The failure of socialism to bring about the nationalisation of monopolistic concerns and its success in despoiling the middle class and in irritating the farmers redounded to the advantage of industrial capitalism. Socialists had not dared to take over the broken down industries; industrial owners were quite willing to reconstruct them. They had to make concessions to the working class. They had accepted the eight-hour working day, collective bargaining, greatly improved wages for unskilled labour, the temporary abolition of piece work and the works councils. They did not mind this as long as they could keep the control of prices to themselves. Treaty clauses for delivering coal had put the execution of important peace terms into their hands; they had acquired a place on the international stage. With the continuation of inflation they seemed to wax rich, whilst the state got weaker and poorer. They embarked on a policy of industrial aggregation; whilst formerly there had been a tendency to horizontal trusts, they now aimed at vertical combines to create self-sufficing enterprises, where raw materials, semi-manufactured and manufactured goods were in the same hand.

As time went on economic power became separated from political power. A Coalition Govt. of Socialists, Democrats and Centrists ruled the state. They were held responsible for the humiliations inflicted on Germany, whilst the real power, the economic power, was in the hands of the industrialists and the slowly recovering landed interest, impeded but little by organised labour. As inflation progressed labour became less and less powerful, and when the infuriated middle class turned away from the coalition parties, the weight of political power was turned into the same direction into which economic power had gone before. The state was broken; big business seemed to rule.

Depreciation of the Mark.—From the summer of 1919 to the end of 1923 German economic life was mainly dominated by the depreciation of the mark. The dollar had risen from par (4·2 marks), to about 14 marks after the signing of the Peace in the summer of 1919. It went up continuously until it bought 100 marks by the end of Feb. 1920. After that it fell to 40 in May. Owing to the loan contracted at Spa it remained between 50–70 until early in 1921. The beginning of the Reparations payment under the London plan (May 1921) forced the mark down to 80 by the end of July. It stood at 100 late in September. Its downward movement was greatly accelerated in Oct. of that year, when the news of the partial loss of Upper Silesia became known. Before the Genoa conference the mark hovered round 300 to the dollar, to go down considerably after its failure, its downward course gathering speed after the murder of Rathenau (June 24 1922). The demand for a moratorium and the abortive conferences about it brought it down to 4,000 in Oct. and 8,000 in Nov., where it remained through the rest of the autumn of 1922. On the day after the occupation of the Ruhr (Jan. 11 1923), it quickly fell to 30,000, reaching 49,000 on Jan. 31. At that time the Reichsbank intervened, bringing down the dollar to 20,000 and keeping it there until April 18. But the dislocation of economic life and the great strain on the finances caused by the struggle of the Ruhr forced the Government to use the printing press at a formerly unheard of rate. The stabilised mark collapsed. By the end of Aug. the dollar had risen to 10·3 millions. And when currency reform was under way, just before the issue of the new Rentenmark, the price of the dollar was practically settled at 2·5 billion marks. No depreciation on such a scale had ever been known, save in Russia.

The primary cause of the decline of the mark was faulty Government finance. At the end of the War the funded debt was estimated at 103 milliards gold marks. Current expenditure had been met by treasury bills, which the Reichsbank was allowed to discount and to use as cover for its notes. From time to time the outstanding Treasury Bills were converted into a funded loan, nine different issues of which were placed amongst the public, bringing in a total of 98·5 milliards.

The War was followed by a revolution. Demobilisation had to be carried out under very difficult conditions. The revenue went down almost to nothing. So most of the expenditure had to be met by Treasury Bills. The Reichsbank became the chief support of the Government, issuing notes against such Treasury Bills as were not taken up by the public. Retrenchment was impossible. When armed insurrection is threatening the foun-

dations of the State, extravagance may be wise and saving may be foolish.

As soon as the worst danger was over, financial reform was undertaken. But the chances for its success were small. The organised working class who were the main support of the Government and on whose co-operation the maintenance of order depended were rather disillusioned. There was a great deal of privation all over Germany. The millennium which they had dreamed of had not come. They had not succeeded in wrenching the control of capital from the capitalistic classes. The least they could do to meet their supporters was to claim for them an enlarged share of the nation's income by way of increased wages. The revolution, it has been said, degenerated into a struggle for higher wages, short working hours, and overemployment in works and Government departments, so as to avoid dismissals. This meant increased Government expenditure, which could not be met by taxation of the working class. In a country where prices are rising rapidly and where there is an actual scarcity of commodities indirect taxation cannot be resorted to by a Government mainly dependent on the masses, the support of which is by no means certain. Taxation was bound to fall on the propertied classes.

As long as the socialistic movement was in the ascendant—even at the election of 1919 socialists failed to get a majority—the capitalist classes, including the landed interest kept quiet. They did not openly fight against taxation. But they naturally tried to save as much as they could. Notwithstanding all sorts of severe regulations a great deal of movable property left Germany in the revolutionary days 1918–9. The so-called " flight of capital " started—a movement quite legitimate in early days, when violent confiscation seemed imminent. Later on it developed into an effort to save property from the severe taxation involved in the financial reform proposed by Erzberger.

The Erzberger Reforms.—In Feb. 1919 a Coalition Govt. had been formed by the Majority Socialists, the Centre party and the Democrats. Differences of opinion about signing the treaty of Versailles led to the withdrawal of the Democratic party. The Majority Socialists and the Centre, who counted 253 in a house of 423 formed a new Government. And Erzberger, who up to now had been Minister without portfolio became Chancellor of the Exchequer. Being dependent on the Socialist vote and having been all his life the representative of a small, rather anti-capitalistic group in the Centre party, his scheme of taxation was bound to weigh heavily on the propertied classes. He introduced a capital levy originally devised to wipe out the deadweight debt and a thorough going taxation of War profits, which nearly wiped them out. He clearly saw that the Treaty of Versailles, which put a crushing burden on the Reich, necessitated the creation of a central Exchequer to which the individual States must be made subservient. All through German history the states have jealously guarded their rights of financial sovereignty. Even Prince Bismarck in the hey-day of his power had not been strong enough to make the central Treasury independent of their control. Erzberger made the Reich the dominant partner in finance. He deprived the states of the main sources of taxation, such as the income tax. He organised an imperial service for their collection and their administration, superseding the old state services. He amalgamated the railways, which hitherto had been the property of the individual states, into the imperial railways. Under the shadow of the Treaty of Versailles he succeeded where Prince Bismarck had failed.

Though part of this legislation was watered down while passing through parliament, it would have weighed heavily on the propertied classes, if the taxes had been paid immediately in stable money, with no interval for the further depreciation of money. But this was plainly impossible, as the new imperial inland revenue service could not start immediately. If properties were valued in marks at a time when the value of the mark was fairly high, and if taxes assessed on this value were paid at a later time when values were low, the burden of taxation could be easily shifted. At the same time the burden of the government debt would decrease automatically.

Reparations.—As the Treaty of Peace had not fixed Germany's total obligations before May 1921, the Budget did not contain proper estimates for reparation payments. This was not merely a grave technical hindrance to reform, it put a premium on financial procrastination. For it was clear that a country whose finances were sound and solid would be charged with a heavier indemnity than a country on the verge of bankruptcy. Balancing a budget after a long spell of inflation is always a difficult and very unpopular undertaking. If by balancing it early the total obligations are likely to be increased in the interest of hostile foreign creditors, the impetus to reform will be greatly weakened. And the same holds good of the taxpaying moral of the individual taxpayer. What good is it, he was bound to say to himself, to strain every nerve so as to enable the exchequer to square all its liabilities, if by doing so I am merely throwing on it new indefinite liabilities?

The London Ultimatum (May 6 1921) enormously strengthened this attitude. The total demands on Germany amounted to 132 milliards of gold marks; the yearly payments might easily rise to eight milliards, or twice the German exports and about double the total revenue of the Empire before the War. The outlook for financial reform became hopeless. Inflation proceeded, and the business world began to realise that the public's loss might be their private gain. They began to look upon the further depreciation of the mark as upon a fateful destiny and, being unavoidable, as quite a legitimate means for getting rid of their debts.

The Budget.—Some courageous efforts to balance the budget were made nevertheless. A plan of either valorising the taxes or revaluing the amount of taxes payable on the day on which they fell due was discussed in 1921. But as it was unwisely called " taxation of real values " and imbued with a certain amount of socialistic acerbity it could not be carried. It was transformed much later into a forced loan, levied from all property owners but in such a stupid way that the owners could take up the loan in paper marks at a time when it cost next to nothing. When the loan was passed in July 1922 the owner of a property worth 100,000 gold marks, had to subscribe 1%, which at the then rate would have come to about 150,000 paper marks. If he did not pay in time he was subject to a fine. But if he did pay the fine and settled at the end of the year he had reduced his liability from 1,000 gold marks to 90 gold marks.

So the issue of Treasury Bills against which notes were printed remained the chief prop of Government finance. As time went on and as the public became more sceptical the proportion of the bills taken up by the Reichsbank and those taken up by the public changed considerably. In Jan. 1921 the bank held 50.6 milliards and the public 104·9; in Oct. 1922 the figures were reversed: the bank held 477.2 milliards and the public 126·3. Moreover, political events continually upset the balancing of the budget. The equilibrium established at the rate of 300 marks to the dollar, would immediately be upset if, in consequence of some political action, the mark went down and prices went up.

There was no immediate parallel movement between the amount of notes issued and the depreciation of the mark, but there was a very distinct connection between political events and the fall of the exchange. The loss of Upper Silesia, the acts of the Reparation Commission, the murder of Rathenau, the occupation of the Ruhr, the speeches of Poincaré are the outstanding dates at which the mark took a headlong downward flight. Each new political crisis brought about a huge demand for foreign exchange in Germany. As the German business world had to get raw materials, or the means to pay for raw materials, or the chance for keeping part of their stock intact, they had to buy foreign exchange, whilst foreign purchasers of marks got frightened and sold out at any price. Notwithstanding stringent regulations capital fled from Germany in many forms.

In the autumn of 1922 the situation had become almost hopeless. The German Government had been asking for a moratorium. The Reparation Commission might have been willing to grant it, but the French Government proved recalcitrant. A conference of neutral experts was called to Berlin to consider the possibilities of stabilising the mark. It agreed with a small group

of German economists that the mark could be stabilised provisionally with the gold of the Reichsbank, and that an effort in that direction might be made the basis for a reasonable reparation settlement. Public opinion, however, greatly influenced by business interests, considered a previous agreement on reparations conditional to stabilisation. Nothing could be done; the last chance for bold action was missed.

Occupation of the Ruhr.—A few months later the Ruhr was occupied. The mark immediately responded by falling to 49,000 marks to the dollar. A tardy stabilisation effort was made in Jan. which succeeded for about eight weeks. But the Government expenditure for the support of the people in the Ruhr, whose works had come to a complete standstill, was enormous. By the end of July the total note issue had reached 43·6 billions against two billions at the end of Jan., the amount of Treasury Bills outstanding 57·8 billions, whilst private bills discounted by the Bank had risen to 18·7 billion marks. Selling bills to the bank had become a very profitable business. Debts were contracted in marks when the dollar was 30,000 and paid back three months afterwards when it had risen to 1,100,000; even a bank rate of 18% was of no avail. By the end of May the bank's gold fund had fallen from one milliard to 758 millions; on Dec. 1923 it was down to 467 million marks.

In the summer of 1923 social disorganisation had become imminent. The farmers refused to sell goods against depreciating paper; the big industrial works revised and paid wages bi-weekly, starting from a kind of dollar basis. But if the money received was not spent before the new quotations from New York had reached the shops its purchasing power might be halved. Whilst the country was drowned in a flood of paper money a scarcity in actual notes was frequent, for the printing press could not keep pace with the rise of prices.

For a long time wages had been below the level of the world market, as home prices had been rising more slowly than prices abroad. It was expected that this advantage in the cost of production would enable Germany to produce more cheaply than other countries and to flood the world market. Nothing of the sort took place. For 1922 German export reached 6·2 milliard gold marks and for 1923 5·4 milliard gold marks, against 10·2 milliard in 1913. Though the accuracy of these figures may well be doubted in some respects, there is no evidence whatsoever to assume a flooding of foreign markets, the total weight of German exports having dwindled from 74 million tons in 1913 to 22 million tons in 1922. As foreign trade was controlled by all sorts of semi-official syndicates, exports were often restricted with the object of keeping the home customer quiet. And as German exports depended on imported raw materials, the scope for expansion of industrial exports was small indeed, as imports were impeded by the fall of the mark. The fear of further depreciation induced the German exporters to keep part of their revenues abroad rather than return them to Germany. The McKenna report valued German assets outside Germany at about seven milliard gold marks. Such people as were unable to invest their savings in a foreign country bought dollar or pound notes; and though the ordinary citizen was forbidden by law to purchase these notes they circulated quite freely though, of course, clandestinely, all over Germany.

The Rentenmark.—At midsummer 1923 the mark as medium of circulation was doomed. An emergency currency such as "gold certificates" was suggested. To stave off the crisis, whilst currency discussion went on, taxation was put on a gold basis; for the first time for many years the landed interest had to bear its share. The plan of the reformers of Oct. 1922 to stabilise first and to settle the reparation business later on was taken up by its quondam opponents. But the obstacles to reform had grown enormously. The Reichsbank, which had not been willing to risk its gold in 1922 when there was a fair chance of success, had thrown away half of its holdings in the hopeless endeavour to raise the course of the mark at a time when the printing of marks proceeded at fantastical speed. A foreign loan, to ensure success, could not be had; a home loan, it was supposed, was out of the question.

A plan for the issue of a new money, to be guaranteed by mortgage bonds, inscribed on real estate, was broached. These notes—they were later called the Rentenmark—were to be secured by interest-bearing bonds; they could automatically be converted into them. The interest was to be a first charge on real estate. The total issue of the new money was to be limited to 4·2 millards, 2·3 of which were to be lent to the Government; the rest to private concerns. The plan which was to provide the Government with funds to carry on the struggle in the Ruhr would have failed lamentably if the Stresemann Govt. had not had the courage to stop the fight, thus doing away with the main cause for unlimited expenditure. It cut down the total issue to 3·2 milliards, and greatly modified the whole scheme. The Government succeeded, against all expectations, in floating a gold loan, which gave it a breathing space; it was echeloned in such small points that it could be used as stable currency during the period of transition. When Luther became chancellor of the exchequer the new currency, the Rentenmark, was issued, and the work of stabilisation began. It succeeded completely.

The cessation of passive resistance in the Ruhr was followed by the ruthless cutting down of expenditure, especially of salaries in Government offices, at a rate probably never heard of before in a civilised country. This brought about the equilibrium of the budget, the gold loan and the loan from the Rentenmark issue bridging over the temporary gap. The new president of the Reichsbank, Dr. Schacht, restricted the bank's credit facilities, thus cutting off business from their accustomed supply of cheap money. They had to rely on their own savings which they had invested in foreign exchange. These hoards played the part of a foreign loan usually contracted for stabilisation purposes. They constituted the foreign currency fund on which the bank could draw for maintaining the mark exchange. German business needing cash had to sell foreign exchange, against which the bank issued its notes, which thus became gold exchange covered. The flight from the mark, which originally had destroyed the German currency, later on provided Germany with the means of stabilising it. After the first quarter of 1924 the foundations for monetary reform had been safely laid. And on this basis negotiations for a reasonable settlement of the reparation problem were started which ended in the acceptance of the Dawes Plan.

The Dawes Plan.—As her economic life was at a low ebb, Germany could not be made liable for a lump sum anywhere within reach of French expectations. The experts had to fix Germany's obligations in such a way as not to sap her energy by incertitude, and at the same time give the Allies a chance of participation in her growing wealth in case she made a quick recovery. To do this Germany's obligations were, so to speak, divided in two halves; the one was to consist of 11 milliard gold mark bonds secured on the German Govt. railways and of five milliards bonds registered as obligations on German industrial property. At a rate of 5% interest and 1% sinking fund these bonds yielded 960 million marks a year, which were to come from the proceeds of the mortgaged properties. These 960 million constituted the minimum annuity to which Germany was liable. If these bonds could be sold at par their total value would be 16 milliard gold marks; the value of two milliard gold marks preference shares of the German railways might be added. This capital sum of nominally 18 milliard gold marks would be paid off within 37 to 38 years by means of a sinking fund of 1%.

The other half was an annuity not yet capitalised, the proceeds of the railway tax and of customs and excise yielding about 1,250 million gold marks a year. The administration of these revenues has to be supervised. An additional surplus was to be paid, in case Germany's capacity to pay increased, which was to be deducted from a carefully constructed index. If the contrary movement took place and if its transfer abroad affected the exchange unfavourably these revenues were to accumulate up to five milliard marks. When this figure was reached payments from these sources would be stopped, until an improved economic situation could permit the resumption of payments abroad. A transitional régime, including a kind of a diluted moratorium, was to be in force from 1924–7 when the yearly payments were to

be 1,000, 1,200, 1,220, 1,750 million gold marks, part of them to be defrayed from loans or from sales of railway shares.

The first result of the Dawes Plan was the flotation of a German loan of 800 million marks in the financial centres of the world, which enabled Germany to pay most of the reparation payments of the first year and to put the Reichsbank on a sound basis. Reorganisation was to furnish amongst other things the mechanism for the gradual disappearance of the Rentenmark.

The Country's Recovery

After inflation Germany was an empty shell. The middle class, the owners of mortgages, of state, municipal and industrial bonds were practically ruined; so were the house-owners who had received scarcely any rent. A tardy restoration was enforced by public opinion 1924–5: private debentures, especially mortgages, were to be valorised at 25% of their original value, the payment to be postponed until 1932. The owners of public securities were to receive but scanty compensation, owing to the prior lien of reparation claims. The loss of the creditors has not benefited the debtors. States and municipalities were, no doubt, relieved of their burdens, but the ruin of well-to-do tax-payers was a very heavy burden to them.

Agriculture.—As far as agriculture is concerned, no fundamental changes have taken place. The big estates have not been split up, though under the different closer settlement schemes 7,300 new holdings have been created in Prussia. Big entails (Fideikommiss) have been broken up. But until lately land has not come into the market in great quantities. It is only now, when an agrarian crisis is setting in, that estates, especially big estates, can be had for a song. Whilst inflation lasted agriculturists had a good time. They saved the money due on their mortgages; some of them may have relaxed their efforts and produced less; others raised their standard of living. The wiser ones—and there were many of them—spent largely on permanent improvements. The great progress in the chemical industry, especially the production of artificial nitrates, enabled them to intensify their production. With a good harvest prices were bound to fall. Working capital, especially for big owners, was rather scarce. As the rate of interest had risen considerably, the number of years' purchase to be given for an estate had considerably diminished, and the total assets capable of being mortgaged had shrunk, whilst the total interest remained the same. Moreover, mortgages were very difficult to get. So financing was done by bills of exchange, which fell due after the harvest and forced the owners to sell at low prices. The agricultural crisis imminent in the summer of 1925 was aggravated by an embargo on grain; its abolition brought prices to the level of the world market, a rise which has not been considered sufficient, inasmuch as a good world harvest depressed the general level. New corn duties of three marks per doppelzentner and a refund for exportation were clamoured for and granted; so far they have been a failure as a remedy for the crisis.

Industry.—The bonded debt of industry, from which inflation freed it, has been estimated at about five milliards of gold marks. Apart from that, the bank had granted huge credits to industrialists, which were paid back in valueless money and cost them very little. Many enterprises used these savings for purposes of expansion, thus increasing their productive capacity; though this is by no means true of all enterprises. Many works, not having been subject to competition for a long time, want modernisation badly; entire trades, like the textile trade, have greatly shrunk. The number of spindles in cotton mills fell from 11,186,000 in 1913 to 9,464,000 in 1924; the consumption of cotton from 486,000 tons to 271,000.

Changes all over the world have greatly affected the position of German industry. The production of bituminous coal is suffering from the competition of lignite, of electricity and of oil. The iron industry, quite apart from the structural changes brought about through loss of territory, has lost the armament market as well as the building market; the construction of houses is far below the pre-War output of 200,000 dwellings a year. The great use of scrap iron has diminished for the time the importance of iron ores.

Inflation greatly facilitated the concentration of industries in a few hands by all sorts of combines. Shrewd business men borrowed money from the banks to buy shares and plants, and repaid the loans in valueless paper money. Some of the new combines were mere amorphous aggregations which fell to pieces immediately when credit became dear. Others chose the so-called vertical combination, trying to concentrate in one hand works representing the different stages of production. This was the type which has been closely identified with the name of Stinnes. The home market was secure, as, owing to falling exchanges, foreign goods could not compete. Wages reckoned in gold were low, trading conditions profitable.

After the mark was stabilised, it was quite clear that industry as well as agriculture was a loser. The middle class, having been ruined, had no purchasing power. Wages, though considerably higher than during inflation days, were below the peace level. The average weekly wages of a skilled metal worker had been 36·36 marks in pre-War days; they were 31·27 marks in April 1924. As the cost of living index had risen to 111 (rent included), wages represented a good deal less purchasing power than before.

Foreign Trade.—Exports could not make good the deficit of purchasing power at home. Germany's total exports had fallen to 6·5 milliard gold marks, 1923–5, against 10·2 milliard gold marks in 1913, not making allowance for the rise of prices. As the purchasing power of neither the home market nor the foreign market equalled the productive capacity of increased plants, many works were running at half speed. And as overhead cost added an increasing proportion to costs when the output was small, prices needs must be comparatively high. Given the small purchasing power of the home market high prices were bound to lead to reduced sales, and reduced sales in their turn must bring about rising costs. Adjustment was very slow as for a long time there was no real free competition in Germany. Foreign competition was kept out by tariffs as well as by the use of import licenses (a practice which has almost disappeared by now). The sheltered home market was controlled by cartels whose policy was to give a chance of living to the most inefficient member-works. All this really meant a reversal of the old German business policy, which had insisted on a big turn-over and a small profit; the new policy aimed at big profits and small turn-overs. As the political power in economic affairs remained in the hands of the highly organised producers of raw materials and half-finished goods who insist on high prices, the general price level was driven up. By the end of 1925 the cost of living index had reacted, and nominal wages were above the pre-War level. The average for the metal workers in Dec. 1925 was 46·24 gold marks (skilled) and 31·16 gold marks (unskilled). In the midst of a crisis Germany had high prices and rising wages.

Most of the legal obstacles to exportation had disappeared in 1925. Germany was admitted to the most favoured-nation treatment, and the licence system was on the wane. But hostile tariffs and decreased international purchasing power have remained, affecting German foreign trade in a peculiar way. Whilst English exports have risen from 284 marks per head 1913 to 385 marks 1923, Germany's quota has fallen from 149 gold marks to 139·6 gold marks 1925. German industry clamoured for a tariff, with the double object of fighting hostile customs barriers and of enabling her to recoup herself on the home market whilst exporting cheaply abroad. The tariff was carried by a combination of the landed interest and the producers of raw materials and half-finished goods. It came into force on Oct. 1 1925.

Credit Position.—Generally speaking it has not achieved much. It may have facilitated the conclusion of minor commercial treaties. But the poverty of the consumer who can either buy goods or keep his money in the bank, but who is unable to do both as he did in days gone by, has deprived industry of its working capital, though the valuation of the plants is rather high. Capital is scarce, and rates of interest (long term) at 12% and more are even now by no means the exception. The Reichsbank was bound to restrict credit, as it had to protect the currency and

STATISTICS OF GERMANY'S PRODUCTION, INDUSTRY AND TRADE

wanted to force down prices. Government increased the stringency by overtaxing the people from fear of failing in their obligations under the Dawes scheme. The surplus in the Treasury has either gone to States or municipalities which not always used it wisely, or lent it out directly or through the banks in rather an indiscriminate way. Foreign credits have been resorted to on a considerable scale. They have been estimated at 3½ milliard marks, which accounts of course for Germany's unfavourable balance of trade (imports 12·5 milliard gold marks, exports 8·8 milliards gold marks). The lending capacity of the banks is very limited. The total capital of the four big Berlin banks before the War (reserves included) amounted to 1,059 million marks, their deposits to 2 milliards. At the end of 1925 capital and reserves have shrunk to 546 million marks and deposits to 1·76 milliards. The savings bank deposits have fallen from 18 milliards gold marks to 2·3 milliards.

The result of this scarcity of credit, which is really due to insufficiency of income, has been a crisis which is now at its height. Amorphous aggregations like those of the Barmats have long ago gone to pieces, but even vertical combines, like the Stinnes concern, had to be dissolved. And the typically German form of the horizontal combine, the cartel, which is an organisation of works producing the same class of goods with the object of getting a monopoly price high enough to keep the weakest partner going, has broken down. There is a tendency already materialised in the chemical trade, and on the way to materialisation in the steel trade, to form a real trust with its advantages of large scale production. Germany is on the way to recovery. But the transition is slow and painful. Owners are naturally unwilling to write down capital on the necessary scale, as indicated perhaps too pessimistically by the valuation of shares on the stock exchange. Bankruptcy is rampant. In Dec. 1925 commercial failures, which were as low as 30 a month in Jan. 1924, have gone up to 1,660, thus greatly surpassing the monthly average of 815 in 1913. Unemployment is spreading. Whilst during the hey-days of inflation (second half of 1922)

less than 50,000 people received unemployment benefit, their number had grown to 1,485,931 at the end of Dec. 1925. Emigration is starting again, notwithstanding all sorts of obstacles; 58,714 emigrants left Germany in 1925. Fortunately, trade unionism has regained its strength. The problem lying ahead of Germany is, how can she become a country with a low level of prices and a comparatively high level of wages.

VIII. CURRENCY.

The New Bank Amendment Act.—On Jan. 1 1911 the provisions of the Bank Amendment Act of June 1 1909 came in force. By this Act the note issue privileges of the Reichsbank were extended for a further 10 years, and the tax-free portion of the issue was again increased (from 450,000,000 marks to 550,000,000 marks; at the end of each quarter to 750,000,000 marks). The note circulation was permitted to exceed the cash reserves by those sums without the Bank having to pay the 5% note tax. This measure was partly due to the severe economic and financial crisis of 1906–7, which had led to abnormally high official discount rates, and to the institution of a thorough inquiry into the working of the Central Bank and of the whole German banking and credit system. The committee of investigation, of which Dr. Havenstein, the president of the Reichsbank, was chairman, had recommended, firstly, that the gold holdings of the Reichsbank should be increased by a larger issue of small notes, by encouraging payments which did not involve the use of cash, and by corresponding measures in regard to foreign payments; secondly, that measures should be taken to diminish the demands for credit from the Reichsbank on the part of public and private bodies, and to strengthen the security and liquidity of the deposits in the banks. The new Bank Act gave effect to most of these recommendations. Bi-monthly balance sheets of the banks were published in the *Reichsanzeiger* from 1912 to Aug. 1914 and again from the beginning of 1925. The liquidity of the German banking and currency system was improved.

The average annual gold holdings of the Reichsbank rose from 827,600,000 marks in 1911 to 1,067,600,000 marks in 1913, the note circulation of the Bank from 1,663,600,000 marks to 1,958,200,000 marks, the gold cover from 49·7% to 54·5%, the holding of bills from 1,077,800,000 to 1,136,000,000 marks, and the total turnover from 377,500,000,000 to 422,300,000,000 marks.

The official discount rate was fairly high during the years immediately preceding the War owing to expanding trade and to the tension on foreign relations, the average rate for 1911 being 4·397%, for 1912 4·946% and for 1913 5·885%. Credit transactions both at home and abroad were regulated by the gold standard, and fluctuations were lessened by the intervention of the Reichsbank. The supply of and demand for capital were harmoniously adjusted, and the markets for short and long term loans were adapted to varying needs by the automatic operation of interest rates. The Reichsbank acted as the bankers' bank and as the ultimate source of credit in the country. The whole credit and currency system stood in the closest relation to the economic organisation of Germany and to its development as a great industrial and international trading centre. Though the balance of trade was adverse, as in other advanced industrial countries, the invisible exports were sufficiently large to enable a steadily increasing volume of capital investment abroad.

The War Period.—When the World War broke out the Reichsbank was faced with new tasks of unexampled magnitude. It also took over the management of the loan offices (Reichsdarlehnskassen) which were set up in 1914 to facilitate borrowing against goods, stocks, shares, etc. It was able to meet the tremendous demands for cash and loans during the mobilisation period and in the early stages of the War without any appreciable rise in its discount rate and without the necessity for a general moratorium. It is true that on Aug. 4 1914 its notes were declared irredeemable in gold, and the liability to pay note tax on excess issues was abolished. Loan office notes were recognised as a cover for Reichsbank notes, and Treasury Bills with not more than three months to run were admitted for discount at the Reichsbank, and accepted as cover for the note issue. This disregard of well-established currency principles would probably not have had very serious results if, as was at first assumed, the War had been of short duration.

As the Reich acquired control over an ever larger proportion of the economic system for War purposes its demands for credit became predominant, and the requirements of private industry and commerce, which at first were very great, fell increasingly into the background. The necessary sums were in the first instance made available by the Reichsbank in the form of Treasury Bill credits, and then converted almost completely into long-term war loans. By a successful collection of gold from the hands of the public, a fund was created for external purposes which proved of the greatest importance, both in the War and in the difficult post-War period, as a means of payment for vital imports. The Reichsbank discount rate, which at the outbreak of the War was raised to 6%, was reduced in the middle of Dec. 1914 to 5% and kept at that figure till the middle of 1922. But owing to the lack of a free gold market it lost a great part of its normal influence as a regulator of the economic system. The circulation of Reichsbank notes rose from an average of 1,958,000,000 marks in 1913 to 5,409,000,000 in 1915, to 9,010,000,000 marks in 1917 and to 13,682,000,000 marks in 1918.[1] The average gold holdings of the Reichsbank rose from 1,068,000,000 marks in 1913 to 2,387,000,000 marks in 1918. The highest figure reached was 2,550,000,000 marks on Nov. 7 1918 (including gold handed over by Russia under the Brest-Litovsk Treaty). The average gold cover of the note circulation fell from 54·5% in 1913 to 17·5% in 1918. The value of the mark remained near to parity during the first two years of the War, and even at the end of the War had only fallen to about half its pre-War value.

Legal Changes.—The most important changes in the legal provisions affecting the Reichsbank after the War were (1) the reduction in the minimum cover for the notes, by the Act of May 9 1921; (2) the authorisation of the Reichsbank to undertake forward exchange business, by the Act of Dec. 16 1919; (3) the inclusion of gold stocks held by the Reichsbank in foreign central banks as primary cover for its notes, by the Act of March 4 1922; (4) the so-called autonomy law of May 26 1922, which made the management of the Reichsbank independent of the Government of the Reich and entrusted it solely to the managing board of the Reichsbank, though this did not appreciably affect the policy of the Bank.

Inflation.—During the years following the World War the economic life of Germany declined, reaching its nadir in 1923. All attempts to stabilise the falling currency were unsuccessful in view of the various burdens imposed on Germany by the Allies. The value of the gold mark in terms of paper marks, as measured by the exchanges on countries with the gold standard, was 2·08 paper marks in Dec. 1918, 10·8 in Dec. 1919, 17·39 in Dec. 1920, 45·72 in Dec. 1921, 1,750 at the end of 1922 and after Nov. 20 1923 a million million. Since the printing press could not keep pace with the depreciation, emergency money was issued without proper control and utter confusion ensued. The money and capital market came to a complete standstill; interest rates rose to fantastic heights; the accumulation of capital ceased. There was a feverish chase after goods and foreign securities. The finances of the state lost all basis. The last phases of this evolution suddenly became catastrophic; the mark became useless as a medium of payment, for in many cases it was no longer accepted, and had already been largely rejected by the business community as either a measure of value or a basis of calculation.

The Rentenmark.—In the chaos of inflation there appeared the beginnings of the transition to a stable currency in the form of loans with a fixed value based on gold or commodities; mortgages, credit and insurance transactions, savings bank deposits, commercial contracts, etc., being reckoned in terms of gold or some other commodity standard. Finally, the Rentenbank was created by the Order of Oct. 15 1923 and was astonishingly successful in leading the way to the stabilisation of the currency. While the convening of the

[1] *Cf.* the figures for the end of each year on pp. 120–1 of *Memorandum on Currency and Central Banks, 1923–4* (Geneva, 1925).

Dawes Committee was still under discussion Germany succeeded, in circumstances of the greatest stress, in stabilising her currency unaided, and in resuming control over her finances. The success of the Rentenbank was largely due to the fact that with its help the finances of the Reich were supported until the collection of the revenue in terms of the new currency, and energetic measures of economy had enabled the budget to be balanced. The Reichsbank was able, on account of its credit policy, without legal regulation, to maintain the value of the Rentenmark at the equivalence of 1 Rentenmark = 1 billion paper marks = 1 gold mark, until the final currency reform was introduced.

In order to support the value of the currency in the meantime, the German Gold Discount Bank was created (April 1924) for the purpose of providing industry and commerce with gold credits, chiefly for export purposes. The unity of currency and credit policy was secured by entrusting to the Reichsbank the management of the Gold Discount Bank and the granting of Rentenbank credits for business purposes.

Acts Regulating the Reform.—The adoption of the Dawes Plan led to the passing on Aug. 30 1924 of four Acts—the new Bank Act, the Mint Act, the Private Issue Bank Act and the Act for the redemption of the notes in circulation of the Rentenbank. These Acts came into force on Oct. 11 1924 after the floating of the German foreign loan of 800,000,000 reichsmarks, in accordance with the proposals of the experts. The Rentenbank and the Gold Discount Bank were put into liquidation, but the latter subsequently resumed its activity as a credit institution in the guise of a department of the Reichsbank. The further issue of Rentenbank notes was prohibited, and the Reichsbank was required to withdraw Rentenbank notes in circulation, within a period of 10 years.

By the Mint Act the gold standard was again proclaimed with the reichsmark as the currency unit, and with the same gold equivalence as the pre-War gold mark, *i.e.*, 1 km. of fine gold = 2,790 reichsmarks. The old gold coins retained their validity and also the silver coins minted under the Act of March 20 1924, the rentenpfennigs and the copper pfennigs issued under the law of July 9 1873. All other coins previously minted of silver, nickel, aluminium, iron and zinc, lost their validity. The minting of silver coins to the value of 1–5 reichsmarks was authorised by the new Mint law. Apart from the Reichsbank notes only the gold coins were given unlimited legal tender. Silver coins were legal tender up to 20 reichsmarks and smaller token coins up to 5 reichsmarks.

Under the new Bank Act the essential features of the Reichsbank were retained, but important modifications were made in accordance with the principles of the Dawes Plan, one of which was the introduction of an element of foreign co-operation exercised through the General Council and the Commissioner of the Note Issue, who is a foreign member of the General Council. The management and administration of the Reichsbank was placed, as under the old Bank Act, in the hands of the Managing Board of the Reichsbank which consists exclusively of German nationals. The original capital of the Bank was contracted from 180,000,000 marks to 90,000,000 reichsmarks. The new Bank Act provides for a capital of at least 300,000,000 reichsmarks.

The functions of the Reichsbank, resulting from its position as the central bank of issue, were laid down in the same terms as in the old Bank Act, but the provisions in regard to credit were made more stringent. The power of the Bank to grant credit to the Reich, the Federal States and the municipalities were narrowly limited or forbidden altogether. The Reichsbank was also given the new function of holding on deposit the sums paid in reparations, for the account of the agent for reparation payments. The exclusive right of issuing notes was granted to the Reichsbank for 50 years. While on the one hand the note circulation was subjected to more severe conditions with regard to its cover, it was also made more elastic, and greater freedom of action was secured by the admission of foreign bills of exchange as cover for the notes in addition to gold. The obligation on the Reichsbank to redeem its notes in gold was for the time being suspended, and its reintroduction was made dependent on the approval of both the Managing Board and the General Council.

Quantity in Circulation.—During 1925 gold coins were not in circulation. The following tables show the volume and composition of the money in circulation in Germany at the end of 1913 and 1925:—

1913
(In Millions of Marks)

Gold Coins	Token Coins	Treasury Notes	Reichsbank Notes	Private Bank Notes	Total Circulation
2,750	850	100	2,593	160	6,453

1925
(In Millions of Reichsmarks)

Token Coins	Reichsbank Notes	Private Bank Notes	Rentenbank Notes	Total Circulation
582	2,961	190	1,476	5,209

Reichsbank Policy.—The Reichsbank was faced with very great difficulties in carrying out its economic functions after the stabilisation of the currency owing to the inevitable crisis of economic reconstruction, to the reparation payments and to the flood of foreign credits which came into the country following on the Dawes loan. Although the new Bank Act had re-established sound principles of banking policy it was not possible for them to be applied in the same way as before the War. As a result of the disrupting effects of war and inflation upon circulating capital there arose a grave discrepancy between the supply of and demand for capital, which only by degrees became less acute. The mechanism of the money and capital market, which had completely broken down, was at the beginning of 1926 still by no means normal, and the automatic regulation of the markets for short and long term loan capital was not yet restored. Under such abnormal conditions the Reichsbank (from April 1914 onwards) found itself compelled to put into force a drastic rationing of credit in addition to a cautious adjustment of its discount rate. It was not till the end of 1925 that it was able to modify in a tentative way the severity of its credit rationing. The discount rate was fixed at 10% after the stabilisation, but was then much below the rates of the private banks. Even when it was lowered in Feb. 1925 to 9%, in Jan. 1926 to 8% and in March 1926 to 7%, there remained an abnormal divergence between the official rate and the rates for private bank credits. By degrees, however, these rates have tended to come closer together.

The difficulties in the way of credit policy are enhanced by the restriction of the pre-War freedom of the Reichsbank in the control of its note issue, since the public funds, the reparation account and the foreign credits are more or less outside the direct influence of the Reichsbank, and are liable to lead to the withdrawal of considerable quantities of notes. The requirements of modern currency policy therefore compel the Reichsbank to watch most carefully the movement of the whole volume of purchasing power and its influence on prices, wages and other economic indices. It is incumbent on it to take or initiate the necessary measures to organise the money and capital market on sound lines, to encourage the formation of capital, and to secure the most economic use of all the available capital, including credits raised in foreign countries.

The Reichsbank augmented its gold holdings from less than 500,000,000 marks in 1923 to about 1,500,000,000 reichsmarks at the end of April 1926. The holdings of gold and liquid assets available for cover amount to 60% of the Reichsbank notes in circulation, but this proportion is not a decisive basis for credit policy as the circulation of Rentenbank notes has to be taken into consideration as well. From the middle of 1925 the total money circulation at the end of each month was in the neighbourhood of 5,000,000,000 marks. The total volume of private credit given by the Reichsbank, the private note banks, the Rentenbank, and the Gold Discount Bank, and including bills rediscounted by the Reichsbank to other bodies amounted in 1925 to about 3,000,000,000 reichsmarks.

After the stabilising of the currency German industry and commerce passed through a severe crisis, and thus heavy burdens were imposed on the Reichsbank as the guardian of the currency. In spite of these difficulties, it proved possible to maintain the value of the reichsmark, and from the beginning of June 1924 onwards all demands for foreign exchange were fully satisfied. It is not yet possible to foresee when the existing restriction on a free gold currency in Germany will be removed. In any case the fact that foreign exchange is available without limitation in exchange for Reichsbank notes is equivalent to the effective redemption of Reichsbank notes in gold. (K. No.)

GHENT, Belgium (*see* 11.919), had a population in 1923 of 163,877, and including the suburbs of Ledeberg, Ghentbrugge and St. Amand of 212,096. The city measures some 16 m. in circumference, much room being taken up by nurseries and gardens, for Ghent has become an important horticultural centre, especially for the cultivation of flowers under glass. Linen weaving has greatly developed, and schools of industry and mechanics have been established. A great international exhibition was held in 1913 in a Palais des Fêtes, specially built in the Parc de la Citadelle. The old cast-iron steeple of the belfry was rebuilt in 1913; subsequently most of the copper work from the new one was removed by the Germans. The hospital and almshouses for old men have been removed from the ancient Byloke, which has been fitted up to house the archaeological museum, previously in the old Carmelite church. The panels of the famous "Worship of the Lamb" by Hubert and Jan Van Eyk, dispersed since 1816, were brought together again in 1920 under the provisions of the Treaty of Versailles. A plaque in memory of Edith Cavell has been fixed on an inn, De Stad Ouden Aerde, where she stayed shortly before her arrest, and a memorial to the inter-Allied dead was unveiled in the cemetery in Oct. 1924. A new lock at Terneuzen enables vessels up to 26 ft. draught to pass at any tide into or out of the canal between that port and Ghent.

Ghent was in the hands of the Germans from Oct. 1914 till Armistice Day, Nov. 11 1918. The west part of the town suffered some damage in the final operations. The Germans published there the *Vlaamsche Post*, an organ professing Flemish sympathies and advocating the partition of Belgium, and made determined efforts to transform the University of Ghent into a purely Flemish institution, in order to widen the breach between the Flemish and Walloon elements. The university was reopened in Oct. 1923.

GIARDINO, GAETANO (1864–), Italian soldier, was born at Montemagno, Italy, Jan. 24 1864. He joined the army in 1882 and saw service in Eritréa (1889–94) and in Tripoli (1911–2). On Italy's intervention in the World War he was appointed chief of staff to the II. Army and was promoted brigadier-general in Aug. 1915. In June 1916 he was given command of the 48th Brigade and played an important part in the attack on Gorizia. In June 1917 he was promoted lieutenant-general but a few days later was chosen Minister of War and made a senator. He held office until after Caporetto, when he was appointed assistant chief of staff to the new commander-in-chief, Gen. Diaz. In April 1918 he was given the command of the IV. Army in the Grappa sector. At the battle of Vittorio Veneto (Oct. 24–Nov. 3 1918) he delivered a general attack on the Austrian lines and after a hard struggle forced the enemy to retreat. In 1919 he was promoted *generel d'esercito*. In Sept. 1923 as the Govt. of Fiume was unable to carry on, Giardino was sent to take charge of the town, where he remained until its annexation by Italy under the terms of the treaty between Italy and Yugoslavia in Jan. 1924.

GIBBONS, JAMES (1834–1921), American Roman Catholic cardinal (*see* 11.936), in 1916 published *A Retrospect of Fifty Years*. He died in Baltimore March 24 1921.

GIBRALTAR (*see* 11.938) has been largely increased in strength as a naval base; with the extension of the mole the deep harbour has an area of 260 ac. and affords anchorage for the largest ships. It was of great importance during the World War as a coaling station and port of call.

In 1922 an executive council was established, but all legislative power remains with the governor. A city council has replaced the board of sanitary commissioners, and currency notes have been issued by the local authority since 1913. Gibraltar is one of the most closely populated places in the world (9,888 to the sq. m. in 1921), but it is not unhealthy, the death-rate in 1921 being 17 per thousand. The population in 1924 was 20,638: 17,160 civilian, 2,932 military and 546 naval. There is a regular motor-omnibus service to La Linea, which has grown considerably and has a population of 63,000. A cross of sacrifice, in memory of those who died and were buried at Gibraltar during the World War, was unveiled in 1922, and a War Memorial in 1923. In 1915 a second reservoir was excavated, and the construction of another is contemplated. The Exchange in Commercial Square, which was burnt down in 1919, was rebuilt and opened in 1922. A public recreation ground was opened above the military school in 1920. The signal station on the summit of the rock has been dismantled. Since 1910 Gibraltar has been a Roman Catholic bishopric, independent of the Spanish hierarchy and subject directly to the Vatican.

GIDE, ANDRÉ (1869–), French essayist and novelist, was born in Paris Nov. 21 1869. Educated at the École Alsacienne and the Lycée Henri IV., he began his literary career with the *Cahiers* and the *Poésies d'André Walter* (1891–2). His first success was followed by a series of works resembling philosophical *causeries* in which an introspective method and great delicacy of expression were combined in an original manner. His dramatic works and criticism are characterised by the same sureness of touch and individual grace. He is considered one of the finest stylists in contemporary French literature, and exercised considerable influence outside his own country. As a novelist, however (as in *Les caves du Vatican*), he was less successful; he is more at home in the easy, discoursing flow of an essay.

Gide's works include: *Le voyage d'Urien* (1893); *Paludes* (1895); *Les nourritures terrestres* (1897); *Le traité du Narcisse* (1899); *Le Prométhée mal enchaîné* (1899); *L'immoraliste* (1902). Criticism: *Lettres à Angèle* (1900); *Prétextes* (1905). Drama: *Saul* (1898); *Le roi Candaule* (1898); *Les caves du Vatican* (1911); *Isabelle* (1911); *La symphonie pastorale* (1919); *Dostoievsky* (1923, tr. 1925); *Les faux Monnayeurs* (1926).

GIDE, CHARLES (1847–), French economist, was born June 29 1847 at Uzès (Gard). Educated at the Collège d'Uzès, he entered the faculty of law of the University of Paris. He early took up the study of economics and became professor of political economy, first at Bordeaux, then at Montpellier, and from 1898 to 1920 at the University of Paris. He is the author of one of the best introductory treatises on political economy, *Principes d'Economie Politique*, first published in 1884 and since translated into English and other languages, and is joint author with Professor Rist of an excellent work on the history of economic theory, *Histoire des Doctrines Economiques* (3rd ed. 1920). Gide devoted a great deal of time and energy to the encouragement and furtherance of the co-operative movement in France, and wrote largely on this question. Professor Gide enjoys a wide measure of esteem amongst scholars in other countries, not only as an eminent economist, but also on account of his unremitting endeavours to maintain and promote harmonious international relations and especially to preserve co-operation amongst intellectual workers in different countries. (*See* FRANCE.)

GILBERT, CASS (1859–), American architect, was born at Zanesville, O., Nov. 24 1859. He studied at the Massachusetts Institute of Technology and in 1883 began his career as an architect in St. Paul, but subsequently moved to New York. He became perhaps most widely known as the architect of the Woolworth building in New York, which has 57 stories and is 760 ft. in height, and, with the exception of the Eiffel Tower in Paris, the tallest structure in the world. Other buildings designed by him include the Minnesota State Capitol, St. Paul; the Endicott building, the Dayton avenue church and St. Clement's Episcopal church, in St. Paul; the United States Custom House and the Union Club, New York; the Brazer building and the Suffolk Savings Bank, Boston; Art building and Festival Hall (for the Louisiana Purchase Exposition), and the Central Public Library, St. Louis; Ives Memorial Library, New Haven, Conn.; Public Library, Detroit. He also drew the plans for the university of Minnesota and for the university of Texas. He was appointed by President Roosevelt a member of the Council of the Fine Arts; and by President Taft a member of the National Commission of Fine Arts, being reappointed by President Wilson. In 1926 he was appointed design architect for the proposed bridge over the Hudson river at New York City.

GILBERT, GROVE KARL (1843–1918), American geologist (*see* 12.7), died at Jackson, Mich., May 1 1918.

GILBERT, SEYMOUR PARKER (1892–), American lawyer and financial expert, was born in Bloomfield, N.J., Oct. 13 1892. He graduated from Rutgers College in 1912, and in the same year entered the Harvard Law School, obtaining the LL.B. degree in 1915. After admission to the New York Bar, he practised in New York City from 1915 to 1918. In the latter year, on the initiative of R. C. Leffingwood, a former Associate Secretary of the Treasury, he joined the War Loan Staff as counsel. In June 1920 he became assistant secretary (later under-secretary) of the Treasury in charge of fiscal affairs. He resigned Nov. 17 1923, and became agent-general for Reparation payments under the Dawes plan Oct. 31 1924.

GILBERT, SIR WILLIAM SCHWENK (1836–1911), British playwright and humorist (*see* 12.9), was drowned at Harrow Weald, Middlesex, May 29 1911. His play, *The Hooligan*, was produced a short time before his death.

GILBEY, SIR WALTER (1831–1914), British wine merchant (*see* 12.11), died at Elsenham Hall, Essex, Nov. 12 1914.

GILDERSLEEVE, BASIL LANNEAU (1831–1924), American scholar (*see* 12.12), died at Baltimore, Md., Jan. 9 1924.

GINER DE LOS RIOS, FRANCISCO (1840–1915), Spanish philosopher and jurist, was born in Ronda (Andalusia) Oct. 10 1840. He graduated in Granada, and in 1867 went to the University of Madrid as a professor of jurisprudence and there came under the influence of Prof. Sanz del Rio, Krause's famous disciple.

In accordance with his belief that philosophy should have a concrete influence on practical life, he devoted himself to the educational question. Twice Giner resigned his chair, together with several of his colleagues, in a stand for liberty of thought in the university against a reactionary government, and was twice reinstated. He helped to found the Institucion Libre de Ensenanza, an educational institution which did much to improve teaching methods in Spain, by the application of philosophical thought to the problems of education. He many times refused election to the Cortes, and in 1873 declined a post in the Government. His greatest influence was personal and direct, for he was a born teacher, a man of refined sensibility, pure in his life as in his ideals.

Giner published several volumes of essays—literary, educational, philosophical and religious—as well as *Lecciones Sumarias de Psicologia* (1871); *Psicologia; Idea del Derecho*, with Alfredo Calderon, trans. from the German of Röder (1885); *Resumen de Filosofia del Derecho*, with Alfredo Calderon (1898); and other works. A complete edition of his numerous works was undertaken a year after his death.

See S. de Madariaga, *The Genius of Spain* (1923).

GINSBURG, CHRISTIAN DAVID (1831–1914), British Hebrew scholar (*see* 12.29), died in London March 7 1914.

GIOLITTI, GIOVANNI (1842–), Italian statesman (*see* 12.31). The elections of 1909 returned a strong Giolittian majority, but Giolitti as Premier found himself faced with the necessity for renewing the steamship conventions which were about to lapse. The Bill presented by his Cabinet on this subject was open to much criticism, having been designed to conciliate conflicting political interests rather than to solve the actual problem. The vigorous attacks of the Opposition, led by Baron Sonnino, induced Giolitti to adjourn the debate until the autumn, when, the Cabinet having been defeated on a point of procedure, he resigned (Dec 2). But he continued to play an active and in fact dominant part in Parliamentary politics, for the majority of the Chamber and of the Senate, being thoroughly Giolittian, the Sonnino Ministry and that of Sig. Luzzatti which succeeded it only remained in power at his discretion. When in March 1911 Luzzatti resigned in consequence of the hostile vote of the Radicals and the resignation of its two Radical members, Giolitti was again called upon to form a government (March 31).

The chief event of his fourth Cabinet was the Libyan War. Personally he was not enthusiastic over the African enterprise, as it introduced new and, to him, unaccustomed and unwelcome values into Italian political life; but he realised that public opinion demanded it and he did not care to run counter to the current. He was criticised by the vestals of constitutional tradition for having declared war without consulting Parliament and for not having summoned it until several months later. During the campaign, he was, moreover, severely blamed on the ground that he acted as though the war were merely an affair of internal politics and party combinations. When peace was concluded fresh elections were held on the new franchise law introduced by the Cabinet, which raised the electorate from 3,000,000 to 8,000,000 votes (Oct. 26–Nov 2 1913); although a Giolittian majority was again returned, his opponents, not only among the Socialists, but also the constitutional parties, were now more numerous, and he felt that opposition to his rule was growing in the country at large even more than in Parliament. The various awkward problems which now faced the Government and the divisions among its own supporters induced him to seize the opportunity of a hostile vote by the Radical group to resign (March 10 1914).

When the World War broke out his attitude was favourable to the absolute neutrality of Italy, as he believed that his country's interests lay in not siding with either group of belligerents, and on the eve of Italian intervention he made an attempt, by using his personal hold over the Parliamentary majority, to upset the Salandra Cabinet, but it was frustrated by an uprising of public opinion in favour of the war. During the progress of the campaign he avoided public affairs, although he assumed a Cassandra-like attitude in all his utterances, and his henchmen in the Press were frankly "defeatist." He consequently lost his influence over the bulk of public opinion and in many quarters was regarded as little better than a traitor. But after the Armistice the unsatisfactory consequences of the peace negotiations, the heavy burden of suffering and loss caused by the War, and, above all, the disputable internal policy of the Nitti Cabinet, which was accused of handing the country over to the Bolshevik Socialists, brought about the return of Giolitti.

When Nitti was forced by the impossibility of governing the country to resign for the third and last time on June 9 1920 a new Giolitti Cabinet was the inevitable alternative. He succeeded by June 15 in forming a Cabinet which comprised a number of non-Giolittians of all parties, but only a few of his own "old guard," so that he won the support of a considerable part of the Chamber, although the Socialists and the Popolari (Catholics) rendered his hold somewhat precarious. His policy of inactivity during the occupation of the factories by the workmen organised by Socialist leaders in Sept. 1920 provoked the indignation not only of the manufacturers but of all the middle-class. He appears to have acted under the impression that the Socialists were much stronger than they really were, and therefore gave them a free hand with the object of avoiding bloodshed, and also perhaps with that of proving to the workmen that they could not run industry without the capitalists and the technical experts. When he realised the strength of the national reaction, he allowed the Fascists free rein to re-establish order and practically exercise many of the functions pertaining to the Government, while he assumed an attitude of Olympic calm and posed as being *au-dessus de la mêlée*, so as to avoid compromising himself with any party.

In foreign affairs Giolitti succeeded in achieving a solution of the Adriatic problem less unsatisfactory than most of the previous proposals of the annexation of new provinces under the peace treaties and of the altered state of public opinion on internal policy, he dissolved the Chamber on April 7 1921, and was confirmed in power by the elections on May 15. But he resigned with his Cabinet at the end of June, being succeeded as Premier by Signor Bonomi.

He played no part in the subsequent events, until at the time of the march on Rome he was one of the statesmen who advised the Premier Signor Facta to resign. On the advent of the Fascist Govt., he expressed his approval of it and instructed his followers to support it. At the elections of 1924 he presented a list of his own in Piedmont, which was not in opposition to but independent of the Government, and in an election speech he attributed many of the achievements of Fascism to his own policy. After the Matteotti affair he definitely went over to the Opposition but did not leave the Chamber, and his hostility remained fairly moderate. In 1922 he published two volumes of memoirs entitled *Memorie della Mia Vita*. (L. V.*)

GIRL GUIDES, a movement for the training of girls based on similar principles to those of the Boy Scouts (*q.v.*). Its aims are: to develop good citizenship; to train girls in habits of observation; obedience, self-reliance, loyalty and thoughtfulness for others; to teach useful service and handicrafts; to promote physical development; to make them capable of keeping good homes and bringing up their children properly. The training runs mainly in four directions: character and intelligence; homecrafts and handicrafts; health and physical development; service for others. The movement is non-political and interdenominational.

Origin and History.—After the Boy Scout movement had been founded by Sir Robert Baden-Powell girls in different places began to copy its activities, and banded themselves together as Girl Scouts. To meet the needs of these girls, Sir Robert and his sister, Miss Agnes Baden-Powell, in 1910 started a separate movement for girls, and gave it the name of Girl Guides. The movement received a charter of incorporation in 1915 and a royal charter in 1923. Princess Mary became president in 1920. Lady Baden-Powell (wife of the Chief Scout) was elected Chief Guide in 1918.

Organisation.—The governing body of the Girl Guides is the council, which meets annually and elects an executive of nine members. Sir Robert Baden-Powell is permanent chairman of the

executive. The executive appoints county commissioners, who in turn appoint division and district commissioners to assist them. Under the latter come the captains, who do the actual training of the girls, grouped into companies. A guide company consists of from eight to 40 girls, and is subdivided into patrols, each under the charge of a patrol leader, who is herself a guide. She is either appointed by the captain or elected by the other guides, and has entire authority over her patrol, and entire responsibility for its conduct and efficiency. The affairs of the company are managed by the court of honour, consisting of the patrol leaders, who meet periodically, under the chairmanship of the captain. A company usually meets once a week, and goes to camp, if possible, for one week in the year.

Membership.—To become a member of the guide movement a girl or woman has to be enrolled. She makes a three-fold promise: to do her best to do her duty to God and the King; to help other people at all times; to obey the guide laws. There are 10 guide laws, namely: a guide's honour is to be trusted; a guide is loyal; a guide's duty is to be useful and to help others; a guide is a friend to all and a sister to every other guide; a guide is courteous; a guide is a friend to animals; a guide obeys orders; a guide smiles and sings under all difficulties; a guide is thrifty; a guide is pure in thought, word and deed.

After enrolment the members of the movement have the right to wear the guide uniform, navy blue with different badges to denote rank or proficiency. The badge of the guides is a trefoil, their motto is "Be Prepared." There are three main branches: the Brownies, aged from 8 to 11, the girl guides, aged from 11 to 16, and the senior guides, from 16 upward, who may be either rangers or sea guides. The officers are called guiders; they can receive training in guide methods at Foxlease Park, Lyndhurst, Hants, England, which was presented to the organisation by Mrs. Archbold Sanderson in 1922.

The guide movement has spread to the British Dominions and other countries. In 1924 a World Camp, attended by some 1,100 guides, from over 30 different countries, was held at Foxlease. At the end of 1925 there were some 613,209 members throughout the world. The Headquarters of the Girl Guides are at 25, Buckingham-Palace Road, London, S.W. The movement is financially self-supporting.

GIRL SCOUTS: *see* BOY SCOUTS.

GLADDEN, WASHINGTON (1836–1918), American divine (*see* 12.63), died at Columbus, O., July 2 1918.

GLASGOW, Scotland (*see* 12.80), enlarged its boundaries in 1912 by the inclusion of Govan, Partick, Pollokshaws and several suburban districts, making it again the second city in Great Britain in population, and increasing its area from 12,975 to 19,183 acres. The number of wards was increased from 26 to 37, and the membership of the corporation from 80 to 113—three representatives of each ward, and two ex-officio members (the dean of guild and the deacon convener of the trades). Since 1918 Glasgow has sent 15 members to Parliament. A further ambitious scheme of enlargement of the burgh was promoted after the World War, owing to the congested state of the city and the fact that many of the housing schemes were situated outside the boundaries. It involved the incorporation of 22,000 ac., and met with opposition from adjacent counties and burghs; eventually, by an Act of 1925 (coming into force in May 1926), about half the proposed area, taken from Renfrewshire, Lanarkshire and Dumbartonshire, and including the important Yoker area near Clydebank, was incorporated. The population in 1921 was 1,034,174 and the rateable value in 1925 £11,040,693.

The Rent Strike.—Housing conditions have been extremely bad, and the new houses erected insufficient to accommodate even the normal increase in population; there has also been much unemployment. A legal campaign by the tenants, contesting the validity of notices of increase of rent under the Increase of Rent (Restriction) Acts, served without previous notice to quit, was supported by the decision of the House of Lords in a test case (*Kerr* v. *Bryde*) in 1922, and in the following year an amending Act to regularise the position was passed. Many tenants, however, refused not only the increased rent but any rent at all, and demanded a return to the pre-War standard. A large number of eviction orders were granted in 1924 and early in 1925, but their execution was rendered impossible in most cases by the violent tactics of the tenants. In June 1925 the unrecovered rents represented nearly a year's rental of tenanted houses in the borough, and the local authorities were seriously embarrassed by the non-payment of rates. A rent commission was then appointed which recommended the simplification of the form of notice required and other reforms in the working of the Increase of Rent (Restriction) Acts.

Public Buildings, Parks.—Additions to the municipal buildings, connected by two bridges with the older buildings, were completed in 1923. The Mitchell library, the largest of the public libraries, was removed to North street in 1911; 25 branch libraries have been established. Since 1913 14 new chairs have been founded in the university, and the western sections were being extended in 1926, to provide new classrooms and a memorial chapel. The block of the Royal Infirmary which contained the famous ward in which Lord Lister first applied the use of antiseptics was pulled down in the course of an extension scheme in 1924, in spite of widespread opposition. A new building for the Ear, Nose and Throat Hospital was opened in St. Vincent Square in 1926. In 1915 the corporation bought the Balloch Castle estate, of which 200 ac. were made into the Loch Lomond Park. Other purchases were the Linn Park of 180 ac. (1919); and the Ruchazie and Frankfield Park of 300 ac. (1920). The Newlands Park was given in 1913, the Glenconner Park in 1914 and the Dawsholm Park in 1920. In 1911, 121 ac. of the grounds of Pollok House were given for use as a public park for a period of 10 years. Statues of Lord Kelvin (1913), Lord Roberts (1916), Thomas Carlyle (1916) and a war memorial to men of the Cameronians have been erected in Kelvingrove Park; and a war memorial cenotaph was unveiled in George Square in 1924. Kelvingrove and College United Free Church and Kelvin Hall, a large building used for exhibitions, etc., were destroyed by fire in 1925.

In 1924 a beginning was made with the provision of further dock accommodation on an area of land acquired by the Clyde Navigation Trustees between Shieldhall and Renfrew. Contracts were signed for the construction of railway lines and a road to the new dock area from the new trunk road of the Glasgow corporation scheme. A big electric generating station was opened at Dalmarnoch Bridge in 1920, and the largest gasworks of their kind in Great Britain were completed at Govan in 1921.

GLASGOW, UNIVERSITY OF (*see* 12.82).—The following 20 new chairs have been founded since 1907: Mining, medicine (Royal Infirmary), obstetrics and gynaecology (Royal Infirmary), surgery (Royal Infirmary), pathology (Royal Infirmary), Scottish history and literature, French, German, organic chemistry, physiological chemistry, bacteriology, mercantile law, applied physics, theory and practice of heat engines, electrical engineering, public health, medical paediatrics, Italian, Spanish and accountancy. New lectureships have been instituted in Celtic, psychology, social economics, geography, dermatology, clinical medicine, clinical surgery, clinical obstetrics, diseases of the throat and nose, diseases of the ear (Royal Infirmary), materia medica and pharmacology, electrical diagnosis and therapeutics, Russian, clinical tuberculosis.

New Buildings.—Considerable progress has now been made with the extensions of buildings which were postponed owing to the World War. The new zoology building, erected at a cost of about £112,000, is now occupied, and the building which is to complete the west wing and includes the War Memorial Chapel is in course of erection. The estimated cost of this building is about £122,000.

The students themselves have been active in furthering the student welfare scheme and, including grants from the Govt., the Carnegie Trust and the proceeds of a bazaar, a sum of about £85,000 has been collected. Out of this fund there have been provided a union for women students and the necessary expenditure to convert the houses presented by Lord Maclay and Mr. Lawrence MacBrayne into men students' hostels and the house presented by Mr. J. M. Robertson into a women's hostel. The money, about £12,000, necessary for the erection of a pavilion on the athletic ground at Westerlands—which is now open—has also been provided out of this fund. Grants have also been made to the athletic club and the boat club. The accommodation of the present union for men students is quite inadequate. A site for a new building has been secured and steps are being taken to secure the remainder of the necessary funds.

Sir Donald McAlister became principal in 1907, and in the university itself, as outside in university matters generally, has exercised a remarkable influence.

Students

Session	Men	Women	Total
1910–1	2,108	682	2,790
1915–6	1,163	658	1,821
1920–1	3,576	1,132	4,708
1923–4	3,275	1,419	4,694
1924–5	3,069	1,529	4,598

The figures for session 1910–1 represent a normal year; 1915–6 a War year. The figures for the other years show the large increase in the numbers of students which has taken place since the War.

GLASS, CARTER (1858–), American politician, was born at Lynchburg, Va., Jan. 4 1858. He received his education in the Lynchburg schools and learned the printer's trade, which he followed for several years, eventually becoming proprietor of the Lynchburg *Daily News* and *Daily Advance*. He was elected to the Virginia State Senate for two terms (1899–1903) and was a member of the State Constitutional Convention in 1901. He was elected in 1902 to the national House of Representatives, and thereafter was continuously re-elected until his resignation in 1918. As chairman of the House Banking Committee he was active in framing and passing the Federal Reserve Bank Law. In 1918 he entered President Wilson's Cabinet as Secretary of the Treasury. Under his guidance the fifth Liberty Loan was floated in April 1919. In Nov. 1919 he resigned, following his appointment and subsequent election to the United States Senate. In 1924 he was elected for the term 1925–31.

GLASS (*see* 12.86).—Since 1910 considerable developments in the glass industry have occurred, both in the glass produced and in the varieties of glass manufactured. In the following article attention is, of necessity, given to the British glass industry. When the War drew attention to the British position in respect of glass generally, it was in the direction of scientific glassware and special glass for certain industries, that the deficiencies were realised. (*See* also OPTICAL GLASS.)

Laboratory Glass.—Before the War nearly all the glass and glass apparatus used in laboratories throughout the United Kingdom was obtained from abroad. The main kinds of glass required for laboratory purposes may be grouped thus: Soft glass for tubing, and for a number of articles and vessels where the highest resistance to chemical action is not required; glass highly resistant to chemical action; very hard glass for combustion tubing; glass for thermometers.

Soft Glass.—Such a glass must be soft enough to be readily worked in a flame, and must stand prolonged heating without showing the changes in appearance and working qualities generally described as devitrification. Before chemical glassware of foreign origin became practically universal in laboratories, vessels and apparatus in great variety were made from lead glass. The advantages claimed for non-lead glass as a material for laboratory apparatus have been proved, and there is no likelihood of a return to lead glass, which, however, can be made of such high resistance to the action of water, and of many solutions which also abstract alkali from glass, that in some special cases vessels made from it are only surpassed by silica in resistance to chemical change.

In the early days of the War it was recognised that there would be a serious shortage of laboratory vessels. A simple sodium-calcium-silicate glass was unsuitable since tubing made from it is practically useless to workers in laboratories. The immediate advance made was the addition of alumina, either as such, or preferably in the form of felspar. The use of alumina for retarding devitrification and for rendering a glass workable in the flame was known in Great Britain, and at least three British manufacturers had for some years produced glasses containing various percentages of alumina up to about 10%.

A sodium-potassium-calcium-aluminium-silicate type of glass has most satisfactory general properties. Arsenic is not permissible, and the only constituent other than those indicated which might be added was a small amount of manganese dioxide, to disguise the green colour due to the presence of iron in the material used. The formula given here shows the approximate composition of a batch mixture expressed in percentages of silica and oxides of the metals in the various ingredients of the batch: SiO_2, 68; Al_2O_3, 4; CaO, 7; K_2O, 6·5; Na_2O, 14·5. This yields a good glass, soft enough for flame-working while possessing good durability.

Use of Potash Felspar.—It became necessary to conserve supplies of potassium compounds, of which the amounts that could be apportioned for use in glass manufacture were sufficient only for the production of certain optical glasses. To some extent nitre was available and was used. Potash felspar, which for long had been an ingredient in certain glasses, was a convenient form of aluminium compound for introducing alumina. The amounts of this material employed varied between wide limits, and glasses of good working qualities were obtained.

Borax.—Varying proportions of borax were employed, and in this way sodium-potassium-calcium-aluminium-boro-silicate glasses of good working qualities and of marked durability were produced, which met many of the requirements of laboratory workers. The boro-silicate glass possessed many desirable properties when the glass was well made and the necessary technical skill had been acquired. It failed, however, when used for X-ray tubes. A glass of the general type indicated in the formula above is quite suitable for such work, and hence X-ray bulbs and tubing can be made from it in the course of working a pot for a variety of other articles.

Experience shows that the best type is on the lines of the formula given, and that the presence of notable proportions of the oxides of aluminium and potassium are essential. Potash felspar has been mentioned as a convenient source of alumina, and part of the alkalies may be usefully added as nitrates. In general, all the materials of the batch mixture should be as pure as can be obtained commercially, so that the composition of the glass may depart as little as possible from that which it is intended to have, and which has been proved to give satisfactory results. One or two remarks which are relevant for almost all glasses may be made here.

Anhydrous Materials.—As far as it is possible to obtain and to store them, all the substances for a batch mixture should be free from water. A glass made from anhydrous materials often differs from one calculated to give the same composition finally, but produced from a wet batch, or from one containing an ingredient having a notable proportion of combined water. In addition to some lack of general stability, the glass from a wet batch may show a greater tendency to devitrification when heated in a flame or by radiation. The amount of water left in a glass may be very small, but it affects the behaviour of the glass. However, the action of water to effect change in glasses either during their production or on subsequently heating them is an advantage in respect of the production of certain coloured glasses and apparently of some opal glasses.

Homogeneity.—All glasses for laboratory use should be made in such a way as to secure the greatest possible homogeneity. As a general rule, the long-founding so much insisted upon by many experienced glass manufacturers cannot be dispensed with if the nicest possible refinements of a good glass are to be realised. Stirring to secure homogeneity is a necessary operation in making optical glass. It is not customary to stir glass for laboratory use, but such glass would be improved by being stirred if it were economically possible.

Annealing.—The subject of annealing has, in recent years, been given much attention, and several investigations have been carried out. Results of much interest and importance have been obtained, dealing with the conditions for removing strain in glass and with the problem of annealing, both from the theoretical and a practical point of view. These results emphasise the importance of thoroughly annealing any glass articles which are required to withstand marked changes of temperature, and of arranging that any vessels, etc., which in the course of production are re-heated locally, shall be re-annealed. Tubing is not customarily annealed as part of the process of manufacture, but for certain purposes, notably with tubes which are to be ground, it is an advantage to anneal them.

"Resistance" Glass.—Laboratory glassware, to deserve this description, must possess great stability, and must part with only minute traces of any of its ingredients when it is exposed to the action of the majority of solutions and liquids used in a chemical laboratory. The chief varieties made can be included in two types: one containing compounds of zinc and the other free from this metal. In neither type is the inclusion of arsenic or antimony considered to be permissible.

The following formulae, illustrative of these two types, give approximate proportions for batch mixtures expressed in percentages of the oxides contained in the various ingredients of a batch:—

(A)		(B)	
SiO_2	66	SiO_2	66
B_2O_3	8	B_2O_3	9
Al_2O_3	9	Al_2O_3	2·5
CaO	5	ZnO	8
MgO	1	MgO	5
Na_2O	8	Na_2O	9·5
K_2O	3		

Adjustments of the proportions given can be made to suit different furnaces and also to fit in with the amount of broken-up glass from previous meltings (cullet), which is incorporated in the batch. Of these two types of resistance glass, (A) requires a rather higher temperature in the making and on the whole presents more difficulties than (B). It has also a somewhat higher coefficient of expansion, is less liable to withstand sudden changes of temperature and has been made of very high chemical resistance and of satisfactory behaviour when quickly heated or cooled through a greater range of temperature than it would usually be exposed to in a laboratory. It

is probably fair to give preference, on the whole, to glass of type (B) as inherently more capable of withstanding sudden changes of temperature, and, being the easier to make, there is less likelihood with vessels made from it of mishaps due to imperfect manufacture. Whichever class of glass is chosen, all vessels and apparatus made from it need thorough annealing.

Combustion Tubing.—Tubing of very hard glass is essential for many laboratory experiments, and is largely used in the analysis of carbon compounds by combustion, but in tubing of various diameters it is required for a number of other purposes. The general composition of Kavalier's combustion tubing is indicated by the following percentages to the nearest whole numbers: SiO_2, 78; CaO, 8; K_2O, 12; Na_2O, 2. Glass of this kind served many useful purposes in laboratories, but it was difficult to use in a blowpipe flame. The Jena glass which took its place possessed greater plasticity over a longer range of temperature. During the War very hard glass tubing was much needed, and as the result of experiments on a laboratory scale and in glass works, tubing of a type similar to the Jena combustion tubing was produced. With regard to hardness and suitability for working in the flame it fulfils its purpose most satisfactorily. Unlike the pre-War glass, it does not show anything like the tendency to become opal when heated for a long time. The following is the composition for a batch mixture, given as for other glasses in the percentage of oxides: SiO_2, 68·5; B_2O_3, 5·5; Al_2O_3,6; CaO, 8; BaO, 6·8; Na_2O, 3·2; K_2O, 2. With this glass there is not much latitude allowable if the full hardness of the glass is to be realised and difficulties in manufacture are to be avoided. The glass requires a high temperature for its successful production.

Thermometer Glass.—The manufacture of thermometers of all kinds has been carried on in Great Britain for many years, and British capillary tubing of high quality and technical perfection made both from lead glass and from various other types of glass, has been in constant demand. Jena thermometer tubing was largely used by British thermometer makers. During the War very great numbers of thermometers were called for, the greater proportion being for medical purposes, but many also for scientific and industrial use. Manufacturers of glass produced tubing to meet the demand, in lead glass, for the production of which they were ready and pre-eminent, and in other varieties of glass having properties closely similar to two Jena glasses of high reputation. One of these can be used for thermometers, capable of standing high temperatures up to about 500° C., and the other is for more general application. The following formulae, given as for other glasses in percentages of oxides and with similar reservations, indicate the nature of batch mixtures for these types of glass:—

High Temperatures		Ordinary Temperatures	
SiO_2	73·5	SiO_2	67·0
B_2O_3	9·7	B_2O_3	2·5
Al_2O_3	5·8	Al_2O_3	2·7
Na_2O	11·0	CaO	6·5
		ZnO	6·7
		Na_2O	14·6

Vessels and Apparatus.—Scientific glassware may be broadly classified as furnace-made and as lamp-blown. The former is for the most part produced by blowing into moulds molten glass gathered from the furnace on a blowing-iron. Before the War, lamp workers for laboratory apparatus were few in number in Great Britain and were chiefly engaged either in making a comparatively small amount of apparatus to special design or in repair work. Glass for such apparatus is supplied to the lamp blower in the form of tubing, in the production of which, therefore, there had also been a great development.

For glass for miners' lamps, a glass withstanding rapid changes of temperature exceptionally well was necessary, since the lamp glasses are thick and the flame of the lamp may often touch them. There was an urgent demand for them early in the War. It was successfully met, and such glasses of British make are now produced in large quantities. Another glass on similar lines, but differing somewhat in composition, was prepared for the production of chimneys for incandescent and high-pressure gas illumination, paraffin lamps, etc. In addition to withstanding heat changes well such a glass must be markedly resistant to the chemical action of hot products of combustion. Both these glasses consist chiefly of alkaline boro-silicates having a high percentage of boric anhydride. They need a high temperature for their successful production in a homogeneous state. When well founded their low coefficients of expansion render articles made from them highly resistant to sudden variations in temperature over a long range.

Glass rods for half-watt electric lamps were required, to hold the thicker tungsten wires which support the filament of this metal. They had to be made specially, since no existing glass of British make capable of withstanding heat changes was also sufficiently reliable in respect of not cracking round the sealed-in wires. This glass in most cases involved also the production of special rods to join with it and with the stem of the lamp.

Other glasses were needed which, while making safe joints with ordinary laboratory tubing, etc., would hold platinum, copper, iron or nickel wires. Such glasses are often described as sealing-in enamels. Several of these have been made, and, generally speaking, they are of the type either of a soft glass containing a high percentage of lead, or of one free from lead and containing a notable proportion of a fluoride, such as cryolite. The coefficient of expansion of the glass, in relation to that of the metal wire used, has to be taken into account.

Jars for Preserving Fruit and Meat.—Though numbers of these had long been made in Great Britain, about 80% of the total number used had been obtained from abroad. Great increase in the production of these vessels was required to meet the needs, enhanced as they were by the War, and the necessity for more economic production led to a review of methods and to the adoption of new machinery.

Glassware for Medical Purposes.—The War caused a great increase in the demand, and very large quantities of vials, tubes, syringes, graduated measures, etc., had to be made. Most of these could be produced from glass, and by methods familiar to manufacturers, but some requirements had to be met by investigation and experiment before suitable glass was produced.

There was considerable increase during the War in the production of coloured glasses, *e.g.*, for spectacles to protect the eyes of the great numbers of men working at steel furnaces. Coloured glasses in considerable variety were also wanted for other purposes, but in comparatively small amounts. Some of them needed investigation and a number of experiments before the conditions for their production could be determined.

Progress in the Use of Machinery.—The greatest advance in the economic production of certain types of glassware was in the direction of the introduction of machinery and minor labour-saving devices which was only rendered practicable by concurrent improvements in the means for assuring a continuous supply of molten glass in a suitable condition to permit of the machines being run continuously. The common practice in the past was to found the glass in pots in direct-fired furnaces. There has been a gradual tendency for tanks, some of them being of very large capacity, holding as much as 300 tons of molten glass, to take the place of the older pot furnaces. Those glasses which are only required in comparatively small quantities or of absolute purity, as in the case of optical glass, certain coloured glasses, and those liable to contamination from furnace gases, will still have to be pot-founded.

Automatic Machinery.—The development of machinery in glass manufacture has been by gradual evolution. In many American factories, neither the raw materials nor the glass is handled at any stage during the progress of manufacture. Conveyors transfer the raw material from the trucks to the storage bin; automatic weighers discharge the requisite quantity of material from the storage bin to a rotary mixer mounted on a trolley; another conveyor transfers the mixed batch to the batch storage bin in close proximity to the charging end of the tank, for the ready release of the batch down a chute at periodic intervals into the tank.

Types of Machines.—The types of machines may be conveniently divided into the following groups: pressing machines for the production of tumblers, meat and jelly jars, bull's-eye lenses, tableware and pavement lights; press and blow machines for all types of bottles, and many kinds of food containers; blow machines for electric lamp bulbs, lamp chimneys and similar articles; rolling machines for plate glass, figured and ribbed glass and reinforced sheet for sheet and window glass, and for drawing tubes and rods.

There are many other types for miscellaneous purposes, including cracking-off machines for severing the fashioned article from the waste glass, employing multiple fine jets of flame which impinge on the line of severance which is usually started by a short diamond cut at the predetermined point: calibrating machines for accurately dividing measuring devices such as thermometers, burettes, pipettes and cylinders; grinding and polishing machines for preparing and finishing the surface of plate glass; machines for forming the stoppers of bottles and for grinding the seating in the neck of the bottle; flowing devices and feeding machines, to withdraw from the pot or tank, by means of a gathering-iron, a sufficient quantity of molten glass to make the article required.

Press Machines.—A very limited number of types of article can be made with a solid mould. Only such as have both an internal and external taper, the diameter being reduced in the direction of the movement of the plunger, are suitable. In all other cases where the ware has external shoulders or ornament, the mould must be hinged. In semi-automatic and fully automatic machines the movements of the plunger and mould are operated by compressed air.

Refractories and Pots.—With the introduction of more efficient pot furnaces and tanks in which higher temperatures were reached it soon became evident that the question of refractories would have to be investigated in order that the pots, tank blocks and furnace parts, would stand up to the increased strain which was being put upon them.

In so far as concerns the majority of types of optical glass, and, if it were an economical proposition, for other glasses also, pots of a porcelain nature or of a composition approximating in relative proportions of alumina and silica to kaolinite have given the most satisfactory results. In connection with the manufacture of optical glass in America for war purposes it was found that a pot of the porcelain type was the best suited to their purpose. In other directions con-

siderable experimental work has been devoted to the production of pots by the ordinary casting and by the vacuum casting processes, and also of pots from osmose clay. In each case results of great promise have been obtained.

The tendency has been to adopt the recuperative principle, in which there are two sets of channels or passages, one for the air supply and the other to carry away the hot products of combustion; the temperature of the air is raised due to interchange of heat by conduction through the common party wall of the channels. As the flow of the secondary air and hot flue gases is constant in direction, there are, therefore, no reversing valves to be operated, as is the case in the regenerative type, and it is claimed that the furnace can be maintained at a more even temperature in the former than in the latter.

The recuperative type of furnace is producer-gas fired. The furnaces, according to the designer, differ in respect of the disposition of their elements; in one type both the producer and recuperators are situated immediately below the furnace, and both the air passages and hot flue-gas passages are disposed horizontally, whereas in another type the recuperators are at the sides, and the air passages are vertical whilst the flue-gas passages are horizontal. It is claimed for the latter type that glass from a broken pot can be more easily dealt with and is not likely to cause so much damage.

Oil firing has not been installed to any extent in the glass industry in England, and in very few, if any, cases has the furnace been designed specifically for oil fuel. During the first half of 1921 some optical glass furnaces in England were fired with heavy oil.

Better results were obtained with the heavier grades of oil, and tank furnaces lend themselves more readily to this type of fuel. In the case of pot furnaces the pots are liable to suffer on account of the irregular heating due to localised combustion.

As a result of efforts to improve the existing types of oil burners in the direction of better efficiency, etc., several oil burners are now on the market, in some of which atomisation is effected by steam under pressure. In others mechanical means and air pressure are utilised. Although more complete atomisation is obtained by the former means, yet the burner utilising air pressure with some mechanical means for assisting atomisation gives more complete combustion, higher temperatures and increased cleanliness without discolouration or deterioration of the glass, due to the effects of the flame coming into contact with it. Moreover, with oil fuel the temperatures can be more easily controlled.

Annealing.—Prior to the War in annealing optical glass an efficient system of well-lagged electrically heated towers ensured a satisfactory result. In other types, however, a primitive, straight-through tunnel (usually coke heated) formed the lehr. It was exceedingly draughty and the glass was hurried through in all too short a time. During the War, however, when the annealing needed to be above suspicion, close attention was devoted to the subject of improved lehrs. Considerable care was exercised to ensure efficiency in this operation. The site was well chosen, the system of heating was considered in relation to the necessity of a variation in the maximum temperature according to the class of ware being annealed, and of a gradual fall in temperature after passing the hottest zone. Precautions were taken to prevent draughts sweeping through the lehr and so defeating the object of the operation. [See W. Rosenhain, *Glass Manufacture* (1919); H. T. Powell, *Glass Making in England* (1923)].

"GOEBEN" AND "BRESLAU."—The escape of the two cruisers "Goeben" and "Breslau" from Messina on Aug. 6 1914 and their flight to Constantinople exercised a large influence on the attitude of Turkey.

Position in Aug. 1914.—When the World War broke out the various naval forces in the Mediterranean were as follows:—

TABLE I.

British forces under Vice-Adml. Sir A. Berkeley Milne:—
Battle cruisers.—"Inflexible," "Indomitable" (8 12-in., 25 knots), 1st Cruiser Sqn., Rear-Adml. E. C. Troubridge; "Defence" (4 9·2-in., 10 7·5-in.), "Black Prince,"; "Duke of Edinburgh," "Warrior" (6 9·2-in., 10 6-in., 22 knots).
Light cruisers.—"Chatham," "Dublin," "Gloucester," "Weymouth."
Destroyers.—5th Flotilla, 16 Destroyers.
French forces under Vice-Adml. Boué de Lapeyrère:—
Battleships.—One Dreadnought, six "Lord Nelson" type (4 12-in., 12 9·4-in.), nine older battleships.
Armoured cruisers.—Six.
Destroyers.—24.
Italian forces:—
Battleships.—Three Dreadnoughts, three "Lord Nelson" type.
Austrian forces:—
Battleships.—Three Dreadnoughts, three "Lord Nelson" type.
German forces under Rear-Adml. Souchon:—
Battle cruiser.—"Goeben" (10 11-in., 25 knots).
Light cruiser.—"Breslau" (12 4-in., 25½ knots).

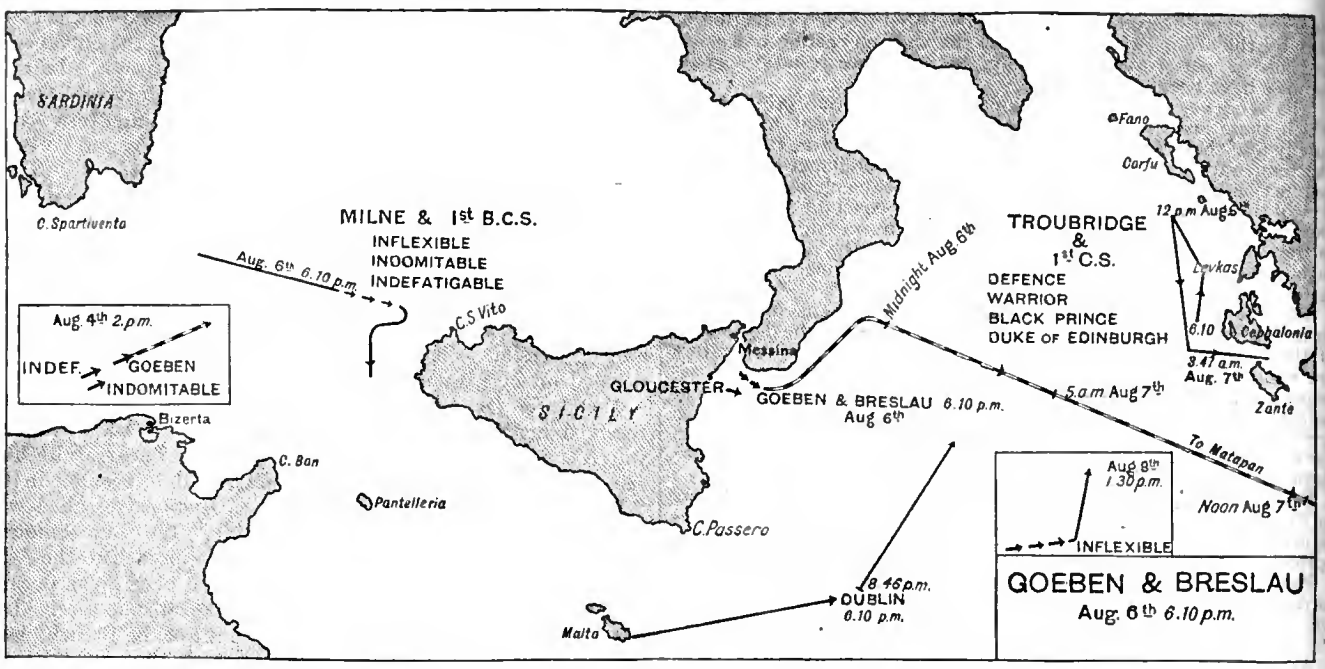
The original orders for the Mediterranean fleet in the event of war were to concentrate at Malta and watch the entrance to the Adriatic, but these were overridden by a series of Admiralty telegrams. The British fleet was at Malta on July 29. On the 30th, Adml. Milne received instructions that his first task was to assist the French in the transport of their troops and to bring the "Goeben" to action if she attempted to interfere. These instructions were sent without reference to the French commander-in-chief, who had not asked for assistance, and the two admirals remained unaware of one another's plans. On July 31 the Italian Govt. informed the British that it intended to remain neutral, a communication of great import, which did not reach the commander-in-chief. On Aug. 1 the "Goeben" and "Breslau" left Brindisi for Messina, the rendezvous decided on in 1913 under the terms of the Triple Alliance.

Search for the "Goeben."—On Aug. 2, at 2:45 P.M., Milne received further orders from home to shadow the "Goeben," watch the entrance to the Adriatic and remain near Malta himself. He accordingly took up his station that evening in the "Inflexible" off Malta, and at 9 P.M. Troubridge sailed with the "Indomitable" and "Indefatigable," the four armoured cruisers and four destroyers to watch the approach to the Adriatic. About 8 P.M. that evening, Milne had been given permission to get in touch with the French admiral, but received no answer to his signals and remained ignorant of the French plans. That night (Aug. 2–3) Milne heard of the "Goeben's" arrival at Messina, and, in answer to his request for instructions, was told by the Admiralty to maintain his watch on the Adriatic, but the "Goeben" was his objective and was to be followed and shadowed wherever she went.

Meanwhile, in Messina, Souchon had received the warning telegram about midnight Aug. 2; he stopped coaling abruptly and put to sea at 1 A.M. Aug. 3 with the intention of bombarding the Algerian coast. The "Chatham" was ordered to look for the "Goeben" in Messina, and passed through the Straits at 7 A.M. (Aug. 3), only to find the harbour empty. In order to locate the "Goeben" and protect the French route, Milne at 9:40 A.M. ordered Troubridge, then on his way to the Adriatic, to proceed west with the "Indomitable," "Indefatigable" and 1st Cruiser Sqn., leaving the "Gloucester" and destroyers to watch the Adriatic. This order was modified at 3:18 P.M. (Aug. 3), when Troubridge was sent back to the Adriatic with the 1st Cruiser Sqn., while the battle cruisers went on to the west, with orders to cruise between Africa and Sardinia. Milne was greatly handicapped all this time by his ignorance of the French dispositions, and received no information from home on this point. Souchon on his way to the African coast received news at 6 P.M. (Aug. 3) of the outbreak of war with France from the Italian wireless station at Vittoria, but held on his way. The Admiralty, having lost sight of the "Goeben," assumed that she was on her way to attack the Atlantic trade routes, and at 8:30 P.M. (Aug. 3) ordered the "Indomitable" and "Indefatigable" to proceed after her to Gibraltar at high speed. They were then south of Sicily and went off at 21 knots.

"Goeben" Sighted.—At 3 A.M. on Aug. 4 Souchon received from Nauen, the great German wireless station, the Kaiser's order to proceed to Constantinople. Deciding to finish his venture, he went on to the African coast, fired a few salvoes into Bône and Philippeville at 6 A.M. (Aug. 4) and made off. At 9:15 A.M. on his way East, he narrowly escaped meeting the French 1st Sqn., which passed him only 24 m. away. Then, by a stroke of good luck, the "Indomitable" and "Indefatigable" on their way westward ran right into him, 40 m. north of Bône, at 10:32 A.M. (Aug. 4). The battle cruisers turned to the east and followed him at 11,000 yards. Their guns were loaded and manned, but war was not declared and they did not fire.

The day was misty, the "Goeben" was at least two knots faster, and by 4:35 P.M. was out of sight. The Admiralty, where it was thought that the "Goeben" was going west, asked the Foreign Office to agree to her being engaged if she attacked French transports, and the order to do so was sent, but did not reach Milne till 5 P.M. Meanwhile he had received during the



afternoon the news of the Italian declaration of neutrality and an order not to approach within six miles of the Italian coast. Italy in her declaration of neutrality had claimed a six-mile limit, which had been accepted without demur. Belligerents were thereby debarred from committing acts of hostility within this limit, but no convention of international law debarred them from entering neutral waters. Italy had not asked for anything of the sort, and the restriction was cancelled on Aug. 6 at 7:46 P.M.; but its immediate effect was to debar Milne from passing through Messina Straits, thus preventing the immediate concentration of any forces he might station at the two entrances.

Meanwhile, the "Indomitable" and "Indefatigable" were still going east on the "Goeben's" track, and were between Sicily and Sardinia when at 6:30 P.M. (Aug. 4) they received orders from Milne to steer west and go slow, and turning round they abandoned the pursuit. In giving this order Milne was evidently influenced, partly by the idea of covering the French transport route, partly by the Admiralty injunction against approaching the Italian coast. He did not know that the French admiral had his whole fleet guarding the route between France and Africa.

Declaration of War.—The warning telegram reached Adml. Milne at 7:02 P.M. (Aug. 4) stating that the ultimatum would expire at midnight. When hostilities commenced at that hour (Aug. 4–5), the "Inflexible" was in Malta channel, steering west to join the "Indomitable" and "Indefatigable"; the "Goeben" was approaching Messina, and Troubridge with the 1st Cruiser Sqn. was about 60 m. west of Zante. The "Goeben" arrived at Messina at 4 A.M. on Aug. 5 and started to get in coal, but on the protest of the British consul difficulties arose and the work was slow. News of her arrival was sent that forenoon by Sir Rennell Rodd, British Ambassador at Rome, to London, and though it did not reach Milne from London till 5 A.M. on Aug. 6, he had already received warning of it from the "Gloucester" at 5:30 P.M. on Aug. 5 and also a report from Malta. At 11 A.M. on Aug. 5 he was off Pantellaria in the Straits of Malta, and proceeded to Bizerta, where the "Indomitable" was sent in to coal. A still more important piece of information never reached the commander-in-chief, namely, that at 7 P.M. (Aug. 5) the Italian authorities had given Souchon 24 hours to leave the port. During the night of Aug. 5 Milne continued to patrol with the "Inflexible" and "Indefatigable" between Bizerta and Sardinia, while the "Indomitable" was coaling at Bizerta, and while Troubridge's cruiser squadron was patrolling on the route from Messina to the Adriatic ready to engage the German ships by moonlight.

"Goeben" Again Escapes.—About 6 P.M. (Aug. 6) Milne decided to close the northern entrance of the straits, and at 6:10 P.M. was 15 m. off Cape S. Vito (the northwest point of Sicily) when the "Gloucester's" wireless began to sound. The "Goeben" and "Breslau" were leaving Messina by the southern entrance. The "Gloucester" followed them closely, and at 8:30 P.M. Capt. John Kelly in the "Dublin," on his way from Malta to join Troubridge, received orders to attack them. He steered to intercept them, but the "Goeben" passed him in the night unseen. Milne was not conversant with the ticklish state of affairs in Turkey, and had merely been told that the Turks were mining the Dardanelles. He proceeded therefore at moderate speed (15 knots) to Malta, arriving there with the battle cruisers at noon on Aug. 7, just as the "Goeben" was approaching Cape Matapan. He was still uncertain of the exact movements of the French, and was still inclined to think of the safety of the western route.

Germans Make for the Dardanelles.—Souchon had been left at liberty to act as he might think fit. He saw nothing but a long spell of inactivity before him at Pola, and had decided to proceed to the Dardanelles. On leaving Messina he made a feint of steering north till about 11 P.M., but the "Gloucester" (Capt. William Kelly) followed him close, signalling his every move. Troubridge with the 1st Cruiser Sqn. was off Cephalonia at 6:10 P.M. Aug. 6, and, thinking Souchon was making for the Adriatic, steered at first for Fano Island (at the mouth of the Adriatic), but, concluding at midnight that Souchon's first course was a feint, turned round and proceeded south at full speed. He had already informed the commander-in-chief that he would not risk his cruisers in a daylight action with the 11-in. guns of the "Goeben," and had been told that the circumstances would not arise. From the positions signalled by the "Gloucester," he found that he could not hope to intercept her before daylight. He therefore abandoned the attempt and altered course to the eastward for Zante at 3:50 A.M. (Aug. 7). Like the commander-in-chief, he saw no great danger in the "Goeben's" course. Its vast consequences were beyond their ken.

At 4 P.M. Aug. 7 the "Goeben" was off Cape Matapan with the "Gloucester" still clinging doggedly behind. She had engaged the "Breslau" at 1:35 P.M. at 11,500 yds. but had received orders not to follow beyond Cape Matapan, and turned back at 4 P.M. The "Inflexible" and "Indefatigable" were then coaling at Malta 400 m. away, and it was not till 12:30 A.M., Aug. 8, that they left for the Aegean in chase. There was still time to do something, for difficulties had arisen as to the "Goeben's" entering the Dardanelles and she was still cruising

in the Aegean, where Souchon had arranged for a collier to meet her off the lonely little island of Denousa (near Naxos). But again an unlucky mischance occurred. A false alarm of war with Austria was sent out from the Admiralty at noon on Aug. 8. Milne received it at 1:30 P.M., when he was halfway to Greece, and, in accordance with the instructions for war with Austria, altered course to the northeast to concentrate the fleet off the Adriatic. The alarm was cancelled a couple of hours later, but as the admiral was informed that the situation was critical, he continued on his course.

At noon on Aug. 9 the "Inflexible" was 40 m. west of Zante, and it was only at 2:50 P.M. that the Admiralty sent him an urgent message to resume the chase. He had lost 24 hours, and did not enter the Aegean till 3 A.M. on Aug. 10. At 5:18 A.M. he passed Belopulon Light (36° 56′ N., 23° 30′ E.), just as the "Goeben," 120 m. to the eastward, finished coaling off Denousa. She had received orders by wireless through the German S.S. "General" at Smyrna to proceed to Constantinople, and shaped course at 5:45 A.M. for the Dardanelles. It was too late to cut her off, nor had Milne any intelligence of her whereabouts. All that day he was searching for her in the Aegean. At 5 P.M. she was off Cape Helles. A Turkish torpedo boat appeared flying the signal "Follow me." She entered the Dardanelles at 16 minutes past 5 on Aug. 10. All the hills of Gallipoli looked down on her as she passed. Milne, still searching for her, received the news at noon on Aug. 11 and was ordered to watch the exit. As the "Weymouth" approached the Straits the guns of the forts began to train. At the beginning of this most fateful chapter of accidents lay the unhappy telegram instructing the admiral to protect French transports, which did not need protection.

The escape of the two ships seriously affected the attitude of Turkey to the Allies. The "Goeben" in particular was very active, and by her operations in the Black Sea involved Turkey in hostilities with Russia. In Jan. 1918 the "Goeben" and "Breslau" left the Dardanelles and attacked British ships off Mudros. The "Breslau" was sunk by a mine, but the "Goeben," though damaged, escaped. She was again active in the Black Sea fleet; and, having been again damaged by a mine, remained crippled in the Sea of Marmora till located there by the Allies after the Armistice.

GOETHALS, GEORGE WASHINGTON (1858–), American engineer, was born in Brooklyn, N.Y., June 29 1858. He graduated from West Point Military Academy in 1880 and received a commission as second lieutenant of engineers. In 1882 he was stationed at Cincinnati, where he was engaged in improving the channel of the Ohio. Later he taught engineering at West Point, but returned to Cincinnati in 1889. Afterwards he was in charge of the construction of the Muscle Shoals Canal on the Tennessee and of a canal near Chattanooga, Tennessee. On the outbreak of the Spanish-American War in 1898 he was commissioned lieutenant-colonel of volunteers and appointed chief engineer of the First Army Corps. In 1900 he was commissioned major in the regular army and three years later was engaged in planning fortifications near Newport, Rhode Island. He was then made a member of the General Staff in Washington, and in 1905 graduated from the Army War College. In 1907 he was appointed by President Roosevelt a member of the Isthmian Canal Commission, with the rank of lieutenant-colonel, and afterwards became chairman and chief engineer. Two years later he was promoted colonel.

The work, hitherto in charge of civilian engineers, was reorganised and directed by army engineers subject to the control of the President of the United States. Several changes of plan, such as widening the canal, were inaugurated, and after seven years' labour Col. Goethals completed his task. On Aug. 15 1914 the canal was declared open to world commerce (*see* PANAMA CANAL). Col. Goethals was appointed the first civil governor of the Canal Zone by President Wilson in 1914 and in the following year was made major-general. He resigned the governorship in 1916, and was appointed chairman of the board constituted to report on the Adamson Eight-hour law. In 1917 he was appointed state engineer of New Jersey, but after America's entry into the World War he was released to serve as manager of the Emergency Fleet Corporation. He had little faith in the plan for a wooden fleet, and resigned after three months. Toward the close of 1917 he was appointed acting quartermaster-general, United States Army, becoming in 1918 chief of the division of purchase, storage and traffic. He was also a member of the War Industries Board. At his request he was relieved from active service in March 1919.

GOITRE (Lat. *guttur*, the throat).—Goitre or Derbyshire neck (*see* 12.101) is a term used for abnormal enlargements, usually chronic, of the thyroid gland in the front of the neck. The enlargement may be general and uniform (parenchymatous goitre), or may be localised to one part of the gland or to the isthmus connecting the two halves or lobes. Local enlargements are either innocent, which are common, or malignant, which are rare; the innocent growths are known as adenomas (adenomatous goitre) which at first solid may soften down and become liquid-forming cysts; these cystic goitres or bronchoceles contain yellow, glue-like material (colloid); from bleeding into their interior may rapidly enlarge, otherwise they grow slowly, or may exist for many years without increasing in size or causing discomfort. They often arise in parenchymatous goitres. Malignant disease commonly starts in an adenoma and is generally a carcinoma which grows slowly but has a special tendency to produce secondary deposits (metastases) in bones. The other form of malignant disease, sarcoma, is much rarer, but runs a rapid course.

Simple Goitre.—This is usually endemic, *i.e.*, occurring in special regions, such as Derbyshire, the Thames Valley, the Yorkshire Dales, Hampshire and Sussex, in the neighbourhood of the Great Lakes in North America, in Switzerland, the Pyrenees and some mountainous parts of Asia, and is then due to some local condition, especially the water supply. In Kashmir Col. R. McCarrison correlated it with infection of the drinking water; "goitre springs" and "wells" are known, and fish and animals may also be affected in endemic areas. The observation that boiling the water prevents the incidence of goitre and the occurrence of epidemics of acute goitre in schools are compatible with this view. But that this is the only cause is uncertain, for simple goitre can be prevented by the administration of iodine and the water in goitrous regions is hard and poor in iodine. Goitre may also occur sporadically in areas where it is rare, but is seldom congenital except in endemic regions. It appears most commonly about puberty and is about seven times commoner in females than in males. Large goitres may give rise mechanically to difficulty of breathing by compressing the windpipe.

Toxic Goitre.—The adenomatous enlargement may remain latent without any symptoms for years, and then become active and produce an internal secretion which excites toxic symptoms resembling, but not exactly the same as, those of exophthalmic goitre, protrusion of the eyes being absent.

The preventive treatment of simple goitre consists in boiling the water, removal from an endemic district, and the administration of iodine, or iodide of potassium, in small doses. But in cases of adenomatous goitre iodine is said to lead to a toxic goitre. Exposure to X-rays may reduce the size of the goitre, but by producing adhesions renders surgical removal, should it become necessary, less easy. Surgical removal is necessary for pressure symptoms, toxic manifestations, and may be desirable for cosmetic considerations.

Exophthalmic Goitre. (Synonyms, Graves' or Basedow's disease.)—This has very striking symptoms—an enlarged thyroid gland, protrusion of the eyes, rapid action of the heart and palpitation, tremor, extreme nervousness, wasting, flushing, sweating and mental irritability. It is indeed the converse of myxoedema. The skin may be pigmented, and in bad cases diarrhoea,

vomiting and indigestion may be troublesome. Ninety per cent, if not more, of the patients are women. The basal metabolism (the minimal production of heat) is raised and this may be connected with the wasting and tolerance to cold. There is a structural change in the thyroid, probably due to poisons from the alimentary canal, but it may come on after mental shock or emotion. As a result of the change in the thyroid its internal secretion is altered (dysthyroidism) and causes the nervous symptoms. The disease is usually chronic; more than half the patients recover and others improve but do not become absolutely normal. Acute infections, such as influenza, are likely to prove fatal. In a few instances the morbid activity of the thyroid gland is followed by atrophy and myxoedema.

Treatment.—The patients should live a simple life in fresh, country air, avoid much protein (meaty) food, stuffy rooms and excitement. Bromides, quinine hydrobromate, belladonna, digitalis and X-rays or radium to the gland should be employed. If these measures fail, and the case is severe, operative removal of part of the gland or ligature of some of its arteries should be undertaken; the operative mortality of excision of half the gland is now about five per cent. Iodine in the form of Lugol's solution improves the patient's condition so that operation can be more safely undertaken. (H. Ro.)

GOKHALE, GOPAL KRISHNA (1866–1915), Indian politician, was born at Kolhāpur of a humble Chitpavan Brahman family. Graduating at the Elphinstone College, Bombay, in 1884, he joined, as professor of history and political economy, the group of teachers at the Fergusson College, Poona, pledged to serve for 20 years on a merely nominal salary. He remained on the staff finally as principal, until 1902.

Throwing himself fervently into politics, he was associated with the Indian National Congress from its start, and became for some years its joint secretary. In 1897 he paid the first of several visits to England, and gave evidence before the Royal Commission on Indian Expenditure. From then onwards he specialised as a critic of Indian official finance. In 1902 he became a member of the Bombay Legislature and was elected in 1902 to represent the non-official members thereof in the viceregal legislature. His persuasive eloquence, close reasoning, accurate knowledge of the subjects discussed, and instincts of statesmanship won him the Indian leadership, and Lord Curzon recognised his earnest patriotism by nominating him for the C.I.E. in(1904).

Consulting him freely in reference to his projected constitutional reforms, Lord Morley wrote of him to the Viceroy as appreciating executive responsibility and having an eye for the tactics of common sense (*Recollections*, vol. 2, p. 181, 1917). He was fiercely assailed by the extremist section, which never succeeded in his lifetime in capturing the congress machinery. In 1905 he became president of that body, on the occasion of its meeting at Benares. In the same year he founded at Poona his Servants of India Society, whose members take vows of poverty and lifelong service to their country in a religious spirit. In the enlarged viceregal legislature set up in 1910 Gokhale was the commanding Indian figure. His quickness in debate, the attractive literary style of his speeches, his studied moderation, and the care which he took to master his subjects, made him a most effective critic of the Govt. though he indignantly disclaimed the title of the leader of an opposition party.

Besides his brilliant handling of general topics, and more particularly of the annual budgets, he promoted measures for compulsory education on a basis of local option, but did not survive to see this principle introduced from 1918 onwards in all the large provinces. Though his last years were clouded by illness he went to South Africa to acquaint himself at first hand with the grievances of Indians in that country. His last public duty was to serve as a member of the Indian Public Services Commission 1912–5. His death at Poona Feb. 19 1915 was a severe blow to the Constitutional party at a critical moment in India's political history. His last political testament, entrusted on his death-bed to the Aga Khan, was published in Aug. 1917, and outlined plans of reform based on provincial autonomy.

Gokhale's intense patriotism, powerful grasp of facts and great industry raised him head and shoulders above his contemporaries; and his moderation, invariable courtesy and lofty personal character marked him out as one of the last and greatest of the old school of congress politicians before the age of non co-operation.

GOLD (*see* 12.192).—Since the rise of the Spanish Empire in the New World, over £4,000,000,000 of gold has been produced. Only 15% of this amount was produced between 1493 and the Californian alluvial discoveries of 1848, and nearly half has been produced in the first quarter of the century. It is worth while to turn back to the earlier figures in order to measure the rapidity of the advance.

Value of World Output

Period	World's Output	Proportion %
1493–1600	103,000,000	2·5
1601–1700	125,000,000	3·1
1701–1800	259,000,000	6·4
1801–1900	1,568,000,000	38·4
1901–1925	2,026,000,000	49·6
Total 433 years	4,081,000,000	100

Of the total the United States has contributed 22%, the Transvaal 21% and Australasia 19%. The following table shows the value of the production in different areas:—

	Total amount	Amount produced in 1912–26
	£	£
United States (practically since 1849)	894,000,000	203,000,000
Transvaal (since 1884)	844,000,000	519,000,000
Australasia (since 1851)	709,000,000	92,000,000
Russia and Siberia (since 1814)	370,000,000	40,000,000
Mexico (since 1521)	140,000,000	40,000,000
Canada (since 1858)	116,000,000	58,000,000
India (since 1880)	67,000,000	29,000,000
Rhodesia (since 1898)	61,000,000	41,000,000
West Africa (since 1880)	26,000,000	17,000,000
	3,227,000,000	1,039,000,000
South America, etc. (since 1493)	854,000,000	113,000,000
Total 433 years	4,081,000,000	1,152,000,000

Mr. Eduard Suess has calculated that during the period 1848–75 the annual yield of £22,000,000 was obtained as to £19,300,000 or 88% from alluvial and as to £2,700,000 or 12% from lodes. By 1890 the output of £24,500,000 was derived as to £11,000,000 or 45% from alluvial, as to £11,500,000 or 47% from lodes and as to £2,000,000 or 8% from the stratified banket of the Transvaal. So productive has the last source of the metal become that of the World's gold production of £81,500,000 in 1925, £41,000,000 or 50% came from banket, while lode mining yielded £34,000,000 or 42%, and alluvial had fallen to £6,500,000 or 8%. Thus has the day of the individual digger disappeared; much of the alluvial production is now obtained by dredging, and exploitation by organised capital has taken the place of earlier methods.

Though production has advanced so rapidly in the course of the present generation, there are indications that, apart from any new discoveries which may yet be made, the output reached its zenith in 1915. Thereafter, partly as a result of restriction of production due to the increased costs resulting from the World War, but partly also as a result of exhaustion of mines, the annual total fell from £96,400,000 to £65,500,000 in 1922 (a year exceptionally affected by a white miners' strike in the Transvaal) recovering to £81,500,000 in 1925. The principal figures of the output for the period 1911 to 1925 are given in tabular form on opposite page.

This table shows clearly the commanding position of the British Empire, which was responsible in 1925 for 70% of the production and particularly of the Transvaal, which yields three-fourths of the Empire's and half of the World's total. It also indicates

World's Gold Production, 1911 to 1925
(In millions of pounds at 84s. 11½d. per fine oz.)

	Transvaal	Australasia	Canada	Rhodesia India, and W. Africa	British Empire total	United States	Rest of the World	World Total

	554·0	104·6	60·3	94·0	812·9	222·7	210·4	1,246·0

that such countries as Australia and the United States are declining. So far as can be foreseen the recovery from the post-War year 1922 has largely spent itself.

The destination of the gold taken out of the earth in the period since 1493 can be fairly gauged and is given in the following table, the first line of which is necessarily conjectural:—

Consumption of the World's Aggregate Gold Output, 1493–1924, with Proportions of Production Consumed
(In millions of pounds at 84s. 11½d. per fine oz.)

	Industrial Arts (Europe and America)[1]		India[2]		China and Egypt[3]		Available as Money (difference)		World's Output[4]
1493–1834	? 300	53%	?66	12%	?		? 196	35%	562
1835–1844	25	73%	4	12%	?		5	15%	34

1865–1874	101	40%	35	14%	?		118	46%	254
1875–1884	112	52%	22	10%	14	6%	68	32%	216
1885–1894	102	38%	15	6%	8	3%	140	53%	265
1895–1904	144	26%	56	10%	25	4%	334	60%	559
1905–1914	216	24%	146	16%	20	2%	519	58%	901
1915–1924	180	23%	155	20%	10	1%	445	56%	790
	1,263	32%	560	14%	77	2%	2,100	52%	4,000

[1] Based on Soetbeer for 1831–80 and on the Bureau of the United States Mint for 1890–1913, the later figures being approximated by the writer on the Bureau of the United States Mint's incomplete statistics.

[2] Years to March 31 following. Net imports plus country's own production.

[3] Egypt from 1879 only and China from 1889 only, plus, in the case of the latter, the country's own production.

[4] Mostly based on figures supplied by the Bureau of the United States Mint.

The industrial arts and India have the first call on gold production. They largely increased their demands after the outpourings of gold by California and Australia after 1848 and 1851, thereby serving to moderate the great increase of prices of commodities which took place, and largely maintained their rate of absorption for some time after the gold output had commenced to decline. Again, after production in the 'nineties started its great climb to the height of 1915, they increased their demands exceptionally until for the 20 years to 1924 industry absorbed £20,000,000 and India £15,000,000 per annum. On the whole they have taken 46% of the aggregate gold production, and all of this has been effectively withdrawn from the amount available as money, for India's imports and its own production have been wholly turned into jewellery, possessions and hoards, gold not circulating. The proportion left for addition to the world's stock of gold money to date has been a little more than one-half.

The distribution and re-distribution of the aggregate output between the end of 1913 and the end of 1924 is as follows:—

Distribution of World's Aggregate Gold Production in 1913 and 1924

	Dec. 31 1913		Dec. 31 1924	
	£	%	£	%
State banks and Treasuries	960,000,000	30·8	1,750,000,000	43·7
Other banks	130,000,000	4·2	160,000,000	4·0
In circulation	497,000,000	15·9	110,000,000	2·8
Hoarded	..	..	80,000,000	2·0
World's stock of gold money	1,587,000,000	50·9	2,100,000,000	52·5
Absorbed by industrial arts (Europe and America)	1,062,000,000	34·0	1,263,000,000	31·6
Absorbed by India	398,000,000	12·8	560,000,000	14·0
Absorbed by China and Egypt	73,000,000	2·3	77,000,000	1·9
World's gold output (from 1493)	3,120,000,000	100	4,000,000,000	100

The figures set down for money in circulation and hoarded are necessarily guesswork and may be too high, but the table serves to show that while about £400,000,000 has been taken out of the pockets of the public as the result of the monetary changes produced by the World War, about twice that amount has been added to the stocks in Central Banks.

GOLD COAST (*see* 12.203).—The British territory in West Africa known as the Gold Coast includes Gold Coast Colony proper (23,490 sq. m.), Ashanti (24,560 sq. m.), the protected Northern Territories (30,600 sq. m.) and the British mandated portion of the former German colony of Togoland (13,040 sq. m.) making a total of 91,690 sq. m., with a population of 2,298,383, of whom 1,173,439 are in the colony proper.

The colony, which is under a governor assisted by an executive and a legislative council, consists of an agglomeration of small, self-contained and mutually independent native states, each of which is under the immediate management of its own tribal organisation. The paramount chiefs are chosen by the tribesmen from families from among whose members alone a chief can be selected. Each paramount chief is the occupant of a stool, which is reputed to be the seat of office of the original founder of the tribe, and he is assisted by a number of sub-chiefs whose jurisdiction is personal rather than territorial. Permanent cultivation due to the extensive planting of cocoa has led to the definition of the territorial limits of tribal areas.

The remarkable economic advance of the Gold Coast has been accompanied by a great extension of the means of communication. Under Sir Hugh Clifford (1912–9), the railway extension from Mangoase via Koforidua to Tafo was completed, and numerous important public works were constructed. Under his successor, Brig-Gen. Sir Gordon Guggisberg, the railway was carried west-north-west to Kumasi, the capital of Ashanti (July 5 1923), which had previously been reached by the line from Sekondi (Oct. 1 1903).

Railways.—Railway communication now consists of the Sekondi-Kumasi line (167 m.), with branches and the Accra-

Kumasi line (196 m.); and a railway is being constructed from Huni Valley, on the Sekondi-Kumasi line, to the neighbourhood of Kade (120 miles). These railways are on the 3 ft. 6 in. gauge. There is also a system of good roads, 1,268 miles in length, maintained by the Department of Public Works, and other roads maintained by the chiefs. Motor transport has been introduced with good effect. The harbours at Accra and Sekondi have been greatly improved, but have not been adequate to the growing trade of the colony, which was valued at £17,408,075 (imports £8,448,862: exports £8,959,212) in the year 1923. In 1921 it was decided to construct a deep-water port at Takoradi, not far from Sekondi, at a cost of £1,600,000, and this work is now in progress.

Industries.—The chief agricultural industry is cocoa growing, and the United Kingdom now receives fully two-fifths of its cocoa imports from the Gold Coast. Cultivation is almost entirely in the hands of the native peasantry, who have made a great success of this industry; the value of the cocoa export in 1923 being £6,566,973. Other products are kola, timber (especially mahogany), palm oil and a small quantity of cotton. Mining is an important industry, especially of gold and manganese. The former is widely diffused throughout the Colony, Ashanti and some parts of the Northern Territories, while the latter exists in large quantities close to the railway line within 40 m. of the port of Sekondi. The shipments of manganese ore reached 181,623 tons in 1923–4, valued at £410,182, and the value of the gold exported in the same year was £852,548. Diamonds are also exported and valuable deposits of bauxite have been discovered.

Claridge, *History of the Gold Coast and the Ashanti* (1915); Lady Clifford, *Our Days on the Gold Coast* (1919); *The Red Book of West Africa*, ed. by Allester Macmillan (1920); Sir Charles Lucas, *The Gold Coast and the War* (1920); Sir Hugh Clifford, *The Gold Coast Regiment in the East African Campaign* (1920); J. Maxwell, *Gold Coast Handbook* (1923); Brig.-Gen. Sir G. Guggisberg, *The Post-War Gold Coast: A Review of the Events of 1923* (1924).

(P. E. L.)

GOLDIE, SIR GEORGE DASHWOOD TAUBMAN (1846–1925), the founder of Nigeria (*see* 12.211), from 1908 to 1919 was an alderman of the London County Council, on which he served as chairman of the finance committee. From 1905 to 1914 and from 1915 to 1920 he was president of the National Defence Association. He died in London on Aug. 22 1925.

GOLDMARK, KARL (1832–1915), Austrian composer (*see* 12.212), died at Vienna Jan. 2 1915.

GOLDZIHER, IGNAZ (1850–1921), Jewish Hungarian Orientalist (*see* 12.219), died at Budapest Nov. 13 1921. Since 1910 he has published "The Influence of Parsism on Islam," trans. in C. P. Tiele, *The Religion of the Iranian Peoples* (1912, etc.); *Die Richtungen der islamischen Koranauslegung* (Leiden, 1920).

GOLF (*see* 12.219).—Since 1910 the popularity of golf has increased steadily in Great Britain, while in the United States of America it has spread like a prairie fire. There could be no more striking evidence than the fact that the profession of the golf architect has now become an exceedingly busy and prosperous one. Tracts of woodland, where it would once have been deemed impossible to make a course, have been hacked and hewn into shape, tree stumps have been blown up with dynamite and on one famous course in America, the Lido, sand has been sucked up from the sea by giant engines and spread over a flat marsh in picturesque hills and valleys. The designing of courses has developed into an art requiring skill, experience and imagination.

This, which may be called the second great boom in the history of the game, began with the coming of the rubber-cored ball and is no doubt largely due to it. The ball made the game far easier and pleasanter for the average man to play, but it has had its disadvantages. The ball goes so far that there has been a constant cry that courses are too short. Consequently clubs have had to remake their courses, taking in more ground with great attendant expense. Some attempts have been made, though not with any conspicuous success, to limit the ball's activities. In 1920 there was passed a rule, still in force, which lays down that the weight of the ball shall not be greater than 1·62 oz. avoirdupois and the size not less than 1·62 in. in diameter. The "implements committee" of the U.S. Golf Assn., after exhaustive experiments, proposed a further slight limitation. At the autumn meeting of the Royal and Ancient Club in 1925 it was proposed that a ball thus further limited should be used in the open and amateur championships of 1926, but the proposal was rejected by a large majority.

The Game in the United States

In the United States, in the earlier years of this century, golf may be said to have altered largely the lives of the upper and middle classes there, by the introduction of the "country club" habit. Now it has spread to all classes of society. Many American towns have public links where anybody can play either on the payment of a small fee or for nothing. Chicago heads the list with nearly 20 of such courses, and all over the country they are growing rapidly. It is significant that there has been officially instituted by the U.S. Golf Assn. a public links championship which draws many entries and produces fine golf, the winner being often one who was a caddie in boyhood.

Standard of Play in the U.S.A.—In these circumstances it is only natural that the Americans should have produced very good players. Their standard of play is now unquestionably higher than Great Britain's. As long ago as 1904 Mr. Walter Travis, an Australian born who had become an American citizen, won the British amateur championship at Sandwich. Curiously enough although the standard of play in America is now far higher than in Mr. Travis's day, no other American amateur won the championship until 1926, when the coveted prize fell to Mr. Jess Sweetser. Mr. Travis's fine victory marked the beginning of the American challenge, but it was not until eight years later that the menace to British supremacy was fully realised. In 1913 Harry Vardon and E. Ray went touring through America and took part in the open championship at the country club at Brookline, Mass. They seemed certain to have tied for first place when almost at the end of the day Mr. Francis Ouimet, a young Boston player who had only lately played in his first amateur championship, managed to tie with them by means of a great finish. On the next day the tie was played off over holes in horrible conditions with sheets of rain and muddy ground Mr. Ouimet held his two opponents all the way, gradually worn them down and beat them handsomely.

Changes during the World War.—A year later golf practically ceased in Great Britain owing to the War but it naturally continued to grow and flourish in America. Up till that time most of the professionals in America had been imported Scotsmen or Englishmen, but there was gradually arising a race of "home bred" professionals and after the War they were both formidable and numerous. When the British open championship began again in 1920, the great British golfers, Vardon, Braid, Taylor and Herd, had grown a little too old. They were, as they still are very fine players, but their youth is not perennial and the long strain of a championship had become something too much for them. Great Britain had then, as to-day, many very skilful professional golfers but none perhaps who combined skill with temperamental virtues as did those four.

In 1920 the series of American invasions began with Hagen a "home-bred," and Barnes, a Cornishman who had gone to America as a very young man. Barnes did well, but Hagen failed on this his first visit and Duncan, for whom that year was an *annus mirabilis*, won the championship. Next year they tried again and Hagen was clearly becoming acclimatised to British golf; but the winner was Jock Hutchison, a St. Andrew's-bred player, professional to the Glenview Club near Chicago who though a Scottish golfer, played a typically American game. He tied with Mr. Roger Wethered, who had the misfortune to lose one vital stroke by kicking his own ball, and then won easily on the play-off. At the third attempt in 1922 Hagen was successful winning at Sandwich by a single stroke, despite a wonderful spurt by Duncan in the last round. The next year was one of encouragement for Great Britain, for Havers, a young professional of great power and promise who learnt his game at Norwich, managed to beat Hagen by one stroke. There were other invaders from America, Barnes, Macdonald Smith, one of a

great Carnoustie family, and Gene Sarazen, a young "home-bred" player of Italian parentage, who had suddenly come into prominence. Barnes and Sarazen failed to qualify but Macdonald Smith finished high on the list.

In 1924 all four came to Hoylake and Hagen won by one stroke, chiefly by means of a most gallant finish. Indeed he has shown himself to possess unique powers of recovering from difficulties and of turning defeat into victory. In 1925 he did not come but Barnes won, beating Ray and Compston by a stroke. Macdonald Smith appeared at one time almost assured of victory but failed badly in the last round, during which he was rather hampered by an enormous crowd. The names of American professionals already mentioned make up a large part of the history of the American open championship but there is a word to be said about one truly astounding golfer, Mr. R. T. Jones, commonly called "Bobby." Mr. Jones has actually won the American open championship only once, a feat equalled by Mr. Jerome Travers, Mr. Ouimet and Mr. "Chick" Evans, but in the championship since the War his aggregate of scores is better by 19 strokes than that of the next best man, Walter Hagen. That is an eloquent piece of statistics to which nothing need be added.

The Walker Cup.—The history of American and British amateur golf centres chiefly round the Walker Cup which was given by a well-known golfer, Mr. Walker, for matches between the two countries. In 1920, an American amateur team came to take part in the amateur championship at Hoylake, played a match against a British team, and won decisively. That was before the giving of the cup. Walker Cup matches have since been played on the National golf links, Long Island, in 1921, at St. Andrews in 1923 and at Garden City, New York, in 1924. The American team has won on each occasion, very easily in its own country, by a narrow margin and a most courageous finish at St. Andrew's. The American team won also in the two following years, 1925 and 1926. In Messrs. Jones, Evans, Ouimet, Guilford, Gardner and Sweetser they had the nucleus of a side stronger than any Great Britain could command; and it is certain that any American team will always be a very formidable one. The American amateur is invariably well taught and grounded in his boyhood and he has a steadiness and consistency to which very few British amateurs seem able to attain. This is the more remarkable because, unless he goes to Pinehurst or Palm Beach or other southern courses in the winter, he probably plays less golf than do British golfers, who can and do play all the year round.

Golf in France and Elsewhere

Before coming to British golf, something must be said of that in other countries. As long ago as 1907, Arnaud Massy, originally a Biarritz fisherman, won the British open championship. He has never repeated that feat, though he tied with Vardon in 1911 and has several times beaten strong fields of British players in the French championship and did so once again in 1925. There has been no other French professional as good as Massy, but there has been a number of very good ones, such as the late Louis Tellier, Gassiat, Laffitte, Daugé, and one most remarkable one-armed player, Yves Bocatzou. The French amateurs have hardly yet reached the same standard, but France has produced one extremely good lady player, Mlle. Simone de la Chaume. She is already a very fine player and in soundness of method probably comes nearer to the British lady champion, Miss Wethered, than any other lady.

There are to-day some very good courses in France. Paris has La Boulie, Chantilly, St. Cloud and Fontainebleau. Le Touquet, near Étaples, is excellent, a mixture of seaside sand and inland pine trees; and Wimereux, lately remodelled, promises well. In the Riviera English visitors have made courses of varying quality. Cannes has one very pleasant one among pine trees at Napoules and the new Cannes country club, rather further off at Mougins, is probably better. Sospel, in a mountain valley above Mentone, is very charming, and others that are at least pretty and worth playing on are Costebelle, Valescure and Cagnes, near Nice. On the Côte d'Argent there is La Nivelle, near St. Jean de Luz, where Massy is the professional, and Biarritz. Moreover, close to Biarritz a new course is being made of which its promoters think very highly. Nor must Pau be forgotten. It is a club of now almost venerable age, one of the oldest out of Scotland. Switzerland and Italy have courses which are at least very beautiful. Indeed there are courses wherever British people are to be found. Canada, if it has not yet quite attained to the American standard of skill, is almost as keen and spends almost as much money on its courses and club houses. Australia has some good courses, notably perhaps Seaton near Adelaide and Kensington near Sydney; and it has bred at least one first-class professional, Joseph Kirkwood, who has several times done well in the British open championship and is now one of the leading professionals in America.

Japan has taken to the game with enthusiasm although the turf of the country is not of the best kind. It possesses a golf paper, *Golfdom*, and has some good players, although none have yet reached the standard of its lawn-tennis players. In short, in regard to its world-wide character, the game is now only second to lawn tennis.

The Game in Great Britain

In Great Britain golf has become steadily more and more popular, and nowhere more markedly than in its original home, Scotland. In Scotland it is essentially the people's game and there are many municipal courses on which it can be played at the minimum of expense. In England it is still largely the game of the comparatively well-to-do, but municipal golf is on the increase and wherever it arises it is an instant success, as witness the public course in Richmond Park which is crowded with all sorts and conditions of players. There are to-day far more golfers than there used to be who have begun the game as boys. It is not a school game but many boys play in their holidays; and considering this fact it is rather surprising that Great Britain does not breed more good young players. The universities of Oxford and Cambridge are full of golfers, but only a few of them are good golfers and the standard of university teams is not noticeably higher than it used to be. The number of players who may fairly be called good has of course increased very greatly throughout the country as a whole, and championship fields have correspondingly increased.

British Amateurs.—It has already been said that when the game was resumed after the War, the leading British professionals were a little past their best. Much the same may be said as regards the amateurs. Mr. John Ball, Mr. Hilton and others of their generation had naturally begun to think of retiring and their places were left open. Two very brilliant young players, too young to be heard of before the War, at once made their presence felt after it, Mr. Cyril Tolley and Mr. Roger Wethered. Of all British golfers in late years, these two have been the most essentially dramatic, and have taken the largest share of public attention. Both can hit the ball enormous distances, both are on their day almost unapproachably good and both can be, on an off day, disappointing. They lack the consistency of such a player as Mr. John Ball, but the game as played by them is an exciting and attractive one. Each has won the amateur championship once. Mr. Tolley has won the French open championship against a strong field, and Mr. Wethered did the best thing which any British amateur has done for a long time when he tied for the open championship with Jock Hutchison.

A golfer of a rather different type, Sir Ernest Holderness, has twice won the amateur championship since the War and, though he has not the magnetic powers of a Tolley or a Wethered, he is beyond doubt a very fine player. In the matter of consistency and steadiness he challenges comparison with the best of the elder amateurs. In 1925 another eminently consistent player, Mr. Robert Harris, won the amateur championship. It was a most popular victory, for Mr. Harris has now been among the leading amateurs for a long time; he was in the semi-final of the amateur championship as long ago as 1907 and in the final in 1913 and 1923.

These two players, Sir Ernest Holderness and Mr. Harris, probably make the safest models for the young amateurs of the present day, for the reason that they are both essentially straight and accurate. There is some danger lest too much importance should be attached to length and that young golfers should indulge in an orgy of slogging. Still, in the last few years, there has been noticed a great increase of driving power. This cannot be wholly accounted for by the increasing skill in the manufacture of the rubber-cored ball. On the whole the amateur standard is going up; but there is still room for a combination of the elder and younger virtues.

British Professionals.—No one or two professionals have definitely succeeded to the throne left vacant by the "triumvirate," Vardon, Braid and Taylor. Duncan appeared likely to do so when he played so wonderfully well in 1920, but he has since been somewhat fitful and inconstant. He is a magnificent golfer but lacks something of solidity and stolidity. Much the same may be said of Abe Mitchell, who has never yet won the open championship, though he has been very successful in tournaments by match play. It is almost impossible to imagine anything better than Mitchell's golf when things are going well; his brother professionals always expect him to win; but he too seems to want that power of rising superior to circumstances, which Hagen so conspicuously possesses. The two Whitcombes, George Gadd, Ockenden, Havers and many others all play exceedingly well without quite rising to the greatest heights. In 1925, however, there appeared suddenly another player, Compston, who adds great determination and character to great physical strength and may possibly be the man for whom the British golfing world has been waiting. He was unquestionably the player of the year and appears, far from relaxing his efforts after a victory, to go from strength to strength. Late in the year he was rather heavily defeated by Abe Mitchell, who played golf of overpowering brilliancy, but this will not discourage him.

Golf for Ladies.—In its ladies' golf Great Britain is strongest. For the first few years after the War Miss Cecil Leitch was the outstanding figure. She has all the qualities of a great player; it is possible to criticise her rather unorthodox methods, but not their results. She is still as good as ever, but she has been surpassed by Miss Joyce Wethered, who to equal strength and courage adds a sounder method. Indeed she is so sound in everything she does that it is impossible to suggest even the smallest loophole in her armour. She won the English close championship five times in succession and the open championship three times in four years, the last time after a terrific struggle with Miss Leitch, in which both played superbly. She has now no worlds left to conquer. These two ladies have dominated ladies' golf since the War, but there are some other excellent players, such as Miss Fowler, Mrs. Macbeth, Miss Chambers, and amongst American invaders, Miss Glenna Collett and Mrs. Fraser, formerly Miss Alexa Stirling. Lady golfers, although they now drive a great deal further than their predecessors, have not yielded to the passion for big hitting as have some of their male contemporaries. For the most part they play very accurately. Their iron play is a great deal more forceful than it used to be and, generally speaking, the difference between good men's golf and good women's golf to-day is one not of kind but only of degree.

Some Golf Courses

The select list of championship courses has been slightly enlarged. Two amateur championships have been played at Westward Ho, and one at Deal, which had previously been only upon the rota for the open championship. The open championship has been played at Troon and is to be played in 1926 at Lytham and St. Anne's. The fixed rota has in both cases been abandoned and, as time goes on, other fresh courses will no doubt get their turns. The management of the two championship meetings is now in the hands of the championship committee of the Royal and Ancient Golf Club. Its members are appointed by the Royal and Ancient but are not necessarily members of that club. They are chosen from representative golfers in different parts of the country. It may here be added that England, Scotland, Ireland and Wales has now each its own Golf Union. There is also a large number of county unions county matches and county championships. Mention may also be made of the Professional Golfers Assn. which does a great deal of useful work on its members' behalf and manages certain competitions, such as *The News of the World* and *The Daily Mail* tournaments open to its members.

It would be impossible to enumerate all the new and good courses which have come into existence since 1910. There are not so many new sea-side ones of quite the first rank, though there is certainly one, Prince's, Sandwich, which is as fine as any in the country, and another, Saunton, in North Devon, which promises to be so. The great increase is in good inland courses. This is largely due to the discovery that the country of fir trees and heather, such as is to be found particularly in Surrey, can be turned into the very best kind of inland course. The London golfer has consequently a wonderful choice of fine courses within easy distance, Sunningdale, Walton Heath, Woking, Worplesdon, West Hill, St. George's Hill and Addington are among the leading ones. Ganton and Alwoodley, in Yorkshire; Hollinwell, in Nottinghamshire; Sandwell Park, near Birmingham; and Gleneagles, in Perthshire, are perhaps the best outside the London district, but the list is really unending. Finally it has regretfully to be recorded that golf is no longer played on Blackheath, its earliest home in England. The classic heath is now given over to football players and its sacred turf has been largely kicked to pieces. The Royal Blackheath Club has, however, moved its home to Eltham, where it still flourishes and retains its proud claim to be the oldest golf club in the world.

Winners of British Championship, 1911–26

Year	Open	Amateur	Ladies
1911	H. Vardon (Prestwick)[1]	H. H. Hilton, (Prestwick)	Miss D. Campbell (Portrush)
1912	E. Ray (Muirfield)	J. Ball (Westward Ho!)	Miss G. Ravenscroft (Turnberry)
1913	J. H. Taylor (Hoylake)	H. H. Hilton* (St. Andrews)	Miss M. Dodd (St. Anne's)
1914	H. Vardon (Prestwick)	J. L. C. Jenkins (Sandwich)	Miss C. Leitch (Hunstanton)
1915–1919	No Matches		
1920	G. Duncan (Deal)	C. J. H. Tolley (Muirfield)	Miss C. Leitch (Newcastle, Co. Down)
1921	J. Hutchison (St. Andrews)[2]	W. I. Hunter (Hoylake)	Miss C. Leitch (Turnberry)
1922	W. Hagen (Sandwich)	E. Holderness (Prestwick)	Miss J. Wethered (Sandwich)
1923	A. G. Havers (Troon)	R. H. Wethered (Deal)	Miss D. Chambers (Burnham)
1924	W. Hagen (Hoylake)	E. Holderness (St. Andrews)	Miss J. Wethered (Portrush)
1925	J. M. Barnes (Prestwick)	R. Harris (Westward Ho!)	Miss J. Wethered (Troon)
1926	Robert T. ("Bobby") Jones (St. Anne's)	Jesse Sweetser (Muirfield)	Miss C. Leitch (Harlech)

(B. D.)

GOLITZIN, BORIS BORISOVICH, PRINCE (1862–1916), Russian physicist, was born on Feb. 18 (old style) 1862 in St. Petersburg (Leningrad). He was educated in the naval school and naval academy. In 1887 he left the active service for scientific studies and went to Strasbourg. In 1891 he was appointed *privat-docent* at the University of Moscow and in 1893 professor of physics at Dorpat. The same year he was elected fellow of the Academy of Sciences in St. Petersburg and in 1908 a member of the same. His early research was in spectroscopy, but his world-known work is on the methods of earthquake observations and on the construction of seismographs, which are used in all Russian and in many foreign observatories. His valuable book, *Lectures on Seismometry* , was published in 1912 and translated into German in 1914. He received the degree of D. Sc. from the University of Manchester in 1910. In 1911 he was elected president of the International Seismological Association. In 1913 he was appointed director of the Central Physical (now Geophysical) Observatory at St Petersburg and achieved good results in the organisation of the meteorological service throughout Russia, especially during the World War, but his work was cut short by his death from pneumonia on May 4 1916 at New Peterhof, near St. Petersburg. He took part twice in expeditions for observations of solar eclipses, once in 1896 at Novaya Zemlya and the second time in 1914 near Riga, where he obtained splendid photographs of the corona. (A. Fo.)

GOLLANCZ, SIR ISRAEL (1864–), British scholar, was born in London of a Jewish family July 13 1863. He was educated at the City of London School and afterwards at University College, London and Christ's College, Cambridge. From 1892 to 1895 he was Quain student and lecturer in English at University College, London and in 1896 was appointed university lecturer in English at Cambridge, becoming in 1906 university professor of English language and literature at King's College, London. He became secretary of the British Academy on its foundation in 1903 and was knighted in 1919. He was general editor of the *Temple Classics* and *King's Library* series and of the *Book of Homage to Shakespeare* which appeared in 1916. His published works include *Cynewulf's Christ* (1892); an edition of C. Lamb's *Specimens of Elizabethan Dramatists* (1893); *Exeter Book of Anglo-Saxon Poetry* (1895) and *Hamlet in Iceland* (1898).

GOLTZ, COLMAR VON DER (1843–1916), Prussian general, military writer and organiser of the Turkish Army (*see* 12.227). Gen. von der Goltz was made a field-marshal in 1911 and retired in 1913. In Aug. 1914 he was appointed Governor-General of Belgium, then occupied by German forces. In Nov. of the same year he was attached to the Turkish headquarters as aide-de-camp-general to the Sultan. In April 1915 he was placed in the chief command of the I. Turkish Army in Mesopotamia, and succeeded in investing Gen. Townshend's British forces at Kūt-el-Amāra in Dec. 1915. He died April 19 1916 at Baghdād and was said to have been poisoned by the Young Turks. His latest work was *Kriegsgeschichte Deutschlands im 19ten Jahrhundert*, 2 vol. (1910–4).

GOLUCHOWSKI, AGENOR, COUNT (1849–1921), Austrian statesman (*see* 12.227), died at Lemberg March 29 1921.

GOMPERS, SAMUEL (1850–1924), American labour leader (*see* 12.230), was convicted in 1907 and sentenced to 12 months' imprisonment for contempt of court in disobeying an injunction prohibiting *The Federationist* (the organ of the American Federation of Labour), from blacklisting the Buck Stove and Range Co. of St. Louis. On his appeal, the U.S. Supreme Court waived the conviction on technical grounds. New proceedings were instituted and another conviction and sentence in the lower court was set aside by the Supreme Court on the ground that the statute of limitations had expired before the second prosecution was launched. Although in theory opposed to all war, after the outbreak of the World War he resisted any tendency in labour unions to favour peace at any price. He was appointed a member of the Advisory Commission of the U.S. Council of National Defence in 1917.

Gompers represented the American Federation of Labour at the Peace Conference in Paris 1918–9, and was appointed chairman of the International Committee on Labour Legislation. He was also Chairman of the American labour delegates at the convention of the International Federation of Trades Unions at Amsterdam in 1919. He consistently opposed socialistic movements among the unions and favoured collective bargaining. He opposed compulsory arbitration in labour disputes and urged that labour unions be exempt from the anti-trust law. In 1921 he was elected president of the American Federation of Labour for the 40th time. In Dec. 1924 he was taken ill at Mexico City, whither he had gone after attending the annual convention of the American Federation of Labour at El Paso, Tex. As he had expressed a wish to die on U.S. ground he was placed on a special train, bound for New York City. He died at San Antonio, Tex., Dec. 13.

GOMPERZ, THEODOR (1832–1912), German scholar (*see* 12.230), died at Baden, near Vienna, Aug. 30 1912.

GOODHUE, BERTRAM GROSVENOR (1869–1924), American architect, was born at Pomfret Hill, Conn., April 28 1869. He studied architecture in New York City with James Renwick and in 1891 entered the office of R. A. Cram in Boston, Mass., later becoming a partner. In 1903 the firm opened an office in New York City of which Goodhue took charge. After 1914 he practised alone. He designed churches and cathedrals which were thoroughly modern yet Gothic in inspiration. At the same time he was one of the most prominent exponents of the sky-scraper building. Among the structures designed by him are St. Thomas's Church, the Chapel of the Intercession, and the Church of Saint Vincent Ferrer, New York City; the Nebraska State Capitol, Lincoln, Neb.; St. Mark's Church, Mount Kisco, N.Y.; St. Thomas's College, and the National Academy of Sciences and National Research Council in Washington, D.C.; Mandel Hall, at the University of Chicago; the California Institute of Technology, Pasadena, Cal.; and the Exposition buildings for San Diego, Cal. He was also the architect for the Cathedral of Maryland, Baltimore. He died in New York City April 24 1924.

GOODNOW, FRANK JOHNSON (1859–), American educationist, was born in Brooklyn, N.Y., Jan. 13 1850. Educated at Amherst College, Mass., he studied law at Columbia (LL.B., 1882), subsequently proceeding to the École Libre des Sciences Politiques, Paris, and the University of Berlin. He was appointed instructor in history and lecturer in U.S. administrative law at Columbia University in 1883, becoming professor in 1891, and Eaton professor of administrative law and municipal science in 1903. During 1906–7 he was acting dean of political science. He was legal adviser to the Chinese Govt., stationed at Peking, during the years 1913 and 1914. He was appointed president of Johns Hopkins University, Oct. 1 1914.

Among his published works are *Comparative Administrative Law* (1893); *Municipal Home Rule* (1895); *Municipal Problems* (1897); *Politics and Administration* (1900); *City Government in the United States* (1904); *Principles of the Administrative Law of the United States* (1905); *Municipal Government* (1910); *Social Reform and the Constitution* (1911); *Principles of Constitutional Government* (1916).

GOODWIN, NATHANIEL CARL (1857–1919), American actor (*see* 12.239), died in New York Jan. 31 1919.

GOODWIN, WILLIAM WATSON (1831–1912), American scholar (*see* 12.240), died in Cambridge, Mass., June 16 1912.

GORE, CHARLES (1853–), British divine (*see* 12.254), was, in 1911, appointed Bishop of Oxford, where he remained until 1919 when he resigned and settled in London. His recent works include *New Theology and Old Religion* (1908); *Orders and Unity* (1910); *The Question of Divorce* (1911); *The Religion of the Church* (1916); *The Epistles of St. John* (1920); *Belief in God* (1921); *The Holy Spirit and the Church* (1924).

GORGAS, WILLIAM CRAWFORD (1854–1920), American army surgeon, was born at Mobile, Ala., Oct. 3 1854. He was educated at the University of the South, Sewanee, Tenn., and Bellevue Hospital Medical College, New York, taking his M.D. in 1879. In 1880 he entered the Medical Corps of the U.S. Army. During the Spanish-American War he served as major in the Medical Corps, and was sent, after the Santiago expedition, to Havana, where he was in charge of yellow-fever patients.

From 1898 to 1902 he was chief officer in charge of sanitation measures in Havana, and there conducted many experiments in connection with the discovery that yellow fever was transmitted by the mosquito. Because of his success in eliminating yellow fever there he was made assistant surgeon-general, U.S. Army, with the rank of colonel, by special Act of Congress in 1903.

In 1904 Gorgas was sent as chief sanitary officer to Panama, where two of the main obstacles to building the Canal were yellow fever and malaria. Here again his methods were so effective that in two years he eliminated yellow fever from the Canal region. Malaria also was brought under control. In 1907 he was appointed a member of the Isthmian Canal Commission by President Roosevelt, and the following year was U.S. delegate to the first Pan-American Medical Congress, held at Santiago, Chile. He was president of the American Medical Association, 1908–9. In 1913 he was called to the Rand Gold Mines in South Africa to suggest means for combating the frequent epidemics of influenza. This he found was largely due to crowding the labourers together in barracks. In 1914 he was made surgeon-general, U.S. Army, with the rank of brigadier-general, becoming major-general in 1916. In 1918 he was retired. He then became the permanent director of the yellow-fever work of the International Health Board of the Rockefeller Foundation. He went to Central America, and under his direction investigations of yellow fever were made in Guayaquil, Ecuador and Guatemala. In 1919 he accepted a contract with the Government of Peru to carry out a sanitary programme in that country. He died in London July 3 1920, and was buried in the Arlington National Cemetery, Washington, D.C.

GÖRGEI, ARTHUR (1818–1916), Hungarian soldier (*see* 12.256), died May 21 1916.

GORST, SIR JOHN ELDON (1835–1916), British politician (*see* 12.261), died in London April 4 1916. His son, SIR JOHN ELDON GORST, died at Castle Combe, Wiltshire, July 12 1911.

GOSSE, SIR EDMUND (1849–), British critic (*see* 12.268), retired from the post of librarian to the House of Lords in 1914. In the previous year his autobiographical *Father and Son* (1907) was crowned by the French Academy, and an edition of his *Collected Essays* was issued. In 1917 he published his important *Life of Algernon Charles Swinburne*, the fruit of his great knowledge of the poet and many years' friendship with him. He received numerous honours from universities and governments, British and foreign, and was knighted in 1925. He continued to write weekly critical articles in *The Sunday Times*, and selections from these were reprinted in *Books on the Table* (1921) and *More Books on the Table* (1923).

GÖTEBORG or GOTHENBURG, Sweden (*see* 12.271), with a population in 1923 of 227,343, is now the first port of Sweden and the chief centre of the shipbuilding industry. The value of its foreign trade increased from 811,409,000 kronen in 1915 to 1,725,061,000 kronen in 1924. The harbour, which has been considerably enlarged, is the largest in Sweden, and was made a free port in 1922; a dry dock was in course of construction in 1925. Göteborg is now a port of registry for steamers to all parts of the world, and is no longer only a port of call. The town, which is an important industrial centre, with over 400 factories in 1920, has an area of 7,407 hectares. The first Swedish fair, held in the town in 1918, was later recognised by the Government as an international industrial fair. Among new buildings are a commercial institute, Lorensberg (1914); a Latin high school (1919); the Natural History Museum in Slottskogen Park (1923); a fine public school (1917); and Masthugget church (1916). The Navigation School was rebuilt in 1916, and a marine museum, with models of vessels, shipbuilding exhibits, etc., was opened in 1913 and endowed with over 1,000,000 kronen in 1917. A new botanical garden was opened in the Anggården in 1923. The restoration of the Kristine church was undertaken in the same year. The railway line to Stockholm was undergoing electrification in 1926.

GOTO, SHIMPEI, VISCOUNT (1856–), Japanese politician, was born in Iwate-Ken and studied medicine in Germany. As the first civil administrator of Taiwan (Formosa) under Gen. Kodama in 1898, and as the first president of the South Manchuria Railway in 1906, he laid the groundwork of Japan's colonial enterprises. He was Minister of Communications in 1908 and 1912; of Home Affairs in 1916; Foreign Affairs in 1918; and mayor of Tokio (1921–2). He exchanged conversations with M. Joffe regarding the reopening of Russo-Japanese relations upon his own initiative and personal responsibility in 1922. After the great Japanese earthquake in 1923 he became again Minister of Home Affairs and president of the reconstruction board.

GOUGH, SIR HUBERT DE LA POER (1870–), British soldier, was born Aug. 12 1870, a son of Gen. Sir C. Gough, and joined the 16th Lancers in 1889. In 1911 he became brigadier-general commanding the III. Cavalry Brigade at the Curragh, where his attitude with regard to Ulster and the use of the troops in 1914 caused a grave political crisis (*see* ENGLISH HISTORY). He took his brigade to France in Aug. of that year, and after successive promotions was given command of the newly constituted V. Army; with this he played an important part in the battle of the Somme. In 1917 he was for some time in charge of the Ypres offensive, where his conduct of the operations received considerable criticism. The brunt of the great German offensive of March 1918 fell on his troops, who were unable to withstand the pressure and fell back with heavy loss in personnel and material. Gough's dispositions under circumstances of the utmost difficulty were appropriate, and responsibility for the disaster did not rest with him; nevertheless he was deprived of his command by the Government—punished, as was commonly said, for the failings of 1917, that had now been amply balanced. In 1919 he was for some months head of the British Mission to the Baltic States.

GOUIN, SIR LOMER (1861—), Canadian politician, was born at Grondines, Quebec, March 19 1861. Educated at Laval and McGill universities, he was called to the bar in 1884, and became Q.C. in 1900. In 1897 he was elected to the Quebec Legislature and from 1905 to 1920 was Prime Minister and Attorney-General of the province. He declined to join Sir Robert Borden's coalition Ministry, subsequently declaring his allegiance to the Liberal opposition. Knighted in 1908, Gouin received the K.C.M.G. in 1913. Sir Lomer was included in the Cabinet formed in 1921 by Mr. Mackenzie King, as Minister of Justice. He was one of the Canadian representatives at the fourth assembly of the League of Nations at Geneva, when he succeeded in obtaining an interpretation of article 10 of the Covenant in the form of a resolution. In 1924 he attended the Imperial and Economic Councils in London as one of Canada's representatives, but later in the year retired from politics. Gouin's first wife (d. 1904) was a daughter of Honoré Mercier, a former Premier of Quebec.

GOURAUD, HENRI JOSEPH ÉTIENNE (1867–), French general, was born at Paris on Nov. 17 1867. He entered St. Cyr in 1888, and was commissioned to the infantry in 1890. In 1894 he was seconded for duty under the colonial administration; and thereafter he gained much experience of active service in the French Sudan, in which he served almost continuously for two years. In 1904 he was promoted lieutenant-colonel, made commandant of the Chari (Congo) territory, and an officer of the Legion of Honour. In 1907 he was promoted colonel. He next served in Morocco, where he remained until the outbreak of the World War.

On Sept. 17 1914 Gouraud was promoted temporary general of division, and the following Jan. was appointed commander of the Colonial Army Corps. On Feb. 15 1915 he was made a substantive general of division. In May he replaced D'Amade as commander of the force in Gallipoli, where he was so badly wounded that his right arm had to be amputated. He was awarded the médaille militaire on July 10 1915. On recovering from his wound he went to Italy in charge of a mission, and then in Dec. 1915 he was appointed to command the IV. Army. A year later he was sent temporarily, as commissioner general, to Morocco; but he again took command of the IV. Army in June 1917. From 1915 to the summer of 1918 the sector of the IV. Army was relatively quiet, save for one moment in the spring of 1917 in which it was drawn into the ambit of Nivelle's offensive

on the Aisne, and at that time Gouraud was in Morocco. Thus, when on July 15 1918 the Germans launched their last offensive on the Champagne front, Gouraud had had little executive experience as an army commander in battle, and before the "zero" day Pétain had had some difficulty in convincing him of the necessity of a "coil spring" defence. But when the time came Gouraud carried out its principles admirably, and brought the Germans' last effort to a standstill in his battle zone. Gouraud was awarded the grand cross of the Legion of Honour on Dec. 28 1918. In Oct. 1919 he became high commissioner in Syria and commander-in-chief in the Levant. He was succeeded by General Weygand in 1923 and was appointed military governor of Paris.

GOURMONT, RÉMY DE (1858–1915), French writer, was born at Bazoches-in-Houlme (Orne) April 4 1858. He was descended from a family of painters and engravers well known in the 15th and 16th centuries, and on his mother's side from the poet Malherbe. He settled in Paris in 1883, and entered the Bibliothèque Nationale. In April 1891, however, he was requested to leave, after he had published an article in the *Mercure de France* entitled "Le Joujou Patriotisme." He continued to contribute to this periodical and to numerous other papers. His work, which is of great variety and extent, is remarkable for its bold and flexible ideas and great erudition, and his wide range of subject is shown by *Sixtine*, a "*roman de la vie cérébrale*," his *Esthétique de la langue Française*, a notable essay on language and phraseology to his series of *Promenades Littéraires* and his notorious *Lettres à l'Amazone*. He died in Paris Sept. 27 1915.

In addition to the works mentioned above he wrote: *Le Pélerin du Silence* (1896), *Le Livre des Masques* (1896–8), *Le Problème du Style* (1902), *Physique de l'Amour* (1903) and *Pendant la Guerre* (1917).

GOVERNMENT (*see* 12.292).—Short as it is, the period since 1910 has been momentous in the development of government. The period divides itself into three parts: the years before the War, 1910–4, the years of War 1914–8, and the years of reconstruction after the War. But in the history of government the years 1914–8 stand out in large letters. War, and especially modern war, sees the state writ large. Yet, divided as it thus is, the period 1910–26 should be seen also as a whole. For the ideas of state organisation and control which were put into practice in 1914–8 were forming in the preceding years of peace.

The steady growth in the functions of the state, especially in the seven years before 1914, made easier the task of the mobilisation and control of national resources in time of war. So again after the War, while the years of reconstruction saw a reaction against control, yet the range and the boldness of state action in war, and the magnitude and complexity of the problems of resettlement, left both the theory and the practice of the state more advanced than in the pre-War years. Despite therefore, the exceptional conditions of the years of War, the period presents a unity in its development greater than at first sight appears. As events recede and the period can be seen from a greater distance this will become more evident.

The General Idea of the State.—In judging the position of the theory and practice of government at any period of time it is useful to ask three questions: (1) What changes have there been in the general idea of the state? (2) What developments stand out in the forms of government? (3) What is most noteworthy as regards the scope and functions of the state? The most fundamental question is, What change is there in the general idea of the state? Three things in this period deserve special emphasis. First, the remarkable growth in the sphere of government. The period might be called that of the changing state, with a great and on the whole steady increase in the functions of government. The movement of state and community control, which had been gaining momentum for over a generation, extends in a wide variety of directions. The movement is universal, inasmuch as it shows itself in varying forms and degrees in all countries with a developed system of self-government, and with a highly organised economic life.

Second, there is the growth in the moral idea of the state. Right not might is the valid basis of the state, but the significance of this wins recognition slowly. Yet this period will be seen to mark a great advance in this respect. The state exists to make life good. The idea of social justice reveals itself more fully both in the relations of the individual to the state and in the relations of states one to the other. The challenge to the crude theory of the state as might is made in deed as well as in word. There is a new emphasis on the truths that there can only be one morality for the individual and the state, and that, as the state exists to secure justice, its acts, as much as those of the individual, must conform to common moral principles.

The third aspect is the new emphasis on the value of the individuality or personality of the individual and of the group. The end of the state is the individual. The doctrine of sovereignty becomes less formal and dogmatic. The idea of the community transcends that of the state. For the community embraces the great family of groups and associations which the state must recognise as also sharing with it in the expression of man's social and political nature.

I. FORMS OF GOVERNMENT

There have been in the period very important developments in the structure of government, international, national and municipal. But of these by far the most memorable has been the great international constitution embodied in the Covenant of Nations 1919. The establishment of the assembly and of the council of the League, with their regular meetings and with their important array of permanent and special committees, the organisation of the secretariat of the League, the establishment of the international labour bureau under the Treaty of Versailles, and the creation of the Permanent Court of International Justice, (*q.v.*) are achievements of the highest significance in the history of government. The years 1899–1910, opening with the first Hague Convention, had seen a great advance in international arbitration and methods of peaceful co-operation; the crucial year 1914 had seen the ratification of the first of the treaties between the United States of America and other countries to submit all questions under dispute to a tribunal of investigation before recourse to war; but it is above all to the years 1919 and after that one must look for the foundations of the international polity.

Second, this period has been marked by the importance and variety of developments in government within the British Empire—in itself a league of nations, whose constitutional experience has had a peculiar value for the great world League. The Union of South Africa in 1910, expressed in a constitution distinctive in type from that of the other great federations within the British Empire; in the Government of India Act of 1919, embodying a bold experiment in diarchy; the constitution of the Irish Free State, under the Government of Ireland Act 1922, with the status of a Dominion; and the establishment of the Parliament and Government of Northern Ireland, under the Government of Ireland Act 1920, the first example of legislation and evolution within the United Kingdom, are events of great constitutional interest.

Meanwhile important developments have taken place affecting the general system of relations within the Empire. The imperial conference of 1911—the organisation and work of the committee of imperial defence, the development of the imperial War cabinet in 1917–8, and the conscious advance towards fuller equality of status with the mother country on the part of the Dominions—especially the world recognition of the Dominions and of India as member states in the League of Nations, and the efforts made by post-War conferences to provide more effective methods of imperial consultation and co-operation—mark the period as one of the highest importance in the constitutional history of the British Empire.

Third, this period will be notable for the advance throughout the world in the adoption of representative forms of government and in the progress of democratic ideas and institutions. The political constitutional changes since 1910 in China, including the establishment of a republican form of government, are the most striking indication of the changing East. However super-

ficial and subject to reaction many of these changes may be, they are evidences of the will to learn from the political experience of the West, and, with Eastern participation in international institutions of government, are part of the great movement which is bringing the world closer together.

In Europe itself the World War brought many changes in government, and the new constitutions in Germany, the Baltic States, Poland, Czechoslovakia and Yugoslavia mark the advance throughout Europe of common representative forms of government. In most cases these new constitutions show an acceptance of the cabinet idea of responsible government, but methods of direct popular judgment through the referendum and the initiative have also a wide place in modern European constitutions. Notable also is the widespread adoption, in new and old constitutions, of proportional representation.

It remains to be seen how far the organisation of government on these lines is going to provide a sufficiently strong and stable executive, and how far experience may lead those nations which have adopted the system of parliamentary government to study and follow more closely the British model, which has secured a greater measure of stability and of clearness of responsibility than has resulted from other types of parliamentary government.

Trend Towards a Working Harmony.—In this connection also it may be noted that the trend of opinion, based on experience during the period, has been in favour of the system which secures close harmony between the legislature and the executive. In states where the established system was based on a more marked acceptance of the division of powers, and where, as in Sweden, the constitution presented a "dualistic character," development has been steadily towards greater harmony between the parts of government, giving thereby a more unitary character to the constitution. Even in the United States of America, the great example of the separation of powers, there has been an increasing recognition of the value of closer relations between the parts of government, and the working system of the constitution seems to be moving towards the realisation of this object. In this connection one of the most notable developments has been the adoption of a budgetary system by the Federal Govt. in 1921, as well as by individual states of the Union. In general it may be said that the increasing body of comparative evidence on the practical efficiency of different methods of legislative and administrative organisation is bringing about a closer approximation of the different forms of government one to another, and a clearer understanding of the qualities and defects of each type.

While this has been happening in the progress of a representative government, it is also important to recognise that in this same period there has been a great increase in the critical attitude of mind in almost all advanced countries towards the working of representative institutions. Discontent with parliamentary and congressional institutions has been vocal, and the reaction has expressed itself in various ways. In Russia, with the revolution of 1917 a new system of government, based on councils of soldiers, workers and peasants, has been developed. The challenge of this type to the established representative system of parliamentary government has not so far succeeded in the states of Central and Eastern Europe which have given themselves new constitutions since 1918. On the other hand, especially in the Southern European states, the reaction against the weakness and corruption of government has led to the establishment of a series of dictatorships which, even when they maintained the form of parliamentary government have denied it the substance of power. These reactions from representative government are significant. War increases the strength of the executive, and the experience of the first years of peace emphasised the need of authority and leadership. But, apart from this, there has been a growing recognition that, even in normal times, good government in democratic States requires clearness of responsibility and the power to act, and that in many cases representative institutions, parliamentary and congressional, have dissipated power and obscured responsibility.

Functional Representation.—In another direction, closely related to the foregoing, the period has also shown interesting developments in the growth of ideas and of institutional forms expressing what is called functional representation. The school of thought which has given prominence to these ideas has in its more extreme expression challenged the authority of a parliamentary system based on regional representation, and has sought to replace this by methods which would directly reflect the opinions of the various economic and social groups within the community. The vogue of this school of thought has been due, not simply to dissatisfaction with the working of the existing forms of representative government, but also to a sense of the importance of securing the expert knowledge of the group mind and of giving to the groups the largest measure of self-government and control in the development of their functions.

In practice, the great increase in the organisation, not only of industrial and economic but of social and cultural groups within the body politic, extending often beyond national boundaries, has influenced the institutions of government, local, national and international. Nowhere is this more clearly seen than in the formation of representative councils or committees, usually consultative, but in some cases invested with considerable statutory authority, which have been associated with the public departments of administration in Great Britain. In Germany the place given in the new constitution to the economic council of the empire is an expression of the same tendency. This does not, however, involve the overthrow of the well-established forms of representative government. Gradually the adjustment of the new to the old order is taking place, and the theory of representative government is thereby enriched and strengthened. For there is no alternative to representative government if democracy is to survive in the modern world. Such at least seems to be the trend of progress through the changing complex of political, social and economic conditions.

It is worthy of note also that in this political evolution there is going on a process both of centralisation and decentralisation. In all federal states there has been during this period a marked growth in the power of the central government, while in states with a more unitary type of constitution, like Great Britain and France, methods of devolution and of regional reconstruction have been making headway. But in both types, centralisation and decentralisation are actively proceeding, a consequence of the growth in the functions of the state and of clearer differentiation of the powers which should belong respectively to local, national and international authority.

Nor should the increased attention in this period to local government, urban and rural, be overlooked. Nowhere have developments in this field been more significant than in the United States. The great amount of experiment in that country in the forms of municipal government indicates a more active period of interest in local affairs, while the progress of the municipal home rule movement is a further expression of the democratic idea that government must be decentralised, and that the sense of local responsibility has to be safeguarded in the great modern nation state. Thus this period has brought forth important developments in international, federal, national and local government. It will stand out also as one in which the nations have been coming nearer to one another in constitutional thought and in forms of government.

II. FUNCTIONS OF THE STATE

The years 1910–25 have seen a great extension in the functions of the state. In the last quarter of the 19th and to an increasing degree in the first decade of the 20th century the state has been abandoning the policy of *laissez faire*, and building up a constructive plan of community action, aiming at better social and economic standards of life. In education, in public health, in provision for housing, in factory and workshop standards, in the regulation of industrial disputes, in the development of municipal services, the new idea of the functions of the state was being progressively revealed. The years 1906–10 opened up rich fields of state activity; and 1910–4 saw further important developments, which, however, were checked by the outbreak of hostilities.

Extension of State Activity.—In Great Britain the establishment of the development commission and of the road board marked a new constructive policy of state aid. Thus, the resources placed at the disposal of the development commission enabled a comprehensive scheme of agricultural research to be undertaken, while later the establishment under the Privy Council of the committee for scientific and industrial research, and of the medical research committee were further recognition of the great and growing function of the state in this sphere. The road board was also the forerunner of developments of state policy in co-ordinating and controlling transport, culminating in later years in the establishment of a ministry of transport. So again the pre-War years saw the establishment of national health insurance and the first steps in the development of unemployment insurance under the National Insurance Act of 1911.

The outbreak of war led to a great extension of state functions. Voluntary methods gradually gave place to state control. The regulation of man power, the control of imports and exports, the nationalisation of the supplies of munitions, the regulation of agricultural production, the rationing of food supplies and of raw materials for industrial requirements—these and other measures of state action demonstrated the power of state organisation in time of war. Peace brought with it a reaction. Nevertheless, after the War there remained a wider idea of community right and obligation. The gravity of the problem of unemployment led to measures of relief by central and local authorities of a character and amount hitherto unknown. The state has also been called upon to exercise extended functions in relation to the national resources of coal, power and transport; while the development of a much more comprehensive policy for the assistance of agriculture and forestry and the establishment of the Food Council are indications of the steady growth in state function.

Voluntary Effort.—But side by side with the growth of governmental power is the increase in voluntary economic and social organisation, and in the association of voluntary with statutory bodies in the work of government. There is great significance for the future in this renascence of voluntaryism. It marks a new stage in the development of government, in which not simply do the people by their votes choose their rulers, but in which to an increasing extent they are associated with the administration of government in its many branches. The state is becoming more flexible. The organisation of the community is proceeding, not simply by bureaucratic efficiency, but by the democratic method of making the people experience to an increasing extent, through voluntary organisations, the part which they alone can fill in the work of government.

Just as the theory of *laissez faire* had to yield to changing conditions, so the theory of a socialistic state, meaning thereby state ownership, state operation and state control, is giving place, at least in the Anglo-Saxon countries, to a conception of community life, in which there is not only room for individual and voluntary organised effort, but in which it is seen that the increase of state action to be really effective and desirable has to be accompanied by a growth in the more flexible forms of association which come under the category of voluntary and self-help movements. It may well be that, as the Anglo-Saxon race has contributed beyond any other people to the development of representative institutions of central and local government, so the political genius of the race may reveal the part which voluntary associations have to play in the development of democracy and in the meaning of community life. In all these respects the period 1910–25 is significant in the history of government. (*See* SOCIAL SERVICE.)

BIBLIOGRAPHY.—The main sources of evidence for the study of modern governments are to be found in the official records of parliamentary proceedings in the several countries and in the reports of the administration departments and of special commissions on committees of inquiry. For the text of the constitutions W. F. Dodd, *Modern Constitutions* (1909) and P. Dareste, *Les constitutions modernes* (1910) are the most convenient collections while the most useful source for the post-War constitutions is the *Jahrbuch des öffentlichen Rechts* (Tubingen). As regards general studies of modern government, Viscount Bryce, *Modern Democracies* (1921); A. Esmein, *Éléments de droit constitutionnel français et comparé* (1921) and G. Jellinek, *Allgemeine Staatslehre* (1922) are of standard value. A wide range of studies of government in War time has been issued by the Carnegie Endowment for International Peace. A useful series of studies in governmental organisation is published by the Institute for Government Research (Washington, D.C.). (W. G. S. A.)

GRACE, WILLIAM GILBERT (1848–1915), English cricketer (*see* 12.308), died at Eltham, Kent, Oct. 23 1915. His elder brother, EDWARD MILLS GRACE (1841–1911), died at Thornbury, Glos., May 28 1911. See F. S. A. Cooper, *W. G. Grace, Cricketer* (1916), Lord Hawke and others, *The Memorial Biography of Dr. W. G. Grace* (1919).

GRAF, ARTURO (1848–1913), Italian poet and critic (*see* 12.315), died at Turin May 29 1913. *Poesie*, a collection of his best poems, appeared in 1915.

See Sartori Treves, *Arturo Graf, romanziere e poeta* (1904).

GRAIN ELEVATOR.—The term elevator has been universally adopted on the North American continent to describe a granary consisting of deep bins or silos, the grain being elevated to the top of these bins for the purpose of filling them. It is also commencing to be generally used by such other countries as have adopted this method of grain storage.

The grain elevator is the natural outcome of the bulk-handling

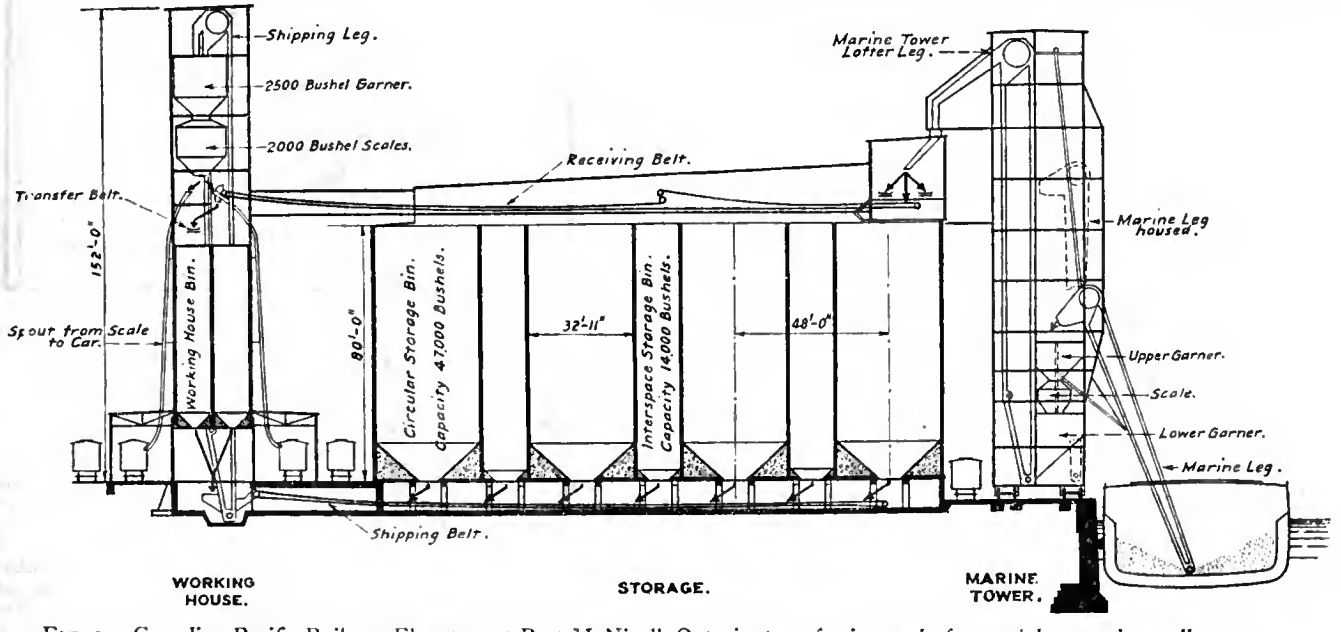

FIG. 1.—Canadian Pacific Railway Elevator, at Port McNicoll, Ontario, transferring grain from a lake vessel to railway cars. Its storage capacity is 4,000,000 bushels.

system as distinguished from the bagging system, and it is this that makes it possible for a port, equipped with up-to-date elevators and grain galleries, to receive and ship out such vast quantities of grain as are handled at Canadian and United States ports, of which Montreal holds the premier position with an export record of over 4,000,000 tons per annum. Previous to the introduction of the bulk-handling system, grain was, and still is, in many countries, handled in bags. To attempt to handle a large grain crop in bags is about as economical as supplying city water in buckets instead of water mains. Grain is a semi-fluid material, and the bulk-handling system uses this fact.

Distribution of Elevators.—Although Canada and the United States are still the only countries in which grain is handled entirely in bulk through elevators, there has been a noticeable movement toward this method in several other countries and already there are examples of up-to-date elevators in Europe, Australia and the Argentine. Russia has a few dotted over her vast grain territory, and South Africa has also made a commencement. The complete bulk-handling plan adopted by the New South Wales Govt. with its chain of elevators from the grain growing districts to the ports and a 5,500,000 bushel terminal elevator at Sydney, is the most complete example of a bulk-handling system of elevators outside North America, the entire system having been constructed under the supervision of the Metcalf Co. of Montreal. The two elevators at Manchester and also that at Dock One, Buenos Aires, are examples of this type by the same company.

Capacity.—The storage capacity of the elevators of the United States is approximately 1,000,000,000 bu.; that of Canada 250,000,000 bu. and the portion of the Australian system already completed 20,000,000 bu., whilst the entire up-to-date elevator storage of the remainder of the world probably does not exceed 5% of the totals of those countries.

Construction.—Until about the end of the 19th century, elevator bins were almost universally constructed of wood, but about that time a demand for a fireproof form of construction began to be felt, owing to the heavy losses by fire and, to some extent, to the increasing price of timber. Steel plate and also tile bins commenced to take the place of those of wood, but this era did not last owing to the introduction of reinforced concrete, which has become practically universal for this class of building.

Use of Concrete.—Since the adoption of concrete as a material of construction, the size of elevator bins has been considerably increased. Circular bins of over 30 ft. in diameter are quite common, and the depth has been increased to as much as 110 feet. The square form of bin, which was almost essential in wood construction, has been largely superseded by circular concrete bins. Another marked advance since 1910 is the general adoption of individual motor drives to all units of machinery, such as belts and lofter legs, and the substitution of silent chain or double-helical gears as a means of power transmission in place of the rope drives formerly used.

Car Dumpers.—One of the most drastic changes in American elevators for many years has been in the method of unloading grain from railroad cars. Until quite recently this was done by means of power shovels. The inner grain door of the car was removed by means of a crowbar and frequently destroyed in the process. Two large scoops or shovels were then carried to the ends of the car by hand and automatically drawn back by ropes operated by drums on the line shaft. This method, although still in general use, entails considerably more man power and more time than is at all in accordance with modern ideas on grain handling. The mechanical car dumper, which automatically opens the grain door without damaging it and dumps all the grain out through the doorway of the car without any manual labour, is being rapidly adopted in the newest types of elevators.

The operation of the Metcalf car dumper is as follows: The car to be unloaded is hauled on to a platform about 58 ft. long, over rails which are in line and continuous with the track rails at either end of this platform. The car, having been run on to this platform, is automatically clamped in position. The platform, with the car, is then raised 10 ft. by means of wire cables, and simultaneously tilted sideways through an angle of 14° and the grain door rammed in. The platform with the car upon it is then tipped endways, first in one direction and then in the other, until all the grain has run out into a pit with a hoppered bottom below rail level. The grain is drawn off from this pit on to a belt conveyor, is conveyed to an elevator leg, carried up to scales above bins, weighed and distributed in the usual manner.

One of these car dumpers is capable of unloading seven 2,000-bu. cars per hour, and as there are batteries of four dumpers at the Harbour Commissioners of Montreal Elevator No. 3, the Baltimore and Ohio Railroad Company's elevator at Baltimore and the Santa Fé Railroad Company's elevator at Kansas City, each of these plants has an unloading capacity of 28 tons per minute. (L. C. H.)

GRAIN PRODUCTION AND TRADE (*see* 12,322).—According to the official statistics furnished to the International Institute of Agriculture, the production of cereals in those countries for which figures are available during the period was as follows:—

World Production of Principal Cereals (Russia and China excluded) Millions of cwt.

	Average 1909–13	Average 1919–23	1923–4	1924–5	1925–6
Wheat . .	1,590	1,621	1,836	1,627	1,753
Rye . .	503	410	447	357	491
Barley . .	486	415	487	442	520
Oats . .	980	948	1,062	1,019	1,094
Maize . .	1,705	1,713	1,804	1,527	1,759
Total . .	5,264	5,107	5,636	4,972	5,617

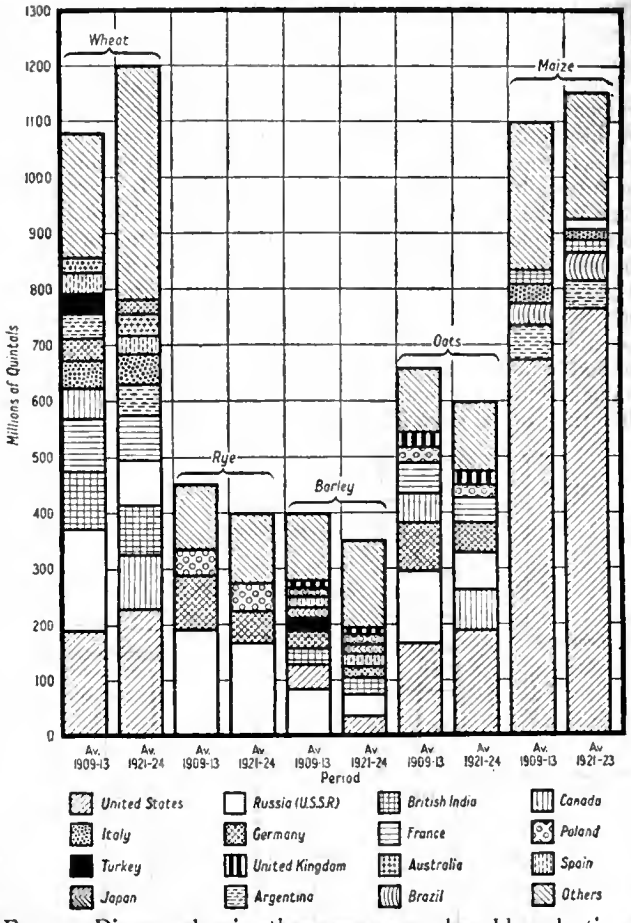

FIG. 1.—Diagram showing the average annual world production of Wheat, Rye, Barley and Oats, for the period 1909–13 to 1921–4, and of Maize for 1909–13 to 1921–3. The production in the principal producing countries for which figures are available is indicated. "Others" includes the production in Egypt, Hungary, Mexico, Rumania, Yugoslavia and the other minor producing countries, and an estimate of production in those countries for which no figures are available. The diagram is based on figures given in the International Yearbook of Agricultural Statistics for 1924–5.

These statistics do not include the crops of Russia or China, but they give an approximate indication of the yields in the rest of the world. Apart from those two countries, the world's production of these five cereals taken together on the average of the five years after the Armistice was nearly up to the pre-War average. In 1923–4 the world had an exceptionally good crop of cereals, 7% above the pre-War average, but in the following year 1924–5 the yield was poor, being 6% below the pre-War average. In 1925–6 the harvests were exceptionally good, 13% better than in 1924–5, practically equal to the good yield of two years before, and 7% above the pre-War average. According to official statistics furnished for Soviet Russia, its average yield of these five cereals for the five years before the World War was 1,247,000,000 cwt., in 1924 it was only 767,000,000 cwt., and in 1925–6 increased to 1,069,000,000 hundredweight. This last estimate was perhaps too sanguine, as the Russian harvests suffered from bad weather; but it may be said that for the world as a whole, including Russia, the yield of these five cereals in 1925 was much better than it was in 1924, and somewhat higher than the pre-War average.

These five grains form a large proportion of the food of the inhabitants of the temperate regions, but perhaps nearly as much grain in the form of rice and millet is consumed by the inhabitants of the tropical and sub-tropical countries. The world's yield of rough rice (excluding China) in 1924 was 1,613,000,000 cwt., as compared with 1,413,000,000 cwt., the pre-War average, and if statistics for China were available it would appear that in the world as a whole the weight of rough rice produced is greater than that of wheat. Of that quantity 132,000,000 cwt. was exported, as compared with the wheat export of 430,000,000 hundredweight.

I. THE WHEAT YIELD

Yield.—The yield of wheat in those areas for which comparable statistics are available was approximately as follows:—

Yield of Wheat in Millions of Quarters of 480 lb.

Area	Average 1909–13	Average 1919–23	1923–4	1924–5	1925–6
Europe (excluding Russia)	167·8	135·5	155·0	130·2	170·7
North America	112·3	145·1	160·7	143·2	137·7
Asia	48·7	49·0	52·0	50·8	46·8
Africa	12·5	12·4	14·1	11·4	14·5
Argentina	18·4	23·5	31·0	23·9	26·8
Australia	11·3	12·7	15·6	20·2	12·5
Total (excluding Russia)	371·0	378·2	428·4	379·7	409·0
Soviet Russia	94·2	..	..	47·7	82·7
Total (including Russia)	465·2	..	..	427·4	491·7

These figures do not include China and a number of unimportant countries, and it may be roughly estimated that on the pre-War average the whole world produced about 490,000,000 quarters. The statistics for Soviet Russia are not very trustworthy, but, if they be included, the totals indicate that, for the world as a whole, the wheat harvest of 1925–6 is considerably above the pre-War average. For the countries other than China and Soviet Russia, it appears that on the average of the five years after the War the yield of wheat was about equal to the pre-War average. On the average of the three years 1922–3 to 1924–5 their yield was 405,700,000 qr.—that is, 9% above the pre-War average.

If a comparison be made between the average pre-War yield and the average yield of 1922–3 to 1924–5, it appears that the average yield of Europe (excluding Russia) has decreased from 168 to 152 million qr., and there is a very large but indeterminate decrease in the yield of Soviet Russia. The average yields of Asia and Africa were much the same as before; but there was an increase in Canada from 25 to 48 million qr., in the United States from 86 to 97 million, in Argentina from 18 to 27 million, and in Australia from 11 to 16 million. These increases more than made up for the decrease in the average yield of Europe and Soviet Russia. The average yield of wheat in the whole world may be therefore roughly reckoned at about 500 million qr., of which about 50 million qr. are grown in the Southern Hemisphere and reaped in Dec. and Jan., while the remaining 450 million qr. are grown in the Northern Hemisphere and reaped at various times between March and October.

Import and Export.—As the production and consumption of wheat are much more important in the Northern than in the Southern Hemisphere, it is convenient to adopt for the world's cereal year the 12 months ending with July, just before the principal new harvests are reaped north of the equator. For cereal years so calculated the following statistics give approximately the net imports and the net exports of different areas, flour being reckoned as wheat at the rate of three of flour equal to four of wheat.

Net Imports of Wheat in Millions of Quarters

Area	Average 1909–14	Average 1914–9	Average 1919–22	1922–3	1923–4	1924–5
Importing countries of Europe	69	..	69	70	70	80

Total all exporting countries (including others not mentioned above)	82	70	81	87	100	93

Apart from the years of war, the demand for wheat from abroad of all the importing countries of the world was, on the average of the three years after the War, much the same as it was on the pre-War average, but on the average for the three cereal years completed in 1925 it increased from the pre-War 82 to 93, having risen to 100 in 1923–4, when wheat was cheap owing to the exceptionally good harvests of that year, and fallen again to 93 in 1924–5, when the price of wheat had risen owing to comparatively poor harvests.

The demand of the British Is., which import about 30% of the whole world's surplus for export, remained remarkably steady, notwithstanding great fluctuations in price, and averaged 28,000,000 qr. for 1922–5, *i.e.*, from Aug. 1 1922 to July 31 1925, as compared with the pre-War average of 27,000,000 quarters. Belgium and Holland taken together imported an average of 8,200,000 qr. as compared with their pre-War average of 8,900,000 quarters. The demand of France, Italy and Germany, which produce a large proportion of the wheat they require for their consumption, varies considerably. On the average of the years 1922–3 to 1924–5 France's import was 5,400,000

qr. compared with the pre-War 5,500,000, but it rose to 6,500,000 in 1923–4, when prices were low, and fell to 3,900,000 in 1924–5, when prices were high. Italy's import averaged 11,500,000 qr., against the pre-War average of 6,600,000 for a smaller population, but it was considerably higher in 1922–3 and 1924–5, when Italy had poor harvests, than in 1923–4, when she had a very good harvest. Germany's average import was 6,100,000 as compared with the pre-War average of 8,500,000 qr. for a larger population; and it was only 3,700,000 in 1923–4, when her own harvest was fairly good but her currency was disorganised, and rose to 9,900,000 in 1924–5, when her harvest suffered greatly from wet weather, and her exchange was on a better footing. Greece, with her increased population, has raised her average import from 900,000 to 2,300,000 quarters. Egypt's average is much the same as pre-War. Japan has raised her average from 500,000 to 2,200,000 qr., but this includes the exceptional import of 3,500,000 qr. in 1923–4, due chiefly to the effects of the great earthquake.

The many importing countries outside Europe, for which detailed statistics are not available, including China, Brazil and other tropical and sub-tropical areas, have apparently imported on the average of 1922–3 to 1924–5 about 20,000,000 qr. against the pre-War average of 13 million. They are even more ready than the European countries to increase their consumption of wheat when it is cheap and to lessen it when it is dear, and they imported much more wheat in the cheap year for wheat 1923–4, when rice was comparatively scarce and dear, than in the year before or the year after, when wheat was dearer and rice cheaper.

As regards the exporting countries, the most remarkable feature was the disappearance of Russia as an exporter. Before the War the Russian Empire on the average produced 102,000,000 qr. of wheat, more than one-fifth of the world's total yield, and exported annually 20,500,000 qr., one-fourth of the world's exports. On the average of the three years after the War, she imported 3,000,000 qr., largely as famine relief, and during the three years 1922–3 to 1924–5 she imported nearly as much as she exported. In the year 1925 she had a much better harvest. The Danubian countries also, Rumania, Bulgaria, Yugoslavia and Hungary, which before the War had an average export of 13,200,000 qr., on the average of those three years exported only 2,400,000, their average yield having fallen off from 39,200,000 to 30,000,000 qr., no doubt owing largely to the impoverishment caused by the War and to the partition among the peasants of the large estates, which formerly furnished a great part of the exports. India had before the War an average yield of 43,800,000 qr., and an average export of 6,200,000 quarters. During the five war years her average yield was 44,000,000 and she exported an average of 3,700,000 quarters. The three years 1919–21 included two poor harvests—the average yield was only 37,800,000 qr., and there was practically no net export; but the three years 1922–4 were years of good harvests, with an average yield of 45,600,000 and an average export of 3,600,000 quarters. This makes the average consumption of these three years about 42,000,000, against an average pre-War consumption of about 38,000,000 quarters. Apparently India utilised her increase of prosperity to increase her consumption of wheat, more especially as during part of that period wheat was unusually cheap and rice unusually scarce and dear.

While Europe and Asia thus failed to maintain their former supply of surplus wheat, the deficit was more than made up by North America, Argentina and Australia, although their exports varied greatly from year to year. During the five war years Canada increased her average export from 11,800,000 to 19,700,000 qr., the United States from 13,400,000 to 27,500,000 qr. and Argentina from 10,300,000 to 11,000,000 quarters. Australia's average export remained about 6,600,000 qr., the difficulty of transport over such a great distance in time of war having made it impossible to export the whole of her surplus. On the average of the three years 1919–20 to 1921–2 Canada exported 18,400,000, the United States 31,300,000, Argentina 18,700,000, Australia 12,500,000 qr.; and on the average of the three cereal years 1922–3 to 1924–5 their exports were, Canada 34,500,000, the United States 21,000,000, Argentina 18,100,000 and Australia 10,600,000 quarters. Thus on the average of these three years the requirements of all the importing countries of the world, amounting to 93,000,000 qr., were supplied approximately in the following proportions: Canada 37%, United States 23%, Argentina 19%, Australia 11%, India 5%, other countries 5%.

Consumption.—If it be assumed that the consumption of a country during a cereal year is represented by its yield plus or minus the quantity imported or exported, the following statistics give a rough idea of the consumption of certain countries for which comparable statistics are available:—

Consumption of Wheat in Millions of Quarters

Country	Average 1909–14	Average 1914–9	1922–3	1923–4	1924–5	Average 1922–5
British Isles	34·4	32·7	35·2	36·5	35·0	35·6
France	45·1	36·8	36·1	40·9	39·0	38·7
Italy	29·5	30·2	34·6	36·9	32·5	34·7
Germany	27·5	..	13·7	16·7	21·1	17·2
Canada	12·8	12·1	13·6	16·2	13·1	14·3
U.S.A.	72·3	75·2	85·0	83·5	82·7	83·7
Argentina	8·0	8·3	8·5	8·5	8·5	8·5
Australia	4·7	7·2	6·4	6·5	6·0	6·3
India	37·6	40·2	42·2	44·1	40·8	42·7

During the World War the importing countries of Europe had great difficulty in obtaining the wheat they required from abroad, and took special measures to reduce the consumption of wheat; and as a result of these measures, and of the great rise that took place in the price of wheat, several of those countries considerably reduced their average consumption. For the British Is. the pre-War average of 34,400,000 fell to an average during the War of 32,700,000 quarters. On the average of 1923–5 it rose to 35,600,000 qr., while the population increased from 45,200,000 in 1911 to 47,400,000 in 1921. During the War the French consumption was reduced from the pre-War average of 45,100,000 to 36,800,000 quarters. For 1922–3 to 1924–5 it only averaged 38,700,000 qr., although the population (including Alsace-Lorraine) was practically the same in 1922 as it had been in 1911. On the other hand, the people of Italy found it difficult to keep down their consumption of wheat, and during the War the average annual consumption increased from 29,500,000 to 30,200,000 quarters. For 1922–3 to 1924–5 it averaged 34,700,000 qr., the population having increased from 34,700,000 in 1911 to 39,700,000 in 1923. The consumption of wheat per head in Germany is much less than it was before the War, as, according to the statistics, the average consumption of 1922–3 to 1924–5 for a smaller population was only 17,200,000 qr. as compared with the pre-War average of 27,500,000 quarters. Canada and the United States, with an increased population, consumed correspondingly increased quantities. Australia during the War was unable to export the whole of her wheat surplus, and much of it was wasted or was still in the country at the end of the War. Her average consumption for 1922–3 to 1924–5 was 6,300,000 qr. as compared with 4,700,000 qr. before the War, owing chiefly to increase of population. India also had difficulty in exporting her wheat surplus during the War, and her consumption therefore increased. For 1922–3 to 1924–5 it averaged about 42,000,000 as compared with the pre-War average of 38,000,000 qr. although the increase of population between 1911 and 1921 was only from 315,000,000 to 319,000,000.

The Question of Price

The price of wheat varies greatly according to its variety, cleanliness, purity, uniformity, strength and condition. It also varies often very rapidly, with reported changes in the world's weather and expected changes in the relation between the world's supply and the world's demand. The cost of ocean freights is another factor in the calculation. The pre-War average freights on wheat imported into the United Kingdom were approximately per qr. of 480 lb.: from New York 2s., from Buenos Aires 3s. 6d., from Karāchi 4s. and from Australia 7s. The pre-War average prices of wheat, in importing countries, after deducting import duties, were approximately, per quarter of 480 lb.: Britain, home-grown 32s., imported 35s.; France 32s.; Italy 33s.; Germany 32s.; and Austria 37s.; and in exporting countries—Russia 33s.; United States (Chicago) 30s.; Canada (Winnipeg) 30s.; India (Karāchi) 31s.; Argentina (Buenos Aires) 31s. and Australia (Melbourne) 31s. Owing to the cheapness of ocean freights there was no great difference in the average prices in importing and in exporting countries; and hardly anywhere in the world, except in places far from the sea, or in countries where there was a high import duty, was the pre-War average price of wheat below 30s. or above 35s. a quarter.

During the War, owing to the destruction or immobilisation of many ships, to urgent military requirements and to the increase of risks, there was a great rise in ocean freights, and after a time the British Govt. took control of the whole merchant shipping of the

Empire and of the arrangements for the import of wheat, not only into Britain, but into the Allied countries also. At the date of the Armistice freight rates being paid for wheat per qr. to the United Kingdom were—from New York 50s., from Buenos Aires 48s. and from Karāchi 53s. After the Armistice the control of shipping was maintained for a considerable time, but the rates of ocean freight fell very rapidly, and by Dec. 1920 (when the movements of shipping were practically freed from control) the rates were approximately—from New York 8s., from Buenos Aires 8s. 7d., from Karāchi 9s. 1d. and from Australia 22s. 6d. After that date there was a further great fall in these rates, and in Nov. 1925 they were approximately—from New York 3s., from Buenos Aires 3s. 4d., from Karāchi 4s. 3d. and from Australia 8s. 9d.—that is to say, freight rates were not very much higher than before the War, and as prices were about 55% higher than before the War this meant that shipowners in 1925 brought wheat to Britain on payment of only about two-thirds of the pre-War value in commodities. This great fall in the commodity value of freight rates was no doubt mainly due to the fact that the world's gross tonnage of seagoing steel and iron steamers had increased since 1914 by 38%, while the quantity of merchandise requiring cargo space was less.

In order to trace the course of the world's price of wheat during the period 1913–25, it will be sufficient to quote the prices of wheat about the middle of Nov. (when it is usually possible to frame an approximate estimate of the yield of the harvests in the northern hemisphere and of their probable yield in the Southern Hemisphere) for Chicago and Winnipeg as representing the exporting countries, and for London or Liverpool as representing the importing countries, to which may be added the average price obtained about that date by farmers in England and Wales for home-grown wheat, according to the corn trade returns.

Price of Wheat about Nov. 15

Year	Chicago cents per 60 lb.	Winnipeg No. 1 Manitoba, cents per 60 lb.	London or Liverpool No. 1 Manitoba, shillings per 480 lb.	England and Wales Home-grown shillings per 480 lb.
1913	88	83	34	31
1914	114	119	48	35
1915	108	104	57	53
1916	184	200	77	69
1917	217	221	83	70
1918	223	224	80	72
1919	227	224	78	73
1920	188	211	116	90
1921	119	111	50	46
1922	117	106	49	42
1923	105	97	44	40
1924	156	167	66	54
1925	164	140	55	48

During the War the price of wheat rose rapidly both in exporting and in importing countries. After the Armistice, the price of wheat continued to rise for a time, and in July 1920 wheat sold both in Chicago and Winnipeg at about 280 cents per bushel—more than three times its pre-War price. Soon after that date government control began to be removed and freights and prices rapidly fell, and by Nov. 1921 the price of wheat at Chicago was only 119 cents per bushel and at Winnipeg 111—that is, only about 35% above the pre-War average. In the following two years there was a further fall, and in Nov. 1923 the prices quoted were at Chicago 105 and at Winnipeg 97—that is, less than 20% above the pre-War price. Similarly in the British Is. the price of wheat rose until in Nov. 1920 No. 1 Manitoba wheat was being supplied by the Govt. at 116s. per qr., and the British farmer was being paid about 90s. per qr. for home-grown wheat. These prices again were about three times the pre-War prices, but it must be remembered that they were reckoned in sterling, and that in that year the British paper pound was only worth about 75% of the gold sovereign. After control was removed there was a very rapid fall in the price, and by Nov. 1921 Manitoba wheat was selling in Liverpool at 50s. per qr. and British wheat was sold at 46s.—that is, about half the price obtained 12 months before. There was a further fall of price in the following two years, and in Nov. 1923 Northern Manitoba wheat sold at 44s. and British wheat at 40s. per qr. or only about 30% above the pre-War price.

These very low prices in 1923 were no doubt mainly due to the exceptionally good harvests of that year, both in Europe and in the world as a whole, and to the impoverishment of the importing countries of Europe. The low price continued through the winter of 1923–4; but after May 1924 drought developed in south and southeastern Europe, and Canada and central and northern Europe suffered a cold, wet summer, and it became evident that the harvest in the Northern Hemisphere as a whole would be a poor one. The world price of wheat accordingly rose rapidly until at the end of Feb. 1925 the price of No. 1 Manitoba in Liverpool was 76s. 6d.—61% above its price 12 months before. It then came to be realised that this price was higher than was justified by the prospects, and the price fell rapidly in March and April to about 60 shillings. In consequence of the good harvests of 1925 in the Northern Hemisphere it fell further to 55s. in the middle of Nov. 1925, but then rose again owing to the disappointing harvests in the Southern Hemisphere, and in Jan. 1926 was about 62s.—almost double the pre-War price, while the British farmer was getting 53s. a qr. for his home-grown wheat—about 70% above the price of 1913.

(J. Wt.*)

II. THE GRAIN MARKETS

Great Britain is the only country where the demand for imported wheat is constant and extensive. There are many others which import wheat from time to time, but merely by way of supplement to their home-grown food crops. These circumstances have resulted in the establishment of the London grain trade in the commanding position of the chief market of the world, primarily for wheat business, but also for maize, oats and barley. It is not only for delivery in London itself that this trade is done. A very large portion is for other destinations, and cargoes for ultimate discharge in Scotland, Ireland or Wales, at Dutch, Belgian or German ports, or even in the Mediterranean, are bought and sold by London brokers, on the accustomed basis of London contracts. A considerable business in grain from overseas which does not enter London is registered daily in the grain trade journals, cargoes of wheat and maize forming the greater portion.

The usages and terms of the London market are matters within the competence of the London Corn Trade Assn., a corporate body including members of all grain trade firms of consequence, in Great Britain, on the continent of Europe, and among exporters from North and South America, from India, Australia and Africa. Brokers and traders in all the principal towns of Britain, and millers with establishments in many parts of the world, find it advantageous to belong to the London Corn Trade Association. Most of those not strictly connected with London are also members of their own local associations, of which the Liverpool Corn Trade Assn. is the most important, and is followed by those of Hull, Bristol, Leith, Antwerp, Hamburg, Genoa, etc. The main object of these associations is the protection of the common interests, by defining terms of contract, by providing for arbitration in cases of dispute, and by taking measures to uphold the rights of traders against infringement. The predominance of North America among the grain markets of the world is an outstanding fact, and it is not too much to say that the wheat quotations of Chicago and Winnipeg are those most regarded as deciding the course of the world's grain trade from day to day. In some seasons the Chicago price is all-important, in others it shares supremacy with Winnipeg. The qualities quoted are so well known that is is needful only to mention No. 2 Winter or No. 1 Manitoba in order to afford a definite basis of transactions. In this respect the business in North American grain is done on terms differing from those adopted by other exporting countries.

In the United States and in Canada the system of government inspection of grain for settling grades is very efficient, and the certificate of the government inspector is accepted as final. By far the greater part of the grain business in the United States is in connection with produce intended for internal consumption or manufacture, and the terms agreeable to American buyers have therefore to be accepted by exporters from the United States. In Canada the relative size of overseas trade is much greater, but the system of inspection and grading is even more precise than in the United States, and is accepted by exporters. In dealing with Argentina, whence the tropical passage may cause the grain to deteriorate on the voyage, the contract basis throws this risk on the shoulders of the exporter in South America, and wheat is sold with a guarantee of natural weight to be verified at discharge of the grain. Wheat from Australia is sold as fair average quality at time and place of shipment, and similar stipulations are made in the special contract form for Indian wheat, with a guarantee in case of damage by weevil, or deterioration by the excessive mixture of barley or any other extraneous matter.

By far the larger portion of the world's wheat crops finds its way to the flour-mill, though some considerable quantity is used for cattle or poultry food. The miller, therefore, may be set down as the ultimate buyer of wheat. With the gradual consolidation of mills under the management of a few leaders of the industry, each of these millers has become, individually or in his corporate capacity, a very important factor in the grain trade. He is, in most cases, the original buyer of grain for British ports, to be discharged direct from the ship into his warehouse communicating with the mill by grain elevators and conveyors. In the British grain trade of to-day there is very little scope for the merchant who formerly purchased a wheat cargo for apportionment in suitable quantities amongst millers. The miller does not manufacture flour entirely from one cargo, or even from one sort of wheat. In the ordinary way, when supplies from various exporting countries are plentiful, he will probably mix three or four different kinds, in carefully defined percentages, in order to provide the baker with just such flour as he has been accustomed to sell to the public.

In most of the exporting countries there are well-established firms who employ agents to buy from the farmers, and thus collect adequate quantities for loading their chartered ships. In countries such as Canada and Australia the farmers themselves have formed pools or syndicates, with managers who negotiate with exporters. In the United States, grain export business is so interdependent with future trading that it may be more conveniently treated under that heading. With the exception of relatively small parcels of wheat, very little is sold on the corn exchanges after arrival. It has become the practice for millers to buy, even for their minor requirements, when the grain is still overseas or on passage. It is also customary for bakers to contract two or three months ahead for flour to be delivered, and these contracts are sometimes made with Canadian, Australian and American millers.

Futures.—Apart from direct sales of overseas wheat to millers, considerable business is done by traders who buy wheat for shipment and, either immediately or later, sell a similar quantity for delivery at a future period. This future delivery trading, known also as *marché à terme* or *mercado á término*, originated in the United States and has been established at Liverpool for nearly half a century. It was adopted at Buenos Aires in 1908 and is now carried on at Winnipeg. There are future delivery exchanges, including grain contracts, at Antwerp, Paris, Berlin, Genoa, etc. At Chicago and Buenos Aires futures trading is established for wheat, maize and oats; at Winnipeg for wheat and oats; in all three and in Liverpool wheat absorbs the chief attention. It may be considered as essential that, to avoid cornering, a future delivery exchange should have an ample available supply of such qualities of wheat as are in favour with millers; in other words, the exchange should be located on a main route of transit between the grower and the consumer. Unless this condition is fulfilled the business organisation seldom succeeds.

By means of one or other of these exchanges the farmer can, if he chooses to do so, sell his crop of wheat whenever the price suits him, months before it is ready for the reaper, and thus practically eliminate any risk of falling prices. The miller who has purchased a cargo of wheat can sell an equal quantity in the form of contracts for future delivery. Naturally, he will not find this course desirable unless there is an apparent profit between the price paid for his cargo and that obtainable for future delivery of wheat. He has also to buy wheat for his mill, and if he sells the contracts for future delivery his next enterprise is to sell the flour to be manufactured later, and as he achieves this to buy in his wheat contracts. He thus makes four transactions in place of the simple purchase of wheat abroad and the sale of flour at home. He has safeguarded himself against market losses, and is ready to continue his day-to-day disposal of the flour. It will be noted that in selling wheat for future delivery in a given market he has to rely upon others for fulfilment of these wheat contracts, for he does not intend to deliver from his purchased cargo; hence it is clearly his aim to deal only on markets where there is a steady influx of wheat.

This series of transactions needs only to be multiplied indefinitely, and attributed to traders who are not millers, in order to form a basis of opinion on the grain futures markets. Speculation of course exists, and may carry prices too high or too low. Fluctuations in quotations for future delivery are often extreme and very rapid, for on receipt of some information affecting crops the first interpretation of its meaning is shown in the future delivery market. Sharp fluctuations are not, however, always misfortunes. The purchaser of a wheat cargo who has duly sold futures against it may find that his contracts for sale can be repurchased at a discount of say 3 %, and that he can resell his cargo at a discount of 2 %. He may probably do the business both ways and come out with a net profit of 1 %; he has sacrificed 2 % on the original price of the cargo, but the sacrifice is more than compensated by the 3 % gain on the future delivery side.

Future trading involves, in effect, a daily settlement by seller and buyer alike of difference in price arising from market fluctuations, and a payment by both parties at the time of making the contract of a cash margin according to the regulations which form part of the contract stipulations. In all four markets, Chicago, Winnipeg, Buenos Aires, Liverpool, the grain trade clearing house attends to these matters, keeping a registry of the contracts entrusted to it by members of the association which carries out the future delivery business; non-members are not recognised by these associations as entitled to obtain this security of position. The penalty for non-payment of differences at the appointed time is the immediate sale or purchase, as the case may be, of all contracts standing in the name of the defaulting member in the clearing-house registry. These powers are entrusted by their own members to the Liverpool Corn Trade Assn. to the Chicago Board of Trade, the Winnipeg Grain Exchange and to the Buenos Aires *Mercado á Término de Cereales*, respectively.

At Chicago, which is by far the greatest grain futures market, there has always been an avoidance of strictness in procedure as regards details, and a resulting immense business in contracts for future delivery. The trade is in contracts for future delivery, not in wheat for future delivery, and it is not surprising that this business in contracts should annually reach an aggregate far exceeding the U.S. yearly wheat crop. The tenderable descriptions of wheat comprise many varieties; in practice, Hard or Red Winter wheat is the effective basis. There are certain specified places where delivery may be made, and American farmers make great use of the Chicago Board of Trade.

At Buenos Aires the Mercado á Término not only registers the contracts submitted to the clearing house, but in consideration of a small fee takes up the contracts with buyer and seller respectively, accepting the responsibility towards each party during the currency of the contract. It therefore devolves upon the Mercado to call for sufficient margin, and to collect the day-to-day differences. Naturally the Mercado, in its own interests, keeps strict watch over the extent of trading done by its members, and the managers can call for increased margins if they are dissatisfied with the position created. The basis of the wheat contract is the typical wheat of the country in sound condition, with the proviso that the natural weight attains the requisite standard. Delivery may be made at any railway station in the republic, with adjustments for transport expenses just as is customary in transactions for immediate delivery.

In Liverpool wheat may be delivered from any of the following descriptions: American winter or spring Manitoba, Argentine or Australian, provided that the sample fulfils the requirements of grade.

Maize.—The trade in maize is a very large one, though not equal to that in wheat; except in Mediterranean and Danubian lands all maize consumed in Europe is imported, chiefly from Argentine and South Africa. Although the enormous maize crop in the United States comprises three-fourths of the world's yield of maize, very little of it is sent abroad; the United States are not usually sellers of maize on European markets, though it is generally possible to buy this grain from them for special requirements, by paying a moderate premium. The course of prices for maize is governed by quite different factors from those which affect the wheat market. The extent of consumption in some European countries varies greatly at different seasons of the year, for droughts may reduce the hay and fodder crops and throw the demand on maize, or a season favourable to field growth may curtail requirements seriously. The United States maize crop is chiefly consumed locally, for hog or cattle feeding, and most of it is therefore never sold as maize on the open market. Any examination of market conditions in the United States is therefore incomplete unless the meat and provision trades are also studied. Of all the varieties of grain brought from overseas, maize requires the most care in selection for an ocean voyage. It contains a larger percentage of water than does wheat, and is also more likely to spoil by heating, if put on board soon after harvest or in the summer weather of six or eight months later.

Barley.—Most of the oversea trade in barley is in the varieties suitable for malting or distilling; compared with wheat or maize the business is small, and in few hands. On the British markets, the supplies of home-grown barley and those of all kinds of foreign barley are about equal in quantity, so that brewers and maltsters can select the desired quality from either source. The suitability of barley for malting is one of the technical studies of the grain trade, and a really accurate judgment on a particular sample is not an easy matter. California and Canada are the main exporters of good malting barley, but these crops are seldom equal in quality to that of England. Russian and Danubian barley are classed much lower down than Canadian, but generally contain a valuable percentage of grains fit for malting, separable by machine.

Oats.—The British trade in oats is chiefly in home-grown grain; of the country's ordinary requirements over 80 % is produced in the British Is., and a very large proportion is used locally for dairying or other cattle food, or horse provender. Imported supplies are chiefly from North America.

Rye.—Finally, rye enters little into trade in Great Britain. The great producing countries are Russia, Poland and Germany, whence supplies are drawn for Belgium and Holland also. Germany is sometimes a buyer and sometimes a seller, while Russia, with an immense production, did not offer to sell for export in 1925, except during harvest time. Except under the stimulus of high post-War prices the United States has not grown rye at all freely, and now exports but little. (J. H. Hu.)

GRAMOPHONE: *see* PHONOGRAPH.

GRAND RAPIDS, Mich., U.S.A. (*see* 12.350), had a population of 137,634 in 1920 of whom 28,355 were foreign-born, including the largest colony in the country from The Netherlands (11,422). In 1925 the official estimate was 153,698. Annexations of territory in 1915, 1924 and 1925 increased the area to 22 square miles. While the city kept its title as "the furniture capital of America," the manufacture of aeroplanes and other essential products during the World War led to the permanent expansion and further diversification of industries. The commission-manager form of government was adopted in 1916. The aggregate value of manufactured products rose from $42,231,100 in 1909 to $109,135,000 in 1919, and, after a slight decrease in 1921, to $130,277,997 in 1923. In 1925 a reconstruction of the city was under way in conformity with a comprehensive city plan, adopted in 1922. The public schools were in process of reorganisation and a junior college had been added; there was a supervised playground within half a mile of every child's home; the filtration plant, built in 1914, had been doubled in size; a sewage disposal plant was under construction; several fine hotels, hospitals and office buildings had been erected. Grand Rapids is second only to Des Moines in the proportion of homes owned (50·2% in 1920). It has a high proportion of children at school, a small amount of child labour, a low percentage of illiteracy, a low general death-rate and a low infant mortality.

GRANT, DUNCAN (1885–), British painter, was born at Rothiemurchus, Inverness-shire, son of Major Bartle Grant, and was educated at St. Paul's School, London. He early showed his remarkable decorative sense, working with Roger Fry at the Omega Workshops, London, and at the same time produced some highly individual painting. His early work included "The Lemon Gatherers" (1911), now in the Tate Gallery, and the "Seated Woman" (1912). Modern French influences, particularly those of Cézanne, made themselves strongly felt in his design and brushwork, as may be seen in the "Tightrope Walker" (1918), "Snow Scene" (1921), "The Hammock" (1923) and many still-life pictures of this period. Grant, who became a member of the London Group, also carried out interesting domestic and scenic, decorations and designs for embroideries. See Duncan Grant, *A Collection of Plates*, with introduction by Roger Fry (1923).

GRANVILLE-BARKER, HARLEY GRANVILLE (1877–), British playwright, was born in London Nov. 25 1877. At the age of 13 he was sent to the Theatre Royal, Margate, then a combination of stock company, theatre and dramatic school. He first appeared in London in the following year, at the Comedy Theatre, under Charles Hawtrey. His first play, written in 1893, was produced by amateurs. From 1895 onwards he acted in a variety of plays, in Shakespeare with Ben Greet, and, with William Poel, in *Richard II.* and Marlowe's *Edward II.* In 1899, his play *The Weather-hen* (written in collaboration with Herbert Thomas) was produced in London. In 1900 he became interested in the newly formed State Society, first as actor, then as producer, and his own play, *The Marrying of Ann Leete*, was produced by the Society in 1901. In 1903 he collaborated with William Archer in the framing of *A Scheme and Estimates for a National Theatre*. In 1904 he joined J. E. Vedrenne in the management of the Court Theatre, London. There, during three years he produced, and at first acted in, a variety of plays by Ibsen, Bernard Shaw, St. John Hankin, John Galsworthy, John Masefield, Maurice Hewlett, Gilbert Murray (translations from Euripides) and his own *The Voysey Inheritance* (1905). In 1906 he published *Prunella* in collaboration with Laurence Housman. A later play, *Waste* (1906), was banned by the Censor, but was privately performed by the Stage Society. *The Madras House* (1909) was produced by the Frohman Repertory Company at the Duke of York's Theatre in 1910, and a revised version of it was revived in 1925. By 1910 he had given up acting, but until 1914 produced plays in London, including two by Shakespeare upon a platform stage with "conventional" decoration. After the War he maintained no active connection with the Theatre. He published various other works, including *The Exemplary Theatre* (1922), dramatic criticism, also translations of several foreign authors. He was public lecturer on the art of the theatre to the University of Liverpool in 1921–2 and he delivered the British Academy Shakespeare lecture in 1925.

GREAT BRITAIN.—The following article is a continuation of the one on the UNITED KINGDOM (*see* 27.598). The change in title is rendered necessary by the altered political status of Ireland. As the change took place during the period under review reference must necessarily be made to Irish affairs, but primarily the article is concerned with Great Britain only (*i.e.*, England with Wales and Scotland), with the lesser islands belonging thereto. It deals with seven matters: (I.) Constitution; (II.) Local Government; (III.) Defence; (IV.) Finance and Banking; (V.) Population; (VI.) Industry and Trade, including agriculture; (VII.) Communications. (*See* also BRITISH EMPIRE; ENGLISH HISTORY; IRELAND, NORTHERN; IRISH FREE STATE; SCOTLAND; WALES.)

I. CONSTITUTION

The years 1910–25 were momentous in the history of the British constitution. They opened with an acute struggle between Lords and Commons which has left a permanent mark on the constitution, in the shape of the Parliament Act. Four years later, with the outbreak of the World War, the country entered on a period of arrested development; a truce was called between the two great political parties and a kind of constitutional moratorium declared in which the operation of the Parliament Act, alike in its application to the duration of Parliament and to the machinery of legislation, was arrested; two statutes, the Welsh Church Act and the Government of Ireland Act, which had been forced through under its automatic action, were suspended.

During the same critical period many rules of the constitution—some statutory, others conventional—were also in abeyance; the re-election of Ministers, on acceptance of an office of profit under the Crown, was one; the cabinet system, in its normal aspect, was another. A kind of super-cabinet, known as the War Cabinet, came into existence, and with it another constitutional novelty, the "Cabinet Secretariat" as a liaison between the Government departments. The liberty of the subject, as the result of that *lex regia* the Defence of the Realm Act and its successors, coupled with a latitude of judicial interpretation which reached its high-water mark in *Rex* v. *Halliday* (*ex parte Zadig*), underwent severe restrictions, and, for the period of the

War and some time beyond it, the country lived under a kind of statutory martial law as unprecedented in its history as the tremendous struggle which necessitated it.

Return to Constitutional Principles.—With the end of the War and the return to normal conditions of existence, constitutional principles reasserted themselves. The courts of law, always jealous of the liberty of the subject, administered severe and salutary checks to the encroachments of the executive, and a series of remarkable judicial decisions, most notably *Chester* v. *Bateson* ([1920] 1 K.B. 829) declared one "D.O.R.A." regulation after another *ultra vires*, while at the same time, in the great constitutional case of *De Keyser's Royal Hotel* v. *the King* ([1920] A.C. 508; [1919] 2 Ch. 197), the courts asserted, if they did not actually extend, the right of the subject to sue the Crown by petition for losses sustained as the result of the exercises of the prerogative in the matter of requisitions. The Defence of the Realm legislation lapsed with the efflux of time, though not the bureaucratic temper to which it ministered, and Parliament, in endowing the executive with somewhat similar powers, in cases of "emergency," under the Emergency Powers Act 1920, was careful to impose the most stringent parliamentary checks upon their exercise. As the result of the De Keyser case, the executive found itself threatened with thousands of claims for compensation, and an Indemnity Act, imposing a time-limit upon such claims and establishing a special procedure for dealing with them, was placed on the Statute Book. The Act had been most jealously scrutinised in its passage through the legislature, and it soon became apparent that Parliament was as little inclined as the judiciary itself to tolerate a continuance of the usurpations of the executive, whose sole justification had been their temporary character. With the fall, in Oct. 1922, of Mr. Lloyd George's Coalition administration, the conventions of the constitution resumed their sway.

Statutory and Other Changes.—It would, however, be a great mistake to regard post-War conditions as testifying to a mere reversion to type. Great statutory changes of a permanent character took place, the most notable of which were the Representation of the People Act 1918, the Parliamentary Qualification of Women Act 1918, and the Sex Disqualification Removal Act of 1919, statutes which, among other things, effected a complete revolution in the civic position of women, removing, as they did, all disqualifications of sex for admission to the franchise, to a seat in the Commons, to service on juries and all public functions. Constitutional changes of equal magnitude were effected by the grant of self-government and Dominion status to Southern Ireland, and by the establishment of representative legislatures and, in some measure, of self-government in India (*see* INDIA). Equally important were the developments in the status of the Overseas Dominions (*see* BRITISH EMPIRE; CANADA, etc.).

Many statutes of considerable constitutional importance, dealing with legal procedure and the administration of justice, were enacted during the years 1920–5, such as the Administration of Justice Acts 1920 and 1925, the Judicature Act 1925, the Criminal Justice Act 1925; and for a long time two such fundamental rights of the subject as procedure by indictment before a grand jury and trial by jury in civil actions at common law were seriously threatened as the result of innovations during the War, which, long after its termination, appeared likely to perpetuate themselves by statute. Another Act of considerable constitutional importance was the British Nationality and Status of Aliens Act 1918, which amended the British Nationality and Status of Aliens Act of 1914. The period under review was also notable for the number of leading cases in constitutional law. Moreover, the growing political consciousness of the working classes had, even before the War, been productive of new conditions, some permanent, others transient. One was the judicial decision known as the Osborne case (*Osborne* v. *Amalgamated Society of Railway Servants* [1909] A.C. 87), resulting in legislation (the Trade Union Act of 1913) for the protection of minorities against the political levy on members of trade unions; another, of which the issue has yet to be seen, was the claim to the active exercise of political power. The policy of direct action, *i.e.*, the exercise of political pressure upon the Government of the day by resort to the weapon of a general strike, was the immediate cause of the action of Parliament in conferring drastic powers on the executive, in case of emergency, to deal by proclamation with any such threats to the normal economic life of the community. The Govt. exercised this power effectively during the general strike of May 1926.

The appearance of a minority Government in 1923 raised a constitutional question, long dormant, namely the right of a Prime Minister, even though in a minority in the House of Commons, to ask and receive authority from the King to dissolve Parliament. This was a question as to which there could be no real doubt in the minds of those acquainted with constitutional developments since 1858, but none the less it had been the subject of much dispute when Mr. Ramsay MacDonald accepted office in Jan. 1924. His exercise of this prerogative of the Crown in the following Oct. may be said to have settled the question beyond further dispute.

THE PARLIAMENT ACT AND OTHER MEASURES

Parliament.—The enactment of the Parliament Act in 1911, consequent upon the rejection of the Finance Bill by the House of Lords in the preceding year, limited the authority of the House of Lords. (*See* ENGLISH HISTORY.) It was an emergency measure, designed to secure the immediate passage into law of a Liberal Govt's. legislation. The preamble recognised this to the extent of admitting the necessity of further legislation "to substitute for the House of Lords as it at present exists a second chamber constituted on a popular instead of a hereditary basis." The implied promise has never been redeemed and the problem still awaits solution, a solution that has become all the more imperative in view of the vast extension of the franchise effected by the Act of 1918, the peculiar sensitiveness of post-War governments to public opinion, and the appearance on the political scene of a new and powerful party whose avowed object is to revolutionise the economic basis of society by legislation. Nor did the authors of the Act foresee its constricting effect upon the legislative procedure of the House of Commons itself. The confusion in which the Government of the day found itself involved in its financial legislation during the session of 1914 was an indirect consequence of the Parliament Act, for new questions as to the legitimacy of tacking non-financial provisions on to finance and revenue bills were raised.

The discretion given to the Speaker under the Act, of deciding whether, in giving or withholding his certificate, a bill comes within the new statutory definition of a money bill, has invested his ancient office with a judicial authority the particular exercise of which no government can foresee. That authority has hitherto been exercised with the complete independence characteristic of the Speaker's office, but the new powers conferred upon him, constituting as they do the sole constitutional safeguard against sudden and revolutionary legislation by a party temporarily in a majority in the House, may yet expose the office to political capture—to quote the expression of the Trade Union Congress in Oct. 1924.

The effects of the provisions of the Parliament Act confining the Lords to a suspensory veto in ordinary, as distinct from financial, legislation have been less apparent, as only two measures had, up to the end of 1925, been forced through under their operation; but they have invested the process of legislation in the Commons with a new rigidity, owing to the necessity of any bill, which is to take advantage of the automatic machinery of the Parliament Act, retaining the character of the same bill in each successive session. An incidental result is the restriction of the right of private members to propose amendments to a government bill, by way of suggestion, in its later and automatic stages.

The constitutional crisis of 1910–1 was productive of another statute, equally novel but much less revolutionary in its character—the Provisional Collection of Taxes Act. That crisis disclosed the fact, long known to constitutional lawyers, that the budget resolutions under which duties are collected have no legal force, and, as the result of the case of *Bowles* v. *the Bank of England* ([1913] 1 Ch. 57), it was found necessary to enact a statute giving, for the future, statutory effect, for a limited period of time, to Ways and Means resolutions varying or renewing taxation imposed during the preceding financial year.

The procedure of the House of Commons during the period under review has undergone little change and the problem of how to secure more effective control of the House over the estimates remains exactly where it was. It is essentially a problem of parliamentary time, which is limited, and the increasing devolution of the legislative functions of the whole House to standing committees has, with the increasing demand for legislation, not solved the question. A new departure was made in 1921 by the appointment of an estimates committee, but it is confined by its terms of reference to considering what economies can be effected "consistent with policy," which in practice means that it had no power to deal with questions which Ministers choose to regard as outside its jurisdiction. The mere fact that its reports are presented after Supply is concluded has deprived it of any effective voice in the control of expenditure.

An interesting departure in the grant of legislative autonomy to the Established Church was effected by the Church of England Assembly Powers Act of 1919. Under the Act powers of legislation are delegated to the newly constituted National Assembly of the Church, but subject always to the control of Parliament to be exercised through an "ecclesiastical committee" consisting in equal numbers of members of both Houses. Upon the report of this committee, measures submitted by the Assembly shall, if approved by a resolution of both Houses, be presented to His Majesty for the royal assent in the same form as a bill. The co-ordinate authority assured to the House of Lords by this Act, and the legislative independence secured to members of both Houses, is a noteworthy departure, but the legislation contemplated does not, of course, partake of the character of a government bill. None the less the Act is a noteworthy experiment in devolution.

The Electorate.—The electoral changes effected by the Representation of the People Act were immense, far surpassing in magnitude the three Reform Acts of the preceding century. Not only did it enfranchise women and add no less than 13,000,000 electors to the register, but it also altered and simplified the law of registration, effected a redistribution of seats, abolished the property qualification and, much more questionably, removed the pauper disqualification. At the same time it reduced the qualifications for the exercise of a vote, in the case of men of 21 years of age, to the simple requirement of six months residence, or, in the alternative, occupation of business premises, either or both of which might confer the right to vote, not more than two votes being so conferred. In the case of women the minimum age is 30, and the basis of qualification has to be sought in the local government franchise. Innumerable other changes in the machinery of registration and election were effected by the Act. Taken in conjunction with the two Acts previously mentioned its effect is, except in the matter of age, to assimilate the civic status of women entirely to that of men. A curious anomaly exists, however, in regard to the position of peeresses. The wife of a peer may be elected to the House of Commons, but a peeress in her own right may neither be elected to the Commons nor take her seat in the Lords: this was the decision of the Committee of Privileges in *Viscountess Rhondda's Claim* (1922).

The Cabinet and the Ministry.—An important, if limited, change in the law governing the acceptance of office by Ministers was effected by the Election of Ministers Act 1919. Temporary measures had been passed during the War relieving new Ministers on appointment from the necessity of seeking re-election; the Act in question perpetuated this departure, to the extent of providing that no member on appointment should in future vacate his seat if his acceptance of office should take place within nine months after the issue of a proclamation summoning a new Parliament. For such a measure there is much to be said, in that it dispenses with the necessity of a whole Ministry, constituted on the resignation of its predecessor after a defeat at the polls, from being subjected to the hazards of a by-election. In 1926 the House of Commons passed a measure designed to dispense altogether with the necessity of seeking re-election on the acceptance of office.

Some of the new ministries created during the War disappeared, but four became permanent—Pensions, Labour, Transport and Air, the last being responsible for the creation of a new Secretaryship of State. The number of Secretaries of State was further raised to seven by the Secretary for Scotland being raised to that dignity. The status of the Dominions overseas has been recognised by the creation of a Secretaryship of State for the Dominions, but though legally distinct from the Secretaryship for the Colonies it is united with it in the person of one and the same minister. The Local Government Board was reorganised and renamed the Ministry of Health. With the establishment of the Irish Free State the Irish Office was abolished and Irish affairs were transferred to the Colonial Office.

The immediate result of the War appeared to be the exaltation of the position of the Prime Minister to a personal ascendancy incompatible with the principles of cabinet government. The institution of the War Cabinet, whereby a small inner council of Ministers freed from all administrative duties decided all questions of policy—other Ministers being summoned to these deliberations at the discretion of the Prime Minister communicating with them through his own secretariat—could only be justified in time of grave national peril. The result was to place in his hands an almost exclusive power of initiative in Cabinet business, and to undermine the time-honoured principle of the collective responsibility of Ministers. The evil results of this system were manifest long after the War, with effects upon ministerial discipline which were forcibly illustrated by the circumstances attending Mr. Montagu's resignation of the seals as Secretary of State for India.

The disappearance of the War Cabinet, and of the Coalition Govt. of which it had been the offspring, marked a return to normal procedure. In two respects, however, the ascendancy of the Prime Minister would appear to have become permanent: one is that the Permanent Under-Secretary to the Treasury has come to be regarded as the head of the whole civil service, and as an official through whom the Prime Minister may exercise a certain degree of authority over all departments otherwise than through the Ministers in charge of them—possibly an anomalous position; the other is the precedent created by Mr. Asquith when he obtained from the King before the dissolution of 1910 a contingent guarantee that if the Government were successful at the polls such a number of peers would be created as the Prime Minister might think necessary to secure the passage of the Parliament Bill into law.

In one important respect the precedents created by the War Cabinet have left their mark on the constitution. The Cabinet Secretariat, although completely disestablished as an instrument in the hands of the Prime Minister, survives to the extent that minutes of Cabinet proceedings are now kept by a permanent official, who is thus placed in a position of peculiar delicacy if not of peculiar authority. The tradition of "Cabinet secrecy" is to that extent changed. The departure has been much criticised by constitutional purists, but the exact position is obscure.

The Executive.—The outstanding constitutional problem is the continual encroachment of the executive either by using the prerogative or by the presumed exercise of statutory powers, upon the rights and liberties of the subject. The only safeguard against this tendency is the vigilance of Parliament and the independence of the judiciary. The term of office of the Labour Govt. was marked by an attack by the Prime Minister upon the independence of the judiciary in the person of Mr. Justice McCardie, who in the case of *O'Dwyer* v. *Nair* (reported in *The Times*, May 1–June 6 1924) had made certain observations on the attitude of the executive in the case of General Dyer. For this Mr. Justice McCardie was severely criticised in the Commons by Mr. Ramsay MacDonald. On behalf of the judge it was urged that the subject-matter of the judge's remarks was directly raised by the defendant in his plea of justification, and was therefore such as the judge was bound, by the duties of his office, to deal with. The claim put forward by the Prime Minister to the immunity of the executive from judicial criticism was a far-reaching one.

In the *Board of Education* v. *Rice* (1911) the court of appeal and the House of Lords had reminded a department that "it is not an autocrat free to act as it pleases," and had granted rules for the issue of writs of *mandamus* and *certiorari* to control its arbitrary disregard of the law in the exercise of the semi-judicial powers conferred upon it by the Education Act. In *Dyson* v. *the Attorney-General* ([1911] 1 K.B. 410, and [1912] 1 Ch. 158), the Court laid down for the first time that a subject threatened with penalties by the revenue authorities, for non-compliance with interrogatories which were *ultra vires*, had the same right of access to the courts for a declaration of the law against the executive as if the defendant were a private person. These cases are only two out of many. The whole subject is both too large and too technical to be dealt with here, but reform is urgent in two directions: (1) in the assimilation of the rights of the subject to sue the Crown to his rights against a private defendant, (2) in the restoration of both judicial and parliamentary control over the exercise of powers of "subordinate legislation" by Government departments. In one respect there has been a notable reform—namely, the Acquisition of Land (Assessment of Compensation) Act of 1919. This statute provides that where, in the pursuance of any statutory power, land is acquired compulsorily by any government department or local authority, the right of the owner to the assessment of compensation by an independent arbitrator, instead of an official valuer, is to be restored.

The Liberty of the Subject.—For some months during the War the subject was deprived of his rights to trial by jury even in criminal cases, under the Defence of the Realm legislation, but the suspension of this right was short-lived. In the case of the right to a jury in civil actions the situation was much more serious. For seven years, from 1918 to 1925, this right was taken away, and it was the exception, instead of, as hitherto, the rule, that a litigant in a common law action should, on demand, have the right to have his case tried by jury. In the case of *Ford* v. *Blurton* (38 T.L.R. 801) this invasion of an ancient right of the subject was vigorously criticised by the Court of Appeal itself, and the old rule was eventually restored by the Administration of Justice Act of 1925. So too the ancient process of indictment by grand jury was abolished during the War, and for it was substituted, as the accusing authority, the attorney-general. After the War, however, it was restored.

In the case of *R.* (*ex parte O'Brien*) v. *Secretary of State for Home Affairs* ([1923] 2 K.B. 361; A.C. 603), the executive, acting under an order in council which purported to be made under Defence of the Realm legislation, reincarnated as late as 1923 in the form of regulations under the Restoration of Order in Ireland Act, had

arrested, with a view to summary deportation to Ireland, an Irishman resident in England; he applied for a writ of *habeas corpus*. The Court of Appeal, in an exhaustive survey of this "subordinate legislation," severely criticised the action of the executive, declared the legislation in question *ultra vires* and granted the rule for the issue of the writ. The judgment may be regarded as the classical authority on the scope of *habeas corpus*, and the House of Lords, on appeal, upheld it, at the same time laying down the important principle that their appellate jurisdiction, while always available against a refusal of the writ, does not extend to an appeal against the grant of it—in other words, the right of the subject to summary release, on the determination of an inferior court that he is illegally detained, is established.

II. LOCAL GOVERNMENT

There have been no radical changes in the system of British local government since 1902, when the *ad hoc* education authorities, the school boards, were abolished and their functions transferred to the county and town councils. The hierarchy of local authorities stands in general as it was reorganised in the last two decades of the 19th century. In England and Wales the chief administrative units are counties, county and non-county boroughs, urban and rural districts and parishes.

The county of London has a unique subdivision into the city and the 28 metropolitan boroughs, and there are also in the metropolis and elsewhere a number of joint authorities for special purposes—asylum boards, hospital boards, water boards, burial boards, etc. Scotland has counties, burghs—royal, parliamentary and police—and district committees of the counties in place of the English rural districts. It also has *ad hoc* education authorities and lunacy authorities (district boards of control). The Scottish parish council is the poor law authority, corresponding to the board of guardians in England and Wales. Northern Ireland in the main follows the English system, while in the Irish Free State local government in 1926 was in the melting pot.

The principal reforms of recent years in Great Britain fall under four heads:—

1. The old central authorities, the Local Government Board and the Scottish Local Government Board, were abolished in 1919 and their functions transferred to new creations, the Ministry of Health (for England and Wales) and the Scottish Board of Health;
2. The local government electorate was enlarged by the Representation of the People Act 1918, which extended the vote to women and to certain classes of men hitherto disfranchised;
3. The Rating and Valuation Act 1925 remodelled the machinery of assessment and rating, abolishing the parish overseers and putting their duties in the hands of the county borough and urban and rural district councils;
4. Apart from these specific reforms there has been a general tendency to enlarge the powers of the local authorities, especially in the sphere of the social services. Acts dealing with maternity and child welfare, tuberculosis, venereal diseases, mental deficiency, housing and town planning and education, have all added considerably to the work of the county and town and district councils. At the same time the big towns have grown still bigger, not only by increase of population, but often by extension of their area through the absorption of surrounding districts.

All these developments have revealed grave defects and inconveniences in the system, and have led to a widespread demand for reform. The counties have struggled against the constant encroachments of the county boroughs. The county boroughs and the more important non-county boroughs and urban districts complain, and with reason, that while their functions have been increased they are still unduly controlled and thwarted by the central authority and Parliament. And the absorption of surrounding districts by the big towns and the expansion of public needs have made it more and more difficult to administer effectively such services as transport, water supply, electricity, regional planning, police, etc. This problem is particularly acute in the metropolitan area, and in 1921 a royal commission, under the chairmanship of Viscount Ullswater, was appointed to inquire into the local government of Greater London. The majority of the commission, however, reported unfavourably to any substantial change. They contented themselves with recommending:—

(*a*) Some redistribution of functions inside the administrative county;
(*b*) A reduction in the number of the petty local authorities in the outer districts;
(*c*) The creation of a statutory advisory committee to assist central departments in dealing with questions of transport, housing and town planning and main drainage;
(*d*) A scheme for further equalisation of rates within a 10-mile radius from Charing Cross.

There were two minority reports. The first proposed that Greater London should be made into a congeries of county boroughs with certain services reserved for administration by a centralised authority. The second recommended a new authority, popularly elected, for the governance of the whole area. This body would be directly responsible for all the large central services, and would require to have carefully defined powers of co-ordination and supervision of the work of the minor local authorities within its area.

In 1923 another royal commission was appointed, with the Earl of Onslow as chairman, to inquire in particular into the question of the creation and extension of county boroughs and generally into the constitution, areas, functions and mutual relations of all local authorities. It issued a first report in 1925, which proposed certain reforms in the machinery for creating or extending county boroughs. The most important of these were:—

1. All proposals for the constitution of county boroughs should be made by private bill instead of by provisional order. Proposals for the extension of county boroughs should also be made by private bill, unless the county borough concerned prefers the provisional order procedure and no other local authority concerned objects.
2. The minimum population entitling a borough to apply for county borough status should be 75,000, instead of 50,000.

This somewhat conservative report was generally regarded as a compromise, designed in the main to ease the friction between the counties and the towns. In 1926 the commission was preparing to deal with the second part of its reforms, which it was clear would be considerably affected by the proposed legislation for the break-up of the poor law.

The main problems, therefore, remain unsolved. New wine is bursting old bottles, and no general agreement has been reached as to the kind of new bottle that is wanted. On two points, however, there is a growing consensus of opinion. A concession must be made to the demand of the great municipalities for decentralisation—for local discretion, that is to say, to carry on their services or extend their enterprises, including "municipal trading" schemes, with less interference from Westminster and Whitehall. This power they claim in the interest alike of efficiency, economy and democracy. On the other hand, there is urgent need for a large measure of local centralisation, for the constitution of areas and authorities adequate to the performance of services which transcend existing boundaries. The attempt may be made to meet this need either

(*a*) By special joint committees of neighbouring local authorities for various services such as transport, water supply, electricity and so on; or, better, (*b*) by a more drastic reorganisation which would set up new authorities—"super-local authorities," so to speak—for these services, as well as for the general supervision of local government throughout their areas.

This was what the second minority report of the Ullswater Commission recommended for London, and it is obviously capable of application in other parts of the country. It is in principle the line of reform advocated by the "regionalists." Regionalism implies a re-organisation in which the whole country would be divided into a number of regions or provinces, say seven or ten or a dozen. These provinces would be natural and not merely artificial units, since different parts of the kingdom have distinct ties of common interest, both economic and "cultural" (*e.g.*, London and the Home Counties; East Anglia; the West Country; "Lancastria"). They would, it is claimed, be the most efficient possible units for administering the larger services; and on them would be devolved the bulk of the present central

authority's powers in respect of the supervision of the work of the subordinate, but largely autonomous, local authorities within each region.

Webb: *The Parish and the County* (1906); *The Manor and the Borough* (1908); *The Story of the King's Highway* (1913); *Statutory Authorities for Special Purposes* (1922); and *English Prisons under Local Government* (1922); also S. Webb, *Grants in Aid* (1920). (C. M. L.)

III. DEFENCE

In 1913 an important investigation was held by the Committee of Imperial Defence into the principles which govern the defence of Great Britain. For several centuries there had been two schools of thought. The one, supported by several eminent soldiers, held that it was necessary to maintain a large army for defence against invasion. The other, supported by the majority of great seamen, held the view that it was essential to the economic life and prosperity of the population to maintain a navy of sufficient strength to keep open their sea communications against any single foreign navy, or any anti-British combinations at sea; and that a fleet, strong enough to achieve that purpose, would also be in a position to secure the immunity of British territory from invasion by a foreign army. The invasion school met this plea with the argument that the British Fleet might be "enticed away" from home waters and the opportunity then seized to pass a foreign army across the Channel or the North Sea; and, furthermore, that the larger the home defence army, the greater the force that must be employed by prospectively hostile foreign countries for effective invasion, and the easier the task of the navy, upon which "freedom to manoeuvre" would thus be conferred during the lengthy process of assembling the hostile invading army, and transporting it across the intervening sea.

The Question of Invasion.—The invasion school was particularly active during the years immediately preceding the World War, partly in order to maintain the proposition that the recently-established Territorial Force was required mainly for home defence, as the terms of enrolment of its members seemed to indicate, and partly in order to support a widespread movement for the introduction of national service for a similar purpose. The controversy came to a head during the years 1913–4, when the Committee of Imperial Defence devoted much time to an exhaustive inquiry into the question whether invasion by a German army, bearing in mind the size of the German mercantile marine, was a more feasible proposition than invasion by a French army, which had been ruled out of court some years before, after a similar investigation by the Committee of Imperial Defence, mainly on the plea that French merchant shipping did not suffice for the purpose. The inquiry of 1913–4 resulted in the conclusion that invasion, defined as a military operation on a large scale intended to conquer the country, was not a danger against which it was necessary to make special provision under the then existing conditions of relative seapower, but that the landing of military "raiding forces" upon British shores was a possible contingency, against which military forces must be provided.

The situation was thus summed up by the late Sir Julian Corbett in his official history of the War:—

> The truth is that, with rare and special exceptions, as when the enemy's chief naval force was not based in the Home Area, our main or Grand Fleet always operated from its home station. Its paramount duty was to secure the command of Home Waters for the safety of our coasts and trade . . . . For defence against invasion the system was obviously the only one possible; for control of trade it had been found efficacious, and never more so than proved to be the case in the War of 1914..

In order to draw up definite plans to meet the assumed danger from military raiding forces in time of war, the War Office required definite estimates of the strength of such forces which might succeed in slipping past the naval dispositions. As the strength of these forces must depend upon the number and size of the transporting vessels, this was clearly a question for the Admiralty. The maximum strength agreed upon and accepted by the naval authorities was a military raiding force of 70,000 men, and Sir Julian Corbett has told us that, in naval opinion, no such raid was likely to be attempted except across the North Sea. In the actual event, the coasts of Great Britain were immune from military raiding forces in the World War, although on several occasions definite rumours of their probability caused the authorities to make dispositions for which considerable military forces were employed, at periods when there was an urgent need for their services beyond the seas. For instance, in March 1918, during the time of greatest anxiety for the safety of the British Army on the Western Front, over 41,000 officers and nearly 130,000 other ranks of the army, classed as "fit for general service in any theatre of war in all respects, both as regards training, physique and mental qualifications," were retained in the United Kingdom, while the total strength of the home army, mostly of men in lower categories, reached a total of nearly 2,000,000. In that connection it is also necessary to bear in mind the need to maintain military forces in Great Britain in aid of the civil power, should such a demand arise. The attitude of the population of parts of Ireland, which necessitated the presence in that country of British troops during and after the War provides an example.

There was yet another demand for soldiers in the United Kingdom, to guard, against "evilly-disposed persons," certain vulnerable points of which the loss or destruction would adversely affect the navy, army or air forces. Large numbers of men belonging to the combatant forces, most of them unfit for service abroad, were employed upon work of this nature, besides strong forces of police.

Personnel.—It was also necessary to provide military personnel, especially artillery and engineers, to man the defended ports and naval bases and anchorages, essential for the use of the navy, mercantile marine, and troop transports. The arrangement between the Admiralty and War Office was that the army should be responsible for the fixed defences, guns, forts, electric lights, and so forth and for defence of the land fronts, while the Admiralty provided floating booms as obstructions, and, at some places, submarine mines and the personnel connected therewith. The Admiralty also made arrangements for an examination service, to visit and examine vessels before they were allowed to enter British harbours. A few places, including Scapa Flow in the Orkneys and Cromarty on the east coast of Scotland, received special treatment, the Admiralty providing marines to man the coast batteries and lights. Another important task which fell upon naval personnel was mine sweeping, to keep free of enemy mines the channels leading to and from British ports and anchorages, and there was an additional and only partially foreseen demand for coast watching, in aid of the coastguard. This task was performed to a great extent by volunteer watchers, the boy scouts taking a very active part in the movement.

Coast Defences.—In connection with the general question of fixed coast defences, it is important to realise their limitations. "People often say," wrote Admiral Mahan, "that such and such an island or harbour will give control over such a body of water. It is an utter, deplorable and ruinous mistake." The same author explains further that "control of a maritime region is ensured primarily by a navy, and secondarily by positions, suitably spaced from one another, upon which, as bases, the navy rests, and from which it can exert its strength," and that "in a naval war coast defence is the defensive factor, the navy the offensive. Coast defence, when adequate, assures the naval commander-in-chief that his base of operations—the dockyards

and fuel-depôts—is secure. It also relieves him and his Government, by the protection of commercial centres, from the necessity of considering them and so leaves the offensive arm perfectly free." On the whole it may be said that British defences adequately performed these functions in the World War, but it is necessary to take note of the point that they did not secure complete immunity for the coastal population; Scarborough, Hartlepool and other places suffered from bombardment by hostile war vessels. Owing to popular demands, these bombardments affected both the movements and the distribution of the sea forces in home waters.

Attacks During the War.—Reviewing the situation, from the defence point of view, of the British Isles in the World War, it is found that naval strength and dispositions secured the country from military invasion or raids, but that some places on the coast, which were considered to be immune under international agreements arrived at in conferences at The Hague, were subjected to bombardment from the sea. The special provision referred to is to be found in Article 25 of the 1907 Hague Conference, which forbids the bombardment, "by any means whatsoever," of undefended towns.

Air Raids.—This is a new feature in warfare, which affects very seriously the defence of Great Britain. The situation was thus described in Aug. 1914:—

> It seems safe to assume that the few hundred aircraft at present at the disposal of any military power would be unable to bring serious pressure to bear upon a hostile nation numbering many millions, spread over wide areas. The moral effect which would be produced by highly mobile aircraft dropping bombs first over one city, and a few minutes afterwards over another city a hundred miles away, would no doubt tend to produce local panics, but, given the right spirit, the material effect would not suffice to produce concerted action amongst the population to force their government to stop the War. (*Sea, Land, and Air Strategy*, 1914.)

This prediction was borne out in the years 1914–8, but considerable damage was suffered in the United Kingdom from air raids. These raids provide the only precedent, derived from actual experience, of the effect of air raids upon the civil population of Great Britain. Putting aside the comparatively trifling loss of naval and military personnel, 619 civilians were killed by aeroplane raids and 498 by air-ship raids, the numbers of injured being 1,650 and 1,236 respectively. Of the total of 1,117 killed, 618 were women and children. Of the 2,086 injured, 1,562 were women and children.

There was no question of pressure being put upon the Government for this reason to end the War without victory. The tendency was to stiffen the determination of the nation to endure all things rather than accept defeat. The deductions to be drawn from the statistics are (1) that airships, owing to their vulnerability, do not afford cause for anxiety, provided that the experience of the World War is studied and adequate defensive measures are adopted; but (2) that the menace from aeroplanes is more serious, though strictly limited in radius. Whether this radius can be increased much beyond the estimate in 1924 of 200–300 m.[1] is a question for the future. The point has been advanced that a reduction of bombing-load, and therefore an increase of fuel-radius, can be effected by substituting lighter and more deadly chemicals and gases for heavy explosive bombs. The increase in range of artillery fire was yet another development which may affect the future defence of Great Britain, for certain ports on the East Coast, and even inland towns, could now be subjected to bombardment from positions on land.

Comparison Between Pre-War and Post-War Conditions.—The situation in 1925, as compared with that in 1910, can thus be summarised. As long as a sufficiently strong navy is maintained, immunity from invading armies can be ensured in the future, as it has been in the past. The menace from the air would depend upon the country with which Great Britain might be engaged in hostilities, and would not be very serious except in a war against countries within the radius of action of bombing aeroplanes starting in large numbers from land aerodromes. Long-range bombardments of certain places near the East Coast cou be effected by heavy ordnance in similar localities. The nav and the merchant shipping under its protection, would be op to air attack when carrying out their task of keeping up the tran port over the high seas of essential goods to and from Gre Britain; air forces, under naval control, would be essential meet this menace. The general effect of the air menace, as factor in the problem of British defence, may be gathered fro the attitude of successive British Govts., which have found necessary to adopt a "one-power" standard of strength in t air, to establish a separate air force controlled by an Air Minist and to appoint an air officer as commander-in-chief of the hon air forces, a step which, in time of peace, has been considere to be against the best interests of the nation if applied to t military forces.

Irish Free State.—The grant of self-government to the Irish Fr State has a considerable effect upon the defence of Great Britai This quasi-political question cannot be dealt with exhaustively an article devoted exclusively to defence. Its main features are (the control by the Free State Govt. over its own forces; (2) t loss of a large number of recruits, of a wide area of recruitme for the British Army, and of important training grounds; (3) t prospect for Great Britain in future emergencies of having a friend population in southern Ireland, in place of one bitterly hostile a requiring the presence of a strong British garrison; (4) the continu provision of a small nucleus of British troops in certain defend ports, and also the question of the ability, if not the eagerness, the Irish of the Free State to deny their harbours to war vesse hostile to Britain, and to provide an organisation for coast-watchi to ascertain and report, as was done by British coastguards 1914–8, the movements of such vessels within sight of the Iri coast. Unless these services are adequately fulfilled, the establis ment of a Free State in Ireland would, in a grave emergency such the World War, affect adversely the defence of Great Britain.

Conclusion.—In conclusion, we have noted that the princip change between 1910 and 1925 in the defence of Great Brita has entailed the provision of a large localised Air Force, controll by an Air Ministry and an air officer commanding-in-chief; addition to the air forces needed to accompany British flee and armies upon their world-wide mission. Nevertheless, t burden of home defence may bear less heavily upon the Briti people than their responsibility for defending people of oth races and nationalities, spread over both hemispheres (*see* A Forces; Army; Coast Defence; Navy; etc.).

IV. FINANCE AND BANKING

The years immediately preceding 1914 were a period of rapid growing expenditure, due (1) to the increase of the navy ar (2) to social reforms.

National Expenditure

	1908–9	1914–5 (Estimates)
Debt	£28,000,000	£23,500,000
Army	26,840,000	28,885,000
Navy	32,188,000	51,550,000
Old Age Pensions	..	12,710,000
Insurance of Working Classes	..	9,312,000
Other Expenditure	65,264,000	81,064,000
Total	£152,292,000	£207,021,000

The growth of £15,800,000 in other expenditure was largel natural expansion, *e.g.*, an increase of £8,000,000 in the po office. The increase in total expenditure (after allowing for t reduction of £4,500,000 in the debt charge) was £59,000,000, which defence contributed £21,400,000 and social legislatio £22,000,000.

So great an increase in expenditure had naturally involve additional taxation. The extensive measures of new taxatio imposed by Mr. Lloyd George's budget of 1909 (which was re jected by the House of Lords and was only passed after a gener

[1] Report of Sub-Committee of Committee of Imperial Defence (Cmd. 2029, 1924).

election) provided the greater part of what was required. The feature in that budget of greatest permanent importance was the institution of a supertax, that is to say an additional income tax on large incomes. Incomes above £5,000 were taxed at 6d. in the pound on the excess over £3,000. At the same time the rate of income tax on unearned income was increased from 1s. to 1s. 2d. After the great effort of 1909 the natural expansion of revenue sufficed to cover expenditure till 1914. In that year further taxation became necessary, and the budget as finally adopted (before the War crisis) provided for an increase in estate duties, a rise in the income tax on unearned incomes from 1s. 2d. to 1s. 3d. (the earned still remaining at 9d.), and an important extension of the supertax. Supertax was applied to all incomes over £3,000, and was more elaborately graduated (the rate on the excess of an income over £8,000 was 1s. 4d. in the pound). The estimated yield for a full year was thereby raised from £3,300,000 to £7,770,000 (*see* INCOME TAX).

The War Period.—From the beginning of the War in Aug. 1914 it became impossible to dissociate the budget position from the state of credit generally. In the first place, the Government had to come to the assistance of the financial world and support credit through the initial crisis. Secondly, expenditure on the War soon grew to such dimensions as to put an almost unbearable strain on the financial fabric of the country.

The outbreak of the War threw first the stock exchanges and then the foreign bill markets of the world, but above all of London, into utter disorder. The machinery of remittance to London broke down almost completely and the London accepting houses found themselves faced with bankruptcy. The Government was forced to step in and to proclaim a moratorium for debts, statutory power was taken for the Treasury to issue legal tender currency notes for £1 and 10s. and the Government guaranteed advances by the Bank of England to acceptors to pay off pre-moratorium bills (*see* STOCK EXCHANGE).

WAR BORROWING AND INFLATION

It was in the midst of this state of confusion that the early stages of the War were financed. For the initial expenses, advances of £14,720,000 were obtained from the Bank of England on "Ways and Means" (*i.e.*, under the powers annually conferred by the Consolidated Fund Act and Appropriation Act). The War was costing about £1,000,000 a day. There followed half-a-dozen issues of Treasury bills of £15,000,000 at a time. In Nov. 1914 additional taxation was imposed and a loan of £350,000,000 (3½% at 95, redeemable 1925–8) was decided on. By that time serious unsoundness was already developing in the situation. The issue of £90,000,000 of Treasury bills did not in itself overstrain the market. But the advances made by the Bank of England for the pre-moratorium bills, with its advances to the Government and large imports of gold, destroyed the Bank's power of controlling the money market. Bank Rate had been reduced to 5% on the reopening of the banks on Aug. 7, but in Sept. it ceased to be effective and the market rate fell to 3%. In Nov. it fell below 3. Part of the 3½% loan was taken by the banks, and in any case the loan was not applied to strengthen the position of the Bank of England. In Feb. 1915 the market rate of discount fell below 2%. The private deposits at the Bank of England exceeded £130,000,000.

At last, in March 1915, severe measures were taken to counteract the growing inflation, which had already caused a considerable rise of prices. The Bank of England came into the Money Market as a borrower at call on the same footing as the discount houses, and lent the proceeds to the Government. The money was accumulated in balances, and public deposits at the Bank rose from £27,000,000 at the end of Feb. to £114,000,000 at the end of March and other deposits fell to £90,000,000. On April 13 a new departure was made, in that Treasury bills in unlimited quantities were placed continuously on sale at fixed rates of interest to all comers. But the rates were still low (2¾% for 3 months, 3⅜% for 6 months, 3¾% for longer maturities). Public deposits rose to £130,000,000 and more. It was the Treasury bill rate, and not bank rate, which regulated the money market.

By that time the cost of the War had risen to £3,000,000 a day and exceeded one-third of the national income (even if this be assumed to have risen in proportion to prices, which were 25% higher than in 1913). This outlay (after deducting a modest contribution from the tax revenue) far exceeded the amount that the people could save. But inflation only made the situation worse. That the cost of the War was itself swollen by the high prices was the least part of the evil. Easy credit makes trade profitable, because it encourages buying and consumption. It directs savings away from gilt-edged investments into trade. In 1915 conditions were extremely abnormal, but, for all that, this tendency was at work. Lavish expenditure by the public on consumable goods was competing with the Government, not only for the investment of the available savings, but for the employment of the available labour and productive power. Inflation, once started, continued throughout the War and for some time afterwards and only spasmodic and half-hearted steps were taken to check it till 1920, when prices had risen to three times the pre-War level.

Mr. McKenna, in June 1915, brought out the second war loan (4½% at par, redeemable 1925–45). It was for no specified total amount. The banks again undertook to subscribe for a very large amount, but the loan was planned much more for the ordinary investor and less for the money market than the 3½% loan of November. It also remained open longer, and there was more propaganda. Subscribers were given the right to convert their holdings into any future long-dated war loan. Holders of 3½ per cents or of consols were allowed to convert these securities into the new loan if they subscribed in addition a certain amount of cash to it. The loan yielded £587,000,000 of cash, but £200,000,000 came from the banks, and the balance was but a modest contribution from genuine savings towards the growing expense of the War.

While the loan was still being subscribed, ominous signs of weakness began to appear. The rise of prices was resumed. The exchange on New York fell below $4.80 to the £1 sterling; at the end of Aug. it dropped to $4.50. The Government sought a remedy in the sale of gold and securities in New York. Gold received in 1914 and deposited at Ottawa, gold displaced from circulation by currency notes, gold extracted from the precious reserves of France and Russia, all were drawn upon. The total net imports of gold into the U.S. in 1915 were $420,000,000, of which two-thirds came in the second half of the year. The British Govt. collected American securities from British holders, and either sold them or pledged them in America. There was also direct borrowing in America, starting with the Anglo-French loan of Oct. 1915 ($500,000,000, five-year 5 per cents at 98).

By means of these resources it became possible to "peg" the exchange at 4·76½. That measure made inflation more ruinous to the country than before. Inflation creates an excess of imports, which can be corrected, if the gold standard is abandoned, by an adverse movement in the exchanges. If the Government prevents that adverse movement by undertaking to sell foreign currencies to all comers, the excess of imports continues, and the Government has to pay for it. There were obstacles to imports in 1916 (especially lack of shipping), but the burden assumed by the Government was still a formidable one. The British Govt. also had to supply the necessary resources for pegging the French franc.

What was needed above all was the cessation of inflationary finance. The 4½% war loan had been of some assistance. In Aug. 1915 the lowest rate for Treasury bills was fixed at 4½%. In Sept. new taxation was imposed calculated to yield over £100,000,000 in a complete year, and in May 1916 further increases brought the revenue for the year 1916–7 above £500,000,000. But the cost of the War had risen to £4,500,000 a day and the rise of prices above the peace-time level exceeded 50%. In Dec. 1915 five-year 5% Exchequer bonds were put continuously on sale from day to day, but yet in March 1916 the floating debt (Treasury Bills and Ways and Means Advances) was almost £600,000,000.

In July 1916 Bank Rate was raised to 6%, and the Treasury bill rate to 5½. The effect of Bank rate on borrowing depends on the profits of trade; 6% is by normal standards a very high rate,

but in face of the profits promised by an orgy of inflation it counts as low. At any rate it was not high enough to have much effect in 1916. The sale of five-year Exchequer bonds (raised to 6% in Oct. 1916) continued till Jan. 1917. Mr. Bonar Law, who had become Chancellor of the Exchequer in Dec. 1916, then decided on a third World War loan.

This took two forms: 5 per cents at 95 (redeemable 1929–47) and income-tax free 4 per cents at par (redeemable 1929–42). A "Depreciation Fund," equal to ⅛% per month, was to be applied to buying up stock in the market whenever it was below the issue price. The amount asked for was unlimited, and the zeal of the public was stimulated by intensive propaganda. It was wisely decided to ask for no direct subscriptions from the banks. The cash raised was £816,000,000, and Treasury Bills subscribed amounted to £124,000,000. In addition holders of 4½% war loan and of the Exchequer bonds since issued were entitled to convert into the new stock. The total amount created was £2,067,000,000 of 5 per cents and £52,000,000 of 4 per cents.

Even after this great effort the floating debt at the end of the financial year (March 31 1917) amounted to £680,000,000. Prices were almost double the peace-time level. Growing difficulty was experienced in providing resources for the support of the American exchange. The vast quantities of gold sent to the United States (whose net imports of gold from Jan. 1915 to March 1917 amounted to $1,192,000,000) not only paid for goods, but brought about a credit inflation and rise of prices there. Indeed otherwise the discrepancy in value between the pound and the dollar would have been far too great for any pegging operation to be feasible. But the effect of the credit inflation in America was to make borrowing there more difficult in face of the insistent demands of trade for all available supplies of capital. It was found possible to raise loans of $250,000,000 in Aug. 1916, $300,000,000 in Oct. 1916 and $250,000,000 in Jan. 1917, but the market was growing more and more reluctant.

All such anxieties were dispelled by the entry of the United States into the War in April 1917. Thenceforward the necessary resources both for supporting the exchange and for buying food and materials were advanced to the British and Allied Governments by the American Govt. itself. The British Govt. continued to provide funds to enable the Allies to buy goods in England, but the amount lent was about equal to the amount borrowed from the American Government. Inflation in the United States was accelerated and the export of gold thence was prohibited. The price index rose from 162 in March 1917 (100 being the average of 1913) to 203 in Nov. 1918. The English price index in Nov. 1918 was 229. The cost of the War to the British Exchequer had risen to £7,000,000 a day. Bank Rate had been reduced to 5½% on Jan. 18 and to 5% on April 5 1917.

After the 5% war loan, borrowing was effected through Exchequer bonds, re-christened in Sept. 1917 "National War Bonds." They were 5 per cents, but were repayable on maturity at a premium (2% on the 5-year bonds, 3% on the 7-year and 5% on the 10-year), and were convertible at the holder's option into 5% war loan at 95 (*i.e.* a £100 bond would buy £105 5s. 3d. of war loan). There were also income-tax free 4% 10-year bonds, repayable at par, and convertible into 4% war loan. National War Bonds were continuously on offer till the Armistice and thereafter till May 1919 (those issued after Jan. 1919 having no conversion rights).

Much attention had been given to the attraction of savings from the working classes. Special facilities were given for the purchase of the 4½% war loan of 1915 in bonds of small denominations. In 1916 a special issue of War Savings Certificates was started. The subscriber paid 15s. 6d. for a certificate entitling him to £1 after five years, and he could obtain repayment at any time at the sacrifice of a part of the accumulated interest. The interest accumulating, and not payable periodically, was not liable to income tax, and to prevent too extensive an evasion of income tax by well-to-do holders, the amount of certificates which could be held by any one person was limited to £500.

On March 31 1919 the National Debt amounted to £7,481,000,000, an increase of £6,775,000,000 since March 31 1914. The external debt was £1,365,000,000, or, if certain items which could be set off against debts due to the British Govt. from Canada, France, Italy and Russia be omitted, £1,179,000,000. The internal floating debt was £1,339,000,000[1] including £455,000,000 of Ways and Means Advances; the latter included sums lent by Government Departments (partly from the Currency Notes Account, partly from trading accounts and many other sources). But a large part was money borrowed at call through the Bank of England from the Money Market, extra interest being paid for foreign-owned balances.

War Taxation.—Though there were heavy increases in indirect taxation, far the greater part of the war taxation was direct, as the following comparison shows:—

Taxation in Peace and War

Source of Revenue	1914–5 (Peace Estimate)	1918–9
	£ millions	£ millions
Customs and Excise	75·3	162·2
Income Tax	48·1	255·6
Supertax	5·8	35·6
Excess Profits Duty	..	285·0
Other Direct Taxes	42·1	45·9
Other Revenue	35·8	104·7
	207·1	889·0

The rate of income tax had been raised to 2s. 6d. in 1915–6 and to 5s. in 1916–7. In 1918–9 the rate was raised to 6s.; the effect of this last increase was not fully seen till 1919–20, when the yield was £317,000,000. Supertax rates had likewise been raised, and the highest zones of income paid 4s. 6d. The biggest tax of all was the Excess Profits Duty, which had been imposed by Mr. McKenna in Sept. 1915. This was a tax on the excess of the profits made by any firm or company in the year of assessment over the annual profits made before the War (computed in the case of a business established since the outbreak of war from its capital). Administratively it was an off-shoot of the income tax, for the income tax assessments disclosed both the current profits of a business and its pre-War standard. The rate of tax was at first 50%, and was raised in 1916 to 60% and in 1917 to 80%. Excess Profits Duty was a powerful corrective of inflation. It provided £645,000,000 revenue in the three years 1916–7 to 1918–9, and £540,000,000 more in the difficult years that followed. It diminished the evil tendency of inflation to accentuate the inequalities of wealth. By it the extravagant profits which made trading enterprises unduly attractive to capitalists, in competition with the needs of the Government, were materially reduced. Excess profits duty was never anything but a makeshift. It was full of anomalies and minor injustices. But these, in the emergency of the time, were as dust in the balance compared to its advantages.

The indirect taxes imposed included import duties on motor-cars, clocks and watches, musical instruments and cinema films—officially known as the new import duties, but more commonly called the McKenna duties. They are noteworthy as being the first protective duties imposed since the days of the Peelites.[2] They were ostensibly intended to support the exchange and to economise tonnage.

The Cost of the War

An exact calculation of the cost of the War to Great Britain would be impossible, and what follows can be regarded as no more than an approximation. The day after the declaration of war with Germany the Government obtained from Parliament a vote of credit of £100,000,000, for "expenses, beyond those provided for in the ordinary grants of Parliament, arising out of the existence of a state of war." Certain services, such as naval and military operations, maintenance of trade, relief of distress, were specifically mentioned, but the total was not divided into subheads like an ordinary vote. Till March 1919 the cost of the War was met from successive votes of credit. The total audited expenditure from votes of credit was £8,417,000,000. The table on the opposite page shows the principal details.

Civil Departments drew on votes of credit for any expenditure in excess of their own votes, attributable to the War. Some items so met (*e.g.*, for cost of living bonus to civil servants) were not part of the cost of the War. But on the other hand the ordinary votes bore many war charges such as the civil pay of staff absent on military service, or the cost of administrative work arising out of the War. The total includes £1,665,000,000 of loans to Allies and Dominions. These were an immediate burden when advanced, but the ultimate burden is only such part as is never repaid. The immediate burden was relieved by the advances received from the Canadian and American governments.

[1] Exclusive of Treasury bills amounting to £73,000,000, included in external debt (see Cd. 1648).

[2] Except the ephemeral corn duty of 1902.

Receipts[1]	254·4	265·7	110·8	43·4	29·7
	486·7	(8·0)[2]	38·6	16·2	(14·1)[2]

[1] Mainly sales of war stocks, ships, etc., but exclusive of reparations.
[2] Excess of receipts over expenditure.

A further net sum of £22,250,000 was provided through the vil contingencies fund (advances, 1919–20, £64,500,000; reayments 1919–20 to 1921–2 £42,250,000). The total net war xpenditure is thus (in £ millions):—

Total War Expenditure

	British Expenditure	Loans to Allies, etc.	Total
Votes of Credit	6,084	1,665	7,749
Subsequent Years	376	166	542
	6,460	1,831	8,291

Advances *from* Allies were:—

United States	865
Canada	184
France, Russia and Italy (gold)	136
	1,185
Voluntary contributions from India and Colonies (principal only) up to 1923	90
	1,275

This may be regarded as reducing the net "immediate burden" of advances to Allies to £556,000,000. The burden of War pensions, actuarially capitalised at some date in the midst of the War, may be put at £1,000,000,000.

Finance After the War

In 1919 the tremendous overstrain of the War period was still making itself felt in the direction of inflation. The most obvious symptoms of weakness were in the floating debt and the external debt (see above). The shortage of tax-revenue and genuine savings, as compared with the expenditure to be met, was made good partly by drawing on foreign resources, partly by bank credits. Practically, with the cessation of advances from the American Govt., foreign resources ceased to be available. Bank credits meant the creation of the means of payment out of nothing—pure inflation. Excessive Government borrowing seemed so entirely adequate an explanation of the growing inflation that a more insidious cause was hardly taken into account. Bank rate had remained at 5%, but had not been made effective. The Treasury bill rate, which governed the market, had been reduced since Feb. 1918 to $3\frac{1}{2}$%. Under war conditions the effect of cheap commercial borrowing in stimulating business was undoubtedly much diminished though not entirely avoided. With the return of peace its full effect would be felt.

The committee on currency and foreign exchanges after the War, presided over by Lord Cunliffe, had presented a grave and authoritative report in Aug. 1918. The report urged the cessation of Government borrowing, but also the use of a high Bank rate to protect the gold reserves. The foundation of all their recommendations was that "under an effective gold standard all export demands for gold must be freely met." "The conditions necessary to the maintenance of an effective gold standard in this country no longer exist, and it is imperative that they should be restored without delay." Unless the remedies approved by experience were applied, "there will be very grave danger of a credit expansion in this country and a foreign drain of gold, which might jeopardise the convertibility of our note issue." The Committee condemned proposals for "a liberal supply of money at low rates," based on a further growth of the note issue, because "in the result the gold standard will be threatened with destruction through the loss of all our gold."

In spite of these wise and emphatic recommendations, the gold standard was abandoned without an effort, as soon as the arrangement for supporting the New York exchange with American credits was brought to an end. A regulation under the Defence of the Realm Act, replaced in 1920 by the Gold and Silver (Export Control) Act, prohibited the export of gold (March 1919). The régime of cheap money continued. Burdened with heavy war commitments the Budget for 1919–20 brought the prospect of a heavy deficit. In June a new 4% loan was offered for subscription in two forms, the funding Loan, at 80, redeemable 1960–90; and the Victory Bonds, at 85, repayable by annual drawings at 100.

During the War the issue of loans at a considerable discount had been avoided, the lowest price of issue being 95. This was a favourable contrast to the policy during the Napoleonic wars, which swelled the nominal amount of the debt and diminished the effectiveness of the big conversion operations of the 19th century. The Funding Loan represented a change in that respect. It secured the investor against the reduction of his interest after 1960 unless the market rate of interest had fallen by then below 4%. That is a very slight advantage to the investor, and any difference that it made in the price of the loan would not go far to compensate the Government for the loss of what might be a valuable option in the future.

The twin loans yielded £475,000,000, but £92,000,000 had been subscribed by banks, so that the real contribution towards sound finance was only £383,000,000. Moreover, the well estab-

lished but deceptive city tradition of fertilising a loan with cheap money had been followed. The sale of Treasury bills had been absolutely suspended, and the Government had borrowed at a low rate from the money market and so far as necessary from the Bank of England. The inflationary tendency, already serious, was accentuated. The sale of Treasury bills was resumed on July 14. In Oct. came a change; the rate for three months bills was raised from 3½% to 4½%—the first step towards a restriction of credit. In Nov. the rate was raised to 5½% and Bank Rate to 6%. In Dec., pursuant to a recommendation of the Cunliffe Committee, a limit was imposed upon the currency note issue. A Treasury Minute of Dec. 15 1919 (a purely administrative instrument without statutory validity) prescribed that the fiduciary issue of currency notes (those uncovered by gold or Bank of England notes) in any year should not exceed the maximum fiduciary issue recorded in the preceding year. The actual maximum recorded for 1919 was £320,600,000, and accordingly this became the prescribed maximum for 1920. Under this rule the limit can decrease but cannot increase. The limit for 1926 was £247,900,000.

Inflation in Great Britain works through bank credits, but a limit on the supply of legal tender money, if really meant to be effective, was bound to react on the creation of credit. Nevertheless in the opening months of 1920 inflation continued unabated. The price level (*Statist* index, 1913 being 100) rose from 217 in April 1919 to 313 in April 1920. The American exchange fell one-third below par. In April 1920 the sales of Treasury bills at the fixed rate of 5½% fell off, and £55,000,000 had to be borrowed from the Bank of England on Ways and Means. An abyss of inflation seemed to be opening. The Treasury bill rate was thereupon put up to 6½%, and Bank Rate to 7% (April 15).

The next week Mr. Austen Chamberlain introduced the Budget for 1920–1. Inflation was swelling the revenue from the heavy taxes already in existence, but fresh taxation was nevertheless imposed. A tax revenue exceeding £1,000,000,000, in addition to enormous receipts from liquidation, was budgeted for, and the estimated surplus was £234,000,000. The severe régime of high discount rates and no Government borrowing, recommended by the Cunliffe Committee, was being applied. But after a year of unconscionable inflation, a stronger dose was needed than they ever contemplated, and produced results which they never thought of. A year of 7% Bank Rate caused a tremendous collapse of prices, while the exchange was little improved (*see* CURRENCY), and the gold standard was not restored.

The peril of inflation had vanished. It was excessive deflation that was now the trouble. But a contraction of credit, while it brings depression, bankruptcy and unemployment, nevertheless, after the first passing phase of stringency, causes a rise in the prices of fixed-interest securities and favours funding operations, just because it diminishes the profits of production and trade.

When the budget for 1921–2 was introduced in April 1921, little progress had been made with the floating debt, which still amounted to £1,243,000,000. The loan issues of 1919, together with an issue of 5¼% Exchequer bonds in Feb. 1920, had been mostly used up in meeting a deficit of £326,000,000 for 1919–20 and a large amount of maturing bonds. The surplus of £230,000,000 for 1920–1 had been needed partly to pay off external debt (including $250,000,000 of the Anglo-French loan of 1915 maturing in Oct. 1920), and partly to pay off bonds. Further heavy maturities were in prospect. By April 1922, £138,000,000 of Exchequer bonds would have to be met, and between Oct. 1922 and Feb. 1924 the 5-year National War Bonds, amounting to £574,000,000. Certain securities also had the privilege of being used in payment of Death Duties and Excess Profits Duty. The total amount so used had been averaging £70,000,000 a year. The Depreciation Fund on the War Loan of 1917 required over £30,000,000. All these obligations had to be met if the floating debt was to be prevented from increasing.

In the Budget statement in April 1921 was announced the issue of a new 3½% Conversion Loan. It was to be a funded stock like Consols, being redeemable only at the option of the Government (after 1961), and not at any fixed due date. A sinking fund of 2% per annum on the amount outstanding was to be applied so long as the price was below 90. Cash subscriptions were not asked for, the loan being destined only to be exchanged for the 5-year and 7-year National War Bonds. At that time gilt-edged stocks had not recovered far from the lowest levels of 1920. The 4% funding loan which had fallen to 66 in Dec. 1920, stood at 71. The 5% War Loan had risen from 81½ to 88. The National War Bonds (carrying a premium on redemption) were slightly below par. From £160 to £163 of 3½% Conversion Loan was offered to the holder of £100 of National War Bonds. The stockholder was secured a return of about 5⅞% on his money, and the interest could not be reduced before 1961, and even then only if the Government was able to borrow at less than 3½%. By good fortune the loan was a failure. Only £164,000,000 of National War Bonds were converted, out of £630,000,000 to which the offer applied, but even so the increase in the nominal amount of the debt was about £100,000,000.

A year later, still months before the earliest maturities of National War Bonds, the situation had been transformed by the trade depression. The 4% Funding Loan at 88½, and the 5% War Loan at 99 were well above their issue prices. The Conversion Loan, which had been offered in April 1921 on terms corresponding to a price of 62, had risen to 77¾. Treasury Bonds to yield 5½%, and then, as the market improved, 5% had been sold to an amount exceeding £400,000,000. In 1922 a further batch of £70,500,000 of National War Bonds were converted into 3½% Conversion Loan on the basis of a price of about 75. When the bonds were above par it ceased to be profitable to use them in payment of duties. And now that the 5% War Loan was well above the issue price, the option attaching to National War Bonds of converting into it at the issue price became profitable, and in the three years 1922–5, £251,000,000 were so converted. No difficulty was found in raising the money to pay off £100,000,000 in cash in the same period, and in addition the floating debt was reduced from £1,243,000,000 in March 1921 to £742,000,000 in March 1925 (inclusive of £166,500,000 of advances from Public Departments).

In April 1921 the pre-War system of selling Treasury bills by public tender was reverted to. The change was an important one, because it meant that in respect of the discount rate the Treasury followed the market instead of leading it. So long as the Treasury sold all the bills that the market would buy at a prescribed rate and no more, the Bank of England was bound to lend to the Treasury if the sales of the bills did not produce enough. A Bank Rate appreciably above the Treasury bill rate could not be made effective. A Bank Rate below the Treasury bill rate would be equally unworkable. In fact the Treasury had usurped the place of the Bank as regulator of credit. So long as bills are issued by tender in just sufficient amounts to meet the needs of the Treasury, the Bank of England can discharge its responsibilities undisturbed.

In 1924 a new form of Conversion Loan was created, a 4½% security redeemable in 1940–4, in order to make a beginning with the conversion of the great 5% War Loan. The Government has the option of repaying that loan at par at any date after 1929. The amount involved is enormous. Conversions of National War Bonds had raised the total in April 1924 to £2,100,000,000. Difficulty might be experienced, even in a favourable market, in dealing with so great a mass of stock, if notice were given in respect of the whole in or after 1929, and there may therefore be advantages in converting moderate portions at a time by offering suitable terms to the holders. The amount converted into 4½% was £148,000,000.

American Debt.—The net external debt had been reduced from £1,179,000,000 in March 1919 to £948,000,000 in March 1922, of which £856,000,000 represented the debt to the American Government. But these figures exclude the interest on the American debt which the American Government had spontaneously suspended in 1919 and which had been accumulating ever since. Towards the end of 1922 it was decided to negotiate with the American Govt. for the settlement of the arrangements for paying off the debt. A sum of $100,000,000 was paid on account and in March 1923 an agreement was negotiated by Mr. Baldwin, the Chancellor of the Exchequer, who with Mr. Norman, Governor of the Bank of England, visited the United States for the purpose.

The loan had been till then in the form of an obligation payable "on demand" and yielding interest at 5%. The agreement reduced the suspended interest to 4¼%, and fixed the future interest at 3% for 10 years and thereafter at 3½. The capital of the debt (including past interest) was rounded down by a small cash payment to $4,600,000,000, and was to be paid off by instalments in 62 years, starting at ½% ($23,000,000) and rising gradually so as to keep the annual obligation for interest and principal together approximately fixed at about $161,000,000 for 10 years and $184,000,000 thereafter. Great Britain has the option of paying the debt either in "U.S. gold coin of the present standard of weight and fineness" or in gold bullion or in bonds of the U.S., and may postpone the

payment of half of any instalment of interest. There was in addition a debt of $61,000,000, being the balance of the advances of silver made for the benefit of India under the Pittman Act of 1918. This sum was paid off in 1923 in cash. (*See* DEBTS, INTER-ALLIED.)

Sinking Fund.—The sinking fund in operation at the beginning of the War (a fixed debt charge of £23,500,000 inclusive of interest) had become obsolete. Surpluses of revenue over expenditure were legally applicable to the redemption of debt (the "old sinking fund"), and under the Finance Act of 1920 a surplus could be so applied as it accrued, instead of being accumulated in Exchequer balances till the end of the year. The accumulation of a surplus of £200,000,000 like that of 1920–1 would have been an absurdity. The Finance Act of 1923 repealed the fixed debt charge arrangement, and established a new sinking fund. A sum of £40,000,000 was to be included in the expenditure of the year for the redemption of debt in 1923–4, £45,000,000 in 1924–5 and £50,000,000 in 1925–6 and subsequent years. With the fixed debt charge the saving of interest went to increase gradually the amount applicable to debt redemption. Under the sinking fund of 1923 it goes in diminution of expenditure, the sum applicable to debt redemption remaining at £50,000,000. Surpluses, however, remain, as before, applicable to debt redemption. Realised surpluses have been as follows (in £ millions):—

1920–1	1921–2	1922–3	1923–4	1924–5
230·6	45·7	101·5	48·3	3·6

Repayments of principal of War advances to Dominions and of relief loans are paid to the National Debt Commissioners for debt redemption, without appearing in the Exchequer account.

Post-War Taxation.—The year 1919–20 was financially a War year, with a heavy deficit. The Excess Profits duty was reduced from 80 to 40 %, but at the same time heavy additional duties were placed on beer and spirits, calculated to produce an additional revenue exceeding £50,000,000, in a full year. The budget of that year (Mr. Chamberlain's) is noteworthy for the introduction of preferences in favour of products of the British Empire. Protective duties were not introduced for the purpose, but the preference was grafted on the revenue duties already in existence (sugar, tobacco, tea, etc.) The year 1920–1 saw the end of War deficits. Nevertheless big additions were made to taxation, further increases on beer and spirits, an increased super-tax, a new tax on the profits of limited companies, a rise in Excess Profits duty to 60 per cent. On the other hand an important simplification of the system of Income Tax abatements involved a loss of revenue in a full year of about £30,000,000 (at 6s. in the pound). This year saw tax revenue at its maximum, £1,031,700,000.

The years 1921–2 to 1924–5 were years of steady remissions of taxation. Excess Profits duty was repealed (1921). Corporation Profits Tax was first halved (1923), then repealed (1924). Income tax was reduced from 6s. to 5s. (1922), to 4s. 6d. (1923) and to 4s. (1925). The duties on beer (1923), sugar (1924) and tea (1924) were reduced. The "McKenna" duties were repealed by Mr. Snowden in 1924, but reimposed by Mr. Churchill in 1925. The Safeguarding of Industries Act, 1925, imposed a number of protective duties.

Analysis of Expenditure

	(£ millions)					
	1919–20	1920–1	1921–2	1922–3	1923–4	1924–5
I. Ordinary						
Debt	332	350	332	324	347	357

Other	123	157	196	135	148	146
Total ordinary	793	882	904	762	784	792
II. Exceptional						
Bread subsidy	50	40	..	..	..	..
War expenditure	741	258	149	60	16	4
	1,584	1,180	1,053	822	800	796

Expenditures.—These liberal reductions of taxation could not be effected without substantial economies in expenditure. In 1921 a Committee with Sir Eric Geddes as Chairman made a searching investigation of the expenditure of public departments and recommended extensive savings. The foregoing table analyses public expenditure up to 1924–5 (appropriation accounts) and distinguishes ordinary from War expenditure.

The diminution of £142,000,000 in ordinary expenditure in 1922–3 is not wholly due to economy. The exclusion of Irish services relieved civil votes of about £20,000,000. The heavy fall of prices relieved expenditures not only directly, but also through the consequent reduction of the bonus dependent on cost-of-living, which is added to civil service salaries. The increase in ordinary expenditure in 1922–3 was due to the rise of £23,000,000 in debt charges, consequent on the establishment of the new sinking fund and the beginning of the payment of the American debt.

BANKING

During the post-War period, and especially in the period 1918–20, the British banking system underwent a process of change which, although from the historical standpoint only a continuation of tendencies which had been in operation for many years, in fact altered the whole balance of power within the sphere of domestic banking, and altered considerably the relations which used to obtain between the sphere of the domestic banks and those operating predominantly overseas. As a consequence there arose a series of problems which were still unsolved at the end of 1925. These were the adjustment of the internal economy of the banks to the new scale of business which they were undertaking; the relations of the banks with the central bank and the money market in the technical sense; and the relations of the banks with their customers and to the national economic life as a whole.

The Amalgamation Movement.—This consisted in the process of reducing the total number of independent banks. In contradistinction to the developments in Germany, the technical form assumed by the process of concentration was exceedingly simple. Whereas in Germany a whole series of intermediate forms existed between complete fusion of banking establishments and completely independent institutions, such as the exchange of shares, pooling of resources, agreements not to invade territory, interlocking directorates and stock-ownership without the extinction of the legal existence of the firm whose shares had been acquired, the founding of subsidiary enterprises by joint action, etc.; but in Great Britain, when two banks amalgamated, the separate legal and economic existence of the amalgamating establishments ceased. Moreover, the field of operation of the British joint-stock banks was confined to England and Wales: Scottish and Irish banking being conducted under different legal codes, it was thought impossible to amalgamate such institutions with English banks: and no attempt was made, except shortly before the War, to invade the sphere of the foreign and colonial banks. It was only in 1905 that the first attempt was made by an English joint stock bank (the Midland) to open a separate branch in the City of London for the conduct of foreign operations, an example which was very soon followed; whilst in 1911 the first overseas venture of an English joint-stock bank was made when Lloyds Bank acquired the business of Armstrong and Co. in Paris.

Simple as the nature of the British amalgamation movement was, both as regards form and aim, it had sufficed to reduce very materially, even in pre-War years, the total number of separate banks. By 1910 the total number of separate joint-stock banks

in England and Wales had been cut down to 45, the number having been 104 in 1890 and 77 in 1900. At the same date there were only nine private partnerships conducting a banking business—a sufficient proof of the extent to which the process of absorption by joint-stock banks had affected a transformation of banking conditions since joint-stock banking was first permitted under the Act of 1826. These 45 banks possessed between them 5,102 branches, paid-up capitals and reserves of £81,000,000, deposits amounting to £721,000,000 and outstanding acceptances to the amount of £52,000,000. At the same date the deposits of the remaining private bankers were only some £27,000,000. By 1914, the number of joint-stock banks had fallen to 38, their branches had risen to 5,869, their capitals and reserves stood at £82,000,000 and their deposits at £896,000,000, whilst the number of private banks had decreased to eight, and their deposits stood at £33,000,000. The leadership among English joint-stock banks at that date already belonged to the five banks which have since become known as the "Big Five." At the end of 1914, the deposits and numbers of offices of these banks stood as follows:—

	Deposits £	Offices
London, City and Midland	125,700,000	1,027
Lloyds	117,700,000	1,085
London County and Westminster	101,000,000	363
National Provincial	74,900,000	447
Barclays	167,400,000	606

Behind these leading banks ranged four large banks with deposits of over £40,000,000 each, viz.: Parrs, the Union of London and Smiths, the London Joint Stock, and the Capital and Counties, whilst five banks possessed deposits of between £20,000,000 and £30,000,000.

Home Absorptions.—The history of the amalgamation movement after 1918 is but a description of how the leading five banks completely absorbed their powerful but somewhat smaller rivals, by a process of competition among themselves. The critical years were 1918 and 1919. In those two years, to mention only the more important events, the National Provincial absorbed the Union of London and Smiths, the Sheffield Banking Co. and the Bradford District Bank: Barclays (having absorbed the important United Counties Bank in 1916) took over the just amalgamated London, Provincial and South Western Bank; the Westminster absorbed Parrs Bank and the Nottingham and Nottinghamshire Banking Co.; Lloyds Bank took over the Capital and Counties and the West Yorkshire Bank; finally, the Midland absorbed the London Joint Stock Bank. In the same years the Bank of Liverpool amalgamated with Martins Bank, and absorbed the Halifax Commercial Bank, the Palatine Bank and Cocks, Biddulph and Co., thus forming a new and powerful group, better able to stand centripetal pressure from the older and more powerful combinations. The competition to absorb did not relax in later years, and affected particularly the remaining private bankers. In 1920 the Westminster took over Beckett & Co. of Leeds; in 1923 Cox and Co., and H. S. King and Co. were absorbed by Lloyds, and Holt and Co. by Glyn Mills and Co. In the following year the old firm of Child and Co. was acquired by Glyns, and Grindlay and Co. by the National Provincial, while the Royal Bank of Scotland absorbed Drummond and Company. In the same year also the National Provincial absorbed the Guernsey Banking Co. and the Westminster took over the Guernsey Commercial Banking Co.

Affiliations and Extensions Oversea.—Even more significantly, the amalgamation movement no longer confined itself to traditional forms and areas. During and after the War, the "Big Five" converted their undertakings from unified structures to banking groups with a main stem representing the amalgamations, with branches from the main stem in the shape of affiliated and subsidiary undertakings, and with undertakings owned in common. Thus the Midland affiliated the Belfast Banking Co. in 1917, the Clydesdale Bank in 1920 and the North of Scotland Bank four years later: Barclays control two affiliated institutions, the British Linen Bank (1919) and the Union Bank of Manchester (1919), and possesses subsidiaries in the shape of Barclays Bank (Overseas) Ltd., Barclays Bank S.A.I. at Rome, and Barclays (Dominion, Colonial and Overseas) Bank. Barclays' holding of shares in the Colonial Bank and the Anglo-Egyptian Bank were turned over to the last named, formerly the Colonial Bank, with which the Anglo-Egyptian Bank and the National Bank of South Africa are amalgamated. Lloyds Bank has a footing in India through the acquisition of Cox and Co. and H. S. King and Co., is affiliated with the National Bank of Scotland and the Bank of London and South America (an amalgamation of the London and River Plate Bank and the London and Brazilian Bank), is joint owner with the National Provincial Bank of Lloyds and National Provincial Foreign Bank Ltd., and is a shareholder (as are also the Westminster, the National Provincial and the Standard Bank of South Africa) in the Bank of British West Africa.

The Westminster Bank has affiliated the Ulster Bank, is a shareholder in the Royal Bank of Canada as well as in the British Italian Banking Corporation (as are also its leading competitors, Lloyds and the National Provincial), and owns the Westminster Foreign Bank Ltd. The National Provincial has affiliated Coutts and Co. (1920), is a shareholder in the P. and O. Banking Corporation, and is half owner of Lloyds and National Provincial Foreign Bank. Thus with the exception of the Midland Bank, all the leading institutions are interested directly in overseas banks. The tendency to be interested in such concerns has affected even the smaller joint-stock banks: thus Williams Deacons Bank and the Union Bank of Scotland are both shareholders in the British Overseas Bank, and a very large number of concerns other than those already mentioned are included among the shareholders of the British-Italian Banking Corporation.

Effect of Amalgamations.—So vast a development as this was well calculated to attract public attention and to cause alarm. But, in the main, public attention and criticism have been confined to the absorption and extinction of competing banks within the confines of the country and have concerned themselves little with the other features of the situation, which, as a matter of fact, represented a more significant breach with tradition. On March 11 1918, when the competitive amalgamation movement was at its height, the Treasury appointed a committee on bank amalgamations to investigate the whole position. The committee reported on May 1 of the same year, but the evidence laid before it was not made public. The committee was clearly not very impressed by the argument that the growth in the scale of business undertakings justified the latest amalgamations, and was influenced by the view that when two banks of national scope join together, the effect is a net reduction of competition.

It thought the tendency for amalgations to reduce the ratio of capital and reserves to deposits undesirable, and gave cautious assent to the view that circumstances might produce something approaching a money trust at a comparatively early date. The committee therefore recommended legislation requiring that the prior approval of the Government must be obtained before any amalgamations are announced or carried into effect, "including under this term proposals for interlocking directorates, affiliations, and in fact, any arrangements which in effect would alter the status of a bank as regards its separate entity and control." Though no such legislation was carried, the prior consent of the Treasury is obtained before amalgamations are carried into effect, and Lloyds' Bank was refused permission to acquire the shares of the National Bank of India in 1919. So far as the domestic situation is concerned, Treasury control does not appear to have affected the course of events very much.

The alarm which the movement has created is in the main due to the feeling that the absence of effective competition would mean less ample facilities and higher charges for the public, as well as greater rigidity in the business intercourse with banks. It is almost impossible to gauge how far the latter fear may have been subsequently justified: it is perhaps also significant of the greater power of the banks that they had not, by the end of 1925, raised the rate on time-deposits to the pre-War level of 1½% below bank rate. What is undoubtedly true is that the amalgamation movement has not in any way checked competition among the banks in the creation of new offices. These continue to increase in a ratio for which there would seem to be very little real justification.

The amalgamations of 1918–9 were undoubtedly in part competitive: the leading banks absorbed others lest some competing bank should do so. The cost of acquisition was thus in some cases unnecessarily high, but the relative smallness of British banking capitals—a disadvantage from other standpoints—prevented these high acquisition costs from being a very serious permanent burden. A more legitimate reason for expansion was undoubtedly the feeling that the end of the War would see intensified competition between Great Britain and Germany, for which strong and powerful banks were needed: but whilst this was hardly a justification for the internal absorptions (in view of the already large size of the then existing banks) it was a legitimate argument as regards overseas expansion. On the other hand, the later and lesser amalgamations which accompanied the trade depression of 1921 and subsequent years

were no doubt forced upon the absorbing banks by the position of the weaker banks, and by the fear that a general distrust of the banking system would arise if a series of failures were allowed to take place.

Occurring at a time when all economic phenomena were affected and distorted by the War (in particular, in the case of banking figures, by inflation) it is impossible to say to what extent the actual movements of deposits, loans, investments and advances would have been different, had amalgamations been less frequent.

The most significant changes are the decline in deposits since the maximum of 1921 and the fall in investments accompanied by a rise in advances and discounts. This would indicate that the banks are responding to the needs of trade by reducing their holdings of fixed interest-bearing securities and of Treasury bills. Substantially the same results are revealed by taking the total banking figures of Great Britain, as under:—

Statistics of the "Big Five" Joint Stock Bank

	At June 30							(At Dec. 31)

(T. E. G.)

V. POPULATION

The decennial census due in 1921 was planned for April 24 of that year. Owing to the coal dispute then in progress the enumeration was postponed to June 19. The total population found at this latter date may be compared with that found in 1911 as follows:—

Before 1921 the decennial increase per cent had never been less than 10% for England and Wales. The number of females to 1,000 males in England and Wales, had, since the date of the first census in 1801, never been less than 1,036 (in 1821) and never, until 1921, been more than 1,068 (in 1901 and 1911). For the large excess of women in 1921 and for the unusually small increase per cent that occurred during that period, the War is in part responsible. The effect of the War can be more clearly seen when the crude birth rates and crude death rates since 1911 are considered. The crude rates are the numbers born and the numbers dying per 1,000 of the population during the year to which they refer. Deaths due to the War occurring abroad are excluded.

TABLE I. *Total Population of Great Britain*

Area	Date of Census	Persons	Population	Increase of Population since the preceding Census	Decennial increase per cent of Population	No. of Females to 1,000 Males
England and Wales	1911	36,070,492	M 17,445,608 F 18,624,884	3,542,649	10·89	1,068
England and Wales	1921	37,886,699	M 18,075,239 F 19,811,460	1,816,207	4·93	1,096
Scotland	1911	4,760,904	M 2,308,839 F 2,452,065	288,801	6·5	1,062
Scotland	1921	4,882,497	M 2,347,642 F 2,534,855	121,593	2·6	1,080

The effect of the War upon the death rate was to check the decline which had been in evidence previously. The influenza epidemic of 1918, which may be traced to the War, caused a high death rate that year. Since the War the death rate has declined to a lower figure than was ever shown before 1914. When the infant mortality rates for these years are considered (that is the number of children dying under one year of age per 1,000 born) it appears that the greatest improvement has been effected in the case of infants. The infant mortality rate, for instance, which in England and Wales was 128 for the period 1901–1910 and 100 for the period 1911–1920, declined to 83 in 1921, to 77 in 1922, and to 69 in 1923.

The effect of the War upon the birth rate was to cause during the progress of hostilities a more rapid decline than had been in evidence before and to cause after the end of hostilities a sudden rise to a higher figure in 1920, since when it has declined to a lower figure than was ever reached before. The decline in the crude birth rate which had been taking place for more than 50 years is mainly to be accounted for by decline in the number of children born to wives of reproductive age, but partly also by a change in the age distribution of the population. Owing to this change in age distribution there is now a smaller percentage of wives of the most reproductive ages than formerly.

These two facts may be illustrated as follows. In the period 1911 to 1915 there were 189·7 births per 1,000 wives aged 15 to 45; whereas there were in 1921, 176·5; in 1922, 161·6; and in 1923, 156·3. During the same period, however, of 100 wives

TABLE II. *Birth Rates and Death Rates: 1911–1924*

Date	Birth Rate per 1,000 of the Population		Death Rate per 1,000 of the Population	
	England and Wales	Scotland	England and Wales	Scotland
1911	24·3	25·6	14·6	15·1
1912	23·9	25·9	13·3	15·3
1913	24·1	25·5	13·8	15·5
1914	23·8	26·1	14·0	15·5
1915	21·9	23·9	15·7	17·1
1916	20·9	22·8	14·4	14·3
1917	17·8	20·1	14·4	14·3
1918	17·7	20·2	17·6	16·0
1919	18·5	21·7	13·7	15·4
1920	25·5	28·1	12·4	14·0
1921	22·4	25·2	12·1	13·6
1922	20·4	23·5	12·8	14·9
1923	19·7	22·8	11·6	12·9
1924	18·8	21·9	12·2	14·4

under 45 the proportion of wives under 35 has decreased, and this partly accounts for the decline in the number of children per wife. Thus in 1901 there were 593 wives under 35 years of age out of every 1,000 wives under 45; in 1911, 559; and in 1921, 535.

The changes in age distribution revealed by the census indicate that the proportion of young persons in the population is declining while that of old persons is increasing. There were, for example, out of every 10,000 of the population in England and Wales, 2,094 persons under 10 years of age in 1911 and 1,806 in 1921, whereas there were 207 persons of age and over in 1911 and 344 in 1921. The fact that the average of both sexes in Scotland was 28·0 in 1911 and 29·6 in 1921 illustrates a similar change in that country.

Distribution in Urban and Rural Areas.—The density of the population in England and Wales was 649 per sq. m. in 1921 and 164 per sq. m. in Scotland. The population was distributed as between urban and rural areas in the following proportions: England and Wales 79·3% urban and 20·7% rural in 1921, as compared with 78·1% and 21·9% in 1911; Scotland 77·3% urban and 22·7% rural in 1921 as compared with 75·4% urban and 24·6% rural in 1911. When making comparisons between England and Wales on the one hand and Scotland on the other in this respect, it must be remembered that owing to differences in local government between the two areas the terms "urban" and "rural" are used in somewhat different senses.

Two further points should be borne in mind when considering figures for urban and rural areas. These areas do not remain constant from census to census. Areas, formerly classed as rural, are from time to time added to the total urban area owing to changes in the organisation of local government. The population classed as urban therefore occupies a somewhat larger area at each succeeding census. Again the urban area includes many small towns and therefore not all those classed with the urban population are living under strictly urban conditions. A better picture of the urbanisation of the country is provided by the fact that 33·8% of the population of England and Wales were in 1921 living in towns of over 200,000 inhabitants each. The concentration of population in certain areas may also be illustrated by the fact that out of the 53 counties in England and Wales the 12 most populous counties contain 67·1% of the population while the 7 most populous of the 33 counties of Scotland contain 71·9% of the population.

Another method of illustrating the same point is to calculate the proportion which each county respectively contributed to every 100,000 of the population in 1921. It is then found that Lancashire contributed 13,007, London 11,838, Yorkshire 11,041, Durham 3,905, Essex 3,881, Warwickshire 3,669, Staffordshire 3,560, Middlesex 3,307 and Glamorganshire 3,305. Eight counties in England and Wales show an actual decrease in total population between 1911 and 1921. They are Cornwall, Herefordshire, Montgomeryshire, London, Rutlandshire, Westmoreland, Cardiganshire and Merionethshire. London as a whole, it may be noticed, has increased, the increase having taken place outside the county administrative area. In Scotland 17 of the 33 counties show decreases within the same period. Every county in England and Wales shows an increase in total population between 1801 and 1921, but in Scotland five counties, Argyll, Berwick, Orkney, Perth and Sutherland, had in 1921 fewer inhabitants than in 1801.

The most populous towns of England and Wales in 1921 were as follows:—

London (administrative county)	4,484,523	Sheffield	480,639
Birmingham	919,444	Leeds	458,232
Liverpool	802,940	Bristol	376,975
Manchester	730,307	West Ham	300,860

In Scotland the most populous towns in 1921 were:—

Glasgow	1,034,174
Edinburgh	420,264
Dundee	168,315
Aberdeen	158,963

In England and Wales there were 46, and in Scotland four towns each with more than 100,000 inhabitants.

Distribution by Occupation.—The first use which can be made of the information collected at the census regarding occupation is to classify the population according to industrial status. Table III. illustrates the result.

The number of women recorded in Table III. as "gainfully" occupied is relatively small because most women not "gainfully" occupied are married and household duties are not included in in the term "gainful" occupations. Of the 10,542,599 women in England and Wales for instance, in 1921 over 12 years of age, who were not "gainfully" occupied, 6,886,931 were married.

TABLE III. *Industrial Status of Persons Gainfully Occupied, 1921*
12 Years of age and over

Industrial Status	England and Wales		Scotland	
	Males	Females	Males	Females
Employers	563,203	73,708	88,745	9,445
Employees	10,800,276	4,664,603	1,354,078	584,096
Working on own account	749,239	327,021	91,996	39,244
	12,112,718	5,065,332	1,534,819	632,785

The population may next be classified according to the occupations followed. The chief occupations in England and Wales and in Scotland respectively were as follows:—

TABLE IV. *Chief Occupations by Sex, 1921*

England and Wales			
Occupations of Males	Total in each Occupation	Occupations of Females	Total in each Occupation
Metal working	1,540,235	Personal service	1,676,425
Transport and communication	1,420,593	Textile workers	608,964
Agriculture	1,171,298	Makers of textile goods and dress	548,013
Commerce and finance	1,063,120	Commerce and finance	496,056
Mining and quarrying	1,061,749	Clerks and typists	429,695
Clerks and typists	568,034	Professional	359,982
Scotland			
Metal working	280,210	Personal service	168,149
Agriculture	169,984	Textile workers	92,407
Transport and communication	169,912	Commerce and finance	83,111
Mining and quarrying	151,884	Makers of textile goods and dress	53,967
Commerce and finance	116,360	Clerks and typists	67,966
Workers in wood and furniture	80,860	Professional	44,970

Since a new classification by occupation was used in 1921, comparisons with former censuses cannot easily be made. It should be remembered that this classification is by occupation and not by industry. It might with care make possible a rough estimate of the numbers engaged in sedentary and non-sedentary occupation, in skilled and unskilled occupations and similar comparisons. It does not show the numbers engaged in different industries. Thus clerical workers are placed in a separate group. If all such workers are allocated to the industries with which they are usually associated, it is possible to classify the population by industry. This is done in the following table.

TABLE V. *Chief Industries, 1921*

England and Wales		Scotland	
Industry	Total in each Industry: Both Sexes	Industry	Total in each Industry: Both Sexes
Commerce and finance	2,275,148	Commerce and finance	289,369
Manufacture of metals	2,196,014	Manufacture of metals	368,610
Personal service	2,046,825	Personal service	199,648
Public administration and defence	1,335,879	Agriculture	183,086
Mining and quarrying	1,283,728	Mining and quarrying	179,952
Transport and communication	1,203,566	Transport and communication	155,564
Manufacture of textiles	1,153,829	Manufacture of textiles	151,166
Agriculture	1,123,962	Public administration and defence	143,191

The precise scope of the industries included in the above table requires careful examination if the figures are to be properly appreciated. Thus commerce and finance includes persons engaged in al

forms of wholesale and retail dealing, in auctioneering and valuing as well as in banking and insurance. Shop assistants therefore form a large part of the total in this group. The manufacture of metals includes also the manufacture of machines, implements, conveyances, jewellery and watches. Personal service includes not only domestic service but also service in lodging houses, hotels, clubs, laundries and restaurants. Public administration and defence includes, in addition to the fighting services, those employed both by local and central government authorities. Transport and communication includes those employed in connection with storage. The manufacture of textiles includes not only those engaged in the manufacture of cotton, wool and silk goods but also those engaged in the manufacture of various miscellaneous products such as lace, carpets, rope, asbestos, tents and tarpaulins, as well as those engaged in dyeing, printing, bleaching and calendering.

When the population is thus classified, it is seen that those engaged in certain industries are less in number than those engaged in the corresponding occupations. Those engaged in the transport industry, for example, are fewer in number than those engaged in the occupation of transport and this is so because some of those who follow transport as an occupation appear in the industry table as belonging to another industry. Thus while a railway man would appear among those engaged in transport both as an industry and as an occupation, a carter employed by a mining company would be classed as following the occupation of transport but belonging to the industry of mining. Those who follow the occupations of mining and agriculture comprise nearly all those who are engaged in the corresponding industries, whereas those engaged in commerce and finance as an occupation only form about half of those engaged in the corresponding industry owing to the fact that numerous clerical workers who follow the clerical occupation belong to the industry of commerce and finance. Four of the eight chief industries are not industries in the everyday meaning of the term, namely, commerce and finance, personal service, public administration and defence, and transport and communication. If they are omitted from consideration, the industry of the manufacture of metals takes the first place in Great Britain.

The low place of agriculture is noteworthy. It was once considered remarkable when those engaged in agriculture were less numerous than those engaged in all other industries taken together. Agriculture is now not even the most important industry from the point of view of numbers, having fallen to the fourth place in England and Wales and to the second place in Scotland. It is possible to classify industries broadly into those which are extractive, manufacturing, distributive and certain miscellaneous groups. If agriculture, mining and fishing are regarded as extractive and commerce and finance and transport and communication as distributive, then the following result is obtained. In England and Wales of all those engaged in industry, those engaged in manufacture comprise 43·6%, in distribution 20·3%, in extraction 14·0%, in personal service 11·8%, in public administration and defence 7·7%, in professions 2·9%, in sport and entertainment ·7%. In making this calculation the 162,767 persons engaged in the gas, water, electricity industrial group have been included among those engaged in manufacture. It should be noticed that about 60,000 of them are employed by local authorities and that a certain percentage of all those in this group should more properly be included among those who are engaged in the work of distribution.

Housing.—For the purpose of the census a structurally separate dwelling is defined as any room or set of rooms having separate access to the street or staircase. Thus a flat is such a dwelling. In counting the number of rooms, sculleries, bath rooms, shop or office rooms are excluded. The total number of dwellings was found to be 7,759,821, having a total number of 39,894,618 rooms. There were thus an average of 5·14 rooms per dwelling in England and Wales, but as some dwellings were occupied by more than one family there were only on the average 4·55 rooms per family. As the average number in a family was 4·14 the average number of rooms per person was 1·1. But these averages by themselves give little or no idea of the actual housing conditions of the population. Thus there were no fewer than 3,480,273 private families with less than ·5 rooms per person, while there were 17,429,709 persons belonging to families with less than one room per person. Again 9·6% of the total private family population was living with more than two persons per room in England and Wales. Judged according to this standard the counties vary greatly. London has 16·1% of the population living with more than two persons per room while Cornwall has only 2·8. These figures, however, take no account of the size of the rooms. Housing statistics tend to show a progressive improvement when the returns of one census are compared with those of preceding censuses, though the figures for 1921 exhibit a check to the rate of improvement. The following figures for Scotland show the number of occupied houses per 100 of the population: 1881, 19·8; 1911, 21·3; and 1921, 21·7.

Marital Conditions.—Of the male population in England and Wales in 1921 55% was single, 41·4% married and 3·6% widowed. Of the female population 53% was single, 38·3% married and 8·2% widowed. The large number of widows, 1,621,658, is noticeable, amounting to nearly three times the number of widowers. There were at this date 8,464 men and 8,218 women divorced.

Language.—The census returns show that the use of Welsh and Gaelic is declining. The proportion of persons three years of age and over in Wales and Monmouthshire speaking Welsh only was 85 per 1,000 in 1911 and 63 per 1,000 in 1921, while in Scotland the proportion of those speaking Gaelic only was 4·56 in 1911 and 3·47 in 1921. The proportion of those speaking both English and Welsh and English and Gaelic has also declined.

VI. INDUSTRY AND TRADE

The period of 1910–3 was one of steadily improving trade, but during the first seven months of 1914 there was a perceptible decline of prices and employment.

The War Period.—The principal effects of the World War were the alteration of the normal directions of foreign trade, owing to the interruption of commerce between the belligerent nations and the influence of blockage policies on the commerce of neutral countries; the gradual assumption of control by the Government over both production and distribution; the diversion of production and distribution; the diversion of production into new channels for the supply of War requirements and to make good the loss of imports due to the interruption of commerce; and great changes in labour conditions.

Government Control.—The progress of control by the Government is thus described in the Report of the War Cabinet for the year 1917 (Cmd. 9005, p. 130).

As the military struggle developed in scope and intensity, and the necessity of concentrating national efforts on the War became more pressing, section after section of industry was taken over, and wages, prices and profits, from raw material to finished product, were placed under Government control. The process of extending State control, taking over more works and applying it to an always widening range of products, continued unbroken right up to the end of 1916. Whilst no exact demarcation line can be fixed, if a broad definition of the character of the movement to that period were attempted it would be that industries essential to War needs had been taken under Government control whilst industries serving the civil population were still left in private hands. In the same way 1917 may be described as the year in which State control was extended until it covered not only national activities directly affecting the military effort but every section of industry—production, transport and manufacture.

Towards the end of June 1917 the country was faced by a serious crisis in the cotton industry, owing to the difficulty of securing supplies of raw cotton. With the co-operation of the industry, a cotton control board was set up. The production of the cotton mills was cut down to 60%, extensions only being allowed on payment of levies, and the sum thus raised utilised for the benefit of the work-people in the less employed mills. The control board thus established contained representatives of the employers and the employed and also of the Government.

A board of control on somewhat similar lines was set up for the wool textile industry, to deal with the difficult problems which arose from the fact that, after Government requirements had been met, rather less than 20% of the output of the trade was left for civil needs. According to the War Cabinet Report for 1918 (p. 210), there was no question raised in connection with the wool textile industries to the solution of which the board did not contribute a most valuable part. Somewhat similar arrangements were made for the jute, flax and hemp industries.

One important effect of the Government control and of the strain put upon various industries by War conditions was the attempt made to extend the standardisation of production even into the clothing industries. By the end of 1918 there had been put on the market £15,000,000 worth of standard suits, over 2,000,000 lb. weight of hosiery, 1,000,000 blankets and 8,000,000 pairs of standard boots. These schemes of standard-

isation did not long survive the end of the War, though they may have led in some degree to simplification and the reduction of patterns. Of more lasting effect was the great alteration brought about in the productive capacity of various industries.

The manufacture of explosives and propellants was chiefly carried out in special Government factories, but shell cases, rifles, guns, trench weapons, aircraft, tanks, etc., could be produced in different classes of engineering works, and the engineering industry of the country was by degrees almost entirely absorbed in this work, which led to a very considerable expansion of engineering capacity. The same cause brought about a 50% expansion of capacity in the iron and steel industry, and varying increases in many smaller industries.

Various new industries had to be created to supply essential products which were formerly imported from sources rendered unavailable by the War. Amongst these may be mentioned dyestuffs, a large range of fine chemicals, optical and scientific instruments and their components, and various special products such as magnetos. A special Act (The Dyestuffs [Import Regulation] Act 1920 [10 and 11 Geo. V., Ch. 77]). was passed in 1920 prohibiting the importation of dyestuffs except under licence, the idea being gradually to build up by these means British production of essential dyestuffs. In 1921, the Safeguarding of Industries Act (11 and 12 Geo. V., Ch. 47), subjected to an import duty of 33⅓% a wide range of the other articles mentioned above.

War conditions brought about:—

(*a*) Changes in wages, (*b*) new methods of negotiation and relations between employers and employed, (*c*) the introduction of new processes and spread of repetition work, (*d*) improvement in the position of unskilled relatively to skilled labour, (*e*) an enormous increase in the industrial employment of women and (*f*) an increased interest in the improvement of methods of production and the welfare of workers.

Prices and Wages.—The complete control assumed over various industries fixed on the State the responsibility for the control of wages. The cost of living rose steadily during the War (from 100 in July 1914 to 205 in July 1918), and as the demand for War material was practically unlimited the adoption of the cost of living as a standard in the fixation of wages was almost inevitable. This principle was, however, not universally adopted, nor was there any generally accepted decision as to whether the increase should be a flat rate for all workers (on the ground that all need approximately the same minimum amount of food, clothing, etc.), or a rate proportional to earnings or varying inversely with earnings. The method generally adopted by the Government in the controlled industries was, however, to give a flat rate War wage.

This principle had the very important effect of introducing a change in the relation between skilled and unskilled labour, the position of the unskilled being very greatly improved. The following summary by Professor Bowley of the progress made from 1914–20 may here be quoted:—

After a few months of unsettlement the demand for War materials and the withdrawal of men to the Army resulted in very plentiful employment. The opportunity of increased family earnings at former rates of pay together with an active patriotic spirit prevented for some time demands for increased wages. As food became scarce and prices rose, however, earnings became insufficient in some cases to meet the reasonable needs of efficient subsistence, and bonuses and War wages were given, while the great demand for labour had its natural effect in raising rates of wages. So far as generalisation is possible, we may state that the growth of rates of wages generally lagged behind that of prices, but earnings, in those very numerous cases where piece rates or overtime gave facilities for additional work and pay, increased more rapidly than prices from the outbreak of the War to the Armistice. In the early part of 1919 the War rates continued, though earnings probably tended to fall; and the working classes, fairly content with existing rates in view of the slight fall in prices, devoted their attention to reduction of hours, so that in fact the normal working week was generally reduced by some 10%, while the same money was received for the shorter week as formerly for the longer. When the rise of prices set in again there were continued further upward movements of wages, and at the same time several of the more powerful trade unions made definite efforts to secure a higher standard of living than before the War, while the principle of a minimum wage, intended to be sufficient to allow a livelihood more liberal than had been customary, was widely applied. The result was that during 1919 and 1920 there was a race between wages and prices.

With regard to the employment of women, the following figures sufficiently illustrate the position:—

Average figures for men and women in industrial employment (manufacturing)

	July 1913	July 1918	July 1924
Men	6,301,000	5,058,000	6,016,900
Women	2,178,600*	2,970,600	1,987,990

The end of the year 1920 marked the peak of prices, and the slump of 1921 came upon a chaotic wage position. In some classes of work real wages were higher than pre-War, but in others they were lower. Railway workers, coal-miners, dockers and others had definitely obtained improvements in their standard of living. The effects of War tendencies continued in varying degrees in different industries, sometimes without due consideration for what the commercial conditions enabled the industry to sustain. Moreover, the operation of foreign competition upon certain industries created a great disparity between wages in these industries and those in the non-competitive or sheltered industries (covering about one-half of the total persons employed), and it is the general view of industrialists that the high level of these latter wages added a very considerable burden of cost to the less fortunate industries and seriously hindered their revival. (*See* PRICES; WAGES.)

Industrial Relations.—The experience of such bodies as the cotton and wool control boards, the spirit of comradeship engendered by the War, and the strengthening through War experience of the nation's realisation of the dangers of industrial strife, created a new attitude towards the relations between employers and employees. This found expression in individual works in the growth of works committees and other co-operative methods, and nationally in the establishment of the scheme for joint industrial councils, recommended by what is known as the Whitley Committee's Report. Of these there were by the end of the year 1921 between 50 and 60 in operation, covering such important industries as wool and allied textile, heavy chemical, printing, pottery, flour milling and gas and electricity supply.

The fact that the scheme was not adopted in coal-mining, cotton, engineering, railways, iron and steel, and certain other industries was largely due to the existence in those industries of well-tried conciliation schemes, which neither party desired to change. The intention of the scheme was that the councils should include in their scope not only conciliation but a wide range of subjects of general interest to the industry, such as technical education, etc. This intention has only been very partially carried out. Another evidence of the new spirit was the foundation of such bodies as the National Alliance of Employers and Employed (now called the National Industrial Alliance); the Industrial Welfare Society; the Institute of Industrial Psychology; the Industrial Fatigue Research Board, bodies which still survive to carry on the useful work indicated by their titles. (*See* INDUSTRIAL RELATIONS.)

Scientific Research.—The War strongly stimulated a most beneficial movement for scientific research. In 1917 Parliament voted a sum of £1,000,000 to be administered by a special committee of the privy council in grants to trades willing to form research associations. In 1924, 23 industrial research associations were in actual operation, and the privy council committee was able in its report for 1923–4 to record the opinion that the scheme promised to be a marked success. There has also been a substantial extension of research work by individual firms. (*See* INDUSTRIAL RESEARCH.)

Trade Organisation.—Shortage of raw materials and other factors made it absolutely necessary for the Government, when handling industrial questions, to be able to deal with trades as a whole. This led to the formation of voluntary representative associations in a considerable number of industries, while the increased realisation on the part of industrialists of the importance of mutual consultation and co-operation for commercial

purposes led to the foundation in 1916 of the Federation of British Industries, a strictly non-political body dealing solely with commercial questions.

The tendency towards amalgamation of individual firms was also much stimulated by War experience and by the recommendations of Government committees, which brought home to industrial leaders the necessity of safeguarding supplies of raw material, enlarging the scale of production, etc. The armament firms, faced with large extensions of plant, sought to facilitate the employment of these after the War by the acquisition of subsidiary businesses, capable of acting in the capacity of suppliers of material or buyers of partly finished products. There were also considerable amalgamations in the iron and steel, electrical engineering, in cocoa, chocolate, biscuit and glass industries. The formation of a large combine in the jute trade in 1920 may also be mentioned, but there was not any very general enlargement of units in the textile industries. These various amalgamations have not all been equally successful.

Trade Development.—Owing to changes in values and methods of recording it is difficult to compare post-War trade with that of 1913. The following chart and tables show the course of trade of the United Kingdom and in certain specified industries. Figures are for the whole of the British Isles up to April 1 1923, and for Great Britain and Northern Ireland after that date. The quantity index has been compiled to compare the post-War overseas trade with that for 1913.

Overseas Trade of the United Kingdom in value and volume, 1913, and 1919 to 1925

1. Imports

Year	Food, Drink and Tobacco		Raw Materials and Articles mainly unmanufactured		Manufactured Articles		Total	
	Mill. £	Index of vol.	Mill. £	Index of vol.	Mill. £	Index of vol.	Mill. £	Index of vol.
1913	295	100	270	100	201	100	769	100

less than in 1913 by varying degrees, and that this position was suddenly changed in 1921, when the volume of exports fell to a fraction of the volume in 1913, though the values continued to be substantially higher. Thereafter quantities gradually rose and values fell. The causes of the slump were described as follows in a report issued by the Federation of British Industries in the year 1922:—

Although there was, for various reasons, considerable delay in the resumption of the normal flow of orders for manufactured goods after the War, and the intake by the countries normally buying large quantities of such goods was during 1919 and 1920 far below the normal, the demand was more than the capacity of the manufacturing countries, hampered and reduced as it was by the effects of the War, could supply.

At the end of 1918 a boom in manufactured goods was experienced in Japan, which passed to the United States, and later in turn to Great Britain, to France and Belgium and finally to Germany. In these circumstances, and with Central Europe very largely unable to import at all, Great Britain was in a relatively fortunate position for obtaining supplies of food and raw materials. In 1919 the necessary foreign credit was secured in the first few months by a continuance of borrowing, and subsequently to a large extent by the very high earnings of our shipping and the abnormal prices we were able to secure for our coal exports. To the goods we were able to buy in this way have to be added the considerable imports on government account ordered during the War, but not shipped till after the Armistice. In 1920 the demand for our manufactured goods was so intense, that though the tonnage exported was small compared with 1913, the total value was very much larger, the average price being nearly four times the average pre-War price.

These developments were accentuated by the fact that many countries had heavy accumulated stocks of raw materials which they were unable to realise, as these accumulations were largely of materials normally taken by the Central Empires and other countries which were still out of the market. Unable to realise their products, these countries in turn were unable to buy the manufactured goods they required, and the normal circle of commerce was interrupted. The effect was immediately to prick the bubble of prices. Purchasers all over the world ceased to buy our goods, and, as prices fell, tended to defer purchasing altogether until they could see some sign that prices had touched bottom. On the one hand, therefore, manufacturers were left with high-priced goods for which the demand had suddenly ceased, while, on the other hand, there were heavy accumulations of unsold agricultural products and raw materials in the hands of potential buyers in distant parts of the world. This has had the result of checking production throughout the world both of agricultural products and manufactured goods.

Another factor which acted as a depressing influence immediately the slump commenced (and had, indeed, prevented some industries from profiting by the boom) was the liquidation by the Government of the enormous stocks of War material held by them at the conclusion of hostilities.

The table on page 273 gives the production of various industries, together with the trend of population in Great Britain and the outward passenger movement for the periods 1911 to 1913 and 1919 to 1925.

Statistics (Production and Population) for the United Kingdom

Year	(1) Cotton Spindles (000's omitted)	(2) Cotton Consumption (in thousands of bales, 000's omitted)	(3) Raw Wool Imports retained in the U.K. (in millions of lb.)	(4) Pig Iron production (in thousands of tons)	(5) Steel production (in thousands of tons)	(6) Gross merchant tonnage launched in Great Britain and Ireland (in thousands of tons)	(7) Coal Raised (in thousands of tons)	(8) Iron Ore produced (in thousands of tons)	(9) Imports of Wheat retained for home consumption (in millions of cwt.) (1) Raw cotton spinning spindles based on the July issues of the International Cotton Federation statistics, not including doubling and waste spindles. (2) Consumption of American cotton lint based on the International Federation's spinners' returns for years ending July 31. (3) Total raw wool retained in the United Kingdom compiled from the trade returns for the U.K. (4) and (5) Production of pig iron and steel according to statistics compiled by the National Federation of Iron and Steel Manufacturers. (6) Lloyd's Annual Summary of shipbuilding. (7) Production excluding Ireland from 1922. Prepared from the Board of Trade Returns. (8) Output according to the annual report of the Secretary for Mines. Production excluding Ireland from 1922. (9) Total wheat retained for home consumption compiled from the U.K. trade returns. (10) Estimated population compiled from the annual reports of the Registrar-General. (11) Board of Trade Returns.

The Various Industries

Coal.—The story of the coal industry was a particularly unhappy one. In 1914, 1,133,746 men were engaged in the coal mines of Great Britain, of whom 150,000 approximately joined up for war services. At the end of the War there were 1,008,867 and in 1924 1,230,248 men in the industry. Immediately after the War huge demands for coal arose. During this time due attention could not be given to maintenance problems, and this, coupled with the return of the miners from the armies, created acute difficulties in organisation, leading to increased costs with reduced outputs. The market showed considerable inequalities, export prices being extremely high as against home prices. During 1920–1 exports steadily fell, but in 1922–3 there was a sudden and sustained improvement, due to the disturbance of continental production through the occupation of the Ruhr. As this factor gradually ceased to operate the depression set in again. In 1925 the Government appointed a Commission to inquire into and report upon the economic position of the industry. Their report was published on March 10 1926 (*see* Coal).

Iron and Steel.—The export figures increased very largely in 1922, the reason in this case also being the French occupation of the Ruhr. When this artificial stimulus was withdrawn the prosperity of the industry immediately declined. This decline continued through 1924 until the last quarter of 1925. The following statement by the National Federation of Iron and Steel Manufacturers summarises the position at the commencement of the last quarter of 1925.

Blast Furnaces in Operation.—There are in the United Kingdom some 480 blast furnaces for the production of pig iron, which is the basic material for the manufacture of iron and steel. If the demand for pig iron required it, some 360 of these furnaces could be blowing at one time. In 1913 there was an average of 338 furnaces blowing throughout the year; the maximum number blowing at any one time since the War was 303 in Sept. 1920. At the present time there are only 129 furnaces in blast, the number having steadily fallen since May 1923.

Pig Iron.—The decrease in the number of furnaces in operation is naturally reflected in the production of pig iron. Pig iron reached its maximum production in the year 1913, when 10,260,300 tons were produced. In 1920 the output amounted to 8,034,700 tons, but in 1924 this had fallen to 7,307,400 tons or an average of 609,000 tons monthly, and this has still further fallen in the present year, so that the average monthly output for the first nine months amounted to only 529,400 tons, the output for Sept. amounting to 448,700 tons.

Steel.—The output of steel ingots and castings in 1913 amounted to 7,664,000 tons, but owing to war needs the steel-making capacity of the country was expanded by approximately 4,000,000 tons per annum, and the country has now the capacity to produce at least 12,000,000 tons annually. In 1920 the output of steel ingots and castings amounted to 9,067,300 tons. In 1924 the output had fallen to 8,201,100 tons, or an average of 683,400 tons monthly, and in the first nine months of 1925 the average was 609,400 tons.

Exports.—The prosperity of the iron and steel industry depends very largely upon the extent of its export trade. In 1913 the total exports of iron and steel amounted to 4,969,200 tons; in 1924 exports were 3,853,100 tons, or an average of 321,100 tons a month, while the average in the first nine months of 1925 was no higher than 300,000 tons a month. In Sept. exports touched their lowest point for 1925 and amounted to 273,200 tons.

Imports.—Imports, on the other hand, have increased in spite of the fact that the increased capacity during the War was sufficient to make it unnecessary for any steel to be imported. Imports of iron and steel in 1913 averaged 186,000 tons a month; in 1924 they had increased to 202,400 tons a month, and in the first nine months of 1925 amounted to 227,000 tons a month.

The decline in this trade has been due to causes which have affected other industries, *i.e.*, depreciated exchanges abroad, lower taxation, lower wages, longer hours in other countries and high foreign tariffs, the difficulties of the steel trade being accentuated by the increase in productive capacity both here and abroad.

Engineering.—In regard to the engineering industry, the same causes were in operation. The year 1925, on the whole, saw an improvement. An unfavourable feature, however, was a rise in the average value of machinery imported in comparison with the average value of machinery exported, showing that the imported goods are of a more highly developed and costly character than those exported. The position of the electrical side of the industry was more satisfactory than that of the other branches, no doubt because of the great increase throughout the world in the consumption of power.

Shipbuilding.—Particularly unfortunate was the experience of the shipbuilding industry. The productive capacity of the world has, since the slump of 1921, been greatly in excess of demand, due to the extension of plant throughout the world necessitated by the rapid wastage of tonnage during the War, and also to the continued depression of international trade which reduced the demand for freight.

Cotton.—The position of the American section of the cotton trade was continually unsatisfactory. Owing to short cotton crops the price of material was so high that the relatively poor markets, in which the great majority of sales are made, were unwilling to pay the prices which manufacturers were compelled to ask. Here again the year 1925 gave promise of an improvement. In regard to the finer side of the trade, that using Egyptian cotton, the raw material supply was more satisfactory, and trade was consequently better. Moreover, this side of the industry suffered less than the American section from the tendency of cotton-growing countries to install spinning machinery. Finally, reference should be made to the policy of recapitalisation at higher values during the boom period, the subsequent effects of which seriously embarrassed a number of firms (*see* COTTON).

Wool.—In regard to the woollen and worsted industry, there was very rapid recovery of trade in the second half of 1921, which continued, subject to a slight setback at the end of that year, through 1922 and 1923, the demand generally being for the finer class of goods at the expense of lower grade. During 1923 there was a further setback largely due to the disturbance in continental trade through the Ruhr occupation, which had so substantially benefited the iron and steel and coal industries. During the first half of 1924 there was a gradual recovery, which, however, affected the heavy more than the finer goods; but in the second half of that year the depression returned, and continued during the opening of the year 1925. In the latter part of 1925 there were signs of recovery. In this industry, as well as in cotton, there was a world shortage of material which maintained prices at a relatively high level, and was detrimental to consumption in the impoverished state of most markets. In neither wool nor cotton had the policy of central control, initiated during the War, maintained its power (*see* WOOL).

Chemicals.—The chemical industry includes heavy chemicals, dyestuffs and intermediates, fine chemicals and fertilisers. The progress of the heavy chemical trades since the War was extremely variable, as is shown by the export figures in the above tables. These have been chosen as samples, the great variety of products in the industry making any general statistical statement impossible.

Dyestuffs and Intermediates.—At the outbreak of War less than 20% of the colours used here were actually made in Great Britain, the market being dominated by the German industry. The cessation of imports soon created a dye famine, and prices rose to unprecedented heights, to the great injury of the textile and other dye-using industries. By the end of the War, however, British makers were able to supply not only their own essential requirements, but also some of the needs of our Allies. Government assistance and finance were necessary to enable this result to be attained. In addition the Government assisted the formation of a new company called the British Dyestuffs Corporation, Ltd., an amalgamation of various existing concerns, and itself invested a large sum in the corporation. In 1925 it was claimed that the British industry was meeting 80% of the needs of British colour users, and that an average reduction of 50% in prices had been effected since 1921. The working of this system of protection and partial Government control had not, however, been altogether happy, and during 1925 a reorganisation was carried through, the Government giving up its shareholding in the corporation.

Fine Chemicals.—The following summary is taken from the volume *Chemicals* by Ashe and Boorman (Ernest Benn, Ltd. 1924) in the series, on *The Resources of the British Empire:*—

Prior to 1914 the fine chemical industry was practically a monopoly of Germany, although several British firms possessed an international reputation for some of their products. The War cut off entirely our normal supplies of all kinds of fine chemicals, and beyond the stocks in the country we had no means of obtaining supplies of drugs such as aspirin; of anaesthetics such as novocaine; of remedies such as salvarsan; of synthetic photographic chemicals which were vital to aerial photography and for X-ray work in the hospitals; of synthetic tannins required in the leather industry; of analytical reagents for chemical analysis in the great steel works and in practically every other industry; and of a variety of other fine chemicals necessary for research work and in industry. Fine chemical manufacture was hurriedly undertaken in Great Britain, under most adverse conditions in respect of buildings, plant and processes, and very substantial progress was made. In a few months British salvarsan and salicylic acid were on the market; other drugs soon followed, and before hostilities ceased there was scarcely a synthetic drug of real importance that was not made in this country in sufficient quantities, and in many cases with a margin for export. The same was true of the synthetic photographic chemicals, amidol, metol, paramidol and glycin, and at the present time British photographic chemicals are second to none in quality. Of the synthetic perfumes and flavourings a certain number were made here before the War, but since the production has been largely developed. At the end of 1925 it was estimated that the British production was thrice as great and the volume of exports double what it had been before the War.

Fertilisers.—The fertiliser industries, producing basic slag, sulphate of ammonia and superphosphate of lime suffered much from the agricultural depression, due to bad harvests throughout the world, and from the fact that many of the products are the by-products of other industries. Before leaving the chemical industry mention must be made of the successful establishment since the War of a large scale plant for the fixation of nitrogen by synthetic process; this is a matter of great importance as Great Britain was previously entirely dependent on imports of nitrate of soda.

Motorcars.—The progress of this industry is well illustrated by the tables given above. Satisfactory features were the increased exports in 1923–4 and reduction of imports in 1924. It may be noted that a $33\frac{1}{3}\%$ *ad valorem* duty on imported motor cars, components and accessories was imposed in 1917, removed in July 1924 and reimposed in July 1925.

Artificial Silk.—Before the War artificial silk was not regarded as of sufficient importance to be allowed a special heading in official statistics. The figures given above show how prominent a place the trade held in Great Britain in 1925. It must be remembered that the figures represent values only, and that prices fell during the period 1921–5 (*see* ARTIFICIAL SILK).

Sugar Beet.—The development of the sugar-beet industry in Great Britain is in too early a stage to make any statistical record possible. The Government pledged itself to a generous scheme of subsidy, and the new industry started under favourable auspices. At the end of 1925 there were 10 factories actually in operation.

VII. AGRICULTURE

The period 1911–25 witnessed great changes in the cultivation of the soil, in the prices of agricultural produce, in the ownership of land, and still more in the relation of the State to the industry. Indeed, the period witnessed the popular acceptation of the idea that agriculture stood on a different footing from other industries and as such demanded that the State should have a "policy" calculated in one way or another to encourage the full cultivation of the soil.

Before the World War, Government action was of a very limited character. Its most important function was the eradication of contagious diseases of animals in continuation of the policy begun in the '60s for the prevention of the spread of foot-and-mouth disease, cattle pleuro-pneumonia, swine fever and rabies. A beginning had, it is true, been made in promoting agricultural education and research, in the extension of small holdings, and in the improvement of light horse breeding, but generally in this period the policy of the Government, apart

from the suppression of animal diseases, was one of non-interference with the industry, combined with some tentative efforts towards education and the spread of information.

The War Period.—With the outbreak of war, agriculture assumed a new significance. It ceased, at least for the time being, to be an industry pursued, like other occupations, entirely for the benefit of those engaged in it. The production of food became a national question. For a time it seemed as though the increased prices would in themselves provide sufficient stimulus, and it was not immediately obvious in what direction the State could usefully intervene. Gradually, both the food and labour supply became increasingly difficult, and in Jan. 1917 the Food Production Department was established under the Board of Agriculture with a view to more active steps being taken through county war agricultural committees and otherwise to stimulate the cultivation of the soil.

The Corn Production Act.—In the following March the Government announced an entirely new policy, which was afterwards incorporated in the Corn Production Act, 1917. This new policy was based on the view that in order to get farmers to plough up grass land and grow more cereals it was necessary to give them confidence in the future course of prices by providing a Government guarantee that the prices of wheat and oats should not fall below a certain figure during the next few years. The Act, as ultimately passed in Aug. 1917, fixed the prices as follows:—for 1917, wheat 60s. and oats 38s. 6d. per imperial quarter; for 1918–9, 55s. and 32s.; and for 1920–1–2, 45s. and 24s. respectively. Provision was made for the payment to the grower of the average difference between these prices and the average price ruling in the seven months following the harvest in each year. These guarantees, however, never became operative, as the actual price throughout the period was above the guaranteed price. Apart from the guarantees, the Act embodied another new and important departure in policy by providing for the establishment of an agricultural wages board, whose duty it was to fix minimum wages for workmen in agriculture and to see that not less than these wages were paid. This was combined with restrictions on the raising by land-owners of agricultural rents, and with power to enforce the proper cultivation of the land by farmers. Thus the policy contained in this Act was of a dual character: on the one hand it ensured to farmers for a period of six years certain minimum prices for their two principal cereal crops and protected them against any undue raising of rents; on the other hand it required them to pay adequate minimum wages to their workers and to cultivate their land in accordance with the rules of good husbandry.

As a policy of a less permanent character, very active steps were taken by the Food Production Department (under Lord Lee) during 1917–9 in the direction of increasing the area under the plough and generally in promoting the output of food. The increase in the area of the corn and potato crops between 1916 and 1918 was over 1,500,000 acres in England and Wales alone, while the total increase in the United Kingdom was just on 3,000,000 acres.

The Selborne Committee.—In the meantime, the question of the policy to be adopted in regard to agriculture after the War had been considered by the Agricultural Policy Sub-Committee, of which Lord Selborne was chairman. The reference to this committee was " to consider the methods of effecting an increase in the home-grown food supplies, having regard to the need of such increase in the interests of national security," and their report was issued in July 1918. It contains a full exposition of the position of agriculture in this country and deals in detail with the various problems presented, the object being " to formulate a scheme of agricultural policy which may be generally accepted by the nation and adhered to through a long course of years." Briefly, the committee took the view that the security and welfare of the State demanded that agricultural land should be made to yield its maximum production of foodstuffs, and that if this object was to be attained it was necessary to provide a basis of security and stability in the conditions under which agriculture is carried on. The method they recommended was the permanent adoption of the principles underlying the Corn Production Act, viz.: a minimum wage for the agricultural labourer, a guaranteed minimum price for wheat and oats for the farmer, and a control of cultivation sufficient to ensure to the State a permanent development of agriculture and the proper utilisation of the land.

These principles were incorporated in the Agriculture Act which, after prolonged discussion, was passed on Dec. 23 1920. The minimum prices guaranteed under this Act were to be ascertained annually on the basis of the estimated cost of production in any year as compared with 1919. Within a few months of the passing of the Act, however, it became apparent that a serious slump in agricultural prices was taking place and that the burden on the State involved in the guaranteed prices would be very large. This was combined with a general financial stringency which demanded a reduction in all Government expenditure.

A Reversal of Policy.—The result was that the main operative clauses of the Agriculture Act, 1920, were repealed by the Corn Production (Repeal) Act, 1921, and the whole policy of the the intervention of the State in agricultural wages, prices and in the control of cultivation was abandoned. Some temporary compensation was given to farmers by the payment of a subsidy on wheat and oats grown in 1921, which amounted to the sum of £18,000,000, and the sum of £1,000,000 was added to the development fund, mainly for the purpose of promoting agricultural education and research. The Agricultural Wages Board was abolished, and in its place conciliation committees representing both employers and workers were established to fix wages by voluntary agreement.

Between 1921 and the end of 1925, a great deal of discussion took place as to the adoption of some national policy in regard to agriculture, and a large number of proposals were put forward. A conference representative of the various interests was proposed with the object of arriving at some agreed method which would be acceptable to all parties and shades of political opinion, but owing to preliminary differences this conference was never held. The Council of Agriculture, which is a statutory but unofficial body, proposed a scheme which, among other matters, involved a subsidy amounting to some £5,000,000 or £6,000,000 for the encouragement of arable cultivation in England and Wales, but public opinion appeared generally to be opposed to subsidies of any kind.

Thus, at the end of 1925 there was no broad national policy recognised by the State in regard to agriculture of a character comparable with what was attempted by the Corn Production Acts. On the other hand, between 1921 and 1925 a great many agricultural questions were dealt with separately, and very extensive action was taken by the State in the direction of fostering and promoting agriculture. Very considerable sums are voted annually by Parliament with this object, and the position may be summed up by saying that policy is in the direction of helping the farmer to help himself without the intervention of the Government either in regard to prices or cultivation.

Agricultural Wages.—In regard to agricultural wages, the State again intervened and by the Agricultural Wages Regulation Act, 1924, provided machinery whereby minimum wages for workers in agriculture must be fixed in England and Wales. It was not thought necessary to include Scotland in its provisions because Scottish workers appeared able to arrive at satisfactory agreements with their employers without any assistance. The English Act provides for wages to be fixed locally by 47 committees covering the whole country, each committee being composed of an equal number of employers and workers (usually six to eight on each side), two impartial members appointed by the Minister of Agriculture and a chairman. In the event of failure to agree, an agricultural wages board similarly constituted has power to act in default.

Apart from this action in regard to labour, the newer features of the agricultural policy are the action taken in regard to land settlement, education and research, and sugar beet, to which may be added the enquiries and investigations carried out in the first instance by the Linlithgow committee and subsequently

by the Ministry of Agriculture in regard to the marketing of agricultural produce. Combined with these developments is a continuance of the older policy in regard to the control of contagious animal diseases, more especially foot-and-mouth disease, which of late years has presented a more formidable problem than it did for a long period prior to the World War.

Land Settlement, Education and Research.—A forward movement was begun after the Armistice in the direction of settling ex-service men on the land, and under the Land Settlement (Facilities) Act the area of land in England and Wales held by public authorities for letting as small holdings was more than doubled, viz.: from 201,000 ac. at the end of 1918 to 447,000 ac. at the end of 1924, while the number of occupiers increased from 13,874 to 30,177. As regards research and education enormous progress has been made, research institutes (connected in most cases with universities) being now provided for the study of all the scientific sides of agriculture, while instruction of a practical character is undertaken under the direction of the local authorities in every county in the country. This work is maintained or aided by grants from the Ministry of Agriculture, the expenditure from Parliamentary funds in England and Wales alone in 1925–6 amounting approximately to £647,000.

Another direction in which Parliament is providing large funds for the assistance of agriculture is by encouraging the establishment of the sugar beet industry by subsidising the manufacture of sugar from home-grown beet for a period of 10 years under the British Sugar (Subsidy) Act, 1925. The acreage under this crop rose to 55,000 ac. in 1925, and it was expected that this figure would be doubled in 1926. Considerable expenditure is also incurred in the direction of the improvement of livestock. An attempt was made under the Agricultural Credits Act, 1923, to establish a scheme of co-operative credit societies aided by loans from the State, but the number of societies actually established is very small (*see* CO-OPERATION).

The change in the attitude of Parliament towards agriculture may to some extent be measured by the change in expenditure. Thus in 1911–2, the total expenditure of the Board of Agriculture and Fisheries was £251,000, of which possibly 10% represented expenditure on fisheries. This covered England and Wales and Scotland. In 1925–6, the gross estimate for the Ministry of Agriculture (excluding expenditure on fisheries) was £3,277,000 for England and Wales alone, while the estimate for the Board of Agriculture for Scotland amounted to £452,000. The bulk of this expenditure took the form of grants for the purposes mentioned above and involved in most cases considerable additional expenditure on the part of local authorities and others.

A factor which has vitally affected both agriculture itself and the policy of the State has been the change in the price of agricultural produce since the War. During the War, prices naturally rose very considerably, and the rise continued till towards the end of 1920. In the middle of 1921 a severe and continuous slump set in, with the result that the prices of agricultural produce generally, which were 202% above pre-War prices in Sept. 1920, fell to 57% above in Sept. 1922, and with some fluctuations remained more or less at this level for the next three years, the figure for Nov. 1925 being 53%. The sudden fall in prices resulted in severe capital losses, and made agriculture, at any rate for a time, a very precarious undertaking (*see* AGRICULTURE).

In this connection, reference may also be made to another factor connected with the change in the value of money. The prevailing system of tenure in Great Britain is that of landlord and tenant, whereby the land and buildings are provided and maintained by the landlord at a rent which is generally admitted to give only a very small return by way of interest on the capital represented. The much higher rate of interest obtainable during the post-War period on first class securities led to extensive sales of estates, and is said to be resulting in a gradual change in the older system in the direction of a greater tendency towards occupying ownership. Such statistics as are available suggest that the percentage of land occupied and farmed by the owner increased from about 15% in 1920 to 25% in 1924.

Changes in Cultivation.—The changes in cultivation in Great Britain in the 14 years 1911 to 1925 reflect the policy of the period. Up to 1916 there was little development; in 1917 the pressure for increased food production began to make itself felt and reached its maximum intensity in the following year. With the close of the War the impetus was lost, and the proportion of land under the plough gradually decreased and fell below the pre-War level. The following figures, in thousands of acres, show the changes in Great Britain from 1911 to 1925: –

Acreage under Crops and Grass (000's omitted)

	Corn Crops	Arable Land	Permanent Grass	Total Acreage under Crops and Grass
1911	7,041	14,648	17,447	32,095
1917	7,308	14,606	17,251	31,858
1918	8,974	15,852	15,896	31,749
1925	6,321	13,912	16,549	30,461

The decline in the total acreage under crops and grass is to some extent compensated by an increase in mountain and heath land and rough grazings not included under that heading. The area under wheat (included in the above table under corn crops) which was 1,906,000 in 1911, reached a maximum of 2,636,000 ac. in 1918, and declined to 1,547,000 ac. in 1925. In regard to livestock, a very striking feature was the way in which on the whole the flocks and herds were maintained during the War, notwithstanding the shortage of feeding-stuffs. From 1916 to 1920, however, there was a quite noticeable decline in the number of sheep, part of which has since been recovered. As compared with pre-War years cattle are somewhat more numerous, while the pig population, always a fluctuating factor, reached a maximum in 1924. As a broad indication of the magnitude of the industry it may be mentioned that the total value of the "output" of agricultural land in Great Britain represented by the produce sold off farms for consumption elsewhere was estimated in 1923 at £259,000,000.

Agricultural Policy in 1926.—In Feb. 1926 the Government issued a considered statement on agricultural policy, which declared that the Government was not prepared to recommend subsidies for the increase of corn growing or arable cultivation and that it was definitely opposed to compulsory control of cultivation. "The right course in the best interests of the industry itself and of the nation as a whole is to proceed on the lines of education and encouragement rather than of coercion, to endeavour to create that confidence which is essential for progress, to stimulate the private enterprise of those engaged in the industry, and to assist them to organise themselves on an economic basis." It then went on to indicate the lines on which the Government would proceed, such as the development of agricultural credit, small holdings, afforestation, land drainage, marketing of agricultural produce, housing in rural areas, protection against disease and the development of sugar beet cultivation.

VIII. COMMUNICATIONS AND TRANSPORT

At the outbreak of the War the Government took complete control of the railways under an agreement whereby the companies were guaranteed their pre-War revenues. The fact that the War lasted for more than four years, and involved a far-reaching rearrangement and redistribution of the trade and traffic of the country, made the strict terms of the agreement practically inapplicable. A huge sum of money was required to put the companies back into their pre-War condition of repair and efficiency. Rolling stock had been removed to other countries, stations closed, permanent way and other plant allowed to fall into comparative disrepair, staff seriously depleted, and the arrangements for the routing of traffic widely altered. The costs of operation had also risen enormously.

The Ministry of Transport.—The Government, foreseeing the difficulties which would arise if control were suddenly removed, passed in 1919 the Ministry of Transport Act, which gave the Minister powers to control the operation of all existing means of internal transport. One provision in the Act has proved of permanent importance. This was section 21, which provided for the setting up of the Rates Advisory Committee composed of five members: one person of legal experience (to be chairman), two representatives of trading and agricultural interests, one representative of transport interests, and one representative of labour. It was laid down that before directing any revision of charges, etc., the Minister should consult this committee.

The Act was immediately followed by a reference from the Minister to the committee to report upon an interim revision of railway rates for merchandise and minerals. The committee reported in favour of a general increase varying according to class from 25 to 60%, with flat rate additions, and increased charges for collection and delivery. This was brought into operation on Jan. 15 1920. On May 11 the Minister announced his determination to undertake to complete revision of railway charges and invited the committee to report on the general principles which should govern the revision, including the classification of merchandise traffic. Meanwhile he directed the increase of rates up to 100% above pre-War as from Sept. 1 1920.

As a result of the committee's general report, there was finally passed the Railways Act 1921, which had the effect of entirely reorganising the railway system of the country. The Act's most important provisions may be summarised as follows:—

1. The railways of Great Britain were amalgamated into four large groups, the Southern, the Great Western, the London, Midland and Scottish and the London and North Eastern.
2. A new tribunal called the "Railway Rates Tribunal" was set up to which almost all the powers of the Railway and Canal Commission and many new powers were entrusted, its most important function being the settlement of the schedules and charges of the amalgamated companies. The tribunal consists of one person of legal experience, who is chairman, one person of railway experience and one of commercial experience, and is obviously the successor of the Rates Advisory Committee.

The first of these provisions was intended to facilitate working economies by eliminating costly competition, and the second to provide a cheap and business-like tribunal for exercising the necessary control over the new system

Charges and Wages.—The Act laid down an entirely novel principle in regard to the basis of charge. Section 58 provides that the charges be fixed on a basis estimated to yield an annual net revenue ("the standard revenue") equivalent to the aggregate net revenues in the year 1913 of the various companies absorbed by the amalgamated company together with allowances for interest on capital expended or raised since Jan. 1 1913, or capital which had not at that date become fully remunerative. Section 59 provides for periodical revisions of the charges and also lays down that if on any such review the tribunal finds that the net revenue of the company is substantially in excess of the standard revenue, such excess shall be divided between the public and the railway companies, 80% being allocated to reduction of charges and 20% being retained by the company as profits. This increased standard (the old standard plus 20% of the excess) is then to become the standard revenue of the company.

The tribunal was also given power to revise the classification of goods, and some control was vested in it of exceptional rates. There is no doubt that the framers of the Bill intended, by extending the number of classes and instituting a strict revision of exceptional rates, to reduce the complexity of the rate books, which were said to include more than 80,000,000 exceptional rates, many of them obsolete. The powers which the Bill proposed to vest in the tribunal for this purpose were however strenuously opposed by both traders and railway companies, and, although the tribunal has increased the number of classes from 8 to 21, it is improbable that the new provisions will succeed in substantially reducing the number of effective exceptional rates. In regard to wages and provisions of service, the Act provides that all disputes in regard to these shall be referred to two bodies, the Central Wages Board and the National Wages Board, the latter acting as a court of appeal from the former. Both these bodies are in the nature of conciliation committees including representatives of the companies and their employees; the National Wages Board also includes representatives of railway users.

Between the passing of the Act and the end of 1925, the Railway Rates Tribunal was more or less continually involved in the carrying out of the reorganisation of the railway system entrusted to it by the Act. The ascertainment of the standard revenue proved a very great difficulty, and might indeed have proved impossible but for the formation of a committee known as the traders' co-ordinating committee, representative of all trades substantially interested in railway traffic, and of such great organisations as the Federation of British Industries, the Association of British Chambers of Commerce, etc. This committee has been legally represented before the Tribunal and has been able to negotiate settlements with the railway companies. It appears likely that the almost insuperable difficulties involved in the application of the Act will be surmounted in this way. Reverting to the question of charges, these have been reduced by successive concessions in 1922 and 1923, till at the beginning of 1925 they were 50% above pre-War, with certain flat rate additions, some of the heavy traffic standing at 40%.

In July 1914 the railway trades unions were preparing a claim for improvement of conditions and increase of wages, to be presented in Nov. 1914, when an existing agreement was due to run out. On the outbreak of War it was agreed between the unions and the companies that the existing agreement should continue, but should be terminable by six weeks' notice on either side. The government during the War granted various increases of wages, and in Nov. 1918 the unions gave notice to terminate the agreement. There followed a prolonged negotiation in which the unions, the companies and the government were all involved, and on Sept. 26 1919 500,000 railway workers came out on strike. Work and negotiations were resumed on Oct. 5, and an agreement reached on March 20 1920. Under this rates were divided into two classes, "A" rates and "B" rates. The "A" rates represented the pre-War rates plus certain flat rate additions. These latter were to be subject to adjustment according to the cost of living. The "B" rates represented practically the pre-War wages plus 100%, and it was agreed that, whatever the change in the cost of living, wages should not fall below this level. In 1925 the railway unions put forward claims for a general increase of wages, and the companies counter-claimed for a general reduction. The National Wages Board rejected both claims, but provided that new entrants into the railway service should no longer be entitled to the benefit of the "A" rates. The Board also stated that they did not regard the "B" rates as an "irreducible minimum."

The Removal of Control.—The position of the companies after the removal of Government control in 1921 was an unfavourable one. The economies promised through amalgamation were slow in materialising, and the trade depression resulted in a decline of traffic which was only temporarily alleviated by the great increase in the iron and steel and coal traffic caused by the French occupation of the Ruhr. At the same time the rapid increase of road transport has diverted from the rail a considerable and increasing volume of the high grade traffics which were the most lucrative to the railways, whose position has been further complicated by the great increase in working costs. Expenditure in 1924 exceeded that of 1913 by £96,000,000 or 117%, whereas to meet this additional burden receipts had only increased by £88,000,000 or 70%. Coal was 142% higher than in 1911 and 89% over 1913; other materials were 67·9% and wages 153% above 1913. There was an increase in staff due to the operation of the eight hours' day, the staff in the four amalgamated companies having increased by 76,000 or 13%.

The companies' financial position was, however, relieved by the fact that in 1922 the Government, in order to clear up claims for compensation under the control scheme, handed over to them sums amounting in all to £62,000,000, making over £100,000,000 so distributed since the beginning of control. The companies were able in the years 1923 and 1924 to maintain their dividends by drawing money (over £5,000,000 in 1924–5) from their reserve funds, which had been enormously augmented by these grants. It should be mentioned that the companies have made efforts to secure legislation enabling them to carry by road, but hitherto without success. Meanwhile, they are no doubt endeavouring to effect economies in their operating expenditure. Electrification schemes are being put in hand, notably by the Southern Company. The L.&N.E.R. and the G.W.R. have taken steps to increase the size of the mineral trucks on their systems, the ideal apparently being a 20 ton standard; and passenger services are being co-ordinated, etc. Attempts are also being made to obtain relief from the burden of local rates.

Canals.—During the War the Government took over the great bulk of the canals, the object being to relieve the railways as far as possible of traffic which could equally well go by water. The arrangements for compensation were similar to those made with the railway companies. The great value of the canals during the War caused a revival of interest in their potentialities, especially as the railway system was very congested during the early post-War period. The

government instituted inquiries into the possibility of reviving the canals which had largely fallen into disuse prior to the War, but no government felt justified in undertaking the somewhat ambitious schemes of reorganisation which have been recommended at various times. Local schemes, have, however, been under consideration in various districts, and with government and municipal assistance important improvements are being made on the waterways between Nottingham and the Humber. It is possible that further developments may be undertaken, notably between Birmingham and the Mersey, and Birmingham and the Severn.

Roads.—The development of road transport during the first decade of the 20th century directed attention to the condition of the roads in the country, and as a result the Development and Road Improvement Funds Act was passed in 1909. Under this Act a Road Board was constituted with powers:—

(*a*) To make advances to county councils and other highway authorities in respect of the construction of new roads or the improvement of existing roads;

(*b*) To construct and maintain any new roads.

The income of the Road Improvement Fund was to be derived from motor spirit and carriage licence duties. During the World War the income was absorbed into the general revenue of the country and road development was arrested. By an order in council dated Sept. 22 1919 the powers and duties of the Road Board were transferred to the Ministry of Transport. In 1919–20 a special fund of £10,536,000 was set aside for the road and bridge programme, and arterial road construction actively proceeded with, particularly in the London area. Under the Finance Act 1920 a new system of taxation, registration and licensing of mechanically propelled vehicles was introduced and came into force on Jan. 1 1921. Special schemes were put in hand for the relief of unemployment, for which £4,000,000 was provided from the Road Fund in 1920–1. The income of the Road Fund in 1922–3, derived from motor spirit duties, carriage licenses, Exchequer grants and motor taxation, was £12,802,754: these receipts had increased in 1924–5 to £15,234,225. During the period 1919–25 arterial roads were constructed in the London area, Scotland, etc.; the total length of new construction was 169 miles, and 48 miles of existing roads were widened. On March 31 1925 the total commitments of the Road Fund amounted to £36,087,000. Expenditure by local authorities on the maintenance, improvement, etc., of roads increased from £18,903,840 in 1913–4 to £28,413,674 in 1919–20 and to £45,431,036 in 1921–2. The great increase during the post-War period was due partly to the practical cessation of work during the war period and partly to local unemployment relief schemes. After 1921–2 expenditure by local authorities was considerably reduced.

Postal Service.—Telephone tariffs varied widely in different areas in 1910, but by 1921 a system of uniform charges had been instituted as far as possible. The National Telephone Company's system was transferred to the Post Office on Jan. 1 1912. The number of exchanges increased from 1,566 in 1910 to 3,971 on Dec. 31 1925, and the number of telephone stations from 619,399 in 1910 to 1,357,908 on Dec. 31 1925. The acceptance of telegrams from subscribers by telephone, and delivery to them by the same means increased greatly between 1910 and 1925. Rates for inland telegrams on Sept. 1 1920 were double those of 1910.

The following table shows the more important alterations in postage rates between 1910 and 1925:—

Changes in Postal Rates

	1910	June 1918	June 1920	June 1921	May 1922
Initial letter rate (inland and imperial) .	1d.	1½d.	2d.	2d.	1½d.
Initial letter rate (foreign)	2½d.	2½d.	2½d.	3d.	2½d. (May 1923)
Postcard rate (inland)	½d.	1d.	1d.	1½d.	1d.
Initial printed paper rate	½d.	½d.	½d.	1d.	½d.
Inland parcel rate (up to 2 lb.) . . .	4d.	6d.	9d.	9d.	6d. (May 1923)
Inland parcel rate (up to 11 lb.) . . .	11d.	1s.	1s. 6d.	1s. 6d.	1s. 3d. (May 1923)

Air Mails.—The post-War period was marked by the development of commercial aviation. The Post Office inaugurated air mail and parcel services between London and the Continent. Mails are accepted by the air mail for Belgium, France, Morocco, Algeria, Germany, Denmark, Norway, Sweden, etc.; air services established in Continental countries are used to supplement this service. The total weight of letter mail despatched by air in 1925 was 15,520 pounds. The air parcel service carried during that year 50,000 lb. of parcel air mails to Paris, Holland and Germany including the Rhine Army.

Wireless and Cables.—Wireless services considerably increased between 1910 and 1926. A new wireless station was built at Hillmorton, near Rugby, and was opened for service from Jan. 30 1926. This station was able to send messages which could be picked up by ships at sea and by every efficient receiving station in the world. In 1925 the British Govt. owned and worked two cables between Great Britain and Halifax, Nova Scotia. One, in German ownership before the War, is worked directly between London and Halifax. The other, purchased from the Direct United States Co., and taken over by the British Post Office in 1922, is worked from London to Newfoundland and Halifax. The two cables are called the imperial cables.

(C. T.)

GREAT LAKES AND ST. LAWRENCE (*see* 12.399 and 24.21).—The Great Lakes and the St. Lawrence form one of the greatest and most important transportation routes in the world, rivalling in tonnage and economy of operation any other existing water transportation route. To July 1 1924 the United States Federal Govt. had expended about $150,000,000 for improvements in the Great Lakes-St. Lawrence system, exclusive of expenditures by Canada, by States or Provinces and by municipalities.

Traffic.—During the 30 years 1895–1925 over 1,500 million tons of freight moved through the locks at Sault Ste. Marie alone. The 72,000,000 tons which passed through these locks in 1924 included 13,500,000 tons of flour and grain and 42,500,000 of ore, moving east, and 13,500,000 tons of coal moving west. Except for the construction of several experimental Diesel engine-driven vessels, no great developments were made in the type of the large bulk freighter in the 15-year period ending in 1925. The highly specialised freight-handling equipment at the terminals, which has in large measure accounted for the economic system of transfer, has developed only in size during the same period. The record for handling cargo between shore and ship is 16½ min. for loading 12,508 gross tons of ore and 3 hr. 5 min. for unloading.

During the 20 years 1905–25 a considerable tonnage in limestone and sulphur grew up. The stone, used as a flux in ore furnaces, is transported on self-unloading vessels between harbours on Lake Huron and the great iron and steel centres in the vicinity of Lakes Michigan and Erie. Sulphur is carried by water from the wells in Texas and Louisiana to New York, and thence in barges through the New York State barge canal to Buffalo, Cleveland and other points on the Great Lakes. Package freight on the Great Lakes has not kept pace with bulk freight, though still amounting to over 1,000,000 tons. Over 90% of the commerce has been confined to the upper lakes, a small portion only passing into Lake Ontario and the St. Lawrence. Traffic on the upper lakes has increased to such an extent that the locks at Sault Ste. Marie in existence in 1910 (two American and one Canadian) were not sufficient to cope with the traffic, and two new locks (numbered 3 and 4) were constructed on the American side and put in operation in 1918. Each of the new locks is 1,350 ft. long and 80 ft. wide, with 24½ ft. of water over the sill. The old Weitzel lock has not been in operation since 1918.

Harbours.—Originally the mouths of rivers were used as harbours on the lakes. It was necessary to dig out the bars which usually formed at the lake entrance, and later piers were constructed at river mouths which contracted the area of flow and tended to keep the channels scoured out. Still later, breakwaters were built in the lakes to protect pier entrances from wave action. As conditions became more congested in the rivers, the breakwaters were extended to form large outer harbours. These structures were originally stone-filled timber cribs, the tops of which, after the timber decayed, were replaced by concrete or stone. The more recently constructed breakwaters are formed of a line of concrete caissons sunk side by side, or of a long rubble mound composed of stones varying from half a ton to 10 and 12 tons in weight, more or less carefully placed. Some of these outer harbours are as much as four and five m. long and afford ample protection to the largest lake vessels.

Maintenance dredging must be carried on at all times in most of the harbours of the Great Lakes. About 65 harbours on the upper lakes (excluding Lake Ontario) have an authorised pro-

ject depth of 19 ft. or more at low water; about 65 others on the Great Lakes-St. Lawrence system have been improved so as to be available for smaller vessels.

Connecting Waterways.—The critical points in the navigation of the lakes are the connecting waterways. These, like the harbours, require continuous dredging to preserve project depths and to remove obstructions. The Lake Carriers' Association, a federation including nearly all the owners of freight-carriers on the lakes, have formed an efficient system of communication and supervision which permits them to take advantage of water conditions and load their vessels to the greatest possible depth. The deepening and widening of the connecting channels authorized some years ago have practically been completed; and at many of the most critical points, such as the Neebish channels below Sault Ste. Marie and the channels between Lakes Huron and Erie, separate upbound and downbound passageways are maintained. On the upper lakes the minimum width of channels used for two-way traffic is 500 ft., whereas 293 ft. is the least width of channel now used for one-way traffic. The controlling depth of water between Lakes Erie and Superior is still 20 ft. at low-water datum. A dike on which sluice gates are installed has been constructed across St. Mary's river near Sault Ste. Marie. The gates are operated under the supervision of an international board of control in order to maintain water-levels in Lake Superior and to compensate for diversions on both the Canadian and the American sides at Sault Ste. Marie for power purposes.

The question of diversion of water from Lake Michigan into the Chicago drainage canal for the purpose of sewage disposal has not been settled. The Supreme Court of the United States decided against Chicago in a suit instituted to enjoin the Chicago sanitary district against withdrawing water. However, in order to permit the Chicago Sanitary Commission to prepare plans and construct works necessary to take the place of the prevailing system of sewage disposal, temporary authority to divert 8,500 cu. ft. of water per sec. from Lake Michigan was granted by the United States War Department for a period of five years under certain conditions, which, when carried out, will permit the reduction and perhaps the eventual discontinuance of the diversion for sewage purposes. The question is of importance because of enormous losses claimed by shipping interests on account of lower water levels. It has been stated by government engineers that the diversion of 8,800 ft. from Lake Michigan affects the level of Lake Erie from ·38 to ·43 ft.; of Lakes Michigan and Huron from ·42 to ·44 ft.; and of the St. Lawrence river at lock No. 25 from ·6 to ·65 of a foot.

Erie-Ontario Routes.—Two navigable routes (1926) connect Lake Erie with Lake Ontario. The Erie branch of the New York State barge canal system, completed in 1918, connects Lake Erie and the Niagara river through the Oswego branch of the barge canal with Lake Ontario at Oswego. The barge canal route continues through the State of New York and connects with the Hudson river at Troy, forming a complete waterway available for vessels of less than 12-ft. draft and requiring not more than 15½ ft. of head room. A new Welland canal between Lake Erie and Lake Ontario is being constructed to replace the existing one. It is estimated the work will be completed in 1930. Seven lift locks will replace the 25 locks in the present canal, and the distance between the two lakes will be shortened to 25 miles. The new canal is being excavated to a depth of from 25 to 26½ ft. below Canadian low-water level. The new locks will be 820 ft. long by 80 ft. wide, and, in order to provide for possible future deepening of the canal, will be constructed so as to accommodate vessels drawing 30 ft. of water. The estimated cost of the completed structure is $110,000,000.

The question of improvement of the St. Lawrence river from Lake Ontario to tidewater in the interest of navigation and power development is being seriously considered by joint action of the United States and Canada. The St. Lawrence river affords opportunity for the development of over 4,000,000 H.P. of hydro-electric energy. On account of the many interests involved on both sides of the border, it had been difficult to effect an agreement on the question of the St. Lawrence improvement.

By treaty stipulation the amount of water that may be diverted from the Niagara river for power purposes has been limited to 36,000 cu. ft. per sec. on the Canadian side and 20,000 cu. ft. per sec. on the United States side. Of the Canadian diversion all but about 10,000 cu. ft. per sec. is used by the Hydroelectric Power Commission of Ontario, in three plants, the largest of which, near Queenstown, has a head of over 300 ft. and develops about 500,000 H.P. from the nine turbo-generators installed. Of the American diversion practically all the water is utilised by one concern with an installation of over 500,000 horsepower.

Boundary Water Treaty.—In 1909 the United States and Great Britain signed a treaty known as the "Boundary Water Treaty," whereby the waters between the United States and Canada were guaranteed free and open to the inhabitants of both countries on equal terms, and principles governing the use of boundary waters were laid down. An international joint commission, consisting of three members from Canada and three members from the United States, was established.

TABLE I.

Lakes	Area of Water Surface	Maximum Recorded Depth	Mean Elevation Approved Low-Water Datum	Ordinary Fluctuations, Water Surface	Average Date of Opening of Navigation	Average Date of Closing of Navigation
	Sq. Miles	Feet	Feet	Feet		
Superior	31,810	1,180	601·6	2·5	April 23	Dec. 9
Michigan	22,400	870	579·6	2·8	April 12	Dec. 15
Huron	23,010	750	579·6	2·6	April 6	Dec. 17
St. Clair	460	26	573·8	. .	March 30	Dec. 18
Erie	9,940	210	570·8	3·0	March 29	Dec. 17
Ontario	7,540	738	244·5	3·3	April 5	Dec. 18

TABLE II.

Rivers	Length	Least Width	Greatest Width	Limiting Depth at Low Water	Current in Navigated Portions	Discharge at Mean Stage
	Miles	Feet	Feet	Feet	Miles per Hour	Cubic Foot-Seconds
St. Marys	63	300	24,000	21	1–3½	[1]
Strait of Mackinac	30	10,900	100,000	110	. .	47,000
St. Clair	40	800	5,100	20	1–5	203,000
Detroit	31	1,900	19,000	22	1–6	208,000
Upper Niagara	20	1,500	8,000	10–23	1–7	207,000
Lower Niagara	15	210	2,600	30	1–2½	207,000
St. Lawrence to Montreal	179	1,200	40,000	14	1–6	240,000

[1] In its original condition the mean stage discharge of the St. Marys river was about 78,000 cu. foot-seconds. The flow of this river is now entirely controlled by regulating works.

TABLE III.

Commerce (in short tons) on the Great Lakes

Year	Total U.S. Commerce on Great Lakes (Adjusted)	Canals at Sault Ste. Marie (Reported)	Detroit River (Estimated)	Welland Canal (Reported)	St. Lawrence Canals (Reported)	N.Y. State Barge Canal (Reported)
1910	92,044,843	62,363,218	73,526,602	2,326,390	2,760,752	3,073,412[1]
1920	111,139,686	79,282,496	80,410,082	2,276,072	3,067,962	1,421,434
1921	71,460,170	48,259,254	63,973,308	3,076,422	3,734,065	1,457,802
1922	94,038,090	66,067,258	68,497,062	3,391,419	4,319,919	2,260,763
1923	125,517,551	91,379,658	92,170,460	3,755,912	4,541,528	2,572,635[2]
1924	109,831,279	72,037,390	80,073,850	5,037,412	5,536,374	2,658,674[2]

[1] Old canal system partly closed down between 1910 and 1918 during construction of a new 12-ft. canal.

[2] Includes 566,351 and 626,357 tons for 1923 and 1924 respectively of local terminal traffic that did not pass through the canals.

(H. T.*)

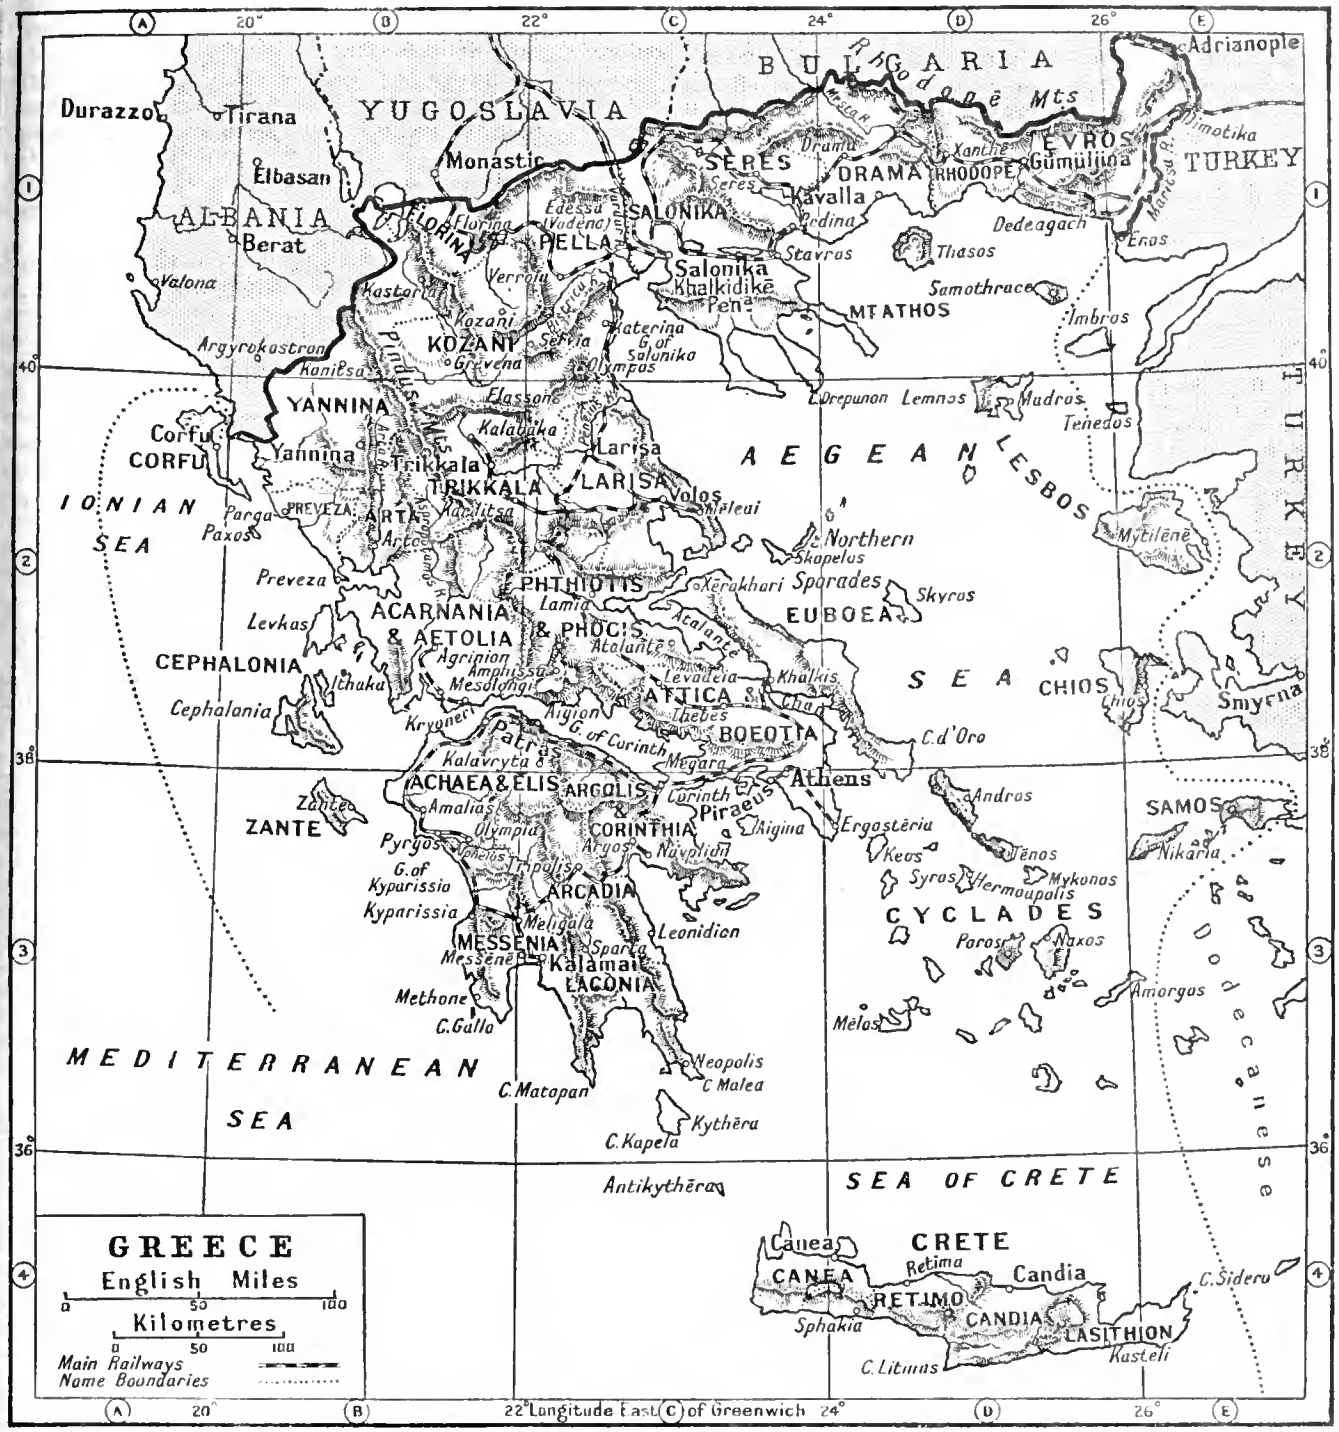
GRECO-TURKISH WAR: *see* BALKAN WARS.

GREECE (*see* 12.425), a republic of southern Europe and a member of the League of Nations. Its area is 49,200 square miles. The area of Old Greece in 1912 was 24,400 square miles. The Balkan Wars of 1912–3 resulted in the addition of New Greece, consisting of Macedonia, Epirus, Crete and a number of islands in the Aegean, with an area of about 21,600 sq. m., making the total area of the country about 46,000 sq. m. in 1914. After the World War, Greece occupied Thrace and a part of the vilayet of Aidin in Asia Minor, and these occupations were confirmed by the treaties of Neuilly and Sèvres. But, as the result of the Asia Minor campaign, Greece in 1922 evacuated Asia Minor and Eastern Thrace in favour of Turkey, and by the Treaty of Lausanne in 1923 she also retroceded Imbros and Tenedos. The area of Greece after these various changes, is now about 49,200 square miles.

A census taken in 1920 gave the total population of Old and New Greece as 5,536,375, including Thrace. An estimate which allows, on the one hand, for the subsequent loss of territory and for the transfer of the Moslem inhabitants of Greece to Turkey, and, on the other hand, for the influx of some 1,400,000 refugees from Turkey after the war in Asia Minor, would place the population in 1925 in the neighbourhood of 6,200,000.

The various racial migrations which have been brought about by the wars from 1912 onwards, whether voluntary or compulsory, involving the transfers, in either direction, of nearly 2,500,000 Greeks, Bulgarians and Turks, have had the result of introducing homogeneity in the regions affected, where before there was great diversity. Thus the proportion of Greeks in the population of Macedonia and Western Thrace, which stood at 43 and 36% respectively before the Balkan Wars, is, in 1925, 88 and 62%.

(L. G. R.)



I. POLITICAL HISTORY

In Jan. 1910 the Military League had summoned Veniselos from Crete as their political adviser, and he had arranged for the election of a National Assembly. But the obstruction of the party leaders soon obliged him to take the premiership himself and to appeal once more to the electorate. When the second revisionary National Assembly met on Jan. 22 1911, he took office at the head of an overwhelming majority. During the following 18 months the constitution was revised, internal administration was thoroughly overhauled, army and navy were remodelled and trained under French and British missions, and the Macedonian feud was forgotten.

The Balkan Wars.—A treaty was signed with Bulgaria (May 1912) who had already signed a treaty with Serbia for the partition of Macedonia, and in Oct., the first Balkan War broke out. Montenegro declared war on Turkey, Oct. 8; Turkey declared war on Bulgaria and Serbia, Oct. 17, but offered Greece the island of Crete and other concessions to remain neutral. Veniselos however realised the supreme importance of including Greece in the new grouping. The long-excluded Cretan deputies were admitted to the Greek Chamber and Greece declared war on Turkey on Oct. 18 1912.

The Balkan allies gained rapid success. The Greek Army cleared Macedonia and occupied Salonika (Nov. 9); the fleet blockaded the Dardanelles. Greece refused to sign the armistice obtained from the other allies (Dec. 3) but joined the conference which met a fortnight later in London. The allies demanded from Turkey the surrender of all the territory their armies actually held in Europe together with the fortresses invested. The seizure of power by the "Young Turkish" party at Constantinople prevented the acceptance of these terms, and hostilities were re-opened on Feb. 3 1913. But after Adrianople had surrendered to Bulgarians and Serbs, Scutari to the Montenegrins, and Janina to the Greeks under Prince Constantine—who 12 days later (March 18) became King on the assassination of his father George I. at Salonika—Turkey by the Treaty of London (May 30) signed away collectively to the Balkan allies all her territory in Europe west of a line drawn from Midia on the Black Sea to Enos on the Aegean Sea, leaving the Powers to settle the problems of Albania and the Aegean Islands.

Second Balkan War.—The erection of an independent Kingdom of Albania, by excluding Serbia from the Adriatic, rendered inevitable a quarrel between the allies. Greece, alarmed at the menacing attitude of Bulgaria, had in June signed a defensive alliance with Serbia, and when Bulgaria attacked without warning (June 30) she was heavily defeated, and after the intervention of Rumania was compelled to sign the Treaty of Bucharest (Aug. 10 1913) which excluded her from the Aegean port of Kavalla and carried the frontier of Greek Macedonia eastwards to the river Mesta and northwards to Doiran and Florina. The course of events had thus compelled Veniselos to substitute a policy of balance of power for that of a Balkan League.

The Aegean Islands.—The Powers assigned to Greece (Conference of London, Feb. 1914) all the islands of the Aegean actually occupied by the Greek fleet during the war, with the exception of Tenedos and Imbros and of the islands of the Dodecanese which Italy had occupied in 1912 as security for the Turkish fulfilment of the Treaty of Lausanne (Oct. 18 1912) pledging her good faith that her occupation should be conditional and temporary. After the World War, Veniselos negotiated an agreement with Signor Tittoni (July 29 1919) by which all these islands were to revert to Greece unconditionally, the cession of Rhodes alone being made contingent on a plebiscite to be held within five years of England's cession of Cyprus. This agreement was recognised by the Supreme Council, the time limit within which the plebiscite was to be held being extended to 15 years, on the signature of the Treaty of Sèvres (Aug. 10 1920) in accordance with which Tenedos, Imbros and Lemnos, which had been occupied during the War by the British fleet, were handed over to the Greek authorities on June 25 1921. The Tittoni agreement was repudiated by Italy, who remained in occupation of the Dodecanese, after the fall of Veniselos and the non-ratification of the Treaty of Sèvres. Turkey closed the Balkan war with Greece by a provisional agreement (Treaty of Athens, Nov. 13 1913) but refused to accept the decision of the Powers of Feb. 1914; consequently the *de jure* possession of the islands remained in suspense until the Treaty of Lausanne (July 24 1923) whereby Turkey renounced in favour of Italy all rights over the Dodecanese, and recognised Greek sovereignty over the remaining islands as conferred by the Conference of London, subject to certain provisions for their demilitarisation, and with the exception of Imbros and Tenedos, which were retroceded to Turkey on condition that they should enjoy full local autonomy.

The World War.—Greece definitely annexed Crete and thus emerged from the Balkan Wars with a very large acquisition of territory in Epirus, Macedonia, Crete and the Aegean Islands, with a total population of over 1,800,000, or almost as much as that of "Old Greece." Turkey's refusal to recognise the ruling of the London Conference was accompanied by a boycott of Greek shipping and an organised persecution of the Greeks in Asia Minor. But her evident intention of re-opening hostilities with Greece was anticipated by the outbreak of the World War. The attitude of the Greek Govt. as stated by Veniselos was never in doubt. Not only did her interests and tradition bind her to support Great Britain and France; she was bound to Serbia by her defensive alliance, the purpose of which would best be served if Greece stood by to prevent Bulgaria from making any hostile move and to guard Serbian communications with the Aegean. King Constantine on the other hand naturally inclined to Germany for family reasons, and believed in her victory; but he never found the courage to declare openly his intention to remain neutral, preferring to temporise.

In Feb. 1915, when England definitely required Greek help for attacking the Dardanelles, the proposals of Veniselos for specific Greek forces to co-operate with the British fleet were unanimously approved by his own majority in the Chamber, and by a Crown Council of all the political leaders in the kingdom. King Constantine however dismissed Veniselos and dissolved the Chamber (April 10 1915). The new premier Gounaris co-operated with the German propaganda in Athens to represent Veniselos as inspired only by love of war and hatred of the King. King Constantine was thus brought into party politics as a personal opponent of Veniselos and leader of the "pro-German" policy of neutrality. In mid-June the electors nevertheless returned the Liberal (Veniselist) party with a majority. But when Veniselos, after a delay excused by the King's illness, at last returned to office (Aug. 22), his efforts to immobilise Bulgaria by threatening Greek action were useless, because Germany had already been secretly informed that Greek neutrality would be guaranteed by King Constantine even in the event of a Bulgarian attack on Serbia. Bulgaria mobilised on Sept. 19 1915, and King Constantine allowed his Prime Minister to order a counter-mobilisation, and even to suggest to England and France that they might reinforce the Greco-Serbian co-operation with some of their own troops, a suggestion which led to the Allied landing at Salonika. But as soon as Veniselos, on the eve of the Bulgarian attack, explained once more his well-known policy of defending Serbia and received a vote of confidence, he was abruptly dismissed, and M. Zaimes was put up (Oct. 5) to explain that the Greco-Serbian Treaty had "a purely Balkan character." The Chamber was again dissolved and elections held in December. The Liberals abstained from the polls, as a protest against this second and unconstitutional dissolution, and a government was formed under M. Skouloudes (Nov. 6), who declared "very benevolent neutrality" towards the Entente.

From this time forward the King began not only to expect but eagerly to desire a German victory. The violence of his partisans was aggravated when the "Three Protecting Powers," Britain, France and Russia, demanded certain administrative changes which might prevent any connivance between the Govt. and the German espionage (June 21 1916). The Greek Army, which owing to the known sentiments of its general staff threatened, or at least inconvenienced, the Allied base at Salonika, was at last demobilised; whereupon the Bulgarians invaded Macedonia and seized Kavalla. Meanwhile King Constantine would from time to time change his Premier (Zaimes, June 23; Kalogeropoulos, Sept. 16; Lambros, Oct. 9; Zaimes, May 3 1917) and ask the French or British minister to suggest terms on which it might suit him to abandon his "neutrality." When in Aug. Rumania joined the Allies and the King still refused to move, Veniselos seceded to Salonika (Sept. 25 1916) with Gen. Dankles and Adm. Condouriotes, set up a Provisional Government and out of half the kingdom which declared its allegiance to the Triumvirate began to organise a state militant. The Allies refused their official recognition to the Salonika Govt., although Veniselist troops were already fighting for them. At Athens the French admiral suggested that King Constantine might surrender some of his war material. The King was understood to consent; but when French and British marines landed to take delivery they

ere shot down by Greek troops from prepared positions (Dec. 1916).

The Allies now broke off relations with the King, but, owing o the hesitations of Russia and Italy, did not demand his abdiation till June 1917. He retired to Switzerland (June 12) and is second son Alexander was put on the throne. Veniselos eturned to Athens as Prime Minister of a nominally united Greece (June 26), recalled the Chamber which had been unconstitutionally dissolved in Nov. 1915 and formally declared war gainst Germany, Turkey and Bulgaria (June 20). By April 918, the Greek Army had been mobilised and re-equipped. In uly 250,000 Greek troops shared in the Macedonian offensive which culminated in the capitulation of Bulgaria (Sept. 30 1918).

Treaty of Sèvres and Fall of Veniselos.—At the Peace Conference (Paris, Jan. 1919) Veniselos' presentation of the Greek claims was remarkably successful. As affecting Bulgaria these were embodied in the Treaty of Neuilly, to which was annexed a Greco-Bulgarian convention for the protection of racial minorities, etc. (Nov. 27 1919). Bulgaria was cut off from the Aegean, the Allies undertaking to ensure her an "economic outlet." This problem has not hitherto been solved, as it was found impossible at Lausanne (Jan. 1923), even with the guarantee of the League of Nations, to devise any scheme, other than a territorial corridor, acceptable to Bulgaria. The Treaty of Sèvres (Aug. 10 1920) assigned to Greece the greater part of Thrace, and a mandate, based on Greece's interest in the Greek population of Asia Minor. It also assigned to her the basin and hinterland of Smyrna under a strictly controlled régime. Greek troops had landed at Smyrna at the request of the Supreme Council on May 15 1919.

Unfortunately during these negotiations Veniselos had lost touch with his people, and the Govt. at Athens had proven incompetent and corrupted. The resulting discontents were exploited by Constantine's agents. Not the Greek peasants only but many of the urban population were innately averse to Veniselos' 20th-century ideas. In Aug. 1920 Veniselos returned to Athens tired out, and angrily refused any electioneering compromise with the 16 leaders of opposition. Then King Alexander, playing with a pet monkey, was bitten. He died of blood-poisoning (Oct. 25) and his younger brother Prince Paul having refused the Government's offer of the throne, the restoration of King Constantine became the real issue at the general election. On Nov. 14 1920 Veniselos was heavily defeated at the polls. He resigned, and with many of his ministers and officials left the country. A government was formed by the aged Demetrius Ralli which entrusted the Regency to the Dowager Queen Olga.

After the formality of a plebiscite King Constantine returned to Athens (Dec. 19 1920). The Allied Powers refused to recognise him officially, withdrew their financial assistance, and agreed to reconsider the Treaty of Sèvres, which though signed had not been ratified and had already been repudiated by the Turkish Nationalists. The withdrawal of their support was serious. The armistice concluded with Turkey (Oct. 30 1918) had made very incomplete provision for the disarmament of the Turkish forces and it was partly in order to restore order in Asia Minor and protect the Christian populations that Greek forces had been authorised to land at Smyrna. But the Supreme Council, although it had finally (July 1920) asked the Greek troops, in Mr. Lloyd George's words, "to clear up the whole neighbourhood between Smyrna and the Dardanelles," a task successfully accomplished in 10 days, had set very definite limits to the Greek army of occupation: and Mustafa Kemal had had time to organise a formidable force. Greece was isolated; France and Italy both, overtly or covertly, supported Turkey, and Great Britain declined to embark on expensive Eastern adventures.

Greco-Turkish War.—Yet the new premier M. Kalogeropoulos (Feb. 7 1921) and his successor M. Gounaris (April 7) rejected the moderate proposals of a Conference of the Three Powers (Britain, France and Italy) which met in London (Feb. 21) to reconsider the Treaty of Sèvres; and instead actually ordered from London an offensive (March 24) against the Turkish Nationalist positions, which after seizing Afiun Qarahisar and Eskishehr, was disastrously defeated (April 5) with 4,000 killed and wounded. On June 11 (anniversary of the fall of Constantinople in 1453) King Constantine left for Smyrna hailed by the government press as emperor designate of Constantinople and commander of the Anglo-Greek forces in the Near East. On June 10 the Allied Powers again offered "their friendly services to prevent the reopening of hostilties," but the offer was magniloquently rejected. The Greek forces opened their new offensive in July. A month later they were within 60 m. of Angora. But in August they were disastrously defeated on the river Sakkaria with very heavy losses. On Sept. 29 1921 King Constantine returned to Athens. On Oct. 16 Gounaris and his foreign minister Baltazzi, after receiving a vote of confidence in the Chamber, left for London and at last placed the interests of Greece without any reserve in the hands of Lord Curzon. Meanwhile the French "Franklin-Bouillon" agreement with Kemal had been signed at Angora (Oct. 20 1921); and Lord Curzon's ability to make peace was limited by the difficulty of coming to a preliminary agreement with France and Italy. Gounaris thus abandoned all Greek interests vested in the Treaty of Sèvres. He also gave up all claim to the balance of credits guaranteed to Greece by the Allies during the War and received in return permission to raise a loan on the open market if he could (agreement with Sir R. Horne, Dec. 21 1921). At Athens this was represented as a financial triumph, and thus arose considerable outcry in British Press and Parliament to the effect that England was secretly financing the Greek Army. Meanwhile the true situation was hidden from the Greek people; the persecution of Liberal deputies and journalists continued. Nor were the Liberals consulted when Gounaris on returning to Athens (March 10 1922) was compelled to reform his government. When the Near East Conference met in Paris, proposals for an armistice and the evacuation of Asia Minor by the Greek Army were transmitted to Athens and the two Turkish governments of Constantinople and Angora (March 26). The real Turkish power, that of Angora, explained away the apparent acceptance of these terms at Constantinople by making it plain that Turkey would accept only the immediate evacuation of Asia Minor.

A few days before the Conference Gounaris had privately addressed to Lord Curzon a desperate appeal for help and confession of imminent disaster. On May 11, after vainly following Mr. Lloyd George to Genoa, he resigned and joined M. Stratos in a coalition under the premiership of M. Protopapadakes, who had previously as Minister of Finance raised a forced internal loan by cutting in half all the bank notes in circulation. The first act of the new Govt. was to remove the commander-in-chief, Gen. Papoulas, who had privately advocated strengthening the front by the reinstatement of Veniselist officers previously removed, and to appoint in his stead Gen. Hadjanestes. In July the Govt. had the independence of Ionia proclaimed by the high commissioner of Smyrna, M. Sterghiades. They also issued a report that the Allies would shortly allow the Greek Army to occupy Constantinople; while Gen. Hadjanestes, a figure of notorious eccentricity, completed the demoralisation of the front and actually transferred large bodies of troops from Asia Minor to Thrace. The Turks attacked on Aug. 26 and entered Smyrna on Sept. 9 1922; five days later the whole city, with the exception of the Turkish quarter, was burned to the ground.

Revolution of Chios.—The Govt. resigned on Sept. 8, after ordering the demobilisation of the troops who were leaving Smyrna. But the attempt to scatter the remnants of the army as they were evacuated from Asia Minor failed. Many units landed on the island of Chios; and there a revolution headed by Col. Plasteras broke out on Sept. 26. King Constantine left the country and died in the following Jan. at Palermo. Eight of his principal ministers and advisers indicted by a special Commission of Enquiry were tried before an extraordinary court martial of 11 officers. Six of the accused (Gounaris, Stratos, Baltazzi, Theotokes, Protopapadakes and Hadjanestes) were shot immediately after the verdict (Nov. 28 1922). The executions shocked Europe. The British Minister, Mr. Lindley, who had refused to take the responsibility of guaranteeing that the accused, if

reprieved, should never again take part in politics, left Athens. But they had a salutary effect on the Greek Army. Thousands of deserters returned to the colours, and a small but efficient army, reformed on the Thracian frontier under the command of Gen. Pangalos, greatly strengthened the hands of the Greek representative (Veniselos, who had consented to represent his country abroad) and of all the Allies at the second Conference of Lausanne which finally succeeded in signing peace with the Turks on July 24 1923.

Refugees and Minorities.—Meanwhile the Revolutionary Govt., after proclaiming an amnesty for all political offences (Jan. 22 1923), was confronted with the problem of the million destitute refugees expelled from Asia Minor. For some months the settlement of the refugees on a productive basis was organised with the help of American charitable societies; later the Greek authorities had to depend entirely on their own resources until a loan was raised (Dec. 1924) the administration of which was guaranteed by the League of Nations. In 18 months the Refugee Settlement Commission of the League of Nations had settled more than half a million refugees in new villages and urban districts throughout Greece. This settlement increased the homogeneity of population on the Greek frontiers, where the problem of alien minorities had already been reduced by a system of exchanging populations, embodied in the Greco-Bulgarian Convention (1919) for the voluntary emigration of minorities and the Greco-Turkish Convention (Jan. 30 1923) for the compulsory exchange of Moslem and Greek-orthodox minorities. These agreements (together with the Turco-Bulgarian agreement of 1913) completed and regularised a series of migratory movements which had begun with the Balkan Wars and had transformed the populations of Thrace and Macedonia. Thrace east of the Maritsa is now completely Turkish, Western Thrace predominantly Greek; and in Sept. 1925, the League of Nations Refugee Settlement Commission reported that Greek Macedonia was then "crowded with an active and industrious population, of which more than 90% were Greeks by race and sentiment" (*see* REFUGEES).

The Corfu Incident.—On Aug. 27 1923, the murder of the Italian member of the Greco-Albanian Frontier Commission led to the Italian bombardment of Corfu. Greece appealed to the League of Nations through whose agency the dispute was ultimately settled (*see* LEAGUE OF NATIONS). Greece's correct and conciliatory attitude in this unfortunate dispute did her great credit.

Return of Veniselos.—At home the revolutionary Govt., led by Cols. Gonatas and Plasteras with M. Alexandres as Foreign Minister, made genuine attempts to return to constitutional government. They failed however to form a moderate centre party (Sept. 1923); and a month later the extreme Royalists, under Gen. Metaxas, attempted to raise a counter revolution, which was easily suppressed. There was evidence that Gen. Metaxas had been in communication with King George II. The Republicans thus received a tremendous impetus, and though at the elections (Dec. 16 1923), from which the Royalists abstained, they were defeated, they had secured the support of the army and the navy, under the influence of Gen. Pangalos and Capt. Hadjikyriakos, whose pressure was so energetic that the Govt. to avoid disorder requested the King to absent himself during the meeting of the National Assembly which was to decide the future of the Throne. On Dec. 18 1923 the King and Queen left for Rumania. Adm. Condouriotes was appointed Regent and Veniselos was invited to return to Greece. In view of the apparent unanimity of the appeal he found it impossible longer to refuse. He returned (Jan. 4 1924) only, he was careful to announce, temporarily, in order to "put an end to civil war." and proposed to solve the constitutional problem by an immediate plebiscite. The Revolutionary Committee resigned and Col. Plasteras retired into private life.

Establishment of a Republic.—A week after his arrival Veniselos unwillingly accepted the premiership. He proposed (Jan. 23) that a plebiscite should be held in two months' time, under the supervision of committees representing every party, to decide whether a republic was desirable, and if not who should be king. The decision was to be followed by a general election held under a system of proportional representation. He found himself opposed however by the extreme Republicans under M. Papanastasiou who insisted on the immediate expulsion of the dynasty and establishment of a republic by a vote of the Assembly. Veniselos resigned the premiership (Feb. 4) to M. Kafantares who also favoured a plebiscite. He succeeded (Feb. 27) in defeating the Republican motions in the Chamber and was proceeding to negotiate for a joint programme with the Royalists when t[he] Officers League was reformed and demanded from Regent a[nd] Premier that a republic should be set up without more ado. [M.] Kafantares resigned, Veniselos left Greece (March 10) and [a] government was formed by M. Papanastasiou, who proposed [to] settle the fate of the throne by a resolution of the Chamber [to] be ratified by a subsequent plebiscite. After the King had refus[ed] a very generous offer if he would abdicate voluntarily, there w[as] no difficulty in getting the necessary vote. The republic w[as] proclaimed on March 25 1924. The plebiscite, the arrangemen[ts] for which were accepted by the Royalists, was held on April 1[3] when 758,742 voted for the republic and 325,322 for a monarch[y]. The republic under the provisional presidency of Adm. Co[n]douriotes was recognised on April 23 by England, who had resume[d] diplomatic relations on Jan. 16.

The Govt. of M. Papanastasiou was strengthened by th[e] inclusion of Gen. Pangalos, Col. Kondyles and Adm. Hadjiky[ri]akos; but the two last-named officers soon left it again and M. Papanastasiou resigned, and was succeeded by M. Sofoules o[n] July 19, after a violent attack on the Minister for War, Gen Pangalos, by M. Mihalakopoulos who himself formed a govern[ment] on Oct. 7.

The Unratified Protocol.—At the end of July 1924, Bulgarian komi[tadjis] captured on Greek territory at Tarlis were shot down by thei[r] escort, and a month later a Commission of Inquiry appointed by th[e] League of Nations censured the local authorities though it exonerate[d] the Greek Govt.; a satisfactory feature was that the report wa[s] signed by the Greek member of the commission. On Sept. 29 th[e] Bulgarian and Greek delegates (Col. Kalfoff and M. Politis) meetin[g] at Geneva signed a protocol providing that each Power should ap[point] as its official advisers for carrying out the treaty protectin[g] the interests of minorities Col. Corfe (British) and Major de Roove[r] (Belgian), who were already at work on the frontier as members o[f] the existing mixed commission for the exchange of populations ap[pointed] under the Greco-Bulgarian convention of 1919. Thei[r] authority would be a protocol embodying provisions contained i[n] the Treaty of Neuilly and repeated in an annexe to the Treaty o[f] Sèvres. Unfortunately this sincere and generous movement was re[garded] at Belgrade as an arbitrary recognition of the existence o[f] "Bulgar" minorities in Greece which might lead Bulgaria to claim similar privileges for "Bulgar" minorities in Serbia. Serbian annoyance and Greek suspicion were quickened by exaggerated rejoicing in the Bulgarian press. On Nov. 27 Serbia denounced the Alliance with Greece and this undoubtedly determined Greek repudiation of M. Politis. On Feb. 3 1925, the Greek Chamber refused to ratify the protocol and on March 14 it fell to Veniselos to announce and defend this refusal before the Council of the League.

Negotiations with Serbia.—On April 27 1925 negotiations for renewal of the Greco-Serbian alliance were opened at Belgrade and soon broke down over the preliminary demands of Serbia. Serbia demanded the control and exploitation of the railway from Ghevgeli to Salonika; an extension of the Serbian zone on the harbour of Salonika; and a recognition that the Slavs of Macedonia were not "Bulgars" but "Serbs." This last demand was referred by Greece to the League of Nations. With regard to the railway line she offered to rebuild and reorganise the line or to appoint a permanent League of Nations official to arbitrate on all Serbian complaints but objected to any such cession of rights as would be not only a diminution of sovereignty but a continual source of friction. The negotiations were broken off on June 1, and a subsequent proposal that the line should be worked by a French company (Oct. 9) was not more successful. With regard to the larger question of the Alliance, which remained in suspense, there was a possibility that, both Powers having disclaimed any territorial ambitions, negotiations might be re-opened (Jan. 1926) for the conclusion of a Balkan security pact analogous to that of Locarno.

The Patriarchate.—At the Conference of Lausanne the Turks had consented to the maintenance of the Oecumenical Patriarch at the Phanar provided he exercised no civil or administrative powers. But on Jan. 30 1925 the new Oecumenical Patriarch was expelled from Constantinople by the Turks, who contended that he was not an "inhabitant of Constantinople" and that accordingly he was not exempted by the Treaty of Lausanne from the provisions of the Convention for the Exchange of Populations. In any case the Greeks had put themselves in the wrong by ignoring the usual formalities of election and failing to obtain Turkish consent to his candidature. The Council of the League of Nations referred the dispute to the Hague Court (March 14); but meanwhile Greece and Turkey arrived at a settlement, Greece persuading the expelled Patriarch to resign.

Gen. Pangalos Seizes Government.—Meanwhile the National Assembly had not yet succeeded in voting the new constitution

and there were numerous complaints of peculation and administrative inefficiency. On June 16 M. Mihalakopoulos reformed his government but 10 days later, confronted by an ultimatum from Gen. Pangalos and Adml. Hadjikyriakos, he resigned. Gen. Pangalos formed a government (June 26) including Adml. Hadjikyriakos, M. Kofinas and, later, M. Rentes (July 2), an experienced diplomatist, and after receiving a vote of confidence dissolved the Assembly. The new constitution, issued by proclamation on Sept. 30, provides for a president to be elected for a term of five years and a Senate of 150 members, 100 to be elected by the parliamentary franchise, 30 by various guilds and corporations and 20 by Chamber and Senate. Gen. Pangalos promised that it should be submitted for ratification after elections to be held in the new year. A proposal to court martial M. Papanastasiou for issuing a democratic manifesto was cancelled (Oct. 5) but Gen. Plasteras was expelled from Athens (Oct. 24). Two officials were publicly hanged for embezzlement.

On Oct. 19 there occurred a fresh frontier "incident" with Bulgaria, in the course of which the latter appealed to the League of Nations (*see* LEAGUE OF NATIONS: *Work of the First Six Years*). The commission ordered Greece to pay damages and found she had violated the Covenant by occupying Bulgarian territory with her troops. The commission also made various recommendations for avoiding frontier incidents (including a system of frontier guards under neutral officers), and for completing without friction the convention for the Exchange of Populations. The undoubted success of the League was obscured in Athens by an inevitable comparison with the Corfu affair, but the decision of the Council in accordance with the report was accepted by the Greek Govt. on Dec. 15.

Meanwhile Gen. Pangalos was making strenuous efforts to suppress political rancour at home. On Nov. 24 at a conference with the party leaders he received assurances that the constitutional question would not be raised at the elections in March and on this understanding the election of a senate was fixed for Jan. 10, and two Royalists, M. L. Roufos and M. Schiotes, entered the Government. Apparently however it was too much to expect political leaders not to talk politics. On Jan. 3 1926 and in subsequent proclamations Gen. Pangalos announced that the senatorial and parliamentary elections would be indefinitely postponed and that his Government had decided to concentrate all executive and administrative powers in its own hands; with the declared aims of economy and internal order and the forcible reconciliation of contending factions the Ministries of National Economy and Public Assistance were abolished, the permanence of the civil service was suspended and the Press was forbidden to publish any articles written by MM. Kafantares, Papanastasiou and Mihalakopoulos. Adml. Hadjikyriakos and M. Schiotes immediately resigned. At the Ministry of Finance M. Tantalides, replacing M. Kofinas who had gone on a debt-funding mission to Washington, issued a forced loan similar to that of 1922 from which foreigners were not to be exempted (Jan. 23). All these measures were received by the people with the fatigue and listlessness which were becoming almost a substitute for political stability. Indeed while the agreeable M. Roufos remained at the Foreign Office to develop the improving relations with Serbia, Italy and Albania there was a prospect that Greece might at last enjoy a period of tranquillity and good government. The dictatorship of Gen. Pangalos had the merits as well as the defects of a fire-eating common sense, and it had the advantage of not being disguised in any pretentious ideology. (J. N. M.*)

THE COUNTRY'S DEFENCE

The normal duration of military service, which is compulsory for all Greek citizens, is two years in the active army, 11 in the reserve and eight in the territorial army. Men are called up at the age of 21, and are liable for service until 51. Territorials are only called up in case of invasion or threat of invasion, and are only called up for training twice in the fourth and eighth year for a fortnight. The peace-time strength of the army is 12 infantry divisions, 1 cavalry division and a certain number of units unattached. The total personnel in 1924–5 was 66,484. The Greek Navy consists of 5 old battleships, 1 armoured and 1 protected cruiser dating from before the World War, 11 destroyers and 36 smaller units, including 2 submarines. (X.)

II. ECONOMIC AND FINANCIAL HISTORY

Pre-War Position.—The economic situation of Greece during the early years of the present century, up to the outbreak of the Balkan War in 1912, was marked by a steady if moderate progress. Industrial enterprises for local purposes were established in considerable number. Communications by road and railway were extended, and large additions were made to the mercantile marine. The premium on gold gradually declined, and finally disappeared in 1909. By the Valaoritis law of 1910, providing for the automatic issue and withdrawal of notes against gold or foreign exchange, the currency was definitely stabilised at par on the gold exchange system, to the great advantage of the general economy and the credit of the country.

The state of the public finances, though less satisfactory, also showed signs of improvement at the latter end of the period. A series of deficits from 1907 to 1909 had to be met out of a portion of the proceeds of a new foreign loan raised for this and other purposes in 1910. At the same time, a programme of fresh taxation was introduced, including income tax and succession duties, with the result that the accounts up to 1912 showed a substantial surplus of revenue over expenditure. The varying interest on the old gold loans, payable out of surplus revenues in the hands of the International Financial Commission, marked a sensible upward progress.

The Balkan Wars of 1912 and 1913 threw a considerable strain on the resources and the finances of Greece, which was, however, relieved in some measure by the material assistance rendered by Greeks abroad. Immediate war expenses were defrayed chiefly out of the balance of the 1910 loan and the proceeds of various provisional loans, which were liquidated by means of a new consolidated loan issued in 1914, and taken up for the greater part in Paris and London. This loan was secured on the revenues assigned to the International Financial Commission, an institution which, though regarded as an encroachment on the sovereign rights of the country, has been found useful on repeated occasions as a means of providing security for fresh loans. The economic strength of Greece was greatly enhanced by the acquisition of territories of both actual and potential value, including the important port of Salonika, the rich tobacco-growing districts of Drama and Kavalla and extensive areas in Macedonia capable of productive development.

The World War.—After the outbreak of the World War, and during the period of neutrality of Greece, which lasted from 1914 until 1917, there was a considerable accumulation of private wealth in the form of foreign balances, but the country suffered severely from internal conflicts, from the economic blockade of Old Greece in 1916–7 and from the prolonged mobilisation and war preparations. Noteworthy economic events during this period were: the law of 1915 facilitating the formation of co-operative societies; the connection, in 1916, of the railway system of Greece with those of Europe; and the agrarian legislation of 1917, which provided for the expropriation of large estates in favour of the peasants, and at the same time prohibited the alienation or mortgage of the peasants' holdings and their subdivision at death.

The entry of Greece into the War in 1917 involved a large increase in military and naval expenditure. Fresh taxation was imposed, including a tax on War profits, and a certain sum was raised by an internal loan and by the issue of National Defence bills. But the bulk of the funds required was provided by advances in kind from the Allied Powers and by credits opened by the latter for expenditure in Greece, against which payments were effected in notes by the Greek Government. These credits were treated as cover for the note issue. The very considerable expansion in the paper currency which resulted from these arrangements did not cause at first too heavy a

demand for exchange, for the factors which contributed to strengthen the foreign balances during the period of neutrality continued to operate until the end of the War.

With the close of the War, however, and the suppression of restrictions on trade, the accumulated purchasing power of the country made itself felt in a large demand for foreign goods. Large purchases of Greek and other securities were made in foreign markets, and the depreciating currencies of Europe offered an attractive field for the speculator. The resultant pressure on the exchange funds of the note-issue was so great that before the end of 1919 the available reserves were exhausted, the exchanges began to fall away from the gold parity, and the Valaoritis law became a dead letter. In the course of 1920 a portion of the Allied credits was realised, but this was quickly absorbed by purchases of supplies, and the excess of imports reached unprecedented proportions.

Effects of the Greco-Turkish War.—At the same time, the Govt. found itself involved in fresh liabilities in connection with the military operations in Asia Minor. To raise the considerable funds required, recourse was had to a large internal lottery loan, to issues of National Defence bills, to loans from the National Bank and, finally, to inflationary issues of paper money. The fall in the exchanges was accelerated by the withdrawal of financial support and credits by the Allies on the return of King Constantine in 1920. By the end of that year the drachma had lost 60% of its gold value. This depreciation of the currency reacted unfavourably on the budget, while the prosecution of the Asia Minor campaign entailed ever-increasing expenditure. In 1921 and 1922 issues of paper money and National Defence bills were effected on a large scale, without authority from the International Financial Commission taxes were raised and a forced loan was extracted from note-holders by compelling them to surrender one-half of each note in exchange for a government bond. The disaster in Asia Minor in 1922 reduced the finances and credit of the country to the lowest ebb, and by the end of the year its securities were quoted on the international markets at prices yielding 20% to the investor, while the drachma had lost 94% of its gold value. This collapse of the monetary unit, with the concomitant rise in the price-level, profoundly disturbed economic conditions throughout the country, and caused serious losses among particular sections of the community. The bulk of the public debt being on a gold basis, the real charge of its service on the state finances was not greatly reduced by the depreciation.

Refugee Settlement.—The influx from Asia Minor and Thrace of a vast number of destitute refugees threw a fresh burden on the resources of the country, and enlisted the sympathy and assistance of foreign countries, especially of England and America. Under the auspices of the League of Nations an independent refugee settlement commission was set up in 1923, for the establishment of the refugees, and a refugee loan was issued in 1924, in London, New York and Athens, guaranteed by revenues assigned to the International Financial Commission. Meanwhile, the Govt. made strenuous efforts to put its finances in order. Considerable fresh taxation was imposed in 1923, including a capital levy to be spread over five years, which has given very mediocre results. The floating debt was largely increased in 1923 and 1924. A fresh uncovered issue of paper money was made in 1923, and at the same time a law was passed authorising further issues against cover in funds abroad. The exchange, after violent fluctuations, settled down in 1924 to about one-tenth of the gold parity. By 1925 the public finances had so far recovered that the Govt. was able to allocate special revenues to the reduction of the floating debt, and to present a balanced budget. But this equilibrium was afterwards disturbed by fresh expenditure and by a renewed fall in the exchanges, due to an inflationary banking policy and a maladministration of the foreign exchange fund created by the law of 1923. At the end of 1925 the drachma had again fallen back to one-fifteenth of its gold parity.

Notwithstanding the instability of the political régime, of the public finances and of the monetary policy, the country as a whole showed remarkable powers of recuperation after a period of 10 years of war ending in a great national disaster. The refugee population tended to become an asset instead of a burden. The refugees settled in Macedonia, extended the cultivated area and increased the production of crops, while large numbers found employment in industrial and other occupations. The expropriation of agricultural properties for the benefit of refugee and other peasants was accelerated, on terms very unfavourable to the owners, by special legislation in 1923 and 1924. The mercantile marine, which had been reduced by nearly two-thirds during the War by sales and losses through enemy action, was restored to its original strength. Exports expanded slowly, but the growth of imports bore witness (apart from the portion attributable to foreign loans) to the extent of the country's additional resources in the form of shipping and other profits, of remittances from emigrants and of investments that were held abroad.

The greatly increased burden of public debt was mitigated by the fact that the larger part of it was held by her own nationals. Nascent local industries, hampered during the War for lack of fuel, took a fresh upward stride, stimulated in some degree by high tariffs and other protective measures, and by the influx of refugee labour. The extension of building operations and other forms of economic activity afforded evidence of increased prosperity, but an exact measure of real progress could not be ascertained while inflation continued. Railways, roads, ports and urban services generally were still in a backward state. At the end of 1925, however, numerous projects were in contemplation or in course of execution, with the aid of foreign capital, for extensive improvements in these directions and for the further development of local resources.

Statistical Comparisons.—The following statistical table summarises the changes in some of the salient economic and financial features of Greece over an interval of rather more than ten years, *i.e.*, 1914 to 1924.

	1914	Present day	
Area, square miles	46,000	1925	49,200
Population	4,800,000	1925	6,200,000
Production of cereals, tons	847,000	1925	871,000
Production of tobacco, tons	25,000	1925	66,000
Production, currants, tons	158,000	1925	133,000
Production of emery, tons	16,000	1925	20,000
Production of lignite, tons	20,000	1925	111,000
Exports, drachmas	178,500,000	1925	4,320,000,000[1]
Imports, drachmas	318,800,000	1925	9,834,000,000[1]
Joint stock companies	68	1925	325
Companies, capital of, drachmas	363,000,000	1925	2,190,000,000[1]
Co-operative societies	5	1925	3,655
Letters carried	29,810,000	1924	73,403,000
Telegrams despatched	1,968,000	1924	5,502,000
Telegraph lines, miles	5,735	1924	11,225
Railways open, miles	1,366	1925	1,689
Piraeus entries, steamships	3,809	1925	7,915
Piraeus entries, net tonnage	4,067,000	1925	5,044,000
Mercantile marine, steamships	474	1925	467
Mercantile marine, gross tonnage	830,000	1925	912,000
Bank deposits, drachmas	474,000,000	1925	5,755,000,000
Bank deposits, postal savings, drachmas	700,000	1925	93,500,000
Note circulation, drachmas	253,000,000	1925	5,339,000,000
Public debt, gold £	43,900,000	1925	77,800,000
Public debt, currency, drachmas	173,600,000	1925	7,918,000,000
Ordinary revenue, drachmas	207,700,000	1924-5	4,719,000,000
Athens cost of living, index no.	100	1925 Dec.	1,644
Exchange on London, drachmas per £	25	1925 Dec.	378

[1] These figures must be considered in relation with the exchange.

GREEK LITERATURE, ANCIENT (*see* 12.507).—Our knowledge of ancient Greek literature has been increased greatly since the beginning of the century. In 1918 Sir Frederick Kenyon knew of 920 literary papyri: Professor Oldfather in 1923 counted 1,167. No entirely new authors have been discovered equal in importance to Bacchylides, Herondas and Timotheus, and no new treatise quite equal to Aristotle's *Constitution of Athens*.

The New Comedy.—Of Menander we have considerable fragments—found in 1907—from seven plays, ranging from 550 lines to 88, and can form some opinion of at least three: *The Epitrepontes* (Appeal to Arbitration), with ten characters; *The Perikeiromenê* (Girl with her Hair Cut), with eleven; and perhaps *The Samian Woman*. Again, we have part of the plot of *The Priestess*. A man's wife has left him (possibly for religious reasons) and become a priestess; he does not know what she did with their son, and the priestess is unapproachable. His slave pretends to be possessed by a demon, and so gets taken in to the priestess to be treated. He finds out that the boy is being reared as their own by certain neighbours, and tells the father, who goes straightway to claim his son. But these neighbours also have a genuine son of their own, and by mistake the old gentleman lights upon him. The boy decides that the old man is mad, and tells his foster brother, who, consequently, when his father approaches him on the same subject, humours him as a lunatic. . . .

An opening like this shows how far we have travelled from the simple *μῦθοι* of the 5th century. We can see that Menander invented his plots, and invented them with an ingenuity and complexity utterly beyond the conceptions of the great tragedians. We can appreciate his exquisite style; colloquial, yet refined, subtle and witty and capable of much emotional power. It is palely reflected in the *urbanitas* of Terence. Contemporaries who were still under the spell of tragedy and the Old Comedy could ask themselves "whether Menander copied life or life Menander"; but on a modern reader he will not make an impression of realism. Lost or exposed children, recognitions, betrayed maidens, captured cities and heroines sold into slavery, faithful or ingenious slaves, indulgent or cross parents, play a larger part on his stage than they ever did in real life.

Yet the general effect does give a vivid picture of Hellenistic Athens. It is an easy-going and cultivated commercial society, steering as best it can, with much understanding and sympathy and humour, amid the shipwrecks of a tormented world. There are no villains, no cruelty; the women have character, the betrayed maidens have generally been betrayed in the excitement of some wild religious festival, and the betrayer suffers torments of remorse. Except in the exposing of children, a favourite motive of Hellenistic fictions, Menander's moral outlook would compare favourably with that of Molière, not to speak of Congreve.

Callimachus.—Callimachus too has become a reality and we can understand the immense influence he exercised upon the Augustan poets. We possess many fragments from his *Aitia* or *Origins*, one of them 80 lines long. Unfortunately nothing is complete; but the fragments show a mastery of the Greek elegiac couplet unknown before. The diction is rather precious. The style often reminds one of Ovid, romantic with a touch of self-mockery, as though the poet felt the absurdity as well as the loveliness of the archaic legends which he collected with so much zest. The Alexandrian courtier is shown in his "Lament on the Death of Arsinoe," his "Coma Berenices" (which we know in a Latin version by Catullus) and other fragments. His gnomic poems are written in the assumed character of the ancient Hipponax, but have none of that satirist's ferocity. One tells the story of the prize for wisdom, which was offered first to Thales but refused by him because Bias was wiser, and by Bias because someone else was wiser and so on by all the wise men in turn. Another contains a contest for superiority between the laurel and the olive, somewhat flat to modern taste.

Another acquisition is a large fragment of a *Life of Euripides* by Satyrus, a Peripatetic of the 3rd century B.C. It takes the form of a dialogue; one of the characters is a woman; and the tone is that of drawing room *belles lettres* rather than history. There is much gossip and anecdote, given for what it is worth; many quotations, and some good literary criticism, *e.g.*, the observation that Euripides wrote the "things that held the new comedy together, peripatetics, betrayed maidens, supposititious children, recognitions by rings and necklaces, etc." The fragment comes from Satyrus' *Lives* in six books, the last of which dealt with the lives of the tragedians. It is extremely interesting as a specimen of the new subject of study introduced by the disciples of Aristotle, personal biography of writers and *savants*. Satyrus seems to have been the chief authority for the anonymous *Life* which has come down to us with the MSS. of Euripides.

Lyric Poets.—Another new author of great interest is the Boeotian poetess Corinna, a contemporary and compatriot of Pindar, though curiously different from him. She stands right outside the sphere of Homeric influence. Her language is the colloquial Boeotian which she spoke, unaffected by literary tradition. Her themes, to judge from the two poems preserved, "The Contest of Kithaeron and Helicon," and "The Daughters of Asopus," are little more than local folklore. She cannot have been quite uneducated; her metre is too correct; but her work leaves the impression that Boeotian women in the 5th century, though they learnt *Mousikê*, did not know much literature. Unlike Sappho, she was a neither a bluestocking nor a genius.

Sappho herself is now represented by about 100 new fragments, but the papyri have been so crushed and broken that very little is continuous or intelligible. The most beautiful of the new songs is perhaps equal to the best known before and has the same poignancy. It begins: " . . . and simply I long to be dead. She left me sobbing, and said: 'Sappho, we have suffered terrible things. I swear, against my will I leave you.'" The exceptionally careful study of the whole material by Mr. Lobel has shown, first, that the papyri are very exact in reproducing dialect, and secondly that Sappho, except in poems modelled upon epic, wrote almost entirely in her native Lesbian. She stands between the rusticity of Corinna and the literary polish of Alcaeus.

Alcaeus also is represented by more than 100 new fragments, various in subject and metre, but seldom large enough to yield continuous sense. A comparison of Helen and Thetis, a few lines about Sisyphus' attempt to outwit Death, much about *dura navis, dura fugae mala, dura belli* confirm but do not greatly enrich the impression made by the previous fragments. There is style, spirit, vigour, variety and there must have been a mass of minute and intimate history. But we find perhaps more continuous beauty in the new fragment of Ibycus, passing in dreamy memory the great shadows of the Trojan War, or the short burst of lyrical hexameters in the style of Alcman.

Pindar, of whom we had before only *epinikia* (victory songs) is now represented by considerable fragments of paeans, *parthenia* (girl songs) and dithyrambs. The paeans show the same abrupt and tortured magnificence of style as the extant *epinikia;* the *parthenia*, as Dionysius of Halicarnassus (Demosth. 30) had remarked, are simpler, and show Pindar in a new mood. "Maidenly thoughts be mine and maidenly speech upon my tongue," says one fragment.

The Drama.—There is also much beauty in the lyrics of Euripides' *Hypsipyle*, one of which is a nurse's song to a baby, with the accompaniment of a rattle and a new effect in one of the scenes where a mother, raging against the nurse who has inadvertently caused the death of her child, is suddenly reduced to silent tears by the presence of the gentle sage, Amphiaraus. The quiet exit of Amphiaraus to his foreseen death, and the subtle indications of Hypsipyle's life-song devotion to Jason, the brief romance of her youth, are in Euripides' most characteristic style. The fragments of Sophocles' Satyr-Play, the *Ichneutae* (Trackers), have great charm. The infant Hermes has stolen the cattle of Apollo; the Satyrs go as detectives to track the thief, and hear underground the first music known on earth—the child playing on the lyre he has made. The remains of Sophocles' *Eurypylus* are very small, but show the great 5th century style.

Increase of Historical Knowledge.—If we turn from our direct gains in beautiful literature and try to estimate the new light thrown by recent discoveries on the history of Greek literature

as a whole, the results are much larger. The excavations of Minoan Crete, though they have brought us no Greek text, make a difference to our understanding of the Homeric poems and of the whole heroic tradition. We see quite clearly now that the poems do not stand at the beginning of literature. There were ages of literature before them. Even their heroic subjects can in many cases be shown to have been already known in or before the 16th century B.C. Gems and frescoes of that date show us the siege of a city, like Troy; a man under the belly of a ram and clinging to its long wool, like Odysseus escaping from the Cyclops' cave; a scene in a deep glen, where a young man attacks an older man in a chariot, as Oedipus attacked Laius. This means that some of the main romantic motives used in Greek heroic poetry were already traditional then, attached to what names we know not. Again, the celebrated "Ring of Nestor" (*Jour. Hellenic Studies*, 1925) shows scenes of initiation and of the next life, ideas which have generally been considered post-Homeric and even for the most part post-classical. We see now that they were in existence before Homer as well as after; and the characteristic theology of Homer, with its avoidance of these ideas, shows itself to be not a thing of primeval simplicity, but a peculiar product of the "Heroic Age" (*i.e.*, the age of the destruction of Minoan civilisation by the Northern invaders). Again, while the excavations indicate pretty clearly that neither of the Homeric poems as a whole is "history," they also show that both are full of historic memories, in various degrees confused and fragmentary, and transmuted into the "heroic" mould.

Variety in Greek Literature.—But what we chiefly learn from the papyri is to appreciate the immense variety of Greek literature, especially in the Hellenistic Age. We have now specimens of three Satyr-Plays, instead of only the *Cyclops*. We have large masses of the New Comedy. We know something of the Alexandrian elegy and idyll, including bits of Euphorion as well as Callimachus. We discover the prevalence of poems in the style of different ancient writers: compositions in imitation of Hipponax, of Epicharmus, of Anacreon, of Alcman and letters professing to come from Hippocrates. We are reminded of the Delian Hymn with its claim to be by "Homer" himself.

Religious or ritual poetry is represented by several hymns and paeans connected with the temple of Apollo at Delphi or that of Asclepius at Epidaurus. The most curious is a paean to Asclepius, which occurs in four almost identical copies of different dates and places. It seems to have been a stock form, with places left open, so to speak, for the names of the particular city or individual wishing to perform the rite. More primitive worships, though in late form, are expressed in the Cretan Hymn to the Kouretes and the Eretrian Hymn to the Idaean Dactyls. The religious literature connected with Egyptian gods, such as Isis and Serapis, is of course extensive, but is generally in prose.

Peculiarly striking is the great mass of light lyric poetry from Hellenistic or early Roman times. A poignant "Paraclausithyron," or "Weeping outside the Door," by a woman; another, less good, by a man; several love-songs in loose Ionic metres (one starting with the poignant line *κατάκειμαι μεθ' ἑτέρου, σὲ μέγα φιλοῦσα*); soldiers' songs; sailors' songs; a song to the Rhodian winds; a song of spring in the woods; a lament by a boy who has lost his pet cock; a powerful though roughly written complaint, of Roman date, by a girl whose lover is being sent to fight in the amphitheatre as a *mirmillo*, and who desperately wants to buy him off; a charming quasi-philosophic flute-song, written in a tricky metre with a refrain (*αὔλει μοι*), the first letters of each stanza forming an acrostic.

Novels and Light Verse.—Our own commonest form of light literature, the novel, is also well represented. There are three fragments of the preposterously romantic *Chaireas and Callirhoe* of Chariton, which had evidently great popularity: one of Achilles Tatius. The new evidence shows that these romances are much earlier than was supposed, Chariton about 200 A.D. and Achilles about 300. There are also fragments of several novels hitherto unknown—*Semiramis and Ninus*, *Herpyllis*, *Chionê*, *The Dream of Nectanebo*, etc. The supply of novels is equalled by that of "Mimes," or short realistic dialogues for acting or reading aloud. They are poor stuff, illustrating perhaps the pleasure in sheer coarseness which sometimes marks an over-refined age.

More interesting are the poets who write under the inspiration of the Cynic "diatribê," or popular philosophical appeal to conscience. The confusions and inequalities of Hellenistic society stimulated a contempt for worldly standards and civilised conventions and a tendency to exalt the poor, the untaught, and the oppressed. In poetry this led to a revival of the scazons, or "lame iambics," of old Hipponax, which affected both Callimachus and Herondas in later times, and has left us fragments of a 3rd-century anthology, in which the chief figure is Phoenix of Colophon. Better than these scazons are the "meliambi" of Kerkidas the Cynic (*flor.* 250 B.C.), who is known as a friend of the general Aratus, and is perhaps to be regarded as the author of the anthology itself. They are full of strange words and fantastic compounds which suit the mordant and rather brutal style of his "diatribê." It is instructive to observe that Cleanthes the Stoic, when writing his more ideal exhortations, avoids the deliberately fractious metres and uses the harmonious hexameter or iambic.

In prose philosophy we have some striking specimens of 5th-century sophistic; a fragment of Hippias (?) on Music, deriding the theories which invested it with subtle moral values; and two of Antiphon the Sophist, known previously for his denunciations of slavery, with a highly provocative treatment of the difference between *Phusis* and *Nomos*. There is also a fragment of a dialogue by that strange character, Aeschines Socraticus. And meantime the charred remains of the library of the Epicurean philosopher at Herculaneum are slowly being deciphered; much Philodemus, Polystratus "On Unreasoning Contemptuousness," with fragments of Demetrius Laco, and the Stoic Hierocles. Nor should we forget the uncommonly interesting Epicurean Gospel, inscribed by Diogenes of Oenoanda on a large wall, so that the world may read and be saved (2nd century A.D.) "*Grammatikê*" or philology is represented by Chrestomathies, "Lives" or "Sayings" of eminent writers, by scholia and glossaries and by a valuable fragment of Didymus' Commentary on Demosthenes.

History, etc.—The additions to our historical literature are considerable. Besides the *Constitution of Athens* we have more than 500 complete lines of a 4th century historian, who after much controversy seems likely to be identified with Ephorus, rather than with Theopompus or Cratippus. It deals chiefly with the year 395 B.C. Other fragments attributed to Ephorus treat the history of Sicyon and other subjects. There are small pieces of Timaeus, the Sicilian historian, and of Philochorus, the Attic chronicler. There are bits of what seem to be the authentic despatches of the third and second Ptolemies, and perhaps also of the first (*P. Oxy.*, 679), dealing with their own campaigns; also of Sosylus, who lived in Hannibal's camp, and, according to Polybius, "gossipped like a barber," on the "Deeds of Hannibal." Of Satyrus we have spoken above. There is some history also in the new fragments of the orators Lysias and Hyperides.

But both as history and as literature the largest and most surprising additions to our knowledge are to be found in the non-literary papyri, of which there must be more than 10,000. They may be divided into (*a*) official and (*b*) private, the first consisting of laws, rescripts, edicts, documents about taxes, judicial proceedings and the like, the second of contracts, receipts, wills, manumissions and private letters or memoranda. Their value is increased by the fact that they often fall into large coherent groups, such as the papers about the Serapeum, the correspondence of Cleon, the public architect, or of Zenon, the great estate agent. Combined with the rich mass of Hellenistic inscriptions, these documents have illuminated the life and social history of the Hellenistic age to a degree undreamed of before.

BIBLIOGRAPHY.—The new texts are to be found in the principal collections of Papyri, *e.g.*, B. P. Grenfell and A. S. Hunt, *The Oxyrhynchus Papyri* (1898, etc.), *The Tebtunis Papyri* (1902) and *The Hibeh Papyri* (1906). See also *Berliner Klassikertexte*, *Berliner Griechische Urkunden*, Boll. della Societa Papyrologica Italiana,

rchiv für Papyrologie, and the various publications of the British luseum. The following separate publications are convenient (dates fer to first edition): S. Sudhaus, *Menandri reliquiae* (1914); . Schroeder, *Novae Comoediae Fragmenta* (1915); R. Pfeiffer, *allimachi Fragments* (1923); E. Diehl, *Supplementum Lyricum* 1910); Hans von Arnim, *Supplementum Euripideum* (1913); E. Diehl, *Supplementum Sophocleum* (1913); F. Bilabel, *Kleinere listorikerfragmente* (1923); F. Blass, *Bacchylidis Carmina* (1912); . Crusius, *Herondae Mimiambi* (1923); B. Lavagnini, *Eroticorum raecorum Fragmenta Papyracea* (1922); A. S. Hunt, *Hellenica xyrhynchia* with fragments of Theopompus (1909) and *Tragicorum raecorum Fragmenta Papyracea* (1912). Larger and more important re W. G. Headlam and A. D. Knox, *Herodas* (Cambridge, 1922); E. obel, *Sappho* (Oxford, 1925); J. U. Powell, *Collectanea Alexandrina* —smaller fragments of poets of Alexandrine age, epic, elegiac, lyric nd ethical (1925). See also the lists in W. Schubart's *Einführung in lie Papyruskunde* (1918) and *The Greek Literary Texts from Greco-Roman Egypt*, by C. H. Oldfather, University of Wisconsin (1923); Vilamowitz-Moellendorff, *Menander, Das Schiedsgericht* (1925).

(G. G. A. M.)

GREEK LITERATURE, MODERN (*see* 12.524).—The troubled years from 1910 to 1925 were marked by one event of capital importance to the literature of modern Greece, the all but total conquest of the entire literary field by the spoken language, commonly called the demotic or romaïc, after a century's struggle with the official or scholastic tongue, called the pure or catharévoussa.

In 1910, Costis Palamas published the remarkable narrative lyrical poem *The King's Flute*, in which he celebrates, in the moving atmosphere of Byzantium, the continuity of Greek throughout the ages. In *The Immutable Life* he appears as a bold innovator, inspired by French intellectualism, and definitely establishes his position as a poet of world wide fame. Before losing himself in memories of his childhood, as he does in his next work (*Longings for the Lagoon*, 1912) he shows that he possesses the eternal spirit of ancient Hellas, of Byzantium and of modern Greece. He is a poet of the intellect and of thought, whose work, while showing the influence of Western symbolism, is yet filled with imagery and with glowing verbal music. In works such as *Iambs and Anapaests* and *The Grave* he has given expression to the deepest emotions. He was strongly influenced by the prophetic genius of Joannes Psuchares, a master in every *genre* of prose, who introduced into Greece all the most recent linguistic theories. Without his example it is unlikely that Palamas would have succeeded in realising his powers. So was founded the new School of Athens. Palamas, himself an occasional novelist and critic, became the centre of the popular renaissance.

Among the stylists pure and simple of the school we find John Gryparis, a disciple of Hérédia; Laurence Mavilis, strongly influenced by Italian literature, who was killed in the war of 1912; the Baudelairean Papantoniou Costas Ouranis; Aristos Cambanis, whose work is chaste and, if anything, a little cold; and the delicate genius of Malakassis, who owes much to Moreas and to *The Intermezzo*. Peter Vlastos wanders from sphere to sphere, revelling in subtlety of rhythm and metre. All the storied past of Greece comes to life in his work. Apart from these, the dreamy Lambros Porphyras has written his *Shadows;* Sotiris Skipis has sung of his longings for his own country (*Song of Apollo*) and the sufferings of the fugitives from Anatolia. Myrtiotissa in his moving work has sung of passion, while G. Souris and Pol Arcas have turned to satire, and Drossinis, forerunner of many others, has produced his picturesque idylls.

But apart from simple melodists like these tardy Parnassians, the newer poets venture even further than Palamas into uncharted territory. Among them are Angelos Sikelianos, who rediscovered the secrets of the ancient myths of sea and land, and who hymns the greatness of life; Rigas Golphis, bitter, eloquent and passionate; the fiery Varnalis, Ph. Yophyllis, who embodies in his work the minutest details of modern life, and Kavaphis, who, apart from the others, evokes, in a strange and unadorned style, the Alexandrian decadence which resembles his own depression.

Prose Writings.—Modern Greek prose is unusually rich both in *conte* and in the novel. The scattered but recently collected work of Papadiamandis, who disappeared in 1908, remains unequalled. Carcavitsas and Ephtaliotis painted the sea and the islands, and left models for others, as also did the regretted poet, novelist, critic and translator, C. Hatzopoulos. Costis Passayannis, Vlakhoyannis and the Epirote Ch. Christovassilis are accomplished writers of the heroic and the picturesque. D. Voutyras is more deeply moved by the troubles of the working classes. There are also C. Theotokis of Corfu, who combined criticism of society with the study of character, and showed himself in his novels, *The Slaves in their Chains* and *The Life and Death of Karavelas*, as a cruel and unrelenting realist, also C. Paroritis, the powerful author of *Red He-Goat*, and Madame J. Dendrinos, who excels in depicting the ravages of passion. No one, however, in the novel or the theatre has excelled G. Xenopoulos, the creator of a whole gallery of pictures of Zante and Athens (*Isabel*, *Woman from Three Aspects*).

But Xenopoulos is not alone among Greek dramatists. Paulos Nirvânas, that fine critic and subtle observer, brought Ibsenism into fashion. Spyros Melas and Pandelis Horn achieved remarkable work with a high social aim, D. Tangopoulos distinguished himself in philosophical drama and N. Poriotis shows in *Rhodopi* that tragedy in verse is still to be found in Greece. Among the younger writers Constantinides in *Photinoula* reveals himself as a coming dramatist, and Valsa wrote a model of philosophic comedy in *The Council of Ministers*.

In other spheres, we may mention the names of J. Dragoumis as a critic, of Philindas and of Triandoephyllides in philology and the study of language, while we must not forget the well-known Psuchares, Lambros in history, Politis in folklore, Andréades in political and social economy, Xenopoulos, Nirvânas and Cambanis in literary criticism, Voutieridis in the history of literature. The influence of the literary reviews is shown by the fact that modern Greek literature is becoming more and more westernised in inspiration and form and ceasing to be Byzantine. (P. Le.)

GREEK RELIGION (*see* 12.527).—Our knowledge of this subject has been put on a new basis by researches into the beliefs of pre-Dorian Greece and Minoan Crete. N. M. P. Nilsson's conclusions, that a Mother-goddess and a divine child, who is born, is suckled by an animal and dies annually are characteristic of Crete and of the mainland, that this pre-Greek goddess survives in the Olympian pantheon as Athena and as Hera, that at Eleusis and many other places a cult was continuously practised from prehistoric times, and that the great cycles of Greek mythology all centre round sites important in the Bronze Age, are of the utmost value.[1]

How far this Minoan religion, which has clear affinities with Asia Minor, Philistia and Cyprus, was part of a general Aegean or even Mediterranean culture, we cannot yet say: Sardinia offers a remarkable point of contact.[2] These researches into prehistoric beliefs have transformed the study of Greek mythology. We recognise in it not a little confused history, even if Forrer's identification of Eteokles and Andreus, mythical kings of Orchomenus, with potentates mentioned in the Hittite tablets from Boghaz-Köi (*see* Archaeology: Asia, West), should be seriously contested; we see in it also the reflex of old sacred traditions or rites (thus the death by burning of Herakles on Mount Oeta reflects a fire-ritual there annually performed), the influence of folklore motives distributed over a wide cultural area, and the effects of the desire to tell a good story for its own sake.[3] This study is in a favourable position, since Wilamowitz, Robert and others have done much to determine the earliest form and later developments of heroic stories,[4] while Nilsson, Eitrem, Farnell and many writers in *Religionsgeschichtliche Versuche und Vorarbeiten* have increased our knowledge of ancient ritual.[5]

Others, again, have investigated, not without exaggerations, the survival of ritual forms in drama and in the great games, and the gain to knowledge is clear, though it must be remembered that the search for a single origin of a human custom may well

[1] Summarised in his *History of Greek Religion* (Oxford, 1925).

[3] *Cf.* F. Pfister, *Philologische Wochenschrift* (July 1922); L. R. Farnell, *Greek Hero Cults and Ideas of Immortality* (Oxford, 1921), is of great value.

[4] C. Robert, *Die Griechische Heldensage* (1920-) is noteworthy as giving a learned and critical survey.

[5] S. Eitrem's chief work is *Opferritus und Voropfer der Griechen und Römer* (Oslo, 1915). A good survey is F. Pfister's article "*Kultus*" in Pauly-Winowa Real-Encyclopädie.

prove illusory, that a rite can arise independently or by parallel development in two places and that at the same time few rites or beliefs have developed unchanged by external influences. Not all athletic contests started as acts of homage to a dead man, but some did, just as all heroes are not degraded gods, but some (as, for instance, Hyakinthos) are.[1] Ritual origins can be forgotten; so could also the original meaning of certain survivals of primitive culture in historic Greece.[2] At the same time, the value of anthropological parallels appears in W. F. Otto's conclusions, partly based thereon, that in Homer the ψυχή or soul in Hades is not the θυμός or soul of the living man.[3] The study of cult has further shown how moral requirements grow out of ritual requirements, and how important is the group as contrasted with the individual.[4] In the study of cults and in particular of their geographical distribution has lain the chief advance in knowledge of Greek religion of the central period.[5]

Meanwhile we have learned much of the Hellenistic age as the period in which Eastern beliefs made their way into the West, and in which many of the religious phenomena of the Empire have their roots; among these are ruler-worship, astral and other mysticism, as also certain liturgical forms and the type of magic familiar in Roman Egypt.[6] Side by side with newer ideas the old worships lived on; there is no simple formula which expresses the religious attitude of the three centuries following Alexander's death. Survivals of ancient paganism in Christianity[7] and in modern Greek beliefs and folklore have been much discussed; on many important points agreement has not been reached, but much progress in detail has been realised.

Deubner, *Archiv. für Religionswissenschaft*, 20 (1924); Weinreich, id., 23 (1924); Gruppe, *Bursians Jahresberichte*, vol. 186; and in *The Year's Work in Classical Studies* (annually).

(A. D. N.)

GREELEY, ADOLPHUS WASHINGTON (1844–), American soldier and scientist, was born at Newburyport, Mass., March 27 1844. Enlisting in 1861 as a private, he served in the Civil War, and rose to be brevet major. In 1867 he was appointed second lieutenant in the regular army and became chief signal officer and brigadier general. While commanding at Lady Franklin Bay, one of the 13 international circumpolar stations, 1881–4, he reached, in 1882, 83°24′ N. 42°45′ W., the farthest north at that time. Two relief expeditions failed to reach him, and wh the third, under Capt. Schley, rescued him at Cape Sabine, a but seven of his party were dead. From 1887 to 1906 he admi istered the Weather Bureau and the Signal Corps. Under hi were built more than 25,000 m. of cables and telegraph lines Alaska, China, Cuba, Porto Rico and the Philippine Island Promoted major-general in 1906, he conducted relief operatio in San Francisco and put down the Ute rebellion. He serve with the international conference, London, 1904, at the reque of the British Govt. and was dean of the American delegatio to the wireless conference at Berlin that year. Retired for ag in 1908, in 1910 he was sent by President Taft to represent th United States at the coronation of King George V. He wrot extensively on meteorological, electrical, geographical and othe subjects. His best known popular volumes are *Three Years o Arctic Service* (1885); *Handbook of Polar Discoveries* (1909) and *Handbook of Alaska* (1925).

GREENOCK, Scotland (*see* 12.548), had a population o 81,123 in 1921. The area of the borough is 2,045 acres. Ther are several large shipbuilding yards, and a torpedo factory. Th old West Kirk is to be removed and re-erected at Seafield to permit of the extension of Messrs. Harland and Wolff's ship-yard. The new works at the harbour include a tidal basin and an "always afloat" dock, the entrances of which are closed by caissons to keep in 32 ft. of water at low tide. In 1921 there were three miles of quays in the port. Lady Alice Park was given to the town in 1910, and Lady Octavia Park in the following year; in 1919 Togo House was presented and opened as a maternity hospital.

GREGORY, ISABELLA AUGUSTA, LADY (1852–), Irish playwright and author, was born March 5 1852, the youngest daughter of Dudley Persse of Roxborough; Co. Galway. In 1881 she married Sir William Gregory, a well-known Irish M.P. She produced many plays, essays, volumes of folklore, versions of ancient sagas and romances concerning early Irish heroes, and did much to popularise the Anglo-Irish dialect of English as spoken in the west. She translated for the Abbey Theatre several of Molière's plays into this dialect under the title of *The Kiltartan Molière* (1910). Her work as playwright and director of the Abbey Theatre, in association with W. B. Yeats, was extremely fruitful. This theatre was opened in 1904 and Lady Gregory told its story in *Our Irish Theatre* (1914). Sir Hugh Lane, whose life she wrote, *Hugh Lane's Life and Achievement* (1920), was her nephew.

Among Lady Gregory's other works are: *Cuchulain of Muirthemne* (1902); *Gods and Fighting Men* (1904); *Seven Short Plays* (1909); *The Kiltartan History Book* (1909); *Irish Folk History Plays* (1912); *The Golden Apple* (1916); *The Kiltartan Poetry Book* (1919); *The Dragon* (1920).

GRENADES (*see* 1.869 and 12.578).—A grenade is a small metal missile, usually filled with high explosive, which may be thrown by hand or projected with the aid of a rifle. Grenades may also be charged with poison gas and incendiary or smoke-producing compositions, but the essential features of the various kinds remain the same. Gunpowder grenades, made of wood, bronze and other materials, were used in the 16th century, to be revived later in a high explosive form at the siege of Port Arthur in 1904 and in the trench fighting of the World War. Grenades are described as percussion or time grenades, according as to whether they explode on impact or after a definite time interval.

Hand Grenades.—At the commencement of the World War, the limited supply of grenades in the British Army was of the percussion type, in which a needle in the head of the grenade is by direct impact caused to fire the detonator, a head-on fall being insured by means of tail streamers. At a later date, an all-ways fuse was suggested which would fire the grenade in whatever position it alighted. The main disadvantage of the percussion type is the danger of it exploding if accidentally dropped after being made "live" prior to throwing by the withdrawal of the safety pin or other safety device. These considerations led to the adoption of time grenades as being safer in action and allowing time in case of accident for the bomber to get clear or

row away the grenade. Furthermore, time grenades are more sily improvised than percussion ones, and during the period of vere shortage of munitions in the World War, many such gre- des were constructed locally out of any handy receptacle. For is purpose a short projecting length (usually 5 sec.) of safety se terminating in a detonator (for high explosive fillings) within e grenade was employed. Various friction or strike and cap mbinations were used to ignite the fuse before throwing.

The principle of the time grenade is represented in its greatest rfection in the Mills grenade (see fig. 1), invented during the War, which enormous quantities were supplied to the British Forces. consists of a barrel-shaped iron casting, *a*, externally grooved in gments to ensure good fragmentation, and of a size to be con- eniently clasped in the hand, weighing 1 lb. 8 oz. and containing ½ to 3 oz. of high explosive, *b;* amatol or ammonal in powder form convenient. The essential principle is that the ignition of the me arrangement *c* is caused mechanically, as soon as the grenade aves the bomber's hand. This is effected by the release of a

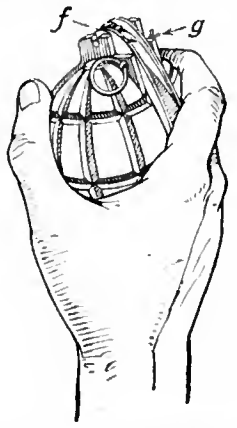

FIG. 2.—Grip for throwing.

striker *d* actuated by a powerful spring *e* which until then is restrained by a lever *f*. On withdrawing the safety pin *g*, this lever is still held to the grenade by the thrower's fingers (see fig. 2), but on the grenade leaving his hand, the loose lever flies off and a cap *h* is struck which ignites the 5 sec. length of safety fuse *c*, which in turn fires the detonator *j* and explodes the grenade.

Rifle Grenades.—Previous to the World War rifle grenades had been designed in order to obtain an increase of range beyond the restricted limits of hand throwing. These grenades were of the percussion type with a steel tail rod, with or without a gas check, which was inserted about 10 in. into the muzzle of the ordinary service rifle and propelled by the gases from a blank cartridge, which impinges on the tail rod. The rodded rifle grenade described above is open to serious objections, being unhandy, and liable to bulge and split the barrel, particularly if the rod is not accurately straight and consequently tends to buckle. In any case, a severe strain is thrown on the rifle, which is eventually bound to damage it. This led to the introduction from the French of the discharger-cup or *tromblon*, which is a short cylindrical cup attached to the muzzle of the rifle, into which the grenade is fitted and from which it is propelled by the gases from a blank cartridge fired in the rifle, acting on the base of the grenade. The Mills grenade can be adapted for firing from a discharger-cup by the addition of a gas check plate, which is screwed into the base; the side of the discharger-cup holds the loose lever in position until the grenade is projected clear, when it flies off and sets the grenade in action. In this way rifle and hand grenades can be made practically interchangeable, thus simplifying both supply and transport in the field.

Future Design.—The tendency of future design is in the direction of percussion grenades, which are considered to be more effective than time ones, chiefly in that no time is given in which to get clear or to throw back the grenade before it explodes, in the event of the time fuse being too long in its burning. The chief difficulty to surmount is so to design the grenade that it is safe if dropped vertically by accident, but is made "live" in the space of a short flight. Other essential conditions are to act in any position of impact or fall after throwing, to be interchangeable with trifling adjustment as a hand or rifle grenade, to be weatherproof and mud proof and to be simple in manufacture and use.

GRENFELL, WILFRED THOMASON (1865–), British medical missionary, was born Feb. 28 1865 at Parkgate, Cheshire. He was educated at Marlborough and Oxford, where he took the degree of M.D., and studied medicine at the London Hospital under Sir Frederick Treves. At his suggestion Grenfell, in 1889, joined the Royal National Mission for Deep Sea Fishermen and for three years cruised with it in the North Sea as medical missionary. In 1892 he went to Labrador as first medical missionary and there did a great work, building hospitals, establishing homes and missions for the inhabitants, and organising industrial schemes and co-operative stores. In 1906 he received the C.M.G. in recognition of his services. Besides the work he did locally in Labrador and northern Newfoundland, culminating in the opening by King George of the Seamen's Institute at St. John's in 1912, Grenfell lectured in Canada, America and England in order to raise funds, and the mission expanded rapidly until, in 1912, its English, American and Canadian branches were united by the formation in New York of the International Grenfell Association, of which Grenfell became superintendent. During the early part of the World War he was attached as major to the Harvard Surgical Unit in France. In 1920 he became F.R.C.S. and in the same year received the gold medal of the National Academy of Social Sciences of America.

Grenfell's publications include: *Vikings of Today* (1895); *The Harvest of the Sea* (1905); *Labrador: the Country and its People* (1909, re-issued 1913 and 1922 with additional chapters); *Adrift on an Ice-Pan* (1910); *A Labrador Doctor* (1920, abridged 1925); *Northern Neighbours* (1923).

GRETNA, Great Britain, was the scene of a great undertaking during the World War. On a tract of land some 10 m. long and from one to two m. wide, partly in Dumfries, along the north shore of the Solway estuary, and partly in Cumberland, hundreds of stone, brick and steel buildings were erected for the making of munitions and providing for the wants of the workers who flocked there. These buildings included administrative buildings, schools, churches, messrooms, shops, halls, post-offices, fire-stations, etc., as well as factories, glycerine and ether distilleries, electric light and refrigerating plants. The buildings fell largely into two groups, one at Dornock to the west, and one about seven m. to the east at Mossband and Longtown. There were in addition two garden villages, one at Gretna, in the centre, and one four m. to the west at Eastrigg, with some 16 sq. m. of agricultural land, which has since been settled with ex-service men. The whole undertaking, about which great secrecy was preserved during and after the War, cost over £9,000,000 and employed at one time 24,700 people. It was sold in July 1924, although some members of Parliament made efforts to secure its use as a national factory.

GREY, ALBERT HENRY GEORGE, 4TH EARL (1851–1917), British administrator, the son of Gen. Charles Grey, Queen Victoria's private secretary, and grandson of the 2nd earl, the Prime Minister (*see* 12.586), was born Nov. 20 1851; he was educated at Harrow and at Trinity College, Cambridge, where he graduated with a first class in law and history in 1873. As his uncle, the 3rd earl, had no children, Albert Grey was the heir-presumptive to the earldom, and he sat in Parliament as a Liberal, first for South Northumberland, and then for the Tyneside Division, from 1880 to 1886. The Liberalism which he displayed in the House of Commons and developed greatly in a crowded after-life was unlike the conventional Radicalism of the period. He was an enthusiastic social reformer, and a whole-

hearted imperialist. He was one of the 93 dissentient Liberals who by voting against the Liberal Govt. decided the fate of the Home Rule Bill of 1886. He lost his seat in the ensuing General Election and did not reappear in Parliament till he succeeded his uncle in the earldom in 1894. The interval had been largely filled with travel—chiefly along the by-ways of the British Empire. He was in South Africa when his uncle died, and his knowledge of, and interest in, that country led to his appointment in 1895, after the Jameson Raid, as administrator of Rhodesia in succession to Dr. Jameson. There he became a close friend and ardent admirer of Cecil Rhodes, and it was natural that, on returning to England, he should join, in 1899, the board of the Chartered Company. He visited Lord Milner in South Africa after the Boer War, and returned once more in 1912 to unveil the Rhodes memorial on the slope of Table Mountain.

Canada, however, where he went as governor-general in 1904, was the part of the British Empire to hold the first place in his affections. He was no stranger there, but had already visited the Dominion twice, being brother-in-law of his predecessor, Lord Minto. His enthusiasm for the land and the people, his idealistic outlook, his bright and simple manner, his utter lack of conventionality and stiffness, his fondness for travelling and nature and sport captivated the Canadian heart. His term of office was twice prolonged; but Canada was loth to see him go in Oct. 1911, even though his successor was to be the Duke of Connaught. Never much of a party man, he was still less so after his return to public life in England. He devoted himself to the causes which appealed to him. Of these the Federation of the Empire was the first, and he would only contemplate Irish Home Rule as part of a federal scheme. He made a helpful contribution to licensing reform by the institution of the Public House Trust, and he worked hard for proportional representation. He forwarded all promising efforts for the improvement and organisation of agriculture. Lord Grey died at Howick, Northumberland, after a serious operation, on Aug. 29 1917, leaving, by his wife Alice Holford, a son who succeeded him in the earldom.

GREY OF FALLODON, EDWARD GREY, 1ST VISCOUNT (1862–), British statesman (*see* 12.588), became Foreign Secretary in Sir Henry Campbell-Bannerman's Ministry formed in Dec. 1905. Sir Edward Grey (as he then was) had previously announced that the Liberal Govt. would maintain Lord Lansdowne's policy of an *entente* with France and an alliance with Japan, and during the general election of Jan. 1906 he was asked by France, who was being pressed by Germany about Morocco, whether, in case of a Franco-German war, she could reckon on British assistance in arms. He replied that he could promise nothing which would not be fully endorsed by public opinion, but that, if war were forced on France through the *entente* respecting Morocco, he believed British public opinion would rally to her support. The French Govt. then suggested conversations between military experts.

After consulting the Prime Minister, the Chancellor of the Exchequer and the War Minister, he agreed, on the understanding that such conversations should in no way bind the British Government. The Algeciras conference on Morocco followed in the spring of 1906, and the constant support which, on his instructions, the British representatives accorded to the French helped to produce a satisfactory result and to strengthen the Anglo-French entente. In 1907 he came to an understanding with Russia. He concluded a convention with her about Persia, by which the integrity of that country was to be maintained, but Britain recognised that Russia had rights and interests in the northern zone and Russia recognised that Britain had rights and interests in the southern zone. In the same year he forwarded Anglo-American friendship by sending Mr. (afterwards Lord) Bryce to Washington as British Ambassador; and concluded a convention with Spain binding the Powers to maintain the *status quo* in the Straits of Gibraltar and neighbouring waters.

In 1908—the year in which Mr. Asquith, an intimate friend of Sir E. Grey, became Prime Minister—the European situation was considerably modified by the assertion in Oct. by Prince Ferdinand of the independence of Bulgaria and his assumption of the title of King and the simultaneous annexation by Austria-Hungary of Bosnia and Hercegovina, which she had administered under the Treaty of Berlin. These strokes of policy moved the indignation of both the Russian people and the Russian Govt.; but the German Emperor announced that he would stand by his Austrian ally in "shining armour" and Sir E. Grey, though he protested against the infraction of the public law of Europe, was naturally unable to promise Russia anything more than diplomatic support. The action of the Central Powers confirmed him in the view that it was they who might be the principal danger to European peace; but he was able to keep on friendly terms with them.

The labours of the Foreign Office, coupled with membership of the House of Commons, left him little leisure for forwarding the general policy of the Government. Nevertheless, as occasion arose, he defended all the principal controversial measures. His main preoccupation, however, was British relations with Germany, who gave dramatic notice of her dissatisfaction with the spread of French aims and influence in Morocco by dispatching, at the beginning of July 1911, the gunboat "Panther" to the northwest African coast at Agadir, to protect, it was alleged, German interests. In view of this further attempt to test, and if possible loosen, the entente, he issued a warning, through the mouth of Mr. Lloyd George speaking at the Mansion House, that Britain intended at all hazards to maintain her place among the Powers. The warning sufficed to make Germany lower her tone, and subsequently Sir E. Grey explained to Parliament that the foreign policy of the Government was a continuation of Lord Lansdowne's and had got rid of the constant trouble with France and Russia; that British friendship with these Powers, far from constituting a hostile encirclement of Germany, afforded a guarantee that neither would pursue an aggressive policy towards her; but that, when a nation had the biggest army and was increasing its already big navy, it was natural that other Powers should be apprehensive.

While a section of Radicals and Labour men were suspicious of Sir Edward's policy, public opinion in general (including the Conservative Opposition) supported him and was pleased when in the following year his able services were marked by the very unusual distinction, for a commoner, of the Order of the Garter. In the beginning of 1912 he was a party to sending Lord Haldane on an informal mission to Berlin to reassure the Emperor and his Government as to the pacific intentions of Britain and to probe the intentions of Germany. The Cabinet formally notified the German Govt. that Britain would neither make, nor join in, any unprovoked attack on Germany. But nothing would content the German Govt. but an absolute pledge by Britain of neutrality if Germany were engaged in war—a pledge which Sir E. Grey naturally could not give. Largely in consequence of this ominous rebuff, he exchanged letters on Nov. 22 1912 with the French Ambassador, agreeing that, if either Britain or France had grave reason to expect an attack by a third Power or a menace to the general peace, both Governments would consult whether they should co-operate and what measures they should take in common. Still he found himself able to work in general harmony with the German Govt. in the efforts made by the Powers, in conference in London, to bring a settled peace to the Balkans, which had been distracted in 1912–3 by a series of local but furious and barbarous wars.

In this matter the diplomacy of Germany had appeared so reasonable that he was taken aback by her unyielding attitude in the negotiations arising out of the Austro-Serbian dispute. As soon as he heard of the Austrian ultimatum delivered at Belgrade on July 23 1914, he realised at once that Russia could not allow Serbia to be crushed and exerted himself in the most strenuous fashion to save Europe from the threatened catastrophe. Acting generally in conjunction with France and Russia, one or both, but in face of a lukewarm or hostile Germany, he urged upon Austria the extension of the alarmingly short time-limit of 48 hours; he proposed indefatigably various schemes for conciliation and conference; he pressed upon Serbia the

necessity of going as far as possible to meet Austria. In fact, Serbia accepted almost the whole of the Austrian demands; but Austria would be content with nothing less than complete submission, and on the expiry of the time-limit declared war on Serbia. On July 29 Germany, asserting that war was inevitable if Russia attacked Austria, endeavoured to purchase the neutrality of England by undertaking, if England remained neutral, to make no territorial acquisitions at the expense of France—an undertaking which did not extend to the French colonies—and by promising to respect Belgian integrity, after the War, if Belgium had not sided against Germany. Sir E. Grey next day absolutely refused to make any bargain of the sort at the expense of France and Belgium. In view of the apparent threat to Belgium, he asked France and Germany whether they were prepared to respect Belgian neutrality provided it was not violated, and he asked Belgium whether she would remain neutral. France and Belgium both replied affirmatively, while Germany temporised. Hopeful negotiations which had been begun directly between Russia and Austria were wrecked by a German ultimatum to Russia to countermand her mobilisation; and on Monday Aug. 3 Germany declared war on France.

The moment for decision had come for Great Britain. Russia had asked her to declare herself against Germany and so give the German general staff pause; France had asked her to co-operate as Germany was about to invade French territory. The Cabinet had hitherto been divided, a strong section pressing for the preservation of neutrality, and so Sir Edward had been unable to reply favourably to either Russia or France. But now Germany had declared war on France, and was apparently about to disregard the neutrality of Belgium. The Opposition, through Mr. Bonar Law, tendered support for active measures to aid France and Russia; and Sir Edward, with a Cabinet rallying, with few exceptions, to his view, was able to make an appeal in the House of Commons on Aug. 3 for public and Parliamentary support to a policy of action. The speech finally decided a wavering public opinion; with the exception of some Radicals and extremist Labour men, all parties, including the Irish Nationalists, accepted the necessity of war. Sir Edward demanded next day that Germany should respect the neutrality of Belgium, and, on the German refusal, England went to war.

One of Sir Edward's first tasks was to turn the association of the Powers fighting Germany and Austria into an alliance, which bound its members to fight in common, and make peace in common. In the course of the negotiations for this purpose he did not hesitate to guarantee the support of Great Britain for the attainment of long-cherished national objects, provided that these did not conflict with the aims of liberation and self-development common to the Allies: the most striking case being the promise, after Turkey entered the War on the side of the Central Powers, that Russia should have Constantinople. Much of his time and attention was occupied by difficult questions arising out of the blockade of Germany and the consequent interference with the trade of neutrals. Public opinion in Great Britain constantly complained that the blockade was not enforced with sufficient strictness; while the United States, as the principal neutral, harassed the British Govt. by repeated notes, denouncing the methods of the British Navy as unnecessarily prejudicial to American trade and contrary to international law. He was perhaps more successful in his answers to the Americans than in his justification to the British public; and a large body of opinion in America accepted his explanations as reasonable.

The tenure of the Foreign Office by a statesman so high-minded, sincere and experienced as Sir Edward Grey was everywhere regarded as such a valuable asset for Great Britain that it appeared only natural and fitting for Mr. Asquith, when contemplating the formation of a coalition government in May 1915, to lay down, as one of the essential conditions, that there should be no change in the office of Foreign Secretary. No one could refute with such authority the intermittent assertions of the German Chancellor that it was England and not Germany that was responsible both for the origin and for the continuance of the War. When the pacifists called for negotiations in May 1916, he showed that when the Germans professed a readiness for peace it was only for a peace on the basis that Germany had won and the Allies were beaten; but the Allies were not beaten, and the first step towards peace would be taken when Germany began to recognise the fact. Credit must be given to Sir Edward for facilitating, in the early summer of 1915, the entry of Italy—till May 3 a member of the Triple Alliance—into the War against the Central Powers. It was, however, a bitter disappointment to him that his grave warnings failed to prevent Bulgaria, in the autumn of the same year, from taking the field against the Allies. Allied troops were sent to Salonika, and he offered Cyprus to Greece in order to induce her to carry out her treaty obligations and go to Serbia's aid against Bulgaria. But on this issue King Constantine won the support of his people against M. Veniselos, and Serbia was crushed before help could reach her.

In July 1916 an affection of the eyes, which had been giving him increasing trouble, made it advisable that he should have as much relief from work as possible, and he accepted a peerage. When a few months later, in Dec., his friend and chief Mr. Asquith was succeeded in the premiership by Mr. Lloyd George, failing eyesight and political comradeship both united to determine him to bring his 11 years' tenure of the Foreign Office to a close. He had served for a longer consecutive period than any predecessor, and in his official methods he carried out his own precept—that foreign policy required not striking effects nor bold strokes but careful steering.

After his resignation Lord Grey took little or no part in public life for several years. Happily, though he never regained normal vision, rest and quiet gradually worked a decided improvement in his eyesight. But, with the exception of a three months' mission in 1919 to the United States to deal with questions arising out of the peace, he did not definitely emerge from his retirement till 1922. It was the time of the decadence of the coalition government and Lord Grey urged that it was not trusted and should come to an end, which happened within a few months; he was also anxious to resuscitate the Liberal party, a process which was only partially effected. In foreign affairs he pressed for the re-establishment of good relations with France, and for the arrangement of an inclusive peace pact, beginning with France. When such a pact was concluded at Locarno in 1925 he welcomed it warmly. But the cause to which he devoted most of his energy was that of the League of Nations. He was especially anxious that Germany should be included as a member at the earliest possible date, and maintained that this should be the only business of the spring meeting of the League in 1926, which unfortunately separated without effecting it.

Much of his time in these years was taken up in the compilation of a straightforward narrative and vindication of his course in foreign policy, which was published in 1925 under the title *Twenty-five Years, 1892–1916*. He had published in 1899 another volume on *Fly-Fishing*, his favourite recreation. In 1885 he married Dorothy, daughter of Shallcross F. Widdrington, of Newton Hall, Northumberland. She was killed in a carriage accident in 1906, and in 1922 Lord Grey married, as his second wife, Pamela, sister of George Wyndham, widow of the 1st Lord Glenconner. (G. E. B.)

GRIERSON, SIR JAMES MONCRIEFF (1859–1914), British soldier, was born at Glasgow Jan. 27 1859 and joined the Royal Artillery in 1877. Noted from the outset as an exceptionally keen student of his profession, from 1896 to 1900 he was military attaché at Berlin. As a colonel he was with Lord Roberts during the advance from Bloemfontein into the Transvaal; but he was then transferred to China to act as British military representative on the staff of Count Waldersee, commander-in-chief of the Allied forces against the Boxers. In 1904 he was appointed director of military operations. He commanded the 1st Div. at Aldershot from 1906–10, and was in 1912 put in charge of the Eastern command. On the outbreak of the World War Sir J.

Grierson was selected for the command of the II. Army Corps. He proceeded to France, but died suddenly on Aug. 17 1914 while his troops were still assembling in the area of operations. A good linguist and unusually well acquainted with most of the European armies, Grierson had an understanding of "la grande guerre" and an intimate knowledge of the German Army that made his premature death an incalculable loss to the British cause.

GRIFFITH, ARTHUR (1872–1922), Irish politician, was born in Dublin March 31 1872 and began his working life as a printer. When the Irish party was divided over the Parnell case, Griffith, like Dublin artisans in general, sided with Parnell and against the clergy. But the rancorous quarrels which then disfigured Irish politics disgusted young men and led them to despair of success along constitutional lines.

New organisations came into existence in Dublin, the most important being the Gaelic League for the revival of the Irish language. Griffith joined this movement, but, since it was professedly non-political, his main activities were with the Celtic Literary Society, the leading figure of which was William Rooney. Over and above all these minor groups there existed the Irish Republican Brotherhood or Fenian Society, of which Griffith became a member. He went to South Africa in 1896, owing to lack of employment in Dublin, but home-sickness brought him back to Ireland in 1898. In 1899 *The United Irishman*, a weekly paper, was established, through the columns of which he was destined to influence Ireland.

Early Writings and Aims.—At first Rooney counted for more in the new movement than Griffith, for he possessed that personal magnetism in which Griffith was lacking, yet after his death in 1901, the paper strengthened rather than weakened. No such journalism had appeared in Dublin since the time of Young Ireland. It was savagely political; but its politics had an idealism which was foreign to the agrarian revolution. Griffith cared passionately for the things of the mind; his own writing had the beauty of trenchant steel; and he welcomed contributions from the best writers in Ireland, W. B. Yeats, "A. E." and the rest. No contributor expected to be paid, for all knew that Griffith himself lived on a pittance.

Later, when the power of his pen was recognised, generous offers were made to him, but he rejected them, and steadily pursued his own aim. That aim was both destructive and constructive. He sought first to divert his countrymen from the attempt to win self-government through parliamentary action at Westminster, and secondly to persuade them to work for it in their own country. Physical force was then popularly regarded as an illusion; and Griffith, though all his intimate associates were Fenians, recognised that the majority of Irish Nationalists did not think separation from Britain possible. He therefore resigned membership of the I.R.B., and aimed at winning over the separatists to work for a Parliament in Ireland united to that of England only by the link of the Crown. As a means to this end, he proposed passive resistance and an appeal to moral force. Payment of taxes was to be refused. Members elected to Parliament were to absent themselves from Westminster, and to sit in Ireland as a Council and govern only by the assent of the nation. Tribunals were to be set up to which cases should be brought, and the British courts were to be deserted.

Rise of Sinn Féin.—This policy was first publicly announced at a meeting in Dublin in Oct. 1902. The body which met called itself Cumann nan Gaodheal or "Society of the Gaels." But the name chosen to represent their policy was Sinn Féin "Ourselves"—Irish words which in their proverbial use mean roughly "Stand together." The name was soon transferred from the policy to its adherents. Candidates were put forward at municipal elections and by 1906 there were 14 Sinn Féiners on the Dublin corporation. But Griffith's propaganda was mainly confined to the capital; and in 1907 a member of the Irish party, who resigning his seat, stood for re-election as a Sinn Féiner, was heavily defeated. The attempt to return a Sinn Féiner to Parliament was not renewed for 10 years.

The new policy at first did not make much headway. Resistance to taxation proved difficult because all taxation except income tax was indirect, and a large proportion of income t payers were Unionists. The only effective forces were the p sonality and the pen of Arthur Griffith. His paper changed name in 1906 when damages for libel were awarded against t *United Irishman*. That journal disappeared, and re-emerg as *Sinn Féin*. In 1907, when the Parliamentary party had su fered a reverse, *Sinn Féin* appeared as a daily paper, but th experiment soon had to be abandoned, and after another banl ruptcy *Eire* became its name. Griffith wrote no books: but h published in 1905 a pamphlet called *The Resurrection of Hunga* which described how an almost vanished language had been r stored to national use, and how the elected deputies of an ancien nation, through a policy of abstention from the Austrian Assem bly, gained full freedom under a dual monarchy.

The Volunteer Movement.—Griffith, during these years, taugh the rising generation to despise and distrust not only the method but the character of those who were then leading the mai national movement and he was less scrupulous in his modes o attack than a publicist should be. Yet when it became clear i 1911 that a Home Rule Bill was seriously intended, he an nounced his intention not to hamper Redmond. But the measur proposed was wholly unlike his ideal and he condemned it root and branch, his most furious opposition being directed against that partition of Ireland which he was later constrained to accept. In the shaping of events, neither he nor his paper counted for much till the growth of the Ulster Volunteers revived the hopes of the physical force party.

Griffith supported the counter-organisation of the Irish Volunteers by word and deed. He was one of those who received the rifles landed at Howth in July 1914. The outbreak of the World War revived all his importance. The Volunteers split, nine-tenths of them adhering to Redmond in support of the British cause but the remainder, active and determined, remained in Ireland; and Griffith's paper was their main organ. The censorship attacked it, but instead of *Eire*, there came out *Scissors and Paste*, a journal consisting of extracts from war news arranged to give an impression very unfavourable to the Allies. It was only one of many journals. Griffith had founded a school, a "mosquito press" and had set the example of tenacity and courage.

The Easter Rising.—The Easter Rising of 1916 was a surprise to the majority of Irishmen. Griffith took no part in it, and thereby lost influence with the extremists. But the British authorities remedied this by putting him into Frongoch, the detention camp in Wales, which became a crowded academy of Sinn Féin. Yet when in July 1917 the prisoners were released, Mr. de Valera was chosen as their leader. Griffith proposed this election at the Convention of Sinn Féin, while he himself returned to his desk, re-issuing his paper as *Nationality;* this also was suppressed and re-appeared as *Eire Og*. He was again put in gaol in 1918. At the General Election after the Armistice, Sinn Féin swept the board outside Ulster, and Griffith's policy was put into force. The elected members (such as were not in prison) assembled as Dail Eireann, the Irish Parliament. But, going beyond Griffith's plan, they declared for an Irish Republic, electing Mr. de Valera as President and Griffith as Vice-President. Both these men were then prisoners; but after some months the President escaped and Griffith was liberated.

Griffith as Leader.—During Mr. de Valera's absence in America, from June 1919 to the close of 1920, Griffith acted as head of the "Irish Republic." His policy now was carried out in its entirety. The elected bodies, county councils and municipalities refused to take orders from the British authorities in Dublin Castle; Sinn Féin courts were set up and functioned with notable success; income tax was withheld. But these forms of passive resistance were effective only because active resistance was in progress. Griffith neither launched nor controlled the guerilla war, to the pressure of which England finally yielded.

During that struggle, power rested with Collins and other young men. Yet Griffith had still a great part to play. When the truce was proclaimed and negotiations were opened in July 1921, Mr. de Valera refused to accept the responsibility of abating the full separatist demand. Griffith, thereupon, undertook

the leadership of the delegation which finally secured the inclusion in the treaty of the substance of Sinn Féin's original demand. Defending this settlement in the Dail, he spoke with the conviction of one whose ideal had been accomplished and who knew that it satisfied the desire of Nationalist Ireland in general. Without his authority, prestige and sense of realities, it is unlikely that any settlement of the difficult Irish question would have been reached.

Many of those who supported him would not accept the full consequences of the treaty; and when Mr. de Valera resigned, Griffith was elected President, not of the Free State, but of the Republic and the army continued to be in theory the Republican army. To meet the difficulty, Griffith set up a Provisional Govt. with Michael Collins as Chairman to carry on till a general election should have ratified the treaty. This resulted in an illogical division of authority and as months passed Griffith's public utterances as President were often contradicted by the action or inaction of the Provisional Government. During the final discussions with the British Govt. in June 1922, concerning the treaty, he interviewed the leading Irish Unionists and pledged himself to secure them full representation in the public life of the Free State. His conception of Ireland was less narrowly Gaelic than that of Sinn Féin in general.

After the elections on June 16, when a plain verdict was given for acceptance of the treaty, the Government was at last forced to take action against the mutinous section of the army. Civil war began on June 27. In July the main bodies of the Irregulars were everywhere decisively beaten, and on Aug. 11 a force sent round by sea occupied Cork, the last important town to be regained. On the morning of Aug. 12 Griffith fell dead suddenly on the way to his office in Dublin. The strain had killed him, and the completion of his life work was left to a younger generation. Essentially he must rank as a publicist, an educator, an inspirer of action. Few men in history have accomplished more for their country than he by his unpaid pen. (S. G.)

GRIMSBY, England (*see* 12.603), has an area of 2,868 ac. in the county borough and of 1,798 ac. in the parish, with 117 ac. of water and 248 of foreshore, and a population in 1921 of 82,355. The fishing trade has increased largely since 1910 and has necessitated the provision of a new dock; there are considerable imports of timber and ice, and the town has some ice factories. The tramways were taken over by the corporation in 1925. St. Augustine's Church was built in 1911, St. Luke's in 1912 and St. Peter's (Roman Catholic) in 1919; a new parish, that of St. Stephen's, was made in 1911. A children's home in Brighowgate was opened in 1913, and Queen Mary's hostel, built by the National Mission to Deep Sea Fishermen, in 1925. A War Memorial in Bargate was unveiled in 1921. The Grimsby trawlers and their crews did splendid work in sweeping for mines during the World War (*see* MINELAYING).

GROSSMITH, GEORGE (1847–1912), British comedian (*see* 12.619), died at Folkestone March 1 1912.

His son, GEORGE GROSSMITH (1874–), British comédian, and third of the name, who made his first appearance at the Shaftesbury Theatre in an operetta by his father, became a well-known figure in musical comedy, especially at the Gaiety Theatre, London. He was the author, or part author, of many musical plays, songs and revues, and took a leading part in popularising revue in London. Together with Edward Laurillard he became lessee and manager of several London theatres. During the World War he served as lieutenant in the R.N.V.R.

GRUNDY, SYDNEY (1848–1914), British dramatist (*see* 12.640), died in London July 4 1914. His last play, *A Fearful Joy*, was published in 1908.

GUAM (*see* 12.648).—American naval station in the North Pacific, the largest of the Marianas Islands. The native population, 60% of which lives in the chief town, Agaña, was 14,912 on June 30 1923, and 15,160 on June 30 1924. On the latter date there were also living on the island 550 non-natives, besides the personnel of the naval establishment amounting to 814. With the non-natives are included the families which are the result of marriages with native women.

Production.—Agriculture is the chief occupation, and the Government is making efforts to develop this, so that the island may be more nearly self-supporting and have a larger surplus for export. Copra is the chief crop and about the only export, the normal crop being about 800 tons. In 1923–4 the first coconut-oil mill in the island was erected. Maize and other foodstuffs grow readily. A good grade of coffee is produced, and excellent tobacco can be grown. Fish are plentiful in the waters surrounding the island, but the fishing industry has never been developed to its full capacity, and fish foods are imported.

Education.—Education is compulsory up to the age of 12. In 1923–4 there were 16 primary schools, one intermediate school, one high school and one school for Americans, besides two private schools. Pupils attending the schools were 2,833, of whom 2,676 were in the public schools. The number of American teachers increased from 4 in 1922–3 to 14 in 1923–4. Teaching is in English. Athletics are a recognised part of the curriculum, and baseball is played enthusiastically throughout the island. About 40% of the public receipts are expended on education.

Finance and Trade.—The revenues for the fiscal year 1923–4 amounted to $137,805, and expenditures to $152,781. Revenues for 1923–4 included land taxes, about $42,000; licences, about $15,300; court fees and fines, about $10,650; customs and revenue collections over $9,000 (approximately $6,657 being customs collections); and productive industries, about $27,600. The Government is also collector of customs and revenues. The balance of trade is heavily against Guam. Imports and exports in 1923 were valued at approximately $674,556 and $94,086, respectively, and in 1924 at approximately $632,721 and $66,095 respectively. In 1923 1,432,568 lb. of copra were exported to the United States, and in 1924 2,110,000 pounds. The heaviest import is of food supplies, amounting in 1924 to over $245,000. The only banking institution is the Bank of Guam which was established by the Naval Govt. in 1915, for general banking business and as a depository of the Naval Govt. of Guam. It has a capital stock of $15,000 fully paid up. On June 30 1924 its surplus amounted to $20,000.

Administration.—The administration is directly under the Department of the Navy, and the Governor is a naval officer with the rank of captain who is appointed by the Secretary of the Navy. The Governor has full power and authority to make laws for the government of the island, from which there is no appeal. He is assisted by a native Congress which has only advisory power. The Guam Congress on July 1 1925 resolved that the Congress of the United States be petitioned to enact a law making all native Chamorros of Guam citizens of the United States, or that Congress grant them the privilege of becoming citizens of the United States by naturalisation. The cadastral survey is proceeding rapidly and new roads are being constructed. The Dollar Line has established a regular service to Guam, and there are regular sailings to Manila and Japan. Recent public improvements are a new post-office in Agaña, the capital, school buildings and a number of roads.

GUARDIANS, BOARD OF: *see* POOR LAW.

GUATEMALA (*see* 12.661).—A republic of Central America and a member of the League of Nations. Its estimated area is 48,250 square miles. The capital, Guatemala City, was completely destroyed by earthquake between Jan. 25 1917 and Jan. 24 1918.

I. POLITICAL HISTORY

Guatemala was little affected by the World War, but on April 27 1917 she broke off diplomatic relations with the German Govt., and on April 23 1918 adopted "the same belligerent attitude as the United States." Guatemala was one of the signatories to the Treaty of Versailles June 28 1919. In 1915 Manuel Estrada Cabrera, who had been dictator since 1898, was

re-elected for the term 1917–23. In 1920, however, a group of intellectuals known as the Unionist party opened a newspaper campaign against him, which developed into a revolutionary movement and spread to the National Assembly. When the army became infected Cabrera resigned (April 1920) in favour of the vice-president, Carlos Herrera, who was elected President by the National Assembly. His Government was promptly recognised by the Powers. Herrera, who had wide experience of agriculture, banking and commerce, aimed at encouraging foreign capital, stimulating immigration and internal development. He worked energetically to repair the damage caused by the earthquake of 1917–8, and erected many valuable public buildings. On Oct. 10 1921, after prolonged preliminary negotiations, Guatemala, Honduras and Salvador signed a pact of union at San José, agreeing to form a Central American Union. (*See* CENTRAL AMERICAN UNION.)

Each state, for the time, was to conduct its own internal affairs; but the signatory states were to constitute a unit on foreign affairs and for matters of common interest. Costa Rica and Nicaragua failed to enter the Union. On Dec. 7 1921 the Opposition overthrew Herrera, leader of the Unionist party which was favourable to the Union, and Gen. Orellana, leader of a military faction, was elected President in March 1922 for a term of six years. A revolt against him in July was put down with bloodshed. Pres. Orellana repudiated the Pact signed on Aug. 20 1922 by Nicaragua, Honduras and Salvador (*see* CENTRAL AMERICAN UNION) on the ground of avoiding "entangling alliances." His Government was represented, nevertheless, at the Washington Conference of 1922–3 and signed the conventions there agreed upon. In June 1924 it was the first Central American republic to adopt the international commissions of inquiry provided for by the Washington Conference. The National Assembly ratified the general Treaty of Peace and Amity there drawn up.

In Aug. 1924 Guatemala reached an agreement with the United States, according mutual most-favoured-nation treatment in customs, and in Nov. effected a commercial treaty with Germany on the same principle. By a decree of April 28 1925 all foreign companies domiciled in Guatemala must appoint a representative for legal and non-legal transactions. In April 1925, also, women obtained independent legal personality. Under the 1923 general Treaty of Peace and Amity, Guatemala agreed to limit its armed forces for a period of five years to 5,200, and moreover to restrict aircraft to 10 aeroplanes and to maintain no navy.

Education.—Primary education is free and compulsory between the ages of 6 and 14. In 1917 there were 1,942 government schools, with 54,479 pupils in attendance. After the destruction of Guatemala City by earthquake in 1917–8 education suffered a check until 1924, when it received special attention. In 1924 there were 1,477 Government schools, and a number of private secondary, professional, normal and vocational schools, as well as four schools of commerce. There were 94,177 pupils in attendance and 4,284 teachers.

II. SOCIAL AND ECONOMIC CONDITIONS

The census of 1920 gave a population of 2,004,900, and the estimates for 1923 were 2,454,000. About 60% of the population are pure Indians. In Oct. 1924 a contract was authorised for the admission of one hundred Czechoslovak farmer families, for whom were assigned 4,500 hectares of undeveloped lands. Dwellings, medical attendance, schools and hospital service were included in the contract.

Finance.—A new monetary system was introduced in Nov. 1924, with the quetzal (equal to the dollar) of 1·504665 grammes of pure gold as the unit, having a value of sixty pesos. It was to be coined in 5, 10 and 20 quetzal denominations, with subsidiary silver and copper coins. The silver peso in Oct. 1924 was worth $.5376, although only unconvertible paper currency was then in circulation. Provision has been made since Feb. 1925 for a circulation reserve fund, by a tax of an added 50 cents a quintal on coffee and a graded tax of 20 to 30 cents on sugar exports.

The Government budget for the years 1921–4 was (in pesos):—

	Expenditures	Revenues
1921	387,365,234	256,261,970
1922	348,489,894	306,810,074
1923	396,121,964	385,874,260
1924	471,969,841	466,190,332

In 1924 revenue in quetzales was 8,101,686 and expenditure 8,095,573. Current expenditure for 1921 deducting items not requiring cash outlay, such as amortisation of the external debt by transfer securities in London to the Council of Foreign Bondholders, was actually only 324,049,887 pesos. Increase in 1922 revenues was largely due to the high rate of foreign exchange and to collection of the export tax on coffee in gold.

The total debt Dec. 1922 was £1,908,563 constituted as follows:—$1,257,898, 11,923,401 silver pesos and 181,887,314 paper pesos. At the end of 1924 the external debt was considered as £1,875,600 and the internal debt £1,426,961. The total debt was then in dollars 13,239,240.

Industry.—Exports mainly consist of coffee and sugar; cotton and bananas are among the growing exports. The figures of the years 1922–4 for the exports of coffee, sugar and bananas were:—

	Coffee (lb.)	Sugar (lb.)	Bananas (bunches)
1922	94,000,000	24,000,000	3,884,170
1923	96,000,000	27,000,000	4,384,077
1924	89,000,000	18,000,000	5,547,531

The principal imports are cotton goods, flour and other foodstuffs. The average wheat production is 400,000 bu., equivalent to 90,000 barrels of flour. Milling is not commercially developed. During the year preceding May 1 1925 the cotton crop reached 30,000 quintals, a large increase in spite of poor crops in certain parts. Commercial conditions in 1925 were excellent, due to high coffee prices. Importation of automobiles and other luxuries was heavy. Import duties for 1924 amounted to 19,921,316 pesos and $3,009,315, or a total of 3,341,336 quetzales. Exports produced revenues of 56,713 pesos and $1,435,492, or a total of 1,436,437 quetzales. A banking decree stabilising exchange aided merchants in the conduct of business.

A contract for developing petroleum fields by a New York company in the departments of Ezabal and Alta Verapaz was approved in Nov. 1924. Another contract provided for similar development in Alta Verapaz, Quiché and Huehuetenango. Changes in the mining and petroleum development law make the sole tax 10 per cent on the gross product in two zones and eight per cent in two others. Contracts endure 40 years; the geological surveys must begin within six months from the date of the concession.

The foreign commerce for 1913 showed imports worth $10,062,000 and exports worth $14,450,000. For recent years the figures were:—

	1923	1922	1921
All countries			
Imports	$10,840,781	$10,751,660	$13,369,611
Exports	14,725,567	12,065,949	12,130,826
United Kingdom			
Imports	1,665,643	1,599,131	2,289,047
Exports	355,249	306,591	133,618
France			
Imports	307,148	355,678	480,143
Exports	24,694	17,977	11,985
Germany			
Imports	1,302,267	1,199,910	1,240,360
Exports	2,047,320	1,961,395	1,757,306
United States			
Imports	6,519,630	6,644,449	8,177,442
Exports	11,330,986	7,883,386	8,114,117

For 1924 the exports to the United States were $10,089,156, and the imports $8,823,542.

Communications.—British interests in the International Railways Co., incorporated in 1912, and controlling 597 m. of railway, were acquired by American capitalists in 1924. A branch is to be constructed from the Mexican boundary and the Caribbean coast to the Southern end of Salvador. A new line south to Asunción Mita has been approved by the minister of promotion. A private road-building programme, initiated in 1924, provides for the building of new roads from Guatemala City to San Jose; from Antiqua to Panajachel, thence to Quezaltengo; and from Guatemala to Santa Ana in Salvador. The first of these will serve important coffee and sugar export interests. Three wireless stations largely supplant telegraph lines, which are difficult to maintain in the tropical forest. They are at Quezaltenango, a gift from Mexico, Puerto Barrios and at the capital.

Mejia, *Geografía descriptiva de la República de Guatemala* (1922); *Department of Overseas Trade Reports on the Economics and Financial Conditions in Guatemala*, published by H.M. Stationery Office, London. See also the annual reports of the various government departments, Guatemala. (H. I. P.)

GUCHKOV, ALEXANDER (1862–), Russian politician, was born in Moscow. He studied at the universities of Moscow and Berlin and, after leading an adventurous life of travel, entered politics. He helped to found the Russian "Octobrist" party in the hope that the Tsar's Govt. would work with the moderate Liberals of the Zemstvo, while safeguarding the monarchical principle. In 1910 Guchkov was elected president of the Duma, but as Stolypin became more reactionary, the Octobrists lost their standing ground, and Guchkov eventually resigned the presidentship of the Duma. In the elections to the fourth Duma he failed to secure a seat. During the World War, however, he was in charge of the Red Cross organisation on the German front, and devoted his energies to refitting the army on the technical side. When the March Revolution of 1917 broke out Guchkov became Minister of War, but he was powerless against the mounting flood of desertion and demoralisation in the army, and resigned in despair. Emigrating he found himself without proper place and influence, and later took refuge in Paris, where he pleaded for a reunion of all parties against the Bolsheviks.

GUERRINI, OLINDO (1845–1916), Italian poet (*see* 12.672), died at Bologna Oct. 21 1916.

GUESCHOFF, IVAN EVSTRATIEW (1849–1924), Bulgarian politician, was born at Philippopolis Feb. 1849. He was educated first at Philippopolis, and was then, in 1865, sent to Owens College, Manchester, for four years. He remained at Manchester in business with his father until 1872, when he returned to Bulgaria. In 1877 he was arrested by the Turkish governor and condemned to death for political propaganda against Turkish rule, but was saved by the intervention of the British and American Consuls. He then began to send accounts of the Turkish atrocities to *The Times* and *The Daily News* (London). In 1878 Gueschoff became general manager of the Bulgarian National Bank at Sofia, and was Minister of Finance from 1894 to 1897. He was elected president of the Sobranie (National Assembly) in 1901 and became Prime Minister in 1911. As such, he concluded defensive alliances with Serbia, Greece and Montenegro against Turkey, and so paved the way for the Balkan victories of 1912. After the London peace treaty, May 30 1913, Gueschoff resigned with his Cabinet. During the World War he retired from politics and became president of the Bulgarian Red Cross. He died at Sofia March 11 1924.

GUESDE, JULES BASILE (1845–1922), French socialist (*see* 12.672), died in Paris July 28 1922.

GUIANA, BRITISH (*see* 12.676).—The sole British possession on the continent of South America, has an area of 89,480 sq. miles. The population of the colony at the end of 1924 was 301,204.

Sugar maintains its position as the principal export from British Guiana; of the area under cultivation 57,000 ac. are reaped. The value of the sugar exported in 1924, with its by-products—rum, molasses, molascuit—was approximately £2,000,000. Between 1915 and 1924 machinery to the value of £1,500,000 sterling was imported for the equipment and improvement of the sugar factories. Exports of rice in 1924 were valued at £65,120, an increase on the exports for 1923, which were valued at £57,018. The production of diamonds has increased since 1913; in 1923 214,385 carats were exported, valued at £1,032,585. The output of gold has decreased; in 1924 the exports were valued at £19,600, as against 63,803 ounces exported in 1914 and valued at £232,085. The value of bauxite exported in 1924 was £176,200, and in the same year balata valued at £164,400 was exported. The chief imports are foodstuffs, manufactured textiles and machinery. Under the British preferential tariff imports from the United Kingdom, Canada and other British possessions have increased, while imports from the United States have decreased.

The forest area of 78,000 ac. contains many valuable woods—greenheart, which is produced only in British Guiana, and mora, both of which are suitable for shipbuilding and are resistent to marine borers, purpleheart and crabwood. 168,454 cu. ft. of timber, valued at £26,006, were exported in 1924. Difficulty of access has limited the exploitation of the mineral and timber wealth of the colony to the northern half. The development of the forest lands is being actively pursued by the newly-created Forestry Department, which began its work of locating fresh sources of supply of commercial timbers in Nov. 1925. British Guiana participated in the British Empire Exhibition in London 1924–5, and a resident trade commissioner has been appointed in London.

BIBLIOGRAPHY.—J. B. Harrison and F. A. Stockdale, *Rubber and Balata in British Guiana* (1911); A. Leechman, *The British Guiana Handbook* (1913); Board of Trade, *Colonial Import Duties*, Cd. 7641 (1914); *Statistical Abstract for the Several Self-Governing British Dominions 1899–1913*, Cd. 7786 (1915). See also *Annual Reports* and *Blue Books*.

GUIANA, DUTCH (*see* 12.680).—The only Dutch possession on the South American mainland, has almost doubled its population since 1910. Statistics obtained in 1925 gave the population as: Europeans, 1,422; natives, comprising Indians and bush negroes, 56,339; Javanese, 18,685; Hindus, 30,074; Chinese, 1,454. The population of the capital, Paramaribo, in 1925 was 44,772. In 1923 there were 55 public schools in the colony with 5,296 pupils in attendance, a Government normal school with 127 students, and 55 private schools attended by 9,481 pupils.

The shortage of labour that followed on the abolition of slavery in 1863, causing the reduction of the plantations from 500 to 5 sugar plantations and 66 for other products, created a labour problem that led to the introduction of Chinese, Javanese and Hindus as contract labourers. The chief products are sugar and coffee; next in importance come bananas, rice and cocoa. Cotton is produced on a small scale, and oranges and coconuts are grown by the crofters, many of whom were originally contract-labourers. The principal articles of export are sugar, coffee, bananas, cocoa, balata. Timber is furnished from the hinterland and gold is mined in many districts. Important deposits of bauxite are known to exist in the colony, but hitherto this mineral has not been worked on any large scale. The balance of trade is usually adverse, and the deficit is adjusted by an annual subvention paid by the Netherlands Government. During the four years 1922–5 the sum required for the state subvention has progressively decreased. Imports in 1924, mostly foodstuffs and manufactured articles, were valued at £624,704. Exports, consisting of agricultural and mineral products, besides timber and balata, were £617,453 during the same year.

See J. M. Brown, *The Dutch East* (1914); A. S. Walcott, *Java and Her Neighbours* (1914); also *Jaarcijfers voor het Koninkrijk der Nederlanden*, annual publication of the Colonial Office, The Hague. (J. C. K.)

GUIANA, FRENCH (*see* 12.681), has an area of about 32,000 sq. m. and a population (1921) of 44,202, including 2,368 Indians (natives). Some Indian tribes may have escaped enumeration, but in any case the colony is very sparsely inhabited. About 10% of the people are whites and another 10% negroes; the remainder are mostly of mixed blood and locally are called Creoles. Cayenne, the capital and chief port, had 10,146 inhabitants; St. Laurent du Maroni, 1,300. The colony is best known as a penal settlement and as including the Iles du Salut, one of these islands being the notorious Devil's Island. The 1921 census figures included 3,775 convicts.

The natural resources of the country remain very little developed. The chief industry is gold mining, the gold produced representing fully half the value of the exports. The mines are near the Dutch and Brazilian frontiers respectively. The forests contain valuable timbers. Rosewood is exported and there are factories for the extraction of rosewood essence. Balata is also obtained from the forests. Small quantities of coffee, cocoa and sugar figure in the exports, but labour is scarce and dear and

only a very small portion of the land is cultivated. The adverse trade balance in 1921 was 25,000,743 francs. The cost of the penal settlement is borne by France. There are few roads and but 15 m. of railway. A seaplane service is maintained between Cayenne and St. Laurent and there is a wireless telegraph station. The colony is represented in the French Parliament by one deputy. See *Le Journal de la Société des Américanistes de Paris*, for articles on the history and explorations of the country.

GUILD SOCIALISM: *see* SOCIALISM.

GUILLAUMAT, MARIE LOUIS ADOLPHE (1863–), French soldier, was born at Bourgneuf, Charente Inférieure, Jan. 4 1863. He left the military school of St. Cyr in 1884, and became a captain in 1893. He served for three years in Tongking with the Foreign Legion, and during the Boxer rising in 1900 was in Tientsin where he received his first wound. In 1903 he was appointed professor of military history at St. Cyr and in 1908 lecturer on infantry tactics. After being director of infantry at the Ministry of War from 1911, he became *chef de cabinet* to the Minister of War, M. Messimy, in 1914. At the outset of the World War, Guillaumat, who had already taken part in 12 campaigns, commanded a division at the battle of the Marne and later in the Argonne. Subsequently, in command of the I. Army Corps, he took a notable part in the battle of Verdun and the Somme. In Dec. 1916 he was given the command of the II. Army in front of Verdun and directed the attack of Aug. 20 1917, which succeeded in freeing the position.

In Dec. 1917 he was sent to Salonika as commander-in-chief of the armies in the East (*see* SALONIKA CAMPAIGNS) but was recalled in July 1918 to take command of the entrenched camp at Paris in face of the enemy advance. He urged the launching of an offensive in Macedonia both at the Inter-Allied War Council at Versailles and before the British War Cabinet; and on Sept. 4 1918, at the London conference, his advice was adopted. In Oct. 1918 Gen. Guillaumat was given the command of the V. Army on the Aisne for the final advance. After the war he was president of the commission of inquiry into the surrender of the frontier fortresses and later was elected a member of the Conseil Supérieur de la Guerre. After being entrusted with a mission to Athens, where he drew up a plan for the reorganisation of the Greek army, he took command of the army of occupation in the Rhineland at the end of 1924.

GUILLAUME, CHARLES EDOUARD (1861–), French physicist, was born at Fleurier, Switzerland, Feb. 15 1861. Educated at Neuchâtel, he became a *docteur-ès-sciences*, and devoted himself to the study of practical physics. He is principally known for his invention of the metal, invar, an alloy of nickel and steel which, having a co-efficient of linear expansion of only ·0000008 for one degree Centigrade, is in general use as a material for standard measures and instruments of precision. In 1920 he was awarded the Nobel Prize for physics and he became director of the international bureau of weights and measures.

Guillaume's works include: *Traité pratique de la thermométrie de précision* (1889); *Les radiations nouvelles; Les rayons X*, etc. (1896); *Les applications des aciers au nickel* (1904); *Détermination du volume du kilogramme d'eau* (1910); *Compensation des horloges et des montres* (1921); *Les récents progrès du système métrique* (1907–21).

GUINEA, FRENCH (*see* 11.102). Revised estimates give the area as 90,000 sq. m. and the population (1925) as 2,000,000. There were 2,000 Europeans, of whom half were French. From the port of Konakri (population 9,000) a railway 411 m. long was completed in 1915 to Kankan, on the Upper Niger. Palm oil and kernels, ground nuts, rubber and hides are the chief exports. Since 1922 cotton has been grown in the Niger regions. Coffee and bananas are other crops.

GUISE, BATTLE OF: *see* FRONTIERS, BATTLES OF THE.

GUITRY, LUCIEN GERMAINE (1860–1925), French actor (*see* 12.705). In 1920 he came to London with his son Sacha, and achieved an immense success in *Pasteur*, when he played the title rôle. He also played in his son's play, *Mon père avait raison*. He died in Paris June 1 1925. Sacha Guitry's play, *Deburau*, had a successful run in New York and London.

GULLSTRAND, ALLVAR (1862–), Swedish physician, was born June 5 1862 at Landskrona. In 1894 he became professor of diseases of the eye at Uppsala and in 1913 was appointed professor of physiological and physical optics at the same university. His investigations concerned the general laws of dioptrics, a new conception of the theory of optical images; the extrication of the optical images in the eye, and the eye's relation to the diffusion of light. In 1911 he was awarded the Nobel Prize for medicine. Among Gullstrand's works are *Allgemeine Theorie der monochromatischen Aberrationen* (1900), *Die optische Abbildung in heterogenen Medien und die Dioptrik der Kristallinse des Menschen* (1908) and *Einführung in die Methoden der Dioptrik des Auges des Menschen* (1911). He received the honorary degree of Sc.D. at Dublin in 1912 and became honorary member of the Ophthalmological Society of the United Kingdom in 1916.

GUN: *see* ARTILLERY: ORDNANCE.

GUNNERY, NAVAL.—It is no easy matter to hit, and keep on hitting a moving target at sea, with a gun mounted upon an unstable platform that is also moving in relation to the target. With a single gun firing, at short ranges, the gunlayer can follow the path of his shot and see it strike the water or target, and can correct his sights so that the next shot will hit. With several guns firing, under battle conditions at even moderate ranges, this becomes a sheer impossibility for anyone stationed at the guns. Hence the necessity for controlling the fire of the guns of a ship from a central position remote from the guns themselves. The control officer is usually stationed high up in the ship where he is in a good position to spot the fall of the shot and has all the available information for estimating the hitting range and for communicating it to the guns. The gunlayers keep their guns continuously laid upon the target and the guns are fired at the command of the control officer.

Let us consider a simple case of a ship firing at a towed target at a range of about 10,000 yards. The range of the target is obtained by the rangefinder and certain corrections, which will be explained later, are applied to the rangefinder range to obtain the estimated "gun range" which is passed to the guns. As the firing ship and the target are both moving, it is obvious that the range must be changing at a certain rate. This rate of change of range is estimated and is applied to the gunsights at set intervals. The deflection is estimated by the control officer and is applied to the sights. The control officer then fires a salvo of two or more guns and watches the fall of the shot. He makes a spotting correction in range and deflection, calculated to get the next salvo to fall, if possible, upon the other side of the target to the first one. If this happens he halves his original spotting correction, applies it in the opposite direction and fires again. This third salvo should fall very close to the target, if it does not hit, and if the rate of change of range has been estimated correctly, subsequent salvoes will, theoretically, continue to hit. This is a very simple case of a bracket system, which is used in one form or another by all control officers.

Corrections.—The corrections which must be applied to the range observed by the rangefinders in order to obtain the hitting or gun range are due to (1) the variations in muzzle velocity caused by the wear of the guns, (2) the change in muzzle velocity due to changes in the temperature of the charges, (3) the direction and force of the wind and (4) the height of the barometer and thermometer. The first two are usually applied as a correction upon the sights of each individual gun and remain more or less constant for any one day. The last two factors are variable from hour to hour and are applied as a direct correction to the rangefinder readings. The rate at which the range is changing is a variable factor since it depends upon the relative bearing between the two ships, which is constantly changing. The same applies, in a lesser degree, to the deflection, and constant corrections are necessary in both rate and deflection to maintain hitting after it is once established.

Increase of Range.—Thus there are many problems to be solved, even in the simple case of firing at a target at 10,000 yards. Battle ranges have now been extended up to 20,000 yd. or more, and as the range is increased the problems with which

he control officer is faced become much more complicated. At anges which approach the limits of visibility the observation of he fall of shot becomes extremely difficult, and it is practically mpossible to tell whether shot are falling over or short, unless hey are falling directly in line with the target. As the range ncreases errors caused by the roll, yaw and pitch of the ship, which at moderate ranges are not so serious, become accentuated nd have to be taken into account.

Trial and Error Process.—The trajectory of the shell reaches very high altitude and the wind and atmospheric conditions n the upper air cannot be known with sufficient accuracy to enble a correct forecast to be made of the effect upon projectiles. he effects of the variations in muzzle velocity, due to the wear f the guns, to changes in the temperature of charges and to ther more obscure causes, become more pronounced. Range obervation, even with the most perfect instruments and with the est trained observers, becomes unreliable when the visibility is oor and the errors in the rangefinders themselves become reater as the range increases. It thus becomes a matter of great ifficulty to make an accurate forecast of the initial gun range nd deflection. It has become the practice to obtain the hitting ange by a process of "trial and error," employing a large bracket ystem and using the gun as its own rangefinder, obtaining what ssistance is possible, under prevailing conditions, from the inruments of observation. This can be done as long as the fall f shot can be observed, but becomes impossible as soon as this ondition ceases to exist. The use of aircraft to assist the spotng officer, or to carry out the whole of the observation of fire at xtreme ranges, naturally suggests itself, and it is in this direcion, followed by the possible introduction of some form of ndirect fire, that future developments may be expected.

The Mechanism of Fire Control

The installation used for the control of fire was intricate in he years before 1914, and War experience has made the addition f further complications necessary. Little can be said of the deails of the various instruments used, as the majority of them are onfidential, and the functions, and even the existence, of some f them are kept as secret as possible. The main problems are the ame for all and may be divided into three parts:—

(1) The communications between the control stations and he guns.

(2) The apparatus for obtaining the hitting range and deection and for keeping them both correct.

(3) The arrangements for firing the guns and for observing the all of shot.

Communications.—The positions between which communication nust be maintained are the observing positions aloft, the principal ontrol position, usually in the vicinity of the conning tower, the ransmitting station and the turrets or other gun positions. Comunications must be rapid and sure, as most of the information sent s only of value at the moment of transmission and loses its signifiance if any delay occurs. Hence several lines usually exist between mportant stations, any one of which can be used in the event of reakdown of the others. All lines of communication are usually conentrated from outlying stations into the transmitting station. This tation is situated in the centre of the ship, well below the armoured leck in the quietest position that can be selected and is the centre f the whole control organisation.

Voice-pipes are used to a great extent between stations that are ermanently manned and that are moderately close together. To be fficient a voice-pipe must be as straight as possible, and there are ell-defined limits of length for each diameter of pipe beyond which he acoustic properties are lost. Voice-pipes are difficult to make atertight and gastight.

The telephone is used between all stations, often in addition to the oice-pipe. There is usually a telephone exchange, in or near the ransmitting station, solely for the use of the fire control organisation nd quite independent of the general telephone system of the ship. The telephone transmitters and receivers are of many patterns and re specially designed for use by operators who have other duties to erform, or who have to use the instruments in positions which are xposed to the weather. Electro-mechanical transmitters and reeivers are used for passing ranges, deflection, bearing, orders and ther information of a standard character between the control ositions and the guns. There are several different patterns of these nstruments, those most commonly used in all navies being the Barr & Stroud "step-by-step," and the Vickers "counter" types.

Frequently one transmitter is arranged to work a number of receivers in outlying stations. A development of these instruments is found in the "follow the pointer" method, which is commonly used for sending ranges from the transmitting station to the guns. The transmitter takes the form of a sight dial upon which the range is set by moving a pointer to the required setting. The motion of the pointer is transmitted electrically to pointers upon the gunsights. A mechanical pointer, geared to the mechanism which works the gunsight, is kept in line with the electric pointer by the sightsetter, and the sight is thus kept set without the sightsetter having to watch the movements of a separate instrument. The large clock-faced dials and other similar arrangements which are often seen about the upper works of warships are used for communicating the range and deflection in use to consorts who may be firing at the same target. Their place will doubtless be taken in the future by wireless telegraphy or telephony.

Rangefinding and Rangekeeping.—In the transmitting station are situated the majority of the calculating instruments, and to this position are passed the results of all observations of range, bearing, course of enemy, fall of shot, etc. Also all orders from the chief control officer to the guns are passed through the transmitting station. As a rule the control officer is in direct communication with the officer in charge of the transmitting station by means of a large, direct voice-pipe. The functions of the majority of the instruments in the transmitting station and their details are naturally confidential. Broadly they consist of arrangements for deducing the course and speed of the enemy from such data as may be available, and for calculating from this the rate of change of range and deflection that should be applied to the gunsights. In the British service the Dreyer calculating table is in general use, and to this constant improvements are being made to meet the changed conditions brought about by the increasing range at which the guns are used. The details of this calculating table are secret, but there are other patented apparatus, notably the Argo and the Ford, which aim at achieving the same results. Apart from the calculating apparatus, some form of which is in use in all navies, there are a certain number of instruments which are generally employed.

Rangefinders.—The rangefinder most commonly used by all navies, and which forms the equipment of the British fleet is the Barr & Stroud coincidence instrument. In a capital ship there are at least six large rangefinders, mounted in various positions, and the number and size of the instruments are reduced proportionately in smaller ships. The observations of each instrument are transmitted electrically to the transmitting station, where apparatus exists for obtaining rapidly a mean of all the observations, thus giving what is called the "mean rangefinder range." To this are applied corrections for the density of the air, the effect of wind, the temperature of the charges, the nature of the projectile, the change of range during the flight of the projectile and for several other variables. The result is the gun range which is passed to the guns.

Change of Range Calculators.—To obtain the rate at which the range is changing at any moment involves the solution of two triangles, the functions of which are the course and speed of the firing ship, and the bearing, course and speed of the target ship. The first two of these are known, the third is easily observed, but the other two can only be obtained by calculation, or judged approximately by observation. There are several types of calculators for this purpose, but that used in the British service is the Dumaresque in which the elements are set graphically, and the resulting rate of change of range corresponding to the settings is read off in "yards per minute" which is what is required. The speed of the target ship must always be guessed in the first instance, but instruments known as inclinometers are being experimented with, whereby the angle between the course of the target ship and the line of fire can be observed with fair accuracy at any moment. The course of the target ship is thus obtained.

Range Clocks.—Some type of clock, which can be set to run at the rate at which the range is changing is used in all navies. In the British service the Vickers clock is used. This consists of a powerful clockwork escapement, driving a large pointer around a clock face, the perimeter of which is graduated in yards. A method of altering the speed of the pointer is fitted, so that it can be made to move at speeds of 0 to 2,000 yd. per min. in either direction. Arrangements are made for large corrections in range to be put on the perimeter of the clock without interfering with the motion of the pointer, so that the clock can always be run at the gun range that it is desired to transmit to the guns. There are many other uses to which it can be applied.

Deflection Calculators.—It is a difficult matter to obtain the correct deflection for hitting a target at long range. There are many types of deflection calculators, wherewith, by using the data available in the transmitting room, an approximation to the theoretical deflection can be obtained. All these instruments, however, have their limitations, because, although the allowance can be made for the wind at the firing ship, at long range the wind effect at the target may be entirely different. Also the direction of the wind in the upper air, through which the trajectory of the projectile passes, is an unknown factor. The practice is to calculate the proper setting as near as possible and to correct it by observation of fall of shot. Deflection is of the greatest importance in ranging, for at long

ranges, unless the shot fall in line with the target, it is impossible to tell whether they are short or over.

Bearing Indicators.—These instruments are mounted in the control positions, and consist of a bearing plate, mounted with the zero in the fore and aft line of the ship. A telescope or binocular is suitably mounted and the bearing of any object, with reference to the ships fore and aft line, can be readily observed. In the Evershed type used in the British Navy, the bearings are transmitted electrically to the guns and to the transmitting station. This forms a ready method of indicating the correct target to the guns, and from the observations the rate at which the bearing is changing can be obtained.

Observing and Firing the Guns

Before the range at which heavy guns are used at sea became so extended, a single gun was used for ranging, before opening fire with the whole broadside. The differences between the ranging of individual guns, due to wear and a variety of other causes, become accentuated at long ranges, and no two guns can be built that will always shoot precisely the same.

This leads to a "pattern," or spread, resulting when a number of guns of the same size are fired at the same elevation. Apart from this, in practice the errors in laying of the individual gunlayers have to be taken into account. The "spread of the salvo," as it is called, can be reduced by making careful adjustments, but it can never be eliminated entirely, even if there are no errors in laying the guns. The spread can, however, be made an approximately constant quantity, by careful adjustments and training of the personnel, and this quantity is known to the control officer of each individual ship. To base the corrections for the broadside upon the result of the fall of a shot from a single gun is obviously liable to lead to large errors, and at extreme ranges the splash of a single shot is extremely difficult to see.

It is now the general practice to range with a salvo of several guns, usually half the broadside, and to continue firing alternate salvoes of an equal number of guns. The object of the control officer, knowing the approximate spread of his salvoes, is to give such corrections, using some form of bracket system, as will bring the mean point of impact of the salvo on to the target. This is termed a straddle—that is, some shots short and some over, and when this is achieved, the control officer knows that he is obtaining the maximum hitting effect from the armament that he is controlling.

Director Firing.—Practically all navies have now adopted some form of master sight or director, whereby all guns can be fired by a single layer. This system of firing has many advantages, chief amongst which are the elimination of smoke interference between the guns; the reduction in personal errors in laying; and the fact that it is far easier to spot the fall of a salvo that falls "all together" instead of being spread out over an irregular time interval.

In the British Navy the director installation invented by Adml. Sir P. Scott is used. This consists of a director sight mounted aloft, or in a director tower well separated from the guns themselves. The sight is similar to a gunsight and is carried in a mounting which can be trained and elevated in the same way as a gun mounting. The motion of the director mounting is transmitted electrically to training and elevation receivers at the guns. On these receivers are mechanical pointers geared to the training and elevating gear of the turret or gun. The gun is moved in training and elevation so that the mechanical pointers are kept in line with the electric ones worked by the director mounting. The guns thus follow the motions of the director or master sight and are laid at the desired elevation and training. The gun range and deflection are set upon the director sight, and the director telescope is laid upon the target in the same manner as a gunsight. The firing circuits of all guns are brought to a single trigger at the director sight, so that all guns can be fired simultaneously by the director layer.

This brief description indicates the principle upon which the director is worked, but in actual practice there are many complications. Corrections have to be made for the relative positions and levels of the different gun mountings and the director sight and for many other matters. The installation is intricate, but has stood the test of prolonged war service and the results achieved by it have been invaluable. In capital ships there are, as a rule, two director sights, one mounted aloft and one just above the level of the guns, which can be used alternatively for the main armament. A director is also fitted for use with the secondary armament. Light cruisers are fitted with directors for the main armament, and a modified form is used in destroyers.

Squadron Control.—In the foregoing, the control of the fire of the guns of a single ship has been dealt with, but under modern battle conditions, it often happens that one or more ships will engage the same target. When this occurs, unless there is some pre-arranged organisation between the firing ships, confusion will occur owing to the spotting officer taking the fall of another ship's salvoes for his own. Therefore a pair of ships firing at the same target generally fire a salvo or pair of salvoes alternately, each waiting upon the other and correcting the gun range by the fall of the other's salvoes. This necessitates an intimate interchange communication between the two control officers, which is possible by wireless telegraphy.

A squadron of four ships may fire together at the same target, the fire being controlled by the control officer of the leader, who orders the gun range at which each ship shall fire, after receiving the result of observations as to fall of shot from his own and the firing ship's spotting officers, and possibly from the air. In a case such as this, the object of the squadron control officer is the same as that of the control officer of a single ship, that is to bring the mean point of impact of the shell from the armament he is controlling as near the target as possible, for then only can he be sure that he is getting the maximum hitting effect. In view of the extreme ranges at which future actions at sea will be fought, it appears certain that fire tactics will tend to develop in the direction of concentrated fire by pairs of ships or by squadrons, aided by observation from the air. The perfecting of the intricate organisation of the fire control of any ship is the most important item in making her an efficient fighting unit and requires arduous and painstaking exercise lasting over many months. (*See* Ordnance.) (S. H. W.)

GUNPOWDER: *see* Explosives.

GWALIOR, MAHDO RAO SINDHIA, Maharaja of (1876–1925), was born Oct. 20 1876, and succeeded his father, Sir Jayaji Rao Sindhia, in 1886 (*see* 12.748). He threw himself with the utmost keenness into the supervision of every detail of state management, endowing Gwalior with an excellent system of light railways, carrying out irrigation projects, husbanding the revenues and raising the standards of administration by unceasing vigilance. In the World War his two regiments and transport corps fought with distinction in France, East Africa, Egypt, Palestine and Mesopotamia. A boundless and inventive generosity found scope in his constant presentation of munitions of war and princely donations to various relief funds. He took the main part in purchasing, equipping and maintaining the hospital ship "Loyalty," which carried 15,000 war patients; and provided a convalescent home at Nairobi in East Africa—to mention only a few of his gifts. A lieutenant-general in the British Army, he was Hon. A.D.C. to King George V., and the bearer of several Grand Crosses; his permanent dynastic salute was raised to the maximum of 21 guns, and Oxford and Cambridge conferred honorary degrees upon him. King George V. also honoured him by becoming sponsor to his heir, George Jivaji Rao (b. 1916). The Maharaja went to Europe in the spring of 1925, partly to recuperate his impaired health, but died in Paris on June 5.

GYMNASTICS (*see* 12.752).—This form of athletic sports has changed little since 1910. The undoubted influence of the revived Olympic Games upon the modern development of athletic sports and exercises has not greatly affected gymnastics, perhaps because of the already high state of efficiency reached prior to the revival. The International Gymnastic Federation, which has but one affiliated nation outside Europe, *i.e.*, the United States, was founded in 1881, and 20th-century efforts have tended rather to consolidation and perfection than to extension and progress. One important feature was the foundation, in 1923, of an International Federation for the promotion of the educative, instead of the executive, branch of the art. Both federations have their British affiliations, that to the Fédération Internationale de Gymnastique being the Amateur Gymnastic Ass'n and that to the Fédération Internationale de Gymnastique Educative being the Ling Association.

The enormous development of athletic sports throughout most of the European countries has not caused gymnastics to suffer; the great festivals at Nuremberg, Leipzig, Frankfort and in Sweden, France and Switzerland continue to attract thousands of gymnasts. On the continent of Europe the movement is national: in Great Britain, and to a lesser extent in the United States, interest in gymnastics is individual. The repetitive character, the absence of the competitive spirit, perhaps also the collective discipline so necessary, appear to have too little in common with the Anglo-Saxon character for gymnastics ever to arouse the enthusiasm which prevails in the European countries. The inclusion of gymnastic competitions at the Olympic Games has not appreciably affected the situation. (*See* Athletics; Olympic Games.) (P. Lo.)

GYNAECOLOGY: *see* WOMEN, DISEASES OF.

GYROSCOPE (*see* 12.769).— This instrument has rapidly become of technical and commercial importance after having been regarded as little more than a toy or means for use in demonstrating the dynamics of solid bodies. The developments in its construction and application, since torpedoes, submarines and aeroplanes came into extensive use, have been numerous. Inventive efforts in connection with it were greatest about the year 1920. From a commercial standpoint, the successful application of the gyroscope in the arts has led to the establishment of important industries turning out gyroscopic appliances with rotors weighing up to about 90 tons.

Improvements in Construction.—Since 1910 many improvements have been made in the construction of the gyroscope and its modification, the gyrostat, independently of accessories for rendering them useful in the arts. Messrs. Gray and Burnside's gyrostat, designed chiefly for experimental purposes, is essentially a direct current electric motor, the rotor of which, in the form of a Gramme ring secured between the peripheral parts of two magnalium disks, serves as the wheel or rotor of the gyrostat. The field magnet and brush gear are within the space between the disks, and the commutator is secured to the inner side of one of the disks. The rotor, made up of the heavy ring, the very light disks and the commutator, is mounted on a stationary shaft and may be driven at a speed of 25,000 revolutions per minute. Enclosed in a magnalium casing, the whole forms a compact, portable apparatus.

In Rutt's gyroscope, the relative arrangements of the parts is reversed, so as to leave the rim of the rotor entirely free, the rotor being mounted adjustably on a central gimbal carried by a rotary shaft.

It is important that the rotor of a gyroscope should be mounted in accurately adjusted bearings, especially when the rotor is spun at a high velocity. In order to satisfy this requirement, when ball bearings are used, Messrs. Griffin and Sons, Ltd., mount the rotor on a tubular spindle encircling a screwed rod secured within the Cardan ring carrying the rotor; the ends of the spindle rotate against ball bearings held in correct position by adjustable sleeves on the rod. The spindle and rod are concentric but do not touch each other. The rotors of many gyros are rotated in a partial vacuum to reduce frictional resistance. In order to minimize the resistance and at the same time keep the interior of the gyro casing cool, Messrs. Anschütz, near Kiel, circulate hydrogen, helium or other light gas through the casing.

Gyrostatic Horizon.—On ships, aeroplanes, etc., where the use of a mercury bath for obtaining an artificial horizon is often impracticable, one of the methods adopted is to employ a gyrostat with its spinning axis vertical and carrying a plane reflector at right angles to that axis. This, the first practical use of the gyro, was introduced by M. Serson in 1774.

Since 1910, several forms of this type of apparatus have been designed. Fig. 1 shows the main features of the gyrostatic horizon of Messrs. Anschütz & Co. A box *a* is mounted on knife edges by a suspension differing from the ordinary Cardan in that the horizontal line joining the knife edges *b*, which directly supports the box, is below that joining the knife edges which support the outer ring, both lines being higher than the centre of gravity of the box and its attachments. Within the box is the rotor *c* supported by ball bearings *d*, *e* and rotated by any suitable motor. A rotary ring *f* carries an adjustable weight *g*, by means of which the centre of gravity of the whole is moved out of the gyroscopic axis so that this axis is constrained to precess in such a way as to compensate for the effects of the earth's rotation; by means of a scale, graduated in degrees of latitude, the weight can be adjusted correctly. An annular vessel *h*, containing mercury or oil, and formed with perforated partitions, is employed for damping precessional movements of the gyro.

Gyro-compass.—This instrument of precision is used in the various navies of the world, and in the mercantile marine; it is used extensively in submarines, for which the magnetic compass is unsuitable. A gyro-wheel, mounted to rotate rapidly about an axis free to turn in any direction, but provided with a form of gravity control, limiting its tilting movement, tends to set itself so that its axis points in the direction of the true north. This represents the working of the principle on which the construction of the gyro-compass depends. The many forms of gyro-compass which have been patented differ mainly in the construction of their gravity control.

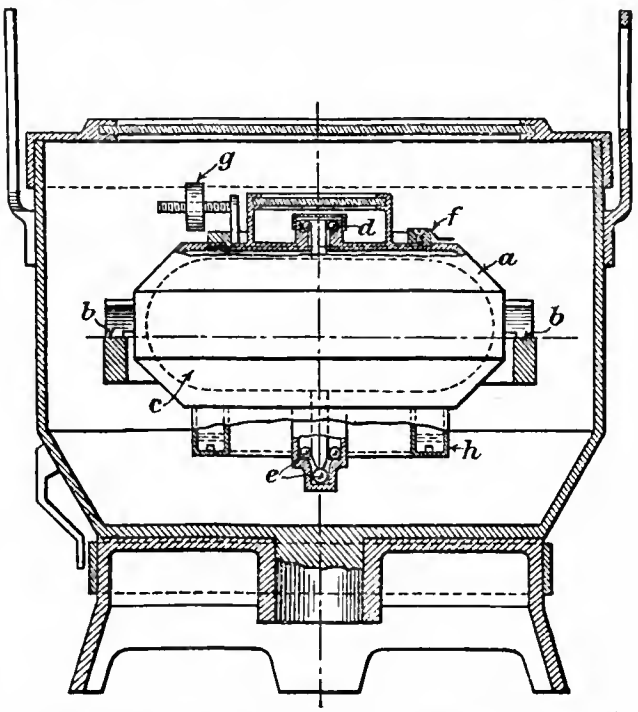

FIG. 1.—Diagram showing the main features of the gyrostatic horizon of Messrs. Anschütz & Co.

In 1852 Foucault used a gyro apparatus to demonstrate the earth's rotation; this was the first practical step towards the production of the gyro-compass. A form of gyro-compass, constructed by Sir W. Thomson (afterwards Lord Kelvin) was exhibited in 1884. In the early part of this century the increasing use of submarines demanded the provision of a compass unaffected by magnetic conditions, and Dr. Anschütz invented a gyro-compass in which the rotor and its casing were mounted in a support floating in mercury, thus limiting movement about a horizontal axis. This compass was unreliable when the ship was rolling, and, to overcome this defect, Messrs. Anschütz & Co. introduced, in 1912, an apparatus comprising three gyros, two of which eliminated errors due to rolling. This apparatus was used in the German navy.

In the gyro-compass of The Sperry Gyroscope Co., of New York (British patent specifications, Nos. 15669 of 1911 and 135500), the gyro-wheel casing is supported by a suspended wire, any twist of which caused during the working of the compass is taken out by a follow-up mechanism of special construction. The Sperry Co.'s compass was adopted for use in the British and Allied navies, and was improved by Messrs. Harrison and Rawlings, who introduced a mercury control attachment (British patent specification, No. 131987).

The suspension of the vertical axis in the Brown gyro-compass (British patent specification, No. 124529) is provided by a pulsating column of oil under great pressure. In Henderson's gyro-compass (British patent specification, No. 166570) the gyroscope has its centre of gravity and that of its gravity-control apparatus at its centre of suspension, and relative motion between the gyro and gravity control is arranged to produce a controlling couple.

Gyro-apparatus for Stabilising Wheeled Vehicles.—About the year 1905, Mr. L. Brennan, of Gillingham, introduced his monorail car, in one form of which he employed two gyrostats rotating in opposite directions and mounted in a horizontally pivoted frame. The gyrostats were geared together so as to rotate in opposite directions; one was provided with means for automatically accelerating the precession when the car swayed to one side, thus effecting stabilisation, in accordance with Lord Kelvin's rule that acceleration of the precession causes the gyro to rise

against gravity. In 1909, Mr. Brennan introduced powerful mechanism to control the precessional movements or to alter the position of the centre of gravity of the car, *e.g.*, by sliding the car body on the under-carriage.

The car was generally unreliable when running rapidly round sharp curves, and its gyro bearings were liable to overheating. Several of the cars were exhibited at different times; a large one was run at the Brennan factory, on Nov. 10 1909. This car had two bogies, each with two double-flanged wheels. The rotors, 15 cwt. each, were rotated at a speed of 3,000 r.p.m.; the gyros were encased and in a partial vacuum. At a speed of about 7 m. an hour, the car travelled satisfactorily on a curved track and could travel on gradients up to 1 in 13.

Gyroscopic Apparatus for Stabilising Ships.—The earliest u of the gyro principle for stabilising ships was made by E. Schlick, of Hamburg, in 1903. He mounted a number of gyr stats in the ship and used, for eliminating precessional motio a braking-mechanism exerting a constant pressure on the gy mountings. His invention was improved by Messrs. Swa Hunter and Wigham-Richardson by using spring-controlled floating bearings for the gyro frames and regulating the braki effect in accordance with the degree of rolling of the ship.

The gyroscopic apparatus of E. A. Sperry and The Sper Gyroscope Co., of New York, is of an active kind, for its acti is not limited by the rolling of the ship but may itself impart the ship a rolling motion so that the ship may be listed and he

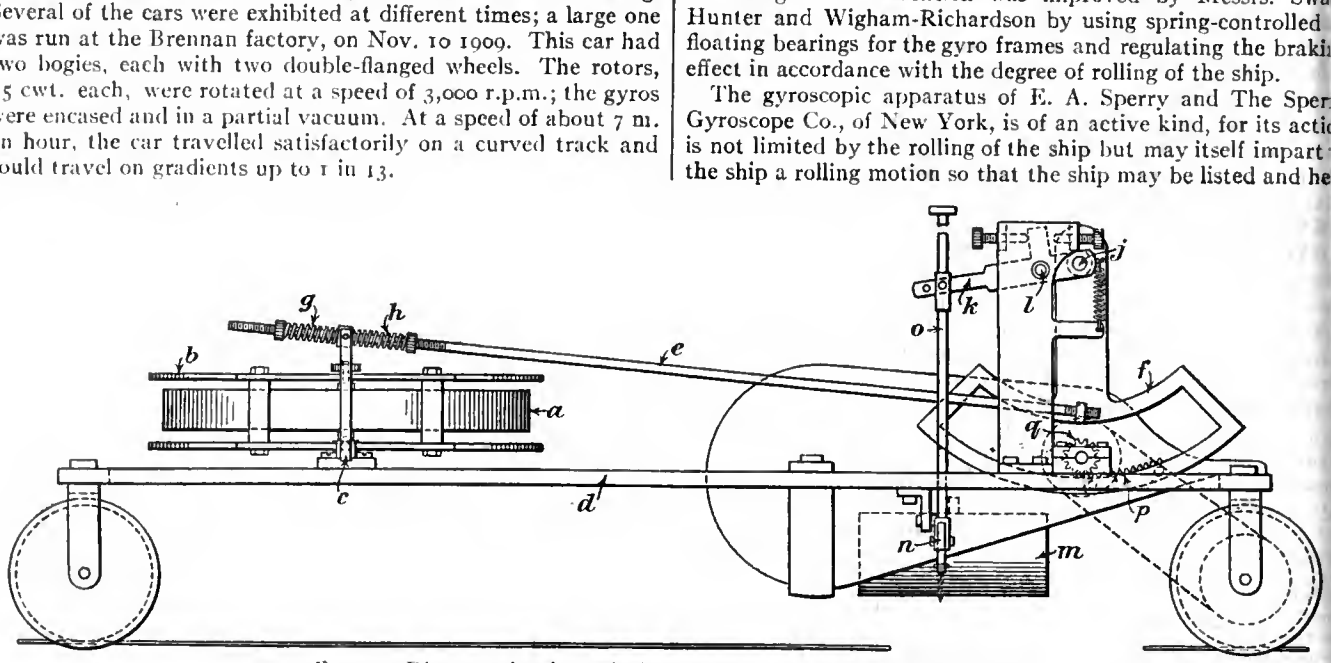

FIG. 2.—Diagram showing principal parts of P. Schilowsky's Auto-car.

The monorail car of R. Scherl, of Dresden, had one or more gyrostats with their rotors on vertical axes and mounted so as to be in unstable equilibrium and positively connected to the car at every moment. Scherl's car was not successful, difficulties having been experienced on inclines and when running round curves to right and left.

In the auto-car of P. Schilowsky, described in British patent specifications, Nos. 12021 of 1909 and 941 of 1914, the gyrostat, like Scherl's, is unstable. Fig. 2 shows diagrammatically the principal parts of the car. The rotor *a* is mounted in a frame *b* supported by pivots c^1, one at each side of the car frame *d*. A rod *e* connects the gyro to a quadrant *f*; this rod is encircled by adjustable springs *g*, h^1, to obtain a yielding connection. The quadrant *f* is suspended at f^2 from a lever *k*, fulcrummed at l^1 and caused to oscillate by the action of a pendulum *m*; the pendulum is pivoted to the car frame and presses against a cord which extends from a fixed part of the frame over a pulley and then beneath the pendulum, on its way to one arm of a bell-crank lever *n*; this is connected to a rod *o*, which rocks the lever *k*.

When the pendulum presses against the cord, as a result of the tilting of the car to one side, the quadrant *f* is lifted and a rack p^1 on the quadrant engages with a rotating pinion q^1; consequently, pressure is applied by the rod *e* to the gyro mounting with the result that its oscillations are annulled and the car brought into an upright position. Although only one pendulum is shown in fig. 2, the auto-car had two pendulums to enable the car to reverse and take curves to right and left. The inventor, in 1914, made trial runs in cars of this type and met with much success. Claiming that a monorail system of transport would be quicker and cheaper than the existing systems, Messrs. Scherl and Schilowsky, at different times, have considered plans for laying down extensive networks of lines, especially in Germany, but nothing seems to have been done.

Dr. J. G. Gray, of Glasgow University, has designed a two-wheel car controlled gyroscopically. This car has a front and a rear compartment, each running on a wheel and connected together by a vertical swivel-joint. The front compartment carries a gyrostat mounted in fixed lateral bearings and the rotor is spun in the vertical plane containing the wheel base. A motor for driving the car is installed in the rear compartment. A car of this kind was shown at a meeting of the Inst. of Civil Engineers, on June 17 1925. The car was driven forwards and the gyro rotor was spinning clockwise as seen from the left-hand side of the car, but when the car swayed to one side the two compartments were thrown out of line. Then, in consequence of the propulsion by the rear compartment, an acceleration of the gyroscopic precession was effected and the car was brought back to the upright position.

up to the full strength of the gyro apparatus installed. Con trolled in this way, the ship may be extricated from a difficul position, may be used as an ice-breaker or, as set out in Britis patent specification, No. 140439, a rolling motion of predeter mined magnitude may be maintained in a warship while her gun are being fired.

The important elements of a Sperry stabiliser are the main gyro the small control gyro, the precession engine and the system o electric circuits. The main gyro may have its spinning axis vertica and is so mounted that a precession can be imparted to it by mean of a circular rack which engages with a pinion of the precession en gine. The control gyro, spinning on a horizontal axis, is so sensitive that it precesses as soon as the ship begins to roll and effects the closing of an electric contact which, by means of relay switches operates the precession engine, thus bringing into action a powerfu stabilising couple. Next, the control gyro stops the precession engine and is ready to deal with the next wave impulse.

Among the stabilisers built by The Sperry Gyroscope Co. is that for the liner "Huron" of 18,000 tons displacement. A large bicon ical casing encloses the main gyro in a partial vacuum and the gyro wheel, made by bolting together two disks each 13 ft. diam., weighs about 100,000 pounds.

In the stabilising apparatus of Sir J. B. Henderson, of the Royal Naval College, Greenwich, the velocity of the gyroscopic precession is controlled wholly by means of a single mechanism, which may be a continuously variable speed-gear of the variable-stroke pump type, of the mechanical type or of the viscous resistance type. Fig. 3 shows the mounting of a gyroscope and its hydraulic connections with the ship and fig. 4 a controlling means comprising a variable-stroke pump.

The rotor casing *a* is mounted on trunnions *b* in the Cardan ring *c*, which is carried by trunnions *d* supported by standards *e*, bolted to the deck so that the trunnion axis *d* extends fore and aft. The ring *c* is connected by rods *f* to the buckets *g* of the single acting pumps *h*, *j*, which have suction valves *k* and spring-controlled delivery valves *l*; the suction pipes *m* and delivery pipes *n* may lead to the sea far below the water line. When a wave strikes the ship, the pressure in one of the pumps *h*, *j* increases at once and tends to force the gyro to roll with the ship. The hydraulic cylinders *o*, *p* of the precession-control apparatus are mounted on the ring *c* and their plungers *q*, *r* are connected to a crank *s*, fixed to the trunnion *b* of the gyro case. In order to prevent the ship from rolling, the velocity of the plungers *q*, *r* should be proportional to the difference of pressure in the cylinders *h*, *j* and the ratio between them must have a certain value. To effect this, the cylinders *o*, *p* are respectively connected by pipes *t*, *u* to the cylinder of a variable-stroke pump *v*, the

iston of which is connected to a spring-controlled piston *w*, working
1 a cylinder *x*; the ends of this cylinder communicate with the pumps
and *j* respectively, by means of pipes *y*, *z*.
In a gyro apparatus designed by the Tokio firm, Mitsubishi
osen Kaisha, the precessional movements of one or more
yrostats effect the closing of electrical circuits controlling an engine
hich is geared up to rotary retractile fins projecting from the ship's
ilge.

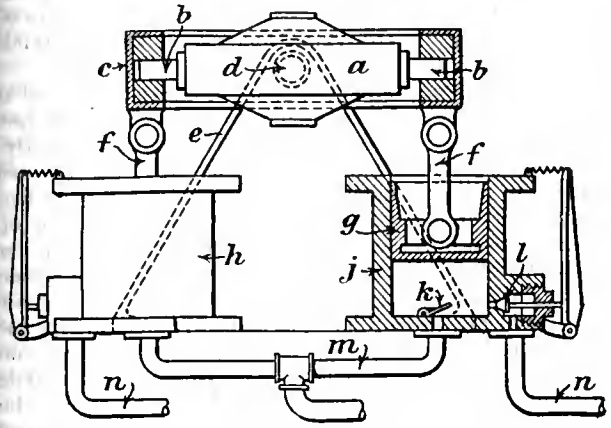

Fig. 3.

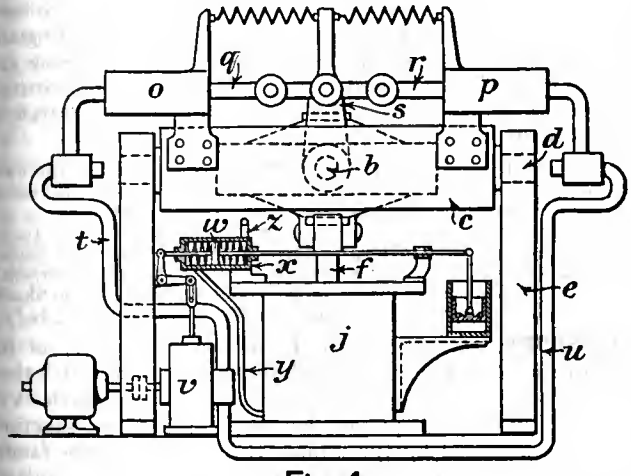

Fig. 4.

FIG. 3.—Diagram showing the mounting of a gyroscope, and its hydraulic connections with the ship; and FIG. 4, a controlling means comprising a variable stroke pump.

Gyro-stabilisers for Aircraft.—One of the more recent of these stabilisers is The Sperry Gyroscope Co.'s, which has two pairs of oppositely rotating gyrostats, with their precession axes vertical, mounted in a Cardan suspension, the outer ring of which has its pivots above the centre of gravity of the gyro-apparatus. The lateral and longitudinal balancing planes of the aeroplane are respectively actuated by relative displacements between the gyro-apparatus and two control arms carried on the aeroplane. These arms control the working of a motor which adjusts the planes. A still more recent stabiliser, that of the Société Anonyme des Établissements Marmonier Fils, comprises two gyros mounted in an elongated frame supported by horizontal pivots, each gyro carrying a pendulum bob. The rotors spin in a horizontal plane and in opposite directions with equal velocities.

Gyro-steering Apparatus for Torpedoes.—Since 1910, improvements have been mainly in details in connection with the driving of the gyro-rotor, its locking and releasing mechanism, or the arrangement of the gyro-apparatus to minimise the effects of rolling of the torpedo.

Gyro Turn-indicators.—In a form developed at Farnborough, the rotor was mounted outside the aeroplane and driven by the wind, the rotation being in a vertical plane at right angles to the direction of flight. The direction and rate of turn was indicated by a precession-actuated pointer. In the Reid control indicator, a compact combination of gyro-turn-indicator, airspeed indicator and clinometer, manufactured by Messrs. Vickers, Ltd., the rotor of the turn-indicator is driven by a jet of air passing through a compound Venturi tube placed in the slip stream of the propeller. The turn is indicated by means of precession-actuated electric contacts, which switch on one, two or more green lamps, if the turn is to the right, or one, two or more red lamps, if the turn is to the left; the number of lamps switched on is directly proportional to the rate of turn (*see* AIR NAVIGATION).

Gyro-apparatus for Indicating Rate of Angular Motion.—This is usually employed for recording the rolling motions of a ship. In the Cunard liner "Laconia," fitted with Frahm's anti-rolling tanks, a gyro pendulum was used for recording the rolling motions. Its rotor was horizontal and driven by an electric motor; the rotor was mounted in a Cardan ring suspended in a stand secured to the deck, the pivots of suspension being fore and aft. The angular motion of the stand relatively to the gyro represents the rolling of the ship and is recorded by a pencil beneath which a paper band travels continuously.

Gyroscopic Transmission Gear.—The gyro principle has been utilised in transmitting power, the gyro serving as a flexible connection between a driving and a driven shaft. (*See* VARIABLE TRANSMISSION GEAR.)

Other Applications.—In apparatus for measuring deviations of bore-holes from the vertical, the gyroscope has been employed to compensate for rotation, in the bore-hole, of the outer casing containing the measuring apparatus. Messrs. Krupp's fire control apparatus for use with naval guns makes use of a gyrostatic apparatus at the observation station and a precisely similar apparatus at the gun station, both apparatuses being connected electrically so as to operate strictly in unison. The gyroscopically controlled photographic camera of Prof. Sir J. B. Henderson comprises a gyro-controlled prism for counteracting the effects of lateral movements and pitching of the support and a gyroscopically rotated sensitive plate to compensate for rolling movements. The camera is intended chiefly for aerial photography and is rigidly secured to an aeroplane.

(T. E. L.)

HAAG, CARL (1820–1915), British painter (*see* 12.780), died at Rother Thurm, Oberwesel, Germany, Jan. 17 1915.

HAASE, FRIEDRICH (1827–1911), German actor (*see* 12.782), died in Berlin March 17 1911.

HAASE, HUGO (1863–1919), German politician, was born Sept. 29 1863, at Allenstein in East Prussia. At the outbreak of the World War he was parliamentary leader of the Social Democratic party in the Reichstag, but in 1916 he seceded with the Independent Socialists, who refused to vote the estimate and war credits, and became their leader. In this capacity he exercised a moderating influence upon the extreme section of the Independents, who at a later date (1920) joined the Communists. He was one of the commission of six who conducted the Government of the German Reich, in the name of the people, immediately after the revolution of Nov. 1918. Haase died on Nov. 7 1919 from wounds received in an attempt upon his life while he was entering the Reichstag building.

HABER, FRITZ (1868–), German chemist, was born in Breslau Dec. 9 1868. He studied at the universities of Berlin and Heidelberg and at the technical high schools at Charlottenburg and Carlsruhe. He was then appointed staff professor at Berlin University and afterwards became director of the Kaiser Wilhelm Institute for physical chemistry and electrochemistry. He made a special study of thermodynamic technical gas reactions, and also made experiments in connection with the equilibrium of ammonia and the influence of very high pressures and high temperatures. During the World War he studied the gases used in warfare and their effective frustration by gas masks and chemical means. He conducted particularly important researches in collaboration with Bosch, which led to the establishment of the Haber-Bosch process for the production of nitrogen manure. After the War the large works at Leuna, near Halle, produced more nitrogenous manure, according to this process, than was imported previously in the form of nitrate of soda. The chief characteristic of the process is the continuous reaction under a pressure of 200 atmospheres, and the most important raw material used is water gas, produced from coke and gypsum (*see* NITROGEN, FIXATION OF). His recent works include *Beitrag zur Kenntnis der Metalle* (1919); *Über die Synthese des Ammoniaks: Die Chemie im Kriege* (1922); *Fünf Vorträge aus den Jahren 1920–3: Über die Herstellung des Ammoniaks aus Stickstoff und Wasserstoff* (1924).

HABITUAL OFFENDERS.—In the law, as in common parlance, a habitual offender is one who is repeatedly guilty of criminal offences, who makes a business of crime. In this broad sense the term is identical in meaning with recidivist, a constant backslider. In a more restricted and accurate sense, however, habitual offender denotes one who has become a recidivist by force of habit, and this opens up a wide and interesting divergence of opinion among psychologists as to the mainsprings of conduct. One school of students of this science stresses the hereditary element in human nature—instinct, impulse, the innate characteristics—and to the most extreme of these every "true" criminal is by propensity if not in act, a recidivist. The criminal is born, not made. The other school, believing that our original endowment differs only in degree and not in kind, lays the emphasis on environment, the individual's experience of life. The criminal is the product of circumstances.

The Schools of Thought.—Without drawing too fine a line between the adherents of these two schools of thought, it may safely be asserted that the medical criminologists tend to align themselves with the former and the sociological criminologists with the latter. Many psychiatrists have committed themselves to the view that all recidivists, if not all criminals, are either insane or psychopathic personalities. There is, on the other hand, a strong current of psychological thought in evidence at the present time, which strongly supports the view expressed in the popular maxim, "man is a creature of habit." Habit is not only a manner of acting but of thinking and feeling as well. Will, conscience, impulse, are all the fruits of habit. Indeed they *are* the habit of which the external act or conduct is only the expression. The habitual offender is what he is because his experience of life has been such as to cultivate criminalistic ways of thinking, feeling and acting.

Probably no one would deny that the development of these anti-social tendencies comes easier to some than to others, but the clear implication of this doctrine is that, given a sufficiently evil environment, no man that is born of woman is so endowed by nature as to resist its moulding influence. On the other hand it is conceded that some, probably a very small proportion of the whole, are born into the world with such a defective equipment as to render them very unlikely subjects for the development of a socially useful character. Such are the neurotic individual who early in life develop into insane or psychopathic personalities. The notion, current a few years ago, that the feeble-minded are of this sort, has now been generally abandoned. Mental defect is a handicap in leading any kind of life, good or bad, but it involves no predisposition towards the latter. The net result is that the good life is not an individual endowment but a social achievement, and the same is true of the evil life.

That the habitual offender is not irredeemable appears to have been demonstrated by the experience of Camp Hill in England and by fortunate periods in the recent history of Sing Sing and Auburn prisons in the United States. "Habit is second nature," but like the original nature, it is still plastic and susceptible to new and more wholesome influences.

BIBLIOGRAPHY.—The literature of the subject is still, for the most part, to be found in psychologic and other periodicals. Books or articles that may be read with profit are:

John Dewey, *Human Nature and Conduct* (New York, 1922); S. Hobhouse and F. Brockway, *English Prisons To-day* (London, 1922); B. Glueck, "A Study of 608 Admissions to Sing Sing Prison," in *Mental Hygiene*, 2 (1918); "Jack" Black, "Breaking the Shackles," *The Call* (San Francisco, 1918, 1926). (G. W. K.*)

HABSBURG (*see* 12.787), the former ruling dynasty of the Austro-Hungarian Empire. The Habsburgs' relations with their subjects were defined in the 18th century, when Charles VI., last of the Habsburgs proper, issued the pragmatic sanction which was accepted by the estates of his peoples. The family dominions were hereby declared indivisible, and the descendants of Charles were accepted as their hereditary rulers in perpetuity so long as a male or female member of them remained. The dynasty of Habsburg-Lorraine, founded by Charles's daughter Maria Theresa, and her husband Francis I., ruled in virtue of this contract. In 1918 there were over 120 archdukes or archduchesses, descendants of Maria Theresa, who could thus succeed to the throne.

Results of the War.—Charles I. (*q.v.*), the last ruling Emperor of Austria and King of Hungary, succeeded his great-uncle on Nov. 21 1916. At this time his subjects still protested loyalty to the dynasty; but during the collapse of Oct. 1918 one nation after another repudiated its rule. The Poles of Galicia, who had long been practically independent, formed a national council at Cracow on Oct. 28 1918 and soon after adhered to the republic of Poland. The Ruthenians of East Galicia decided on Oct. 19 to form a separate state. The Czechoslovaks on Oct. 21, in a manifesto dated the 18th, declared themselves independent and expressly repudiated Habsburg rule. The Yugoslavs made very similar proclamations during the last days of October. On Oct. 27 Count Andrássy, the Austro-Hungarian Foreign Minister accepted President Wilson's demands "regarding the rights of the peoples of Austria-Hungary, particularly those of the Czechoslovaks and Yugoslavs." The states of Poland, Yugoslavia and Czechoslovakia soon after came formally into being and although Charles never renounced his sovereign rights in these territories, the Habsburg family has made no serious claim to reassert them; although a small monarchist party in Croatia

since toyed with the idea of reuniting with Hungary under bsburg rule. The treaties of Saint Germain and Trianon petuated the boundaries of these States, and confirmed Italy l Rumania in the possession of their parts of the former bsburg monarchy. Most of the treaties of the "Little tente" (*q.v.*) are expressly directed towards the maintenance these frontiers, especially those of Hungary, and thus im-citly (the forms of those states being what they are) to the clusion of the Habsburgs from these territories.

Position of the Emperor Charles.—There remained only rman-Austria and Hungary. On Nov. 11 1918 Charles issued proclamation in which he stated:

"till, as ever, filled with unchanging love towards all my peoples, ill not oppose my person as an obstacle to their free development. ecognise in advance the decision which German-Austria will take its future form of State. The people has assumed the government ough its representatives. I renounce any share in the affairs of te. At the same time I remove my Austrian Govt. from its ce."

The Provisional Govt. of German-Austria proclaimed a public on the following day. On March 12 1919, following elections, the first national assembly repeated this declara-n. Charles, however, refused to abdicate in his own name and t of his dynasty. Thereupon the national assembly, by decree April 2 1919, banished all Habsburgs from Austria and con-cated the family property for the benefit of the War invalids. bsburgs who renounced all rights other than those of private izens were, however, allowed to live unmolested in Austria, d several of them did so. The legitimist movement in Austria s been very weak since these events. Vienna is almost fanati-lly republican, and even in the provinces, the monarchist move-nt in favour of the Wittelsbach dynasty has been quite as ong as the legitimist Habsburg movement. Austrian repub-ans claim that Charles's acceptance in advance of the republic is equivalent to a renunciation of the throne.

Charles and Hungary.—Charles issued a similar proclamation Hungary on Nov. 13 which Karolyi answered by proclaiming e Hungarian Republic on Nov. 16. When, however, the ight regained power in Hungary after Karolyi's and Kun's gimes, it proceeded by Act I. of 1920 to abolish all legislation ssed by these two Governments. Hungary, therefore, reverted the status of a kingdom, and controversy arose whether or not harles's action has annulled the pragmatic sanction, in which se the monarchy in Hungary, under her old constitution, was ective or not. "Legitimists" and "free electors" disagreed olently, the latter usually demanding the election of a Habs-rg but one whose person and wife should be more popular an those of Charles.

On Feb. 2 1920, during the discussions on the draft treaty of rianon, the Allied and Associated Powers declared that a absburg restoration in Hungary would be a matter of inter-national concern and that they would neither recognise nor lerate such a restoration. They attempted to insist on Hun-ary's styling herself a republic, but finally, in view of the bjections raised by the Hungarian delegation, compromised on he word "Hungary."

Charles returned to Hungary and attempted to assert his aim on March 27 and Oct. 20 1921 (*see* HUNGARY). On April 4 he Conference of Ambassadors insisted that Charles should ave Hungary. After the second coup, under pressure from he Powers and the Little Entente, the Hungarian Parliament assed a decree (Nov. 3 1921) whereby the sovereign rights of Charles and the pragmatic sanction were declared forever brogated and the right of the Hungarian nation to elect its king y free choice restored. On Nov. 10 Hungary addressed a note o the Powers consenting only to elect its king in agreement ith the Powers and accepting the notes of Feb. 2 and April 3 921. The Legitimist party, however, still looks on Otto as the egitimate king since Charles's death on April 1 1922. Otto and is mother share this view.

Habsburgs are scattered over Europe. Most reside in Hun-ary, Austria and at the Spanish Court. Their financial position various. They have lost all valuables and estates owned in virtue of their rank. Great controversy was aroused by the fact that Charles took with him, and sold, the crown jewels. Many of the family, however, as the Modena and d'Este branch, own vast private fortunes and great estates. The Hungarian branch was fortunate in this respect, as their wealth was not touched by the non-socialist Government. The Polish Govt. at first sequestrated Habsburg estates, but afterwards released them. Austria confiscated all estates, etc., that were not purely private property. The income of the senior branch of the family is small.

The Archdukes.—The remaining Habsburgs have not been prominent outside the realms of politics. The Archduke Frederick (b. 1856) became inspector-general to the Austro-Hungarian army after the murder of the Archduke Francis Ferdinand (*q.v.*) in June 1914. His command was only nominal, his chief of staff, Conrad von Hötzendorf, performing the real duties. In 1917 the Emperor Charles took his place. The Archduke Eugen (b. 1863) also held a high command, assisted by Gen. Krauss. The Archduke Joseph (b. 1872) resided in Hungary, where he enjoyed great popularity. During the World War he commanded a division, and later an Army Corps. At the debâcle he assumed a nationalist Hungarian attitude, recalled the Hungarian troops under his command from the front and acted as intermediary between the King and Karolyi's Government. While Karolyi still took the oath of loyalty to King Charles, Joseph had already repudiated the monarchy and his own title. He lived quietly on his own estate as "Joseph Habsburg" throughout the Commune; but after its fall, he assumed power on Aug. 6 1919 as administrator of Hungary. He was forced to retire on Aug. 22, as the Entente declared that they would not negotiate with Hungary under a Habsburg and were "obliged to insist upon the present pretender to supreme power in the Hungarian State resigning." After this time Joseph took little part in public life.

The Archduke Albert (b. 1897), son of Archduke Frederick supported by his wife, Isabella, became the chief candidate of the "free Electoral party" in Hungary, with whom he had close relations. The Archduke Stephen (b. 1860), whose estates were in Galicia, was put forward as a candidate by the Polish monarchist party. His son, the Archduke William (b. 1895), at one time aspired to the throne of the Ukraine. Although many archdukes, including Frederick and Francis Ferdinand, were known as collectors, the Habsburgs have not been prominent as creative artists. Archduke Leopold Wölfling wrote a book entitled *Habsburger unter sich.* (*See* AUSTRIA.) (C. A. M.)

HADFIELD, SIR ROBERT ABBOTT, (1850–), British metallurgist, was born in Sheffield Nov. 29 1859. Educated at Sheffield Collegiate School, at an early age he interested himself in metallurgy, subsequently becoming chairman of Hadfields, Ltd., Hecla and East Hecla Works, Sheffield, and director of other important companies. In 1883 he patented his process for the production of manganese steel (*see* 14.809) and became famous as the inventor and improver of various metallurgical processes, including low hysteresis steel and many other special ferrous alloys. He became a member of many scientific committees, and was president of the Iron and Steel Institute (1905–7), of the Faraday Society (1914–20), and of the Society of British Gas Industries (1917–8), besides being master cutler of Sheffield 1899–1900. In 1908 he was knighted; the following year became F.R.S., and was created a baronet in 1917. Sir Robert received many honours, including 10 gold medals, from scientific and learned societies; and became corresponding member of the French Academy of Sciences; hon. member of the Royal Swedish Academy of Sciences; and officer of the Legion of Honour. He published over 160 scientific and technical papers of considerable importance. His book *Metallurgy and Its Influence on Modern Progress* is a standard work of reference.

HADLEY, ARTHUR TWINING (1856–), American economist and educationalist (*see* 12.798), was elected a director of the New York, New Haven and Hartford Railway in 1913. In 1914 he lectured at the University of Oxford on "Institutions of the United States." In 1915 he endorsed college military camps and advocated the counting of military training for a degree.

In 1920 he resigned as president of Yale University and the same year was elected a director of the Atchison, Topeka and Santa Fé Railway. He wrote *The Moral Basis of Democracy* (1919) and *Economic Problems of Democracy* (1923).

HADLEY, HENRY KIMBALL (1871–), American composer, was born at Somerville, Mass., Dec. 20 1871. He studied theory and composition under Emory and Chadwick in Boston, completing his studies in Vienna. In 1904 he went to Germany, where he was Kapellmeister in Mainz Opera House for two seasons, and produced his opera *Sofie* in 1909. Returning to the United States in the same year, he was conductor of the Seattle Symphony Orchestra until 1911, and of the San Francisco Symphony Orchestra 1911–5. In 1921 he became associate conductor of the N. Y. Philharmonic Orchestra. He produced three grand operas: *Azora* (Chicago Opera Co.), *Bianca* (Society of American Singers) and *Cleopatra's Night* (Metropolitan Opera House). He composed also ode-music for the Worcester (Mass.) Festival (60th Anniversary) and *Resurgam* for the Cincinnati Festival, 1923, in addition to four symphonies, overtures and cantatas, three tone poems, ballet suites and over 150 songs. He was elected a member of the American Academy of Arts and Letters in 1924.

HADOW, SIR WILLIAM HENRY (1859–), British scholar and musician, was born at Ebrington, Glos., Dec. 27 1859. He was educated at Malvern and Worcester College, Oxford, and after taking his degree remained at Oxford as a tutor and fellow of his college. In 1909 he became principal of Armstrong College, Newcastle, retaining this post until 1919, when he became vice-chancellor of Sheffield University. He was in 1918 appointed assistant director of education for the troops by the War Office and also worked for the Y.M.C.A. He was knighted in 1918 and was made a C.B.E. in 1920. In 1922 he became Stevenson Lecturer to the University of Glasgow. Well known as a great authority on the history of music, Sir Henry Hadow also composed many songs and pianoforte pieces besides the incidental music to Robert Bridges' *Demeter* (1905).

He published *Studies in Modern Music* (1894 and 1895); *Sonata Form* (1896); *A Croatian Composer*, a valuable tract on Haydn (1897); the section "The Viennese Period" (1904) in *The Oxford History of Music*, of which he was the editor; *Citizenship* (1923); and *Music* (1924) in the Home University Library.

HAECKEL, ERNST HEINRICH (1834–1919), German biologist (*see* 12.803), died at Jena Aug. 8 1919.

HAFSTEIN, HANNES THÓRDUR (1861–1922), Icelandic statesman and poet, was born Dec. 4 1861. As a young man he became known as a lyrical poet. In 1901 he was elected a member of the Althing, and soon became a leader of the Home Rule party. It was chiefly owing to his influence that Denmark consented, in 1903, to the transfer of the residency of the Minister for Iceland from Copenhagen to Reykjavik. On Jan. 31 1904 Hafstein was appointed to this office and inaugurated a new era of practical reform. His first work was to arrange a telegraphic cable to Great Britain and a net of telegraphs and telephones all over the island. His efforts, however, were hampered by the extremists, who demanded greater political independence from Denmark. Their obduracy led to his resignation in 1908. On the victory of the Home Rulers in 1911, Hafstein again became Minister in 1912, but had to resign in 1914 after new and fruitless efforts to effect reconciliation. He lived, however, to see the full reconciliation between the two countries in 1918, and the recognition of Iceland as an independent state in union with Denmark. He died Dec. 13 1922.

HAGENBECK, CARL (1844–1913), German collector of wild animals (*see* 12.814), died at Hamburg April 14 1913.

HAGGARD, SIR HENRY RIDER (1856–1925), British novelist (*see* 12.816), was knighted in 1912. Among his later novels are *Child of Storm* (1913); *The Ivory Child* (1916); *Love Eternal* (1918); *The Ancient Allan* (1920); and *Heu-Heu: or the Monster* (1924). Much of his time, however, in his later years was devoted to matters affecting the welfare of the Empire. As a member of the Dominions Royal Commission he travelled round the world and, to further schemes for settling ex-service men on the land, he visited various parts of the Empire, writing a ... *port* to the Royal Colonial Institute. He also wrote *Rural D mark and its Lessons*, 1911. He died in London May 14 19

HAGUE, THE (*see* 12.817), with a population in 1923 328,581, continues to be a centre of diplomatic and internatio movements. In 1910 the tribunal of arbitration of the No Atlantic Fisheries met in the city, and in 1915 the Internatio Congress of Women. In 1917 an agreement was reached h by British and German representatives as to repatriation disabled prisoners, etc., and in 1920 a committee of the Leag of Nations Council met here to frame a scheme for the Permane Court of International Justice. (*q.v.*) In 1913 the Palace of Pea to which most countries of the world contributed gifts, was de cated. In 1922 the house, lent to the town, with his pictures a furniture, by Dr. Bredius, the art historian, was opened to t public; in 1924 a museum, chiefly for educational purposes, wi large Greek, Asiatic and Egyptian collections, was established.

HAIG, DOUGLAS HAIG, 1ST EARL (1861–), British soldie was born in Edinburgh June 19 1861, son of John Haig, Cameronbridge, Fife. He was educated at Clifton and Bras nose College, Oxford, and in 1885 joined the 7th Hussars. H was promoted captain in 1891, afterwards passed through t staff college and was employed with the Egyptian Army i 1898 during the Nile campaign, for which he was given a brev majority. On the outbreak of hostilities in South Africa in 189 he went out to Natal on the staff, and was present during th opening engagements near Ladysmith. He was afterwards chi staff officer of the cavalry division during Lord Roberts' vi torious advance from Cape Colony through the Orange Fre State into the Transvaal, and was promoted brevet lieutenant colonel for his services.

In the later phases of the struggle he was in command of column and later was controlling groups of columns; at the clos of the war he was appointed A.D.C. to the King, promoted bre vet-colonel, and given the C.B. Col. Haig subsequently com manded the 17th Lancers for a year, after which he went out t India as inspector-general of cavalry; this appointment he hel until 1906, having been promoted major-general in 1905, i which year he married the Hon. Dorothy Vivian, daughter o the 3rd Lord Vivian. From 1906–9 he was a director in the Wa Office, and during this time he was intimately concerned in th development of the general staff and the improvements effecte in the organisation of the army, which were set on foot whil Lord Haldane was Secretary of State. In 1907 he published volume of *Cavalry Studies*. His next appointment was that o chief of the general staff in India, which he held for three years being promoted lieutenant-general in 1910. In 1912 he wa brought home to take the command in Aldershot, and in 191 he was made a K.C.B.

On the mobilisation of the Expeditionary Force in 1914, Si Douglas Haig took the field as commander of the I. Army Corps which he led during the Mons, Marne and Aisne operations and the first battle of Ypres; he was promoted full general i Nov. for his services. On the division of the British Expedi tionary Force into two armies at the beginning of 1915, he wa placed at the head of the first. On the front of his army durin 1915 there took place the battles of Neuve Chapelle, Festube and Loos, and at the end of the year he succeeded Sir Joh French in the chief command. He had been made a G.C.B. i the autumn.

At this time the armies were passing through a period o transition. The regular army with the exception of its cavalry had almost ceased to exist and the first need was to weld it remnants, the new armies created by Lord Kitchener and th Territorial Army, into a whole capable of combined action bot in attack and in defence. This involved the creation behind th lines of a large number of schools of instruction in the use of th new weapons, which the requirements of trench warfare ha created, and of the old ones which had been brought back wit the service of war. Beyond and above this technical instructio came the training of the larger formations of all armies and fo this it was necessary that a certain number of divisions shoul

placed sufficiently far behind the line to allow them the ound and the opportunities for gaining experience.

This remained one of the chief items of Sir Douglas Haig's ilitary policy until a late period of the War. It was a policy hich often brought him into discussion both with the French enerals and with the French statesmen, who were continually essing him to take over a larger extent of front. Sir Douglas aig pointed out that it was not possible to compare a national my created during the course of the War with one which had en long established in time of peace, and that the Germans roughout the War maintained a greater density of men oppote the British lines than they did elsewhere. In the event, his olicy was justified by the fact that in the latter half of 1918 the itish Army, was as a whole, at least as efficient as any which as then fighting in the War.

The campaigns and battles of the British Army in France and elgium are dealt with elsewhere and it is here only necessary to fer to the principles which guided Sir Douglas Haig in certain f the crises of the War. The first of these during his command rose out of the German attack on Verdun during the first half f 1916. On that occasion he assisted the French by relieving eir troops in the front and by preparing for the battle of the omme. While that battle disclosed defects both of preparation nd of execution, its results convinced Sir Douglas Haig that it ad caused such exhaustion of the German armies as should be xploited at the earliest possible moment. He therefore agreed ith Joffre to renew the battle early in 1917.

But the battle of the Somme had caused grievous losses and he gains of ground as shown on the maps appeared trifling. herefore, neither French nor British statesmen were prepared o agree to a policy which to their minds seemed likely to exhaust heir resources before it caused the enemy to yield. The conequence of this was the replacement of Joffre by Nivelle and he assembly of an Allied Conference at Calais at the end of eb. 1917, at which it was decided to give Nivelle the general irection of the British Army, while he was at the same time to e in active command of the French Army. This arrangement, nilitarily unsound, early produced friction. For Nivelle, who as ill-informed of events on the British front, issued to Haig nstructions which were inappropriate both as to form and subtance. These differences were adjusted at a further conference n London, but they created the impression that Haig was pposed to any form of unity of command, which was not true.

The direct result of the failure of Nivelle's campaign was a wave of depression which spread through the French Armies nd resulted in serious mutinies. Pétain, who had succeeded Nivelle, appealed to Haig to keep the Germans occupied while e was restoring the morale of the French troops. To this ppeal Haig responded by opening in the summer of 1917 a ampaign in Flanders, which began with Plumer's victory at Messines and was followed by the battle of Passchendaele. It was only with difficulty that Haig won the consent of the British Govt. to this campaign. By the middle of Oct. of that year Pétain was able to tell Haig that the French Army was sufficiently restored to be able to look after itself; and it might have been wiser to have stopped the battle of Passchendaele then, as no adequate return was gained for the exhaustion caused by the prolongation of the attack in execrable weather.

The crisis brought about by the success of the German-Austrian attack on the Italians at Caporetto following on the collapse of Russia, resulted in the creation in Nov. 1917 of the Supreme War Council, the first meeting of which was held at the end of the following January. This meeting had been preceded by a renewal of French demands for an extension of the British front, which Haig eventually met by agreeing to take over a portion of the line at and south of Peronne with his V. Army. At this meeting a difference of policy between Haig and his Govt. was disclosed. The commander-in-chief anticipated an early attack by the Germans and asked for reinforcements: the Prime Minister wished for an offensive campaign in Palestine, and won his way; and at this same conference, it was decided to create an Allied general reserve on the Western Front under the control of the military representatives of the Supreme War Council with Foch as chairman. During Feb. 1918 Haig became more than ever convinced that a great German attack on his front was imminent, in which he differed from the military representatives, who did not expect it before May. When the military representatives applied to him for divisions for the general reserve, he answered that in view of the lack of reinforcements, the extension of his front and the massing of German troops, he would be unable to furnish these divisions, and the formation of the general reserve broke down.

With what calm determination Haig met the great German offensive of the spring of 1918 is described elsewhere. In the most critical days of that offensive it was Haig's direct intervention with the British Govt. which brought Lord Milner to France, a visit which resulted eventually in giving Foch direct control of the Allied Armies. With Foch Haig's relations were as harmonious as they had been with Joffre, and in the late summer of 1918 the British commander-in-chief reaped at last the reward of his patient policy. When in Aug. 1918 Rawlinson's IV. Army won the victory of Amiens, Foch desired that Rawlinson should follow up his success. Haig, convinced that this would result in another deadlock, and confident now in the superior morale and efficiency of his army, persuaded Foch to agree to an extension of the battle northwards, and so came about the breaking of the Hindenburg line which made it clear that victory could be won in 1918.

For his great services Sir Douglas Haig was raised to the peerage as Earl Haig and Baron Haig of Bemersyde and was given a grant of £100,000. The Order of Merit was also conferred upon him, and the ancestral home of the Haigs at Bemersyde was purchased by national subscription and presented to him. On returning home he was for a short time commander-in-chief in Great Britain, but when that position was abolished he refused other offers of employment and devoted himself wholly to the welfare of ex-service men. He succeeded in uniting other organisations with the British Legion, of which he became president. He also created and became president of the British Empire Services League, a union of the ex-service men's organisations of Great Britain and the Dominions; he was also appointed chairman of the United Services Fund, which together with the fund he established for the benefit of ex-service men forms one of the largest benevolent organisation in the country. (*See* LOOS; NEUVE CHAPELLE; SOMME and articles on other battles of the World War; also WESTERN FRONT.) See *Sir Douglas Haig's Despatches*, ed. J. H. Boraston (1920) (F. B. M.)

HAINISCH, MICHAEL (1858–), Austrian statesman, was born Aug. 15 1858, at Aue, near Gloggnitz, Lower Austria, the son of a manufacturer, and Marianne Hainisch, a pioneer of women's rights. After a short career in the Austrian public service, he devoted himself to the study of social and agricultural questions. He was founder with Engelbert Pernerstorfer of the Gesellschaft der Fabier on the model of the British Fabian Society. Hainisch, who was particularly active in the cause of popular education, founded and endowed many hundreds of popular libraries. His works include: *Die Zukunft der deutschen Oesterreicher* (1892); *Voraussetzungen und Berechtigung des Sozialismus* (1919); *Die Landflucht* (Jena, 1923). Hainisch was elected first President of the Austrian Republic in Dec. 1920 and re-elected unanimously for a further period of four years, Dec. 1924.

HAITI (*see* 12,824), a republic in the West Indies and a member of the League of Nations. Its area is 10,204 square miles. No reliable census of the population has been taken. Estimates vary from 1,500,000 to 2,500,000, the most reliable giving 2,028,000 in 1924.

I. POLITICAL HISTORY

The principal event in Haitian affairs in the period 1910–25 was the military intervention on the part of the United States, which developed into a close political and fiscal protectorate. The first part of the period was marked by constant revolutionary turmoil and by rapid political disintegration. In July 1911

President Simon was overthrown and on Aug. 14 1911 Cincinnatus Leconte became president. A year later (Aug. 8 1912) the presidential palace was blown up and Leconte and a number of his followers killed. The National Assembly at once elected Tancrede Auguste, a prominent planter; he died the year after, and on May 4 1913, Senator Michel Oreste was elected.

Intervention of the United States.—Dec. 1913 ushered in a period of political turbulence, and three military presidents assumed office in quick succession: Oreste Zamor, on Feb. 8 1914; Davilmar Theodore, on Nov. 7 1914; and Vilbrun Guillaume Sam, on March 4 1915. The last named, after withstanding the attacks of his opponents for several months, was compelled to seek refuge in the French legation in the night of July 26 1915, while 200 political prisoners in the gaol of Port-au-Prince were massacred by order of one of his followers. At the funeral of the victims a party of mourners invaded the French legation, dragged out the ex-president, handing him over to the mob for death, and killed the ex-gaoler. Two hours later a U.S. cruiser arrived at Port-au-Prince and landed marines. U.S. forces occupied the country, disarmed the natives and restored order. Although U.S. naval officers assumed charge of most administrative functions, the Haitian governmental organisation remained intact. On Aug. 12 1915 Sudre Dartiguenave was chosen by the Haitian Congress as president. A treaty having been accepted by the Haitian Govt. in 1916, the U.S. Senate advised ratification. Ratifications were exchanged at Washington and the treaty was proclaimed on May 3 1916.

Modelled upon the American-Domingo Convention of 1907 *(see* 24.194), this instrument was designed to secure political stability and economic development in Haitian affairs by a political and fiscal protectorate, to remain in force for a period of 20 years. By its terms the President of Haiti appointed, on the nomination of the President of the United States:—

(*a*) a receiver-general of customs to take charge of the customs houses;

(*b*) a financial adviser to be attached to the Ministry of Finance;

(*c*) American officers to organise and command a Haitian constabulary (gendarmerie) which was to replace the Haitian armed forces, such officers to be later succeeded by qualified Haitians;

(*d*) engineers and doctors to supervise the public works department and public health services respectively.

Haiti agreed not to increase the public debt and not to modify the customs duties without the consent of the United States; the United States undertook to intervene when necessary for the preservation of Haitian independence and the maintenance of a stable and effective government. The treaty provisions were promptly put into effect, and determined entirely the subsequent course of events.

In the early period of American intervention the division of authority caused friction, but with the appointment in 1922 by the President of a high commissioner to supervise and co-ordinate the activities of the treaty officials and the military occupation, native irritation and the friction between the American authorities and the Haitian Govt. disappeared. The U.S. marines were later withdrawn from all interior points and concentrated at Port-au-Prince and Cape Haitien. The maintenance of order was placed in the hands of the Haitian gendarmerie. This was composed of native troops, but the officers generally were officers and enlisted men of the U.S. Marine Corps.

The future of Haiti presented in 1921 the gravest problem of United States influence in the Caribbean (*q.v.*). Early termination of military occupation was, in the opinion of those in responsible charge, certain to result in reversion to old conditions. On the other hand, public sentiment in the United States did not view with satisfaction the definitive abandonment of the one great opportunity left the negro race to demonstrate, even after repeated trial, an ultimate capacity for self-government. Until 1921 the establishment of civil order had engaged the best energies of the American officials. With this accomplished, opportunity was afforded for rendering the further offices contemplated by the treaty in a way conducive to the ultimate assumption of civil authority by the Haitian Govt.; subject only to those reservations as to political stability and fiscal solvency in force in other areas within the range of American influence in the Caribbean.

Borno as President.—Louis Borno, who was elected on April 10, was inaugurated on May 15 1922 as president of the republic. He found civil order firmly established through an efficient native gendarmerie. Roads had been constructed and bandit eliminated, and the peasantry enjoyed, for the first time p haps in their country's history, complete freedom. Pub health services had been greatly improved under American supe vision, great progress being made in town sanitation. A vigoro policy of financial reform was adopted, with very satisfacto results. The public debt, which in 1915 amounted to $36,000,00 had been reduced to $22,046,252 at the close of the fiscal ye 1924–25. The budget had been balanced and a comfortal surplus realised by 1923–4, thus enabling the Govt. to spe substantial sums on public works and other development Borno was re-elected president in 1926.

II. ECONOMIC HISTORY

Production and Trade.—The chief crop is coffee, which represent in 1925 some 75% of the total income of the country. Other impo tant products are cotton and sugar. Great efforts are being made develop systematic cultivation, for even in 1925 coffee and cott grew semi-wild. An agricultural school had been established at Por au-Prince, experimental stations set up under American officials, system of premiums inaugurated to encourage coffee growers, a attempts made to improve the coffee and sugar crop and encoura the growth of other crops, such as cocoa, sisal, hemp and tobacc A modern sugar-cane mill and refinery were erected at Port-a Prince, as well as a smaller plant near Cape Haitien, and also cott ginning plants, etc. Means of communication and transport a being improved in order to open up the country and develop t agricultural, forest and mineral resources; in 1925 some 7,500 m. road were open to traffic, motor roads totalling about 650 m. linki up the chief towns. Only some 60 m. of railway line were in operati in 1925, but the lines were being extended. Banking is in the han of the National Bank of Haiti, a subsidiary of the National Ci Bank of New York, and the Royal Bank of Canada.

Foreign trade had greatly improved between 1915 and 192 The following table shows the value of imports and exports fro 1916 to 1924:—

	Imports	Exports
	$	$
1916–7	8,606,086	8,932,887
1917–8	10,180,693	7,743,530
1918–9	17,117,608	24,762,220
1919–20	27,398,411	21,620,928
1920–1	11,957,206	6,590,409
1921–2	12,350,271	10,712,210
1922–3	14,157,963	14,591,012
1923–4	14,696,128	14,176,332
1924–5	20,237,565	19,403,762

The chief articles of export in 1923–4 were coffee, valued a $10,361,776; raw cotton, $2,068,628; raw sugar, $620,412; logwoo and logwood extract, $440,670; cotton seed, $202,580; and cocoa $139,341. Exports to France were valued at $9,369,923; the Unite States, $1,329,251; Denmark, $847,118; the United Kingdom $722,699; Germany, $652,688; and Belgium, $509,375. Import were mainly from the United States, $11,817,376; the Unite Kingdom, $984,600; France, $885,228; and Germany, $447,99 Both imports and exports increased during 1924–5, when the tota trade approximated $40,000,000, with a small balance in favour o Haiti.

HALDANE, RICHARD BURDON HALDANE, 1ST VISCOUNT (1856–), British statesman, philosopher and lawyer (*see* 12.831). In 1910 he was appointed chairman of the royal commission on university education in London. To organise a university of the first order in, of, and for London, which should secure for science and scholarship, under wise conditions, the full use of the great resources, human and material, of the capital of the British Empire, was a task demanding constructive statesmanship in a high degree. The report of this commission (Cd. 6717) dated Dec. 1911 dealt faithfully and vigorously with the problems placed before it. Effect has not yet been given to its

commendations. Time may show that the university will and n reform itself from within. If, and when, the university sets self, or is set, in order, the counsels of this commission, which ar the impress of the chairman's mind, will form the basis of s new activities.

In March 1911 he was raised to the peerage and appointed a ember of the Judicial Committee of the Privy Council—that ost important tribunal which constitutional lawyers know to a practical bond of Empire. As a student of the principles hich underlie all systems of law, he found the cases brought efore the committee to be of absorbing interest, perhaps, most pecially, those from India, where the fundamental principles Hindu law are based on religious duty and philosophic con-pts, unfamiliar to the west.

In 1912, at the request of the Cabinet, he visited Berlin to iscuss disarmament proposals and on his return reported to the abinet information he gathered there as to the attitudes and onditions of those then guiding the policy of Germany. To be a nessenger of conciliation and co-operation between the two ations was a duty for which he was in every sense especially quipped, but he was, and soon knew he was, to be baulked by he conditions under which Germany was then ruled. Much arty capital was made out of this visit, both then and later uring the War. To have refused the opportunity was impos-ible. To have sent any other member of the Cabinet, would ave been infructuous. Something resulted from the mission, ut not all that he had hoped for. Lord Haldane accepted the hwarting of the full result he had looked for with characteristic ourage and dignified silence. In 1912 he succeeded Lord Lore-burn as Lord Chancellor and presided over the House of Lords vith dignity and efficiency.

When the War broke out in 1914, the great reorganisation of he War Office which he had effected was tested to the extreme. His labours were justified by their fruit. A new model had been created. There was a new spirit in the army. It had been set on the way of becoming a learned and scientific profession. It had been organised in accord with sound principles and its constituent elements had been brought into close relationship nd enabled to co-operate with and understand one another. By the creation of the Officers' Training Corps in 1909, the universi-ties and schools were able to contribute in the time of need exactly the type of officer required. The Militia had been replaced by a Special Reserve of real value as events showed. The Territorial Army had been created, and saved the situation more than once. The General Staff was brought into existence by the issue of a special army order, establishing it on the foot-ing it held during the War and after. To Lord Haldane, again, is due the decision of the Dominion Conference in 1907, accept-ing the principle of an Imperial General Staff, by which con-certed action and intelligent co-operation between armies drawn from all parts of the Empire was made possible. The experi-mental mating of Minerva with Mars had, indeed, been fruitful and felicitous.

Practical reasons and popular prejudice account for his absence from the first Coalition Ministry in 1915, when he received the Order of Merit. He was then free—as free as any patriot of his nature and temperament could be in such stressful days—to turn to philosophy. He published in 1921 *The Reign of Relativity*, a masterly presentment of profound, scientific and metaphysical thought, and in 1922, *The Philosophy of Human-ism*, an abiding memorial of the dictum *Das Geistige allein ist das Wirkliche*. When Einstein came to England to lecture, he was the guest of Lord Haldane, who presided over the gathering which heard the exposition of the theory of relativity from its discoverer. Always eager to promote national education, Lord Haldane devoted much time and energy to the Workers' Educa-tional Association, which owes much of its success to his support.

Lord Haldane was Lord Chancellor in the Labour Ministry of Mr. Ramsay MacDonald (1924), and working chairman of the Committee of Imperial Defence, where his experience, tact and indefatigable industry were invaluable, and, on the fall of the Labour Ministry, Mr. Baldwin invited him to continue his long association with it. The report of the Machinery of Govern-ment Committee (Cd. 9230, 1918), of which Lord Haldane was chairman, pointed out that "Further provision is needed in the sphere of civil government for the continuous organisation of knowledge and the prosecution of research in order to furnish a proper basis of policy." Accepting this declaration of principle, Mr. Baldwin established in 1925 the Committee of Civil Re-search, on which Lord Haldane has served as a member. Thus, through every department of State, in education, in university life, in the army, in the law and in industry are found the effects of his master mind, of his clear vision, of his resolute adherence to first principles and of his practical philosophy. Elected first Chancellor of Bristol University, he has been Lord Rector of Edinburgh, and has received many honorary degrees. His book, *Before the War*, gives an account of his political activities at that time.

HALE, GEORGE ELLERY (1868–), American astronomer, was born at Chicago, Ill., June 29 1868. He studied at the Harvard College Observatory and the Massachusetts Institute of Technology, graduating in 1890. He was director of the Kenwood Astrophysical Observatory, in Chicago, from 1890 to 1896. From 1892 to 1905 he was at the University of Chicago as associate professor of astrophysics, professor, from 1897, and director of the Yerkes Observatory, after 1895. In 1904 he became director of the Mount Wilson Solar Observatory (Cal.) of the Carnegie Institution of Washington, a position which he held till 1923, when he became honorary director in charge of policy and development. He invented the spectroheliograph first used in 1892 for photographing solar prominences, and won an international reputation for his solar and stellar spectroscopic work. He was awarded the Janssen Medal by the Paris Academy of Sciences in 1894, the Rumford Medal by the American Acad-emy in 1902, the Draper Medal in 1903, a gold medal by the Royal Astronomical Society in 1904, the Bruce Medal by the Astronomical Society of the Pacific in 1916, and the Janssen Medal by the Astronomical Society of France in 1917. He was the author of *The Study of Stellar Evolution* (1908) and *Ten Years' Work of a Mountain Observatory* (1915), besides numerous papers in scientific publications.

HALIFAX, Nova Scotia (*see* 12.843).—The population of the city in 1921 was 58,372. The public buildings and many of the houses built of stone show a considerable taste in architecture. Much of this stone was brought from the dismantled homes and fortifications of Louisburg. About one-tenth of the city area was devastated by the explosion on Dec. 6 1917, of a French steamer carrying 3,000 tons of T.N.T., on colliding with a Norwegian steamer on its way with a relief cargo for Belgium. The recon-struction of a Greater Halifax has been carried out on modern lines of town planning.

The harbour is accessible all the year round to the largest vessels. New docks and railway stations, in course of construc-tion, will give it an area of over 200 ac. and make it one of the best equipped ports in the world. Grain elevators and conveyor systems will meet the needs of expanding commerce. Halifax claims to have the lowest port charges on the Atlantic coast. There are a number of manufacturing industries, including the largest sugar refinery in Canada, and the city is also an important distributing centre. Halifax is the chief winter port of Canada and the Atlantic terminus of the Canadian National Railways. It has a naval dockyard and training school.

HALL, GRANVILLE STANLEY (1846–1924), American psy-chologist and educationalist, was born at Ashfield, Mass., Feb. 1 1846. He graduated from Williams College in 1867 and took the degree of Ph.D. at Harvard in 1878. After holding the chair in psychology at Antioch College, 1872–6, he pursued further studies at Berlin, Bonn, Heidelberg and Leipzig. He was pro-fessor of psychology in Johns Hopkins University, 1881–8, and was then elected the first president and made professor of psy-chology of the newly formed Clark University, Worcester, Mass. which, under Hall's personal leadership, was devoted, during its first two decades, chiefly to educational research. He became widely known as an exponent of the culture-epoch theory of

mental development, a doctrine set forth in his most influential work, *Adolescence*, 2 vol. (1904). During the later years of his presidency his influence perceptibly diminished, this being partly due to the lack of scientific method in his work. He resigned in 1920 and died April 24 1924.

Hall's numerous published works include: *Educational Problems* (2 vol., 1911), *Founders of Modern Psychology* (1912), *Senescence* (1922), and *Life and Confessions of a Psychologist* (1923).

HALLE, WILMA MARIA FRANCISCA, LADY (1839–1911), Anglo-German musician (*see* 12.853), died in Berlin April 15 1911.

HALSBURY, HARDINGE STANLEY GIFFARD, 1ST EARL OF (1823–1921), British lawyer and politician (*see* 12.867), died in London Dec. 11 1921. The year of his birth, earlier given as 1825, was subsequently found to have been wrongly stated. The records of Merton College, Oxford, show him to have been born on Sept. 3 1823.

HAMBURG, Germany (*see* 12.871), with a population in 1922 of 1,025,502, is the second city of Germany. Its commerce, industry and shipping had been increasing up to the outbreak of the World War, which sharply arrested its development, but after the Armistice it began to recover. In 1923 the port was entered by 13,192 seagoing vessels of 15,344,990 tons, as compared with 16,427 of 14,185,496 tons in 1913. Traffic at the end of 1925 was about 90% of the pre-War figure. The proportion of shipping flying the German flag was only half what it had been, and emigrant and tourist traffic much less. The Hamburg-Amerika line, which had made great strides before the War, had 89 steamers of 386,000 tons in 1924. Since 1910 new docks have been built on Waltershof Is., forming a second free port, and large shipyards were laid down at Finkenwerder in 1918. New buildings include the Trade Corporation House (1912–6) in Neustadt, the Museum of Hamburg Antiquities (1914–20) and two ten-storyed office buildings of vitreous brick on the Messberg. The Exchange was rebuilt in 1908–12, and the Institute for Tropical Diseases in 1914. Great S. Michael's Church, burnt down in 1906, has been re-erected on the old lines and the Kunsthalle, to the east of the Binnen-Alster, has been much enlarged. The tunnel under the Elbe from the St. Pauli district to Steinwärder, which is entered by lifts, was finished in 1911; but a two-storyed bridge over the river, begun in 1914, was still unfinished in 1925.

The university, founded in 1918, with a democratic constitution, is in Rotherbaum, to the north of the city, in a building originally designed as a lecture hall. Near it is a statue of Hermann von Wissman, the explorer, which was erected at Dar-es-Salaam and removed here in 1922. Space in Ohlsdorf cemetery for 700 graves of men who died in the district during the World War has been acquired by the British Government. A memorial commemorating the seamen of Hamburg who died as prisoners of war in America was unveiled in 1920.

In 1917 a commission was appointed to bring about a reform of the class franchise which had hitherto existed in the Hanseatic cities, and a measure of electoral reform was adopted. The city and territory had nevertheless as severe an experience of the revolutionary movement as any region of Germany. The Council of Workmen and Soldiers assumed complete political power in Nov. 1918. The region of Cuxhaven belonging to Hamburg declared its independence in Jan. 1919 under Communist leadership, but the republic only lasted four days. In Jan. and Feb. 1919 Communist disturbances broke out in the city itself. The new constitution adopted in 1920, reduced the authority of the senate, and the power which it formerly wielded is now in the hands of the Bürgerschaft (representative assembly), which consists of 160 members elected on the system of proportional representation.

HAMBURG, UNIVERSITY OF.—By a process of natural development the University of Hamburg was formed in 1919 from the material of the Colonial Institute, and consists of the faculties of law, medicine, philosophy and natural science. Special facilities exist for study of the history and culture of the Orient generally, of India, China, Japan, Africa and the South Seas. Anthropology, folklore and missionary problems among the many notable features of the courses—especially summer course, which attracts a large number of students.

HAMILTON, SIR IAN STANDISH MONTEITH (1853– British soldier, was born at Corfu Jan. 16 1853. Educated Wellington College and in Germany, he joined the army 1872. He served with the 92nd Highlanders in the Afghan W and the Boer War of 1881, and was severely wounded on Maju Hill, one arm being permanently disabled. He was then several years intermittently on the staff of Sir F. (Lord) Rober He served in the Nile Expedition of 1884–5, in Burma in 1886- and on the staff of the Chitral Relief Force in 1895. He co manded a brigade on the North-West Frontier in 1897, and aft wards the School of Musketry, Hythe. In the South Afric War he commanded a mounted infantry division during t advance from Bloemfontein to Pretoria and into the easte Transvaal. He returned home early in 1901 to become milita secretary at the War Office, but towards the end of the ye went back to South Africa nominally as chief of the staff Lord Kitchener, although in reality he was employed chiefly the commander-in-chief's deputy to control particular grou of operations from time to time during the closing stages of t struggle.

He was afterwards again military secretary and then quarte master-general at the War Office, and in 1904 he went out to t Far East to accompany the Japanese armies in the field. H impressions under the title *A Staff Officer's Scrap Book* (2 vo 1906–7), by reason of the interest of its subject, the charm the author's style, and the combination of war experience and imagination which inspired his judgments and criticisms, at on took rank in Europe as a modern military classic. His litera ability, though a token of unusual imagination and clearness thought, rather prejudiced him throughout his career in the ey of old-fashioned soldiers. On his return he had charge of t Southern Command until 1909, and was afterwards adjutan general at the War Office for a year. He took a prominent pa on behalf of the voluntary service system during the campaig in favour of compulsory service led by Lord Roberts, and in t course of this controversy he published a book *Compulso Service* (1910), which he wrote at the request of Lord Haldan In 1910 he was appointed commander-in-chief in the Med terranean and inspector-general of the Overseas Forces.

On the outbreak of the World War in 1914 Hamilton serve for some months as commander-in-chief of the Home Defen Army in England. Then in March 1915, he was selected to tak charge of the Mediterranean Expeditionary Force (*see* DAR DANELLES CAMPAIGN). The naval effort to force the Dardanelle having failed, he found himself obliged to undertake operation in the Gallipoli Peninsula, and although his army was very ill equipped for the task, he succeeded in landing it in the face of th enemy, but was brought to a standstill. Having, after consider able delay, received substantial reinforcements, he made a grea effort in Aug. to improve his position, but partly through th inertia of some of the local commanders, sent out without con sulting him, the operations miscarried, and a situation of stal mate arose. The Government consulted him in Oct. as to th expediency and feasibility of withdrawing from the peninsula and on his pronouncing himself strongly opposed to such policy he was replaced by Sir C. Monro and returned home In 1920, after the issue of the *Report* of the Dardanelles Com mission, he published his own story of the campaign under th the title of *Gallipoli Diary* (2 vol., 1920), and in 1921 *The Sou and Body of an Army*. For this *Encyclopædia* Sir Ian wrote brilliant article on WAR. (B. H. L. H.)

HAMILTON, Ontario (*see* 12.891), had in 1921 a population o 114,351. It was estimated (1924) at 120,235. Hamilton's geo graphical position gives it excellent shipping facilities on the Great Lakes. The city is on the Canadian Pacific and Canadian National Railways and is connected with several lines of the United States. It is the centre of a system of city and suburban lines, and the municipal supply of electric power is cheap and prac tically unlimited. Hamilton has about 700 factories, including

.e largest plough works and implement works in the British mpire. Besides its Anglican and Roman Catholic cathedrals, .e city has 89 churches, 50 banks, 45 schools (public, private id technical), five hospitals and three public libraries.

HAMMARSKJÖLD, HJALMAR (1862–), Swedish statesan, was born at Tuna Feb. 4 1862 and educated at the Uniersity of Upsala, where in 1891 he was appointed professor . civil law. After establishing his reputation as a jurist, he ayed an important part in national politics and became Minter of Justice in the Van Otter Cabinet, holding this post from)01–2 when he was appointed president of the Göta high court. 1 1905 he was Minister of Education in the Lundeburg Cabinet id also a delegate to the conference with Norway at Karlstad the time of the dissolution of the union. He was Swedish Minter in Copenhagen from 1905–7 when he became governor andshörding) of the province (län) of Upsala. He had been wedish delegate at the Hague conferences in regard to private ternational law in 1900 and 1904, and from 1904 was Swedish ember of the Hague International Board of Arbitration. In)07 he was Sweden's leading delegate to the Hague Peace Conrence and in 1909 acted as president of the Franco-German oard of arbitration in regard to the Casablanca affair. He prided in 1913 over the Franco-Italian arbitration court regarding ie seizure of vessels during the Tripoli War. In Feb. 1914 he ucceeded Staaff as Prime Minister, retaining this post during ie World War until 1917 (*see* SWEDEN). Hammarskjöld became member of the Institut de Droit International and a curator f the Académie de Droit International at The Hague. In Dec. 924 he was appointed by the Council of the League of Nations hairman of the commission relating to the codification of interational law.

HAMMERSTEIN, OSCAR (1847–1919), American musical irector, was born in Berlin. He went to the United States in 863, where he made money as an inventor of cigar manufacuring machinery. In 1870 he became lessee and manager of a owery theatre and after 1880 built and operated the Harlem)pera House, the Olympic, the Victoria and other theatres. In 906 he built the Manhattan Opera House, in avowed rivalry vith the Metropolitan Opera House. In the operas which he roduced there he broke away from the classics and presented he works of modern composers, for example Massenet's *Thäis*,)ebussy's *Pelléas et Mélisande* and Charpentier's *Louise*. He ecured artists such as Melba, Tetrazzini, Bonci and Renaud vith Campanini as conductor and artistic director. In 1911, owever, he was compelled to sell his concern to the Metropoltan Opera Company, agreeing to abstain from producing grand)pera for 10 years within the latter's territory. He then went o London and built the London Opera House, but here again he ailed to make a commercial success of the undertaking. Returning to New York in 1912 he built another theatre for the purpose of entering his former field of grand opera, but the Metropolitan Opera Company secured an injunction prohibiting him from so doing. He opened his new house under the name of the Lexington Theatre in 1914, with the usual form of theatrical programme. He died in New York City Aug. 1 1919.

HAMMOND, JOHN HAYS (1855–), American mining engineer, was born in San Francisco March 31 1855. He studied at the Sheffield Scientific School, Yale University (Ph.B., 1876), afterwards taking a course at the Royal School of Mines, Freiburg, Saxony. In 1880 he was engaged in the U.S. Geological Survey of the California gold fields, afterwards practising as consulting engineer, in which capacity he visited most of the countries of North and South America. In 1893 he became associated with Barnato Bros. and Cecil Rhodes in South Africa, acting as consulting engineer for the Consolidated Gold Fields Co. of South Africa, the British South Africa Co., and the Randfontein Estates Gold Mining Company. As one of the leaders of the Rand faction, he was, in Jan. 1896, after the Jameson Raid, arrested and condemned to death, but the sentence was commuted, and later he was released on payment of a $125,000 fine. In 1900 he returned to the United States and became largely interested in mining properties and irrigation projects both in the United States and Mexico. He was president of the Panama Pacific Exposition Commission to Europe, 1912; chairman of the World Court Commission, 1914–5; and chairman of the U.S. Coal Commission 1922–3. He became general manager and consulting engineer of the Guggenheim Exploration Company.

His son, JOHN HAYS HAMMOND, JR. (1888–), American inventor, was born in San Francisco April 13 1888. He studied at the Sheffield Scientific School, Yale University (B.S., 1910). Devoting himself to electrical developments and experiment, he invented a torpedo for coast defence controlled by wireless energy, a system of radio control of ships and a system of selective radio telegraphy; also various electrical devices the use of which for military purposes was secured by the U.S. Government.

HAMSUN, KNUT (1859–), Norwegian author, was born Aug. 4 1859 at Lom in the Gudbrandsdal Valley, the son of poor parents. He started to write at the age of 19 when he was a shoemaker's apprentice at Bodö in North Norway, and for the next 10 years earned his livelihood in various ways such as coal trimmer and country schoolmaster. He eventually went to America, where he became a tram conductor in Chicago and a farm labourer on the prairies. In 1888 he published, in a Danish magazine, the fragment of a novel, *Sult*, which was later translated into English, as *Hunger*. This work at once attracted attention by the beauty of style and originality of treatment. His works from this time onward revealed a richness of talent which rapidly increased his reputation. He is akin to the Russians in his psychological analysis of morbid types, but the American influence is apparent in his use of startling metaphors and the aptness of his expressions. An intense love of nature also characterises his work. He is chiefly known to the English-speaking world by his three novels, *Hunger*, *Growth of the Soil* and *The Woman at the Well*. In 1920 Hamsun was awarded the Nobel Prize for literature.

HANDICRAFTS, ARTISTIC (*see* ARTS AND CRAFTS, 2.700).—The revival of interest in and the practice of the artistic handicrafts which was organised in the early 'eighties in England by Morris, Crane, W. A. S. Benson, W. R. Lethaby and their associates exercised an influence which soon extended to other European countries, the United States and Canada. Although it must be admitted that the dream of its founders has not been and cannot be realised, that influence is not dead. The quality of production may and must vary from time to time with the varying skill of the worker; but a standard of excellence has now been promulgated which is—if not yet equal to the hopes of the pioneers of the movement—at least well advanced in that direction.

The arts and crafts movement was, and is, a protest against machine-made goods and commercialism, and though these, in the nature of things, must continue, definite results have been achieved. The influence of the movement upon the trade side of art-industry has been undeniable. The machine-made article cannot—or, at all events, does not yet—equal in technical execution the hand-made article. But in colour, in pattern, in form, one has only to compare the shop-window display of the period since 1910 with that of the earlier period, to see how great has been the advance of taste. And there has never been so great a demand for books, magazines and the written word generally relating to the arts, as there is at present; in itself a fairly convincing evidence of the growth of interest in the subject on the part of the public.

1. HANDICRAFTS IN GREAT BRITAIN

An effort is being made, in Great Britain, by various societies and with some support from the Govt., in the direction of a general revival of village handicrafts. It is too soon to measure its success; but the movement is worthy of record.

Furniture.—While it is true that the most important of the industrial arts, the making of furniture, is suffering to some extent from a fashion for 18th-century reproductions, steady progress is being made towards what may turn out to be a veritable 20th-century style, of which the distinctive features appear to be simple construction based on good joinery rather

than on cabinet-making. The use of woods selected for their natural beauty and undefiled with polish or stain is another characteristic. Ornament is scantily applied and with increasing attention to utility and comfort; and the general tendency is towards rather substantial and even massive forms, although work on more delicate lines is not wanting. Undoubtedly the most distinguished figure in these, and in other, branches of craftsmanship was Ernest Gimson, whose style seems to be well on its way to becoming a tradition. But distinguished work in England has also been done by E. A. and S. H. Barnsley, P. Waals, A. Romney Green, S. Gordon Russell, C. A. Richter and Ambrose Heal. The wood carving of G. Jack and Lawrence Turner and the carved wood puppets and other figures by William Simmonds are especially notable. Continental furniture follows much the same principles, with perhaps more reliance on mass than on line; as for instance in the work of Louis Sognot of Paris, Hans Hloucat of Vienna and the productions of the Deutsche Werkstätten, Munich.

Silversmiths' Work.—In silversmiths' work, progress has hardly been maintained so far as regards a demand on the part of the public for really fine personal craftsmanship, although, again, the design characteristic of the revival is being reflected to some extent in commercial products. Most of those who are concerned with presentation plate still seem afraid to entrust their commissions to artists whose names and individuality would enhance values. For church purposes, however, admirable work has been done, especially as altar furniture, pastoral staves, etc., by Alwyn Carr, Henry Wilson, Omar Ramsden, Edward Spencer and others; and the series of episcopal and other seals engraved by Cecil Thomas would come into this category. A search for variety has revived, in new form, a combination of shagreen with silver or copper, worked with considerable success by Paul Cooper. Modern jewellery, with its distinctive use of stones *en cabochon* rather than cut, has perhaps kept its small place, but has not affected the more popular taste to any appreciable extent, and of enamels it can only be said that the art has lost rather than gained ground. The silversmiths' work of the Scandinavian group shows promise and originality, and French artists still display extraordinary technical skill and ingenuity; but for obvious reasons there is little new movement to record.

Textiles.—Textile fabrics generally show a tendency towards simple and effective colouring, side by side with a revival of the brocade and chintz patterns of the 18th century, and a still powerful oriental influence. Patterns directly based on flower and plant form have no longer the vogue of the earlier years of the century; though the renaissance of good needlework, due very largely to the efforts of Miss May Morris and Mrs. A. H. Christie, as well as to the effective work done by the Dept. of Textiles of the Victoria and Albert Museum under Mr. A. F. Kendrick, seems to be firmly established in Great Britain. On the Continent, peasant design has influenced pattern, and a definite revival of tapestry in Sweden is to be noted. In this class reference must be made to the effect of the costume designs of Léon Bakst originating a new movement which has spread far beyond its original purpose. Design in carpets and rugs, so far as it exists at all, appears to be almost entirely subservient to Persian and Near Eastern motives; apart from these, however, public taste seems to prefer unpatterned colours to an increasing extent.

Glass.—Much more attention has recently been given to original design in glass-ware on the continent of Europe than in Great Britain; and while there is perhaps too strained an effort in this direction, it cannot be denied that a fair amount of good work is being done. That of Marinot of Paris is decidedly in this class, for it keeps well within reasonable limits in appropriate treatment of the material and yet achieves a novel and highly decorative effect. Some excellent glass for table use is being made in Sweden and Denmark; and the more highly elaborated designs of E. J. Margold of Darmstadt and of the cut-class made under the direction of Prof. G. Beckert of Czechoslovakia are enterprising in pattern and by no means without interest. If in this department Great Britain is behind, in stained glass she l made distinct progress. A Gothic tradition is, in this instan almost essential; but its treatment of subject can be, and sufficiently modern for all practical purposes. The designs Christopher Whall, P. Woodroffe, G. Kruger Gray, G. Parl and others have continued and developed the new life instill in this art by William Morris and Sir P. Burne-Jones.

(E. F.-S.)

II. HANDICRAFTS IN THE UNITED STATES

In the first quarter of the 20th century the artistic han crafts, or arts and crafts, have made substantial progress in t United States of America. When the revival began with t Boston Exhibition in 1897, the standards were not particula high and the amount of work being done throughout the count was insignificant. The Boston Society of Arts and Crafts w organised in this year and has maintained its leadership in t movement ever since. Its annual sales have increased fr $4,000 in 1901 to over $200,000 in 1925.

The arts and crafts were taken up with fervour and a lar number of societies were soon organised. The result was th with the showing at the St. Louis Exposition in 1904 and at t Boston Exhibition in 1907, fairly good standards were establish in all branches of craft work. It must be admitted that craftsm who were foreign-born and trained contributed largely to th rapid advance. While some of the initial enthusiasm died dov after a few years, there has been a decided renewal of intere since the World War. Distinguished work is now being don which has had considerable influence on commercial work a in the improvement of popular taste.

Probably the most important advance has been made in th field of stained glass, in which it may be said that an outstandi American style has been established, notable for its decorati character and its emotional quality of colour. While it ve definitely carries on the traditions of the early stained glass, is already adding traditions of its own. The fact that the in portation of fine stained glass from Europe has dropped off at lea 75% in the last ten years, although there has been an unprec dented number of fine churches built, is due to the work of suc men as Charles J. Connick, Nicola D'Ascenzo, Henry Wyn Young, J. Gordon Guthrie, Lawrence Saint and Joseph C Reynolds.

In metal work, there has been the greates advance in ironwor and jewellery. Samuel Yellin is doing some masterly work i iron, as well as Frank L. Koralewsky, Morgan Colt and Mis Marie Zimmerman. In quality of design and technique, hig standards have been reached by such jeweller-craftsmen a Frank Gardner Hale, Edward E. Oakes, Herbert Kelley, Mis Margaret Rogers, Mrs. Josephine H. Shaw, Mrs. Eda Lord Dixo and Horace E. Potter. The early American silversmiths carrie their art to a high point of perfection, and those of the presen generation have been content to follow along the Colonial line without attempting much originality or change. American silve is characterised by good lines and plain surfaces, with les decoration than is usual in Europe. The marked increase in th demand for handwrought silver is due to the notable work o Arthur J. Stone, George C. Gebelein, James T. Woolley, Georg E. Germer (who has done some fine ecclesiastical pieces), Dougla Donaldson, George J. Hunt, Porter Blanchard, Karl F. Leinonen John P. Petterson and F. J. R. Gyllenberg. A growing demand for pewter is recently apparent, stimulated by the work of Leste H. Vaughan.

The leading American woodcarver is undoubtedly I. Kirch mayer, who has developed a style of his own which he call American Gothic, characterised by the introduction of architectural motives in the drapery, but more especially by strength o character, reverence and a mastership of all the best traditions. In furniture, as in silver, there has been a harking back t Colonial times, and the standards of public taste have been raised enormously through the great vogue of antique pieces and good modern reproductions. No new styles have been developed.

In textiles the advances have been largely in batik and block

rinting. The names of Miss Lydia Bush-Brown, Miss Helen)ryden, Charles S. Todd, Jean Paul Slusser, Arthur Crisp, Miss Cell Witters, Gilbert Fletcher and Mrs. Marion Maecklein Woodbridge stand out prominently. Weaving has been restricted rgely to Colonial models.

Creditable work is being done in pottery. The porcelains of Irs. Adelaide A. Robineau and the tiles of Henry C. Mercer and Irs. Mary Perry Stratton have a high reputation. Other master otters are Charles F. Binns, Arthur E. Baggs, Edmund de '. Curtis, H. Varnum Poor and R. Guy Cowan.

Some excellent illumination has been done by Sister Olive rances, Sister Magdalen, Miss Winifred M. Crawford and Mrs. ertrude S. Bassett. The demand for hand bookbinding must lways be limited, but good work was done by Miss Mary Crease ears, Mrs. Averill Cole Howland, John F. Grabau and Miss leanor I. van Sweringen. In the field of fine printing and ypography it is generally conceded that such men as Bruce ogers, D. Berkeley Updike, and T. M. Cleland are among the eaders. The demand for good commercial printing and binding as stimulated many of the leading publishers to put out books f really artistic merit. American craftwork is holding its own ith that of Europe and, in comparison, its dominant characeristics seem to be its conservatism and restraint.

(H. P. M.)

HANGAR: *see* AERODROME.

HANIHARA, MASANAO (1876–), Japanese statesman, as born in Yamanashi-Ken. He graduated from Waseda Uniersity, Tōkyō, in 1897 and entered the diplomatic service. In 899 he went to the legation at Seoul (Korea), as attaché, being ransferred to Washington in the same capacity in 1901. After year of service there, he was made secretary, invited specially o study American affairs, and later became chief secretary for oreign affairs. He felt that American-Japanese relations were nsatisfactory and wished to impress upon the citizens of the nited States the necessity for friendly co-operation with the apanese. He was sent to San Francisco as consul-general in 916, remaining until the end of 1917. Returning to Tōkyō he irst became director of political affairs and then, in 1919, Vice-Minister for Foreign Affairs. As vice-minister he was one of the our delegates to the Washington Conference 1921–2. In 1923 e was appointed Japanese Ambassador to Washington, and it s maintained in America that his reference, in a public speech, to the " regrettable consequences which would follow the passage " f the Immigration bill, was responsible for the bill becoming aw. The Japanese Govt., realising that some blunder had been made, recalled Hanihara in 1924.

HANKOW, China (*see* 12.919).—A great commercial entrepôt is provided for China by the three large cities, Hankow, Hanyan and Wuchang, at the point where the Han flows into the Yangtze Kiang. The population was given in 1923 as 1,646,800. In summer the surrounding country is flooded, and vessels drawing 29 ft. can get up to Hankow, but during the winter the port is accessible only to vessels drawing 12 ft., even at favourable periods, and as the water falls hulks are moved out from the banks, with which they are connected by staging. In 1921, however, a river commission was formed, and the work of levelling the river bed from Hankow downstream was begun. The advisability of flood prevention works is also being investigated. Hankow, owing to its strategical importance, suffered considerably during the Revolution of 1911, and in Nov. two-thirds of the city was destroyed by fire, as a result of bombardment by the Imperialists. By 1914 80% of the area was again covered with houses on the old pattern. Several new roads, however, have since been laid out to the rear of the native city on reclaimed land, and a scheme for housing large numbers of the poorer classes on new areas, to relieve the housing problem, has been promulgated.

The industrial development of the district, increasingly active after the World War, is reflected in the building of a number of factories and workshops, and foreign interests are largely increased. The British Bund has become the banking and commercial centre, and a number of imposing banks and offices have been erected, including a customs house, a large Chinese hospital in European style in the native quarter, and a church in the French Concession. The British Concession has been enlarged, and the concessions, each with its own municipal council, now extend for over 2 m. along the river. Those of the Germans and Russians have been taken over by the Chinese authorities. The water supply of the city is good, and there have been no recent outbreaks of cholera. After the World War trade expanded steadily, though the black tea trade, Hankow's staple industry in former days, has declined, largely because of the elimination of the Russian market. The interruptions to communications and the constant impositions which have resulted from the internal troubles of China, as also the increased competition since the re-entry of German traders, have greatly troubled exporters.

HANN, JULIUS (1830–1921), Austrian meteorologist and climatologist, was born near Linz, Upper Austria, March 23 1830. In 1865 he became editor of the *Zeitschrift der Oesterreichischen Gesellschaft für Meteorologie*, and from 1877 was occupied in the Central Meteorological Institute at Vienna. In 1873 he was appointed professor of physics at the University of Vienna. He acquired a world-wide reputation for his works on atmospheric dynamics and thermodynamics, the " atmospheric pulse," cyclones and climatology. His principal works are *Die Erde als Ganzes; Die Atmosphäre und Hydrosphäre* (1872); *Handbuch der Klimatologie*, 3 v. (1908); *Lehrbuch der Meteorologie*, 3d ed. (1914) and many papers in his own *Zeitschrift* and the reports of the Akademie der Wissenschaften. He died in Vienna Oct. 1 1921.

HANUSCH, FERDINAND (1866–1923), Austrian politician, was born Nov. 9 1866 in Oberndorf, Silesia, the son of a poor Silesian weaver. After a childhood of crushing poverty, Hanusch became in 1900 secretary of the Austrian Textile Workers' Union. In 1907 he entered Parliament as a deputy. He was a pioneer of the Austrian trade union movement, especially in his own branch of industry, and did much to improve conditions for this class of labour, which were abnormally bad. In Oct. 1918 he became secretary of state in the new ministry of social welfare, and was author of most of the social legislation of the period, including the eight-hour day, the Works Councils Act, the law compelling employers of 14 hands or more to increase their staffs by 20% in order to reduce unemployment, and the laws dealing with the unemployment dole. He was universally respected for his personal probity and first-hand knowledge of labour problems and conditions. He died Sept. 28 1923.

HARA, TAKASHI (1856–1921), Japanese politician, was born at Morioka. After studying law and practising journalism he entered the diplomatic service, and was *chargé d'affaires* in Paris in 1886. In 1892 he was appointed director of the commercial bureau at the Foreign Office, and in 1895 became Vice-Minister of the department. He acted as minister to Korea from 1896–7, when he became chief editor of the Osaka *Mainichi*. Still deeply interested in politics he became the leading spirit of the Seiyu-Kai (Liberal) party. From the end of 1900 to May 1901 he was Minister of Communications in the Ito Ministry. He then reverted to journalism, and became chief editor of the Osaka *Shimpo*, and was elected a member of the House of Representatives for Morioka in 1902. Definitely abandoning journalism he was appointed Minister for Home Affairs in the first Saionzi Ministry of 1906, in the second Saionzi Ministry of 1911 and in the Yamamoto Ministry of 1913. On Sept. 29 1918 Mr. Hara, as the first commoner to become Prime Minister of Japan, formed a Cabinet based, for the first time in the history of Japanese politics, on strictly parliamentary principles. He was assassinated by a demented youth in Tōkyō on Nov. 4 1921.

HARBORD, JAMES GUTHRIE (1866–), American soldier, was born at Bloomington, Ill., March 21 1866. He graduated from the Kansas state agricultural college, Manhattan, Kan., taking the degree of B.S. in 1886. He joined the 4th Infantry in 1889 and was commissioned in the cavalry in 1891. Serving in the 5th, 11th, 10th and 1st Cavalry, he became a major in 1914. From 1903 to 1914 he served in the Philippine Constabulary. He became brigadier-general in 1917, and was chief of staff of the American Expeditionary Force in France 1917–8. He com-

manded the Marine Brigade near Château-Thierry, June 1918, being appointed major-general on June 26. He commanded the 2nd Div. A.E.F. in the Soissons offensive under Mangin, July 1918, after which he was placed in command of Service of Supply. He was reappointed chief of staff A.E.F., May 26 1919, and was head of the American military mission to Armenia, Aug. 1919. He served as deputy chief of staff, U.S. Army, 1921–2. Retiring from the army Dec. 29 1922, he became president of the Radio Corporation of America.

HARCOURT, LEWIS VERNON HARCOURT, 1ST VISCOUNT (1863–1922), British politician, was born in London Feb. 1 1863, the elder son of Sir William Harcourt (*see* 12.939). He was educated at Eton and afterwards travelled widely, becoming well known for his interest in art. In 1899 he married the only daughter of Walter H. Burns, of New York. In 1904 he was elected Liberal M.P. for the Rossendale division of Lancs., retaining the seat until 1916, and on the formation of Sir Henry Campbell-Bannerman's Government (1905) he became First Commissioner of Works. In 1910 he became Secretary of State for the Colonies in the Asquith Cabinet, and on the formation of the Coalition Government in 1915 again became First Commissioner of Works. In 1917 he was raised to the peerage. He died in London Feb. 24 1922, leaving a young son who succeeded to his title.

HARDIE, JAMES KEIR (1856–1915), British politician, was born on Aug. 15 1856 at Legbrannock in Lanarkshire of very poor parents. He was a message boy at six, and at 10 a "trapper" in a mine. After 13 years underground he became a miners' agent and helped to form the Ayrshire Miners' Union which was the first organised body to put forward the demand for a Labour party. In 1888 he stood as Labour candidate for Mid-Lanark and in the same year formed the Scottish Labour party. In 1892 he was elected for West Ham as the first Independent Labour M.P. At the formation of the Independent Labour party in 1893 he was made chairman, and eventually succeeded, with James Ramsay MacDonald, in forming the Labour party. He lost his seat in 1895, but was returned for Merthyr in 1900, 1906 and 1910. In 1894 he founded *The Labour Leader*. In 1908 he made a tour of the world. As a begetter of the Labour party and on account of his personality and courage he is considered one of the party's heroes. He died in Glasgow on Sept. 26 1915.

See J. B. Glasier, *Keir Hardie; the Man and His Message* (1919); W. Stewart, *J. Keir Hardie. A Biography* (1921); F. Johnson, *Keir Hardie's Socialism* (1922); D. Lowe, *From Pit to Parliament; the Story of the Early Life of James Keir Hardie* (1923).

HARDINGE OF PENSHURST, CHARLES HARDINGE, 1ST BARON (1858–), British diplomat, was born in London June 20 1858, second son of the 2nd Viscount Hardinge. He was educated at Eton and Trinity College, Cambridge, and in 1880 entered the diplomatic service. He became secretary of legation at Teherān in 1896, and in 1898 went to St. Petersburg as secretary of embassy. In 1903 he returned to England and became assistant Under-Secretary for Foreign Affairs, becoming later (1906–10) permanent Under-Secretary. In the latter capacity he accompanied King Edward VII. on his foreign visits. He was created K.C.M.G. in 1904, G.C.M.G. in 1905 and K.G. in 1916. From 1904 to 1906 Sir Charles Hardinge was ambassador to Russia, and in 1910 was appointed Viceroy of India and raised to the peerage. Lord Hardinge returned to England in 1916 and was reappointed to the post of permanent Under-Secretary of Foreign Affairs. In Nov. 1920 he succeeded Lord Derby as ambassador in Paris, retiring in 1922.

HARDING, WARREN GAMALIEL (1865–1923), 29th President of the United States, was born at Corsica (then Blooming Grove), Morrow co., Ohio, Nov. 2 1865, son of George Tyron Harding, a farmer and country doctor, and Phebe Elizabeth Dickerson. He studied in the common schools, and from 14 to 17 at the Ohio Central College at Iberia. He taught in a country school for a year, read law for a short time, worked in a newspaper office and in 1884 became editor and proprietor of the *Marion Star*. On July 8 1891 he married Florence Kling. Having attracted the notice of Senator Joseph B. Foraker (*see* 10.628), he was encouraged to enter state politics, and was early recognised as an effective speaker. He served two terms in the Ohio senate (1900–4), and during the second was influential in securing Senator Foraker's re-election to the U.S. Senate. From 1904 to 1906 he was lieutenant-governor of Ohio, but in 1910, when nominated for governor by the Republicans, was defeated by a plurality of 100,000. In the campaign of 1912 his paper supported President Taft. In 1914 he defeated Foraker in the Republican primaries as candidate for the U.S. Senate, and was elected with a majority of 100,000 for the term of 1915–21; but his friendship with Foraker remained unabated.

In 1916 Mr. Harding was delegate-at-large from Ohio to the Republican National Convention, of which he was chosen permanent chairman. In the Senate he was regarded as a "safe" man, who could be relied upon to support orthodox Republican policies. In 1915 he urged "preparedness" for naval defence. In 1916 he voted against the confirmation of Louis D. Brandeis as associate justice of the U.S. Supreme Court. In 1917 he gave his support to the declaration of War against Germany, and also to all the War measures, including the Selective Draft and Espionage bills. He favoured the death penalty for spies, but after the War advocated amnesty for political prisoners. He opposed the suggested Federal control of food and fuel. He favoured the Prohibition Amendment, and voted for the Volstead Act, enforcing War-time prohibition, over the President's veto. He favoured the anti-strike clause of the Cummins Railway bill, and voted for return of the lines to their owners within a year after the end of the War. He was for exempting American shipping from Panama Canal tolls and also supported woman suffrage. He was opposed to the Covenant of the League of Nations, holding that "either the Covenant involves a surrender of national sovereignty and submits our future destiny to the League, or it is an empty thing, big in name, and will ultimately disappoint all of humanity that hinges its hopes upon it." He voted for the Lodge reservations and also for the Reed reservation that the United States alone should judge whether matters of direct interest to it should be brought before the League; and finally he voted against ratification of the Treaty as submitted by President Wilson. He maintained that Americans should show chief concern for America, and opposed all tendencies toward internationalism. He supported the Knox resolution declaring that war with Germany was ended.

At the Republican National Convention in 1920 Mr. Harding was not at first among the prominent candidates for president. On the first ballot he received 65½ votes (493 being necessary for choice), 39 of these being from his own state. On the eighth ballot he received 133½ votes, on the ninth 374½ votes, and on the tenth he secured the nomination with 692½ votes, the result being due largely to the support of certain influential U.S. Senators, delegates to the convention, who hoped that as president he would be amenable to the Senate. He did not "stump" the country, but conducted his campaign from the "front porch" of his own home. Mr. Harding based his campaign chiefly upon criticism of the Wilson administration, denouncing especially the excessive power that, as he maintained, had been exercised by the executive as a result of War centralisation; he demanded as speedy as possible a return to normal conditions, political and industrial.

While opposing the Covenant of the League of Nations, Mr. Harding gave to many of his supporters the impression that he desired an "association of nations" which, without the characteristics of a super-state (such as he believed the League to be), might safeguard peace. But he retained the political support of many who were opposed, like Senators Borah and Johnson, to any sort of international association. In the Nov. elections he won an overwhelming victory over James M. Cox, the Democratic nominee, also from Ohio; he carried, generally by immense majorities, all the northern states and all but one of the states on the border between North and South, and he cut down materially the Democratic majorities in the South. The electoral vote was 404 for Harding against 127 for Cox. The popular vote was 16,138,000 for Harding against 9,142,000

for Cox. In Ohio the popular vote was 1,182,000 for Harding against 780,000 for Cox. The sweeping character of his victory was due less to his own personal strength or to the weakness of Cox than to the national reaction against the Democratic party and the popular feeling against President Wilson. Mr. Harding resigned from the U.S. Senate in Dec. 1920, and was inaugurated March 4 1921, the sixth President to come from Ohio.

The promise frequently made by Republican campaign leaders that Mr. Harding would surround himself with advisers of capacity and experience, seemed to be fulfilled by his choice of Cabinet members. The outstanding names were those of Charles E. Hughes and Herbert C. Hoover, who became Secretary of State and of Commerce respectively. The distinguished career of the former and the widespread confidence in his ability and political integrity had marked him for the most important position in the Cabinet; and there had been a general demand that the new administration should utilise the organising ability displayed by Hoover in many fields. Various elements in the Republican party, nevertheless, had stoutly opposed their appointment, so that the President's choice showed that he was prepared to exert his independence of party managers and to insist upon administrative efficiency. The choice of Andrew W. Mellon, a wealthy banker and ironmaster of Pittsburgh, as Secretary of the Treasury, was welcomed by men of business; and though that of Will H. Hays to be Postmaster-General was in the nature of payment of a political debt to the man who had been the manager of the Republican campaign, it was early justified by his administration of the Federal postal service.

Mr. Harding's inaugural address, and his first message to Congress, delivered in person on April 12, voiced his desire to return to "normalcy," as he expressed it. Retrenchment in expenditure formed a major item in his programme, together with a prompt and thorough revision of taxation. He advocated the adoption of a national budget system, and the Congress having passed a Budget bill similar to that vetoed by Mr. Wilson in 1920, he approved it on June 10 1921; it provided for a Budget Bureau in the Treasury Department and the appointment of a director of the budget, the first being Charles G. Dawes, formerly general purchasing agent of the American Expeditionary Force. President Harding's first budget was presented Dec. 5 1921. The President was insistent upon the need of repealing the excess profits taxes and reducing transportation taxes and income surtaxes. The need of financial retrenchment led to his opposing the proposal that War veterans should receive a cash bonus. In this matter, as in others, he proved his ability at this early stage to resist political pressure. As regards the tariff he advocated, as a temporary stop-gap, the passing of the emergency tariff, which had been vetoed by President Wilson, but which with slight alteration was approved by Mr. Harding on May 27 1921. He urged the need of adopting a permanent tariff policy, and on Dec. 5 1921 suggested a "flexible tariff" which might provide for the adjustment of rates to meet unusual and changing conditions. Such adjustments might be made, in his opinion, by the executive on the advice of the Tariff Commission.

Mr. Harding's interest in agricultural problems was keen; in his first message he asked special protection for agricultural interests, and in his second he declared that something more than protection must be given the farmers, advocating warmly the encouragement of co-operative marketing plans. As regards domestic legislation, the President, in general, assumed the rôle of moderator. He disclaimed any desire to enlarge the powers and responsibilities of the executive, which, he declared, were already too large; and he aimed at close co-operation with Congress. In marked contrast to his predecessor, he left administrative responsibility to the members of his Cabinet. Foreign policy was largely determined by Hughes, financial by Mellon, and the problem of unemployment was thrown upon Hoover. The President, however, frequently played an active rôle in the conferences necessary to secure general agreement, as on Aug. 9 1921 when an accord was reached between the Treasury and the Representatives on the taxation plan.

The foreign policy of the administration at first seemed likely to emphasise independence of action, on contradistinction to that of President Wilson; the threatened war between Panama and Costa Rica was prevented by a sharp note from Secretary Hughes; the claims of the Japanese to a mandate over Yap were stoutly denied; the administration refused to follow Great Britain in resuming trade relations with Soviet Russia. President Harding made plain in his first message that the United States would not enter the League of Nations. But he expressed himself warmly in favour of active co-operation with other nations of the world, and by accepting the invitation to participate in inter-Allied councils indicated that he would avoid a policy of isolation. In rejecting the League Covenant, he said "we make no surrender of our hope and aim for an association to promote peace, in which we would most heartily join." The President advocated a declaration of peace with Germany by resolution, and the immediate negotiation of a treaty. This policy was adopted by Congress, which agreed upon a joint peace resolution, signed by him on July 2. On Aug. 25 1921, a treaty with Germany was signed, embodying the President's plan of including most of the stipulations of the Versailles Treaty, but repudiating adherence by the United States to any clause referring to the League of Nations. This treaty and similar pacts with Austria and Hungary were ratified by the Senate, Oct. 18 1921.

The most important step taken by President Harding during the first year of his administration was the calling of an international conference on the limitation of armaments. On May 25 1921 the Senate had adopted an amendment of Senator Borah to the Navy bill, authorising and inviting the President to call such a conference. Mr. Harding's preliminary invitations to the principal naval Powers (Great Britain, Japan, France and Italy) were sent July 10, and formal invitations Aug. 11. He made clear his belief that the question was closely connected with the problems of the Pacific and Far East, and invitations were also sent accordingly to China and to the smaller European Powers with Far-Eastern interests—Holland, Belgium and Portugal. The invitations were accepted, and the conference assembled at Washington on Nov. 12. President Harding avoided the example set by his predecessor, and did not himself participate as a delegate. He displayed his political tact in the choice of the American delegation, which was led by Secretary Hughes and included, besides Elihu Root, two members of the Senate, Lodge and Underwood, the Republican and Democratic leaders respectively. The policy drafted by the President and Mr. Hughes was direct and vigorous. They refused to permit the vital problem of limitation of armaments to be side-tracked, and surprised the conference by proposing a 10-year naval holiday and a drastic scrapping of tonnage by the three chief naval Powers. The President made it clear that he regarded the conference merely as a step in securing international understanding and goodwill; he advocated the convening of succeeding conferences as a possible means of securing an international association for the promotion of peace, and he approved the principle of substituting an understanding between the United States, Great Britain, France and Japan regarding Far-Eastern problems, for the existing Anglo-Japanese Treaty. (*See* WASHINGTON CONFERENCE.)

The Washington Conference was the highwater mark of the Harding Administration. Thereafter he faced the development of blocs in the Republican party which destroyed its solidarity, and the growth of criticism which was manifested by the elections of 1922, as a result of which the Republican majority in the House was reduced. Mr. Harding's veto of the Bonus bill indicated his unwillingness to sacrifice principle to expediency. But he found difficulty in explaining the administrative incompetency, or worse, of office-holders in Washington; resentment was felt against the Republican national organisation controlled by the Old Guard; there was outspoken criticism of the new tariff; keen discontent among the farmers led to the election to the Senate of Shipstead and Magnus Johnson. Again the threat of a Third party became imminent.

In the summer of 1923 Mr. Harding set forth on a tour across the United States and to Alaska, designed to reassure the

farmers and reawaken enthusiasm for the Administration. The President, already tired, became ill on the trip back from Alaska and was stricken with pneumonia in San Francisco. On Aug. 2 1923 he died suddenly. (C. SEY.)

HARDY, THOMAS (1840–), English novelist (*see* 12.946); in later years received increasing recognition, not only as a great novelist but also as a poet. His great epic-drama *The Dynasts* (1904–8), a chronicle play of England's struggle against Napoleon, with an accompaniment of philosophic comment chanted by a chorus of "phantom intelligences," was in part produced at the Kingsway Theatre, London, in the early months of the World War, and again at Oxford in 1920. several volumes of lyrical poetry followed (*Selected Poems* in 1916; *Collected Poems* in 1919—but now incomplete). His first wife died in 1912, and in 1914 he married Florence Emily, daughter of Edward Dugdale, herself a writer of children's books and articles in periodicals. Both on his 70th and on his 80th birthday he received tributes of respect and admiration throughout the English-speaking world.

Thomas Hardy's career naturally divides itself into three periods. The first of these contains his work as a novelist, and ends with *Jude the Obscure* in 1896 (*The Well-beloved*, published in book form in 1897, appeared serially in 1892). The second period consists of *The Dynasts*, the three parts of which were issued separately in 1904, 1906, 1908: no doubt the greatest single achievement of his career. The third period may be said to begin with *Time's Laughing-stocks* in 1909, and is wholly devoted to lyrical poetry. It is not often that an artist's life can be divided so definitely into separate stages, each stage characterised by the use of a different form; and, next to its length and plenty, and consistently noble idiosyncrasy, this tripartite division is perhaps the most remarkable feature of Mr. Hardy's career as a whole. The lyrical period, however, does not give us an entirely new development of his genius.

While he was writing novels, he had occasionally experimented with poetry, and some of the results were published, in *Wessex Poems* (1898) and *Poems of the Past and the Present* (1901), between *Jude the Obscure* and *The Dynasts*. The volumes published since *The Dynasts* also contain a good many more of these earlier poems. But from 1909 onwards Mr. Hardy wrote nothing but lyrical poetry, and this may therefore truly be called his lyrical period. (*A Changed Man* in 1913 merely rescued from the periodicals of former years several stray pieces of minor fiction.) It represents a new concentration of his power, but certainly no diminution of it. Devotion to lyrical expression has produced a mastery almost as signal in its kind as his command of the art of fiction; and his 70th year saw him beginning, with *Time's Laughing-stocks*, the series of volumes—*Satires of Circumstance* (1914); *Moments of Vision* (1917), *Late Lyrics and Earlier* (1922), *Human Shows, Far Phantasies* (1925), which has shown him to be the most original, the most poignant, and also the most copious, of contemporary lyrical poets.

The originality of the technique in these volumes does not by any means consist in a mere breach with the accepted conventions, but rather in its highly individual—to some, perhaps, rather disconcerting—compound of the conventional and the unconventional. Most of these lyrics maintain an exact and even rigid formality of stanza, in which a scheme of rhymes is imposed, as it seems, arbitrarily and at all costs. The effect is sometimes justified by its music; but more often by the compact force its pressure gives to language almost conversational in its idiom and choice of words. Yet the diction which defies poetic tradition and seems to despise the magic of elaborated verbal suggestion, is oddly blended with stiff literary phrases and even with words that one might expect only lexicographers to think of. The truth seems to be that, in lyrical technique, Mr. Hardy has no prejudices either for or against the conventions. He is simply concerned with the matter which intense feeling and profound understanding have enabled him to imagine in a way peculiarly his own, and to express this faithfully he has forged a technique peculiarly his own, out of whatever the language of literature or of speech could offer him. Readers who are willing to allow him this liberty can hardly fail to be impressed, as perhaps nowhere else in recent poetry, by the subtlety, depth and variety of his versions of the experiences common to humanity: the commonplace becomes in his hands something rich and strange. Naturally the habit of thought and outlook on the world, which we find progressively insistent in the series of the Wessex novels, and which inspire the turbulent matter and monumental structure of *The Dynasts*, are very evident also in the lyrics; which indeed are often in the nature of marginal comments on themes previously used.

But something like the quintessence of his tragic power may be found in such ballads as "A Trampwoman's Tragedy," or such keen discrimination of pathos as "Near Lanivet," and something too like the quintessence of his irony to be altogether comfortable in *Satires of Circumstance* or "Ah, are you digging on my grave?" Nor is the rustic humour of his beloved Dorset villagers wanting, nor the vivid delight in nature, in the extraordinary range of his lyrical art. It is, in fact, the same Hardy in the lyrics as in the novels and *The Dynasts;* but a Hardy who, if his lyrics were all we had of him, would surely, by virtue of them alone, hold a secure, indeed a unique, position in modern English literature. (L. AB.)

HARE, SIR JOHN (1844–1921), British actor (*see* 12.948), died in London Dec. 28 1921. He made his latest appearance on the stage in a revival of Grundy's *A Pair of Spectacles* at Wyndham's Theatre in 1917.

HARINGTON, SIR CHARLES HARINGTON (1872–), British soldier, was born at Chichester May 31 1872 and commissioned in the King's (Liverpool) Regiment in 1892. After service in the South African War, he held a series of staff appointments, and on the outbreak of the World War went to France as general staff officer, 2nd grade, of the III. Corps. His ability brought him rapid promotion and in June 1916 he became major-general, general staff of the II. Army. He remained chief of staff to Gen. Plumer in France for nearly two years, with the exception of a short interval in Italy. The combined talents of the two men were such that the II. Army became proverbial for its excellent staff work and for carrying out any operation with the maximum economy of life. Messines 1917 was perhaps their most brilliant feat. In April 1918 Harington was recalled to the War Office to become deputy chief of the Imperial General Staff. In the following year he was created Knight commander of the Bath. In Sept. 1920, he succeeded Gen. Milne as Commander-in-chief of the British forces, and subsequently of the Allied forces at Constantinople and in the Black Sea. His tact and diplomacy in a difficult situation, especially during the Chanaq incident, helped to avert serious complications, and was fittingly acknowledged in Parliament. On his return to England in Oct. 1923 he was appointed to the Northern Command.

HARLAN, JOHN MARSHALL (1833–1911), American jurist (*see* 12.954), died in Washington, D.C., Oct. 14 1911.

HARPIGNIES, HENRI (1819–1916), French painter (*see* 13.15), of whose drawings there was an exhibition in London in March 1910, died in Burgundy Aug. 25 1916.

HARRIGAN, EDWARD (1845–1911), American actor (*see* 13.17), died in New York City June 6 1911.

HARRISON, FREDERIC (1831–1923), British man of letters (*see* 13.23). Frederic Harrison's death at Bath from sudden heart failure at the age of 92, on Jan. 14 1923, closed an unusually long and active career devoted to literature and religious service.

In his last book *De Senectute* (1923), which he did not live to see published, he re-affirmed his life-long principle and attachment to the religion of Auguste Comte, and no estimate can do him justice which does not take into account the essentially religious character of his life, of which all his written works may be said to be a contributory expression. Though Frederic Harrison originally came into prominence in the days (1850–80) of fighting agnosticism, he was never himself an "agnostic," and in fact was severely criticised by the leading agnostics, notably by Huxley and Herbert Spencer, etc.; moreover, as a Positivist, he was a republican in spirit and, what was new at that period, a sociologist. It was this positivist sociology which caused him as a young

man to espouse the cause of trade unionism, which he did with such energy and legal skill as adviser to the Royal Commission on Trade Unions in 1867, that he was really the inspirer and founder of the trade union law as it existed from 1868 to 1906. None the less, his religion did not permit him to embark upon a public career. He virtually retired from politics (in the party sense) and from legal practice in mid-life, this latter very largely as the enforced consequence of his pioneer fight on behalf of trade unionism, and took to letters.

At the age of 80 he published his *Autobiographic Memoirs*, 2 vol. (1911). Among the books that flowed almost annually from his pen may be mentioned: *Memories and Thoughts* (1906); *National and Social Problems* (1908); *Tennyson, Ruskin, Mill and other Literary Estimates* (1899); *George Washington, etc.* (1901); *The Creed of a Layman* (1907); *Realities and Ideals* (1908); *Novissima Verba* (1920); *De Senectute* (1923). As an historian Frederic Harrison did not belong to the modern school of specialisation, and ranks as a "literary-historian"; as essayist, he excelled, occupying a distinguished place both for the soundness of his judgment and for the vigour and clarity of his style. Politically, he stood in the position of an unofficial proconsul, and for some years before the World War he repeatedly warned his countrymen of the impending crisis arising out of the armed system of Europe, and of the necessity of British preparation to meet it. An article he wrote in *The English Review* in 1913 proved to be only too prophetic. During the War he stood unfalteringly for victory and for the cause of France. His son, René, was killed in Flanders in 1915.

Frederic Harrison can hardly be classified either as a pure man of letters or as politician by virtue of his religious opinions which debarred him from active participation in worldly affairs, and even as a critic the humanist motive was uppermost. His life may be described as an attempt to introduce Comte's Humanist sociology into this country, to which end he devoted all his energies. For 20 years he was the leader of English Positivism and regularly lectured at Newton Hall, being also a co-founder of and contributor to *The Positivist Review*. His political views were zealously put forward in that organ. He was not a Radical in the party sense though always a Liberal in spirit. Internationally, he was a life-long supporter of France, and in 1870 vehemently urged British support of Gambetta as against Bismarckianism. If he was a "Little Englander," it was because of his championship of the "Little Peoples," and during the Boer War his pronounced anti-jingoism led him into acute controversy. Publicly, his attitude was often misunderstood for that reason. He may be said to have been a republican in spirit, a humanist by conviction and a "meliorist" as politician.

Frederic Harrison had not originally wished to found a Positivist centre or sect, but after the secession of Dr. Congreve on the crucial issue of allegiance to French Comtists, he virtually had no alternative, and it was thus that Newton Hall came into being. As the head of that body, Frederic Harrison found copious use for his scholastic knowledge and energies as lecturer and teacher, and though in that position he was "labelled," the sincerity and disinterestedness of his opinions were so universally recognised that his public moral authority did not lose through isolation. In this way he occupied a kind of "chair" of public morals, such as is hardly conceivable in any other country, hence his unflinching war determinism in 1914 caused him to be more popularly known and appreciated in extreme old age than had been the case during the Victorian epoch when, as a humanist, he found himself neither on the one side nor the other of the great Victorian struggle for "liberty of thought," the foundation of which intellectually had been laid by Auguste Comte and Charles Darwin.

In this great battle of "reason," which started at Oxford, Harrison played a conspicuous part, though never as an iconoclast and in interest, spiritually; *i.e.*, outside the intellectual ethicism arising out of the new criticism, for he neither adhered to the utilitarianism of Mill nor to the "dry light" of the debaters in the famous Metaphysical Society of which he was a member. Positivism was at that time regarded as a "heresy" both by orthodoxy and by the agnostics, and in the controversies that ensued Harrison drifted somewhat out of the movements of his time. He was perhaps the last survivor of the "great" Victorians. He will be remembered as a supreme individualist, a slashing controversialist, as a practical idealist and citizen. Thus he consistently advocated the return of the "Elgin Marbles" to Greece on the ground that the statuary belonged to the historical religion of the Greeks. He was a friend of President Roosevelt and twice lectured in the United States. He was at his best as critic of life and art in the relation of the past to the present, which was Comte's "law" of continuity, but Harrison was alive to the academic weaknesses in Comte's *Polity* and rejected any dogma. In his latter years he resided at Bath, of which city he was given the freedom. He refused all titles or "honours." His ashes, mingled with those of his wife, repose in an urn placed in the chapel of Wadham College, Oxford, according to his last wishes. See Austin Harrison, *Frederic Harrison: Thoughts and Memories*, 1925. (A. Hn.*)

HART, SIR ROBERT (1835–1911), Anglo-Chinese official (*see* 13.30), died at Great Marlow, Bucks., Sept. 20 1911.

HARTLEPOOL, England (*see* 13.34), had a population (1921) of 20,097 and an area of 924 acres. It is connected with West Hartlepool by rail and tramway over Hartlepool Bay. West Hartlepool had in 1921 a population of 68,689 and an area of 2,958 acres. The parish church was restored in 1921, and the Baptist church, destroyed by bombardment, was rebuilt. An obelisk has been erected in Victory Square, West Hartlepool, as a war memorial. In 1924, 5 ac. of land were levelled for additional timber storage, and a quay was built for the fishing industry in 1910. The total area of docks in the Hartlepools is now 200 acres. In Dec. 1914 the towns were shelled by German cruisers and a little damage was done.

HARTLEY, SIR CHARLES AUGUSTUS (1825–1915), British engineer (*see* 13.35), died in London Feb. 20 1915.

HARTLEY, JONATHAN SCOTT (1845–1912), American sculptor (*see* 13.35), died in New York City Dec. 6 1912. Among his last exhibits were "Young Hopi Stick Thrower" (1911) and "The Cradle of Pan" (1912).

HARVARD UNIVERSITY (*see* 13.38).—The history of Harvard University after 1909, when Abbott Lawrence Lowell succeeded Charles William Eliot as president, is one of change and growth to meet new needs and opportunities.

Buildings.—Three residence halls for freshmen (Gore, Standish and Smith) accommodating about 450 men, built near the Charles river at a cost of approximately $2,500,000, were opened in 1914; and in 1919–20 a number of other dormitories, originally erected by private enterprise, were purchased by the university, thus largely increasing the residence halls under its control; in 1924–5 over half the undergraduates of Harvard College and a considerable proportion of the students in the graduate schools located in Cambridge were housed in buildings owned by the university. In 1925–6 Massachusetts Hall, which was a residence hall from 1720 to 1870, was again occupied by students, and two new dormitories, Lionel and Mower halls, became available for seniors; the erection of a third dormitory in the Yard was begun, while by the Charles river a fourth large dormitory for freshmen was under construction. Two new chemical laboratories, the Wolcott Gibbs and the Thomas Jefferson Coolidge, Junior, Memorial, were opened in 1913–4; these facilities for the study of chemistry were, in 1925–6, being increased by large laboratories, which at time were under construction at a cost of approximately $2,000,000.

During 1914–5 the university's museum buildings as originally planned by Louis Agassiz in 1859 were completed by an addition to the Peabody Museum. A building for the Music Dept. and the Cruft High-Tension Laboratory were also opened in 1914–5. In the same year the Widener Library, the largest of college libraries, erected by his mother in memory of Harry Elkins Widener, of the class of 1907, who lost his life in the "Titanic," was first used. The Germanic Museum, to exhibit the evidences of Germanic civilisation in the widest sense, was completed and opened in 1921. The new Counting-House, finished in 1925, provides

adequate offices for the officials, except the treasurer, who have charge of the university property and accounts. In the same year work was begun on the buildings for the Graduate School of Business Administration, provided through the gift of $5,000,000 by George F. Baker; these buildings occupy a large tract on the Boston side of the Charles river. The erection (1925–6) of a new Art Museum at a cost of $1,200,000 to take the place of the Fogg Museum, long outgrown, was also made possible by friends of the university. Improvements have been made in athletic fields, gymnasia, etc.

Endowments.—The period under consideration was remarkable for the rapid increase of funds. In spite of the World War, graduates and friends gave approximately $17,000,000 in the decade 1909–19. Of this about $5,000,000 was for buildings and immediate use; $12,000,000 for permanent endowment. With the close of the World War the alumni revived a project, started before the War but then suspended, to secure additional endowment, and organised in 1919 a committee for the purpose. At the close of the fiscal year 1924–5 over $14,000,000 had been subscribed, of which over $12,875,000 had been paid into the treasury. The total productive endowment of Harvard University on the same date was approximately $70,000,000.

New Plan of Admission.—In 1910–1 a new plan of admission to Harvard College was adopted, which endeavours to test the intellectual condition of the applicant for admission and to establish a closer co-operation with preparatory and high-school authorities. From experience the plan is found to secure closer articulation, especially with public schools, and to provide the college with a better grade of student. In its essential features the "new plan" has been followed by a number of other important colleges. In 1923 the experiment was begun of admitting without examination students who have completed in regular course in a good secondary school a programme of study which fulfils in all respects the requirements for admission to the privileges of examination under the new plan, provided they have ranked in scholarship in the last two years of their school course among the highest seventh of the boys in the graduating class and are recommended by their school. So far as can be judged, students so admitted are above the average of their class in scholarship. In 1924, 48·4% of the freshman class entered from public schools.

The former free elective system, which furnished little or no direction to a student's choice of studies, was modified in 1910 by requiring each student to choose enough courses in one field of knowledge to enable him actually to gain considerable knowledge of that subject; and by distributing a certain number of courses among other fundamental subjects to secure a more systematic and well-rounded education. At the same time the "degree with distinction" was established for high attainment in general, coupled with distinguished success in the subject to which the student has given most attention. Beginning with 1916, general final examinations on the student's field of concentration were introduced in the departments of history, government and economics for all students; the plan was later extended to all other departments except the natural sciences.

In the years following 1916 a system of tutors was developed to direct the private reading of the students. The tutor meets his men individually each week and advises as to their private study; he is in no sense a coach. The results thus far show that the tutorial system is of great educational value; it encourages the student to think of his chief subject as a whole, and to read independently in his field; while the general final examination gives an opportunity to test his capacity at the end of his course. The two have resulted in increased interest on the part of the students and in higher scholarship among students of varying abilities. In 1925 out of the 516 students who presented themselves for the general final examinations in their several fields, 111, or 21·4%, obtained degrees with distinction.

The Engineering School.—In 1915–6, after the Massachusetts Institute of Technology had decided to move from Boston to Cambridge, all instruction in engineering was virtually transferred to it under a co-operative agreement entered upon between the Institute and Harvard. There being doubt, however, as to whether such co-operation was allowed under the terms of the Gordon McKay bequest which was given to Harvard University to further applied science, application was made by the university authorities to the Supreme Court of Massachusetts. The decision of the court in 1917 was adverse, and Harvard again established a School of Engineering Sciences, which, in spite of conditions caused by the World War, made a successful beginning, and in 1924–5 had 36 instructors and 258 students on the register.

Graduate Schools.—The period under review was marked by constant developments in the graduate schools of the university. The Graduate School of Arts and Sciences grew steadily in numbers, although in common with other departments it suffered a temporary check by the World War. Its students are mostly preparing for careers as teachers and scholars; and, in spite of the economic disadvantages under which the profession of teaching still labours, it is impossible to meet all requests coming to the school for teachers and research workers. In 1924–5 the total attendance was 763. The preparation for the scientific management of business given to young men by the Graduate School of Business Administration won wide appreciation, causing large resort to the school (614 in 1924–5) and it became necessary to limit the number of students. In the Law School a post-graduate year of study was established, leading to the degree of S.J.D., intended especially for men wishing to prepare themselves for teaching law and for research in jurisprudence. In 1924–5 the number of teachers was 24 and of students 1,201, representing 175 colleges. In the Medical School departments of pharmacology, of tropical medicine and industrial medicine were organised, and a School of Public Health was established. Affiliation with hospitals, many of them grouped near the school, and changes in the faculties secured one of the largest and strongest organisations for the teaching of medicine and for medical research in the United States.

A separate faculty of architecture was established in 1914, having under its charge the Graduate Schools of Architecture and of Landscape Architecture, which respectively had (1924–5) 48 students from 19 colleges, and 39 students from 22 colleges. In 1920 the instruction in education, which had previously been given under the faculty of arts and sciences, was organised as the Graduate School of Education with a separate faculty. To this school women, as well as men, who hold an academic degree are admitted, this being the only part of the university where co-education is recognised. In the year under review the school had 37 instructors and 272 students, representing 86 colleges. The Theological School was created in 1922 by an affiliation between the Harvard Divinity School (1816) and Andover Seminary (1808); but this union was dissolved by a decree of court in 1925. With the Divinity School are associated the Episcopal Theological School (in Cambridge), Boston University School of Theology and Newton Theological Institution. The degrees of Master of Theological Science (S.T.M.) and Doctor of Theology (Th.D.) were established for those wishing to continue their studies after obtaining the ordinary degree, and the ordinary degree itself (S.T.B.) is now given on the basis of a general examination at the end of the student's three-year course.

University Extension.—Subsequent to 1909 Harvard University united with Boston University, Boston College, the Massachusetts Institute of Technology, Simmons College, Tufts College, Wellesley College, the Boston Museum of Fine Arts, the Massachusetts Board of Education and the School Committee of the City of Boston in offering courses in university extension. These courses are given ordinarily in Boston to a considerable number of students each winter.

War Services.—Ten thousand Harvard graduates and students entered the army or navy of the United States during the conflict; of these 70% received commissions. No complete records exist of those who engaged in non-military service, but it may safely be said that over half the Harvard men of every age took an active part during the World War. The Roll of Honour contains 372 names of men who gave their lives.

The number of students in 1924–5 was as follows:—

College	3,009
Graduate School of Arts and Sciences	763
Special Students	32
Engineering School	258
Theological School	74
Law School	1,201
Medical School	506
Dental School	204
School of Public Health	30
Graduate School of Business Administration	614
Architecture	87
Graduate School of Education	272
Bussey Institution	25
Summer Schools of 1924	2,686
(446 deducted for duplication)	
Total	9,315

n 1908–9 the corresponding total was 5,250. The number of fficers of instruction and administration in 1924–5 was 1,319; in 908–9, 743. The total number of volumes and pamphlets in the niversity library in 1924 was over 2,320,000. Radcliffe College for women), in which instruction is given by Harvard teachers, lthough not part of Harvard University, had in 1924–5 908 tudents. (C. H. M.)

HARVEY, GEORGE BRINTON McCLELLAN (1864–), merican editor and diplomat, was born at Peacham, Vt., Feb. 6 1864, and was educated at the Peacham Academy. At the ge of 18 he became a reporter on *The Springfield* (Mass.) *Republican*, and later on *The New York World*. In 1885 he was ppointed by Governor Green of New Jersey as aide-de-camp n his staff, and was reappointed by Governor Abbett. The tter also made him insurance commissioner of New Jersey in 890. During 1891–4 he was managing editor of *The New York Vorld*. Then for several years he was engaged in the construcion of electric railways, and in 1898 organised a syndicate hich secured possession of the lines in Havana, Cuba. The ollowing year he purchased *The North American Review*, which hereafter he edited for several years. During 1900–15 he was resident of the publishing house of Harper & Bros., and during 902–13 was editor of *Harper's Weekly*. In 1903 he purchased *The Metropolitan Magazine*.

Harvey was said to have been the first to suggest (in 1906) Voodrow Wilson, then president of Princeton, as a presiential possibility. In the campaign of 1912 he gave Wilson trong support; but after the latter's nomination an estrangeent developed, due, as it was generally understood, to the act that Wilson intimated that his cause was being jeopardised y Harvey's officiousness. In 1916 Harvey urged the election f Charles E. Hughes, the Republican candidate for President. He was strongly opposed to the League of Nations, on the ground hat it involved the yielding of national sovereignty. In 1918 e established *The North American Review's War Weekly*, later alled *Harvey's Weekly*, which bitterly denounced the Wilson dministration. In 1921 he was appointed ambassador to Engand by President Harding, a position which he held till Nov. 923. He became editorial director of *The Washington Post* in May 924, resigning May 31 1925. Harvey's books include *Women* 1908) and *The Power of Tolerance, and Other Speeches* (1911).

HARWICH, England (*see* 13.47), with a population of 13,046 n 1921, and an area of 1,541 ac., including Halstead, added to he borough in 1917, is the most important naval base on the ast coast of England. Flotillas operating from the harbour did nagnificent work during the World War, particularly in mine weeping in 1917. The main quay was extended by 1,000 ft. n 1911, and there are now berths for nine steamers, and moorngs for nine more in the river. A train ferry to Zeebrugge was naugurated in 1924. The parish of Dovercourt has been united with that of Harwich for purposes of local government. A cemetery was opened at Parkeston in 1910. The electricity supply was taken over by the municipality in 1925.

HAUPTMANN, GERHART (1862–), German dramatist (*see* 13.68), hardly added to his reputation as a dramatist after 1909. He produced *Kaiser Karls Geisel* (1908); *Griselda* (1909); *Die Ratten* (1910), the latter in his earlier realistic manner; *Gabriel Schillings Flucht* (1912); *Das Bogen des Odysseus* (1914); *Winterballade* (1917); *Indipohdi* (1921) and *Peter Brauer* (1921). His novels include *Der Narr in Christo Emanuel Quint* (1910); *Atlantis* (1912); *Der Ketzer von Soana* (1918); *Phantom* (1923) and *Die Insel der Grossen Mutter oder Das Wunder von Ile des Dames* (1924). In 1921 appeared *Anna*, an epic poem.

See C. Holl, *Gerhart Hauptmann*, etc. (1913); W. Bonsels, *Das junge Deutschland und der grosse Krieg, aus Anlass des Briefwechsels Romain Rollands mit G. Hauptmann über den Krieg und die Kultur* (1914); A. Esprey, *G. Hauptmann und wir Deutschen* (1916); P. A. W. Gaude, *Das Odysseusthema bei Hauptmann* (1916); J. H. Marschan, *Das Mitleid bei G. Hauptmann*, with bibliography (1919); Paul Fechter, *Gerhart Hauptmann* (1922).

HAVANA, Cuba (*see* 13.76).—The population of Havana, the capital of Cuba, was 360,517, according to the census of 1919. Since that time it is estimated that there has been a still further increase to perhaps 500,000 inhabitants in 1926, for which immigration, mainly Spanish, is largely responsible. Havana, once rather backward in civic improvements, now compares as favourably with other cities of the world in its attractive, up-to-date appearance as it does in commercial and industrial importance. Motor cars swarm the streets, which for the most part are very narrow, but this condition has been relieved by having traffic go one way in all but the wider thoroughfares. In keeping with the wealth of Cuba, the capital has an unusual number of splendid private residences, excellent hotels, and luxurious club houses. The Spanish clubs are astonishingly rich. One of them, the Galician Club, has 67,712 members, while the Asturian Club has 60,351. The university of Havana, the principal educational institution of Cuba, has over 4,000 pupils, of whom some 3,000 are in daily attendance.

Havana is the economic, as well as the political, social, and intellectual centre of Cuba. Nearly all of the larger commercial companies and banks have their main offices there. The volume of trade through the port of Havana surpasses that of any city in the Western Hemisphere, except New York. About 75% of all Cuban imports enter at Havana, but the proportion of exports is considerably less. The customs receipts at this port are some 75% of the total collected in the island. Havana is connected with other parts of the world by means of a number of steamship lines and cables. There is even through freight train service from the United States, making use of a ferry from Key West, which is six hours away. (C. E. Ch.)

HAVRE, LE (*see* 13.82), the second seaport of France, had a pop. of 163,374, including the garrison, in 1921. Work has been continued on the last stages of the 1909 programme of port improvement, which includes a large graving dock and wharfage in the tidal basin, a floating dock and pontoons, a basin for large oil tankers and reservoirs in the outer harbour, and a wharf and mole for goods storage in the north part of the port. A petroleum pipe-line to Paris has been built, but Havre is still only linked by one line of railway to the capital, and is badly connected with other towns in its own district. An escalator is to be built in Rue de Montmorency, one of the steepest streets. In Aug. 1924 a monument was unveiled commemorating the hospitality shown by the town during the War to the Belgian Government, which was housed in a hostel at St. Adresse to the northwest of Havre, after the fall of Antwerp. At the same time a golden sword of honour was presented to the King of the Belgians on behalf of the French people. During the World War large numbers of British and American troops and vast quantities of ordnance and stores passed through the port, and after the Armistice it formed one of the American embarkation points. Trade has again reached its highest pre-war point. In 1924, 4,021 vessels of 8,264,645 tons entered and cleared the port, as compared with 4,018 vessels of 5,671,075 tons in 1907, previously the highest figures recorded.

HAWAII (*see* 13.83).—A group of islands in the North Pacific Ocean, annexed to the United States on Aug. 12 1898, and now represented in the American Congress by a delegate elected biennially. In 1925 the population, including military and naval personnel of 17,094, was 323,645 (an increase, exclusive of such personnel, of 59·7% since 1910).

Race must not be confused with nationality. Birth in Hawaii, as well as elsewhere in the United States, makes one an American citizen. Of the above total, 202,165 were Americans and 121,480 (including Filipinos who are neither citizens nor aliens) were not. Immigration of Orientals in the earlier stages produced an abnormal ratio not only of aliens to citizens but of adults to children and males to females, but later there was a rapid tendency toward normality. Except among Americans and Filipinos, the increase in population was in 1925 mainly through births. Departures have latterly exceeded arrivals, and the departures have been largely of adult aliens. The birth-rate was 41·57 and the death-rate 12·74 per 1,000 in 1925. While there was a growing tendency toward intermarriage among all races, the extremists in preserving racial solidarity are the Koreans and Japanese. The most noticeable social feature in Hawaii is the comparative absence of those racial antagonisms and prejudices prevailing in Asia and Europe.

Immigration has been occasioned by the rapid growth of industries. Many Latin and Oriental unskilled labourers were assisted to reach the country but this is now impossible under the immigration laws. Many of these with their children under improved conditions become skilled labourers. Hence the constant need of replenishing the supply of unskilled labour. The last immigration assisted by the Government (1906–12) comprised 5,288 Spanish, 4,962 Portuguese and 2,056 Russians. Since then the only assisted immigration has been of Filipinos by the sugar producers. These increased from 2,318 in 1910 to 49,335 in 1925. Chinese immigration, restricted previously, has been prohibited since 1898. The Chinese decreased until 1910, but have since increased slowly. The Portuguese, Porto Ricans and Koreans are increasing slowly and the Spanish are decreasing. The Japanese departures have exceeded arrivals since the "Gentlemen's Agreement" of 1907. The native-born Japanese, being American citizens, present the most important problem for the future. They increased from 4,855 in 1900 to 70,860 in 1925. Experience tends to show that the Japanese as well as the Chinese vote will be intelligent and conservative. Notwithstanding the comparatively small percentage of Anglo-Saxon Americans, the atmosphere—political, social and commercial—is conspicuously American.

Industries and Commerce.—Due mainly to the enterprise of the Anglo-Saxon element, the application of scientific methods, favourable soil and climatic conditions, location at the cross-roads of the Pacific and the American protective tariff, Hawaii has enjoyed prosperity for half a century.

Although prices of the principal products were low in 1925 the gains since 1910 were marked. Exports increased from $47,029,631 to $105,599,818; imports from $26,152,435 to $81,802,547; taxable property from $150,268,467 to $360,832,895; bank deposits from $13,324,305 to $60,809,716. Trade was chiefly with the mainland of the United States—$104,095,273 of exports and $72,145,418 of imports in 1925. The exports comprised sugar, $71,468,150; fruits and nuts, chiefly canned pineapples, $27,943,493; coffee, $1,197,535; sugar machinery, $616,270; and smaller values of molasses, hides, tallow, wool, canned fish, bananas, rice, honey and other products. Imports from foreign countries are largely nitrates from Chile, bags from India, and food supplies from Japan.

The sugar crop has increased considerably in recent years, not by increase of acreage, but by scientific discoveries of better methods of cultivation, fertilisation and irrigation, and new varieties of cane. The most striking feature in Hawaiian industries is the extent to which science is applied—through such agencies as the sugar planters' and U.S. experiment stations, the University of Hawaii and the territorial Bureau of Agriculture and Forestry. The yield of sugar per acre is larger than in any other country; but the cost is greater and 18 months is required for a crop. In 1925 the crop was 776,000 short tons—an average of about 6½ tons per acre. A few fields yielded over 18 tons, and one plantation averaged over 12 tons throughout. Half the acreage is irrigated by means of conduits from mountain streams, storage reservoirs and pumping from artesian and surface wells. The crops from the irrigated lands, though more costly, are so much greater as to be more profitable in general than those from the unirrigated lands in the wetter districts. The industry is conducted by corporations owning the mills and raising the cane. The capital stock is widely distributed and bought and sold freely on the exchange. The labourers receive house, fuel, water and medical attendance free. Day labourers, few in number, receive a minimum of a dollar a day plus a turnout bonus of 10% if they work 23 or more days a month plus a profit-sharing bonus of 1 % for each ¼ of a cent by which the average price of sugar for the month exceed 4½ cents. About 95% of the labourers take work by contract, as thi gives them greater remuneration and more independence. Much ha been accomplished in improving the living conditions of the em ployees by replacing tenements with cottages and garden space providing hospitals, entertainment halls and motion-pictures play-grounds, kindergartens, social-service workers, instruction i industrial methods and creating an *esprit de corps* by various means

The canned pineapple industry is entirely a growth of recen years. Its output in 1925 was 8,728,580 cases of two-pound cans One factory is the largest fruit cannery in the world. The cro has been increased materially by the use of mulching paper. This i rolled out on the fields in long strips, through holes in which th plants are set out. It serves many purposes, such as preventing weed from growing, conserving moisture, etc. While Hawaii exports an imports a larger percentage of what it produces and consumes tha most countries, there is nevertheless much subsistence farming, an several industries, such as the livestock and fishing industries, figur largely in local trade. Much attention has been given to the importa tion and raising of thoroughbred stock. The principal food of th Hawaiians is *poi*, manufactured from the root of the *taro*. There ar no mineral products except building stone, lime and salt. Althoug Hawaii is essentially an agricultural country, the industries are suc as require much manufacturing, not only directly, as in sugar, ric and coffee mills and fruit and fish canneries, but also indirectly, a in iron and fertiliser works and can factories of large size. Manu factures of other products, such as biscuits, macaroni, starch, shoes clothing, boats, etc., are on a small scale. Strikes of serious exten have occurred only twice, in 1909 and 1920, and unionism has ob tained little foothold. There is a compulsory Workman's Com pensation law.

Communications.—Commerce on the Pacific is growin rapidly owing to industrial development on both sides of th ocean and the construction of the Panama Canal. The Fed eral and territorial Govts. and private enterprises have de veloped shipping facilities in Hawaii, located as it is at the com mercial cross-roads provided facilities at lesser ports for inter island traffic; and developed the principal port on each of th four large islands for trans-Pacific and inter-island traffic. Al the newer wharves are of concrete. At Honolulu there ar electrical freight-handling apparatus, automatic coal-handlin plants, oil storage tanks connected with the wharves by pipe lin and floating dry-docks. From 1910–25 the number of deep-sc steamers, exclusive of naval vessels, army transports and coal bunker vessels, increased from 545 to 1,037; while sailing vessel decreased from 232 to 31, and the combined tonnage increase from 2,589,097 to 7,993,137 tons. Some of these vessels ply solely between Hawaii and ports of the United States, mainl San Francisco, Los Angeles and Seattle, but in part Atlanti ports; others are trans-Pacific, making Hawaii a port of cal between San Francisco and the Orient, Canada and the Antip odes, the Orient and Mexico or South America, while other are round-the-world steamers. A fleet of 13 steamers is engage exclusively in the inter-island trade. There are 350 m. of seve railways on the four principal islands and over 600 m. of privat railways on the sugar plantations. Hundreds of miles of con crete and macadam roads have been constructed. Besides cable there are four powerful wireless plants for trans-Pacifi communication, and smaller stations for communication be tween the islands and with ships at sea. The five larger island are well covered with efficient telephone systems.

Administration.—A direct primary law has been in operatio since 1913 and woman suffrage since 1920. Racial distributio of voters differs much from that of population, depending i the case of each race partly on eligibility to naturalisation an partly on the percentage born in the United States and th length of time the race has been in Hawaii. Hawaiians and part Hawaiians are citizens; adult immigrant Portuguese, Spanis and Porto Ricans have generally been ineligible for naturalisa tion because of illiteracy; and Chinese, Japanese and Koreans ar ineligible under the Federal laws. In 1924 the registered voter comprised 21,575 men and 13,164 women, as follows: Hawaiia and part-Hawaiian, 16,685; Latins, 5,203; other Caucasians 9,124; Chinese, 2,016; Japanese, 1,711. There are two mai political parties, Republican and Democratic, with the forme usually in the majority.

Finance.—The bonded debt of the territory on June 30 1925 was 17,990,000. This has been incurred since 1910 for public improvements. Much current revenue also is expended on public improvements. The only local-government indebtedness consists of $2,080,000 public improvement bonds of the city and county of Honolulu and $1,280,293 district improvement bonds, the latter payable solely by the property benefited, but $6,776,872 of the territorial debt has been incurred for county improvements, for which the counties reimburse the territory in interest and sinking funds. The total revenue of the territory and counties for the year ending June 30 1925 was 17,756,070 of which $8,283,262 went to the territory and $9,425,390 to the counties ($47,418 undistributed) as compared with $2,621,758 and $1,394,695 respectively in 1910. The Legislature has recently provided for a territorial budget system, a pension system for territorial employees, and a uniform accounting system for the counties.

Education.—The educational system of Hawaii ranks high in efficiency. It includes all grades from kindergarten to university as well as a normal school and schools for the physically defective and feeble-minded. There is much manual work and industrial training. Medical inspection of pupils is regularly made and treatment is furnished free or at moderate prices and attention is given to nutrition. The university, established in 1907, has 1,096 students. It possesses an aquarium and marine biological laboratory, conducts extension work and performs important services in industrial experimental and research work. The number of pupils in the schools increased from 25,537 in 1910 to 64,916 in 1925, of whom 55,044 were in the public schools and 9,872 in private schools. The cost of the public school system is about $5,000,000 a year. More than half the pupils are Japanese. In addition the Japanese maintain an extensive system of so-called language schools. In 1920–5 laws were passed subjecting all foreign-language schools, including some Chinese and Korean, to the supervision of the Department of Public Instruction, limiting the sessions to shorter periods restricted to after public school hours, requiring the teachers to pass satisfactory tests in the English language, American history and institutions and ideals of democracy, and providing for textbooks of superior pedagogical value and more suitable in subject matter for American pupils. In 1912 a territorial library was opened in Honolulu, with numerous stations throughout the territory which it supplies through travelling libraries.

Charities.—Of all the departments of the territorial government none except that of education is of wider scope or expends more out of current revenues than that of public health. Physicians are employed or subsidised so that all, however indigent or remote from population centres, may have proper medical attendance. The principal territorial institution under this department is the leper settlement on the island of Molokai, with its auxiliary hospital in Honolulu. Formerly emphasis was laid on isolation, but since 1909 emphasis has been placed on treatment, with the result that the number of lepers has been greatly reduced. Much progress has been made through scientific research and experimentation in effecting cures. Charitable and welfare institutions abound in Hawaii.

History.—Hawaii's recent growth in importance has been marked not only in the scientific development of industries and as the commercial cross-roads of the Pacific, but as a great tourist resort, as the great western military and naval outpost of the United States, and as the friendly meeting-place of East and West. The tourist business has come to rank third in extent. In 1909 the chain of small islands extending 1,200 m. to the northwest of the larger islands was created a bird reservation—the largest and most numerous bird colony in the world. In 1916 the active volcanoes of Kilauea and Mauna Loa and the extinct crater of Haleakala were created a national park. The capital city, Honolulu, has grown rapidly. The naval station and military post in Oahu Island are the greatest belonging to the United States. Honolulu has been the seat of numerous Pan-Pacific conferences to foster among Pacific peoples the spirit of inter-racial brotherhood and promote co-operation among them for their common welfare—scientific, educational, press, commercial and food conferences in 1920–4 under the auspices of the Pan-Pacific Union, and the Institute of Pacific Relations, patterned after the Williamstown Institute in 1925 under independent auspices. These unofficial conferences as well as the official Washington Conference bear witness to the growing importance of the Pacific area in world affairs. In 1920 the centenary of the landing of the missionaries was celebrated. The governors since 1907 have been: W. F. Frear, 1907–13; L. E. Pinkham, 1913–8; C. J. McCarthy, 1918–21; W. R. Farrington, 1921–.

HAWTREY, SIR CHARLES HENRY (1858–1923), British actor (*see* 13.104), was knighted in 1922 and died in London July 30 1923.

HAYASHI, TADASU, COUNT (1850–1913), Japanese statesman (*see* 13.109), died at Tokyo July 10 1913.

HAYES, PATRICK JOSEPH (1867–), American Cardinal, was born in New York City Nov. 20 1867. Graduating from Manhattan College in 1888, he continued his studies at St. Joseph's Seminary at Troy, N.Y., and was there ordained priest in 1892. After a graduate course at the Catholic University of Washington, he became curate of St. Gabriel's parish in East 37th St., New York City. In 1903 Archbishop Farley of New York, who had been his parish priest, appointed him his secretary and chancellor. In the same year Cathedral College was opened, and he became its first president, an office which he held for 11 years. In 1914 he was consecrated titular bishop of Tagaste and bishop auxiliary of New York. In the following year he was made rector of St. Stephen's Church, and on Nov. 24 1917 was appointed Catholic chaplain bishop for the U.S. Army and Navy, in which capacity he travelled extensively, appointing chaplains to the various camps. He was made Archbishop of New York in 1919. Early in 1924 he was summoned to Rome by Pope Pius XI. and was made a cardinal at a consistory held on March 25, being assigned the Church of Santa Maria in Via as his titular church.

HAZLITT, WILLIAM CAREW (1834–1913), British bibliographer (*see* 13.120), died at Richmond, Surrey, Sept. 8 1913.

HEALTH: *see* PUBLIC HEALTH.

HEALTH, MINISTRY OF.—The English Ministry of Health was set up by statute in 1919. The Act had as its principal object the concentration of the health services of England under a single Minister responsible to Parliament. These services had grown up under many departments: The Local Government Board, the Insurance Commissioners, the Privy Council, the Home Office and the Board of Education. The Act established a Minister of Health for England and Wales with a parliamentary under-secretary. Wales was given a Board of Health separately constituted but responsible directly to the minister. A similar Act was passed in the same year setting up a Scottish Board of Health. This last is a separate organisation and its parliamentary chief is the Secretary for Scotland, who has a parliamentary under-secretary for health for Scotland. There are thus two separate national health administrations in Great Britain whose only link is the association of their parliamentary chiefs in the Cabinet.

Powers of the Ministry.—The main organisation in the new Ministry of Health was the transformed Local Government Board, and this explains many of the functions, remote from its title, which the Ministry still exercises, such as, for example, its power over the finance of local authorities. When the Ministry came into being (July 1 1919) it assumed from that date the whole of

the powers and duties of the Local Government Board, and of the English and Welsh Insurance Commissioners, save for the powers of the latter over the Medical Research Council (then the Medical Research Committee). The powers of the Privy Council relating to midwives were immediately vested in the new Ministry. On Oct. 1 it took over, as provided by the Act, the powers of the Board of Education with respect to the health of mothers and young children, and of the Home Office in relation to infant life protection under the Children Act 1908. On Dec. 1 the Ministry further assumed responsibility for the duties of the Board of Education regarding the medical inspection and treatment of children and young persons. Arrangements had, however, to be made to enable certain of these latter duties to be carried out by the Board of Education on behalf of the Minister of Health.

In May 1920 the Ministry took over from the Home Office the administration of the Anatomy Acts and of certain powers and duties in relation to lunacy and mental deficiency. Many powers inherited from the Local Government Board have been similarly transferred to other departments, such as the Home Office, the Board of Education, the Electricity Commissioners and the Ministry of Transport. An example of this process may be seen in the Order in Council dated May 27 1921, transferring the powers of the Ministry over electoral registration and elections to the Home Office.

Activities of the Ministry.—The activities of the Ministry are classified in five main sub-divisions: (1) public health, (2) local administration and taxation, (3) housing and town-planning, (4) administration of the Poor Law and of the Old Age and Widows and Orphans, Pensions Acts, (5) national health insurance. Of these, housing is the greatest purely post-War development, and has under the 1919 (Addison) Act and the 1923 (Chamberlain) and 1924 (Wheatley) Acts expanded so greatly as to form almost a Ministry in itself. Important matters relating to health services and administration are still under other departments. Of these the Privy Council holds perhaps the greatest share, though the Home Office has duties in relation to the inspection of factories and workshops, etc., of much importance to national health. The Medical Research Council, as stated above, was not transferred to the Ministry with the other branches of the Health Insurance Commissions, but passed under the Privy Council. (The Medical Research Council originated under the Insurance Act of 1911 as the Medical Research Committee.) In addition the General Medical Council, the controlling body of the medical profession, is under the Privy Council and not the Ministry of Health.

The Scottish Board.—The Scottish Board of Health performs duties in Scotland almost identical with those of the Ministry of Health in England. It is derived similarly from the Scottish Local Government Board and the Scottish Insurance Commission. The only service with no English counterpart is that financed from the Highlands and Island Medical Services Fund (instituted by statute in 1913), which provides practically a State medical service in these areas and is subsidized directly from the Exchequer.

It will be seen that the Ministry of Health is in no sense a department corresponding, say, to the Ministries controlling any of the fighting services, with a unified authority and sole responsibility for one task and one task only, which in this case would be the safeguarding of the nation against disease and the increase of its physical efficiency. The fact that the health services are worked almost entirely through local authorities, themselves popularly elected, would make this in any case impossible. It is not yet certain, even, whether these "health" functions will ever form a major portion of the Minister of Health's task. So far, the housing problem, the supervision and overhauling of local government, and, from time to time, the solving of vexed questions in the national insurance schemes have thrown altogether into the background the direct purposes from which, presumably, the Ministry originally received its name. It is indeed more than doubtful whether the health problems of the nation, affected as they are so intimately by finance, by food supply and by distribution of population, can ever be satisfactorily separated from the other activities with which they interlock.

BIBLIOGRAPHY.—Very full information on all the subjects referred to will be found in the annual *Reports* of the Ministry and of the Scottish Board of Health. Health questions in particular are exhaustively dealt with in the separately published *Annual Report* of the Chief Medical Officer "On the State of the Public Health."

HEALTH INSURANCE: *see* INSURANCE, SOCIAL.

HEALY, TIMOTHY MICHAEL (1855–), was born at Bantry on May 17 1855, the son of Maurice Healy, clerk of the Bantry Union. His mother was the daughter of a schoolmaster in this little west Cork town. Three of her brothers, A. M., T. D. and Donal Sullivan, became Members of Parliament, as did three of her sons, Thomas, Maurice and Timothy Healy. The eldest married his cousin, a daughter of T. D. Sullivan. This group of closely related politicians was the nucleus of the "Bantry Band" which included also W. M. Murphy, M.P., founder of *The Irish Independent*. In the succeeding generation, Kevin O'Higgins, Timothy Healy's nephew by marriage, became vice-president of the Irish Free State when his uncle was made its first governor-general.

But the future governor-general inherited nothing but brains and a strong nationalist tradition. He began to earn his living at 13, and his early youth was spent as a shorthand clerk in a railway office at Newcastle-upon-Tyne. Here he became well known in Irish political and literary societies. In 1878 he moved to London and began in his spare time to contribute to the New York *Nation*. In 1879 Parnell on his first mission to America found that he needed a secretary and wired for Mr. Healy, who was already known to him. In 1880, after Parnell had been elected chairman of the Irish party, a parliamentary vacancy occurred in Wexford City, and Mr. Healy was elected.

From the first he slapped the House of Commons in the face, but he attended very closely to all its business. In 1881 Mr. Gladstone's Land Bill began the revolution which gave the Catholic Irish ownership of the land instead of being mere cultivators under landlords. Mr. Gladstone said that with the exception of three Irish law officers only Mr. Healy understood it, and it is doubtful whether anybody but Mr. Healy understood the effect of the famous "Healy clause." Introduced as an amendment, this guaranteed that in future rent should not be chargeable on tenants' improvements. When the bill became an act, Mr. Healy, called to the bar in 1884, defended the tenants' interests in innumerable cases that arose in its application. In 1883 his audacious tongue secured him the distinction of being sent to gaol. Later in the year when a Liberal seat became vacant in County Monaghan he was selected to make the first Nationalist inroad on Ulster. He won. At the general election of 1885 with the extended franchise Monaghan became a safe seat. Mr. Healy attacked South Derry and won the constituency—by surprise tactics. In 1886, however, he was defeated, but was returned for North Longford.

His relations with Parnell now became less friendly, and he joined Biggar in opposing the candidature of Captain O'Shea for Galway City. The opposition was only overborne by Parnell's personal intervention. But in 1889, when the divorce petition against Parnell was undefended, Mr. Healy drafted the resolution carried by the party in favour of Parnell remaining at his post. "Parnell," he said, "is not a man, but an institution." Later, however, in face of Mr. Gladstone's declaration, he changed his mind, and from the time the "split" began, no speeches were so envenomed as Mr. Healy's. He was twice publicly beaten; but no form of menace had ever the least effect on him. In 1892 he became member for North Louth, and, as a member of the anti-Parnellite party to which the large majority of Irish Nationalists belonged, he was specially supported by the Catholic clergy. His rivals for leadership, Mr. O'Brien and Mr. Dillon, had more following among the laity, but Mr. Healy was always a priests' man. At this time he devoted less time to politics, for his practice at the bar was increasing, and in 1899 he became Q.C.

On the reunion of parties in 1900 he joined Mr. O'Brien in urging that Mr. Redmond, leader of the Parnellite minority, rather than Mr. Dillon, leader of the anti-Parnellites, should be chosen as chairman of the united body. But a long indulgence in the savage spirit of faction which followed the Parnell "split" had rendered Mr. Healy difficult to work with, and in 1902, on the motion of Mr. William O'Brien, he was expelled from the United Irish League, though he retained the support of the Catholic hierarchy and of Mr. Murphy's influential newspaper. In 1906 Mr. William O'Brien, having split away from Redmond's main body with a few followers, made a working alliance with his former adversary and his brother Maurice, member for Cork City. In 1910, when Mr. Healy was beaten in North Louth, Mr. O'Brien provided him with a constituency in north-east Cork.

Mr. Healy joined the English bar in 1903 and took silk in 1910. He was unceasingly employed on English cases, more especially of a political character, and defended many of the suffragettes. In Parliament no speaker was more able to draw a crowded house, and his wit and eloquence were specially popular with the Tories, because he said more biting things of the Nationalist party than Englishmen could invent. With Mr. O'Brien he opposed the Budget of 1909 which led to the clash with the House of Lords; and on the Home Rule measure of 1912, while giving it general support, he furiously opposed partition.

In 1914 he was a vigorous supporter of Britain in the World War, but the course of events from 1916 onwards, culminating in the introduction of conscription, drove him finally to side with Sinn Fein, and in 1918 he resigned his seat to allow an imprisoned Sinn Feiner to be returned. Little was publicly heard of him during the years of turmoil which followed until, at the close of 1922, the constitution of the Irish Free State having been made law by the Irish Parliament, and subsequently by the British, the office of governor-general had to be filled. When Mr. Healy's name was first mentioned for the post there was general incredulity, but the appointment soon commended itself to Irishmen of all sections. The Free State Government, speaking through the mouth of Mr. Healy's nephew, Mr. Kevin O'Higgins, defended the choice of "an old man of the people," while others realised that Mr. Healy, though an extreme nationalist, had in many respects a most conservative mind. Those who feared the worst from a tongue and a temper which he had never before governed were surprised by the result; for during his continuance in office as the representative of King George Mr. Healy in no way added to the Government's difficulties, while he did more perhaps than any other person to cultivate the good will of the Protestant minority. (S. G.)

HEARST, WILLIAM RANDOLPH (1863–), American newspaper proprietor, was born in San Francisco, Cal., April 29 1863. He entered Harvard in 1882, but left after three years without finishing his course. As the only child of George F. Hearst, a mining man of great wealth, he had the use of ample capital at the outset of his career. In 1886 he became proprietor of *The San Francisco Examiner*, the first of a long chain of papers to come under his control. In 1895 he bought the New York *Journal* and in the following year founded *The Evening Journal*, the morning paper being known after 1902 as *The New York American*. Other papers founded by him were *The Chicago American* (1900); *The Chicago Examiner* (1902); *The Los Angeles Examiner* (1902); *The Boston American* (1904); and *The Atlanta Georgian* (1906). He also purchased *The Boston Advertiser* (1917); *The Chicago Herald* (1918), thereafter combined with *The Examiner* as *The Herald and Examiner; The Washington Times* (1919); and the Milwaukee *Wisconsin News* (1919). He was likewise proprietor of *The Cosmopolitan Magazine; Good Housekeeping Magazine; Harper's Bazaar; Hearst's Magazine; Motor Magazine;* and *Motor-Boating Magazine.*

Hearst's papers were sensational in form and contents and had an enormous popular circulation. They upheld the cause of the people against the moneyed interests, but the charge was often brought that they appealed to the baser passions. They were America's chief representatives of "yellow journalism" (*see* 19.569). In 1916 they were barred from circulation in Canada "because of garbled dispatches" concerning the World War. After America's entrance into the War they were frequently charged with disloyalty, and in many towns attempts were made to suppress them. From 1903 to 1907 Mr. Hearst was representative in Congress from New York, and in 1904 had support as presidential candidate at the National Democratic Convention. In 1905 he was Democratic candidate for mayor of New York on the Municipal Ownership ticket, and four years later on the Independence League ticket; in 1906 he was candidate for the governorship of New York on the Democratic and Independence League tickets, being defeated in every instance. He strongly opposed the League of Nations. He became head of the news syndicate known as the International News Service.

HEART, DISEASES OF THE (*see* 13.132).—The years from 1910 to 1925 have been a brilliant epoch in the history of cardiology. Most of the credit for this must be given to British workers, amongst whom the late Sir James Mackenzie and Sir Thomas Lewis have been pre-eminent. For a long time Mackenzie had been carrying out his memorable investigations on the venous pulse, using for this purpose a modification of Dudgeon's sphygmograph; but it was not until after his invention of the Mackenzie ink polygraph in 1908 that the investigation of cardiac arrhythmia by graphic records became at all general as a clinical routine. By means of this instrument, or better still by Lewis's modification of it, it is easy to obtain a prolonged simultaneous record of the arterial and venous pulses together with time marks of $\frac{1}{5}$ of a second. The careful study of such records yields much valuable information.

Electrical Records.—Electrical records of the heart beat have given even more accurate results. A minute electrical current is generated when the heart, or any other muscle, contracts; and in 1887 Waller was able to record the electrical current generated by the human heart beats, using for this purpose the capillary electrometer. In 1903 Einthoven, of Leyden, invented his string galvanometer (*see* 11.430), an extremely sensitive instrument capable of detecting a current of less than $\frac{1}{60,000}$ millionth of an ampère; this has the advantage of being practically aperiodic and free from "lag," grave defects of galvanometers previously used. It consists essentially of a powerful electro-magnet, between the poles of which is stretched a very fine fibre, usually a filament of drawn quartz, silvered to facilitate conduction.

If a minute electrical current passes along this fibre the fibre moves across the magnetic field in one direction or the other according to the direction of the current through it. By putting the human heart in electrical connection with the fibre, either by means of contacts from the chest wall in front of the heart, or, more conveniently, by three electrodes in which the two hands and one foot are immersed, the fibre is found to oscillate with each heart beat. The movements of the fibre are magnified by a projection lantern and photographed on a moving plate; the source of light is interrupted rhythmically at a known rate (usually every 1/25 of a sec.), and thus is obtained a curve of the electrical variations associated with each heart beat together with appropriate time marks. On such a curve the variations due to auricular and ventricular contraction respectively can be very clearly differentiated, the wave representing auricular contraction being designated arbitrarily as "P," and that representing the commencement of ventricular contraction "R." The time interval between these two components of each normal heart beat can be measured very accurately.

Heart Block.—In health this time interval is between 0·18 to 0·20 sec.; if the junctional tissues between auricle and ventricle are injured, either by disease or by cardiac poisons, conduction between auricle and ventricle is delayed and the "P.R." interval may become 0·24 sec., or even more. This state of affairs is known as heart block; and in its early stages can be recognised only by means of graphic records. With more severe damage of the junctional tissues, higher grades of auriculo-ventricular block ensue; thus the ventricle may respond only to every alternate auricular beat, or to every third or fourth auricular beat; or, finally it may be impossible for any stimuli to reach ventricle from auricle, in which case there is complete

dissociation between the upper and lower chambers of the heart, the former beating at their usual rate of 60–80 per min. while the ventricles take on a rhythm of their own, usually at a rate of about 35–40. This condition is known as complete heart block. The presence of these more serious grades of heart block can often be surmised on clinical grounds, but graphic records are essential for their certain recognition. Heart block is one of the rarer causes of irregular heart action.

Other Features.—There are other causes of cardiac arrhythmia, some of which are benign, others serious. Quite early in the century it was impossible to differentiate with certainty between the benign and the serious types. Now, thanks to the knowledge derived from graphic records, this differentiation can be made with confidence, and often without the necessity for taking polygraphic or electio-cardiographic tracings. For instance, previously "intermissions" of the pulse were always considered to be serious. Probably many an operation has been unnecessarily postponed or cancelled on account of what are known as "premature beats"; these are extra-contractions which arise, either in auricle or in ventricle, independently of the ordered sequence of normal beats, every one of which arises in the upper part of the right auricle (the sinu-auricular node) and spreads thence from auricle to ventricle. These premature beats are now easily recognised and, in itself, this type of arrhythmia is devoid of serious import; no surgeon would now think of postponing an operation merely because of the presence of this type of arrhythmia, which is almost invariably present from time to time in most elderly subjects.

Auricular Fibrillation.—But there is another common type of cardiac arrhythmia known as auricular fibrillation which is of much more serious prognostic significance. Here, as a result of serious pathological changes in the heart muscle, the auricles cease to contract rhythmically as a whole in a series of orderly beats; but the auricular musculature is in a constant state of incoordinate and futile twitchings; in consequence, the ventricles, instead of being stimulated from above rhythmically at the rate of about 70 per min., now are overwhelmed by a series of stimuli which pour down on them like an avalanche. They do their best to respond, and contract rapidly and irregularly at a rate of 120–180 per minute. This condition, sometimes known as "delirium cordis," is very constantly associated with cardiac failure, usually ending in dropsy, shortness of breath and eventually, if progressive, in death. It is a dangerous condition, but when recognised—and about its recognition there is now seldom any difficulty—it may be controlled by the administration of digitalis. This drug depresses the conductivity between auricle and ventricle, and consequently only the more powerful auricular stimuli reach the ventricle after its use; the ventricle now beats, still irregularly, but more slowly, and consequently, having time for a longer rest between each beat, more powerfully. The auricles may fibrillate in paroxysms lasting a few minutes, hours or days; but more commonly the condition is a permanent one. It brings about a very considerable degree of disability, but, if properly controlled by the use of digitalis and if the patient is content to live within his limits, it is often compatible with 10, 15 or even 20 years of very fair health.

The Circus Movement.—Lewis has recently demonstrated by means of the string galvanometer that in auricular fibrillation, as in its sister condition, auricular flutter, instead of each auricular beat arising, as described above, in the sinu-auricular node and radiating thence throughout the auricles, a "circus movement" takes place in the auricular muscle, often around the mouths of the great veins entering the right auricle. We have to conceive of a wave of contraction whirling around, usually in an irregular circle, and one whose disposition in space varies from beat to beat. From this contractile path are projected into the surrounding auricular muscle countless stimulating impulses, very much as sparks are thrown out from a catherine wheel, and, as a result, the whole of the auricular musculature is thrown into incessant, shimmering contractions. So soon as this explanation of auricular fibrillation was put forward and accepted, it was manifest that, if we could bridge the gap between the advancing crest and the retreating wake of the contracting wave in its "circus," the heart might revert to normal rhythm. It has been found that quinine and its allied alkaloids, of which quinidine is the one usually employed, have such an effect. In rather more than 50% of cases of auricular fibrillation it is possible to bring about a reversion to normal rhythm by the use of quinidine. Unfortunately the process is not devoid of risk, and there is a tendency for many of the cases to relapse into fibrillation when quinidine is withdrawn, so that cases for quinidine therapy should be carefully selected and its administration should not be attempted by those inexperienced in its use.

Paroxysmal Tachycardia.—This is yet another condition the recognition of which is often possible only with the aid of electrocardiographic records. Here the heart beats with great rapidity (rates of 150–200 per min.), but regularly. There is an abrupt transition from the normal and slow, to the abnormal and rapid rhythm; the attack may last for a few seconds, or for a few days, and ends as abruptly as it began. Such attacks may be associated with great respiratory and mental distress, and may lead to cardiac failure. Their differentiation from a purely nervous form of rapid heart action may be impossible without an electrocardiogram taken during both normal and abnormal periods. It is very important from the point of view of both outlook and treatment to be able to decide whether a case of palpitations is a purely nervous phenomenon, or true paroxysmal tachycardia, a more serious and intractable condition.

X-rays in Cardiology.—Of recent years X-rays have been used more and more in the investigation of cardiac disease. By their help alone really accurate information can be obtained as to the size of the heart and aorta. Percussion of the chest wall, and the location of the apex beat of the heart by the finger, are all we have to rely on, apart from X-rays, in estimating the size of the heart, and the information derived therefrom is vague and often misleading. By means of the X-rays the dimensions of the cardiac silhouette can be determined to a nicety, and much work has been done, particularly by French physicians, in ascertaining the normal standards of measurement of this cardiac silhouette and in tabulating departures from such standards in various pathological states.

Vital Capacity.—Much work has been done with regard to the vital capacity in health and disease. The vital capacity is the maximal amount of air which an individual is able to expire from the lungs after taking the deepest possible inspiration. As a result of vast numbers of observations by many different investigators all over the world we now know what the vital capacity of any healthy individual of a given height and weight should be. Disease of either heart or lungs may very materially diminish the vital capacity, and the figure obtained for an individual's vital capacity increases or diminishes according as the disease in question advances or tends to recovery. This, therefore, is a means of recording numerically a functional disability and its progress. This is a possibility the value of which is greater than is at first apparent. Unfortunately, the statement of a patient that he is better or worse is not always a true index as to the progress of his disease; and even when his doctor thinks there is an improvement, sometimes the wish is father to the thought.

The trend of all this instrumental investigation of the heart's action has been to stress the importance of the heart's muscle in cardiac pathology and to minimise the effect of valvular lesions, to which so much attention was formerly paid. Possibly the pendulum has swung a little too far in this direction, with the result that there has been a tendency to make light of, or even altogether to ignore, quite definite valvular lesions in the absence of any evidence of muscular defect. Such an attitude is deplorable, for it is doubtful if the heart's valves are ever diseased without, at the same time, some defect in the heart's musculature, and, in any case, it is manifest that a heart of which one of the valves either leaks or is narrowed is not as efficient an organ as one whose valves are healthy. The essential point is that the physician should refrain from diagnosing valvular disease unless he is sure of his grounds. Many of the cardiac mur-

murs heard through the stethoscope are not necessarily indicative of valvular or of any other disease. The innocuous nature of these "exo-cardial," "cardio-respiratory," or "haemic" murmurs, had long been known to the more experienced physicians, but it required the mass experiment of the World War to teach the lesson to the rank and file of the profession.

Lessons of the War.—During the early stages of the War thousands of healthy men were refused for general service on the grounds of such murmurs, and many thousands more were unnecessarily invalided out of the army, often with pensions, by reason of the discovery of such murmurs after enlistment. Another lesson of the War was that the condition known as soldier's heart is usually not associated with any disease of the heart itself. The rapid heart action which is the most striking feature of this condition, though it is, in fact, only one of many symptoms present, is due to a general rather than to a local condition.

In Dec. 1925 Yandel Henderson, of Yale University, published some work which may well prove to be of the greatest importance in clinical medicine as well as in physiology. He has succeeded in perfecting a comparatively simple method of determining in adult or child, healthy or sick, the output of the heart per beat. From this it is easy to calculate the actual work done by the heart, and to recognise with certainty departures from the normal standards of efficiency. Thus we now have, at last, a simple method of ascertaining with accuracy whether a heart is functioning normally or not, and of re-examining the patient from time to time, and observing whether a defect of cardiac function previously discovered is stationary, improving or deteriorating.

However valuable may be the information derived from electro-cardiographic and X-ray examination, from analyses of inspired and expired air, or of arterial and venous blood, and from many other modern methods of clinical investigation, no one of these ancillary diagnostic aids as yet surpasses or equals in importance the old-fashioned method of medical history taking. Symptoms properly elucidated and interpreted, are to-day, as previously, more important than physical signs and laboratory tests. An ache beneath the breastbone brought on by exertion and passing away with rest, is of more significance than an aberrant electro-cardiogram. It will be a bad day for clinical medicine when physicians devote their time entirely to laboratory methods of investigation and neglect the less dramatic but equally vital elucidation of the patient's symptoms.

(M. A. C.*)

HEART AND LUNG, SURGERY OF (*see* 13.133).—Since 1910 new surgical work on the heart has been mainly devoted to three subjects.

I. SURGERY OF THE HEART

Removal of Foreign Bodies Retained in the Heart Wall.—The safety of the methods of surgical approach to the heart has been further demonstrated. Surgeons in many countries have removed war missiles from the wall of the heart and from the pericardium with a surprisingly small mortality. R. le Fort (*Bull. et Mém. Acad. de Méd.*, vol. 80, p. 147, 1918) removed 11 foreign bodies from nine patients, with one death. Roberts successfully removed a bullet from the posterior wall of the left ventricle, which had been present for seven years and was causing cardiac disturbance. The approach by resection of one rib and traversing the pleura was excellent. He had also removed four fragments of shell from the pericardium in four patients by the same route, with no mortality.

Operations for Stenosis of the Valvular Orifices of the Heart.—A new field for surgery in the treatment of what has for long been a purely medical subject is being opened up by work which is at the present moment largely experimental. The subject is still in its infancy, but enough has been done to show that with further experience certain selected cases of mitral stenosis, in which the musculature of the heart has not been too much damaged, may be submitted to operation with a fair prospect of improvement. Duff S. Allen and E. A. Graham (*Jour. Amer. Med. Assoc.*, Sept. 23 1922 and *Arch. of Surg.*, Jan. 1924) have invented an instrument which they call a cardioscope. This is a tube, closed at one end by a lens, which is introduced into the heart through a small incision. When the lens is pressed against the heart wall so that no blood intervenes, the endocardium, illuminated by a small electric bulb, is clearly visible. In the wall of the tube is fitted a rod ending in a small knife, with which a stenosed valve may be incised under direct vision. In dogs, when the incision to introduce the cardioscope was made in the auricular appendix, all the dogs recovered. E. C. Cutler and S. A. L. Levine (*The Boston Med. and Surg. Jour.*, June 28 1923), believing that a mere incision in the stenosed ring will heal without relief of the stenosis, invented an instrument which punches out a piece of tissue.

They have used this successfully in the case of a girl, aged 12, suffering from mitral stenosis. She was alive 10 months later and was still improving. H. S. Souttar (*Brit. Med. Jour.*, Oct. 3 1925) reports a brilliant operation on a girl of 15 with mitral stenosis and regurgitation. He exposed the heart by a flap operation, and placed a light clamp on the base of the auricular appendix. After two guide sutures had been inserted, the appendix was incised and drawn over the finger like a glove, haemorrhage being thus obviated. The interior of the auricle was easily explored by the finger, no effect on the pulse being noted. The blood pressure instantly fell to zero as the passage of blood through the orifice was abolished. Souttar intended to divide the stenosed orifice with a knife passed along the finger, but as the stenosis was found to be of moderate degree with little thickening of the valve, he contented himself with stretching the orifice with the finger. The appendage was ligated at its base and the wound of the chest wall closed. The patient's condition was improved and she was well three months later, though still somewhat breathless on exertion.

Cervical Sympathectomy for Angina Pectoris.—The cause of this very distressing disease is not settled with certainty. But as changes in the cardiac muscle, coronary arteries and aorta are usually present it may be considered.

Jonnesco, of Bucharest, in 1916 first performed the removal of the left cervical sympathetic chain, including the upper and middle cervical ganglia and the first thoracic ganglion. The result, followed for four years, was complete relief from symptoms. T. Jonnesco operates under spinal anaesthesia (*La Presse Méd.*, April 26 1922). W. B. Coffey and P. K. Brown (*Arch. Int. Med.*, vol. 31, p. 200, 1923) report six cases with one death and great improvement in the other five, H. Lillienthal (*Arch. of Surg.*, vol. 10, p. 531, 1925) three cases. In one, the cervical sympathetic was removed on both sides. All were cured. H. H. Kerr (*Ann. of Surg.*, vol. 82, p. 354, 1925) reports five cases. He removes the superior cervical ganglion only, under local infiltration anaesthesia by novocain, and obtains the same results as the others by the more formidable operation performed by Jonnesco.

II. SURGERY OF THE LUNG

Since the World War the surgery of the lung has made great strides, and in all countries is engaging the attention of active workers. While differential pressure anaesthesia of some kind is still advisable, the introduction of intra-tracheal insufflation has enabled the elaborate and costly pressure chambers to be dispensed with. For many types of operation ordinary inhalation anaesthesia, especially by nitrous oxide and oxygen, suffices. Local infiltration anaesthesia, combined with nerve blocking by novocain or some similar drug, is largely used, and for some operations is essential. It is being combined with light analgesia by nitrous oxide and oxygen, or even ether by some surgeons in the case of nervous patients, for whom deep general anaesthesia is inadvisable (*see* ANAESTHETICS).

Surgical Treatment of Pulmonary Tuberculosis.—Direct operations on the tuberculous lung, either by drainage of tuberculous cavities or the resection of one or more lobes of the lung, have been abandoned by the majority of thoracic surgeons. The great advance in latter years has been in devising methods of collapsing the affected lung either temporarily or permanently.

Principles of Collapse Therapy.—In all other parts of the body it is found that rest of the affected part is beneficial, but in the case of the lung the respiratory movements, exaggerated by coughing, continue unless the lung is compressed. By collapse, stasis in the lymphatic vessels occurs, preventing spread of tubercle bacilli to other parts of the lung and diminishing the entrance of toxins into the general circulation with consequent improvement of the general resistance of the body. Congestion of the collapsed lung with blood appears to occur, favouring the formation of fibrous tissue and healing of the lesions. Mechanically, the effect is to allow the retraction of the new formed fibrous tissue and to collapse cavities and dilated bronchi. This prevents the retention of secretions, which often become secondarily infected with other organisms, and allows the walls of the cavities to come in contact and so to heal. This retraction occurs normally to a limited extent by the pulling up of the diaphragm, the pulling over of the mediastinum, and the assumption of the expiratory position by the ribs, but falls far short of that necessary for complete obliteration of the cavities.

Methods of Producing Collapse.—Artificial pneumothorax was first proposed by James Carson, of Liverpool, in 1821, but was introduced into practice by Forlanini, of Pavia, in 1882 (*Gazz. d. Osp.*, 1882). It is now extensively practised by physicians all over the world. By the introduction of air, oxygen or nitrogen through a hollow needle into the pleural cavity the lung may be more completely collapsed than by any other method. As this method is simple and satisfactory it is the method of choice, and other operations are only undertaken when this is impossible, through the presence of adhesions binding the two layers of the pleura together (*see* PNEUMOTHORAX).

Division of Adhesions.—Where the adhesions are few and bandlike, so that a partial collapse only can be obtained, it is necessary to divide them. The operation of thoracotomy and division of the bands by direct vision is unnecessarily severe. Jacobaeus, of Stockholm, in 1913 devised an instrument similar to a cystoscope, which he calls a thoracoscope. After the induction of a pneumothorax this is introduced under novocain anaesthesia through a canula. Through a smaller canula a galvanocautery is introduced. Thus the adhesions may be burnt through under the vision of the operator without opening the chest cavity (H. C. Jacobaeus, *Proc. Roy. Soc. Med.*, 1922–3, vol. 16, p. 45). By using the cautery at a red heat only, haemorrhage is avoided. The adhesions often pull out a cone of lung substance in which may be a prolongation of a lung cavity, so that it is important to burn the adhesions through as near the chest wall as possible.

Paralysis of the Diaphragm.—Stuertz first proposed this operation by division of the phrenic nerve in the neck, which was independently devised by Sauerbruch. The result of depriving the diaphragm on one side of its motor innervation is that it rises in the thorax as much as 2½ to three in., thus allowing the lower lobe partially to collapse and putting it at rest. The operation is easily done in a few minutes under local anaesthesia by novocain, the nerve being found running obliquely across the scalenus anticus muscle in the neck. At first the nerve was simply divided, but it was found that accessory fibres joined it below the point of section in 20–30% of individuals. W. Felix's operation of " Exairesis " (*Deutsch. Ztsch. f. Chir.*, No. 171, p. 283, 1922) has gained favour. In this modification the lower end of the divided nerve is seized in forceps and gradually drawn out of the thorax. Sometimes the whole length of the nerve as far as the diaphragm is successfully extracted, but in any case the collaterals which join it in its upper part are also severed so that the paralysis is complete. The operation is used where basal adhesions are preventing full collapse in pneumothorax, as an addition to thoracoplasty, in some cases of early tuberculosis of the lower lobe only and for the relief of pain in the region of the diaphragm on coughing.

Extrapleural Pneumolysis.—The operation consists in separating the parietal layer of the pleura from the chest wall over a limited area and filling the space thus formed with some material which is not absorbed, thereby compressing the lung beneath. A portion of one rib is resected and the posterior periosteum and endothoracic fascia are carefully incised. The gloved finger then separates the outer surface of the parietal pleura from the inner surface of the endothoracic fascia. As the air which enters the cavity thus formed is rapidly absorbed it is necessary to provide some filling. Tuffier, in 1910, first used fat obtained from omentum or a lipoma. This has become one of the favourite methods, the fat being obtained from the patient's thigh (Tuffier, *Bull. et mém. Soc. de Chir. de Paris*, vol. 49, 1249, 1923). If a very careful aseptic technique is not followed the fat may be extruded. Owing to the difficulty of obtaining enough fat, Baer, in 1913, used a paraffin filling (H. Baer, *Münch. med. Wochenschr.*, vol. 68, 1921). This is readily available but is heavy, and tends to be extruded later in many cases. E. W. Archibald, of Montreal (*Am. Rev. of Tuberc.*, vol. 4, p. 828, 1921), has used a pedicled muscle graft obtained by detaching the pectoral muscle.

The operation is almost confined to apical lesions and is used either alone, or following thoracoplasty, in cases where the apex of the lung is incompletely collapsed. It may also be of service where the apex alone is adherent and a satisfactory pneumothorax has collapsed the lower part of the lung.

Extrapleural Thoracoplasty.—Collapsing operations on the chest wall were suggested as long ago as 1888 (Quincke) and 1890 (Spengler). In 1907 Brauer and Friedreich removed large portions of the ribs in their lateral portions. Wilms, in 1911, removed portions both posteriorly and anteriorly. The modern operation of paravertebral thoracoplasty is due to Sauerbruch and the Scandinavians: Bull, of Osol; Saugman, of Veilefiord; Jacobaeus and Key, of Stockholm. The operation may be done in one, two or more stages and consists essentially in resecting a portion of the first to the 10th or 11th ribs posteriorly through a long incision posterior to the scapula and turning forwards along the 10th rib. The muscles attached to the scapula are divided and the scapula is turned forwards. It is essential that the ribs should be resected as far back as the tips of the transverse processes of the vertebrae. The length of rib removed varies from ½ in. of the first rib to 7 or 8 in. of the middle and lower ones. The operation is a severe one, but the mortality, which was at first about 8% has been reduced by proper selection of cases to about 2% in the hands of experienced operators. Many operators still prefer a local anaesthesia by novocain, but the tendency now, except in cases with profuse sputum, is to operate under general anesthesia by nitrous oxide and oxygen preceded by an injection of morphine and hyoscine. The results of these operations have shown that in cases of unilateral or mainly unilateral pulmonary tuberculosis which are not improving under sanatorium treatment a new field of hope is opening out. F. Sauerbruch (*Chir. der Brustorgane*, 1920), H. C. Jacobaeus and E. Key (*Acta Chir. Scand.*, 1923); P. Bull (*Proc. Roy. Soc. Med.*, 1924, vol. 17, p. 1); J. Alexander (*Surg. of Pulmon. Tub.*, 1925); J. Gravesen (*Surg. Treat. of Pulmon. and Pleur. Tub.*, 1925).

Bronchiectasis.—Three types of operation are used in the treatment of this distressing condition: (1) Drainage operations, (2) operations to collapse the lungs, (3) radical excision of the affected part of the lung. (1) Drainage operations are palliative only and aim either at drainage of abscess cavities or, by making a permanent bronchial fistula, at reducing the amount of sputum. (2) All the forms of collapsing operations which are in use for pulmonary tuberculosis have their place in the treatment of bronchiectasis. They are phrenicotomy, pneumothorax, extrapleural pneumolysis and extrapleural thoracoplasty. The principles involved are, firstly, that the spaces in which secretions collect and decompose are obliterated by the collapse of the lung, and secondly that the new formed fibrous tissue in its contraction no longer pulls open the walls of the bronchi softened by inflammation, but can now pull inward the mobilised walls of the thorax. (3) In certain types of bronchiectasis the results of collapsing operations are not satisfactory, and in consequence amputation of the affected lobe or lobes of the lung has been performed. This procedure has produced real cures but the mortality of the operation is high. The longest series of cases is that published by H. Lilienthal, of New York (*Arch. of Surg.*,

ol. 8, 1924), whose mortality is nearly 50%. Many of his atients were, however, desperately ill. Evarts A. Graham *Arch. of Surg.*, vol. 10, p. 392, 1925) has practised pneumectomy y the actual cautery, in one or several stages, on 20 patients. f these, 50% were cured, 30% improved and 20% died.

Intrathoracic Tumours.—Innocent intrathoracic tumours are eing diagnosed with greater frequency owing to the increasing se of X-rays. H. C. Jacobaeus and E. Key (*Acta. Chir. Scand.*, ol. 53, p. 573, 1921) have successfully removed four fibromata y the transpleural route. T. P. Dunhill (*Br. Jour. of Surg.*, 922) removed a fibroma by Gask's modified sternum splitting peration. J. E. H. Roberts (*Tr. Roy. Soc. Med.*, 1926) has emoved four innocent tumours, two fibromas, an encapsuled ndothelioma and a dermoid cyst, three by the transpleural oute and one by sternum splitting.

Malignant Tumours of the Lung.—Radical operations for the emoval of carcinomata of the lung are rarely possible owing to he later stage at which patients come under observation. . Sauerbruch (*Chir. der Brustorgane*) has operated in five cases:)ne, with a carcinoma of the lower lobe the size of a small fist, as alive five years later; another was alive after three years. auerbruch advises a two-stage operation or three-stage opera- ion, ligature of the branch of the pulmonary artery to the ffected lobe being done as a preliminary followed by thora- oplasty and resection of lung.

Palliative operations often give great relief from distressing ymptoms and prolong life for many months; they are (1) rainage of a secondary lung abscess or empyema, (2) drainage f a sterile abscess due to necrosis of growth, (3) exposure of he growth for the insertion of radium, (4) treatment by X-rays.

HEAT (*see* 13.135).—The summary of recent works, given elow, is arranged for convenience as far as possible in the order f the earlier articles connected with heat in the 11th ed. of the *E.B.*, as enumerated in 13.157, and references to them are made here necessary.

International Notation.—The symbolic notation here adopted s based on that recommended by the International Commission or the Unification of Physico-Chemical Symbols at their meet- ng at Brussels in 1913, as extended by a special Committee of he Physical Society of London under the presidency of Sir J. J. Thomson. Fortunately their recommendations coincide in the nain with the notation employed in the 11th ed. of the *E.B.*, ut a few changes have been made for the sake of uniformity, s indicated in the following list.

Alphabetic Index of Symbols.

A = 1/J, Reciprocal of mechanical equivalent of heat.
a, Numerical factor for reducing PV to heat units.
B, Constant of integration in expressions for E and H.
b, Co-volume in characteristic equation of gas.
C, Cooling-effect of Joule and Thomson (*see* 27.901).
c, Co-aggregation volume in gas-equation.
E, Intrinsic energy.
G, Gibbs' function, TΦ − H.
H, Total heat of vapour, E + aPV.
h, Total heat of liquid.
J, Joule's equivalent.
K, *k*, Thermal Conductivity, and Diffusivity.
L, Latent heat.
M, Mass.
m, Molecular weight or mass-flow.
N, Number of atoms or molecules.
n, Index in formula for *c*.
P, Pressure generally.
p, Saturation-pressure.
Q, Quantity of heat energy.
R, Gas-constant in PV = RT.
S, Specific heat of vapour; *s*, of liquid.
T, Absolute temperature; *t*, from 0°C.
U, Velocity of motion.
V, Specific volume of vapour; *v*, of liquid.
W, Work.
X, Cross-section of pipe or nozzle.
Φ, Entropy of vapour; *φ*, of liquid.
β, Radiation constant in $\beta v T$.
γ, Ratio of specific heats of gas.
Λ, Velocity of light, 3×10^{10} cms/sec.
λ, Wave-length; *ν*, frequency.
η, Viscosity of gas.

CALORIMETRY

Units of Heat.—One of the most fundamental points in the measurement of heat is the relation between the practical units corresponding to the various methods discussed in the earlier article (*see* 5.60), in which the most important experimental evidence then available was described and reviewed. Some of the conclusions reached have since been contested, but additional experimental evidence has been obtained which seems to confirm the views previously maintained.

The experiments of Rowland by the mechanical method, agreeing closely with those of Joule when reduced to the scale of the gas thermometer, showed that the gram-calorie at 20° C. (defined as the quantity of heat required to raise the temperature of 1 gram of water at 20° C. under atmospheric pressure by 1° C. on the scale of the hydrogen thermometer) was equivalent to 4·180 joules of mechanical energy. Those of Reynolds and Moorby between 0 and 100° C. gave the equivalent of the gram-calorie as 4·1832 joules for the mean of the whole range, showing that the mean calorie was nearly the same as the calorie at 20° C., in contradiction to the results of earlier experimentalists who had obtained much higher values for the mean calorie. The best of the previous results by the method of mixtures for the variation of the specific heat of water between 0° and 100° C. were those of Lüdin (*see* 5.64, fig. 6), which gave a somewhat improbable curve for the variation, indicating a value 4·206 joules for the equivalent of the mean calorie, if the calorie at 20° C. was equivalent to 4·180. Most of the older results for the mean calorie, *e.g.*, those of Dieterici (*Wied. Ann.*, 33, p. 417, 1888), giving 4·244 by an electrical method with an ice-calorimeter, were much higher than Lüdin's. On the other hand, the continuous electrical method (*see* 5.65), in which platinum thermometers were employed in place of mercury thermometers, while agreeing very closely with Rowland's results from 5° to 30° C., gave a much slower rate of increase than Lüdin's for the specific heat between 40° and 100° C., and a value 4·186 joules for the mean calorie, confirming Reynolds and Moorby.

The later experiments of Dieterici, by the method of the ice-calorimeter employing a 10 times smaller current with a coil of higher resistance in order to reduce the uncertain errors of the electrical measurement, gave an equivalent 4·192 joules for the mean calorie. He also redetermined the constant of the ice-calorimeter, using water at 100° C. sealed in thin bulbs of quartz-glass, and obtained a value 15·491 milligrams of mercury per mean calorie, appreciably higher than the value 15·44 previously employed. This has since been confirmed by E. Griffiths (*Proc. Phys. Soc.*, 26, p. 1, 1913) who found the value 15·486 for a mean calorie of 4·184 joules. Owing to the smallness of the quantities of heat available for measurement at low temperatures, the ice-calorimeter is unsuitable for investigating the variation of specific heat in the neighbourhood of the freezing-point, but the observations of Dieterici at temperatures above 100° C. by the same method gave a rate of increase of the specific heat of water slightly exceeding that found by Regnault, which could not be reconciled with Lüdin's curve showing a maximum of specific heat at 87° C.

Messrs. W. R. and W. E. Bousfield (*Phil. Trans.*, A, 211, pp. 199–251, 1911) succeeded in reproducing Lüdin's results with remarkable fidelity by a most ingenious method of electric heating with a vacuum-jacket calorimeter. The heating-coil consisted of a long spiral of small-bore glass tubing filled with mercury, the expansion of which in a capillary tube was made to indicate the actual temperature of the mercury at any time when traversed by the electric current. The observers were thus enabled to avoid the source of error due to the superheating of the conductor above the temperature of the calorimeter. The uncertainty of heat-loss by evaporation from the surface of the water was minimised by protecting the surface with a cover in the form of a metal box maintained as nearly as possible at the same temperature as the water during an experiment. The rise of temperature over predetermined ranges, 0°–13°, 13°–27°, etc., was observed with suitable mercury thermometers of limited scale, standardised at the National Physical Laboratory. The corresponding quantities of electrical energy supplied, when corrected for external heat-loss and for the thermal capacity of the calorimeter, gave the increase of total heat of water, or the mean specific heat over each range. By adding the increments of total

heat for each range, the *variation* of the total heat h, or the small difference $h-t$, could be obtained at each of the points of observation, as in the following table:—

Temperature C.	13°	27°	40°	55°	73°	80°	100°
Bousfield	0·058	0·058	0·059	0·124	0·242	0·306	....
Lüdin	0·057	0·059	0·064	0·119	0·285	0·371	0·633
Formula (1)	0·070	0·072	0·054	0·038	0·046	0·062	0·159
Dieterici	0·010	0·011	0·013	0·031	0·090	0·128	0·303

Bousfield's observations did not extend beyond 80°, owing to the difficulty of excessive evaporation with an open calorimeter. According to his curves, the corresponding values of the specific heat appear to be approaching a maximum at 80° C., a little lower than that shown by Lüdin's curve. The value of the specific heat at 80° C., according to Lüdin's formula, is 1·0184 in terms of the specific heat at 20° C. taken as unity, and exceeds the value given by the continuous electric method by 1·55 %. This looks alarming at first sight, but the method of comparison in terms of the actual specific heat, though commonly adopted, is really unfair, because the quantity actually observed in Lüdin's method is the total heat, which shows a difference of only 0·31 calorie according to the above table at 80° C. Dieterici's observations at 100° C., where they were most reliable, differ by only 0·14 % from the continuous electrical method, and he does not claim an order of accuracy greater than 0·1 % for the ice-calorimeter.

Continuous Mixture Method.—Since the number of separate determinations of the specific heat of water at points between 50° and 100° C. by the continuous electric method was only 12, and since these were made under conditions of exceptional difficulty, and differed most widely from the values found by Lüdin and Bousfield, it was felt to be desirable to confirm the variation in this region by an entirely independent method of equal accuracy. The continuous mixture method (Bakerian Lecture, *Phil. Trans.*, A, 1912, vol. 212, pp. 1–32) was devised for this purpose, and consisted in passing a steady current of water, initially at 100° C., through an interchanger, in which it gave up a large part of its heat to a current of cold water initially at 25° C., emerging at a temperature in the neighbourhood of 70° C., without having actually mixed with the cold current. The same current was then cooled to an accurately regulated temperature in the neighbourhood of 25° C., and re-entered the interchanger as the cold current. The point of the method is that the circulation is continuous, so that the water equivalent of the interchanger is not required, and that the hot and cold currents are *the same*, so that the quantity of the current divides out of the equation (except in the small term representing the external heat-loss) and need not be determined with an accuracy greater than 1 %, since the external heat-loss can easily be reduced to a small fraction of 1 % of the heat-exchange between the currents. The actual temperatures t_1 and t_2 of the hot current on entering and leaving the interchanger, and those of the cold current, t_3 and t_4, were observed with platinum thermometers to 0·001° C. If s' is the mean specific heat of the hot current between t_1 and t_2, and s'' that of the cold current between t_3 and t_4, we have the equation

$$s'(t_1-t_2)=s''(t_4-t_3)+X/M,$$

where X is the external heat-loss in gram-calories per second, and M the value of the water current in grams per second. The heat-loss was determined, as in the continuous electric method, by varying the flow M while keeping the temperatures the same. In a large number of trials it was found that the ratio of s' to s'' agreed with the value 1·0050 given by the continuous electric method, but disagreed materially with the value given by Lüdin's formula. It was concluded that the discrepancy from Lüdin's formula was probably to be attributed to the unavoidable errors of his method, due to losses by evaporation at temperatures above 50°, and to the uncertainties of zero-point and stem-exposure which cannot be eliminated in the employment of mercury thermometers.

Formulae for the Specific Heat of Water.—It is usual to employ an empirical formula of the type, $s=1+at+bt^2+ct^3+$etc., which is familiar and convenient for the application of the method of least squares to the results of observation. The formulae most often quoted for water are those of Lüdin and Dieterici, which are as follows in terms of the calorie at 20° C.:—

Dieterici, $s=1\cdot0013-0\cdot0104(t/100)+0\cdot0208(t/100)^2$

Lüdin, $s=1-0\cdot07668(t/100)+0\cdot196(t/100)^2-0\cdot116(t/100)^3$
$\pm0\cdot00025 \quad \pm0\cdot040 \quad \pm0\cdot030$

The probable errors of the coefficients, as given by Lüdin, are shown in the line below his formula. The formula of Dieterici represents his observations satisfactorily from 50° to 300° C., but does not apply to the variation near the freezing point, which cannot be represented satisfactorily by this type of formula without an additional term. The formula of Lüdin is fairly accurate between 0° and 25°, but appears to give results about 1 % too high between 60° and 90° C. It is also inconvenient in practice, because the coefficients are large and of opposite signs, giving the small variation required as a difference between relatively large terms. In the preliminary reduction of the results of the continuous electric method (*B. A. Rep.*, 1899) it appeared that a formula of this type would be unsuitable, and the observations were accordingly represented by three simple formulae for different ranges of temperature between 0° and 200° C., as given in the previous article (*see* 5.66). These have since been combined into a single equivalent formula, which is more convenient for several purposes:—

$$s=0.98536+0\cdot504/(t+20)+0\cdot0084(t/100)+0\cdot009(t/100)^2 \quad (1)$$

The value of the constant is adjusted to make $s=1$ when $t=20°$. The other terms are small and positive, and can be calculated with sufficient accuracy for all possible purposes by means of a 10-in. slide rule. This formula agrees very closely with the table previously given, but represents a later and more accurate reduction. It is of no theoretical significance, and cannot safely be extrapolated much above 100°C., but still agrees very closely with Regnault's observations at 160° C. Above 100° C. it is better to use the thermodynamical formula (*see* 27.903) suggested by McF. Gray, which agrees very closely with experiment from 40° to 100° C., but does not represent the increase of specific heat with fall of temperature near the freezing point. Gray's formula was re-defined by Callendar as representing the change of total heat of water under saturation pressure, and then agrees very closely with the observations of Dieterici at high temperatures, when corrected to give the change of total heat in place of the intrinsic energy. It has a simple theoretical foundation, and greatly simplifies the thermodynamical relations between liquid and vapour. There is good reason to believe (Callendar, *Properties of Steam*, pp. 160, 196) that it continues to hold satisfactorily right up to the critical point, where the specific heat becomes infinite.

By experiments on the supercooled liquid, Prof. H. T. Barnes has shown that the increase of specific heat with fall of temperature continues to follow the same curve above and below the freezing point. By very accurate experiments on mercury, using the continuous electric method, he has shown that a diminution of the specific heat with rise of temperature occurs as in the case of water, but persists up to a minimum at 140° C. It appears probable that a similar phenomenon would be found for all liquids at low vapour pressures, but it is masked in the case of volatile liquids by the opposite effect of the vapour-molecules, as represented by the thermodynamical formula. The diminution of the specific heat of water was attributed by H. A. Rowland to the presence of a small proportion of solid-molecules in the liquid near the freezing point. The rapid increase of the specific heat of a solid as the fusing-point is approached may similarly be attributed to the presence of a small but rapidly increasing proportion of liquid-molecules in the solid. The proportion required in either case, to explain the diminution of hardness and rigidity of the solid, or the anomalous expansion of water near the freezing point, is small, but cannot be calculated with certainty on account of our imperfect knowledge of molecular forces and dimensions. Such a theory would be difficult to verify in any case by experiment for the liquid and solid molecules.

Specific Heat of Gases and Vapours.—The continuous electric method was first applied in the case of steam (*see* 27.901) and gave results near 100° corroborating Regnault's value at higher temperatures. The same method was applied to air and CO_2 by W. F. G. Swann (*Phil. Trans.*, A, 1910, vol. 210, p. 199), who found results from 2 to 5 % higher than those of Regnault. Swann's formula has since been verified by Holborn and Jakob (*Zeit. Ver. Deut. Ing.*, 58, p. 1429, 1914) and it is now generally recognised that this method is the most accurate for the determination of the specific heat of any fluid at constant pressure. Swann's values for air at 20° and 100° C. were closely consistent with those of Joly at constant volume (*see* 5.67), and gave a ratio of specific heats very nearly equal to 1·40, as required by the kinetic theory for a diatomic gas. They also showed a very small increase with temperature at the rate of only one-half of 1 % for 100° C. His values for CO_2 verified with improved accuracy the rapid increase with temperature found by Regnault and Wiedemann for this gas, which amounted to 12 % for 100°. This increase of specific heat was not accounted for on the kinetic theory, which required that all the degrees of freedom of a gas molecule should be equally excited, and should contribute constant terms to the specific heat. The apparent discrepancy was explained (*B. A. Rep.*, 1908, p. 340) by supposing that a natural frequency of the gas-molecule would be excited by radiation in direct proportion to the intensity of the corresponding frequency at each temperature. It was shown that a natural frequency having a wave-length of the order of 15 microns would be competent to produce the observed effect in the case of CO_2, contributing, when fully excited, a term R to the specific heat. An attempt was accordingly made to investigate the relation between the variation of the specific heat of gases and the absorption and emission bands in their infra-red spectra. Some qualitative agreement was found, but it was very difficult to make quantitative measurements of the kind required, or to frame a consistent theory. For instance, there is a strong band at 4·4–4·5 microns both in the emission and absorption spectra of steam. This band corresponds to the maximum ordinate of the wave-length spectrum of full radiation at a temperature T=647° C., the critical point of water, and appears to be closely related to other properties of steam. There is no doubt

that the properties of any substance are intimately related to the natural frequencies of the molecules, but the form of the relation cannot be predicted with certainty; and the quantitative measurements are not yet sufficiently exact to distinguish between many possible hypotheses.

The experiments of A. Eucken (*Sitz. Akad., Berlin*, 33.1, p. 141, 1912) on the specific heat of hydrogen at low temperatures were very instructive in this connection. The gas was electrically heated at various temperatures in a thin steel vessel under considerable pressure at constant volume. The specific heat was found to diminish from nearly 5R/2 at ordinary temperatures to nearly 3R/2 at T=60°, after which it remained practically constant down to T=35°. The experiments were undoubtedly of considerable difficulty, but there seems no reason to doubt their substantial accuracy.

Eucken's results have recently been confirmed with remarkable precision by J. H. Brinkworth (*Proc. Roy. Soc.* (A) 207, p. 542, 1925) using an entirely independent method of experiment. He observed the cooling effect in adiabatic expansion with a compensated platinum thermometer at various temperatures between 20° C. and −183° C., and deduced the corresponding values of the ratio of the specific heats at constant pressure and at constant volume. The actual specific heats at any temperature could be deduced with certainty from these observations. This method is unaffected by the thermal capacity of the containing vessel, whereas in Eucken's method the thermal capacity of the vessel must be known with considerable accuracy. Brinkworth also showed that the heat-loss could be most satisfactorily eliminated by using vessels of different sizes. Assuming that the variation of the specific heat was due to the response of some particular frequency of the molecule to the same frequency in natural radiation at each temperature, he states that Callendar's radiation formula fits the observations better than Planck's but that satisfactory agreement cannot be obtained by assuming a *single* frequency. Reiche's calculations do not seem to improve the agreement. The effect is probably due to an absorption band of $\lambda = 25$–30μ in the infra-red.

Specific Heat of Solids at Low Temperatures.—The early experiments of Sir J. Dewar, Sir W. A. Tilden and others, had shown that solids at low temperatures deviated from Dulong and Petit's law of the constancy of atomic heat in the same way as carbon, boron and silicon, at ordinary temperatures, but they failed to show the full extent of the deviation, or to indicate a probable explanation. A. Einstein suggested (*Ann. Phys.*, 22, p. 180, 1907) that the atom of a solid might be regarded as an electric resonator with three degrees of freedom possessing a particular frequency, independent of the temperature, and capable of responding to the same frequency of radiation. Adopting Planck's theory and radiation formula, he showed that the specific heat at constant volume should approach the limit 3R = 5·94 calories per gram-atom at high temperatures, as required by Dulong and Petit's law, but that the variation at low temperatures should be given by the expression

$$s = 3Rz^2e^z/(e^z-1)^2 = 3Rf(z) \qquad (2)$$

where $z = \beta\nu/T = C/\lambda T$, as in Planck's formula. The symbol ν denotes the natural frequency of the atoms, and λ the corresponding wave-length in cm. such that $\nu\lambda = \Lambda = 3\times10^{10}$, the velocity of light. The constant, $\beta\Lambda = C$, is Wien's constant of radiation. Taking H. F. Weber's observations on the variation of the specific heat of the diamond, extending from T = 222° to 1258°, Einstein showed that they agreed qualitatively with this formula, if we could assume the diamond atoms to possess a single frequency corresponding to the wave-length 11 microns. Taking the substances, CaFl, NaCl, KCl, $CaCO_3$ and SiO_2, for which the optical frequencies in the infra-red were known, he showed that the frequencies agreed in order of magnitude with those required by his formula, but that the observed wave-lengths were somewhat shorter than those calculated from the specific heats. This could be attributed to the fact that most of the substances showed more than one frequency, and that the frequencies were not strictly monochromatic, as indicated by the width of the corresponding absorption bands. In any case there were other effects, such as work of expansion, included in the specific heats as ordinarily measured, and it might be doubted whether the optical frequencies corresponded exactly with the thermal vibrations of the atoms.

An important series of experimental measurements, extending down to the temperature of liquid hydrogen, was made by W. Nernst, F. A. Lindemann and their collaborators (*Sitz. Akad., Berlin*, p. 494, 1911), on a number of metals and other solids, including those for which the optical frequencies were known. They found, as already indicated, that Einstein's formula gave too low values for the specific heats at low temperatures, if the optical frequencies were assumed in calculating the value of $f(z)$, and that much better agreement could be obtained by taking the mean of $f(z)$ for the optical frequency, and a similar term, $f(z/2)$ at half the optical frequency:—

$$s = 3R[f(z)+f(z/2)]/2 = 3Rf''(z) \qquad (3)$$

The same function, $f''(z)$, of z was assumed to apply to other substances, such as the metals, but the appropriate values of z were selected to fit the observations on the specific heats. Some substances, such as SiO_2 (in the forms of quartz and quartz-glass) and benzine, C_6H_6, which gave a different type of curve, were represented by formulae with two or three different values of z, each value of $f''(z)$ being multiplied by a fractional coefficient representing the proportion in which the corresponding molecule was supposed to be present. But such cases could not be regarded as a verification of the theory, because it would obviously be possible to represent almost any type of variation in this way. Einstein objected that even the simplest of these formulae, namely (3), was too empirical to be satisfactory from a theoretical standpoint; that a cubical crystal, such as KCl, or NaCl, could not have two different frequencies; and that there was no evidence in either case of an optical frequency with half the experimental value, since, according to Rubens, the crystals became again transparent before this frequency was reached, and had a value of the refractive index which was nearly normal. He also indicated two other objections to the "quantum" theory on which Planck's formula was based. (1) According to the quantum theory it did not follow, as required by the classical mechanics, that the oscillator with three degrees of freedom would have three times the energy of a linear oscillator. (2) It was very difficult to conceive the distribution of energy among the oscillators at low temperatures required by the theory. Thus for the diamond at T = 73° only one molecule in 100 millions would possess a single quantum of energy, all the rest would be absolutely quiescent. It was physically impossible to conceive such a distribution of energy, which moreover would make the thermal conductivity of the diamond at such temperatures entirely negligible, whereas, according to Eucken, it was nearly as great as that of copper at ordinary temperatures. For these reasons Einstein preferred to rely mainly on the expression for the energy of an electric oscillator in equilibrium with radiation as deduced from Maxwell's equations, and to regard Planck's formula for the distribution of energy in full radiation simply as representing the results of experiment.

Debye's Theory of Specific Heat of Solids.—The theory now most commonly accepted is that of P. Debye (*Ann. Phys.*, 39, p. 789, 1912), who attributes the heat energy to mechanical or acoustic vibrations of the solid with all possible frequencies up to a certain limit ν_m. According to a theorem attributed to the late Lord Rayleigh (*Sound*, i., p. 129, 1877) the number of possible degrees of freedom of a system of N discontinuous mass-points will be 3N. According to another theorem by the same author (*Phil. Mag.*, 49, p. 539, 1900), the number of possible frequencies in a given volume of a *continuous* medium between the limits ν and $\nu+d\nu$ may be represented by $C'\nu^2d\nu$, where C' is a constant depending on the volume and the velocity of propagation. The total number of possible frequencies from 0 up to a limit ν_m is $C'\nu_m^3/3$. If we equate this to 3N, we find $C' = 9N/\nu_m^3$. Adopting Planck's expression for the energy of an electric oscillator with one degree of freedom as applying to each possible frequency of the N atoms in a gram-atom, we obtain the energy $(RT/N)z/(e^z-1)$ for each frequency. Multiplying this by the number of frequencies between ν and $\nu+d\nu$, namely $(9N/\nu_m^3)\nu^2d\nu$, and integrating from 0 to ν_m, we obtain the energy of a gram-atom at T, from which the specific heat at constant volume is obtained by differentiation with regard to T. Unfortunately the integral cannot be expressed in finite terms and is too complicated to reproduce here. It is evident, however, that it will be a function of z_m, or $\beta\nu_m/T$, or T_m/T, where $T_m = \beta\nu_m$.

Thus the *form* of the curve representing the variation of the specific heat (which depends on a single parameter T_m or ν_m) is the same for all substances on Debye's theory, if the temperature scale is altered for each in proportion to ν_m. This point has been very carefully tested by E. H. Griffiths and E. Griffiths (*Phil. Trans.*, A, 214, pp. 319–357) for the metals Al, Ag, Cd, Cu, Fe, Na, Pb, Zn. Their results indicate qualitative agreement with the theory, but show characteristic differences, greatly exceeding the limit of experimental error, which may possibly be attributed to other effects not included in the simple theory. Thus the curve for Fe differs from that for Cu by nearly 20% between corresponding temperatures, which may be attributed to the magnetic properties of Fe. The curve for Na shows a rapid rise towards the melting point, reaching an excess of 25% above 3R, followed by a diminution of specific heat for the liquid, as in the case of water and mercury. Many simple compounds, such as NaCl, show curves of a very similar type to the metals, which has been used as an argument that the specific heat must be attributed entirely to the atoms, and that the free electrons supposed to exist in metals cannot make any appreciable contribution. Thus if there were two free electrons per atom, as required by some theories, the electrons alone would account for the whole specific heat according to the kinetic theory at ordinary temperatures; and it would be necessary to suppose that the number of free electrons diminished to zero at low temperatures, which would make it difficult to account for the enormous increase in electric conductivity of pure metals demonstrated by Kamerlingh Onnes in the neighbourhood of the absolute zero.

One of the commonest objections to Debye's theory is the arbitrary nature of the assumption of an abrupt limit of frequency ν_m. This assumption is made on account of its simplicity, but is highly improbable from a physical standpoint, though it might be expected to give results of the right order of magnitude. W. Sutherland (*Phil. Mag.*, 20, p. 657, 1910) had previously shown that the wave-length of the elastic vibrations of solids was of the same order of magnitude as the distance between the atoms for frequencies corresponding to the optical frequencies in the infra-red, so far as these were known. If the forces holding the atoms in place in a crystal lattice are electromagnetic, as commonly assumed, we should expect that the energy would be shared between matter and aether, and that the natural frequencies of the optical and mechanical vibrations would be the same. The wave-length and velocity of the natural

frequency as measured outside the crystal would be reduced inside the crystal in the same proportion as the ratio of the velocity of light to that of an elastic vibration, or of the wave-length outside the crystal to the lattice constant, *i.e.*, in the case of rocksalt, NaCl, about in the ratio 2×10^5 to 1. Since the energy in the cube of the wave-length remains constant, the energy-density of the external radiation of the natural frequency would be increased in the cube of this ratio, and would be of the right order of magnitude to explain the specific heat of the solid on the usual theory of resonance as applied by Einstein. We have seen, however, that the assumption of Planck's radiation formula gives too low a value for the specific heat at low temperatures on Einstein's theory. If on the other hand we interpret Lord Rayleigh's formula, namely $C'Te^{-\epsilon}\nu^2 d\nu$, as representing the *partial pressure* $pd\nu$ of radiation between the limits of frequency ν and $\nu+d\nu$, the latent heat of emission or absorption of radiation per unit volume between the same limits, according to Carnot's principle, is represented by the expression

$$T(dp/dT)=C'T\nu^2(1+z)e^{-z} \qquad (4)$$

and the total heat of a gram-atom of solid in equilibrium with radiation having this distribution of energy is given by

$$H=3RT(1+z)e^{-z} \qquad (5)$$

The specific heat as ordinarily measured, when the external pressure is small as compared with internal pressure, will be simply

$$s=3R(1+z+z^2)e^{-z} \qquad (6)$$

This expression, unlike that similarly deduced from Planck's formula, gives good agreement with the observed value of the specific heat in the case of rocksalt, when the optical frequency corresponding to 51 microns is assumed, at a temperature corresponding to the maximum of the frequency curve, where $z=2\cdot732$, $T=100^\circ$, and $s=8\cdot67$ (doubled for a gram-molecule of NaCl). We should expect to get good agreement at this point, in spite of the fact that the actual vibrations in a solid cannot be strictly monochromatic (as Einstein pointed out) but extend for a distance of an octave or more on either side of the maximum, as indicated by the absorption spectrum. The effect of this is to reduce the steepness of the monochromatic curve, bringing it into good agreement with observation at high and low temperatures, without materially affecting the agreement at the mean point corresponding to the maximum of the frequency curve. If we assume the value $\lambda_m T=0\cdot290$ for the wave-length λ_m (corresponding to the maximum ordinate of the wave-length spectrum of full radiation at T), in deducing the appropriate value of Wien's constant βA in formula (4), the maximum ordinate comes out the same as in Planck's formula, provided that the same value of the Stefan-Boltzmann constant σ is assumed in the fourth power law σT^4 for the total radiation. The two curves also agree so closely throughout their whole extent that it would be very difficult to decide between them by experiments on radiation. We should therefore be justified, according to Einstein's reasoning, in applying formula (4) in the deduction of the specific heat of a solid, especially when we find that the result gives such good qualitative agreement with the optical frequencies.

An obvious objection to Debye's theory in the case of transparent substances, such as quartz and rocksalt, is that, if the atoms have all possible frequencies below a certain limit, they ought to be completely opaque in this region, and to become suddenly transparent when the limit ν_m is surpassed. Experiment shows, however, that, *e.g.*, quartz, which begins to be opaque at about four microns, and has optical frequencies corresponding to 9 and 21 microns approximately, and possibly one lower, becomes almost perfectly transparent below 100 microns. The variation of its specific heat is of an entirely different type to that given by Debye's theory but corresponds closely, according to formula (4), with its optical frequencies. Ice and benzol, which are also hexagonal, show a variation of specific heat similar to quartz, according to Sir J. Dewar. The corresponding optical frequencies have not yet been observed, but it appears that water must have some frequencies below 100 microns to account for its remarkable opacity to long wave-lengths, and the variation of its specific heat. We should naturally expect that the torsional vibrations of an elastic solid, which are of the same kind as those of light, would be excited by radiation, and would be intimately connected with the optical frequencies. It is quite possible, however, that the compressional vibrations, which are of a different type, and propagated with a different velocity (that of sound), would continue to exist at low temperatures without affecting the transparency. These acoustic vibrations, though not capable of being excited directly by radiation, would be necessarily excited by the impacts of the molecules of the surrounding gas, with a distribution of energy corresponding to the Maxwellian law, and might be expected to provide a term in the specific heat of a somewhat similar character to the Debye term for compressional waves at low temperatures. It is noteworthy that Nernst and Lindemann in their latest reductions have found it necessary to retain the original Einstein term $f(z)$ for transparent substances in their formula (3), but have replaced the hypothetical term $f(z/2)$ by a term of the Debye type. The appropriate frequencies are calculated in most cases by Lindemann's semi-empirical formula from the molecular weight m, the atomic volume V, and the temperature of fusion T_f, but with different values of the constants for the two terms, as follows:—

$$\nu_e=2\cdot12\times10^{12}(T_f/m)^{1/2}V^{-1/3}$$
$$\nu_m=3\cdot08\times10^{12}(T_f/m)^{1/2}V^{-1/3} \qquad (7.$$

of which the first gives the optical frequency of Einstein and the second that of Debye. The cube root of the atomic volume is proportional to the lattice constant, and the elastic constants of a solid must be closely related to the temperature of fusion. Nernst and Lindemann assign equal importance to the two terms, but we should naturally expect from elastic theory, as given by Debye and other previous writers, that the numerical coefficients should have different values, and should be proportional to $1/u_1^2$ for the compressional waves, where u_1 is the velocity of sound, and $2/u_2^2$ for the torsional waves, where u_2 is the velocity of light *in the solid* for the particular optical frequency considered. This may not fit so well with Planck's radiation formula for the Einstein term, but appears to give better agreement with experiment if formula (4) is substituted for Planck's. The appropriate frequencies cannot be calculated from the elastic constants for a discontinuous medium without introducing arbitrary hypotheses, which are unsatisfactory because the effect of the hypothesis selected is most important at the point where the discontinuity commences and it is difficult to avoid selecting an hypothesis to give the desired result. There is the further difficulty that the values of the elastic constants are somewhat uncertain and liable to vary with temperature and to depend on the particular specimen tested, especially with metals.

Sir J. Dewar (*Proc. R. S.*, 1913, A, 89, pp. 158–169) has measured the mean specific heats of the elements between the boiling points of hydrogen and nitrogen by means of his liquid hydrogen calorimeter. The results for the specific heats, when plotted against the atomic weights, give a curve showing a most remarkable coincidence with the well-known curve of atomic volume as a periodic function of the atomic weight. In other words, the specific heat is nearly proportional to the atomic volume, or to the cube of the lattice constant, for similar substances, at this low temperature corresponding to a mean about $T=50^\circ$. The relation does not pretend to be exact, though it is a fair approximation over the range 20° to 80°, but it illustrates the point that the atomic volume is the most important factor in determining the frequencies.

In the case of the metals, which are opaque to all frequencies below a certain limit, we should expect the possible frequencies to extend over a considerable range, and to be grouped about a mean in a similar way to the velocities of gas molecules on the kinetic theory. But there are many possible alternatives to the somewhat arbitrary hypothesis of Debye. We might suppose, for instance, that of N molecules in a gram-molecule, the number possessing the frequencies between the limits ν and $\nu+d\nu$ was represented by an expression of the type

$$(N/2)e^{-x}x^2dx \qquad (8$$

in which $x=\nu/\nu_0=\beta\nu/T_0=\theta z$, where z denotes $\beta\nu/T$, and $\theta=T/T_0$. Multiplying this by expression (6) divided by N for the specific heat of a single molecule of frequency ν, at a temperature T, and integrating the product from 0 to ∞, we obtain for the specific heat of a gram-molecule

$$s=3R(\theta^3/(1+\theta)^3)(1+3/(1+\theta)+12/(1+\theta)^2) \qquad (9)$$

This is much simpler than Debye's expression, but gives a very similar curve. The *mean* frequency, $\nu_m=3\nu_0$, is nearly the same as Debye's limiting frequency. More accurately, Debye's characteristic temperature corresponds to $2\cdot91T_0$, in place of $3T_0$, on account of the difference in the values of the constant β, which are in the ratio $4\cdot9651/4\cdot8284$ in Planck's and Rayleigh's formulae for radiation. If Debye's scale is multiplied by $2\cdot91$, his curve agrees very closely with (9) from $\theta=0\cdot6$ to $\theta=1\cdot0$. Below $\theta=0\cdot6$, (9) agrees better with the Nernst-Lindemann curve (3), except that (9) tends to vary as T^3 at very low temperatures, instead of vanishing exponentially. Above $\theta=1$, the curve (9) lies above Debye's by a quantity corresponding to the difference of the specific heats at constant pressure and volume. This is to be expected, because (9) represents the rate of change of total heat, which is the same as that of intrinsic energy for all practical purposes under the condition of small external pressure and negligible expansion. Thus in the case of water under atmospheric pressure, the increase of total heat between 0° and 100° C. is 100 cals. C., and exceeds that of intrinsic energy between the same limits by only 0·001 cal. C., which is 100 times smaller than the limit of accuracy of observation; whereas the change of total heat *at constant volume* between the same limits in the case of water exceeds that of intrinsic energy by 21 cals., approximately; but the correction from constant volume to constant pressure is very uncertain, even in the best known cases. It therefore appears to be more logical to employ a formula giving the specific heat at constant pressure directly, in place of applying an uncertain correction. It should be observed, however, that (9) assumes the mean frequency ν_m to be independent of T, as in Debye's formula, which may be a good approximation in many cases, but cannot be exactly true if the molecule changes its state. Curve (9) reaches $s=3R$ a little above $\theta=2$, attains a maximum $3\cdot195R$ at $\theta=4$, and falls again to 3R at $\theta=\infty$. The fall is of the right

order of magnitude to explain the diminution of specific heat in the case of water, mercury and sodium. The distribution postulated in (8) appears to apply fairly to most of the metals, but it fails notably for many other substances. Such cases might be treated empirically by modifying the distribution, or assuming special frequencies, but such hypotheses would be of little value unless their physical meaning could be interpreted with reference to other properties of the substances.

Conduction of Heat

In 1910 the very attractive theories of P. Drude and H. A. Lorentz were still commonly maintained, and were continually being applied to the explanation of electrical and thermal effects. According to their views a metal contained a number of free electrons moving in all directions with velocities corresponding to those of gas-molecules on the kinetic theory. Drude showed that this assumption led to an approximately correct value of the ratio of the thermal to the electric conductivity in the case of pure metals, and Lorentz showed that it accounted for the long wave radiation from hot bodies. There were numerous other applications of the theory which appeared to correspond in a remarkable manner with experimental facts, but there were also serious difficulties which appeared to render the adoption of such a theory premature.

The fluid state of scientific opinion on the subject in 1911 is well illustrated by the views expressed about that time by J. H. Jeans. In the report of the Solvay Congress, 1911, *On the Theory of Radiation and Quanta* (Gauthier Villars, Paris, 1912), assuming that there were two free electrons per atom of the metal, Jeans took the view that the specific heat of metals was entirely due to the movement of free electrons and not at all to the movements of the atoms, " a hypothesis which accords well with our knowledge of the internal movements of solids." On the other hand, in his report on the quantum theory (*Phys. Soc.*, London, 1914), he adopted the theory of Debye (according to which the specific heat was entirely due to the movements of the atoms) as probably " destined to be final," and concluded that the free electrons do not contribute sensibly to the specific heat.

Sir J. J. Thomson, *Corpuscular Theory of Matter* (1907), had already pointed out that the number of free electrons required to explain thermal and electric conductivity was too large to reconcile with the facts of specific heat on the assumption that the electrons possessed the same energy of agitation as gas molecules at the same temperature, and had proposed an alternative theory (*loc. cit.*, p. 86) previously suggested in his *Applications of Dynamics to Physics and Chemistry* (1888). According to this view, the metallic atoms, owing to their close proximity in the solid state, were capable, under the influence of an electric field, of forming Grotthus chains, along which they could exchange electrons. There were no free electrons in the sense contemplated by Drude and Lorentz, with velocities depending on the temperature and contributing to the specific heat, but the thermal agitation of the atoms tended to break up the chains, so that their number and length varied with the electric field in the manner required to explain the relation between electric and thermal conductivity and many other effects.

In a later paper (*Proc. Phys. Soc.*, 27, p. 527, 1915), the same theory was applied to explain the striking phenomena of superconductivity discovered by Onnes, who found that at very low temperatures, in perfectly pure metals, a current once started might continue for days instead of stopping almost instantaneously on the cessation of the exciting field. According to J. J. Thomson's theory, it would naturally follow that, below a certain point, the thermal agitation would be insufficient to break up the chains when once they were formed, which would explain why it is that the electric resistance of most pure metals tends to vanish (apart from impurities) at a temperature *above* the absolute zero. A working hypothesis of this kind is very useful to the experimentalist as affording a mental picture of the physical conditions, and may help to explain the remaining difficulties with regard to the specific heats.

Conductivity of Gases.—Prof. Knudsen drew special attention (*Solvay Report*, p. 133) to the data for the thermal conductivity of gases, as being more scarce and discordant, owing to experimental difficulties, than determinations of other properties, and as requiring attentive examination for the elucidation of the law of action between molecules. The hot-wire method of T. Andrews (*Phil. Trans.*, 1840) offers special facilities for relative measurements, such as the comparison of conductivities of different gases, or of the same gas at different temperatures, and has frequently been applied with this object in recent years. It has also been improved by introducing the usual compensation for end-effects, and employing more accurate methods of electrical measurement. But it remains liable to the difficulties depending on the small dimensions of the wire, and the uncertainty of the corrections for convection and radiation. For these reasons the parallel plate method, adopted by E. O. Hercus and T. H. Laby (*Proc. R. S.*, A, 95, p. 190, 1918) for measuring the *absolute* conductivity of air, deserves special mention, owing to the great care with which the method was applied, and the complete elimination of convection effects. They also give a very complete reduction of previous results for different gases with the view of testing the value of the numerical coefficient f in the relation, $k=f\eta s$, between the conductivity k, the viscosity η, and the specific heat s at constant volume. According to the theoretical investigations of S. Chapman (*Phil. Trans.*, A, 211, p. 433, 1911) the value of the coefficient f should be 2·5 for a gas constituted of spherically symmetrical molecules, which agrees with Maxwell's theory based on the inverse fifth-power law of force, and also with experiment for monatomic molecules. Unfortunately the variation of viscosity with temperature does not satisfy the fifth-power law, which requires that the viscosity should be directly proportional to T. The conclusion is that monatomic gases may have spherically symmetrical molecules, but that the law of force is different. Theory gives no clear indication with regard to the appropriate value of f for other types of molecules. Experiment gives approximately a linear relation, $f=2{\cdot}816\gamma-2{\cdot}2$, between f and the ratio of the specific heats. This gives $f=7/4$ for diatomic gases, which show fair agreement with each other. The experimental values for polyatomic gases are much less certain.

Thermodynamics

Since the general principles of thermodynamics have not undergone any material change for the last 50 years, it will readily be understood that such progress as there is to record relates chiefly to matters of expression or convention, and to the practical application of the principles to engineering problems. The evolution of the steam turbine and the internal combustion engine, along thermodynamical lines, has illustrated the importance of an exact and consistent theory of the conditions limiting the efficiency, and of an accurate experimental study of the properties of the working fluid in either case. Thus the improvement of the internal-combustion engine has depended greatly on the extension of the thermodynamical efficiency of the cycle by using higher compression-ratios, which has necessitated careful attention to the reduction of heat-losses, to the properties of various fuels in respect of detonation, and to the specific heats of the products of combustion at high temperatures.

The displacement of the reciprocating engine by the turbine for large power units has similarly depended on the possibility of improving the economy by utilising high vacua. The high speed of the turbine has directed special attention to the importance of losses due to friction and supersaturation, which depend on the rapidity of expansion. The turbine realises the ideal condition of steady flow with an exactitude unattainable by the reciprocating engine. This has made it worth while for engineers to adopt the thermodynamical definition of total heat first proposed by Callendar in the 10th ed. of the *E.B.*, in place of Regnault's definition, which had sufficed for many years, but continually gave rise to minor difficulties and complications when applied to the turbine. In the article cited, and as repeated in the 11th ed. (*see* 26.811), the total heat was defined as the thermodynamic function $E+PV$, and was denoted by the special symbol F in order to distinguish it from Regnault's total heat H, representing the quantity of heat added to the fluid under the condition of constant pressure equal to that of vaporisation. By general convention, the symbol H has now been defined as representing $E+PV$, a property of the substance depending only on the state, and the symbol Q has been allocated to any quantity of heat added under special conditions.

Equations of Steady Flow.—These depend on the law of conservation of mass, and on the law of conservation of energy, of which they afford some of the simplest possible illustrations. If a fluid is flowing steadily at a constant rate M (mass per second) through a

circuit (pipe or nozzle) of variable cross-section X, at a point where the mean volume is V per unit mass, and the mean velocity U units of length per second, we have $MV=kUX$, where the constant k is unity in any consistent system of units, *e.g.*, if U, X and V are measured in ft., sq. ft. and cu. ft. respectively. It is common practice, however, to measure X in sq. in., which must be reduced to sq. ft. by putting $k=1/144$; and similarly for other arbitrary systems. If we consider any two points (1 and 2) of a circuit for which M and X are known, the relation $MV=kUX$ makes it possible to determine either U or V at each point if the other is known. A second relation is obtained from the conservation of energy. Suppose for example that the points 1 and 2 represent the admission and exhaust of a turbine. When the flow is steady, for each unit mass entering at 1, unit mass must leave at 2. Unit mass entering at 1 carries with it its intrinsic energy E_1 and its kinetic energy $U_1^2/2g$, in addition to which work P_1V_1 is done by the pressure P_1 in forcing the volume V_1 into the turbine. Reducing these to heat units by the appropriate numerical factors, a and J, we have finally for the total energy entering the turbine with each unit mass of fluid, $H_1+U_1^2/2Jg$, where H_1 is the initial value of the total heat, which is always tabulated in heat units per unit mass. Similarly the total energy carried out per unit mass at 2 is $H_2+U_2^2/2Jg$. Since the total quantity of energy existing in the turbine remains constant when the conditions are steady, the excess of the energy carried in over that carried out must be equal to the external work W/J done by the turbine together with the external heat-loss Q, both expressed in thermal units per unit mass passing through the turbine. We thus obtain the general equation representing the conservation of energy:—

$$\text{Heat-Drop, } H_1-H_2=W/J+Q+(U_2^2-U_1^2)/2Jg \qquad (10)$$

The reduction factors, a, J, g, can be omitted for absolute or C.G.S. units, but it is better to retain them explicitly, because the various quantities can seldom or never be measured in absolute units in practical work and the retention of the symbols saves much trouble and many mistakes.

In this equation, as applied to a turbine, the term W/J, representing the external work, is the most important on the right-hand side. The external heat-loss Q, and the leaving-loss, depending on the kinetic energy wasted in the exhaust, can be reduced to small corrections, which are readily applied. The external work is the equivalent of the corrected heat-drop, which can be calculated if the initial and final states of the steam are known. The equation takes exact account of any work wasted in internal friction, which does not appear explicitly in the equation because it affects both sides equally. The same equation can be applied to a reciprocating engine, or to any appliance admitting of steady flow.

Joule and Thomson (*Phil. Trans.*, 1854-62; *Proc. R. S.*, 1856) were the first to employ the function E+PV in their experiments on the flow through a porous plug or orifice. They discussed the various terms in the equation with great precision, but did not apply it to a steam engine, which was first done by Hirn and Rankine, though the equation is commonly attributed to Zeuner. In an ideal throttling experiment, such as that designed by Joule and Thomson, the equation shows that the total heat remains constant, $H_1=H_2$, provided that $U_1=U_2$ and that W and Q are negligible. The lines of constant total heat on the PT diagram can be determined by observing the initial and final values of P and T in a sufficient number of throttling experiments. It is then possible to deduce the actual values of H under any conditions by measuring the specific heat and latent heat at any one pressure, preferably atmospheric for most fluids.

In applying the equation to the discharge through an orifice Joule and Thomson showed that the kinetic energy generated was equivalent to the drop of E+PV, or H, which follows immediately from equation (10) if W and Q are negligible. In the usual case, starting from rest, U_1^2 is negligible as compared with U_2^2, so that U_2 is given by the simple relation

$$U_2=(2Jg)^{\frac{1}{2}}\,(H_1-H_2)^{\frac{1}{2}} \qquad (11)$$

For given conditions, V_2 is known in terms of H_2 and P_2, so that the discharge M/X per unit area can be deduced by applying the relation $M/X=kU/V$. Joule and Thomson showed that the discharge would reach a maximum in the case of air under adiabatic conditions when the final pressure after passing the orifice was 0·52 of the initial pressure, a result which had previously been deduced in a similar way by de St. Venant and Wantzel (*Comptes Rendus*, 1839) from Poisson's equation for the adiabatic, namely $PV^\gamma=$constant. They also showed that the velocity of the discharge under this condition was simply related to the velocity of sound in the air at the original temperature and pressure, but they failed to interpret the relation. Osborne Reynolds (*Phil. Mag.*, 1886, p. 194), using the same equations for a perfect gas, showed that the velocity at the throat or minimum area of the stream was *the same* as that of sound in the gas under the same conditions, so that, when this velocity was reached, no further lowering of pressure beyond the throat could possibly increase the discharge. The same result is easily shown to apply to any fluid, either liquid or gas, in the absence of friction. The condition that M is to be a maximum for a given value of X gives $d(M/X)=0$, whence $dU/dV=U/V$. Eliminating dU/dV by differentiating (11), we obtain, for isentropic flow (Φ const.)

$$U^2=aJgV(dH/dV)\phi = aJgV^2(dP/dV)\phi \qquad (12)$$

which is the expression for the velocity of sound. This equation also gives the maximum discharge by substituting M/X for kU/V.

In steady-flow calorimetry the drop of H between given initial and final states can be deduced from equation (10) by observing the quantity of heat Q which must be abstracted, under conditions such that W and U^2 are negligible. The pressure is usually constant, but if there is a large drop of pressure between the initial and final states, as in Regnault's experiments on the total heat of water, the difficulty is avoided, without changing H_1, by using a throttle, which is precisely what Regnault did, though he was unable, owing to the defective state of thermodynamics at that time (1847), to appreciate the exact effect of this proceeding. The same method can be applied for measuring the total heat of steam in any state, including the latent heat. In all cases of steady flow the quantity measured is the change of total heat, which is the most important property to determine for steam engines or refrigerating machines working on any modifications of the Rankine cycle. On the other hand the intrinsic energy E is the property required for the constant volume cycle of the internal-combustion type.

A very simple and instructive illustration of the equation of steady flow is that of the temperature gradient in a fluid under gravity. If a current of air is flowing steadily upwards at a moderate speed, the external heat-loss Q and the change of kinetic energy are negligible, and the drop of total heat is equivalent to the work done against gravity, giving $W/J=1$ calorie C. for each 1,400 ft. of ascent. This would evidently be the same for any fluid whatever. In the case of dry air the specific heat is nearly independent of the temperature and pressure, and the change of H is equal to $S(t_1-t_2)$, where $S=0{\cdot}241$ is the specific heat at constant pressure. The drop of temperature will therefore be $1/0{\cdot}241=4{\cdot}15°$ C. in 1,400 ft.; or the temperature gradient, 0·296° C. per 100 ft. This result is evidently quite independent of the initial temperature, or pressure, or height, so long as we can afford to neglect the small variations of S and g. In an ascending column of *damp* air, condensation sets in with formation of cloud as soon as the temperature falls below the dew point. The drop of H remains 1 calorie per 1,400 ft., but the temperature gradient is greatly reduced by the liberation of the latent heat of the vapour. On the other hand, in a descending current, as in the ventilating shaft of a mine, the temperature increases with depth at the rate of nearly 3° C. per 1,000 ft., which, however, is usually much less than the natural gradient of underground temperature (due to outflow of heat through the earth's crust), which sometimes exceeds 10° C. in 1,000 ft. In this case there will be no condensation, but the air may be cooled by evaporation, if the mine is kept wet to reduce dust, as is usually the case.

According to equation (10) the rate of increase of temperature with depth, denoted by dt/dx, is equal to $1/JS$, and is uniform in adiabatic flow if S is constant. The *pressure* gradient, dp/dx, in gravitational units, is equal to the density $1/V$, or p/JRT, if R is expressed like S in calories per 1°. Dividing by dt/dx, we have $dp/dt=Sp/RT$, giving the adiabatic equation, which is commonly assumed as the starting point to find the temperature gradient. But the reverse order is more instructive as showing why the temperature gradient dt/dx is uniform.

Properties of Radiation.—The flow of heat by radiation from one body to another at a lower temperature is the commonest case of steady flow. Owing to the high velocity of radiation and the absence of thermal capacity in the circuit, the steady state is established in a small fraction of a second if the temperatures of source and sink are constant. The quantity measured in a radiation experiment is not the energy E of the radiation, as is frequently assumed, but the total heat E+PV, which is the same in the case of radiation as the latent heat of emission, namely $VT(dP/dT)$, for a volume V, according to Carnot's principle. This is universally admitted in the deduction of the fourth-power law (*see* 13.155), which follows from the fact that the pressure of full radiation is one third of the energy-density, so that the latent heat of emission per unit volume is four times the pressure. The quantity directly measured in experiments on full radiation is the quantity of heat emitted per sq. cm. per second from a black-body or perfect radiator at a temperature T, and is denoted by σT^4, where σ is the Stefan-Boltzmann constant of full radiation. By the geometrical conditions of the problem, the quantity σT^4 is $A/4$ times the latent heat per unit volume, or $A/3$ times the energy-density in an isothermal enclosure at T, where A is the velocity of light. The qualitative verification of the fourth-power law requires only a receiver capable of giving correct relative values of the radiation received, and is now generally accepted as satisfactory; but the absolute measurement of the value of the constant σ is a much more difficult problem, which has frequently been attacked in recent years without obtaining so high a degree of concordance as is desirable in so fundamental a research. The value $5{\cdot}32\times10^{-5}$ ergs per sq. cm. per second, found by F. Kurlbaum in 1898 (*see* 13.155), was accepted for several years, though it rested on a somewhat doubtful value of the absorption coefficient of the bolometer. Moreover, the assumption that the radiant energy measured was equivalent to the electric energy required to

produce the same rise of temperature in the bolometer, was rendered somewhat uncertain by conduction effects at the ends of the strips. A similar bolometer, with the end-effects compensated, as employed in the solar eclipse of 1905, gave the somewhat higher value $5{\cdot}60\times10^{-5}$. Kurlbaum (1912) gave the corrected result $5{\cdot}45\times10^{-5}$. F. Paschen and W. Gerlach, by a modification of Ångström's method (*Ann. Phys.*, 38, p. 41, 1912), found the value $5{\cdot}80\times10^{-5}$, which was confirmed by G. A. Shakespear (*Proc. R. S.*, A, 86, p. 180, 1912), and by H. B. Keene (*Proc. R. S.*, A, 88, p. 49, 1913), who found $5{\cdot}67\times10^{-5}$, and $5{\cdot}89\times10^{-5}$, respectively. W. Coblentz (*U.S. Bur. St.*, 12, p. 553, 1916), by a method similar to that of Paschen and Gerlach, found the value $5{\cdot}72\times10^{-5}$, which is a fair mean of the previous results. One of the most promising methods is that of the radio-balance (*Proc. Phys. Soc.*, 23, pp. 1–34, 1910), in which radiation received through a measured aperture is completely absorbed in a small copper cup, and is compensated by the Peltier cooling-effect due to a current through a thermojunction. Unfortunately, these experiments were interrupted by the War, and the final reductions have not yet been completed. There seems to be little doubt that Kurlbaum's original value was too low, but there are many pitfalls in such difficult experiments, and most of the methods adopted are liable to some objections.

It is generally admitted that the distribution of energy in the spectrum may be represented within the limits of experimental error by Planck's formula (*see* 13.156), namely,

$$E d\lambda = C'\lambda^{-5} d\lambda / (e^{c''/\lambda T} - 1) \qquad (13)$$

If this formula is integrated from 0 to ∞, and equated to σT^4, assuming that it represents the distribution of energy in the spectrum as observed experimentally, we find for the constant C', in terms of c' and σ, $C' = 15\sigma(c'\pi)^4$. The value of the distribution constant c' is most readily deduced from the wave-length λ_m corresponding to the maximum ordinate of the energy curve at T, since by Wien's law the product $\lambda_m T$ is the same for all temperatures. According to Planck's formula the maximum occurs at the point $\lambda_m T = c'/4{\cdot}9651$. Planck took $\lambda_m T = 0{\cdot}294$, and $\sigma = 5{\cdot}30\times10^{-5}$, giving $C' = 3{\cdot}735\times10^{-3}$, and $c' = 1{\cdot}460$. But if $\lambda_m T = 0{\cdot}289$, and $\sigma = 5{\cdot}72\times10^{-5}$, then $C' = 3{\cdot}708\times10^{-3}$ and $c' = 1{\cdot}435$, according to the latest values of $\lambda_m T$ and σ. A comparatively small error in c', which is raised to the fourth power, suffices to neutralize the error in σ. The weak point of the method is that the position of the maximum of an experimental curve cannot be fixed with any certainty when the curve (as in this case) is far from symmetrical on either side of the maximum.

It is too commonly assumed that Planck's radiation formula, in spite of the weighty objections that have repeatedly been urged against it, is so firmly founded in theory and experiment, that no other formula is worth considering in comparison with it. It is also frequently asserted that no formula based on the "classical" mechanics can possibly satisfy the required conditions. The argument is somewhat as follows. The number of possible vibrations per unit volume of a continuous medium possessing the properties of the ether, between the limits λ and $\lambda+d\lambda$ of wave-length, should be represented by $8\pi\lambda^{-4}d\lambda$, according to Lord Rayleigh's method of calculation (*Phil. Mag.*, 49, p. 539, 1900), if the length of path between each reflection is restricted to an integral multiple of half a wave-length. If the different frequencies are regarded as separate inconvertible entities, like the molecules of different gases, between which the energy must be equally divided, the whole of the energy would accumulate in the infinitely short waves, which is absurd and contradicts experiment. It would be more natural, however, from a physical standpoint to regard Lord Rayleigh's formula

$$(8\pi RT/N)e^{-c''/\lambda T}\lambda^{-4}d\lambda \qquad (14)$$

as corresponding to the partition of energy among a number of *similar* molecules, according to Maxwell's law, which is universally admitted in the kinetic theory of gases, as resulting from the steady state produced by collisions. The steady distribution of energy of radiation in equilibrium with matter arises in a similar manner from the Döppler effect, by which the energy of a group of waves is changed in the same proportion as the frequency at each encounter with a moving obstacle. The frequency, or the reciprocal of the wave-length, corresponds to the energy, and occurs in much the same way in Rayleigh's formula, as the square of the velocity, or the kinetic energy, in Maxwell's law. On this view, Lord Rayleigh's formula evidently represents the distribution of pressure-energy between the different wave-lengths about a mean value RT/N, which, according to the law of equipartition, should be the same as the pressure-energy of a single gas-molecule at the same temperature.

If we take Rayleigh's formula as representing the pressure distribution in full radiation, the expression for the latent heat of absorption L as measured experimentally (corresponding to (4) above, but expressed in terms of the wave-length λ in the normal spectrum) may be written

$$L d\lambda = C''(T + c''/\lambda)\lambda^{-4}e^{-c''/\lambda T}d\lambda \qquad (15)$$

Integrating from 0 to ∞ we find $C'' = \sigma c''^3/4$. The maximum of this curve occurs at the point where $c''/\lambda T = 2+2\sqrt{2}$, whence $c'' = 4{\cdot}8284\lambda T$. The absolute value of the maximum ordinate comes out $0{\cdot}65603(\sigma T^4\lambda_m)$. The value of the same ordinate, calculated in the same way for Planck's formula (13), but with $c' = 4{\cdot}9651\lambda_m T$ comes out $0{\cdot}65755(\sigma T^4\lambda_m)$. It is a curious and significant fact that the maxima should be so nearly the same when the same values of the experimental data are assumed for both curves. The total areas of the two curves are the same, and they agree so closely throughout their whole extent that it would be practically impossible to distinguish between them with certainty by experiments on the distribution of heat in the spectrum. The greatest difference amounts to about 1% of the maximum ordinate, and occurs near the point $\lambda = \lambda_m/2$ on the short wave-length side, where the curve is very steep. This difference becomes quite appreciable in the specific heats, when the curves are differentiated, and seems to lead to better agreement with experiment than Planck's formula as explained above.

The most serious difficulty from an experimental standpoint in applying Planck's formula, is that the latent heat of emission per unit volume is always tacitly assumed (following Planck) to be the same as the energy-density, without taking any account of the pressure, whereas the existence of the radiation pressure is universally admitted as the basis of the deduction of the fourth-power law. The work done by the pressure, if it exists, cannot consistently be neglected in experimental measurements of radiation in steady flow. This is one of the most fundamental points in practical thermodynamics, but had not up to 1921 received sufficient attention from the mathematicians who have worked so elaborately on the theory.

Vaporisation

A good deal of attention has been devoted in recent years to the study of the properties of vapours employed in heat engines and refrigerating machines. The importance of the thermodynamical aspect of the problem has been widely recognized by engineers as the only sure guide to improvements in efficiency, and it has been realised that equations employed to represent the properties of the working fluid must be exactly consistent with the laws of thermodynamics, if it is desired to avoid discrepancies in the results of calculations by different methods. The principal properties of vapours were discussed from this point of view in the earlier article (*see* 27.807). The theory there given still holds good, but it will be of interest to discuss some of the evidence which has since accumulated on the experimental side. The case of steam, for which the experimental data are more accurate than for any other substance, will be taken, as being far the most important to engineers, and as illustrating the properties of vapours at moderate pressures. At high pressures, on the other hand, in the neighbourhood of the critical point, the data for steam are somewhat deficient, owing to the difficulty of the experiments, and the impracticability of using steam as a working fluid under these conditions. In the critical region the properties of carbonic acid have been most widely studied on account of its use for refrigeration.

Properties of Steam.—The equations for steam, first proposed by Callendar in the 10th ed. of the *E.B.* (1902), were founded on experimental measurements (1) of the specific heats, *s* and S, of water and steam by the continuous electric method, (2) of the Joule-Thomson cooling-effect C with a differential throttling calorimeter and (3) on the adiabatic index γ for dry steam with a very sensitive platinum thermometer. These experiments, taken in conjunction with the laws of thermodynamics, sufficed to determine all the required properties fairly accurately at moderate pressures.

The experiments on the specific heat of water extended from 0° to 100° C., and, when taken in conjunction with those of Regnault at higher temperatures, showed that the total heat *h* under saturation pressure could be represented, with sufficient accuracy for the purpose, by the thermodynamic formula

$$h = st + av\mathrm{T}(dp/d\mathrm{T}) = st + v\mathrm{L}/(\mathrm{V}_s - v) \qquad (16)$$

in which the constant $s = 0{\cdot}99666$ is chosen to make *h* at 100° C. = 100 cals. C., or 180 B.T.U. per lb. at 212° F., reckoned from 32° F. The symbol *a* is the factor for reducing any product of dimensions *pv* to heat units. When *p* is in lb. per sq. in. and *v* in cu. ft. per lb., the reciprocal $1/a$ (which it is most convenient to use with a slide rule) has the value 9·722 on the Centigrade scale, and 5·401 on the Fahrenheit scale of temperature. V_s and *v* are the volumes of the dry saturated vapour and the liquid respectively, and $dp/d\mathrm{T}$ is rate of increase of saturation pressure *p* with temperature. When taken in conjunction with Clapeyron's equation for the latent heat, formula (16) gives a very useful relation between the total heat H and the volume V for *wet* saturated steam in any state,

$$\mathrm{H} - st = a\mathrm{V}\mathrm{T}(dp/d\mathrm{T}) = p\mathrm{V}\Pi \qquad (17)$$

The factor $\Pi = p/a\mathrm{T}(dp/d\mathrm{T})$, which varies slowly and is independent of the wetness, has been tabulated, as affording the most

expeditious and accurate method of calculating either H or V when the other is known. The relation between H and V when p is given is that most commonly required in practical work. The same formula leads to a simple expression for the entropy Φ,

$$\Phi = s \log_e (T/T_0) + aV(dp/dT) \qquad (18)$$

which applies to wet steam of volume V, and also to the liquid if v is substituted for V. T_0 represents the freezing point, 273·1° C. or 491·6° F.

Values ranging from 0·305 at 0° C. to 0·665 at 160° C. had been proposed by various writers in 1900 for the specific heat of steam, but the direct measurements by the continuous electric method at atmospheric pressure from 100° to 160° C. gave results but slightly exceeding those of Regnault over the range 124° to 224° C., and showed that the limiting value S_0 at zero pressure was probably nearly constant and equal to 0·477. This was confirmed by L. Holborn and H. Henning (*Ann. Phys.*, 18, p. 739, 1905) in a qualitative manner by comparison with air over the range 110° to 820° C.

The experiments on the cooling-effect C, when combined with those of the specific heat S, showed that the product SC was a function of the temperature only, and gave the simple expression for the total heat,

$$H = S_0T - SCP + B \qquad (19)$$

for dry steam at any pressure P. The values for dry *saturated* steam, given by putting the saturation pressure p in this expression, while differing materially from Regnault's formula, gave good agreement with the experiments (*see* 27.902) of Dieterici at 0° C., and of Griffiths at 30° and 40° C., when the constant B was deduced from Joly's observations at 100° C. with the aid of the experiments on the specific heat of water. This formula was closely confirmed by the observations of H. Henning (*Ann. Phys.*, 21, p. 849, 1906) on the latent heat between 30° and 100° C. His later observations (*Ann. Phys.*, 29, p. 441, 1909) also gave good agreement with the same curve at 180° C., but showed a discontinuity at 120° C., which may be attributed to inevitable experimental errors in such difficult work. At higher temperatures, up to 260° C., equation (19) received theoretical confirmation from the formula for the latent heat proposed by M. Thiesen, namely, $L = L_1(t_c - t)^{1/3}$, based on the vanishing of the latent heat at the critical temperature t_c. As first applied by Thiesen himself (*Ann. Phys.*, 9, p. 80, 1902) to the case of steam, with 365° C. for the critical temperature, this formula gave results which were much too low for the latent heat. It was shown, however, by Traube and Teichner (*Ann. Phys.*, 13, p. 620, 1904) that the true value of t_c was 374° C., which brought Thiesen's formula into agreement with (19) to less than 1 in 1,000 all the way from 0° to 260° C., when the constants were properly determined from the known values at 0°, 100°, 180° and 374°, giving the result

$$\log L = 1·9638 + 0·3151 \log (374 - t) \qquad (20)$$

in the logarithmic form as required for practical calculations. The importance of this formula arises from the fact that direct determinations of H_s (for dry saturated steam) become exceedingly difficult and uncertain at temperatures above 180° C., owing to errors from leakage and wetness, and that a formula of this type has been verified for many other substances in the critical region, so that it affords the best guide to the probable variation of H_s between 200° and 374° C.

The throttling experiments showed that there must be a considerable variation of S with pressure, corresponding to the variation of SC with temperature. But the experiments on the adiabatic expansion of dry steam showed that the index $n+1$ in the equation $P/T^{n+1} = \text{constant}$, was very nearly constant and equal to 13/3 over a wide range of P and T. Since $S_0/R = 13/3$, it followed that the total heat of dry steam must be expressible in the form

$$H = (13a/3)P(V - b) + abP + B \qquad (21)$$

giving the convenient expression for the volume of dry steam,

$$V = (3/13a)(H - B)/P + 10b/13 \qquad (22)$$

It also followed that the coaggregation volume $c = c_0(T_0/T)^n$ in the equation

$$V - b = RT/aP - c \qquad (23)$$

must vary with temperature according to the index $n = 10/3$, giving for the variation of S and C, in terms of c, the formulae

$$SC = a(n+1)c - ab \qquad (24)$$

$$S = S_0 + an(n+1)cP/T \qquad (25)$$

It was obvious that these could not apply accurately at high pressures in the critical region, but they afford ample accuracy for all purposes in the pressures required in steam-engine practice.

The Munich experiments (*Forsch. Ver. Deut. Ing.*, 21, 1905) by O. Knoblauch, R. Linde and K. Klebe, on the volume of steam, proved to be quite inconsistent with the well-known equation of Zeuner, then commonly accepted, but showed the most remarkable agreement up to 180° C. with formula (23) deduced from the throttling experiments.

The variation of S with pressure given by (25), as predicted by the experiments on C, was qualitatively confirmed by the experiments of O. Knoblauch and M. Jakob (*Forsch. Ver. Deut. Ing.*, 36, p. 109, 1906) extending to 8 atmospheres.

Knoblauch and his collaborators have since extended their observations on the specific heat up to 30 atm. (425 lb.), and have published Steam Tables (Oldenbourg, Munich, 1923) extrapolated to 60 atm. (850 lb.). These results are in very fair agreement with (19), (22) and (23), especially near the limit of 850 lb. at a moderate degree of superheat, but show a rapid fall of total heat on approaching saturation. (See also "World-Power," for May and June 1924, and June 1925.) Callendar has since extended his observations with the differential throttling calorimeter to 1,000 lb. pressure, and finds (as explained in *Properties of Steam*, p. 83) that the assumption that the cooling-effect C is a function of the temperature only gives better agreement with experiment at high pressures near saturation than the Joule-Thomson equation (23), though both are in practical accord at moderate pressures or high superheats. There is always a difficulty in securing accurate observations of the total heat or specific heat of *saturated* steam owing to systematic errors of wetness, but results accurate to 1 in 1,000 may readily be obtained at a moderate degree of superheat.

Adiabatic Heat-drop.—The change of total heat H in frictionless adiabatic expansion or compression is frequently of considerable interest as representing the work done by or on the fluid in the ideal case, when there is no internal friction, and when no heat is supplied or lost externally. If the laws of thermodynamics are summarised in the form

$$dQ = Td\Phi = dH - aVdP \qquad (26)$$

in which dQ represents heat supplied per unit mass by friction or otherwise, we observe that, in the case of isentropic flow, for which $d\Phi = 0$, the change of H is equal to the integral of $aVdP$ along the adiabatic, which is readily obtained by substituting for V in terms of H and P from (22) or (17), for any given initial state and final pressure. We may also obtain the general expression for Φ from those for H and V by integrating $d\Phi = dH/T - (aV/T)dP$. These expressions may be put in various forms according to the purpose for which they are required. One of the most useful for dry steam is

$$DH_\phi = (H' - H'')_\phi = (H' - B - abP')(1 - T''/T') + ab(P' - P'') \qquad (27)$$

in which H', P', T', and H'', P'', T'', represent the initial and final states. An exact expression for the adiabatic heat drop DH_ϕ, in the case of wet saturated steam, is readily obtained in terms of H' and T', T''. But in practice it is usually more convenient to tabulate H and ϕ, and the Gibbs' function $G = T\phi - H$, which has the advantage of being a simple function of the temperature only, and independent of the wetness for a mixture of water and steam in any proportions. From the definition of G, if ϕ is constant at its initial value ϕ'', we obtain immediately the convenient expressions

$$DH\phi = (T' - T'')\Phi' - G' + G'' = H' - H_s'' + T''(\Phi_s'' - \Phi') \qquad (28)$$

The first expression is general, and is readily applied if G' and G'' are tabulated. The second is obtained by substituting for G' and G'' in terms of H and ϕ, but is applicable only if the final state is saturated, so that H_s'' and ϕ_s'' are the tabulated values for dry saturated steam.

Effects of Supersaturation.—For the general theory of the behaviour of a vapour when cooled below the saturation temperature without condensation *see* 27.898–9. The state of supersaturation is very common, in rapid expansion, and has proved to be of some practical importance, as affecting the discharge through a nozzle, and the efficiency of a turbine. It appears that steam usually follows the dry adiabatic, $P/T^{13/3} = \text{constant}$, for some distance below the saturation point. The drop of temperature is about three times as rapid as along the wet adiabatic, and the volume is smaller than that of saturated steam at the same P and H. The heat-drop, and the velocity generated, are also smaller, for a given pressure drop, than in the case of steam which is assumed to remain in the equilibrium state of saturation throughout the expansion. If the initial steam is dry saturated, it usually remains dry for some distance beyond the throat of a nozzle, so that the discharge, as given by equation (12), is obtained from the dry adiabatic, by substituting $(dP/dV)_\phi = 1·3P/V$ at the throat, which leads to values about 5 % larger than those given by the equations for wet steam. This is confirmed by experiment, and is represented by the numerical formula for the discharge M/X_t in lb. per sec. per sq. in. of throat, when P' is in lb./sq. in. and V' in cu. ft./lb. in the initial state,

$$M/X_t = 0·3155(P'/V')^{1/2}, \quad P_t/P' = 0·545 \qquad (29)$$

in which the small quantity b is neglected as being usually beyond the limits of possible accuracy of measurement.

The defect of heat-drop on reaching the throat is about 5 %. If the steam continued to follow the dry adiabatic to low pressures, the defect of heat-drop would often reach 20 %, which would be very serious. But soon after passing the throat, the coaggregated molecules begin to act as condensation nuclei, according to Kelvin's equation (*see* 27.898). When this limit is reached, the condensation takes the form of a very thick fog of exceedingly fine particles, and is extremely rapid, owing to the enormous number of nuclei available, about 10^{22} per lb. of steam. If the expansion is relatively slow, the steam is transformed into the saturated state, and remains nearly saturated for the rest of the expansion. But if the expansion is very rapid, as in an expanding nozzle at a velocity of 3 or 4,000 ft./sec., the steam will remain near the supersaturation limit with a loss of heatdrop amounting to nearly 8 % at low pressures, involving a corresponding loss of efficiency. According to Wilson's experiments at low pressures (*see* 27.899), the supersaturation limit is reached when the pressure is about 8 times the normal saturation pressure corresponding to the actual temperature of the steam. The equivalent wetness of the steam at this point, when transformed to the

saturated state at the same P and H, would be about 3%. This appears to be confirmed by turbine tests at these pressures, but Wilson's experiments do not afford any direct evidence with regard to the limit at which condensation starts at higher pressures. It appears on theoretical grounds that the pressure ratio corresponding to the supersaturation limit should not be so high as 8 at high pressures, which would require an excessive increase in the drop of temperature and in the equivalent wetness of the steam at high pressures.

There is some evidence that the equivalent wetness at the supersaturation limit is the same, namely 3%, at high as at low pressures. This would permit a very simple method of calculation, but more experimental tests are required to decide the point. The effect of initial superheat in improving the efficiency of a turbine cannot be satisfactorily explained on the older theory that the steam is in the equilibrium state of saturation throughout the expansion, but is a necessary consequence of the phenomenon of supersaturation. The loss due to supersaturation may be entirely eliminated if the superheat is sufficient to prevent supersaturation. In any case the loss will be greatly reduced by superheat, and the results of calculation appear to indicate that the improvement of efficiency may be exactly accounted for in this way. This point has been very fully discussed by H. M. Martin, in "A New Theory of the Steam Turbine" (*Engineering*, vol. 106, 1918); and also by H. L. Callendar, *Properties of Steam*, pp. 305–12.

Carslaw, *Fourier's Series and Integrals;* and J. H. Jeans, *Dynamical Theory of Gases*. For experimental details it is always necessary to refer to the original papers, but *Physical and Chemical Constants* by G. W. C. Kaye and T. H. Laby (1921) gives a handy and up-to-date summary of numerical results. (H. L. C.)

HEATING AND VENTILATION (*see* 13.160 and 27.1008).—The close association between heating and ventilation, especially in modern practice, makes it desirable to treat the two subjects together.

I. HEATING

When the temperature inside a building is maintained above that out-of-doors, a sufficient quantity of heat must be continuously supplied to replace that which passes by conduction through the walls and roof of the building and to warm the considerable quantity of in-leaking air. The heating system has to produce the proper amount of heat and to distribute it.

The earlier forms of heating apparatus, such as the stove and the fireplace, deliver their heat to the room principally by radiation. In general, heating by convection is to be preferred from a standpoint of comfort in severe climates, and for this reason and because of the dirt and labour necessitated by their care, the stove and the fireplace are being largely superseded, especially in North America, by the warm-air furnace or by steam and hot-water systems. In Great Britain the fireplace is still an acceptable method of heating because of the relatively mild climate.

Warm Air Furnace.—The warm-air furnace system satisfies the requirement of a source of heating removed from living quarters, gives a fairly successful distribution of heat throughout the house and is very low in cost compared with steam and hot-water systems.

It consists of a firepot in which the fuel is burned and a more or less extended flue for the gases of combustion, the whole being surrounded by a sheet-metal casing through which a current of air passes, absorbing heat from the hot surfaces of the firebox and flue and passing thence through metal ducts to the rooms above. Air is supplied to the base of the furnace casing either from out-of-doors or, more economically, by a return duct from some central room of the house. The fundamental difficulty with the warm-air furnace is that the force producing the circulation of air through the system, being due only to the difference in the densities of the heated air in the pipes and the unheated air without, is necessarily very small and consequently it is difficult to heat rooms remote from the furnace, particularly under adverse wind conditions.

Steam-Heating.—This system consists of a boiler in which the steam is generated, a number of so-called radiators located in the rooms to be heated, and a system of piping which conveys the steam to the radiators and returns the water of condensation to the boiler.

The Vapour System.—The so-called vapour system is a steam system operating at a pressure of only a few ounces above atmosphere as compared with a pressure of one to five pounds for the ordinary steam system. In the vapour system the steam enters the radiator through a valve near the top and the displaced air and the water of condensation are conveyed away by return piping, the air being finally discharged from the system through a vent near the boiler. To prevent the flow of steam from the radiator into the return piping, a trap is usually installed at the discharge end of each radiator.

For large buildings the vacuum steam system is used very extensively. The arrangement of the radiators and piping is nearly the same as in the vapour system, and a vacuum pump is connected with the return piping. This increases the differential pressure through the system and promotes the rapid flow of steam to the radiators and the complete removal of air.

Hot-water System.—In the hot-water system, which is widely used in Great Britain, water is heated in a central heater, flows through pipes to the radiators, where it delivers its heat, and thence back to the heater. Circulation is produced, in the simple gravity type system, by the difference in weight of the column of heated water in the supply pipe and the column of cooler water in the return pipe. Most large systems employ forced circulation, produced by a pump in the circuit, thus insuring positive flow and permitting the use of smaller pipes. The hot-water system, because of the thermal capacity of the water contained in it, gives a less fluctuating output of heat to the rooms, but is for the same reason less readily capable of responding when the outside temperature changes. The hot-water system, using forced circulation, is frequently employed in heating groups of buildings because the heat output can be readily controlled from a central point by adjusting the temperature of the water.

Steam is produced for a heating system by a boiler which usually has the furnace or firepot incorporated in it. Where electricity is used for heating—a procedure sometimes employed where coal is expensive and electric current cheap—the boiler is fitted with electric heating elements of the submerged resistance type. In recent years, due to the increasing cost and scarcity of anthracite coal, boilers have been developed which will burn bituminous coal successfully and without excessive smoke. (*See* BOILERS.) This is accomplished by the introduction of air at certain points in the furnace or by other means for burning the volatile matter before it is chilled by contact with the cold boiler surfaces.

Temperature Control.—Temperature control is frequently applied to schools, offices and public buildings in order to secure constant room temperatures. There are several systems in use which regulate the flow of steam to radiators and adjust the position of dampers, under the control of a thermo-stat. Compressed air or electricity are used to furnish the power required.

Central Heating.—In Great Britain, and in Europe generally, the term central heating usually refers to the heating of a building by means of a furnace instead of fireplaces. As understood in North America, however, the term refers to the supplying of heat to a number of separate buildings from a central plant. When portions of a city are thus heated the term district heating is often synonymously used.

Either steam or hot water may be used as the medium for conveying the heat from the central plant. The pipes are carried either in tunnels, permitting ready access to them, or are buried a few feet below the surface enclosed in some form of conduit to insulate the pipe against excessive loss of heat and to protect it. The conduit sometimes consists of a thick-walled wooden box or tube in which case the wood serves as the insulating material; or it is made of concrete or clay tile and a layer of magnesia or asbestos is applied to the pipe as an insulator.

There are extensive systems of this type distributing steam commercially for heating, cooking and to some extent for power in New York City, Detroit, Pittsburg, Rochester, St. Louis and elsewhere. The largest areas covered are about one sq. m. in extent. Business districts and good residential districts of high class are the desirable territory.

Frequently the exhaust steam from electrical generating plants is utilised and is distributed at a pressure of from 2 to 10 lb. above atmosphere; but in some cities steam direct from the boilers at pressures up to 100 lb. or more is used. The consumption of heat by the individual buildings is metred either by a steam meter in the supply pipe or by a meter which measures the water of condensation as it is drained from the heating system of the building. Losses of all kinds between the boiler outlet and the consumer's meter are, in the more efficient systems, from 15 to 20% of the steam sent out from the boilers. Hot water is used as the distributing medium in some cases, but is not regarded as commercially satisfactory, largely because of the lack of a suitable means of measuring the amount of heat used by each consumer

II. VENTILATION

The modern conception of ventilation (*see* PUBLIC HEALTH) distinguishes between the internal and the external effects of the atmosphere upon the body. Those factors having an internal effect are chiefly the humidity of the air affecting the mucous membranes in the respiratory passages, the amount of dust and bacteria in the air and the nature and strength of odours. Externally, the temperature, humidity and motion of the air play perhaps an even more important part by controlling the rate of heat loss from the skin. It is only recently that this cooling power of the air in ventilation has been quantitatively studied. In 1913 Sheppard and E. V. Hill established by tests a comfort zone, which showed, for still air, the relation between temperature and humidity necessary for comfort. More recently Houghten, Yaglou and others, in an investigation sponsored by the American Society of Heating and Ventilating Engineers, the U.S. Bureau of Mines and the U.S. Public Health Service determined the complete relations between temperature, humidity and air motion as they affect bodily comfort.

An adequate system of ventilation must supply a sufficient quantity of air, properly heated and humidified, so that its cooling effect will be correct. Dust and bacteria must be reasonably absent, and odours not excessive. In the more elaborate systems of ventilation, such as are used in schools, theatres, auditoriums and other densely occupied buildings, the air used for ventilation is drawn by a centrifugal fan over steam coils, passed through an air washer for cleaning and humidification, and forced by the fan through a system of ducts to the various inlet points of the rooms to be ventilated. Air is withdrawn from each room, through properly located outlets, into an exhaust duct and discharged to the outside by the exhaust fan.

Arrangement of Ventilating System.—The air washer consists of a spray chamber, in which the air is humidified, followed by a series of baffles wet by sprays which remove most of the dust, and finally there are a number of dry baffles which serve to remove any entrained water. The ventilating system may be used for heating as well as for ventilation.

Artificial cooling is sometimes used in theatres by supplying refrigerated water to the air washer (*see* REFRIGERATION).

HEBREW LITERATURE (*see* 13.169).—Modern Hebrew literature, the beginnings of which go back to the 18th century, is universal in scope and secular in spirit, thus contrasting with the purely legal, ritualistic or homiletic works of earlier times. This literature took its rise in Italy (M. H. Luzzatto, 1707–47), whence it shifted to Germany, showing at first, notably through the influence of Moses Mendelssohn (1729–86), a rationalistic and cosmopolitan tendency.

Following a brief period of activity in Galicia dominated by Biblical criticism and historical scholarship (Krochmal, 1785–1840; Rapoport, 1790–1867), Hebrew literature assumed a new character in Russia and Lithuania, where the so-called Haskalah movement developed—a humanistic and humanitarian spirit which set itself against the traditional exclusiveness of the Jew. It found expression in the historical and scientific compendia of Kalman Schulman (1819–99), in the novel (Mapu, 1808–67) and in poetry (Lebensohn, 1828–52; J. L. Gordon, (1831–92). The novelist P. Smolenskin (1842–85) heralded a reaction, hastened by the pogroms against the Jews, towards a Jewish national policy, which culminated in Zionism. Since his day Hebrew literature has been largely dominated by the idea of a national revival. This idea has found its most complete expression in the essays of Asher Ginzberg (Ahad Ha'am) who has resisted the tendency to lay undue stress on the economic and political factors in Zionism and has insisted on the conception of Palestine as the cultural centre of the Hebrew race.

The individualistic and symbolic spirit in Hebrew literature has been greatly influenced by the modern mystic movement among the Jews known as Hassidism. In the sphere of fiction this spirit found its foremost representative in Isaac Loeb Perez (1851–1915), whose stories are distinguished by artistic beauty and tenderness. Humour is the dominant characteristic of two other famous Hebrew story-writers—S. J. Abramowitsch (known as "Mendele," 1835–1918) and S. Rabinowitz (known as "Sholem Aleichem," 1850–1916). Judah Steinberg (1863–1908), author of many stories, excels in the delineation of character, and in him the individual finds more complete and varied representation than elsewhere in Hebrew literature. This fact, and the clearness and fluency of his style, give him high rank among Hebrew novelists. Another novelist of some distinction is R. A. Brandes (1851–1902), who chose the struggle for religious reform as the theme of his principal novels.

Poetry has made rapid strides in modern Hebrew literature. There is a host of contemporary poets, the most representative of whom is Hayyim Nachman Byalik (1873–). With the exception of Judah ha-Levi (fl. 12th century) he is perhaps the leading Jewish national poet, inheriting the idealism and the prophetic seriousness of his people. He is pre-eminently the poet of Jewish woe. To Jewish national hopes and aspirations he seldom gives expression in his verse. None of the Hebrew poets has grasped and represented the spirit of the Ghetto and its poetry with so much sympathy and so much tenderness of feeling as Byalik. The ideas of Ahad Ha'am and the influence of Gordon's style and form are traceable in his poems. Next to Byalik and in strong contrast with him stands Dr. Saul Tschernichowski (1875–). He was the first to introduce into Hebrew poetry an admiration for the Greek spirit and the sense of complete enjoyment of life. His work is remarkable for its easy gracefulness and its varied rythms and metrical forms. Dr. Jacob Cahan (1880–) is an idealist, whose poems bear the stamp of a marked individuality. In the poems of Zalman Schneor (1886–) there is at times a gentle pessimistic vein, and his verse is full of life and beauty; the rhythm has harmony and tunefulness, the imagery is rich, varied and striking, and the movement quick and bold. His prose, too, is marked by the same qualities. Among a list of poets of less distinction may be mentioned, Jacob Steinberg, Jacob Fichman, Isaac Katzenelson, J. J. Koplewitz, David Schimonwitz, the brothers Simon and Pesach Ginsburg, Hillel Bavli, Judah Karni, A. Schlonsky, Uri Zebi Greenburg, Avigdor Feuerstein, Benjamin N. Silkiner and Simon Leo Halkin. Modern Hebrew poetry, like Hebrew poetry in general, has been strongest in lyric.

The various transformations of Jewish life brought about by the Zionist and other Jewish movements and the influence of foreign literatures had their effects upon the shaping of contemporary Hebrew fiction, notably the short story and the novel. There has been created a Hebrew short story, artistic in technique and generally psychological in presentation, delineating the individual in a variety of moods and situations; but at the same time marked by a minute, torturing self-analysis, by an impotence in the will of the heroes and by an outlook upon life that is gloomy and despondent. The creators of these stories are followers of Micah Joseph Berdyczewski (1865–1921), who in his view of life was influenced by the individualistic theories of Nietzsche. Among the most notable story-writers of this group are Isaiah Domoschvitzky (known as J. Bershadsky, 1870–1908), Joseph Hayyim Brenner (1881–1921), Gershon Schofmann, Uri Nisan Gnessin (1880–1913), Hirsch David Naumberg and Isaac Dob Berkowitz. The melancholy and morbid spirit which some of these writers have introduced into the Hebrew sketch and novel is almost entirely traceable to the influence of the Russian and Scandinavian literatures of the last few decades. A notable exception to this tendency is S. J. Agnon, an original symbolico-mystical writer of short stories and a master of Hebrew style. Other writers of fiction who are free from this pessimistic strain are A. A. Kabak, Moses Smilansky, L. A. Orloff, S. Ben-Zion Guttman, Eliezer Steinman, Asher Barash and A. Reubeni.

The adaptation of the Hebrew language to the needs of modern life owes much to Eliezer Ben-Yehuda (1858–1923), one of the pioneers of the idea of a Jewish national renaissance, whose ten-volume Hebrew dictionary (*Thesaurus totius Hebraitatis*) is a monument of a life's devotion to the revival of Hebrew. The talent of David Frischmann (1863–1922) extended over the domains of the feuilleton, the short story, poetry and criticism. Dr. Joseph Klausner (1874–), the editor of the leading Hebrew monthly *Hashiloah*, is active in many fields—criticism, history, scholarship and journalism. He possesses considerable erudition and historic insight. Hillel Zeitlin, a mystic, has made original contributions to various phases of modern Hebrew literature. The greatest Jewish journalist, writing for Jews in Hebrew and in many other languages, is Nahum Sokolow. Reuben Brainin is a fine stylist and an able critic but his literary ideas and tastes are perhaps too much determined by outside influences. Dr. Simon Bernfeld (1860–) Hebrew literature has a many-sided and very prolific writer with a gift for presenting the results of scholarly research in attractive literary form. Wolf Jawitz (1847–1924) was a historian and a philosopher of religious romanticism. David Neumark (1866–1924) made original contributions to the study of Jewish philosophy. Jacob Klatzkin, Fishel Lachower, S. B. Maximon, Dr. S. M. Melamed, Joel Blau, Osias Thon, Mordecai Ehrenpreis, S. I. Hurwitz and others have contributed much to the development of the essay in Hebrew literature.

Hebrew literature, including its vernacular is a primary factor responsible for the rejuvenation of the national Jewish spirit and for the emancipation of Jewish life from external influences. Literary activity came to a virtual standstill as a result of the World War and its consequences, which bore with especial severity on eastern Europe, formerly the chief centre of Hebrew literature. During the last few years there has been a revival in eastern Europe, and a certain development in America; but the centre of this activity has shifted to Palestine.

HECTOGRAPH: *see* OFFICE APPLIANCES.

HEDIN, SVEN (1865–), Swedish explorer, was born in Stockholm Feb. 19 1865. He was educated at the högskola in Stockholm, and Uppsala University and later studied at Berlin and Halle. In 1885–6 he travelled through Persia and Mesopotamia, and in 1890 was attached to King Oscar's Embassy to the Shah of Persia. In the same year he visited Khurasan and Turkestan and reached Kashgar in 1891. He is best known through his travels in Tibet, which placed him in the first rank of modern Asiatic explorers. Between 1893 and 1897 he travelled across the Asiatic continent from Orenburg by the Ural over the Pamirs and the plateau of Tibet to Peking. During two other expeditions, (1899–1902, 1906–8) he made valuable additions to the scientific knowledge of these tracts and explored specially the sources of the Sutlej and the Brahmaputra. In 1902 he became a Swedish noble, and in 1909 the Indian Government invested him with the K.C.I.E. During the War he made frequent visits to the Turkish front and in 1923 he travelled round the world, through the United States, Mongolia and Russia.

Sven Hedin's writings include: *Journey through Persia and Mesopotamia and the Caucassus* (1887); *Journey through Khorasan and Turkestan* (1892–3); *Through Asia* (1898); *Central Asia and Tibet* (1903); *Adventures in Tibet* (1904); *Scientific Results of a Journey in Central Asia 1899–1902*, 8 vol. (1904–7); *Transhimalaya*, 3 vol. (1909–12); *Overland to India*, 2 vol. (1910); *Bagdad, Babylon, Nineveh* (1917); *To Jerusalem* (1917); *Southern Tibet*, 12 vol. (1917–22); *Eine Routenaufnahme durch Ostpersien*, 2 vol. (1918–24); *My Life as an Explorer* (1926).

HEDJAZ: *see* HEJAZ.

HEIDENSTAM, VERNER VON (1859–), Swedish writer, was born July 6 1859 in Olshammar. He lived for several years in the south of Europe, Egypt and the East. On his return home, he began his literary career with a collection of poems entitled *Vallfart och Vandringsaar* (Pilgrimage and Years of Wandering) (1888) based on oriental life, and which formed a protest against the naturalism then prevalent in Swedish literature. This led to the great literary renaissance of 1890 in Sweden. In 1889 he published *Endymion*, an oriental story, and in 1892 his great work, *Alienus*, a fanciful romance concerning a pilgrimage in search of beauty through various ages and countries. His other collection of *Poems* (1895) indicates the author's transition to national ideas. This national tendency attained its zenith in his great prose work, *Karolinerna* (The Carlists), translated into English in 1902, a collection of stories about the time of King Charles XII. Then followed *Den Hellige Birgittas Pilegrimsfaerd* (St. Bridget's Pilgrimage) in 1901, besides descriptions of Sweden in ancient times and in the Middle Ages in *Folkungaträdet*, 2 vol. (1905, 1920), and *Svenskarna og deres høvdinger* (Swedes and Their Chieftains), 2 vol. (1908, 1909). In 1915 Heidenstam published *Nya Dikter* (The New Poet), and in 1916 was awarded the Nobel Prize for literature. See F. Böök, *Sveriges moderna litteratur*, 2nd ed. (1921).

HEIJERMANS, HERMAN (1864–1924), Dutch writer (*see* 13.212). His later plays include *Schakels* (1904); *Allerzielen* (1906); *De Groote Vlucht* (1908); *Ahasuerus* (1912) and *Eva Bonheur* (1919). He lived for a few years in Berlin, but returned to Holland in 1912 in order to manage a society of players, and devoted himself to that work. He died in 1924.

HEJAZ (*see* 13.217).—Under the Ottoman régime the Hejaz, extending from Ma'an and 'Aqaba in the north to Hali Point on the Red Sea coast in the south, formed a *Vilayat* with a *wali* resident at Mecca, controlling a garrison of about 7,000 troops. In 1904 Turkish control of the northern part of the Hejaz was strengthened by the completion of the Hejaz Railway down to Medina. In 1908 Husain ibn 'Ali was appointed to be Amir of Mecca, and soon set himself to thwart the Turkish Govt., particularly in the matter of the extension of the railway to the city of Mecca.

The War Period.—The proclamation of a *Jihad* by the Turks at the outset of the World War made Arabia a source of potential danger to the Allied cause. Effective control of the Hejaz would have enabled the Turks and their Allies to threaten the sea route to the East, and Great Britain sought to counter this danger by entering into negotiations with Sharif Husain. The latter, inspired by great personal ambition, was ripe for rebellion against the Turks, and, after a lengthy correspondence on the subject of the terms on which he should espouse the Allied cause, raised the standard of revolt on June 5 1916. Mecca and Jidda (the latter after bombardment by British ships) were soon wrested from the Turks, and Taif surrendered to the Sharifian forces in September.

The Sharifian armies were unable to make any impression on the strong Turkish defences at Medina, but at this time Col. T. E. Lawrence appeared upon the scene, and in concert with Husain's third son, Amir Faisal, organised a brilliant guerilla campaign against the Hejaz Railway and the Turkish positions further north. The ports of Yenbo', Wejh and 'Aqaba (1917) fell in rapid succession, and with the subsequent capture of Ma'an and Shaubak, the Hejaz reached the northern frontier which it kept till July 1925. Medina, successfully defended by Fakhri Pasha till the end of the War, only surrendered on the receipt of explicit orders from Constantinople in Jan. 1919. The Amir Faisal represented Husain, who had assumed the title of king in 1916, at the Peace Conference of 1919 at Paris, and the Hejaz was admitted as an original member of the League of Nations, but King Husain eventually refused to ratify the Peace Treaties. In March 1919 King Husain's relations with Ibn Sa'ud became strained owing to a dispute over the oasis of Khurma, and in May his forces advanced to occupy the place. They were routed by the Wahhabis at Turaba, and later (1922) Khaibar and Taima were in turn occupied by Ibn Sa'ud.

Meanwhile, in the summer of 1921, Lawrence visited Jidda on behalf of the British Govt. to negotiate a treaty with King Husain, but negotiations broke down owing to the latter's inability to accept the *de facto* position in Palestine. Negotiations were subsequently kept alive by Dr. Naji al Asil, Hashimite representative in London, but were finally abandoned on the outbreak of war between Nejd and Hejaz in Sept. 1924.

Post-War Events.—The Sharifian administration, mild enough during the War, became more and more autocratic and even tyrannical with the passage of time. King Husain alienated the sympathies of his own people, and went out of his way to court the enmity of his neighbours. By the terms of the Peace Treaties he undertook to maintain the annual pilgrimage under satisfactory conditions for all Moslems, but this part of his administration left much to be desired. There was much corruption in all government departments. Education was wholly neglected. Even the army was not maintained on an efficient basis. An Air Force was inaugurated in 1921, but was allowed to disintegrate owing to the King's parsimony—it was revived in the autumn of 1924 by his successor and reorganised in 1925. An effective scheme of wireless communication, with eight or nine well-equipped stations, was perhaps the brightest feature of King Husain's administration. The nucleus of a transport fleet (four ships) was also formed by him, and proved invaluable during the war with Nejd. A local coinage and stamp issue emanated from Mecca during these years, and a semi-official newspaper (*Al Qibla*) was started by the King for propaganda purposes.

Meanwhile the storm was approaching. King Husain refused until too late to send a representative to the Conference convened at Kuwait by the British Government. In Jan. 1924 he arrived in Transjordania on a visit to his son, 'Abdullah, and, while there, he assumed the vacant title of *Khalifa* on the deposition of the Turkish Sultan-Khalifa by the Kemalist Govt. of Angora. He then hastened back to Mecca to issue invitations to the Moslem world to recognise his new status, but his overtures met with little success, and the Wahhabi Sultan realised that his ambitious enemy must be crushed at once.

Husain Abdicates.—In Sept. 1924 Ibn Sa'ud launched his armies on the Hejaz. Taif fell without a show of resistance. Consternation reigned at Mecca, and King Husain, under pressure from the notables of Jidda, abdicated on Oct. 5 in favour of his eldest son, 'Ali, who was acclaimed as "King of the Hejaz only." King 'Ali evacuated Mecca and hastily recruited an army from Palestine, Syria and Transjordan to defend Jidda. Tahsin Pasha al Faqir, the commander of the so-called "Victory" division, organised a strong defensive position of trenches and barbed-wire entanglements in a semi-circle round the town. Ibn Sa'ud himself arrived at Mecca in Dec. and the attack on Jidda began on Jan. 4 1925. The Wahhabis occupied the few villages outside the entrenched position, but had not succeeded in reducing the town at the end of June when the siege was temporarily raised to enable them to perform the pilgrimage. Meanwhile Ibn Sa'ud, having occupied the ports of Qunfida and Lith south of Jidda and that of Rabigh north of it, extended his operations further north. Medina and its seaport Yenbo' were invested, while Umlaj, north of the latter, was occupied. On Dec. 5 Medina surrendered and Wejh followed suit. King 'Ali realised that his situation was hopeless and abdicated on Dec. 19. Jidda then surrendered simultaneously with Yenbo', and Ibn Sa'ud was master of all Hejaz, of which he was formally proclaimed King at Mecca on Jan. 8 1926. For bibliography *see* ARABIA. (H. St. J. B. P.)

HELFFERICH, KARL (1872–1924), German financier and politician, was born in Neustadt-on-the-Havel July 22 1872. In 1901 he became a professor of political science in Berlin, and in 1906 went to Constantinople as manager of the Anatolian Railway. He returned to Berlin in 1908 to take up the chairmanship of the Deutsche Bank. In 1913 he was the chief German delegate at the Paris conference for the settlement of Balkan financial affairs. In 1915 Helfferich was appointed Secretary of State for the Imperial Treasury, where he followed the principle of defraying the cost of the War by borrowing rather than by fresh taxation, relying on a final German victory. In June 1916 he left the Treasury for the Home Office. In June 1918 he was appointed to succeed Count Mirbach, who had been assassinated, as Germany's representative in Moscow. He was, however, unable to occupy this post, and returned to Berlin to conduct the economic and industrial demobilisation of Germany after the Armistice. He was fatally injured in a railway accident near Bellinzona April 23 1924.

HELICOPTER: *see* AIRSCREW.

HELIGOLAND BIGHT, BATTLE OF THE.—This naval action was fought in the Bight on Aug. 28 1914 between British and German naval forces. According to the original British plan three submarines were to lie off Heligoland to attack German cruisers, while three others were to be posted to the west to entice their destroyers out. The Harwich flotillas were then to come in from the north and, sweeping on a nine miles front to the westward, were to cut off any light craft patrolling to the west of Heligoland. Adml. Jellicoe proposed to reinforce the flotilla with Vice-Adml. Beatty's battle cruisers and the 1st Light Cruiser Squadron. This proposal was only approved on Aug. 26 and, as there was no time to send the operation orders north, Beatty left Scapa with only a general idea of the plan and no details of the intended movements of the submarines. The forces from Harwich had already sailed and did not know that Beatty was on his way to reinforce them.

British Forces.—On Aug. 27 the British forces were all on their way to the Bight, organised as follows:—

TABLE I.

Sweeping Force (Commodore Reginald Tyrwhitt): "Arethusa," 2 6-in., 6 4-in., 28·5 knots; "Fearless," 10 4-in., 26 knots. Third Flotilla, 1st, 2nd, 3rd and 4th Divs., 16 destroyers; First Flotilla, 1st, 2nd, 3rd and 5th Divs., 15 destroyers. Total: 2 light cruisers, 31 destroyers.

Submarine Force (Commodore Roger Keyes): "Lurcher," "Firedrake," E4, E5, E9 (off Heligoland); E6, E7, E8 (west of Heligoland).

Battle Cruiser Force (Vice-Adml. Sir David Beatty): 1st Battle Cruiser Sqn., "Lion," "Queen Mary," "Princess Royal," all 8 13·5-inch.

Light Cruiser Squadron (Commodore W. E. Goodenough): "Southampton," "Falmouth," both 8 6-in.; "Birmingham," "Nottingham," "Lowestoft," 9 6-in.; "Liverpool," 2 6-in., 10 4-inch.

Cruiser Force K (Rear-Adml. Sir A. G. Moore): "Invincible," "New Zealand," with four destroyers.

Cruiser Force C (Rear-Adml. A. Christian): "Euryalus," "Bacchante," "Cressy," "Hogue," "Aboukir," all 2 9·2-in., 12 6-in.; "Amethyst," 12 4-in.

Total Forces: 5 battle cruisers, 9 light cruisers, 5 armoured cruisers, 37 destroyers, 6 submarines.

It was light at 4 A.M. Goodenough with the 1st Light Cruiser Squadron had met Tyrwhitt at 3:45 A.M. and was at first mistaken for an enemy, but the cruisers were recognised in time. By 5 A.M. the sun had risen, and the forces were in position some 60 m. northwest of Heligoland. It was a fine morning with a smooth sea and a gentle breeze blowing from the northwest. Beatty's battle cruisers were some 30 m. to the westward and all was ready. The flotillas started off to the southeast at 20 knots, the "Arethusa" and 3rd Flotilla ahead, with the "Fearless" and 1st Flotilla 2 m. astern. The 1st Light Cruiser Squadron followed 8 m. behind. From a point 12 m. west of Heligoland, which he should reach at 8 A.M., Tyrwhitt intended to turn west and sweep anything in the Bight into his net. The Germans knew nothing of the impending attack. Posted round Heligoland in a semi-circle they had two lines of patrols, an outer line of nine destroyers 25 m. from the island and an inner line of older vessels (3rd Minesweeping Div.) 13 m. from it. These were supported by a flotilla at Heligoland, three cruisers on outpost duty, and a battleship in the Jade.

German Forces.—The German disposition in detail was as follows:—

TABLE II.

Outpost Forces: Outposts, Outer line, 9 destroyers; Inner line, 11 torpedo boats.

In Support of Outposts: 11 destroyers, 5th Flotilla (Heligoland). Light cruisers, "Stettin" (10 4·1-in.), "Hela," 4 4·1-in. (off

Heligoland), "Frauenlob," 10 4·1-in. (off Jade). Battleship, "Heligoland," 12 12-in. (in Jade).

In Wilhelmshaven Roads, Wilhelmshaven and off the Ems: Light cruisers, "Ariadne," "Kolberg," "Cöln" (Rear Adml. Maas, First Leader of Flotillas), "Strassburg," "Stralsund," "Rostock," "Mainz" (off the Ems). Battle cruisers, 1st Scouting Group, "Seydlitz," "Moltke," "Von der Tann," "Blucher." Battleships: 1st and 3rd Sqdns. (7 dreadnoughts).

Total Forces: 8 battleships, 4 battle cruisers, 10 light cruisers, 20 destroyers, 11 torpedo boats, 8 submarines.

The movements of the heavy German ships were governed entirely by the time of low water on the outer Jade bar. This was at 9:33 A.M. and meant that between 7 A.M. and noon no German battleship nor battle cruiser could put to sea.

The Early Operations

The activities of this eventful day started at 4:45 A.M. when the British submarine E7 fired a torpedo at the destroyer G194 patrolling some 25 m. northwest of Heligoland, and Rear-Adml. Maas, the German flotilla admiral, at 6:45 A.M. sent out the 5th Flotilla from Heligoland to hunt the submarine. The sea was smooth, the sky overcast and weather dull. At 6:53 A.M. the "Arethusa" struck the outer patrol line and sent G194 flying towards Heligoland with the "Laurel" and her division in hot pursuit. They drew away to the east and at 7:26 A.M. Tyrwhitt turned to the southeast to support them. A few minutes later they sighted the German 5th Flotilla coming up, and sent it also flying back.

The report from G194 reached the German flagship about 7:30 A.M., and on it becoming clear that a considerable force of British destroyers had penetrated into the Bight, the light cruisers were ordered to proceed. The "Stettin" was already on her way at 7:58 A.M., though she had not raised a full head of steam. By this time the German 5th Flotilla was calling loudly for cruiser support. The alarm had gone at Heligoland, and by 7:50 A.M. the whole fortress was standing to its guns. The visibility was then about 16,000 yd., and German destroyers came into view driving pell-mell towards the island. The British were overhauling them. One of the destroyers had been hit in the stokehold at 7:50 A.M. and her position was becoming critical, when at 7:58 A.M. the "Stettin," coming round the north of Heligoland, appeared on the scene and opened fire on the "Laurel's" division at 9,300 yards. A 8:05 A.M. the "Fearless" sighted her and opened fire; the "Stettin" retired behind Heligoland to get up steam for full speed, while the "Fearless," receiving a signal at 8:12 A.M. to alter course to west-quarter-south, turned accordingly to begin the sweep.

This brief respite had enabled the German 5th Flotilla to get clear and they came streaming in towards Heligoland. The inner patrol line was under a heavy fire from the "Arethusa," and the torpedo boats D8 and T33 suffered severely, but at 8:08 A.M. the "Frauenlob" arrived on the scene from the south and engaged the "Arethusa" on a southwest course. A sharp action ensued at 6,500 to 4,000 yards. Only the forecastle gun of the "Arethusa" remained in action, and eight men were killed. The "Frauenlob" received some 10 hits and had nine killed and 28 wounded. At 8:25 A.M. the "Arethusa" turned to west-quarter-south and the "Frauenlob" turning south broke off the action.

The Second Phase (see fig. 1).—By 8:30 A.M. this phase of the operation was over and both flotillas were proceeding to the west with the "Fearless" some 6 m. north of the "Arethusa." Goodenough's light cruisers had also turned west at 8:30 A.M. and were some 12 m. to the westward. Beatty was moving to and fro with his battle cruisers about 45 m. to the northwest. The attack had not developed according to plan, for the German patrols had broken back and reached home with one exception. This was V187, the flotilla leader's boat, which the "Fearless" sighted to the westward at 8:15 A.M., and which was sunk after a hot chase by the "Goshawk," "Phoenix" and "Ferret" at 9:10 A.M. The destroyers had lowered boats to rescue the survivors, but the "Stettin," which had now got steam up, reappeared on the scene and drove them off. Five boats in the scurry had to be left behind, but E4 (Lt.-Comm. E. W. Leir), emerging suddenly, rescued the "Defender's" men, took an officer and two of V187's crew "as a sample," then disappeared as suddenly and silently as she came. By 8:55 A.M. the "Fearless" had rejoined the "Arethusa" and the flotillas were now from 12 to 15 m. west of Heligoland steering west-quarter-south.

Commodore Keyes, in the "Lurcher," not knowing Goodenough's cruisers were on the scene, had mistaken them for the enemy and asked for help, but recognised them at 10 A.M., and as the "Southampton" had already attempted to ram E6, Goodenough decided to withdraw to the west and leave the field clear for the submarines. Tyrwhitt had turned boldly back to help Keyes at 9:45 A.M. The "Arethusa" stopped for repairs at 10:17; her engines were disabled and she was only able to go 10 knots. A lull of half an hour ensued. By this time the Germans were beginning to appreciate the situation. At 8:20 A.M. the commander-in-chief, Adml. von Ingenohl, had taken over the command from Hipper, the admiral of scouting forces, and had ordered the battle cruisers to raise steam and to proceed as

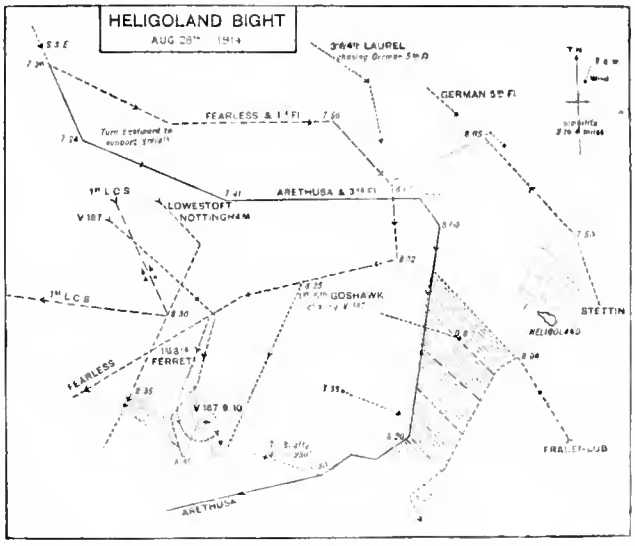

FIG. 1.—Flotillas at 8:30 A.M.

soon as there was water on the bar. The German light cruisers, eager to attack, were pushing out as soon as they could raise steam. They now began to appear on the scene.

The "Arethusa" had got under way again at 10:40 A.M. and was making slowly to the west when at 10:46 A.M. the "Strassburg," which was trying to get in touch with the "Stettin," appeared in the southeast, coming up on a north-north-west course. She opened fire at about 8,400 yd., crossed the "Arethusa's" stern, turned and disappeared to the north in the mist. The "Cöln" had come up behind her at 11:5 A.M., but after exchanging a few salvos she too passed on. At 11:16 A.M. the "Strassburg" reappeared to the north and steering a parallel course to the west opened a heavy fire at 8,650 yards. The 1st and 2nd Divs. of the 3rd Flotilla went off to the northwest and, joined by the 1st Div. of the 1st Flotilla, attacked her at 11:35 A.M. Two torpedoes ran past her and she disappeared in the mist. The destroyers rejoined the "Arethusa" and continued their course to the westward.

When the "Cöln" appeared Tyrwhitt had signalled for support, and when the "Strassburg" came in sight the second time, Capt. Blunt of the "Fearless," foreseeing the concentration which the German light cruisers were striving to achieve in the mist, sent an urgent signal to Beatty for assistance. Beatty had been waiting and watching round a position in 54° 28′ N., 6° 20′ East. The situation was obscure, but between 11 and 11:30 A.M. it was clear that Tyrwhitt was engaging a cruiser some 30 m. to the eastward, and at 11:20 A.M. Goodenough was ordered to support him. Then came Capt. Blunt's signal from the "Fearless" couched in terms of urgency. Beatty did not know that the "Arethusa" could only go 10 knots, but he knew that

the flotillas were only 26 m. from Heligoland, and that the German base at Emden lay close to their flank. He decided at once to take his whole force in the Bight. At 11:24 A.M. his battle cruisers had been formed in single line ahead, and working up to full speed he proceeded east-south-east to throw their tremendous weight into the issue of the day.

The Main Action

The "Mainz" had left the Ems shortly after 7 A.M. and was making at full speed to the east to cut off the British destroyers and to join the "Strassburg" and the "Stettin." At 11:30 A.M. she was sighted almost right ahead by the 2nd, 3rd and 5th Divs. of the British 1st Flotilla as they came west with the "Fearless" and "Arethusa" some miles behind. The "Mainz" turned to the north and opening a heavy fire chased the destroyers to the north for 20 minutes. But at 11:50 A.M. the situation suddenly changed. Out of the mist to the north-north-west there appeared four light cruisers coming down at high speed. They were Goodenough's cruisers. For an anxious minute the destroyers were uncertain whether they were friend or foe, then they recognised them and turned eagerly to join them. The "Mainz" recognised them too and fled to the southward at 25 knots. The range was over 7,000 yd.; she received two hits and drew away in the mist, sending at noon a signal—

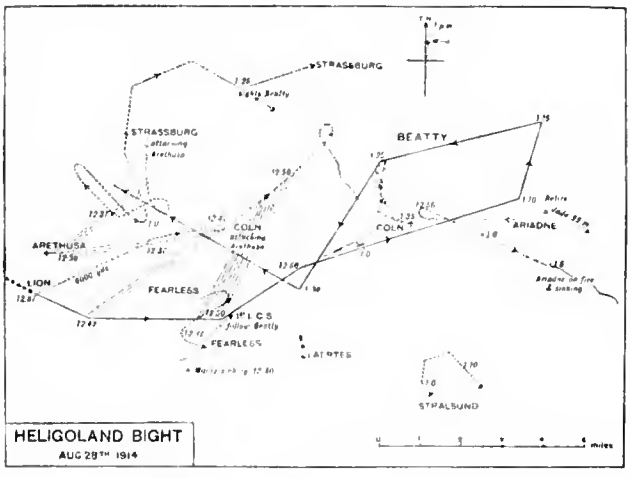

FIG. 2.—Beatty Enters the Fight.

the last she sent—that she was being chased by a battle cruiser. It was received at 12:05 P.M. and the "Moltke" and "Von der Tann" were ordered to proceed, screened by the German 8th Flotilla. In the river it was clear, and no one had informed the German command of the mist prevailing in the Bight. The "Mainz," running to the southeast had hardly drawn away from the light cruisers when at 12:08 P.M. she sighted the "Fearless" and the 3rd Flotilla coming west. She swung round to south as the 1st and 2nd Divs. of the British 3rd Flotilla turned to north and the 4th Div. to south to engage her.

Sinking of the "Mainz."—In the action that ensued the "Mainz's" rudder was damaged and her port engine brought to a stop. She then concentrated her fire on the 4th Div. at about 5,000 yards. The "Laurel" was hit by the first salvo; the fourth blew up a number of lyddite shells, and with her captain severely wounded and her after funnel blown away, she crawled away hidden in her own smoke and steam. The "Liberty" had her mast shot away and her captain killed. The "Laertes" was hit four times by a single salvo at 4,000 yd., and stopped dead. But the "Mainz" had been hit at 12:15 P.M. on the port side amidships by a torpedo fired by one of the destroyers, and Goodenough's cruisers which were now closing, opened a deadly fire which reduced her quickly to a wreck. At 12:25 P.M. they ceased fire; the "Lurcher" coming alongside saved her crew and at 1:08 P.M. she settled by the bows and sank.

British Battle Cruisers in Action.—The situation was still far from clear; the flotillas were scattered; the "Strassburg" and "Cöln" had appeared to the northeast and opened a heavy fire. Then suddenly out of the mist there emerged Beatty's four great battle cruisers steaming at high speed. They swept past the sinking "Mainz" and on to the northeast with Goodenough and his light cruisers following in their wake. The German cruisers fled, but it was too late. At 12:37 P.M. the "Lion" sighted the "Cöln" on the port bow and opened fire at 3,800 yd.; the "Cöln" ran desperately to the northeast, but a heavy shell disabled her engines. Then she gained a brief respite, for the "Ariadne" was sighted by the "Lion" trying to cross her bows on a southeast course. Fire was opened on her. She was hit by the first two salvos and disappeared in the mist to the southeast, on fire and sinking.

Beatty now decided to withdraw, and at 1:10 P.M. made the signal to retire. The "Lion" came gradually round to a westerly course and at 1:25 P.M. sighted the "Cöln" again, steering slowly to the southeast. Her admiral had fallen; her captain was seriously wounded. The "Lion" sent a 13·5-in. shell into her; she listed to port and sank with flag flying at 1:35 P.M. By this time both the "Stettin" and "Strassburg" had sighted and reported the British battle cruisers, and at 1:50 P.M. the German light cruisers were ordered to fall back on the "Moltke" and "Von der Tann." It was not, however, till 2 P.M. that the battle cruisers passed the bar of the Outer Jade. The German battleships were then raising steam, and the battle cruisers were ordered (2:41 P.M.) not to advance against the British, but to wait for the "Seydlitz" 25 m. west of Heligoland.

By 3:50 P.M. the three German battle cruisers had reached that position, and there they were joined by the "Strassburg," "Kolberg" and "Stralsund." They made a short sally, but there were no signs of any British ships, and they turned back before reaching the spot where the "Cöln" had sunk. For the British it remained only to get home. At 4:30 P.M. Rear-Adml. Campbell's cruisers met the destroyers and the "Laurel" was taken in tow by "Amethyst." The "Arethusa" struggled on at six knots till 7 P.M., then signalled for assistance, and at 9:30 P.M. was taken in tow by the "Hogue" and returned safely.

Results of the Battle.—Mist, uncertainty and the speed of the German light cruisers had hampered the British submarines. The German submarines had all been held back off Heligoland and by the time they were finally dispatched to attack the British battle cruisers, the latter were out of reach. The engagement was a severe blow to the German fleet. They lost three light cruisers and one destroyer, and their casualties were 63 officers and 649 men killed, 20 officers and 361 men wounded, nine officers and 140 men prisoners; a total of 1,242 against the British 35 killed and some 40 wounded.

The engagement had important ulterior consequences. When Beatty swooped down on the Bight, he drove a great wedge into German naval policy, for the loss of the cruisers confirmed the Kaiser in his determination to restrict the German fleet to a strictly defensive policy. For the British Navy and Nation the victory came at an opportune time. The irresistible advance of the German Army had filled many with something like dismay. The news of a naval victory at the very gates of the enemy lightened the gloom, and gave the nation faith in the navy's ability to face its gigantic task.

HELIOTHERAPY (*see* PUBLIC HEALTH; THERAPEUTICS).—Heliotherapy, or treatment by sunlight, has been intermittently practised since the dawn of history, but its scientific exploitation dates from the time of Finsen, who especially developed light treatment by the employment of artificial sources of light, notably the carbon arc. It owes much to the work of Bernhard and Rollier, who commenced treatment with natural sunlight early in the present century. The latter especially, by the brilliance of his results and his enthusiastic advocacy, has done much to popularise its use, especially in nonpulmonary tuberculosis.

Its employment on an extensive scale in Great Britain was initiated with the establishment of the Treloar Cripples' Hospital at Alton. It was employed to some extent with gratifying results on septic wounds contracted during the War, but interest

has been especially aroused since that period, the abnormally fine summer of 1921 and the institution of Daylight Saving calling general notice to the importance and significance of sunlight in our lives both in health and disease. Further researches of numerous investigators have done much to demonstrate the manner in which sunlight is of therapeutic value.

Essential Conditions.—The most obvious benefits are noted by clinical observation on patients suitably exposed to solar rays. Certain essentials are necessary to demonstrate these beneficial results. The patient exposed to the sunlight should first be acclimatised; he must never be too hot or too cold; in brilliant sunshine his head should be protected, and if there is much glare his eyes should be shielded by dark goggles. Exposure should be gradual: first the feet are sunned for short periods daily, the length of exposure and the area exposed being increased slowly, so that at the end of a fortnight exposure of the whole body may be generally tolerated with safety. Periods of exposure are gradually lengthened, until eventually the patients are often able to tolerate and benefit by exposure of the nude skin for from three to four hours daily.

There are great variations in the optimum exposure of different individuals. Generally speaking, brunettes tolerate exposure better than blondes; individuals who freckle but whose skins do not brown must be exposed with great caution, while albinos can barely tolerate exposure at all. On the normal skin an erythema develops within six hours of exposure; care should be taken not to exceed this erythema, and blistering is to be avoided. Gradually the skin becomes bronzed, and as this bronzing or pigmentation deepens so may exposure be prolonged, the pigment protecting the patient from the harmful effects of the actinic rays.

Insolation necessarily involves exposure of the body to the cold air, and the latter has been shown to increase the metabolic activity of the subject treated. The rays of greatest therapeutic value are the ultra-violet or actinic rays, the light waves of shortest wave-length in the solar spectrum. These are most intense at the seaside or on the mountains. Excess of heat rays is to be avoided, and insolation for its therapeutic value is thus better carried out in temperate than in tropic regions. Properly timed exposure on the individual responding to treatment is associated with a tonic and exhilarating effect; exposure unduly prolonged results in fatigue and exhaustion, and is to be avoided.

Effects of Insolation.—While properly applied insolation exercises a tonic effect on the body, it has been demonstrated that it is equally stimulating to the mind. The exposed subject is notably more cheerful and exhilarated, and evidence has been adduced to show that mental responses are brisker and mental activities more pronounced. On the body the effect of insolation may be described as local or direct and remote or indirect. Light exercises a beneficial effect on superficial lesions by reason of the direct bactericidal action of the actinic rays, assisted by the favourable inflammatory response which carefully timed exposure elicits.

The remote beneficial effects are more marked but less easy to explain. Eidenow has shown that the haemobactericidal power is often raised after an erythema dose. This enhanced power of the blood to destroy pathogenic organisms is obtainable equally when a portion or the whole of the skin is exposed, and, if increased haemobactericidal power is alone sought, fractional exposures of different portions of the skin at consecutive sessions is the method of treatment of choice. Sonne has demonstrated that the visible rays of the solar spectrum have considerable penetrative power, pass through the skin, and are absorbed in the subjacent blood, their physical being transformed into thermal energy. He has suggested that this local heating effect is of value in destroying deleterious circulating toxins. Investigations have shown that the calcium, phosphorus and iron content of the blood may be raised by insolation.

Sunlight treatment has its greatest therapeutic value in increasing and maintaining bodily tone and energy, in the treatment of the various manifestations of surgical tuberculosis, in the treatment of rickets and the relief of nervous asthma. It is of proved value in certain affections of the skin, notably psoriasis. It is of great assistance in a variety of conditions, accelerating and consolidating the cure, particularly in convalescence from debilitating diseases such as infectious fevers. Its stimulating effect is seen in increasing fecundity and in the treatment of certain defects of the endocrine glands. The range of its usefulness is being rapidly extended, in the main, as an aid to cure rather than as a specific treatment. See A. Rollier and others, *Heliotherapy* (1923). (H. J. G.)

HELIUM (*see* 13.233).—Helium, next to hydrogen, is the lightest of all the chemical elements. Except at exceedingly low temperatures, it exists only in the gaseous form.

Sources of Helium.—Investigations carried out since 1895 have shown that helium is widely diffused throughout the earth. It can be obtained from many types of rocks, minerals and earths, and it is present in varying amounts in probably all natural gases and spring waters. It is present, too, in the atmosphere of the earth to the extent of about one part in 185,000 by volume. Evidence that helium is universally distributed is afforded by the fact that many of the white stars exhibit its absorption spectrum, while certain other stars and nebulae show the bright line spectrum of the gas. Helium has also been found in a meteorite that reached the earth at Augusta Co., Va., United States of America.

Helium from Rocks and Minerals.—In the case of most of the rocks and minerals that contain helium in appreciable amounts the gas is present as a result of the radioactive disintegration of the uranium or of the thorium present in them. Of all the minerals examined, thorianite, which consists chiefly of thorium oxide, is probably the richest in helium. It has been found to contain 9·5 cu. cm. of helium per gramme.

Monazite, a phosphate of thorium and other rare earths, contains on the average about 1 cu. cm. per gramme. Cleveite, samarskite and fergusonite contain a little more than monazite. Helium is found in minute quantities in practically all the common minerals of the earth, and its origin in them has been traced to radioactive matter that is universally distributed in minute amounts in the material constituents of the earth's crust. In two cases helium has been found in minerals in the absence of appreciable amounts of uranium and thorium compounds, namely in beryl and in sylvine (potassium chloride). It is interesting to note, however, in this connection that potassium and rubidium in their elemental state as well as in the form of chemical compounds have been shown to be radioactive at least to the extent of emitting beta rays. In extracting helium from the mineral thorianite, which is imported from Ceylon usually for the manufacture of thoria, the method generally followed is that given by Lord Rayleigh. The mineral dissolves readily in strong nitric acid, and the helium contained is then liberated. The gas contains a certain amount of hydrogen and of oxides of carbon, also traces of nitrogen. To get rid of carbon some oxygen is added to the helium and the mixture is exploded with an electric spark.

All the remaining impurities, including the excess of oxygen, can then be taken out of the gas by Sir James Dewar's ingenious method of absorption with charcoal cooled in liquid air. Helium is but slightly absorbed by the cold charcoal, and consequently can be pumped off from the vessel containing the charcoal in a state of the highest purity. If liquid air is not available helium can be purified by the methods employed for argon, the various impurities present being removed by one or other of the agents —calcium carbide or metallic calcium, copper oxide, caustic potash and phosphorus pentoxide. If thorianite is not available, monazite, which is more abundant, may be utilised. In 1895 Lockyer showed that the helium contained in minerals could be extracted from them by heat; J. A. Gray (*Proc. Roy. Soc.*, 82A, p. 301, 1909) confirmed this discovery at a later date, and showed that helium could also be extracted by simply grinding the minerals into a fine state of division.

Helium from the Atmosphere.—Helium may be extracted from the atmosphere by passing ordinary air through tubes cooled with liquid hydrogen. At the temperature of liquid hydrogen all elements in the air become solidified excepting helium, and the latter, after passing through the tubes, can be collected in a highly

purified state. In the process of the liquefaction of air, or in that of extracting nitrogen or oxygen from the air by liquefaction and rectification in large industrial plants, it has been found feasible to include in the machines used for the purpose devices that allow the helium and the neon of the air to be separated out, these two gases being the only constituents of the atmosphere that remain in the gaseous form when air is liquefied. As charcoal cooled with liquid air has more condensing power for neon than for helium, it is generally used to separate out the helium from a mixture of these two gases. Final purification, however, is best effected by the use of liquid hydrogen.

Helium from Mineral Springs and Natural Gases.—Helium is found in the gases evolved from many thermal water springs. Moureu and Lepape, who made an exhaustive determination of the helium content of the gases evolved from mineral springs in France, found that many of them contained a considerable proportion of helium. At one spring in Maizières it amounted to 5·92%, and at two others in Santenay (Côte d'Or) helium contents of 8·4% and 9·76% by volume were found. In the hot springs of Bath, England, the helium amounts to about one-thousandth part of the gas evolved. Traces of helium have been found in the gases of the thermal springs in Iceland, and also in many of the natural gases of the other countries in Europe. The quantities involved in the latter, however, are extremely small and the occurrences unimportant. Lord Rayleigh has suggested that the helium found in hot springs may be derived from the disintegration of common rocks at great depths.

By far the best practical sources of helium are the natural gases of America. In Canada, while natural gases are found in all the provinces, they exist in commercial quantities only in the provinces of Alberta, Ontario and New Brunswick. The helium content of these gases has been determined on several occasions, and the latest results are those given by the Mines Branch of the Dept. of Mines of Canada. This report shows that while helium is found in all the Canadian gases it has not been found to be present in any of them to a greater extent than 1%. A conservative estimate of the amount of helium recoverable from the natural gases of Canada would be 5,000,000 cu. ft. per annum.

In the United States of America the main helium resources occur in the Texas, Mid-continent and Appalachian natural gas-fields, where the supplies of helium-bearing gas are widely distributed, and where in some localities they are of great magnitude. The helium content of the gases from a majority of the wells is not greater than 0·6%, but in Kansas a number of wells exist that give a supply of natural gas containing from 1·5% to 1·84% of helium. It is estimated that it would be possible to extract nearly 50,000,000 cu. ft. of helium yearly from the natural gases of the United States.

Properties of Helium.—Helium is less soluble in water than any other gas, and recent determinations by Antropoff give the following values for its solubility: 0° C. ·00967, 10° C. ·00991, 20° C. ·00996, 30° C. ·01007, 40° C. ·01029, 50° C. ·0108. Quartz glass at a red heat is freely permeable to helium. The effect is even perceptible at a temperature as low as 180° Centigrade. At 500° C. quartz glass has been shown by Williams and Ferguson to be 22 times as permeable to helium as to hydrogen (*Jour. of Am. Chem. Soc.*, Oct. 1922). This property has been put forward as the basis of a practical method of separating helium from other gases. M. Travers has suggested, also, that it may explain the liberation of helium from minerals by heat, the gas being enabled to permeate the siliceous materials in which it is enclosed. Thorianite, however, contains no silica, and until it is shown that metallic oxides are permeable to the gas this explanation can scarcely be accepted as valid. With rubbered balloon fabrics the permeability to helium has been found to be less than to hydrogen, the ratio of helium to hydrogen permeability being about 0·7. With skin-lined fabrics the ratio of helium to hydrogen permeability has been found to be about unity. The temperature coefficient of increase of pressure at constant volume is perfectly normal for helium, and has a value of 0·0036614 (Fourth Int. Cong. on Refrigeration, June 1924). The thermal conductivity at 0° C. is given by Schwarze as 0·0003386, and the viscosity as determined by Schultze at 15° C. is 1·086 compared with that of air as unity. This determination has been confirmed by Rankine.

The velocity of sound in helium at 0° C. is 971 metres per sec., and the ratio of the specific heats, C_p/C_v, has the value 1·671 at 180° C. and 1·659 at 18° C., which indicates the monatomic character of the gas. At 18° C. the specific heat at constant pressure, C_p, is 1·251, and the atomic heat consequently 5·004. The refractive index of helium at normal pressure and temperature for the wave-length 5890Å is 1·000035. Helium has two resonance potentials, 19·77 volts and 20·5 volts, and its ionisation potential is 24·5 volts. The minimum sparking potential for helium is 261 volts. Gaseous helium at normal pressure and temperature has for its dielectric constant 1·000074. Helium as a gas is diamagnetic, and according to Hector (*Phys. Rev.*, Oct. 1924, p. 148) it has a volume magnetic susceptibility of $-0{\cdot}78\times10^{10}$ at 20° C. and 760 mm. pressure.

Helium Atoms and Nuclei.—The atomic weight of helium is 4, and its density is 1·095. Since the gas is monatomic its atomic and molecular weights are the same. Of all the rare gases helium alone has no isotopes (*q.v.*). The square root G of the mean square molecular velocity of the atoms of gaseous helium at 0° C. is $13{\cdot}11\times10^4$ cm. sec^{-1} and the mean free path at normal pressure and temperature is $28{\cdot}5\times10^{-6}$ centimetre. The molecular diameter as deduced from the viscosity of the gas is $2{\cdot}18\times10^{-8}$ centimetre. Like the atoms of other elements, those of helium have a nuclear structure, the positive electric charge on the helium nuclei being 2ϵ where ϵ is the elemental charge of electricity. The two electrons that neutralise the nuclear charge are supposed to describe about the nucleus two nearly circular orbits with planes inclined to each other at an angle of 120° Centigrade. The radius of these orbits is approximately $1{\cdot}25\times10^{-9}$ centimetre. Spectroscopic evidence goes to show that while helium in its normal state exists in the form of atoms with crossed electronic orbits it can also, under electric excitation, be transformed into a metastable state designated as orthohelium. With atoms in the latter state the electronic orbits are supposed to be in the same plane with one orbit circular and the other elliptical, the major axis of the elliptical orbit being approximately four times as great as the diameter of the circular one.

For spectroscopic purposes helium, with its atoms in the normal state, is sometimes given the designation parhelium. The alpha rays expelled by radioactive substances have been shown to be helium nuclei. The initial velocities with which they are expelled from such substances vary from $2{\cdot}22\times10^9$ cm. sec^{-1} to $1{\cdot}45\times10^9$ cm. sec^{-1} according to the radioactive substance that gives rise to them. The corresponding kinetic energies are $1{\cdot}53\times10^{-6}$ and $0{\cdot}645\times10^{-5}$ ergs. It was by observations on the scattering of alpha rays of very high speeds through large angles by thin sheets of matter that Rutherford in 1911 established the view that atoms generally possess a nuclear structure.

Through phenomena associated with this scattering of alpha rays by matter it has been shown that the nucleus of a helium atom possesses very great stability. Helium nuclei themselves are supposed to be complex in their structure and to consist of four hydrogen nuclei and two electrons. Numerous experiments lead one to take the view that a helium nucleus or alpha particle behaves in impacts with nuclei of other atoms as if it were a perfectly elastic body, spheroidal in shape, with its minor axis 4×10^{-13} cm. in the direction of motion and its major axis 8×10^{-13} centimetre. The mass of a helium atom is slightly less than the combined masses of the hydrogen nuclei and electrons of which it is constituted, and this indicates that a large amount of energy must be liberated during its formation in the form of radiation of wave-length approximately $1{\cdot}75\times10^{-11}$ centimetre. A view held by astrophysicists generally is that the exceedingly high temperature of certain stars that exhibit a helium hydrogen spectrum can be accounted for by assuming them to be the seat of the formation of helium out of hydrogen. By bombarding the nuclei of the atoms of various elements with alpha rays, Rutherford has proved that atomic nuclei generally have a complex structure with hydrogen nuclei and electrons as primary constituents, and in some cases with helium nuclei as secondary ones.

Liquid Helium.—The liquefaction of helium was achieved by H. Kammerlingh Onnes at Leyden in 1908. In Jan. 1922 a cryogenic laboratory was instituted in the University of Toronto and helium was liquefied in Jan. 1923. Finally, in the summer of 1925 helium was liquefied in small quantities in the Reichsanstalt, Charlottenburg, Germany. Liquid helium is a colourless, very mobile liquid with a low surface tension. According to Onnes and Boks (*Leyden, Comm.*, No. 170) the density of liquid helium has a maximum value of 0·1462 at 2°·39 K with a value 0·1404 at 3°·19 K. and one of 0·1456 at 1°·49 K. assuming the absolute zero to be −273°·09 Centigrade.

The saturation vapour pressure (p. in mm.) of liquid helium is 4·15 at 1°·475 K., 359·5 at 3°·516 K., 757·5 at 4°·205 K., 1329 at 4°·9 K. and 1668 at 5°·16 Kelvin. The heat of vapourisation at 4°·25 K. has been estimated to be 19·38 gr. calories. The critical temperature of helium is 5°·19 K., the critical pressure (p. in Int. Atm.) 2·26, and the critical density 0·066. The "slope diameter" is −0·0033 and the boiling point at atmospheric pressure is 4°·21 Kelvin. The triple point temperature and pressure (p. in Int. Atm.) are respectively less than 0°·80 K. and 0·002 (see *Report* of Fourth Int. Cong. on Refrigeration, June 1924). According to Kammerlingh Onnes the Boyle point lies close to 20° K. and the "inversion temperature" to 40° Kelvin.

From certain considerations brought forward by Perry (*Jour. of Phys. Chem.*, vol. 28, No. 10, Oct. 1924) it can be shown that the optimum working pressure to use when liquefying helium, after cooling it with liquid hydrogen, is between 15 and 20 atmospheres. The lowest temperature attained by H. Kammerlingh Onnes with liquid helium boiling under low pressure was a few hundredths of a degree below 0°·9 kalium. The vapour pressure corresponding to this temperature was estimated to be 0·013 millimetres of mercury.

Liquid helium has been extensively used as a refrigerating agent by H. Kammerlingh Onnes and his collaborators and by others when investigating the physical and chemical properties of various substances at the lowest attainable temperature. Though the great majority of the investigations carried out have been connected with the thermal properties of substances, others dealing with the phenomena of phosphorescence and fluorescence, magnetism and magneto-optics, crystal structure, radioactivity and electrical conductivity have led to results of great scientific value. Probably the most interesting phenomenon discovered and investigated by H. Kammerlingh Onnes through the use of liquid helium is that of electrical super-conductivity in metals. In this field of investigation Onnes has shown that at temperatures attainable only with liquid helium the metals mercury, lead, tin, indium and thallium offer no resistance to the passage of electric currents through them and become perfect electrical conductors. It may be added that up to 1926 helium, alone of all the elements, had not been solidified.

Chemical Activity of Helium.—Although helium is chemically inert under ordinary conditions, evidence obtained in recent years suggests the possibility of its exhibiting chemical activity under certain very special conditions. Particularly under the influence of the electrical discharge, helium atoms may be united with other helium atoms in the same state or with atoms of other elements, to form compounds either of a fugitive or a permanent character. The fact that helium under certain conditions can be made to emit a band spectrum in addition to its line spectrum connotes the possibility of the gas existing in the molecular form.

Experiments made by E. H. Boomer (*Proc. Roy. Soc.*, vol. 109, No. A 749, p. 198) with an intense electric discharge from an incandescent tungsten filament in helium at low pressures show that a distinct and stable compound can be formed out of tungsten and helium with the formula $W He_2$. Boomer has also obtained evidence of chemical combination of helium with the vapours of mercury, iodine, phosphorus and sulphur. These compounds are fugitive in character and appear to be stable only at very low temperatures.

Industrial Uses.—In 1914 Sir Richard Threlfall put forward a suggestion to the Board of Inventions of the British Admiralty, that if helium were available in large amounts it might be used to replace hydrogen as a filling for airships. The fact that helium is non-inflammable and non-explosive and possesses 92% of the lifting power of hydrogen makes it a most suitable material for giving buoyancy to airships. Following up the suggestion, Prof. McLennan and his associate Mr. John Patterson initiated experiments for the British Admiralty on a semi-commercial scale on the natural gases of Canada. A machine was designed, constructed and successfully operated, with results that showed it was quite feasible to extract helium economically from natural gases when helium was present in them to the extent of only 0·33%. At the same time vastly greater experiments were initiated and carried through independently by the military and naval authorities of the United States, in co-operation with the Bureau of Mines of that country. Enormous quantities of helium were extracted from the natural gases of Texas, and the possibility of separating out the helium from the natural gases at a low cost was fully demonstrated.

In the electrical industry helium may be used for the construction of thermionic amplifying valves of the ionisation type and of gas arc lamps. In spectroscopy, especially for investigations in the ultra-violet region, helium is of use and possesses an advantage over most other gases in that it is transparent to light of extremely short wave-lengths. Owing to its high dielectric properties and its high heat conductivity it has been proposed to use helium in place of oil as a filling for transformers and for surrounding the switches and circuit-breakers of high tension electric transmission lines. Tests have been made by the General Electric Co. of the United States on the use of hydrogen as a cooling medium for large electric generators. These machines were operated in an atmosphere of hydrogen, with the result that owing to the lightness of hydrogen the windage loss was reduced, and owing to its high heat conductivity compared with air, the generators were made to give a 30% greater output with the same temperature rise. Since helium is also a light gas with a thermal conductivity slightly greater than that of hydrogen and can be used without the danger of explosions occurring, it would appear that it may be used for the same purpose if obtainable in large quantities at a low cost.

In 1917 considering the hygiene of labor, it was suggested by Elihu Thomson and others that if divers and workers in tunnelling operations carried on under high atmospheric pressures were supplied with a mixture of oxygen and helium in place of air the liability to caisson disease might be minimised or perhaps eliminated. Preliminary tests made in this direction by R. R. Sayers, W. P. Yant and J. H. Hildebrand for the United States Bureau of Mines (*Reports of Investigations*, Serial No. 2,670) have shown that through the use of helium and oxygen mixtures as a substitute for air in diving work the time of decompression can be materially reduced. This results from the fact that helium diffuses more readily out of the blood and body tissues than nitrogen. As the depths at which divers can operate depend largely on the duration of the period of decompression these experiments open up the possibility for extending somewhat the safety depth limit for diving operations.

Spectra Modified by Action of Helium.—A number of investigators, including Merton, Barrett, Johnson, Cameron and others, have shown that profound modifications may be observed in the spectrum of an element when it is present in small quantities in a discharge tube containing helium at a comparatively high pressure. As an example, the "comet-tail" spectrum discovered by Fowler is greatly enhanced by high-pressure helium. Merton and Pilley, too, were able with the addition of helium not only to bring out the hitherto practically unknown arc spectrum of atomic nitrogen, but also to isolate it completely from the spark spectrum of this element. McLennan and Shrum recently made some observations on the spectrum of small quantities of air in a large admixture of helium, and analysis of the spectrum obtained by them with these mixtures showed the presence of a line at $\lambda = 5577{\cdot}35$ Ångström units. When mixtures of oxygen and helium were used and an uncondensed discharge passed through, the line $\lambda = 5577{\cdot}35$ Å. was enhanced.

The line was obtained with the strongest intensity when the partial pressure of the oxygen in the mixture was about ½ that of helium, the partial pressure of the latter being about three centimetres. The line was also obtained with pure oxygen, which shows that it belongs to the spectrum of this element. As the intensity of the line when obtained with pure oxygen is low, it would appear that the function of the helium is to maintain the oxygen atoms in a state that permits them to radiate the light $\lambda = 5577{\cdot}35$ when once they are brought into that state by electrical stimulation. These results have a bearing on problems connected with the identification of the lines in the auroral spectrum, and McLennan and Shrum's experiments are of interest in that the wave-length $\lambda = 5577{\cdot}35$ Å. which they obtained with oxygen is identical with that of the green line in the spectra of auroras that has long defied identification. The result is also interesting in that it may be taken as evidence of the existence of helium containing a small amount of oxygen in the upper atmosphere, for it is known that auroral displays originate at atmospheric heights of about 100 kilometres.

The Spectrum of Helium.—Both theory and experiment indicate that in the ultra-violet spectral region the radiation emissible by helium does not include any wave-length shorter than $\lambda = 228$ Ångström units. The line spectrum of helium as observed ordinarily in vacuum tubes consists of a system of singlet series and a system of doublets. The doublets are very close and are somewhat unusual in that in the sharp diffuse series the more intense component is on the more refrangible side, while the first principal line has its stronger component on the side of the greater wave-length. It is generally accepted by spectroscopists that the singlet series of wave-lengths in the spectrum of helium originate in parhelium, and that the doublet series have their origin in atoms in the metastable or orthohelium state. Besides the line spectrum there is, as previously stated, an interesting band spectrum of helium which is well developed under appropriate conditions. Fowler has shown that the heads of some of the stronger bands, in contrast with all other known band spectra, are arranged in accordance with the laws of line series. There is, however, no apparent relation between the band and the line series, except that the main series of bands runs nearly parallel with the principal series of helium doublets.

All lines in the helium spectrum that have been investigated are resolvable by magnetic fields into normal Zeeman triplets. Recently Curtis and Jevons (*Nature*, Nov. 21 1925) showed that a Zeeman effect can be obtained with certain lines in the band spectrum of helium. The wave-lengths of a number of lines in the spectrum of helium were accurately measured by Merrill at the Bureau of Standards, Washington (*Astrophys. Jour.*, 46, p. 357, 1917) and are now accepted as secondary standards for the purpose of spectrum analysis. They are as follows:—

(I.A.)	(I.A.)	(I.A.)
2945·104	4026·189	4921·929
3187·743	4120·812	5015·675
3613·641	4143·759	5047·736
3705·003	4387·928	5875·618
3819·606	4437·549	6678·149

3964·727	4713·143	7281·349

BIBLIOGRAPHY.—An extensive bibliography of the work on helium is given in *Circular* of the Bureau of Standards, Washington, No. 81 (1919).

For the results of low-temperature investigations the *Communications* from the Physical Laboratory of the University of Leyden should be consulted. (J. C. McL.)

HELSINGFORS or HELSINKI (*see* 13.252), the capital, chief seaport and only large town of the republic of Finland, had a population in 1922 of 201,435. The chief buildings are largely classical in style, but a number of modern ones showing the national spirit by using local materials and peasant decorative motives, have been erected, in particular a church overlooking the town, the cyclopean parliament buildings on the heights of Brunnparken, a new railway station and a fine memorial to those who fell in the Finnish fight for freedom. The town is an industrial centre, and the harbour accommodates the largest vessels, but it is usually closed by ice from Jan. to the end of April, except for a channel kept open by an ice-breaker. The harbour has been much improved in recent years, and had over 7,000 yd. of quays in 1924; in 1925 a coal wharf was in erection, and a goods station was to be built alongside the harbour. In 1918 civil war, promoted by Bolshevist intrigues, broke out in Finland, and Helsingfors was occupied by Red Guards. Later they were defeated by Finnish nationalists under German leadership.

HEMY, CHARLES NAPIER (1841–1917), British painter (*see* 13.265), died at Falmouth Sept. 30 1917.

HENDERSON, ARTHUR (1863–), British politician, was born in Glasgow of working class parents Sept. 15 1863; but his work and interests subsequently lay at Newcastle (where he served an apprenticeship as moulder at Robert Stephenson & Co.'s works), and in the county of Durham. He became prominent in the trade union movement, and after a while took a leading part in local affairs, being for some years a member of the Newcastle city council and the Darlington borough council. He was mayor in 1903; and was made a magistrate for the county of Durham. He entered Parliament for Barnard Castle, as a Labour member, at a by-election in 1903, and soon made his mark. In 1908 he was elected chairman of the party, a post which he held for two years and to which he was re-elected after the outbreak of war in 1914, when the then chairman, Mr. Ramsay MacDonald, had to resign owing to his pacifist views. As chairman, at the opening of the new session in that autumn, Mr. Henderson promised the full support of organised Labour in maintaining the "splendid unity" of the nation.

When the first Coalition Ministry was formed by Mr. Asquith in 1915, Mr. Henderson was included in the Cabinet mainly as adviser of the Government on labour questions arising out of the World War, with the office, first of President of the Board of Education, and afterwards of Paymaster General. He showed himself resolved on a strenuous prosecution of the War, strongly advocating both the Munitions Bill and the Registration Bill, and having no hesitation in taking the further step of compulsory service. He followed up this action by urging the Labour party to rally in Dec. 1916 to Mr. Lloyd George, and by accepting himself the position of an original member of the War Cabinet of four without portfolio. In the spring of 1917 he visited Russia, just after the Revolution, on behalf of the British Govt., and found the then provisional Govt. at St. Petersburg (Leningrad) strongly in favour of an international Labour and Socialist conference, which was to meet at Stockholm under the auspices of the International Socialist Bureau. He came to the conclusion that, provided the Conference were merely consultative, it would be better that British representatives should go, rather than permit Russian representatives to meet German representatives there alone; and accordingly, on his return to England, being still secretary of the Labour party as well as a member of the War Cabinet, he promoted the participation of British Labour therein. But public opinion in general was strongly against any conference with Germans in the midst of war; the Sailors and Firemen's Union refused to carry the delegates; French, Belgian, Italian and American Labour declined to have anything to do with the conference; and all his Labour colleagues in the Government opposed his views. On Mr. Lloyd George expressing the surprise of the rest of the War Cabinet at his action, and their dissent from his policy, he resigned.

Mr. Henderson warmly espoused the Labour decision of the latter part of 1918 to take the Labour men out of the government and to appeal for support on a purely Labour platform in conjunction with the pacifist wing of the party. This cost him his seat in Parliament at the general election of Dec. 1918, when no pacifist Labour candidates were successful. Indeed, ill-luck pursued him also at the next two general elections, in 1922 and 1923; but in all three cases he returned to the House of Commons a few months later at a by-election. In the Parliament of 1923–4 he had the satisfaction of having two sons as fellow members, though they were both defeated in the autumn of 1924. In MacDonald's Ministry he was secretary of state for home affairs.

but he was not conspicuous either in administration or in debate. He actively endorsed the policy of his party in 1925–6 in severing themselves definitely from the Communists who advocated armed revolution; and he protested strongly, in March 1926, against the suggestion made by the Independent Labour party for the formation of a comprehensive international society which should include the Communists. (G. E. B.)

HENRI, ROBERT (1865–), American painter, was born in Cincinnati, O., in 1865. In 1886 he entered the Pennsylvania Academy of the Fine Arts, Philadelphia, Pennsylvania. Proceeding to Paris in 1888 he studied at Julien's and the École des Beaux Arts and visited Spain and Italy. Returning to the United States he became in 1891 an instructor at the Women's School of Design, Philadelphia. In 1896–1900 he was again in Paris and exhibited at the Salon. During an extremely active life as a painter, he found time to teach, many of his pupils attaining marked distinction. During the period 1915–23 he taught at the Art Students' League, New York City, and also travelled extensively. His portraits are distinguished for their vigour and vivacity. Of his works, "La Neige" was purchased in 1899 for the Luxembourg in Paris, and "Girl in White Waist" (later destroyed by fire) was purchased by the Carnegie Institute, Pittsburgh, in 1904. His other works include "Young Woman in Black," in the Art Institute, Chicago; "The Spanish Gypsy," in the Metropolitan Museum, New York City; and "Indian Girl in White Ceremonial Blanket," in the Corcoran Gallery, Washington, D.C. He wrote *The Art Spirit* (1923).

HENRY, EDWARD LAMSON (1841–1919), American painter (*see* 13.299), died at Ellenville, N.Y., May 9 1919.

HENRY, O. (1862–1910), American short story writer, was born in Greensboro, N.C., Sept. 11 1862. His real name was William Sydney Porter. Until the age of 15 he attended school, then for five years served as clerk in his uncle's drug store. The indoor employment threatened his health, and in 1882 he went to a friend's ranch in La Salle co., Texas. Here he spent two years, absorbing the colour and robust life of the southwest. In 1884 he moved to Austin, Texas, worked as bookkeeper and then spent four years in the General Land Office.

In 1887 he was married, and about this time he began to send paragraphs and humorous sketches to newspapers. During 1891 he was teller in the First National Bank of Austin. In 1894 he bought Brann's *Iconoclast*, a satiric weekly, and transformed it into an extraordinarily humorous farrago of skit and burlesque, illustrated by himself; the venture was not a success and in 1895 he joined the staff of the Houston *Post*, writing a daily column. In 1896 he was indicted on a charge of having embezzled funds (amounting to about $1,150) from the bank in Austin. The details of this affair have never been cleared up; there seems no doubt that he was innocent; the bank's affairs were very slipshod; he may have been shielding some friend; in any case, in a moment of insane impulse he fled from trial and went to Honduras. The fatal illness of his wife brought him back in 1897. While waiting for trial he had the first news of acceptance of some of his stories by important magazines. In 1898 he was sentenced to five years in the Ohio Penitentiary. His term was reduced to three years and three months for good behaviour. In prison he seriously settled down to story-writing, and probably took his famous pseudonym from the name of a French pharmacist mentioned in a dictionary of drugs. He left prison in 1901 and went to New York in 1902. In 1903 he contracted to do a short-story a week for the New York *World*, at $100 each. His first book, *Cabbages and Kings*, was published in 1904. In 1907 he was married to Miss Sarah Coleman, a boyhood friend. He died in New York June 5 1910, and was buried in Asheville, North Carolina.

The varied phases of O. Henry's life are reflected in his stories. The extraordinary productivity of his eight years in New York brought him rapid fame, though he himself lived secluded and known to few. The sale of his books has been enormous and they have been translated into many languages. For ingenuity of plot and racy vividness of narration he has rarely if ever been surpassed, but he has been sharply criticised for turning the short story into a "vaudeville stunt." But the genial magic of his fine imagination, antic humour and brilliant narrative skill triumph over the occasional journalism of his method. Subsequent tendencies in literary technique run in an altogether different current, yet O. Henry remains endlessly and enchantingly rereadable. His New York stories are the most famous, but it is probable that some of the southern and western tales, in which there is less strain for glittering effect, are of more lasting value. The tragedy of his own life taught him a chivalrous tenderness for the unlucky; some of the greatest native endowments a writer can have were undeniably his, but his reckless use of them often arouses the trained reader's amazement. Of him, as much as of any modern writer, it can be said that he had "no talent, only genius."

O. Henry's stories were collected in book form under the following titles: *Cabbages and Kings* (1904); *The Four Million* (1906); *The Trimmed Lamp* (1907); *Heart of the West* (1907); *The Gentle Grafter* (1908); *The Voice of the City* (1908); *Roads of Destiny* (1909); *Options* (1909); *Whirligigs* (1910); *Strictly Business* (1910); *Sixes and Sevens* (1911); *Rolling Stones* (1912); and *Waifs and Strays* (1917).

See C. Alphonso Smith, *O. Henry Biography* (1916) and also posthumous collections of sketches and fragments, *e.g.*, *O. Henryana* (1920), *Letters to Lithopolis* (1922), *Postscripts* (1923). (C. My.)

HENRY, VICTOR (1850–1907), French philologist (*see* 13.301), died at Sceaux, near Paris, Feb. 8 1907.

HERBERT, VICTOR (1859–1924), American musical composer, was born in Dublin, Ireland, Feb. 1 1859. His musical education was received in Germany, where he studied under the leading masters. He became principal violoncello player in the Court Orchestra, Stuttgart, also appearing as a soloist on the concert platform in European musical centres. In 1886 he accepted a position as solo violoncellist in the Metropolitan Orchestra, New York City, being subsequently connected with other orchestras as soloist and conductor. In 1894 he was appointed bandmaster of the 22nd. Regt. (N.Y.) Band. In 1898 he became conductor of the Pittsburgh Orchestra. He composed the music for a number of light operas, of which his greatest successes were *Babes in Toyland* (1903), *Mlle. Modiste* (1905), and *The Red Mill* (1906). In 1904 he organised Victor Herbert's New York Orchestra. In 1911 he wrote a grand opera, *Natoma*. More successful, however, was the music which he composed for the photoplay, *The Birth of a Nation*. In his later years he composed much for musical revues. He died in New York City May 26 1924.

HERCEGOVINA: *see* BOSNIA-HERCEGOVINA.

HERCZEG, FERENCZ (1863–), Hungarian novelist and dramatist, was born at Versecz (Viršet) of a family of German extraction. He decided first to adopt a legal career, but soon turned to literature, and after the publication of his first novel his reputation and popularity steadily increased. He became honorary president of the Petöfi Society and a member of the Hungarian Academy. He was several times elected a deputy and through the medium of his review, *Magyar Figyelö*, showed himself to be a staunch supporter of Count Tisza. He was a master of the psychological novel, excelling in the analysis of the feminine mind and in depicting the life of the nobility and of the well-to-do *bourgeois* class. Among the most notable of his historical novels are *Pogányok* (The Pagans) (1902) and *A hét sváb* (The Seven Swabians), while his tragedy *Byzance* (1912) is considered a masterpiece. His novels and plays have been translated into nearly every European language.

HEREDITY (*see* 13.350 and BIOLOGY; CYTOLOGY; EMBRYOLOGY; EVOLUTION; MENDELISM; SEX).—Heredity is the relation of organic continuity between successive generations. It is a genetic or flesh-and-blood relation, effected by the germ-cells which are liberated from parents and develop into offspring. Heredity secures the continuance of a specific organisation; it implies some measure of racial entailment or organic inertia; and yet it does not preclude variability, that is to say the occurrence of marked differences between offspring and their parents.

Even if there had been no evolution there would still be heredity; it would be the genetic relation between successive

generations of unprogressive Protists. But there could be no evolution without heredity, for heredity implies the possibility that new departures can be entailed from generation to generation. It is possible that in early times and among simple types there was greater variability than is common nowadays and among more advanced types, and that the evolution of the hereditary relation, *e.g.*, in the advance from asexual to sexual reproduction, put a useful check on the occurrence of variations. But it does not conduce to clearness to say that variation is older than heredity, or to make any antithesis between the two sets of facts. There is a contrast between complete hereditary resemblance in successive generations, which might be compared to inertia in the physical domain, and marked variation, which might be compared to kinetic divergence; but the hereditary relation is such, especially in sexual multiplication, that it allows of novelties or new departures. In short, heredity includes the possibility of variation.

Vehicle of the Inheritance

By inheritance is meant all that the organism is or has to start with in virtue of its hereditary relation to its parents and ancestors. Thus it does not include ante-natal infection, or any imprint impressed on the embryo before birth, or any result of being nurtured in the same environment as the parents. In asexual multiplication the vehicle of the inheritance is obviously the separated off-bud or portion, and it is of interest that a small fragment of a polyp or of a leaf may develop into a perfect organism, always provided that the initial amount be not too minute, that it contain a fair sample of the different kinds of cells in the body, and that it find the appropriate environment. Thus drops of minced sponge, forced through a sieve, may develop into typical forms.

In sexual reproduction the vehicle of the inheritance is obviously in the sex-cells or gametes, but the question arises whether the cytoplasm counts at all as a bearer of hereditary qualities, or whether these are restricted to the chromosomes. That the latter bear many of the hereditary characters is practically proved by Mendelian and micro-dissection experiment, and it is believed by many students that the characters or, more strictly, their initiatives, technically called "factors" or "genes," lie in linear order in each individual chromosome.

The Chromosome Theory.—Some of the arguments for this chromosome theory of inheritance may be briefly stated (*see* Mendelism). (1) There must be significance in the persistence of a particular number of chromosomes for each species, *e.g.*, two for the threadworm of the horse and 48 for man. (2) There is a parallelism in oögenesis and spermatogenesis such that the normal number of chromosomes is reduced to one half by a chance meiotic division, and this conforms to the facts of Mendelian inheritance. (3) In fertilisation there is a restoration of the normal number ($\frac{n}{2}+\frac{n}{2}=n$), and homologous chromosomes from the two parents unite in couples. The two parents contribute in equal amounts the chromosomal warp and woof of the offspring web, as Van Beneden first showed in his famous paper of 1883. But the full force of this cannot be realised without linking the fertilisation to the antecedent maturation. As McClung puts it:—

> In preparation for the union of the sperm and ovum in fertilisation, by which the duplex chromosome series is established in a new individual, each of these germ-cells reduces its own duplex state to a simplex one by segregating its maternal and paternal members of each pair into different cells by chance distribution in relation to the others.

We may perhaps say that this shuffling of the hereditary cards is one of the opportunities for the origin of fresh permutations and combinations—new departures in short. But there is another suggestion of variability in the fact that in the pairing of chromosomes before maturation-division there is an intimate physical contact (synapsis) in virtue of which there may be interactions and resulting changes. This may be another fountain of variation. (4) In related species there is often a close resemblance in the shape and structure of the chromosomes, and several cases are known in which the numbers of the chromosomes in a group of species form an arithmetical series, such as multiples of seven in roses. (5) In some cases there is strong evidence to warrant associating a particular chromosome with a particular character in the organism, notably McClung's correlation of the accessory chromosome with sex (*see* Sex).

An individual chromosome with a recognisable peculiarity of shape has sometimes been traced from generation to generation, and there is no getting past the large fact that the chromosomes are the only individualised elements that perpetuate themselves with precision from generation to generation. (6) In some cases the unit characters or separably hereditary characters of an organism form a number of linked groups of unequal numerical value, and with these there is sometimes correlated a similar number of chromosomes, differing proportionally in size. (7) Here also may be noted the growing evidence that there is in the chromosomes of the various individuals of a species a definite and constant linear arrangement of factorial areas or chromomer. Plainly, then, there are many reasons for regarding the chromosomes as the bearers of the hereditary factors.

The Cytoplasm in Inheritance.—On the other hand, the cell is a unity, and a physiological firm, so that the cytoplasm of the ovum may be very important although it is not the bearer of the hereditary factors. The experiments of Wilson, Conklin and others show that an egg-cell may contain definitely localised materials that are made use of in the development of particular structures in the embryo. These, therefore, must be components contributing to the resultant, yet it has to be kept in view that the organisation of the materials in the egg is effected under the control of the nucleus and its chromosomes.

Since modern studies of genetics have had very largely to do with the newer and more external specific characters, it seems premature to shut out the possibility that the vehicle of the older and fundamental hereditary characters may be in part at least carried by the cytoplasm of the egg-cell, which would not necessarily mean that they were outside nuclear influence. Loeb maintained that racial characters were cytoplasmic and specific characters chromosomal. Yet, since the quantity of cytoplasm in the spermatozoön as compared with the ovum is very minute, on Loeb's view the female parent should count more predominantly than it does. The question should not be foreclosed.

Fundamental Facts of Heredity

The largest fact is that all kinds of inborn characters, normal or abnormal, "bodily" or "mental," important or trivial, structural or functional, except complete sterility, may be continued on in the next generation. Even subtle characters, such as longevity and fecundity, may form part of the hereditary organisation which is continued on in the lineage of germ-cells. The term "transmitted" should be given up, since it suggests the erroneous idea that the parent makes and endows the germ-cells that become the offspring. The parent is more like a trustee.

Continuity of the Germ-Plasm.—The large fact of the persistence of a general resemblance from generation to generation depends on the continuity of the germ-plasm. What Weismann and Galton suggested has been confirmed in detail, that the germ-cells from which offspring develop are continuous along an unspecialised cell lineage with the fertilised ovum that gave rise to the parent. In many cases the future germ-cells are segregated at an early stage in development (even at the first cleavage in Ascaris), but whether they are set apart very early or not, the germ-cells are those cells which have remained unspecialised, with approximately the whole inheritance intact, not having shared in body-making and the differentiations therein involved. Some saving clauses must be added:—(*a*) for plants where the distinction between germ-plasm and somatoplasm is only incipient (a piece of leaf readily developing into a whole plant, flower and all); (*b*) for animals in which the reproductive organs are late of being recognisable, *e.g.*, when there is a prolonged asexual larval period as in Echinoderms and many of the higher insects; and (*c*) for a few more difficult cases, known experimentally in adult higher animals, such as the frog, where body-cells are said to be

able to form germ-cells. But on the whole, the fact of the continuity of the germ-plasm is a firm foundation-stone.

Germinal Origin of Variations.—It follows theoretically from the continuity of the germ-plasm that any novel peculiarity in the germ-cells, still more in the fertilised egg-cell, may be continued in the germ-cell lineage of the offspring and thus reappear in the next generation, and so on. But what is possible on general grounds must be proved for particular cases; and it is known of many new departures of germinal origin that they come to stay. The variants breed true. This leaps to the eye when the novelty is pathological, but it holds even more true of the normal. It holds (*a*) for what may be called "recombination-characters," where the novelty is interpretable as a reshuffling of ancestral factors, yielding, as it were, a new pattern; and (*b*) for mutations which are more distinctively novel—brusque emergences of some feature which was not distinctly represented in the ancestry. Thus new combinations and mutations agree in being in many cases very heritable, whereas it is uncertain that this can ever be said of exogenous "modifications," which do not emerge from within but are imprinted from without.

In his prolonged studies of garden snapdragons, Prof. Erwin Baur finds that there is an abundant occurrence of small mutations (of unexplained germinal origin) which are hereditarily entailed and summed up into stable varieties. For this organism it seems that the minute mutations count for more than striking large mutations in the establishment of stable cultivated races; and it is interesting to note that they correspond closely to the small variations that Darwin started with as his main form of evolutionary raw material. In other organisms, however, new combinations may count for most, and in others large mutations; the indispensable quality is that the germinal new departures are such that they can be hereditarily continued.

Disappearance of a Germinal Variation.—The non-continuance of a variation of germinal origin may come about in different ways. Its chromosomal representative (a "factor" or "gene") may be lost in a maturation-division, *e.g.*, in the formation of the first polar body which is given off from the ripening egg-cell and never comes to anything, though it carries off one member of each of the chromosome-pairs. Or it is possible that when two homologous chromosomes are coupled in intimate synapsis, an influence passing from one to the other may change the nature of a factor. When they eventually separate they may have lost or gained by "crossing-over" (*see* MENDELISM). Or it may be that a factor or gene changes in character just as a microbe sometimes does, perhaps in response to a subtle environmental stimulus.

Another possibility is that the new departure may be fatal or lethal, or that it may result in a sterile organism. What often happens is that a variation seen in the first filial generation does not reappear in the next owing to the absence of some environmental or nurtural influence necessary for its developmental expression. But what is common to all theories of evolution is the verifiable postulate of *the heritability of variations*. What distinguishes the Lamarckian school is the inclusion of somatic "modifications" as part of the evolutionary raw material.

Unit Characters.—Another foundation stone laid by experimental work is the concept of unit characters, features that are continued on, intact, from generation to generation, without blending or fractioning, either present fully or absent altogether. In other words, unit characters illustrate Mendelian inheritance, and the analysis of the organism into a bundle of unit characters has for its corollary the germinal representation of these unit characters by a set of factors or genes in the chromosomes of the germ-cells. What a "gene" is, we do not know; perhaps a group of molecules in some particular collocation. They are often compared to ferments. The progress of investigation has indicated that genes are not immutable, that they may influence one another and be influenced by their cellular environment, that they may be distributed in linked groups, that several different genes may be concerned in the development of one character, that one gene may influence several different characters. Finally, the expression that the genes find in development may be dependent on the presence of the appropriate liberating stimulus in the environment.

What has been actually proved is that the organism includes a congeries of unit characters which are hereditarily continued as units, somewhat like the radicals in chemical reactions. It is possible, however, that part of the inheritance consists of a consolidated bloc of fundamental racial characters, which undergo little if any change in the course of generations. It is possible, for instance, that the characters constituting a rabbit a rodent are not hereditarily continued in the same way as the unit characters that constitute the rabbit an Angora.

Galton's Two Laws.—Also important as averaging statistical conclusions are Galton's laws of inheritance. According to the law of ancestral inheritance an inheritance is not merely dual, it is multiple; and the average contributions made by grandparents, great-grandparents and so on, are definite and diminish in a precise ratio according to the remoteness of the ancestor. The two parents between them contribute, on the average, one-half of each inherited faculty, each of them contributing one-quarter of it. The four grandparents contribute between them one-quarter, or each of them one-sixteenth; and so on backwards. This will not apply to cases which illustrate clear-cut Mendelian inheritance; but when characters blend, or have so many factorial units involved that they seem to blend, there may be value in Galton's conclusion that on the average the inheritance of an individual is a mosaic of ancestral contributions. The second law is that of filial regression, or what might be called the tendency to approximate either upwards or downwards to the mean or average of the stock. As Galton said:—

> The more bountifully a parent is gifted by nature, the more rare will be his good fortune if he begets a son who is as richly endowed as himself, and still more so if he has a son who is endowed yet more largely. But the law is even-handed; it levies an equal succession-tax on the transmission of badness as of goodness.

The value of a fine parentage is obvious, but "the ablest of the children of a few gifted pairs is not likely to be as gifted as the ablest of all the children of a great many mediocre pairs." On the other hand, two gifted members of a poor stock may be personally equivalent to two ordinary members of a good stock, but the children of the former will tend to regress; those of the latter will not. To take Prof. Karl Pearson's illustration, the mean height of the sons of, say, 1,000 six-ft. fathers will be 70·8 in.; the mean height of the sons of 1,000 66-in. fathers will be 68·3 in., again a regression toward the mean of the general population. "The father with a great excess of the character contributes sons with an excess, but a less excess of it; the father with a great defect of the character contributes sons with a defect, but less defect of it. The general result is a sensible stability of type and variation from generation to generation." Galton's laws are statistical, not physiological; they require correction in regard to characters which are subject to persistent keen selection, either natural, sexual or artificial; they will not apply to sharply defined "unit characters" which do not blend. The data which Galton utilised were chiefly the records of family faculties, as to stature, eye-colour, temper, artistic ability and so on, but they were to some extent supplemented by measurements in Galton's anthropometric laboratory, and by observations on plants and animals. The most reliable data were those relating to stature, and they are open to the criticism that they included indiscriminately what is due to somatic modification and what is due to germinal constitution. In the view of many biologists this greatly lessens the value of Galton's laws.

The Past in the Present.—Looked at broadly, the facts of heredity illustrate the way in which the past lives on in the organism, active and acting. The inheritance includes many items of different degrees of antiquity, some very ancient. These have for the most part useful inertia, but there is often a striking persistence of anachronisms, both of structure and function. There is a remarkable staying power in characters that illustrate Mendelian inheritance, whether for good or ill. There is an indubitable recapitulation of phylogeny in ontogeny,

especially in organogenesis; and it is the continuity of the germ-plasm that makes all this possible. For the same reason, there is a conservation of advantageous tentatives in so far as these are the outcome of germinal variations. In short, heredity and development show us the organism as a historic being, and moreover as one that enregisters the ages that are past.

Heredity and Development

The most elusive of problems concerning heredity is the most familiar one: how does the hereditary material in the chromosomes and in the cytoplasm develop into the organism. There is a hereditary preformation of some sort in the chromosomes with their genes, and to this the cytoplasm—with so little in the way of organisation to start with—responds in a perfectly precise and controlled way; but physiological embryology, though rapidly progressive, is still a long way from an understanding of what occurs. As to the mind of Aristotle, so to the biologists of to-day, development remains a central secret (*see* Embryology).

Transmissibility of Somatic Modifications.—Some advance has been made in regard to the long-standing problem often designated "the inheritance of acquired characters." The history of the discussion shows that Weismann and Spencer, who took opposite sides, meant by "acquired characters" only one kind of thing—those somatic changes that are directly due to some peculiarity in use and disuse, nutrition, or environmental influence, and which persist in the individual, for some time at least, after the inducing conditions have ceased to operate. It is irrelevant and illegitimate to maintain that "acquired characters" should mean something else. As long as the Weismann-Spencer argument continues, it is necessary to keep to the original use of the terms. That there are corollaries must be allowed, such as (*a*) the transmissibility of the secondary effects of modifications, or (*b*) the possibility of a specific influence being impressed simultaneously on soma and on germ-cells. But the main question is a precise one: Can a modification, as defined, affect the germ-cells in such a specific or representative way that the offspring will, through its inheritance, exhibit, even in a slight degree, the modification which the parent or parents acquired? May there come about in the germ-cells a heritable registration of some specific modification imprinted on the parental body?

To get a clear issue, as regards the precise problem, there should be an avoidance of (*a*) data referring to Unicellulars, where there is only a beginning of the contrast between somatoplasm and germ-plasm; (*b*) data which involve the possibility that the germ-cells may be influenced along with the body by some penetrating toxin or hormone or radiation or the like, connected with the imprinting of the original modification and (*c*) data relating to viviparous organisms, *e.g.*, mammals and seed-bearing plants, where it may be that a modification of the parent, such as acquired immunity or acquired evergreenness, comes to be shared by the offspring because of the intimacy of the antenatal partnership. If this occurred it would have in the first generation the same practical result as if there had been a specific repercussion on the germ-cells, but it would not be a convincing case, unless it held good when the modification was exhibited by the male parent only. Both for placental mammals and for seed-bearing plants it is easy to conceive of specific metabolic products or metabolites passing from the mother to the offspring before separation occurs.

Need for Data from at Least Three Generations.—When organisms are transferred to novel surroundings or conditions of life, such as those of a colder climate, it often happens that an advantageous modification is induced, such as a longer coat of hair in a mammal; and it may be that this modification appears in increased expression in the next generation. But this would prove nothing more than modifiability, for the second generation was exposed for a longer time than the first to the modifying influence. But if the character in the third generation was larger in amount than in the second, an interesting fact would be established.

Changed Environment.—Yet the crucial cases must be those where the offspring of modified parents develop in an environment which does not include the modifying factor which effected the change in the parental soma. Thus in Prof. W. E. Agar's model experiments, specimens of the entomostracan Simocephalus that were reared in water with certain nutritive peculiarities, showed a distinctive reversal of their two shell-valves doubtless due to the altered metabolism. They were reared to maturity and then transferred to ordinary water where they liberated their ova. These developed into individuals which showed the modificational peculiarity that their parents had acquired.

Later on, however, when the parents again liberated ova, the abnormal effect was seen only to a very slight degree, and in a third brood (not generation) it had dwindled away. This very instructive case suggests that the abnormal nurture had resulted, not in any disturbance of the inheritance, but in the formation of some peculiar non-living metabolite, which was included in the cytoplasm of the egg, passed passively into the body which developed from the egg, and there produced on the body of the offspring the same effect as it originally produced on the body of the parent which acquired the character in question. As the supplies of the metabolite were exhausted, its influence dwindled in the second brood, and disappeared in the third. This illustrated the importance of changing the environment in such experiments.

Alcoholised Animals.—Many experiments have been made on the effect of alcohol (usually inhaled fumes) on animals, but the results are not altogether in accordance. Thus while there may be no observable deterioration in the treated guinea-pigs, there is clear evidence of this in their untreated offspring. On the other hand, Prof. Raymond Pearl found that after alcohol treatment his fowls produced offspring which were superior in a marked degree to those produced by non-treated controls. Pearl's interpretation of this is that the alcoholic treatment eliminated all the inferior germ-cells in the ovary of the fowls, leaving the coast clear for the superior ones to produce the next generation. Of the reality of this process of germinal selection there is some histological evidence.

In Dr. F. B. Hansom's experiments on white rats there was no observable effect on to the end of the second generation. Those that were subjected to inhalations of alcohol were in no way different from their relatives that breathed normally. Moreover, the treated offspring of the treated parents were indistinguishable from their first cousins, the untreated offspring of untreated parents. But in the third generation, a change occurred. At the age of 20 days, before any individual treatment, the members of the treated lineage showed themselves inferior in body weight, body length and tail length, when compared with their counterparts on the untreated lineage. When alcohol-inhalation began, the difference became more marked, as if the animals were responding to the abnormal condition with a new susceptibility. It reached a maximum of nearly 10 times the probable error.

Now the natural inference at this stage in the experiments would have been that the influence of two previous generations of alcoholic inhalation was beginning to make itself felt. And as the effects were observable before individual treatment began, the inheritance of the generally deteriorative influence of alcohol might have been held as proved. But the remarkable fact is that the fourth generation showed a marked improvement! "The treated side of this generation for the first half of its growth curve is back to the fold with the first two generations. Later there is some response to the treatment and a consequent dropping off in the curve." This remarkable result suggests that some process of germinal selection may have been at work, an elimination of inferior germ-cells; but it also suggests caution.

Prof. Charles R. Stockard's experiments on alcoholised guinea-pigs, continued for 13 years, showed no deterioration of the treated parents up to seven years, which is a great age for these animals. But the deteriorative influence on the immediate offspring and on later descendants was shown in debility, short life and arrested development. Yet there was no evidence of the transmission of any particular character. The probability is that the alcohol, saturating through the body of the parent, poisoned the germ-cells and deteriorated the constitution of the offspring

n a general way. But here, again, there was the remarkable phenomenon, that after three generations of treating, there was a marked improvement. The members of the fourth filial generation of treated "pigs" were actually superior in vitality to the controls. This may have been due to the elimination of the weaklings and defectives, perhaps also to a sifting out of germ-cells.

Other Striking Experiments.—Dr. Bentley and Dr. Griffith found that some of the progeny of rats rotated for a long time on a round-about showed a high degree of disequilibration and deterioration, but it is possible, as Dr. Detlefsen has suggested, that some microbic infection (causing inflammation of the auditory labyrinth) may have complicated the issue.

Pointing towards a transmission of specific modifications are the intricate experiments of Prof. M. F. Guyer and Dr. E. A. Smith on the continuance of artificially induced eye-defects in rabbits. Very suggestive in the same direction are Dürken's experiments on the colour of the pupae of the common white butterfly, where there seemed to be a hereditary effect of artificial illumination. To many biologists it seems that there is unquestionable validity in the numerous experiments of Kammerer which point in several cases to the hereditary continuance of a parental modification. Thus when the young of the spotted salamander are kept on black backgrounds the black patches on their skin increase in size, while if they be kept on yellow backgrounds the yellow patches increase. This change towards greater blackness or towards greater yellowness was found to be to a considerable extent heritable, for the offspring of the modified parents showed a similar change in a marked degree. Indeed they began in a colour phase nearly, though not quite, as advanced as that at which their parents left off.

Thus it would be possible to continue citing cases first on one side and then on the other, on both sides open to detailed criticism. But the moral seems to be that this long-discussed question cannot even now be regarded as closed. There must be a patient accumulation of more data, more rigorously tested or verified; and the question at issue is of such importance as to forbid any hurry to a conclusion.

Nature and Nurture

Wider than the question of the transmissibility of somatic modifications is that of the relation between hereditary nature and environing nurture. The difference between the two complementary factors is referred to in Prospero's description of Caliban as "a devil, a born devil, on whose nature nurture will never stick." It is evident, however, that the two factors should not be opposed as if they were antithetic, for while no amount of nurture will make a bad inheritance good, there can be no development at all without a minimum of nurture, and on the generosity of the nurture the development of the heritable character will in some measure depend.

At the beginning of the individual life the implicit organism and the inheritance are one and the same, but by subjecting germ-cells and embryos of the same origin to different "nurture" (functional, nutritional and environmental) it can be shown that there are different reactions according to the developmental conditions. The young proteus kept in darkness remains unpigmented, but its neighbour reared in a well-lighted laboratory becomes dark. A Chinese primrose (*Primula sinensis*) reared at 25° C. will have white flowers (var. *alba*), but its neighbour, or, later on, itself brought under the influence of higher temperature (30° C.), shade and moisture, will have red flowers (var. *rubra*). According to diet a tadpole may become large and poorly differentiated, or small and well-differentiated. There are scores of such cases.

Eggs, embryos, larvae and so on, of the same genetic origin, may develop very differently according to the conditions of life, and, conversely, differently endowed young organisms may develop very differently though reared in nurtural conditions which are precisely the same, as we see when good seed and poor seed are sown in the same plot. Therefore, it is legitimate to distinguish the hereditary factor in development from the functional or the environmental factor. As we have said, an antithesis between hereditary "Nature" (Galton's "natural inheritance") and extrinsic "Nurture" (all manner of environs mental, nutritional and functional influences) is illegitimate, since both are necessary components of a resultant, as clay and heat to brick, or water and wind to wave; yet for the reasons given, it is permissible and useful to discriminate between the two aspects. It is sound biology to say of some particular peculiarity in an organism that it is due (*a*) to the loss of some item in the natural or germ-plasmic inheritance, or (*b*) to some nurtural defect which inhibited the developmental expression of items that were certainly present in the inheritance, as subsequent breeding shows. Similarly, on the positive side, it makes a difference if the development organism has received factors for a particular character from both parents; and it makes a difference if the nurture is unusually stimulating as regards the expression of a particular character.

Environment and Inheritance

Some biologists are so sensitive to the abstractness of all the biological pigeon-holing, that they have seriously proposed to include the normal appropriate environment of the young organism as part of its "heredity," for, as they say, what does the inheritance amount to if the appropriate environment is wanting—a bundle of cheques but no bank. Perhaps, however, this is unnecessarily pedantic, after it has been agreed that these various "aspects" are devices for scientific analysis. Every living creature must have its surroundings; every embryo must have its nurture; function is only the unending sequence of actions and reactions between organism and the environment. All this may be granted, and yet it is useful and necessary to try to distinguish in development the respective influences of "nature" and "nurture"—including in the latter three sets of conditions: environmental, nutritional and functional.

Up to a certain point the fertilised ovum of a mammal may be induced to develop outside the mother, or an isolated neuron of a chick-embryo will grow in a droplet under the microscope, thus illustrating the hereditary inertia. Yet if the larval proteus be reared under red light in the laboratory, the minute primordium of the eye, which in the normal cave-environment remains arrested and buried, increases in size and in the differentiation of optic structures. It may actually grow to meet the skin and become a seeing eye, thus illustrating the potency of altered environment as a liberating stimulus. No doubt there are nurtural limits outside which normal development will not occur, but the majority of organisms in natural conditions find this minimum environment at least. This will be agreed to by all. What is more interesting is the question how far changes in the nurture, such as are of frequent occurrence in natural conditions, will serve as inhibitants and stimulants. The same kind of sponge may grow into a dwarf that lives in a hole excavated in an oyster-shell, or in conditions of greater freedom it may grow into a large vase. If a bonellia larva rests for a while on the proboscis of the adult and absorbs inhibitant nutritive material from the skin, it develops into a pygmy male; but if, after the free-swimming stage, it settles down in the mud, and not on a proboscis, it develops into a large and vigorous female.

Function and Heredity.—Along with the environmental and nutritional influences, those of active functioning must be included, though it is of course evident that the activity or inactivity, the restlessness or sluggishness of the developing organism is an expression of its particular inheritance. The free-swimming tunicate larva has in ordinary cases no alternative to becoming sedentary; the collapse is an expression of the inheritance. Yet in some cases the individuals of a family, clutch or litter, vary demonstrably in their heritable constitutional bias in the direction of greater or less activity—perhaps the commonest of all variations—and thus there arise differences in development which afford raw material for natural selection. Especially in relatively less stereotyped forms, *e.g.*, in fishes compared with mammals, the importance of active functioning in the course of development is momentous, for it is on the active functioning that the detailed expression of hereditary characters depends. A

vicious circle must be avoided, but not so timorously that we thereby miss a great truth.

The degree of development, *i.e.*, the expression of hereditary characters, depends in part on surroundings and food, but it also depends on the activity of the young creature such as the fish-larva, and on the action of part on part. The degree of this activity depends largely on the inherited constitution (and partly on food and environment), therefore we are not suggesting that it is a separate entity or anything of that sort. We are only emphasising a commonplace that is often missed: The differentiation of characters in development depends in part on the functioning of the young organism, and changes in the intensity of the functioning will result in changes in the evocation of structure. The changes in intensity of functioning may be of the nature of germinal variations, or they may be reactions to environmental stimulus. If the environmental stimulus should become constant, a modificational specific character might arise.

It is possible that many constant characters of a species are really of the nature of constantly re-impressed modifications. As Dr. Harry M. Kyle puts it: "The constancy of a species depends upon the persistence of a normal environment." From this point of view we get a useful new light on heredity. To some extent, especially in the lower grades of life, the inherited material may be moulded this way or that way if the nurture is changeful, or it may find a deceptively stereotyped expression when the nurture is very constant from generation to generation. Between inheritance and environment comes the activity of the individual. Dr. Kyle's *Biology of Fishes* (1926) may be cited for its many illustrations of this important thesis.

Heredity and Disease

For biological purposes a disease may be defined as a deteriorative process which tends to disintegrate the unity of the organism. The associated pathological changes cannot be separated off in any hard and fast way from ordinary vital changes, and what is a disease in one animal may be normalised in another type—let us think of the growth and decay of the stag's antlers. Yet disease implies that certain processes of metabolism have got out of place, out of time and out of tune.

For biological rather than medical purposes, again, we may distinguish four kinds of disease:—(1) There are environmental diseases, such as debilities due to lack of light or to deficiency in certain constituents of the food. Perhaps rickets may serve as an example. (2) There are functional diseases, which are due to overwork, lack of exercise or to some deteriorative factor in the occupation. Some kinds of heart strain, certain forms of obesity and lead poisoning may serve as examples. (3) There are the familiar microbic and parasitic diseases, due to the poisonings, lesions, blockings and so forth that are produced by intruding organisms of a hostile character; as in plague, tuberculosis, sleeping-sickness, malaria, and the disturbance brought about by hookworm, bilharzia, and other non-microbic invaders of man's body. It has to be recognised that part of what is, for practical purposes, called the disease in such cases, is the organism's defensive or even offensive reaction to the intruder, as in the phagocytosis associated with inflammation. (4) On a different plane are organic or constitutional diseases, which are due to some very early germinal or embryonic disturbance or defect.

A deteriorative peculiarity in the metabolism associated with excretion may find expression in kidney disease; or some defect in the inheritance may express itself later in one of the forms of epilepsy; or some inborn and at present inexplicable lack of balance in the functioning of the endocrinal glands may lead to one of the forms of diabetes. Apart from parasites, there is almost no disease in wild nature, where it is speedily nipped in the bud if it shows itself; in mankind and in his stock, where selection for health is less searching and insistent, where the struggle for existence is rarely with the gloves off, and where the conditions of life are often very artificial, disease is rife. In the case of organic or constitutional diseases, the organism starts with an inherited handicap, to which ill-advised nurture may add. In the other kinds of disease, the immediate cause is in great part extrinsic, though less so in occupational diseases, but the extrinsic influence may have its deteriorative effect increased by some hereditary predisposition on the organism's part, which has then to fight a battle with two fronts.

A few general statements may be made in regard to heredity and disease. There is no proof that modification-diseases (environmental, occupational or habitudinal) can be transmitted from parent to offspring, but they may bring about a general weakening of the germ-plasm, and they may influence the child prejudicially through the mother. Microbic diseases are not transmissible, though a susceptibility to them may be, and though very early—ante-natal—infection may bring about a semblance of heritability. As a disease is a process, there are few instances of hereditary disease in the strict sense; but there are many instances of definite heritable taints, that is to say, constitutional predispositions or susceptibilities that render the organism peculiarly liable to deteriorative influences in surroundings, in nutrition and in functioning, or to the assaults of intruding microbes. If a hereditary taint is a recessive Mendelian character it will be masked by the corresponding dominant character, that is by normality. Thus it will not find individual expression, though it remains part of the inheritance. It is possible that a pathological feature, *e.g.*, a nervous disturbance, may find expression earlier and earlier in development, until it becomes fatal at a very early stage (Sir F. W. Mott's "law of anticipation").

Heredity and Consanguinity

The older view that consanguinity is necessarily of itself deteriorative has not been confirmed experimentally. Leaving man's case apart, where psychological and social considerations complicate the issue, there is abundant evidence that the inbreeding or endogamy of healthy stock may go far without any deteriorative results. In the early chapters of the establishment of some of the famous stocks of domesticated animals there has been very close inbreeding. If there is a well-defined taint of some sort, it is plain that inbreeding will increase it if it is exhibited by both the parents. If a given character exhibits Mendelian inheritance, the result of inbreeding must always be the isolation of homozygous types—pure as regards the character in question. It matters not whether the character is advantageous or detrimental, except that in the latter case it may soon cross the limit of viability. If we suppose that a herd includes a percentage of individuals with a recessive taint, this will tend to become less conspicuous in conditions of outbreeding or exogamy, since the offspring of recessive tainted and dominant normal will appear normal.

But in conditions of inbreeding or endogamy, the taint will become more and more conspicuous, since the chances of two tainted parents coming together will be greater, and the offspring will be homozygous recessives. Thus there will come about an isolation of a homozygous tainted type (or, in more complex cases, types), and the rapidity of the isolation will be in proportion to the intensity of the inbreeding. When the taints interest the breeder practically he fixes his attention on them, and thus, in the past, consanguinity has been blamed for causing what it merely discloses. It should be noted that there may be remarkable combinations of deteriorative recessive characters, previously hidden by their dominant allelomorphs, and that there may be a general reduction in the vigour of the herd as taints diffuse. We cannot wonder, then, that inbreeding has come to have a bad name. But the facts all point to the conclusion that what the inbreeding itself does is to expose undesirable characters that already existed, but have been masked by their dominants. It follows that inbreeding can be used as a sieve for the radical improvement of a stock, since the exposed abnormalities, deficiencies and undesirabilities can be artificially eliminated.

A subsequent outbreeding with good stock will re-invigorate the purified inbred stock, for there will be a pooling of good qualities comparable to the previous accentuation of bad ones. Moreover, there may be a useful outcrop of fresh variations, for

his often follows the introduction of fresh blood. It may be definitely concluded, then, that inbreeding is not injurious because of the consanguinity, and that if the breeder understands what is happening, it may be made highly beneficial. The experimental evidence will be found conveniently in *Inbreeding and Outbreeding*, by E. M. East and D. F. Jones (1919). There seems to be no biological reason for objecting to the marriage of two thoroughly healthy cousins; and it would appear that the alternation of periods of inbreeding and outbreeding has counted for much in the history of human stocks and tribes and races.

Conclusion.—One cannot turn from this survey without referring to the fatalistic impression that the study of heredity is apt to produce: the hand of the past has such a heavy grip. Yet "the other side of heredity" must also be emphasised—the persistence of the stable, the conservation of advantageous qualities, the continual emergence of the new, the influence of nurture in determining the degree of development to which the hereditary nature attains, and, in man's case, the dominant importance of the extra-organismal or social heritage. A man cannot alter the number of his separate hereditary "talents," to use the phraseology of the immortal parable, but he can trade with what he has, and he is thus not only born, but made.

HERGESHEIMER, JOSEPH (1880–), American author, was born at Philadelphia, Pa., Feb. 15 1880, and was educated at a Quaker school in Philadelphia. As a writer of fiction he is distinguished by the warmth and colour of his descriptive passages and by his psychological insight.

His publications include: *The Lay Anthony* (1914); *Mountain Blood* (1915); *The Three Black Pennys* (1917); *Gold and Iron* (1918); *Java Head* (1919); *The Happy End* (1919); *Linda Condon* (1919); *San Cristóbal de la Habana* (1920); *Cytherea* (1922); *The Bright Shawl* (1922); *The Presbyterian Child* (1923); *Balisand* (1924); *From an Old House* (1925); *Tampico* (1926).

HERKOMER, SIR HUBERT VON (1849–1914), British painter (*see* 13.364), died at Budleigh Salterton, Devon, March 31 1914.

HERMANT, ABEL (1862–), French author and dramatist, was born in Paris Feb. 3 1862. A brilliant wit and an exquisite stylist, he consistently devoted his abundant talents to describing the lighter side of life. His most characteristic works are those grouped under the general title, *Mémoires pour servir à l'histoire de la société* (1905), wherein, with unfaltering gaiety and a humour saved only by the delicacy of its expression from appearing scabrous, he mocks the aristocracy and wealthy bourgeoisie of France. He excels, too, in long series of amusing dialogues. *Le Caravansérail* (1917), a study of rich foreigners plunged into the cosmopolitan circles of Paris, is perhaps his best-known work, but the series of *Scènes de la vie des cours et des ambassades*, which includes *La carrière* (1894) and *Le sceptre*, (1900), no less pungently portrays the complications of diplomacy in a dignified Central European court. Among his plays may be noted *La meute* (1896), a comedy of parasites, and *Sylvie, ou la curieuse d'amour* (1900), which with infinite grace displays the reactions of a light-headed woman to the successive phases of revolutionary and imperial France.

HERRICK, ROBERT (1868–), American author, was born at Cambridge, Mass., April 26 1868. He was educated at the Cambridge Latin School and at Harvard University where he graduated in 1890. He was appointed instructor in rhetoric at the Massachusetts Institute of Technology in 1890 and three years later accepted a similar position at the University of Chicago, where he became professor of English in 1905. His novels and short stories deal with the complicated problems of modern life in realistic fashion. They include *The Man Who Wins* (1895); *The Gospel of Freedom* (1898); *The Web of Life* (1900); *The Real World* (1901); *The Common Lot* (1904); *The Memoirs of an American Citizen* (1905); *The Healer* (1911); *One Woman's Life* (1913); *The Conscript Mother* (1916); *Homely Lilla* (1923); *Waste* (1924); *Wanderings* (1924); and *Chimes* (1926).

HERRIOT, EDOUARD (1872–). French politician, was born at Troyes, in Champagne, July 5 1872, the son of an officer. He was sent first to the Lycée of La Roche-sur-Yon, and afterwards to that of Louis-le-Grand, which bore the reputation of being the best school in France. He then entered the École Normale Supérieure, which included many eminent teachers such as Brunetière and Gaston Boissier, both of whom were men of authority and unquestioned reputation. Here he remained working assiduously for several years, and while delighting in the pursuit of learning thoroughly enjoyed the interchange of ideas with his fellow-students, on whom he left an unforgettable impression. In 1894 he graduated with high honours. Whilst undergoing his military service at Nancy, his favourite relaxation was the study of Greek literature. His book *Philon le Juif* (1897) was crowned by the Académie Française.

Having been appointed a professor at the Lycée of Nantes, he was entrusted the following year first with the Chair of rhetoric, and then of higher rhetoric at the Lycée of Lyon. He imparted to his pupils not merely the principles of knowledge but also the love of it for its own sake; a scholar of great refinement, he possessed the gift of stimulating others, and his discourses were so lucid and attractive that all who heard them were captivated. On relinquishing his Chair he became a popular lecturer, as well as journalist and propagandist, and his book, *Madame Récamier et ses Amis* (1905), achieved widespread popularity. His *Précis de l'histoire des lettres françaises* (1905) shows that his literary criticism was based on a minute study of the text.

A man of M. Herriot's wide sympathy could not fail to be drawn into public life. In May 1904 he was made a municipal councillor and deputy Mayor of Lyons and the following year became Mayor. Thenceforward, with the exception of three months, he guided the destinies of Lyons; for at each successive election of the Municipal Council he resumed office. In 1910 he became a member of the conseil général and in 1912 senator for the department of the Rhône. From Dec. 1916 to March 1917 he occupied the post of Minister of Public Works, Transport and Supplies in the Cabinet of M. Briand. During this time he inaugurated a policy of restriction which enabled France to economise her resources, while at the same time lessening the drain on them caused by the World War, and enabling her to gain a more speedy victory. Having to a large extent solved the problem of supplies, he proceeded to bring order into the transport service. Stations, railway lines and ports were cleared and an efficient service was maintained.

M. Herriot now felt that by entering the Chamber, he would be better able to carry out his cherished ideas. He therefore renounced his office as senator, and was elected in Nov. 1919 deputy for the Rhône department. He was then appointed a member of the Finance Commission and reporter-general of the Budget of Public Instruction. The Radical party now chose him as their leader, and as a defender of the principles of democracy he soon reached the front rank of French statesmen. As an orator he showed subtlety and versatility, combined with a vivid imagination, while his delivery was pleasing and impressive. At times he was a man of the people, then at other times his eloquence was that of the scholar soaring into metaphysics. Both in speaking as well as writing M. Herriot always approached his subject from the loftiest standpoint—the result of his wide knowledge,

culture and absolute integrity. His chief qualities might be summed up in three words: logic, wisdom and conviction; and it was the combination of these which enabled him to draw up a formula for an experimental policy.

Even before hostilities had ceased, M. Herriot turned his attention to post-War problems. By his actions as well as in the Press he insisted on the necessity for the reconstruction and economic development of his country. In 1916, at the moment when the victory of Jan. seemed imminent, he organised the Lyons Fair, that magnificent international market which not only promoted the economic interests of the town and district, but at the same time contributed in a remarkable degree to national prosperity. This exhibition, though it cost the inhabitants of Lyons nothing, possessed a great palace to which each successive year new pavilions were added. That it proved a formidable rival to the Leipzig Fair, and had an ever-increasing success, was a striking testimony to M. Herriot's robust optimism. In 1917 he published *Agir*, a book which at a time when the fate of France was so uncertain, bore the character of an unflinching act of faith; for in it M. Herriot maintained that the culture and civilisation of France were too deep-rooted and too strong to be overcome. This gospel of action soon inspired the faint-hearted with fresh hope.

After the victory, M. Herriot brought out a work in two volumes, *Créer* (1919), dedicated to the youth of France. It contained his programme of reconstruction, and gave his compatriots a fine example of resolution, fearlessness and patriotism. A similar example emerged from his visits to Russia, the U.S.A. and Canada. He was soon confronted with an even harder task than before, for as head of the Radical party the eyes of all French democrats were turned towards him. It was he who inspired the opposition and acted as its mouthpiece, yet he remained faithful to his original ideals, and even in the heat of conflict never allowed himself to forget that one day the responsibility of office might fall to him again. After the elections of May 1924 he became Premier and Minister of Foreign Affairs and immediately set to work to reform the policy of France. During the London conferences, in the application of the Dawes plan and finally over the Geneva protocol, he displayed a rare combination of idealism and common sense, and outlined those great aims, in pursuit of which the nations of the world should unite to avoid war. By these efforts he gained the confidence of all men of good will, not only in Europe but over the whole world. Germany in consequence offered to draw up a security pact destined to be signed eight months later at Locarno.

This admirable achievement, however, by no means disarmed M. Herriot's adversaries. The financial problems which he had to face were the occasion of innumerable attacks upon him and finally a hostile vote of the Senate obliged him to resign in April 1925. A few days later, he was elected president of the Assembly by the deputies who desired to testify to the courage, zeal for work and talents of the leader of the Left. The office of President gained an added lustre through the tact, good humour and timely exercise of his authority shown by M. Herriot, and everyone cheerfully submitted to his arbitration. During the many critical moments in the history of contemporary French politics, M. Herriot, with his idealism, practical wisdom and patriotism, proved a guiding light. He devoted his few leisure hours to writing *Dans la forêt Normande*, a book worthy not only of a great writer, but also of a philosopher. (L. Ri.)

HERTLING, GEORG, Count von (1843–1919), German statesman, was born in Darmstadt Aug. 31 1843. In 1882 he was appointed professor of philosophy in the University of Munich. From 1875 to 1890 and again from 1893 to 1912 he was a member of the Reichstag, from 1909 being for a short time the leader of the Centre (Catholic) party. In 1912 he was appointed president of the Bavarian ministry and minister for foreign affairs, and in 1914 was elevated to the rank of count by King Ludwig III. On Nov. 1 1917 he accepted the chancellorship of the Reich, which he had refused in July of that year; and for 12 months he strove against the encroachments of the military authorities upon the political affairs of the Empire. The failure of the German offensives in 1918 finally destroyed his hopes o being able to negotiate with the Allies on anything like equa terms and feeling at last unequal to the struggle against th introduction of real parliamentary Government, he resigned Sept. 30 1918, and returned to his home at Ruhpolding in Upper Bavaria, where he died Jan. 4 1919. His reminiscences were published in 1919 under the title of *Erinnerungen aus meinem Leben*. See also Karl Hertling, *Ein Jahr in der Reichskanzlei* (1919).

HERTZ, JOSEPH HERMAN (1872–), Chief Rabbi of the United Hebrew Congregations of the British Empire, was born in Rebrin, Czechoslovakia, Sept. 25 1872. Emigrating to America as a child, he was educated at New York City College, Columbia University, where he took the degree of Ph.D., and the Jewish Theological Seminary of America. He was a Rabbi in Johannesburg, South Africa, from 1898 to 1911 and, during the Boer War, was expelled by President Kruger for pro-British sympathies and for advocating the removal of religious disabilities from Jews and Catholics in the South African Republic. From 1906 to 1908 he was professor of philosophy at Transvaal University College. Dr. Hertz was elected to the Chief Rabbinate in succession to Dr. Hermann Adler, in 1913. In 1920–1 he undertook an extensive pastoral tour, visiting the Jewish communities in South Africa, Australia, New Zealand and Canada. He became President of Jews' College, London, in 1914. In 1925 he was made one of the board of governors of the University of Jerusalem and chairman of the administrative board of its institute of Jewish studies. He also became vice-president of the Anglo-Jewish Association, the London Hospital and the League of Nations Union. Among other Jewish writings, he published an anthology *A Book of Jewish Thoughts* (1917), of which 17 editions had appeared in 1926. He was a member of the original board of translators of the Jewish Bible Version, 1896–1903.

HERTZOG, JAMES BARRY MUNNIK (1866–), South African politician, was born at Wellington, Cape Colony, April 3 1866. Educated at Victoria College, Stellenbosch and Amsterdam University, he became a judge in the Orange Free State in 1895, and served through the South African War of 1899–02. He voted against peace at Vereeniging and, frankly hostile to the British connection, he helped to keep alive this anti-British feeling after the War. On the grant of responsible government in 1907, he became attorney general and minister of education in Fischer's ministry, and forthwith began to undo the work of the Crown Colony Administration. He tried to force upon the schools a system of compulsory bi-lingualism—Dutch and English—which was crude and impracticable. The director of education resigned, and one of the three inspectors, dismissed without enquiry, won an action for libel against Hertzog in a *cause célèbre*.

In the first Union Cabinet, in 1910, Hertzog became minister of justice under Botha, but his attitude made the position untenable. Botha resigned in 1912, took office again, reconstructed his Cabinet and left Hertzog out. The latter then formed an opposition party with complete independence of Britain as its goal, and his perfervid nationalism gained him much influence among the old Republican Boers. After the World War he continued his separatist policy but finally formed a "pact" with the Labour party. In 1924 this Coalition came to power with Hertzog as prime minister, whereupon he disclaimed any practical application of his republican policy. In 1925 he brought the native question into the forefront of the political arena, thus rendering a great service to the future of the country owing to the increasing gravity of the problem in its relation to the continued supremacy of a comparatively small white population. (H. Gn.)

HERVIEU, PAUL (1857–1915), French dramatist and novelist (*see* 13.405), produced his last play, *Le Destin est maître*, in 1914. He died in Paris Oct. 25 1915. See A. Binet, *Portrait psychologique de Paul Hervieu* (1914); H. Burckhardt, *Studien zu Paul Hervieu* (1917).

HEWART, GORDON HEWART, 1st Baron (1870–), British lawyer, was born Jan. 7 1870 at Bury, Lancashire.

Having graduated as a scholar of University College, Oxford, he was called to the Bar in 1902 and practised on the northern circuit. After an unsuccessful contest in Northwest Manchester in 1912, in which year he took silk, he was elected as a Liberal for Leicester in 1913, and after the rearrangement of constituencies in 1918 represented the eastern division of that city from 1918 till his retirement from Parliament. In Dec. 1916 he was appointed solicitor-general in Mr. Lloyd George's Coalition Government. Having afforded useful support to the administration by his talents as a debater, he was made attorney-general 1 Jan. 1919, and was admitted to the Cabinet in 1921. He gave material assistance in the conduct of reconstructive legislation, and took an active part in the final phase of the negotiations with the Sinn Feiners, being one of the signatories of the so-called Irish Treaty. He acted as president of the War Compensation Court from 1922. He had been knighted in 1916; on Jan. 16 1918 he was sworn of the privy council, and on March 24 1922 was appointed lord chief justice, being at the same time created Baron Hewart of Bury.

HEWLETT, MAURICE HENRY (1861–1923), British man of letters (*see* 13.417). The best of his later works are *Mrs. Lancelot* (1912); *Bendish* (1913); and *Mainwaring* (1921). His main interest, however, was directed from fiction to verse. *The Song of the Plow* (1916) has been recognised as one of the most considerable narrative poems of the century; it describes the fortunes of the English farm labourer from the earliest times to the World War, and though occasionally the imaginative beauty is obscured by necessarily prosaic detail, contains numerous passages of a fine masculine vigour. *The Village Wife's Lament* (1918) is a more uniform and but slightly inferior poem. In *Love of Proserpine* (1913), Hewlett attempted, with some success, to hint in delicate prose at the mystical semblances of nature, and his essays, *In a Green Shade* (1920), were warmly received. His translations and imitations of the sagas, including *Thorgils of Treadholt* (1917), also deserve mention. The popularity of his earlier fiction concealed from many of his contemporaries the strength and originality of his later work. He died at Broadchalke, near Salisbury, June 15 1923.

HEYSE, PAUL JOHANN LUDWIG (1830–1914), German novelist, dramatist and poet (*see* 13.438), received the Nobel prize for literature in 1910. His later works include *Helldunkles Leben* (1909); *Italienische Volksmärchen* (1914) and *Letzte Novellen* (1914). He died at Munich April 2 1914. Several volumes of his letters have appeared (1916, 1917, 1919). See also H. Raff, *Paul Heyse* (1910).

HIBBEN, JOHN GRIER (1861–), American educationist, was born at Peoria, Ill., April 19 1861. He graduated from Princeton University in 1882; was a student at Princeton Theological Seminary from 1883 to 1886; and later studied at Berlin. In 1887 he was ordained a minister in the Presbyterian Church and was a pastor for four years at Chambersburg, Pennsylvania. In 1891 he returned to Princeton, where he taught logic as an instructor (receiving the degree of Ph.D. in 1893), assistant professor, and from 1907 professor. In 1912 he succeeded Woodrow Wilson as president of the university.

His works include *Inductive Logic* (1896); *The Problems of Philosophy* (1898); *Hegel's Logic* (1902); *Logic Deductive and Inductive* (1905); *The Philosophy of the Enlightenment* (1910, contributed to the *Epochs of Philosophy*); *A Defence of Prejudice and Other Essays* (1911) and *The Higher Patriotism* (1915).

HIGGINSON, HENRY LEE (1834–1919), American banker, was born in New York City Nov. 18 1834. At the age of 17 he entered Harvard University, but before finishing his course entered the banking house of S. and E. Austin, of Boston. He later went to Vienna for a year, where he studied music. In the Civil War he served as a volunteer officer. In 1863 he was severely wounded at Aldie, Va., and in the following year was honourably discharged. In 1868 he joined the banking firm of Lee, Higginson and Co., of Boston, with whom he remained until his death. His interest in music led to his founding the Boston Symphony Orchestra in 1881. A long line of distinguished directors placed this organisation in the first rank. It was a stimulating source of musical education in America and won full recognition abroad. In 1891, as a memorial to certain friends who died in the Civil War, he presented Soldiers' Field to Harvard University; and in it the stadium was built. In 1899 he erected the Harvard Union as a general meeting-place for all undergraduates. For many years a fellow of Harvard University, he died in Boston, Mass., Nov. 14 1919. See Bliss Perry, *The Life and Letters of Henry Lee Higginson* (1921).

HIGGINSON, THOMAS WENTWORTH (1823–1911), American author (*see* 13.455), died in Cambridge, Mass., May 9 1911. See *T. W. Higginson: The Story of His Life* (1914), by his wife, Mary Potter Higginson.

HILDEBRANDSSEN, HUGO HILDEBRAND (1838–1925), Swedish meteorologist, was professor of meteorology and director of the Meterological Institute at Upsala from 1878 to 1906. He was an associate member of the Comité Permanent International Météorologique from 1882 to 1885, ordinary member from 1891 and general secretary from 1900 to 1907. In 1886 he undertook, in conjunction with the Hon. Ralph Abercromby, the classification of cloud forms, and he published in 1896 his *Atlas international des nuages* (with Riggenbach and L. Teisserenc de Bort), together with *Les bases de la météorologie dynamique* (1898–1907), in collaboration with Teisserenc de Bort. Hildebrandssen became an honorary member of the Royal Meteorological Society of London in 1888, which awarded him the Symons Gold Medal in 1921, and also a member of the Royal Institution of Great Britain. He died in 1925.

HILL, DAVID JAYNE (1850–), American diplomat, was born at Plainfield, N.J., June 10 1850. After graduating in 1874 from the University of Lewisburg, Pa. (later known as Bucknell University), he became instructor in Greek and Latin there and from 1877 professor of rhetoric. In 1879 he was elected president of Bucknell, and in 1888 of the University of Rochester. In 1896 he resigned and went abroad to study public law. In 1898 he was appointed assistant secretary of state by President McKinley. While in Washington he was also professor of European diplomacy in the school of comparative jurisprudence and diplomacy. In 1903 he was appointed minister to Switzerland, being in 1905 transferred to Holland. He was a delegate to the Second Peace Conference at the Hague in 1907. From 1908 to 1911 he was ambassador to Germany. In 1914 he was proposed as a candidate for the Republican nomination for the U.S. Senate from New York to succeed Elihu Root.

Hill's best known work is his *History of Diplomacy in the International Development of Europe*, embracing *A Struggle for Universal Empire* (1905); *The Establishment of Territorial Sovereignty* (1906) and *The Diplomacy of the Age of Absolutism* (1914). His other writings include *World Organisation as Affected by the Nature of the Modern State* (1911, lectures delivered at Columbia University); *Impressions of the Kaiser* (1918); *Present Problems in Foreign Policy* (1919); and *American World Policies* (1920).

HILL, JAMES JEROME (1838–1916), American capitalist (*see* 13.464), died at St. Paul, Minn., May 29 1916. He resigned the chairmanship of the board of directors of the Great Northern Railway in 1912. He had long thought that the farmers and millers of the north-west needed a large financial institution near at hand to which they could easily turn for aid. Accordingly in 1913 he secured control of the First and Second National banks of St. Paul and merged them, thereby increasing local facilities for loans. On learning in 1914 that friends had raised $125,000 for establishing as a tribute to him a chair of transportation at Harvard he added a like amount. During his later years he gave much attention to the Hill Reference Library, in St. Paul, to which he contributed liberally. He was the owner of a remarkable collection of modern French paintings, including fine examples of Puvis de Chavannes, Corot, Delacrois, Millet and others. He was the author of *Highways of Progress* (1910), a work dealing with the subject to which he had dedicated his life.

HILL, OCTAVIA (1838–1912), British philanthropist (*see* 13.465), died in London Aug. 13 1912.

HINDENBURG, PAUL VON (1847–), German soldier. Paul Ludwig Hans von Beneckendorff und von Hindenburg was born in Posen Oct. 2 1847, the son of a Prussian officer. His childhood was spent in his parents' house, and later in Pinne and Glogau. In 1858 he entered the cadet school at Wahlstatt in Silesia, afterwards joining the chief cadet academy in Berlin. At an early age the severity of the training in the Prussian cadet corps lent a note of inflexibility to his character, and developed in him strength of will, resolution and cool-headedness. Intellectually, he developed relatively late, owing to early illnesses and to too rapid physical growth. Ambition awoke in him slowly; but as success crowned his efforts it grew unceasingly, and won him the reputation of a particularly gifted pupil. At the age of 18 he entered the 3rd Foot Guards at Danzig as a second-lieutenant in 1866, and soon after made his first appearance on the battlefield. At the battle of Königgrätz he stormed with his squadron an Austrian battery under fire. He took part in the war of 1870–1 as adjutant to a battalion, and after gaining distinction at St. Privat, became adjutant to the regiment.

After three years at the staff college in Berlin, he served with the general staff in 1877, and was soon promoted to the rank of captain. The next years were spent as company commander and chief of battalion and in various posts on the general staff. In 1883 he became an instructor at the Staff College in Berlin; and later, on the general staff under Count Schlieffen, he was the spiritual pupil and assistant of that strategist of genius. Several years' labour in the Prussian War Office developed his talent for organisation. After serving from 1893 to 1896 as commander of the 91st infantry regiment (Oldenburg), he was promoted major-general, and for four years served as chief of the general staff of the VIII. Army Corps at Coblenz, subsequently commanding the 28th Div. at Karlsruhe for three years. In 1903 he became general in command of the IV. Army Corps at Magdeburg. In 1911, being 65 years old, he was placed on the retired list.

The Outbreak of War.—The outbreak of the World War found him leading a life of seclusion in Hanover. It was in response to the threatening development of the opening campaign in the East against the Russians that on Aug. 22 1914 he was appointed commander-in-chief of the VIII. German Army, and had assigned to him Maj.-Gen. Ludendorff as chief of staff. Though hardly acquainted with one another previously, a reciprocal confidence soon resulted, which, despite divergence of character, led to a unity of thought and deed without analogy in history. Hindenburg has given a detailed account of his relations with Ludendorff in his memoirs. When, in Germany, after the War, from personal and political motives, attempts were made to make a scapegoat of Ludendorff, the marshal denied these accusations, saying: "We belong to one another till death. Gen. Ludendorff acted in constant accord with me. He who strikes at him strikes at me." General Ludendorff, too, in his war memoirs, fully reciprocates this attitude of complete trust and confidence.

It must be recognised that the disposition of Ludendorff was the more active, that a demonic spirit resided in him which was responsible for those decisive acts which changed the course of the world's history. His memoirs of the War and his demeanour in German politics after the War are instinct with the vehement passions of one who has been subjected to many attacks, just or unjust. During the War it was only the presence of the marshal's authority that prevented the vivid, sensitive and at times well-nigh fanatical temperament of his colleague from losing self-control. The character of Ludendorff was the harder, that of Hindenburg the greater. Their processes of thought ran upon separate lines, but each tested his own conclusions and completed them by reference to the other. Ludendorff bore the whole burden of the technical execution of the decisions, a task which he carried through with titanic strength. Hindenburg remained predominantly in the sphere of pure thought, supplying rather the static element in leadership, and leaving the dynamic side in the other's hands.

Hindenburg possessed a gift of inestimable value, and Ludendorff enabled him to develop it—that of economising his own mental energy and guarding it against strain and premature exhaustion. He was thus enabled to retain his nerve force until t end of the War, when he was then able to assume a heavier a more thankless task, that of saving his fellow-countrymen fro the whirlpool of the revolution. In the political sphere, Ge Ludendorff's vigorous intervention frequently involved the ma shal in spite of all his distaste for political activities, in que tions which he would probably have otherwise avoided. Hinde burg as a soldier was hampered by mistrust of his own politic ability. Ludendorff frequently had to convince the chief of t general staff of the necessity for taking political decisions. On the constraint of conscience and the sense of moral responsibili caused Hindenburg and Ludendorff to intervene at all in politic questions.

Tannenberg.—The battle of Tannenberg, which lasted fro Aug. 26 to 31 1914, found its origin in the dispositions, involvin the assembly of strong forces on the southwest flank, adopted b the superseded Gen. von Prittwitz after breaking off the en gagement at Stallupönen (Gumbinnen). Hindenburg's meri lay in converting the possibility thus acquired of a successful de fence against Samsonov's Russian Army of the Narew into victory, whereby despite the numerical inferiority of the Ger mans the enemy were twice encircled and practically annihilated The most brilliant feature of the operations was the concentra tion of all available forces in order to overwhelm this enemy despite the threats to Hindenburg's rear, first by Rennenkamp in the north and later by new Russian forces which were ap proaching from the south. In the subsequent battle of the Ma surian Lakes, Sept. 7–12, the Niemen army under Rennenkamp was so thoroughly dispersed in the wood and marsh lands as to b unfit for further operations for weeks. In the opening of his cam paign in East Prussia Hindenburg showed consummate master in the employment of interior lines and in using a central positio to prevent hostile forces which were advancing from differen directions from uniting on the battlefield. His plan was to over whelm the first of these with lightning swiftness, and then to turn with all his strength upon the others.

Hindenburg was unable to follow up his victories in Eas Prussia by advancing across the Lower Narew; the Austro Hungarian allies had suffered a heavy defeat in Galicia, and th German commander was compelled to hasten to their immediat aid with the bulk of the German forces available in the East This led to the combined offensive of the German IX. Army through Southern Poland towards the Vistula and of the Austri ans in Galicia across the San. The German advance met with little resistance, but the roads were mere morasses. On Oct. the Vistula was reached between Jozefoff and Dęblin (Iwangerod after an advance along the Opatow-Radom line. The attempt t cross the river failed, and the Austrian allies, too, came to standstill. Finally, the German offensive drew upon itself greatly superior Russian forces which, advancing past Warsaw, assailed its left flank. In this way the ally was relieved. Hindenburg himself succeeded in escaping the threatened envelopment from the north by a timely withdrawal upon Upper Silesia. With the vision of genius he grouped the great bulk of his forces about the railway line running to West Prussia, and at the beginning o Nov. advanced in a surprise attack from the Wrzesnía-Thorn line upon the right flank of the main Russian forces lying in southern Poland. He succeeded at the battle of Lódź in bringing the "Russian steamroller" to a standstill, and eventually com pelled the enemy to withdraw behind the Bzura and Rawka.

Further Operations in the East.—Hindenburg in the meantime had been appointed marshal and commander-in-chief of all the German forces in the East. His next blow was in Masuria in Feb. 1915 against the northern wing of the Russian Army on the Upper Bobr, and led to the annihilation of the X. Russian Army. But the attempt to advance across the Narew to Bialy stok failed, owing to a powerful Russian counter-offensive at Prazasnysz. The general eastern campaign, directed by Gen von Falkenhayn, was now concentrated upon Galicia, where on May 8 the break-through at Gorlice-Tarnow initiated a promis ing offensive. The front line of the army group of Hindenburg stretching from the upper Vistula as far as Courland, remained

stationary throughout this period, except for local offensives and a large scale cavalry raid. Not until the middle of July was Hindenburg's front-line set in motion, in co-operation with the victorious progress of the offensive in Galicia and southern Poland. But Gen. von Falkenhayn and the Marshal differed fundamentally in their attitude towards the cardinal problem of the War. Hindenburg's conviction, founded on the teaching of Clausewitz, was that the salvation of the Central Powers depended on the destruction of the Russian colossus. He believed that a great "Cannae" was attainable in the East, and that with such a victory all political and military considerations which fettered the commander in his power of decision would vanish.

Falkenhayn, on the other hand, held that it was sufficient by means of a "campaign with limited objectives" to keep the Russian Army at bay and to cripple its offensive power. Hindenburg's proposal was to take the offensive on his extreme left flank on the Niemen northwards past Kovno in the direction of Wilna and beyond, and thus to sever the northern arteries of the Russian Army—namely, the railways. This plan was rejected by Falkenhayn in favour of the advance across the lower Narew, which proved successful, for in conjunction with the successes of Mackensen and of the Austrians in southern Poland it caused the whole Russian front line to waver. Yet it was only gradually and in consequence of continual front-line engagements that the enemy allowed themselves to be driven back upon their rearguard communications towards the East. Several times during the operations Hindenburg brought up the question of his original project; he also carried out unaided the attack upon the fortress of Kovno, which fell on Aug. 18. Eventually, early in Sept., Falkenhayn gave way ostensibly, without, however, placing at Hindenburg's disposal the strength requisite for carrying out his plans. The offensive upon Wilna, begun too late, encountered powerful Russian forces, and it was only possible to press back the Russian front line, no decisive encounter having taken place.

From the autumn of 1915 onwards Gen. von Falkenhayn treated the East as a merely subsidiary seat of war; for while he was striving to wear down the French forces at Verdun the German eastern front was condemned to inactivity. This facilitated the great Russian successes in June and July against the Austro-Hungarian front, which was broken through and almost shattered at Luck. In Aug. when the danger was at its greatest, the whole of the eastern front from the Gulf of Riga to Galicia was united under Hindenburg. He brought order where chaos had reigned. On the upper Sereth, at Brody and on the Styr a new rampart arose, which, however, proved tenable only where German troops stiffened their allies' resistance. Meanwhile the struggle for Verdun continued to rage, and the battle on the Somme reached its culminating point.

At Headquarters.—When in Aug. Rumania joined the Entente, the Marshal, who was now the national hero, was appointed chief of the general staff in place of Falkenhayn, while Gen. Ludendorff remained with him as quartermaster-general. The new German High Command found itself confronted with innumerable heavy tasks. While the campaign against Rumania had to be improvised, it was necessary to stand on the defensive in the West. The offensive against Verdun was abandoned, not without the French having gained numerous local successes towards the end of the year. Hindenburg expressed his final aim in the words: "We intend, not to hold out to the end, but to conquer." An intensive submarine campaign was carried out as a reply to England's hunger blockade.

In the East every nerve had to be strained to force Russia to make a separate peace, while in the West the defensive campaign continued. The end of 1917 found the Quadruple Alliance, despite the tremendous demands made upon their strength—nay, despite the fact that they were almost exhausted—considerably nearer to their objective. The U-boat warfare was slowly but surely producing its effect. The Italians had in a brief but powerful offensive been, not indeed annihilated, but decisively defeated. In the East the German hammerblows at Tarnopol, Riga and Ösel (Saaremma) had broken the fighting spirit of the new Russian ruler Kerensky, and carried the Bolsheviks into power. Peace was negotiated with them and with Rumania at Brest-Litovsk and Bucharest and, under military pressure, was finally attained in the winter of 1918. There remained the last and hardest task, the reckoning with France and England in the West, before America should be in a position to intervene as a military factor in the War on land.

In the spring of 1918 Hindenburg set himself to place the cornerstone upon the structure of his military achievements. All available effectives were utilised for this decisive conflict. The great offensive on both sides of St. Quentin was to break through the front line of the French and British on the southern flank of the latter, to roll them up towards the north and drive them towards the coast. From the tactical point of view the first blow in the direction of Amiens was a brilliant success. But it led to no practical advantage, and was supplemented by the attack upon the Lys front. But, here, too, the operations for a break-through miscarried, resulting only in a second massive concentration on the enemy front. Hindenburg, notwithstanding, clung to his resolve to deal the British a decisive blow in Flanders.

It was necessary, however, to effect a diversion in order to draw off the French reserves and to occupy them elsewhere. This led to loss of time, from which the enemy derived advantage. For the intervention of America loomed threateningly near. The first diversion at the Chemin des Dames gained considerable ground and drew in a large number of the French reserves, but not enough to pave the way for the decisive blow in Flanders. A new diverting attack on both sides of Rheims failed, whereupon Marshal Foch seized the initiative and from Villers Cotterêts attacked the German Marne position on the flank with strong forces. The Americans now appeared in the capacity of attacking troops. Hindenburg abandoned the Marne salient and held up the break-through on the Vesle. But from henceforth the initiative remained steadily in the hands of the French generalissimo, while the German reserves melted steadily away.

From a military standpoint the War was lost with the reverse of Aug. 8. Yet Hindenburg still hoped to cripple the fighting spirit of the enemy by a strategic defensive and to secure a peace compatible with the dignity of the German people. But Bulgaria's defection caused the complete collapse of the Macedonian front, and Hindenburg realised that an immediate armistice was necessary to give the army breathing space. With a just appreciation of their prospects of victory, the enemy took their time over granting an armistice, and summoning the full strength of their tremendous material superiority proceeded to force the German Army to throw in its last reserves. Meanwhile Turkey and Austria abandoned their rôles as allies of Germany, who found herself flung entirely upon her own resources in the final struggle. Hindenburg and Ludendorff wished to rouse the people to a final heroic effort of exertion; but the Cabinet of Prince Max of Baden lacked the capacity to check the revolution, and Germany was handed over unconditionally to the dictates of the enemy.

The marshal, victor in countless battles, had to return home, therefore, not as supreme war-lord but as a beaten general. Yet even in misfortune and profound humiliation his spirit remained unbroken, and he succeeded in extricating his country from the disorder of the revolution. On April 26 1925, the German people elected him President of the Reich.

Hindenburg stands out as the typical German, a personality of classic mould, unbroken by the tragedy of his life. He had a profound understanding of all human affairs, and he was thus enabled to pursue a steady line of conduct and to adhere to it during the appalling downfall of his country.

Ludendorff, *Meine Kriegserinnerungen 1914–8* (1919), trans. as *My War Memories 1914–8* (1919); P. von Hindenburg, *Aus meinem Leben* (1920), trans. by F. A. Holt, as *Out of My Life* (1920).

(W. F.)

HINDUISM (*see* 13.501).—In Hinduism we may discern four main elements: religion, race, country and social organisation. They may not be separated. They are inextricably interwoven.

The life of each is bound up and is an integral factor in the life of the others. It is a living whole forged by the organic stresses of history and a long past, from diverse sources from various materials and it is still a living vigorous whole.

Its diversity is appalling. Uniformity could not be expected as a feature of the religious experience of 232,000,000 people of different racial origins, of different history, of different environment, tradition and social structure. Yet there is a true Hindu polity: there are features common to North and South, to East and West. Much of it belongs obviously to the universal pattern for the agelong problems, whose presentations, at various times, in differing modes, constitute the stimulus to religious activity, are based ultimately on certain definite universal experiences and facts. Man is born of woman, grows and withers like the grass. Whence and whither and why? The debate of fate, foreknowledge, freewill follows inevitably certain lines, and the solutions to these problems conform to type because they are universal problems, wherever, as is markedly the case in India, thought has turned to the scrutiny and analysis of experience.

What of unity is there in all this? Where is it to be found? What is the factor or force that transcends this welter of diversity and binds it into a whole? Not community of origin, not community of speech. A clue may be found in the view that "Though Hinduism has no one creed, yet there are at least two doctrines held by nearly all who call themselves Hindus. One may be described as polytheistic pantheism . . . the second doctrine is commonly known as metempsychosis, the transmigration of souls or reincarnation, the last-named being the most correct." Here most certainly are elements which Hinduism shares with and derives from lowlier cults. From these very elements and beliefs, the social fabric draws its strength. The new-born child is no stranger, dropped from the skies: he is one of the community returning for a brief while to the world to which again and again he will come till liberation shall have been won. These beliefs we now know to be part and parcel of the socio-religious manifestations of many so-called savage tribes. They make for the stability of social structure. They validate morality. They have a survival value.

The Hindu does not admit that a belief in reincarnation expresses pessimism. By judicious and timely expenditure a sinner may escape hell, but he cannot escape a disadvantageous rebirth—a belief which establishes a closer and more vital and socially valuable connection between morality and religion, which he cannot discover in other types of religion. What gives perennial force to these beliefs is their practical relation with the structure and rules of Hindu society and their ethical value.

In another aspect this belief lays emphasis upon the continuity of life while recognising to the full that change is ceaseless. The continuity of the Universe, which to a materialistic world is enshrined in the scientific dogmas of the indestructibility of matter and the conservation of energy, is a real doctrine of perpetual validity and practical ethical import in Hinduism, which recognises a material law in the spiritual world, as well as a spiritual law in the material world.

The charge is brought that Hinduism exhibits both intellectual and moral extravagance, yet the value of truth and of progressive revelation in religion is rated high. The moral extravagance, as the West judges morals, which exists in Hinduism, is in large part the result of the intellectual extravagance whereby logic is exalted to perilous heights unchecked by reason.

Is it absurd to affirm that Deity cannot be fettered, must be free in all respects, may act when and where and as it will? If this be true of the Divine, then in like measure as some men are the vessels of divinity, so will they be set free from the trammels and conventions that bind the ordinary lesser man. Such at least would seem to be the argument. The consequences drawn from it justify the criticism that what may be true of the Divinity is in practical reason inapplicable to humanity.

The sense of mystery, the recognition of power, the apprehension of an order dimly seen but always felt, are there. Hinduism provides a mode of life as well as a religion, a guide to and an interpretation of the relations between man and man, between one group and another, between humanity and divinity. To regulate these relations, to secure safety for all, there are minute observances and ordinances which seem to be, but at deeper view are not, incongruous with the philosophic subtlety characteristic of Hinduism at its highest and best.

Hindu polity is aristocratic, not egalitarian. It recognises and utilises and explains the inequalities of individuals and of groups of individuals. It is based on a sense of duty and of reciprocal obligation permeating the whole society from the King to the peasant. *Dharma* is duty. In the caste system with its hierarchical gradations, its complex relations, its jealous endogamy, its fissiparous nature, it expresses an exclusiveness which at first sight seems to create a rigid barrier, but its process of proselytisation is by the absorption of whole communities, and that process is still active. The groups find a place, and some in course of time are known to have risen high by use of political and other circumstances. The highest height is still reserved for the Brahmin who, when a long view is taken of Indian history, has often proved himself worthy of the trust he has inherited.

Times are changing. The printing press is active. The schoolmaster is in the land. There is talk, loose talk, much talk of rights. Democracy and the ballot box constitute the court of final appeal. Ideas spread fast, faster than exact knowledge, and wisdom lingers. Yet appeals to the old ideals are heard and heeded by millions. Saintliness and character are recognised for what they are, great social forces. An emotional need awakened and created by the stirring political events of this period was satisfied by the worship of *Bande Mataram*, the symbolic identification of a religious entity with a racial and political ideal.

The old spirit lives and exerts its influence in countless ways. The development of industrialism in India has already made vast alterations in the mode of life of millions by changing the distribution of wealth and by augmenting the range of human and social ambitions. Those who but yesterday were poor and without honour, today are prosperous and seek for esteem and recognition. Hindu polity in the social order is based on the principle of "attaching more importance to the differences between social groups than to that which they have in common." Wealth is power and power is worshipful always. Wisdom, too, is power and still has its meed of respect, though perhaps not as fully as in the golden days, when great was the "influence exercised by Indian philosophers in every grade of society, from the highest to the lowest, solely by reason of their superior intellectual qualities and personal virtues."

Much has been, much yet remains to be, learnt by the serious student of religious and social problems from the vast array of Indian religious experience in which, daily, fresh contacts are established between Hinduism, Islam, Christianity and Primitive Culture. The diversity, polytheism, philosophic monotheism, practical henotheism, of Hinduism affect profoundly and intimately all it touches, and it assumes fresh forms and provokes change and reaction within the religious communities it touches. The census records display losses and gains and analyse them fairly. Within it the cement of philosophy which binds together the aboriginal beliefs, its prime material, is still strong as are the reforming movements like the Brahmo Samaj which, judged by numerical standards, is weak, even declining but is ever gaining fresh hold on the intelligentsia, especially of Bengal. The Arya Samaj in the Punjab has gained greatly in recent years. It has developed the practice of *Shuddhi:* (*a*) the conversion to Hinduism of persons belonging to foreign religions; (*b*) the reconversion of those who have recently or at a remote period adopted one of the foreign religions; and (*c*) reclamation of the so-called Depressed Classes. In conservative Southern India whence great movements have originated in the past, so much so that "it would be more correct to describe Indian religion as Dravidian religion stimulated and modified by the ideas of Aryan invaders," many forces are at work which are

destined surely to find expression in religious modes, perhaps as before, in a development of an emotional theism founded on the belief that "every man by his own efforts can come into immediate contact with the Great Being whom he worships."

Hinduism needs no apology. As Sir Charles Eliot has finely said: "If Hinduism were really bad, so many great thoughts, so many good men would not have grown up in its atmosphere. More than any other religion it is a quest of truth and not a creed . . . it is truly dynamic and in the past, whenever it has seemed in danger of withering, it has never failed to bud with new life and put forth new flowers. More than any other religion Hinduism appeals to the soul's immediate knowledge and experience of God. It has sacred books innumerable, but they agree in little but this, that the soul can come into contact and intimacy with its God, whatever name be given Him and even if He be superpersonal . . . the task of religion is . . . not to promote the welfare of tribes and states, but to effect the enlightenment and salvation of souls." Purified from within, Hinduism in its highest expression by which it, as any other religion, has a right to be judged, with its great vitality, its power of adaptation, its philosophic tradition, its insistence on the development of the powers that are latent in man and are in jeopardy of being atrophied by modern dependence on machinery, may yet serve humanity by correcting the stress laid by other schools of thought upon the material to the neglect of the spiritual.

BIBLIOGRAPHY.—The Census reports for 1911 and 1921 contain valuable data and critical examination of the statistical evidence collected. The Provincial reports are also full of matter. The publication of *The Tribes and Castes of Bombay*, 3 vol. (1920), completes a series of most important books so far as the main part of continental India is concerned. The religions of the Lower Culture are dealt with in the *Birhors*, by Sarat Chandra Roy (1925) and the monographs of the Assam and Burma Ethnographical Surveys.

Sir Charles Eliot's *Hinduism and Buddhism* (1921) is a fine presentment of facts based on personal knowledge and a critical investigation of the texts. Such works as *The Crown of Hinduism* by J. N. Farquhar (1913), *The Chamars* by G. W. Briggs (1920) and *The Village Gods of Southern India* (1921) by the Rt. Rev. Henry Whitehead, D.D., may also be consulted.

HINES, WALKER DOWNER (1870–), American lawyer, was born at Russelville, Ky., Feb. 2 1870. He was educated at Ogden College and the University of Virginia. From 1893 to 1904 he was with the Louisville and Nashville Railway in the legal department and, after 1901, as first vice-president. He practised law in Louisville, Ky., 1904–6 and in New York City 1906–16, becoming specially versed in questions of interstate commerce. In 1906 he became general counsel for the Atchison, Topeka and Santa Fé Railway, later becoming also chairman of the executive committee, and then chairman of the board of directors. In Feb. 1918, after the U.S. Govt. had assumed control of the railways as a war measure, he was appointed assistant director-general, and in Jan. of the following year director-general. He resigned in May 1920, and was designated by President Wilson as arbitrator in the distribution of German, Austrian and Hungarian inland shipping under the Peace Treaties. In Oct. 1921 he resumed the practice of the law in New York City. In 1925 he made an investigation and report of navigation on the Rhine and Danube for the League of Nations.

HIPPIUS, ZINAIDA (1869–), Russian poet and prose writer, was born Nov. 8 1869 at Belev, in the Tula province. She married Dmitry Mereshkovsky in 1889 and went to live in St. Petersburg (Leningrad). Later she went to live in Paris. Hippius was one of the leading poets of the Russian symbolist movement of the 'nineties and her poetry bears the usual character of the movement: the cult of beauty, mysticism and individualism. The influence of Nietzsche's philosophy is also apparent as in the famous line "I love myself as I love God" which became the slogan of the Russian "decadents." Her later poetry shows the influence of the neo-Christian theories of Mereshkovsky but at the same time reveals deep individual and emotional power. Her prose works were much inferior to her poetry, but under the pseudonym of "Anton Krainy" she was known as a trenchant literary critic.

HITCHCOCK, GEORGE (1850–1913), American painter (*see* 13.533), died on the island of Marken, Netherlands, Aug. 2 1913.

HITCHCOCK, GILBERT MONELL (1850–), American politician, was born at Omaha, Neb., Sept. 18 1850. He was educated at Omaha and Baden-Baden (Germany), and the law school of the University of Michigan. He was admitted to the bar in 1881 and practised law in Omaha for four years. In 1885 he founded the Omaha *Evening World*, and four years later bought the Omaha *Morning Herald*, combining the two papers into *The World-Herald*. He was representative in Congress 1903–5 and 1907–11. He was elected U.S. Senator for the terms 1911–7 and 1917–23. After the sinking of the "Lusitania" in 1915, he believed that action on the part of America should be limited to a demand for reparation. In 1917, however, he supported the resolution for a declaration of war against Germany, and in 1918 became chairman of the Senate committee on foreign relations. When the President submitted to the Senate the Treaty of Versailles, Senator Hitchcock led the administration forces by virtue of his office, giving strong support to the League of Nations.

HOBART, Tasmania (*see* 13.544), the capital of Tasmania, is the political and social, but not the commercial or trade centre, as it is reached from the north coast by a slow railway journey. Since electric power has been available from generating works at Great Lake, which began to give a large output in 1021, zinc works, a chocolate and sweet factory, and carbide manufacturing works, have been started near the town. A large number of summer visitors from the Australian mainland provide a livelihood for many inhabitants of Hobart, which had a population of 53,132 in 1921 (including suburbs), representing a quarter of the population of Tasmania. The magnificent sheltered harbour in the river Derwent, which is 2½ m. wide at Hobart, has some 2½ m. of wharfage, with depths of 45 to 65 ft. alongside the pier.

HOBHOUSE, LEONARD TRELAWNEY (1864–), British sociologist, was educated at Oxford; he became fellow of Merton College in 1887, and of Corpus Christi in 1890. Engaging at first in journalism, he served for five years on the staff of *The Manchester Guardian*. An active Liberal, he was secretary of the Free Trade Union in 1903–5 and published several political works, notably *The Labour Movement* (1893; 2nd ed., 1898) and *Democracy and Reaction* (1904), showing strong sympathy with collectivism, which he maintained to be not inconsistent with Liberalism. But in 1907 he was appointed Martin White professor of sociology in the University of London, and next year became editor of *The Sociological Review*. Thenceforth, except for a few war publications, he devoted his energies to writing and lecturing on ethical, psychological and sociological subjects. His principal works are *The Theory of Knowledge*, 3rd ed. (1921); *Mind in Evolution*, 2nd ed. (1915); *Morals in Evolution*, 2 vol., 3rd ed. (1915); *Development and Purpose* (1913); and *Principles of Sociology* in four separate sections (1918–24); the social application of ethical principles; in collaboration with G. C. Wheeler and M. Ginsberg, *The Material Culture and Social Institutions of the Simpler Peoples* (1915); and with J. L. Hammond, *Lord Hobhouse; a Memoir* (1905).

HOCKEY (*see* 13.554).—Since the World War, hockey has definitely established itself in Great Britain as a very popular game. During the years immediately before 1914 there was a steady increase in the number of clubs affiliating to the various county associations, and also in the number of teams put into the field. To-day there are about 1,000 clubs in England alone. In Ireland, the game more than held its own, but in Scotland and Wales there was little or no progress, due in some measure to lack of suitable grounds. In the services and at the universities, however, every year saw new adherents to the game, and since 1908 Cambridge has given a "full blue" for hockey. In 1910 the foreign countries in which hockey was played were France, Germany, Belgium, Denmark and the Netherlands. An annual match was instituted between England and France in 1907 and in 1913 Germany was also met. Turning to British dependencies, we find associations flourishing in Australia, New Zealand, South Africa and India.

The post-War period in Great Britain is noteworthy for the fact that the game is rapidly becoming more democratic. This is largely due to the initiative of the large banks, insurance companies and business houses in providing larger and better grounds for their employees. A newcomer to the ranks in the services is the Royal Air Force, which has some 30 affiliated stations. This arm of the services, together with the navy and the army, form the Combined Services Hockey Assn., which plays annual matches with one or other of the five divisions into which the English counties are grouped. The number of public schools playing hockey is now considerable.

The Game throughout the World.—It is, however, in foreign countries and, in a less degree, in the Dominions, that hockey has made a large stride forward since the World War. Taking Europe first of all, Spain, Austria, Switzerland and Czechoslovakia, have many flourishing clubs. The French have taken to the game with enthusiasm, and they hold inter-regional matches, corresponding to the divisional matches held in England. The Belgians are forging ahead and the Germans have a large number of players, Hamburg being the chief centre.

Turning to the Dominions, Australia and New Zealand are making headway. In South Africa, too, the game is increasing in popularity, with the result that in 1925 a South African Federation was formed. But so far as numbers are concerned, India is the biggest hockey country in the world. It is roughly computed that there are about 3,000 teams in India and recently an All-India Federation was formed to include the 24 provinces. The game in India is generally played all the year round; the natives are very fast and amongst them are many clever players. Japan is a newcomer to hockey and has formed an association to which some 50 clubs are affiliated. The Japanese Army and Navy have also included the game in their athletic curriculum and there are several service teams. In China a few of the more educated Chinese prefer hockey to association football, and it is extensively played in China by foreigners of various nationalities, principally in Hongkong, Shanghai, Pekin and Tientsin.

Frost and H. J. Cubberley, *Field Hockey and Soccer for Women* (1923); K. E. Lidderdale, *Hockey for Girls and Women* (1924); see also *The Hockey Annual*, and *The Hockey and Amateur Football Monthly* (London). (S. H. S.)

United States and Canada.—The game of Ice Hockey is native to Canada and was first played in an organised way in the cities of Kingston, Quebec and Montreal and before many years it was the acknowledged national winter game of the country. The game was introduced into the United States in the early 90's, when Canadian teams played in New York City and Baltimore. To-day it is a recognised winter sport throughout many of the northern states.

Although in Canada and the United States the game is very generally played on open-air rinks, all organised club or league hockey is played in covered rinks. Practically all the covered hockey rinks in the United States and a considerable number of those in Canada have artificially frozen ice surfaces, which give assurance of a good sheet of ice, no matter how the weather conditions may vary during the ice hockey season. In Canada and the United States, organised hockey is played under the jurisdiction of leagues or associations—the professionals, the amateurs, the colleges and the schools having their respective leagues or associations. The playing rules and the laws of the game are fundamentally the same in all leagues or associations. There is some variation in the rules pertaining to off-side play, penalty for fouls, and other minor points.

The principles of the game are quite simple. An ice hockey team is composed of six players, each one having a designated position. There are the goal guard, the right and left defence, and the three forwards—right-wing, left-wing and centre. A stated number of substitute or relief players are allowed each team—not more than six. The game requires steadiness and speed on the skates, dexterity and agility, the capacity to think and act quickly, and physical fitness. The hockey stick is made of elm wood, except for some of the lower grades that may be made from ash. It is with the stick alone that the player manipulates the object called the puck, which is a disc made of rubber, one inch thick and three inches in diameter. The objective point in the game is to score by driving, pushing or sliding the puck through the opponents' goal. Present-day rinks are laid out to give an ice surface of anywhere from 180 to 210 ft. long by 80 to 85 ft. wide. A goal post with nets attached is fixed at each end of the ice surface about 10 to 15 ft. from the end board. The goals are four feet high and six feet wide. (T. Ho.)

HODGES, FRANK (1887–), British politician, was born at Woolaston, Gloucestershire. At the age of 14 he entered the Vivian Colliery at Abertillery, S. Wales. His fellow miners provided him with a scholarship to Ruskin College, Oxford, in 1909, and he later went to France. Returning to the mines, he also conducted classes in economics and French. In 1912 he became a miners' agent and six years later secretary of the Miners' Federation of Great Britain. In 1921 he was made joint secretary of the National Wages Board. Elected to Parliament in 1923 as member for Lichfield, he resigned his post as Secretary of the Miners' Federation. He became a Civil Lord of the Admiralty in the Labour Ministry of 1924. He lost his seat at the election of that year; and in 1925 was made General Secretary of the International Miners' Federation. He is the author of *My Adventures as a Labour Leader* (1925).

HODGKIN, THOMAS (1831–1913), British historian (*see* 13.557), died at Falmouth March 2 1913.

HODLER, FERDINAND (1853–1918), Swiss painter, was born at Gurzelen in the canton of Berne March 14 1853. He received his early education in drawing from a Swiss landscape painter at Thun, but his artistic career began at Geneva in 1872, where he worked under Barthelémy Menn, at the same time studying at the university. In 1874 he won the Calame prize for a landscape. After various journeys, notably in Spain, which explains the Spanish influence in much of his earlier work, he settled down in Geneva where, with a few intervals, he remained until his death. Among his most important pictures are the "Cortège des Lutteurs" (1887), "La Nuit" (1891), "L'Elu" (1894), "Eurythmie" (1895), "L'Émotion," "La Vérité" (1905), "Le Jour," "L'Amour" (1908). He also painted humorous portraits and landscapes, together with many water colours and lithographs. He received many commissions for decorations from official bodies, notably the large-scale decoration on the wall of the Hall of Arms in the National Museum of Zürich called "La retraite de Marignan" (1900). In 1907 he was entrusted with the decoration of the University of Jena, and in 1911 he painted his "Unanimité" for the town hall at Hanover. He died at Geneva May 19 1918.

HÖFFDING, HARALD (1843–), Danish philosopher (*see* 13.561), resigned his professorship at the University of Copenhagen in 1915. Among his later works are: *Moderne Filosoffer* (1904, English version 1915); *Spinoza's Ethica* (1906, etc.); *Henri Bergson's Filosofi* (1914, English version 1915); *Den store Humor* (1916, English version 1924); *Totalitet som Kategori* (1917); *Oplevelse og Tydning* (1918); *Ledende Tanker i det 19de Aarhundrede* (1920); *Relation som Kategori* (1921).

HOFFMAN, MALVINA (1887–), American sculptor, was born in New York City June 13 1887. She studied sculpture in New York with Herbert Adams and Gutzon Borglum, and in Paris with Auguste Rodin. After obtaining recognition in Paris, where she was awarded a first prize at the Salon in 1911 for "Russian Dancers," she settled in New York. Her memorial group, "The Sacrifice," presented to Harvard University by Mrs. Robert Bacon, but placed temporarily in the Cathedral of St. John the Divine, New York City, is considered the finest of her works. Three portraits by her of Paderewski, when exhibited in New York in 1920, attracted great admiration. Other works of hers are "John Muir" in the American Museum of Natural History, New York City; "Modern Crusader" in the Metropolitan Museum of Art, New York City; "Bacchanale Russe" in the Luxembourg Musé, Paris, and "Gervase Elwes" in Queen's Hall, London. One of her latest commissions was a

heroic size stone group over the entrance of Bush House, Strand, London. Miss Hoffman was married to Mr. S. B. Grimson June 6 1924 in New York City.

HOFMANNSTHAL, HUGO VON (1874–), Austrian poet, was born in Vienna Feb. 1 1874. He took the degree of Ph.D. at the University of Vienna and when still a schoolboy originated the Romantic School in Austria by his lyric and semi-dramatic poetry, which aroused much controversy at the time. He was not uninfluenced by Stefan George's example and Hermann Bahr's criticism, but the melody and colour of his language, and the art with which he gave poetic expression to complicated spiritual moods, in particular, were entirely new. A genius for appreciating bygone cultures and a sensitive understanding of the beautiful in art and in nature, characterised both the youth and the man. Hofmannsthal is little indebted to contemporary realism, but his almost too susceptible personality is tinged by innumerable literary influences from the Attic tragedians down to Victor Hugo, Swinburne, Browning and D'Annunzio. This lack of originality is especially noticeable in his dramatic poems, not a few of which are simply old plays of Sophocles, for example, of Calderon, Molière and Otway cloaked in modern form and spirit. Nevertheless he has an abiding place in the history of literature as founder of the whole German neo-romantic drama. A few of his dramas became known outside Austria through the music of his friend Richard Strauss, others through Reinhardt's Festival at Salzburg. His collected poems appeared in 1911. In later years he turned his attention to society comedy. The most characteristic of his dramas are: *Gestern* (1892); *Der Abenteurer und die Sängerin* (1899); *Der Tor und der Tod* (1900); *Der Tod des Tizian* (1901); *Oedipus und die Sphinx* (1906); *Cristinas Heimkehr* (1922); *Das Salzburger grosse Welttheatre* (1922); and his libretti: *Elektra* (1903) and *Der Rosenkavalier* (1911). See monograph by Sulger-Gebing (1905).

HOGG, SIR DOUGLAS McGAREL (1872–), British lawyer and politician, was born Feb. 28 1872, the son of Quintin Hogg, founder of the Polytechnic, London. He was originally intended for a business career, and on leaving Eton spent eight years with his father's firm of West India merchants. After serving in the South African War (1899–1902), on his return to England he abandoned commerce for the law. Called to the bar in 1902 he forthwith took a leading position as a junior, and when he became K.C. in 1917, immediately came to the front. His deadly power of cross-examination, easy mastery of facts and figures and persuasive speech made him formidable in every kind of case.

In 1922, on entering Parliament as Conservative Member for Marylebone, he became Attorney General and a Privy Councillor in Mr. Bonar Law's Government, receiving the usual knighthood given to a law officer. In opposition, or in office he showed himself a powerful debater, his vigorous speech on the Campbell prosecution (*see* ENGLISH HISTORY) had not a little to do with the defeat of Mr. Mac Donald's Labour Government. When the Conservatives returned to power in 1924, Sir Douglas Hogg was reappointed Attorney General, with a seat in the Cabinet.

(R. S–D.)

HOLLAND, HENRY SCOTT (1847–1918), English divine, was born at Ledbury, Hereford, Jan. 27 1847. He was educated at Eton and Balliol College, Oxford; in 1872 he was ordained, becoming the same year a tutor at Christ Church. In 1882 he was senior proctor of the university, and the same year was made a canon of Truro and examining chaplain to its bishop. He was appointed a canon of St. Paul's in 1884, and in 1886 precentor. He refused the offer of the see of Norwich in 1893, but in 1910 was appointed regius professor of divinity at Oxford. He died at Oxford March 17 1918. Scott Holland was closely associated with the Christian Social Union for many years. He was a successful tutor and a popular professor; but it is as a preacher that he is most vividly remembered. In 1905 his *Personal Studies*, which first appeared in *The Commonwealth*, were published in book form. He also wrote a notable essay on *Faith*, several volumes of sermons and a life of the singer, Jenny Lind. See *Life*, by Stephen Paget (1921).

HOLLAND, JOHN PHILIP (1841–1914), American inventor, was born at Liscannor, County Clare, Ireland, in 1841. He was educated at Limerick, and was a school teacher in Ireland prior to migrating to the United States. He was teaching in New Jersey when the Civil War broke out and the conflict between the "Merrimac" and the "Monitor" suggested to him the idea of a submarine. He became a pioneer in this field and one of the most successful designers of submarine craft. The first boat, built in 1875, was a failure and it was not until his ninth attempt in 1898 that he produced a serviceable submarine from the practical standpoint. This boat was commissioned for the U.S. Navy and orders for others were placed with Holland. His great achievement was the furnishing of the submarine with two methods of propulsion, a 50 H.P. gasolene engine to be used when on the surface and electric storage batteries when submerged. The British Admiralty acquired all the patents for Great Britain, although his avowed purpose had been to invent a craft that would overcome the British naval supremacy. Holland then turned his attention to the construction of submarines for sea-going purposes, constantly improving upon his original model, and all his subsequent boats were built for the U.S. Navy, the types tending constantly to become larger. He died at Newark, N.J., Aug. 12 1914.

HOLLAND: *see* DUTCH LITERATURE; NETHERLANDS.

HOLLYWOOD, Cal., U.S.A., the principal seat of the motion-picture industry, was annexed to Los Angeles (*q.v.*) in 1910.

HOLMES, OLIVER WENDELL (1841–), American jurist, was born at Boston March 8 1841, the son of Oliver Wendell Holmes, the poet and essayist (*see* 13.616). He graduated from Harvard in 1861. On the outbreak of the Civil War in that year he enlisted and served three years in the 20th Mass. Volunteers, rising to the rank of lieutenant-colonel. He was wounded three times—at Ball's Bluff, Antietam and Fredericksburg. He concluded his military career as aide-de-camp on the staff of the 6th Div., retiring in July 1864. In that year he commenced the study of law at Harvard, obtaining his LL.B. in 1866, and was admitted to the Suffolk (Mass.) bar March 4 1867. He practised law in Boston, and in 1870 was appointed instructor in constitutional law at Harvard, at the same time becoming editor of *The American Law Review*, which latter position he held for three years. In 1871–2 he was university lecturer in jurisprudence. In 1873 he edited the 12th edition of Kent's *Commentaries*, since recognised as the standard edition. In the same year he became a member of the firm of Shattuck, Holmes & Munroe and engaged in an active practice.

In 1880 Holmes was appointed lecturer on common law at the Lowell Institute. His articles in *The American Law Review* contained the germs of the lectures which he delivered before the institute, and these in turn, in an amplified form, were published in 1881 under the title *The Common Law*. The object of the work was to present a general view of the common law, and this was done with a wealth of illustration, a charm of language and a clarity of reasoning which, apart from the erudition displayed, gave Mr. Holmes an international reputation. In 1882 he was appointed professor of law at the Harvard Law School, but resigned to accept an appointment on Dec. 8 of the same year as associate justice of the Supreme Judicial Court of Massachusetts. This position he occupied for 17 years, becoming Chief Justice on Aug. 2 1899. On Dec. 4 1902 he became an associate justice of the Supreme Court of the United States. As a judge his opinions are conspicuous for their literary style and epigrammatic force. In 1924 he was awarded the Roosevelt Memorial Association Medal for the development of public law. In addition to the works already mentioned he published in 1891 a small volume of *Speeches*, re-issued with additions in 1913 and *Collected Legal Papers* (1920).

HOLROYD, SIR CHARLES (1861–1917), British painter-etcher (*see* 13.618), died at Weybridge, Surrey, Nov. 17 1917. He arranged for the transference of a large portion of the Turner bequest to the Tate Gallery, London.

HOLTZMANN, HEINRICH JULIUS (1832–1910), German theologian (*see* 13.620), died at Baden-Baden Germany Aug. 6 1910.

HONDURAS (*see* 13.649).—A republic of Central America and an original member of the League of Nations. On Nov. 15 1922 Honduras notified the League of its intention to withdraw because of the onerous annual contribution. The area is estimated at 36,000 square miles. The population in 1914 was estimated at 562,000; official figures gave the population in 1923 as 773,408. The capital, Tegucigalpa, had an estimated population in 1923 of 40,000; the population of La Esperanza was 11,453; and that of Santa Rosa 10,574. The inhabitants are mostly Indians and mixed races: there are a few Spaniards and a large proportion of negroes. Honduras broke off diplomatic relations with Germany on May 17 1917, and on July 19 1918 war was formally declared. The constitution of Honduras was remodelled and proclaimed in a new charter on Oct. 3 1924, which gave the legislative power to a congress of 43 deputies in the ratio of one member for every 15,000 inhabitants.

I. POLITICAL HISTORY

In 1910 Miguel R. Dávila (the creature of President Zelaya of Nicaragua), who was elected president of Honduras for four years in 1906, was eliminated in a rapid campaign by Manuel Bonilla, the former president. Dr. Francisco Bertrand, who had been chosen provisional president at a peace conference brought about by the United States, served as vice-president until the death of Bonilla in 1913, when he succeeded to the presidency and was elected to a second term of office in 1915. In the campaign of 1919 a Liberal revolt forced Bertrand to resign office and flee the country. Gen. López Gutierrez, who led the revolt, caused himself to be declared dictator, and was elected president in October.

An attempt to overthrow the President was made by revolutionists from Nicaragua in Aug. 1922; and when, in May 1923, war material of the 1922 movement was discovered near the boundary, new civil disturbances were foreseen. By June many of the citizens had been driven into exile by the warring factions. Further violence marked the presidential campaign in Oct. when Gen. Tiburcio Carias, a Conservative, was opposed to two Liberal candidates. The returns of the election indicated that Carias was the popular choice, although he was a confirmed revolutionist and opposed by the Government. Early in 1924 conflicts between the three presidential candidates, Dr. Arias, Dr. Bonilla and General Carias, caused American casualties, and marines were sent to the Nicaraguan boundary and to Tegucigalpa. In April 1924 Mr. Sumner Welles was sent by President Coolidge to arrange a conference between the contestants and the neighbouring republics at Amapala. The conference was successful, and Gen. Vicente Tosta was elected president with the moral support of the United States, superseding Gen. Fausto Dávila, the provisional president.

At the beginning of July, as no arrangement could be made regarding the future president, serious disaffection was manifested and political disturbances again broke out. Both the political leaders and the revolutionists accepted Dr. José María Caseo and Ramón Alcero Vastro as president and vice-president respectively. The election at which a successor to provisional president Tosta was to be chosen was postponed from Nov. 25 to Dec. 28–30. The elections were held on the postponed date without any disorder, and Dr. Miguel Paz Baraona was elected president, with Presentación Quesada as vice-president. The new president was inaugurated on Feb. 1 1925. In March diplomatic relations with the United States, which had been severed in Feb. 1924 were resumed. In 1925 political disturbances were recurrent: Tegucigalpa was held in a state of siege in May by revolutionists, and in the west Gen. Gregorio Terrera had been actively in rebellion since February. Nicaraguan and Honduran officials prevented revolutionists from Nicaragua entering the country. Martial law prevailed. In Aug. General Tosta, as Minister of War and Marine, announced at Tegucigalpa that peace had once more been restored. Honduras ratified the first three of the Washington conventions of 1922–3, and the 13th, providing for international commissions of inquiry (*see* CENTRAL AMERICAN UNION). In Aug. 1925 eight of the agreements were awaiting the final approval of the republic.

Defence.—Military service is compulsory for all citizens of Honduras on attaining the age of 21. Under the convention signed at Washington on Feb. 7 1923 the standing army of the republic was limited to 2,500. A congressional decree of April 9 1923 fixed the strength of the regular army at 3,036 of all ranks.

Education.—Primary education, which is secular, is free and compulsory from seven to 15 years of age. The number of children who do not receive instruction is high, estimated at 57%. Of 79,199 children of school age in 1922 it was estimated that 32,976 attended school. In 1922 there were 850 public schools with 1,127 teachers. There were five public secondary schools and four training colleges. The National University at Tegucigalpa was staffed in 1922 with 36 professors and attended by 107 students. Military and aviation schools have been established at the capital, and a school of jurisprudence at Comayagua. The Government offers two exchange scholarships with the United States. Expenditure on education in 1919 was 384,980 pesos.

II. FINANCIAL AND ECONOMIC HISTORY

Finance.—The budget of 1923–4 was adopted by Congress as the budget for 1924–5 owing to political disturbances in 1924. Revenue and expenditure were estimated to balance at 9,204,244 silver pesos; the budget for 1925–6 was estimated at 10,832,439 pesos. The fiscal years 1914–5 to 1920–1 showed a deficit; surpluses occurred in the years 1921–2 to 1924–5. Recent political warfare has, however, eliminated all surpluses. Military expenditure was the largest item in the budget, constituting in the fiscal year 1920–1 45% of all government expenditure. The foreign debt, as reported by the Corporation of Foreign Bondholders, amounted in Oct. 1924 to £29,114,775. The contract for the adjustment of the external debt was approved by the Council of Bondholders and forwarded to the National Congress for sanction. This ratification had not been given by Feb. 1926. The basis of the arrangement took the sum of £452,000 as the representative value of the external debt incurred in the wars of 1867, 1869 and 1870, and interest on this sum at 8·86% was allowed for the period of the new agreement. The total payment was to consist of £1,200,000 in semi-annual instalments of £20,000 for 30 years.

Production and Industry.—Business prosperity was depressed in 1923 and 1924 by wars. In the early part of 1925 complete stagnation followed bad political conditions, banditry on the frontiers and floods in the fruit districts. The principal culture is that of bananas and coconuts. In 1920 the export of bananas was 11,524,149 bunches; in 1923 the exports were 12,520,495. Coconuts dropped from 12,647,508 in 1920 to 8,360,720 in 1922. The 1924 sugar production in the Puerto Cortes district, 30,532,950 lb., was twice that of 1923 and four times that of 1922. The prospect was that the 1925 production would show a further increase. Silver production increased in 1924, when more than 2,000,000 oz. were produced. Bananas rank first in order of importance amongst the exports, and next in order are sugar, silver, coconuts, hides, cattle, gold. Imports, in order of importance, are manufactured products, foodstuffs, raw materials and lumber. The United States has 90% of the trade. The chief figures for trade totals of three years were:—

	1924	1925
All countries		
Imports	11,137,917	12,752,761
Exports	7,897,046	11,983,051
United Kingdom		
Imports	401,218	295,921
Exports	658,320	203,888
Germany		
Imports	198,792	308,197
Exports	10,485	28,170
United States		
Imports	9,783,811	10,252,257
Exports	7,186,045	11,072,463

Communications.—The national railway of 66 m., which was taken over by the Government in 1912, was in 1920 placed in the

ontrol of the Compañía Agrícola, which in 1924 was reconstituted as the Cortes Development Company. The line has been overhauled to meet the demands for transporting the banana crops. Four other railroads are owned by fruit companies. In 1924 the mileage of the railways was 934. Telegraph lines in 1922 totalled 4,662 and telephone lines 873 miles.

Elliott, *Central America* (1924); W. S. Robertson, *History of the Latin-American Nations* (1925). See also Department of Overseas Trade, *Reports on the Economic and Financial Conditions in Honduras.* (H. I. P.)

HONDURAS, BRITISH (*see* 4.615).—A British Crown colony in Central America. Its area is 8,598 sq. m. and the estimated population (1923) is 45,527; the birth rate was 37·91 per 1,000 and the death rate 20·50. Belize, the chief town, had a population in 1921 of 12,661. In 1923 there were 65 primary schools with 3,774 pupils on the registers. The Government expenditure on public education in 1923 was £10,615. There were five private schools conducted by religious institutions, with 499 pupils.

Finance and Commerce.—The chief sources of revenue were customs duties, excise and land tax and the sale and letting of Crown lands. Revenue and expenditure for the four years 1921–4 were:—

	1920–1	1921–2	1922–3	1923–4
Revenue . .	£232,496	£227,409	£234,059	£224,928
Expenditure .	191,114	290,284	226,114	247,576

Customs duties levied on the majority of imports were, in 1923–4, £115,969; preferential treatment is accorded to goods of British origin, 10% *ad valorem* being accorded to manufactured goods.

Forestry products are the chief source of the colony's wealth, but agriculture has tended to engage the population. The forest area was estimated at 4,000,000 ac., or nearly one-half of the entire area; and 9,967,186 superficial ft. of mahogany were exported in 1923, as well as 663,437 superficial ft. of cedar wood. Primitive methods of cultivation employed have prevented the development of banana cultivation: in 1923, 332,500 bunches of bananas were exported, and 5,964,706 coconuts. The chief imports were, in order of importance, clothing and articles of apparel, foodstuffs, cotton goods, hardware and machinery. The balance of trade was adverse during the years 1922–4. The total trade figures were:—

	1921–2	1922–3	1923–4
Imports	£688,000	£692,716	£830,594
Exports	627,000	593,178	657,794

In 1922, 71% of the export trade was with the United States and 19·38% with Great Britain.

The United States gold dollar is the monetary unit, and British and United States gold coin are legal tender. In 1912 banking business was taken over by the Royal Bank of Canada. Deposits in the six Government savings banks were in March 1924 $164,236.

See A. B. Dillon, *Geography of British Honduras* (1923); *Colonial Office Reports*, annual series, London.

HONGKONG or HIANG-KIANG (*see* 13.657) is an island off the southeast coast of China, 11 m. long and from 2 to 5 m. broad. It is a British Crown Colony and was ceded to Great Britain by the Chinese Govt. in 1841. The total population of Hongkong and the leased territory of Kowloon was estimated (1923) 681,000, of whom the majority are Chinese British subjects. At the Washington Conference the Chinese delegates asked (Dec. 3. 1921) for the surrender of all the leases of Chinese territory, including Kowloon, to foreign Powers, but Mr. (Lord) Balfour declared that Great Britain could not contemplate the surrender of Kowloon, as without it Hongkong would be strategically untenable. He also pointed out that Hongkong ranks "easily first among the ports of the world," was a free port and therefore that its preservation was not only a British but a world interest.

Shipping and Trade.—The total shipping entering and clearing at Hongkong in 1924 was 764,492 vessels of 56,731,077 tons; barely more than one-third of the tonnage of ocean going ships was British. Hongkong's annual turnover of trade aggregates nearly 150 million sterling a year. Her import of opium remains important, amounting in 1923 to 550 chests uncertificated Indian opium and 216 chests Persian opium. The Persian opium went to Formosa; of the Indian opium 200 chests were for the Macao opium farmers and 186 for the Government monopoly. The total imports of all goods in 1924 (including bullion) were valued at £75,155,000, of which 13·1% came from the United Kingdom; the total exports at £63,675,000 of which only 1·2% were consigned to the United Kingdom. There are no duties upon imports and exports except on liquors and tobacco and a light due on shipping of 2 cents per ton for each call. Hongkong itself produces little and is principally a port of trans-shipment for goods. Some of her chief exports are rice, tin, tea, tobacco, etc.

Revenue and Expenditure.—The budgets for the three years 1924–6 are as follows:—

	Revenue Hongkong dollars	Expenditure Hongkong dollars
1924	24,209,638	26,726,426
1925 (revised estimate) .	22,279,855	30,032,127
1926 (estimate) . . .	23,790,615	21,367,743

In spite of apparent deficits the Colony's credit balance was expected to be over $5,000,000 at the end of 1925 and about $2,500,000 at the end of 1926 as the Government, in view of large balances in the Treasury from previous years deliberately budgeted for deficits.

Industries.—The four leading industries are shipbuilding, rope-making and the manufacture of sugar and cement. Other industries are glass blowing, soapmaking and toy manufacture, etc. In 1921 Hongkong's shipbuilding yards launched more vessels than the rest of the British Empire, outside the United Kingdom, together.

The Boycott of 1925.—For 80 years Hongkong progressed in mutually advantageous trade relationships with Amoy, Foochow and Canton and Swatow in South China, but in June 1925, an anti-foreign boycott began in China which interrupted commercial intercourse. The circumstances leading to this boycott were mainly the discontent of "young China" with foreigners' extra-territorial rights and with foreign concessions, and the impotence of the Central Government in Peking to enforce its own mandates. At the beginning this anti-foreign feeling was mainly directed against Japan and led to various strikes in Japanese cotton mills in Shanghai in the early part of 1925. On May 30 1925 the famous "Shanghai incident" occurred when a meeting was held by Chinese students to protest against the action of Japanese mill-owners who a fortnight before had fired in self-defence on Chinese strikers. Ordered to disperse the students resisted and attacked the police station. The police fired on the mob, killing four outright and wounding several, five fatally. This incident was the signal for a violent anti-foreign outbreak. As British interests predominate in China British firms were the main objects of attack by means of a commercial boycott and Hongkong, as the exemplification of the British Empire, was an obvious target.

The first serious manifestation was the withdrawal of ships' crews on June 19, followed by a general exodus of workers. Regulations were promulgated by the "All China General Labour Union" and the "Canton-Hongkong Strike Committee," the main points of which *vis-a-vis* Hongkong were that goods exported from or imported to Kwangtung should not pass through Hongkong and that foreign vessels passing through Hongkong should not discharge cargo in Kwangtung. In consequence of this boycott serious damage has been done to Hong-

kong's trade. The policy adopted by the British Govt. has been that of patience, *i.e.*, allowing the Chinese merchants to discover for themselves that Hongkong is not the only sufferer by the suspension of trade relations. (*See* CHINA.)

BIBLIOGRAPHY.—Hongkong General Chamber of Commerce *Report* for 1925; *The Directory and Chronicle of China, Japan, etc.* (1926), *China Year Book* (1925).

HOOKWORM (*see* 2.58), parasitism caused by the hookworms *Necator americanus*, *Ankylostoma duodenale*, and, more rarely, *Ankylostoma braziliense*, which inhabit a relatively small portion of man's small intestine. A single healthy female hookworm passes daily several hundred eggs which leave man in his excrement. Under favourable conditions, such as its deposit on suitable soil, larvae form therein, hatch, develop to an infective stage, and enter the soil. Infection ordinarily occurs through the piercing by infective larvae of the skin, commonly of one who walks barefoot over infected soil. Carried by the circulation from the skin to the lungs, larvae reach the air passages and, like all foreign bodies, are driven up these to the throat, are swallowed, and so finally reach the small intestine. Man's normal mechanisms are thus subverted to the hookworm's use.

The treatment of ankylostome infestation involves, firstly, disinfestation by a vermifuge or anthelmintic, and, secondly, neutralisation of ill effects consequent on infection. To increase their concentration in the bowel, and presumably their efficacy, anthelmintics have customarily been preceded by purging and fasting. Accumulating evidence however suggests that purging lessens effectiveness. Starvation, beyond the ordinary nightly fast, increases, for some drugs, risk of poisoning the host. Anthelmintics are best given in the early morning. The ideal vermifuge, with a dosage which poisons all hookworms without endangering the host, is non-existent. The dosage employed for any drug should give the greatest efficiency compatible with safety, and may be termed the optimum dose. Attainment of increased safety is attempted by dividing the optimum dose into fractions, usually 3 or 4, given with intervals of one or two hours, by which means treatment can be stopped at any stage should ill effects appear, while efficacy is apparently increased; nevertheless supervising costs of mass treatment are thereby increased. Subsequent removal of the drug by purgation lessens risk of poisoning.

The many millions of persons infected throughout the tropics necessitates mass treatment, the essentials of which, namely safety, efficacy, cheapness, and palatability are varyingly combined in the five anthelmintics in present or recent use. These are eucalyptus-chloroform, betanaphthol, thymol, oil of chenopodium, and carbon tetrachloride. By some they have been administered promiscuously to whole communities in which examination of a few individuals has shown a high rate of infection.

Eucalyptus-chloroform has been almost completely abandoned as inefficient. Pure betanaphthol, in optimum dosage of two grammes, is inefficient; in larger doses it has caused deaths in India and Brazil. Thymol and oil of chenopodium, in their respective optimum doses of 4 grammes and 1·2 cubic-centimetres or mils (the latter dose equalling 48 drops or 20 minims) have for *N. americanus* equal efficiency and minimal risk; contrary statements emanate from the use of oil of chenopodium in excessive dosage of 3 mils, due apparently to considering a drop of this liquid as equivalent to a minim. For *A. duodenale* chenopodium appears the better drug, and is, in London, the cheaper. Its active principle is ascaridol. Unfortunately the oil contains markedly varying quantities of this substance, and its amount lessens on keeping. Ascaridol, extracted and administered in place of the whole oil, is effective but relatively costly. Carbon tetrachloride, recently introduced, has been taken by many thousands of persons in dosage of three mils, and has proved most efficient. The medicinally pure drug produces in large doses, in dogs, extensive fatty degeneration, followed by necrosis of the liver, and, apparently, of the kidneys; changes aggravated by starvation and fatty food, and lessened by glucose. Extensive similar change has been present in man when death has followed the 3-mil dose. A number of such deaths are now recorded. Clearly this dose requires reduction, so that the efficacy of carbon tetrachloride under optimum dosage has still to be ascertained. It is the cheapest of all advocated treatments. A combination of this drug with ascaridol is being tested.

Hygienically viewed, treatment of whole unsanitated communities lessens the risk of further infections; since destruction of female worms diminishes the seeding of egg-containing material upon the soil, and, on the whole, the number of infective larvae originating therefrom. Nevertheless, an imperfectly treated, and still lightly infected, person, seeding a favourable spot, is a danger to the community.

Individually viewed, disinfestation, by treatment, of the obviously ill and presumably heavily infected, restores health if always provided damaged tissues be still repairable. In the case of apparently healthy, but infected, persons, comparison of their condition of general health, wage-earning capacity, blood state and, in children, development of body and mind, before and again a sufficient period after, disinfestation shows that they are often markedly improved by disinfestation; so that a light infection definitely handicaps the apparently healthy. Whether the lightest infections do, or may, penalise the individual is questioned. If, as now appears likely, we can detect infection by a single female worm, treatment producing complete disinfestation of such cases, combined with critical observation of conditions before and after effecting this, will doubtless shortly settle this point, so vital to the individual and community.

Iron and arsenic, ineffective before, may be essential for combating anaemia after disinfestation. Treatment of skin lesions at the site of infection varies with the condition present. (*See* PARASITOLOGY; TROPICAL MEDICINE.)

(C. LA.)

HOOKER, SIR JOSEPH DALTON (1817–1911), British botanist (*see* 13.671), died at Sunningdale, Berks., Dec. 10 1911.

HOOPER, HORACE EVERETT (1859–1922), publisher of *The Encyclopædia Britannica*, was born in Worcester, Mass. Dec. 8 1859. He was of English descent, his father's family having settled in New England about 1650, while his mother was a descendant of John Leverett, Governor of Massachusetts 1672–9. Having been educated in the public schools of Worcester and of Washington, D.C., he started in business in early life at Denver, Colo., but a few years later removed to Chicago where with others, he organised the Western Book & Stationery Company, with book stores in a number of the large western cities. In 1895 he moved to New York and joined a company for the sale of *The Century Dictionary*, and his success in this enterprise led to wider fields. In 1897 he went to London and arranged with A. & C. Black, publishers of *The Encyclopædia Britannica*, for a reprint of the 9th Edition of that work, and with *The Times* for its sale through that paper. Later he purchased the copyright. By reducing the price and by providing for payments in small monthly instalments the sale of the work was revolutionised, 70,000 sets being sold in the next five years.

The success of this enterprise led Mr. Hooper to have prepared, in 1902, a large supplement in 11 volumes (under the editorship of Sir Donald Mackenzie Wallace, President Arthur T. Hadley of Yale, and Mr. Hugh Chisholm) which, added to the volumes of the 9th Edition, formed the 10th Edition. For this also there was a large sale. His next enterprise was *The Historians' History of the World*, 1904, a work in 25 volumes. Meanwhile Mr. Hooper's relation with *The Times* grew more close. He took an intimate part in the business management, and it was at his suggestion and under his personal direction that *The Times Book Club* was formed. In 1908 when the proprietorship of *The*

imes passed into the late Lord Northcliffe's hands, Mr. Hoop-'s connection with that paper came to an end.

In 1903 Mr. Hooper entered upon a larger enterprise than any t attempted, the preparation of an entirely new edition, the th, of *The Encyclopædia Britannica*, under the editorship of r. Hugh Chisholm. This was published in the closing months 1910 and the first of 1911 under an arrangement with the unbridge University Press. Hitherto all large works of refer-ce had been issued volume by volume over a period of years. y his energy and the liberal expenditure of money, Mr. Hooper ranged that the 11th Edition of *The Encyclopædia Britannica* ould all be published at the same time, thus greatly enhancing e usefulness of the work. Of this edition 75,000 sets were sold the next few years, the use of India paper being one factor in success. In 1915 Mr. Hooper published the work in a smaller d cheaper form known as the Handy Volume Issue, the con-nts being identical with the original issue. In this form nearly 0,000 sets were sold within a few years. The last enterprise in ich Mr. Hooper was engaged was the publication in 1922 of e Three War Volumes of *The Encyclopædia Britannica*, which pplemented the 11th Edition, and with the 29 volumes of that ition constituted the 12th Edition.

Mr. Hooper's success in publishing and distributing so widely e important works mentioned above lay partly in the original-y, boldness and brilliance of his operations, but chiefly in his ith in the intelligence and ambition of the great masses of the ople. He believed in the educational value of good books, and at the people would order such books and use them if the atter were properly placed before them. The ideals he set fore himself were the maintenance in *The Encyclopædia Bri-nnica* of the highest standard of scholarship and the placing of e work as an educational aid in the greatest number of homes. any professional educationalists of note have done less than he ward popular enlightenment. For a number of years Mr. ooper lived in England. He was a strong believer in the unity the English-speaking peoples, and exerted his influence toward e removal of causes of friction between England and America d the establishment of cordial feeling and a mutual under-anding. He died at Bedford Hills, N.Y., June 13 1922.

HOOVER, HERBERT CLARK (1874–), American engineer d public official, was born of Quaker parentage on a farm at est Branch, Ia., Aug. 10 1874. After the death of his father 1878 and of his mother three years later, he was brought up in e farm homes of Quaker relatives in Iowa and Oregon. At the e of 13, while attending night school at Salem, Ore., he began earn his own living, working in truck gardens and as an office y. When Leland Stanford, Jr. University was opened in 1891 entered with the first class and specialised in engineering. raduating in 1895, he worked for a time with the U.S. Geo-gical Survey, in California mines, and as a junior engineer in alifornia, Colorado and New Mexico. In 1897 he went to ustralia as mining engineer; returned to the United States in 99; and subsequently accepted the post of chief engineer of e newly established Dept. of Mines at Peking, China. In hina he made extensive surveys, which, however, were inter-pted by the Boxer outbreak. He returned to California in 00 and thereafter was engaged as an engineer in the United ates, China, Australia, Burma and elsewhere. When the War rought this phase of his career to a close in 1914, the companies r which he was directing engineer employed upward of 175,000 en.

Mr. Hoover was in Europe in 1914 on a mission for the pro-cted Panama-Pacific Exposition, and so happened to be in ondon at the outbreak of the World War. At that time thou-nds of Americans in Europe found their funds shut off, and Ir. Hoover organised a committee for their relief, facilitating e return of over 100,000. The sudden invasion of Belgium by e Germans rendered a large part of the Belgian civilian popu-tion destitute, and on Oct. 22 1914, the Commission for Relief Belgium was organised and Mr. Hoover appointed chairman. *ee* RELIEF). Its activities were later extended to devastated orthern France. This organisation administered over $950,-000,000, provisioning some 10,000,000 people—a task requiring the most rigorously economical system of food distribution. The commission operated a fleet of about 200 ships. Mr. Hoover's services were rewarded by King Albert I. of Belgium, who, as a unique distinction, ordained him "Citizen of the Belgian Nation and Friend of the Belgian People."

In Aug. 1917, after the entry of the United States into the War, President Wilson appointed Mr. Hoover U.S. Food Administrator. He at once established an organisation throughout the United States for stimulating production, preventing speculation and hoarding, and conserving food supplies. Exports of food were increased from a pre-War rate of 6,000,000 tons per annum to a rate of 20,000,000 tons per annum. He established the U.S. Grain Corp. and the Sugar Equalisation Board, which, together with the Food Purchase Board under his direction, purchased and delivered all army, navy and foreign supplies, the total turnover amounting to over $11,000,000,000. Mr. Hoover also served as chairman of the Interallied Food Council. After the Armistice, which at his suggestion provided for the furnishing of food supplies to enemy countries, he became chief executive officer of the joint Allied committee which later developed into the Supreme Economic Council. He also established the American Relief Administration, which, together with the U.S. Food Administration and U.S. Grain Corp., was instrumental in alleviating the food situation of Europe, separate food administrations being formed in 23 different countries. By the autumn of 1919 these organisations had handled some $700,000,000 worth of supplies. As a result the great typhus epidemic in Poland and Rumania was successfully resisted. Six million outcast and ill-fed children were cared for through a special fund. After the Armistice Mr. Hoover raised a fund of over $50,000,000 with which to continue child-feeding in eastern and central Europe during 1920 and 1921. In 1922, he superintended the systematic distribution of food to 12,000,000 persons in the famine-stricken districts of Russia, a task requiring over 1,000,000 tons of food and an expenditure of over $65,000,000.

In 1920 Mr. Hoover's friends conducted an unsuccessful campaign to secure his nomination for the presidency on the Republican ticket. After Harding's election as president, Mr. Hoover entered his Cabinet as Secretary of Commerce. He signalised his assumption of office by a complete reorganisation of the department, his object being to change the attitude of government toward business from that of interference to that of co-operation. He sought the aid and advice of prominent men engaged in industry, agriculture and commerce, and, with their co-operation, co-ordinated the various bureaux of his department, in order that it might serve most effectively the interests of producers, manufacturers and distributors. Noteworthy among the means employed was the encouragement, through a Division of Simplified Practice, of a general reduction in the number of different varieties and sizes in which articles of commerce were manufactured. (*See* STANDARDISATION.) Both as a means of stabilising credit and production and as an aid in the expansion of foreign trade, the statistical services of his department were widely expanded and made promptly available. The Patent Office and the Bureau of Mines were transferred to Mr. Hoover's department in 1925. Legislation pending in 1926 for the placing of civil aviation and wireless telegraphy under its supervision failed.

Early in 1923 Mr. Hoover had aroused interest by pointing out the danger of a foreign monopoly of raw materials and urged a world-wide search for new sources and increased supplies of rubber. This action was directed chiefly against the alleged monopoly of rubber by Great Britain, the government of which had passed legislation affecting the price of rubber, the United States being the chief consumer of this commodity. His other important activities included the chairmanship of the St. Lawrence river and Colorado river commissions and of the North-eastern Super-power committee. He presided over a number of national radio conferences and served on the World War Foreign Debt commission. At the Republican National Convention of 1924 he was put forward, against his protest, for the Vice-Presidency, and received 334½ votes, Gen. Dawes being nominated

with 682½. He was at different times offered the Secretaryship of the Interior and of Agriculture, but he preferred to remain at the head of the Dept. of Commerce.

Outside his official activities Mr. Hoover organised in 1922 the American Child Health Assn. and became its first president. He also served as trustee of Stanford University, where he founded the Hoover War Library. In 1925 he accepted the chairmanship of the National Research Endowment, which undertook to raise $20,000,000 for research in pure science.

He wrote *Economics in Mining* (1906); *Principles of Mining* (1909), and, jointly with his wife, Lou Henry, a translation (1912) of Agricola's *De Re Metallica*, a Latin treatise on mining and metallurgy which had remained the standard textbook for almost 200 years after its appearance in 1550. He published *American Individualism* in 1922. (J. W. T.)

HORNADAY, WILLIAM TEMPLE (1854–), American zoologist, was born at Plainfield, Ind., Dec. 1 1854. He was educated at the Iowa State College. Having made a special study of zoology, he travelled extensively to collect specimens, visiting (1874–9) Florida, Cuba, the West Indies, South America, India, Ceylon, the Malay Peninsula and Borneo. From 1882 to 1890 he was chief taxidermist at the U.S. National Museum, Washington, D. C. In 1896 he became director of the N.Y. Zoological Park at the Bronx, New York City, from which position he retired in 1926. He was active in promoting game preserves and instigating legislation for the protection of wild life, having been instrumental in founding the Permanent Wild Life Protection Fund ($105,000). It was largely due to his action that the bison was saved from extinction on the American continent.

Hornaday wrote a number of fascinating works on animal life, among which may be mentioned *Two Years in the Jungle* (1885); *American Natural History* (1904); *Camp-fires in the Canadian Rockies* (1906); *Our Vanishing Wild Life* (1913); *Minds and Manners of Wild Animals* (1922); *A Wild Animal Round Up* (1925).

HORNE, HENRY SINCLAIR HORNE, 1ST BARON (1861–), British general, was born Feb. 1 1861. He joined the Royal Artillery in 1880 and served on the staff throughout the South African War (1899–1902). In 1912 he became inspector of artillery, and in Aug. 1914 he went to France in command of the artillery of the I. Army Corps. At the end of 1915 he was given charge of the XV. Army Corps in Egypt and he took this to France in April 1916, and commanded it during the opening phases of the battle of the Somme. His method of employing his guns during these operations attracted much attention and was signally successful, as was recognised by his being chosen in Sept. to succeed Sir C. Monro as leader of the I. Army. His troops took a prominent part in the battle of Arras, 1917, and when the enemy, in March and April 1918, made his great effort they repulsed all attacks that were made upon their front. Then, when the Allies' counter-offensive developed in the late summer, their part in the final victories was conspicuous. For his services he was raised to the peerage as Baron Horne of Stirkoke, and received a grant of £30,000.

HORNE, SIR ROBERT STEVENSON (1871–), British politician, was born at Slamannan Manse, Stirlingshire, Feb. 28 1871. Educated at George Watson's College, Edinburgh, and the University of Glasgow where he graduated as M.A. and LL.B. he took first-class honours in philosophy in 1893 and in 1895 became lecturer in philosophy at University College, Bangor. Called to the Scottish bar in 1896, in 1910 he became a K.C., and stood unsuccessfully as a Unionist for Stirlingshire in both the general elections of that year. In the course of the War he was appointed assistant inspector-general of transportation. In 1917 he was made director of the Admiralty Dept. of Materials and Priority. In 1918 he became director of the Admiralty Labour Dept., being also made Third Civil Lord of the Admiralty and created K.B.E. Later in the same year he was elected Unionist member for the Hillhead Division of Glasgow. In 1919 he became Minister of Labour and as such presided over the National Industrial Conference of February and April 1919. In 1920 he became President of the Board of Trade and received the G.B.E. In 1921 he was appointed Chancellor of the E chequer in succession to Mr. Austen Chamberlain, in Mr. Llo George's Coalition Ministry, but he did not accept office und Mr. Bonar Law or Mr. Baldwin. Instead he associated hims with the management of two or three large commercial unde takings, including one of the leading English banks and becar an important figure in business circles. He was elected lo rector of Aberdeen University in 1921.

HORNIMAN, ANNIE ELIZABETH FREDERICKA (1860– British theatrical manager, was born at Forest Hill, Londo on Oct. 3 1860. Educated privately, she studied art for a peri at the Slade School under Prof. Legros. At an early age she b came interested in the theatre, and to the furtherance of th cause most of her subsequent life was devoted. Her first theat cal enterprise at the Avenue Theatre, London, in 1894 was failure. In 1904 she became associated with the Abbey Theat Dublin, and subsidised the Irish National Theatre Society, whi presented a series of plays by Irish dramatists dealing with va ous phases of Irish life. She will be chiefly remembered, howev for her institution in 1907 of the Repertory Theatre moveme in Manchester. She acquired the Gaiety Theatre, Mancheste in 1908 and converted it into a repertory house in which some the best known plays of modern times were originally pr duced. In 1921 she relinquished her control as owner and co ductor of this enterprise, after 14 years of unbroken success.

HORSE-RACING (*see* 13.726).—During the World War hors racing and the breeding of thoroughbreds were beset with u precedented difficulties. The latter was quietly carried on spite of the scarcity of forage. As for the former some owners racehorses went out of business altogether, but many carried with the restricted racing permitted by the Government.

RACING BEFORE THE WAR

In 1910 the colts that gained classic distinction were N Gow (Two Thousand Guineas), Lemberg (The Derby) a Swynford (St. Leger). When both colts were really well the was little or nothing between Lord Rosebery's Neil Gow, a s of Marco, and Mr. A. W. Cox's Lemberg by Cyllene. Thou Lemberg was beaten by a few inches by Neil Gow for the Gui eas, revenge came in the Derby. Lemberg won; Neil Go who had developed curb trouble a day or two before the rac was unplaced. Yet, when Neil Gow was right again, the p ran a memorable race for the Eclipse Stakes and a dead he resulted. Swynford came on the scene rather late in the seaso Lord Derby's big colt, a son of John O'Gaunt, matured lat and was never heard of until he won the Liverpool Summ Cup under a low weight. There was a big gap to be bridg between that achievement and the winning of the St. Leg but Swynford was a colt right out of the ordinary. He dev oped with amazing sureness and rapidity, and, ridden by Fra Wootton, then a boy jockey of rare skill and understandin he won; though Maher, who had the mount on Lemberg, w much blamed at the time for riding with poor judgment, whic it was alleged, robbed the Derby winner of the honou Lemberg was Cyllene's third Derby winner. His fourt Tagalie, came only two seasons later. The two earlier ones h been Cicero (1905) and Minoru (1909). Both Lemberg a Swynford were destined to achieve fame at the stud. It is i teresting to recall that in 1910 the highest priced yearling amo the Sledmere lot made only 1,900 guineas. In 1920 Lord Glan gave 14,500 guineas for Blue Ensign from the same stud.

In 1911 the Derby winner, Sunstar, bred and owned by M J. B. Joel, was above the average. This brown son of Sundrid and Doris won both the Two Thousand Guineas and the Derb in addition to the Newmarket Stakes. He could not be train again through breaking down in the Derby, which he won b three lengths. This explains his absence from the field for t St. Leger, which that year was won by Prince Palatine, a bay s of Persimmon. There was nothing in Sunstar's two-year-o career to suggest such distinguished classic honours, though h was a smart colt. His dam, Doris, was an insignificant litt mare by Loved One that could win only a paltry selling rac

lated with Sundridge, who was no more than a brilliant sprinter hen in training, Doris produced the high class Sunstar, whose al worth was disclosed when he came through a great trial in rivate for the Two Thousand Guineas. He proved to be an stonishing foal getter, and included in his progeny were some f the highest class horses of their day, *e.g.*, Buchan (twice the inner of the Eclipse Stakes), Craig an Eran (winner of the Two housand Guineas in 1921), Galloper Light (winner of the rand Prix), Sunny Jane (winner of the New Oaks), Somme iss, Blink, Skyrocket and Zambo. It was the owner of unstar, who, in the following year, gave £40,000 for Prince alatine after that horse had won the Ascot Gold Cup in ddition to taking St. Leger honours in 1911. Prince Palatine as bought primarily for stud purposes, but he was not a suc- ess, and after a few seasons was sold to France, and later, was ocated in America.

The year 1912 was not a good year for three-year-olds. There as no outstanding horse unless it was Tracery, who was late maturing, and on that account was only "half" a horse when n the occasion of his debut, he was able to run third for the erby to the grey filly Tagalie and Jaeger. It said something or the poverty of the colts when Sweeper II., owned by Mr. uryea, who bred the colt in France from American parents, on the Two Thousand Guineas. Sweeper II. was trained in reat Britain and ridden by Maher. It was believed that he ould win the Derby, but he proved to be sadly deficient in tamina. It was in the One Thousand Guineas, the classic race or fillies, that Tagalie forced herself on public notice. The ather mean-looking daughter of Cyllene could stay, as well as o fast, and the combination of virtues enabled her to win the erby. Greys were sufficiently rare on our racecourses at that ime to attract special notice. Then she was a filly, and though ignorinetta had won the Derby as well as the Oaks only four ears before, the instances of fillies winning the Derby were still ery few indeed.

When Tracery won the St. Leger he was a different horse. nstead of being lacking in strength and development generally e was now "made up," though still leaving further scope for mprovement as a four-year-old. He won the St. Leger by five engths and among his victims far down the course was the grey Derby winner. Tracery was destined to become noted as a sire. He did well in Great Britain and was sold to the Argentine reeder, Señor Unzue, for the unprecedented sum of £53,000. He left behind him a Derby winner in Papyrus (1923), and subsequent to that event he was repatriated for a big sum, but did not live for more than one covering season.

The Derby of 1913 was a drama of thrills. There was the hot favourite, Craganour, belonging to Mr. Bower Ismay, who had paid between 3,000 and 4,000 guineas for the son of Desmond and Veneration II. as a yearling. Craganour was a high class two-year-old, and grew into a medium-sized colt, of a light bay colour. Onlookers said he won the Two Thousand Guineas; the judge said he did not beat Mr. Walter Raphael's Louvois, who had a clear margin to spare. Craganour made no mistake about winning the Newmarket Stakes, and came to Epsom an outstanding favourite for the Derby. He was ridden by the American, Reiff, who for some years had been riding in France. The unknown Aboyeur, in the colours of Mr. A. P. Cunliffe, led the favourite into the straight. They raced close together, and just as the favourite had appeared to get the better of a somewhat rough argument the outsider left the rails and bored and probably bumped Craganour. They passed the winning post with Craganour's head in front. The stewards held an inquiry, the outcome of which was that they disqualified Craganour and awarded the race to Aboyeur. Craganour within a few days was sold by his owner for £30,000 to Mr. Martinez de Hoz for stud purposes in the Argentine, where he proved to be a valuable stallion. Mention may be made of the St. Leger success of Night Hawk, an unconsidered outsider, bred and owned by Colonel Hall Walker, afterwards Lord Wavertree. This again was a non-vintage year.

The Tetrarch.—In 1913 a horse appeared that was destined to make remarkable history, both on the racecourse and at the stud, that wonder, The Tetrarch, the weirdly marked grey with big irregular white splotches, something after the manner of the nursery rocking horse. He was a well developed colt by Roi Herode, a French-bred stallion that had been located at the Straffan Station Stud in Ireland, and, mated with Vahren, produced The Tetrarch, who as a yearling found his way into the sale ring and at 1,300 guineas passed into the possession of Major Dermot McCalmont. He ran seven times as a two-year-old and was never beaten. He was a prodigy, and it is a pity that through injuring a leg while galloping, he could not be trained as a three-year-old. As a sire he became an immediate success. His progeny showed themselves to be possessed of remarkable speed, and the outcome was that there was immense competition for his stock in the sale rings, while breeders keenly sought his services for their mares. He did not sire a Derby winner, but he is represented in the records by no fewer than three winners of the St. Leger in Caligula (1920), Polemarch (1928) and Salmon Trout (1924).

The classic winners of 1914 were Kennymore (Two Thousand Guineas), Princess Dorrie (One Thousand Guineas and Oaks), Durbar II. (Derby) and Black Jester (St. Leger). They did not possess much distinction; in fact the Derby winner, who belonged to Mr. Duryea and was brought from France, was probably the worst Derby winner of the century. Princess Dorrie was a daughter of the St. Leger winner Black Jester (who went to the Argentine), but though such a fine stake winner, she did little of note as a matron at the stud. Black Jester was a son of Polymelus, one of the greatest sires of the period under review, for in several years he headed the list of winning sires. Black Jester only did fairly well at the stud, though he had many moderate winners to score for him.

Racing During the War.—It was not long before the effects of the War on racing were noted. Agitation against racing of any kind so far influenced the Government that representations were made by the Cabinet to the Jockey Club, the outcome of which was the cancellation, in 1915, of horse racing at all places except Newmarket. This took effect on the eve of what should have been the Derby meeting at Epsom. Thereafter for that year racing was restricted to Newmarket, and so that those concerned should not be hit too hard the Jockey Club instituted a series of extra meetings. It was at one of these that special races took place for the three-year-old colts and fillies, an arrangement lasting till 1918. There was a New Derby and a New Oaks.

It is extraordinary that while Rock Sand in 1903 was the last horse to win the triple crown, the Two Thousand Guineas, Derby and St. Leger, yet three horses in four years were each capable of winning the Two Thousand Guineas and the substitute races for the Derby and St. Leger known as the New Derby and the September Stakes. The explanation does not wholly lie in the fact that Pommern (1915), Gay Crusader (1917) and Gainsborough (1918) were above the average of Derby winners. In peace times horses must visit Epsom and Doncaster in search of classic honours as well as Newmarket. The mere variation of ground and the possibility of flukes, such as the splendid fairness of Newmarket must reduce to a minimum, have doubtless been contributing to the strange fact that Rock Sand in 1903 was the last horse to win all three classic races.

Pommern, who was by Polymelus from Merry Agnes, was bred by his owner, Mr. S. B. Joel, and from the manner of winning his races was a worthy holder of the highest honours on the turf. Not improbably the best three-year-old of 1916 was Hurry On, an unusually big and powerful chestnut colt by Marcovil from Tout de Suite, bought for less than 1,000 guineas by Lord Woolavington as a yearling and never beaten during his three-year-old season. It was the only year of racing he had, and before it was over he had disposed of all brought against him, including Clarissimus, who had won the Two Thousand Guineas for Lord Falmouth. Fifinella, a filly by Polymelus from Silver Fowl, bred and owned by Sir Edward Hulton, was unquestionably the classic heroine of the year, for in the same week she won

both the New Derby and the New Oaks. She was no doubt a brilliant filly.

It is a pity that such a horse as Gay Crusader, by Bayardo from Gay Laura, should not have lived in times when he could have been tested at Epsom and Doncaster. All we know is that he was an exceptional colt as a three-year-old, carrying all before him and causing his great trainer, Alec Taylor, to regard him as the best horse he has ever trained, not excepting Bayardo himself. Gay Crusader was the first foal of his dam, and was a light fleshed horse with plenty of size and simply perfect action. He was equally brilliant, according to his trainer, at five furlongs or two miles, and it was a great regret to him that he could not train him as a four-year-old. From the same stable came Gainsborough to win the Guineas and the two substituted classics at Newmarket in 1918. He was a son of Bayardo from Rosedrop, who ranks as the winner of the Oaks in 1910. He was of a different type and possessed of more substance. Both he and Gay Crusader, have made their mark as sires, and Gainsborough has the distinction of siring Solario, the St. Leger winner of 1925.

Racing After the War

After the War racing at once entered upon a period of great prosperity. Attendances increased by many thousands at all racecourses, and the prices of bloodstock soared to astonishing heights. It was in 1919 after winning the Derby with Grand Parade, a son of Orby, and a number of big races at Ascot, that Lord Glanely spent money lavishly on young bloodstock. When he gave 11,500 guineas for a yearling by Swynford from Blue Tit, bred at Sledmere, he established a new record for a yearling, hitherto held by Sceptre, who had cost 10,000 guineas. In 1920 Lord Glanely gave 14,500 guineas for a yearling by The Tetrarch from Blue Tit. Prices remained high to the end of 1925, which was associated with the wonderful dispersal sale of Sir Edward Hulton's bloodstock.

Among classic winners Grand Parade was rather less than the average height of racehorses, and this has been true of more than one other Derby winner since the War, *e.g.*, Papyrus and Manna, while Humorist was not by any means a big horse. On the other hand Captain Cuttle (1922) and Spion Kop (1920) were undoubtedly big horses, especially Captain Cuttle, who was a son of Hurry On. Grand Parade was just an average Derby winner, neither more nor less. Spion Kop was a son of Spearmint, who won the Derby as far back as 1906. With his four white legs Spion Kop, who belonged to Major Giles Loder, was a conspicuous horse. He certainly won in fine style, though, like Sansovino, the hero in 1924 in Lord Derby's colours, he was not destined to do much afterwards. This has been a feature of the post-War Derby winners. Grand Parade went to Ascot, where he had great difficulty in beating a single opponent. He went forthwith to the stud. Spion Kop was kept in training until he was four years old, but he was a disappointment.

Then came the ill-fated Humorist in 1921. Donoghue, who rode Captain Cuttle, Papyrus and Manna to victory, in addition to Pommern and Gay Crusader, rode one of his most brilliant races on him, and within a month the horse died. He was found in his box dead from internal haemorrhage. Humorist had been sired by Polymelus, and was the foal of Jest, a delightful little mare that had won both the One Thousand Guineas and the Oaks for her owner and breeder, Mr. J. B. Joel. Captain Cuttle by a very easy victory stamped himself as a high-class colt, but he did not stand much further training, though he won afterwards. Papyrus, as a yearling, cost Mr. Ben Irish, a farmer, who had won an Ascot Gold Cup with Periosteum, 3,500 guineas. He was a Derby winner well up to the average, a medium-sized dark brown son of Tracery, with marked quality and a beautiful temperament. After finishing second to Lord Derby's filly, Tranquil, for the St. Leger, he was sent to New York to run a match against America's champion, Zev. With only a month in that country, on strange going, and after a trip across the Atlantic, the Derby winner had little or no chance, and he was beaten. Papyrus was unlucky as a four-year-old, for when giving away much weight he was second for the Eclipse Stakes and for the Jockey Club Stakes. At least he did train on better than the others.

Sansovino won the Derby in heavy going in 1924, and when the weather was about as bad as it could be. He was twice asked to race at Ascot, and though he won the first time he seemed to go all to pieces afterwards. He won once as a four-year-old and then went to the stud, after breaking down during the race for the Jockey Club Cup. The three-year-olds of 1925 were above the average. Manna, a charming colt by Phalaris that cost 6,000 odd guineas as a yearling, won both the Two Thousand Guineas and the Derby for Mr. H. E. Morriss. He broke down at the start of the St. Leger won by Solario, and that was the last of him on a racecourse. It is true, therefore, that the post-War classic winners have not trained on as they should have done. The last Derby winner to win an Ascot Gold Cup was Persimmon, and that was in 1897. In 1926 the Derby was won by Coronach owned by Lord Woolavington.

The Bloodstock Market

It was after the War that the Aga Khan took up ownership and then breeding in Great Britain on a large scale. His investments, chiefly in yearlings, for two or three years must have run well into six figures, and he had many horses in training and one of the finest studs in Ireland. He won the Two Thousand Guineas (Diophon) and the St. Leger (Salmon Trout). He was second for the Derby to Manna with Zionist, a colt that was good enough to win the Irish Derby. With Mumtaz Mahal, a daughter of The Tetrarch, for which he paid 9,700 guineas as a yearling, he had a remarkably fast two-year-old. By his enterprises he had much to do with the flourishing state of the bloodstock market. At Doncaster in 1925 Sir Victor Sassoon gave 12,000 guineas for a yearling filly by Tetratema from Confey, and the Aga Khan paid 10,500 guineas for a filly by Gay Crusader from Tête-à-Tête, both being greys. At Sir Edward Hulton's wonderful sale a total of 288,380 guineas was realised. The highest price was 17,000 guineas paid on behalf of an American buyer for the Oaks winner, Straitlace, a daughter of Son-in-Law. Other mares made respectively 12,000 and 12,500 guineas, a two-year-old filly, Silvretta, 13,000, and a two-year-old colt Legatee, that had never seen a racecourse, 9,100 guineas. In 1926 racing in England was flourishing, with apparently more wealthy owners than ever, even though the old race of patrician owners would appear to have died out. The breeding industry is in a healthy state, with all the countries of the world coming to Great Britain for replenishment.

The story of racing and breeding in England during the period under review would not be complete without some reference to the demonstration made in England by French-bred horses, and to the steadily ascending values of the high-class British thoroughbred in what is unquestionably a world-wide market. The latter may be said to embrace every country in the world in which racing takes place, and which must periodically come to England for the replenishment of its studs and stables. In particular, reference is made to North and South America. First, however, as to the successes of the French horses in England, even though for the most part the blood of well-known strains emanating from England can be found in their pedigrees.

Racing in Foreign Countries

France.—France, even more than England, neglected racing and breeding during the war. The result was that for about three years after the War, matters were at a low ebb in France. Several successful raids were made on the Grand Prix de Paris when it came to be re-established. This race is open to all, unlike the French classic races, which are strictly confined to horses bred in France, whereas the English classic races are open to the world. The first English post-War Grand Prix winner was Mr. Anthony de Rothschild's Galloper Light, a son of Sunstar, and undoubtedly a high-class horse. Next came the undistinguished-looking black horse, Comrade, owned by M. de St. Alary, but

bred in Ireland and trained in England. His was a most romantic case if only for the reason that he was actually bought for only 25 guineas in the sale ring as a yearling by Mr. P. P. Gilpin, who trained him. Such a low-priced horse was not entered in the English classic races, but luckily he was put in the Grand Prix to triumph in it. Then a third year did England triumph in France's big race at Longchamps. The hero this time was Lemonora, a chestnut son of Lemberg, that had been purchased as a yearling for several thousand guineas on behalf of Lord Manton. Lemonora won the Newmarket Stakes and was placed third in the Derby won by Humorist. Two or three weeks later he was in France, and there won the Grand Prix.

The position was destined to alter most abruptly. England had not won the Grand Prix since up to 1925, perhaps because no first-class horse has endeavoured to do so. On the other hand the French have failed in England's classic races, but they achieved a signal success in 1924 when their fine stayers, Massine and Filbert de Savoie (the latter a Grand Prix winner), finished first and second respectively for the Ascot Gold Cup. In the same year the fastest horse in France up to a mile, Épinard, came over to win the Stewards Cup of six furlongs at Goodwood. This the brilliant horse did under a big weight for a three-year-old. Later in the year he was beaten only by a neck for the Cambridgeshire when his weight was the very big one for a three-year-old of 9 stone 2 pounds.

It was in 1924, too, that Sir Galahad III., a French classic winner, was exploited at Lincoln and won the Lincolnshire Handicap. A year later another French classic winner in Tapin was similarly successful in the same race, but history will always tell that the most notable achievement of horses sent from France was when Forseti won the Cesarewitch and Masked Marvel the Cambridgeshire of 1925. Both these horses were owned by the same man, Mr. A. K. Macomber, who for some years past has maintained elaborate breeding and racing establishments in France.

Argentina.—Argentine breeders, as has been already stated, purchased Tracery for £53,000 and Craganour for £30,000. They have bought freely since, but the really big business since the War has been with the United States, in which country there has been rapid development of breeding and racing. The boom was doubtless encouraged by the visits of the English Derby winner Papyrus, and of Épinard, but their breeders have not been afraid to pay large sums for some notable horses. High-class sires that have gone there include Stefan the Great (by The Tetrarch), Royal Canopy (by Roi Herode), Bright Knight (by Gay Crusader) and St. Germans (by Swynford). It is said that £20,000 was paid for St. Germans. The others also cost sums running well into five figures. High-priced yearlings and mares have found their way there, including Straitlace, as stated, for 17,000 guineas, and Sunny Jane, a New Oaks winner in England during the War.

India.—India has not bought so freely since the War as just before, but the reason is economic and is not concerned with any falling off in appreciation. She has simply been outbid by other countries. South Africa, Australia, Egypt and the Far East are regular customers. To Germany went Caligula, a winner of the St. Leger since the War. Austria and Hungary are countries that are rapidly regaining ground, their breeders having purchased for large sums the sires Light Hand, by Sunstar (declared by Lord Astor to be the best colt he has ever bred) and Tamar, by Tracery, second in the Derby and also bred by Lord Astor. Italy is well in the market, while France is at all times a buyer. These facts explain why the value of the British thoroughbred in a general sense has never been so high in history as since the War. Moreover, this is true after making due allowance for the depreciation in money values and the fluctuations in the exchanges.

RACING IN THE UNITED STATES

United States.—There is the greatest possible difference between the surroundings of racing in Europe and in the United States. "Time" is the great factor in the States, instead of varying weights, in determining the speed and endurance of a horse, and training methods are totally distinct. There is no one representative body governing racing, but the states of New York, Maryland, Illinois and Kentucky have each its own body, so that punishments and penalties are limited to the individual area; this is not good for the sport. Jockeys, after passing their apprenticeship, are totally beyond control, except when riding; and, owing to a foolish emasculation of the Scale of Weights, most of the good riders of the United States are obliged to migrate to Europe almost as soon as they become really competent. The card of any day—exclusive of fixed weight stake events—will average 20 lb. below the scale for each horse started, irrespective of age or distance.

Until the jockey passes from his apprenticeship and is eligible to a contract to ride, good care is taken of him. In a number of Associations or Jockey Clubs there are churches, nightschools, gymnasiums and hospitals; for the horses there are ambulances to remove injured animals from the course, and hospitals. As for racing proper, the Westchester Racing Assn., near the City of New York, is probably the most beautiful and the most perfectly equipped course in the world. Its grandstand covers and seats 30,000, and its lawns and tree-studded, flower-bedded paddocks cover several acres.

The famous "Ten Thousand Pounder" races of Europe were balanced in U.S. racing, in 1925, by the £11,700 Futurity, the £11,500 Coffroth Derby, the £10,700 Pimlico Futurity, the £10,600 Preakness, the £10,600 Kentucky Derby, with a great probability of the Belmont and the Hopeful Stakes far exceeding these figures in 1926. All of these amounts have been built since the crucial year of 1911, when Charles S. Hughes (later Secretary of State) was Governor of the State of New York and was responsible for the passage into law of the Agnew-Hart bill, and for the drastic enforcement which caused the arrest of more than 300 well-known people only to have them discharged later for lack of evidence, and which frightened the six important associations in the state into ceasing racing for two years and caused the exportation of animals of the best blood in the country to the value of about £400,000. Racing would probably have been killed utterly in the state but for the courageous amateur sportsmen of the United Hunts Racing Assn., who laughed the law to scorn, declined to be intimidated, asked for arrest and went on racing. Two years later the important associations found courage to open their gates, and, by the underwriting of expenses by certain prominent lovers of the sport, racing was resumed at a minimum scale, and under the same, unamended law which closed the courses has prospered like the proverbial green bay tree.

In 1925 17 states accounted for 1,656 days of sport with 11,579 races decided; the stakes alone represented a value of £460,000 as against £132,700 in 1910; and the yearling sales in 1925 had a total value of £373,360, with an average of £640, as against the 1910 record of a gross value of £36,000 and an average of £65. In 1925 a new record price for a yearling was reached, this being the £10,000 paid for the colt by Man O'War, out of Tuscan Red by William Rufus. During 1925 £2,515,450 was distributed in stakes and purses, as against £600,000 in 1910.

As to the really great horses appearing since 1910, personal opinions vary widely, all depending on the quality of competition met. The interesting high-lights on the question are that Luke McLuke proved that the famous Domino strain could go a distance if properly prepared; Hourless, by Negofol, was a great performer in 1917; and in 1920 came Man O'War (whose one scandalous defeat must not be reckoned against him). He defeated every rival, and this son of Fair Play out of Mahuba, by Rock Sand, proved a remarkable sire, for all of his dozen or so progeny have won good races. Regarding the visits of foreign horses, Papyrus never had a chance, as he was shod for a fast course and raced in mud, but his conqueror, Zev, has been

useless since the contest. Épinard, the French horse, was unlucky, and should have won at least one of his three races. Neither race proved anything or threw any light upon the excellences of U.S. horses bred mainly from English blood, as against the British home-bred product. (W. P. P.*)

HORTHY DE NAGYBANYA, NICHOLAS (1868-), Hungarian admiral and regent, was born June 18 1868 at Kenderes, in the family mansion in the county of Szolnok (Eastern Hungary). His family belonged to the landed gentry, and from 1635 ranked amongst the nobility. After studying at the naval academy at Fiume he entered the navy of the Dual Monarchy. After considerable sea service he was appointed A.D.C. to the Emperor Francis Joseph, and served in the naval department of the War Ministry in Vienna. At the outbreak of the World War he was appointed to command the cruiser "Novara." After Italy joined the Allies Horthy distinguished himself in the naval raids on Porto Corsini and San Giovanni di Medua, and particularly at Otranto, where on May 14 1917, with the cruisers "Novara," "Saida" and "Helgoland," he broke through the ship cordon blockading the Straits of Otranto. Horthy, although severely wounded, remained on deck and continued the fight until he succeeded in returning safely with his ships to his home port, despite the enemy's heavy fire. He was awarded the Military cross of Maria Theresa. Near the end of the War Horthy was appointed commander-in-chief of the Austro-Hungarian fleet.

After the collapse of the Monarchy and when revolution broke out in Hungary Admiral Horthy returned to the home of his ancestors and began to organise the counter-revolutionary forces in southeastern Hungary. Thanks to his popularity as a war hero, Admiral Horthy added considerably to the influence of the informal counter-revolutionary Government of Count Julius Kârolyi, which in Hungarian territory occupied by French troops endeavoured to form a nucleus for all partisans of law and order. When it became obvious that the fall of Bolshevism was imminent, the second "Szeged Government" appointed Horthy to be commander-in-chief of the national army, which, after the flight of the people's commissioners (Aug. 1919), entered Transdanubia and succeeded in restoring order in territories where law and discipline had been upset by the Red Terror of Bela Kun. When the Rumanians finally withdrew their troops from the centre of Hungary the new national army, with Horthy at its head, entered Budapest on Nov. 16 1919 amidst the cheers of the population.

The restoration of order was no light job, and it was done with no light hand by a sailor who regarded the spirit of discipline in his ship as more important than the praise of kings or the blame of politicians. Horthy has been frequently attacked for failing to restrain retaliatory outrages of those who suffered under the Red Terror, and who themselves created what has generally been termed the White Terror. It must be remembered, however, that all the normal forces for maintaining order had previously been dispersed, and that without such forces it was practically impossible to control what was a natural reaction, however regrettable. When in Feb. 1920 the national assembly of Hungary was elected, Admiral Horthy, still commander-in-chief of the army, was practically the only possible candidate for the regency. Consequently he was elected to this office on March 1 1920.

As regent or governor, as the office is variably termed, Admiral Horthy had the bitter duty of ratifying the Treaty of Trianon, which his second Government, that of Count Paul Teleki, carried through in Nov. 1920. The gravest responsibilities, however, which the regent was called upon to meet were the two attempts of the late King Charles to regain the throne of Hungary. The regent of Hungary was then in a desperate conflict between an allegiance sworn as admiral and privy councillor to his king and the oath taken as regent to the Hungarian national assembly. First, in April 1921, he refused to obey the summons to hand over the Government to King Charles when the latter came to Hungary unarmed. On that occasion the Hungarian Govt. succeeded by peaceful means in getting the king to leave the country. At his second venture, in Oct. 1921, King Charles came with troops against the capital. The regent and Count Bethlen's Government had no alternative but to fight him, as the Allied Powers and the states surrounding Hungary were definitely opposed to the restoration of a Habsburg monarchy. It was a poignant task for the regent to disarm and hand over to the former enemy powers the anointed bearer of St. Stephen's crown.

As the disturbances inevitable after revolution, Bolshevism and monarchical "putsches" died down, and the life of the country became more normal, the personality and actions of the regent ceased to have such critical importance. Representative government, exercised through the national assembly, resumed its ordinary sway, and Admiral Horthy performed his duties with constitutional correctness, supporting the efforts of Count Bethlen's Government towards the economic reconstruction of the country. He had to lead his country through difficulties which few men in history have had to face, and it is small wonder that in doing it he had to take drastic measures and has made many enemies. It is doubtful, however, if Hungary could have found a regent more energetic in times of peril or equally constitutional in times of peace. Horthy may be described as a typical sailor, frank and simple and direct in manner, with no suspicion of diplomacy, and devoted to sport, but in official life a strict observer of the ceremonies which appertain to the head of a state that is still a monarchy.

(W. Go.*)

HOSPITALS (*see* 13.791) (1912–25).—At the beginning of the period under review two special points should be noted in connection with the general development of hospitals:—

1. The development of operating and clinical methods led to an increasing specialisation in the departments of general medicine and surgery in hospitals.

2. From the architectural point of view, simplicity and comfort were being increasingly sought, and buildings and hospital premises were being to an increasing extent adapted to the necessities of sanitation and hygiene.

General Features.—Attempts to create large hospitals outside urban centres and in favourable climatic conditions have been to a large extent successful. In the case of old hospitals, where it was difficult to make rapid changes, the various services have been installed in special buildings and annexes, divided one from another, each dealing with a special subject, *e.g.*, surgery, clinical work, ophthalmic work, otolaryngology, children's diseases, gynaecology, epidemies, etc. Whereas in Anglo-Saxon hospitals the principle of placing hospitals under independent management maintained by voluntary aid has been adhered to, in continental countries there has been an increasing tendency to centralise hospitals by placing them under municipal, local or national authority. The former method tends to encourage individual initiative and the desire to make each hospital as perfect as possible. The latter allows of the most practical and economical distribution of the various services between the departments concerned.

Statistics.—Hospitals were more frequented in 1912 than in previous years. This fact must be attributed not to the increase in the tendency to disease, but to the addition of a large number of buildings and wards which allowed of a larger number of patients being received. The dissemination of the principles of hygiene has familiarised the public with medical methods and has caused a marked increase in the number of patients under treatment. Various statistics show the movements of patients in hospitals during the years preceding the War. In 1913, 106 hospitals in London (general hospitals, children's clinics, gynaecological hospitals, anti-tubercular hospitals, etc.), with 9,171 beds, dealt with 134,749 patients, and were attended by 1,329,567 persons.

In 1912, the Paris Department of Public Relief (*l'admtnistration générale de l'assistance publique*) admitted to its general hospitals (Andral, Beaujon, Boucicaut, Broussais, Charité, Cochin, Hôtel-Dieu, Laennec, Lariboisière, Necker, Pitié St. Antoine, St. Louis and Tenon) 147,828 patients, and 46,601 patients to the special hospitals (St. Louis, Maternité, Broca,

:c.). Germany, in 1912, had 9,054 hospitals with 535,579 'eds. This figure includes general hospitals, military and naval ospitals, lunatic asylums, sanatoria, maternity homes, special inics, children's hospitals, homes for the blind, etc. In 1912, ie medical institutes of Vienna dealt in all with 82,030 patients. n the United States there was a noticeable increase in the umber of hospitals and clinics, and there was a considerable evelopment of the specialisation of medical and surgical departments.

War Conditions.—The World War of 1014 compelled hospitals o adapt themselves rapidly to new requirements, *e.g.*, assistance or the wounded, ambulance work, mobile hospitals in the army ones, medical staff, additional nurses, etc. Existing hospitals 'ere transformed to meet the new requirements. In addition, a irge number of extra establishments were improvised.

Military and naval hospitals are directly dependent on the ilitary medical service and are divided as follows:—

(*a*) Permanent military hospitals, already existing in time of peace, ere specially adapted for the reception of sick and wounded soliers;

(*b*) Civil hospitals were placed, together with their staff, under the irection of the military authorities;

(*c*) Hospitals were installed in public or private buildings, such as otels, schools, private houses, etc., to receive and deal with the low of wounded from the front;

(*d*) Hospitals in the zone of military operations were carried on in ermanent premises or under canvas, even underground, nursing osts and relief posts dealing with first aid to the wounded before heir evacuation to the rear.

(*e*) As described in the article MEDICAL SERVICE (ARMY), ambuances of every type were employed. Aeroplanes, trains, barges and iners, specially converted and equipped, were used for the transport of sick and wounded to base and home hospitals.

(*f*) Special hospitals for orthopaedic, for tuberculous, neurasthenic, aralysed and gassed cases were organised. Electro-therapeutical, ydro-therapeutic, helio-therapeutic massage and special sections ere also developed.

(*g*) Convalescent homes were set up and many private mansions ere used for this purpose.

(*h*) Temporary hospitals were erected to receive influenza patients, nd malaria camps were organised.

Neutral Countries.—In non-belligerent countries there was no very considerable change in the organisation of hospitals between 1914–9. By the force of circumstances, the construction of new buildings was slowed up, technical methods remained more or less stationary, and the nursing staff tended to diminish, in view of the large number of volunteers serving in the belligerent countries. In 1917–8, statistics of the movement of disease and mortality remained more or less equal to those of 1914. Anti-epidemic hospitals were organised in large numbers in Poland, Russia, Hungary, Rumania and the Baltic countries.

Quaranline Stations.—Quarantine stations, which before the War were limited to maritime ports, were, after the War, set up on the borders of Poland, Czechoslovakia, Rumania, Hungary and the Baltic States, for the supervision of travellers arriving from countries contaminated by exanthematic typhus and relapsing fever. Three model stations, set up by the International Red Cross Committee at Narwa in Estonia, Riga in Latvia, and Iniö in Finland, dealt with the reception, supervision and disinfection of thousands of prisoners arriving from Russia on the convoys of repatriated prisoners between 1919–22.

Special Hospitals.—The Italian Red Cross has been most active in districts affected by malaria, and with this end in view has organised the anti-malaria sanatorium of Massalubrense, together with a number of motor ambulances. In Georgia, the tropical institute of Tiflis is engaged in centralising the work of the various clinics and hospital stations. In 1913 12,500 malaria patients were treated in the hospitals of Tiflis. In Oriental countries may be mentioned the leper hospitals (the Indies and Siam), hospitals for the treatment of snake-bites (Siamese Red Cross at Bangkok), and the anti-epidemic and summer hospitals of the Chinese Red Cross at Shanghai. Hospitals have been supplemented by dispensaries, preventive homes, consulting offices, convalescent homes and mountain sanatoria and seaside hospitals. Venereal disease and dermatological hospitals have considerably developed. Cancer hospitals have been improved and perfected, especially as regards radio-therapeutic services, anatomo-pathological laboratories and radio-therapeutical, photo-therapeutical and radiological work.

Developments.—In 1924, the number of hospitals in London was 118 (as against 106 in 1913), the number of beds 13,460 (as against 11,840 in 1913), the number of patients treated 177,300 (as against 145,600 in 1913) and the number of consultations 6,677,000 (as against 5,020,000 in 1913). Among the principal hospitals included in these general figures, St. Thomas's Hospital alone received 10,130 in-patients and gave 488,600 consultations; St. Bartholomew's Hospital received 8,648 in-patients and had 344,226 out-patients, the London Hospital 17,331 in-patients and 553,065 out-patients, Guy's Hospital 0,405 in-patients and 487,452 out-patients. In Paris, the number of sick persons received was 238,012 in 1923, of whom 153,794 were in the general hospitals, 43,403 in the special hospitals, 29,329 in the children's hospitals, 2,071 in the mental hospitals and 10,315 in various homes and asylums.

C. de Gronkel (1925). (E. M.*)

United States.—During the period from 1912, and more particularly from 1914 to 1025, the development of hospitals in the United States has been unprecedented. This development may be considered under the heads of (*a*) the present trend of hospitals as a social factor, (*b*) the present day construction, (*c*) specific examples and (*d*) statistics of 1025 and the increase during the period in question.

Hospitals as a Social Factor.—While there is a continued development and refinement of the care of the sick in the hospital to-day, the conception of the function of this institution has materially broadened, with a rapidly increasing tendency to regard it as a community health centre from which to radiate all health activities, particular emphasis being placed upon the development of out-patient departments (this as a means of teaching and practising preventive medicine and thereby obviating the necessity of the hospital bed), district nursing and social service. In the larger cities medical centres are being developed, in which case the foregoing community functions are associated with the instruction of student bodies in various branches, including medicine, nursing, public-health work, social service, and, in many instances, dentistry.

The tendency to develop isolated speciality hospitals is being replaced by provisions for the specialities as departments of the general hospital or by the affiliation of already existing speciality hospitals with existing general hospitals. The different types of schools teaching health work, with the various hospitals, form these medical centre groups, in which are included convalescent homes as an integral or co-ordinated part.

Present-Day Construction.—While in the earlier period hospital development in the United States was largely patterned after the developments in Europe, the present trend of large institutions is toward the "skyscraper hospital"—as St. Luke's Hospital Annex, in Chicago, with 19 stories; the Jefferson Hospital, in Philadelphia, with 17 stories; and the new Presbyterian Hospital of the Medical Centre of New York City, now under construction, with 22 stories. This tendency is extending even into the country districts where the value of land is not a factor—the University Hospital at Ann Arbor, Mich., with its nine stories, being an example.

Economy and effectiveness of administration is claimed by the promoters of the multi-story hospital movement. The newest developments lay emphasis upon small wards with a maximum of 10 or 12 beds, numerous single rooms for patients of all types, and elaborate facilities for private patients. In this type of construction it is quite common to find the kitchen, laundry and all essential services provided for in a single building along with the housing for the patients. This type of construction and administration, which is distinctly American, is not at this writing being followed in the United States to the entire exclusion of the methods commonly pursued in Europe.

Specific Examples.—A typical example of the hospital movement in the large American cities is to be found in the Medical Centre in the City of New York, in which the Columbia University College of Physicians and Surgeons, Presbyterian Hospital, Sloane Hospital for Women, Vanderbilt Clinic, The Babies' Hospital, Neurological Institute, State Psychiatric Institute and Hospital, Presbyterian School of Nursing and certain other schools and hospitals are reconstructing their institutions on a single plot of ground, having jointly undertaken all the branches of medical teaching, research and care of the sick, their simultaneous constructional programmes involving $20,000,000.

Increase in Recent Years.—At the close of the year 1925 a complete census of all the hospital facilities in the United States, however owned and controlled and for whatever type of patient, showed that there were 8,695 hospitals—a figure somewhat in excess of 50% of the number of institutions of this character in the world. These hospitals provided a total of 836,576 beds, of which 34,511 were bassinets. This compares with 5,037 hospitals, with 532,481 beds, in 1914. Of the total number specified, 341,480 beds are devoted to the care of mental and nervous diseases.

While the development of the large institutions has made unusual progress, yet the growth of the small institutions in the smaller communities seems to have a special significance and to be indicative of the popularisation of the hospital in the public mind. While in 1920 44% of the 3,027 counties in the United States had community hospitals, the record of 1925 shows an increase to 56%; 52% of all the hospitals in the United States being of 40 beds or less. The close of the period finds recorded 1,117 new buildings planned, with $300,000,000 involved in a year's construction; the total value of hospital properties being variously estimated between $4,000,000,000 and $5,000,000,000.

In the year 1925 the 56 privately owned hospitals of all types in New York City receiving partial support from the United Hospital Fund reported 12,022 hospital beds, 230,988 cases, and 3,456,111 days of hospital care—this being independent of the state and municipal hospitals in New York City. All types of hospitals in New York City, excepting those for the insane, provided 32,167 beds, treated 510,859 patients and gave 8,813,721 days of hospital care; treated 1,028,347 cases in out-patient departments and had a total of 3,595,261 out-patient department visits.

HOUGHTON, ALANSON BIGELOW (1863–), American diplomat, was born at Cambridge, Mass., Oct. 10 1863. He was educated at Harvard (B.A. 1886), subsequently studying at Göttingen, Berlin and Paris. He associated himself with the Corning Glass Works N. Y., in 1880, becoming successively vice-president and president, and, in 1918, chairman of the board of directors. He was elected a member of Congress in 1919 and re-elected in 1921, resigning in 1922 on his appointment by President Harding as U.S. ambassador to Germany, a position which he held until 1925, when he was appointed ambassador to Great Britain in succession to F. B. Kellogg.

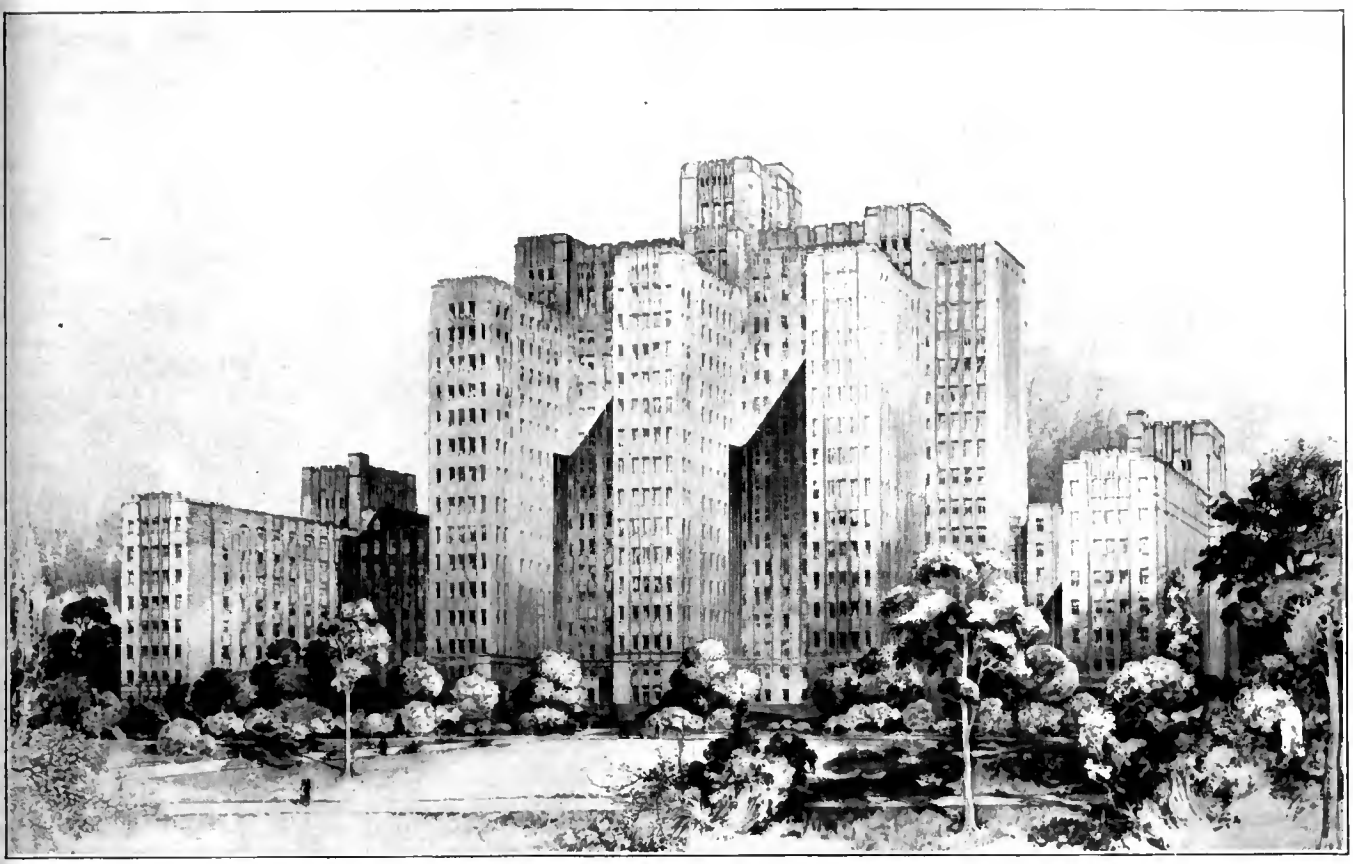
HOUGHTON, WILLIAM STANLEY (1881–1913), British playwright, was born at Manchester Feb. 1881, and educated at Manchester grammar school. He became a cotton broker, but employed his leisure in dramatic criticism for *The Manchester Guardian* and in the writing of plays. *The Dear Departed* (1910) was produced by Miss Horniman at the Gaiety Theatre, Manchester, in 1908 and afterwards in London. With *Hindle Wakes* (1912) he leapt into fame. It had a long run in London and later in the same year *The Younger Generation* (written and played in Manchester in 1910, 2nd ed. 1913) was successfully produced at the Haymarket Theatre, London, with *Trust the People* (1913) the following year at the Garrick and *The Perfect Cure* (1912) at the Apollo. His early death in Manchester, Dec. 10 1913, cut short a career of much promise.

HOURS OF LABOUR (*see* Labour Legislation, 16.7).—The position in regard to hours of labour reached in the years immediately following the Armistice of 1918 was further consolidated during the succeeding years and in some directions a movement was made towards a further reduction of the daily and weekly working hours, in practice as well as by legislation. The European economic crisis, however, particularly that occasioned by the fall of the German mark, the abnormal unemployment in Great Britain, in Switzerland and later in Germany reacted on the national and international position in regard to working hours and tended to check the movement towards general reduction. The weight of the reparations burden upon Germany weakened the campaign of the trade unions there towards shorter hours, and Germany's rivals felt the influence of the longer hours ("Mehrarbeit") which were instituted, with the consent of the German trade unions, in certain branches of industry in 1924.

Many workers during this period showed themselves ready to undertake overtime work whenever possible, or even to work a "second eight"—in another factory or workshop at the conclusion of their normal day's labour. This latter case was made, on grounds of social policy, a statutory offence in some countries, and was frequently used as an argument in favour of the short working day. These phenomena contradict the experience of the pre-War period; they are explained in certain countries with depreciating currency by the failure of wages to keep pace with rises in the cost of living, in others by the prevalence of unemployment, which has given the employer a powerful weapon against the worker whose chance of obtaining new employment, once thrown out of work, is very slight. In either case the force of the temptation upon the worker to earn as much as possible is obvious, and the trade unions have sometimes (notably in France and Italy) had to abandon their traditional opposition towards overtime, or even moderate their insistence upon increased rates of pay for overtime work. In Germany the trade unions ceded for a time their demand for overtime pay in regard to the "Mehrarbeit" hours, whilst retaining it for any further hours. In Great Britain, the overtime rates were almost universally maintained owing to the strength of organised labour.

I. THE GENERAL INDUSTRIAL STANDARD

Standard Day and Week.—But these weakenings of the general movement were everywhere recognised as exceptional and as due to temporary factors. Public opinion in general as reflected in the various legislatures supported the trade unions in their resistance to any demand for extension of hours, and the "standard" working day or working week has successfully maintained itself. In Great Britain collective agreements showed no tendency towards an extension of hours; successive parliamentary attacks on the Belgian 8-hour Act of 1919 were easily repulsed; in the Netherlands, though the 45-hour week established by law became 48 hours for certain branches of industry and commerce (and thus was brought to the international normal) exceptions to the latter were permitted only temporarily and to meet special emergencies. The ceding of the "Mehrarbeit" in Germany, whereby the workers in certain industries agreed to work additional hours, usually four to six per week, without demanding an increased rate of pay for these hours, was their contribution towards improving the situation brought about by the necessity of reparations payments. It led directly to a corresponding extension of hours in the neighbouring and competing heavy iron industry of Polish Silesia (declared by the Government to be temporary and dependent on the German situation), and



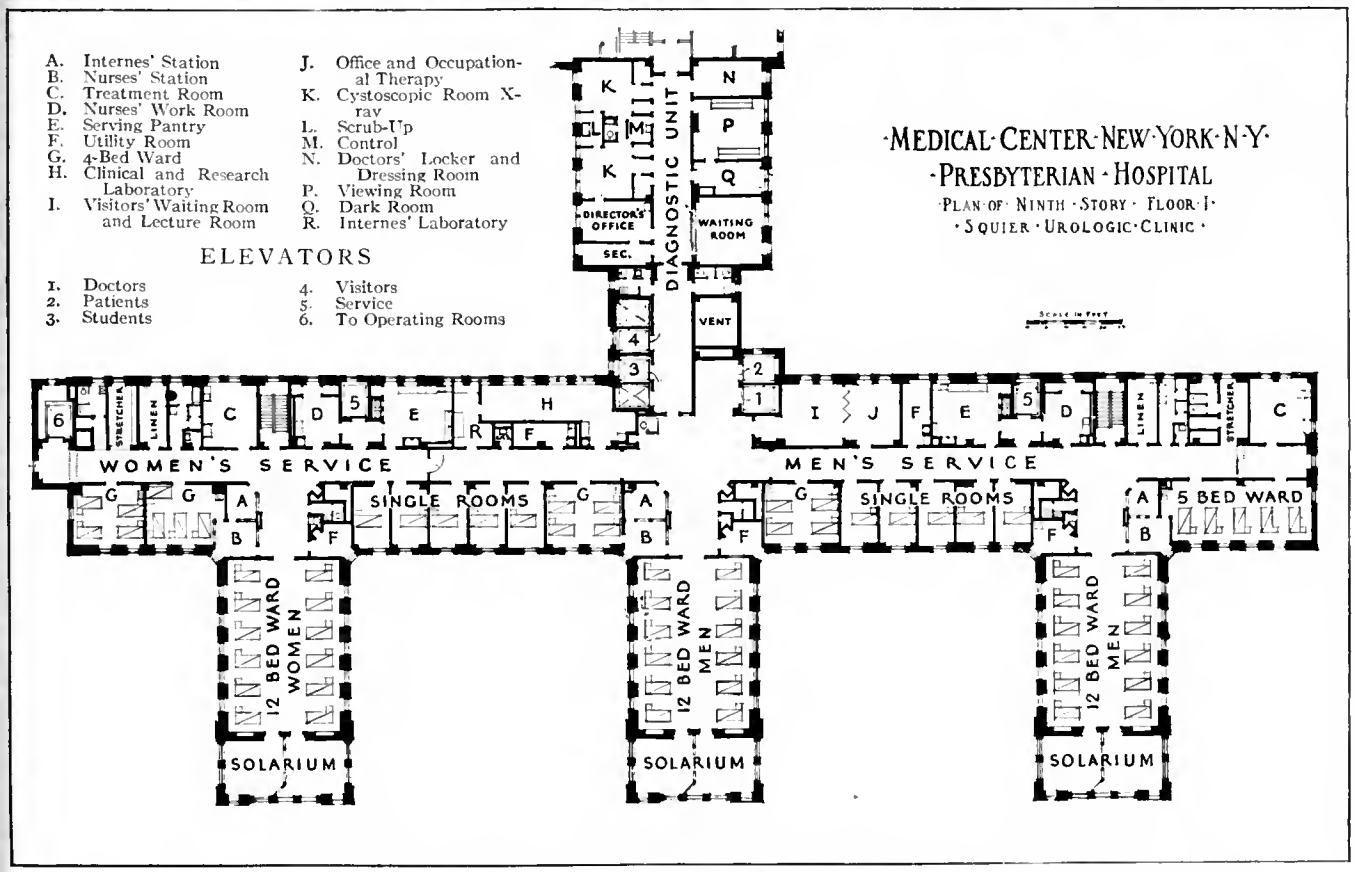


FIG. 1. Sketch Perspective:—typical example of American "Skyscraper Hospital."
FIG. 2. Floor plan of the same.

used difficulties, without however actually bringing about extension of hours, in Czechoslovakia. The "Mehrarbeit" is only temporary: a statement of the German Minister of Labour in March 1926 showed that less than 500,000 industrial workers out of a total of 12,000,000 workers covered by collective agreements worked normally more than the 48-hour week. The position in Poland was amended *pari passu* with the improvement in Germany. From Aug. 1925 the extensions permitted, which allowed in certain branches of industry a 10 instead of an 8-hour day, were gradually withdrawn, and the situation at the end of 1925 was nearly normal.

The "8 and 48" rule maintained itself as a "standard," and in some quarters was even held to have the demerit of many standards, since movement towards it may be from below 48 as well as from above it. The Netherlands 45-hour week became in effect a 48-hour week; the Polish 46 was in the same danger.

A working week of less than 48 hours is not uncommon. Rigid application of the 8-hour day in combination with the "English week-end" leads to a 44-hour week, which became the legal industrial limit in New South Wales and Queensland from Jan. 1926. West Australia, however, rejected a bill to this effect. In Great Britain working hours (except in regard to women and children, mine-workers and employees in certain "sweated" trades) are not regulated by law, but by collective agreements. Very many such agreements provide for a week shorter than 48 hours. In the metal trades, wood-working and furniture, and the engineering and shipbuilding it is 47; in building generally 44; in textiles, whilst most agreements provide for 48, the frequent practice is to work 45 or 46. A proposal by the engineering employers in July 1925 to extend the working week from 47 to 50 in view of foreign competition met with no success, and a similar proposal made for the same reason to extend the miners' working day from seven to eight hours was not supported by the Commission which enquired into the conditions of the coal industry in 1926. Attacks in 1924 and 1925 on the Polish 46-hour week similarly failed, though their basis was the opportuneness of a return to the "normal" 48.

It would seem fairly clear that the rule is to be maintained, and not merely as a standard, but as a maximum. It seems to be a stage definitely gained, from which further advances in social progress may be made as conditions permit.

Application of the "8 and 48" rule.—In fact the "8 and 48" rule is now very generally established for industry throughout Europe, including Soviet Russia, either by law or by collective agreement. The details of its application vary. It is not universally applied to all factories and workshops; in Sweden and Switzerland it is not applied to very small establishments. Nor is it equally rigidly enforced: factory inspection, which is very efficient in Germany, the Netherlands, Belgium, Great Britain, Czechoslovakia and the Scandinavian countries, is much less efficient in France and Italy and virtually non-existent in certain other countries. Its application depends, too, upon the vigilance and consciousness of the trade unions. Where they are strong, law or collective agreement is valid in practice; where weak, both employers and workers can often offend against either with comparative impunity. Nevertheless, such dependable statistics as are available show a high degree of uniformity in the average hours actually worked in corresponding industries in the various European countries; and, at least in the great industrial states, arguments concerning unfair competition based on alleged differences in hours—except in rare and unusual cases—should be very carefully examined before being accepted.

The rule holds too in the British Dominions generally, though again with differences of application, and has recently made much progress in the United States, where however it tends to take the form less of a fixed maximum than of a "basic" rule for the determination of wages. A decision (1925) of the Railroad Board, for example, provides that all hours worked over eight in the day shall be paid for at increased rates; thus the 8-hour day is accepted as the normal whilst the working of additional hours is not prohibited. This is in agreement with the International Convention of Washington, which makes no attempt to restrict overtime internationally further than to insist on an overtime rate of 25% above the normal. In South America, wherever legislation on the subject exists, the "8 and 48" rule prevails.

In the important industrial states of Asia the working day and week are normally longer than in the countries hitherto mentioned. Progress in the reduction of hours except in India has been slow. The reluctance of Japan to reduce her working hours is probably the main factor in the situation. A second is the confused state of China, where factories working 12 and 14 hours a day exist side by side with others which have introduced and 8- or 9-hour day. An attempt to reduce hours by general agreement in certain Chinese cities, notably Shanghai, met with partial success only. Persia has not many industries susceptible of regulation in this matter; in her carpet industry, which employs numbers of children, sometimes of tender years, hours are restricted to eight daily. In Palestine, although legislation was lacking, the immigrant Jewish population, which brought with it the industrial concepts of Europe, secured for itself by agreement with the employers the almost complete application of the "8 and 48" rule, which it endeavoured to extend to the Arab workers. In 1925 Turkey adopted legislation providing for a 60-hour week—the first limit imposed by statute—to include the time necessary for prayer and for the cleaning of work-places and machines. Miners work a 6-hour day.

Hours of Labour in Asia and Africa.—Recently increased attention has been paid to the question of the working hours of native races not yet accustomed to the regularity demanded by modern conditions and now forced upon them in the rapid development of many hitherto untouched areas. Plantations, mines, road and railway construction and even factories are making enormous demands upon the native populations of, for example, Central Africa, and the transition to modern industrial conditions appears to be very difficult. Many experts in colonial affairs hold that an 8-hour day for many of these natives is much too arduous; yet much longer hours are often exacted. The mortality rates among native workers are disquieting; in recent years rates of 8 and 10% per annum have been recorded in Africa, and these in areas where supervision is better than the average. Some attempts have been made to meet the situation; hours are limited to eight in certain African mining areas; the immigrant Chinese workers in Samoa (under mandate to New Zealand) have an 8-hour day, and it is becoming regular both in Asia and in Africa that, where workers are engaged under indenture or contract, the number of daily working hours (usually eight) shall be inscribed in the indenture. In the more important islands of the Dutch East Indies hours are regulated by law, or are prescribed in indenture. It is clear, however, that the problem of the utilisation of the labour of these peoples without injury to their physique and their numbers is far from being solved, and that the question of their working hours has not yet been sufficiently examined.

Exceptions to the "8 and 48" rule.—The "8 and 48" rule clearly cannot be and is not applied to all industrial occupations indifferently, and some have been excepted from its application both in national and international legislation. Among the difficulties of application is the redoubtable scourge of the 12-hour day in certain continuous processes, and in some seasonal industries. The two-shift system in continuous processes is replaced, in the International Convention on hours, by that of three shifts: the 12-hour day and 84-hour week thus becoming the 8-hour day and 56-hour week. This change, which involves a large increase of staff, has been strongly resisted, and has not yet been inscribed in all national legislations; but the old system is disappearing, even in the United States, where the two-shift system and the 12-hour day were specially prevalent. In some seasonal occupations, notably in the sugar beet industry in Europe, the great difficulty of bringing more temporary workers and accommodating them near their work for the 10 or 12 weeks of the "season" has prevented the reform in some areas; in others where conditions are more favourable, it has been carried out in spite of the handicap in competition involved; the social advantages have triumphed over the economic disadvantage.

The distribution of work over the days of the week implied in the "8 and 48" rule may not always correspond, not only to the economic needs of a particular case, but to general changes of opinion on these matters. The English week-end (short Saturday), for example, has become much more general over the continent of Europe; it is the rule in the British Dominions and in the United States and spreading elsewhere. It is not consonant with a strict application of the 8-hour day and the 48-hour week, and has led sometimes to the institution of a 44-hour week, sometimes to the working of more than eight hours on some days to compensate for the shortened Saturday.

A relatively new development—the five-day working week—shows signs of becoming popular. In certain industries it has long been the practice, in Great Britain, France and other countries, to complete the working week in five days, since the overhead expenses made it uneconomic to work a short Saturday of four or five hours. In Great Britain, especially since the War, with the consent of employers and workers, the practice extended, notably in boot and shoe factories and chocolate works where it is almost the normal, and it appears to be favourably received even where the economic argument is not perhaps so powerful as in the industries (*e.g.*, dyeing) to which it was first applied. The social attractions of the five-day week begin to outweigh the disadvantages involved of a 9- or 10-hour working day.

II. IN COMMERCE, AT SEA AND IN AGRICULTURE

Hours of Labour in Commerce.—In commerce, legislation on hours of labour generally belongs to the post-War period. The increasing development of the large departmental store has changed fundamentally the position in the shop-keeping world and has forced the regulation of working hours, either by legislation or by collective agreement.

In Great Britain both methods have been used, but the Shops Act of 1912 affects only the labour of young persons under 18 and provides for a maximum working week of 72 hours (including rest periods). Collective agreements and general practice have largely superseded the provisions of the Act. Few employees of large urban establishments now work 72 hours in the week, some only 43. The agitation of the organisations of shop-assistants for reduction has been generally successful. The obstacles to progress are the numerous small establishments which are frequently managed by their owners and have few or no paid workers in the ordinary sense; it is considered unjust to compel establishments which have employees to close whilst leaving open the small shops of the owner-workers. There is also the difficulty of changing the shopping habits of the general population.

Certain British regulations on closing hours adopted during the War period have not given general satisfaction. Nevertheless, many European countries have introduced legislation: Austria (1919), Czechoslovakia (1918), Finland (1917), France (1919), Germany (1923), Italy (1923), Poland (1919), Portugal (1919) and Russia (1922) have each adopted Acts which fix the normal working week in commercial establishments at 48 hours. In the Netherlands, the law of 1922 imposes 10 hours per day and 55 per week as maxima. In the other cases the 48-hour week seems to be rather the principle than the practice. The legislation itself provides for numerous exceptions and in a very much more elastic manner than is general in industry.

In Germany the hours may be lengthened by collective agreement between workers and employers, or by the judgment of an arbitration court, and the 48-hour week in commercial establishments is probably rather the exception than the rule. In Czechoslovakia, the law is seldom strictly applied. The French Act of 1919 permitted the application by decree of the 8-hour day and 48-hour week not only to industry but also to workers in shops and offices. A number of decrees have been issued, affecting for example employees in banks and public offices, and shop-assistants. Most of these decrees are regional in their application: it has been found easier to regulate hours in the larger towns. The decrees affecting industry (now covering all but very minor branches) cover the commercial workers attached to the industry (clerks and employees in the offices) also. In Italy a similar system of regulation is in effect in the larger towns.

A vast amount of local legislation, by-laws, etc., govern this matter, shop-keepers themselves very often fixing closing hours through their associations. Very little of this form of regulation however is definitely based on the notion of restricting working hours for employees; other factors enter into account.

Hours of Labour at Sea.—The seafarers' hours are still more difficult to regulate and relatively little national legislation on the question exists. The different categories of workers employed on a modern vessel, and the difference in the effort demanded of them is one cause of difficulty; another is found in the risk attached to the sea-service and the necessity of abandoning all regulation in time of stress. Yet a third arises, curiously enough, in the seaman's problem of what to do with himself on board ship when he is neither at work nor asleep. This latter is gradually being overcome by the more satisfactory conditions now insisted upon by many states in regard to living accommodation on board.

The vast majority of seamen, including the British, have obtained regulation of hours by means of collective agreements, but in many cases the legislatures have intervened. The most interesting, and probably the most successful interventions, are the Acts of Finland (1924), Norway (1919) and Sweden (1919). These divide the personnel of a vessel according to the nature of its work: the engine-room staff is required to do not more than 16 hours work in two consecutive days, whilst the ordinary seaman works not more than 24 hours in the same period. Other arrangements are made for small vessels, for cases where the crew is not divided into watches, for coastal traders and for work whilst in port. These Acts seem to have been fairly satisfactory in application, though the seamen concerned demand a reduction of the hours prescribed. A French decree of 1925 extending the application of the 1919 general Act to the sea service provides alternative methods, either an 8-hour day may be worked, or a 48-hour week, irregularly divided as regards the daily limit or an averaging of hours over a month, the 8-hour average being conserved. These hours are subject to exceptions to meet sea emergencies. Greece in 1923 extended her general labour legislation by decree to cover sea workers, but it does not appear that her hours legislation, which is somewhat special and not applied as yet to all land industries, has been adopted at sea. In Portugal working hours are regulated by a decree of 1923; whilst in port the 48-hour week is maintained, at sea the hours for the deck staff and for stewards and pursers are 84, and for the engine-room 56. A Spanish decree of 1919 lays down as maxima a 10-hour day for officers, 12 for ordinary seamen, and 8 for the engine-room crew. In Yugoslavia a decree of 1924 provides a 10-hour day and 60-hour week. Uruguay has applied the 48-hour week and Argentina has under consideration the question of the regulation of hours at sea by legislation. Denmark is revising her maritime legislation upon the lines of the Finnish, Norwegian and Swedish Acts.

The French decree above mentioned makes an important new departure in defining "hours of *effective* work." An Act of 1919 on which this and earlier decrees were based had stipulated the 8-hour day, but in practice and by a decree of 192 it had been construed that 12 hours of presence were held to constitute eight hours of *effective* work. In 1925 the Council of State found this to be abusive and defined "hours of effective work" as "the time during which the crew are, in consequence of an order given, at the disposition of the captain and away from their ordinary living quarters." This very important and far-reaching decision will have its effects on other national legislation and agreements, including probably the projected legislation under consideration in Germany and the Netherlands. In both these cases the proposed reforms are stated to be based upon the principle of the 8-hour day.

In Great Britain the matter is dealt with solely by collective agreements, which are exceedingly complicated and not universally applicable. They are not so much intended to limit the hours of labour directly as to secure that overtime rates are paid after a daily "normal" has been reached, and thus to penalise employers who exact the longer day. Emergency cases (of which the master of the vessel is sole judge, and which may be cases of salvage, fog, fire, stranding or other circumstances affecting the safety of the vessel) are not usually affected by these overtime pay arrangements. In general, the agreements provide for overtime rates when the working day in port exceeds eight hours, with special arrangements for Saturday (five or six hours) and Sunday (ordinary necessary routine work up to four hours), and for days of arrival and sailing. At sea the ordinary system of watches results in a longer day being worked, except for the categories known as day-workers (*i.e.*, those who normally work only during the day) who have similar hours to those detailed above.

This may be taken as fairly typical of the terms arranged by collective agreement, not only in Great Britain but elsewhere in countries where legislation has not been adopted. The Australian and New Zealand seamen however have secured better terms. By agreement they have a strict 8-hour system which is probably the most favourable to the workers yet obtained anywhere; the question of its consecration in legislation is stated to be under consideration.

Hours in Agriculture.—The attempt to apply the regulation of hours of labour to agriculture has aroused keen controversy. Legislation on the subject is still experimental, and a perfect system has yet to be devised. Little or no legislative regulations existed before 1918, though Ecuador in 1916 passed an Act that "No labourer . . . engaged in agriculture shall be compelled to labour more than eight hours daily, six days per week." Information as to the successful application or otherwise of this law is lacking. Where so much depends upon the seasons and the weather, and where the care of animals and crops makes demands that have often little reference to a time-table, the regulation of hours is complicated and difficult. Nevertheless it has been more or less scientifically attempted by law in several countries, and has come into practice by agreement in others.

The German regulations, issued under the provisional Agricultural Labour Act of 1919, make a serious attempt to deal with the question of seasonal variation of work, prescribing daily maxima of

0 and 11 hours during three four-monthly periods into which the r was divided for this purpose. Time spent in travelling to and n the farm is calculated as working time—another point which caused much difficulty in agriculture and in other occupations. n Czechoslovakia, the Act of 1918, which introduced the 8-hour very generally, seems to have become in practice an Act for reasing wages, so far as agriculture is concerned. There does not pear to be in fact any limit upon the hours worked, but overtime es must be paid for hours worked beyond an average of eight day. Portugal (1922) prescribed a maximum working day. tonia (1921) prescribed a maximum yearly average of nine hours ly, Austria an average of 10 in Lower Austria; in Upper Austria, e consecutive hours of rest and two hours for meals are provided , the possible working hours being thus limited. An Estonian t of 1921 created district joint commissions which were empowered agree upon hours, with a maximum of nine daily on a yearly aver- ; it is stated however that these commissions do not work well, d that the hours situation is confused. The Spanish decree of 19 does not appear to be rigidly applied, and little information available as to the working of a Costa Rican decree of 1920. In th cases the 8-hour day was the basis of the systems laid down. In Italy collective agreements from 1900 onward specified gener- y "from sunrise to sunset" as the limit of working hours, with t periods of from three to four hours during the summer day and orter ones in spring, autumn and winter. In April 1919 an agree- nt was made in regard to day-workers (mostly the seasonal rkers employed in rice cultivation) providing an 8-hour day, with gher rates for overtime. The collective agreements made between 00 and 1923 secured progressively favourable conditions for ricultural workers; the advent of Fascism however changed the stem fundamentally and the rural custom of collective bargaining ems virtually over. Alongside the system of agreements in Italy a gislative code governs hours in agriculture. The migratory workers the rice areas, who are mostly women, were the subject of legisla- on as early as 1866, and their hours are now determined (apart om the results of collective agreements) by regulations of 1908 sued under the Public Health Code of 1907, which prescribe a 10- ur day for workers resident on the rice estates and a 9-hour day r others. Other agricultural workers (day-workers and those with fixed annual salary) are further covered by a Royal decree of 23, issued in pursuance of a Legislative decree of the same year, hich lays down the 8-hour principle but permits a 10-hour day dur- g a period not exceeding three months in the year.

In England and Wales legislation does not directly affect hours, ut the Agricultural Wages (Regulation) Act of Aug. 7 1924 regu- tes them indirectly and indeed has given the best results of legis- tion in any country. The District Committees set up under the ct have the power of fixing weekly wage rates, and in so doing they ave based the rates upon a certain number of hours of work per eek, in general between 48 and 52, but in some cases extending to 2. Longer hours than these are indeed worked, but must be paid r as overtime, and are thus avoided or reduced to a minimum wher- ver possible with suitable arrangement of hours. The agricultural orker here further enjoys the "guaranteed week"; he is guaranteed he full minimum week's pay even though weather or other condi- ions make it impossible to work the total number of hours. This uarantee of pay in occupations where irregularity of hours is a eature, may prove a solution of much difficulty. It exists on the ritish railways, and in a modified form at the docks. Excepted rom the guarantee in agriculture are, in general, female workers, whose wages are usually fixed on a casual hourly basis.

Collective agreements are not ruled out by the British legisla- ion quoted, and in fact play a large part, within the framework provided by the work of the District Joint Committees, in the ixing of hours.

III. INTERNATIONAL ACTION

The Washington Convention.—The standard "8 and 48" rule was consecrated in the Convention on Hours in industry adopted by the first session of the International Labour Conference, held at Washington in 1919. Its adoption was based upon general prac- tice at the end of the War and upon the resolutions of many in- ternational congresses and conferences of previous years, as well as upon the opinions of governments expressed in the documents prepared for this session. The Convention provides, in brief, for an 8-hour day and a 48-hour week in industrial establishments of all sizes except in workshops where only members of the same family are employed. It makes special provision (eight hours daily and 56 weekly) for continuous processes; it permits more than eight hours daily where a short Saturday is worked; it allows excep- tions of a permanent nature for workers whose duty it is to pre- pare beforehand for the general running of the establishment, as for example enginemen in a factory, or who must be employed for a time after the general work of the establishment has ceased, and for intermittent work; it provides also for exceptions of a temporary nature to meet unusual pressure of work. By a special and very elastic Article it permits the 48-hour week to be ex- ceeded, provided the average of 48 is maintained over a period of three weeks or more, where the ordinary rule is not capable of application. It leaves overtime to be regulated by the states themselves, stipulating only that employers and workers shall be consulted, and that an overtime rate of not less than one and a quarter times the normal rate shall be paid.

Since 1919 the question of the ratification of this Convention by the State Members of the International Labour Organisation has been the predominant issue in international labour affairs. By March 1926 Bulgaria, Chili, Czechoslovakia, Greece, India and Rumania had ratified it unconditionally and Austria, Italy and Latvia conditionally upon the ratification of certain other countries. In Brazil, Denmark, Estonia, France, Germany, Lithuania, the Netherlands, Poland, Spain and Uruguay the governments concerned had recommended its ratification to their Parliaments, but the latter had not yet signified their approval. The great European industrial states were still hold- ing back, as was Japan. In India, which had ratified the Conven- tion and materially reduced her working hours in consequence, employers and workers alike continued to protest that, with Japan refusing to reduce her working hours, amelioration in India and China was impossible. The great European states were reluctant to bind themselves unless assured that their industrial competitors would be equally bound. At first some governments held that the provisions of the Convention were too rigid; then, that they were too elastic, and that their ratification and applica- tion would not necessarily, owing to different interpretations of their terms, lead to uniformity of action. Hence the conditional nature of the ratifications of Austria, Italy and Latvia and hence also similar conditions inscribed in the bills for ratification sub- mitted to the parliaments of certain other countries.

In Great Britain, difficulties of another nature hindered the progress of a bill for regulating hours and making possible the ratification of the Convention which was introduced by the Gov- ernment of Mr. MacDonald. It was held in some quarters that the existing agreements regulating the hours of work on railways could not be brought into accord with the Convention; the rail- way employees were reluctant to change these agreements, and the Government therefore hesitated to take action which might, it was thought, precipitate a crisis. Differences of interpretation were possible also on various other points and consequently, in order if possible to arrive at agreement upon them before ratifi- cation, a meeting of the Ministers of Labour of Great Britain, Belgium, France and Germany was held at Berne in 1925. The meeting was partially successful, but the British Govt. decided to convoke the same ministers, with a representative of the Ital- ian Govt. in addition, to a conference in London in March 1926.

The London Agreement, 1926.—At this meeting, which was prepared for by the circulation to the governments concerned of a memorandum on the points at issue, to which all replied, complete agreement was reached on all the issues raised, with one exception mentioned below. This agreement, signed by all the Ministers present, is likely, to have far-reaching effects on the fate of the Washington Convention and on the question of industrial working hours in general. It covers the following points:—

Working hours are defined as those during which the workers are at the disposal of the employer; deductions for rest pauses and breaks, except scheduled breaks for meals, are therefore not possible, and this decision disposes of much controversy on the question of "effective" working time and the system of grading occupations in accordance with a scale. This is made even clearer by the agreement upon a definition of "intermittent work," the effect of which is to confine the application of this term to such occupations as those of door- keepers and watchmen which "are not concerned with production properly so-called and which, by their nature, are interrupted by long periods of inaction during which these workers have to display neither physical activity nor sustained attention, and remain at their post only to reply to possible calls."

The Conference further agreed upon matters concerning the five- day week (see above) the regulation of overtime, and overtime pay (with the agreed minimum of 25%), the working of railways (thus removing an important British difficulty), and the recuperation

of time lost by holidays. On all these questions opinion was unanimous, but on one last point—the possibility of the suspension of the application of the Convention "in the event of war or other emergency endangering the national safety"—the British Minister reserved approval pending consultation with his Government.

The conclusion of this agreement removed many important difficulties in the way of ratification of the Convention by the European industrial powers. The ministers undertook to report to their Governments, which could then proceed with their consideration of the question of ratification. In the cases of Great Britain and Germany, at least among these Powers, it would be necessary to secure the adoption by the parliaments of new legislation, and in France and Italy new administrative measures would be required. If these difficulties could be overcome, and the ratifications of the five countries registered (simultaneously or otherwise) the international position of the "8 and 48" rule would be secured.

Protection.—The Berne and London Conferences of Ministers of Labour were reflections of the preoccupations of the governments and of the employers more directly than of the workers, who meanwhile formulated and discussed other policies in regard to the Washington Convention. In British trade union circles, for example, the revival by the Safeguarding of Industries Act of the policy of protection gave rise to the proposition that what workers should be more precisely protected against is that form of unfair competition which consists in exploiting their fellow workers abroad, and that the only form of "protection" acceptable to the workers as a whole would be one which would differentiate against goods produced by such methods and, in particular, by the exaction of excessive working hours. The adoption of such a policy, it is claimed, would give a powerful weapon to the more advanced states and enable them to insist on social progress in other countries whose backwardness retards the general advance in welfare. Similar ideas inspired the Austrian Social Democrats who carried in the Lower Chamber a resolution to increase import duties by one-third in the case of goods coming from countries where the conditions of employment, particularly in the matter of hours, were not satisfactory.

In the international field the same ideas appear to be gaining ground. In 1925 a joint committee of the International Socialist Congress and of the International Trade Union Congress decided to examine the possibility of a system of boycott applied to goods manufactured in countries where the Hours Convention is not observed. Later on in the same year a committee of the British Labour party published a report recommending such a boycott, which, it was stated, was not without precedent. Books which contravened the law on copyrights, and goods manufactured in foreign prisons cannot be imported into Great Britain; the great chocolate manufacturers have agreed not to purchase slave-grown cocoa. On the same principle, goods produced under conditions inimical to the worker should, it was argued, be refused admission. These proposals indicate a tendency which may develop as Labour or Socialist Govts. become more general and as the interdependence of states one upon another in the matter of social amelioration becomes more widely recognised. The Washington Convention affects industry only; hours in commerce, agriculture and employment at sea are not as yet regulated by any international convention.

Commercial, Maritime and Agricultural Hours.—The International Labour Conference has not yet considered the question of working hours in commercial undertakings. In 1920 a draft Convention instituting the 8-hour day, with suitable modifications, for seafarers was lost at the Conference of Genoa by a fraction of a vote. Since then the question has been the subject of constant negotiation between seamen and shipowners, and the organisations of the former, national and international, have decided (1926) to urge that the subject be placed again on the agenda of the Conference. The Conference at Geneva in 1921 held the moment not ripe for the regulation of hours in agriculture. Indeed no proposal to limit working hours in agriculture in the precise way which is possible in industry was ever put forward. Agricultural conditions do not lend themselves so readily as do those of industry to the fixation and limitation of hours, but it seems probab that international action in the matter cannot be long delaye the hours exacted from agricultural labourers in many countri are unconscionable and are a powerful factor in bringing abou the very active migration to the towns, which is a troubleson social problem in almost all modern states.

Charter for Native Labour.—Equally pressing is the need f international action in regard to the hours of labour exacte from subject populations in colonial areas. Here again the i creasing force of competition makes it difficult for one countr to advance in this as in other social matters unless neighbourin areas move forward also; yet it is probably true that the sufferin entailed by delay is more intense and the economic waste and lo is relatively greater in these areas than in the countries where th population is capable of defending itself. As has been said above local legislation has made a beginning and on the basis thus pr vided it seems possible that international action may be earl called upon to build. The discussions on the Draft Conventio on Slavery adopted by the Assembly of the League of Nations i 1925, though it did not enter into the details of the regulatio of native labour, showed clearly enough that there was a wide spread feeling that a "Labour Charter" for native peoples wa an urgent necessity. The resolution of the Assembly whic called the attention of the International Labour Organisation t this necessity will not, it is to be supposed, remain without effect and undoubtedly the hours question must be one of the first, a it is one of the most important, to be dealt with by the member of the League of Nations.

REFERENCES.—The texts in English, French and German of mos of the Acts cited above, and in general of Acts relating to Hours o Labour, are published by the International Labour Office in it "Legislative Series." Monographs on the hours situation in a num ber of important countries have been issued from the same source For the general situation in regard to the Convention of Washington see the Directors' Reports to the successive sessions of the Inter national Labour Conference since 1919. The text of the conclusion of the London Conference of March 1926 was published in the *Times* of March 20. For hours of work in agriculture (England and Wales) see Report of Proceedings under the Agricultural Wages (Regulation) Act, 1924, issued by the Ministry of Agriculture and Fisheries. (H. A. G.*)

HOUSE, EDWARD MANDELL (1858–), American statesman and diplomat, was born at Houston, Tex., July 26 1858, the seventh son of Thomas William House and Mary Elizabeth Shearn. His father, who had left England as a boy, came to Texas when it formed part of Mexico, joined the revolution, and helped to free it and bring it into the Union. The younger House was educated at the Hopkins Grammar School and Cornell University, and returned to Texas in 1880, where he lived for more than 30 years as planter. His chief interest, however, was public affairs. He took an influential part in the successful campaigns of Governors Hogg, Culberson, Sayers and Lanham, and during the period 1894–1904 his political influence in Texas was regarded as decisive.

He refused invariably to become a candidate for office himself, but he acted as the intimate adviser of the several governors named. Although frequently urged to participate in national politics he remained aloof from the disastrous Democratic campaigns that followed the Bryan candidacy of 1896; but in 1912 he played a major rôle in securing the nomination of Woodrow Wilson, and at the time of the election Wilson had come to put full trust in him, offering him a choice of Cabinet positions. Following his custom, House refused any office, but politically as well as personally he remained closer to the President than any member of the official family. It was upon his recommendation that Wilson chose a number of his Cabinet; after the inauguration both President and Cabinet utilised his wide knowledge of men and his shrewd estimate of political effects to help them in meeting legislative and administrative problems; he exercised a great influence in the framing of the Federal Reserve Act and also played an important part in the organisation of the original Federal Reserve Board. Wilson spoke of him as his "independent self."

House's chief interest lay in foreign affairs, and through close ntact with American ambassadors abroad and his intimacy h European statesmen, as well as the confidence of the esident, he was able to influence the course of American reign policy. In 1913 he helped to tide over the crisis in ations with Great Britain over the Panama tolls exemption til Wilson secured the repeal of the exemption. In 1914 he dertook formal negotiations with the diplomatic representa- es of Argentina, Brazil and Chile, which led to the drafting a pan-American pact designed to guarantee peace in the estern Hemisphere. The proposed pact was never translated to a formal treaty, but it was of historical significance as arking an initial step in the development of Wilson's policy of eating a League of Nations. In the spring of 1914 House, ap- ehensive lest war should break out in Europe, sailed for ermany to offer the assistance of the United States in reaching me arrangement between England and Germany which might oid war. He talked with high officials of the civil Government, e army and navy, and had a conference with the Kaiser, in hich he received some encouragement. William II. later said:— The visit of Colonel House to Berlin and London in the spring 1914 almost prevented the World War." At London he found r Edward Grey ready to entertain any feasible plan to preserve eace. This, House wrote to the Kaiser on July 7 1914. The urder of the Archduke Francis Ferdinand, however, pre- pitated war before the plan could be developed.

Returning to the United States, House maintained close in- macy with the British and German ambassadors and thus elped to smooth American relations with the belligerents. n Jan. 1915 Wilson sent him abroad to study the possibility f American mediation. He suggested the principle of the Freedom of the Seas," after visits to London, Berlin and Paris, s a possible step towards a compromise; but the sinking of the Lusitania" ruined all chances of success. In the autumn, House proposed that Wilson suggest to the Allies that a peace onference should be summoned; if Germany refused the con- erence or rejected terms calculated to ensure a just settlement, he United States would enter the War on the side of the Allies o enforce such terms. House left for Europe again in Dec. 915, visited England, Germany and France, and finally made he aforesaid offer to the British, the substance of which was ncorporated in a memorandum drafted by Grey and himself. The Allies, however, refused to take advantage of it.

In the summer and autumn of 1916 House took an influential art in the campaign which led to Wilson's re-election. At the ime of the "Sussex" crisis and the German Peace Note of Dec. 916, his private negotiations with Bernstorff were of high im- portance. After the United States entered the War, he kept in lose touch with the chiefs of the war-making agencies, and was in consultation with the special envoys of the Allies: Balfour, Northcliffe, Tardieu, Reading. In the autumn of 1917 Wilson named him chief of the special American mission designed to co-ordinate Allied war needs, especially the problems of finance, supply, tonnage and man-power. The conferences in London and Paris which he attended proved to be the turn of the tide. After his return he was intimately concerned in Wilson's drafting of the Fourteen Points, and at the request of the President he drafted a tentative covenant for a League of Nations, which formed the basis of Wilson's later plan. In Oct. 1918 Wilson sent him to Paris to represent the United States at the Allied Council which granted an armistice to Germany.

After some difficulty, House succeeded in pledging the Allies to Wilson's Fourteen Points as a programme for peace. He had previously organised "the Inquiry," a body of experts for collecting authentic data for the use of the Peace Conference. House was one of the U.S. Peace Commissioners signing the Treaty of Versailles, and although ill at the opening of the conference he played an important rôle by reason of his intimacy with European statesmen. He was a member of the commission that drafted the League of Nations' Covenant, and ultimately most of the details connected with the formation of the League were settled with his co-operation. In July and Aug. 1919 he represented the United States in the organisation of the Mandates system. After his return to the United States he urged President Wilson, by letter, to compromise with the Senate so as to secure ratification of the Versailles Treaty and the entrance of the United States into the League. A serious illness, coming at the same time as the physical breakdown of Wilson, combined with other factors to interrupt the close relations between the two men which had persisted since 1911.

Col. House had won a reputation for such sagacity and disinterestedness that his advice was continually sought by political leaders even after the overthrow of the Democratic party in 1920. Arthur Griffiths asked that he be named arbiter in the Anglo-Irish dispute. He continued his interest in international questions and maintained close relations with the ruling statesmen of Europe.

In 1912 House published, anonymously, a political romance, *Philip Dru;* in 1921 he edited (with Charles Seymour) *What Really Happened at Paris*, a series of essays on the Peace Conference written by members of the American Delegation. He also wrote, after 1920, a number of articles upon contemporary politics and political leaders for *The Philadelphia Public Ledger*, *Foreign Affairs*, *Harper's* and *The Encyclopædia Britannica*.

BIBLIOGRAPHY.—*The Real Colonel House*, by A. D. Howden Smith (1918), a brief but accurate biography covering House's career to 1918; *The Intimate Papers of Colonel House*, arranged as a narrative by Charles Seymour (1926). (C. SEY.)

HOUSEHOLD APPLIANCES.—The working equipment for the household has achieved a new importance in recent years. In the 19th century, labour-saving machinery was adopted in industry; the 20th century has witnessed a progressive application of such machinery to the work of the household, the most important advances falling within the period following 1910. This change is little indebted to the initiative of the housekeeper herself, although a growing desire for the elimination of drudgery, together with a scarcity of domestic help, has provided an incentive to the engineer and manufacturer to meet this need with numerous mechanical devices.

The wide adoption of such appliances has owed much to the increasing availability of electricity for power and to the development of automatic machinery and standardised methods of production. A large part in their distribution has been played also by advertising, demonstrations in stores and the home and similar methods employed by manufacturers to make known their products. A number of manufacturing and distributing plants, including gas and electric-light companies, especially in the United States, are now maintaining home-service departments directed by women trained in home economics.

Schools and colleges, and also government departments, have been giving attention to the subject of household appliances during recent years in the United States, Canada, Great Britain and, to some extent, in other countries. A significant factor in this development of household devices, in some of the English-speaking countries, has been the work accomplished by enterprising home magazines that have established service bureaux, and also laboratories for the testing and investigation of household appliances.

ELECTRICITY IN THE HOME

The outstanding feature in the development of household appliances, during the period under review, 1910–26, has been the greatly extended use of those operated electrically. This fact in turn has had an important bearing on one aspect of house construction, namely, the wiring, which is increasingly ordered with a view to the use of electrical appliances. This involves the installation of a large number of appliance outlets, properly placed, instead of a limited number of lamp sockets. In districts where electricity is very cheap, houses are being wired with circuits of high current capacity to provide for electric ranges and certain other cooking devices which cannot be used on ordinary circuits. There has been a general improvement in the fittings or fixtures, such as switches, sockets, plugs, etc., the restrictions of regulatory bodies having helped to main-

tain minimum standards which in practice have been exceeded by the better manufacturers. Attachment plugs have largely been standardised, thereby ensuring the same interchangeability in appliance connections as appertain to incandescent lamps. In the United States the parallel blade plug is superseding all others.

The electric curling iron is reputed to be one of the oldest, if not the oldest, of electrical appliances. In 1926, however, the electric flat iron had a far greater sale than any other electrical appliance. The electric toaster leads in the field of small table devices, but there are many others which find a place in the kitchen or dining-room, such as percolators, table-stoves, grills, hot plates and waffle irons. The general use of nickel chromium resistance wires, introduced about the year 1910, assured the practicability and therefore the beginning of a really extensive use of electric heating appliances. These alloys can be heated to redness in the air without oxidation and the physical properties of ductility and malleability they possess permit the fabrication of heating units in a wide variety of designs. The popularity of electrical heating devices owes much to the ease with which the heat may be regulated, and this is often automatically accomplished, notably in ranges, flat irons, warming pads and percolators, by means of thermostats, which may either limit the temperatures or keep them at the desired level. In some cases additional controls are provided to start and stop the current at predetermined times. In certain central house-heating plants an electric motor controlled by a thermostat operates dampers and drafts. If the fuel used is oil or gas the heating becomes, by this device, entirely automatic, but if coal is burned, refuelling is necessary. (*See* HEATING AND VENTILATION.)

Small Motors.—Among the more important factors in the wider application of electricity to household appliances has been the perfection of light-weight, efficient motors. The motor of small size and light weight has made possible portable electric vacuum cleaners, electrically driven mixers, floor-polishers, coffee-grinders, knife-sharpeners, sewing-machines, etc. Sewing-machines designed for the incorporation of a motor are portable, light in weight and easy to operate. In motor design the important problem is lubrication, because, in the household, motors frequently go unoiled for relatively long periods and their use is intermittent, often being confined to an hour or two each week. It is now customary to provide oil-wells of relatively large capacity, which do not need replenishing for long periods. In many instances ball bearings are provided, packed in grease, so that lubrication will not be required, perhaps for the life of the device, or at least until some other parts need attention or replacement, when the ball bearings can be repacked.

The tremendous increase in the use of electrical appliances in the United States during recent years has been due, in no small degree, to the almost complete standardisation of the type of current furnished for consumer supply, namely, 110 or 120 volt 60-cycle alternating. Direct current is mainly confined to a few large centres, where its use is economically feasible. In many other countries a lack of a standardised current has placed almost insurmountable obstacles in the way of a general use of electrical appliances in the household. An indication of the rapidity with which they have been adopted in the United States is afforded by the fact that the number of electric vacuum cleaners in use rose from an estimated figure of 18,000 in 1910 to 5,000,000 in 1925. In the same period the number of electric washers increased from 3,000 to 3,500,000. The number of houses wired for the use of electric current rose from 2,934,000 in 1910 to 13,406,777 in 1925. Incidentally those equipped for the use of gas increased from about 5,000,000 in 1910 to 10,720,646 in 1925.

THE EQUIPMENT OF THE KITCHEN

As regards the kitchen the present trend is in the direction of a smaller kitchen, used only for the preparation of food. In the smaller modern apartments the kitchen has become a kitchenette, with more wall space than floor space. This fact as well as the desire to obviate unnecessary motions, has led to careful planning in the arrangement of the refrigerator, work-cabinet, range and sink. The working surfaces at sink, range, work-table and kitchen cabinet have been raised to a height better adapted to the worker, that found most generally suitable for the sink being 34 in. from working bottom to the floor. The kitchen cabinet, as a valuable space saver, is growing steadily in favour in the United States, Canada and possibly in a few other countries. More recently these cabinets have been supplemented with additional storage units, a cupboard and a broom unit. Thus equipped, the cabinet really brings the storage pantry to the work-table and provides compact and convenient storage space. While it would be sounder engineering practice, as applied to the kitchen, to have in sight all tools and materials needed for daily use, popular taste apparently objects to having utensils hanging uncovered on hooks beside the proper working centre, or to seeing food containers on open shelves. Kitchen cabinets are, therefore, all provided with doors, behind which equipment and food materials are stored. These cabinets are available in so-called built-in units which may include a refrigerator, storage and broom cupboard and may be installed to form part of the permanent fittings of the kitchen. Cabinet cases and their accompanying units are usually finished in either white or grey enamel, and nearly all cabinets have porcelain-enamelled iron table-tops, usually so constructed as to permit being drawn out for use and pushed back within the general body of the cabinet when not required.

Porcelain-enamelled iron linings have become very common for refrigerators. The most noteworthy development in domestic refrigeration has been the increasing use of mechanical units to supplant ice. In the United States and Canada up to the present time the actuating part of the unit has been almost exclusively of the compressor type operated by an electric motor. In some European countries machines operating on the so-called expansion principle are coming into use. In these machines there is no motor, the compression of the gas refrigerant being accomplished in closed vessels through the application of heat. The source of heat is usually gas or electricity. Sinks are usually provided with drainboards frequently cast in one piece with the sink, the material used being porcelain-enamelled iron, porcelain or vitreous china. Combination faucets for hot and cold water have proved very convenient. As steps toward making the precision of the laboratory possible in the kitchen, the capacity of kitchen measuring cups has been standardised and thermometers have been specially designed for registering the temperature of the oven, of the fat in deep frying and of syrups in home candy-making.

Ranges.—Ranges are frequently equipped with thermostats for the automatic control of oven temperatures. In both gas and kerosene ranges, there has been a marked improvement in the construction of the burners, making possible better combustion. In England the "all-gas" kitchen, in which gas is used for cooking, heating and water-heating, is a development of the years 1915–26. The cabinet type of gas cooker or range, in which the oven is located adjacent to the cooking top, has become common in England and in the United States. Some electric and gas ovens have been constructed to utilise the principle of the fireless cooker, by which baking is done on retained heat. Another development is the improved insulated gas-range oven, designed for the greater conservation of fuel. Porcelain-enamelled iron is used for the exterior of gas ranges, and some have oven linings of this material.

Fireless cookers have been improved by the use of aluminium linings and by the employment of heated radiators producing oven temperatures for baking, the latter innovation necessitating a safety valve in the cover of the cooker to provide for the escape of steam, thereby avoiding danger of explosion. A later development was the electrically-heated cooker. The pressure cooker is employed for canning and for high-altitude cookery. In this device, the steam generated is confined within the cooking utensil and, by the increased pressure, raises the boiling point of the liquid. Cooking, therefore, takes place more rapidly and with a consequent economy of fuel.

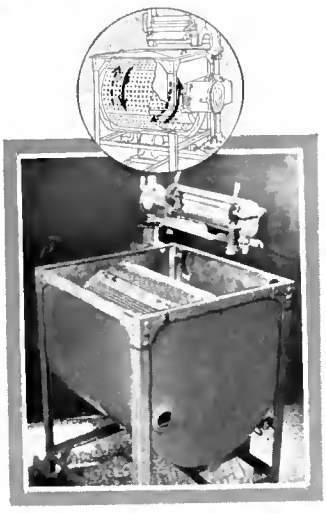
Laundry and Cleaning Equipment

This ironing-machine has an electrically heated shoe and the padded roll is revolved by a small motor. The operator's right hand is on the lever controlling the mechanism that moves the shoe away from or up to the roll. Mechanically operated ironers are rapidly superseding the older types of machines which require considerable exertion on the part of the operator in order to bring the roll and shoe together against the action of the springs which maintain the pressure. Similar household ironing-machines use gas for heating the shoe instead of electricity.

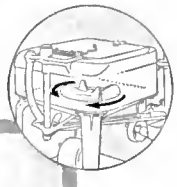
The floor scrubbing and polishing-machine above has a ¼ horsepower motor mounted on a circular base. The motion of the motor shaft is transmitted by gears and a chain drive to a brush or polishing pad under the base.

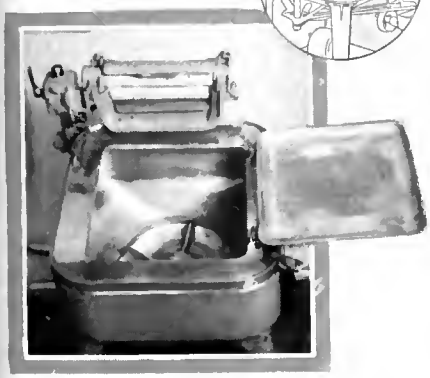
In electric suction cleaners air, moved by a motor-driven fan, enters the floor nozzle carrying dirt into a fabric bag which retains the dirt as the air passes through the pores of the bag. Generally a tractor or a stationary brush is fitted to the nozzle. Other cleaners have a brush in the nozzle revolved by the motor. Another type has a combination agitator and brush which taps the floor covering to loosen the dirt.

Obviously there are many ways to produce the relative motion between clothes and water necessary to flush the dirt out of the fabrics and in this way wash them. As a natural result many different types of washing machines have been developed. The machine at the right represents the cylinder type, in which clothes are placed in a cylindrical container having perforated sides or ends and transverse baffles to lift the clothes as the cylinder revolves. The cylinder is revolved about its axis in another container holding water to a depth about half way between the bottom of the cylinder and the axis. The motion of the cylinder usually is arranged to reverse periodically to prevent tangling of the clothes.



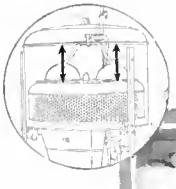
The machine illustrated at the left is an oscillator washer. In machines of this type the clothes are placed directly in the water in a tub that generally is shaped somewhat like a cube with two of the ends rounded. The tub is rocked or oscillated on its transverse axis so that the water and clothes are tumbled about in the washing process. Both machines at the left have power-driven wringers, the direction of rotation of the rolls being reversible and the wringer being movable about the support so that it may be used in any one of several positions, such as wringing from tub to basket. Washing-machines similar to these illustrated have a capacity of about six double sheets which is approximately nine pounds of dry clothes.





The washer, at left, has a tub of square cross section with rounded corners. The washing action is produced by a dasher or gyrator, a circular plate having vertical vanes or paddles. The clothes are dragged back and forth through the water, and the water is rather violently agitated by the gyrator as it rotates around the vertical axis. This machine has a power wringer.

In the machine at the right, the inverted hollow hemispheres are moved up and down in the clothes and water contained in the cylindrical tub. This action is typical of so-called vacuum cup washers. The one illustrated has no wringer, the drying being accomplished by centrifugal extraction. During the drying operation the inner basket is spun about the vertical axis at high speed.



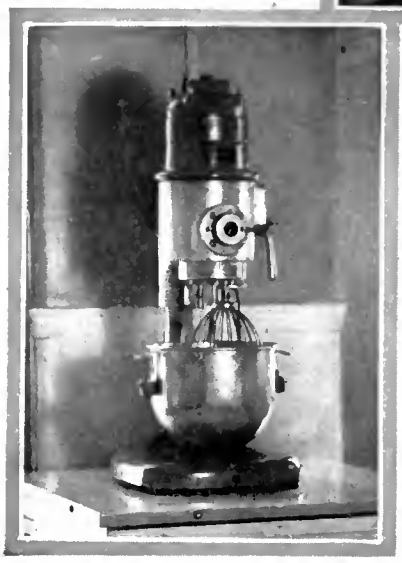
HOUSEHOLD APPLIANCES

Kitchen Equipment

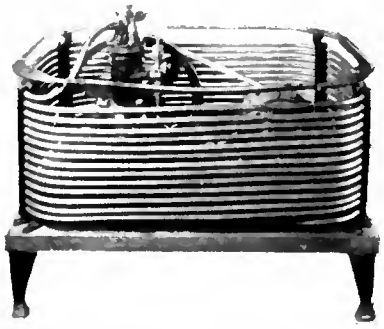
A lighting fixture, adapted to kitchen or laundry, designed to give proper diffusion and distribution of light with a high brilliancy incandescent lamp.

Glass of special composition which will withstand oven temperatures is being used extensively for oven cookery in casseroles, baking cups, platters and other suitable forms.

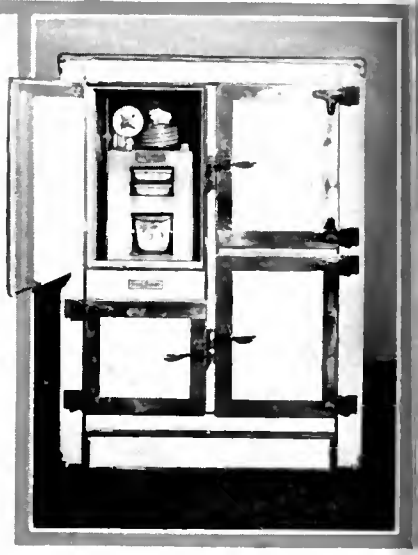
Advantages of the steam pressure cooker are economy in time and fuel. It has important applications in cooking at high altitudes, and for canning.



This beater and mixer is operated by the motor at the top which, through gears, drives two vertical spindles below, to which whips or beaters may be attached. A horizontal shaft drives other attachments such as coffee grinder, food grinders, ice chopper and ice-cream freezer. Three speeds are available.



The motor-driven compressor compresses a gas refrigerant that becomes liquid in the condenser coil. The liquid is expanded in a coil in the refrigerator absorbing heat from surroundings. Expanded gas passes to intake of compressor and cycle is repeated.



The tank in this refrigerator is the portion of the refrigerating unit which takes the place of ice. In it is a coil through which passes the refrigerant, such as sulphur dioxide, methylchloride, ethyl chloride, propane or isobutane. Outside of the coil is brine or other liquid having a low freezing point.

The appliances shown above include, from left to right, table stove, waffle iron, insulated cooker, toaster, and coffee percolator urn. All of these are electrically heated.

To the left is an English "all gas" kitchen having a cooker or range, a gas fire or room heater and a boiler or water heater.

The dishwasher at right is motor-operated and part of a kitchen sink. The motor is connected with a vertical shaft which projects through the bottom of the tank. On top of the shaft is a dasher to splash water over the dishes held in suitable racks. A cover is provided to reflect the splashed water over the dishes. There is a valve-controlled drain to the house waste pipe.

The dish-washer, both non-electric and electric, although available for some years, has been slow to meet with popularity. It depends on the action of a spray of hot water over the dishes, the motive force being provided either by water pressure from a faucet or by an electrically-driven agitator immersed in water. A metal dish-drier, valuable in the saving of time and in the possibilities for sanitary dish-washing, has not yet come into as general use as it deserves. A machine of many uses in the kitchen is the electric beating and mixing machine. It has a variety of attachments for various types of work. Among the minor devices of value should be mentioned stainless steel cutlery, first developed in England (*see* RUSTLESS STEEL); oven-proof glass; and a foot-lever attached to garbage cans, by which the cover may be operated without the necessity of any stooping on the part of the user.

CLEANING AND LAUNDRY WORK

The scrubbing brush is being eliminated partly through changes in floor coverings and surface finishes, which lend themselves to easier cleaning methods, and partly through improvements in cleaning devices. The push-broom has come into wide use, the brooms with stout, heavy fibre being largely replaced by vacuum sweepers for cleaning carpets and rugs. Brushes of specialised design and material have been adapted to a large number of different uses, the bristles varying in stiffness, size and arrangement and the shape and handle being adjusted to the function for which the brush is intended. There is a tendency to replace wood by metal for the backing of such brushes. An important labour-saving device is a scrubbing brush rotated by an electric motor, which may be used for polishing waxed floors.

Vacuum Cleaners.—The first vacuum cleaners were hand-operated and were of the pump type. An electric cleaner, introduced a little before 1910, was made by attaching a motor to one of these hand-machines. In other machines a centrifugal fan, directly attached to the motor shaft, replaced the suction pump. Increased efficiency of the motor and fan has permitted a great reduction in the size and weight of the cleaner. There are two general classes of cleaners: those relying on suction and those depending mainly on a motor-driven brush. Those of the first class clean by creating, through and across a floor covering, a current of air, which is carried through the cleaner by revolving fan and takes the particles of dust with it to be deposited inside a bag provided for the purpose. Some of these so-called "vacuum cleaners" are provided also with fixed brushes inside or outside the nozzle or with revolving brushes within the nozzle, the motion of the brush being transmitted by the wheels on which the machine travels. These machines are distinguished from the second type by the fact that the action of the brush is secondary in importance to that of the air current. In the second type, called "suction sweepers," the brush itself, revolved by motor, does the major part of the work, agitating the floor covering in such a way as to loosen the dirt. The suction produced by a fan raises the floor covering to the mouth of the nozzle and carries the dirt into the bag. Various attachments may be used with electric cleaners for cleaning cushions, upholstered furniture, draperies and other surfaces.

Laundry Equipment.—Although primitive equipment and methods of laundering are still widely used, modern laundry methods are gradually driving out those century-old pieces of equipment—the washboard and the boiler. These are not necessary in machine-washing, when there is available a supply of hot water and soaps in flake and chip form or in cakes. The use of stationary tubs, made of glazed porcelain or porcelain-enamelled iron, is becoming more common and, as in kitchen equipment, tubs and ironing boards are being raised to a more comfortable minimum working height. The use of the combination faucet for hot and cold water is increasing. Washing-machines, both hand and power-operated, are to a considerable extent supplementing the stationary tubs. The electric washing-machine was first used a little before 1910, and by 1926 was in rather general use in the United States and Canada.

The purpose of all washing-machines is to drive the soapy water through the soiled clothes with sufficient force to wash out the dirt. In the so-called "dolly," one of the earliest types, the clothes are dragged back and forth through the water in a tub by means of prongs or pegs projecting into the tub from a base that is moved first in one direction and then in the other around its vertical axis. The sides and bottom of the tub are generally corrugated, so that there is something like a washboard action as the clothes are dragged back and forth by the prongs. A second type might be called the "pump circulating type." It consists of a tub in which a water-pump operated by an electric motor maintains the circulation of water, and the clothes are carried around and kept continuously in motion by the circulating stream. Another type has several paddles mounted on a plate in the bottom of the tub. It moves first in one direction and then in the other around its vertical axis, swirling the clothes and water back and forth.

The vacuum-cup, or suction, washer has two, sometimes three, cups shaped like inverted funnels or hollow hemispheres, which move up and down so as to plunge down into the clothes and water and force the water through the clothes. There is a constant shifting of the relative position of cups and clothes to ensure thorough washing. The oscillating type of washer consists of a tub generally shaped somewhat like a cube with rounded ends, in which a rocking action keeps the clothes in motion.

In the cylinder, or rotary-type, washer the clothes are placed in a perforated cylinder supported in a tub containing water. The cylinder revolves in one direction and then reverses, repeating this regularly, thereby keeping the clothes in a backward and forward motion over strips of wood or metal along the inner surface. Washing-machines often have power-driven wringers attached. Among the improvements introduced into the wringer is the use of semi-hard rolls, to prevent breaking of buttons and serious injury to the fingers of the operator if accidentally caught between the rolls. There is also a type of washer fitted with a centrifugal drier instead of a wringer in the form of an inner perforated container, which revolves rapidly, throwing the water out of the clothes. For filling these power-machines and emptying them there are fillers and drainers, working with a syphon action. Labour is saved, however, by having a supply of hot and cold water piped directly to the machine with a piped outlet for waste water. This arrangement involves having the machine permanently installed in the house. Clothes driers heated by gas are available for indoor drying, and indoor clothes racks have been ingeniously designed with a view to economy of space.

Ironing Machines.—The ironing-machine (formerly called mangle) was first operated by hand and, not being heated, accomplished its work entirely by pressure. The power-driven heated ironing-machine was developed in the United States about 1910. Both gas and electricity may be used for supplying heat, and mechanical control is, in some cases, now substituted for manual control. The larger machines have a roll length of about 48 in. and the smaller ones of about 28 inches. Water-softening plants are sometimes installed for use with household laundries to meet the problem of softening hard water.

HEATING AND VENTILATING

In a large number of homes electrically-driven fans have long been used to give a cooling breeze in the summer. It is becoming more generally recognised that fans may be advantageously used in winter to improve the circulation of air in a closed room or to assist in direct ventilation to outdoors, thereby ridding the air of smoke or vapour. A specialised fan has been designed for attachment in window frames of kitchens for the purpose of ridding the room of cooking odours.

Auxiliary room-heaters, utilising the easily controlled fuels, are in common use. Gas heaters, of the so-called radiant type, have been making big strides in this field. They were first used in England, where they were practically always placed in front of a coal fireplace. Later "built-in" gas grates were introduced,

and these have greatly increased in use. These grates take up less floor space and require a much smaller flue than the coal fireplace. Kerosene heaters, mainly taking the form of a large kerosene burner set in a suitable case having a steel drum for radiating heat, find frequent use in the autumn and spring to take the chill from one or more rooms and to help the main heating plant in periods of extremely cold weather. Electric-heaters of the radiant type are in general use, but more extensive development in electric house-heating appliances has been prevented through the relatively high cost of electricity in comparison with other available fuels.

Water-heaters.—In assuring a supply of hot water for household uses water-heaters play an important part as labour-saving appliances. One of the older methods for obtaining hot water where plumbing was installed was the provision of a hollow cast-iron section or water-back for one side of the fire-box of the kitchen range, this section communicating with a tank for storing the hot water. A similar method uses a coil or pipe inserted in the fire-box of the house-heating furnace or boiler and communicating with a storage tank. These methods of heating water suffer from the disadvantage that they cease to function when the furnace is not being used and when some other fuel is used instead of coal in the kitchen range. One of the cheapest methods of obtaining an abundant supply of hot water in the coal-burning regions of the United States is a small stove especially designed for the purpose of communicating with a water-storage tank. Gas is used extensively for heating water, sometimes in addition to a water-heating attachment to the house furnace. There are several types of gas water-heaters, the simplest consisting of a gas burner placed below a coiled pipe or cast-iron water-container attached to a tank by two pipes to permit circulation of water through the coil or container. This type of heater is frequently known as the side-arm heater. It is generally designed to be operated whenever hot water is desired, but attachments are made so that it can be converted into a thermostatically controlled heater to maintain a constant temperature in the storage tank. Another type of control is of the clock variety, so arranged that the gas flame will be extinguished after the burner has been in operation for a definite time, which can be varied as required. Another type of gas water-heater is simply a combination of gas burner and storage tank with automatic temperature control, known in the United States as the automatic-storage type. To avoid loss of heat during idle periods the tanks of these heaters are heavily insulated with such materials as corrugated asbestos paper, in layers sometimes 1½ to 2 in. thick, mineral wool, ground cork, etc. An adjustable thermostat controls the burner, which has a pilot light burning continuously.

The so-called instantaneous type of gas water-heater is controlled by the opening and closing of any hot-water faucet on the pipe line attached to the heater. This control is effected by means of a hydrostatic valve, which operates through differences in pressure. When all the faucets on the hot-water line are closed the conditions of pressure on both sides of the hydrostatic valve are such that the latter remains closed, but when any faucet is opened, the release of the pressure operates the valve, which in turn opens the gas valve supplying the burner.

Kerosene or coal-oil water-heaters are in use in districts where gas is not available. The majority of these heaters are practically identical in principle with the side-arm gas water-heater already described. Some kerosene water-heaters, however, consist of a complete unit of tank and burner. This unit has a thermostatic control, which extinguishes the burner when the water in the tank reaches a certain maximum temperature. Electric water-heaters have not come into very general use because they are comparatively expensive to operate, unless electricity is very cheap. They are easy to control, the heating elements do not require oxygen as do the burners of any device depending upon combustion, and there are no products of combustion to pollute the air. The efficiency, also, can be made relatively high, because the heating elements may be immersed directly in the water.

HOUSING (*see* 13, 814).—Even before the outbreak of War the problem of sanitary and suitable housing deeply engaged the attention of all persons interested in promoting the welfare of the population, especially of the working classes. The population of modern large towns had risen very rapidly through influx from outside, and the working classes in particular were crowded together in narrow, over-populated quarters. Thus a chief aim of pre-War housing reform was the construction of cheap workmen's accommodation, together with the clearing of the city slums. The methods of this reform hardly went beyond the provision of easy building credits and cheap sites, the reduction of building costs, the systematic planning of new residential districts, and the encouragement of co-operative building activity. The ideal form of dwelling, the so-called garden city, which aims at giving every family a beautiful and healthy home surrounded by a garden, could only be realised in a few model examples.

I. A GENERAL SURVEY

Apart from the so-called "public utility building," which aimed at no profit beyond a normal and fixed return on capital, almost all building activity before the War was conducted by private enterprise. The margin of profit was arrived at by estimating the difference between the sum necessary for amortisation of the capital invested and the proceeds of the annual rent, after deduction of all taxation and costs of repairs, upkeep and administration. This margin was not as a rule very high, but represented a secure income for the landlord-proprietor; experience had shown this to be one of the safest of all forms of investment.

Changes During the War.—The World War brought first a falling-off of demand, followed later by a very rapid increase in the costs of building, which reduced and finally abolished altogether the return on capital in new buildings. Moreover the economic weakness of states and individuals made it impossible to allow rents to rise at the same rate as building costs. The raising of rents on this basis was almost always countered by the state with restrictive legislation, partly out of consideration for the families of the soldiers called up for active service and partly in the belief that the universal and increasing rise of prices was only a temporary phenomenon. It seemed advisable, therefore, to let rents form an exception to this rise; this was achieved by prohibiting the raising of rents, either in all dwellings or in particular categories of them. This prohibition was regularly supplemented by other restrictions, such as prohibition of notice to quit. Thus there arose in almost all European countries a special tenant protection legislation, which imposed artificial restraints on the natural development of prices on the housing market.

Thus arose the difference between the rent paid for old dwellings and the economic rent of new dwellings, a difference so great that tenants could not pay for dwellings in new buildings. But at the same time rents, kept stationary at the pre-War level, had lost so much purchasing power in view of the general rise of prices that they often barely sufficed to cover the costs of the most necessary repairs. In most cases they no longer counted as a source of income for the landlord-proprietor. Thus private capital withdrew from building activity, as it could find much more profitable application in many other branches of production.

Housing Shortage.—Therefore a demand for housing accommodation, which grew suddenly and rapidly, especially after the War, was confronted with a complete lack of supply of free dwellings. Moreover, the housing accommodation to hand was on the decrease, since little or no renovating or repairs had been carried through for several years. Since it was impossible in most countries suddenly to let rents rise at one bound to a level which would make the construction of new dwellings completely economic, there was no resource but to draw the necessary building capital out of national resources through other channels than those of free initiative.

State and Municipal Assistance.—States and municipalities were forced to spend on this object, under various headings and in various degrees, in part even by an actual subsidy of building activity. They took over the payment or guaranteed payment for interest, redemption charges, amortisations and repay-

ment of advances for building purposes, granted loans from public funds, either free of interest or on easy terms; and granted non-repayable building subsidies (in the form of premiums, subsidies *à fonds perdus*, etc.), either to cover the annual interest and redemption charges or to cover the so-called "non-recoverable building costs," *i.e.*, that part of the capital invested in building on which interest and amortisation cannot be obtained.

Social Aspects of State Assistance.—This far-reaching financial assistance of building activity enabled the public authorities to fulfil certain social requirements in the dwelling houses which they helped to erect. Public assistance in building was as a rule confined to the construction of small dwellings and workmen's houses, subject to the fulfilment of certain minimum conditions of a social, hygienic and ethical nature and usually assistance was only given to the "public utility" building activity of the local authorities and co-operative societies. Only in its later stages was this public assistance extended to include private building activity, and then mostly on the pre-War lines of remission of taxation and of credit facilities. As, however, the resources which could thus be applied to the construction of new dwellings were, even so, usually insufficient to meet the actual demand, it seemed imperative to supplement them by measures controlling existing housing accommodation.

Post-War Housing Policy.—Post-War housing policy may thus be divided into three groups of measures, under the headings: "tenant protection," "distributive" and "productive housing policy." Rents in existing dwellings should only be raised to a degree justified by the general economic situation and the general ability of the population to meet them. This ideal can only be realised when the conditions governing notice to quit can be regulated at the same time (tenant protection). Since low rents encourage an uneconomic utilisation of existing accommodation and, combined with the restrictions on notice, make an adjustment of the housing market difficult, it is necessary to ensure proper utilisation and just distribution of existing dwelling accommodation through official supervision (distributive housing policy). The systematic encouragement of direct building activity becomes a task for legislation and administration, as explained above (productive housing policy). Although tenant protection and distributive housing policy are essentially exceptional measures which infringe on the liberty of the individual to dispose of his property, they have nevertheless lent a characteristic stamp to the housing policy of almost all European states.

Tenant Protection.—Tenant protection assumed different forms in different legal systems. In countries where fixed-period leases are customary (France, Belgium, Italy, Rumania, the Canton of Geneva), the extension of the period of lease was secured by law in some cases, in others left to the decision of special rent conciliation offices or tenant protection commissions composed of landlords' and tenants' representatives in equal numbers. In countries where leases are regularly contracted for indefinite periods and are terminable by notice (Central and North Europe) the right of giving notice is legally restricted, subject to the legitimate interest of the landlord (personal requirement), on condition that the tenant can find another suitable dwelling; offences committed by the tenant (arrears in payment of rent, disturbance of the peace, sub-letting without approval, etc.); or considerations of public interest (alteration of the house, official requirement of accommodation, etc.). In Germany, the right to give notice has been abolished altogether and replaced by application to a court of law for termination of the lease. Tenant protection has also often been extended to the increasingly common case of sub-tenancies. Special provisions for periods of grace in case of notices to quit are designed to eliminate, where possible, compulsory evictions, which are undesirable if only in the interest of public peace.

Restriction of Rents.—Measures for the protection of tenants and sub-tenants against increases of rent have varied widely in different countries according to the intensity of the housing shortage. In many of the neutral countries (*e.g.*, Holland, Spain) commissions were set up, usually giving equal representation to landlords and tenants, to consider whether a disputed increase of rent was justified. Other countries (England, France, Belgium, Italy, the Scandinavian countries, etc.) went further, introducing legislation or regulations by which certain categories of tenants or dwellings where such protection seemed advisable were liable to increases of rent only on a fixed graduated scale. In determining the percentage of increase, the taxable value of the house, the average expenditure necessary for its upkeep, etc., were taken into consideration. According to the country's general housing policy, the tendency was apparent, in greater or lesser degree, to bring rent gradually into line with the general level of prices and thus clear the way for the removal of rent restrictions.

The countries most severely affected by the housing shortage, especially those of Central and Eastern Europe, sometimes even reached the stage of making every increase of rent illegal, on the principle of placing the whole question of fixing rents on an exactly defined legal basis and thus abolishing freedom of contract in rent questions. As these were the very countries where the devaluation of currency with its devastating economic consequences appeared in its acutest form, the adaptation of the real rent, which had often sunk to a minute sum, to the new monetary conditions, formed a particularly difficult problem.

Allocation of Existing Dwellings.—These are the countries which were forced to take the most drastic measures in their distributive housing policy. In western countries, the authorities generally confined themselves to prohibiting the demolition of dwelling-houses, the utilisation of dwelling-space for other than dwelling purposes, the use of two or more dwellings by one occupant, etc. In many cases, too, permits to enter and settle in a district were introduced to restrict the liberty of moving (especially in Switzerland and Czechoslovakia) in order to secure the available dwelling-space for the native population. In some cases strangers were excluded from the benefits of tenant protection.

In the countries of Central and Eastern Europe, where the housing shortage was worst, housing policy even resorted to the radical measures of official requisitioning and allocation of available dwelling-space. Here again the interpretation of the word "available" varied sensibly. In some cases only dwelling-room which was actually empty or easily dispensable was subject to these measures, in others the dwelling-space allowed per head, or rather, the number of heads allowed per dwelling-room was fixed by law, and every dwelling-room beyond this was requisitioned and allocated to persons requiring accommodation (Germany, Austria, Czechoslovakia). Such measures were not far from the socialisation of dwelling-space, as actually practised in Hungary under the Communist régime and in Soviet Russia, where the Govt. carried its principle of "condensing" housing so far, that not only dwelling-rooms, but also unused corners of rooms were requisitioned and officially occupied. Even so, the housing crisis in Russia surpassed that of the worst-situated of the European countries.

Economic Effects of Rent Restriction.—The allocation of requisitioned dwelling-space presupposed a just and rigorous classification of the applicants according to the urgency of their needs. An entirely new and very responsible administrative branch was therefore created in public, especially municipal administration, which created an expensive and intricate apparatus (housing offices). The economic consequences of the restriction of rents in comparison with those of before the War was a far-reaching alteration in the utilisation of the national income. Of the enormous sums which had formerly been employed in the form of rent to pay interest and amortisation of the capital invested in dwelling-houses and to maintain the stock of dwelling-houses, only a small fraction was now applied to the same end. In this way the capital invested in dwelling-houses was partly consumed without any compensation being received. How far this was the case in the different countries is best seen from the table on the next page, which shows the percentage expenditure on rent in the total budget of a workman's family before and after the War.

But a closer observation of the consequences of rent restrictions seems to show that the alteration in the distribution of the national income goes far deeper than is apparent at first sight,

Percentage Expenditure on Rent in the Total Budget

Country	Pre-War	July 1922	July 1924
Denmark	14·2	11·14	11·22
Norway	15·7	11·40	11·30
Sweden	11·9	11·2	12·38
Switzerland	10·4	9·9	9·88
Great Britain	16·0	13·7	13·76
Finland	11·8	10·3	11·92
France	12·0	7·2	6·60
Italy	11·4	4·34	6·84
Germany	18·0	0·34	10·62
Austria	14·6	0·66	1·18
Poland	18·1	3·44	5·07
Hungary	18·0	0·22	0·77

and that the relative expenditure on different objects of the working population in particular has been deeply influenced by the fall in rents. For it became the almost universal practice to determine wages by reference to the general level of prices, so that the real wage of the workman, that is the purchasing power of his wage measured in commodities, should remain essentially stable. In reckoning the general level of prices, rent was considered as a factor. The workman who only paid in real value half as much or less for his dwelling as before the War, could therefore be content with a proportionately smaller real wage without impairing his general standard of life.

In view of the fall of the national income in many countries, this reduction of the workman's real wage, while not perceptible to himself, was perhaps actually necessary, at any rate advisable as making cheaper production possible. In any case, similar consequences of the rent restrictions also had their effect on the income and relative expenditure of other classes of the population. It became impossible to find paying tenants, especially for new working-class dwellings erected at greatly increased cost. They could not therefore be built with any prospect of a return on the capital invested, and were not built at all except where the state or the municipality intervened with assistance from public funds. But even this fund was modest in comparison with the capital which had been employed before the War in erecting dwelling-houses. A further consequence of this rent policy has been therefore a change in the application of the available national capital.

Modification of Restrictions.—Under these circumstances, all countries which did not aim at complete destruction of the value of housing property as a step towards socialism began to feel the need of restoring normal economic conditions in the housing market and of gradually raising rents into line with the general price level. The legislative methods adopted, the so-called "modification of rent restrictions," varied greatly in different countries; it was a general rule that the dwellings of the poorer classes were affected last by the rise in rents, and only quite gradually. Some governments found it expedient not to restore to the house owners that part of the national income which the increases of rent had rediverted into its former channels, but, after covering the expenses of repairs, upkeep and administration, to reserve the remainder as "rent duties" for public ends, either the construction of new dwellings for the most necessitous classes of the population, or else (as, for example, in Germany) for the general financial reconstruction of the state. In any case, since the raising of rents, if severe shocks to the economic system are to be avoided, must almost always be distributed over a long period, the capital necessary for new building had to be drawn from other sources than private capital seeking investment.

Other Methods of Financing Building.—The application of public money to housing is generally confined within as narrow limits as possible. Attempts have often been made to induce employers to help in raising the necessary means. Building subsidies from public funds have often been made conditional on the employers' providing subsidies of an equal amount. Some countries (*e.g.*, Yugoslavia) have even imposed a legal compulsion to build, on well-to-do individuals and firms who have been obliged at their own expense to provide by building for the accommodation of themselves, their families and their employees.

Reduction in Costs.—Another important way of bringing the rent of new dwellings into correspondence with the means of tenants is by reducing the cost of building. This can be done by using less expensive forms of construction, employing cheaper materials, standardising and typifying certain elements of the house. In almost all countries architects, engineers and contractors have been occupied with these questions. In England, the Govt. has made elaborate enquiries in this direction, and has recommended certain useful new types of building. Attempts have been made to reduce building costs by co-operative methods. Encouraged by many municipal authorities and by the trade unions, guilds, building organisations and social building enterprises have sought to solve the financial problem by eliminating profit and increasing output. But surrounded as they are by a world organised on non co-operative lines, they have achieved no more than partial successes. No new method, no new system has been fully successful in combating the housing crisis. The qualitative elements in housing—the improvement of hygienic, ethical and social standards—have to be considered under the head of CITY PLANNING.

II. HOUSING IN VARIOUS COUNTRIES

The neutral states of Europe naturally suffered least from the housing crisis consequent on the World War. Nevertheless, they did not wholly escape it, and, in fact, the Scandinavian states, Holland and Switzerland all adopted a more or less extensive tenant protection policy. These countries, however, suffered very much less than the belligerents from the stoppage of building; in none of them did building cease altogether. Therefore they could set about filling up their gaps much sooner. Holland is the only country besides Spain in which extensive building activity since the War has already brought the end of the housing shortage in sight.

Countries of Western Europe.—Those victorious states which found wide stretches of their country in ruins at the end of the War had to reconstruct many thousands of ruined houses. This gave a welcome opportunity within the narrow limits of financial possibility of realising as far as possible the ideas of the housing reformers by building small family houses in garden settlements. Remarkable successes have been achieved on these lines in the reconstructed districts of Northern France, Belgium and Italy. Poland and Yugoslavia have also carried through the work of reconstructing their devastated districts with much success. In Belgium, the *Société Nationale des Habitations à Bon Marché*, with its wide network of local organisations, has done excellent work in public utility housing construction, and financial assistance has been given by the State.

In Italy legislation for the *case popolare ed economiche* has been of great importance, whereas the French housing action based on the legislation *pour les habitations à bon marché* does not appear to have given really satisfactory results, although considerable financial assistance has been given and a great apparatus of offices and *sociétés d'habitations à bon marché* established. Great Britain has attacked her housing problem with much greater energy and correspondingly greater success, as will be seen in the article on the following page.

Germany and Austria.—Most states of this group have been compelled to requisition housing accommodation. The methods adopted were often influenced by political tendencies. Their degree of success depended mainly on the economic capabilities of the different countries. Germany suffered a severe housing crisis as an effect of the depreciation of her currency, though she spent large sums from public funds and inaugurated a most successful housing policy in many industrial districts, *e.g.*, in the Ruhr. The particular character of her housing problems was met by the organisation of housing offices, official control of the exchange of dwellings, the assistance of rural building from the funds of the so-called "productive unemployment relief," the construction of miners' homes out of the proceeds of a duty on coal, self-help associations such as the Lüneburg "Notgemeinschaft," building guilds, state-assisted limited companies for erecting dwellings for dismissed employees, etc. Germany's rent

policy aimed at raising rents in comparatively rapid stages to their pre-War level; the landlord-proprietor receives, however, only so much of this increase as will correspond to the revaluation of mortgages in progress in 1925.

The housing shortage in Austria brought with it a strict tenant protection policy. In Vienna, rents were kept down in a way which amounted to expropriation of the landlords in favour of the tenants. The municipality of Vienna then itself took over the building activity for the city, covering the deficit which it incurred out of general and special taxation (rent tax).

Other Countries.—The more favourable financial situation of the other succession states enabled Czechoslovakia and Yugoslavia especially, both to undertake state-assisted building activity on a much larger scale and to resume private enterprise. The reduction of war and emergency measures dealing with tenant protection and distributive housing policy is already far advanced in these countries, as also in Hungary, Poland, Rumania, Bulgaria and Greece.

In Russia, the change of system in general economic policy in 1923 brought a return to more fruitful methods of housing policy after the original epoch of municipalisation and socialisation without, however, bringing noticeable relief. The European housing shortage thus presents a problem of such extent that, in view of the continuous increase of the population, it will be long before it vanishes from the order of the day. (K. P.)

NOTE.—The above sketch is based chiefly on the volume *European Housing Problems since the War*, published by the International Labour Office, Geneva (1924).

United States.—Housing conditions in the United States closely parallel those of European countries. The conflagration risk, however, is greater, due to the large use of wood in the construction of dwellings. On the other hand, the much more general use of modern systems of plumbing, heating and lighting makes for greater comfort. The relative newness of American cities means that they are less harassed by the survival of obsolete types of dwellings. The problem of slum demolition is therefore not as acute or as prevalent as in Europe.

The National Housing Assn., established in 1910, and directed by Mr. Lawrence Veiller, has promoted the study of local housing conditions and the framing of state housing laws and city housing ordinances. Approximately 100 local housing surveys have been made in the last 20 years, most of them resulting in improvements of local housing conditions. State-wide surveys made in California by the State Commission of Immigration and Housing and in New York State by the Commission of Housing and Regional Planning are especially noteworthy.

Legislation.—The revised edition of Lawrence Veiller's Model Housing law has been used as the basis of housing acts in a large number of states and cities. The Recommended Minimum Requirements for Small House Construction of the United States Dept. of Commerce, prepared by a special committee with the co-operation of Dr. John M. Gries, Chief of the Division of Building and Housing, are widely used as the basis for building codes, and that division has played an important rôle in promoting building, housing and zoning legislation and in providing general information on these and kindred subjects.

Agencies of Improved Construction.—Among the scores of limited dividend companies for improved housing, the City and Suburban Homes Co. of New York City is conspicuous for the extensiveness of its building operations. The Metropolitan Life Insurance Co. and the Bayonne Housing Corp., with the aid of Andrew J. Thomas, architect, have made notable advances in tenement house architecture, especially in planning for sunlight. The most striking of recent developments in row and group housing have been made by the City Housing Corp. of New York City in their Sunnyside development and by the Bridgeport Housing Assn. at Bridgeport, Conn., and the Octavia Hill Assn. in Philadelphia. The garden community designed by John Nolen at Mariemont, near Cincinnati, O., although not designed for wage-earning families, is the best recent example of community planning with detached housing.

Co-operative Housing.—A movement for co-operative ownership of apartments has been cultivated by the National Assn. of Real Estate Boards. The only important recent venture in co-operative suburban housing is that of the Garden Homes Co., near Milwaukee.

Industrial Housing.—Several hundred American industrial corporations have provided industrial villages or extensive improved housing developments for their employees. Among these should be mentioned the U.S. Steel Corp., which has built in scores of communities; the General Motors Co. at Flint, Mich.; the Goodyear Tire and Rubber Co. at Akron, O.; Norton Co. at Worcester, Mass.; the Mount Union Refractories Co. at Kistler, Pennsylvania and the Ford Co. at Detroit.

Governmental Housing.—In the United States the building of houses is left to private enterprise. During the World War the Federal Govt., through the U.S. Housing Corp., the Emergency Fleet Corp. and the War Dept. built many thousands of houses in well-planned communities, as an emergency measure. These projects have since been disposed of by sale to individuals or corporations. They have, however, served to interest many leading architects and town planners in the problem of industrial and suburban housing, and thus have led to improvement in general standards of industrial housing.

Housing Finance.—There is no provision by the Federal or state governments for public loans for small-house construction. The recent attempt by the state of North Dakota to provide such loans has been pronounced unsuccessful. The construction of private dwellings is largely financed through building and loan associations, which are semi co-operative in their organisation and methods. In 1924 there were 11,844 associations of this character, with a membership of over 8,500,000 persons, and total assets amounting to over $4,700,000,000.

Educational Agencies.—In 1922 Better Homes in America, Inc., was established by Mrs. William B. Meloney to organise local committees to study and improve local conditions of housing and home-life. Under the leadership of its president, Herbert Hoover, Secretary of Commerce, this organisation in 1926 formed 2,937 committees in cities, towns and villages throughout the United States. These committees have arranged lecture and discussion programmes, contests for home improvement and demonstrations of the better types of small house architecture, furnishing and landscaping.

The Architects' Small House Service Bureau, established by the American Institute of Architects, has contributed greatly to the improvement of prevailing standards in small house planning and design by issuing hundreds of plans of single-family houses of from three to six rooms. Such plans, with specifications and quantity surveys, are sold at nominal cost to families throughout the United States who are interested in building homes of their own. (J. F.)

III. HOUSING IN GREAT BRITAIN

Despite legislation during the preceding 50 years or thereabouts, housing of the working classes throughout England and Wales in the census year of 1911 was far from satisfactory. Economic facts mainly account for the paradox of surplus accommodation (5·6%) existing in conjunction with some 250,000 families surplus to structurally separate dwellings; 405,010 tenements of four rooms and less were occupied by more than two persons in one room. Insanitary areas and unfit houses abounded. The conditions in Scotland were worse. Local authorities, even later than 1890, with few exceptions, did not consider that housing the people fell within the essentials of their activities, and up to 1909 a legal obligation existed to sell, within 10 years, houses erected in discharge of rehousing obligations.

Unregulated and speculative individual effort dominated this branch of the building industry to the extent that some 95% of pre-War working-class accommodation was built by private enterprise. Increasing cost of production operated to diminish output until fear, inculcated by the taxation of land, produced by the Finance (1909–10) Act, dried up the sources of

speculative house building. The dangers due to increasing population cribbed by inadequate and wasting accommodation failed to secure national recognition, although private bills to stimulate production by subsidy were introduced unsuccessfully from 1911 to 1914.

Thus the outbreak of the World War in Aug. 1914 found housing in arrear. War conditions, causing large migrations and increased marriages, rapidly absorbed vacant accommodation in the cities. Rent Restriction Acts controlling rents and preventing evictions, but aggravating slum conditions, followed. Normal upkeep of houses was checked, and new construction was suspended by military requirements. Production and import of building materials ceased, and the ranks of skilled labour became depleted. The end of the War revealed a deplorable condition. The perpetual housing problem due to poverty had been intensified, and accommodation was lacking for many whose capacity to pay was undoubted. It was estimated (1918), possibly in excess of the immediate effective demand, that a deficiency of approximately 500,000 houses existed, of which 100,000 were needed in Scotland.

The census of 1921 later revealed 760,543 families in England and Wales surplus to structurally separate dwellings. The replacement of unfit dwellings to an approximate amount of 205,000 was not included. In addition, the London County Council required 29,000 new dwellings and immediate clearance of insanitary areas involving rehousing of 40,000 persons. It is noteworthy that nevertheless health statistics were good.

The problem presented was incapable of rapid solution. Skilled operatives were reduced by 50% as compared with 1908, and the remainder absorbed in maintenance and by contract builders. Material was scarcely procurable. An unparalleled financial stringency prevailed, with cost of living of wages and of material increased by over 100% on pre-War figures. The working classes, which constitute about three-fourths of the population, mainly require houses let at weekly rents. Even if building for sale were feasible, to let at an economic rent was impossible.

The Act of 1919.—In these circumstances the Coalition Govt., stimulated by the slogan "Homes for Heroes," rapidly passed the Housing, Town Planning, etc., Act 1919. This epochal Act embodied three principles: an obligation on local authorities to effect housing schemes, a State subsidy to housing and stringent penal clauses relating to compensation payable for insanitary property. The State shouldered all liability on approved schemes exceeding a 1d. rate borne by the local authority. The standard of housing was raised, but the incentive to local extravagance, countered by paralysing departmental centralisation, combined with exclusion of private enterprise, marred the Act. Prices soared until an annual loss per house of £50, to be met throughout the loan period of 60 years, was not uncommon. The average cost, exclusive of London, in 1920 was £860 for non-parlour and £972 parlour type. Nearly £100 must be added to building prices for land, roads and sewers. In London it cost as a minimum £158 per person housed as compared with £43 per person pre-War, and the average per habitable room in a tenement block attained £375 comparable with less than £100 pre-War. A total of 174,540 houses excluding some 3,000 temporary huts was the result of the Act at a (Treasury) cost of about £175,000,000, exclusive of the 1d. rate borne by the local authorities.

The Act of 1919.—The Housing (Additional Powers) Act 1919 remedied the exclusion of private builders, to whom a lump sum subsidy averaging about £240 a house was given, which provided nearly 40,000 houses at a total cost to the Government of £9,493,155; it forbade conversion or demolition of dwelling houses, and, to conserve labour for dwellings, attempted prevention of "luxury" building; the latter prohibition proved more injurious generally than beneficial. Both output and cost were seriously affected by the trade unions of this sheltered industry, which defeated all attempts to increase production by a dilution with ex-service men or otherwise. The results attained by the 1919 Act were not commensurate with the cost. Therefore in June 1921 the Government curtailed the scheme to "the number built, building or for which tenders have been approved," and notified a contribution not exceeding £200,000 a year for the improvement of insanitary areas in England and Wales. The suspension of the Act led to a fall in prices, and a vain hope of abolishing subsidy was entertained in some quarters. The average cost (excluding London) in 1922 for non-parlour type was £362 and with parlour £393. By 1925 prices had reached £440 and £495 respectively, but in 1923 it was deemed expedient to enact a limited subsidy (£6 a year for 20 years) for houses or flats of specified dimensions and containing a bath. The (Chamberlain) Act successfully aimed at promoting private enterprise and owner-occupiers both by subsidy and loan. The Small Dwellings Acquisition Act 1899 was extended and co-operation with public utility and building societies sought. Up to the end of 1925 over 278,484 houses had been arranged for under the Acts of 1923 and 1924, of which 151,102 were completed.

Acts of 1923 and 1924.—Before the 1923 Act could become operative the advent of a Labour Govt. led to fresh legislation, to run *pari passu* with the 1923 Act. After conferring with the building industry and the local authorities a financial basis was agreed as between taxpayer and ratepayer. The former was to pay twice as much as the latter, viz.: £9 and £4 10s. respectively, for 40 years, and any remaining gap between cost of production and income should be filled by rent from the tenant. Heretofore rent fixation had proceeded on the basis of comparable accommodation in the neighbourhood; now special conditions were attached on the basis of pre-War rents as amended by Rent Restriction Acts. This would diminish rent where production costs were low. In agricultural parishes, of defined limits, the subsidy was raised to £12 10s. because of the special difficulties of rural conditions. The Housing (Financial Provisions) Act 1924 propounded a fifteen years' programme, subject to biennial revision of contributions, under which 2,500,000 houses should be provided; an apprenticeship scheme, under which the ratio to craftsmen was increased to one in three, instead of the unattained permitted maximum of from one in four to one in seven, was an essential adjunct of the Act. But an apprenticeship scheme requires several years before fruition, and augmentation of craftsmen was overdue.

The continuing shortage of skilled labour led to investigation of new methods and materials for cottage construction. Concrete speedily established itself as a substitute for brick, but the necessity of eliminating plasterers' and bricklayers' work evolved novel types, notably the factory-made "steel" house. Progress in such types has been hindered by the hostility of the building industry and the timidity of local authorities.

Consolidating Act of 1925.—The permanent law relating to housing was consolidated into the Housing Act 1925, and the attached table shows progress up to the end of that year. In the London area progress was retarded by special difficulties, mainly due to London's magnitude, the population being eight times that of Birmingham, the next largest city (excluding Scotland), and the inaccessibility of housing sites.

The housing problem is not solved, and the economic position, now as ever, refutes the idealistic standard of one dwelling one family, every family a dwelling. It will take much expenditure and many years of persistent national endeavour to achieve a practical standard enabling all capable of paying a moderate rent to occupy a structurally separate dwelling, to establish a margin of surplus accommodation, to suppress overcrowding and to abolish insanitary areas and unfit houses. But a postulate lies in an adequate supply of skilled labour, and a measure of town planning applied to built-up areas is indicated as a corollary.

Pre-War Number of houses provided	Greater London	England and Wales	Scotland
Average per year in five-year periods ended—		(including Greater London)	
1904	25,500	116,370	14,553
1909	17,860	102,706	9,120
1914	9,330	60,648	2,850
Post-War.			
To end of 1920	2,642	221,000[1]	35,000*
1921	12,921		
1922	16,913		
1923	10,229	71,934	
1924	17,339	125,762	
1925	23,000[1]	166,952

HOUSMAN, ALFRED EDWARD (1850–), British poet nd scholar, was born March 26 1859 and educated at Bromsrove School and St. John's College, Oxford. From 1882–92 e held a post in the Patent Office, and then became professor of .atin at University College, London, until 1911. He filled the Kennedy Chair of Latin at Cambridge from 1911 onwards, being lso elected fellow of Trinity College. His editions of Manilius 1903–20) and of Juvenal (1905) are well known to classical cholars, but he is most widely famed as the author of the lyric equence, *The Shropshire Lad* (1896), a work with few rivals of ts kind in the language. His only other published volume of poetry was *Last Poems* (1922), which showed a command of delicate cadence and a fine sensibility no less distinguished than hose of his early work.

HOUSSAYE, HENRY (1848–1911), French historian (*see* 13.828), died in Paris Sept. 23 1911. After his death were published *Iéna et la campagne de 1806* (1912), and *La patrie guerrière* (1913). See L. Sonolet, *Henry Houssaye* (1905).

HOUSTON, Texas, U.S.A. (*see* 13.828).—A few years after the World War, Houston became a world port, with 33 steamship ines in 1925 operating regularly to the principal ports of North nd South America, Europe and the Orient. Its total tonnage of exports, imports and coastwise traffic (1924) was 5,343,598 tons, valued at $294,796,871. The first bale of cotton was exported in Nov. 1919; shipments for the season 1924–5 were 1,821,828 bales. The 25-ft. ship channel, completed in 1914, was deepened to 30 ft. and widened between 1919–25. Under an enabling Act, passed in 1921, the navigation district of Harris co. assumed operation of the port and made extensive improvements in port facilities. The projected intracoastal canal from the Mississippi river to the Houston Ship Channel will connect the port with 6,000 m. of inland waterways. The value of manufactures within the city limits was $23,015,000 in 1909; $86,874,000 in 1919; $89,133,777 in 1923. The area was increased from 17·4 sq. m. in 1910 to 36·5 sq. m. in 1920 and to 41 sq. m. in 1925. The population in 1920 was 138,278, of whom 33,960 were negroes and 12,088 foreign-born; in 1925 it was estimated at 164,954; the local estimate for the metropolitan district was 250,000. Between 1920 and 1925 great progress was made in paving and widening streets, constructing sewers and bridges, improving the fire department, building driveways along the bayous, adding parks and beautiful public buildings and transforming the business section with modern office buildings and hotels. Rice Institute opened for its first academic year on Sept. 23 1912 in buildings on its 300-ac. campus.

HOWARD, LELAND OSSIAN (1857–), American entomologist, was born at Rockford, Ill., June 11 1857. He graduated from Cornell University, becoming B.S. in 1877 and M.S. in 1883. After serving as assistant entomologist at the U.S. Dept. of Agriculture, Washington, D.C., in 1878, he was made chief of the Bureau of Entomology in 1894. From 1904 he was consulting entomologist in the U.S. Public Health Service, and from 1895 honorary curator of the U.S. National Museum. He was in 1917 a member of the committee on agriculture and chairman of the sub-committee on medical entomology of the National Council of Defence.

Howard wrote *Mosquitoes—How They Live* (1901); *The Insect Book* (1902); *The House Fly—Disease Carrier* (1911); a monograph on mosquitoes for the Carnegie Institution (1912); and many government bulletins.

HOWELLS, WILLIAM DEAN (1837–1920), American novelist (*see* 13.839), died in New York May 11, 1920. In 1915 he received the gold medal of the National Institute of Arts and Letters for his work in fiction. To within a short time before his death he continued to contribute to the "Editor's Easy Chair" of *Harper's Monthly*. His later works included *My Mark Twain* (1910); *Imaginary Interviews* (1910); *Parting Friends: a Farce* (1911); *Familiar Spanish Travels* (1913); *New Leaf Mills: a Chronicle* (1913); *The Seen and Unseen at Stratford-on-Avon: a Fantasy* (1914); *The Daughter of the Storage and Other Things in Prose and Verse* (1916); *The Leatherwood God* (1916); and *Years of My Youth* (1916). In 1920 he edited with an introduction *The Great Modern American Stories*. He left unfinished *Years of My Middle Life*.

HRDLIČKA, ALEŠ (1869–), American anthropologist, was born at Hampoletz, Bohemia, March 29 1869. His early education was received in Bohemia. He studied at the New York Eclectic College becoming M.D. in 1892. In 1894 he joined the New York State service, investigating the insane and other defective classes, and became in 1896 associate in anthropology in the State Pathological Institute. He was a member of the Hyde expeditions to Mexico and the southwestern United States in charge of physical anthropology, 1898–1903. In the latter year he was appointed assistant curator in charge of the division of physical anthropology at the U.S. National Museum, Washington, D.C., becoming curator in 1910. As a member of various anthropological expeditions he made researches in many parts of the globe. He became a leading exponent of the theory that the North American Indian is of Asiatic origin. Among his works are *The Eskimo Brain* (1901); *Ancient Man in North America* (1907); *Ancient Man in South America* (1912); *Anthropological Work in Peru* (1914).

HROZNY, BEDRICH (1879–), Czech orientalist and archaeologist, studied in Prague, Vienna, Berlin and London. In 1904 he took part in the Seelin excavations in Ta'anuk (north Palestine), on the basis of which he wrote *Die Keilschrifttexte von Ta'annek* (1904) and *Die neugefundenen Keilschrifttexte von Ta'annek* (1906). In 1905 he was appointed professor at the University of Vienna, and in 1919 became professor of cuneiform research and ancient Oriental history at the Charles University of Prague. Hrozny's name became known chiefly in connection with the study of the ancient Hittites. He left the solution of the Hittite hieroglyphics to chance, proceeded to work on the basis of Hittite documents from the Boghazkoi archives written in cuneiform script, and in 1915 thus succeeded in deciphering the Hittite language, which he proved to be an Indo-European tongue, closely akin to the Iranian, Celtic, Italic and Slavonic families of speech. His solution was attacked from many quarters, but he substantiated his claim by the success with which he read and translated a number of documents, among others a Hittite legal code (published in Paris, 1922, under the title: *Code Hittite provenant de l'Asie Mineure, 1. Partie: Transcription, traduction française*). In 1925 excavations for the purpose of further research were made under his direction by a Czech scientific expedition to Asia Minor.

HUBAY, EUGENE DE (1858–), Hungarian composer and violinist, was born at Budapest Sept. 15 1858. His first teacher was his father, who was a professor of the violin, as well as a composer and conductor. From 1871–5 he studied in Berlin under Joachim, and later, on the recommendation of Liszt, gave successful violin recitals in different countries including England. While in Paris he was associated with Vieuxtemps and Massenet. In 1882 he succeeded Wieniawski as professor of the violin at the Brussels Conservatoire, and in 1886 was appointed to a similar post at the Budapest Academy, of which he has been the director since 1919. His pupils include many eminent violinists, among them Vecsey, Jelly d'Aranyi and Szigeti. Hubay has written the following operas: *The Violin Maker of Cremona; Anna Karenina; Alienor; Die Maske; Moosröschen; Lavottas Liebe*, etc. His other compositions include symphonies, violin concertos, and solos and songs. His early works, based on Hungarian and French elements, were exclusively lyrical, while his later compositions show more dramatic rhythm as well as more modern tone-colouring.

HUBER, MAX (1874–), Swiss lawyer, was born Dec. 28 1874 at Zürich. He became doctor of law at Berlin University in 1897 and, on the conclusion of his studies, travelled extensively and made a prolonged sojourn in the Far East. From 1902 to 1921 he held a law professorship—first extraordinary and subsequently ordinary—at the University of Zürich. In 1921 he resigned his chair and became honorary professor. The Swiss Federal Council on many occasions consulted him as an expert in international questions and he was a Swiss representative at the Hague Conference in 1907. During the World War he was

legal adviser to the Swiss Political Department. In this capacity he was entrusted with several missions to the Peace Conference, to the League of Nations and to various governments. In 1920 and 1921 he was deputy delegate to the Assembly of the League of Nations. He was a member of the Jurists' Committee of the Council of the League of Nations dealing with the Aaland Islands question and of the International Blockade Commission. He became both a judge of the Permanent Court of International Justice and a member of the Permanent Court of Arbitration.

HÜCH, RICARDA (1864–), German poet, was born in Brunswick July 18 1864 and educated there. Later she studied in Zürich, where she took her degree. She was appointed secretary of the library in Zürich and married first Dr. Ceconi, and later Dr. Richard Hüch, a lawyer. She wrote a number of romantic and imaginative novels, among which may be mentioned *Aus der Triumphgasse* (1902); *Vita Somnium Breve, Ein Roman* (1903); *Der grosse Krieg in Deutschland* (1912–4); and *Der wiederkehrende Christus* (1925). Her most important historical works are *Blüthezeit der Romantik* (1899); *Ausbreitung und Verfall der Romantik* (1902); *Das Risorgimento* (1908). In 1919 appeared a volume of reflections, *Der Sinn der heiligen Schrift*, which reveal a profound knowledge of psychology.

HUDSON, WILLIAM HENRY (1841–1922), British naturalist and writer, was the son of Daniel Hudson (1804–68), who was himself born of English parentage at Marblehead, Massachusetts. W. H. Hudson, Daniel's third son, was born at Quilmes, near Buenos Aires, Aug. 4 1841, and remained with his family on the pampas until about the age of 20, when he came to England. From then the greater part of his life was spent in poverty, and his difficulties were accentuated by frequent ill-health. His wife, Emily, long kept a boarding-house in London, where Hudson too lived, known to only a small circle of appreciative friends. A civil list pension granted in 1901 aided him somewhat, but he voluntarily relinquished this in later years when belated success reached him. He died in London Aug. 18 1922 and was buried at Broadwater, Sussex. His writings include the memorable pictures of the South America of his youth, such as *The Purple Land* (1885); *A Crystal Age* (1887); *El Ombú* (1902); *Green Mansions* (1904); *Far Away and Long Ago* (1918); of the English countryside, such as *A Shepherd's Life* (1910); *Dead Man's Plack* (1920); and the posthumous *A Hind in Richmond Park* (1922); ornithological works, as his collaboration with P. L. Schlater in *Argentine Ornithology* (1888–9); and his own *British Birds* (1895); and *Birds of La Plata* (1920); and many pamphlets for the Society for Protection of Birds. A bird sanctuary with a decoration by Jacob Epstein was erected to his memory in Hyde Park, London, in 1925.

See H. J. Massingham, *Untrodden Ways: Adventures among the Works of Hudson, etc.* (1923); Morley Roberts, *W. H. Hudson* (1924).

HUGEL, FRIEDRICH VON, BARON (1852–1925), Catholic theologian, was the son of Karl von Hugel (1775–1870), Baron of the Holy Roman Empire, a German by birth, an Austrian subject, and Austrian minister to the grand ducal court of Tuscany at Florence where on May 5 1852 Friedrich was born. Baron Karl had married Elizabeth Farquharson, a convert from Presbyterianism to the Catholic Church. In 1867 the family went to England and made their home at Torquay.

Friedrich von Hugel's education was curiously miscellaneous: brought up a Catholic, he was early made acquainted with Anglican forms and doctrines; from 8 to 15 he had a Rhenish Prussian Lutheran tutor, whom he loved, the Catholic historian Alfred von Reumont meantime supervising the course of the teaching; to his father perhaps he owed a turn for science, studying geology and entomology. Hebrew he learnt from a Rabbi and from the Catholic priest—Professor Gustav Bickell, the Biblical critic and commentator on Job. This singular upbringing, his mixed ancestry and his knowledge of languages, together with his natural gifts helped him to become one of the most sympathetic, resourceful and persuasive religious teachers of his age, and won him many friends in many lands. He took into his purview all history, all races, all religions, all philosophies, all literature. But while he possessed a generous sympathy for all seekers after truth, he held the Catholic Church to posse in its creeds, worship, history and institutions, the fullest, ric est and deepest realisation of religion. He accepted the Papac and the principle "*ubi Petrus ibi ecclesia*," but at the same tin he thought that the government of the Church was ove centralised, and he believed that the bureaucratic tendency cou be counteracted by the healthy interaction of energy between t head and the members of the whole body of believers.

His Biblical scholarship led him into relations with the High Criticism and he accepted what he regarded as the assured resul of such studies. This association with modernist Biblical criti led him to be classed with Modernists. When the crisis of Mo ernism was over, he made it more and more clear that friendl and sympathetic as he was to them, as to all others who we troubled by doubts, he could not follow the Modernists who r volted from Rome and that he rejected altogether their theo of belief. He wrote that the main spiritual influence, dating fro 1886, which had strengthened his faith, had been the teachin and the example of the Abbé Huvelin, a remarkable French pries who wrote no books but "wrote in souls." Baron von Hug himself brought out no book until he was fifty-eight. A letter i The *Times Literary Supplement* of May 25 1922 on Lou Duchesne is of value for its treatment of the subject, but als as an apologia for the Baron's own religious belief.

In 1873 the Baron married Lady Mary Herbert, a daught of Sydney Herbert (Lord Herbert of Lea). He died in Londo Jan. 27 1925 and by his own wish was buried in Downside Abbe Bath, Somersetshire. He asked that his library should be give to St. Andrews University. In his will are the words "I desi to die as I have striven to live, a devoted member of the Catholi and Roman Church."

His works include: *The Mystical Element of Religion as studied i St. Catherine of Genoa and her Friends* (1908, new and rev. ed. 1923 *Eternal Life, a Study of its Implications and Applications* (191 2nd ed. rev. 1913); *The German Soul in its Attitude towards Ethic and Christianity*; *The State and War* (1916); *Essays and Addresses o the Philosophy of Religion* (1921).

HUGGINS, MARGARET LINDSAY, LADY (1848–1915), Britis astronomer (*see* 13.857), died in London March 24 1915.

HUGHES, CHARLES EVANS (1862–), American lawye and statesman, was born at Glen Falls, N.Y., April 11 186 He attended Colgate University from 1876 to 1878, whence h proceeded to Brown University (B.A., 1881; M.A., 1884). H studied law at Columbia University, taking his LL.B. degree i 1884 and obtaining a prize fellowship at the Columbia law schoo In the same year he was admitted to the New York bar, an engaged in practice till his appointment as professor of law a Cornell University in 1891, a position which he relinquished i 1893 in order to resume practice. He continued, however, t maintain his connection with Cornell in the capacity of speci lecturer, and, in addition, was a special lecturer at the Ne York law school from 1893 to 1900.

In 1895 he was retained as counsel for the Stevens Gas Com mission, appointed by the New York State Legislature to inves tigate the cost of gas; and in the same and following years wa counsel for a committee of the New York State Legislatur known as the Armstrong Insurance Commission, formed fo the purpose of investigating life insurance companies. In 190 he was nominated for mayor of New York City by the Repub lican convention, but declined to stand. In the coal investiga tion of 1906 he acted as special assistant to the Attorney-Genera of the United States. In the same year he was elected Governo of the State of New York, defeating William Randolph Hearst and was re-elected in 1908. He resigned Oct. 6 1910, on bein appointed Associate Justice of the Supreme Court of the Unite States by President Taft.

Candidate for the Presidency.—In 1916 he resigned from th Supreme Court on being nominated for the presidency by th Republicans, but was narrowly defeated by President Woodro Wilson, who had been renominated by the Democrats. Hughes' election was considered assured when the campaign began; bu though he "stumped" the country widely he disappointed th

people because he took no definite position on any of the specific questions involving the stand of America in the World War, and especially as regards the sinking of the "Lusitania." The result of the election was doubtful until a full count had been made, and eventually hinged upon Minnesota and California, normally Republican states. Hughes carried Minnesota by a few hundred votes, but lost California by a few thousand. The electoral vote was 277 for Wilson against 254 for Hughes. The popular vote was 9,129,606 for Wilson against 8,538,221 for Hughes. The following year he again entered upon the practice of law in New York City. In 1917 he was appointed chairman of the Draft Appeals Board of New York City by Governor Whitman, and in 1918 he acted as special assistant to the U.S. Attorney-General in charge of the investigation of alleged waste and delay in the construction of aircraft. He was president of the New York Bar Association in 1917–8, and of the Legal Aid Society 1917–9. He was the leader of the New York Bar Association in its opposition to the expulsion of the Socialists from the New York State Legislature in 1920.

As Secretary of State.—On the inauguration of President Harding, March 4 1921, he became Secretary of State. One of his first steps was to intervene in the Panama-Costa Rica dispute respecting their boundaries. The two states had drifted into actual hostilities, but on March 18 1921 Mr. Hughes advised them, in terms which practically amounted to an ultimatum, to arrange for a peaceful delimitation of their joint frontier—a suggestion which they ultimately accepted. The Soviet Govt. approached him in his first month of office asking that the United States should resume trade relations with Russia, but he promptly rejected the Soviet proposals. Later on M. Chicherin communicated with him with a view to the recognition by the United States of the Soviet Republic, but this also was refused, Dec. 19 1923.

In 1921 Mr. Hughes, under authorisation by President Harding, sent out invitations suggesting a conference on the limitation of armaments to be held at Washington. The conference was held—Mr. Hughes being chief U.S. delegate—with the result that seven treaties were negotiated relating to limitation of naval armaments, the fortification of islands in the Pacific and relations between China and other Powers (*see* WASHINGTON CONFERENCE).

In a speech at New Haven in Dec. 1922 Mr. Hughes dealt at length with the matter of German reparations, and unofficially suggested a committee of experts to investigate. This was the genesis of the committee which ultimately prepared what is known as the Dawes Plan (*see* REPARATIONS). The Tacna-Arica dispute afforded another instance of Mr. Hughes's intervention on behalf of peace (*see* TACNA-ARICA). It was largely due to Mr. Hughes's efforts also that a convention was signed between the U.S. and British governments by which the U.S. authorities were permitted to search British vessels on the high seas within a 12-mile limit from shore, the purpose being to prevent the smuggling of liquor into the United States. One of the last acts of Mr. Hughes before he retired from office was to suggest a solution of the controversies between Brazil, Colombia and Peru as to certain portions of their boundaries. A settlement was effected in March 1925.

Mr. Hughes's attitude in respect of foreign affairs during his term of office was well set forth in an address entitled "The Pathway of Peace," delivered by him before the Canadian Bar Association Sept. 4 1923. "The League of Nations," he said, "by its constitution presupposed that peace could be maintained by economic pressure and military force." He dissented from this, since he believed that there was no path to peace except as the will of peoples might open it. The way to peace was through agreement, not force. "There is no lawgiver for independent states; the outlawry of war necessarily implies a self-imposed restraint." Upon this hypothesis was consistently based his whole attitude towards world politics. He was, however, in favour of the adherence of the United States to the World Court of International Arbitration. The judicial impartiality of Mr. Hughes's character fitted him admirably to succeed in handling the international problems confronting him as Secretary of State, but he lacked the dramatic and popular qualities which might have led to his choice as chief executive of the nation.

He resigned office March 4 1924 and retired into private life. He was, in the April following, elected president of the American Society of International Law. In 1925 he acted as chairman of the New York State Reorganisation Commission, appointed to investigate the structure of the State Government. The commission reported March 1 1926, urging that the 180 state bureaux and departments be merged into 18, and that an executive budget system be introduced.

In addition to numerous addresses, most of which have been reproduced in pamphlet form, Mr. Hughes has published *Addresses and Papers* (1908); *Conditions of Progress in Democratic Government* (Yale Lectures, 1910); *Addresses 1906–16* (1916); *Foreign Relations* (1924); and *The Pathway of Peace* (1925).

(H. W. H. K.)

HUGHES, SIR SAMUEL (1853–1921), Canadian soldier and politician, was born at Darlington, Ont., Jan. 8 1853. In the Fenian raids of 1870 he served with the Canadian volunteer militia, and in 1873 he was gazetted to the 45th Regiment. Educated at Toronto University, he lectured at a Toronto collegiate institute until 1885, when he took up journalism, being editor and proprietor of the Lindsay *Warder* from 1885 to 1897. In 1892 Hughes was elected to the Dominion Parliament, but service in the South African War interrupted his political career. Returning to Canada after the coronation of King George V. in 1911, he became Minister of Militia and Defence, and was chiefly responsible for the creation of the overseas force which sailed for Europe in 1914. In 1915 Hughes was created K.C.B. and promoted major-general; but in the following year disagreements with Sir Robert Borden resulted in his resignation. Hughes criticised severely the strategy and leadership of Sir Arthur Currie. In July 1921 he announced his intention of retiring from Parliament, and he died at Lindsay, Ont., Aug. 24 1921.

HUGHES, WILLIAM MORRIS (1864–), Australian statesman, was born Sept. 25 1864 at Llansantffraid, Montgomeryshire, Wales, and received his early education at Llandudno Grammar School. Moving to London, he became a pupil teacher at the Burdett-Coutts schools, Westminster, where he attracted the attention of Matthew Arnold, then an inspector of schools; and at the age of 20 he emigrated to Australia. Here he began a period of picturesque wanderings, which it would be hard to parallel in the life of any statesman, ancient or modern. He drove sheep and cattle across the vast spaces of New South Wales and Queensland, worked on farms and cooked for harvesting gangs, became a sailor on coasting steamers, prospected for gold, tramped from station to station doing odd jobs, mended everything, from umbrellas to locks and from ovens to violins, taught children in remote settlements, walked hundreds of miles organising for the Australian Workers' Union, and in the end drifted back to Sydney and gravitated, as was only to be expected from the bent of his mind and character, to politics. He formed the Sydney waterside workers into a militant organisation, and entered the New South Wales Parliament in 1894 as member for the Lang division of Sydney.

As a member of the Opposition Mr. Hughes had no chance of showing administrative ability, but he became known as an effective debater, and devised the Labour party's caucus system of settling all internal dissensions outside the House and presenting a united front in Parliament. Then in 1901 came federation, and as member for West Sydney in the first House of Representatives Mr. Hughes found the wider scope that his political genius demanded. In 1904 Mr. J. C. Watson formed the first Labour Ministry, and Mr. Hughes, who in the midst of his industrial and political work had found time to qualify as a barrister, became Minister for External Affairs. The Ministry was short-lived, but thenceforth it was clear to friends and foes alike that a new force had entered Australian politics. During the years that followed Mr. Hughes went on developing until the hesitating, ineffective speaker of the 'nineties became one of the most brilliant and powerful orators in the Empire, and his

courage, energy, intellectual gifts and dominating personality made his succession to Mr. Fisher almost inevitable.

Mr. Hughes was attorney-general in the Fisher Ministry of 1908, and revealed not only a remarkable gift of eloquence and a mordant wit, but a breadth of view and a warm Imperialism hardly to be looked for in a party which, not so many years before, had toyed with the idea of "cutting the painter." He was largely responsible for the scheme of compulsory military service which later proved so valuable, and he was heart and soul with his leader when Mr. Fisher, who had returned to office after the Liberal defeat of 1913, made his historic offer in 1914 of Australia's last man and last shilling. In 1915 Mr. Fisher went to London as high commissioner, and Mr. Hughes, as his logical successor and the man to whom Australia looked for strong leadership in the dark days of war, succeeded him as Prime Minister. Thus this frail little man, who weighed only seven stone, who suffered increasingly from deafness and ill-health, and who had depended for higher education entirely on what reading he could find time for in the intervals of work ranging from the mending of kettles to the organising of strikes, had as his reward the highest honour that his countrymen could offer.

On the whole they were not disappointed. Mr. Hughes, by his driving force and faculty of kindling enthusiasm, gave an immense stimulus to the raising and maintenance of the Australian Expeditionary Forces; and with equal energy he devoted himself to the task of eradicating German commercial influence from Australia. Germany, he found, had almost a monopoly of the output of Australian mines, and German firms controlled even the supplies of metals needed by the British Govt. for munitions. By the end of 1915 he had brought forward legislation which annulled all German contracts, transferred control of output to the newly established Australian Metal Exchange, prevented trading with the enemy, and disinherited enemy shareholders in commercial enterprises of every kind. This was practical statesmanship of very real importance.

In the following year he visited England and attracted wide attention by preaching a renaissance of the British race based upon a greater development of the Empire's resources and a closer-knit economic system. Returning to Australia with the conviction that a stronger flow of reinforcements was needed, he attempted to introduce conscription. On this issue the Labour party split, and the result was that Mr. Hughes formed a coalition government composed of the Liberals and that section of the Labour party which followed him on the conscription issue. The conscription referendum, on which the Government was defeated, was marked by great bitterness, and there followed a period of industrial and political strife without parallel in Australia's history. Mr. Hughes was hotly attacked for his autocratic methods, for his excursions into state shipowning and shipbuilding, and for his policy of concentrating power in his own hands by means of the War Precautions Act, the establishment of boards to control industry, and the appointment of special tribunals to settle industrial disputes over the head of the Arbitration Courts. But so long as the War lasted there was no alternative leader acceptable to the people, and the Prime Minister left to attend the Peace Conference with his prestige higher than ever. His assertion of Australia's right to proclaim something rather like a Monroe Doctrine for the Pacific did a great deal to awaken Americans and the world to the importance of Australasia; and at Versailles his advocacy, as eloquent as it was dogged, of the Commonwealth's right to a mandate over the former German colony of Papua, helped to make history. His quarrel with President Wilson, embittered by mutual dislike, gave rise to some of the most piquant passages in the annals of the conference.

In Australia, on his return, Mr. Hughes found grave industrial troubles disturbing a country already weighed down by an immense load of debt and the problem of reabsorbing 400,000 men into civil life. In peace as in war he gave Australia a bold and brave lead, and a gift of £25,000, raised by private subscription, showed that some at least of his countrymen were not ungrateful. But he could not prevent discontent revealing itself in the secession of certain Liberal-Nationalists and the formation of a new Country party. As the conditions which had brought it into existence disappeared, the War party which he led began to crumble, and in Feb. 1923, after holding office as Prime Minister for eight years, he was forced by a Liberal-Country party coalition to resign in favour of the Treasurer, Mr. S. M. Bruce. Then, a leader without a party, he stood aside and awaited his chance. (G. C. D.)

HULL, England (*see* 13,870), with a city area of 11,854 ac. including 2,495 ac. of the river Humber, had a population in 192 of 287,013. The port was enlarged in 1914 by the opening o King George's Dock, with an area of 53 ac. and provision fo future extension to 85 ac., a large grain silo and fine equipment The total water area of the docks is 236 ac. with 10 m. of quays The extensive and varied traffic of Hull was much affected b the World War, as the city was in the area of the North Se operations, but the volume of trade had almost recovered i 1926. The numerous industries include a large production o vegetable oil. There are some 300 steam trawlers in the fishin fleet, which did valuable service during the War. In 1914 th chief magistrate was created lord mayor.

New churches include St. Colomba's (1914), St. Mary's Sculcoates (1916), St. Nicholas', Hessle Common (1915) and th German Lutheran church (1911). A Friends' meeting house wa built in 1919, a synagogue in 1914 and a large Wesleyan-Methe dist Hall in 1910. The City Hall and Municipal Art Gallerie were opened in 1910, and the Guildhall enlarged in 1915; a statu of the 1st Baron Nunburnholme was placed in front of the latte in 1913. In 1912 a home for incurables was built and a new poo law hospital in 1914. During an air raid in that year some 4 houses were wrecked and 24 persons were killed. The counc chamber at Trinity House, together with many art treasures, wa destroyed by fire in 1924. The Rt. Hon. T. R. Ferens, a bene factor to the city in various directions, initiated in 1925 a fun for the establishment of a university college with a gift of £250, 000. He had previously given land on Cottingham road, o the outskirts of the city, as the site of a new technical colleg but this is to be made available for the university college.

HUMAN GEOGRAPHY.—Geography is defined (*see* 11,619 by Dr. Mill, as the exact and organised knowledge of the dis tribution of phenomena on the earth's surface. Human geog raphy on this view would be the corresponding type of know ledge of phenomena relative to mankind. While it is possible t bring in a great deal under this heading of distributional study yet this does not express the aim towards which many worker have striven from at least the time of Herodotus onwards.

Ratzel, Vidal de la Blache and Herbertson.—Space cannot b given for a historical survey, else we might discuss the stand points of thinkers of many centuries and regions down to Montes quieu, Humboldt, Ritter, Le Play, Buckle and Reclus. Ratze reacted against writers who overemphasised personality in in terpretations of history. He urged that in treatises touchin both history and geography the history was likely to expand un duly. His anthropogeographic studies discuss especially th human relations of natural features and his method has been de veloped by Miss Semple into that of a study of influences o geographic environment. Some workers on these lines hav failed to see how much of an "environment" has been made b man's previous work. Vidal de la Blache made a special contri bution to the clarification of thought on human geography. Fo him the study of place is the foundation and the place-relations o modern life are the centre of interest. Proceeding from descrip tion to interpretation, he was led to look upon those place-rela tions as stages in long courses of evolution from the past toward the future. Indeed the realisation of the time factor is a grea feature in all his work.

He again has contributed markedly to the idea of man as a agent modifying the world about him, influenced by the stage o human action as he found it, but also doing much to make th setting wherein his successors are to act their parts. One of hi typical statements may be rendered thus: "The personality o a country, its *genius loci*, is not a matter given beforehand by

inanimate nature, it is in large measure a product of the activity of man, of an activity which confers a unity on matters that would otherwise lack it," and again, "If a region has personality, it has been gained through the effort of its successive inhabitants." He saw, as did Herbertson, that the *genius loci* changes with the spirit of the time. In a sense, then, the student of human geography aims at picturing the settings of the stage of human activity at all places and at all times, even if he is primarily concerned with the present. If he limits himself by not looking back to the past out of which the present has come, he is not likely to be able to glimpse the future arising out of the present, and his work will be still-born.

Evolution and Human Geography.—It is obvious from what has been said here that human geography is a daughter of Darwinian thought, for Darwin brought to a head the problem of relations between organisms and environments and their influences upon one another, and for him also the present was but a stage in the succession from past to future. The application and modification where necessary, of the thought brought to fruition by Darwin, has occupied the minds of biologists ever since. The stages of conquest of the land by backboned animals from fish-like beginnings up to the varied orders of mammals are being worked out in ever increasing detail, and equally the dead-ends of evolution, the extinct orders, are followed to their disappearance.

The extension of Darwin's point of view to man has proceeded some distance, but, in the study of man's relations with his environment, that extension meets with difficulties largely because of the highly varied fields of study, which must necessarily come, whether directly or indirectly, into consideration. Outlines of the progress of men's relations with their environments from the earliest days of stone to the latest days of steel are being worked out in many ways, and also, just as in the study of animals, dead-ends, such as the jungle-covered cities of Ceylon, the monuments of Easter I., are receiving attention from many points of view, including that of the geographer. At the same time, it is well that one should guard against too ready acceptance of theories of determinist sequences in history such as those suggested by Flinders Petrie and Spengler.

Culture Origins.—It is unfortunately as easy as it is dangerous to argue, largely *a priori*, that a given environment produces certain results in human culture, and there have been thinkers who have argued that numbers of the more fundamental inventions such as metal tools, pottery, cultivated wheat, domestic cattle have been made independently in several regions as parallel responses to the influences of those environments. Enquiry has thrown doubt on several of these conclusions and many now think that food production had one localised origin, while probably the same conclusion is true for pottery (*see* ARCHAEOLOGY; SOCIAL ANTHROPOLOGY). The varying spreads of these main folk-inventions, probably quite as much by contacts as by migrations, have been important means of modifying men's relations with their surroundings far from their place of origin. Thus is introduced into the study of the setting of the scene of man's activity a cultural-historical element, and geography is brought into close relation with folk-history. Geography studies the scene, history the sequence of the action, but both need the sister science of anthropology in its widest sense, the science which analyses the types of man and of his forms of expression.

Geography, History and Anthropology.—In the study of men's life and work on earth there is thus special opportunity for co-operation of human geographer, historian and anthropologist, the first contributing his survey of the factors of place in men's work, the second elucidating the time-sequences, and the third helping to discriminate types of humanity and of human expression involved. It is on the increase of such co-operation rather than on more definite separation of studies that hopes for a great future advance of knowledge in human affairs depend.

The great man of history is often the man who has a special dynamic vision of the world about him, who sees whither the minds of multitudes are tending and what the work of contemporary pioneers will mean in the coming days, and he crystallises out inchoate thoughts. He thus depends very much upon the scene as he finds it. With Francis of Assisi and with Peter the Great, for example, we have the personal factor of vision, energy and initiative extraordinarily developed, yet even here the scene whereon they play their part has its influence upon that part, and the geographer, with his spatial discipline, his study of place, has his share to contribute towards the interpretation even of these mighty personalities and of their work.

If human geography works, especially at the analysis of place relations of mankind, it is deeply concerned both with the comparison and classification of the scenes of human work and with studies of distributions of human phenomena of every kind. For their interpretation it seeks to relate these distributions to one another in order to see how one influences another in the present, and how one in the present has been influenced by another from the past. The collection of data for maps, and the creation of maps which picture the data collected in the most useful way for study of their mutual relations is thus one of the tasks of the human geographer, a task as yet only begun (*see* FOLKLORE).

Culture Distributions.—Among the studies of cultural distributions made in order to get a picture of life in various environments and to suggest interpretations thereof, one may mention especially those of Clark Wissler in North America, and refer the reader to, *inter alia*, his study of *Man and Culture* (1923).

The discussions which followed, for example, the publication of Jovan Cvijic's *La Péninsule Balkanique* (1918) with its studies of cultural distributions show how much need there is for co-operation between students of types, be it of houses or other forms of human expression, and students whose aim is that of the human geographer, namely, the statement of the setting of the stage of human action.

The human geographer utilises, with understanding, the results of his colleagues' work, but concentrates on his own task, his study is the study of places, but in the idea of place are included the features of the place which are due to man's work. He needs that understanding of his colleagues' work, perhaps most of all as a protection for himself against the ascription to influences exerted by the place under discussion of features which may be imported or which may have arisen through other types of sociological influence such as those elaborated by Rivers (*v. inf.*). At the present stage of development, there is scope both for the human geographer, who will concentrate on the picturing of the scene and for the worker in the border zone, who may try both to make the morphological analysis of the facts discussed and to picture the setting of the stage as far as he can.

The anthropological student with his morphological discipline distinguishes types of men, of material objects or of customs or forms of expression in language, and he then seeks their relations with one another and is thereupon impelled to map their distribution in space. In this way, for example, he is led to see a great awakening of life near the western shores of Europe at or just before the dawn of the metal age. He sees the germ of that life developing in the west of the Iberian peninsula, according to some from local, according to others from imported, seeds. He follows the new life to the Garonne estuary, the south and west coasts of Brittany, Ireland and even farther. To make his story live he needs the help of the human geographical point of view accustomed to picture man's relation with environments. The study of copper objects and their successors in bronze must be far more than merely a classification of types.

Human geography can help archaeology (*see* ARCHAEOLOGY) to see the setting of the life of the bronze age. And on the other hand, the human geographer, who is trying to see the modern relations between man and environment in what we may call the Celtic fringe of Europe will miss a great deal unless he appreciates the early days of metal and has some notion of the inheritances those days have left to our own. With this equipment the human geographer is enabled to avoid the gross error of seeking to state the relations of particular men to their particular environment solely in terms of relations observable at present, as well as the other gross error of stating that such relations have come into existence on the spot at which they may now occur.

Culture Spreads and Contacts.—Few thinkers have done more in our day than the late W. H. R. Rivers, to show how spreads of culture have altered men's relations to their environments. He worked just outside the sociological frontier of geography and emphasised not only the apparent naturalisation of imported elements of culture, a naturalisation sometimes so marked that *a priori* arguments could easily be constructed to show that these elements of culture must be native, but he has also shown that there is much more in the matter. Importation of elements of culture has often led and still often leads to the weakening of local custom, that is to the removal or abrogation of ancient habits. He has shown that, in some cases, the weakening affects so much that the whole life of the people concerned is dislocated beyond repair and they die out (*see* ANTHROPOLOGY, APPLIED). Sometimes the weakening of old custom due to new contacts has avoided this catastrophe, but has been sufficient to set free a large amount of human initiative and effort. In such cases, new features have appeared that are the result of the play of this liberated initiative, but quite probably have no close relationship to the imported elements of culture. These last acted as the ferment; their direct part in the ultimate result may be small enough.

Especially following Rivers' work and that of the "Kulturhistorische" School in Germany, the study in cultural distributions has had its importance increasingly recognised. We see far more fully than heretofore some of the founts of human initiative, of human influence over environment. We appreciate in a deeper way the fact that men may knit widely differing relations with one and the same region, for we see how much will depend, for example, on the dominance of ancient custom in one case and the importation of cultural elements and associated liberation of initiative, or it may be its destruction, in another. The contrasts between native Patagonian huntsmen and Welsh agricultural immigrants at Chubut illustrate these points.

We see also the wide bearings of the principle illustrated, for example, by the commonplace fact that railways began by linking together places already in existence and then went on not only to modify them and their activities, but also to create new centres, in England new groups of factories, new suburbs, new watering places, in Canada new capital cities, new agricultural lands and the like.

Synthetic Regional Studies.—One of the most appropriate tasks of the human geographer is the study of a particular region, as the setting of human life, and multifarious have been the recent efforts in this direction. Vidal de la Blache wrote his classic *Tableau de la Géographie de la France* (1903) and his followers have written monographs on several of the "pays" or natural units of human life in that country. The monographs vary greatly in value, but on the whole avoid fairly well the errors in the argument of physical determinism. There cannot be said to be a physical predestination of the special developments of human activity in a particular region, the efforts of man, the contacts of autochthones and immigrants and their consequences, all need to be brought into the story. A distinguishing feature of the monographs of this school is the intimacy of the writers with the district about which each writes; that intimacy and attachment have been emphasised by Herbertson and by Younghusband as valuable aids in serious regional study. In several of the monographs in question, on the other hand, there is a lack of maps of cultural distributions especially as regards distributions giving clues to the local beginnings of civilisation; historic documents, however, are widely utilised. J. F. Baddeley's *Russia, Mongolia and China* (1919) and Sir M. A. Stein's *Serindia* (1921) are monumental works on their respective regions which have appeared recently, while Hilton Simpson has made studies of the people of the Aures massif. New works on regional planning for Dublin, Deeside, Doncaster and East Kent are valuable examples of applications of the regional study of human geography.

Scope of Human Geography.—In this province of study of a region and in that of study of cultural, including commercial distributions, the work of the human geographer is well recognised even if he be held to need for this work some systematic knowledge of allied sciences that his work must necessarily touch. The subject of general human geography is, on the other hand, still at such an early stage of development that its content and scheme are still subject to argument.

Huntington.—Ellsworth Huntington's attempt to give a scheme avoids a claim to be more than a sketch to help young students to form pictures of the world about them. He treats of men in relation to location, land forms, bodies of water, soil and minerals, climate, vegetation, animals and other men. For him the subject is a mass of problems of the relations between environment and human activity. In the course of the work, he touches upon the very deep problem of the relation of man to climate, of his varying energy and initiative in different environments and he thus introduces study of man along with study of place, with this justification, namely, that such study of man is essential if there is to be a reasonable picture of men in their various environments.

Schrader.—F. Schrader, towards the end of his life, sketched a characteristic policy for the development of human geography in the 20th century, suggesting that with the modern development of world-wide connections there was an immensely increased practical need for increase of our knowledge and our sense of the natural laws which rule material and spiritual exchanges of activity between man and the world. Geddes has long emphasised the need for correlated studies of place, work and folk, but without detaching from this wide general task the special part which the geographer should undertake, unless it be that of place.

Brunhes.—Brunhes has made an attempt to be more systematic and has suggested human geography as the study of all those facts of the surface of the earth in which human activity plays a part. He tries to work out first the facts of such occupation of the soil as is not directly productive, and treats especially houses and roads; then he takes up man's work with vegetable and animal material for productive purposes; next he takes up man's destructive influence on plants, animals and inanimate materials. Subsequently, after giving analyses of the social life of a number of natural units of humanity, he proceeds to study the bearings of his earlier pages on growth of human society and its organisation. The debt of this writer to the thought of the sociological school of Le Play seems to be considerable.

De la Blache.—Vidal de la Blache left at his death notes for a large work and these have been arranged for publication. Starting as do both Schrader and Brunhes with the idea of the world's effective unity, he makes the study of the distribution of population the first concern of human geographers, who must try to follow its forms of nucleation and its types of scattering, its migrations and oscillations. Following this, he considers in regional succession the great agglomerations of human population. In the second place, he includes study of the forms of civilisation to be pursued, especially regionally, but apparently to be discussed under subjects such as materials, food, constructions, sites, habitations and so on. In the third place, he proceeds to the study of the circulation of men the world over, roads, railways, sea-transport and so on. It was evidently his intention to proceed to survey the evolution of races and the dispersion of cultures, and he sketched maps of the distribution respectively of animal and of vegetable products used by man and of constructions which may be supposed to be autochthonous in different regions of the world.

Commercial and Political Geography.—G. G. Chisholm's encyclopaedic work, *Commercial Geography* (1889–) may be looked upon as a type of study of a special subdivision of human geography, which has a peculiar importance for practical life. Several other recent works have discussed commercial or economic geography with a considerable measure of success.

A few words on political geography may be added. Ratzel is here one of the chief pioneers and his followers in most countries make the state the unit of treatment, describing and sometimes seeking, to interpret the physical, demographic and economic facts of each state. A large body of material for political geog-

aphy has been published in the British Foreign Office and Admiralty handbooks designed to assist discussion of the treaties of recent years. This study is in a sense an applied development of general human geography; in another sense it is an alternative study. Human geography in the stricter sense could not at all generally accept state frontiers as natural boundaries for divisions of its discussions and might well seek, as in some recent studies of frontiers, the geographical interpretation of those boundaries which are in essence human facts.

Conclusion.—The contrasts between Huntington, Brunhes and Vidal de la Blache are evident. In Huntington's work we find the emphasis on man; in that of Brunhes the main emphasis is on work; in Vidal de la Blache, the repeated efforts towards serial consideration of regions gives emphasis to place. But all see that studies of forms of civilisation occurring in various environments, *i.e.*, that studies on a regional basis are a fundamental task; and all bring out the impossibility of the attempt to delimit at all strictly mutually exclusive spheres for what may be called human geography and anthropology. It is possible at present only to urge that, in the latter, the main object of study is man, his various physical, social and other forms, *i.e.*, primarily morphological.

In human geography, on the other hand, the main object of study is place relations of men of all kinds, and of any or all of their forms of expression the world over. The place relations of the present day are not the only legitimate objects of study. We need the study of these place relations in the past as well if we are to have an eye to the future, but it is the present that gives us the truest starting point, for it is here that we may observe most directly how man influences and is influenced by environment. From a study of the present, also, as from nothing else, we may be led to say that man and his surroundings are changing together, and that we cannot set man and environment in opposition to one another, save for convenience of discussion, and with the full consciousness that as we do this we deliberately sacrifice something of the concrete reality. We may accept these drawbacks for the sake of reaching generalisations of a manageable kind, but we must recognise the incompleteness that is a necessary consequence.

There is reason to hope that, on the one hand, regional studies will progress and that on the other hand studies of distribution of men and of their forms of expression, present and past, will be deepened. The first will need intimate acquaintance, loving familiarity, to use Herbertson's phrase, as its starting point, and, however much it may concentrate on the present, it will need to consider the past at every turn; it may well need also to bring into its purview some results of study of the differences between man and man; it must remember that the environment presents to man opportunities and difficulties, possibilities rather than compelling influences. The second will need increase of emphasis on the study of the places involved and the possibilities they offer or deny; that is to say, the student of place will be called upon to play an increasing part here, but it remains obvious that the student of the morphology of the forms of expression studied is equally important, and this is a field especially for a combined effort of students of place, time and type in relation to human beings and their forms of expression, both material and spiritual.

HUMPERDINCK, ENGELBERT (1854–1921), German musician (*see* 13.891), died at Neu Strelitz Sept. 27 1921. His last opera, *Die Marketenderin*, was played at Cologne in 1914.

HUNEKER, JAMES GIBBONS (1860–1921), American musical critic, was born at Philadelphia Jan. 31 1860. He graduated at Roth's Military Academy, Philadelphia, and was a law student for a time, subsequently studying the piano in Philadelphia, Paris and New York. He was teacher of the piano at the National Conservatory, New York City, 1886–98, becoming musical and dramatic critic for the New York *Recorder* and *The Morning Advertiser*. From 1900 to 1912 he was musical and dramatic critic for the New York *Sun*. In 1912 he joined the New York *Times*, but returned to *The Sun* in 1919. He died in Brooklyn, N. Y., Feb. 9 1921. His writings on music, literature and art are notable for their style and popular appeal. His published works include *Chopin: the Man and his Music* (1900); *Overtones: Music and Literature* (1904); *Franz Liszt: a Study* (1911); *Ivory, Apes and Peacocks* (1915). He also supplied the text for Josefy's edition of Chopin's works.

HUNGARIAN LITERATURE (*see* 13.924).—Hungarian literature at the beginning of the 20th century was on the brink of a revolution. The intellectual life of the country was undergoing a crisis. After 1,000 years of a history sometimes glorious, but more often tragic, Hungary was faced by new difficulties which threatened her very life: the social question, the defence of her civilisation and her language against the Slav and Teutonic races, and the antagonism between the essentially rural nature of the Hungarian people and the Americanism and cosmopolitanism of the capital, Budapest.

Writers were divided into two camps: the traditionalists and the moderns. This division still persists. The older generation, inspired by Hungarian nationalism, had joined in the celebration of the country's 1,000th anniversary in 1896 and had accepted modern civilisation but remained firmly opposed to cosmopolitanism and radicalism. They still longed for the Hungarian steppes and the old folk songs. From this generation originated what is known as the Turanian movement, which draws its inspiration and its themes from the East and endeavours to arouse in the Hungarian people the consciousness of their non-European origin. The numbers of this older generation diminish year by year. The patriotic and classical poets, Joseph Lévay (1825–1918) and Alexander Endrödi (1850–1920), followers of Jean Arany, towards the end of their lives burst again into song. In 1910 Hungary lost the novelist Koloman Mikszáth, the most notable successor of Jókai, the immortal painter of the Slovak peasant and the aristocracy of Northern Hungary. Among contemporary writers of this school are the poets Jules Vargha and André Kozma, the novelist Ferencz Herczeg and the critic and essayist Eugene Rákosi, their organ being the review *Budapesti Szemle*, edited by Géza Voinovich.

In opposition to the older generation were the moderns, who hailed the advent of capitalism and industrialism in place of the old provincial spirit. These intellectual radicals wished to eliminate from literature all national characteristics, and to promote the cause of realism with its materialistic philosophy. They turned their faces towards the West, not the chauvinistic West, but the home of cosmopolitanism and anti-nationalism. The moderns gathered their forces in the early years of the 20th century, using as their rallying point a review with the symbolic title *Nyugat*, edited by Ignotus. Round it gathered the young poets of the symbolist and romantic school.

Chief among these men was André Ady, an original Magyar genius, whose primitive and prophetic gifts place him in the first rank of Hungarian poets. Influenced as he was by French symbolism as well as by the works of Zola, he drew inspiration also from the days before the school of Arany, from the melancholy, sometimes crudely expressed, Protestant hymns of the 16th century, from the songs of the rebels against the Austrians, from the archaic and primitive beauties of the Hungarian Bible. His robust language and brilliant vision illumine the depths of the soul. He tilts against conventional morality and describes love with all the voluptuousness of the realist: a trait which is, in fact, common to all the moderns. He is distinguished by a certain aristocracy of mind, as, for instance, in his attitude towards the Nietzschean cult of the Ego, but in his general outlook, and in his hedonistic glorification of blood and treasure, and above all, in his sympathy for the poor and despised, he inclines towards Socialism.

Compared with him, modern lyrical poets such as Michael Babits, Jules Juhász, Désiré Kosztolányi, Árpád Tóth, Gabriel Oláh, Ernö Szép have confined themselves to pure aestheticism, seeking to express the emotions of a cultivated, almost neurasthenic, minority. The realistic novelists found a successor in Sigismond Móricz, whose preoccupation with brutish peasants and corrupt petty tradesmen reflect his political tendencies. His work is the antithesis of that of idealistic novelists such as Géza Gárdonyi (d. 1923) and Cécile Tormay.

When the World War broke out, these two camps, the traditionalists and the moderns, were still divided by a great gulf. Cosmopolitan literature was silent for a time. The poets of tradition hailed the conflict with acclamation. One poet, a soldier, Géza Gyóni, in a language learnt from the moderns, turning his back on *l'art pour l'art*, succeeded in expressing the horrors and pathos of the War. The moderns were not long in making themselves heard, but, as might have been expected, their pacifist leanings were only accentuated by what had happened. Far from joining in the martial chorus which then predominated, their symbolist and decadent verse reflected the trouble in their souls, whilst glorifying man and life.

The final disaster, and the revolution of Oct. 1918 unmasked the political connections of *Nyugat;* its contributors joined hands with the rabble. In the intoxication of the first success the moderns threw off the mask. Their review declared itself to be definitely on the side of the revolution and of Count Karolyi. They looked forward to the end of the old feudal agricultural Hungary, the Hungary of officialdom, of the nobility and of the nationalist writers grouped around both.

During its four months' reign Bolshevism kept literature under strict control. Newspapers were suppressed and the right of publication withdrawn. A single publisher held all the world of thought in fee: the State printed nothing but propagandist papers and pamphlets. The socialised theatres were forced to produce plays in celebration of the revolution. Futurist and expressionist writers alone were protected and subsidised by the "literary directory." This upheaval brought no good to literature. Expressionism pushed to extremes led nowhere.

After the fall of communism, literature set itself to assist in the task of national regeneration. With no definite theories of art or literary programme it expressed the grief of the divided country and its longing for the lost provinces. Although historic Hungary was divided into five parts, Magyar literature kept its unity. In political Hungary the novel took the place of the lyrical poetry of the pre-War period. Désiré Szabó, in his loftily conceived work, describes the great cataclysm of the World War and the determined defence made by the Hungarians, in both the material and moral spheres, against the foreign invader.

Hungarian literature from this time onward endeavoured to break the bonds of torpid decadence and of anti-national radicalism, and to place before a people, struggling in the shadows of adversity, a new conception of the world which should be healthy, energetic and modern, thus again proving that Hungarian literature has always been something more than a mere exercise in aesthetics. Modern drama is striving to create new and lasting values, both poetic and philosophical. Romanticism has reappeared, and talented dramatists such as Ferenc Herczeg, Ferencz Molnár, Louis Biró and Melchior Lengyel have attained to well-deserved success in the theatres of Europe and even in those of America. Realism and purely theatrical effect have, for the time, being quite vanished from the Hungarian stage.

In discussing Hungarian literature we must not forget that of the lost provinces of Hungary. In Transylvania in particular there has been a remarkable renaissance. The reawakening of a feeling for the mother country has also made itself felt in the Northern Carpathians. There, poets such as the Transylvanian Végvári often express under pseudonyms the sadness which, as Magyars, they cannot but feel.

HUNGARY (MAGYARORSZÁG, *see* 13.894), an independent kingdom of Central Europe. Previous to 1918 Hungary formed part of the Austro-Hungarian Empire, whose monarch was Apostolic King of Hungary. The Lands of the Hungarian Crown had an area of 125,402 sq. m., of which Croatia and Slavonia, which were in political union with Hungary, occupied 16,420 sq. miles. The census of 1910 gave the population of Hungary as 20,886,487 including 10,050,575 Magyars (for racial statistics *see* AUSTRIA-HUNGARY). The Treaty of Trianon (*see* TRIANON) in 1920 deprived Hungary of all Croatia, Slavonia and Transylvania and much of Hungary proper. Her new frontier runs as follows:—

Starting from the junction of the Czechoslovak and Austrian frontiers near Bratislava, southeast to the mouth of the Ipel river; then along its course to a point 10 km. below Lučenec; hence southeast above Salgotarján, northeast up to a point lying 20 km. south of Košice, southeast above Sátoraljaújhely to Csap, thence along the Tisza to the junction of the Rumanian and Czechoslovak frontiers. After running west of the Satul Mare Oradia-Mare line, it turns west, and runs south of Makó to the Yugoslav frontier below Szeged; hence south of the junction of the Maros and Tisza southwest to a point on the Dráva south of Pécs; hence west and northwest along the Dráva to the mouth of the Mur; along the Mur, then north to Szentgotthard; hence north to Köszeg, then makes a loop to include Sopron, crosses Lake Neusiedler (Fertö), thence north to the Czechoslovak frontier.

The area comprised within these frontiers is 35,916 square miles. Population (1920), 7,989,143. Of these 7,147,530 were Magyars, 551,211 Germans, 141,882 Slovaks, 23,760 Rumanians, 36,858 Croats, 17,131 Serbs, 1,500 Ruthenians, 69,271 other races. Some 3,250,000 Magyars were living within the frontiers of Czechoslovakia, Rumania, Yugoslavia and Austria (*see* MINORITIES). The Treaty took from Hungary all her gold, silver, copper, salt and mercury mines; all but one of her iron mines; her largest and best collieries; and 86% of her forests. The only branch of productive territory of which she retained over half is viticulture (68%). The strongest social element left to her was her peasant class (4,449,105 persons were engaged in agriculture). There was a very large intellectual class, composed largely of ex-state employees formerly resident in the territory of the present Succession States, the settlement of which formed a grave problem.

I. POLITICAL HISTORY

At the fateful Crown Councils of July 7 and July 19 1914, the only person present who opposed the idea of an attack on Serbia or any measure beyond the formulation of severe but acceptable demands to Serbia was Count Stephen Tisza, then Hungarian Minister President. Thanks to his influence alone, a passage was entered in the minutes of the second council as follows:—

The Common Cabinet Council, on the motion of the Minister President of Hungary, decided that immediately after the commencement of hostilities the foreign Powers should be notified of the fact that the monarchy was not waging a war of conquest, and that it was not the object of the monarchy to annex the Kingdom of Serbia.

Tisza, however, made no statement on his conduct until Oct. 17 1918 when he mentioned it in the Lower Chamber of the

Hungarian Parliament, enumerating the documents in which it was recorded (*see* AUSTRIA-HUNGARY).

The Collapse of the Monarchy.—The causes of the catastrophe of 1918 were partly internal, partly international. After the death of Francis Joseph I. on Nov. 21 1916 the rule of the Dual Monarchy gradually lost its character of stability. Austria was already weak; and the dismissal of Tisza (May 22 1917) made Hungary, too, helpless. However, as the armies of the monarchy still occupied considerable enemy territories, few people thought of the possibility of its sudden collapse. The protracted war had become extremely and increasingly unpopular. The general desire for peace and the weak and irresolute policy of the Government contributed to encourage the defeatist agitation. The peace propaganda was furthered by the publication on Jan. 8 1918 of President Wilson's Fourteen Points, which were accepted with implicit faith by the Hungarian people, who have always shown a sincere enthusiasm for the great ideas of mankind. The return home of large numbers of soldiers released from Russian captivity after the Treaty of Brest-Litovsk (Mar. 3 1918) furthered the growth of communistic and anti-militarist ideas, which were enormously strengthened by the privations and suffering caused by the blockade. Only on the capitulation of Bulgaria (Sept. 29 1918) did the situation become quite clear. The revolutionary movement now ceased to be a merely sporadic phenomenon; foretokens of the coming upheaval became everyday occurrences.

The first signal of the process of upheaval was a demonstration of students on Oct. 25, the crowd being, however, dispersed by the police. The same day the so-called National Council was formed, with Károlyi as its president, together with a soldiers' council and a students' council. Lieut.-Gen. Baron Lukachich, who had been appointed military governor of Budapest, suggested that Károlyi and the members of the National Council be arrested; but the suggestion was not approved by the Government just resigned. Two days later the National Council issued a proclamation with the title "Amnesty and land for the soldiers," which foreshadowed the coming of Bolshevism. Now events succeeded one another with bewildering rapidity. Two companies ordered to the front mutinied and, joining the groups of demonstrators during the evening of Oct. 30, attacked and seized the headquarters of the commander of the garrison, the telephone exchange and the general post office. Gen. Lukachich telephoned to Vienna for instructions, but the King refused to consent to the employment of the armed forces at the Baron's disposal. By the morning of Oct. 31 the town was completely in the hands of the revolutionaries; Károlyi was appointed Prime Minister. His Cabinet included principally persons without seats in Parliament, Social Democrats and Radicals; of the parliamentary parties only the Independence party (Kossuth party) was represented in the Government, several of the ministers chosen by Károlyi belonging to it.

The same afternoon Count Stephen Tisza was murdered, probably by emissaries of the soldiers' council. His friends had repeatedly warned him; but he had remained in Budapest in a final effort to unite all the elements of order against the rabble. Tisza knew how critical was the situation and he knew that he was threatened by death. The followers of Károlyi ordained as a national holiday the very day on which they laid Tisza low. On the other hand, it appeared to Károlyi's opponents that with the disappearance of a formidable antagonist he lost his personal initiative and became little more than a puppet in the hands of Jászi, the Radical party and the Socialists.

The first measure taken by the new Government was to demobilise and scatter in all directions the soldiers pouring back from the front. The war minister—Béla Linder—declared that he "did not wish to see soldiers"; and Hungary was thus disarmed and rendered powerless both to stem the internal anarchy of the country and to resist occupation from without. The first result was universal looting and robbery; then followed the invasion of the Czechs, Rumanians and Yugoslavs. The Czechs were able to occupy the almost impregnable fortress of Komárom on the Danube without striking a blow, for the troops of occupation met not the slightest resistance anywhere. In vain did the inhabitants everywhere protest against the occupation; the Government was both unable and unwilling to do anything to lend weight to their protests.

On Nov. 1 the Austro-Hungarian delegates had met the Italian

generals Diaz and Badoglio to conclude an armistice. Point 3 of the conditions enunciated was that the Austro-Hungarian troops were to evacuate all enemy territory occupied in the War; a line of demarcation was drawn in the southwest; elsewhere it was to consist of the former political frontier. Gen. Weber, who was authorised by the Hungarian Govt. to negotiate for Hungary, accepted these conditions in the name of Hungary. Károlyi and a delegation of his Government, however, believing that he could get better terms from the Entente, called on Gen. Franchet d'Esperey in Belgrade, who concluded a separate "military convention" with them on Nov. 13. This fixed a line of demarcation well within the old political frontier (Bistrita-Nagy-Szamos-Marosfalli-Subotica-Baja-Pécs), the line of the Drava. Hungarian troops were to withdraw behind this line, but Hungarian police, gendarmerie and civilian control would continue to function. The Allies were entitled to occupy any towns or other points of strategic importance but would not interfere with the internal administration. Hungarian troops were to remain to secure the line of demarcation.

In fact, however, the occupying troops, backed by the inter-Allied missions in Budapest, denied Hungary any sovereign rights in the territory outside the line of demarcation; assumed the civilian administration, removing the Hungarian officials; disarmed the gendarmerie and police; set up an economic boundary; interrupted communications; forced inhabitants to take an oath of allegiance to themselves, and even pressed them into military service. It thus became abundantly clear that Károlyi could not obtain better terms from the Entente, and his popularity at once began to wane.

Proclamation of the Republic.—On Nov. 13 Charles IV. issued the Eckartsau manifesto, declaring that he "resigned all share in the conduct of state affairs and was prepared in advance to accept any decision to be taken by Government respecting the future form of government of Hungary." The Károlyi Govt., without consulting Parliament, at a mass meeting in Budapest proclaimed Hungary a republic (Nov. 16). Under pressure from the Government the House of Deputies proclaimed its dissolution; the only protest against this arbitrary measure was that contained in the declaration read by Baron Wlassich, president of the Upper House (House of Magnates), who at the same time announced that the Upper House had adjourned its sittings for an indefinite period. The counter-revolution received legal sanction from the illegality of the proclamation of the republic. William Böhm, who was Minister of War under Károlyi, writes that there were 50 cases of riot, most of them involving fatal consequences, while 14 different military formations were raised to deal with the counter-revolutionary movement. Complete anarchy prevailed in the administration. The Government admitted that the "national councils" of the provincial towns were daily guilty of grave abuses but alleged that it was powerless to prevent them. Jászi admitted that they had made a revolution without having any men to do the everyday work.

Not only did they fail to do anything to save the territorial integrity of Hungary, they were even incapable of achieving any radical reform. They were not satisfied with a mere republic, "it had to be a people's republic." The plebiscite promised by the National Council was never held by the Károlyi Govt., for their few months of power yet sufficed to make them not dare to appeal to that national public opinion in the name of which they consistently spoke and acted. Károlyi was proclaimed President of the Republic on Jan. 11 1919 and on Jan. 19 formed a Cabinet under the presidency of Denis Berinkei, then Minister of Justice. It had no proper support either among the bourgeoisie or among the socialists; yet it created a whole series of laws and ordinances. Never had there been so rapid and so general a promotion of public employees, for the older employees were in general regarded as unreliable. Following the precedent of the United States Károlyi as "provisional President of the Republic" took part in the Cabinet Councils and frequently spoke at these meetings.

There were two questions of first-rate importance: universal suffrage and land reform. A protracted discussion preceded the drafting of an ultra-modern suffrage bill (drafted and passed *intra muros*, without reference to Parliament, which did not exist). But the bourgeois parties were beginning to recover from their apathy. The suppression of individual liberty, the intimidation of the bourgeois press, and the policy of internment at last began to change their initial lethargy into a determination to rally their forces; and it was already clear that a very strong Catholic party would contest the elections; consequently, Government continually postponed the elections and finally manoeuvred them off altogether. Nor did Government materialise the promised scheme of land reform.

The Allied Powers meanwhile bombarded Hungary with ukases. Col. Vyx, their representative in Budapest, permitted the Czechs, Rumanians and Yugoslavs to pass at will beyond the line of demarcation. The Government still maintained that a "peace by agreement" would follow; shortly afterwards however, the radicals and Jászi resigned from the Cabinet, which was now clearly lacking the support of public opinion.

The Soviet Republic.—The agents of the Russian Soviet had long since begun their work in Budapest. Béla Kun, who had been sent home from Russia to organise the Hungarian Soviet had been in Budapest with some associates since Nov. 19. These men had money; they were daring and active and rapidly gained a following, not only in the organised proletariat but also among the socialists and the "intellectuals." They arranged demonstrations among the soldiers returned from the front; they demanded the payment to these men of immediate relief. Continuously increasing their demands, they gained larger and larger masses to the cause of revolution. On Feb. 20 1919 a mass meeting of unemployed yielded entirely to Communistic influence. To intimidate the Socialists they attacked the offices of their organ the *Népszava*, killing seven policemen and wounding 80. After protracted discussion the Government imprisoned Béla Kun and his followers. The funeral of the murdered policemen was a gigantic demonstration of the people against Bolshevism and in favour of Socialism. It seemed as if Bolshevism had been finally overthrown.

On the morning of March 20, Col. Vyx handed Károlyi a note establishing a new neutral zone between the Hungarian and Rumanian troops. This area comprised some 2,000 sq. m. of predominantly Magyar territory. Vyx afterwards stated that the zone was to be purely neutral, remaining under Hungarian administration. Károlyi contended that Vyx had stated that Rumanian troops would occupy this area. At a Cabinet Council the same evening Károlyi resigned as President of the Republic and a resolution was passed that, as the Coalition Govt. saw no prospect of solving the political crisis or of ensuring production the Social Democrats must take over the government. The Socialists, however, were too weak unless supported by the Communists. On March 21, at noon, the Socialists decided to come to terms with the Communists, undoubtedly at Károlyi's personal instance. It is true that the difficulties were numerous but Károlyi and Jászi had been unequal to them. The hopes aroused by their promises had not been fulfilled and their phase of the revolution had ended in chaos.

The agreement between the Socialists and Béla Kun was made in the prison. The Communists dictated and the Socialists accepted everything. The whole Social Democratic party united *en bloc* with the Communists. Pending the decision of the Third International the new party was styled "the Socialist party of Hungary"; it was to take over the power at once in the name of the proletariat; the dictatorship was to be wielded by the Labourers, Peasants and Soldiers' Council; urgent steps were to be taken to organise a "class army" and completely disarm the bourgeoisie; a reign of terror was to be proclaimed to ensure the rule of the proletariat; a close military and spiritual alliance was to be made with the Russian Soviet.

By the evening (March 21 1919) the streets were in the hands of armed Communists; at 6 P.M. the public prosecutor visited the prisons to release the prisoners. At the head of the governing council was placed Alexander Garbai, a bricklayer. His asso-

ıtes in the council of people's commissaries were Kun, Joseph ɔgány, president of the Soldiers' Council and Sigismund Kunfi, secondary school teacher who had been a member of Károlyi's ıbinet. The people's commissaries and practically all the lead- g persons were Jews, a fact which explains the anti-Jewish eling which later prevailed in Hungary. Károlyi's revolution ıd been in part an imitation of that of Kerensky; Hungarian mmunism took Lenin as its model, though Lenin is said to ve warned Béla Kun to take into due account the fact that nditions in Hungary were essentially different from those pre- iling in Russia. As the majority of the people's commissaries ıd been prisoners of war in Russia, they often spoke Russian their meetings. They ordained the " communisation " of the nd, of industrial establishments, of houses and factories, of all ıdertakings and shops. Jewels of a value in excess of 2,000 owns were to be surrendered; the deposits entrusted to the ınks (both savings and current account deposits) were seized ıd communised.

From the outset there were two distinct currents of opinion the Government: a moderate and an extremist. At first the cialist influence predominated and the action of the communists as more of a chicanery than a persecution. On April 4 Gen. nuts arrived in Budapest to negotiate with Kun's Government ı behalf of the Allies. He offered to recognise the disputed ne, not as a political frontier, but as a line of demarcation only,) be bordered by a neutral zone. Kun insisted that the Bol- ıevik system must be introduced in the neutral zone. Smuts roke off negotiations. On April 16 the Rumanians advanced ong the line of demarcation up to the Tisza (Theiss). As their osition was now menaced by the danger of a counter-revolu- on, the Bolsheviks resorted to undisguised persecution. In udapest alone they took 481 " hostages," and several thousands ıore throughout the country. The Red Army was organised, rimarily to ensure the maintenance of the dictatorship. Later, hen they saw that the national feeling and popular exaspera- on was growing even more formidable, and that terror, intern- ıent, torture and assassination could no longer keep passions ı check, the Bolsheviks commenced an offensive campaign, efeated the Czechs, occupied Košice (Kaschau) and advanced p to the Polish frontier at Bardiov (Bartfa). But, after receiv- ıg Clemenceau's note of protest dated June 8, they withdrew ıeir troops, and on June 13 were fixed the definitive frontiers hich condemned Hungary to dismemberment and helplessness.

This catastrophe instilled fresh courage into the counter- evolutionaries. On June 24 the cadets and officers of the mili- ary academy, assisted by the Danube monitors, some of which ere stationed in the winter harbour at Ó-Buda, assumed the fensive. On this occasion the Red Army suppressed the coun- er-revolution; but communism never recovered from the shock. nd no one believed it could long maintain its position. As there ıd been counter-revolutionary movements in the provinces too, he Red Terror made its appearance. Indisputable official data ave recorded the murder by the terrorists of 585 persons, includ- ng Louis de Navay, a former Speaker of the House of Deputies nd one of the most distinguished Hungarians of his day; the ıumber of persons of obscure origin who may also have fallen victims to Szamuely's thirst for blood is unknown. Throughout he Commune Budapest suffered from a disastrous shortage of ɔrovisions, due not only to the blockade, but still more to the ɔassive resistance of the peasantry.

The Communists employed their money for propaganda pur- ɔoses, particularly in Austria. Budapest lived mainly on pearl ɔarley and vegetable marrow; anyone desirous of obtaining bet- er food was compelled to go to the provinces and offer clothes ɔr petroleum in exchange for meat or bread. Unrest and dis- ontent were general; even the trade unions were beginning to urn in secret against the Soviet régime. There was a breach ɔetween Béla Kun and Haubrich, commander of Budapest and eader of the iron and metal workers. As an open rupture seemed mminent, it was proposed that the garrison of Budapest should ɔe placed under Szamuely, the most bloodthirsty of all the Jack Ketches in the service of the dictatorship. Luckily, the Italian colonel, Romanelli—who had already collaborated with the American mission to save the lives of hostages and prisoners—prevented this baleful scheme.

On July 20 Béla Kun began hostilities against the Rumanians in the hope that his propaganda had demoralised their troops. The Rumanians defeated him easily and advanced on Budapest; whereupon the outbreak of internal discontent overthrew the Bolshevik régime. The Soviet Govt. resigned on Aug. 1. Most of its leaders fled to Austria. A Socialist Govt. under Peidl was formed, which guaranteed the sanctity of private property. On Aug. 4 the Rumanians entered Budapest. Two days later the organised bourgeoisie overthrew the Socialist Govt. in which they felt no confidence since its recent connection with the communists, and a Government was formed under the presidency of Stephen Friedrich.

The Counter-Revolution.—The restoration of a stable régime in Hungary proved extremely difficult. In May 1919 a counter-revolutionary Government had been formed at Arad—then already occupied by the Rumanians—under the presidency of Count Gyula (Julius) Károlyi, which endeavoured to act as the representative—as against the reign of terror of the Commune—of the ideas of bourgeois order, of the historical integrity of Hungary and of the principle of legal continuity. At first this was little more than a demonstration, since it lacked real power. After a few days the Rumanians sent this Government under military escort, first to the state estate at Mezöhegyes and then to Szeged which, was at that date occupied by French troops.

The Szeged Govt. began to organise a counter-revolutionary army out of a nucleus of volunteers who had distinguished themselves during the War and had fled to Szeged to escape the Bolshevik Terror. Its sphere of authority hardly extended beyond the inner confines of the town, but the authorities in occupation made many difficulties for both the military organisation and the civil administration. A certain success was achieved by the Szeged Govt. through its representatives in Vienna, under the guidance of Count Bethlen. This " detachment " kept in touch with foreign countries and informed public opinion of the West of the misdeeds of the Hungarian Soviet régime.

After the fall of the Commune the Szeged Govt. suspended its activity, and those detachments of the Hungarian national army which had been formed at and near Szeged moved their quarters to Siófok on Lake Balaton. The Government appointed Admiral Nicholas Horthy commander-in-chief of the national army.

In Budapest, meanwhile, the popular Archduke Joseph assumed the government, assisted by Stephen Friedrich as Prime Minister; but the Supreme Council in Paris refused to recognise any Habsburg in a position of authority in Hungary and sent four generals to Budapest to represent the four Principal Allied Powers. The Archduke Joseph was forced to resign. The four generals were fully occupied in thwarting the excesses of the Rumanian troops of occupation in Budapest, who plundered and destroyed property wholesale. According to the report dispatched by Col. Lorec to Paris, the value of the goods requisitioned by the Rumanians exceeded 00,000,000 gold crowns (about £3,750,000). The Rumanians also aggravated the difficulty of the Friedrich Government. The Entente then deputed Sir George Clerk to negotiate as plenipotentiary delegate of the Supreme Council and pave the way for the constitution of a Coalition Government to include all the political parties with which the Entente could properly conclude peace. On Nov. 22 Friedrich resigned, and a Government, including representatives of all parties, was formed, Huszár being Minister President.

On Nov. 14 the Rumanians withdrew to the line of the Tisza (Theiss), and Horthy entered Budapest at the head of the small national army, amid the enthusiasm of his many adherents. General elections were held in Jan. 1920 on the basis of a suffrage (secret ballot) of a practically universal character. They gave a considerable majority for the parties of the Right which formed the Government alone. This was a natural reaction after nearly a year of excesses committed by the extreme Left. Those regrettable

acts of violence known and described abroad as the "atrocities of the White Terror" sprang from a similar revulsion. It is a fact that, immediately after the fall of the Commune, certain "detachments" were formed in various parts of the country, which arbitrarily executed Communists; however, such atrocities were nothing like as numerous as those committed by the Soviet régime. The victims of the period following the overthrow of Communist Dictatorship number, according to data compiled by the Hungarian Ministry of Justice:—

Victims of the White Terror	270
Killed while attempting armed resistance	0
Killed in flight	19
Total	307

By Act I. of 1920 the new National Assembly restored and once more put into force all that part of the ancient constitution which had been destroyed or eliminated by the revolutions. Act XLV. of 1921 proclaimed Hungary to be a monarchy (kingdom), the decision relative to the exercise of the kingly power being postponed to a later period. On March 1 1920 the National Assembly elected Horthy to the office of Regent unanimously and by acclamation. At the same time a law was passed defining the constitutional power of the Regent.

The Treaty of Trianon.—The Hungarian peace delegation, headed by Count Albert Apponyi, Count Paul Teleki and Count Bethlen, arrived in Paris Jan. 7 1920. On Jan. 15 it received the conditions of peace framed by the Allied Powers, to which it replied on Feb. 27 in the form of a long memorandum, which, together with Count Apponyi's speech made when handing it over to the representatives of the Allied Powers, took the view that the conditions were unjust and must lead to catastrophic results. But the leading members of the Peace Conference would not agree to a plebiscite. The delegation was, however, allowed to put its observations before the Peace Conference itself with better success. Thus, M. Millerand promised, in the name of the Allied Powers, that the boundary commissions should be instructed, where they found the new frontiers involved any economic or ethnical injustice, to appeal to the League of Nations. Unfortunately, the Conference of Ambassadors found that any alteration of the frontiers, however slight, would be equivalent to a breach of the Peace Treaty.

The Treaty of Peace was signed on June 4 1920 in the Trianon by the Hungarian delegates and ratified by the Hungarian Parliament on Nov. 15. M. Simonyi-Semadam, who had succeeded M. Huszár as Prime Minister in March 1920 with a transition Cabinet, resigned in July 1920. Count Paul Teleki, the new Prime Minister, carried through the first stages of Hungarian consolidation. There were only slight differences among the four Government parties. The orthodox Legitimists and Liberals formed the Opposition. On the monarchist question Legitimists and Free Electionists were found in Government and Opposition parties alike.

King Charles' Attempts at Restoration.—On March 27 1921 King Charles IV., misled by the general depression which followed the signature of the treaty, and ill-advised by his entourage, arrived at Szombathely, whence he motored to Budapest, driving straight to the residence of the Regent, whom he called upon to hand him over the power. Horthy replied that the nation was spiritually unprepared for so sudden a change, which might involve a grave upheaval. The Little Entente might use the restoration as a pretext to annihilate Hungary's independence. King Charles returned to Szombathely. Meanwhile the ministers of the Great Powers, of Yugoslavia and of Czechoslovakia declared that the continued residence of King Charles in Hungary might involve the most serious consequences.

On Oct. 20 of the same year King Charles and Queen Zita left Switzerland by aeroplane, landing at Dénesfa, near Sopron. The gendarme battalion stationed at Sopron joined the King, and its example was followed by other troops. The King appointed a Cabinet, with Stephen Rakovszky as Premier, and on Oct. 22 he started for Budapest, his soldiers following him. Telegraphic and telephonic communication with Budapest had been interrupted. As soon as the Government were informed of what had happened, they declared that, in view of the foreign political situation, the King was not entitled to exercise royal prerogatives in Hungary and called upon him to leave the territory of the country. The Regent sent a letter to the King explaining to him that, if he entered Budapest, this might result in the ruin of Hungary. His Majesty should come alone, unaccompanied by soldiers or by his Cabinet, and clear the situation in conference with the legal Government of Hungary and with the ministers of the Entente Powers. However, the King continued his journey, refusing all intervention. On the next morning, Oct. 23, a small skirmish took place between the King's troops and those of the Government, at Budaörs, near the capital. The King's troops retired and dispersed. The royal couple were taken to the abbey of Tihany, near Lake Balaton, there to await the decision of the Entente Powers. Yugoslavia and Czechoslovakia had already decreed mobilisation. On Oct. 31 the Conference of Ambassadors demanded the formal deposition of Charles and of the dynasty. On Nov. 3 the Hungarian Govt. introduced a bill abrogating Charles' sovereign rights, and on Nov. 5 declared that before proceeding to settle the question of the election of a future king, they will agree previously with the Great Powers represented on the Conference of Ambassadors, and will not act without their consent.[1] On Nov. 1 the King and Queen had left Hungary on the British monitor H.M.S. "Glowworm" for Funchal on the island of Madeira (*see* CHARLES).

Period of Depression.—In April 1921 Count Bethlen had succeeded Count Teleki as Premier. The international position of Hungary had been seriously shaken by the royal attempts at restoration. The tension only abated very gradually and the events at Budaörs were doubly unfortunate since they followed closely on the Venice Conference (Oct. 11 and 12 1921) by which, thanks to the intervention of Italy, an agreement had been reached with Austria that a plebiscite should decide the future of the town and environs of Sopron (Oedenburg). The plebiscite went in favour of Hungary (*see* BURGENLAND).

At the end of the Commune the Hungarian crown had still been quoted in Zurich at 20% of its pre-War value. Since then it had declined steadily. The chief cause of the financial catastrophe was naturally the historical and political collapse of Hungary, which had been followed very rapidly by a general economic crisis. From the occupied territories several hundreds of thousands of public employees and their families had been pouring into the country, and they had to be provided for by the Government. As there was a great dearth of housing accommodation in Budapest, most of the miserable refugees had to live in railway trucks, indeed, incidentally monopolising for years a considerable proportion of the rolling stock of the State railways, already grievously diminished by Rumanian requisitioning. The destitution and misery of the population was fearful; everybody everywhere demanded assistance from the state, which, despite its meagre revenue, was compelled to assist, unless thousands were to die of starvation. The state resorted to inflation and the currency soon became worthless. Business stagnated. The rate of interest at times reached 40–50% per month. Speculation was rife. No efforts of the successive finance ministers, neither the stamping of the currency notes—a measure taken to avoid a further inflation—nor the sequestration of 20% of the cash deposits, 15% of the shares and 17% of the larger estates, could remedy the situation. The rate of exchange in Zurich fell to 0·0003. One or two branches of industry—such as the textile industry—prospered, since they were protected by high tariffs and labour was cheap; but the state and a very large part of the population were faced with utter ruin.

Conditions at home required a strong Government and a working majority in the National Assembly, and such an issue could only be secured by new elections. On the expiration of the prescribed period of two years, in Feb. 1922, the National Assembly was dissolved, and the elections held in the spring gave the Government a big majority. There was, however, a strong opposition consisting of Liberals, Democrats, Kossuthites (independents), 24 Socialists and 20 "Neutrals." In order to secure the working capacity of the National Assembly, the standing orders of 1907 were revised with beneficial results. In the elections of June 1922 the Bethlen Government secured a great majority and formed the United party of smallholders, bourgeois, industrials and great landed proprietors. Out of 242 seats in the national assembly the United party secured 143.

[1] See letter from Bauffy to the Conference of Ambassadors, Nov. 5 1921, in *Engagements internationaux pris par la Hongrie en ce qui concerne la dynastie des Habsbourg.* (League of Nations, Doc. 132 and 160 of 1922.)

e Christian National United Party 32. The Social Democrats cured 24 mandates.

Count Bethlen now reconstructed his Cabinet with a pro-amme of "the complete liquidation of the revolutionary spirit, ie extension of civil rights and economic reconstruction." His ain object was to ensure consolidation. The tide of extremist ission was on the ebb, and the policy of the golden mean proved ost likely to achieve favourable results. The conditions of ublic safety were restored. The outrages perpetrated against ie Elizabeth Ward Club (on April 2 1922) and against the Inn songrád (somewhat later) were the last attempts to subvert public rder. It now became possible to set about realising the two most rgent reforms: agrarian reform and financial reconstruction.

Agrarian Reform.—The land reform question is inseparably onnected with the name of the late Minister of Agriculture, tephen Szabo de Nagyatad. To provide the landless with land levy was raised upon the latifundia. Official figures for the eriod Jan. 1921 to Nov. 1925 show that 845,567 cadastral ac. r cadastral ac. = 1·422 English ac.) were requisitioned and llotted respectively for 168,263 house sites and for the forma-ion of "dwarf" and small holdings, while in 650 parishes 123,-63 cadastral ac. were taken over for the formation of small aseholds. Proceedings for the compulsory purchase of land or the purpose of grants to the landless have been instituted or pplications for such institution filed in altogether 3,532 parishes. o carry through such proceedings, the national land distribu-ion tribunal has dispatched judges to 3,526 parishes, and the ribunal has exercised its right of pre-emption in 300 cases, ffecting altogether an area of 15,816 cadastral acres. Landed roperty has been parcelled out in 273 cases, the area involved eing 62,328 cadastral acres.

The Reconstruction Plan.—As a result of the World War and the ubsequent revolutions, the Hungarian state budget and balance of ayments both showed a considerable deficit, while the unsettled eparations problem perpetuated grave uneasiness in Hungary which gain made foreign capital adopt an attitude of absolute reserve. he Government was convinced that economic reconstruction was ut of the question unless adequate capital was available to stabilise he crown until public finances were again balanced. The Govern-ent could only secure the necessary capital by means of a foreign oan, but there were grave obstacles in the way of a negotiation of uch a loan, since, for the security of their reparation claims, the llied States had the right to regard those claims as a charge on all he assets and revenue of the Hungarian State ("... the first charge pon all the assets and revenues of Hungary shall be the cost of eparation and all other costs arising under the present treaty ..." rt. 180 of the Treaty of Trianon). The loan which the Hungarian overnment desired to take up through the intervention of the eague of Nations could not be negotiated until the reparation com-ission had, with the consent of all the states claiming reparation, eleased the assets and revenues of Hungary from the general charge hus stipulated, and until Hungary, as a member of the League of Nations (she had been admitted Sept. 18 1922), had submitted a re-uest to that effect.

On Oct. 17 1923 the reparation commission agreed in principle to suspend the priority of charges on the assets and revenues of Hun-gary and thus to approve of the negotiation of the foreign loan to be taken up under the aegis of the League of Nations. The Council of the League, at its session in Paris in Dec., was thus able to discuss the flotation of the loan, while the experts sent to Budapest by the Council elaborated—in conjunction with the Hungarian Government—a programme of reconstruction. By request of the Council the financial committee of the League—on the basis of negotiations carried on in respect of questions of detail with the parties concerned—drafted two protocols (*procès-verbals*), which were accepted by the parties concerned and adopted—*nem. con.*—at the meeting of the Council held on Dec. 20.

The first protocol was of political nature. Great Britain, France, Italy, Rumania, Yugoslavia and Czechoslovakia engaged to respect the territorial integrity, sovereignty and independence of Hungary, not to endeavour to obtain any economic advantages calculated to endanger that independence, and to abstain from all action likely to run counter to the spirit of the agreements to be concluded for the purpose of furthering the financial reconstruction of Hungary; Hungary engaged to meet her international obligations faithfully and punctually, and similarly to abstain from all action in defiance of the agreements to be concluded for the purpose of furthering her financial reconstruction. The protocol affirms Hungary's full liberty of action in respect of all questions affecting her own economic system and commercial relations, while requiring her not to put into force in her relations with any other state such special measures as might be calculated to endanger her independence.

The second protocol contains the detailed conditions relating to the floating of the loan: —

The Hungarian Government shall submit to the League the programme of reforms to be gradually materialised and of economic reconstruction; detailed statements being presented every six months during the period of reconstruction of the minimum revenue expected and the maximum expenditure which the country is able to under-take, and the measures proposed to decrease expenditure and increase revenue; the whole must comprise a scheme which shall provide for the restoration of the balance of the public budget by June 1926. The programme must preclude any recourse being had to any other loan, or to inflation. Hungary engages to endeavour to conclude commercial agreements, in particular with the neighbouring states, for the purpose of eliminating the obstacles impeding trade. The Hungarian Govt. undertakes to secure the approval of the scheme by the National Assembly. It is empowered—within the period required for the restoration of the balance of the budget—to take up a foreign loan of 250,000,000 gold crowns to secure surplus ex-penditure, the proceeds of such loan to be available only in accord-ance with the provisions of the protocol. Hungary consents to the League of Nations appointing a commissioner-general to be resident in Budapest, whose duty it shall be to control the execution of the reform programme. The commissioner-general shall submit to the council a monthly report on the results obtained during the work-ing out of the programme. As security for the loan the Hungarian Government mortgages the gross revenue of the customs, the sugar tax and the tobacco régie, the net revenue of the salt régie, and where required such other special sources of revenue (mortgage rights) as that Government shall appoint by agreement with the commissioner-general, save only the revenue of the Hungarian state railways. The Hungarian Govt. engages not to take any such measures as in the opinion of the commissioner-general are cal-culated to prejudice the value of the charges thus stipulated. This protocol also contains a provision to the effect that the obligations devolving on the Hungarian Govt. shall only be in force in the event of the reparation commission taking a decision to that effect.

At its meeting held on Feb. 21 1924 the reparation commission released the state revenues acting as security for the loan, and agreed to the floating of a loan of 250,000,000 gold crowns. At the same time the reparation commission fixed the payments and de-liveries to be made by Hungary in respect of reparation liability within the limits of a fixed schedule amounting to 200,000,000 gold kronen spread over 20 years. These payments and deliveries are graduated from 880 tons of coal or its equivalent in value from Jan. 1 1924 to Dec. 31 1926; then until Dec. 31 1928, annual payments of 5,000,000 gold kronen which increase by degrees until 14,000,000 per annum is reached in 1942 and 1943. This removed the last obstacle to the putting into force of the Geneva protocol which was formally signed at Geneva on March 14 1924. The commissioner-general appointed by the League of Nations, Mr. Jeremiah Smith, an American citizen, took up his duties on May 1 1924.

Connected with the reparation question are the liabilities under-taken by Italy and by the Succession States, viz.: Poland, Rumania, Czechoslovakia and the Serbo-Croat-Slovene State, to pay to the Reparation Commission the value of the state properties (railways, forests, public buildings, etc.) of the former Austro-Hungarian Monarchy situated in the territories ceded to them, and further a contribution to the expenses incurred by the Allies in liberating the people of the said territories. These liabilities, which in the aggregate would amount to a very large total, were to be paid off, with 5% interest, in 30 years from Jan. 1 1926, but no payment has hith-erto been made. It should also be mentioned that Italy and the Succession States were, in accordance with a now generally accepted principle of international law, required to take over a share of the pre-War Austrian and Hungarian public debts proportionate to the Austrian and Hungarian territories they respectively acquired.

The reconstruction imposed heavy burdens on the Hungarian people. The state was obliged to exercise the utmost economy in order to balance its budget; it had to dismiss many thousands of public servants—25,000 had been dismissed up to Dec. 1925—and withdraw the subsidies previously granted to numerous branches of production. All taxes had to be raised to the utmost point possible. Yet the reconstruction proved a decided success, and the balance of the public finances was restored at the very opening of the period appointed for the reconstruction. The League of Nations expressed great satisfaction at the success of the scheme; and both the Council (in September 1925) and the General Assembly, during its 1925 session, conveyed to the Hungarian Govt. and the commissioner-general its sincere appreciation, also expressing its admiration for the generosity and self-sacrifice of the Hungarian taxpayers.[1] During 1924-5 the Hungarian Govt. was actively engaged in an endeavour to settle the questions still pending with other states, and in particu-lar with Hungary's immediate neighbours, and to develop the friendly character of Hungary's international relations.

[1] In June 1926 the Council of the League of Nations decided to terminate the control of Hungarian finance on June 30, the recon-struction having proceeded more rapidly than had been expected. Supervision was retained in two respects only—over the revenues assigned as security for the Reconstruction loans, and over the un-spent balance of those loans.

A series of agreements were concluded with Austria, Rumania, Yugoslavia and Czechoslovakia, referring to legal questions and a general rapprochement in respect of economic and commercial questions and of financial and credit transactions. Hereby the Hungarian Govt. has shown indubitably that it is desirous to remain true to its own policy, the cardinal principles of which are consolidation and the solution of the fundamental problems of peace. These latter naturally include also the securing of the cultural, economic and political liberty of the Hungarian minorities living in the territories separated from Hungary by the Treaty of Peace.

Defence.—Under Article 108 of the Treaty of Trianon the strength of the Hungarian Army (Royal Hungarian Honved) is limited to 1,750 officers, 2,334 N.C.O.'s and 30,916 other ranks —35,000 in all. Up to July 1 1922 the Honved officers had to be recruited exclusively from among former regular officers. The term of service for the rank and file is 12 consecutive years. Only voluntary recruiting is permitted. The army consists of seven mixed brigades; there are also four regiments of Hussars, four batteries, three battalions engineers. A mixed brigade consists of two regiments of infantry (each containing three battalions) one cyclist battalion, one squadron hussars, one artillery group of three batteries, one trench-mortar company, one signals company, one horse-transport detachment, one mechanical transport detachment. Heavy reductions were made on the application of the reconstruction scheme, and it is understood that the permanent establishment of the army in 1926 was much below strength. The police and gendarmerie consists of 2,100 officers and 9,900 men; the term of service is 20 years for the officers and 6 years for the men. See League of Nations, *Armaments Year Book* (1925–6).

(X.)

II. ECONOMIC AND FINANCIAL HISTORY

Agriculture.—Of the population of Hungary in 1925 about 56% were engaged in agricultural work as compared with 30% in industry and commerce. Agricultural production was therefore the basis of the country's economic development.

In the five years which preceded the World War, Hungary's agricultural production showed a gradual but constant development in consequence of the draining of flooded areas and the extended use of agricultural machines and artificial manures. This development was arrested by the War, the succeeding revolutions, the occupation of the country by foreign Powers and by the provisions of the Peace Treaty. Owing to the scarcity of labour, draught animals and manure, the arable land, amounting to 5,600,000 hectares, could not be properly cultivated, and a considerable decrease of production resulted. The downward tendency reached its lowest level in the years 1919–20; from that time, progress, at first slow and later quicker, was visible, some crops showing in 1925 a yield which compared well with those of pre-War years.

The index numbers of the five principal crops showing favourable development (the average of the years 1911–5 being equal to 100) are as follows:—

Years	Wheat	Rye	Barley	Maize	Potatoes
1911–5 average	100	100	100	100	100
1920	52	64	66	84	106
1921	79	79	67	67	91
1922	75	79	67	82	68
1923	92	99	75	93	69
1924	70	70	45	125	79
1925	95	96	73	156	118

The following table shows the yield of seven principal crops:—

Crop	Average of the Years 1911–5	in 1920	Average of the Years 1921–4	in 1925
	(In metric quintals)			
Wheat	19,950,076	10,322,119	15,812,439	18,942,014
Rye	8,042,139	5,143,169	6,586,079	7,742,259
Barley	7,141,212	4,718,519	4,693,232	5,224,057
Oats	4,404,705	3,237,901	3,187,092	3,560,879
Maize	15,055,696	12,742,081	13,444,601	23,483,383
Potatoes	19,458,893	20,722,294	14,915,207	23,054,775
Sugar Beet	15,019,512	6,398,261	8,706,781	15,252,572

These results are due in part to favourable weather, but credit must also be given to the diligence and perseverance of the people of Hungary. The abolition in 1923 of export and other arbitrary restrictions on trading, and the subsequent stabilisation of the currency under the League of Nations reconstruction plan, also greatly contributed to increased production by assuring the farmer sure markets at stable and profitable prices.

The values in millions of pounds sterling of the seven principal crops mentioned above amounted in 1920 to 14·2, 1921 to 22·7, 1922 to 29·4, 1923 to 33·0, 1924 to 51·6 and in 1925 to 59·1 million sterling. Before the War the same seven crops produced in the territory of present Hungary (calculated on the basis of the prices of 1913) had a value of £48,400,000. The total value of the agricultural products for 1925 was approximately £80,000,000. There is no reason to think that the production of 1925 cannot be maintained or even improved, provided increased credit facilities for implements and plant are forthcoming.

Live stock, which in consequence of the War and occupations by the enemy had suffered serious losses, showed in 1925 an improvement both from the point of view of quantity and quality. Poultry farming also showed great advance after the War. While only £700,000 worth of poultry and poultry products (eggs, feathers, etc.) were exported by Hungary in 1922 these exports approximated to £2,900,000 in 1925. The production of wine also showed an increase over pre-War figures for the same territory, and there was steady development in fruit-growing, bee-farming and silk production.

Land mortgage loans granted by the principal financial institutions in Hungary amounted in 1913 to £167·7 million, or 41% of their capital. The land mortgage loans granted by the same concerns at the end of 1924 only amounted to £83,000 or 0·3% of their capital. In other words, the land in Hungary was practically free of all mortgage, owing to the depreciation of the currency. Towards the close of 1925 the 9·3 million hectares of land in Hungary were worth £582·2 million, of which the 5·6 million hectares of arable land were valued at £406·5 million.

Industry.—The total production of Hungarian industries (present territory) in 1913 amounted to 1,641·4 million gold crowns, and in 1924 only 1,531·12 million gold crowns, *i.e.*, 6·5% less. The average production for each factory was 790,000 gold crowns in 1913 and only 560,000 gold crowns in 1924, *i.e.*, a diminution of 29·1%. The value of the average working capacity of one worker was 7,485 gold crowns in 1913 and only 6,066 gold crowns in 1924 *i.e.*, a decrease of 19%.

In the various industries production figures were as follows:—

Industries	Value of Production in Millions of Gold Crowns	
	1913	1924
Iron and metal	252·49	193·58
Machines	251·30	160·49
Stone, pottery and glass	70·87	52·34
Wood and bone	41·42	36·14
Leather, hair and feathers	44·95	51·62
Spinning and weaving	82·24	193·44
Clothing	24·81	31·86
Paper	10·69	7·23
Foodstuffs	695·43	702·55
Chemicals	124·50	84·20
Printing	42·60	18·07

The larger industries showing the greatest progress since the War are sugar and textiles. In 1924–5 the sugar industry manufactured 1,770,000 and exported 892,000 quintals of refined sugar, as compared with an output of 1,500,000 quintals in 1923. Out of home requirements in textiles amounting to 447,000,000 gold crowns, home production in 1925 was able to supply textiles to the value of 260,000,000 gold crowns, as compared with only 82,400,000 pre-War. Next to Minneapolis, Budapest has probably the largest flour-milling capacity in the world, but only about 30% of the capacity was utilised in 1925, owing to lack of the grain that formerly came to Budapest from the southern territories now separated from Hungary.

Foreign Trade.—The foreign trade figures of Hungary for 1925 showed rapid improvement. For the first time since the War there was a favourable balance in August. The figures for the six years ending 1925 are as follows:—

Year	Import	Export	Excess of Import	Increase of	
				Import	Export
	In millions of pounds sterling			Expressed in Index Numbers	
1920	17·3	6·8	10·5	100	100
1921	21·6	10·5	11·1	125	155
1922	22·4	13·7	8·7	129	201
1923	17·6	14·1	3·5	101	206
1924	29·2	23·9	5·3	168	350
1925[1]	30·9	29·2	1·7	179	429

[1] The figures for 1925 are provisional.

The increase of the unfavourable balance in 1024 may be explained by the fact that after the abolition of import restrictions a great number of goods were imported in a short period. The steady tendency of the commercial balance towards equilibrium was also shown by the decrease of the proportion of the unfavourable balance to total imports: 60·6% in 1920, 38·8% in 1922, 18·2% in 1924 and 5·5% in 1925.

The new international commercial free harbour on the Danube at Budapest, which was partly open in 1925 for traffic, is likely to be an important aid to increased trade between the Western States and the Balkans and the Levant.

Employment.—The unemployment returns compiled by the trade unions—the only available statistics—showed a reduction from over 36,000 in Jan. 1925 to about 26,000 in Nov. of the same year. The average wage level for full time was then over 100% of pre-War in gold and between 80% and 90% in home purchasing power.

Price.—The wholesale price index reached its peak at the beginning of 1925 at 159, and the retail index (Pester Lloyd) at 141, exclusive of rent. By Nov. of that year they had fallen to 129 and 123 respectively.

Trade Conventions.—The breaking up of the Austro-Hungarian Monarchy, with its single customs union, into seven independent customs territories naturally proved a handicap to close trade relations between Hungary and her neighbours. In the beginning of 1925 an autonomous customs tariff was brought into force. Although the new duties—partly for the protection of home industries and partly as a basis of bargaining—were relatively high, there was a marked increase of imports, indicating that the duties were by no means prohibitive. By the end of 1925 Hungary had concluded commercial agreements with 17 states on the basis of the most-favoured-nation clause, and definitive commercial treaties with five other states on the basis of special tariff concessions. Negotiations with other and particularly with neighbouring states were proceeding, though slowly, with a view to substituting the existing provisional agreements by definitive treaties. Among the many obstacles was the unwillingness of adjacent states to avail themselves of the direct transit facilities offered by the Hungarian railway lines. As a result of this diversion of traffic to more roundabout routes, encouraged by artificial rates, Hungary's ton-kilometre railway figures have fallen steadily—an instance of the problems that confront any solution of the economic difficulties in the Danubian basin.

The Country's Finances

Budget for 1924–5 and 1925–6.—The state budget for the fiscal year ending June 30 1925, as approved by the League of Nations, provided for a deficit of £4,200,000. Instead, there was a surplus of about £2,600,000. The budget for the year ending June 30 1926 estimated for a surplus of £1,200,000, although the League of Nations had originally estimated that in this year there would be a deficit of £2,100,000. The results of the first six months of the fiscal year 1925–6 indicated that the more favourable estimates were being borne out by actual results. The principal items of the budget for 1925–6 were as follows:—

Budget headings	Million pounds sterling
Expenditure for material	3·6
State debts	2·4
Treaty charges	0·3
Expenditure for personnel	8·0
Contribution to expenditure of autonomous bodies, comitats, etc.)	1·3
Pensions	3·1
Capital outlay	0·5
Total	19·2
Deficit of undertakings	0·4
Total of expenditure	19·6
Receipts from revenue, etc.	20·8
Surplus	1·2

Both expenditure and receipts showed increases over the League estimates, partly due to the rise of 17% in the value of the crown since the date of stabilisation.

In view of the satisfactory condition of the budget, the League of Nations in June 1925 released for productive capital expenditure 30,000,000 gold crowns from the reconstruction loan which had not been needed, as originally anticipated, to balance the budget, and also agreed that the budget surplus for 1924–5 should be applied similarly and for bringing the salaries of state employees nearer to the pre-War level. In Dec. 1925 the League released from the reconstruction loan a further sum of 20,000,000 gold crowns for capital expenditure in 1925–6; also, conditionally, 50,000,000 for 1926–7, leaving 82,000,000 out of the original loan of 250,000,000 gold crowns still to be released. As at Nov. 30 1925 the commissioner-general's account showed the available balance of reconstruction loan to be 152,000,000 gold crowns.

State Debt.—The total Hungarian state debt amounted to £329,800,000 sterling before the War, which represents a burden of £15·7 *per capita* of population. The debt of present Hungary, as constituted under the Peace Treaty, amounted to £57,600,000 sterling at the end of 1924, due allowance having been made for the allocation of the pre-War debt and of part of the War debt as provided by the Peace Treaty. Of this amount £2,000,000 represents the funded internal debt, £48,700,000 the funded foreign debt and £6,900,000 the floating debt. The burden *per capita* of the population amounts to £7, much less than the pre-War burden, mainly in consequence of the depreciation in the value of the obligations of the state.

Savings and Credit.—Coincidently with the stabilisation of the Hungarian currency on the £ sterling there was a marked increase in savings deposits. Figures from the postal savings banks and the 13 principal financial institutions in Budapest show that savings deposits steadily increased from £210,063 at Dec. 31 1923 to £5,012,500 in Nov. 1925, while current account deposits with the same institutions and over the same period increased from £4,876,952 to £13,029,166. The gross total of deposits is only about one-quarter of the pre-War amount.

The bank rate, which in March 1925 was 12½% was gradually lowered until in Oct. 1925 it reached 7%, credit and money conditions becoming correspondingly easier. This was facilitated by the introduction of foreign capital. In addition to relatively large short-term commodity credits for flour, sugar, etc., principally from England, and the participation of foreign capital in two of the leading Budapest banks, two long-term foreign loans were successfully floated towards the end of 1925, one of $10,000,000 in New York for 48 Hungarian municipalities, and another of £1,000,000 sterling in London against land mortgages.

Taxation.—Prior to the period of reconstruction in 1924 the Hungarian Govt. had recourse to many taxation expedients and drastic measures in their struggle to maintain revenue in the face of an ever-depreciating currency. The system of assessing taxation on the incomes and revenues of the previous year soon ceased to have any meaning. As a result of the War, the revolution and the Rumanian occupation there were also outstanding arrears due for some three or four years. In 1920 there was a forced loan by the stamping of notes amounting to 50% of the currency then in circulation, in 1921 a heavy capital levy, and in 1924 another forced loan based on the earned income and capital of each individual or firm

operating in Hungary. Consumption (excise) taxes were fixed at a proportion of the actual price of the articles consumed, and the "turn-over" tax, payable simultaneously with the purchase of all articles, was introduced. The latter tax was fixed originally at 1·5% and subsequently at 3% of the sale price of each article and on each handling, thus amounting in many instances to a tax of 12%. (In Aug. 1925 this tax was reduced to 2%.) Arrears of taxation were drastically compounded, and land taxes were made payable in wheat or wheat values. Finally, by the passage of Act IV. of 1924 the Government were empowered to levy all taxes in values of gold crowns.

In a report presented to the League of Nations in Oct. 1925, the League commissioner-general in Hungary estimated that on the Hungarian Budget for 1925–6 the taxes levied by the state, excluding local taxes, amounted to 60 gold crowns *per capita* of population. This compared with approximately 45 gold crowns *per capita* pre-War, which, after making allowance of 35% for the depreciation in the value of gold, also worked out at 60 gold crowns *per capita*. Adding local to state taxation, the commissioner-general estimated that the total *per capita* taxation was 72 gold crowns per head. Estimating the national income of Hungary at approximately 3,600 to 4,000 million gold crowns, the commissioner estimated that the total taxation of Hungary represented between 14 and 17% of the national income. This compared with between 13 and 14% pre-War. According to the same authority this taxation was by no means light for an agricultural country such as Hungary. From one-fifth to one-quarter of these taxes were raised in 1925 by direct and from three-quarters to four-fifths by indirect taxation.

On the basis of the Government assessment for the fiscal year ending June 30 1926 the direct taxes, according to Commissioner-General Smith, were divided as follows:—

	Millions of gold crowns
Land tax	42
House tax	24
State participation in house rents	23
Corporation tax	10
Income tax	41
Property tax	8·7
	148·7

The estimates of indirect taxation for the same period are as follows:—

Turnover tax	103·6
Stamp and other similar taxes	52·4
Tax on commodities	55·6
Customs	85·6
Salt monopoly (net)	11·2
Tobacco monopoly (gross)	97·6
Transport tax	9·2
	415·2

Currency.—During the existence of the Dual Monarchy, Hungary and Austria had a joint monetary system and a joint bank of issue. After the outbreak of the revolution the Austro-Hungarian Bank was able for some time to continue its work in Hungary, but the Bolshevik régime seized the entire stock of notes. When these began to run short the so-called soviet republic issued their own notes. After the collapse of soviet rule in 1919, the Hungarian Govt. issued the necessary decree to enable the Austro-Hungarian Bank to continue its statutory work as "Manager of the Hungarian business of the Austro-Hungarian Bank."

In March 1920 the Government ordered the stamping of the notes of the Austro-Hungarian Bank which were in circulation within the country, and requisitioned 50% of these notes as a forced loan in order to secure, so far as possible, the carrying on of the state administration without constant application to the note printing press. As the creation of a special issuing institution appeared to be inevitable in consequence of the liquidation under the Peace Treaties of the Austro-Hungarian Bank, the state itself provisionally established the Royal Hungarian State Note Institute (M. Kir. Allami Jegyintézet), which began its activities on Aug. 1 1921. The notes of the Austro-Hungarian Bank, which had been provided with the Hungarian stamp, were exchanged in the same year against state notes.

When the State Note Institute commenced its work, the financial and economic position was such as to compel the state to cover its budgetary requirements not from revenues but by means of the note printing press. This naturally resulted in the gradual depreciation of the crown. The forced loan raised by stamping notes had covered the budget deficit only for a short time. In 1921 the Government had recourse to a non-recurring capital levy, but by the time most of the proceeds reached the Treasury the value of the crown had so depreciated as to nullify these efforts. In the first half of 1921 the exchange rate of the crown rose temporarily in Zürich from 1·05 to 2·85 Swiss francs (100 crowns), owing to the impression created by the taxation and other plans of the then Minister of Finance, M. Hegedus. When it was seen that these plans were impossible of realisation, and as Hungary's balance of payments became more and more unfavourable, the crown continued to fall, until in March 1924 it reached 0·0085 Swiss francs for 100 crowns. As the result of long negotiations the League of Nations loan was raised, and the restoration of normal economic and currency conditions was thus made possible (*see* above, *Political History*). All restrictions in foreign exchange were abolished in Oct. 1925, when the currency was considered to be sufficiently stabilised to be left to fluctuate freely according to supply and demand.

Central Bank.—The re-establishment of an independent bank of issue was in the forefront of the programme of reconstruction. The Hungarian National Bank was founded, with a capital of 30,000,000 gold crowns, and commenced its activities on June 24 1924. From that day the state notes then in circulation were regarded as bank-notes. Under its statutes the bank is precluded from lending to the state, and is required to maintain against its note circulation a percentage of cover in precious metal and stable foreign exchanges, on an ascending scale, beginning at 20% during the first five years. The bank return of Dec. 31 1925 showed the proportion of cover to be 56·46 per cent. Since July 1924 the currency has been stable on a sterling basis. In Oct. 1925 the basis of stabilisation became gold, and all restrictions on dealings in foreign exchange were abolished.

The following table shows the development of the note circulation:—

Date	Issuing institution	Circulation in paper crowns
Dec. 31 1920	Hungarian management of Austro-Hungarian Bank	14,307,808,630
Aug. 1 1921	State Note Institute	15,787,175,750
Dec. 31 1921	State Note Institute	25,174,941,187
Dec. 31 1923	State Note Institute	931,337,334,630
June 24 1924	Hungarian National Bank	2,520,113,700,576
Dec. 31 1924	Hungarian National Bank	4,513,989,561,419
Dec. 31 1925	Hungarian National Bank	5,193,937,447,500 (415,514,995·79 pengös)

New Currency.—On Dec. 31 1925 the currency *per capita* of the population was approximately 43 gold crowns. In the latter part of 1925 the new monetary unit was chosen and named the pengö, divided into 100 fillér; 3,800 new units go to one kilogramme of fine gold, so that 1 pengö contains 0·26315789 grammes of fine gold. The Currency Reform Law passed on Nov. 6 1925 provides for the minting of gold coins for 20 and 10 pengös from an alloy consisting of 900 parts of gold to 100 of copper, so that 3,420 pengös will be struck from one kilogramme of this alloy. The National Bank is required to buy gold in bars at a fixed price without limit and on demand. Silver coins of one pengö will be put into circulation to a total nominal value of not more than 45,000,000 pengö.

From Jan. 1 1927 the pengö will be the obligatory unit of account in Hungary. The rate of conversion from the old to the new currency is 12,500 paper crowns to one pengö, or one gold crown = 1·1585365 pengö. 1 pengö is therefore equal to 0·0359388 pound sterling, or 0·1748985 dollar.

HUNTING: *see* FOX HUNTING: SHOOTING.

HUSAIN IBNA'LI (*c.* 1854–), Amir of Mecca from 1908 to 1916 and King of Hejaz from 1916 to 1924, was the second son of Muhamnad Ibn'Aun of the 'Abadila clan of Ashraf. He was brought up in Bedouin surroundings, but spent a great part of his life at Constantinople. Reputed to harbour Anglophil tendencies, he was deeply versed in the byways of Ottoman politics and his best trait was a profound knowledge of the desert, for which he always maintained a genuine affection. At the beginning of his Amirate he won golden opinions by his sagacity and modesty and set himself vigorously to forward Turkish interests in Arabia. In 1910 he subdued a rebellion in 'Asir and subsequently invaded Qasim without result, but in 1913 he began to show his true colours by opposing the extension of the Hejaz Railway to Mecca.

When the World War broke out he entered into negotiations with the British, which culminated in the Arab revolt in June 1916. In Oct. he proclaimed himself "King of the Arab Countries" though he was formally recognised only as King of Hejaz. At the Versailles Peace Conference (1919) he was represented by his third son, Faisal, but refused to ratify the treaty as a protest against the mandatory *régimes* imposed on Syria, Palestine and 'Iraq. Subsequently his domestic policy was marked by ever increasing avarice and reaction, while he

sowed the seeds of future trouble by deliberately courting the enmity of Ibn Sa'ud. In March 1924, while on a visit to Transjordan, he proclaimed himself Caliph, but war with Ibn Sa'ud was already imminent and the Wahhabi attack on Zaif in Sept. found him unprepared. On Oct. 5 he abdicated and proceeded to 'Aqaba, whence in July 1925 he was conveyed by a British warship to Cyprus, where he took up his residence.

By his first marriage Husain had three sons: 'Ali; 'Abdullah, Amir of Transjordan, and Faisal. The first of these, 'Ali Ibn Husain, who was born about 1880, took no conspicuous part in affairs during his father's Amirate. After the World War he became Amir of Medina and in that capacity did much useful work in connection with the reconstruction of the Hejaz Railway. In 1924 he was pressed to accept the Amirate of Transjordan but declined in favour of returning to Medina. He succeeded his father as second King of Hejaz on Oct. 3 1924, but abdicated on Dec. 19 of the following year (*see* HEJAZ) and returned to Baghdad to live as the guest of his brother Faisal.

HURGRONJE, CHRISTIAAN SNOUCK (1857–), Dutch orientalist, was born at Oosterhaut Feb. 8 1857. After completing his studies in theology and Oriental languages he went to Arabia, where he stayed for several years, and to other parts of the Near East. The result of these travels was his work *Mekka* (2 vol., 1888–9). He refused a nomination as professor of Arabic at Cambridge University in succession to Robertson Smith and also nominations in Germany and at Leyden, preferring to continue his studies on Islam in the Dutch East Indies (1889–1906) where for some years he was counsellor to the Government in Mahommedan affairs. In 1893–4 he published *De Atjehers*, which was translated into English in 1900. He returned to Holland in 1906, where he accepted the chair of Arabic at the University of Leyden; in 1907 he was nominated counsellor for Indian and Arabian affairs to the Dutch and the Dutch East Indies Government. Among his other works are *Nederland en de Islam* (1911); and *Verspreide Geschriften* (1923ff.).

HUTCHINSON, SIR JONATHAN (1828–1913), British surgeon (*see* 14.13), died at Haslemere, Surrey, June 23 1913.

HUTMENTS: *see* BARRACKS.

HUYSMANS, CAMILLE (1871–), Belgian politician, was born at Bilsen in Belgian Limbourg May 26 1871. After graduating in Germanic philology at Liége, he became a professor, first at the Collège Libéral at Ypres, and then at the Université Nouvelle, Brussels. He edited the *Petit bleu* and the *Peuple* and after the War started the *Volksgazet* in Antwerp. He entered the Chamber in 1910, first as deputy for Brussels and then for Antwerp, where he became an alderman of public instruction. In 1914 he was secretary of the Socialist International party and while in Holland endeavoured to organise a congress at Stockholm. Though he was severely criticised for this by his fellow socialists at the time, he completely regained their confidence later and became the chief organiser of the Socialist party in Antwerp. In June 1925 he became Minister of Science and Arts in M. Poullet's Government. His chief works are: *Limburgsch Jaarboek* (1891–5); *Zoponymische studie over Bilsen* (in conjunction with J. Cuvelin) 1897; *Stockholm* (1919); and numerous socialist brochures.

HWANG-HO (*see* 14.23).—A reconnaissance of the flood-stricken delta of the Hwang-Ho was undertaken by the American Red Cross in 1911 and 1914; a promising series of observations by the Kiang-Hwai engineers under H. E. Chang Chien was begun in 1911, and a critical review of these previous findings was made in the field in 1919–20 by John R. Freeman, partly in connection with his work for the Grand Canal Improvement Board.

Through the province of Shantung the Hwang-Ho's fall to the sea has been found to be about 1 in 5,000, a steep gradient for so large a river. The current is therefore very swift, and the river not only carries along great quantities of sediment, but the muddy bottom itself steadily works forward and the bed of the channel is raised. Measurements by Freeman's staff show that the river carries over 4% *by weight* of silt, and may even carry 13% in greatest flood. Naturally the stream drops a part of its heavy burden whenever its velocity decreases. Three types of deposit are to be considered: outside the outer dikes; between the dikes; and along the river bed within the main channel.

Deposits outside the Outer Dikes.—When the river overflows or breaches the outer dikes, it deposits over the land a sloping ridge of sediment which varies greatly in size, but probably during the past 1,000 years has not exceeded the equivalent of 10 ft. close to the main dike, tapering off to almost nothing at 5 or 10 m. away.

Deposits between the Inner and the Outer Dikes.—Whenever the river floods the space between the outer and inner dikes, the waters as they subside deposit their silt and a flood plain is formed. These flood plain deposits between the dikes, while varying from 12 to 20 ft., average 15 ft. above the low-water level. Probably they accumulate somewhat rapidly. It is this very action which can be utilised to form a permanent barrier of surpassing strength if the river be trained as Freeman suggests (*Proc. Amer. Soc. Civil Engineers*, May 1922, pp. 1113–67).

Deposits within the Main Channel.—When the summer floods subside, the river, in narrowing to its winter channel, slows up and deposits sediment on its own bed. Although much has been written about the Yellow river continually raising its bed, compelling the inhabitants constantly to build the dikes higher, there were no facts upon which to base such statements until the Red Cross in 1914, and the Grand Canal Improvement Board in 1919, gave cross sections, extending far beyond the dikes, showing broadly the relation of the elevation of the river bed to that of the adjacent country. These show that the river has done remarkably well in conveying nearly all of its silt to the sea, and that the rise of its bed has been extremely slow, in general not more than 15 ft. during the past 1,000 years, or perhaps 2,000 years—say a foot a century. Great as the river's land deposits have been, they are small in comparison with the total volume of sediment transported in 1,000 years, if the river during that time carried anything like the percentage of sediment recently observed. It appears that the Yellow river during all the historic period has carried to the sea 99% of the burden of silt gathered in the loess country.

The flow of the Yellow river varies much with the season, being ordinarily three times as great in flood as at low water. In the summer of 1919 a flood flow of 265,000 cu. ft. per sec. was measured (the highest for 10 years) with a minimum of 10,600 cu. ft. per second. This is remarkably small, considering the great extent of the drainage area; much of it, however, is a land of little rain, and the losses on the way are very large. Moreover, this river has no tributaries for some 300 m. from its mouth. Its only connections are with irrigation and navigation canals which serve during high-level periods to draw off water. Though practically useless for navigation, the Yellow river may, in spite of its relatively small discharge and variable flow, be a blessing in the way of drainage and irrigation if it is properly dealt with. (C. K. E.)

HYATT, ANNA VAUGHN (1876–), American sculptor, was born at Cambridge, Mass., March 10 1876. Educated at a private school at Cambridge, she commenced the study of art in Boston, proceeding later to New York City. There she studied a short while with H. A. MacNeil and Gutzon Borglum, under whose influence she acquired that knowledge of horses which is so signally exemplified in some of her works. She devoted herself chiefly to small bronzes. Her equestrian statue, "Jeanne d'Arc," was selected for Riverside Park, New York City, in 1915, and copies of it were erected at Gloucester, Mass., and Blois, France. This work, a "Saint Joan of Arc" in the Cathedral of St. John the Divine, New York City, and a "Diana" have been her chief figure compositions. Notable among her other works is a colossal "Lion on a Boulder" executed for the Dayton High School. In 1923 she married Archer Milton Huntington.

HYDE, DOUGLAS (1860–), Irish scholar and writer, was born at Frenchpark, Co. Roscommon, 1860, and was educated at Trinity College, Dublin. In 1891 he acted as interim professor of modern languages at the University of New Brunswick, Canada. He formed in 1893 the Gaelic League, for the preservation and extension of the Irish language, and was president of that body until 1915. In 1899 his production, before a vice-regal committee on education, of letters from leading Celtic scholars throughout Europe saved the Irish language on the intermediate board which regulated the curricula for Irish schools. During 1905 he toured America and raised £11,000 for the Gaelic League. On his return he was appointed a member of a royal commission on Irish university education. Dr. Hyde was made professor of Modern Irish at University College, Dublin, in

1900. He was co-opted by the Free State Senate in 1922, but failed to secure re-election in 1925. In the latter year he became editor of *Lia Fáil*. The movement created by him initiated an enthusiasm for the native language, which finally resulted in the teaching of the language being made compulsory in Irish schools.

Among Dr. Hyde's more important works are *A Literary History of Ireland* (1899); collections and translations of the *Love Songs of Connacht* (1893); *Raftery's Irish Songs* (1904); *The Religious Songs of Connacht* (1906). He also wrote several short plays in Irish.

HYDERABAD, SIR MIR OSMAN ALI KHAN, Nizam of (1886–), was born April 6 1886 and succeeded his father, Sir Mir Mahbub Ali Khan, on his death on Aug. 29 1911. His education had been under an English tutor, Sir Brian Egerton, and a nobleman of the state, of scholarly attainments, Imad ul Mulk (Saiyid Husain Bilgrami). Soon after accession he abandoned the traditional system of governing through a Diwan, and for five years was his own prime minister. In 1919 he constituted an executive council with a president and eight other members, each in charge of one or more departments. During the World War he enjoined on his subjects the duty of firm and steadfast devotion to the British cause and prohibited anti-British propaganda in his dominions. The War expenses of the state amounted to over three-fifths of the annual income. His Highness, already a G.C.S.I., was awarded the G.B.E., was promoted to hon. lieutenant-general in the British Army, and in 1918 King George V. conferred upon him the new and special title of Exalted Highness.

HYDROELECTRIC ENGINEERING.—The extent to which the water powers of the world have been investigated and developed during the past decade forms one of the striking engineering features of the period. Although falling or flowing water formed the earliest of the natural sources of energy to be utilised for providing power, some two-thirds of the water power at present in use has been developed since 1910.

The reasons for this are partly technical and partly economic. The technical development of electric generation and transmission has made it economically possible to utilise powers remote from any industrial centre, while the great developments in electrochemical, electrophysical and metallurgical processes have provided an outlet for such energy as could be cheaply developed. Most of these processes require relatively large amounts of energy, and all are economically dependent on the cheapness of this energy. They have created a demand for large blocks of cheap power which can, under favourable circumstances, be satisfied more readily from a water-power installation than from any other source.

Developments.—The urgent demand for energy to supply the abnormal requirements of the War period, combined with the increased cost of fuel, was responsible for an unprecedented rate of development in those countries having available water-power resources and normally dependent on imported fuel. Thus in France something like 2,500,000 of water-horsepower is now developed as compared with 750,000 H.P. in 1914. In Switzerland, the present output is 1,500,000 H.P. as compared with 880,000 H.P. in 1914. In Italy it is estimated that the total output will shortly amount to 3,000,000 horsepower. Japan, which only recently began to investigate her water-powers, has, since 1916, developed over 1,200,000 H.P., or about 20% of her available resources. Step by step with developments on the electrical side, advances have been made in the design of hydraulic turbines. These various developments have made it commercially possible to make use of large water-power at sites quite remote from any centre of industrial activity. In many cases industrial communities, attracted by the cheapness of the power, have grown up around such sites. In others the energy has been transmitted electrically for long distances, in some cases between 200 and 300 m., to some more convenient centre.

Available Water Power.—An estimate, based on papers presented to the World Power Conference at London in 1924, and on other sources, indicates that the amount of water-power, respectively available and developed in some of the chief countries of the world, is approximately as follows:—

Millions of Horsepower		
	Available	Developed
Great Britain	0·9	0·25
Canada	23·0	3·28
Remainder of British Empire including Australia, Africa (East), Africa (South), Africa (West), British Guiana, India and Ceylon, New Zealand, Papua	35·0	0·7
Austria	3·7	0.28
South America	54·0	0·42
Dutch East Indies	8·0	0·08
France	4·7	2·5
Germany	1·5	0·75
Italy	5·4	2·5
Japan	6·4	1·5
Norway	13·3	1·32
Russia	20·0	0·83
Spain	6·0	1·26
Sweden	8·8	1·42
Switzerland	4·0	1·49
United States	28·0	9·8

From these figures it appears that some 200,000,000 H.P. is available, of which approximately 27,000,000 is at present developed or in course of development.

Uses of Hydroelectric Energy

While a large proportion of the energy developed from water power is utilised for industrial purposes and for lighting and traction, an increasing proportion is being used for pulp and paper making and electrochemical and electrometallurgical processes; indeed the chief outlet for hydroelectric power in the near future is likely to be in connection with such processes and, probably, railroad electrification. The amount of power already used in electrochemistry is large. Thus the world's production of calcium carbide alone requires some 500,000 H.P. and when it is remembered that such products as aluminium, carborundum, chromium, cyanamide, caustic soda, chlorates, magnesium, phosphorus and silicon are only rendered commercially possible by such processes, it will be realised that the future demand for energy for their manufacture is certain to be large. Nitrogen fixation is also likely to make great demands. In Norway alone some 400,000 H.P. is available for this purpose, and in view of the rapid depletion of the natural nitrate deposits, from which four-fifths of the world's nitrogen consumption has hitherto been supplied, and of the diminution in fertility of many of the great wheat and cotton growing areas of the world, the production of artificial fertilisers by one or other system of nitrogen fixation must, in the near future, become a question of great importance.

Railroads.—The electrification of railroads has made rapid strides of recent years. In the United States some 3,300 m. of track have been electrified, while the Chicago, Milwaukee and St. Paul Railway has the longest electrified section in the world (850 m.), the power for operation being obtained from hydroelectric stations. In France, much of the track of the Compagnie du Midi in the region of the Pyrenees has been electrified with the aid of water power, and it is anticipated that the whole system of about 3,000 km. will be electrified within 10 years.

The hydroelectric stations supplying these lines have a capacity of close on 300,000 horsepower. The Orleans Co. has a scheme for electrifying 3,000 km. of its lines, part of which is to be supplied from hydroelectric stations having a capacity of about 210,000 horsepower. In Austria some 1,800 km. of line is in process of electrification for which 120,000 H.P. is available from hydroelectric stations. In Germany about 1,200 km. is now electrified, its electricity coming from hydroelectric schemes. Much of the Swiss Railway system has been electrified, and the electrification of further trunk lines in these and other countries

is at present under consideration. Such developments will open up a very large field for the utilisation of water-power where this is available. (*See* RAILWAYS, ELECTRIFICATION OF.)

Agriculture.—Much energy is now being utilised in the United States of America for purely agricultural purposes. In California, for example, there is in effect one vast system of electrical supply extending over a distance of 800 m. with 7,200 m. of high-tension transmission lines. This is fed from 75 hydroelectric stations interconnected with 47 steam plants, to give a total output of 785,000 horse-power. A further group of 13 hydroelectric schemes now under construction will add another 520,000 horse-power. A large proportion of this power is used in agriculture, and it is estimated that electric motors equivalent to over 500,000 h.p. are now installed on Californian farms. The Californian rice industry is almost wholly dependent on irrigation made possible by electric pumping, whilst most of the mechanical processes involved in farming are being performed by electric power.

The economic development of many of the tropical dependencies of the British Empire, whose latent wealth is practically untapped, is directly inter-connected with the development of their water-power resources. Not only would an abundant supply of such power enable railroads to be operated, irrigation schemes to be set on foot, and mineral deposits to be tapped and worked, but it would go far toward solving the labour problem which promises to be one of some difficulty in the future.

While those outlets for electrical energy which are now in sight promise to absorb all the energy which can be cheaply developed for many years to come, there are many other probable directions in which such energy might find a new and profitable outlet. Among these may be mentioned the purification of municipal water supplies; the dehydration of food products; and the preservation of timber.

LAY-OUT OF HYDROELECTRIC SCHEMES

High Head Schemes.—The layout of a hydroelectric scheme depends on the physical characteristics of the catchment area and site. High head schemes are of necessity located in mountainous country and are usually fed from streams of relatively small volume. Owing to this a comparatively small reservoir is often sufficient to provide sufficient storage of the head waters to give uniform output over a considerable portion of the year at a reasonable cost. The water may be brought directly from the reservoir to the power house through a pipe line or pressure tunnel if the gradient is suitable. Often, however, it is possible to bring it through an open canal at a very flat gradient, to a forebay on the hill-side above the power-house, whence a short pipe-line conveys it to the turbines.

Low Head Schemes.—Low head schemes are usually located on rivers where the gradient is small, the head being provided by a dam, or naturally by means of rapids or a waterfall. A river dam, by raising the natural level of the water, provides a certain amount of storage, but seldom more than is sufficient to store the night flow for use during the day. Such a scheme can therefore only give a continuous output equal to the dry weather capacity of the river, unless operated in conjunction with some steam station capable of equalising the output at such times.

Several types of low head layout are available. Where a dam is built, the power house is often constructed on one flank of the dam with a short head race or tail race as is most convenient, and the dam itself is used as a spillway over which excess water is discharged in times of flood. Where the river flows in a narrow and steep gorge the power-house may sometimes with advantage be constructed in the dam itself, which now consists of a hollow reinforced concrete structure. Where the river forms a long bend, it is often possible to cut across the neck of the bend and to utilise the head between the two points.

Medium Head Schemes.—In medium head schemes—utilising between 40 and 200 ft. head—the layout is usually similar in broad outline to those involving either high or low heads. Where such a scheme involves the use of a long closed supply pipe to the turbines, having only a small gradient, somewhat special treatment, however, becomes necessary. Owing to the large inertia of the column of water in the pipe line, any sudden demand for water caused by opening the turbine gates on an increasing load causes a relatively large drop of pressure at the turbines, which renders governing very difficult. To reduce this difficulty, a surge tank is fitted to the pipe-line at a point as near to the turbines as possible. This is a stand pipe surmounted by an open tank having a comparatively large surface area, whose upper level is slightly higher than that of the water in the reservoir. Any sudden demand is then supplied in part by flow down the stand pipe and the drop of pressure is greatly reduced. At the same time any rise in pressure caused by suddenly closing the turbine gates is also reduced.

In a low head station the available space is usually limited by the width of the dam on which it is built. In consequence, in such plants, there is a tendency to locate the switch gear and transformers either on floors above the machine-room, or, as is becoming more common, in an entirely separate building on the river bank. In some few cases all the transformers and high-

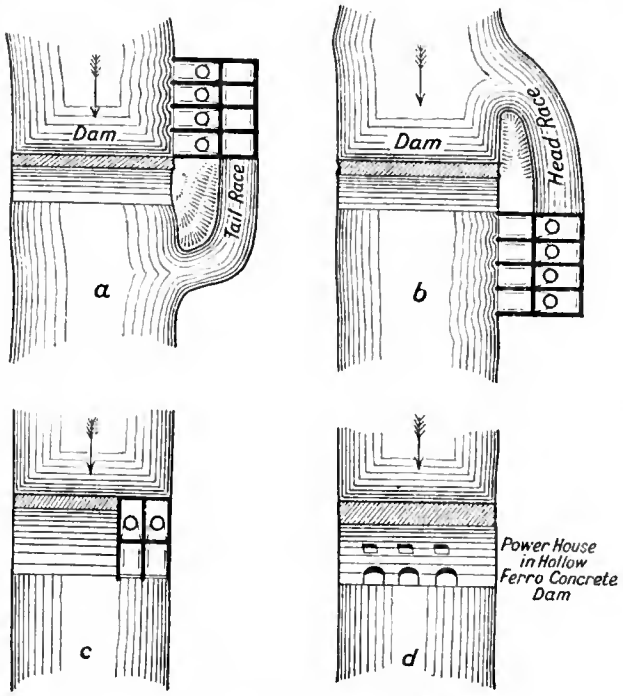

FIG. 1.—Types of Low-head Development.

tension switch gear are out of doors, and this will probably become standard practice in the future. It has even been proposed to place the whole generating plant outside, merely providing a portable cover for use during repair work. The recently planned Muscle Shoals development in Alabama was originally schemed along these lines. It has finally been decided to adopt the conventional type of station building, but the complete outdoor generating station will doubtless arrive in the near future.

Turbines.—The inward flow pressure turbine and the Pelton wheel are the only types of turbine used in modern hydroelectric schemes of any size. The type to be adopted depends largely on the available head. The Pelton wheel is a slower running machine than the pressure turbine and is therefore better fitted for very high heads. It has the further advantage for such heads, that since the water is discharged through one—or at the most two—nozzles, these may be of reasonable size when dealing with the small volumes of water normally available in high head schemes. The pressure turbine on the other hand with its full peripheral admission of water is well adapted to utilise the large volumes necessary in low head schemes, and its higher speed of rotation is also a great advantage in low and medium head plants, in enabling the cost of the electrical generators to be reduced Broadly speaking the Pelton wheel is more suitable for heads above about 700 ft.; the pressure turbine for heads below about 250 ft. in small units and below about 500 ft. in large units;

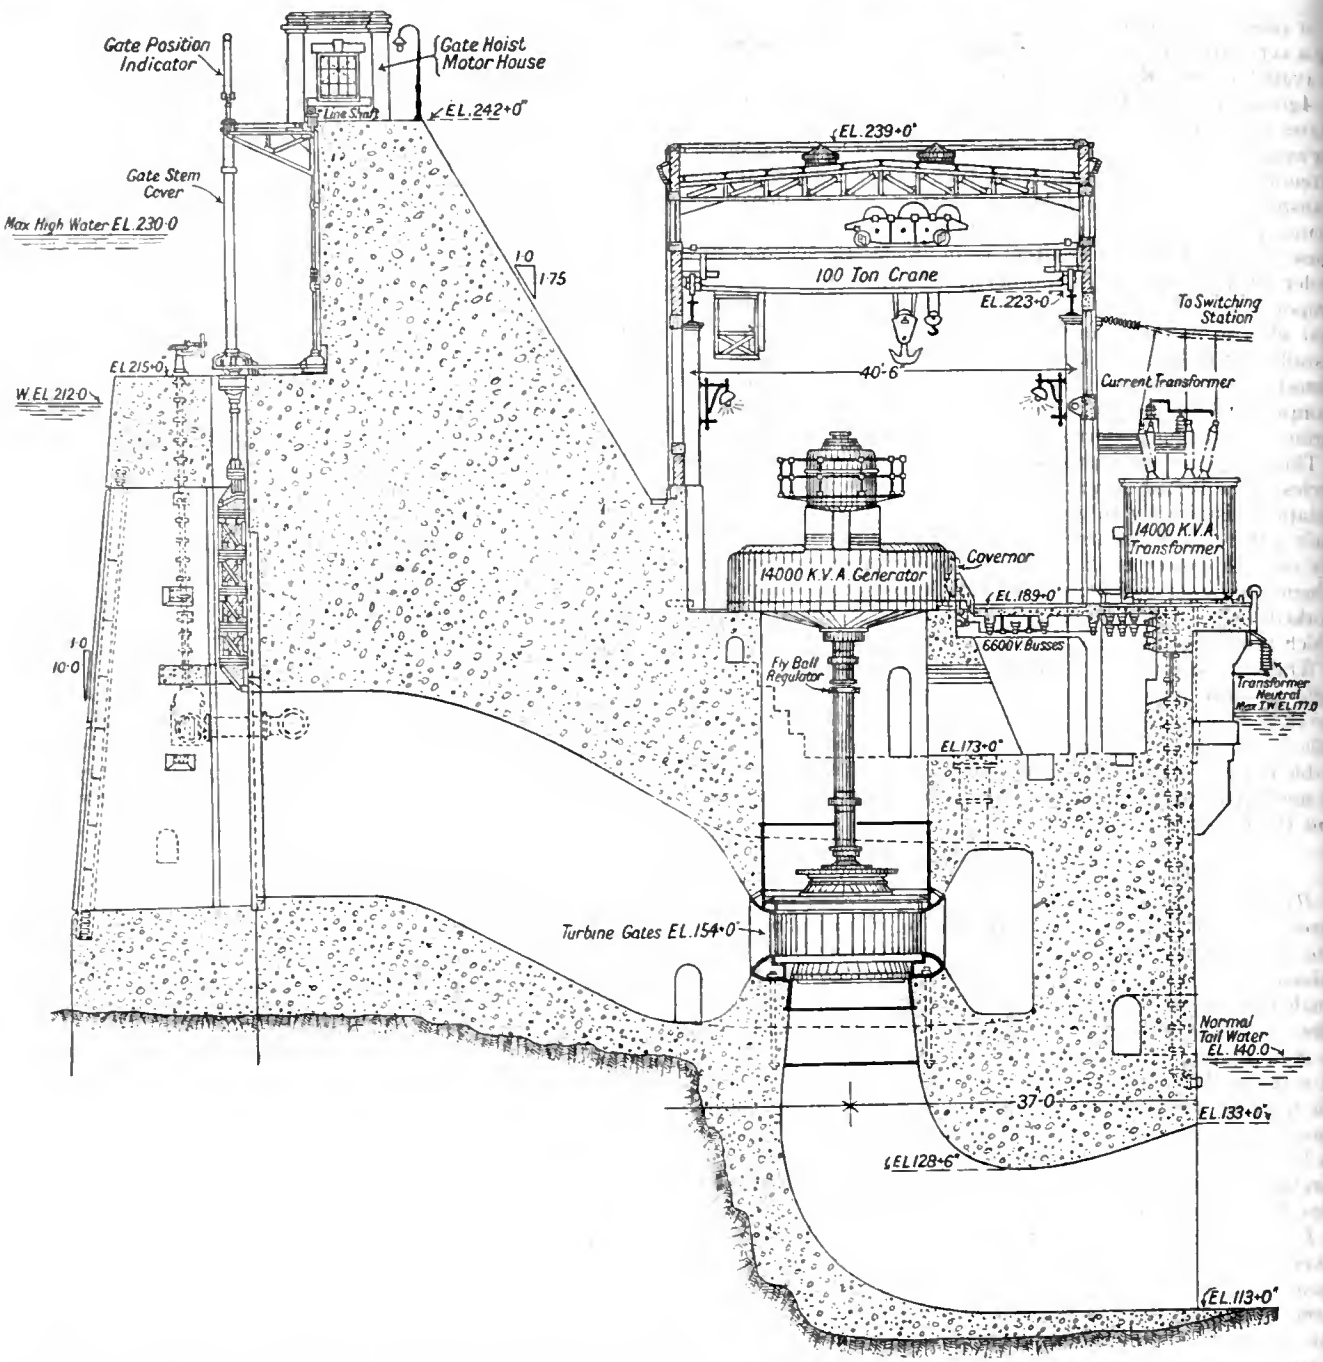

FIG. 2.—Hydroelectric station with outdoor transformers and high-tension switch gear. 14,000 K.V.A. under 80 ft. head.

while over the intermediate range of heads much depends upon the size of the units and the special circumstances.

All modern pressure turbines are of the mixed flow type, having inward radial flow through guide vanes surrounding the runner, and axial discharge. Pivoted guide vanes are universally used, speed regulation being attained by simultaneous rotation of these about their axes. Low head turbines—up to about 40 ft. head—are usually set in an open forebay. Either vertical or horizontal shaft machines may be used, but the former are becoming more common, especially for large units. For higher heads the water must be supplied through a pipe-line and the turbine is enclosed in a spiral casing so designed as to distribute the water evenly around the periphery of the guide vane ring. For heads up to about 120 ft. this casing may be moulded in concrete, but for higher heads and pressures a metal casing becomes necessary. This may be of cast iron, cast steel or of steel plate construction, and in order to give rigidity and increased safety in case of surges of pressure is sometimes embedded wholly or partially in the concrete of the substructure. Modern development is tending in the direction of units having a single runner and a vertical shaft on the top of which the electrical generator is mounted. The weight of the shaft, runner and generator is then carried from a single thrust bearing of the Michell or Kingsbury type. This type lends itself to a simple and efficient form of setting, while the friction losses are extremely low.

One of the great drawbacks of the low head turbine in the past has been its relatively slow speed of rotation, which necessitated either a slow speed and costly generator or expensive gearing. As a result of experiment it has, however, been possible so to modify the form of the runner as greatly to increase the speed of rotation under a given head without seriously reducing the efficiency.

Such runners are characterised by their small number of vanes—often not more than four being used—and approximate in form to that of a marine propeller. In one of the latest types,

the Kaplan, the vanes are capable of rotation about their own axes so as to enable the vane angles to be adjusted to suit the varying flow of water at part loads. Further developments in the direction of increasing the speed are in active progress and promise to give important results. At the present time, however, turbines are in existence which are capable of efficient operation at speeds at least three times as great as would have been thought possible 10 years ago.

The pressure turbine is now built in units capable of developing upwards of 70,000 H.P. under a head of 300 ft., and this size could readily be increased if necessary. If well-designed and installed in a suitable setting the efficiencies are remarkably high. Efficiencies of 93% have been obtained on tests of vertical shaft turbines at Niagara and values approximating 90% are quite common. In a medium head plant the following are typical values:—

Fraction of full load	·25	·5	·75	·90	1·0
Percentage efficiency	70	82	88	90	88

Pelton wheels are usually built as horizontal-shaft units with one or two nozzles, and in sizes up to about 30,000 horse power. Speed regulation is usually performed by a deflector which cuts off the jet from the wheel, acting in conjunction with a central needle or spear which slowly reduces the size of the jet while the deflector returns to its original position. The mechanism is operated by a relay cylinder supplied with pressure water or oil through a pilot valve actuated by the governor. In a well-designed plant the instantaneous speed variation corresponding to a sudden application of full load should not exceed 12 to 15%. The difference between the initial and final steady speeds should not exceed 2% between full load and no load, and should not exceed 5% with a load variation.

At constant speed the efficiency of a Pelton wheel falls off comparatively slowly as the load is diminished. A well-designed wheel should have approximately the following efficiencies:—

Fraction of full load	·25	·50	·75	·99	1·0
Percentage efficiency	77	83	85	86	83

The lack of a suitable pipe-line has, until recent years, tended to retard the development of plants for very high heads. Under such heads the necessary wall thickness, even with a moderate pipe diameter, becomes too great to permit of the use of riveted joints. Recent developments in electric welding and oxyacetylene welding have, however, rendered it possible to construct suitable welded pipes and by their aid, and by the use of solid drawn steel pipes in extreme cases, it has been found possible to harness some very high falls. The highest as yet utilised is at the Fully installation in Switzerland. Here the working head is 5,412 ft., corresponding to a working pressure of 2,360 lb. per sq. inch. The pipe-line is 19.7 in. in diameter and 1¾ in. thick at its lower end, and each of the three Pelton wheels in the power-house develops 3,000 horsepower.

Pipe-lines.—The pipe-line for a water-power plant may be constructed of steel, reinforced concrete or wood. Steel is the most usual, riveted pipes being suitable for all but the highest heads. For heads up to about 200 ft., reinforced concrete pipes are suitable and have the advantage of not deteriorating appreciably with age. As compared with steel pipes the materials are more easily transported and the friction losses are less. Large pipes are moulded in site, and as the bulk of the materials is usually obtained locally, only the cement and reinforcement require to be transported for any distance. For small diameters, pre-moulded concrete pipes with loose-sleeve or spigot-and-faucet joints are often used.

For moderate heads, wooden pipes are extensively used in countries where suitable timber is cheaply available, and under favourable conditions have a useful life of at least 25 to 30 years. They are built up of wooden staves about 6 in. wide, shaped to the correct radius and jointed end to end by thin metal plates driven into saw cuts on both the abutting ends, covering the joint. The staves are so arranged that the circumferential joints are not continuous. They are held together by circumferential steel bands which resist the bursting pressure, and whose diameter and spacing depends upon the pressure to be anticipated in each section of the pipe. The materials are easily transported and neither erection nor repair require any great degree of skill. If suitable timber is available the mill can be set up on the site and only the bands and shoes require transporting.

As heads and diameters increase the amount of steel necessary for the bands increases until it becomes comparable with that required for a steel pipe for the same duty. In general the range of useful heads is from 20 to 200 feet. These pipes have been constructed in sizes up to about 18 ft. in diameter.

Generation and Transmission.—Generators to be driven by hydraulic turbines range from the simple open-type machine which is often applicable to small units, to constructions approaching those of steam-turbine driven alternators, which are necessary for the largest high-speed machines.

At the present time the energy is almost universally generated as alternating current, on account of the simplicity and reliability obtained with a moderate generating pressure which is readily transformed to the highest pressures which may be required for economical transmission. Occasionally, however, the advantages of high-tension direct-current transmission may outweigh the essential difficulties of its generation, in which case the Thury system is available. Of the two types of alternating current generators, the synchronous and induction types, the latter has come largely into use in recent years, especially for automatic stations, on account of its robustness of construction and simplicity in operation.

Frequencies.—The question of the most desirable frequency is simplified by the fact that in most countries two frequencies—a high and a low—have become recognised as standard. In the U.S.A. and Canada, either 60 or 25 cycles per sec. is almost universally adopted; on the Continent 50, 16⅔ and 15; in Great Britain and South America 50 and 25 cycles. As regards the number of phases there is little freedom of choice, the question being largely determined by the nature of the load. Single phase supply, though offering some advantage in simplicity of equipment, involves increased losses in the generators and generally less reliable performance. This system is only used where absolutely necessary, as for direct supply to alternating current railways using commutator motors. Of the polyphase systems, three-phase is preferable to two-phase for general power purposes, since the plant is more fully standardised and therefore cheaper, while rotary converters are smaller, more efficient, and give better commutation on three-phase than on two-phase systems.

Distribution.—For distribution within a short radius of the power-house the voltage of generation and transmission will be the same as that required for the supply to consumers; but for transmission to greater distances, for which the voltage is stepped up, there is a wide choice of the voltage of generation. An unduly low voltage involves heavy and expensive bus-bars and switch-gear, and in large units presents difficulty in the construction of the stator windings of the generators. A very high voltage, on the other hand, requires a winding with many windings in series per slot, a greater thickness of insulation and involves a generally reduced reliability. From the point of view of the construction of the generator it is desirable to have two conductors per slot, and the stator current should then vary from about 300 ampères in the smallest to 1,000 ampères in the largest machines. It may therefore be shown that the most suitable voltage of generation, when not otherwise restricted for a three-phase machine, should vary approximately as follows:—

Output (kw.)	200	500	1,000	2,000	5,000	10,000	15,000
Pressure (volts)	450	900	1,500	2,500	5,000	9,000	11,000

The power factor is here assumed to be 0·8. For two-phase machines the phase pressure should be about 0·9 times the above values.

One of the most important modern developments in transmission has been in the direction of reducing the losses by increasing the voltage of the transmission lines. (*See* ELECTRICITY, TRANSMISSION OF.)

Automatic Generating Stations.—The automatic generating station is especially suited to systems where numerous small-power falls are available. In such a case the expense of an operating staff at each would be prohibitive, but if each station can be made automatic, and all are linked into a common distribution system, the labour cost is reduced to a minimum. The first of such stations was set in operation in 1917. This is on the system of the Iowa Railway and Light Co., where it operates in parallel with a steam plant situated about two miles away. The automatic station contains three 500-K. V. A. generators driven by Francis turbines operating under a head of 10 feet. Normally the starting and stopping of these sets is accomplished automatically through the medium of float switches actuated by the change in the level of water above the dam. Provision is also made for controlling these operations as well as the gate openings of the individual turbines by push buttons in the central power-house. Other plants of this type have since been installed, and this method of development promises to do much to render it economically possible to utilise many low head river falls which have hitherto been neglected.

Combined Operation of Hydraulic and Steam Plants.—Owing to the variability of river flow, it is impossible to utilise more than a fraction of the total available energy unless machinery is installed which will have to be idle during the greater portion of the year. Broadly speaking it is found that the most economical results are obtained when the capacity of the turbines is such as will enable them to be run at full load for about six months in the year.

By operating a steam plant in conjunction with the hydraulic installation, it becomes economically possible to increase the capacity of the hydraulic plant, the defect of its output at times of less than normal flow being made good by the steam installation. The latter also serves as a stand-by in case of a breakdown of the hydraulic plant. (*See* SUPER-POWER.) The best method of operation of such a combination depends upon the type of load, storage capacity, etc., and can only be determined by special reference to the special circumstances of each individual plant. Very often, however, the steam station is entrusted with the special duty of carrying the peak load. (A. H. GI.)

HYGIENE: *see* INDUSTRIAL WELFARE; PUBLIC HEALTH.

HYMANS, PAUL (1865–), Belgian politician, was born at Ixelles, Brussels, March 23 1865. He became a barrister in 1885, and from 1898 to 1914 was professor of comparative parliamentary history at Brussels University. From 1900 he was deputy for Brussels and soon became the Liberal leader. After a mission to President Wilson in Aug. 1914 he was plenipotentiary in London, 1915–7, when he became head of the Ministry of Economic Affairs. From 1918–20 and 1924–5 he was Minister for Foreign Affairs. In Nov. 1918 he attended the inter-Allied Council at Versailles; he also represented Belgium at the Peace Conference in 1919 and on her behalf signed the Peace Treaty. In the same capacity he attended the conferences at San Remo, Boulogne, Brussels and Spa. He played a leading part in the settlement of the Ruhr question, the Dawes Plan, the Security Pact and the economic union of Luxembourg with Belgium. In Jan. 1920 he was appointed Belgian representative on the League of Nations, and in the same year was made president of the first Assembly at Geneva. A member of the Académie Royale de Belgique, M. Hymans wrote *L'histoire parlementaire de la Belgique* and *Frère Orban*.

HYNDMAN, HENRY MAYERS (1842–1921), British politician, was born March 7 1842 in London. His father was a barrister and founder of the Hyndman Trust for building churches. After leaving Trinity College, Cambridge, he travelled extensively and became war correspondent for *The Pall Mall Gazette* during the Austro-Prussian War of 1866. In 1881 he founded the Social Democratic Federation and from this time on was the chief exponent of Marxism in Great Britain. As such, he came into conflict with William Morris and later with J. Ramsay MacDonald. Hyndman opposed the South African War; took an active part in the Second International; but, in spite of his sympathies with India's demand for self-government he took a strongly Imperialistic line at the outbreak of the World War in 1914. He died in London Nov. 22 1921. One of his latest books, *The Evolution of Revolution* (1920), clearly sets out his general views; in addition to numerous other propagandist works he also wrote *Records of an Adventurous Life* (1911); *Further Reminiscences* (1912); and *The Future of Democracy* (1915). See Rosalind T. Hyndman, *The Last Years of H. M. Hyndman* (1923).

HYTHE, CONFERENCE OF (May 15 to 17 1920), a meeting between the British and French Prime Ministers, together with the Chancellor of the Exchequer and the French Minister of Finance, in preparation for the Conference of Spa (*see* SPA, CONFERENCE OF). A French proposal that France should be granted priority in reparation payments seems to have been put forward but not pressed, and the linking up of the reparation problem with the question of inter-Allied debts was proposed publicly for the first time in the official communiqué.

BÁÑEZ, VICENTE BLASCO (1867–), Spanish novelist and politician, was born at Valencia Jan. 29 1867. He became an impassioned political agitator and suffered exile, hard labour and frequent imprisonment for his opinions, although : was returned to Parliament on eight occasions by his native ty. His early novels, of which *Canas y Barro* is considered the est, deal with life in Valencia and are in some respects superior to s later productions. Although a republican, Ibáñez held strong nti-feminist opinions. He travelled extensively and achieved orld-wide success as a writer for the cinematograph. Among is best-known novels are *La Catedral* (1903, English translation, *The Shadow of the Cathedral*, 1909); *Sangre y Arena* (1908, English translation, *Blood and Sand*, 1913); *Los cuatro Jinetes del pocalipsis* (1916, English translation, *The Four Horsemen of e Apocalypse*, 1918) and *Mare Nostrum* (1918, English translation, *Our Sea*, 1920). He was unpopular in Spain, where his ritings were ignored by the majority, and he eventually settled 1 Paris, becoming the centre of a group of politicians with nti-monarchical views.

ICELAND (*see* 14.227), an independent State in personal union ith Denmark. Its area is 40,437 sq. m. and its population is bout 100,000. In 1918 Iceland was recognised as a separate ingdom, with unlimited sovereignty, in personal union with)enmark. According to the Act of Union there are no real oint affairs; Denmark, however, provisionally till 1940, takes harge of the foreign affairs of Iceland as its mandatory. For he same period Danish and Icelandic citizens, residing in either tate, enjoy in every respect equal rights. Since 1915 Iceland as had its own merchant flag; since 1918 its own national arms. broad Danish legations act on behalf of both Denmark and celand. Iceland has a legation in Denmark, and Denmark legation in Iceland; other states are represented in Iceland by onsulates.

Constitution.—According to Iceland's new constitution (1920) he King shares the legislative power with the Parliament, the lthing, an assembly of 42 members, sitting in two divisions, he Upper House (14) and the Lower House (28), but in cases of lissension it can assemble as a joint parliament. The Cabinet onsists of three ministers, but there is no governor-general, and very legislative Act passed by the Althing and many administrative measures must be sent to the King in Copenhagen for ignature. Since 1920 Iceland has had its own supreme court, nd (since 1911) its own university. Other improvements in ducation are the establishment of a teachers' seminary and a ystem of public schools. In almost every other respect Iceand in this period has made constant and rapid progress.

Population.—The total population in 1925 was 100,000 (1901, 78,000), about 50% living in towns and trading-stations. There are seven towns with chartered privileges, the greatest of which is the capital *Reykjavik*, which has about 22,000 inhabitants (1901, 6,700).

Industry.—The fishing trade has been considerably improved by the introduction of new methods, especially steam trawlers and motor cutters, and the export of fish products, chiefly cured split cod, herring and fish oils increased from a value of 11,000,000 kr. in 1911 to 68,000,000 kr. in 1924. The cultivation of the soil is also constantly improving, though in a smaller degree, and dairy farming after the Danish method has been introduced, by which the production of butter has been greatly improved. With the exception of several handicrafts in the towns there is almost no industry. Some woollen factories have been established, and yield a good return, but capital is lacking to provide as many as are needed.

Water Power.—In its innumerable waterfalls (the greatest and most accessible estimated to represent about 4,000,000 horse power). Iceland is in possession of almost inexhaustible motive power, and it is very likely that considerable industries may grow up in Iceland in the near future; both Danish and Norwegian companies during the War petitioned the Althing for concessions to utilise some of the greater falls. The realisation of this plan was, however, hindered partly by the Icelanders' reluctance owing to their fear of invasion of foreigners and partly by the common European economic crisis. Thus far the water power has only been used to produce electric light in most of the towns and on some few farms.

Minerals.—The only mining industry is that of the precious calcareous spar, only found in Iceland, as the many rich sulphur mines and the lignite mines, worked during the War cannot pay on account of difficult transport to the coast. Both iron and copper and even gold have been found, and English as well as German experts have declared that the working of the gold mines near Reykjavik would be remunerative; here a German-Dutch Company was still engaged in preparatory investigations in 1925.

Communications.—Communications are constantly developing, and driving roads have been made in almost every district; bridges have also been constructed over most of the rivers, and a scheme for construction of a railway was in 1925 fully prepared by the Government. A telegraph cable to Shetland was opened in 1906, and telegraph and telephone lines inland have been extended practically throughout the whole country. In 1917 a wireless telegraph station was erected in Reykjavik and broadcasting (radio) introduced in 1925. The lighthouse system is yearly improving, and at Reykjavik a modern harbour with quays and cranes has been built. In 1914 Iceland acquired its own steamship company, which in 1925 controlled six mail steamers.

Public Health.—The birth-rate in 1923 was 26·5 per 1,000 and the death-rate 12·5 per 1,000, the latter showing a marked improvement on pre-war figures. A mental hospital and a sanatorium for tuberculosis, together with some other minor infirmaries, have been established and the building of a great state hospital in Reykjavik was commenced in 1925.

Liquor Control.—From 1912 onwards there came into force a system of complete prohibition of import and making of any liquor containing more than 2¼ % of alcohol, with the exception of medical requirements and denaturalised spirits for industrial use. But in 1923 Spain (the chief market for Iceland's fish products) forced Iceland to allow import and sale of Spanish wines, while the prohibition for the rest has been maintained.

(V. G.)

ICELANDIC LITERATURE (*see* 14.240).—As in the previous period poetry takes the foremost place; although great progress was made in novel writing, and the drama also gained in significance. Among the many lyrical poets Einar Benediktsson and St. G. Stephanson, resident in Canada, were the most important, both rather heavy in style, but rich in ideas and weighty in thought. Lighter and more elegant in style are Davíd Stefánsson, Stefán frá Hvítadal and Hulda (pseudonym Unnur Bjarklind), while the best novelists are Einar H. Kvaran and Gunnar Gunnarsson. Gudmundur Fridjónsson, Jón Trausti (pseudonym Gudmundur Magnússon) and Gudm. G. Hagalínre portray folk life with considerable skill; so do J. M. Bjarnason and Laura Salverson; both reside in Canada and portray the life of the Icelandic colonists there, the latter writing in English, *e.g.*, *The Viking Heart*. The best dramatists are Jóhann Sigurjónsson and Gudm. Kamban, whose dramas achieved a great success at the Royal Theatre in Copenhagen. The drama, *The Mother-in Law*, by an Icelandic countrywoman, Kristín Sigfúsdottir, was produced at Reykjavík and Winnipeg, and was much admired.

Among the more notable writers on other subjects were, Tón Adlis, Páll E. Olason and Jon Helgason on history, J. Th. Thoroddsen on geography, and Sigfus Sigfússon on folklore. Sigfús Blöndal published an Icelandic-Danish Dictionary, the first complete dictionary of modern Icelandic.

BIBLIOGRAPHY.—Halldór Hermannsson, *Islandica*, vol. 6, 16 vol. (1908–24); *Icelandic Authors of To-day* (1913); Sigurdur Nordal, *Islenzk Lestrarbok* (1924); Edmund Gosse and W. A. Craigie, *The Oxford Book of Scandinavian Verse*, p. 331–423 (1925).

IDAHO (*see* 14.276).—The population in 1920 was 431,866, of which the rural population, 312,820 constituted 72·4%. The total population in 1926 was estimated by the Bureau of the Census at 522,175. The average number of inhabitants per sq. m. increased from 3·9 in 1910 to 5·2 in 1920. Boise, the capital and largest city, had in 1920 a population of 21,393 (17,358 in 1910).

Agriculture.—Agriculture continues to be the principal source of wealth. In 1925 the number of farms was 40,582 as compared with 42,106 in 1920 and 30,807 in 1910. Nearly two-fifths of all the farms were between 100 and 174 acres. The average value of land and buildings per farm in 1925 was $9,213 as compared with $313,811 in 1920 and $7,955 in 1910. The number of mortgaged farms nearly doubled in the 10 years 1910–20. The farm value of all crops in 1923 was $81,308,000 as compared with an average value for the period 1917–21 of $106,209,000. The following table indicates the statistical position of several of the more important crops for the year 1924:—

Crop	Acreage	Production	Farm value
Oats	184,000	6,624,000 bu.	$ 3,842,000
Barley	162,000	2,958,000 bu.	2,426,000
Wheat	933,000	17,828,000 bu.	23,355,000
Hay	1,018,000	2,059,000 tons	25,120,000
Potatoes	67,000	10,725,000 bu.	5,792,000

Specialised cash-crop agriculture is replacing the older type of farming. Because of transportation costs on bulky products, more attention is being given to seed production, beans, peas, head lettuce and the like. Dairying is of increasing importance, much of the output being marketed in the form of cheese. As a sheep-producing state, Idaho ranked fourth in 1924 with nearly 2·05 million head having an estimated farm value of 22 million dollars. The total value of all livestock on Idaho farms was estimated at $49,000,000, in 1924. Poultry production for the Pacific Coast market is rapidly becoming a leading agricultural enterprise. About half the farms in the state were under irrigation in 1920. The enlarged American Falls Dam, which was in 1925 the largest Federal reclamation project, was undertaken to provide additional storage capacity for the existing irrigated areas of southern Idaho.

Mining.—Mining continues to rank second in economic importance. The following table shows the value of mineral production since 1920:—

	Gold	Silver	Lead	Copper	Zinc
1920	$459,000	$8,379,000	$22,292,000	$ 491,000	$1,785,000
1921	552,000	6,184,000	9,559,000	172,000	94,000
1922	458,000	6,149,000	11,762,000	394,000	431,000
1923	733,000	6,158,000	18,550,000	2,292,000	603,000

Lead is first in importance, the principal mines being in the Coeur d'Alene district. Successful developments of lead-silver and lead-zinc ores have been made in the east central part of the state, largely stimulated by the mining activities of the Ford Motor Co. The extraction of silver is in most sections incidental to lead mining. In recent years there has been a renewed exploitation of zinc ores. The Interstate-Callahan Mine is probably the third largest producer of zinc ore in the United States. The largest copper-producing area is in Custer county. The Seven Devils range in Adams county is one of the most extensively mineralised copper belts in the west. Tungsten mines are being developed in Lemhi county. In southwestern Idaho are great quantities of phosphate rock which are being gradually exploited.

Manufactures.—There has been a marked growth since 1910 both in the number of manufacturing establishments and in the value of their products. The following are the chief industries, in order of importance: lumber, flour and grist mills, car and railway shops, printing and publishing. About half of the value of all manufactured goods is represented by lumber products. Idaho ranks first among the states in the area of state and national forests, aggregating approximately 19 million acres. In addition there are large stretches of privately owned timber land.

Transport.—In 1923 the state had 2,877 m. of steam railway and 89 m. of electric track. In 1915 the Celilo Canal, on the Oregon side of the Columbia river, was opened and vessels ca now pass from the Pacific to Lewiston, a distance of 480 mil

Government.—The legislature of 1919 completely re-organis the state civil administration in so far as the limitations impos by the state constitution permitted. The Administrative Co solidation Act abolished some 46 boards, commissions and o fices and gave Idaho a consolidated form of state government, o as it is locally called, a cabinet or commission form of gover ment, with the governor at the head, assisted by nine depar mental commissioners. These nine departments are: Agricultur Commerce and Industry; Finance; Immigration; Law Enforc ment; Public Investment; Public Welfare; Public Work Reclamation. Each commissioner is appointed by the governo and, except "those under the constitution who are appointed f specific terms," may be removed by him at his discretion. I certain departments a small number of designated officers a appointed by the governor, but on the whole the organisatio within each department is under the control of the commissione This consolidated form of government concentrates authority i the hands of the governor to a marked degree. The law provid an executive budget system for the state. The Eighteenth (Pr hibition) Federal Amendment was ratified Jan. 8 1919.

Education.—In 1924–5 there were 137,256 pupils enrolled i the state schools, of whom 19,759 were in the high schools an 117,497 in the elementary schools. The state university com prises colleges of Letters and Sciences, Agriculture, Engineerin and Law; schools of Forestry, Mines, Education, Business Ad ministration and Graduate Study. The total enrolment in 192 was over 2,000. Idaho has attracted much attention because o its scientific and economical administration of higher education A Board of Education of five members appointed by the gover nor for terms of five years, has general supervision over the nor mal schools and the Technical Institute, and, as a Board of Re gents, over the university as well. The result is a unified systen of higher education with little duplication, low cost and excel lent standard.

The governors during the period 1910–25 were: James H Brady, Rep., 1909–11; James H. Hawley, Dem., 1911–3; John M. Haines, Rep., 1913–5; Moses Alexander, Dem., 1915–9; D. W Davis, Rep., 1919–23; C. C. Moore, Rep., 1923–

ILLEGITIMACY (*see* 14.301).—Illegitimacy may be measured in different ways. One way is to state the number of illegitimate births in every 1,000 births as in Table I. The range of variation there shown between different countries is much more striking than the variation between different times in the same country. Where the figures are small they may be incomplete. Statistics are not given for the United States as a whole; in New York the rate is in the neighbourhood of 12, and in Pennsylvania, 20. In countries affected by the War the rates were generally highest during the War period; thus, in Germany, the rates in the periods 1911–4, 1915–8, 1919–22 were 94, 115, 109; in Hungary, they were 90, 104, 76; in France, 87, 132, 132 (the last for 1919 only). Taking the rates as recorded, two causes might account for this: it might be due to a rise in the number of illegitimate births, or, as in this country, chiefly to a fall in the total number of births; the second movement sometimes disguises the other. But it must be borne in mind that the figures for successive periods are not really comparable for countries with altered territories.

A better method of measurement is to refer illegitimate births to the total of unmarried women at fertile ages. Thus, from the date when the decline of the birth-rate in England began, about 1876–80, to 1919–23, the number of legitimate births, per 1,000 married women between the ages of 15 and 45, had fallen 44%; the number of illegitimate births, per 1,000 single and widowed women between the same ages, had fallen 46%; while the number of illegitimate births per 1,000 of all births had only fallen about

o per cent. Table II. shows the illegitimate rates, calculated by is better method, in a few countries for which data are avail-le in a pre-war and a post-war period. The trend, though some cases slight, is downward, and we know that the same nd was apparent in earlier years. This does not necessarily ply a rise in the standard of morality: it may denote an in-easing use of means to prevent conception.

In Table III. the number of illegitimate births in England and ales in 1921, expressed per 1,000 of the total census population, is alysed according to locality and according to extent of urbanisa-on. The third column shows these rates as percentages of the rate the country as a whole. The last column represents an attempt the registrar-general to allow for the number of potential mothers ong the unmarried at different ages between 15 and 45 in each ality or class of area; for this purpose certain standard fertility tes applicable to different age-groups are used, and the actual rths are compared with the "expected" births. The rates are gher in Wales and the northern counties than in the southern and idland counties. The more accurate index also emphasises the ghness of the rate in rural districts. These differences are in part le probably to differing degrees of familiarity with the use of con-aceptive measures. (*See* POPULATION.)

TABLE I. *Mean Number of Illegitimate Births per 1,000 of all Births, excluding Stillborn*

Country	1911–4	1915–8	1919–22	1923	1924
England and Wales	43	52	49	42	42

London	0·89	87	79
County Boroughs	1·09	107	103
Other Urban Districts	0·96	94	94
Rural Districts	1·07	105	120

(D. C. J.)

ILLINOIS (*see* 14.304).—The population of Illinois according to the U.S. Census of 1920 was 6,485,280, as compared with 5,638,591 in 1910 and 4,821,550 in 1900. The rate of increase 1910–20 was 15% as against 14·9% for the whole United States and as against 16·9% for the state in the preceding decade. The population as of July 1 1926 was estimated to be 7,202,983. The increase of 1910–20 was urban, the rural population continuing to decline. In 1920 the percentage of urban population in towns and cities of 2,500 or over was 67·9% and 41·7% of the total population lived in the city of Chicago. In 1920, 52·5% of the state's population was in cities greater than 25,000. Population in villages of less than 2,500 declined from 12% in 1910 to 10·5% in 1920. Purely rural population fell from 26·4% in 1910 to 21·6% in 1920.

Population of Cities of over 40,000

City	Population 1910	Population 1920	Increase %	Estimate 1925
Chicago	2,185,283	2,701,705	23·6	2,995,239
Cicero	14,557	44,995	209·1	62,238
Decatur	31,140	43,818	40·7	50,359
East St. Louis	58,547	66,767	14·0	71,423
Peoria	66,950	76,121	13·7	81,564
Rockford	45,401	65,651	44·6	76,462
Springfield	51,678	59,183	14·5	63,923

Agriculture.—While the census of manufactures shows Illinois to be an industrial rather than an agricultural state, there has been no absolute decline in her agriculture. According to the census of 1920 Illinois was second only to Iowa among the states in agricultural importance. Based on crop values, in 1923, Texas was first, Iowa second, and Illinois third, with farm crops amounting to $459,500,000. Cereals are still the main crop and maize is the leading cereal. The largest crop was that of 1917 when 418,000,000 bu. were produced from 11,000,000 acres. In 1923 the crop of 337,000,000 bu. was a slight increase over the years immediately preceding. In 1923, 62,506,000 bu. of wheat were produced, grown on 3,470,000 acres. The production of oats has declined, but in 1923 with a harvest of 135,100,000 bu. from 3,860,000 ac. she took third place in the United States. In 1923 Illinois ranked seventh in the production of barley and rye, producing 3·33% of the barley and 5·56% of the rye grown in the United States. In livestock, Illinois, Jan. 1 1923, with 1,125,000 milch cows, ranked fourth among the States; and in other cattle, numbering 1,477,000, ranked sixth. In number of swine, 4,460,000 and the number of horses, 1,277,000, Illinois ranked second only to Iowa.

Manufactures.—In the value of manufactures, Illinois, in 1923, ranked fourth among the States. In 1919 the total value of her manufactured products was $3,366,452,969. In 1923 the total value had risen to $5,041,519,455. Manufactures employed 645,433 wage-earners, working in 14,348 establishments. The ten most important industries with the values of their respective products in that year are as follows:—

Manufactured Products, Illinois, 1923

Slaughtering and meat packing (wholesale)	$606,320,553
Foundry and machine shops	275,955,047
Iron and steel, steel works and rolling mills	213,671,552
Electrical machinery and supplies	211,366,206
Clothing, men's	186,683,333
Cars, steam road (not back in repair shop)	159,364,227
Printing and publishing, book and job	138,227,215
Printing, publishing, newpaper, etc.	132,288,355
Cars, and general construction, steam	113,604,362
Bread, and other bakery products	105,289,516

The tendency in manufacturing was toward large-scale production and corporate ownership. Of the 18,593 establishments in the state in 1919, the 799 producing $1,000,000 or over turned out some 75% of the products. In these industries 389,686 wage-earners were employed. Chicago, with its tributary manufacturing suburbs of Maywood, Harvey, Cicero, Blue Island, Chicago Heights, and, in Indiana, Hammond and Gary, is the greatest manufacturing centre of the state. A lesser manufacturing centre has grown up in the net of railways that centre at St. Louis, Collinsville, Granite City and Edwardsville. The third centre

is formed by Moline and Rock Island with Davenport, Iowa. Joliet and East St. Louis were second and third respectively to Chicago in the value of products in 1919. Manufactures in Chicago, are generally diversified. The same is usually true in the smaller centres, although a few cities are noted for their special products. Thus, Rockford is best known for its furniture manufactures, Kewanee for boilers, Elgin for watches, Moline for farm implements and automobiles.

Minerals.—In mining and allied interests Illinois occupies an important position. Coal constitutes her leading production. During 1924 67,880,000 short tons were mined, a total exceeded only by Pennsylvania and by West Virginia. The value of her petroleum production in that year was$14,200,000. Limestone, sandstone, fluorspar, lead and zinc are the other leading products.

Communications.—For transportation, Illinois relies chiefly on its steam railways. With 12,046 m. of main line she was in 1924 second only to Texas. For over 30 years little new main-line road has been built. The important extension has been in double-tracking and improvement of the right-of-way and terminals. The field of passenger and light freight and coal transport, since 1900, has been invaded by the electric lines, which by 1924 operated 3,555 m. of track. The Illinois Traction System operates a ramification of electric lines across the state from Danville to East St. Louis and radiating throughout central Illinois; on certain runs it operates sleeping and parlour cars. Illinois' most important water transportation system is that of the Great Lakes. Receipts of grain at Chicago by lake have steadily declined of late years, although the lakes are still the usual route for shipment of wheat to eastern points. Flour shipments by lake are comparatively insignificant, an important fact in view of the increasing quantity of grain milled at Chicago. Iron ore is still shipped to Chicago and South Chicago by way of the Great Lakes. In 1900 the Sanitary District Channel was opened, providing a waterway with a depth of 20 ft. for navigation between Chicago and Lockport. But from Lockport to Utica, on the Illinois river, a distance of 62 m., there was no adequate means of water transportation. A legislative Act of 1919 actively supported by Gov. Frank O. Lowden provided for the issue of bonds to the amount of $20,000,000 for the construction of an eight-foot channel, "The Illinois Waterway," connecting the points mentioned. Little actual progress had up to 1925 been made towards carrying out this project for the Lakes-to-the-Gulf water route.

The improvement of the roads in the state of Illinois has in recent years been given marked attention. A state highway commission was created in 1905, various laws facilitating local road improvement were passed, and in 1914 state appropriations for hard roads were made from the proceeds of automobile licence fees. Actual construction was begun in 1914. Acts of Congress of 1916 and 1919, apportioning Federal aid in behalf of roads, allotted to Illinois $3,300,000 and $8,700,000 respectively. The question of issuing $60,000,000 in bonds based on automobile license fees for the construction of 4,800 m. of hard roads was submitted to the voters of the state in Nov. 1918 and was approved by them. Construction of roads under Federal aid and by means of this bond issue has been going forward. In 1922 722 m. were completed and over 1,000 m. in 1923. The state Legislature in 1923 authorised a bond issue of $100,000,000, providing for the continuance of a state-wide system of hard-surface roads, and this legislation was approved by the people at the General Election of 1924.

Banking.—The northern part of Illinois lies in the 7th Federal Reserve District and the southern part in the 8th, with headquarters respectively in Chicago and St. Louis. In 1925 there were 501 National banks in Illinois with aggregate capital stock of $94,480,000, aggregate surplus of $63,265,000 and total resources of $1,701,448,000. Of these banks 32 are located in Chicago, having resources amounting to $1,103,339,000. Side by side with the National banks is the system of state banks created by the Act of 1887, and operating under the supervision of the Auditor of Public Accounts. In 1925 there were 1,396 state banks with a total capital of $160,240,000, and aggregate resources of $2,682,196,000. Of the state banks 176 are in Chicago, having resources amounting to $1,926,594,000.

Government.—Despite the difficulty of changing the organic law, in the period 1910–25 there were far-reaching changes in the organisation of the machinery for government. Under the constitution of 1870 an amendment must be initiated by two-thirds of both Houses in the General Assembly and approved by a majority of all persons voting at the next election. Further, in a session an amendment to but one article can be proposed, and no two amendments to any article can be offered within four years. Revision of the constitution by amendment, therefore, proved too difficult, and in 1917 the General Assembly voted to submit to the people the question of a constitutional convention, which was approved at the election of Nov. 1918. Accordingly, in 1919 an Act was passed for a convention to meet Jan. 6 1920. Difficulties arose over Chicago's representation in the General Assembly, and in Dec. 1920 the convention adjourned with its work unfinished to meet in Sept. 1921. Sessions were held at intervals until June 28 1922 when the constitution was adopted for submission to the people for ratification at a special election to be held Sept. 12. The new constitution, in this election, was defeated by a decisive majority.

Changes in the state's system of appointments have been effected. First, in time, was the extension, by the Act of 1911, of the civil-service system, to the greater part of the state's employees. Civil service now covers all state appointees except those appointed by the governor and confirmed by the Senate, the scientific and academic staff of the University of Illinois and the normal schools, and a few others. All examinations are competitive, although for some scientific posts "unassembled examinations" are given which consist of questions as to training and experience. By an amendment of 1917 all appointees may be removed by the appointing authority, but are allowed an appeal to the state Civil Service Commission on allegation that the removal is due to race, politics or religion. Reorganisation of governmental machinery was begun in 1909 with the abolition of separate boards for the various state charitable institutions and the establishment of one central board of control possessing also certain powers over private charitable institutions. In addition to this board a supervisory state charities commission was created. There remained, however, over one hundred state boards, bureaus and offices, paid and unpaid, created to execute various acts and to supervise various state institutions. The result was disorder and waste. A reorganisation recommended by a committee in 1914 was in great part adopted in the State Consolidation Act of 1917. This Act necessarily left untouched the constitutional offices, secretary of state, auditor of public accounts, treasurer, attorney-general and superintendent of public instruction, but set up in addition to them nine departments—Finance, Agriculture, Labor, Mines and Minerals, Public Works and Buildings, Public Welfare, Public Health Trade and Commerce, Registration and Education. The heads of these various departments, who are appointed by the governor and Senate, have acted as a Cabinet for the governor. Illinois ratified the Eighteenth (Prohibition) Federal constitutional amendment Jan. 14 1919.

Public Finance.—Expenditures authorised by the Legislature for the biennium 1925–7 amounted to nearly $300,000,000. Of the appropriations for 1925–7, $131,000,000 was for the continuance of the hard-roads plan. It was anticipated that $35,000,000 of this amount would be supplied from money received by the state for automobile licences, while the remainder would come from the sale of $100,000,000 in bonds, the issue of which was approved by the people at the Nov. election of 1924. Among other more important items of appropriation were: Public Welfare Dept. including state charitable, penal and reformatory institutions, $28,979,000; omnibus bill, $23,718,000; state treasurer, retirement of and interest on bonds, $23,575,000; public schools, $16,223,000; University of Illinois, $10,620,000; state normal schools, five in number, $3,150,000; Agricultural Dept. $2,691,000; Health Department, $1,041,000.

Education.—In 1924 there were enrolled in the elementary hools of Illinois 563,614 boys and 534,684 girls. In the state gh schools there were 106,735 boys and 111,005 girls. This presents an increase of 113·76% in the number of high school ipils during a period of ten years. In addition to the public hools there were, in 1924, 960 private schools with 105,552 ipils. The total number of teachers in the elementary schools 1924 was 42,865. In that year there were 9,117 high school achers. The net expenditure, including new grounds and ildings and payments of bonded indebtedness with interest 1922 was $103,375,359. Of this amount, $70,126,323 was ent on current expenses, $20,386,043 for new grounds, buildgs and equipment, $2,224,466 for cancellation of bonded debtedness, and $1,638,627 for interest on bonds. The salaries id to teachers were comparatively low. The average salary r men was $1,679; for women, $1,449. A notable development the public educational system was the growth in the number township high schools, and the number of community high hools following the legislation of 1917. Under the township igh-school law some 200 high schools were organised. Acts of 913 and 1915 directed the payment by local school authorities f tuition for children who wished to attend high school elsehere when there was none in their district. During one year, 920, 167 community high schools were organised, and at the nd of 1922 there were 465 such schools in the state. At the close f the year 1924 the number had risen to 915. With the rapid rowth in the numbers of high school graduates (24,507 in 1924) here was a corresponding increase in the enrolment in the uniersities and colleges of the state. The attendance at the niversity of Chicago, 1923–4, was 13,357; University of Illinois 1,083; and Northwestern University, 9,150. In addition, there re in the state 29 colleges of recognised standing and 6 teachers' olleges. Located in Chicago are four Class A medical schools, wo Class A law schools, three Class A dental schools and nine chools of theology.

Recent Political History.—In 1912, as a result of the Progressive secession, the Republican party for the first time in 16 years ost control of the state, the Democratic presidential elector vinning by a vote of 405,038, as against 386,478 for the Progressives and 253,503 for the Republicans. The Democratic tate ticket headed by Edward F. Dunne was elected by a somewhat larger plurality over Gov. Charles S. Deneen, Republican, nd Frank H. Funk, Progressive. The Democrats, however, did ot control the General Assembly on joint ballot, and had to ompromise with the Republicans on the election of one Democratic Senator, James Hamilton Lewis, and one Republican, Lawrence Y. Sherman, the latter to fill an unexpired term to 1915. By 1914 the normal Republican majority in the state reasserted itself, the popular vote for Senator in that year being L. Y. Sherman, Republican, 390,661; Roger Sullivan, Democrat, 373,403; Raymond Robins, Progressive, 203,027. President Woodrow Wilson lost the state in the presidential election of 1916 by 160,000 votes. Frank O. Lowden, Republican, was elected governor over Edward F. Dunne.

In spite of the appeal for the support of the administration of Woodrow Wilson which was made on patriotic grounds, only five Democratic Congressmen were elected by the state in 1918, and Medill McCormick, Republican, defeated J. H. Lewis, Democrat, for Senator by 53,024 votes. In 1920, after an extremely bitter primary fight in the Republican party, Len Small was nominated for the governorship over John J. Oglesby. In the election, Republican state and national tickets swept the state by overwhelming majorities. In the primary election for governor, April 8 1924, Gov. Len Small received a plurality of 59,920 votes over Thurlow G. Essington, and Norman L. Jones was nominated by the Democratic party. Charles S. Deneen defeated Senator Medill McCormick for nomination for the U.S. Senate on the Republican ticket. Governor Small made his campaign chiefly on his record for the promotion of the construction of hard roads. The road-bond issue of $100,000,000 for this purpose was voted on at the same time. Gov. Small was re-elected with a plurality of 345,028 votes over the Democratic nominee. Deneen was elected to the U.S. Senate. The governors of Illinois after 1905 were: Charles S. Deneen, Rep., 1905–13; Edward F. Dunne, Dem., 1913–7; Frank O. Lowden, Rep., 1917–21; Len Small, Rep., 1921–5, and 1925– .

See, in addition to the books listed in 14.311, *Centennial History of Illinois* (5 vol., published by the state, 1918–20) and later volumes of the *Illinois Historical Collections*. (J. A. J.)

ILLUMINATING ENGINEERING, term now used to denote all applications of natural and artificial light in the service of mankind. Progress in Great Britain since 1910 is largely the result of the formation (in 1909) of the Illuminating Engineering Society, in which makers of lamps and lighting appliances and users of light co-operate; all illuminants are represented and all aspects of the subject, economic, hygienic and artistic are considered. A similar body, the pioneer in this field, has been in existence in the United States since 1906, and corresponding bodies have been formed in Germany (1913), Austria and Hungary (1925) and Japan (1915). In Germany two additional societies operating in Karlsruhe and in the Rhine-Westphalia district have also been created.

Attention has been paid to illumination at many international congresses, thus promoting the exchange of views between experts in different countries. The re-organisation of the international photometric commission, founded in 1900, as the international illumination commission, was stopped by the World War, but a fresh start was made in 1921, and the leading countries are now represented with national committees for the respective countries.[1]

Much has been done towards standardisation and agreement on common principles. Definitions of the main photometric quantities have been adopted, and a more extended series of definitions, symbols, etc., framed, while sub-committees to deal with lighting legislation, automobile headlights, etc., have been formed. At the session held in Geneva in 1924 further activities were initiated and the Commission is now extending its work to deal with various practical problems.

The International Candle.—A noteworthy step, dating from 1909, has been the agreement between France, the United States and Great Britain and, recently, also Russia, on an international candle so that the same unit of light is now in use in all four countries; but in Germany and some other countries the Hefner candle (equal to 0·9 international candle) is still in use. Preservation of the unit of light is now effected by the exchange of specially prepared electric lamp-standards between the official laboratories in the countries concerned. Meantime experiments are being made with a view to evolving an absolute standard of light, *e.g.*, one based on the maintenance of a "black body" at a specified temperature. In the United States the standard is the *lumen* or the amount of light that would fall on a surface so placed that all its parts are at a distance of one foot from a light source of one candle power.

Technical Progress.—Progress in illuminants has kept pace with this advance on the scientific side. Electric lamps, filament and arc, have been developed (*see* ELECTRIC LIGHTING). In the field of gas lighting there has been steady progress in design, one instance being the smaller and more compact forms of high-pressure gas lamps, now rated to give 60 candles per cu. ft. of gas consumed. In low-pressure gas lighting the use of superheated clusters of inverted mantles has made possible a gain in efficiency estimated at 30%. The distribution of the light from a number of smaller mantles is considered an advantage, and the smaller types of mantles are the most durable. Cluster-lamps giving up to 2,000 c.p. are now available.

Theory of Radiation.—Researches into the theory of radiation and the principles underlying illuminants provide a clearer understanding of the luminous efficiency theoretically obtainable. Thus a light source yielding visible white light and no non-luminous vibrations would operate at approximately 26 c.p. per watt, whilst if the light were confined to the most efficient yellow-green section of the spectrum as much as 60 c.p. per

[1] See J. W. T. Walsh, "International Co-ordination in Illumination," *Trans. First World Power Congress*, vol. 3 (Wembley, 1924).

watt might be obtained. But in the case of new illuminants efficiency is not the only consideration; such special qualities as the colour of the light (as in the neon lamps) or the nature of the supplementary invisible radiation (as in the quartz tube mercury vapour lamps) may be of even greater importance.

Reflectors, etc.—The design of shades, globes and reflectors for use with lamps has assumed great importance. By suitable design of a reflector the distribution of light from a source may be altered with wide limits. Thus extensive, intensive and focusing forms of reflectors yielding standard curves of light distribution have been designed, and corresponding rules for height and spacing, designed to give even illumination on the working plane have been derived. In most cases a shade or reflector is designed to direct most of the light downwards, where it is chiefly needed. But other cases occur, for example in shop window lighting and the illumination of large posters, etc., where reflectors are so designed and spaced as to yield an illumination over an extensive vertical area.

Glare Prevention.—Another function of shades and reflectors is to screen the actual source of light from the eye. Even when only vacuum metal filament electric lamps were available the glare from exposed filaments irritated the eye and prevented it from registering the full effect of the illumination provided. In the case of the gas-filled lamps, with their very much brighter filaments, the need for scientific screening is yet more evident. Hence in the leading stores concealed lighting of show-windows, with the light thrown on the goods but the sources concealed from the eyes of observers, is coming to be regarded as the correct method; and it is only in the smaller shops that exposed sources of light are still too frequent.

A special instance of a concentrating reflector is to be found in the "floodlighting" units, consisting of an incandescent lamp with a special "bunched" filament at the focus of a parabolic mirror. Such units are miniature searchlights and are now being used to illuminate the façades of buildings. It is possible to limit the angle of dispersion to about 15° and with a 500 watt lamp a beam with a candle power exceeding 300,000 has been obtained. With the searchlight proper, using an arc, the dimensions of the source of light can be reduced to much smaller dimensions, and a beam of many millions of candle power attained.

Searchlights.—A notable advance during the War was the design of searchlights using specially cooled electrodes leading to a yet smaller and more brilliant source and corresponding greater concentration. The cooling has been effected by two distinct methods, a blast of air and a spray of alcohol; in both cases a very substantial increase in beam-candle power for a given current consumption was obtained.[1] The brightness of the crater in such cases has been estimated at 200,000–300,000 candles per sq. in., as compared with 85,000 c.p. per sq. in., in the case of the ordinary searchlight. In Germany, Lummer, working with an arc operating in a chamber under an air-pressure of 22 atmospheres, is said to have attained the enormous brightness of 1,500,000 candles per sq. in. But this method has apparently not yet reached a practical stage.[2]

Coloured Light.—An apparatus capable of projecting pure spectrum colours on the stage, which is in effect a giant spectroscope, has been designed. By the Mutochrome projector,[3] a series of superimposed patterns can be projected on the screen and the colour of each varied at will. This is likely to prove of considerable value to designers of wallpapers and coloured fabrics, as well as having a possible application for the projection of luminous scenery on the stage.

Artificial Daylight.—Efforts have also been made to provide "artificial daylight," *i.e.*, to correct the light from artificial illuminants and render it equivalent to normal daylight for the matching of colours. Two methods of effecting this correction have been applied. In the Sheringham unit the light from a gas-filled lamp is reflected from an upper surface coated with a pattern of green, blue and a small amount of yellow in suitable proportion. In the system usually associated with the name of Mr. F. E. Lamplough, the light is filtered through a combination of tinted glass. In either case the efficiency of the apparatus is necessarily low, 60% or more of the original light being lost in making the correction. But the advantage to firms in the dyeing industry and others concerned with delicate colour-matching of having an invariable artificial light, independent of the wide variations of natural daylight, is very considerable.

Industrial Applications.—The problems of the lighting of streets, schools, factories, shops, etc., of the avoidance of eye strain in cinema theatres and the importance assigned to proper lighting in factories, the interests of health, safety and efficiency of work, have been investigated by the Illuminating Engineering Society and Home Office Committees.[4] Evidence on lighting requirements in factories has been collected from many different sources, and records of over 4,000 tests of illumination in different factories have been presented. The minimum values of illumination in the interests of safety (0·25—0·4 ft.c.) are established. Recommendations on the subject of avoidance of glare, flickers and inconvenient shadows have been made, and the illumination required for carrying out work done is shown to be not less than three foot-candles for fine work and five foot-candles for very fine work. Consultations with various joint industrial councils are now proceeding with a view to determining what constitutes suitable and adequate lighting for processes in their respective industries.

Progress in the United States.—In the United States detailed codes of industrial lighting have been adopted in seven different states. In principle these follow closely the recommendations of the British Committee. Methods of grading various lighting units according to the degree of "glare" are outlined, and the positions which may safely be assigned to such units in a workshop are tabulated. The codes also contain standards of the illumination requisite for various processes, a distinction being drawn in the most recent codes between the minimum value desirable and higher values recommended in the interests of economic production. A considerable amount of research has been devoted to the relation between conditions of illumination and efficiency of work. Thus it has been shown by Dr. Ives of the United States Public Health Service that the dispatching service in post offices was expedited and rendered more accurate by better conditions of illumination;[5] tests in laboratories in Germany have likewise revealed a close connection between illumination and many processes involving exact vision and manual dexterity.[6] The subject of industrial lighting has likewise been studied by the International Labour Bureau of the League of Nations in Geneva.

Particularly difficult cases of industrial lighting also form the subject of study by the committee on illumination, working under the department for scientific and industrial research, on which eminent architects and medical men, besides lighting experts, are represented. This committee also deals with all inquiries bearing on illumination received from the various government departments. In connection with this and other aspects of lighting, increased attention is now being devoted to the hygienic side, and at the international congress for the study of industrial hygiene held in Geneva in 1924 a special resolution was passed accepting good illumination as of equal importance with heating, ventilation and sanitary conditions, in the interests of health and safety.

Standardisation.—Standardisation in various fields is being dealt with by various sub-committees, working under the British Engineering Standards Association, which have prepared specifications on the performance and dimensions of electric lamps, and have also recently issued standard specifications for portable

umination photometers[1] and reflectors used for industrial lighting.[2] Other subjects now being dealt with include lighting glassare, and the illumination of schools, offices and streets.

Traffic and Lighting.—Experience during recent years has own that the questions of lighting and transport are closely lated. With the progressive increase in the volume of fast-iven motor-traffic the necessity for good public lighting has come even more urgent than in the past; and the increase in e number of street accidents year by year has drawn public tention to the importance of the question. A new problem presented by the lighting of arterial roads connecting cities. hese routes are primarily intended for fast motor traffic and eir utility will not be fully realised unless adequate artificial ghting is provided, enabling them to be used with safety by ght as well as by day. Special methods of illuminating such utes are now the subject of consideration.

Many devices eliminating glare from powerful automobile eadlights have been suggested, some of the most promising ased on the limitation of the main portion of the beam below a ertain horizontal plane so as to avoid the direction of rays into ne eyes of approaching drivers or pedestrians. But the most opeful solution lies in the provision of better public lighting, hich would render very powerful headlights unnecessary.

Progress in these various directions has been aided very greatly y the introduction of simple forms of instruments for measuring lumination, of which quite a variety of types are now available. he information acquired in this way has been very helpful in raming recommendations for the degree of illumination necesary for various purposes.

ILLUSTRATION (*see* 14.321).—By 1910 the rapid advance in he various methods of process reproduction had resulted in the complete liberation of the draughtsman from any of those considerations which had limited him in the days of the reproductive wood-engravers. This new freedom was in some ways a misfortune, especially as photography made it possible to reduce a lesign to any convenient size, so that the artist too often forgot altogether that his object was to decorate a book. The perfect illustrator is rare, and the most admirable drawings, when they are merely attached to an author's text, may not be illustrations at all.

The new interest in typography, stimulated by the work of William Morris, but in reaction against the heaviness of his types, has resulted during the decade 1915–25 in an enormous increase in the number of beautifully printed books issued from the press. Many of the English editors content themselves with fine typography, embellished perhaps with occasional head pieces and *culs-de-lampe*, but most of these decorative details are well-conceived, and pleasantly arranged with reference to the size of the page and the area of the type.

The possibilities of the woodcut have been most fully appreciated and exploited on the European continent. Its advantage over the intaglio methods, such as etching or copper-engraving, is that the wood block can be printed with the type by a single operation. Technically, however, it is a reaction, and the smallness of its field makes it unsuitable for use in illustrating popular magazines. The efficiency of modern reproduction makes it possible for an artist to design in almost any medium, with the reasonable hope that his intentions shall not be travestied on the printed page.

Some Notable Work.—Some of the best examples of the use of the half-tone and line-block processes in England are still to be found in *Punch*, and range from the graceful, elegant manner of Lewis Baumer and (until recently) of Claude A. Shepperson, to a sympathetic treatment of proletarian types in George Belcher's reproduced pencil drawings. The "sequence picture," influenced by the cinema, but drawing its first inspiration perhaps from Caran d'Ache, receives competent treatment at the hands of H. M. Bateman and "Fougasse." W. Heath Robinson in known not only as a comic artist of fantastic invention, but as a delicate illustrator of fairy tales. More purely decorative is the work of Edmund Dulac, who relies, as does also Arthur Rackham, on the three-colour process. The last three artists named have done much to raise the standard of the illustration of children's coloured books. The nursery picture-books of about 1900, in spite of the previous example of Kate Greenaway and Randolph Caldecott, were often crude in colour and ugly in design.

The influence of Beardsley is seen in the work of John Austen, Harry Clarke and "Alastair," while artists like H. M. Brock continued the Hugh Thomson tradition. F. Cayley Robinson and Russell Flint are perhaps best known for their painting, outside the sphere of illustration, but they have both done good work within it. Ethel Gabain (Mrs. John Copley) may be included in the English school, although her most important lithograph illustrations have been issued by French publishers. Two able architectural draughtsmen are E. H. New and F. L. Griggs, while Frank Brangwyn brings to the illustrations of books, such as Southey's *Life of Nelson* and Kinglake's *Eothen*, the same power of emphatic statement and grandiose conception as distinguishes his larger work. The early death of Lovat Fraser cut short a career of great promise which, in spite of its brevity, has exercised a far-reaching influence on various British arts. His method of working in flat tones and simple outline was peculiarly suited to modern colour-reproduction, and his example has been widely followed. Of the more "advanced" artists, many of whom have exploited the possibilities of the original woodcut, may be mentioned V. Gribble, R. Gibbings, Paul Nash, Albert Rutherston, Ethelbert White, A. Buckels and S. Gooden. The last-named has done much to revive the use of line-engraving on copper.

French Workers.—Enthusiasm for the original wood-engraving is greater perhaps in France than in any other country, and so much excellent work has been done by this method alone that the chief difficulty lies in the selection of representative names. A more or less homogeneous group is formed by Maxime Dethomas, with his dignified line, Hermann-Paul, with his broad handling and strong dramatic feeling; and Carlègle. The well-known *éditions Crès* are decorated admirably by Gus Bofa, by Siméon, by Sylvain Sauvage, by Contel and by Daragnès. The last-mentioned artist has used etching as well as wood-engraving, and indeed—now that the chief aim of the woodcut, to harmonise with the printed page, has been generally accepted—there is no reason why artists should not avail themselves of lithography, as does L. A. Moreau, or of line-engraving, like Laboureur, or of etching, like C. Laborde. Mention should be made of the colour woodcuts of Falké, the work of Brissaud, of Deslignères, of Galanis, whose curious use of white hachures is well known to English amateurs; of Raoul Dufy, better known in England as a painter; of Paul Vera, of Laboureur, with his curiously effective deformations; of Jean Marchand, and of Raphaël Drouart, all of whose work goes to make this present epoch of book production in France a very notable one.

Germany.—Germany perhaps more than any other country has felt the influence of the most extreme aesthetic theories. The disorder following the War and the sense of humiliation in defeat tended to anarchy and disillusionment in the arts also. An amazing number of fine books has been produced, but the illustrations to some of these are conceived in a slap-dash, sketchy fashion, impossible to harmonise with the necessary orderliness of a printed page. Even artists of the standing of Lovis Corinth and Max Slevogt sometimes scribble over, rather than illustrate, the works entrusted to them. The mass of modern German

work, however, is impressive. A few names may be singled out:—Max Pechstein, Alfred Kubin, Willy Geiger, Fritz Heubner, Julius Diez, Oskar Oestreicher, Wilhelm Wagner, Richard Seewald and George Grosz, the last-named being an able artist who exemplifies that curious obsession with sex which characterises too much modern German art. The general standard of book production in Germany is higher than it has ever been, and it is from Germany that the smaller countries of Europe, with the possible exception of a francophil Poland, draw most of their inspiration.

United States.—The comprehensive word "illustration" covers two main branches of the art—the self-contained picture and the picture which forms the amplification of a literary theme. In the former, the illustrator is called upon to supply a picture of some situation of life or some theme or fantasy, complete and self-explanatory. In the latter, the illustrator has to embellish sympathetically the meaning of his accompanying text.

The subdivisions in both these classes are numerous. The self-contained illustration can be anything from a comic strip drawing to a poetic fantasy, but it essentially has to rest on its own individual merits. The illustration which has a literary partner can be anything from an advertising design to the pictorial embellishment of the finest periodical, book or treatise. These are the extremes covered by the word Illustration.

Perhaps the most prevalent and important branch of the art today is the illustration of magazines, books and newspapers. In recent years this art has reached a very high degree of proficiency, both in artistic technique and in the process of reproduction. Indeed it is probable that the vast improvements in reproductive methods and the refinement of paper have acted as incentives to illustrative artists. Illustrations for books, magazines and papers should be wedded to the text, and at the same time should extend the meaning of the text by their realistic, artistic or imaginative quality.

Most illustrations of to-day have realism as a predominating feature; it therefore might be argued that the great advances in artistic photography might supersede the hand-made illustration, but it is not so. The art of the illustrator cannot be dispensed with, for in its best form all the necessary realism is there, plus the almost indefinable pleasure which technique produces on the observer, whether he be an artist or not.

The best fiction illustration of the period is perhaps to be found in America. There are several very powerful illustrators in Europe, but on the whole the American illustrator excels. Amongst the many exponents of the art, selection is difficult, but it is not easy to imagine better or more applicable illustration than the work of Dean Cornwell in half tone and Dana Gibson in line—both men being leaders of schools of illustrative thought. The mere mention of these two names makes it hard to refrain from enumerating a host of other most capable illustrators, but space will not permit. The English counterparts to the above two artists are difficult to select, but the work of Frank Craig in half tone and of Frank Reynolds in line have provided some exquisite illustration. The work of all four has allowed artistic technique to help the story and yet not engulf it. They have all been great "stylists" and have many followers.

This analysis of illustration as an art holds good throughout the world, and in theory has been approximately the same since man became capable of illustration in even the primitive forms. There have naturally been modifications and peculiarities in ability and style due to elementary conditions; and there have been differences of technique, due in the main to racial causes. (B. B.)

IMMIGRATION: *see* MIGRATION.

IMMINGHAM, England, a seaport situated on the Lincolnshire shore of the Humber estuary, 9 m. S.S.E. of Hull and 5 m. N.N.W. of Grimsby, England. Constructed (1906–12) by the Great Central Railway Co. (now part of the London and North Eastern), the dock comprises a square basin and two long arms (including a graving dock) running parallel to each other on the western side, of a total area of 45 ac., with 5,400 ft. of quayage; the depth (30–35 ft.) is sufficient for practically any vessel afloat. The dock is specially designed and equipped for dealing with the coal, timber, grain and wool trades, and was officially opened by the King on July 22 1912. The area of the dock property is 2½ m. in length and 1 m. in greatest depth, is just over 1,000 acres with a river frontage of 1½ miles. The site was chosen because the deep-water channel of the Humber, which lower down runs midway between the shores, here makes an inward sweep and leads right to the dock gates, thus obviating much initial dredging, providing ingress and egress at any state of the tide, and rendering the towage of vessels unnecessary.

The original village of Immingham lies a little inland, but a new town is growing up near the docks. The Grimsby electric tramways have been extended to Immingham and, in addition, a light railway runs between the two places.

IMMUNITY (*see* BACTERIOLOGY, 3.175).—The term "immunity" is used in science in the technical sense. An animal is described as *naturally immune* against the microbe of disease if the microbe in question cannot establish itself in the organism, and as *artificially immune* if it was naturally susceptible and has been rendered insusceptible. Similarly, an animal is described as *naturally immune* against a poison if its organism is naturally proof, and as *artificially immune* if its organism has been rendered proof against the poison.

Natural Immunity.—A few words may be said first with respect to natural immunity against infection. We may attribute the fact that the body normally remains free from microbic infection to a conjunction of causes:—*First*, to the fact that its external and internal coatings furnish mechanical protections against infection (this point need not be further considered here); *secondly*, to the fact that the body is equipped with special machinery for the destruction of microbes (the nature of this machinery will be discussed below in connection with acquired immunity); and, *thirdly*, to the fact that certain of the conditions which normally prevail in the animal organism are inimical to the growth of microbes as a whole or at any rate to the growth of certain classes of microbes. Of the conditions here in question two which are of quite dominant importance were discovered in the course of researches on wounds carried out in the World War.

Antitrypsin.—The first and more generally important is the antitryptic power of the blood fluids. Such antitryptic power will in every case hamper, and in the ordinary case completely inhibit, bacterial growth. It will achieve this by neutralising, in part or completely, the digestive ferments of the microbes which would otherwise convert the unassimilable native albumens of the blood-fluids and serous discharges into assimilable nutrient materials. Antitrypsin in the blood-fluids will therefore mean for the microbes therein implanted, either, a restriction of their food supply, or complete starvation. The facts, as far as known, all comport with this inference.

To begin with, only a few species of microbes (the staphylococcus, streptococcus, pneumococcus and perhaps the microbes of all genuinely septicaemic diseases) can proliferate in antitryptic blood fluids. Further, these microbes (we may conveniently call them *seropbytic* microbes) produce when grown in plasma (we are here generalising from observations made with staphylococcus and streptococcus) trypsin which quenches the antitryptic power of the surrounding blood fluids and then digests vacuoles in the surrounding clot. Again, all seropbytic microbes grow very much more vigorously (the streptococcus for example very many thousand times more vigorously) in the blood fluids when these microbes have, by an artificial addition of trypsin, been relieved from the task of themselves producing enough trypsin to quench the antitryptic power of the surrounding medium. And finally, all those kinds of microbes which are unable to grow in antitryptic blood fluids begin to pullulate there the moment trypsin is added—

d let it be noted here that a spontaneous addition of trypsin urs regularly in wounds as soon as the emigrated leucocytes broken down under the influence of bacterial growth and favourable external influences.

Effect of Alkaline Reaction.—Again—and here the second of restraints on microbic growth spoken of above comes into estion—in the course of research work on wound infections nducted in the course of the War, it was established, in conction with the microbe of gas gangrene, that the proliferaon of this bacillus in the blood fluids and serous effusions is hibited not only by the antitryptic power but also by the rmal alkaline reaction of these media. Proof of this is furshed by the fact that as soon as the alkaline reaction in quesn is blunted off by the ante- or post-mortem formation of tic acid in muscles deprived of their blood supply, or more rectly by an infusion of any acid into the blood, the bacillus of ngrene multiplies without restraint.

Natural Susceptibility.—The problem as to why a particular imal is naturally susceptible to particular poisons is likewise a emical problem, but a chemical problem of a different order. rmulated in the technical terms which were introduced by hrlich the problem is that as to why the tissues of the insusptible animal contain no *receptors* for the poison, that is to y, no organic substratum upon which that poison can anchor self. This is a question of the aboriginal chemical constiition of the body—a question as to why a particular species of imal was constructed of one kind of elements rather than of nother.

Acquired Immunity.—The problem presented by acquired mmunity to infections or poisons differs in important respects om that presented by natural immunity. With respect to such inforcement of the natural resistance it will be well to note at ne outset (*a*) that it can be achieved apart from any violent hysiological commotion; (*b*) that acquired immunity does not etray itself in any altered habit of body; and (*c*) that the conition may in many cases be present to-day and gone to-morrow. ll these facts indicate that the acquired immunity cannot nvolve anything in the nature of a revolutionary physiological pheaval such, for example, as a fundamental alteration in the lood elements, or a cutting out of receptor elements from cells.

Anticipating here, we may say that later it will be shown with egard to acquired immunity to infections that this depends pon the development of (*a*) increased antibacterial substances n the blood fluid, (*b*) increased efficiency in the leucocytes and (*c*) increased capacity for producing antibacterial substances in esponse to infection. Similarly it will be shown with regard to cquired immunity to poisons that this depends upon the appearance of neutralising elements (so-called antitoxins) in the lood coupled with the acquirement of increased capacity for laborating these elements in response to an incorporation of he corresponding poisons.

Early Doctrines.—Confining ourselves to the problem as to ow the bacterial infections are combated in the organism, we ay begin by considering the two chief opposing doctrines which were promulgated, when, under the prompting of Pasteur's practical achievements in the field of prophylaxis, problems of immunity began to be first seriously considered. These theories included natural as well as acquired immunity.

Humoral Theory.—In the theory which goes by the name of the humoral theory, natural immunity is attributed to the bactericidal substances contained in the normal blood fluids, and acquired resistance to the acquisition or increase of such bactericidal power. The general thesis, at any rate, of this theory stands secure. Where microbes are killed otherwise than by physical agencies or by inanition, their destruction must inevitably result from some form of chemical action. So, too, the acquisition of greater power of destruction must of necessity be imputed to the achievement of more potent chemical powers. On the other hand, it cannot of course be *a priori* certain that the antibacterial elements concerned in the destruction of microbes will be found in the blood fluids and only in these. That the blood fluids do, in point of fact, possess bactericidal power was demonstrated by Fodor and Nuttall, and it was at first thought, though a careful study of Nuttall's results should have prevented this, that such bactericidal action was exercised upon microbes without distinction of kind. Later research has, however, shown that the blood fluids are directly poisonous only for certain species of microbes such, for example, as the typhoid bacillus and the cholera vibrio. Certain other species of microbes, and in particular the microbes of specifically septicaemic diseases are, as we have seen, serophytic—the number that grow out in serum being as great as the number which grow out in the best artificial nutrient medium. Thus, the so-called *humoral theory*, though it would account for the organism possessing considerable resistance to typhoid and cholera, leaves unexplained the fact of the normal organism offering very considerable resistance to serophytic microbes.

What applies to natural, applies also to acquired immunity. There is nothing to show that increased resistance to serophytic microbes and septic infections generally is accompanied by the development of any bactericidal power in the blood fluids.

Phagocytic Theory.—An entirely different conception of immunity is that familiarly known as Mechnikov's *theory of phagocytosis*. In the humoral theory the problem of immunity is envisaged from the point of view of the bacteriological specialist and to some extent also from the standpoint of the chemist. Mechnikov for his part approached the problem from that of the morphologist who takes the whole field of animal life as his province. His theory of immunity therefore starts with the generalisation that the protozoa feed upon the lower forms of life such as microbes. It further regards the fact that the higher animals have been evolved out of colonial aggregations of protozoa. In every such colonial aggregation certain of the associated cells instead of becoming specialised persist in the condition of wandering cells.

With regard to these free-living members of the protozoal colony Mechnikov divined that they function as defensive cells. And he showed in connection with sponges and other invertebrates that these wandering cells collect round invading microbes and other foreign intrusions and that they thereafter proceed to ingest and digest them or, to aid otherwise in their elimination. Lastly Mechnikov pointed out that the leucocytes of the vertebrate were homologous to those wandering cells and performed exactly the same defensive offices. In particular when leucocytes emigrate from the capillaries into a focus of bacterial infection, in the normal case, they follow this up by ingesting the intruding micro-organisms, and killing them intracellularly. *Natural* or *native immunity* was thus, in the conception of Mechnikov, due to efficient leucocytic functioning; and *acquired immunity* to the leucocytes having by a *process of training* (as he called it) acquired a power of more effectively confronting, ingesting and destroying microbes.

Eclectic Theory.—The central tenet of the Mechnikov theory—the tenet that the leucocytes play a very important rôle in the defence of the body against infection—has now found universal acceptance, but at the same time the doctrine that resistance to infection depends in every case on the action of the leucocytes has proved untenable. In connection with the defence of the organism we must distinguish between (1) defence against infection by serophytic microbes, that is against microbes which like the streptococcus and staphylococcus proliferate in the normal serum, (2) defense against infection by microbes which are incapable of multiplying in the antitryptic normal serum but are not directly killed by it, and (3) defence against microbes which are directly killed by the serum.

(*a*) In connection with the first kind of microbe the fact that although they grow freely in the serum and plasma, these are killed in large numbers in the blood and in the serum, when living leucocytes are added, shows that the cellular elements of the blood here do the work of destruction.

(*b*) In connection with the successful killing of these microbes, the leucocytes must, however, in all cases have free mechanical access to the microbes. There would for example be default in this respect if, as would happen in dealing with infected

defibrinated or infected centrifuged blood *in vitro*, the leucocytes settled to the bottom and the microbes were buoyed up out of their reach in the serum. The same would of course happen *in vivo* in all serous effusions.

(*c*) In connection with those microbes which are not directly poisoned but fail to proliferate in the serum, the most important restraining influence is the native antitryptic power of the blood, but once the antitryptic inhibitory action of the blood fluids and serous effusions has been neutralised the leucocytes, even when everything else favours them, will be impotent to inhibit microbic growth. On the contrary as soon as the leucocytes degenerate they will furnish a further quantum of trypsin and in this way directly conduce to the pullulation of all manner of microbes.

Lastly, the leucocytes do not seem to contribute to the defence of the organism against those microbes which, like the typhoid bacillus and the cholera vibrio, are directly poisoned by the serum. When we implant such microbes into defibrinated blood and then incubate and make microscopic preparations those microbes which are quickly ingested are found intact within the phagocytes while those which are left exposed to the action of the serum are distorted and dissolved. And again, when living emigrated leucocytes are brought to bear upon typhoid bacilli it would seem that few of the microbes are killed. Precisely similar results are obtained with extracts made from leucocytes. It was shown by Schattenfroh that such extracts exert bactericidal action upon the staphylococcus and streptococcus while they exert no such action upon the typhoid bacillus and the cholera vibrio. And again it was shown by Colebrook that the products of inflammation derived from foci of inflammation set up by incorporating into rabbits lint soaked in typhoid vaccine are powerfully bactericidal for the staphylococcus and streptococcus while for the microbes of typhoid and cholera they are not more bactericidal than ordinary serum.

This review of the facts shows that only in the case of serophytic microbes does the defence of the body depend upon the leucocytes and that when it is a question of defence against the other two classes of microbes (those whose growth is entirely inhibited and those which are directly poisoned by the serum) the leucocytes are either impotent or directly harmful.

Properties of the Leucocytes Concerned in Immunisation.—Mechnikov originally taught that the leucocytes were attracted to microbes and induced to phagocytose them by the toxin secreted by the microbes; and that there was here only an interaction between leucocytes and microbes and that the blood fluids could be left entirely out of the story. That that doctrine cannot be sustained can be demonstrated by a very simple experiment.

We begin by receiving a sample of blood taken direct from the vessels into normal salt solution. We then centrifuge and recentrifuge in further volumes of this normal salt solution so as to wash the cellular elements free from all traces of the blood fluids. We then make two so-called *phagocytic mixtures* combining in the one case (*a*) one volume of a bacterial suspension with (*b*) one volume of washed leucocytes and (*c*) one volume of 0·85% *salt solution*; and in the other case (*a*) one volume of washed leucocytes, (*b*) one volume of the same bacterial suspension and (*c*) one volume of *normal serum*.. These mixtures are then placed in the incubator and after a suitable lapse of time a sample of each is examined under the microscope. In the first phagocytic mixture—that in which no serum was employed—the leucocytes have failed to ingest any microbes. In the specimen in which serum has been employed, the microbes have been plentifully ingested. This result depends not upon any stimulating effect exerted upon the leucocytes, but upon the fact that the serum has effected a chemical change—a so-called *opsonic change*—in the microbes. That this *opsonic change* does not in any sense affect the vitality of the microbe is shown in the case of serophytic microbes by the fact that the serum that exerts an opsonic effect furnished culture medium in which the affected microbes will all grow out into colonies. The blood fluids intervene further in the destruction of microbes in the interior of the phagocyte by combining with them in such a way as to favour their intracellular digestion. This action, which w first described by Douglas, is known as the protryptic action the blood fluids.

The living leucocyte can also kill microbes apart from phag cytosis. The following experiment is instructive. A shall receptacle is filled with a solid nutrient medium whose surfa has been uniformly implanted with staphylococcus or strept coccus. The centre portions of the three cover glasses are thick carpeted with living leucocytes obtained direct from the bloo We now, after different treatment, impose these cover glass side by side upon the implanted nutrient surface. In the case the *first* cover glass the adhering leucocytes are brought in application in conjunction with the adhering serum; in the ca of the *second* they have been washed free from every trace serum; and in the case of the *third* cover glass the adheri leucocytes, instead of being employed living, have been kill by drying.

The whole preparation is now incubated at blood heat f 12 hours or more. The microbes will then be found to have grow out forming an uninterrupted sheet of colonies over the who surface of the nutrient medium except under those areas cover glasses 1 and 2 which are carpeted with living leucocyte Here the implanted microbes have not proliferated, and micr scopic examination of the cover glasses shows that where t leucocytes came into action in conjunction with serum t microbes are all lying intracellularly; while where the leucocyt were washed free from serum— the microbes are all lying extr cellularly. The experiment thus shows that microbes can killed by leucocytes both intra- and extra-cellularly, *i.e.*, both phagocytosis and also apart from phagocytosis. This holds tr both under the conditions obtaining in this particular experimen and also in numerous other conditions. That destruction microbes by leucocytes without the intervention of phagocytos occurs also very frequently *in vivo* is practically certain.

Results of Experiments.—Research has thus shown that t destruction of microbes in the body does not proceed only alon the lines laid down in the humoral and phagocytic theorie Instead of there being, as was assumed in those theories, onl one physiological device by which microbes without distinctio are killed in the organism, nature would appear to provid different distinctive devices for different microbes. Some path ogenetic microbes are combated by the bactericidal action the serum unassisted by the leucocytes, others again are pr vented from proliferating by special agencies, such for example the antitryptic power of the blood; and again a third descriptio of microbe, the serophytic microbes, are destroyed intrace lularly and extracellularly by the leucocytes aided, or as the cas may be, unaided, by the blood fluids.

The above deals only with the normal protective machine of the body as distinguished from that which comes into pla in artificial immunity. In connection with the latter Mech nikov, as will be remembered, taught that acquired resist ance was due not to any changes in the blood fluids, but to t leucocytes having been subjected to a process of training whic gave to them a greater capacity for confronting and ingestin microbes. This doctrine had to go by the board when it was show in numberless cases that increased phagocytosis goes hand i hand with increasing opsonic power in the blood fluids.

From this it was incautiously assumed—though this tene was never definitely formulated—that the leucocytes co stitute in artificial immunity an invariable, and the blood fluid the only variable, factor. That the phagocytic efficiency of t leucocytes was also a variable factor was first shown by Shattoc and Dudgeon, who observed that the phagocytic efficienc of the patient's leucocytes is in many cases of pyrexial infectio greater than that of the normal man. The phagocytic efficienc of a patient's leucocytes may also, as was further shown b Shattock and Dudgeon, be less than normal.

These observations have a direct bearing upon Mechnikov' doctrine with respect to acquired immunity, since, in all infec tions which are associated with constitutional disturbances antigens from the foci of infection are being brought int

o ration—in other words the organism is experiencing and is
ting to *auto-inoculations*. It follows that, conformably with
t doctrine of Metchnikov, the leucocytes should in every
c of pyrexial infection be conducted by successive degrees to
a condition of continually increased phagocytic efficiency.
I tead of that these cellular elements are, sometimes in localised
i ctions, and practically always in streptococcus septicaemia,
r uced to a condition of diminished efficiency.

Artificial Immunisation.—We have to consider next how to
i rease the effectiveness of the anti-bacterial machinery, *i.e.*, how
t oduce artificial immunisation against infection. The origi-
n point of departure was the observation that those patients
w had contracted and recovered from an infectious disease
v e thereby rendered proof against reinfection. That obser-
v ion led, in connection with smallpox, to the adoption of a
p cedure for the warding off of the disease. The procedure
a pted in various parts of the world and introduced to Europe
f m Turkey, consisted in the implantation into the susceptible
i ividual of material obtained from a patient suffering from
s allpox. This procedure, which was denoted inoculation be-
c se it resembled the grafting of an *eye* or *bud* into a new stock,
i in reality the parent from which all other procedures of
a ificial immunisation are derived. What required still to be
d ne was to purge inoculation of its dangers and to regulate the
i munising stimulus. This was successfully done in Jennerian
v ccination. But the achievement of Jenner was in point of
f t purely empirical.

Pasteur's Work.—After Jenner came Pasteur and with Pasteur
s entific methods are for the first time brought into appli-
t tion in connection with prophylactic inoculation. His initial
h ievement was to recognise that the essential in Jennerian
v ccination was that for a virulent infective organism obtained
f m actual cases of smallpox there has been substituted an
i fective organism which by the operations of nature—to wit
t transfer to the cow—had been attenuated in such a manner
as to render it non-lethal for man. By the exploitation of that
g neral principle, by the employment of pure culture and by a
t chnique of artificial attenuation adapted with infinite resource
to each separate case, the whole series of Pasteurian successes in
t e field of artificial immunisation were one after another
a hieved. Artificial immunisation was not, however, purged
f m all its risks by the procedures of Pasteur.

It had not yet been transformed into a scientifically regulated
p ocedure. The Pasteurian vaccines were in point of fact standard-
i ed only thus far that recourse to attenuation placed in each
c se a certain limit upon the proliferation of the vaccinating
m terial in the organism of a normally resistant man or animal.

Standardisation.—A great step in advance was taken when it
w s established in connection with anti-typhoid inoculation
t at the antigen required for the setting in motion of the machin-
e y of immunisation can be furnished by the incorporation of
s erilised microbic cultures. And further, important steps to
t e achievement of a standardisation of bacterial vaccines
w re made when a technique for the enumeration of the microbes
i bacterial suspensions was devised, and when it was recognised
t at weighed quanta of desiccated and powdered bacterial sub-
s tance could be employed in cases where, owing to the felting
t gether of the microbes, enumeration of the microbial suspension
w s impracticable. The counting of the microbes or the weigh-
i g of the bacterial substance is, however, only a means to an
e d—the standardisation of a vaccine, *i.e.*, the determination of
t e doses which will give the best "curve of immunisation."

The Curve of Immunisation.—The expression *curve of immunisa-
tion* calls attention to certain fundamentally important points in
connection with the reaction of the body to the incorporation of
vaccines. In the pre-Pasteurian and Pasteurian periods, when
ideas about the nature of immunising response were still vague,
it was assumed with regard to vaccines that they produced
their effects only after a certain incubation period (ordinarily
only after 10 days). And it was further taken for granted that
the curve of immunisation would from the beginning move
always in the upward direction. When, however, immunisation
curves came to be constructed (and this was done first in con-
nection with anti-typhoid inoculation) unanticipated features
revealed themselves and in connection with these also time-
relations which did not conform with expectation.

Negative and Positive Phases and Practical Importance of These.—
In what may be called the normal case—*i.e.*, in the case where the
dose of vaccine inoculated is sufficient to produce an appreci-
able constitutional disturbance, a bi-phasic curve of immunisa-
tion is obtained. For 24 or more hours after the inoculation the
antibacterial power of the blood is reduced. This—the so-
called *negative phase*—is followed by a phase of increased
antibacterial power—the so-called *positive phase*—which may
last for one or two or a number of days as the case may be.
After this the antibacterial power falls away gradually to a
level only slightly higher than the original normal. But despite
this there would seem to persist in the organism (and this
would seem to be the chief profit from inoculation) a power of
making more rapid and more ample immunising response to
any subsequent incorporation of antigen whether in the form of
a subsequent inoculation of a similar vaccine, or actual infection.

When, instead of a quantum of vaccine which produces a con-
stitutional disturbance, a smaller dose is inoculated, the negative
phase is elided and a positive phase is well developed already
24 hours after the incorporation of the vaccine. And, finally,
when excessive doses of vaccine, such as produce very severe
constitutional disturbances, are incorporated, the negative phase
may be correspondingly intense and may persist for many
weeks. These facts have an important bearing upon prophy-
lactic operations; they must also, as reflection will show, have
an importance in connection with the immunisation procedure
to which horses are subjected with a view to their producing
antibacterial and antitoxic sera. Again substantially the same
relations as between the quantum of vaccine inoculated and the
type of response elicited, obtain in the case where vaccines are
inoculated into patients who are the subjects of infection. But
in that case the conditions are so far different that we have to
consider in each case two quanta of antigen: that administered
in the vaccine, and that already contained in the patient's
organism. Where a patient is the subject of only a minimal
infection, we may employ doses of vaccine nearly as great as
those employed for the prophylaxis of healthy men. Where a
patient is heavily infected, we are restricted to the employment
of minimal doses, and finally, when the patient is already labour-
ing under an excessive infection, the injection of vaccines can
only do harm.

The principle that the kind of response, and the amplitude of
the reaction, and the time-relations of the phases are in each
case a function of the quantum of antigen brought into appli-
cation is found to apply also to the case where the vaccine is
added to the extravascular blood. We obtain *in vitro* every
variety of effect according to the dose of vaccine brought into
application and the time for which it operates upon the blood—
the effects varying from an instantaneous increase of bacteri-
cidal power to a loss of most of that destructive power. And
further different effects are obtained according as we select now
one and now another method of testing. We obtain for example
one result when we measure the bactericidal power of the whole
blood; another when we measure the opsonic power of the serum;
a third when we measure the phagocytic efficiency of the leu-
cocytes. It must remain for the future to unravel these compli-
cations. For the moment the essential point to note is that
the machinery of immunisation which was supposed to be con-
structed upon a very simple—and one may add foolproof—plan
is in reality built up of very delicate and complicated elements.

The lessons which can be drawn from immunisation curves
may now be summarised. The first of these is that excessive
doses of vaccine may delay and possibly interfere with the pro-
phylactic response, and further that such excessive doses of
vaccine administered to patients suffering from an infection may
definitely aggravate their condition. Other important lessons
are that when appropriate doses of vaccine (*i.e.*, doses which are
not followed by a negative phase) are administered, prophy-

lactic effects may be obtained almost immediately after inoculation. And further it should be possible to arrest a general infection by inoculating in the incubation period and then employing a reduced dose of vaccine.

In connection with this attention may be directed to the statistical records of Haffkine's anti-plague inoculations in the Byculla Jail in the City of Bombay, and to the cases put on record by Miss Corthorn. The records of the Byculla inoculations make it probable that a prophylactic effect was here exerted already 24 hours after the vaccine had been given. And the cases recorded by Miss Corthorn seem to make good that attacks of the plague were not unfrequently aborted by the inoculation of the vaccine (*see* PLAGUE).

Further evidence showing that immunisation develops very rapidly after the inoculation of an antigen is furnished in the work of von Pirquet. If a first implantation of vaccinia is followed by similar implantations on successive days, the response to these latter differs from the response made to the first. This altered clinical response—which would appear to indicate a more rapid destruction of the later implanted infective material—was described under the name of *allergy*. It was further shown by Von Pirquet in connection with the inoculation of foreign serum that the supervening clinical reaction—which appears to indicate the throwing out of that foreign serum from the blood—is accelerated when the injection of serum is made into an organism which has been before subjected to that procedure. The interval between the injection of the foreign serum and the clinical manifestations associated with its elimination from the blood (normally 10–14 days) may be reduced to a very few minutes.

Further Questions in Connection with Artificial Immunisation.—A series of further questions in relation to artificial immunity have to be considered (1) Are there agencies other than vaccines proper—in other words, other than living or dead microbes or substances derived from the bodies of microbes—which will affect the bactericidal power of the blood and leucocytes? (2) Again are the antibacterial substances in the serum specific in the sense of operating only upon one particular variety of microbe or are they non-specific? (3) Further, will leucocytes which have acquired increased phagocytic efficiency, ingest more actively only one particular species of microbe, or all microbes without distinction? (4) Finally, what are the cells in the body which elaborate the anti-bacterial substances? All these questions are intimately linked up.

Non-bacterial Vaccine.—In connection with the question as to whether there are agencies other than vaccines proper which can increase or, as the case may be, diminish the bactericidal power of the blood, it has been shown that the infliction of burns increases the bactericidal power of the serum for the anthrax bacillus. This increased bactericidal power is no doubt referable to an absorption into the blood of disintegration products derived from the burnt tissues. Again, it has recently been ascertained that increased bactericidal power can be developed in the blood *in vitro* by adding to it foreign sera and also non-foreign sera which have been artificially altered by heating to 60° C. Lastly, it has been shown in connection with the irradiation of the skin with ultra-violet light, the light of the electric arc and sunlight, that by these agencies also the bactericidal power of the blood is increased, such increased bactericidal power depending upon an increased phagocytic power of the leucocytes and also an increased antibacterial power in the serum (*see* HELIOTHERAPY and PUBLIC HEALTH). It is not yet known how irradiation produces these results, but the consideration that radiations such as are here in question are much more likely to act by breaking down than by building up albuminous substances, taken together with the fact that increased bactericidal power is achieved only with a certain quantum of irradiation and that the blood suffers deterioration when larger doses are employed, would seem to point to the conclusion that we are here, in each case, dealing with effects produced by the absorption into the blood of an antigen in the form of disintegration products generated by the irradiation.

Specificity.—The non-bacterial antigens which have been under discussion above occupy at present a position apart in the respect that it would generally be held with regard to them that they might quite likely evoke a non-specific immunising response; whereas it would be generally held that bacterial vaccines would produce only specific immunising response. But against this there is conclusive evidence to show that bacterial vaccines also evoke non-specific immunising response in the form of increased bactericidal power in the blood, increased phagocytic efficiency in the leucocytes and sometimes also increased antibacterial power in the serum. Thus, for example, by the incorporation of staphylococcus the blood can be rendered more bactericidal for streptococcus. This can be achieved also by the addition of staphylococcus vaccine to the blood *in vitro*. Similarly an addition of tuberculin to the extravascular blood will increase the bactericidal power of the blood to staphylococcus, increasing at the same time the phagocytic efficiency of the leucocytes.

These laboratory experiments are in consonance with the statistical results obtained in connection with anti-pneumococcus inoculations at the Premier Mine in the Transvaal. Here, in 1912, in addition to a striking reduction in the incidence and death-rate of pneumonia, there was achieved a striking reduction in the incidence and death-rate from "other diseases."

Derivation of Product of Immunisation.—The discussion of the deeper problems as to where anti-bacterial substances are elaborated in the body, and as to how their production is to be explained, may be deferred for a moment. For the facts relating to immunisation against bacterial toxins must first be taken into consideration, by bringing out the following points: (1) The machinery of immunisation is in reality a machinery for neutralising or otherwise disposing of poisonous substances—poisonous substances being by definition those which enter into crippling or lethal chemical combination with the blood fluids and tissues. (2) The machinery of immunisation achieves its end by furnishing substances which enter, as the case may be, into neutralising or precipitating or destructive union with the poisonous substances above spoken of. (3) The machinery of immunisation is brought into operation only by a particular class of poisons—to wit, by those which enter into crippling but not immediately lethal chemical combination with the cellular protoplasm—those which, to use the expressions of Ehrlich, intrude themselves into the "side-chains" and not into the "vital ring" of that protoplasm. Of such poisons four kinds specially invite attention. These are: (*a*) the poisonous constituents of the bacterial protoplasm, (*b*) the albuminous substances contained in foreign sera and certain other foreign albuminous substances, (*c*) bacterial toxins such as those which can be filtered off from cultures of diphtheria and tetanus and (*d*) vegetable and animal toxalbumens such as abrin, ricin and the various snake venoms. With respect to the first the body responds to their inoculation by a production of *bacterio-tropic substances*, *i.e.*, substances which enter into detrimental or lethal chemical combination with bacteria. The inoculation of sera is followed by the elaboration and delivery into the blood of *sero-tropic substances* which neutralise and precipitate these sera. The inoculation of bacterial toxins in like manner—and this sovereign discovery was made by Behring—leads to the production and delivery into the blood of toxitropic substances. These, known as bacterial *antitoxins*, neutralise and precipitate the corresponding toxins. And, finally, the inoculation of toxalbumens is followed by an elaboration and delivery into the blood of the appropriate neutralising substances.

Practical Results.—The discovery of bacterial antitoxins has led to important practical applications in connection with the treatment and prophylaxis of, in particular, diphtheria (*see* INFECTIOUS FEVERS) and tetanus (*q.v.*) By virtue of the fact that toxins and antitoxins lend themselves to accurate quantitative study, it has contributed much to our knowledge of the machinery of immunisation. It was through the study of the curves of immunising response made to the inoculation of tetanus toxin that the negative phase first became known

n it was by the study of antitoxin production that it was for irst time unequivocally established that the organism which made previous response to even a minimal quantum of a n is thereafter capable of responding to any further quantum hat poison with a prompter and ampler elaboration of toxins.

urther, by the study of the antitoxin content of the blood in elation to diphtheria toxin, it has been shown that the pres- e of even a small quantum of antitoxin in the blood protects nst infection, and further that the insusceptibility of the ority of adults to diphtheritic infection is correlated with the session of a minute quantum of antitoxin derived, as it would n, from repeated minimal diphtheritic infections contracted heir earlier life. The same would appear to hold also of the let fever streptococcus. We have here, as reflection will show, s which illuminate the epidemiology of diphtheria and scar- na and show that it is possible and may under circumstances advisable to substitute for a prophylactic inoculation of a terial vaccine, an injection of antitoxin, or alternatively an ection of such quantum of toxin as will evoke an antitoxic onse.

Two further points about antitoxins have important bearings on the problem as to where and how products of immunisa- n are produced in the organism. (1) Antitoxins are quite rigidly cific—each antitoxin neutralising only the particular kind toxin in response to which it was engendered. (2) After a first culation of toxins antitoxins are only very slowly produced. dinarily an interval of 10 to 20 days elapses before they make eir appearance in the blood.

These properties are not, let it be noted, differential properties antitoxins; they characterise also certain kinds of bacterio- pic substances. Specificity and comparatively tardy appear- ce in the blood characterise for example agglutinins, and the -called "thermostable immune bodies."

Since there are two kinds of products of immunisation: e kind that are eminently non-specific and which are produced mediately (and can, as we have seen, be produced in the blood *vitro*); and another kind which are rigidly specific and are borated only after a considerable lapse of time and are so r as appears produced only *in vivo*; we may now seek for an swer to the problem as to how and where these various prod- ts of immunisation are engendered. Since it may be taken as rtain that these two kinds cannot well originate in the same lls and be engendered by the same kind of metabolic operation, e may divide up the problem and consider first by what cells d by what kind of metabolic operation the non-specific anti- cterial substances are produced and then take up the question s to where and how antitoxins and such antibacterial substances s are specific are geuerated.

Production of Non-specific Antibacterial Substances.—The former uestion presents no difficulty. The facts set forth above make clear that non-specific antibacterial substances are elaborated y the leucocytes. And further the facts suggest that the leuco- ytes produce these substances as ordinary secretion incited y the chemical products derived from bacterial and cellular isintegration products applied in suitable concentration.

Further the facts comport with the idea that leucocytes which ave elaborated antibacterial secretions but have not as yet ex- reted these into the environing blood fluids will, by virtue of heir increased content in antibacterial substances, possess in- reased antibacterial efficiency, while the blood fluids will not ave gained anything in antibacterial power.

Conversely leucocytes that have excreted their antibacterial ubstances will exhibit diminished antibacterial power and the lood fluids which have received these secretions will have eceived an accretion of antibacterial power.

Production of Specific Products of Immunisation: Ehrlich's Side-chain Theory.—The problem as to how these products of mmunisation which indenture chemically with only one counter- art substance are engendered in the body, is of quite another rder of difficulty, and it is one of the memorable achievements f Ehrlich to have conceived how the furnishing of such specific products of immunisation could be accounted for. The problem presented itself to Ehrlich's mind in the following vivid manner: "If," it was thus that Ehrlich communed with himself, "If I take a guinea-pig—that is to say, a creature whose country of origin is Southern America—and administer to it abrin—a poison derived exclusively from Africa (and thus one which neither the tame guinea-pig nor its ancestry can ever have encountered) and if I now find that my guinea-pig furnishes me with an antidotal substance which indentures with the abrin as does a key with the wards of the lock for which it is made, is there then for me any way of escape from the conclusion that the organism of my guinea-pig has specially constructed an antidotal substance to fit the particular kind of poison I have administered—performing in this a feat of chemical analysis and synthesis which would balk the ablest chemist?" From the intellectual *impasse* into which this interrogatory seemed to conduct there was, Ehrlich discerned, a possible way of escape. He reflected that there must of necessity exist in the organism of any animal which is affected by a given poison a counterpart substance (or to use his technical term) a *receptor* which enters into chemical combination with that poison. In other words there must exist already pre-formed in the organism of susceptible animals, substances which have a chemical constitution such as would admit of their functioning as antitoxins.

At the same time these counterpart substances differ fundamentally from the non-specific antibacterial substances which were considered above. First of all they are not, as are the substances last mentioned, available in the form of secretory products produced only with a view to their being ejected from the cell. Instead of that, specific counterpart substances are integral elements of the cellular protoplasm, and elements of which it may be assumed with certainty that they subserve special functions in the internal economy of the cells of which they are constituents. Further the specific counterpart substances we are here considering differ from the non-specific antibacterial substances in the respect that while these latter are elaborated only in one particular variety of cell (to wit, in the leucocyte) the former are widely distributed in the organism, being located in each case in a different assortment of cells. Thus, for example, the counterpart substances to which the diphtheritic toxin would anchor itself would be located in a different assortment of cells than the counterpart substances with which the tetanus toxin would combine. And again the counterpart substances which would combine with abrin would be different. This would hold true also of the counterpart substances which would unite with the poisons derived from each particular variety of bacterial protoplasm.

So far it has been shown only that susceptible animals must by the very nature of things contain in their cell-protoplasm constituent elements which are the exact chemical counterparts of poisons. We are still very far from the solution of the mystery (*a*) of the organism furnishing antitoxins in the circulating blood; (*b*) of its furnishing antitoxins only to special classes of poisons; and (*c*) of its furnishing these in quantities far in excess of the quantum of counterpart substances originally contained in the organism. Ehrlich, in exploring for some way of exit from the labyrinth constituted by these questions oriented himself by the aid of a ground-plan, in which there was set out his general conception of the stereo-chemistry of protoplasm. In the plan in question the protoplasm is a structure made up of side-chains assembled round a central ring—the continued life of the protoplasm depending upon the integrity of the central (or as we may call it *vital*) ring; while the side-chains consist of elements which are integrated into the protoplasm for its nourishing and vital functioning. To this original ground plan there was now added by Ehrlich a new feature. The conception which he now added was that the side-chains of the protoplasm would, as soon as they became redundant, be cast forth from the cell into the circulating blood, forming there what he called *free receptors*.

Interpreted in the light of this so-called *side-chain* theory, the incorporation of poisons which make a chemical attack upon the

vital ring of the cell protoplasm would abrogate the life of the cell and would therefore be incompatible with an elaboration of antitoxins. The situation is entirely different when the poison, instead of directing its attack to the vital ring, anchors itself on to one of the side-chains. After a temporary putting out of action of those functions which are discharged by the particular side-chains in question, this would lead to the replacement of the crippled side-chains, and thereafter to a hyper-replacement and to such redundancy of these in the protoplasm as would involve casting forth these side-chain receptors into the circulating blood. This theory, which is quite as applicable to the production of specific antibacterial substances as to the production of antitoxins—would seem to lie open to critical assault in that the hyper-replacement of side-chains does not necessarily conduct to an excretion of these into the circulating blood. In point of fact in the case of muscle, on which Ehrlich here relies, it leads to something very different, to a hypertrophy of this tissue.

Finally, the side-chain theory has met with hostile criticism more especially on the ground that it would compel us to believe that the noble tissues, such as those of the central nervous tissue which are poisoned by the toxins of diphtheria and tetanus, can be converted into secretory organs so prolific as to furnish in the blood tens and hundreds of thousands of units of the corresponding antitoxins. In point of fact the side-chain theory does not in any way require us to believe this. It would do so only if it had been established that poisons such as diphtheria and tetanus toxins attack only the central nervous system. But in point of fact Ehrlich assumed that the poisons which are responded to by a production of antitoxins are all *polytropic*—in other words they turn towards and combine chemically with a number of different tissues. So far therefore as the side-chain theory is concerned, we are thus authorised to assume that, not the cells of the central nervous system, but all or any of the other and less noble tissues which are affected by the toxins, are those which produce the harvest of antitoxins.

See E. Mechnikov, *Immunity in Infective Diseases*, trans. by F. G. Binnie (1907); Sir A. E. Wright, *Technique of the Test and Capillary Glass Tube* (1921). (A. Wr.)

IMPERIAL PREFERENCE.—This consists in the charging, by states belonging to the British Empire, of lower import duties on goods coming from another state of the Empire than on like goods coming from countries outside the Empire, or in exempting Empire goods from duty altogether.

History of the Movement.—Until after the middle of the 19th century, colonial products enjoyed a preference in the customs tariff of Great Britain, and British goods in the tariffs of the colonies. Preferences in both directions disappeared about the same time. But while Great Britain removed tariff restrictions equally from all imports, from whatever source, the Colonies—now obtaining responsible government, and looking upon customs as the only available source of public revenue—proceeded to impose equal duties on all imports, from whatever source. The British Govt. in vain protested in 1859 against the imposition of duties by Canada on British goods. The Govt. of Canada insisted on "the right of the people of Canada to decide for themselves both as to the mode and extent to which taxation shall be imposed." The principle of tariff autonomy was henceforward acquiesced in by the British Govt. and acted upon by the self-governing colonies.

This was the situation for almost 40 years, in the course of which colonial tariffs became distinctly heavier. So great, however, was the reliance in Great Britain on the most favoured nation clause in her commercial treaties with European countries, that by her treaty with Belgium in 1862 and with the German Zollverein in 1865 she actually bound her colonies, without consulting them, to grant as favourable treatment to the products of the treaty country as to those of the mother country, *i.e.*, to grant no preference to Britain.

Changed Sentiment.—A new stage in intra-imperial trade relations was opened in 1897. In that year Canada granted tariff concessions to all countries treating her on equally favourable terms. In effect this was a preference to British goods; and in 1898 the Canadian Tariff Act was converted from one general reciprocity to one avowedly of British preference. The Imperial Govt. had already in 1897 given notice to terminate the treaties with Belgium and the Zollverein.

In 1902 the policy of Canada became the policy of the Dominions. At the Colonial Conference of that year in London the following resolution was passed:—

> That . . . it is desirable that those colonies which have not already adopted such a policy should, as far as their circumstances permit, give substantial preferential treatment to the products and manufactures of the United Kingdom. That the prime ministers of the colonies respectfully urge on H.M.'s Govt. the expediency of granting in the United Kingdom preferential treatment to the products and manufactures of the colonies, either by exemption from or reduction of duties now or hereafter imposed.

Effect was given to this resolution by New Zealand and South Africa in 1903 and by Australia in 1906.

Tariff Reform.—Meanwhile in England the re-imposition for revenue purposes in 1902 of the old registration duty of 1 shilling per quarter on imported wheat had raised hopes of preference in Canada which were defeated by the abolition of the duty next year. The episode completed the conversion of Joseph Chamberlain to the principle of preference; and imperial preference was a prominent element in the policy of Tariff Reform which he laid before the country in 1903. The movement, however, failed at the time to receive sufficient popular support in Great Britain. At the next Colonial Conference in 1907, though the resolutions of 1902 were reaffirmed by the colonial representatives, the British Govt. put in a definite reservation that they could not assent in so far as the resolutions implied that it was necessary or expedient that the fiscal system of the United Kingdom should be altered.

Progress during the War.—The World War and the generous support which the Dominions gave the mother country had considerable effect on public sentiment in Great Britain. Early in 1917 the important committee appointed by the Govt. to consider commercial policy after the War (presided over by Lord Balfour of Burleigh) recommended:—

> That H.M.'s Govt. should now declare their adherence to the principle that preference should be accorded to the products and manufactures of the British overseas dominions in respect of any customs duties now or hereafter to be imposed on imports into the United Kingdom.

A few weeks later the Imperial War Conference expressed itself in favour of "the principle that each part of the Empire, having due regard to the interests of our Allies, shall give special favourable treatment and facilities to the produce and manufactures of other parts of the Empire": a resolution now passed unanimously by the representatives no longer of the Dominions alone but also of Great Britain. In April 1917 Mr. Lloyd George and Mr. Bonar Law, on behalf of the Coalition Govt., announced their acceptance of the principle of preference, making it clear that this did not involve the taxation of food. In Sept. 1919 the British Govt. withdrew from the Brussels Sugar Convention on the express ground that they had "now approved the principle of giving preference to Empire sugar." And, finally, in the Finance Act, introduced by Mr. Austen Chamberlain as Chancellor of the Exchequer in April 1919, preferential rebates or imports from the colonies or exemption from surtax were granted on practically all articles dutiable under the existing tariff.

The range of dutiable articles had been increased under stress of war. For many years before 1915 the only duties imposed by Britain were either purely for revenue purposes—those on tea, cocoa, coffee, sugar and tobacco; or for revenue with a certain mixture of ethical motive—those on wines and spirits. But the Finance Act of 1915 had introduced duties also on certain manufactured goods (the "McKenna duties")—cinema films, clocks and watches, motor-cars and musical instruments. These were intended as luxury taxes, but had some protective effect. On these the measure of 1919 was now able to give preference.

Post-War Changes.—The area of preference was still further enlarged by the Safeguarding of Industries Act in 1921. Part I. of this Act provided for the imposition of duties on certain

rticles produced by "key industries." The list included cameras nd optical lenses and a large number of scientific instruments nd apparatus, chemicals and special appliances, deemed essenal for the safety of the Empire; and from these duties Empire oods were entirely exempted.

The growth of manufactures in Canada had affected the sitation by enlarging the possibility of advantageous preference Great Britain beyond the primary foodstuffs: motor-cars are n example. A similar extension of possibilities from Australia as brought about by the growth of fruit farming, largely as ne result of the settlement on the land of ex-soldiers. The ritish Govt. took the opportunity of the Imperial Conference 1923 to announce its readiness to enlarge the existing prefrence on dried fruits, to increase the rebate on Empire tobacco nd on certain wines, and to take other action of a similar charcter. Before these promises could be fulfilled, the Baldwin ovt. fell from power. The MacDonald Ministry which followed eclined to carry out the intentions of its predecessors; abolished ne McKenna duties; and, though it did not entirely throw over reference in revenue duties, so reduced the tax on sugar, tea nd dried fruits as to make the preference of less value.

Preferences Granted by Britain.—On the return to office of Mr. aldwin at the end of 1924, the McKenna duties were restored ith the accompanying preferences; and the preference on dried uits, tobacco, wines and sugar was increased. The range of reference was further widened in two directions. The new afeguarding of Industries (Customs Duties) Act, 1925, imposed uties on imported cutlery, gloves and incandescent mantles; hile the budget of that year introduced duties on silk, natural nd artificial. To each of these new duties, Empire preference as attached.

Since the first grant of preference to the mother country by ne great Dominions, changes have from time to time taken lace both in the general rates of duty and in the extent of the reference. In 1923 Canada, having in mind the removal of ertain restrictions on the importation of cattle into the British arket, undertook to give a discount of 10% on existing duties n British goods coming through Canadian ports. Australia ncreased its preference to British goods in 1920, and gave assisance to British trade both by anti-dumping legislation and by easures with respect to dyes. And during the last two decades whole complex of preferences has grown up between the several ominions and Colonies, many of them the result of definite reaties. And thus Preference within the British Commonwealth f Nations has already become a considerable factor in the eco-omic and political world situation. (*See* also TARIFFS.)

BIBLIOGRAPHY.—The least partisan and most complete history of he whole movement down to 1921 will be found in a *Report* on olonial Tariff Policies (1922), prepared for the U.S. Tariff Comission. Much information as to the views of the Dominions and as o the volume of trade affected is given in the *Record of Proceedings* f the Imperial Economic Conference of 1923 (Cmd. 2009, 1924). he nature and extent of the preferences accorded to Great Britain, own to March 1925, together with the conditions governing the oncessions, will be found in the *Survey of Overseas Markets* (1925) y the Committee on Industry and Trade appointed by the British ovt. in 1924. That committee reported that "while it is difficult to btain any exact statistical measure of the benefit to British trade of he preferential treatment, the surveys of British Dominion markets nd the statistics of distribution of British trade leave no room for oubt that the advantage has been substantial." (WM. A.)

IMPRESSIONISM: *see* PAINTING.

INCHCAPE, JAMES LYLE MACKAY, 1ST VISCOUNT (1852–), British shipowner, was born at Arbroath, Forfarshire, ept. 11 1852, and educated there and at Elgin. In 1874 he ent to India to join the firm of Messrs. Mackinnon, Mackenzie & Company, Calcutta, of which he ultimately became senior artner; he became a member of the legislative council of the iceroy in 1891 and a member of the Council of India in 1897. He was created K.C.I.E. in 1894. In 1902, consequent upon the Boxer rebellion, Sir James Mackay negotiated a commercial reaty with China (*see* 6.204); he was then created G.C.M.G. n 1911 he was raised to the peerage as Baron Inchcape of Strathaver. Before the World War broke out, Lord Inchcape was already one of the most prominent figures in the British business world. As a representative of the shipping industry he took a leading part in all its affairs both during the World War and after. He served on most of the Government commissions of inquiry both in India and England. He was a member of the Geddes committee on national expenditure (1921), and chairman of the Indian retrenchment committee (1922). In 1924 he was created viscount and G.C.S.I. The positions of chairman of the P. and O. Steam Navigation Company and director of the National Provincial Bank and Suez Canal Company made him a leading figure in business circles.

INCOME TAX (*see* 14.356).—War provides a fertile soil for taxation, and a tax on income has been adopted during and since the World War in some countries which had hitherto rejected this form of direct taxation, long the sheet anchor of British finance.

I. THE UNITED KINGDOM

The British tax has been developed gradually in detail, reflecting at various stages in its history the growth of opinion, equality and justice, until to-day it is a financial instrument of great intricacy, subtlety and power. None the less the broad scheme of the law has remained unchanged in many essential characteristics for nearly a century. Flexibility is provided by the annual re-enactment of the whole income tax code through the medium of the continuation clauses in the yearly Finance Act, which serves also as the medium for amendments, extensions and declarations of the construction of the law.

The salient characteristics of the tax may be grouped under eight heads.

Scope.—The tax extends, broadly speaking, to all income arising in the United Kingdom by whomsoever it may be enjoyed, and to all income accruing to persons residing in the United Kingdom without regard to the place where it may arise. The tax walks, so to speak, upon the two legs of origin and residence. It therefore leads to the problems of double taxation. Provisions for relief against this defect, resting upon the principle of division of the total tax between the two taxing jurisdictions, exist as respects income liable both to United Kingdom tax and tax in any of the British Dominions overseas, except in the case of the Irish Free State, where the relief is based upon the principle of charging tax only in the country of residence. Further provisions for double taxation relief also exist as respects profits on shipping. One code of laws applies, generally speaking, to individuals, partnerships, companies and other bodies of persons. In the main the tax is a tax on the incomes of individuals, nearly 90% of the total actual income brought into charge being distributed among individuals who are actually resident in the United Kingdom.

Administratively, the tax is levied under five separate categories or schedules of income. But this is a matter of machinery only, and the tax borne by individuals is in reality only one tax on the total income of the individual, and not, as is often thought, a series of taxes on the separate sources of his income.

Definition of Income.—In respect of the ownership of lands, houses, etc., in the United Kingdom, the measure of income is the annual value, which means broadly the rent at which the property is let, or is worth to be let by the year (the tenant bearing his usual rates and taxes), less certain statutory deductions for repairs, and an average cost of additional expenditure on repairs, maintenance, insurance and management.

In respect of the profits on occupation of land in the United Kingdom, the measure of profit is made on a conventional basis, which assumes profits bearing a fixed relation to the annual value of the land occupied. To-day that relation in the case of land used mainly for the purposes of husbandry is one of equality, and in other cases it is a relation of one-third of the annual value.

No definition is necessary in the case of interest on public funds. Income from dominion and foreign securities (other than public debts) or from foreign and dominion stocks, shares and rents is normally liable on the full amount of the income, less charges which must necessarily be met abroad.

There remain the two main classes: income from trades or professions and income from employments. Here the broad rule is that the income to be charged is the excess of the gross receipts over the expenses incurred wholly, necessarily and exclusively in earning the profits or income in question.

The British income tax, in the words of one of the judges, "is a tax on income," and this is strictly construed by the exclusion from the scope of the tax of profits which are in the nature of capital gains; and in this respect the British system is strikingly different from that in force in the United States of America. In consequence, the law prohibits, in arriving at profits for income tax purposes, any deductions in respect of capital charges, lost capital or losses unconnected with the business. Provision is, however, made for a deduction from the statutory profits liable to tax of an allowance in respect of the depreciation of machinery or plant.

Computation of the Statutory Income.—The amount of income liable to be taxed *for* any year of assessment (a year running from April 6 to the subsequent April 5) may be, but frequently is not, equal to the amount of income earned or received by the taxpayer *in* the year. This arises from the great variety of rules which govern the computation on various bases of the statutory income of different classes. For instance, income from trades and professions or from dominion and foreign stocks, shares and rents was charged on an average of the three preceding years. Employments and income from interest on public debts or from dominion and foreign securities are charged on the basis of the year of assessment. In other cases an average of five years is used. Proposals were, however, made to Parliament in 1926 for sweeping away some of this medley of different bases, and for substituting in the case of profits from trades and manufactures, mines, railways, iron works, gas works and water works, etc., and of income from dominion and foreign securities and possessions, a uniform base of the profits of the year preceding the year of assessment.

Differentiation.—More than a century of agitation passed before this feature of the income tax was established in 1907. At first it was effected by a reduction of the normal rate of tax in favour of earned income. To-day the differentiation is granted by deducting from the earned income an allowance of one-sixth of that income subject to a maximum deduction of £250.

Graduation.—This is the principle of levying a heavier percentage upon large incomes than upon small. From the inception of the tax graduation in some form or other has figured among its characteristics. During the last half of the 19th century graduation was effected on small incomes by a scale of abatements which from 1909 to 1918 was continuously developed and widened. To-day graduation is effected as follows:—

The total of the statutory income from various sources having been ascertained, the amount of any earned income allowance is deducted therefrom. From the balance, called assessable income, there is then deducted an aggregate of various personal allowances and deductions (*e.g.*, for self or self and wife, children, housekeeper, dependent relatives, etc.), leaving a balance constituting the taxable income. Tax is calculated upon this taxable income by charging the first £225 thereof at half the standard rate and the remainder thereof at the standard rate. From the amount of tax so arrived at there is deducted any relief, expressed in terms of tax, due in respect of life insurance premiums or dominion tax.

If the system of graduation stopped at this point, the relevant curve would rise steeply until incomes in the neighbourhood of £2,000 were reached, but after that point it would flatten rapidly. In order to continue graduation an additional duty of income tax called super-tax is charged on any individual whose total income from all sources for the preceding year, as computed for income tax, exceeds a fixed sum which stands at £2,000. For administrative reasons this additional tax is assessed and collected separately from income tax, but it is only a part of the scheme of graduation for the direct taxation of incomes exceeding a fixed amount. The super-tax therefore continues the process of graduation by imposing an additional rate of tax on successive sections of the total income above £2,000. The effect of this system as a whole is to levy an effective rate of tax on each £ of the total income of an individual, rising gradually from a fraction of a penny in the £ until the rate closely approaches a maximum rate represented by the sum of the standard rate of income tax and the highest rate of super-tax.

The following table of the amount of income tax and super-tax and the effective rate of tax per £ of income on specimen incomes clearly illustrates the graduation of the tax in the case of married couples without children for the year 1926–7. It shows how the effective rate rises in the case of earned income from 2d. in the £ for a total income of £300 by gradual stages up to 9s. 7½d. in the £ on an earned income of £150,000. The rate for unearned income rises from 2½ for an income of £250 to 9·7½ to one of £150,000. Plotted on a graph, these effective rates fall upon a very smooth line unbroken by any abrupt jumps.

Income Tax and Super-Tax

Married Couples without Children, 1926–7

Total income	If income all "earned" income					If income all "investment" income				
	Income tax (including super-tax, if any)			Effective rate		Income tax (including super-tax, if any)			Effective rate

150,000	72,138	15	0	9	7½	72,188	15	0	9	7½

Collection of the Tax.—Perhaps the most famous characteristic of the British tax is the principle of collection at the source. Seligman has called it, "perhaps the chief cause of the success of income tax." It dates from as early as 1803. Under this principle the tax is obtained, whenever it is possible to do so, by deducting it before the income reaches the person to whom it belongs. The formal assessment is accordingly laid, wherever this course is possible, on each source of income by itself and on persons who are debtors in respect of income belonging to other persons. Power is given to the payer of income to deduct the appropriate tax from the payments made to the ultimate proprietors of that income. For instance, a limited liability company is assessed to tax at the standard rate on the whole of its profits, without reference to their ultimate destination. On paying interest to its debenture holders, or dividends to its shareholders, the company is entitled to deduct and retain the amount of tax appropriate to the interest paid or dividend distributed, and the investor thus receives his interest or dividend subject to this deduction of tax. It is estimated that approximately two-thirds of the net yield of the tax is collected at the source.

Whether the tax charged in respect of any income brought into assessment is collected by deduction at the source or not thus depends upon the ultimate proprietorship of the income assessed. So far as the person charged is not the ultimate proprietor, the tax is collected by deduction at the source; so far as he is, the tax is collected directly. The chief classes of income in respect of which the tax is collected directly are the profits from trade of individuals, whether sole or partnership traders; the like profits of limited liability companies so far as they are not distributed to shareholders, debenture holders, etc.; profits from the occupation of land; income from professions and most employments; income from dominion and foreign securities and possessions not paid through agents in the United Kingdom; income from certain interest, discounts, etc.

The income of individuals upon which tax is collected directly is charged in the assessments, as far as possible, at the respective half standard and full standard rates on the taxable income, that is on the balance of the assessable income remaining after deduction of the personal allowances and deductions due. As the total income of any individual taxpayer may be made up of a number of separate items, on some of which tax is borne by deduction at the source at the full standard rate, and on others of which tax is collectible directly, adjustments are in numerous cases necessary in order to restrict the total tax payable to the amount proper to the actual circumstances of the individual concerned under the scheme of graduation and differentiation already described. These adjustments are made as far as possible when dealing with tax collected directly, any balance being dealt with by repayment of tax. They are greatly facilitated by the fact that personal statements of total income are rendered

nually by almost every individual taxpayer, for purposes of either come tax or super-tax.

With the exception of tax collected at the source on interest on blic debts and on income from foreign dividends, etc., which is id at or shortly after the time of payment of the income from hich the tax is deducted, income tax contained in the main assess-nts for the year is due and payable on or before Jan. 1 in the year assessment; tax contained in additional assessments signed after at date is payable on the day after the date of signature. To this neral rule there are, however, some other important exceptions. ne bulk of the tax charged on income from the ownership of prop-ty, tax charged on any individual or firm in respect of lands occu-ed for husbandry, or tax charged on any individual or firm in re-ect of a trade, profession or vocation, and of most employments, is yable in two equal instalments, the first on or before Jan. 1 in the ar of assessment, and the second on or before the following July 1. ilway companies in England and Ireland pay tax on their profits four quarterly instalments, on or before the 20th June, Sept., ec. and March. Manual wage earners assessed half-yearly pay x in respect of each half-year. Tax in respect of employments der the Crown is deducted (usually quarterly) at the source.

Administration.—In this sphere there is a striking division of thority. The original basis of income tax administration is odelled to a certain extent on provisions in the Land Tax Acts of e 18th century. The main conception in 1806, as well as in 1842, as that of a temporary impost to be assessed and collected locally th a minimum of interference by the Exchequer. The responsibility for assessment and collection of a very large part of the tax was id upon the local bodies of Commissioners possessing certain prop-ty or other qualifications. Benches of these local or district com-issioners were and are still appointed for certain cities and bor-ughs and for parts or all of a geographical county. The individual mmissioners are entirely unconnected with and independent of ficial control. Each body has its own clerk. The Commissioners ere also empowered to appoint assessors of taxes and collectors of xes. Except as respects profits from commercial, financial and pro-ssional activities, the assessor was charged with making the assess-ent of tax; in the case of the income arising from the activities entioned this duty was laid upon a body of commissioners known the additional commissioners. On the main body of the local or strict commissioners distinguished by being known as the general mmissioners, fell the statutory duty of signing and allowing sessments made either by the assessor or the additional commis-oners and of hearing and determining appeals against such assess-ents. Fitted into this scheme was the officer of the Crown, known iginally as the Surveyor of Taxes, and to-day as H.M. Inspector Taxes. In law his part was primarily to safeguard the interests of ne revenue with strictly defined rights of intervention and objection t various stages of the formal procedure laid down by the statues.

Even in the early years this broad scheme was honeycombed with xceptions which have grown rather than diminished with the pas-ge of years. Certain assessments for instance are hived off under ne single jurisdiction of a body known as the Special Commissioners f Income Tax, each of whom, still independent of the revenue uthority, is appointed by H.M. Treasury. This body performs all ne duties of district commissioners in Northern Ireland; it makes all ne assessments on railway companies and on their officials; the ssessment of foreign and dominion dividends paid through agents the United Kingdom is under its care; it is also solely charged with ne whole of the administration of the super-tax. Then there are ommissioners for the various public departments of State who are harged with making all assessments on official salaries, etc. The ank of England and the National Debt Commissioners also act as ommissioners for assessment of individual salaries, etc., paid by hese bodies and those of the Bank of England are also responsible or the assessment of the profits of the bank. Again all assessments n manual weekly wage earners which are for a half year only are ade by H.M. Inspector of Taxes. The taxpayer normally charged y the District Commissioners may, if he wishes, elect to be dealt ith by the Special Commissioners and even if he allows his assess-ent to be made by the District Commissioners, he may take an ppeal against that assessment to the Special Commissioners.

During the past 50 years income tax grew so much in importance nd complexity that its efficient administration compelled a con-iderable development of the methods of administration. The high graduation of the tax rests very largely upon the factor of the total ncome from all sources of the taxpayer. As business and finance ave grown in complexity, the sources of individual incomes have amified accordingly, necessitating close and continuous inter-ommunication between various parts of the country. The scheme f administration originally laid down having made no adequate rovision for inter-communication between the various bodies of ommissioners, this defect has been almost of necessity filled by the evelopment of the official organisation of the Inspectorate of Taxes, unctioning under the direction of the Board of Inland Revenue. In practice, therefore, to-day the Inspector of Taxes carries out, with the full concurrence of the various bodies of commissioners, most of the duties that are vitally essential to the smooth-working efficiency of the machinery of administration. Nevertheless, the key functions of the district commissioners have been preserved throughout. In the absence of any detailed accounts or other evidence, it is the additional commissioners who determine the amount of the assessment upon business profits; even more important, the general commissioners still retain their appellate functions and so stand in an independent and impartial position between the taxpayer and the representative of the revenue.

Rates and Yield of Tax.—During the three years preceding the War, 1911–3, the normal rate of tax was 1s. 2d. in the £ and the net produce of each penny of the rate was round about £3,000,000. At that time the exemption limit stood at £160 and out of some 19,000,000 of occupied persons only 1,200,000 were within this scope of the tax. In 1915–6, the exemption limit was reduced to £130. Notwithstanding the depreciation in the value of money it remained at that level until 1920. In 1920–1, when the system of differentiation and graduation was radically altered in accordance with the recommendations of the Royal Commission on the Income Tax of 1920, the effective exemption limit was raised to £135 of assessable income, or £150 in terms of earned income. Under the influence of the change in the price level and the consequential movement of wages the total number of individuals within the scope of the tax rose in 1919 to 7,800,000, but it had fallen in 1925–6 to 4,200,000.

The standard rate of tax was changed on six occasions between 1914 and 1925. The peak rate of 6s. in the £ stood for the four years from 1918–9 to 1921–2 inclusive. It was reduced to 5s. in 1922, to 4s. 6d. in 1923 and to 4s. in 1925. The statutory income of persons liable to tax amounted in 1913–4 to £951,000,000 and the net tax collected in that year amounted to £43,500,000. These figures relate to the whole of the United Kingdom of Great Britain and all Ireland. For 1924–5, the total statutory income of persons liable to the tax for the new United Kingdom of Great Britain and Northern Ireland was estimated at £2,300,000,000. In 1924–5 the Exchequer receipt was nearly £274,000,000; in 1925–6 the Exchequer receipt was £259,000,000 and it was estimated that the collection in 1926–7 would amount to £255,000,000.

The preceding figures relate to income tax alone and do not include the yield of the super-tax. Prior to the War the point at which liability to this tax commenced was £5,000. Incomes below that figure were exempt from this impost. In 1914 the exemption level was reduced from £5,000 to £3,000. In 1918–9 the scope of the tax was altered to include all incomes exceeding £2,500 and in 1920–1 further extension was made by the alteration of this limit to £2,000. Before the War the rate of super-tax was 6d. for every £ of the amount by which the total income exceeded £3,000, although, as noted, no liability arose unless the total income exceeded £5,000. A graduated scale was introduced in 1914–5, increased in weight in 1915 and 1918, until it reached the peak rates in 1920, when it ranged from 1s. 6d. in the £ for every £ of the first £500 of the excess over £2,000, to 6s. in the £ on every £ of income above £30,000. A reduced scale[1] of rates of tax came into force in 1925–6. In the year before the War only 14,000 persons were liable to this tax. In 1924–5, the number of individuals charged had risen to 90,000. A similar and even greater increase marks, of course, the annual yield of the tax. From £3,250,000 in 1913–4 the year's collection had grown to £68,500,000 in 1925–6. These figures may be completed by noting that during the 10 years from 1916–7 to 1925–6 inclusive, the British taxpayer paid £2,768,000,000 in income tax and £493,000,000 in super-tax, making a total of £3,261,000,000. This burden was borne in addition to £1,280,000,000 in the form of Excess Profits Duty and Corporation Profits Tax, each of which was levied upon business profits before the income tax and super-tax were due to be computed.

II. THE BRITISH DOMINIONS

Taxation according to faculty, that is, direct taxation based upon the principle of ability to pay, so early established in Great Britain, was naturally carried overseas to the various British possessions. It is not therefore surprising to find income taxes firmly established to-day in South Africa, in the provinces and protectorates there as well as in the Union, in Canada, where also there are provincial income taxes as well as the Dominion tax, Australia, where a similar widespread use of the tax is made, New Zealand, India and in most of the West

	Rate in the £ s.	d.

Indian islands. Naturally also there is a strong family resemblance between the various income tax systems, most of them having been strongly influenced by British law. Income is usually defined broadly but comprehensively, but there is a general absence of the schedular arrangement of the British tax. Broadly speaking, the year preceding the year of assessment is favoured as the basis of computation of the income to be charged. The minimum amount of income exempted from tax varies, but personal allowances to the taxpayer, his wife and children are general. Graduation of the tax is a common feature, and the device of an additional tax, or super-tax, is freely adopted. In some Dominions, graduation is extended also to companies. The methods of graduation range from simplicity to formulae of great complexity. Differentiation in favour of earned income is found, but is not widely favoured. Taxation at the source is a frequent feature, especially in respect of dividends paid by companies. The rates of tax vary widely, as may be expected from the range of budget requirements of communities of different populations and varying degrees of wealth. As a rule, the income tax in the British Dominions overseas is one tax levied upon the base of the total income, irrespective of the nature of the components of that income. In this respect, the British tradition is followed.

III. SOME EUROPEAN COUNTRIES

Latin Countries.—In Latin communities, a more complex system of income taxation is commonly found. There the development of the income tax as a fiscal instrument has been slower, and has met with much greater opposition. The influence of the ancient taxes in France of the real estate tax (*contribution foncière*), the door and window tax (*contribution des portes et fenêtres*), the business tax (*patentes*) and the personal property tax (*contribution personelle et mobilière*) led to the introduction by Caillaux, shortly before the World War, of an income tax, in the form of seven schedular taxes on income, combined with a general income tax on total income. Under this system, the schedular income taxes (*impôts cédulaires or impôts sur les revenus*) are but lightly linked together. Different rates may be, and often are, imposed under the several schedules; each schedule may have its own scale of personal abatements or reliefs; each may have its own rules for the computation of income. In France, the seven schedules cover buildings and land, agriculture, dividends, interest, etc. (again divided into four subgroups), industrial and commercial profits, salaries and pensions, professional earnings and mining. Each of the seven schedules has its own method of assessment, usually its own particular allowances, and its own special rate of tax. The general income tax (*l'impôt général sur le revenu*) is steeply graduated.

Belgium, on introducing an income tax into her fiscal system in 1910, followed the same method of schedular taxes combined with a general income tax. Here, there are three schedular taxes, on income from real property, income from investment of personal property and, lastly, income from trade business or profession or employment. Agricultural profits are included under the third schedule. For the first two schedules there is the same flat rate, but for the third, the rate of tax is graduated according to the amount of income. The general income tax is also graduated. In Spain and Italy similar systems prevail.

An income tax, designed to measure and to tax the almost infinite variations of methods by which men seek the means to satisfy their wants can never be simple, but the schedular system adds complexity to complexity. Moreover, so far as the rates of tax are differential, they tend to affect the ordinary incidence of an income tax, and so to set up reactions upon economic effort which defy measurement. There is also a strong tendency to regard the schedular income taxes, not as personal taxes but as real income taxes, a contradiction in terms which is at present proving a grave obstacle to the development of a satisfactory solution of the problem of double taxation.

IV. THE UNITED STATES

Although taxes on gains and profits derived from personal ability as distinguished from property—so-called "faculty" taxes—were employed in the American colonies before the middle of the 17th century, no successful use of the general income tax was made in the United States until the Civil War; and the income taxes then adopted were soon thereafter repealed, or fell into practical disuse. The demand for effective income taxation, however, showed great vitality. It kept moribund income tax laws on the statute books in several states; led to abortive experiments with the tax, particularly in the 'forties and 'nineties; and finally in 1909 resulted in the adoption of a Federal excise tax "with respect to the carrying on or doing business" by corporations, equivalent to 1% of the annual net income over and above $5,000. This proved to be in substance a corporation income tax.

State Income Taxes.—In 1911 the State of Wisconsin adopted a general income-tax law applicable to individuals, partnerships and corporations. The practical success of this tax encouraged other states to adopt similar laws or to vitalise the administration of unsuccessful income-tax laws already on the statute books; and although a few states either repealed or rejected the tax, about one third of the states in 1925 had income taxes. The adoption of income taxes by the states has been largely for the purpose of replacing the unsatisfactory personal-property tax (particularly on intangible personal property) and the so-called corporation franchise tax. The newer state income taxes are generally administered by state or central authority, but provide for the return of a substantial portion of the tax to the county or local governments. There is an increasing tendency to assess the tax on the basis of the Federal income-tax return and an effort is made by apportionment devices to exempt in whole or in part business or corporation income derived from property located and business transacted outside the state. Jurisdictional questions and multiple taxation thus constitute fundamental problems. The various state income taxes differ considerably in their exemptions and rates, but in general the rates are much lower than in the Federal tax, the highest rates—in S. Carolina—being one third of the Federal rates. However, the combined Federal and State taxes represent a serious burden on the larger incomes.

Federal Income Tax.—The foundation for the Federal system of income taxation was laid by the ratification on Feb. 25 1913 of the Sixteenth Amendment to the Constitution, which provides:—

> That Congress shall have power to lay and collect taxes on incomes, from whatever source derived, without apportionment among the several states, and without regard to any census or enumeration.

The development of the Federal income tax is suggested in the accompanying tabular statement. Under the Revenue Act of 1926 the income tax carries exemptions of $1,500 for single individuals, $3,500 for heads of families and $2,000 for corporations. Under the personal income tax there is a further specific exemption of $400 for each child under 18 years and for every dependent incapable of self-support. Individuals are subject to a split normal tax of 1½% on the first $4,000 of taxable income, 3% on the next $4,000 and 5% on the remainder, and to a surtax ranging from 1% of the net income between $10,000 and $14,000, to 20% on the net income in excess of $100,000. Corporations are subject to a flat rate of 13½%. (since Jan. 1 1926). Earned income (to the extent of $20,000) is taxed 25% less than unearned income, all incomes of $5,000 or less being considered as earned. Net income is defined as all income and gains "from whatever source derived," excluding certain specified classes of income and less certain specific deductions.

The most important characteristic of the Federal income tax is its striking productivity, the elasticity of which is illustrated in the table. The present exemptions are high compared with similar exemptions allowed in other countries, and only a small proportion of the population is directly affected by the tax. A large proportion of the tax is collected in the industrial or urban states and is thus marked by some unfortunate class and sectional characteristics. Compared with similar taxes of other countries the rates on small and moderate incomes are low, while the rates on the larger incomes were until the year 1925 unusually

Federal Income Tax

Personal Income Tax	1913	1916	1918	1919	1921	1923
Total number of returns[1]	357,598	437,036	4,425,114	5,332,760	6,662,170	7,698,321

[2] For net income of $5,000 and over, this exemption was reduced to $2,000.

high. From the technical standpoint, the striking characteristics of the Federal tax are: The high ratio of surtax to normal tax; the marked difference in the normal tax applicable to individuals and corporations respectively; the taxation of gains from the occasional sale of capital assets, at a flat rate of 12½%; its failure, largely because of constitutional limitations, to reach interest on municipal bonds and other tax-free securities; the small use of "stoppage-at-source" (whereby the normal tax is withheld and paid direct to the government by payers out of payments due to corresponding payees); and the credit accorded for income and profits taxes paid to foreign countries on income derived from sources therein.

The tax law is extremely complex, largely owing to the taxation of capital gains and to certain "cushions" or relief provisions designed to protect the tax-payer against hardship; but the law has been simplified in a measure by the repeal of the excess-profits tax and of many of the special war provisions such as allowances for amortisation, inventory losses and the like. This has been accompanied by a movement away from centralised administration of the tax, and by a steady reduction in the rates. Nevertheless, complexity, centralisation and high surtax rates still cause excessive delay in the audit of the larger returns. The interpretation of the law has been much improved by the creation in 1924 of a Board of Tax Appeals (an extra-administrative tribunal whose decision is final unless modified by the courts), and by giving local revenue agents the power to audit and settle the smaller cases. The American tax reveals a gradual approach to the British position on capital gains and losses, which are taken into account at a special rate of 12½%.

INDEX NUMBERS.—The phrase index number is sometimes applied to any series in which a chosen term is written as 100 and the other terms expressed as percentages of it. The earlier and more general use is, however, consonant with the following definitions:—"An index number [is] a number adapted by its variations to indicate the increase or decrease of a magnitude not susceptible of accurate measurement" (Edgeworth, *Economic Journal*, 1925, p. 379); "index numbers are used to measure the change in some quantity which we cannot observe directly, which we know to have a definite influence on many other quantities which we can so observe, tending to increase all or diminish all, while this influence is concealed by the action of many causes affecting the separate quantities in different ways" (Bowley, *Elements of Statistics*, 1920, p. 196). Thus index numbers are applied to the measurement of the *general* movement of prices, cost of living, wages, production, consumption, employment, etc.

The data from which index numbers are formed consist of records of particular quantities at two or more dates or places and information about the relative importance of these quantities in a general measurement. In constructing an index number to measure the movement of any defined magnitude it is necessary to decide on the choice of the separate quantities, on their relative importance, on the period or place to be taken as base, and on the formula of compilation. Thus, in the *Statist* index number the objective is the measurement of the change of

wholesale prices in the United Kingdom, 45 commodities are selected and regarded as of equal importance, the period 1867–77 is taken as base and the average price in that period of each commodity is equated to 100, the terms in each series of prices are expressed as percentages of that average (" price-relatives "), and the simple average of the 45 relatives in any year form the index number for that year.

A distinction is drawn, but not by all writers, between two classes of index numbers: (*a*) where, as in the definitions quoted above, the object is to measure the movements of a magnitude without specific reference to any pre-determined application, *e.g.*, the purchasing power of money in general (" indice monétaire ") as conceived by Jevons, *The Variation of Prices and the Value of Currency since 1782* (1865); (*b*) where the measurement is to be applied to a defined group, *e.g.*, the changes in the cost of a quantitative standard, such as is used in a Cost of Living index (" indice budgétaire "). Many index numbers, however, are intermediate between these classes, and much of the analysis of the form and content of the numbers is appropriate to both. Thus, in all cases of price measurement, only those commodities can be included which are measurable in a defined and unchanged unit, and for which the price can be ascertained, and (unless the geometric mean is used) a base period in which each price is equated to 100 must always be selected.

(*a*) In the measurement of the purchasing power of money in general it is argued that the prices of all commodities, not subject to regulation or monopoly, are equally significant. Theoretically the problem is one of pure sampling, and the precision of the result in any year is directly proportional to the square root of the number of independent terms included and inversely proportional to the mean dispersion of these terms from their average in that year. In practice, the terms are not completely independent, for the prices of related commodities influence one another, and the precision is thus reduced. Also, the greater the interval from the base year, the greater tends to be the dispersion and the smaller the precision. In periods when prices are changing rapidly, as in the years 1914 to 1923, the dispersion is usually considerable and the measurement loses accuracy.

There are three types of averages applicable to price-relatives: their arithmetic mean as described above for the *Statist* index number; the geometric mean of the same numbers, that is the nth root of their product if there are n commodities; and the harmonic mean, which is the reciprocal of the arithmetic mean of the reciprocals. Thus, for two commodities whose prices were 6d. and 10d. in the base year, and 1s. and 2s. 1d. in any other year, the price-relatives are 200 and 250, their A.M. is 225, their G.M. is $\sqrt{(200\times250)}=223\cdot6$, their H.M. is $1\div\frac{1}{2}(\frac{1}{200}+\frac{1}{250})=222.2$ If the latter year is taken as 100, the relatives in the original base year are 50 and 40, the A.M. is 45, and $45:100=100:222\cdot2$. The H.M. of the " forward " relatives gives the same measurement as the A.M. of the " backward " relatives; or, if the comparison is between two places the H.M. of the relatives when the first is taken as base gives the same measurement as the A.M. when the second is so taken.

These statements are more readily expressed algebraically. Write $P_1, P_2 \ldots$ for the prices in the first year (or place), and $p_1, p_2 \ldots$ for the second. Write $100\frac{p_1}{P_1}=r_1=A(1+d_1) \ldots$ where $A=\frac{1}{n}\Sigma v$ is the A.M. of the price-relatives.[1] Then $\Sigma d=0$, the Geometric Mean, $G=\sqrt[n]{(r_1.r_2\ldots)}$ and

$\therefore n \log G=\Sigma \log A(1+d_1)=n \log A+\Sigma d-\frac{1}{2}\Sigma d^2 \ldots = n \log A-\frac{1}{2}ns^2$, approx. where s is the standard deviation of the dispersion of the relatives each divided by A, and mean d^3, etc., are neglected. Hence $A=Ge^{\frac{1}{2}s^2}=G(1+\frac{1}{2}s^2)$, approx. if s is small.

Also the Harmonic Mean, $H=1\div\frac{1}{n}\Sigma\frac{1}{v}=nA\div\Sigma(1+d)^{-1}$

$\therefore A=H\times\frac{1}{n}\Sigma(1-d+d^2-\ldots)=H(1+s^2)$, approx.

$\therefore H=G(1-\frac{1}{2}s^2)$, and $\sqrt{AH}=G$, approx.

Thus, if s is small A, H, G differ little from each other, but $A>G>H$. If G is the correct measurement A exaggerates a rise and underestimates a fall (since $100-A<100-G$), while H has the opposite effect. The G.M. of A and H is very nearly G. For the *Statist* index number in 1913 (1869–79 base period) $A=85\cdot0$, $G=80\cdot9$, $H=76\cdot5$, $s^2=\cdot104$. As regards precision of sampling A may be written as $A\left(1\pm\frac{s}{\sqrt{n}}\right)=A(1\pm\cdot053)=85\pm4\cdot4$ if the 45 correlated entries are taken as equivalent to 30 independent (*Statistical Journal*, p. 316, Mar. 1926). In this case the standard error attributable to sampling is about the same as the difference between A and G.

A general change in the relation of currency to its use tends to affect all prices in the same proportion, and " if other disturbing causes may be considered proportional to the ratio of change of price they produce in one or more commodities, then all the individual variations of prices will be correctly balanced off against each other in the Geometric Mean " (Jevons, *Investigations in Currency and Finance*, 1884, pp. 121–2; see also Bowley, *Economic Journal*, 1921, p. 202). The Geometric Mean is therefore considered appropriate to this problem. It has the advantage that it gives less importance to extreme measurements than does the Arithmetic Mean. It has the further advantage that the comparison by its use of any two years is independent of the choice of the base year (*see* below).

(*b*) The method generally used in the more objective problem of measuring the change of cost of a fixed aggregate of goods is as follows: The quantities of defined commodities which are produced or consumed in a year, or exported or imported, or are purchased in a week by a family, are estimated and the prices per unit are ascertained in a base year or period and also in the year to which the measurement is to refer. This budget of quantities is valued at the base year prices and again at the prices of the year in question; the latter total expressed as a percentage of the first gives the required index number. The computation is often effected by writing down the relative expenditure (quantity × price) on each commodity in the base year, applying to each the percentage that its price in the second year forms of that in the first, and adding the products. This sum (divided by the total of the base year's relative expenditures) gives the same index number as before. Cost of Living index numbers are computed by this method. In this form the index number appears as a " weighted average," where the weights are the relative expenditures and the things weighted are the price-relatives. From the theory of weighted averages it is known that considerable roughness in the weights has little effect on the result. It may also be regarded as an average of price-relatives which form a sample of a larger group than that included, and therefore—as under (*a*)—its precision depends on the square root of the number of independent relatives and, inversely, on their dispersion about their average.

Write $Q_1, Q_2 \ldots$ for the number of units of quantities, $P_1, P_2 \ldots$ for the prices in the base period, $p_1, p_2 \ldots$ for those in the year in question. Then $E_1=Q_1P_1+Q_2P_2+\ldots$ is the total expenditure in the first year, and $E_2=Q_1p_1+Q_2p_2+\ldots$ is the total expenditure in the second year. Then the index number is $I_1=100E_2\div E_1$.

Now write $Q_1P_1=l_1E_1$, $Q_2P_2=l_2E_1 \ldots$, with $l_1+l_2+\ldots=1$. Write $100p_1=r_1P_1$, $100p_2=r_2P_2 \ldots$, so that $r_1, r_2 \ldots$ are the price relatives. Then the new index number is $l_1r_1+l_2r_2+\ldots=(Q_1P_1r_1+Q_2P_2r_2+\ldots)\div E_1=100(Q_1p_1+Q_2p_2+\ldots)\div E_2=I_1$ The weighted Geometric Mean, $G_1=\sqrt[n]{(r_1^{n_1}r_2^{n_2}\ldots)}$ where $n_1+n_2+\ldots=n$, so that $n \log G=n_1 \log r_1+n_2 \log r_2+\ldots$ The English Board of Trade, for its index number of wholesale prices, uses a similar form in which, if for example n_1 is the weight assigned to cereals, $r_1^{n_1}$ is replaced by ${}_1r_1 \times {}_2r_1 \times \ldots$ to n factors where ${}_1r_1, {}_2r_1 \ldots$ are price relatives of n_1 different quotations of cereal prices. When $n_1, n_2 \ldots$ are once chosen the comparison between any two years A and B is independent of the base year;

[1] Such an expression as Σv is to be read $v_1+v_2+\ldots+v_n$ where n is the number of similar terms.

or if the price ratios for the years are written ${}_ar_1$, ${}_ar_2$ . . . and ${}_br_1$, ${}_br_2$ . . . and G_a, G_b are the resultant means, then $\log \frac{G_b}{G_a} = \log G_b - \log G_a = n_1(\log {}_br_1 - \log {}_ar_1) + n_2(\log {}_br_2 - \log {}_ar_2) + \ldots = n_1 \log {}_{ab}r_1 + n_2 \log {}_{ab}r_2 + \ldots$, where ${}_{ab}r_1$, ${}_{ab}r_2$ . . . are the ratios of the prices of the year B to those of the year A, and the prices in the base year do not enter. If with similar notation the arithmetic average is used, we have $A_b \div A_a = (n_1 \cdot {}_br_1 + n_1 \cdot {}_br_2 + \ldots) \div (n_1 \cdot {}_ar_1 + n_2 \cdot {}_ar_2 + \ldots)$, in which no corresponding elimination takes place.

The weakness of this method is that, when we make a comparison between two years or two places, the relative expenditures generally differ and each scheme appears to have an equal claim to be included. This difficulty may be met theoretically by computing the index twice, first with the expenditures in year or place A and then with those in B and averaging the result. For comparison between places this method is applied, but it is seldom that the necessary "weights" can be obtained for more than one year, and till there is a further census of production or a new collection of working class budgets the double computation cannot be made. Further, if the weights are available for three years or places, A, B and C, the index for B in reference to A multiplied by that for C in reference to B does not by any weighted average formula give that for C in reference to A (÷100), as it should. This so-called "condition transitive" is not satisfied by any formula that is symmetrical with regard to weights.

Write ${}_aQ_1$, ${}_aQ_2$ . . . and ${}_aP_1$, ${}_aP_2$ . . . for quantities and prices in A, and ${}_bQ_1$, ${}_bQ_2$ . . . , ${}_bP_1$, ${}_bP_2$ . . . in B. The "forward" index number is $I_a = 100\Sigma_a Q_1 \cdot {}_bP_1 \div \Sigma_a Q_1 \cdot {}_aP_1$ and the "backward" index number is $I_b = 100\Sigma_b Q_1 \cdot {}_bP_1 \div \Sigma_b Q_1 \cdot {}_aP_1$. The Geometric Mean $\sqrt{I_a \times I_b}$ is Prof. Irving Fisher's "Ideal index number" (*The Making of Index Numbers*, 1922, p. 220). The arithmetic average, $\frac{1}{2}(I_a + I_b)$ and the form $I_2 = 100\Sigma\frac{1}{2}({}_aQ_1 + {}_bQ_1) \cdot {}_bP_1 \div \Sigma\frac{1}{2}({}_aQ_1 + {}_bQ_1) \cdot {}_aP_1$, may be conveniently used. The three forms of average may be expected to give nearly identical results. I_2, in which the quantities at the two dates are averaged, is perhaps the simplest in idea. Each average lies between I_a and I_b, and is greater than I_a if an increase of prices of a commodity above the general increase from year A to a later year B is correlated with a relative decrease of the quantity purchased, as may be expected if there is a possibility of substitution of one commodity for another without any general change of standard (Bowley, *Statistical Journal*, 1919, pp. 343 *seq.*).

In their measurement of the change of Import or Export index prices from year A to the consecutive year B, the Board of Trade uses the formula I_b and for comparison with the next year C the formula $100 \times \frac{\Sigma {}_bQ_1 \cdot {}_bP_1}{\Sigma {}_bQ_1 \cdot {}_aP_1} \times \frac{\Sigma {}_cQ_1 \cdot {}_cP_1}{\Sigma {}_cQ_1 \cdot {}_bP_1}$ which does not equal $100\frac{\Sigma {}_cQ_1 \cdot {}_cP_1}{\Sigma {}_cQ_1 \cdot {}_aP_1}$ obtained by direct re-valuation of the C quantities by the A prices and, if there is a very rapid change of quantities and prices, may differ considerably from it. This is an example of the "step-by-step" or "chain" method of index numbers. Note that from A to B, $100\frac{\Sigma {}_bQ_1 \cdot {}_aP_1}{\Sigma {}_aQ_1 \cdot {}_aP_1}$ is an index number of quantity of trade (prices constant), and $100\frac{\Sigma {}_bQ_1 \cdot {}_bP_1}{\Sigma {}_aQ_1 \cdot {}_aP_1}$ is the index number of value of trade. The product of these measurements of price and quantity is the index of value (× 100).

Since no form of index number satisfies all the conditions which can properly be laid down (see *e.g.*, Gini, in *Metron*, 1924, pp. 81 and 134), on the one hand we must select the form most suited for a particular purpose, on the other we can only expect precision when different relevant forms give approximately the same result, for which the conditions are that the dispersion of prices from their average should be small and the number of constituent elements should be considerable. *See* COST OF LIVING: PRICES. (A. L. Bo.)

INDEX SYSTEM: *see* OFFICE APPLIANCES.

INDIA (*see* 14.375).—The fifth regular census of the Indian Empire (March 1921) gave a total population of 318,942,480, of whom 247,003,293 dwell in British India, and 71,939,187 in the Indian States. The corresponding figures of area were 1,805,332 sq. m., of which 1,094,300 lie in British territory, and 711,032 in the Indian States. With an area rather more than half that of the United States, the country has a population about three times as large. But the increase in population, 1.2% during the decade 1911–21, was the lowest in any similar period since the decennial census was instituted:—the result of a widespread failure of the crops through drought in 1918, and an epidemic of influenza which is estimated to have carried off anything up to 10,000,000 victims.

Political Divisions.—British India consists of (*a*) nine major or "Governor's" provinces, viz.: Assam, Bengal, Bihar and Orissa, Bombay, Burma, Central Provinces and Berar, Madras, Punjab and United Provinces of Agra and Oudh; (*b*) two minor provinces, viz.: Baluchistan and the North-West Frontier Province; and (*c*) certain smaller administrative areas, viz.: Ajmer-Merwara, Andamans and Nicobars, Coorg and Delhi. The present article deals exclusively with British India, except where the contrary is stated.

The Indian states are governed by ruling princes and chiefs, and are in political relation with the British Government through the medium of political officers specially attached to the larger units or groups. The rulers of 119 states have a salute of guns, which forms a rough measure of their relative importance, as it varies from 21 guns to 9; the remaining 442 states and estates have no salute. Many of the smaller estates are divided up among several sharers. The more prominent individual states are Hyderabad, Mysore, Baroda, Kashmir and Gwalior; and apart from these units the main territorial groups of states are Rajputana, Central India, the Western India states, the Punjab states and the Madras states. Burma contains a number of Shan states, which technically form part of British India, though they are administered through their hereditary chiefs.

Religions, etc.—A classification by religions would divide every 1,000 of the people into 686 Hindus, 217 Moslems, 37 Buddhists, 31 Animists, 15 Christians, 10 Sikhs and 4 Jews, Parsees and followers of other faiths. The census recorded 22,600,000 as literate, in the sense of being able to write a letter in their own vernacular tongue; and 2,500,000 were returned as able to read and write English. Seventy-one per cent of the people are supported by agriculture, 1% only by organised industry, another 9% by the simple hand industries, 7% by trade and transport, 1½% by the professions and liberal arts, and 1½% by the administration and protection of the country.

I. GENERAL HISTORY

Lord Hardinge as Viceroy.—In the spring of 1910 the appointment of Lord Kitchener to succeed Lord Minto as Viceroy seemed probable. Fate reserved Lord Kitchener for other tasks, and the choice fell on Sir Charles Hardinge, permanent Under-Secretary for Foreign Affairs and formerly ambassador at St. Petersburg, who was raised to the peerage as Lord Hardinge of Penshurst. His long viceroyalty (Nov. 1910–March 1916) was strenuous and eventful. The earlier years were marked by the visit of King George V. and Queen Mary to India, the selection of Delhi as the site of the future capital of the Indian Empire, the revision of the "partition" of Bengal and the nefarious attemps of anarchists to compass the deaths of the Viceroy and his wife on the occasion of their state entry into Delhi. The closing years saw India in the throes of the World War.

Lord Hardinge, like his predecessor, had an hereditary connection with India, as his grandfather, the 1st Viscount Hardinge, was Governor-General (1844–8) in the stirring times of the first Sikh War. The goodwill of Indians towards the new Viceroy deepened as they saw his genuine liking for their country; his zeal to obtain redress of the grievances of Indians residing in other parts of the Empire; and his endeavours to associate

their political leaders with the work of government under the reformed Councils scheme. His diplomatic and Foreign Office experience and knowledge of the politics and conditions of the East enabled him to handle dexterously and effectively the external affairs of India and to enter into the difficulties and apprehensions of Indian Mahommedans. He cordially pursued the policy of friendship and co-operation with the ruling chiefs of native States that Lord Minto had inaugurated. When the World War came in 1914, the popularity of his administration and the personal influence and friendship which he had acquired with the ruling princes had much to do with the magnificent response of India to the call of the Empire.

The Morley-Minto Reforms.—The scheme of administrative reform which had been worked out between Lord Minto and Lord Morley, then Secretary of State for India, was in full operation when the new Viceroy arrived. The main object of the India Councils Act, 1909, had been to enlarge the Legislative Councils and make them more fully representative, introduce the elective principle, give greater powers of discussion and of obtaining information from the executive. In each Council the nominated members comprised: (1) a substantial *bloc* of officials, the *bloc* in the Imperial Legislative Council being large enough to secure, together with the members of the Executive Council, an absolute majority; (2) non-officials nominated to represent classes or interests which would otherwise be unrepresented or inadequately represented.

In all the councils, with the exception of that of Bengal, the nominated members exceeded in number the elected members. The number of the latter in any province was too few to admit of any system of territorial constituencies and direct voting. Special constituencies therefore were formed, such as universities, chambers of commerce, groups of municipalities and district boards, and also for Mahommedans as a separate class or community. The councils were empowered to discuss and move resolutions on the annual budget and in like manner to raise discussions by resolution on matters of general public interest. But they did not vote the budget, and resolutions operated only as recommendations which were not binding on the Government. The councils had no direct control over the executive, though they could inform and influence it; Lord Morley had emphatically said that India was not ripe for parliamentary institutions and that he would be no party to creating them. The Act increased the number of members of the executive councils of Madras and Bombay from two to a maximum of four, thereby providing a seat for an Indian or two Indian members; it also authorised the creation of an executive council in any province having a lieutenant-governor. The policy of associating Indians with the executive government thus affirmed as regards to provinces, was given effect to in the Government of India by the appointment first of Mr. S. P. (afterwards Lord) Sinha, and then of Sir Ali Imam as Law Member of the Governor-General's executive council.

Working of the Reforms.—Lord Minto had predicted that the conciliatory measures embodied in and associated with these changes would clear the political atmosphere. He prophesied rightly. On Jan. 5 1911, a deputation from the Indian National Congress presented an address to the new Viceroy expressing deep and heartfelt loyalty to the Crown and appreciation of the reforms which "had done much to bring about a better understanding between the Govt. and the people." As the enlarged Legislative Councils settled down to their work, even the advanced party found in the new powers a healthy outlet for their energies. As consultative and critical bodies the reformed councils exercised a real and growing influence and were an educative force. They formed, directed and developed public opinion in political matters. They acted as a restraint upon the autocratic tendencies of the Executive and made it more responsive to popular demands, and they strengthened its hands when it had to sustain Indian interests against the interests of Great Britain or of the self-governing Dominions.

The King's Visit.—The royal visit in the winter of 1911 was a complete success. The presence of the King-Emperor and his Consort in India touched the imagination of the people. ' Delhi ceremonies drew vast crowds eager to see and salute sovereign. When a visit to Calcutta followed, the welco given by the populace of that city was even more enthusias and unrestrained. On Dec. 12 1911, in a great arena outs Delhi specially prepared for the occasion, the King held a co nation durbar at which he received in person the homage of great officers of state and the ruling princes and chiefs of Indian Empire. Largesse and "boons" of various kinds w granted, and an announcement made of great political mome The seat of the Govt. of India was to be transferred from C cutta to Delhi; Eastern Bengal was reunited to Bengal and enlarged province given a Governor in Council; Bihar, Ori and Chota Nagpur, tracts which are loosely connected w Bengal proper were made a Lieutenant-Governorship in Coun and Assam was reformed into a chief commissionership. T secret had been well kept, and the surprise was complete. T scheme, though open to obvious objections was ingenious a cleverly balanced. A reasoned exposition of its object is co tained in a despatch, dated Aug. 25 1911, from the Govt. India to the Secretary of State, submitting the proposed chang for the home Govt's approval in advance of the King's visit.

Time alone will test the wisdom of these changes, autocra cally conceived and dramatically carried out. The building the new capital was thrown back by the World War, and t cost, which was originally estimated at £4,000,000, will great exceed that amount. New Delhi, it is urged by opponents of t scheme, will be merely cold-weather headquarters of an offici hierarchy, an imposing mass of buildings untenanted for c matic reasons during eight months of the year; while the Gov of India, rotating between it and Simla, will live perpetually in bureaucratic atmosphere. On the other hand the drawbacks Calcutta were many, and constitutional changes have emphasise the desirability of removing the supreme Govt. from immedia contact with the internal administration of Bengal. The pres dential Government of reunited Bengal is an undoubted succes the bitterness of feeling engendered by the "partition" has di appeared, and the interest of the Mahommedan population the Eastern districts receives a just measure of attention fro the local Government. The province of Bihar and Orissa is th weak feature of the scheme. The artificial union of two bloc of territory, geographically apart and without linguistic racial affinities, can never be a convenient administrati unit.

Lord Hardinge's internal Administration.—The beginning of sustained advance in popular education was made at the Dell coronation durbar, at which a recurring grant of 50 lakhs (£333 000) to local Govts. for the purpose was announced. This wa followed in succeeding years by larger grants. From 1911–5 non recurring grants amounting to £3,250,000 and recurring grants £826,000 were made to the provinces. The total annual expend iture on education rose during the period by nearly £3,000,00 and the number of boys and girls at school or college by 1,500,000 This expansion was numerically greatest in the primary schools A wide educational policy was laid down, embracing the univer sities and secondary and technical schools and colleges. Re search and post-graduate instruction were promoted in th universities. A well-equipped medical college was establishe at Lucknow, raising the number of medical colleges in India t five, schools of tropical medicine were founded in Calcutta an Bombay, and an institute of science at Bangalore. Non-recurrin imperial grants for public health service, amounting to £2,700 000, and recurring grants of £368,000 were made, rendering prac ticable the execution of sanitary measures which a few years be fore seemed beyond the limits of financial possibility. The appointment of a royal commission under the presidency of Lor Islington, to inquire into and report on the public services of India with a view to increasing the proportion of Indians in the highe offices was warmly approved. Another popular measure was th establishment of a Legislative Council in the Central Provinces

Indians in the Dominions and the Colonies.—Serious dis content was provoked by the position of indentured labour in

colonies to which it was permitted, and by the treatment of Indian residents in South Africa and Canada. The first trouble arose over the refusal of the Natal Govt. to accept Indian immigrants as permanent citizens of the Union after the expiration of their indentures. As no redress was obtained the Govt. of India in 1911 prohibited for the future indentured emigration to Natal. In the following year the grievances of the Indian domiciled in the Union against the Union Govt. came to a head. The Indian settlers resorted to "passive resistance." The situation was aggravated by strikes and riots among Indian labourers in Natal. Intense feeling was aroused in India by reports of the treatment of passive resisters by the magistrates and the rough handling of strikers and rioters by the police. In a speech delivered in Madras (Nov. 24 1913), Lord Hardinge expressed evident sympathy with the passive resisters in their struggle against "invidious and unjust laws," and pressed for an inquiry in South Africa by a strong and independent committee on which Indian interests should be fully represented. The Union Govt. resented the Viceroy's language, but the calculated indiscretion served its purpose. A commission of inquiry was appointed, and a solution was at length reached and embodied by the Union Govt. in its Indian Relief Act, 1914. This closed the passive resistance struggle. In the action they took Lord Hardinge's Govt. had the warm approval of the educated classes. With regard to Canada the grievances of Indians were less easy of settlement, and Lord Hardinge could only advise a policy of reciprocity, which could be made effective without direct retaliation and would not raise questions of the personal status of Indians in Canada.

Revolutionary Crime.—A new and sinister feature in Indian life had forced its way to the surface soon after Lord Minto arrived in the country. The wide-spread unrest, which he found among the educated classes, and endeavoured to appease by political reforms, had its echo among other classes which were permeated by economic discontent and with whom crude notions of self-rule and political freedom easily "yoked themselves," as Lord Morley put it, "to deep invisible roots of alien race, creed and inviolable caste." Secret societies, composed chiefly of young men belonging to respectable families, sprang up in many districts of Bengal, having for their object the deliverance of India from the foreign yoke. This they sought to compass by assassination and terrorism. The art of bomb-making was imported from Europe. Revolutionary literature and the use of pistols and explosives were sedulously studied, and a series of anarchical crimes occurred from 1907–9.

A group of measures were passed for dealing with seditious meetings, publications and associations, and for establishing special procedure and special tribunals for the trial of anarchical crime. Quiet was apparently restored; but in Bengal trouble broke out again towards the close of 1912; and by the end of 1913 the ordinary forces of law and order in that province had been definitely beaten. On Dec. 23 1912, as the Viceroy was making his first state entry into Delhi, a bomb was thrown and exploded in the *howdah* of the elephant on which he and Lady Hardinge were riding, severely wounding him and killing an attendant. The assailants were never brought to justice, but there is little doubt that they were connected with the anarchical movement in Bengal which had extended to the Punjab. In 1914 and 1915 revolutionary activities became more daring, with the assistance of German agents in America and the Dutch East Indies; but the vigorous use of the special powers provided by the Defence of India Act broke up the movement for the time being and restored order. The organisation of the revolutionary societies, their inter-connection and propaganda methods, their success in corrupting the educated youth of the country, are minutely described in the report of the Sedition Committee (1918) over which Mr. Justice Rowlatt presided.

The War Period

India's Effort.—On the outbreak of the World War in Aug. 1914, the response made by India to the needs of the Empire was final testimony of her pride in the British connection. The political leaders instinctively suspended their controversies with the Government, and gave her their support. The martial classes eagerly responded to the call to arms. From the rulers of native states lavish offers of help poured in. They were recounted in the Viceroy's telegram to the Secretary of State, dated Sept. 7 1914, which was read in both Houses of Parliament and circulated throughout the Empire. As a wonderful demonstration of loyalty and generosity, its effect on popular feeling was immense.

With this confidence and enthusiasm were mingled some alarm and bewilderment. Trade came to a standstill. There were runs on the banks, encashment of currency notes and hoarding of coin. In the remoter districts rumours of the Collapse of the British *raj* disturbed the countryside. The Mahommedan peasantry in parts of the Punjab raided and burned the houses of Hindus and moneylenders, and military force was required to restore order. In Bengal the revolutionary societies redoubled their criminal activities. In San Francisco and Vancouver an Indian revolution was openly preached to the Sikhs settled there, and numbers of them were incited to return to the Punjab to take part in a general rising. Their designs were detected, but for some months the Punjab was disturbed by murders, dacoities and robberies, and the reckless use of arms and explosives.

India as a whole however was so calm that the Govt. was able to denude itself freely of its military resources to meet the demands of the home Govt. for troops and war material. Most of the British troops, the flower of the Indian army, the best of the artillery, and large quantities of ammunition were despatched to France and other theatres of war. In Sept. 1914 a force of 70,000 men was sent to France. By the end of 1915 India's contribution amounted to nearly 80,000 British and 210,000 Indian officers and men. At one time the original British garrison was reduced to only 15,000 men. These were gradually supplemented by territorial and garrison troops from home, but throughout the War the British element in the army in India was far below the defensive needs of the country.

The entrance of Turkey into the War placed Indian Mahommedans in a difficult position; but they loyally rallied to the side of the Crown. Against a few prominent agitators only was it necessary to take action. The premier Mahommedan prince, the Nizam of Hyderabad, and the Begum of Bhopal, in addresses to their co-religionists, effectively stated the British case, and exposed the falsity of the pretexts by which Enver Bey and his associates sought to justify the entrance of Turkey into the War. These addresses and a declaration by the Govt. of India as to its attitude towards Islam in general and the Holy Places in particular served greatly to maintain tranquillity.

Retirement of Lord Hardinge.—In Nov. 1915 Lord Hardinge completed his fifth year as Viceroy, but at the request of the home Govt. remained in office until the following April. In a farewell speech to his Legislative Council he expressed his wish to see "the early realisation of the just and legitimate aspirations of India," but he besought his hearers not to be led astray by impracticable ideals, but to look facts squarely in the face and to realise that in the Dominions self-government had been the slow product of steady and patient evolution.

Lord Chelmsford's Administration.—Lord Chelmsford, the new Viceroy, assumed office on April 4 1916. Previously Governor of Queensland and of New South Wales, at the time of his appointment he had been serving as an officer with a territorial battalion in India; and he was cast at once into one of the most difficult periods of British-Indian history, momentous alike in the number and magnitude of the problems demanding solution and in the gravity of the issues they have raised. In the very first year of his administration the political peace enjoyed by his predecessor came to an end. In the early part of the year Mrs. Besant succeeded in getting her scheme of Home Rule considered by leading members of the National Congress and the Moslem League. She continued to advocate it with great energy among students and school-boys in Madras, established a Home Rule League, celebrated a "Home Rule" day, and declaimed in her paper *New India* against the Government. Mr. B. G. Tilak, who up to 1914 had been serving a sentence of six years'

imprisonment for sedition, was equally active in Bombay. In Oct. 1916, a group of elected Indian members of the Imperial Legislative Council submitted a memorandum on proposed reforms to the Govt. of India. They described the Morley-Minto reforms as having created Legislative Councils which were mere advisory bodies without any effective control; they propounded a scheme which, while retaining irremovable executives responsible to Parliament and the Secretary of State, would have subjected them in legislation, finance and administration, to the orders of a legislative body in which elected members would be predominant.

At meetings held in Lucknow in Dec. 1916 the National Congress and the Moslem League agreed upon a scheme of reforms as the irreducible minimum with which the National party would be content. The Moslem League, originally founded for the protection of Moslem interests against Hindu ascendancy, had fallen under the influence of the "young" Mahommedans, who made Home Rule their objective and joined forces with the Congress on the condition that in certain provinces in which the Mahommedans were in a minority they were guaranteed a proportion of seats in the future Legislative Councils in excess of the number they could hope otherwise to win. Effect was given to this compact, henceforth known as the "Lucknow Compact," in the Congress-League scheme. Following the Lucknow conferences an energetic Home Rule campaign was opened in all provinces. The stir in the Nationalist camp was quickened by the knowledge that the views of Lord Chelmsford's Govt. on political reforms had for some time past been before the home authorities. A preliminary and informal examination of the changes possible and prudent had been made by Lord Hardinge. Lord Chelmsford immediately on assuming office took up the inquiry from the point where his predecessor had left it. At the close of 1916 his government submitted to the Secretary of State a considered scheme of reforms, and asked for an authoritative declaration of policy. Was the goal for the Indian peoples to be responsible government? If so, by what stages and steps should it be reached? The questions raised were large and delicate. The Cabinet was preoccupied by the War. In July 1917 the Secretary of State Mr. (Sir) Austen Chamberlain, resigned on the report of the Mesopotamian Commission.

Declaration of Aug. 20 1917.—It fell to his successor, Mr. E. S. Montagu, to announce on Aug. 20 1917, in the House of Commons, the Indian policy of the government.

> The policy of H.M. Govt. is that of increasing the association of Indians in every branch of the administration and the gradual development of self-governing institutions with a view to the progressive realisation of responsible government in India as an integral part of the British Empire . . . . Progress in this policy can only be achieved by successive stages. The British Govt. and the Govt. of India, on whom the responsibility lies for the welfare and advancement of the Indian peoples, must be the judges of the time and measure of each advance, and they must be guided by the co-operation received from those upon whom new opportunities of service will thus be conferred and by the extent to which it is found that confidence can be reposed on their sense of responsibility.

In the course of the winter Mr. Montagu visited India, and a joint report, dated April 22 1918, by himself and the Viceroy was drawn up before he left.

War Conference of 1918.—The Montagu-Chelmsford report was nearing completion when attention was recalled to the pressing realities of the War. In the Near East, German troops had penetrated the Caucasus and Turks were invading Persia. With the collapse of Russia, the opening up of a road to Afghanistan and thence to India seemed possible. In a telegram (April 2 1918), the Prime Minister made an appeal to the Govt. and people of India to redouble their efforts and prevent German tyranny from "spreading to the East and engulfing the world."

Lord Chelmsford's reponse was to convene a War conference at Delhi, to which many ruling princes and representatives of all provinces of every shade of opinion were invited. The conference heartily and loyally responded to the appeal, and agreed upon a programme of measures of no small value. In the five months preceding the Armistice 200,000 men were recruited, and had the War gone on this number would have been greatly creased. In the spring of 1917 the Legislative Council had cepted the Govt's. proposal to make a free gift of £100,000 to the home Govt. towards the expenses of the War. This in addition to the obligation the Indian Govt. had undert of bearing the normal charges of all troops on the Indian es lishment sent overseas. The part borne by India in the War the sacrifices made by her people for the common cause are resented by an addition of over 230 crores of rupees (£153,0 000) to her debt, the sending overseas of 800,000 combatants 400,000 non-combatants, and the furnishing of foodstuffs other supplies at the cost of much privation among the po classes. If the agriculturists as a body and some other sect of the community made money out of the War, the urban cla and the multitude of persons on small salaries and fixed inco suffered greatly from the dearness and scarcity of food clothing.

India After the War

Reception of Montagu-Chelmsford Report.—The Armistic Nov. 1918 was the signal for general rejoicings but ushered season of political strife and agitation unfavourable for the pe ful introduction of the new constitution. The Montagu-Chel ford report had been published in the previous July. In the S session of the Legislative Council the report was refer for consideration to a committee of the non-official memb and was approved by them, with certain qualifications. moderate party held a special conference in Nov. at Bomb and accepted the general principle of the Montagu-Chelmsf scheme, while urging that it should be enlarged in certain wa On the other hand the National Congress, which had become the organ of the extreme national party, wholly demned the scheme at its Dec. meeting, demanded full vincial autonomy at once, and asserted India's right to s determination. Unhappily another controversy now ar which was fated to overshadow and prejudice the consti tional question by the passions which it kindled and bitterness which it imported into the relations of the peo and the Government.

The Rowlatt Bill.—The report of the Sedition Commit over which Mr. Justice Rowlatt presided had discussed outbreaks of seditious crime, particularly from 1907, and provided impressive evidence of the existence of a revolution and anarchical conspiracy in Bengal and elsewhere and the in fectiveness of the ordinary criminal law to deal with it. Committee proposed to strengthen in certain minor respe the existing law, and to endow the Governor-General in Cou with emergency powers, to be used only in specified areas, only after a notification declaring the existence of a state of aff in those areas which demanded emergency measures. Th measures included: (*a*) the trial of seditious crime by three jud of the highest status, without juries or assessors who were lia to be affected by public discussion or deliberate terrorism; (*b*) the investing of a provincial Government with powers internment similar to those conferred under the Defence of In Act, but modified by checks in the shape of local investigat and visiting Committees. In Jan. 1919 the publication of draft bills embodying the Committee's proposals was follow by a violent campaign by the Nationalist press and Nationa politicians. They were represented as an attack upon the po lar liberties, an attempt to invent crimes, a monstrous engine tyranny and oppression, the forerunner of a policy of react and an unmerited slur upon the loyalty and law-abidingness the Indian people. A whirlwind of excitement swept through cities of upper India, a strange medley of ignorance and ala of political unrest and domestic discontents, of conscious ex geration and mendacity.

While the bills were before the Legislative Assembly, Mr. K. Gandhi, a well-known social and religious reformer, reve in the Bombay Presidency as an ascetic and holy man, initiat a passive resistance movement. *Satyagraha*, as he termed meant insistence on truth and a reliance on soul force. On

Rowlatt bills receiving the Viceroy's assent, Mr. Gandhi announced a day of general mourning and cessation of business. On March 30 a *hartal*, or closure of shops, took place at Delhi, the mob came into collision with the police, and deaths occurred. A wave of excitement passed over the Punjab. Violent disturbances broke out in Lahore, Amritsar and other centres when news came that Mr. Gandhi had been forbidden to enter the province and had been sent back to Bombay under arrest. Between April 10 and 15 mobs were in possession of these and other towns in the central Punjab. Disorder assumed the character of open rebellion, definitely anti-government and anti-British, communications were cut, and the civil authority was only maintained by military force. Martial law was proclaimed in Amritsar on April 14, was extended subsequently to other districts and was not finally withdrawn from every part of the Province until June, although order was generally restored by the end of April. But the situation remained critical owing to the Afghan War, and it was thought prudent to run no risks.

In Bombay the news of Mr. Gandhi's arrest at Delhi was the occasion of an immediate outbreak of disorder in Ahmadabad, the capital of Guzerat, and in neighbouring towns. The military had to be called in, but not before numerous acts of incendiarism and violence and some loss of life had occurred. The disturbances culminated on the arrival of Mr. Gandhi, who expressed great sorrow at the excesses of his followers and was allowed to address an enormous meeting at which he upbraided the people for their violence.

Amritsar.—On April 13 "the tragedy of Amritsar" occurred. In that city banks and other buildings had been pillaged and arnt and Europeans murdered. The civil officers, finding themselves powerless to cope with the mobs in possession of the city, called upon the military to restore order. Brigadier-General Dyer, the officer commanding, deemed it necessary in the course of his operations to disperse forcibly an unlawful assembly held in the Jallianwala Bagh. Nearly 400 persons were killed by the fire of his troops, and probably thrice that number wounded. His action aroused intense indignation among Indians of all shades of political opinion, and became the subject of most bitter controversy, which was in no wise allayed by the appointment towards the end of the year of the Hunter Committee to inquire into the whole disturbances which had arisen in consequence of the Rowlatt legislation. General Dyer's action was condemned by this committee, and it was decided by the authorities that he should receive no further employment in India. After a warm debate in the House of Commons (July 8 1920), this action was approved by 230 votes to 129, but the House of Lords, on July 20, by 129 votes to 86, passed a motion "deploring" the treatment of General Dyer as "unjust" and as "establishing a precedent dangerous to the preservation of order in the face of rebellion." *The Morning Post*, taking this view, raised a considerable sum as a testimonial to the censured officer. In June 1924, the case came into the law courts in London. Sir Michael O'Dwyer, who was lieutenant-governor of Bengal at the date of the Amritsar affair brought an action against Sir Sankaran Nair, formerly member of the viceroy's council, whose book *Gandhi and Anarchy* had attributed to him a responsibility for the shooting. Sir Michael O'Dwyer won the action, receiving £500 damages, and the judge, Mr. Justice McCardie, expressed the view "that the time and the method of General Dyer's punishment, if he were wrong, were most unfortunate."

The Afghan War, 1919.—Relations with Afghanistan had been uniformly good ever since the Amir Habibullah's visit to Lord Minto in 1908. He had been received in state at Agra on Jan. 9 of that year, and afterwards went to some of the principal cities in India and made a prolonged stay in Calcutta. The Amir was delighted with his reception, and let it be known that his friendship with the British Govt. had been immensely strengthened. During the World War he was staunch; but on Feb. 20 1919, he was murdered, and his son Amanullah ascended the throne.

The succession was disliked by powerful factions in the state; and in his difficulties the new Amir lent an eager ear to the distorted reports of the disturbed state of the Punjab and of the nature of the Rowlatt Acts which found their way to Afghanistan. He concluded that an invasion of India might prove a solution of his domestic differences, appealing as it would to the religious fanaticism of his Mahommedan subjects, deeply stirred by the humiliation and defeat of Turkey and by the British conquest of Mesopotamia. His plan was to incite the independent tribes to rise and to follow up their raiding parties with his Afghan regular forces. But the frontier tribes were slow to move. Aggressive movements of his troops in the Khyber were countered by the rapid mobilisation of the army in India early in May, the occupation of the Afghan advanced base at Dacca and the bombing by aeroplanes of Kabul and Jalālābād. By the middle of May the Afghans asked for a cessation of hostilities, and in June the Amir accepted an armistice. In July his representatives attended a conference at Rawalpindi and on Aug. 8 a treaty of peace was signed, under which the Amir lost his subsidy and the privilege of importing arms through India. A separate letter officially recognised the freedom of Afghanistan from foreign control. Doubts have been expressed as to the wisdom of this concession. But control over the foreign policy of Afghanistan has always been nominal rather than real, and the withdrawal of the subsidy in itself implied the rescission of the reciprocal obligation.

Waziristan Expedition.—The Rawalpindi Treaty did not end the troubles on the frontier. The independent tribes of Wazirs and Mahsuds, who occupy a large block of country south of the Khyber line between Afghanistan and the British districts to the east, had risen in May at the instigation of the Afghans and raided the adjoining British districts. The Indian Govt. determined to undertake the permanent pacification of the country, a serious undertaking, as the tribes could place some 30,000 well-armed men in the field. A strong force was assembled on the frontier in Oct. and an ultimatum given to the tribes. The Wazirs in the Tochi Valley were soon subdued, but the Mahsuds fought with dogged obstinacy and great skill. There were two considerable encounters (on Dec. 21 1919 and Jan. 14 1920) with heavy British casualties. In the end the Mahsuds accepted the terms imposed upon them, and the military operations closed on May 7 1920.

The Non-co-operation Movement.—In Dec. 1919 the Montagu-Chelmsford scheme of constitutional reform became law by the passing of the Govt. of India (Amendment) Act. The King's proclamation of Dec. 23 dwelt in eloquent and arresting language on the political advancement conferred upon the Indian peoples, authorised the Viceroy to extend the royal clemency to political offenders in the fullest measure compatible with the public safety, and announced that the Prince of Wales would visit India to inaugurate the new constitutions. The effect of these gracious words was unfortunately marred by the excitement which attended the inquiry of Lord Hunter's Committee then in progress into the Punjab disturbances of the preceding April. The National Congress met at Amritsar, and passed resolutions denouncing the Government's action in the Punjab, demanding the recall of Lord Chelmsford and condemning the reform scheme as disappointing and unsatisfactory. This hostility towards the administration and rejection of the reforms by the extreme section of the Nationalists developed in the ensuing months into a definite "non-co-operation" movement organised by Mr. Gandhi.

The publication in 1920 of the report of the committee presided over by Lord Hunter, and of the correspondence between the Govt. of India and the Secretary of State regarding its findings, and the subsequent debates in Parliament renewed the bitterness and indignation which the Amritsar proceedings had aroused in India. About the same time the terms of the Sèvres Treaty became known to Indian Mahommedans and added flame to the "Khilāfat" agitation, which the pro-Turk section of that community had been vigorously fomenting. In Aug. Mr. Gandhi proclaimed in a letter to the Viceroy his adoption of non-co-operation as a remedy against a Government for which he retained "neither respect nor affection" on account of its "un-

scrupulous, immoral and unjust " action in the matter of the Caliphate and its failure to punish adequately the officials responsible for " the wanton cruelty and inhumanity " with which the disorders in the Punjab were suppressed.

In Jan. 1921 the Duke of Connaught visited India in place of the Prince of Wales, and inaugurated the new constitutions. The speeches delivered by him in opening the Legislative Assembly, the Council of State and the Chamber of Princes at Delhi and the Legislative Councils of Madras, Bengal and Bombay made a deep impression. His earnest appeal, as an old friend of India, to all parties, British and Indian, " to bury along with the dead past the mistakes and misunderstandings of the past," struck a note which found response in the proceedings of the new legislatures and in the Indian Press.

On April 2 1921 Lord Chelmsford made over the office of viceroy to his successor Lord Reading. No viceroy had been more tried by circumstances beyond his control, and no viceroy had shown more steadfast courage, patience or devotion to the highest ideals of his great office. The era will be a landmark in the history of modern India. It saw India started on the road to self-government and admitted on equal terms to a partnership in the British Empire. (T. W. Ho.)

The New Constitution

During Lord Chelmsford's viceroyalty an important change had taken place in the political machinery. The Morley-Minto reform had introduced the electoral principle into the Indian legislatures, and given them a wider sphere of influence over the executive government. But in effect they remained advisory bodies, and the absence of any administrative responsibility whetted their critical faculty without giving them any corresponding practice in the actual work of government. The executive authorities, imperial and provincial, remained governments of officials, responsible to the Secretary of State, and through him to the British Parliament, and not amenable in any direct sense to popular control in India.

From this arrangement to the announcement of Aug. 29 1917 was a wide step, involving organic change and not taken before time. The enthusiasm which had welcomed the Morley-Minto reform had long evaporated, and the demand by the Indian leaders for administrative power was insistent. The Montagu-Chelmsford report conceded the justice of the demand, and proposed that responsible government, in the sense of government by ministers primarily responsible to an elected assembly, should be conferred on India by progressive stages. It recognised that India was not yet ready for full responsible government, that an electorate had to be created and that its representatives must at first be inexperienced. Its authors proposed therefore to confine the first stage of advance to the major provinces, and in these provinces to set up a dual form of government, generally known as " diarchy." This device, accepted only after all possible alternatives had been found impracticable, was a division of the provincial field of government into two sections, one of which would be transferred to the control of ministers chosen by the Governor from the elected members of his legislative council.

In July 1919 a bill embodying this scheme, with certain modifications, was introduced into the House of Commons, read a second time and referred to a joint select committee of both Houses presided over by Lord Selborne. The committee, after an elaborate investigation and hearing nearly 70 witnesses, accepted the main principles of the scheme, and dealt at length with the political and administrative problems involved in the bill. Their report (H.C. 203) is a most valuable constitutional document, indispensable to a study of the new régime. The bill passed both Houses substantially as amended by the committee, and received the Royal Assent on Dec. 23 1919. It takes the form of amendments of the Government of India Act, and has been so drafted as to admit of its being textually incorporated into the principal Act. As is usual with statutes relating to India, it left a great deal of the new constitution to be worked out by rules drafted and applied by the Government to meet the needs of each particular case.

Demarcation of Spheres.—If its provisions were taken in logi sequence, the first feature of the new Constitution would be demarcation of the duties of the " central " or Imperial Go from those of the provincial Governments. The former reta certain powers of supervision and control over the provinc administrations; but its direct functions are now specifica listed, and the departments which are under the provinc Govts. are similarly enumerated. These Governments der their revenue from the departments under their own. c trol, *i.e.*, land revenue, stamps, excise, forest, etc. The Impe Govt. takes the yield of its own central departments—railwa post and telegraphs, customs, income tax, salt, opium, etc. present, however, these do not balance its budget, which carr the whole cost of the defence of India; and consequently it h to levy subsidies from the provinces, though it is pledged to fo go them when the development of its own resources shall perm As with the administrative and financial powers, so also are t law-making powers of the central and the provincial authoriti carefully delimited.

The Provincial Sphere.—Each of the major provinces is nc placed under a Governor. The whole of the provincial depar ments are divided in each province into two groups, the " r served " and the " transferred." The former (at present law a order, justice, police, the land, etc.) are administered by t Governor and his executive council (of whom at least one mer ber is an Indian); the latter (education, public health, excise, etc are administered by the Governor and two or more Minister who are chosen by him from among the leaders of the provinci legislature. These two bodies work independently, each in i own field; and their responsibilities are clearly distinguishe The Governor is the link of union, and has full discretion to brir them together for joint consultation on matters of commc interest. The Executive Council in its control of reserved su jects, is responsible through the Govt. of India and the Secretar of State to the British Parliament; the Ministers in their contr of transferred subjects are responsible to the legislative counc on the spot. This, in the briefest terms, is the system which h been named or nicknamed " diarchy." Its purpose is to provic a field of actual duty in which Indian leaders can be trained b actual practice in the art of Government. On the one hand, the will have the assistance of the Governor, and opportunities consulting their official colleagues in the executive council. O the other hand, the field entrusted to them will be carefull defined. so that their work can be seen and judged by the ele torate, and so also that any consequences of their inexperienc may not affect the sphere of administration which remains in th hands of the executive council.

The legislative council in each province has a large electe majority, with an element (under 30 %) of officials and nominate members. The elections are direct and the constituencies mair ly territorial. A property qualification, differing in differen provinces, determines the franchise. The vote has been given t about 5,000,000 of the adult male population in the whole c India, female suffrage being left to the local option of the provir cial councils. For whatever legislation and supply they requir both halves of the Government are dependent on the legislatur thus constituted. In the " transferred " sphere, Ministers mus secure the support of the legislature. If they fail, their polic fails; and the ordinary course is for them to resign or be dismisse by the Governor, so that they may be replaced by Ministers wh can carry the legislative council with them.

In the " reserved " sphere, it is the task of the Governor an his official colleagues to reconcile the legislature to their policy But if they fail, their responsibility for right policy to the Britis Parliament is in no wise diminished; certain safeguards ar accordingly provided against the event of the council refusing law or supply for which it has been asked by them. The Goverr or has an exceptional power to pass such a law by his own decre if he certifies that it is essential for the discharge of his respons bility; but a measure enacted in this way has to be reserve for His Majesty's pleasure. Similarly the Government may re store a grant for expenditure which has been refused or reduce

the council if the Governor certifies in the same sense; and case of emergency he may authorise any expenditure which nay be in his opinion necessary for the safety or tranquillity the province or for the carrying on of any department." Fi-lly, should the legislature take action in any department which e Governor regards as dangerous, he has wide powers to stop a l, or to refuse assent to it, or to return it for reconsideration, or reserve it for the consideration of the Governor-General. :tensive safeguards thus exist against the possible misuse of its wer by the provincial legislature.

The Imperial Sphere.—In the central Government there no diarchy. The Governor-General and his Executive Council whom there are now in practice not less than three Indian mbers) still remain in sole and undivided responsibility to rliament for the supreme Govt. of India. The central legisla-re, however, has been radically altered by the 1919 Act. ie Lower House, or Legislative Assembly, has 144 members, 103 whom are elected direct by constituencies similar to those hich elect to the provincial legislatures but larger in area and th a higher property qualification. In the Upper House, or ouncil of State, are 60 members, of whom 33 are elected on a ll more restricted franchise. In neither Chamber therefore is ere an assured majority for the Government, to secure the ws, the taxation measures or the expenditure grants which it quires for the administration of the country. The underlying nception of this unusual situation is that it should throw the overnment more upon the support of the elected representa-ves of the people and weaken its reliance on the direction of the cretary of State. It was anticipated that, where the Executive ovt. and its legislature are in accord on policy, there would be a nvention of non-interference by the Secretary of State, subject course always to the overriding power of the British Parlia-ent. It was not, however, unforeseen that the Central Govt. ay not always be able to carry the legislature with it, and ma-inery was provided for avoiding a deadlock in such an event. In legislative business a difference between the two Chambers ay be referred to a joint sitting. If in either Chamber a bill is oposed or amended so as to affect " the safety or tranquillity British India or any part thereof," the Governor-General may op it. He may also, as under the previous constitution, veto a ll, or refer it for His Majesty's pleasure. Should he recommend bill which either Chamber accepts and the other rejects, he may eat it as enacted; or if both Chambers reject it, he may make it to an Act on his own responsibility. In both cases, however, the overnor-General must first have certified that the " passage of ie bill is essential for the safety, tranquillity or interests of ritish India or any part thereof," and the measure must subse-uently be laid before both Houses of Parliament; effect may ot be given to it, unless in a state of emergency, until His Maj-sty's assent has been received. In financial business the supply rants have to be voted by the Legislative Assembly; but if a rant which the Governor-General declares to be essential to ie discharge of his responsibilities is refused or reduced, he may store it. Expenditure on defence and in the political and ec-lesiastical departments, charges prescribed by law, loan charges nd certain salaries and pensions need not be voted; and the overnor-General has power to sanction vital expenditure in ases of emergency.

Further Development.—The above is an outline of the complex cheme that comprises the first stage in what the preamble of the 919 Act describes as " the gradual development of self-govern-ng institutions." As " the time," to quote the Act again, " and he manner of advance can be determined only by Parliament," t is provided that, 10 years after the passing of the Act, a Par-amentary Commission will go to India, to inquire into the work-ng of the reforms, and to report on the desirability of establish-ng the principle of responsible government, or of extending, odifying or restricting the degree of responsible government lready existing. In other words, the retention or otherwise of he electoral system and diarchy will be examined on the evi-lence of the work actually achieved; and it will be decided, if liarchy is retained, whether further departments should be transferred from the official half of each provincial Government to the control of Ministers. It has been necessary to recite the main features of the new constitution because of the influence they exercised on the political history of Lord Reading's vice-royalty.

Lord Reading's Viceroy ty 1921–6

Arriving in April 1921, the Earl of Reading brought to the office of Governor-General a prestige not exceeded by that of any of his forerunners. Having served as Law Officer of the Crown, Cabinet Minister, Lord Chief Justice of England and British High Commissioner in the United States, he enjoyed an eminence both as a lawyer and as a statesman which made his selection a particular compliment to India. The task which confronted him required all his courage and all his experience. Though the actual machinery of the new constitution had begun its work with relative smoothness, the country was seething with an excitement for which the political changes were merely a pretext. A moderate section of Indian leaders commanded the Councils and furnished ministers to the provincial Governments. But they owed their position to the boycott of the whole scheme by the extremist politicians, whether Hindus or Moslems, who had taken no part in the elections of the previous winter, and now held no place in the Councils or the Ministries. The real battle of India's future was being fought outside the domain of constitutional Government.

Hindu Extremism.—The more advanced Nationalist party were gaining strength and audacity under the magnetic leadership of Mr. Gandhi, who had been appointed virtual dictator of their forces at the National Congress of Christmas 1920. He was sweeping the country with his cry of non-violent non-co-operation. The yoke of foreign dominion was to be thrown off and the curse of western commercialism eradicated. India would then be worthy of complete Home Rule, and a date (at first Sept. 30 1921, but subsequently extended on several occasions) was actually prophesied for the disappearance of the British Government. In his campaign Mr. Gandhi was aided by bands of " national volunteers," pledged to deliberate lawlessness, and carrying the spirit of unrest from the towns into the rural areas. Outrage after outrage showed the inability of the masses to distinguish between non-co-operation and anarchy. The tide of disaffection was rapidly rising, and the jails could no longer contain the volunteers who courted a tolerable martyrdom. The condition of the country had not been worse since 1858.

Mahommedan Extremism.—Moslem feeling also had been growing in acerbity for several years. Long persuaded that it might rely on the special consideration of the British Govt., it had been rudely shocked by the reversal of the partition of Bengal in 1911, for the severance of Eastern Bengal into a separate province had been regarded as a measure for the protection of the large and impoverished Moslem community in that area. Genuine distress was felt at the misfortunes of Turkey in Tripoli (1911–2) and the Balkans (1912–3); and among the younger men a movement of active sympathy with the " Young Turk " party made considerable headway. When the Sherif of Mecca revolted against his Turkish overlords it was not only the young Indian Moslems who condemned his action, or resented the part which they were convinced that Great Britain had played in fomenting it. Though there was very little active disloyalty during the war, and although the cooler heads among the Indian Mahommedans disapproved the action of Constantinople in siding against Great Britain in the World War, an under-current of religious solidarity was stimulated by economic discontent and a lively sense of the waning of the power of Islam.

The Treaty of Sèvres was attacked as a device of England to humiliate her former friend and ally; and a movement of protest was headed by two brothers, Mahomed Ali and Shaukat Ali, whose liberty had been restrained for seditious agitation during the War. Their followers were known as the Khilafat party from their claim that the temporalities of the Sultan, as Khalifa of Islam, should be restored. With them there was no pretence of non-violence; they attempted to seduce the Mahommedan

troops, played on religious fanaticism and talked of proclaiming an Indian republic. Seeing in them a useful adjunct to his own campaign, Mr. Ghandhi took the Khilāfat movement under his wing. It was in a struggle against this combination of forces that the first three years of Lord Reading's Govt. were mainly spent.

The Moplah Rising.—In Aug. 1921 the most serious of many unpardonable deeds of violence broke out. The Malabar country in Madras is occupied by 2,000,000 Hindus and about 1,000,000 Moplahs, an ignorant Mahommedan peasantry of mixed Arab and Indian descent with an evil reputation for outbreaks of fanaticism. Among the latter the Khilāfat excitement spread like wildfire; and during July and Aug. 1921 meetings were held and arms collected to prepare for the coming of an Islamic millennium and the overthrow of British rule. When the magistrate of Calicut attempted to make some arrests, he was met by armed force, and rebellion immediately broke out. Railway and telegraph lines were cut, roads blocked, Government offices burned and a Moplah king proclaimed. The few Europeans who failed to escape from the district were brutally murdered, and then the Moplahs turned upon their inoffensive Hindu neighbours. They burned villages, sacked temples, outraged women, massacred and attempted wholesale the forcible conversion of the Hindus to Islam. The extraordinary difficulties of the country made the task of suppression particularly difficult; and the troops which were locally available had to be reinforced at the beginning of Oct. by four battalions, a pack battery and a section of armoured cars. A drive was then made through the affected area, and the rebellion gradually collapsed. It is estimated that during the campaign the Moplahs lost 3,000 in killed alone.

The whole tragedy was a definite fruit of the extremists' challenge to law and order. It was also the first shattering blow to the Hindu-Moslem unity which the extremists had hoped to establish for their own purposes; Mr. Gandhi and his lieutenants professed to belittle the outbreak, but it soon became apparent how gravely the Moplah atrocities rankled in the minds of the ordinary Hindus. Meanwhile the Ali brothers had got to the end of their tether. In Oct. 1921 they were arrested, tried at Karachi and sentenced to two years' imprisonment. But the Khilāfat agitation was not now to be checked, and it soon gained fresh momentum.

Visit of the Prince of Wales.—On Nov. 17 1921 H.R.H. the Prince of Wales landed at Bombay for the visit to India which had been postponed in the preceding year. Efforts, partly successful, but frequently defeated by the Prince's arresting popularity, were made to boycott the public ceremonials arranged in his honour; yet the tour was courageously carried through. He rapidly traversed British India, carried through a heavy tale of ceremonies and interviews, visited several of the leading Indian States, as well as Nepal, inspected the northwest frontier, attended the Kadir Cup (pig-sticking meet) near Meerut, and finally left for England from Karachi in March. The just comment on results of the tour is a quotation from the Viceroy's telegram to the Prince on his departure: "You leave India having won India's heart, for the road to the heart of the people lies through knowledge and sympathy. From the day you landed in India you set yourself to gain the one; Providence has endowed you with the other."

Decline of Non-co-operation.—The year 1921 marked the apogee of the extremist movement, and among moderate men of all classes it was felt that the Govt. of India was approaching the limits of permissible patience. Mr. Gandhi was preparing a scheme of mass civil disobedience, both aggressive and defensive, and was on the eve of launching it, when on Feb. 4 1922 another hideous outrage occurred. At the Chauri Chaura village, in the east of the United Provinces, 21 policemen and village watchmen were set upon by a mob of "volunteers" and excited peasants and battered to death or burned alive. Mr. Gandhi at once suspended his orders for civil disobedience, issued a new "constructive programme" which threw his followers into confusion, but he was at last arrested on March 10 1922. Put on trial at Ahmadābād on three charges of spreading disaffection and instigating the overthrow of the Government, he pleaded guilty and was sentenced to six years' simple imprisonment. His trial produced no popular excitement. It was overshadowed by the resignation by Mr. E. S. Montagu of his office as Secretary of State, as a sequel to his having published, without Cabinet approval, a dispatch from Lord Reading's Govt., in which His Majesty's Govt. was urged, in deference to Mahommedan sentiment in India, to revise the Treaty of Sèvres.

The cause of non-co-operation now began to waver. The volunteer movement was collapsing from want of funds. Mr. Gandhi's repeated prophecies of the millennium had been falsified. The Nationalist schools which had been started to rival the Government institutions had been failures, and masses of students saw their careers imperilled. Nor was the boycott of the bar maintaining its popularity among the lawyers who abounded in Mr. Gandhi's camp. The unity of Hindu and Mahommedan action was severely shaken by the numerous outbreaks of racial violence. Above all, good harvests were steadying the masses and economic discontent was being allayed. By the end of 1922 a strong section of the Nationalist party wished to reverse the policy of holding aloof from the councils.

The Akali Riots.—The unsettlement, however, which the Nationalists had engendered, was no longer theirs to curb, and took little heed of political manoeuvres. It had now penetrated the slow-moving Punjab, and the doctrine of non-violent obstruction to authority was bearing strange fruit on unlikely soil. For some years there had been a reforming movement among the Sikhs, directed at recovering a number of scattered temples of their religion from hereditary incumbents (Mahants) and employing their revenues for the spiritual service of the people generally. The puritan reforming section (Akalis) had got into the habit of taking the law into their own hands, and ejecting by violence the Mahants of whom they disapproved. The latter appealed to the courts, or engaged armed retainers to defend their property. In either case it was necessary for the Government to intervene; and it suited the employers of the Akali bands, adherents of the non-co-operation movement, to distort this intervention into hostility against the Sikh religion. All attempts by the Government to bring the Akali fervour into orderly channels were frustrated, and in 1922 the Akalis established such a reign of terror that military assistance had to be supplied to the police.

Then came the episode of the Guru-ka-Bagh, one of the most extraordinary stories of recent Indian history. At a small temple 10 miles from Amritsar the police had prevented some Akalis from trespassing and cutting trees; whereupon from all over the Punjab bands of Sikhs assembled to assert their right over the land. The method they employed was bewildering in its departure from the usual martial spirit of the Sikh. A band of Akali volunteers started every morning from Amritsar, under a vow to employ no violence but to reach the temple or to return senseless. The police who were deputed to protect the property were obliged to use their batons (in India, their *lathis* or iron-shod bamboo staves) sufficiently to stun the volunteers, who were then carried trimuphantly back to Amritsar in the ambulance cars which their sympathisers had in readiness. This demonstration went on day after day, until the whole Sikh community was in a ferment and its traditional loyalty to the Government was all but destroyed. In 1923 the animosity of the Sikhs was turned against the administration of the Nabha State, the Maharaja of which had abdicated rather than face an inquiry ordered by the Govt. of India. Regrettable incidents occurred; but the futility of the whole business at last began to dawn upon the Sikh mind, and by the end of 1924 common sense was reasserting itself.

It was not only in the Punjab that 1924 and 1925 were difficult years. Moslem feeling was very bitter about Great Britain's treatment of Turkey. Susceptibilities were set on edge by the Greek invasion of Asia Minor, and subsequently elated by the victories of Mustafa Kemal. Either emotion had a tendency to bring the Moslems into conflict with their Hindu neighbours,

racial tension again became acute in the latter half of 1922. The following two years were thus marked by an almost continuous succession of sporadic disturbances in Northern India.

Second Phase of Lord Reading's Viceroyalty.—At the end of 1923 came the second general election. A strong section of the Congress Party, adopting the label of Swaraj (Home Rule), broke away from Mr. Gandhi's programme of boycott and put up a mass of candidates for the councils. The Liberal or Moderate party, which had predominated in the first triennium of the new legislatures, were attacked as having supported the Government in bolstering up an unpopular constitution. They had also lost cohesion and discipline, and a new party, describing itself as Independent, but standing on no common platform, made serious inroads on their position. For the Swarajists the election was a substantial victory. They secured nearly half the elected seats in the Central Assembly; and in at least two of the provinces they commanded the provincial councils. Their discipline was good, and they had entered the legislatures with the avowed object of "uniform, continuous and consistent obstruction with a view to make Government through the Assembly and the Councils impossible." It was only in the central provinces, however, that they proceeded at once to extremes, rejecting the budget provision for the salary of Ministers, and ultimately compelling the Government to resume the "transferred" subjects and suspend the operations of diarchy. In the central legislature, which first met after the elections on Jan. 31 1924, they concentrated on demanding that the grant of full responsible government should be conceded. When this was not endorsed by the Government, they retaliated, in coalition with a sufficient number of members of the other parties, by rejecting the Finance bill for the year, with the result that the Viceroy had to use his emergency powers and certify the necessary expenditure of the administration. The episode, however, and the subsequent conduct of the Nationalist Coalition during the remainder of the session, established them in the rôle of a constitutional opposition, thus marking a new stage in the political development of the country, so that the second phase of Lord Reading's viceroyalty may be taken as dating from Jan. of 1924.

The last prop of non-co-operation was knocked away when, in a special summer session of the legislature, the Swaraj party voted with the Government on a tariff measure; and Mr. Gandhi, who had now returned to politics, threatened to lead his followers out of the National Congress into a campaign of social reform and Hindu-Moslem unity. Of the latter the prospects were gloomy, for the tale of racial conflicts and bloodshed was ever lengthening. The culminating outbreak occurred at Kohat in Sept. 1924, and ended in the whole of the Hindu population fleeing from the town. A unity conference, hurriedly got together at Delhi, though attended by representative members of all the Indian communities, ended in little but good resolutions. Equally ineffective was an attempted coalition of all the political parties in the councils; but Mr. Gandhi was won back to the Congress camp, and the opening of 1925 found the Swaraj party temporarily in a position of considerably improved strength. In Bengal, in voting their policy on opposition to an ordinance which the Government published against a recrudescence of revolutionary crime, they refused for a second time to vote salaries for Ministers, with the only result that the Governor in Executive Council assumed control of the transferred departments and diarchy for the time was at an end. But in the Central Assembly the policy of wrecking took second place to a growing divergence between the new Independent party and the Swarajists.

The Muddiman Inquiry.—In the autumn of 1924 an important inquiry into the working of the new constitution was held by a committee under the presidency of Sir Alexander Muddiman. This appointment was in response to the demand by the Nationalist politicians for the early abolition of diarchy in favour of some form of provincial autonomy. Its business was to advise on any defects in the working of the 1919 scheme and on any amendments compatible with the general purpose and structure of the scheme. The report (published as cmd. 2,360 of 1925) was a twofold one. A minority of the members found that the new system had broken down, that transitional measures were inappropriate, and that steps should at once be taken to establish a permanent constitution. The majority on the other hand recorded their opinion that, though the experiment had worked too short a time to justify a final verdict, they were not convinced that it had failed. They recommended several minor improvements in the machinery and procedure; but they concluded that, "except by some form of dualism, it was not possible to afford an equally valuable training towards responsible government in India and still to safeguard those conditions upon which government depends." The Swaraj claim that responsible government should be expedited was by implication rejected.

While the controversy which followed the publication of the Muddiman report was running its course, Lord Reading accepted an invitation from the Secretary of State for India (now the Earl of Birkenhead) to visit England for the purpose of personal discussion in the summer of 1925; the Governor of Bengal, Lord Lytton, officiating as Viceroy in his absence. This was the first exercise of a new Act enabling viceroys and provincial governors to obtain leave during their term of office. It was obviously desirable to announce a line of policy in answer to the protestations of the Nationalists that the 10-year period of experiment should be curtailed, and that the British Parliament ought not to impose its judgment as to the fitness of India for self-government.

On July 10 accordingly Lord Birkenhead made a careful statement in the House of Lords, reviewed the working of the Reform Act of 1919, and emphasised the lack of co-operation and the actual hostility displayed by a section of the Indian leaders. He expressed his willingness to consider any practical scheme of advance on which Indians could agree, and he did not close the door to an antedating of the statutory inquiry due in 1929, if Indian leaders gave evidence of a sincere and genuine desire to work the present machinery. On Aug. 20 a corresponding speech was made by Lord Reading in opening the autumn session of the Indian legislature, coupled with a plea for a closer co-operation. This did not avail to dissuade the Assembly from rejecting the advice of the Muddiman Commission; but when, in the same month, the Chamber had for the first time to elect its own president, its choice fell on Mr. V. J. Patel, who accepted the office and solemnly dissociated himself from all parties, although he had been formerly one of the most advanced non-co-operationists in the Swaraj camp.

Regrouping of parties was the keynote of the caucus meetings at Christmas 1925. The die-hard Swarajists flung an ultimatum at the Government, with threats of civil disobedience, obstruction and the refusal of office; and over this the Congress split. A new wing of the party, representative mainly of western India, broke off and declared for a policy of "responsive co-operation." At a separate conference the Liberals prepared a separate platform; so did the Independents; and a powerful gathering of Moslems at Aligarh assented to a definite anti-Hindu propaganda. The united front which political India had seemed to present in 1921 was seriously disintegrated by 1926; but the processes of schism and reunion are never at an end.

Administrative Progress.—Although political excitement during Lord Reading's viceroyalty seriously hampered the daily routine of administration and often went near to paralysing the legislatures, yet the administrative system was too firmly rooted to be rendered fruitless. In the provinces the output of legislation was abundant; and in the Central Assembly measures of much importance were painfully hammered out, notably in the removal of racial privilege, in establishing a protective fiscal system, and in meeting problems of organised labour which were for the first time emerging in India. The rural community, it is true, were left the Cinderella, as well as the catspaw, of political advance; but Lord Reading sufficiently appreciated their dominant importance to procure, on the eve of his departure, the appointment of a royal commission to go into the whole question of agriculture. Fortunately there had been steady advance in agricultural prosperity. A short monsoon in 1920 necessitated considerable famine-relief operations in the succeeding year; but thenceforward a series of remarkably good harvests lowered

prices and restored the contentment of the masses. The epoch of economic distress in 1920–1 had affected the manufacturing classes even more than the patient agriculturists. Labour trouble came to the front as never before, 1921 witnessing no fewer than 400 strikes of varying magnitude, and legislative measures of a new type began to appear on the statute book.

Social Organisation.—An amended Factory Act in 1922 prescribed a 60-hours week and raised the minimum age of child workers from nine to 12. A Mines Act in 1923 dealt with the employment of women and children below ground, restricted the hours of adult labour to 60 above ground and 54 below, and enacted a weekly day of rest. The first Workmen's Compensation Act came into force in 1924, and measures were undertaken for the regulation of trade unions and the settlement of industrial disputes. Many of these steps were taken in ratification of the conventions adopted by the International Labour Conference held at Washington in 1919. They were described by the Director of the Geneva Labour Office as "the first tangible results in the East of the ideals inspiring Part XIII. of the Treaty of Peace." The same official formally thanked the Govt. of India for "the conspicuous example of social and labour progress which it is showing to the world." Besides these legislative measures, a quieter process was at work in the steady improvement of the depressing housing conditions in the large labour centres, such as Calcutta, Bombay and Cawnpore. The city improvement schemes there and elsewhere have produced remarkable results, which, even from a purely material point of view, should prove remunerative; for nothing has prejudiced the efficiency of Indian labour more than the periodical flights of the labourer back to the healthier conditions of his native village.

In the social organisation of India the post-War record is one of considerable change. The non-Brahmans of Madras struck against Brahman domination, and seized power in the new provincial legislature. The lowest strata of outcasts or "untouchables" have shown signs of organising for their own protection and betterment, and Mr. Gandhi led a vigorous, if not a wholly popular mission for their uplift. Some flutterings of a feminist movement were perceptible. An accomplished Indian lady, the poetess, Mrs. Sarojini Naidu, occupied the chair of the National Congress of 1925. Numerous ladies of the classes which formerly prided themselves on their seclusion are now to be met on political and other platforms, and some little progress is being made towards the recognition of the re-marriage of Hindu widows. Social progress, however, lags far behind political aspirations.

Recrudescence of Political Crime.—Allusion has already been made to the inroads on the tranquillity of the country which ensued on extremist agitation. They unfortunately provided cover for a revival in Bengal of revolutionary crime on the familiar lines:—dacoities, looting, assassination and the intimidation of witnesses. Conspiracies multiplied in 1923; and early in 1924 an inoffensive Englishman was shot in the streets of Calcutta in mistake for a police official; the Bengal Provincial Conference in the following July passing a resolution laudatory of the "noble self-sacrifice" of the murderer. In Oct. 1924 came a special ordinance for dealing, by exceptional procedure of arrest and trial, with anarchical offences in the province; and among the earliest suspects against whom it was enforced were two members of the Bengal Legislative Council, and the chief executive officer of the Calcutta Municipal Corporation. By the extremists some capital was made of this departure from the ordinary and not too effective methods of the criminal law; but the restoration of order which followed the ordinance was its justification.

The Indian Civil Service.—Not least among the anxieties of the time was the effect of political change on the public services which constitute the main structure of Indian administration. It was not only that members of the Indian Civil and other services found their position substantially altering, as they became transformed from the originators of policy into the subordinate executants of a quasi-parliamentary system. This was inevitable, but it was accompanied by virulent attacks from Indian politicians, who impugned the good faith of the services and made no secret of their desire to replace Englishmen by their own countrymen; and it was accentuated by the domestic anxiety wh resulted from the growing cost of living, of passages to Engla and the like. Many valuable public servants retired premature and the English universities soon stopped the supply of recru of the type that had previously been available.

In 1923 a royal commission was appointed to inquire into t whole problem; it was composed of four Englishmen and fo Indians with Lord Lee of Fareham as chairman. In May 19 it presented a report[1] remarkable for its unanimity. It reco mended a large increase in the recruitment of Indians for t services, and the entrusting entirely to local Governments recruitment for the "transferred" services. On the other ha it advised several alleviations of the financial position of Eu peans in the services, the adequate protection of the services the execution of their duties, and the establishment of a Pub Service Commission on the lines familiar in several of the Dom ions. These proposals were attacked in the Assembly, but t Govt. of India showed their intention of accepting the repo and its implications, and certain declarations by the hon Govt. made it clear that they were determined to maintain t policy of keeping a strong and competent European eleme in the leading services. Recruitment almost immediately i proved, though certain of the services, particularly t civil medical appointments, cannot pretend to offer the former attractions to Englishmen.

Indians Abroad.—The Indian Relief Act of 1914 in the Unio of South Africa and the outbreak of the War in the same ye pushed into the background for a time the indignation felt India about the treatment of its nationals in certain of the domi ions and crown colonies. But the grievance soon acquired increas impetus with the argument that Indian troops were considered goo enough to fight by the side of forces from parts of the Empi which refused civic rights to Indians in peace time. Raised in definite form at the Imperial Conferences of 1917 and 1918, th issue led to a "reciprocity agreement." Trouble revived, how ever, in various forms in Natal and the Transvaal, in East A rica and in Fiji; and the Imperial Conference of 1921 was aga called into consultation. It passed a resolution to the effect th British Indians domiciled in another part of the Empire shou be given recognition of their right to citizenship. South Afric however, where it is estimated that 160,000 Indians are settle declined to be a party to this declaration, and has uniformly urged its own responsibility for regulating the status of its in habitants in its own interests. In Natal (where the most of th Indians are domiciled) and the Transvaal the tendency, in spit of theoretical concessions, has been to discourage Indian settle by imposing definite civic disabilities; and the Union Govt' support of the "Class Areas bill" has alarmed the Indian se tlers, who believe that it will be used as a weapon for the com pulsory segregation of Asiatics in urban areas.

Bitter though the feeling became in South Africa, it reache an even more acute point in Kenya, where at one time ther seemed an imminent prospect of open hostilities between th British and the Indian settlers. There the Indians had fou grievances: the closure of the highlands of the colony to them compulsory segregation, inadequacy of their franchise and repre sentation and threats to stop immigration. From an inquir held by the Colonial Office in 1923, a policy was announced b H.M. Govt. which, though conciliatory on most of the points a issue, failed to allay the sympathetic agitation in India; and th whole question was again brought before the Imperial Confer ence in the same year. Four of the Dominions and the Colonia Office itself accepted the principle of consultation with th Govt. of India on the status of Indians in the Dominions and Colonies; South Africa stood alone in refusing to hold ou any hopes of the extension of the political rights of the India residents. From the informal discussions that ensued, a mor accommodating temper developed. In Kenya the former settle ment was modified by the Labour Govt. in 1924, and tensio was relaxed by the local Indians accepting certain nomination for the legislature. In South Africa the patient labours of a depu

[1] East India (Civil Services in India), Cmd. 2128 of 1924.

t on from India paved the way for the appointment of a con-
f nce to which the Union Govt. assented in April 1926.
or those who do not know India, there is difficulty in appre-
c ing how seriously these grievances react on the political situa-
t there. They are universally interpreted as betokening racial
a ogance, an intention to humiliate Indians as such, and the
r ction in practice of that Imperial citizenship which India is
b ng offered in theory. They provide extremists with a handle
f stimulating popular indignation against the British Govt.
a they complicate its task. On the other hand, little allowance
i ften made in India for the considerations which are of vital
n ment to a European community imbedded in a vastly larger
i genous population.

The North-West Frontier.—On the conclusion of the War which
t new Amir forced on India in 1919, there came clear evidence
c revival of Russia's old thrust towards India. It was with a
w to fomenting revolutionary trouble in India that Bolshevik
t tacles were pushed into Persia and Afghanistan; and when in
1 a Russo-Afghan treaty was concluded, one of its chief fea-
t es was the establishment of Russian consulates so near the
I ian border as Kandahar and Jālālābad. The Amir was not
e se from playing off one of his neighbours against the other;
a l after inviting a mission from India to come to Kabul and
n otiate an Anglo-Afghan treaty, he kept it dangling through-
c 1921 before coming to final terms in Nov. of that year.
e conditions included the complete independence of Afghan-
i n, and the opening of legations at London and Kabul. With
t accrediting of an Afghan Minister to the Court of St. James,
a eriod of greater cordiality was inaugurated, though serious
t sion arose in 1923 over the Afghan attitude towards certain
f ntier outrages, and in 1925 a Russo-Afghan Trade Conven-
n indicated the continued flirtation of the Amir with his Soviet
i ghbours. He has also secured a treaty of alliance and mutual
e ence with the new Turkish Govt. of Angora. Meanwhile he
s embarked on a programme of domestic reform and progress,
w ich offers some promise of opening his country to European
i luences.

Relations with the frontier tribes improved after the cam-
igns of 1919 and 1920; but in 1923 a gang of outlaws in Afghan
ritory were guilty of slaying two British officers near Landi
otal, of shooting the wife and abducting the daughter (after-
rds gallantly rescued) of an officer in Kohat cantonment, and
murdering another officer and his wife at Parachinar. Apart
m the necessary punitive measures, the Govt. of India initi-
ed a permanent policy of controlling the Mahsud country, one
the chief storm-centres on the border. Dropping the plan of
litary occupation, they adopted a scheme of penetration of
ads suitable for motor transport, guarded by local irregulars,
d commanded by two strong posts at Razmak and Manzai.
even higher importance was the extension by five years of
bour in the most forbidding country, of the Khyber railway
m Jamrud to Landi Khana; the first train through the Khyber
ss being run on Nov. 2 1925. A new treaty was signed with
epal in Dec. 1923. It contains provisions for mutual informa-
n of any trouble with adjoining states, and others for regulat-
g the transport of arms and merchandise. The traditions of
iendship with this allied state have been strengthened.

Retirement of Lord Reading.—At the end of March 1926 Lord
eading laid down the office which he had filled with courage
d distinction during a period of special difficulty. By the exer-
se of extreme patience, he had allowed the vehemence of 1921 to
chaust itself without deriving fresh food from any untoward
ep of the Government and he had guided the inevitable reaction
to constitutional channels. He had taken measures for the
nancial health of India, and particularly for economy in its
ilitary administration. He had been diligent in removing
rievances within India and vigilant for her interests abroad.
n retirement he received the high honour of promotion to Mar-
uess: and he was succeeded by Lord Irwin of Kirby Moordale, a
randson of the Sir Charles Wood who, as Secretary of State for
ndia, had laid down the lines of the existing educational system
n 1854.

II. EDUCATION

The dominant factor of the educational system continues to be, as from the East India Company's days, the insistent demand of the middle-classes for secondary and university education as a means of livelihood. This has been supplied by the State to the limits of its means on very cheap terms, to the comparative neglect of the agricultural and labouring classes who, while not actively hostile to the schoolmaster, were well content to do without him. The effects of this neglect, the failure of secondary education to meet the needs of the country's industrial development and the largely unsatisfactory character of such education for any purpose combined to make educational reform the most urgent, as well as one of the thorniest, of current administrative problems. The lines laid down by Lord Hardinge's Govt. were vigorously pursued by his successors.

University Education.—The Calcutta University Commission reported in 1919. Presided over by Sir Michael Sadler, it consisted of seven members, of whom four came direct from England and two were Indians. The report condemned in emphatic and impressive language the whole system of secondary and university education, as it existed in Bengal, and, subject to qualifications, in other parts of India. It was based on an external examining university and a multitude of affiliated colleges scattered throughout the country. It was content to leave the ordinary student to believe that the passing of examinations is the only thing of value in a university training. The affiliated colleges were, as a rule, poorly staffed and equipped; the teaching mechanical; and the conditions for the students pitiable. The secondary schools feeding the colleges were even worse; and boys entered the university so ill-prepared that the first two years were spent in what was really school and not college work.

The commission advised radical reforms. The universities should be centralised, unitary, residential, teaching bodies with a government of their own. Tuition of a preparatory and not a university type should be removed to a new grade of intermediate colleges, where the curriculum would be of a varied kind and would lead up to appropriate examinations not under university control though qualifying for entrance to a university, and having an independent value as a certificate of general education. Students would thus enter the universities at a later age and at a stage represented by the old "intermediate" examination, thus relieving the universities of a part of their unwieldy host of undergraduates. These recommendations were generally welcomed, and most of the former universities (including the Hindu University at Benares, which owed much to the energy of Mrs. Besant) have been re-constituting themselves accordingly, while new universities of the teaching and residential type are being built up at Dacca, Aligarh (Moslem), Lucknow, Rangoon, Patna, Nagpur and Delhi; yet another being under contemplation at Agra to relieve the external work at Allahabad. The multiplying of universities, however, may go too far; there is already some danger of the lowering of standards, in competition for undergraduates; and it is hoped that an Inter-University Board for all India will be strong enough to maintain standards and insist on modern methods of instruction. The latest returns were materially affected by the boycott of governmental institutions under Mr. Gandhi's stimulus; but they showed the number of students at universities and colleges to be in the neighbourhood of 60,000, of whom more than two-thirds were Hindus, and not so many as 3% women.

Secondary Education.—The establishment of "intermediate" institutions advised in the Sadler report, and the equally essential improvement of the mass of high schools, have not progressed so rapidly as university reform, mainly owing to the shortage of funds. Boards for secondary and intermediate education, however, have been set up in several provinces and improvements are being slowly effected. The attendance at secondary schools of a non-technical type in 1922 was 1,240,000, females being in the ratio of rather over 10%. The "national" schools, with their cult of the spinning-wheel, which Mr. Gandhi started at the height of his non-co-operation movement, have

now largely disappeared, the best of them having been rescued by applying for official recognition. Technical and commercial schools were equally handicapped by narrow means, and the 1922 attendance at them was only some 21,000.

Primary Education.—The pace of development here has recently been seriously retarded by financial difficulties; in 1909 the number of children at primary schools was 4,420,000; in 1918 it was 6,000,000; by 1922 it had risen only to 6,310,000. And yet it is from them that all true improvement must start, as well as all hope of creating an intelligent electorate. The difficulties are many: the traditions which confine education to certain castes, communal troubles, bad communications, the dearth of competent teachers, but above all the poverty of the rural parent, who cannot spare his sons from the ranks of the bread-winners and has no belief whatever in educating his daughters. To these permanent obstacles must be attributed the fact that, according to the census of 1921, only 122 in every thousand men, and 18 in every thousand women, in the country can read and write. Scarcely 3% of the population are enrolled in the primary schools, and the total numbers under instruction of all sorts are 9,300,000 out of the 247,000,000 inhabitants of British India. In face of these figures it is not surprising that the legislatures have frequently turned to the remedy of compulsion. Acts asserting the compulsion principle have been passed in several provinces, but the translation of principle into practice is still incomplete. Meanwhile the decentralisation of primary education offers a prospect of greater elasticity, especially in adapting the school curriculum to rural needs.

III. DEFENCE

Indian Frontiers.—The defence of India is a three-fold problem—the protection of its land frontiers, the maintenance of internal order and the guarding of its seaboard. It is natural to think of the frontier problem mainly in terms of the turbulent northwest border, where the military strength has so long been obliged to concentrate. Not only is the attitude of the tribes incalculable, but Afghanistan, though the present treaty relations with it are excellent, has too often developed a spirit of unprovoked aggression in the past; and the ancient menace of a Russian invasion through Afghan territory has, after long abeyance, revived in the new form of Bolshevik activity directed against the stability of government generally and British government in particular. "The road to London," declared Lenin in 1920, "is through Kabul and India."

But grave though these preoccupations are, other frontiers must not be forgotten. On the northeast, Nepal is a state of considerable military importance which furnishes, from its Gurkha peasantry, some of the best material in the Indian army. Fortunately it has a long tradition of friendship with India and many common interests. Behind it however and marching with India on its flanks lies Tibet, harmless enough in normal times, but always liable to Chinese influence. China herself adjoins Burma for over 1,000 m., and occasional lawlessness affords some indication of what might follow the development of an unfriendly spirit at Peking or even in the province of Yunnan. Further south, a fringe of French Indo-China and then 600 m. of Siam complete the Indian border.

Nevertheless, the northwest frontier remains at present the focus of interest. Its military risks are enhanced by the extraordinary physical difficulties of the country, by the almost unparalleled fierceness of its climate, by the fact that the sturdy mountaineers are now well-armed, and also by the oscillation of the British Govt. in the past between a policy of standing on an artificial borderline against the Pathan tribes and a forward policy of advancing the British sphere of influence, or even of control, towards the frontier of Afghanistan proper.

The Kitchener Reorganisation.—It was thus on the defence of the northwest frontier that Lord Kitchener riveted his attention when, in the course of his long tenure of the post of commander-in-chief, he set himself to the task of reconstituting the army in India. Though able men before him had done much to make it an efficient instrument of war, Lord Kitchener brought to bear upon the problem new ideas and methods. The organisation the Indian Army which he inherited dated from the Mutin It failed, he considered, to distinguish sufficiently between the quirements of internal security and those of offensive warfa It did not earmark troops for these two distinct purposes a train and equip them accordingly, but left the selection a mobilisation of an active army in the event of war to the la moment. Lord Kitchener aimed, therefore, at creating out the forces at his disposal (some 230,000 men in all), a field arm capable of being immediately mobilised, of the strength whi he considered would be required to defend India against a Ru sian advance through Afghanistan, until help could be obtain from England. He proposed to mark off this army from t troops allotted for internal defence, to distribute it convenient by divisions (each division comprising some 13,500 combatar of all arms), in homogeneous military areas, and to train it war formations under the generals who would command in t field. He broke up the four army commands which he fou existing, and replaced them by nine divisional commands. each divisional command he proposed to place a self-contain division of the field army, together with the necessary compl ment of garrison troops that would be left behind for interr defence in the event of mobilisation. When fully mobilised t field army would comprise some 120,000 combatant troops, more than half the total strength of the army in India. Adequa transport and supplies were to be provided and every arrang ment made to enable each division of the field army, thorough trained and fully equipped, to pass rapidly to a state of war, wh required, without confusion and dislocation.

It was a large scheme, involving many subsidiary reform such as enlarged staffs, extensive re-grouping of troops and buil ing of barracks, better training and equipment, increased p and allowances for the soldier. It had only been partially p into execution when the War broke out; financial difficulties h intervened, and the fear of Russian aggression had been allay by the Anglo-Russian agreement of 1907. In the meantime mu greater progress had been made in the United Kingdom in t organisation, training and equipment of the British Army. T expeditionary forces dispatched from India were found in t earlier stages of the War to be inferior in these respects to t British troops. Then came the serious complaints of the efficien of the higher military command in the Mesopotamian campaig leading to the inquiry set up by Act of Parliament, and t grave indictment of the Indian military system as regards bo administration and organisation, contained in the report of Lo George Hamilton's Commission (Cmd. 8610 of 1917). The sy tem was described as cumbrous, slow-moving and over-centralis in the last degree. Almost immediately ensued the Afghan W of 1919, followed by the Waziristan campaign, with renew complaints against Indian army administration.

The Esher Committee Report.—It was thus decided to set a Committee, with Lord Esher as chairman, to inquire into t organisation and administration of the army in India. In t judgment of this committee, which reported in 1920, the existi military system was defective in many respects. Their reco mendations involved considerable modifications of the Kitchen scheme. To one of them prompt effect was given; the nine div sional commands created by Lord Kitchener were replaced smaller territorial units, and these were grouped into four arm commands, the commanders of which would take over much the responsibility which had hitherto been centralised in t commander-in-chief and army headquarters. The more im portant proposals of the committee regarding the functions the military forces in India in any scheme of Empire defenc the authority to be exercised over them by the British W Office, and the position and duties of the commander-in-chi were hotly contested by the Indian Nationalists, who saw them a design of subordinating the Indian Army to the neces ties of the Empire and of encroaching on the independence India.

Indian Army.—The army in India is composed of Briti regular troops, which form part of the British Army transfer

period of service to the Indian establishment, and of the n Army. The latter consists of Indian troops raised by ndian Govt. and commanded by Indian officers holding Viceroy's commission and by British officers holding the 's commission. The numerical proportion in which the component parts of the army should stand to each other fixed in the first instance in 1858, and further considered 393, when the ratio of one British soldier to 2·5 Indian ers was definitely adopted and has since been adhered to as permanent basis. The proportion is struck on the regular s, including the imperial service troops maintained by Indian s. No account is taken, on the one hand, of the Auxili- Force, recruited from the European and Anglo-Indian nunity, or, on the other hand, of the reserves of the Indian y, the Indian territorial force, the armed police, or the es of the Indian states.

he British troops are necessarily the most costly part of the nisation; both on this account and from a sense of national , Indian critics of military expenditure constantly press reduction in the British element. In the course of a de- in the Central Assembly in March 1921, the then commander- ief, Lord Rawlinson, stated the case for not altering the ortion of British to Indian soldiers while the existing irements of internal and external defence remained. Other sures of great importance however have been taken to meet aspirations of Indian Nationalism for an Indian share in country's defence. Since the War, King's commissions been made available for Indian gentlemen who qualify as ts at the Royal Military College, Sandhurst, where 10 ncies are reserved for them annually. In order to secure ble candidates for Sandhurst, a military college has been blished at Dehra Dun, with a six-years' course of preparatory cation. The question of providing a Sandhurst training lly in India was subsequently referred to a special committee, which two of the Nationalist leaders consented to serve.

or the effective employment of young Indian officers hold- the King's commission, it has been arranged to officer eight s of the Indian Army entirely by Indians, gradually as their s and length of service may justify, with the object of thus stituting the nucleus of a national Indian Army in the future. ther momentous step was the enrolment of an Indian terri- al force in 1921. It consists of 20 provincial battalions, ut 12,000 strong, liable for general military service; and e are in addition a number of university training corps. ngside of these the old volunteer force continues under ther name. It is now the Auxiliary Force, confined to opean British subjects, and liable only for local service in rgencies.

n 1914 when the War broke out, the regular forces in India prised 75,575 British soldiers, including 2,689 commissioned cers; 159,861 Indian Army troops, including 2,771 Brit- commissioned officers and 341 British warrant and non- missioned officers; and 21,069 imperial service troops. The rves of the Indian Army numbered 36,000 odd, and the unteer force consisted of some 38,000 Europeans and Anglo- lians. During the War the Indian Army was greatly enlarged. demands were made upon it by the home Government for vice abroad. In the last year of the War the Govt. of lia undertook to raise an additional 500,000 combatant ruits, and no doubt the full number would have been secured l the Armistice not intervened. Demobilisation began ly in 1919, but was interrupted by the Afghan War and the sequent campaign against the tribes in Waziristan. On Jan. 1926 the Indian troops serving in the country mustered 4,668 men, or approximately the pre-War strength; the itish troops were only 60,350 men, or some 20,000 below pre- ar strength. The defence charges in India before the War were out £20,000,000 a year; after all the economies advised by e Inchcape Committee, they are in the neighbourhood of 7,500,000, which represents an annual charge, for the pro- tion of their country, of 3s. per head of the population of itish India.

Naval Defence.—The third branch of India's defence, the protection of her vast seaboard, has hitherto been left to the British Navy, with minor assistance from the Royal Indian Marine. Without that powerful aid, India's weakness would be disastrous. "Her sea-borne trade," writes Professor Rushbrook Williams, "is rich; the proportion of her wealth collected into centres within practicable distance of her coastline very great. Good harbours are few; and from the naval point of view, with certain exceptions, not easily defensible. It seems, therefore, no exaggeration to state that adequate naval protection will in future constitute a postulate of her national existence. Should her surrounding seas fall under the dominance of her foes, she can never be secure along the road to prosperity." At present India makes an annual payment of £100,000 towards the navy, and maintains the Royal Indian Marine. Nationalist sentiment has combined with a recognition of India's helplessness at sea to claim the institution of an Indian Navy and the creation of a class of Indian naval officers; there is also a demand for an Indian mercantile marine assisted by the State. In the spring of 1926 the Government announced its intention of setting up a Royal Indian Navy, at a cost of 63 lakhs (£420,000) a year. With its headquarters at Bombay, it will be composed at first of 4 sloops, 2 patrol craft vessels, 4 trawlers, 2 service ships and 1 depot ship. It is to be a sea-going force, whose function in peace time will be the training of personnel for war service in the Indian Ocean and Persian Gulf, port defence, survey work and marine transport. (ME.)

IV. THE INDIAN STATES

The relations now subsisting between the Indian states and the British Govt. are the outcome of an evolutionary process which still continues (*see* 14.407 *seq.*). The Mutiny, the passing of the East India Co. and the grant of *sanads* of adoption to the rulers in 1862 obliterated the peril of annexation, breached the barriers of isolation and inaugurated for the states a new era of union under the Crown. Queen Victoria's proclamation of 1858 announced to the "Native Princes of India" that all treaties and engagements made with them would be scrupulously observed and that their rights, dignity and honour would be respected. The British Govt., while emerging as paramount power, thus guaranteed to the ruling princes and chiefs the measure of sovereignty which they severally possess in their internal affairs. As regards the nature and extent of this sovereignty, the following extract from a minute by Sir Henry Maine may be quoted: "There may be found in India every shade and variety of sovereignty, but there is only one independent sovereign, the British Government. . . . The mode or degree in which sovereignty is distributed between the British Govt. and any Native State is always a question of fact which has to be separately decided in each case, and to which no general rules apply." Two important principles have, however, been laid down by statute, namely, first, that the Indian states "have no connections, engagements or communications with foreign powers," and second, that the British Govt. has the right to protect and govern subjects of the states when resident or found abroad. For international purposes, therefore, state territory is in the same position as British territory, and state subjects as British subjects.

Status of the Princes.—The assumption of the Govt. by the Crown in 1858 called the princes to greater responsibilities as well as to higher honours. Lord Curzon speaking at Gwalior in 1899 claimed the rulers of the states as his colleagues and partners in the administration of the country. Their new prerogatives involved obligations not envisaged when the treaties were framed, but proceeding naturally from the solidarity of the states with British India. Many forces were at work tending to draw the relationships between the princes and the Crown into conformity with a single type, and also to increase the Govt. of India's interest in the administration of the states. The result was over-rigidity of treatment and the formulation of rules which seemed to the princes to transcend the provisions of treaties. Lord Minto, perceiving an atmosphere of discon-

tent, took the occasion to make a declaration of policy, during a visit to the Maharaja of Udaipur in Nov. 1909. He interpreted the proclamations of Queen Victoria and King Edward as inculcating a more sympathetic, and therefore a more elastic policy, and he laid stress on the fact that the foundation stone of the whole system must be the recognition of identity of interests between the Imperial Govt. and Durbars and the minimum of interference with the latter in their own affairs. Lord Minto had already taken the princes into his confidence by consulting them officially on the question of the growth of sedition in India. His declaration and the spirit in which it was acted upon gave great satisfaction to the ruling princes.

Lord Hardinge, pursuing the same policy, in 1913 and 1914 invited some of the princes to meet him in conference at Delhi to discuss a scheme for founding a central college at Delhi at which students from the various chiefs' colleges might complete their education and take a degree. H.H. the Maharaja of Bīkaner delivered a notable speech at the 1914 gathering when, speaking on behalf of his brother princes, he said:—

> We trust, and we are confident that Your Excellency will before long convene similar meetings to deal with other subjects in which we and the states represented are no less closely concerned than this one of the college, and on which our deliberations will not only be of the greatest advantage to ourselves, our states and our people, but also, we hope, of some value to the Imperial Government.

Lord Hardinge in 1914 created a new post of political secretary to the Govt. of India, in order that closer attention might be devoted to relations with the states. The past fifteen years had proved an era of striking progress and development, and the rulers themselves, encouraged to play more important parts in the drama of Indian affairs, were becoming daily more advanced in their own administration, so that new methods of political treatment were required.

In Aug. 1914, on the outbreak of the War, the princes vied with each other in the offer of loyal service. In a telegram which stirred England the Viceroy reported that the rulers of the states in India, numbering nearly 700, had with one accord rallied to the defence of the Empire and offered their personal services and the resources of their states. From among the many princes who had volunteered for active service Lord Hardinge selected seven rulers, including the veteran Sir Pertab Singh (Regent of Jodhpur), who would not be denied his right to serve the King Emperor in spite of his 70 years. His nephew, the Maharaja, who was but 16 years old, went with him. Contingents of all arms were accepted from 12 states, besides a camel corps from Bīkaner. A hospital ship was given by various states at the instance of the Maharaja of Gwalior, and as the War progressed there were many fresh evidences of the spirit of loyalty animating the princes and their peoples. The support afforded by the Durbars in the matter of raising recruits was of particular value.

Minorities and Successions.—In 1916 Lord Chelmsford, in spite of War preoccupations, decided to invite the princes to another conference. In his opening speech he laid stress on the magnificent assistance rendered by the states. The most important of the subjects discussed at the conference related to the form of administration to be adopted in a state during a minority. In 1909 Lord Minto had become aware that several of the rulers felt strongly that they had a right to be made acquainted with the considerations which guided Government in minority administrations. He therefore ascertained the opinion of the leading Durbars, and prepared a statement of the general policy of Government in the matter. In 1915 attention was again drawn to the matter in consequence of representations made by certain of the rulers that in some cases in the past the rights and privileges of states guaranteed by treaty or otherwise had been unwittingly infringed during the minority period by the exercise of the prerogative of the paramount power.

Lord Hardinge thereupon convened a committee consisting of three rulers of states and three political officers to consider the question. Their recommendations were fully debated in the conference of 1916, with the result that a resolution was published in Aug. 1917 laying down the principles for the conduct of minority administrations. In it the Govt. of I asserted their rôle as trustees and custodians of the ri interests and traditions of a state during a minority, admitted that the special conditions of each state req special treatment, and promised to attach due weight to req by individual ruling princes or chiefs regarding any princ which they might wish to be adopted in the case of their states or families, while reserving to themselves freedor action in dealing with such requests. Seventeen general p ciples were laid down for observance during minority adm trations. The resolution was received with much satisfac by the princes, and the general opinion was that the pronou ment of Government was an event hardly second in cons tional importance to the *sanads* of adoption granted by L Canning.

The next conference, held in 1917, saw the decision of ano very important question, viz.: the form of recognition by G ernment of successions in the states. Lord Chelmsford nounced that in the case of the succession of a direct natural recognition on the part of a paramount power was purely for and that the obligation on the part of the new ruler to ob it in no way impaired his inherent right to succeed. He also nounced the relaxation of the requirement that rulers of st before paying visits to places in British India should obtain previous concurrence of the local Government concerned. requirement had proved irksome in practice, and under the arrangement the obligation was limited merely to visits to stations and other places where special local conditions mi render concurrence of the local authorities necessary.

The Chamber of Princes.—His Highness the Maharaja Bīkaner, who earlier in the year had been one of the Ind representatives at the Imperial Conference and a member of Imperial War Cabinet, took the lead in this conference. In final address to the Viceroy he expressed the hope of the prin that before the British Govt. came to any decision on the s ject of political reforms to be introduced in British India ruling princes would also be consulted. He stated:—

> We feel that we too must keep a definite goal in front of us, i whilst it is essential that our rights and privileges and our posit as allies and friends guaranteed to us by solemn treaties and enga ments with the British Govt. remain unaltered, our states can afford to lag behind in the general advance which India's assoc tion with Great Britain alone has rendered possible. It is for th reasons that we are now all the more anxious to see the early est lishment of a constitutional chamber which may safeguard interests and rights of ourselves and of our states.

Lord Chelmsford replied that any scheme which they mi put forward would receive most careful and sympathetic c sideration from the Govt. of India. A draft scheme was acco ingly prepared by a committee, and was discussed informally the Viceroy and certain of the princes in the presence of M Montagu in Feb. 1918 during his visit to India. In Dec. 1 the King issued a royal proclamation signifying his assent the establishment of a chamber of princes, which was ev tually inaugurated by the Duke of Connaught in Feb. 19 From the proclamation then read, we quote the following:—

> In my former proclamation I repeated the assurance, given many occasions by my Royal predecessors and myself, of my det mination ever to maintain unimpaired the privileges, rights a dignities of the princes of India. The princes may rest assured th this pledge remains inviolate and inviolable. I now authorise r Viceroy to publish the terms of the constitution of the new chamb My Viceroy will take its counsel freely in matters relating to t territories of the Indian States generally, and in matters that affe those territories jointly with British India, or with the rest of t Empire. It will have no concern with the internal affairs of indiv ual states or their rulers or with the relations of individual states my Government, while the existing rights of the states and th freedom of action will be in no way prejudiced or impaired.

His Royal Highness also conveyed to the princes a speci message of thanks from His Majesty in public acknowledgme of their splendid record of achievement during the War. H alluded to the fact that H.H. of Bīkaner had taken part in t Peace Conference and had signed the Treaty of Versailles, whi

f. the Maharaja of Nawanagar had attended the League of ions Assembly at Geneva. H.H. the Maharaja of Bīkaner appointed to be the first chancellor of the chamber (Naren-Mandal), and was re-elected to the office each year until 1926 n he was succeeded by H.H. the Maharaja of Patiala.

With the growth of new conditions and the unification of ia under the British power, a body of usage affecting the ty position of the states had insensibly come into being, and Durbars were therefore anxious that for the future they ht have a voice in the formulation of political practice. ommittee of princes, known first as the codification com-tee and afterwards constituted as the standing committee the chamber, accordingly met at regular intervals and ieved useful work with the advice and assistance of officers n the secretariat and administrative departments of the t. of India in revising the summaries of political practice er various heads such as mining concessions, railways, tele-hs and telephones, mints and currency, opium, extradi-, etc. The results were reported at successive meetings of chamber of princes.

he Salute states in the Punjab Province were taken into ct relations with the Government of India in Nov. 1921, ugh the appointment of an agent to the Governor-General. imilar arrangement was made in 1923 for the five states in Madras Presidency, and in 1924 for the Bombay states of hiāwār, together with Cutch and Palanpur. A new first-s political appointment was created for the last-mentioned up, and the Bombay Political Dept. was amalgamated with t of the Govt. of India. In 1921 the Gwalior state was arated from the Central India Agency and was brought direct contact with the central Government through a single rmediary officer, while in Rājputāna the states of Bīkaner, hi and Jhālawār were at different times placed in direct tions with the agent to the governor-general instead of ugh a subordinate political agent. At the meeting of the mber in the autumn of 1921, Lord Reading announced that the future, except at installations and investitures, where al custom would continue to be followed, the King had been ased to dispense with the presentation of nazars at ceremonial its or receptions, either to himself or to the members of his ily or to any of his officers to whom it had hitherto been tomary to present them.

In 1918 and 1921 the King conferred many honours and tinctions upon ruling princes and chiefs and others in ognition of the services rendered by the Indian states during War. The style of "His Exalted Highness" was conferred on the Nizam of Hyderābād, and the title of "Faithful Ally of British Govt." was formally confirmed to him. The Prince Wales, during his Indian tour, in the winter of 1921–2, visited ny of the states and was received with loyal enthusiasm and endid hospitality. At the Imperial Conferences of 1921 and 23 respectively T.H. the Maharao of Cutch and the Maharaja Alwar were included among the representatives of India, and the meetings of the League of Nations from 1921 onwards H. the Maharao of Cutch, the Maharaja of Navānagar (twice), e Maharaja of Bīkaner and the Maharaja of Patiāla.

Soon after the War, certain problems in connection with the ganisation, training and maintenance of the Imperial service oops were taken up by the Govt. of India in consultation with e ruling princes and chiefs concerned. His Highness the aharaja of Alwar, after pointing out that the greater states d, during the War, not only placed their units of Imperial rvice troops at the disposal of Government but had depleted their an power to keep these units up to full strength, advocated a mplete policy of trust in the states and asked that the policy ight be applied in such a manner as to eliminate all distinctions tween Imperial service units and the local forces or armed olice of the states. After prolonged consideration, a compre-ensive scheme was prepared for the reorganisation of the ate forces, embracing not only the first line troops but also the regular troops and the state police. The armament and equip-ent of the first line troops was to be improved, the irregular troops were to be armed and organised in such a way as to transform them into an efficient reserve, while the police were to be given suitable weapons to enable them to cope with dacoits. More than thirty states joined in the scheme. To facilitate the training of military officers, certain vacancies at the Prince of Wales' military school at Dehra Dūn were offered to boys nominated from Indian states.

In view of the contemplated repeal of the Press laws of British India, a resolution passed in the chamber of princes in 1921 asking that some special means of protection might be given to the Indian states in place of the relevant provisions of the Press Act. Lord Reading's Govt. considered that they were obliged in honour to agree to such protection, but the Legislative Assembly vigorously opposed a bill which was brought in under the title of Indian states (Protection against Disaffection) bill. It became necessary for the governor-general to exercise the extraordinary powers allotted to him by the Govt. of India Act, and to certify that the bill was essential for the interests of British India. The bill was passed by the council of state and eventually became law.

In 1908 the Govt. of India recommended to the Secretary of State that the necessary legislation should be undertaken in order to enable subjects of Indian states, while retaining their primary allegiance to their states of origin, to become eligible for certain services in India, admission to which was under the existing law confined to British subjects. The required provision was eventually made in Section 96A of the Govt. of India Act.

A New Indian State.—Before Lord Minto left India, he announced at Benares that the Govt. of India, with the sanction of the Secretary of State, had decided to grant to the Maharaja of Benares and his successors a permanent status amongst the rulers of India, by constituting part of the family domains as a state. This remarkable step, which involved the transfer of some 300,000 persons from British to Indian rule, was taken in view of the unique position of the Benares House, representatives of which had played important parts in relation, first to the court of Delhi, and afterwards to the British Government. The change was effected by means of an instrument of transfer, the provisions of which ensured to the residents of the territories the rights and privileges which they had enjoyed under the British administration. In 1910, in view of the success of the measure, the town of Rāmnagar, adjacent to Benares City, was also handed over to the Maharaja for use as his capital. In 1913 the instrument of transfer in virtue of which the province of Mysore had been transferred in 1881 to the present ruling family of the Mysore state was superseded by a treaty, the wording being altered in certain respects to meet the wishes of the present ruler. The change was announced during Lord Hardinge's visit to the state in the same year.

Constitutional Development.—While the paramount power has parted with none of its prerogatives, the evolutionary process has gradually led to a certain breaking down of the isolation of the states among themselves, the strengthening of their position and the advancement of the dignity of the princes. They not only gained, in the chamber, means for expression of their collective needs and opportunity for influencing the development of political doctrine, but they were admitted, as joint representatives of India, to the innermost councils of the Empire through the appointment of a member of their order to successive Imperial Conferences and meetings of the League of Nations.

Thus the integral connection of the states with the British Empire has been further emphasised, and the possibility that constitutional changes in British India may react on the states has been more effectively recognised. In a few advanced states, legislative bodies have been constituted analogous to those in British India, Mysore being a prominent example, while in others the rulers have devised means for the people to voice their grievances and aspirations more easily through consultative councils. The movement is unhurried, as the time and manner of change, if change there is to be, rests with each individual ruler. But it cannot be denied that the processes at work in British

India must impair the vitality of the conservative traditions which have their stronghold in the states, and for this reason, the princes must be keenly interested in the development of constitutional reforms beyond their borders. While it is an accepted axiom that the independence of the states in matters of internal administration carries with it the counter-obligation of non-interference in British Indian domestic affairs, any fundamental change in the system of government in British India may be claimed to fall within the category of matters of Imperial or common concern, in regard to which the princes may reasonably expect to be heard. (R. Hn.)

V. ECONOMIC HISTORY

General Survey.—The economic history of India during the seventeen years 1909–25 falls naturally into three chronological divisions: pre-War, War and post-War.

The first period was one of rapid progress. After the famine year of 1908 the monsoons were satisfactory, and the harvests good. The general conditions of world trade favoured Indian commerce and Indian prosperity. Exchange was steady, budgets showed surpluses. As a debtor country India profited by the general rise of prices, needing to export smaller quantities of goods to meet interest charges. As also the prices of foodstuffs and raw materials were rising faster than those of manufactured goods, the exchange of Indian exports for imports was carried on with greater profit to India. In these five years the money values of Indian sea-borne trade increased by 40%; the gross earnings of the railways and of the post office by one-third. Characteristically, the increased purchasing power was used to absorb gold and silver to the amount of £127,000,000. But also some notable new industrial enterprises were launched, and a stronger spirit of enterprise was displayed both in commerce and industry.

The outbreak of the World War produced a temporary panic, quickly allayed. The interruption of foreign trade threw India largely upon her own resources. Efforts were made for the production of manufactured articles, particularly War requisites, not previously attempted, and various industries which work up native raw materials for the home market expanded considerably. A strong stimulus was given to the old demand that the State should take a leading part in the development of Indian resources, both by means of a protective tariff, and by helping private enterprise in the raising of capital, by research and by developments of the educational system; and a great change took place in the attitude of the Government to these questions.

The transition from the War period to international peace was marked by the "famine" of 1918, followed by another monsoon failure in 1920; by the visitation of influenza, which in 1918 and 1919 probably killed not fewer than 10,000,000 people, by much political agitation and the recasting of the constitution. A post-War boom of trade in 1919 and 1920 was followed by a severe slump in 1921 and 1922; exchange fluctuated violently, the sterling value of the rupee first rising to a record height, and then falling in a most embarrassing manner. Five years in succession showed budget deficits, amounting in the total to over 100 crores.[1] But in 1922 a steady recovery began, well maintained till the end of 1925. The monsoons, during the five years 1921 to 1925, were on the whole good, and, given good monsoons, Indian commerce is solidly based on an imperative world need for Indian staple products. There was a "return to normalcy," but not to the pre-War normal. The War cataclysm has left among its permanent effects important economic and political changes including a reversal of fiscal policy from free trade to protection.

Agriculture and Irrigation

Since the census of 1921 showed that 70% of the total population of the Dominion were supported by agriculture and pastoral industry, not Indian agriculture only, but all Indian economic prosperity is necessarily a gamble in rain. During the period under review only two serious monsoon failures occurred, those of 1918 and 1920. That of 1918 was one of the worst on rec over all India the estimated out-turn both of rice and of wh was in 1918–9 25% below the previous quinquennial aver This was much worse than in the great famine of 1899, but th was no corresponding distress; the maximum numbers on re never went beyond 600,000, as compared with 5,000,000. T was partly because the harvest of 1917 had been a record c so that the famine year was helped by an unusually large ca over; but it also indicated that government efforts to prom agricultural prosperity had achieved a large measure of succe The great shortage in the total amount of grain available in country necessitated exceptional measures, in addition to well-tried methods of dealing with unemployment and de tution. Export of grain was prohibited; the surplus of Bur was secured by India, and 200,000 tons of wheat were impor from Australia. The failure of the later rains in 1920 produ famine conditions in certain districts in the early part of 19 and the number on relief went up to 400,000; and it was till after the country had recovered from that shortage t export of grain could again be freely permitted.

At the biennial meeting in Pusa, in Dec. 1919, of t Board of Agriculture, a conference of Imperial and Provinc Departments of Agriculture, the problem of famine policy v once more re-examined in the light of the experience of 19 and a new programme was drawn up of measures calculated minimise the loss of grain, fodder and cattle during years deficient rainfall, including plans for improving the storage grain, the growing of better fodder crops, evolution of improv varieties of drought-resisting cereals and emergency means irrigation. Special attention was given to the great loss cattle, though this had been mitigated in the Bombay Decca one of the worst areas, by the success of the Bombay ag cultural department in turning prickly pear into valuable fod by burning off the prickles in the flame of the blacksmit forge. Meanwhile among the intelligentsia of the towns the arose a foolish and short-sighted demand for the prohibition export of foodstuffs even in normal years, a demand which, successful, would multiply and intensify famines by removi the commercial incentive to agriculturists to produce a surplus.

The Departments of Agriculture had been reorganised ea in the twentieth century, and, with still very inadequate p sonnel and funds, they have achieved important results in great variety of directions. One important branch of th work consists of the introduction of improved varieties of plan This involves, firstly, research in order to obtain from abroad, evolve locally, the variety which will prove its superiority und Indian conditions; secondly, growing the improved variety sufficient quantities to furnish the ryots with seed; thirdly, co vincing ryots by means of demonstration farms, and otherwis of the advantage offered; and, fourthly, in many cases, watchi over the subsequent fate of the new variety to prevent it fro being swamped by inter-mixture with others. The area sown 1923–4 with improved varieties popularised in this way c ceeded 5,000,000 ac., including over 2,000,000 ac. under whe and rice, and even more under cotton. The work on whe accomplished by the Imperial Research Institute at Pusa famous; very valuable work has also been done on sugar Coimbatore. The work of provincial departments is too vari to be even summarised here; as examples, taking one provin (Madras) only as representative, mention may be made of t Agricultural College at Coimbatore; the introduction and po ularisation of Cambodia cotton, which gives upwards of 200 l of superior lint per acre, as compared with the ordinary Indi crop of 80 lb. of short staple cotton; the vigorous propaganda single paddy transplantation and the growing of green manu which has been of immense value to rice cultivators; the selli on a large scale at cost price of fish manure; the fight again insect pests of cotton and other crops by the Madras Pest Ac and its system of popular education in agricultural science b means of simply expressed tracts in the vernaculars.

A forward step was taken along the lines of linking togeth the efforts of all the agricultural departments by the establis

[1] Lakh = 100,000 rupees; crore = 10,000,000 rupees.

it in 1920 of the Indian Cotton Committee, which is financed b a small cess on each bale of cotton produced. This has been fo owed by measures for the control of cotton gins and the t nsport of cotton in order to prevent adulteration of superior g ths, and the inter-mixture of seeds of improved with u nproved varieties. It is perhaps significant that there is n more Indian cotton to be found on the Liverpool market t n before the War, and the difference in the price it realises as c pared with American has almost disappeared. The total c o of Indian cotton has now reached 6,000,000 bales of 400 lb. e h, as compared with a pre-War quinquennial average of 4 0,000 bales. A great deal of the extra cotton grown goes to t Japanese and Chinese mills. It is intended to apply the s e principles of inter-provincial co-operation to the still more d cult problem of cattle improvement. The Tamil proverb, " e calf of the good cow dies, " gives a scarcely exaggerated i of Indian backwardness in the science of cattle-breeding. n extension of the irrigated area is the most effective of all m sures of famine prevention. The area annually irrigated by G vernment works has now reached some 28,000,000 ac., which i ot much less than the total cultivated area of Great Britain. T e area irrigated by wells and other privately owned sources is a ut 21,000,000 acres. The two greatest irrigation schemes t world has ever known are being carried out in the Indus B in, the Sutlej valley scheme and the Lloyd (Sukkur) barrage. T e way for the former was prepared by the Triple Canal proj- , sanctioned in 1905 and completed in 1917. The surplus v ters of the Jhelum are held up by a head weir, and carried s thwards by a canal to the Chenab, part being used to water a rge area between these rivers, but most being poured into t Chenab above the intake of the old Chenab canal. The d nand on Chenab water being thus reduced, some 20 m. higher u a new head weir on that river has been constructed, which w ters a great area between the Chenab and Ravi, and, crossing t Ravi river, passes on to water the northwestern half of the L wer Bari Doab, which is land lying between the Ravi and Sut- j. Altogether over 1,700,000 ac. are annually irrigated by the c nals; and the execution of the project makes it possible to u lise the Sutlej river, not only to complete the irrigation of the B ri Doab, but also to irrigate a great area on the southeastern s e of the Sutlej.

By the Sutlej valley scheme four head weirs are being con- s ucted on that river, three above and four below its junction w th the Chenab; 2,075,000 ac. will receive a perennial supply o water; 3,033,000 ac. a controlled supply from the beginning o April to the middle of October. The new canals will super- s de a number of " inundation canals," which give a somewhat u certain supply from May to Sept.; and also will bring into c ltivation 3,750,000 ac. of desert waste. An interesting f ture of the work is that mechanical excavators are being u ed because of shortage of labour.

At Sukkur, where the combined five rivers of the Punjab enter I inde through a narrow gorge, the Lloyd barrage is being built, 4 725 ft. long between the faces of the regulators on either side, w ich will control the flow of water into seven great canals. W hen fully developed the area annually irrigated will approach 0 000,000 ac., considerably more than the whole cultivated a ea of Egypt. As a necessary corollary the port of Karachi, of w ich the trade has already nearly quintupled since 1897, will b further developed by harbour works at a cost of £2,000,000.

Nowhere in India outside the Indus basin is there scope for s rks of equal magnitude, but a great scheme is being carried o t for the irrigation of Oudh, by canal fed from the Sarda river. T his project has been under contemplation for 50 years, but has b en in abeyance because of the opposition of the Oudh land- o vners (taluqdars). They have now altered their views as a r sult of the experience of 1918, and the increasing cost, due to r sing wages, of well irrigation. The area to be irrigated is e timated at 1,700,000 acres. In Madras even older schemes a rst planned by Sir A. T. Cotton, the great pioneer of scientific i nal irrigation in India, have been revived, for great storage r servoirs in the Cauvery, Bhavani, Tangabhadra and Kistna rivers; and the Cauvery scheme has been sanctioned. All over India smaller works are being planned, debated and put into execution. (*See* IRRIGATION.)

Co-operation.—The policy of active encouragement of rural credit banks on the Raiffeisen plan, as the most effective means of remedying the chronic indebtedness of cultivators and improving the business side of agriculture, was adopted, after long discussion, by the Act of 1904. Registrars of co-operative societies were appointed for the different provinces, to draft model rules, register, inspect and audit the accounts of co-operative banks, and also to carry on propaganda and education in co-operative principles. In 1912 an amending Act was passed, as the result of eight years' experience; and also to extend the official encouragement to co-operation in other fields. The number of registered societies increased from 5,432 in 1911 to 61,106 in 1924; the membership from 308,000 to 2,314,000; the capital employed from Rs. 227 lakhs to Rs. 4,053 lakhs[1] (about £30,000,000). The great majority of the societies are village banks; but there are 522 " Central Banks " situated in towns, which gather in deposits, supply funds to the rural banks in their neighbourhood, and act as links between them. There are also " Apex " banks, for the provinces of Madras, Bombay, Bengal, Bihar and Orissa, Burma, the Central Provinces, Assam and Mysore. Encouraging progress is being made by societies for purchase and sale; sales to members aggregating Rs. 113 lakhs in 1924 and purchases from members Rs. 93 lakhs. There were 442 cattle insurance societies, with 6,693 members, a small but very hopeful beginning; and there is a promising movement in urban areas to use the principle of co-operation in house building and milk supply.

MANUFACTURING INDUSTRIES

On the basis of the number of people who are employed hand-loom weaving is still by far the greatest of Indian non-agricultural industries. The census of 1921 found very nearly 2,000,000 hand-looms at work, and the actual number was probably considerably greater. The Indian Industrial Commission (1916–8) discovered that the consumption of mill-spun yarn by hand-loom weavers increased by about 30% in the two decades before the War, which would more than compensate for the diminution in the output of hand-spun yarn. The War itself helped the weaver, Indian mills not being able to make up adequately the deficiency of imported cloth; so also did the very high prices of mill-woven cloth after the Armistice. But from 1922 onwards weavers' difficulties have greatly increased. The development of mill manufacture in China has deprived the Japanese mills of part of their Chinese market, and caused them to make greater efforts to dispose of their output in India. In the fierce and very equal competition which so ensues between Indian and Japanese mills, it is the hand-loom weavers who suffer most. In some districts after a struggle to live on less than subsistence earnings, they have been compelled to abandon their hereditary calling; in others, where the level of skill and enterprise is higher, they have given up cotton weaving for silk, or textures with gold or silver thread interwoven, which are called in India " lace work. " The industry as a whole shows a surprising degree of vitality, fly-shuttles, which increase a weaver's output from 20 to 100%, have been adopted widely, and so also have simple machines for winding and warping, owned and used co-operatively.

Out of some 1,400,000 workers in factories of all sorts, about one-quarter are employed in cotton-mills, and some 80,000 in cotton gins and presses. This industry has had very considerable vicissitudes, but taking bad years with good, it has been prosperous and progressive. The total Indian consumption of mill-woven cloth is much the same now as in the years immediately preceding the War, in spite of the very great increase of price. But whereas before the War Indian mills supplied just under 30% of this production, their share has risen (1924–5) to 52%; while the share of the United Kingdom has fallen from 68·5% to 42·5, Japan now getting 4% of the market. On the

[1] Lakh = 100,000 rupees; crore = 10,000,000 rupees.

other hand Indian mills have lost in China their chief foreign market. The supremacy of Bengal in jute is more firmly established than ever; nearly two-thirds of the jute grown is consumed by the Bengal mills, as compared with less than half before the War; so that Bengal now produces about twice as great a bulk of jute manufactured goods, mainly in the form of gunny bags, hessian cloth and cordage, as all the rest of the world. Such industries as leather tanning, paper manufacture, brewing, woollen manufacture, which are of considerable though minor importance, were greatly stimulated by War conditions, and maintain part of the advance so won.

The two most notable new enterprises launched in the five years immediately preceding the outbreak of War were projects of the late Mr. J. N. Tata, which were brought to fruition by his sons and their partners after his death in 1904. The Tata Iron and Steel Company was successfully launched in 1907 with Indian capital; it began operations in 1908 and produced iron first in 1911. When the World War broke out it was in a position to be of great service both in Mesopotamia and in other war theatres; and, since the military requirements were for steel, the company converted into steel as much as possible of the iron it produced, though the sale of iron in the open market would have been much more profitable. Dividends of 20% on the ordinary and 290% on the deferred shares were paid in 1917 and 1918; again in 1920 and 1921 ordinary shareholders got 16% and deferred shareholders 200%; but since 1922 no dividends have been paid except preference shares; and the heavy fall in the price of steel caused by intense international competition compelled the company to seek governmental aid. Various other attempts have been made in India to produce steel on modern lines; and in the boom period after the Armistice a number of schemes for exploiting the extraordinarily rich and abundant ore deposits of Orissa for this purpose were floated; the chief result of which was to increase the potential output of the Bengal Iron Company. The Tata Iron and Steel Company is the only one actually producing steel.

Equally notable was the Tata project of utilising the heavy rainfall on the Western Ghats to supply Bombay with electric power. In order that power should be available throughout the year it was necessary to create great storage reservoirs on the Deccan tableland. The first completed was at Lonavla, whence there is a fall of 1,725 ft. to the power-house at Khopoli. The works were formally opened on Feb. 8 1915. The Andhra valley project with its artificial lake further to the north, was initiated in 1916 and completed in 1922, and supplies 100,000 horsepower. It is being followed by the Nila-Mula scheme to the south of Lonavla, expected to supply 150,000 H.P., and preliminary work is being done on the Koyna Valley project, still further to the south, to yield 350,000 horsepower. The original purpose of these schemes was to make the Bombay mills independent of coal; but as the amount of power available has increased, it is becoming possible also to revolutionise the methods of transit and consequently the conditions of housing of Bombay. By the electrification of the railways in the immediate neighbourhood of Bombay it is hoped that third-class fares may be reduced to a rate of 11 m. for one anna (approximately one penny). This will make effective the work of the Bombay Improvement Trust, which is charged with the duty of reclaiming the islands to the north of Bombay and converting them into residential and industrial areas, thus making it possible for the most prosperous, but also the most terribly congested, city in India to expand to healthy dimensions.

The close of the World War was marked by a great outburst of speculation. The aggregate authorised capital of new joint stock companies floated in the year 1919–20 alone was Rs. 281 crores, whereas the paid-up capital of all registered companies in existence in 1914 was only 75 crores. Subsequent liquidations were heavy. The most important of the new projects which failed to realise expectations was the Tata Industrial Bank, the shares of which were being bought eagerly in the early part of 1920 at a high premium. Its object was to finance new industries on much the same lines as those followed by the "D Banks" in Germany; but after a short run it was amalgamated with t Bombay Central Bank, which does ordinary banking busine the capital being considerably written down.

Banking.—On the other hand an important step towards t organisation of a more complete and effective banking syst for India was taken in 1920 by the amalgamation of the Pre dency Banks of Bengal, Bombay and Madras into the Imper Bank of India. The Imperial bank was authorised to establis branch in London, which had not been allowed the Presiden Banks, and its London Branch takes over from the Bank England the business which the latter had previously do for the Govt. of India. The Imperial Bank has also been quired to open 100 new local branches to supplement the branches of its three constituents. A great deal more remains be done to knit together the various sorts of banks operating India into a sound and efficient system. There was a heavy m tality among Indian joint stock banks in 1913–7. The cau of this weakness still in large measure remain, and it must regarded as a factor retarding the progress of India towards complete financial autonomy.

The Government and Industry

Since 1910 there has been a change of policy in relation to dustry. In that year the principle of *laissez-faire* was asserted Lord Morley's despatch refusing assent to the plans of t Madras Govt. for the encouragement of new industries, a incidentally sentencing the Madras Department of Industr to temporary impotence. This department had been built step by step since Dec. 1897 by the initiative and under the co trol of Sir (then Mr.) Alfred Chatterton. At a total net cost £33,000 a prosperous manufacture of aluminium hollow-w had been established, the use of oil engines for pumping wa for irrigation popularised, well-boring carried on extensively, t use of the fly-shuttle, automatic dobbies and subsidiary machir introduced among hand-loom weavers, and other importa work accomplished. A similar policy had been initiated in t United Provinces by Sir John Hewett; and there also it w dropped in consequence of Lord Morley's adverse judgment the case of Madras. The outbreak of War brought a change the attitude of the India Office, and in May 1916 the Indi Industrial Commission was appointed to report on possil means of direct governmental encouragement of industry n incompatible with the existing fiscal system. Its positive reco mendations were numerous and varied. Departments of I dustry were in consequence re-created in Madras and t United Provinces, established also in the other provinces, an under the reformed constitution, put in the charge of Indi ministers.

Tariffs.—The reservation excluding the existing fiscal syste from review was only temporary. The Reform of the Cons tution was speedily followed by the appointment in O 1921 of the Indian Fiscal Commission, which reported in favo of "rapid industrialisation by means of discriminating prote tion." In accordance with that recommendation an Indi Tariff Board was appointed in July 1923, to report on the indu tries referred to it which had applied for protection. The fi and most important of these was steel, and the Tariff Boa recommended that bounties should be paid on the producti of heavy steel rails and fish plates on a descending scale beg ning at Rs. 32 per ton, and that specific duties roughly equivale to 30% *ad valorem* (*c.g.*, Rs. 40 per ton on steel rods) should levied on other forms of British or other imported steel. Th assistance not being sufficient to enable the Tata Iron and St Company to manufacture steel at a profit, an additional boun of Rs. 20 per ton on 70% of the monthly ingot production w voted for the period from Oct. 1 1924 to Sept. 30 1925; and it w subsequently decided that this bounty should be continued the diminished rate of Rs. 12 per ton till March 31 1927. 1925 also an old controversy was concluded by the resolve the Government to abolish the excise duty of 3½% *ad valorem* t cotton cloth woven in Indian mills. Hence the duty of 11% imported cloth becomes undisguisedly protective.

abour Organisations.—The post-War period has seen a re-kable increase of class consciousness among Indian urban w-ers. Trade unionism on British lines made its first appear- during the War in Madras, the pioneer society, the Madras our Union, being a fairly solid organisation of the cotton- operatives, which quickly found imitators among the alu- um workers, the employees of the oil companies and others. great rise of prices and the industrial boom of 1919 furnished most favourable possible conditions for a rapid advance of unionism; increased wages were necessary, employers most anxious to avoid stoppages, but they were not in all ready to grant increases in proportion to the rise of prices ot under pressure, for fear the rise in price might be only porary.

ombay was the chief storm centre. The cotton operatives in cular showed unsuspected staying power, and not only se- d advances during the boom which meant an increase in as well as nominal wages, but also, in 1925, won a more re-kable victory in resisting successfully a reduction of wages ng the slump. Indian trade unions are still largely dependent e help of outsiders as organisers, and the success of particu- nions mainly depends on the single-mindedness with which voluntary associates work for the material benefit of the bers. There can be little doubt that in the future trade nism will prove a permanent and growing element in Indian strial life.

abour Legislation.—India was represented at the Interna- l Labour Conference at Washington, which was followed n "All India Industrial Welfare Congress" held in Bom- in April 1922. Important labour legislation was enacted in ame year. The Factories Act of 1922, which came into force uly 1, raised the age of admission for children from 9 to 12, ull time work from 14 to 15, prohibited night work for wom- nd enacted for all workers a maximum day's work of 11 s and a maximum week of 60 hours. The Mines Act forbade employment of children and young persons below ground, e still permitting that of women, and limited the week's to 60 hours above ground and 54 hours below. The Work- 's Compensation Act of the same year was a very carefully ted measure providing, on conditions designed to minimise ation, for compensation for death or accident for 3,000,000 in- rial workers. The contention that long hours of labour are e tolerable and justifiable under Indian than under European litions springs from interested motives, and is not based upon al fact.

ailways.—In 1907 the route mileage of Indian railways open affic reached 30,000 m., of which over 15,000 m. was standard 5') gauge, and most of the remainder metre gauge. On March 925 the mileage was 38,269 m., of which 18,781 m. were standard ge. At that date 1,200 m. were under construction and 1,084 m. dition had been sanctioned. A great deal of unfavourable criti- has been levelled against the railway policy—or, rather, policies the Indian Govt., with special justification on the counts of of enterprise, vacillation and undue complexity. But the broad remains that nearly 40,000 m. have been constructed with a tal liability of £500,000,000, which convey passengers at an age rate very little over one farthing (3·74 pies) per mile, and ds at an average rate of one half-penny (6 pies) per ton per mile. reover, they make profits which are sufficient to meet all in- st charges and also to make substantial contributions to the nue of the country.

mportant changes are now taking place in railway administration. relations between the Railway Department and the general ad- istration are being altered to give the railways more financial onsibility and independence; on the termination of the leases of East Indian Railway and the Great Indian Peninsula Railway I. R. and G. I. P.), together comprising nearly 5,000 m., the king of these two lines was taken over by the State; and the em of departmental management is being superseded by divi- al organisation, which was tried successfully first on the Great ian Peninsula Railway.

oreign Trade.—In the years immediately preceding the War ian foreign trade made rapid progress. Very high freights and t difficulty in securing cargo space during the War necessarily ced the volume of sea-borne traffic very greatly; but the impera- need of belligerent countries for many sorts of Indian produce sed prices to rise so much that the money value of the goods ied was not greatly altered. The exports of private merchandise from India were valued at Rs. 249 crores in 1913–4 and at Rs. 253 crores in 1918–9; imports at Rs. 183 crores and Rs. 169 crores respectively. In 1924–5 the value of the exports went up to Rs. 398 crores and of imports to Rs. 243 crores. These figures disguise rather than reveal the essential facts with regard to the changes in Indian foreign trade. There has been a considerable reduction in the volume of imports, most marked in cotton goods and other textiles; but from this decline, in spite of protective duties, iron and steel have been exempt, the increase in Indian production being no greater than the increase in Indian demand; and there has been a very great increase in the imports of machinery and mill work. Other imports which have greatly increased are mineral oil and motor-cars. The volume of exports is now at least at as high a level as before the War; but the character has considerably altered. Less grain is being exported and more tea; much less raw jute and a great deal more manufactured; the export of raw cotton has increased, and so has that of cloth, particularly coloured piece-goods, but the export of yarn has greatly declined.

India has in fact become much more self-sufficing with regard to manufactures, and less disposed to export food and raw materials except where, as in the case of cotton, high prices and increased production make export specially profitable. The causes of this change are partly to be found in higher freights and higher import duties; partly also in the changed condition of world trade as a whole, regarded as an interchange of manufactures for foodstuffs and raw materials, in consequence of which the Indian peasantry get only a small increase of price for most of the things they sell, but have to pay a great deal more for what they buy. But it is also partly due to Indian progress in manufacturing equipment and industrial organisation. (G. SL.)

SUMMARY STATISTICS

		1913–4	1923–4
Area under cultivation		(million ac.) 219·2	222·5
Area under forest		(million ac.) 82·6	86·0
Yield of rice		(million tons) 28·8	28·2

VI. NATIONAL AND PROVINCIAL FINANCE[1]

The Indian revenues are largely dependent on the seasonal rains. If the monsoons are weak and the crops fail, land revenue has to be remitted or its collection postponed, railway receipts fall off, the agricultural population consumes less, the Customs and Excise revenue declines, heavy expenditure is incurred in the relief of distress, exports diminish and the exchanges move against India, increasing the cost of meeting her obligations abroad. Good and bad seasons tend to occur in cycles. Lord Hardinge's viceroyalty started in a good cycle. The four years 1910–4 were years of financial prosperity. The ordinary revenues were expanding, and there were large windfalls in the opium receipts, due to the high prices which the Chinese were offering during the last few years of a trade that was being steadily reduced under an agreement for the complete cessation of the export of opium from India to China in a given period. It thus became possible to make large grants to the provinces for education and public health.

The War Period.—With the outbreak of war in 1914, Indian finance enlarged its experiences. Direct expenditure on the War was at first small, as India was charged only with the normal cost of her armies engaged on the various fronts; and the pre-War military charges of about £20,000,000 rose only gradually to £29,000,000 in 1917–8. But India's external trade was dislocated, and her railway and Customs receipts suffered accordingly; so that the first two years were marked by deficits. In 1916–7 additional taxation was imposed, but the export of war material had now begun to assume large proportions, and agriculture was also flourishing. In 1917 the financial position was sufficiently strong to justify the Indian Govt., with the approval of the Legislative Council, in making a contribution of £100,000,000 to the home government towards the cost of the War; and in 1918 a further contribution was volunteered, which had, however, to be subsequently revised after the Afghan War, and was adjusted finally at about £14,000,000. In 1917–8 taxation was again increased, but such was the activity of trade and the general prosperity of the country that a surplus of £8,000,000 was realised.

Then the tide turned, and for a series of years the national accounts failed to balance. The old standard of military expenditure was doubled; the Afghan War of 1919 and the succeeding troubles in Waziristan threw a heavy burden on the revenues; a weak monsoon in 1920 was followed by considerable agricultural distress; the trade boom which had been stimulated by the heavy manufacture of war material slowly exhausted itself, and exchange was crumbling; while a rapid rise in the cost of living left the government with no option but to make some corresponding increase in the wages of its army of employees. The deficits were met by temporary expedients which had recently been strangers to the Indian financial system—dipping into balances, accommodation from the banks and borrowing for revenue purposes.

The New System.—With 1921–2 started a new era. The estimates of the central administration were entirely separated from those of the provinces; and the former were for the first time subjected, with reservations already explained, to the vote of a popular Assembly, which took the place of the old and comparatively complacent Legislative Council. In an attempt to balance the budget, the Customs tariff was raised from a general *ad valorem* rate of 7½% to 11%, with 20% on certain luxury articles; postal and railway rates were enhanced, and the taxation on incomes stiffened. But a severe trade depression had now set in, and there had been two feeble monsoons. The year closed with over £22,000,000 to the bad; and, what was even worse, the government was compelled to budget for a further deficit in 1922–3, the legislature having rejected several of its proposals, among which a rise in the salt duty was prominent, for improving the revenue.

But sharp retrenchment had now become imperative; and in the winter of 1922 a special committee under Lord Inchcape attacked the whole problem of expenditure. Their recommen tions,[2] comprehensive and drastic, extending to military as we civil charges, were put into effect, so far as time admitted, in estimates which were laid before the Assembly in March for the ensuing year. To complete the rehabilitation of the b get, the government proposed to double the salt tax (rou from a farthing to a half-penny per pound); and when this prop was defeated in the Assembly the Viceroy restored it by the of his exceptional powers, thereby provoking a fierce polit controversy. The result justified the means, for a marked vival in trade combined with the financial reforms to sho small surplus at the end of 1923–4. The budget for the succ ing year was wrecked as the result of an extremist demons tion in the Assembly; and the Viceroy had again to interpose arbitrary authority, though he was careful to certify expendi at a minimum figure which allowed the salt tax to revert t old rate of 1¼ rupees per 82 pounds.

Railways.—Despite this untoward start, 1924–5 went w trade steadily improved, and with it exchange revived, the y ending with a substantial surplus. Its course was marked by important financial changes. On the one hand, the financ the railways was definitely separated from the general accou and now became a self-regulating entity instead of a handm to the general revenues and the sport of their vicissitudes. railway budget is now framed upon considerations of a consist railway policy, and its only connection with the national bud is that it is bound to make an annual contribution from its ceipts, calculated at 1% on the capital liability of the penultim year, plus one-fifth of the surplus profits, if any, in that yea

The Protective Tariff.—The second landmark of 1924 was enforcement in practice of the policy of discriminative protec which a tariff committee of some years earlier[3] had recommen for the Steel Industry Protection Act of 1924 imposed import du which were clearly expected to be prohibitive on certain articles m ufactured from steel, while it granted bounties on heavy steel r fishplates and railway wagons manufactured in India. Hardly the Act passed when the bounties were found inadequate to t purpose and were enhanced. Schemes for similar protection to o domestic industries continued to be formulated, and the whole tr of Indian political opinion is in their support. The following year another fiscal measure of great, if more sentimental, importa The excise duty on cotton goods manufactured in India, which originally been imposed to counterbalance the tariff on impor cottons, and which had for many years been resented as a sacrific Indian interests to Lancashire, was at last abolished from De 1925, in fulfilment of an arrangement which had been reache settlement of a disastrous strike among the cotton-mill worker Bombay. The accounts for 1925–6 seemed likely to close on the ri side; and the estimates for 1926–7 again presumed a surplus, altho the law of averages would point to the near approach of a sh monsoon.

Budget of 1925–6.—The main constituents of the central budg if 1925–6 be taken as a sample, are as follows:—

Source	Revenue	Object	Expend ture
	£ millions		£ millio
Customs	30·9	Defence (net)	37·5
Taxes on income	11·6	Debt services	12·1
Salt	4·6	Civil administration	7·3
Opium	2·4	Other charges	8·3
Railways (net)	3·5		65·2
Currency and mint	2·7	Surplus	·5
Provincial contributions	4·5		
Other receipts	5·5		
	65·7		65·7

The customs tariff, which long stood on a purely revenue foot with a 5% charge all round, is now divided into protective, n protective and general sections. The protective section is at pres restricted to manufactured iron and steel, but the so-called n protective duties include luxury rates, such as 25% on sugar a 75% on cigars, while the *ad valorem* duties in the general sect range from 2½% to 30%. There is a low export tariff on jute, hid rice and tea. The taxation on incomes includes a supertax, and cl attention has been given to perfecting what used to be a most satisfactory source of revenue; all income from agriculture is exem

[1] In this section the rupee is taken throughout at a conventional value of 16 pence. The full story of exchange is discussed later.

[3] *Report of the Indian Fiscal Committee, 1921–2* (Cmd. 1764).

he production of salt, whether from mines, lakes or sea water, is a overnment monopoly, and the duty on it used to be treated as the serve or balancing factor in the Indian budget; but popular pres- ure now seems likely to standardise it at 1½ rupees per maund, or bout one farthing per pound. Opium is a steadily diminishing gure; in 1918 there were 207,000 ac. under cultivation for the opium ppy, in 1924 there were only 133,000 ac.; exports to the Chinese arket were extinguished, and in May 1926, it was announced that l exports of every kind are to cease, even to foreign governments. his cessation is to be by a tenth each year.

Provincial Finance.—Obviously, however, the figures quoted ove do not cover the whole field of the state's revenue and ex- enditure. Quite £50,000,000 of receipts, representing their collec- ons of land and irrigation revenue, excise, stamps and forest in- me, appear in the budgets of the nine provincial governments. A milar sum is expended by them on their administrative business, stice, education, public works, police and gaols, public health, etc. his clear-cut demarcation of financial responsibility was part of the w constitution. From 1833 up to 1921 the accounts of the imperial d provincial authorities had been amalgamated; in the budget of 21–2 they were separated. The local governments now receive the ield of the sources which they administer, and are responsible for the penditure of the provincial departments, both reserved and trans- rred. By far the most important of their resources is the land venue, which, together with the cognate receipts from irrigation, mpose more than half the total budget provision of the provinces. pinions differ as to whether it is a rent or a tax; but it is a legacy om Mogul rule, and proceeds on the assumption that all the land the property of the Crown.

In Bengal and Northern India a class of intermediary landlords as been gradually evolved, and they are assessed on their rent rolls; Madras and Bombay the revenue is assessed directly upon the *ot* or cultivating occupant, with reference to the estimated output his land. The whole system is being caught up into the region of olitical argument, as problems of much importance are beginning to ivide popular feeling, *e.g.*, the permanency or otherwise of the ssessments, the security of tenure in the landlord provinces and the ght of the State to determine rents. In order to enable local govern- ents to discharge their new functions, they have been given powers taxation, scheduled so as not to invade the sphere earmarked for he requirements of the central Government. They have been uthorised, for the first time under the new constitution, to raise ans, either through the central Government or independently, and ome of the provinces have already borrowed, for works of improve- ent such as irrigation and city development schemes.

Provincial Contributions.—The severance of provincial finance rom the general accounts brought to the front a problem inherent in ll federal constitutions, even if they are as embryonic as in India o-day. In former years the central Government used to finance it- elf in part by taking a share of the revenues collected in the prov- nces; and incidentally it thereby kept alive its right to intervene in he management of the sources from which such revenues flowed. When on the road to provincial autonomy a point was reached at vhich this right was curtailed, and the provincial revenues were redited wholly to the provincial exchequers, it became apparent hat the central Government had no longer the control of funds ufficient for its own business. In India the customs, salt, opium and et railway receipts, income tax, etc., when once they ceased to be upplemented by a share of the provincial land revenue, stamps and xcise receipts, etc., proved inadequate to meet the demands of efence, the public debt and the other liabilities reserved by the cen- ral Government.

Under this compulsion, and arguing that the provinces should equitably contribute to the defence of the country, the Govt. of India (with the full concurrence of the Select Joint Committee of Parliament) imposed a levy on the provinces. The total sum which hey were asked to pay was about £6,500,000. It was distributed among the provinces in rough ratio to the advantage which each had gained by ceasing to share its provincial revenues with the central Government; and hopes were entertained that the central finances would improve with sufficient rapidity to enable those tributes to be gradually reduced and in a short period completely remitted. Ad- versity defeated those hopes, and the reduction has been slow and irregular. Meanwhile the provincial legislatures, with rare exceptions, have fastened on the arrangement as the main cause of their own financial stringency, and have magnified a not unreasonable and purely temporary expedient into an intolerable grievance, under cover of which there has been a tendency to evade the imposition of taxation that might have balanced their own budgets. Several local governments claim, in addition to their own separate revenues, a share of the taxation upon income collected within their boundaries; and some concession on this point has been yielded as an exception to the general rule of separate resources, by giving each province an allowance of three pies for every rupee by which the income assessed within the province exceeds the income that was similarly assessed in 1920–1.

Local Finance.—The 772 municipalities of British India have the disposal of an annual revenue of over £9,000,000, exclusive of Govern- ment grants and borrowings; and the district and local boards have a normal revenue of about £8,000,000. Both classes of bodies have been endowed by the 1919 constitution with a financial independence commensurate in its degree with that of the provinces. The six port trusts have statutory powers for their own business, and control an income in the neighbourhood of £5,000,000; Bombay and Calcutta in particular having raised considerable loans which rank only second in the Indian market to Government securities.

Indebtedness of India.—The Govt. of India borrows both locally in rupees and in England in sterling—the former now to a very much larger extent than before the War. The position at the beginning of the War was thus described officially:—

Out of a total debt equivalent to £274,000,000 outstanding at the end of March 1914, only about £13,000,000 represented ordinary or unproductive debt. The annual interest on the latter was £750,000 only, and on the productive debt about £8,500,000, so that our total interest charges amounted to some £9,250,000. Railways and irrigation works in the same year yielded us a return of £15,250,000. Thus we had left some £6,000,000 of clear revenue from our great capital undertakings, after meeting interest charges on our entire public debt.

This was the result of a long, careful policy of converting unproductive debt, *i.e.*, money raised for military purposes and the like, into productive debt, by the device of short borrowing for the capital required on railways and irrigation. It had put India into a very strong position to face the changes brought about by the War. The War debt, inclusive of the gifts to the home exchequer, the loans for the expenditure on the Afghan War and subsequent frontier operations, as well as the borrowing necessitated by the series of budget deficits, all went to swell the volume of the unproductive debt; and on March 31 1926 the total indebtedness of India was:—

In India	Crores of rupees
Loans	368·35
Borrowed from the paper currency reserve	49·65
Other obligations	93·27
	511·27

In England	£ millions
Loans	266·43
Other obligations	76·05
	342·48

Of the total it was considered that about 23% was unproductive. The productive loans included the capital liabilities for irrigation, which were taken over by the provinces when that subject became wholly provincial. The "other obligations" are mostly unfunded debt, such as post-office cash certificates and savings bank accumulations, provident funds, etc.; while in England £57,500,000 are accounted for by capitalising liabilities which are being liquidated by certain terminable railway annuities. In lieu of a general sinking fund an arrangement was started in 1924 by which an annual sum is appropriated from revenue for the reduction or avoidance of debt; it is calculated at four crores plus one-eightieth of the amount by which the outstanding debt of the year exceeds the debt outstanding on March 31 1923.

VII. CURRENCY AND EXCHANGE

The foundation of the currency system is the rupee (16 annas or 192 pies), a coin weighing 180 gr. and containing 165 gr. of pure silver. The subsidiary coinage comprises pieces of silver, nickel and bronze; all being legal tender up to one rupee only, except the 8-anna piece, which, like the rupee itself, is legal tender without limit. The sovereign also circulates as freely as Gresham's law permits. Alongside of these is a paper currency, at first of slow and lingering growth, in the form of Government currency notes, the higher denominations of which are, strictly speaking, encashable only in the currency circle (usually an area of one or two provinces) for which they were printed. The favourite notes are for 1, 5, 10 and 100 rupees; but there are also others for 2½, 20, 50, 500, 1,000 and 10,000 rupees. The note circulation as a whole is backed, as to more than one-half, by a reserve of gold and silver, and as to the balance by Government securities held partly in England and partly in India, with a margin for seasonal expansion based on trade bills up to a strictly defined amount.

The exchange value of the rupee follows the ordinary economic law and depends on India's trade balance with the outer world. When there is a big surplus of exports, import bills are at a premium and the rupee rises in terms of sterling; when in bad years exports decline and there is a relative glut of import bills, the rupee falls in terms of sterling. The operation of this law, however, assumes a fairly constant adjustment of the volume of currency to the requirements of trade. If there were no restriction on the output of rupees, the gold value of the coin would tend to fluctuate with the gold value of silver. Up to 1873, although the Indian mints were open, the rupee continued steady at an exchange value of 2s.; then the price of silver began to tumble until the rupee dropped almost to 1s., and so disastrous were the consequences to the finances of the country that in 1893 it was decided to close the mint to free coinage and establish a "managed" currency, with the rupee as a token coin. By this policy an equilibrium was sought.

The Rupee During the War.—By the beginning of the War this system had reached considerable strength. The rupee had been given by law a parity of 16d., and trade conditions had never put it beyond the power of the Government to maintain the exchange at approximately that figure. The machinery for managing the currency was simple. The Indian Govt. bought silver and coined rupees to meet the requirements of the country. So long as silver was under 43d. an oz. there was a profit on the operation, which was placed to the Gold Standard Reserve and (except for a brief and partial diversion) invested in sterling securities in London. Against this reserve the Govt. of India could sell sterling drafts (technically known as " reverse Councils "), if the exchange value of the rupee threatened to fall. On the other hand, if it were rising, the Secretary of State could increase his normal sales of rupee drafts on India (technically known as " Councils "), which would be met out of the Govt. of India's reserves of rupees or, if necessary, by fresh minting. Should this fail to check the rising exchange, it was generally possible to count on a free importation of private gold which would either pass into circulation or be presented to the Government for the purchase of rupees. All these arrangements were working smoothly in 1914. The Gold Standard Reserve stood at £26,000,000, all except £4,000,000 being held in gold or gold securities in England. A continued favourable balance of trade had encouraged the import of gold, of which £70,000,000 worth had been absorbed between 1910 and 1914. The Paper Currency Reserve had £24,000,000 in gold or gold securities, and the note circulation had risen to 66 crores (£44,000,000).

With the War came new and disturbing demands. India was called upon to supply the British Govt. and the Allies with immense quantities of raw materials, manufactured goods and foodstuffs for War purposes, and also to provide funds in India and in countries where Indian troops were fighting. The Indian Govt. had therefore to disburse a rupee currency in very large amounts. The home Government repaid its debts by credits in London, but the Indian Govt. required money in India, and the difficulty was to remit specie. Gold was unobtainable, silver was becoming very scarce in the London and American markets. The Indian Govt. was therefore compelled to increase the note issue without a corresponding increase of rupees held against the notes. The notes were convertible and their encashment drained away the reserve stock of rupees. The time drew near when either inconvertibility must be declared or silver obtained in large quantities for coinage. So seriously were the political effects of inconvertibility regarded that the Government strained every nerve to avert it. The 1-rupee and 2½-rupee notes were invented; the import and export of the precious metals were put under the strictest regulation; and the mints worked night and day.

The Pittman Act.—Yet, with the world shortage of silver, inconvertibility was all but reached in 1918, when help came from the Govt. of the United States. Congress was prevailed upon to pass the Pittman Act as an emergency measure. This Act enabled the Government to borrow from the Treasury the greater part of the dollar reserve of 375,000,000 oz., held as security for silver certificates. The United States Govt., as soon as it obtained this authority, allowed the Indian Govt. to purchase 200,000,000 oz. of silver dollars on terms much below the current market prices, and accelerated the dispatch of the metal to India. From July 1918 onwards American silver began to arrive in large quantities and was coined into rupees. For some months the new money went out of the reserves as fast as it was coined, but by Dec. 1918 the convertibility of the note issue was secured. Between March 1916 and March 1920 the output of the mints was represented by the enormous quantity of 1,390 million new rupees (£93,000,000) as currency.

Throughout this struggle another anxiety grew apace, in the risk of being unable to maintain the rupee as a token coin at its statutory parity with sterling. Sterling was depreciating and silver was rapidly appreciating. From its pre-War price of about 26d. per oz., silver advanced to an average of 31d. in 1916, of 48d. in 1918 and of 61d. in 1920, touching the figure of 89d. in Feb. of that year. As the conversion of the rupee into bullion became profitable when silver touched 43d., the rapid rise beyond that figure led to a wholesale melting down of rupees for clandestine export; and the Government was forced to protect itself by hurriedly pushing up the parity of the rupee until it stood at 2s. 4d. in Dec. 1919, while for a short time private remittances fetched over 2s. 10d.

The Indian Currency Committee.—The whole problem was then referred to a committee of currency and banking experts sitting in London. Reporting early in 1920, this body (with one notable dissentient) recommended[1] that the rupee should be correlated to gold, and not to sterling, which by that time had depreciated in relation to gold and had no certain value, and that it should be given a new statutory ratio equivalent to one-tenth of the gold contained in a sovereign. This would give the rupee the equivalence of 2s. when the pound sterling returned to parity with the sovereign. The committee were of opinion that the price of silver expressed in pence would remain at the point that would make the retention of a 1s. 4d. rupee impossible unless the coin itself was diminished in weight or fineness. This alternative they rejected. They thought that, having regard to the higher price levels of the world, India would still b able to maintain a favourable trade balance with a 2s. rupee, an that any consequent readjustment of rupee prices of Indian expo staples would be to the advantage of the Indian consumer by actin as a drag on internal prices.

The Indian Govt. accepted the committee's recommendation, an in Sept. 1920 the Indian Coinage Act established the new ratio of th rupee as one-tenth of a gold pound. But currency was alread laughing at the law. There was a rush of remittances to Englan and at the same time the export trade of India fell off. In commo with other countries whose exports consist of raw materials, Indi found the demand for its produce suddenly dry up. The former su plus of exports gave place during the second half of 1920 to a larg adverse trade balance which had to be liquidated by bills on Londo Exchange persistently dropped from 2s. 6d. the rupee, which in th first months of 1920 roughly represented the parity of one-tenth of gold sovereign, to below 1s. 4d. in the early part of 1921, and th price of silver receded to 32d. the ounce. The Government endeav oured to maintain the rupee at its new exchange value by sellin drafts on their resources in London, but economic forces were to strong for them, and after they had diminished their gold holdings i this way by well over £50,000,000, they abandoned the struggle an left exchange to find its own level. It steadily dropped to betwee 1s. 4d. and 1s. 5d., when the sale of Councils was tentatively recom menced, at whatever they could fetch without regard to the statu tory parity. In the hope of ending this anomaly, another currenc committee was appointed towards the end of 1925, when the rupe had become fairly steady near 1s. 6d.; it had not reported whe Lord Reading resigned. Meanwhile, the position had improved i readiness for any further attempt to control exchange. The Gol Standard Reserve had reached £40,000,000 of sterling securities, point at which it was decided that further accretions should be em ployed in reducing the rupee securities in the Paper Currenc Reserve. The latter in March 1924 contained £68,000,000 in gol and silver, and over £9,000,000 in sterling securities.

The strenuous efforts made during the War to preserve the con vertibility of the currency notes were rewarded by a rapid expansio of their popularity. The circulation (66 crores) of March 1914 almo trebled in the next 10 years, touching 186 crores in March 192 notwithstanding the practical disappearance of the 2½-rupee and th 20-rupee notes. In 1920 the whole system was improved by th Paper Currency Amendment Act of that year, which allowed a unlimited note issue provided a metallic basis of 50% was observe required the gold backing to be held in India and introduced th principle of a certain definite expansion of the note issue during th busy season against trade bills of a durance not exceeding 90 day Before the note circulation became so firmly established as it now i several attempts were made to lighten the task of supplying Ind with silver currency by the employment of gold. Among them wa the opening of a branch of the British Mint at Bombay, intended t coin sovereigns and 15-rupee gold pieces. Like all other simila experiments, it was defeated by the immediate disappearance of gol into the hoards of the people. Nearly 3,500,000 gold coins we minted at Bombay in 1918–9, and work was then abandoned.

BIBLIOGRAPHY.—In contrast with the former scarcity of goo books on India, they now abound; and the following is necessarily a arbitrary selection from the newer works. The standard all-roun text-book is *The Imperial Gazetteer of India*, vol. 1 to 4. Add to th the *Statistical Abstract of British India from 1914–5 to 1923–* (Cmd. 2534 of 1925); and the reports to Parliament on the Mor and Material Progress of India, now published as *India in 191 1919, 1920, 1921–2, 1922–3, 1923–4* and *1924–5*, written by Pro Rushbrook Williams, and bringing a full narrative of current even up to date.

Historical: Sir Verney Lovett's *India* in the " Nations of To-day series (1923) is the latest authoritative work. Sir V. Chirol's trilo should be studied: *Indian Unrest* (1910); *India Old and New* (1921 and " India " in *The Modern World* series (1926).

Constitutional and Political: The key book is the *Report o Indian Constitutional Reforms* (Cmd. 9109 of 1918) by the la E. S. Montagu and Lord Chelmsford. With it read *Dyarchy* b L. Curtis (Oxford, 1920), which contains the text of the Selbor Committee and the Act of 1919. Other works are E. A. Horne, *T Political System of British India* (Oxford, 1922); Sir C. Ilbert, *T Government of India* (Oxford, 1922); Ilbert and Meston, *The Ne Constitution of India* (1923).

Problems of To-day: Sir Verney Lovett, *History of the Indi National Movement* (1920); Bishop Whitehead, *Indian Proble* (1924), and as studies in Indian psychology, Lord Ronaldshay trilogy, *Lands of the Thunderbolt, India a Bird's-eye View*, and *T Heart of Aryavarta*, published by Constable in 1923–4, respectivel

Economic and Finance: Dr. P. P. Pillai, *Economic Conditions India* (1925) and Gyan Chand, *The Financial System of Ind* (1926). (ME.)

INDIANA (*see* 14.421).—The population in 1920 was 2,930,39 an increase of 229,514, or 8·5% over the 2,700,876 of 1910, against an increase of 7·3% in the preceding decade. Fro ninth in rank among the states in 1910 Indiana fell to eleven

[1] Report of Committee on Indian Currency (Delhi, 1920).

1920. The density in 1920 was 81·3 to the sq. m.; in 1910, 9. The population as of July 1 1926 was estimated at 3,124, 9. The urban population (in places of over 2,500) was 50·6% the whole in 1920, as against 42·4% in 1910.

The six cities of Indiana with a population of 50,000 or more re:—

	1920	1910	Increase %	Estimated 1925
Indianapolis	314,194	233,650	34·5	358,819
Fort Wayne	86,549	63,933	35·4	97,846
Evansville	85,264	69,647	22·4	93,601
South Bend	70,983	53,684	32·2	80,091
Terre Haute	66,083	58,157	13·6	71,071
Gary	55,378	16,802	229·6	76,870

Agriculture.—In 1925 there were 195,785 farms of five acres d over, the total farm land area, which forms 94% of the total ea of the state, being 91,917,780 acres. The assessed value in 24 of all farm property was $2,218,034,991. The chief crops e corn, wheat and oats which produced in 1924, 100,317,606, ,353,066 and 58,782,554 bushels respectively. Hay and rye e also produced. In 1924 the area under tobacco cultivation s 20,695 ac., yielding 18,362,243 pounds valued at $3,057,000. rge quantities of tomatoes are grown besides other vegetables d fruits of all sorts. The number of livestock reported on n. 1 1925 was 557,472 horses, 103,235 mules, 1,296,163 cattle, 4,000 sheep and 3,006,242 swine.

Mineral Products.—Coal mining was the principal industry, ,340,000 short tons being mined in 1924, the state continuing rank sixth in this respect. Petroleum wells yielded in the me year 935,000 barrels valued at $1,700,000. The large stone arries of Monroe and Lawrence counties produced 70% of the estone used in the United States for building, the 1923 output ing valued at $17,692,112. Indiana oblitic limestone is used in arly every state and in foreign countries. Indiana has valu- le clays, shales and kaolin, and is sixth among the states in ramic production, her clay products in 1923 being valued at 5,643,128. Drainage tiles, encaustic tiles, fire-proofing, terra- tta, sewer pipe and stove linings are other important clay oducts. Pottery products include earthenware, stoneware, hite granite, semiporcelain, sanitary ware and porcelain elec- cal ware.

Education.—In 1921 the state increased the tax levy for com- on-school support as well as for the support of the higher edu- tional institutions and provision for teachers' pensions was acted. There was a tax levy of five cents on each $100 of tax- le property for the support of the three higher educational stitutions of the state, producing about $2,750,000, and a levy a fraction of a cent for vocational education producing yearly out $115,000. In 1924 $64,696,230 was spent on education. 1925 the tax levy for higher education was repealed and the ree state schools received special appropriations.

Constitution and Government.—During the decade 1910–20 ere was much discussion over amending the constitution of e state, a difficult undertaking under the constitution of 1851, asmuch as amendment requires the assent of two legislatures d ratification by a majority of the electors. In 1914 an effort as made to bring about a state convention to revise the con- itution. A conference was held at the state university, out of hich grew the Constitutional Convention League, whose pur- se it was to bring about such a convention. Under the in- uence of this league, while the Legislature refused to call a nstitutional convention, it agreed to submit to the voters by ferendum in 1916 the question whether such a convention ould be held. The proposal was voted down by a large ma- rity, partly because of the expense involved, partly from fear radical innovations. The vote for the convention was, how- er, so large that two Assemblies approved a series of 13 amend- ents which were submitted to the voters in 1921. All the nendments but one were rejected.

During the 12 years 1913–25 much legislation was passed tending governmental functions. Only a summary of this n be attempted here: In 1913 an inheritance tax was imposed. In 1915 laws were enacted dealing with industrial aid to the blind; flood prevention; the direct primary for state nomina- tions; workmen's compensation for injuries; and arbitration in industrial disputes. In 1917 a Prohibition Act was passed, made more drastic in 1925 by provisions making the possession of intoxicants a penal offence and the Eighteenth (Prohibition) Federal Amendment was ratified Jan. 14 1919. Provision was also made for a system of state parks, with a commission charged with reforestation and the conservation of natural resources; and a Highway Commission was created charged with building a complete system of state roads, for which purpose, in 1923, a gasoline tax of 2 cents a gallon was provided, increased to 3 cents in 1925, bringing to the commission for road building from $6,000,000 to $7,000,000 annually. In 1921 a state budget sys- tem was adopted, and cities were allowed, at their option, to provide for city planning and to adopt the city manager or com- mission form of city government. In 1921 the Riley Hospital for children, a memorial gift from citizens to the state, was es- tablished under the care of the university. In 1921 the univers- ity took over the only Dental College in the state.

Since 1909 the governors of the state have been as follows: Thomas R. Marshall (Dem.), 1909–13; Samuel Moffet Ralston (Dem.), 1913–7; James Putnam Goodrich (Rep.), 1917–21; Warren T. McCray (Rep.), 1921–3; Emmet F. Branch (Rep.), 1923–5; Ed. Jackson (Rep.), 1925–

Moran; Woodburn, *Scotch-Irish Presbyterians in Monroe County* (Indiana Historical Society's publications); Dr. Logan Esarey, *History of Indiana,* 2 vol.; W. H. Smith, *Hist. of Ind.,* 2 vol.; the files of the *Indiana Magazine of History* and the publications of the Indiana Historical Commission, especially *Constitution Making in Indiana,* by Charles B. Kettleborough; and the collections of the Indiana Historical Survey of Indiana University. (J. A. W.)

INDIANAPOLIS, Ind., U.S.A. (*see* 14.427), which claims to be the largest city in the world not situated on navigable water, ranked 21st in size in 1920, with a population of 314,194, of whom 34,678 were negroes and 16,958 foreign-born. In 1925 the official estimate was 358,819. The population increased 34·5% between 1910 and 1920, but the number of foreign-born decreased 14·2%. The area was increased from 33 sq. m. in 1910 to 43·5 sq. m. in 1920, and to 49·5 in 1925. The output of its factories was valued at $126,313,000 in 1909; $398,667,000 in 1919; $262,- 285,896 in 1921; and $346,858,158 in 1923, when there were 783 establishments within the city limits employing 45,818 workers. The leading industries were meat-packing, manufacture of auto- mobiles and automobile accessories, metal trades and machine shops, canning, manufacture of wearing apparel and printing.

After the disastrous Ohio Valley floods of 1913, a concrete levee 40 ft. high was built along the west side of the White river with a 60 ft. driveway on the top. This was completed in 1916. A new street lighting system was installed in 1915 and improved from time to time. A $3,000,000 sewage purification plant was installed in 1925. The elevation of the railway tracks entering the Union station was begun in 1917, and the old Union dépôt was rebuilt and enlarged into an attractive and commodious station. A city plan commission was established in 1919, and a zoning ordinance adopted in 1922. The park area had been in- creased by 1925 to 2,544 ac. and there were 53 m. of boulevard and 46 city playgrounds. The War Memorial Building, costing $10,000,000, which houses the national headquarters of the Amer- ican Legion, was nearing completion in 1925. The cost of living is relatively low in Indianapolis (94% of the average for 31 American cities in Dec. 1924), as would be expected from its excep- tional transportation facilities and its favourable location with respect to agricultural and manufactured products and coal mines.

INDIAN LITERATURE.—In Europe literature is, as regards its subjects, largely international, and any new fashion, such as romanticism, pessimism, the psychological novel, the detective novel, is quickly propagated. The individual qualities of promi- nent writers are soon known, directly or through translations,

and evoke responses more or less obvious. Moreover, the similarity of social conditions and outlook lends interest to the same problems everywhere, and international science causes them to be approached from the same points of view.

English and European Forms.—In India the bulk of the educated public is acquainted with English; new English publications are quickly available in the libraries and reading rooms; any new book which has obtained a vogue in England will soon be reviewed in India and be a subject of articles in magazines. Moreover, India has in England, America, France, Germany and elsewhere numerous students, and some journalists, who are living the lives of those countries and sharing their interests; and we have also to reckon with the presence in India of a considerable community of English and other administrators, teachers, missionaries and business men. Consequently, there is a very large output of writings which in spirit and manner, and often in subject, are not properly Indian, but either international or what may be termed "colonial." In Bengal alone over 1,000 publications in English (irrespective of bilinguals) are produced annually, and there are over 100 English periodicals of different kinds. We might mention in addition the large number of works by Indians and officials or ex-officials in India which are actually published in England.

A second department of Indian literature consists of writings in Indian languages which are based upon European models or deeply affected by such. Here we have a great mass of fiction, biography, history, much drama, lyric poetry, travels, political and social pamphleteering and an immense magazine literature, modes which are simply copied from European models. In this sphere we should not overlook the considerable number of actual translations or adaptations of individual works in English, French and so forth. This might be described as the vernacular literature of absorption.

A third stage is represented by that vernacular literature which, while it has absorbed European influences, has yet recovered an Indian outlook and temper, whether in the course of nature or in obedience to the strong reactionary feeling. Already in the 'eighties of the 19th century Bengal had produced a novelist, Bankim Chandra Chatterjee, whose work exhibits a creative synthesis of the new and the old; and at the present day the Bengālī language has, irrespective of its outstanding representative, Sir Rabindranath Tagore, a modern literature conscious of an independent inspiration.

A fourth department is constituted by the continuance of ancient modes and conceptions.

Linguistic Distribution.—Apart from the influence of particular centres, such as universities, the literature is very unevenly distributed. The matter must be stated in terms of languages. In the field of Assamese, Oriya, Bihārī, Punjābī, Sindhī, Nepālī and Kāshmīrī, the Rājasthānī dialects and Malayālam of southern India, the old modes may be said to prevail with little innovation.

High Hindī, in regard to which the same might a few years ago have been said, is rapidly equipping itself with literary and scientific compositions on modern lines. Urdū, the chief organ of Mahommedans in Hindustan, the Panjāb and Central India, is further advanced in the same direction. The two chief languages of the Bombay Presidency, Gujarātī and Marāthī, more especially the former, have a considerable modernising literature. The Telugu of Madras is perhaps not so far advanced; but Tamil has a large productivity, hardly second to Bengālī. Special educational efforts have led to the publication of a fair number of manuals in Kanarese (Mysore), as also in Gujarātī (Baroda) and Urdū (Bhopal and Hyderabad); but other Indian States are not productive on modern lines.

English.—For publications in English about the same proportions hold as for modernised vernacular literature. English works are, indeed, far more prevalent in the provincial capitals, whereas those in the vernacular abound in the less anglicised districts, Gujarātī, for instance, favouring Ahmadābād, Marāthī Poona. The non-modernised literature is also published in all considerable places.

Classical and Other Languages.—The chief classical language India, Sanskrit, is represented by editions of two kinds, those old Indian lines with or without commentaries in Sanskrit or modern vernaculars, and those with commentaries in Englis The former are very widely published in the Deva-nāgarī cha acter, or in Bengālī, or in Gujarātī or in the south Indian alph bets, sometimes even in the Panjābī or Urdū; and there a various combinations of these scripts. Editions on Europe lines appear for the most part in the provincial or state capita or in the university towns. New original works in Sanski are not infrequent in the sphere of oriental philosophy, philo ogy, science and religion; occasionally there appear new poer and dramas of considerable extent and literary merit; and the are also Sanskrit periodicals, including even a daily newspape

Other classical languages are: (1) Prākrit, usually that of tl Jains and published in the Bombay province or in the Hindī- Mārwārī-speaking areas; (2) the Buddist Pāli, rare in India; (the Tibetan, published at Calcutta and Darjeeling; (4) tl Pahlavī of the Parsees, published in Pahlavī or Gujarātī scri in the Bombay Presidency; (5) the Arabic, appearing chiefly Delhi, Lucknow, Hyderabad; (6) the Persian, more occasion Many of the vernacular languages also have their old or classic periods, and prominently the Dravidian group, Tamil, Telug Kanarese and Malayālam; re-editions of their classical worl are very frequent, and for the most part they are publishe within the areas of the respective vernaculars.

Translations of Sanskrit works are innumerable in nearly a the vernaculars, the *Bhagavad-gītā* for instance being repr duced many times every year; and some degree of the sam favour extends to some of the local classics, the Hindī poems Tulasī-dāsa, and the Hindī *Bhaktamāla*. Among modern Hind writers Swami Vivekānanda, Bankim Chandra Chatterjee, S Rabīndranāth Tagore, Romesh Chunder Dutt and Haraprasa Sāstrī have also a popularity in several languages; and popul novels, in particular the favourite *Chandrakāntā* (from th Hindī), and its imitators, are frequently translated. Portugue publications appear at Goa, French at Pondicherry and Chande nagore; the Roman Catholic missions print some brochures i Latin, and there is even an Italian periodical issued from Ma galore (*La Missione di Mangalore*).

Alphabets.—The literature of India is, therefore, highl polyglot, while individual publications are very often bilingu at least. The alphabetic aspect of the matter has also bee partly indicated. In spite of the attention which has bee given to the possibility of a common script for India, son advocating the Roman, some the Devanāgarī (which has Hindī periodical devoted to its interest), there is no evidence progress toward simplification; there is a certain amount Roman-Urdū, and Roman is usually employed for the Konka form of Marāthī and for the rendering of previously unwritte languages. But in general each leading language holds to i traditional script. Sometimes it has more than one; for th Mahommedan writes his Panjābī or Hindī or Malayālam Tamil (not, however, his "Musalmānī-Bengālī") in the Urd character, with any necessary modifications. The Sikh ma write his Sindhī in the Gurumuphi of the Panjāb. Bilingu books are therefore unusually also bialphabetic (except regards the above-mentioned case of the Sanskrit, or simil cases with Pahlavī and Gujarātī, or Arabic texts with Persian Urdū); and this adds to the multiform appearance of th Indian literary output, already sufficiently variegated, even we overlook such characters as the Multānī, Modī, Kaith Savara, which indeed are rarely printed, or the numerous ol writings appearing philological works. The format of th book is not seldom at of the old Indian *pothī*, sometimes (i Bengal) even print on palm leaves; while the Panjāb Gur muphi and the Mah mmedan Arabic are much less often print than lithographed from handwritten originals.

Subjects and Forms

To begin with the lowest stratum, we must note the existen in India of an extensive, really popular literature in verse.

parts of India, but especially perhaps in the Punjāb, in the ınarese country and in the Tamil area, there is a constant ɔduction of songs and ballads, provoked by any notable :asion, such as a prize fight, a flood or calamity, a crime, a ıgedy, a personality or social event, an act of administration; ɛse have a real, though probably in general a brief, life upon ɛ lips of the people, who sing them over their work or in their :ial gatherings. Of late years this form has been largely used : political propaganda, innumerable small collections of ational songs " appearing in all the chief languages. There ɛ also many collections of songs for special occasions; *Garbhī* ıgs for women, marriage songs, songs for the Holī (spring) ɨtival and other celebrations, boat songs for aquatic sports in ɨissa and Bengal and so forth. At certain times of the year e Mahommedans put forth vast quantities of " verses " in nour of Mahomet or dirges for Hasan and Husain. Religion s a large share in this poetic activity: songs in honour of ɨishna (especially in Hindustan, Bengāl and Orissa, but also in ıjarāt and Southern India), of Caitanya (*kīrtans* in Bengal), Kārttikeya, Ganeśa, Dattātreya, Vithobā (in the Marāthī ea); songs for pilgrims to or at the various shrines (innumer- le in the Telugu and Tamil country); songs for temple rites; llections of Jain hymns; and the many publications of Chris- ın sects, which in some cases (Roman Catholic) even deign follow Indian models. Not all this popular literature is verse, since there are occasions when sacred stories in prose *Hari-kathās* and the like) are narrated in or near the temples.

Oral Preservation of the Classics.—An oral existence appertains so to a good part of the various classical writings of India. his is the case not only with Sanskrit works such as the Mahāb- ɨrata and Rāmāyana, some parts of the Purānas, and some ɔries such as those of Sāvitrī and Hariśchandra, but also to the ıssics of the several vernaculars. Not to mention the substance stories and legends, the texts of such poets as Kabīr and ılasī-dāsa in the Hindī area; Vidyāpati, Govind Dās and many hers in Bengal; Narsinh Mehta, Mīrā Bāī and Prēmānand in ujarātī; Nāmdēv and Tukārām in the Marāthī country, llā in Kashmir; the Sūfī poets of Sindh; the Vaishnava and ıiva saints and moralists of the Tamil country, are very familiar ı the lips of ordinary people in their respective areas, and, esides being used in education, are frequently re-edited. In e Punjāb some parts of the Sikh *Granth* are similarly used.

The Drama.—On the borderland between the oral and the erary we have the drama. In India it was indigenous in many rms, from the heroic down to the morality, miracle play, the rce, the shadow or puppet show. Except in the extreme south India, it would seem that the popular forms of representation ıve been more or less levelled out. The ordinary play, pro- ıced chiefly in Calcutta, Bombay and Madras, is similar to ıe European forms—melodrama, social sketch, burlesque, roblem play (the old man and the young wife, the modern ɔung man or woman and so forth), love story: it is generally terspersed with verses, and these are often separately published ɔr popular use. The more literary drama, still sometimes in anskrit, takes its subjects chiefly from old Indian poetry and gend, and is not seldom an adaptation of a particular Sanskrit ork (the *Śakuntalā*, the *Mahābhārata* and *Rāmāyana* or pisodes therein, and so forth). The choice is to some extent ffected by local celebrity, and occasionally a political applica- on may be suspected.

Magazines.—The pabulum of the ordinary reader in India is ırnished by the magazine, containing essays, biographies and escriptions, short stories and serials, notes and not rarely llustrations. The total output is enormous; for in addition to ıe diversity of languages we have to reckon with the division f the Hindus into castes with their separate interests and claims. mportant castes prefer an organ (or competing organs) of their wn, which, along with the ordinary magazine material, will entilate any matters having a communal bearing. This litera- ure, therefore, presents no ordinary problem to the bibliog- aphers; somewhere in India it should be sedulously collected nd preserved, on account of the special biographical and sociological items which it contains. Schools and colleges have their organs (usually, however, in English). The mission- ary agencies, including the Salvation Army, issue innumerable periodicals of all grades, both in English and in the vernacular. Trades and the business world, professions (teaching, medicine, law, astrology, and so on), and grades of official service all con- tribute to the mass of vernacular organs. There are further a *Hindī Punch*, a *Hindī Graphic*, a Gujarātī and Marāthī *Tit-Bits*, and short story magazines; music and the stage are also represented by popular periodicals. Special interests, such as the cause of women, social service, co-operation, labour, economics, business, arts and sciences, travel, boy-scouting are similarly equipped. The chief vernaculars have usually at least one literary periodical of a fairly high type. In some cases they have flourished during long periods: the *Sentamil* of Madras is in its 24th volume, the Hindī *Saravatī* in its 25th, the Bengali *Bhāratī* in its 49th, the Gujarātī *Samālochak* in its 30th, the Marāthī *Vividhajñānavistara* in its 56th. The Urdū *Humāyun* also is of some standing.

Indian Poetry.—Modern Indian poetry, excepting transla- tions and adaptations of old Sanskrit works and themes, is usually in the form of short lyrics issued in small collections. Larger productions are for the most part collected works of single authors, or anthologies or the outcome of literary Eisteddfods. In the Hindī area the ballad of old style attains a greater length, as do Tamil *Kāvyas* on classical models. The poetry is generally erotic, ethical, philosophical or religious; but the satirical and controversial, and also, as we have seen, the political, claim a place. The verse forms are usually the traditional ones: only Bengālī, it appears, manifests original power in this direction.

Fiction.—Fiction on European lines is making rapid headway in India, and it is supplanting the old romantic tales, at least so far as prose is concerned. The Punjab may still reprint its *Hīr* and *Ranjhā*, *Rāja Rasālu*, etc., the Sindh its *Sassī* and *Punnūn*, the Urdū language its *Lailī* and *Majnūn*, and Hindī the tales of *Bhartarī* and *Gopīchand*. The novel is popular both in the form of the short story and of more substantial narratives; and it reflects all the varieties of subjects which have a vogue in English, historical, social, romantic, adventurous (including the detective novel). A new feature is the translation of well- known (including English) novels into several languages and the immense vogue of such popular stories as that of the Hindī *Chandrakāntā*.

Religious Literature.—Indian religious literature, in so far as it is not lyrical, philosophical, argumentative or philological, consists mainly of manuals of ritual for daily life (*dinacaryā*) or for particular occasions (marriage, burial, times and seasons, pilgrimages, vows), and of the stories therewith associated; for instance, the story of the Tulasī plant and that of Satya-Nārāy- ana are constantly reproduced. Benares takes a prominent part in such publications. Since each section, from the Vedic *Śākhās* downwards, must have its separate rituals, it results that the number of such publications is very great. Especially in southern India the innumerable local shrines have their little manuals, each setting forth the sacred legend and the rites to be observed. In the case of the orthodox and older sects, which have sacred texts in Sanskrit, this literature is often bilingual (at least), reproducing or copiously citing the originals.

We pass to a consideration of the activity in the reproduction of old canonical texts, with or without commentaries, for the purpose not of ritual but of study and edification. This accounts for a great mass of republication: in the Punjāb, for instance, there is a steady stream of thick volumes of *Selections from the Ādi-granth*. There are some valuable series of such canon- ical texts; the Jains have several and the Madhva doctrine of south India and the sect of the Mahārājas in Bombay have thus made accessible their chief writings. Important sects have usually one or more periodical organs, which, amid other matter, publish and comment upon their authoritative books. Many religious texts are, of course, not the property of any particular sect, and are therefore variously reproduced; and from

these we can hardly separate those which are of a philosophical rather than of a religious character: such are the Vedānta writings, the Madras periodical *Vedānta-dīpikaī*, and other philosophical journals; of wider scope, the *Siddhānta-dīpikaī* and the Marāthī *Tattvajñāna-vistara*. There are English periodicals belonging to one or the other of the above two groups: such are the *Vedānta-kesarī* of Madras, the Ahmadī *Review of Religions* and *The Theosophist* (which also has vernacular allies). Modern philosophy is represented by the Calcutta Philosophical Society, and by a now extinct Indian Philosophical Review published during several years in Baroda.

Philology.—Philology of a more general character is no longer in India restricted to one or two classical languages, Sanskrit, Prākrit, Tamil, Pahlavī, Persian, Arabic. There are societies which devote themselves to the publication of old texts in the existing vernaculars. The Bangīya Sāhitya Parishat, with its *Pattrikā* and its series of separate old Bengālī texts, has a very honourable record. The Tamil Sangam of Madura (which issues the *Sentamil*) is likewise distinguished. There are now other Sāhitya Parishats in the province of Bengal, and for Telugu also there is the Āndhra Sāhitya Parishat. For Hindī there are the Nāgari-prachārini Sabhā and certain Mandalas; for the Panjāb the Khālsā Tract Society; in Gujarāt, where societies for publication seem to flourish, the oldest is the Gujarāt Vernacular Society, while there is also a Sāhitya Parishat, and a Sāhitya-vardhana Society; in Marāthī an important series of editions of old poetry was published under the title *Kāvya-samgraha*. In literary history there are very important and extensive works by Rai Saheb Dineschandra Sen (Bengālī); Sir G. Grierson and the Misra brothers (Hindī); G. M. Tripāthī and K. M. Jhāverī (Gujarātī); Prof. W. B. Patwardhan (Marāthī); and Vīresalingam Pantulu (Telugu).

As to the general philological activity of India, it is hardly possible to draw any clear line between indigenous scholarship and that affected by European methods: the main aim and procedure of scholarship are the same everywhere, and whether a commentary is in Sanskrit or Bengālī or English seems to make little essential difference. Only comparative philology is new to India. This philological activity, wherewith is associated the investigation of archaeology and pre-British history, and from which we may exclude the astounding output of educational work up to the level of university text-books, is connected chiefly with organisations of some kind. The Govt. of India itself maintains an Archaeological Survey, which publishes annual reports in the several provinces and at headquarters, and splendid quarto and folio monographs on special matters, as well as a periodical relating to Epigraphy (*see* ARCHAEOLOGY: *India*). This example is followed by Indian States, Mysore, Travancore, Hyderabad, Kashmir. Several provincial governments have published catalogues of Sanskrit MSS. (Bengal, the United Provinces, Bombay, Madras, the Central Provinces); States, small and great, Kashmir, Nepal, Baroda, Mysore, Travancore, Alwar, Bhaunagar, have taken their part. Important series of Sanskrit or Arabic texts, too, are officially edited in Bombay, Mysore, Travancore, Kashmir, Hyderabad, Baroda.

After the Governments we may mention the universities, colleges and libraries as active in the publication of texts and researches (the universities of Calcutta, Madras, Lahore, the Benares Sanskrit college, the Maharajahs' College, Vizianagram, the Bankipur public library). Important journals are issued by societies (the Asiatic Society of Bengal, which has also published under the title *Bibliotheca India* a vast collection of Sanskrit, Arabic, Persian and Tibetan texts; the Bombay branch of the Royal Asiatic Society, the Mythic Society of Bangalore, the Bihar and Orissa Research Society, the Hyderabad Archaeological Society, the Bhandarkar Oriental Institute); and some, like the *Sanskrit Research*, the *South Indian Research* and the *Jain Purātattva*, are occasionally started independently or by religious bodies. The books issued by authors, editors, or individual publishers are, however, more numerous and on the whole the Indian publication of philological, historical and archaeological matter relating to pre-British India quite dwarfs in bulk all that is done outside. Much is highly meri rious, and some of it is fully equal to the best production Europe. The monumental *Linguistic Survey of India*, edited Sir G. Grierson for the Govt. of India, is now (1926) alm completed (*see* PHILOLOGY).

History.—For educational purposes and general readi many short histories of India, of England and of other countr are produced both in English and in the vernaculars. B original research and independent judgment will be found chie in the few first-hand histories of particular states and dynasti and with a few exceptions (such as the Marātha researches Rai Bahadur, D. B. Parasnis and the volumes of Marāt records published by the Marātha Historical Society of Poor the volumes of Professor Sarkar concerning Aurangzeb, t biography of Jahāngīr and the *Journal of Indian Histo* published by the Allahabad University School of Indian Histo the works on South India by Professor Kumāraswāmy Aiyang Subrahmanyam Aujar and a few others) in the works of Englis men. The valuable monographs produced in Europe or Inc by Indian scholars relate for the most part to ancient times, a are less historical than philological. Many volumes of recor and calendars in English have been published by local gove ments; the gazetteers also are replete with historical inform tion not absorbed in formal histories; and there are several soc ties, the Bengal Historical Society, the Panjāb Historic Society and the United Provinces Historical Society, whc journals are composed of original matter.

Biography.—Biography, including autobiography, is now po ular in India, taking chiefly the form of short memoi which in the case of princes and of important religious leade such as Debendra Nāth Tagore and Dayananda Sarasvatī, m attain a considerable length; so also in the case of historic personages, Sivājī, Jahāngīr and others. A very favourite for of which there are old examples, is the serial biography, contai ing lives of saints, lives of famous women, hierarchical, dynas and family biographies. Valuable work of this kind has be done in regard to the Tamil and Telugu saints and poets, a the poets of Bengāl and Gujarāt. Small volumes of "pris reminiscences" have been published by political offenders, a the number of short "lives" of popular heroes, such as M Tilak, Mr. Gokhale and Mr. Gandhi, is beyond countin The old form of biography in verse is still favoured in relati to saintly and historical characters: naturally, it has aims oth than information and research. Many Indians, from prince downwards, have written accounts of their travels, whether England, on the continent of Europe, in America or in oth countries, including the Far East. But India itself furnish rich material and occasions for travellers' experiences, especial in connection with its shrines and pilgrimages, so that such titl as *Bhārata-bhramana* quite naturally recur. (F. W. TH.)

INDIANS, NORTH AMERICAN (*see* 14.452).—The Indians a no longer warlike nor to any extent resistant of the white man methods for their civilisation.

I. IN THE UNITED STATES

The United States assumes that health, education and industi are essential to the Indian's self-support and citizenship. Accor ingly, the Federal policy is to hasten his advancement and pr tect his personal and property rights. By Act of June 2 1924 a Indians within U.S. territory not already citizens were made s Under the administration of the Bureau of Indian Affairs the are provided health supervisors, school and agency physician field matrons, nurses and travelling dentists, whose duties def nitely pertain to the physical welfare of the Indians, and ho pitalisation is widely maintained against all forms of disease.

Education.—For education, the Federal Govt. conducts 14 day schools, 59 reservation and 18 non-reservation boarding schools, having an attendance of over 25,000 pupils. The cours of study prescribed combines scholastic with such industria training as is well adapted to Indian needs and temperament The aim is to prepare girls to become good housewives an mothers, and to fit boys for practical farming or to give ther

ch knowledge and practice in mechanical industries as will d to skilled workmanship. The day-schools carry six grades, d the boarding-schools six, nine or 12 grades. The object of e latter is to embrace six elementary grades, a junior high urse of three grades, and a senior high course of three addi- nal grades. From the more advanced schools students may quire full training in such chosen trade or occupation as may alify them to engage in remunerative pursuits upon their aduation. In all Federal schools prominence is given to hy- ene, to moral conduct, to religious culture in any Christian nomination and to the practice of thrift. State public schools ve become accessible generally to Indian children, and in these hools there are over 34,000 enrolled. Over 7,000 are received mission and private schools. Approximately 87% of the Indian ildren of the United States are enrolled in some school. There s been a steady increase in the number who speak, read and rite English.

To promote reservation industries there are maintained dem- nstration and experimentation farms, and several hundred rmers, stockmen and assistants are employed in giving prac- cal instruction in modern methods of agriculture and the up- reeding and handling of live stock. Loans have been made to nergetic Indians from tribal or public funds as initial capital, nd these measures have been generally successful. Special tention has been given to the reclamation of arid and semi-arid ndian lands, resulting thus far in a total area of lands under nstructed works approximating 636,000 ac., with an ulti- ate area approximating 1,370,000 acres. The annual crop alues derived from these irrigated lands are equal to all prior st. Tribal herds of sheep and cattle have been maintained on number of reservations with financial profit, but chiefly to ncourage individual ownership and enterprise.

Alaska.—The affairs of the Alaskan natives are supervised by he U.S. Bureau of Education. Eighty-five schools are conducted y six superintendents, nine physicians, 27 nurses and 157 teachers. ive hospitals are maintained. The work is carried on in 85 villages attered along the coast and on the great rivers. Imperfect trans- ortation and climatic conditions render the service very difficult, ut the progress is substantial. Despite the heavy mortality from isease, the population has slowly increased to approximately 27,000. he Bureau of Education has established three industrial schools, ituated at Eklutna, 28 m. north of Anchorage, on the Alaska Rail- oad, at Kanakanak, on Bristol Bay and at White Mountain, on Vish river, 25 m. from Golovin, on Norton Sound. Instruction is iven in carpentry, in boat-building, mechanical and marine engineer- ng, for boys; and for the girls: home-making, nursing and sanita- ion. When the Alaska school service was established, about 1885, he aborigines of Alaska were in primitive conditions, which have radually disappeared. In many of the villages, the old huts have been replaced by neat well-furnished houses. Many Indians are employed by the great canneries of southern Alaska. They own nd operate fleets of power-boats, which are of service in transport- ng fish from the fishing grounds to the canneries. Some find employ- ment in the mines, while others are pilots, trappers, storekeepers, oggers or ivory carvers. In northwestern Alaska the reindeer ndustry is the basic industry, introduced to furnish a vocation that guarantees food, clothing and transportation. Herds were found in 1926 near all of the principal native settlements of western Alaska and at various other points. So rapidly have the herds increased that the total number of reindeer in Alaska was in 1925 estimated at 350,000, of which about 255,000 are owned by the natives.

General Progress.—Under the policies outlined, the North American Indians have made unusual progress during the years 1910–26. Their population is greater than at any time in the preceding half-century. They depend less upon "medicine men" and more upon medical science and sanitation. As compared with earlier periods, they are giving more attention to permanent homes; are less nomadic and superstitious. The women are better housekeepers, and infant mortality is decreasing. The day of paint and feathers and blanket garb has almost passed away. The younger school-trained element is creating a new leadership, manifested in changing habits, customs, industrial pursuits and social life. Marriage by tribal custom is yielding to legal rites, and crime is diminishing. Substantial advancement is noticeable in agricultural operations and stock raising, in the use of modern machinery and methods and in large gains in individual funds.

The acceptance by the Indians of American principles of government and civilisation was in some sense disclosed by the World War. In the United States the number of Indians in military service was more than 10,000, three-fourths of which represented voluntary enlistment. In Canada the number exceeded 4,000, all of whom entered voluntarily. The percentage of Indian male population of military age in the World War was probably equal to that of the whites thus engaged, and their proportion of volunteers even greater. They were distributed almost entirely in white organisations, and were highly commended by their officers. Indians ineligible for war duty were active in Red Cross and other relief work and responded to emergency demands for productive labour. (C. H. Bu.)

Comparative Information About the Indians in the United States, Exclusive of Alaska

Population and Citizenship	1911	1925
Population	322,715	349,595
Indians receiving allotments of land	164,215	245,521
Indian citizens of the United States	179,830	349,595
Educational and Vital Conditions	**1911**	**1925**
Indian children eligible for school	63,411	77,597
Indian children in Federal schools	23,647	25,706
Indian children in state public schools	11,000	34,452
Indian children in mission and private schools	4,750	7,280
Total Indian children in all schools	39,397	67,438
Capacity of all schools for Indians	43,015	64,910
Hospitals and sanatoria maintained	50	84
Capacity of hospitals and sanatoria	1,268	2,573
Indian patients treated	8,408	27,775
Indians given medical examination	42,645	83,306

II. IN CANADA

The Indians in Canada numbered in 1923 about 109,000 and are now slowly increasing. They are regarded as minors under the law and are administered by the Department of Indian Affairs under the Indian Act, whose aim is to promote the advancement of the Indians in the arts of civilisation. If, and when, enfranchised they lose the advantages of protection by the Department and are merged in the general population. Agents, 114 in number, have been appointed to encourage the Indians to settle in the Reserves set apart for them which amount to 4,911,259 ac., valued at $52,941,629. The capital of the Indian Trust fund on March 31 1923 amounted to $11,516,213. The attendance at the 340 schools provided for them was 66·5% of the pupils enrolled—6,931 boys and 6,792 girls. The total income of Indians for 1923 from all sources was estimated at $9,940,349.

INDO-CHINA, FRENCH (*see* 14.490), French colony in Asia, consisting of the colony of Cochin China (under a governor, with 20 provinces, each under an administrator); the four protectorates of Tongking (23 provinces), Annam (16 provinces), Cambodia (13 provinces), Laos (10 provinces), each with a *resident supérieur;* and the territory of Kwangchow Bay, leased from China for 99 years, under an *administrateur en chef.* Its area is 299,621 sq. m. and the population (1924) 19,624,000, of which 26,137 were Europeans (24,882 French) and 14,522,000 Annamese.

Political History and Administration.—Indo-China contributed two fighting and 17 labour battalions during the War, 48,900 other war workers and much war material. It contributed largely (Europeans and natives alike) to the war loans. Political troubles during the War were trifling, in spite of enemy agitation. The governor-general during the War was M. Ernest Roume. M. Alexandre Varenne, a Socialist Deputy, was appointed in Nov. 1925. His arrival coincided with the accession of a new emperor in Annam. Relations between the emperor and the French authorities were settled by the convention of Nov. 6 1925. The *résident supérieur* of Annam has been granted permanent authority by the emperor to consult the representatives of the people and to discuss with them any important reform or questions which may arise.

The powers of the governor-general have been reinforced by a decree of Sept. 2 1920. His local decrees (*arrêtés*) have real legislative force. He can dissolve or suspend the *conseil colonial*. He fixes taxes and contributions (except customs duties) leviable in the colony as a whole, or locally, with the advice of local authorities and vote of local chambers. The *conseil supérieur* (*see* 14.491) has been superseded since Oct. 24 1911, by a council of government with very similar duties and composition, and thus still almost entirely official; but it now includes *délégués* (elected by French votes) for Tongking, Annam and Cambodia; native representation is increased from four to five.

In Dec. 1924, the governor-general, Martin, announced a sweeping reorganisation of the whole system. The council will bear the name " congress of the Indo-Chinese union " and consist of 44 members (27 representing the French, 17 the native element) elected by the local elective assemblies of Cochin China, Tongking and North Annam, Annam and Cambodia and Laos. It will have extended financial powers. The old council and its committee will continue under new names and with reduced membership; the new congress will send delegates to both. M. Varenne will probably bring the system into force. The colonial council in Cochin China has been reorganised, its powers extended, and its electoral and native elements strengthened. Natives now have five-twelfths of the representation. The native franchise has been radically reorganised; it now includes all male native French subjects with a clean judicial bill who possess either a property qualification (payment of a land tax of 21 piastres, or a corresponding dealer's licence) or a capacity qualification gained by possession of educational diplomas, exercise of certain public functions, or " services rendered to France." This franchise gives the vote to very many small peasant proprietors; abolishes the headman oligarchies; and amounts to a far-reaching social and political revolution in the villages.

In the protectorates the councils have been democratised on similar lines and natives given an increased share in self-government. This is, it is true, limited mainly to budgetary and fiscal matters; but the change has worked smoothly; the natives have often given sound advice on technical questions. They are keenly interested in self-government, education, etc. There are also native provincial councils and native representation in the municipalities of the large towns. The system will be extended under M. Varenne.

Education and Culture.—The educational movement is parallel to the political, but as the province has over 2,000,000 children of school-going age much remains to be done. In 1924–5 primary and secondary French schools had an attendance of 2,525 (about half natives); the 3,395 Franco-native official schools, an attendance of 213,977; the private schools (native and missionary) one of 99,790, the expense on education being 6,000,000 piastres (1924). The 1917 public instruction code laid down the principle of the teaching of French, even in elementary schools, but there are reservations, defined in the *arrêté* of Sept. 18 1924. French is taught with the native tongue during the first three years of primary instruction, and is the obligatory teaching medium of the last two, which are, however, attended by only 23% of the native pupils. The " University of Indo-China " at Hanoï is a high school with many branches giving practical and theoretical training; it aims at turning out competent native assistants for the different French administrators, and training lawyers, planters, traders and manufacturers. Most of the students are Annamese. The *École Française d'Extrême Orient* at Hanoï, under the patronage of the *Institut de France*, conducts valuable research work in native art, history and language. It has a fine library and museums in Hanoï, Tourane, Saïgon and Phnom Penh, and has done epoch-making work in its *Inventaire* of Cambodian and Cham monuments, its excavation of the ruins of Angkor, etc. (see its two vols., *L'École Française d'Extrême Orient depuis son origine jusqu'à 1920* (1922) and its semi-annual *Bulletin*).

Budget.—The general budget, under 24,000,000 piastres in 1901, was 64,602,000 piastres in 1925, almost all drawn from indirect taxation. Local budgets (drawn from land tax, etc.) were 48,978,000 piastres. Each spent about 30% of receipts public works. Reimbursements to the French budget for m tary expenditure reached 10,000,000 fr. in 1925. The debt only 400,000,000 fr., absorbing 2·8% of the total revenue.

Defences.—The divisional general commanding troops in Inc China (Hanoï) has under him three brigadier-generals (Ton king two, Cochin China). Troops consist of two regimer French Colonial Infantry (Tongking, Cochin China); two b talions of the Foreign Legion; two regiments artillery; t detachments French gendarmes; two flying squadrons, whi also do excellent work in mapping and fiscal service. There a four native regiments of tirailleurs in Tongking, one in Coch China. There are five " military territories " on the Chine frontier and in Laos. The medical service is relatively importar and helps in the general sanitary organisation. The navy under the command of a *capitaine de vaisseau* (Saïgon). T local squadron has been reduced almost to nothing since t War. There is question of handing the Saïgon Arsenal over to private enterprise.

Commerce, Agriculture, Industry.—Although there is still plethora of French officials (about 4,600), especially in the low ranks of the Customs and Excise and similar services, there a over 3,000 French non-officials (males), traders, manufacture and planters. In 1922 there were from 250–300,000,000 f invested in private French enterprises. Rice remains the stap product; 4,750,000 ac. in the Mekong Delta were under ri in 1920. There were 62,500 ac. of rubber plantations and oth tropical plants were cultivated successfully. The anthraci mines of Hongay and Dongtrieu produce 1,000,000 tons ann ally. The production of zinc (40,000 tons) and phosphat (20,000 tons) is important. In 1925, 33,833 hands were engag in mining (329 Europeans). The presence of coal has given bir to a rapidly expanding industry in the Red river delta, whe there are large cement works, brick, tile and ceramic work three naval yards (beside the Saïgon arsenal), two importa French river steamer companies, three large cotton spinni works and minor industries. Home industry (lace-making, etc employs many native women. The piastre, worth 2·50 fr. befo the War, was in 1926 worth 15 fr.; but on a piastre basis, expor have increased by 77% since 1900, imports by 14% only. Sin the end of the War exports are some 164,000,000 piastres ann ally, imports 132,000,000, rice being the main article exporte (maximum, 2,325,000 tons in 1921). Imports to France fro Indo-China in 1925 were 612,000,000 fr., exports 760,000,000

Communications.—There are now 2,075 km. of railways. A important line, 126 km. long, is planned which will run fro Tanap to Thakhek and link up Central Laos with Central An nam. Tourist traffic is now possible and encouraged. Over 20 000,000 piastres were spent during the years 1919–25 on dredgin irrigation, etc., and 50,000,000 piastres on roads, of which the are now over 30,000 km. (11,000 metalled, 9,000 made possib for motors in the dry season).

BIBLIOGRAPHY I.—Official and semi-official publications: *An nuaire général de l'Indochine* (Hanoï annual); *Rapports au Conseil c Gouvernement* (annual); *Bulletin Economique de l'Indochine* (ever two months with monthly statistical annexes); *Bulletin de l'Éco Française d'Extrême-Orient* (bi-annual). Among the publications c the school must be noted: *Inventaire archéologique de l'Indochin* 1. Monuments du Cambodge, 3 vol. with atlas by Lunet de l Jonquière (Paris, Leroux 1902–12); 2. Monuments Chams d l'Annam, 2 vol. by H. Parmentier (*ibid.*, 1909–18); *Bibliothec indosinica*, by H. Cordier, 4 vol. (Paris, Leroux 1912–5), an ac mirable bibliography of books and papers on the whole Indochines Peninsula; *Mémoires du service géologique de l'Indochine* (Hano Imprimerie d'Extrême-Orient); *Revue indochinoise*, 1925, xxviit year (*ibid.*); Henri Brenier, *Essai d'Atlas Statistique de l'Indochin Française* (Hanoï, 1914), 88 charts, 38 maps, with commentaries *Service géographique de l'Indochine*, Map Scales: 1/1,000,000 1/500,000; 1/100,000; 1/25,000 (deltas); *Bulletin des Amis du Vieu Hué* (articles on Annamere history, archaeology and art); J. d Galembert, *Les Administrations et les services publiques Indochinoi* (Hanoï, 1924); Henri Lecomte, Membre de l'Institut, *Flore Général de l'Indochine* (Paris, in course of publication); *Les Bois d'Indochin* (in preparation 1926). NDUSTRIAL ASSURANCE: *see* INSURANCE, SOCIAL.

NDUSTRIAL EDUCATION.—In the United States special ining for industry in regularly organised courses is of recent gin. It was common before the World War and before re- ictive legislation checked the influx of immigrants from Europe American industries to secure most of their skilled workers m the Old World. The pressure of industrial competition manufacturers to see that America must do something to in workers, and the labour situation during and since the r led to a rapid expansion of industrial education. The War o led to a complete redistribution of the men and women o were engaged in industry and greatly stimulated agencies oted to the training of adults. The Federal Govt. attempted ring the period of demobilisation to provide for the industrial djustment. Especially was the effort made to care for abled and partially disabled soldiers by training them in ms of work suited to their physical and mental abilities.

The first serious effort in the United States to provide indus- al education in public schools was made by the State of Mas- husetts in 1905. A commission was appointed by the Gov- or under the authority of the Legislature to make a report on matter of industrial legislation. This commission was fol- ved by a second, and the final outcome in 1913 was a code of ws providing for state-aided and compulsory vocational edu- ion. In 1911 Wisconsin adopted a law creating for the state d for local districts, school boards in control of vocational ucation separate from those in charge of the common schools. is radical step has not been imitated in other states.

The Federal Board for Vocational Education.—In 1917 the ngress of the United States was persuaded by a group of in- strial managers and by a small group of educators, chiefly se interested in the Massachusetts and Wisconsin experi- nts, to set up a Federal board known as the Federal Board for cational Education, which was the disbursing agent for a ge Federal appropriation to be distributed to the States on dollar-for-dollar arrangement for the purpose of encouraging lustrial courses, especially in high schools. This board is au- orised to supervise courses in agriculture, commercial subjects, me economics and industrial or trade courses. The latter are w provided in public schools either in all-day trade schools, all-day courses in technical high schools, in part-time courses continuation schools, in part-time courses on the co-operative an or in night schools, and in so-called extension classes or portunity schools, where workers come for training when not oc- pied in wage earning. Much of the industrial training outside the all-day schools is arranged so as to be available for adults.

Statistics.—The number of centres to which Federal support as been given in successive years and the registration in indus- ial courses in these centres are shown in the following tables:—

Trade and Industrial Schools

	Evening	Trade Extension	General Continuation	All-day
1918	300	341	..	168
1920	435	119	322	199
1922	620	150	506	237
1924	776	238	582	279
1925	816	225	556	297

Number of Pupils Enrolled

	Evening	Trade Extension	General Continuation	All-day
1918	46,333	53,005	..	18,596
1920	48,354	17,159	98,082	21,224
1922	66,477	33,106	167,911	31,390
1924	84,973	35,475	256,133	33,262
1925	86,540	30,400	265,335	39,666

Relation to General Education.—The tendency at the time the Federal Board for Vocational Education was organised was to make a sharp distinction between general education and academic education. This tendency was strengthened by the example of Germany, which was regarded before the War as the most successful nation in developing industrial education. The tendency in 1926 was to unite trade training and general education rather than separate them. Many high schools have made industrial courses a part of their regular programme. On the other hand, trade schools have found that it is necessary to include general courses if young people are to be properly trained for life in a democracy. *See* also COMMERCIAL EDUCATION.

(C. H. J.)

INDUSTRIAL PSYCHOLOGY.—Industrial psychology may be defined as the study of the conduct of men and women in their capacity as wage earners. It aims at describing and explaining all those activities by means of which a person adjusts himself to his economic environment; hence it must take into account the fundamental elements of man's constitution, his innate tendencies and their expression in thought, feeling and action both on the conscious and unconscious level, as well as his acquired aptitudes. As yet, only a tentative beginning has been made, so that we are far from even an approximation to scientific generalisation.

HISTORY OF THE SCIENCE

The development of industrial psychology has been largely determined by its history. Prior to 1914, psychologists concerned themselves but little with industrial problems. A few writers occasionally saw a possible industrial application of some psychological generalisation; and in 1913 Münsterberg[1] made a more ambitious attempt. Industrial development had been governed by the claims of machinery, rather than of man. The enormous improvement in machinery during the 19th century, the studies made in the natural sciences, the growing knowledge of the mechanism of the body, all tended to focus general interest on man's likeness to a machine. The phrase "the human machine," which is rightly applied to part of his structure, became synonymous with man himself rather by implication than by design. The outbreak of the World War, with its urgent demands for increased production in all departments of activity, brought home to society the futility of considering the worker merely as a machine.

Industrial operations, as usually conducted, had been implicitly based on a crude mathematics. If 6 units of work could be done in one hour, then 6 x 8 would be done in 8 hours, 6 x 12 in 12 hours. The physiological necessity for sleep prevented the complete working out of this principle. Up to about 6 or 7 hours, according to the nature of the work, there seemed nothing obviously wrong with the calculation; when however, the problem was one of 12 hours, the discrepancy between the facts and the calculation challenged investigation. Though it was not then recognised, that stage marked an epoch in the history both of psychology and of industry. The focus of interest was changed from the machine to the worker of the machine, and the assistance of psychology, hitherto looked upon as a somewhat recondite study, was invoked.

The Work Curve.—Previous work of a more or less theoretical character into problems of fatigue suggested the lines of investigation. Hence the earliest work in industrial psychology was concerned with fatigue. As the time was one of urgency, the problem had to be dealt with practically, and the only measure to hand was the one which had prompted the inquiry, viz., the work curve, obtained by computing and graphing the hourly output records of numbers of workers. The reproach is sometimes made against industrial psychology that it is primarily interested in output. The truth is that output happens to be a convenient measure. Psychology's real interest lies in what is measured.

Hours of Work.—Thus the earliest systematic inquiries of industrial psychology concerned the problem of the 12-hour day in munition factories, and used as data the records of large

[1] H. Münsterberg, *Psychology and Industrial Efficiency* (1913).

numbers of people working over long periods. Comparisons were made between groups of people working a 12-hour day and other comparable groups working a 10-hour day.[1] In many processes the results of the latter groups showed such an increase in hourly output as more than counterbalanced the shorter time available for production, so that the total production was actually greater than when the hours of work were longer. Similarly lost time and sickness were found to diminish with the shorter working day. When hours are shortened, a long period elapses before adaptation to the new conditions is fully obtained; on the other hand, when hours are lengthened, there is sometimes an immediate reduction in hourly output.

Since the War, researches along these lines have been pursued in such different occupations as: charging of blast furnaces, silk weaving, shell making, metal-polishing, tinplate manufacture and in the processes of collar machining, folding and shirt ironing in the laundry trade. The curves of the output of the average worker, when graphed, usually assume the same general shape, viz., a rise at the beginning of the spell, a period of relative stability, and a fall at the end. The interpretation of these empirical facts cannot yet be given. Slight variations occur according to the arrangement of the hours of work, but the type remains characteristic of many industrial processes. Muscio, experimenting on women medical students doing mental tests, obtained similar curves.

Rest Pauses.—An important innovation stressed by the industrial psychologist has been the introduction of short rests, in the middle of a working period, of about 10 or 15 min. duration. These regular breaks are technically known as rest pauses. It is sometimes argued that frequent irregular rests are invariably taken by the workers, either voluntarily or because the supply of work fails, and that regular rest pauses are therefore not required. Where, however, direct experiment has been possible, it has shown that the organised rest pause is the better working arrangement.

The observations of H. M. Vernon for the Health of Munition Workers' Committee proved the advantage of breaking up working spells, and since then it has been verified in the boot industry, in metal-polishing, in celluloid-polishing, in shirt ironing, in sweet-packing, in handkerchief-folding and in stamping lids. The introduction of a rest about the middle of the spell of work improves the output as a rule by about 5%, and in some processes it affects advantageously the period preceding the rest. Not only is the work improved, but the regular rest is much appreciated by the worker. The probability is that the improvement is largely due to changes in feeling; most people can face with equanimity and possibly enthusiasm the prospect of two hours' work at the end of which will come a period of free time, but to face four or five hours of unbroken labour is depressing.

The subject of rest pauses has not yet been exhaustively studied, and particular cases need particular study; still the above statements seem to be valid in general. Exactly when a rest pause should occur must depend on the nature of the work, while the amount of actual increase in output will vary with the relation of the human factor to the machine factor in the particular process.

Physical Environment.—Among other influences which have been shown similarly to affect the worker and have been effectively measured by means of the output curve are improvements in lighting, heating, ventilation and seating. (*See* FACTORY AND WORKSHOP LAW; FACTORY DESIGN; OFFICE MANAGEMENT.)

MOTION AND TIME STUDY

At an early stage the young science of industrial psychology had to encounter the previous application of quasi-scientific methods to industry, initiated in America by Taylor and Gilbreth. Their general object was to study the nature and rate of the movements made by a worker in order to eliminate the unnecessary ones. This is technically known as motion and time study. Unfortunately this study had resulted in imposing on all the so-called "one best way," obtained by analysing the r[illegible]ements of the quickest workers. So unnatural a procedure a[illegible]ened much criticism and no little resentment. It is not irrel[illegible] to note that the movement originated with engineers, not [illegible] psychologists.

Properly conducted, motion and time study are but sp[illegible] applications to industrial processes of the laws of habit forma[illegible] Young learners pick up, by watching proficients, many ac[illegible] of industry; with practice they evolve a commendable copy[illegible] uncritically they may adopt some unnecessary movem[illegible] which, while apparently not interfering with the work, ma[illegible] come fixed; the result is that the worker develops mus[illegible] habits harmful to himself, or fails to attain a speed commens[illegible] with his real ability. Just as the skater, swimmer or golfe[illegible] proves by expert teaching, itself the resultant of careful stud[illegible] does the industrial worker. In such varying trades as [illegible] weaving, metal-polishing, chocolate covering, it has been f[illegible] that by systematising movements and by training novices i[illegible] relevant motions, a saving of energy results, which is ad[illegible] vantage to all concerned. Faulty methods of learning are [illegible] only a hindrance during the learning period, but there is als[illegible] invariable tendency for the worker to regress to them u[illegible] certain conditions, even when they are apparently overc[illegible]

The aim of Taylor and Gilbreth, in standardising the time [illegible] method taken to perform a task, was primarily to reduce the [illegible] of production, and they also had in mind the welfare of [illegible] worker and higher wages. From the worker's point of [illegible] however, the drawback of their system was that it produc[illegible] feeling of being always keyed-up. From the psycho-physiolo[illegible] point of view it was based on the fallacy that the shortest [illegible] speediest movements were necessarily the least tiring and [illegible] the best style of movement could be obtained from comb[illegible] a number of best movements adopted by different worker[illegible] the study of industrial processes in relation to the worker [illegible] be scientific, it must consider the whole of the conditions, [illegible] part; it must regard the worker as a human being, not as the [illegible] former of a limited set of movements.

LEADERSHIP AND MONOTONY

Important though the material environment undoubtedl[illegible] no workers can do their best unless the general mental env[illegible] ment is right. Not even the very best material conditions [illegible] result mechanically in good work, and sometimes even [illegible] material conditions can be nullified by good mental condit[illegible] By this is understood the conditions governing the group [illegible] whole, dependent primarily on the efficiency or otherwise [illegible] leadership. Industrial life is often criticised for failing to su[illegible] that effective stimulus of working for a common end, whi[illegible] more obviously evident in the army. Actually there are [illegible] factories where there is this sense of working for a common en[illegible] well as for individual wages, than those not familiar with [illegible] inside working of factories are aware of.

If, as McDougall[3] asserts, "the personalities of its lea[illegible] more effectively than any other factor engender national u[illegible] and bring it to a high pitch," it is no less true that a factory [illegible] its corporate unity to the personality of its leader and [illegible] deputies. The time may come when it will be possible to tes[illegible] leadership as it now is for intelligence; at the moment the p[illegible] lem has only been formulated. The qualities of leadership [illegible] required by all those in charge of others, and there is no cor[illegible] tion between ability to do a job and ability to superintend ot[illegible] doing it. To the psychologist there are certain types, alr[illegible] neurotic, whose symptoms find expression chiefly in their [illegible] tions with others. The person who reacts always to the emo[illegible] aroused in himself by a situation and not to the situation it[illegible] the inevitable "nagger" who can never govern easily bec[illegible] he is always at war with himself, the "obsessional"[4] whose [illegible] session can be readily touched up by the work—these repre[illegible]

[4] M. Culpin, *The Nervous Patient*, p. 92 (1924).

ew whose emotional development makes life much harder some of their subordinates and unbearable for others. If ir other qualities, *e.g.*, their business acumen, are so outnding as to justify their position, then they need as emotional erpreter someone of different temperament to neutralise their re pernicious effects.

A good leader should possess vitality, sympathy, justice and nour, as well as knowledge of the work. The emotional, and a corollary, the physical effect on subordinates of different es of leaders is patent throughout industry. Where the comnds of one are cheerfully obeyed, those of another arouse culent antagonism or sullen acquiescence. Can anyone doubt effect on the health, happiness and efficiency of the workers? ny authorities are unwittingly the cause of the sick leave they plore among subordinates.

Monotony.—In addition to the effect of the leadership, one to accept the fact that in modern industry, with its subision of labour, a large number of people are employed in eating the same limited set of movements for hours, days, nths and years. This "repetition of movement" is often oneously called monotony. Literally "monotonous" means f one tone;" it suggests absence of change and refers rightly the general mental atmosphere and not to the movements of the worker. Repetitive movements must either be studied as h, in which case they belong to the psychology of habit formaon, or else put in their complete setting, including, at least, the petition work, the varying amount done as the hours go on, opinions of fellow workers and authorities about that work, ysiological changes, emotional changes, and the collective life the factory. The total reaction at any given moment will be reaction to a composite situation which constantly changes. The worker on one process often stigmatises some other pros as monotonous, when to the observer there is nothing to oose between them. There are compensations too in many ocesses if one studies the worker as a human being and not rely as the performer of a repetition process; *e.g.*, some workers erience a sense of power in operating a large or a delicate chine. It is not suggested that repetition work is good in elf; but merely to describe the repetition work as monotonous d to imply that such description embraces the whole psychoical situation, is misleading.

Vocational Guidance and Selection

Observation of workers shows that in particular posts some are ich more successful both subjectively and objectively than ers. Hence arises the question of vocational guidance, which st be distinguished from vocational selection, a simpler oblem. The latter problem sets out to select a worker to fit e job, the former to select for a given person (usually an olescent) that job most suited to his capacities. This theoretily presupposes a knowledge of the person, a knowledge of all ssible occupations, and a power of relating one to the other. hose who have done most work in this field are convinced that e most useful measure of a person is his general intelligence.

Mental Ratio.—By suitable tests it is possible to gauge with a gh degree of accuracy the intelligence of any child, and to exess it in a quantitative form, known as the mental ratio. This mains fairly uniform throughout the years of growth, and born intelligence does not develop to an appreciable extent yond the age of puberty. It is the amount and kind of knowlge and interests that separate the adult from the child, not the elligence with which he deals with that knowledge and those erests. To put a child of a high level of intelligence to a job quiring little, is wasteful, while the reverse process is futile; oreover, the one provokes discontent, the other worry.

Temperament and Character.—In other directions, viz., the measement of temperamental and character qualities, less advance s been made. In this field, observation and interpretation are ll the only methods available. There are some occupations here people of a particular temperament are more likely to come inefficient and break down than in others.[1] This temperament is characterised by a disproportionate development of fear in some form. Whether this is due to its innate strength or to an environmental repression, or both, cannot be adjudged yet. The sufferer shows over-anxiety concerning things he cannot alter, is unduly sensitive to the opinions of authorities, etc. Sometimes the symptoms appear in a more objective form, masking their actual subjectivity, so that the focus of anxiety appears outside the sufferer, who, with more than normal frequency complains of machine trouble, unsuitable keys (in telegraphy), etc.

Such people, in the interests of themselves, their fellow-workers and the work, ought to be diverted from occupations where their mental make-up cannot fail to be expressed in the work. If they enter such occupations as telegraphy or dispensing or even coal-mining they will almost certainly break down: the breakdown will be attributed to overwork, although actually the over-work may have rather subjective than objective reality. If there is an occupational disease recognised as such, the problem is still further complicated.[2]

When the qualities of the applicant for a job have been assessed and the requirements of various trades are known, it is possible to advise a child as to what he may most advantageously take up.

Organisation.—A vast field is however still untouched. Most of the studies made so far relate to those aspects of industry which are primarily means to an end, not ends in themselves, and even in this limited sphere there is much to be done. Little is known as yet, for example, about the organiser and his organisation. It is obvious that the organisation of a big business is no mere rule-of-thumb working out of principles gained by even a scientific analysis of other places; it has some of the qualities of a work of art, and the attitude of mind of an original organiser is akin to that of the artist. No real appreciation of the field of industry is possible without a recognition of this.

INDUSTRIAL RELATIONS (*see* Arbitration and Conciliation, 2.331).—The term "industrial relations" is used to denote the relations between all those who are engaged in industry. The history of industrial relationships up to the outbreak of the World War is a history primarily of conflict. The workpeople had only achieved something like equality of bargaining power by dint of unremitting struggle, first for the right of association, then for the recognition by the employers of their organisations as their authorised mouthpieces.

Strikes and lock-outs, when they occurred, were increasingly stubborn as the fighting resources of the trade unions multiplied, and increasingly devastating in the economic losses which they entailed to both parties as their scope became magnified. In order to prevent the outbreak of these deadly contests, the State was compelled to set up machinery for conciliation and arbitration, and statesmen were forced to pay increasing attention to industrial questions in drafting their political programmes. But in the heat of this long-drawn-out battle between the two opposing forces the essential community of purpose which should have united them was almost completely forgotten by both sides. That both derived their living from industry and that both would perish if it withered, was a thought which seldom occurred either to Capital or Labour as a whole, the one intent upon maintaining the inalienable right of the capitalist to undivided ownership and responsibility, the other on demanding some form of

[1] M. Culpin, *The Nervous Patient*, p. 175 *et seq.* (1924).

[2] The serious nature of this is well brought out in the occupational disease known as Miners' Nystagmus. *Cf.* (1) Special Report Series, Medical Research Council, Nos. 65, 80. *Reports of the Miners' Nystagmus Committee*, London (1922–3). (2) W. Eddison, "Psycho-neurotic aspects of Miners' Nystagmus," *Brit. Jour. Med. Psychology*, vol. 3, pt. 2 (1923). (3) W. Inman, Critical Notice, *Brit. Jour. Med. Psychology*, vol. 3, pt. 3, pt. 4 (Cambridge, 1923).

socialisation, a term with many and fluid meanings but generally interpreted as implying the ownership and control of industry by the State. It is true that both parties counted in their ranks men who held that a new order, substituting co-operation for conflict, was the only road to individual or national prosperity. Their voices were seldom heard, however, above the din rising from the two contending camps, each firmly entrenched in its doctrinal positions and defying assault.
