 along radii a distance ϵ outside of A and the annulus A_2 a distance ϵ into A . Furthermore, there exist submanifolds

$$A \supset N_k \supset N_{k-1} \supset \dots \supset N_1 \supset \emptyset$$

such that $f(N_i) \subset \text{int } N_i$ and $\bigcap_{m \in \mathbb{Z}} f^m(N_i - N_{i-1})$, $i = 1, \dots, k$, and $\bigcap_{m \in \mathbb{Z}} f^m(A - N_k)$ are the periodic orbits of f .

PROOF. The proof of this lemma is almost identical to that of Lemma 3.2, so we shall use the notation of that proof and simply indicate the necessary changes. This consists mainly of changing the definition of the flow ρ defined

on the annulus A with discs $\{x \in A \mid |x - a_k| < \delta - R\}$ removed.

Let $b_k = (3/2, 2(k-1)\pi/n)$ and $D'_k = \{x \in A \mid |x - b_k| < \delta\}$. Note that δ and R may be chosen as small as desired, so that $D'_k \cap (D_k \cup B_k) = \emptyset$ and $D'_k \cap A_1 = \emptyset$. Define a flow ρ on $B = A - \bigcup_{k=1}^n (D_k - B_k)$ with the following properties (Figure 6):

FIGURE 6

- (a) ρ maps the annulus A_1 along radii outside of A a distance ϵ at time 1, and ρ maps A_2 along radii into A a distance ϵ at time 1;
- (b) ρ maps the n annuli B_k inward along radii a distance of ϵ at time 1;
- (c) ρ has n saddle points at $b_1, \dots, b_n$ and all other points are wandering;
- (d) ρ commutes with rotation through $2\pi/n$.

If f is defined as in 3.2, then f is a diffeomorphism with domain A which has the same periodic data as the diffeomorphism in 3.2 and differs only in that it maps a neighborhood of the inner boundary of A outside of A instead of into A .

Finally, $A \supset \bigcup_{k=1}^n D_k \supset \bigcup_{k=1}^n M_k^1 \supset \dots \supset \bigcup_{k=1}^n M_k^k \supset \emptyset$, where the M_k^i are as in 3.2, and these submanifolds satisfy the properties in the statement of the lemma. Q.E.D.

In the proof of the theorem, we shall write the 2-manifold M as a union of annuli and discs, $\bigcup A_i$, and construct $f \in \text{Diff}(M)$ such that $f|_{A_i}$ is one of the examples constructed above. These submanifolds will be pieced together so that they would give a filtration for f if $f|_{A_i}$ had only one periodic orbit. On the other hand, as seen in the preceding lemmas, $f|_{A_i}$ would have a filtration on A_i if $f(A_i)$ were always contained in A_i . We can combine these subdivisions to get a filtration for f , and we state the following as a lemma for purposes of reference.

LEMMA 3.4. Let $f \in \text{Diff}(M)$ and suppose there exist submanifolds $M_1, \dots, M_k$ and $N_1^1, \dots, N_{\nu_1}^1, \dots, N_1^k, \dots, N_{\nu_k}^k$ of M , with boundary and of the same dimension as M , satisfying

- (1) $M = M_k \supset M_{k-1} \supset \dots \supset M_1 \supset \emptyset$ and $f(M_i) \subset \text{int } M_i$;
- (2) for $i = 1, \dots, k$, $M_i - M_{i-1} = N_{\nu_i}^i \supset \dots \supset N_1^i \supset \emptyset$ and

$$f(N_j^i) \subset \text{int } N_j^i, \quad j = 1, \dots, \nu_i - 1,$$

$$\bigcap_{m \in \mathbb{Z}} f^m(N_j^i - N_{j-1}^i) = \Lambda_j^i, \quad j = 1, \dots, \nu_i,$$

where $\{\Lambda_j^i\}_{i,j}$ are the basic sets of f . Then f has a filtration on M .

PROOF. We have

$$\begin{aligned} M &= M_k = M_{k-1} \cup N_{\nu_k}^k \supset \dots \supset M_{k-1} \cup N_1^k \supset M_{k-1} \\ &= M_{k-2} \cup N_{\nu_{k-1}}^{k-1} \supset \dots \supset M_2 = M_1 \cup N_{\nu_2}^2 \supset \dots \supset M_1 \cup N_1^2 \supset M_1 \\ &= N_{\nu_1}^1 \supset \dots \supset N_1^1 \supset \emptyset, \end{aligned}$$

where $f(M_j \cup N_i^{j+1}) \subset \text{int}(M_j \cup N_i^{j+1})$ and

$$\bigcap_{m \in \mathbb{Z}} f^m[(M_j \cup N_i^{j+1}) - (M_j \cup N_{i-1}^{j+1})] = \bigcap_{m \in \mathbb{Z}} f^m(N_i^{j+1} - N_{i-1}^{j+1}) = \Lambda_i^{j+1},$$

for all i, j . Q.E.D.

We shall now prove that the conditions of the theorem are sufficient when M is a compact, connected 2-manifold. By the classification theorem for compact surfaces (see Massey [4] for a reference), M is homeomorphic to a sphere, torus, connected sum of tori, projective plane, or connected sum of projective planes. We shall denote these surfaces by S^2 , T , X_n , P , and Y_n respectively.

THEOREM. Let M be a compact, connected 2-manifold. There exists a Morse-Smale diffeomorphism f of M homotopic to the identity with periodic data $\{(p_i, u_i, \Delta_i)\}$ if

- (a) $u_i = 0$ and $u_j = 2$ for some i and j ;
- (b) $\prod_{k=1}^n (1 - \Delta_i t^{p_i})^{(-1)^{u_i}} = (1 - t)^{\chi(M)}$, where n is the number of periodic orbits.

PROOF. Since M is a 2-dimensional manifold, u_i is 0, 1, or 2 depending on whether γ_i is a sink, saddle, or source. Furthermore, in the case of a diffeomorphism homotopic to the identity, Δ_i is +1 when γ_i is a sink or source, and may be +1 or -1 when γ_i is a saddle. Assume that the periodic data is

$$\{(p_1, u_1, +1), \dots, (p_m, u_m, +1), (q_1, 1, +1), \dots, (q_l, 1, +1), (r_1, 1, -1), \dots, (r_s, 1, -1)\},$$

where $u_i = 2$ for k indices i and $u_i = 0$ for $m - k$ indices; that is, the periodic orbits consist of k sources and $m - k$ sinks of periods $p_1, \dots, p_m$; l saddles of periods $q_1, \dots, q_l$ and orientation type $+1$; and s saddles of periods $r_1, \dots, r_s$ and orientation type -1 . Then by condition (a), $k \geq 1$ and $m - k \geq 1$, and by condition (b),

$$\frac{(1-t)^{\gamma(M)} \prod_{i=1}^l (1-t^{q_i}) \prod_{i=1}^s (1+t^{r_i})}{\prod_{j=1}^m (1-t^{p_j})} = 1. \quad (*)$$

We shall consider the case of each compact, connected 2-manifold separately.

(1) $M = S^2$. If $M = S^2$, then $\chi(M) = 2$. After reindexing the q 's, we can write the equation (*) as

$$\frac{\prod_{i=1}^{l+2} (1-t^{q_i}) \prod_{i=1}^s (1+t^{r_i})}{\prod_{j=1}^m (1-t^{p_j})} = 1, \quad \text{where } q_1 = q_{l+2} = 1.$$

By Lemma 2.1, $m = l + 2$ and there exist integers $a_1 \geq 0, \dots, a_m \geq 0$ such that the set $\{p_1, \dots, p_m\}$ equals the set $\{2^{a_1} q_1, \dots, 2^{a_m} q_m\}$ and the set $\{r_1, \dots, r_s\}$ equals the set

$$\{q_1, 2q_1, \dots, 2^{a_1-1} q_1; \dots; q_m, 2q_m, \dots, 2^{a_m-1} q_m\}.$$

Note that in this notation, the equation is

$$\prod_{k=1}^m \left[\frac{(1-t^{q_i})(1+t^{q_i}) \cdots (1+t^{2^{a_i-1} q_i})}{(1-t^{2^{a_i} q_i})} \right] = 1.$$

We see that there is a natural grouping of the data for sources and sinks with the data for saddles. In fact, we can rewrite the periodic data now as

$$\begin{aligned} & \{(2^{a_1}, u_1, +1), (1, 1, -1), \dots, (2^{a_1-1}, 1, -1); \\ & (2^{a_m}, u_m, +1), (1, 1, -1), \dots, (2^{a_m-1}, 1, -1); \\ & (2^{a_i} q_i, u_i, +1), (q_i, 1, +1), (q_i, 1, -1), \dots, \\ & (2^{a_i-1} q_i, 1, -1), i = 2, \dots, m-1 \} \end{aligned}$$

and the idea of the proof is to construct m diffeomorphisms on subsets of S^2 , each of which contributes one block to the data set.

Write S^2 as a union $S^2 = A_1 \cup \dots \cup A_m$, where A_1 and A_m are 2-dimensional discs, $A_2, \dots, A_{m-1}$ are 2-dimensional annuli, and the sets overlap in the following way: $A_i \cap A_{i+1}$, $i = 1, \dots, m-1$, are annuli of width R (where R is small compared to the diameters of the discs and the widths of the annuli), and all other intersections are empty. We shall construct a diffeomorphism of S^2 by piecing together suitable diffeomorphisms f_i defined on A_i . The f_i are all special cases of the mappings constructed in Lemmas 3.1, 3.2, 3.3 or their inverses. Thus, each such f_i will

have the property that it maps annuli of width R containing $\partial A_i \cap A_{i-1}$ and $\partial A_i \cap A_{i+1}$ along normals to ∂A_i a fixed distance ε , where $\varepsilon < R$, either outside A_i or into A_i . Therefore, in piecing together the f_i , the only thing we must be sure of is that f_i and f_{i+1} both map $A_i \cap A_{i+1}$ in the same direction. Below, we shall simply indicate in each case whether f_i maps $\partial A_i \cap A_{i-1}$ outside or into A_i and $\partial A_i \cap A_{i+1}$ outside or into A_i .

Assume that the p 's are indexed so that $p_i = 2^{a_i} q_i$. Then $p_1 = 2^{a_1}$, $p_m = 2^{a_m}$ and there are three possibilities: 2^{a_1} and 2^{a_m} are periods of two sources, two sinks, or one source and one sink.

(i) Suppose that p_1 is the period of a source and p_m is the period of a sink (that is, we have $(2^{a_1}, 2, +1)$ and $(2^{a_m}, 0, +1)$ in the given data). Let f_1 be a diffeomorphism of A_1 onto its image with periodic data

$$\{(2^{a_1}, 2, +1), (1, 1, -1), (2, 1, -1), \dots, (2^{a_1-1}, 1, -1)\}$$

and which maps ∂A_1 out of A_1 . Such a diffeomorphism exists by Lemma 3.1 (taking inverses).

Also by 3.1, there exists a diffeomorphism f_m of A_m onto its image with periodic data

$$\{(2^{a_m}, 0, +1), (1, 1, -1), (2, 1, -1), \dots, (2^{a_m-1}, 1, -1)\}$$

and which maps ∂A_m into A_m .

Now we have one orbit which is a source and one which is a sink, and $m-2$ such orbits left to define, $k-1$ sources and $m-k-1$ sinks (where $k-1$ and $m-k-1$ may be zero). Without loss of generality, we may assume that the p 's are indexed so that

$$p_2 = 2^{a_2} q_2, \dots, p_k = 2^{a_k} q_k$$

are periods of sources and $p_{k+1} = 2^{a_{k+1}} q_{k+1}, \dots, p_{m-1} = 2^{a_{m-1}} q_{m-1}$ are periods of sinks. By Lemma 3.3 (taking inverses), there exist diffeomorphisms $f_2, \dots, f_k$ with domains $A_2, \dots, A_k$ respectively, such that f_i has periodic data

$$\begin{aligned} &\{(2^{a_i} q_i, 2, +1), (q_i, 1, +1), (q_i, 1, -1), \\ &\quad (2q_i, 1, -1), \dots, (2^{a_i-1} q_i, 1, -1)\} \end{aligned}$$

and such that f_i maps $\partial(A_i) \cap A_{i-1}$ into A_i and $\partial(A_i) \cap A_{i+1}$ out of A_i .

Also by 3.3, there exist diffeomorphisms $f_{k+1}, \dots, f_{m-1}$ with domains $A_{k+1}, \dots, A_{m-1}$ respectively such that f_j has periodic data

$$\begin{aligned} &\{(2^{a_j} q_j, 0, +1), (q_j, 1, +1), (q_j, 1, -1), \\ &\quad (2q_j, 1, -1), \dots, (2^{a_j-1} q_j, 1, -1)\} \end{aligned}$$

and f_j maps $\partial(A_j) \cap A_{j-1}$ into A_j and $\partial(A_j) \cap A_{j+1}$ out of A_j (see Figure 7).

FIGURE 7

FIGURE 8

Since f_i and f_{i+1} agree on $A_i \cap A_{i+1}$, $i = 1, \dots, m-1$, we can define a diffeomorphism F of S^2 by $F(x) = f_i(x)$, $x \in A_i$. Then the periodic data of F is the union of the sets of periodic data of the f_i . Therefore, F has the given periodic data.

Let $N_i = \bigcup_{j=i}^m A_j$. Then $S^2 = N_1 \supset N_2 \supset \dots \supset N_m \supset \emptyset$, $F(N_i) \subset \text{int } N_i$, and for $i = 1, \dots, m$, $N_i - N_{i-1} = A_i$ satisfies condition (2) of Lemma 3.4. Therefore, F has a filtration on S^2 . By the Ω -stability theorem [10], there exists a neighborhood N of F such that any $h \in N$ has the same periodic data as F . By the Kupka-Smale theorem [1], [7], there exists $f \in N$ such that f satisfies the transversal intersection condition. Thus, after a small perturbation of F , we have a Morse-Smale diffeomorphism f of S^2 with the given periodic data.

(ii) Now suppose that p_1 and p_m are both periods of sources. Let $g_1 = f_1$ and $g_m = f_m^{-1}$, where f_1 and f_m are defined in (i).

Then g_1 and g_m have domains A_1 and A_m respectively, g_i maps a neighborhood of ∂A_i out of A_i , and g_i has periodic data

$$\{(2^a, 2, +1), (1, 1, -1), (2, 1, -1), \dots, (2^{a-1}, 1, -1)\}$$

for $i = 1$ and $i = m$.

Assume that the p 's are indexed so that $p_2, \dots, p_{k-1}$ are periods of sources and $p_k, \dots, p_{m-1}$ are periods of sinks. Note that $k-1$ may be zero, but by condition (a) of the theorem, there must be at least one sink, so $m-1 \geq k$. Let $g_i = f_i$ for $i = 2, \dots, k-1$, where f_i is defined in (i). Then g_i has domain A_i , g_i maps $\partial A_i \cap A_{i-1}$ into A_i and $\partial A_i \cap A_{i+1}$ out of A_i , and g_i has periodic

data

$$\{(2^a q_i, 2, +1), (q_i, 1, +1), (q_i, 1, -1), (2q_i, 1, -1), \dots, (2^{a_i-1} q_i, 1, -1)\}.$$

By Lemma 3.2, there exists a diffeomorphism g_k of A_k onto its image such that g_k maps both $\partial A_k \cap A_{k-1}$ and $\partial A_k \cap A_{k+1}$ into A_k and such that g_k has periodic data

$$\{(2^{a_k} q_k, 0, +1), (q_k, 1, +1), (q_k, 1, -1), \dots, (2^{a_k-1} q_k, 1, -1)\}.$$

Finally, let $g_{k+1}, \dots, g_{m-1}$ be diffeomorphisms with domains $A_{k+1}, \dots, A_{m-1}$ respectively such that for $i = k+1, \dots, m-1$, g_i has periodic data

$$\{(2^a q_i, 0, +1), (q_i, 1, +1), (q_i, 1, -1), \dots, (2^{a_i-1} q_i, 1, -1)\}$$

and g_i maps $\partial A_i \cap A_{i-1}$ outside of A_i and $\partial A_i \cap A_{i+1}$ into A_i (see Figure 8). Since g_i and g_{i+1} agree on $A_i \cap A_{i+1}$, we can define a diffeomorphism g of S^2 by $g(x) = g_i(x)$, $x \in A_i$, and g has the given periodic data.

Let

$$N_i = \begin{cases} \bigcup_{j=i}^m A_j, & i = 1, \dots, k, \\ \bigcup_{j=k}^{m+k-j} A_j, & j = k+1, \dots, m. \end{cases}$$

Then $S^2 = N_1 \supset N_2 \supset \dots \supset N_m \supset \emptyset$, and $g(N_i) \subset \text{int}(N_i)$ for each i . Also, $N_i - N_{i-1}$ satisfies the conditions of Lemma 3.4 for each i , so g has a filtration on S^2 . Therefore g is Ω -stable, and there exists a diffeomorphism f of S^2 which is topologically conjugate to g on Ω and which has transversal intersections. Then f is a Morse-Smale diffeomorphism of S^2 with the given periodic data.

(iii) The case when p_1 and p_m are both periods of sinks follows immediately from (ii) by taking the inverse of g (after suitable reindexing of the p 's).

(2) $M = T$. In this case, $\chi(M) = 0$ and the canonical form of the equation (*) is

$$\prod_{i=1}^m \left[\frac{(1 - t^{q_i})(1 + t^{q_i})(1 + t^{2q_i}) \cdots (1 + t^{2^{a_i-1} q_i})}{(1 - t^{2^{a_i} q_i})} \right] = 1,$$

where there are no restrictions on the q_i .

Write T as a union $T = A_1 \cup \dots \cup A_m$, where the A_i are 2-dimensional annuli such that $A_i \cap A_{i+1}$, $i = 1, \dots, m-1$, and $A_m \cap A_1$ are annuli of width R (where R is small as above), with all other intersections empty.

Assume that $p_1 = 2^{a_1} q_1, \dots, p_k = 2^{a_k} q_k$ are periods of sources and $p_{k+1} = 2^{a_{k+1}} q_{k+1}, \dots, p_m = 2^{a_m} q_m$ are periods of sinks. By condition (a) of the theorem, $k \geq 1, m - k \geq 1$.

By Lemma 3.2, there exists a diffeomorphism f_1 with domain A_1 such that f_1 has periodic data

$$\{(2^{a_1}q_1, 2, 1), (q_1, 1, 1), (q_1, 1, -1), \dots, (2^{a_1-1}q_1, 1, -1)\},$$

and such that f_1 maps the boundaries $\partial A_1 \cap A_m$ and $\partial A_1 \cap A_2$ out of A_1 . Also by 3.2, there exists a diffeomorphism f_{k+1} defined on A_{k+1} with periodic data

$$\{(2^{a_{k+1}}q_{k+1}, 0, 1), (q_{k+1}, 1, 1), (q_{k+1}, 1, -1), \dots, (2^{a_{k+1}-1}q_{k+1}, 1, -1)\}$$

and such that f_{k+1} maps the boundaries $\partial A_{k+1} \cap A_k$ and $\partial A_{k+1} \cap A_{k+2}$ into A_{k+1} . Now let $f_2, \dots, f_k, f_{k+2}, \dots, f_m$ be diffeomorphisms defined on $A_2, \dots, A_k, A_{k+2}, \dots, A_m$ respectively with the following properties:

(i) for $i = 2, \dots, k, f_i$ has periodic data

$$\{(2^a q_i, 2, +1), (q_i, 1, +1), (q_i, 1, -1), \dots, (2^{a-1} q_i, 1, -1)\}$$

and f_i maps $\partial A_i \cap A_{i-1}$ into A_i and $\partial A_i \cap A_{i+1}$ out of A_i ;

(ii) for $i = k+2, \dots, m, f_i$ has periodic data

$$\{(2^a q_i, 0, +1), (q_i, 1, +1), (q_i, 1, -1), \dots, (2^{a-1} q_i, 1, -1)\}$$

and f_i maps $\partial A_i \cap A_{i-1}$ out of A_i and $\partial A_i \cap A_{i+1}$ ($\partial A_m \cap A_1$) into A_i (see Figure 9).

FIGURE 9

Such diffeomorphisms exist by Lemma 3.3.

Let $F(x) = f_i(x)$, $x \in A_i$. The f_i are constructed so that F is well defined. Then F is a diffeomorphism of T with periodic data

$$\begin{aligned} &\{(2^a q_i, 2, +1), (q_i, 1, +1), (q_i, 1, -1), \dots, (2^{a-1} q_i, 1, -1); \\ &\quad (2^a q_j, 0, +1), (q_j, 1, +1), (q_j, 1, -1), \dots, (2^{a-1} q_j, 1, -1); \\ &\quad i = 1, \dots, k, j = k+1, \dots, m\}. \end{aligned}$$

Now define sets

$$N_i = \begin{cases} \bigcup_{j=i}^m A_j, & i = 1, \dots, k+1, \\ \bigcup_{j=k+1}^{m+k+1-j} A_j, & i = k+2, \dots, m. \end{cases}$$

Then $T = N_1 \supset N_2 \supset \dots \supset N_m \supset \emptyset$, $F(N_i) \subset \text{int}(N_i)$, and the $N_i - N_{i-1}$ satisfy the conditions of Lemma 3.4. Hence, F has a filtration on T and is Ω -stable. Then there exists a diffeomorphism f of T with the same periodic data as F and which satisfies the transversal intersection condition. Therefore, f is a Morse-Smale diffeomorphism of T with the given periodic data.

(3) $M = X_n$, $n \geq 2$. If M is the connected sum of n tori, then $\chi(M) = 2 - 2n$ and by condition (b),

$$\frac{\prod_{i=1}^l (1 - t^{q_i}) \prod_{i=1}^s (1 + t^{r_i})}{(1 - t)^{2n-2} \prod_{j=1}^m (1 - t^{p_j})} = 1.$$

By Lemma 2.1, after reindexing the q 's, we can write this product as

$$\frac{(1 - t)^{2n-2}}{(1 - t)^{2n-2}} \prod_{i=1}^m \left[\frac{(1 - t^{q_i})(1 + t^{q_i})(1 + t^{2q_i}) \dots (1 + t^{2^{a_i-1}q_i})}{(1 - t^{2^{a_i}q_i})} \right] = 1.$$

Assume that $p_1 = 2^{a_1}q_1$ is the period of a source and $p_m = 2^{a_m}q_m$ is the period of a sink. Let $T_1, \dots, T_n$ be n tori. By part (2), there exists a diffeomorphism f_1 of T_1 with periodic data

$$\{(1, 0, +1), (1, 1, +1); (2^{a_i}q_i, u_i, +1), (q_i, 1, +1), \\ (q_i, 1, -1), \dots, (2^{a_i-1}q_i, 1, -1), i = 1, \dots, m-1\}.$$

Again by (2), there exist diffeomorphisms $f_2, \dots, f_{n-1}$ of $T_2, \dots, T_{n-1}$ respectively such that f_i has one sink of period 1, one source of period 1, and two saddles of period 1 and orientation type $+1$.

Finally, let f_n be a diffeomorphism of T_n with periodic data

$$\{(1, 2, +1), (1, 1, +1); (2^{a_m}q_m, 0, +1), (q_m, 1, +1), \\ (q_m, 1, -1), \dots, (2^{a_m-1}q_m, 1, -1)\}.$$

It is clear that the f_i can be constructed so that there exists discs $D_1 \subset T_1, \dots, D_{n-1} \subset T_{n-1}$ about the sinks of period 1 and discs $D'_2 \subset T_2, \dots, D'_n \subset T_n$ about the sources of period 1, and an $\varepsilon > 0$, small compared to the diameter of the discs, such that $f_i|_{D_i}$ is a contraction by ε , $i = 1, \dots, n-1$, and $f_i|_{D'_i}$ is an expansion by ε , $i = 2, \dots, n$. Let $R_1 \subset D_1, \dots, R_{n-1} \subset D_{n-1}$, $R'_2 \subset D'_2, \dots, R'_n \subset D'_n$ be annuli of width R containing the boundary of the disc, where R is small compared to the diameters of the discs.

Now delete the discs $D_i - R_i$ and $D'_i - R'_i$ from T_i . For $i = 1, \dots, n-1$,

identify the sets R_i and R'_{i+1} by identifying $\partial R_i \cap \partial D_i$ with $\partial R'_{i+1} \cap \text{int } D'_{i+1}$ and $\partial R_i \cap \text{int } D_i$ with $\partial R'_{i+1} \cap \partial D'_{i+1}$. Then X_n is the connected sum

$$X_n = T_1 \# T_2 \# \cdots \# T_n,$$

where T_i is attached to T_{i+1} by this identification. The identification is made so that f_i and f_{i+1} agree on R_i (see Figure 10). Therefore, we can define a

FIGURE 10

diffeomorphism F of X_n by setting $F(x) = f_i(x)$, $x \in T_i$. Then F has periodic data

$$\left\{ (2^a q_i, u_i, +1), (q_i, 1, +1), (q_i, 1, -1), \dots, (2^{a-1} q_i, 1, -1), \right. \\ \left. i = 1, \dots, m; \underbrace{(1, 1, +1)}_{2n-2 \text{ times}} \right\}.$$

If $N_i = T_i \# T_{i+1} \# \cdots \# T_n$, then

$$X_n = N_1 \supset N_2 \supset \cdots \supset N_n \supset \emptyset$$

satisfies the conditions of Lemma 3.4, so F has a filtration on X_n . Therefore, by the Ω -stability theorem and the Kupka-Smale theorem, there exists a Morse-Smale diffeomorphism f of X_n with the given periodic data.

(4) $M = P$. In this case, $\chi(M) = 1$, and after reindexing the q 's, the canonical form of the equation (*) is

$$\prod_{i=1}^m \left[\frac{(1 - t^{q_i})(1 + t^{q_i}) \cdots (1 + t^{2^{a_i-1} q_i})}{(1 - t^{2^{a_i} q_i})} \right] = 1, \quad \text{where } q_1 = 1.$$

Let $S^2 = \{x \in \mathbb{R}^3 \mid |x| = 1\}$, and let $\sim$ be the relation on S^2 defined by identifying antipodal points of S^2 (so $x \sim y$ if and only if $y = x$ or $y = -x$). Then P is the quotient $S^2/\sim$, and a diffeomorphism of P is a diffeomorphism of S^2 which preserves the relation. We wish to construct a diffeomorphism of P with periodic data

$$\{(2^a, u_1, +1), (1, 1, -1), \dots, (2^{a-1}, 1, -1); (2^a q_i, u_i, +1), \\ (q_i, 1, +1), (q_i, 1, -1), \dots, (2^{a-1} q_i, 1, -1), i = 2, \dots, m\},$$

where $u_i = 2$ for k indices i and $u_i = 0$ for $m - k$ indices.

Suppose $u_1 = 2$, so that $p_1 = 2^{a_1}$ is the period of a source. Then $u_i = 0$ for some i , say u_m . Write S^2 as a union of subsets $S^2 = A_1 \cup \dots \cup A_{2m-1}$ with the following properties:

(a) A_1 is a disc with center $(0, 0, 1)$ and $A_2, \dots, A_{m-1}$ are cylinders on the upper hemisphere of S^2 such that $A_i \cap A_{i+1}$ is a small annulus of width R , $i = 1, \dots, m-2$;

(b) A_m is a cylinder containing the equator of S^2 (points $(x_1, x_2, x_3) \in S^2$ such that $x_3 = 0$) with the property that if $x \in A_m$, then $-x \in A_m$ and such that $A_m \cap A_{m-1}$ is an annulus of width R ;

(c) for $i = m+1, \dots, 2m-1$, A_i is the set of antipodal points of A_{2m-i} .

Choose diffeomorphisms $f_1, \dots, f_m$ defined on $A_1, \dots, A_m$ respectively such that

(i) f_1 has periodic data

$$\{(2^{a_1}, 2, +1), (1, 1, -1), (2, 1, -1), \dots, (2^{a_1-1}, 1, -1)\}$$

and f_1 maps ∂A_1 outside of A_1 (Lemma 3.1);

(ii) for $i = 2, \dots, m-1$, f_i has periodic data

$$\{(2^a q_i, u_i, +1), (q_i, 1, +1), (q_i, 1, -1), \\ (2q_i, 1, -1), \dots, (2^{a-1} q_i, 1, -1)\}$$

and f_i maps $\partial A_i \cap A_{i-1}$ into A_i and $\partial A_i \cap A_{i+1}$ out of A_i (Lemma 3.3);

(iii) f_m has periodic data

$$\{(2^{a_m+1} q_m, 0, +1), (2q_m, 1, +1), (2q_m, 1, -1), \\ (2^2 q_m, 1, -1), \dots, (2^{a_m} q_m, 1, -1)\}$$

and f_m maps $\partial A_m \cap A_{m-1}$ and $\partial A_m \cap A_{m+1}$ into A_m (Lemma 3.2). It is clear from the proof of Lemma 3.2 that f_m can be constructed so that $f_m(x) = -f_m(-x)$. In that case, $f_m^n(x) = -f_m^n(-x)$ for any n . Therefore, if x_i is a periodic point of f_m with period k , then

$$f_m^k(-x_i) = -f_m^k(x_i) = -x_i,$$

so $-x_i$ is also periodic with period k .

For $i = m+1, \dots, 2m-1$, define f_i with domain A_i by $f_i(x) = -f_{2m-i}(-x)$. Then the periodic orbits of f_i in A_i are the antipodal points of the periodic orbits of f_{2m-i} in A_{2m-i} .

Let $F(x) = f_i(x)$, $x \in A_i$. Then F is a diffeomorphism of S^2 such that $F(x) = -F(-x)$. Therefore, F induces a diffeomorphism $\hat{F}$ of P . The periodic orbits in A_i and A_{2m-i} are identified for $i = 1, \dots, m-1$, and in $A_m/\sim$, $\hat{F}$ has periodic data

$$\{(2^{a_m} q_m, 0, +1), (q_m, 1, +1), (q_m, 1, -1), \dots, (2^{a_m-1} q_m, 1, -1)\},$$

since each orbit of $F|A_m$ consists of points x and their antipodal points $-x$. Therefore, $\hat{F}$ has the given periodic data. Just as in (1), there is a subdivision of P satisfying the conditions of Lemma 3.4. So there exists a filtration of P for $\hat{F}$, and by the Ω -stability theorem and the Kupka-Smale theorem, there exists a Morse-Smale diffeomorphism f of P with the given periodic data.

The case when $u_1 = 0$ follows in exactly the same way.

(5) $M = Y_n$, $n \geq 2$. If M is the connected sum of n projective planes, then $\chi(M) = 2 - n$. After reindexing the q 's, the canonical form of the equation (*) is

$$\frac{(1-t)^{n-2}}{(1-t)^{n-2}} \prod_{i=1}^m \left[\frac{(1-t^{q_i})(1+t^{q_i})(1+t^{2q_i}) \cdots (1+t^{2^{q_i-1}q_i})}{(1-t^{2^{q_i}p_i})} \right] = 1.$$

Let $P_1, \dots, P_n$ be n projective planes.

Assume that $p_1 = 2^{a_1}q_1$ is the period of a source and $p_m = 2^{a_m}q_m$ is the period of a sink. By part (4), there exist diffeomorphisms $f_1, \dots, f_n$ of $P_1, \dots, P_n$ respectively with the following properties:

(a) f_1 has periodic data

$$\{(1, 0, +1); (2^{a_i}q_i, u_i, +1), (q_i, 1, +1), \dots, (2^{a_i-1}q_i, 1, -1), i = 1, \dots, m-1\};$$

(b) for $i = 2, \dots, n-1$, f_i has one sink of period 1, one source of period 1, and one saddle of period 1 and orientation type $+1$;

(c) f_n has periodic data

$$\{(1, 2, +1); (2^{a_m}q_m, 0, +1), (q_m, 1, +1), (q_m, 1, -1), \dots, (2^{a_m-1}q_m, 1, -1)\}.$$

Just as in part (3), the f_i can be constructed so that if we delete discs about the sinks of period 1 in $P_1, \dots, P_{n-1}$ and the sources of period 1 in $P_2, \dots, P_n$ and attach the P_i along the boundaries of these discs, then we can define a diffeomorphism F of $Y_n = P_1 \# P_2 \# \cdots \# P_n$ by $F(x) = f_i(x)$, $x \in P_i$. Then F has periodic data

$$\left\{ (2^{a_i}q_i, u_i, +1), (q_i, 1, +1), (q_i, 1, -1), \dots, (2^{a_i-1}q_i, 1, -1), i = 1, \dots, m, \underbrace{(1, 1, +1)}_{n-2 \text{ times}} \right\}.$$

Also, it is clear that F has a filtration on Y_n . Therefore, by the Ω -stability theorem and the Kupka-Smale theorem, there exists a diffeomorphism f of Y_n with the given periodic data. Q.E.D.

4. Further consequences of the canonical form. The canonical form derived in Lemma 2.1 has several other consequences.

PROPOSITION 4.1. *Let M be a compact, connected 2-manifold. Suppose f is a Morse-Smale diffeomorphism of M homotopic to the identity such that the orientation type of every saddle is -1 . Then*

(a) $M = S^2$;

(b) *all the periods of orbits of f are powers of 2; in fact, there exist $n \geq 0$, $m \geq 0$ such that the periodic orbits of f consist of one source of period 2^n , one sink of period 2^m , and $n + m$ saddles of periods $1, 2, \dots, 2^{n-1}, 1, 2, \dots, 2^{m-1}$ respectively.*

PROOF. Suppose $p_1, \dots, p_k$ are the periods of sources and sinks of f and $r_1, \dots, r_l$ are the periods of saddles. Then

$$\frac{(1-t)^{\chi(M)} \prod_{i=1}^l (1+t^{r_i})}{\prod_{j=1}^k (1-t^{p_j})} = 1.$$

Since f has at least one source and one sink, $k \geq 2$. Therefore, $\chi(M) \geq 2$, so $\chi(M) = 2$. Hence, $M = S^2$, $k = 2$, and by Lemma 2.1, there exist $n \geq 0$, $m \geq 0$ such that $p_1 = 2^n$, $p_2 = 2^m$ and the set $\{r_1, \dots, r_l\}$ equals the set $\{1, 2, \dots, 2^{n-1}, 1, 2, \dots, 2^{m-1}\}$. Q.E.D.

Note that the sphere is the only compact surface which admits a Morse-Smale diffeomorphism with no saddles. In the case of other compact surfaces, a Morse-Smale diffeomorphism must have a certain minimal number of saddles. We state this as a lemma.

LEMMA 4.2. *Let M be a compact, connected 2-manifold and let $\lambda(M)$ be 0, $2n$, or n depending on whether M is a sphere, connected sum of n tori ($n \geq 1$), or connected sum of n projective planes ($n \geq 1$). Then a Morse-Smale diffeomorphism f of M which is homotopic to the identity must have at least $\lambda(M)$ saddles of orientation type $+1$.*

PROOF. Suppose f has k sources and sinks and l saddles of orientation type $+1$. Then by Lemma 2.1, $k = l + \chi(M)$. Since $k \geq 2$, $l \geq 2 - \chi(M)$. Therefore, if $M = S^2$, $l \geq 0$; if M is the connected sum of n tori, $l \geq 2 - (2 - 2n) = 2n$; and if M is the connected sum of n projective planes, $l \geq 2 - (2 - n) = n$. Q.E.D.

We remark that it follows from the Morse-Smale inequalities [8] that any Morse-Smale diffeomorphism of M must have at least $\lambda(M)$ saddles, although we can say nothing about the orientation type in this case.

If $f \in \text{Diff}(M)$ has no more than $\lambda(M)$ saddles of orientation type $+1$, then we have results similar to Proposition 4.1.

PROPOSITION 4.3. Let M , $\lambda(M)$ be as above, and let f be a Morse-Smale diffeomorphism of M which is homotopic to the identity. If f has exactly $\lambda(M)$ saddles with orientation type $+1$ and period 1, then there exist $n \geq 0$, $m \geq 0$ such that the other orbits of f consist of one source of period 2^n , one sink of period 2^m and $n + m$ saddles of periods $1, 2, \dots, 2^{n-1}, 1, 2, \dots, 2^{m-1}$.

The proof follows as in 4.1.

In general, given a fixed number of sources and sinks, we can construct a Morse-Smale diffeomorphism with an arbitrarily high number of saddles of orientation type -1 . The situation is different if we allow no such saddles.

PROPOSITION 4.4. Let f be a Morse-Smale diffeomorphism of a compact, connected 2-manifold homotopic to the identity, and suppose f has no saddles of orientation type -1 . If $\chi(M) \geq 0$, then for any saddle of period q , f has a corresponding sink or source of the same period. If $\chi(M) < 0$, then f has $-\chi(M)$ fixed point saddles and for any other saddle of period q , f has a corresponding sink or source of the same period.

PROOF. Suppose $p_1, \dots, p_m$ are the periods of sources and sinks of f , and $q_1, \dots, q_l$ are the periods of saddles. Then

$$\frac{(1-t)^{\chi(M)} \prod_{i=1}^l (1-t^{q_i})}{\prod_{j=1}^m (1-t^{p_j})} = 1.$$

Suppose $\chi(M) \geq 0$. Then by Lemma 2.1, the set $\{p_1, \dots, p_m\}$ equals the set

$$\left\{ \underbrace{1, \dots, 1}_{\chi(M) \text{ times}}, q_1, \dots, q_l \right\}$$

and the result follows. If $\chi(M) < 0$, then the set

$$\left\{ p_1, \dots, p_m, \underbrace{1, \dots, 1}_{-\chi(M) \text{ times}} \right\}$$

equals the set $\{q_1, \dots, q_l\}$. Then we can reindex the q 's so that $q_1 = \dots = q_{-\chi(M)} = 1$. Thus, there are $-\chi(M)$ fixed point saddles and for $i > \chi(M)$, there exists j such that $p_j = q_i$. Q.E.D.
