MECHANICAL GEARING FOR HOISTING DEVICES, &c.

UNITED STATES PATENT OFFICE.

WILLIAM C. ALSDORF, OF ST. LOUIS, MISSOURI.

MECHANICAL GEARING FOR HOISTING DEVICES, &c.

SPECIFICATION forming part of Letters Patent No. 305,877, dated September 30, 1884.

Application filed January 3, 1884. (No model.)

To all whom it may concern:

Be it known that I, WILLIAM C. ALSDORF, a citizen of the United States, residing at St. Louis, in the county of St. Louis and State of 5 Missouri, have invented certain new and useful Improvements in Mechanical Gearing for Hoisting Devices, &c.; and I do declare the following to be a full, clear, and exact description of the invention, such as will enable oth-10 ers skilled in the art to which it appertains to

make and use the same, reference being had to the accompanying drawings, and to letters or figures of reference marked thereon, which form a part of this specification.

Figure 1 of the drawings is a side view. Fig. 2 is a plan view. Fig. 3 is a detail view. Fig. 4 is a detail view, and Fig. 5 is a sec-

tional detail view of the shaft I and its clutch mechanism.

This invention has relation to mechanical gearing for elevators and hoisting apparatus; and it consists in the construction and novel arrangement of devices, as hereinafter set forth, and pointed out in the appended claims.

In the accompanying drawings I have illustrated my invention in its application to a beltgeared elevator.

The letter Z indicates the driving-belt, moving continuously in the same direction.

Upon the shaft A is secured the fast pulley B. C is a loose-geared pulley on said shaft, having a pinion, a, and D is an idler-pulley between the pulleys B and C. The belt Z is designed to be shifted on these pulleys. On 35 the shaft A is rigidly secured the pinion b.

On a parallel shaft, E, is keyed the spurwheel F, which engages the pinion b, and a spur-wheel, G, which is designed to engage a spur-wheel, H, which is loose on a third shaft,

I. The shaft E, acting through the gear F or G and the gearing J J', turns the shaft L, which carries the large drum on which the cable is wound. By means of a belt-shifting lever, c, pivoted on a fulcrum-bearing, x, op-45 erated by a moving nut, d, on a threaded part

of a shaft, M, carrying a spur-wheel, N, the belt Z may be shifted. When the belt is shifted from the fast pulley B to the loose geared pulley C, the direction of revolution of the shaft

A remains unchanged; but as the pulley C is turned it is apparent that by the engagement | indicated at u u, to engage the loose clutch-

of its pinion a with the loose spur-wheel H, in gear with the driving spur-wheel G of the shaft E, the motion of the shaft E and its gearing is reversed, running the cable in the op- 55 posite direction. In this manner I am enabled by simply shifting the belt to reverse the gearing and the movement of the cable.

On the brake-shaft M is keyed fast an eccentric, P, engaging the arm e of the brake R, 60 which is provided with springs S. The arm e of this brake works in a box, g, whereby it is prevented from revolving. When the checkline V is pulled, turning the shaft M, the eccentric is turned, putting on the brake, and at 65 the same time the shifter is operated to move the belt over upon the idler-pulley; or, when the belt is on the loose geared pulley and the shifter is moved to throw the belt over on the idler, the springs of the brake will give, allow-70 ing the eccentric to revolve one-half turn more.

Trepresents a pulley which is equal in width to the three pulleys B, C and D, and is journaled to a lever-arm, h, pivoted at k and provided with a bearing, d'. The pulley T is designed 75 to lie upon the running belt, revolving with the motion thereof. If the belt should break, the pulley T will fall, and its arm will, by its end bearing, l, intersect the counter-shaft I, and at the same time will move the loose clutch- 80 collar l' to engage the tight clutch-collar m, which operates the cog wheel N, and thereby turns the \cos wheel p and the brake shaft to which the cog-wheel p is keyed, throwing the belt and putting on the brake at the same time. 85

W indicates a pulley on the lever s', which is continuously held up by the strain of the cable r. Should this cable break, or anything come in contact with the elevator-platform while descending, causing the cable to become 90 slack, the machinery will be instantly stopped by the fall of the pulley W and its lever, which, intersecting the shaft I, causes the loose clutchcollar t to engage the clutch-collar v, turning the wheels n and p and automatically putting 9: on the brake and shifting the belt, as before described.

In order to operate the shifter and brake automatically when the elevator-platform is at its highest or lowest point, the shaft E is 10 threaded on each side of a chain-wheel, U, as

collars f f, which are provided with threaded bearings to engage the threaded portions u u of the shaft. The chain-wheel is loose on the shaft, and the clutch-collars $v\ v$ on each side 5 of said wheel are keyed or pinned fast to the hub of the wheel. The traveling collars f f are held from turning by connections at a', which, however, allow them to travel back and

forth on the shaft E, according to its direction ic of revolution. When this shaft turns in one direction or the other, one of the traveling collars is moved up to engage the clutch-collar on the same side of the chain-wheel, turning the latter and operating the chain J, which

15 turns the chain-wheel U' on the brake-shaft M, throwing the shifter and operating the brake. Having described this invention, what I claim, and desire to secure by Letters Patent,

1. The pulley T, as wide as the belt-pulleys B, C, and D, and having a lever-arm adapted to operate a loose clutch-collar on a countershaft, in combination with a tight clutch-collar and a spur-wheel engaging a spur-wheel on

25 the brake-shaft, and adapted to turn the latter, substantially as specified.

2. The pulley W, held up by the strain of

the cable, and having a lever-arm adapted to operate a loose clutch-collar on a countershaft, in combination with a tight clutch-col- 30 lar and a spur-wheel engaging a spur-wheel on the brake-shaft, substantially as specified.

3. The reversing shaft E, having threaded portions and traveling collars thereon, in combination with a chain-wheel loose thereon and 35 having lateral clutch-collars, a chain-connection, and a chain-wheel on the brake-shaft, substantially as specified.

4. A brake-shaft having an eccentric, in combination with a brake having springs, and 40 an arm working in a bearing to prevent rotation, substantially as specified.

5. The combination, with the brake-shaft, of an eccentric brake, and a belt shifter adapted to operate in connection with pulleys B, C, and 45 D, and a belt running continuously in the same direction, substantially as specified.

In testimony whereof I affix my signature in presence of two witnesses.

WILLIAM C. ALSDORF.
