UNITED STATES PATENT OFFICE.

DANIEL DRAWBAUGH, OF EBERLY'S MILL, PENNSYLVANIA, ASSIGNOR TO THE PEOPLE'S TELEPHONE COMPANY, OF NEW YORK, N. Y.

INDUCTION-COIL.

SPECIFICATION forming part of Letters Patent No. 344,818, dated July 6, 1886.

Application filed November 12, 1883. Serial No. 111,546. (No model.)

To all whom it may concern:

Be it known that I, DANIEL DRAWBAUGH, of Eberly's Mill, Cumberland county, Pennsylvania, have invented a new and useful Im-5 provement in Induction-Coils, of which the

following is a specification.

The invention relates to an improved form of induction-coil, adapted for use in telephones and other apparatus, that are often made of 10 such a shape that the limited space necessitates the coil being constructed of long and narrow form, in order to obtain the desired induction effect. It is well known, however, that the induced currents in a long narrow 15 induction - coil having a single continuous core are not reversed quickly and sharply, and hence that such a coil is ill adapted for telephonic purposes.

My present invention consists in an induc-20 tion-coil of the aforesaid shape, which is exceedingly sensitive, and which is especially

well suited for telephonic use.

In the drawings hereto annexed I show my induction-coil arranged in a telephone, 25 the instrument being of a form necessitating a coil of this shape, in order to obtain the best results from its use as a telephone-transmitter.

The invention consists, more particularly, in 30 an induction-coil having a core transversely divided into two or more sections, or, in other words, containing a number of short cores placed end to end, pieces of non-inductive material being arranged between the ends of the 35 cores or core-sections.

In the accompanying drawings, Figure 1 is a front view of a telephone-transmitter containing my improved induction-coil, the diaphragm of said transmitter being removed,

40 in order to show the internal arrangement. Fig. 2 is a vertical section on the line x x of Fig. 1. Fig. 3 is an enlarged partial longitudinal section of the induction coil.

Similar letters of reference indicate like

45 parts.

The induction coil is shown at J, Figs. 1

Referring more particularly to Fig. 3, A B C is the divided core or series of cores, and D | cores or core-sections placed end to end, and

and E are pieces of non-inductive material 50 placed between the ends of said core. I is the primary coil surrounding said core, and F is the secondary coil. G and H are the heads or flanges. J' and K' are the terminals of the primary coil, and J" and K" the termi- 55 nals of the secondary coil.

The particular construction of telephonetransmitter here shown, the conformation and arrangement of the case and of the electrodes, and, generally, all other parts and portions of 60 the apparatus excepting the induction coil, which specifically forms the object of this application, are herein disclaimed, the said parts and their various combinations and arrangement having already been fully de- 65 scribed and claimed by me in other applications already filed, or to be filed simultaneously herewith.

Referring to Figs. 1 and 2, which show my improved form of induction-coil applied to a 70 telephone-transmitter, P is the box or case of the instrument, having a hollow or recess to receive the coil J. K is the cover; L, the diaphragm; M and N, the carbon electrodes; O, a metal rod supporting the electrode M, the 75 said rod resting upon and being supported by the spring R. The circuits in the instrument proceed as follows: From the battery to the binding-post 1, to the primary I of the induction-coil J, to a contact-piece, Q, to a contact- 80 piece on the diaphragm, and thence by a wire (these parts not being shown) to the electrodes N and M, to the rod O, to the spring R, to the binding-post 2, and thence to the battery.

The secondary wire F of the induction-coil 85 proceeds to the line by the binding-posts 3 and 4, from which posts extend wires to the binding-posts 5 and 6, to which a receiving-instrument may be attached.

The operation of the instrument is fully 90 set forth in the other applications above referred to, and is therefore not here explained.

I claim as my invention-

1. An induction-coil having two or more cores or core-sections placed end to end, and 95 not in contact, substantially as described.

2. An induction coil having two or more

having interposed pieces of non-inductive material arranged between the proximate ends of said cores or core sections, substantially as DANIEL DRAWBAUGH. described.

3. In an induction coil, the combination of the cores or core sections A B C, the interposed pieces of non-inductive material, D and E, and

DANIEL DRAWBAUGH.
