UNITED STATES PATENT OFFICE.

WILLIAM S. BURROUGHS, OF ST. LOUIS, MISSOURI, ASSIGNOR TO THE AMERICAN ARITHMOMETER COMPANY, OF SAME PLACE.

DEVICE FOR RECORDING NUMBERS.

SPECIFICATION forming part of Letters Patent No. 420,618, dated February 4, 1890.

Application filed July 11, 1888. Serial No. 279,609. (No model.)

To all whom it may concern:

Beit known that I, WILLIAM S. BURROUGHS, a citizen of the United States, residing in St. Louis, in the State of Missouri, have invented 5 certain new and useful Improvements in Devices for Recording Numbers, of which the

following is a specification.

My invention relates to that class of recorders in which a series of printing-wheels 10 are turned to positions to bring the type formed thereon into alignment to record by printing the numbers indicated by such type, and more especially to that class of recorders connected with the mechanical calculators 15 in which the wheels are set in position by the operation of keys; and my invention consists in constructing said wheels and combining therewith certain appliances, as fully set forth hereinafter, so as to prevent the 20 wheels from getting out of alignment, preserve the faces of the type, and restore the wheels to zero after printing, without interfering with their free movement by their actuating devices, and otherwise to increase 25 the efficiency of the recording device.

In the accompanying drawings, Figure 1 is a side view of sufficient of a mechanical calculator, one side frame being removed, to illustrate my improvement in recorders con-30 nected with said calculator. Fig. 2 is a onepart sectional elevation showing the parts in a different position. Fig. 3 is a transverse section on the lines 3 3, Fig. 1. Fig. 4 is a detached view of the recorder in side eleva-35 tion. Fig. 5 is a sectional elevation of parts of the device, showing the same in a different position from that illustrated in Fig. 4. Fig. 6 is a view of the dog and platen.

The recorder, upon which different num-40 bers are set up, and from which they are printed, consists, as shown, of a series of notched type-wheels B³, each turning freely upon a shaft g, carried between and by two links d^4 , each jointed to an arm d^3 , connected 45 with a shaft a^4 , having its bearings in the side frames of the machine. The shaft g is also carried by a frame B5, pivoted at the

shaft a^4 , bringing the parts to different positions. (Shown in Figs. 2 and 4.)

The adjustment of the different typewheels to bring the required figures in line with each other above the platen is effected 55 by means of devices operated from a series of keys A', which devices need not be here described, as they constitute no part of this invention, and as they are fully set forth in an application for Letters Patent for a me- 60 chanical accountant, No. 388,116, dated August 21, 1888.

The frame B^5 may be depressed by the rocking of the shaft a^4 , as before described, or by means of a handle or arm f^{31} , Fig. 3, 65 extending from the frame and adapted to be operated directly by hand, the frame being elevated, when the handle is released, by a spring n. When the shaft a^4 is used as the operating medium, it may be rocked by means 70 of a handle B6. In either case the frame B5 is raised or depressed, and the printing is effected by the depressing of the frame by bringing the properly-adjusted recorder against an ink-ribbon c⁸, supported by spools 75 co co, and forcing the ribbon against a sheet

lying upon the platen B⁴.

A pawl d¹¹, carried by the frame B⁵, engages with a ratchet upon the spool c^{10} and turns the latter slightly at each vibration, carrying 80 with it the ink-ribbon with a step-by-step mo-

It is generally desirable that the printingwheels shall be restored to zero-that is, with the cipher of each wheel directly above the 85 platen—after any number has been printed from the recorder, in order that it may be in position to be properly reset to print any other number. To effect this I combine with each wheel a rack-bar B⁸, sliding in bearings 90 do do upon the frame Bo, and each gearing with a pinion g^2 at the side of one of the wheels, and a spring-blade e^2 , secured to a cross-bar e^3 , bears upon a pin or shoulder e^4 upon each rack-bar B⁸, so as to throw it in the 95 direction of the arrow, Fig. 5, until a pin a^{11} at the side of the type-wheel B3, contacts with ends to a cross-bar x, and beneath the recorder is a platen B^4 , to and from which the 50 recorder is carried by the rocking of the to be set by the operation of the keys, it is 100

perfectly free without resistance, and the shaft e^3 , which carries the spring e^2 , is therefore hung in the frame B5, so as to swing freely during the adjustment of the wheels. When the wheels, after printing, are to be restored to position, the shaft e^3 is turned in the direction of its arrow, Fig. 4, allowing all the springs e^2 to bear against the pins e^4 , when 10 each bar B⁸ will slide in the direction of the arrow, Fig. 5, until the pins a^{11} of all the wheels are in contact with the shoulders y^3 of the pawls B^7 , as shown in Fig. 4.

The movement of the shaft e^3 requisite to 15 bring the springs to bear upon the pins e^4 results from the rocking of a crank-lever B9, pivoted upon the shaft f^{5} , carried by the frame B^5 , and one arm f^3 of this lever bears upon the pin e^5 , projecting from an arm e^6 20 upon the shaft e^3 . The long arm f^6 of the lever B9 extends downward and forward, and, in conjunction with a similar arm at the opposite side of the machine, carries a cross-

bar e^{7} .

A spring f^9 (shown in dotted lines, Fig. 4) is connected with the lever B9, and tends to raise slightly the lower end of the arm f^6 , and a lug e⁸, Figs. 1 and 2, at the end of said arm, is arranged to engage with shoulders y^4 30 y^5 upon a stop-arm E, hung from one of the side frames of the machine to swing freely.

Arms e⁶¹, Fig. 4, projecting from the shaft e^3 , carry a cross-bar e^{41} , upon which the springs

 e^2 may be brought to bear.

When the frame B5 is depressed to effect the printing, the lug e^8 is carried beneath the shoulder y^5 of the stop-arm E, so that when the frame B⁵ again rises the lever B⁹ will be held in its position shown in Fig. 2, when the 40 arm f^3 will be brought to bear upon the lug e5 to swing the shaft e3 in the direction of its arrow, Fig. 4, and thereby carry the cross-bar e^{41} away from the springs e^2 , when they will spring inward and carry the bars B8 with 45 them and restore all of the printing-wheels to zero. The parts remain in the position described until the frame B5 is about horizontal; but as it rises higher the lever B9 will be slightly retracted, withdrawing the lug e8 50 from the shoulder y^5 , when the spring f^9 will lift the lever until the luges strikes the shoulder y^4 , as shown in Fig. 1. This upward movement of the lever B⁹ carries the arm f^3 away from the pin e^5 and leaves the shaft e^3 55 free from all restraint, so that the spring e^2 can swing without resistance, leaving the bars B8 and their connected wheels B3 free to move under the action of the wheel-operating

devices. In order to secure the proper alignment of the numbers upon all the wheels, I make use of the cross-bar e^7 in connection with the **V**shaped notches w in the printing-wheels. Thus as the recorder descends the cross-bar $65 e^7$ is received into the notches of the wheels and all are brought to bear upon the crossbar until turned with the lower numbers in as set forth.

necessary that they should be left to turn | line with each other and the faces parallel with the face of the platen, the bar e⁷ preventing any independent movement of any of the 70 wheels. As the recorder rises, the bar e7 remains in its place until the wheels are above the latter, when they are free to turn under the action of their operating devices.

An L-shaped dog F, Figs. 2, 3, and 6, is 75 hung loosely to the shaft g of the recorder, so that one arm may extend over one of the bars d^9 , which acts as a stop, while the other pendent arm h is provided with an inclined edge v, so arranged as to be struck by the 80 cross-bar e^7 when it enters the notches w.

In the platen B^4 is a notch i^3 , so arranged that when the cross-bar e^7 is in the lower row of notches to its greatest depth, as shown in Fig. 4, it will contact with the dog F, and the 85 latter will enter the notch i3 and the printing will be effected. When, however, the crossbar e^7 is in the position shown in Fig. 1, the dog F will swing to such a position that its lower end will in descending strike the face 90 of the platen and prevent the full descent of the frame B5 and the battering of the type, which results if any of the wheels strike the platen before the face of the type is brought parallel with the latter. Thus if one of the 95 wheels was out of adjustment the cross-bar $e^{ au}$ could not enter to the full depth of the notches w, and the dog F would not therefore be moved by the cross-bar sufficiently to permit its end to enter the opening i^3 .

Other means than those described may be employed for bringing the springs e^2 to bear at the proper time upon the bars B8 and leave them free at other times—as, for instance, a handle f^{20} , connected with the ros shaft e^3 , as shown in dotted lines Fig. 4, the

100

115

said handle being operated by hand.

In some instances it is desirable to print the date upon each slip upon which the number is printed. This I effect by arranging 110 dating-wheels T upon the shaft g, as shown in Fig. 3, the said wheels being set by hand or otherwise, and a separate ink-ribbon c^{80} , extends from spools c^{90} beneath the said dating-wheels.

Without limiting myself to the precise construction and arrangement of parts shown, I

1. The combination, with the independent type-wheels of a recorder, of springs for mov- 120 ing said wheels in one direction, a detent to prevent the movement of each wheel after it is at zero, and devices for throwing the springs into and out of action on the wheels, substantially as set forth.

2. The combination of a vibrating frame, a platen, a recorder having independent printing-wheels carried by the frame, detents limiting the movements of the wheels in one direction, springs for turning the wheels in 130 said direction, and means, substantially as described, for throwing the springs into and out of action upon the wheels, substantially

a recorder having a series of printing-wheels, a platen, springs connected to move the said wheels, an arm extending from the frame 5 connected with said springs, and a stop arranged to contact with the arm as the frame ascends to swing and put the springs under tension, substantially as and for the purpose set forth.

4. The combination, with the series of printing-wheels carried by a frame, and with a platen, of a series of bars gearing with pinions connected with said wheels, a series of springs suspended from a rock-shaft to con-15 tact with bearings upon said bars, and a lever carried by said frame and bearing against an arm upon said shaft to rock the latter and carry the springs against their bearings as the frame ascends, substantially as set forth.

5. The combination, with the series of printing-disks carried by a vibrating frame. of an aligning-bar and stop device F, arranged

3. The combination of the frame carrying | in position to engage said bar when the latter is in position to hold the disks in alignment, substantially as set forth.

6. The combination, with the series of printing-disks carried by a frame, of an aligning-bar carried by arms, one of which is provided with a lug, and a stop-arm provided with shoulders arranged to engage the said lug, 30 substantially as and for the purpose set forth.

7. The combination, with the independent wheels of a printing-recorder, of rack-bars, actuating-springs, and spring-operating devices for bringing the springs to bear on and 35 for throwing them out of action on the bars, substantially as set forth.

In testimony whereof I have signed my name to this specification in the presence of two subscribing witnesses.
WILLIAM S. BURROUGHS.
