## United States Patent Office.

EDWIN E. BEAN, OF BOSTON, MASSACHUSETTS.

## SHOE-SEWING MACHINE.

SPECIFICATION forming part of Letters Patent No. 524,986, dated August 21, 1894.

Application filed April 13, 1894. Serial No. 507,431. (No model.)

To all whom it may concern:

Be it known that I, EDWIN E. BEAN, of Boston, in the county of Suffolk and State of Massachusetts, have invented a new and useful 5 Improvement in Shoe-Sewing Machines, of which the following, taken in connection with the accompanying drawings, is a specification.

My invention relates to attachments to be combined with the working parts of a shoe 10 sewing machine described in Letters Patent of the United States No. 513,048, dated January 16, 1894, subject shoe sewing machine, the object being to make a shoe sewing machine that will rapidly make a lock stitch 15 having two threads, one of which only goes through the stock. This object I attain by means of the mechanism shown in the accompanying drawings, in which-

Figure 1 is a view in elevation showing the 20 principal parts of a shoe sewing machine, having my improvements. Fig. 2 is a perspective view showing the stitch forming parts, the stitch being partly formed. Fig. 3 is a perspective view showing the stitch forming 25 parts, the stitch being about complete. Fig. 4 is a perspective view showing a part of a shoe, illustrating the stitch and the method of making it.

In the drawings, A represents a part of the 30 frame of the machine and to which the mov-

ing parts are attached.

In the following description I refer to such parts only as it may be necessary to an understanding of the working of the stitch form-35 ing appliances. The mechanism for operating such parts may be of the kind shown and described with patent above referred to, or of any desirable construction.

B is a lever pivoted at B' to the frame A of 40 the machine; a thread clamp B2 is rigidly attached to the front end of this lever by screws

B<sup>8</sup> B<sup>4</sup> or otherwise.

C C<sup>4</sup> is a pendent arm pivoted to the lever B at C'. This arm C C<sup>4</sup> moves bodily up and down with the front end of the lever B and has in addition a swinging movement imparted to it by the link C2 which is operated by a is so curved and arranged that it, together 50 with the arm C C4 forms a thread holder and

carrier for the second thread S'.

For convenience in description, I designate the thread S', the second thread. This thread forms the "bite" (see S<sup>8</sup> S<sup>4</sup> Fig. 4) and ensaging with the loop T' T<sup>2</sup> of the thread T (first thread) and makes a lock stitch of it. The second thread passes downward in a channel made on the under side of the arm C C4 and is pushed forward in said channel by 60 the thread pushing arm E. This pushing forward of the thread S' causes it to form a loop S<sup>3</sup> S<sup>4</sup> in front of the end of the carrier C<sup>4</sup> which forms a bite or lock for the stitch formed by the first thread T. The pushing 65 forward of the second thread to form the "bite" is effected by the following described device: The thread pushing arm E' E is pivoted at D<sup>3</sup> to the lever D while the said lever D is pivoted in turn to the pendent arm CC4 70 at D' and has an arm D5 attached to it, so arranged that as the pendent arm C is moved downward by the lever B and inward by the link C2, the arm D5 will come in contact with the pin A2 which will stop its downward 75 movement and thus cause the lever D to swing so as to throw its lower end inward; this action will carry the feeder E in the same direction, which in turn will take the "second" thread with it and thus form the 80 loop or "bite" S3 S4. The feeder E E' is held in contact with the thread by the spring F. Now the loop-bite being formed as shown in Fig. 2, the loop-bite holder H will descend so as to enter and hold the loop-bite as shown 85 in Fig. 3. The pendant arm C C<sup>4</sup> will be swung outward by the motion of the link C2. This movement will cause the thread to be drawn taut, since the part S5 is held by a previously made stitch, and that part of the 90 thread that is between the holder H and the reel S will be clamped and held by the clamp plate B2 and the pendent arm C; for the reason that the clamp B2 is relatively stationary while the arm C C4 is made to swing against 95 it, thus pinching the thread S2 and giving it cam or other suitable mechanism; a plate C<sup>3</sup> the required tension for insuring the proper is attached to the front of the arm C C<sup>4</sup> and drawing up of the loop-bite. The lever D is

held in its normal position by a spring D6 and a pin C<sup>5</sup> which limits the movement of the

upper end  $D^4$  of the lever D.

While the above described formation of the 5 loop-bite from the "second" thread S' has been taking place, the stitch from the first thread T has also been made as I will now explain.

The thread Tor first thread comes through the looper k which passes it around the point 10 of the needle i so as to engage with the hook of the needle; now the needle retreats and draws the thread through the stock and forms a long loop T'  $T^2$  (Fig. 2); this loop is thrown off the hook of the needle by the cast-off e15 and immediately the take-up (not shown) operates to draw the loop tight down upon the loop-bite and the stitch is complete (see Fig. 3).

In the above description, the presser-foot, 20 feed device, and awis, have not been described as they form no part of my present invention and are fully illustrated and described in the Patent No. 513,048 above re-

25 I claim—

1. In a sewing machine, the combination of

the lever B, carrying the thread clamp B2, and the pendent arm C C<sup>4</sup> pivoted to the lever B, and adapted to swing back and forth in relation to the thread clamp B2 and therewith form 30 a tension device for the thread S' S2; with the clamp B<sup>2</sup> substantially as and for the purpose set forth.

2. In a sewing machine, the combination of the lever B, carrying the thread clamp  $B^2$  and 35 the pendent arm C  $C^4$  pivoted to the lever B and having attached to it a plate C3 adapted to act in connection with channeled part C4 of the arm C C4 as a thread-holder and carrier; with the lever D pivoted to pendent arm 40 C C4, thread pushing arm E, arm D5 attached to said lever D and pin A2, all adapted to operate together substantially as and for the purpose set forth.

In testimony whereof I have signed my 45 name to this specification, in the presence of two subscribing witnesses, on this 30th day of

March, A. D. 1894.

EDWIN E. BEAN.

Witnesses:

Frank G. Parker, FRANK G. HATTIE.
