R. J. T.	ROBERT JOHN THOMPSON, C.B., O.B.E. Assistant Secretary, Ministry of Agriculture and Fisheries, London.	Great Britain: *Agriculture.*
R. L. W.	RAY LYMAN WILBUR, A.M., M.D., LL.D. President and Formerly Dean of the Medical School, Leland Stanford Jr. University, California.	Leland Stanford Jr. University.
R. Ma.*	RENÉ MARAN. Novelist. Awarded the *Prix Goncourt* in 1921 for his novel *Batouala*. Author of *Le visage calme*; etc.	French African Literature.
R. Mac.	ROBERT MACHRAY. Contributor to magazines and journals especially on subjects connected with the Middle and Far East, the Baltic states; etc.	Gdynia.
R. M. H.	ROBERT MITCHELL HENRY, M.A. Professor of Latin and secretary of the Academic Council, Queen's University of Belfast, Ireland. Chairman of Trade Boards of Northern Ireland. Author of *The Evolution of Sinn Fein*; etc.	Ireland: *Political History.*
R. P.*	ROBERT PEELE, E.M. Professor of Mining in the School of Mines, Columbia University, New York. Author of *Compressed Air Plant*. Editor-in-chief of *Peele's Mining Engineer's Handbook*; etc.	Mining.
R. P. B.	ROBERT PRESTON BROOKS, PH.D. Dean of the School of Commerce, University of Georgia; formerly Professor of History. Author of *A History of Georgia*; *The Agrarian Revolution in Georgia*; etc.	Georgia (*U.S.A.*).
R. Po.*	ROSCOE POUND, A.M., PH.D., LL.D. Carter Professor of Jurisprudence and Dean of the Faculty of Law in Harvard University. Sometime Commissioner of Appeals of the Supreme Court of Nebraska. Author of *Readings on Roman Law*; *The Spirit of the Common Law*; *Interpretation of Legal History*; etc.	Legal Education.

R. Rn.	R. Romein. Member of Transit Section, League of Nations, Geneva.	**Inland Water Transport; Oder.**
R. Ro.	Sir Ronald Ross, K.C.B., K.C.M.G., M.D., D.Sc., F.R.S., F.R.S. (Edin.). Director in Chief, Ross Institute and Hospital for Tropical Diseases, Putney Heath, London. Consultant in Malaria, British Ministry of Pensions. Formerly Consultant in Malaria to the War Office, London. Nobel Prizeman for Medicine, 1902. Former Vice-President and Royal Medallist of the Royal Society, London. Author of *The Prevention of Malaria.*	**Malaria** (*in part*).
R. S.*	Reinhard Scheer. Admiral and Commander-in-Chief, German High Seas Fleet, 1916–8, and Chief of German Admiralty Staff till 1919. Author of *Deutschlands Hochseeflotte im Weltkriege.*	**Germany:** *Naval Policy.*
R. Sc.	Robert Scott, M.B., Ch.B. Barrister-at-Law. Formerly Major in the R.A.M.C.	**Medical Legislation.**
R. S. C.	Robert Seymour Conway, Litt.D., F.B.A. Hulme Professor of Classics, Victoria University of Manchester. Author of *The Restored Pronunciation of Greek and Latin*; *The Italic Dialects*; *New Studies of a Great Inheritance*; *The Making of Latin*; etc.	**Latin Literature.**
R. S.-D.	Richard Storry-Deans, LL.B. M.P. for the Park Division of Sheffield. Barrister-at-Law. Author of *Parent and Child*; *Students' Legal History*; *Notable Trials*; *Trials of Five Queens*; etc.	**Hogg, Sir Douglas.**
R. V. S.	Richard Vynne Southwell, M.A., F.R.S. Fellow and Lecturer in Mathematics, Trinity College, Cambridge. In charge of Non-Rigid Airships Design at R.N. Air Station, Kingsnorth, 1915–8, and of Aerodynamic and Structural Experiments at the Royal Aircraft Establishment, Farnborough, 1918–9. Late Superintendent of the Aerodynamics Department, National Physical Laboratory, Teddington.	**Materials, Strength of.**
R. V. V.	Roland Venables Vernon, C.B. Financial Adviser to Government of 'Iraq. Assistant Secretary, Ministry of Munitions, 1915–8. Deputy Accountant-General, Board of Education, 1920–1. Appointed on financial mission to 'Iraq for British and 'Iraq Governments, 1925.	**'Iraq:** *Financial and Economic History.*
R. We.*	Raymond Weeks, A.M., Ph.D. Professor of Romance Languages, Columbia University, New York. Inventor of instruments for the study of phonetics.	**Foreign Languages** (*in part*).
R. W. P.*	Sir Robert William Perks, Bart. Chairman of the Metropolitan District Railway, 1902–6. Treasurer, Wesleyan Methodist Twentieth Century Million Fund. M.P. for the Louth Division of Lincolnshire, 1892–1910.	**Methodism** (*in part*).
R. W. S.-W.	Robert William Seton-Watson, Litt. D. Masaryk Professor of Central European History at King's College, London. Founder and joint editor, 1916–20, of *The New Europe.* Joint editor of *The Slavonic Review.* Author of *The Rise of Nationality in the Balkans*; etc.	**Montenegro.**
S. A. K. W.	Samuel Alexander Kinnier Wilson, B.Sc., M.D., F.R.C.P. Junior Neurologist, King's College Hospital, London. Consulting Neurologist, Metropolitan Asylums Board. Croonian Lecturer, Royal College of Physicians, London. Editor of *The Journal of Neurology and Psychopathology.*	**Neuro-Muscular System.**
S. C. H.	S. C. Hammer, M.A. Oslo Correspondent of *The Times*, London. Editor of *The Norway Year Book.*	**Norway:** *Financial and Economic History*; **Norwegian Literature.**
S. Cr.	Samuel Crowther, B.S., LL.D. Author of *Common Sense and Labour*; *Life of George W. Perkins*; *My Life and Work* (with Henry Ford).	**Henry Ford.**
S. G.	Stephen Lucius Gwynn. Irish Correspondent of *The Observer* (London). Member of the Irish Convention 1917–8. Author of *Irish Books and Irish People*; *The Irish Situation*; *The History of Ireland*; etc.	**Griffith, Arthur; Irish Free State:** *Political History*; **Healy, T. M.**
S. H. S.	S. H. Shoveller. Vice-President of the English Hockey Association. Captain of the English team, 1909–14, and 1920–1. Author of *Hockey.*	**Hockey** (*in part*).
S. H. W.	Captain Stanley H. Wilton, R.N. (ret.). Late Assistant Director of Naval Ordnance, Admiralty, London.	**Gunnery, Naval; Ordnance** (*in part*).
S. J. B.	Solon Justus Buck. Superintendent of the Minnesota Historical Society. Professor of History in the University of Minnesota. Author of *The Granger Movement*; *Illinois in 1818*; *The Agrarian Crusade*; etc.	**Minnesota.**
S. L.	Suzanne Lenglen. Winner of the Ladies' Singles, Ladies' Doubles and Mixed Doubles Lawn Tennis Championships at Wimbledon, London, 1925 and earlier years.	**Lawn Tennis.**
S. L. C.	Stevenson Lyle Cummins, C.M.G., M.D., LL.D. Colonel, Army Medical Service (retired). David Davies Professor of Tuberculosis, University College of South Wales and Monmouthshire, Cardiff.	**Influenza.**

S. Le.	STEPHEN BUTLER LEACOCK, PH.D., LITT. D., F.R.S. (Can.). William Dow Professor of Political Economy, McGill University, Montreal. Author of *The Elements of Political Science*; and of many literary satires including *Nonsense Novels*; *The Hohenzollerns in America*; *The Garden of Folly*; etc.	New Brunswick; Nova Scotia; Ontario.
S. McC. L.	SAMUEL MCCUNE LINDSAY, PH.D., LL.D. Professor of Social Legislation in Columbia University, New York. President of New York Academy of Political Science, New York. Author of *Railway Labor in the United States*; *Financial Administration of Great Britain*; etc.	Liquor Laws, *United States*.
S. R.	SAMUEL ROSENBAUM. Formerly Assistant U.S. Attorney and Assistant City Solicitor, Philadelphia. Author of *Commercial Arbitration in England* and *The English County Courts*.	Judicial Reform.
S. S.	SOPHY SANGER. Chief of section in the International Labour Office of the League of Nations, Geneva, 1920–4; Secretary of British Section, International Association for Labour Legislation, 1906–19, and Editor of the English Edition of the *Bulletin* of the International Labour office (Basle).	Factory and Workshop Law.
S. Sp.	SIGMUND SPAETH, PH.D. Formerly member of the Editorial Staff of *The New York Times*, and Musical Correspondent of *The Boston Transcript*. Author of *Milton's Knowledge of Music*; *The Common Sense of Music*.	Musical Instruments.
T. Co.	SIR THEODORE ANDREA COOK. Editor-in-chief of *The Field* (London). Author of *A History of the English Turf*; *The Art and Science of the Oar*; *The Fencer's Song*; etc.	Fencing; Olympic Games.
T. E. G.	T. E. GREGORY, D.SC. Cassel Reader in Banking and Currency, London School of Economics. Author of *Tariffs: a Study in Method*; etc.	Great Britain: *Banking*.
T. E. L.	THOMAS EAST LONES, M.A., LL.D. Formerly Senior Examiner in H.M. Patent Office, London. Author of *Aristotle's Researches in Natural Science*; *Zinc and Its Alloys*.	Gas, Manufacture of; Gyroscope; Inventions; Liquid Air; Meter.
T. G. G. H.	LIEUT.-COL. T. G. G. HEYWOOD. General Staff Officer, British Territorial Army Air Defence Formations.	Intelligence, Naval and Military.
T. Ho.	THOMAS A. HOWARD. Of Messrs. A. G. Spalding & Bros., Sports Outfitters, London and New York.	Hockey (*in part*).
Th. R.	TH. RUYSSEN. Professor of the History of Philosophy, University of Bordeaux. General Secretary, International League of Nations Union, Brussels.	Minorities.
T. N. C.	THOMAS NIXON CARVER, PH.D., LL.D. Professor of Political Economy, Harvard University. Author of *The Distribution of Wealth*; *Principles of Rural Economics*; *Principles of Political Economy*; etc.	Federal Farm Loan System.
T. R.	TERRY RAMSAYE. Editor of film productions and writer on motion picture subjects. Author of *A History of the Motion Picture*.	Motion Pictures: *History*.
T. S. A.	THOMAS SEWALL ADAMS, PH.D. Professor of Political Economy in Yale University. Adviser on Taxation, U.S. Treasury Department. Author of *Taxation in Maryland*; etc.	Income Tax (*in part*).
T. W. Ho.	SIR THOMAS WILLIAM HOLDERNESS, BART., G.C.B., K.C.S.I. Late Permanent Under-Secretary of State for India. Author of *Peoples and Problems of India*; *Narrative of the Indian Famine, 1896–97*.	India (*in part*).
U. B. P.	ULRICH BONNELL PHILLIPS, PH.D. Professor of American History in the University of Michigan. Author of *The Life of Robert Toombs*; *American Negro Slavery*; etc.	Michigan.
V. G.	VALTYR GUDMUNDSSON, M.A., D.PH. Professor of Icelandic Language and Literature in the University of Copenhagen. Member of the Icelandic Parliament, 1894–1914.	Iceland.
V. L. E. C.	VICTOR LOUIS EMILIEN CORDONNIER. General commanding the French Army in the East under General Sarrail. Author of *The Japanese in Manchuria*.	Frontiers, Battles of the (*in part*).
W. A. B.	WILLIAM ADAMS BROWN, A.B., PH.D. Roosevelt Professor of Systematic Theology, Union Theological Seminary, New York. Author of *The Essence of Christianity*; *The Church in America*.	Fundamentalism and Modernism.
W. B.-A.	W. BROUGHTON-ALCOCK, M.D. Director of the Central Laboratory, Ministry of Pensions, London.	Malaria (*in part*).
W. B. H.	WALTER B. HARRIS, F.S.A. Moroccan Correspondent of *The Times* (London). Author of *The Land of an African Sultan*; *Travels in Morocco 1888–9*; *Morocco that Was*; etc.	Morocco, Campaigns in.

W. Bn.	WILLIAM BATESON, M.A., F.R.S. Late Director of the John Innes Horticultural Institution, Merton Park, Surrey, and Professor of Biology, Cambridge University. Author of *Mendel's Principles of Heredity*; *Problems of Genetics*; etc.	**Genetics; Mendelism.**
W. B. S.*	WILFRED B. SHAW. General Secretary, Alumni Association, University of Michigan. Author of *History of University of Michigan.*	**Michigan, University of.**
W. D. L.	WILLIAM DRAPER LEWIS, PH.D., LL.D. Director of the American Law Institute. Formerly Dean of the Law Department, University of Pennsylvania. Author of *Restraint of Infringement of Incorporeal Rights*; *Life of Theodore Roosevelt*; etc.	**Judicial Reform.**
W. E. El.	WALTER ELLIOT ELLIOT, M.C., D.Sc., M.B., CH.B. M.P. for the Kelvingrove Division of Glasgow. Parliamentary Under-Secretary of Health for Scotland.	**Health, Ministry of.**
W. E. I.	MAJOR-GENERAL SIR WILLIAM EDMUND IRONSIDE, K.C.B., C.M.G., D.S.O. Commandant, Staff College, Camberley, Surrey. Commander-in-Chief, British Forces in Russia, 1918–9. Author of *Tannenberg: the first thirty days in East Prussia.*	**Masurian Lakes, Battles of the.**
W. F.	LIEUT.-COL. WOLFGANG FOERSTER. Late General Staff, German Army. Keeper of Public Records, Potsdam. Formerly member of the Historical Section of the General Staff. Chief of the General Staff of the XI. Corps, 1915. Author of *Prinz Friedrich Karl von Preussen*; *Graf Schlieffen und der Weltkrieg.*	**Hindenburg, Paul von; Ludendorff, Erich.**
W. F. B.	WILLIAM F. T. BUTLER, M.A. Assistant Commissioner of Intermediate Education, Ireland. Formerly Professor of Modern Languages in Queen's College, Cork. Member of the Royal Irish Academy.	**Irish Free State:** *Education.*
W. F. F.	WALTER FRANCIS FREAR, LL.D. Formerly Chief Justice and late Governor of Hawaii. Chairman of the Hawaiian Code Commission, 1903–5. Author of *The Evolution of the Hawaiian Judiciary.*	**Hawaii.**
W. F. O'C.	LIEUT.-COL. SIR WILLIAM FREDERICK TRAVERS O'CONNOR, C.S.I., C.I.E. Formerly Resident in Nepal and British Envoy in Nepal. Signatory of Treaty between Great Britain and Nepal, 1925. Author of *Folk Tales from Tibet*; etc.	**Nepal.**
W. F. W.	WALTER FRANCIS WILLCOX, PH.D., LL.D. Professor of Economics and Statistics, Cornell University. Author of *The Divorce Problem—A Study in Statistics*; etc.	**Negro.**
W. G. Ma.	SIR WILLIAM GRANT MACPHERSON, K.C.M.G., M.B., D.P.H. Major-General, Army Medical Service. Editor-in-Chief, *Medical History of the War.* Served at the War Office as Deputy Assistant and Deputy Director-General of the Army Medical Service, and as a Member of the Advisory Board for Medical Services, and of the Army Sanitary Committee. Director of Medical Services, British Force in Macedonia, 1915–6.	**Medical Service, Army.**
W. Go.*	SIR WILLIAM A. M. GOODE, K.B.E. Unofficial Adviser to the Hungarian Government. President of, and British Representative on, the Austrian Section of the Reparation Commission, Vienna, 1920–1. Author of *Economic Conditions in Central Europe*; etc.	**Horthy, Admiral; Hungary** (*in part*); **Karolyi, Count.**
W. Gr.	WALTER GRAVELL, PH.D. *Ober Regierungsrat* in the Statistical Offices of the Reich, Berlin. Member of the German Statistical Society. Author of *Abhandlungen über Bevolkerungs-Berufs- und Betriebsstatistik*; etc.	**Germany:** *Area and Population.*
W. G. S. A.	WILLIAM GEORGE STEWART ADAMS, M.A. Gladstone Professor of Political Theory and Institutions, Oxford University. Fellow of All Souls College. Member of the British Development Commission.	**Government.**
W. H. C.	W. H. COATES, LL.B. Secretary of Nobel Industries, Ltd. (London).	**Income Tax** (*in part*).
W. H. Di.	WILLIAM HENRY DINES, F.R.S., F.R.MET.SOC. Author of *Characteristics of Free Atmosphere* and of numerous scientific articles in the *Proceedings* of the Royal Society, *The Journal of the Royal Aeronautical Society*; etc.	**Meteorology** (*in part*).
W. H. L.*	W. H. LEFFINGWELL. Management Engineer. Author of *Office Management*; etc.	**Office Appliances; Office Management.**
W. K. McC.	WILLIAM KIDSTON MCCLURE, C.B.E. Correspondent of *The Times* (London) in Rome. War Correspondent of *The Times* on the Italian Front, 1915–7. Author of *Italy's Part in the War*; *Italy in North Africa*; etc.	**Italian Campaigns; Italo-Turkish War.**
W. L. B.	WILLIAM LEWIS BLENNERHASSET, D.S.O., O.B.E. Formerly acting British Vice-Counsul at Kovno, Lithuania. Member of the London Stock Exchange.	**Finland:** *Political History*; **Lithuania:** *Political History.*
Wm. A.	SIR WILLIAM JAMES ASHLEY, PH.D., M.A., M.COM. Formerly Vice-Principal and Professor of Commerce of the University of Birmingham. Member of numerous British Committees on Economic Questions. Author of *Introduction to English Economic History and Theory*; *The Rise in Prices*; *The Economic Organisation of England*; etc.	**Imperial Preference.**

W. Me.	WILFRED MEYNELL. Editor of the Collected Works of Francis Thompson. Author of *Life of Benjamin Disraeli*; etc.	**Meynell, Alice.**
W. Mi.	WILLIAM MILLER. Correspondent of *The Morning Post* (London) in Athens and Rome. Author of *The Latins in the Levant*; *The Ottoman Empire and its Successors*; *A History of the Greek People* (*1821–1921*); etc.	**Fiume; Macedonia.**
W. M. J.	WILLIAM M. JARDINE, B.S., LL.D. United States Secretary of Agriculture. Formerly President of Experiment Station, Kansas State Agricultural College.	**Farmers' Organisations** (*in part*).
W. N. R.	WILLIAM NELSON RUNYON, A.B., LL.B. Judge, U.S. District Court, District of New Jersey. Instructor in New Jersey Law School. Formerly Acting Governor of New Jersey.	**New Jersey.**
W. O. S.	WILLIAM OSCAR SCROGGS, A.M., PH.D. Financial Writer on *The New York Evening Post*. Formerly Professor of Economics and Sociology. Louisiana State University. Author of *Filibusters and Financiers*.	**Louisiana.**
W. P. P.*	WOLF POCKLINGTON POND. Editor of *The Spur*, New York. Correspondent of *The Sporting Chronicle*, Manchester.	**Horse-Racing** (*in part*).
W. Rn.	WALTER ROSENHAIN, F.R.S., D.Sc. Superintendent of the Department of Metallurgy in the National Physical Laboratory, Teddington, Middlesex. Member of International Committee on Nomenclature of Iron and Steel. Author of *Introduction to the Study of Physical Metallurgy*; etc.	**Metallurgy.**
W. S. B.	AIR VICE-MARSHAL SIR WILLIAM SEFTON BRANCKER, K.C.B. Director of Civil Aviation at the Air Ministry, London. British Representative on the International Commission of Air Navigation.	**Flying.**
W. S. L.-B.	WALTER SYDNEY LAZARUS-BARLOW, M.D., F.R.C.P. Member of Cancer Committee, Ministry of Health, London. Late Professor of Experimental Pathology and Director of Cancer Research Laboratories, Middlesex Hospital, London. Author of *A Manual of General Pathology*.	**Medical Research.**
W. S. N.	HON. WILLIAM S. NOSWORTHY. Minister of Finance, Stamp Duties, Agriculture and Immigration; and Minister in charge of Land and Income Tax, State Allowances, Valuation, Tourist and Health Resorts and Legislative Department, New Zealand.	**New Zealand:** *Population and Settlement.*
W. W. M.	WILLIAM WATTS MACON. Editor of *The Iron Age*, New York.	**Iron and Steel.**
Y. H.	YRJO HIRN. Professor of Modern Literature, University of Helsingfors, Finland. Author of *Det heliga skrinet, Studier i den Katolska Kyrkans Poesi ock Konst*; etc.	**Finnish Literature.**

THE
ENCYCLOPÆDIA BRITANNICA

THE SECOND OF THE THREE NEW VOLUMES

FABRE TO OYAMA

FABRE, JEAN HENRI (1823–1915), French entomologist, was born at St. Léons in Aveyron Dec. 21 1823. He received the elements of a classical education at Rodez, continuing it further at the école normale of Vaucluse. But his whole bent was for science, and after he had become a teacher at Carpentras, he worked in his spare hours at physics and mathematics, and became interested in insects, the study of whose habits was to form his life-work (*see* 3.626, 6.672, 14.180). His observations were published in *Annales des sciences naturelles* (1855–8), followed by *Souvenirs entomologiques* (1879–1907). He died at Sérignan, Provence, Oct. 11 1915.

FACTORY AND WORKSHOP LAW (*see* 16.7).—Factory and workshop law forms part of the mass of modern legislation referred to as "industrial law" or "labour legislation" (*see* 16.7). The limited term "factory and workshop law" arose from the way in which the British Parliament defined workplaces for the purposes of regulation. The line of demarcation thus drawn between manufacturing and other occupations and the particular grouping of subjects regulated by the British Factory and Workshop Acts are more or less arbitrary and are not necessarily found in the laws of other countries. Nor is it possible, in a practical study of British legislation, to adhere strictly to Factory and Workshop Acts properly so-called. There are many statutes of recent years which affect the health, safety and welfare of workers in factories and workshops without fitting in to the general scheme of the Factory and Workshop Acts. A list of Acts since the beginning of 1911, amending those Acts or having an important bearing upon conditions of work in factories and workshops is appended. In addition, a large number of Orders have been issued both under the Act of 1901 and under the later Acts, which have given important new powers of regulation to the Home Secretary. Indeed it is largely by Orders that the factory and workshop law of Great Britain has been kept up to date.

I. GREAT BRITAIN

Taking the matters regulated by the Consolidating Factory and Workshop Act of 1901, as a basis, we may consider recent developments under the following six headings:—

1. *Health and Safety.*—The formerly important provisions for protecting children from risk of accident or injury to health became obsolete, when "children" as defined by the Act of 1901 were excluded from work of all kinds in factories and workshops. On the other hand, certain general provisions of the Employment of Children Act, 1903, apply, in Scotland only, to girls and boys of 14 years of age employed in factories and workshops, since the Scottish Education Act of 1918 raised to 15 the age of children affected by them. The provisions of the Act of 1901 relating to humidity and ventilation in cotton-weaving sheds were modified by regulations substituted for them under powers given by the Cotton Cloth Factories Act of 1911. The conditions under which accidents must be notified have been changed both as regards the nature of the accidents notifiable and as regards procedure.

Under sections included in the Workmen's Compensation Act, 1923, any accident occurring in a factory or workshop causing death or disabling a worker for three days must be notified, and notice is given to the inspectors of factories only, the former duties of certifying surgeons in this connection having been abolished by the Police, Factories, etc. Act, 1916. However, the duties of certifying surgeons in connection with health remain, and have been extended both by Orders making several further diseases compulsorily notifiable, and also by the Lead Processes Act of 1920, which prescribes the periodical medical examination of all women and young persons employed in lead processes (a rule which previously existed only in those lead trades for which it had been prescribed by regulations). This Act contains, in addition, some general rules of hygiene to be observed whenever any woman or young person is employed in contact with lead compounds. It is, however, chiefly important in having been adopted in order to give legal confirmation to a recommendation of the International Labour Organisation (I.L.O.), since nearly all the ground was already covered by regulations under section seventy-nine of the Act of 1901.

Great progress has been made with regulations under that section. Between 30 and 40 codes of regulations are in force, mostly very detailed and highly technical. By means of this system of regulations, the British law for the protection of workers in trades involving special risks is kept fully abreast of medical knowledge and scientific discovery. Many other countries have, especially in recent years, adopted a similar system. But none can show regulations more carefully and scientifically prepared or better observed in practice. The regulations are aimed at every kind of special industrial risk—risk of poisoning, risk of infection, risk from injurious fumes and from excessive and injurious dust, risk of accident, risk of overstrain. The regulations of 1925 restricting the lifting of weights in the woollen or worsted industry relate exclusively to the last-named risk. One of the most interesting sets of regulations, and quite the most elaborate, is the code for the pottery industry drawn

up in 1913 after an exhaustive investigation by a departmental committee. Every process and branch of this complicated industry is dealt with in detail.

Interesting examples of technical rules for the prevention of accidents are to be found in the regulations of 1922 for woodworking and in the revised regulations for dock work issued in 1925. Occupations less ostensibly dangerous than those regulated under section 79 of the Act of 1901 may be made the subject of so-called Welfare Orders under section 7 of the Police, Factories, etc. Act of 1916. Welfare orders may deal with facilities for preparing and taking meals, with the supplying of drinking water, protective clothing, ambulances and appliances for first-aid, seats in work-rooms, washing facilities and accommodation for clothing, with the supervision of workers and (a later addition, by Order) with the provision of rest-rooms. Many of the subjects thus relegated in the British system to Orders are to be found in the statutes of other countries and will no doubt be included in some future consolidating British Act. Meantime these Orders provide a practical, if gradual, means of bringing the British law of a quarter of a century ago up to date as far as the health and well-being of the workers is concerned. Arrangements for "first-aid" (or ambulance rooms) were later prescribed for all "factories," namely by section 29 of the Workmen's Compensation Act, 1923. This section also gave the Home Secretary wider powers in the matter of accident prevention. For instance, sub-section (3) gives powers so defined as to enable him to require employers to put into operation modern safety methods (inspired largely by American practice and adopted of recent years by many British firms on their own initiative), such as the appointment of safety engineers or representative safety committees, whose business it is to check the human as well as the mechanical element in accidents (*see* SAFETY FIRST). The Anthrax Prevention Act, 1919, was adopted in order to enable practical use to be made of a newly discovered method of disinfecting raw wool and hair likely to be infected with anthrax.

2. *Hours of Work.*—The provisions of the Factory and Workshop Acts relating to hours of work have been only slightly altered during the period under review. Consequently they have grown out of date, and are in practice largely obsolete. The restrictions placed upon the night work of women and boys by the Act of 1901 were supplemented by the Employment of Women, Young Persons and Children Act, 1920, adopted so as to embody in law the provisions of the Conventions on that subject. As far as concerns women the Act made no practical difference. But as regards male young persons it allows fewer exceptions to the general prohibition of night work than the old law and never allows boys under 16 to work at night. It therefore overrules or modifies many of the special exceptions formerly allowed both as regards employment in night shifts and as regards encroachments on the rigidly prescribed period of 11 hours night's rest.

The Act introduced another important change, permitting the employment of women and boys over 16 in two day-shifts of eight hours. This necessitated an extension of the strict outside limits for employment under the Act of 1901, since the two shifts could not be fitted in unless the second shift could continue at work up to 10 o'clock at night. The clause aroused considerable opposition and was eventually adopted in a guarded form. In the first place, it was of only temporary operation, and from 1925 needed to be annually extended. In the second place, the Home Secretary may only allow the two shifts in any undertaking on the joint application of the employer and a majority of the workers concerned, and the Act enables an organised trade as a whole to resist the introduction of the two-shift system by means of a kind of veto. The Home Secretary may attach conditions to the permission, such as the adoption of various "welfare" arrangements, including, for instance, the provision of special transport facilities for women and young persons having to travel to or from work at an unusually early or late hour. The indirect effect of the Trade Boards Acts on hours in factories and workshops may well be noted. Although the trade boards cannot directly regulate hours of work, they influence actual hours by fixing a standard week (usually about 48 hours) beyond which higher rates of wages must be paid.

3. *Exclusions from Industrial Work.*—As regards the exclusion of persons from industrial work, the most important recent change has been the raising to 14 of the age limit for young workers to enter upon such employment. This rule was applied by the Employment of Women, etc. Act of 1920 to "industrial undertakings," so defined as to cover all "factories and workshops." The same result had already been attained by the two Education Acts of 1918, which are still relied on for controlling the admission of children to domestic workshops. The Scottish Education Act of 1918 excludes children from factories and workshops up to the age of 15 unless they have procured exemption from school attendance. Both under the Education Act of 1921 and the Scottish Act of 1918, employers may be required to allow young persons over 14 time off from their work for attendance at continuation classes. The Lead Processes Act, 1920 (see 1 above) out of deference to a recommendation of the International Labour Organisation, excluded women and young persons by law from certain lead processes in which, in practice, they were not employed at all.

4. *Home Work.*—Home Work Orders were issued in 1911, 1912 and 1913, extending to a number of trades the provisions of the Act of 1901 relating to lists of outworkers and the prohibition of work in unwholesome or infected premises.

5. *Particulars of Work and Wages.*—Part VII. of the Act of 1901, relating to particulars of work and wages, has been extended by Order to a large number of additional trades.

6. *Enforcement of the Law.*—The factory inspectorate was entirely reorganised after the War. For this no legislation was necessary. One result of the reorganisation was the abolition of the special women's branch and the admission of the women inspectors to all grades with the same duties as the men inspectors. The enforcement of the sections of the Act of 1901 relating to the employment of women after childbirth and to bakehouses have been transferred to the Ministry of Health and the Scottish Board of Health.

II. THE BRITISH DOMINIONS

Both in Northern Ireland and in the Irish Free State the British factory and workshop law existing at the time when the recent constitutional changes were introduced remains in operation for the time being. The Parliament of Northern Ireland can now amend or develop the law, subject to the possible intervention of the British Parliament. The Irish Free State, like all other self-governing Dominions, is free to legislate on this matter quite independently of the British Parliament, but up to March 1926, had made no changes beyond issuing two sets of regulations under section 79 of the Act of 1901. The other British Dominions have steadily developed their industrial legislation. In Australia factory and workshop law of old standing and often amended has in many cases been consolidated more or less recently. It is important to note that industrial arbitration awards and the determinations of wages boards form an essential part of the law in Australia and New Zealand and represent a type of regulation not to be found in so fully developed a form in any other country, though South Africa has recently adopted a somewhat similar method suited to her industrial conditions. In Canada, the most interesting recent legislation from the point of view of factory and workshop law is that of British Columbia putting into operation the proposals of the I.L.O. on hours of work and the employment of women before and after confinement. In India, likewise, certain proposals of that body have been put into force by an Act which made many important amendments in the Factory Act.

III. EUROPEAN COUNTRIES

Both in the years immediately preceding and during the War, nearly all the countries of Europe were gradually developing or consolidating their industrial law. France began the codification

of her labour laws in 1910, and Book II. of the Code of Labour, which covers most of the subjects here considered, was issued in 1912. All existing Industrial Codes have been amended more or less since 1910 and new and improved Factory Acts, superseding older laws, were adopted in Sweden in 1912, Denmark in 1913, Switzerland in 1914 and Norway in 1915. Special laws protecting women and young workers only were newly adopted or amended in Austria, the Netherlands and Portugal in 1911, in Greece and Spain in 1912 and in Belgium in 1914, while developments in legislation concerned with industrial hygiene and safety may be noted in Finland (1914), Germany (the Home Work Law of 1911), Greece (1911, and a bakeries law of 1912) and the Netherlands (a special law for the protection of dock labourers, 1914; and an amendment of the Safety Act, 1915). Finland issued an ordinance in 1917 covering nearly all the ground of factory and workshop law.

Since 1918 there has been a still more remarkable activity in labour legislation, due in large measure to the industrial ferment caused by the War. As the process of legislation goes on, we can continually trace the influence of the I.L.O., tending to make the laws approximate broadly in aim, but not preventing them from differing widely in form and detail. The newly created or enlarged countries have the task of adapting the laws already existing in newly acquired territory. Of these, only the Serb-Croat-Slovene Kingdom has as yet fully co-ordinated and codified her industrial law (by the Workers' Protection Act of 1922). Poland has incorporated certain principles of industrial regulation in her Constitution.

The most striking part of post-War labour legislation is that which restricts the hours of labour of adult men (as well as of women and boys) to approximately eight a day (*see* HOURS OF LABOUR). Many countries have, in addition, amended their law so as to conform to various proposals of the I.L.O. relating to the employment of women and boys at night and in lead processes, the protection of women workers before and after childbirth and the age limit for the employment of children. It should be noted that night-work for adult men is prohibited in general, subject to special exceptions, in several European countries (Belgium, Czechoslovakia, Netherlands, Norway, Poland and Switzerland) and may be restricted by order in Hungary and the Serb-Croat-Slovene Kingdom. Home-work laws, dealing with hygiene as well as wages, were adopted in 1918 in Austria and Norway, and in 1919 in Czechoslovakia. The tendency for compensation laws to deal also with accident prevention should not be overlooked. A new departure may be noticed in recent laws giving workers the right to a period of annual leave with pay. Laws have been adopted in a number of countries to establish or reorganise systems of inspection, and the influence which works councils (*q.v.*) may have upon the observance of factory and workshop law should be noted. Soviet Russia has produced a comprehensive labour code and a large number of detailed regulations for health and safety.

IV. THE UNITED STATES AND SOUTH AMERICA

In the United States, labour legislation has been checked to some extent by the lack of a uniform standard among the States, and by the rigid application by the courts of constitutional principles now out of harmony with public opinion. But, in spite of this, factory and workshop law has steadily developed in most of the States during the period under review, and some States have now advanced labour codes. The problem of child labour has been receiving much attention and a constitutional amendment is being considered to enable Congress to regulate the employment of children. In some States great improvement in accident prevention and hygiene have been brought about through the action of industrial commissions or boards, with wide powers of investigation into, and regulation of, trades. An original plan has been adopted to provide for the rehabilitation of workers permanently injured by their work, on the analogy of those injured by war (Vocational Rehabilitation Act, 1920).

In the republics of Central and South America, a considerable amount of factory and workshop law is to be found, in some cases embodied in elaborate codes. In Mexico, the Labour Codes of the various States are based on general principles laid down in an amendment to the federal Constitution of 1917.

V. ASIATIC COUNTRIES

Factory and workshop law made a start in Japan with the Factory Act of 1911, which was amended in 1923 and supplemented by an Act on the minimum age for industrial employment in order to put into operation certain of the standards specially recommended for Japan by the I.L.O. The only other Asiatic country where factory legislation is, as yet, at all advanced, is India, to which reference has already been made. But, in 1923, a Factories Act emerged in China, and Persia issued a decree for the protection of workers in carpet factories.

BIBLIOGRAPHY.—(1) *British Acts since 1910.* The Factory and Workshop (Cotton Cloth Factories) Act, 1911; and the Women and Young Persons (Employment in Lead Processes) Act, 1920 (these two Acts, with the earlier Factory and Workshop Acts, are termed collectively the Factory and Workshop Acts, 1901–20); The Police, Factories, etc. (Miscellaneous Provisions) Act, 1916; The Employment of Women, Young Persons and Children Act, 1920; The Workmen's Compensation Act, 1923 (sections 28 and 29); The Education Act, 1918 (section 14); The Education Act, 1921; The Education (Scotland) Act, 1918; The Ministry of Health Act, 1919; The Scottish Board of Health Act, 1919; The Anthrax Prevention Act, 1919; The Checkweighing in Various Industries Act, 1919; The Celluloid and Cinematograph Film Act, 1922; Trade Boards Provisional Orders Confirmation Act, 1913; Trade Boards Act, 1918.

Great Britain: *Redgrave's Factory Acts*, 13th edition by C. F. Lloyd (Butterworth, 1924); *Factory and Workshop Orders*, issued every few years by the Home Office (H. M. Stationery Office); *Annual Reports of the Chief Inspector of Factories.*

United States of America: *Labor laws of the United States with decisions of courts relating thereto*, Bulletin of the Bureau of Labor Statistics, No. 370, 1925 (see also list of other *Bulletins* on labor legislation and court decisions, appended to No. 370). (S. S.)

FACTORY DESIGN.—The selection of the site and the design of factory buildings are most important economic factors in manufacture because they may contribute very seriously to the cost of production, not only on account of the initial outlay of capital required, but because of their influence on efficient production. The elimination of waste, whether of material, time or effort, is the chief feature of all manufacturing, and the design of factory buildings plays its part in this elimination.

The haphazard methods of erecting factory buildings are passing, and more systematic consideration is being given to their planning and erection, though even at the present time more effort is devoted to providing good machinery than good, suitable buildings. The factors most largely influencing the design of factory buildings are large scale and standardised production; factory legislation, both government and local; building by-laws; insurance conditions, and the welfare of the employees.

Regarding the actual design and building of factories, the determining factor is naturally the character of the product, but certain general considerations apply whatever the product. The architect of every new factory should make himself thoroughly familiar with the processes and products of the factory before attempting his design, which should be made with a view to meeting adequately the future needs of the industry which, under favourable conditions, will naturally expand, especially as the present-day tendency is towards amalgamations and the formation of large corporations. One of the best ways of providing for this contingency is to design all buildings on the principle of suitable standardised units which can be increased as necessity arises. These standardised units should represent a complete organisation, but should be so arranged as to make future extensions possible without interfering with the existing business.

Selection of Site

The effect of location is common to all factory design, and in selecting a site all the following should be taken into account:—

Nearness to raw material supply is an important factor where raw materials are bulky and cheap, but as the bulk decreases and the value increases this factor becomes less important. It is necessary to study the convenience of existing railway lines, freightage, etc. Proximity to a canal is not the important feature it was formerly. The contour of the land should be studied, not only in so far as it presents a suitably level site for building purposes, but also in relation to canals, railways and other means of transport.

The supplies of electricity, gas and water are all important considerations, especially where, as in the case of some industries, enormous quantities of any one are needed, as, for example, in the pulp and paper industry, which requires a vast amount of water; or where the cost of power represents a large part of the ultimate cost of the product. The climate is an important factor in certain industries, as for example, in the textile industry where a humid atmosphere is necessary, though in this case it is becoming less important than formerly because the humidity can be controlled artificially.

Suitable Labour Supply.—Where the necessary labour supply is of the unskilled type this is not an important factor, but where skilled labour is essential, it is necessary to locate the industry in a district where training and heredity have developed the required type. Skilled labour is not so migratory as unskilled on account of social and family attachments, etc.

Room for Expansion.—It would, of course, be futile to place a factory in a crowded and congested area where there is no space for expansion. The present tendency is for factories to be built on the outskirts of existing industrial areas because here (providing transport facilities are satisfactory, which is not always the case) land is usually cheaper, taxation lower and working conditions better than in the towns. It is, however, difficult to induce labour that is accustomed to town life to migrate to country districts and this, coupled with the housing question (*see* Housing) may be an important factor operating against an otherwise ideal site. Further, some industries may be dangerous or offensive, and these must be located well away from congested areas.

Other Factors.—Capital available for investment, laws affecting the tenancy of land, sewage, floods, drinking water supply, etc., are all important points to consider in the selection of a site.

Types of Factory Building

The type of building erected for a factory depends entirely on the product to be manufactured, and the architectural form is dominated by this factor, and, in the majority of cases, by the great need for economy, but an attractive looking plant has a marked effect on employees, and has an advertising value.

Main Types.—There are, in general, three main types of factory building:—

1. The single story building of the weaving-shed type, having a saw-toothed roof consisting of a series of unequally inclined ridges, glazed usually only on the north side which permits of uniform lighting without shadows. In the single story type when the site does not permit of north lighting, the ridges, which must be equally inclined, can be glazed on both sides. This type (see fig. 1 on plate) is not well adapted for overhead shafting, cranes, etc.
2. The one-story building with large truss spans, provided with accommodation for travelling cranes, etc. This is the foundry, forge and machine shop type and is suitable for medium and heavy work (see fig. 2 on plate).
3. Multi-story buildings for all kinds of manufacture and storage, except in the case of the heaviest industries (see fig. 1 on plate).

Naturally, each type has its advantages and disadvantages and must be considered in relation to the product of the factory, but generally, when cost of land is not prohibitive, and the product is bulky, the natural choice would be towards a one-story building. Each of these three types of building permits of a construction of any one of the following kinds:—

(*a*) Timber and masonry, known as "Mill construction."
(*b*) Steel framework.
(*c*) Reinforced concrete.

Whatever type of construction is employed, the predominating necessity is "fireproofness." In the event of a fire, although the actual amount of material damage is recoverable by insurance, the loss through disorganisation is not recoverable, and frequently is so overwhelming as to prevent ultimate reorganisation.

Mill Construction.—Mill construction is of various types, but in the main, the outside walls are of masonry, the floors of wood, and the roofs, posts, joists and girders of wood or metal. Where much timber is involved the great disadvantage of this type, which for other than heavy work is in other respects satisfactory, is that for fire-resisting purposes it cannot be recommended. This type of building is seldom used for heights of more than six floors on account of its lack of lateral stability, which is chiefly dependent on the masonry of the walls, and which, if developed to any height, would require to be supported by excessive-sized pillars and increased thickness in the lower stories. The adoption of this type of building is getting less and less.

Steel Framework.—Buildings of this type were made possible by the introduction of the Bessemer process of steel manufacture. Here rolled steel structural members are used and filled in with walls, floor and roof, etc. The steel members are riveted, or bolted together. Where long spans without support are necessary, steel framework is essential, and it is also necessary in the case of high walls exposed to wind pressure and to the lateral forces of moving cranes. Steel framework buildings are not fireproof because exposed steelwork twists and buckles when subject to intense heat, thus wrecking the building more quickly than the fire itself. If the structural steel framework is encased in fire-resisting material such as concrete, it is admirably suitable for the interior of a factory (*see* Ferro-Concrete).

Reinforced Concrete.—Buildings of this material have come to be recognised as one of the standard types for industry. The material is classed as "fireproof" and will stand the destructive effects of fire as well as any material. It is not usually damaged beyond repair by fire, and seldom, if ever, destroyed. It is a particularly durable material, and its durability improves with age. It is particularly well suited for multi-story buildings containing vibrating machinery or machines with heavy reciprocating parts. "Daylight factories" giving the maximum of natural lighting have come into vogue with reinforced concrete

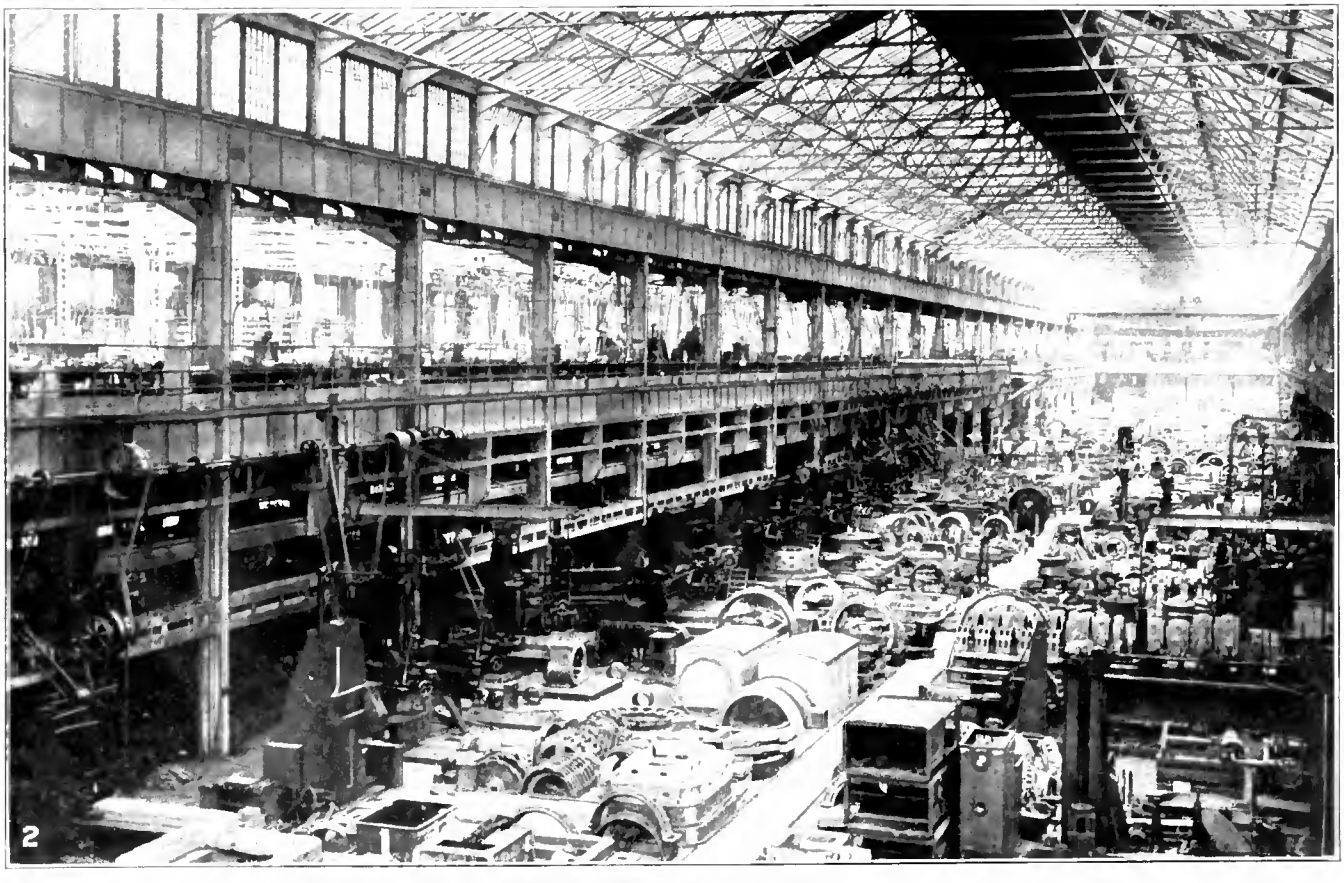
MODERN FACTORY DESIGN (AMERICAN)

Shoe-factory, near Boston, Mass., designed for a maximum of daylight. Harry Field Kellogg, Architect. This L-shaped building, with combined clock and sprinkler-tank tower at its western angle, is built of reinforced concrete throughout. The piers are between 16 and 17 ft. apart, with glass in metal sashes extending from pier to pier. The brick curtain walls, of no structural function, lend a touch of colour to the building; being only the height of a work-bench, they do not decrease the effective lighting of the factory. The floors are of flat slab construction.

FACTORY DESIGN



MODERN FACTORY DESIGN

because columns or pillars may be more slender and the steel framework windows used give an increased lighting area. In cases where the floor load is higher than 200 lb. per sq. ft., reinforced concrete buildings are cheaper than those of mill construction.

Reinforced concrete buildings have developed almost entirely since 1910. The first line of development was along the form of beam and girder construction, but now the flat slab method of flooring is used, especially in cases where the live load is 150 lb. or more per square foot. For lighter loads, the development has been towards the long span joist construction with a filler of metal, tile, terra-cotta or gypsum block, which reduces dead load and saves concrete.

Details of Construction

Foundations.—In choosing a site an important point is that of its levels, and a site poor in this respect purchased at a low figure may eventually prove a most costly one. It is also important to have full knowledge of any mineral workings going on, or likely to go on, as these might cause subsidence. The foundations of buildings which are to house heavy machinery must be ample enough to absorb vibration, and in the case of such implements as the steam and power hammer, or jarring machinery for foundries, the foundations should be entirely separate from all building structures or their foundations. It is important to choose a site where there exists a good subsoil of clay or rock, otherwise the expense of piling or rafting might make the cost of the buildings very high or even prohibitive.

Floors.—These should be designed to provide facilities for future changes, especially if they are of reinforced concrete, and ducts should be arranged to accommodate pipes, etc. Conduits should be properly placed and openings provided for belts, shafting and other accessories, properly protected. Where apparatus must be taken through floors, ample openings and trap doors or removable floor slabs are essential. Floors formed of concrete and merely spade-finished are unsuitable, and their durability should be increased by some form of floor-hardener or by the application of paving. Pavings are of many kinds, metallic, granolithic, cemented, of fir boarding laid on battens, pitchpine boarding, bricking, maple boarding, rock asphalt, wood blocks, etc. Each of these types has its advantages and disadvantages, some being unsuitable on account of dust, others on account of the discomfort to workers, and every building requires separate consideration. Floor areas must be laid out so as to avoid the conflict of travel in opposite directions and to permit of easy transport.

Lighting.—Windows, while no more expensive in initial outlay than walls, are an expensive item in upkeep, and with a large area of glazing the size of glass forming a unit should be of the order of 1 ft. 4 in. by 2 ft. or even larger, if of the roughcast or "Prismatic" type. It is not usually essential that all parts should be made to open. Steel sashing, although difficult to clean and a source of lost heat, is preferable to wooden sashing as it provides increased lighting facilities, giving 80% to 90% light area as against 50% to 70% for wooden sashes and frames. One-story saw-toothed buildings should have roof windows facing north to avoid direct sunlight.

Walls.—The thickness of building walls is dictated by Building Acts and by-laws, and in most countries there is no possibility of erecting such walls of less thickness than 9 in. or 14 in., depending on the height and length of the wall and whether steel framework is used. As already stated in connection with the various types of building construction, various materials are used for walls such as brick, concrete, stone, etc. Where hoists and cranes are fitted these must be provided with ample support.

Roofs.—Roofs are one of the large items in building construction. Their particular form is dependent upon the intended purpose of the building; a high pitched gabled roof is the best for forges, foundries and other shops engaged in hot processes in which large quantities of heat require to be dissipated, and in other cases where a level ceiling is not required; the glazed saw-toothed form of roof provides the best condition of steady, uniform, natural lighting; the flat roof is the natural type for buildings with interior columns. Whatever the type the essential features are water- and fire-proofness. For general purposes the best material is mineral rock asphalt, which is unaffected by heat or cold and requires no yearly treatment, and is also capable of withstanding traffic without damage. Where sloping roofs are used, steel or reinforced concrete roof principals are employed, and this method of support is now as cheap as steel. Slates as a covering are high in first cost and heavy for long span roofs, but if of good quality are very durable. Bituminous felts and other compositions in sheet form are low in first cost, but require special treatment every few years.

Heating and Ventilation.—Of these two subjects the latter is the more important. In an ordinary factory the air should be changed three to five times per hour, while under some circumstances it should be changed as many as 20 times per hour. The temperature also varies with the nature of the work carried on, but a good average is 57° F., though for heavy manual labour a lower temperature should prevail, and for sedentary work, a higher. Various systems of ventilation and heating are employed, but the most suitable for the particular case must be selected, care being taken to economise space and avoid interference with cranes, conveyors, etc. (*see* Public Health).

Stairways, Lifts, Elevators, etc.—Stairways should be ample for emergencies, and give passengers the least inconvenience, a 6½ in. rise being considered good practice. Lifts should be encased with brick walls to prevent the spread of fire, and the openings should be fitted with doors of fire-resisting material made to close automatically in case of fire.

Power Supplies.—Where power is generated on the site, the plant should be located at a point most convenient for the handling of fuel and ashes, and all boiler and engine-room equipment should be capable of extension. Where live steam is used in the manufacturing processes, the power plant should be situated centrally in order to avoid the necessity of long lengths of piping and excessive loss of heat.

Fire Protection.—The installation of apparatus to deal with outbreaks of fire is a necessity in all industrial buildings. The most usual form is by the sprinkler system in which pipes are fixed horizontally along the ceiling, and supplied with water which is not released until the temperature in the building is sufficiently high to melt the solder which holds the automatic valve of the sprinklers in position. When this is released the water is discharged over the affected area. Where sprinklers are not used, hydrants with lengths of hose should be fixed near stairs and in easily accessible positions and fire buckets and chemical fire extinguishers should be placed within the reach of anyone in the building. In the case of some trades, buckets of sand are more useful than water. Lightning-conductors should be fixed to all buildings.

Willard Case, *The Factory Buildings* (1922); British Fire Prevention Committee, *Building Materials and Fire Prevention*, 31 books. (P. N.)

FAEROE ISLANDS (*see* 10.123).—A group of 21 islands belonging to Denmark, situated in the North Sea, 7° east, 62° north. The area is 511 sq. m. and the population (1921) 21,532. Since 1910 the development of an active movement in favour of self-government has been the most prominent feature of politics in the Faeroes. Though the *Sjálvstýrisflokkur*, or Home Rule party, was first organized as lately as 1906, it is true that some points in the nationalist programme have an earlier origin.

Rise of Nationalism.—The endeavour to secure for the national speech of the inhabitants a position of equality with the official Danish may be said, indeed, to date from the middle of last century, when V. U. Hammershaimb, by systematising the local language, adapted it to literary use. The encouragement of this language was a main plank in the programme of the *Föroyingafelag*, a society instituted in 1889. The addition, however, to such comparatively innocent expressions of nationalism, of claims for complete political autonomy and even independ-

ence, is doubtless largely due to the stimulus of recent events. The success of a similar movement in Iceland (*q.v.*), which secured for that colony, in 1918, a status of sovereign independence, has no doubt played its part, and it is significant that it was in the same year—1918—that the Home Rule party of the Faeroes first obtained a majority in the local Lagting. To this stimulus was added, at about the same time, the prominence given to self-determination during and after the World War.

But above all, the dispute between Denmark and Norway over the question of Greenland revived old complaints as to the methods whereby the Danish negotiators, at the Treaty of Kiel in 1814, managed to retain possession of the ancient Norwegian colonies, Iceland, Greenland and the Faeroes, while the separatist tendencies of the Home Rulers were encouraged by certain sections of the Norwegian press and by private individuals in Norway. Under these influences the nationalist leader in the Faeroes, Johannes Patursson, went so far, in 1923, as to suggest the possibility of complete separation from Denmark and an ultimate union with Norway. This, however, is no part of the official programme of his party, the political aims of which do not seem to go much further than an effort to secure autonomy by giving to the Lagting legislative instead of, as at present, merely advisory powers.

With regard to the language question, some progress has been made, and since 1912 the use of the local as well as the Danish language in education and in the conduct of religious services has, to some extent, been authorized. The claims of extreme nationalists in this respect are, however, not yet satisfied. The complaints of Danish misrule made by Home Rulers seem, as is usual in such cases, based more on the events of the past than the present. The Danish Govt. has voted considerable sums towards the construction of roads and harbour works, as well as to the support of education. The large increase in the population, which has nearly doubled since the beginning of the century, indicates a considerable measure of prosperity.

(G. M. G.-H.)

FAGUET, ÉMILE (1847–1916), French critic and man of letters (*see* 10.125), published in his later years *Rousseau penseur* (1910); *Madame de Sévigné* (1910); a study of *Rostand* (1911); *Vie de Rousseau* (1911); *Les amies de Rousseau* (1912); *Rousseau artiste*, etc. (1912); *En lisant Molière* (1914) and *Mgr. Dupanloup* (1914). He died in Paris June 7 1916.

FAIRBAIRN, ANDREW MARTIN (1838–1912), British divine (*see* 10.129), died in London Feb. 9 1912.

FAIRBANKS, CHARLES WARREN (1852–1918), American politician, was born near Unionville, O., May 11 1852. Graduating from Ohio Wesleyan University in 1872, he was admitted to the bar in 1874, and began practice at Indianapolis, Ind., where he became a railway financier. He was chairman of the Republican State Convention in 1892, 1898 and 1914, and in 1896 was elected to the U.S. Senate. He was chairman of the U.S. representatives on the British-American Joint High Commission for dealing with Canadian questions in 1898 and 1903, being re-elected to the Senate in the latter year. In 1904 he was elected Vice-President as a Republican with Theodore Roosevelt. In 1916 he was again nominated for the vice-presidency, but was defeated. He died at Indianapolis June 4 1918.

FAIRBANKS, DOUGLAS (1883–), motion picture actor and producer, was born at Denver, Colo., May 23 1883. He studied at the Colorado School of Mines and later attended Harvard University, but left the university to enter a brokerage firm in Wall Street. In 1901 he abandoned finance and took up the stage as a career, eventually starring in several plays, among them *The Man of the Hour* and *The Gentleman from Mississippi*. Leaving the stage in 1915, he devoted himself to the screen and achieved success in *The Lamb*, his first picture. In 1917 he became head of his own producing company. His pictures have been distinguished by the wholesomeness of their themes and the extraordinary amount of action displayed. His later productions, such as *The Thief of Bagdad*, exhibit great mechanical ingenuity and a genius for picturesque background. His other pictures include, *The Mark of Zorro, The Three Musketeers, Robin Hood, Don Q* and *The Black Pirate*. He married, March 28 1920, as his second wife, Mary Pickford.

FAISAL AL HUSAIN (1885–), King of 'Irāq, was born at Taif, the third son of the Sharif Husain. Faisal traced his descent from Fatimah, only surviving child of the Prophet, through Hasan, her eldest son by marriage with 'Ali Ibn Abi Talib, fourth Amir Al Muninin. After the custom of his house, Faisal was sent when only seven days old, to Rahab Palace, the country seat of the Al 'Aun family, in the territory of his clan, Beni 'Abadiyah and their confederates the 'Ataibah. Here the boy was raised among the tribesmen, and remained until he was seven. In 1893, when Husain was ordered to Constantinople, Faisal accompanied him and was educated privately in that city. In 1905 he married his cousin, and returned to the Hejāz in 1909, when his father was appointed Sharif.

In 1913 Faisal became deputy for Jiddah and proceeded to identify himself with the Arab National movement. He commanded his father's forces in 'Asir in 1914, and was at Mecca on the outbreak of the World War. He was posted with the Turkish Governor of Syria in 1915, but escaped to the Hejāz early in the following year, and there played a leading part in the Arab revolt, commanding the Arab forces with Gen. Allenby's army until the capture of Aleppo in Oct. 1918. His influence with the tribes did much to keep Husain's tribal levies in the field. As Commander-in-Chief of the Arab Army under the Allied Commander-in-Chief he then undertook the administration of the newly-constituted Syrian State, and after attending the Peace Conference in Paris returned to Syria in April 1919. In Sept. he again visited Europe and remained until Feb. 1920; in the following month he was proclaimed King of Syria, but being unable to come to terms with the French Mandatory power he left Damascus in July 1920. After spending the winter in England he proceeded to 'Irāq as candidate for the throne in June 1921, and was elected king by a plebiscite in which he received 96% of the votes cast (*see* 'Irāq).

FALKENHAYN, ERICH VON (1861–1922), Prussian general, was born Sept. 11 1861 at Burg Belchau in the district of Thorn (Torun). He took part in the China expedition of 1900 and remained in China with a brigade of occupation till 1903. In 1906 he was appointed chief-of-staff of the XVI. and afterwards of the IV. Army Corps; in 1913 he became general and was appointed Prussian minister of war. He succeeded Gen. von Moltke in Dec. 1914 as chief of the general staff of the army, was advanced to the rank of general of the infantry, and helped to plan the summer offensive of 1915 against Russia and the operations by which in the winter of 1915–6 Serbia was overrun. He was made responsible, however, for the ill-success of the German attacks of 1916 at Verdun, and was replaced as chief of the general staff by Hindenburg in Aug. of that year. He was then assigned the leadership of the IX. Army against Rumania. In 1917 he took command of the so-called Asiatic Corps, for operations in the Caucasus, and in 1918 and 1919 was at the head of the X. Army. Falkenhayn wrote *Die Oberste Heeresleitung 1914–6 in ihren wichtigsten Entschliessungen* (1920) and *Der Feldzug der 9. Armee gegen die Rumänen und Russen 1916–7* (2 vol., 1921). He died April 8 1922 at the castle of Lindstet, near Wildpark.

FALKLAND ISLANDS, BATTLE OF THE.—One of the principal naval actions of the World War was fought on Dec. 8 1914, to the southeast of the Falkland Is. between a British battle-cruiser squadron under Vice-Adml. Sir Doveton Sturdee and the German squadron under Vice-Adml. Graf von Spee. The table on p. 7 shows the details of the respective forces

Fleet at Port William.—Adml. Sturdee arrived at Port William (adjoining Port Stanley) in the Falklands in the forenoon of Monday, Dec. 7. The "Canopus," an old battleship, was already there, moored in Port Stanley and waiting with the local volunteers to resist any attack. The squadron was ordered to keep steam for 12 knots at two hours' notice; the "Macedonia"

took the guard, and coaling started. Adml. Sturdee's own colliers had not arrived: there were only three in harbour and the coal in one had deteriorated. The " Carnarvon " finished coaling at 4 A.M. Dec. 8; the " Invincible " started at 6 A.M., and the " Inflexible " at 7:20 A.M. The " Bristol " had drawn fires to remedy defects and the " Cornwall " had opened up one engine. This was the situation when at 8 A.M. the " Glasgow " fired a gun.

German Fleet Sighted.—A signal was flying at the look-out station on Sapper's Hill above the harbour. It reported two strange ships in sight. A scene of bustle and commotion ensued. At 8:14 A.M. the signal was made to prepare to weigh and raise steam for full speed. Colliers were cast off, guns cleared away and great clouds of smoke began to pour from the funnels as the ships raised steam. The ships which had appeared so unexpectedly were the " Gneisenau " and " Nürnberg," which Von Spee had sent in advance to effect a landing. They were not visible from the " Canopus," but with the help of a fire control station on the hill she opened fire on them with her 12-in. guns at 9 A.M. The range was over 14,000 yd. and the shots fell short, but they made the " Gneisenau " turn away.

The " Scharnhorst " was still some 15 m. off but the clouds of smoke rising over the hills had made Von Spee uneasy. From the " Gneisenau " came a report of six warships in the harbour, and the German admiral, confirmed in his misgivings, ordered her to steer east and not to accept battle. By 10 A.M. the " Invincible," " Inflexible " and " Cornwall " were under way and leaving harbour. Huge clouds of smoke hid them for a time, but they cleared away, revealing the tripod masts of battle-cruisers and Von Spee knew that his hour had come.

Pursuit of German Fleet.—By 10:30 A.M. Sturdee was clear of the harbour; the Germans were hull down to the southeast about 11 m. off, and the admiral hoisted the " general chase," a signal for each ship to steam as hard as she could in pursuit. It was a perfect day with a blue sky and calm sea. A light wind was blowing from the northwest. The day may be resolved into two phases —the pursuit from 10:20 A.M. to 1:20 P.M., and the action from 1:20 P.M. to 6 P.M. At 10:50 A.M. Sturdee ordered the " Inflexible " to take station on his port quarter, thereby annulling the signal to chase. By 11 A.M. the Germans were showing above the horizon and the battle-cruisers eased to 24 knots. The " Glasgow " was on the " Invincible's " port bow, the " Kent " on her port beam. The " Carnarvon " and " Cornwall " were 5 m. astern.

The crews were piped to dinner and, to give the " Carnarvon " a chance to get up, the admiral reduced to 19 knots. Meanwhile Von Spee's colliers had been sighted to the westward off Port Pleasant (20 m. west of Port William) and the " Bristol," which was just leaving harbour, was sent after them with the " Macedonia " at 11:30 A.M. By this time the chase was gradually coming round to southeast by east. The " Carnarvon's " efforts to get up were unavailing and Sturdee increased to full speed. By 12:50 P.M. the battle-cruisers were going 25 knots, overhauling the Germans fast.

The " Leipzig " soon felt the pace and began to drop behind. At 12:55 P.M. her range had fallen to 16,000 yd. and the " Inflexible " opened fire on her. Von Spee, to save his light cruisers, ordered them to scatter at 1:20 P.M. and they broke away to the southward, but the British cruisers were ready, and without waiting for orders, the " Glasgow," " Cornwall " and " Kent " went off in hot pursuit (see fig. 1).

Conflict of Battle-Cruisers.—Von Spee, as his light cruisers left him, turned at 1:25 P.M. to the eastward to accept battle, and took station ahead of the " Gneisenau," while Sturdee's battle-cruisers to the northward turned into line ahead on an easterly course. At 1:30 Von Spee opened fire at 14,000 yd. but the range was too great for the 8·2 in. guns and he led round to the northeast. The range fell to 12,500 yd. and about 1:45 P.M. the " Invincible " was hit, and Sturdee turned away to open the range and take advantage of his heavier guns. The windward position was a severe handicap. Dense clouds of smoke

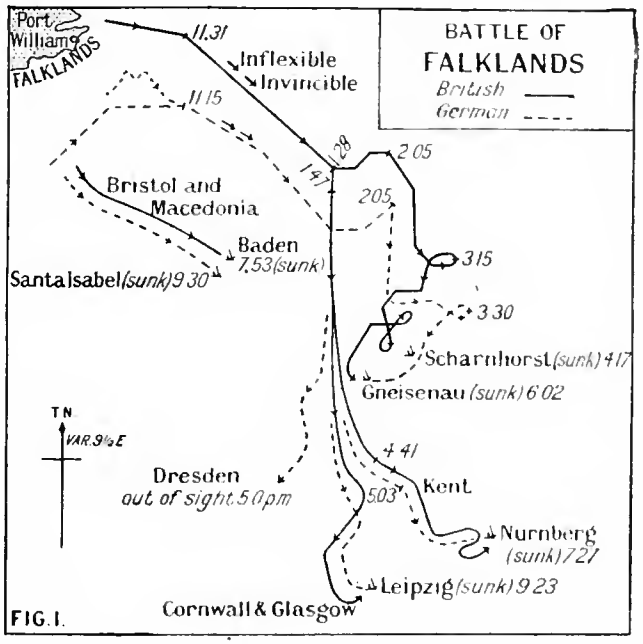

FIG. 1.

were pouring from the battle-cruisers shrouding the ships and smothering the range. By 2 P.M. the range had increased to 16,000 yd. and the guns ceased fire. No serious damage had been done, the " Gneisenau " had received only two hits, and one of her 8·2 in. casemates had been temporarily disabled.

At 2:05 P.M. Von Spee turned right away to the southward, bringing the battle-cruisers right astern, and some minutes elapsed before the movement was seen; then Sturdee turned after him to the southward, increasing speed, and the chase began again (see fig. 2). It continued for nearly 40 min., while Sturdee crept gradually up on von Spee's port quarter. At 2:50 P.M. the range was down again to 14,000 yd., and turning two points to port, Sturdee opened fire again. Von Spee again accepted action and turning to the east opened fire at 2:55 P.M. (see fig. 2). The action ran to the eastward till 3:15 P.M. with the range falling gradually to 11,000 yards. The British guns were now establishing a mastery. The " Scharnhorst " was burning, her fire had slowed down and she sheered to starboard for a time with a damaged rudder.

But again the smother of smoke made spotting difficult, and at 3:15 P.M., to escape from it, Sturdee turned the battle-cruisers right round to port together, so that the " Inflexible " was now leading to the westward. Von Spee in reply at 3:27 P.M. led round to port, in succession bringing his starboard guns into action. The action now ran to the south-westward with the

British battle-cruisers circling round the Germans at a range of 11,000 to 12,000 yards. By 4 P.M. the "Scharnhorst" was blazing from stem to stern, her guns were silent, her superstructure was a mass of ruins; she was listing heavily to port and barely making 12 knots. Smoke was again obscuring the range and the "Inflexible," to get rid of it, circled round to starboard at 4:10 P.M. engaging the "Gneisenau" on a northeasterly course (see fig. 2).

End of the "Scharnhorst."—The "Invincible" ran on a little farther to the southward and then circled round to the northeast. The "Scharnhorst's" end was now near. She turned to starboard a mass of smoke and flame, then at 4:17 P.M. heeled completely over to port and sank with her flag flying. Not a soul was saved. The "Invincible" and "Inflexible" were now engaging the "Gneisenau" on an opposite course; at 4:30 P.M. Sturdee, then on a northeasterly course, circled round to starboard, and ordering the "Inflexible" to form single line ahead

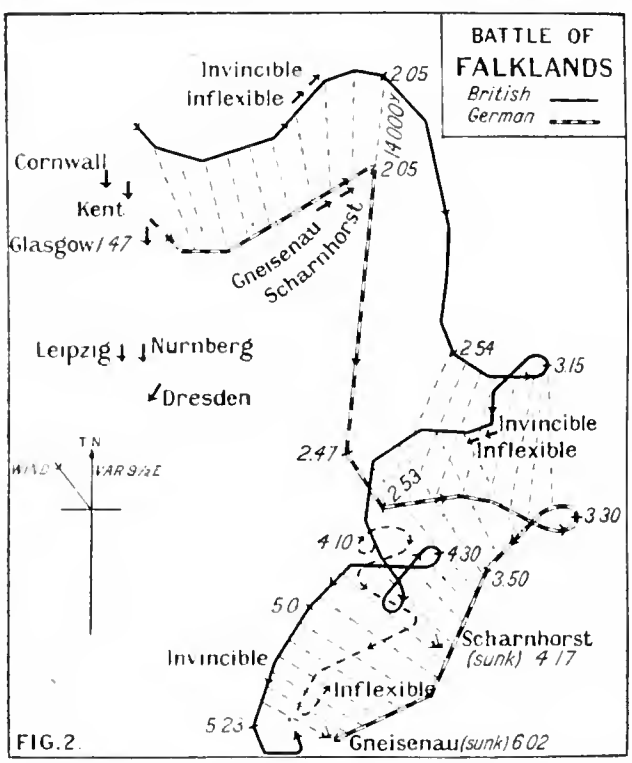

FIG. 2.

shaped course to the westward. The "Gneisenau" was some 13,000 yd. to the southeast, struggling desperately along on a southwest course.

The "Gneisenau" Sunk.—At 4:45 P.M. the "Inflexible," again hampered by the smoke, turned to port, and, leaving the flagship, ran to the eastward, opening on the "Gneisenau" with her starboard guns, and turning southwest again at 4:55 P.M. kept the "Gneisenau" at about 12,000 yards. By 5:15 P.M. the latter was in a sorry plight. Her foremost funnel had toppled over; she was listing heavily to starboard and barely making headway. The sunshine had gone and a drizzling rain had commenced to fall. Her fore turret still fired fitfully. At 5:45 P.M. she fired her last shot and at 6:02 P.M. heeled slowly over to starboard and sank. The British rescued 187 survivors from the icy water.

Pursuit of Light Cruisers.—Meanwhile the German light cruisers were heading to the southward with the "Glasgow," "Kent" and "Cornwall" at their heels. The actual speeds are doubtful. On the British side, the "Glasgow" could probably go 25 knots, and the "Cornwall" and "Kent" can be credited with at least 22½ and 22 knots. The "Dresden" could probably go 25 knots, the "Nürnberg" 22, while the "Leipzig," whose engines and boilers were in bad condition, could barely do 20 to 21. The German ships, which had been cruising continuously for four months, found it hard to maintain their speeds. When the chase began the British cruisers were some 10 to 11 m. behind. The "Glasgow" soon forged ahead and at 2:53 P.M., in spite of the efforts of the "Dresden" to divert her by sheering off to the southwest, opened fire on the "Leipzig" and obtained a hit on her which reduced her speed.

Light Cruiser Action.—By 4:15 P.M. the "Cornwall" was coming up and opened fire on the "Leipzig" at 12,000 yd., but the range in the failing light was too great, and it was not till 4:25 P.M. that her shots were falling close. The "Glasgow" had received one or two hits and, forsaking any attempt to overtake the "Dresden," circled to starboard at 4:27 P.M. and passed behind the "Cornwall." The chase continued to the southeastward till 4:55 P.M., when the "Leipzig" turned to the southwestward, and the "Cornwall," following suit, engaged her with the port guns (see fig. 1). The "Glasgow" came into action again, the "Leipzig's" speed gradually sank and the British cruisers kept her under continuous fire at 9,000 to 10,000 yards. By 6 P.M. a drizzling rain had begun to fall and the "Glasgow" signalled to close. The "Cornwall" crept up and Capt. Ellerton began to fire lyddite with terrible effect.

The "Leipzig" Sunk.—By 7 P.M. the "Leipzig's" speed was reduced to 15 knots, but she was still firing fitfully. The whole of her stern was wrapped in flame and the main mast, melting in the heat, had collapsed. The British cruisers ceased fire and closed, but her flag was still flying defiantly and, at 7:50 P.M., they reopened fire for a quarter of an hour. Boats were lowered to rescue the crew. She was heeling heavily to port and at 9:23 P.M. turned over and sank (53° 55′ S., 55° 55′ W.). Only five officers and 13 men were saved.

"Nürnberg" in Action.—The "Kent," to the eastward all this time, had been vigorously pursuing the "Nürnberg" and by feeding the fires with all the spare wood in the ship, from hen coops to capstan bars, had brought the range down to 12,000 yd. by 5 P.M. The "Nürnberg" opened fire and was sending her 4·1 rounds right over the "Kent," when the latter's 6-in. guns were still falling 1,000 yd. short, but the weather was growing thick and it was becoming difficult to spot. Then came a change; the "Nürnberg's" boiler tubes gave out; her speed sank to 18 knots and the "Kent" overhauled her rapidly. At 5:45 P.M. the "Kent" was on her port quarter 7,000 yd. off, and the "Nürnberg" turned to northeast to engage her (see fig. 1).

The light was failing and Capt. Allen forced the pace and closed to 3,000 yards. The "Nürnberg" could not stand the fire and turned away to the southward at 6:02 P.M., but the "Kent" followed her round. By 6:10 P.M., the "Nürnberg" was blazing with only two guns in action, and the "Kent" circling round raked her at 3,500 yards. By 6:25 P.M. she was merely a burning wreck, listing heavily, but with her flag still flying, and the "Kent" opened fire again. Just before 7:30 P.M. the "Nürnberg" turned over and sank, but though the boats were searching up till 9 P.M., only seven survivors were found.

The following table shows the casualties of the British and German forces:—

Ship		Hits Received	Casualties	Rounds Fired
British	"Invincible"	22	0 k. 1 w.	573 12-in.
	"Inflexible"	3	1 k. 2 w.	661 12-in.
	"Glasgow"	2	1 k. 4 w.	316 6-in.
	"Cornwall"	18	0 k. 0 w.	1,000 6-in.
	"Kent"	36	4 k. 12 w.	646 6-in.
	"Carnarvon"	0	0 k. 0 w.	..
German	"Scharnhorst"	Sunk	All	..
	"Gneisenau"	Sunk	187 saved	..
	"Leipzig"	Sunk	18 saved	..
	"Nürnberg"	Sunk	7 saved	..
	"Dresden"	Escaped	..	..

k. = killed. w. = wounded.

German Colliers Captured.—Meanwhile the German colliers "Santa Isabel" (Hamburg-South America) and "Baden" (Hamburg-America) had been found by the "Bristol" and "Macedonia," chased to the southeast and captured about 4 P.M. (see fig. 1). Sturdee had given the order to sink all transports, and, though they were not transports, but colliers full of valuable coal, they were sunk. The "Seydlitz" (Norddeutscher

Lloyd) escaped to the southward and found safety amongst the icebergs of the Antarctic. The "Dresden" had disappeared to the southwest about 5 P.M. and reached Magellan Straits on Dec. 10. Three long months elapsed before she was hunted down and sunk by the "Glasgow" and "Kent" on March 14.

Conclusion.—This was the end of the engagement known as the Battle of the Falklands, the end of Von Spee's squadron, of Von Spee and both his sons. It marked the end, too, of a definite phase of the struggle at sea. The German cruiser warfare collapsed, and outside the North Sea and the Baltic, England held an unchallenged command of the sea.

FALL RIVER, Mass., U.S.A. (*see* 10.155), was outranked in 1919 by New Bedford (*q.v.*) in the value of cotton goods produced. In 1920 it ranked first in the proportion of children employed, 18·5% of all 10–15 years of age; second in illiteracy, 11·9% of the population 10 years of age and over being unable to write; third in the proportion of women at work, 41·6% of all females 10 years of age and over, and had a high infant mortality. The total value of its manufactured products was $64,146,000 in 1909; $163,246,000 in 1919; $133,407,969 in 1921; $172,395,700 in 1923. The average number of wage-earners in the factories was practically the same in 1909 and 1919 (37,139 and 37,015 respectively), and after a drop in 1921, rose to 37,018 in 1923. Fall River was seriously affected by the general depression of 1920–1 and by the growing competition of southern cotton-mills. At times, after the close of the World War, the number of unemployed was estimated at 20,000 or 30,000, or even more. In 1922 a fuel-oil refinery, with a monthly capacity of 1,000,000 barrels, was added to the industries of the city. The construction of an electric super-power plant on the Taunton river was begun in 1925. A city plan was adopted in 1923.

FAMILY ALLOWANCES.—The custom of paying, in addition to wages, allowances for children and sometimes for wives, grew up out of the economic conditions during and after the World War, though before that vestiges of it existed here and there in a few occupations, notably in agriculture, where payments in kind varying with the size of the labourer's family have long been general in most countries. During the War all the belligerent States paid allowances for the wives and children of the men in the fighting services, and in the public services of most European countries, the war bonuses made necessary by the rise in prices were proportioned in some way to the size of the worker's family, or at least differed for married and unmarried. Probably these two war customs prepared the way for the rapid development which has followed in some countries.

In the services of the State and of local authorities the payment of allowances for children has become established in France, Germany, Belgium, Holland, Switzerland, Italy, Czechoslovakia, Jugoslavia, Norway (municipal services only) Sweden, Finland and Poland. In several of these (*e.g.*, Switzerland and Italy), attempts have been made, so far unsuccessfully, to drop the payment as conditions became more normal. In most countries, a distinction is made between the children of salaried officials and those of weekly wage-earners, the allowances for the former being at a higher rate and continuing during the years of university education, while those of the latter terminate at 13 or 14. Otherwise the allowances do not vary with the remuneration of the worker, except in Holland, where they are expressed as a percentage of his salary, with a minimum and a maximum. In Switzerland, allowances are confined to the lower paid officials. Everywhere the allowances represent only a small part of the cost of a child; being on a flat rate they are more important to the lower paid than to the higher paid officials. Thus in Germany, where the allowances in the public services are relatively more important than in most countries, and where they include an allowance for the wife, it is reckoned that the average income of a married official is raised by this means from 15 to 30%, according to his grade, above that of an unmarried official. For a man with a large family the value is of course considerably more than this. The Federal Govt. of Australia gives the children of its employees an allowance of 5s. a week until the age of 14.

Next to the public services, mining is the occupation where the system is most widely established. It is practically universal in the mining industry of Germany, France, Belgium, Austria and Yugoslavia and in some of the mining districts of Holland, Czechoslovakia, Poland and Sweden. Here, as elsewhere, the allowance represents only a contribution towards child maintenance. It is reckoned that in the Ruhr a workman with three children receives by this aid about 16% more than a single man. In Germany and France the cost of the allowances to the employers is equivalent to about 6 or 7% of the wage bill. In most countries the married workers' privileges include coal and in some a house free or at a low rate.

THE SYSTEM AT WORK

In other industries, the family allowance system is widely extended only in France, Belgium, Germany and Austria, though there are instances of it in other countries.

The French System.—In France its development has been greatly helped by the device of the equalisation fund (*Caisse de Compensation pour allocations familiales*), which guards successfully against the danger that family allowances paid for by employers might prejudice men with families in obtaining employment. Such funds were first proposed in 1918 by M. Romanet, a benevolent Roman Catholic employer of the metallurgic industry of Grenoble. The idea spread rapidly, and by the end of 1925 there were in France 180 equalisation funds, covering over 10,000 firms. The method is simple:—The fund may be either "professional," *i.e.*, confined to a single industry or kind of occupation, or "regional and interprofessional" *i.e.*, open to all employers who desire to join within a given area. The scale of allowances (which varies considerably in different funds) having been fixed, the number of children covered is ascertained at fixed periods, and each adherent employer is assessed for his share of the cost, the assessment being based either on the amount of his wage-bill, the number of his workers or the number of hours worked. When the number of workers is the basis, some funds fix a lower scale for women and youths than for adult male workers. Some funds actually pay the allowances to the parents; in others the employer pays and subsequently claims from the fund the excess, or pays into the fund the deficiency of his payment over the sum due from him.

The allowances are usually paid monthly and, in an increasing proportion of funds, not to the workman but to the children's mother. It is found that this method is not only more certain to benefit the children, but less apt to arouse the jealousy of the single man, who is thus led to regard the allowances, not as an addition to wages, and thus an infraction of the principle of equal pay for equal work, but as a recognition of the separate service of parenthood. The desire for an increased population is shown by the grading of the allowances upwards, *e.g.*, in May 1924 the average of the scale in all the funds was per month 19 fr. for one child, 46 for two children, 81 for three, 124 for four. At this date the average monthly wage of an adult labourer was 500 francs. Many funds also pay bonuses at childbirth (*primes de naissance*) and during the period of lactation (*primes d'allaitement*). Many maintain subsidiary health services, such as health visitors, day nurseries, convalescent homes, etc.

The cost of the allowances to employers varies from 1 to 7% of the wage bill. Including the public services, mines, railways and other large enterprises, which pay allowances directly, the number of workers covered in 1925 was reckoned at 3,500,000 and the annual cost of allowances at over 1,000 million francs.

The system is increasingly popular with employers, who find their reward in the increased well-being and contentment of their workers. The attitude of the trade unions has changed from one of suspicion to a definite and cordial acceptance of the principle, coupled with resentment of employers' control and demand that it shall be made universal, compulsory and collectively controlled.

Other European Countries.—In Belgium, the methods adopted are modelled closely on those of France. Progress began several years later, but has been rapid; and the system appears equally destined to become a permanent part of industrial life, welcomed both by employer and employed. In his report for 1925, the British commercial secretary attributed the freedom of the country from industrial strife partly to this cause and says:—

It is almost generally admitted now that the family bonus system is of real economic value, and that by improving the present and future conditions of the working class it is capable of exerting a direct and beneficial influence on the prosperity and producing capacity of the country.

In Germany, during the five years following the World War the payment of family allowances was probably as common as in France,

but much less generally popular. Employers tended to regard the allowances as a temporary addition to wages which could be dropped when conditions became more normal. Hence few equalisation funds were started, and the allowances being paid to the worker with his wage was apt to excite the single man's jealousy, while the married man feared to be prejudiced in seeking work. In 1925 the number of collective agreements containing family allowances showed a falling off. It is not yet certain whether the tendency will be permanent.

In Austria, the payment of children's allowances through equalisation funds was, in 1921, made compulsory on all employers, as a kind of compensation to the workers for the removal of the bread subsidy. The amounts, however, were exceedingly small, and at the end of the period stipulated by the law, the system, to a great extent, lapsed, except in the public services and in the mining industry.

Australia.—In Australia, since 1907, wages have been subject to a legal minimum, settled by the Courts and supposed to be roughly based on the needs of the "normal" family of five persons (four persons in New South Wales). In 1919, owing to the discontent caused by rising prices, a Royal Commission on the basis wage, composed of equal numbers of representatives of employers and employed with an impartial chairman, was set up to determine what was the actual cost of maintenance of a five-member family at a standard of reasonable comfort. The sum fixed for each of the five States averaged £5 16s., the existing basic wage being then £4. The Commonwealth statistician promptly reported that the whole produced wealth of the country, if equally divided, would not yield the necessary amount. The chairman of the commission, Mr. A. D. Piddington, then submitted the proposal that the basic wage should be based on the needs of man and wife and supplemented by an allowance of 12s. per week for each child, paid out of a State fund to which each employer should contribute 10s. 9 p. per week per employee. He pointed out that the ordinary conception of the basic wage postulated 2,100,000 non-existent children, the total number of actual children (under 14) of employees being 900,000. The only actual fruit of this proposal, up to 1926, has been the aforesaid 5s. allowance paid for each child of a Commonwealth employee. But child endowment has figured largely in the programme of Australian politicians. A Bill embodying Mr. Piddington's proposal passed the Lower House of New South Wales in 1920; a Bill for the State endowment of children was introduced by the succeeding Labour Govt. of New South Wales. The South Australian Labour Govt. in 1925 promised, but failed, to introduce a similar measure. The Federal Govt. has also played with the question.

Great Britain.—Although Great Britain possesses the earliest equalisation fund in existence (in fact though not in name) in that established about a century ago by the Wesleyan community for children of ministers, the family allowance system has so far not taken much root in the country, except in the fighting services. The subject, however, has been widely discussed since the development of the foreign schemes. It is significant of its growing hold on public opinion that during 1925 the London School of Economics introduced substantial educational allowances for the children of its professorial staff, the Independent Labour Party adopted as part of its programme a state scheme of children's allowances, and the Coal Commission report recommended such allowances as "one of the most valuable measures that could be adopted for increasing the well-being and contentment of the mining population."

Conclusions.—Advocates of the principle contend that as the national income or dividend is an uncomfortably tight fit, it will be impossible to satisfy the general demand for a reasonably high standard of life so long as the needs of the family during the years of its greatest dependency are only met through a wage paid equally to the childless man. They further argue that the value of children to the community, as its future citizens and workers, is not adequately recognised by a system which assigns to the family unit an income no larger than that enjoyed by the single individual; that as a result the more thoughtful and ambitious workers are tending drastically to restrict their families, while the less thoughtful and less ambitious practise no such restriction. To this is added the plea that the maximum production of wealth will only be achieved when competition between men and women workers is at once free and fair; that this is impossible without "equal pay for equal work," and that this again is impracticable until family responsibilities are met by family allowances.

There is a division of opinion among advocates of family allowances in Great Britain between those who prefer the foreign system of equalisation funds paid for by employers, those who would like to see family allowances provided through contributory insurance, and those who believe that the whole cost should be met by the State.

FARINA, SALVATORE (1846–1918), Italian novelist (*see* 10.179), died at Milan Dec. 15 1918. His best-known work is *La più bella fanciulla dell' universo* (1911). See V. Dendi, *Un Romanzo dimenticato, S. Farina* (1921).

FARINACCI, ROBERTO (1892–), Italian politician, was born Oct. 16 1892 at Isernia, in the province of Campobasso. Educated at Cremona, he entered the railway administration, becoming station-master at Cremona. While still a very young man he took to politics, and on the outbreak of the World War conducted an active interventionist propaganda. As soon as Italy went to war he volunteered for active service, but 18 months later was ordered to resume his civilian duties. After the Armistice he was one of the first to join Mussolini's Fasci di Combattimento and he organised the movement in Cremona. In 1921 he was returned to the Legislature as member for Mantova-Cremona, but was unable to take his seat in the Chamber, being under age. He had now become the leading figure in Cremona, and through the daily paper founded by him, *Cremona Nuova*, acquired an increasing influence in the Fascist party. He also found time to complete his studies and secured a university degree in law. When Mussolini came into power, although not given office, Farinacci continued to be one of the Premier's most trusted advisers. In 1924 he was again returned to the Legislature and in March 1925 he became, on Mussolini's nomination, general secretary of the Fascist party.

FARMERS' ORGANISATIONS (*see* 10.181).—The wholesale intervention of various Governments in agricultural production and the regulation of prices which was necessary during the World War have provided great stimulus to the organisation of farmers into associations capable of negotiating with the Governments of their respective countries. The growth of the Federation of Farm Bureaus in the United States and of the National Farmers' Union in Great Britain are but examples of associations not called into existence by the War but which have strengthened their position and learned to play a representative part during these critical years.

It has become evident, however, that any national movement for the stabilisation of the prices of agricultural produce at a level that will be remunerative to the farmer must be severely limited by international competition in the world's market. Consequently a widespread feeling has grown up that an international combination between producers is necessary in order to secure some common action among the farmers of all countries whereby their interests may be protected.

The International Institute of Agriculture at Rome is, however, organised on an official basis. There is no direct representation of farmers, and the line of work taken up by the Institute has been mainly confined to the collection and dissemination of information. The constitution of the Institute which is defined by treaty provides no machinery for enabling farmers' associations to formulate an international expression of agricultural opinion, but the question is still under consideration. There exists an International Commission of Agriculture with its seat in Paris, which from time to time (1923 in Paris, 1925 in Warsaw) convenes an International Congress of Agriculture. It is under consideration whether this organisation cannot be given a character more directly representative of the associations of farmers in various countries.

The same basic idea has been earnestly advocated by the writings and personal influence of Dr. E. Laur, the Director of the Swiss Farmers' Union. In Sept. 1925, Dr. Laur summoned an international conference of representatives of agricultural associations which met at Berne and was largely attended by delegates of farmers' organisations in Europe and the United States

of America. The Conference affirmed the need for an international organisation that could promote common action amongst agricultural producers all the world over and decided to take steps to secure the support of the properly constituted bodies in the various countries. A meeting was convoked in Rome for April 1926 on the occasion of the meeting of the General Assembly of the International Institute of Agriculture. (A. D. H.)

Organisations in the United States

The following article deals with the development of Farmers' Organisations in the United States, where the movement has grown more rapidly and attained greater dimensions than in any other part of the world. For similar organisations in other agricultural countries, the articles thereon should be consulted. (*See* also Agriculture; Co-operation, Agricultural; Marketing.)

The organisations in the United States fall into two general classes: (1) organisations interested in the general problems of agriculture, *i.e.*, education, legislation, credit, transportation, etc.; and (2) co-operative organisations of farmers formed for the purpose of marketing farm products or purchasing farm supplies. This classification does not include the various state and Federal institutions engaged in agricultural teaching, research and service.

Principal Organisations.—Prominent among the general farmers' organisations are the Grange or Patrons of Husbandry, the American Farm Bureau Federation, the Farmers' Educational and Co-operative Union, and the Equity. Other organisations that restrict their activities to a special industry or phase of agriculture are the National Co-operative Milk Producers' Federation and the National Council of Farmers' Co-operative Marketing Associations. A number of local or regional organisations serve the interests of farmers and shippers of farm products. The organisation of the Grange comprises subordinate (or local) county and state granges. The state organisations make up the National Grange. The work of the local granges is chiefly fraternal, educational, social and recreational, while the state organisations and the National Grange give attention to broad questions of agricultural policy, education and legislation. The local units of the American Farm Bureau Federation are county organisations, which were formed originally to employ and co-operate with an agricultural adviser for the county, who was also a state and Federal employee. In most states the county agricultural adviser was in 1926 paid wholly from public funds, though he might work in close co-operation with the county farm bureau or other farm organisation. County farm bureaus were first federated in state organisations, and in 1919 the national organisation, the American Farm Bureau Federation, was formed. This organisation obtained a membership of over 1,000,000 farmers the first year of its existence. Since 1920 it has taken an active part in the formation of large-scale, co-operative marketing agencies for grain, live stock and fruits and vegetables. Some state farm bureaus have a close affiliation with co-operative marketing associations which they have fostered.

Marketing.—The organisation of farmers for business purposes has been mainly in the field of co-operative marketing. The most reliable estimates placed the total business of co-operative marketing associations at $2,500,000,000 for the year 1925. This business was conducted by approximately 12,000 associations, whose membership totalled over 2,700,000, more than one-third of the total number of farmers in the United States. The number of farmers who were members of co-operative associations was divided by commodities as follows: grain, 520,000; dairy products, 460,000; cotton, 300,000; tobacco, 300,000; live stock, 400,000; fruits and vegetables, 180,000; eggs and poultry, 50,000; wool, 50,000; nuts, 20,000; all other, 420,000.

The first nation-wide survey of the extent of co-operation among farmers was begun in 1913. Data for the years 1912, 1913, 1914 and 1915 were collected and tabulated. The most complete information was secured for the year 1915. Reports were received from 5,424 co-operative associations with an estimated membership of 651,186 and an estimated volume of business amounting to $635,838,684. The largest volume of business, $289,689,200, was credited to the farmers' grain elevators. Fruit and vegetable associations with $201,542,600 were second, and associations marketing dairy products were third with $89,061,300. The second survey was made in connection with the taking of the 1919 census. Sales through farmers' marketing organisations at this time were reported as $721,983,639 and 511,383 farms reported sales through such organisations. At the same time 329,449 farms reported purchases through farmers' buying associations totalling $84,615,669. The third survey was undertaken by the U.S. Dept. of Agriculture in 1921. Reports had been received from 10,500 associations up to 1925, and it is on these reports that the estimate of total business, already given, is based. The interesting feature as regards these figures as compared with those given for 1915 is the increase in the amount of business done by cotton, tobacco and live-stock marketing associations. In fact, large-scale co-operation in the South has developed entirely since 1920.

Local Associations.—In Jan. 1926 there were approximately 11,500 active local co-operative associations—independent organisations and units of federations—whose members were for the most part limited to farmers using the same shipping point. The local association is the earliest form of co-operation among farmers in the United States. It performs, as a rule, the services of a country dealer. Fruit and vegetables are assembled, packed and stored by local associations; milk is manufactured into butter and cheese; grain is bought; live stock is assembled and shipped and supplies are purchased and distributed by this type of organisation. Most of them handle only one commodity or a group of related commodities, such as several vegetables, or butter and eggs. Approximately 9,500 of the local associations operate independently. They sell their products to local dealers or through commission merchants in the terminal markets. In some cases they employ the services of private distributing firms, or more rarely sell direct to wholesalers.

About 2,000 local organisations, however, are member units of federations formed for the purpose of performing the selling services which the small independent local associations cannot handle to the best advantage. The federation is an organisation in which the local units are the members and own the stock of the organisation, if it is incorporated with capital stock. Over 450 creameries in Minnesota, for example, have affiliated to form a federation to sell the butter manufactured by them. Two hundred local citrus packing associations in California sell their products through a co-operative central ageney which they own and control. In this manner the group of local units are adequately represented in the markets at a reasonable cost. Approximately 50 federations were in operation in 1925. The annual sales aggregated $400,000,000, and over 220,000 farmers were members of the local units that affiliated to form these federations.

Regional Associations.—A third type of co-operative organisation is the centralised regional association. The first co-operative organisation of this type was formed in 1912. Since 1920, associations for the marketing of tobacco, cotton, fluid milk and dried fruit have been formed according to the centralised plan. A centralised regional association usually extends over a large area, frequently an entire state, or a producing region including portions of several states. It combines the functions of the independent local association and the federation. All members affiliate directly with the organisation, it owns the local warehouses and other necessary local facilities, and performs the local functions of assembling, storing, grading, or processing the product in addition to the marketing functions of distributing and selling. The number of members in associations of this kind exceed 60,000 in some instances. About 75 associations of this kind have been formed. They have approximately 900,000 members, and their total sales in 1925 were approximately $600,000,000. It will be noted, therefore, that approximately one-third of the co-operative marketing business was carried on in 1925 by 125 centralised regional and federated regional organisations. Sales agencies for the co-operative handling of live stock have been established at 20 of the terminal markets. During 1925 these agencies received live stock which sold for more than $280,000,000. Co-operative terminal market agencies have also been formed in a few markets for the sale of grain.

Capper-Volstead Act.—The rapid growth of large-scale co-operative organisation, which began in 1920, created a demand for state laws providing for the incorporation of the co-operative associations. In 1925, 46 of the states had laws permitting co-operative organisations to incorporate, with or without capital stock, and to incorporate in their articles of incorporation and by-laws provisions that would ensure the co-operative nature of the enterprise. Many of these laws also define the status of co-operative associations with reference to state anti-trust laws. In 1922 Congress enacted the Capper-Volstead Act which, in effect, sets forth the right of producers of agricultural products to act together in associations, and prescribes certain conditions which organisations of agriculture producers must meet in order to be considered co-operative for the purposes of the Act. The second section of the Capper-Volstead Act provides that the

Secretary of Agriculture may take steps to prevent the undue enhancement of prices of agricultural products by co-operative organisations.

The steady growth of co-operative marketing among farmers in the United States indicates that it has become established as a permanent method of marketing farm products. Since 1924 the development of new co-operative enterprises has been comparatively slow. More effort is being directed toward strengthening existing organisations and introducing more efficient methods of marketing farm products.

FARM MACHINERY.—The increased demand for food supplies is met in two ways, by increasing the yields and by increasing the acreage, both of which require more labour in agriculture. To increase or even to maintain the efficiency of farm labour, and to keep down production costs in countries where labour is scarce, farm machinery is a necessity. It is sure to be in the future, as in the past, a factor of increasing importance in the agricultural, social and industrial structure of all civilised countries. In the United States the value of farm machinery manufactured yearly has increased approximately 250% since 1910, and the inventory value of machinery on farms has more than trebled. Progress may be classified under four headings: (1) new implements; (2) changes in design to adapt well-established implements to mechanical power; (3) changes in sizes of implements to meet changes in farm practice; and (4) refinements, standardisation, improved materials and research in farm machinery. Of the mechanical changes, those under items (2) and (3) have been the most extensive and have had the most influence in countries which have long used farm machinery.

Some New Implements Described

Corn Picker.—The mechanical corn (maize) picker, although not a new idea, is being increasingly adopted by the farming public. This machine snaps the ears from the standing stalks, then husks and elevates the ears to a wagon drawn at the side of the picker. It is fast becoming a necessity in economical production in the great maize areas where hand labour is scarce.

Ensilage Cutter.—The field ensilage cutter may also be classed as new since 1910. As an attachment to a tractor this device cuts the maize into ensilage lengths directly from the standing stalk, and loads the finely cut material on a wagon hauled at the side. The material is then drawn to the silo and blown into it by a blower. Although this method may not always lessen the cost of ensiling maize, it eliminates much hard hand labour and frees the farmer somewhat from the obligations of exchanging labour with his neighbours. Not long ago it was said that shocking grain and loading manure were the only big jobs left on the farm for hand labour. But since then the grain shocker and the manure loader have been developed sufficiently to be listed as distinctly new devices. Each of these, however, still presents some difficulties.

Cotton Picker and Beet Topper.—Neither the mechanical cotton picker nor the sugar-beet topper has been perfected sufficiently to go into general use. When the cotton picker is widely used it will undoubtedly revolutionise the agriculture of the more highly developed cotton areas; its influence socially and industrially is hard to predict.

Sugar-cane Harvester.—A new machine displacing much hand labour in the sugar-cane industry is the mechanical harvester which cuts, strips and bunches the cane in one operation. The successful application of a large, expensive machine of this kind to a specialised industry suggests the future use in general agriculture of large machines which combine operations and save labour and cost. The attention which farmers in humid regions are giving to the combination grain harvester and thresher illustrates this progressive tendency. It is only by recent investigations that the grain combine has been found to have possibilities outside of the semi-arid sections of the United States. Another example of "combine" machinery is a machine that will cut, dry and bale alfalfa hay in one trip over the field.

Adaptation to Requirements of Small Farms

Tractors.—The introduction of the tractor (*q.v.*) as a new form of power effected many changes in the older farm implements. About 1916 the light four-wheeled tractor appeared, soon to create somewhat of a revolution in the farm machinery field. The light tractor, costing less than its predecessors, has carried power farming to thousands of farms which perhaps could not have otherwise afforded it. This demanded an accompaniment of lighter and less costly implement units, leading to the introduction of the light, rigid hitch, two-wheeled tractor plough, and to the two-three-wheeled plough which uses three wheels while ploughing and only two while turning or being transported. The latter is equipped with a semi-floating hitch instead of the full floating hitch of its predecessors or the rigid hitch common in the typical two-wheeled tractor ploughs. These light ploughs, while not distinctly new implements, embody radical changes in plough design. They accompanied the light tractor into all countries into which the latter has penetrated, and have helped introduce power farming and have had a great influence in agriculture—they are one of the outstanding developments in farm machinery.

Implements Adapted to Tractors.—As the economy of the tractor on the average farm depends to some extent upon the number of uses to which it can profitably be put, manufacturers have tried to adapt to the tractor as many existing types of implements as possible. Grain drills equipped with tractor hitch and power-lift, so that the operator can control the lifting and dropping of the furrow openers from the tractor seat, have appeared during the last few years. If the farmer wishes to use his light, four-wheeled tractor for cultivating, he can secure a tractor hitch for a two-row cultivator; then by using an extension control, a comparatively new development, he can control and guide the tractor from the cultivator seat.

A special tractor mower is on the market. This machine is like the standard mower, but is built heavier and carries the control levers and lifting mechanisms which can be operated from the tractor seat. Potato and beet machinery is now furnished with either tractor or horse hitches. Some tractors now carry a "power take-off," through which power to propel the mechanism of the implement attached is taken directly from the tractor motor. This arrangement has caused some changes, especially in grain binders and corn pickers, and may prove revolutionary in general implement design. The grain binder so driven is lower and more compact, since the main wheel need not be used to develop power.

General Purpose Tractor.—Another tractor development that bids fair to influence farm machinery design widely is the idea of a general-purpose tractor. Attempts to make the tractor itself the base to which implement elements can be attached are beginning to be successful. A mower bar as an attachment to a light tractor was developed about 1918, but in a more recent tractor of special design four cultivator rigs can be attached to accomplish double-row cultivating. When the same power base is needed for mowing hay, the cultivator attachment is removed and a mowing attachment is set upon the tractor's draw-bar. Undoubtedly the designers of such a general-purpose tractor contemplate for use with it a four-row planting attachment and perhaps a raking attachment. Thus the same power unit will perform the ploughing, harrowing, grain seeding and grain harvesting operations of its predecessors, and will be able to work in row crops and in the hay field where the conventional type of tractor is somewhat handicapped. The essential part of the implement as an attachment for the tractor will be less expensive than the complete independent unit designed to be hauled. Hence, the tractor has greatly influenced existing design, and may influence future developments even more.

Size of Implements.—Increased attention has been given to the size of implement units which would prove most economical as to capacity, power and labour requirement and investment. The two-row cultivator has recently increased in popularity, because with it one man can cultivate 90% more acreage a day than with the single-row machine, with an increase of only 50% in power. Within the past few years 10-ft. grain binders have appeared for use with tractors. The tendency, however, is not toward larger sizes of all kinds of machines. The reduction of the combined harvester and thresher to a more economical size for the smaller grain farms is bringing this machine into quite general use in the principal wheat sections of the world.

The advent of mechanical power on farms of medium size makes it possible for the farmer to accomplish independently some belt-power jobs which formerly he had to hire to have done. As a result there is increasing demand for the small grain-thresher and for the small sizes of ensilage-cutters, huskers, shredders and shellers. In some countries the "custom" thresherman seems doomed. This present tendency toward small sizes of some belt machines to accompany the small tractor is not as fundamental as, nor should it seem contradictory to, the previously mentioned tendency of farmers to think about larger, faster, cheaper ways of producing food. At present the popular sizes of implement units depend upon the popular sizes of farms; and the size of farm has been determined largely by other than the machinery factors. The implement size, therefore, has been a result rather than a cause. But one must not overlook the possibility of modern agricultural thought and vision leading to farm machinery changes in both type and size that may reverse the old status. Farm machinery development may point the way to rather pronounced changes in agricultural organisation, and competition may be the direct cause for the transition. There seems to be renewed interest in the possibilities of corporate farming. Rather pertinent claims are made concerning the possibility of carrying to the farm more of the manufacturing process, allowing the larger, industrialised farm to deliver its product in more fabricated form. If the economics involved dictate such procedure, farm machinery will be of paramount importance.

Refinements in Design.—Refinement in farm machinery design and manufacture has continued during the past decade. Implements are now of neater design or are more trim; their parts are more accessible; fast-wearing parts can be replaced at minimum cost; weight has been reduced where possible; the operator's efficiency has been increased by changes in design which consider his problems and convenience; greater efficiency in the implement itself is sought constantly; and closer inspection at the factory assures the purchaser of a more reliable product. The use of better materials has resulted in increased strength with less weight, in better soil-working surfaces and in greater durability. Improved types of ball and roller bearings have recently found a definite field in farm machinery. Simplification of implement types as well as standardisation of implement parts is in progress.

Research.—Studies of the trend and application of farm machinery, research in its design and behaviour, and investigations of the necessary requirements are approaching the fundamentals in the Americas as well as in England and in continental Europe. To illustrate with one of many examples, development in soil-working machinery is handicapped to some extent by absence of adequate information on some phases of soil dynamics. Highly scientific analyses have been made of the mathematics and mechanics of some machine parts designed to till the soil, but the application of such information cannot be fully realised until more is known about the causes for certain behaviours in soils. There is not even a world accepted standard by which the efficiency of tillage machines can be measured or compared. The agricultural engineer comes face to face with crops and soils problems heretofore unsolved and sometimes unseen by the agronomist. The emergency is forcing co-operative effort in basic research. The field is not only a wide one, but also a promising one for the scientist. Agricultural, engineering and other scientific societies are beginning to foster such research, even on an international basis. (C. O. R.)

FARM ORGANISATION AND EQUIPMENT.—The study of the organisation of the farm is a comparatively recent development of modern agricultural research. In its earlier stages the investigation of the farmer's problems was confined to matters arising out of the application of the physical sciences to the production of crops and the feeding and breeding of live stock. The basis of the organisation of agricultural research was that the practice of farming was, in its essentials, the application of the knowledge of the chemist, the botanist, the zoologist and so forth.

More recently it has come to be recognised that important as this aspect of agricultural development undoubtedly is, farming is also a business, the successful conduct of which can be determined only by a study of its economic structure. The production of crops and stock is in many respects an art, but is an art by which the farmer has to live, and maximum productivity secured by the uncontrolled application of scientific knowledge concerning the properties of feeding stuffs and manures is not always synonymous with maximum profit.

Law of Diminishing Returns.—So long ago as 1879 Sir John Lawes drew the attention of farmers to this question. He showed that there was no connection between maximum production and economic production; on the contrary, over-stimulation of the crop might bring the scientific farmer to economic disaster. In other words, agricultural production conforms to the law of diminishing returns.[1] The point at which increased production becomes unprofitable depends upon the price of the commodity, other things being equal; in a rising market this point will rise and the farmer will be justified in farming for a higher output; but in a falling market the man who has to live by the land must reduce his capital outlay notwithstanding the facilities for higher production which science has placed at his disposal (*see* AGRICULTURE).

An illustration of the importance of the study of organisation is to be found in the comparisons which are often instituted between the intensity of farming in England and in certain Continental countries, notably Denmark. The case of Denmark is cited as an example of what can be done to develop production from the land without the artificial stimulus applied in certain other European countries. It is pointed out that, notwithstanding a fiscal policy which admits of free imports of agricultural produce, Danish agriculture has flourished during a period in which the industry in England has been stationary; the extent of arable land, and, with this, the agricultural population, has been maintained whilst the land of England has been going back to grass to the accompaniment of an exodus of the rural population; that the yield of the soil of Denmark has steadily increased until it has reached a point considerably in excess of that of this country (*see* DENMARK: AGRICULTURE).

In their crude form these statements appear to be justified, but a study of the organisation of farming in the two countries goes far to disprove the crude conclusions so often drawn to the detriment of the business acumen and technical capacity of the English farmer. The economic circumstances which give rise to the differences in agricultural progress in England and on the Continent may be classed under two heads: (*a*) the proportion of small farmers, and (*b*) the competition of urban industries. (*See* LAND TENURE; TARIFF.)

Only by the study of farm organisation, both at home and abroad, can a proper interpretation be placed upon crude statistics of agricultural production, which are apt to prove dangerous weapons without it.

Size and Efficiency as a Productive Unit.—The maintenance of a high standard of production is very generally associated in Continental agriculture with farming in small units, and the advocates of the extension of the small-holding movement in this country base their case very largely on this fact. Figures collected in the course of investigations of farm organisation go to show that this extra production is apparent rather than real, and that it is purchased by the expenditure of capital and labour which would be more productively employed on larger areas Here is a table showing the manual labour and the horse labour requirements of farms in three agricultural districts, grouped by

[1] *Is Higher Farming a Remedy for Lower Prices?* J. B. Lawes. A Lecture delivered before the East Berwickshire Agricultural Association, May 3 1879. *Rothamsted Memoirs*, vol. 5.

size; it will be seen that in each of them the labour required in production, whether manual or horse, varies inversely with the size of the holding, or, alternatively, that the efficiency of labour varies directly with the size of the holding:—

Size Group	Persons Employed per 100 Acres	Draught Horses Employed per 100 Acres
Acres	No.	No.
District 1		
Under 50	7·1	4·4
50–100	5·0	3·7
100–150	4·0	3·0
Over 150	2·4	2·5
District 2		
Under 50	7·1	5·1
50–100	6·4	3·7
100–150	4·2	3·5
150–250	3·3	2·5
Over 250	2·6	2·1
District 3		
Under 100	4·1	5·3
100–300	3·0	3·7
300–500	2·3	2·6
500–700	2·5	2·3
700–1,000	2·3	2·3

It might be argued, however, that the higher labour requirements on the smaller farms are the measure of their greater productivity, and the following table, showing the extent to which the production per unit of land and per unit of labour is affected by the size of the holding, supplies some confirmation of this. The sales per acre in the group shown here (which corresponds to District No. 2 in the above table) show that the total production varies inversely with the size of the farm. The economic effect of this, however, is considerably discounted by the next column, showing the sales per person employed, when once more the greater advantage of the larger holdings is clearly indicated:—

District 2 Size Group	Sales per Acre			Sales per Person Employed		
Acres	£	s.	d.	£	s.	d.
Under 50	11	19	9	168	19	0
50–100	9	19	2	156	2	0
100–150	7	19	1	189	0	0
150–250	7	5	8	222	12	0
Over 250	8	4	4	316	19	0

To consider, now, the capitalisation of the farm, evidence of the influence of size is afforded by the table below, in which is shown the value of the implement equipment, per 100 acres, on farms in three other districts. Here, again, it is apparent that the capital cost of the implements per unit of land falls as the size of the holding increases.

District A		District B		District C	
Size Group	Value of Equipment	Size Group	Value of Equipment	Size Group	Value of Equipment
Acres	£	Acres	£	Acres	£
Under 100	446	Under 100	374	0–49	328
101– 300	286	101–180	266	50–99	294
301– 500	192	181–300	212	100–149	269
501– 700	164	Over 300	157	150–199	234
701–1000	173	..	..	200–299	213
..	..	..	..	300–499	179
..	..	..	..	Over 500	139

The question at once suggests itself—" What is the economic unit of production? " The answer will not be forthcoming until more work on the study of farm organisation and equipment has been carried out. In some of these tables it will be observed that the rate of variation slows down as the size of the holdings increases; in fact, if curves were plotted they would rise or fall steeply through the smaller size groups and then tend to flatten out from about the 300–400 acre farm upwards. In other words there is evidence that the " economic unit " of farming, in the districts used for the purposes of illustration, does not occur until this size group is reached, and that it continues for some considerable period above it. Evidence is not yet complete on the question of a top limit, but there are certain indications that one-man management does not continue its efficiency beyond a certain point. Thus, in a certain district, which contained a good many holdings extending to 1,000 acres and over, the efficiency curve rises sharply from the " under 100 acres " size group up to the " 300 acres—500 acres " group, flattens out from this point up to the " 500 acres—700 acres " group, and then shows a distinct tendency to fall. This is illustrated in the following table, showing the production per man employed (*i.e.*, sales less cost of raw materials) according to size of holding:—

Size Group	Value of Production per Man Employed
Acres	£
Under 100	181·1
100–300	211·6
300–500	254·2
500–700	283·2
Over 700	245·1

This result is no more than an indication of what may be expected to emerge in future work, but the point is worth studying. For American conditions, *see* UNITED STATES: AGRICULTURE.

However, the study of farm organisation according to the size of the holding gives other results besides evidence of efficiency. The next table shows the influence of size on the nature of the farmer's business. In the district chosen it is clear to what an extent dairying is the concern of the small farmer, whereas sheep and corn growing become intensified as the size of the farm increases. It is interesting to note that as regards meat the size has very little influence on the quantity produced, but an examination of the data shows that it is mainly pork and veal in the case of the smaller groups, and beef and mutton in the case of the larger ones.

Production per Acre

Size Group	Meat	Dairy Produce[1]	Per Acre		Potatoes	Hay	Straw
			Wool	Grain and Pulse			
Acres	Lb.	Lb.	Lb.	Lb.	Lb.	Lb.	Lb.
Under 100	56	638	..	353	46	163	7

700–1,000	50	72	2·0	484	25	178	110

[1] In terms of milk.
[2] This high figure is due to the influence of one farm in the group which specialized entirely in potatoes.

Economic Research.—On the continent of Europe investigation has been conducted mainly by the aid of book-keeping, directed towards the determination of the cost of the main products of the farm, the capitalisation of different farming systems, the rental value of the land, the labour income of the peasant and so forth. In particular, the work of Dr. Ernst Laur amongst the Swiss peasant farmers and that of Dr. O. H. Larsen, in Denmark, may be cited. In America a great development of economic study of the agricultural industry has been witnessed during the present century. About the year 1905 " farm management " became definitely a subject of study at the hands of the technical staffs of the agricultural colleges. As on the continent of Europe, book-keeping afforded the principal instrument of study, and cost investigations were conducted in most of the clearly defined crop areas. Following the formation of the American Farm Management Association, a few years later, by those engaged in this work, the attention of economists as well as of agriculturists was attracted to this subject. The number of workers in the field increased rapidly, methods of study were rapidly developed and the Association was reconstituted as the American Farm Economic Association with a membership which now runs into hundreds, and a quarterly Journal (*see* FARMERS' ORGANISATIONS). The importance with which the

economic study of farm organisation is regarded in the States to-day was foreshadowed by the Secretary of Agriculture in his Foreword to the *Year Book* of the United States Department of Agriculture for 1921:—

The *Year Book* for 1921 emphasises the economic side of our agriculture because help in their economic problems is now the most urgent need of our farmers. That is not to say that the Department is losing sight of production matters. The farmer needs all the help in his production problems that the Department of Agriculture, colleges and experimental stations can give him; but the need of the most importance now is the development of an entirely new realm of organised knowledge bearing upon the economic factors of agriculture looking forward toward cheaper production, improved methods of distribution and enlargement of markets, in order that prices the farmer receives shall be more fairly related to his cost of production.

The agricultural work of the colleges and experimental stations is now largely directed to serving the ends indicated in the foregoing quotation, and a significant fact is the institution of the new Bureau of Agricultural Economics in the Department of Agriculture at Washington.

In England, the study of farm organisation and equipment on a systematic basis dates from the establishment of the Agricultural Economics Research Institute in 1913, as a result of an application by the University of Oxford to the Ministry of Agriculture for a grant in aid of economic research in agriculture. As in other countries the Institute started its work by the costing method, and allowing for the interruption caused by the War it has continued with it as one line of investigation ever since. Costing is, of course, only the means, it is not the end itself and it may be useful to those who have not studied the process to give a few examples illustrating the kind of information got from this rather complicated exercise.

First, there is the evidence it supplies on the efficiency of farm management in all its aspects. To take one of these for example, the use of manual labour. One object of any system of farming should be to give employment to a regular staff of men at all seasons of the year. Few systems do this better than the ordinary four-course rotation and some of the modifications of it, but many rotations make the farmer dependent to a large measure on casual seasonal labour. The results of costing show that dependence on casual seasonal labour has the effect of raising unit labour costs, and though systems of farming involving much seasonal labour are often justified on account of the usually profitable nature of the crops grown (as in the case of potatoes), it may well be that in certain cases the relative costliness of the labour involved may lead the farmer to consider whether after all it gives him an adequate return for the extra working capital and trouble involved. The introduction of silage or of the sugar beet crop into the rotation can have a very upsetting effect on labour organisation, unless plentiful supplies of casual labour are available at the right seasons, and cost records are the only means by which to confirm or correct the farm-manager's general ideas of the economic value of these and other new crops.

To take, as a second example, the organisation of the horse labour on the farm. It costs so much to keep a horse for the year, and on the great majority of farms the figure does not vary very appreciably. But it does not follow that there is little variation in the cost of horse labour, for the cost of a day's work depends not only on the cost of keeping the horse, but on the number of days during which it is effectively employed. Allowing for Sundays and Christmas Day and for Saturday half-days, the maximum number of working days is 286 in the year, and every day less than this number worked by horses adds proportionately to the cost of the labour performed. Figures collected recently from seven farms showed that the percentage of idle days varied from 13% up to 39%, and it will be realised how seriously the cost of horse labour mounts up in proportion as the number of idle days increase. This is a typical example of the way in which costing may direct the attention of the farmer to possible weaknesses in his management. It may be simply that he has too many horses, in which case results such as these will make him consider the possibility of their reduction. It may be that his system of cropping is such that he needs an abnormal equipment of horses at certain seasons of the year, in which case he will be led to consider whether his system is so profitable as to make the idle horses at other seasons worth while, or whether he could not modify it in some way which would enable him to keep his horses more regularly employed.

A third example of the use of costing is the compilation of comparative labour costs, to establish measures of individual efficiency in the use of manual labour. The figures in the following table, compiled by Mr. A. Bridges, represent the normal utilisation of labour for crops and live stock on a series of farms in the eastern counties of England; similar figures have been published by Dr. A. G. Ruston, of Leeds, and various tests of a like character can be devised which serve as standards of efficiency for other aspects of farm management.

Average Labour Requirements of Farm Crops and Stock
Arable Land

	Man days per Acre
Cereal Crops	
Winter Wheat	6·85
Spring Wheat	6·58
Winter Oats	7·58
Spring Oats	6·21
Barley	7·13
Beans	6·50
Peas	10·23
Root Crops	
Turnips and Swedes (eaten off)	8·31
Mangolds	16·73
Potatoes	33·80
Carrots	61·42
Seeds	
Mown	2·18
Grazed	0·71
Grass	
Meadow Hay	2·09
Pasture	0·09
Live Stock	
Cows	23·00
Other Cattle	7·13
Pigs	1·90
Sheep (Arable Breeds)	1·29

In the absence of data such as these nothing is more baffling than the attempt to trace leakages in farm management which cannot be located by any other means and which are often most surely responsible for the difference between profit and loss in farming. In a great number of cases the partial failure of the farmer is due to faulty organisation of labour or to some similar cause which defies detection by any process of inspection. As the practice extends of recording daily the operations on the farm it will be possible to establish, district by district, certain efficiency standards by which to test individual farm management. A good example of what has been done already in this direction is afforded in the case of milk-recording where, by careful observation and record, the farmer is provided with the means of weeding out the unprofitable elements in his dairy herd. The case provides an illustration of that which will be possible in many other directions when full records of the various matters arising in farm management are available, and similar weaknesses in the organisation of production can be detected.

Although the costing method was thus the first line of attack on the problems of agricultural economics it was always realised that it would not be sufficient in itself, and it was suggested that valuable information could be collected by means of economic surveys of farming districts. The evidence to be got in this way is less complete than that furnished by the more intensive costing method; on the other hand, a much greater mass of it can be collected by the expenditure of an equal amount of time and energy. At the outset, these surveys were planned to deal with particular problems; thus, Mr. A. W. Ashby conducted a survey of allotments and small-holdings in Oxfordshire, as the basis for a study of the rural allotments and the small-holding problems, and similarly, Mr. J. Orr conducted surveys of the systems of farm management in the counties of Oxfordshire and Berkshire,

and considered the problems arising therefrom. But this method was found to be incomplete, for although it may happen that special problems will arise for investigation, the study of farm economics as a whole cannot best be pursued by the examination of particular questions. It was decided, therefore, to inaugurate general surveys, designed to collect all the information of any kind whatever which can be got by inquiry on the farm, for tabulation in a variety of ways, and then to study the tables in order to see what information they afforded. The method has been made familiar by the work of American farm economists. This work has formed a part of the activities of the Oxford Institute, and data have been collected from nearly 1,500 farms.

A more recent investigation undertaken by the Institute, and one likely to be developed in the near future, is the study of the organisation of agricultural marketing. The economic weakness of the existing marketing methods has often been a subject of comment, and particular attention has been attracted to it recently by the Report of the Departmental Committee on Distribution and Prices of Agricultural Produce. It was felt that it should be possible to organise an advisory service for farmers in marketing problems, in fact, that such a thing should be an essential part of the general advisory services available to them (*see* AGRICULTURE: ECONOMICS and MARKETING).

Since 1922 arrangements have been completed by the Ministry of Agriculture for the local study of farm organisation and equipment throughout England and Wales, to supplement the work carried on by the Agricultural Economics Research Institute at Oxford and with this body as a co-ordinating centre. For the purpose of advisory work among farmers the country was mapped out, some years ago, into provinces, each of which is equipped with an advisory staff of experts in the various branches of agricultural science. These staffs have now been strengthened by the inclusion in each of an advisory economist, who is occupied with the study of farm management problems arising within his particular province. Their function is mainly to assist the farmers of their districts to greater efficiency in the control of farm management, whilst, at the same time, the information and data accumulated by them in the course of their work is available for the use of the central institute at Oxford for co-ordination and review upon a national basis.

FARNELL, LEWIS RICHARD (1856–), British scholar, was born in Salisbury Jan. 19 1856. Educated at the City of London School and Exeter College, Oxford, in 1880 he won a fellowship at Exeter College. After studying classical archaeology in Berlin and Munich and travelling in Greece and Asia Minor, he became classical lecturer at Exeter College in 1883, and the following year sub-rector. Later he became university lecturer in classical archaeology. In 1893 he was appointed senior tutor of Exeter College and in 1894 proctor of the university. In 1909 he was elected first Wilde lecturer in comparative religion and in 1911 Hibbert lecturer. He was appointed rector of Exeter College in 1913 and from 1920 to 1923 was vice-chancellor of Oxford University. Among his written works are *Cults of the Greek States*, 5 vol. (1896); *The Evolution of Religion* (1903); *Greece and Babylon* (1911); *The Higher Aspects of Greek Religion* (1912); and *Outline History of Greek Religion* (1920).

FAROE ISLANDS: *see* FAEROE ISLANDS.

FARRAND, LIVINGSTON (1867–), American educationalist, was born at Newark, N.J., June 14 1867. After graduating from Princeton University in 1888, he studied medicine at the College of Physicians and Surgeons, New York (M.D., 1891). During the next two years he studied at Cambridge, England, and at Berlin. From 1893 to 1903 he was an instructor and, from 1901, adjunct professor in psychology at Columbia University; from 1903 to 1914 he was professor of anthropology. In 1897 he accompanied the Jesup North Pacific Expedition, which visited the Indians of British Columbia. From 1912 to 1914 he was treasurer of the American Health Assn. and editor of *The American Journal of Public Health*. From 1914 to 1919 he was president of the University of Colorado, but in 1917 was granted leave of absence, following his appointment by the International Health Board of the Rockefeller Foundation to direct the work against tuberculosis in France. In 1919 he was made chairman of the central committee of the American Red Cross. In 1921 he was elected to succeed Jacob Gould Schurman as president of Cornell University. He wrote *The Basis of American History* (1904) and various articles on psychology and anthropology.

FASCISM.—The Italian Fascist movement dates officially from the foundation in March 1919 by Benito Mussolini (*q.v.*), then editor of *Il Popolo d'Italia*, of the first *Fascio di Combattimento* at Milan, although many of its ideas had been inspired by the Nationalist movement dating from 1910, and by Syndicalism, of which Mussolini himself had been a leader. This first Fascio was composed of some 150 of Mussolini's friends who had supported his interventionist action at the beginning of the World War, mostly ex-socialists of the Syndicalist wing, and nearly all ex-combatants. The first Fascist programme was confused, demagogic and had a Republican trend, but the national patriotic note was conspicuous, and proper recognition was demanded for the men who had fought and won the War. The word *Fascio* means a bundle or bunch, and was taken to define the close union of the adherents of the movement; as an emblem, the *fasces* of the Roman lictors on a tricolor shield was adopted.

At first the Milan Fascio only attracted a fraction of the people who opposed Bolshevik Socialism, and it still savoured too much of Mussolini's revolutionary past to secure general support. Fascism was also inspired by a sense of exasperation at the foreign policy of the Government, which did not, the Fascists believed, defend Italian interests at the Peace Conference with sufficient firmness and dignity. This aspect of Fascism was largely the outcome of nationalism, which had first given the Italian people a sense of the importance of foreign affairs and of the necessity for colonial expansion. After D'Annunzio's evacuation of Fiume at the beginning of 1921 many of his *legionari* joined Fascism, some of whose outward manifestations and the semi-mystical character, as well as the Roman reminiscences and ritual, they inspired.

The Squadre.—At the elections of 1919 none of the Fascist candidates were returned. During the troubles of 1919 and most of 1920 Fascism as an organisation played but a small part. But the Fascist idea was spreading all over Italy, and during the municipal elections held in many cities in the late autumn of 1920 the Fascists collaborated with the other anti-Socialist parties, and in several instances formed with them national blocs, which defeated the Reds. In the Bologna riots (Nov. 1920), which broke out on the occasion of the inauguration of the Socialist-Communist town council, it was the Fascists who, although only 200 strong, organised the reaction of the majority of the citizens and brought about the rapid collapse of the Red organisations, first in that city and subsequently throughout the Po valley. The first armed Fascist *squadre* were now formed for the defence of the nation against what amounted in many places to revolutionary tyranny. These *squadre* consisted of young men, mostly ex-combatants, many of them decorated for valour and adorned with wound badges, of others too young to have served and of not a few older men, exasperated at the spectacle of their country, victorious in the War, but fallen into a slough of despond and browbeaten by a factious minority. There was as yet no real Fascist doctrine beyond this vague sense of outraged patriotism. The *squadristi* were mostly

armed with cudgels, although many possessed revolvers and carbines, for at that time a large number of ex-service men had brought back arms of some sort from the War. Another weapon, a novelty in partisan conflicts, was castor oil, large doses of which were administered to recalcitrant Socialists and Communists, and sometimes even to other opponents of Fascism. During 1921 and 1922 encounters between Fascists and the Reds were of almost daily occurrence. In that period over 1,000 Fascists fell victims to their opponents, and in most cases were murdered by treachery for no other reason than that they were Fascists; but their comrades were not slow to avenge these outrages. When early in 1921 the Communists broke away from the Maximalist Socialist party and indulged in a series of murderous outbreaks in the hope of terrorising the masses into joining them, the Fascist reprisals were ruthless.

What attracted the sympathy of public opinion towards Fascism was the extraordinary bravery and devotion to an ideal of the *squadristi*. At a time when armed Communists were lying in wait at street corners or behind closed shutters to attack anyone wearing the Black Shirt or the Fascist badge, these youths marched on regardless of danger, ready to sacrifice their lives for the national cause. Even orthodox Liberals, Catholics and others supported Fascism, in which they saw the only hope for the salvation of the country from chaos. Many adhered to the movement for selfish reasons—landlords and manufacturers who simply regarded it as a form of protection for the rights of property which the Government allowed the seditious elements to violate with impunity, and others became Fascists out of a spirit of adventure, to secure positions for themselves or for other personal reasons.

A Mass Movement.—In its early days the movement was unconnected with any particular labour policy, although Syndicalists were among its founders; later, individual workmen, peasant-proprietors and farm hands joined it individually; but, with the success of the Fascist campaign against the Red organisations in the Po valley at the end of 1920 masses of workers became Fascists, and often whole unions came over in a body. This development changed the character of Fascism, and converted it from a minority to a mass movement. At the elections of May 1921, held under the auspices of Sig. Giolitti, 38 Fascists were returned, including Sig. Mussolini himself, and 10 Nationalists. In the new Chamber the Fascists and Nationalists formed a fighting band of vigorous youths strenuously opposed to the Reds—a nucleus which gathered around its standard members of other patriotic parties. At the Fascist congress in Rome in Nov. 1921 a review of the Fascist forces was held, and Fascism was constituted as a regular political party, the *Partito Nazionale Fascista*, and its statutes were then drafted.

The Programme of the Fascists

The programme of the Fascists differs from that of other parties, as it represents for its members not only a rule of political conduct, but also a moral code. The programme states that

"the nation is not merely the sum total of living individuals, nor the instrument of parties for their own ends, but an organism comprising the unlimited series of generations of which individuals are merely transient elements; it is the synthesis of all the material and non-material values of the race."

The state must be reduced to its essential functions as a legal and political organ, the powers of parliament limited to questions concerning the individual as a citizen and the state as the organ for realising the interests of the nation, whereas the activities of individuals as producers should be dealt with by technical councils. Trade unions must be encouraged as a means of developing production, but they should not arbitrarily level all capacities. The prestige of the state must be restored at all costs. The national finances must be placed on a sound basis, free from all traces of demagogy. Fascism recognises the social functions of private property, proposes a system of State discipline over class conflicts, and demands that both employers' and workmen's organisations shall be legally recognised and invested with responsibility; no strikes in the public services are to be tolerated. The state should restore to private enterprise all industrial undertakings which it has proved incapable of running. In foreign affairs Italy must "reaffirm her right to complete historic and geographic unity, and fulfil her mission as the bulwark of Latin civilisation in the Mediterranean." The party is indissolubly bound up with its *squadre*—the volunteer militia at the service of the state. It was this congress that declared that Fascism would substitute itself for the State whenever the state should prove incapable of suppressing the elements of disorder and disintegration.

The organs of the party are: the Directorate—the executive organ, composed of the general secretary and 10 other members elected by the national council, the central committee, composed of the various district delegates and the members of the Directorate, elected by the national council for a year and entrusted with the conduct of the political and administrative action of the Fasci and with disciplinary authority; the national council, composed of the members of the central committee and the provincial secretaries, and invested with controlling authority over the Fasci; the general secretariat, nominated by the national council; the Fasci, or local sections of the party, all the Fasci of a province constituting a provincial federation; *the squadre di combattimento;* entrusted with the duty of repelling the violence of adversaries, which should hold themselves in readiness to act at the bidding of the leaders of the party for the defence of the national interests; the parliamentary group, composed of the Fascist members of Parliament; the various auxiliary groups, such as *the Women's Fasci, the Avanguardie, the Balilla, etc.;* the congress, composed of delegates of the provinces, which meets at irregular intervals to express the views of Fascism as a whole.

Attitude to Monarchy.—Fascism had been gradually shedding its demagogic elements, and at Udine, on Sept. 29 1922, Mussolini expressed his adherence to the monarchy, thereby securing widespread support for Fascism among many who had hesitated on account of its "implicit republican tendency." Fascism has ended by becoming the strongest bulwark of the monarchy, because, unlike other monarchical parties, it had no need to conciliate the revolutionary elements. The whole conception of Fascism is based on rigid hierarchy.

Italy under the Fascists

When Fascism came into power (Oct. 28 1922), Sig. Mussolini, although rejecting alliances with other parties, accepted their collaboration, and admitted several of their members into his first Cabinet. Nationalism was absorbed by Fascism early in 1923, but as the Opposition became more violent in its attacks, especially after the Matteotti murder, the party tended to concentrate more and more on itself, satisfied with its own strength and the general approval of public opinion, not attached to any party; and it still has millions of supporters who are not Fascists. The party underwent certain changes in its constitution, among which the most important were the fusion with nationalism and the creation of the Fascist grand council. This body, which sums up, co-ordinates and directs all the activities of the party, is composed of the Prime Minister as chairman, all the Fascist members of the Government, the general secretary of the party and certain other party officers both central and local. At its meetings the opinion of Fascism in the direction of various legislative reforms is manifested, and the proposals voted are then submitted to the Cabinet. Although party and Government are separate, the connection between the two is very close, as Sig. Mussolini is at once the head of the Government and the leader of the party.

Relations with the Vatican.—Fascism, since it has become the Government of Italy, has shown a marked sympathy for Catholicism, which as the religion of the vast mass of the Italian people is regarded to some extent as a national institution. Relations between Fascism and the Vatican have become very friendly, and the anti-Fascist tendencies of the *Partito Popolare* are by no means approved of in Vatican circles. Occasional minor disagreements with the Vatican in no way affect the general policy of the party.

Fascist Aims.—The Fascist tendency to isolate itself and reject alliances with other parties was steadily advocated by Roberto Farinacci (*q.v.*) after his appointment as general secretary early in 1925. After the Matteotti trial in March 1926, he resigned his appointment, having accomplished the task of reorganising the party, and was succeeded by Auguste Turati. The party directorate was also changed. But the general character of Fascism remains unaltered. Its aim is to get its main principles generally accepted by the nation and embodied in a series of legislative reforms which shall make of Italy an essentially National State, as opposed to the pre-existing Liberal State, wherein the seditious elements were free to conspire against the general welfare in the interests of class or clique. These reforms comprise the restoration of national finance, the reorganisation of the bureaucracy in the interests of efficiency, the reform of education, the peaceable regulation of labour conflicts, the re-establishment of discipline in every department of the state and every aspect of national life, the improvement of agriculture and the progress of industry. Many of these reforms have already been carried out, and others are in progress. Opponents accuse Fascism of crushing liberty; but the Fascists reply that if the freedom of the Press is limited, and parties, other than the Fascist, are reduced to inactivity, the essential liberty of the people has been secured as never before—the freedom to work and produce for the common good—and that only a strong Government like that of Sig. Mussolini could achieve such a series of necessary and far-reaching reforms, which Liberal Governments may have desired, and even attempted, but had always failed to carry out owing to the tyranny of parliamentary obstruction. The people, he said in July 1924, never asked him to free them from a tyranny which did not exist, but asked for railways, houses, roads, bridges, drains, water and light.

Fascist Doctrine.—Fascist doctrine, as it has been evolved during the last years, was authoritatively set forth by Prof. Alfredo Rocco, Minister of Justice, in a speech at Perugia on Aug. 31 1925. After rejecting the liberal, socialist and democratic theories of the state, he declared that, according to Fascism, society does not exist for the individual, but the individual for society; although Fascism does not annul the individual as the individuals annulled society under certain older doctrines, but merely subordinates him to society, while securing his right to develop his personality. Economic progress is a social interest, but Fascism considers it best to leave the production and distribution of wealth to individual enterprise in order to secure the maximum results in the interests of the community. The social problem is not solved, however, by merely rejecting the socialist doctrine; Fascism wishes to secure justice between classes, but class warfare must be eliminated, as it is the state which must establish justice between classes just as it does between individuals. Sig. Mussolini in an article in *Gerarchia* (Oct. 1925) compares "the incessant and fertile activity of the Government with the paralysis of all the opposition parties within the Chamber and without. Everyone, explicitly or otherwise, is convinced that in the Italy of 1925 Fascism alone towers like a giant." The defects of Fascism are the general defects of the Italian character: the tendency to rhetoric, *arrivismo* (excessive pushfulness of men on the make), which has been accentuated by the creation of the many party offices and appointments, often filled not by the worthiest but by the most pushful and ambitious. Of the deeds of violence occasionally committed by Fascists, usually reprisals for similar deeds committed by adversaries, Sig. Mussolini wrote in the above-quoted article: "This violence does not facilitate the work of the Government, but compromises it."

Fascist Labour Organisation.—Labour syndicalism has become one of the most important aspects of Fascism. The first statute of the party, drafted in Dec. 1921, defined the Fascist labour corporations. Labour is declared to be the basis of human welfare and progress, and all who devote themselves to productive work are regarded as workers. Fascist syndicalism, unlike the Socialist unions, accepts the patriotic idea, recognises the importance of capital, and considers the fate of the worker as bound up with that of the whole nation. There are now 21 corporations, each of them representing "the union of the various trades, arts or professions related to or dependent on the same kind of labour or industry," and comprising separate unions of manual workers, engineers and experts, and managers and employees. It was not found possible to unite both employers and employed in the same corporations, but there are many joint committees for various purposes. All corporations and syndicates are united under the confederation of corporations, which is the supreme organ of Fascist syndicalism, entrusted with the task of reconciling the interests of the various categories and classes, securing equitable labour contracts with the employers and promoting social legislation. The whole idea of class war is rejected, as classes cannot be allowed to take justice into their own hands any more than private individuals. Fascist syndicalism is gradually coming to monopolise labour, as the older Socialist and Popolare unions are losing all influence over the masses, and the Fascist corporations have become the sole representatives of the working classes in their dealings with the employers. Time will show whether the system will work out satisfactorily, but there is no doubt that the development of Fascist syndicalism has reduced strikes to negligible proportions, increased production and improved the conditions of the working classes by progressive social legislation and in other ways. In Dec. 1925 a law was enacted granting the syndicates legal recognition, and creating the labour tribunals to which all labour conflicts must be referred; strikes and lock-outs are therefore illegal. This is the most far-reaching reform of the Fascist Government. The president of the Fascist federation is the deputy Edmondo Rossoni, elected by the national council. The whole organisation is strictly centralised and hierarchical.

The National Milizia.—Before Fascism came into power its action was largely that of the armed *squadre*, and it was the 200,000 Black Shirts[1] who effected the "March on Rome," enabling Fascism to become the government of the country. But once this was achieved, the existence of irregular Fascist forces was incompatible with Sig. Mussolini's intention of constitutionalising the Fascist movement. To have disbanded them would have savoured of ingratitude, while their constituent elements might still be useful to overawe the revolutionary and anti-national parties and to consolidate the Fascist *régime*. At a Cabinet Council on Dec. 28 1922 it was decided to disband all the *squadre—Fascist, Nationalist, Arditi* and *Legionari fiumani*, and by royal decree of Jan. 14 1923 the *Milizia volontaria per la sicurezza nazionale* was created in their place. The force was voluntarily recruited from among the *squadristi*, the men appointed by the Prime Minister or the authorities delegated by him, and the officers by royal decree on the proposal of the Ministers of War and of the Interior. Neither officers nor men are paid, except those on permanent duty at the general or territorial headquarters (700 in all), while those who are temporarily called out for service outside their place of residence receive a daily allowance.

The total budget comes to 35,000,000 lire annually, although certain special detachments, such as the railway *milizia*, are paid for by other departments. The force, which comprises some 190,000 men, is "at the service of God and the Italian Fatherland, and takes orders from the head of the government." Its duties are "to assist, together with the armed forces for the public safety and the army, in the maintenance of internal order and to prepare citizens for the defence of Italian interests in the world." It has relieved the army of many troublesome services, and although it has never been necessary to employ it to put down revolutionary outbreaks, its mere existence has sufficed to deter the seditious elements from such action. The organisation of the *milizia* was subsequently brought into closer harmony with existing institutions; the royal decree of Aug. 4 1924 provides that its members shall take the oath of allegiance to the King, and that the officers shall be recruited from among the reserve officers of the Army, Navy and Air Force. The force is also entrusted with the pre-military training of youths under 20; the object of this measure is to give a large part of the nation a military education without involving the country in too heavy expenditure. Three legions of the *milizia* have served with distinction in Libya.

In 1926 the party comprised 9,000 Fasci, with about 742,978 registered members (April 21). The party directorate decided at this time not to accept any more members to the Fascist party, all new applications for admission being held on until 1927. There were also

[1] Estimates of their number vary considerably, owing to the fact that while 200,000 or more men were mobilised not all of them actually entered Rome.

590 *Women's Fasci* with 25,000 members, 16 *Legioni Avanguardisti* (youths from 15 to 18 years old) and 18 *Legioni Balilla* composed of boys under 15. In addition the Fascist labour syndicates comprised about 2,150,000 members not counting the Fascist railwaymen's syndicate (80,000 members), the maritime federation and certain other special unions.

BIBLIOGRAPHY.—Of the vast literature on Fascism the following works may be quoted:—

(*a*) *Italian works in favour of fascism:* The speeches of Mussolini, collected in various volumes, including one in English edited by Baron Quaranta di San Severino; the speeches of Enrico Corradini (Discorsi politici, Florence, 1923); the speeches of Carlo del Croix and of Edmondo Rossoni; Camillo Pellizzi, *Problema e realtà del fascismo* (Florence, 1924); Margherita Sarfatti, *Life of Mussolini* (English trans. London, 1925); Carmelo Licitra, *Dal liberalismo al fascismo* (Rome, 1925); Pietro Gorgolini, *Il Fascismo nella vita italiana* (Turin, 1922); also published in English: *The Fascist Movement in Italian Life* (London, 1924); Luigi Villari, *The Awakening of Italy* (London, 1924), and *The Fascist Experiment* (London, 1925).

(*b*) *Italian Works Against the Movement:* Carlo Avarna di Gualtieri, *Il Fascismo* (Turin, 1925); Ivanoe Bonomi, *Dal socialismo al fascismo* (Rome, 1924), also published in England; *From Socialism to Fascism* (1924); G. Ferrero, *Da Fiume a Roma* (Milan, 1923), also published in English; *Four Years of Fascism* (1924); G. Matteotti, *Un anno di domino fascista* (Rome, 1923), English trans.; *The Fascisti Exposed* (1924); Luigi Sturzo, *Pensiero antifascista* (Turin, 1925).

Urban in *Guida bibliographica di cultura fascista* (Rome, 1925). (L. V.*)

FASHION: *see* COSTUME.

FATIGUE OF METALS.—This is a generic term denoting all phenomena associated with the behaviour of metals subjected to repetitions of a range of stress. The term, however, is more generally applied to the progressive deterioration, leading to ultimate fracture, caused by repetitions of a cycle of stress, the maximum stress of the cycle being numerically less than that stress which causes failure on a single application. Fracture by fatigue can be caused by repeated cycles of direct, bending, torsional or combined stresses, and is accelerated by the presence of shock conditions or surface defects, sudden discontinuities of section, etc., which create local concentrations of stress.

Three Types of Stresses.—Cyclical variations of stress can be divided into three main types: *Alternating stresses* (maximum and minimum stress of cycle differ in sign), *pulsating stresses* (stresses vary from zero to maximum value) and *fluctuating stresses* (vary in magnitude but not in sign). *Any* stress cycle is defined numerically by the expression, $M \pm \frac{1}{2}R$, where M is the average stress, and R is the range of stress (algebraic difference of maximum and minimum stresses). Fatigue range or limiting range (R_L) is the greatest range of stress which can be applied for an indefinitely great number of repetitions without causing fracture. *Endurance*, under a given range of stress, is the number of repetitions necessary to cause fracture.

In 1849 Jones and Galton investigated the behaviour of cast-iron bars subjected to pulsating bending strains. Fracture occurred in less than 100,000 strainings when the range of strain exceeded one-third of the static ultimate deflection. The endurance decreased at an increasing rate with increased ranges of strain. Bars which had been partially fatigued suffered no loss in static ultimate strength. Somewhat similar tests, on a wrought-iron built-up girder, were made by Fairbairn in 1860–1. The loading was applied with shock. Fairbairn's conclusions confirmed those of the earlier workers and also pointed to the existence of a definite fatigue range for metals. These conclusions received further support from the experiments of Wohler (1871), in which, for the first time, strict attention was paid to the *magnitude* of the applied stresses. Wohler used iron and steel subjected to cycles of direct, bending and torsional stresses.

Subsequent to these early classical investigations, the fatigue of metals has formed the subject of several hundreds of independent researches. The main objects of these investigations and the conclusions drawn from the results are briefly summarised below.[1]

Evidence of a Limiting Range of Stress.—The results of a series of endurance tests, where any one type of straining action and a constant value of the mean stress of the cycle are employed, show that the endurance (N) to fracture increases at an increasing rate as the range of stress (S) decreases. A curve connecting S and N tends to become parallel to the N axis. It is regarded as established that, in the case of ferrous metals, the S/N curve, has become parallel to the N axis at values of N of 10^7 or 2×10^7 reversals, and remains so for the maximum endurances investigated (10^8 to 10^9 cycles). This is also true for some of the pure metals and non-ferrous alloys. Tests on *some* non-ferrous metals and alloys, however, have shown fractures to occur after several hundred millions of reversals, although, at these endurances, the slope of the S/N curve is very small. In general, *sound metals appear to possess a definite limiting range of stress* (R_L).

Two relations have been suggested both of which can be expressed by the formula $R_L = R_{LR}(1-\frac{M}{f})^x$ where R_L is the limiting range when M is the corresponding value of the mean stress, R_{LR} is the limiting range when $M=0$, f is the static ultimate strength of the metal, and x has the value of 1 or 2. Some experimental results agree with one of these relations, others conform to neither. For cycles of direct stresses, the linear relation is generally a safe rule between the limits of $M=0$ and $M=\frac{1}{2}R$. Some experiments employing torsional stresses have shown that the value of R_L is not altered appreciably by wide variations in the value of M.

Effect of Frequency of Cycle (F) on Limiting Range (R_L).—It is now established that a constant value of R_L is obtained at frequencies up to 5,000 cycles per minute. Tests made on copper, iron and mild steel at frequencies of 3,000, 30,000 and 60,000 cycles per minute gave progressively greater values of R_L at the higher frequencies.

Under repetitions of the limiting range, or a numerically inferior range, a state is ultimately reached when no further plastic strain occurs; approximate elasticity only results as strain hysteresis can be detected. These *natural* elastic limits are not related to the *primitive*, or original, elastic limits of the material. When the applied range of stress exceeds the limiting range, plastic deformation occurs until the cracking stage is reached.

Effect on Limiting Range of Temperature of Test.—Available data relate only to reversed stresses ($M=0$). The limiting range (R_L) is largely unaffected in value until temperatures of about 400° C. are reached. At higher temperatures R_L decreases, the rate of decrease varying with different metals. The effect of elevated temperatures on R_L is not, in general, as marked as on the static ultimate strength under prolonged loading; *e.g.*, the values of $\frac{1}{2}R_L$ for 4 steels and 1 non-ferrous alloy, at various temperatures between 550° C. and 750° C., has been found to be *equal to*, or *greater than*, the static strength (under prolonged loading) at the same temperatures.

Effect of Repeated Stresses on Microstructure of Metals.—Repeated stresses applied to *crystalline aggregates* cause slip bands to appear on the surfaces of favourably orientated crystals. If R_L is not exceeded, this local action ceases after a certain number of repetitions and the metal becomes strain-hardened. Under repetitions of greater stress ranges, microscopic cracks are initiated in the regions of maximum slip, and fracture is caused by propagation of these cracks throughout the metal. Even in ductile materials, the process of initiation and propagation of these cracks may be so highly localised that the appearance of fracture is one usually associated with that of brittle materials. Precisely similar surface phenomena are exhibited by single metallic crystals subjected to repeated stresses, suggesting that fatigue failure is essentially a process of deterioration of crystalline material and that the chief effect of the inter-crystal boundaries in aggregates is to inhibit slip due to the change in orientation of neighbouring crystals.

[1] Except where otherwise stated, the remarks apply only to tests conducted at air temperature.

A fundamental theory of fatigue has yet to be advanced. The attrition theory (Ewing and Humfrey) is not supported by the results of recent research. A number of theories have been based on the assumption (Beilby) that plastic strain in metals causes a change from the crystalline to the amorphous state on the surfaces of slip. The manner in which the fatigue crack is initiated has not been explained satisfactorily. The results of experiments on single crystals (Gough, Hanson and Wright) suggest that the effect of slip is to produce local distortions within the crystal, thus setting up internal stresses which, under repetitions of stress ranges, lead to the disruption of inter-atomic bonds and the initiation of cracks. The breaking-up, under strain, of a crystal grain into a number of crystallites of slightly varying orientations, is an alternative hypothesis which is consistent with observed facts. Little doubt exists that, in some manner, fatigue failure is the direct result of local plastic deformation, and it seems highly improbable that fatigue would occur in a material which is truly elastic.

The importance of an understanding of fatigue phenomena in its relation to industry cannot be over-estimated. Those machine and structural components whose working conditions can be so adjusted as to exclude the possibility of fatigue failure constitute a very small minority. The whole trend of development of modern engineering lies in the direction of the employment of higher working stresses, speeds and temperatures. These considerations, together with the necessities of eliminating unnecessary material —to reduce first cost—and the reduction of the weight power factor—which has become of prime importance since the advent of aircraft—tend to make the static strength properties of metals (except at elevated temperatures) of less relative importance than their fatigue properties. A conservative estimate of failures in modern engineering practice attributes 80% of such failures to fatigue. As fatigue failures are usually unaccompanied by any marked preliminary warnings, a deplorable loss of life has often resulted. *See* METALLOGRAPHY; METALLURGY; MATERIALS, STRENGTH OF.

FAURÉ, GABRIEL (1845–1924), French musical composer (*see* 10.209), died at Passy Nov. 4 1924.

FAUVISM: *see* PAINTING.

FAWCETT, MILLICENT GARRETT (1847–), British writer and political worker, was born at Aldeburgh, Suffolk, June 11 1847. In 1867 she married the economist, Henry Fawcett (*see* 10.215). She herself produced various works on economics, including *Political Economy for Beginners* (1870), *Tales in Political Economy* (1874) and, with her husband, a volume of *Essays and Lectures* (1872). Mrs. Fawcett was one of the early workers for women's suffrage, and in 1907 became President of the National Union of Women's Suffrage Societies. She was strongly opposed to the tactics of the militant suffragists, and expressly dissociated the N.U.W.S.S. from any sympathy with such methods. The constitutional methods adopted by the body included an alliance formed with the Labour party (1912) by which the society agreed to support Labour candidates in preference to Liberal when the latter proved unsatisfactory on the suffrage question. Her later books include *Life of Queen Victoria* (1895); *Life of Sir William Molesworth* (1901); *Five Famous French Women* (1906); *Women's Suffrage* (1912); and *What I Remember* (1924). She was created G.B.E. in 1925.

FAYOLLE, MARIE ÉMILE (1852–), French soldier, was born at Puy (Haute-Loire) May 14 1852. He entered the École Polytechnique in 1873, and joined the 16th regiment of artillery in 1875. Captain in 1882, he entered the École de Guerre in 1889, and returned there as professor (of the artillery course) in 1897; in 1900 he was made titular professor and remained there till 1907. In the face of the orthodox doctrine he urged the importance of concentration of fire and the obstacle it offered to an attacker; this view he expressed in an admirable brochure entitled *Concentration des feux et concentration des moyens* (1912). On Aug. 13 1914 Fayolle who had been made a general of brigade in 1910 was given the command of the 70th reserve division. He distinguished himself at the battle of le grand Couronné and afterwards in Artois. The 70th division together with the 77th formed under Gen. Pétain the III. Army Corps which played a brilliant part in the offensive of May 9 1915. Gen. Fayolle succeeded Gen. Pétain on June 21 in command of the XXXIII. Corps, which he directed during the attack at Souchez and Vimy of Sept. 1915.

On Feb. 26 1916 Gen. Fayolle was given the command of the VI. Army which took part in the battle of the Somme; in the beginning of May 1917 he succeeded Gen. Pétain at the head of the Centre Group of armies (holding the Champagne and Verdun fronts). On Nov. 18 1917 he was sent to Italy but was recalled on Feb. 8 of the following year in expectation of the German offensive, which came on March 21; two days later he took command of all the forces engaged between Péronne and Barisis—which formed the Reserve Army Group. By March 31 the German attempt to break through was definitely checked, as also a fresh effort between June 9 and 13. In July the Reserve Army Group comprised the I., III., X. and VI. Armies which carried out the two great offensives of July 18 and Aug. 8 1918. After the armistice Fayolle's Army Group was entrusted with the occupation of the Rhine provinces; he entered Mainz on Dec. 14 1918, making Kaiserslautern his headquarters. He was made a marshal of France on Feb. 21 1921.

FEBVRE, ALEXANDRE FRÉDÉRIC (1835–1916), French actor (*see* 10.231), died in Paris Dec. 14 1916.

FEDERAL FARM LOAN SYSTEM.—The Federal Farm Loan Act of 1916 was adopted in the United States at a time when the increasing use of costly equipment and the rising price of farm land had combined to make the problem of financing the American farmer a difficult one.

His need for short-time credit, generally, had been met in various ways; his chief difficulty was to find long-time or mortgage credit. When the farmer must make a heavy investment, he needs a long loan. The only satisfactory security he can offer is a mortgage, and the market for farm mortgages is limited. Local mortgage brokers or bankers having the necessary expertness could lend on a limited number of mortgages and, after adding their own endorsements, discount the loans with eastern investors. In other cases, some of the large insurance companies sent their own experts into selected regions to place loans secured by mortgages. Again, a number of large corporations, commonly called mortgage banks, were organised to lend on mortgage security and to sell their own bonds to the investing public. Such a corporation, having bought a number of mortgage notes aggregating $100,000, would deposit them with a trustee as security for its own bonds to the same amount. These bonds were then sold to the general investing public, but sold on the general reputation of the corporation issuing them, and not on the buyer's expert knowledge of the individual mortgages.

The Act of 1916.—The Federal Farm Loan Act of 1916 was passed to extend this principle and enable it to meet the need for mortgage credit throughout the country. This Act created a Federal Farm Loan Board, consisting of the Secretary of the Treasury and four others to be appointed by the President, to have general administrative control. Under this board there were created 12 farm land banks, located in the 12 districts into which the country was divided; in each district there are organised, under its farm land bank, an indefinite number of farm loan associations, composed wholly of farmers desiring to borrow money on mortgage; and they borrow from the farm land bank of their district.

The 12 Federal farm land banks are located in the following cities:—Springfield, Mass.; Baltimore, Md.; Columbia, S.C.; Louisville, Ky.; New Orleans, La.; St. Louis, Mo.; St. Paul, Minn.; Omaha, Neb.; Wichita, Kan.; Houston, Tex.; Berkeley, Cal.; Spokane, Wash.

The Act permits joint stock land banks to come in under the Federal Farm Loan system. Sixty-nine had done so before Feb. 28 1925, with capital stock of $35,307,085, with bond issues aggregating

$454,540,200, and with loans to farmers aggregating $464,873,770. Every Federal farm land bank was required to have, before beginning business, a subscribed capital stock of not less than $750,000, from which to purchase the first batch of mortgages from the farm loan associations. Additional funds were to be raised through the sale of bonds to the investing public. Each issue of bonds was to be based upon a batch of mortgages previously purchased and deposited as security under the direction of the farm loan board. If the total $750,000 of capital stock of any Federal farm land bank was not subscribed within 30 days after the opening of the books, it became the duty of the Secretary of the Treasury "to subscribe the balance thereof on behalf of the United States," and amendments were passed (Jan. 18 1918 and May 26 1920) authorising the Secretary of the Treasury to purchase $200,000,000 of such bonds during 1918–21.

On Feb. 28 1925 the U.S. Govt. held $1,513,045 of the capital stock of the farm land banks. The total bonds authorised and issued by them was $949,130,492. The total capital stock of the 12 farm banks amounted to $50,390,330, held as follows:—

By the U.S. Govt.	$ 1,513,045
By National Farm Loan Assns.	48,471,970
By borrowers through agents	403,730
By individual subscribers	1,585

The total amounts loaned by the 12 Federal land banks, as recorded for 1920 and 1925, are as follows:—

	To Nov. 30 1920.	To Feb. 28 1925.
Springfield	$13,550,345	$ 35,930,637
Baltimore	14,732,783	51,142,223
Columbia	20,406,515	57,481,504
Louisville	27,691,200	92,287,466
New Orleans	25,811,705	93,063,031
St. Louis	30,951,675	66,280,807
St. Paul	49,554,700	113,430,039
Omaha	48,905,890	114,387,435
Wichita	31,531,300	83,282,745
Houston	40,754,766	104,651,436
Berkeley	18,645,900	39,531,815
Spokane	46,084,535	93,520,832
Total	$368,621,314	$944,989,970

The course of the money is as follows: first, from the investor to the farm land bank in exchange for bonds; second, from the farm land bank to the farm loan association in exchange for a batch of mortgages; third, from the farm loan association to the individual farmer in exchange for an individual mortgage. The securities, however, proceed in the opposite direction; first, a mortgage is given by the individual to his local farm loan association in exchange for money; second, this and other similar mortgages are transferred from the farm loan association to the farm land bank in exchange for money; third, the farm land bank deposits these mortgages under the direction of the Federal Farm Loan Board and, on that security, issues its own bonds and sells them to investors.

Under the Farm Loan Act the bonds of the farm land banks are exempt from taxation, in order to make such bonds so attractive to the general investor as to compensate for a low rate of interest, and thus to enable the farmer to borrow at a lower rate than would otherwise be possible. Bonds issued prior to May 1 1920 paid 4½%. Subsequent issues pay 5%. This provision was bitterly attacked on the ground that it was class legislation, discriminating in favour of farmers as against other classes. The matter was under litigation for many months, but finally in February 1921 the Supreme Court decided in favour of the constitutionality of the Act. (T. N. C.)

FEDERAL RESERVE BANKING SYSTEM: *see* BANKING: UNITED STATES.

FEDERAL TRADE COMMISSION.—This American commission was created by Act of the U.S. Congress, approved Sept. 26 1914, for the prevention of unfair methods of competition in commerce and for the collection of information respecting corporations engaged in interstate commerce and respecting export trade associations and conditions. It is composed of five members appointed by the President, and confirmed by the Senate; not more than three members may be of the same political party. The commission elects its own chairman. It entered upon its official duties March 16 1915. With it was merged the Bureau of Corporations, previously under the jurisdiction of the Department of Commerce.

Powers.—If the commission has reason to believe that a "person, partnership or corporation" practises any unfair method to the prejudice of the public interest, it shall serve a notice upon such party, submit a statement of the charges and set a date for a hearing. The party complained of has the right to appear and show cause why the commission should not require the cessation of practices alleged to be in violation of the law. If the party refuses to obey the orders of the commission, the commission may apply to the U.S. Circuit Court of Appeals. Banks and common carriers are excepted, they being under other Federal supervision. The commission is empowered to investigate from time to time "the organisation, business, conduct, practices and management" of any commercial corporation excepting banks and common carriers, and its relation to any other corporation, and to make recommendations for a readjustment of its business alleged to be violating the anti-trust laws, including those relating to price discriminations, intercorporate stock-holdings and interlocking directorates. The purpose of the commission is to advise and regulate. It is also empowered to investigate trade conditions of foreign countries as affecting the foreign commerce of the United States, and to report to Congress with recommendations. The commission comprises three departments: administrative; economic, in charge of investigations; and legal, whose duty it is to conduct investigations in connection with applications for the issue of notices, gather evidence for use in trials, and furnish examiners and lawyers to represent the commission in proceedings before the commission and in court.

Methods.—The activities of the commission are (*a*) quasi judicial, (*b*) economic. Under the first heading comes the prevention of unfair methods of competition. On its economic side the commission investigates (i) on its own initiative any corporation engaged in interstate commerce; (ii) on the direction of the President or either House of Congress any corporation alleged to be violating the anti-trust Acts; (iii) either on its own initiative or that of the Attorney-General the manner in which a court decree dissolving a trust is being carried out. It can also, at the instance of the Attorney-General, recommend the readjustment of the business of any corporation alleged to be violating the anti-trust Acts so as to conform to the law.

Another Act of the U.S. Congress, approved Oct. 15 1914 (commonly called the Clayton Act), specifically declared certain practices illegal and gave the Federal Trade Commission jurisdiction to prevent them. (*See* also INTER-STATE COMMERCE; TRUSTS.)

FEDERZONI, LUIGI (1878–), Italian politician and journalist, was born at Bologna Sept. 17 1878. Educated at the university there, he took to journalism and literature, and for several years was on the staff of the *Giornale d'Italia*, Rome. In politics he was a Conservative, and became a warm supporter of the Nationalist movement. After the Florence Nationalist congress in Dec. 1910, he helped to found the *Idea Nazionale*, at first the weekly and subsequently the daily organ of the Nationalist movement. At the elections of 1913 Federzoni was elected for one of the divisions of Rome. In the Chamber he never missed an opportunity to combat the Socialists, Republicans and Democrats. As soon as Italy intervened in the World War he joined the army as a lieutenant of artillery; he afterwards joined a trench mortar battery and was awarded a medal for valour. Federzoni supported Mussolini when the latter issued his manifesto of Oct. 26 1922 announcing the march on Rome. In the Cabinet formed by Mussolini five days later Federzoni was Minister for the Colonies. In this capacity he provided for the reconquest of all the Libyan territories evacuated during the War, and proceeded to reorganise the whole colonial administration. After the Matteotti murder in June 1924 Mussolini selected Federzoni for the post of Minister of the Interior.

FÉLIX, LIA (1850–1908), French actress (*see* 10.239), died in Paris Jan. 15 1908.

FENCING (*see* 10.247).—The period from 1910 to 1926 was a very critical one for British fencing. Up till 1914 it was increasing in popularity and rising in its general standard when, with the outbreak of the World War, its activities came to an abrupt end. When, in 1919, more normal conditions had returned, the outlook was not of the best. The experienced fencers were suffering from their long period of inaction and there were no young fencers ready to step into their places; for fencing, above all

other sports, demands a long period of apprenticeship. It is a wonderful tribute to the fascination of the art, that in 1925 fencing had become more popular than ever, that its general standard is considerably higher than in the years before the War and that its appeal is far more general.

Fencing in the Services.—A marked feature of this improvement is to be seen in the Royal Navy, the Army and the Royal Air Force. In the past the leading civilian fencers regarded the fencing of army and navy officers with scant respect, but in the six years from 1020 to 1025 inclusive, 5 out of the 18 amateur championships held with the three weapons, foil, épée and sabre, were gained by officers on the active list of the services. This improved standard is to be noted also at the universities and at the public schools, though naturally not to the same extent.

Fencing Clubs.—The most hopeful development for the future, however, lies in the more general appeal of fencing. In addition to the established salles, the London Fencing Club with Prof. Mimiague, the Salle Bertrand, Salle Tassart, Salle Alibert, Salle Gravé, the Royal Automobile Club with Prof. Volland, other fencing clubs have been recently formed which extend the pleasures of fencing to a class which in pre-War days never thought of it. Such are the Grosvenor Club, the Lensbury Club and the Tom Hughes Club, among others, and the members of these clubs are rapidly attaining a marked proficiency with foil and épée. Outside London, in the provinces, at Birmingham especially, and in Scotland, the popularity of fencing is increasing.

Two features of present-day fencing are to be regretted. In the first place the introduction of épée methods into foil play has become marked in recent years, and as long as the foil is regarded as a competitive weapon these methods will no doubt continue. In the two competitions for the Thompson trophy, between American and British representatives, the former easily defeated the more stylish British foil-fencers by using the weapon as a fighting rather than as a fencing implement, and their victories no doubt had an effect on the younger generation of foil-fencers.

The second indictment refers to épée fencing. Assaults with that weapon are now decided in international events by two hits out of three instead of by a single hit. There appear to be three good and sufficient arguments against this practice: (*a*) Where the target is the whole body, so great concentration is required that a single hit is quite sufficient to determine the issue: (*b*) the knowledge that a single hit is not fatal tends to carelessness over the first hit; (*c*) a fencer who has won the first hit can win the encounter equally with a good second hit or a coup double, and anything which tends to exploit the coup double is much to be deprecated.

The Olympic Games.—In the Olympic Games of 1912, the British team did not make a great show, but in the International Fencing Tournament, held at Earl's Court, London, Comm. E. W. H. Brookfield, R.N., tied for first place with the sabre. In 1914 that fine fencer, R. Montgomerie, by his victory in the épée championship, brought up the number of his individual championship successes to eight, a record for a British fencer. In the Olympic Games of 1920 Capt. R. Dalglish, R.N., was placed sixth in the final sabre pool and also awarded a special prize for "good sportsmanship."

Anglo-American Contests.—This Olympiad, with its apparently inevitable squabbles and bickerings, resulted in a special rapprochement between the teams of the United States and Great Britain and started the competition between the two nations for the Thompson trophy. The first meeting was held in America during Nov. 1921, and resulted in a victory for the United States by 25 points to 21, but Great Britain turned the tables in the summer of 1923. In 1923 E. Seligman won the sabre championship, a feat which he repeated in 1924, and so became the first British fencer to gain a championship with all three weapons, and he further distinguished himself by reaching the final pool of the foil championship in the Olympic Games of 1924 in Paris, when he had to retire owing to a strain, after beating the winner. He also qualified for the second round of the sabre championship and Capt. R. Dalglish, R.N., also did well; while C. H. Biscoe reached the semi-final pool of the épée championship. In these same Olympic events, the United States were well represented by Bloomer, Boyce, Calnan, Jeter, Breed, Milner, Gignoux, Macpherson, Lyon and Costner.

In 1923 two Grands Assauts d'Armes were held at the Hotel Cecil and the Grocers' Hall, London, and one in 1924 at the Royal Automobile Club, London. In these many of the most distinguished continental fencers took part, both amateur and professional, including A. Massard, M.C., L. Gaudin, R. L. Heïdé, C. Lafontan, A. Pope, Aldo Nadi, E. Tack, F. de Smedt, J. Rossignol and many others. Fencing among women has developed extraordinary popularity. In 1925 the three outstanding women fencers in Great Britain were Miss Gladys Davis, Miss Gladys Daniell and Mrs. Freeman.

Winners of the Amateur Championships

	Foil	Épée	Sabre
1910	R. Montgomerie	E. M. Amphlett	A. Ridley-Martin
1911	E. M. Amphlett	J. P. Blake	W. Hammond
1912	P. G. Doyne	R. Montgomerie	Capt. C. F. Vander Byl
1913	G. R. Alexander	G. G. M. Vereker	A. Ridley-Martin
1914	R. M. P. Willoughby	R. Montgomerie	W. Hammond
1920	P. G. Doyne	M. D. V. Holt	Lieut. C. A. Kershaw, R.N.
1921	R. Sutton	Capt. H. F. S. Huntington	W. Hammond
1922	R. Sutton	G. M. Burt	A. H. Corble
1923	Maj. Stenson Cooke	M. D. V. Holt	E. Seligman
1924	Flight-Lieut. F. G. Sheriff	C. H. Biscoe	E. Seligman
1925	Flight-Lieut. F. G. Sheriff	Maj. C. B. Notley	Lieut.-Comm. C. A. Kershaw, R.N.

FENG YU-HSIANG, Chinese soldier, and the so-called "Christian general" first came into prominence when, on Aug. 25 1921, he was appointed tuchun, or military governor, of Shansi. In 1922 he was transferred to Peking and played a decisive part in the Chihli-Fengtien war of that year. During 1923 his troops were stationed at Nan-Yüan, near Peking, and it was inevitable, in view of the doubtful authority of the President and his Ministry, that he should play an important part in the political intrigues of the capital. These manoeuvres culminated in his resignation, the flight of President Li and the *coup d'état* which resulted in the assumption of office by Tsao-Kun. Feng retired to the northwest frontier, where he became director of defence, but returned to aid Chang-Tso-lin against Wu Pei-fu in 1924. After Wu's defeat, Feng turned against his ally and seized Peking, thus forcing Chang to retreat to Mukden. He dominated the capital throughout 1925 and at the end of the year captured Tientsin. Chang's victory at Mukden, however, led to Feng's retirement to Mongolia. Feng earned his sobriquet by embracing Christianity after witnessing, it is said, the heroism displayed by missionaries during the Boxer outrages.

FERDINAND (1861–), EX-KING OF BULGARIA (*see* 10.269).—King Ferdinand in 1911 was the instigator of the Balkan League between Bulgaria, Serbia, Greece and Montenegro, which was formed in 1912 and enabled these four states to declare war against Turkey that same year. This pact provided for the future division of the Balkan Peninsula, reserving to the arbitration of the Emperor of Russia the solution of any doubtful claims. The war started in Oct. 1912, before the conclusion of the Treaty of Ouchy, which put an end to the Italo-Turkish War (Oct. 15). Under the command of King Ferdinand, the Bulgarian Army dealt the most rapid and decisive blows to the enemy; victorious on the battlefields of Kirk Kilisse and Lule Burgas, and having conquered most of Macedonia and Thrace, it started on the open road to Constantinople. Europe grew alarmed; the Great Powers brought about the armistice of Dec.

3 1912, and the London Conference, which started on Dec. 13.

These discussions, however, ceased abruptly, and military operations were resumed on Feb. 3 1913. The Bulgarian armies attacked at Gallipoli and Chatalja, and after a gallant siege entered Adrianople on March 26 1913. However, the Treaty of London which followed did not sanction these victories, and its decisions instead of inaugurating peace, provoked a war between the Balkan States, which began on June 30 1913, by a simultaneous attack of the Serbs and Bulgarians. The former allies became bitter rivals, Rumania and Turkey joining Montenegro, Greece and Serbia against Bulgaria, who, finding herself closed in by four enemies at once, was forced, after a few weeks of brave but useless resistance, to submit unconditionally to the victors' terms. The Treaty of Bucharest, signed on Aug. 10 1913, annihilated in one stroke the brilliant results obtained through the heroism of the Bulgarian armies in 1912–3. It deprived Bulgaria of all her conquests including the town of Silistra and part of the Dobruja and gave to the Serbians and Greeks the province of Macedonia for which Bulgaria had made all the sacrifices of the first Balkan War. This treaty was the principal cause of Bulgaria's participation in the World War on the side of Germany. It explains the resentment of King Ferdinand and his Govt. against the other Balkan States. Had the Allied Powers in 1914 guaranteed the revision of the Treaty of Bucharest, Bulgaria would have co-operated with them; but as they failed to do so, Germany was able, by illusory promises, to induce Bulgaria, who felt she had been unjustly treated, to fight for the German cause. These German manoeuvres did not succeed at once, for King Ferdinand began by proclaiming the neutrality of Bulgaria in Nov. 1914.

During May 1915 the Bulgarian Govt. sounded the four Great Powers, with regard to the fulfilment of Bulgaria's legitimate claims in Macedonia. As no concrete answer was returned, King Ferdinand turned to Germany, where his application was received with great cordiality. Berlin made lavish promises at once. German envoys hurried to Bulgaria, with a view to persuading the King and the Govt. to conclude a military alliance with Germany. The desire for revenge against Serbia, Greece and Rumania inspired Ferdinand to bind Bulgaria to the Central Powers. On Sept. 21 1915 he gave the order for general mobilisation, though his Govt. advised armed neutrality. In view of this equivocal situation Russia sent an ultimatum to Bulgaria on Oct. 4 1915, which was succeeded by formal declarations of war against Bulgaria on the part of Serbia, France, Great Britain and Italy. Bulgaria was definitely in the German camp; under Gen. Gekoff, commander-in-chief, her armies were victorious on most of the battlefields of Macedonia, Thrace and Rumania, in 1915, 1916 and 1917, against the Serbs, and against the Rumanians. The Kaiser, the King of Saxony and the King of Würtemberg all paid official visits to King Ferdinand at Sofia. However, in Sept. 1918, the Bulgarian Army, discouraged by innumerable hardships, was defeated at Dobropole, Macedonia, by the Allied troops. This was the sign for a general retreat. An armistice was signed at Salonika on Sept. 30 which ended the war between Bulgaria and the Allies. After this catastrophe King Ferdinand abdicated in favour of his son Boris on Oct. 4 1918 and left Sofia the same evening for Coburg where he has lived since in retirement. (A. St.)

FERDINAND I. (1865–), King of Rumania, was born Aug. 24 1865 at Sigmaringen, Prussia, the second son of Prince Leopold of Hohenzollern-Sigmaringen. As King Charles had no son it was decided that the succession should be continued in the family of Prince Leopold, and Prince Ferdinand, Charles's nephew, became Crown Prince of Rumania and heir presumptive to the Rumanian throne in March 1889. Prince Ferdinand took a great interest in military questions and the organisation of the Rumanian Army on modern lines was in no small measure due to his energy and enlightened advice. He was commander-in-chief of the Rumanian armies during the Bulgarian campaign of 1913. On Jan. 10 1893 he married Princess Marie, eldest daughter of the Duke of Edinburgh, Duke of Saxe-Coburg-Gotha. Six children were born of the marriage.

When Ferdinand ascended the throne on Oct. 11 1914, Rumania was passing through one of the most critical periods of her history. At the Crown Council held under King Charles at Sinaia soon after the outbreak of the World War, the members of the Cabinet who were in favour of intervention on the side of the Central Powers were greatly outnumbered and in spite of Charles's support of the minority, it was almost unanimously decided that Rumania should remain neutral. Later King Ferdinand, who had in the meantime succeeded to the throne, found himself in an extraordinarily painful situation when he realised that an armed intervention in the cause of Rumania's national unity was unavoidable. He, however, conquered his feelings as a German and a Hohenzollern, and when the moment came, he did not hesitate to declare war on his native country. As a consequence he was disowned by the Hohenzollern family.

When Bucharest was occupied by General Mackensen, King Ferdinand and the Royal family withdrew with the Government and the army into Moldavia. There he endured with the rest of the population a most appalling period of anxiety, sickness and want. The Bolshevist revolution and the collapse of the Russian armies came as a crowning misery. Fortunately however, the Rumanian Army, headed by King Ferdinand, repulsed the German attack at Mărăşeşti, thus saving the rest of the country from invasion. In 1918 the provinces of Bessarabia, Bucowina, Transylvania and the Banat had become united with Rumania, and on Oct. 15 1922 King Ferdinand was crowned at Alba Julia King of all Rumanians.

Two most important reforms, the agrarian reform and the inauguration of universal suffrage, were enacted under Ferdinand's reign. The expropriation of large estates and their conversion into small holdings did much to guarantee the peaceful development of an agricultural country such as Rumania. King Ferdinand was the first landlord to hand over his estates to his peasant-soldiers. It was also due to his initiative that the thorny Jewish question was solved by the grant of full civil and military rights to the Rumanian-born Jews. In Dec. 1925 Ferdinand's eldest son, Charles, renounced his claims to the throne, and Charles's son, Michael, became heir apparent. (G. Bo.)

FERRERO, GUGLIELMO (1871–), Italian journalist and author, was born at Portici, near Naples, July 31 1871. At an early age he joined the staff of the Radical semi-republican *Secolo* of Milan. He travelled abroad considerably, and made a certain reputation by his books *L'Europa giovane* (1897) and *Il Militarismo* (1898); Engl. tr., 1902. Later he studied Roman History, and in 1902 published his *Grandezza e decadenza di Roma*, which established his fame as historian among the general public rather than among scholars. He, in fact, applied the methods of journalism to history. In politics a Radical Democrat, on the outbreak of the World War he was an ardent supporter of the Allied cause, which he identified with that of democracy, and advocated Italian intervention. After the War he published numerous articles and several books in Italy and abroad, inspired by the most gloomy forebodings of imminent catastrophe for Italy, Europe and the world's civilisation. Among these later works is *Da Fiume a Roma* (Milan, 1923), also published in English under the title *Four Years of Fascism* (1924).

FERRIER, PAUL (1843–1920), French dramatist (*see* 10.288), died at Nouan-le-Fuzelier Sept. 11 1920.

FERRO-CONCRETE ENGINEERING (*see* also Bridges; Dams; Factory; Road Construction).—Owing to a combination of circumstances, technical, economic and manufacturing, great developments in reinforced concrete have taken place since 1910, and as a structural system it is now widely appreciated for many purposes on account of its adaptability, lightness and economy of first cost and maintenance. The scarcity of steel during the World War caused reinforced concrete to be used for many structural purposes for which steel had hitherto been considered the most suitable material. Another factor in the development has been the progressive improvement in the strength and reliability of Portland cement as evidenced by the latest revision of the British standard specification for Portland cement, 1925, which calls for a neat cement tensile strength at 7 days of 600

lb. per sq. in. as compared with 450 lb. for the previous specification, 1912.

Rapid progress has also been made with a new type of aluminous cement ("ciment fondu"), originating in France, but now also made elsewhere, which, while setting initially no quicker than Portland cement, nevertheless attains or exceeds in 24 hours the strength of Portland cement at seven days, so that concrete made with such cement can be brought into service, if need be, in a day or two. It is claimed also that the cement resists the action of sea water, and that owing to the heat generated in setting, it can be used in frosty weather.

Along with the improvements in cements much progress has been made in the subject of proper grading, proportioning and mixing of aggregates, sands, cement and water in order to attain the densest, strongest and most watertight concrete. It is well recognised now that, with aggregate and sand of a given material, that mixture of graded material (large, medium and fine) which has the smallest proportion of voids, and which consequently weighs most per unit volume, will be capable, when mixed without excess of water, of furnishing the strongest concrete.

Technical Studies.—On the technical side, much work has been done in the theoretical analysis of the moments and stresses in arches and continuous framed constructions of varied forms, and the results are available for use in the more accurate determination of stresses and sections. Considerable study has also been given to the elastic properties of concrete in relation to the secondary stresses arising from temperature variations and shrinkage of the concrete.

Foundations.—Reinforced concrete construction is adapted to varied uses in foundation work. Thus, retaining walls of ample strength can be readily constructed in places where there is no room for a gravity wall of mass concrete. Heavy columns can be supported on a relatively thin but widespread foundation of reinforced concrete with great saving in weight, volume and depth of construction, as compared with mass concrete. On weak ground, a complete layer of light reinforced concrete in the shape of a plain or ribbed slab may be provided to distribute the entire load over the whole basement area of a structure in an economical and efficient manner unattainable with other methods of construction.

Caissons and Floating Craft.—An important development in subaqueous foundation work, such as dock walls, breakwaters and bridge piers (*see* PORT ENGINEERING) consists in the use of reinforced concrete caissons of rectangular, cylindrical or other form, which may be constructed in dry dock or on a staging on dry land, then launched or floated out, towed to the site, and deposited in position on a bed prepared by dredging or by divers. Such caissons form a permanent part of the construction and are generally used as a working base for further operations of sinking downwards and building upwards, the top being kept always above water. Sinking downwards through suitable materials may be effected by grabbing through open wells in the interior of the caisson, while for difficult cases the excavation may be carried on by men working under compressed air. Large concrete caissons have been applied in the construction of the upper portions of breakwaters as at Valparaiso[1] and elsewhere. In the Oswald Street Bridge at Glasgow,[2] cylindrical caissons 20 ft. diameter were used for the foundations of the piers. These caissons were constructed on a staging ashore, fitted with a false bottom, lowered into the water, floated out to position, deposited on the prepared bed, and after removal of the temporary bottom, sunk to the necessary depth by grabbing and excavation inside, the pier on top of a group of caissons being built up as the sinking proceeded.

Concrete Ships.—The results of the construction of reinforced concrete cargo vessels were satisfactory and indeed surprising as regards watertightness, main longitudinal and transverse strength and lightness of construction. The hull weight in careful designs was less than that of a wooden vessel, though somewhat greater than that of a steel hull. The principal disadvantage lay in the relative tenderness of the thin skin construction under the bumping and rubbing to which a vessel is often subject when in port and when touching the ground. The results were instructive as regards the possibilities of carrying out light watertight concrete constructions with rich concrete of small aggregate without the addition of any special waterproofing material and with very fine limits of cover of concrete and spacing of bars. In Great Britain, in addition to numerous barges and steam tugs, a few self-propelled cargo vessels were also constructed, the principal being the "Armistice"[3] of about 1,100 tons dead-weight capacity.

Flat Floors.—There has been a continued tendency toward simplification of structure with a view to speeding up and cheapening construction, culminating in the extensive use in the United States of the flat slab floor. In this type main and subsidiary beams are dispensed with and a floor of constant thickness with a flat under surface is supported directly on the columns, which have enlarged heads of square or moulded shape. The floor reinforcement consists of several systems of rods mainly radiating from the columns and placed near the upper surface over the columns and near the lower surface in the interior of panels.

The design of such floors is based on very approximate theory controlled by the results of stress measurements in tests of actual floors. The method has hitherto found but little application in Britain, where much more use had been made of light flat ceilinged floors having in their lower part rows of hollow tile blocks set so as to leave intermediate spaces for the formation of narrow reinforced beams, the floor being completed by a continuous concrete layer placed over the tiles and beams. Floors of this type are well adapted for filling in the panels between the main floor beams of structural steel-framed buildings, and have the advantages of lightness and good insulating qualities, while a plaster ceiling can be applied to the grooved soffits of the tiles.

Rich Concrete.—Greater recognition is now being given to the value of the cement element in concrete as affecting the strength, watertightness and endurance of the material. Starting from 1:2:4 mixture, the one most commonly used in reinforced construction, which is seldom quite watertight and on that account may in certain circumstances fail to protect the rods sufficiently, it is found that up to a 2:2:4 mixture the addition of cement is accompanied by a roughly proportionate increase in the compressive strength as well as by enhanced reliability, watertightness and protecting properties, to the extent that porosity in a 2:2:4 mixture is quite exceptional. The richest mixtures are required for sea construction, such as jetties, especially for the parts above low water, also for tanks, conduits and floating craft which have to withstand water pressure, and for piles which have to undergo severe hammering. Pressure conduits have been constructed of 20 ft. diameter for 50 ft. head and in smaller sizes for a maximum pressure of 180 ft. head. (*See* AQUEDUCTS.)

Long Span Arch Construction.—Wherever abutment and headroom conditions are suitable and the span is not small, arch construction compels consideration, as thereby a single main truss member (the arch) serves to carry the load as compared with two main members and a web system in the case of a beam or truss. Further, the arch has the economical advantage that the thrust is principally taken by concrete, which is cheaper for this purpose than steel, and in large arches only a relatively small proportion of reinforcement is required to take care of such tensile stresses as may develop due to live-load variations and the effects of shrinkage, temperature and rib-shortening in the concrete. The arch form, in addition, lends itself to the attainment of good appearance. The largest arch bridge completed in 1926 is the 432 ft. span road bridge across the Seine at St. Pierre du Vauvray, France. Whereas formerly 400 ft. was looked on as being near the practicable limit for a concrete arch, recent developments have greatly extended the limits and completely worked-out projects are now in existence for more than one bridge with spans of about 600 ft., and spans of well over 1,000 ft. do not appear to be unattainable.

[2] *Engineering News Record*, Oct. 1925.
[3] *Proceeds of Inst. of Naval Architects*, 1918.

Aesthetic Appearance.—Surfaces of concrete do not lend themselves very readily to satisfactory architectural treatment, so that in many fine buildings the supporting framework of reinforced concrete is entirely hidden behind facework of masonry or other material. Good effects in buildings can be attained when the visible concrete is well finished and confined to well-proportioned and suitably lined vertical and horizontal bands of the framework, the rest of the elevation being formed of panelling and facework of other materials. In bridges, principal reliance must be placed on satisfactory form and proportions combined with very careful work in constructing and setting the moulds which form the exposed surfaces. Parapets and pillars of good finish and appearance may be precast in small pieces in carefully finished moulds, preferably of metal.

FERTILISERS: *see* AGRICULTURE: SCIENTIFIC DEVELOPMENTS.

FEZ, Morocco (*see* 10.306), has been since 1912 under the French Protectorate. The population in 1921 was 70,540, including 2,218 Europeans. The city has still an active native industrial life and prosperous trade, while European industries, such as oil and soap manufacture, have been established. The town is lit by electric light derived from the falls of Wadi Fez. The municipal services have been reorganised by the French under the native pasha and his council, and an office of native industries has been set up to conserve the ancient handicrafts. The erection of the new European-town of Fez has been begun near Dar Debi Bagh. Fez is connected with Rabat and Ujda by narrow-gauge lines, and the line to Tangier is finished as far as the Spanish frontier. There are some 30 native olive oil factories round the Bab-el-Ghisa, and the manufacture of silk textiles occupies about 30,000 people. There are good roads to Taza, Meknes and Qnitra. The new port at Qnitra is the nearest to Fez.

FIBRES (*see* 10.309).—No fundamental changes have taken place in the technology of fibres since 1910, although there have been many minor developments, including an increased use of the lesser fibres for industrial purposes. It is rather in the employment of substitutes and in the evolution of processes which have produced practically new substances such as "artificial silk" (*q.v.*) that the most striking changes have taken place.

War Substitutes.—During the World War period interesting technical experiments were made, particularly in Germany and Austria, with various substitutes. These were caused by the shortage of cotton and wool, due partly to the blockade and partly to the huge demand for these fibres for military purposes. Cotton was required for explosives and wool for uniforms and the like. Early in the War, German experts began to examine the possibilities of other fibres, hoping thereby to supplement their inadequate supplies of cotton and wool. From the standpoint of fibre technology, these experiments are undoubtedly important but so far have not been of much industrial use.

Experiments were made with nettles and with twisted paper yarns. The substitution of wood cellulose for cotton cellulose proved of the greatest immediate value to Germany. To a large extent she was thereby enabled to eke out her supplies of cotton cellulose and produced considerable quantities of nitro-cellulose propellant explosives from wood pulp. The wood cellulose was prepared from the bisulphite pulps of the paper industry by hydrolytic treatments and the result was a cottonisation of the pulp. This material is usually known as "Supersulfit" and has proved of considerable value during the post-War period for the making of paper. (*q.v.*).

Paper Yarn.—The "paper yarn" industry developed under the pressure of the War to an annual output of 200,000 tons. These yarns were used to quite a considerable extent for textiles, even complete suits being made from "paper cloth," but were characterised by the defects of short fibre length and failed to establish themselves as serious competitors with the older fibres such as cotton and wool.

Nettle Fibre.—Valuable experiments were made with nettle fibre, resulting in indications that it is almost a total failure. The common nettle or *Urticaceae* contains a rough fibre, and since the plant belongs to the same order as Ramie or Rhea fibre, high but illusory hopes were entertained that from it might be obtained a fibre of similar or even better quality, which could be used in the textile industry. Nettle fibre has great length of bast, and great variability in dimensions and has to be prepared by chemical methods of separation. The crop-weight is low and it is difficult to cultivate on a commercial basis. While stout plants can be gathered wild, when transferred to cultivated soil and planted in regular rows, they tend to deteriorate and become thin and weak. These difficulties may be surmounted, but so soon as the War ended fibre users quickly returned to the older and more satisfactory raw materials.

Jute.—Long before the War it was known among fibre experts that by treating jute with caustic soda a "woollenising" effect is produced. The structure of the fibre is altered, has many resemblances to wool, can be "carded," and mixes well with wool. This process was revived in Germany and Austria during the War and mixtures containing as much as 60% of this vegetable fibre were worked up and spun into serviceable yarns.

Sisal.—In the post-War period, so far as the old series of hard fibres are concerned, the most important developments have been in the direction of increasing their output by opening up new areas in which they are being grown on a commercial scale and in developing alternative plants, such as the expansion of the sisal industry in the British colony of Kenya. The sisal is an agave which is indigenous in Florida, the West Indies and Yucatan, and from its leaves sisal hemp is produced. The plant has, however, been transported to distant areas, and at Kenya it is now one of the chief exports of the country. In 1912 only 2,500 cwt. were exported; in 1919 the quantity had risen to 126,937. In 1924 Kenya and Uganda together exported 218,740 cwt. of sisal fibre and 9,720 cwt. of sisal tow.

The demand for sisal is due to the increasing demands for binder twine, needed by the mechanical reapers which are being employed in ever increased quantities by the great grain producing countries such as the United States, Canada, the Argentine and Australia, particularly for those machines which reap and at the same time bind into sheaves. Sisal hemp, a substitute for the original hemp, *Cannabis sativa*, is itself threatened by new competitors such as Mauritius hemp, Manila hemp and New Zealand hemp or *Phormium tenax*, which were well known and widely used before the War.

Bowstring Hemp.—This plant flourishes in the shade of old rubber and may therefore prove a valuable crop in old rubber clearings. It is propagated by seed, division or leaf cutting, the latter method being the most satisfactory. The distance of planting is two feet apart each way and the average yield is $1\frac{1}{2}$ tons per acre. The plant produces a fine, tough, white and elastic fibre, which is extracted from the leaf by methods similar to those employed in the preparation of sisal. It is usually shipped in bales of four to five hundred-weights. Although much valuable scientific information has been acquired concerning this plant—and it undoubtedly has considerable possibilities—its production is still in the experimental stage.

Roselle Fibre.—This is obtained from an annual shrub which belongs to the order of the hibiscus. The fibre is obtained from the branches and main stem, but the latter is of inferior quality. The fibre is suitable for making rope and good quality string, and it is claimed that it can be spun like jute but, so far, it is not certain that it can be produced on a commercial scale. The plant grows to a height of 10 or 12 ft. and therefore must not be planted within a radius of 5 ft. of young rubber trees. It is prepared by

retting in stagnant or slow moving water for 8 or 9 days, and all the work can be done by native hand labour and requires no elaborate machinery. It must, however, be bale-pressed for export.

Arghan.—This fibre stands half-way between the hard and soft fibres and appears to have some of the characteristics of each. It was originally discovered by Sir Henry Wickham in South America, but attempts are now being made to develop it on a commercial scale in Malaya. It was first considered as a material for twine and cordage but it possesses a tensile strength which gives a breaking strain of 50% above that of the finest Italian hemp or even the best flax. Moreover, it can be spun to a much finer lea than is required for twine. A firm cloth which bleaches and dyes well has been woven from it. Till recently it could only be spun on a flax machine but it now seems possible to use ordinary cotton machinery. It is a lance-leafed plant, similar to a pineapple, and the long leaves contain more than 20% of pure fibre. It is easily split up into long fibres, 7 feet or more in length, which are almost as delicate as silk, Specific leaves on each plant produce a softer and finer fibre than the others, and planters are concentrating attention on these. Arghan still is more of scientific than of commercial interest but possesses considerable possibilities.

Kapok.—This soft fibre is obtained from the pods of the Kapok or cotton tree, indigenous to Malaya, Java and the Philippines. Considerable and increasing quantities are being exported chiefly to Australia, America and Great Britain. The chief distributing centre in Europe is Amsterdam. It is non-absorbent and lighter than water. When stuffed into life-saving apparatus or into cushions, etc., it will sustain a heavy weight in water for many hours. In consequence it has largely replaced cork-lined appliances. The fibre is as buoyant as cork and can be compressed *en masse*. The peculiar property of the fibre is due to its structure. The fibre canal holds a large amount of air, and the smooth contour of the fibre and the resilience of the air-filled tube give a large air volume to the mass, even when compressed. The fibre is short, light and brittle, and despite much experiment so far, attempts to spin it on a large scale have not been successful. It has a fine lustre and great elasticity.

Flax.—Special efforts have been made to develop the production of flax in various parts of the British Empire in order to replace Russia who, in pre-War days, produced annually 525,000 tons of flax and exported at least half of it to Europe. Flax from the new Baltic States and from Soviet Russia has again begun to appear on the markets. The Belfast linen industry, in conjunction with the government, have in recent years devoted special attention to increasing the supply of fibre. In particular, efforts are being made to develop flax growing in England. A special committee was set up in Oct. 1924 to consider anew the whole matter, and in the *Journal of the Ministry of Agriculture* (1925, 32, 310) it was stated that the government had adopted the recommendation of this committee and had acquired two factories and constituted a society, not trading for profit. This society is The Flax Industry Development Society and its primary object is the supply of seed of good quality. It is believed this society will be able to supply a far better type of seed than that at present obtainable by flax growers and so lead to a great extension of flax growing of the finest quality within the British Isles and throughout the Empire. (*See* CELLULOSE.)

FIJI ISLANDS (*see* 10.335) have an area of 7,425 sq. m. and a population of 130,541 (1911). The dominant feature of Fijian history during the years 1915–25 was the celebration at Levuka, on Oct. 10 1924, of the islands' jubilee as a Crown Colony. After 50 years of British rule the same "lali" or native drum was beaten at the same hour and place by the old chief who beat it at the cession of 1874, announcing the ceremonies arranged in honour of the occasion. Peace was the object of the cession, and the Fijian fully appreciates the peace that for nearly 50 years has remained unbroken. A large tahua (whale's tooth), presented on the occasion of the jubilee, was accepted by King George as a token of the loyalty and affection of his Fijian subjects.

Population.—The census of 1911 shows that the population in that year was 139,541; in 1921 there were 88,464 males and 68,802 females, total, 157,266. Of this total, Europeans number 2·4%, Fijians 53%, Indians 38%; the rest are mainly half castes, Polynesians, Rotumans and Chinese.

Constitution and Administration.—The present Constitution is regulated by Letters Patent of Jan. 31 1914 (amended in July 1916). It provides for an Executive Council to advise the Governor, and a Legislative Council; the former now consists of four official and two nominated unofficial members, and the latter consists of the Governor, not more than 12 nominated, 7 elected and 2 native members. The natives, however, retain a large share of self-government, and in the remote districts, where little commercial development has taken place, there is but slight modification in the old communal methods of native society. Younger natives, who through a certain amount of education have come under the influence of a European social system, are disposed to secure release from communal obligations and to support themselves on their own land or become wage-earners for varying periods in industrial centres or on plantations. Many are now engaged in the sugar-mills, and a considerable number as clerks, sailors, carpenters, boat builders and domestic servants. The vast majority, however, remain agriculturists living in native villages and cultivating their tribal lands. Educational administration was completely changed in 1916, when a board of education replaced the school boards, an education department was formed and ordinances passed to allow grants to be made to primary and vernacular schools. European education in the colony has made considerable progress, in spite of the fact that the problem is rendered more complex by the numerous races now domiciled in the islands. Facilities for primary education are good, and those for vocational training constantly improving.

Land Tenure.—The sale of native lands, except to the Government for specific purposes, was prohibited by an ordinance of 1912. The standard tenure is leasehold up to 99 years, with security to the tenant for permanent and unexhausted improvements. A native lands commission, comprising a European officer and three native chiefs, has been established to survey and register all native lands.

Trade and Industry.—The total trade in 1924 was £2,565,528, as against £1,999,004 for 1912, £2,329,908 for 1913 and £2,301,139 for 1914—a steady increase which has since been well maintained. There is a preferential tariff in favour of the products and manufactures of the British Empire; and of the total trade of the colony over 60% is with British Possessions, and about 11% with the United Kingdom, the balance, about 25%, being with Europe and the United States of America. The main agricultural industries have for long been the production of sugar, copra and bananas. The sugar industry has been hampered by inadequate labour and by a great increase in the world's production; copra has suffered from a restricted market, the banana industry from plant disease and a protective customs tariff in Australia. Hence the Government continues to make efforts to develop the new rice industry, which is important to the Colony with its large East Indian population. The cultivation of cotton, which had ceased in 1900, was resumed in 1922 and is almost entirely in the hands of East Indians. Other developing industries are dairying, sawmilling and the growing and canning of pineapples.

Communications.—There is regular monthly communication to and from Sydney via Auckland or directly, and also to and from Vancouver via Honolulu. The Colonial Sugar Refining Company has a narrow gauge railway extending from Tavua to Na Singatoka, a distance of 120 m. over which passengers are carried on specified days. The first section of the main trunk road, which ends at Sawani, was completed and opened to traffic in 1924, and, though the total length of metalled roads is less than 100 m., there is a good length of gravelled roads and of communally-maintained bridle tracks.

Finance.—The revenue for 1924 amounted to £484,834 as against £283,947 in 1912. Notwithstanding fluctuations the revenue has been steadily expanding for years, and though expenditure in the last 10 years has frequently exceeded it, there was a surplus of £50,316 in 1923 and of £33,764 in 1924. (A. R.*)

FILDES, SIR LUKE (1844–), British painter (*see* 8.339), was born at Liverpool and educated privately at Chester. He studied at the art schools of Warrington, South Kensington and

the Royal Academy, and exhibited his first Academy painting in 1872. Introduced to Dickens by Millais, Fildes was illustrating *Edwin Drood* at the time of the novelist's death. "The Casuals" (1874) showed him as a genre painter of power, and a series of Venetian pictures were very popular. He was made A.R.A. in 1879, and R.A. in 1887. "The Village Wedding" (1883) and, more especially, "The Doctor" (1892) is probably the most widely famous of his works. In later years he painted many portraits, among them state portraits of Edward VII. (1902), Queen Alexandra (1905), and George V. (1912). Knighted in 1906, Sir Luke Fildes became K.C.V.O. in 1918.

FILON, PIERRE MARIE AUGUSTIN (1841–1916), French man of letters (*see* 10.345), died at Croydon, England, May 13 1916. In 1910 he published a short biography, *Marie Stuart*, and in 1911 *L'Angleterre d'Edouard VII.*, and a dramatic poem, *Shakespeare amoureux*. His *Souvenirs et documents*, relating to his former pupil, the Prince Imperial, appeared in 1912.

FILTER-PASSING MICROBES.—These organisms are those which are small enough to pass through a "bacterial" filter. Bacterial filters are made of unglazed porcelain or compressed infusorial earth. The grains of the china clay or infusorial earth used for their manufacture are sufficiently small and uniform to leave insterstices, the cross section of which is 0·2 to 0·8 μ in diameter. If a liquid containing microbes whose smallest diameter exceeds 0.2 μ be pressed through the filter, the microbes remain impacted in the smaller crevices. As 0·2 μ is also the limit of size of a particle which can be resolved by the best microscopes (*see* MICROSCOPY) when white light is used, filter-passing organisms are either invisible or on the margin of visibility. Hence, most of them have been classed as "ultravisible viruses."

Discovery.—The first discovery, that an ultramicroscopic or filterable virus was the cause of an animal disease, was made by Loeffler in 1898 in the course of some experiments upon foot-and-mouth disease, in which a filter of infusorial earth was used to remove ordinary recognisable bacteria from the diluted contents of the superficial vesicles which are characteristic of this disease. The filtrate was free from any particles visible by the microscope and no bacteria developed in it on cultivation. Nevertheless, injection of this filtrate into animals caused disease. Material removed from the vesicles of the animal so infected and filtered again reproduced the disease in a fresh animal. Similar experiments were carried out through a number of generations of animals, so that there was no doubt that a virus capable of propagation in the animal body was contained in the filtrates. In the next few years the filterability of the virus was established in the case of infectious pleuro-pneumonia of cattle, South African horse-sickness and fowl plague.

Yellow Fever.—The cause of yellow fever has been shown by Noguchi to be a spirochaete which, owing to its thinness and motility, can pass through a bacterial filter.

Human Diseases.—Up to 1925 the virus of about 40 diseases of man and domestic animals had been found to pass through a bacterial filter by some reliable observer. The more important of these are the following: foot-and-mouth disease, contagious bovine pleuro-pneumonia, African horse-sickness, fowl plague, yellow fever, cattle plague, sheep-pox, *epithelioma contagiosum* of birds, swine fever, rabies, cow-pox (vaccinia), *molluscum contagiosum* of man, equine infectious pernicious anaemia, canine distemper, "blue tongue" of sheep, dengue fever, papataci or sand-fly fever, smallpox, trachoma, poliomyelitis, measles, typhus fever, trench fever, mumps, Rocky Mountain spotted fever and *herpes labialis*.

Influenza.—Recently, Olitzky has succeeded in propagating on special culture media seven varieties of small microbes from the filtrates through a "bacteria proof" filter of washings of the throats of individuals suffering from catarrhal diseases. One of them is credited, on substantial grounds, with being the cause of pandemic influenza (*q.v.*), another is supposed by its discoverer to be responsible for our common colds. The others do not appear to be of pathological significance.

Cancer Research.—There is now reason to suppose that filterable viruses play some part in the origin of cancer (*q.v.*). When a fragment of a malignant tumour is implanted in the tissues of an animal of the same species it generally grows and ultimately kills the animal. The animal cells of which the cancer is composed are endowed with a faculty for growth, uncontrolled by those factors which determine normal tissue equilibrium. The possibility that this property was due to infection of the cells by a microbe has, in the past, occupied the attention of investigators, but no experimental basis for this view was afforded till 1911, when Peyton Rous described a sarcoma of the fowl which differed from mammalian tumours in that it was transmissible from chicken to chicken by means of a filtrate from a filter which kept back all of the malignant cells (much too large to traverse its pores) and also any bacteria of ordinary dimensions. This filtrate could be dried at a low temperature and the powder retained its activity for years. It had no effect when injected into animals other than chickens, and it always produced the same type of tumour.

As the same result could not be obtained with a filtered extract of other malignant growths, this very important discovery was interpreted to mean that this fowl-sarcoma was a thing apart, although in structure and behaviour it closely resembled the mammalian sarcomata. Subsequently, its discoverer found that two other malignant tumours of fowls possessed similar properties, and quite recently Carrel has recorded the formation of malignant tumours in fowls following local irritation of the tissues with tar or arsenic, filtrates from which were also infective for chickens. Rous believed that the filterable agent which caused the tumours he studied was, probably, an extremely small microbe, but as he did not succeed in propagating it outside the body its nature remained undetermined. The nature of the infective agent in the filtrate of Rous's tumour has recently been disclosed by Gye, who has succeeded in growing it in test tubes in a special medium. The culture has been carried on through several generations of transplantations. By this means the virus has been purified from the other constituents of the original implant. The inoculation of this purified virus alone did not give rise to a tumour, but if mixed with an extract of the fresh tumour, in which the virus had been killed by chemical agents and which alone was innocuous, a tumour occurred. In other words, the conjunction of two factors, living virus and some non-living chemical substance or substances, is necessary to provoke the cells of the animal to that anarchical development which is characteristic of malignant growth.

Gye's Experiments.—Gye has also succeeded in showing that chicken sarcoma is not peculiar, as hitherto believed, and that a particular mouse sarcoma will sometimes yield an infective filtrate. In this case, however, a special technique had to be employed, the original method of Rous proving unsuccessful. This is a discovery of much significance and it seems probable that an extrinsic origin may be found in the case of other cancers in the near future.

The virus of Rous sarcoma has been presumed to be particulate as it is held back by the finer grades of filter, and recently Barnard, using ultra-violet light, has obtained photographs of small globoid bodies about 0·1 μ in diameter from cultures of the virus. These small bodies occurred in masses, suggesting colonies. They were not discovered in the medium before inoculation or when the cultivation of the virus proved unsuccessful. Whether they represent the microbes or aggregations of colloidal particles produced from the proteins of the medium by chemical changes associated with the growth of the virus occurring therein, is not at present determined.

Plant Diseases.—Filterable organisms are also responsible for many diseases of plants (*see* PLANT PATHOLOGY). In fact, their existence was first brought to light by Iwanowski in 1892 in connection with the mosaic disease of the tobacco plant. Iwanowski's discovery was lost sight of and the fact was rediscovered by Beijerinck in 1898. Many varieties of plants, including potatoes, tomatoes, beans, peaches, clover, peas, cucumbers, turnips, spinach, *datura*, *hyoscyamus*, *capsicum*, sugar-cane,

maize, sorghum and various grasses suffer from mosaic diseases. In most mosaic diseases the only obvious lesion is bleaching of the leaves in patches of varying extent, but sometimes, as in "leaf roll" of potatoes, "curly top" of beet and "spike" disease of sandalwood trees, definite destruction of tissue leading to malformation occurs. The loss of chlorophyll interferes with the nutrition of the plant by limiting the leaf area capable of utilising the radiant energy of the sun for the building up of carbohydrate from carbonic acid and water. To this handicap local necrosis of portions of the leaf and stalk is in some varieties superadded. The economic effect of these diseases may be, as in the case of the mosaic of sugar-cane, almost negligible or, as in the case of "peach yellows" and the "spike" of sandalwood, serious, as it destroys these trees.

Between these extreme instances, the infection results in more or less diminution of crop. Only the growing leaves are affected. Nevertheless the virus extends throughout the plant and sometimes to the seeds. Mosaic diseases are very infectious. Mere handling of a healthy plant after touching an infected one is, in some instances, sufficient to transmit infection. The disease is spread by leaf flies or beetles and by grafting (*see* ENTOMOLOGY, ECONOMIC). The virus is not capable of maintaining itself in the soil. There is a large number of different viruses which produce mosaic diseases. Some of them infect more than one species of plant. They can also inhabit resistant species of plants without these manifesting any symptoms, but the disease can be transferred from resistant plants to susceptible species by insects or grafting. Many attempts have been made to propagate these plant viruses in the laboratory upon plant-juices without success, but the virus of one of the mosaic diseases of the potato appears to have been recently cultivated by Olitzky.

Properties of Micro-organisms.—Little is known about most of these filterable viruses. They appear to be of various natures, and the only property common to them is minuteness. The parasite responsible for yellow fever is a small spirochaete, those occasioning bovine pleuro-pneumonia and human poliomyelitis are globoid in shape and just on the margin of visibility with the best microscopes.

It is not improbable that many of them flourish only inside the cells of animals and plants, which may explain the difficulty in cultivating them in artificial media. In some cases, small bodies of definite size, shape and staining characteristics are always to be seen in the cells at the seat of the lesion (trachoma, *molluscum contagiosum*, variola, vaccinia, bird-pox, typhus and Rocky Mountain spotted fevers). Whether these represent the microbe or granules in the cell contents produced under the influence of the virus is a matter of opinion. Until cultivation outside the body is achieved this controversy will not be settled.

Definite Results.—At present only the viruses of pleuro-pneumonia, poliomyelitis, yellow fever, chicken sarcoma and the microbe probably responsible for influenza have been certainly cultivated, although many claims to have accomplished this with other viruses have been made. Some of these viruses occur in the blood of the patient during the acute stage of the illness and are transported to a fresh host by the bite of blood-sucking insects.

Transmission of Infection.—The infections of yellow fever (*q.v.*) and dengue are conveyed by the mosquito (*Stegomyia fasciata*). That of papataci fever is transmitted by the sandfly (*Phlebotomus papatasii*) (*see* SANDFLY FEVER) and that of typhus and trench fevers by lice (*see* INFECTIOUS FEVERS). With these three fevers and also in the case of some of the mosaic diseases of plants which are transferred by leaf flies, some days elapse before the insect is capable of handing on the infection, indicating that an interval for the multiplication of the parasite is necessary. It is possible that a stage in the life-history of the parasite can only occur in the body of the insect host. Some filterable viruses, such as smallpox, cow-pox, foot-and-mouth disease and *molluscum contagiosum* give rise to superficial lesions, and are spread by contact; others occasion catarrh of the respiratory passages and are distributed by coughing and intimate contact, as in distemper, measles and pleuro-pneumonia.

Conclusion.—Most filter-passing microbes which have been discovered hitherto cause disease of plants or animals. It would be strange if only parasitic forms existed, for the majority of the larger microbes are not pathogenic but are concerned with the multifarious putrefactive and fermentative changes in organic matter on the surface of the earth. Accordingly, it would be natural to suppose that sub-microscopic germs with similar activities would be ubiquitous. The indications, at present, are, however, against this supposition, and sub-microscopic dimensions seem to be an attribute, more especially, of germs which are parasitic upon animals and plants. (C. J. M.*)

FILTRATION.—In many industrial processes it is necessary to separate finely divided solid materials from liquids. The process of filtration consists in passing the liquid through a porous medium, which retains the solid particles. In some cases this is done for the sake of purifying the liquid; in others the recovery of the solid is the main object. Many different types of filter are in use, and it is necessary to consider (1) the various porous materials which are available for filtration, and (2) the construction of the apparatus in which these are applied.

Filter Materials.—The following are the main types of material which are in use:

1. Sheets of woven or felted material. These comprise porous filter paper, cotton, woollen or linen cloth, felt and woven metal.
2. Unwoven fibrous material, such as cotton wool, linen fibre, cellulose pulp, metal fibres, sponge.
3. Granular or powdered materials, such as gravel, sand, earth, coke, sawdust, cork.
4. Porous plates of stone, porcelain, carbon, silica, etc.

The choice of material depends upon (*a*) the fineness of the substances to be filtered, (*b*) the chemical nature of the liquid, (*c*) convenience in collecting the solid material after filtration.

Laboratory Filtration.—Porous paper is generally used as the filter medium, being resistant to most of the liquids which require filtration. The commonest method of filtration is to fold a circular filter paper twice at right angles, and open it out to a cone with three thicknesses of paper at one side and one at the other. This is placed in a conical glass funnel, and the liquid is poured into it. In some cases, the filter funnel is provided with a hot-water jacket to keep the liquid warm during filtration. Filter paper is also manufactured in the form of thimbles, for extractions with solvents, such as alcohol and ether, in special apparatus.

The Buchner funnel is made of porcelain and has a flat, perforated bottom on which a circular filter paper is placed. This form of filter has the advantage that the filtration may be assisted by the application of suction below the filter.

The Gooch crucible is a porcelain cup with a perforated bottom. A thin layer of asbestos serves as the filter, and the crucible can be weighed, after drying, to ascertain the weight of solid material collected.

A recent advance in laboratory filters consists in the use of discs made up of a fritted mass of hard glass, which has been ground and sieved to a definite degree of fineness. These are fused into various types of glass apparatus, and are resistant to almost all chemical reagents.

Filtration of Drinking Water.—Domestic filters are usually supplied in the form of earthenware vessels with a filter bed of charcoal; in some cases filters of paper, asbestos or stone are used. It was originally thought that charcoal filters would unfailingly remove micro-organisms, but the action was subsequently found to be less complete than had been believed. Indeed, if the filter material be not removed at intervals, it may become the seat of organic growths. Large-scale filtration of town supplies of water is generally effected in sand filters.

Industrial Filtration.—When possible, it is advantageous to allow the solid precipitate to settle in the liquor for some time, and to run off as much as possible of the clear liquid. The sediment may then be stirred up with water, allowed to settle, and the liquid again decanted, so as to minimise the bulk of liquor to be filtered, and to facilitate the subsequent washing. The design of industrial filters varies according to the requirements. The chief considerations are that the filter shall present

a maximum available surface without occupying too much factory space, that it shall withstand the required pressures, that it shall not be easily clogged, but shall be readily cleaned and easily controlled at all points. In some cases, continuous working is desirable.

Simplicity and economy of construction often outweigh all other considerations, and for many purposes it is sufficient to filter through a bed of sand, or through a simple sheet of cloth resting on a flat, perforated support. Suspended bags of cloth are also frequently used, and have the advantage that the bag can be squeezed or wrung out after filtration to remove as much liquor as possible from the solid material.

Vacuum Filters.—As in laboratory filtration, suction is frequently applied to accelerate the flow of liquid. A filter cloth is spread on a perforated plate of earthenware or other material, and the receiver into which the filtrate flows is connected with a vacuum pump. Conversely, pressure may be applied to the surface of the liquid in the filter. In place of cloth filters, porous plates are sometimes used; these may be either flat plates or cylindrical " candles " of porous material, presenting an increased filter area.

Leaf filters may be used either for suction or pressure. A typical form of leaf consists of a rectangular frame of perforated pipes to which is attached a stiff, corrugated surface of coco-nut matting or other material, and the whole enveloped by a cloth bag. The liquid passes from the exterior to the interior of the leaf, and is assisted either by external pressure or by internal suction. A filtering unit consists of a number of parallel leaves, and thus presents a large filtering surface.

Filter presses are somewhat similar in principle. In one form, a number of recessed plates are supported on a framework, so that they can be firmly pressed together by a screw press. Sheets of cloth are placed between the plates, and thus, when the filter press is assembled, it forms a series of narrow partitions separated by cloth filters. Channels are provided so that the sludge to be filtered can be forced under pressure between the cloth sheets, and the filtered liquid is collected from taps at the bottom of the plates. After filtration, the plates are separated, and the cake of solid material is removed. In place of recessed plates, some filter presses have alternate plates and distance frames.

In centrifuges the filtration is assisted by the rapid rotation of a circular pan. The periphery of the pan is perforated, and provided on its inner side with a filter cloth, supported by a basket of metal. The rapid rotation (up to about 1,000 revolutions per minute) whizzes the liquid through the filter, with a force several hundred times greater than in gravity filtration.

In the above-mentioned filters, the solid material has to be collected at intervals, and this necessitates stopping the filtering operation. Continuous filtration can be effected by rotary filters. A hollow drum is supported in such a way that it can be rotated on a horizontal axis. The periphery of the drum is covered with a filter cloth, and the drum dips into the liquid to be filtered. By suction, the liquid is drawn through the filter cloth to the interior of the drum, and the solid remains on the outside. The drum rotates slowly, and a scraper is fixed in such a position that it scrapes off the solid material continuously.

A recent advance in filtration methods is the stream-line filter, which permits of the separation of extremely finely divided solid matter, which would pass through ordinary filter cloths. A large number of sheets of paper are pressed together, and the liquid is forced through the edge of the pack by the application of pressure. The channels between the sheets are so minute that the finest precipitates are retained. The filter is made in various forms to permit of continuous filtration, etc.

Aids to Filtration.—The greatest difficulties in filtration are presented by slimy substances, which clog the filter. Application of increased pressure only accentuates the difficulty, and considerable importance attaches to methods whereby the slimy material may be caused to clot together and settle out. This can be effected by the addition of kieselguhr, fuller's earth, clay, talc, silica-gel and various carbonates. Another procedure is to coat the filter with a layer of finely divided kieselguhr, boneblack, sawdust or other finely porous material, which retains the slime and prevents it from penetrating into the filter material. (R. C. F.)

FINANCE: *see* BANKING; CURRENCY; and the sections on national finance in FRANCE; GERMANY; GREAT BRITAIN; UNITED STATES, etc.

FINLAND (*see* 10.383).—A republic of northern Europe and a member of the League of Nations, in Finnish it is Suomen Tasavolta. Its area is 132,550 sq. m. and the population 3,435,249.

I. POLITICAL HISTORY

In the closing decades of the 19th century there was a remarkable development of Finnish nationalism, primarily directed against the Swedish language and Finno-Swedish cultural domination.

Second Period of Russification 1908–14.—The successive governors of Russia, however, regarded the democratic, almost self-governing grand duchy as infringing the principle of the autocratic state, and delivered their first attack upon the liberties of Finland (1899–1905). The policy of repression was arrested by the Russian revolution of 1905, the manifesto of the Emperor-Grand Duke of Nov. 4 (Oct. 22) annulling all unconstitutional interferences. But after two years of peace, internal progress and political development, the same pan-Slav conception of a great homogeneous Russia stretching from the warm-water ports of Scandinavia to the Pacific, which had caused the conflict between Finland and the Tsar, involved her in fresh collisions with the Duma.

New and provocative interference with Finland's constitu-

tional rights began. The Tsar peremptorily fixed an annual contribution in lieu of military service (Ukase of Oct. 7 1909) and the Imperial Duma approved of the principle (imp. law of Jan. 23 (U.S.) 1912). The Finnish Diet, though ready to compromise, was twice dissolved, and all the large measures of domestic reform which it passed were never heard of again. Such was the fate of the bill for the prohibition of alcohol, of measures relating to the care of children, insurance, old-age pensions, education, public health and the betterment of the landless worker upon the soil. Civil marriages, however, were instituted, illegitimate children placed upon a better basis, and the principle of "equal pay for equal work" was applied in teaching, the printing trade and, in 1913, in the state service. The Duma considered itself competent to decide what questions affected the interests of the Russian Empire, and for that reason did not fall within the competence of the Finnish Diet. The law, known as "Imperial Legislation Act," was passed on June 30 (17th) 1910, amid shouts of "Finis Finlandiae."

Immediately two imperial laws were laid before the Diet, which refused them both, and was thereupon dissolved. In one, already referred to, the Duma affirmed the principle of an annual Finnish indemnity in lieu of service, in the other full citizen rights were accorded to temporary Russian residents in Finland. The consequence of the last-named measure, apart from its injustice, was the overlapping of two different codes of law. Judges resigned rather than be a party to it; high officials suffered exile or imprisonment; every single provisional governor left voluntarily or under compulsion. The country was ruled by a packed Senate, the Diet was capriciously summoned and dismissed, the press censored. The Russification inflicted by the Duma was as oppressive as that of the Tsar.

The World War 1914–8.—It was left to Lt.-Gen. F. Seyn, the governor-general, to supervise the harassing restrictions of liberty which the World War brought with it. Though Finland escaped foreign invasion, two systems of fortified lines were constructed to protect the chief railways and the long sea border. The mercantile marine, exposed to destruction in the Baltic Sea, remained locked in the harbours of the Bothnian gulf, and, there being no leaks—as in Sweden and Denmark—in the Allied blockade, the price of living gradually rose by 25%. On the other hand, industries connected with military supply, as also iron, leather, glass, chemical and paper-manufacturing concerns, attained unexampled prosperity. The Russians, sporadically anxious to please, remitted the annual military indemnity, and merely imposed a 5% tax on property and mortgage.

Finland naturally feared that Russia, if she emerged victorious, would again turn oppressor. A strong party was anxious for a German victory, from patriotic motives. Only some 2,000 Finns volunteered for the Russian Army. About the same number enlisted on the German side, though ostensibly only for service on the eastern front.

The Russian Revolution, March–Nov. 1917.—The Tsar Nicholas II. abdicated on March 15 1917 and the new Provisional Govt. of Russia restored representative government in Finland. The Russianised Senate was disbanded and a temporary body of 12, half of whom were Social Democrats and the remainder representatives of the bourgeoisie, assumed executive power. Stakovich became governor-general and Rodichev, a tried friend, Secretary of State for Finland. The Socialist speaker of the Diet, M. Tokoi, was nominated president of the Senate; Kullervo Manner, of the same party, Speaker of the Diet. But in view of the anarchical conditions in Russia, the propertied classes of Finland quailed before the rising power of the Social Democratic party, which was politically orientated towards Russia. The intense industrial development of the last three years had strengthened hooliganism, and the War had brought to Finland some 40,000 Russian refugees from food shortage and the incipient riot. The Swedo-Finns aimed at complete independence, and the Finnish Govt. proclaimed that such was its policy.

The struggle between the Provisional Russian Govt. and the Finnish Diet crystallised around the law of July 18 1917 by which the Diet resolved that it alone decided, confirmed and put into practice all laws of Finland relating to home affairs, taxation and customs. This law reflected the standpoint of the Social Democratic majority, which demanded complete internal freedom but was ready to recognise Russia's supremacy in military matters and in foreign policy. Upon this issue a deadlock ensued, which the dilatory Russian Provisional Govt. never succeeded in settling. The Finnish Diet passed *en bloc* all reform bills previously held up by the Tsar, including the total prohibition of alcohol and the eight-hour day. Yet it passed no effective measure to avert the food-shortage, which was the inevitable result of the industrial effort of recent years and the neglect of agriculture. Prices soared ever higher, and from March 1917 to Feb. 1918 a veritable strike mania threatened the existence of the nation.

Meanwhile, the Bolshevik advent to power in Russia in Nov. 1917 created fundamental social and economic differences between the political parties in Finland. The pro-Russian sympathies of the Social Democrats deepened; on the other hand, the propertied classes—primarily the Swedo-Finn and Finno-Finn bourgeoisie—sought to cut adrift from a Russia which had no settled government. Accordingly, on Dec. 6 1917 the Diet and the now bourgeois Senate drew up an old-fashioned declaration of independence, which is held to mark the birth of Finnish freedom. The Bolsheviks on Jan. 4 1918 declared that the step taken conformed with their policy, whereupon the Swedish Govt. and the other Scandinavian countries acknowledged the independence of Finland. France did likewise and was followed by Germany. Immediately after their declaration of independence, the Finnish Govt. entered into negotiations with Germany. The Treaty of Brest Litovsk (March 3 1918) confirmed Finland's independence, and four days later she concluded a treaty with Germany which made her Germany's commercial ally and vassal.

The Bolsheviks, however, were bent on precipitating civil war. The Finnish Social Democrats were almost all Maximalists and anti-militarists, and, as such, averse even to the formation of a citizen army for the maintenance of order. They pinned their faith on the Muscovite connection to save their country from invasion—oblivious of the fact that the Russian revolutionary *soldateska* (reinforced from Russia), without restraint of discipline, starving and unpaid, was, to say the least, an uncertain factor. Soon so-called "Red Guards" began to ransack the country, while the White Guards, hurriedly organised by reactionaries, together with doubtful elements of the disbanded gendarmerie, resisted. The White Army, under Baron Carl Gustav Emil Mannerheim, a former Russian general of cavalry, proved insufficient to maintain order. Foreign intervention was sought, but while Sweden refused help, the Germans did not hesitate.

A German composite division, initially some 12,000 men strong under the Prussian General Count Rüdiger von der Goltz, landed in the rear of the Red forces and held these in a successful action near Karis on April 6. This enabled General Mannerheim to win the battle of Tammerfors, whereupon Goltz freed Helsingfors, entering this capital officially on April 14. Finally, the German victory over the Reds (April 30—May 2) at Lahti-Tavastehus contributed to Mannerheim's decisive victory near Viborg (April 28–29). The remnants of the Red Army were forced into Russia, but the cruelty of the Red insurrectionaries led to a White counter-terror. Some 15,000 men, women and children were slaughtered and, by June 27 1918, 73,915 Red rebels, including 4,600 women, were prisoners of war.

The Diet, which met in June 1918, was moderate in colour, since the Socialists, who formed 46% of the electorate, were excluded from the register. It authorised the Germanophil senator, Pehr Evind Svinhufud, to exercise the supreme power in so far as it had not already been conferred on the Senate, which was offering the crown to Prince Frederick Charles of Hesse, brother-in-law of the German Emperor.[1]

[1] Prince Charles accepted the crown, but never proceeded to Finland and the question of the Finnish monarchy was allowed to lapse.

But the Germans pursued the ulterior object of securing Finnish military co-operation against the Murman railway, which was guarded by a British expeditionary force. The claim of the liberators upon the gratitude of the Finns was assuming the most peremptory forms known to diplomacy when, on July 18, the Allied offensive in the west diverted Germany's forces. Thus valuable time was gained until the Armistice of Nov. 11 1918 caught Finnish reaction between wind and water. Svinhufud was succeeded on Dec. 12 by General Mannerheim as Regent, who formed a Coalition Govt. composed of six Republicans and six Monarchists. The most prominent pro-Germans were dismissed; Finland turned definitely towards the Entente and the monarchical period of German influence gave way to the democratic régime associated with England and America. The German troops, in part mutinous, were conveyed back to Germany in December. General Mannerheim, who was a monarchist, but not a pro-German, wielded the power of a quasi-dictator.

Restoration of Order.—In 1919 Mannerheim organised the "Skyddskorps" of 100,000 men to maintain order. The general election of March 1 showed the following division of parties: Social Democrats 80, Agrarians 42, Coalitionists 28, Progressives 26, Swedish 22, Christian Labour 2. The tendency towards a Republican form of government was outlined by the Agrarian party composed of small land-owners hostile to the Swedish-speaking monarchist section. The Social Democrats lost 12 seats, largely owing to the disfranchisement of 40,000 voters for participation in the Red revolt.

Mannerheim's popularity with the Right and the army tempted him to exploit the military impotence of Soviet Russia. When, at the end of May 1919, the Entente intervention on the Murmansk front brought the 237th Brigade (of the expeditionary force under the British Major-General Maynard) to the head of Lake Onega, the Finnish Govt. offered co-operation in return for the possession of Petrozavodsk. The offer being declined, a Finnish volunteer force nevertheless assaulted the town independently, but without success. Again, at the close of the year, when the White Russian General Yudenitch was marching on Petrograd, Mannerheim sounded the Allies on proposed Finnish intervention. He received no encouragement from Paris or London, nor from the Moderates at home.

Establishment of the Republic.—On June 17 1919 the Finnish Diet resolved to establish a republic. The new constitution came into force on July 17. There is a single chamber, the Diet, in which the sovereign power of the people is embodied. The executive power is in the hands of a president, who is elected for six years by 300 presidential electors elected by the citizens. He ratifies new laws or withholds consent, dissolves the Diet, orders new elections and conducts foreign affairs. All his powers are exercisable through the ministers and his decisions have to be taken in the Council of State (Cabinet) consisting of 10 ministers, who are legally and politically responsible. There are nine departments for local government, closely following the linguistic distribution. Both Finnish and Swedish are official languages. On July 25 Professor Kaarlo Juho Ståhlberg was chosen as first president by 143 votes against 50 recorded for Mannerheim. A Coalition anti-socialist government under M. Erich held office till April 9 1921. The Vennola Govt., a coalition of Progressive and Agrarian parties, then came into power. Commanding only 64 out of 200 seats in the Diet, it introduced the Amnesty bill which, after a chequered career, was passed on Dec. 18 by 165 votes to 68. On May 6 1919 Great Britain recognised the independence of Finland and the existing Govt. *de jure.*

A peace treaty was signed with Soviet Russia at Dorpat on Oct. 14 1920. Pechenga was ceded to Finland, which thus obtained an outlet on the Arctic Ocean, although Russia retained Eastern Karelia, where, after the collapse of General Skobelzine's White Russian Army, fighting had occurred with Bolshevist troops with results satisfactory to Finnish arms. The treaty was approved on Dec. 1 by the Diet with only 27 dissentient voices and ratified on Dec. 11 by the President. On Dec. 16 1920 Finland was admitted as a member of the League of Nations. As such it claimed sovereignty over the Aaland Is. (*q.v.*) which was disputed by Sweden. In June 1921 the League of Nations gave its decision in favour of Finland.

Despite the Treaty of Dorpat, relations with Soviet Russia did not improve. In Oct. 1921 the native Karelian population, racially allied to the Finns, broke out into open revolt against Moscow. After initial success, this "war of independence" was crushed by a Soviet army. But the Karelian question remained, and, at the instance of Finland, occupied the League of Nations all through 1923. The Permanent Court of International Justice, to which the legal aspect of the question was referred, decided in July not to deal with this matter, as Soviet Russia was not a member of the League and might not recognise its competence. The Council of the League, however, determined that this view of the Permanent Court should not hinder an attempt at a settlement, which resolve the Assembly of the League of Nations strongly supported. But the Soviet Commissar for Foreign Affairs, M. Chicherin, protested against the intervention of the League and declared Karelia part of Soviet Russia. His argument had the support of the Red battalions, which, after completely discomfiting the insurrectionaries, held the trump card of power. This rendered all diplomatic negotiation nugatory.

In these years, the guidance of Finnish foreign policy remained in the hands of Dr. R. Holsti, under successive administrations. In March 1922, this statesman met at Warsaw the Foreign Ministers of Estonia, Latvia and Poland, and signed an agreement by which the parties undertook "to observe benevolent neutrality towards any of the signatory states which might be attacked without provocation and to consult immediately with regard to subsequent steps to be taken." The Finnish Diet, in its spring session, refused to ratify this agreement, and Dr. Holsti relinquished office. The principle of policy enunciated upon this occasion by the Diet—the avoidance of treaty commitments of a military nature, continued to rule Finland's Baltic policy. On June 27 1924 Finland signed bilateral conventions with Sweden, Norway and Denmark for compulsory arbitration in the event of disputes.

Internal Policy.—The Karelian dispute with Soviet Russia reacted on Finnish internal politics. The long land-frontier to the East made it impossible to keep out Russian propagandists, and the discontent, thus fomented, threatened to imperil the economic recovery of the country. In May 1922 the Vennola administration resigned, but the new "Government of Officials" formed by Professor Cajander, did not long outlive the general election, which was held in July. The Social Democrats retained only 53 seats, while the Agrarians, with 45 and the Union party with 35, showed small gains, and the Progressives with 15 and the Swedish party with 25, small losses. The true victory lay with the Communists, who made their first appearance in the Diet with 27 seats. In Nov. 1922, therefore, the Agrarians, who had held their ground, formed a Centre Govt. under M. Kyösti Kaalio.

This administration passed the Religious Liberty Act, the Military Service bill and the "Lex Kaalio," which made provision for the landless population. In Oct. 1923 the Communist party was suddenly dissolved, its newspapers were suppressed, and 25 of its parliamentary representatives imprisoned. But this stroke reduced the Diet to a rump, and new elections became necessary in April 1924. The Kaalio Govt. resigned on the eve of the poll, being superseded by Professor Cajander's (second) "Government of Officials." The Social Democrats obtained 60 seats (+7), Communists 18 (−9), Agrarians 44 (−1), Union party 38 (+3), Progressives 17 (+2), Swedish party 23 (−2). On May 31 the Cajander Govt. made way for the non-Socialist Coalition Govt. formed by Professor Lauri Ingman (Union party).

M. Lauri Relander was elected President on Feb. 16 1925. The candidate of the Agrarians, he was elected by their votes and by those of the Finnish coalition and the Swedish party, which supported him when it was clear that their own candidates had no chance of success. He was president of the Diet in

1919 and was appointed Governor of the Viborg district in 1920, a position which he still occupied at the time of his election. He is a landed proprietor who has always taken great interest in agricultural questions and has published works on forestry in Swedish, Danish and German. His political views are moderate.

The Government of Professor Tulenheimo, in which the Union party and the Agrarian Union were represented, took office on March 31 1925. The chief political question it had to face was that of the military and naval estimates, which the parties of the Right desired to maintain at a comparatively high figure, while those of the Left desired a reduction. This left the cost of defence by land and by sea within reasonable bounds—at approximately 17% of the national expenditure.

In Dec. a new Government was formed by M. Kyösti Kaalio (Agrarian) in which again the Agrarian Union and the Union party were represented. (W. L. B.)

II. FINANCIAL AND ECONOMIC HISTORY

All through the War Finnish export trade, shut off from a large part of its foreign outlets, had to struggle with great difficulties. Until 1917, Russia remained a very considerable buyer of Finnish goods, but the revolution brought about a complete reversal of conditions, and trade with Finland became insignificant. At the close of the War, Finland, accordingly, had to shoulder the task not only of regaining her old markets in the West, but also of creating new markets to set off the loss of Russian trade. Similar difficulties were met in the import trade.

Imports and Exports.—The adjustment to the changed conditions was achieved with surprising rapidity, in spite of the unfavourable business conditions which prevailed on the leading markets. It was temporarily helped by the declining tendency of the Finnish exchange, which in the autumn of 1921 brought quotations down to a bottom level.

	Exports		Imports	
	Value Mill. Finnish marks	Percentage of volume of 1913	Value Mill. Finnish marks	Percentage of volume of 1913
1913	404·8	100·0	495·4	100·0
1919	880·4	47·6	2,509·9	77·8
1920	2,926·4	68·6	3,626·5	52·8
1921	3,389·4	69·0	3,585·7	54·5
1922	4,467·6	93·5	3,969·9	74·7
1923	4,392·5	94·8	4,600·3	101·5
1924	4,970·6	112·7	4,715·5	99·3

Great Britain took about 40% of Finnish exports in 1924. In the import trade the part played by Great Britain (19% in 1924), though considerable, is inferior to that of Germany (30% in 1924). The trade with Great Britain during recent years has gained ground when compared with pre-War conditions, but trade with Russia has not yet recovered. Timber products have long been of paramount importance in Finnish export trade, and timber exports after the War reached, and even exceeded, the record level of 1913. In 1924 the timber industry contributed close upon 60% of the total exports. The paper and pulp exports are second in importance only to the timber exports, the share of this industry in total exports amounting in 1924 to about 28%. Agricultural exports gradually revived, but the import of cereals, a very large item in Finnish foreign trade, was temporarily reduced. As a whole, Finnish agriculture showed some advance in comparison with pre-War conditions.

Currency.—The outbreak of war opened a period of serious monetary disturbance. The depreciation of the Finnish mark was, at first, largely due to the strain which Russian war finance put on the Finnish banking system. When, at the end of 1917, Finland gained her independence, she had to cover the increased expenditure imposed by her new position as an independent state, and that incurred in the suppression of the Red rebellion in the spring of 1918. As, in the disturbed state of the country, the taxes could not be punctually collected, the Government resorted to increased borrowing. Part of this demand for credit was met by means of new note issues which were made by the State Bank.

During the course of the years 1919, 1920, and 1921 the Finnish exchange declined seriously. In the latter part of 1922 the Bank of Finland embarked on a policy of stabilising the Finnish exchange in relation to the dollar, and since that date variations have been slight. At the end of 1925 the Finnish monetary system was put on a gold basis, the level of parity being approximately 193·23 Finnish marks to the £ sterling.

Finnish Monetary Statistics

	Rates of exchange on New York quoted by the Bank of Finland. Par 5·18 mks. = 1 dollar		Index of Wholesale Prices
	Highest	Lowest	Annual Average Base 1913 = 100
1921	80·50	28·00	1263
1922	54·50	35·25	1219
1923	40·75	35·85	1095
1924	40·44	39·70	1100
1925	39·70	39·70	1129

Banks.—The leading banking institutes are at present Nordiska Föreningsbanken, Kansallis Osake-Pankki, Helsingfors Aktiebank and Unionbanken, which at the end of 1924 held about 80% of the total home deposits of the 19 joint stock banks in existence. The note circulation of Finland's Bank, the bank of issue, at the end of 1925, amounted to 1,309,000,000 gold Finnish marks, backed by a gold reserve of 331,000,000 gold marks and foreign assets exceeding 1,000,000,000 gold marks.

National Budget.—The improved conditions of production and trade formed a firm basis for financial reorganisation. Before the War the bulk of the Finnish State revenue was derived from customs duties and other indirect taxes and from the earnings of Government enterprises, mainly the railways. The chief change in national finance since the War has been the introduction of an income and property tax. The customs duties still form the main part of the state revenue, but direct taxes now yield about a quarter of the total tax revenue. The income from state enterprises is relatively less than before the War. The public debt, foreign and internal, in Sept. 1925, was estimated at a sum equivalent to $94,300,000. The debt is balanced by state forests, railways and other state property. There has also been a reorganisation of municipal taxation.

Tariff Policy.—The pre-War tariff might be characterised as a Protectionist one, but it granted practically no protection to grain-growing. Post-War legislation has provided agricultural protection and, with the elimination of the special facilities formerly existing between Russia and Finland, the grain duties now established may be expected sensibly to influence agricultural conditions. The new policy made no radical change in the tariff on manufactured goods, but sought to promote a more scientific distribution of duties and to secure as large an income as possible to the state. But the revision of the tariff was not completed in 1925. Commercial agreements have been concluded with France (July 13 1921), Great Britain (Dec. 14 1923), the United States (May 2 1925) and several other countries during the post-War period. Finland's prohibitory legislation in regard to wines and alcoholic liquors in some cases made the task of negotiation a difficult one. To Estonia Finland granted (Oct. 29 1921) considerable fiscal concessions not granted to any other Power, but Estonia plays a very small part, about 1% in Finnish trade.

Social Legislation.—An active policy aiming at improving the position of the numerous landless agricultural population had been set on foot some time before the War. After gaining her independence Finland adopted laws which with certain limitations gave tenants the opportunity of purchasing their holdings at a price below their value in the open market, and a large number of tenants have been turned into small owners. Recent social legislation further includes the adoption of an eight-hour day. Financial considerations have limited the scope of actual legislation for social insurance, but workmen's compensation for accidents has been put on a new and more comprehensive basis by legislation of 1917 and 1925.

The co-operative movement has made considerable progress in Finland. This holds true of consumers' co-operation as well as of several branches of agricultural co-operation. The central co-operative butter export association "Valio" has carried on by far the greater part of the total exports of butter and has, no doubt, been of great service in improving and standardising the quality of dairy produce. The butter exports mainly consist of high grade ware, and the grading takes place under state control. (A. My.)

FINLAY, ROBERT BANNATYNE FINLAY, 1ST VISCOUNT, (1842–), British lawyer and politician, was born at Edinburgh July 11 1842. He was educated at Edinburgh Academy and University, and graduated in medicine. In 1867 he was called to the bar, in 1882 becoming a Q.C. and a bencher of the Middle Temple. He was elected as Conservative member for Inverness Burghs in 1885, and held this seat until 1892. In 1895 he regained the seat, and was made Solicitor-General in Lord Salisbury's Govt., when he was knighted. In 1900 he became Attorney-General, remaining in the Govt. until the Conservative defeat of 1906. In 1910 he was elected M.P. for Edinburgh and St. Andrews universities, and in 1916, on the formation of Mr. Lloyd George's Govt., became Lord Chancellor and a life peer. He retired in 1918, and in 1919 was created a viscount. In 1920 he was appointed British member of the Permanent Court of Arbitration at The Hague, and in 1921 became a member of the Permanent Court of International Justice established by the League of Nations. From 1902 to 1903 he was lord rector of Edinburgh University.

FINNISH LITERATURE (*see* 10.386).—Several of the writers in Finnish mentioned in the earlier article have since died. P. Cajander died in 1913, after having completed his translation of Shakespeare's plays in the previous year. Karl Bergbom, who made the Finnish National Theatre and was its first manager, died in 1906. Of lyric poets, J. H. Erkko died in 1906 and Arvi Jännes in 1915. The old peasant writer, P. Päivärinta, died in 1913, and his younger colleagues, Kauppis Heikki, in 1920 and J. Reijonen, in 1924. S. Ingman later took the name of "Ivalo" and abandoned the realistic description of present-day life for the historical novel. S. Alkio became a politician and leader of the Agrarian party, being several times a Cabinet Minister. Arvid Järnfelt, in his works published during this period, managed to shake off the preponderating influence of Tolstoy.

Prose.—The greatest writer of Finnish prose literature, Juhani Aho, died in 1921. Amongst his later works mention may be made of *Rauhan erakko* (1916), in which the writer protests against militarism, *Muistatko* (1920), an autobiographical study of childhood, and *Lastuja VIII.*, a collection of essays on salmon and salmon fishing, dating from the year 1921.

The most notable of the younger writers were Johannes Linnankoski (1869–1913) and F. E. Sillanpää (b. 1888). Linnankoski achieved European renown by his novel *Laulu tulipunaisesta kukasta* (1905)—"The Song of the Blood-Red Flower"—which has been translated into a number of languages. His best work from an artistic point of view is *Pakolaiset* (1908). Sillanpää has written several collections of short stories dealing with peasant life, and one great novel dealing with the time of the Red insurrection, which is an important document of social history. His strength lies in psychological descriptions of subconscious states. No other Finnish writer has been so successful in depicting the atmosphere in which the peasant lives his everyday life. Teuvo Pakkala (1862–1925) made his name by realistic studies of proletarian life, short stories and plays about the peasantry, and studies of children, which show great psychological insight. Joel Lehtonen (b. 1881), like Sillanpää, wrote novels inspired by the Red insurrection. The novels of Ilmari Kianto (b. 1874) on the peasantry are flavoured with satire. Kyösti Vilkuna (1879–1922) produced novels, short stories and plays. Among other things, he described the part which he himself played in the legal struggle against Russia and in the events leading up to the war of independence.

Of the numerous women writers, the following deserve mention: Aino Kallas (b. 1878), short story writer, one of her volumes, *The White Ship*, being published in English in 1924. The wife of an Estonian scientist and diplomat, she obtained an intimate knowledge of Estonian life, which forms the subject of many of her stories. Mailo Talvio (b. 1871) wrote numerous novels concerning life among the peasants and higher ranks of society. Maria Jotuni (b. 1880) possesses a realistic power and a robust humour which inform all her stories, novels and comedies. L. Onerva (b. 1882) is best known for her lyric poetry, but also wrote fiction and plays.

Poetry.—Among the poets writing in Finnish, Eino Leino (1878–1925) was unusually productive. He published dramas in prose and verse, novels, short stories, literary studies and numerous volumes of lyric poetry. His most successful works are his *Helkavirsiä*, historic poems in ballad form of a strongly national colour. Leino has also translated Dante's Divine Comedy into Finnish blank verse. Larin Kyösti (b. 1873) was another prolific writer, who achieved a well-deserved popularity by his popular poetry. The lyrical poetry of Otto Manninen (b. 1872) is highly esteemed by connoisseurs. Manninen did invaluable work as translator of the Iliad, Odyssey, Molière's metric comedies and other works. V. A. Koskenniemi (b. 1885), professor of literature at the Finnish University of Turku (Åbo) published numerous volumes of poetry. He lacks the spontaneity of Leino and Larin Kyösti, but is unsurpassed in Finnish literature as the creator of a lofty style, his favourite verse forms being the sonnet and the elegy.

Literature in Swedish.—The Swedish literature of Finland includes a number of poets who have gained reputations both in their own country and in Scandinavia. Mikael Lybeck (1864–1025) achieved his first successes with lyric poetry, but abandoned verse for prose during the last 20 years of his life. His short stories, novels and dramas are highly esteemed by literary critics, though they have not achieved any widespread popularity. Bertel Gripenberg (b. 1878) is the chief master of form among the poets writing in Swedish. He has handled many different kinds of verse with great skill, but specially favours the sonnet. The characteristics of his first volumes were dark passion, sensualism, pessimism and an aristocratic romanticism, but he has also found words to sing of the Finnish wildernesses, and has written patriotic lyrics, inspired by the Red insurrection and the War of Independence, in which an echo of Runeberg's heroism may be heard. Jakob Tegengren (b. 1875) writes in an elegiac key, and descriptions of nature occupy a large part of his works. In his later volumes a religious tendency is visible. Hjalmar Procopé (b. 1868) has written a few dramas, but is best known as a lyric poet. Arvid Mörne (b. 1878) sings of the archipelago, peasant life and the scenery of the Swedish-speaking districts in the south of Finland. He is the poet of the sea, more than any other of the writers in Swedish. But Mörne's writings also reflect his deep, radical opinions. He was ardently interested in social reform and the movement for popular education. In his later works, however, this spirit has given place to a subdued resignation. Mörne also achieved success as a dramatist and novelist.

Emil Zilliacus (b. 1878) published some highly appreciated collections of lyrical poetry. Jarl Hemmer (b. 1893) is the most lyrical and spontaneous of the Swedish poets of Finland. His poetry still preserves something of the melodiousness characteristic of Topelius's lyrics. Hemmer's verse has a winning, youth-

ful charm which yet does not preclude the expression of loftiness of thought. He also wrote a play, short stories and a novel dealing with the time of the War of Independence.

Runar Schildt (1888–1925) was the most eminent writer of Swedish prose in Finland. His short stories are characterised by a highly developed style, penetrating psychological insight and a humane, tolerant view of life. The subjects of some of them were taken from the War of Independence and the Red insurrection. Schildt was also a very successful dramatist. Vers libres and expressionist prose also found enthusiastic, and in some cases, gifted champions among the writers of Finland, both Swedish and Finnish.

FIRE CONTROL: *see* GUNNERY, NAVAL.

FIRE PREVENTION (*see* 10.401).—Steadily mounting fire losses, particularly in North America, have greatly stimulated efforts looking toward fire prevention. Fire losses of created resources in the United States increased from $447,886,677 in 1920 to $548,810,639 in 1924. The latter figure exceeds the loss in 1906, the year of the San Francisco earthquake and fire, although in 1924 there was no great single conflagration. In Canada, the destruction of created resources increased in the same period from $27,600,000 to $33,300,000.

I. IN NORTH AMERICA

In forest fires, also, similarly excessive losses are sustained by the United States and Canada. In 1924 (U.S.A. Forest Service estimate) 29,000,000 ac. of forested land in the United States were swept by fires, numbering 92,000 in all and entailing an actual money damage of $38,000,000, a figure exceeding by $18,000,000 the previous nine-year average. Owing to different statistical methods in use, an exact comparison with European experience is at present impossible. In general, however, it may be stated that a stricter surveillance is observed in the State forests in Europe, made possible in part by the smaller areas to be watched. The State forests of Finland, in the period 1911–21, were damaged to the extent of less than 1/20th of 1% annually. In Norway, during the period 1913–23, the average yearly damage amounted to about $24,000, the area burned being about 1,770 ac. each year. In the Prussian State forests, 1901–10, the average forest area devastated annually by fire was about 1620 acres. In the Bavarian State forests, 1900–12, an average of 103 fires burned about 380 ac. annually, which was less than 1/50th of 1% of the total forest land.

Prevention of Forest Fires.—The chief causes of forest fires are lightning, incendiarism, sparks from locomotives and carelessness of campers and of lumbermen. To check the operation of these factors the supervision of forest areas, particularly in the United States and Canada, has been instituted by governmental action. Fire lanes are cut through the forest to act as breaks and are kept open by fire rangers in the employ of the Government. Other duties with which fire rangers are charged include an oversight of lumbermen, campers and other visitors in forest areas with a view of inculcating carefulness. They are expected also to take immediate action in the event of fire. Watch towers and airplanes are used in detecting any incipient conflagration.

Buildings and Stock.—The causes of fires in buildings and stock are chiefly defective chimneys; carelessness in handling fire and inflammable material; defects in electrical installations, and exposure, that is, ignition from fires in adjacent property. The use of wooden shingles on roofs and, in mercantile districts, wooden window trim in otherwise fire-resistant buildings facilitates the spread of flames. Some of the more recent conflagrations (1910–25) in the United States have been those of Paris, Tex. (1,440 buildings, loss $11,000,000); Nashville, Tenn. (648 buildings, loss $1,450,000); Augusta, Ga. (680 buildings, loss $4,500,000); Atlanta, Ga. (1,938 buildings, loss $5,500,000); Berkeley, Cal. (584 buildings, loss $10,000,000); and Chicago, Ill. (loss $8,000,000). To reduce fire risk, automatic fire alarm systems, automatic sprinklers and chemical fire extinguishers have been installed in the larger buildings and to some extent, in private houses. Conveniently hung coils of garden hose with means for attachment to the water tap are also of value.

In order to educate the public to the importance of such measures, fire prevention is taught in the schools of many of the United States and a " fire prevention week " has been instituted to call attention to this form of preventable waste. Among the agencies in promoting fire prevention in North America is the National Fire Protection Association, which formulates standards of fire protection appliances, and co-operates with local associations in lessening fire risks, such as furthering the use of safe electrical installations. The National Board of Fire Underwriters maintains laboratories for the testing of materials and devices falling within the scope of its services, makes civic surveys covering elements entering into fire risks, and furnishes a model building code for the guidance of cities desiring one. The U.S. Chamber of Commerce, also, acting through a committee on fire waste, promotes special studies of fire-risk conditions in individual communities and urges such action as appears desirable. In most cities, desirability of action along the following lines has been indicated: (*a*) Competent inspection by the fire department; (*b*) a more general use of fire-resistive roof coverings, protected window and door openings and automatic sprinklers; (*c*) adequate ordinances governing the storage and use of explosives and inflammable substances; (*d*) adequate means for the conviction of incendiaries; (*e*) public education in the transmission of fire alarms and use of first-aid extinguishing devices. (F. H. W.)

II. IN GREAT BRITAIN

With the growth of cities and consequent risk of conflagration, fire prevention is a subject which has received much attention since 1910. Societies have been formed for the special consideration of the matter, and public bodies and insurance companies have given every possible assistance in devising means and methods for the prevention of fire. Great Britain is much behind in the matter of official regulation for fire prevention, and insurance companies have done more than the authorities by encouraging improvements in construction and the introduction of appliances such as automatic sprinklers, automatic alarms, fire doors, etc.

A large proportion of fires is due to carelessness. There is the thoughtless individual who throws away a match before the spark is out, without looking where it falls, and the careless smoker who leaves cigarette ends in close proximity to combustible material. The " no smoking " sign in factory and warehouse is often ignored, and the guilty individual fails to realise how his act is a menace to life and property. If notices prohibiting smoking in factories or other buildings are posted up, they should be rigorously enforced. Smoking should be prohibited in all factories, and the growing tendency to allow smoking in theatres and music halls should be strongly deprecated.

There has been a large increase in the use of highly inflammable liquids and material, and public attention should be called to the danger, both in the use and in the storage of these. Many hazardous processes in manufacture from a fire hazard point of view can be rendered innocuous by the precautions recommended by insurance companies. Apart from individual carelessness, fires are often caused through defective building construction, such as wooden joists or beams under hearths and entering flues, etc., insecure heating apparatus and defective lighting systems.

Precautions.—In large cities, building by-laws are fairly strict, but insurance companies have done more than the authorities to encourage improvements in construction. Party walls through and above the roof and fireproof doors, where communications exist between buildings, often keep a fire from spreading. Insecure stoves and flue pipes should never be allowed and proper fenders and guards for fireplaces are amongst the simplest preventatives. Electric light installations should be overhauled by experts from time to time, and fuse boxes should not be tampered with by people ignorant of their use. Gas brackets and all

fittings should be securely fixed. It is the duty of each occupier of a building to watch for signs of defects, and either to report them or have the defects remedied.

Many devices are in use for detecting fire, known as automatic fire alarms. The general principle is that the heat generated by a fire causes a metal to expand, making electric connection and setting an alarm bell in motion. Automatic fire alarms may be connected up direct with fire brigade stations, thus securing an immediate turn-out to a fire. In spite of precautions, fires will occur, and every means should be taken to summon assistance and extinguish the outbreak. Fire precaution is a natural step after fire prevention. Every occupier of a building should know the exact position of the nearest fire alarm, so that the fire brigade can reach the scene without delay.

It is often said that the first five minutes at a fire is worth more than the next four hours, and water should be at hand to put out the flames. Buckets of water or chemical extinguishers should be in every building. There are many extinguishers on the market, some containing liquids, others powdered chemicals, but no class of fire extinguisher is a cure for all fires. The extinguishing agent must have either the property of allaying heat or a blanketing effect or a combination of both of these. Fire in ordinary combustible materials can be put out with water, but fires in oils, greases, etc., must be put out with a blanketing agent. Certain chemicals put a film or thin blanket over the liquid or material, thus excluding the oxygen long enough to allow the mass to cool below its burning point.

Fireproof buildings, efficient fire brigades and adequate water supplies have all contributed to reduce fire waste, but special mention should be made of the protection offered by automatic sprinkler installations. The installation of these is becoming quite common, and they have proved in practice to be wonderfully effective. Automatic sprinklers consist of a head or water-jet connected with water pipes, in which a pressure of water is maintained, the head being released by the melting of solder when there is sufficient heat generated by an outbreak of fire and the water automatically plays upon the fire, quickly subduing it. In connection with the installation there is also a fire gong, which automatically works with the opening of a sprinkler head, and assistance is thereby summoned at once.

(E. M. M.)

FISCHER, EMIL (1852–1919), German chemist (*see* 10.426), died in Berlin July 15 1919.

FISHER, JOHN ARBUTHNOT FISHER, 1ST BARON (1841–1920), British sailor (*see* 10.428). From 1910 until Oct. 1914 Lord Fisher remained in retirement, although Mr. Churchill, now at the Admiralty, constantly consulted him and it was on Fisher's advice that Jellicoe was designated admiral of the Grand Fleet in the event of war. (At the time of the Agadir crisis, however, Fisher had expressed to Lord Esher and others strong disapproval of the War Office plans engaging us in extensive land operations in France.)

Fisher was recalled as First Sea Lord in place of Prince Louis of Battenberg in the critical days at the end of Oct. 1914. The "Audacious" had been sunk, Cradock heavily defeated off Coronel, German submarines were active and there was no effective blockade of Germany. Fisher took the responsibility of weakening the British fleet in home waters and detached the "Invincible" and "Inflexible" to engage von Spee, with the result that a complete victory was gained in the battle of the Falkland Islands. To Fisher's boldness and realism again were due the new blockade policy and the laying of extensive mine fields. The association between Churchill and Fisher was most happy until it was broken by the Dardanelles enterprise. Fisher had never liked it; his own preference was for a landing on the coast of Prussia and the employment of Russian troops against the heart of Germany. But he was persuaded by Churchill into acquiescence.

When, however, the first attempt to force the straits had failed, and German submarines had made their appearance in Turkish waters, and it seemed doubtful whether the demands of the French campaign would allow the British to send the necessary reinforcements to the army in Gallipoli, Fisher felt that he could no longer continue to countenance the project of forcing the Dardanelles. At the War Council of May 14 1915 he had declared that "he was against the Dardanelles and had been all along." Churchill afterwards told him that it was not fair to obstruct necessary measures at the Dardanelles and then when things went wrong to turn round and say "I told you so, I was always against it." Fisher replied "I think you are right—it isn't fair." That night Mr. Churchill in order to encourage the entry of Italy into the War on the side of the Allies gave instructions that four cruisers should go to the Mediterranean 48 hours before the time arranged, and the minute was signed "First Sea Lord to see after action." That was the first document seen by Fisher on beginning work as usual at four o'clock next morning. He resigned and never entered the Admiralty again. His resignation coinciding with the crisis about high explosive shells, brought down the already shaken Liberal Govt., and led to the formation of the first Coalition. The manner of his leaving the Admiralty became Fisher less than anything in his life, but his motives were neither personal nor unworthy. He felt that as things were he had lost his power of service; that he could only hamper the Dardanelles and be "unfair" to Churchill without influencing events in the direction which he felt was right.

Fisher did useful work later in the War as Chairman of the Inventions Board, and when he died on July 10 1920 and was buried in Westminster Abbey, the crowds felt that they were mourning the greatest British sailor since Nelson. Their reverence was the more remarkable because Fisher never commanded a fleet in action, nor, except the Falkland Islands, is any great victory at sea traceable to his direct inspiration. His enemies accused him of exaggerating the material side of naval power at the expense of the moral and intellectual. He was not good in the logical presentation of an argument; he thought pictorially and the sequence of his ideas expressed themselves in a series of verbal explosions. But his prescience amounted at times almost to second-sight, and he had a genius for the burning phrase that lights up the truth from within. The most amazing quality of the man was that as he grew older he became more radical and revolutionary in his ideas. To the old man in 1919 his own Dreadnought of 13 years was a symbol of effete tradition; his slogan "Sack the lot" was not the prosecution of a personal vendetta against the Admiralty chiefs, but expressed his conviction that though the spirit was eternal, its forms were only made to be broken. He wrote two volumes of memoirs: *Memories* (1919) and *Records* (1919), before his death; somewhat scrappy and disorderly in composition but full of his glowing vitality. Fisher married, in 1866, Miss Kate Broughton, by whom he had one son, Cecil, and three daughters.

FISHER, ANDREW (1862–), Australian politician, was born at Crosshouse, Kilmarnock, Aug. 29 1862, and began life as a coal miner. He emigrated to Queensland at the age of 23, and eight years later was elected to the Queensland legislature. He was elected to the Commonwealth Parliament in 1901, joined Mr. Watson's Labour Cabinet of 1904 as Minister of Trade and Customs, and became leader of the Labour party in 1907 on Mr. Watson's resignation. In 1908 he became Prime Minister, but his administration lasted only six months. At the general election in 1910, however, his party was returned with a sweeping majority, and he was Prime Minister for three years, during which period he tackled the question of imperial defence, adopted Lord Kitchener's report of 1909 and passed a measure establishing universal military training. His Ministry fell in 1913, but at the election of Aug. 1914 he was again returned to power and gave Australia a vigorous lead in the early days of the World War. At the end of 1915 he resigned and took up the high commissionership vacated by Sir George Reid. This office he held until 1921.

FISHER, HERBERT ALBERT LAURENS (1865–), British man of letters and politician, was born in London March 21 1865. He was educated at Winchester and New College, Oxford, being elected in 1888 to a fellowship at the latter college, where he lectured for some years. He earned recognition as a scholarly

historian, and in 1911–2 was appointed Chichele lecturer in modern history at Oxford. He was also a member of the royal commission on the public services of India (1912–5). In 1912 he was appointed vice-chancellor of Sheffield University. In 1916, Mr. Fisher accepted the invitation to become Minister of Education in Mr. Lloyd George's Cabinet and was elected to Parliament for the Hallam division of Sheffield. In 1918 he was elected Liberal member for the English universities. An Education bill was introduced by him in Aug. 1917, which contained many important reforms (*see* EDUCATION). In Jan. 1925 he was elected warden of New College, Oxford, and he resigned his seat as member for the combined universities in Feb. 1926.

Among his books are *The Mediaeval Empire* (1898); *Studies in Napoleonic Statesmanship* (1903); *A Political History of England* (1906); *Bonapartism* (1908); *Life of F. W. Maitland* (1910); *The Republican Tradition in Europe* (1911); *Political Unions* (1911); *Napoleon Bonaparte* (1913); *The Common Weal* (1924), besides essays and review articles.

FISHER, IRVING (1867–), American economist, was born at Saugerties, N.Y., Feb. 27 1867. He studied at Yale (A.B., 1888), Berlin and Paris. At first he taught mathematics at Yale; but in 1895 was made assistant professor of political economy, and, in 1898, professor. He was editor of *The Yale Review*, 1896–1910. He served as chairman of many commissions dealing with public health, prohibition and labour. An authority on money inflation, he proposed that the purchasing power of the dollar be stabilised (*see* DOLLAR STABILISATION).

His writings include: *Mathematical Investigations in the Theory of Value and Prices* (1892); *A Brief Introduction to the Infinitesimal Calculus* (1897); *The Nature of Capital and Income* (1906); *National Vitality* (1910); *The Purchasing Power of Money* (1911); *Stabilising the Dollar in Purchasing Power* (1919).

FISHERIES (*see* 10.429).—Dealing first with British fisheries, it may be said that during the 20th century development has been rather slow, having been directed rather to the perfection of existing classes of boats and nets than to new inventions.

The otter is still the chief net for trawling from steam vessels. Its mouth must be given as wide a gape as possible, so that floats and other devices are being employed to prevent its upper rope from sagging so as to close its aperture; a third otter board is sometimes used in this position. The same trawl, but with reduced mesh, is also dragged to catch fish swimming near the bottom, particularly herrings; further development in midwater fishing in the deeper oceanic areas seems probable. Seining, or the surrounding of areas by netting so as to enclose the fish, a method extended by the Danes, is now generally pursued in all the shallower waters of the North Sea; it results in large catches, particularly of haddock and plaice, the fish arriving in less bruised condition than after the long haul of the sac-like trawl.

Surface Fishing.—Surface fishing methods show little change; they are now mainly practised by steam drifters, which follow the successive shoaling of herrings from the northwest coasts of Scotland in Jan. to the Shetlands and, down the east coast of Great Britain, to Lowestoft in October.

Trawling.—Steam trawlers varying up to 145 ft. in length have still further replaced sailing vessels, fleets of the latter only being maintained at Lowestoft (136 vessels), Brixham (90), Ramsgate (25), and Plymouth (12). Experiments in the utilisation of oil fuel are now proceeding. These changes mean the further concentration of the industry in large ports and under companies or big firms. The hake is now generally recognised as a table fish and is trawled as far south as the Moroccan coast to depths of 250 fathoms; this fishery, in association also with that of soles and skate, has resulted in important fishery developments in Milford Haven, Swansea and Cardiff. To the north, trawlers regularly fish in the Barents Sea and off Iceland, and trial voyages have been made from Hull to the Greenland banks (1925); otherwise there is little increase in the fishing area. The Norway haddock (*Sebastes*) is now regularly marketed at Aberdeen, and the sea bream and skate have generally found favour. In recent years the inshore fisheries have been greatly helped by a loan scheme of the Development Commissioners for the installation of motors in the smaller sailing craft; a further scheme on business lines for the insurance of inshore fishing craft has also been financed by the commissioners, thus giving the inshore industry the power to secure its capital. On other sides the production of sterilised ice is a development of importance, and an entirely efficient method of preservation by freezing in brine has been perfected, but not yet applied in Great Britain. The use of fish waste to form nutritive fish meals has been undertaken in the greater ports, and on the retail side fish-frying shops have so immensely increased that they form an important factor in the feeding of town populations.

EUROPEAN FISHERIES

European countries, bordering on the Atlantic, show in their high-sea fisheries similar changes to those of Great Britain and are serious competitors on most fishing grounds. Norway, in particular, has developed all its fisheries; its export trade of salt cod and other fish products is of importance. Russia, the oceanic fisheries of which have to some degree retrograded, has interfered on several occasions with British trawlers working off her northern coasts; here, as also off Iceland, Spain, Norway and Morocco the maintenance of the territorial limit of three miles is regarded by the British fishing industry as of vital interest. France shows development in all the fisheries of the Bay of Biscay, especially in sardines and tunny; her trawling fleet has increased and her larger boats still proceed on regular annual voyages to the Newfoundland banks and to Ireland. Spain and Portugal are more organised and have extended the catching power of their fisheries, but still confine their voyages to adjacent waters.

AMERICAN, ASIATIC AND AFRICAN FISHERIES

With increase of population the importance of fisheries is more widely realised, and, in North America, the United States and Canada have pursued an active policy of development in both fresh and salt waters; they export large quantities of canned and frozen salmon to Europe. Newfoundland is still mainly exporting salt-dried cod, not having as yet adequately exploited her large shoals of herring and her salmon.

Asia.—Japan shows advance in every direction, and New Zealand and various states of the Commonwealth of Australia are concerned with the exploitation of their fishing grounds.

Africa.—South Africa, which has extensive areas of suitable depths to the south and west, maintains a trawler fleet, while a crayfish fishery has been opened off Natal. Many trawlers were sold after the War to go to tropical countries, but so far systematic fishing in such waters by large power vessels has not proved profitable. The largest areas of suitable depths still almost unfished are between the Falklands and Patagonia and in that great bay to the east of the Malay peninsula. The "Discovery" expedition to south Georgia should throw light on the possibility of southern grounds, while the Malay Govt. has a research steamer on the stocks (1926).

THE INDUSTRY IN GREAT BRITAIN DURING THE WAR

In 1914 there were about 100,000 fishermen of all classes in Great Britain. Practically 40% of these at once joined the navy, while over 10% quickly responded to the urgent appeals of the military authorities. About 3,000 steam fishing vessels, trawlers and drifters in about equal numbers, were requisitioned for service, and many more were built for the same purpose. They were largely manned by fishermen recruited from those still fishing; often a requisitioned vessel carried her whole crew with her. They were employed in the Auxiliary Patrol, in mine-sweeping from the White Sea to the Straits of Marmora and in all operations necessary to keep the sea open for the operations of the British fleet, for the transport of troops and material to France, for the advent of forces from oversea colonies and the United States, and, above all, for the due arrival of food from every part of the world. The few vessels left continued fishing, and a system of fleets fishing in selected areas under the protection of their own guns and those of the navy was devised. The success of this was seen in the fourth year of the War, only 4 steam trawlers being sunk by enemy submarines as compared with 156 in the previous year. By the middle of 1917 there were only about 14,000 men still fishing, of whom over 10,000 were over age or unfit for service. Yet in the same year about 8 million cwts. of fish were landed, about 40% of the average annual catch for the 20 years preceding the War; the value, however, was nearly the same.

Arrangements were made whereby Belgian and Dutch fishing vessels were based on British ports. The shell-fish industry was fostered and developed. The deficiency in fish was further reduced by importation, particularly from Norway and Holland.

Reconstruction Problems.—The reconstruction of the industry after the War presented problems of peculiar difficulty owing to the rapid fall in the price of fish, while all commodities used in the industry remained at over double pre-War costs. The greatest difficulty of all was to preserve the herring fishery, which depended for its existence on the export of about 80% of its catch to Germany and Russia as brine-cured herring, thus differing from the trawl fishery, the output of which is absorbed by the home market. The fishermen concerned had taken an essential and vital part in national defence, and their industry was threatened with complete annihilation, the loss of its skilled craftsmen and the rotting of its boats. The government took over the finance, and thus practically the management of this fishery by the "herring guarantees" of 1919 and 1920. The cost of this bold and unprecedented action amounted to £1,712,675. It was eminently successful, for the industry, thus re-established, survived a disastrous seasonal fluctuation in 1921 and now again flourishes, aided by good subsequent years and a new export trade of fresh herrings to the Continent.

Administration.—The interests of the fishing industry are cared for by the fisheries department of the Ministry of Agriculture and Fisheries, by the Fishery Board for Scotland and by corresponding departments in Ulster and the Irish Free State. There is a series of local county Sea Fisheries Committees around the coasts of England and of Boards of Conservators of certain salmon rivers; they are responsible for local by-laws for their territorial waters and rivers, but any such can be disallowed by the central authority. There are practically no restrictive regulations to administer, the central departments being maintained to help and foster the industry in the interests of the state. The high seas outside territorial waters are open to the fishermen of all countries and supply about 96% of the British catch, the larger trawlers and drifters not being allowed to fish within territorial waters. Under powers sanctioned by Parliament in 1889, the Moray Firth was closed to British trawlers, but this regulation is not enforceable against the trawlers of other nations outside the three-mile limit. For the most part the government departments act as expert intermediaries in the interests of the industry with all the government offices concerned (Admiralty, Board of Trade, Foreign Office, etc.), with market authorities and with railways. Officers are stationed in all the larger ports to help and advise the fishermen and to keep the Ministry informed of current fishery matters. The organisation of the statistics relating to the industry has been mainly the work of the English Ministry, difficulties due to the necessarily rapid handling of the fish on arrival in ports having to be overcome by the devising of unobjectionable tests and checks of all sorts.

Scientific Investigations.—The Fishery Departments of England, Scotland and the Irish Free State have each a scientific division, and each has its own research vessel with headquarters respectively at Lowestoft, Aberdeen and Dublin. The Irish vessel is also used for local policing purposes, as also is a further vessel under the Lancashire and North Western Sea Fisheries Committee. Fisheries protection on the high seas is a function of the navy. Great Britain also maintains a staff of fish measurers, who go to sea on commercial fishing vessels. Something of the kind is done by other countries.

International Investigations

In 1902 the International Council for the Exploration of the Sea was organised, Denmark, Germany, England, Finland, the Netherlands, Norway, Russia and Sweden being signatories to an agreement for the pursuit of scientific research into all the waters off northern Europe. It naturally became inactive during the War, but was reconstructed in 1920, France then giving her adhesion. It now includes all the countries of western Europe except Germany and Russia. Each country according to its means maintains research vessels, and each works on a determinate scheme, settled at the annual meeting, at which the facts collected are discussed. The departments of Scotland and Ireland organised scientific divisions to carry on their share of the work, but that of England was managed until 1910 by the Marine Biological Association.

The International Council is divided into Statistical, Hydrographical, Limnological and Plankton committees, together with committees for the following areas: North Sea, Baltic Sea, Atlantic Slope, North Western (Iceland, Faroes, etc.), North Eastern (off Norway and Arctic), with, as their first care, to consider the practical fishery problems arising, or likely to arise, in their own areas. Its greatest accomplishment of recent years has been the organisation of the collection of statistics of all countries concerned on a uniform basis, the form adopted being largely that of the statistical branch of the Ministry of Agriculture and Fisheries.

Problems Investigated.—The main problem before the council is to trace to their causes the fluctuations to which statistics show that all the great fisheries are subject. To this end the council has organised a general programme of biological work for all its members, co-operative research, the results of which are generally published nationally. In Great Britain there was a fear that the areas of the principal fisheries were being overfished; the fish supposed of most importance here was the plaice, as to which there were no reliable statistics, while its life-history was little known. Consequently a large part of the research power of England and Scotland has been concentrated on this fish, and the depletion of the plaice fishery of the North Sea by overfishing almost to the limits of safety has been established.

Various remedies have been suggested and carefully examined, such as regulating the size of the mesh of nets employed, prohibiting the sale of undersized fish, and completely or partially enclosing some of the nursery grounds. The first, so far, has been found to be impracticable, as the trawl has to catch round as well as flat fishes, but experiments with a view to overcoming the difficulties are being made. The second would entail undesirable regulations and costly inspection. In respect to the third, the closure of the North Sea during the War formed a gigantic experiment, the catch by English vessels in this sea increasing from 24,000 tons in 1913 to 33,000 in 1920, but falling to 22,000 tons in 1923. The fall was clearly due to overfishing, as shown by steam trawler average daily catches of 2·1, 3·4 and 1·9 cwts. of plaice in the three years respectively. The difficulty of closing areas lies in the necessity of negotiating international agreements, as all desirable areas to be closed are outside the limits of territorial waters to the east of the North Sea.

Other notable reports of the International Council, which has its headquarters at Copenhagen, and of the British Fishery Departments deal with the natural history and growth of the herring, of the plaice and of the cod, the determination of the water movements of the North Atlantic, the deposits of the North Sea, the movements of certain fish as shown by marking experiments, and the transplantation of plaice to the Dogger Bank. A report of the English Ministry describes the gear employed in 1023 and a Report of a Treasury Committee published in 1908 in the evidence recorded gives a full account of nearly every aspect of the fishing industry as it then existed. The annual administrative reports of the English and Scotch departments should also be consulted.

The researches of the government departments concerned are also largely aided by the work of the staffs of scientific marine laboratories situated at Plymouth, Cullercoats, Millport and Port Erin, each of which has its public aquarium. These, while founded by private enterprise, are materially assisted by grants from the Development Commission, on the recognition of the well-known fact that economic results usually follow scientific researches. Of these the largest is Plymouth with special departments for zoology, physiology and fisheries; it is the property of the Marine Biological Assn., which in its *Journal*, by agreement, publishes the result of research from all the British marine laboratories.

Statistics of the Industry

The approximate total value of the sea fisheries catch of the countries of western Europe in 1922 amounted to £48,000,000 (British Is., 39·5%; France, 17·6%; Spain, 15·5%; Norway, 7·5%; Denmark, 5%; Holland, 4%; Portugal, 3·4%; Germany, 3·3%). Canadian fisheries in 1924 were $44,500,000 (Provinces: Atlantic, $17,500,000, Inland, $5,500,000 and Pacific $21,500,000); Pacific salmon, $13,000,000 and Atlantic lobsters, $4,000,000; over 60% was exported. The recorded values for the United States in 1923 were about the same, but the inland fisheries were $13,000,000; exports were $12,000,000.

Great Britain

	Catches		Craft Employed		Employment	
	Demersal fish cwts.	Principal Pelagic fish cwts.	1st Class	2nd Class	Regular	Irregular
1909–13 average	11,613,066	10,769,178	6,602	5,203	67,962	13,150
1920 .	12,573,805	8,333,991	5,581	6,227	61,683	10,925
1924 .	10,880,251	9,800,481	4,921	5,777	54,610	8,947

This table shows vividly the modifications which have taken place in the Fishing Industry of Great Britain during the period under review. The type of fishing-boat has also changed greatly. In 1913, 3,233 steam-boats (3,222 1st class and 11 2nd class boats) were employed. In 1924, the number was 3,087, of which 3,078 were 1st class. Motor-craft, however, increased from 842 in 1913 (335 1st class and 507 2nd class) to 4,311 in 1924 (1,192 1st class and 3,119 2nd class). Sailing craft in 1913 were 7,730 (3,045 1st class and 4,685 2nd class), while in 1924 they were 3,300 (651 1st class and 2,649 2nd class). Corresponding figures are not available from other countries where statistics are based on different data and collected by different methods.

FISHING: *see* ANGLING.

FITZMAURICE-KELLY, JAMES (1857–1923), British man of letters, was born in Glasgow June 20 1857. Educated at St. Charles's College, London, he became Taylorian lecturer in Spanish at Oxford in 1902. From 1909 to 1916 he was Gilmour professor of Spanish language and literature at the University of Liverpool; and in 1908 and 1912 Norman MacColl lecturer at Cambridge University. During 1907 and 1908 he lectured for the Hispanic Society of America at various American universities and at London University. In 1916 he was appointed Cervantes professor of Spanish language and literature at the University of London, a post he held till his resignation in 1920. Among his numerous published works should be mentioned *The Life of Miguel de Cervantes Saavedra* (1892); an introduction to the editio princeps of *Don Quixote* (1898–9); a *History of Spanish Literature* (1898); *Cervantes in England* (1905); *Miguel de Cervantes: a memoir* (1913); *Cervantes and Shakespeare* (1916); *Góngora* (1918); and *Fray Luis de Leon* (1921). He edited among other publications, the *Oxford Book of Spanish Verse* (1913) and the complete works of Miguel de Cervantes Saavedra (1901–). He died at Sydenham, London, Nov. 30 1923.

FIUME (Slav "Rijeka" both meaning "the river"), a port on the Adriatic (*see* 10.449). As the only port of Hungary, Fiume had had little history, but the city sprang into world-wide notoriety and became a burning question after the World War. The question of Fiume even threatened to become the cause of a further war between Italy and Yugoslavia. The "secret" treaty of London of April 26 1915, which contained Italy's terms for entering into the War, assigned Fiume to Croatia, and Senator Tittoni (subsequently Minister of Foreign Affairs) informed the writer that Baron Sonnino who negotiated that treaty for Italy, never once asked for Fiume; had he done so at that time, he could have had it for the asking. This point is important, because the Italian Press afterwards blamed the Allies for "refusing" Fiume to Italy.

The Italian Claims.—The first Italian claim to Fiume was made by Sig. Bissolati immediately after his resignation from the Cabinet at the end of 1918. Baron Sonnino's inaction in this matter was due to the fact that in 1915 he had neither anticipated, nor desired, the total breakup of the Dual Monarchy, but wished, while annexing the purely Italian provinces of Austria, to leave Fiume to Hungary, instead of including it, as a future rival to Trieste and Venice, among the Italian ports at the head of the Adriatic. But in 1919 the official Italians demanded Fiume on the principle of "self-determination," because the majority of its inhabitants was Italian, and largely so if Fiume proper were separated from its Yugoslav suburb of Sušak on the opposite side of the rivulet, which had given to Fiume its name, and which the Slavs called simply Rečina, and the Italians "Eneo"—a poetical title for so prosaic a stream. That Fiume was in 1919 predominantly Italian is true, but the Italian element had immigrated within comparatively recent years; the very detailed description of Fiume about 1855 by Charles Lever (the British consul at Trieste) in his novel, *That Boy of Norcott's*, mentions Slavs and Hungarians but never Italians there.

Meanwhile, on Oct. 23 1918, Croat troops had seized Fiume and in Nov. there was a dual occupation, against which the Yugoslav national council protested, by Italian and Serbian troops, while Italian naval forces entered the harbour. The Serbian troops were, however, withdrawn and replaced by Americans, pending the decision of the Fiume question by the Peace Conference. The Italians' position was similar to that known in English law as "pleading inconsistent defences." They claimed North Dalmatia, overwhelmingly Slav by race, in virtue of the Treaty of London, which President Wilson repudiated, and Fiume in virtue of the Wilson principle of "self-determination."

The D'Annunzio Adventure.—They ultimately obtained Fiume, thanks to the raid made by Gabriele D'Annunzio, who mustered a body of men at Ronchi near Trieste, and on Sept. 12 1919 occupied the contested town. There despite official notes, he remained as "commandant," offering to a prosaic age the spectacle of a poet as governor, and surrounding a commonplace town with the glamour of his dithyrambic speeches. He drew up a constitution for the "Carnaro," as he called his miniature state, and soon Fiuman divorces became the fashion for Italians unable to dissolve their marriages at home. He delivered frequent speeches, and represented the oppressed nationalities of the whole world as looking to Fiume, "the holocaust city," for consolation in their affliction. He descended with his "legionaries" upon Zara and meditated an extension of his territories still farther southward. While successive Italian Governments gave him no official support, he received considerable sympathy from the Nationalist elements in Italy and was regarded with corresponding aversion by the Yugoslavs, whose prowess in the Middle Ages he had sung in a poem of encyclopaedic erudition at the outset of the War.

But when Signor Giolitti in 1920 became for the last time Premier and concluded the treaty of Rapallo with the Yugoslavs, he resolved to turn the poet out of Fiume, and that eminently common-sense politician did so by force. The "commandant's" official residence was bombarded by the "Andrea Doria," and he narrowly escaped the martyrdom which he had proclaimed for himself and his followers, a "holocaust" for his country. After the "heroic age" of his rule there came the prosaic interlude of his local rival, Sig. Zanella, who represented the autonomous, as opposed to the Italian National, party, and aimed at bringing about a good understanding with Yugoslavia. A *coup d'état* by *Fascisti* and "legionaries" took place in 1922; the Government offices were stormed; Sig. Zanella abdicated in favour of a "government of national defence," and was escorted over the frontier in an armoured car; Sig. Prodan, a local engineer, succeeded him, and annexation to Italy was proclaimed. Official Italy, however, acted with caution and persuaded Sig. Giurati, a *Fascista* deputy, to decline the proffered post of "Civil Commissioner," while D'Annunzio from his retreat on the lake of Garda denounced the dissensions of Fiume, and refused to return and lead the Fiuman movement.

Negotiations between Italy and Yugoslavia.—Finally General Giardino became Governor, and Signor Mussolini made a serious attempt to come to terms with the Yugoslavs. The river had in the course of generations changed its course, forming a

" Delta," as it was called, and thus rendering doubtful the boundary of Fiume towards Sušak. Both Italians and Yugoslavs claimed the " Delta." The smaller harbour, too, called in Hungarian times " Port Baross " after a former governor, but rechristened by the Italians " Porto Nazario Sauro " after one of the heroes of the War, was a matter of dispute, but by a letter written by Count Sforza, then Italian Minister of Foreign Affairs, a few hours after the signature of the treaty of Rapallo in Nov. 1920 it was ceded to Yugoslavia.

Even after the refusal of D'Annunzio (afterwards created by the Fascisto Government " Principe di Monte Nevoso "), bickerings still continued and the two rival races did their best to give one another economic pin-pricks and thereby nearly ruined the trade of the once flourishing port of Hungary. Thus, the Italian railway time-table was so arranged that the trains did not connect at the frontier-station of Postumia, while the Yugoslavs stopped their through railway service to Fiume altogether, so that the traveller from Fiume into Yugoslavia had to drive across the wooden bridge into Sušak and thence a mile or more to a roadside station on the line to Zagreb. Grass grew in the dockyards of the port and there were at one time only two steamers in the harbour. Just before the Corfu incident, Sig. Mussolini sent an ultimatum to Yugoslavia, and the fleet which bombarded the Greek island is said to have been originally intended for Fiume. But milder counsels prevailed, and at last a series of arrangements was concluded at Florence between the Italian and Yugoslav Govts. on Jan. 27 1924. Fiume with the larger harbour was definitely recognised as Italian; Port Baross and " the Delta " became Yugoslav, and through railway traffic, after several years' intermission, was renewed.

In 1925 the trade of the town improved; and the passage across the bridge to Sušak was no longer impeded by formalities. But the Fiuman frontier towards the north is fantastic, for a mere corridor, through which the road and railway run, connects the town with Abbazia, and is commanded by the old Roman fortress of Castua, high on the hills which dominate the Quarnero. Superficial peace reigns at Fiume; but Italy does not need three ports in the northern Adriatic and the opening (in Aug. 1925) of the last link in the Lika railway connecting Spalato with the Yugoslav hinterland is a fresh blow to Fiume, while the old Hungarian-Croatian steamship line now rechristened " Jadranska Plovidba " (" Adriatic Steamship Co.") starts from Port Baross and boycotts Italian Zara. The delimitation of the frontier by the Italo-Yugoslav commission has just been concluded. Population of the town of Fiume (1921), 45,000.

FIVES (*see* 10.450).—In Great Britain the forms most usually met with are known as Eton Fives and Rugby Fives. There are also Winchester Fives and other less-known varieties. A few rules of an older form of the game as played about 1825 still existed in 1925. Both the main games are played chiefly at the great public schools, but there are also a number of courts in various parts of the country, and the game is played in the north of England by working men. In 1924 a Fives Assn. was formed and two open competitions, one at Eton Fives and one at Rugby Fives, were instituted.

FLAG (*see* 10.454).—As one of the international attributes of a state or a sovereign, a flag has in modern times been liable to assume a new form or disappear, according to the vicissitudes of the individual political entity to which it is appurtenant. The years since 1910 witnessed greater transformations in the flags of the world than were occasioned even by the Napoleonic wars and the Congress of Vienna. As a result of the World War three Imperial houses came to an end, some European states ceased to exist as such, new states emerged and old states assumed new forms. A necessary consequence of this was that historic banners such as the standards of the Hohenzollerns, the Habsburgs and the Czars ceased to exist or became obsolete, new national flags appeared and the blazonry of some of the old flags was materially changed.

Most of the states brought into existence by the Treaty of Versailles adopted flags which, though varying in design, embodied heraldic features of older banners. For example, the republic of Austria adopted the former flag of the Austro-Hungarian imperial navy without the charge, whereas the new flag of Hungary is that of the former Kingdom of Hungary. The new flag of the German Republic substitutes the national colours, black, red and gold, in place of the black, white and red which had been the distinguishing colours of the German mercantile marine. On the other hand, the former Russian national colours gave place to a new design, which departed from all traditions of heraldic law, *i.e.*, a flag bearing the letters РСФСР (Russian Socialist Federation of Soviet Republics) imposed on a red ground. Of the new Baltic States, Finland, Latvia and Lithuania adopted flags devised in historic affinity with mediaeval banners associated with their respective localities. Estonia, however, brought into existence a new flag of no heraldic value, bearing three horizontal bars, blue, black and white, signifying respectively the blue sky, the black earth and the white shirt of the peasant. The port of Danzig adopted with modifications the flag of the city when it was an independent member of the Hanseatic League. The historic flag of Poland—before the partition—consisted of a scarlet field with a white eagle in the centre, but the flag of the new republic is of scarlet and white, the eagle being discarded. The former design is used, however, as a badge in the shape of a shield when necessary. The flag of the Kingdom of the Serbs, Croats and Slovenes is a combination of the old Serbian royal flag with that of Croatia, both these older flags having red, blue and white in differing orders, and the Montenegrin flag has disappeared.

Outside of Europe the changes have not been so marked. Egypt, as a sign of release from Turkish suzerainty, has in her flag discarded the red ground and substituted green, the design otherwise remaining intact. The Republic of China has rejected the historic dragon on a yellow ground, replacing it with a flag of five horizontal bars of different colours representing her five racial elements, *i.e.*, Mongol, Chinese, Manchu, Mahomedan and Tibetan. The flag of Morocco, as an acknowledgment of French suzerainty, now carries a tricolour canton. An entirely new flag is that of the Kingdoms of the Hejaz and 'Iraq, whilst the flags of Portugal, Panama, Turkey and Siam have undergone changes of varying importance.

See the plate of flags here given; also *Admiralty Book of Flags of All Nations*, printed for H.M. Stationery Office, London, 1916, kept up to date by the publication periodically of *Errata* officially issued.

FLAGG, ERNEST (1857–), American architect, was born at Brooklyn, N.Y., Feb. 6 1857. He studied at the École des Beaux-Arts, Paris, and in 1891 began to practise as an architect in New York City. He designed St. Luke's Hospital and the Singer Building, New York City, the tower of the latter (612 ft.) being the highest commercial structure in America at the time of its erection (1908). Other public buildings designed by him include the Corcoran Art Gallery, Washington, D.C., and the U.S. Naval Academy, Annapolis, Maryland. He also designed many private residences and wrote *Small Houses—Their Economic Design and Construction* (1922).

FLAMETHROWER (Ger.: *Flammenwerfer*).—This weapon was first used by the Germans in the winter of 1914–5, and with marked success in the Bois d'Avocourt (Verdun) on Feb. 26 1915. The French followed in their use. The British used them on the Somme and in the Zeebrugge attack, St. George's Day, 1918. The American Expeditionary Force did not use them at all.

Structure.—A flamethrower consists of (*a*) the container filled with some mixture of heavy and light oils, (*b*) the strong walled vessel filled with air, nitrogen, CO_2, etc., under high pressure, and (*c*) a discharge tube, with nozzle and, in most cases, an ignition device. Between (*a*) and (*b*) is a reducing valve, and between (*b*) and the nozzle a firing valve or trigger. Flamethrowers were short-range weapons, and were of two types, the

heavy and the portable. The heavy type attained an extreme range of 134 yd. (British model), while with the portable British model a range of 45 yd. was attained, and maintained some 15 to 18 shots from a single filling of three gallons. The most satisfactory propellant was found to be nitrogen—either the pure product or a "deoxygenated air" produced in one field by a mobile plant.

Ignition was effected in the British types by two sparking plugs mounted in a cup containing petrol and fired by a magneto generator. The French fixed to the nozzle a tubular magazine which held a long stick of alumino-thermic composition kept up by a coiled spring and primarily ignited by a cerium steel briquet. The Germans used a double-walled cylinder, attached to the nozzle and charged with an alumino-thermic composition open to the air at the top. Inside the hollow of the cylinder and in prolongation of the bore of the nozzle tube were a piston, a spring, a striker needle, mounted on a pellet, and a cap with powder-relay. Between the cap and the needle was a fixed disk of cardboard. On release the impact of the jet on the piston compressed the spring and the striker against the cardboard disk, the needle penetrated the disk, and the spring, depressing itself, forced it on to the cap and fired the powder-relay which ignited the composition.

It is not possible to formulate any definite opinion as to the tactical value of heavy flamethrowers of the battery type. The portable type was found on occasions to be more useful than other close range auxiliaries of the infantryman.

FLATS: *see* ARCHITECTURE.

FLECKER, JAMES ELROY (1884–1915), British poet, was born at Lewisham, London, on Nov. 5 1884. He was educated at Dean Close School, Cheltenham, of which his father, W. H. Flecker, was headmaster; at Uppingham School; Trinity College, Oxford (1902–6), and Caius College, Cambridge (1908–10). He then entered the British consular service and went to Constantinople in 1910, in the same year issuing his *Thirty-six Poems*, reissued in 1911 as *Forty-two Poems*. *The Golden Journey to Samarkand*, with its notable preface summing up Flecker's Parnassian theory of poetry, appeared in 1913, after he had been compelled by consumption to leave his post at Beirut for treatment in Switzerland. He died at Davos-Platz Jan. 3 1915 and was buried at Cheltenham. Later in 1915 appeared *The Old Ships*. His spectacular Oriental drama, *Hassan*, was published in 1922 and produced in 1923, and an earlier play, *Don Juan*, appeared in 1925. His *Collected Poems* were issued in 1916. The most interesting of his few prose works was a novel, *The King of Alsander* (1914). See *Life* by Geraldine Hodgson (1925).

FLEMING, SIR SANDFORD (1827–1915), Canadian engineer and publicist (*see* 10.494), died at Halifax, N.S., July 22 1915.

FLETTNER RUDDER.—The design of this rudder constituted a radical departure from the design which for so long remained unaltered. All rudders may be said to be current-operated, but in this type the current is also used for altering the position of the rudder. The forces necessary to move the rudder of a big ship against the action of the current are very great; and a ship's steering engine requires to be of considerable horse-power, and of very robust construction. The gearing attached is heavy and more or less complicated. Such powerful steering gears should no longer be necessary. With the current-operated rudder, large ships can be steered direct by hand by the utilisation of the variations in pressure of the current on the rudder.

The principle of the invention is that of inducing negative pressure by moving the after-portion of the blade of the rudder, and of using the lateral effect thus caused by the difference of pressures on its after-part to move the rudder itself. For ships up to about 10,000 tons the Flettner rudder requires no engine to operate it, whilst in larger vessels the only additional effort necessary is that to overcome the friction in the transmission gear. The saving in effort is round about 95%. Instead of the large rudder it is only necessary to move a small one, having superficial area equal to about one-twentieth of that of the large rudder. Again, the small secondary rudder can never be placed in a position relative to the current which would cause the centre of pressure to move backwards at high speeds of ship. Manoeuvring power is greatly increased, because the rudder adjusts itself to the stream. The rudders are made either single or three-bladed, the most favoured design being the single-bladed spade type of more or less square form, which will be described in some detail.

Description of the Rudder.—The partially balanced main rudder, which is free to rotate about its axis, is steered by the secondary rudder, also balanced, hung at its after-edge. Movement by the secondary rudder is effected by the operating gear contained in a housing fixed to the main rudder.

A vertical shaft leads downwards from the operating gear through the hollow rudder stock, and terminates in a yoke which is coupled to a similar yoke on the secondary rudder by a pair of connecting rods. The operating gear is driven direct through a system of shafts and bevel wheels from alternative steering positions situated respectively on the bridge and the poop deck. In addition to the hand wheel, automatic steering is also provided by a gyroscopic compass gear, working through a ½-H.P. electric motor coupled to the steering wheel on the bridge by a chain.

The horizontal section of the rudder is of stream-line form. This shape avoids the disturbance in the even flow of water over the surface of the rudder which would otherwise be caused by the protrusion of the thick rudder-stock. It also adds to the stability of the rudder in the midship position. Moreover, this shape gives room for the protection of the connecting rods operating the secondary rudder except at the after-end, where an additional sheet-steel covering is built on as previously stated. The main rudder, which is free to rotate about its axis, is steered by the secondary rudder on its after-edge. When the latter is moved by its connecting rods, relatively to the main rudder during movement of the ship or in the slipstream of the propeller, the resulting deviation of the slipstream causes a different balance of pressures as between main and secondary rudders, *i.e.*, the main rudder being free to move, is deflected by the current through a certain angle. In going astern the balance of pressures is reversed through 180 degrees so at the moment when change of direction of the slipstream occurs the rudder automatically *turns* round through half a circle. The operating gear on the rudder-head determines the movements of the secondary rudder with relation to the steering wheel, the main rudder and the ship. (F. J. D.)

FLEXNER, SIMON (1863–), American pathologist, was born at Louisville, Ky., March 25 1863. Graduating from the University of Louisville in 1889, he pursued his studies further at Johns Hopkins University and the universities of Strasbourg Berlin and Prague, and at the Pasteur Institute, Paris. He was associate professor and later professor of pathological anatomy at Johns Hopkins during 1889–99, becoming in the latter year professor of pathology at the University of Pennsylvania. In 1903 he was appointed director of the laboratories of the Rockefeller Institute for Medical Research, New York. Dr. Flexner became widely known in 1905 for his successful treatment of cerebrospinal fever by the use of a serum, the administration of which reduced the mortality rate from 90% in untreated cases to 46·3% in cases where the serum was used. He has published numerous monographs, including *The Pathology of Toxalbumin Intoxication* and *Mode of Infection, Means of Prevention and Specific Treatment of Epidemic Meningitis* (1917).

His brother Abraham Flexner (b.1866) became, in 1917, secretary of the General Education Board. His views on education as set forth in *A Modern School* (1916) and *A Modern College* (1923) occasioned much discussion. He wrote also *Prostitution in Europe* (1914) and works on medical education. (*See* SPINAL MENINGITIS.)

FLINT, ROBERT (1838–1910), British divine and philosopher (*see* 10.521), died in Edinburgh Nov. 25 1910.

FLINT, Mich., U.S.A. (*see* 10.521), had a population in 1910 of 38,550, and in 1920 of 91,599, of whom 15,213 were foreign born; in 1925 the Census Bureau estimated the population at 130,316. The area in 1910 was 8,120 ac.; in 1925, 19,115 acres

The manufacture of motors and trucks, and of such contributory articles as sparking plugs, carburetters, motor axles, paints and colours, and malleable iron castings is the backbone of its prosperity. Postal receipts increased fourfold between 1910 and 1924. Industrial development was paralleled in the building of homes, including noteworthy projects by some of the large motor companies; street paving and lighting; and the construction of hotels, banks, department stores, theatres and office buildings. A city-planning board was created in 1917. The park area was increased to 882 ac. by 1925. Schools were built rapidly and sites acquired to provide for future expansion. In 1923 a belt-line railway was opened.

FLORIDA (*see* 10.540).—The population of the state in 1920 was 968,470, a gain of 215,851 in the decade 1910–20. During the five years 1920–5 the increase of population has been even more remarkable, the state census for 1925 showing an increase of 295,079, or 30.4% since 1920, the total population being given as 1,263,549. In 1925 there were 21 cities with a population of over 5,000; those then exceeding 10,000 were: Jacksonville (95,206), Tampa (94,808), Miami (69,754), St. Petersburg (26,706), Pensacola (24,958), Orlando (22,273), West Palm Beach (19,122), Key West (13,533) and St. Augustine (10,190). The rapid development of Florida cities and towns is giving the state a larger proportion of urban population than any other southern state. However, Florida's population is still predominantly rural. In 1920 only 36.7% of the entire population was urban (living in cities or towns of over 2,500). During the winter months the population is largely augmented by thousands of tourists and winter residents, quite a number of whom become permanent residents or invest in Florida property. For many years the coast resorts were the chief objectives, but many of the inland towns and cities are now attracting out-of-state visitors. Far larger numbers of pleasure seekers have visited Florida in the two years 1924–5 than ever before, and this movement is certain to grow.

Industries and Commerce.—Florida's most extensive industry is agriculture. According to figures of the Florida Experiment Station there were approximately 5,940,000 ac. of land in farms in 1925, not including open or fenced range lands. Of this, 1,400,000 ac. were in crops, and 618,000 ac. of crop lands were idle; 275,000 ac. were in fruit; 1,500,000 ac. were in pasture; and 2,147,000 ac. in woodland. On approximately one-third of the cultivated acreage crops were produced by intertillage (the growing of two or more crops on the same land at one time) and by succession planting (where two or more crops follow each other on the same land in one year). The number of farms in Florida, was 50,016 in 1910, 54,005 in 1920 and 59,817 in 1925. Fruit is Florida's most important crop. The citrus industry has prospered despite the fact that some of the groves in the more northern part of the state have suffered from heavy frosts in severe winters. In 1920 the production of oranges was 8,500,000 boxes, and of grape fruit 5,000,000 boxes. In 1925 the production was 10,700,000 boxes of oranges and 6,300,000 boxes of grape fruit. In the sub-tropical part of the state pineapples, lemons, guavas, and avocadoes are grown profitably on a commercial scale. Other fruits produced are peaches, pears, bananas, grapes, figs and limes. The more important crops with their 1925 acreage yields and values, are tabulated in the next column.

There was a falling off in the production of cotton during the decade 1910–20; however, a good cotton season during 1925, and the use of short staple cotton which is more resistant to the boll weevil, more than doubled the state's production over the crop of 1920. The tobacco-growing section of western Florida produces profitably a shaded leaf, grown from Cuban and Sumatran seed, which is in great demand in cigar manufacturing. The pecan industry is comparatively new, most of the commercial groves having been planted since 1905. It is believed that in the northern part of the state the pecan crop may soon compete closely with the citrus crop of the southern part. The production of early vegetables for the northern markets is developing rapidly, and the Florida producer can put vegetables on the markets earlier than any of his competitors. The chief obstacles are costly rates and inadequate railway freight and express service. Much attention was formerly paid to stock-raising, but with the taking up and development of much of what was formerly open-range land, the figures for 1925 show a decided shrinkage in the production of livestock since 1920. In 1925 there were 662,000 cattle, including milch cows, valued at $13,240,000;

	Acres	Production	Value
Staple Crops:			
Corn	580,000	8,700,000 bu.	$ 8,700,000
Cotton	106,000	40,000 bales	3,541,000

Peaches	..	115,000 bu.	190,000
Pecans	..	1,340,000 lb.	348,000

61,000 sheep, valued at $200,000; 506,000 swine, valued at $3,289,000; 31,000 horses, valued at $3,000,000 and 43,000 mules, valued at $5,934,000. These livestock statistics include only farm animals.

In 1925 Florida produced mineral products to the value of $10,908,000, the more important of which were phosphates, lime, limestone, brick, tile, kaolin and fuller's earth, of which latter Florida produces about three-fourths of the entire U.S. output. In 1924 the production of phosphate was: land pebble, 2,348,137 long tons, valued at $7,987,752; and hard rock, 199,516 long tons, valued at $1,071,675. Florida's lumber production, due to exploitation, shows a decline since 1916, when an output of 1,425,000,000 ft. was reached; the 1924 production, mainly cypress and yellow pine, was 980,014,000 feet. Considerable hard wood (chiefly hickory) is produced. Naval stores are produced from the pine forests, where the sap of the trees is collected and distilled, yielding turpentine and resin. In 1923 Florida produced 9,747,000 gal. of turpentine valued at $10,000,000 and 660,000 bbl. of resin valued at $4,000,000.

In 1924 Florida manufactured 546,799,000 cigars, valued at $35,000,000; and 2,767,000 cigarettes, valued at $55,000. A rapidly developing manufacture is that of commercial fertilisers, large amounts of phosphate mined in the state being used for this purpose. Some index of Florida's recent business growth can be gained from the following banking statistics: deposits in National banks in Jan. 1920, $187,286,267; in Jan. 1925, $375,042,947; in state banks and trust companies in Jan. 1920, $197,809,947; in Jan. 1925, $287,636,588.

History.—The outbreak of the World War in 1914 interrupted two of Florida's more important exports to Europe, *i.e.*, naval stores and phosphates, thus creating a temporary business depression. In the naval-stores industry the recovery was comparatively rapid, owing to the high prices of and increased domestic demand for the products, after the first few months of the War. The phosphate industry was more seriously affected, as Germany had been a large purchaser. Many phosphate mines closed down, to resume operations only after the signing of the Armistice.

The political history of the state during the years 1910–25 was uneventful. The question of Prohibition played a large part in state politics until the ratification of the Eighteenth Federal (Prohibition) Amendment by the Florida Legislature

Dec. 14 1918. Since 1876 Florida has been uniformly Democratic and, except in 1916, when a contested primary election in the Democratic party resulted in the nomination of Sidney J. Catts as a prohibitionist and in his election as governor, all of the state's executives have been Democrats. The governors since 1910 were: Albert W. Gilchrist (1909–13); Park Trammell (1913–7); Sidney J. Catts (1917–21); Cary A. Hardee (1921–5), and John W. Martin, (1925–). In 1924 Florida adopted an amendment to the state constitution forbidding the Legislature to levy an income or inheritance tax. (J. M. L.)

FLOUR MILLING (*see* 10.548).—Profound changes have occurred during the period covered by our work (1910–26) in the geographical distribution of the flour-milling industry. The great increase that took place in the production of wheat in the U.S.A., Canada, Australia and Argentina, the relatively low cost of production in those countries, and the cheapness of transportation, together with the universal drift of the population from the rural to the urban districts, brought about the building of large flour-mills at the principal ports of Great Britain and other countries, and the gradual extinction of many small rural mills.

American Milling.—In the three Canadian provinces of Manitoba, Saskatchewan and Alberta, alone, in less than a quarter of a century the quantity of wheat grown was increased from 23,000,000 to 446,000,000 bu., and the export flour trade rose from 306,339 bar. (196 lb.) in the season 1871 to over 11,000,000 barrels in the season 1924–5. As wheat production increased, so also did the number of flour-mills, which were built regardless of domestic requirements in the United States, Canada and Australia. This was based on the assumption that flour could be most economically milled in the countries in which the wheat was grown.

European Milling.—In Europe, Germany and France, in particular, aimed at growing sufficient cereals for their own use, and heavy duties were levied on imported grain and flour to aid the process; in these cases, also, there was an increase in the capacity of the flour-mills to correspond with requirements. Great Britain and a few other countries placed their reliance on imported wheat, which was more suitable for breadmaking purposes than the native varieties; but here, again, they increased their capacity for the manufacture of flour, notwithstanding the same tendency in the wheat growing countries.

Active Competition.—Thus a situation arose in which the capacity of the mills in several countries exceeded the requirements of the population. Millers began to seek hungrily for trade farther afield. American, Canadian and Australian mills made unremitting efforts to supply Europe and the Far East with flour, entering alike overloaded and deficient countries. This current of trade in Europe was met by other currents flowing from England, Germany, France and other countries, the result being a swirl of competition that, however beneficial to the consuming public, engendered a certain amount of anxiety in the trade.

In the years which immediately preceded the War, a world-wide scramble for trade had begun. From 1914 to 1918, however, the feeding of the armies and the civil population was under the control of the respective governments concerned, and with the redistribution of supplies all the mills were kept going at full speed. In Great Britain additions were made to some of the plants, the aggregate peacetime capacity of which already exceeded requirements. The millers of England and Wales found themselves at the end of the War in possession of a potential manufacturing capacity of 40,000,000 sacks (280 lb.) of flour per annum, or an excess of 10,000,000 sacks over requirements. Scotland and Ireland were and had remained under-milled, but the English mills can supply their deficiency and still have several million sacks to spare.

After the state had liberated the industry from control in March 1921, British millers were compelled more than once by stress of circumstances to impose voluntary control upon their business, notably in 1921, when there was a record slump in the price of wheat, values declining by more than 40s. a quarter in a brief period.

For several years the situation was relieved by the demand for breadstuffs on the European continent. Shattered as these countries were by the four years of war, they could not, as formerly, grow or grind sufficient wheat for themselves, and one after another they relaxed or abolished their tariffs on imported cereals and flour. During this period the exports of flour from Great Britain rose to the unprecedented height of over 3,000,000 sacks.

But so soon as the grain-growers on the Continent had succeeded in increasing their production more nearly to correspond with national requirements, both they and the flour millers exerted themselves to secure the re-imposition of tariffs. In Germany there was resistance from the urban element, but in Oct. 1925 grain and flour imported to Germany were again subject to customs duties. In France, millers were compelled by law to mix rice and other cheaper flour with their wheaten flour, and these regulations were finally removed in 1925.

The growing Chinese and Japanese demand for wheaten products was met partly by American and Canadian mills. But in these Far East as in other countries at present under-milled, new flour-mills were erected to meet the increasing demands, so that further readjustments in distribution appear to be inevitable. In the U.S.A., Canada, Australia and England, the mills were unable to work at their full capacity. In New South Wales (Australia) the quantity of flour required by the population of 2,250,000 people was 225,000 tons per annum, and the mills of this State could produce exactly double that quantity. The U.S.A. and Canadian mills shared the same difficulties. In Minneapolis, the largest flour-milling centre in the world, the mills were not able to work to anything like their full capacity for several years. In Great Britain, whilst the excess capacity amounted to 10,000,000 sacks per annum, on an average 4,000,000 sacks of flour came into this country from the U.S.A., Canada, Australia and elsewhere, so that the problem in this case is intensified by imports.

The tendency generally is towards large scale production. It is estimated that 50% of the flour required by the population of Great Britain is milled at the principal ports, approximately 17% at mills in large inland centres of population, and 33% at mills in country areas. The flour-milling industry has encountered inexorable economic laws, from the authority of which there is no escape, and, unless there is a voluntary arrangement to produce flour to conform with requirements, the fittest only will survive the stress of competition.

FLYING, COMMERCIAL (*see* also AERIAL NAVIGATION; AERONAUTICS; AEROPLANE; AIRSHIP; etc.).—Commercial aviation may be said to embrace all forms of flying other than that carried out by the fighting forces and may be divided into the following categories: (1) Air transport; (2) Aerial survey; (3) General flying; (4) Flying schools; (5) Air racing.

I. AIR TRANSPORT

This section is confined to that particular branch of aeronautical activity described as air transport.

Air transport is an entirely modern innovation. Balloons were employed for the carriage of messages from Paris during the siege of 1870, a war measure for evading the besieging army which, in other circumstances, could not have claimed to be a practical method of carrying mails. Between 1909 and 1914 various demonstrations were made to prove the suitability of the aeroplane as a rapid conveyance for mail matter, and a considerable number of journeys by air were accomplished by private individuals; but none of these enterprises, though interesting and daring, could fairly be described as the real beginning of air transport.

That air transport would become a practical proposition was, however, recognised, and in 1910 a conference was held in Paris at which an International Convention in regard to aerial navigation was drafted. The credit for the first genuine commercial air service lies with Germany; from March 1912 until Nov. 1913, the rigid airships "Victoria Luise," "Hansa" and "Sachsen" plied regularly between Berlin and Friedrichs-

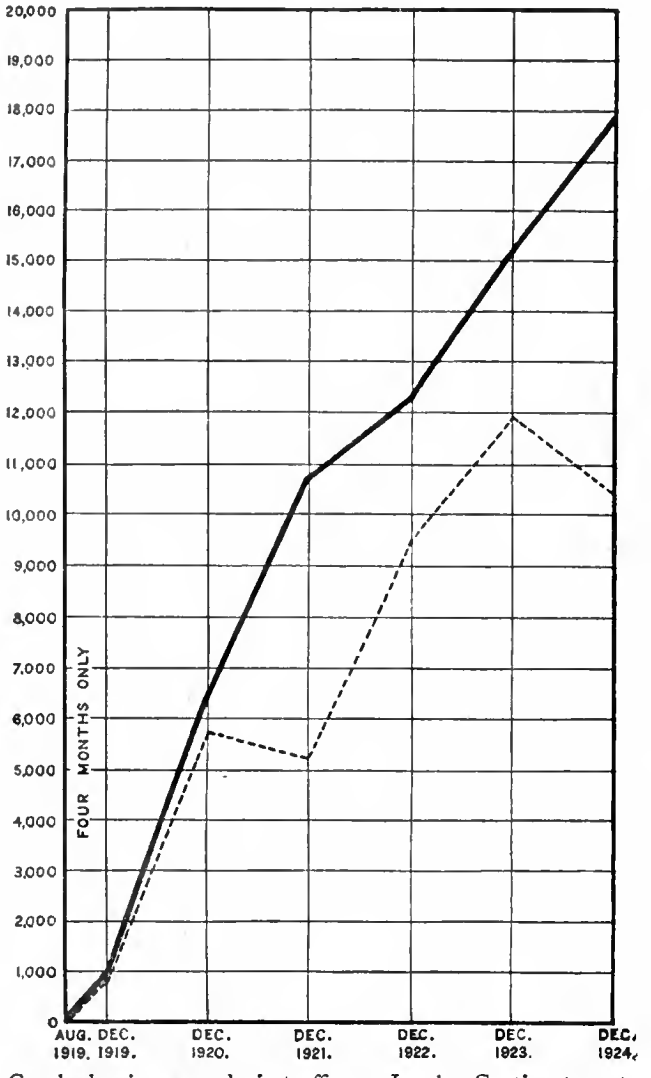
hafen, and in 881 flights, totalling 65,500 m., carried 19,105 passengers without injury and in considerable comfort.

History in Great Britain

The British Government can claim to be the first government to study the possibilities of air transport seriously. On May 22 1917 a Civil Aerial Transport Committee was appointed to advise the Air Board on the steps that should be taken for the development and regulation of aviation for civil and commercial purposes. This committee examined the possibilities of air transport from every point of view, and eventually submitted a report to the Air Council on May 11 1918.[1]



Graph showing annual air traffic on London-Continent routes. Total passengers (continuous line), and passengers carried by British aircraft (broken line).

Aeroplanes and Seaplanes.—At the conclusion of the War, the whole world began to turn its attention to the possibilities of aviation as a commercial activity. Five years of forced technical progress and intensive production had left a great heritage in aerial resources; practically every combatant nation possessed large numbers of pilots and mechanics and vast stores of surplus war aircraft. Military aircraft had been used for purely communication purposes with complete success; and the operations of war had proved clearly that flying under peace conditions should be both safe and comfortable. It was obvious that, if air transport was to accomplish even a small proportion of that which enthusiasts claimed for it, international regulations must be put into force as soon as possible, and the necessary steps were taken at the Peace Conference in Paris during 1919.

International Convention.—The Treaty of Versailles brought into being an International Convention for the Regulation of Aerial Navigation in which all the Allies participated; under the terms of this convention a permanent commission for Air Navigation was to be set up and placed under the direction of the League of Nations. In Great Britain, except for a brief period during Easter Week 1919, post-War civil aviation did not commence officially until May 1 1919. On Aug. 26 1919 international civil flying from Great Britain was first started under temporary air navigation regulations.

The International Air Convention by June 1922 had been ratified by a sufficient number of signatory states to make the introduction of its regulations practicable. It was brought into force in Great Britain by the Air Navigation Order dated June 20 1922. Accordingly the first meeting of the International Commission for Air Navigation was opened in Paris on July 11 1922.

The Start of the Service.—Air transport began its career under somewhat evil auspices. On the one hand, a large body of enthusiasts claimed the certainty of immediate commercial success, and consequent financial profits; on the other, conservative scepticism pooh-poohed the idea that aeroplanes could ever be a safe and economical means of transport, and cynically supported financial subsidies to the new industry. England led the way in accomplishment. On Aug. 25 1919 the Aircraft Transport and Travel Co. despatched the first aircraft to fly on a regular commercial service to Paris and on Nov. 10 1919 an aeroplane belonging to the same company carried the first regularly established air mail to the same destination. The British Handley-Page Air Transport Co. and the French Messageries Aériennes were quick to follow and by Jan. 1 1920 there were three British and two French companies operating on a regular time-table across the Channel. These operations were nearly all carried out by military aircraft, or by military aircraft modified to carry passengers in some degree of comfort.

Need for State Aid.—From the first it was obvious that such aircraft could not pay their way. It was, therefore, clear that air transport could not at once become self-supporting and would need some financial assistance from the state, until experience was gained and aircraft specially designed for commercial purposes were produced with the aid of that experience.

The French Government had already realised the vast possibilities of air transport and a costly and ambitious policy of financial assistance was inaugurated in 1919 and has been continued until the present day. To some extent this policy was inspired by its potential political and military influence on the countries flown over, but its ultimate object was to attain rapid communication between Paris and the French Colonies in Africa and Asia.

In England, on the other hand, there was not sufficient money allotted for even a very low standard of aerial defence, and air transport was therefore relegated to the background as an enterprise which the nation could not afford. In fact, the British Empire had as much to gain from its development as any other country in the world. Consequently the pioneers, and with them the public who had supported their new enterprises financially, walked towards inevitable ruin. The general financial crisis of the autumn of 1920 brought matters to a head, and the Aircraft Transport and Travel Company went into liquidation in Dec., whilst in Feb. 1921 the Handley-Page Transport Company suspended operations, leaving the French in unchallenged occupation of the cross-Channel routes. This disaster brought about a parliamentary and press agitation which galvanised the Government into facing facts and doing something; and from March 1921 the cross-Channel services have been subsidised in varying degrees.

Governmental Committees.—The following are the various committees and boards which were set up by the British Government from 1917 to 1923 to consider the possibilities of air transport and to make recommendations as to how it could best be supported and developed:—

TABLE I.

Name of Committee	Date of Appointment	Date of Demise	Reports
Civil Aerial Transport Committee	May 22 1917	Feb. 7 1918	"Reports of the Civil Aerial Transport Committee with Appendices," 1918. (Cd. 9218, price 9d.)
Advisory Committee on Civil Aviation (Weir Committee)	June 8 1919	Feb. 1922	1st Report: "Report on Imperial Air Routes," dated Oct. 30 1919 (Cd. 449, price 1d.). 2nd Report: "Report on Government Assistance for the Development of Civil Aviation," dated April 19 1920. (Cd. 770, price 2d.)
Commercial Airships Committee	May 5 1920	June 1 1920	Only Report dated June 1 1920. (Report not presented to Parliament.)
Cross-Channel Subsidies Committee ("Londonderry Committee")	March 2 1921	April 1921	Only Report dated April 1921. (Report not presented to Parliament.)
Conference of Prime Ministers and Representatives of the United Kingdom, the Dominions and India, held in June, July and August 1921	Conference opened June 20 1921	Conference closed Aug. 5 1921	Appendix III. to Report: "Report of the Imperial Air Communications Committee" dealing with Airships. (Cd. 1474, price 9d.)
Civil Aviation Advisory Board	Feb. 1922	July 8 1924	1st Report: "Report on Imperial Air Mail Services," dated July 25 1922. (Cd. 1739, price 1s.) 2nd Report: "Report on Aerodrome Facilities of London," dated Jan. 29 1923. (Cd. 1816, price 3d.)
Civil Air Transport Subsidies Committee ("Hambling Committee")	Jan. 2 1923	Feb. 15 1923	"Report on Government Financial Assistance to Civil Air Transport Companies," dated Feb. 15 1923. (Cd. 1811, price 6d.)
Air Mails Committee	June 1923		"Interim Report of the Air Mails Committee," dated Jan. 19 1924. (Cd. 2038, price 6d.)

From March 1921 until March 31 1922 two British companies continued limited operations between London and Paris under a system of government financial support which guaranteed them a 10% profit on the receipts obtained for traffic carried. Whilst this temporary and admittedly extravagant measure was in force, the Londonderry Committee put forward a new scheme which was accepted by the Government, and was in operation from April to Sept. 1922.

Government Aid: the Londonderry Scheme.—This new scheme comprised the provision of half the fleet of each company by the Government on a hire purchase system, and a subsidy based partly on the load carried and partly on the gross earnings of the companies. Three companies, the Handley-Page Air Transport, the Instone Air Line, and Daimler Airways, operated to Paris, and one company, the Instone Air Line, flew to Brussels. It was very soon found that the hire purchase scheme was impracticable. Moreover, the traffic available between London and Paris was not sufficient for five competing companies (three British and two French), and it was obviously unsound that British companies should be subsidised to compete against one another.

Modified Scheme.—On Oct. 1 1922, therefore, this scheme was modified on the basis of avoiding competition between British companies and extending British air transport into Europe as far as possible with the money available. On this system the approved services in operation from this date until March 31 1924 are given in table in next column.

Meanwhile, owing to the various difficulties which had arisen and the apparent wastefulness of maintaining four separate organisations for a comparatively small volume of traffic, the Hambling Committee was assembled in Jan. 1923. This committee definitely recommended the amalgamation of the four existing companies into a single national company with great freedom of action. They indicated that the company must be provided with a substantial capital, and be guaranteed a monopoly of subsidy for a term of years.

"Imperial Airways" Founded.—As a result, in March 1924, a national company, Imperial Airways, Ltd., was brought into being with a guarantee of a total subsidy of £1,000,000 spread over a period of 10 years, for regular flying carried out within Europe, the contract with the Government permitting liberty of action as to the services actually operated. The frequent modifications of system and changes of policy had naturally militated against serious progress, and when at length this new organisation came into being it encountered many setbacks and difficulties in its first 18 months of operation, but it now promises to bring air transport on to a definitely self-supporting basis before any other similar enterprise receiving a subsidy from its Government.

Firm	Service	Annual Minimum Services in Each Direction	Annual Minimum Total Mileage	Annual Maximum Subsidy
				£
Handley-Page Transport, Ltd.	London, Paris	300	....	15,000
Instone Air Line, Ltd.	London, Brussels, Cologne	300	....	25,000
Daimler Hire, Ltd.	Manchester, London, Amsterdam, Hamburg, Berlin	....	253,846	55,000
British Marine Air Navigation Co., Ltd.	Southampton, Cherbourg, Havre, and Channel Islands	....	60,000	10,000

History in Other Countries

In other parts of the British Empire, air transport generally made little progress, with the exception of Australia, where a good deal has been done.

Australian Development.—Australia has subsidised three important air lines—Western Australian Airways, Ltd., operating once a week from Perth to Derby (1,442 m.); Queensland and

Northern Territory Aerial Services, Ltd., Cloncurry to Camooweal; and the Larkin Aircraft Supply Co., Ltd., Adelaide to Cootamundra, with two branches, one from Mildura to Broken Hill and one from Hay to Melbourne.

German Activity.—Germany had entered the lists as soon as the conditions of peace permitted her and, to encourage private enterprise, offered a simple subsidy on a kilometric basis. As a result there are to-day two substantial German air transport companies—the Deutscher Aero Lloyd A.G. and the Junkers Luftverkehr A.G. in operation. The former is supported by some of the leading banks and shipping companies and utilises various types of aircraft. The latter is the property of the great Junkers engineering firm and is equipped entirely with all-metal Junkers aircraft.

The Junkers Co. has created a world-wide reputation by means of a comprehensive scheme of standardisation in manufacture. Endeavours have been made to establish subsidiary companies in various countries in Europe and in other parts of the world, over which control has been obtained by the provision of the initial fleet in exchange for shares. A scheme for the economical overhaul of all these aircraft at a flat rate at the Junkers works has also been evolved. Junkers companies exist in Switzerland, Denmark, Sweden, Austria, Hungary, Finland, Estonia, Latvia, Russia, Trans-Caucasia, Colombia and Argentina, in addition to which Junkers have created numerous subsidiary companies within Germany itself. This bold scheme is almost identical with that on which the British Air Transport and Travel Co. was embarking when it came to an untimely end through lack of Government support in 1920. Its progress has been remarkable, but its eventual success must depend on the power of the Junkers Co. to bear the heavy capital charges involved in the provision and maintenance of these fleets until such time as the subsidiary companies' shares attain a serious financial value.

French Progress.—France meanwhile has put her house in order and now has three main companies operating in different zones:—

Air Union, Paris–London.
Compagnie Internationale de Navigation Aérienne (late Franco-Roumaine), Paris–Constantinople.
Compagnie Générale d'Entreprises Aéronautiques (late Latécoère), Toulouse–Dakar.

All these companies are generously subsidised by the French Govt. and in addition Czechoslovakia, Yugoslavia and Rumania give financial support to the C.I.D.N.A., whilst the C.G.E.A. is assisted by French Morocco.

American Policy.—America did not participate in the International Commission for Air Navigation and has adopted an entirely different line of policy from the European nations. She refused all assistance to private enterprise and even neglected to bring any form of air navigation regulations into force. At the same time, she started and operated a most efficient but somewhat extravagant air mail service between New York and San Francisco. This service was equipped with old war aircraft of British design and Liberty engines, and was administered by the Post Office. Its operations were remarkable for their efficiency and regularity, and in 1924 the first regular night flying service in the world was carried out on the central section between Chicago and Cheyenne.

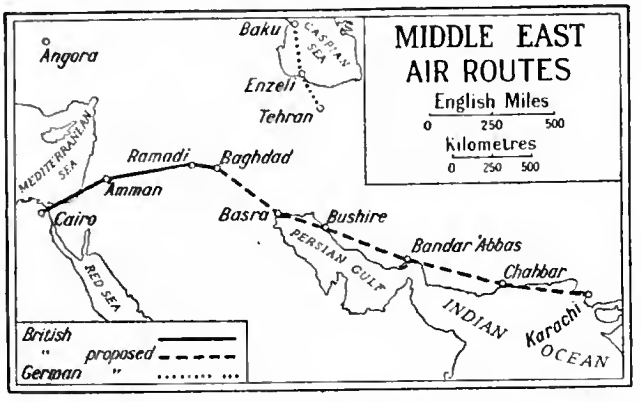
In 1925 America opened negotiations with a view to handing over the mail route to private enterprise, and is endeavouring to persuade private operating companies to undertake mail services on the other routes on a letter surcharge basis. Air Navigation Regulations have also been finally approved and prepared for promulgation. During the above period other nations were coming into the field of air transport.

Air Transportation in other Countries.—The Dutch created a subsidised company called the Koninklijke Luchtvaart Maatschappij voor Nederland en Kolonien towards the end of 1919, which has operated to London and Paris with great efficiency, equipped with Fokker aircraft and British engines. Belgium has organised a national company called the Société Anonyme Belge pour l'Exploitation de la Navigation Aérienne. In Europe it operates during the summer between Brussels and Basel, and in Africa it has established a very successful service in the Belgian Congo from near Leopoldville to Luebo and Elizabethville. Spain, Sweden, Poland, Switzerland, Denmark, Austria, Hungary, Finland, Estonia, Latvia, Norway and Russia have all established air transport companies and put them into operation. Czechoslovakia, Italy and Yugoslavia have companies which in 1926 were about to commence operations on a fairly extensive scale.

Air Service to India.—The British Govt. is at present establishing an air service operating aeroplanes between Cairo and Karachi. The section between Cairo and Baghdad has already been flown once a fortnight by military aircraft belonging to the Royal Air Force for the carriage of mails and official passengers.

It is now proposed to hand this section over to Imperial Airways and to extend it to Karachi via Basra and the coast of the Persian Gulf.

The preliminary reconnaissance of the route has been carried out and the necessary arrangements made with the governments of Egypt, Palestine, 'Iraq, Persia and India. A contract involving



the payment of a subsidy for five years has been signed, a lump sum being given for each completed stage between Cairo and Basra and between Basra and Karachi. It is probable that this service will commence operations in Nov. 1926 with aircraft of the latest type equipped with three air-cooled engines.

Construction, Cost and Service

During the years that elapsed between 1918–26 many lessons were learned and certain facts established.

Safety.—First, it has been proved that air transport when properly administered and operated is a safe means of travel.

In the British air service between May 1919 and March 1925 there were six fatal accidents, only four of which involved the death of passengers, for 3,698,000 m. flown, the equivalent of 148 times round the equator. In Australia there was only one fatal accident[1] and 570,000 m. were flown between the starting of operations in Dec. 1921 and the end of 1924.

Reliability.—A very high standard of efficiency has been reached and a standard of as much as 97% and 98% regularity in flying to a published time-table is claimed for certain air lines operating during summer weather. Three quarters of the failures to maintain perfect regularity are due to weather and failure of power-plant, 66% being due to weather and 34% to mechanical defects throughout the year. This high standard of regularity and safety in British air transport was obtained very largely through the skill and determination of the pilots; and throughout Europe it may be said that good piloting has usually been the greatest factor in any success obtained. Thus it can be claimed that by the end of 1925 much valuable experience had been gained, and a very creditable standard of security and regularity had been attained; this standard was certainly as high as could be expected with the equipment available.

Economy.—On the other hand, although some progress was made during these six years towards economical operation, air transport is still far from arriving at a point at which it can be counted on to operate commercially without artificial financial assistance.

Cost of Operating.—There are two main reasons for the high cost of air transport as compared to other means of locomotion. First, an aeroplane expends a considerable proportion of its horse-power in climbing into the air and on maintaining itself at a safe height without regard to forward speed; in all other forms of transport the vehicle can remain at a fixed level on or in its particular element without expenditure of power. Secondly, in order to obtain as great a disposable load as possible for any given horse-power, the structure of both engine and aircraft must be extremely light. Consequently the air transport vehicle is costly to construct, and through its comparative fragility involves a high rate of maintenance. The cost of operation per hour depends to a great extent on the horse-power employed; thus every endeavour is being made, not only to increase the total weight per horse-power carried, but also to ensure that the greatest possible proportion of this total load is devoted to disposable load at the expense of structural weight. Progress in this direction, however, has received certain setbacks by the proved necessity of carrying extra instruments, safety devices, heating and ventilating apparatus, etc.

As indicated above, a considerable measure of reliability and safety has already been attained, and steady progress is being made towards increasing this standard to a basis of equality with other forms of transport.[2] The problem of reducing the operating cost to really commercial rates is more difficult, and represents the most important question before the designers of commercial aircraft to-day. Progress is being made on broadly two main lines, the reduction of maintenance costs, and the increase of paying load per horse-power. Air-cooled engines are just coming into use; all-metal construction is beginning to replace wood and fabric; and a robust engine burning crude oil is promised in the near future. Each and all these innovations will appreciably reduce the cost of operation.

Design, Cost and Carrying Capacity.—England leads the way in the development of air-cooled engines and Germany in metal construction. On the other line, various mechanical developments are being applied to increase the disposable load without adding to the weight and size of the aircraft itself. The greatest load which an aircraft can carry is that with which it can take off and land safely. Once at a safe height in the air, the normal aircraft has plenty of lifting power in hand. The planes are being fitted with adjustable slots and flaps which permit of a greater load being lifted from the ground in safety, and which lower the landing speed of heavily loaded aircraft which otherwise might be dangerous. Considerable increase in horse-power is being obtained without serious additional weight by means of various systems of supercharging and "boosting" aircraft engines. Variable-pitch propellers are just emerging from the experimental stage, by the use of which much more efficient application of the horse-power available will be attained. The newly invented de la Cierva autogiro promises to be a very valuable factor in progress towards carrying greater loads.

Data regarding costs per ton-mile are not at present available from foreign nations, and in England, owing to constant changes of policy and administration, it is difficult to obtain reliable figures. It is claimed, however, that with existing aircraft it is possible to operate at a speed of 85 m. an hour at 5s. a ton-mile, of which 3s. a ton-mile represent operating costs and 2s. overhead charges, including maintenance and depreciation.

By means of various steps in technical progress, including those mentioned above, it should be possible to reduce these costs to less than 1s. a ton-mile for operating costs, and as safety and reliability are enhanced, traffic will increase and overhead charges will drop to a rate which may also be estimated at 1s. a ton-mile. With a total cost of 2s. a ton-mile, air transport should be able to pay its way on many lines of communication between the great centres of the world's commercial activity.

Summary of Conclusions.—To sum up it may be stated that by the end of 1925 air transport operated by means of aeroplanes and seaplanes has proved to be safe, and under European summer conditions very reliable. This new means of communication cannot function, however, without artificial financial assistance. Great progress is being made towards evolving aircraft which will be able to earn their costs of operation. As the receipts for traffic approximate more and more to the expense of flying, air transport activities will rapidly increase; and when air transport with aeroplanes and seaplanes eventually reaches a paying basis, it must inevitably become one of the most important means of communication between the various parts of the world.

Airships.—Since the early Zeppelin enterprise in Germany

[1] At inaugural flight of Western Airways' operations.

[2] Lee, "The Lessons of Six Years' Experience in Air Transport" in *Jour. of the Royal Aeronautical Society*, No. 179, vol. 29 (Nov. 1925).

during 1912 and 1913, no regular commercial airship service has been put into operation, with the exception of the experimental service with the "Bodensee" run by the Zeppelin Company from Aug. to Dec. 1919. Germany, the chief user and most experienced designer of rigid airships, lost practically the whole of her airship organisation under the terms of the Treaty of Versailles; the ships which were handed over by her to the Allies were not suited for commercial work; England and France had not the necessary faith in the future of airships to justify the expenditure necessary for their further development; and it was only in America that progress was continued. This general stagnation was further justified in the minds of unbelievers by the disasters which overtook the British ship R38 in Aug. 1921 and the French "Dixmude" in Dec. 1923. The finest performance by an airship since 1918 was the flight of the British-built ship R34 from England to New York and back during the summer of 1919. (Left England July 2 1919, arrived America July 6 1919: 108 hours. Left America July 10 1919, arrived England July 13 1919: 75 hours).

Airship Service.—Although America led the way by the construction of the "Shenandoah" and the demand that the ZR3, later the "Los Angeles," should be built in Germany as part of her war reparation, it was England that made the first serious step towards establishing a genuine commercial airship service.

This policy was initiated during 1923. After much discussion, towards the end of 1924 the construction of two large airships was put in hand, one to be built by Government and the other by private enterprise. In the design of these airships the orthodox type of Zeppelin girder has been departed from, and many improvements, the result of practical scientific research, will be incorporated in the structure. In connection with this scheme the existing airship station at Cardington near Bedford is being enlarged and a terminal airship station is being erected in India at Karachi. A temporary refuelling station has been established at Ismailia on the Suez Canal. The contract for the privately built ship includes a satisfactory flight to India along this route.

The following data are given to indicate the progress in rigid airship construction attained during the last few years:—

	Description	Horse-power	Speed m.p.h.	Extreme radius at this speed (without paying load)	Disposable load
				Miles	Tons
R34	Old British ship built in England during the War . .	1,250	Max. 63·5 = Cruising 45 =	3,286 4,905	26·55
ZR3	Zeppelin ship built in Germany for U.S.A. . . .	2,000	Max. 79 = Cruising 68 =	5,490 7,937	46
R101	Ship under construction by British Govt.	3,500	Max. 78 = Cruising 65 =	7,900 13,000	85

Use of Helium.—America has introduced helium gas to replace hydrogen as a lifting agent. Helium (*q.v.*) has the advantage over hydrogen that it is totally non-inflammable, but its production is extremely costly, and its lifting power 15% less than that of hydrogen, which facts will prove a very serious handicap in the commercial development of the airship in America, if this policy is continued. In England, it is the intention to fit crude oil engines to the big ships and so eliminate the element of danger incurred by carrying petrol. No dependable data exist from which the cost of operating an airship can be estimated, but there is little doubt that if the constructional and handling difficulties which have been connected with airships up to date can be overcome, the operating cost per ton-mile will be very much less than in heavier-than-air craft, although the initial capital cost involved is very much greater. The possibilities of the airship as a means of communication over long distances and across the great oceans are therefore enormous.

Co-operation with Aeroplanes.—It seems certain that in the future airships and aeroplanes will work in co-operation. As existing schemes develop, traffic for 'Iraq will reach Egypt by airship and proceed thence by aeroplane to Baghdad; for India, to Colombo by airship and thence to various great cities by aeroplane; for Australia, to Perth by airship and onwards to the northern and eastern cities by aeroplane.

International Agreements

Air transport is the most truly international of the transport industries; international laws and regulations are necessary for the operation of ships at sea and of trains across great continents. But the scope of these two activities is strictly limited, whereas aircraft can penetrate anywhere and fly over the territories of several different nations in a journey of a few hours' duration (*see* Aerial Law).

It has always been evident, therefore, that international air navigation regulations were of vital importance, and during 1922, on ratification of the International Air Convention, to which reference has already been made, the International Commission for Air Navigation (known as the I.C.A.N. in England and as the C.I.N.A. on the continent of Europe) came into being. The following states are parties to the convention and send representatives to this Commission:—

1. Belgium.
2. Great Britain and Northern Ireland.
3. Canada.
4. Australia.
5. Union of South Africa.
6. New Zealand.
7. Irish Free State.
8. India.
9. Bulgaria.
10. Chile.
11. France.
12. Greece.
13. Italy.
14. Japan.
15. Persia.
16. Poland.
17. Portugal.
18. Rumania.
19. Kingdom of the Serbs, Croats and Slovenes.
20. Siam.
21. Czechoslovakia.
22. Uruguay.

The general principles laid down by the Convention are as follows:—

1. Innocent passage of commercial aircraft of the members over the territories of all.
2. Designation of customs aerodromes at suitable points at which aircraft must land.
3. Issue of licences to all members of the crew and airworthy certificates to all aircraft engaged in international commerce. The forms of these licences and certificates and the qualifications and tests to be demanded have been agreed by the Commission.
4. The establishment of a wireless and meteorological organisation and a lighting system along air routes authorised by the nation over whose territory they lie.

The full Commission now meets twice every year, the place of meeting being decided on the invitation of one of the Governments represented. Meetings have taken place, so far, during 1922 in Paris and London; during 1923 in Brussels, London and Rome; during 1924 two meetings in Paris, and during 1925 in London and Brussels. The Commission has appointed standing subcommissions for the detailed study of operational, technical, medical and legal problems, and these meet as convenient at various dates between the meetings of the full Commission. Most European nations who are not members of the International Commission have drawn up regulations of their own, approximating to those of the International Commission, and many of them have entered into agreements of various classes and duration with one another and with members of the International Commission in order to facilitate the operation of international air transport.

Since its creation the Commission has taken steps to modify two articles of the Convention which were unacceptable to certain ex-neutral and ex-enemy countries. These modifications will come into force in the near future on the completion of ratification, when it is likely that several other European nations will join the Convention. As already stated, America,

although a signatory to the Convention originally, has never deposited her ratification and is considering Federal legislation for the administration of inter-state air transport.

Each country through its national legislature gives effect to the International Air Convention and to the decisions of the International Commission. In Great Britain this is done by the Air Navigation Act, 1920, and by the air navigation orders and air navigation directions issued by the authorities from time to time thereunder.

II. AERIAL SURVEYS

Aerial survey came into existence during the World War. The necessity of photographing trench-lines and hostile positions became more and more vital as operations progressed, and by 1918, military aerial photography had reached a high pitch of efficiency. It was only in a few cases, however, that it was necessary to employ aerial photography as a means of measuring distances on the ground; as a rule, comparatively accurate maps were available, and the photographs were required for filling in details of natural features, buildings, roads, etc., and for disclosing the dispositions of the enemy.

At the end of the War, it was clear that aerial photography must provide a very valuable aid to ordinary survey, and from that date onwards aerial survey has been very successfully developed in various parts of the world.

Aerial Survey Problems.—The greatest problems of aerial survey activities are:—

1. To correct for the errors which must obviously result from photographing tracts of country in which considerably different height levels exist.
2. To ensure that photographs are taken with the camera axis as near as possible vertical and to correct the results of deviations from this ideal.
3. To fly straight and level and at a constant height so as to ensure regular overlap of all negatives obtained, and as near as may be a constant scale.
4. To reduce operation costs to a standard at which aerial survey can compete financially with other forms of survey.

Canadian Progress.—Canada has been the pioneer of this new industry. Her vast and comparatively flat northern regions offered an ideal field for the young enterprise to prove its commercial value. Operations have for the most part been carried out by flying boats working from the numerous lakes and waterways which intersect large expanses of unsurveyed and unexploited forest land.

Two systems have been employed; vertical photography aided by certain points previously fixed by triangulation; and oblique photography along a line already traversed by means of ground survey.

Combined with aerial survey, a system of forest fire patrol has been established. During the forest fire seasons, constant air patrols are maintained over important areas, and all fires reported by wireless to fire-fighting stations; in some cases, the fire-fighting parties and apparatus are actually carried to the site of the fire in aircraft. Enormous tracts of timber have been saved by this means. In 1923, it was calculated that 2,120,000 acres of forest were destroyed in Ontario; in 1924 the total destruction was reduced to 140,000 acres, and the saving in labour totalled 50,000 man-days. The *United States* has followed Canada in aerial survey progress. Her operations have included oil surveys, coast-line and river surveys, the alignment of new roads and railways, and municipal surveys and town planning.

France and Germany.—In France, a new law demanding accurate plans of all fair-sized municipalities has led to much activity in the survey of towns. In Germany, forest survey has been carried out extensively and successfully, and great progress has been made in solving the scientific problems connected with stereoscopic plotting and the aerial photography of mountain tracts.

English Experience.—In England, owing to the fact that very accurate surveys everywhere exist, operations have been confined to experimental work and research, together with a great deal of commercial photography of estates, factories, etc. British aerial survey expeditions have, however, carried out most successful work in British Guiana, Burma and Borneo. Experience has enabled fairly reliable estimates of cost to be prepared, and it seems certain that complete and accurate aerial photographs of any normal area can be produced for from £3 to £10 a square mile, depending on the position and extent of the area to be surveyed. Triangulation on the ground is necessary for both air and ground surveys, but this price compares very favourably with any other method of filling in the topography of all except the most open type of country, while at the same time it gives considerably greater details with all necessary accuracy. It is likely that aerial survey operations will develop rapidly in the near future. One of the difficulties of the operator at present is that a single aeroplane can cover large areas so quickly that it is almost impossible to find employment for an aerial survey unit throughout the year, and so be able to distribute overhead charges over a really large area of operations.

III. GENERAL FLYING

Immediately after the World War, a large number of very cheap aircraft were thrown on the market. In several countries, but particularly in Great Britain and America, demobilised pilots purchased one or two aeroplanes and set out to make their living by giving the general public short flights in the neighbourhood of their landing place. The following figures show the measure of this activity in Great Britain:—

	Flights	Passengers		Flights	Passengers
1919–20	37,067	66,785	1922–3	13,578	25,253
1920– 1	23,513	36,694	1923–4	22,842	39,227
1921– 2	21,767	36,048	1924–5	23,519	43,766

This purely local flying was in some cases extended to the maintenance of aircraft plying for hire to carry passengers at a mileage rate to any required destination. The demand for this useful activity has proved small in England, but is likely to increase as operational costs are reduced. Joy-riding has served a useful purpose both in England and America in educating the public as to the possibilities of aviation.

In England an original use for aviation was devised in the introduction of sky-writing. A British company was formed shortly after the War and proceeded to advertise various commodities by means of writing their titles with smoke at a height of about 12,000 ft. in the air. This British company also obtained a large contract for advertising in the United States during 1922 and 1923.

IV. CIVIL FLYING SCHOOLS

Owing to the heavy cost involved, flying instruction to the general public has been very limited. In most of the greater countries, however, civil flying schools exist which depend largely on government assistance for their existence. In England there are five civil flying schools which undertake the annual training of officers. At these schools a private individual can obtain a very good grounding in the art of flying for about £100.

In France there are 11 civil flying training schools at Buc, Le Crotoy, Mourmelun, Orly, Angers, Nîmes, Orléans, Bordeaux Lyon, Clermont-Ferrand, Châlon-sur-Seine.

Pilots are trained for military purposes in these schools and it is from those who have had that military training that the civil aviation companies draw for their pilots.

In Germany there are three types of schools where the training of civil pilots is carried out:—

(1) Schools conducted by aircraft constructors; (2) schools conducted as an independent enterprise; (3) schools conducted by associations. In addition, there is an organisation known as the "Sportsflug" which has started six of its own schools.

In England a movement has just been started which will also give the private individual an opportunity of learning to fly. Private flying clubs have been formed which charge entrance fees and annual subscriptions to all members; at these clubs tuition on small aeroplanes can be obtained at low rates. The Gov-

ernment has guaranteed a certain measure of financial assistance to five of these clubs.

V. AIR RACING

The first form of air racing to come into being consisted of competitions between free balloons, the prize being given to the balloon which eventually landed at the greatest distance from the starting point.

The first recorded race of this class was the Grand Prix which took place in France in 1905. In 1906 the Gordon Bennett Challenge Cup was instituted and has been competed for ever since, with the following results:—

Gordon Bennett Balloon Cup Winners

Paris—1906. Sept. 30—Oct. 1 1906.—*America*, Frank S. Lahm. Balloon, "United States" (2,080 cm.). Paris—Fylingdales, Yorkshire. Distance, 647·098 km. Duration, 22 hr. 5 minutes.

St. Louis, U.S.A.—1907. Oct. 21–23 1907.—*Germany*, Oscar Erbsloh. Balloon, "Pommern" (2,200 cm.). St. Louis—Bradley Beach, New Jersey. Distance, 1,403·559 km. Duration, 40 hours.

Berlin—1908. Oct. 11–14 1908.—*Switzerland*. Col. Schaeck. Balloon, "Helvetia" (2,200 cm.). Berlin—Bergest, nr. Bud. Norway. Distance, 1,212 km. Duration, 73 hours.

Zurich—1909. Oct. 3–4 1909.—*America*, E. W. Mix. Balloon, "America II." Zurich—Ostrolenka, Poland. Distance, 1,121·110 km. Duration, 35 hours.

St. Louis—1910. Oct. 17–19 1910.—*America*, Alan R. Hawley. Balloon "America II." St. Louis—Peribonka River, nr. Chicoutimi, Quebec, Canada. Distance, 1,884 km. Duration, 44 hr. 25 minutes.

Kansas City, U.S.A.—1911. Oct. 9 1911.—*Germany*, Lieut. Hans Gericke. Balloon, "Berlin II." (2,200 cm.). Kansas City—Halcombe, Wis. Distance, 758 km. Duration, 12 hr. 28 minutes.

Stuttgart—1912. Oct. 27–29 1912.—*France*, Maurice Bienaime. Balloon, "Picardie" (2,200 cm.). Stuttgart—Riga. Distance, 2,191 km. Duration, 46 hours.

Paris—1913. Oct. 12–14 1913.—*America*, Ralph H. Upson, Balloon, "Goodyear" (2,200 cm.). Paris—Bempton, nr. Bridlington. Distance, 618 km. Duration, 43 hr. 10 minutes.

1914 to 1919, inclusive—No contest.

Birmingham, U.S.A.—1920. Oct. 23 1920.—*Belgium*, Ernest Demuyter. Balloon, "Belgica" (2,200 cm.). Birmingham—North Hero Island, Vermont, U.S.A. Distance, 1,760 km. Duration, 40 hr. 15 minutes.

Brussels—1921. Sept. 18–19 1921.—*Switzerland*, Capt. Paul Armbruster. Balloon, "Zurich" (2,200 cm.). Brussels—Lambay Island, Ireland. Distance, 766 km. Duration, 27 hr. 23 minutes.

Geneva—1922. Aug. 6–7 1922.—*Belgium*, Ernest Demuyter. Balloon, "Belgica" (2,200 cm.). Brussels—Skollersta., Sweden. Distance, 1,115 km. Duration, 21 hours.

Brussels—1924. June 15–17 1924. *Belgium*, Ernest Demuyter. Balloon, "Belgica" (2,200 cm.). Brussels—St. Abbs Head, Berwickshire. Distance, 714 km. Duration, 43 hr. 16 minutes.

Won outright by Belgium; replaced by *second* Gordon Bennett Balloon Cup.

Second Gordon Bennett Balloon Cup

Brussels—1925. June 7–9 1925.—*Belgium*, A. Veenstra. Balloon, "Prince Leopold." Brussels—Cap Torrina, Spain. Distance, 1,345 km. (840 m.). Duration, 47 hr. 30 minutes.

In 1905, the French Aero Club founded the Fédération Aéronautique Internationale to control all international sporting aviation. This body has laid down and published a code of rules for air racing. The aero club of each country appoints delegates to the Fédération, which meets once a year, discusses modifications to the regulations, decides on conditions for current international competitions and investigates and ratifies claims for world's records.

The first aeroplane races ever held took place at an international meeting at Reims in Aug. 1909. At this meeting an international challenge cup for speed was presented by Mr. Gordon Bennett to be won outright by the country which was victorious three times running. Below are given the principal international competitions for aeroplanes and seaplanes with the results up to date:—

Gordon Bennett Aviation Cup
(Speed Contest)

Reims—1909.—*America* (Representative, G. H. Curtiss). Distance 20 km. (12·4 m.). Time, 15 min. 50⅗ sec. Curtiss biplane, 30 H.P. Curtiss engine.

Belmont Park, New York—1910.—*United Kingdom* (Representative, C. Grahame-White). Distance 100 km. (62·1 m.). Time, 1 hr. 1 min. 4·74 sec. Bleriot monoplane, 50 H.P. Gnome engine.

Eastchurch, Sheppey, England—1911.—*America* (Representative C. T. Weyman). Distance, 150 km. (94 m.). Time, 1 hr. 11 min. 36⅘ sec. Nieuport monoplane, 100 H.P. Gnome engine.

Chicago, U.S.A.—1912.—*France* (Representative, J. Vedrines). Distance, 200 km. (124·8 m.). Time, 1 hr. 10 min. 56 sec. Deperdussin monoplane, 140 H.P. Gnome engine.

Reims—1913.—*France* (Representative M. Prevost). Distance, 200 km. (124·8 m.). Time, 59 min. 45 sec. Deperdussin monoplane, 160 H.P. Gnome engine.

1914 to 1919, inclusive—No contest.

Étampes—1920.—*France* (Representative, Sadi Lecointe). Distance, 300 km. (186·5 m.). Time, 1 hr. 6 min. 17⅘ sec. Nieuport biplane, 300 H.P. Hispano-Suiza engine.

Won outright by France; replaced by Deutsch de la Meurthe Cup.

Henry Deutsch de la Meurthe Cup
(To be won outright after two victories running)

1921—*France*.—Société Nieuport-Astra. Pilot: Georges Kirsch. Villesauvage, Oct. 1 1921. Nieuport-Delage, 300 H.P. Hispano-Suiza engine. Distance, 300 km. Time, 1 hr. 11 min. 39⅘ seconds.

1922—*France*.—Société Nieuport-Astra. Pilot: Fernand Lasne. Villesauvage. Sept. 30 1922. Nieuport-Delage, 300 H.P. Hispano-Suiza engine. Distance, 300 km. Time, 1 hr. 2 min. 11⅘ seconds.

Won outright by France; replaced by Beaumont Cup.

Beaumont Cup
(To be won outright by two victories running)

1923—No contest.

1924—*Istres*. June 22 1924.—Sadi Lacointe. Nieuport-Delage monoplane, 450 H.P. Hispano-Suiza engine. Distance, 300 km. Time, 57 min. 50 sec. Speed, 311 km. (193·2 m.) per hour.

1925—*Istres*. Oct. 18 1925.—Sadi Lacointe. Nieuport-Delage monoplane, 600 H.P. Hispano-Suiza engine. Distance, 300 km. Time, 57 min. 36⅖ sec. Speed, 312·5 km. (194 m.) per hour.

Won outright by France.

Pulitzer Trophy
(Speed Contest)

1920—*Mineola, Long Island*. Nov. 25 1920.—Lieut. C. C. Mosley, U.S. Army. Verville machine, 600 H.P. Packard engine. Course, 132 m. Time, 44 min. 29·57 seconds.

1921—*Omaha*. Nov. 3 1921.—N. Acosta, Curtiss Navy biplane, 400 H.P. Curtiss C.D. 12 engine. Speed, 176·7 m. per hour.

1922—*Detroit*. Oct. 14 1922.—Lieut. R. L. Maugham, U.S. Army. Army Curtiss Racer, 375 H.P. Curtiss D. 12 engine. Triangular course of 160 m. Speed, 206 m. per hour.

1923—*St. Louis*. Oct. 6 1923.—Lieut. J. A. Williams, U.S. Navy. Curtiss R.2.C.1, 460 H.P. Curtiss D. 12 engine. Course, 124·28 m. Time, 30 min. 36 sec. Speed, 243·67 m. per hour.

1924—*Dayton, Ohio*. Oct. 4 1924.—Lieut. H. H. Mills, U.S. Army. Verville-Sperry cantilever monoplane, 500 H.P. Curtiss D. 12 A. engine. Course, 124·7 m. Speed, 215·72 m. per hour.

1925—*Mitchel Field, Long Island*. Oct. 12 1925. Lieut. Cyrus Bettis, U.S. Army Air Service. Army Curtiss Racer, 619 H.P. Curtiss V. 1,400 engine. Course, 124·27 m. (200 km.). Time, 29 min. 56·9 sec. Speed, 248·99 m. per hour.

The Jacques Schneider Maritime Cup
(List of Winners)

Monaco, 1913.—M. Prevost (France) on a Deperdussin float seaplane, 160 H.P. Gnome. 150 nautical m. in 3 hr. 48 min. 22 sec. (45·25 land m. per hour).

Monaco, 1914.—Mr. Howard Pixton (Great Britain) on Sopwith float seaplane, 100 H.P. Monosoupape Gnome. 150 nautical m. in 2 hr. 0 min. 16 sec. (86 land m. per hour).

1915 to 1918, inclusive.—No contest.

Bournemouth, 1919.—Race annulled because, owing to fog, no competitor covered the correct course; but as the Italian aviator, Signor Janello, on a Savoia flying boat came nearest to covering the correct course, the competition was held the following year in Italy.

Venice, 1920.—Signor Luigi Bologna (Italy) on a Savoia S. 19 flying boat with 550 H.P. Ansaldo engine. 202 nautical m. in 2 hr. 10 min. 35 sec. (106·7 land m. per hour).

No English machines competed.

Venice, 1921.—Signor Giovanni de Briganti (Italy) on a Macchi 7 flying boat with 260 H.P. Isotta-Fraschini engine. 200 nautical m. in 2 hr. 4 min. 29 sec. (110·9 land m. per hour).

Naples, 1922.—Mr. H. C. Biard (Great Britain) on Supermarine Sea Lion flying boat with 450 Napier Lion engine. 200·2 nautical m. in 1 hr. 34 min. 51⅘ sec. (145·7 land m. per hour).

Cowes, 1923.—Lieut. David Rittenhouse (U.S. Navy) on Curtiss float seaplane C.R.3 with 465 H.P. Curtiss D.R.A. engine. 186 nautical m. in 1 hr. 12 min. 24⅘ sec. (177·38 land m. per hour).

1924.—British and Italian machines entered for the competition which should have been held at Baltimore. Italian entry did not mature and British machine crashed just before it was due to leave for U.S.A. Thus, if the American competitor had simply flown over the course, he could have claimed a win. As it was, the Americans declared "no competition."

Baltimore, 1925.—Lieut. Doolittle (U.S. Army) on Curtiss R.3 C.2 with Curtiss V. 400 engine. 191·4 nautical m. in 56 min. 6·37 sec. (232·57 land m. per hour).

Air racing has done much as an incentive towards attaining very high speeds, and although the actual racing machines are usually of small practical use, it has proved comparatively easy to develop from them aircraft of great military value.

BIBLIOGRAPHY.—Very little literature exists which deals seriously with commercial aviation, but the following publications touch on its various aspects and cover the details of most of its early history: André Beaumont, *My Three Big Flights* (1912); C. Grahame-White and H. Harper, *Air Power* (1917); L. Hirschauer, *L'aviation de Transport* (1920); H. B. Pratt, *Commercial Airships* (1920); G. Holt Thomas, *Aerial Transport* (1920); Sir Walter Raleigh, *The War in the Air*, vol. I (1922, etc.); Sir Ross Smith, *14,000 Miles thro' the Air* (1922); C. G. Grey, *Aircraft Yearbook* (1923, etc.); Aero Chamber of Commerce of America, *Aircraft Year Book* (1925); Fred T. Jane (C. G. Grey), *All the World's Aircraft* (1925); E. H. Lewitt, *The Rigid Airship*, a Treatise on Design and Performance (1925).

(W. S. B.)

FLYING CORPS: *see* AIR FORCES.

FOCH, FERDINAND (1851–), French marshal, was born at Tarbes Oct. 2 1851. His father's family had long been settled in the south of France, leaving the district of Ariège in the 17th century to establish themselves as woollen manufacturers in the small town of Valentine where they took a prominent part in municipal affairs. On his mother's side, Marshal Foch came of a race of soldiers, his maternal grandfather having been a gallant officer of the Grand Army. His father was a lawyer at Tarbes (Hautes-Pyrénées) who later became a revenue official; and he was frequently transferred from place to place, taking his son with him. The future marshal thus received his education successively at the Lycées at Tarbes and Rodez, the seminary at Polignan and the Jesuit college at St. Etienne.

It was not long before his teachers were struck with his "geometrical mind" and it was decided that he should enter the École Polytechnique, to prepare for which he was sent to St. Clément's College at Metz. After a few months there, however, the war of 1870 interrupted his studies. He enlisted in the infantry but the armistice came before he saw any fighting, and he returned to Metz to finish preparing for his examination. One of his fellow-students has described how, in the midst of a lesson, they learned, on March 11 1871, by the booming of the German guns, that the treaty of peace had made Metz a city of the German empire. None could foresee that the young student was destined, as marshal, to restore the city to France.

He sat for his examinations at Nancy, which was still occupied by Manteuffel's troops, and was admitted to the École Polytechnique, where he made his mark. In 1873 he was commissioned, and served successively at Fontainebleau, Tarbes and Rennes. He then passed into the École Supérieure de Guerre where, after a tour of duty on the general staff, he was appointed a professor on Oct. 31 1894. His lectures soon made a sensation, both by the evident soundness of the matter and the originality of the form. Even thus soon his pupils bore witness to the excellent qualities of their professor, who presently became one of the leaders in military doctrine. The lessons given between 1894 and 1900, collected in volumes, constitute the chapters of Foch's great works: *De la conduite de la guerre* and *Des principes de la guerre*, which appeared in 1897 and 1899.

In teaching six batches of staff college students Foch fortified his own military science as well; his years of Paris were in fact of capital importance in the higher development of his intellect. When he vacated his post no one doubted that he would return ere long in another capacity. After holding two regimental commands of artillery and spending a year on the staff of the V. Corps, he was, so to say, imposed on the Government by the opinion of the whole army as the fittest selection for the command of the École de Guerre that he had made famous. It was Clemenceau—at that time Prime Minister—who made the appointment, giving him the rank of general, and from that day began the cordial relations between the great statesman and the great soldier which were to be revived later under memorable conditions.

The general held his post as head of the École for four years, during which time he threw himself with untiring zeal into the work of this famous centre for military study, giving it a permanent stamp and forming a whole new generation of picked officers. When, in 1911, he was nominated to the command of the 13th Div. at Chaumont, Foch was one of the very few outstanding figures of the army and it was not surprising that, after a brief period in command of the VIII. Corps, the wish of everyone acquainted with the higher military personnel brought him to the head of the splendid XX. Corps, stationed about Nancy, which was accounted one of the best elements of the "Couverture." Thus, in 1913, he entered, to the sound of trumpets, the town where he had passed his examinations to the tune of the German army fifes and whence, before long, he was to march out for the War.

General Foch, who had married Mademoiselle Julie Bienvenue, had at that time three children— two married daughters and a young son who was destined to be one of the first to fall in the War. Although still attached to his Pyrenean home, the general spent his holidays on a small estate that he had acquired at Trofeunteniou in Brittany. In the summer of 1914 France was so far removed from any idea of attacking Germany that Foch had left Nancy to spend a month in far-away Brittany. A week later events led to his recall and he went into harness.

The Outbreak of War.—He was then a man of 63, but his rare moral, intellectual and physical vigour kept him singularly young. Foch was a man of thought and also, above all, a man of action. Gifted with an intelligence which was never allowed to be idle, ever widening the scope of his knowledge, reflective and delighting—to use his own striking phrase—to "phosphoresce," the great soldier is even stronger in will than in intellect. "Victory=*Will* . . . . Victory goes always to those who deserve it by the greater force of *will* . . . . A battle won is a battle in which one *will* not acknowledge oneself beaten"—these are but a few of the maxims found in his books, in which the word *will* occurs on every page. And in truth, although his grey eyes sparkle with intelligence, the forehead and, even more, the mouth reveal that will which he was able to communicate to all those who came in contact with him in the course of war. It is this will which gives such solidity to his character and protects it from all weaknesses. What is more, it stimulates both conscience and intelligence. He speaks of "these natures, hungry for responsibility, which alone turn out great men," and his own is one of these natures, that no sentimental considerations can either divert or check. For the rest, his clarity of mind translates itself by a realist and somewhat ironic common sense. "What is it about?" is a favourite phrase of his in all circumstances, for he believes in clear vision before direct action.

The XX. Corps formed part of the II. Army and Foch was therefore one of the commanders of Castelnau's army, which, on Aug. 19 1914, was thrown into annexed Lorraine. It will be remembered that this army, after some successes, came up against a formidable resistance in the region of Morhange and failed with heavy losses. Foch had had no part in forming the plan, which met with so cruel a check; he was but one of the executants. He had thrown his army corps resolutely at Morhange and, when repulsed, was still able to organise with perfect coolness its retreat on the solid positions of the Couronné de Nancy. Not content to await the enemy there, he resumed the offensive and, on Aug. 20, threw himself on the German regiments which were waiting to attack in the "gap of Charmes," and in overthrowing them prepared the victory in Lorraine. He was preparing to take his part there when he was called to the Grand Quartier Général, where Joffre entrusted him with the command of an army.

At that time the French were retiring in good order from Belgium and the Ardennes towards the region of the Marne. As a gap tended to open between the IV. and V. Armies, Joffre gave Foch the mission of forming a new army (the IX.) between them, co-ordinating his action with theirs. He was on the ground before the corps entrusted to him had arrived. In a few days he forged out of them a solid and supple little army which was

already well in hand when the celebrated order of Sept. 4 arrested the retreat and prescribed the battle which was to lead to the victory of the Marne.

Foch, after passing the marshes of St. Gond, established himself on the heights which dominate the Petit Morin and of which Fère Champenoise marks the crest. It was thought that his rôle would be limited to supporting Franchet d'Esperey's army on his left. But when the German armies, which, instead of turning the left of the French armies as they had expected, were themselves turned on the right, they tried to penetrate the allied centre precisely in this region of Fère Champenoise and Foch had therefore suddenly to support the main strain of the battle, and that with troops inferior in number. The heights were for a moment carried by the Germans from Mondemont to Fère Champenoise. It was then that, by a clever manoeuvre, Foch rapidly transferred the 42nd Div. from his left to his centre and thus was able to gain the upper hand and force the enemy back. The extreme fatigue of his troops prevented him from pushing his successes, but he hung on to the retreating Germans and entered Châlons-sur-Marne behind them. His part in the victory of the Marne was capital and it was recognised by a glorious citation in general orders.

His reputation was so increased after this great crisis that Joffre immediately entrusted him with a new mission—this time one without parallel. Scarcely had the operations of the Marne terminated when, the two armies mutually trying to outflank one another, the " race to the sea " set in from the Oise to the Flemish coast which was only to be closed by the arrival of the Belgian Army and the formation of a continuous front right to Nieuport. The British corps, for their part, had been moved into the region of Ypres, while Joffre detached from the now stable front between the Oise and the Vosges all the forces that he could spare to meet a great attack between the Oise and the sea.

To co-ordinate the action of the heterogeneous troops hurriedly thrown into these regions, a leader of great authority was wanted at once to take the higher direction of the operations of the French armies and to co-operate harmoniously with the Allied armies so as to assure the co-ordination necessary to victory. On Oct. 4 Foch was sent to the Nord to fulfil this mission with the title of " deputy to the commander-in-chief."

He did not limit himself to giving the French armies, from Picardy to Flanders, the most energetic orders but put himself in close and cordial relations with Field-Marshal Sir John French and King Albert I., and established the essential liaison between the Allied armies. Ceaselessly finding the necessary reinforcements and dispatching them to the aid of the hard-pressed British and Belgian corps, he was able by his friendly and generous activity to impose his own resolute ideas and so make himself the soul of the battle of Flanders that, after the fierce fighting of the Yser and of Ypres, ended in mid-Nov. by the definitive check of the German invasion for the year 1914. In all this Foch had not merely confirmed his prestige as a strategist, but had won for himself the friendly admiration of his Allies so completely that, even then, it could be foreseen that if, one day, circumstances required unity of command there could be no better choice for it than Foch. Did not Mr. Lloyd George say: " He could not have done more for us had he been one of our own generals."

Foch was left therefore in contact with the British and Belgian corps in the capacity of general commanding the Group of Armies of the North. He held the post for two years and thus presided over the two Artois offensives of May and Sept. 1915 and the battle of the Somme in the summer of 1916 which the German attack on Verdun prevented from assuming the amplitude and decisive character that had been intended.

After brilliant initial successes the Somme battle seemed to sink in the autumn mud. The disappointment that it caused led to a movement of dissatisfaction with the higher leaders who had presided over it. Joffre having been relieved of his command, Foch was deprived of his also and relegated to Senlis for a mission of inspection. The story was that he was fatigued. This was hardly the case, but he accepted this semi-disgrace with resignation and his valuable advice was always at the disposal of General Lyautey, who had become Minister of War.

When, in May 1917, Gen. Pétain was called to the chief command, he himself suggested to the Government that Foch could be usefully employed in the post of chief of the general staff. Having been sent into Italy on the morrow of Caporetto to establish a much-needed understanding with Gen. Cadorna's headquarters, and having remained in constant and cordial relations with Field-Marshal Haig, there was little doubt that when the time came Foch would appear as the single commander that so many people desired by the end of 1917. When, in March 1918, the Germans launched their first grand offensive and the Allied line threatened to break, the necessity of this command became obvious to everybody. It was at Doullens that Foch, on March 29, received from the representatives of the French and British Govts. that mission of higher co-ordination that on April 14 became more precise in the form of the chief command of all the Allied armies fighting in France. Already he had grasped this command with a firm hand. Thanks to the close co-operation of the Allies he stopped the Germans at the gates of Amiens, and thereby brought about the final failure of their attempt to break the Anglo-French front and penetrate to the Channel.

Henceforward his whole energies were directed towards assuring this fruitful co-operation. Thus he brought strong French reinforcements to help the British armies, attacked in March and April, and engaged British and American divisions in the battle of the Aisne in May, thus twice checking German offensives that, for a moment, were triumphant. And when the Germans came to a standstill in the pockets that they had driven into our front, he prepared the counter-offensives which, when the hour struck, were to shake and crumple the German front.

The counter-offensive was on the point of being launched against the flanks of these pockets, from the Aisne to the Marne, when, on July 15, a new German offensive took place. This met with a partial check which, as we know, had the effect of deepening the pocket in which Foch intended to grip the enemy. The victorious attack of July 18 on the enemy's flanks forced him to retire and gave the signal for the grand Allied offensives.

Foch was now determined to halt no more. He realised that the German armies were beginning to be exhausted but that if they were to be overthrown, the blows must fall thick and fast. The great offensive of Aug. 8 in the region of the Somme which, as it gradually spread and became more violent, forced the Germans to retire on to the Hindenburg Line, was almost immediately followed by the new offensive against that strong position where French and English vied with each other in valour. Once the line had been forced, Foch launched his famous " directive " of Sept. 3 which was in fact the programme of the general attack. The stages of this semi-concentric attack are well known. It stretched from the Meuse into Flanders and was designed to draw the enemy from all parts back on to the region of the Ardennes, where Foch hoped to pin them and grasp them. The " directives," which issued from the headquarters of Bombon (and later, Senlis) are clear, resolute and pitiless. At this point Pétain, Haig and Pershing worked in closest harmony with their French colleague. The directives of Oct. 10 and 19 were followed by successes—hard won and unequal, it is true, but which on Nov. 5 culminated in the general retreat of the beaten and exhausted German armies.

Foch, following them closely, had already prepared an operation on a large scale to make an end of them. While the Germans were to be thrown back into the difficult Ardennes region, a huge group of armies under the orders of Castelnau with Mangin as principal executant, were to attack on the Moselle and the Sarre and, reaching the Rhine, were to bar the line of retreat from the encircled Germans. It was at this point that the Germans asked for the Armistice. On Nov. 8 Foch, who had been engaged in drawing up the conditions for three weeks past, received the German plenipotentiaries at Rethondes and, by his masterful attitude, brought them to accept all conditions on Nov. 11,

obtaining with the occupation of the left bank of the Rhine the results which he had expected to gain from the supreme battle.

The career of Foch was not at an end. Europe acclaimed him as the leader who had secured the victory. Marshal of France since Aug. 7, he now became a British field-marshal and later a marshal of Poland. He was elected a member of the *Académie française*, which body, emulating the *Académie des sciences*, gave him a wonderful reception, and at Paris, on July 14 1919, he passed under the *Arc de triomphe de l'Etoile* at the head of the victorious troops. From New York to London and from Brussels to Warsaw he passed from triumph to triumph. He was not, however, content with a parade rôle, and, as president of the Inter-Allied military commission, he was repeatedly called upon to take measures in support of the action of the Allied Governments. This presidency he still retains—the last vestige of that single command of the armies led by him to the common triumph, the triumph which was the outcome of that "will" always regarded by him as the great and essential mainspring of victory.

BIBLIOGRAPHY.—Marshal Foch's own works are *Des principes de la guerre* (1903), with English translation by Hilaire Belloc (1918); *De la conduite de la guerre*, 3rd ed. (1915); *Préceptes et jugements du Maréchal Foch extraits de ses oeuvres, précédés d'une étude sur la vie militaire du maréchal par A. Casset* (Nancy, 1919); with English translation by Hilaire Belloc (1919). See also A. H. Atteridge, *Marshal Ferdinand Foch* (1919); A. L. Grasset, *Le Maréchal Foch* (1919); H. de Lacroix, *Le Maréchal Foch* (1921); P. Painlevé, *Comment j'ai nommé Foch* (1923). See also the Marshal's article on MORALE in this *Encyclopaedia*. (L. M.)

FOERSTER, JOSEF BOHUSLAV (1859–), Czech composer, was born Dec. 30 1859 in Prague, and studied under Fibich. He became an organist and a writer on musical subjects; later he was appointed professor at the Conservatoire in Hamburg and eventually, in 1918, professor at the Conservatoire in Prague. As a composer he developed from symphonic and chamber music to opera, which formed the most important part of his work. Foerster was a type of cultured musician, deeply emotional in his resources, who replaced the vagueness of expression which marked his early period by purity and technical perfection. His operas *Deborah* (1891), *Eve* (1897), *Jessica* (1904), *The Unconquered* (1906), *The Heart* (1922) are distinguished by psychological depth and by the subjectivity of their artistic understanding. Of his other compositions, the most important are a symphony entitled *From my Youth* and a number of suites.

FOGAZZARO, ANTONIO (1842–1911), Italian novelist and poet (*see* 10.590), died at Vicenza March 7 1911.

See Eugenio Donadoni, *Antonio Fogazzaro* (1913); L. Gennari, *Fogazzaro* (1918); and F. Crispolti, *Antonio Fogazzaro; Discorso Commemorativo* (1911).

FOKKER, ANTHONY HERMAN GERARD (1890–), Dutch aeronaut and aeroplane constructor, was born April 6 1890 at Kediri, Java. He obtained his international pilot certificate in 1911 and in the following year he established an aeroplane factory at Johannesthal, near Berlin. In 1913 he founded another factory at Schwerin in Mecklenburg and during the World War supplied the German Army with flying material, notably the Fokker biplane. After the War he returned to Holland and established the Fokker Aircraft Works in that country. In 1924 the Atlantic Aircraft Corporation was founded in the United States, Mr. Fokker being a director; and a factory was started at Hasbrouck Heights, New Jersey. Meanwhile he had set up a plant in Madrid, which was already producing machines for the Spanish Government. He devoted much of his time to researches in the field of commercial aircraft development, one of his latest designs being the Fokker triplane. His early experiments with regard to gliding with motorless machines, of which he gave a demonstration in England in 1922, did not meet with very much success.

FOLKESTONE, England (*see* 10.600b), with a population of 37,511, has been improved as a seaport. Before the World War the harbour pier was lengthened to 1,480 ft., so that it now has berths for eight steamers, a railway platform and raised promenade along the whole length, and a lighthouse at the end. The area of the inner and outer harbours is a little over 12 acres. In 1915 there was a large landslip in the Warren; the railway line between Folkestone and Dover, which was buried or damaged for a distance of nearly two miles, was closed and was not reopened until Aug. 1919. In 1920 the Earl of Radnor presented the Warren and East Cliff to the town. A zigzag path has been built between the Undercliff and the Leas. In 1921 the foundation stone of an addition to the Royal Victoria Hospital was laid. In 1924 remains of a large Roman villa were excavated near the East Cliff, and the corporation undertook the roofing of a portion of the site, which contains a mosaic pavement.

Folkestone was an important embarkation point during the World War and one of the ports permitted to civilians. Many Belgian refugees passed through in the early days; it was estimated that 64,500 destitute Belgians arrived between Sept. 1914 and March 1915, besides about 44,600 who had sufficient money to pay railway fares for themselves. There were later large numbers of Canadian troops at Shorncliffe Camp near the town and also camps for American troops and for Chinese and Zulu labourers. On May 25 1917, during an air raid, a bomb fell in a crowded street, killing 33 people.

FOLKLORE (*see* 10.601).—Folklore, the science of popular beliefs, traditions and customs, has made great progress since 1910, especially in countries which till then remained more or less outside general scientific movements. Unfortunately scholars in countries like the Balkan States, Finland, Czechoslovakia, Yugoslavia, now publish the results of their work in their national language, thus adding to the difficulties of comparative study. This scientific decentralisation may perhaps culminate in concentration and standardisation, as has been effected in physical anthropology. The need for some such measures is evident. The scope of folklore needs to be defined. Its methods must be organised and, where necessary, renovated.

Scope of the Science.—Early students of folklore limited their studies to beliefs, tales, legends, myths, songs and games—that is to a great extent to "literary traditions." Early in the 20th century folklore was only a section of comparative literary history and of comparative mythology. But in some countries, as those under Habsburg rule and Slavonic areas, investigations covered the details of dress and ornaments, of houses and villages, of arts and crafts, as well as literary material. In these countries folklore was thus inevitably associated directly with ethnography.

While such conditions obtained, it was true that folklore was the ethnography of European peoples, and ethnography the folklore of the non-European peoples. Such indeed, but only as regards beliefs and popular literature, was the attitude of the Folklore Society of London, which in its publications has always granted equality of place to "primitive or half-civilised" savages, as to the peasants of Europe. Again, Sir James Frazer in his *Golden Bough* and in *Folklore of the Old Testament* has included all popular documents without geographical or chronological distinction. For him, as for the majority of folklorists of the older school, the term folklore referred only to intellectual, not to material, culture. Obviously the variations of dress, houses and implements have not, in Great Britain and the Central States of Europe, the same importance as in eastern and southern Europe, although certain areas, such as Scotland, the Alps, the Pyrenees and parts of Germany, have preserved vestiges of very ancient cultures.

Rütimeyer has discovered in Switzerland many prehistoric survivals, instruments, decorations, even modes of life. The Spanish Anthropological Society has started investigations in Spain into local fashions of dress, which have already yielded interesting results. In eastern and northern Europe the varieties of material culture and survivals of the Stone, Bronze and Iron ages are even more numerous and better preserved. In these countries, therefore, folklore has gathered in more such data than in those where it was first organised. The scope of folklore needs enlargement, so as to include the study of varieties of types of houses, villages, utensils of every sort, furniture, jewels, dress and every expression of popular art. Since the War, a movement

in this direction has been started in England and in France by the publication of numerous monographs on country houses, too often in a purely utilitarian, rather than in a scientific spirit, because conditioned by the exodus of people in towns towards the country. But the investigations of Bancalari, Meringer and the school of students in Finland, Russia, Bulgaria, Rumania, Serbo-Croatia and Czechoslovakia into the material culture of those areas have been undertaken in strict accordance with the scientific rules of folklore.

Methods of Investigation.—The ampler the scope of folklore and the wider its domain, the more rigorously must its rules be determined. No single method of approach is adequate. The historical method is necessary—so also is the comparative method necessary; for in distinction from the historical method it does not put chronology into the first place, but compares the data according to their intrinsic nature, according to their technique and their external forms, without note of conditions of time and place. Frazer, Lang, Hartland and Westermarck in England, de Basset, Sebillot, Cosquin, Gaidoz in France, Mannhardt and his followers in Germany used this method, which had the advantage of bringing to light the gaps in the historical method of which the older philological method was but a secondary variation. A new philological method was founded by Edmond and Gilliéron, who published the great linguistic Atlas of France. Their study of words such as *Scier* forced them and their fellow workers to investigate things as well, such as *faux, fauciIle, segue, scie*, etc. Thus came into being a new scientific department, in which folklore and linguistics were united. So great was its success in Germany that Meringer and his pupils founded a review, *Wörter und Sachen*, in order to exhibit the scientific advantages of this combination. And so useful is it that modern folklorists are obliged to give heed to this class of investigations.

Human Geography.—Under the name of anthropo-geography or human geography (*q.v.*), the science of geography lends valuable aid to folklore. While the comparative method eliminated all conditions of place, geography regards them as essential. The union of the two has produced a new method which, so long as it holds a just balance, will continue to produce valuable results. As in modern linguistics, distribution maps are now essential in folklore studies. By this means the easy generalisations of the comparative school can be rectified, as has been done by Van Gennep for the Savoy area, where more than 630 parishes were examined, with the result that the generalisations of Mannhardt and Frazer, etc., were found to be not valid in the areas studied. There are local variations, and even disappearances of customs, which the older, comparative method failed to explain.

Not only must the data be strictly localised but they must also be related to all their concomitant conditions. In addition to the historical, linguistic and geographic qualities already mentioned, note has to be made of the psychological, economic and political conditions. In short, to make due progress, folklore must adapt the psychological method to its needs, as well as the sociological method, by which all elements in the social life are classified. Folklore is concerned with social and collective, not individual and isolated, phenomena—its very derivation proves this. A tale, a myth, a ritual act, a dance, a ballad, a mode of dress, a type of house, are collective expressions.

The Individual in Invention.—This does not mean that these are collective inventions. Every study of the growth of an element of this nature reveals an individual act as the origin or moment of borrowing—never the act of a large group. A small and limited group behaves as an individual just as the admirers of a popular poet, the followers of a prophet or the pupils of a painter or a sculptor form a school. Thus a new end is given to folklore. The comparative method has disclosed to us the dominant and constant elements for all mankind. This was necessary to ascertain the conditions in which these dominant and constant elements came into existence, by whom, how and why, variations in them are effected in distribution of place and time. In short, it is its business to discover the action of individuals, or of small groups of individuals, as well as the mental and material evolution of collectivities.

Collection and Preservation of Data.—The wider the scope of folklore, the more delicate become its methods of interpretation and the more necessary is it to gather its data in a strictly scientific manner. At the outset, complicated questionnaires were used almost at random. They are now prepared on a less ambitious scale and with more precise terminology. Personal experience goes to show that questionnaires are useful only if used by an investigator who has an adequate general knowledge of manuals and comparative studies.

Folklore Material.—The data of folklore fall into two series, intellectual and material. No great dictionary or encyclopaedia as yet exists to cover the first group of topics, as has been accomplished for other sciences. The only attempt in this direction in Europe is the *Folklore of France* by Paul Sebillot, in four volumes, which, but for the untimely death of this great pioneer, would have been followed by four other volumes; and in America the two volumes of the *Handbook of the American Indians* by Hodge (Bureau of Ethnology). In most countries recourse must be had to collections of monographs, such as those published by the Folklore Society of London, by Pitre in Italy, and by Machado y Alvárez in Spain. The work that has to be done in this direction could, and should, be accomplished by international co-operation. The Finnish authority, Antti Aarne, has drawn up a list of catch-words which, with items supplied by his co-adjutators, contains more than 3,000 items concerning specially the themes of tales and legends.

Museums.—The material data, implements, dress, etc., find their place in museums. But it is still rare to find a museum specially devoted to folklore, properly termed. Such are the Nordic Museum at Stockholm, the finest of all, then the Museum of Völkerkunde at Berlin; the folklore museums at Hamburg and Basel, the Museum of Popular Traditions at Paris (Trocadero), the national museums at Prague, at Bucharest, Cluj Klausenburg at Zakopane, at Warsaw and Cracow and at Budapest. In almost all big towns where there is an archaeological museum, there is a section set apart in it for folklore material, specially of historical and artistic nature. Of peculiar interest are sections of this kind at South Kensington, at the German Museum in Nuremberg, at the Landes Museum at Zurich, the Natural History Museum, Vienna, the Polytechnic Museum, Moscow, and the Alsatian Museum, Strasbourg. In most large provincial towns in England, France, Germany, Switzerland and Austria there are local museums which contain folklore objects, such as exhibits of ancient costumes, as well as coins, pictures and historic objects of every kind.

Nevertheless, the scientific organisation of folklore museums has not yet been founded. We are still at the simple stage of curiosity and rarity. The historical point of view in general overrules the special aspect of folklore interest according to which specimens should be collected and classified in technological and evolutionary series. The folklore material of non-European peoples is naturally much better represented, for it is ethnography pure and simple. The number of ethnographic museums has increased greatly in this period and their organisation improved, notably in the United States, Switzerland and The Netherlands.

BIBLIOGRAPHICAL NOTES.—*General:* The *Volkskundliche Bibliographie*, ed. by E. Hoffmann-Krayer (Berlin, 1919, etc.), deals with all elements in folklore and, in some degree, with ethnography. The *Gypsy Bibliography* by George F. Black (1914) deserves mention.

Manuals and Method: Charlotte S. Burne, *The Handbook of Folklore*, London Folklore Society (1914); Paul Sebillot, *Le Folklore. Littérature Orale et Ethnographie Traditionelle* (Paris, 1914); A. Van Gennep, *Le Folklore, Moeurs et Coutumes Populaires* (Paris, 1924); Luis de Hoyos-Sainz, *Etnografia, sus bases, sus metodos y aplicaciones á España* (Madrid, 1917); Karl Reuschel, *Deutsche Volkskunde*, 2 vol. Basque Folklore.—*Revue des Études Basques* (Bayonne), the annual review and monthly bulletin of *Notes and Queries* by the Society of Euske-Folklore founded by José Miguel de Baran in 1921 at Vittoria: also memoirs on the Basques by C. Schuchardt of Graz, N. Densusianu of Bucharest, and M. Haberlandt of Vienna.

France.—On the death of Paul Sebillot, in 1918, the Société des Traditions populaires was amalgamated with the Société française d'Ethnographie et des Traditions populaires which has published a review since 1919. The review *Melusine* has not appeared regularly since the death of Eugène Rolland. Volume 13 appeared in 1912. Regional reviews and the publications of academies and local learned societies contain much material. In the *Revue de folklore*, to appear in 1926 under the direction of A. Van Gennep, provincial researches will be centralised.

The folklore of Northern Africa is dealt with in the *Revue tunisienne*, and the *Revue africaine;* Western African folklore in the *Bulletins* published at St. Louis and at Brazzaville. In the *Revue indochinoise* and the *Bulletin de l'École française d'Extrême-Orient* will be found material dealing with the folklore of India and China. The *Bulletin de la Société des Études océaniennes* has articles on folklore.

British Empire.—*Folklore*, published by the Folklore Society of London, is both comparative and descriptive. The society also publishes a collection of monographs dealing with the folklore of England under various headings. There are no special folklore reviews for Scotland or Ireland, or, for the most part, of the Dominions; Canadian folklore finds a place in the *Journal of American Folklore;* Asiatic folklore, especially Indian, is dealt with in the *Journal of the Asiatic Society of Bengal;* and Chinese folklore is also recorded in the *Journal* of the North China Branch. The Chinese Society also deals with such material from time to time. There are also local reviews and publications in the African territories which are not, however, centralised. As regards Australia, the publications of the local geographic societies must be consulted.

Belgium.—The publication of *la revue Volkskund*, interrupted by the War, has now been resumed under the direction of A. de Cock, Victor de Meijère and J. Vercoulie. In Walloon Belgium *Folklore brabançon* has now commenced to appear in both languages under the direction of A. Marinus. The Belgian Folklore Society proposes to publish a centralised bulletin dealing with folklore in both portions of Belgium.

Switzerland.—In spite of the War, La Société Suisse des Traditions populaires has continued the publication of archives and separate memoirs and monthly bulletins dealing with Swiss folklore. Much information has been collected and classified in the *Glossaire des Patois de la Suisse romande* now appearing in instalments. The Dictionary of patois suisse-italien has commenced publication, and includes a description of material, objects, customs, etc., and distribution maps covering northern Italy as well.

Italy.—For central and southern Italy, and especially Sicily, see the *Archivio italiano Tradizioni popolari* and the review, *Il Folklore italiano*. The review *Augusta Praetoria* deals with the valley of Aosta and neighbouring regions, and, from time to time, local or general papers publish folklore material.

Germany.—All German folklore societies are united in the Verband deutscher Vereine für Volkskunde which publishes *Mitteilungen* (reports). The Swiss society is a member, and the Scandinavian, Dutch and Czech-German societies also form part of this league. Its reports deal with the activities of various societies under the various headings of folklore. The best folklore reviews are:—Berlin, *Zeitschrift fur Volkskunde;* Munich, two reviews, *Bayerische Hefte* and *Bayerische Blätter für Volkskunde;* Giessen, *Hessische Blätter für Volkskunde;* Leipzig, *Mitteilungen des Ver. für sächische Volkskunde;* Breslau, *Mitteilungen der Schlesischen Gesellschaft für Volkskunde*. Further folklore articles, essays and bibliographies will be found in *Anzeiger für deutsches Altertum; Archiv für das Studium der neueren Sprachen; Archiv für Religionswissenschaft; Wörter und Sachen; Zeitschrift für Ethnologie*. The German output of folklore is by far the most important in the whole world because it is recognised to constitute an element in German nationality, and because the German country people are very conservative in their manners and customs.

Scandinavian Countries.—Most periodicals in Scandinavian countries publish folklore articles, such as, the *Danske Studier a Copenhague, Ymer* at Stockholm, etc. There are special reviews, such as, *Norsk Folkekultur* at Christiania; *Folkminnen och Folktankar* at Stockholm, and for Finnish Swedes *Folkloristiska och etnografiska*.

Finland and the Baltic Countries.—The Finnish-Ugrian Society publishes an excellent journal. The academy of Helsingfors publishes memoirs relating to the Ugrians, the Mongols, the Manchus, the Votiaks Voguls, the Tcheremisses and the Estonians. The Society of Folklore Fellows publishes at Helsingfors the well-known *Communications comparatives*, under the editorship of Antri Aarne. There are also folklore societies at Dorpat, in Latvia and in Lithuania.

Russia.—Nearly all periodical publications came to an end during the War and the revolution. Among them were *Zhiva 'ia Starina*, published by the Geographical Society of St. Petersburg, and *Etnografitcheskoye Obozrienie*, published by the Polytechnic Museum of Moscow. At Kieff, however, a laboratory of Anthropology and Ethnology has been founded by the Academy of Science of the Ukraine, which publishes a bulletin in Ukrainian, in which folklore is dealt with. In Manchuria a periodical appears, published by the local historical and archaeological society, and deals with Russian, Mongol, Manchu and Chinese folklore.

Poland.—While the review, *Wisla*, has ceased to appear, the Academy of Science at Cracow continues the publication of much material. The principal centre of activity is, however, at Lemberg, the headquarters of the Polish Society for Ethnology and Folklore. Its publication, *Lud*, is in its 23rd year, and appears simultaneously at Warsaw, Cracow, Posen and Vilna under the editorship of A. Fischer.

Czechoslovakia.—On the death of Zibert, the review, *Cesky Lid*, ceased to appear, but the *Narodopisny Vestnik Cesko-Slovansky* is still published under the editorship of G. Polivka. Other local reviews, notably in Slovakia, deal with folklore.

Austria.—On the break-up of the Habsburg Empire the scope of the Societies which publish journals of folklore has diminished; each element in the population prefers its own language as a means of publication so that there are local reviews in the Tirol, Styria, etc. Much folklore material is published by the Museum of Volkskunde and the Anthropological Institute in their publications.

Hungary.—Folklore material is centralised by the Academy of Science at Budapest, by the *Revue Ethnographique*, and in the reports of the Ethnographic Museum.

Bulgaria.—The Academy of Science publishes an important series of volumes on the popular manners and customs of Bulgaria.

Rumania.—The Bucharest Academy has already published some 50 vol. on Rumanian manners and customs. Then N. Densusianu has founded the review, *Grai si Suflet*, devoted to linguistics and to folklore. Local material is also published by the Universities of Jassy and Klausenburg.

Yugoslavia.—There are three important centres for folklore work in the country; the first at Belgrade where the Academy of Science and the university publish important memoirs from time to time; secondly, at Zagreb, where the review *Norodna Starina* (National Antiquities) is published under the editorship of Josip Matasovic; and thirdly, at Lubljana, where *Carniola* and *Mitteilungen des Museum-Vereines für Krain* are published. It may be indeed that Yugoslavia is one of the countries richest in folklore materials.

Greece.—The Hellenic Folklore Society founded by Politis at Athens, in 1910, publishes a review *Laographia*, to which also it has published as supplementary a collection of the complete works of Politis himself.

America.—In North America a distinct division of labour is observable. Indian folklore is centralised with the Bureau of Ethnology and the Smithsonian Institution and the *American Anthropologist*. The folklore of peoples of European and African origin falls to the *Journal of American Folklore* on behalf of the American Folklore Society, which also publishes memoirs. This society deals only with popular literature, tales, legends, songs, and not with popular material culture. Mention must be made here of the important investigations of Marius Barbeau on French Canada, and of Elsie Clews Parsons on the Bahamas.

Central America.—Gamio, in Mexico, deals with the folklore of the Indians in the publications of the Ministerio del Fomento. In Cuba, Fernando Ortiz has commenced publication of *Archivos del Folklore Cubano* (San Ignacio del Habana). Venezuela, Brazil and Chile are commencing publication of their folklore material, both of Indian and European origin. An annual bibliography of a complete nature, dealing with the folklore of North, Central and South America, has been published since 1917 by G. Rivet, of the Society of Americanists of Paris. (M. A. VAN G.)

FOLKSONG: *see* SINGING.

FOOCHOW, China (*see* 11.271), a treaty port, had an estimated population, according to the Chinese maritime customs; of 320,900 in 1923. The streets have been widened and paved,

the steps leading to the Long Bridge have been removed, and the road between it and the city planted with trees. Electric light has been installed, and also an ice-making plant to supply the fishing boats. In 1921 the Fukien Christian University was established on a site of 50 ac. below Kushan Point. The trade of Foochow has declined with the decline of the tea trade. The timber resources of the country are waning, and the trade in camphor is small. The demand for and the output of lacquer ware has increased. Ships discharge and load at the Pagoda anchorage, 10 m. below Foochow, since above this the Min river, divided into a number of channels, is obstructed by shoals and bars. A conservancy board was formed in 1919, and plans were worked out for directing the river into one channel, and permitting navigation by vessels drawing 17 ft. up to Nantai, the harbour of Foochow. The work was almost completed in the first and third sections in 1925, and the second section only required improvement by dredging.

FOOD, PURE (*see* ADULTERATION, 1.218).—It is only within recent years that the transfer of the manufacture of food from the home to the factory, and the transportation of food for greater and greater distances, have made it necessary for governments to promote systematically and scientifically the purity and truthful labelling of food products.

The purity of foods, drugs and other commodities was everywhere adversely affected by the conditions prevailing during the World War. There was a great increase in the practice of adulteration, and a marked falling off in the quality of manufactured foods. The use of substitutes and inferior products in times of shortage is a necessity; the subsequent restoration of higher standards is slow. Borax, formaldehyde and other food preservatives were tolerated to an almost unlimited extent in some European countries during the troubled period attending the War, and the users of these substances, after a few years of unmolested privilege, have been unwilling to give way.

Scientific Developments.—One phase of the movement for pure food was a proposal by the newly organised International Union of Pure and Applied Chemistry to study the practice of conserving foods by chemical means—a subject extensively investigated in the United States between 1904 and 1912. A report upon the laws governing the use of chemical preservatives in foods was presented at the fourth meeting of the International Union of Pure and Applied Chemistry at Cambridge, England, in June 1923 (Comptes-rendus de la quatrième Conférence Internationale de la Chimie, p. 133–6). The trend of public and scientific opinion at the present time is toward the complete elimination of chemical preservatives from foods. In addition to their own injurious action, food preservatives disguise the effects of putrefaction, and their use in many cases has put a premium upon the unsanitary handling of foods. Certain advocates, notably Prof. E. Paterno of the University of Rome, have defended the use of preservatives. It has been asserted that the extensive consumption of meats, preserved by boric acid or formaldehyde, as an exigency of war, produced no injurious effects. The lack of cold-storage facilities, such as are everywhere provided in the United States, has been advanced in many countries as an argument for the use of chemicals in preserving perishable foods. Legislation to exclude completely all foreign chemicals from foods has been held to be inconsistent so long as copper compounds, arsenates and other substances are permitted in agriculture as insecticides, fungicides and disinfectants, since traces of these nearly always occur in the fruits and vegetables so treated. Nevertheless opinion among hygienists, manufacturers and the general public is decidedly adverse to the use of chemical preservatives. It has been suggested that an important factor in the increase of certain diseases is the presence of chemical preservatives and metallic poisons in foods.

British Committee on Preservatives.—In England the Minister of Health appointed on July 7 1923 a Committee on the Use of Preservatives and Colouring Matters in Food. In accordance with their recommendations the Minister of Health announced on Feb. 17 1925 a Draft of Rules and Orders that completely excludes from foods boric acid, salicylic acid, formaldehyde, fluorides and all other chemical preservatives except benzoic acid and sulphur dioxide, which are permitted in minimum amounts for preserving a limited number of foods and beverages. According to these regulations a food preservative is defined as:—

> any substance which is capable of inhibiting, retarding or arresting the process of fermentation, acidification, or other decomposition of food or of masking any of the evidences of any such process or of neutralising the acid generated by any such process; but does not include common salt (sodium chloride), saltpetre (sodium or potassium nitrate), sugars, acetic acid or vinegar, alcohol or potable spirits, spices, essential oils or any substance added to food by the process of curing known as smoking.

It was objected that the new rules would operate to the detriment of both the trade and the general public on account of storage difficulties and of the increased price at which it would be necessary to sell food under the changed conditions. The new British Public Health (Preservatives, etc., in Food) Regulations of 1925 are to come into operation on Jan. 1 1927 with slight extensions of this date in the case of butter, cream and a few other products.

Standardisation.—A basic requirement in pure food control is the establishment of official standards of purity. The differences of opinion which prevail with regard to what constitutes pure sausage, marmalade, chocolate, catsup, ice cream and numerous other foods would make the task of the analyst an impossible one unless he had available certain recognised standards which are accepted as just by the trade and by regulatory officials. In Germany, Great Britain and the British colonies much valuable pioneer work has been done by the public analysts toward establishing standards of composition for many articles of food. In the United States a joint committee of nine experts selected equally from the U.S. Bureau of Chemistry, the Association of Official Agricultural Chemists and the Association of Dairy, Food and Drug Officials, by joint conferences with the trade, has established definitions and standards for a large variety of foods.

FOOD LAWS IN THE UNITED STATES

In the United States the control of foods is exercised by the Federal Govt. of the United States under the Federal Food and Drugs Act, the Meat Inspection Act, the Tea Inspection Act and certain Acts relating to specific products such as filled cheese, filled milk, butter and mixed flour. Forty-seven of the 48 states of the Union have some form of food control legislation. A number of states have laws which follow the general principles of the Federal Food and Drugs Act, but other states have laws differing very materially from that Act. In some states foods are controlled under the general provisions of one Act, in other states they are controlled under a number of Acts relating to specific food products. Each state has complete control of the foods produced and consumed within that state. The Federal Govt. has control of foods shipped into interstate or foreign commerce.

The Federal Food and Drugs Act, approved on June 30 1906 and amended in 1912, 1913 and 1919, provides in general that all foods coming within its jurisdiction be prepared in a cleanly manner from pure and wholesome materials; free from any added substances which might render them injurious to health; not labelled or sold under representations which are in any manner deceptive. Food packages must bear a plain and conspicuous statement of the quantity of the contents.

The Meat Inspection Act, approved on June 30 1906, provides that every establishment in which cattle, sheep, swine or goats are slaughtered or their carcasses are wholly or in part canned, cured, smoked, salted, packed, rendered or otherwise prepared, for transportation or sale as articles of interstate or foreign commerce, shall be inspected under the Act. The inspection begins when live animals are received for slaughter, and includes a thorough ante-mortem and post-mortem examination, a rigid inspection of products such as smoked or cured meats, lard and by-products, and a final inspection when meats and their products leave the inspected establishments.

The Tea Inspection Act of March 2 1897, amended on May 16 1908, provides that all shipments of tea offered for entry into the United States shall be inspected to see that they comply with the standards of quality and purity adopted each year by a board of tea experts appointed by the Secretary of Agriculture. Every consignment of tea offered for entry into the United States is inspected, and only such tea admitted as complies with the standards.

The Bureau of Chemistry in the enforcement of the Federal Food and Drugs Act endeavours to see that out of the great volume and variety of foods coming from other countries only such as comply with the Act are allowed to enter the United States. Shipments in violation of the Food and Drugs Act are denied entry into the United States, and if not exported within three months are destroyed. If the violation is a form of misbranding that can be entirely corrected by relabelling, the importer is permitted to relabel the shipment, after which it may be admitted to the country, if the relabelling is correct. Foods that are harmful to health, however, are not admitted to the United States and must be exported or destroyed.

For the control of interstate commerce two forms of action are provided by the Federal Food and Drugs Act—criminal prosecution against the party responsible for the violation, and seizure of any shipments of adulterated or misbranded foods or drugs found in interstate or foreign commerce. Both actions may be invoked when necessary. Under the Federal Food and Drugs Act more than 14,000 cases, including both criminal prosecutions and seizures, have been terminated in the Federal courts and the results published in the form of notices of judgment. This number represents only those instances of flagrant misbranding or adulteration in which court action was necessary to check the practice. Countless minor violations have been corrected by serving notices on the firms responsible without recourse to formal legal action.

Most of the grosser forms of adulteration and misbranding which prevailed at the time of the enactment of the Federal Food and Drugs Act and Meat Inspection Act in 1906 have been eliminated as general trade practices. Occasional sporadic instances on the part of widely scattered dealers to adulterate and misbrand in the old way are still detected at intervals, but such practices are no longer general. New and more subtle forms of adulteration, however, are being detected. As a result of the effects of pure food legislation by the Federal and State Governments, and by the application of the principles of sanitary science in the food industries, very great improvement was made in the purity of food in the markets of the United States between 1910 and 1925. No other classes of merchandise are to-day, on the whole, so free from adulteration and misbranding as foods.

(C. A. BR.)

FOOD POISONING (*see* 18.29).—The term food poisoning as used by public-health workers and bacteriologists does not include the deliberate addition to food of poisonous substances with criminal intent, nor yet individual idiosyncrasy or sensitisation to certain proteins such as those contained in strawberries, eggs, milk or shellfish. Food idiosyncrasy depends primarily on a peculiar condition of the human body rather than on any dangerous quality in the food itself. The various "deficiency diseases," such as *beri-beri* (*see* 3.774d), *scurvy* (*see* 24.517b) and perhaps *pellagra* (*see* 21.69b) and *goitre* (*see* 12.191d), which are due to the lack of some essential element in the diet, are also not usually considered as types of food poisoning.

The manifestations ordinarily grouped as food poisoning at the present time are those due to:—(1) the presence of poisonous substances in healthy, untreated plant or animal tissues; (2) the introduction into food by accident, or design, of more or less familiar organic and inorganic poisons; (3) the presence in the food of living pathogenic bacteria or other parasites;(4) the presence in the food of poisonous substances elaborated by the growth of various micro-organisms.

Poisons in Plants and Animals.—Certain normal plant and animal tissues contain substances poisonous to man, and when eaten may cause illness and death; such are poisonous mushrooms and certain fish found in tropical waters. Fatal cases of oxalic poisoning from eating the leaves of the common rhubarb have occurred. Horses and cattle grazing free on the western ranges are frequently poisoned when forage is scanty and they resort to weeds and plants generally left untouched, such as the larkspur, the lupins, the water hemlock and the death Camas. Poisonous weeds eaten by cattle may indirectly produce poisoning in man. The disease known to the pioneer settlers in parts of the United States as *milk sickness* was early recognised to be connected with the occurrence of *trembles* in milch cows, but its origin long remained obscure. It is now believed that both *trembles* and *milk sickness* were due to a poisonous substance in the white snakeroot (*Eupatorium*) which was eaten by the cows when other pasturage failed.

Mineral Poisons.—Occasionally mineral poisons like arsenic and lead find their way by accident into food in the process of manufacture, as in the famous outbreak of *peripheral neuritis* (*see* 2.654) in several of the Midland countries in England in 1900, involving at least 6,000 persons and causing about 70 deaths. This was traced to the presence of considerable quantities of arsenic in the beer coming from certain breweries; it was found that the brewing sugars had been impregnated with arsenic by the sulphuric acid used in their preparation, the arsenic itself being derived from the iron pyrites used in making the sulphuric acid. More recently the cocoa sold by an English firm contained a small amount of arsenic derived from the potassium carbonate employed in its manufacture.

Long-continued action of food on containers may dissolve harmful metals such as lead, copper or tin. Tin poisoning from canned foods, although theoretically possible, is so rare as to have little practical significance, doubtless partly because such tin as is dissolved is largely fixed in an insoluble form by the solid portions of the canned food and eliminated directly from the body. Copper, although not a violent irritant, may have a highly injurious effect when absorbed during many years, as in the constant use of distilled liquors containing copper derived from the copper worm of the condenser; cirrhosis of the liver (*see* 16.803) may be caused in this way. Lead, owing to its well-known cumulative effect on the human body, is an undesirable substance to come in contact with food or drink. As long ago as 1767 the local malady of *Devonshire colic* was shown by Baker to be due to the action of cider on lead vessels. Lead poisoning has also resulted from the frequent use of acid beverages in bottles with lead stoppers. When lead was generally used in glazes and enamels for cooking vessels, recognised poisoning from these sources sometimes occurred; the enamelled ware at present in common use in England and the United States is lead-free.

Food Preservatives.—The use of food preservatives constitutes a very difficult and important phase of the problem of the addition of poisonous substances to food. Numerous substances have been added to food intentionally for the purpose of preventing the growth of micro-organisms and consequent spoiling. Some food preservatives (*see* 10.612) once widely used are now known to be poisonous for man as well as antiseptic for microbes and have been generally discarded or prohibited. Such are formaldehyde and hydrofluoric acid and their derivatives. Regarding some other preservative substances there is great diversity of opinion among those who have given the matter most study. The use of boron and salicylic acid compounds is generally, but not universally, disapproved. Benzoic acid, sulphurous acid and sulphites are regarded by many hygienists as permissible in certain foods under controlled conditions. The differences of opinion emphasise the insufficiency of our knowledge. Until information commanding the respect of all competent experts is available, it is well to err on the side of caution and minimise the use of preservatives.

The practice of adding poisonous substances to food merely for the sake of altering colour or appearance has nothing to recommend it. At the present time any danger of actual poisoning

from colouring matter added to candy, pastries and the like is slight. In most countries the health authorities maintain a list of the substances, such as certain coal-tar dyes, which are permitted, and prohibitory regulation is strictly enforced. In the United States no colours and no preservatives in foods are permitted unless they are deemed harmless. (*See* FOOD, PURE.)

Bacterial Poisoning.—Food may serve as the vehicle for certain kinds of disease-producing bacteria and other parasites. In some instances the bacteria are exclusively of human origin and occur in or upon the food as the result of contact with sewage-contaminated water or through handling by a *carrier* of disease germs, *e.g.*, the contamination of oysters with typhoid bacilli present in polluted water and the contamination of milk by a typhoid carrier on a dairy farm. In other instances the bacteria present in the food are derived from an infection of the food animal. This second class of infections is especially important in any survey of food poisoning since the gastro-intestinal symptoms produced are often sudden and violent; many of the most typical and best known mass outbreaks of food poisoning belong to this group. The nausea, vomiting and diarrhoea that characterise these attacks usually attract attention to some article of food eaten shortly before. An attack of this kind rarely terminates fatally, and the symptoms pass off within 24 to 48 hours, having little after effect. Often a history of illness in the slaughtered animal can be secured. Some of the most extensive outbreaks of meat poisoning in European countries have been traced to the use of meat from an animal noticed to be ailing and promptly killed by the thrifty peasant as an emergency measure.

The bacteria that cause this typical form of food poisoning belong for the most part to the group of *paratyphoid* bacilli, organisms closely related biologically to the typhoid bacillus, but distinguishable by laboratory tests. Within the group of paratyphoid bacilli there are several different species (*e.g.*, *B. enteritidis*, *B. aertrycke*, *B. suipestifer*) that primarily cause disease in various domestic animals, but secondarily and occasionally give rise to food poisoning in man. Food poisoning from paratyphoid bacilli would probably be much more common than it is if foods were not usually cooked. These bacteria are killed by boiling, and the history of many attacks shows that, while parts of an animal eaten raw or partly cooked have given rise to illness, other portions cooked before being eaten have been quite innocuous. Sausages made from uncooked meat or internal organs (liver sausage, blood sausage, etc.) have been the cause of food poisoning in a disproportionately large number of cases. Unfortunately inspection of the meat before sale may fail to reveal any evidence of infection, so that protection against this form of food poisoning depends chiefly on (*a*) the selection of healthy animals for slaughter and (*b*) thorough cooking of all foods of animal origin.

Foods may be also contaminated with paratyphoid bacilli by the agency of rats and mice. These rodents suffer from natural infections with these bacteria and can become carriers. Rodent contamination must always be reckoned a possibility in investigating outbreaks of this type.

Certain of the higher animal parasites occasionally enter the human body in contaminated food. The small roundworm (*Trichinella*) that causes trichinosis is one of the best known. Thorough cooking is an effective safeguard.

Ergotism.—One of the earliest established instances of poisoning due to the products formed by the growth of micro-organisms in food substances is the disease of *ergotism* (*St. Anthony's Fire*) (*see* 9.738) so prevalent in the Middle Ages. Ergot is the poison formed by a fungus that grows on rye; in times of famine the enforced use of rye that would not otherwise have been eaten led to much suffering and many thousands of deaths.

Ptomaines.—It was long believed that many instances of gastro-intestinal disturbance—the typical food poisoning of the layman—were due to the products of various micro-organisms found in partly spoiled or decomposed food. Definite chemical substances—*ptomaines* (*see* 3.174)—were incriminated, and the expression *ptomaine poisoning* (*see* 22.629) came for a time to play as large a part in popular self-diagnosis as "influenza" or "the grip." In point of fact ptomaine poisoning, if it occurs at all, must be exceedingly rare. Ptomaines appear in food substances in the later stages only of putrefaction—after about a week! Alleged instances of "ptomaine poisoning" when investigated by modern methods may almost always be traced with greater plausibility to some other form of food poisoning. "Ptomaine poisoning" may be a convenient refuge from aetiological uncertainty; it is not a satisfactory diagnosis for illness or death.

The products of paratyphoid bacilli that have grown in food may in some instances be the cause of food poisoning, even when the bacteria themselves have been killed. The determination of this question presents great technical difficulties and has not yet been settled.

Botulism.—The most conspicuous and definite example of poisoning from a microbic product formed in food is *botulism* (*see* 18.30). The chief symptoms of botulism are nervous rather than gastro-intestinal. Disturbance of vision (double vision), great weakness and difficulty in swallowing, are common signs; there is little or no fever and the temperature may be subnormal; there is rarely any pain and the mentality remains clear; the disease is always serious, over 60% of the cases resulting fatally. From 1899 to 1924 in the United States 129 outbreaks occurred, affecting 435 people and causing 290 deaths. In the only outbreak known to have occurred in Great Britain (Loch Maree, 1922), eight persons were affected and all died. Botulism is due to a specific germ (*Clostridium botulinum*) which has great heat resistance and is also able to grow in the absence of oxygen. Under favourable conditions it elaborates a toxin which is one of the most poisonous substances known. Although the germ is widely distributed in soil in many parts of the world, the conditions necessary for its development in foodstuffs are so seldom present that botulism is one of the rarest of human affections. The lack of a suitable temperature, a certain degree of acidity of the culture medium, an over-abundant supply of oxygen, the presence of certain other micro-organisms are factors that may interfere with the growth of this organism and prevent toxin formation. Nevertheless scattered cases of botulism have occurred at intervals in Europe and America for over 100 years. The first cases to be described were caused by sausage, hence the name botulism. Meat pickled in brine has also been known to contain botulism toxin. In recent years canned foods of various kinds, vegetables as well as meats, have been implicated.

The majority of the cells of *Cl. botulinum* are killed by temperatures slightly above boiling, but a very small number may survive prolonged exposure to 115° C. or even higher.

The most obvious mode of protection against this form of food poisoning is to ensure cleanliness in all foods subjected to preservative processes and, in the case of heat-preserved foods, to use so far as practicable temperatures high enough to destroy the most resistant spores of *Cl. botulinum*.[1] The majority of canned foods proved to contain botulism toxin give sensible evidence of spoilage. The botulism toxin, unlike the organism that produces it, is readily destroyed by boiling. The immediate rejection, without tasting, of any food showing signs of spoilage, and the re-cooking of canned foods before serving, constitute a second line of defence. If these precautions are followed, botulism already rare should become practically unknown.

FOOD PRESERVING: *see* CANNING.

FOOD SERVICE.—In the United States there has been, since 1910, an increasing tendency on the part of Americans to take their meals outside of their homes, *i.e.*, the growth of the community kitchen and its corollary the community dining room.

Community Kitchens and Dining Rooms.—Many reasons may be assigned for this movement. In the first place it was a natural step in view of the changes in the home itself: the urban home had become smaller, for every square inch of floor area, every cubic inch of space, cost money in rent, and consequently the functions of the home were limited so as to effect a reduction of space. The home kitchen shrank first to the kitchenette and is now in process of vanishing entirely. Even where the space for an elaborate kitchen is available, the problem of getting suitable servants is so troublesome as to induce many to get along with a minimum of domestic service, and, as the mistress of the house is herself less willing to be a kitchen drudge than formerly, many meals are taken outside the home, particularly those of an elaborate nature. Private hospitality is more and more offered in hired hotel space in preference to the home. Banquets and other special functions are easily handled in public dining rooms and involve little responsibility on the part of the host and hostess. The emancipation of women is another factor. Many women have succeeded in establishing themselves, professionally or commercially, before marriage. They prefer financial independence to keeping house. The small, compact, efficiently arranged apartment is the result, with meals away from the home.

These factors are intensified by the constantly rising standards of living and by the greatly improved marketing technique which has stimulated a demand for many possessions previously non-existent or rare. Demands upon the family income have advanced, encroaching upon the former budget allotment for rent and servants. Small and servantless homes come as a natural sequence. If even then the income is too meagre, the modern woman has no hesitation in aiding her husband to double it by taking a position herself. Another blow to the home as the chief or sole source of prepared food has been dealt by the automobile and touring habit. It is estimated that in 1910 there were in the United States less than 350,000 automobiles; in 1925 over 17,000,000 were registered. Such an increase in the use of a personal means of conveyance with a day's travel radius of, say, 200 m. could not but have its effect on the food habits of the nation. "Automobile" business is considered a substantial part of the total business of hotels and restaurants.

The hotel kitchen, like its domestic counterpart, has had its troubles with its personnel, and for similar reasons. Working, however, on a larger scale and increasingly on standardised products, it can make readier use of machines as a substitute for labour. The modern quantity kitchen is thinly staffed but splendidly equipped. Washing-machines for dishes, glassware and silver, each adapted to the task in hand, enable two men to do the work of ten and to do it better. There is less breakage, the silver bears an enhanced sheen, and the bacteria count is reduced 90 per cent. Dirt and filth, once the bugbears of any but the most expensive dining places, are now perhaps more rare in hotels than in the home. There are also the great mixers which, for example, beat up a bushel of mashed potatoes or a gallon of cream with equal facility, the steam-cookers, the potato-peelers and a host of smaller indispensables that save time, labour and space where food is cooked on a wholesale scale. Electricity has helped in cookery and is now applied to refrigeration.

The Cafeteria System.—The service side of the problem has also advanced. The use of the steam-table has solved one of the problems of public service by keeping dishes hot and food tasty during the minutes or even hours that elapse between preparation and eating. The modern coffee-urn makes possible the preparation of five gallons at one time, a difficult feat under the old procedure. The newer methods of service bring the consumer and his food together without delay. The cafeteria system, under which all the dishes in the menu are displayed before the customer, who helps himself, has made quick service possible and cheap. Whatever losses there may be aesthetically, and these need be few, are broadly balanced by the pleasure of being able to make a direct selection of food. Incidentally, the cafeteria system has placed a premium on attractive, neatly arranged dishes. Another development, exclusively metropolitan, for those who want only a little food quickly, is that of the sandwich shop, luncheonette or expanded soda-fountain counter, where light refreshments are dispensed under conditions that permit high speed. Frequently these places are operated in chains, so that large numbers of sandwiches, for instance, are prepared in a locality where rent is low and trucked to small luncheon counters crowded into nooks that tap main streams of city workers. Such places appeal to the clerical worker or office girl who has little to spend and who seeks only a light lunch.

A closely related development is the delicatessen store, which sells prepared food but does not serve it. These, located in territories of concentrated population, present still another solution to the consumer's problems of limited space and few and high-priced servants. They eliminate much of the work and annoyance of cooking food in small, ill-ventilated apartments, while permitting the enjoyment of family privacy in consuming it. Similarly, in the large apartment hotels recently erected in the big cities, provision is usually made for extensive "room service." The kitchens of the hotel make it a part of their business to prepare meals which will be served in the rooms of the apartment dwellers. Special elevators and floor pantries assist, and special dishes and equipment have been devised to help keep the food in its best condition. Such a combination of wholesale cookery with individual service is practicable only in large, high-grade apartment hotels, but it has distinct advantages where conditions permit its use.

The conditions described are evident to all observers. Accurate statistics on the subject are lacking, however. Difficulties in the definitions of hotels, restaurants, boarding-houses and other eating places make current figures unreliable, and even less reliable the figures of 1910. Two estimates may be mentioned. The *Hotel Monthly* calculates that nearly 5,000,000 persons in the United States take a majority of their meals in public eating places and that they spend therein over 1,250 million dollars a year for a total of 4,000 million meals. *Hotel Management*, on the other hand, estimates that about 8,000 million meals per year are served outside homes and, taking a somewhat higher average amount spent (50 cents as compared with 35), reaches a figure of 4,000 million dollars of annual expenditure in public dining-rooms. This wide divergence between two competent authorities illustrates the difficulty of accurate estimate in hotel and restaurant statistics. It is evident, however, that the nation's restaurant bill might conservatively be estimated at over 1,000 million dollars a year. If the value of the food eaten by the employees and managers themselves and that sold for immediate consumption is included, but the canned and package-prepared foods omitted, a figure of 2,000 millions was probably too low rather than too high in 1925. (H. B. M.)

FOOD SUPPLY.—War influences the food supply in belligerent countries directly, and in neutral countries indirectly, through deterioration or distortion of agriculture, disorganisation of shipping, disintegration of finance and changes in consumption. During post-war reconstruction the abnormalities persist in modified form, broadly proportional to the severity and duration of the struggle, often attended by new disturbances contingent on inherent developments or proceeding from misdirected efforts at restoration of the *status quo ante bellum*. Sooner or later, a new equilibrium is established between agriculture, industry, transportation and finance.

During a war of large extent and long duration, agriculture suffers heavily in the belligerent countries and prospers seemingly in unadjacent neutral countries. After the war, agriculture recovers in the belligerent countries, but in the neutral countries undergoes liquidation. The governmental restraint of competi-

tion, effectual during war, is likely to be followed by excessive competition. It is from this panoramic viewpoint that a scrutiny of the results of the World War on the food supply of the world is to be undertaken.

I. THE WAR AND AGRICULTURE

Shortage of Men, Horses and Fertilisers.—No matter how categorically agriculture is classified as an essential industry in a country at war, the labouring forces of the land are drawn on by the military authorities. Landowners, tenants and hired workers are mobilised for military service. Horses are requisitioned. In the World War this recruiting of rural workers continued intermittently until the farm work was done largely by males past middle age and under 16, and by women. The working forces suffered in number, in skill and experience. Some replacement was effected by stationing prisoners of war on the land, but the agricultural result was everywhere inconsiderable. The requisitioning of horses made it necessary to use cattle as work animals, to the direct injury of the milk supply.

Only a partial picture of the effect of military recruiting is obtained by contrasting with the rural population the number of soldiers drawn from the land. The effect was more than the numerical ratio, and worsened progressively as the War continued. It was only by the redoubled and heroic efforts of old men, women and children that agriculture was kept going. Not alone human and animal forces were reduced, but material forces also. After the second year of the War there was practically no upkeep of implements. Deterioration of equipment rendered cultivation of the soil ineffective and imposed undue hardship on the workers, and agricultural practice became primitive and manual.

Pre-War European agriculture was heavily dependent on the use of chemical fertilisers, the supply of which declined rapidly. The United Kingdom drew saltpetre from Chile, phosphates from the United States and potash from Germany; under scarcity of tonnage and the munition demand for nitrogen, Chile saltpetre as a fertiliser became practically as scarce in the United Kingdom as was potash from Germany, and imports of phosphate declined. Despite huge domestic deposits of potash, Germany was unable to maintain the pre-War use of potash, though large amounts were applied to certain areas for particular crops in the vain hope of making good the lack of nitrate and phosphate. Since no imported phosphate rock was available to Germany, a grossly inadequate volume of Thomas slag remained her only source of phosphate. In France, the use of phosphate rock, saltpetre and potash declined to insignificant amounts.

In all belligerent countries, the by-product ammonia, previously largely used as fertiliser, went into munitions. Deprived of German potash, the agriculture of the United States was limited to the petty amounts of potash produced in War-born plants. Phosphate the United States had in abundance, until transportation became too congested to permit of normal movement. Saltpetre continued to be used on the soil in that country, though to a reduced extent. Sugar-producing areas, such as the West Indies, the Hawaiian Is. and Java, found their supplies of nitrate and ammonia greatly reduced. The neutral countries of Europe were little better off than the belligerents. Germany did, indeed, furnish potash to Holland and Scandinavia, as deliveries in blockade bargainings, but the amounts were small. Everywhere in Europe the prices of nitrate, ammonia, phosphate and potash became excessive for agriculture, when contrasted with the returned increments in crop yields.

The cumulative results of withdrawal of men and horses, deterioration of farm implements and lack of fertilisers operated in belligerent countries, so far as field crops were concerned, in four directions, mainly: (1) Acreage was reduced. (2) Yields per acre were lowered. (3) Weeds, pests and diseases had free run with corresponding deterioration of farm products. (4) The losses attending unfavourable weather were accentuated.

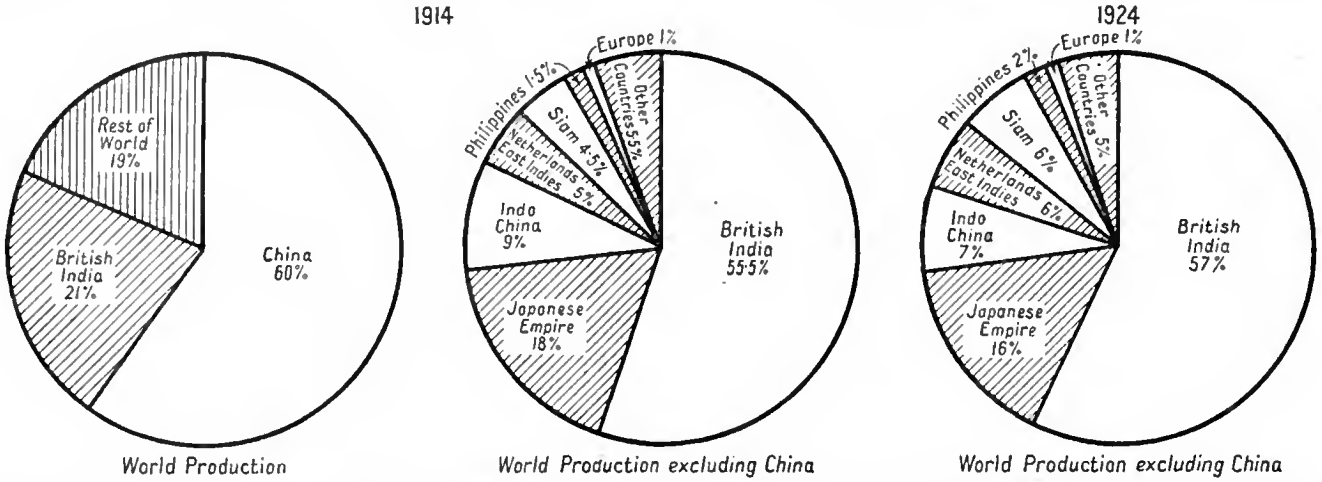

FIG. 1.—The total world production of rice in 1914 was estimated at 2,000,000,000 quintals. The total annual production of countries for which returns were obtained averaged 769,496,000 quintals for the period 1909–10 to 1913–4, and 849,415,000 quintals for 1924–5. The world's total production in 1924–5 was estimated at 1,300,000,000 quintals. (NOTE.—Percentages are necessarily approximate owing to incomplete data. No data is available for China after 1914.)

Preference to Primary Foodstuffs.—It became a necessary War policy of agriculture in belligerent countries to use land for primary foodstuffs in place of raising feeding stuffs out of which meat and dairy products might be produced. According to common European practice, an acre of land devoted to bread grains would produce more than four times as many calories for human food in the form of flour as could be secured in the form of meat and dairy products if the land were devoted to animal husbandry. In the case of potatoes, the economy in land was still greater. Contrasting beef cattle, hogs and dairy cows, the greatest waste of land occurred in the production of beef, the ratio of return being much greater in the form of pork or milk. On the other hand, cattle subsisted largely on forage not suitable for human food, while hogs were raised to a considerable extent on cereals adapted to human use or on special fodders grown on land that could produce cereals, potatoes or sugar. In order to make the best use of the land in terms of human nutrients, belligerent countries were compelled to reduce heavily the herds of swine and beef cattle. The count of dairy cattle was somewhat reduced, though efforts were made to conserve the milk supply.

As a result of these operations, some performed voluntarily by the

peasants and others executed under governmental orders, the count of cattle in Europe was reduced probably by 20–25% and of swine 30–40%. Despite the fact that sheep stood somewhat apart from cattle and swine, the general result was much the same, though some countries like Germany increased the number of sheep and goats. Sheep competed little with human beings for products of the soil or in the use of acreage, subsisting largely on feeding stuffs inappropriate to human use and grown on terrain unadapted to cultivation. In addition, wool was highly valuable; nevertheless, some countries showed a heavy reduction in the count of sheep.

The yield of meat and fat per animal was reduced owing to scarcity of feeding stuffs and to an abnormally high percentage of slaughter of immature animals. On the other hand, peasants concealed animals from the authorities, reporting fewer animals than they had and delivering less of products that they produced. This duplicity on the part of the peasants was due partly to predilection for animal husbandry, partly to the greater profits of animal products as against cereals or other primary foodstuffs. The evasion thus described was least in evidence in Great Britain. In every country one found after the War widely contrasting areas, some in which animal husbandry was most deplorably reduced, while in others the conditions were practically normal.

It is difficult to compare estimates of acreage under cultivation and counts of domesticated animals with those of the pre-War period on account of the changes in the map of Europe. It seems probable, regarding Europe (excluding Russia) as a whole, that the acreage under cultivation and the count of domesticated animals has been restored generally to the pre-War level. The restoration of cultivated acreage has not been accompanied by restoration of pre-War yields, since there is still shortage of fertilisers. Also, the yield of meat and dairy products per head of animals is below the pre-War level, due to shortage of imported feeding stuffs. It is difficult to accomplish a restoration of animal husbandry in Europe until feeding stuffs from Russia are again freely available. Broadly considered, the recovery of European agriculture in the seven years after the World War was more rapid than was to have been expected, in consideration of the extent and duration of the struggle.

Adaptive Devices of Agriculture.—Efforts were quite generally made in the belligerent countries, following agricultural policies that varied in accordance with the characteristics of the region, to raise the maximum volume of foodstuffs in terms of calories. The agrarian class everywhere had two motives: patriotism and price, though patriotism was perhaps less effective than price as a stimulant to production. In many countries peasants would give their sons without question, but not their crops, particularly not their animals. In order to stimulate production, farm prices were advanced, costs of distribution were reduced by establishing control of middlemen, and prices to consumers fixed at the lowest relative level possible; but the systems adopted worked out less well in some countries than in others. As the burdens and costs of agriculture rose, the price demands of peasants increased. In every country the rural population believed there was profiteering by urban industries, a belief which led to reprisals by agrarian classes in the form of pressing demands for higher prices for farm products. Governments everywhere were trying to satisfy the city with lower prices and the country with higher prices, usually failing in both directions. In some countries, farm prices of produce rose to four or five times pre-War figures.

In the neutral countries of Europe the situation was much the same. These countries were exporting farm produce to the belligerents. Usually the warring groups were bidding against each other. Each belligerent group used the power of the blockade to coerce the neutral countries of northwestern Europe. The governments of these neutral countries were concerned with keeping the urban cost of living down; but they had an interest in permitting the peasants to exploit the belligerents as much as possible. The peasants in neutral countries had valid grounds for high prices, since the costs of agriculture and of consumers' goods had risen. They demanded coverage prices, then still more. Under these circumstances, in the neutral countries of Europe, as well as in belligerent countries, wherever transportation permitted movements of foodstuffs and feeding stuffs, there was a continuous trend towards higher prices for farm products, restrained or directed by governmental control, though practically unrestrained by competition between producers.

All growers of cane sugar were at the mercy of the Allies, and sugar prices were definitely restrained; nevertheless, War prices were substantially higher than those prevalent before the War. In belligerent Canada and Australasia, prices of essential foodstuffs rose gradually throughout the War, particularly those destined for shipment to Europe. The neutral countries of South America were able to secure relatively higher prices for essential foodstuffs, though the prices of some unessential foodstuffs declined. Raising wheat in Argentina was a better business than raising coffee and chocolate in tropical America.

The markets of the Central Powers were closed to neutral overseas countries by blockade; shipments from neutral overseas countries to the markets of neutral European countries were restricted by allocations by the Allies. Entrance to the markets of the Allies was restricted by governmental control over imports, attempting to separate essentials from non-essentials (*see* CONTROL), with the result that necessaries were able to command higher prices, while the prices of non-essentials declined heavily in the countries of origin.

II. EFFECT OF THE WAR ON CONSUMPTION

The *per-capita* intake of food was relatively reduced all over Europe, and absolutely reduced in the belligerent countries. Nevertheless, the *per-capita* food needs were higher in war than in peace; Europeans worked harder, wore poorer clothing, and heated their houses sparingly, all of which meant increase in food requirements.

In many belligerent countries it was impossible to secure a balanced diet with the requisite quantities of proteins and vitamins, and the situation became worse with each year of the War. With increased heat requirements, *per-capita* shortage of calories resulted in loss of body weight. Scarcity in the indispensable factors of the diet, together with a low intake of protein, resulted in retardation of growth of children, and in the development of marasmus and dyscrasias. Despite a quite general lowering of the birth-rate, in many countries morbidity and mortality were increased in children below the 10th year. Stunted growth was frequently observed between the 10th and 15th years; and the physical structure of many European children has been permanently injured by the nutritional disturbances of the War diet. The course of tuberculosis was intensified and the decline of the aged accelerated. Mere loss in body weight, quite generally observed in healthy adults in the countries of the Central Powers, was probably on the whole not an injury.

The pre-War level of consumption of food, in quality and in quantity, was not restored with peace. Indeed, in many parts of Europe, despite extensive relief operations conducted by the American Relief Administration (extending practically through three years following the Armistice), malnutrition and subnutrition persisted for years. Even in Jan. 1926 the diet of Europe in the comparative pre-War sense was, perhaps, normal only in Scandinavia, Spain, Portugal and Holland. The *per-capita* diet of the former belligerent countries is still probably somewhat subnormal in quantity and abnormal in respect of certain components, especially the relations of primary and secondary foodstuffs. Europe, as a continent, has to-day a notably heavier vegetarian diet than before the War, and this may be expected to persist for some time to come.

The diet of Europe is still probably deficient in fats. The supply of animal fats was reduced by slaughter of animals. Furthermore, the animals were insufficiently fed, and gave less milk-fat and less carcass-fat. Before the War Europe imported large supplies of vegetable oils. Russian export of vegetable oils ceased in 1915, and the blockade prevented edible oils from reaching the Central Powers from overseas. Scarcity of tonnage and marine warfare reduced the importation of edible vegetable oils to the allied countries. Importations into the neutral countries of Europe were reduced by blockade rationing. The effect was to lower the ratio between the fat and starch components of the diet of each country. Shortage of fat was more severely felt than shortage of sugar, and intensified the effects of shortage of milk.

The War induced modifications of the diet in many countries in Europe as the result of peasant reactions to governmental control. Illicit trade in foodstuffs, inevitable under any system of war control, became worse as the War continued and the technique of evasion was developed. (National pyschologies differed; there was comparatively little illicit food trade in England; in Germany it was rampant.) Food smuggling became a profession. As the War proceeded and the difference in price-returns between cereals and animal products became more extreme, the peasants concealed animals, delivered to market at the fixed price as little of animals and animal products as possible, sold as much as possible at high prices through illicit traffic, and increased the farm-household consumption. Milk, the most important single food for the urban population, suffered most because butter was the favourite article of illicit traffic. There was in most countries, therefore, a substantial degree of justice in the contention of urban Socialists, that the country districts were treasonably enriching the rural diet at the expense of the urban working classes.

This situation did not terminate with the War. Even after seven years of peace in many countries of Europe, of which perhaps Russia is the most notable illustration, the diet of the rural classes is richer in animal products than it was before the War; the diet of the urban classes is poorer. With deterioration of the buying power of urban workers since the War, this has had the result of increasing rural consumption of animal products; the town diet has become more vegetarian.

III. LIQUIDATION OF WAR CONDITIONS

The abnormalities in the production, marketing and consumption of foodstuffs during the reconstruction period were due to a

variety of factors. Manufacturers who enlarged plants, making goods usable during peace as well as war, but subject to particular wastage during war, foresaw the dangers of such war expansion as would represent over-extension after the War, and in a variety of ways sought to evade the losses of post-War liquidations. The world still has unliquidated War expansions in flour-milling, sugar-refining, milk-condensing, food-canning, copper-smelting and leather-making, to mention only a few illustrations. Agriculture was generally urged to expand, with the result (naturally with exceptions in different countries and to different extents in different regions) that at the close of the War agriculture was over-extended by comparison with the pre-War position, and particularly with respect to the purchasing power of the world.

Over Europe the emphasis on the extension of primary foodstuffs, the reduction in the herds of domesticated animals, the scarcity of fertilisers and the deterioration of farm implements, together with the pressure to produce food stuffs to the maximum extent, led to the ploughing up of grass lands, to be used for the raising of primary foodstuffs. Agricultural authorities foresaw clearly the inevitable future repercussion of this movement. The policy of turning pasture to tillage reached its highest expression in the United Kingdom, and the deplorable post-War results are most clearly seen there, though observed to a lesser extent on the Continent.

Since the War, the agriculture of the United Kingdom has experienced a crisis as severe as that which characterised the period of agitation over the Corn Laws. British farmers have found that the enlarged area of tillage cannot be remuneratively cultivated; operative costs have been high, and the country has been deluged by agricultural produce flowing from overseas countries also suffering from War-expansion of agriculture. Throughout Europe, one of the results of agrarian distress, proceeding more or less from War over-expansion in the different countries, has been the revival of agrarian protectionist movements. This is not to be interpreted to suggest that Europe contemplates de-industrialisation in favour of agriculture; it represents merely a grasping at what seems to be an instrument of first aid. In part, it is a beggar-your-neighbour movement.

Cereals.—Europe may be expected slowly to recover her pre-War output of primary and secondary foodstuffs. This has been practically attained for cereals, and will soon be accomplished for sugar. In Russia, the recovery of agriculture has been most delayed, and the period of reconstruction may be notably prolonged. The recovery of agriculture is more rapid in western Europe than in the central countries between the Baltic and the Adriatic seas, on account of the higher natural position of agriculture, better railways, sounder fiscal policies and superior governments. Since the World War, western Europe has been compelled to secure a larger proportion of her imports of cereals from overseas, so that overseas countries have temporarily replaced Russia and the Danubian and Balkan States.

Sooner or later (probably sooner for the Danubian and Balkan States and later for Russia), these States will return to their natural position as preferred primary sources of supply of cereals for western Europe—for the one main reason, in addition to others, that these exporting countries must pay for necessary manufactured goods from western Europe with exports of cereals. During this time of readjustment the over-extended surplus-producing countries of North America, South America and Australasia face a gradual reduction in the scale of this agriculture, in so far as they may not be able to find new markets in the expanding population of the world.

The average acreage of the staple cereals in the United States during the years 1918, 1919 and 1920, was 230,000,000; the acreage in 1924 was 218,000,000. But for wheat the extent of liquidation represents a reduction of something near 20,000,000 acres. In the case of Canada, Argentina and Australia, there has been no such decline in wheat-growing. Indeed, the combined acreage in these three countries suggests continued expansion rather than contraction. When the definitive restoration of wheat-growing occurs in Eastern Europe, wheat-growers in Canada, Argentina and Australia will face liquidation with the development of a diversified agriculture, as has happened in the United States, or new markets for wheat must be acquired. The outcome will depend, among other things, upon development in the standard of living in the world, the penetration of industrialisation into Russia and Asia, and the competition between wheat, rice, millet and maize.

Sugar.—A good illustration of the disturbance in a staple foodstuff as a result of war is to be observed in sugar. Before the

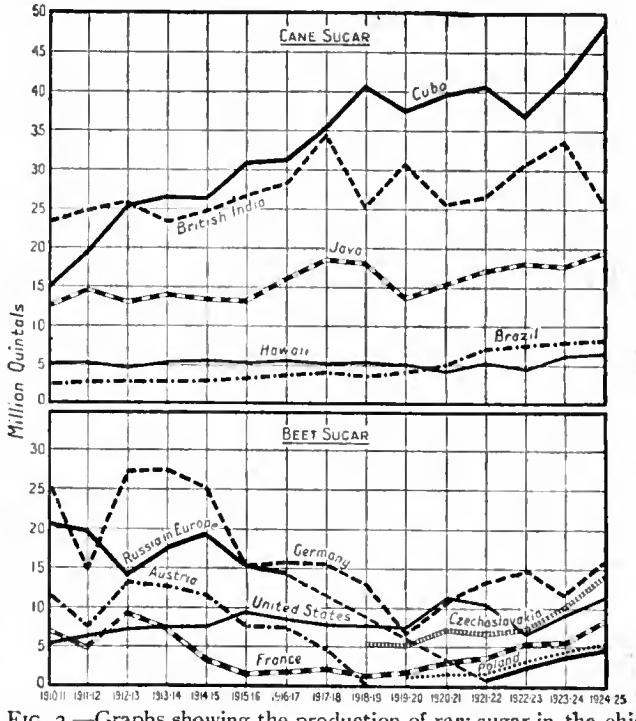

FIG. 2.—Graphs showing the production of raw sugar in the chief sugar-producing countries, for each year from 1910–1 to 1924–5.

War, beet sugar and cane sugar competed internationally. Beet sugar was grown little outside Europe and Russia; cane sugar was grown in practically all tropical countries, and could readily be expanded. The production of beet sugar was greatly reduced during the War. The countries of western Europe replaced the beet sugar they had previously purchased from central and eastern Europe in part with cane sugar from overseas. A widespread expansion of sugar-cane growing followed. In some of the sugar-cane countries the planting is annual; in others the cane is cut, without replanting, over a number of years. When a new stand of sugar cane has been set and provided with transportation and refinery, this culture tends to persist, since sugar-growing is a form of agriculture associated with large capital.

In 1909–13 the world crop of beet sugar was about 8,000,000 short tons and of cane sugar about 10,000,000 short tons. In 1920–1 the world crop of cane sugar was over 13,000,000 short tons and of beet sugar only 5,000,000 short tons. Since then the production of cane sugar has continued to increase; at the same time, the beet-sugar areas are being restored. The sugar crop of the present season is over 17,000,000 short tons of cane sugar and over 9,000,000 short tons of beet sugar. When beet-sugar cultivation in Europe and Russia has been fully restored, unless there is some diminution in the output of cane sugar, the whole crop will be something like 18,000,000 short tons of cane sugar and 10,000,000 short tons of beet sugar. Can the world absorb this sugar? Certainly—at a price. Whether, with the restoration of the beet-sugar yields, the expanded cane-sugar acreage can be maintained or must be reduced, remains to be seen. In the meantime, the result for the world is a large supply of sugar at a beneficent price. Recent complicating developments are governmental restriction of cane-sugar production in Cuba and governmental bounty on beet-sugar production in Great Britain.

Other illustrations of agricultural expansions that became

transformed into problems of liquidation are cattle-raising in the United States and Argentina and sheep-raising in Australasia. The expansion in cattle-raising in the United States was relative rather than absolute; none the less, the difficulties of American cattlemen have been due in good part to an increase in export of beef products from something like 150,000,000 lb. per annum just before the War to over half a billion lb. in 1918–9, with subsequent recession to the pre-War level. This restriction of outlet, together with other factors, has necessitated a heavy liquidation. In the case of Argentina, the volume of the War market for chilled, frozen and packed meats resulted in over-expansion of the industry, followed by a post-War crisis so severe as to have prompted governmental action in price-fixing and subsidy. This also holds true of animal husbandry in Australasia, which, despite the distance, was led to over-expansion as a result of heavy demand for chilled and frozen meats during the War. In Australia also, the crisis of liquidation found expression in the use of public funds for the purpose of stabilising prices and minimising losses.

There is scarcely a country in the world in which some particular form of agricultural production was not over-stimulated during the War. Hence, post-War problems of liquidation of varying extent and severity have everywhere arisen—writing-off of inventories and absorption of losses, liquidations imperative for the safe conduct of future business. Students of world agriculture may agree that producers exploited the belligerent countries during the War. They will also probably agree, a decade from now, that the gains of such profiteering have already been lost, or more than lost, to the agriculturists as a whole, if not to particular individuals. And high food prices imposed on consumers between 1915 and 1920 have since been requited by dumping foodstuffs at less than the cost of production.

In particular countries, certain crops did not share in the World War expansion but have nevertheless suffered in the post-War liquidation. Of these, illustrations are wheat-growing in Australia and sugar-raising in Java. Australia was too far from Europe to have much call on ocean tonnage for shipment of wheat, and wheat accumulated in Australia during the War. These accumulations were exposed to heavy losses; grain is marketed in Australia in bags, storage capacity is limited, and large amounts of grain were exposed to vermin and the elements. Australia had no opportunity remuneratively to unload wheat on the world before the collapse of the wheat price in 1920. The situation thus created was one of unusual gravity for the small population of the Commonwealth, and has found expression in more or less continuous pooling and price regulation. In the case of Java, western European needs for sugar could be covered with sugar purchased on money borrowed from the United States and with a much shorter ocean haul. Thus the sugar industry of Java was stagnant during the War, and although it enjoyed a short period of high prosperity just after the War, this was soon terminated by the collapse of sugar prices.

The history of sugar prices during and since the War furnishes a good illustration of the contrast between correct statistics and incorrect opinions. Following decontrol of sugar, with the failure of purchase of the Cuban crop for the season 1919–20, the public, including sugar-producers, American importers, refiners, wholesalers, fruit-packers and candy-makers, assumed that the supplies available to the United States were short and inadequate to her needs, that demand for sugar in that country would prove to be quite inelastic, that sugar-hungry Europe would expand her importations, and that the rest of the world contained no visible or invisible stocks of moment. On the basis of these assumptions, a veritable trade hysteria resulted, culminating finally in a sugar price of some 23 cents. These stated assumptions were all more or less unfounded, and as the facts became revealed the price of sugar declined precipitously. The Cuban supply proved larger than anticipated; consumers' demand in the United States was found to be relatively elastic; sugar-hungry Europe did not demand more sugar at high prices. Instead of a shortage of sugar stocks throughout the world, sugar poured in from every conceivable direction. Hoarding was replaced by dumping. The huge gains in the spectacular rise of price (some realised, but mostly paper profits) were replaced by huge real losses that fell on producers, refiners and traders. Since sugar-beet growing in Europe is a long-view proposition, the recovery of this branch of agriculture was aided little by the price rise and has been retarded little by the price decline.

IV. CONSIDERATIONS BEARING ON MOVEMENT OF FOODSTUFFS

Despite the fact that the food supply is classed as the prime necessity of society, demand for foodstuffs is somewhat elastic and there is considerable variability contingent on adaptations and substitutions provoked by price relations. To a considerable extent, also, the distribution of foodstuffs is contingent on fluidity of finance; abundance or scarcity of credits has exerted considerable influence on the distribution of staples since the War. Credits from the United States, as well as the foreign investments of American nationals, tourist expenditures and immigrant remittances, have directly and indirectly facilitated the export of surplus agricultural produce from the United States, to some extent to the detriment of corresponding exports from Canada, Australia and Argentina. Public money has been used in Argentina and Australia in furtherance of the marketing of agricultural produce, and this, we may infer, to the injury of exportable produce from the United States. If surplus-producing countries employ public funds in furtherance of exports, the international movement of foodstuffs will be different from what would be expected if purely competitive relations obtain. It is difficult in surplus-producing countries to resist the political influence of agrarian blocs in their insistence on some form of relief through the use of public funds.

One post-War difficulty of agriculture, more or less general the world over, that finds expression in the food supply, has been the increased cost of labour. Without entering into the reasons for this advance in wages, it is sufficient to state that in most countries, both importing and exporting, the level of wages has risen substantially above the pre-War plane. To a considerable extent also labour costs have risen, since in many directions the efficiency of labour has not increased proportionately to the increase in the wage scale.

For many countries the position has been accentuated by the trend of movement of workers from country to city. Enlargement of wages of farm workers has resulted in increase in cost of production of farm produce. Since increase in wages of industrial workers has, at least to some extent, and in many directions, resulted in notable elevation in prices of industrial goods, this has had the effect of lowering the purchasing power of agricultural products in terms of goods and services. The measure for each year since the War in the different producing countries of the world of the purchasing power of staple foodstuffs—for example: wheat, corn, sugar, cattle, hogs, wool and coffee—amply confirms the broad fact. Only under special circumstances has the purchasing power of agricultural produce been raised relatively above the pre-War level. There is considerable readjustment in this direction to be expected the world over, since if such readjustment does not occur, this would imply a lower standard of living on the farm than in the town. This readjustment may be expected to include, from the side of agriculture, the elimination of submarginal areas and increase in efficiency of cultivation and management over the remainder; and, on the part of industry, increase in the efficiency of labour and improvement in mechanical operations, with resulting lowering of production costs.

A survey of the total commerce of the world in successive years since the War shows a relative overproduction of agricultural produce and a relative underproduction of industrial goods, though the margin is being gradually reduced. This has had the effect of lowering the purchasing power of agricultural produce in terms of industrial goods, which was relatively low at the beginning of the century and notably higher just before the War. After the War this relationship again became comparable to that existing at the beginning of the century.

The food supply of the world is modified by conditions of transportation, since both fluidity and cost of movement have influence on distribution and marketing. Transportation has been a limiting factor in the export of grains and oil seeds from Russia since the War. The railways of western Europe have been largely restored to their pre-War efficiency, except in the Danubian and Balkan States, whose crippled facilities still impose limitations on the movement of farm produce. The effective service of railways has been one of the outstanding features of the post-War situation in the United States and Canada. Ocean shipping rates have been low since the War, and this has facilitated movement to importing countries of surplus supplies from exporting countries the world over.

V. PROSPECTS OF THE NEAR FUTURE

Changes in the food supply of the world will depend to some extent upon developments in industry as well as in agriculture. During the period 1915 to 1925 numerous backward countries of the world increased their manufacturing facilities and thus rendered themselves less dependent on European goods. If these new industries maintain themselves, the retardation of recovery of European industries (whose output as a whole is still considerably below normal) will be prolonged, unless new markets and a higher standard of living in the world result in a general expansion of demand for manufactured goods. A point of particular importance is Russia. If the present low standard of living is continued in Russia, this will have an indirect effect on the food supply and manufacturing activity of Europe. The degree to which goods from manufacturing industries in India, China and the British dominions are able to supplant the products of corresponding industries in the United Kingdom, is another point of importance.

It is probable that the food supply of the world during the next 10 years (1926–36) will be relatively below the pre-War level and more vegetarian. It would be an error to expect the world to direct the first energies solely toward the restoration of the pre-War food supply, leaving the restoration of the standard of living in the matter of other goods and services to be deferred. Various groups of demands will compete in their claims on income, and the demand for food will not be able to secure a proportion of the income so large as to insure in the near future the restoration of the pre-War diet. The best that can be hoped for, so far as Europe is concerned, is to secure a diet competent in the nutritional sense; but a cheaper diet, less diversified, and less luxurious than was the case before the War. The agriculture of the surplus-producing countries will necessarily have to adapt itself to these developments.

We are accustomed in world trade to view manufactures from the standpoint of the international division of labour. If the food supply of the world is to be correctly appraised, it must be considered from the same standpoint. The world faces during the next decade the necessity of establishing a new equilibrium in the demand and supply of foodstuffs, representing a new equation between effective demand and remuneratively produced supply, a revised international distribution of labour in agriculture and manufacture, distorted, however, to an unforeseeable extent, by artificial controls, bounties and protective tariffs.

Since the War, Europe has been financing the importation of foodstuffs largely with borrowed money, credits, tourist expenditures and immigrant remittances. Before the War, Russia was a borrowing country; but, with Russia excluded; Europe was a lending continent. Outside of the United Kingdom, which remains a lending country, Europe, as a result of the War, has become a borrowing continent. With each year since the War, European governments, industries and even agricultures contract new loans at relatively high interest rates. Disregarding entirely European payments of War debts to the United States, the service charges on post-War European borrowings will represent a growing burden on the continent, a burden certain to be reflected in international trade, since the difficulties of transfers of international payments find their ultimate expression in the commerce of goods and services.

Ultimately, Europe must pay her international obligations with goods and services; but this is not to be expected during the next five or 10 years, during which time we expect adjustments to occur largely through the invisible items in the international accounts. But the time approaches when Europe must raise a larger proportion of her food supply or pay for a larger proportion of it with goods and services. The necessary adjustments contingent on these developments form part of the new equilibrium between demand and supply of foodstuffs toward which the world is inevitably trending. (A. E. T.)

FIG. 3.—World exports of refrigerated Beef, Mutton and Lamb. The increasing importance of South America in the supply of meat products is clearly seen by these diagrams, in which exports for 1910 and 1925 from each country are shown as a percentage of total world exports. (See Table.) The chief importing country is Great Britain, which takes some 60% of the world's available supply.

BIBLIOGRAPHY.—International Labour Office, *Enquête sur la Production* (1923); International Institute of Agriculture, *International Yearbook of Agricultural Statistics* (Annual); United States Department of Agriculture, *Agricultural Yearbook* (Annual); see also Reports of Ministry of Agriculture of Great Britain, etc.

The accompanying diagrams and tables illustrate the principal sources of food supplies, except wheat, maize, oats, rye and barley, which are dealt with in the article on GRAIN PRODUCTION AND TRADE, during the period 1910 to 1925.

Sugar.—The production of both cane and beet sugar greatly increased after 1910. The following table gives the exports of sugar in *short tons* from the chief exporting countries for the average of the period 1909–13 and for 1922.

Country	Average 1909–13	Average 1922
Cane Sugar		
Cuba	2,009,899	5,581,376
Dutch East Indies	1,412,555	1,582,691
Mauritius	226,255	322,692
Brazil	38,284	277,903
Peru	146,736	302,447
Philippine Islands	179,432	399,112
Dominican Republic	92,351	189,195
Beet Sugar		
Germany	873,161	13,915
Austria-Hungary	848,830	..
Czechoslovakia	..	350,366
Netherlands	200,490	219,477
Russia	293,514	..
Poland	..	65,344
Belgium	154,476	177,594

The production of sugar in the chief producing countries for each year from 1910–1 to 1924–5 is shown in the chart below, based on figures given in *The International Year-book of Agricultural Statistics*. The total world production in the pre-War period and in 1924–5 was:

Average	Beet Sugar quintals	Cane Sugar quintals
1909–10 to 1913–4	83,990,000	95,668,000
1924–5	81,690,000	150,845,000

Meat Products.—The table below shows world exports of refrigerated beef, mutton and lamb for 1910, 1913, 1917 and for each year from 1920 to 1925. Of particular interest is the great increase in exports owing to war demands, the growing importance of Argentina,

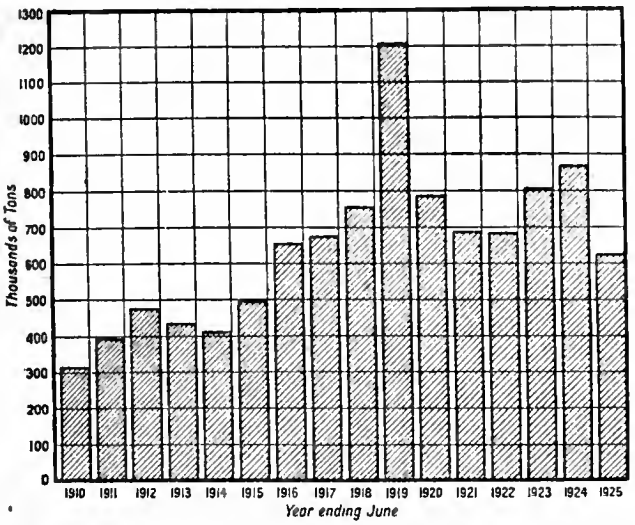

FIG. 4.—Exports of Pork and Pork Products from the United States. The United States is the source of over two-thirds of the world supply of pork products. This diagram shows the export of fresh, canned and pickled pork, cured hams and shoulders, bacon, lard and neutral lard for each year from 1909–10 to 1924–5. The chief importing countries are the United Kingdom and Germany.

Brazil and Uruguay, and the decline in exports from the United States. Exports from the chief exporting countries are shown in fig. 3 as a percentage of the total. The importance of the United States as a source of pork products is clearly shown in fig. 4.

FOOT AND MOUTH DISEASE: *see* VETERINARY SCIENCE.

FOOTBALL, ASSOCIATION (*see* 10.621).—The Football Assn. of England, having helped materially in the development of the game in Europe, made a departure in 1910 when, at the invitation of the South African Assn., a team of amateurs and professionals was sent in May to that Dominion. A successful tour carried forward the work of the Corinthians, who visited South Africa in 1897, 1903 and 1907. In 1920 another mixed team was dispatched to Cape Town. After years of preparation the Commonwealth Football Assn. of Australia arranged with the English Football Assn. to send out in 1925 a party of players, who were mostly professionals. The results of these excursions may be tabulated thus:—

		Matches	Won	Goals For	Goals Against
1910.	South Africa . .	23	23	143	16
1920.	South Africa . .	14	14	64	10
1925.	Australia . .	25	25	139	13

Such enterprises were a continuation of the policy of the Football Assn. to popularise the game, the Dominion organisations paying the expenses and retaining all revenue. In 1917 the parent body in England presented a shield to Japan to foster the game in the schools of that country, and in the years immediately following the World War it gave challenge cups for competition to South Africa, Australia, New Zealand and Canada. To stimulate the game and to encourage English amateurism, the Assn. also entered teams for the Assn. football tournaments at the Olympic Games of 1908, 1912 and 1920, but withdrew from participation after the Antwerp Olympiad, as the definition of an amateur in England and the practice in some other competing countries were not in unison.

In 1910 the Football Assn. took another important step, as in April the rule regulating the maximum wages which could be paid to professionals by English clubs was removed. Such financial matters were deputed to the executives of the leagues, which thus became the controllers of all payments to professionals. The Football Assn. celebrated the jubilee of its existence in Oct. 1913 by a banquet, and to mark the occasion endowed a benevolent fund with £5,000.

During the season of 1913–4 a schism which had afflicted the game was brought to an end. As amateurs declined to co-operate in the government of all football, including professional clubs, a rupture had occurred in 1907–8. The Amateur Football Assn. was established and carried on a separate organisation until Feb. 2 1914, when representatives of the older universities and the Corinthians met the Football Assn. in conference and settled the dispute. The Amateur Football Assn. became affiliated to the Football Assn. under the same conditions as the Army Football Assn. and other auxiliary bodies. A momentous season was closed, King George V. attending the final match for the Assn. Cup at the Crystal Palace, London, on April 25 1914 and presenting the trophy to Burnley, who had beaten Liverpool.

Effect of the War.—In spite of the outbreak of the World War, the season of 1914–5 was carried through by league clubs employing professionals and therefore having legal contracts and commitments, but all the national associations cancelled their international matches, and in the spring of 1915 the Football Assn. took powers to suspend professionalism and all its cup competitions, although local tournaments for amateurs, for munition workers and soldiers on leave, were arranged by the

Exports, in Tons, of Refrigerated Beef, Mutton and Lamb, 1910 to 1925

Football League. The Football Assn. imposed rigid conditions, and monetary inducements for men to play football were strictly forbidden. The Football Assn. and the league did much to assist the Red Cross Society, to provide comforts for the troops, and to help refugees in England. A football national war fund was founded in Dec. 1917 to relieve those connected with the game who had been stricken by the misfortunes of war, either on active service or in munition work.

Post-War Progress.—In the spring of 1919 the work of reorganisation was commenced and victory international matches were played. The season was lengthened by the addition of the last Saturday in Aug. in one year and the first Saturday in May of the year following, and a boom in the game was experienced in 1919–20. King George V. attended a league match for the first time at the Manchester City ground on March 27 1920 and witnessed the final match for the Assn. Cup at Chelsea, on April 23 1921, presenting the trophy to Tottenham Hotspur. In the next month the Football Assn. entered into an agreement with the British Empire Exhibition to play the final tie for a term of years in the stadium at Wembley.

The cup competition of 1922–3 is memorable for the first entry of the Corinthians and the first final played at Wembley. This match between Bolton Wanderers, who won the cup, and West Ham United attracted at least 150,000 people, the receipts being £27,776. The Football Assn. has also a cup which is restricted to amateur teams, and each year plays a charity shield match, which is quite apart from the £20,000 per annum that the clubs contribute to local charities. Receipts from the practice matches in Aug. are earmarked for this purpose by the Football Association.

Changes in Laws.—The International Football Assn. Board, which was established in June 1886 by the Football Assn., the Scottish Football Assn., the Football Assn. of Wales and the Irish Football Assn., have continuously revised the laws of the game at their annual meeting in June of each year. Gradually, but surely, forwards have been given more scope. In 1907 the board decided that a player is not out of play "when he himself is within his own half of the field of play at the moment the ball is played, or thrown in from touch by any player of the same side." At the meeting in 1920 it was resolved that "no one shall be offside when a throw-in is taken." In 1925 the board relaxed the fundamental law relating to off-side so that a player would be on-side if only two opponents were nearer their own goal than himself when the ball was last played by one of his own side. The board determined, in 1924, that a goal may be scored from a corner kick, and a year later the player, throwing-in from touch, was ordered to stand with both feet on the ground outside the touch line and facing the field of play, so as to throw the ball in over his head with both hands in any direction.

Football Leagues.—The Football League, founded by 12 clubs in 1888, expanded greatly after the World War. When the league considered the revival of the two competitions, on March 10 1919, the clubs in divisions I. and II. were increased to 22 in each section. On May 31 1920 the Southern League was, at its own request, absorbed by the Football League and became division III. in associate membership but without the right to vote at the annual general meetings of the league. On the same day a projected northern group, a part of division III., was sanctioned, but its formation was deferred until March 8 1921, so as to give clubs the opportunity to strengthen their playing power and secure financial stability. Thus the league had, for the season 1921–2, not only divisions I. and II., but both sections of division III., north and south each with 22 clubs. Thus the original membership of 12 clubs had increased to 88 clubs—a powerful alliance with authority to devise rules for their domestic affairs, although these must be in conformity with the rules and by-laws of the Football Assn. and sanctioned by the supreme body.

A Welsh National League, with northern and southern groups, was inaugurated in 1921–2. The Scottish League, which remained active during the War, had a moribund second division, but in 1923–4 this was galvanised into life by the adoption of the system of promotion and relegation. The first division was therefore no longer a closed corporation. The invigorated second division was supplemented by a third division, so that the clubs of England, Scotland and Wales became classified into groups for the first time. The Irish Football Assn. had not the same opportunity, being limited to Northern Ireland. The Irish Free State founded a governing association body and created its own cup and league competitions.

International Football Associations

La Fédération Internationale de Football Association, which is composed solely of the governing body of each country playing the game, was formed at Paris on May 21 1904, with the object of developing and controlling association international football. It grew so rapidly that, in 1910, the members included Austria, Belgium, Denmark, England, Finland, France, Germany, Hungary, Italy, Luxemburg, Sweden and Switzerland. During 1911, Ireland, Wales and Scotland joined, and the secretary's report stated that all European countries with a governing body were members except Rumania. In 1912, with the Argentine Football Assn., and the pan-Russian Football Assn. included, the Federation was recognised officially by the International Olympic Committee, although Spain, Portugal and the Balkan states were not properly organised. In this year, English became the official language for minutes and correspondence, and it was decided to adhere to the laws of the game as passed by the International Board of Great Britain. The Federation was admitted to this board with the right to send two delegates. During 1913, Canada and Chile were affiliated, and when the World War broke out the Federation had 26 members, including the United States.

The Federation was dormant during hostilities, and when it was restored to activity the British nations withdrew from membership, as they declined to sit with the representatives of those countries which had been their enemies. In 1924 they rejoined on their own conditions, which were that the articles of the Federation should not affect the inter-relations of the various parts of the British Isles and their own autonomy. By Aug. 26 1925 the Federation had affiliated the governing bodies of the following: Argentina, Austria, Belgium, Brazil, Bulgaria, Canada, Chile, Czechoslovakia, Denmark, Dutch East Indies, Ecuador, Egypt, England, Estonia, Finland, France, Germany, Hungary, Ireland, Irish Free State, Italy, Latvia, Lithuania, Luxemburg, Netherlands, Norway, Paraguay, Peru, Poland, Portugal, Rumania, Russia, Scotland, Siam, South Africa, Spain, Sweden, Switzerland, Turkey, Uruguay, United States, Wales and Yugoslavia, with headquarters at Amsterdam. At a congress held in Prague in May 1925 the following resolution was passed: "The congress of the Fédération Internationale de Football Assn. declares that it considers the Fédération Internationale de Football Assn. the highest authority on all football matters, and that it cannot accept the interference or guidance of anybody else in such matters." At a conference between representatives of the four associations of the British Isles at Liverpool on Sept. 5 1925 it was decided that the Fédération be informed that if this resolution were confirmed the conference would have no alternative but to advise the associations of the United Kingdom to withdraw from the Fédération. In Nov. the president and secretary of the Fédération officially explained that by Article 34 of its Constitution the authority and competence of the International Board were recognised and that the resolution applied only to "some powers strangers to football."

It is clear that association football has become a world game. In 1906 South Africa visited South America, and in 1923 and 1924 Chinese University students and a Canadian combination went to Australia. At the Olympiad of 1908 in London and of 1912 in Stockholm, England won the international tournament. In 1920, at Antwerp, England was defeated and Belgium won, while in 1924, at Paris, the representatives of Uruguay were the victors. It has been difficult to organise comprehensive government in countries of large area, but South Africa founded an association in 1892, Canada in 1912, the United States in 1913 and the Commonwealth of Australia in 1921.

In the United States there has been much activity to make this code pre-eminent as the fall and winter game. During 1920 an American-born team from St. Louis visited Scandinavia, while a Scottish set of players, under the auspices of the Third Lanark Club of Glasgow, toured in Canada and the United States in 1920–1. The sequel in the United States was the formation of the American Soccer League with a higher standard of play than had previously obtained in that country.

FOOTBALL, RUGBY (*see* 10.618).—The history of the game of Rugby since 1910, not only in Great Britain and Ireland, but in the British Dominions overseas and also in France, has been one of steady development. Rugby is the national game in New Zealand and in South Africa, and to a less extent in Australia, while in a somewhat different way it is played in America. In France it has obtained the official recognition of the government, so that it is now played over the entire country. France possesses more clubs and more players than any other nation. In England many public schools, which have for years been devoted to the Assn. game, now play Rugby. Since the World War there has been a marked increase in the number of Rugby clubs in England, and the game is now played in many districts where at one time its very name was almost unknown. In the northern counties, which suffered so severely from the inroads of professionalism, Rugby is rapidly regaining its old popularity and prestige, and for some years now they have been able to provide valuable members of the English team. The number of old boy clubs, particularly in London, has been greatly increased.

I. THE BRITISH EMPIRE AND FRANCE

The year 1910 was an *annus mirabilis* for England, since it saw the opening of the national ground at Twickenham, Middlesex, with a brilliant victory over Wales. The revival of English Rugby may fairly be said to date from this year, for England won the championship for the first time since 1892, and from then till 1925 has won it outright on five occasions, besides dividing the honours twice. The visit of the All Blacks in 1905 had demonstrated the weakness of the game in England, and for some seasons players had been endeavouring to improve both their tactics and their physical condition.

Much of the credit must go to A. D. Stoop, who persevered amid much discouragement in developing the open style of play, and who without doubt had his reward. He gathered round him a band of brilliant halves and three-quarters, and after a few years had the satisfaction of seeing his principles generally adopted and England gaining victory after victory. Next in importance to these tactics was the improvement in English forward play. For many years now the English selectors have aimed at discovering an all-round type of forward, clever with hands and feet and able to hold his own in the rough and tumble of international matches. Forwards are no longer content to be mere pushing machines, their duties do not nowadays finish with the breaking up of the scrummage, rather do they then begin. From 1910 to the end of 1925 England won 9 out of 11 matches with Scotland; 9 out of 11 with Ireland, the other 2 being drawn; 8 out of 11 with Wales; and 10 out of 11 with France. That is to say, out of 44 matches England won 36, drew 3 and lost 5, a record probably without parallel.

Scottish Rugby.—In Scotland Rugby continues to flourish, new clubs are springing up and old ones are showing a decided increase in power and in the standard of their play. The national side has achieved a very fair record since the World War, though it had to wait a long time for its first victory over England and for its first actual championship triumph since 1907. During the last few seasons Scotland has had to come south, especially to Oxford, for her three-quarters. Scottish forwards are as formidable as ever, the halves are sound, and, unlike England, Scotland has been fortunate in the possession of a succession of really first-class full-backs. The chief blots on the Scottish escutcheon since the World War are the three defeats by France, one of which was inflicted at Inverleith, where in 1921 France won by a try to nil. There are signs that Scottish Rugby is now at the beginning of a new era of prosperity.

Irish Rugby.—Irish Rugby naturally suffered severely during the World War, and also after it, owing to the disturbed state of the country generally. Indeed the wonder is, not that Irish teams have been defeated, but that they have been able to exist at all. But now old-established clubs are regaining their normal strength, and new ones are making good. During the last few seasons several international matches have been won, and the prospects for the future are bright. A number of young and promising players have been discovered, and Irish back play is developing well. The forwards too are recovering their old dash and are again a force to be reckoned with.

Welsh Rugby.—In 1910 Wales lost a sensational match to England, the first English victory since 1898, but they were still a formidable side, and in 1911 secured the international championship once more. Gradually Welsh Rugby began to lose its force, and triumph no longer automatically followed triumph. The World War dealt Welsh Rugby a very heavy blow, and although Wales gained a brilliant victory over England at Swansea in 1920, and carried off the championship in 1922, the Welsh game has not been up to its former standard. The curious point is that Welsh club football is practically as good as ever, or at any rate is still superior to English club Rugby, and Saxon victories over the great Welsh organisations are still few and far between. Yet the national side is no longer the force it once was, and the natural conclusion is that something is wrong with the principle of selection. Defections to the professional game now and again deprive Wales of potential international players, but not to an extent sufficient to explain the decadence of the Welsh fifteen.

French Rugby.—In France the game prospers amazingly. Reference has already been made to the three victories gained over Scotland. Ireland has also been beaten three times, but England and Wales have so far escaped defeat. England, it is true, had a very narrow escape in 1922, when the match at Twickenham ended in a draw, of which it is only fair to say that France had very much the better and were unlucky not to win. Tours in France are very popular nowadays with British clubs and they do an immense amount of good in more ways than one. French Rugby has suffered a good deal from the indiscriminate praise lavished on it in the early days, when it really needed constructive criticism, but the French authorities themselves were never misled, and always recognised the necessity of interchanging visits with British clubs and also of strict and adequate refereeing.

South African Rugby.—Since 1910 only two teams from the Colonies have visited this country. In 1912 a South African side, under W. A. Millar's captaincy, paid a visit which was remarkably successful. Of the 27 matches played, 24 were won and only three lost. A record was set up by their defeat of all the five countries, a feat no other touring side has rivalled. The matches lost were with Newport, London and Swansea. The strength of the team lay in the forwards, who were exceptionally powerful and fast, but the backs, if not as effective as those of the 1906 contingent, were by no means negligible.

In 1910 Dr. T. Smith, an Irish international, captained a British side in South Africa. It met with moderate success, winning 13 matches out of 24, and losing eight. Of the three test matches one was won and two were lost. About 12 international players took part, but the team was, of course, very far from representative of the full strength of Great Britain and Ireland. R. Cove-Smith led the fifth British team to tour in South Africa, but with rather unsatisfactory results. Of the 21 matches played nine were won and nine lost. Three of the four test matches ended in defeat, the other being drawn.

Persistent ill-luck followed the team in the matter of casualties, and the side, none too powerful to start with, was hardly ever at full strength. Indeed, toward the end it was difficult to find fifteen men sound enough to play. Most of the defeats were by comparatively moderate margins, but there is little doubt that the team was not strong enough for the task it undertook.

New Zealand Rugby.—In Sept. 1924 the second New Zealand team, captained by C. G. Porter, began a wonderfully successful tour. They actually won all their 28 matches in England, Ireland and Wales, no fixtures having been arranged in Scotland. Their triumphs were due to their splendid physical condition, and to their marvellous and intensive combination. Nothing finer has ever been seen in Rugby than the way in which the men supported one another; there was always somebody at hand to carry on and drive home an attack. They were naturally hardly at home in their first few matches, and they had a very narrow escape from defeat by Newport. But they steadily improved and in due course developed into a very fine side indeed, though in the opinion of many they were never quite the equals of Gallaher's men.

II. THE GAME IN THE UNITED STATES

The rules that govern American Rugby football were drastically changed in the winter of 1906 by a combined Rules Committee, six of whom represented the newly formed National Collegiate Athletic Assn., the other six being members of the old Rules Committee. This amalgamated committee was the outgrowth of a conference of representatives of a large number of colleges and universities which, because of the large and increasing number of deaths and serious injuries, was called for the purpose of doing away with football, or of radically changing the rules. This conference was a direct result of the football season of 1905 which had been marked by 21 deaths and by many serious injuries.

Changes in the Rules.—Vital changes in the rules were made at the meeting of this combined committee, these being on the following lines: (1) Doing away with heavy mass play, (*a*) by making it impossible for tackles and guards to be used as battering rams to precede the runner with the ball; (*b*) by doing away with "chain interference", and (*c*) by abolishing pushing and pulling of the runner with the ball. (2) Encouraging attempts to advance by throwing the ball forward, provided it was thrown across the line of scrimmage not nearer than five yards to the point where it was put in play. (This has since been changed to allow the ball to be thrown anywhere over the line of scrimmage.) (3) Stimulating kicking by making all players on the kicking side, except the centre, eligible to receive the ball as soon as it touched the ground. (This rule has since been rescinded.) (4) Encouraging the offensive team to take chances in free running, forward passing and on side kicking, by compelling the offensive team to make 10 yards instead of five in three trials. (5) Shortening the playing period of each half from 35 min. to 30 min., thereby reducing the strain. In 1912, each half was divided into two 15-min. periods, with a 2-min. interval to permit time to change goals. The above changes proved to be effective in doing away with serious injuries; also in opening up the game. Since then, comparatively few changes of importance have been made in the rules.

One of the most important changes occurred when the forward pass was allowed to be thrown anywhere over the line of scrimmage and at any time, provided the passer was at least five yards behind the line. This change, together with one allowing the man who first received the ball from centre to cross the lines of scrimmage at any point, permitted the doing away with the checker-board marking of the field, thereby reverting to the gridiron or cross marking that was in vogue preceding 1903. Another important change adopted in 1910 required seven men of the offensive side to be on the line of scrimmage. The development of the forward pass brought about a change in the shortening of the field between the goal lines from 330 ft. to 300 ft., with end zones of 30 ft. beyond each goal line in which forward passes could be completed. With the shortening of the field, the kick-off was moved from the centre of the field to the 40-yd. line of the kicking side. The value of a touch-down has gone through a series of changes, in which it has counted four, five and finally six points. In the same way, a goal from the field, whether from a drop kick or a place kick, has had a similar variation, but downward from five to four and finally to three points. Four trials instead of three are now allowed to gain 10 yards.

Development of the Game.—The game itself has developed in a most interesting way. Previous to 1915, it was rare to see a team which did not play its quarter-back close up behind centre to receive the ball and pass it to the runner, or carry the ball himself. Nowadays, however, none of the men in the backfield need play in specified positions all the time. The quarter-back calls the signals, but arranges the backfield in one of a variety of formations from which the center makes a direct pass to one of the backs. Probably the most common arrangement of the linemen is to have four on one side of the centre and two on the other, creating what is called the "unbalanced" line with a strong and a weak side. Some coaches instruct their players to assume these positions deliberately, the strong side being on the right or left according to the signal. Others have a preliminary arrangement of the guards or tackles lined up behind the centre and jump into position either to the right or left, thus forming a strong side.

A favourite backfield formation is to line one back, known as the wing back, slightly outside and a yard behind the end man on the strong side, while the other three men form a diagonal tandem, the back man assuming a position four to five yards behind centre. Sometimes one of the other two men forms a wing back in a similar position on the short side. Some teams play a "solid line"; others direct the end man on the long side to play out from one to two yards, while the end on the short side lines out from two to four feet, in which case the wing back on the strong side usually lines behind the opening. Another favourite formation is known as the punt formation, in which two backs usually arrange themselves in tandem from three to four yards back of the line of scrimmage on the right, while a single man stands about three yards back in a corresponding position on the left, and the fourth man from six to ten yards directly back of centre.

This formation lends itself peculiarly well to what is termed the "triple threat" style of play, in which the man farthest back may run, make a forward pass or punt. Shift plays are being used by many coaches; in these usually four line men assume a preliminary position from one to two yards behind the line of scrimmage and then jump into balanced lines or into lines with one man over or two men over, while the four men in the backfield adjust themselves in various ways according to the plan of the coach. Owing to the tremendous noise attending games, at some of which there are as many as 80,000, or 90,000 spectators, some of the teams use what is called the "huddle system." Instead of the quarter-back calling out a string of numbers with the players in their regular positions, he gathers the team around him and tells them the play. The team then quickly springs into position, and the play begins, either with or without a further signal.

Offence and Defence.—The offence in football has now reached a certain degree of standardisation after many years of experimentation of the widest divergence. Fortunately, offensive football will never be completely standardised, because the possibilities of manoeuvring the players are so many that coaches of inventive genius are constantly lured into the multifarious forms of strategy always possible to the clever tactician.

In defence, the general usage is to employ either a six or seven man line. If a six man line is used, the centre and four other men are arranged in what is called the 2–2–1 formation;

that is, two men backing up the line two or three yards behind it and separated from each other by three or four yards, while two others line up about 10 yards back of the defensive ends, and the safety man plays from 15 to 30 yards back. Another favourite style is known as the "box" defence, in which seven men play in the line with two men backing up the line from two to four yards back and three to five yards apart, while two other men play at points from 12 to 18 yards back and behind their respective ends. Many coaches still favour the "diamond" defence, in which seven men play on the line of scrimmage, while one man plays from three to five yards behind centre and two backs line up 10 to 12 yards behind the defensive ends, the safety man lining up 20 to 30 yards from the scrimmage. The above three defensive formations have become quite standardised. Some teams employ all three kinds, according to the part of the field they are in and according to the number of the "down," the number of yards to be gained, also the type of formation the opponents are using.

Until 1926, the use of the forward pass has been encouraged because it has made possible the playing of games between small and large institutions. In 1926 a new rule came into effect that a penalty of five yards is to be inflicted for every uncompleted forward pass, after the first one.

Formerly, all school and college teams were coached by graduates without salary. Later, paid seasonal coaches were employed. In 1925, most coaches were members of the athletic department. Since the World War, football in the United States has had an unprecedented public interest. An era of stadia building has swept over the country, most colleges and universities having built or planned to build one. Many high schools also have them, and several cities have erected stadia holding 100,000 people. (A. A. St.)

FORAKER, JOSEPH BENSON (1846–1917), American politician (*see* 10.628), died in Cincinnati May 10 1917. In 1916 he published *Notes of a Busy Life.*

FORCED LABOUR: *see* SLAVERY AND FORCED LABOUR.

FORD, HENRY (1863–), American manufacturer, was born on a farm near Dearborn, Mich., nine miles west of Detroit, of William and Mary Litogot Ford. William Ford was of English descent but born near Cork, Ireland, whence the Ford family emigrated to America in 1847, settling near Dearborn. Mary Litogot was born in the United States of Dutch parents. Mrs. Ford died when her son was 12. Henry Ford went to school until he was about 15, but worked on the farm after school hours and during vacations. He began early to develop an intense interest in mechanics. He was attracted first to watches, and at 13 he took a watch apart and put it together again. In a little while he was repairing watches and clocks throughout the surrounding country, not for pay but because he had a burning curiosity to see how watches and clocks were made. His only tools were a screwdriver made from a knitting needle and a pair of tweezers fashioned from an old watch spring. All this work was done at night; later it was done secretly, because William Ford objected to the son giving his services free. Also, he wanted the boy to be a farmer, while the boy wanted to be a mechanic.

At 16 Henry could no longer tolerate farm work. He left home, walked to Detroit, and apprenticed himself in a machine shop at a weekly wage of $2.50, working 10 hours a day. His board and lodging cost him $3.50 a week. In order to make up the deficit he took employment with a jeweler from 7 to 11 in the evening, for which he received $2.00 a week. In about a year he turned from machine shop to an engine shop to learn something of the building of engines. There he stayed two years. A company manufacturing small steam engines for farm use needed a man to install them; Ford took the place and for two years more set up and repaired these engines. He had gone back to the farm to live; there he spent all of his spare time in a little workshop trying to build a farm tractor—for his experience with the portable engines, as well as his own farm experience, had convinced him that power should be put to work on the farm and that it was a waste to keep horses.

Eventually he built a single-cylinder engine steam tractor, but he could not devise a boiler to provide pressure enough to keep the tractor at work ploughing and yet be light enough for his requirements. For the time being he gave up his tractor until he could discover a more suitable boiler. Large steam tractors were already in use, but Ford's thought even then was in the direction of inexpensive, simple apparatus which could be bought by everyone.

In 1884 Ford's father offered him 40 ac. of land in order to draw him away from his mechanics. The land was mostly wooded. Henry cut the timber, set up a sawmill and sold lumber. In the summer he repaired farm engines. In 1887 he married Clara Bryant, who lived in the neighbourhood. He sawed the lumber for his house, which he built himself on his plot of ground, and having done this he moved his workshop from his father's farm to his new home.

Securing a job with the Detroit Edison Co. as an engineer and machinist he moved from the farm to Detroit, where he set up his shop in a shed at the back of his house. After hours he worked on the building of a gasolene motor car. In 1892 he completed it—although it did not run properly until the following year. This, his first car, had two cylinders with a 2½-in. bore and a 6-in. stroke, set side by side over the rear axle, and developed about 4 H.P., which was transmitted from the motor to the countershaft by a belt and from the countershaft to the rear wheel by a chain. He ran this car about 1,000 m. and then sold it for $200, in order to start the building of another car which would be lighter and stronger.

In 1899, feeling that he had the experience he needed, Ford left his job with the electric light company and went into the making of automobiles as a business, with a company, of which he was the chief engineer, known as the Detroit Automobile Company. He held only a small portion of the stock, and the company would not follow the lines of manufacturing to which he had committed himself. The directors wanted to make cars to order only; Ford had in his mind a universal car which could be made in quantities. In 1902 he resigned in order to go into business for himself—when the opportunity arose. In the meantime he rented a one-story brick shed and continued his experiments. He built several cars, two of them solely for speed. One he called the "999" and the other the "Arrow." Each had a four-cylinder engine giving 80 horsepower. The "999" won every race it entered, and in 1903, on the reputation of this speed car, Ford formed the Ford Motor Co., with a capitalisation of $100,000. Actually only $28,000 in stock was ever subscribed, and of this only about one-half was in actual cash. The company in 1926 had assets of about $1,000,000,000. It is the largest motor car company in the world and the third largest industry in the United States, comprising in itself about 50 other industries and employing some 200,000 people directly and an equal number indirectly. It has been built up entirely by turning back profits into construction. The company has never issued bonds or borrowed money; nor has it issued stock otherwise than to enlarge the original capitalisation so as to have it more nearly correspond with values.

The company is entirely owned by Henry Ford and his son, Edsel B. Ford, they having bought out the minority stockholders in 1919 for $70,000,000.

During its first year the company built a two-cylinder, 8 H.P. car with a chain drive, and of these 1,708 were produced and sold. In the second year the company made three models and for five years the company made various models of four-and six-cylinder cars. The automobile at that time was considered a pleasure vehicle, but Ford had conceived of it as a universal method of individual transportation and he was working to produce a light car of great strength, which would require a minimum of care and cost in upkeep. What delayed him was finding a steel sufficiently strong for his purpose, and it was quite by accident that he came upon a piece of vanadium steel, which was not then made in the United States. With that steel he designed Model T—which is what is known today as the "Ford car." In 1909 Mr. Ford announced that thereafter the

company would build only one type of chassis, that it would be Model T, and that "Any customer can have a car painted any colour that he wants, so long as it is black."

The principles upon which the Ford industries are founded, as Mr. Ford has stated them, are:—

1. An absence of fear of the future or veneration for the past. One who fears the future, who fears failure, limits his activities. Failure is only the opportunity more intelligently to begin again. There is no disgrace in honest failure; there is disgrace in fearing to fail. What is past is useful only as it suggests ways and means for progress.
2. A disregard of competition. Whoever does a thing best ought to be the one to do it. It is criminal to try to get business away from another man—criminal because one is then trying to lower for personal gain the condition of one's fellowmen—to rule by force instead of by intelligence.
3. The putting of service before profit. Without a profit, business cannot extend. There is nothing inherently wrong about making a profit. Well-conducted business enterprise cannot fail to return a profit, but profit must and inevitably will come as a reward for good service. It cannot be the basis—it must be the result of service.
4. Manufacturing is not buying low and selling high. It is the process of buying materials fairly and, with the smallest possible addition of cost, transforming those materials into a consumable product and giving it to the consumer. Gambling, speculating and sharp dealing tend only to clog this progression.

In the Ford practice the cycle of production starts with the consumer. Mr. Ford holds that a commodity must first of all be designed to fit the needs of the largest possible number of consumers both in quality and price, and that the number of consumers will be continuously increased by constantly lowering the price of the article. At the same time, by paying the highest possible wages to those engaged in the production and distribution of the article, he creates a high buying power. In Jan. 1914 Mr. Ford raised all wages in his industries to a minimum of $5.00 for an eight-hour day. The average wage throughout his industries at that time was $2.40 for a nine-hour day. The minimum wage in 1926 was $6.00 a day, with an average of $8.00. Model T (the touring car), which in the beginning cost $850, in 1926, with the average wage about four times larger than then and with materials costing at least double, sold for $310, with a self-starter and many improvements. From the introduction of Model T on Oct. 1 1908 it took the company until Dec. 10 1915 to produce 1,000,000 cars, but under the new wage programme and the constant lowering of prices the company was in 1926 producing at the rate of 2,000,000 cars a year.

The general theory of production in the Ford plants is that everything must be kept moving and that the work must go to the man instead of the man to the work. For example, the cylinder block is cast on a moving platform in a mould made on a moving platform. Thereafter it passes, without stopping, through a series of machines which perform all the necessary operations, and then, still moving, it passes into assembly, where to it are added, one by one, the hundreds of parts to create a complete motor. Then it moves into the final assembly, where it is joined by other parts until eventually an automobile leaves the final assembly line under its own power. Every part of the motor car has a similar train of construction and assembly, all converging either into the final assembly or into boxes or freight cars for shipment. No man uses more than one tool, all the work comes waist high, a man never has to stoop or to move his feet to get anything, and the speed of the work is controlled not by the worker's will but by the pace of the conveyer.

The Ford industries have been steadily reaching back to sources in order to cut out intermediate profits. The industries have their own iron mines, coal mines and forests, their own railway, and an extensive fleet of lake- and ocean-going steamships, all of which are operated on the principle of high wages, high production and low cost. In the forests no tree is permitted to be cut under 10 inches. The logs are taken directly to the sawmill and, instead of being first converted into lumber and the parts sawed from the lumber, the parts are sawed directly from the log. All the wood-working is done at the forest mill, the waste goes to a wood distillation plant, and there is no waste whatsoever in shipment. At the River Rouge plant, the iron from the furnace goes directly into the foundries and is poured without reheating. The slag from the furnaces goes to a cement plant. A combination of electric furnaces and a large rolling mill converts all of the steel scrap. In every direction the pressure is toward preventing the waste of time, men or material.

As the business developed, it became apparent that it was a waste to assemble the cars at the factory and ship them complete. The manufacturing plants then ceased in effect to manufacture automobiles; instead, they make parts, and these are shipped to 35 branches in the United States, where they are assembled into complete motor cars. Similar branches or associated companies are located in nearly every part of the world, and these branches also manufacture if the costs permit. Foreign branches, under the theory of building consumption, employ only natives of the country in which they are located. All the branches use the same methods and pay the same wages as the home plants. The industry does not use a single warehouse—everything is in transit.

The centre of the industry is at Detroit, Mich., and at River Rouge, Mich., on the outskirts of Detroit; but with the method of assembling cars at the point of use, a decentralising of manufacturing is taking place and comparatively small plants are being located out in the country wherever proper water-power sites are available. Each of these plants makes only a single part; the thought behind their establishment is to strike a balance between industry and agriculture. None of these plants employs more than 500 men, and in most cases the men divide their time between agriculture and industry. This is one of the most important developments.

Mr. Ford is firmly against paternalism in any form. He believes charity greatly harms those who receive it. Carrying out this thought, he has a trade school for the education of boys with dependents, in which the boys make useful articles. They earn an average of about $15 a week while receiving their education. The Henry Ford hospital in Detroit, which is open to any one, is conceived on the theory that a hospital should be self-supporting. All its rooms are precisely alike, all have baths attached, all the fees and services are at a scheduled rate, which is the same to everyone, and all the surgeons, physicians and nurses are on salary and have no financial relations with the patients. The Ford Motor Co. also builds a light farm tractor under the same methods and principles as the motor car, and in 1926 was building experimentally all-metal airplanes and maintaining for experimental purposes a number of air routes with the eventual aim of putting the Ford principles into aeronautics.

Henry Ford has taken no active part in politics, although he was nominated in 1918 for United States Senator from Michigan; at the election he was defeated by a small margin. He took no part whatsoever in the campaign. In 1915 he was convinced by certain peace advocates of foreign extraction that it might be possible to end the World War if a sufficient gesture were made. He thereupon chartered a ship and proceeded to Christiania, Norway. Then, convinced that the mission was futile, he returned home. Mr. Ford does not believe in war, but he is not an active pacificist. For this *Encyclopaedia* he wrote the article MASS PRODUCTION.

A full account of the origins, theories and practices of the Ford industries is contained in *My Life and Work* (1922), and *Today and Tomorrow* (1926), both by Henry Ford in collaboration with Samuel Crowther. (S. CR.)

FOREIGN LANGUAGES, TEACHING OF.—The revolution that has taken place in the methods of teaching modern languages may be said to date from Viëtor's pamphlet *Der Sprachunterricht muss umkehren* (1886). His doctrines were largely adopted in the Frankfurter Reformschulen, but it was not till after 1900 that the movement became widespread in England and France. Broadly speaking, the idea of the reformers was to substitute direct comprehension and acquisition of the foreign language for mere knowledge attained through the medium of the mother tongue.

They insisted on oral study at the outset of the language, involving explanations in the foreign tongue itself, on inductive

methods of learning grammar and on the use of reading and of free composition in place of formal grammar and translation from or into the foreign language. Hence the introduction of the phonetic script and chart; the employment of gesture; the utilisation of pictures, postcards, coins and other *Realien;* and the stress laid on the teacher and not the text-book being the centre of the instruction—the whole idea being to render the classroom a sort of French or German *enclave*, and to make the pupil think as far as possible in the language.

Some of these doctrines were pushed to excess. Certain teachers attempted to exclude the mother tongue entirely from the classroom; others devoted an inordinate time to phonetics or conversation on pictures, and exalted the oral side as the goal of all teaching. Others again neglected the grammar or interpreted their new-won liberty as a right to teach as they pleased, irrespective of their colleagues. To-day, while phonetics (*q.v.*) have been generally accepted in England (though not in France), it is seen that the extent of their use (apart from the chart) may be left to the choice of the teacher. Again, new grammar points should be learnt inductively, but the grammar must be systematised and codified. With most pupils grammatical points are more safely explained in English. Due co-ordination of method can usually be secured by the appointment of a head of department. Translation from or into the foreign language is often begun two years before the final examination and not often earlier. As regards the exclusion of the mother tongue, we may take it as an axiom that the cleverer the child the more direct the teaching. Hence with the duller child the aim should probably be to concentrate rather on reading and translation than on composition (free or otherwise). At the extreme end of the scale there are, in the opinion of some experts, a few non-linguistic pupils who would be more profitably engaged in confining themselves to the mother tongue.

It is probable that the earlier reformers laid insufficient stress on the rapid acquisition of vocabulary, possibly from their dread of rote-work. To-day there is a fruitful tendency to learn by heart, not merely poems but duly prepared prose passages, a practice that is at the back of much of the mastery attained by the French in their own language. Of course such passages need occasional revision. Again, the principle of private reading, which has made such strides in English, has been promoted by the formation of class and school libraries, and the practice has been further fostered by the introduction of free study periods in certain schools. Such are the main features of the teaching in English secondary schools, up to the first school examination.

In the central schools, which often prepare their fifth-year pupils for similar examinations, the methods are largely the same, except that in the first year the classes, which are larger, are sometimes divided for conversation, with excellent results. In the advanced courses of the secondary schools, the methods of reading and *lecture expliquée* without translation are largely followed, and essays on literature are written in the foreign language. A burning point is that the universities which conduct the higher certificate examinations appear to prefer answers in English in the literature papers. A possible solution would be the award of extra marks for one question to be answered in the foreign tongue. In the evening schools methods have been modernised, but the need of covering the ground more quickly necessarily limits the employment of the more leisurely practices of the direct method. (C. Bre.)

In the United States

The attempt to make general the employment of the "direct method" in the teaching of the foreign modern languages in the United States had begun to subside before 1909, when it became clear that the method was looked on askance in the best high schools and preparatory schools, and especially in the colleges and universities. Many teachers were well acquainted with foreign languages by ancestry and study abroad; but some could not speak such languages with ease. Also, the increasing desire for travel in Europe, now so manifest, was only beginning to develop. In the universities and colleges, the professors laughed the method out of court. An anecdote is told about a professor of French in a certain university, who, when asked if he spoke French, answered: "I don't speak French, I teach it." When we consider, however, that at present no teacher of French in the United States would answer in this way, we see that the agitation over the direct method has borne fruit. Indeed, nearly all the text-books in modern languages bear an imprint, however faint, of the direct method, whose influence has been beneficial. It is true, furthermore, that the War gave a strong and perhaps lasting impulse to the study of the spoken language. It is said that when the United States entered the War, the accredited newspaper reporters sent to Europe were remarkable in only one regard: their inability to say the slightest thing in French. This would no longer be the case.

Much of the improvement in the teaching of the modern languages came from another source: the introduction of Phonetics. This study made its way under two forms: formal or theoretical Phonetics and experimental Phonetics. The first came from both France and Germany, as well as from the English school of Bell and Sweet; the latter came from France. The French influence was seen in the steady extension through the universities and high schools of the International Phonetic Alphabet, which is now the only one used in teaching the foreign spoken languages. This alphabet was contrived by Paul Passy (who took hints from Ellis, Bell, Sweet and others) and commenced to be known in the early 'nineties. Its use has become so general that it forms the basis of instruction in diction, music and phonetics, as is seen in the brilliant work being done in New York by such teachers and authors as Adele Baldwin, Marguerite DeWitt, May Laird-Brown and William Tilly.

Experimental Phonetics came from the indefatigable zeal of its founder, the Abbé Rousselot, whose laboratory at first was in the Institut Catholique, Paris, then in the Collège de France. Two or three Americans had begun experimental research at about the same time as Rousselot, but they did not have laboratories at their disposal. None the less, their example prepared the way for the introduction of Rousselot's methods, which have left a permanent impress on the teaching of the modern languages in the United States.

The War favoured the extension of French. Combined reports from about 76% of the elementary schools, public and private, and the high schools and academies and from about 80% of the colleges and universities indicate an enrolment during the year 1923–4 of 629,000 students of French, 392,000 of Spanish, and 65,000 of German. (R. We.*)

FORESTRY (*see* 10.645).—No summary of the timber resources of the world can be described in any sense as accurate or reliable. The facts available are insufficient, the statistics on which estimates are based are often incomparable and even the sources of information are not always above suspicion; overstatements by government departments to attract capital or to justify increased exploitation are as common as understatements by foresters or traders to insure conservation of resources or enhanced prices.

The British Empire contains not less than 1,100 million acres of woodlands, but has under 1,100 forest officers—that is to say, taking the Empire as a whole, less than an average of one forest officer for every 1,000,000 acres. Brazil with 1,000 million acres of tropical and semi-tropical forests has in the European sense no organised forest service at all. The information about the Russian forests, said to be 1,200 to 1,500 million acres in extent, even before the War, was unsatisfactory, especially as regards the virgin softwood forests in Asia and northern Europe. Since the War little authoritative information is obtainable, and such information as there is, is, therefore, for the most part, too old to be of any real utility.

The World's Timber Resources

For purposes of comparison the timber resources of the world may be divided into hardwoods and softwoods, the former being, generally speaking, broad-leaved and, in the temperate

zone, deciduous trees; the latter coniferous and non-deciduous. The hardwoods themselves fall naturally into two classes—hardwoods of the temperate zone, some 1,200 million acres in extent, and tropical hardwoods, estimated at 3,600 million acres. The softwoods of the world cover a much smaller area, just over 2,500 million acres. These forests, with the exception of the Paraná pine forests of Brazil, Chile, India and Australasia, are situated in the Northern Hemisphere, over 80% of the total being found between the 45th and 70th parallel north. The more important commercial timbers of the world, the softwoods and temperate hardwoods (calculated on an acreage basis), are situated to the extent of 95% and 89% respectively in the Northern Hemisphere, where 75% of the population exists. While, as a means of estimating timber resources, a calculation by acreage is unsatisfactory, the stand of timber to the acre varying with species, soil and climatic conditions, no unit of measurement can be given which more accurately gives a picture of forest wealth.

Only about 10 to 15% of the world's forests are worked under systematic management, and about these forests alone is reliable information available as to stocks, annual growth, fellings or losses by pests, etc. Of the other forests, 15 to 20% may be classed as commercial forests either in process of exploitation or about to be exploited. About these forests some general trade information is usually available. The balance 65 to 75%, is virgin forest not utilised for commercial purposes, and about which information is non-existent or unreliable. The estimates of acreage have, in the main, been taken from the work of Messrs. Zon and Sparhawk entitled *Forest Resources of the World*. These two distinguished members of the United States Forest Service have succeeded in making a more or less coherent picture of the available data about the forests of the world, supplemented by personal investigations and inquiry where full information was not previously available.

Hardwood Supplies

The hardwood timber supply of the world need give little real cause for anxiety. There will be in the future, as in the past, shortages of supplies of individual species. The hardwood forests, however, are so vast in extent, and include so many different types of timber, that the increase of information about recently developed countries, and the advance in the science of timber testing, seasoning and wood technology, should make the substitution of new species for old a more simple and certain proceeding than has formerly been the case. The solution of the hardwood supply question would therefore appear to lie not only in the conservation of existing resources, but also in the ordered investigation of new sources of supply, together with the initiation of such steps as are necessary to make such supplies available as and when they are found in quantities that make their exploitation commercially possible.

United States.—The United States has taken the lead in this matter. Owing to the wholesale clearances of their more accessible hardwood forests by uncontrolled felling, and the almost complete destruction of their valuable chestnut forests by the chestnut bark disease (*Endothia parasitica*), the Federal U.S. Department of Agriculture has for some time been inquiring through its Forest Products Laboratory, Madison, Wis., about the potential supplies of hardwood timber outside the States. Important results have already been obtained in Central and South America.

British Empire.—Inside the British Empire equally good work has been and is being done; at Dehra Dūn in India, at Montreal in Canada and in England under the aegis of the Forest Products Research Board, at Kew, as well as at the Imperial Institute, timbers are being tested and new species identified. In this section of Imperial development it is necessary to insist on one point that has been passed over, viz., that it is not only necessary to educate and indeed to persuade the consumer by scientific and practical tests of the possibilities of a given substitute species, it is also necessary to prove to the satisfaction of wood merchants that that substitute is available on a commercial scale and that the forests in which it is found are suitably situated for exploitation. An Imperial Forestry Bureau advocated by two consecutive Imperial Forestry Conferences is a necessary link between the consumer and the merchant on the one hand, and the systematic botanist, the timber testing centre and the producing units of the Empire overseas on the other.

Softwood Supplies

The future supply of softwood timber is disquieting, the most unsatisfactory feature being the rapidity with which the accessible virgin forests are being destroyed. In the more progressive and industrially developed countries timber, other than firewood, is used in the proportion of 80% of softwood to 20% of hardwood. Great Britain, the greatest importing country in the world, brings in softwood in the proportion of nine to one hardwood. According to the latest figure available, Finland and Siberia are the only two "net" exporting countries in the world where the resources of softwood timber are not being reduced by annual felling at a greater rate than is made good by annual growth.

United States.—The United States, which consumes nearly one-half the converted timber of the world, is using up its softwood timber reserves at about four times their rate of growth. Only 137,000,000 ac. of virgin forest remain. These are being felled at the rate of 5,500,000 ac. per annum. The situation has caused such general anxiety that the President himself made the following statement in 1924: "Expressed roughly we have left about 745 billion cu. ft. of timber. From this the annual drain is 25 billion cu. feet. This total drain is most significant when we reflect that towards offsetting it we have an annual growth of only six billion cu. ft., and even in our young forests where this growth is taking place cutting has already outstripped growth. We must face the situation that at this rate we are not far from timber exhaustion."

The course of timber denudation in the United States is interesting. First the New England states, then the Lake states and now the South Atlantic states have been cut out in rapid succession. In the Southern states the departmental report of 1920 states that of the 5,400 mills owning or controlling practically the entire remaining virgin stand in the South, 4,419 mills will be cut out in five years or less, and that a further 800 mills will cut out their timber in the next ten years, *i.e.*, by the end of 1930 or thereabouts.

When this last forest reserve on the eastern freeboard is exhausted, the export trade of softwood timber will be concentrated almost entirely in the Pacific states, distant from the main commercial centres by 2,000 m. of railroad or 4,000 m. by sea. This fact is important from two points of view—(*a*) the price of timber must rise very considerably in the Eastern states, where four-fifths of the population are centred; (*b*) that, consequent on a rise in prices due to the lack of local supplies, sea freight and canal charges, America may come into the European market for construction timber, just as she does to-day into the Canadian and European markets for her pulp-wood. In a statement made by Col. W. B. Greeley, Chief of the United States Forest Service, at the British Empire Forestry Conference in 1923, the virgin softwood forests of the United States at the then rate of destruction would be cut out in 25 years, and after that date the industry would have to depend on "cut-over" woods and the less accessible of the Federal reserves.

Canada.—The position in Canada is but little more satisfactory. According to Mr. Craig, the Canadian statistical officer (report of 1923), the total amount of softwood in Canada amounts to 198,000 million cu. ft., one-half of which can be profitably operated under existing conditions. The amount of softwood used annually for all purposes is about 900,000,000 cu. ft., but owing to the method of exploitation this entails the destruction of 1,700,000,000 cu. ft. of standing timber. In five years the annual loss of merchantable timber from fire had amounted to 790,000,000 cu. ft., and in 10 years destruction by the spruce bud worm had averaged 1,300,000,000 cu. feet. Other insects and forest diseases have also caused serious loss in the forest, so that the annual drain on the resources of the Dominion is probably

not less than 4,000,000,000 cu. feet. At this rate the accessible stands of virgin forest would last 25 years.

Europe.—In Europe the softwood position is by no means satisfactory. The demand of industrial life for an adequate timber supply increases in volume much more quickly than the growth of the population, yet there is no margin for increased production outside Russia, and the estimates of Russian reserves are founded on quite insufficient data.

Three of the principal softwood exporting countries in Europe are Norway, Sweden and Finland. Norway has been living on her forest capital for many years, and her softwood timber consumption exceeds growth by about 51,000,000 cu. feet. Sweden until recently was supposed to be living well within her forest means. A recent survey has shown that the annual growth, especially in the north, is less than was previously calculated, and consumption exceeds growth by 100,000,000 cu. feet. Finland is reported to be using 140,000,000 cu. ft., less than the annual growth. Two facts must be borne in mind—(*a*) that her calculation of annual growth will probably have to be revised, (*b*) that the extension of her saw-milling industry is rapid.

Russia.—To what extent the virgin forests of Russia can come to the aid of Europe and America is difficult to estimate. Apart from political questions there are certain limiting factors which are bound to affect continuous production.

1. The main group of softwood forests is situated north of the 50th parallel. The rate of growth is necessarily slow; on the Finnish and Swedish analogy, probably not more than 20 cu. ft. per ac. per annum. In the extreme north the rate of growth is probably only half that rate, while owing to the infrequency of seed years restocking must necessarily be a slow process.
2. The extent of land over which Russian forests are spread is so great and the communications so poor that only a relatively small portion is accessible under existing conditions and at present day lumber prices.

Mr. Fraser Story in his review of the softwood resources of Europe estimates that 90,000,000 ac. of the Russian forests are merchantable as opposed to 243,000,000 ac. unmerchantable. He includes as unmerchantable all woods in which the cost of extraction is prohibitive, or on which the land is so poorly stocked or the timber of such a character of growth as to be unsuitable for commercial use. The merchantable area includes the areas which before the War could have been exploited without undue commercial risk with the means of extraction and utilisation then available.

3. Russia has a population nearly as large as the United States. She is already an importer of timber in her southern states. Her consumption of hardwoods and softwoods before the War was calculated at only 66 cu. ft. per capita per annum. It is not improbable that with the relaxation of forest regulations her per capita consumption has materially increased and may approach that of Norway and Sweden, 130 cu. ft. per annum.
4. It is calculated that before the War Russia was living on her capital, *i.e.*, that her consumption exceeded her annual growth by 1,851 million cu. ft. per annum.

Siberia.—The productive Russian forests in Asia probably amount to 500 to 600,000,000 acres. Only one-fifth of this area has ever been surveyed. The Pacific slopes and the forests tributary to the Amur and other small coastal rivers are the only areas capable of exploitation under existing trade conditions, and may amount to 40,000,000 acres of softwood and hardwood forests, only one-tenth of which has been surveyed. The main supplies of Central Siberia will only be available when political conditions are such as to permit of the investment of capital, the creation of railways and the establishment of banks and credit institutions. Even in the more easily developed area an export trade will have to be built up from its very foundations. Before the War there were said to be only 74 producing sawmills in Siberia; since the War exports of timber to Japan and China have increased; but even to-day, considering the size of the country, they are relatively unimportant.

Other Areas.—The remaining virgin softwood forests of the world can be dismissed in a very few words. In Japan consumption is rapidly overtaking production. Japan has for long been anxious about future supplies, and has embarked on the largest planting programme of any country in the world. The recent survey by the United States Forest Service in Alaska has proved disappointing. While the hinterland contains important reserves of pulp wood, the milling timber is confined to a strip of land on the coast averaging, it is said, only a few miles in width. Australia and New Zealand, despite their softwood supplies, are importing countries. The Paraná pine forests of Brazil, once considered as an important timber reserve for the southern hemisphere, are being rapidly cut out and no system of reforestation has yet been adopted.

Conclusion.—It would appear that while information about the softwood forests of the world leaves much to be desired, there are sufficient data to warrant certain conclusions:—

1. That except in Russia—an unknown quantity—the main softwood virgin timber reserves will be exhausted before very long, and producers will have to depend more and more on "cut-over" forests or woods raised or restocked by the agency of man.
2. That the United States shortage is likely to come more quickly than the European one.
3. That the more the American supply becomes centred in the Pacific Coast States the greater is the probability of the industrial States of North-eastern America coming into the European market for saw-timber in the same way as they do now for pulp of wood.
4. That as the United States consumes 13,750 million cu. ft. of softwoods as opposed to a total European consumption of 9,120 million cu. ft., the United States advent into European markets will have an important bearing on European prices.

FORMOSA (*see* 10.669).—The island of Formosa (Taiwan) has an area of 13,839 sq. m. and on Oct. 1 1920 the population was 3,655,308, representing a density per sq. m. of 264 inhabitants. The population was estimated at 3,758,900 on Oct. 1 1923. The chief towns are Taihoku, Tainan, Kagi and Taichu. The Hokoto Is. (Pescadores) are included in Taiwan.

Administration and Finance.—Taiwan was placed under a civil administration in April 1896, and legislative steps were taken in the following year to put the finances of the island on an independent footing. Meanwhile a grant was made from the Imperial Treasury, but the subvention was withdrawn in 1906 owing to the satisfactory financial condition of the island. Furthermore, with the development of its industry and the increase of various public establishments, finance was greatly expanded and the total revenue and expenditure in the Budget for 1924–5 are put at 91,553,193 yen (excluding the extraordinary budget).

Government Monopolies.—The Government monopoly undertakings on the island are opium, salt, camphor and tobacco, the importation of opium and the manufacture and smoking of the drug being strictly prohibited since 1896, except by licence in the case of confirmed smokers. The number of licensed smokers had decreased from 117,000 in 1900 to 38,673 at the end of 1923.

In May 1899 the Government took steps to improve the quality and increase the quantity of salt produced, which had hitherto suffered from the fluctuations due to irregular and sporadic private enterprise. The total area of the salt-fields is now over 2,348 kō (about 4,500 ac.); the quality of the salt has decidedly improved, and the annual output has been steadily increasing, having risen to 404,000,000 kin (242,400 metric tons) in 1923, sufficient to satisfy local requirements and also for export to Japan, Chosen, Karafuto, etc. In 1899 the production of camphor was also controlled, and in 1905 the monopoly system was extended to Taiwan-cut tobacco, in both cases with beneficial results.

Trade.—The chief commodities exported from Taiwan are tea, rice, sugar, camphor, turmeric, flax, hemp, jute and coal. Foreign trade, consisting of oversea trade and trade with the homeland (Japan proper), has grown year by year. The development of Taiwan trade with foreign countries was affected adversely by the duties which have been increased frequently since the revision of customs tariffs in 1899, but its trade with the homeland has made steady progress with the development of various industries,

stimulated by the growing perfection of banking and communication facilities in the island.

In 1907 the volume of trade with Japan and overseas trade was 58,340,000 yen, while in 1910 it was 108,880,000 yen (largely owing to the development of the sugar industry). In 1923 the total trade reached 308,720,000 yen. Of this the exports to foreign countries were valued at 29,150,000 yen, and the exports to Japan proper at 169,440,000 yen, a total of 198,590,000 yen. The imports amounted to 39,110,000 yen from foreign countries, and 71,010,000 yen from the homeland, totalling 110,120,000 yen. Thus the excess of total exports over total imports for 1923 amounted to 88,460,000 yen.

Agriculture and Industry.—Almost the whole of Taiwan is a rice-growing country, yielding two crops a year. In 1923 the rice crops amounted to 4,866,087 koku (24,102,639 bu.), though in that year they suffered from the worst drought ever known. The oolong and souchong teas, produced in the north of the island, are important exports to foreign countries; the value of the oolong exported abroad in 1923 was 5,160,965 yen.

The sugar industry enjoyed great prosperity in 1916 and 1917, the value of exports being 11,317,643 yen and 15,775,205 yen respectively. The area under sugar-cane cultivation in 1923 was 114,710 kō (1 kō = 2·45 ac.) which, owing to the satisfactory growth of the plant, yielded raw sugar amounting to 6,192,040,773 kin (1 kin = 1·323 lb.). There were operating 44 plants of the latest style with a capacity of 34,650 English tons, 11 improved-style factories with a capacity of 820 English tons and 101 old-style factories, which altogether produced 521,501,144 kin of centrifugals, 59,878,831 kin of refined sugar and 10,860,026 kin of brown sugar, aggregating 592,240,001 kin.

Gold, alluvial gold, silver, copper, coal, petroleum and sulphur are all found in the northern part of the island. The total value of mineral products in 1923 was 12,915,908 yen, being an increase of a little over 210% over the 1913 figure. The gold produced in 1923 was 411,649 grammes; placer gold, 8,306 grammes; silver, 569,576 grammes; coal, 1,445,000 metric tons; and petroleum, 25,289 hectolitres.

The fishing industry of Taiwan owes much of its present prosperity to Government encouragement, although owing to the favourable ocean currents, fishing can be carried on all around the island. Artificial rearing of oysters, prawns, carp, etc., is accomplished both in salt and brackish waters, and it is a characteristic of the Formosan fisheries that whilst the natural produce is valued at about 4,000,000 yen, the value of the products of fish culture is 2,000,000 yen.

Banking.—The Bank of Taiwan (est. 1897) is the central bank of the island, and has an authorised capital of 45,000,000 yen and a paid-up capital of 39,375,000 yen. The bank is empowered to issue bank-notes, and to transact ordinary banking and foreign exchange business. There are several ordinary banks and many credit associations.

A great increase in the business of the Post-Office Savings Bank took place during 1910–23, the number of depositors having risen from 90,893 in 1909–10 to 457,869 in 1922–3, the deposits increasing from 1,900,700 yen to 8,171,201 yen.

In 1899 the Government commenced planning out a trunk line from north to south of the island, connecting the ports of Keelung and Taku and passing through Taihoku, Taichu and Tainan. Branch lines, further opening up the rice, sugar, tea and mining districts, were gradually completed, so that at the end of the financial year 1922–3 there were 468·70 m. of railway open to traffic. In the same year over 13,000,000 passengers and more than 3,000,000 tons of goods were carried, the receipts being over 12,000,000 yen. In addition to the state railways, there were at the end of 1922 1,242 m. of railway belonging principally to sugar factories and 547 m. of track for hand-propelled cars, an important means of local transport peculiar to the island. (H. Sa.; K. M.)

FORREST, JOHN FORREST, 1st Baron (1847–1918), Australian statesman and explorer (*see* 10.672), was acting premier of Australia in 1907 during the absence of Mr. Deakin in London. He took office again as treasurer in Mr. Hughes's "National" Cabinet of 1917, but resigned owing to ill-health early in 1918, when he was raised to the peerage, being the first Australian to be so honoured. He died at sea on his way to London to take his seat in the House of Lords, Sept. 3 1918.

FORSTER, EDWARD MORGAN (1879–), British novelist, was educated at Tonbridge School and King's College, Cambridge. His first novel, *Where Angels Fear to Tread* (1905) was followed by *The Longest Journey* (1907) and *A Room with a View* (1908). Wider attention was won by *Howards End* (1910), but thereafter, except for some short stories, *The Celestial Omnibus* (1911), he published little until 1924, when *A Passage to India* appeared. This was a fruit of first hand observation of modern Indian life and with it Forster entered into a fuller public recognition of his powers as a writer with a gift for keen analysis of social character and relationships. Wartime work in Egypt enabled him to write a useful book on *Alexandria: A History and a Guide* (1922), from which came the material for the short studies of Alexandrian history, ancient and modern, in *Pharos and Pharillon* (1923).

FORSYTH, PETER TAYLOR (1848–1921), British Nonconformist divine (*see* 10.677), died in London Nov. 11 1921. Among his later works were *The Person and Place of Christ* (1909); *The Principle of Authority* (1912) and *This Life and the Next* (1918).

FORTIFICATION: *see* SIEGECRAFT.

FORT WORTH, Tex., U.S.A. (*see* 10.728), entered on a period of rapid development after the establishment of Camp Bowie (1917) and three flying fields for the training of Canadian and American aviators, and the erection (1918) of the army and navy helium plant. With the discovery of the Ranger and Burkburnett and other important new oilfields, it became the geographical centre of the oil-producing region of the southwest, and by 1925 was the greatest petroleum pipe-line centre in the world. Its refineries had a daily crude capacity of 75,000 barrels. Natural gas was brought in from 15 fields. Beginning about 1920, the transition in western Texas from ranching to stock-farming and diversified agriculture (especially cotton, wheat and feed crops) added a large and prosperous population to Fort Worth's trading territory, supplied raw materials for new industries, stimulated meat-packing and flour-and-feed-mills and enlarged its grain and livestock markets. A textile mill was established in 1924; a cement plant in 1925. Bank deposits were $15,425,000 in 1910; $78,540,000 in 1925. The value of manufactured products was $8,661,000 in 1909; $38,160,000 in 1919; $75,163,236 in 1923. In 1922 the area of the city was more than doubled by the annexation of 22 sq. m., including Niles Polytechnic, and a large suburban territory. The population in 1920 was 106,482, of whom 15,896 were negroes and 7,502 foreign-born; in 1925, 185,000 according to a local estimate, taking into account the suburban territory annexed in 1922.

A new charter, adopted in April 1925, established the Council-manager form of government and created a city plan board. Plans were under way (1925) for the construction of a Union passenger station and an interchange belt railway, and for a great project of water conservation, flood control and irrigation, by Tarrant County Water Improvement District Number 1. The leading educational institutions include Texas Christian University, Southwestern Baptist Theological Seminary and Texas Woman's College, established in 1914, with which the older Polytechnic College was merged.

FOSDICK, HARRY EMERSON (1878–), American divine, was born at Buffalo, N.Y., May 24 1878. He graduated from Colgate University in 1900, proceeding thence to Union Theological Seminary, New York City. Ordained into the Baptist ministry in 1903, he was pastor of the First Baptist Church, Montclair, N.J., 1904–15. He rapidly acquired a high reputation as a preacher, especially among the universities. Becoming instructor in homiletics at Union Theological Seminary in 1908, he was appointed Morris K. Jesup professor of practical theology in 1915. In 1918 the First Presbyterian Church of New York City was founded by amalgamation of The Old First, Madison Square and University Place churches, and Dr. Fosdick became its associate minister and permanent preacher Dec. 29 1918.

On May 21 1922 he preached a sermon entitled "Shall the Fundamentalists Win?" making a wide plea for tolerance in religion and asking that the door of Christian fellowship be left open to all who sincerely desired to follow Christ, regardless of specific credal belief. The Presbytery of Philadelphia formally brought the matter of Dr. Fosdick's teaching before the General Assembly of the Presbyterian Church at Indianapolis in 1923, stigmatising it as heretical and demanding action. The New

York Presbytery, acting on the request of the Assembly, appointed an investigating committee which reported to the General Assembly of 1924 that they found Dr. Fosdick's teaching and preaching to be in accordance with Presbyterian standards. This report was vehemently attacked by the Fundamentalist element in the Assembly and was referred to the Judicial Commission of the church, which, after hearing evidence, decided that Dr. Fosdick must take the vows of a Presbyterian minister (implying acceptance of the Westminster Confession) or vacate his pulpit. He thereupon tendered his resignation, Oct. 6 1924, which was accepted and took effect March 1 1925. Immediately thereafter the Park Avenue Baptist Church of New York called Dr. Fosdick to its pastorate, agreeing to open its membership to all Christians without insisting on its traditional ordinance of baptism and also to remove from its present site and build an amply equipped church on Morningside Heights—the educational centre of the city.

His works include *The Second Mile* (1909); *The Manhood of the Master* (1913); *The Assurance of Immortality* (1913); *The Meaning of Prayer* (1915); *The Challenge of the Present Crisis* (1917); *The Meaning of Faith* (1918); *The Meaning of Service* (1920); *Christianity and Progress* (1922); *The Modern Use of the Bible* (Yale lectures, 1924).

FOSTER, SIR GEORGE EULAS (1847–), Canadian statesman, was born in New Brunswick Sept. 3 1847. Educated in New Brunswick, Edinburgh and Heidelberg, he took up teaching in Canada. In 1882 he became Conservative member in the Canadian Parliament, representing New Brunswick, and in 1885 became Minister of Marine and Fisheries. From 1888–1896 he was Minister of Finance. In the Borden Administration of 1911 he was Minister of Trade and Commerce, retaining the portfolio in the Union Govt. of 1917. In 1917 Foster was summoned to the Senate of Canada.. He was a great advocate of preferential trade within the Empire, and in 1903 he made a series of speeches in England in support of Mr. Chamberlain's policy. Sworn of the Imperial Privy Council in 1916, he was in the same year appointed one of Great Britain's four representatives at the Economic Conference at Paris. In 1918 Foster was created K.C.M.G., and he represented Canada at the Peace Conference, 1919, and at the first assembly of the League of Nations in 1921. He was later elected a vice-president of the assembly.

FOUILLÉE, ALFRED JULES ÉMILE (1838–1912), French philosopher (*see* 10.737 and 18.250), died at Lyons July 16 1912.

FOURTEEN POINTS, THE.—During the winter of 1917–8 talk of peace was prevalent throughout the world. Between Russia and Germany actual peace negotiations were in progress during the opening months of 1918; and on Jan. 5 1918 the British Premier outlined the terms upon which Great Britain and her Allies would be prepared to negotiate for peace.

On Jan. 8, three days after Lloyd George's speech, President Woodrow Wilson, in his address to the joint session of Congress, formulated under 14 separate heads his ideas as to the essential nature of a post-War settlement. Before the delivery of his address he had received from a committee of inquiry, set up by Col. House in Sept. 1917, a report upon the territorial settlement that should follow the conclusion of the War. It has been stated that no fewer than six, and these the territorial points, of Wilson's Fourteen Points were "directly framed" upon the recommendations contained in the report. It has also been stated that the report was drawn up by Dr. S. Mezes, D. H. Miller, and Walter Lippmann.[1]

In any consideration of the Fourteen Points it must be borne in mind that in drafting the Points, especially the first five, regard was had not merely to the future, but also to the fact that they could be used as a diplomatic weapon in the present.[2] In drafting Point 4 the President was probably inspired by the example of the United States, where each State has only a militia for the preservation of internal order; the safety of all from external attack being guarded by the Federal Army.

The Fourteen Points were:—

1. Open covenants of peace openly arrived at, after which there shall be no private international understandings of any kind, but diplomacy shall proceed always frankly and in the public view.
2. Absolute freedom of navigation upon the seas outside territorial waters alike in peace and in war, except as the seas may be closed in whole or in part by international action for the enforcement of international covenants.
3. The removal, so far as possible, of all economic barriers and the establishment of an equality of trade conditions among all the nations consenting to the peace and associating themselves for its maintenance.
4. Adequate guarantees given and taken that national armaments will be reduced to the lowest point consistent with domestic safety.
5. A free, open-minded and absolutely impartial adjustment of all colonial claims based upon a strict observance of the principle that in determining all such questions of sovereignty the interests of the populations concerned must have equal weight with the equitable claims of the Government whose title is to be determined.
6. The evacuation of all Russian territory, and such a settlement of all questions affecting Russia as will secure the best and freest cooperation of the other nations of the world in obtaining for her an unhampered and unembarrassed opportunity for the independent determination of her own political development and national policy, and assure her of a sincere welcome into the society of free nations under institutions of her own choosing, and more than a welcome, assistance also of every kind that she may need and may herself desire. The treatment accorded Russia by her sister nations in the months to come will be the acid test of their goodwill, of their comprehension of her needs as distinguished from their own interests, and of their intelligent and unselfish sympathy.
7. Belgium, the whole world will agree, must be evacuated and restored without any attempt to limit the sovereignty which she enjoys in common with all other free nations. No other single act will serve as this will serve to restore confidence among the nations in the laws which they have themselves set and determined for the government of their relations with one another. Without this healing act the whole structure and validity of international law is forever impaired.
8. All French territory should be freed, and the invaded portions restored, and the wrong done to France by Prussia in 1871 in the matter of Alsace-Lorraine, which has unsettled the peace of the world for nearly 50 years, should be righted in order that peace may once more be made secure in the interest of all.
9. A readjustment of the frontiers of Italy should be effected along clearly recognisable lines of nationality.
10. The peoples of Austria-Hungary, whose place among the nations we wish to see safeguarded and assured, should be accorded the freest opportunity of autonomous development.
11. Rumania, Serbia and Montenegro should be evacuated, occupied territories restored, Serbia accorded free and secure access to the sea, and the relations of the several Balkan States to one another determined by friendly counsel along historically established lines of allegiance and nationality, and international guarantees of the political and economic independence and territorial integrity of the several Balkan States should be entered into.
12. The Turkish portions of the present Ottoman Empire should be assured a secure sovereignty, but the other nationalities which are now under Turkish rule should be assured an undoubted security of life and an absolutely unmolested opportunity of autonomous development, and the Dardanelles should be permanently opened as a free passage to the ships and commerce of all nations under international guarantees.
13. An independent Polish State should be erected which should include the territories inhabited by indisputably Polish populations, which should be assured a free and secure access to the sea, and whose political and economic independence and territorial integrity should be guaranteed by international covenant.
14. A general association of nations must be formed under specific covenants for the purpose of affording mutual guarantees of political independence and territorial integrity to great and small States alike.

President Wilson developed his theories during 1918 in a series of speeches, to which reference was subsequently made during the Armistice negotiations. These are as follows:—

The Four Principles.—In the "Four Principles" speech in Congress, Feb. 11 1918, he declared:—

1. That each part of the final settlement must be based upon the essential justice of that particular case and upon such adjustments as are most likely to bring a peace that will be permanent;
2. That peoples and provinces are not to be bartered about from sovereignty to sovereignty as if they were chattels or pawns in a game, even the great game, now forever discredited, of the balance of power; but that
3. Every territorial settlement involved in this War must be made in the interest and for the benefit of the populations concerned, and not as a part of any mere adjustment or compromise of claims amongst rival States; and

[1] R. S. Baker, *Woodrow Wilson*, vol. 1, pp. 110–1.
[2] C. Seymour, *Woodrow Wilson*, pp. 235 *seq.*

4. That all well-defined national aspirations shall be accorded the utmost satisfaction that can be accorded them without introducing new or perpetuating old elements of discord and antagonism that would be likely in time to break the peace of Europe, and consequently of the world.

The Four Ends.—In the "Four Ends" speech of July 4 1918 occurs the following passage:—

These are the ends for which the associated peoples of the world are fighting and which must be conceded them before there can be peace:—

1. The destruction of every arbitrary power anywhere that can separately, secretly, and of its single choice disturb the peace of the world, or, if it cannot be presently destroyed, at the least its reduction to virtual impotence.

2. The settlement of every question, whether of territory or sovereighty, of economic arrangement, or of political relationship, upon the basis of the free acceptance of that settlement by the people immediately concerned, and not upon the basis of the material interest or advantage of any other nation or people which may desire a different settlement for the sake of its own exterior influence or mastery.

3. The consent of all nations to be governed in their conduct towards each other by the same principles of honour and of respect for the common law of civilised society that govern the individual citizens of all modern States, and in their relations with one another, to the end that all promises and covenants may be sacredly observed, no private plots or conspiracies hatched, no selfish injuries wrought with impunity, and a mutual trust established upon the handsome foundation of a mutual respect for right.

4. The establishment of an organisation of peace which shall make it certain that the combined power of free nations will check every invasion of right and serve to make peace and justice the more secure by affording a definite tribunal of opinion to which all must submit and by which every international readjustment that cannot be amicably agreed upon by the peoples directly concerned shall be sanctioned. These great objects can be put into a single sentence. *What we seek is the reign of law, based upon the consent of the governed and sustained by the organised opinion of mankind.*

The Five Particulars.—The "Five Particulars" (speech of Sept. 27 1918) were:—

1. The impartial justice meted out must involve no discrimination between those to whom we wish to be just and those to whom we do not wish to be just. It must be a justice that plays no favourites and knows no standards but the equal rights of the several peoples concerned.

2. No special or separate interest of any single nation or any group of nations can be made the basis of any part of the settlement which is not consistent with the common interest of all.

3. There can be no leagues or alliances or special covenants and understandings within the general and common family of the League of Nations.

4. And, more specifically, there can be no special selfish economic combinations within the League and no employment of any form of economic boycott or exclusion, except as the power of economic penalty, by exclusion from the markets of the world, may be vested in the League of Nations itself as a means of discipline and control.

5. All international agreements and treaties of every kind must be made known in their entirety to the rest of the world. Special alliances and economic rivalries and hostilities have been the prolific source in the modern world of the plans and passions that produce war. It would be an insincere as well as an insecure peace that did not exclude them in definite and binding terms. (*See* also EUROPE.)

BIBLIOGRAPHY.—The text of the Fourteen Points will be found in C. Seymour, *Woodrow Wilson and The World War*, vol. 3, pp. 42–5 (1921). See also R. S. Baker, *Woodrow Wilson and World Settlement*, 3 vol. (1923); H. W. V. Temperley, *History of the Peace Conference of Paris*, vol. 1, pp. 431–5 (London, 1920).

FOX-HUNTING (*see* 13.947).—The years immediately preceding the World War were in many ways the Golden Age of this great English sport. Money was plentiful and it was noticeable that newcomers to the country-side were inclined to favour hunting rather than shooting. Increased facilities for transport enabled people to hunt from towns. Horse-breeding and hound-breeding had been placed on a sound basis, and hunting, generally, had been organised and stabilised under the supreme authority of the Masters of Foxhounds Association.

War Difficulties.—Then came the War. The drain on horses was tremendous; subscription lists dropped to practically nothing; and, worst of all, at the height of the submarine menace, the feeding of hounds became an almost insoluble problem. The expense was enormous and there was a considerable outcry to the effect that hounds should be suppressed altogether as useless animals which consumed useful food. In 1917–8 hunting very nearly ceased altogether, and had it once come to an end it is extremely improbable that it would ever have been revived. The Association of M. F. H., however, in collaboration with Sir William Buxton, tackled the problem. All over the country the number of hounds was reduced, the reduction being effected partly by killing off hounds, but mainly by drafting large numbers out of the country, notably to America, and by breeding fewer.

These drastic measures had their reward. Not only was hunting saved, but it was far easier for the staffs, greatly depleted by the War, to deal efficiently with these reduced packs. Further, half a century of hound shows had given the general breeder a very sound idea at what to aim; so that, in spite of these reductions, not only was the total number of hounds in England in 1925 very nearly up to the pre-War strength, but the quality of English hounds was as high as ever. Not a single well-known hunt ceased to exist. In 1926 there were over 200 packs of foxhounds in the British Is. and 86 in the United States and the British Dominions.

Post-War Developments.—The end of the War by no means put an end to the difficulties which faced hunting. Judicious reductions, compensated for by breeding on sound lines, settled the hound difficulty. The question of horses largely answered itself by the release of an enormous number of animals from the army. After the War, too, whether as a direct result or not it is impossible to say, there was a decided improvement in the quality of the horses; this has been accentuated by the judgments given at horse shows. Before the War the showing animal and the hunter were two distinct types; the animal that won prizes was not likely to prove of much use across country and vice versa. But after the War the show animal was displaced by the real hunter, who is quite capable of winning a prize in the show ring in the summer and a point-to-point in the spring, the ideal at which to aim. The subscriber difficulty was also automatically solved by the return of the armies and, at any rate immediately after the Armistice, there were more people hunting than before the War.

Speaking generally, then, fox-hunting recovered in a surprising way from the direct consequences of the War. But an indirect consequence still had a great and adverse effect on the sport, namely, the change in the social and territorial conditions of rural England. This began before 1914, but was enormously accentuated by the War. In the old days rural England was largely in the hands of the great landowners, who were probably hunting men themselves, or at any rate supporters of hunting, and their tenant farmers, who took their cue from their landlord. Then came the extensive sales of landed property, due to the heavy taxation of the War period and after with its adverse effects on the sport. (C. L. R.)

FRACTURES.—The treatment of fractures has received considerable attention during the 15 years 1910–25, with a corresponding improvement in the general level of results. The development of radiography (*see* RADIOTHERAPY) and its more general application have produced a greater knowledge of the displacements which occur and may remain after a fracture, and a more critical spirit toward the results of these injuries has developed.

Normal Form.—The restoration of the normal form of the broken bone is an important factor if the best result is to be obtained. After the fracture of a long bone of the lower extremity, correctness of alignment is undoubtedly of the greatest importance; in the upper extremity, however, good functional results may be obtained when the position of the bone deviates considerably from the normal. The demand for accurate reposition of fragments has been met by wider use of open operations, whereby replacements of the fragments can be carried out under the eye of the surgeon, and fixation secured by the insertion of metal or bone plates, or suture material. With the precision of modern surgical technique, such intervention is possible without the risk of infection which held back the older surgeons from undertaking such procedures save in exceptional cases.

Function.—The restoration of function in the injured limb after a bone has been broken has received increasing notice. The

problem is recognised as a complicated one, each aspect of which must receive consideration. Restoration of the normal line of the bone is of the first importance, but the repair of the soft structures overlying the fracture has an equal influence on the final result. Moreover, stiffness in joints near the fracture may develop in cases immobilised for too long, and, if persistent, is a source of serious disability. These complications have been avoided or minimised by modified splint treatment, early massage and controlled movements. Various forms of electrical treatment have also been found helpful.

War Experience.—The intensive experience in the treatment of fractures afforded by the World War came during the development of methods on the above lines, and yielded a store of improvements in technique, while it tended to crystallise opinion on the relative value of various methods of treatment for the individual case. The general introduction of splints, which allow traction to be made on the injured limb, facilitated the control of bone alignment without open operation. Other mechanical improvements elaborated enable direct traction to be made on bone fragments. The transfixion of the bone with pins, and the use of metal calipers to grip the fragments, are examples of such procedures.

Present Tendency.—In general at the present time the tendency to carry out open operations on all fractures of long bones is less in evidence. This is due partly to the advance in methods of splintage, but also to the fact that operations of this character, coupled with rigid fixation by means of metal plates, delay the process of union, and may be the source of subsequent adhesions between bones and the subjacent soft structures. In America there has been a movement to employ slips of the patient's own bone for the purpose of fixation at open operations. This procedure involves a more elaborate technique, but certainly overcomes some of the disadvantages of plating with metal.

Compound or Open Fractures.—The introduction of infection into a fracture has always been a bugbear of surgeons, as, once suppuration is established in bones, it runs a slow course and is liable to lead to sequestration, or death, of some part of the bone, and slow union. War experience has shown clearly that antiseptics are of little value in the disinfection of a lacerated wound. The best method of eradicating infection in connection with wounds of this kind was found to be the excision of the track and the removal of all contaminated tissues. The application of this process of wound excision or *débridement* to the more severe types of compound fracture has greatly improved the results. Once the infection has been avoided or overcome, a compound fracture offers no more serious problem in treatment than does a simple one.

Un-united Fractures.—Though delay in the process of union is common enough for several reasons, failure of bones to unite firmly in healthy individuals is rare. It is, however, met with in those cases in which a large part of the bone substance has been destroyed or damaged by the primary injury or subsequent infection. These cases are now treated with a high measure of success by bone grafting. Fresh bone taken from the patient himself gives the most reliable results. In cases in which the original broken bone ends can actually be brought together, a beef bone and preserved human bone have been employed with some measure of success. As to the degree to which the grafted bone replaces normal bone, the consensus of opinion is that the graft acts as a scaffold along which new bone grows, rather than that it becomes a part of the host skeleton. At any rate it forms a firm bond about which, under suitable conditions, new bone formation takes place. (C. M. P.*)

FRANCE, ANATOLE (1844–1924), French man of letters (*see* 10.775).—For 30 years French literature was dominated in the eyes of all the world by the fame of Anatole France. Although his influence declined in the last period of his life the value of his art was still widely recognised. His ideas were questioned, but not his style nor the services rendered by him to the language. In his old age he was revered as a genius and a patriarch. No reputation since Voltaire's has been found comparable with his.

The son of a bookseller called Thibault, this youth who was to make illustrious the pseudonym of Anatole France started his career quite humbly. He was fond of literature, he was studious and erudite, but negligently preferred reading to writing. He composed publishers' puffs and contributed a weekly article signed " Gérôme " to the *Univers Illustré*. For his own amusement he wrote verse, *Les poèmes dorés* (1875) and *Les noces Corinthiennes* (1876), which showed learning, charm and taste. In 1879 he published his first volume of stories, *Jocaste et le chat maigre*, and in 1881 his first novel, *Le crime de Sylvestre Bonnard*, which was acclaimed by the discriminating as delightful.

In 1883 he first met Madame Arman de Caillavet, with results that profoundly influenced his career. Mme. de Caillavet became his life-long friend. She was clever and active; she had a host of acquaintances and her receptions were attended by the leading figures of literature and politics. She laboured for the fame of Anatole France, and she forced him out of his inertia into composition. The extracts from her correspondence with him prove the important share she took in his writings, and in the dedication of *Crainquebille* (1904) Anatole France could say: " To Madame de Caillavet, this book which I should not have written without her help, for without her help I should write no books."

For 40 years Anatole France poured out a series of lively, solid, graceful and profound works. There are the pungent and mischievous short stories, *Balthazar* (1889), *L'étui de nacre* (1892), *Le puits de Sainte-Claire* (1895); the meditative and critical books, *Les opinions de Jérôme Coignard* (1893), *La vie littéraire* (4 vol. 1883–92); a philosophical novel, *La rôtisserie de la Reine Pédauque* (1893); an historico-philosophic novel, *Thaïs* (1890), describing Alexandria at the beginning of our era and contrasting the ideals of dying paganism with those of nascent Christianity; an admirable novel on the French Revolution and the Terror, *Les dieux ont soif* (1912); a society novel, *Le lys rouge* (1894), a powerful study of jealousy set amid the artistic treasures and lovely vistas of Florence; then the series of political satires, the four volumes of *L'histoire contemporaine—L'orme du mail* (1897), *Le mannequin d'osier* (1897), *L'anneau d'améthyste* (1899), *M. Bergeret à Paris* (1901), where Anatole France creates the legendary figure of M. Bergeret and portrays society before and during the Dreyfus affair; novels of a revolutionary tendency, *Sur la pierre blanche* (1903), *L'île des Pingouins* (1908), *La révolte des anges* (1914), a biography of Joan of Arc (1909–10); lastly the reminiscences, *Le petit Pierre* (1918), *La vie en fleur* (1922). Such is the sum of this work admirable in its wealth and variety.

The philosophy of Anatole France developed during the course of his career. Until 1900 he was primarily a sceptic. As Voltaire's spiritual son, he delighted in the play of ideas and observed without pity the stupidity and the silliness of men. He probed the past and the present and spared no example of human inconsistency, error or weakness. *Les opinions de Jérôme Coignard* gives the reader much pleasure, so witty and mischievous is the author, and gives him, too, a complete lesson in scepticism. The same remark may be passed on *Les dieux ont soif*, where Anatole France considers almost exclusively the failures of the French Revolution. At this time the author seems to have kept respect for beauty alone, the beauty of natural or artistic forms or of such superior intelligence as was shown in the great Greek and Latin writers. Meanwhile he beamed indulgently upon an imperfect universe. As he believed in nothing, he did not believe in a better or a worse. In the writings prior to 1900 may even be found conservative and aristocratic maxims. A supreme indifference inclined him to accept what is rather than risk what might be.

On the outbreak of the political crisis of 1900, his temper changed. He was then seen to show a preference for the progressive parties, and little by little went on to the revolutionary parties which became honoured by his support. He was no orator; words came slowly, and neither his mind nor his phrases were of the kind likely to be popular. The part taken by him at public meetings was undistinguished, being limited to signing manifestos and applauding resolutions, especially those with an

international objective. He was more powerful with his pen. An opponent of Church and State, he seemed to put his faith in the people and to expect the world to be renewed by some kind of revolution. On this point his ideas remained rather vague. In one of his books, *Sur la pierre blanche*, he ends the description of future society with a dreadful cataclysm that destroys everything, and here he is nearer to nihilism than to socialism. The World War changed the trend of his thoughts. As he was too old to serve in the field he wanted at least to show his good will and asked to be employed in a Tours office. This great upheaval left him uncertain concerning the destinies of humanity. Perhaps extreme scepticism is not for long tolerable, and Anatole France felt the need of escape into a revolutionary faith which he refused to define, leaving it a mere aspiration.

What is indisputable is the quality of Anatole France's art. The younger generations, tried by war, and witnessing the consequent political difficulties, ill comprehend the detachment of dilettante M. Bergeret. They need more moral discipline, they believe more in virtue and action. But they do not deny the master who charmed their elders with his graceful wit and magic phrases. As a storyteller, in lucidity of thought and form, Anatole France is incomparable. In his style, too, there is a sweetness, an almost voluptuous grace, which distinguishes his phrases from those of any other writer. He owed much to Voltaire, much to Renan, much to the old French romances, to memoirs and to chronicles. He had read and remembered much; but what he borrowed he made his own; all was changed, and for the better, by his style and interpretation. He translated into a pungent idiom all that could delight or stimulate the intelligence of his cultured contemporaries. He was a deep admirer of classicism, and to the end of his life, when he mentioned Molière, Racine or Stendhal his conversation or his writing attained their richest substance and most pleasant harmonies.

He makes another strong claim on the attention of posterity. He was the finest flower of the Latin genius. His knowledge of antiquity was great, and his work contained the essentials of Greek and Latin wisdom. He portrayed in *Thaïs* characters who distil the philosophy of the ancients. He put into the mouth of Jérôme Coignard maxims which likewise represent the sum of the meditations and arguments common to antiquity. If all the works of the Hellenic and Roman periods were lost their shadow and purpose might be found in the works of Anatole France. He knew what he owed them, and paid them the most splendid homage.

Lastly, in all periods of his career, whatever his theories, he was a deep student of human nature. He expressed in tuneful sentences most of the wisdom that may be acquired from the observation of life and the reading of history. He created characters who persist in the memory: Jérôme Coignard, Jacques Tournebroche, M. Bergeret, Madame Martin Bellème, Catherine, the lace worker, Paphmuce, Nicias, Evariste Gamelin. He described what was comic and evil in mortals. He described, too, what was august in man, sacred in man's labours and sufferings. Though he lacked enthusiasm and ardour, his critical intelligence did not prevent him from brooding over human misery, and in the story of Crainquebille he showed his heart. While humbling himself before the invincible forces of fate and lust, he dedicated his work now to irony—which brought brightness into his life—and now to pity—which at other times reminded him that life deserves a serious, a solemn attention. And so he became twice fortunate, for he was at once a subtle artist acclaimed by the critics and a universally respected publicist who influenced the simple-minded. He died at Tours, Oct. 13 1924.

The works of Anatole France have been translated and edited by Frederic Chapman and James Lewis May and published by The Bodley Head, London.

FRANCE (*see* 10.775), a republic of Western Europe and member of the League of Nations. The area of France, increased on Nov. 11 1918 by the addition of Alsace-Lorraine, is now 212,737 sq. miles. Her domiciled population (1921) was 39,209,518.

I. POLITICAL HISTORY

The situation of France at the beginning of 1911 was difficult enough, though no acute trouble was manifest at any point to account for the general uneasiness everywhere apparent. In Nov. 1910 M. Briand, after breaking the great railway strike, reconstructed the Ministry, over which he had presided since the fall of M. Clemenceau in July 1909, to include a larger proportion of Moderate elements. As is usual in such cases, the reconstruction had disintegrated the governmental majority instead of strengthening it. The Chamber elected in 1910 leaned further to the Left than the Prime Minister, and showed its dissatisfaction by reducing the majority to 16 on a vote of confidence on the application of the Congregation Laws. M. Briand might still have remained in power had he really wished, but he preferred to resign (Feb. 20 1911) with honour rather than cling to office. Although himself sprung from the Socialist ranks, he felt the necessity of preserving public order against subversive elements, and saw that the deputies were more and more inclined to force the issue, and moreover, he saw no way of extricating himself satisfactorily from the very delicate negotiations with Germany.

The Years Before the War

The Conflict over Morocco.—Since the Algéciras Conference in 1909 French diplomacy had alternated between two courses. Confident in the Russian alliance and the Entente of April 8 1904 with England, she had effectively resisted German pressure. But she saw on all sides evidence that Germany intended to obtain by indirect means what she had failed to win by intimidation—a footing in Morocco and the disruption of the Triple Entente. The Berlin Cabinet took every opportunity of thwarting the organisation of a French protectorate in the Shereefian Empire; moreover, acting in conjunction with Vienna, they persistently insinuated in political and journalistic circles in Paris that France would enjoy greater facilities in Morocco in return for complaisance towards German expansion in the East. This alluring propaganda had its effect upon the Radicals and Socialists, while the Russian Alliance and the Entente Cordiale found favour mainly among the Conservatives, Progressives and Liberals. To the Left of these parties—whom the pacifists accused of militarism—hopes were entertained of an understanding with Germany which, by removing the risk of war, would permit of the normal development of democratic institutions. M. Pichon, Foreign Minister in the Clemenceau and Briand cabinets, did not share this view; but, inspired with a great desire for conciliation, he gave certain confidential assurances to Berlin, supplementing the Franco-German declaration of Feb. 9 1909, under which nationals of both countries were to be associated in Morocco in any transactions for which they could obtain contracts. But at the beginning of 1911 the cabinets of Paris and Berlin were in fact in complete disagreement on the application of the 1909 declaration, and it was therefore without regret that Pichon left the Quai d'Orsay.

Monis, a senator from La Gironde, formed (March 2) a Radical Ministry, giving Caillaux Finance, Berteaux War, Steeg Public Instruction, Delcassé the Navy, Messimy the Colonies and Paul-Boncour Labour. He immediately found himself in difficulties of various kinds. Himself opposed to proportional representation, he had to deal with a Chamber which favoured this method; and although he yielded to Socialist pressure on social questions he was unable to calm the effervescence of the extreme Left. In the department of Aube he was

threatened by a quasi-revolt of the vine-growers, whose right to sell their wine under the name of champagne had been disputed. The Moroccan question was again disquieting. The strongest personality in the Ministry was Caillaux, who, though he stood for better relations with Germany, cherished the ambition of "giving" Morocco to France—that is to say, releasing the protectorate in Morocco from the obligations of Algeciras by arrangement with Berlin. With the concurrence of Berteaux he pressed forward the Morocco campaign. His Foreign Minister, the lawyer Cruppi, failed to realise the risk of military initiative without diplomatic preparation. In April, when the French troops entered Fez, Germany formulated reservations, and Spain claimed her right to similar military occupations, notably at Larache. The question of calling a second conference at once arose; at the moment of this diplomatic crisis a tragic accident put an end to the Monis Ministry, for Berteaux was killed and Monis seriously wounded (May 20) by the fall of an aeroplane on the aerodrome at Issy-les-Moulineaux. For a month the Govt. struggled on. The Senate settled the Aube wine question by removing the strict definition of champagne. On June 23 the Govt. was defeated in the Chamber, and resigned.

Invited to form a ministry, Caillaux took the Interior himself, assigned Finance to Klotz, left Steeg and Delcassé at Public Instruction and the Navy, gave Messimy War and entrusted Foreign Affairs to de Selves, a senator and a successful prefect of the Seine. Caillaux's programme included a project for the "reorganisation of Africa." This scheme, previously worked out with Messimy, had formed the subject of secret negotiation with the German Govt. in the spring. At that time the proposals entailed the cession to Germany of the political administration of French Equatorial Africa under the form of railway exploitation. A document, which was to remain secret, stipulated that: "if the construction of the railway is authorised, Germany may be practically assured that sooner or later Cameroon will be able to annex the Sanga, Ubangi and Shari basins. The economic preponderance of Germany in these countries will in effect inevitably entail her political ascendancy."[1] This move, which meant disguised annexation, failed; but the German Govt., disillusioned by the failure of the agreements made with the Briand Ministry, proceeded with a definite plan. Jules Cambon, French ambassador in Berlin, went to Kissingen during the ministerial crisis to talk over matters with Kiderlen-Waechter.

The Agadir Incident.—On July 1, the day after the reading of the ministerial declaration in Parliament, the reply came. Germany's representatives abroad notified all the Powers signatory to the Act of Algeciras that in response to the appeal of German commercial firms and of German protégés for the protection of Agadir, their Government had sent a warship, the "Panther," to the Moroccan port. This brusque announcement, which meant that France must either forego the military protectorate of Morocco or compensate Germany, was made two days before the date fixed for the embarkation of the President, M. Fallières, and the Foreign Minister, M. de Selves, on a visit to the Queen of Holland. For four months the new Ministry was absorbed in extremely delicate negotiations. Confronted with the uncompromising attitude of Great Britain and Russia, Germany, whose military and naval equipment was not yet complete, did not persist in her original claims on the Congo. To hasten the issue, Caillaux ventured, unknown to de Selves, to make to Berlin secret proposals exceeding the limits conceived possible by the Foreign Minister. Disagreeable complications ensued. Finally, on Nov. 5, a treaty was signed ceding to Germany territory which gave access to the Ubangi and the Congo and organising an economic protectorate in Morocco.

The bill for the ratification of the treaty provoked stormy debates in the Chamber. It was passed at the end of Dec.; but when, some days later, M. Caillaux's secret offers were disclosed at the Commission on Foreign Affairs of the Senate, at which Léon Bourgeois presided, there was a dramatic scene which led to de Selves's resignation. Caillaux offered the Foreign Office to M. Delcassé, who hesitated; the Marine successively to Poincaré, Admiral Germinet and Pierre Baudin, who refused. Finding it impossible to complete his Cabinet, the Prime Minister resigned on Jan. 10.

The replacement of a third of the Senate on the first Sunday in Jan. 1912 produced no sensible modification in either the spirit or the composition of the Upper Chamber.

At the request of Fallières, Raymond Poincaré now quickly formed a ministry. Taking the Foreign Office himself, he made Briand Minister of Justice, gave Léon Bourgeois Labour, Steeg the Interior and Delcassé the Navy. In his declaration on Jan. 16 he announced as his programme the prompt ratification of the treaty of Nov. 4, an *entente loyale* with Spain, courteous and frank relations with Germany, loyalty to alliances and friendships, the restoration of the principle of authority, rigid repression of crime and of offences against persons or property and electoral reform. Under the influence of the Prime Minister moderate ideas began to find favour. When Henri Brisson died, Paul Deschanel was elected to succeed him as president of the Chamber. The municipal elections in May were in favour of the Moderates. A rather complicated franchise Act embodying proportional representation was passed by the Chamber. But, as in the previous year, attention was riveted primarily upon foreign affairs.

A treaty providing for the protectorate was signed by the Sultan of Morocco on March 30, and Gen. Lyautey was appointed Resident-General. There followed disturbances at Fez, negotiations with Spain and long discussions in Parliament. The Sultan Moulai-Hafid abdicated, and was replaced by Moulai-Youssef. The liquidation of the Moroccan affair was attended by a series of complications.

The Balkan Crisis.—Italy had thought it necessary to undertake a parallel enterprise in Tripoli, thus involving herself in a war with Turkey. Certain questions of neutrality arising out of this led to unpleasant incidents, one of which—that of the "Carthage" and the "Manouba"—caused acute tension between Paris and Rome. Here arbitration prevented actual conflict. But the annexation pure and simple of the whole of Libya by Italy, the closing of the Dardanelles and various other incidents aroused such excitement and such hopes in the Balkans that a Balkan League was formed for the purpose of liberating the Christian races on the peninsula. Poincaré was briefly informed of this by Izvolski on April 1, and of the details only in Aug. on the occasion of his visit to Nicholas II. at St. Petersburg. He attempted to intervene as a moderator, but the German and Austrian cabinets which had had warning from secret sources at the beginning of April, allowed events to take their course in the hope that Serbia might be crushed. During the Balkan wars Poincaré continued to urge the localisation of the conflict and the maintenance by the Great Powers of a disinterested attitude in respect of territory. At the London Conference, which opened in Dec., his thesis was: "The Balkans for the Balkan States."

The diplomatic crisis had become serious over the question of Scutari and of Serbia's access to the sea when, Fallières's tenure of office having expired, Poincaré was elected President of the Republic (Jan. 17 1913) by 483 votes against Pams with 269. He carried the day in spite of Clemenceau and the preliminary nomination of Pams by a majority of the Left groups. In his presidential address to the Chambers he made clear his intention to take a more active part than his predecessors had done in the politics of his country. "Weakening of the executive power" he said, "is no part of the creed of Chamber or Country." He insisted further on the necessity of maintaining the military power of France at its highest level, for "it is not possible for a nation to have an effectively pacific policy unless it be always prepared for war."

Briand's Cabinet of Jan. 1913 was formed in accordance with these ideas. Taking the Interior himself, he gave Foreign Affairs to Jonnart and Justice to Barthou, leaving most of the other ministers in their offices. He demanded extraordinary credits for material of war, and put forward a bill for the re-establishment of three years' service, proposing thus to counterbalance

[1] *Documents secrets*, published by A.G. Journal des Débats Jan. 11 1912.

the military measures of the German Govt., which had asked for a special grant of a milliard marks for the reorganisation of the army (*see* GERMANY). Meanwhile he was placed in a minority in the Senate on the question of proportional representation and, on March 18, gave in his resignation.

Barthou, who now became Prime Minister, with Pichon as his Foreign Minister, set himself to secure the passing of the Three Years' Service bill, considered indispensable for national security by the French general staff. Meanwhile he decided to retain with the colours the class whose term of service would expire in October. It was only after a hard struggle and in the face of violent opposition from the Socialists throughout the country that the bill was passed by the Chamber, and then only with an amendment made by Painlevé which placed recruitment a year earlier, at 20 instead of 21, so that the 1912 and 1913 classes were called up together, allowing the 1910 class to be released at the appointed time. The Senate passed the bill almost unanimously.

Barthou's ultimate success was due to the ever-growing menace of a European war. In April a petty dispute between German travellers at Nancy and the inhabitants nearly led to a diplomatic quarrel. Even when the peace of Bucharest (Aug. 10 1913) ended the second Balkan War, the air was still charged with electricity, both in Europe and the East. In France anxiety increased with the rapid growth of pan-Germanism and the concentrated pressure exercised on the Quai d'Orsay by the cabinets of Vienna and Berlin with the object of raising loans to drain French savings invested in those countries which were under the influence of the two empires. In the beginning of Nov. Pichon learned through Jules Cambon, who had been confidentially charged by the King of the Belgians to convey the warning to the French Govt., that the Kaiser had said to King Albert at his official visit to Potsdam: "War with France is inevitable and imminent. . . . . This time it must be decisive. Your Majesty can have no conception of the irresistible enthusiasm that will sweep over the entire German nation when that day comes." Other remarks, of no less grave import, were made by von Moltke, chief of the German general staff, who was in attendance.

Vigorously attacked by the Left, Barthou had to contend with strong opposition from the Radicals, led by Caillaux, and the Socialists. After the parliamentary vacation his majority collapsed on a question of finance. The floating debt, which had been increased by the expenses in Morocco, made it necessary to raise a loan. The loan proposed by Dumont, Minister of Finance, was defeated by 290 to 265. The objection to the extension of the guarantee of fiscal immunity enjoyed by the existing *rentes* to the new *rente* demanded by the minister was, however, only the nominal pretext; the real opposition of the Left was due to Dumont's refusal to impose an income tax.

Ribot and Jean Dupuy failed successively in their attempts to form a Moderate cabinet on account of Radical opposition of which Caillaux was the rallying point. Poincaré, mindful of Caillaux's diplomatic activities in 1911, was unwilling to put him into power. He therefore instructed Doumergue to form a Radical ministry in which that statesman would take Foreign Affairs. Doumergue entrusted Caillaux with Finance, René Renoult with the Interior and Viviani with Public Instruction. He obtained a vote of confidence from the Chamber (302 votes against 141) for "a policy of democratic reforms, based on republican opinion and supported by an exclusively republican majority." This new Govt. indicated a reversion to the sectarian policy known as "Combisme." It was in favour of a tax on income, which was adopted by the Chamber. The reform of the franchise was definitely rejected by the Senate in March, and the approaching elections were therefore to be on the old basis of the *scrutin d'arrondissement.*

The Menace of "Preventive" War.—Although the Ministry had promised the loyal application of the Three Years' Service law, it was known to dislike the system. But the external situation became more and more disquieting. German militarism entered upon a provocative phase. The Zabern incident (*see* ALSACE-LORRAINE) produced a deep impression throughout the country. In March the *Kölnische Zeitung* stated that the "legend" of historical Russo-German friendship had been finally exploded. The question of the "preventive" war was openly discussed in the principal Berlin papers. The *Kreuzzeitung* expressed regret that Germany, in 1905, had missed the opportunity of demanding a decisive explanation from France when the conditions were most favourable. The *Berliner Tageblatt* held the view that "in certain cases, a state surrounded by too-powerful neighbours owed it to herself not to wait for the knock-out blow to be delivered." It and other papers declared that Germany must make haste to act before the Habsburg Empire fell to pieces. For several weeks the newspapers harped on this theme. The cordial sentiments exchanged at the Elysée on April 21, when the King and Queen of England visited Paris, reassured the public for a time; but fresh signs of trouble soon disturbed its peace. A noisy campaign was organised in Germany against the Foreign Legion, and complications arose at various points in the East.

The Assassination of Gaston Calmette, and the Elections.—A sensation was caused on the eve of the elections by the assassination of Gaston Calmette, editor of the *Figaro*, by Madame Caillaux. On Caillaux's resignation Renoult became Minister of Finance, and Malvy Minister of the Interior. The elections took place a month later (April 26 and May 10). The re-election of Deschanel by 401 votes as president of the Chamber made a majority for the Radicals and Socialists seem unlikely. All the vice-presidents too were chosen from among the partisans of the Three Years' Service bill. Nevertheless the Unified Socialists carried 102 seats, and the Radicals were reinforced; their combined strength was such that no Cabinet could dispense with their support. Doumergue, deferring to custom, had resigned after the elections, and the President of the Republic appointed Viviani with instructions to maintain the Three Years' Service law. But Viviani, confronted with the opposition of the Radical-Socialists, who demanded a return to two years' service, resigned. Poincaré then called on Ribot, who completed on June 9 a Cabinet composed of Moderates and of friendly Radicals, such as Léon Bourgeois and Jean Dupuy. But this Cabinet fell at the first meeting of the Chamber on June 12, when a majority of 306 against 26 announced the resolve: "to give a vote of confidence only to a government capable of bringing about the union of the Left groups." Ribot had drawn the attention of the Chamber to the gravity of the general situation and the increase in German armaments; but the Socialist deputies, absorbed in their own affairs, maintained that these armaments were not directed against France. Viviani, summoned once more by Poincaré, now found the Radicals more accommodating, and succeeded in his task. He took Foreign Affairs himself; gave Justice to Bienvenu-Martin, the Interior to Malvy, War to Messimy and the Navy to Augagneur. The ministerial declaration announced the Government's intention of applying the Three Years' law until further notice and of carrying into effect the income-tax proposals so long held up by the Senate. The Ministry secured a vote of confidence by 370 against 137 votes.

THE EUROPEAN CRISIS

On June 28 the Archduke Francis Ferdinand and his wife were assassinated at Sarajevo by two Bosnians who were Austro-Hungarian subjects. While diplomatic and military preparations for a war of aggression were being carried on in the greatest secrecy in Vienna and Berlin, President Poincaré and Viviani were embarking for Russia on a visit to the Tsar, while the French people were passionately absorbed in the proceedings against Madame Caillaux (July 20–8) at the Seine assizes. The verdict of acquittal produced a great sensation, but at this very moment the designs of Austria and Germany were revealed in a flash. Poincaré had scarcely left Russia, on July 23, when—at a moment chosen by Vienna and Berlin to prevent the President and the Tsar from coming to any agreement—the Austro-Hungarian Foreign Minister sent Serbia an ultimatum couched in terms which were intended to make it unacceptable. In Paris, the Austrian and German ambassadors declared to Bienvenu-Martin,

acting Premier and Foreign Minister, that the conflict was to be localised to Austria and Serbia. M. de Schoen added that "any intervention by another Power would, automatically, under the existing alliances, produce incalculable results." A wireless message led Poincaré and Viviani to cut short their proposed stay in Stockholm and cancel their visits to Christiania and Copenhagen; they arrived at Dunkirk on July 29.

On resuming the direction of affairs on the night of the 29–30th, Viviani found the situation desperate On the night of the 25th Austria had broken off diplomatic relations with Serbia, and declared war on the 28th. At the Quai d'Orsay Schoen insistently demanded from Bienvenu-Martin and Philippe Berthelot a public declaration of the "political solidarity of France and Germany"—that is to say, the abandonment of Russia by France. On the 31st Graf Lichtenfeld, Bavarian Charge d'Affaires in Berlin, informed Munich that "the Prussian great general staff face war against France with the most complete confidence and count upon the complete defeat of France in four weeks."

During the presidential voyage anxious French Socialists had got in touch with German Socialists at Brussels. Jouhaux, general secretary of the *Confédération générale du travail*, inquired categorically of Legien, the Social-democrat representative, whether his party would allow themselves to be mobilised in case of aggression on the part of Germany. He received no reply. On the morning of the 31st the German Govt. declared a "state of emergency" (Kriegsgefahrzustand) preliminary to general mobilisation. On the same day the Austrian and Russian governments simultaneously ordered a general mobilisation. At 3:30 P.M., Bethmann Hollweg desired Schoen to inform Viviani that the German mobilisation inevitably meant war, and to ask him whether in a war between Russia and Germany France would remain neutral. His concluding instructions—marked "secret"—to Schoen were:

> If, as there is no reason to suppose, the French Govt. should declare that they will remain neutral, I beg your Excellency to inform the French Govt. that we should require, as pledges of their neutrality, the handing-over of the fortresses of Toul and Verdun; these we should occupy and return after the war. The reply to this question should be in our hands before 4 P.M. to-morrow.

At 7 o'clock Schoen fulfilled his mission to the Quai d'Orsay. A few minutes later, Jean Jaurès, leader of the French Socialist party, who had returned, greatly disheartened, from Brussels, was assassinated by a fanatic in a restaurant. During the day three councils were held at the Elysée. Poincaré sent King George an urgent letter, insisting on the importance of unity of diplomatic action on the part of the Triple Entente and on the moderating effect that could not fail to be produced in Vienna and Berlin by the certainty "that the Entente Cordiale would be affirmed, in case of need, even to the extent of taking the field side by side." In spite of the extreme gravity of the situation Viviani had not yet ordered general mobilisation, but only the completion of the second defence line. No moderating influence could now alter the course of events, determined by the two Central Powers. The French Govt. had concurred in all the British and Russian proposals for the prevention of a general conflagration, whether by the summoning of a conference, by arbitration by the Hague Court, or by mediation. In spite of some wavering between Vienna and Berlin at the eleventh hour the situation was so well defined that Schoen made his preparations for departure on the evening of the 31st, without waiting for the reply that Viviani was to give him the next day. With the "punishment" of Serbia as the initial pretext, the conflict insensibly assumed the form desired by the German general staff. From Austro-Serbian and Austro-Russian it became German-French, without a mistake or even the slightest imprudence having been committed at any point by the French Government.

The Declarations of War.—On Aug. 1, without awaiting replies from France and Russia, William II. approved the text of the declarations of war against these two Powers. The Federal Council assembled in Berlin took note of the two documents, and agreed to their dispatch in case the expected replies should prove unsatisfactory. At 11 A.M. Viviani replied to Schoen that France would do what her interests demanded. There was no mention of Toul and Verdun by Schoen. At 3:40 P.M. France ordered a general mobilisation. At the same hour, and before the arrival in Berlin of Schoen's telegram relating his interview with Viviani, the order for general mobilisation was given in Berlin, the public announcement following at 5 o'clock. At 5:30 Schoen went again to the Quai d'Orsay, where Viviani expressed to him his hope that, in spite of the mobilisation, negotiations would be continued on the basis of the most recent proposal put forward by England, which had the warm support of the French Cabinet. At 7 P.M. Count Pourtalès delivered Germany's declaration of war to Sazonov. At midnight Izvolski appeared at the Elysée, where a Cabinet meeting was in progress, to ask what France intended to do. The Cabinet decision was to fulfil all the obligations of the Alliance, but that France should not take the initiative in breaking off relations nor declare war. A state of siege was proclaimed, and the Chambers were convoked for the following Tuesday. During the night German detachments invaded French territory at four different points.

On the morning of Aug. 2 a French corporal was killed on the Delle road by a German lieutenant who had entered France at the head of a patrol. In Berlin the expediency of an immediate invasion of France was being discussed. After consulting the war ministers and the general staff, the Chancellor decided in the negative. "We hope," he reported to the Kaiser, "that the French will attack us." But this hope was not realised, the French troops having orders not to respond to provocation. The German Cabinet then ordered the German Minister at Brussels to carry out the instructions contained in a sealed note that had been sent with a telegram on July 29; these instructions were that the Belgian Govt. be summoned to allow the passage of the German Army. At the same time the chief of the German Admiralty informed the commander of the fleet that hostilities against France would probably commence on Aug. 3. The Belgian Govt. rejected the German summons, as also the proposal of H. Klobukowski, the French Minister, to send five French army corps to defend Belgium's neutrality. In London assurances were made to M. Cambon by Sir Edward Grey that if the German Fleet came into the Channel or through the North Sea to undertake military operations against the French coast or shipping, the British Fleet would give all the protection in its power, and that the British Govt. were considering whether they would declare in Parliament the next day that the violation of Belgium should be regarded as a *casus belli*.

On Aug. 3, France having nowhere furnished any pretext for aggression, the German authorities spread false reports of supposed invasions of German soil or German skies by French soldiers. Bethmann Hollweg telegraphed to all the European capitals that "France's action was the most serious violation of neutrality imaginable." Between 1 and 2 o'clock he ordered Schoen to deliver to the French Govt. at 6 P.M. the same day a declaration of war couched in these terms:—

> The German administrative and military authorities have established a certain number of flagrantly hostile acts committed on German territory by French military aviators. Several of these have openly violated the neutrality of Belgium by flying over the territory of that country. One has attempted to destroy buildings near Wesel; others have been seen in the district of the Eifel, one has thrown bombs on the railway near Karlsruhe and Nürnberg. I am instructed, and I have the honour to inform your Excellency that, in the presence of these acts of aggression, the German Empire considers itself in a state of war with France in consequence of the acts of this latter Power.

Viviani made vigorous protests both to Schoen and in a note sent to the representatives of the Powers in Paris. There was some brawling in the streets of the capital where German or Austro-Hungarian subjects owned shops and some of these were pillaged. But order once being restored by Viviani, no further disturbance took place in the following days. That evening he reconstructed his Cabinet to suit the circumstances, himself remaining president of the council but relinquishing Foreign Affairs, which passed to Doumergue. Augagneur succeeded Gauthier for the Navy.

On Aug. 4, amid general excitement but without disturbance anywhere, Parliament reassembled to hear the Government's communication. In his message the President of the Republic recalled the fact that for over 40 years France, resolutely putting aside her desire for legitimate reparation, had used her rejuvenated energy solely in the interest of progress and for the good of humanity; that she might be justly proud of having made supreme efforts to avert the war which had just broken out, the crushing responsibility of which would be laid upon the German Empire by history. The message, to which the two Assemblies, greatly moved, listened standing, proclaimed the "*union sacrée*" of all sons of France. Viviani then explained at length the events and negotiations that had taken place, concluding with these words: "We are without fear, we shall be without reproach." Thus invoked, the "sacred union" became a reality. Even as the army mobilisation proceeded throughout the country in perfect order, so the mobilisation of the spirit, which prepared the population to endure long and terrible trials, was effected with a quiet dignity. Parties ceased to exist. Bowing to the evidence of German aggression the Socialists stood loyally by the Government. They sought no vengeance for the murder of Jaurès, and the Viviani Cabinet, confident in their patriotism, refrained from using their discretionary powers of preventive arrest even on the most suspect in their ranks—those whose names were on "List B." The whole country, moved by one will, rose with the same enthusiasm against the invader.

By a succession of laws, passed without debate, the country was organised for a state of war. The state of siege was to be maintained for the duration of the War; commercial settlements were postponed and credits prolonged; legal proceedings against citizens called up for service were suspended, and a moratorium was decreed for bank deposits. Allowances were voted for necessitous families whose breadwinners were in the army; the Govt. was authorised to open by decree credits for the requirements of national defence. Notes on the Banque de France became compulsory currency, and the limit of emission was raised to 12 milliards. Measures were taken against alcoholism, in particular the sale of absinthe was forbidden. To avoid press indiscretions it was forbidden, under penalty of imprisonment, to publish any information regarding national defence apart from that given in official communications, or any military or any diplomatic article of a nature "favourable to the enemy or calculated to depress the minds of the army and the population." No preventive censorship was established, but a Press bureau installed at the Ministry of War received the damp proof-sheets of the newspapers and marked such passages as were not to be printed. Any paper which failed to comply was liable to be warned, and, in case of a second offence, suspended. The passages suppressed were represented by blank spaces as it was impossible to replace them at the last moment; these were known as "caviare."

In a few days the conflagration had spread from one end of Europe to the other. Austria, however—the original instigator—affected a sort of ignorance of events in her relation to France. Her ambassador continued his functions in Paris. Under pressure of public opinion, infuriated by this cynical attitude, Doumergue sent Graf Szecsen his passports on Aug. 10 and instructed Dumaine to ask for his. The British Cabinet followed the same course with regard to Count Mensdorff.

The War Period

After the loss of the battle of the frontiers (Aug. 20–4) the Ministry realised the need of reconstruction or—as Viviani phrased it—of broadening its basis. On Aug. 26 the government of National Defence was constituted, containing representatives of the Republican parties, and including for the first time two Socialists, Guesde and Sembat. Viviani remained as Prime Minister without portfolio; with Briand, Delcassé, Malvy, Millerand, Ribot, Sarraut and Doumergue. At the same time Jouhaux, together with the Archbishop of Paris, Cardinal Amette, was appointed to the National Aid committee (*Comité de l'oeuvre du secours national*), created for the assistance of refugees from the invaded departments and presided over by the head of the Paris Faculty of Science, M. Appel. No sooner was the new Govt. formed than it departed to Bordeaux (Sept. 3) unwilling to risk being shut up in Paris as in 1870. The capital was left in the hands of a military governor, Gen. Galliéni, whose short proclamation became famous: "Inhabitants of Paris, the members of the Govt. of the Republic have left Paris in order to give a new impulse to National Defence. I have received a mandate to defend Paris against the invader; this mandate I shall carry out to the end" (Sept. 3). Nevertheless more than a third of the population left the city. German aeroplanes flew over Paris daily.

The installation at Bordeaux of the Govt., the foreign missions, the principal departments of state, the most important Paris newspapers, and a multitude of pusillanimous or curious persons was not effected without some disorder at first, and even some scandals. But life in the provisional capital rapidly attained the necessary dignity. On the side of the Govt. it showed great activity. On Sept. 5 M. Delcassé obtained through M. Cambon a declaration signed in London by which the British, French and Russian governments mutually agreed to conclude no separate peace during the existing War, nor, when peace terms came to be discussed, to propose conditions without first coming to an agreement with each of the other Allies.

The victory of the Marne (Sept. 6–10) brought relief, and, indeed, gave rise to exaggerated hopes; but disillusionment was to follow. On Aug. 2 a German-Turkish alliance had been concluded, unknown to the ambassadors of the Triple Entente duped by the triumvirate Talaat-Enver-Djemal; there followed the disaster of Tannenberg, the penetration of the "Goeben" and the "Breslau" into the Sea of Marmara, and Turkey's entry into the War on the side of Germany at the end of October. Munitions became exhausted and the line of trenches now extended continuously from the Vosges to the sea. Paris was no longer in danger, but six departments had been invaded, and none could say when they would be liberated. The situation being thus stabilised, the Govt. was reinstalled in Paris in the latter half of December. The Chambers which had not sat at Bordeaux, although assembly rooms had been reserved for them, met again on Dec. 22. Thenceforward they were to be permanently in session with but few interruptions. The experience of the preceding months had shown that there were serious objections to the suppression of Parliament and of the Press. An outside stimulus was needed to correct the errors of judgment and fatal imprudences that had been committed. In the Chamber the criticisms were many and vigorous; notably these formulated with asperity by Clemenceau in his paper *l'Homme Libre* which, after being suppressed by the censor, reappeared as *l'Homme Enchaîné*. But Viviani was able to curb excessive recriminations in the Chamber and to insist on the maintenance of the *union sacrée*. He consented to the formation of big parliamentary commissions, which were to prove discreet and very useful collaborators of the Government. Certain deputies and senators were sent on missions to the armies.

Annual budgets were dispensed with. All credits were voted by douzièmes described as provisional. As taxes were not coming in well and it was considered impolitic to raise them at a time when the nation's whole resources were being strained to restrict invasion, resort was had to loans. The most successful financial resource was the issue of National Defence bonds, which had been Ribot's idea. These were actually Treasury bonds in the form of coupons bearing a fixed rate of interest, payable in advance, which could be realised at three, six or 12 months and were negotiable at sight.

The Ministry was vigorously attacked on the subject of the men—named *embusqués*—mobilised or liable to be mobilised, who shirked service at the front. In the hurry to produce munitions many factories had to be set working again and authority was given to their directors to recall such of their workpeople or staff as seemed to them indispensable. Similarly, members of the universities and specialists whose technical knowledge was indispensable to different services had to be allotted to non-combatant corps. As a result the trenches had been held, since the middle of 1915, mainly by peasants and employees. On the

initiative of Dalbiez, therefore, the Chamber passed a rigorous law (June 26), which did not however entirely remove the *embusqués* scandal. In July two under-secretaryships were created: Joseph Thierry for supply and Justin Godard for the medical services. The discussion aroused by all these complicated questions weakened Millerand's position. In the Senate, Clemenceau, as president of the Army Commission, carried on a ruthless campaign for the adaptation of the services to the needs revealed by the War.

The Intervention of Italy.—In the field of foreign politics the spring was a period of great promise followed by great disappointment. In the Dardanelles the naval expedition sent to force the Straits failed (March 18) with heavy losses. In May there was joy on hearing of Italy's intervention on the side of the Allies. A treaty between the Triple Entente and Italy, of which the tenor remained a secret for the whole of the War, had been signed on April 26 in London. Although the clauses relating to the proposed cession to Italy of territory inhabited by Slavs were not divulged, they were known in substance to the Slav peoples and created great indignation, thus strengthening Austro-Hungarian resistance. Then, too, in defiance of a formal stipulation in the Treaty of London, Sonnino declared war on Austria only. It was not until Aug. of the following year that he declared war on Germany, who benefited meanwhile by Italy's neutrality. Then again, England and France, who were already providing military material for Russia, had now to manufacture it for Italy also, although they had not enough for themselves. The crowning humiliation was Rumania's failure to come in till over a year later instead of with Italy, as the Allies had expected.

The Intervention of Bulgaria.—Yet another intervention was to follow, disconcerting the Allied Ministers and precipitating the fall of Viviani's Cabinet. When Bulgaria ordered a general mobilisation on Sept. 22, the Allies flattered themselves that it was directed against Turkey. For three days Delcassé and Millerand denied the evidence. When the truth came out, Delcassé, on being questioned in the Chamber, was subjected to such severe criticism that he had to retire. Viviani then took over the portfolio of Foreign Affairs (Oct. 13). He was still able to obtain a vote of confidence of 372 to 9; but, by the abstention of the Socialists and a large number of Radicals, the *union sacrée* was broken. Viviani was a victim of the general uneasiness caused by successive disappointments and by the non-success of the great offensive in Champagne (Sept. 15). Sensible of the disaffection of the majority, who were opposed to the secret committees instituted by the Chamber, Viviani handed in his resignation on Oct. 28.

Briand rapidly formed a new Cabinet, keeping Foreign Affairs himself. The Ministry of Justice fell to Viviani, War to Gen. Galliéni, Navy to Adm. Lacaze, Public Instruction and Invention to Painlevé; Ribot retained Finance and Malvy the Interior. Five seats in the Cabinet without portfolio were created for de Freycinet, Léon Bourgeois, Combes, Guesde and Denys Cachin, and an Under-Secretariat for Munitions for Albert Thomas, the young Socialist deputy. The Ministry, which embraced political veterans of all parties and some new men in addition, was unusually well received. Briand's speech, taking as its motto: " peace through victory," was followed by a vote of confidence in the Chamber of 516 to 1. The *union sacrée* seemed to be restored in spite of the sympathy shown by a considerable and energetic Socialist minority with the pacifist resolutions passed at the International Socialist conference at Zimmerwald early in September. This minority grew gradually bolder. At the second International Socialist Conference, held also in Switzerland at Kienthal in April 1916, three French deputies presented themselves.

Restrictions and Finance.—In spite of goodwill the Briand Cabinet had some hard knocks at home and abroad. In the hope of preventing a rise in the price of essential foods and of slowing down the increase in the cost of living, the Govt. provided the bakers with flour (at a loss) and fixed maximum prices for certain commodities. They had eventually to proceed to stricter measures and to ration each family for bread, coal and sugar. Summer time, introduced in June for the sake of economising coal, was maintained in spite of the dislike of the rural population. The prolongation of the War made it more difficult to enforce extraordinary regulations which had been accepted originally as temporary. The restrictions on the consumption of alcohol, to which the trade raised strong objections, and the prohibitions laid down by the military authorities aroused complaints which reverberated unpleasantly in the Chamber. On Feb. 1 1916 Galliéni, having been rudely interrupted, left the tribune and even the hall. Although he was brought back it was only to complain, " You force me to do work for which I am not fitted." It was not for long. Galliéni, being exhausted and threatened with appendicitis, resigned on March 16. On May 26 he died as the result of an operation. His funeral was made a national event. He was succeeded by Gen. Roques, who was thus the fourth War Minister in 20 months.

The necessity of providing the Treasury with other resources than those raised by loans compelled the Govt. to demand new sacrifices. A tax on income, passed by the Chamber before the War, but laid aside by the Senate, had already been imposed; but owing to the respite granted to mobilised men only 133,000 were found to have an income over 5,000 fr. (the minimum taxable figure), and as their total income was under three milliards, only half the expected sum was realised. Ribot hoped at least to cover the interest on new loans by the tax. He therefore proposed to double the tax on land, the tax on income, and to increase the duties on tobacco, sugar and alcohol; also to suppress the rights of vineyard proprietors to distil without paying duty on the yield of their vintage. On this latter point in particular Ribot met much opposition, and exemption on 10 litres of pure alcohol per family was conceded. The Senate accepted this condition, though objecting to the distillers' privileges. The doubling of direct taxes was rejected in favour of a tax on war profits, which from this time onward often appeared excessive. The Socialists took advantage of the national unrest to promote their cause, and internationalism made some headway in the National Council of French Socialists. Late in Aug. a vote was passed protesting against the doctrine which denied that a country had the right to defend itself when attacked, and calling for a durable peace based upon reparation of the wrong done in 1871 and the restoration of independence to oppressed nations. But the minority continued to grow and, by Dec. 28, had 1,081 votes against 1,836. Only by 1,637 votes against 1,372 was Thomas authorised by the party to return to Munitions.

Verdun and the Somme.—During the whole of 1916 military interest was concentrated on the siege of Verdun (*q.v.*). By June the general anxiety had reached such a pitch that Viviani consented to let the Chamber sit in secret committee (June 16–22). After animated discussion a resolution was passed, by 440 against 97, expressing at the same time confidence in the Govt. and the Chamber's desire " to exercise effective control of all services engaged in providing for the requirements of the army . . . while strictly abstaining from interference with the conception, direction or execution of military operations." Actually this control was carried out without serious hitches, and the committee continued to sit in secret whenever the situation was felt by the deputies to be too serious to be discussed at a public sitting.

On July 1 a Franco-British massed attack was launched against the line of the Somme. It was a brilliant performance, with heavy losses on both sides, but the result was negative; for after weeks of struggle the Allied line had only advanced some kilometres to the East. On the second anniversary of the War efforts were made to sustain the morale of the army and the population by proclamations from the President of the Republic, the Prime Minister and the army chiefs. The Govt. urged private individuals to put their gold into the Banque de France and place their realisable foreign securities at the disposal of the state. In response to these appeals some three milliards were collected, making it possible to limit depreciation of the franc to 10 or 12%.

The Eastern Campaigns.—But events in the East took a disastrous turn. The second Dardanelles expedition—no more successful than the first—was abandoned in the autumn, and the

troops thus released were sent to Salonika and placed under Gen. Sarrail, who had instructions to go to the aid of Serbia. But Sarrail, lacking adequate means and thwarted by the opposition of King Constantine, was unable to get into touch with the Serbs, whose army retreated under terrible conditions across Albania to the Adriatic. In vain did the British and French governments urge Constantine to range himself on the side of the Allies; he dismissed Veniselos and the Chamber, and persisted in an unfriendly neutrality. Briand opened negotiations with the Greek Govt., which produced nothing but irritation and disappointment to France. On Aug. 17 1916 a treaty of alliance with Rumania brought the Allies renewed hopes of an early victory. But after some success there came a fresh disaster. Rumania was attacked by Bulgaria, on whose neutrality she had relied; the Russian contingents promised to her were delayed, the promised offensive by Sarrail's army was not launched and her territory was finally invaded and occupied by the enemy as far as Moldavia. Encouraged by these events and urged on by Berlin, Constantine went so far as to attack some detachments of French marines on the outskirts of Athens and a number of Veniselists in the streets of the city. French residents had to take refuge with the fleet.

Briand and Adm. Dartige du Fourmet, commanding in Greek waters, had been doubtfully advised in their later negotiations with the Cabinet in Athens. They had in fact speculated on Constantine's goodwill. In France, where the Rumanian catastrophe had come as a surprise, these latest events made a painful impression. A secret committee of the Chamber (Nov. 28–Dec. 7) passed a resolution "taking note of the Government's declarations on the reorganisation of the command and approving its resolution to concentrate on the conduct of the War and its economic organisation." Briand thereupon reconstituted his Cabinet. He suppressed the five ministers of state, made Gen. Lyautey War Minister (replacing him in Morocco by Gen. Gouraud), promoted Thomas to be Minister of Munitions, and gave Herriot Supplies. Loucheur was made Under-Secretary of Munitions. A war committee of five ministers was formed and, at the end of the month, the reform of the high command, so long desired by the many who had lost confidence in Joffre's methods, was timidly brought about. Joffre was attached to the War Committee as technical adviser, and was made a Marshal of France. His successor was neither Foch nor Pétain, but Gen. Nivelle, who was appointed commander of the armies of the north and northeast. But Briand's authority was now seriously impaired. In the Chamber he was subjected to wearisome criticism and recrimination, and the deputies refused him the necessary powers to deal by administrative order with questions affecting national defence. Even the Senate's vote of confidence was only passed by 190 votes against 37. With each successive vote his majority decreased while the number of abstentions steadily increased. At last, during a session in which certain deputies demanded a secret committee on military questions, Gen. Lyautey retorted bluntly that there were some things which could not be said even in secret committee. This suggestion of possible indiscretions—there had been leakages—was greeted with angry murmurs, and Lyautey decided to resign. As Painlevé refused to take his place, Briand tendered the resignation of the whole Cabinet on March 17 1917.

Peace Offers.—One of the last acts of the Cabinet had been the rejection of a disputable offer from the four enemy governments "to enter upon peace negotiations." This proposition, couched in grandiloquent phrases and enhanced by sensational addresses from the heads of the governments in Berlin, Vienna and Sofia, lacked precision. As M. Briand said, speaking on Dec. 1 1916, it was a proposition to "*d'avoir a négocier la paix.*" The Russian, Italian and British ministers denounced its insincerity. About the same time, too, a note from Mr. Lansing invited the belligerents in the name of President Wilson to "take soundings." It was a profound shock to France to see all the belligerents—aggressors and victims—put thus on the same footing. Two days later the Swiss Govt. made a similar move. On Dec. 23 the French Senate announced its determination "to carry on the War which has been imposed upon us to a victorious conclusion." The governments of the other Allies expressed their determination with equal force. On Dec. 30 they sent collective and identical notes to the neutral states charged with the protection of their interests in enemy countries, stating that the conclusion of peace was contingent upon the restoration of rights and liberties that had been violated and recognition of the complete independence of the small states. Wilson still pleaded for "peace without victory" at the Senate on Jan. 22; but, Germany having declared for unrestricted submarine warfare, (Feb. 1) he broke off diplomatic relations with that country on Feb. 3.

Paul Deschanel, the president of the Chamber, having declined to undertake to form the new Ministry, it fell to Ribot to accomplish this task in 24 hours. Taking Foreign Affairs himself, he gave War to Painlevé, Labour to Léon Bourgeois, and retained several of the former Ministers—notably Malvy as Minister of the Interior. Lyautey returned to Morocco. The ministerial declaration, of considerable substance and detail, was approved by 440 votes against 61 abstentions. Ribot was confronted with some extremely important problems. The Russian Revolution, the forced abdication of the Tsar, and the installation of the weak provisional Govt.—soon to be succeeded by the Bolsheviks—upset all the military combinations of the Allies on the eve of a great offensive for which minute preparations had been in progress for months. At the same moment (March 17–24) the Germans effected a strategic retreat on the Somme front, leaving a desert behind them. A formidable problem presented itself: should the offensive, prepared in conjunction with the British, be carried out in spite of the modification in the general conditions unfavourable to the Allies? To what extent should the Govt. interfere in the direction of military operations? Intimate discussions took place between the ministers and Gen. Nivelle. The declaration of war on Germany by the United States (April 6) served, it is true, to restore the equilibrium destroyed by the Russian Revolution, but it would be many months before it could have any effect on the military situation. As the Govt. still hesitated Nivelle offered his resignation, but withdrew it on receiving definite assurance that the offensive would take place as arranged. On April 16 the French troops, who had been magnificent in launching their attack, were brought up against insurmountable obstacles and came to a standstill after heavy losses. The depression felt by the army and the public led, among other changes, to the replacement of Nivelle by Pétain, with Foch as chief of the general staff.

Side by side with military operations, secret negotiations were proceeding between Paris and Vienna. In Jan. and Feb. the Emperor Charles I. commissioned his brother-in-law Prince Sixtus of Bourbon to communicate his desire for peace to President Poincaré. After several journeys Prince Sixtus of Bourbon presented Austria's peace conditions (May 5) at the Elysée. They were the conditions of a conqueror, and the alliance with Germany, Bulgaria and Turkey was again affirmed. After another journey to Vienna, Prince Sixtus returned to the Elysée with a personal letter from the Emperor, who expressed his willingness "to forward in every possible way the just claims of France to Alsace-Lorraine and to use his personal influence with his Allies to that end." Although these conditions were unacceptable to the Allies of France, Poincaré and Ribot did not reject them offhand. On April 19 Ribot went to St. Jean-de-Maurienne with Lloyd George, who had been fully informed, to meet Sonnino. Lloyd George offered Sonnino Smyrna if he would give up Trieste; but the Italian Minister insisted that the conditions of the Treaty of London had represented a minimum and that any concession would provoke risings in Italy which would place the Govt. in danger. Subsequent conversations only attested the impotent vacillation of the Austro-Hungarian Government. Other secret proposals were exchanged during the summer at Fribourg in Switzerland between Count Revertera, for Austria, and Count Armand for the French general staff. But these emphasized the inconsistency of proposals which proved abortive.

French Action in Athens.—It was thought that only by force of arms could the enemy be checkmated. Ribot therefore decided, after consulting the British Govt. in London, to settle the Greek question by expelling Constantine and freeing the Salonika Expeditionary Force from the risk of attack by the Germanophil Greek forces. He gave full powers to Senator Jonnart, appointed High Commissioner of the Allied Powers for the occasion. Jonnart left for Brindisi on June 2 and appeared before the Piraeus at the head of a fleet on the 5th. In spite of strong protests from the British, Italian and Russian Ministers at Athens, all of whom were opposed to the expulsion of the King, Jonnart demanded and obtained Constantine's capitulation, after having had Thessaly and the Isthmus of Corinth occupied by Allied troops. On June 13 King Constantine left Athens with his family. Jonnart then recalled Veniselos, who had constituted a provisional government at Salonika, and the King's second son, Prince Alexander was called to the throne with the title of King Alexander I., his elder brother George being passed over because of his German sympathies.

The Socialist Movement.—This success was warmly approved in Paris inside and outside Parliament. It helped to consolidate the Cabinet, which, however, was soon to be shaken by the Socialist manoeuvres. At a plenary session of the party held in May, the Socialists had decided to attend the International Congress at Stockholm which had been called with the object of stopping the War. The Govt. refused their passports, and the Chamber, after a secret session, passed a resolution of approval by 467 votes against 52, and with a further resolution on the conditions of peace that:—

The Chamber, while countersigning the unanimous protest made to the National Assembly in 1871 by the representatives of Alsace-Lorraine, forcibly torn from France, announces that it expects, as the result of the War imposed upon Europe by the aggression of Imperialist Germany, not only the liberation of invaded territory, but the restoration of Alsace-Lorraine to the mother-country and just reparation for damages.

The Chamber further declared itself to be " far from any idea of conquest or of the subjection of foreign populations," and defined the goal towards which the armies of the republic were striving as " the laying down of permanent guarantees of peace and independence for great and little nations by an organisation of which the basis is now being prepared by the League of Nations." On June 7 a similar motion was passed unanimously in the Senate, which in addition requested the Govt. to take all necessary precautions at home and abroad for the safety of the nation, in view of the number of recent strikes of a suspicious nature in which undesirable foreigners had taken part.

These transient troubles, which yielded to firm handling, coincided with a peace move staged in Berlin (*see* EUROPE), and rumours on the subject of a journey to Leningrad (Petrograd) undertaken by Doumergue and Castelnau under the late Ministry. As regards the latter, Ribot stated in the Chamber on July 31 that Doumergue had made a note of the Tsar's promise to support the re-annexation of Alsace-Lorraine to France and " to leave France free to seek guarantees against renewed aggression, not by annexing the territories on the left bank of the Rhine, but by creating if necessary an autonomous state out of these territories, which would protect us, as well as Belgium, from invasion from beyond the Rhine." Meanwhile disturbances stirred up by Teutonic influences with the aim of depressing French opinion and bringing into power in Paris men who would be willing to take the initiative in peace proposals, provoked a governmental crisis. In view of the anti-patriotic propaganda that was being carried on by means of pamphlets and the revolutionary paper *Le Bonnet Rouge*, the Senate held a secret committee (July 19–20). Clemenceau took Malvy, Minister of the Interior, vigorously to task on the matter of his relations with Almereyda, an adventurer who edited *Le Bonnet Rouge*. This episode marks an epoch in the internal history of France during the War, for it created the schism between the Socialists and the Government.

The Senate and the Chamber successively passed votes of confidence, in spite of the resignation of Adm. Lacaze and Denys Cochin. The Socialist group allowed Albert Thomas to remain in the Cabinet; but the rupture took place, following on the action brought against *Le Bonnet Rouge*. Almereyda, who had been arrested on Aug. 6, was found dead in his cell on the 14th. He had been strangled with one of his bootlaces. The official experts gave a verdict of suicide, but such a suicide was at lowest a singular reflection on the supervision exercised, and public opinion was up in arms. Malvy had been away a few days for his health, but he now resumed his functions. Meanwhile it was learnt that a cheque of suspicious origin which had been seized at the frontier from the director of *Le Bonnet Rouge* had been restored to him by the favour of Leymarie, Director of Public Safety, and at the same time director of the bureau of the minister. Leymarie declared he had acted without consulting the minister, and resigned. On Aug. 31 Malvy, accused of having relations with Almereyda, resigned. It was first thought that the Ministry might be simply reconstituted, but the attempt failed, and the Cabinet resigned on Sept. 7. Ribot, charged with the task of forming a new Ministry, failed, because the Socialists refused to collaborate with him, while Painlevé refused to remain in the Cabinet unless the Socialists came back. The Socialists could not forgive Ribot for refusing passports to Stockholm, and Painlevé was being pushed into power by friends who regarded him as the man of the hour.

Thus it fell to Painlevé to form a Cabinet which, by a curious contradiction, did not include a single Socialist. He was his own War Minister; Ribot retained Foreign Affairs, and Loucheur became Minister of Munitions. On Sept. 18 Painlevé secured a vote of confidence, unanimous but for the abstention of the Socialists and some Radicals (among them Caillaux). The Ministerial Declaration contained nothing new in general policy, but promised that justice would take its course, unhesitatingly and without any respect of persons, in the judicial inquiries then proceeding or about to be opened. This promise the Ministry was almost immediately called upon to fulfil. On Oct. 7 Turmel, a deputy, was arrested for having received money of suspicious origin. Then came the Bolo scandal. It was discovered that Bolo—known as Bolo Pasha, that title having been conferred on him by the former Khedive, now dethroned and an instrument of the Central Powers—had received 10,000,000 fr. in the United States from Von Bernstorff, the German ambassador. With this sum he had bought 1,100 shares in the *Journal*, the editor of which, Senator Charles Humbert, had made himself known by a noisy campaign demanding " guns and munitions." Bolo was arrested on Sept. 29. On Oct. 4 Malvy himself appeared in the dock. The former Minister of the Interior was accused of treason by Léon Daudet, editor of the *Action Française*, in a letter addressed to the President of the Republic, which was read out in the Chamber. After a judicial inquiry the Govt. announced, on Oct. 15, that there was no foundation for Daudet's accusations. The Govt. obtained only 246 votes against 89 in the Chamber on an interpellation on the subject. It was shaken; an outside incident brought about its fall.

The Lancken-Briand Incident.—Meanwhile the Berlin Cabinet, itself torn by internal dissensions, was trying to implicate certain Frenchmen in its *défaitist* negotiations. M. de Lancken, German civil commissioner in Brussels, conveyed proposals to Briand by means of Belgian intermediaries—notably Baron Coppée and his son. He told him that William II. was ready to make peace and to send a qualified personage to Switzerland to confer with the former Prime Minister. Briand wrote to inform Ribot, and suggested the conditions under which conversations might be initiated; but Ribot strongly opposed conversations which might be exploited by the Germans. Lancken therefore waited in vain for Briand at Ouchy, and the matter dropped. But a legend grew in the lobbies of the Chamber to the effect that Ribot had turned down peace feelers which held some promise of the return of Alsace-Lorraine to France. On Oct. 12, when Georges Leygues made an interpellation in the Chamber on the personnel and action of the diplomatic body, Ribot took the opportunity to denounce in veiled language Austria's manoeuvre to separate France from Italy and the pitfalls laid by Germany,

"who only the other day, caused perfidious suggestions to be whispered in the ear of a man of high standing." The concluding words of this sentence caused a commotion at the Palais Bourbon, and were therefore suppressed in the official records. On the 16th, the Socialist deputy Mayeras moved to discuss the discrepancy between the words spoken in Parliament and the text as printed. The motion was discussed in a stormy secret committee which gave the Govt. a small majority. Briand's friends, displeased with the allusion of Oct. 12, voted with the Socialists, who were still full of resentment over the refusal of the Stockholm passports. The Cabinet were so badly hit that Painlevé contemplated resignation. Poincaré would not accept his resignation, but Ribot and his other colleagues handed in theirs collectively so as to give the Prime Minister a free hand to reconstruct his Cabinet. On Oct. 28 the Ministry was reconstituted, Painlevé contenting himself with replacing Ribot by Barthou; but far from consolidating the Govt. the substitution only weakened it. The ministerial majority, which had stood at 362 on the 12th and 316 on the 19th, fell to 288 after Painlevé's and Barthou's speeches on the 25th.

Nevertheless, Painlevé took the same attitude as Ribot towards Stockholm, and refused passports for the Congress then in progress. He hoped to appease the Socialists by an investigation of the *Action Française* affair, but the Court found no cause to prosecute. Meanwhile *Le Bonnet Rouge* and the *Journal* scandals grew more serious, and Caillaux himself was attacked in *l'Homme Enchaîné* for his conduct when travelling in Italy. Then came the Italian disaster of Caporetto and the advent of the Bolsheviks in Russia, which made it necessary to hold an inter-Allied conference at Rapallo for the co-ordination of military effort.

The Rapallo conference over, a troubled period set in for France. M. Paix-Séailles, who had formerly been attached to Painlevé's bureau, was accused of divulging information from documents dealing with national defence. Caillaux was brought before the juge d'instruction to give an account of his relations with Bolo Pasha, and had an exchange of letters with Clemenceau which caused a sensation. On Nov. 13 Painlevé announced in the Chamber the results of the Rapallo conference. These were, an extension of the British front, Franco-British economic co-operation, the strengthening of the blockade and the creation of an Inter-Allied Supreme War Council. Only 250 votes were recorded in approval against 192, a further diminution of the Government majority. This was speedily transformed into a minority when the Prime Minister demanded the postponement of motions relating to internal order until after the Inter-Allied Conference to be held at the Quai d'Orsay at the end of the month. The Chamber voted against the postponement by 277 against 186, and at the close of the sitting Painlevé handed his resignation to Poincaré: his authority in Parliament was at an end.

The Clemenceau Ministry.—Public opinion indicated Clemenceau as Prime Minister, the Senate supported the choice, and the Chamber was prepared to acquiesce, little as it liked the remorseless controversialist who criticised ministers and even the President of the Republic so fiercely in *l'Homme Enchaîné*. In spite of his 76 years, Clemenceau was universally regarded as the incarnation of the determination to "fight to a finish," to punish weakness or faltering, whatever their origin, and to subordinate everything to the pursuit of final victory. The great majority of Frenchmen felt that such a man was needed at the head of the Government. Ignoring all other considerations, Poincaré therefore called upon Clemenceau (Nov. 15) to form the new Cabinet. Clemenceau accepted, and completed his mission the next day. He took War himself, confiding Foreign Affairs to Pichon, the Interior to Pams, Navy to Leygues, Munitions to Loucheur, Finance to Klotz; and divided the war services between five under-secretaries. The Ministerial Declaration announced the intention—

to carry on the War, to punish crime and faltering: weakness would be complicity. Accused persons to be tried by court-martial. No more pacifist campaigns, no more German conspiracies; neither treason nor demi-treason; but the War and nothing but the War. Our armies shall not be caught between two fires. Law shall prevail. The country shall know that its defence is sure.

In the debate on the declaration Clemenceau spoke in the same tone. There were to be no more party men, himself not excepted.

Who has been more of a party man than I? I have been only too much of one, as I see to-day. . . I shared—and perhaps still share—many of your prejudices, but where I differ from you, deputies of the extreme Left, is that you want to introduce purely intellectual conceptions into the domain of realities—and that is impossible.

The vote of confidence was passed by 418 against 65. Clemenceau was as good as his word. Turmel, a deputy, was tried by court-martial on Nov. 22; parliamentary impunity was suspended by the Senate in the case of Humbert; and Malvy asked the Chamber to appoint a commission to inquire into the grounds for his accusation. Although the accusation had no legal basis, and the rules of the Chamber did not prescribe the procedure in such a case, the Chamber, greatly embarrassed, sent him before the Senate, which, having reinstituted a procedure in disuse since 1875, constituted itself a high court and ordered a supplementary inquiry (Jan. 28). On Dec. 22, at the request of Gen. Dubail, military governor of Paris, the Chamber voted for the suspension of parliamentary immunity for Caillaux by 396 against two votes and 100 abstentions. The accusation of intelligence with the enemy and of a criminal attempt against national security was founded on documents seized during the Bolo case, indicating a singular intimacy between Caillaux and Bolo and Almereyda. The official reports of the French naval and military attachés in Rome also drew attention to the attitude and the defeatist proposals of the former Prime Minister.

On Jan. 14 Caillaux was arrested. Inquiry conducted in the United States had revealed relations with the German Legation at Buenos Aires, at the time of his mission in the Argentine; and from various telegrams sent by Von Bernstorff, German ambassador in Washington (deciphered by the State Cryptographic Dept.) it seemed that Caillaux had spoken contemptuously of the members of the Govt.—Briand excepted. When reporting Caillaux's remarks to Berlin, Von Bernstorff asked his Govt. to instruct the German cruisers to take precautions with regard to the ship on which the French statesman was returning. Finally, in the safe of a Florentine bank rented by Caillaux there was found among the securities a packet labelled "Rubicon," which contained the outline of a scheme to be carried out when Caillaux should again become Prime Minister. This scheme resembles the constitution of the consulate.

These events were discussed in the Chamber, together with the royalist escapades of the *Action Française*, and the resolution passed stigmatised "all proceedings, royalist or other, which tend to divide the country in the face of the enemy." The Socialists and Caillautists voted against the words "or other," assuming that they referred to the "Rubicon." Bolo's trial by court-martial (Feb. 4–14) ended in sentence of death for the ex-pasha for his dealings with the enemy, which included relations with the former Khedive, transactions in America with Von Bernstorff and the payment of German moneys intended for the purchase of French newspapers. He was executed at Vincennes on April 17. To all attacks, direct or indirect, by the Socialists, Clemenceau presented an unmoved front, and claims of every kind—economic, financial and military—were met with the same imperturbability. By a bill passed on Dec. 24 the election was postponed on account of the mobilisation of several million electors. A loan of 10 milliards was liberally supported. Very severe restrictions on the consumption of bread were imposed, and the 1919 class was called up prematurely.

The Russian Defection.—This last measure was necessitated by the defection of the Russians and by Austrian arrogance. Count Czernin, in his elation over Caporetto, boasted that he was fighting as much for the defence of Germany as for the Austro-Hungarian frontiers—"We are fighting for Alsace-Lorraine just as Germany fought for Lemberg and Trieste. I make no distinction between Trieste and Strasbourg." At Brest-Litovsk the Bolsheviks concluded an armistice with Germany,

in spite of Russia's undertaking, on Sept. 4 1914, not to negotiate or conclude a separate peace; they also intimated their intention not to honour the financial engagements of the Tsarist government. The French Govt. sent a note of protest, stating that "financial engagements entered into previously in the name of Russia were independent of the changes of government which had occurred since and might occur again in that country, and that, consequently, they were and would continue to be binding upon those by whom Russia was represented." The Socialists now asked for passports for Leningrad (Petrograd) to attempt to dissuade Russia from making a separate peace; but Clemenceau refused them, because he regarded such a step as useless, dangerous and even unseemly. The signing of the Treaty of Brest-Litovsk on March 3 definitely broke the Russian alliance.

From the end of Jan. 1918 the bombing of Paris by aeroplanes ("Gothas," as they were called) recommenced with fresh vigour after a long respite. The raid of Jan. 31 took a toll of 45 killed (31 in Paris and 14 in the suburbs) and 207 wounded; that on March 9, carried out by a dozen squadrons, left 13 dead and 50 wounded. Life in Paris was seriously inconvenienced by the precautions imposed—as the reduction of street lighting, closed shutters and the warnings given by sirens. But it was quite another matter when, on March 23, shell, fired from colossal guns more than 100 km. distant, fell direct on Paris, without there being at first any clue to their place of origin. Monuments situated in the danger zones had to be protected by sandbags. On March 29 (Good Friday) a shell fell on the church of St. Gervais, at 4 P.M., just as a sacred concert was beginning, killing 75 people and wounding 90 others, of whom several afterward succumbed. Terrible bombardments at Dunkirk, Calais and Rheims simultaneously drove the inhabitants into the cellars. The motive behind these attacks was that of terrorising the country at the moment when the German general staff was launching (March 21) a mass offensive against the British front which was intended to be decisive. But the morale of the country was not shaken, any more than was the spirit of the high command. Although there were days of acute strain in March and April Clemenceau never faltered. At the end of March he obtained consent from the Allies for Foch's nomination as generalissimo of the armies on the Western Front. He then proceeded to tighten food restrictions, ordered three meatless days a week, reduced the consumption of paper, etc.

The Czernin Incident.—During these troubled times Teutonic intrigues followed fast upon each other. The most sensational of these was that launched by Czernin (April 2), when he boldly asserted in a speech delivered to the municipal representatives in Vienna that Clemenceau had asked him, shortly before the beginning of the Western offensive, if he were "prepared to enter into negotiations and on what basis." He went on to insist on Austria's loyalty to Germany, and vowed "a terrible vengeance" upon the enemies of the Central Powers. Clemenceau's reply was simply, "Count Czernin lied." By way of retort Czernin recalled the *pourparlers* between Count Nicholas Reverterā and Count Armand in Feb. 1918. On April 8 Clemenceau exposed Revertera's "attempt to decoy us into a German peace," and announced "another attempt of the same sort by a person of much higher rank." Czernin in reply accused Clemenceau of having wrecked this effort by refusing to enter into negotiations based on the renunciation of the re-annexation of Alsace-Lorraine. Clemenceau thereupon disclosed the fact that the Austrian Emperor had with his own hand recorded his willingness to agree to "the just claims of France on Alsace-Lorraine."

At this point the Emperor Charles himself intervened with a telegram to William II., in which he declared Clemenceau's statement to be untrue and proclaimed the "perfect solidarity" between the two Central Empires. An official communiqué from Vienna followed, emphasising this denial. On April 12 Clemenceau published the Emperor Charles' letter to Prince Sixtus. After some sharp dispute with the Emperor and Empress, Czernin announced that the text of the letter, which had been entirely private and personal, had been published in Paris in a garbled version. He maintained that the Emperor had written: "I would have used all my personal influence in favour of the French claims with respect to Alsace-Lorraine had they been just claims; but this they are not." Clemenceau again stated the facts, and denounced "les consciences pourris." An embarrassed note from the Ballhansplatz on the 15th then declared the incident closed.

The Decisive Days.—A fortnight later the *Bonnet Rouge* trial opened before the court-martial. Although Almereyda, the principal conspirator, was dead, the evidence revealed by the inquiry was sufficiently serious for sentence of death to be passed on Duval—who had received over 1,000,000 fr. from a Mannheim banker named Marx—and for several of his associates to be sent to penal servitude. The Socialist party, of which the anti-war section had won a majority in the national council of the party, agitated in vain for a "white peace"; the threat to refuse military credits left Clemenceau unmoved. Only for an instant at the end of May, when a new offensive brought the Germans up to the Marne from Château-Thierry to Dormans, did he consider the idea of evacuating the Government and a portion of the population from Paris. He had become as military-minded as—if not more so than—the soldiers themselves. Paris was a city like any other, and it seemed to him a wise precaution to abandon the capital as in 1914. But the circumstances were very different. After four years of fierce fighting the occupation of Paris by the enemy would have appeared as a German triumph in the eyes of the world at large, and the consequences, both material and moral, would have been incalculable. The evacuation project, which had been kept secret, was therefore opposed by the President of the Republic and the presidents of both Chambers. In a special council at the Elysée, at which other persons besides ministers were present, it was finally decided that the Govt. should stay in Paris and that the decisive battles should take place in front of and not behind the capital. On June 11 a successful counter-attack by Mangin's army threw back the Germans some kilometres, and, on July 18, Foch opened the great offensive which was to continue until the Armistice. Czechoslovak and Polish legions, formed of deserters and volunteers, fought side by side with French troops.

On July 16, before the Senate, sitting as a high court, Malvy was accused of complicity "in treason which threatened the very existence of the country." The Senate, however, rejected the charge of treason, on Aug. 6, unanimously but for two votes, and that of complicity in communicating with the enemy by 125 votes against 36. Senator Etienne Flandin then made the subsidiary charge: "Is Malvy guilty of having committed the crime of *forfaiture* while residing in the territory of the Republic and during the discharge of his ministerial functions within the last 10 years?" At the following session this accusation was definitely formulated. It was directed against the minister's attitude towards Almereyda and certain other anarchists. On Aug. 6 the Senate declared Malvy guilty of *forfaiture* by 101 votes against 81, and condemned him to five years' banishment, but without civic degradation. There remained the Caillaux affair—by far the most serious. Was Caillaux to come before a court-martial or the High Court? The Govt. decided that if the case were one of intelligence with the enemy the court-martial should deal with it, but if it were that of crime against the security of the state it should come before the High Court. The latter solution was adopted, and the Senate met for the purpose on Oct. 29 and found that there were grounds for instituting an "instruction," the affair being thereby indefinitely adjourned.

The Armistices.—Beaten by the Govt., the Socialists confined themselves to protests. At their National Congress in Oct. the advanced group, headed by Longuet, carried the day by 1,528 votes against 1,212 and 181. Cachin was made editor of *l'Humanité* in place of Renaudel. But the people remained indifferent, being concerned only with the retreat of the German armies, the crumbling of the Bulgarian front, the abdication and flight of the Tsar Ferdinand, the progressive reoccupation of the devastated departments and the entry of the Belgian Army into Bruges. Under these auspices was launched on Oct. 20 the

fourth great loan, the Liberation Loan, which realised 22 milliards. On the night of Oct. 30–31 Turkish plenipotentiaries signed an armistice with Adm. Calthrop at Mudros; on Nov. 3 the Austro-Hungarian armies signed an armistice; the break-up of the old Dual Monarchy was already far advanced.

A far-reaching problem now confronted the Allies. Was it wiser to conclude with Germany the Armistice which her desperate Govt. had asked from President Wilson, or to force the German armies to capitulate, and so enter Berlin? French ruling spirits were divided. Foch held that " war is only waged for its results, and, if these results are obtained by the Armistice, no one has the right—the aim being achieved—to cause one more drop of blood to be shed." The generalissimo knowing nothing of the developments of the revolution overshadowing Germany believed that it would still take several months to throw back the enemy across the Rhine. The conditions of the Armistice were therefore discussed, first at Senlis by the military delegates, then in Paris and Versailles among the heads of the Govt. and the foreign ministers of the Allied and Associated Powers, the discussions being based exclusively on military considerations. The statesmen agreed unreservedly to the proposals of the military council at Versailles. Many of them, at that moment, were so far from thinking the proposed conditions too mild that they feared the German plenipotentiaries would refuse certain exceptionally severe clauses, such as the surrender of the fleet and the fortresses of Alsace-Lorraine. The Germans, however, terrified by the prospect of invading enemy armies who would be tempted to avenge themselves for the abominations committed in Belgium and France, signed all the conditions on Nov. 11.

The proclamation of the Armistice, accompanied by the ringing of bells, led to scenes of enthusiasm that day in the streets and in Parliament. The two Chambers proclaimed that " Citizen Clemenceau and Marshal Foch have deserved well of their country." On the following day Foch was elected a member of the Academy of Sciences, and on the 21st the *Académie Française* elected Foch and Clemenceau, having previously elected Joffre (Feb. 14). Clemenceau, a doctor of medicine, was elected a member of the Academy of Medicine on Dec. 3. Finally the *Académie des Sciences Morales* opened its doors to Marshal Pétain, and the Beaux Arts elected Gen. Castelnau. Only the Socialists, while joining in the general rejoicings, professed an interest in the Russian revolution which was hardly justified in view of Russia's behaviour at the end of the War. The motion drawn up by the " Permanent Administrative Commission " of the party was disavowed by members of the minority, who announced their determination not to allow the methods even of revolutionary socialism to be confounded with Bolshevik practices, which did not allow universal suffrage to function. The French authorities now took possession of Alsace-Lorraine. On Nov. 17, in front of the statue of Strasbourg on the Place de La Concorde, from which the emblems of mourning had at last been removed, a magnificent ceremony was staged. At Metz Pétain was presented with his marshal's bâton, and on Nov. 25 the victorious troops entered Strasbourg amid scenes of frenzied enthusiasm. The War was over; it remained to " win the peace."

The Peace

The Armistice of Nov. 11 contained no political clause. It was assumed that, as was customary, some of the essential political conditions would be settled in peace preliminaries before the final treaty was signed. Had preliminaries been so arranged as to coincide with one of the three renewals of the Armistice, it should have been possible to take immediate measures for ensuring the position of those regions whose lot was to be changed—notably Poland, Upper Silesia and the Baltic States—where such measures were of the first importance. Certain opinion in France urged that this should be done. But for reasons that are still unexplained, no steps were taken to arrange such preliminaries, which, if arranged a few weeks after the military capitulation—so it was agreed—would have enabled the Allies to insist on all the points that seemed to them advisable. The end of the year was spent in rejoicings. The King of the Belgians and the King of England paid official visits to Paris, and President Wilson, before settling in Paris for the conference, visited England and Italy. When the conference opened on Jan. 18, Germany was more or less reassured, and on vital points Clemenceau was no longer in position to impose his views. He had to consult with President Wilson and Lloyd George. Indeed, in consenting to the form of procedure—Council of Ten, Council of Five, Council of Four, absolute secrecy, rigorous censorship of diplomatic indiscretions—he automatically forfeited the support which would have been gladly accorded to him by the representatives of the smaller powers, by Parliament and by influential publicists. Although both the President of the Republic and the presidents of the two Chambers disapproved of these " cellar negotiations," the system was maintained till the end. The conference only met in full open session to register preconcerted decisions. Thus Clemenceau, although he made spasmodic attempts at resistance, saw himself forced to concur in certain solutions that were contrary to his intentions.

This was particularly the case with the Rhine frontier. In common with the military authorities, many university men and several publicists, Clemenceau would have constituted the Rhine France's military frontier and formed the German countries lying between that river and the political frontier into an autonomous state. He was not even able to obtain the restitution of Saarlouis and Landau which had been severed from France by the Allies of 1815, in spite of their formal engagement (signed on March 13 1815, after Napoleon's return from Elba) to preserve intact France's frontiers of May 30 1814. He committed the imprudence of offending President Wilson by scoffing at the projected League of Nations, and prevented M. Bourgeois from bringing forward the plan of a league drawn up by French specialists. Surrounded by colleagues chosen from among his immediate circle, he was not amenable to any advice or suggestion and was neither wise enough to limit his original demands to what might be accepted nor to exact effective compensation for his successive concessions. To crown his misfortunes, he was wounded (Feb. 18) by three shots from a revolver by an anarchist named Cottin. When negotiations were resumed on March 14, after his recovery, decisions, contrary to his wishes, had been taken. France was only to have Alsace-Lorraine; the Inter-Allied military occupation of the left bank of the Rhine was fixed for 5, 10 or 15 years according to the zone; Germany was to renounce all rights in Morocco; power was taken to regulate the zones of Savoy; and Great Britain and the United States were to give a military guarantee against unprovoked German aggression, Britain's guarantee being dependent upon the ratification of that of the United States by the Senate in Washington.

The amount to be exacted for reparations for the terrible damages caused by the enemy was not fixed; a Reparations Committee was set up to settle it and to draw up the conditions of payment. Germany was to pay down on reparations account a sum of 20 milliard gold marks before May 1 1921. It was assumed in France—and Mr. Lloyd George's speeches in England appeared to justify the assumption—that Germany would pay for everything. Clemenceau and Klotz were under that illusion, for they brought in a bill passed on April 17 1919 by which those who had suffered damages were enabled not only to claim the price of their possessions at a pre-War valuation, but also the cost of reinstalment or reconstruction, taking into account the rise in prices since 1914. This arrangement was fated to bring about a financial catastrophe. Some hundred milliards had to be paid out on this score, and (in the event) Germany was to go bankrupt to evade payment. It was the same with similarly lavish promises of demobilisation premiums, pensions and allowances to the military victims of the War and their dependants; these had been made on the conviction that Germany would pay, but they made another deep hole in the budget. Other holes were made by the extravagant decision to

buy in at the rate of 1·25 fr. all German marks left in Alsace-Lorraine (quoted then at 0·70 fr.) and buy back in dollars for a large sum the American war stores which, if sold direct by the American stores department, could have been usefully absorbed by the population without involving the Treasury. These rash measures were to react disastrously on the whole of the national life.

The Socialist Movement.—The propaganda carried on by German Socialists infected their French comrades, who had been roused by the acquittal of the assassin of Jaurès on March 29 1919 at the assize court of the Seine, and were to be appeased neither by the passing of the Eight-hours' Day bill by both Chambers at the end of April nor by the maintenance of the price of bread below cost price. On May 1 they proclaimed a strike, and proceeded to demonstrations which led to the dismissal of several Socialist leaders holding government posts. The disturbances lasted all through the spring. The *confédération Générale du travail* itself was powerless to maintain discipline among its adherents; it alternately curbed their turbulence and yielded to their demands. When the peace treaty was being discussed with the German plenipotentiaries and the Allied military intervention against the Bolsheviks was proceeding, labour troubles became more marked. But the public faced the situation with such firmness that the general strike arranged for July 21 miscarried. Clemenceau was nevertheless awkwardly situated in the Chamber and had to replace the Food Controller Boret by Noulens.

The Versailles Treaty.—After several crises, particularly with respect to the question of the Adriatic and Danzig, the peace conditions, comprising 440 articles and numerous annexes, were ceremoniously presented to Graf von Brockdorff-Rantzau, the German plenipotentiary. The counter-proposals made by the German delegation provoked lively discussion among the Allies, several important modifications being supported by the British Government. Towards the middle of June the Allies at last came to an agreement to maintain almost in its integrity the text of May 7, the only really significant modification being the substitution of a plebiscite in Upper Silesia for the annexation pure and simple of that province to Poland. On June 16 the final text was submitted to Brockdorff-Rantzau with the warning that it must be accepted without reservation within five days. He resigned, and an extension of two days was granted. On the 23rd a new German Cabinet with Gustav Bauer at its head declared itself willing to sign, and on the 28th—the anniversary of the Serajevo murders—MM. Hermann Müller, Bell and von Haniel, the German plenipotentiaries, in the Hall of Mirrors at Versailles in which the German Empire had been proclaimed in 1871, signed the treaty of peace which established the territorial integrity of France, celebrated the triumph of right over might and destroyed Germany's supreme effort to achieve a world hegemony. The treaty by which England and the United States agreed to assist France in case of unprovoked attack was signed by Lloyd George and President Wilson the same day.

The treaties, taken as a whole, certainly were imposing, and marked an epoch in history. All the same, the French nation experienced a shiver when the clauses became known in detail. It was realised, as Poincaré said, that the peace was to be *une création continue*. Many serious problems were left unsettled. Several plebiscites, which would normally have been taken between peace preliminaries and the conclusion of the treaty, were adjourned until a time when—the demobilisation of the Allied armies having been effected—there would be no means of ensuring a true ballot. No precise sanctions had been stipulated in the event of the non-execution of the treaty by Germany. The League of Nations Covenant, was held by French opinion to be vague as to the principal obligations of its members. The terms were drawn in language permitting the contracting Governments to interpret it in favour of evading liabilities. In short, it became plain to the French that the Versailles Treaty would be carried out to their advantage only if the Allies, especially Great Britain, wished it. Except for Alsace-Lorraine they had received nothing but promises; their right to exact the fulfilment of Germany's engagements without the assent of all the Allies, was contested. The ratification of the treaty (Aug.-Sept.) therefore aroused violent opposition in the Chamber. Men like Louis Marin and Franklin-Bouillon called for its rejection. To reassure the deputies the Finance Minister announced, on Sept. 5, that Germany would put down a round sum of 450 milliards. In the end the ratification was agreed by only 372 votes against 52, with 73 abstentions. By the Senate, in Oct., it was approved without difficulty. But very soon it became known that the American Senate refused to ratify the Treaty of Versailles and the Treaty of Guarantee, and that, in consequence, the British guarantee disappeared. The most stupefying discovery was, however, that during the peace year of 1919 military expenditure exceeded that of 1918 with its fierce fighting, and that the National Debt had risen during the 12 months of peace from 170 to 218 millards. Under the shock of these affairs the country embarked on the election.

The Elections.—It was indeed time to return to normal constitutional life. All the elective assemblies had to be renewed, having outlived their legal term. The parliamentary elections took place on Nov. 16 according to the system adopted by the Act of July 12 1919: *scrutin de liste* according to department, with proportional representation in cases where none of the lists showed an absolute majority, together with the support of 25% of the electors on the roll. It was at first intended to maintain the political *union sacrée* by including Clemencistes, Liberal, Radical, Radical-Socialist and Moderate Socialist candidates on the same list; but the unified Socialists repudiated the union, and the Moderates—such as Herriot, Viviani, and Painlevé—separated from the Coalition after agreeing to it. Lists were accordingly framed as follows: the *Bloc national* including all moderate candidates—as, for instance, from Millerand to Maurice Barrès in Paris; and lists for the Unified Socialists, Radical Socialists and Independents of different categories.

The *Bloc national* had as its programme Millerand's Paris speech of Nov. 7 at the Ba-ta-clan hall. This speech denounced the class struggles, indicated the need of strengthening the Executive, of adopting a broader basis for the nomination of the President of the Republic, and for the constitution of the Senate. Clemenceau for his part made a great anti-Bolshevist speech at Strasbourg. At that moment, when demobilisation was complete and the opinions of the soldiers an unknown quantity, Bolshevism was thought to be the chief danger. In the beginning of Nov. a general strike was attempted. The newspapers were especially affected and, from Nov. 11, they ceased to appear; but they agreed between themselves to publish one organ in common, the *Presse de Paris*, in which space was reserved for a brief political article from each paper. This expedient was well received by the public. Soon the *Presse de Paris* appeared twice a day, corresponding to the morning and evening issues. The *Bloc* won the elections, and the new Chamber was made up of 56 Unified Socialists, 5 dissenting Socialists, 28 Republican Socialists, 129 Radicals and Radical-Socialists, 114 Republicans of the Left, 138 Progressives, 15 Liberals, 74 Conservatives and 3 adherents of the *Action Française*. The Bolshevist candidates were swept away; even in a suburb of Paris the list containing the names of Longuet and Sadoul was lost.

The municipal elections of Nov. 30 gave the same results. From the outset the Moderate elements carried all before them, not only in Paris but in many towns where they had formerly been in a minority as, for instance, at Toulouse. The check to the revolutionary parties was emphasized by the end of the newspaper strike on the same day. On Dec. 14 *conseils généraux* and *conseils d'arrondissement* were elected. Here the Left was more successful in holding its seats, based as it was on solid local organisations, and was able to recover lost ground on the senatorial elections (Jan 12), in which the prefects exercise considerable influence. Only 26 seats were lost by the Radicals, and Léon Bourgeois was elected president of the Senate by 147 votes against Antonin Dubost (with 125), the retiring president, of much the same political tendency.

The Presidency of the Republic.—Opening on Dec. 8, the Chamber had no important affairs to deal with before proceeding to elect a successor to Poincaré, whose seven years' tenure expired on Feb. 17 1920. The only outstanding event of its short session was the declaration of the Alsace-Lorraine deputies, whose entry into the Palais-Bourbon had been made an impressive ceremony. After recalling the protests of their ancestors against the Treaty of Frankfurt the representatives of the two reannexed provinces recorded the fact that no protest had been raised during the elections against the Treaty of Versailles. "France," they said, "has obtained a unanimous vote at the genuinely plebiscitary elections of Nov. 16."

On the choice of the future President of the Republic opinion was divided. Though he desired election, Clemenceau had not come forward openly. Deschanel stood as candidate. In spite of Clemenceau's disturbing antecedents, his popularity as victor was so great that the choice would have fallen upon him out of gratitude rather than from confidence in his political wisdom, had he not wounded the sensibilities of a large number of the *bloc national*. He had steadily refused them the satisfaction of re-establishing diplomatic relations with the Vatican, although they had pledged themselves to their constituencies to demand it. Moreover, while declaring that he would in no case remain Prime Minister, he showed a marked preference for former ministers ousted by the *bloc*. He also retained among his most intimate colleagues certain men who inspired justifiable suspicion. Unmoved by the insistence of the deputies, who were bent on seeing him rewarded by the supreme magistrature of the state, he refused to make any concession. Indeed, he openly announced his intention of reigning at the Elysée as the head of the Govt. and not as the Constitutional head of the state, and thus alienated many of the electors. On the eve of the Congress at a preliminary meeting, Clemenceau obtained only 389 votes against Deschanel's 408. Consequently he refused to stand, and Deschanel was elected by 734 votes out of 888 (Jan. 17 1920). The Cabinet resigned next day.

As leader of the *bloc national* Millerand was called upon to form the new Cabinet, which was constituted (Jan. 19) as follows: Millerand, Foreign Affairs; Interior, Steeg; Public Works, Le Trocquer; François-Marsal (a banker, not a member of Parliament), Finance. Poincaré was appointed President of the Reparations Commission. On Jan. 22 the Chamber passed a vote of confidence by only 272 votes against 23, half the members having abstained from voting in token of their resentment at having a Radical (Steeg) appointed to the Interior. But the majority rose to 481 against 70 on the 30th, after explanations by the Prime Minister.

Strikes and the Caillaux Case.—The internal situation did not realise the expectations inspired by the happy ending of the War. The *confédération générale du travail*, carried away by the masses it was supposed to control, instigated a strike of railwaymen in the spring, which was followed by miners', dockers' and seamen's strikes. None of these were successful, but they served to aggravate the industrial crisis caused by the rise in prices. That communist ideas were gaining ground in the Labour world was apparent at the Socialist Federal Congress of the Seine (Feb. 22), when the extremist motion put by Loriot, after an exchange of recriminations, was carried by an enormous majority. It looked as if the wave of revolution would sweep all before it. The disturbances coincided, not fortuitously, with the Caillaux case, which took its course before the Senate, constituted a high court, from Feb. 20 to April 23. Caillaux was condemned to three years' imprisonment and ten years' loss of civic rights; for five years his place of residence would be strictly that indicated by the Govt., and he was ordered to pay the costs of the trial. He was found guilty of corresponding with the subjects of an enemy country since the declaration of war, and notably in 1914, 1915, 1916 and 1917, both in France (especially in Paris) and abroad, the said correspondence having furnished the enemies of France with information detrimental to the military or political situation of France or her Allies—(Article 78 of the Penal Code). The high court admitted extenuating circumstances, and dismissed the charge of high treason. As Caillaux had already been detained in preventive arrest for two years and four months, he was released.

Relations with the Vatican.—Relations with the Vatican, which had been suspended since 1904, were now re-established in accordance with the wishes of the majority in the Chamber and in the country, by a bill granting the necessary credit for setting up an embassy to the Holy See. Without waiting for the passage of the bill Millerand sent a *chargé d'affaires* to the Vatican to prepare for the resumption of relations (March 23 1920). The bill was not actually passed until Nov. 30 by the Chamber (379 votes against 109) and not until Dec. 16 1921 by the Senate (174 against 129). The Senate, with its Radical majority and anti-clerical traditions, bristled instinctively at any projects which looked like an infringement of laicisation, and the situation was further complicated by the problem of voluntary parochial corporations (*cultuelles*), which dated from the Act of Separation between Church and State (1905). The Holy See, having refused to acknowledge the separation, had forbidden the creation of *cultuelles*. Even the simple mutual ecclesiastical associations which several of the bishops desired to found as retreats for aged priests came under the ban.

The position of the French Church was therefore ill-defined and precarious, and Benedict XV. was as anxious to put an end to it as was the French Government. Since 1905, however, all the bishops had been nominated in Rome from among candidates intransigent towards the civil power, and the Pope was surprised to find, on the occasion of the Joan of Arc canonisation festival (May 16 1920) when Hanotaux represented the French Govt., that they were strongly opposed to the bill. Those of them who had come to Rome delivered a collective letter to this effect to the Pope. But as Jonnart had been appointed ambassador to the Vatican on May 16 1921, the papacy responded by the appointment of a Nuncio, Mgr. Cerretti, who arrived in Paris on Aug. 6. In spite of all efforts on both sides the question was still unsettled at the time of the Pope's death (Jan. 23 1922). Two years later, Pius XI., his successor, promulgated the Encyclical of Jan. 18 1924, by which permission was given to organise, by way of an experiment, "diocesan" corporations—that being the name chosen in place of *cultuelle*, as placing emphasis on the absolute power of the bishop over the corporation.

Execution of the Versailles Treaty.—The application of the treaty, both at home and abroad, was the chief concern of Millerand's Cabinet. The reconstruction of the devastated regions swallowed up vast sums which Germany—contrary to public expectation—failed to produce. Considerable sums also went in restocking the country with essential materials, above all, coal. The British Govt. exacted payment for British coal at a decidedly higher rate than the home prices. Since 1919, too, it had done away with common accounts. During 1920 France had to borrow nearly 38 milliard francs, thus raising the budget to close on 20 milliard (as against 5 milliards in 1913). These sacrifices were not compensated by other facilities from the Allies. In successive conferences—held in London in Feb., at San Remo in April, at Hythe in May and at Spain in July—Millerand obtained nothing but verbal expressions of sympathy although he gave way on some points of the treaty to the advantage of Germany. At San Remo, in return for the definite abandonment of Mosul, which came into the sphere of French influence as defined by the convention of May 16 1916 (Sykes-Picot Agreement, *see* EUROPE; INTER-ALLIED DIPLOMACY), France was presented with those shares in the Turkish Petroleum Co. (25%), which had formerly belonged to the German Government. Lloyd George felt obliged to devote himself principally to the economic recovery of Germany, which he assumed to be a necessary condition for the development of English markets in that country, and for the maintenance of European peace. Millerand had to fight some hard diplomatic battles on this subject with the Cabinet in London. He found himself in collision with Lloyd George on the Polish question when the Bolsheviks invaded the young republic in August. Lloyd George wanted the Polish Govt. to abandon Warsaw;

Millerand retaliated by recognising Gen. Wrangel's government in South Russia, and by sending a group of French officers to Warsaw under Gen. Weygand's orders. The friction thus caused was not dispelled by the retreat of the Bolshevik armies, for while London was pessimistic as to Poland's future, Paris regarded Poland's independence as the keystone of the new Europe. France complained that, in taking up her mandate over Syria according to agreement, she was thwarted by British agents.

A deplorable accident occurred to complicate the situation. On the night of May 24, when making an official journey, the President of the Republic fell from his sleeping-car on to the railway line. Although not seriously injured he was so badly shaken that he was forced to rest from his work, and resigned on Sept. 16, bidding farewell to the Chamber in a moving speech. On Sept. 23 Millerand was elected President of the Republic by 695 out of 892 votes. In offering himself as a candidate he had announced his intention of making more effective use than his predecessors had done of the prerogative assigned to the head of the state by the constitution. After election he defined his views with greater emphasis, and, once installed at the Elysée, he acted in conformity with his programme.

The Leygues Cabinet.—The changes in the Ministry necessitated by Millerand's election as First Magistrate were reduced to a minimum. Georges Leygues became president of the Council and Minister of Foreign Affairs and the other Ministers retained their portfolios. This Cabinet had a brief and troubled life. The *Bloc national* adopted an even more exacting and defiant attitude towards it than towards the preceding one. André Lefèvre, Minister of War, resigned on Dec. 6 because he was not allowed a free hand in securing German disarmament. On Jan. 12 1921, on the eve of a London conference and in consequence of an interpellation by Bonnevay, the Chamber overthrew Leygues by 447 votes against 116 on the pretext that it wanted no "negotiations in the dark." Nevertheless Leygues was in no way to blame; on the contrary, he had re-established the friendly relations with the states of the Little Entente which had been upset by the action of the Quai d'Orsay the year before.

Briand's Cabinet.—Briand now formed a Cabinet in which he held Foreign Affairs, giving Justice to Bonnevay, War to Barthou, Finance to Doumer and the Liberated Provinces to Loucheur. He was well received by the Chamber on Jan. 20 and obtained a vote of confidence by 462 votes against 77. The inter-Allied conference for the settlement of reparations, which had been planned in London, was held in Paris on Jan. 24–8. It was with difficulty that an agreement was reached; Germany's payments were spread over a period of 42 years, the sanctions to be applied in case of non-payment being left vague.

They were to be as those securing German disarmament—*i.e.*, prolongation if necessary of the occupation of the Rhineland; the seizure of German customs; the occupation of new territory, including the Ruhr; the application in Rhineland of customs duties or others. In any case, as these sanctions were not to function automatically, negotiations would be necessary each time they were to be applied. From Feb. 3 to 9 these questions were discussed by the Chamber which finally approved the Government's action by 363 against 114. Germany having by this time announced her inability to meet her immediate obligations, a conference was held in London on Feb. 20, as the result of which an ultimatum was sent to Germany (March 3) stipulating for: the occupation of Duisburg, Ruhrort and Düsseldorf, a levy on the sales of German goods in the Allied countries and the establishment of a customs frontier on the Rhine if Germany should persist in her opposition. These sanctions were to be applied automatically if Germany did not send a favourable reply by March 7. The reply was not forthcoming, and the Allied troops proceeded to a joint occupation of the three towns named. These events were discussed in the Chamber on March 15–7 and a vote of confidence was passed by 490 votes against 69. Meanwhile, the vote on the budget of 1921 had at last been taken, on April 30, after four *douzièmes provisoires*. This time the budget exceeded 21 milliard francs.

On April 30 a new conference was called in London to study "the situation created by the total failure of Germany to fulfil the dispositions of the Versailles Treaty as regards disarmament, the punishment of guilty persons and the reparations." The Reparations Commission had fixed Germany's total payment at 132 milliards of gold marks. A sum of 12 milliards was due and could be exacted on May 1. It was not paid. The conference agreed to warn Germany to meet the obligations named by the commission within 12 days, failing which the Ruhr would be occupied. There was nevertheless great opposition to this form of sanction in England; the French Govt., on the contrary, was acting under the pressure of public opinion. It was decided, on May 3, to mobilise the 1919 class, recently authorised, and the *Conseils généraux*, then sitting, voted for the most part in approval of this attitude. On May 5 there appeared the official text of the Allied declaration, which announced the occupation of the Ruhr on the 12th, failing the submission of Germany. But on the 11th Germany capitulated. The Chamber, on its return from recess on May 19, held a debate on this whole affair, the upshot of which was a fresh vote of confidence (390 votes against 162). The governmental majority was even larger on June 3, when a debate was held on the advances made for damages in the liberated regions (457 votes against 67). When the Chambers rose on July 12 the Inter-Allied Conversations were resumed, taking place in Paris (Aug. 16) for the settlement of Belgian priority and the costs of occupation and at Wiesbaden (Aug. 27) on deliveries in kind. The Conversations coincided with important negotiations of another description.

The Angora Convention.—With respect to Turkey, Briand held views which were not shared by observers of the Eastern question. He believed Turkey to be both powerful and sympathetic to France, and instead of endeavouring to consolidate the Treaty of Sèvres (Aug. 10 1920), by which Eastern affairs had been settled with due regard to the just claims of the Christian populations affected, he listened to the Kemalists. Acting under the influence of the Hellenophobes and of the unfavourable impression he had formed of British agents, whether in Syria or the neighbouring provinces, he sent out Franklin Bouillon—a pro-Turk and anti-English deputy—to Angora with instructions to make a special convention designed to put an end to disputes on the Turco-Syrian frontier. On Oct. 20 Bouillon signed an agreement at Angora which made exorbitant territorial and political concessions to the Turks, and contained additional clauses which were even more questionable. The text was kept secret. It leaked out nevertheless that France stood committed by one of the annexed clauses "to endeavour to solve in a friendly spirit (*esprit de cordiale entente*) all questions dealing with the independence and sovereignty of Turkey." Yielding to his Turcophil obsession, Bouillon had concluded something in the nature of an alliance rather than agreement of liquidation. He had even promised the Turks war material, which he requested the high commissioner in Syria to deliver to them; but this called forth such vigorous protests from those who were *au fait* with Eastern affairs in Paris that the material was stopped. Briand hastened to have the Angora agreement ratified by the President of the Republic without submitting it to the Chambers, which had met again on Oct. 18. On Oct. 28 he left for the conference on naval disarmament that was about to open in Washington.

The Washington Conference.—In spite of repeated warnings from well-informed personages, Briand insisted on going himself to Washington as France's representative, his idea being to act as arbitrator between Britain and the United States—assumed to be divided on the question of reducing naval armaments. He made one great public speech which for a moment gave him the illusion of success; but, as might have been foreseen, the British delegation came to an agreement with the American Govt. without considering French interests and even using arguments against them which were strongly challenged.

By the Washington Convention the French Navy, reduced by the War to a position in the third rank, was condemned to be placed on a still lower level. Although the state of her shattered finances prevented France from resuming her former position

as a naval power, public opinion was hurt by an agreement which gave an official seal to the naval preponderance of friendly Powers which had profited by circumstances to assert their dominion over the seas. Briand's authority was undermined, and it was not long before another negotiation compromised it still more.

The Cannes Conference.—Returning from Washington in Dec., Briand departed almost immediately for London, where he was to confer with Lloyd George on the subject of the payments due on Jan. 15 and Feb. 15 1922 which Germany declared herself unable to meet in full. But instead of insisting on the settlement of this particular matter he allowed himself to be persuaded into calling a meeting of the Supreme Council at Cannes for Jan. 6. In the interval he found himself placed in an awkward position in the Chamber with regard to the Industrial Bank of China, a concern which was in difficulties and had been guilty of irregular transactions. One of the administrators, Senator André Berthelot, was the brother of Philippe Berthelot, secretary-general of the Ministry for Foreign Affairs. At first Briand tried to exonerate Philippe Berthelot, who was accused of having improperly used his influence to shield the bank; but he finally gave up the attempt and, on Dec. 27 1921, accepted his resignation. On the following day his majority in the Chamber was only 361 against 238.

His fall was brought about by differences over the conference at Cannes. As Premier, Briand was aware that President Millerand, with a majority of the public behind him, was profoundly opposed to the recognition of the Soviet Republic and to the modification of the French claim on Russia for the repayment of loans. But at Cannes, Briand agreed to a European Conference at Genoa, with a wide programme, to which Russian representatives were invited. Simultaneously, he was negotiating with Lloyd George the scheme for a pact designed to replace the stillborn convention of June 28 1919, which had been made void by nonratification in the United States. In Paris, the British guarantee, though almost identical with the former treaty, was regarded with suspicion because first, it contained no military convention, and secondly, it was accompanied by a memorandum which laid down a common policy for Britain and France, so limiting French liberty of action in Europe. Briand was bitterly accused of yielding to Lloyd George's persuasions and his policy was denounced as "cinematographic." The treaty made Great Britain responsible for resisting, with France, any violation by Germany of the military and naval safeguards of the treaty of Versailles but it was held that these guarantees were insufficient. Feeling ran high, in the Senate particularly. The Commission on Foreign Affairs, over which Poincaré presided, dispatched a telegram to Briand, reminding him of the indispensable conditions of an agreement, and the President of the Republic took the further step of requesting his urgent return to Paris. After a conversation at the Elysée and without waiting for a motion by the Chamber, to which he offered vague explanations, he gave in his resignation on Jan. 12 1922.

The Poincaré Ministry

In response to an almost universal public demand President Millerand appealed to Mr. Raymond Poincaré to deal with the crisis. He formed a Ministry on the 15th. He took Foreign Affairs, giving Justice to Barthou, Finance to de Lasteyrie, War to Maginot and Public Works to Le Trocquer. The heads of the Radical party had refused to join the new Ministry. Warmly welcomed by the public, Poincaré gained a vote of 434 against 84 in the Chamber on his ministerial declaration which was unusually firm in tone. He had to take a firm stand at Genoa without delay. He might have stopped the meetings and dissociated himself from the policy agreed upon by his predecessor without the government's consent. This would have meant a quarrel with Lloyd George. He preferred, however, to let the meetings fixed for the 10th April proceed, and went over to Boulogne for a talk with Lloyd George on Feb. 25. The only result of this somewhat chilly interview was a banal communiqué affirming the Entente between the two Governments.

The Genoa Conference.—At Genoa, where Barthou was in charge of the French delegation the Entente was only preserved with difficulty. Lloyd George who had, at the time of the Peace Conference, talked of inviting the Bolshevik delegates to Prinkipo, now made marked advances to them on the pretext that Russia's collaboration was necessary to the restoration of normal life in Europe. But the inopportune publication of a Russo-German treaty, concluded at Rapallo under the very nose of the conference, made it plain to all that the Germans and the Bolsheviks were also concerned with their own interests, whatever the rest of the world might think about it. At the General Council of the Meuse, Poincaré, who was president, made a speech in which he reiterated his intention to allow no reduction or limitation of the claims and guarantees of France recognised by the Treaty of Versailles. The Genoa Conference, which had been marked by various tragic-comic incidents, ended its futile existence on May 19. The Chamber signified its approval of the Government by 436 votes against 96. During the Conference the President of the Republic had made an extended tour in Morocco and Algeria.

Meanwhile the Chamber had been working at the reorganisation of military service to meet post-War conditions. After lengthy debates a bill was passed (June 29) by 365 votes against 205, reducing the period of active service to 18 months and prescribing the incorporation of the 20-year-old recruits in two contingents so that there would always be at least two half-classes with the colours. This bill was not passed by the Senate until the following winter. It came into force on April 1 1923.

The Eastern Conflict and Reparations.—In Aug. a fresh conference held in London failed to reconcile the English view that Germany should be allowed a moratorium without corresponding compensation, and the French view that this should only be granted in return for a share of 60% in certain German industries, the establishment of customs depôts at the exits from the Ruhr, the collection of taxes in the occupied territories and the exploitation of forests, and of the Ruhr mines. At this moment an Eastern tragedy broke in upon the situation. The reorganised Turkish Army, set free on the Syrian side, broke the exhausted and badly led Greek Army on the Afiun Qarahisar front on Aug. 26, reconquered Asia Minor, took Smyrna on Sept. 8 and advanced on the Straits, occupied at Chanaq by Anglo-French contingents. Poincaré, unwilling to expose the French contingent to conflict with the Turks, gave orders for it to cross to the European side—to the surprise and indignation of many Frenchmen. A sharp crisis with Lloyd George ensued; he had sympathized with the desire of Greece to achieve a national destiny in the near east.

Lord Curzon went to Paris Sept. 19 to smooth the trouble. On Sept. 23 the lines of a new treaty of peace with Turkey were agreed, with the participation of Count Sforza, and after a second visit to Paris by Lord Curzon an armistice was signed at Mudanya (Oct. 11), when it was agreed that the plenipotentiaries authorised to settle the Eastern question should meet at the end of November. But the differences of opinion between the Cabinets of Paris and London, both on the measures to be adopted with regard to Turkey and on the subject of reparations, persisted in spite of the resignation of Lloyd George and the advent of the Bonar Law Cabinet at the end of October.

French politics were at this time entirely dominated by the question of reparations, that is to say the execution of the "scale of payments" fixed in London in May 1921. Opinion became more and more irritated at seeing Germany devote the sums which she was under obligation to pay to the Reparations Commission to the completion of her industrial equipment, the extension and improvement of her communications, and extravagant domestic expenditure. Poincaré's protests were formally approved by the Chamber (with nearly 500 votes) and by an almost unanimous Senate. In London, on the contrary, the first consideration was that Germany's internal economy should not be disturbed. Bonar Law's attitude towards France was more amicable than that of Lloyd George, but the solutions which he proposed were hardly more favourable. In short, he

sought rather to pursuade Poincaré to renounce for an indefinite period his claim for payment than to force Germany to pay. Then again the old spirit of rivalry between the chancelleries persisted, diplomacy being untouched by the fraternity of arms. France's efforts to secure the execution of the peace treaties were put down to imperialism. The London proposals were impregnated with distrust of France. Thus, at the Lausanne negotiations as in the Paris meetings, friction continued.

The Ruhr.—On Nov. 14 Wirth, the German Chancellor, announced Germany's inability to pay for an indefinite period, a declaration repeated by his successor Dr. Cuno. Outrages were committed at Stettin, Passau and Ingolstadt against Allied officers. On Dec. 9 Bonar Law, Poincaré, Theunis and Mussolini met in London to discuss a new note from Cuno, while Lloyd George, at the same moment, made a violent attack on France in the United Press. Unable to reach agreement, the Conference broke up, and another meeting was arranged for Jan. 2 in Paris. Poincaré secured the approval of the Chamber on Dec. 15 by 562 votes against 76, and of the Senate (carried unanimously) on Dec. 21. On the 27th the Reparations Commission[1] took note of two intentional defaults by Germany, and notified the Powers concerned. The Inter-Allied Conference opened at the Quai d'Orsay on Jan. 2 1923 when Bonar Law submitted the following scheme: a four years' moratorium; the Reparations Commission to be replaced by a Foreign Council for German finance, a German Minister presiding; the reduction of deliveries in kind; reduction of the German debt to 30 milliard gold marks; compensation for Inter-Allied European debts by allotting to England the milliard of French gold and the Italian bonds held as a guarantee by Great Britain; the first series of German bonds to be allotted to France by priority. This somewhat complicated scheme deviated completely from those of France, Belgium and Italy. If it abolished Inter-Allied debts it did away with any serious expectation of payments except to Great Britain.

On Jan. 3 after a ministerial council and consultation with Theunis and Della Torretta, Poincaré declared Bonar Law's scheme to be quite unacceptable. The conference closed down on the 4th, in view of the impossibility of agreement. While refusing to subscribe to the French propositions, the British delegates declared that the friendly sentiments of the British Govt. and people remained unchanged. On the 9th the Reparations Commission, having heard the German delegates, made a statement (Great Britian dissenting) that Germany had "deliberately failed" to deliver coke and coal. Poincaré then informed the German Govt. (Jan. 10) of the sanctions which he was going to apply, viz.: control of industrial production in the Ruhr by French engineers under the protection of an adequate military force. President Ebert protested, and the industrial workers in the Ruhr refused to carry out the deliveries of coal by order of their Government. The Franco-Belgian occupation was accordingly established from Essen to Bochum and Dortmund. On the German side passive resistance was organised.

Such were the facts, the consequences of which were to be felt throughout the year. In proportion as passive resistance became more stubborn French control became firmer and more extended. With Poincaré, everything else was subordinated to the success of the undertaking. Disturbing incidents followed in quick succession. On Jan. 18 for instance, the Chamber passed a resolution by 371 votes against 143 for the suspension of parliamentary immunity for Marcel Cachin who had been charged before the High Court with conspiring against the security of the state. But the Senate declined on May 24, and the Cabinet tendered its resignation to the President of the Republic, who refused to accept it. On this occasion (June 14) Poincaré furnished explanations on his internal policy long awaited by the *Bloc national*, who supported him consistently without having any share in the administration. "Leave the extreme parties isolated," he said; "republicans who wish to belong to the majority should not risk their alliances and their friendships among them." His majority was only 376 against 207, neither Radical-Socialists nor Socialists being included in it. Poincaré did not change his methods, however, but relied on the Right for his foreign and on the Left for his home policy. He kept the Chamber busy by devoting over 20 sittings to academical debates on teaching reforms, particularly on the reintroduction of compulsory Latin.

Meanwhile the Lausanne negotiations were concluded. To the great regret of many of their compatriots the French plenipotentiaries missed the opportunity of joining hands with Lord Curzon on the Eastern question. They showed considerable complaisance to the Turks, and sacrificed the interests of Christian populations and of institutions under the traditional protection of France. A portion of the Paris Press expressed disapproval of the treaty, which was finally signed on July 24.

In Aug. a change took place in Germany. In face of the slow but sure effect of the measures taken in the Rhineland, the Cuno Cabinet had to resign and was replaced by a Stresemann Govt. more inclined to submission. On Sept. 24 passive resistance came to an end, announced by President Ebert in a proclamation which called the people to submit, while indulging in violent recriminations against France. At this point Poincaré, under the influence of the more extreme Nationalists, took the serious step of acquiescing in, if not encouraging, a separatist movement in the Rhineland, whereas he had, up till then, proclaimed himself in favour of pure autonomy. German opinion was once more exasperated. Mr. Baldwin, who had been assured of Poincaré's moderate views when visiting Paris on his way from Aix-les-Bains, was taken by surprise, and foreign opinion in general, at first favourably impressed by French success in the Ruhr move, now turned against France. The franc fell, and the cost of living rose. Poincaré then withdrew his support from a movement palpably artificial; but the harm was done. The opportunity of exploiting the Ruhr victory had been lost. The anger of the separatists, the disappointment of the public and the accusations of the extreme Left disturbed opinion. Poincaré now accepted the idea of having a new scale of payments drawn up by outside experts in accordance with Germany's real capacity. On Nov. 30 the Reparations Commission decided to send two committees of experts to seek means of balancing the budget, to decide upon the measures to be taken for stabilising German currency and to "seek means of evaluating and bringing back exported capital." The execution of the Treaty of Versailles had taken a new turning.

The Financial and Internal Crisis

In vain did Poincaré defend his policy in impassioned speeches on all occasions—and particularly on Sundays; public confidence was shaken, loans became impossible, the exploitation of the franc by speculators had to be countered by a mass manoeuvre in dollars, cost of living increased and the claims of wage-earners and officials grew in proportion. On Jan. 6 1924 one-third of the Senate was replaced, but without any serious change in the composition of that Assembly. On the other hand, the elections in the Chamber, fixed for May 11, became the focus of a fierce struggle. The government scheme for straightening out the financial situation so as to avert the fall of the franc met with decisive opposition from the Left. The augmentation of taxes, particularly the *double décime* was passed with difficulty. The proposal to authorise the Government to proceed by decree with administrative reforms estimated to save a milliard was only adopted by 333 votes against 205 in the Chamber (Feb. 7) and came near being thrown out by the Senate which had approved the general financial scheme by only 151 votes (March 18). The parliamentary horizon was overcast. On March 26 the Cabinet was put in a minority in the Chamber (271 against 264) on the question of pensions, and resigned. Poincaré was charged to re-form the Ministry, which he did by giving François-Marsal Finance, de Selves the Interior, Loucheur Commerce and Henri de Jouvenal Public Instruction. Thus many radical Ministers were replaced by Moderates. The electoral law of 1919 was slightly modified to do away with certain inconsistencies and to reduce the number of deputies to 584. On Jan. 25 Poincaré had signed a Franco-Czechoslovakian alliance with Dr. Beneš.

[1] The British member dissenting (Ed. *E.B.*).

The election campaign was a heated one. Millerand's sensational speech at Evreux on Oct. 14 had really been the starting-point. The President of the Republic insisted on the necessity of confining legislative power to its proper function and of strengthening the prerogative of the head of the state. During April Poincaré made several important speeches in which he drew nearer to the *Bloc national*. The Radicals, Radical-Socialists and Socialists formed a Cartel, taking as their motto opposition to financial retrenchment and anti-Poincaréism. In several divisoins the Cartel included the Communists. When May 11 came, more than 9,000,000 voted out of 11,000,000 electors—a proportion never before attained. The results gave 277 seats to the Cartel, 267 to the *Bloc National*, 29 to the Communists and 11 to the candidates who belonged to no group. Of the Cartelist deputies 139 were Radicals and Radical-Socialists, 36 Republican-Socialists and 102 Unified Socialists. Taking the number of votes over the whole country, about half had gone to the *Bloc national*; the Republican Entente group alone accounted for 3,200,000 voters while the whole Cartel had only 3,400,000 to its credit.

Doumergue's Election.—Poincaré handed in his resignation at once, but carried on with current affairs until the opening of the new Chamber. On June 2 the Socialist Congress came to the unanimous decision not to take part in the new government, though supporting the Radical Socialists. Painlevé was elected President by the Chamber on June 4 by 296 votes against Maginot's 209. On the 5th Millerand offered to put Herriot in power, but Herriot refused to form a Cabinet so long as Millerand remained President of the Republic. He and his partisans could not forgive Millerand for having opposed them under the last Legislature. After turning in vain to friends such as Steeg, Millerand had at last to give in. He formed an interim Cabinet on June 8, under François-Marsal, for the purpose of laying before Parliament a memorandum in which he set forth his claim, to the effect that he had always respected the constitution and was still abiding by it in refusing to surrender his office without a definite vote from both Houses. The Senate refused to take action. The Chamber flatly refused to enter into relations with a government "which by reason of its composition, is the negation of parliamentary rights." On June 11 Millerand therefore resigned. The Cartel candidate for the Presidency was Painlevé, but at a preliminary meeting of the Congress 149 votes were given to Doumergue, president of the Senate, and it was he who was elected on June 13, by 515 votes against 309 for Painlevé.

Herriot's Ministry.—Herriot now proceeded to form the new Ministry, which was complete by June 14. Taking Foreign Affairs himself, he entrusted René Renoult with Justice, Clémentel with Finance and filled the remaining departments with other Radicals. The ministerial declaration marked a return to anticlericalism by announcing the suppression of the embassy to the Vatican and the intention of bringing Alsace and Lorraine within the scheme of French legislation as soon as possible, including secular education. The Chamber approved it by 313 votes against 234 (June 19); but on the same day the Senate elected de Selves as president, in place of Doumergue, by 151 votes against 134 for Bienvenu-Martin, the Cartel candidate. The two Assemblies, both Radical, were not of the same school.

The new majority made a point of reversing the work of their predecessors in every point and expressed the intention to secure for their own party "all the appointments, and that at once," as their principal organ the *Quotidien* phrased it. Some measures have therefore a symbolic importance. Gen. Sarrail was recalled for service without age-limit; the review of July 14 at Longchamps was cancelled; university reforms were dismissed with a stroke of the pen; the monopoly on matches was reinstituted; the economic and military evacuation of the Ruhr was brought under consideration; the Moscow Govt. was recognised *de jure* (Oct. 28) without any condition or guarantee for the Russian debt; an amnesty was proposed to be applicable to fiscal offences, events connected with strikes, desertion, cases of intelligence with the enemy and cases of *forfaiture*—the last two named categories including the cases of Caillaux, Malvy and the *Bonnet Rouge*. Not until the end of the year (Dec. 16) did the Senate pass this Act of Amnesty, voted by the Chamber as early as July. The anti-clerical policy of the Government produced considerable agitation. A letter was sent to the president of the council from the French cardinals denouncing the lay laws as "persecuting laws," and a "National Catholic Federation," presided over by Gen. Castelnau, was formed, which had a large following in the west and also in Alsace and Lorraine, where church schools are traditional, whereas French law recognises only lay and neutral schools. A National Republican League on parallel lines was formed by Millerand on Nov. 7 to combat "demagogy, revolution and anarchy."

The Dawes Plan.—Herriot's attitude with regard to Reparations was the reverse of Poincaré's. Instead of merely changing methods of negotiation which were open to criticism, he abandoned without resistance the positions held by his predecessors. On a visit to Ramsay MacDonald at "Chequers," he associated together the three problems, reparations, inter-allied debts and security. As a result, MacDonald felt authorised to issue a programme for the Inter-Allied Conference which allowed for concessions, hitherto regarded as inadmissible, on the part of Germany's creditors. Feeling ran so high in France that Mr. MacDonald hurried over to Paris on July 8 in order to draw up a fresh programme. It was in fact a question of accepting and applying the Dawes Plan which had been put before the Reparations Commission on April 9.

At the London Conference of July 16–Aug. 16, at which German delegates were present from Aug. 5 onward, conditions—very favourable to Germany—were adopted; attenuation of the debt; limitation of the Reparations Commissions powers; a loan of 800,000,000 gold marks; suppression of coercive measures and of Franco-Belgian *régie* in the Rhineland; a promise to evacuate the Ruhr before Aug. 15 1925; while Mr. Ramsay MacDonald undertook to seek a solution of the Inter-Allied debt problem, bearing in mind all these points. On his return to Paris Herriot was vigorously criticised in Parliament. In the Chamber, after six sittings devoted to debate, he obtained a vote of confidence by 336 votes against 204 (Aug. 23). In the Senate, on the 26th, he secured 181 votes. His task was not made easier by Ramsay MacDonald's rejection of the Treaty of Mutual Assistance which had been elaborated in agreement with Lord Cecil by a commission appointed by the League of Nations. At the fifth meeting of the League Herriot succeeded, however, in regaining a portion of his prestige, by proposing the principles of "arbitration, security, disarmament," which became the basis of the Geneva Protocol. A few weeks later, on Oct. 30, he was able to settle by arbitration the dispute over the free zones of Savoy with Switzerland (*see* SWITZERLAND).

On the reopening of the Parliament the Radicals and Socialists continued their policy of supporting the Government, with the approval of their party Congresses. The Communists adopted a hostile attitude to the Socialists. On Nov. 23, when the ashes of Jaurès were transferred to the Panthéon, they gave the ceremony the appearance of a *revue* of Communist forces in the streets of Paris, entailing an accusation of weakness against the Government. Great difficulty attached also to the preparation and discussion of the budget in view of the promises made during the election period and the demands of the Socialists. Clémentel, who represented the moderate element in the Cartel, had retained the taxes voted by his predecessors; but no sooner was the equilibrium within sight of accomplishment than it was upset by a new revision of the scale of officials' salaries. From the expected figure of 32,800 millions the budget rose to 36 milliards and the pound sterling, which stood at 70 francs during the elections, was now at 91. The programme of the Socialist Conference at Grenoble in Feb. 1925, the Communist strike (accompanied by bloodshed) at Douarnenez, the fracas on Feb. 8 at Marseilles, which resulted in the death of three and wounding of 20 people at the close of a Catholic meeting—combined to bring discredit to the Government. No less grave and significant was the Quartier Latin affair in March. An immense majority of the students protested against the nomination of an ill-qualified

candidate as lecturer in the faculty of law in Paris. The dean of the faculty was suspended by the Ministry for having refused to allow the police to enter the premises. The whole Press rang with the consequent disturbances.

The suppression of the embassy to the Vatican and the threat of lay-teaching in Alsace and Lorraine threw those two provinces into a state of growing unrest. On April 2 Clémentel resigned on account of his bad reception by the Senate. He was replaced by Monzie, who demanded of Herriot the retention of the embassy to the Vatican; but this patching up could not save the Cabinet, and on April 10 the Senate, exasperated by an inflation of four milliards concealed in the balance-sheet of the Banque de France in despite of solemn promises, threw the Government out. In February, following on a German note suggesting a pact of security in the West, confidential negotiations were opened between the Cabinets concerned. These were continued in semi-secrecy until autumn.

The Painlevé Ministry.—This particular crisis was difficult to solve, as the Socialists refused to accept portfolios, but Painlevé finally succeeded on April 17 1925. He took War and the presidency of the council, giving Foreign Affairs to Briand and Finance to Caillaux. This last appointment caused a great sensation, but as the public had, after all, faith in Caillaux's technical ability and desired principally to see the financial problem settled, his war antecedents were overlooked. The ministerial declaration was manifestly designed to relieve the strained situation. It proclaimed the retention of the embassy at the Vatican in a new form, and reassured Alsace-Lorraine against any too precipitate assimilation. The Government had a majority of 304 against 217 votes. The agitation in the Latin Quarter was allayed by the reinstallation of the dean in the faculty of law. Unfortunately, the Communist agitation ended in the shooting of four partisans of the Youthful Patriots (*jeunesses patriotes*) in the rue Damrémont at the close of a meeting. The Prime Minister and the Minister of the Interior attended their funeral at Notre-Dame. To prevent the recurrence of like incidents, May Day processions in the open street were forbidden and May 1 therefore passed in perfect calm. The Government likewise forbade all street processions on May 10, the fête of Joan of Arc, but the usual delegations made their pilgrimage to the statues of the saint, and the Prime Minister deposited a wreath in person. Herriot had been re-elected president of the Chamber by 266 votes only. On April 5 Millerand was elected Senator of the Seine by 520 out of 1,025 votes. The municipal elections (May 3 and 10) showed a slight progress towards the Left as compared with those of 1918, and at the same time a striking set-back for the Communists.

Abroad the outlook was still uncertain. The Conference of Ambassadors had decided, in conformity with the Versailles Treaty, that the Cologne zone should be evacuated only after Germany had completed her disarmament. An Inter-Allied financial conference, that was held in Paris on Jan. 14, had settled the distribution of payments to be made under the Dawes scheme and that of the profits accruing from the occupation of the Ruhr. The election of Hindenburg to the presidency of the Reich (April 26) on the sudden death of Ebert had aroused great uneasiness among the Allies. In May a considerable financial and military effort was entailed by 'Abdel-Krim's attack on the Moroccan front. Painlevé flew over to Morocco by aeroplane to review the situation. He then sent Malvy to Madrid to arrange a plan for collaborating with Spain, and Marshal Pétain to Morocco to direct the military operations. In October, after the Riffs had been thrown back on their old front, Marshal Lyautey was replaced as Résident-Général by Steeg. Monzie became Minister of Justice and Yvon Delbos took the Ministry of Public Instruction. This first reconstitution of the Ministry had no political significance, but this could not be said for the next.

Dislocation of the Cartel.—July 12 saw a rift in the Cartel. For the first time, on the subject of the budget and the sales tax, the Socialists, Radical-Socialists and a certain number of Radicals voted against the Ministry, which was saved by the votes of the Opposition who were anxious above all to find a way out of the financial predicament. The *Conseils généraux* elections (July 19 and 26) showed a slight leaning to the Left and the intransigeance of the Socialists became more marked. On Aug. 15 the Socialist Congress in Paris began by excluding Deputy Varenne from the party because of his acceptance of the post of Governor-General of Indo-China. A motion was then passed (by 2,210 against 559) against Blum's proposal to censure any support of Painlevé's Cabinet but permitted the support of a Ministry "determined to bring about the reforms demanded by the proletariat." Inclusion in the Ministry remained forbidden in any case. The ever-increasing financial difficulties intensified the dissension. Caillaux failed to justify the hopes reposed in him. Instead of holding fast to a general financial scheme he became involved in party politics. To clear up the situation by the settlement of Inter-Allied debts he left for the United States in September, but only to return in October empty-handed. The consolidated 4% gold loan, which he had launched during the summer and by which he hoped to realise some 20 milliards produced barely six. Confidence was gone. At the end of Oct. misunderstandings in the majority ranks found expression at the Radical Congress at Nice, the speeches of Herriot and Caillaux revealed a fundamental difference, and Painlevé's long speech rather served to add to the confusion. Finally the Congress, unable to decide between the levy on capital and the more practicable taxes, adopted a vague formula recommending a "special contribution payable on all kinds of income and capital."

The Second Painlevé Ministry.—The brief credit enjoyed by the Government on the conclusion of the agreements signed on Oct. 16 at Locarno—for which Briand had paved the way during the 6th meeting of the League of Nations by agreement with Chamberlain, Benes and Skrzynski—did not help them for long. For one thing, French opinion was by no means unanimous in its approval of the agreements which were designed to replace both the Geneva Protocol (never ratified), the Security Pact of June 28 1919 and certain guarantees of the Versailles Treaty. On returning from Nice, Caillaux was unable to secure his colleagues' approval of his financial projects. To get rid of him Painlevé handed in the resignation of the Cabinet collectively on the 28th, and formed a new Ministry in which he took Finance himself. But in the Chamber he obtained a majority of only 221 votes against 189, owing to the abstention of the Socialists. The Socialist National Council, for its part, voted against him by 1,431 against 1,228. At the same time Gen. Sarrail's anti-clerical sectarianism, Turkish sympathies, presumption and blunders in Syria brought about sanguinary encounters in the Jebel Druz and later in Damascus, which amounted to local disasters. Painlevé was at last obliged to recall him. When he put his financial schemes—badly conceived and co-ordinated—before the Chamber, he was already discredited. On Nov. 22 he was thrown out by 277 votes against 249. The Treasury was so hard pressed that he had to pass an emergency vote for an advance of 1,500 million francs from the Banque de France.

Another Briand Ministry.—Entrusted with the construction of a new Cabinet, Briand failed at first through the non-collaboration of the Socialists. Doumer, and after him Herriot, met with no greater success. Then, as the Socialists were meditating a *coup de force*, Briand yielded to the pressure of the President of the Republic and tried once more. He succeeded on Nov. 28, taking Foreign Affairs himself, sending Painlevé back to the War Office and, in spite of his objections, gave Finance to Loucheur who imagined he could straighten out the situation. The Ministry was still Cartellist, although Georges Leygues (Navy) and François Jourdain (Pensions) represented the Moderate elements. A change of policy was now perceptible, the developments of which appeared in December. Loucheur's scheme, once published, proved so great a disappointment that the Finance Minister had to resign. After groping a while pursued by the clamour of the extreme Left, Briand replaced Loucheur by Doumer. Several Cartellist ministers talked of resigning, but Briand unmoved stood by Doumer and gained the approval of the entire Cabinet for his schemes. The pound sterling oscillated at about 130 and the dollar at about 26 to 27 francs.

As soon as his Ministry was formed Briand went to London to sign the Locarno agreements (Dec. 1). By the end of the year foreign affairs looked more promising. The Dawes scheme functioned accurately, and the Cologne area was evacuated without incidents. In Morocco the vanquished 'Abdel-Krim saw himself abandoned by the tribes; in Syria Henry de Jouvenel, appointed high commissioner, began to restore order and confidence; in central Europe, Poland and the Little Entente (*q.v.*) were following a policy parallel to that of France. Relations with England were cordial. The one great remaining problem remained the settlement of Inter-Allied debts, the shadow of which darkened a financial horizon already heavy with clouds. (A. Gn.)

The Locarno treaties were ratified by the French Chamber on Nov. 2 1925. The chief preoccupation of ministers in the new year was the financial crisis, the solution of which was rendered more difficult by the lack of an absolute majority in the Chamber. The Govt. made the tax on payments, M. Doumer's most important proposal, a matter of confidence. They were defeated by 274 votes to 221. Their resignation (March 6) took place two days before the opening of the special session of the Assembly called to arrange for the admission of Germany to the League.

The fall of M. Briand was a calamity at this moment, and, after a fruitless invitation to M. Herriot to form a cabinet, M. Briand assembled a ministry, with M. Raoul Peret at the Finance Ministry. A Finance Bill, providing for new or increased taxation, was passed (April 29), but the franc still fell. At the end of April it stood at 147 to the pound. Money was required for Morocco, where the new offensive was begun early in May. On May 19, on M. Peret's return from London without having settled the debt, the franc fell to 171. In June M. Peret resigned, and then the whole Government. After a delay of a week, during which M. Herriot had failed to form a ministry, M Briand again took office, with M. Caillaux at the Ministry of Finance, and the latter was faced at once with the problem of protecting the franc. (Ed. *E.B.*)

II. ECONOMIC AND SOCIAL HISTORY

In the course of the negotiations for the payment of France s debts to her Allies it has been persistently said, in particular by Americans, that France is the richest country in Europe, or at least in continental Europe. This opinion, very flattering to the French, is in some respects well founded; for since the fall or the amputation of the great empires of central Europe, France is, after Russia, the most extensive European country. Her soil is fertile. She owns the richest iron deposits in Europe, and, if her coal does not suffice for home consumption, she has by way of compensation more water power than any other European country except Norway. In addition she has a colonial empire, the second in the world and 20 times the size of the mother country. It is true that her population places her fifth in order of countries, but it is by her own choice that its increase is limited.

But the formidable damages inflicted by the War are not taken sufficiently into account. The world still remembers France's rapid recovery after the war of 1870–1, and supposes that this is a similar case. But the two situations are not in any real sense comparable.

If the national wealth of France were evaluated in gold currency or, to be exact, in the currency of 1914 (which is not the same thing, for we know that gold has lost a great deal of its value), we should arrive at a figure far below that of 1914. It is difficult to make a definite statement, but, speaking generally, the accepted pre-War figure was 300 milliard gold fr. whereas the present figure would not, we believe, reach 200 milliards, in spite of the restoration of Alsace-Lorraine.[1]

But leaving aside these general considerations let us examine, in two successive sections: (1) agriculture, mines, industry and commerce, with a comparison under each heading of the present situation with that of 1911–3; (2) the changes that have taken place in respect of workers' legislation, the social movement and population.

Production

Agriculture.—French agriculture suffered cruelly in the War; (*a*) in consequence of the occupation and of the destruction of part of its area; for certain portions of the ground—the part since known as the Red Zone (about 30,000 hectares)—were laid waste by shell to such an extent that they could no longer be cultivated in any way; (*b*) in consequence of scarcity of labour, live stock and manure, which had the effect of bringing cultivation to a standstill or of greatly impoverishing the crops for a long time after the War; (*c*) by the destruction of forests (several hundred thousand hectares) which must take 20 to 50 years or even longer, to grow again.

The area under cultivation is smaller to-day, whether we take the absolute or the relative figures, than it was before the War. From 1904 to 1913 its extent was 23,000,000 hectares (cereals, fodder, leguminous crops, vines, etc.), which represented in relation to France's total area of 52,952,000 hectares 47%. In 1923 it was only 20,432,000 hectares, although the area of France, aggrandised by Alsace-Lorraine, amounts to 54,400,000 hectares. The proportion is therefore now only 37·5%. This reduction of the cultivated areas is explained by the diminution and the high cost of agricultural labour, as the result of which landowners find it more profitable to convert their land into pasture.

It may be argued that the decrease in the areas matters little if there is a compensating increase in yield. Unfortunately this is not the case. There is certainly a general improvement in the yield per hectare, but not enough to compensate for the decrease in area. The result is that production is decreasing in the case of almost all agricultural products. The following are the figures for certain products, taken from a paper by M. Augé Laribé in the *Revue d'Economie politique*, March–April 1925.

		1904–13	1923–4
Cereals	Million quintals	88	76
Potatoes	Million quintals	133	127
Beetroot	Million quintals	58	44
Milk	Million litres	128	117
Wool	Million kilogrammes	34	20

It is only in the case of vines and fodder that production shows a small increase.

The live stock of the country, greatly reduced by the War, is still below pre-War numbers. It is evident from the following figures (*Annuaire statistique de la France*) that the deficit is still very considerable.

	1913	1924	Decrease
			%
Horses, mules, donkeys .	3,222,000	2,859,000	11
Oxen and cows . . .	14,788,000	14,025,000	5
Sheep and goats . .	16,131,000	10,172,000	37
Pigs	7,036,000	5,802,000	18

Nevertheless, in some directions, progress has been made. Manure is being more largely used, thanks to the work of the agricultural syndicates, but France is still far behind other countries in this respect, although she possesses very abundant supplies of phosphates in Northern Africa and, since the restoration of Alsace, a rich deposit of potash also. The employment of electric power, whether derived

[1] Mr. Harvey E. Fisk of the Bankers Trust Co., New York, concludes his exhaustive analysis of French public finance (1922) in these terms: "We believe that, notwithstanding the losses occasioned by the War, the wealth of France today, estimated on a specie basis, closely approximates or perhaps equals her pre-War wealth. This is partly due to the repatriation of Alsace and Lorraine, but it is also due to the fact that the War apparently served to intensify the normal saving habits of the people and thus enabled them to meet the burden which it brought without seriously impairing the pre-War national fortune." (Ed. *E. B.*)

from waterfalls or from coal, is beginning to spread in country districts owing to the formation of co-operative societies of consumers of power. The state has voted a credit of 600,000,000 fr. for this purpose. The shortage of labour is being compensated by the immigration of foreign workers who are mainly Italian and Spanish in the south, Polish and Belgian in the north. The southern region which lies along the Garonne had become a deserted country in consequence of the decrease in the local population, but is now being restored by the Italians, who come not merely as labourers, farmers or métayers, but also to buy land and settle on it. It is undoubtedly an anomaly, this colonisation of so ancient a country as France, and the results may be dangerous from a national point of view. But even if it be an evil, it is at the same time a remedy for that greater evil which has proved fatal to other countries, viz.: desertion of the land for lack of men to work it. The depreciation of the currency has been a blessing in so far as it has enabled most small holders to pay off their mortgages and many farmers to buy their farms outright.

Mines and Water-power.—The invaded regions were the very ones richest in mines. They produced half of France's total output of coal and three-quarters of that of iron. The coal-mines were systematically destroyed by the Germans; during the War 112 shafts and 1,910 kilometres of galleries were demolished or burnt out, and have had to be not merely repaired, but entirely reconstructed. In 1925, by dint of immense efforts, production had been brought back to the pre-War figure, but the output of 12 whole years had been lost.

It is true that, through the recovery of the Lorraine mines, France—already a large producer of iron ores—has come into the front rank among European nations in that capacity. Her production of coal, however, was always much below her consumption, and the restoration of Alsace-Lorraine has not altered this state of things.

The figures of coal production and consumption are as follows:—

Year	Production	Consumption
	tons	tons
1911	39,280,000	59,500,000
1913	40,844,000	64,800,000
1924	44,955,000	76,900,000

At first sight there would seem to have been a considerable increase both in production and consumption, but this is an illusion. As regards production, of the 45,000,000 tons produced in 1924, more than 5,000,000 are from the restored Lorraine region; deducting this amount, it will be seen that from the rest of France the output is slightly below the pre-War figure, so that there has been no progress at all in the 12 years. Similarly, as regards coal consumption, Alsace alone consumes 11,000,000 tons, so that in 1924 the consumption of France without that province was only 66,000,000, or about the same as in 1913. The deficit has in fact been augmented, for while in 1911 it amounted to 20,000,000 tons only, in 1924 it had risen to 32,000,000 tons. It is made up by the import of coal, which comes mainly from the Saar, Germany and England. If the Saar basin were to become permanently French, it would go far in redressing the insufficiency of coal; but this question is to be settled by a plebiscite in 1935, and it is probable that the decision will be in favour of Germany. In that case, however, Germany would have to pay France the value of the Saar mines, which has been fixed at 300,000,000 gold marks.

There is, however, a real and considerable increase in the production of iron and its derivatives; production is in fact nearly doubled, as may be seen from the following figures:—

Year	Iron Ore	Pig Iron	Steel
	tons	tons	tons
1911	16,600,000	4,470,000	3,837,000
1913	22,000,000	5,207,000	4,687,000
1924	29,000,000	7,693,000	6,900,000

Consumption, however, lags far behind production; even before the recovery of Lorraine, France was unable to absorb all her production, and is less able to do so now. The reason is that she produces very little coke, and coke is indispensable in the production of pig-iron. She has, therefore, no alternative but to export her surplus of ore and of manufactured iron, and even this is a matter of difficulty as, since the War, the metallurgic industry has been in a state of depression marked by underselling and falling prices. In the matter of her metallurgical wealth, therefore, France has less cause for satisfaction than is generally supposed.

As to petroleum, France had formerly none at all, but with Alsace she has now acquired a few small wells. An oil-field has just been found in the Mediterranean region (department of Hérault) but it is not yet known what the yield will be.

The insufficiency of coal-mines is to some extent counterbalanced by the abundance of waterfalls which can be used for motor power. With the Pyrenees, the Alps, and the mountains of the centre, France is at least as well equipped as Switzerland and Norway. Before the War the amount of power utilised was valued at no more than 480,000 kilowatts (640,000 H.P.). In 1924 the figure was over 1,000,000 kilowatts. Plans for the utilisation of 4,000,000 additional kilowatts are in progress, and the total utilisable energy is calculated at 8,000,000 or 10,000,000. The increase, however, though extremely rapid after the War, is now tending to diminish owing to the great rise in the cost of installation, so that coal-power once more becomes the cheaper of the two. Nevertheless, France has already found in water-power a source of considerable wealth, for in addition to the amount employed for lighting and for running railways and tramways, a large number of industries, both metallurgical and chemical, have arisen as a consequence of this new motor power.

Industry.—French industry was hit even more directly than agriculture by the War. Those regions which were invaded, and in great part devastated, represented, it is true, only 5% of the total area of France, but they accounted for more than 10% of the population, 14% of the total number of industrial workers, 29% of the textile and 53% of the metallurgical production. They were in short the focus of the nation's industrial activity. Reparation of the damage done has cost the state 84 milliard fr., and 20 milliards have still to be paid. From the financial standpoint the losses are irreparable. We are not, however, concerned here with the financial situation, but with the question of whether, from the industrial point of view, a complete recovery has been made. The answer is yes, and no.

In certain respects undoubtedly, French industry gained through the terrible experience of war. Factories reconstructed in the devastated areas made good use of the enormous indemnities that they received from the state. They are reported to have had the use of extravagant sums, but they justify their case by saying that the money was spent on installing the latest improvements and that those installations would probably not have been made but for the War. In like manner factories have learnt to renew their stock of tools and to adapt themselves to new requirements by manufacturing at home articles for which France had formerly sent abroad, particularly to Germany; these included, for instance, chemical products, dyes, magnetos for motors, Diesel engines, electrical apparatus for wireless telegraphy, optical and photographic lenses and all the industrial requirements of aviation. The motor industry has made immense strides; the pre-War figure of about 100,000 cars in use has been increased to over 450,000 in 1925. Even the oldest industries received a new impetus through the War. In the bakery trade, for instance, only half of the establishments used a mechanical kneader; and after the War it was used by 88%. It must be said that the general adoption of the eight-hour day hastened the introduction of mechanical contrivances but this itself was a result of the War.

But while admitting these points, it is none the less true that French industry, taken as a whole, has not yet recovered from the shock of war. Certainly, the losses among industrial workers —(267,000 killed and about 130,000 disabled)—were less heavy than among agricultural labourers, because the greater number of skilled workmen were withdrawn from the front to work in munition factories. The deficit was more than covered, too, by the immigration of foreign workers. Every year, since 1922 especially, there is a contingent of 200,000 to 300,000 of whom two-thirds are industrial and one-third agricultural workers. In the mines to-day, something like one-third of the personnel is made up of foreigners.

But if there is no diminution in numbers, there is nevertheless diminution of output. Not only does the foreigner, who is often inexperienced in his particular branch of employment, produce less than the Frenchman of earlier days, but the Frenchman himself produces less than before the War. It is difficult to say whether this is the result of a limited working day or of discontent connected with Socialistic ideas; in either case, the facts are incontrovertible. To take one example only, the quantity of coal produced per head in 1913 was about 660 kilogrammes; in 1925 it is 510 kilogrammes. The diminution is rather less if the calculation is based upon the underground workers who extract the coal, but even in their case the quantity extracted shows a

diminution of 5%, the present figure being 568 kilogrammes as against the earlier 595.

Then again, although the technical advance in industry has just been demonstrated, the total of horse-power used in industry, excluding transport, has not risen to any great extent (1911, 3,141,000 H.P.; 1913, 3,539,000 H.P.; 1922, 4,800,000 H.P.).

But Alsace-Lorraine accounts for a large share in the last of these figures and, if we deduct that share, the augmentation for pre-War France remains inconsiderable. It is a different matter with water-power, but that we have already discussed.

Taking the principal industries, we shall see that production has diminished, notwithstanding assertions to the contrary. The following are the figures for silk, which is pre-eminently a French industry:—

	Weight of Cocoons	Weight of Silk Yarns	Value of Silk Piece Goods
	kilos	kilos	francs
1911	5,109,000	411,000,000	414,000,000
1922	2,585,000	209,000,000	2,229,000,000
1923	4,180,000	. .	2,812,000,000

It is evident that production has greatly diminished, the quantity produced being almost halved. The third column figures, taken alone, show on the contrary a septuple augmentation; but on what does it rest? Merely on the fact that the price of raw silk has been multiplied by 8, mounting from 35 fr. a kilo in 1911 to 278 fr. in 1923. We have therefore only to divide this nominal figure of 2,812,000,000 by 8 and we have left 350,000,000 gold fr., that is, a figure smaller than that of 1911.

In the case of sugar refineries the diminution amounts to one-third, as these figures show:—

1911–3 . . . . average 671,000,000 kilogrammes
1922–4 . . . . average 446,000,000 kilogrammes

Lastly, there is the building industry, that industry which supports so many others—as the French proverb has it: "When building goes well, all goes well." In the War years, it was practically non-existent; in 1924 and 1925 it was coming to life again, but only slowly. In Paris in 1911 there were 1,792 applications for permits to build houses, in 1919 only 173—not even one-tenth! But in 1925 building was resumed on a considerable scale in the capital.

Commerce.—Internal commerce has suffered but little, even during the War; it recovered immediately after the War, gaining a fresh impetus from the rise in prices caused by the depreciation of the franc, and profiting also by the influx of foreigners attracted precisely by that depreciation, which set a premium on their dollars, pounds or florins as the case might be. We have an indication of the fluctuation of the internal commerce in the special tax on sales. This tax brings in round figures 4 milliards of paper francs. As it is established at a fixed rate of 1·30%, it assumes an annual sales figure of 300 milliards—one might safely say, 400 to 500 milliards, *i.e.*, about 120 milliards of gold fr. on the basis of the exchange in 1924, for the declarations are assuredly much below the real figures. But unfortunately this tax did not exist before the War and we have therefore no basis of comparison.

Progress on the railways is, however, easier to assess; there is considerable increase in passenger traffic (35%) but less in goods (13%):—

	Goods	Passengers
1911	184,000,000 tons	511,000,000
1923	208,000,000 tons	689,000,000

In spite of a large increase in gross receipts the railway companies are losing money at the rate of 1,000,000,000 fr. a year. This is because the French charges, though they have been frequently raised, are still (on a gold basis) lower than they are in other countries.

The total length of the railway system has not been increased since the War (40,615 km. in 1911; 41,853 km. in 1923; but of these 1,250 were for Alsace), because the cost of construction is so heavy that even the old tracks have to go unrepaired. The system is, however, practically large enough to meet requirements.

In the mercantile marine, there has been a considerable increase: 1911, 1,413,000 tonnage net; 1913, 1,582,000 tonnage net; 1923, 2,145,000 tonnage net.

Sailing vessels account for only 386,000 of the total tonnage of 2,145,000. The increase since 1913 is therefore more than a third (35·6%). France lost nearly half of her merchant fleet during the War (700,000 net tonnage), but Germany was made to hand over to her an equivalent fleet. Besides, the enormous rise in freights after the War (now a thing of the past) was a great incentive to construction.

As regards international commerce, it is generally held that the position of France is excellent, better indeed than before the War. This is true, but only in part; the figures need more careful inspection. The following are the statistics of values and quantities:—

	Imports		Exports	
	Value in Millions of Francs	Weight in Millions of Quintals	Value in Millions of Francs	Weight in Millions of Quintals
1912	8,231	397	6,712	203
1913	8,421	442	6,880	221
1924	40,132	565	41,454	294
1925	43,980	474	45,413	302

It will be seen that a comparison of the mean of the years 1912 and 1913 with that of the years 1924 and 1925 shows an enormous increase in values, the imports being more than five times, the exports more than six times larger. At the mean rate of exchange in 1924 and 1925 the import figures would be 12 and 11 milliards of gold fr. respectively; the export figures 12·2 and 11·2 milliards respectively. The increase in quantities has been less: 24% on the imports, 40% on exports. It is not to be denied, moreover, that this increase is due to the depreciation of the franc to which we just now attributed the influx of foreign visitors, for this is why, despite the rise of prices in France, actual prices (gold prices), costs of production, and wages are lower in France than in foreign countries.

But the greater increase in exports and the smaller increase in imports has in fact served to turn the trade balance in favour of France. For while in 1911 and 1913 the export figures remained lower by nearly 2 millards of fr. than the average import figures, in 1924 on the contrary they exceeded the import figures by more than 1,300,000,000 (300,000,000 gold francs).

It would seem, therefore, that this favourable balance ought to improve the exchange and bring about a rise in the franc, all the more as the unknown, but considerable figure (probably more than 1 milliard gold fr.) of what are called invisible exports —that is, purchases made by passing visitors—may be added. On the other hand it must be remembered that France has almost entirely lost her credits held abroad in the shape of shares, debentures and state loans. Of this wealth, which amounted to 40 or 50 milliard gold fr., a large portion was diverted during the War. Another part, comprising Russian, Austrian and Turkish bonds, has practically melted away; and this magnificent holding of foreign credits cannot unfortunately be restored, or at least can only be restored by secret methods, because an unintelligent fiscal policy prohibits or at least handicaps heavily all kinds of investments abroad. The figures of French commerce include those of the trade done between the mother country and her colonies and these can have no effect on the exchange, the currency being the same on both sides.

It is not our intention to discuss the immense question of protection. We will only say that the War, far from having shaken Protectionism, has fortified it, not only because fiscal necessities call for the imposition of duties, but because fear of blockade leads each nation to think that she ought to be self-sufficing; and if, in those countries which appeared to be converted for good to free trade, such as England, Holland, Denmark and Switzerland, protection is gaining ground, with how much more justification will it become rooted in France? The only hope is that the breath of internationalism, which has created the League of Nations, may also bring into being economic unions between several countries. No serious progress has yet been made with those economic understandings between France and Germany which have many times been proposed on both sides of the Rhine.

Social Economy

Labour Legislation.—During the War, social questions naturally lost their interest for the public. Even the application of laws for the protection of men and women workers was set aside in the interests of national defence. Workers mobilised in muni-

tion factories, worked day and night without protest, stimulated both by the incredibly enhanced rate of pay and by the fear of being sent to the front.

Even when the War was over, the opinion of business men and economists held that this intensive labour should continue, at least until the day when the ravages of war should have been repaired on the ground that the work of restoring the devastated areas was no less urgent than that of national defence. But the workers were deaf to this appeal; indeed they clamoured for the adoption of the eight-hour day awaited for 20 years, and celebrated in anticipation on each May Day. Parliament dared not resist this pressure, and the Act of April 19 1919 established in principle the eight-hour day, leaving, however, the application of the law to be adapted to the special conditions of individual industries by technical commissions. This was a difficult task, not yet satisfactorily solved. So far the eight-hour day is only applied to some 5,000,000 workers distributed among 30 trades. The trades unions protest violently against these delays; but all business men and a fair number of economists persistently oppose the Act, in which they see one of the principal factors in the rise of prices. Its partisans argue that in the case of a number of industries productivity has been maintained and even augmented, notwithstanding the eight-hour day.

Several other laws, on the same lines as this general law, have been promulgated to secure the weekly holiday for tradespeople by compulsory closing of the shops and to forbid night work in the bakeries. These laws meet with violent opposition on the part of small traders or small bakers who, as they employ no paid labour, claim the right to work themselves when and how they please. There is also a law of June 10 1915 ensuring a minimum wage to women working at home. This is in imitation of the similar law in England. The insurance benefits against accidents, which had only been granted to industrial workers, were extended to agricultural labourers by a law of Nov. 15 1922. Another law of 1916 concerns economic life; it prohibits "illicit speculation," that is, the extravagant raising of prices. This law was, it is true, repealed in 1922, but there is an agitation for its renewal. The question leads to passionate arguments, for it opposes the idea of equitable prices to the classic law of supply and demand. There are numerous laws by which loans on state funds are granted to co-operative societies, concerned with credits, consumption or production; also to societies of artisans employed in small industry and of agricultural workers for the acquisition of land, special advantage being given to disabled ex-soldiers. We may also mention the creation of a National Economic Council composed of members elected by all the great national organisations. It has no legislative powers but aims at enlightening the Government and preparing draft legislation.

In addition there are numerous important measures under consideration, vigorously demanded by the *Confédération Générale du Travail* and by the Socialist party. The following are the principal demands:—

(*a*) The establishment of a *general social insurance*, covering all the risks in life: illness, old age, disablement, unemployment, maternity, etc. This project likewise arouses lively opposition, on account of the enormous charge entailed on industry and on the national budget at a time when the financial situation is in itself critical. Neither is it favourably regarded by the Mutual Insurance Societies, corresponding to English Friendly Societies, who depend on the voluntary contributions of their members and see themselves in danger of being eliminated by a compulsory insurance scheme. Nevertheless, it is certain that the bill will be passed, in a more or less modified form, for the Radical Socialist party has declared its intention to side with the Socialist party in supporting it.

(*b*) The establishment of a *contrôle ouvrier* which would authorise the workers—or rather the trades unions—in every factory to intervene in all questions of labour organisation, such as the workshop regulations, engagement, dismissals, discipline and so on.

(*c*) The workers' right to claim a certain number of days as holidays: this would give legal sanction to a custom which is becoming general to-day.

(*d*) The right to receive a minimum wage, increased by allowances proportionate to the number of children. Here again it is a case of legal sanction for a custom of family allowances which, though of recent introduction, is already in use in many establishments. But these allowances are at present paid actually by the employers, and the trades unions will not accept this, seeing in it a means of binding the worker on the pretext of assisting him. They claim family allowances, but on a compulsory basis.

The Social Movement.—As long as the War lasted we had, if not social peace, at least a truce from social strife as from political strife. The middle class and the working class had fraternised in the same trenches. But this truce did not last. The working classes returned from the War disappointed and irritated. They had been laden with laurels for saving their country, promised a new world, and when they had to go into harness again, life seemed harder and the wage system more intolerable than ever. The rise in prices, due to a factor of which for years the public remained ignorant, viz.: depreciation of the currency, increased that irritation. Undoubtedly a rise in wages followed the rise in prices; in the first years of the War it anticipated it indeed, but after the War, the advance in wages fell behind the advance in prices, and adjustment was frequently obtained only through fighting and strikes. The index number of wages which had (almost) caught up with the index number of prices, again lagged behind on account of the fall in the value of the franc at the end of 1925.

The two columns below show the index numbers of retail prices and those of wages at corresponding dates. The parallelism of the two ascending lines would be still clearer if shown in a graph. It should be remembered, however, that index numbers of wages are far more difficult to determine than those of prices. Instead of taking more or less arbitrary averages, we have chosen to take wages in a single industry, that for which the most definite statistics are obtainable, namely the coal-mining industry (taking underground and surface workers together) as indicative of the wage movement in general.

	1914	1920	1921	1924	1925
Retail Prices .	100	390	352	401	435
Wages . .	100	360	349	423	437

The same parallel movement is found in the salaries of minor employees and officials, but not at all in the case of higher officials whose salaries have often not even been doubled.

It must be admitted that when the worker does obtain wages proportionate to the rise in prices, he is not satisfied, for he does not see why, with his wages quadrupled, he cannot satisfy his requirements better than before the War. He feels that he is being duped and it irritates him. Then, too, the worker's requirements—particularly those of the agricultural worker—are much greater since the War. This is due to the lavish distribution of meat, coffee, tobacco and alcohol to the soldiers, the taste for which has survived and the desire for which is stimulated by the spectacle of the scandalous fortunes that are acquired through the rise in prices and through speculation.

The people's saving-banks have had their deposits greatly augmented, but not in proportion to the rise in prices, as the following figures show:—

	National Savings Bank	Municipal or Private Savings Banks	Total
	Fr.	Fr.	Fr.
1913 . . .	1,818,000,000	4,011,000,000	5,829,000,000
1914 . . .	1,904,000,000	3,909,000,000	5,813,000,000
1924 . . .	3,306,000,000	8,814,000,000	12,120,000,000

If we convert the actual total (12 milliards) to pre-War francs on the basis of the mean exchange in 1924 it becomes less than 3 milliard fr., that is, to a figure below that of 1911. The savings-bank deposits are influenced by the degree of confidence inspired by the national credit at any given time. This applies even to the municipal or private banks, for these also put nearly all their deposits into state funds. Among the lower classes confidence is greatly shaken by the fall in value of state bonds.

It might be supposed that, given the discontent prevailing among the working class, trade unionism would show a great increase, and a study of the official statistics appears to confirm that supposition: 1911, 1,029,000 trade unionists; 1925, 1,846,000 trade unionists.

But these figures are of little value because most of the trade unionists figure only on paper, and also, since the Moscow revolution, trade unionism has been disorganised. Actually it is represented by three organisations more or less hostile to each other.

1. The oldest of all (dating from 1895)—the *Confédération Générale du Travail*, the famous C.G.T., whose secretary Jouhaux is well known. Its effective membership rose from 1,000,000 before the War to nearly 2,000,000 in 1920. As the result of an attempted general strike provoked by unemployment, of which the C.G.T. did not approve, although it dare not disavow it, and especially of the withdrawal of the Communists in 1921 which was inspired from Moscow, the number of its members fell to 400,000. It has recovered since then, mainly through the adhesion of intellectual workers and officials (among whom are 110,000 teachers) and is said to have 700,000 members at the present time. Although it was declared illegal by a legal decision, never put into execution, its programme is reformist rather than revolutionary.

2. In consequence of the schism just mentioned, another *Confédération Générale du Travail* was formed which qualified its title by the additional word *unitaire*, a strange term for dissentients. Its programme is that of Moscow: the dictatorship of the proletariat. This organisation is known as the C.G.T.U. It has not succeeded in rallying more than 200,000 to 300,000 members and will probably return before long to the older organisation.

3. Finally there is the *Fédération des syndicats catholiques* which is not much in the public eye, but is said to be growing since the War.

The co-operative movement, more favourably situated, has grown steadily since the War in France, as indeed in all countries, particularly as regards consumers' co-operation. The reason for this lies not only in the rise in prices, which has forced the middle class as well as the working class to seek means of reducing the cost of living; there is also a psychological reason—reaction against the existing economic organisation. The classic laws of political economy are no longer accepted, and there is therefore a sympathetic public for a new doctrine such as this, which claims to replace competition by co-operation, the law of supply and demand by fair prices, production for profit by production for service, thus abolishing the profiteer.

The following figures show the progress that has been made:—

	Number of Societies	Number of Members	Sales Figures
			fr.
1918	3,280	865,000	317,000,000
1922	4,300	2,330,000	1,747,000,000

It will be seen that the increase in the sales is much less than it appears, for in 1922 the franc had already fallen to 0·27; the 1,747,000,000 therefore represent only 576,000,000 of 1913 francs. But the progress of the movement is shown above all in the development of central organisations and in the growing part which co-operatives play in national and international economic life. The importance of the movement received official acknowledgment at the end of the War in 1918 when the Conseil Supérieur de la Coopération was created and its advice asked on all questions of interest not only to co-operatives, but to consumers generally, just as the Conseil Supérieur du Travail is called in to advise on questions which concern workers.

Agricultural co-operative societies for mutual credit, have also been greatly multiplied:—

1911	3,946 societies	185,000 members
1923	5,212 societies	284,000 members

but their development is to a large extent artificial, being due as it is principally to the loans granted by the state (about 600,000,000 (150,000,000 gold fr.) up to date in 1924). These funds are not taken from the budget, but from the immense profits which the state draws from its partnership in the Banque de France.

As to the industrial producers' societies, the oldest and most typical of all co-operation in France, they comprise within a small ring some 500 societies in all with 30,000 members. The most celebrated, and one which has been visited by co-operators from all countries is the *Familistère de Guise*. The friendly societies, which in their day were the elementary schools of social solidarity, are now rather out of date. Their field of activity, hedged in on the one hand by employers' institutions, on the other by the extension of compulsory state insurance, is becoming more and more limited.

Population

The demographical position of France was already bad before the War, and was bound to be aggravated by a war which robbed the country of the flower of its population. In 1911 the population was 39,605,000; in 1921 it was 39,240,000.

Thus the population has diminished in the course of these 10 years, but the diminution is even greater than it seems; for Alsace and Lorraine, which did not figure in the 1911 returns, are included in the census of 1921. Now these provinces account for 1,719,000 inhabitants, and if we deduct these from the figure of 39,209,518 we are left with a population of 37,521,000 for France as it was before the War. There is therefore a diminution of more than 2,000,000 and this diminution is only too easily explained:—(1) by the number of men killed in the War (1,400,000) and (2) by the fall of the birth-rate during the War.

The sudden rise in the number of births immediately after the War—a familiar phenomenon—was succeeded by a quick drop to the pre-War figure. Fortunately, the death-rate has sensibly diminished, with the result that the annual excess of births over deaths is greater than before the War:—

	Births	Deaths	Excess of Births over Deaths
1911–3 (3 years average) .	746,000	724,000	22,000
1922–4 (3 years average) .	758,000	679,000	79,000

It is clear that even could this natural increase be maintained over a period, it would take 26 years to replace the 2,000,000 dead or the unborn of the War. The state endeavours to stimulate the birth-rate by grants to families in proportion to the number of children. But it is hard to believe that these premiums will cause many children to be born; they are only a means of giving material aid to the parents of large families.

Happily foreign immigration goes far towards restoring the balance, for the number of immigrants is now far greater than the number of births in excess of deaths. The annual number of immigrants, taking the average over the three years 1922, 1923, 1924 is 290,000. We may suppose then that the coming census of 1926 will give France a population of 40,600,000 inhabitants. This places her fifth among the great European powers. But she has also a population—black, yellow and white—of 50,000,000 to 60,000,000 in her colonies.

III. NATIONAL FINANCE

On the eve of the World War the public finances of France were in a relatively poor condition, a circumstance which has influenced the whole evolution of French finance since Aug. 1914, and was due solely to the indifferent way in which the finances had been handled.

The Budgetary Deficit.—For the three years 1908–10 the national budget showed a total deficit of 147,000,000 francs. In 1911, it is true, there was a surplus of 141,000,000 fr., but in the following year the deficit reappeared. Although the accounts of the year 1912 show an apparent surplus of 112,500,000 fr., this was only obtained by including 153,000,000 fr. which were extraordinary resources of the Treasury arising from the "Compte provisionnel." In reality this apparent surplus masked a deficit of 40,500,000 francs. For 1913 the budget showed the following results:—

	fr.
Receipts	5,066,900,000
Expenditure	5,038,100,000
Surplus	28,800,000

But the receipts included 172,000,000 fr. again coming for the "Compte Provisionnel," so that the real deficit on the budget was 143,000,000 francs. When the budget for 1914 was under discussion the deficit was estimated at 800,000,000 francs. In reality these deficits were even larger, as a number of items of expenditure which should have been included were withdrawn from the budget by accounting devices. A bad example had been set by the law of Feb. 17 1898, which instituted the special Treasury account for the improvement of military equipment.

On Jan. 1 1914 there were still 173,000,000 fr. of short-term bonds issued in virtue of this law, of which 11,000,000 fell due in 1914, 124,000,000 in 1915 and 38,000,000 in 1916. A subsequent law of March 30 1912 created the account for the improvement of naval equipment and, although annual sums were allotted from the budget for this purpose, the expenditure over the five years 1912–6 exceeded the allocation by 139,293,000 francs.

These extra-budget expenditures, which had become to some extent both regular and normal, were not the only ones. The diplomatic tension at the time of the Agadir incident in 1911 had drawn the attention of the French Govt. to the inadequacy of the military equipment of France, and caused it to embark on very considerable expenditure without the formal authorisation of Parliament. In 1912, 22,000,000 fr. were spent in this way but in 1913, owing to the passing of the three-year military service law, the figures rose to 300,000,000 fr., and in 1914, 488,000,000 fr. extra-budget credits were estimated for the army and 128,000,000 for the navy.

The "Compte Provisionnel."—In order to hide, at least in part, the deficit, the "Compte Provisionnel" was created by the law of Feb. 20 1912. This was a treasury device which enabled any surplus to be carried over from one financial year to the next, thus violating the fundamental rule of an annual budget. During the first year, in 1912, a sum of 159,000,000 fr. was paid into the "Compte Provisionnel," arising from the anticipated repayment by the Compagnie des Chemins de Fer de l'Est of advances made to it by the state as a guarantee of interest. In the following year it was credited with 141,000,000 fr., the surplus of the financial year 1911 and with a further 31,000,000 fr. from non-recurring sources. In 1914 it received 112,500,000 fr., the surplus of the financial year 1912.

The Reform of the Tax System.—Treasury expedients of this type, besides being inadequate, did not provide a solution, which it is clear could only be found by voting the necessary taxes, as was demanded by M. Poincaré when Minister of Finance in 1906. There were two obstacles in the way of this solution: firstly, the usual unwillingness of all politicians to impose new burdens on their electors—an unwillingness which from 1904 to 1914 prevented the French Parliament from voting more than 236,000,000 fr. of new taxes as against additional expenditure of 1,777,000,000 fr.; secondly, the political battle which raged round the question of reform of direct taxation. After prolonged controversy, which dated from the reform proposals of M. Caillaux in 1907, the law of March 29 1914 was passed, which provided for the reorganisation of the tax on property not built over and for the increase of the tax on income from securities. But this did not bring in any additional revenue, because at the same time the former tax was lowered by an amount equivalent to the yield of the new taxes on securities. On the eve of the declaration of War, however, a decisive step towards fiscal reform was taken by the creation of the general income tax. This was a slightly progressive supplementary tax on incomes levied on that part of the total income in excess of 5,000 francs. This new tax only came into force in 1915, and therefore could not help to meet the deficit at the moment it was voted.

The Treasury and the Loan of July 1914.—The whole of the current and accumulated deficits were covered by an increase of the floating debt, which amounted to about 2,100,000,000 fr. on Dec. 31 1913. While the necessity of issuing a loan to fund part of the floating debt was realised as early as 1913, the measure was delayed by a controversy over the question whether or no the interest on the new rente should be exempt from taxation. Finally, in June 1914, a law was passed authorising the issue of a loan of 805,000,000 fr. of 3½% redeemable rente subject to taxation and issued at 182 fr. for each 7 fr. of rente. The subscribers were only required to pay down 20 fr. on allotment of a nominal 200 fr. of loan, the balance being payable in three subsequent instalments. As a result of this mode of subscription the loan was chiefly subscribed by the banks, who hoped later to dispose of the shares at a profit to the public. To sum up, the following was the financial situation in July 1914, on the eve of the War: a considerable budget deficit; a relatively large floating debt; a loan recently issued and taken up by the banks but not placed with the public and involving a heavy burden on all credit institutions on the declaration of War.

French Finance during the War (1914–8)

The Declaration of War and the Credit Crisis.—The outbreak of War brought with it a very grave credit crisis, of which the first manifestation was a panic on the Stock Exchange in the last days of July 1914. The settlement of future transactions was suspended for the time being, and on Sept. 3 the Bourse was closed. Hence the funds advanced to speculators to support their forward transactions were locked up, and ceased to be available for industry and commerce. The banks were forced to rediscount bills with the Bank of France, whose holdings of commercial bills rose from 1,554,000,000 fr. on July 25 to 4,000,000,000 fr. on Aug. 4. The Bank of France raised its discount rate from 3½% to 6%, and its rate for advances from 4½% to 7%. On July 31 the settlement of all commercial liabilities was postponed, and on Aug. 1 a moratorium was proclaimed for the deposits of the banks except for small sums not exceeding 250 francs. The Bank of France never refused to rediscount bills; therefore it seems questionable whether the moratorium was really unavoidable for the other banks. The crisis, though very acute during the first weeks of the War, was not of long duration. The Bourse was reopened on Sept. 27 for spot transactions, and, with the aid of a loan of 200,000,000 fr. from the Bank of France, it proved possible by Sept. 30 1915 to liquidate all commitments carried over during the moratorium, including the loan of 805,000,000 fr. of July 1914. The commercial moratorium was of longer duration. Most of the bills of exchange, etc., maturity of which had been prolonged were taken up by the Bank of France, whose holdings of these securities reached their maximum of 3,977,000,000 fr. on Dec. 24 1914. Many of these bills were relatively quickly absorbed, and their total fell to 1,938,000,000 fr. by the end of 1915. Owing to this credit crisis it was necessary to wait till the end of 1915 before the first big consolidated loan could be issued.

War Expenditure.—The following table summarises the growth of French expenditure for the War:—

Expenditure (Millions of Francs)

	Military Charges	Public Debt	Civil Services	Recoverable Expenditure	Special Accounts	Total
1914	6,526	1,360	2,005	372	108	10,371
1915	14,712	1,818	2,479	1,914	1,197	22,120
1916	23,853	3,327	2,817	2,947	3,904	36,848
1917	28,662	4,816	4,119	4,081	2,983	44,661
1918	36,120	7,021	5,443	5,952	2,113	56,649
	109,873	18,342	16,863	15,266	10,305	170,649

The item "recoverable expenditure" covers that expenditure for which Germany was rendered liable by the Treaty of Versailles. The item "special accounts" comprises the deficits of the special services of the Treasury which were created during the War, and which include extra-budget expenditure, advances to Allied Governments, cession of material to foreign Governments, feeding of the civilian population, etc.

Taxation.—The budget revenue raised during the War amounted to 26,200 million fr., or about 15% of the total expenditure. When France is reproached with not having made a more considerable fiscal effort it must be remembered that she was deprived by invasion of about one-fifth of her tax revenue. Mobilisation caused the greater part of her labour to be called up, and withdrew many of the financial officials. Further, it is untrue to say that fresh taxes were not voted during the War; the general income tax was increased on three occasions, in 1916, 1917 and 1918, and carried from 2% to 20%; in 1917 the old direct taxes were replaced by the new system of income-tax schedules; taxes on succession, stamp duties and taxes on insurance were increased; finally, in 1916, an extraordinary tax on exceptional War profits was imposed. Additional taxation brought in about 2,800 million fr. during the War, and tax revenue rose from 4,100 million fr. in 1915 to 6,800 million fr. in 1918.

Advances of the Bank of France.—The following table shows the total of advances authorised to be made by the Bank of France and of advances actually given:—

	Total Advances Authorised (000,000 omitted)	Total Advances Made (000,000 omitted)
	fr.	fr.
Dec. 31 1914 . . .	6,000	3,900
Dec. 31 1915 . . .	9,000	5,000
Dec. 31 1916 . . .	9,000	7,400
Dec. 31 1917 . . .	15,000	12,500
Dec. 31 1918 . . .	21,000	17,150

To this total 3,750 million fr. must be added for loans granted by the French Govt. to foreign governments.

The French Exchange and Foreign Loans.—Prior to Aug. 1915 the French exchange, in spite of a deficit in the balance of trade amounting for eight months to 1,600 million fr., was kept at or very near par, thanks to the falling due of foreign coupons, to the export of small quantities of gold, to the placing of £12,000,000 of Treasury bills on the London market, and to an American advance of $10,000,000. Between April 1915 and April 1917 the total deficit of the French balance of trade rose to 27,000 million francs. This deficit was covered partly by expenditure incurred by the British Expeditionary Force in France, partly by the sale of a portion of the French holdings of foreign securities, but chiefly by British and American credits. France sent gold to London to the value of 2,840 million fr. and obtained credits in exchange to the value of 9,000 million francs. At the same time she procured credits amounting to $650,500,000 from the United States. By these means the depreciation of the franc was kept within reasonable limits. On March 31 1917 the franc was 11% below par in relation to the dollar, 13·5% in relation to the Swiss franc, and 21% in relation to the peseta and the Swedish krone.

In April 1917 the United States entered the War, and from then onwards its financial assistance was very great. Between April 1 1917 and Dec. 31 1918 the French balance of trade showed a deficit of 32,000 million fr. which was mainly covered by credit operations; £290,000,000 were placed at the disposal of France by the British Treasury, and $2,500 million by the American Treasury. Smaller loans were also contracted in other countries, *e.g.*, 100,000,000 gold pesos in Argentina, 350,000,000 pesetas in Spain, 100,000,000 yen in Japan, etc. As a result of this assistance the French exchange at its worst never fell more than 44·7% below par in relation to the Swedish kroner and 39·1% in relation to the peseta, while on Dec. 31 1918 the depreciation was not more than 9·5% and 7% respectively.

Internal Loans.—The principal medium for the transfer of funds to the Govt. for War purposes was the National Defence Bills devised by M. Ribot and issued in virtue of the decree of Sept. 13 1914. These bills were Treasury securities with a currency of one year, six months, three months and even one month after April 1918. They were repayable at par, and could be discounted at the Bank of France within three months of maturity. They could be crossed like cheques. In fact, they acted as deposits with the Treasury which could very easily be mobilised. In view of their convenience and elasticity they quickly proved a great success, and the Treasury succeeded by this means in mobilising a considerable part of the available funds of the nation for its requirements. The National Defence Bills had, however, one danger—the abnormal expansion of the floating debt. To retard the increase of the floating debt the French Treasury made successive issues of National Defence Bonds with a currency of 10, 6 and 5 years.

Finally, when the credit crisis referred to above had been overcome, the state decided to issue a series of irredeemable loans—the 5% loan of 1915 (real rate 5·73%); the 5% loan of 1916 (real rate 5·71%); the 4% loan of 1917 (real rate 5·83%); and the 4% loan of 118 (real rate 5·68%).

Table Showing Loans Raised by France
(In millions of francs)

	1914	1915	1916	1917	1918
Irredeemable Loans (net yield)	..	6,265	5,425	5,174	7,246
Short Term Loans	465	..	..	..	..
National Defence Bills and Bonds	1,858	10,487	12,955	13,054	16,611
Funds deposited at the Treasury	..	..	53	360	436
Total	2,323	16,752	18,433	18,588	24,293

French Finances from 1919 to 1926

At the end of the War France was faced with three very grave financial problems—the liquidation of the War; the reconstruction of the devastated regions; and the reorganisation of her fiscal system on an entirely new basis. The liquidation of the War involved heavy outgoings in respect of unexpired contracts, extraordinary civil expenditure, the progressive liquidation of the special accounts of the Treasury, etc., which were not completed till the end of 1921, and may be estimated at about 36 or 37,000 million francs. The reconstruction of the devastated regions was regulated by the law of April 17 1919. This law, which was voted at a time when everyone believed that Germany would make good the whole of the damage in accordance with the provisions of the Treaty of Versailles, was conceived in a very liberal spirit. It laid down that all those who had suffered loss were entitled to an indemnity fixed by a special *ad hoc* body, and equivalent to the pre-War value of the property. If, further, the victim undertook to reconstruct his destroyed property he had a right to the refund of additional expenses caused by the rise in prices. The total cost of reparation thus calculated is estimated at 82,000 million francs. In addition to this there must be added the permanent increase in expenditure resulting from high prices and salaries and the service of the debt.

The story of the French financial effort since 1918 falls naturally into four periods: (1) the year 1919; (2) 1920–1; (3) 1922–June 1924; (4) June 1924–Jan. 1926.

1919 and the Period of Inflation.—The events of the year 1919 weigh heavily on the financial destiny of France. At the end of Dec. 1918 the English pound stood at 29·97 fr. and the dollar at 5·45 francs. At the end of Dec. 1919 the pound sterling was valued at 41·48 fr. and the dollar at 11 francs. This fall was due to the persistent deficit in the balance of trade (24,000 million fr. in 1919). The deficit was again met in part, as in previous years, by foreign credits. But on Jan. 3 1919 the British Treasury announced that it would make no further advances to the French Treasury, and in Dec. the American Treasury followed suit. Nevertheless, the external debt of France increased in 1919 by about 11,000 million francs. The expenditure of the state, swollen by the accompanying inflation, amounted to 54,200 million fr. scarcely less than in the last year of the War. This total included 15,500 million fr. of "recoverable expenditure," comprising costs of reconstruction and War pensions. Budget revenue, on the other hand only amounted to 11,600 million francs. The Chamber of Deputies elected in 1914 could not make up its mind to impose new and heavy taxes on the eve of a new election. As a result the floating debt increased in 12 months by 27,653 million francs. The Crédit National, created specially for the finance of the devastated regions, raised a loan at the end of 1919 which brought in 3,960 million francs. Finally the Treasury borrowed 8,370 million fr. from the Bank of France—a larger sum than in any year of the War. It was this wholesale inflation which put the seal on the depreciation of the franc.

During the year 1919, which could and should have been the first year of financial reconstruction, the financial methods of the War were merely perpetuated, under the direction of the Finance Minister, M. Klotz. Financially the War did not finish till the end of 1919. In six years the Treasury had spent 224,000 million fr., which were raised in the following way:—

	fr.
Taxation	38,000,000,000
Internal Loans	112,000,000,000
Foreign Loans	44,000,000,000
Advances from the Bank of France	30,000,000,000
Total	224,000,000,000

Deflation (1920–1).—During 1920 and 1921, when MM. François Marsal and Doumer were at the Ministry of Finance, there was an effective reaction against the methods of the preceding years. On Jan. 13 1920 the estimates for the current year were laid before the newly elected Chamber. The estimates provided for 17,861 million fr. of ordinary and 7,568 million fr. of extraordinary expenditure; the former was only covered by normal revenue to the extent of 9,368 million fr. and the latter to the extent of 3,000 million fr. yielded by the sale of War stocks. To this budget deficit of 13,000 million fr. must be added the final deficits of the special accounts of the Treasury (which in 1920 amounted to 5,092 million fr.) and a further 22,000 million fr. of credits for "recoverable expenditure," which after July 1920 appeared under the heading "Special Budget of Recoverable Expenditure," and continued till 1925. In actual fact the expenditure was greater than had been anticipated, and amounted to 58,100 million francs. In June 1920 additional taxes to bring in 7,752 million fr. were voted to balance the ordinary budget, the normal revenue being thereby increased to 20,100 million francs. There still remained, however, a deficit of 38,000 million fr. which was covered by loans. A 5% long-term loan was issued in Feb.–March 1920, and a 6% loan in Oct.–November. The total subscriptions to these two loans were 43,000 million fr., of which more than 18,000 million fr. were new money, the rest consisting of conversions of former loans or of floating debt. In 1921 the financial situation was further improved. The total expenditure was reduced from 58,100 million fr. in 1920 to 51,000 million fr., and revenue rose to 23,100 million francs. The deficit fell to 28,000 million francs.

The following table summarises the Treasury operations during these two years:—

I. *Expenditure*
(In millions of francs)

	Military Charges	Debt	Civil Service	Recoverable Expenditure	Special Accounts	Refunds to Bank	Total
1920	7,600	11,700	11,400	22,300	5,100	..	58,100
1921	6,000	11,100	9,900	21,400	2,700	2,100	53,200

II. *Receipts*
(In millions of francs)

	Budget Revenue	Internal Loans	Advances from the Bank of France	Total
1920 . . .	20,100	38,400	500	59,000
1921 . . .	23,100	29,700	..	52,800

In the years 1920 and 1921, despite the very large deficit, the financial situation was easier. It proved possible not merely to stop inflation, but to inaugurate a systematic policy of deflation. The chief author of this courageous policy was M. François Marsal, who was Minister of Finance in 1920, and who in June 1920 carried through the imposition of 8,000 million fr. of new taxation; in addition he consolidated more than 12,000 million fr. of floating debt, and in Dec. made the agreement with the Bank of France by which the state undertook to repay 2,000 million fr. annually. The exchange also benefited by this policy. The dollar, which had risen to 17 francs in 1920, fell to 12·50 francs in June 1921, and even as low as 11 francs in April 1922. Wholesale prices fell more than 40% as compared with the spring of 1920.

The Budget Deficit and the Exchange Crisis of 1924 (Jan. 1922–May 1924).—Throughout 1922 and 1923 the franc depreciated in value, and at the end of 1923 the dollar was worth more than 19 francs. This was due to several causes, and undoubtedly questions of foreign policy—the discords amongst the Allies on the subject of reparations and the Franco-Belgian occupation of the Ruhr—played their part. But the basic reason is to be sought above all in the financial situation of France herself. State expenditure, which, though slowly decreasing, remained very large, was divided into three big groups—the general budget, to be met out of taxation; the special budget of "recoverable expenditure" (pensions and interest on reparations debt), which in theory should be met by Germany; and the costs of reconstruction, which quite properly were covered by loans. The results are shown by the following figures:—

	General Budget (in millions of francs)		Special Budget (in millions of francs)	
	1922	1923	1922	1923
Expenditure . . .	24,688	24,163	9,905	10,382
Revenue	23,382	24,202	160	109
Balance	−1,306	+39	−9,745	−10,273

Hence the total budget deficit amounted in 1922 to 11,051 million fr. and in 1923 to 10,234 million francs. These deficits were covered by loan operations, and the state was even able to reduce the total of the advances from the Bank of France from 24,150 million fr. to 23,100 million francs. It was, however, becoming increasingly difficult to raise long-term loans. The Crédit National was alone in being able to place a loan with the public of 5,000 million francs. The rest of the expenditure was covered by an increase in the floating and short term debt. This situation was soon reflected in the movement of the foreign exchanges. There was a violent crisis at the beginning of 1924, and the pound sterling rose from 85 fr. to 117 fr. and the dollar from 19·60 fr. to 27·20 fr. on March 11. This crisis was the result of intensive speculative selling which developed in continental centres such as Vienna, Berlin, Milan, Basle and Amsterdam, and was in a large measure artificial. None the less it revealed how precarious was the financial situation of France. Under the energetic direction of M. Poincaré, the Prime Minister, a great effort was made to retrieve the position. The Govt. asked Parliament to vote 6,000 million fr. of taxes in order to cover the expenditure of the special as well as of the general budget, and it asked for powers to cut down expenditure by 1,000 million fr. by administrative decree. These measures were voted by the end of March 1924. At the same time exchange credits were raised in London and New York, and on April 20 the pound had fallen to 65 fr. and the dollar to 14·80 francs.

The Elections of May 11 1924 and the Return of Inflation.—The new elections resulted in the victory of the parties of the Left, which had refused to vote the last fiscal measures proposed by M. Poincaré. The Socialist party had a good deal of influence in the new Govt., and its revolutionary programme disquieted the propertied classes of the country. The budgetary equilibrium which had only just been restored was again destroyed, for the new Chamber voted 1,700 million fr. of supplementary credits, and suspended the realisation of the 1,000 million fr. of economies adopted by the preceding Chamber. There was thus a deficit of 3,000 million fr. on the budget of 1924. This deficit was enhanced in 1925 by the increase of 1,405 million fr. in War pensions, by the increase of the salaries of officials, and by expenditure in Morocco and Syria. The situation was aggravated by the falling due of quantities of bills and short-term bonds, of which about 8,000 million fr. had to be paid off in 1925. To this figure must be added the deficit in the subscriptions to the National Defence Bills, the amount of which reached 9,000 million francs. To meet these liabilities the Treasury issued, in Nov.–Dec. 1924, 5% Treasury bills at 150 repayable in 10 years (effective rate 9·20%), and in July–Oct. 1925 an irredeemable 4% loan with an exchange guarantee. These two loans brought into the Treasury a nominal sum of 11,000 million fr., but in fact very much less, because the greater part of the subscriptions only represented the consolidation of the floating debt.

It was under these conditions that France returned in 1925 to the *régime* of inflation, for the first time since 1919. In April 1925 the state asked the Bank of France for 4,000 million fr. of new advances, in June for a further 6,000 million fr., in Nov. for 1,500 million fr., and in Dec. 1925 for 6,000 million francs. All these credits were not in fact exhausted. Nevertheless, at the beginning of 1926 the advances from the bank to the state had risen from 22,000 to 36,000 million fr., and the total of notes in circulation from 40,500 to 52,000 million francs. Parallel with this the French exchange continued to fall, and the pound sterling, which was worth 88 fr. in Dec. 1924, exceeded 130 fr. in Dec. 1925. At the beginning of 1926 the position was as follows. The budget, with a total expenditure of 37,200 million fr. (the general budget and the special budget were amalgamated in 1925), shows a deficit of 4,500 million francs. Part of this deficit was covered by 3,000 million fr. of new exceptional revenue voted on Dec. 4 1925. All parties were agreed as to the necessity of creating a sinking fund to consolidate the floating debt. Successive Ministers of Finance, M. Doumer and M. Raoul Péret, proposed new taxes amounting to nearly 5,000 million francs.[1]

The French Debt and the Work of Reconstruction.—To have a sound understanding of the financial situation and its handling since 1918 it is desirable to relate the debt to the effort made for the reconstruction of the devastated regions. The two following tables show—(1) the situation of the French internal debt on April 30 1925; (2) the expenses devoted to the reparation of War damage to Dec. 31 1924.

I. *French Internal Debt*

	Annual Charge	Capital Debt
Perpetual and Long-term Debt	7,451,232,802	155,252,268,681
Short-term Debt . . .	2,692,869,140	44,274,769,000
Floating Debt	2,762,584,000	86,646,656,500
Total	12,906,685,942	286,173,694,181

II. *Expenses Resulting from Reparation of War Damage*
(In millions of francs)

Damage to Persons	Private Property	Railways, Public Property, and Costs of Administration	Interest paid on Indemnities	Interest on Loans Contracted	Total
36,436	59,283	12,760	2,594	19,000	130,073

In conclusion, 45% of the internal debt of France comes from expenditure for the reparation of War damage, and one-sixth of the French budget was devoted in 1926 to the service of this debt.

BIBLIOGRAPHY.—Reports of the Rapporteurs of the Finance Committees of the Chambre des Députés and of the Sénat, published as supplements to the *Journal Officiel; Reports on the Economic and Industrial Conditions in France* (annual, Stationery Office, London). *Effect of the War upon French Economic Life*, ed. C. Gidé, (Carnegie Endowment for International Peace, 1923). (E. MI.)

[1] The crisis in the franc was due to a loss of confidence, which showed itself in a reluctance on the part of the public to invest in the floating debt. M. Loucheur, while Minister of Finance in Dec. 1925, obtained a measure imposing a special additional income tax (non-recurrent), and steps were taken to hasten the collection of the ordinary income tax. The "heavy revenue collections" thus obtained were sufficient to meet all needs in the opening months of 1926. The At last, M. Raoul Péret, procured the passage of a budget which balanced at 37½ milliards, with a surplus of 250 millions, additional taxation to the amount of 4½ milliards being imposed.

But meanwhile the exceptional revenue receipts of Dec. and Jan. could not continue, and a further block of three milliards of maturing bonds had to be met early in May. The exchange began to give way and rose above 140. The outbreak of the general strike in England at the beginning of May was the signal for something like an exchange panic, and after wild fluctuations, in the course of which the exchange reached 176, the French Govt. intervened with support, and brought it back for the moment almost to 140. At the beginning of June M. Péret appointed a committee of French financial experts to make recommendations for the future. (Ed. *E.B.*)

IV. DEFENCE

National defence in France underwent some material modifications after the World War. The reforms were based on the somewhat conflicting demands of national economy and of national security against aggression. In practice they resolved themselves as follows:—

(1) army and navy, in time of peace, to be limited strictly to the scale necessary for covering national mobilisation in case of aggression and allowing that mobilisation to be carried out at a speed compatible with that of the said aggression; the colonies and the communications with overseas possessions to be safeguarded; and

(2) the general organisation of the nation in war time to be minutely worked out.

Conscription.—Compulsory personal service was therefore maintained, but the duration was reduced to 18 months (Act of April 1 1923). The following tables show the effectives and the budgets of 1925 compared with those of the preceding years:—

	Aug. 1 1914 Pre-War	Aug. 15 1914 after Mobilisation	Nov. 1918 Armistice	1925
Army				
Effectives (French and Colonial)	947,000	3,850,000	4,200,000	695,000
Inf. Divs	44	87	112	32
Cav. Divs	10	10	6	5
Field Guns	2,800	4,044	5,000	1,350
Heavy Guns	250	308	5,100	1,000
Air Force				
Number of Aeroplanes	120	120	4,700	1,850
Navy				
Effectives	69,000	100,000	174,000	56,000
Battleships	26	26	10	9
Cruisers	31	31	15	18
Aeroplane-carriers	..	..	..	1
Destroyers	..	..	2	8
Torpedo-boats	83	83	51	63
Submarines	72	72	33	66

National Defence budgets (including gendarmerie, military, naval and colonial aviation, and certain expenses connected with public works undertaken in the interests of the army):—

In Millions of Gold Francs

Year	Army	Navy	Colonies	Total
1914	1,720	513	92	2,325
1925	955	308	50	1,313

General Organisation of National Defence.—The lessons of the War showed the necessity of a general organisation of the nation in readiness for war-time, the object of which should be to prepare in advance the mobilisation of civil and military forces alike to organise the nation's entire economic and industrial resources, etc. A bill to this effect was laid before Parliament on July 7 1925.

The general direction of a war devolves upon the Government. To assist the Govt. in their task, consultative and research bodies are placed at their disposal in war-time and also, for the purpose of advising upon the necessary precautions to be taken in peace-time. These are: the *Conseil Supérieur de la Défense Nationale*, composed of the appropriate ministers; the *Commission d'Études* of that council (composed of the highest functionaries of the various ministries), and the General Permanent Secretariat. The actual conduct of operations remains the exclusive province of the commanders-in-chief of the military and naval forces.

The Army

The army proper is formed by calling up the reserves. The permanent army is but the nucleus; its functions are: to train contingents as they are called up; to protect overseas possessions; to prepare for mobilisation and, in case of aggression, to protect the frontier while mobilisation is proceeding.

The recruiting Act of April 1 1923 provides for:—

(1) an active army, formed by:—

the calling-up of recruits, all young men who have reached the age of 20 being obliged to serve for 18 months; half of the contingent is called up in May, half in November;

voluntary enlistment (engagements, re-engagements, commissions) by which lower professional cadres, necessary both in peace and in war, are formed; and

auxiliary or reserve cadres.

(2) a first reinforcement (*disponibilité*) in which the citizen is reckoned for a period of two years following his term of active service; in case of need he is liable to be recalled;

(3) a first reserve, for use also on active service in which the citizen serves 16½ years, and a second reserve to which he is posted for 8 years; this reserve is designed for local services and work in industrial mobilisation.

The duration of service is reduced to one year for eldest sons of large families (minimum of 5 children). Special advantages are accorded to prospective reserve officers who have followed the military training course with success.

The 695,000 men of the fighting troops (France, countries of occupation, colonies) which constitute the army are thus distributed:—

French (1½ contingents of conscripts and professional soldiers)	457,000
Foreign Legion	14,000
North-African natives	97,000
Native colonials	82,000
Irregulars and auxiliaries	16,000
Gendarmerie and Republican Guard	29,000
	695,000

Out of this total of 695,000 men, only 395,000 are serving in France; the remainder—some 300,000 men—are engaged on the Rhine, in Algeria, Morocco, the Levant and the various colonies.

Organisation of the Army.—The Act dealing with the constitution of cadres and strengths which had passed the Chamber of Deputies but has not, at the end of 1925, been discussed by the Senate, distributed these effectives between the various arms and services. Pending the final passing of the Act, the Minister of War was authorised to proceed with re-groupings by which the army was reconstituted as follows:—

Large Units, 32 divisions of infantry of which 5 are on the Rhine; 5 divisions of cavalry of which 1 is on the Rhine.

Redistribution of Troops.—The following table gives the proportionate distribution between the various arms on mobilisation in 1914, at the Armistice, and in the army of today:—

Arms and Services	Aug. 1 1914	Nov. 1918	1925
	%	%	%
Infantry	65·6	43·7	53·8
Tanks	·0	0·6	1·8
Cavalry	9·0	3·5	8·0
Artillery	16·1	27·4	16·6
Engineers	3·0	8·0	5·2
Air Force	0·3	3·3	4·1
Transport	1·3	7·7	3·4
Administrative Services	2·3	5·2	3·0
Gendarmerie	2·4	0·6	4·1

This table shows the extent to which those arms employing principally mechanical weapons (tanks, artillery) have developed.

In accordance with the experience gained from the War, the army is being organised and trained on the basis of an increase in all arms of fire-power.

The Navy

During the War.—While hostilities were proceeding, the French Navy underwent a considerable reduction, both on account of War losses and of the obligation under which it stood to devote the greater number of its arsenals and private workshops to satisfying the needs of the army.

The tonnage of 1914 and that of 1919 are as follows: 1914, 816,000; 1919, 590,000.

The falling-off is therefore considerable and it becomes more striking if the heavy wear of the ships still in service—particularly the small vessels—be taken into account.

Since the War.—From the end of the War up to 1921 the French Navy has had to pay for a great many special expenses of its own, inevitably arising out of War-time necessities. Thus burdened, its budget rose to 1,962,000,000 gold francs in 1919 as against 515,000,000 in 1914 and a yearly average of 813,000,000 during the War. As it was impossible to put any further strain on the exchequer, the reconstruction of the fleet, which continued to decline in tonnage (falling, in 1924, to 394,000), had to be delayed. At Washington, in 1922, France consented to the proposed reductions, according to which the total tonnage of her capital ships might not exceed 175,000 tons.

The building of battleships was postponed. With a view to protecting the country's vital communications, particularly in the Mediterranean and the North Atlantic, the French Navy turned its attention to the use of submarines, aeroplanes and light vessels with protected bases. Light cruisers and submarines were laid down as follows: in 1922, 3 cruisers of 8,000 tons, 6 destroyers, 12 torpedo-boats, 12 submarines, 1 aeroplane-carrier (these units are nearly ready); in 1923, 9 submarines; in 1924, 2 cruisers of 10,000 tons, 6 torpedo-boats, 2 submarines; 1 cruiser of 10,000 tons, 3 destroyers, 4 torpedo-boats, 9 submarines (of which two are mine-layers), 1 surface mine-layer and 1 aircraft transport are to be proceeded with at once. This represents an extremely modest effort; the naval budget has not exceeded a total of 330,000,000 gold francs on an average, from 1921 to 1925.

The Future.—The schemes for the future of the French Navy have been dealt with in three bills which are still (1926) under consideration. The high-seas fleet, exclusive of special vessels, would consist of: battleships up to 175,000 tonnage, aeroplane-carrying vessels up to 60,000 tonnage, in conformity with the Washington Treaty; in addition, 360,000 tons of light vessels (cruisers, destroyers and torpedo-boats) and 90,000 tons of submarines. Age-limit: battleships and aeroplane-carriers 20 years; cruisers 17 years; destroyers and torpedo-boats 15 years; submarines 12 years. The naval air force would be composed of 50 flights of aeroplanes, of which 35 are fully equipped and aircraft of various kinds (dirigibles, captive balloons, etc.) varying in number.

For coast defence there would be coast flotillas of submarines, coast patrols, mine-sweepers, mine-layers, etc.; artillery, obstacles, detection systems, aeroplane service and, finally, troops and other means, controlled by the War Office, which will be placed at the disposal of the navy. Although no term has been fixed for the execution of this programme, the Dept. of Marine intends to have it completed within 20 years.

The Air Force

There is in France no organisation analogous to the British Air Ministry. A certain amount of centralisation has been achieved however as regards technical research, which is under the authority of the Under-Secretary of State, who is also responsible for preparing the mobilisation of aircraft industries.

A comparison of the numbers in 1914 and in 1918 shows the effort that was made in the War. During the 4 years 40,000 new aeroplanes and 92,000 engines were constructed.

Evolution of the Air Force, 1914–25

Aeronautic Section	Aug. 1 1914		Nov. 1918		1925			
	Army	Navy	Army	Navy	Army	Navy	Colonies	Civil Aviation
Aviation								
No. of flights	23	0	322	0	130	11	3	
No. of machines	120	8	3,430	1,264	1,500	389	30	700[1]
Balloon Service								
No. of captive balloons	12	0	77	190	18	21	..	..
No. of dirigibles	8	0	0	37	..	13	..	..

[1]200 are for training purposes.

The increase in the total of the four budgets (military, naval colonial and civil), which rises from 367,000,000 fr. in 1920 to 791,000,000 fr. in 1925, may be put down to the necessity for replacing *matériel* (some of which dates back to the War) and above all to the expenses connected with building and preparation of the aerodromes and landing grounds. This budget would, if expressed in pounds (at 120 francs) amount to £6,600,000.

Organisation of Military Air Force.—The 130 squadrons of the military air force are distributed in 14 regiments and five autonomous groups. Two regiments of the balloon service deal with captive balloons. Nine of those regiments are formed in division and constitute the two air divisions.

Organisation of the Naval Air Force.—The naval air force, a War creation, is undergoing reorganisation. Its final status is defined by a bill which was still under consideration at the end of 1925. The 11 squadrons of the naval air force were at that time distributed between different centres (Cherbourg, Brest, Saint-Raphaël, etc.).

France was spending, in 1925, 44%[1] less on national defence than in 1914. The national defence budget, in which certain expenses figure, which in many countries fall upon budgets other than those of the army and navy, represented in 1914 44% of the general budget; in 1925 it represented only 17% of it. In her deep desire for peace France reduced her military expenses to the utmost extent and only hopes to effect still greater reductions. In that spirit she has made every effort to assure safety by putting into practice the pact of the League of Nations and furthering the development of arbitration and ideas of international solidarity. See *Armaments Year Book* (League of Nations, 1926) where the references to decrees on national defence are given. (B. S.)

V. INVADED REGIONS

In 1917 and 1918 when French ministers visited the Front they often wondered if it would ever prove possible to repair the dreadful ruin accumulated under their eyes. At Lens, for instance, the magnitude of the disaster was overwhelming. Not a house standing, 101 great pithead super-structures overthrown, their iron carcasses lying twisted on the ground, everywhere a terrible confusion of bricks, tiles, remnants of furniture—in one word, chaos. In the coal-mines, all the galleries flooded, the apparatus removed, the efforts of three generations completely annihilated. To-day there is hardly a trace of ruin, Lens is a city of wide streets and comfortable houses, the new arrangements of its mines are excellent; and the production of coal is equal to and even greater than that before the War. How could all this be brought about?

Extent of the Losses.—First, a few figures. When the damage was catalogued at the time of the Armistice, it was discovered that 289,000 houses had been completely destroyed and over 400,000 more or less damaged. Nearly 2,000,000 hectares of land had to be restored for cultivation. More than 6,000 factories had been destroyed or emptied of their machinery. The monetary value of these losses was about £1½ milliard; to reconstruct them (assuming the work to cost 3 times as much as before the War) 110 milliard gold francs would be required. Immediately after hostilities had ceased, M. Clemenceau abolished the Ministry of Munitions, replacing it by the Ministry of Reconstruction, of which the present writer was in charge. The new ministry first dealt as quickly as possible with those factories where the buildings and part of the machinery still remained and hastened to equip them to employ the industrial population. There were 500,000 unemployed; a year later unemployment had practically disappeared; the workmen had restored the factories, which had been hurriedly got going and were clearing away ruins and beginning reconstruction. The industrial districts thus received the first attention. This is one of the matters for which the Government has been most severely criticised; but it was the logical course, and as events showed, the right one.

[1] This figure is based on the changed value of the franc.

In restoring the soil itself, in rebuilding the farms and enabling those fertile lands to resume the production of the wheat urgently required by the rest of France, the inhabitants themselves assisted in an amazing degree. The French peasant is deeply attached to the soil; he returned to it as soon as he could. He found it covered with shells, with strands of barbed wire, with block-houses. He found his home and farm buildings in ruins. Not for a moment did he lose heart. He set to work at once, surrounded by difficulties which would have daunted many a brave heart, even by grave dangers; so many unexploded shells remained that between 1919–24 more than one person a day, on an average, was killed in unearthing them. Nothing could stop the French peasant. The state helped by granting him little by little, as needed, financial assistance—the sums necessary to rebuild his dwelling and his farm buildings—and found him labour to clear his fields.

A year later, some 90% of the Département du Nord had been restored to cultivation, and in 1925 France's production of wheat had reached its pre-War figures, and of sugar very nearly so. The industrialists too, faced with empty or ruined factories, went bravely to work; but the farmers whose efforts saved France were even more admirable. To-day at least 90% of the farms have been reconstructed. Everywhere, thanks to the good harvests of recent years, prosperity has returned, and the zones where the havoc has so far defied restoration are growing daily smaller, and we may hope that, with rare exceptions, they will disappear altogether. Some reservation is necessary: the surroundings of Verdun are a frightful example of what is meant. As Minister of the Liberated Regions the present writer had to sign the act recording the final disappearance off the map of France of 11 villages of which nothing, hardly a heap of stones, remained. On every square metre there were so many fragments of shells that the whole of this territory might really have been exploited as an iron-mine, but it was useless to think of putting it under the plough. The signature of the act consecrated to death beyond repeal these villages where so many generations had lived, in whose defence so many good men had died.

Building Reconstruction.—The rebuilding of dwellings was a much longer task. Dr. Rathenau, with whom the reparations question was discussed at Wiesbaden, was surprised that the Ministry had not decided to rebuild the towns, not on the old sites, but near by, on virgin fields, constructing regular rows of houses and laying out the plans in the American style. Dr. Rathenau displayed ignorance of the French spirit in supposing that Frenchmen, with their profound individualism, could have adapted themselves to such a system. Each man has chosen the site of his house, he wishes to keep it, to rebuild it in its old place, different in size and shape from that of his neighbours, on his own plan, in his own style. To-day the city of Rheims, which was so completely ruined, is almost entirely restored. It has retained the mark of its old architecture, the houses are on the same spots as before. Some districts, however, of the devastated regions wanted to follow the ideas explained by Dr. Rathenau. The experiment was unsuccessful. Thus there are some large villages with roads which are too straight and too broad, which have not re-assumed their pre-War life. It is a grievous error to attempt to do violence to the psychology of a nation. The reconstruction of landed property is far advanced. In each village so-called "reconstruction co-operative societies" have been established, through which a few devoted men have set themselves to restore the homes of their fellow-citizens. They have lacked means, the parsimony of the last three annual budgets has complicated their task, but little by little, assisted by local loans, their efforts have made headway.

Finance of Reconstruction.—How has all this been paid for? From 1919–22 by loans from the state; but after 1922, financial difficulties grew more pressing and the sufferers from the devastation have been paid to a large extent by state loans redeemable in 10 years, which they have had to get taken up as they could; this has resulted in a serious fall of these bonds. To-day, since the Dawes plan has come into force, it has been possible to spread out the effort over three or four years, and should be about completed by the end of 1928. In 1926 a sum equal to about £100,000,000 still remained to be spent. The sum was not large in comparison with what had been spent up to date, but it represented a great effort.

Such are the broad outlines of the work of reconstruction of the liberated districts. It was successful, thanks above all to the united effort of French citizens and thanks to the fact that for several years the whole of France consented to burden herself in order to pay unassisted for the restoration of her ruins, for it must be admitted with regret—except in a few individual instances, France and France alone has had to shoulder her expenditure. The writer does not forget the assistance granted by various British municipalities. In many French villages and towns one may see public rooms or fountains paid for by the generosity of British towns. (L. L.)

VI. THE COLONIAL EMPIRE

Description.—The French colonial domain appears at first sight extremely various and scattered, since there is no continent in which France cannot count her colonies. In fact, it consists of two very different parts. First the remains of the old colonies, Saint Pierre and Miquelon, on the Canadian coast; Martinique and Gaudeloupe in the West Indies, near New Orleans; Guiana in South America; five enclaves in British East India, Pondicherry being the most important; Réunion I. in the Indian Ocean near Mauritius, a relic of the match between Bougainville and Cook; a series of islands, of which the most important are New Caledonia, Tahiti and the New Hebrides, held in common with Great Britain. These are, if one likes to call them so, the aristocratic colonies. The American and Indian colonies and Réunion have their deputies and senators in the French Parliament. They are united with France by old bonds of affection. They have given her scholars, administrators and great men of letters. In certain cases they derive special importance from their situation on the great international routes, or their great resources. But, above all, their value for France is sentimental and historic; they are the outline of the first empire lost in the 18th century. The colonies of the 19th century on the other hand, form a homogeneous system. They are divided into two groups, African and Asiatic, both closely concentrated—with the exception in Africa of Jibuti and Madagascar.

The following table shows the respective importance of the three groups:—

Colony	Area in sq. km.	Population census 1920–1
I. America and Australasia (group of old colonies)	129,491	652,300
II. African group	11,516,224	35,919,405
III. Asiatic group	879,355	22,250,333
	12,525,070	58,822,038
France (for comparison)	550,985	40,000,000

The African group consists of Northern Africa (Algeria, Tunisia, Morocco); French West Africa (Senegal, Guinea, the Ivory Coast, Dahomey, Niger); French Central Africa, which stretches from the Congo to Lake Chad and the Nile Basin; Madagascar, the third largest island in the world; and the French Somali Coast, at the mouth of the Red Sea. In addition, France has mandates in Togo and Cameroons. This group, by its proximity, seems specially destined to act as an extension of the mother-country. It is naturally commanded by Northern Africa, which is only 750 km. distant from France, 20 hours' journey by sea, or six hours by air. From Northern Africa the railroads and aerial routes spread out towards the tropical and equatorial territories; it links the mother-country and the other African colonies. Algeria, lying as it does between Morocco and Tunisia, is the pivot of this system, and is rightly considered

the key position, whether judged by the number of French which inhabit it (600,000 out of 800,000 Europeans, against 5,000,000 natives) or by the loyalty of its population and their ready acceptance of French culture. Owing to its Mediterranean situation, Syria, administered by France under mandate, may also be included in this group, although lying in Asia. The Governor of Algeria and the Residents-General in Morocco and Tunisia meet every year in conference in one of the three capitals in Northern Africa alternately. In 1926, for the first time, the Governor of French West Africa attended this meeting.

The Asiatic group consists of French Indo-China, or the Indo-Chinese Union, including six colonies or protectorates—Cochin-China, Cambodia, Annam, Tongking, Laos and the territory of Kwangchow. This union was organised in 1887. A series of treaties with Siam (the most recent dated 1926) and with China have now regularised its relations with all its neighbours. Indo-China has become the base of French policy in the Far East.

Administration.—The administrative ties which unite these French colonies with the mother-country are very various. There is no central colonial body in Paris. The Conseil Supérieur des Colonies, which consists of a number of persons distinguished in politics, commerce and the arts who are competent to speak on colonial affairs, is merely an advisory body. Plans for uniting under the control of a single body all the different colonies of North Africa, or of Indo-China and the Australasian possessions, have not been realised. Algeria is administered by the Ministry of the Interior; it is divided into departments administered by prefects and sub-prefects appointed by this Ministry and belonging to the home civil service. The protectorates of Tunisia and Morocco and the mandated territory of Syria are under the Ministry of Foreign Affairs, which appoints to them sub-agents from the diplomatic or consular lists, or from a service special to these three countries. The Colonial Ministry is in charge of the other colonies, and the École Coloniale in Paris furnishes their administrators and colonial governors. In fact, even the countries directly subordinate to the Colonial Ministry enjoy a degree of autonomy, and the governors have very full discretionary powers. The reason for this liberal system of administration lies as much in the conditions under which the French colonial empire grew up as in the French temperament. At the moment when explorers or soldiers conquered these domains for France, France did not need them.

She had no surplus population requiring an outlet. Agriculturally, she was self-sufficing; industrially, her commerce, which was principally one of luxury articles, found its market in the more highly developed countries. The colonies were therefore subjected to no exploitation, and were often administered by soldiers—that is to say, by the class of ruler who is least interested in economic production. The relations between the administration and the natives were consequently marked by a particularly liberal character. Moreover, the colonies were granted financial autonomy as early as possible. The French colonial estimates have always been meagre—in 1925 only 270,000,000 francs. The financial administration of the colonies did not, therefore, concern French political life, which is essentially parliamentary. Nor was there any rivalry between the careers of the Frenchman—as soldier, official or great landowner or merchant—and the native. Things were different, for example, in Tunis, where the Italian and the native compete with one another. The colonial governors, apt, like all Frenchmen, to apply parliamentary formulae to life, and often themselves parliamentarians, were anxious to develop local councils and local assemblies, even with the power of voting taxes, in the countries which they were charged to administer. Finally, the Frenchman has little race or colour prejudice. All this contributes to give French colonisation the aspect of a friendly collaboration not dissimilar from the method of mandates.

French emigration is not due to the need for economic expansion or to divert a surplus population, but to the need of moral expansion. Missionaries, professors and soldiers form the largest contingent of emigrants. The colonies replace for them fields of action closed to them in Europe or America. Whether in India, China, Madagascar, Tunisia or Morocco, even in the Sudan, the effort of the French administrator has awakened national sentiment in these countries, after putting an end to the civil wars with which they were all torn. Certain races—for example, those of Cambodia—have been saved from a fatal torpor. Archaeologists, painters, and men of letters constitute a relatively high proportion of the French element, and in Indo-China and Morocco, for example, the artistic and intellectual regeneration of the colonised people cannot but strengthen their vitality. The colonial exhibition at Marseilles in 1922 illustrated this method. These considerations explain why France has sometimes been reproached with not having thoroughly exploited her colonial possessions.

Resources in Men and Wealth.—The War led French statesmen to take account of colonial resources in men and material wealth. First, it supported the theories of those who considered that France's military expenses might be reduced by enlisting native troops. The colonies contributed 545,000 combatant soldiers to the French Army. The strength (about 180,000) of the colonial army in 1925 rested mainly on native recruiting. The colonies are also a reservoir for the manual labour in which France is deficient. Many of the 183,928 colonial workmen brought to France during the War remained, and this immigration continues.

The various plans for exploiting colonial resources, the most complete being that put forward in the Chamber of Deputies by M. Albert Sarraut in 1921, have been inspired by a desire to lessen the dependence by France on foreign countries for raw materials. The French colonies are especially rich in minerals (phosphates, iron, coal). The production of phosphates in North Africa reached 2,600,000 tons in 1922; that of iron ore 1,800,000; Indo-China supplied Southern China with coal (900,000 tons); New Caledonia is the greatest producer of nickel after Canada, and her deposits of chrome are second only to those of Rhodesia. As regards agriculture, the production of cereals in Northern Africa in 1922 was 19,400,000 quintals of wheat, 19,200,000 quintals of barley; the production of wine was 10,900,000 hectolitres. There are 28,000,000 olive trees in Algeria and Tunisia alone; the exportation of fruits exceeded 300,000 quintals in 1922; that of early vegetables, 400,000 quintals. The live stock includes 17,650,000 sheep and 475,000 horses. French West Africa exported 153,000,000 fr. worth of ground nuts in 1922. Indo-China is the second exporting country in the world in rice—1,440,000 tons in 1922. The live stock comprises 4,000,000 oxen and buffaloes. The total area of colonial forests is 600,000,000 hectares, that is, about twice the total surface of France.

The private capital invested by France in colonial enterprises, exclusive of banks and railways, and of the milliards of francs spent by the state to pacify, organise and protect the colonies, exceeded 2,000 million fr. in 1924. The trade which France did with her colonies was 9,366 million fr. out of a total trade of 81,600 million francs. The public debt of the colonies is only three milliards. The colonies contribute a share to the central budget; in 1925 they paid 33,000,000 fr. as a contribution to military expenses, upkeep of the École Coloniale, the Institute of Colonial Agriculture, the general agency of the colonies and the colonial air service. This share is very small, but shows the assistance which they can render France.

Such are the general characteristics of this colonial domain, the possession of which has had its effect on the traditional aspect of French policy. The French colonies have 15,086 km. of railways, 49,968 km. of roads, which are excellent in Northern Africa and Indo-China; and, although the Empire has not yet found its Kipling, French imagination has succumbed to that rosary of names, so exotically appealing to the tourists, Tunis, Algeria, Fez, Marrakesh, Damas, Angkor or Timgad, which envelop with a magnetic circle the central core of France. The French mercantile marine has found its true base in the colonies. The quickest routes between South America and Europe, will eventually lie across French Africa. This is mainly due to the railway between Algeria and Dakar, which has already been traced, and the air routes or motor roads already in use. French statesmen, thanks to this fact and also to the fact that many of them have already occupied high posts as governors in Africa or Asia, are gradually recovering the habit of thinking not merely nationally but geographically, and while the first place in their watchful eye is always the security of France, they have been led to play a practical part in world problems, where their predecessors confined themselves to theory.

VII. RAILWAYS

In 1911 the French railways consisted of five great private-owned and one state-owned line, with a combined mileage open to public traffic of 40,615 km. and a capital value of about 17 milliard francs. After the War acquisition of the Alsace-Lorraine lines, with mileage

of 2,255 km., brought the total mileage up to 42,870 km., while owing to this increase and the large amount of reconstruction effected after the War on the Nord and Est lines, their total capital value rose to about 39 milliard francs.

In 1911 the French railways carried 511,000,000 passengers, in 1924, 776,000,000; the mean annual increase has risen from 3% to 6%. In 1911 184,000,000 tons were carried by goods train; in 1924, 265,000,000, an increase of 37% in three years.

The commercial development of the railways was arrested by the War; not so their technical activity. Between 1914–8 they bore 41% more traffic than in peace time—the lines near the front, 200%. 15,400 trains were used during the period of mobilisation and concentration; between Sept. 1914 and Nov. 1918 about 100,000 troop trains carried some 6,000,000 men; besides returning empties, rations trains, munitions trains, leave trains, ambulances and a daily average of 200 trains carrying engineering material. Between March 21 and Nov. 11 1918, when traffic was densest, 50,000 military trains of all sorts were moved; counting returning empties, the traffic on the Nord system reached about 900 trains in 24 hours.

Most of this traffic fell on those parts of the Nord and Est lines not in enemy occupation; here important works had to be carried out during the campaigns. In Sept. 1914 bridges, etc., destroyed during the retreat from Belgium were reconstructed and lines and stations adapted to permit the extension of the Allied front to the Belgian coast, an operation which required 2,169 trains for the movement of troops alone. During the subsequent period of stationary warfare, single lines were doubled, railheads constructed, engineers and munitions dumps formed, whole new lines built; 13,500 km. of line were built, nearly 6,000 being behind the British front, and 28,000,000 cu. m. of embankment erected. These works, serving purely military purposes, were generally dismantled after the War.

The German Army in its retreat destroyed 2,047 km. of line (about half being double line), 600 stations, 1,100 bridges, 24 tunnels and all workshops and watering stations in its area. When these lines were reconstructed, the opportunity was seized to enlarge and improve the stations, lay the permanent way more rationally and introduce the latest electric, pneumatic or hydraulic points and signals. Especial attention was paid to the great goods yards in view of their importance for the reconstruction of the devastated areas. Lille-Délivrance station, for example, which dominates the goods traffic of Northern France, was constructed to clear 4,500 trucks daily. Its tracks are so arranged that it functions by the force of gravity, and requires only a small staff; it acts like a filter, all traffic, being passed in the same direction.

Locomotives and rolling-stock have increased in numbers and power, especially on the Nord and Est systems. There were 20,383 locomotives in 1924, compared with 13,434 in 1911; the load of the fastest passenger trains rose from 400 tons to 550 tons. Between 1920–4 the number of passenger carriages increased by 11%, of goods trucks by 20%; they are also much stronger and of increased capacity. The new all-steel one-piece carriages on the Nord line deserve especial mention. Examples of the carriages used on other lines were shown at the Exhibition of Modern Decorative Arts in 1925. Most goods trucks before the War carried a maximum load of 10 tons, few of over 20 tons. In 1925, of 525,000 goods trucks, 254,500 carried 10–20 tons; 227,000, 20–30 tons; 41,000, 30–40 tons; 2,500, 40 tons or over. The average carrying capacity of trains, especially on the main lines, has greatly increased. Many take 80 trucks, and 1,500 tons.

In the devastated areas, the railways were reconstructed earlier than the dwellings; so that the companies had to provide accommodation for their workmen on a large scale. The Nord built 11,141 houses of modern types, sometimes constructing regular towns, besides providing their employees with 6,300 other dwellings.

The problem of electrification only became urgent after the War when the altered economic conditions compelled France to utilise all her natural resources. A scheme was drawn up involving an expenditure of five milliard francs on the construction of power stations and the electrification of about 9,000 km., including 3,350 km., or nearly half, of the Paris-Orléans line; 2,300 km., or a quarter, of the P.L.M. line, and 3,200, or over three-quarters, of the Midi line.

An agreement between the state and the railway companies, made on June 28 1921, established a close financial and technical connection between the state lines of the Etat and Alsace-Lorraine and the group of the five great private companies. After satisfaction of the claims of shareholders and personnel, all proceeds are pooled; a deficit on one line is thus compensated by a surplus on another, the tariffs are fixed high enough to avoid a general deficit. Tariffs are uniform and common throughout France; rolling-stock is pooled; important purchases, as those of rails, sleepers, etc., are made in common; common are all arrangements regarding pay, promotion, employment, etc., of the 500,000 employees. All important questions of management are discussed in a committee composed of the Presidents and Directors of the seven lines; all matters affecting the employees or national interests are discussed in the Conseil Supérieur des Chemins de Fer, in which the above committee is reinforced by elected representatives of all grades of the personnel, the presidents of Chambers of Commerce and representatives of the principal national industries and of the state. The workings of this innovation have proved most satisfactory. See *Statistiques des Chemins de fer français* (annuel). (P. J.)

FRANCHET D'ESPEREY, LOUIS (1856–), French soldier, was born at Mostaganem in Algeria May 25 1856. Commissioned to the infantry in 1876, he early saw active service in Tunisia, Tongking and N. China. In 1908 he became general of brigade, and the same year a tour of the Balkans and his published studies thereon worked the beginning of an interest in that region which was to have important results. In 1913, as general of division, he carried out a vigorous campaign in Morocco, after which he was appointed to the I. Army Corps at Lille. This corps he commanded during the battle of the Frontiers, Aug. 1914, and on the eve of the battle of the Marne he succeeded Gen. Lanrezac as commander of the V. Army. In March 1916 he was advanced to command the eastern group of armies, and later the northern group. On the recall of Guillaumat in June 1918, Franchet d'Esperey was sent out to replace him as Commander-in-chief at Salonika. Adopting and developing his predecessor's plan for an offensive in the Balkans, Franchet d'Esperey ensured the success of his break-through by the skill with which he denuded the rest of the front to concentrate an overwhelming preponderence on the narrow Sokol-Dobropolye sector, west of the Vardar. Success beyond anticipation crowned the stroke; with their reserves pinned down by vigorous pressure elsewhere the Bulgarians were unable to repair the breach, and as the Serbian spearhead drove in deeper, the whole Bulgarian front collapsed, and on Sept. 29 Bulgaria capitulated—the first defection among the Central Powers. If he owed much to his predecessor, to Franchet d'Esperey was the glory of execution and realisation. Exploiting this victory, he cleared Serbia of the Austrian troops and later, on Jan. 5 1919 took prisoner the German Marshal von Mackensen, in Hungary. He afterwards commanded the Allied forces in Turkey until Nov. 1920 and was created a marshal of France on Feb. 21 1921.

FRANCIS FERDINAND (1863–1914), Archduke of Austria, was born at Graz Dec. 18 1863. The eldest son of the Archduke Charles Louis and a nephew of the Emperor Francis Joseph, he became, after the death of the Crown Prince Rudolph, the heir to the Austro-Hungarian monarchy. In 1875 he took the title of Archduke of Austria-Este, as heir to his uncle the Duke of Modena, with whose death the male line of this branch of the house became extinct, and to his possessions in Austria-Hungary and Italy.

Until the death on Jan. 30 1889 of the Crown Prince Rudolph, Francis Ferdinand was only known in limited circles and even then he was not invited by the Emperor Francis Joseph to take part in state affairs, although the Emperor frequently commissioned him to represent him abroad. On July 1 1900 he married Countess Sophie Chotek (1868–1914), after having overcome, by tenacious persistence, the obstacle due to the fact that the lady was not of royal family, and renounced a few days before the ceremony the succession rights of any children of the union. This renunciation was not only inscribed in the records of the imperial family, but ratified in the Austrian and Hungarian Parliaments and sanctioned by a law of Dec. 4 1900.

After that time the Emperor gradually allotted to him responsibilities of his own, not only in military matters but occasionally in questions of domestic politics. The difference of outlook of the two men, however, became more and more marked; for with advancing age Francis Joseph was less and less willing to consider far-reaching reforms, was anxious to avoid any conflict with the nationalities, and preferred advisers who knew how to untie a knot gently instead of hacking through it. Francis Ferdinand was convinced that the Magyar preponderance in the affairs of the dual monarchy must be broken in the interests of the monarchy and the dynasty. For some time he held that Federalism was the best solution. At another period he inclined to "Trialism." Later, influenced by the Hungarian minister Kristoffy, he inclined to strengthen unity by changing the Delegations into a Central Parliament and attaching the annexed provinces Bosnia and Hercegovina, with a state organisation of their own, to the Empire. The opposition which he met on all sides from the ruling

party in Hungary strengthened his conviction that here lay the essential obstacle to the healthy recovery of the monarchy. In the severe conflicts between the Magyars and the Crown from the beginning of the 20th century onwards he, therefore, maintained the opinion that no concession must be made, and that there should be no shrinking even from the use of armed force for the defence of the rights of the monarchy and the dynasty.

The zeal with which he sought the solution of domestic political problems by strengthening the central power is explained by his firm conviction that this was the indispensable condition of the monarchy as a Great Power, which he desired to maintain and to increase. Francis Ferdinand was not an unconditional adherent of the group which thought his aim would only be attained by force of arms. But he was firmly determined to tread this path if it was the only one by which the goal could be reached. He considered that friendly relations with Great Britain were desirable, but towards France, and still more towards Italy, his attitude was cool and negative. He was convinced that there must inevitably be a day of reckoning between the monarchy and Italy. He never adopted an anti-Slav policy. He wished to avoid conflicts with the principal representatives of the Slav nationalities, and recognised in the Tsar of Russia the strongest support against revolutionary movements in monarchical states. At the same time he expressed the decided opinion that the encroachments of the Greater Serbia movement of Austro-Hungarian soil should be resisted with all the forces of the monarchy. He stood by Germany, yet was determined that the monarchy should not fall into dependence on her powerful ally.

Francis Ferdinand was a man of more than average ability. He would immediately recognise the essential point in any business in which he was engaged. What he lacked was knowledge of men and calmness and constancy in his relations with the men who had been placed in high offices of state by his influence. He asked from the citizens of the monarchy not affection, but submission to the will of the ruler. To him the state was identified with the divinely appointed person of the monarch. He was shot June 28 1914, with his wife, by Bosnians of Serbian nationality at Serajevo. (*See* EUROPE.)

BIBLIOGRAPHY.—Some account of Francis Ferdinand's life is contained in his *Tagebuch meiner Reise um de Erde* (Vienna, 1895); Theodor von Sosnosky, "Franz Ferdinand," in *Deutsches Biographisches Jahrbuch* (1916); Franz Conrad von Hoetzendorf, *Aus Meiner Dienstzeit* (Vienna, 1921); M. FRANCIS JOSEPH I. (1830–1916), Emperor of Austria and King of Hungary (*see* 10.942).—In the last years of his reign Francis Joseph continued to strive to preserve peace for his realm, while maintaining the prestige of Austria-Hungary and her position as a Great Power. Perceiving that this aim was threatened by the confusion reigning in the Balkans, he agreed to the plan of his Foreign Minister, Aehrenthal, to take advantage of the Young Turk movement to annex the territories of Bosnia and Hercegovina occupied in 1878, and to embody them permanently in the monarchy. During the serious crisis following on the annexation Francis Joseph backed Aehrenthal with the whole weight of his influence, and subsequently supported him in his endeavours to restore friendly relations with the Great Powers which had been signally disturbed by the annexation, and to put an end to the risk of international conflicts. By his personal intervention he in fact repeatedly succeeded during the years 1908 to 1914 in averting dangers threatening the peace of Europe. When in 1912 the Balkan wars, which he had untiringly but unsuccessfully striven to avert, began, he thought they were the gale before the hurricane, and when, in Aug. 1913, the Peace of Bucharest provided a provisional settlement he expressed the opinion that this peace was only the breathing space before a fresh war.

The behaviour of the Serbs filled him with the greatest anxiety. When the murder of the heir to the throne, the Archduke Francis Ferdinand (June 28 1914), led the Vienna Govt. to take energetic measures against Serbia, Francis Joseph hesitated to follow, and it was with a heavy heart that he gave his consent to the dispatch of the severe ultimatum to Serbia, and, after its rejection, to the declaration of war. He did not believe that the war could be localised, as he would have wished it to be, and was pessimistic about the chances of a world war. Even then he was of the opinion that "war is beyond our strength," and said he would be glad if the monarchy escaped "with a black eye." The attitude of the rulers of Italy and Rumania offended him deeply, and strengthened his doubt of a favourable outcome of a war against an ever-increasing number of adversaries. Francis Joseph stood immovably by the alliance with Germany, to whose ruler he was bound by a friendship based on reciprocal liking; it never occurred to him to separate from his ally. He would never have agreed to a separate peace; yet he favoured and supported every endeavour to put an end to the War by a peace which should safeguard the interests of all his allies and the position of Austria-Hungary as a Great Power.

In all questions affecting the constitution of the monarchy, and in particular the relations between Austria and Hungary, Francis Joseph continued in the later years of his reign to stand by the principles of the *Ausgleich* of 1867. He would not consider the federalisation of the Empire, but stood unmoved on the basis of dualism. He went a long way to meet the efforts of the Hungarian Govt. for independence, but refused energetically during this period demands tending towards the severing of the remaining bonds between the two halves of the monarchy, especially that of the united army. In the increasingly violent conflicts between the different nationalities inhabiting the Cis-Leithan territories Francis Joseph stood above party. This was all the easier for him on account of his indifference towards all the nationalities of his vast realm, even towards the Germans, although to the end of his life he felt himself to be a German prince. As in the earlier part of his reign, so in the last decade, the separate nationalities were favoured or neglected, but always played off one against the other. The meaning of *viribus unitis* for Francis Joseph was to use all in the interests of the dynasty.

But national consciousness had grown so strong that this policy had no success. The concessions which he granted in the years just before the War to the Slav peoples increased their self-confidence, and led them to make ever greater demands, the non-fulfilment of which caused a weakening of their sentiment for the dynasty. As the differences between the national parties represented in the Austrian Parliament became in the course of years so great that there was no prospect of effective co-operation, Francis Joseph ignored parliamentary activity from 1914 onwards. Experience of the World War led the old Emperor to recognise that he had done the Austrian-Germans an injustice; but isolated attempts to alter the trend of affairs had no lasting effect, and in the end he let things take their course. When he died, severe inroads had been made on the affection of the Austrian peoples; what remained was only just sufficient to disguise the disappearance of loyalty to the dynasty.

As years went on the Emperor became more and more lonely. His son had committed suicide in 1889, his wife had been murdered in 1898; of his brothers only the youngest was still alive, and he resided at a distance and in the strictest seclusion. There had never been any cordial relationship with the heir to the throne, Francis Ferdinand; and with the years, especially after Francis Ferdinand had married Countess Sophie Chotek, the estrangement between the two men increased, so that personal intercourse became rare. Among the remaining members of the Imperial House Francis Joseph only cared to frequent the circles of his two daughters, Gisela and Marie Valerie, and their children. He was bound by ties of true friendship to Katharina Schratt, formerly an actress at the Burgtheater, and in her society he spent his sparingly measured hours of recreation. The summer he usually spent at the watering place of Ischl, and there he devoted himself to the chase, the only pleasure for which he cared passionately to the end of his life.

The Emperor had long enjoyed excellent health. It was not until he had passed his 75th year that disease of the respiratory

organs began. In 1911 this became so serious that a catastrophe was feared. All the preparations for Francis Ferdinand's accession were made. But the old Emperor recovered; and his physical as well as his mental energy improved from year to year, so that he was able in the first two years of the World War to transact fully all the business of government. It was only in the year 1916 that his faculties began to fail. He died peacefully of a fresh attack of his old malady on Nov. 21 1916.

Francis Joseph was not one of those of whom contemporaries, especially those at a distance, form any definite impression. The reserve which he observed even towards the great majority of his advisers made it more difficult to penetrate his real nature. He had a deep sense of his exalted position as a ruler. To the end of his days he remained profoundly convinced that the Empire over which he ruled was *his* empire, and the peoples *his* peoples. This conception of the majesty of the office bestowed on him by God found expression in his bearing. He always maintained a regal attitude. He showed kindliness and winning courtesy to everyone. Nothing was farther from him than posing, and no one ever heard him utter sonorous phrases; but he avoided any kind of intimacy even in his intercourse with members of the Imperial House, and, even with them, knew how to maintain his distance. His intellectual gifts were not remarkable, but he possessed sound common sense and wit. He had a strikingly good memory for persons and events. As a ruler he was a model of the sense of duty. From early morning to evening he attended to business with clocklike regularity, and dealt with all the documents laid before him with the greatest punctuality. This industry and his exact memory made him one of the best authorities in all Government affairs. He sometimes startled his ministers by his intimate knowledge of the details of the business in hand, and occasionally embarrassed them. But he went no further than details, and lacked the power of surveying the whole.

The Emperor also lacked, especially in his later years, the ability to take the initiative in important questions, to form independent resolutions and to carry them to their logical conclusions. In an ever-increasing degree he left the decision to his responsible ministers. He was not without skill in the choice of his advisers, but had an instinctive dislike for men whom he felt to be his intellectual superiors. He also disliked people of proud and upright character, and even within the family circle he preferred those who were more subservient. He was essentially cold in temperament, with great self-control increased by practice. Among the European rulers he enjoyed, during the last decades of his reign, great respect, which he owed to his age, experience, personal amiability, blameless conduct, and above all the fact that his word could always be relied upon. He was a faithful son of the Catholic Church, and looked up with reverence to the Holy Father; but, quite in the spirit of the traditions of his House, he guarded the rights of the dynasty and of the State with the utmost tenacity, even against the Pope. He took no interest in the arts and sciences, being in this respect more of a Lorrainer than a Habsburg; but whenever he expressed an opinion on these subjects, he showed a decided aversion from the modern tendencies. (A. F. Pr.)

FRANKFORT-ON-MAIN, Germany (*see* 11.17), has changed little outwardly since 1910, though the area of the city is now 33,277 ac., and the population according to the census of 1919 is 433,002. The life of the place still centres in the ancient and picturesque city, though in recent years blocks of old buildings round the cathedral have been swept away, and garden cities have arisen on the outskirts.

Frankfort is now an important inland port; heavy barges can navigate the Main as far as Aschaffenburg, and canalisation is being carried as far as Würzburg. The Rhine-Main-Danube canal is under construction, and a scheme has been prepared for a waterway to the Weser, which will link Frankfort with Bremen. Considering the difficulties of the process, the famous banking houses weathered the period of inflation well, and have led the way to the restoration of Germany's economic position in the world. The metal, chemical and electrical industries of the district are improving, and the old trade fair was revived in 1919. In 1914 a university was founded, and in connection with it is an academy of labour, designed to provide a new class of leaders for the labour movement. During the World War Frankfort was several times bombed, and it was occupied for a short time by the French in 1920 during the invasion of the Ruhr area by German militarists.

FRASER, ALEXANDER CAMPBELL (1819–1914), British philosopher (*see* 11.38), died at Edinburgh, Dec. 2 1914.

FRASER, CLAUD LOVAT (1890–1921), British artist and designer, was born in London, May 15 1890, and was educated at Brighton and Charterhouse. He began to follow his father's profession as a solicitor in 1908, but abandoned this three years later for art. After working with Walter Sickert for a time, he exhibited in 1913, being responsible in the same year for the decoration of the *Flying Fame* chapbooks and broadsheets. He served in France with the Durham Light Infantry during 1915–6, but was gassed and invalided home. His gift for spirited design and lively colour, based to a great extent on 18th century conventions, developed rapidly, and he not only illustrated successfully many books, but exercised a rejuvenating influence on English stage designs by his production of *The Beggor's Opera* (1920), *As You Like It* (1920) and *If* (1921). A career of great promise was cut short by his death, June 18 1921, at Sandgate, Kent. See John Drinkwater and Albert Rutherston, *Claud Lovat Fraser* (1923).

FRAZER, SIR JAMES GEORGE (1854–), British anthropologist, was born at Glasgow, Jan. 1 1854. Educated at Helensburgh, Glasgow University and Trinity College, Cambridge, he was elected a fellow of the latter college in 1879 and called to the Bar in the same year. He was knighted in 1914, received the O.M. in 1925 and became Commander of the Legion of Honour in 1926. A prolific writer, he is famous as the author of *The Golden Bough*, first published in 1890 and re-issued in 12 volumes under seven titles between 1907 and 1915. In 1922 appeared an abridged edition under the original title. This work is an elaborate study of ancient cults and folk lore and covers a vast field of anthropological research. In 1926 he issued vol. 1 of *The Worship of Nature*, dealing with the worship of the sky and of the earth. Among his many other publications are: *Totemism* (1887); *Adonis, Attis, Osiris, Studies in the History of Oriental Religion* (1906, 2nd ed. 1907, 3rd ed. 1914); *Totemism and Exogamy* (1910).

FREDERICK VIII. (1843–1912), king of Denmark (*see* 11.52), died at Hamburg May 14 1912.

FREEMASONRY (*see* 11.78).—The total membership has at least doubled since 1910 and, according to the Masonic Year Book, Chicago, is (1926) about 3,922,318. In addition there are at least 1,000,000 "unrecognised" masons, the most important group being the "Negro" masons of the United States of America. Of the "regular" masons, all save 208,388 belong to the various Grand Lodges of the U.S.A. and of the British Empire, which indicates that freemasonry is essentially an Anglo-Saxon institution.

Social Work.—In the U.S.A. and Holland the most noticeable change has been a tendency to take an active part in the social betterment of the nation. While avoiding controversial political questions, the aim is to increase the interest of members in the well-being of their fellow citizens outside the door of the lodge. This tendency is less marked in the British Grand Lodges, owing to their anxiety to avoid any appearance of interfering *as Masons* in politics, although in the field of charity they are particularly active.

Anthropological School of Research.—Among British masons one of the most notable changes has been the rise of a new school of masonic research, which aims at tracing the history of Freemasonry anterior to 1717. Faced by the paucity of documentary evidence, due to the nature of the obligations taken by medieval masons, this school has adopted the principles used in the study of anthropology and of comparative religions. It has discovered that figures carved,

or painted, by medieval masons, are often depicted making certain signs still known to Freemasons, and that in the scenes represented these clearly convey the same inner meaning as to-day.

Examples of such secret messages have been found in medieval and Comacine work and also in that done by members of the Roman Collegia. There also exists documentary evidence connecting these three groups of builders. A similar use of signs in Ancient Egypt, in the Hung Society of China and among savage races when initiating a boy into manhood, has also been demonstrated. On the basis of these facts, which are unquestionable, the theory is being developed that Speculative Freemasonry is descended via the Comacines, the Roman Collegia and the Mysteries from primitive rites, once universal in the dawn of history, survivals of which are to be found to this day in Central Africa and Australia. Concurrent with this work has been the careful study of the modern rituals, and the comparison of certain peculiar features in them with similar incidents in the ancient mysteries and in savage rites. The facts so far disclosed suggest that in modern freemasonry we may have an intellectualised survival of the cult of the Dying God and of the Fertility rites. Although this school has produced much interesting data, its conclusions are not yet universally accepted by the older or "documentary" school, the members of which consider that coincidence may explain the similarities to which their attention has been directed. If, however, the views of the Anthropological School are ultimately accepted, the result will be that the origin of freemasonry will be pushed back thousands of years.

The Mystical School.—Quite as important has been the rise of a distinctly spiritual school of thought, which endeavours to interpret the meaning of the ceremonies, and considers that in the rituals of the various degrees we have an allegory of the quest of the soul after mystic union with the Supreme Being. While often differing in detail, since they approach the subject from different angles, all the exponents of this school agree in the main principles, although in historical research they are often sharply divided, some belonging to the documentary school and others to the anthropological. Perhaps, however, the most important fact is the ever increasing interest among the rank and file in a subject which, even a few years ago, would have been treated with complete indifference.

Masonic Relations.—Since 1910 events have proved that the breach between Latin and Anglo-Saxon masonry was based on a fundamental divergence of opinion as to the basic principles on which the order rests, and this breach tends to grow wider year by year. The disastrous results of interfering in politics has been shown by the fact that the Italian and Hungarian Govts. have declared Freemasonry to be a danger to the State, and have suppressed it within their jurisdictions. In France opposition to the political activities of the Grand Orient culminated in 1914 in the formation of a new body, "Grande Loge Nationale Indépendante et Regulière pour la France," which avoids politics, and insists on belief in God. This body, which has increased rapidly in numbers, is recognised by the Grand Lodge of England. At the same time, one by one, most of the American Grand Lodges which were still in fraternal relations with the Grand Orient have felt compelled to sever relations.

United States.—Since 1920 freemasonry in the United States has grown with amazing rapidity, and in 1926 had a membership of nearly 4,000,000 men, organised in 50 grand lodges. While in many ways gratifying, the influx of new members raised many problems, to meet which two movements were started.

First, the National Masonic Research Society was organised in 1914, under the sanction of the Grand Lodge of Iowa, to encourage the education of Freemasons in the history, symbolism and philosophy of freemasonry. Its headquarters are in St. Louis, where its journal, *The Builder*, is edited. Second, the Masonic Service Assn. of the United States organised in 1919 more than 30 grand lodges—the first great co-operative movement in American freemasonry. It grew out of the service of the fraternity in the War, and had two objects, as stated in its constitution; firstly relief in time of nation-wide calamity, whether it be war, pestilence or other disaster; secondly education—the teaching of freemasonry as it has to do with the daily lives of citizens and the problems of the nation.

The educational programme of the association is based upon the doctrines of the fatherhood of God and the brotherhood of man, under five heads: religious liberty, equality before the law, equality of opportunity, the dignity of labour and charity. Its work is carried on by means of short talk bulletins read in the lodges of member jurisdictions, speaker's bulletins, lectures illustrated by films and moving pictures, books, and its journal *The Master Mason*, edited from its headquarters in Washington. The association is managed by an executive commission, composed of one member from each group of states into which the country is divided. As a result of these movements a better kind of masonic literature has been created, at once more accurate and more popular—a national masonic library of nine volumes, and a little masonic library of 20 volumes. The whole intent of the movement is to know more about freemasonry and to do more with freemasonry for the service of mankind.

Recent years have witnessed the building of great temples of freemasonry in many of the chief cities of the country, and also a remarkable growth of philanthropic activity—the building of homes for the aged and indigent, orphanages and hospitals and the organisation of the national masonic tubercular sanitoria association. Since the World War there have been tentative attempts to form an International Masonic Assn. but they have been largely abortive, so far as American freemasons are concerned, owing to the refusal of freemasons in the United States to affiliate with foreign bodies which remove the Bible from the lodge and do not require faith in a supreme being as a requisite of membership.

FRÉMIET, EMMANUEL (1824–1910), French sculptor (*see* 11.96), died Sept. 11 1910.

FRENCH, DANIEL CHESTER (1850–), American sculptor (*see* 11.98), numbers among his more notable recent works the four groups representing Europe, America, Asia and Africa for the New York Custom House; the Melvin Memorial at Concord, Mass. (1916); the 1st Division War Memorial, Washington, D.C. (1924), and the statue "Memory" (1911), which was purchased by Henry Walters and given to the Metropolitan Museum of Art. His statue of Abraham Lincoln, executed for the Lincoln Memorial, Washington, D.C. (1920), portraying Lincoln seated and in a meditative mood, occupies a superb though simple setting and is considered the crowning work of French's life.

FRENCH AFRICAN LITERATURE.—The enormous continent, of Africa on account of its geographical configuration, is apt to appear as a single unit. But this could only be if all negroes were of the same race; whereas, ethnically speaking, owing to the intermingling of blood and the differences of latitude and longitude, there are as many races of negroes as there are African tribes. An Englishman differs less from a Russian than an Ourlaf from a Haoussa, and a Haoussa from a Kaffir.

The outbreak of the World War brought home to France her need for man power, and she then began to turn her attention towards a race which sent her its men by thousands. In the midst of the madness and destruction that overwhelmed Europe, she realised that she had to do with men who were like children and whose virgin minds required cultivation. She was forced to recognise that, in spite of solid, imposing and well-documented volumes, the theories with regard to the natural superiority of the Aryan races, set forth by Count Gobineau in his *Essai sur l'inégalité des races humaines* (1853–5), had received an unpleasant shock. Moreover, the ideas which Dr. Cureau, a former Governor of French Equatorial Africa, and a follower of Gobineau, expressed in his learned and interesting *Sociétés primitives de l'Afrique equatoriale* (1912) have, after much dis-

cussion, been strongly attacked, first by Jean Finot, whose work *Le préjugé des races* (1905) has attained world circulation, and later by Doctor Huot, in "L'âme noire."[1]

The soul of the negro, as compared with that of the white man, is emotional, unstable, variable and incomprehensible. It cannot be fathomed either in the tales of the old navigators—they dealt too much in fable and fantasy—or in the journals of contemporary explorers. Those who have lived long enough with the negro have learned to hold him in affection, which, according to Stendhal, is nothing but the crystallisation of feelings and inclinations.

We cannot number among the initiated either Pierre Loti, impassioned admirer of the exotic—the poet and magician who was inclined to bewitch himself with his own incantations—or even Fromentin, whose *Un été dans le Sahara* (1874) and *Une année dans le Sahel* (1859) conjure up before us burning sand and blinding light; but we must include Isabelle Eberhardt, the *bonne nomade*, whose whole work is a glorification of Islam; and a group of other writers of whom the most outstanding are Robert Randau, whose novels *Les Colons* (1907), *Les Algérianistes* (1912) and *Cassard le Berbère* are powerful and vivid; F. Duchene with *Au pas lent des caravanes* (1922), *Thamil'la* (1923) and *Le roman du Meddah* (1924); Maximilienne Heller with *La mer rouge* (1923) and many others. These works, however, have been inspired less by the influence of Africa than by that of the Mediterranean. In spite of such works as *Terres de soleil et de sommeil* (1916) and *Le voyage du centurion* (1916) by Lucien Psichari, *Visions congolaises* by Louis de Raulin and *Les explorateurs* (1909) and *Le commandant et les Foulbé* (1910) by Robert Randau the true African influence has only prevailed since 1919.

Since that time there has been a harvest of such literature, including the remarkable *Visage de la Brousse* by Pierre Bonardi (1920) and *l'isolement* by Dominique Combatte, which exude the stifling atmosphere of a tropical forest. *Des inconnus chez moi* (1920), by Lucie Cousturier, is a work profoundly true, profoundly human as well as infinitely pathetic. *Batouala* by René Maran (1921), *La randonnée de Samba Diouf* (1922) by the brothers Tharaud, *Koffi* (1922) by Gaston Joseph, *Diato*, a mine of Mandingo folk-lore, by André Demaison (1923), *Métempsycose* by Madeleine de Valcombe (1923), *Pellobellé, gentilhomme soudanais*, by Oswald Durand, *Ulyse, cafre* (1924) by the brothers Marius-Ary Lebland, *Les Chansons de Kou-Singa* by Jean Marville have also contributed to the researches of such men as Delafosse, Bruel and missionaries of all classes, lay, military, commercial and religious. These works may not perhaps have the lyric character which runs through *A travers l'Afrique* (1910) by Captain Baratier, nor the humour of that caustic adventurer to whom Pierre Mille, the French Kipling, has given the name Barnavaux. They are, however, a valuable contribution to the study of the negro mind, and as such increase our knowledge of humanity. (R. MA.*)

FRENCH LITERATURE (*see* 11.110)—The 15 years between 1911 and 1925 were overshadowed historically by the events which preceded the War of 1914, by the War itself and by post-War preoccupations and difficulties. If the course of literature was not entirely determined by this concurrence of great events, it at least responded to them, and bears deep traces of their influence. These marks can be found in the writings of practically all those who were at work during this period. Two literary generations occupied these 15 years; one, the older, that of the writers who belonged to the preceding period, already famous or recognised in 1911, who were only continuing their work; the other, a younger generation, that of the writers who made their first appearance in 1914 or after 1918.

I. THE PRE-WAR GENERATION

The most important writers of 1911 and succeeding years have already been accounted for in the preceding period. It will suffice here then merely to recall their names and the books which they published after 1911. It will be more interesting to note the general tendency of literature at this point.

[1] *Mercure de France* (Sept. 1921).

The peculiar characteristic of French literature in 1911 lay in the fact that the great movement of reaction against the excesses of naturalism which had started 20 years before had reached its culmination, and with entire success. About 1889 the doctrine of naturalism was still triumphant, and had imposed a general conception of things which was affirmed by the scientific spirit. It was material, subject to reason, in no way sentimental. It had invaded the novel with Zola, the theatre, and even made its way into philosophy. It claimed to make use of the discoveries of savants, of Berthelot in chemistry and Darwin in biology. It was fatalistic, pessimistic, setting itself against religious beliefs and even against the tradition of the things of the spirit. It claimed to reduce all life, even the life of the soul itself, to a mechanism of causes and effects, to a purely physiological basis.

It was about the year 1889 that new tendencies were manifested simultaneously in poetry, in philosophy, in criticism and in the novel. While keeping as a fundamental principle the recognition of the fact, that is to say the method of observation, the newcomers insisted upon their observation being complete, upon its taking into account the whole of reality, not merely facts, but also all the stuff of feeling, aspiration, of the impulses of the soul, of spiritual energy. As a result of all this, thought became re-invigorated, took a new lease of life. Such was the accomplishment of men very different in their inspiration and their convictions. Paul Bourget and Barrès among the novelists, Henri de Régnier among the poets, Rémy de Gourmont, Charles Maurras and André Gide among the critics, played a great part in this change. Groups like those of the *Mercure de France*, the *Nouvelle Revue Française*, the *Cahiers de la Quinzaine*, under the leadership of Charles Péguy, did their capable share.

It may be said that in 1911 the distinction had been clearly made between science, which establishes laws and fundamental causes and sets them forth in abstract terms, and art, which manifests these causes sympathetically by appealing at one and the same time to the reason, the heart and the senses. The works of a mathematician of genius, like Jules Henri Poincaré, had made for the development of a more exact conception of science and the scientific method. The books of Henri Bergson, especially the one which appeared in 1907 (*L'évolution créatrice*), had created a new spiritual awakening. Everything thus contributed towards liberating the spirit from the narrow boundaries of naturalism. A literary outburst was the result, the main characteristic of which is that each work reflects the temperament and the tastes of the author, without dependence on any school. Certain writers remain faithful to their conception of the novel (Gustave Geffroy, *Cécile Pommier*, 1922), and the Académie Goncourt continue the tradition of objectivity and naturalism. But the brilliant group of psychological writers that followed Paul Bourget and Maurice Barrès goes back to Benjamin Constant and Stendhal, indeed even invokes Balzac, and attempts to make of the novel a complete representation of life, of the spiritual life as well as the social and material.

During the 15 years (1910–25) there appeared a brilliant series of psychological studies. Writers already famous continued their work. Paul Bourget produced *Le Démon de Midi* (1914), *Némésis* (1918). Maurice Barrès wrote *Greco, ou Le secret de Tolède* (1912), *La colline inspirée* (1913), and just before his death published that *Enquête aux pays du Levant* (1923), which unites in itself all his peculiar qualities of thought and expression and which remains one of his finest books. René Bazin (*Les nouveaux Oberlé*, 1919); Henry Bordeaux (*La maison*, 1913, and *La résurrection de la chair*, 1920); René Boylesve (*Tu n'es plus rien*, 1914, *Elise*, 1921); Louis Bertrand (*Jean Serbal*, 1924); Edouard Estaunié (*Les choses voient*, 1913, *L'ascension de M. Baslèvre*, 1920), attest the vitality of a *genre* which was tried with success also by Emile Clermont (1878–1915), author of *Laure* (1913); Louis Codet (1877–1918), author of *La petite Chiquette* (1911), *César Capéran* (1918), *La fortune de Bécot* (1919); and Roger Martin du Gard, of a more philosophical turn (*Jean Barois*, 1914, and *Les Thibault*, 1922).

The analytic and descriptive novel of manners continued with

Henri Lavedan, *Irène Olette*, *Le chemin du salut*, 1920–3); Abel Hermant *Les Renards* (1912), *L'aube ardente* (1919), *La journée brève* (1920); with Gaston Chérau (*La prison de verre*, 1912, *Le monstre*, 1913). Jérôme and Jean Tharaud (*L'ombre de la croix*, 1917, and *Un royaume de Dieu*, 1920); Gilbert de Voisins (*L'enfant qui prit peur*, 1912); the tales of Henri Duvernois (*Le veau gras*, 1912, *Edgar*, 1912); Edmond Jaloux, Marcel Boulenger, Eugène Montfort, Claude Anet, Charles Géniaux. An offshoot of the symbolist movement, the poetic novel of fantasy has its most illustrious exponents in the poet Henri de Régnier (*La pêcheresse*, 1920, *Le divertissement provincial*, 1923); in the poet Francis Jammes (*M. le Curé d'Ozeron*, 1918, *Le poète rustique*, 1920); and in the young Alain Fournier (1886–1914), snatched away too soon from letters by the War, whose book *Le grand Meaulnes* (1914) remains a charming and impressive work. Finally, exotic literature, dominated by the great name of Pierre Loti, finds brilliant expression in Claude Farrère (*La Bataille*, 1911, *Dix-sept histoires de Marins*, 1914); Jérôme and Jean Tharaud (*La fête Arabe*, 1912); Pierre Mille, Marius-Ary Leblond, and in the posthumous book of Louis Hémon on Canada, *Maria Chapdelaine* (1916), which had a prodigious success.

Women have always excelled in the literature of imagination. Three writers occupy the first rank in this respect—Colette, who has added to her already famous list of works *La vagabonde* (1910), *L'entrave* (1914), *Chéri* (1920), *La maison de Claudine* (1922) and *La fin de Chéri* (1926); Gérard d'Houville, daughter of the great poet J. M. de Heredia, wife of Henri de Régnier, who has a rare poetic gift and who tells in the most fluid style prose stories of charming and often profound imagination, (*Le séducteur*, 1914, *Jeune fille*, 1916, *Tant pis pour toi*, 1920), and who has written in *L'enfant* (1926) a little masterpiece; and Comtesse de Noailles, a poet of passionate and inspired quality as well, who in 1923 under the title of *Les innocentes* published a series of novelettes and meditations in which lyricism is made the vehicle of a daring frankness. Mme. Marcelle Tinayre published in 1920 *Persephone* and in 1922 *Priscille Séverac*. Mme. Lucie Delarue-Mardrus, a very gifted story-teller, observant and poetic, wrote *L'âme aux trois visages* in 1919 and *Graine au vent* in 1925. Mme. Andrée Corthés received in 1920 the novel prize of the Académie française for her book entitled *Pour moi seule*.

At the theatre that most personal of writers, François de Curel, produced *Terre inhumaine* (1923), *La viveuse* and *Le moribond* (1925). G. de Porto-Riche pursued his vigourous studies of passion with *Le vieil homme* (1911) and *Le marchand d'Estampes* (1918). Maurice Donnay, so charming, and, at the same time, so melancholy and whimsical, has continued his social studies in *Les éclaireuses* (1913) and *La chasse à l'homme* (1920). Alfred Capus, a lucid realist, ironical and with a gift for natural dialogue, produced *Hélène Ardouin* in 1913 and *L'institut de beauté* in 1914. Henry Bataille (1872–1922), hypersensitive, slightly involved and exotic, brought out *Le Phalène* in 1914 and *L'homme à la rose* in 1922. Henry Bernstein after a series of dramatic and violent plays (*L'assaut*, 1922), brought out *Le secret* (1917), in which his effects are drawn from psychology and character. Comedy has owed its greatest successes to Robert de Flers (*L'habit vert*, 1913, *M. Brotonneau*, 1914, *Les nouveaux messieurs*, 1925); to Tristan Bernard (*Les petites curieuses*, 1920); to Francis de Croisset (*Le coeur dispose*, 1912); and to Sacha Guitry, whose vivacity and wit find triumphant expression in *Le veilleur de nuit* (1911), *L'illusionniste* (1921) and *L'amour masqué* (1924). The most interesting attempts in the way of original work have been made by François Porché, who in *Les butors et la Finette* (1918) and *Le Chevalier de Colomb* (1922) combines in a curious way the relics of ancient traditions with an entirely modern feeling for symbolism; and by P. Claudel, author of *L'otage* (1911), *L'annonce faite à Marie* (1912), *Le père humilié* (1920) and *Le pain dur* (1918), works sometimes obscure, but freighted with purpose of an incontestable quality, and with austere emotion.

In the domain of poetry all the squabbles of the schools had already been silenced by 1911. Symbolism had done its work. Its most illustrious representative, Henri de Régnier, had returned to traditional forms. Master of rhythm and of rhyme, connoisseur of language, sumptuous and self-contained, he has amplitude and richness. Cultured, a great reader of history and old books, he knows the past. He has at his command all the images supplied by legend, history, nature and art. The outcome of this is a magnificent and lordly poetry which is the mirror of the passions, the adventures, the glories and all the multiple forms of human destiny (*Poésies*, 1907, *Vestigia Flammae*, 1921). Much nearer symbolism, Francis Vielé-Griffin has studied the ancient myths and has attempted to interpret their eternal significance (*Voix d'Ionie*, 1914). Francis Jammes is the poet of nature and divinity. He knows the country well, and he speaks of it with a charming simplicity and freshness (*Les Géorgiques chrétiennes*, 1911–2). He shows the same ingenuousness, the same healthy realism, the same humility in his poetry of religious inspirations; he has in him something at once bucolic and Christian (*La Vierge et les sonnets*, 1919). Comtesse de Noailles is on the contrary pantheistic and pagan. Impetuous and consciously unrestrained, heavy with doom like a priestess of old time, she has sung in eloquent and remarkably rhythmical verse of youth, love, the beauty of the universe, and also of human unhappiness, implacable destiny and death (*Les vivants et les morts*, 1913, *Les forces éternelles*, 1920). In her last verses (*Poème de l'amour*, 1924) she has adopted a deliberately simple and bare style, in which is traceable a growing melancholy, a strange lassitude in her ardent work, and, by way of substitute for resignation, a courage full of serenity. Paul Claudel, a vigorous personality, penetrated by a faith which, unlike the tenderness of Francis Jammes, is austere and sometimes sombre, and has written poems (*La cantate à trois voix*, 1914, *Trois poèmes de guerre*, 1915, *La messe là-bas*, 1919), which present a mixture of rather obscure metaphysics, rather self-conscious simplicity, and vivid and powerful imagery.

Charles Péguy, ardent, sophisticated and simple, Socialist and patriot, has shown in his poems *Le mystère de la Charité de Jeanne d'Arc* (1910), *Le mystère des Saints Innocents* (1912), *Eve* (1914) a fluency which is slightly wearing because of his repetition of the same themes, but at the same time a real power due to sincerity, tenderness and the human need for faith and piety. Finally, Paul Valéry, who had made his appearance between 1889 and 1898 in reviews of poetry and letters, *La Conque* and *Le Centaure*, after having kept silence for a long while, published in 1917 *Le jeune Parque*, and in 1922 *Charmes*. These two extremely slender collections contained much substance under an unpretentious form, and established his reputation. Mathematician and philosopher, a subtle and experienced artist, a disciple of Mallarmé, to whom he owes much, he gives expression to an abstract and intellectual life which though slightly arid is still passionate, and his work has a deep full note. The tendency to return to simple, pure and classical sources is found also with Paul Fort, whose *Ballades françaises* are full of colour and imagination; with J. P. Toulet, Fernand Gregh, Abel Bonnard, Franc-Nohain, whose *Fables* (1921) are delightfully humorous; with Alfred Droin and Pierre Camo; while symbolistic description is the more natural vehicle for Jean Royère.

If one were obliged, in spite of this diversity of temperaments, to characterise the period between 1911 and 1914, one might make two observations. One is that in matters of form pre-War writers went back almost without exception to classical traditions, to proportion, simplicity, clearness. The other is, that as far as guiding principles went they were for the most part occupied with furnishing a moral discipline to their contemporaries, and that in the wake of dilettantism and naturalistic pessimism they laboured to restore notions of order, of decorum, of hierarchy, which to them seemed useful to the national life. Whatever may have been the glory of Anatole France, it was not he who was then a leader, and who exercised an influence over men's souls; it was Paul Bourget and Maurice Barrès. There appeared at the approach of that danger constituted by

the War a phenomenon worthy of remark by historians of the future. The grandson of Renan, Ernest Psichari, wrote in 1913 *L'appel des armes*, and shortly afterwards *Le voyage du centurion* (1916). Political crises and intellectual visionings had brought about a state of uncertainty that might prove a cause of weakness. Under the pressure of national exigencies that were apparent to all thoughtful minds, French literature in 1911 was mainly inspired by the attempt, which has been justified by the facts, to assure the future of the threatened country, to make readers acquainted with the strenuous life and the fundamental principles of the social and moral worlds.

II. THE POST-WAR GENERATION

The War abruptly ended the literary careers of many young men, who were killed on the field of battle, men who in all branches of literary activity gave high promise—novelists like Alain Fournier and Emile Clermont, poets like Paul Drouot and J. M. Bernard, essayists like Dufresnoy and Pierre Gilbert. But with those who survived it and had passed through its fires it only stimulated the desire for expression. During the course of the War there appeared a series of brilliant books of diverse character, but sincere and passionate, retracing the heroic years. It is impossible to mention all, but we must at least set down here *Le songe* (1922), by Henry de Montherlant; *Les croix de bois* (1919), by Roland Dorgelès; *Le feu* (1916), by Henri Barbusse; *La flamme au poing* (1917), by H. Malherbe; *Gaspard* (1916), by René Benjamin; *Civilisation* (1918) and *La vie des martyrs* (1917), by Georges Duhamel; *Sous Verdun* (1916), by Maurice Genevoix; *La guerre à vingt ans* (1924), by Philippe Barrès; *Fond de Cantine* (1920), by Pierre Drieu la Rochelle, and *Les récits de guerre dits à une femme*, by Camille Mayran. None of these books pretends to give a summary or to describe the whole of the War. It will be a long time before these great events will find their poet to synthesise and express them; Bonaparte had to wait for Victor Hugo. But all these works powerfully represent direct impressions and strong emotions; they have a meaning, and our grandchildren will find in them one day a sincerely moving record of a period that was shaken by a terrible storm.

This interesting and noble outburst necessarily faded as the events moved further away. The current of life which had been interrupted for four years took up its course again. All countries had to repair the consequences of the conflict. New problems arose. Difficulties mounted. The combined effect of all these causes was that there was no longer a collective effort. Everyone returned to his own preoccupations, to the world of his own imagination and fancy. More or less indifferent to the heritage of their elders, the young writers appeared to be under the impression of existing in a new world where they had to recreate everything. But nevertheless they remained under the influence of the past, sometimes without suspecting it themselves. They discovered, by the very fact that they lived in a predetermined epoch, the result of the labours of their elders. Tendencies, varieties of talent and aspirations are very diverse. There is little unity in the literature of the younger generation. Everyone follows the inclinations of his own temperament. The situation viewed as a whole gives the impression of a melting pot in which everything is in a state of fusion but out of which one day something new and unforeseen will spring. Let us try, in so far as we can to-day, to discern what this may be.

The dominating form in modern literature is always the novel, and it will serve as a type. It is not distinctively, in spite of the definition, a narrative representing life, but often consists of recollections like a book of memoirs or of reflections like a book of essays. The strongest influence to appear has been that of Marcel Proust (1873–1923). According to the date of his birth he belongs to the pre-War generation; but one finds that his work appeared almost entirely during or since the War. Only the first volume of his great novel *A la recherche du temps perdu*, namely *Du côté de Chez Swann*, had appeared by the end of the year 1913. All the others appeared in sequence down to 1925. Marcel Proust is remarkable for the depth and daring of his analysis. Gifted with an acute, morbid sensitivity, he probed deeply into the motives of the heart and soul. With an extraordinary delicacy and detail, he succeeded in expressing new and original nuances of thought in sinuous and often interminable sentences. The bold analysis of the emotions in French literature had begun some years before Marcel Proust; by Anatole France but with discretion, and later with more freedom by the female writers; but Marcel Proust has gone much further. He has carried the taste and feeling for introspection to the extreme limits. By this one can say he has enlarged the scope of the novel, and that is the reason for his great prestige and influence among post-War writers.

This preoccupation with analysis is found in a series of works the most characteristic of which are: Jacques Rivière's *Aimée* (1921), Jacques de Lacretelle's *Silbermann* (1922) and *La Bonifas* (1925), and Drieu la Rochelle's *Etat civil* (1921). In reality a gift as personal and exceptional as that of Marcel Proust encourages tendencies more than it provokes imitation. Psychological introspection is part of our period. It appeared in the course of the War more acutely and frequently than ever. Carried to the extreme, it has resulted in the formation of the super-realist (*sur-réaliste*) school, which in essentials existed already before the War, but which has been revivified by younger enthusiasts. The object of literature in the opinion of this school is to seize upon the pure thought itself, in its barely conscious stage. The outcome of this is a series of jottings, often obscure, or at least unintelligible according to the ordinary processes of the understanding, and a series of images which has certain associations with the art of the cinema and which neglects traditional logic. At this extreme point the work of analysis is entirely occupied with the subjective, and hardly takes into account at all the exterior world. Although there have been young men of talent like Aragon among the followers of this school, it has as yet produced no work which has touched the world outside the literary cliques. Those who appear to have the most individual temperaments have detached themselves from the group, like J. Cocteau (*Thomas l'imposteur*, 1923) and Drieu la Rochelle (*Plainte contre inconnu*, 1924), and they are little by little returning to the classical forms. This attempt has had, however, up to the time of writing one result:—it has rid literature of all trace of rhetoric. In spite of a marked tendency towards simplicity and brevity for many years, there still remained traces of a declamation whose origin went very far back. The prestige of the sublimities of Hugo and of de Michelet was very great, and it nourished a love of the phrase. With all its excesses, the development in the direction of sketchy notations, suppression of logical associations and extravagant simplification has been made at the cost of a classic and sober art.

The writers who have been most successful in these last years escape any attempt at classification. Each follows his own temperament and inclination. Recourse to the past is necessary to distinguish influences, forerunners, schools. In contemporary literature the only thing that can be distinguished is the individual. The choir of young poets protest their personal freedom (Tristan Derême, Charles Derennes, Géraldy, Roger Allard, Chabaneix). The novelists do the same; M. Pierre Benoit is a master of the novel of adventure; he knows how to construct; he knows how to tell a story; and addressing himself to a public which, as after every period of upheaval, is in need of distraction, he has been able to captivate the attention in a series of well-made novels (*Koenigsmark*, 1918; *L'Atlantide*, 1919; *Mlle. de la Ferté*, 1923; *Le puits de Jacob*, 1924)—in which he shows a remarkable facility in employing imaginary or historical events and in keeping the reader breathless with suspense over the turns of his stories.

It is only necessary to recall *Le kilomètre 83*, by Henry Daguerches (1913), to show that since before the War the taste for the novel of adventure had been revived. The influence of Anglo-Saxon literature, and particularly that of Kipling, had been a powerful stimulant in this development. The War naturally only accentuated this tendency. A proof of this is

found in the books of Pierre MacOrlan (*La cavalière Elsa*, 1921), of Louis Chadourne (*Terre de Chanaan*, 1921) of Jean d'Esme (*Les Barbères*, 1925), of Roland Dorgelès (*Le reveil des morts*, 1923), of René Bizet (*La sirène hurle*, 1921) and of J. Kessil (*La Steppe rouge*, 1922, *L'Equipage*, 1924). All of these appeared between 1918 and 1925. Actually, however, it does not seem that this form of literature is capable of much further development, except in the case of the exotic, historical or colonial novel. French literature is traditionally psychological. It is characteristic that the best book of Pierre Benoit, the most popular writer of novels of adventure, is a novel of manners, *Mlle. de la Ferté* (1923).

Francis Carco is a painter of the lower depths of society, of the world of the apaches and of the outer boulevards. He deals, as did Francois Villon in his day, with the world of thieves. He has handled this difficult subject with a great deal of tact (*Les innocents*, 1916, *L'homme traqué*, 1922, *Perversités*). Francis Carco is a true artist with a quick sensitivity. He has made a study of those who take no count of laws nor of social conventions; he has caught human beings with all their passions and all their energies. He has shown how they live beyond the law and current morality; how they have made their own laws, created their own code of honour and conventions. There are in his work many amusing, picturesque and curious scenes, but there is more. He has analysed, often with profound sympathy, these creatures of an outcast world and their imagination, dreams and miseries.

Jean Giraudoux is also a subtle analyst. He has a capricious imagination and a very individual, if somewhat complicated, poetic manner, which makes him difficult reading; but he is provocative. There is in him much humour, often of an unexpected kind, difficult to understand. The world of images has no secrets from him. Unusual comparisons and strange associations of ideas abound in his books. The most successful of these is *Suzanne et le Pacifique* (1921), the story of a shipwrecked young girl who lives alone on a desert island. She has to reorganise her life, and by a series of chances and deductions she discovers that the War, of which she knew nothing when she left, is going on. Psychology in this book takes precedence over adventure, for the author primarily wished to portray the reactions of an isolated human being in face of the vast world.

Henry de Montherlant is one of the most gifted among the young writers. He has a sense of style, and is capable of vigorous mental activity. After *Le Songe* (1922) he wrote about Verdun, and about sports (*Les onze devant la porte dorée*, 1924), books which disclose his national and moral preoccupations. He is interested in the disciplines which make a human being master of himself, permit him to live under the best conditions, and give the greatest possible value to his acts. He is very modern, and at the same time deeply attached to tradition; his works are filled with youthful ardour, strength of will, and an impetuosity which express themselves in vivid and poetic language.

François Mauriac is a harsh and powerful novelist. His books (*Le baiser au lépreux*, 1922, *Genitrix*, 1923, *Le désert de l'amour*, 1925) have placed him among the most notable writers of his generation. Brought up in the Catholic tradition and attached to his faith, François Mauriac is aware both of the demands imposed by a Christian life and of the weaknesses of most human beings. All his work, which incidentally is open-minded, seems dominated by the idea of sin, by the necessary artifices in which egotism and passion entangle human beings, by the nothingness of their desires and the need for discipline. He combines realism, austerity and even daring. Just as in cathedrals, where bold sculpture representing vice and demoniac inspirations are adjacent to sacred arthitectural motives, so he has put into his work scenes that are sordid enough, side by side with aspirations towards purity.

André Maurois, who during the War was interpreter with the British Army, made his début with an impressionistic book, entitled *Les silences du Colonel Bramble* (1918), which had a great success. He published in 1923 *Ariel, ou la vie de Shelley*, which had great charm, and *Des dialogues sur le Commandement* (1924). He is less a novelist than an essayist. He has a penetrating, highly cultivated mind and loves the play of ideas; he excels in delicate analyses, in the nuances of the emotions and in psychological insight.

Valéry Larbaud is interested in the manifestations of the international mind, and has written fascinating novels. *Fermina Marquez* is an original study of the life of young people in South American schools. *Le journal d'A.O. Barnabooth*, which followed, is a novel in which satire is mingled with poetic fancy. In it he amuses himself with drawing the life of a millionaire who can see everything, buy everything, and almost do what he pleases, and yet is stifled with boredom and doubt, finding pleasure only in doing everything that runs counter to the conventions of his social position. This story of the weariness of one of the inheritors of the earth is written with a vivacity which is one of the most curious characteristics of modern art.

Paul Morand represents the impressionist school at its acme of success. His short stories *Ouvert la nuit* (1922), and his novel *Lewis et Irène* (1924) are certainly among the most entertaining studies of the present time. Paul Morand has a keen feeling for the feverishness and instability of contemporary life. He is also keenly aware of the international aspect of post-War cities—the mingling in all countries in the same places, restaurants and hotels of people belonging to every race and nation. He has caught finally the elementary flashes which these cosmopolitans have in common by way of certain instincts and manifestations. His pictures are alive and chaotic. The author contents himself with incisive characterisations and brief formulas. He is full of verbal coinages. He reduces the recital to the bare essential. There is something acrobatic and artificial in this art, but the feat is always successful and entertaining.

A great number of other writers and books should be added to this summary. There is much diversity of literary activity. Works like *Les métiers blessés* (1919), by Pierre Hamp, and *Les entretiens dans le tumulte* (1919) and *La confession de minuit* (1920), by G. Duhamel, are a combination of social study and meditation; others, like those of Jean Rostand (*De la Vanité*), revive the tradition of the writers of maxims and of the moralists; others, like those of Alexandre Arnoux (*La nuit de Saint Barnabé*), constitute in the form of a narrative an interesting attempt to represent material civilisation and to give a picture of the modern industrial and mechanical world.

The attempts at a revival of the theatre, undertaken by the "Théâtre du Vieux Colombier," are continued chiefly by the "Atelier." While plays with Deval and Natanson were rather psychological, with Zimmer rather sombre, with Marcel Achard rather fantastic, with Géraldy rather sentimental, the modern play is sketchy, containing little action, and above all else designed to portray character. So it at least appears among the last comers, J. J. Bernard, Obey, Amiel, Steve Passeur. The construction is loose, without complications. The young dramatic authors seem to desire chiefly directness; they have no ambition to uphold theses, and wish only to amuse and to provoke reflection.

This article does not pretend to give a complete survey of present-day literature. It is being made, and there is no history at present. All that is possible is to indicate general characteristics; the appearance of men of talent may change everything to-morrow; the appearance of a genius may accentuate current tendencies or transform them. If one wished to summarise the various comments which have been made, one might say that literature in 1926 is still dominated by pre-War writers After the activity which showed itself in the years 1918–20, it seems there should have been a sort of fruition. Many talents with a certain ingenuity have been revealed, many young writers with distinctive personal qualities have published their books. But no single work dominates recent years or seems capable of exercising a determining influence.

It is then towards the masters of yesterday, who are still living to-day (except Barrès and Marcel Proust) and who are still exercising their influence, that little by little the younger men are turning their attention. The names of Paul Bourget,

Maurice Barrès and Henri de Régnier, and those of Colette, Marcel Proust and Charles Maurras are dominating our period. Even when they know them only slightly or when they try to free themselves from them, the newcomers live in a society the ideas of which have in some way been fashioned by their elders. They breathe in air which is that of their time. One notices that the psychological analysis of Marcel Proust has strongly influenced some, that the impressionistic realism of Colette has attracted others, while the disciplines formulated by Bourget and Barrès form the mainstay of a great number. It is significant that a young writer like Drieu la Rochelle should leave his particular set and return to the Barrès tradition, and that after years of charming unconformity Jean Cocteau should entitle a book of essays, *Rappel à l'ordre*.

Thus after a detour of 10 years, violently disturbed by the War and its aftermaths, one can say that in 1925 French literature again took up the road which was foreshadowed in 1914. All the schools, after their trials and struggles, have achieved their work and have transmitted the best that was in them. The quarrels between romanticism and naturalism, between the Parnassians and the Symbolists have come to an end. The opposition between scientific rationalism and the world of the spirit has become less acute. It was a long struggle, bearing witness to the vitality of literature; of all the doctrines nothing is left but the trace of whatever in them was useful and true. Present-day French literature seems to be going in the direction of a classic revival in which certain other elements are mingled.

FREUD, SIGMUND (1856–), Austrian physician and psychoanalyst, was born on May 6 1856, at Freiburg in Moravia, and studied medicine and psychology at Vienna, being strongly influenced by Brücke in the latter subject. After working in Paris under Charcot from 1885–6, he devoted himself, in co-operation with the Viennese physician, Josef Breuer, to the study of nerve cases. The results of their joint investigations were published in 1895 as *Studien über Hysterie*, expounding a new treatment, the so-called *catharsis*. This consisted in putting the patient in a hypnotic state, and the examination by the physician, while under this condition, of the forgotten original circumstances under which the symptoms first appeared. Subsequently Freud pursued a path of his own, and developed a special technique (*see* PSYCHO ANALYSIS). The technique and the results of this research work are explained in Freud's most important works: *Die Traumdeutung*, 6th ed. (1921); *Zur Psychopathologie des Alltagslebens*, 7th ed. (1920); *Drei Abhandlungen zur Sexualtheorie*, 4th ed. (1920). Freud's shorter works were collected in four volumes under the title, *Kleinere Beiträge zur Neurosenlehre*.

Freud also published two general sketches of his theory: a shorter one, *Fünf Vorlesungen über Psychoanalyse* (delivered at Worcester, Mass., in 1909) and a comprehensive one in *Vorlesungen zur Einführung in die Psychoanalyse* (1917). These medical-psychological studies yielded surprising results in relation to other subjects, and in the possibilities of their adaptation in other branches of knowledge, *e.g.*, mythology and the history of religion, civilisation and literature. The principal works in this connection are *Totem und Tabu*, 2nd ed. (1920); *Der Witz*, 3rd ed. (1921); *Eine Kindheitserinnerung: Leonardo da Vinci* (1916); *Jenseits des Lustprinzips* (1920); *Massenpsychologie und Ichanalyse* (1921). Freud's works have been translated into English.

FREYCINET, CHARLES LOUIS DE SAULCES DE (1828–1923), French statesman (*see* 11.211) died in Paris May 14 1923.

FRICK, HENRY CLAY (1849–1919), American manufacturer and philanthropist, was born at West Overton, Pa., June 17 1849. As a boy he was clerk for his grandfather, who was a distiller and flour merchant; but he early became interested in the coke business. In 1871 he organised the firm of Frick & Co., which ultimately acquired large coal deposits and ran 12,000 coke ovens. He was chairman of the board of Carnegie Bros., from 1889 to 1892, and in the latter year, during the Homestead strike, was shot and stabbed by Alexander Berkman, an anarchist. He was a director of the Pennsylvania, the Santa Fé and other railways, and of the U.S. Steel Corporation. He died in New York Dec. 2 1919.

Besides large sums left to his family and friends, he left to the city of Pittsburgh land for a park, together with an endowment of $2,000,000. His New York mansion, with its collection of paintings, bronzes and enamels, he bequeathed to the city on the death of his wife, with an endowment of $15,000,000. He divided his residuary estate, estimated at $50,000,000, between various hospitals and educational and charitable institutions. The value of his New York mansion and its art collection was estimated in 1920, to be $50,000,000. Among the chief treasures are the Fragonard panels, Bellini's "St. Francis in the Desert," Velasquez' "Philip IV.," Van Dyck's "Paola Adorno," Rembrandt's "Portrait of Himself," Gainsborough's "The Mall," and "The Hon. Anna Duncan." It includes also fine examples of Titian, Vermeer, Frans Hals, Ruysdael, Cuyp, Rubens, El Greco, Goya, Sir Thomas Lawrence, Millet, Raeburn, Reynolds, Romney and Turner.

FRIEDJUNG, HEINRICH (1851–1920), Austrian historian, was born at Roštìn, Moravia, Jan. 18 1851 of Jewish parents. Friedjung spent much of his career in political journalism; he was a pronounced German nationalist, and the chief author of the nationalist *Unser Programme* of 1885. At the same time he devoted himself to historical research, especially over the period 1848–66, which he covered brilliantly and exhaustively in the three works *Oesterreich von 1849–60* (1908–12); *Der Krimkrieg und die oesterreichische Politik* (1907); and *Der Kampf um die Vorherrschaft in Deutschland*, 10th ed. (1917). His other chief works are the volume *Historische Aufsätze* (1919) and the monumental review of modern times *Das Zeitalter des Imperialismus* (1919–22), which was finished by Professor A. F. Pribram after Friedjung's death in 1920.

Friedjung was a conscientious and an attractive historian, whose works cover all aspects of life during the period with which they deal. The point of view expressed in them is, however, pronouncedly liberal, patriotic and anti-Catholic, and shows little sympathy for the Slav and Magyar nationalist movements in the Dual Monarchy. His last excursion into politics was most unlucky, and undeservedly clouded his name; on March 24 1909 when the conflict between Austria-Hungary and Serbia over the annexation of Bosnia-Herzegovina was at its height, he published an article in the *Neue Freie Presse*, accusing the Serbo-Croat politicians in the Monarchy of treasonable practices with the Government of Serbia, and violently attacking conditions in Serbia. Fifty-two deputies of the Croato-Serb coalition and their leader Supilo separately, sued Friedjung for libel. It was disclosed that Friedjung had received the documents on which his article was based from the Austro-Hungarian Foreign Office, that he had accepted them in good faith but after most insufficient scrutiny and that some at least were blatant forgeries. The affair ended at last in a compromise, but not until it had assumed the proportions of a European *cause célèbre*. Friedjung died in Vienna July 14 1920.

See Dr. R. W. Seton-Watson, *The Southern Slav Question and the Habsburg Monarchy* (London, 1911).

FRIEDRICH, JOHANN (1836–1917), German theologian (*see* 11.216), died in Munich, Aug. 19 1917.

FROHMAN, CHARLES (1860–1915), American theatrical manager, was born at Sandusky, O., June 17 1860. At the age of 12 he started to work at night in the office of *The New York*

Tribune, attending school by day. In 1874 he began work for *The Daily Graphic*. In 1877 he entered the theatrical business, being for a time associated with his brother Daniel in managing the Madison Square Theatre, New York. In 1890 he organised the Charles Frohman Stock Company. On Jan. 25 1893 he opened his Empire Theatre, New York. Other New York theatres with which he was at various times connected were the Criterion, Garrick, Knickerbocker, Lyceum and Savoy. He was an adept in developing talent. Among his successful players were Maude Adams, Ethel Barrymore, Blanche Bates, Billie Burke, William Gillette and Otis Skinner. During 1905–6 he presented E. H. Sothern and Julia Marlowe in Shakespearean plays. He was one of the organisers of the syndicate which for several years controlled the American theatres. Beginning in 1897 he presented many plays in London, leasing at different times such houses as the Duke of York's, Globe, Comedy, Vaudeville and Adelphi. He perished when the "Lusitania" was sunk by a German submarine May 7 1915.

FRONTIERS, BATTLES OF THE.—The generic name of "battles of the frontiers" covers the whole of the actions fought at the opening of the World War in Aug. 1914, on or near the French frontiers. For convenience these are here divided into six sections, each of which deals with a more or less distinct part of the series of operations. These are: I. Early operations in Upper Alsace; II. First battles in Lorraine; III. Battle of the Ardennes; IV. Charleroi and Mons; V. Le Cateau; and VI. Guise.

I. EARLY OPERATIONS IN UPPER ALSACE

At the beginning of the World War the French higher command was governed by two ideas. One was to avoid posing as the aggressors, and consequently the covering troops were withdrawn 10 km. behind the frontier. The other idea was to plant the flag in the lost provinces as quickly as possible. Not only, therefore, were strategy and politics not in harmony, but politics contained a double element, the one pacific, the other aggressive.

First French Advance.—Immediately on the order for mobilisation, an advance on Mulhouse was ordered. The offensive began on the morning of Aug. 7. Its start was promising. Mulhouse was reached and occupied in the evening of the 8th. The news of the approach of large German forces then became known. The French commander feared being caught in a trap, and after an eight-hour occupation the town was evacuated, a position in rear being occupied. During the evening of Aug. 9, the Germans attacked with superior force and drove back the French. The success was not followed up, since German supreme headquarters had prepared for a massed attack on Luxembourg and Belgium, which postulated a strict defensive in the south.

The retreat from Mulhouse was likely to have a prejudicial effect upon the French. To counteract it Joffre formed a special Army of Alsace. Early on Aug. 19 the Germans in front of Mulhouse were attacked and defeated, and at 4 P.M., for the second time in a fortnight, the victorious French entered the town. But though fortune seemed here for the moment to smile upon the French, reverses elsewhere extended their influence to Alsace. Orders were issued for the break-up of the Army of Alsace and the dispersion of its units. Mulhouse was again evacuated on Aug. 25. The fortress of Belfort was thus exposed and open to hostile attack.

Belfort and Dannemarie.—Belfort had two rôles to play, the one permanent and foreseen, the other thrust upon it very early in the War. In the first place, the fortress was designed to close the gap existing between the Vosges and the Jura. It was a vitally important rôle, for if the Germans secured the gap they might penetrate into the heart of France. The other rôle was to form a pivot for the bending back of the whole French line, from the Swiss frontier to Belgium. A vast amount of work had been done during the preceding 40 years to convert the small fortress of 1870 into the immense stronghold of 1914. Much, however, remained to be completed. The completion of the task was necessarily impeded by the fighting in which part of the garrison was engaged during August. Nevertheless, by the time that the Army of Alsace was broken up the enormous undertaking was achieved. The armament of the forts had been completed; numerous batteries had been constructed and armed; centres of resistance had been organised; and inundations in front had strengthened the zone of defence.

On the other hand, the German heavy artillery had introduced a new factor into war. The crushing of the resistance of Liége and Namur was disconcerting. By Aug. 25 there could be no possible doubt that if the Germans were allowed to plant their guns 8 km. from the forts the heart of the place would be bombarded and the forts themselves smashed before the artillery of the defence could fire a shot. Furthermore, by Aug. 25 the Allies were withdrawing all along the line. Clearly the Germans might make a special effort to seize the pivot on which this withdrawal hinged.

In these circumstances, and knowing that he had only his own resources to count upon, Gen. Thévenet, Governor of Belfort, decided not to await the enemy's attack, but at once to assume the offensive. The plan was quickly put into operation. The offensive reconnaissances in front of the fortress began on Aug. 28, and from that date were pursued without interruption. So successful was the operation that by Sept. 10 the advanced guards were over the frontier and 11 m. from the fortress. Eight days later the headquarters of the 57th Div., whose daily reconnaissances had been carried on uninterruptedly in advance of its front, was transferred from Foussemagne to Dannemarie. This transfer made a great impression in France, as also in Alsace, and had all the importance of a victory. It was indeed a considerable success, for the occupation of Dannemarie had been carried out with such precision and solidity that it had now to become definite. From Sept. 18 1914 onward, the French flag never ceased to fly over the little Alsatian town thus reconquered.

II. FIRST BATTLES IN LORRAINE

The first French plan (General Instructions No. 1 of Aug. 8 1914) was purely offensive. It proposed to seek action with all forces united with the right on the Rhine. The two armies of Lorraine (I. and II.) were to lead, the I. in the direction of Saarburg, after having thrown back the German VII. Army towards Strasbourg and lower Alsace, while an isolated corps, the VII., would make a diversion to the east of the Vosges. The II. Army, covering itself from Metz, was to attack in the direction of Saarbrück, pivoting on the I. in the neighbourhood of Étangs. The two left corps were situated to the west of the Moselle, with a view to their eventual employment in the north.

Disposition of Forces.—In front of the I. and II. Armies the Germans had approximately equal strength (VI. and VII. Armies). They would at first keep to the defensive, acting as a pivot to the huge wheel being made by their centre and right. The rapidity of the invasion of Belgium determined the French to hasten the operations in the east in order to make a diversion. On Aug. 13, the I. Army had two corps on the Meurthe (VIII. and XIII.). Gen. Dubail, commanding the I. army, counted besides on the co-operation of the two right corps of the II. Army and on that of the XXI. Corps descending from the Vosges on his right. On Aug. 16 the II. Cavalry Corps was placed under his orders. The final concentration of the complete fighting force, however, could not be complete until the 18th. Nevertheless, the XIII. and VIII. Corps moved on the 14th, and on the 15th entered Cirey and Blamont, pushing back the I. Bavarian Corps, which retired toward Saarburg.

By the evening of the 17th the two French corps had reached the line Vasperveiller-Aspach-St. Georges, and the XXI. extended the line toward the Vosges. The II. Cavalry Corps had orders to go ahead on the 18th towards Saarburg, which was entered after a skirmish. The XXI. Corps pushed to the north-east as far as Walscheid; the XIII. held the heights north and east of Saarburg; the VIII., marching on Heming, seized the passage of the Marne-Rhine Canal and entered Saarburg. The II. Cavalry Corps bivouacked toward Diane-Capelle, in liaison with

the II. Army, which had reached the line Bisping-Château Salins. The Germans held entrenched positions on a front of 40 m., from the neighbourhood of Dobbenheim to Biberkirch.

French Offensives.—It was decided that the I. Army should attack with its left northwest of Saarburg, its centre and right standing fast to repulse an eventual counter-attack in the Vosges. The II. Cavalry Corps was to move on Saar-Union in order to operate south of the Saar. On Aug. 19 the VIII. Corps commenced the attack before dawn, gained the terrain northwest of Saarburg and repulsed a counter-attack. On the 20th it resumed the offensive, but during the morning it became evident that it was incapable of opening a passage for the Cavalry Corps; indeed it was necessary to bring back a division on the canal with heavy losses. In the centre and on the right the French were more fortunate. The XXI. Corps met no resistance on the 19th, and the XIII. had not yet been engaged.

On Aug. 20, the XXI. Corps, attacked by the German XIV. Corps, inflicted on it a serious check near Walscheid; the XIII. Corps, coming into line, attacked to the northeast of Saarburg, disengaging the right of the VIII. Corps, which held the town till nightfall. Dubail's intention was to entrench on the front Kerprich-Soldatenkopf, and to undertake afterwards a methodical advance; but the check to the II. Army led Joffre to direct a retreat in Lorraine. On the morning of Aug. 21 the I. Army retired slowly towards Blamont. Afterwards it was necessary to accelerate the movement on account of the rapidity of the retreat of the II. Army. On the evening of the 23rd, the I. Army extended from Dames-aux-Bois to the Col du Bonhomme. It had suffered heavy losses, the casualties in the VIII. Corps amounting to more than 50 per cent.

The offensive of the II. Army (de Castelnau) had been still less fortunate. On Aug. 14 the XVI. and XV. Corps moved in the direction of Avricourt, with the bulk of the XX., the remainder covering the front to the north. In the evening, it faced to the northeast on the high ground at Gondrexon, the XV. Corps alone having been stopped by the enemy at Moncourt. On the 15th the advance was still checked by the condition of the XV. Corps, which had suffered heavily; the XVI. Corps reached Igney-Avricourt, the XX. Bezauge-la-Petite and Xanrey. The IX. Corps remained on the Grande Couronne east of Nancy and sent out detachments toward the northeast.

On Aug. 16 the Germans continued their retreat and the French followed rapidly as far as Morhange, northwest of Donnelay. On the 17th the army was to swing round to the northwest toward Delme-Chateau Salins-Dieuze. The XVI. Corps progressed without difficulty; the XV. occupied Marsal, but could not bring its main body beyond the Seille; the XX. Corps, in possession of Château Salins, reconnoitred toward the north. Rearguard fights only were expected, but on the 18th the XVI. Corps from the early morning met the enemy in strength. The German artillery held the XV. Corps in the valley of the Seille and prevented it from occupying Dieuze. The XVI. Corps had to fall back on Angviller, and only the XX. advanced to the north of Morville-les-Vic and Château Salins. In spite of the loss of the IX. Corps, sent to the IV. Army on Aug. 18, de Castelnau ordered for the 19th the continuation of the offensive in the direction of Loudrefing, Bensdorf and Morhange.

French Retreat: Aug. 19–20.—From the morning of Aug. 19 the XVI. Corps was stopped on the Salines canal; the XV. could not pass Zommange and Vergaville; and only the XX. could make a real advance, pushing a brigade as far as Morhange. The 68th Res. Div., which had relieved the IX. Corps, insufficiently covered the left of the XX. Corps. De Castelnau ordered for Aug. 20 a combined attack by the two other corps on the line Cutting-Dommon-Bassing; the XX. was to consolidate its positions, ready to march to the north or northeast. On the 20th the corps on the right, instead of progressing, was attacked and even thrown back. The XX. having attacked and not having improved its positions was stopped by de Castelnau, but the Germans, taking the offensive, threw the left back on Château Salins. The right followed this movement on Lidrequin and the 68th Div. resumed its position of the previous day. At 4 P.M. the general ordered a retirement, which began during the night and continued through Aug. 21 under the protection of the XX. Corps and the 68th Division. In spite of the arrival of two new reserve divisions and the II. Cavalry Corps, the II. Army had to retire to the west of the Meurthe, the left to St. Nicholas. To the north, three divisions held the Grande Couronne.

French I. Army Action.—On Aug. 23, the I. Army commenced a three weeks' battle destined to stop the enemy and support the strongly attacked II. Army. To effect this, it took the offensive on the 24th and 25th, while the II. Army threw back the Germans to the northeast. From the 28th to the 31st the Germans stopped the advance of the I. Army, and their VI. and VII. Armies even aimed at forcing "the gap of Charmes," in such a manner as to carry out an enveloping movement to the west of the Vosges. This action was helped by ordering the XXI. Corps to take part in the battle of the Marne.

From these circumstances there resulted a series of very confused fights extending over a large front between the Grande Couronne and the Vosges. On Sept. 6, the German VII. Army, facing Dubail, was broken up, divided between the VI. Army and the German right then engaged on the Ourcq against Gen. Maunoury. But Dubail's army was also enfeebled by the removal of the XIII. Corps to the west of the Oise; and at the same time the II. Army lost to the west the 18th Div. and the XV. Corps. Evidently both sides had given up the idea of striking seriously in Lorraine. After having gloriously held its positions to the east of Nancy and on the Meurthe, the II. Army was itself to be broken up, to be reconstituted on the left of the French Armies in the "race to the sea."

Thus, after checks resulting from an inopportune offensive, the I. and II. Armies had been first able to stop the German progress; then to throw the enemy back to the frontier. Moreover, their merit was all the greater since they had been constantly weakened by the withdrawal of their best units. During the battle of the Marne they provided the unshakable pivot of the vast movement undertaken by the Allies. It was thanks to their efforts that that movement succeeded. But they had paid the price. A single reserve division between Aug. 24 and Sept. 12 lost 140 officers and more than 5,000 men.

(B. E. P.)

III. BATTLE OF THE ARDENNES

On the outbreak of the World War, the III., IV. and V. French Armies concentrated towards the frontier, west of the Meuse, covered by the VI. Corps in front of Verdun, and the II. Corps in front of Stenay. On hearing of the German attack on Liége, Gen. Joffre decided to post the V. Army (Gen. Lanrezac) toward the Sambre and to direct the IV. Army, which he had grouped between Vitry-le-Français and Sainte-Menehould, in the region of Stenay. The concentration, which had scarcely begun on Aug. 8, was nearly finished on the 14th. Until the commander-in-chief had all his forces at hand, no one was allowed to be drawn into an important action.

The German high command had made a similar decision, hence the battle of the Ardennes was the "battle of the two blind men." However, on Aug. 10, a German mixed brigade arrived near Mangiennes and was launched into a mad frontal attack against the advanced posts of the IV. Corps (III. Army). While all its attention was taken up with the attack in front, a brigade of the II. Corps (under Gen. Cordonnier, IV. Army) took it in the rear, and the German brigade was destroyed. After this adventure, no German force made any further attempt against the French covering troops.

French Plan of Attack.—The German plan of operations placed the V. Army between Thionville and Tintigny, the IV. between Tintigny and the Meuse de Dinant,[1] the III. Army between Dinant and the Sambre, the II. on the Sambre and the I. in the neighbourhood of Mons. The III. Army was still in the

[1] Name given to the Meuse between Mezières and Namur.

Ardennes behind the IV. and the I. Army was hastening towards Brussels and Antwerp, when on Aug. 22 Joffre decided to attack.

It was certainly a strategic success to bring about a battle with all his forces in the Ardennes, while the German III. Army was unable to take part in it. Joffre had disposed his III. and IV. Armies in échelon, the left in front, so that he could face the north or east as he wished. On Aug. 16 he decided to attack towards the north with these two armies forming a rigid block, while the 7th Cavalry Div. reconnoitred towards Thionville, and the 4th and 9th Cavalry Divs. to the north towards the Meuse. The result was that in front, and almost everywhere, the Army Corps had only weak and insufficient cavalry for reconnoitring purposes. The liaison between the two armies was to be kept on the axis Marville-Virton-Étalle.

During the night of Aug. 20–1 the whole block moved forward. The only instructions given by G.H.Q. were "to attack the enemy wherever met." G.H.Q. estimated that the IV. Army would have almost nothing in front of it, and yet it was precisely there that the Germans had their IV. and III. Armies, the III. being behind the IV. The Lorraine Army, which consisted of the reserve divisions, groups under Gens. Pol Durand and de Lamaze, was placed under the command of Gen. Maunoury with orders to defend the Hauts de Meuse, or eventually, in the event of the advance of the III. Army, to besiege Metz and Thionville. These reserve divisions were mobilised after the active forces, the men were elderly, they had few officers, and their staffs were inexperienced, so that the III. Army could get little help from them.

On the evening of Aug. 21, after a long period, during which only patrols had been encountered, the block arrived on the line Conz-Lagranville (VI. Corps), Tellancourt (V. Corps), Virton (IV. Corps). At Virton the IV. Corps tried to get in touch with the II., which formed the right of the IV. Army. The line of battle continued by Villers-la-Loue (II. Corps), Geronville (Colonial Corps), Florenville (XII. Corps) and the Semoy (XVII. and XI. Corps). The IX Corps had just arrived from the neighbourhood of Nancy with the 17th Div. (Dumas); the Moroccan Div. (Humbert) was not yet in line. The IV. Army (de Langle de Cary) was to push on towards the north, while the III. Army was to cover the right of the IV. Army against any attack coming from the north or east. Everywhere the advance was made in divisions, except in the case of the II. Corps, which marched entire on a single road.

On Aug. 22, all the columns started in a fog at a very early hour for a long march with the idea of "attacking the enemy wherever met." To march quickly rather than to take precautions was the order of the day and almost everywhere the presence of the Germans was only discovered by receiving shell fire. In the III. Army, the V. Corps sent its infantry to the attack without the support of artillery, and it suffered such terrible losses that the leaders became completely unnerved, and Gen. Grossetti, chief of the staff, had to intervene to prevent a precipitate retreat. In the IV. Army the Colonial Corps exposed a division in column-of-route to the German guns. The XVII. Corps also suffered from a sanguinary surprise. But the most serious danger arose on the right wing of the IV. Army, uncovered by the premature check of the IV. Corps at Virton; and on the right wing of the III. Army, which was not covered either by the 7th Cavalry Div. or the Pol Durand group of divisions.

Fortunately the II. Corps was in a single column so that the rear division was able to make up for the absence of the IV. Corps. On the right of the III. Army there was a leader, Gen. Hache, who with his heroic division gained the necessary time for the other divisions to fall back. The Germans did not exploit their tactical success, but remained practically stationary in their positions. This battle of the Ardennes taught the French the necessity for co-operation of all arms in the field of battle.

Battle of the Meuse.—On Aug. 23, 24 and 25 the III. and IV. Armies retired slowly without being disturbed. On the evening of Aug. 23 the front of the IV. Army was the line Montherme (Meuse)-Montmédy; and that of the III. Army Montmédy-Spincourt. On Aug. 24 they were a little farther to the rear, but not pushed by the Germans. A German staff commander, killed in his motor in front of Avioth, was found to have on him the orders given to the German IV. Army for the forcing of the Chiers and Meuse crossings on Aug. 26 and 27. The III. Army had obtained in a similar way information to the effect that the German 33rd Div. was to leave Metz and attack at Étain. A trap was set, but the Lorraine Army (reserve troops) was not equal to the task and the Germans escaped.

Lorraine Army Dissolved.—On the morning of Aug. 25, the right of the IV. Army retired between the Chiers and the Meuse; the III. Army also approached the Meuse facing eastwards. Thus the two armies practically became one, and it is regrettable that from this time they were not placed under one leader. On the same day, the IV. Corps (III. Army) suffered a severe check at Marville and they feared they would lose their corps artillery, but the II. Corps came to their assistance and convoyed this artillery to Stenay, where they crossed the Meuse. This shows how intimate was the co-operation between the two armies. It was on Aug. 25 also that Joffre gave the first orders which contained the real beginnings of the battle of the Marne. He decided to reinforce the left of the Allied Armies and to lose ground in order to gain the necessary time for his strategic plans. The Lorraine Army was dissolved; the Pol Durand group was to defend the Hauts-de-Meuse; Verdun and Toul were to have their respective mobile forces returned to them; the 55th and 56th Divs. were entrained for Montdidier. Gen. Maunoury had in these two divisions the nucleus of that VI. Army which appeared on the Ourcq and determined the victory of the Marne.

On the morning of Aug. 26 the entire IV. Army was on the left bank of the Meuse, protected on its left flank by the IX. Corps and the 4th and 9th Cavalry Divs. between Mezières-Rocroi and Signy-l'Abbaye, and forming the connection between the IV. and V. Armies. On its right flank it was in immediate contact with the III. Army, which was concentrated on the left bank of the Meuse with the exception of the 42nd Division. So much feared was the envelopment of the III. Army's right, that the 7th Cavalry Div. was sent to the rear to Dombasle, between Verdun and Clermont, as if an extensive enemy movement was expected to take place south of Verdun. The III. Army took no part in the battle of the Meuse; its 7th Div. was summoned to Beauclair in order to help the II. Corps on Aug. 27, but it was not engaged. On the same day the 42nd Div. was taken from the III. Army, reached Varennes, and then served as part of Foch's Army.

Defence of the Meuse.—On Aug. 26, the orders for the IV. Army ran: "From to-morrow the IV. Army will fight a decisive battle on the Meuse. . . . The corps will make every effort to prevent any attempt of the enemy to cross the river."

Generally speaking, the IV. Army was some distance from the left bank. Its object was to carry out vigorous counter-attacks against German infantry who had passed the river before its artillery could come to its support. The Colonial Corps was somewhat driven back by the Germans, who had crossed the Meuse at Inor and Pouilly, but the arrival of reinforcements from the II. Corps soon checked this. The struggle was severe on the whole front. On the right wing the II. Corps had decided successes, three times throwing the Germans back into the river at Cesse and Luzy. On the left wing, the success was still more marked. There the XI. Corps, reinforced by the 52nd and 60th Res. Divs., gained the battle of la Marfée. The German 16th Div., making the same mistake as did the French at the battle of the Ardennes, advanced in massed formation without artillery support and were crushed, leaving in French hands the flag of the 68th Prussian Regiment.

On the evening of Aug. 27 Gen. de Langle de Cary gave the following order: "At all costs the Germans must be thrown back into the river Meuse. The successes gained by the offensive to-day make us hopeful that to-morrow will be equally successful." However, Aug. 28 was not so active as the previous day; the Germans scarcely attacked at all, and the orders given by Joffre for the coming retirement to the Aisne kept the IV. Army to its ground. On Aug. 28 Gen. de Langle de Cary, in a general order,

said: "The army inflicted heavy losses on the enemy, yesterday and to-day. It returns to the Aisne line, in accordance with orders received, to prepare for the offensive in a new direction." On the 29th the movements towards the Aisne commenced—the battle of the Meuse was ended. The French IV. Army had beaten the German IV. Army—a victory without a to-morrow, but certainly a victory.

Battle of Signy-l'Abbaye.—The French V. Army, having been beaten by the German II. Army on Aug. 22 and 23, had to retreat, leaving a gap 25 m. wide between the IV. and V. Armies. The Germans poured into this open space. The only known units were the advanced troops of the XII. Corps—it was really the III. Army commanded by Von Hausen. Gen. Dubois was ordered to fill up this gap and to cover the left of the IV. Army, and was given command of the IX. Corps, composed of the 17th Div. (Dumas), the Moroccan Div. (Humbert), and the 9th Cavalry Div. (de l'Espée). The 4th Cavalry Div. had been given up to the V. Army. Two roads led to the region occupied by the Germans at Rethel. The road Mezières-Rethel was barred by the 17th Div. and the 9th Cavalry Div. at Guignicourt, the road from Rocroi to Rethel by the Moroccan Div. at Signy l'Abbaye Launois.

On Aug. 28, the 17th Div., hearing the guns from la Marfée, had its attention drawn in that direction. On the same day, at 3 A.M., the advanced posts of the Moroccan Div. were attacked by the XII. (Saxon) Corps. At 11 A.M. the Moroccan Div. was turned in the west by the enemy, who seized Signy l'Abbaye and so opened up the way to Rethel. But the Germans did not exploit their success and allowed themselves to be checked at Novion-Porcien. The battle manoeuvres lasted through Aug. 29 and 30. Dubois, by clever movements, brought his forces to the north of Rethel, having thus accomplished his difficult mission. Again German strategy had not made the best use of its superior strength.

IV. CHARLEROI AND MONS

Charleroi and Mons are the names given to the battles fought by the French V. Army and the British Army respectively in the latter part of Aug. 1914, against the right and right centre of the Germans.

The French Position.—Inasmuch as the British did not come up into line until Aug. 22, it will be necessary to deal with the purely French situation first. Germany had declared war on France on Aug. 2 and the right wing had crossed the Belgian frontier on the 5th. By Aug. 20 1914 the forward movement of the German right-wing armies into Belgium, and the failure of the offensive of the French I. and II. Armies, had caused a modification in Gen. Joffre's original plan of campaign. Broadly speaking the intention now was to attack through Luxembourg and Belgian Luxembourg with the object of threatening the communications of such German forces as had crossed the Meuse between Namur and the Dutch frontier. This duty devolved primarily on the III. and IV.—*i.e.*, the centre—Armies of the French. In the south the I. and II. Armies were to make a secondary offensive between Metz and the Vosges to hold the enemy, who might otherwise be able to take in flank the French advancing through Luxembourg; and the French V. Army and the British Army were to act upon the offensive, though this offensive would depend almost entirely on success by the III. and IV. Armies to their right.

On the evening of Aug. 20 the French V. Army was either actually within, or entering, the area bounded by the river Sambre on the north and the river Meuse on the east. The junction of these two rivers formed a very marked salient; but so far from being a point of weakness this locality was at the moment of great strength. It was sealed by the strong Belgian fortress of Namur which was to be the pivot of an Allied right wheel in the projected offensive. On the 20th there arrived from G.H.Q. the orders for Gen. Joffre's new offensive. The orders were to the effect that all information pointed to the intention of the Germans to carry out an outflanking movement in the north. The French III. and IV. Armies had been ordered to march against the line Neufchâteau-Arlon. As for the V. Army, its task was to pivot on Namur and the Meuse, and to seek out the main enemy mass in the north. On the left of the V. Army the British Army would advance towards Soignies in the direction of Nivelles.

British Expeditionary Force.—When England declared war on Germany during the night of Aug. 4–5 her forces available to take the field consisted of a cavalry division, six infantry divisions and some battalions of line-of-communication troops, the whole forming the Expeditionary Force for service overseas. The Govt. decided to retain two divisions temporarily in the United Kingdom and to transport the rest of the Expeditionary Force to France. The first ships sailed on Aug. 9 and, thanks to the perfection of the arrangements for mobilisation and transportation, the operation was completed without a hitch by Aug. 18. Sir John French, the British commander-in-chief, had reached his headquarters at Le Cateau on the previous day; and his army consisted of the I. Corps (1st and 2nd Divs.), Lt.-Gen. Sir Douglas Haig; II. Corps (3rd and 5th Divs.), Lt.-Gen. Sir Horace Smith-Dorrien; and the cavalry division under Maj.-Gen. Allenby, as well as line-of-communication troops. Concentration was completed by the 20th, south of Maubeuge; and the post assigned to the British was on the left of the French V. Army, preparatory to the advance north of the Sambre towards Soignies referred to above.

While his army was concentrating, Sir John French visited Gen. Joffre at Vitry-le-François on the 16th and discussed possible alternatives of action depending on information of the enemy's plans and dispositions. The main intention was, however, to attack. Next day, French visited Gen. Lanrezac at Rethel and there conferred with the commander of the V. Army. Lanrezac considered that it was not possible to carry out at once the order to attack, so far as it affected his V. Army. The whole of his troops had not yet come to hand. Then it had to be borne in mind that the British had not yet come up on the left, and that the action of the V. Army would also depend upon the success of the French IV. Army on the right. Lanrezac therefore confined himself for the moment to issuing orders for the occupation of a defensive position by the X. and III. Corps, south of the Sambre.

German Offensive Plan.—On this same day (Aug. 20), on the side of the Germans, a combined attack had been arranged in which the II. and III. Armies were simultaneously to attack the French V. Army, from the north and east respectively. The German I. and II. Armies were to close up to the line reached on that day, and an offensive against the enemy west of Namur was to be carried out in co-operation with an attack by the III. Army against the line of the Meuse between Meuse and Givet, details being left for decision by the Army headquarters concerned. As regards the British, the German Intelligence Dept. was woefully at fault, for it was stated that a "disembarkation of the British forces at Boulogne and the neighbourhood must be taken into account. It is the opinion here, however, that a landing on a large scale has not yet taken place." At the time, two-thirds of the British force was within 30 m. of Gen. von Bülow.

During the day the Germans attacked the French detachments on the Sambre. The events of the day had resulted in dislocating Lanrezac's preparations for the offensive, and at 12:30 P.M. he wrote to Joffre as follows: "I consider it dangerous to let the V. Army cross the Sambre during the 22nd, minus, on the one hand, the I. Corps, which must hold the Meuse until the IV. Army has made sufficient progress north of Semoy, and minus, on the other hand, the English who on the 22nd will not be able to get farther than Mons." During the evening a reply came from Joffre to say that Lanrezac could choose his own time for the offensive, and he accordingly decided that it would be launched on the twenty-third.

Early on the 22nd, fighting was resumed all along the French front on the Sambre. The X. Corps was forced back, and during the afternoon the road from Fosse to St. Gerard was crowded with artillery, infantry and transport moving southward. Fosse was occupied by the Germans about 8 P.M. Farther west the III. Corps had likewise to give ground. Severe fighting took place early in the afternoon round Chatelet, and both divisions had to retire, the 5th toward Tarcienne and the 6th to Nalinnes. By 1 P.M. the III. Corps had definitely to renounce its grip on the southern outskirts of Charleroi.

As for the XVIII. Corps, it came upon the field, but was south of the Sambre between Thuin and Malines instead of being, as Lanrezac had hoped, on the Mons–Charleroi road in touch with the British. The Cavalry Corps of Gen. Sordet had fallen back during the night to Solre, and in the afternoon was sent to guard the crossings from Jeumont to Thuin, and also to hold the cross-roads at Merbes Ste. Marie on the far side of the river. The night march following on long and arduous work in Belgium had been fatiguing to the horses, and the cavalry corps was in need of rest. Joffre had prescribed that it was to move to the British left, but Lanrezac considered that it was not in a fit state to move until the twenty-third. It was not, however, until the evening of Aug. 25 that it arrived behind the left flank of the British.

To Lanrezac on the evening of the 22nd, the situation of the V. Army seemed grave, but by no means desperate. Only two of his corps, the X. and III., had been engaged, and if these had suffered heavily they had also made the enemy pay the price. Withdrawn to more open terrain, where their artillery could render better support, they could re-form and, so he hoped, in their turn take the offensive. Further, the I. Corps was intact and now becoming available on the right, as was also the XVIII. Corps on the other flank; and the reserve divisions of Gen. Valabregue were coming up to support it. The British were now arriving in position on the left, round Mons. In one way Lanrezac was much more fortunate than he knew. Von Bülow had attacked prematurely by forcing the Sambre on the 22nd instead of waiting for the attack of the III. Army against the Namur-Givet section of the Meuse to take effect, and the retirement of the V. Army during the 22nd had seriously discounted the German chances of enveloping it.

The British Army in Position.—The British Army had practically completed its concentration on Aug. 21 and on the following day took up a position from Condé to Mons and thence southwest of that town, so as to be able to co-operate in the forward movement, pivoting on Namur, as ordered by Joffre. As a matter of fact Namur had been attacked by the Germans and during this day was *in extremis*. This fact was, however, unknown to French, who motored early in the morning from his headquarters at Le Cateau to visit Lanrezac at Philippeville. To his dismay French, on entering the area of the French V. Army, witnessed columns of infantry and artillery moving south. A British liaison officer reported that the Germans had forced the passage of the Sambre and were also making a wide turning movement through Belgium.

French at once decided to give up the attempt to find Lanrezac and returned to Le Cateau. From there he despatched a message to Lanrezac to say that he was waiting for the French Cavalry Corps to be posted on his left, as had been promised, and that he was prepared to fill the rôle allotted to him when the V. Army advanced to the attack. He also pointed out that his position was much in advance of the line now held by that army and hinted that although prepared to carry out his rôle he could not begin to do so until the French V. Army should recover some of the ground already lost. Late at night a French staff officer from Lanrezac's headquarters confirmed the news of the fighting which French had heard of during the day and asked if French, by striking at the right flank of the German columns, could thus relieve the pressure on the V. Army. The British commander-in-chief considered that this was quite impracticable but agreed to hold on to his position for 24 hours.

Situation on Aug. 23.—On the morning of Aug. 23—the day on which the battle of Mons was fought—the general situation of French and British was as follows: The French V. Army faced in two directions, east and north. The I. Corps was on or behind the Meuse, where all bridges had been destroyed except those at Dinant and Hastière. The X. Corps had its right on the high ground south of Fosse and Vitrivel, its left at Scry. The III. Corps (reinforced by a brigade from the XVIII. Corps) was deployed on the line Gerpinnes-Nalinnes-Claquedent. The XVIII. Corps was on the line Ham-Thuin, with detachments on the Sambre as far as Merbes-le-Château. The French Cavalry Corps was holding the passages of the Sambre from the left of the XVIII. Corps to Maubeuge. The 53rd and 69th Reserve Divs. (Gen. Valabregue) were about Solre le Château, and were to relieve the Cavalry Corps, which was to make for Maubeuge with the object of emerging eventually on the left flank of the British Army.

The British right flank was north of the Sambre between Erquelinne and Peissant. From here was the I. Corps—looking northeast—with its left near Mons. In front of the line, about Binche, was the 5th Cavalry Bde., which was subsequently withdrawn. The II. Corps carried on this line, from and including Mons, west of which there was a French division of territorials. The main body of the cavalry was in rear of the British left.

In this position of the theatre of war the I., II and III. German Armies were concerned. The German plan had been that the II. Army was to attack south across the Sambre, while the III. Army was to co-operate by attacking west across the Meuse, sending a strong force across the Meuse towards Rocroi to bar the French line of retreat. During Aug. 23, the I. Army (von Kluck) was to conform to this offensive movement. Gen. von Bülow had, however, made the mistake of attacking prematurely with his II. Army; the combined movement with the III. Army was unsuccessful, and consequently the trend of the fighting drifted westwards to where the advanced guards of the I. Army were coming into contact with the British on the Mons-Condé canal.

Batile of Charleroi.—In his published account of the battle of Charleroi, Lanrezac divides it into two distinct phases, the first from daybreak until 4 P.M., and the second from that hour until nightfall. In the first phase the course of the battle was as follows: The right wing of the X. Corps was driven back, and it reformed between Scry and St. Gerard; the I. Corps deployed on the high ground round St. Gerard with its right about Sart-St. Laurent. This operation was completed about midday, and the I. Corps was then well placed to act against the flank of the German Guard Corps, which was then attacking the X. Corps sharply. Gen. Franchet d'Espérey, commanding the I. Corps, instantly resolved to seize the opportunity and to attack *au fond*. His artillery prepared the way by an intense fire, and the Germans, apparently taken by surprise, suspended their attack to deal with this new danger.

It was now about 1 P.M. and Franchet d'Espérey was about to launch his infantry when disquieting news reached him from his right rear. The 51st Reserve Div., which had relieved the I. Corps on the Meuse, had failed in its task, and had allowed troops of the German III. Army to cross the river. The report went on to say that the reserve battalions had fallen back in disorder and that a detachment of the enemy had occupied Onhaye behind the V. Army. Franchet d'Espérey had no alternative but to suspend his attack and to send a division and a brigade to deal with the peril behind. Emboldened by the enforced inaction of the French, the Guard Corps again pressed on, its artillery maintaining a very severe fire. The French X. Corps and the fraction left of the I. Corps resisted energetically, with the result that in this portion of the field but little ground was lost, and connection was still maintained with the fortress of Namur.

While such was the state of affairs on the right wing, little was, in this first phase, taking place on the left wing. But after 4 P.M. a change for the worse set in, in that portion of the field. The left wing of the III. Corps was taken by surprise and driven back by a sharp attack, with the result that the whole III. Corps

fell back in confusion, while the XVIII. Corps, with its right now uncovered by the retirement of the III. Corps, was forced to withdraw to the stream which runs from Thuilles to Thuin. The reserve divisions of Gen. Valabregue, however, had come up to Bousignies and Thirlemont. On the right wing, in this second phase of the battle, the X. Corps had been forced to admit a loss of ground, but it was only slight. As for the I. Corps, the portion left at St. Gerard was holding its ground.

During Aug. 23 Gen. Franchet d'Espérey had been called upon to deal with the presence of a detachment of the German III. Army which had forced its way over the river. Some sharp fighting took place, and about 10 P.M. the French infantry carried Onhaye with the bayonet. This attack by the French came upon the Germans somewhat by surprise, and the units of the III. Army on the right bank of the Meuse were in consequence retained there for the moment.

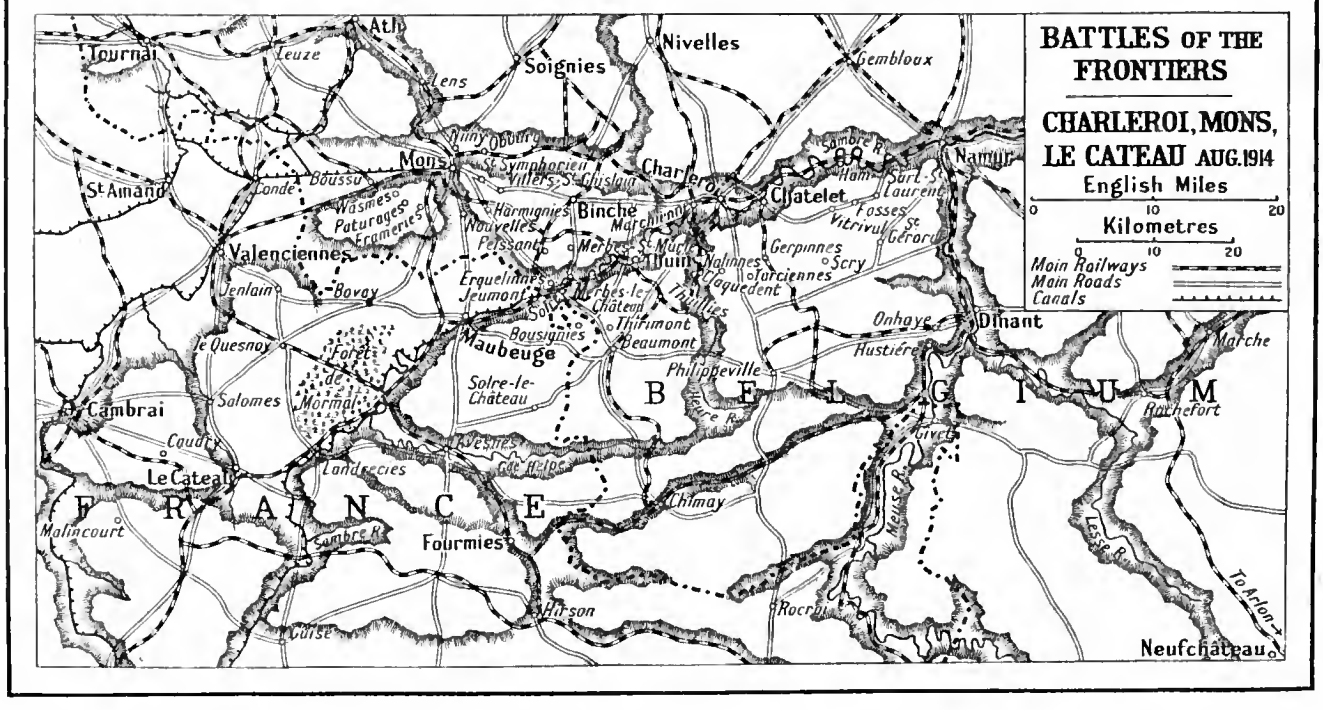
At the end of Aug. 23 Lanrezac came to the conclusion that immediate retreat was called for on the part of the V. Army. The chief causes of his decision are given by himself as follows: In the first place he had learnt definitely that the offensive of the IV. Army had failed and that the beaten troops were falling back to the Meuse with the left of the army on Mézières. The line of the river between that place and Givet was guarded by but a few battalions of reserve troops. The rear of the V. Army was thus threatened once again. In the second place Namur had fallen; in addition the roads on the right flank of the V. Army, already encumbered with thousands of civilian refugees, would be further blocked by the retreating Belgian troops from the fortress. Thirdly, the British Army was checked, and would in all probability be compelled to retire. Lanrezac, therefore, issued orders for the V. Army to retire on Aug. 24 to the line Givet-Philippeville-Beaumont-Maubeuge. Lanrezac's statement that his action was in part due to the conviction that the British would be forced to retire is a variant upon a previously held French opinion that such retirement actually preceded the retreat from Charleroi. How far both these statements are from the truth will now be seen.

The Battle of Mons.—The British position in detail was as follows: On the extreme left, about Condé, was the British 19th Bde., made up of battalions of line-of-communication troops in touch with a French division of territorials. Then came the 5th Div., while next on the right was the 3rd Div., holding a salient round Mons as far southeast as Villers St. Ghislain. The line was continued by the British I. Corps farther southeastwards to Peissant. The cavalry division was in rear of the British left, except the 5th Cavalry Bde., which was posted in advance of the right flank, but later withdrawn.

The British position was thus in shape somewhat like a broad arrow, with the two army corps practically at right angles to one another and facing, generally speaking, north and northeast respectively. As matters turned out, the German attack was directed almost entirely against the II. Corps, and here on the left the situation was not unfavourable to the British, for the canal made a valuable defensive line, while the terrain on the farther side held numerous difficulties for the attackers. Muddy ditches and barbed-wire fences impeded their movement, although, on the other hand, groups of trees and bushes gave cover from view and were of service for the enemy's machine-guns.

South of the canal the crests of the high ground afforded the British useful sites for artillery, but the slag heaps of the numerous mines limited observation to some extent. The line of the canal, however, had one very disadvantageous feature: after running from Condé to Mons in a mathematically straight line, it forms a loop round Mons, thus constituting a marked salient. Such a position might easily be found to be untenable, and Sir Horace Smith-Dorrien had prepared another and more defensible line in rear running through Frameries-Paturages-Wasmes-Boussu.

When day broke on Aug. 23 Von Kluck had three active corps and Von Bülow one, or about 150,000 men and 600 guns, within striking distance of the British force of some 75,000 men and 300 guns. The German I. Army was to march in a southeasterly direction. The British II. Corps on the Mons canal was facing north. Consequently the left of Von Kluck's army must collide with the II. Corps in the neighbourhood of Mons. As a matter of fact the German commander was in ignorance of the position of the British force. The march of the German I. Army, on the 23rd, was therefore shrouded in the fog of war, and, quite early in the day, delay was caused by a report that Tournai was held by British troops. These were actually two French territorial battalions, but, under the impression that they were British, orders were sent to the IV., III. and IX. Corps to halt on the Leuze-Mons-Binche road, in view of the possibility that it might be necessary to make a wheel to the right so as to envelop Tournai. Later reports showed that the British were in strength on the canal, and that the troops at Tournai, now known to be French, had retired toward Lille. The advance of the German I. Army was therefore resumed. But the orders for this resump-



tion of the march were late in reaching the III. and IV. Corps, with results that reacted on the German chances in the battle.

The left column of Von Kluck's army was the 17th Div. of the IX. Corps, and its march was directed towards St. Symphorien and Villers St. Ghislain. On the British side the I. Corps was on the line, generally, Harmignies-Peissant, and as it faced a gap between the German I. and II. Armies its share in the battle of Mons was destined to be very small. It was shelled by German artillery, covered in its advance by the 16th Dragoons, but the British casualties were slight. Of active fighting there was none save for some spirited minor actions between the British divisional cavalry and cyclists on the one hand and German patrols on the other. The bulk of the day's fighting fell upon the salient formed by the canal loop round Mons. So soon as Von Kluck had grasped the real state of affairs his plan appears to have been to envelop both the British flanks while bombarding the front heavily with his guns. The envelopment of the British left did not succeed, owing chiefly to the delay referred to above.

The battle opened in earnest about 10:30 A.M. with a bombardment by some batteries of the German IX. Corps which came into action on a ridge to the north of Orbourg, and from that time onward the guns were gradually extended westwards as battery after battery, first of the IX. and then of the III. Corps, came into action. At 1 P.M. the Germans had established a great superiority of artillery against the front of the British II. Corps. The actual loop of the canal was held by the 4th Royal Fusiliers and the 4th Middlesex Regt., the former being responsible for the bridge at Nimy while the right of the latter regiment held the crossing at Orbourg. At both these places the fighting was very severe, but the British musketry proved a terrible surprise to the Germans, who came on in masses which it was impossible to miss, and the British guns, though outnumbered by the German artillery, gave most effective support. Finally, however, the Germans were able through their superiority in numbers to make a converging attack against the salient from the north and east, and the British were gradually forced back east and south-east of Mons. But the Germans were cautious about pushing into the town, and it was not until after 7 P.M. that the 84th Regt. of the 18th Div. of the IX. Corps entered Mons, where it was thrown for a time into confusion by heavy fire. The British 3rd Div. fell back to a line running east and west through Nouvelles.

West of Mons the left division of the German III. Corps attacked the left of the British 3rd Div.; and still farther west along the canal the right division of the III. Corps, and later towards evening, the advanced guards of the IV. Corps, attacked the 5th Div. of the British. The retirement of the 3rd Div. from the salient round Mons inevitably led to a slight withdrawal of the 5th Div., and by nightfall the II. Corps was on a line which showed an average retirement of some three miles from the canal.

The Retreat Begins.—During the late afternoon and evening French had been receiving disquieting news as to the situation of the French V. Army on his right. At 11:30 P.M. a telegram arrived confirming the reports, to the following effect: Namur had fallen during the day; the French V. Army had been heavily attacked, and was falling back to the line Givet-Philippeville-Maubeuge; Hastière had been captured by the Germans; the Meuse was falling rapidly and had added to the difficulty of defence. In these circumstances not only was the original offensive out of the question, but the British line was now untenable. French, therefore, decided to retreat to a previously reconnoitred line from Jerlain eastwards to Maubeuge, and orders were issued accordingly in the early hours of Aug. 24. The withdrawal was effected without serious loss, and for a moment French thought of taking advantage of the fortifications of Maubeuge; but recollections of the fatal attraction of Metz for Bazaine induced him to pass the fortress, and orders were issued at 3 P.M. on the 24th for the retreat to be continued to the line Le Cateau-Cambrai.

V. BATTLE OF LE CATEAU

The battle of Le Cateau was fought by the left wing of the British Army on Aug. 26 1914, during the retreat from Mons. After Bavai the retreat was handicapped by the Forêt de Mormâl, which compelled the British Army during the 25th to march in two separated portions, the I. Corps east of the forest and the II. on the west. During the previous night the detrainment of the 4th Div. from England was almost completed, and it moved to its position towards Solesmes.

Meanwhile reports showed that the French were retiring all along the line, and Sir John French had now to decide whether to stand and fight on the line Le Cateau-Cambrai, or to continue the retreat at daybreak on the 26th. He decided that the retreat should be continued, and orders to that effect were accordingly issued. The order was complied with by the I. Corps, and after some delay caused by a violent attack by the Germans on Landrecies, the retirement was continued on the 25th in the direction of Guise. In the II. Corps, however, shortly after midnight Sir Horace Smith-Dorrien came to the conclusion that, in view of the fact that many of his troops had just completed over 20 hours of heavy and continuous work, and that the enemy were close along his front, it was out of the question to continue his retirement at dawn. He therefore issued orders to fight on the ridge just south of the Le Cateau-Cambrai road.

Disposition of the Forces.—The force at Smith-Dorrien's disposal was as follows, from right to left: The greater part of the cavalry was between Le Cateau and the Sambre; later it moved to the left flank to get in touch with the French I. Cavalry Corps, which was in the neighbourhood of Malincourt. Then came the 5th Division. The 3rd Div. held the centre as far as Caudry, and on the left lay the 4th Division. Thence to Cambrai was a gap filled by the 4th Cavalry Bde., and later by the French I. Cavalry Corps. The French 84th Territorial Div. was retiring slowly through Cambrai. Each British division had a front of approximately three miles. The 4th Div. was incomplete, lacking divisional cavalry, signal company, ambulances, ammunition columns and heavy artillery. The 19th Bde. was the general reserve.

The German force on the heels of the British was the I. Army whose commander, Gen. von Kluck, was the victim of faulty conclusions before, during and after the battle. He believed that the whole of the B.E.F. was opposite him; he thought that it was holding a position running north and south, whereas the line of the II. Corps was almost due east and west, and he was sure that it was either retreating or about to retreat in a westerly direction. His plan was similar to that which had been tried at Mons, a frontal attack mainly with artillery followed by enveloping movements against both flanks. The cavalry was to pin the British left until the German infantry should arrive.

The German Attack.—Soon after daybreak the British were engaged upon both flanks. On the right some German troops entered Le Cateau and confused fighting ensued, while on the left the 4th Div. became engaged with the enemy. Here the 4th Div., after defending an advanced position for some time, fell back slowly to a second line and brought the enemy advance to a standstill. These events were but preliminaries, and the battle of Le Cateau proper opened with a heavy bombardment, which grew in intensity as the artillery of four German corps came into action. The British artillery made a spirited reply, though heavily outmatched in numbers and weight of metal, and dealt severely with attempts of the German infantry to push forward. These attempts were, however, practically limited to the ground near Le Cateau on the British right, and to the village of Caudry, which now formed a salient in the centre of the line. Throughout the forenoon constant infantry attacks, varied by bouts of heavy shelling, were made against the latter village, from which about noon the defenders were forced out by artillery fire; but a counter-attack at once regained part of it and the German infantry advance was held up.

Until 1 P.M. the line of the II. Corps was everywhere intact in spite of the superior numbers arrayed against it. But on the right the situation was becoming grave, for the 5th Div., with its right

flank uncovered by the retirement of the I. Corps, was being threatened by more and more German columns converging upon the field. Smith-Dorrien realised that at all costs the fight must be broken off if his force was to be saved. Orders were sent to break off the fight and to continue the retirement of the previous days. Before the orders for retreat had reached all concerned the British right had given way before overwhelming numerical superiority. But the Germans failed to exploit this success, and the withdrawal of the II. Corps, thanks largely to the devotion of the British artillery and to the arrival of the French 1. Cavalry Corps on the left, was effected with less difficulty than had been expected. Smith-Dorrien successfully withdrew his columns and marched them swiftly to the Somme at and near Ham. By Aug. 28 the II. Corps was safely across the river.

The losses of the British had been severe, 38 guns had been lost, and the casualties were over 7,800, the 4th Div. suffering particularly. The retreat was practically unmolested, for Von Kluck hurried southwest instead of south, and thus missed a chance not likely often to occur in war.

VI. BATTLE OF GUISE

By Aug. 25 the succession of victories achieved in Lorraine, the Ardennes and on the Sambre had produced an atmosphere of optimism at German general headquarters. It was thought that forces might be safely diverted to East Prussia to deal with the Russian invasion. Accordingly, on the 26th, two corps and a cavalry division received orders to proceed to the Eastern Front. On the side of the Allies, on the other hand, it was imperative to take immediate steps to check the onrush of the German right wing. During the night of Aug. 25–6 Joffre issued a new directive concerning a " new mass of manoeuvre " to be formed on the left flank to carry out an offensive and to consist of the French IV. and V. Armies, plus the British as well as a new French army—the VI.—to be made up of units moved by rail from other sections, chiefly from the right.

On Aug. 26 Joffre and French had a conference on this proposed offensive at St. Quentin, at which the commander of the French V. Army, Gen. Lanrezac, was also present. British co-operation was, however, impossible, for on this day half of French's army was engaged at Le Cateau, where it was very roughly handled. On the following day Joffre promised that the French V. Army would be immediately directed to take the pressure off the British. Accordingly at 1 P.M. on this day an officer arrived at Lanrezac's headquarters with verbal instructions to attack at once and with vigour toward St. Quentin. The French V. Army was at this time retiring over the Oise above Guise, and the attack it was called upon to carry out was with the object of following on the left flank of the German I. Army in order to delay the German onrush.

French Support for the British Army.—Nightfall on Aug. 27 found the French V. Army behind the Oise with its left below Guise and its right about Rumigny, the whole facing generally northeast. Lanrezac's task was a difficult one. He had to suspend a retirement toward the south and convert it into an attack toward the west. At noon on Aug. 28 Joffre came to see Lanrezac at the latter's headquarters at Marle. Lanrezac pointed out his difficulties and explained that his right flank would be considerably exposed in the operation enjoined upon him; but Joffre peremptorily ordered Lanrezac to proceed with the offensive and even threatened to relieve him of his command.

The German Advance Delayed.—At daybreak on Aug. 29 the main body of the V. Army began to cross the Oise above and below Origny, but the plan had to be modified owing to an attack made upon the right east of Guise by two corps of the German II. Army. Accordingly Lanrezac decided to postpone the attack toward St. Quentin and to deal with the threat against his right flank first. It was, however, impossible to carry out this new plan and it was now decided merely to mask St. Quentin and to devote every effort to dealing with the German attack east of Guise. The main body of the V. Army, assisted by a cavalry division, carried out its task with vigour and about 5 P.M. a general offensive took place along the 18 m. front from Origny-Vervins towards Guise. During the night the two German corps fell back across the Oise. This success was somewhat neutralised by events between the Oise and St. Quentin, where the situation took an unfavourable turn for the French.

Having carried out its task of delaying the Germans, the French V. army fell back during the evening of Aug. 30. The operation had been skilfully carried out, but Lanrezac was not in favour with French general headquarters and within a few days he was relieved of his command.

(F. E. W.*)

FROST, ROBERT (1875–), American writer, was born in San Francisco, March 26 1875. His father was a New Englander and his mother was born in Edinburgh. In 1885 he moved with his parents to Lawrence, Mass., studied in the public schools, and entered Dartmouth College in 1892, remaining there one year. From 1897–9 he was a student at Harvard, and from 1905–11 taught English in the Pinkerton Academy, Derry, N. H., and then for a year taught psychology at the N. H. Normal School at Plymouth. In 1912 he went to England, where he remained three years and published his first two volumes of verse. On his return to America he retired to a farm at Derry and gave much time to active farming. During 1916–20 he was professor of English at Amherst College, Mass., a position which he resumed in 1923. His poems portray in realistic fashion everyday country life in New England. Some of the work of his first volume had been denied publication for 20 years, and some of the second for 10 years. He is the author of *A Boy's Will* (1915); *North of Boston* (1915); *Mountain Interval* (1916); *A Way Out*, a play (1917); *New Hampshire* (1923).

FRUNZE, MIKHAILVASSILIEVICH (1885–1925), Russian soldier, was the son of a peasant who had settled in Turkistān and become a surgeon. While at school he came in contact with socialists, and on entering the Polytechnical Institute at St. Petersburg (Leningrad) he joined the Bolshevik group in the social democratic organisation. In 1905 he worked in the industrial district of Ivanovo-Voznesensk and helped to organise the big textile strike of that year. He was frequently arrested and in 1907 was sentenced to four years penal servitude, and to a subsequent six years on the grounds that he had offered armed resistance to the police.

At the end of 1914 his penal servitude was exchanged for banishment to Siberia, where he was arrested for revolutionary activities in the following year, but soon afterwards escaped from prison and the March revolution of 1917 found him in Minsk at the head of an illegal organisation in the army. He became president of a Front Committee, and later president of Soviet in the provinces, and at the time of the Nov. Revolution came to Moscow with a detachment of 2,000 men, with which he took part in the fighting in that city. After the revolt in Jaroslaw he became military commissar of that district, and in Dec. 1918, commander of an army on the Eastern Front. He later became commander in chief of four armies and directed the operations against Admiral Kolchak. When the Eastern Front was divided, Frunze became commander on the Turkistān section of it, where he surrounded and destroyed Kolchak's southern army. He afterwards took part in minor operations in Central Asia, returning to Russia in Sept. 1920 when he took command of the troops that eventually drove General Wrangel out of the Crimea. For this he was rewarded with a sword of honour and a portrait of Karl Marx. He then commanded the military forces in the Ukraine. In 1924 he became vice-president of the Revolutionary Military Council, and, in the absence of Trotsky, the actual head of the Red Army. He became president of this council and People's Commissar for Military and Naval Affairs in Jan. 1925, but died before the end of the year.

FRY, SIR EDWARD (1827–1918), English judge (*see* 11.270), died at Failand, near Bristol, Oct. 19 1918.

FRY, ROGER ELLIOT (1866–), British painter and art critic, son of Sir Edward Fry, was born in London, and educated at Clifton and King's College, Cambridge. He studied painting under Francis Bate and then in Paris, and exhibited at the Carfax Gallery, London, in 1903. His work, notably in his landscapes, is marked by deep feeling for form and a scholarly sense of design and technical means. An active member and exhibitor of the London Group, he gave an exhibition of his own paintings in 1920. As a critic, with his wide knowledge and acute sensibility, Fry became recognised in England and abroad as a leading expert. He published a study of *Bellini* (1899) and edited *Reynold's Discourses* (1905), but is best known by his championship through much opposition and prejudice, of Cézanne and the post-impressionists. Among other publications are *Vision and Design* (1920); *Architectural Heresies of a Painter* (1921), and a book of travel impressions, *A Sampler of Castile* (1923). He was also joint editor of *The Burlington Magazine*.

FRYATT, CHARLES (1872–1916), British seaman, was born at Parkeston, Essex, Dec. 2 1872. He entered the service of the Great Eastern Railway Co., and in 1904 became chief officer in their service of vessels plying between Harwich and Rotterdam. In 1913 he was promoted captain. At the end of July 1916, it was announced that his ship, "Brussels" had been captured and the captain himself arrested and tried by court martial, on a charge of having attempted, on March 28 1916, to ram a German submarine. The German authorities stated that Captain Fryatt had confessed that he had acted under orders from the British Admiralty; but the trial was hurried and secret, no intervention on the part of neutrals being allowed. The captain was condemned to death and shot at Bruges, July 27 1916. The body was, on July 7 1919, brought from Belgium to England and was buried at Dovercourt, near Harwich.

FUAD I. (1868–), King of Egypt, was born at the palace of Gizeh, March 26 1868, the youngest son of the Khedive Ismail Pasha. After his father's débâcle Prince Ahmed Fuad, as he then was, went to Italy where his youth was spent. He returned to Egypt in the 'nineties and was appointed aide-de-camp to the Khedive Abbas Hilmi. He found outlet for his energies by presiding over charitable and educational institutions and was largely responsible for the foundation of the Egyptian University, of which he became president. In 1917 his elder brother, the Sultan Hussein Kiamil died, and as the latter's son, Prince Kemal ed Din, renounced the rights of succession, Prince Fuad became Sultan. After the termination of the British protectorate on Feb. 28 1922, he was proclaimed King of Egypt (March 16). He had married on May 25 1919 the Princess Nazli, daughter of Abdel Rehim Sabri Pasha, a former governor of Cairo, and his heir, Prince Faruk, was born on Feb. 11 1920.

FUEL PROBLEMS (*see* 11.274).—The wood of our forests is our natural fuel. If we were restricted to that material, the enormous fuel demands of our industrial age would long since have razed our forests. As the dearth of wood made itself felt in industrial districts, recourse was had to the fossil fuels which Nature has stored up, coal and peat, and natural oil and natural gas. Bituminous coal was the most important of these fuels, and the iron industry required in particular those coals which gave a metallurgical coke suitable for replacing the wood charcoal in the blast furnace. In some countries, for instance in Germany, brown coal has of late almost broken the predominance of bituminous coal; brown coal is more easily mined and offers advantages as household fuel when briquetted.

Further, modern industry and transport, established on the coal-fuel basis, have recognised the advantages of liquid fuels and their necessity for certain purposes. Oceanic navigation makes an increasing use of crude oils; automobile and aerial motors are no longer to be thought of without gasoline fuel. Again, the cleanliness and precision attainable with gaseous fuels in furnaces and in the preparation of valuable products, have secured to these fuels a preferential position in the production of steel and in the manufacture of glass and of ceramic objects. Extensive systems of gas-pipes distribute gas through towns and industrial centres, even across states.

But the natural fuels, solid, liquid and gaseous, are by no means evenly distributed over our globe. Consequently we are forced to produce the required fuel from other sources, to meet local conditions, unless we are satisfied to depend upon imported fuel. The chemist and engineer are hence confronted with the problem of converting fuels of locally lesser value into fuels for which there is a greater demand. Thus arise many problems, the most important of which is the conversion of coal into oils.

I. GASEOUS FUELS AND THEIR PRODUCTION

From Solid Fuels.—The constitution of the gaseous fossil fuels is easily determined; for the molecules of gaseous substances are generally the smallest and the least complex. The combustible constituents of natural gases, exhaled as natural gas or fire-damp, are almost exclusively represented by methane, CH_4. The methane may have originated from residues of a fossil flora or fauna. The biological processes which resulted in the formation of petroleum took place under scission of methane, which was also produced during the formation of coal and during its natural ageing. Natural gas is therefore found in association with oil-fields and coal seams. As, however, natural gas is not replenished at the rate at which it is consumed in some industrial districts (*e.g.*, Pennsylvania), many works which originally relied upon natural gas have been obliged to adopt producer gas as their fuel. The chemical constitution of gaseous fuels is easily ascertained, and also the production of gaseous fuels from liquid and solid fuels offers no particular difficulties.

Dry Distillation.—For the preparation of gaseous from solid fuels two chief methods are now available. The so-called dry or destructive distillation of coal is historically the first. The gas formed by the thermal decomposition of the coal consists, when the temperature is kept as low as possible, essentially of methane and other hydrocarbons. When the coal is discharged into glowing retorts, as in gas and coke-oven works, the gas liberated will be the richer in hydrogen the higher the temperature. This method of coal distillation furnishes a gas of relatively high calorific value. With low temperature carbonisation, the calorific value may rise to 9,000 calories per cu. metre; at higher temperatures, the figure will lie between 4,000 and 5,000 calories. But the volumes of gas are comparatively limited; only a small portion of the coal substance is gasified, the bulk being transformed into coke. The yield is about 60 to 70 cu. metres of low temperature gas per ton of gas coal, and some 200 or 300 cu. metres of coke per ton. The complete gasification of coal cannot be effected by heat alone. The coke produced by the distillation must be gasified by chemical reactions. This can be done in three ways.

Chemical Reactions.—The reaction of air with white-hot coke yields a gas, theoretically consisting of two parts of carbon monoxide and four parts of nitrogen; this gas is of low calorific value. The reaction $2C+O_2=2CO$ proceeding under considerable liberation of heat, the manufacture of such a gas—air-gas—can be easily carried out continuously in shaft furnaces. The best material is coke; coal may be used provided it does not cake; brown coal briquettes are also suitable. From the standpoint of gas production, the ordinary pig-iron blast furnace may be regarded as a huge air-gas producer, with the difference that the oxygen required for the production of carbon monoxide is taken not only from the blast, but also from the iron ores. This process of coal gasification, the air-gas process, is associated with a pronounced liberation of heat.

Water-Gas Process.—In the water-gas process, however, the reaction $C+H_2O=H_2+CO$, heat is consumed and has to be replenished to sustain the process. The water-gas process can therefore not be carried out continuously in a shaft furnace unless external heat be supplied. The process is hence worked discontinuously. During the first hot run the coke charge is raised by the air blast to a temperature of about 1,000°C.; steam is then admitted, heat is absorbed and water-gas is produced, while the temperature of the layer of glowing coke sinks gradually. When the temperature has fallen a few hundred degrees, the hot-air blast is again turned on.

Mixed Gas Process.—Since the air-gas process liberates heat whilst the water-gas process absorbs heat, technical practice began to combine the two processes before the theory of the reactions was understood. Gas generators were worked with air and steam. Numerous advances have been made during the last decade in the domain of fuel gasification, particularly with regard to the difficulties caused by the use of coal instead of coke in the generation of both mixed gas and water-gas.

By the use of considerable additions of steam we have, in the mixed gas process, further learnt to recover the bulk of the nitrogen contained in the coal, in the form of ammonia (*see* AMMONIA). Success has also been achieved in the perfection of gas producers as economical apparatus for the manufacture of primary tar. The total gasification of the coal and coke has so far laboured under the disadvantage that, as the daily throughputs of gas producers were relatively small, a good many furnacemen and a good deal of stoking were required. Recently gas generators have been built for daily throughputs of 100 tons. This working in large units is one of the most important problems of coal gasification.

From Liquid Fuels.—Further substitutes for natural gaseous fuel can be obtained by the thermal decomposition of liquid fuels, such as crude oils or certain fractions of these oils, gas oil, tars or tar-fractions. The carburation of water-gas is a case in point. Water-gas does not burn with a luminous flame and its calorific power is low; it is therefore carburated by the injection of crude oil or tar oil into incandescent chambers. At temperatures above red glow the oils are decomposed, to a large extent, into gases, some tar and coke. The gases consist of very diverse hydrocarbons of higher calorific values than the water-gas. By mixing the two kinds of gases the water-gas is therefore enriched. In the early days the gas was carburated also for the purpose of rendering it luminous. With the invention of the Welsbach incandescent burners this application has lost its importance; but carburation for the sake of increasing the calorific value still remains important.

The thermal decomposition of oils is practised for the general purpose of obtaining gases of high calorific power. Thus tar or oil gas is manufactured by the decomposition of so-called gas oil. It served chiefly for lighting railway carriages, but is being replaced by electric illumination. The gasification of liquid, relatively inferior fuels, by the aid of steam might become valuable under certain conditions for the preparation of a water-gas rich in hydrogen, by a kind of water-gas process. Thus, petroleum vapours mixed with steam and heated to 1,000° in the presence of bauxite as catalyst can be converted into a mixture of carbon monoxide and hydrogen, which high-pressure catalysis further transforms into synthol and similar products.

From Other Gaseous Fuels.—It may happen that natural gas is available, but that hydrogen is needed. The conversion of methane into hydrogen may be effected catalytically by passing methane through tubes or kilns at the high temperature of 1,000°, when methane is decomposed into hydrogen and carbon. At lower temperatures the decomposition is incomplete. When shaft furnaces are used the carbon deposited can subsequently be burnt out again by blowing hot air into the furnace; the heat liberated is re-utilised to raise the furnace again to the high temperature and to decompose more methane. Like the vapours of liquid fuels (though less easily, owing to its high stability) methane can also be converted, by means of water vapour in the presence of bauxite as catalyst at about 1,000°, into a mixture of carbon monoxide and hydrogen.

The reversed process should finally be mentioned. If desired, the carbon monoxide contained in some available fuel gas mixture can be removed by transforming the carbon monoxide catalytically, at low temperature, into methane, with the aid of the hydrogen in the mixture. This was done experimentally about 1915. The process has not been adopted, however, although the elimination of the monoxide from illuminating gas seemed hygienically advantageous. The catalytic preparation of pure methane from water-gas, tried on an industrial scale some years ago, still remains in the preliminary stage, because the purification of the gas (of sulphur) and the partial removal of the carbon monoxide proved too expensive. Such a process, moreover, involves a loss of about 25% in calorific value, because the proportion of methane, represented by the theoretical mixture of carbon monoxide and hydrogen, possesses only three-quarters of the heat value of the four times larger volume of ($CO+3H_2$) which it replaces. The reason is that this methane formation is a strongly endothermic process.

Purification of Gaseous Fuels.—For many purposes the artificial gaseous fuels require careful purification. Thus, the gas escaping in large volumes from the mouth of a blast furnace has to be freed of all the dust it carries before it can be fed into internal combustion engines. The object is attained by mechanical cleaning and dust separation, by means of filters, centrifugal machinery or sprinkling with water. The electric dust precipitation by the Cottrell process should especially be mentioned (*see* FUME PRECIPITATION). The removal from the gases of the sulphur compounds is frequently a difficult problem. It is chiefly required in the case of illuminating gas, and the sulphur can be recovered in a utilisable condition. The old-established method purifies the gas by means of iron ore (bog ore). Activated carbon has recently been experimented with for the same purpose. The gas is mixed with a sufficient amount of air to oxidise the sulphuretted hydrogen in the gas into sulphur; the sulphur is retained by the carbon, and the process is accelerated if ammonia is present in the gas. The activated carbon impregnated with sulphur is then extracted with ammonium sulphide; the evaporated solution leaves the sulphur as a marketable residue. For most of the catalytic processes removal of hydrogen sulphide alone from the gas is, however, insufficient. The other sulphur compounds, notably carbon disulphide, must also be eliminated.

II. LIQUID FUELS AND THEIR PRODUCTION

The natural liquid fuels, natural oils or petroleums, occur in widely-diverging compositions, and are partly aliphatic, partly naphthenic in character; aromatic compounds are found in some kinds of petroleum. The natural oils are also classified according to the nature, asphaltic or paraffinic, of their high-boiling residues.

As regards the origin of petroleum, the biological hypothesis of Engler has found general support. According to this, petroleum was formed in the course of time by the decomposition of the fatty constituents of small and large organisms. The optical activity of certain petroleum fractions is regarded as affording a strong argument in favour of this view. That, however, liquid hydrocarbons, with which we are essentially concerned, may be prepared artificially in other ways and might naturally have been produced in such ways under certain conditions, has been established within this century, by chemical research in various cases. There are, *e.g.*, carbides, such as uranium carbide, which liberate liquid hydrocarbons when decomposed. It is further known that acetylene and hydrogen may catalytically be combined to form petroleum-like products; and within the last few years it has been shown that the high-pressure synthesis of water-gas leads to the formation first of synthol and further, when this synthol is heated under pressure, of an artificial petroleum. Whether or not petroleum has been formed in some localities by inorganic reactions of cognate nature, cannot be proved, but the possibility cannot be excluded.

From Solid Fuels.—Heating of geologically recent coals under exclusion of air seems to be the simplest method for the production of liquid fuels from solid fuels. Destructive distillation yields, in addition to the gases mentioned and to the residual coke, a tar which, when formed at low temperature, contains constituents of petroleum character. The proportions of such tar obtainable are considerable. Gas coals of more recent geological periods (ordinary coal) yield up to 12% of the tar, cannel coals still more. Certain lignites and oil shales are likewise suitable materials for the manufacture of the tar by distillation. The Scottish shale-oil industry and the brown coal carbonisation works of central Germany operate on these lines.

The large bulk of the tar which comes from our coal gas and

coke works is of a different composition. Owing to the high temperatures which are used in gas-works and especially in coke-ovens, in order to secure high yields of both gas and a firm coke, the tars are essentially aromatic in character and rich in benzene, naphthalene, anthracene, etc. By weight the chief product is in either case semi-coke or coke. The tar yield referred to the weight of coal, lies in general between 12 and 3% (*see* COAL TAR PRODUCTS).

Bergius Process.—Since coal contains only 5% of hydrogen on average, whilst petroleum contains more than twice as much, an increase in the oil yield from coal seems dependent upon a supply of hydrogen. In the Bergius process for the liquefaction of coal, hydrogen is made to react with coal at a pressure of more than 100 atmospheres and at temperatures of about 450°. The coal is ground and kneaded with 30% of tar into a paste; this paste is continuously pressed into the high-pressure autoclave. We may imagine that the coal is first carbonised, the temperature being sufficiently high for this purpose; the products are primary tar and semi-coke. The semi-coke is further hydrogenated and half of it, by weight, is converted into oil. That the reaction may proceed in this way has quite recently been established by experiments in which the carbonisation was effected at ordinary pressure, and only the hydrogenation of the semi-coke was carried out at high pressure. This "bergiannisation" is not equally applicable to all types of coal. Suitable materials are particularly coal of comparatively recent periods, rich in volatile constituents, but not inclined to cake. Such coals which are popular as fuel for gas generators, but in general unsuitable for coking, yield about 50% of oil by the Bergius treatment, whilst low-temperature carbonisation would at the best give 10 to 12% of oil. The oil of the Bergius process is not equal in value to natural oil. It contains, it is true, ample proportions of gasolene, but it also contains about 20% of phenolic constituents, and is hence more closely related in constitution to the primary tars than to petroleum. The Bergius process, which is expensive owing to the high-pressure apparatus required, offers advantages in localities in which there is no market for semi-coke, neither as domestic fuel nor for gasification or the manufacture of powdered fuel. Under other conditions, improved methods of low-temperature carbonisation will be serious competitors.

From Other Liquid Fuels.—Natural, as well as artificial liquid fuels contain in general fractions of almost all boiling points, ranging from ordinary temperature up to 400°. Not all these fractions are, however, in equal demand. In the 19th century lamp and illuminating oils, boiling between 150 and 250°, were the most valuable petroleum constituents. Since then electric and incandescent lighting on the one hand, and the development of automobiles, flying machines and industry generally on the other, have increased the values of the low-boiling benzenes and of the lubricating oils in petroleum, so that the evaluation of the various petroleum fractions has altogether changed. At present the supply of benzene from petroleum is not sufficient to satisfy the demand. Fortunately the high-boiling constituents of petroleum can be converted by cracking processes into low-boiling motor spirits. One-third of the gasolene wanted in America for automobiles is said to be now produced by cracking. Like the oil-gas production mentioned above, cracking involves heating of high-boiling oil fractions up to incipient decomposition. The cracking process is, however, conducted at lower temperatures, in the neighbourhood of 500°, and under pressure, because less gas and more vapours of gasolene type are formed when the pressure is raised. This heating up to partial thermal decomposition of oils of high boiling points is important in other respects. In the Diesel motor (*see* INTERNAL COMBUSTION ENGINE), it is believed, the air is first heated by the compression stroke to cracking temperatures; the oil injected into this hot air is then thermally decomposed and burns in the compressed air; separate ignition of the fuel can be dispensed with.

The dearth of low-boiling gasolene has induced designers of automobile internal combustion engines to use fuels containing high-boiling constituents. These constituents, however, are apt to ignite by the heat due to compression toward the end of the compression stroke and before the dead point is passed. The piston is then forced back and "knocking" occurs. This pre-ignition of gasolene-air mixtures seems to be favoured, if not caused, by the fact that the carbon deposited on the engine cylinder always carries some iron. The tendency to knocking is suppressed by adding to the motor spirit substances such as lead tetra-ethyl which, it is assumed, act by being adsorbed by the ferriferous carbon in the cylinder; the carbon is thus catalytically poisoned and cannot produce knocking. The anti-knocking reagents are, however, dangerous to the human system, and not likely to find favour. The best way of stopping the knocking trouble would be to return exclusively to motor fuels of low boiling points. The world's production of benzene is insufficient for the demand. Synthetic preparation of benzenes may bring the desired solution of this problem.

Some artificial liquid fuels can or should be improved or modified, wholly or partly, before utilisation. Half of the oil fraction of primary coal-tar consists of phenols for which there is little demand. By means of hydrogen at 700 to 800° they can be reduced to the more valuable benzene and toluene. Certain hydrocarbon fractions of primary tars are highly unsaturated; they can be hydrogenated and rendered more valuable in similar ways. The naphthalene of coke-oven tar can be converted into a liquid fuel, tetrahydronaphthalene, commercial tetralin. For this purpose the solid naphthalene is fused, purified by crystallisation and freed of the last traces of sulphur by treatment with metallic sodium. The naphthalene thus purified is then submitted to hydrogenation by means of hydrogen under pressure in the presence of nickel as catalyst, somewhat as in oil hardening; but the product, tetralin, is liquid.

Attempts have also been made to convert high-boiling liquid fuels and also tar and pitch into low-boiling motor spirit by the Bergius process, analogous to cracking but combined with hydrogenation. The process has not found industrial application, apparently because the American cracking processes attain the same object by less expensive means.

From Gaseous Fuels.—Gaseous fuels frequently contain vapours of liquid fuels of low boiling points. Natural gas, for example, very frequently, though not always, carries higher homologues of methane. There are benzene vapours in coke-oven gas, and the gases of low-temperature carbonisation retorts contain vapours of benzene character. These vapours can be removed and recovered by physical methods, scrubbing the gas with oil or treatment with adsorbents, such as activated carbon and recently also silicagel; the use of the latter reagent is so far largely experimental. These vapours are further condensed by cooling or by compression, or by a combination of the two methods. Both methods yield the liquid directly; in the former cases the oil or activated carbon used for the scrubbing or adsorption must afterwards be submitted to steam blowing in order to obtain the liquids.

The object of these processes is simply the recovery of fuels of low boiling point already present. Methods for the synthetic preparation of such fuels have been developed within the past few years. The process is a high-pressure catalysis, starting with carbon monoxide, utilised suitably in the form of a mixture of monoxide and hydrogen, a water-gas containing an excess of hydrogen. A mixture of one part of carbon monoxide and two parts of hydrogen is first carefully purified, especially of all sulphur compounds, and then compressed to about 150 atmospheres. At this pressure and a temperature of about 400°, the mixture is passed over the catalyst, for instance, zinc oxide or chromium oxide. The hydrogen is bound by the carbon monoxide and the reaction $CO+2H_2=CH_3OH$ yields almost pure methyl alcohol. Provided disturbing metals, particularly iron which would form iron carbonyl, be absent, no undesirable secondary reactions likely to diminish the alcohol yield seem to take place. Formation of methane, an undesirable reaction, would be aided by the presence of iron.

This synthesis of methyl alcohol hardly concerns the fuel problem. The alcohol contains almost 50% of oxygen, its

calorific value is about half that of benzene or gasolene, and it is not a motor fuel.

Higher Alcohols.—In the case of the higher alcohols, it is possible to prepare mixtures of those alcohols and ketones by high-pressure catalysis, starting with the same raw materials, carbon monoxide and hydrogen, but resorting to other catalysts. These alcohol mixtures of oily character (*i.e.*, little soluble in water) which may be designated by the general term "synthol," can, for instance, be produced with the aid of iron impregnated with potassium carbonate as catalyst. Ninety percent of this synthol boils below 200°, and it forms an excellent motor fuel, at least equal in value to benzene and gasolene. For the present the synthol process is too expensive. But in the future synthetic motor fuels must be prepared in this or similar ways. Water-gas can be produced from all types of coal and peat. It is therefore possible to manufacture synthetic motor fuels in all districts where some coal but not petroleum is available. This source of fuel would provide for the time when petroleum and petroleum products fail. We have more reliable knowledge as to the occurrence of coal than about oil-fields. The coal resources of the globe will probably hold out for many centuries.

III. SOLID FUELS AND THEIR PRODUCTION

So far man essentially relies on fossil, chiefly solid, fuels for obtaining heat and power. Chronologically these fuels may be classified as peat, brown coal and coal. A discussion of their genetic interrelations is unnecessary. The earlier view which traced the genesis of coal to cellulose is giving way. Microscopical examination of coal indicates that coal is the decay-product of wood. Decay of wood, biological researches teach us, is due to certain fungi; they work by destroying the cellulose, which is transformed into gaseous and water-soluble products, whilst they leave the lignin essentially intact. Chemists have proved that the lignin and the carbon constituents proper of brown coal and coal possess a similar chemical constitution, that is to say, a cyclic structure.

The assumption is, then, that the main constituents of our fossil fuels have been formed by a slow decay of lignin, during which the essential chemical character of the lignin was preserved. Cognate interesting conclusions have been arrived at concerning the bitumen in coal. It would appear that the bitumen of the highly diverse brown coals consists mainly of fatty acids of high molecular weights and of odd numbers of carbon atoms, whilst the biologically easily digested fatty acids, which predominate in the fats of plants and animals, contain an even number of carbon atoms. We may hence assume that the fatty acids of the mother substance of coal, which are easily destroyed in a living organism, have disappeared, whilst the more resistant fatty acids of odd carbon-atom numbers have survived and have been utilised in the formation of bitumen.

The solid fuels—coal, for example—cannot always be used in the form in which they are won. According to requirements solid blocks are broken up and sifted into the desired sizes, or ground up and atomised to yield convenient powdered fuels. Conversely, small coal is rendered more marketable by briquetting; this applies particularly to the lignites, whose moisture of 50% is first reduced to 15%.

Apart from these mechanical modifications, other methods of improving solid fuels have of late acquired importance. Metallurgical coke was first made in coke ovens merely as a substitute for charcoal. The enlargement and perfection of the blast furnace called for a firm, little breakable and friable coke. Then the quality of the coke had to meet higher claims. What is wanted is absence of sulphur compounds. To a slight extent the sulphur is removed with the pyrites when the coal is washed. A complete elimination of the sulphur has been attempted by treating glowing coal with hydrogen; the process has not yet been adopted, chiefly, perhaps, because the purification is not complete, in spite of its high cost. Meanwhile, however, ways have been discovered of controlling the combustibility of the coke. The blast furnace requires an easily combustible coke, the cupola a coke which burns slowly. The former coke can, in general, be obtained by accelerating the coking process and by avoiding subsequent heating, whilst high coking temperatures and long coking periods favour the formation of a sluggishly burning coke.

The semi-coke obtained when temperatures of 500 to 600° are not exceeded in its production is readily combustible. If in a handy, dense and little friable condition, this semi-coke, the so-called smokeless coal, would represent an ideal fuel. To produce such a semi-coke which will not require subsequent briquetting is one of the most important problems of the future; considerable progress has been made in the solution of this problem during the past few years.

The production of solid from liquid fuels is, as a fuel problem, a matter of secondary importance. Retort graphite is produced by decomposing the tar vapours and the hydrocarbons of gas in gas retorts. Petrol coke, so-called, is obtained by coking petroleum pitch. Both these cokes are products of considerable value for the manufacture, *e.g.*, of carbon electrodes; but they do not count as fuels. The soot prepared by the decomposition of vapours of liquid fuels, a high-priced form of carbon, is also utilised in the manufacture of electrodes.

Reference should finally be made to the preparation of solid from gaseous fuels. Here again a soot process should be mentioned in the first instance. Carbon black is obtained by the incomplete combustion of natural gas; the process is wasteful, however, and is only applied when the gas cannot be utilised in other ways. Better results can be secured by the catalytic decomposition of carbon monoxide. This method has not yet found any serious industrial application, but it deserves attention in cases where a carbon absolutely free of sulphur is wanted. The process might be developed in promising directions, since the decomposition of the monoxide $2CO = C + CO_2$ yields carbon dioxide which cyclically can be reduced to monoxide again. The essence of the process is therefore an intermediate gasification of impure coke for the preparation of pure carbon.

See "Fuel and Power Generation," in *Rogers' Manual of Industrial Chemistry* (4th ed., 1925). (F. Fl.)

FULLER, JOHN FREDERICK CHARLES (1878–), British soldier, was born Sept. 1 1878 and gained a commission in the Oxfordshire and Buckinghamshire Light Infantry 1898. After active service in the South African War, he relieved the tedium of peace-time soldiering by extensive scientific and philosophical studies, and gained a considerable reputation as an authority on Hindu mysticism and the Hebrew Kabbalah. These studies provided an unusual groundwork and mental equipment for his military researches later. In the World War, after holding a variety of staff appointments, he became chief general staff officer of the Tank Corps in April 1917. He had a responsible share in the project for the great tank surprise at Cambrai in Nov. 1917, and in the tank successes later, until in July 1918, he was brought back to the War Office to organise the vast tank expansion then contemplated for 1919, had the war continued.

Developing his ideas after the Armistice and preaching his new gospel of war, Colonel Fuller was for a time criticised as a tank extremist, an unpractical visionary. Abroad, however, his views were acclaimed, by the French general staff, who translated and circulated them throughout their army, as "an exact vision of the future." Gradually, however, his prophecies and his teaching permeated the army, gaining power from his appointment, in 1922, as chief instructor at the Staff College, and still more when, in 1926, he was appointed military assistant to the new chief of the Imperial General Staff. The result of his researches into the science of war is incorporated in his *Foundations of a Science of War* (1926), and among numerous other books, his *Tanks in the Great War* (1920), *The Reformation of War* (1923), and *Sir John Moore's System of Training* (1925) attracted wide attention (*see* STRATEGY).

FUME PRECIPITATION, ELECTRICAL.—The precipitation of smoke by electricity was described in 1824 by Hohlfeld, a teacher of mathematics in Leipzig, but only after it was independently rediscovered and critically studied by Sir Oliver Lodge about 1884 did it attract general attention and lead to attempts at industrial applications. At the time, however,

these proved unsuccessful due to the lack of modern equipment. It was not until 1906, following experiments at the University of California, that the process was commercially successful.

The first installation was at the Selby Smelting Works, near San Francisco, where it was used for the removal of sulphuric acid mist from about 5,000 cu. ft. of gases per min.; it was still in operation there in 1926. By 1910 a plant to remove dry dust and fume from 250,000 cu. ft. of gas per min. was built at another smelter, and in 1912 the process was successfully extended to the removal of cement dust at nearly a red heat from 250,000 cu. ft. of gas per min. at the Riverside Portland Cement Company. This mill, of 2,500 bbls. daily capacity, situated in the heart of the Californian orange groves, had been threatened with legal closure as a nuisance because of the dust emitted.

The electrical method as there installed removed 98% of the dust, the daily catch being about 100 tons, aggregating for these 13 years of operation over 350,000 tons, equivalent to a train of fully loaded freight cars 100 kilometres long. Although first applied to mitigate nuisances, the demand for the process to-day is

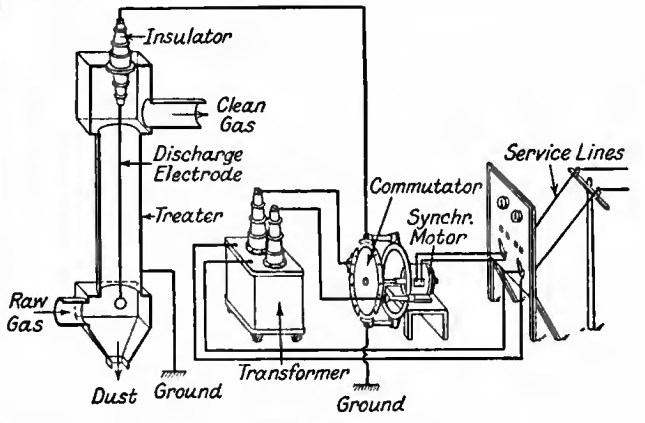

FIG. 1.—Apparatus for the electrical precipitation of dust or smoke from gases.

primarily based on a greater profit to be derived from the gases cleaned or the material removed. At one time during the World War, even the Riverside plant was making more profit from potash incidentally recovered in its dust than from its cement.

Research Corporation.—Another circumstance aiding the development through friendly public interest was the creation in 1912, under the auspices of the Smithsonian Institution, of the Research Corp. in New York City, to hold and administer as an endowment for research most of the United States patent rights to the process. The corporation besides supervising construction and development of this particular process, also serves in general as a clearing house for information and as an intermediary and trustee between inventors, the industries and the public.

The Process.—Technically the process consists in securing a uniform, copious but non-disruptive discharge of electricity from small electrode surfaces of one polarity into a stream of cloudy gas. The fine solid or liquid particles composing the dust, fume or smoke are immediately attracted to, and deposited on, large electrode surfaces of opposite polarity, the particles having become charged from the condensation on their surfaces of a portion of the electricity passing between the electrodes. The process is diagrammatically illustrated in fig. 1. Alternating current from service lines is stepped up in a transformer to a high voltage and then converted to a direct, or rather a pulsating unidirectional, current by a commutator or "rectifier" driven by a synchronous motor. One side of the line is grounded and connected to a pipe or "treater" carrying the fume-laden gases. This pipe serves as the collecting electrode. The other side of the line terminates in a wire serving as the discharge electrode, which is hung axially within the pipe. Voltage is regulated to secure as strong a glow as corona discharge from the wire electrode as possible without passing over into a disruptive discharge, *i.e.*, a spark or arc. This adjustment is easier when the discharge electrode is the negative, though either polarity may be used.

The gas treaters now in general use consist either of a multiplicity of pipes similar to that in the figure, or of plates hung vertically in a flue, the wires being stretched parallel between them. The materials of construction, including the collecting electrodes, vary from iron and lead to reinforced concrete and vitrified earthenware, depending on the composition and temperature of the gas stream to be treated.

Factors in Design.—Most plants are designed with electrodes of opposite sign 2 to 6 in. apart and operating at 30,000 to 80,000 volts. The size of installation is determined primarily by the volume of gas to be treated and the percentage of suspended matter to be removed, the amount, kind and size of particle of the latter being of minor importance. If P is the ratio of outgoing to incoming suspended matter, t the average time in seconds that the gas remains between the electrodes, and K, a constant depending upon the apparatus, voltage, temperature and kind of raw gas, then $P = K^t$. In most commercial practice t averages about 2 seconds and K varies from 0·2 to 0·7, the gases travelling from 10 to 40 ft. through the electric field of linear rates of 3 to 15 ft. per second. Removal of 90% to 99% of the suspended matter is usually aimed at, and the energy required is 1 to 3 kw. hours per 100,000 cu. ft. of gas treated.

Industrial Uses.—The earliest applications of the process were to the smelting and sulphuric acid industries. Installations in such plants in 1926 still outnumbered those in all other industries, and amounted to several hundred scattered throughout the world. Equipments at cement mills were fewer in number but handled a large volume of gas and a large tonnage of precipitate. Other important applications are to the detarring of coke-oven gases, the cleaning of producer and iron blast-furnace gas, the cleaning of ventilating air in crushing, grinding and polishing mills (especially where cost of heating in winter makes recirculation of air important), the recovery of sludge acid fumes in petroleum refineries, the recovery of dust from brown-coal dryers, and the removal of ash from the stack gases of large power-plants burning powdered coal. On a laboratory scale the process has also been applied successfully to sanitary atmospheric analysis and to gas masks, including the removal of bacteria from air, but suitable standard equipment for these small-scale uses is apparently not yet on the market.

The process in itself precipitates only suspended solid or liquid particles and makes no separation between gases. It has, however, an important indirect application to problems in this latter field, involving the recollecting of solid or liquid absorbents which have been dusted or sprayed into gas mixtures. The electrical demulsification or dehydration of crude petroleum and transformer oils, the separation of fine suspensions, such as clays in pure water and other poorly conducting liquids (electrical osmose or electrophoresis) and electrostatic concentration of ores, though dependent on some of the same natural phenomena, differ to such an extent, in principle and equipment required, from the process here described as to preclude their discussion under this heading.

FUNDAMENTALISM AND MODERNISM.—Fundamentalism is the name given to a religious movement which, appearing independently in different denominations in the United States during the period after the World War, steadily gathered momentum until in 1925 it became a subject of national, as distinct from denominational, interest through the trial and conviction of John T. Scopes, teacher of science in Rhea High School, Dayton, Tenn., on a charge of violating the Tennessee law prohibiting the teaching of evolution in the state public schools.

The trial began on July 10 1925, and was concluded on July 21 1925, by the conviction of the defendant and his sentence to pay a fine of $100. The immediate issue was as to whether the defendant had or had not violated the provisions of the state law as to the subjects to be taught in public schools, but the wider issue was as to the extent to which the state, in its control of public education, may determine the nature of the religious instruction given to the students in its schools. The trial itself was the culmination of a movement which had been going on for some years. Alarmed by the steady growth of liberal tendencies, the conservatives of the different churches had banded themselves together to stay what seemed to them the rising tide of negation. The form of the movement differed in the different communions according to the particular issue which was in question at the time, but common to all the Fundamentalist groups was, first, the acceptance of a view of the supernatural which insists that God manifests His presence in nature and history through exceptional and extraordinary activities, transcending the laws of nature; and secondly, the determination to use this conception of religion as a test to limit the freedom of teaching hitherto enjoyed by the ministers of the denomination. In all this there is nothing new. In every age conservatives and liberals have carried on their conflict over some form of this issue. What is new is the wide-spread character of the movement, the missionary enthusiasm which has been brought to it by its advocates and the consciousness on their part of interests transcending denominational lines and calling for a new alignment, with the Fundamentalists of all denominations on one side and the liberals on the other.

The Presbyterian Church.—In the Presbyterian Church the controversy centred about the case of Dr. Harry Emerson Fosdick, a Baptist clergyman who had been invited to act as stated supply for the First Presbyterian Church in New York City. Dr. Fosdick, who is also a professor in Union Theological Seminary in that city and a man of moderate liberal tendencies, made it his condition of accepting the call that he should be allowed to retain his membership in the Baptist Church. A sermon preached in May 1922, entitled "Shall the Fundamentalists Win?" was the occasion of an attack upon his theology by conservative Presbyterians, which led the General Assembly of 1923 to direct the Presbytery of New York to take such action as would require the preaching in the First Presbyterian Church to conform with the Confession of Faith. The Presbytery, after full conference with Dr. Fosdick and the Church, reported that such was now the case, whereupon the Assembly of 1924, without passing any judgment on Dr. Fosdick's theological views, expressed the opinion that if he were to remain longer in the pulpit of the Church, he should accept the standards of doctrine required of other ministers. On this issue Dr. Fosdick withdrew, declaring that "Creedal subscription to ancient confessions of faith is a practice dangerous to the welfare of the Church and to the integrity of the individual conscience."

In connection with this controversy the General Assembly in 1923 reasserted the so-called "Five Points," a declaration originally made in 1910, setting forth as essential doctrines of the Christian faith, the Virgin Birth, the physical Resurrection, the inerrancy of Scripture, the substitutionary Atonement and belief in the Miracles. In reliance upon this statement the judicial commission of the Assembly, in May 1925, declared that the Presbytery of New York had erred in licensing a student who refused to affirm the Virgin Birth. The liberals attacked this procedure as an unconstitutional limitation of the liberty of interpretation accorded to every minister by the terms of subscription, and to the Presbyteries by the historic precedents of the Church. (*Cf.* Auburn Affirmation of May 1924, signed by 1,283 members.)

The Baptist Church.—In the Baptist Church the controversy has taken the form of an effort on the part of the conservatives to secure the adoption by the Annual Conference of a creed which should be used as a test of ministerial fellowship. This attempt failed at repeated conferences, but the conservatives, defeated at this point, have sought to secure their ends by instructions given to their Board of Home Missions as to the conditions to be observed in the administration of their funds. One large bequest was actually accepted by the board on conditions which seemed to some of its critics unduly to limit its freedom. A parallel effort to secure control over the teaching of the seminaries has thus far failed of success.

Not the least important feature in the Fundamentalist movement is its bearing upon foreign missions. In general the policy of the different missionary boards has been to put the responsibility for determining the doctrinal qualifications of candidates upon the home church; and in the work on the foreign field conservatives and liberals have co-operated successfully in various union enterprises. Fundamentalists have challenged this arrangement and attacked the theology of liberal missionaries. On the whole this attack has been unsuccessful, and the unity won on the field has thus far been maintained; but the battle is by no means over or the danger at an end. A case in point is the action of the General Convention of the Disciples at Oklahoma City, Okla., on Oct. 6 1925, in reaffirming the principle of close communion which has been departed from by some of their missionaries in the interest of wider co-operation.

The Episcopal Church.—In the Episcopal Church the controversy has centred about the literal observance of the creeds. On Oct. 5 1923 Bishop Lawrence of Massachusetts made an address (afterwards published in pamphlet form) entitled *Fifty Years*, in which he pleaded for a liberal interpretation of the creeds. On Nov. 14 1923 at Dallas, Tex., the Bishops of the Episcopal Church met this challenge by issuing a Pastoral insisting upon literal acceptance of the creeds and questioning the good faith of those ministers who gave their historic statements a symbolic interpretation. This Pastoral was attacked by the liberals of the Church who were organised in a body known as the Modern Churchman's Union. Sermons were preached by leading liberals, like Dr. Leighton Parks of St. Bartholomew's Church of New York, and Dr. William Russell Bowie of Grace Church of the same city, and manifestoes were issued by theologians like the volume of essays entitled *Creeds and Loyalty* by seven members of the faculty of the Episcopal Theological School of Cambridge, Mass. (1924). As a result of this agitation a trial for heresy begun against the Rev. Lee. W. Heaton for denying the Virgin Birth was abandoned, and for the moment a truce has been declared.

The Bible Institutes.—One of the main sources of popular conservative propaganda is the so-called Bible institutes, of which the most important are the Moody Bible Institute in Chicago and the Bible Institute of Los Angeles. These schools, interdenominational in character, recruiting their scholars from young people without college, and many of them without high school education, insist upon the inerrancy of the Scripture, which they interpret commonly in the pre-millennarian sense. They are carrying on an extensive propaganda partly through periodicals of interdenominational character and partly through conventions (the so-called prophetic conferences), which bring together large numbers of people. While not primarily designed as theological seminaries, many of their pupils are finding their way into the churches and are reinforcing the conservative elements which are already there.

It is against the background of these influences that one must interpret the Tennessee trial. Under the leadership of William

Jennings Bryan, the conservatives had been carrying on an active campaign throughout the country, attacking the views of liberal Christians as fundamentally irreligious and unchristian and insisting not only upon rigid measures on the part of the individual churches, but also upon such a stiffening of the laws of the states as to prevent what they regard as the insidious propaganda of modernism in the schools. The storm-centre of the debate was the doctrine of evolution which, as interpreted by Mr. Bryan, involves a denial of the Biblical doctrine of creation and the surrender on the part of the teacher to an all-devouring materialism. In view of the fact that similar legislation has either been passed or attempted in other states, it is not likely that a final decision will be reached upon this larger issue until the U.S. Supreme Court has passed judgment upon the matter. (W. A. B.)

FURNESS, HORACE HOWARD (1833–1912), American Shakespearian scholar (*see* 11.362c), died at Wallingford, Pa., Aug. 13 1912. His Variorum edition of *Cymbeline* was ready for the printer and appeared in 1913.

FUR TRADE (*see* 11.346).—The most important development in this field in the period 1910–26 has been the rise of fur farming, made possible through the domestication of the silver fox and other fur-bearing animals. This industry had its inception in Prince Edward Island, Canada, those chiefly responsible for its successful development there being R. J. Oulton, Charles Dalton, J. S. Gordon, Robert Tuplin and B. J. and Silas Rayner. As the silver fox pelt is the most valuable skin produced in North America, these men were able to accumulate great wealth for themselves as well as opening the door to similar opportunities for others. Domesticated silver foxes sold at first for as high as $35,000 a pair. Prices have since fallen, with the stabilisation of the industry, to less than $1,000.

Development of the Industry—The Governments of Canada and of the United States have taken cognisance of the new industry by the establishment of experimental ranches and information bureaux. Yearly exhibitions also have been instituted for the comparison and judging of the animals. The industry has since spread widely, ranches having been established in Great Britain, Norway, Sweden, Germany, France and other countries. The domestication of the silver fox has encouraged similar experiments with other animals and these have led to the successful rearing of minks, red foxes, blue foxes, raccoons, karakul sheep (persian lambs), martens and fishers. Muskrats and beavers have also been raised in confinement for the sake of their pelts and require a much larger territory in which natural conditions are maintained and enemies excluded. Under such conditions these animals multiply very rapidly.

Markets and Production.—Prior to the World War London and Leipzig were the two largest fur markets in the world, more than half the total supply being sold at these places. Most of the dressing and dyeing was done in Germany. It is estimated that in 1910 North America and Europe each produced furs valued at $24,000,000, Asia $26,000,000, Australia $6,000,000, South America $2,000,000, and Africa and Oceania $2,000,000. The annual production has, since that time, more than doubled in value, Canada producing the greatest amount and exporting in 1925 pelts valued at $17,119,981 (about $22,000,000 in 1919–20). This increase is to be accounted for in large part by the rise in value of furs, occasioned in the first instance by the scarcity of pelts following the War. Muskrat pelts, the staple fur of North America, which had formerly been sold for from 10 to 30 cents apiece, frequently brought a price of $5.00. The interruption in trade caused by the War resulted also in the rise of a number of new fur markets, notably in St. Louis, New York and Montreal. The combined offerings of muskrat pelts at these three cities in the years 1920–3 amounted on the average to 3,366,516 pelts. The combined offerings of all auctions for these skins held in North America for 1924–5 averaged 4,594,446 pelts per year.

Manufacture in America.—Before 1914 approximately 65% of the furs secured in North America were exported abroad for manufacture and sale. The difficulties of export during the War, however, resulted in a large increase in fur manufacturing in America and particularly in the United States, where it is largely concentrated in New York City. The total imports into the United States from Canada and other countries in 1924 were valued at $87,705,582. About 20,000 concerns in the United States were handling furs in 1924. Of these, New York City alone had 2,000 wholesale manufacturers, who disposed of 80% of the manufactured furs sold in the wholesale trade. The fur-manufacturing establishments in the United States increased from 1,300 in 1914, employing 9,000 people, to 1,700 in 1923, with 19,000 employees. The wages paid increased from $6,000,000 in 1914 to $28,000,000 in 1923. The estimated retail value of furs and fur trimmings sold annually in the United States is $500,000,000.

FURTWÄNGLER, WILHELM (1886–), German conductor, was born in Berlin Jan. 25 1886, the son of the famous archaeologist and university professor, Adolf Furtwängler (1853–1907). He received his musical education in Munich from Beer-Walbrun, Rheinberger and Schillings, and then acted as conductor at Zürich. Later he occupied similar positions at Strasbourg, Lübeck, Mannheim, Vienna and Frankfort-on-Main. In 1922, on the death of Arthur Nikisch, he became director of the Berlin Philharmonic Orchestra and of the Gewandhaus concerts at Leipzig. Ranked among the finest conductors in Germany, Furtwängler also gained an international reputation, which was considerably enhanced by his annual concerts in New York.

GAELIC LITERATURE: *see* IRISH LITERATURE, GAELIC; SCOTTISH-GAELIC LITERATURE.

GAIRDNER, JAMES (1828–1912), British historian (*see* 11.390), died at Pinner, Middlesex, Nov. 4 1912. A third volume of his *Lollardy and the Reformation in England* appeared in 1911.

GALATZ or GALATI, Rumania (*see* 11.396), saw considerable industrial development before the World War. The population, 73,512 in 1914, was estimated in 1919 at 60,000. The export of grain and timber has revived, and there are grain- and flour-mills in the town. The port has been improved, and vessels of 5,000 tons can reach it since dredging on the Danube has been resumed; there is now from 20½ to 23 ft. at low water. The docks accommodate 10 steamers and 20 barges. The communications by road and rail, however, are unsatisfactory, and are liable to be interrupted altogether in winter. Galatz is the seat of the Rumanian naval school. The Rumanian naval base is at Sulina. (*See* DANUBE.)

GALE, ZONA (1874–), American author, was born at Portage, Wis., Aug. 26 1874. Having graduated from the University of Wisconsin, she engaged in newspaper work in Milwaukee, and in 1901 joined the staff of *The World* (New York). After 1904 she devoted herself to fiction, verse and plays, producing among other works, *The Loves of Pelleas and Ettarre* (1907); *Friendship Village Stories* (5 vol., 1908–19); *Birth* (1918); *Miss Lulu Bett* (1920); *The Secret Way*, verse (1921); and *Faint Perfume* (1923). She was awarded a Pulitzer Prize for her dramatisation of *Miss Lulu Bett*, produced in New York, 1920.

GALICIA, EAST (*see* GALICIA, 11.401), a district assigned to Poland in 1923. Its oil-fields are of great value. The province of Galicia, finally assigned to Austria in 1815, fell into two well-defined ethnographical parts. East of Przemysl, some 72% of the population was Ruthenian (Ukrainian), the minority being mainly composed of Poles and Jews, who are extraordinarily numerous in the towns. It was usually contended by the Poles of Galicia that Ruthenes do not exist; and the Austrian Govt. long accepted this theory in order to ensure the loyalty of the Poles. The Russian Govt. also supported this view in order to discourage the nationalist movement in the Ukraine; and the Ruthenes themselves were divided—one party feeling itself Russian, the other Ruthenian-Ukrainian. About 1910, when the Neo-Slav movement partly reconciled the Poles with the Russians, thus shaking their loyalty to Austria, Austria began to encourage the particularist Ruthenian movement as a counterblast to Panslavonic ideas.

During the War East Galicia was the scene of heavy and continuous fighting. During 1916–7, in view of the importance of Poland for the Central Powers, it was proposed to unite all Galicia with Russian Poland in a Kingdom of Poland more or less closely attached to Austria-Hungary. But after the collapse of Russia, the Central Powers concluded a peace with the Ukraine at Brest-Litovsk (Feb. 9 1918) and Austria-Hungary promised to erect East Galicia, with the Bukovina, into a separate Austrian territory (Kronland).

The Ruthenes Claim Independence.—While the claims of the Poles to autonomy were universally recognised, those of the Ruthenes were forgotten. In Oct. 1918 the Austrian Govt. having promised to introduce a federal system, the Polish leaders claimed for themselves all Galicia. The Ruthenes replied that they would rather "fight and die than let themselves be annexed by Poland." They summoned a conference of representatives of all Ruthenes of Austria-Hungary to meet at Lemberg (Lvov, Lwow, Léopol) on Oct. 18. The Socialist party pressed for immediate union with the Ukraine; but the bourgeois parties formed a National Council which determined to form an independent state, inviting the Polish and Jewish minorities to co-operate. On Nov. 1 the Council occupied the government buildings in Lemberg with the help of Ruthenian regiments, and assumed the government of East Galicia within its ethnographical limits. The Poles refused their co-operation, and fighting began between Poles and Ruthenes. The Austrian Govt. recognised the Ruthenian Govt. which was now formed under Dr. Eugen Petrushiewicz, and handed him over a share of the old Imperial assets; but the Poles immediately invaded East Galicia, occupying Lemberg on Nov. 5. The Ruthenian Govt. retired to Vienna, and its activities now became very platonic, being chiefly concerned with propaganda, in which it developed prodigious activity.

Meanwhile on Jan. 3 1919 the Hetman Petlura, who at that time had established his authority in the Ukraine, proclaimed the union of Russian Ukraine and West Ukraine (East Galicia) in a republic. The Ruthenian troops joined the Ukrainian Army with the consent of the East Galician Govt., which recognised Petlura's authority on Jan. 20. Fighting continued throughout 1919, during which time Polish troops occupied East Galicia, in defiance of the efforts of the Supreme Council to arrange a truce and settle the problem. On May 8 the Supreme Council assigned West Galicia to Poland; but on June 24 it decided to give East Galicia the right of self-determination, although authorising Poland to proceed with her military occupation of the district. The East Galician Govt. revoked its recognition of Ukrainian authority on Aug. 28 1919, and continued to assert the legality of its own position and the right of East Galicia to self-determination.

In Dec. 1919 the Allied and Associated Powers announced that East Galicia would be granted autonomy for 25 years under a Polish protectorate, after which time the League of Nations would decide on its future. This remarkable arrangement evoked vehement protests from the Ruthenes. It also caused a crisis in Poland, which desired unconditional possession of the district, and resulted in the fall of Paderewski. Petrushiewicz's Govt. was, however, powerless, and the numerous Ukrainian governments which existed simultaneously or consecutively were fully occupied in war with each other, the Poles, the Bolsheviks or the White Russians. In April 1920 Petlura abandoned his claim to East Galicia in return for recognition by Poland; Petlura's and the Polish armies captured Kiev from the Bolsheviks on May 8; but by Nov. the Bolsheviks had driven Petlura out of the Ukraine and established themselves there firmly. In Galicia, however, the Poles held their own, and the Treaties of Riga, Oct. 12 1920 and March 18 1921, re-established the old frontier of Galicia with the Ukraine.

Petrushiewicz's Govt. was in a disastrous position. It was ignored by everyone; its funds were running out; its choice of allies lay between its hereditary racial enemies, the Poles, and Bolshevik Ukraine. The Poles meanwhile treated the district as their own; held elections to the Polish Diet in it in the autumn of 1922—although practically the whole Ukrainian population abstained from voting—and even pressed Ruthenes into the Polish Army. On March 14 1923 the Conference of Ambassadors recognised Poland's *de facto* eastern, northern and southeastern frontier.

The Polish Régime.—Political activity in East Galicia did not lose its customary complexity after this date. Many political leaders, including Petrushiewicz, came to terms with the Soviet authorities. The great bulk of these unfortunates were unable to return to their homes. A small minority accepted the situation, and attempted to combine with the other racial minorities in Poland. A general law passed by the Polish Diet on Sept. 26 1922, which established local government bodies to deal with purely local affairs, contained the proviso that in the East Galician provinces these bodies should consist of two chambers, of which one should be Ruthenian. This "autonomy," as it was described, was to be introduced within two years; the language rights of minorities in Poland were to be respected, and colonisation forbidden. But in fact, although a language law was passed on July 10 1924, providing that Ukrainian, White Russian or Lithuanian should be the language of administration,

law-courts and schools in districts where the majority of the population speaks one of these languages, and Count Skrzynski showed a not illiberal attitude towards the minorities generally, Polish policy in general was not hampered by an excess of scruples towards the Ruthenes. (C. A. M.)

GALLI-CURCI, AMELITA (1889–), Italo-American singer, was born at Milan, Italy, Nov. 18 1889. As a vocalist she was self-taught. Gifted with a singularly pure soprano voice, she made her début as Gilda in *Rigoletto* at the Constanzi Theatre, Rome, in 1909, and subsequently visited Spain and South America. She made her first appearance in the United States at the Auditorium, Chicago, Nov. 18 1916, where she remained four seasons. She was engaged by the Metropolitan Opera Company, New York, in 1921 and from that date constantly appeared in grand opera and concerts. Among her chief rôles were Butterfly, Juliette, Lucia, Mimi, Rosine, Violetta and Manon Lescaut. She made a concert tour through Great Britain in 1924–5.

GALLIÉNI, JOSEPH SIMON (1849–1916), French general and statesman (*see* 11.418), reached the age limit for retirement on April 24 1914, but was retained on the active list without duty, and on July 31 1914 was officially confirmed as the eventual successor of the commander-in-chief. On Aug. 26 he was appointed Governor of Paris and general commanding the armies of Paris. He took energetic steps for the defence of the capital, and on Sept. 3 issued the following order: "To the Army of Paris and the Population of Paris: The Members of the Government of the Republic have left Paris in order to give a new impulse to national defence. I have been ordered to defend Paris against the invader. This order I shall fulfil to the end."

After Sept. 2 the armed forces in Paris had been placed under the orders of Joffre, who could thus in case of need use the garrison for his operations; consequently, on Sept. 3 Galliéni wrote to Joffre asking for instructions. From information received during the day, however, Galliéni concluded that the German forces marching on Paris were inclined southeast, thus offering him an exposed flank. Joffre's answer to Galliéni's messages arrived on the 4th a little before 3 P.M. and contemplated an attack south of the Marne. Galliéni held that to gain the fullest possible advantage from the situation by enveloping Von Kluck and breaking his lines of communication the attack ought to be made on the line of the Ourcq north of the Marne, and made at once. Galliéni spoke to Joffre on the telephone on the 4th at 5 P.M. and obtained authority to move on the 5th north of the Marne for the attack on the 6th. The VI. Army under Maunoury was placed under Gallićni's command. Maunoury was given all the troops available and ordered to move on the 5th to the heights of the Ourcq, to attack on the 6th. But, while executing this movement, Maunoury was himself attacked on the 5th by the German IV. Reserve Corps, which covered Von Kluck. The two armies were almost equal; six divisions against six. But during the night of the 7th–8th Galliéni sent up the 7th division in taxis from Paris to Nanteuil-le-Haudouin. The Germans retreated and the French armies moved out of the zone over which Galliéni held command.

On Oct. 29 1915 Galliéni became Minister of War in Briand's Cabinet. His period of office was made notable by endeavours to create unity of command and by changes in the position of Gen. Joffre. He resigned for reasons of ill-health on March 16 1916 and died at Versailles, after undergoing two operations, on May 27. His body was given a state funeral, and lay for a time under the dome of the Invalides. He was buried at St. Raphael. On April 21 1921 the dignity of marshal of France was conferred on him posthumously.

GALLIPOLI: *see* DARDANELLES CAMPAIGN.

GALSWORTHY, JOHN (1867–), British playwright and novelist, was born at Coombe, Surrey, Aug. 14 1867. Educated at Harrow and New College, Oxford, he was called to the bar in 1890, but devoted himself to literature. His first novel, *Jocelyn*, appeared in 1898, but he attracted wider attention in 1904 with *The Island Pharisees*, and *The Man of Property* (1906). The latter was the first novel of the sequence to be known later as *The Forsyte Saga*, the others being *The Indian Summer of a Forsyte* (1918); *In Chancery* (1920); *Awakening* (1920); and *To Let* (1921). As a detailed picture of upper middle-class society during the later Victorian and Edwardian eras, the sequence is a remarkable achievement. That picture was supplemented by the greater number of Galsworthy's other novels, of which it is the characteristic social setting, among them *The Country House* (1907); *Fraternity* (1909); *The Patrician* (1911); *The Freelands* (1915); *The White Monkey* (1924). Galsworthy also wrote *The Dark Flower*, 1913, and many short stories, of varying merit, but often worthy of his best work, collected as *Caravan* (1925), essays on current social and moral questions, marked by liberal and humane feeling, and a commentary on the extravagances of war time, *The Burning Spear*.

As a dramatist also, Galsworthy enjoyed a deserved fame. His plays, for the most part, are based on ethical or social problems and are marked by a scrupulously judicial fairness in displaying the opposing points of view typified by his characters. Some have partaken too much of this scrupulousness to be counted as having an essentially dramatic quality, but at their best Galsworthy's plays reflect not only his finest powers as a literary craftsman—for their diction is natural and serious without becoming loose or facile—but also a keen sense of dramatic values. Among them should be noted *The Silver Box* (1906); *Joy* (1907); *Strife* (1909); *Justice* (1910); *The Pigeon* (1912); *The Eldest Son* (1912); *The Fugitive* (1913); *The Skin Game* (1920); *Loyalties* (1922); *The Forest* (1924).

See S. Kaye-Smith, *John Galsworthy* (1916); André Chevrillon, *Trois Études Anglaises* (1924).

GALTON, SIR FRANCIS (1822–1911), British anthropologist (*see* 11.427), died at Haslemere Jan. 17 1911.

GALVANAUSKAS, ERNEST (1882–), Lithuanian statesman, was born Nov. 7 1882 at Vabalninkai. He studied as a mining engineer at Leningrad (St. Petersburg) and Liége, and his activities in the Lithuanian national movement date from his student days. In 1906 he was imprisoned for his attempts to free the country from the Russian yoke. He escaped to Belgium in 1908, where he continued in touch with the Lithuanian liberation movement. The outbreak of the World War found him in Belgrade, and after the enemy occupation of that city, Galvanauskas left with the Serbian Army and shared all the privations of the retreat. He subsequently proceeded to France and volunteered for military service. On the recovery of Lithuanian independence in 1918, Galvanauskas served as a member of the Lithuanian Delegation to the Versailles Peace Conference. He was several times Prime Minister and Minister for Foreign Affairs, and also held the portfolios of Finance and Communications. He became president of the Lithuanian Delegation to the League of Nations and in Aug. 1924 was appointed Lithuania's first envoy extraordinary and minister plenipotentiary to London and simultaneously envoy extraordinary and minister plenipotentiary to The Hague. In Nov. 1925, for services to the Serbian cause in the World War, he received from the King of Yugoslavia, the high military order "Albarrakom Spozeincom."

GAMBIA (*see* 11.437a), a British colony and protectorate in West Africa. Its population was 210,530 in 1921, an increase of 60,000 in 10 years. Bathurst, the capital, had 9,227 inhabitants, of whom Europeans numbered 265 (130 British). Hemmed in landward by French territories, which make but little use of its magnificent waterway, Gambia depends upon its own resources.

The cultivation of the ground nut, entirely a native industry, is the chief occupation of the people. Up to 1915 the nuts (the oil from which is a main ingredient of margarine) went mostly to France, which in 1914 took 78% of the crop. Changes caused by the World War led to over 91% of the export going to England in 1919. France subsequently in part recovered the market. In 1924 England took 54% and France 33% of the crop, which represented some 95% of the total exports. The economic crisis caused by the War was safely weathered and 1920 was a year of trade activity. Imports are mostly cotton piece goods, rice and sugar and, from Sierra Leone, kola nuts. Great Britain's share of the imports averaged over 50% in the years 1914–24; France, Ger-

many (since 1920) and the United States supply most of the other imports. In 1922 it became necessary to demonetise the French five franc piece, the favourite coin of the natives, and this involved the administration in a loss of £187,000.

Taking 1914 and 1924 as normal years the revenue rose from £86,000 to £208,000, the expenditure from £120,000 to £203,000. The tonnage of shipping entered and cleared was 1,100,000 in 1924 compared with 571,000 in 1914. British shipping predominated, but from 1921 Germany became a keen competitor and in 1924 was second, with 158,000 tons as against 643,000 British, 93,000 American and 92,000 French. Since 1901 Gambia has enjoyed political tranquillity, and education and Christianity made progress, if slowly. Most of the natives are Moslems. The Gambia Co. of the West African Frontier Force served with credit in the campaigns in the Cameroons and German East Africa. Bathurst was the first place visited by the Prince of Wales in his 1925 tour.

BIBLIOGRAPHY.—H. F. Reeve, *The Gambia* (1912), an excellent monograph by a retired official; Sir G. Denton, "Twenty-three Years in Lagos and the Gambia," *Jour. African Society*, vol. 11 (1912); *The Gambia* (1920), a British Foreign Office handbook, and the annual reports issued by the Colonial Office, London.

GAME PRESERVES: *see* NATIONAL PARKS.

GANDHI, MOHANDAS KARAMCHAND (1869–), Hindu nationalist leader, was born at Porbandar (Kathiawar, India) of a Bania family with official traditions. At the age of 19 he went to London, studied for a time at University College, and was called to the bar by the Inner Temple. Soon after starting practice in the Bombay High Court he was called, in 1893, on professional business, to South Africa, where he threw himself at once into a long and bitter struggle for the liberties of the Indian settlers in that country. He became leader of the opposition to a variety of measures taken by the local authorities to discourage Asiatic immigration and to limit the rights of citizenship available to Asiatics already resident.

It was in the course of this movement that his conception of resistance without violence developed; he relinquished his large income as an advocate, and founded a colony for his compatriots on Tolstoian lines near Durban. As the price he paid for his championship of the Indians' grievances, besides being more than once arrested and imprisoned he suffered frequent indignities at the hands of angry mobs. This neither checked his energies nor deterred him from rendering service of marked loyalty to the Government on three occasions; for he raised and commanded a Red Cross unit in the Boer War, he organised a plague hospital when the epidemic broke out in Johannesburg, and he led a stretcher-bearer party in the suppression of the Natal revolt of 1908. At last in 1914 a commission of inquiry into the Indian discontent recommended the removal of several of the worst injustices against which Gandhi had striven; and he felt justified in closing down his activities in South Africa and returning to India. There a wider field of political protest awaited him; and he was soon at work organising, in connection with the home-rule movement, resistance to the British Government by "soul force" and nonco-operation.

In Jan. 1919 there were published two bills (subsequently known as the Rowlatt Acts) giving the Government emergency powers for dealing with revolutionary crimes and conspiracies; these had followed the proposals of a responsible commission which had investigated the subject, and the powers they conferred were safeguarded by elaborate protections against abuse. But Gandhi declared them to be an insult, intended to discredit the Indian people on the eve of ostensible political reforms, and he denounced the bills as instruments of oppression. He instituted a campaign of Satyagraha (literally, insistance on truth) or non-violent disobedience to unjust laws in the first instance, enlarging if necessary into disobedience to any law and complete nonco-operation with the Government. Spreading rapidly, the agitation burst into violence in the Punjab and elsewhere, with results which shocked Gandhi into a temporary suspension of his civil disobedience. Later in the year, he formed common cause with the Indian Moslems of the Khilafat party, aggrieved by the terms of peace which Great Britain was offering to Turkey; and in July 1920 he proclaimed a general campaign of "non-violent nonco-operation." Its points were the boycott of Government service, of the new legislatures and of the courts of law; the surrender of all public offices; and the withdrawal of children from Government schools; to which were subsequently added boycott of foreign goods and the adoption of the spinning-wheel as an emblem of economic independence.

The agitation spread rapidly. The unlettered people who saw his earnestness and asceticism, and heard his simple eloquence, regarded him as a saint, and invested him with the title of Mahatma, or Great Soul. By 1921 Gandhi was at the zenith of his power. The national congress, sitting at Christmas of that year, delegated its full authority to him, and empowered him to appoint his own successor. But signs of change were now appearing. The unrest into which the non-co-operation movement had plunged the country culminated in a series of grave outrages, some of a racial character, of which the Moplah outbreak was the worst, and others directed against the agencies of law and order. Gandhi met them by personal penances, and by repeated postponements of the date on which he had foretold that India would be liberated from British rule. But he had generated forces which he had no power to recall or control, and plain people were getting alarmed at the consequences. Moslem support was being deflected from him by the encouragement which Lord Reading's Government was giving to Islamic sentiment over Turkey; and his closest adherents were embarrassed by his frequent changes of policy. Consequently, when he was arrested in March 1922 and put on trial for conspiring to spread disaffection with a view to overthrowing the government of the country, the *coup* evoked little excitement. Gandhi pleaded guilty, accepted responsibility for all that had happened and invited "the highest penalty that can be inflicted upon me for what in law is a deliberate crime and what appears to me to be the highest duty of a citizen."

Condemned to six years' simple imprisonment, he was released in Jan 1924 after an operation in gaol for appendicitis, and the rest of his sentence was unconditionally remitted. He came back to a party which had chosen other leaders, and was soon to reverse his policy of boycotting the administration. Esteemed and consulted though he continued to be by his old followers, he was no longer a power to sway the masses, and at the end of 1925 he announced his intentions of retiring from the world for a year. The nationalist movement was switched on to lines more familiar to western constitutional usage. To the Oriental mind Gandhi symbolised self-sacrifice and high idealism; western enthusiasts were not wanting who, like M. Romain Rolland, compared him with the Founder of Christianity; and the transparency of his character commanded the personal liking of even strong opponents. But he expected too much of human nature, he played recklessly with inflammable material, his economic nostrums were unpractical and he gave way to unexpected bursts of intolerance, as when he described the British government of India as "satanic." His endeavour to unite Hindus and Moslems lacked sincerity; but his enduring legacy to Indian politics will be the part he has taken in consolidating Hindu nationalism.

See Romain Rolland, *Mahatma Gandhi* (Paris, 1924); Eng. trans. by C. D. Groth, 1924.

(ME.)

GARDEN, MARY (1877–), American operatic singer, was born at Aberdeen, Scotland, Feb. 20 1877. At the age of six she was brought to the United States. In 1888 her family settled in Chicago, where her early musical training was received. She went to Paris in 1896, and studied under Trabadello, Chevallier and Fougère. She made her début at the Opéra Comique, Paris, April 3 1900 in the title rôle of *Louise*, taking the place, at a few days' notice, of Mlle. Riotou, who had fallen ill. Her first appearance in the United States was at New York in the title rôle of *Thais* Nov. 25 1907. In 1910 she became a member of the Chicago Grand Opera Company, assuming, among others, the parts of Salome, Thais, Mélisande and Louise. She was appointed general director of the Chicago Opera Association Jan 13 1921.

GARDEN CITY: *see* CITY PLANNING.

GARIBALDI, GIUSEPPE (1879–), Italian general, eldest son of Gen. Ricciotti Garibaldi and grandson of the Liberator, was born at Melbourne July 29 1879. He fought under his father in the Greco-Turkish War in 1897, and served in the South African War, subsequently leading an adventurous life in South and Central America and in the Balkans. On the outbreak of the World War he raised an Italian Legion of 14,000 men, which fought on the side of France in the Argonne. In 1915 Garibaldi returned to Italy, and on Italy's entry into the War he enlisted as a volunteer. He was soon afterwards commissioned, being given command of a battalion, and served with distinction in the IV. Army. He returned to the French front in March 1918 in command of the famous Brigata Alpi, and in June was promoted brigadier-general. He resigned his command in June 1919 and gave up his commission in Feb. 1920. He became opposed to the Fascist Govt. and in the autumn of 1924 was involved in an anti-Fascist agitation organised by the *Italia libera* Association. Deciding, however, that the movement had no chance of success, he departed for New York to devote himself to business.

GARLAND, HAMLIN (1860–), American writer, was born at West Salem, Wis., Sept 16 1860. He graduated from the Cedar Valley Seminary, Osage, Ia., at the age of 21. After teaching in Illinois and taking up a claim in South Dakota (then Dakota territory), he went to Boston in 1884 and engaged in literary work. The drudgery of farm life in the Middle West and the adventurous life of the mountains furnished him with abundant material for his realistic tales. His works, all based on the life of the northwest states, include *Main Travelled Roads* (1890–8); *Ulysses S. Grant: His Life and Character* (1898); *Boy Life on the Prairie* (1907); *The Long Trail* (1907); *Money Magic* (1907); *Cavanagh* (1909); *Other Main Travelled Roads* (1913); *The Tyranny of the Dark* (1905); *A Son of the Middle Border* (1917); *A Daughter of the Middle Border* (1921); *The Book of the American Indian* (1923). He was made a member of the American Academy of Arts and Letters in 1918.

GARSTIN, SIR WILLIAM EDMUND (1849–1925), British engineer, was born in India Jan. 29 1849. He was educated at Cheltenham and King's College, London, and in 1872 entered the Indian Public Works Department. In 1885 he was transferred to Egypt and in 1892 became inspector-general of irrigation and Under-secretary of State for Public Works. He proved himself an indefatigable worker, and by his efforts extensive areas were reclaimed in Egypt and the Sudan. Among his greatest works were the Asyut barrage and the Aswan reservoir. In addition, it was due to him that the White Nile was cleared of sudd, thus rendering possible free navigation between Khartoum and Gondokoro. He was created K.C.M.G. in 1897 and G.C.M.G. in 1902. In 1907 he was appointed British Govt. director of the Suez Canal Company. During the World War he devoted himself to Red Cross Work in England, being created G.B.E. in 1918. He died in London Jan. 8 1925.

GARVIN, JAMES LOUIS (1868–), British publicist, and editor-in-chief of the present volumes of *The Encyclopædia Britannica*, was born at Birkenhead, Ches., April 12 1868. A political writer from the age of 17, he joined *The Newcastle Chronicle*, where from 1891 to 1899 he was leader-writer, literary critic and aide-de-camp to its proprietor, the celebrated orator, Joseph Cowen. From the age of 26 for many years he was a chief contributor to *The Fortnightly Review*, and later to *The National Review* and *The Quarterly*. In 1899 he went to London, joining the staff of *The Daily Telegraph*, which gave him unusual scope. When Mr. Joseph Chamberlain started his historic campaign for tariff reform and Imperial unity, Mr. Garvin became nationally known as that statesman's most powerful lieutenant in the Press. Editor in 1905–6 of the weekly review *The Outlook*, he passed in 1908 to the editorial chair of *The Observer*. He raised that oldest of great Sunday journals to the highest position it had ever reached, and made it quoted throughout the world. Simultaneously from 1912 to 1915 his editorship gave new life to the evening *Pall Mall Gazette*. Steeped in German studies, his articles on foreign affairs, anticipating the World War from as early as 1901, had a deep public influence. In the War his articles were famous; but, equally the advocate of "absolute victory" and a wise peace, he was a searching and damaging critic of the Treaty of Versailles. To promote international reconciliation and co-operation he wrote in six weeks during the Paris conference (1919) his elaborate book *The Economic Foundations of Peace*. His only son, Gerard, who had justified high hopes, was killed at the age of 20 in the battle of the Somme, gallantly leading two companies of the South Lancashire Regiment in a night action. Behind all Mr. Garvin's politics there is a deep background of history and literature. In 1926 he was chosen chairman of the Empire Press Union.

GARY, ELBERT HENRY (1846–), American jurist and business man, was born near Wheaton, Ill., Oct. 8 1846. He attended Wheaton College and then, after studying law for a time in an office, he continued his legal studies at the University of Chicago, and took the degree of LL.B. in 1867. In 1871 he began practice in Chicago, where he became a noted corporation lawyer. In 1874 he organised the Gary-Wheaton Bank, of which he was president. He was elected judge of Du Page Co. in 1882 and again in 1886; was three times elected president of the town of Wheaton, and on its becoming a city in 1892 served as mayor for two terms. He was president of the Chicago Bar Association 1893–4. He early saw the advantages of combination in business and in 1891 was one of the organisers of the Consolidated Steel & Wire Co. In 1898, upon the organisation of the Federal Steel Corporation, with a capital stock of $200,000,000, he became its head and retired from legal practice. This company was merged in the United States Steel Corporation in 1901 with a capital stock exceeding $1,000,000,000 and he was elected chairman of the board of directors and of the finance committee. He continues to fill these offices after twenty-five years of remarkable development of the steel industry, and growth of the corporation. The town of Gary, Ind., laid out in 1906 as a model home for steel workmen, was named in his honour. In 1914 he was made chairman of the committee appointed by Mr. Mitchel, mayor of New York, to study the question of unemployment and its relief.

When America entered the World War in 1917, Gary was appointed chairman of the committee on steel of the council of national defence. Through his own connection with a business essential for munitions of war he exerted great influence in bringing about co-operation between the Government and industry. He was interested in a strengthening the friendship between America and Japan. In 1919 he was invited by President Wilson to attend the Industrial Conference in Washington, and took a prominent part in it as a firm upholder of the "open shop," of which he was always a strong advocate. He also opposed the drastic restriction of immigration effected by the "Quota" law. Miss Ida M. Tarbell's *Life of Judge Gary* concludes with these words: "He has made a lasting contribution to our difficult and often baffling problem of substituting, in American business, balance for instability, mutual interest for militarism, co-operation for defiance, frankness for secrecy, goodwill for distrust. No man in contemporary affairs has more honestly earned the high title of industrial statesman."

GARY, Ind., U.S.A. (*see* 11.480), had become in 1920 a city with 55,378 inhabitants of whom 5,299 were negroes and 16,460 foreign-born. In 1925, the 20th year of its existence, its population was 81,888 (school census); it had an area of 40·83 sq. m., 155·35 m. of improved and 178·45 m. of unimproved streets, 15 m. of boulevards, 45 m. of street railway track, a fleet of motor-buses and 94 m. of water-mains. The assessed valuation of taxable property was $131,006,810. There were over 1,000 retail stores. During the nation-wide strike of the steel workers in 1919, Gary was occupied by Federal troops from Oct. 7 until the strike was called off on Jan. 7 1920. A city-planning commission was appointed in 1919 and a comprehensive zoning ordinance was adopted in 1925. The "Gary Gateway and Railway Developement," which was adopted in 1924, provided for improved freight and passenger facilities and for beautifying a large section.

The public schools of Gary offer academic instruction 48 weeks in the year and physical training for 52 weeks of 6½ days each week. The first superintendent of schools, William A. Wirt, worked out a system with the following features: (1) an enriched curriculum; (2) a school plant adapted to such curriculum, with playground, gymnasium, swimming-pool, shops, laboratories and auditorium; and (3) organisation of classes on a "platoon" system, by which each feature of the plant is in use all the time, thus providing for the most economical utilisation of both plant and teaching force. This administrative scheme (3) became known among educators as the "Gary Plan" and was adopted, with more or less modification, in many cities.

See F. P. Bachman and R. Bowman, *The Gary Public Schools*, a Study by the General Education Board in eight parts (New York, 1918).

GAS IN WARFARE: *see* CHEMICAL WARFARE.

GAS, MANUFACTURE OF (*see* 11.483)—In the period 1910–25 the work done on gas retorts, coke ovens, gas generators, the complete gasification of coal, low temperature carbonisation and other operations in the gas industry has been considerable. During the War, gas-retort and coke-oven plants were worked to their full capacity; repairs and renewals were often unavoidably deferred or effected under difficult conditions. Gas and coke manufacturers have studied nearly every branch of the industry, and therefore many important changes have taken place.

Therms.—In Great Britain the provisions of the Gas Regulation Act of 1920 impose an obligation on the suppliers to charge for gas at a price based on the calorific value of the gas and specified the use of a recording calorimeter for determining this value. The calorific unit selected, the therm, is equal to 100,000 B.T.U.'s or British Thermal Units. Each gas undertaking formally declares the calorific value of the gas it proposes to supply; this is called its "declared calorific value" and is usually from 450 to 500 B.T.U.'s per cubic foot of gas.

The method of reading the gas meter remains the same, but the gas account is made out in therms at so much per therm. The number of therms is easily computed, for, suppose that the meter readings show that 10,800 cu. ft. of gas have been supplied and that 500 is the declared calorific value, then $10,800 \times 500 \div 100,000 = 54$ therms. At tenpence per therm, the gas bill would be £2·5·0.

The Act allows a gas undertaking to declare any calorific value it chooses. Therefore, subject to the requirements of gas purification, the company is free to adopt gas-making processes which will yield the maximum number of therms for every ton of coal treated. Clearly, it may be most profitable to supply a mixed gas, or to leave in the gas constituents which, like benzol, have a high thermal value; with gas and benzol at their present prices, benzol is usually left in the gas.

Calorimeters.—Among the recording calorimeters used by gas undertakings are the Simmance Total Heat, the Fairweather, and the Boys, in all of which the heat of combustion of known quantities of gas to be tested is imparted to a flow of water; the Thomas, in which the heat is imparted to air; and the Beasley, in which a differential thermometer filled with oil is employed. At large gasworks, several calorimeters are used, one in connection with the town's gas supply and the others with the separate gas-making plants.

Refractory Materials.—In Great Britain, siliceous clays containing 80 to 92% of silica and silica clays with more than 92% of silica have been used to an increasing extent in the gas industry and carborundum has also been tried. For the hotter parts of vertical retorts, siliceous and silica clays are commonly used and silica clays have been employed largely in constructing the coke-oven plant of the Consett Iron Co., Ltd., and other companies. In America the use of silica clays is the standard practice, not only for the hotter parts of vertical retorts and for the chamber ovens of the Koppers and other types for supplying gas, but also for horizontal retorts.

Silica bricks are more fragile, and have a coefficient of expansion greater than that of firebricks. Their greater heat conductivity facilitates rapid carbonisation; they sustain high temperatures and keep their shape in a satisfactory way. It is probable that the life of silica is greater than that of fireclay retorts and ovens. At St. Helens, eight Glover-West retorts, in which Friden silica was used, had an average working life of 1,694 days. Some of the American chamber ovens, constructed by Messrs. Koppers, have worked continuously for 15 years and are said not to have needed repairs (*see* ELECTRO-METALLURGY).

Carborundum is very refractory, hard and strong; its coefficient of expansion is very small; its heat conductivity is about five times that of fireclay. The future of this valuable refractory material will depend largely on its initial cost, and on its behaviour in an oxidising atmosphere at high temperatures. Williamson, Cliff, Ltd., of Stamford, have constructed a horizontal retort with a tile of carborundum extending along the central part of the retort sole. In the United States, carborundum has been used in both retort and gas generator construction.

The Retort Controversy.—The question of the best type of gas retort has been decided to a large extent by the selections made by numerous gas engineers when erecting new installations of retorts. There are installations of inclined retorts working satisfactorily and numerous installations of horizontal retorts provided with efficient charging and discharging machines, but the tendency is clearly in the direction of using continuously operated vertical retorts.

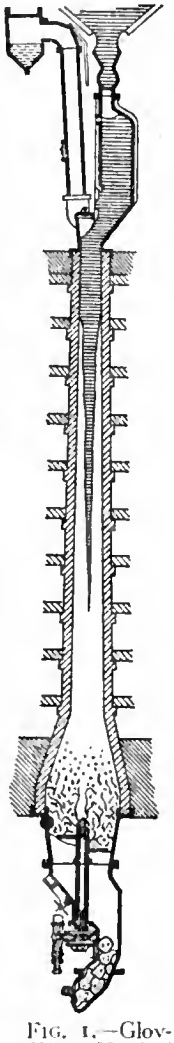

FIG. 1.—Glover-West Vertical Retort.

Horizontal Retorts.—The improvements made since 1910 in these retorts and their settings have been mainly in details. Some continuously operated horizontal retorts erected by West's Gas Improvement Co., Ltd., at Blackpool and Middleton, did not show any advantages over the Glover-West vertical retort, and were abandoned.

Vertical Retorts.—The chief improvements in vertical retorts have been in connection with those of the continuously operated type, in which coal is fed into the top of the retort and coke discharged from the bottom in a continuous and regular manner, the retort increasing in area downward to facilitate descent of the charge. The Glover-West and the Woodall-Duckham vertical retorts are the chief examples.

The Glover-West continuous vertical retort was originally developed on principles deduced from the practice with Scotch shale retorts. In its most approved form, the 40-in. new model, the cross-section is a flattened ellipse, the major axis of the mean section being 40 inches. Vertically, the retort enlarges regularly until the steaming chamber or "bell-bottom," clearly shown in fig. 1, is reached. This chamber opens up the core of coke and permits the exposure of a large surface of coke to the action of steam injected for making water gas. A powerful helix mounted on a vertical shaft, shown in fig. 1, supports the full weight of the coke; it is driven by worm gearing and, as it revolves, the coke is lowered continuously and regularly into the coke chamber, with a minimum of breakage. A step-grate producer generates gas which is led to combustion chambers arranged horizontally across the lines of retorts. The temperature distribution can be readily varied over the whole length, about 25 ft., of the retort, according to the carbonisation requirements of the coal treated. The Glover-West was successfully worked at the St. Helens gasworks in 1909. Since then, more than 135 gas undertakings in all parts of the world have adopted it; the new model has been installed recently at Oldbury, Nine Elms (Gas Light and Coke Co.), Dudley Leicester, Toronto and Malden, United States of America.

In the Woodall-Duckham continuous vertical retort the

continuous and regular discharge of the coke is effected by an extractor roller formed of a series of stars set on a horizontal shaft slightly in advance of each other, so as to form helical blades. The shaft is mounted in a gas-tight hopper, having one side curved so as not to prevent descent of the coke by gravitation while supporting the greater part of its weight.

Heating of the retort is effected by means of a regenerative gas producer. There are two very hot combustion chambers, one at the top of the retort and another lower down for ensuring that the charge is hot enough for obtaining good water gas by the action of steam admitted to the retort. The Woodall-Duckham retorts were installed at the Bournemouth gasworks, 1903–5; since then, numerous installations have been set up in all parts of the world. Among the most recent are those at Dunfermline, Glasgow, Edinburgh, Warrington and Bergen.

Coke Ovens.—The course of development in coke-oven practice has been chiefly in the utilisation of surplus gas for town supply, and in the installation of very large ovens of known types. In Great Britain parliamentary sanction was first given in 1910 for the supply of coke-oven gas. The Board of Trade returns for 1924 gave 16 towns taking gas from colliery and other coke-oven plants, Chesterfield, Sheffield, Leeds, Middlesborough and Pontypridd being included. Most coke ovens in Great Britain do not take a charge exceeding 8 tons, but ovens of the Piette type, of nearly 18 tons capacity, have been built at Stoke-on-Trent by the Semet-Solvay and Piette Co. of Sheffield. In the United States, it is common practice to use coke ovens of about 15 tons capacity.

Charging and Discharging.—The introduction during recent years of efficient charging and discharging apparatus has done much to enable horizontal retorts to compete with other types of retort. Many charging machines, *e.g.*, the Arrol-Foulis hydraulic charger and the de Brouwer, which projects the coal into the retort, are worked in association with a separate discharger. Drake's projector and pusher is a combination of a pusher made up of large, jointed sections, adapted to fold over a rotary, polygonal drum and a rapidly rotating wheel with vanes for projecting coal into the retort; the pusher discharges the retort and is withdrawn, and then the projector comes into operation. A further development is a type of apparatus called a discharging charger, of which Guest and Gibbons' discharging charger is an example; it is described in British Patent Specification No. 103143/1916. A sectional, jointed trough which, as it travels forward from its supporting wheel, discharges the coke, has mounted within it rollers supporting and guiding an endless drag-bar chain. During the withdrawal of the trough, this chain is driven independently and carries coal into the retort so as to fill it completely.

Steaming Practice.—Steam has been used, especially in the Dessau intermittent retorts, to increase the yield of ammonia. During recent years, however, the practice has been greatly extended, especially in working continuous vertical retorts, which are admirably adapted for steaming. The method admits of numerous easy variations; usually superheated steam under a pressure of 10 to 40 lb. per sq. in. through a $\frac{1}{4}$-in. nozzle. As long as the steaming is not excessive, it increases the yield of gas, ammonia (*q.v.*) and tar, and also the total thermal yield, although the calorific value per cu. ft. of gas is lowered.

Coal Blending.—The blending of different kinds of coal has long been practised, especially in America, to obtain suitable charges for use in coke ovens. Coal blending has recently attracted attention, especially in connection with smokeless fuel production. It has been proposed to mix several kinds of coal so as to obtain a blend having a predetermined resinic content or yielding a predetermined amount of volatile matter when heated. By this blending, it is sought to minimise the expansion of the coal when carbonised at low temperature, to facilitate discharge by preventing the coke from sticking to the retort, and to obtain a coke of good quality. Processes of this kind are described in British Patent Specifications Nos. 164104 and 186085 (Illingworth) and 187336 (Roberts).

Coal Cleaning.—The removal of clay, shale, pyrites and other impurities from coal by washing processes is important, especially in preparing charges for ovens used in making metallurgical coke, and in connection with smokeless fuel production to facilitate the making of a good quality fuel. The catalytic action of some of the inorganic constituents during carbonising processes, is also receiving attention.

Carburetted Water Gas.—During recent years, increasing quantities of water gas, especially carburetted water gas, have been made in Great Britain. In America, more than one-half of the gas manufactured is carburetted water gas; Philadelphia is supplied almost entirely with this gas.

In the self-clinkering, self-steaming generator of Humphreys and Glasgow, Ltd., an annular water jacket forms the lower part of the generator and supports an upper firebrick part; the jacket is high enough to prevent adhesion of clinkers to the generator wall. A steam reservoir communicates with the jacket by pipes, and serves as a source of steam supply for the generator. A mechanically operated grate, having an upper conical part, formed with air passages, and a lower cylindrical part, is mounted eccentrically on the base of a rotary water pan. A central conduit conducts the air blast or steam or carries away the down-run gas, when the run is downward, for the run may be upward or downward as desired. During its rotation, the grate crushes and expels the clinker and ash, the carbon content of which has been reduced as much as possible. The speed of the grate is regulated automatically; this regulation may be effected by electric means, the action of which is controlled by the temperature beneath the grate. When carburetted water gas is to be produced, the gas is led from the generator to a carburettor supplied with a spray of heavy oil and thence to a super-heater in which the cracked oil-vapour is fixed.

Many of these generators are working in association with batteries of horizontal or vertical retorts, the whole representing a very advanced development of gas-making plant. The coke

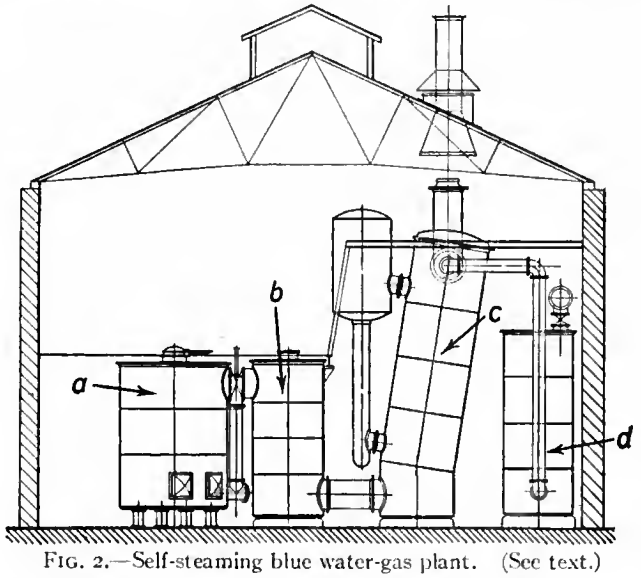

FIG. 2.—Self-steaming blue water-gas plant. (See text.)

from the retorts, in a cold, clean state, is charged into the producers and the operation of the whole installation effects a substantially complete gasification of the coal. The loss of heat of the incandescent coke is of comparatively small importance, for the clean, cold coke is rapidly brought to an incandescent state in the generator and there is no expensive handling of hot coke. A self-steaming, self-contained, blue water-gas plant, erected by Humphreys and Glasgow, Ltd., comprises (*a*) a generator, (*b*) a recuperator, (*c*) a waste-heat boiler and (*d*) a washer-scrubber (see fig. 2). This firm has brought into commercial use a means for automatically operating a generator plant, in which a series of valves governing the interdependent operations necessary in working, *e.g.*, coke feed, air supply, steam supply, duration of blow, etc., is operated by hydraulic power in an order correct in time and sequence. The order of operation, determined by the conditions of temperature, pressure, etc., in, or connected with, the generator, is set once for all by adjusting the indicators of a series of dials corresponding respectively with the various valves. If any valve fails to respond in its turn, the cycle of operations is stopped automatically by the action of electric circuits; this prevents explosions or other accidents.

Complete Gasification of Coal.—Complete gasification of coal in two steps is commercially successful. Numerous attempts have been made to effect complete gasification in one operation, but none appears to have been successful commercially. One of the earliest attempts was made many years ago by Fahnehjelm in the U.S.A.; his apparatus was a compact structure comprising a vertical conical retort, surrounded by heating flues and supported by a generator below. One of the many difficulties of this apparently simple process was that of obtaining in the

generator a regular supply from the retort of incandescent coke suitable for yielding gas. A great deal has been achieved in Germany by extensive trials of Strache's apparatus, which is generally similar to Fahnehjelm's. The problem is, in fact, receiving careful attention and complete success may be achieved.

Low Temperature Carbonisation (*see* FUEL PROBLEMS).—This is a process for the partial destructive distillation of coal at temperatures which are low compared with those of an ordinary gas retort or coke oven; an important aim of the process is to obtain a smokeless fuel suitable for burning in ordinary grates. About 1865, experiments on partial destructive distillation of coal were made by Mr. Scott-Moncrieff, but the process which has led to a more intensive study of the subject is that patented by Mr. Thomas Parker (British Specification No. 14,365 of 1906), for subjecting bituminous coal to destructive distillation at a temperature of about 800° F., until illuminating gases cease to be evolved, then stopping the distillation and quenching the charge. This process, usually carried out in tubular iron retorts, was tried repeatedly and many improvements were made, especially by Low Temperature Carbonising, Ltd., whose retort plant, set up near Barnsley, operates at a temperature between 600° C. and 800° C.

Other investigators have worked processes of this kind. The South Metropolitan Gas Co. (London) has made experiments on low temperature carbonisation with a view to obtain a good quality smokeless fuel. An installation of rotary, inclined retorts, developed by Mr. Nielsen, has also been worked near Barnsley, the temperature of working being about 675° C. By these processes, a smokeless fuel, burning freely with a clear flame, and almost odourless, has been obtained, together with a moderately large quantity of a rich gas, and good yields of tar and ammonia. No plant, however, has been working, on a commercial scale, long enough to justify an assertion that the process is a success. Any plant for which it is claimed that the problem of low temperature carbonisation has been solved may be tested, free of cost, by the Fuel Research Board, so that the possibilities of the process are still being considered.

Bergius Process.—A process which has attracted a great deal of attention, especially in Germany, is the Bergius process, elaborated by Prof. Bergius. Experiments have been made at Mannheim and recently efforts have been made to carry out the process commercially. The chief aim of the process is to obtain oil from coal and it is claimed that coal of poor quality can be used advantageously. The coal is pulverised, mixed with oil residues from a previous operation, and heated to a temperature of about 450° C. in an atmosphere of hydrogen under a pressure of about 150 atmospheres. The product is a viscous mass from which the oils can be separated.

Gas Purification.—During the 15 years under review numerous improvements in the details of construction of gas purifying apparatus have been made, especially in connection with the grids and valves of purifier boxes. In modern gasworks water-cooled tubular condensers, bubble washers of the Livesey type, the Pelouze and Audouin type of tar extractors, and rotary brush scrubbers of the Holmes type are largely in use.

Attempts to introduce new purifying processes have been made. In Birkheiser's process, two rather small oxide purifiers, working together, are used, the crude gas being passed through one for removal of SH_2 while a blast of air is passed through the other to revivify the oxide by converting its absorbed SH_2 into SO_2; this SO_2 is used to recover ammonia. This process and a later modification were tried at the Tegel gasworks, Berlin, and also at Bournemouth, but, apparently, not with complete success.

Processes have been introduced by W. Feld, all ingenious, but most of them too complicated for commercial use. In one, used with success in Germany, the reagents employed are a solution of $FeSO_4$ for washing the crude gas and, in later steps of the cycle of operations, a mixture of SO_2 and air. Both SH_2 and NH_3 are eliminated from the gas, the ultimate products being ammonium sulphate and sulphur, which is filtered off, and thus recovered in solid form.

Gasholders.—Some exceptionally large gasholders have been erected during recent years. The largest gasholders in the world appear to be those of the Astoria Gasworks, New York. Two gasholders in course of erection at Birmingham are intended to have five lifts and a total capacity of 20,000,000 cubic feet. A waterless, or tankless, gasholder recently erected in Michigan, is a chamber of polygonal cross section with a capacity of 1,000,000 cubic feet. The chamber is closed by a piston, which moves up and down within it. A tar seal forms a gas-tight joint between the chamber and its piston and is a very important part of the whole construction. In countries where the winters are severe, a waterless gasholder offers advantages. (T.E.L.)

GASES, ELECTRICAL PROPERTIES OF (*see* 6.864). These vary very greatly with the conditions to which the gas is exposed. A gas in its normal condition is practically a non-conductor of electricity even though it be the vapour of a good conductor like mercury. On the other hand, when it is exposed to such influences as cathode rays, Röntgen rays, intense electrical forces or the radiation from radioactive substances, it becomes a conductor of electricity. The very delicate methods now at our disposal reveal however a trace of conductivity in gases where precautions have been taken to shield off the effects just mentioned.

The most important electrical property of a gas in a normal state is its specific inductive capacity. The significance of this property is best illustrated from the relation $(K-1)/4\pi = NM$, between K, the specific inductive capacity; N, the number of molecules per unit volume, and M, the electrostatic moment which a molecule acquires under unit electric force. As we know N, we can if we know the value of K deduce the value of M, and this will tell us a good deal about the shape and size of the molecule. For example, if we regard the molecules as solid conducting spheres, $M = r^3$ where r is the radius of the sphere. Thus, on this hypothesis we can find the radius of the molecule if we know the value of K, and though the hypothesis itself does not throw much light on the structure of the atom, it is probable that the radius of a conducting sphere which would produce the same electrical moment would be of the same order of magnitude as the linear dimensions of the molecule: the radii of metallic spheres which would give the specific inductive capacities possessed by hydrogen, nitrogen, oxygen and chlorine, are respectively $1{\cdot}19\times10^{-8}$, $1{\cdot}60\times10^{-8}$, $1{\cdot}48\times10^{-8}$, $2{\cdot}04\times10^{-8}$ centimetres. On the more probable hypothesis that the atoms and molecules consist of electrons arranged round centres of positive electricity, the electric force will displace the electrons relatively to the positive centres and thus cause the molecule to have a finite electrical moment. The more rigidly the electrons are connected to the positive charge, the smaller will be this moment and the smaller the specific inductive capacity of the gas.

The values of $K-1$ for the elements belonging to the same family are connected by a remarkably simple and interesting relation, which was discovered by Cuthbertson (*Phil. Trans.* A.207, p.135). It is shown in Table I. where the numbers under the symbols denoting the elements are the values of $\frac{1}{2}(K-1)\times10^6$:—

TABLE I.

			He $144\times\frac{1}{2}$
N 297	O 270	F 192	Ne 137
P 1197 $=299\times4$	S 1101 $=275\times4$	Cl 768 $=192\times4$	Ar 568 $=142\times4$
As 1550 $=258\times6$	Se 1565 $=261\times6$	Br. 1125 $=187\times6$	Kr 850 $=142\times6$
	Te 2495 $=249\times10$	I 1920 $=192\times10$	X 1378 $=138\times10$

Thus the values of $K-1$ for successive elements of the same family—(N, P, As): (O, S, Se, Te): (F, Cl, Br I): (Ne, Ar, Kr, X)—are in all cases very nearly in the proportion 1, 4, 6, 10. In the simple theory, where the molecules are regarded as conductors, this would indicate that the volumes of the molecules of the

successive elements in the same family are in the proportion 1, 4, 6, 10, for each of these types of elements. On the theory which regards the atom as built up of electrons arranged round positive centres, the configuration of the outer layer of electrons for different members of the same family would be similar, and it is easy to show that for similar configurations of electrons the value of $K-1$ would be proportional to the cube of the linear dimensions, *i.e.*, to the volume enclosed by the outer layer of electrons; so that again on this theory Cuthbertson's result shows that volumes of successive elements in the same family are in the same ratio whether the family be that of the inert gases, the halogens, or the oxygen or nitrogen groups.

W. L. Bragg (*Phil. Mag.*, 40, p.169) using the method of Röntgen ray crystal analysis has measured directly the diameters of the atoms of many of the elements. He finds that the cubes of the diameters of F, Cl, Br, and I are proportional to 1, 3·72, 5·45 and 8 respectively; those of O, S, Se to 1, 3·9 and 6, and those of C and Si to 1, 3·6. Thus for these electronegative elements the ratio of the volumes of corresponding elements in two different periods is approximately constant. This, however, is not true for electropositive elements, where the sizes of the atoms in one period increase much more slowly from one element to the next than they do for the electronegative elements.

Another example of the information as to the nature of the molecule afforded by determinations of the specific inductive capacity is that, while the specific inductive capacity of many gases, *e.g.*, H_2, N_2, O_2, CO, CO_2, Cl_2, is equal (as Maxwell's Electromagnetic Theory of Light suggests) to the square of the refractive index, there are, as Bädeker (*Zeitschrift Physik. Chem.*, 36, p.305) has shown, others, such as NH_3, HCl, SO_2, and the vapours of water and the alcohols, whose specific inductive capacity is far in excess of the value given by this rule, and moreover the specific inductive capacity of these gases diminishes much more rapidly as the temperature increases than that of gases of the first type. The difference can be accounted for by supposing that the molecules of gases of the first type have no electrical moment when they are free from the action of an external electrical force, while those of the second type have an intrinsic electrical moment apart from that which may be produced by the external force. When there is no electrical field, the collisions between the molecules will cause the axes of electrical moments of the different molecules to be uniformly distributed, so that the average effect will be zero. An electric force will tend to drag the axes of the different molecules into alignment, and the assemblage of molecules will have a finite electrical moment which will be a measure of the specific inductive capacity. Inasmuch as the collisions between the molecules tend to knock their axes out of line and diminish the specific inductive capacity, the latter will diminish as the temperature and with it the vigour of the encounters increases. The substances which have an intrinsic electrical moment have exceptionally active chemical properties and are good solvents, dissociating the salts dissolved in them.

If the distribution of electrons in a molecule were not symmetrical about three axes at right angles to each other, the specific inductive capacity of a single molecule would vary with the direction of the electric force, but as the molecules in a gas are orientated in equal numbers in all directions we should not detect this by direct measurements of the specific inductive capacity. We can however detect this effect in another way; for if the molecules have different specific inductive capacities in different directions the light scattered by the molecules at right angles to the incident unpolarised light will not be plane polarised as it would be if the molecule were symmetrical (J. J. Thomson, *Phil. Mag.*, 40, p. 393), and if the incident light is plane polarised the scattered light will not vanish in any direction. Strutt (now Lord Rayleigh) (*Proc. Roy. Soc.*, 98A, 57) has measured the departure from plane polarisation for different gases with the results shown in Table II.

This shows that the molecule of argon is very symmetrical, while the nitrogen molecule is more symmetrical than that of oxygen, and this again more symmetrical than that of CO_2.

TABLE II.

Argon	0·46 %
Hydrogen	3·83 %
Nitrogen	4·06 %
Air	5·00 %
Oxygen	9·40 %
Carbon dioxide	11·70 %
Nitrous oxide	15·40 %

Ionised Gases.—Gases may in various ways be put into a state in which they conduct electricity on an altogether different scale from the normal gas. They acquire this conductivity when Röntgen rays or the rays from radioactive substances pass through them, or when they are traversed by cathode or positive rays. Ultra-violet light of very short wave length can impart this property to a gas, while gases recently driven from flames or from near arcs or sparks or bubbled through certain liquids or passed slowly over phosphorus also possess this property.

The conductivity of gases possesses interesting characteristics. In the first place it persists for some time after the agent which made the gas a conductor has ceased to act; it always however diminishes after the agent is removed, in some cases very rapidly, and finally disappears. The conducting gas loses its conductivity if it is sucked through glass-wool, or made to bubble through water. The conductivity may also be removed by making the gas traverse a strong electric field so that a current of electricity passes through it. The removal of the conductivity by filtering the gas through glass-wool or water shows that the conductivity is due to something mixed with the gas which can be removed by filtration, while the removal of the conductivity by the electrical field shows that this something is charged with electricity and moves under the action of the electric force. Since the gas when in the conducting state shows as a whole no charge of electricity the charges mixed with the gas must be both positive and negative. We conclude that the conductivity of the gas is due to the presence of electrified particles; some of these particles are positively, others negatively, electrified. These electrified particles are called ions, and the process by which they are produced ionisation.

The passage of electricity through a conducting gas does not follow the same laws as the flow through metals and liquid

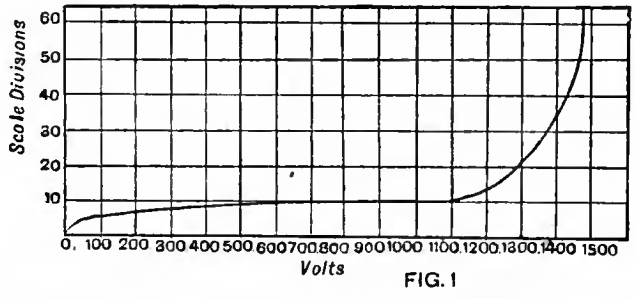

FIG. 1

electrolytes; in these the current is proportional to the electromotive force, while for gases the relation is represented by a graph like fig. 1, where the ordinates are proportional to the current and the abscissae to the electromotive forces. We see that when the electromotive force is small, the current is proportional to the electromotive force, as in the case of metallic conduction; as the electromotive force increases, the current after a time does not increase nearly so rapidly, and a stage is reached where the current remains constant in spite of the increase in the electromotive force. There is a further stage, which we shall consider later, where the current again increases with the electromotive force, and does so much more rapidly than at any previous stage. The current in the stage when it does not depend upon the electromotive force is said to be saturated. The reason for this saturation is that the passage of a current of electricity through the gas involves the removal of a number of ions proportional to the quantity of electricity passing through the gas. Thus the gas is losing ions at a rate proportional to the current; it cannot go on losing more ions than are produced, so that the current cannot increase beyond a critical value which is proportional to the rate of production of ions. This sometimes

produces a state of things which seems anomalous to those accustomed to look at conduction of electricity exclusively from the point of Ohm's law. For example, when gases are exposed to Röntgen rays, the number of ions produced per second is proportional to the volume of the gas, so that, if two parallel plates are immersed in such a gas and a current sent from one to the other, when the distance between the plates is increased the number of ions available for carrying the current and therefore the saturation current will be increased also. Thus the apparent "resistance" will diminish as the length of the gaseous conductor is increased.

The Nature of the Ions.—The question arises, what is the nature of the particles which carry the charges of electricity? Are they the atoms or molecules of the gas, or, for the negative charges, electrons? Information on these points is afforded by measuring the velocity with which the ions move through the gas under given electric forces.

The ion under the action of the electric force will soon attain a steady velocity which will be determined by the condition that the momentum communicated to the ion by the electric force in unit time is equal to the momentum lost by the ion in the same time by its collisions with the molecules of gas through which it is moving. Suppose that the average momentum lost by the ion per collision is qmu where m is the mass of the ion, u its velocity and q a quantity which will depend on the relative masses of the ion and the molecule and also on the force between the ion and the molecules, *e.g.*, if the ions and molecules behaved like elastice spheres q would not be the same as if they acted upon each other with forces varying inversely as the fifth power of the distance between them. The value of q will also depend on the electric charge on the ion. The number of collisions made by an ion with the molecules of the gas in time δt may be written as $\delta t/T$. Where T is the average interval between two collisions, T will vary inversely as the number of molecules in unit volume, *i.e.*, inversely as the density of the gas and will also depend upon the temperature and the masses of the ions and molecules. When the loss of momentum by collisions balances the gain from the electric force F

$$Fe\delta t = \frac{qmu\delta t}{T} \qquad (1)$$

$$\text{or } u = \frac{FeT}{mq}$$

we can determine by experiment the value of u/F and hence the value of T/mq. This will give us information as to the nature of the ions, *e.g.*, we can by the kinetic theory of gases calculate the values of T and q when the ion is a molecule of the gas and when the collision between an ion and a molecule is the same as that between two molecules; on these suppositions the calculated mobility is for most gases considerably greater than that found by experiment. The difference is to be explained by the effect of the electric charge on the collision and also the clustering of other molecules round the charged one to form a more complex ion. These two effects are not independent for it can be shown that if the effect of the charge is large enough seriously to affect the mobility, it follows by the Laws of Thermodynamics that the forces between the ions and the molecules must be great enough to lead to considerable aggregation at room temperatures. The effects to be expected from the formation of such aggregates may be illustrated from the expression for k, the mobility of the ion, *i.e.*, the velocity of the ion under unit force, deduced on the assumption that the force between the ion and the molecule varies inversely as the fifth power of the distance between them, this expression is

$$k = \frac{e}{2\pi N}\left\{\frac{M_1+M_2}{M_1\times M_2}\right\}^{\frac{1}{2}}\left\{1\cdot 1\epsilon\sqrt{(\mu^2-1)/N\pi}+\frac{s^2}{2}\sqrt{2\beta\theta}\right\}^{-\frac{1}{2}} \qquad (2)$$

where M_1, M_2 are the masses of the molecule and ion respectively, N the number of molecules per unit volume, μ the refractive index of the gas, s the sum of the radii of an ion and a molecule and $\beta\theta$ the energy of a molecule due to thermal agitation when θ is the absolute temperature of the gas. For most gases the effect of the term $s^2\sqrt{2\beta\theta}$ is insignificant. When this is so the effect of the complexity of the ion is represented by the term

$$\left(\frac{M_1+M_2}{M_1M_2}\right)^{\frac{1}{2}}$$

This varies but slowly with the complexity, for when the ion consists of a single molecule $M_2=M_1$ and the expression is $\sqrt{2/M_1}$ while when the ion consists of an infinite number of molecules the value is $\sqrt{1/M_1}$ thus this great increase in mass only reduces the mobility in the proportion of 1 to $\sqrt{2}$. The formula given above for k may be used to find the value of M_2/M_1 and for positive ions in most cases this ratio is found to be greater than one. This indicates the formation of complex ions; these under the impact of the molecules break up and new aggregates are formed around the simple ions. This constant change of partners by the ions explains the very remarkable fact that in a mixture of different gases all the ions appear to move with the same velocity. Thus in a mixture of a light gas like hydrogen with a heavy one like methyl iodide we do not find ions of great mobility corresponding to the hydrogen and others of smaller mobility corresponding to the methyl iodide. Wellisch has shown that all the ions in the mixture move with the same velocity. If there had been stable ions with masses comparable with the hydrogen molecules and others comparable with the methyl iodide molecule they could easily have been differentiated. If however the ions form aggregates and the partners of the ions in these aggregates are constantly changing so that during the life of the ion it passes backwards and forwards through a great number of different phases, then though at any particular instant one ion might have a different mobility from another, yet the average mobility taken over a finite time would be the same for all the ions. To detect the different kinds of ions it would be necessary to observe not their average behaviour over a long time but to make the measurements so quickly that the ion had not time to pass from one state to another whilst it was under observation. The life of an ion in a particular phase is, at atmospheric pressure, probably considerably less than the millionth of a second; the length of life will vary inversely as the pressure so that the chance of detecting the different kinds of ions would be much greater at low pressures than at high ones.

Lately Erikson has detected a case when the velocity of the ion changes even though the gas through which it is moving remains the same; he has shown that the mobility of the positive ions in air at atmospheric pressure is, in the first second or so of their existence, about 1·89 but as the ions get older the mobility falls to 1·35, the ratio of these numbers is nearly equal to $\sqrt{2}$ which is the ratio of the mobility of an ion consisting of one molecule to that of one consisting of a very large number. It would thus seem that the old ions are much more complex than the young ones. The surprising thing about Erikson's result is that he found the ions to retain their youthful properties for the best part of a second at atmospheric pressure; during this time the ion will have collided with many million molecules of air, and so might have been expected to form partners in a very small fraction of a second. The results are consistent with the idea that the ion forms a stable connection with the molecules of some very heavy gas present in very small quantities as an impurity. The addition to the gas of small quantities of the vapours of water or alcohol whose molecules have a finite electrical moment produces a marked diminution in the mobility, indicating that they give rise to aggregates of exceptional permanence. Formula (2) is obtained on the assumption that the force between the ion and the molecule is due to electrostatic induction alone and so varies inversely as the fifth power of the distance; if the gas were one like water vapour or ammonia whose molecules are polar, the force between the ion and the molecule would vary inversely as the fourth instead of the fifth power of the distance and the mobility would not be given by formula (2).

We see from this formula that unless M_2/M_1 depends upon the pressure the mobility is inversely proportional to N, *i.e.*, to the pressure of the gas. This law has been verified for positive ions

down to pressures less than 1 mm. of mercury. As however the probability of forming complex aggregates is greater at high than at low pressures, we should expect M_2/M_1 to diminish as the pressure diminishes; this diminution in M_2/M_1 would produce a small increase in the mobility so that the formula would indicate that the mobility would increase just a little more quickly than the reciprocal of the pressure.

The behaviour of negative ions is in many respects quite different from that of the positive ones. In the first place the mobility of the negative ions is for the permanent gases greater than that of the positive; thus, for example, in dry hydrogen the velocities of the negative and positive ions, when the electric force is one volt per cm., are 7·95 and 6·7 respectively, and for air 1·87 and 1·36. The difference is less for moist gases than for dry, while for complex vapours which have comparatively small mobilities Wellisch found that there was very little difference between the mobilities of the positive and negative ions.

For the permanent gases the ratio of the mobilities of the negative and positive ions varies but little with the pressure, until the pressure is reduced below that represented by about 10 cm. of mercury. For lower pressures than this, the mobility of the negative ion increases, as Langevin showed, more rapidly than that of the positive; at the pressure of a millimetre or so the mobility of the negative ion in air may be three or four times that of the positive.

An even more interesting result was discovered by Franck and Hertz, who, when they experimented with very carefully purified nitrogen or argon, found that the mobility of the negative ion was more than 100 times that of the positive. The mobilities in these gases are extremely sensitive to traces of oxygen, and a fraction of 1% of oxygen added to the pure gas will reduce the mobility of the negative ion to less than one-tenth of its maximum value. The enormous mobility of the negative ion in nitrogen and argon as compared with that of the positive shows that in them the negative electricity must be carried by electrons and not by atoms or molecules, while the effect of introducing traces of oxygen shows that these electrons readily attach themselves to the molecules of oxygen though they are unable to adhere to molecules of nitrogen or argon. The same effect has also been observed in helium and hydrogen.

These properties of the negative ion are of great importance in connection with the mechanism of ionisation in gases and the structure of atoms and molecules. In the first place, they furnish strong evidence in support of the view that the first stage in the ionisation of a gas is the ejection of an electron from the molecule of the gas rather than the separation of the molecule into atoms of which some are charged with positive and others with negative electricity. On this view the negative ion begins its career as an electron and not as an atom, while the positive ion from the beginning is of molecular dimensions. As an electron has much greater mobility than a molecule the mobility of the negative ion will at first be much greater than that of the positive. In some gases, such as oxygen, the electron soon gets attached to a molecule, and its mass and mobility become comparable with those of the positive ion. The mobility we measure is the average mobility of the negative ion during its life; part of the time its mobility, being that of an electron, is very much larger than that of the positive ion, while in the other part the two mobilities will be much the same. The excess of mobility of the negative over the positive ion will depend upon the fraction of its life which the negative ion spends as a free electron—a fraction which would tend to increase as the pressure of the gas diminished.

The mobility of the electron may be estimated by formula (2); if the gas is nitrogen we must in that formula put $M_2/M_1 = 1/28\times1800$ which is the ratio of the mass of an electron to that of a nitrogen molecule. Using this value for M_2/M_1 we find that the mobility of the electron is about 220 times that of the positive ion, a result which is confirmed by experiment. Direct experiments on the mobility of negative ions do not give any indication of the existence of two kinds of these ions. This may be regarded as a confirmation of the explanation of the similar result for the positive ions, viz.: that our methods only give the average mobility of the ion through a comparatively long life; for there can be but little doubt that in all but a very few gases the negative ion can exist in two phases, one of them being the electron. The mobility in the electron phase is so exceptional that anything which prolongs the duration of this phase in comparison with that of the other phases must have a great effect upon the mobility. Some observations by Loeb (*Phys. Review*, 17, p.89) give us some information about the time an electron in oxygen requires to unite with the molecule and form a negative ion. He found that the electron made about 50,000 collisions with an oxygen molecule before combining with it and that this number is independent of the pressure. The time taken to make these collisions, taking the velocity of the electron at 0° C. as 10^7 and the free path as 10^{-5} at 760 mm., is 5×10^{-8} sec. and this will measure the life of the free electron. It is evident that, even allowing for the great mobility of the electron, it could not appreciably affect the mobility in experiments lasting for a time comparable with ·01 sec., and the mobility would be practically that of the negative ion, unless the electron were able to break away again from a molecule after it had united with it. The mobility of the carriers of negative electricity as compared with that of the positive one is evidence that the electron is continually changing partners. If k_1 be the mobility of the electron, k_2 that of the negative ion, T_1 the life of the electron, T_2 that of the negative ion, the average mobility will be

$$\frac{k_1T_1 + k_2T_2}{T_1 + T_2}$$

If p is the pressure of the gas, k_1 and k_2 vary inversely as the pressure, let them equal K_1/p, K_2/p, then the mobility is equal to

$$\frac{1}{p}\left\{\frac{K_1T_1 + K_2T_2}{T_1 + T_2}\right\} \qquad (3)$$

Since Loeb's experiments show that the electron makes the same number of collisions before uniting with the molecule whatever be the pressure, and since the interval between each collision is inversely proportional to the pressure, T_1 varies as $1/p$, if the breaking up of the negative ions were due to collisions with the molecules T_2 would also vary as $1/p$ and the ratio of T_1 to T_2 would be independent of the pressure. This from equation (3) would make the mobility of the negative ion like that of the positive vary inversely as the pressure and would not explain the abnormal increase of the negative carriers at low pressures. Hence we conclude that the breaking up of the negative ions is not due to collisions. If T_2 is independent of p, while T_1 increases as p diminishes the product of the mobility and pressure will by (3), since k_1 is greater than k_2, increase as p diminishes, which is in accordance with the results observed by Langevin and others.

The difference between the behaviour of the electron in nitrogen or argon and in oxygen discovered by Franck and Hertz is of great importance in connection with the structure of the atom and molecule, for it indicates that, while a molecule of oxygen can accommodate another electron in addition to those already present, the molecules of nitrogen and argon are unable to do so. It is instructive therefore to consider the results obtained by the study of the positive rays as to the power of the atoms and molecules of the different elements to acquire a negative charge. These show that, while the atoms of hydrogen, carbon, oxygen, fluorine or chlorine readily acquire a negative charge, those of helium, nitrogen, neon and argon do not; and again that, while it is very exceptional for a molecule whether of a compound or an elementary gas to acquire a negative charge, the molecule of oxygen is able to do so. We see that this result is in accordance with the behaviour of the carrier of the negative charge in an ionised gas. Since the atoms in the positive rays show so much greater affinity for the electrons than the molecules, it follows that if the agent producing ionisation were to dissociate some of the molecules of the gas into neutral atoms (and to do this would require the expenditure of much less energy than to ionise the gas), these atoms would be much more effective traps for the electrons than the undissociated molecules. Loeb

has shown that even in oxygen an electron collides on the average with about 50,000 molecules of oxygen before it is captured; thus if the oxygen *atom* could capture an electron at the first encounter, if only one molecule in 50,000 were dissociated into atoms, the effect of the atoms would be as efficacious as that of the molecules in capturing the electrons. When this dissociation into atoms takes place the abnormal velocity of the negative ion will only occur in gases like nitrogen and the inert gases whose *atoms* cannot receive an electron.

Recombination of the Ions.—Even when the ions are not removed from a gas by sending a current of electricity through it, their number will not increase indefinitely with the time of exposure of the gas to the ionising agent. This is due to the recombination which takes place between the positive and negative ions; these ions as they move about in the gas sometimes come into collision with each other, and by forming electrically neutral systems cease to act as ions. The gas will reach a steady state with regard to ionisation when the number of ions which disappear in one second as the result of the collisions is equal to the number produced in the same time by the ionising agent.

If there are n ions of either kind per cu. cm., the number of collisions between the positive and negative ions in one second in a cu. cm. of the gas will be proportional to n^2; hence the number of ions of either sign which are lost by recombination in one second may be represented by αn^2 when α is called the coefficient of recombination. If the ionising agent produces q ions per cu. cm. per sec., then

$$\frac{dn}{dt} = q - \alpha n^2.$$

The solution of this equation, if we reckon t from the instant the ionising agent begins to act, so that $n=0$ when $t=0$, is $k^2=q/\alpha$

$$n = \frac{k(\epsilon^{2k\alpha t}-1)}{\epsilon^{2k\alpha t}+1}.$$

We see that, when the gas reaches a steady state, $n=k=\sqrt{q/\alpha}$, and that the gas will not approximate to this state until t is large compared with $1/2k\alpha$, *i.e.*, to $1/2\,n_0\alpha$ where n_0 is the value of n in the steady state. Thus when the ionisation is very weak it may take a considerable time for the gas to reach a steady state.

When the ionising agent is removed, the ions do not disappear at once, but decay at the rate given by the equation

$$\frac{dn}{dt} = -\alpha n^2.$$

The solution of this, when t is the time which has elapsed since the removal of the ionising agents, and n_0 the number of ions when $t=0$, is

$$n = n_0/(1+n_0\alpha t).$$

Thus the number of ions will be reduced to one-half their initial value after a time $1/\alpha n_0$. We may therefore take $1/\alpha n$ as the measure of the life of an ion when there are n ions per cubic centimetre. The values of α/e, where e is the charge on an ion, have been measured by various experimenters; the results are given in the following table: the agent used to ionise the gas is given in the second row.

TABLE III.

Values of α/e for Various Gases at Atmospheric Pressure and Ordinary Temperature

Gas	Townsend	McClung	Langevin	Thirkill	Hendren	Retschinsky	Rumelin	
	Röntgen rays	Röntgen rays	Röntgen rays	Röntgen rays	α rays	α rays	α rays	β rays
Air	3,420	3,380	3,200	3,580	3,300	4,200	4,240	5,820
CO_2	3,520	3,490	3,400	3,500	..	..	..	..
H_2	3,020	2,940	..	..	..	..	..	..
O_2	3,380	..	..	..	..	..	..	..
SO_2	..	..	..	3,000	..	..	..	..
N_2O	..	..	..	2,960	..	..	..	..
CO	..	..	..	1,780	..	..	..	..

The results ascribed to Thirkill were obtained by extrapolation from experiments made at lower pressures. Since e, in electrostatic measure, is $4{\cdot}8\times10^{-10}$, the value of α for air is about $1{\cdot}6\times10^{-6}$, so that, when there are n positive and n negative ions per cu. cm., the number of ions which recombine per second is

$$1{\cdot}6\times10^{-6}n^2.$$

This shows very markedly the influence of the electric charge in increasing the number of collisions between the particles, for the number of collisions in a second between $2n$, uncharged molecules in a cu. cm. of air is

$$4\times10^{-10}n^2.$$

which is only about 1/4,000 of the number of recombinations between the same number of ions.

The ions like the molecules of the gas will in consequence of thermal agitation be moving with high velocities, and unless the distance between them is less than a certain value will drift apart and not combine. The condition that they should not separate if they are a distance d apart is that the kinetic energy due to their relative motion should be less than e^2/d the work required to separate the ions to an infinite distance. The average kinetic energy due to their relative motion is equal to $\beta\theta$ where $\beta\theta$ is the average kinetic energy of a molecule at the absolute temperature θ; β is equal to $2{\cdot}02\times10^{-16}$. Hence the ions will separate unless

$$2{\cdot}02\times10^{-16}\theta < e^2/d.$$

At 0° C, $\theta=273$ and since $e=4{\cdot}8\times10^{-10}$ this condition shows that they will separate at this temperature unless d is less than $4{\cdot}18\times10^{-6}$ centimetres. This is on the supposition that they are not subject to any influence other than their mutual attraction. As they move through the gas they may, if one or other of them when they are close together comes into collision with a molecule of the gas, lose some of the kinetic energy which would enable them to separate. Assuming that collision with a molecule reduces the kinetic energy due to relative motion to $\beta\theta$, the value it has for thermal equilibrium, it follows that to ensure combination the collision with the molecules must occur when d, the distance between the ions, is less than $e^2/\beta\theta$ and that every such collision leads to recombination. To find the rate at which the ions recombine we have to find the number of collisions between ions and molecules which occur in one second, only those collisions to be counted when an ion is within a distance d of one of opposite sign at the time of collision. It can be shown (see J. J. Thomson, *Phil. Mag.*, 47, p. 337) that this number is equal to

$$\pi d^2\rho\rho^1\sqrt{U^2+U_1^2}(1-\omega\omega^1)$$

where

$$\omega = \frac{\lambda^2}{2d^2}\left(1-\epsilon^{\frac{-2d}{\lambda}}\left[1+\frac{2d}{\lambda}\right]\right)$$

$$\omega^1 = \frac{\lambda_1^2}{2d^2}\left(1-\epsilon^{\frac{-2d}{\lambda_1}}\left[1+\frac{2d}{\lambda_1}\right]\right)$$

where λ and λ_1 are respectively the mean free paths of the positive and negative ion through the gas, U and U_1 the mean velocities of these ions due to their thermal agitation, ρ and ρ^1 the number of positive and negative ions per unit volume and $d=e^2/\beta\theta$.

It follows from the definition that α the coefficient of recombination is given by the equation

$$\alpha = \pi d^2\sqrt{U^2+U_1^2}\,(1-\omega\omega^1).$$

When the pressure is low enough to make $2d/\lambda$ and $2d/\lambda_1$ small, then $1-\omega\omega^1 = \frac{4}{3}d\left(\frac{1}{\lambda}+\frac{1}{\lambda_1}\right)$ approximately,

so that $\alpha = \frac{4}{3}\pi d^3\sqrt{U^2+U_1^2}\left(\frac{1}{\lambda}+\frac{1}{\lambda_1}\right)$.

Both $1/\lambda$ and $1/\lambda_1$ are proportional to the pressure, so that at low pressures α varies as the pressure, which agrees with the results of Thirkill's experiments. When the pressure is so high that λ/d and λ_1/d are small, ω and ω^1 are small and

$$\alpha = \pi d^2\sqrt{U^2+U_1^2}$$

approximately, so that α is independent of the pressure.

When the density is constant the value of α diminishes as the temperature increases. The connection between α and the absolute temperature T seems to be expressed with fair accuracy by the equation

$$\alpha = cT^{-n}$$

According to Erikson, n is equal to 2·3, 2·42, 2·35 for hydrogen, air and CO_2 respectively, while Phillips's experiments gave $n = 2$.

Diffusion of Ions.—In addition to the loss of ions by recombination, there will be a loss due to the diffusion of the ions to the side of the vessel in which they are contained; when the ions strike against the walls they may lose their charges and thus cease to be ions. The loss of ions from this cause will be proportional to the surface of the vessel, while that due to recombination will be proportional to the volume, thus the ratio of the loss by diffusion to that by recombination will be greater in small vessels than in large. Again the rate of diffusion is inversely proportional to the pressure while that of recombination is directly proportional to it, thus the loss by diffusion will be relatively more important at low pressures than at high.

Large Ions.—The ions we have been considering are those produced in dust-free gases by Röntgen or cathode rays. In some cases, however, ions with very much lower mobilities are to be found in gases. Thus Langevin found in air from the top of the Eiffel Tower two types of ions, one consisting of ions of the kind we have been considering, with a mobility of about 1·5 cm./sec., the other of ions with a mobility of 1/3,000 cm./second. Ions with mobilities of the same order as this second type may be produced by bubbling air through water, by passing air over phosphorus or by drawing air from the neighbourhood of flames. They are probably charged particles of dust of various kinds, held in suspension in gas which is exposed to some kind of ionising agent which gives a supply of ions of the first type; these settle on the particles of dust and form the slow ions. The number of these slow ions, when the gas is in a steady state, will depend only on the number of dust particles in the gas and will not be affected by the strength of the ionising agent. This follows from the principle that in the steady state the number of dust particles which acquire a positive charge must equal the number which lose such a charge. A positively electrified dust particle might lose its charge by meeting and coalescing with a negative small ion or by coalescing with a negatively electrified dust particle. These dust particles are, however, so sluggish in their movements that, unless the dust particles are enormously more numerous than the small ions, we may neglect the second source of loss in comparison with the first.

Thus if U is the number of uncharged dust particles in a cu. cm. of the gas, P and N the number of those with positive and negative charges respectively and p, n, the number of positive and negative small ions, then the number of dust particles which acquire per second a positive charge will be $\alpha U p$ and the number losing such a charge by coalescing with a negative ion $\beta P n$, where α and β are constants; hence for equilibrium

$$\alpha U p = \beta P n$$

Similarly by considering the negatively charged particles we get

$$\alpha' U n = \beta' N p$$

Hence we see that the proportion between the charged and uncharged particles of dust depends only upon the ratio of p to n, and not upon the absolute magnitude of either of these quantities. Thus, though it would take much longer to reach the steady state with a feeble source of ionisation than with a strong one, when that state was reached there would be as much dust electrified in one case as in the other. De Broglie estimates that in this state about one-tenth of the particles would be electrified.

Relation Between the Potential Difference and the Current Through an Ionised Gas.—We shall take the case of two infinite parallel metal plates maintained at different potentials and immersed in an ionised gas; the line at right angles to these plates we shall take as the axis of x, it being evidently parallel to the direction of the electric force X. Let n_1, n_2 be respectively the number of positive and negative ions at the place fixed by the co-ordinate x; u_1 and u_2 the velocities of these ions. The volume density of the electrification in the gas, if it is entirely due to the ions, is $(n_1 - n_2)e$ when e is the charge on an ion, hence

$$\frac{dX}{dx} = 4\pi(n_1 - n_2)e \qquad (1)$$

If ι is the current through a unit area of the gas

$$\iota = e(n_1u_1 + n_2u_2) \qquad (2)$$

Hence from (1) and (2) we have

$$n_1e = \frac{\iota}{u_1+u_2} + \frac{1}{4\pi}\frac{u_2}{u_1+u_2}\frac{dX}{dx} \qquad (3)$$

$$n_2e = \frac{\iota}{u_1+u_2} - \frac{1}{4\pi}\frac{u_1}{u_1+u_2}\frac{dX}{dx} \qquad (4)$$

When things are in a steady state, neglecting any loss of ions by diffusion we have

$$\frac{d}{dx}(n_1u_1) = q - \alpha n_1n_2 \qquad (5)$$

$$-\frac{d}{dx}(n_2u_2) = q - \alpha n_1n_2 \qquad (6)$$

where q is the number of ions produced per second in a cu. cm. of gas, and α is the coefficient of recombination; if k_1, k_2 are the mobilities of the positive and negative ions respectively, then

$$u_1 = k_1X \qquad u_2 = k_2X$$

From equations (1), (5) and (6) we get

$$\frac{d^2X^2}{dx^2} = 8\pi e(q - \alpha n_1n_2)\left(\frac{1}{k_1}+\frac{1}{k_2}\right)$$

and, substituting the values of n_1 and n_2, we get

$$\frac{d^2X^2}{dx^2} = 8\pi e\left(\frac{1}{k_1}+\frac{1}{k_2}\right)\left\{q - \frac{\alpha}{e^2X^2(k_1+k_2)^2}\left(\iota + \frac{k_2}{8\pi}\frac{dX^2}{dx}\right)\left(\iota - \frac{k_1}{8\pi}\frac{dX^2}{dx}\right)\right\} \qquad (7)$$

No general solution of this equation has been obtained, but when ι is small compared with the saturation current qle, l being the distance between the plates, an approximate solution is represented by the graph in fig. 2.

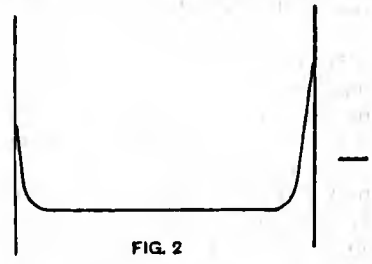

FIG. 2

The force is practically constant, and equal to

$$\left(\frac{\alpha}{q}\right)^{\frac{1}{2}}\frac{\iota}{e(k_1+k_2)}$$

except close to the electrode, where it increases; and as the mobility of the negative ion is greater than that of the positive the increase in the force will be greater at the cathode than at the anode. As the potential difference between the electrode increases, and the current approaches more nearly the saturation value, the flat part of the graph diminishes, and the graph for X takes the form given in fig. 3. When the potential difference is so large that the current is nearly saturated, X is very approximately constant from one electrode to another.

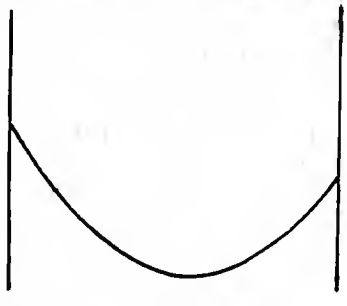

FIG. 3

In one extremely important case, that in which the negative ions are electrons and have a mobility which may be regarded as infinite in comparison with that of the positive ions, equation (7) admits of integration: for by putting $k_1/k_2 = 0$ in equation (8) it becomes

$$\frac{dX^2}{dx} + \frac{8\pi e^2k_2qX^2}{\alpha\iota} = \frac{8\pi\iota}{k_2} \qquad (8)$$

The solution of this is

$$X^2 = \frac{\alpha\iota^2}{qk_2^2e^2}\left(1 + \frac{k_2}{k_1}\frac{\iota - \iota_0}{\iota}\epsilon^{\frac{-8\pi e^2k_2qX}{\alpha\iota}}\right) \qquad (9)$$

when x is the distance from the cathode and ι_0 the amount of negative electricity emitted by unit area of the cathode per unit time.

This distribution of force is represented by the graph in fig. 4; the force at some distance from the cathode is equal to

$$\frac{\iota}{k_2}\left(\frac{a}{q}\right)^{\frac{1}{2}}$$

and is thus proportional to the current; the force at the cathode itself is $\{1+k_2(\iota-\iota_0)/k_1\iota\}^{\frac{1}{2}}$ times greater than this. The fall of potential between the electrodes is made up of two parts, one arising from the constant force; as this force is proportional to ι this part of the potential fall will be proportional to ιl when

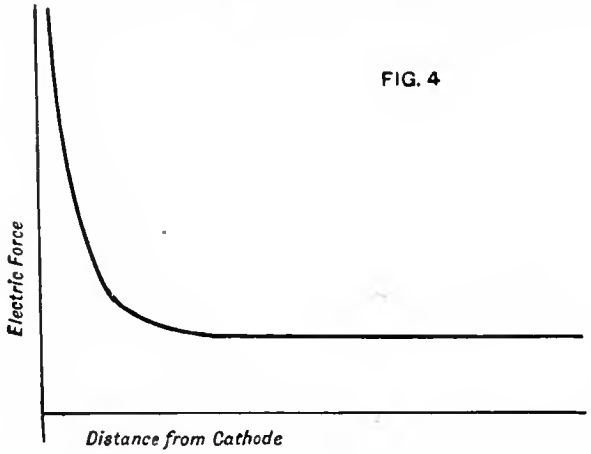

FIG. 4

l is the distance between the electrodes, and may be represented by Ad when A is a constant; the other part of the potential fall is that which occurs close to the cathode. We find from equation (9) that this is proportional to ι^2 and does not depend upon l. Thus, if V is the potential difference between the electrodes when A and B are constants

$$V = Ad+B\iota^2. \qquad (10)$$

H. A. Wilson has shown that an equation of this type represents the relation between the current and potential difference for conduction through flames. In many cases the drop of potential at the cathode is much greater than the fall in the rest of the circuit; when this is so we see that the current is proportional to the square root of the potential difference. The value of B increases with the pressure and decreases with the amount of the ionisation.

Current from Hot Wires.—A case of great importance from its industrial application in hot wire valves is one where all the ions are negative and are emitted from the cathode. Metal wires or plates raised to incandescence emit electrons, and if they are used as cathodes can transmit across a vacuum or gas at a low pressure very considerable currents.

Let the hot cathode be the plate x=o and let V be the potential at the point x, n the density of the negative ions at this point, and ι the current through unit area. If u is the velocity of the negative ion, we have

$$nue = \iota \quad \text{and} \quad \frac{d^2V}{dx^2} = 4\pi ne.$$

There are two cases to be considered; the first is when the hot plate is surrounded by gas of sufficient density to make the velocity of the ions proportional to the electric force; the second is when it is surrounded by a vacuum, and the motion of the ions is not affected by the gas.

In the first case $u=k_2\frac{dV}{dx}$, when k_2 is the mobility of the negative ion, and the equation $nue=\iota$ is equivalent to

$$\frac{k_2}{4\pi}\frac{dV}{dx}\frac{d^2V}{dx^2} = \iota. \qquad (11)$$

The solution of this is

$$\left(\frac{dV}{dx}\right)^2 = \frac{8\pi\iota}{k_2}x+C.$$

Therefore if V is the difference of potential between the anode and cathode, and l the distance between them

$$V = \frac{k}{12\pi\iota}\left[\left(\frac{8\pi ld}{k}+C\right)^{\frac{3}{2}}-C^{\frac{3}{2}}\right] \qquad (12)$$

where C is the constant of integration.

In consequence of thermal agitation some of the electrons near the plate will diffuse backwards and hit the plate; if n_0 is the density of the electrons near the plate it follows from the Kinetic Theory of Gases that the number hitting the plate in unit time is $n_0c/\sqrt{6\pi}$, where c is the velocity of mean square, *i.e.*, $\frac{1}{2}mc^2=\frac{3}{2}R\theta$; m is the mass of an electron, θ the absolute temperature of the electrons and R the gas constant $1\cdot35+10^{-16}$.

If I is the current per unit area emitted by the plate, then in consequence of the diffusion there is a backward current $en_0c/\sqrt{6\pi}$, so that ι, the current going through the gas is given by the equation

$$I-\frac{en_0c}{\sqrt{6\pi}} = \iota.$$

If u_0 is the velocity acquired by the electrons near the plate under the electric force, $\iota=en_0u$, hence

$$\frac{\iota}{I-\iota} = \frac{u_0}{c}\sqrt{6\pi}. \qquad (13)$$

So that, unless ι is small compared with I, u_0 will be comparable with c; in this case, however, the velocity of the ion is no longer proportional to the electric force so that equation (11) no longer holds. Again, when the current approaches saturation, $\iota/(I-\iota)$ is large and therefore by (13) u_0 will be large compared with c. For the negative ion to acquire a velocity of this magnitude the electric field would have to be so strong that sparks would pass through the gas unless the pressure were very low. Thus saturation currents from hot bodies are only obtainable at very low pressures.

Since the electric force when $x=o$ is $\sqrt{C}$, $u_0=k\sqrt{C}$, and therefore by (13)

$$C = \frac{c^2}{6\pi k^2}\frac{\iota^2}{(I-\iota)^2}.$$

Thus if the current is far from saturation, C will be negligible compared with $8\pi ld/k$. When C can be neglected, equation (12) gives

$$\iota = \frac{9k}{32\pi}\frac{V^2}{l^3}. \qquad (14)$$

Thus the current is proportional to the square of the potential difference. A remarkable thing about this expression is that for these very small currents the intensity of the current is independent of the temperature of the plate, although, of course, the range of currents over which this formula is applicable is wider the higher the temperature.

When the hot body is in a vacuum, we have, if the ions have no initial velocity,

$$\tfrac{1}{2}mu^2 = Ve$$

where m is the mass and e the charge on an ion; hence the equation $nue=\iota$ is equivalent to

$$\frac{d^2V}{dx^2}V^{\frac{1}{2}} = 4\pi\iota\sqrt{m/2e} \qquad (15)$$

a solution of which is

$$V = (9\pi\iota)^{\frac{2}{3}}(m/2e)^{\frac{1}{3}}x^{\frac{4}{3}}. \qquad (16)$$

Hence, if V is the potential difference and l the distance between the electrodes

$$\iota = \frac{l}{9\pi l^2}\left(\frac{2e}{m}\right)^{\frac{1}{2}}V^{\frac{3}{2}}. \qquad (17)$$

We see from equation (16) that the electric force vanishes at the cathode, and that the density of the negative electrification is as $x^{-\frac{2}{3}}$; thus it is infinite when close to the cathode and diminishes as the distance from the anode diminishes. The total quantity of electricity between the anode and cathode is proportional to $(l\iota^2)^{\frac{1}{3}}$. We see again that for a given potential

difference the current does not depend on the temperature of the hot wire; this law only holds when the currents are less than the maximum currents which can pass between the electrodes. When the current approaches this value, the current instead of increasing as $V^{\frac{1}{2}}$ becomes independent of V, and the negative electricity between the electrodes diminishes as V increases. Langmuir, who has made a very complete investigation of the currents from hot wires, finds that the expression (17) represents, with considerable accuracy, the relation between the current and

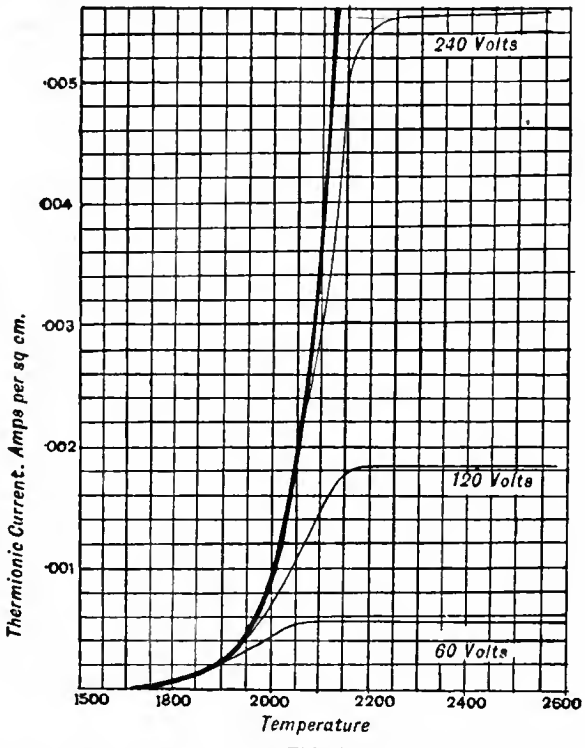

FIG. 5

potential over a wide range in the values of the currents. The curves in fig. 5, given by him, represent the relation between the current and potential for wires at different temperatures. They illustrate the point that a colder wire, until it is approaching the stage of saturation, gives as large a current as a hotter one, though the hotter one, of course, has a wider range of currents.

Ionisation by Collision.—The curve representing the relation between the currents through a gas ionised (say) by Röntgen rays and the difference of a potential between the electrodes is found to be of the form already shown in fig. 1, where the ordinates represent the currents and the abscissae the potential difference. The flat part represents the state of saturation when the potential difference is large enough to send all the ions produced by the rays to the electrodes before they can recombine. When the potential difference is still further increased we see that a stage is reached when the current begins to increase with great rapidity with the potential difference, and reaches values much greater than could be attained by the ions produced by the Röntgen rays. Thus in addition to the ions produced by the rays there must be other ions, and some other source of ionisation associated with the strong electric fields. Now the processes going on in a gas while it is conveying an electric current are:—(1) the ionisation of the gas by the external agent—in this an electron is liberated from the molecule and the residue forms a positive ion; (2) the electron and the positive ion acquire energy under the action of the electric forces; (3) in many gases the electron finally unites with an uncharged molecule to form a negative ion. As the most noticeable change in the conditions when the intensity of the electric field increases is in the energy of the electrons and ions, it is natural to look to these as the source of the additional ionisation. We have, moreover, direct experimental evidence that rapidly moving electrons and ions are able to ionise a gas through which they are passing. Hot wires and metals exposed to ultra-violet light yield a supply of electrons which when they leave the metal have very little energy; by applying suitable electric fields these electrons can be endowed with definite amounts of energy and can then be sent through a gas from which all extraneous ionising agencies are shielded off. When this is done it is found that, when the energy of the electrons exceeds a certain critical value, depending upon the nature of the gas, the gas is ionised by the electrons, but no ionisation occurs when the energy of the electron falls below this limit. It is convenient to measure the energy of the electron in terms of the difference of electrical potential through which the electron has to fall in order to acquire this energy. The potential difference which would give to the electron the energy at which it begins to ionise the gas is called the ionising potential. The values of the ionising potential have been found for several gases, as will be seen from Table IV. There is, however, considerable discrepancy between the results obtained by different observers.

TABLE IV. *Ionising Potentials in Volts.*

The most obvious view to take of this ionisation by moving electrons is that the moving electron comes so near to an electron in a molecule of the gas that the latter receives from the collision enough energy to enable it to escape from the molecule and start as a free electron. If the electrons repel each other with forces varying inversely as the square of the distance between them, and if T is the energy of the moving electron, and d the length of the perpendicular from the electron in the molecule on the initial direction of motion of the moving electron, then the energy communicated to the electron in the molecule by its collision with the moving electron is equal to

$$\frac{T}{1+\frac{d^2T^2}{e^4}}$$

where e is the charge of electricity on an electron. This is on the supposition that the electron is moving so rapidly that the time while it is in close proximity to the electron in the molecule is small compared with the time of vibration of that electron; if this time is comparable with the duration of the collision, the energy taken from the moving electron will be considerably less, and it will become vanishingly small when the duration of the collision is large compared with the time of vibration. The energy given to the electron in the molecule does not increase indefinitely with that of the moving electron, for it vanishes when T is infinite as well as when T is zero; it has the maximum value when $T=e^2/d$. In order that the electron in the molecule should receive an amount of energy Q

$$Q=\frac{T}{1+\frac{d^2}{e^4}T^2}, \quad \text{or} \quad d^2=\frac{e^4(T/Q-1)}{T^2}$$

If Q is the ionising potential, d^2 must be less than the value given by this expression. If n is the number of *electrons* in unit volume of the gas, and if the spheres with radius d described round the different electrons do not overlap, the probability that the moving electrons should come within this distance of one of them, when moving through a distance Δx, is $n\pi d^2\Delta x$, or

$$\frac{n\pi e^4(T/Q-1)}{T^2}\Delta x$$

The coefficient of Δx is the number of ions made per unit path by a moving electron with energy T. The maximum is when $T = 2Q$.

Experiments on ionisation by moving electrons have been made by Kössel (*Ann. der Phys.* 37, p. 406) and by Mayer (*ibid.* 45, p. 1), who found that the maximum ionisation per unit path occurred when the energy of the moving electron was in the neighbourhood of 200 volts. Mayer's results are 125 for hydrogen, 130 for air, and 140 for carbon dioxide. These numbers are much greater than twice the potential at which the ionisation begins, as this potential is of the order of 11 volts. It must be remembered, however, that though there may be some electrons in the atom which can be ejected by 11-volt electrons, there may be other electrons of different types which require more energy for their expulsion, so that, as the energy of the moving electrons increases beyond the energy required to liberate these electrons, fresh sources of detachable electrons will be trapped, and these may more than counterbalance the falling off in the ionisation of the more easily detached electrons. Again, some of the electrons ejected by the primary electrons may have enough energy to ionise on their own account; the total ionisation may thus be increased by ionisation due to the secondary electrons, and also by radiation excited by the impact of the primary electrons against the molecules of the gas.

When, as in the case of cathode rays in highly exhausted tubes or in that of the β rays from radioactive substances, T is very large compared with Q, the number of ions produced per unit path is $n\pi e^4/QT$, and so varies inversely as the energy of the moving electrons. The experiments of Glasson on ionisation by cathode rays, and of Durack on that by β-particles, seem to be in accordance with this result.

Scattering of Electrons.—The researches of Lenard and Ramsauer on the scattering of electrons in their passage through gases, have shown that the relation between the scattering produced by different gases depends to a great extent upon the velocity of the electrons which are scattered. If this velocity is small the scattering by most gases is approximately that which would be produced by impenetrable atoms of the size indicated by the Kinetic Theory of Gases and derived from the measurements of viscosity of gases and so on, there is no clear connection between the scattering produced by a gas and the number of electrons in its atoms. With high speed electrons the laws are much simpler and show proportionality between the scattering and the number of electrons in the atom. We should expect these results on the theory just given. For if 2θ is the angle through which the relative velocity of the electron and the atom is deflected by the collision

$$\sin^2\theta = \frac{1}{1+\frac{d^2}{e^4}T^2}$$

when T is the kinetic energy due to the relative motion of the electron and the atom.

Let us put $$T = \frac{e^2}{C}$$

then if T is expressed as V volts

$$C = 14{\cdot}4\times10^{-8}/V$$

and $$\sin^2\theta = \frac{1}{1+\frac{d^2}{C^2}}.$$

We see from this that θ will not be small unless d is considerably greater than C. Thus we may regard each electron in the atom as deflecting through considerable angles all electrons which pass within a distance C. They may, as far as collisions are concerned, be regarded as producing much the same effect as solid spheres of radius C. Now when the energy of the electrons is represented by 1 v., C is $14{\cdot}4\times10^{-8}$ centimetres. This is much greater than the distance between the electrons in the atom; thus the fields of influence of the different electrons in an atom will overlap, so that an increase in the number of electrons in the atom will not produce much effect on the scattering. On the other hand when T the energy of the electrons is so large that C, which is inversely proportional to T, becomes less than the distance between the electrons in the atom, the fields of influence of the different electrons will not overlap and each electron will provide an additional source of scattering, so that in this case the scattering will be proportional to the number of electrons in the atom.

With very slow electrons the scattering in most gases is independent of the speed but for argon and the heavier inert gases Ramsauer has made the very interesting discovery that very slow electrons are not scattered so much as those moving somewhat faster, it is as if the atoms of these elements were more permeable to slow electrons than to fast.

Ionisation by Moving Ions.—When the moving systems are ions instead of electrons, the collision between them and the electrons are collisions between masses of very different magnitudes, and in consequence a very much smaller fraction of the energy of the moving body becomes transferred to the electron than when the colliding bodies have equal masses.

The amount of energy transferred to the electron when the moving body has a mass M_1 is equal to:—

$$\frac{4M_1M_2}{(M_1+M_2)^2}\times\frac{T}{1+\frac{4d^2T^2}{e^2E^2}\left(\frac{M_2}{M_1+M_2}\right)^2},$$

when M_2 is the mass of the electron and E the charge on the moving body. When, as in the case of the collision between an ion and an electron, M_2 is very small compared with M_1, this becomes

$$\frac{4M_2}{M_1}\frac{T}{1+\frac{4d^2T^2}{e^2E^2}\frac{M_2^2}{M_1^2}}.$$

Thus, if Q is the ionising potential, the minimum value of T, which will communicate this energy to the electron, is $\frac{1}{4}\frac{M_1}{M_2}Q$.

For the smallest possible ion, an atom of hydrogen, $M_1/M_2 = 1{,}700$, so that the minimum energy that will enable an ion to ionise a gas by knocking out an electron from a molecule is equal to $425Q$. Q for many gases is about 10 v.; thus a positive ion must have at least energy represented by 4,250 v. to ionise the gas. With more massive ions the energy required for ionisation would be still greater.

An ion with a mass equal to that of a molecule of oxygen would not ionise unless its energy were greater than 136,000 volts. Thus any ionisation by ions taking place in discharge tubes where the potential difference is in general much less than this value must be due to ions of the lighter elements, hydrogen or helium.

If the ion came into collision with the atom instead of with one of its electrons, it could, since its mass is comparable with that of the atom, give up to this a large fraction of its energy, a very much larger fraction than it is able to give to an electron. Inasmuch as it requires less work to dissociate a molecule into neutral atoms than to dissociate it into positively and negatively electrified ions, the result of such a collision is more likely to be the production of neutral atoms than of electrified ions.

An ion is, however, a much more complex thing than the simple charge of electricity which has, in the preceding considerations, been taken to represent the forces it exerts; and it may be that some strongly electronegative ions have such a strong attraction for an electron that when they pass through the molecule of a more electropositive element they are able to capture one of its electrons and carry it away with them. This type of ionisation would differ from the ordinary type, inasmuch as in it the electron is never free; this type produces negative ions, the other type negative electrons.

It is evident from the preceding considerations that except in very intense fields it must be the electrons and not the ions which produce ionisation by collision. Let us consider what are the chances of an electron acquiring sufficient energy in a uniform electric field; if the electron moved freely under the electric force X for a distance l it would acquire Xel units of energy.

The electron in its course through the gas will come into collision with other bodies; its path will be deflected, possibly reversed, and in moving against the electric field it may lose all the energy it had previously acquired. Thus a collision of this type may destroy any ionising power given to the electron by the electric field before the collision.

Let λ be the average distance passed over by an electron between two collisions; then the chance of an electron moving through a distance l without a collision is $\epsilon^{-\frac{l}{\lambda}}$, but if it moves through a distance l it will acquire energy $=Xel$, hence the chance of an electron acquiring energy equal to or greater than T is $\epsilon^{-\frac{T}{Xe\lambda}}$, and the chance that it should acquire energy between T and T+dT is $\frac{d}{dT}\left(\epsilon^{-\frac{T}{Xe\lambda}}\right)dT$. If it possess this amount of energy the chance that it makes one ion per centimetre of path is $n\pi\frac{e^4}{T^2}(T/Q-1)$; hence α, the chance that an electron should make one pair of ions per centimetre of path, is given by the equation

$$\alpha = n\pi e^4\int_Q^\infty \frac{d}{dT}\left(\epsilon^{-\frac{T}{Xe\lambda}}\right)(T/Q-1)\frac{dT}{T^2}$$

This may be written

$$\alpha = \frac{n\pi e^4}{Q^2}F(\theta)$$

where $\theta = Q/Xe\lambda$

and $$F(\theta) = \theta\int_\theta^\infty \epsilon^{-x}\left(\frac{I}{x}-\frac{\theta}{x^2}\right)dx$$

Since λ for the same gas is inversely proportioned to the pressure p, α will be of the form $nf(X/p)$ where $f(X/p)$ denotes a function of X/p; and since n is proportional to the number of molecules per unit volume, α may be written as $pf(X/p)$. When the spheres described round the electrons with radius d

where $d^2=\frac{l^4}{T^2}\left(\frac{T}{Q}-1\right)$

do not overlap, n will also be proportional to the number of electrons in the molecule. The greatest value of d is $e^2/2Q$; hence if D, the distance between two electrons, is greater than $e^2/2Q$ there can be no overlapping; if D is less than this quantity, there may be overlapping; since the value of d diminishes as the kinetic energy of the electron increases, n for very fast electrons will be proportional to the number of electrons in the molecule.

Some of the electrons will by adhesion to a neutral molecule become negative ions. Let the chance of an electron doing so while passing over 1 cm. be γp. If N be the number of electrons per c.c. at a place fixed by the co-ordinate x, then $\frac{dN}{dt}+\frac{d}{dx}(NU)=$ rate of increase of number of electrons per c.c., where U is the velocity of the electron parallel to x.

The number of electrons passing through the unit of area in unit time is NU. The new electrons produced by the passage of them through the unit volume is $NU\alpha$, while $NU\gamma p$ will disappear; hence:—

$$\frac{dN}{dt}+\frac{d}{dx}(NU) = NU(\alpha-\gamma p)+q \qquad (19)$$

where q is the ionisation due to external sources; when things are in a steady state $dN/dt=0$, and the solution of the equation, when the electric field may be taken as constant from one electrode to another, is:—

$$NU = C\epsilon^{(\alpha-\gamma p)x}-\frac{q}{\alpha-\gamma p}$$

Most of the experiments on this subject have been made without external ionisation; a supply of electrons has been obtained from the cathode, either by raising it to incandescence or by exposing it to ultra-violet light. In such cases $q=0$, and

$$NU = \omega_0\epsilon^{(\alpha-\gamma p)x} \qquad (20)$$

where ω_0 is the number of electrons emitted in unit time from the cathode. Townsend, and Townsend and Kirby have determined the value of $\alpha-\gamma p$ for various gases and over a considerable range of pressure. A series of these values for air are given in Table V.

TABLE V.

X = volts per cm.	Pressure (mm.)				
	·17	·38	1·10	2·1	4·1
20	·24	..	..	..	..
40	·65	·34	..	..	..
80	1·35	1·3	·45	·13	..
120	1·8	2·0	1·1	·42	·13
160	2·1	2·8	2·0	·9	·28
200	..	3·4	2·8	1·6	·5
240	2·45	3·8	4·0	2·35	·99
320	2·7	4·5	5·5	4·0	2·1
400	..	5·0	6·8	6·0	3·6
480	3·15	5·4	8·0	7·8	5·3
560	..	5·8	9·3	9·4	7·1
640	3·25	6·2	10·6	10·8	8·9

It will be seen that, when X is given, the increase in the number of electrons reaches a maximum for a particular pressure. From general reasoning this must be so, for if $p=0$ there will be no collisions to make fresh electrons, and if p is infinite the free path of the electrons will be so small that they cannot acquire sufficient energy to ionise the gas. Since α is of the form $pf\left(\frac{X}{p}\right)$, and γ does not depend upon p, $\alpha-\gamma p$ will be a maximum when

$$f\left(\frac{X}{p}\right)-\gamma-pf'\left(\frac{X}{p}\right)\cdot\frac{X}{p^2} = 0$$

or when $f\left(\frac{X}{p}\right)-\gamma = f'\left(\frac{X}{p}\right)\frac{X}{p}$ where $f'(X/p)$ denotes the differential coefficient of $f(X/p)$ with respect to X/p. This equation determines X/p; hence the critical pressure will be proportional to the electric force. At this critical pressure $Xe\lambda$ bears to Q a ratio which depends upon the way in which the chance of an electron ionising by a collision depends upon the energy of the electron. If, for example, the chance were independent of this energy, provided the energy were greater than Q, the maximum current would be when $Xe\lambda=Q$; this relation would not hold for other and more probable laws connecting ionising power with the energy, but we should expect that for any such law the ratio of $Xe\lambda$ to Q would neither be very large nor very small.

Since the electrons cannot begin to ionise until their energy is equal to Q, and to attain this energy they must pass through a distance Q/Xe, it is clear that we ought in such an equation as (20) to write $x-Q/Xe$ in place of x. If V is the potential difference between the plates, $X=V/d$, so that $x-Q/Xe=x-dQ/V$ if Q is measured in volts. Thus in finding the current between two electrodes we must, if we use equation (20), write $d\left(1-\frac{Q}{V}\right)$ instead of d. Partsch (*Verh. d. Deutsch. Phys. Gesell.*, 14, p. 60) has shown that theory and experiment agree better by this change.

Ionisation Due to Radiation.—When rays of ultra-violet light of very small wave length or Röntgen rays which are vibrations with yet smaller wave length pass through a gas, the gas is ionised. The application of C. T. R. Wilson's expansion method (supra) to this case shows that the effect of the radiation is to expel from some of the gas an electron moving at a high speed. This electron ionises by collision the gas through which it passes and the majority of the ions are produced in this way. This is proved by the fact that on the Wilson photographs (*see* fig. 18) the drops of water which denote the presence of the ions are found to be arranged on lines starting from a molecule of the gas. For the ionisation to take place there must be some process going on by which the energy of the radiation can be concentrated on the minute volume occupied by an electron. The energy with which the electron is expelled from the molecule depends on the frequency of the radiation but not upon its intensity. Thus if the source of radiation be moved further away from the gas the number of high speed electrons ejected is diminished but the

speed of those which are ejected is not affected. This result has led to the quantum theory of radiation, which supposes that radiant energy is made up into units, or at any rate is only communicable by such units, the unit of energy is proportional to ν the frequency of the radiation and equal to $h\nu$ where h is a constant called Planck's constant. On the C.G.S. system of units it is equal to $6{\cdot}55\times10^{-27}$. Since to expel an electron from a molecule requires the expenditure of Ve units of work when V is the ionising potential, if the electron is expelled by the radiation the energy available must be greater than Ve, hence ν the frequency of the light must be greater than the value V given by the equation

$$h\nu = Ve.$$

For example if the ionising potential of helium is 22·7 volts, helium will not be ionised by radiation unless the wave length of the radiation is less than 540 Ångstrom units.

It has been shown by Barkla that when the radiation is wholly absorbed in a gas the number of high speed electrons ejected is independent of the nature of the gas. Thus we may regard the production of a high speed electron as involving the destruction of a unit of radiant energy.

The connection between the wave length of the radiation and the amount of ionisation produced in gases of definitely chemical constitution is a most vital and important one which unfortunately has not received the attention it deserves. One most important question is whether the ionisation is an additive property, or not. If the chemical composition of the gas is represented by $A_xB_yC_z$ where A, B, C, are symbols representing chemical elements, and x, y, z, are the number of atoms of A, B, C, in the molecule, can the ionisation per molecule, when radiation of known frequency passes through the gas, be represented by

$$x(A)+y(B)+z(C)$$

where (A), (B), (C), are constants appertaining to the elements A, B, C, respectively? The evidence on the whole seems to be in favour of such a connection but the tests have not been very severe. The amount of ionisation due to radiation varies enormously with the nature of the gas. Thus the ionisation in hydrogen is so small that some observers consider that such as is observed is due to a trace of impurity. It is not comparable with that which occurs in gases like chlorine, sulphur, bromine, iodine and mercury vapours. It has been found that μ the absorption of radiation of wave-length λ estimated per molecule of the absorbing substance can be represented by formulae of the type

$$\mu = CN^p\lambda^q$$

where N is the atomic number of the absorbing substance and C a constant. The values of p given by different observers range from 2·5 to 4 and of q from 2·5 to 3. Values such as these indicate that the absorption and presumably the ionisation increase rapidly with the molecular weight. Thus if we take $p=3$ the absorption of the rays by an atom of iodine would be about 1,000 times that by an atom of carbon. For the same substance and different kinds of radiation, the ionisation increases as the cube of the wave length. Formulae of the type $CN^p\lambda^q$ hold over only a limited range of frequencies; the values of p and q appear to change when the wave length of the radiation passes through a value corresponding to that of a characteristic radiation of the absorbing substance. The graph representing the relation between the wave length and the absorption is of the type shown in fig. 6.

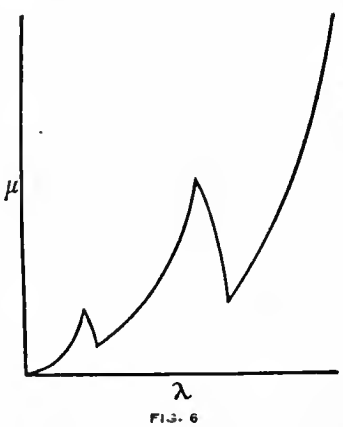

FIG. 6

It will be noticed that this curve differs very materially from the graph corresponding to the visible part of the spectrum. In this part of the spectrum we may have very intense absorption of light of a particular wave length, for example, the absorption by mercury vapour of the line 2536 is so strong that the light cannot pass through more than a few millimetres of the vapour at the pressure of one hundredth of a millimetre of mercury, and yet there is practically no absorption for lines whose wave length is either greater or less than 2536 by 1 Ångstrom unit. With radiation of the ionising type, on the other hand, though the absorption comes in abruptly when the wave length falls below a critical value, it does not fall away abruptly when the wave length is still further diminished but decays according to the λ^3 law. The application of this law leads us to expect that radiation between a certain range of wave lengths say from 20 to 250 Ångstrom units would be exceedingly powerful ionising agents. For the characteristic radiation given out by zinc whose wave length is 1·4 Å, μ has been found to have the values given in the second column of Table VI., the value of μ calculated by the λ^3 law for radiation of the wave length 248 Å, for which the quantum is 50 v., is given in the third column.

TABLE VI. *Values of μ by the λ^3 law.*

Substance	$\lambda=1{\cdot}4$ Å	$\lambda=248$ Å
Carbon	4·26	$1{\cdot}8\times10^{7}$
Air at 0° C. & 760 mm.	$9{\cdot}1\times10^{-3}$	$4{\cdot}0\times10^{4}$
Mg	59	$2{\cdot}6\times10^{8}$
Al	105	$4{\cdot}6\times10^{8}$
Fe	1723	$7{\cdot}6\times10^{9}$
Cu	490	$2{\cdot}2\times10^{9}$

Since the radiation falls to $1/\epsilon$ of its value after passing through a distance equal to $1/\mu$ we see that the radiation with the longer wave length would be practically completely absorbed by a layer of Al or Mg one molecule thick or by a layer of air one centimetre thick at a pressure considerably less than that due to a tenth of a millimetre of mercury. J. J. Thomson has shown by measuring the photo-electric effects produced inside the discharge tube by the radiation produced by the passage of the electric discharge through the tube that this radiation includes not only the visible part of the spectrum where the energy in the quantum is only some two or three volts, but soft Röntgen rays having quanta between 20 and 100 volts. These rays as we have just seen will be greedily absorbed by the gas and produce intense ionisation. A large part of the ionisation in the tube is probably due to these rays which are excited by the passage of cathode and positive rays through the gas and by their incidence on the electrodes and on the walls of the discharge tube.

Spark Discharge.—The production of ions by moving electrons will not by itself explain why a current of electricity can be maintained through a gas by an electric field when all other sources of ionisation are excluded. The electrons are continually being driven towards the anode, and unless there is some source of supply near the cathode the ionisation and therefore the current will rapidly come to an end. One way in which the electrons could be supplied by the action of the electric field would be by the positive ions which strike against the cathode communicating so much energy to the electrode that it is raised to incandescence. Since an incandescent metal gives out large quantities of electrons there will be a continuous supply of electrons from the cathode, which will ionise the gas and produce fresh positive ions to strike against the cathode and keep it hot. This is what happens in the arc discharge when the cathode is kept in a state of incandescence by the discharge. In this case there is a large amount of energy put into the arc. There are, however, other forms of continuous discharge where the cathode does not become incandescent, so that there must be other ways in which the supply of electrons is maintained. From what we know about ions there are several ways in which this might occur.

It has been found by experiment—[Füchtbauer, *Ann. der Phys.*, 23, p. 301 (1907); Saxen, *Ann. der Phys.*, 38, p. 319 (1912); Baerwald, *Ann. der Phys.*, 41, p. 643 (1913); 42, p. 1207 (1913)]—that electrons are emitted from metals when these are bombarded by high speed positive ions even though the metal is not raised to

incandescence. According to Baerwald the emission of electrons from metals bombarded by positive hydrogen atoms does not become appreciable until these have an amount of energy exceeding that represented by 900 volts. Again positive ions ionise a gas through which they pass. This was shown by McClelland, who found that the relation between the potential difference and the current from a hot wire anode surrounded by gas at low pressure was represented by a curve like that shown in fig. 7. The hot wire furnishes positive ions as well as negative ones, and

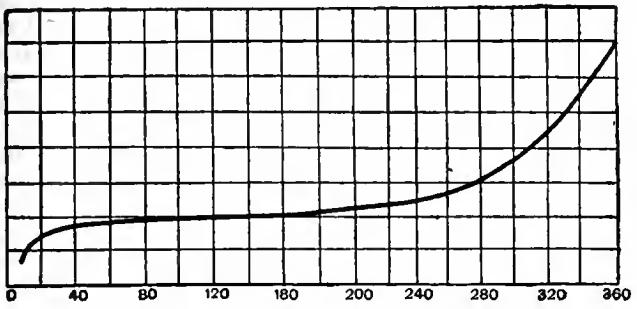

FIG. 7

the curve shows that fresh ions are formed when the potential difference is greater than about 200 volts. This is a much greater potential difference than that needed to produce ionisation by electrons, but it is smaller than would be expected by the considerations given above. As it requires less work to eject an electron from a metal than from a molecule, we should expect that if 200 v. ions could eject electrons from a gas through which they pass they would be able to do so from a metal against which they strike, but from Baerwald's experiments much more energy than 200 v. is required for this purpose. In McClelland's experiments the ionisation might have been into positive and negative ions rather than into positive ions and electrons; before the negative ions could be efficient for ionisation by collision they would have to undergo further dissociation into electrons and uncharged molecules. Curves similar to that in fig. 6 have also been obtained by O. W. Richardson. Pawlow (*Proc. Roy. Soc.*, A. 90, p. 398) and also Franck and E. v. Bahr (*Verh. d. Deutsch. Phys. Ges.*, 16, p. 57, 1914) came to the conclusion from their experiments, that ionisation was produced by positive ions even when their energy did not exceed a few volts; indeed they could not get any evidence of a minimum to the ionising voltage. Horton and Davies (*Proc. Roy. Soc.*, 95, p. 333) could not detect any ionisation in a gas by positive helium ions when the energy was due to 200 volts. They ascribe the ionisation observed by Pawlow, Bahr and Franck to photo-electric effects; they consider, however, that positive helium ions can liberate electrons from a metal against which they strike if their energy exceeds 20 volts. Baerwald considers that it requires an energy measured by 900 v. before positive ions can liberate electrons from metals.

There are thus at least four methods by which the supply of electrons near the cathode necessary to maintain the discharge can be obtained. The gas near the cathode may be ionised by positive ions or by radiation, or the cathode itself may emit electrons under the impact of positive ions or by the incidence of radiation.

When the gas is at a low pressure, the appearance of the discharge has well-marked characteristics which may throw light on the method by which the electrons are produced and the place from which they start. The discharge near the cathode is represented in fig. 8; in contact with the cathode there is a velvety glow, then a space comparatively dark called the cathode dark space; this joins on to a brightly luminous region called the negative glow; passing through this region, and making themselves evident by the luminosity they excite when they strike against the glass wall of the vessel in which the gas is contained, are the cathode rays. These have been shown to be electrons moving with high velocity. These electrons have been liberated by the action of the electric field and have acquired their velocity under the action of that field. The velocity of the cathode rays has been measured, and it has been found that the majority of them have the same velocity. This shows that they must have all fallen through the same potential. They would do this if they all started from the cathode itself, but if they had originated by the ionisation of the gas in the dark space in front of the cathode some would have started from one place and some from another, and they would have acquired different velocities. This is strong evidence in favour of the cathode itself being the primary source of the electrons which maintain the discharge. When a supply of electrons is produced by processes taking place at the cathode, ionisation by collisions of electrons with the molecules

of the gas is sufficient to maintain the discharge through the interval between the negative glow and the anode. This interval, as will be seen from fig. 8, is made up of a short part next the negative glow in which there is comparatively little light, called the Faraday dark space, and then a long uniform portion reaching right up to the anode. Unless the pressure is very low or the spark very short this portion, which is called the positive column, forms by far the larger part of the discharge. The discharge here will be maintained if the rate at which electrons are produced by collision is equal to the number lost by recombination. When this is the case, equation (19) gives $\alpha=\gamma p$, or, since α is of the form $pf\left(\frac{Q}{Xe\lambda}\right)$

$$f\left(\frac{Q}{Xe\lambda}\right) = \gamma$$

thus $Xe\lambda = cQ$ where c is a quantity which does not depend upon the pressure or strength of the field; as λ is inversely proportional to the pressure, this equation is equivalent to $X = c_1 p$, when c_1 is a quantity which will depend on the nature of the gas and possibly on the intensity of the current. If l is the length of the positive column the difference in potential between the anode and the end of the positive column next the cathode is lX, *i.e.*, $c_1 pl$.

Between the cathode itself and the negative glow there is a fall of potential, called the cathode potential fall, which, when the current carried by the discharge is not large, is independent of the current and the pressure of the gas; it depends upon the nature of the gas and the material of which the electrodes are made. If V_0 is the cathode fall, then (neglecting the change in potential in the negative glow and the Faraday dark space, which has been found by experiments to be very small) V, the potential difference between the anode and cathode, will be given by the equation

$$V = V_0 + c_1 lp \qquad (21)$$

It is assumed that the length of the spark is greater than that of the dark space D; at pressures comparable with that of the atmosphere, D is a very small fraction of a millimetre, but at the low pressures which can easily be obtained in highly exhausted vessels D may be several centimetres. It is to be noticed that V is a linear function of lp, and lp is proportional to the mass of gas between the electrodes; hence as long as the mass of gas between the electrodes remains unaltered the potential difference required to maintain the spark will be constant. This law, which was discovered by Paschen in 1889 as the result of a long series of experiments, is known as "Paschen's law." It has been found to be in agreement with the very numerous investigations which have been made on the potential difference required to produce a discharge in an approximately uniform electric field such as that which exists between two slightly curved electrodes.

The relation (21) does not give any indication of the relation between the potential difference and the spark length when the

latter is exceedingly small. When the spark length falls below a critical value which is inversely proportional to the pressure, and which in air at atmospheric pressure is about ·01 mm., the spark potential increases rapidly as the spark length diminishes; this was first observed by Peace. A simple way of demonstrating it is to use slightly curved electrodes and to observe the path of the spark as these are brought closer together. Until the electrodes get very close together the spark passes along the shortest line between them, but as they approach each other a stage is reached where the spark no longer passes along the shortest line

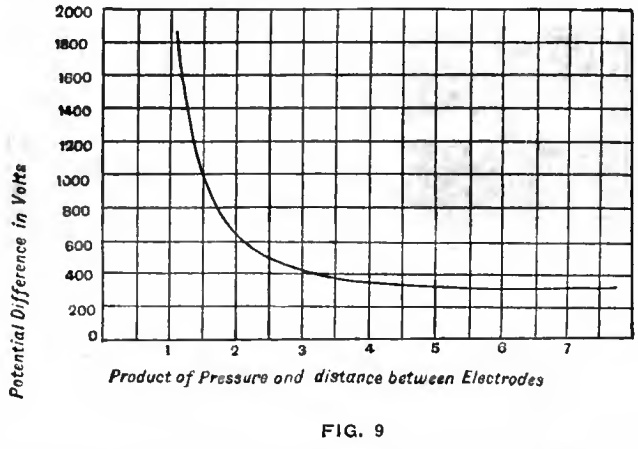

FIG. 9

but goes to one side, taking a longer path, showing that it is easier to produce a long spark than a short one. The relation between the potential difference and the spark length for several gases has been determined by Carr, who finds that Paschen's law that the potential difference depends only on pl is also true for very short sparks; Paschen's own experiments were made with sparks considerably longer than the critical value. Fig. 9 represents Carr's results for the relation between V and pl. The results of Carr's and Strutt's (Lord Rayleigh's) experiments for the minimum spark potential, and the value of pl, at which it occurs, are given in the following table:—

TABLE VII.

Gas	Minimum Spark Potential in volts	pl
Air	341 S[1]	5·7
Nitrogen	251 S	6·7
Oxygen	455 C	..
Hydrogen	{302–308 S {278 C	14·4
Carbonic acid	419 C	5·1
Sulphur dioxide	457 C	3·3
Nitrous oxide	418 C	5
Sulphuretted hydrogen	414 C	6
Acetylene	468 C	..
Helium	261 S	35

[1] S = by Strutt; C = by Carr.

The curves are very flat in the neighbourhood of the minima, so that the critical values of pl may be subject to considerable errors. Strutt found that even very small traces of impurity produced very large increases in the values of the minimum spark potential in nitrogen and helium; these are gases where, as we have seen, such traces produce large diminutions in the mobility of the negative ion. The existence of a minimum for the spark potential and a critical spark length follows from the view that the self-sustained discharge is maintained by radiation produced by electrons or positive particles. The condition for the self-sustained discharge is that an electron in its passage between the electrodes exerts some ionisation effect which produces another electron to succeed it. If V is the potential between the plates, the energy given to the electron is Ve. Let the amount of this converted into radiation be βVe; if μ is the coefficient of absorption, d the distance between the plates, then when d is small the number of ions produced by the electron will be $\beta\mu dVe$. If the electron is to provide a succession this must be equal to unity so that

$$V = \frac{1}{\beta\mu ed}$$

so that the potential difference varies inversely as $1/d$ and is infinite when d vanishes. Since μ is proportional to the pressure of the gas we see that V will depend upon pd so that Paschen's law is fulfilled.

The mechanism we have hitherto considered involves the ionisation of the gas between the electrodes, and no spark could pass across a vacuum. There are, however, other methods by which a discharge might do this. For suppose there was a stray electron between two parallel electrodes in a vacuum; then under the action of the electric field it would be driven against the anode; by the impact Röntgen radiation would be generated which would fall on the cathode, and if it were intense enough to liberate one electron from the cathode the original electron would be replaced and the passage of negative electricity from the cathode to the anode would be repeated. From these considerations it is probable that even the highest vacuum would not act as a perfect insulator for very intense fields.

The linear relation $V = V_0 + c_1 lp$ has been obtained on the assumption that the direction of the electric force was the same in all parts of the field; this is only true when the dimensions of the electrodes are large compared with the distance between them. The potential difference required to produce a spark of a particular length depends upon the size of the electrodes between which the spark passes, and is not a linear function of lp where p is the pressure and l the spark length, unless l is small compared with the linear dimensions of the electrodes. If these are spheres, the spark potential will depend upon their radii and for small spheres may be considerably less than for large ones. Thus, for example, the spark potential in air for a five centimetre spark is 26,000 v. for electrodes ·5 cm. in diameter and 105,000 v. when the diameter of the electrodes is 5 centimetres.

In this connection it may be noted that, if the electric field is sufficiently intense at any place to produce there a local supply of ions, these may redistribute themselves between the electrodes and by their electrostatic action produce a change in the distribution of the electric force more favourable to the passage of the spark than that prior to the production of the ions. To illustrate this, take the very simple case when the electrodes are two parallel plates: if there are any ions available these may distribute themselves so that the force between the plates is no longer uniform. Thus let us suppose that there are enough positive ions to congregate round the cathode in sufficient numbers to produce within the distance of the "critical spark length" or thickness of the cathode dark space, a difference of potential equal to the minimum spark potential. This would ensure a continual emission of electrons from a place in front of the cathode, and even though the electric field from this place to the anode were too feeble to give an electron enough energy to ionise the gas, the electrons coming from the cathode would be able to carry a small current, though this part of the discharge might not be luminous. The ions here would be all of one sign, so that the electric force will increase up to the anode. If the current is gradually increased, the place where the electric force will first rise to the value necessary to make the electrons ionise will be close to the anode. When this occurs a supply of positive ions will start from the anode and move towards the cathode, accompanied by luminosity close to the anode and very faint luminosity through the rest of the tube. The introduction of the positive ions into the region between the anode and cathode will diminish the retarding effect of the negative space charge which existed in this region, so that the current will increase. This increase in current will again increase the ionisation at the anode, and thus the supply of positive ions. In this way there might be a supply of electrons coming from the cathode, and of positive ions from close to the anode, which will maintain the current in spite of the fact that between these places there is a region where the electric

force is below that required to produce ionisation by collision, and the potential difference between the electrodes less than that calculated on the supposition that the electric force was uniform from one to the other. We should expect from these considerations that, if the electric force at any point were intense enough to produce ionisation by collision, some discharge would take place.

Russell (*Phil. Mag.*, 6, xi., p. 237) states that the results of the different experiments made on the potential difference required to produce sparks of various lengths between spherical electrodes of various radii are in good agreement with the rule that the discharge takes place in air at atmospheric pressure if the electric force at any point in the field before discharge begins is as great as 37,000 v. per centimetre. This value agrees well with that required to make electrons produce, in air at atmospheric pressure, other ions by collisions.

The curious lag observed by Warburg between the application of the potential difference and the passage of the spark, which when the applied potential is only a very little greater than that required to produce the spark may amount to several seconds, is naturally explained as the time needed by the ions to distribute themselves so as to produce the distribution of potential required for the discharge.

The discharge of electricity from points affords a good illustration of the preceding considerations. Suppose that the electrodes are a needle point and a plane. When the discharge first begins the only place where any light is to be seen is close to the

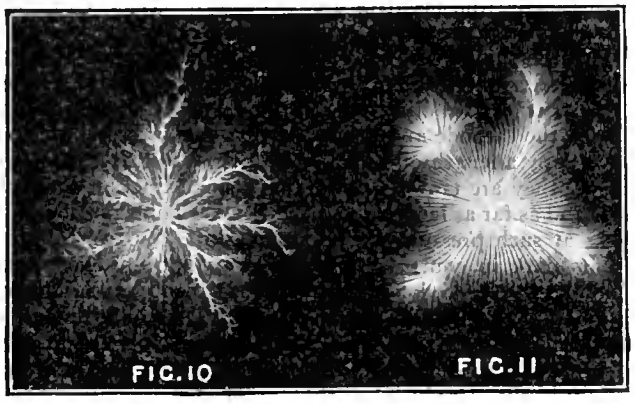

FIG. 10 FIG. 11

point; the current between the electrodes is very small; as the potential difference increases a stage is reached where light begins to appear close to the plate, the space between the point and plate being quite dark. This stage is marked by a large increase in the current. With further increase in current the luminosity extends into the gas and ultimately stretches from one electrode to another.

The potential required to start the discharge is less where the point is negative than when it is positive. This is what might be expected, for to maintain the discharge from the negative point there must be (1) ionisation of the gas by the outgoing electrons, and (2) liberation of electrons by the incoming positive ions, while when the point is positive there must be (1) ionisation of the gas by outgoing positive ions, and (2) liberation of positive ions by the impact of incoming electrons; as the process is not the same as for the negative point we should expect that there would be a difference between the potentials. It is not only the potential difference which is affected but the type of discharge. This can be shown by allowing the point discharge to pass in the neighbourhood of a photographic plate. Beautiful figures are found on developing the plate, and the character of these is different according as the point is positive or negative. Figures 10 and 11 represent discharges from positive and negative points respectively.

The discharge from a negative point is in some gases very much influenced by the purity of the gas; thus Warburg found that the discharge from a negative point in nitrogen increased about 50 times by removing the last trace of oxygen from the nitrogen, though this had little or no effect upon the discharge from a positive point. This can be accounted for by the discovery of Franck and Hertz that in very pure nitrogen the electron does not unite with the molecule and become a negative ion and has therefore a very high mobility. This is true for the inert gases as well as for nitrogen, and Przibram has shown that the difference between the discharges from positive and negative points is exceptionally large in these gases.

Electrical Wind.—The electrified ions' starting from the point in a point discharge sets the gas in the neighbourhood of the point in motion producing a current of air, called the "electrical wind." The momentum gained by the air is lost by the point, so that there is a backward force acting on the point, which has often been measured. This force, as well as the electrical wind, is smaller when the point is negative than when it is positive; this difference is especially marked at pressures low enough to make the negative ion have an abnormally large mobility.

Relation between Potential Difference and Current.—The potential difference required to maintain a discharge will depend upon the current passing in the discharge. The relation between the current and the potential difference for discharge through gases is often a very complicated one. We should expect that this would be so, for in the spark discharge, for example, the potential difference is made up of the cathode fall of potential (this increases with the current when the current is large) and a uniform force along the rest of the discharge, and this force in many cases diminishes as the current increases. Thus whether increases of current produce an increase or decrease in the potential difference will depend on the relative contributions of these two parts.

A curve whose ordinates are the potential difference between the electrodes and the abscissae the current through the gas, is called the "characteristic curve" for the discharge (see fig. 12). From such a curve it is possible to find the current sent through a gas by a given external electromotive force. Suppose that the current sent through a gas by a battery of cells of electromotive force E_0 is required. If R is the resistance of the curves connecting the battery with the electrodes in the gas, then $E_0 - Ri$ is the potential difference between the electrodes in the gas, and one relation between this potential V and the current is represented by the straight line $V = E_0 - Ri$. The other relation is that represented by the characteristic curve; the values of the current through the gas and the potential difference between the electrodes will be determined by the points of intersection of this straight line and the characteristic curve. Unless the straight line cuts the curve there can be no discharge through the gas;

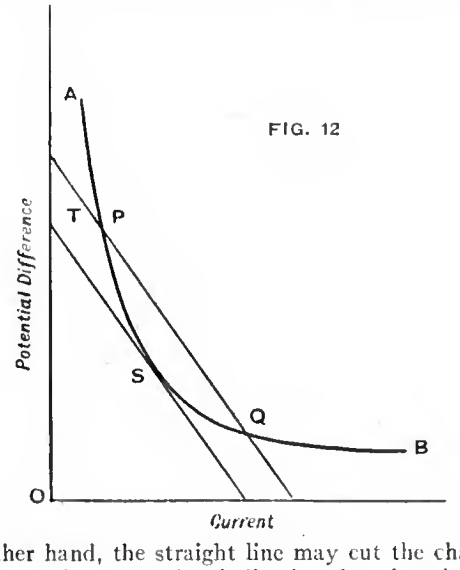

FIG. 12

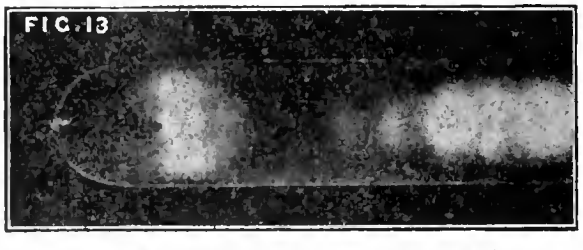
on the other hand, the straight line may cut the characteristic curve in more than one point, indicating that there is more than one type of discharge. Some of these types may, however, be unstable and thus impossible to realise. Thus, for example, if the current is increased by δi the difference of potential given by the battery between the electrodes is diminished by $R\delta i$;

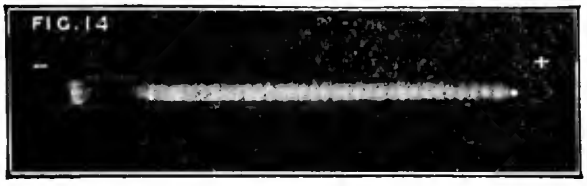
if V is the potential difference between the electrodes required to send a current ι through the gas, then when the current is increased by $\delta\iota$, the increase in the potential required is $\frac{dV}{d\iota}\delta\iota$; thus unless $\frac{dV}{d\iota}\delta\iota$ is less than $-R\delta\iota$, or $-\left(\frac{dV}{d\iota}+R\right)\delta\iota$ be positive, the diminished potential supplied by the battery will not be sufficient to maintain the increase in the current; this increase will stop, the current will return to its original value, and the discharge will be stable; thus if $R+\frac{dV}{d\iota}$ is positive the discharge will be stable. If, however, $R+\frac{dV}{d\iota}$ is negative the fall in potential required to maintain the increased current is so great that, in spite of the diminution of the potential difference supplied by the battery, the residue is great enough to maintain the increased current, the increase in the current will continue, and the discharge will be unstable. Thus the condition for stability is that $R+\frac{dV}{d\iota}$ should be positive, a result first given by Kaufmann. This result is equivalent to the condition that for stability the straight line must, at the point where it cuts the characteristic curve, fall more steeply than the tangent to the curve at that point. Thus if APQB, fig. 12, the characteristic curve and the right line cut at PQ, the type of discharge represented by P is unstable, and that by Q stable. Keeping the electromotive force at the battery constant and increasing the resistance will make the straight line steeper, and Q will move to the left and the current through the tube will decrease; when the line gets so steep that it touches the curve at S, the minimum value of the current consistent with the maintenance of this type of discharge by the electromotive force supplied by the battery will be reached, and any further diminution of the current will result in the extinction of this type of discharge. It is a well-known fact that the existence of most types of luminous discharges requires the current to be above a certain critical value which depends upon the external force. The electric arc is perhaps the most familiar example of this. As the characteristic curve for the arc discharge is a rectangular hyperbola represented by the equation $V=a+\frac{b}{\iota}$; we can easily show that if the external electric force is E, the maximum resistance which can be introduced into the circuit without extinguishing the arc is $(E-a)^2/4b$, and the smallest current compatible with the existence of the arc $2b/(E-a)$. For any stable type of discharge we see that an increase in the external electromotive force will result in an increase of current; at a point corresponding to an unstable condition it produces a diminution.

Structure of the Discharge.—The structure of the discharge at atmospheric pressure is on so fine a scale that its details can only be made out with difficulty; as the pressure is reduced the scale gets larger and larger, until, when the pressure is reduced to that due to a millimetre or so of mercury, the details of the structure become very conspicuous. The appearance of the



discharge at such a pressure is shown in fig. 13, and we see that it is built up of several constituents of very different types. We have already, when considering the spark discharge, given a general description of some of them; there are, however, some features which require further discussion.

Starting from the cathode, we find a thin layer of luminous gas, the colour of which depends on the kind of gas through which the discharge is passing. In most gases the light appears to reach right up to the cathode, but in helium Aston has shown it is separated from it by an exceedingly thin dark space. This luminous layer is sometimes called "Goldstein's first layer"; next to this we have a region where there is comparatively little luminosity called "Crookes' dark space," the boundary of this space being approximately the surface traced out by normals to the surface of the cathode of constant length. The thickness of the dark space, which is of the order of the critical spark length, depends upon the pressure of the gas, varying approximately as the reciprocal of the pressure; for air at the pressure of 1 mm. of mercury the thickness of the dark space is about 2 mm. so that at atmospheric pressure the thickness would not be much more than about 1/400 of a millimetre. If the pressure remains constant and the current through the tube is increased, the thickness of the dark space remains unaltered until the current is large enough to cover the whole of the cathode with the luminous glow; after this stage is reached any further increase in the current



causes a diminution in the thickness of the dark space. Starting from the boundary of the dark space there is a brightly luminous region called "the negative glow." The function of the parts of the discharge from the cathode to the negative glow is to produce the supply of electrons from the neighbourhood of the cathode necessary to keep the discharge going. The dimensions of this part of the discharge are independent of the distance between the cathode and anode; at very low pressures this part may occupy a length of several centimetres, but at atmospheric pressure they are crowded into a very small fraction of a millimetre and as far as length goes occupy a negligible portion of the sparks at such pressures. The Crookes' dark space, though it appears dark in contrast to the negative glow, is not devoid of luminosity; indeed Seeliger, who has made a spectroscopic examination of the dark space, finds that there are some lines, such as the Balmer series lines, which are almost as bright in the dark space as in the negative glow. But many lines are much stronger in the negative glow than in the dark space.

Beyond the negative glow there is another comparatively dark region called the "Faraday dark space"; the length of this is very variable even when the pressure is constant, as it is sensitive to any change in current. Beyond this and reaching right up to the anode is a luminous column called the positive column. The luminosity in some cases is fairly uniform in intensity, but when the pressure and current are between certain limits this column may exhibit remarkable alternations of dark and bright spaces called striations, such as are shown in fig. 14. Under some circumstances a dark space round the anode has been detected by several observers.

When the distance between the electrodes is considerable and the pressure not very low, the positive column forms by far the greater part of the discharge; thus at atmospheric pressures all but a fraction of a millimetre of the discharge next the cathode will consist of the positive column.

Distribution of the Electric Force Along the Discharge.—The electric force is very large indeed in the part of the dark space next the cathode, but diminishes rapidly towards the negative glow. In the negative glow itself it is smaller than in any other part of the discharge; passing the negative glow, the electric force increases in the Faraday dark space, until the positive column is reached. When the positive column is of uniform luminosity the electric force in the column is constant until quite close to the anode, when there is an abrupt change of potential of about 20 volts, called the anode fall of potential. When the positive column is striated, the alternations of luminosity in the positive column are accompanied by alternations in the intensity of the electric force, the maxima of the electric force occurring

at the bright parts of the striae, the minima at the dark. From the equation $\frac{dX}{dx} = 4\pi\rho$, where X is the electric force in the direction of x and ρ the density of the electrification, we see that there is an excess of positive electricity in the cathode dark space and of negative in the Faraday dark space; in a uniform positive column there is no appreciable excess of electricity of one sign over that of the opposite, while in the striated positive column there is an excess of negative electricity on the cathode side of a bright part of a striation and of positive on the anode side.

Cathode Fall of Potential.—Until the glow next the cathode covers the whole of the electrode the difference of potential between the cathode and the negative glow is constant, depending on the gas and the material of which the cathode is made, but being independent of the pressure of the gas and the strength of the current. This constant difference of potential is called the "cathode fall of potential," and there is evidence to show that it is equal to the minimum potential that can produce a spark through the gas. Its value, for different gases and different electrodes is given in the following table, due to Günther-Schulze:—

TABLE VIII.

	K	Na	Mg	Al	Zn	Fe	Pb	Cu	Ag	Aa	Pt
He .	68	80	125	153	143	161	177	177	162	165	163
Ne .	68	75	122	145	136	153	172	221	154	158	152
Arg .	71	78	158	150	155	166	166	155	156	157	162
N .	170	178	210	215	252	256	227	244	254	250	233
H .	172	185	171	192	233	250	316	299	301	330	300
Air .	181	198	240	242	292	281	306	282	305	297	324
ϵ_4	−2·92	−2·72	−1·55	−1·28	−0·76	−0·43	−·12	..	..	..	..

Further light is thrown on the origin of ionisation in gases by the study of the distribution of electric force in the neighbourhood of the cathode. Aston has shown that at low pressures the force in the neighbourhood of the cathode is a linear function of the distance from the cathode, so that if V be the electrostatic point at a point distant x from the cathode

$$\frac{dV}{dx} = C(d-x) \qquad (22)$$

when C and d are constants. If ρ is the density of the electrification at the point x: $4\pi\rho = d^2V/dx^2$, hence for this law of force ρ is constant. We have to consider what law of ionisation is compatible with this result. It can be shown that to make ρ constant the ionisation must be independent of the distance from the cathode, a result which seems much more probable if the ionisation is due to radiation than if it were mainly due to ionisation by collision. We see from equation (22) that dV/dx vanishes when $x=d$. This is the place where the negative glow begins. The potential difference between the cathode and the boundary of the negative glow is called the cathode fall of potential and is a quantity of great importance, of which many measurements have been made which are given in Table VIII. The cathode fall of potential depends on the nature of the gas and of the electrodes but is independent of the pressure.

The consequences of the hypothesis of ionisation by radiation are in fair agreement with the results of experiments; they are as follows:—

The normal cathode fall of potential is independent of the pressure of the gas.

The thickness, d, of the dark space is inversely proportional to the pressure.

The cathode fall of potential V is connected with I the density of the current carried by the positive ions by the relation:—

$$V^2 = \left(\frac{M}{2e}\right)^{\frac{1}{2}} \pi^2 I d^2 \qquad (23)$$

where M is the mass of a molecule of the gas.

The cathode fall of potential is on this view equal to the smallest potential difference that can produce a spark through the gas and the thickness of the dark space at any pressure is the length of the spark which at that pressure passes with the minimum potential difference.

We see from equation (23) that in order to produce the discharge a definite current density as well as a definite potential difference is required. This density, for a flat electrode, is as we see from equation (23) inversely proportional to d^2 and therefore directly proportional to the square of the pressure.

The values of V and I at a pressure of 1 mm. of Hg for plane cathodes (1) of aluminium, (2) of iron, for different gases have been determined by Günther-Schulze (*Zeit. für Physik*, 20.1).

TABLE IX.

Gas	Aluminium		Iron	
	I(am/cm²)	V. volts	I(am/cm²)	V. volts
He .	1·07	153	1·187	161
Ne .	1·81	145	2·000	153
Ar .	14·07	150	15·5	166
N .	38·4	215	42·3	256
H .	9·0	192	9·96	250
O .	54·7	250	60·6	326

V depends on the nature of the electrode as well as upon the gas. Günther-Schulze's experiments indicate that V can be expressed approximately in the form:—

$$V = 35{\cdot}5\epsilon + a$$

where a is a quantity depending on the gas and ϵ, a quantity called the electrochemical normal equivalent, which is given in the last row of Table VIII.

The values of a in volts for different gases are He, 175; Ne, 169; Ar, 174; N, 265; H, 290; O, 350. The preceding values refer to what are called the normal values when the current flowing through the tube is not large enough to cover the whole cathode with glow, so that an increase in the current may occur through an increase in the area over which the current is spread and not from an increase in the mean density of the current.

Günther-Schulze gives the following empirical expression for the dark space, d

$$pd = (\text{constant})\,\lambda V_1$$

when p is the pressure, λ the free path of the molecule at atmospheric pressure, and V_1 the ionising potential of the gas. When the current is so great that the whole electrode is covered with glow V, I and d are no longer constant; the cathode potential fall increases and the dark space diminishes as the current I increases. According to Aston's experiments (*Proc. Roy. Soc.*, 86, p. 178), the following relations exist between these quantities:—

$$d = \frac{A}{p} + \frac{B}{\sqrt{I}}$$

$$V = E + \frac{F\sqrt{I}}{p}$$

Here p is the pressure and A, B, E, F constants.

As the current increases the values of V may increase to many thousand volts and thus be hundreds of times the normal value. According to Aston there is no sudden jump in potential at the cathode itself, some observers (*e.g.*, Westphal) have thought that such a drop occurred and that it amounted to a considerable fraction of the whole potential fall.

Though in many gases and especially in oxygen there is a very sharply defined boundary to the dark space, it must not be thought that no radiation comes from the dark space; it is only for certain types of radiation that the radiation from the dark space is absent. Thus for the type of radiation which is instrumental in producing ionisation, there is no discontinuity in the radiation as we pass across the boundary of the dark space, and Seeliger and his co-workers have shown that even for visible radiation the change in intensity on crossing the boundary depends to a great extent on the wave-length of the light. The electrical conditions inside the dark space differ very much from those outside; inside we have a great preponderance of positive ions over electrons, while outside the two are equal; again outside the density both of free electrons and of positive ions is much greater than inside, and there is recombination of electrons and positive ions outside and not inside. It is not surprising

therefore that radiation produced outside the dark space should differ substantially from that produced inside.

Anode Fall of Potential.—Unlike the cathode fall of potential which is spread out through a length equal to the thickness of the dark space, the anode fall as Skinner has shown occurs quite abruptly so far as it can be tested by experiment. If this fall took place in molecular distances the electric attraction might be sufficient to drag positive ions out of the electrode itself. By using a cathode heated to incandescence, and therefore emitting a plentiful supply of electrons, we can reduce the cathode fall of potential to a small fraction of its normal value; we cannot, however, with a luminous discharge get rid of the anode fall; thus in the arc discharge the anode fall of potential is greater than the cathode fall. Matthies has shown that, in chlorine, bromine and iodine, the anode fall of potential may rise to hundreds of volts, that in air or hydrogen being only about 18 volts. Reichenheim and Gehrke utilised this fact to get positive ions of sodium and potassium projected with great velocity. They made the anode of a mixture of the halogen salts of these metals and graphite, and worked at a very low pressure; under the action of the discharge the halogens were liberated from the anode, and the large anode fall they produced was sufficient to project sodium and potassium ions from the anode with great velocity; this stream of positive ions constitutes what is known as "anode rays."

The electric force in the positive column is a linear function of the pressure; it depends slightly on the diameter of the tube through which the discharge is passing; it also depends on the current through the tube; in most cases, though not invariably, an increase of current produces a decrease in the electric force. The condition determining the electric force in the positive column is that it should give to an electron during its free path the amount of energy that will enable the electrons to produce by collisions as many ions per second as are lost during the same time by recombination.

Striated Discharge.—The form of discharge when the positive column is striated is so beautiful and remarkable that it has attracted a great deal of attention. To get this type of discharge the current and pressure must be within certain limits. The striations are developed more readily in mixtures of gases than in a pure gas; in fact some physicists have advanced the view that they could not be obtained in an absolutely pure gas. There is no doubt, however, about their occurrence in gases in which great attention has been paid to purification. Nörbeck could not get them in pure nitrogen or pure helium, though they were conspicuous as soon as a trace of impurity was admitted. Nitrogen and helium are gases in which, when pure, the carrier of negative electricity is always an electron; in these gases the electron does not join on to a molecule and become a negative ion. Spottiswoode found that, in some cases when the positive column showed no signs of striation when observed in the usual way, striations moving rapidly down the tube could be seen when the discharge was observed after reflection in a rapidly rotating mirror. Aston and Kikuchi, who have studied this effect in neon and helium, are of opinion that the striations are moving in these gases with the velocity of sound; it must be remembered, however, that the velocity of sound in many gases is of the same order as the velocity of a positive ion under the electric forces in the positive column, so that this result does not necessarily prove that the moving striations are analogous to sound waves.

The distance between the striations increases as the pressure diminishes (in hydrogen the distance is inversely proportional to the square root of the pressure); it depends upon the size of the tube: the striations are nearer together in narrow tubes than they are in wide. The distance between the striations also depends upon the current. When several gases are in the tube, spectroscopic observation of the bright parts of the different striations shows that we may have one set of striations corresponding to one gas, another to another, and so on. Thus Crookes observed in a tube containing hydrogen three sets of striations, one set red, another blue and a third grey; the spectroscope showed that the first was due to hydrogen, the second to mercury vapour and the third to hydrocarbons. The striations are often curved with their concavities turned to the anode.

To get a general idea of the causes which might give rise to stratifications, let us consider a case where the current is carried entirely by electrons, the positive ions being regarded as immovable in comparison with the electrons. Let us consider a stream of electrons emerging from the negative glow; these electrons will have very little energy and will be unable to ionise the gas. The electrification beyond the negative glow on the anode side will be due to electrons and will be negative so that the electric force will increase towards the anode. As the electric force increases the energy of the electrons also increases, until it is sufficient to enable the electron to ionise the gas and produce positive ions and electrons; the increase in the number of ions will check the rate of increase in the electric force. The connection between the ionisation and this rate of increase is in the case we are considering represented by a very simple equation. For if n and m represent respectively the number of negative and positive ions per unit volume, X the electric force, and x the distance from the cathode

$$\frac{dX}{dx} = 4\pi(n-m)e \qquad (24)$$

If the current ι is carried, as we have supposed, by the electrons, $neu = \iota$, where u is the velocity of the electron. If we neglect the current carried by the positive ions, then when things have reached a steady state the number of positive ions produced in any region per second must equal the number which disappear owing to recombination. Hence, if q is the rate of ionisation, a the coefficient of recombination, $q = amn$ or $m = q/an$; and (24) is equivalent to

$$\frac{dX}{dx} = \frac{4\pi\iota}{eu} - \frac{4\pi qeu}{a\iota} \qquad (25)$$

Thus as long as q vanishes, dX/dx is positive, but as soon as q becomes finite the rate of increase of X will be retarded; as X increases q increases, and when $e^2qu^2 = a\iota^2$, dX/dx will vanish; but though X reaches its greatest value at this point, the values of u and q, which depend on the energy acquired by the electron, will continue to increase beyond it. For the energy acquired by an electron depends on $\int X dx$, taken over a distance measured by the free path of the electron; at low pressures this may be a centimetre or more, and the place where $\int X dx$ is a maximum will be beyond that where X is a maximum by a length of this order. Thus after X has reached its maximum u and q will increase and dX/dx will become negative, so that X will diminish; the diminution in X will ultimately produce a diminution in $\int X dx$ and also in u and q; the rate of decrease will slow down; X will attain a minimum, and begin to increase again when similar changes will be repeated. Thus the curve which represents the relation between X and x will resemble fig. 15, where the cathode is on the left, giving alternate maxima and minima for the value of X; and $\int X dx$, the energy acquired by an electron, will vary periodically along the path of the discharge. There are two values of this energy which are of special importance in connection with discharge through gases, one the ionising potential we have already referred to, the other, sometimes called the "radiation potential," is the energy which the electron must possess to make the gas luminous. The radiation potential is less than the ionising potential, and electrons with energy between these potentials will make the gas luminous but will not ionise it. Thus the molecules of the gas will give out light but will not be charged. When the energy of the gas exceeds the ionising potential the luminous molecules are or have been charged. If the

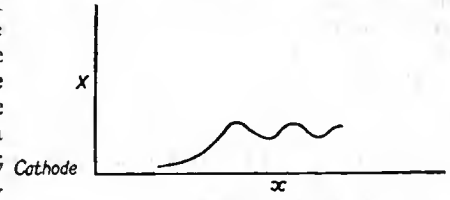


FIG. 15

variations in the energy along the line of discharge are large enough to make it sink below the radiation potential, then along the discharge we shall have: (1) places where the energy is below the radiation potential,—these will be dark; (2) places where the potential is between the radiation potential and the ionising potential,—the molecules here will be luminous and uncharged and will, therefore, not move under the electric field; (3) places where the molecules are luminous and charged,—these molecules will move down the tube towards the cathode with the velocity which the positive ion acquires under the electric field. This velocity, when the pressure is low and the field several volts a centimetre, as it is in the positive column, may be many thousand centimetres per second. Place (1) corresponds to the dark parts of the striations, (2) to the stationary luminous parts, while (3) is the origin of the striations moving down the tube observed by Wulner, Spottiswoode, Aston and Kikuchi.

Cathode Rays and the Discovery of the Electron.—In 1859 Plücker observed on the glass of a highly exhausted tube in the neighbourhood of the cathode a bright greenish yellow phosphorescence, which changed its position when a magnet was brought near to it. About 10 years afterwards Hittorf showed that a solid body placed between a pointed electrode and the walls of the tube cast a well-defined shadow of such a shape as to show that the agent producing the phosphorescence travels in straight lines at right angles to the surface of the cathode. The name "cathode rays" for the cause of the phosphorescence was introduced by Goldstein, who made many important investigations on their properties. The opinion held by Goldstein and generally in Germany was that cathode rays were waves in the ether. Varley and Crookes advanced the view that they were electrified molecules shot off at right angles to the cathode. The discovery by Hertz that the cathode rays could pass through thin layers of gold leaf was difficult to reconcile with this view.

The evidence in favour of the cathode rays being electrified particles was increased by Perrin's discovery that when a pencil of the rays entered the opening in a Faraday cylinder they gave to it a charge of negative electricity. One difficulty which had been urged against the rays being negatively electrified, viz., that, though they were deflected by a magnetic force, an electric force produced no effect upon their path—was removed by J. J. Thomson, who showed that the absence of deflection was due to the gas in the tube acting as a screen and protecting the particles from the electric force. As the gas in the vacuum tube is a conductor of electricity the rays move inside a conductor of electricity, and so will not be affected by an external electrified body. Thomson showed that when the vacuum was very high, so that there was but little gas in the tube, the cathode rays were deflected by an electric and magnetic field, and that the direction of the deflection indicated a negative charge on the particles. His measurement of the deflection by known electric and magnetic forces led to a determination of the mass of the particles which carried the charge, and showed that these particles were not atoms or molecules but something with a mass not one-thousandth part of the mass of the lightest atom known, that of hydrogen.

The deflection due to electric and magnetic forces can be calculated as follows. Suppose that the particles are travelling horizontally between two parallel horizontal metal plates A, B, maintained at a constant difference of potential, there will be a vertical electric force F acting between the plates, and if the axis of y is vertical the equation of motion of the electrified particle when it is between the plates is

$$m\frac{d^2y}{dt^2} = Fe$$

If y and $\frac{dy}{dt}$ are both zero when the particle enters the region between the plates, then, when it leaves this region, after a time

$$y = \tfrac{1}{2}\frac{Fe}{m}t^2 \text{ and } \frac{dy}{dt} = \frac{Fe}{m}t$$

Since the electric force is at right angles to the direction of motion of the particles, v the velocity of the particles will not alter, and if the deflection is small, $t = l/v$ where l is the length of the plates. Thus

$$y = \tfrac{1}{2}\frac{Fe}{m}\frac{l^2}{v^2} \text{ and } \frac{dy}{dt} = \frac{Fe}{m}\frac{l}{v}$$

Suppose the particles strike a photographic plate or a screen covered with a phosphorescent substance at a distance L from the end of the plates, the y displacement at this place produced by the electric force, is given by the expression

$$y = \tfrac{1}{2}\frac{Fel^2}{mv^2} + \frac{FelL}{mv^2} = \frac{Fel}{mv^2}\left(\frac{l}{2}+L\right)$$

Magnetic Deflection of the Rays.—If the rays go through a uniform magnetic field of length l and strength H, then if the magnetic force is vertical the force acting on the moving particles will be Hev, and will be at right angles to the magnetic force and also to the direction of motion of the rays; *i.e.*, it will be at right angles to the plane of the paper; if z is the displacement of the particle in this direction

$$m\frac{d^2z}{dt^2} = Hev.$$

From this we see that the value of z at the screen is given by

$$z = \frac{Hel}{mv}\left(\frac{l}{2}+L\right)$$

Hence

$$\frac{e}{m} = \frac{z^2}{y}\frac{F}{H^2l\left(\frac{l}{2}+L\right)} \qquad (26)$$

and

$$v = \frac{z}{y}\frac{F}{H} \qquad (27)$$

Thus the measurements of y and z, the electric and magnetic deflections, give the values of e/m and v.

The expressions for y and z have been obtained on the supposition that the electric and magnetic fields acted one at a time and not simultaneously. If, however, y and z are small, their values will not to a first approximation be altered if the electric and magnetic deflections occur simultaneously. Thus by making the cathode rays pass through superposed electric and magnetic fields, e/m and v can be got with one exposure by measuring y and z on the screen or photographic plate.

Since from equation (26) above z^2/y is constant as long as e/m is constant, we see that all the particles of the same kind, whatever their velocity, would strike the screen or plate on a parabola, and that if the rays were a mixture of particles of different kinds each kind of particles would trace out a different parabola. Since z/y only depends upon v, all the particles moving with the same velocity will strike the screen in a straight line.

The determination of e/m for the cathode rays led to results of fundamental and far-reaching importance, for it was found that all the cathode rays had the same value for e/m, and that moreover while for a charged atom of hydrogen in liquid electrolytes e/m was equal to 10^4, when c was measured in electromagnetic units, the value of e/m for the particles in the cathode rays was considerably more than one thousand times this value. Thus if e were the same for the particle as for the hydrogen atom (and we shall see later that this is the case) the mass of the cathode particle is only $\frac{1}{1800}$ of that of an atom of hydrogen, the smallest mass which hitherto had been recognised. Again it was found that whatever metal might be used for the cathode, or whatever might be the gas in the discharge tube, the value of e/m was unaltered. As those particles must have come either from the electrode or the gas, it follows that the particles of the cathode rays are a constituent of the atoms of all the chemical elements. These particles are called "electrons."

After the electrons had once been detected in the cathode rays they were very soon detected under many other conditions and found to be of very widespread occurrence. Thus, for example, it was found that streams of electrons are given out by incandescent metals, the rate of emission increasing very rapidly with the temperature. This has received a very important industrial application in what are known as "hot wire valves,"

at which a current from a hot cathode passes through a vessel in which the vacuum is so high that the gas takes no part in the discharge; the current, in some cases amounting to several amperes, is carried entirely by electrons. Lenard found that they were emitted by metals exposed to ultra-violet light. They are emitted when Röntgen rays strike against matter and by radio-active substances. The speed of the electrons ejected either by ultra-violet light or by Röntgen rays does not depend upon the intensity of the radiation but only upon the wave length. The energy acquired by the electrons is $=h\nu$, where ν is the frequency of the radiation and h Planck's constant.

Since the cathode rays are deflected by electric and magnetic forces proportionally to the magnitude of these forces, we can use the deflection of the rays as a measure for electric and magnetic forces. As these rays have practically no inertia they are especially adapted to measure very rapidly alternating forces which could not be detected by any index having an appreciable mass. The cathode ray oscillograph, an instrument by which electric and magnetic forces are measured by the deflection of cathode rays, has already been used in many investigations, and is a very important aid to research. Another property of cathode rays is that when they strike against matter they generate Röntgen rays, the hardness of the latter increasing with the speed of the former. The mass of an electron depends upon its velocity; this effect is not appreciable unless the velocity is comparable with that of light but the increase in mass becomes very marked when as in the case of the β rays from radio-active subjects the velocity exceeds 10^{10} cm./seconds. On the theory of Relativity the relation between m_v the mass of an electron moving with the velocity V and m_0 the mass of an electron at rest is

$$m_v = \frac{m_0}{\sqrt{1-v^2/c^2}}$$

where c is the velocity of light. This relation seems to be in agreement with the measurements which have been made on the masses of the β particles.

If the electron is regarded as a small sphere of radius a then it follows from the laws of electromagnetic action that $m_0 = \frac{2}{3}\frac{e^2}{c^2 a}$ where e is the charge on an electron in electrostatic measure. The value of e/m_0 found by experiment is $1{\cdot}78\times10^7\times c$, the value of e is $4{\cdot}8\times10^{-10}$, and $c=3\times10^{10}$, hence the value of a from the preceding equation is equal to $1{\cdot}9\times10^{-13}$ cm.

Positive Rays.—Goldstein discovered in 1886 that, if the cathode in a highly exhausted tube was perforated, bundles of a luminous discharge streamed through the aperture into the space behind the cathode. The colour of this discharge depends upon the gas in the tube; thus in hydrogen it is rose colour; in air, yellowish. The colour of the light due to these rays is not the same as that produced when cathode rays pass through the gas. In some gases the difference is very striking; thus in neon the light due to the cathode rays is pale blue, while the discharge which streams through the cathode is a gorgeous red. Goldstein called the rays which stream through the hole in the cathode *Kanalstrahlen;* but as they have been proved to consist of positively charged particles it seems more natural to call them "positive rays." These rays produce phosphorescence when they strike against glass and many other substances, though the phosphorescence is generally of a different colour from that produced by cathode rays. They also affect a photographic plate. It was at first thought that the positive rays were not deflected by a magnet, as magnetic forces which produced large deflections of cathode rays had no appreciable effect upon positive ones. Wien showed, however, by using very strong magnetic fields, that they could be deflected and that the direction of the deflection indicated that they carried a charge of positive electricity; they can also be deflected by electric forces.

By measuring the deflection provided by electric and magnetic fields we can determine by using equations (26) and (27) the value of e/m for the particles which constitute the rays. The result is of great interest. Instead of, as in the cathode rays, e/m having the same value for all the carriers, we find that e/m has many different values separated by finite intervals; and instead of e/m being equal to $1{\cdot}78\times10^7$, as in the cathode rays, we find the greatest value of e/m is 10^4, which is the same as its value for a charged hydrogen atom. The values found for e/m depend on the gases in the discharge tube; the outstanding result is that all these values of m correspond to masses of atoms or molecules of the chemical elements or compounds. Thus while the determination of e/m for the cathode rays shows that in a gas at a very low pressure the carriers of the negative electricity are all of the one type, being electrons whose mass is exceedingly small compared with that of any atom, the determination of e/m for the positive rays shows that the carriers of the positive electricity are of many different types; and that all these types correspond to atoms or molecules of the chemical elements or compounds. It has already been shown that if charged particles, after passing through electric and magnetic fields, are received on a screen or photographic plate, all particles, for which e/m is the same, strike the

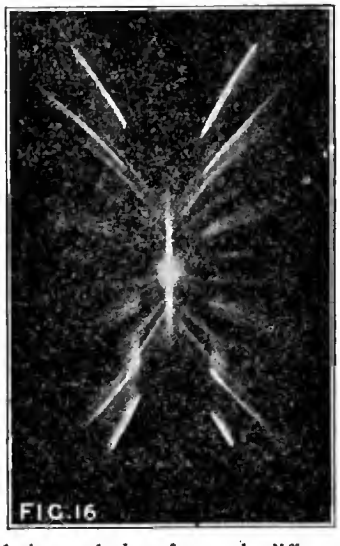

FIG. 16

plate on a parabola, and that for each different value of e/m there is a separate parabola.

These parabolas are shown in fig. 16, which is a reproduction of a photograph made by allowing the positive rays in a tube containing gases liberated by heating a certain mineral to strike against a photographic plate; taken from the top downwards they correspond respectively to the atom of hydrogen, the molecule of hydrogen, the atom of helium, the atom of carbon with two charges, the atom of nitrogen with two charges, the atom of oxygen with two charges, the atom of carbon with one charge, the atom of nitrogen, the atom of oxygen, the molecule of water, the molecule of CO and that of N_2 (these form one parabola), the molecule of oxygen, the molecule of CO_2 and the atom of mercury. We find that many of the atoms can carry more than one charge, for when we find a parabola corresponding to one value of e/m we frequently find another corresponding to twice this value; thus carbon, nitrogen and oxygen occur very frequently with two charges, other atoms such as argon with two and three charges, while mercury atoms have been detected with 1, 2, 3, 4, 5, 6, 7 charges. It is significant that the atom of hydrogen never occurs with more than one charge. Multiple charges generally occur on atoms but not on molecules; there are, however, some molecules such as CO on which double charges have been found. Some of the positive particles, after passing through the hole in the cathode, lose their positive charge and become uncharged, and some of these neutral particles acquire a negative charge; thus mixed with the positively electrified particles there are some negatively electrified ones. This power of acquiring a negative charge is confined to certain atoms; thus while the atoms of hydrogen, carbon, oxygen, fluorine occur with a negative charge, the atoms of nitrogen, helium, argon and neon do not. It is exceptional for a molecule to acquire a negative charge—the molecules of oxygen and carbon, however, can do so.

The equation of a parabola formed by a particle on the photographic plate has already been given

$$z^2 = \frac{e}{m} yC$$

where z is measured parallel to the displacement due to the magnetic field and y to that due to the electrostatic. C is a quantity which depends on the strength of the electric and magnetic fields and on the position of the photographic plate. If, as in fig. 17, we draw a line parallel to the axis of z, the intercept made by a parabola on this line will be proportional to $(e/m)^{\frac{1}{2}}$; thus, if the top parabola is due to the atom of hydrogen, the next to the molecule of hydrogen, the third to the atom of helium and the fourth to that of oxygen, the intercepts AH, AH_2, AH_4, AO are in the proportion of 1, $1/\sqrt{2}$, 1/4. Thus by comparing the intercept made by any parabola X with that made by

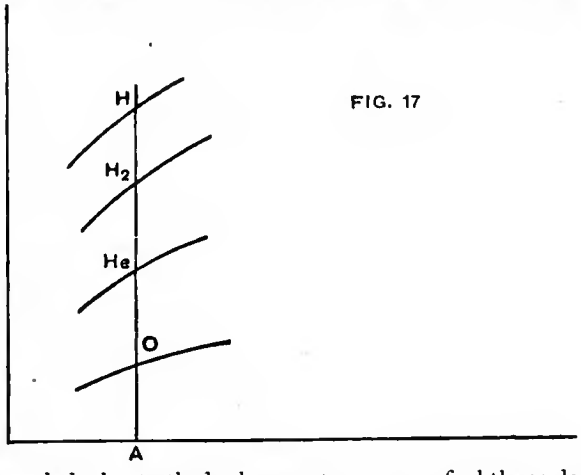

FIG. 17

the parabola due to the hydrogen atom we can find the molecular weight of the substance producing the parabola X.

Positive Rays as a Method of Chemical Analysis.—Since from the measurement of the positive ray photographs we can determine the molecular weight of the gases in the discharge tube, we can analyse a gas by putting a small quantity of it in a discharge tube and taking a photograph of the positive rays. It is thus a method of chemical analysis, and its application has already led to the detection of several new substances. In fact, though it has only recently been introduced, more substances have been discovered by this method than have ever been discovered by spectrum analysis. The method has many advantages. In the first place only a very minute quantity of the gas is required; a small fraction of a cubic centimetre of gas at atmospheric pressure is all that is required to fill the discharge tube at the pressure at which the positive rays are produced. Again, the method is very sensitive, as it will detect the presence of a gas which only forms a small percentage of the gas in the tube. The method not only detects the presence of the gas, but at the same time determines its molecular weight. It indicates, if the gas is an element, whether it is monatomic or diatomic; for if it is diatomic it will give rise to two parabolas, one due to the atom, the other to the molecule. The absence of double or negative charges will suggest that it is a compound and not an elementary gas. The only ambiguity is that it does not distinguish between two substances of the same molecular weight; thus CO_2, and N_2O give the same parabolas, as also do CO and N_2: we can often, however, remove this ambiguity by putting substances in the tube which would absorb one gas and not the other, and testing whether or not this has removed the parabola.

Use of Positive Rays to Determine Atomic Weight.—The measurement of the parabolas give, as we have seen, the atomic weight of the elements producing them; they can therefore be used to determine the atomic weight of elements which can be introduced in a gaseous state into the discharge tube. This method has the great advantage that the presence of impurities does not affect the result. Mr. Aston has lately, by the use of a positive-ray method for determining atomic weights (*see* ATOMIC WEIGHTS), found the very important fact that, if oxygen is taken as 16, the atomic weights of the elements with the exception of hydrogen are represented by whole numbers. Thus in working with chlorine he found no substance with an atomic weight of 35·4, but two substances with atomic weight of 35 and 37 respectively; he regards these substances as identical in chemical properties and inseparable by chemical reactions, and ordinary chlorine as a mixture of about 3 parts of (35^2) and one part of (37^1). Mr. Aston, by the method of positive-ray analysis, has discovered and measured the masses of the isotopes (*see* ISOTOPES) of most of the chemical elements.

The Charges of Electricity Carried by Gaseous Ions and Electrons.—The deflection of cathode and positive rays by electric and magnetic forces supplies a method for finding the value of e/m; for the determination of e, the charge of an ion, other methods have to be employed. One such method used by J. J. Thomson is based on the important investigation of C. T. R. Wilson on the effect of ions on the deposition of clouds and fogs from supersaturated air. If dust-free air saturated with water vapour is suddenly cooled by expansion, no cloud or fog is deposited unless the supersaturation due to the cooling is very large. C. T. R. Wilson found that if ions are present in the gas they act as nuclei round which drops of water are deposited with a supersaturation much below that required for gas free from ions. A beautiful application of this is the detection of the path of an α particle from a radioactive substance. The α particle produces by collision ions all along its path; if the damp gas through which the particle is passing is suddenly cooled by expansion, drops of water will deposit on the ions and thus mark out the path of the particle. One of Mr. Wilson's photographs of such a path is shown in fig. 18. Mr. Wilson found that less supersaturation is required to deposit water on negative than on positive ions.

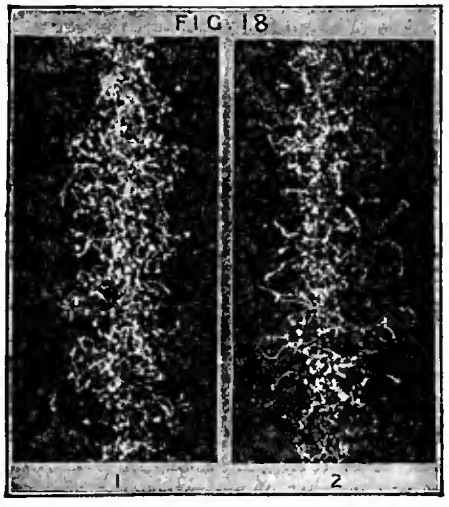

FIG. 18

This result can be applied to find the number of ions in a moist gas, for if the gas is suddenly expanded by an amount sufficient to deposit drops on ions, but not sufficient to produce condensation in their absence, then each ion may be made the centre of a drop, and the problem of counting the ions is reduced to that of counting the drops.

We can calculate the amount of water that will be deposited by any given expansion of the air: hence since we know the volume of the water we can determine the number of drops if we know the volume of a single drop. Observation of the rate at which a drop falls under gravity will give the size of the drop, for Stokes long ago showed that the velocity of a rain drop falling under gravity is given by the equation $v = \frac{2}{9} g \frac{a^2 \rho}{\mu}$; when v is the velocity of the drop, a its radius, μ the viscosity of the gas, g the acceleration due to gravity, and ρ the density of the gas. It has been found that, with the exceedingly fine drops formed round ions where the radius of the drop is comparable with the free path of the molecules of the gas, the velocity is $\left(1 + \frac{C}{pa}\right)$ times

that given by the above equation when C is a constant, and p the pressure. But though this correction makes the relation between a and v a little more complicated, it still enables us to determine a when v is known. Thus the radius, and therefore the volume, of the drop can be determined, and from this, as we have seen, we can deduce the number of ions.

Let n be this number per unit volume; then if a current of electricity is sent through the gas by an electric force X, the current passing through unit area will be neU when U is the mean velocity of the positive and negative ions under the force X. We know that it is proportional to the force and for a force of one volt per cm. is 1·5 cm./second; and hence when X is known U is known, the current neU can be measured, and hence ne deduced; as n has been found by the drops, the value of e can be determined immediately. This was the method used by J. J. Thomson; a simpler method used afterwards by H. A. Wilson was to get drops round the negative ions alone by using an expansion that would deposit moisture on negative but not on positive ions. He then showed the rate of fall of these drops, first under gravity alone, and then under a vertical electrical force X, acting on the drop in the same direction as gravity. Thus, when the electric field is acting, the force on the drop is

$$Xe+\tfrac{4}{3}\pi\rho a^3 g,$$

and when it is off the force is only $\frac{4}{3}\pi\rho a^3 g$. Thus, if v_1, v are respectively the velocities of the drop when the field is on and off,

$$\frac{Xe+\frac{4}{3}\pi\rho a^3 g}{\frac{4}{3}\pi\rho a^3 g} = \frac{v_1}{v}$$

or

$$Xe = \tfrac{4}{3}\pi\rho a^3 g\frac{(v_1-v)}{v}$$

From v, the rate of fall when the field is off, we can calculate as before the radius of the drop, and from the preceding equation we can determine e. Millikan (*Phil. Mag.*, 34, p.1), who has made most extensive and accurate investigations on the value of e, used a modification of the preceding method. Instead of producing water drops by expansion on the ions, he obtained, by means of a sprayer, minute drops of oil; he observed the motion of one of these under an electric field in a gas which was subject to some ionising agent, and from time to time an ion would strike against the drop and alter the charge; this would alter the velocity, and from the alteration of the velocity he could by a formula similar to that just given calculate the charge communicated to the drop by the ion. The value obtained for e by this method is, in electrostatic units,

$$e = 4{\cdot}77\times10^{-10}$$

If M is the mass of an atom of hydrogen the value of E/M can be determined by the positive-ray method, so that as E is known M can be determined. When M is known Avogadro's constant and the number of molecules of hydrogen in a cubic centimetre of gas at standard temperature and pressure are at once determined.

Thus the study of the electrical property of gases gives the most accurate values available of two of the most important constants connected with the constitution of matter. By studying electrified atoms and molecules, we are able to determine their masses and their properties with an accuracy far beyond that attainable by any method which can be used when they are in the normal state. See Sir J. J. Thomson, *Conduction of Electricity Through Gases* (1926) (J. J. T.)

GASOLENE, commonly known in Great Britain as PETROL, is a motor fuel particularly suitable for use in motor vehicles. It has been officially defined by the American Society for Testing Materials as a refined petroleum naphtha which, by its composition, is suitable for use as a carburant in internal-combustion engines. Petroleum naphtha, as understood in the above definition, is any product of petroleum of which not less than 10% distils below 347° F. (175° C.) and not less than 95% below 464° F. (240° C.) when subjected to distillation according to the current tests of the American Society for Testing Materials. The term gasolene (natural gasolene) is applied also to a liquid product of natural gas, which, however, in order to be marketable, must be blended with light grades of petroleum gasolene. On the other hand, among other motor fuels derived from petroleum, which, even in its crude form, is sometimes used for this purpose, are kerosene, which is suitable for tractors, and the distillate fuel oil employed in the semi-Diesel type of engine. Besides serving as fuel in motor-vehicle engines, gasolene is used for aeroplanes, motor-boats, motor rail cars and many kinds of stationary engines.

The increase in the use of motor vehicles, particularly in the United States, has made the question of gasolene supply a matter of vital concern. The consumption in the United States during 1924 was approximately 7,750,000,000 gal., nearly 500 gal. for each of the 16,000,000 cars then in service. The largest consuming countries outside of the United States are, in order: Great Britain, France, Canada, Argentina, Belgium, Australia and Italy. The European consumption for 1924 is estimated at 1,300,000,000 U.S. gal. (⅚ of the imperial gallon). The following tabulation, based on figures supplied by the U.S. Dept. of Commerce, shows the production and consumption in the important countries in typical years.

Production and Consumption of Gasolene

Country and Year	Production	Consumption (in U.S. gal.)	
		Gross	Per Capita
United States	U.S. Gal.		
1914	1,460,038,200	1,255,218,538	..
1923	7,555,945,143	6,685,035,280	..
1924	8,959,690,220	7,780,625,085	69·3
Great Britain	Imperial Gal.		
1914	5,140,364	141,029,305	..
1923	71,000,000	417,027,593	..
1924	95,000,000	549,600,000	11·6
France	Metric Tons		
1913	..	63,113,000	
1923	3,848	261,011,000	..
1924	4,000	297,234,000	..
			..
Canada	Imperial Gal.		
1924	170,000,000	260,252,000	29·0
Argentina	Liters		
1924	50,900,000	68,200,000	8·0
Belgium			
1923	..	35,155,185	..
1924	..	57,272,142	7·6
Australia

1923–4	12,748,800	14,750,000	0·2

Gasolene Supply.—The supply of gasolene depends on the available petroleum reserve (*see* PETROLEUM 21.316), efficiency in refining methods, and economic utilisation. The increase in the yield of gasolene from a given amount of petroleum is to be expected chiefly from more careful fractionation, improved cracking methods, and raising the upper distillation limits in the production of straight run gasolene by straight distillation. According to an estimate made by the United States Bureau of Mines, the gasolene produced from crude oil amounts to

about 33% of the oil entering the refineries. This percentage might be increased to 55, in the opinion of the Committee of Eleven on Conservation, American Petroleum Institute. Of greater promise are possible improvements in engine design, as a result of which the energy available from a given amount of gasolene may be greatly increased (*see* INTERNAL COMBUSTION ENGINE). It is estimated by C. F. Kettering, president of the General Motors Research Corporation, that the percentage of energy in gasolene transformed into work is, on the average, only 5, but that this might be increased to 10 through structural mechanical changes, thereby almost doubling the transportation efficiency of a gallon of gasolene.

Marketing Methods.—Highly specialised methods for the marketing of gasolene have been developed, particularly in the United States. The gasolene is shipped from refineries in tank cars or ships (tankers) to large storage terminals and thence to smaller storage tanks along railways. From these it is taken by motor tank truck to "service stations," garages and curb pumps, where it is pumped into motor vehicles. It is estimated that there are about 100,000 "service stations" in the United States, while innumerable curb pumps are to be found on the city streets and along country highways. Similar marketing methods are employed in Canada. In Great Britain and France the distribution of petrol was largely effected by tins but the gasolene pump has come into wide use. Public service stations for automobiles are now to be seen also in the principal cities of Germany, Belgium, northern Italy and other European countries.

Anti-knock Fuels.—A significant recent development has been the production of a gasolene designed to eliminate or reduce the "knock" of an engine. There are also substances on the market advertised to effect the same result if added to ordinary gasolenes. One such compound, known as ethyl gasolene, consists of commercial gasolene to which has been added a small fraction of 1% of a synthetic oil containing tetraethyl lead. Anti-knock fuels are said to increase the mileage per gallon, to reduce carbon deposits in the motor, to facilitate starting and to improve engine efficiency in cold weather. Of greater importance, however, is the fact that the elimination of "knock" removes the barrier to the introduction of an automobile engine which would greatly increase the mileage per gallon and otherwise compare favourably with the performance of engines now in use.

Gasolene Substitutes.—Benzol, derived as a by-product from coking coal, is used to a limited extent as a blend with gasolene in the United States, the limitation being due to the relatively small production of benzol. The substitutes for gasolene which promise the greatest usefulness are oil derived from shale and especially liquid fuel derived from coal. The use of alcohol (*q.v.*) as a fuel for internal combustion engines is growing in Great Britain, where extraordinary measures have been taken to encourage research and production of this fuel. The French Govt. also has undertaken research to this end and has encouraged the development of a local alcohol industry, the product of which can be used as fuel. The use of alcohol as a motor fuel in Germany was tried some years ago; more recently benzol, prepared by the carbonisation of coal and lignite, has been used as a motor fuel. Methanol, also, produced on a commercial scale from carbon monoxide and hydrogen by the so-called Bergius method for the liquefaction of coal, has attained importance as a substitute for gasolene. (*See* COAL; FUEL PROBLEMS.)

GASQUET, FRANCIS AIDAN (1846–), English Roman Catholic divine and historian, was born in London Oct. 5 1846. He was educated at Downside College, Bath, afterward becoming Superior of the Downside Benedictine monastery (1878–84). Created cardinal in 1914, in 1918 he was appointed prefect of the Vatican archives. He has produced various works on mediaeval church history and liturgies, among them being *Henry VIII. and the English Monasteries* (1888–9); *A Short History of the Catholic Church in England* (1903); *Parish Life in Mediaeval England* (1906); *The Bosworth Psalter* (1908); *Monastic Life in the Middle Ages* (1922); *His Holiness Pope Pius XI.* (1922).

GAUL, GILBERT WILLIAM (1855–1919), American painter (*see* 11.532), died in New York Dec. 21 1919. He was awarded a gold medal at the Appalachian Exposition, Knoxville, in 1910.

GAUVAIN, AUGUSTE (1861–), French journalist and diplomat, was born at Vesoul Oct. 6 1861. From 1889 to 1892 he was on the staff of *Le Journal des Débats* and in 1893 became general secretary to the European Commission of the Danube. In 1904 he was appointed French secretary to the Central Office of International Transport at Berne. In 1908 he returned to the staff of *Le Journal des Débats* and from that time directed its foreign policy. By the continuity and clearness of his views, his freedom from bias and, above all, by his exceptional talent as a writer, M. Gauvain came to exercise considerable influence. He gave early warning of the menace of German imperialism, and more especially of the danger threatened to Europe by the condition and policy of Austria-Hungary. He was an unceasing advocate of energetic action and moderation in aim on the part of the Allies in the World War. Gauvain, who became a member of the Academy of Moral and Political Sciences, published verbatim in 14 volumes all his articles in *Le Journal des Débats* from 1908 to 1920. (*See* FRANCE: HISTORY)

Among his other works are: *Les origines de la guerre européenne* (1915); *L'Europe avant la guerre* (1917); *L'affaire grecque* (1917); *La question Yougoslave* (1918); *L'encerclement de l'Allemagne* (1919).

GDYNIA or GDINGEN.—This Polish seaport and naval base is situated on the small bay of Gdynia, opening out into Danzig Bay, on the Baltic. It is 12 m. northwest of Danzig, with which it is connected by the railway running westerly from that city to Stolp and Stettin. The Polish Govt., in building a railway to the port which will pass over territory entirely Polish, has also a scheme for a canal to the port from a convenient point on the Vistula, thus tapping the whole waterway system of Poland.

During the struggle with Soviet Russia in 1920, the Poles were unable to utilise Danzig for naval or military purposes, and this led them to build a port of their own. A suitable site was found at Gdynia, where a fishing village of about 200 souls already existed. The depth of water near the shore varies from 10 to 20 metres; the bed of the bay gives firm anchorage; and the entrance is sheltered by the peninsula of Hela. The Polish Govt. began the construction of the port in 1921, and by the summer of 1924 had built the southern mole, 550 metres in length, and a breakwater 175 metres long, forming part of the northern mole, together with a landing stage 150 metres long, a narrow gauge railway along the southern mole, an electric power station, water supply and other equipment. A contract for further construction was signed on July 4 1924 by a Franco-Polish syndicate, the date for the completion of the contract being Dec. 31 1930.

Its main provisions are (1) the making of an entrance canal, 11 metres deep, to the harbour, (2) the construction of the harbour with a water area of about 400 ac. and 1,060 metres of quays, together with a basin eight metres deep and a pier for passenger vessels, the depth of water at the quays being from eight to 10 metres and (3) the digging of an inner basin or dock on the foreshore, with a water area of about 100 ac. and a depth of water at the quays of 10 metres. In 1924–5 the northern mole was extended to a length of 700 metres, and considerable dredging and excavation work was done. In addition the Polish Govt. proposes to spend a large sum on the equipment of the port, comprising large warehouses, a grain elevator, powerful cranes, railway sidings and paved roads. In 1930 the port will have quayage for 30 large steamers and a handling capacity annually of 2,500,000 tons, but it will be constructed so as to permit of a great increase in its size and capacity. In 1925, 85 vessels, of 73,351 net tonnage, entered, and 79 vessels, of 69,981 net tonnage, cleared the port, exclusive of coastal shipping.

GEDDES, SIR AUCKLAND CAMPBELL (1879–), British politician, was born June 21 1879, the son of Auckland Campbell Geddes of Edinburgh and the younger brother of Sir Eric Geddes, and was educated at George Watson's College, Edinburgh, and Edinburgh University. He studied medicine, qualified as a practitioner, was at the London hospital for a time and later studied at Freiburg. He was a demonstrator and professor of anatomy first at Edinburgh, then at the Royal College of Surgeons, Dublin, and afterwards at McGill University, Montreal. He also had some military experience in the South African War and afterwards in the World War 1914–6.

In 1916 Geddes became director of recruiting, and in Aug. 1917 Minister of National Service. A seat in Parliament was found for him at Basingstoke and he had little difficulty in accommodating himself to parliamentary life. After the Armistice, Sir Auckland, who had been made a K.C.B. in 1917, became President of the Local Govt. Board and Minister of Reconstruction, and in May 1919 President of the Board of Trade. In this latter capacity he began the removal of the barriers to British Trade which the War had necessarily set up, and he had to deal with the difficulties which immediately arose in the coal industry. In this delicate task he was at least temporarily successful, and managed materially to reduce the price of domestic coal. In the same year an opportunity was afforded him to return to academic life by his election as principal of McGill University. He accepted the appointment, subject to its not being operative till the abatement of the coal crisis allowed of his leaving the Board of Trade. But during the delay the Government prevailed on him to accept instead the post of British Ambassador in Washington. His tenure of the Embassy only lasted three and a half years (1920–3), but the time was crowded with important negotiations in which he showed himself a successful diplomatist. On quitting Washington, Sir Auckland, who had been made G.C.M.G. in 1922, left the public service and became chairman of the Rio Tinto Company. He married in 1906 Isabella Gamble, daughter of W. A. Ross of New York.

GEDDES, SIR ERIC CAMPBELL (1875–), British man of business and administrator, born in India Sept. 26 1875, was the son of Auckland Campbell Geddes of Edinburgh, and the elder brother of Sir Auckland Geddes. He was educated at the Oxford Military College and Merchiston Castle School, Edinburgh. He gained some business experience at lumbering in the United States, and was afterwards connected with railways—first, the Baltimore and Ohio system, and then the Rohilkhand and Kumaton in India. Returning to England he joined the North Eastern Railway Co. under Sir George Gibb, and, having succeeded him in 1906, was himself the general manager of this line when the World War broke out.

Geddes was one of the business men whom Mr. Lloyd George, on becoming Minister of Munitions, enlisted in Government employ. He became deputy director general of munitions supply, 1915–6, and was then appointed, though a civilian, director general of transportation, and succeeded in bringing the British lines of communication in France into a high state of efficiency. He was knighted in 1916, and in 1917 he was created K.C.B. and G.B.E., being transferred to the Admiralty in May of that year as controller, in order to develop and utilise the whole of the shipbuilding resources of the country and concentrate them under one authority. A month or two later, in spite of having no parliamentary experience, he was appointed First Lord of the Admiralty, and was returned to the House of Commons as M.P. for the borough of Cambridge.

After the Armistice Mr. Lloyd George made use of Sir Eric's powers as an organiser by commissioning him to co-ordinate Government departments in regard to demobilisation. His success in these varied tasks was rewarded in Jan. 1919 by the G.C.B. When the Government was reconstructed in that month, he left the Admiralty in order to organise and preside over a new Ministry of Transport. But in the autumn of 1920 there came the sudden break in trade, and it became evident that the country could not afford a department on the proposed scale. In 1921 a bill introduced by Sir Eric for the re-grouping of the railways was passed; he then resigned office in Oct., and the ministry was reduced in personnel and importance. Sir Eric himself was appointed in Aug. 1921 chairman of a small committee, later known as the "Geddes Axe," to recommend public economies to the Government. In various reports in the winter of 1921–2 the committee recommended savings amounting to £86,000,000; but Sir Eric complained that only £52,000,000 of this amount was actually saved. In 1922 he left Parliament and returned to a business career, becoming chairman of the Dunlop Rubber Co. and of Imperial Airways, Ltd. He married in 1900 Gwendolen, daughter of the Rev. A. Stokes, and had three sons.

GEDDES, PATRICK (1854–), British biologist and sociologist, was born at Perth Oct. 20 1854. He was educated at Perth Academy, and in London and France, and became demonstrator in physiology at University College, London, in zoology at Aberdeen and in botany at Edinburgh. In 1883 he was appointed professor of botany at University College, Dundee (St. Andrew's University) and in 1919 he became professor of sociology and civics in Bombay University. As a biologist, in collaboration with James Arthur Thomson, he wrote *The Evolution of Sex* (1889; revised ed. 1901); *Evolution* (1911); *Problems of Sex* (1912); and *Biology* (1925), tending towards a new Lamarckian position. Interested in the synthetisation of science with art and history and its application to the conditions of modern life, especially in the direction of town-planning and housing, he travelled extensively, established a publishing house and promoted civic museums and industrial exhibitions. He was one of the leading members of the Sociological Society founded in 1904. His views are embodied in the papers of this society and in *City Development*, a report to the Carnegie Dunfermline Trust (1904), and *Cities in Evolution* (1915). He also wrote *Chapters in Modern Botany* (1893) and *Life and Work of Sir Jagadis C. Bose* (1920). In collaboration with Victor Branford he edited the series, (*The Making of the Future*, himself contributing volumes, *The Coming Polity* and, with G. Slater, *Ideas at War*.

GEIGER, WILHELM (1856–), German scholar, was born in Nuremberg July 21 1856. He qualified as an academic lecturer in 1886 in Munich and became professor at Erlangen in 1891. In 1920 he was appointed professor of Indian and Iranian philology at Munich. He became the publisher of the *Zeitschrift für Indologie und Iranistik*, the *Zeitschrift für Buddhismus* and the *Grundriss der Iranischen Philologie*. His chief works are: *Handbuch der Avestasprache* (1879); *Ostiranische Kultur im Altertum* (1882); *Ceylon, Tagebuchblätter und Reiseerinnerungen* (1898); *Litteratur und Sprache der Singhalesen* (1900); *Dipavamsa und Mahavamsa und die Entwicklung der geschichtlichen Ueberlieferung in Ceylon* (edited 1905); *Pāli, Litteratur und Sprache* (1916); *Pāli Dhamma* (1921); *Elementarbuch des Sanskrit* (3rd ed., 1923); *Samyutta Nikāya* (Eng. trans., 1924).

GEIKIE, SIR ARCHIBALD (1835–1924), Scottish geologist (*see* 11.552), received the O.M. in 1914. He died at his residence near Haslemere, Surrey, on Nov. 10 1924.

GEIKIE, JAMES (1839–1915), British geologist (*see* 11.553), died in Edinburgh March 1 1915.

GENERATOR: *see* DYNAMO.

GENETICS (*Greek* γένεσις, origin or creation).—This term was proposed at the third International conference on hybridisation, London, 1906, to denote the study of heredity and variation. In that sense it has been generally adopted, and by extension is understood to include the physiology of reproduction and the art of breeding. Though such inquiries have been pursued from the earliest times, the development of a special branch of science relating to them is recent. The primary incentive was the hope that by applying accurate methods of observation and experiment to the course of heredity and variation a more precise knowledge of evolutionary processes might be acquired.

Modern theories of evolution are based on the assumption that species have arisen by descent with modification, and that the constancy and diversity which living things manifest in their reproduction provide a sufficient basis for that conception. It is significant that as a result of the preliminary work done under the new inspiration, attention has been largely diverted from

these more philosophical aims. Beliefs current among naturalists, especially as to the nature and incidence of variability, were at once found to be widely incorrect. The scope and character of these discoveries are referred to below. Their immediate consequence has been that the development of evolutionary theory is tacitly suspended or postponed, and activity is concentrated on the exploration of genetical physiology, the theoretical evaluation of the knowledge thus gained being relegated to the future.

In these researches several methods of investigation are available. Modern genetics began with an attempt to observe empirically the course of contemporary variation from type; but though observations of this class have proved valuable in a preliminary survey, and have often been of use as indicating material for more prolonged investigation, the main advances have been accomplished by either (1) experimental breeding or (2) cytology. Important sidelights on genetical problems have also been obtained through the study of developmental mechanics (*Entwicklungsmechanik*) by experimental methods.

Experimental Breeding

The great stimulus to this method of research was given by the rediscovery in 1900 of Mendel's paper (*see* 18.115). Heredity, long regarded as a fortuitous and seemingly lawless phenomenon, was proved to follow regular principles which could in great measure be ascertained by experiments properly planned. A vast field was at once thrown open for investigation. Mendel's success was made possible by his genius for simplification. Working with peas, he made crosses between distinct varieties and watched the descent of their numerous characteristics, fixing his attention on each separately, and disregarding other differences. He then found that numerous distinctive features behaved in descent as if they were transmitted as units.

These determining elements or units are referred to as *factors* or "genes" (a term especially used by American writers, the equivalent of Johannsen's *Genen*). The differences determined by these factors can commonly be shown to be treated in heredity as pairs of alternatives or opposites, such as tall and short, coloured and colourless, hairy and smooth, each germ-cell being usually pure in respect of one or other of the contrasted characteristics. This is the principle of *allelomorphism*, and the members of such pairs are called *allelomorphs*. The zygote, formed by two germ-cells united in fertilisation, may be made up of two germ-cells alike in respect of any given pair, in which case it is said to be *homozygous* in that respect, or it may be a *heterozygote* if the uniting pair of cells are unlike. Before the germ-cells of the heterozygote are formed a process of *segregation* occurs, and there is a dissociation between the opposing elements introduced at fertilisation, such that the resulting germ-cells are again in normal cases pure in regard to each allelomorph.

In respect of any such pair of differences the character of the heterozygote is sometimes intermediate, but it most often approaches more nearly to one of the parental types. Not infrequently the approach is so close that the pure homozygote cannot be distinguished with certainty from the heterozygote. In Mendel's terminology the character thus prevailing is a *dominant*, the other being *recessive*. The distinction is of importance and is the basis of certain suggestions as to the possible nature of allelomorphism.

After the rediscovery of Mendel's work progress was rapid, and it was soon found that similar principles of descent apply to a great range of characteristics by which living things are distinguished. The number of forms of life studied is now very large, and includes most of the kinds of plants and animals which are readily amenable to experiment or observation. Man is evidently no exception, and we already know that certain features of human colouration, especially of hair and eyes, and several congenital abnormalities are transmitted according to the Mendelian scheme, some being dominant and others recessive.

Scarcely any satisfactory opportunities for studying the genetics of the lower plants (ferns, mosses, algae, etc.) have yet occurred, but one example has been described in a unicellular alga (Pascher). Of the features by which animals and plants are distinguished most have now been shown to be dependent on segregable elements. Reservation must be made in regard to differences which are simply quantitative, for there is a good deal of evidence suggesting that the elements by which size and weight are determined do not often form themselves into simple allelomorphic pairs. A similar doubt exists in regard to numerical or meristic distinctions.

Abnormalities.—Differences in instinct and other characters dependent on nervous mechanism are not, as such, distinct in their genetical behaviour, and some have been proved to depend on segregable factors or elements. In several breeds of fowls the hens are devoid of maternal instincts, and do not sit on eggs. This characteristic is recessive to the normal instinct, and segregation takes place in regard to it. The same is true of the pacing habit in horses as opposed to the trotting habit. The "waltzing" habit of certain Japanese mice is recessive to the normal, segregates from it and breeds true when it reappears. This example is interesting, since the abnormality is almost certainly a consequence of deformity in the semicircular canals of the ear.

Descent in Man.—As to the descent of the normal mental attributes of man little is known with accuracy, but several abnormalities of the nervous system are known to follow modes of descent which prove them to be subject to segregation. Feeble-mindedness is a recessive condition which breeds true. Paralysis agitans is also a recessive. Hereditary chorea descends as a dominant; colour-blindness and a form of night-blindness may also be termed recessive (*see* Sex). In heterozygous combination with the normal there is segregation, but the descent of these conditions is complicated by sex.

It will readily be understood that though the determining factors may be transmitted as units, the distinguishing characters of animals and plants often must be due to the association of many independent units. Of these, some produce their effects separately, but not rarely, though, independently transmitted, two or more unit-factors may be complementary to each other and combine to produce a joint effect or "compound character," as it is sometimes called. Such complementary factors, if separately present in the organism without their complement, need not manifest their presence at all, and it is then only by breeding tests that their existence can be demonstrated.

Organisms may now be represented as aggregates of units which confer upon them their various attributes. The degree to which an organism may be thus resolved is as yet undetermined, but there is presumably a limit to the process, and it is natural to suppose that the detachable elements are implanted on a *basis*, which for a given type is irreducible.

Reversion.—Conceptions, formerly vague, now acquire an exact meaning. For example, reversion or "throwing back" to an ancestral form, previously regarded as a mere caprice of nature, can at once be perceived to be due to one of two definite causes which operate with regularity. The reversion is either (*a*) the reappearance of a recessive characteristic, or (*b*) it is the consequence of the reunion of complementary factors which, though both present together in the ancestor, had been separated by variation and transmitted in distinct strains. For example, when a red-haired child is born to dark-haired parents the fact proves that the two parents are heterozygous in respect of the recessive red, which reappears when two germ-cells carrying it unite in fertilisation. Moreover, if the statistics of a considerable number of such families of children were collected and added together it would be found that the proportion of red-haired was approximately a quarter of the whole. The mere fact that one or both of the parents traces descent from a red-haired ancestor is not the cause of the reversion—for if either of the parents were homozygous in dark hair the red would not have reappeared.

The reversion to an actual or supposed ancestral form consequent on the meeting of complementary factors is less common in the ordinary practice of breeders, but is frequently seen in experimental crossing. When two white orchids crossed together give a coloured flower in F_1, or when a rose-combed fowl bred with a pea-combed bird gives chickens with the walnut comb of the Malay fowl, the production of the unexpected colour or

structure is due to complementary action of two independent factors. But the old interpretation of the phenomenon as a consequence of such an ancestor having occurred in the pedigree is illogical and misleading. In the case of the walnut comb, for instance, it is quite possible that either or both of the parent breeds never had a Malay ancestor. The production of a new form by the meeting of complements should be regarded, like the properties of a chemical compound, simply as the empirical consequence of a certain combination of units, without reference to the previous history of those units.

Purity of Type.—Of greater importance, both theoretical and practical, is the fact that it is now possible to assign a precise meaning to this expression. To the pre-Mendelian evolutionist purity was always a matter of degree, which might be gradually and, as it were, asymptotically approached in successive generations of selection, but never actually attained. The practical breeder also has always regarded purity as a property necessarily dependent on a long course of selection. Purity is now seen to be the condition of the animal or plant which is formed by the union of gametes bearing identical units. In respect of any allelomorphic pair purity may thus be conferred, though in respect of other pairs of units the same organism may be impure, *i.e.*, heterozygous, or, in ordinary parlance, cross-bred. This is the central fact of Mendelism, and on it Genetics is based.

The question of purity must therefore be considered separately for each pair of units. A thoroughbred horse, for example, may be pure in a number of characteristics which go to the making of the breed, but it may be impure in, say, colour. A chestnut horse, however, of whatever parentage, is pure-bred in colour, since that colour is the lowest of the series of horse colours, and chestnuts bred together give chestnuts only. By selection, the likelihood of producing purity is increased, but, as will subsequently appear, no amount of selection can ensure purity. On the other hand, purity in respect of any character may be attained at once in any mating by which gametes of similar factorial composition happen to be brought together in fertilisation. From this proposition the corollary follows that the combination of two strains pure in any given respect will give a family uniform as regards the character considered, and the uniformity of such cross-bred families, especially when one of the parents contains few dominant factors, is in practice one of the simplest and most convincing tests of purity.

Genetic Analysis.—By the institution of a series of crosses with varieties and study of the composition of the succeeding generations an *analysis* of the factorial constitution of a given type can be made. The numerical proportions or ratios in which the several combinations of characters are represented, the number of these terms in the series, and their respective genetical powers of transmission furnish the data from which the nature and number of the factors comprising the parental type may be determined. In the earlier article on Mendelism (*see* 18.115) some of the simpler ratios and their significance are explained, but examples of a much higher order of complexity are often encountered. The unravelling of these complications has led to some important discoveries. The many ways in which it may come to pass that two or more terms in a series of factorial combinations may be indistinguishable from each other cannot be enumerated here, but a knowledge of some of the more significant causes of disturbance of what may be called the normal ratios (9:3; 3:1; 9:3:4; 27:9:9:9:3:3:3:1, etc.) is essential to a proper comprehension of Genetics.

Cumulative Factors.—From certain crosses (especially of cereals) into which only one pair of differences had apparently been introduced it was observed (Nilsson-Ehle; East) that the recessives reappearing in F_2 were only 1:1:5 instead of the usual 1:3. Investigation proved that from the dominant side *two* factors with identical functions, though belonging to distinct pairs, had been introduced. Consequently, among the dominants in F_2 were some containing both these factors and others having one only. Various results suggest that this multiplication, or better, *accumulation*, of similar factors is a common occurrence, and that the process may be extended in special cases.

Inhibiting and Lethal Factors.—Many factors act by producing a negative result, inhibiting the development of some character, the determining elements of which are present though their action is not perceptible or largely diminished. Of these the most easily demonstrable operate by inhibiting the formation of colour. The white pigment of the coats of animals and the feathers of birds, or of flowers, for example, is commonly due to the absence of the elements necessary for the formation of colour, but both in animals and in plants varieties have been found which are white, or nearly so, not through absence of pigment, but through the presence of factors which, in some way not yet defined, inhibit the production of the coloured pigments. From some matings a mixture of white individuals may be obtained, which to the eye look alike or nearly so, though they represent various factorial terms and are genetically dissimilar. The process of inhibition may be carried much further, and there are well-established instances in which the animal or the plant cannot live if it is homozygous (containing two "doses," in popular terms) for a given factor.

The classical instance of such *lethal* factors, as Morgan has called them, was met with in the breeding of yellow mice (Cuénot; F. M. Durham). Mice with yellow coats, bred together, give a majority of yellow, but always throw a proportion of some other colour—for example, chocolate or black. Since in mice yellow is a dominant, it is clearly caused by a factor which the gametes can carry. But the union of two gametes, both carrying this factor, does not give rise to a viable animal. It was suggested that two such gametes could not unite in fertilisation, but later work has practically proved that these fertilisations occur and that the resulting embryo perishes at an early stage (Ibsen). The physiological action of the yellow factor in causing death is not known. In plants the "golden"-leaved varieties are comparable. They cannot breed true, but throw 2 yellow: 1 green. The purely yellow term is missing, and is clearly not viable (Baur). The suggestion has been made that the yellow factor acts not merely negatively by diluting the amount of chlorophyll, but by inhibiting its formation, probably producing a body with this specific power. This is the more likely since golden varieties in dull weather turn almost a full green, whereas in sunlight they bleach to a full yellow, a fact indicating that the production of the inhibiting body is promoted by sunlight. Two doses of this factor kill the plant altogether, probably during embryonic life.

Linkage.—At an early stage in these inquiries it was observed that factorial units belonging to separate allelomorphic pairs are not always distributed independently among the gametes of a heterozygote, but that some combinations occur regularly with a greater frequency than others. The next step was the discovery that this *linkage* depends on the association of the linked factors in the parent from which the heterozygote was formed. For example, if a form AB is crossed with ab the normal expectation is that the double heterozygote $AaBb$ will form gametes AB, Ab, aB, ab in equal numbers; but if there is linkage between A and B, then the parental combinations AB and ab will be more frequently represented in the gametic series than the other, or "cross-over" combinations, Ab and aB. But if the original cross were in the form $Ab \times aB$, then the most frequent gametes will be Ab and aB, the cross-overs, AB and ab being the rarer. This observation forms the starting-point from which modern genetical theory has been very largely developed.

The terminology followed above is that introduced by T. H. Morgan, to whom progress has been especially due. It is sometimes convenient to distinguish the case in which the two dominants ($AB \times ab$) are introduced together by the parent as *coupling*, and the converse ($Ab \times aB$) as *repulsion*, but the physiological process is now recognised as being clearly the same in both cases, and there is no difference in the numerical proportions in which the parental combinations respectively reappear. It should be observed that the factors thus linked have plainly no connection with each other as regards the effects which they produce in the zygote, but may concern the most dissimilar characters. For instance, in the example first observed the linkage was that between the factor which makes the flower of the sweet pea

blue or purple (as distinguished from red) and that which makes the pollen grains long (as distinguished from round). According as the proportion of cross-overs is small or large the linkage is more or less complete. If both parental and cross-over terms are equally common there is no linkage. The most satisfactory test of the linkage-ratio is obviously provided by breeding the double heterozygote (*Aa–Bb*) with the double recessive (*aabb*), and this mating should be carried out reciprocally since it is known that in plants (*e.g.*, *Primula sinensis*) male and female sides of the same plant may show different degrees of linkage (R. P. Gregory), and that in animals (*e.g.*, *Drosophila* and the silkworm) crossing-over may be absent in one sex though occurring in the other.

Allelomorphism: Multiple Allelomorphs.—Apart from linkage, segregation is always a separation of units affecting the same character, and from a very large range of observations it is possible to represent the distinction between the allelomorphic pair as one in which a *positive* element separates from a *negative*. In other words, allelomorphism may commonly be conceived as a difference which consists in the *presence* of something on the one side and its *absence* on the other. This conception is applicable whenever there is definitely pronounced dominance. It is natural that the characteristic which possesses dominance should be looked upon as due to the positive or present element, the recessive being the consequence of its absence. Nevertheless, there is as yet no strict proof that this representation is physiologically correct. For since we know that many factors may operate by inhibition it is always possible to *invert* the conventional representation and by putting negative for positive, to make a factorial scheme which equally agrees with the observed results. Conventionally, for instance, the tall pea is represented as either *TT* (homozygous) or *Tt* (heterozygous), the dwarf being *tt*, from which the positive element *T* tallness is absent.

But we cannot positively declare that the dwarfs may not be *II* homozygous in the presence of an inhibitor *I*, whereas the tall plants might be either *Ii* heterozygous, or *ii* homozygous in respect of the absence of this inhibitor. The significance of this alternative mode of representation will be apparent when the application of factorial systems to evolutionary theory is attempted (*see* MENDELISM). But when the heterozygote is intermediate between the two homozygous forms the " presence-and-absence " method of representation cannot be applied with any confidence. From the existence of such cases and from certain other considerations it has been urged, especially by American geneticists, that the method of representation by presence-and-absence is incorrect, and that a negative allelomorph should be treated as a real entity. There is no valid means of deciding this question as yet. The probability is perhaps that the absence should always be regarded as relative only. As a mode of symbolic expression the representation of the two allelomorphs as differing quantitatively is often convenient, though perhaps not universally applicable.

Types of Allelomorphs.—Allelomorphism is, as the term implies, a relation between two alternatives, and in any one zygote there can be no more than two. Nevertheless, there are instances in which the same unit-factor enters into heterozygous combination with various alternatives in different zygotes, and each of these may thus be in allelomorphic relation with it. Alternatives composing such a group of possibilities have been termed by Morgan *multiple allelomorphs*, and this expression is commonly adopted. Its use, however, makes the application of the term " multiple " to " factors " in a totally different sense a probable source of confusion, and for this reason the word *cumulative* or some equivalent is there to be preferred as suggested above. The distinctions which together make up a set of multiple allelomorphs may commonly be recognised as a series of *quantitative* differences, the character affected being throughout the series the same.

Albinism in Rabbits.—One of the most familiar illustrations is provided by the degree of albinism in rabbits. The fully albino form is white with pink eyes, but there is a variety called Himalayan, which, though born white with pink eyes, acquires some pigment in certain parts. Himalayan is dominant to albino but recessive to the ordinary coloured types. If a coloured type is bred with Himalayan the heterozygotes so raised cannot, when interbred, throw albinos, nor can heterozygotes raised from coloured x albinos throw Himalayans, even though the albino used as their parent had itself been extracted from Himalayans. The degree of albinism put in by the parents comes out in F_2 and in the same degree. Hence it is not possible from similar parents to breed all three kinds, but on the other hand, each family can contain at most two of them.

This phenomenon can be interpreted in either of two ways. The Himalayan pattern may be regarded simply as a quantitative diminution or fraction of the sum total of colour needed to make the self-coloured type. The real albino is thus produced by the absence of the whole unit needed for colour, and the Himalayan by the absence of part of this total. It is then obvious that the heterozygote, coloured x albino, could never produce a Himalayan unless the colour-complex broke up again *de novo*. But on the analogy of the behaviour of other colour patterns the self and the Himalayan might be conceived as each consisting of two units: one for colour and one a factor determining its pattern, intensity or distribution. If there were a very close linkage between each " pattern," factor and colour the observed facts could then be represented; but by continued breeding the supporters of this view would expect the missing cross-over to appear eventually as either a Himalayan associated with recessive albinos or an albino associated with recessive Himalayan. On the ground of simplicity the former view seems preferable. The significance of these two alternatives will presently appear.

Study of Grasshoppers.—More complex illustrations of these possibilities have been described by Nabours in certain grasshoppers (*Paratettix*). The species studied presents a long series of colour forms, and experimental breeding showed that with certain exceptions all the pure forms behaved as if allelomorphic to each other. In other words, whichever two pure forms *A* and *B* were crossed together, the F_1 generation was *A B*, giving in F_2 a family approximating to $1AA:2AB:1BB$. The whole series of colours is thus often described as a vast set of multiple allelomorphs. Nevertheless, there are curious features in this case which raise a doubt whether this account is really correct. Many of the distinctions are plainly *quantitative* degrees in development of some one type of coloration which are, as might be expected, allelomorphic to each other (*cf.* the Himalayan rabbit): but among the elements comprising the total colouration of these grasshoppers there are several in which both the pigments and the positions they occupy are so distinct that the characters cannot easily be represented as determined by factors allelomorphic to each other. Only by a very loose application of the term 'colour' can the distinctions be said to apply to the same character. Hence, in this hitherto generally accepted illustration it seems probable that, in so far as the distinctions are actually quantitative differences in one respect, true allelomorphism may be recognised, but that the appearance of an allelomorphism between factors of differing scope is more probably spurious and referable to close linkage (*cf.* Haldane). No decision on this question can yet be made with any confidence.

Allelomorphic Complexes.—Among modern extensions of genetical theory none is more remarkable than the discovery that large and apparently miscellaneous groups of characters are sometimes governed by elements capable of segregating collectively as a single complex. Nevertheless, in the case of sex, we have long been familiar with one example. Since the distinction between the two sexes in many animals is known to behave in segregation as if it depended on a single Mendelian factor, we have to recognise that a number of distinctions of all kinds, structural and functional, may be treated in segregation as factorially single. In the special case of sex we know further that particular genetic elements may be detached from the complex (*e.g.*, the elements governing spur and broodiness in fowls, the beard in man, etc.), though the possible limits of such disintegration are unknown.

Oenotheras.—Renner's experiments have shown that the inheritance of the protean variations of several Oenotheras is largely

effected by the transmission of similar complexes. Each of these large composite factors or groups of factors (in so far as they prove to be divisible) may govern many characters of form, colour, habit, etc., and the whole group is transmitted as a single heritable entity. Similar discoveries will probably be made in regard to other forms. The details are beyond the scope of this article, but it may be remarked that these complexes in Oenothera supply one of the most striking illustrations of the phenomenon which may be called *anisogeny* (see " Somatic Segregation," *inf.*) or the relegation of a factor or factors exclusively to one sex-side of a plant. For instance, whereas *Oenothera Lamarckiana*, the species which provided de Vries with his most celebrated but unsound evidence of mutation, can be proved to be a permanently heterozygous form having two complexes equally distributed in segregation to both the male and the female gametes, the species *biennis* and many more, though similarly heterozygotes of two complexes, in segregation pass the whole of the one complex into the male gametes and the whole of the other into the female gametes.

The question whether the apparently simple factors which commonly behave as Mendelian units are capable of further resolution is of much theoretical importance in its bearing on the problem of the nature of variation. Such a complex factor as that which determines sex may evidently break up into simpler components, but for various reasons some geneticists incline to the belief that factors in general are permanent and irresoluble. Whenever a series in F_2 derived from two clearly distinct and true-breeding types, consists of a number of intergrading forms, it is possible to interpret this result as due to the operation of a multitude of *originally* distinct factors, or to the fractionation of some one or more of them. Not very rarely in such series an extreme parental type fails to reappear at all [*e.g.*, the many-feathered tail of the fan-tail pigeon (Morgan), or the long glumes of Polish wheat from crosses with ordinary types. It is difficult to interpret the absence of the extremes simply as an indication of their statistical infrequency. The production of an innumerable series of colour-forms, as in the sweet pea, is almost certainly due to the fractionation of the colour-complex. Until systematic crossing was undertaken, the extremes existed, but the intergrades did not. So also in *Drosophila*, of which the normal eye is red, a profusion of intergrades ranging to the white eye, which was discovered first, has now appeared. Though " mutation " is involved, the essential change is probably the disintegration or fractionation of the originally integral complex.

Cytological Interpretations of Genetic Phenomena

Soon after the rediscovery of Mendelian analysis the plausible suggestion was made that the behaviour of the chromosomes in the course of the maturation divisions was consistent with what might be expected if they were actually the bearers of segregable factors. Since, however, the number of segregating factors in many forms far exceeds the number of chromosomes possessed by those forms, it is clear that if the chromosomes are the carriers of factors they must be capable of carrying many. The discovery of linkage, and especially of the fact that linkage was determined by the parental associations of the factors, pointed in the same direction, for, as hinted (by Punnett) in the earlier article on Mendelism (*see* 18.115), linkage or " gametic coupling " as it was then called might not unreasonably be supposed to be based on chromosomal association. The first development of this conception was made by T. H. Morgan, whose investigations relating mainly to the fruit-fly *Drosophila*, have inaugurated a new phase in the development of genetical theory. This insect is a subject unusually favourable for experiment inasmuch as it offers a profusion of variations or " mutations," and reproduces itself with great rapidity under laboratory conditions.

The work began with the observation that the eyes, normally red, may be white, and that this variation is sex-linked, behaving genetically precisely as colour-blindness does in man. The white-eyed male mated with normal females produces offspring all normal. Of these the sons cannot transmit the abnormality at all, whereas the daughters mated with normal males transmit the white eye to half their sons. White-eyed females can only be produced as daughters of white-eyed fathers and all the sons of such females are white-eyed. Supposing the male to possess an X-chromosome, this system of descent would be represented if it were assumed that in the normal the X-chromosome carried the dominant factor for red eye (*see* Sex). The linkage with sex is thus found to be an expression of the association of the two determining factors for sex and red eye in the same chromosome.

Numerous other sex-linked characters were soon after discovered, to which the same considerations apply, all collectively composing one linkage-group. The other factors identified in *Drosophila*, amounting to more than a hundred, can all be represented as grouped in three separate linkage-systems which, with the sex-linked group, make four; and since from cytological observations the haploid number of chromosomes in this animal is also 4 the inference is drawn that the factors composing each linkage-group are borne in one chromosome. Developing this conception, Morgan suggests that the factors are arranged in the chromosomes as beads on a string, each having a position normally fixed in relation to the rest. Crossing-over is thus represented as the consequence of an exchange of material between homologous pairs of chromosomes in synapsis. (*See* Cytology.)

The pairs of chromosomes which then conjugate are with much probability regarded as respectively of maternal and paternal origin. The conjugating pairs seem to twist round each other, and occasionally there is (especially in Amphibia) an appearance of anastomosis between them which is regarded as providing for an exchange of material between the homologous pairs, and thus for the formation of cross-overs. According as the linkage between two factors is more or less complete it is supposed that the distance between the position of the two factors in the chromosome is smaller or greater, and in proportion as factors are placed close together the probability of their being separated in the process of twisting and anastomosis is regarded as diminished.

The proportion of cross-overs is thus taken as a measure of the position of two factors in the chromosome. If *A*, *B* and *C* are three factors in the linkage group, and the closeness of the linkages between *A* and *B* and between *B* and *C* respectively be determined experimentally, then from these two the linkage between *A* and *C* can be calculated, and the result of the calculation is commonly found to agree with the value found experimentally for that linkage. In this way the relative " loci " of numerous factors have been determined with fair consistency, and the fact that this can be done forms a strong argument for the belief that in some way at least the factors must be disposed in linear systems. That these systems are actually arranged along the lines of the chromosomes is as yet a matter of inference.

Attention must be called to the curious fact that in *Drosophila* crossing-over never occurs in the males in any of the four linkage-systems. As in most examples of sex-linkage studies, the linkage with the sex-factor is always complete; but all the other factors are liable to crossing-over in the female, though among the male gametes the original parental combinations reappear unchanged. Conversely Tanaka, examining linkages in the silkworm, observed that a pair of linked factors show crossing-over in the male, but not in the female, and the two facts together suggest some limitation of crossing-over to the sex which is homozygous in sex, the female in Diptera, the male in Lepidoptera. The development of the idea here outlined has become the subject of very active research and is described in a copious but somewhat esoteric literature, which can be followed only with difficulty by those not personally engaged in the work. That the outcome of these researches has led to a valuable codification of genetic principles is not in dispute; but until the main thesis, that the number of independent factors or of linkage-systems is never greater than the haploid number of chromosomes, has been shown to hold generally for animals and plants, this account of the nature of linkage, though probable, cannot be regarded as proved. The defect of the theory at the present time is that it rests on many subordinate hypotheses which are not all capable of independent verification.

The position of the factors, for example, is believed to be liable to changes due to the action of other factors, the effects of age and miscellaneous influences difficult to distinguish. Errors of cell-division long regarded as the most probable source of variation, may also cause disturbance. In two very remarkable instances it has been found possible to connect a disturbance in the normal course of heredity with a visible cytological irregularity—called by Bridges "non-disjunction." In a certain family he observed that a sex-linked character failed to follow its normal distribution to the sexes, and he was able to find that in this family the sex-chromosomes showed corresponding irregularities. In 1921 he obtained similar evidence in regard to the fourth chromosome and the group of genes attributed to it. Thus a definite association between particular chromosomes and the transferable factors must certainly exist.

Giant Forms.—The interrelation of genetical and cytological phenomena is further illustrated by the behaviour of "Giant forms." This name is applied to certain varieties (chiefly of plants) in which the haploid and diploid numbers of chromosomes are double those of normal forms. R. P. Gregory bred such varieties of *Primula sinensis* and found that in respect of various allelomorphs they might be quadripartite and not merely bipartite as the normals are. A plant, for example, might be *DRRR* in colour or leaf-shape, and in consequence of the extra recessive elements, not distinguishable from the ordinary recessive, though in fact capable of throwing a small proportion of dominants. Since recent cytological studies have shown that series of allied forms may contain various multiples of the lowest haploid number (Chrysanthemum, for instance, having 9, 18, 27, 36 or 45) various extensions on these lines may be expected.

Somatic Segregation.—In the genetics of plants a number of phenomena have been encountered which are difficult to reconcile with the view, otherwise not unacceptable, that the distribution of the factors occurs exclusively in the maturation processes of the germ-cells. Apart from certain special conditions best known in variegated plants (which are sometimes irregular mosaics and sometimes consist of an outer "skin" and an inner "core," dissimilar in their genetical potentialities) there are many plants in which the distribution of factors must have been laid down before the formation of germ-cells. E. R. Saunders's results proved that in certain stocks (*Matthiola*) the pollen all carried doubleness though the ovules were mixed in character, single and double. C. Pellew showed that in the hermaphrodite *Campanula carpatica* "pelviformis" the pollen bore exclusively femaleness and preponderantly white flower-colour (the plant being heterozygous for blue). The pollen of *Begonia Davisii* (a wild species with single flowers) carries doubleness exclusively, and several similar examples are known, in all of which the segregation of characters must precede the maturation of the germ-cells. Thus, while it is not a question that segregation depends on some cell-division, and very possibly on a differentiation of the chromosomes, there is evidence that the cell-division in which this differentiation occurs must at least sometimes precede germ-formation. As mentioned, in *Oenothera* this "anisogenous" distribution is exceptionally frequent.

Bearing on Evolutionary Theory.—This aspect of genetics can only be briefly treated here (*see* MENDELISM). Genetic analysis has shown that the appearance of variability as a contemporary and widespread phenomenon is largely illusory. On studying a variable species critically it is found that the various forms cannot all produce each other as was formerly assumed, but that they stand in a regular descending order, being terms in a series of combinations of definite factors. Such series are no evidence of contemporary variability. Many of the terms can be separated in the homozygous condition, and thereafter may breed perfectly true. Even such an appearance of variability as that seen in polymorphic species is frequently not above suspicion of being the consequences of a cross, more or less remote. Contemporary variation certainly may occur; but of the contemporary origination of new species, or of the occurrence of genetic changes which can be colourably interpreted as likely to lead to the production of incipient species in a strict sense, no indication has been found. That the forms of life have been evolved from dissimilar precedent forms we know from the geological record, but as to the process by which this evolution has come to pass we are still in ignorance. All that can be said at present is that variation most commonly arises as an error of cell-division, and that it is quite conceivable that new species have so arisen.

GENEVA, Switzerland (*see* 11.587), had in 1920 a population of 135,059, including suburban districts. In the city proper it was 56,292. Geneva has been much changed in recent years, a large number of public and private buildings having been erected. The manufacture of motor-cars is a new industry, but it is as much an educational and intellectual centre as in the past. An historical and art museum was opened in the Boulevard Helvetique in 1919, and various collections of arms, pottery, coins, pictures, etc., including those from the Arsenal and the Musée Rath, have been brought together there. The Musée Rath, which was the International Prisoners of War Bureau during the World War, is now used for exhibitions. The imposing Electoral Palace was rebuilt with a large hall in 1913–6. A bridge to carry a loop line between the two railway stations has been thrown across the Rhone below the junction with the Arve. A Reformation monument, begun in 1909 on the 400th anniversary of Calvin's birth, was unveiled in 1917; it represents a stretch of rampart, the wall of Geneva with a narrow moat in front. In the centre are colossal figures of Calvin and others, with statues on each side of eminent champions of the Reformation, and bas-reliefs and monumental inscriptions between.

Geneva was chosen in 1919 as the seat of the League of Nations. The Assembly met first in 1920 in the Hall of the Reformation, built by public subscription in memory of Calvin, near the Grand Quay. The league secretariat is housed in the Palace of the Nations, formerly a hotel, beyond the Jetée des Pâques. In Dec. 1925 this building was put up for sale, but as there were no buyers it was decided to retain it for the use of the league. A tablet in memory of President Wilson was placed on the terrace wall in 1924. The International Labour Organisation was housed at first near the Ariana Museum, but for it a new building has been erected near Parc Mon Répos. The office of the International Red Cross is in the Rue de la Promenade du Pin, in the southeast part of Geneva.

GENOA (*see* 11.597), the chief port of Italy and capital of the province of Genoa, had a population of 316,217 in the municipal area of about 12 sq. m. in 1921. The industrial quarter of San Pier d'Arena on the west is now joined to Genoa, and there is a growing residential quarter beyond the Torente Bisagno to the southeast, to which the Via Venti Settembre gives direct access. Large buildings include the imposing Banca d'Italia in the Via Dante, and a building containing the bourse, the post office and a theatre in Piazza de Ferrari. The improvement of this piazza, the central square, was begun in 1913; blocks of houses have been demolished, and the area opened up. The historic Palazzo San Giorgio has undergone complete restoration, and is now the headquarters of the harbour board. A fine new sea front, the Corso d'Italia, adds considerably to the attractiveness of the new residential quarter. During the present century suburbs have arisen on the higher ground, and the Via di Circomvallazione a Monte has been laid out over the hills behind the city.

The tonnage of the port is growing, and is considerably higher than that of any other in Italy, representing almost one-fifth of the total tonnage of the country. Exports are on an average hardly an eighth of the imports, which are chiefly coal and cereals, and the marked drop which began in 1917 was due mainly to the decrease in coal. The doubling of the railway track to Pisa and the development of the stations at San Pier d'Arena and at Genoa Brignole, about two m. east of the principal station, with the extension of electric power to the main line towards Turin and along the coastal line, have improved the port's facilities. A scheme for the extension of the harbour, taken in hand in 1922, included the new Vittorio Emanuele and San Pier d'Arena basins. Shipbuilding is increasing in importance, and there is a considerable motor car industry; the manufacture of hats is also a growing trade.

GENOA, CONFERENCE OF, (April 10–May 19 1922,) a meeting of representatives of the British self-governing Dominions and of 29 European states, including not only the Allies and ex-neutrals, but all the ex-enemy Powers except Turkey (who was excluded on the ground that she was an Asiatic country). Above all, the conference was attended by representatives of Soviet Russia, and the dominant issue was the renewal of relations between Russia and the countries of Europe. The principal result achieved, however, was one which the organisers of the conference had not intended, namely, the signature at Rapallo, on April 16 1922, of a separate treaty between Soviet Russia and Germany.

The prospects of the Genoa conference had been somewhat clouded, before it assembled, by the wave of anti-Liberal-feeling in France, which declared itself politically in the superseding of M. Briand by M. Poincaré as Prime Minister. Since the project of the Genoa conference had already been accepted by the Supreme Council, including the representative of France, before M. Poincaré came into power, he could not reject it altogether, but he took every possible step to interpret the agreed programme in the narrowest sense, and to hedge the participation of Russia with the fullest possible restrictions. He refrained from attending the conference but enforced his policy by giving detailed and stringent instructions to his representative, M. Barthou.

The general conference was preceded by a meeting between M. Poincaré and Mr. Lloyd George at Boulogne on Feb. 25, a meeting of Allied economic experts in London from March 20 to 28 which drew up detailed agenda for Genoa, and two other preliminary meetings of a regional character, one between the members of the Little Entente at Belgrade, and another at Warsaw between Poland, Latvia, Estonia and Finland. The parties represented at Warsaw subsequently conferred at Riga with representatives of Soviet Russia. The invitation to Genoa was accepted by the Soviet Govt. with alacrity, but was declined by the United States.

Adverse Influence of the Rapallo Treaty.—At its first plenary session the conference set up four commissions, the first to examine methods of putting into practice the principles of the Cannes resolution of Jan. 6 1922 (*see* CANNES, CONFERENCE OF), while the other three were to deal respectively with financial subjects, economic and commercial subjects and transport. These three latter commissions, which were concerned with technical questions, all reported before the conference came to an end; but their reports were bound to remain academic unless the first commission achieved positive results. The task of the first commission was more difficult, because it was general and political in character, and its work was soon suspended in favour of informal discussions between the three principal Allied Powers and Belginm on the one side, and the Russians on the other. The Germans, who felt themselves left out in the cold, retorted by negotiating their separate treaty with the Russians at Rapallo, in which, at least on paper, the objects of the Genoa conference were achieved as between these two parties by a mutual renunciation of reparation claims and a resumption of normal consular and diplomatic relations.

However, this separate Russo-German treaty damaged the general prospects of the conference by the shock which it gave to the Allies, and especially to Belgium and France, who, ever since the Armistice, had been oppressed by the nightmare of a military alliance between Germany and Russia. The Rapallo treaty seemed like a first step in this direction, even though the published text contained no military clauses, and the Allies addressed a series of acrimonious though ineffective notes on the subject to the German delegation. In these circumstances there was little prospect of success for a general pact of non-aggression, which Mr. Lloyd George suggested on April 25. Meanwhile at the very first session, M. Barthou had had a hostile encounter with the principal Russian delegate, M. Chicherin; but the conference actually broke down through the intransigence of Belgium. When an attempt was made to secure a common draft of proposals to be presented by the European delegates to the Russians, the Belgians insisted upon the integral restitution of foreign-owned private property in Russia. M. Barthou supported the Belgian contention, and was himself supported in this attitude by M. Poincaré. Eventually a formula on the British lines was carried over M. Barthou's head, even Belgium finally giving way, but it was so evident that, with Great Britain and France divided, no positive result could be achieved, that the Genoa conference was quietly wound up by remitting its agenda to a mixed commission of experts. This conference of experts duly met at the Hague from June 26 to July 20 1922, but it foundered, like the Genoa conference, on the rock of foreign-owned private property in Russia, in regard to which the Russian and the Franco-Belgian views again proved incompatible.

The Reconstruction Standpoint.—Although the Genoa conference led to no positive results, it was interesting as the first general European conference after the War of 1914–8, and because economic and financial problems were approached from the point of view of reconstruction, and not of reparation. It was also interesting as the first attempt at a settlement between the European governments and Soviet Russia. At Genoa the difficulties which proved crucial on later occasions were already encountered. (A. J. T.)

GENTILE, GIOVANNI (1875–), Italian philosopher and politician, was born at Castelvetrano (Trapani) May 29 1875. He studied literature and philosophy at the University of Palermo, and after a series of university appointments became in 1918 professor of the history of philosophy in the University of Rome, where he founded and became director of the school of philosophy. Two years later he founded the *Giornale critico della filosofia italiana*. Created a Senator in 1918, he supported the Fascist movement from its beginnings, and when Mussolini's Govt. came into power, Gentile was appointed Minister of Education. He was then a Liberal, but subsequently joined the Fascist party, of which he became a prominent member. As Minister of Education he carried out an organic reform of the Italian educational system, abolished the traditional shibboleths of positivist and materialist teaching, and suppressed many inveterate abuses. He introduced the system of state examinations and also the teaching of religion into the elementary schools. The universities wholly maintained by the State were limited to 10, while others, maintained privately or by local administra-

tions, received state subsidies if they complied with certain standards. Among Gentile's numerous works are: *Il modernismo e i rapporti tra religione e filosofia* (1909), *I problemi della scolastica e il pensiero italiano* (1913), *I fondamenti della filosofia del diritto* (1917), *Le origini della filosofia contemporanea in Italia* (4 vol., 1917–23), *Il Problema scolastico del dopo guerra* (1920), *La Riforma dell' educazione* (1920), *Il Fascismo al governo della scuola* (1924), *Che cosa e il fascismo* (1925), etc.

GEODESY (*see* 11.607 and 8.801).—The geoid is the surface which coincides with the ocean surfaces and their hypothetical continuations inland in imaginary channels; all tidal movement being considered suppressed. The study of the form of the geoid, frequently referred to as the "Figure of the Earth," is a main object of geodesy. It has been prosecuted by various agencies in separated portions of the land areas. Even in 1926 only a small fraction of the total area of the globe has been examined.

Such results as have been obtained may be co-ordinated by the assumption that the geoid does not differ greatly from a spheroid (ellipsoid of revolution); and the assumption of an ellipsoid of three unequal axes is not at present considered useful. "Determination of the Figure of the Earth" may be used conveniently in the restricted sense of determination of the elements of the most suitable spheroid; while the science of geodesy embraces further the study of the actual geoidal form in detail, and even the explanation of this form.

Figures of the Earth.—During the progress of the science and the growth of observation results, various figures of the earth have been obtained. Each Survey department has made use of that figure which at the time seemed best. A variety of spheroids are now in use as reference figures, on which the calculations of the corresponding surveys are based. There is growing inconvenience in this, and it would be ideal if all the separate geodetic surveys could express their results in terms of a single spheroid. Although there are technical difficulties in the relation of the origins of separate surveys to any unique spheroid, it was none the less decided at the meeting of the International Union of Geodesy and Geophysics at Madrid in 1924 that one spheroid should be internationalised and that, so far as practicable, results should be expressed in terms of it. The International Spheroid is that determined by J. F. Hayford in 1909.[1]

Equatorial radius	6,378,388 ± 18 metres
Reciprocal of flattening	297·0 ± 0·5
Polar semi-diameter	6,356,909 metres

The above figures were derived from observations made in the U.S.A. only; and the introduction of the principle of isostasy (*q.v.*) was the novel feature of the work. Remembering that the entire U.S.A. area of 3,026,789 sq. m. is but 1/66th of the entire earth's area, 197,000,000 sq. m., some doubt might be felt as to their universal applicability and their stated probable errors. An independent consideration by Helmert[2] of Hayford's figures yielded probable errors ± 35 metres and ± 0·8. Further, Helmert[3] in 1915, from a discussion of numerous gravity results from places scattered over the globe found 1/296·7 ± 0·6 for the flattening, which is a very strong corroboration of Hayford's value.

The Reference Spheroid.—That the geoid should be a spheroid was a very plausible conjecture; for a spheroid is a possible boundary for a rotating gravitating fluid mass—the flattening depending on the internal density distribution. When a solid mass is considered in place of a fluid mass some modification in the resultant form may be expected; at the same time the development of isostasy supports the view that the earth behaves in many respects as though it were viscous, tending to the form it would assume if fluid. However, long before such evidence became available, it was tacitly assumed that the geoid was actually a spheroid. Nineteenth century observations were reduced by Clarke and others, treating any discrepancies from spheroidal form as due to observation error. This was justifiable when data were scant, and the instruments, with which they had been obtained, were of poor precision.

More recent data from greatly improved instruments, however, leave no room for doubt that there are measurable differences between the geoid and any adopted spheroid. Geodesists study the actual form of the geoid, expressing it with reference to a spheroid, which is accordingly named the "reference spheroid." When the reference spheroid is in close correspondence with the geoid, the mutual separation is small at all points. This facilitates many computations: for some purposes observed horizontal angles, which are geoidal angles, may be treated as spheroidal angles: as has practically always been done, though in a few cases small correction was really necessary.

The General Origin.—Suppose that the geoidal form were known throughout, and apply to this the international (or any other) spheroid. How is the latter to be orientated? The minor axis of the spheroid may be set parallel to the actual axis of rotation of the earth, whose direction is known unequivocally to the precision of astronomical telescopes. This answers the question of orientation. The location of the spheroid remains at choice. Any point on the spheroid may be brought into coincidence with corresponding point on the geoid; but *only one point can be so treated*, which may be called the "general origin." When this has been done, some portions of the geoid will lie without the spheroid, and other portions will lie within. The two surfaces will intersect in a number of closed curves, on one of which will lie the general origin. The normals to the geoid—verticals—will not coincide with the corresponding normals to the spheroid except at points along certain closed curves, quite distinct from the curves of intersection of the two surfaces. The form of these curves will change if the general origin is changed. The inclination of geoidal and spheroidal normals at corresponding points is what has generally been called the "deflection of the plumb-line." It will be clear now that the deflection of the plumb-line at a point depends on the choice of spheroid of reference and of general origin. It is not an absolute quantity, but dependent on the reference system. When this latter has been selected, there is a unique value of the deflection at any point which has been geodetically connected with the origin. In practice, however, it is necessary to assume separate origins for each detached survey, and accordingly the deflections of surveys on separate origins cannot be regarded as absolute quantities. In this respect the international spheroid cannot be considered as unique as yet.

The Selected Figure.—Meanwhile the study of the geoid in each detached survey may be continued. At any point of the earth's surface, astronomical observations combined with W.T. signals enable both latitude and longitude to be uniquely determined, independently of any assumed reference figure. A number of such points are connected by linear measure and triangulation, and values, called geodetic, of latitude and longitude are computed *on the selected figure*. The differences of astronomic and geodetic values are the deflection components. If these are sufficiently numerous—which may be judged by the smoothness of deflection variation—the separation of the geoid and spheroid can be integrated.

An alternative method of finding this separation is based on the measurement of vertical angles between the triangulation stations combined with spirit levelling and deflection results.

The observed vertical angles are reduced to the spheroidal vertical by application of the appropriate deflections. If the terrestrial refraction[4, 9b], of each ray is computed, it becomes merely a geometrical problem to calculate the differential *spheroidal* heights. Spirit levelling, which with its short rays intimately follows the geoidal surface, yields the *geoidal* heights. Both spheroidal and geoidal heights are thus known, and hence the separation of geoid from spheroid.

Ordinary triangulated heights, uncorrected for the deflection, are not the same as spirit levelled heights, apart from the question of precision; and they certainly are not geoidal heights. Geoidal heights are what enter into practical problems; but from the geodesist's point of view they do not mean much until the form of the geoid, to which they refer, has been determined.

Base Line Measurements.—Modern bases are measured with wires hanging in catenary under constant tension, a system introduced by E. Jäderin of Stockholm. His original plan was to use two wires having different expansion coefficients, whence the temperature could be determined and the necessary corrections applied. With Guillaume's invention of "Invar" this became unnecessary.

A bright wire of small gauge (1·65 mm. is the usual diameter) is not much affected by the sun's radiant heat, and so its temperature does not differ much from that of the air. With the low expansion coefficient of invar, 4×10^{-7} per degree Centigrade, an error of 2°·5 causes an error in length of only 1 in 10^6. The method of using invar

[1] Figures throughout the text refer to notes at the end of the article.

wires has been closely studied by Benoit and Guillaume[5] and their procedure may be confidently followed. It is vastly simpler than the old methods with compensated bars and is also much more accurate; further, much rougher country can be negotiated and so, longer bases become possible.

For the standardisation of wires at the observatory, before and after the measurement of the base, different methods of laying out a length of 24 metres, which is the usual length of the wires, have been employed. An apparatus designed by Sir David Gill for India was fully described in *Engineering* 1915. The ultimate standard of length in this is a nickel bar of H section, one metre long. Standards for ordinary use are H bars of invar, one metre and four metres in length. Invar has been observed to undergo a secular change in length which continues for many years. Investigating this, Guillaume found that the instability is due to the presence of carbon which gradually forms cementite, Fe_3C, with the iron. The addition of chromium, which has a greater affinity for carbon than iron has, prevents this and an invar with ten-fold increased stability has been produced.

Triangulation.—Theodolites with circles of 12 or 10 in. are usually employed for the highest class geodetic triangulation. Mr. Connolly of the India Stores Department considers even that the fullest instrumental accuracy can be incorporated in an 8-in. theodolite fitted with a large objective telescope. Luminous signals, heliotropes by day and lamps by night, are essential. Vertical angles should be taken between 1 and 3:30 P.M., when the refraction is usually a minimum and most regular. None the less there is frequently at this time poor definition, and horizontal angles should be observed at night or by day within three hours of sunrise or sunset.

Control.—Triangulation emanating from a fixed point with observed base and azimuth yields positions of all stations and lengths and azimuths of all sides. Errors are unavoidably generated. Their probable amounts are given by the formulae of de Graaff Hunter[6] now indicated.

These involve the quantity $M=(1+f)m\sqrt{18/l}$, in which l is the average length of side; m (Ferrero's error of mean square of an angle) $=\sqrt{\Sigma(\Delta^2/3n)}$, where Δ is the triangular error and n is the number of triangles; and f, which lies between 0 and 1/6, depends on the type of figures in the series. Further, if O is the starting point and A the station at which errors are sought: R = OA and S = curved distance, OA measured medially through the series, both expressed in units of 100 miles, then P.E. in seconds of azimuth at $A=1\cdot''575\sqrt{\Sigma M^2 S}$, P. E. in 7th figure of log. side at $A=33\cdot2\sqrt{\Sigma M^2 S}$, P. E. in feet in northing or easting at $A=4\cdot03\sqrt{\Sigma(M^2 f R^2 dS)}$.
The summation Σ is in each case for a set of series for which values of M differ.

The first two of these formulae give the means of determining at what intervals control of triangulation is desirable. Clearly an extra base will control the error developed in side length: to control the azimuth it is necessary to form a Laplace point, at which azimuth and longitude are determined astronomically. A numerical example will illustrate the method. It is desirable to introduce a control when the P.E. attains 3 times the error of the control. Two bases are involved, one at each end. If the P.E. of a base is 1 in 10^6 then the P.E. of the control is $\sqrt{2}$ in 10^6. The P.E. of side reaches thrice this amount when $33\cdot2M\sqrt{S}=3\sqrt{2}\cdot10^7$ log. $(1+10^{-6})$. Taking M = 0·2, corresponding to very high class triangulation, we find S is 772 miles.

Next, if ΔA, ΔA_0 are differences astronomic minus geodetic azimuths; L, L_0, λ, λ_0 triangulated values of longitude and latitude of A and O, and T the difference between the local times at A and O, then Laplace's equation is

$$\Delta A_0 \operatorname{cosec}\lambda_0 - \Delta A \operatorname{cosec}\lambda = (L-L_0) - 15T$$

which serves to determine ΔA, a quantity to be subtracted from the astronomic azimuth to give the correct geodetic azimuth. The P.E. of an astronomic azimuth is taken as $0''\cdot2$ for high class work; that of T as $0^s\cdot03$. Hence the P.E. in azimuth determined from Laplace's equation is

$$\sqrt{[(0\cdot2\sin\lambda\operatorname{cosec}\lambda_0)^2+(0\cdot2)^2+(0\cdot45\sin\lambda)^2]}$$

If we take $\lambda=\lambda_0=45°$ this become $0''\cdot42$ and $1\cdot575\times0\cdot2\sqrt{S}=3\times0\cdot42$, whence S is 1600 miles. If the time error could be reduced to $0^s\cdot01$ the value of S would be almost halved and the precision of azimuth would be about the same as that of side control. It is to be pointed out that there is little gain in controlling the side length with great accuracy while the equally important azimuth control is much less precise. Hitherto the ruling criterion has been that of azimuth. The conclusion is that until time observations are more precise, the highest class triangulation is not likely to be much improved by the controls available unless its extent is considerably greater than 1,000 miles.

Determinations of Height.—The precision of spirit levelling is so great as to justify the recognition of the lack of parallelism of the various level surfaces, each of which is approximately spheroidal. It is nowadays customary in levelling of high precision to apply to the observed differences of height the correction [7,8], for the convergence of these surfaces, that is to say, the orthometric correction; and to publish the orthometric heights. As regards differences of height found by triangulation much improvement is called for. Observed vertical angles are referred to the local geoidal vertical; they require correction to the reference spheroid vertical, as well as for refraction, after which the height differences can easily be calculated.

Refraction.—When reciprocal observations have been made at two points A_1, A_2, if E_1, ω_1, δ_1 are respectively the angle of elevation, the refraction and the deflection at A_1 towards A_2, and similarly with changed suffixes for A_2, then

$$E_1+\delta_1-\omega_1+E_2+\delta_2-\omega_2+C=0,$$

C being the angle between spheroidal verticals at A_1, A_2, computed from the triangulation. The ordinary practice is to ignore δ_1 and δ_2 and to assume that $\omega_1=\omega_2=\Omega$; whence $2\Omega=E_1+E_2+C$. The ratio $\Omega/C=k$ has been called the coefficient of refraction, and as $k=\frac{1}{2}\left(1+\frac{E_1+E_2}{C}\right)$ it can be computed when a ray has been observed at both ends.

There are cases when $\delta_1+\delta_2$ is by no means negligible in comparison with $\omega_1+\omega_2$; moreover there is little justification for the assumption $\omega_1=\omega_2$, unless the two stations are at the same height.

Refraction has a diurnal change, falling to a minimum about the time of maximum temperature, moreover the value of the minimum is pretty constant from day to day. It is in this constancy that lies the value of observing vertical angles between the hours of 1 and 3:30 P.M. Consideration [9,9b] of the physical laws leads to a formula which represents the refraction usually met with at these hours. At other hours the refraction is ordinarily larger by an amount which varies as the defect of temperature from maximum and as the cosecant of the angle of elevation of the ray. The physical cause [10] is that the temperature lapse-rate is nearly constant within the height limits of the ray, and does not vary much during the day except comparatively close to the ground. The refractive effect of a plane stratum of air close to the ground can be expressed in terms of the air densities of its upper and lower surfaces. Some confirmation of this view is obtained by considering barometric height readings. Further research is required, and more observations, with full particulars of local deflection, are needed for investigation. In cases where the data are complete, the refraction does not appear so intractable as has generally been supposed.

Astronomical Latitudes.—For the observation for latitude the zenith telescope and the Talcott-Horrebow method seemed to have superseded all others (*see* 11.610); but the method of equal altitudes is worthy of attention. Several special instruments have been designed for this observation, all of which determine latitude and time simultaneously; whereby in association with wireless time signals, deflection in both meridian and prime vertical can be found.

The prismatic astrolabe of MM. Claude and Driencourt, [11, 12, 13], which is made in two sizes, has a horizontal telescope with an equilateral prism mounted in front of the objective. The edges of the prism are horizontal, and one face, that nearest to the objective, is vertical. A mercury bath is suitably placed below and slightly in front of the prism. Light from a star of approximately 60° altitude falls normally on the upper face of the prism, and is reflected internally at the lower face towards the lower half of the objective. At the same time light from the same star falls on the mercury, is reflected into the prism through the lower face, then internally at the upper face, and so to the upper half of the objective. In both cases after reaching the objective, the light is brought to a focus and two images of the star are formed. These approach one another, and the instant at which they pass is timed —this instant corresponding to a fixed altitude depending on the angle of the prism, imperfection in the focus of the telescope and the refraction. The actual altitude is usually regarded as an unknown; corrected for refraction it should be a constant for one instrument.

Provisional values for this, for the latitude and for the time being assumed, the result of one observation can be plotted as a straight line on a chart with time and $\lambda\sec\lambda$ as co-ordinates. Four stars, one in each quadrant, form a set of observations and yield four such lines which should touch a circle of radius equal to the discrepancy of the altitude from that provisionally assumed, both multiplied by $\cos\lambda$. The co-ordinates of the centre of this circle represent the time and latitude sought, and the constancy of its radius is a measure of pre-

cision of the observation. If there is too much wind the partially shielded mercury surface is disturbed, and observation becomes impossible. The adjustments are very simple, as is also the observation when the observer is practised; and there is practically no recording. Computations and preparation of star programme are not excessive. Excellent results have been obtained with this instrument. In the discussion of a paper[14] Jackson stated that the images are elongated, being in reality short spectra; so that stars of different colour would give different results. Other users of the astrolabe have not found this to be appreciable. Practical drawbacks are that each star yields only one observation and that the time estimate is burdened by personality. To overcome the latter L. Favé[15] described equipment to measure the personal equation, but up to 1925 this has not proved completely successful.

An alternative instrument, free from two of the above noted objections is the Circumzenithal Apparatus of MM. Nusl and Fric.[16] In this the light from the star enters the instrument through a parallel plate of glass and falls on a half silvered mirror, being split into two portions. One portion proceeds to a mercury bath, and after reflection there and at a second mirror passes again through the half silvered mirror. Thence both portions enter the observing telescope. The mercury is completely screened from the wind. By means of an achromatic reversible prism placed in front of the plate at which light enters the instrument, a star can be observed at three slightly different altitudes. An additional interior prism in front of the objective, which causes the formation of four images, allows 7 observations to be made on the same star at each altitude.

A simple bent telescope, in which reflection occurs at a mercury bath, has been designed and used by de la Baume Pluvinal. Observing 10 stars on the same evening at the Paris Observatory, he obtained values of latitude and longitude differing by 0″·2 and 0ˢ·03 from the well established observatory values.

In Egypt, Wade has employed a simple method[17] of finding differential latitudes at places a few hundred metres apart.

Longitudes.—Several of the large wireless stations send out special time signals, which can be picked up at very great distances by suitable apparatus. These provide a basis for longitude determination when the local time has been observed.

The very powerful station at Bordeaux is an example; and the precise times of the signals are determined by the "Service Horaire de l'Observatoire de Paris." The signals are of the "rhythmic" type, in which 300 dots are sent out uniformly spaced over 293 seconds. At the end of the set the precise times of those of the previous day are signalled. Very precise comparison can be made by noting at what exact seconds the incoming signals coincide with the beats of the observer's clock: alternatively, when a recording receiver is used, all the 300 dots are recorded and subsequently measured. Owing to the time of duration of the signals and of the clock beats not being precisely equal, there is some personality in the estimate of instant of coincidence. To obviate this Thrum[18] devised a method in which the incoming signals and those of the clock extinguish one another in the telephone when they overlap. Difference of opinion exists as to whether the registration or the audition method is the more precise.

Time signals have been picked up at several of the larger observatories day by day for years. Sampson[19] pointed out and discussed serious discrepancies of the order of 0ˢ·1 in the relative times. The complete explanation is still to be found. On the other hand longitude circuits recently formed by the U.S.C. and G.S. are stated to have closing errors of the order of 0ˢ·01, suggesting that field instruments and conditions are superior to the large instruments and conditions at the fixed observatories.

A world project of longitude was put forward by General Ferrié in 1921. A mixed commission of the International Unions of Astronomy and of Geodesy and Geophysics was formed, and the project has been discussed at Rome, 1922, Madrid, 1924, and Cambridge, 1925. Details have been advanced sufficiently for a decision to execute the scheme in 1926 to be arrived at. It is hoped to fix very accurately the longitude of numerous points over the earth, thus helping to co-ordinate geodetic surveys. At the same time much experience in the highest precision work of this nature will be obtained. A comprehensive account of clock and wireless installations for this purpose is given by the Bureau des Longitudes.[20]

Gravity.—The absence of means of measuring the "sway" or flexure of the stand of pendulum apparatus was perhaps the principal cause of uncertainty in the older pendulum observations. Two methods have been devised and used for a number of years; and a further advance in eliminating the effect of sway has been made by Vening Meinesz.

Of the two methods referred to, one is in vogue in the U.S. and consists in actually measuring the movement of the stand by aid of an interferometer.[20a] It is claimed that the error in "g" from this determination rarely exceeds 2 in 10^7. The other method, due to Schumann, [21] provides a means of mounting a second pendulum on the same stand. The first pendulum is set swinging, and from time to time the amplitude of the second pendulum, originally at rest, is noted. Formulae expressing the effect of sway in terms of oscillations are given. The precision appears to be much the same as that of the first method. Both of these methods regard the sway as a constant during the course of the observations at a station, lasting perhaps three days.

Vening Meinesz [22], [23], [24], solves the problem more completely, and also overcomes the effects of earth movements by always employing simultaneously two isochronous pendulums. These are mounted on one stand so that the distance between their points of support is invariable, and are set swinging in different phases. Denoting the angles of elongation by θ_1, θ_2 then the angle $\theta_1-\theta_2$ may be regarded as the angle of elongation of a hypothetical pendulum which is free from the effects of sway; as also of various irregular perturbations. So far is this the case that apparatus so arranged has been used for determining gravity at sea in a submarine; and determinations have been made in Holland in places where the ground is very unstable. Observation is much as usual in pendulum work, the ray of light passing from the mirror of the first pendulum to that of the second and thereby recording the differential angular movement of the two.

In consideration of its success at sea, Vening Meinesz's method supersedes the earlier work of Hecker and Duffield [25] with hypsometers and barometers. The possibilities opened up are very extensive. Helmert's formula of 1901 has been used widely in pendulum work. It is

$$g_0 = 978{\cdot}030\ (1+0{\cdot}005302\ \sin^2\lambda - 0{\cdot}000007\ \sin^2 2\lambda),$$

λ being the latitude. Bowie, [26] p. 196, taking isostasy into account, found 978·039 as the equatorial value, and ·005294 as the coefficient of $\sin^2\lambda$, while Couchman [27] found Helmert's value too small by ·011 in the case of Indian stations.

In 1915 Helmert[3] gave a formula involving the longitude L,

$$= 978{\cdot}052\ (1 \mp {\cdot}005285 \pm 7\ \sin^2\lambda - {\cdot}000007\ \sin^2 2\lambda + {\cdot}000018 \pm 4\ \cos^2\lambda\ \cos 2(L+17^\circ \pm 6)$$

This is based on 3,000 stations reduced by Borass. It implies an elliptic equator with major axis in 17° W. longitude, whose half length is 230 metres greater than the semi-minor axis—compare Clarke's 3-axial figure results, with 8° 15′ W. as the longitude and 465 metres excess length of the semi-major axis.

The Eötvos Gravity Torsion Balance [28] measures the rate of change of gravity. The change per cm. along meridian given by the formula is $8{\cdot}1\times10^9$ C.G.S. units in latitude 45°; and as the instrument is incredibly sensitive, it is capable of measuring 1×10^9 and less, and easily detects irregularities. Nowadays it is used in prospecting for oil. (*See* GEOLOGY; ISOSTASY.)

GEOGRAPHY (*see* 11.619).—The advance of geography as a subject of scientific study and research in fields other than that of exploration of untrodden ways is largely due to a change in the spirit of the times, which, from a vivid realisation of man's power over nature through his invention of mechanical power-schemes, has swung across to a deep sense of the play of dimly apprehended physical and social influences, which need study for men's sakes.

Within the scientific geographical field special credit must be given to the pioneering work of Réclus in France, to Ratzel and von Richthofen among others in Germany, to Vidal de la Blache and E. de Margerie and their schools in France, to W. M. Davis and others in the United States of America and to A. J. Herbertson in England. The geographer explores the earth and hands over to many specialists the tasks of analyses of geological, meteorological and other data, but he keeps the duty of building up more and more synthetic pictures of the various regions of the world, and he does this especially by studies of the conclusions of structural, physiographical, climatological and biological specialists, and by institution of comparisons of the interrelations of these conclusions as they affect every part of the world. Alongside of this he seeks "exact and organised knowledge of the distribution of phenomena on the earth's surface."

Natural Regions.—He is thus concerned to gain on the one hand general distributional knowledge, and on the other hand synthetic regional vision, the view of interrelations of specialist conclusions with reference to a region. The latter task involves the former, for it is through an appreciation of coincidences of distribution that we are able, scientifically, to recognise a region in geography. Herbertson gave notable service in this direction, for he saw the world as composed of a number of major natural regions within each of which there reigned, for him, partial uniformities of structure, drainage, climate and ecology. Though the progress of knowledge may well alter the relative weights given to different groups of facts, and may thus lead to schemes of natural regions that diverge from Herbertson's, the basic idea, for which he was largely responsible, maintains and develops itself. His major natural regions are, inevitably, almost entirely climatic, and here the problem is relatively simple if we allow enough for transition zones. When the subdivision of major regions is discussed, divergence of view is usually developed, as so much depends on the subjects of election of the disputants.

Physical Geography.—The older form of study of physical features of the earth's surface reviewed matters such as denudation by rain and rivers, coast erosion and deposition of materials, and endeavoured to find types of various natural processes. This type of work has continued, and Dr. Vaughan Cornish has contributed especially to the study of waves. Another physical study has received a great impetus from the publication of E. Suess' masterpiece *Das Antlitz der Erde* (1883–1909). This work, made possible by the researches on mountain structure pioneered for Britain by C. Lapworth, Peach and Horne, gave a glimpse of order, of pattern, in the physique of a country, and turned studies of physical geography in a regional direction, for it was now possible in a far more real sense than previously to see how physical features had come to be as they are. The trend in this direction was encouraged by the prevalence of evolutionary thought at the time. Few fields of research have yielded such harvests in the last generation as have been reaped by the geomorphologists, students of the regional history of the earth's physical features, and advance continues rapid for Wegener's views; and Argand's ideas on the evolution of the mountain systems of the northern hemisphere through northward drift of Africa, Arabia and the Deccan are valuable as aids to thought, whether they themselves stand or fall (*see* GEOLOGY).

Geomorphology.—To geographers, whose business is the synthetic picture of a region, the conclusions of geomorphology are of the first importance, for in no other way, save by the study of geomorphology, is it practicable to gain a vivid and understanding view of the physical features of a region studied. With the help of geomorphology the physical map becomes a palimpsest in which we decipher numerous superposed patterns of hill and valley lines, of basins and domes, of scarps and plains, and the superposition of patterns indicates the course of their evolution.

Mention should be made, incidentally, of the progress of knowledge as to the general factors of the surface history of the earth since Fisher's *Physics of the Earth's Crust* appeared in 1882. The recent outstanding contributions have been Hayford's theory of isostasy (*q.v.*) and Joly's boldly interesting speculations. These researches are bringing with them a vision of law and order in the formation and evolution of characters of the major regions of the earth's surface of both land and water.

To the work of Suess are naturally related the studies of coral reefs and their origins initiated by Darwin, and continued by many workers. Deperet has studied the ordering of coastal terraces around the Mediterranean, and a body of knowledge of coastal plateaus and of their relation to fluvial and fluvioglacial terraces is growing up, especially for Europe and North America. It still needs more detailed comparisons to be made, but already promises to spread the idea of orderly changes as a key to the interpretation, on evolutionary lines, of a large range of surface features most important in the landscape.

We note also the continuation of the work of Penck and his followers on glaciers and moraines in the Alpine regions, of that of de Geer and his students in Scandinavia, and of the extension of this work by Dainelli to the Himalaya and by Renngarten to the Caucasus. The effects of the phases of the last great ice-age on the landscapes of the northern hemisphere are thus becoming known, especially as American workers have brought out parallel studies for their continent. This work may be said to have arisen from the pioneer studies of James Geikie.

Oceanography (*q.v.*).—Studies of physical conditions in oceans and seas have progressed largely owing to the efforts of commissions investigating fisheries. Schmidt's description of the life history and migrations of the eel was an outstanding advance. (*See* DISTRIBUTION OF ANIMALS.) As an example of some bearings of this work on geographical synthesis may be mentioned the work of O. Pettersson on the hydrography of fiords and partially enclosed seas around Scandinavia, in which he suggests secular variations of tidal power as factors of changes of climate from time to time.

Meteorology (*q.v.*).—In climatic study we note J. G. Bartholomew and A. J. Herbertson's *Atlas of Meteorology* (1899), the work of Lyons and others in Egypt, and that of the British Meteorological Office in preparing tables of normal figures for climatic facts, and Dr. G. C. Simpson's theory of the Indian summer monsoon published in 1921 are notable. The study of the general distribution of barometric pressure and of its changes in cyclonic systems is associated in England with the name of Napier Shaw, and there has been a great increase of knowledge of the layering of the atmosphere and of its more detailed conditions at different levels connected with the development of flying-machines and the mapping of air-routes. The many new facts and views attained are modifying very seriously our expositions of factors of the climates of the earth's regions, and here again a stable position has by no means been reached.

Climatology.—Climatological researches in polar regions have been of great value for better understanding of climate elsewhere. C. E. P. Brooks, Berg, Murgoci and others have tried to argue from the present to the climatic conditions of the past, and have thus contributed factors of interpretation of various soil and other features of the present day; von Richthofen pioneered in this direction with his classic work on Loess. (*See* CLIMATE.)

Ecology.—Ecological study of plants (*see* ECOLOGY), animals and man is both geographical and biological, the former in so far as it works out features of the place inhabited, and it is indeed sometimes argued that geography is essentially human ecology. In this field there has been increasing recognition of the fact that the flora and fauna of a region represent no more response to present conditions, but result from accumulation and interference of effect of a long series of past changes. In many cases, such as that of the virgin equatorial forest, a complex and delicate balance of life has been established through the course of ages, and these forests will probably not regrow in anything like their present form if cut down. The work of de la Bathie on Madagascar brought this out specially. Several opinions concerning plant and animal distributions need adjustment if newer views on continental drifts and on climates of the past are established.

Regional Studies.—Another generation saw the appearance of a large number of studies of regions based upon scientific data. Von Richthofen's *China* is rather old in parts, but its influence has been widely extended. Vidal de la Blache's *Tableau de la Géographie de la France* (1903), like F. von Richthofen's *China* (1887–1912), emphasises the facts of structure most of all. J. Dantin Cereceda's work on Spain, in turn, emphasises rather the facts of climate and ecology. The volumes of the Filippi expedition to the Himalaya are conceived in an encyclopaedic spirit, but as yet it is too early to say whether much effort will be made towards synthesis. The American Geographic Society began a series of scientific studies chiefly on Latin America. Sir M. A. Stein's *Serindia* (1921) is another encyclopaedic work with the emphasis largely on cultural distributions. A. Philippson's *Mittelmeergebiet* (1914) may be used as an example of a less encyclopaedic type of work which nevertheless effects with some success a synthesis of a large number of scientific facts. The Atlas de Finlande is another type of the collection, and to some extent the synthesis of scientific data, this time concerning a state. Throughout these works it will be seen that the geographer's special part is to correlate specialist data and to synthesise the facts into a picture of the region.

Great services have been rendered to the science of geography by writers on various regions whose main object is a somewhat different one. H. W. Bates' "Naturalist on the Amazon" (1892), Hudson's works on La Plata (1892) and C. M. Doughty's "Arabia Deserta" (1888) are typical examples in this connection.

Maps.—The map (*q.v.*) is the geographer's special instrument and he must work at its improvement, both as a representation of larger or smaller parts of the earth's surface and as a record of special types of data. The War provided enormous opportunities for surveying and cartography, and remarkable results were also attained by mapping from aerial photographs (*see* SURVEYING). Different tints in turf brought out unsuspected lines on development of the negative and led to interesting discoveries. (*See* ARCHAEOLOGY: AIR SURVEY.) The mathematical theory of map projections has been advanced especially by A. E. Young in England and Adams and Deetz in America. The "One in a Million" map, on the other hand, met some difficulties on its way towards the goal of world-wide unity; political reasons led to the crowding of some sheets with names while others were left nearly blank. Sheets including frontiers led to troubles between states in some cases, and the wave of nationalism after the War thus harmfully affected for the time what promised to be a great step forward in scientific geography. The Italian geographers issued an interesting collection of map sheets showing typical examples both of physical features and of human occupation of the surface.

Demography.—The mapping of various types of data has engaged much attention. General poverty after the War largely stopped improvement of the topographical map. The demographic map, fundamentally giving distribution of population is still in a state of flux. It is generally felt that density of population cannot be adequately marked by contours, and, both in this matter and in that of mapping commercial production, the method of stippling with fine dots has been tried, while Sten de Geer conducted experiments utilising large circles, etc., for the purpose of indicating agglomerates. The mapping of data has spread remarkably as an auxiliary in many fields of study, such as ethnography (*see* FOLKLORE), archaeology, anthropology, history and commerce. In most of these cases the stipple and contour methods of representation are rivals, while new methods tend as much towards insuring graphical power as towards accuracy of detail. The growing tendency to display on any one map only appropriately related facts is a testimony to the acceptance of the map as an instrument of research. The maps in C. Fox's *Archaeology of the Cambridge Region* (1923) illustrate the development of this point of view. (*See* MAP.)

Place Names.—On the border line of geography is to be noted especially the development of the study of place names under Longnon in France, the English Place Name Society in Britain, and the effort of the British Permanent Committee on Geographical Names towards standardisation. (*See* PHILOLOGY.)

GEOLOGY (*see* 11.638).—The progress of geology suffered from a four years' break, which provided, however, a stimulus to economic geology by the compilations on mineral resources required during the peace negotiations, and to monographs on little-known areas such as the war fields (*Die Kriegsschauplätze 1914–1918 geologisch dargestellt*, Berlin, 1923–5).

The accumulation of geological evidence has increased apace owing to the foundation of new universities, the fuller educational employment of research work and the wider recognition of the economic value of geology. Its literature has become overwhelming, while its bibliographies and indexes are less efficient owing to the increasing bulk of material and cost of publication. One of the urgent needs in geological development is co-operation between the agencies which publish synopses of literature to secure prompter and fuller references and less serious omissions.

In the progress of geological philosophy since 1910 three features have been especially remarkable. First, the lessened over-emphasis on the geological conditions of northwestern Europe and the eastern states of North America, with the consequent abandonment (*cf. e.g.*, G. A. J. Cole, *Rep. Brit. Assoc.*, 1915) of that ultra-uniformitarianism which had developed in

those countries. Second, release from the restricted range of geological time that had been declared necessary from physical and mathematical data. Instead of a possible maximum of ten million years, as maintained by Tait, geologists are at liberty to assume 8 to 10 thousand million years, and need not discard hypotheses which demand prolonged time for minor geological phenomena. Third, recognition of the plasticity of the earth's crust, and of the world-wide effect of earth movements on the relations of land and water. The physical evidence has been found to afford a more precise correlation at some dates than that based on fossils. The belief in the plasticity of the crust and the lateral movement of the land masses has led to the study of mountain ranges and crustal movements with renewed zeal, and to a flood of speculative hypotheses which are perhaps a reaction from the mental strain of the War.

Origin and Constitution of the Earth

The discussions on the origin of the earth have marked the steady wane of the nebular hypothesis of Laplace. The hypotheses which are replacing it agree in accepting the solar system as derived from one aggregation of matter; but they attribute its start to the tidal disruption of the parent mass by a passing star. This theory has been put forward in various forms. Its modern development is based upon the planetesimal hypothesis, which has been restated by T. C. Chamberlin in his *Origin of the Earth*, 1916 (and in *Jour. Geol.*,[1] Chicago, 21–29); it has been adopted by J. H. Jeans, *Problems of Cosmogony and Stellar Dynamics*, 1919, and Harold Jeffreys, *The Earth*, 1924.

According to Jeans the parent mass extended throughout the range of the solar system, while according to Jeffreys it was restricted to the inner part. The material of the earth on each of the theories was once loose and was welded by heat due to collisions or pressure. That the original material was gaseous is urged by Eddington, since so many stars have the size appropriate to a gaseous body; but that the earth was constituted by the aggregation of solid meteoritic material agrees with the well-established facts of the earth's high internal heat, zonal structure, and composition. The planetesimal theory has undergone important developments and modifications in recent memoirs by its founder, T. C. Chamberlin. He calls attention (*J. G.*, 28, 1920, pp. 144–6) to the possibility of the planets still receiving matter from the sun, in consequence of such solar explosions as those which in May and July 1919 hurled material to the height of at least 475,000 m. above the sun's surface, and probably outward to the orbits of some planets.

The planetesimals, according to Chamberlin's estimates of 1920 (*J. G.*, 28, pp. 672, 681; 29, pp. 407–8) were originally very minute, and weighed about one-fiftieth of a pound apiece; amongst other phenomena he attributes to them the zodiacal light and Saturn's rings. He compares them (*J. G.*, 29, 1921, pp.407–9) with the chrondrules, the rounded grains found in meteorites, rather than with the meteorites themselves. They therefore approximate to the meteoritic dust, which, according to T. J. J. See, was once spread throughout space. In spite of the small size of the planetesimals Chamberlin regards them as having contributed two-thirds of the mass of the earth by their fall from space as rain upon the original core (*J. G.*, 28, p. 681). Jeffreys, however, denies the possibility of any great accretion of such material, and dismisses the planetesimal hypothesis as no solution of any of the main problems of geophysics, and as quite unacceptable on cosmogonic grounds. He has brought it forward in a modified form, which, according to Chamberlin (*J. G.*, 32, 1924, p.713), accepts all the essential doctrines of the planetesimal hypothesis.

Meteoritic Theory.—Lockyer, the founder of the meteoritic theory, recognised that many of the meteorites which formed the earth had planetary orbits, and that they came from a single source or zone is supported by the work of Sir William Crookes (*Phil. Trans.*, 1918, vol. 217A, pp. 427–30). According to Crookes the stony meteorites consist of the elements which form the bulk of the earth's crust, and he suggests, from the striking similarity in the proportions of their four chief constituents, that they were all derived from the disruption of a planet that once existed between Mars and Jupiter; the nickel-iron meteorites may have been derived from the core of the same planet, or may have come from a different source. The chemical similarity of the core of the earth to the iron meteorites is asserted by L. H. Barnett (*J. G.*, 32, 1924, pp. 615–35) as according to him the core consists of 90% iron, 7% nickel, cobalt and copper, and 3% of the other elements. The elementary constitution of the earth has been recalculated and its agreement with a meteoritic composition follows from Tamman's (1924) estimate that 98% is composed of 7 elements in the following order of abundance—iron, oxygen, silicon, magnesium, nickel, calcium and aluminium; four others—sulphur, sodium, chromium and potassium, constitute another 1.6%; all the other elements together amount to only four parts per 1,000 of the substance of the earth.

The stony meteorites, so far as is known, correspond only to the basic igneous rocks. The occurrence of acid meteorites has been claimed from the obsidianites of Australia, but their microscopic structure indicates their formation as aerial fulgurites by the fusion of dust by lightning during dust storms.

Zonal Structure of the Earth.—The earth consists of a series of layers, and much light has been thrown on their constitution and thickness. The bulk of the earth consists of a nickel-iron mass, the barysphere, which is enclosed by a rocky crust, the lithosphere. Within the barysphere is a core, 1,600 m. in diameter, which, according to the late C. G. Knott, is fluid, as it does not transmit distortional waves. In spite, therefore, of the oft-repeated conclusion that the whole earth is solid, seismology proves this large central core to be fluid. Between the barysphere and the lithosphere, moreover, according to various authorities, is a weak plastic layer, the asthenosphere of Barrell (*J. G.*, 22, 1914), or the fluid layer of basalt glass which, according to Daly (*Amer. Jour. Sci.*, 1923, pp. 347–71), lies below a holocrystalline rigid shell 25 m. in thickness.

The lithosphere has been subdivided into various zones. Suess adopted two: the basic Sima, composed predominantly of silica and magnesia, and the lighter, more acid Sial, composed predominantly of silica and alumina. V. M. Goldschmidt (*Geochemische Verteilungsgesetz der Elemente, Vid. Selsk. Skr., Math.-Nat. Kl., Kristiania, 1923–24*) considers that the nickel-iron core is surrounded by a sulphide and oxide zone which is comparable in metallurgical operations to a matte; above that ore zone is a stony zone which is comparable to a slag, and is subdivided into a lower layer of dense silicates, and an upper layer of light silicates and silica. E. D. Williamson and L. H. Adams (*Jour. Washington Acad. Sci.*, vol. 13, 1923, pp. 413–28) divide the lithosphere into three zones; the lowest consists of heavy silicates mixed with nickel-iron and is comparable to the meteorites of the Pallasite type; this layer passes down into the barysphere and upward into heavy silicates, which are covered by a shell of light silicates and silica.

That the barysphere is composed of nickel-iron was affirmed by Milne from the acceleration of earthquake waves, toward which it behaves as a rigid material; but under the influence of the intense heat and pressure, the material must at that depth be capable of flow into any cavities like a fluid, so that it has been described as elastico-rigid, or 'fluidible.' The work of F. D. Adams (*J. G.*, 20, 1912, pp. 97–118) has shown that the estimates of Van Hise as to the depth at which all rock material would be fluidible must be extended; for Adams, by an experiment suggested by Sir Charles Parsons, found that small cavities remained open for months in a granite cylinder which was laterally supported at conditions comparable to those in the earth at a depth of 11 miles. These experiments, however, deal only with a short period and small cores in a rigid case; they do not represent the conditions of large masses acted upon by immense pressure at a high temperature for long periods. The high rigidity of the surface of the earth against tidal deformation was supported (*J. G.*, 27, 1919, pp. 585–601) by the observations of Michaelson and Gale on a horizontal waterpipe 502 ft. long

[1] This journal is referred to in subsequent parts of the article as J. G.

The limited depth of the lithosphere and the constitution of the barysphere of nickel-iron have been supported by the evidence of radioactivity, for the earth's activity is of a strength which can be explained by the restriction of radioactive materials to a depth of about 40 miles. The material of the nickel-iron meteorites is the only non-radioactive substance that is likely to form a considerable part of the earth. The inner earth is assigned a more moderate temperature than formerly; that of the primitive sun, according to Jeffreys, cannot have been less than 3,000° C., but within the earth the maximum may be much lower, for the temperature may be nearly uniform in such a good conductor of heat as the nickel-iron core.

The Depth of Earthquake Origins

Knowledge of the physical nature of the earth's interior has made most progress from investigation of earthquakes, most of which have been attributed to a depth of 5 or 6 m.; Dr. Oldham (*Quar. Jour. Geol. Soc.*, 78, 1922, p. 57) concludes that the great majority arise less than 10 m. from the surface. Lately, however, physicists have assigned their origin to much greater depths. The late G. W. Walker (*Rep. Brit. Assn.*, 1917, pp. 13–4 and *Phil. Trans.* A.222, 1922, pp. 45–56), from the angle of emergence of earthquakes recorded by the Galitzin seismographs at Pulkova, inferred that some originate at least 800 m. deep. This deep-seated source has been supported by Prof. Turner (*Rep. Brit. Assn.*, 1923, pp. 283–6) who assigns the majority to a zone bounded below at a depth of 145 m., and some to a depth of 300 m., such as the Formosa earthquake of April 14 1906, at 280 miles.

Earthquakes.—The word earthquake originally meant a shaking or quaking of the earth which could be felt, might cause damage and was occasionally accompanied by changes in the aspect of the surface of the earth. Seismology was the department of science which dealt with these disturbances, and was naturally regarded as a minor section of geology; with improved methods of observation and the invention of special instruments the scope of this subject has been enlarged, and it has come to include much that does not belong to earthquakes in the original sense of the word, or to geology, yet cannot be entirely separated. Recent developments in the study of the earthquake, which might be dealt with here, are, therefore, transferred to the article Earthquake.

The shallow origin of some earthquakes was concluded by Milne from the twisting and breaking of telegraph cables by slips of material down submarine slopes. It has been found that such breaks are not recorded on seismographs, so that they cause no widespread vibration in the underlying rocks. The main claim for the superficial origin of a world-shaking shock, other than those due to volcanic explosions, is that by the late Prince Galitzin, who referred an earthquake, on Feb. 18 1911, to a landslip in the Pamir. A mass of earth weighing 7,500,000,000 tons fell into the valley, buried a village and all its inhabitants, and formed a bank over 3 m. long and 2 m. wide, and a lake 15 m. long and 900 ft. deep. Dr. Oldham in a rediscussion of the evidence (*Quar. Jour. Geol. Soc.*, 79, 1923, pp. 237–45) has shown that the landslip was a result of the earthquake and not its cause, for it was not above the centre of the disturbance, which he assigns to a depth of 30 miles.

Volcanic Action

Volcanic studies have been greatly advanced by work at the Observatory on Kilauea in the Hawaiian Islands under the direction of T. A. Jaggar. His weekly letter enables geologists in all parts of the world to follow the changes in that instructive volcano. Its cauldron was enlarged by huge subsidences in 1919, 1922 and 1924, the last being associated with powerful explosions.

The destructive eruption of Vesuvius of 1906 has been described by Perrett (*Publ. Carnegie Institute*, No. 339, 1924), who shows that the weight of the lava in the throat of the volcano broke through the wall, and the relief of pressure on the molten rock enabled its superheated water to explode; the explosion threw up a column of vapour 7 m. high and produced avalanches of hot volcanic sand like that from Mt. Pelée, which overwhelmed St. Pierre, the capital of Martinique, in 1902. The Pelean eruption has been further brought into line with ordinary volcanic phenomena by the eruption of Katmai, at the base of the Alaska Peninsula, in June 1912—the most notable volcanic event of recent years. Katmai is an old volcano of basic andesite resting upon Jurassic sandstones. The eruption was of the paroxysmal explosive type. It scattered 5 cu. m. of pumice and scoria over the district, depositing a layer a foot thick even 100 m. away. The eruption left a great hollow with numerous steam vents on its floor; the summit of the mountain was replaced by a pit 2½ m. wide, and from 2,000 to 3,700 ft. deep. This crater was at first attributed to the explosion, but C. Fenner (*J.G.*, 28, pp. 569–606, 1920) shows that it was due to subsidence, aided by the solution of the older andesites by the 1912 lava.

The eruption is explained as due to the intrusion of a sheet of rhyolite under the volcano. The intrusion shattered the overlying rocks and the rhyolite rose through the fractures. The Katmai obsidian, when heated, froths up to pumice, and when it reached the surface it was blown into fragments by its superheated steam. This eruption has explained two phenomena of the West Indian eruptions of 1902 that had appeared unique. Part of the Katmai area was covered with beds of sand, composed of pumice that had been pulverized by the explosive escape of the steam. This sand is of the same nature as the incandescent dust which fell in an avalanche upon St. Pierre. A new secondary peak named Nova Rupta was formed at Katmai by the forcing of a dome of rhyolite into the overlying rocks; it is similar to the lava spine which was pushed up through the vent of Mt. Pélée.

Volcanic Cauldrons.—The first report that the great cauldron at Katmai was due to an explosion, threw doubt on the origin of some volcanic basins that had been attributed to subsidence. J. S. Diller (*J. G.*, 31, pp. 226–7, 1923) has restated the evidence proving that "Crater Lake" in Oregon lies in a basin due to subsidence. It is therefore a cauldron. This origin has been attributed to some huge volcanic basins in East Africa, such as Menengai in Kenya Colony, and Ngorongoro which has been further described by Barns in his *Across the Great Crater Land* (1923). Mount Aso in Japan remains by a little the largest known cauldron, being 14 m. long by 10 m. wide (Anderson, *J. G.*, 16, p. 499, 1908). Still larger subsidences form sunklands in some of which, such as the Riessenkessel in southern Bavaria, the sunken rock, there a shattered granite, is surrounded by a ring of lava. The ring-shaped intrusion of syenite, 16 m. in diameter, at Pilansberg in the Transvaal, described by W. A. Humphrey (1914), represents the deeper part of such a formation. The importance of such ring-dikes in volcanoes has been shown in the island of Mull in western Scotland. Its central mountains are the deeply dissected foundation of a volcano of the first order; and the tendency of lavas to rise along circular fractures is there well displayed and has been described in *Geological Survey Memoir* (by E. B. Bailey and others), which confirms the view of Judd that the ancient volcanoes of the Western Isles were separate volcanic vents.

Plateau Eruptions.—That some of the Mull lavas were ejected by fissure eruptions is still advocated, but this origin is not shown for any lava left on the island.

Knowledge of the vast lava fields that have been attributed to fissure eruptions has been extended for those in South Africa and South America. Those in South Africa have been described by Du Toit, "Karroo Dolerites of South Africa" (*Trans. Geol. Soc. South Africa*, 22, pp. 1–42), who shows that the Stormberg lavas (of which the age is Rhaetic or Liassic) cover an area around Basutoland 350 m. long by 150 m. wide. A surrounding area of some 320,000 sq. m. is seamed by dolerite dikes, so that the volcanic area was doubtless more extensive than it is now. C. L. Baker, "The Lava Field of the Barana Basin, South America" (*J.G.*, 31, 1923 pp. 66–79), points out that the basalt flows there cover an area of 300,000 sq. m. with an average thickness of 1,000 ft.; and the surrounding country, to the extent of 75,000 sq. m., is penetrated by innumerable sills and dikes of dolerite. These South American eruptions are of the same or of approximately the same age as those of South Africa—namely, at the very beginning of the Jurassic.

Meteoritic Impact Crater.—The view that Coon Butte or Meteor Crater in Arizona was due to the impact of a great meteorite has failed of further support by the explorations of D. M. Barringer. It was suggested that the crater was made by the nucleus of a comet instead of by a single meteorite. Recognition that this body struck the earth obliquely led to a fresh search for the meteorite under the southern rim of the crater and not, where previous borings were made, under the centre. Recent boring found only country rock.

Isostasy

The most significant discussion of the period has been upon the extent of isostasy, *e.g.*, *Bull. Geol. Soc. Amer.*, 33, 1922, pp. 275–410 (*see* Isostasy). The evidence for the greater density of the rocks below the oceans has been strengthened by pendulum observations in a submarine. This high density, according to F. P. Shephard (*J. G.*, 31, 1923) may be due to compression. The view generally adopted is, however, that the rocks below the oceans consist of denser material—the sima. Since the ocean floor must consist in places of sunken continental rocks, the existence of sima so near the sea bed appears uncertain.

Isostasy explains how large areas of the earth's crust may be uniformly uplifted, though the possibility of such a movement was denied by Suess. Burrard (*Prof. Pap. Survey of India*, No. 12, 1912, p. 6) has, however, supplied an instance in which 5,000 sq. m. of country between Saharanpore and Mussurie in northern India were upraised 5 inches during an earthquake. This fact was proved by re-levelling a line that had been surveyed shortly before the earthquake.

Areas of Tension

Areas that are being slowly upraised are torn by tension clefts and broken by normal faults. Faults so weaken the rocks they traverse that the side left upstanding is usually reduced to a gentle slope; nevertheless some recent faults in areas of hard rock are marked by fault-scarps which bound sunklands and rift valleys. Of the latter the greatest extends from Palestine across East Africa, and as shown by Teale and Wilson (1915) south of the Zambezi. Its geology has been described by Gregory (*Geology and Rift Valleys of East Africa*, 1921) and Krenkel (*Bruchzonen Ost-Afrikas*, 1922). That this valley had a longer history than was originally recognised by Suess is now admitted. E. Lehmann (*Zeit. Vulkan.*, Erg. 4, 1924) has described the volcanic area in the Rift Valley north of lake Nyasa and shown that its rocks are alkalic in composition. The tectonic origin of the Gulf of Suez, a branch of the Great Rift Valley, has been proved by the Petroleum Bulletins of the Geological Survey of Egypt, and Prof. Brock has confirmed that view for the Dead Sea (*Quar. Jour. Geol. Soc.*, 75, 1919).

Abendanon, as a corollary to his view of the radial contraction of the earth, considers that some parts are forced upward by the subsidence of others, and that tension in the rising parts gives rise to rift valleys. W. H. Bucher, (*J. G.*, 32, 1924) has illustrated the importance of tensional structures by model shells in which the plan of the crumpled bands of the earth are produced by tension and not by compression.

The deformation of the earth leads to wide areas of subsidence and uplift. Thus the subsidence of an ocean floor, by forcing the material below it to flow outward, may uplift its borders. Where the uplifted area consists of hard rocks, the surface will be torn by a network of tension clefts forming fiords and fiord-valleys (J. W. Gregory, *The Origin and Nature of Fiords*, 1913). The upheaval of these areas accompanied great subsidences that followed the crumpling of the earth's surface during the mountain formation which culminated in the Miocene. Where the surface consists of soft rocks the rupture may control the topography, as in the rectangular valley system of north-eastern France, and S. W. Wooldridge (*Proc. Geol. Assoc.*, 34, 1923, pp. 175–92) suggests that many topographic features of the London Basin were determined by intersecting fractures in the underlying platform of old rocks. The tectonic origin of the Greenland fiords has been supported by L. Koch (*J. G.*, 31, 1923, pp. 42–65) who points out that some of the fiord valleys are pre-glacial, while others are of very late origin and have been but slightly influenced by denudation. These fiords he calls fracture-fiords, as they were formed by the cleavage of gneiss along planes of fracture.

Areas of Compression and Fold Mountain Chains

Alpine Structure.—Intense compression of the crust produces fold mountains, the study of which has been especially active in the Alps. It has long been known that some of the northern Alps consist of blocks of old rock resting on younger beds. These "Klippe," or "mountains without roots" have been pushed sideways on to their present foundations, a process demonstrated in the north-western Highlands of Scotland. There, in some cases, the rocks were broken into short slabs which were forced one over another, giving rise to the "imbricate" structure, such as would be produced if a row of slates on a roof were pressed into a shorter space. In Switzerland the process has taken place on a great scale, and successive slabs of rocks have been thrust one over another as *Decken* or overthrust-sheets.

In some parts of the Alps this structure is indisputable, but in others the evidence depends on an uncertain identification of the rocks. Thus Monte Rosa and the Matterhorn have been interpreted as pinnacles of old rock thrust northward over the Trias. The Triassic age of the underlying rocks is uncertain, and is a tradition dating from the time when many of the Alpine schists were regarded as Jurassic. Bonney's work in the Lepontine Alps showed that the so-called Jurassic schists, like the Carboniferous "fossiliferous gneiss," were beds composed of schist debris, and were infolded amongst the ancient rocks. The pre-Palaeozoic age of the crystalline schists of the Alps is now generally adopted, and the Triassic age of the base of Monte Rosa and the Matterhorn is uncertain. The supposed overthrust parts of those mountains have no similar rocks to the south, so that they must have been transported from afar; and some advocates of the extreme Decken theory regard parts of the overthrust sheets or "nappes" as African in origin. This view is dismissed as fantastic "Ultra-nappismus" by some Alpine geologists, and has led Heritsch to describe the Decken theory as a fantasy.

The distance to which sheets of rock can be thrust is limited by their crushing strength. According to A. C. Lawson the mechanical limit of overthrusting must be between 20 and 30 m., and Oldham has adopted a limit of about 5 miles. An overthrust of 150 m. has been claimed in Scandinavia but appears impossible and is unnecessary on a more probable correlation of the rocks. The Decken theory in its extreme form may prove untenable. Amongst the voluminous literature on the theory reference may be made to Albert Heim's work, *Geologie der Schweiz* (1918–22); to the case for it by R. Staub, *Der Bau der Alpen* (1924); for a critical view to F. Heritsch, *Die Grundlagen der alpinen Tektonik* (1923).

The investigation of Alpine movements has shown that they began earlier than was realised. The movements culminated in the Oligocene and Miocene; but the preliminary buckling began early in the Mesozoic. Increasing importance is attached to the younger granites of the Alps, to which fresh attention has been directed by Steinmann. Movements of the Decken type in the southern and eastern Highlands of Scotland have been advocated by E. B. Bailey (1910–25); but his interpretation has not been generally accepted.

The Decken theory of the Alps agrees in one respect with Suess's interpretation, by attributing the main folding to pressure from the south. That direction of movement has been rejected by L. Kober, *Bau und Entstehung der Alpen* (Berlin, 1923), who denies the asymmetry essential to Suess's view that the Alpine belt has been pushed northward and buckled against the resisting masses of Central France, the Black Forest, Bohemia and the Russian Platform. Kober regards the Alps as symmetrical; he explains Alpine mountains as due to a belt of the crust being crushed between the continental coigns, as they are forced together by the earth's contraction. He regards the Mediterranean basin as one mountain block or "orogen," which has been

crumpled between northern Europe and North Africa, the movements being outward from the compressed belt and therefore northward in the Alps and southward in the Atlas. In the Atlas the pre-Alpine folds are southward; but those of the Alpine period, according to Gentil, are northward. That direction is inconsistent with Kober's requirements. Longwall has pointed out that the structure of the Sierra Nevada of California is also inconsistent with Kober's explanation of the Rocky Mountains; and Hobbs has rejected the theory for the Asiatic Arcs, which he attributes to deep-seated pressure from the rear or concave side.

The Contraction of the Earth.—The view that mountain folding is due to the compression of a contracting earth has been further discussed; arguments against it have been stated by Sandberg (1924) and Keith (*Bull. Geol. Soc. Amer.*, 34, 1923); but it has been more widely adopted owing to the recognition of the fallacy of some objections. It was claimed that the utmost possible shrinkage of the earth was inadequate for the observed compression; that view was based on the limited age of the earth, but with the multiplication of its age 10 or 20 times that argument has become invalid. Jeffreys has pointed out that shrinkage by cooling would be sufficient, and there are other even more potent factors of contraction. T. C. Chamberlin has supported the shrinkage of the earth's crust from the greater density of the earth as compared with the moon. If both originally consisted of similar material, the higher specific gravity of the earth is due to condensation, and to the shrinkage of its circumference by 4,555 miles.

The number of mountain chains in which overthrusting is recognised has been increased, as by the work of Deprat in Tonkin and southwestern China (*Mem. Geol. Serv. Indo-China*); his conclusions in this respect have been confirmed by Jakob. Overthrusting has been recognised in the areas between Indo-China and the eastern end of the Himalayas in northwestern Yunnan (*Phil. Trans.*, vol. 213B, pp. 171–298, 1925). Other mountains, however, though folded, show but slight overthrusting. Thus the Andes, though gently folded in the Upper Cretaceous and Eocene, have subsequently undergone block faulting without thrust planes, as shown by Steinmann (*Geol. Rundsch.*, 1922) Bosworth (*Geol. North-West Peru*, 1922), Douglas (*Quar. Jour. Geol. Soc.*, 1914, 1920, 1921) and H. Backlund (1923). Different parts of one mountain system may have been affected by both types of movement; thus the northern Rocky Mountains are shown by Mansfield (1923) to have undergone intense lateral compression, while Lee (1923) and R. T. Chamberlin (1919) showed that the movements in the southern Rockies were vertical.

Narrow U-shaped Fold-lines.—Suess explained some important topographic features by the fold-lines having been diverted in a hairpin-bend, in Assam, the Caribbean Islands, the South Georgia arc in the South Atlantic, and the Moluccas to the west of New Guinea. This view has been adopted by Hobbs (1925) and extended for the Moluccan Arcuate fold by G. A. F. Molengraaff and H. A. Brouwer (1921); but the evidence for these narrow U-shaped bends is inadequate, as the main Himalayan line of Assam continues eastward into South China; the rocks of South Georgia are fundamentally different from those of the Andes; in the West Indies the contorted foundation of Barbados strikes west to east almost at right angles to the supposed arcuate fold; and in the Moluccan islands the essential strike is across the direction of the chain, and the depression to the west may be due to a foundered block.

Igneous Rocks and Earth Movements.—That distinctive series of igneous rocks are associated with different types of earth movement has been reaffirmed by Harker (*Address, Geol. Soc.*, 1917), but has not been generally confirmed (see for example Loewinsson-Lessing, *Bull. Geol. Soc. France* (4), 23) from the Russian evidence, and for the Australasian area (*cf.*, *Scientia*, 11, 1912, pp. 56–63).

The nature of the intrusions of the great plutonic masses has been discussed by Daly in his *Igneous Rocks and their Origin* (1914), with many luminous suggestions. Hans Cloos of Breslau, from work in southwest Africa and Silesia (*Der Mechanismus tiefvulkanischer Vorgänge*, 1–21, and *Abh. Preuss. Geol. Landesanstalt*, n.f. 89, 1923), rejects Daly's theory that the granite masses eat their way into the crust by assimilating the material they replace. Cloos, agreeing thereby with Suess, concludes that intrusive granite either forces the rocks apart or occupies spaces made during the subsidence of blocks of the crust. Some assimilation naturally occurs on the margin, but Cloos regards it as only a minor incident. According to him the direction of pressure during the intrusion and consolidation of the granite may be inferred from the rifts, joints and dikes in the granite, which are parallel to the general grain of the country. The foliation in the granite he regards as less important, as it expresses only the local pressure.

Stratigraphical Geology

In stratigraphical geology the national Geological Surveys and private workers in all countries have been collecting an immense accumulation of new data. The most notable addition to the Geological Surveys is that of China, which, with the new Geological Society of China, have together made a great contribution to knowledge of that country. Among the principles of stratigraphy the problem whether geological evolution has been even and continuous, or periodic by alternate rapid developments and long intervals of repose, has been further discussed. Shepard (1923) insists that the rate of progress has been on the whole regular; but advance by periodic spurts has received wide support, as from T. C. Chamberlin (1921, etc.), R. T. Chamberlin (1914, 1921), G. Stille, *Die Schrumpfung der Erde* (1923) and Prof. J. Joly (*Phil. Mag.*, 1923, pp. 1167–88) and *Surface History of the Earth* (1925) from his theory of the periodic re-melting of the foundations of the crust by radioactive heat; and also from the distribution of land and water by tetrahedral deformation of the crust and its spheroidal recovery.

The classification of the pre-Cambrian rocks has made much progress, especially in Canada, though there is no general agreement in the nomenclature. The tendency is to subdivide the pre-Palaeozoic rocks into a lower division of gneisses and coarse schists, an intermediate division of strongly metamorphosed sediments, and an upper division of sandstones, which are but little altered and may contain traces of organic remains. Some of the pre-Cambrian limestones, which are especially abundant in the middle division, are often attributed to an organic origin; but the extensive chemical precipitation of carbonate of lime has become more apparent, and some oölitic structure is inorganic as shown by its artificial formation (*e.g.*, Johnston and Williamson, *J. G.*, 24, 1916) and the crystalline structure of some recently formed oölite; Van Tuyl (*ibid.*, pp. 792–7) on the other hand shows how oölites with an organic structure may lose all traces of it.

In stratigraphical geology the process has been especially important in regard to the pre-Palaeozoic and the Palaeozoic. Much work has been done by many British geologists on the Lower Palaeozoic rocks of Wales and the Welsh border country, and on the zonal study of the Carboniferous Limestone, in papers published mainly by the Geological Society of London.

Important proposals for the reclassification of the Lower Palaeozoic have been made by E. O. Ulrich of the U. S. Geological Survey, in a paper which, owing to the extreme changes proposed, has been issued in the Bulletin of the Geological Society of America (23, 1912, pp. 261–680) with a note by the Director of the Survey disclaiming responsibility for its views. Ulrich classifies the Lower Palaeozoic into five systems instead of three, adding the Ozarkian and the Canadian systems between the Cambrian and Ordovician. Neither system is likely to be welcomed by British geologists, for there is little evidence for them in the British Isles. The Ozarkian system is either absent or is represented only by the Upper Lingula Flags; the Canadian system includes the British Tremadoc and Arenig Series. The proposed systems have not been widely accepted in America. The better American representation of this part of the geological record has enabled Dr. Grabau to settle an old problem in the northwest of Scotland; he confirms Salter's view that the Durness Limestone is Ordovician, and not Lower Cambrian, to which it was transferred

from its superposition on the Lower Cambrian quartzites with *Olenellus*.

Much light has been thrown on some stratigraphical problems by the separation and identification of the heavy constituents of rocks—a method especially advanced by the work of Boswell. The Kainozoic classification of many areas has been put on a firmer basis by detailed palaeontological work, which has permitted the correlation of different sequences of beds in independent basins, as in California (for example, by B. L. Clark, 1921), and in Australia and New Zealand, largely by F. C. Chapman. Man has been traced back into the Pliocene by the rostrocarinate implements found in the Red Crag by Moir (*see* ARCHAEOLOGY), which, however, like the early Palaeolithic implements from the Forest Bed of Cromer, are not universally accepted. A great stimulus to the study of the geological history of man followed the description of the Piltdown skull (Eoanthropus) by Sir A. S. Woodward (*Quar. Jour. Geol. Soc.*, 69, 1913), and important skulls have been found in Queensland, South Africa and Palestine (*see* MAN, EVOLUTION OF). Claims have again been made for the occurrence of early man in America, but without carrying conviction. The reports published by various Antarctic expeditions have thrown much light on glacial processes, strengthening doubt as to the extent to which ice erodes hard rocks, attaching increased importance to the shattering action of frost, and supporting the subaqueous origin of boulder clay from its absence on the Antarctic lands and its formation on the floor of the Ross Sea. (*See* PALAEONTOLOGY.)

PALAEOGEOGRAPHY

The steady advance of stratigraphical geology enables palaeogeography to be placed on a firmer footing and its data have been summarised in a series of works by Theodor Arldt, *Handbuch der Palaeogeographie* (1919). Eduard Suess's great work, *Das Antlitz der Erde* was completed in 1909, but the comprehension of his views has been much aided by the French translation edited by Prof. E. de Margerie (completed 1918), with its invaluable collection of maps and supplementary material. Suess's teaching has led to increased recognition of the fundamentally different arrangement of ocean and continent in former times, combined with the stability of some areas and the weakness of others. E. Haug in his *Traité* (completed 1911) has laid stress on the importance of the geosynclinals as mobile bands. C. Schuchert (1923) in several luminous contributions to the palaeogeography of North America has also shown the continuous influence of the geosynclinals and has organised symposia which have collected on various problems expert opinion which might otherwise not have been expressed.

Ruedemann (1923) believes that in spite of the many changes in the earth's geography three archi-continents have persisted throughout geological time. This view has, however, been criticised by W. J. Miller, who considers that it is impossible to distinguish between the pre- and post-Cambrian folding.

L. Kober has extended his theory of the Alpine structure to the world in general; he explains the distribution of land and water as due to the massive resistant coigns having been surrounded by weak belts, which sink in geosynclinals, are then crumpled into fold mountains, and on refoundering may carry down with them adjacent parts of the continental blocks.

Climatic Changes.—In connection with stratigraphy a good deal of attention has been devoted to former variations in climate (*see* CLIMATE), which many authorities refer to changes in the heat emitted from the sun, leading at times to universal refrigeration. This view has been strongly advocated by Huntington and Visher (*Climatic Changes*, 1922) and some change of this nature is regarded as probable by Jeffreys. Prof. Coleman (*Amer. Jour. Sci.*, 1924, pp. 298–404) has called attention to the world-wide nature of the refrigeration during the Pleistocene glaciation. The leading alternative explanation rests on geographical changes in the arrangement of ocean and continent or in the relief of the land. Prof. William Ramsay of Helsingfors (*Geol. Mag.*, 1924) points out that a period of high relief produces a cold climate and that the wearing down of the land into extensive peneplains produces a milder climate. C. E. P. Brooks, *Evolution of Climate* (1922), gives important help to this line of explanation by calculating the quantitative effects of changes in the position of land and water. Of the former glacial periods, the known range of that in the Upper Carboniferous and Permian has been greatly extended, especially in America, in Brazil, Paraguay and the Argentine, and in the eastern United States, where Quayle has shown that the till at Squantum near Boston is a boulder clay of this period. There has been a tendency to attribute all coarse boulder beds to glacial action, though some have now received other explanations. The glaciation in South Australia and Central China is generally regarded as belonging to the upper part of the pre-Palaeozoic instead of Cambrian.

Darwin's theory of coral reefs has gained general acceptance, and the main interest in connection with them has been from Daly's view that their up-growth was due to the rise of sea-level owing to the release of water by the melting of the glacial ice sheets. This argument is largely based on many of the coral reefs rising from banks at the depth of 100 fathoms; but those banks and platforms are probably cut down to that level, as it is the lower limit of wave action. The numerous variations in level of raised coral reefs and beaches do not support a uniform world-wide rise of the oceans. The irregularity in the rise and fall of coral reefs has been explained by Molengraaff as due to the isostatic subsidence of volcanic areas by the weight of the volcanic materials being favourable to the growth of coral reefs.

ECONOMIC GEOLOGY

Perhaps the most marked change since 1910 has been the improved status of economic geology, due to recognition of its increasing practical service, and to the value of its contributions to academic science. The further study of coals has strengthened the view that anthracite is formed from the same vegetation as bituminous coal, the difference being due to subsequent changes. The enormous increase of output of oil, which has been magnified more than threefold in the past 14 years, has roused anxiety as to the duration of the supplies. Oil geology attaches less value than formerly to anticlinal structure as indispensable to a profitable oil field. Oil prospecting has revealed the form and structure of the salt domes, and the oil fields in Persia have become the most important under British control.

The extensive boring stimulated by the high prices of 1916–9 led to energetic well drilling from 1917–22, and to a sensational increase in oil production in California. It is doubtful whether the oil output can be extended to meet the growing demands or even be maintained, although improved methods of extraction of oil from beds will lengthen the life of many fields. The indications of a decline in some of the leading sources of supply have led to increased attention being paid to oil shale, in the expectation that before the end of the century it will be the main source of mineral oil. Discussion on ores of magmatic origin indicates that they are relatively unimportant, unless the term be so defined that practically all primary ore deposits are regarded as magmatic. There has also been increasing recognition of the importance of magmatic water—as in the series of papers by 13 American authors (*J. G.*, 32, 1921, pp. 177–225, 292–310, 373–99, 449–71), who agree that part of the water from the hot springs of the United States is of deep-seated origin.

The deep flowing wells of east-central Australia have continued to decrease in volume, supporting the view that their flow is due partly to the plutonic water which rises from below and mixes with the water stored in the stratified beds. No single chemical distinction has been found by which the proportion of the plutonic to the meteoric waters in a deep-seated supply can be determined; but, with the prolonged age now accepted for the world, a small annual supply of plutonic water would, in the course of geological time, make an important addition to the volume of the oceans.

BIBLIOGRAPHY.—See in addition to the works cited in the text, J. W. Gregory, *Geology of To-Day* (1919); J. Geikie, *Structural and Field Geology* (1920); P. Lake and R. H. Rastall, *A Text Book of Geology*, 3rd. ed. (1920); Sir A. Geikie, *Class Book of Geology*, 6th ed. (1921). (J. W. G.)

GEOLOGY: NEW THEORIES (*see* 11.638).—In considering the origin of continents and oceans it is important to have a clear idea of the magnitudes concerned. If we imagine a globe a foot in diameter to represent the earth, with all its features in their true proportions, by far the greater part of the ocean will be less than $\frac{1}{250}$ in. deep and only its extreme depths will reach $\frac{1}{50}$ inch. Almost the whole of the land will rise less than $\frac{1}{1000}$ in. above the sea and even Mt. Everest will have an altitude of less than $\frac{1}{100}$ inch.

Leaving out of consideration exceptional heights and depths the difference in level between the surface of the land and the floor of the deep oceans will be less than $\frac{1}{250}$ inch. These are the features for which we are trying to account. Of the 12-in. globe all that lies more than an inch beneath the surface is under conditions of temperature and pressure which cannot be approached in our laboratories, and we have no experimental knowledge of the behaviour of materials under such conditions. Moreover, time is an important factor, and our experiments give but little indication of what may happen under stresses acting for thousands or millions of years. It is not surprising that there is no general agreement as to the causes that have produced the present distribution of land and sea.

Earlier Ideas.—Throughout the greater part of the last century geologists in general believed that our present continents and oceans were only temporary features of the globe. It was easy to prove that much of the land had once been beneath the sea, it was not possible to show that any part had always been land. It was reasonable to suppose that much of the ocean had once been land, it was not unreasonable to imagine that no part had always been sea. In the last quarter of the 19th century, however, the idea of the permanence of the ocean basins began to gain ground. It cannot be said that there is any universal agreement upon the question even yet. Many geologists are now inclined to ascribe a high antiquity to the Pacific Ocean but to look upon the Atlantic and Indian oceans as comparatively modern. Haug and others still suspect the former existence of a Pacific continent.

If continents and oceans are not permanent the present distribution of land and sea is only an episode in the history of the globe and has no more significance than the distributions in the past. It was not geologists therefore who first endeavoured to formulate general theories to account for the present shapes of continents and oceans. Those who made such attempts ignored the changes in the past and their speculations were received with little favour by geologists.

The Tetrahedral Theory.—By far the most suggestive of these speculations was the tetrahedral theory of Lowthian Green. It was to some extent foreshadowed by him in *The Edinburgh New Philosophical Journal* in 1857 and was fully elaborated in his *Vestiges of the Molten Globe* in 1875. Following the widely accepted notions of the time, he assumed that the earth is cooling, the interior contracting more rapidly than the exterior, and under the force of gravity the outer crust collapses. Fairbairn's experiments on the crushing of wrought-iron tubes led him to believe that the collapsing sphere will tend to approach a tetrahedral form. The corners of the tetrahedron will rise above the water, forming triangular masses of land; the faces of the tetrahedron will remain covered and will form the oceans. He places one of the corners at the South Pole and the other three in the Northern Hemisphere. The corner at the South Pole is the Antarctic Continent and the opposite face of the tetrahedron is covered by the Arctic Ocean. The triangular masses of land formed by the other three corners are represented respectively by North and South America, Europe and Africa, Asia and Australia, all of them wide toward the north and tapering toward the south. The two last are united in the north, but the Caspian depression is below sea-level and the plain of the Obi but little above it. Between these three land-masses lie the Atlantic, Indian and Pacific oceans, all narrowing toward the north and, in the south, where the tetrahedral edges are lowest, uniting into a continuous belt around the globe.

The actual form which Lowthian Green believes the earth to have reached is the hexakis-tetrahedron (*see* 7.575, fig. 29), and he supposes that all the faces are much rounded so that the departure from the spheroidal form is only slight. Lowthian Green's theory was entirely neglected in England for many years, but was more favourably received in France. De Lapparent seems to have been the first to recognise it as a probable hypothesis and at a later date both Michel Lévy and Marcel Bertrand adopted it in a modified form. Since the closing years of the last century a tetrahedral theory in some shape or other has been accepted by many writers in England, Germany and America.

Modifications of the Tetrahedral Theory.—That the lithosphere shows some approximation to the tetrahedral form is matter of observation and not of theory. But that the approximation is only rough is indicated by the fact that the writers who support the theory do not all place the tetrahedron in the same position. Michel Lévy's tetrahedron, for example, is not the same as Lowthian Green's. The question naturally arises whether so ill-defined an approach to the form is due to some general cause such as Lowthian Green imagined, or to the accidental concourse of a number of minor causes. If the form is due to a general cause, then, since three of the corners of the tetrahedron are placed symmetrically with respect to the axis of the earth, the three land-masses which represent them should have a similar geological history. In particular it might be expected that their coasts should show some uniformity of type. But, as has been pointed out by Suess, the Pacific and Atlantic coasts differ fundamentally in character. The former runs parallel to the folds that have affected the surrounding land, and it is clear that the cause that produced the folds also determined the coast. The Atlantic coast, on the other hand, in general cuts right across the folds that have affected the neighbouring land and must owe its origin to another cause. The difference is too great to be accounted for by later modifications of coasts which were originally of similar origin. Further, if the differences are due to later modifications, the approximation to the tetrahedron should have been closer in the past than it is now. All the available evidence goes to show that the tetrahedron which fits best to the present distribution of land and sea will not fit at all to the distributions in past times.

On physical grounds objection has been raised that the tetrahedron is not a figure of equilibrium for a rotating earth, and even a slight approximation to it cannot be retained. Gregory has suggested that there may have been periods of collapse with an approach to the tetrahedral form, and in the intervening periods the spheroidal form was resumed. Moreover, in these periods of collapse the tetrahedron may not always have been in the same position, and thus we get the different distributions of land and sea in the past. Other writers also place the tetrahedron differently for different periods, but the geological evidence in favour of these views is not convincing.

Suess's Theories.—A great advance in our knowledge of the history of the globe was made by Suess in his *Das Antlitz der Erde*. He showed that there are large areas where even the oldest fossiliferous beds still lie horizontal. Here the crust of the earth has been rigid, in the ordinary sense of the term, since Cambrian times. It has broken, but it has never crumpled. Between these areas lie broad belts in which the strata are often folded. Here the crust has been weaker and has yielded to tangential pressures by crumpling and overthrusting. The crumpling was not a continuous process. There were well-defined periods of folding separated by intervals during which the whole earth was free, or almost free, from such disturbances. During these intervals, however, fracturing of the resistant areas took place and large blocks sank; and there were also wide extensions or "transgressions" of the sea over the land. Some of these transgressions seem to have been nearly simultaneous throughout the world and the whole land-surface must have been greatly reduced. The most extensive of them, so far as positive evidence can be adduced, occurred in the middle and later parts of the Cretaceous period.

In the Northern Hemisphere there are three areas in which the Cambrian beds remain unfolded. These are: (1) "Laurentia,"

which includes most of Canada east of the Rockies and probably stretched to the Western Is. of Scotland, (2) the "Baltic Shield" and "Russian Platform," (3) "Angaraland," which includes a great part, but not the whole, of Eastern Siberia. In all these areas, except upon the Russian Platform, no marine beds of Mesozoic age have been found, and during the Mesozoic era they were land. Probably by that time Laurentia and the Baltic Shield had been united by the folding of the intervening belt that took place at an earlier date.

In the Southern Hemisphere Cambrian fossils have only been found at one or two localities, but there are areas in which the oldest fossiliferous beds known show no folding. The most extensive of these is "Gondwana-land," which includes the greater part of South America east of the Andes, most of Africa between the Atlas and the mountains of the Cape, Arabia, Syria and the Peninsula of India. Strictly speaking, perhaps, the whole of this region should not be called Gondwana-land, for the Cretaceous sea extended far over it and even marine Jurassic beds are found in places. But much the larger part was land throughout the Mesozoic era. A similar remark applies to a great part of Australia. Between the Mesozoic land-areas of the north and those of the south lies a belt in which the Mesozoic beds are for the most part marine. This is the "Tethys" of Suess.

Between the rigid masses of the north and those of the south the more yielding crust beneath the sea of Tethys was crushed, and the great series of mountain ranges which run from west to east across the Old World was elevated. Tethys was much reduced in size and is now represented chiefly by the Mediterranean Sea. About the same time Laurentia and Gondwana-land broke up, large portions sinking beneath the sea, and thus the present Atlantic came into existence.

Such are some of the more important events in the history of the globe according to the researches of Suess, and it is impossible here to enter into further detail or examine the evidence more closely. The Pacific appears to have been sea throughout the Mesozoic era at least, but nevertheless it has functioned as a rigid area.

Suess imagines that the interior of the earth is contracting and the crust settling down upon it. The settling is accomplished partly by the fracturing of the more rigid portions, partly by the crumpling of the more yielding parts between them. Sometimes one portion of the crust is pushed over another and thus there must have been changes in the relative positions of different points upon the surface, but in comparison with the size of the globe these changes are small.

The Wegener Hypothesis.—Wegener introduces an entirely different conception, according to which the relative positions even of whole continents have altered greatly in quite recent times. The idea is not altogether new, for Schwarz had already suggested that Africa and South America were once nearer to each other; and other writers, on less solid ground, have made somewhat similar suggestions. But Wegener goes further than his predecessors and brings forward a much greater body of evidence.

Sial, Sima and Nife.—It has long been known to geologists that the visible part of the earth's crust consists chiefly of the lighter and more acid rocks, and beneath this it has been commonly supposed that there lies a layer of the denser and more basic rocks. The interior core must be denser still. In formulating these ideas Suess proposed the names Sal, Sima and Nife for the three concentric regions respectively. The term Sal is now usually replaced by Sial, and with this modification Suess's nomenclature is widely adopted. It has generally been supposed that the sial covers the whole globe. It may be thinner under the oceans and thicker on the continents, but it is present everywhere. Wegener believes that the sial is discontinuous. The floor of the ocean is formed of sima and the continents are sheets of sial floating in the sima. Because the sial is of smaller density its surface rises above the surface of the sima. The sima is not liquid in the ordinary sense of the word; but there is no perfect solid, and the sheets of sial, supposed to be about 100 km. thick, could not lie upon the sima without the force of gravity pressing them in until they floated like a cork in water. This is quite in accordance with the observations of geodesists, which indicate that the earth is very nearly in a state of isostatic equilibrium.

It was long ago shown by Pratt that there must be an excess of density beneath the oceans and a deficiency beneath the elevated regions; and Airy suggested that all elevated masses must be supported by a downward protuberance of the lighter rock of which they are formed, into a denser layer below—in fact by flotation. It should be noted, however, that all the observations are equally consistent with the notion of a continuous sial thinner in oceanic areas and thicker in elevated regions, the downward extension into the sima bearing such a relation to the protruding portion that the whole is in hydrostatic equilibrium.

Wegener's view is that the sheets of sial are not only separate and floating in the sima but also moving laterally, and that their positions relatively to one another have altered in the past and are altering still. There are certain forces arising from the rotation of the earth and the attraction of the moon which would *tend* to cause lateral movements. Whether they are sufficient to produce such movement through so resistant a medium as the sima is open to question; but it is conceivable that they may be.

Wegener says that if we take the edge of the continental shelf as the edge of the sial sheets and allow for the effects of Tertiary folding, the pieces of sial can be fitted together into one continuous sheet covering about a third of the globe. This, he thinks, was the condition at the close of the Palaeozoic era. He brings Africa and South America together and both into contact with the Antarctic continent. Australia also is placed against Antarctica, and Madagascar and the end of an elongated India are wedged between Africa and Australia. In the north, Greenland, Canada and north-western Europe come together but a wide gap is left between the rest of North America and the continents of Europe and Africa.

Criticisms of the Theory.—There is far too much scope for the imagination in this process. Wegener does not follow the edge of the continental shelf with any precision, and the allowance that he makes for the Tertiary folding is purely fanciful. Moreover, in his fitting he has introduced great distortion. If we keep the masses rigid and fit South America into the Gulf of Guinea, Canada will not come within 1,000 m. of the position it occupies in his scheme. Indeed, if his theory rested solely on the evidence of fitting, it might be dismissed at once. But there is much stronger evidence than this. He says that with his fitting the geological structures on the eastern side of the Atlantic become the direct continuation of the structures on the western side. The argument is weakened by the great amount of distortion that he has introduced to make them fit, it is almost entirely destroyed by the real facts. Several of his statements are quite at variance with those of the actual observers, and others rest on a very imperfect basis.

It is in the Southern Hemisphere that the geological evidence for a former union of the continental masses is strongest, and it is perhaps significant that the nearest approach to a fit is that between Africa and South America. The close similarity between the rocks and fossils of these two areas has led most geologists to assume a former land connection. Both regions are characterised by the occurrence of the fossil *Glossopteris* flora, which differs considerably from the contemporaneous flora of Europe. The same flora has also been found in India and Australia. All these are brought together in Wegener's scheme and the similarity in rocks and fossils is at once explained. But the argument is considerably weakened by the fact that the *Glossopteris* flora is also found in Siberia and northern Russia, which in his reconstruction become farther away from the presumed home of *Glossopteris* than they are at present. In view of our very imperfect knowledge of the geology of Asia, and the discovery of the *Glossopteris* flora in a few other Asiatic localities, it seems probable that it had a wide distribution and was far from confined to the regions that Wegener brings together.

Associated with the *Glossopteris* beds in South America, Africa,

India and Australia there is a boulder bed containing glaciated boulders, which has long been a puzzle to geologists. On the most favourable supposition with regard to the position of the South Pole the ice that carried the boulders must have extended nearly to the tropics, and it seems improbable that any glacial period could have reached the required intensity. In Wegener's reconstruction of the period all these areas come together and would lie within a reasonable distance of a suitably placed pole. But here again there are difficulties. A similar boulder bed, also associated with beds containing a *Glossopteris* flora, has been found in Afghanistan, which, with Wegener's fitting, must have been within thirty degrees of the equator when the other areas were centred about the pole. The Afghanistan boulder bed was laid down near sea-level, for it is associated with an alternation of marine and terrestrial deposits.

In general it may be said that Wegener's theory removes certain difficulties, but in removing them it introduces others of equal magnitude. By far the most suggestive point in his favour is the resemblance between the African and South American rocks and fossils. Even here Coleman, who has examined the South American boulder bed, states that the ice which deposited it reached the sea on the eastern side of South America.

Joly and Radio-activity.—Joly's theory is based on the effects of radio-activity. Like Wegener he thinks that the continents are sheets of sial floating in the sima, which forms the floor of the ocean. Relative displacements of the continents may have taken place, but only at certain periods.

The sial and the sima are both radio-active and the radio-active elements in them are continually generating heat. Unless this heat can escape the temperature must rise. The melting point of the sial rocks is known to be much higher than that of the sima, which is basaltic in composition.

Suppose that at a certain period the whole of the sial is solid and the sima also is solid down to a considerable depth. Heat can only escape by the slow process of conduction. Beneath the sial there will be no escape from the sima, because the base of the sial itself, owing to its own radio-activity, must be nearly at the melting point of sima.

Since the escape of heat is so slow the temperature rises and the sima melts to within some 20 m. of the surface. Tidal movements in the molten sima acting upon the downward projections of the sial move the whole crust so that the local accumulations of heat originally formed beneath the sial come to lie under the thin layer of solid sima beneath the ocean. This is quickly thinned still further, and molten sima escapes through fractures. The loss of heat now becomes more rapid and an era of cooling and consolidation begins.

We must suppose, then, that there are periods during which the sima layer melts more or less completely and periods during which it solidifies down to a considerable depth. It has been shown experimentally that basalt, and most other rocks that have been tried, expand on melting and decrease in density. As the sima melts it expands, and therefore the general level of the earth's surface is raised. But because the density of the sima is decreased the masses of sial which are floating in it sink more deeply into the layer. Their surfaces, owing to the general rise, become farther from the earth's centre, but, relatively to the surface of the sima they are depressed. In this way the widespread transgressions characteristic of certain geological periods are explained. As the sima cools again and becomes denser the surface falls, but the sial masses rise relatively to the sima.

When the sima begins to cool, the crust upon it, if not already complete, is soon completed by the consolidation of molten material in its fissures. Together with the sial masses it now covers the whole globe. But the sima continues to contract further, and the covering becomes too large. And now begins a period of folding and other earth movements to enable the crust to descend with the sima.

It is not possible here to enter further into the consequences of the theory. Its great merit, from the geological point of view is that it seems to offer a clear explanation of the most remarkable features in the history of the globe, the periodicity of earth-folding and sea-transgressions and their widespread character.

Conclusion.—In view of our ignorance of what goes on in by far the greater part of the interior of the globe it remains improbable that any theory founded on examination of a thin external skin can be wholly true. The old hypothesis of a contracting core fits the observed facts of geology as well as any other. It has been urged that the possible amount of contraction is insufficient, but on this point it is unsafe to dogmatise. Recent astronomical observations show that the companion star of Sirius consists of gas and yet is denser than any material upon the earth's surface. A discovery so unexpected leads us to revise our ideas and, though the conditions are very different, renews interest in the suggestion of Arrhenius that the interior of the earth is gaseous.

GEOMETRY (*see* 11.675).—The usual history of the development of the ideas of a student of geometry in England to-day is somewhat as follows: After a more or less prolonged (and highly desirable) course of experimental geometry, very largely (and undesirably) limited to a plane, in which a line is a mark made on paper, and a straight line is a mark which agrees with a physical object (a ruler), the student passes through a course in which he is shown that there is a logical connection between the geometrical conceptions his experience may have led him to form.

I. FOUNDATIONS

At first, and for a long time, often permanently, lines and circles are regarded as objects of perception and, for instance, there is no hesitation in accepting the idea of two lines being in the same direction, and it appears intuitive that two points must have a certain distance, a result of familiarity with the rigid bodies which the student has had put before him. This teaching, after a certain knowledge has been obtained of the detailed relations of circles and lines, often painfully acquired and difficult to remember, is continued on the same plan, for the so-called geometrical properties of conic sections, though these are apt to appear at first as much less concrete than circles.

After this, as soon as some facility with algebraical computation is acquired, the student learns that a straight line has an *equation*, and that, *e.g.*, the common points of two circles depend on the solution of a quadratic equation, while the common points of two conics depend on a quartic equation. If his instruction is pursued far enough, he learns, with the expenditure of much time and energy, a vast number of algebraical devices, and is now, if apt in using them, capable of proving algebraically almost any question that his usual examinations are likely to require of him.

For his further efficiency to this end he is probably taught towards the close of his career something about harmonic relations, about homography, and about projections. In particular, for example, he may be taught that the equations which give the foci of a conic are obtainable by applying the analytical conditions for a circle to the equation of the pair of tangents to the conic from any point. If he is fortunate it may be pointed out to him, near the end of his laborious drilling in detail, that a circle behaves as if it were a conic with two definite (albeit imaginary) points; and if he must in any case know the properties of conics he may, for economy of memory, seize hold of this remark, and come also to a geometrical description of the property of foci just referred to—and pursuing this course, if circumstances allow, he may finally reach a framework of hypothetical constructions including the so-called circular points and the circle at

infinity, from which, looking back, as from a hill-top, he sees the whole country of geometrical fact, with which he has so laboriously become acquainted, shrink into a landscape dominated by very few main routes.

He may now be at the stage of the third year university student. With continued consideration he may be led finally, even if only with the purpose of summarising his geometrical outlook in the fewest possible ideas, to regard as working hypotheses such as the following: (*a*) there is no fundamental difference between points at infinity and those not at infinity; (*b*) there is no difference in reality between real and imaginary points; (*c*) there is no gain but great loss in refusing to consider space of more than three dimensions; (*d*) distance, as a fundamental conception is unnecessary. And with these will come a recognition that the so-called non-Euclidean geometries are logically prior to the Euclidean geometry.

Leaving aside now the tempting pedagogic question of whether he has been justly treated in being so long denied the synthesis which, if he could have appreciated it, would so much have lightened his task of becoming familiar with the details, we remark that he finally works with a conceptual scheme which includes the perceptual experiences by which it has been suggested —but discards many ideas which at earlier stages his perceptions seemed to suggest as necessary. For instance, the points of a line are not now in (linear) order, and lines have lost their straightness, the lines of threefold space being for many purposes better regarded as points of a quadric in five dimensions.

Questions then arise such as: is geometry unique in thus replacing the first crude ideas of physical experience by a conceptual scheme of entities, whose properties are determined logically, not from a set of *definitions* which tell us what these entities are, but from a set of fundamental propositions or statements of relations between them? And connected therewith: are the ideal entities of such a conceptual scheme less *real* than those, for example, which the physicist employs, say the aether or electrons, to explain his conceptions? May the statement that distance is not necessary as a fundamental conception be fairly replaced by the statement that distance in the abstract is an illusion? It would seem that the difference is one only of the degree of abstractness of the conceptual scheme employed. We may in geometry itself have different levels of abstractness; for example, we may in the first instance regard the points of a line as conforming to our idea of an abstract order of such a kind that the so-called Dedekind's axiom is applicable, although finally when we allow the so-called imaginary points we discard this notion of order and use the word line in a still more abstract sense. It would seem that every science as it advances in comprehensiveness must similarly evolve for itself a conceptual scheme of ideal entities; and that in strict logic, no proposition can be asserted to be true or false except in reference to entities whose fundamental relations have been made explicit.

Such questions as these arise when it is assumed that it ought to be possible to ascertain by observation whether the world is finite, or still more whether space (in the abstract) is Euclidean or non-Euclidean. If the attitude which has been suggested is sound, the most that can be done is to inquire what would be the modifications in our statements of perceptual regularity which would follow if we adopted a particular scheme of conceptions in regard to the extent of the world, or the character of space.

Of such conceptions, those which have reference to a method of measurement are of fundamental importance. And if measurement is possible at all, it must presumably be based upon a scheme for assigning identification numbers to the points of bodies which are to be measured. This is not the same as assigning numbers to points of space, nor, even if this could be done, would the method of measurement be determined uniquely thereby. A way of assigning identification numbers to the points of a figure must be conditioned (*a*) by the fundamental theorems of incidence of the elements of the figure (as that a line is determined by two points, or that two planes meet in a line); (*b*) by the nature of the numbers to be used (whether they allow commutative multiplication, for example); (*c*) by the freedom of the assignment, that is the number of points of the figure for which the corresponding numbers may be assigned arbitrarily, the numbers belonging to any other point being then determinate; (*d*) which is in fact included under (*a*), by the character of the " infinity " of the figure (as whether the space of the figure is open or closed); and even then (*e*) it appears to be necessary to assume one or more definite limiting theorems of incidence.

In the way which has been studied most in detail, as being that which is most naturally suggested by the Euclidean scheme in which geometrical thought has developed, the numbers being taken to be those of ordinary arithmetic, it is possible to assume arbitrarily the numbers for three points of a line, so long as this is considered by itself, the numbers of four points of a plane regarded as isolated, and the numbers of five points of a three-dimensional space; this space is regarded as closed, the numbers belonging to a point are regarded as ratios of numbers, and infinite values of numbers are thereby excluded from consideration—and the assumption is made that four lines of which no two intersect have two common transversals. It is shown that the introduction of this assumption is equivalent (other things being equal) to assuming that the numbers used are commutative in multiplication. The number space of Descartes, in which each point is represented by three ordinary numbers, one or more of which may be infinite, may be regarded as a particular case of the so-called projective space thus described.

In his famous *Habilitationsschrift* (1854), when 28 years old, B. Riemann considered a Cartesian space in which each point is specified not by three but by n numbers or co-ordinates, and proposed to measure the distance between two neighbouring points by means of a quadratic function of the small differences of their corresponding co-ordinates. He remarked then that such a space has not necessarily any rigid bodies capable of movement without change of linear dimensions. For this to be possible it is necessary and sufficient that certain functions of the co-efficients in the quadratic form and their differential coefficients should be constant. The number of these functions is $n^2(n^2-1)/12$; for instance, for $n=2$, this number is 1, and for $n=3$, it is 6. When these conditions are satisfied the space is said to be of constant curvature. But it is to be remarked that a Cartesian space of n dimensions, such as that considered by Riemann, is in reversible, point-to-point correspondence with a quadratic manifold (also of n dimensions), in a projective space of $n+1$ dimensions. In such a space of $n+1$ dimensions, as was first remarked by Cayley, we can set up a measurement of distance between any two points by taking, quite arbitrarily, a quadric manifold of reference. It is then the case that Riemann's definition of distance, when his space is of constant curvature and allows rigid bodies capable of movement, is so obtainable after Cayley's manner.

These details appear to bring out very clearly that even when the difficult step has been made of passing from the descriptive properties of a geometrical figure to the assignment of co-ordinates, it is a further step of much artificiality to introduce a measure of the distance between any two points.

In recent years, under the stimulus of A. Einstein, H. Minkowski, H. Weyl and others, Riemann's dearest dream of a uniform formulation of all phenomena of physics, has, it would seem, been brought appreciably nearer to realisation, in what is known as a Theory of Relativity. An event, occurring in a definite place at a definite time, is regarded as depending on three co-ordinates for its position, and one for its time, and these four together are spoken of as its co-ordinates in a Cartesian space of four dimensions. As formulated by Einstein, there is an interval between two neighbouring events, given by a quadratic in the differences of their corresponding co-ordinates; this quadratic will then have 10 co-efficients. (*See* RELATIVITY; SPACE-TIME.)

It can be shown that there exist functions of these coefficients and of their derivatives in regard to the point co-ordinates, which are unchanged in value if calculated for the quadratic form into which the given one is transformed by any transformation of the co-ordinates; for instance, the 20 functions which, as has been stated, arise in the consideration of what is called the curvature, are such functions. It is clear that the vanishing of such an invariantive function expresses a fact which is not altered by any simplification that may be possible in the form of the quadratic expression. For instance, if the 20 functions above referred to all vanish, the quadratic expression has a form the same as in Cartesian Euclidean geometry; and if they are all equal to the same quantity independent of co-ordinates, the quadratic expression has the form considered by Riemann.

In Riemann's theory, following Gauss, account is taken of curves, called geodesics, which satisfy the condition that the integral $\int ds$, taken along such a curve, shall be stationary according to the ordinary rules of Lagrange's *Calculus of Variations*, where ds is the square root of the quadratic expression referred to. Einstein's suggestion is that the path of a particle under the influence of what we call gravitating masses may be represented as such a geodesic, provided the coefficients in the quadratic form are chosen to depend suitably upon these masses; and this has proved capable of verification in the case of the planet Mercury, and in the case of a ray of light passing near to the sun.

An analogous suggestion has led Weyl not only to the equations belonging to the theory of gravitation, but also to those which

express the phenomena of electromagnetism (and light). And it is very interesting from our present point of view to see the character of the modifications which Weyl has been led to make in Einstein's mathematical formulation in order to attain this end. For our present purpose we may state this in a twofold manner without entering into the logical connections. In the first place, in Weyl's theory, instead of the quadratic form ds^2 being regarded as definite for two specified neighbouring events, a product ϕds^2 is regarded as definite, where ϕ is a function variable from point to point, whose derivatives in regard to the co-ordinates are utilized to represent electromagnetic phenomena.

As Weyl writes (*Math. Zeitschrift*, ii., p. 397, 1918), "Riemann machte die . . . Annahme, dass sich Linienelemente nicht nur an derselben Stelle, sondern auch an zwei endlich entfernten Stellen ihrer Länge nach miteinander vergleichen lassen. Die Möglichkeit einer solchen ferngeometrischen Vergleichung kann aber . . . nicht zugestanden werden." This is precisely in the spirit which has moved geometers increasingly since the publication of G. K. C. von Staudt's *Geometrie der Lage* (1847). It introduces however evidently a wide arbitrariness which Weyl limits by adopting as a datum the possibility of the translation of a vector given at one point to another neighbouring point *without change of direction*. This conception, adopted from T. Levi-Cività (see Levi-Cività, *Palermo, Rendiconti*, xlii., 1917, pp. 173–205, and F. Severi, *ibid.*, p. 254), is as follows: The two elements of direction defined by (*a*) the vector at the first point P and (*b*) the displacement from P to the neighbouring point P′, define a family of geodesic directions through P, forming a surface; the parallel vector at P′ is that whose direction *on this surface* makes with the direction PP′ the same angle as that made by the vector at P. Evidently the assumption of the possibility of this determination of unchanged direction is fraught with large consequences or conditions. A suggestion subsequent to Weyl's (A. S. Eddington, *Proc. Roy. Soc.*, xcix., 1921, pp. 104–122), begins with Levi-Cività's differential equations for parallel displacement of a vector, but working backwards towards the quadratic differential form leads to a generalisation of Weyl's formulation.

So much of detail in regard to these remarkable contemporary speculations seems necessary in order to compare the geometrical aspects with those of older conceptions. In the so-called space of Einstein, still less in Weyl's space, there exist neither bodies, nor movement; and what are the fundamental geometrical conditions assumed prior to the establishment of the system of co-ordinates is as yet undetermined. The latter fact, which is equally true of any Cartesian space, may provisionally be evaded by regarding the space as being in point to point correspondence with a quadric manifold in a projective space of five dimensions; the former fact, which relates to the consideration of a quadratic differential expression, is most probably, if it proves finally to be possible to put the phenomena of physics into exact correspondence with geometrical considerations, suggestive of a physical theory which, given some fundamental relations of experience, shall be developed not by computation, but by descriptive methods. For the aim of geometry, towards which since Von Staudt's time, much progress has been made, is such a descriptive conception of the relations of figures in space as may render computation unnecessary.

II. GENERAL THEORY OF SURFACES

The older theory of circles and conics, or of rational curves in general, as also the theory of quadric surfaces, of cubic surfaces or of rational surfaces in general, can be placed in (1, 1) correspondence with the geometry of lines, or of planes, respectively; it deals ultimately with linear equations when viewed analytically. A consideration of cubic curves on a plane, or of the curve of intersection of two quadric surfaces, soon shows that these do not depend upon linear equations ultimately—or more precisely that the points of a plane cubic curve cannot be put into (1, 1) correspondence with the points of a line. And it further appears that a quartic curve in a plane is again of a higher category, and cannot be put into (1, 1) correspondence with a cubic curve.

This fact first emerges clearly in Abel's great paper on the integrals of algebraic functions. The general theory of the so-called Higher Curves was then historically subsequent to the theory of algebraic functions and the integrals of these; though, when this theory had received a sufficient development, it proved possible to elaborate a descriptive theory of these curves embodying the results obtained by the earlier analytical methods. In geometry, entities which can be put into exact (1, 1) correspondence are equivalent for geometrical purposes, and conversely, for purposes of a general theory, it is vital to know whether two entities have this equivalence or not. It is one of the most important recent developments of geometry to have made it clear that criteria can be given by which to determine whether two surfaces have this (1, 1) correspondence.

And it is interesting to remark that historically the development in this case has been on similar lines to that by which the corresponding result was obtained for curves; in the first place, over many years, Picard developed the theory of algebraic integrals associated with surfaces on lines as far as possible analogous to those which had been followed in the case of curves, therein in part carrying out a suggestion due to Klebsch and Noether, though the integrals which have proved most effective hitherto were not those suggested by Klebsch; after this the geometrical aspect of the matter was investigated by Italian geometers, more especially Enriques, Castelnuovo and Severi, who have succeeded in surpassing in beauty and generality even the distinguished contributions of their own countrymen to the theory of curves. It is impossible indeed to convey to a non-geometrical reader any idea of the interval which separates the development of geometry in Italy to-day from the development reached in England.

The new theory is under the disadvantage that an appreciation of it is impossible without sympathy and acquaintance with the theory of algebraic functions and their integrals, and it may be some time before detailed applications of it become the common property of mathematicians. But it offers a limitless scope for new work, its importance cannot be doubted and its permanence is assured.

BIBLIOGRAPHY.—For the question suggested by the Einstein-Minkowski work, ample material arises in attempting to sift into logical coherence many of the current writings on Relativity. An ample bibliography of these concludes the work of Hermann Weyl, *Raum-Zeit-Materie*, Vierte erweiterte Auflage (Berlin, 1921). The English reader will find much stimulus to geometrical consideration in Eddington's volumes, *Space, Time and Gravitation* (Cambridge, 1920) and *The Mathematical Theory of Relativity* (2nd ed., Cambridge, 1924); and should consult E. Cunningham's two fundamental volumes on *Relativity*, and A. A. Robb, *A Theory of Time and Space* (Cambridge, 1914). Emile Picard's work is summarised in his book, *Théorie des fonctions algébriques de deux variables indépendentes* (Paris, 1897–1906), which concludes with a summary by MM. Castelnuovo and Enriques (t.ii., pp. 485–522) of the results obtained by the Italian geometers up to 1906. The reader may also consult the article by Severi in vol. 11 of Pascal's *Repertorium of Higher Mathematics* (German Edition, pp. 741–782, 1922). Subsequent progress is recorded (and scattered) in the various mathematical journals, mainly of Italy. (H. F. BA.)

GEORGE V. (1865–), King of Great Britain and Ireland (*see* 11.745), succeeded to the British throne on the death of his father, King Edward VII., May 6 1910. By the Regency Act, 1910 (a temporary constitutional necessity in view of the fact that King George's eldest son, Prince Edward, was then not 16) his consort Queen Mary was at once nominated regent in the event of a demise of the Crown while the heir to the throne was under age. A new civil list fixed at £470,000 a year, was approved by Parliament in 1910. An important change in the King's accession declaration was also embodied in an Act of that year, the following short and simple formula being substituted for the old manifesto:—

> I do solemnly and sincerely in the presence of God profess, testify and declare, that I am a faithful Protestant, and that I will, according to the true intent of the enactments which secure the Protestant succession to the Throne of my Realm, uphold and maintain the said enactments to the best of my power according to law.

The coronation at Westminster Abbey, on June 22 1911, was attended by representatives from all parts of the Empire and other countries and, in order to complete the public assumption of royal authority throughout the United Kingdom, the King and Queen, with the Prince of Wales and Princess Mary made state visits to Ireland, Wales and Scotland during July. Later in the year Their Majesties visited India, and coronation ceremonies took place at the ancient capital of Delhi (Dec. 12 1911).

From the very first King George and Queen Mary showed in all their actions their earnest desire to use their royal position

in the most public spirited manner. Great Britain was fortunate in the fact that so much had already been done, by Queen Victoria and King Edward VII., to establish the Throne in the hearts of the people as a central and unifying national and Imperial force, distinct from sectional interests of party or class. Under King George this tradition was steadily maintained. He and Queen Mary devoted themselves to the task of making the influence of the court a pure, useful and kindly one in the life of the country; they mingled with different classes of society and were ever active in accepting new opportunities of service. The personal tastes of both were known to lie in characteristically domestic directions. The royal stamp collection is the most complete in existence, and in 1920 the King assured the Junior Philatelic Society of his "unabated interest in stamp-collecting."

The War Period.—The value of the influence of the Crown, as standing above and outside domestic party politics, was emphasised by the Buckingham Palace conference of 1914 on the Irish deadlock; and by the conduct during the World War of the King and Royal Family who in various ways strengthened their hold on the affections of the British people. From the opening of the World War in Aug. 1914 the King and Queen jointly and severally set themselves to make the royal influence an encouragement to every form of national activity in aid of the fighting forces. The King and Queen regularly went in state to prorogue and open Parliament in successive sessions and on frequent occasions during the War royal visits were paid to important factories and workshops at the munitions centres throughout Great Britain, as well as to shipbuilding yards, hospitals and other institutions engaged in war-work of one kind or another. The King's inspections of provincial industrial establishments included visits to Glasgow and the Clyde, Coventry and Birmingham, Leeds and Sheffield, Nottingham, Liverpool, Manchester, Barrow and Gretna, Newcastle-on-Tyne, Hull and Rosyth, Bristol, Bradford and Huddersfield. Moreover, periodical visits were made by him to the Grand Fleet. In 1917 Queen Mary accompanied the King to France. Finally, after the Armistice, the King made another visit to Paris and to the battle-fields, Nov. 27–Dec. 10 1918, and had an enthusiastic reception in the French capital (Nov. 28–30).

In other directions during the war period, the King's desire to set an example of patriotic self-abnegation was frequently apparent. The long record of royal attendances at notable ceremonies included such occasions as the funeral services at St. Paul's for Lord Roberts (Nov. 19 1914) and Lord Kitchener (June 13 1916); the commemoration service there on the entry of the United States into the War (April 20 1917); the Albert Hall commemoration of the first Seven Divisions (Dec. 15 1917); the thanksgiving at St. Paul's on Their Majesties' silver wedding (July 6 1918); the presentation to the King at Buckingham Palace by the special Japanese mission of the sword and badge of a Japanese field-marshal (Oct. 29 1918); and other events. On the occasion of Their Majesties' silver wedding, the King and Queen were received at the Guildhall (July 6 1918) and were presented with a cheque for £53,000, subscribed by the citizens of London, to be devoted to charities by Their Majesties' wish, together with a silver tankard once owned by Charles II.

On July 17 1917 it was announced that King George V. had abandoned all German titles for himself and his family. At the same time a proclamation was issued to the effect that henceforth the royal house of Great Britain and Ireland would be known, not as the house of Saxe-Coburg-Gotha, but as the house of Windsor. It had previously been announced (June 20 1917) that the King had decided that those princes of his family who were British subjects but bore German titles should relinquish those titles in favour of British names.

Post-War Incidents.—With the return of peace it was possible for the more normal activities of court life to be resumed, but in the long list of later royal functions some stand out as worthy of record for their special appeal to contemporary public interest. Immediately after the Armistice in 1918, the King and Queen on successive days made popular progresses through different sections of London, and received general ovations, in carriage drives through the city (Nov. 11), to a special thanksgiving at St. Paul's (Nov. 12), through the East End (Nov. 13), the south (Nov. 14), the north (Nov. 15), the northwest (Nov. 18) and the southwest (Nov. 22). On Dec. 27 a banquet was given in honour of President Wilson at Buckingham Palace, where he and Mrs. Wilson were staying with the King and Queen.

On June 21–2 1921 the King and Queen visited Belfast, where His Majesty inaugurated the new Parliament of Northern Ireland. The King, in his speech on that occasion, made an appeal to all Irishmen to pause and stretch out the hand of forbearance, to forgive and forget and to make for the land they loved a new era of peace, contentment and good-will. When, in the following Dec., an agreement was at last reached with the Irish Free State, the King in his telegram of congratulation to Mr. Lloyd George, ventured to hope that his own speech at Belfast might have contributed to bring it about.

On Feb. 28 1922 the King's only daughter, Princess Mary, was married in Westminster Abbey to Viscount Lascelles (*q.v.*), eldest son of the Earl of Harewood. The King and Queen paid a state visit to Belgium on May 8. Early in the following year (Feb. 7) a son was born to Princess Mary and on April 26 the Duke of York was married to Lady Elizabeth Bowes-Lyon, fourth daughter of the Earl of Strathmore and Kinghorne. Two days later the King inaugurated the new Stadium at Wembley, Middlesex, constructed in connection with the projected British Empire Exhibition, by attending the final cup tie of the English Football Association. On May 5 the King and Queen paid a state visit to the King and Queen of Italy, remaining in Rome for some days. They were received by the Pope at the Vatican on May 9, and on May 12 the King visited Montecchio to inspect the graves of British soldiers, who had fallen in Italy.

The outstanding event of 1924 was the opening by the King on April 23 of the British Empire Exhibition at Wembley. He and the Queen made frequent subsequent visits to the Exhibition, both privately and accompanied by their royal guests, the King and Queen of Rumania and the King and Queen of Italy, who made state visits to London during May. On Sunday, May 25, an Empire Thanksgiving Service was held in the Stadium, conducted by the Archbishop of Canterbury and attended by the King and Queen. On July 19 the King and Queen visited Liverpool and were present at the dedication of the new Cathedral. On Aug. 21 a second son was born to Princess Mary. Nearer the throne was the daughter born to the Duke and Duchess of York on April 21 1926 and named Elizabeth Alexandra Mary. On May 9 1925 the King and Queen opened the second year of the Wembley exhibition. (H. Ch.; J. E. C.)

GEORGE I. (1845–1913), King of Greece (*see* 11.746).—In 1910 King George promptly recognised Venizelos' rare ability and gave him his whole-hearted support, though the latter had long denounced the royal policy of *laissez faire*. Internal politics played only a secondary part in King George's reign; the Panhellenic idea had absorbed the thoughts and resources of the Greek people ever since the recognition of the independence of Greece. The King consistently strove to restrain the patriotic exuberance of his subjects on the one hand, while endeavouring, on the other, to use his great personal influence and family connections abroad in favour of the aspirations of the Greek people. His policy was consistently pacific. Even in Oct. 1912, when Greece was preparing to declare war against Turkey, King George made it clear to Venizelos that he only consented to the venture because of his obedience to the constitutional principle. He was about to celebrate his jubilee when he was assassinated by a Greek named Schinas at Salonika on March 18 1913. He was succeeded by his eldest son, Constantine I. *See* Capt. Walter Christmas, *King George of Greece* (1914).

GEORGE II. (1890–), ex-King of the Hellenes, eldest son of King Constantine, was born on July 20 1890 at Tatoi, the royal villa near Athens. On account of his supposed Germanophil tendencies during the World War, he was excluded from the succession by the Allies in favour of his younger brother, Alexander, upon the deposition of his father by the ultimatum of

June 11 1917. After his father's restoration to the throne in 1920, he married on Feb. 27 1921, Princess Elizabeth, elder daughter of King Ferdinand and Queen Marie of Rumania. Upon the second deposition of his father by the revolution of Gen. Plasteras, his younger brother Alexander I. having died in 1920 he succeeded to the throne on Sept. 27 1922. After the unsuccessful counter-revolution of Oct. 1923, his position became more difficult, although there was no proof that he had been a party to that rising. Republican feeling grew under the leadership of M. Papanastasiou and others, and, despite M. Veniselos' advice to await the decision of the National Assembly, a number of military and naval officers demanded the deposition of the Glücksburg dynasty. On Dec. 19 1923 the King and Queen left Greece. Next day, Admiral Condouriotes, for the second time, became regent. On March 25 1924 the Assembly deposed the dynasty and forbade its members to reside in Greece; and the plebiscite of April 13 confirmed the vote of the Assembly (*see* GREECE).

GEORGE, DAVID LLOYD (1863–), British statesman (*see* 16.832). The 1910 conference of British party leaders lasted from June till November. It was a strange pause of calm in the midst of the stormy events of that period. It is not true to say that the conference was a failure. The conferring leaders, on the contrary, nearly arrived at a very comprehensive and far-reaching scheme of agreement, affecting all the disputed issues—the House of Lords, Home Rule, tariffs and conscription. But the six months of secrecy ended in detaching the leaders from their followers. Perhaps the secrecy was overdone, because very few whispers came from behind the closed doors of the conference room to prepare the party followers for the agreements which required to be ratified by the parties before they could become valid. The result was that when the party leaders on both sides emerged from the conference room they found their followers quite unprepared to grant the concessions required from them. While the leaders had passed into a mood of conciliation, the followers were still living in an atmosphere of party warfare. On both sides the proposals put forward were regarded as surrenders.

Mr. Balfour (later Lord Balfour) and Mr. (later Sir) Austen Chamberlain found themselves in peril of being isolated, and Mr. Lloyd George was immediately denounced as an opportunist. Being party leaders themselves they were compelled to bow to the storm. Yet it is a fit reflection now that, but for the World War, this conference presented to Great Britain at that moment the last solid alternative to the civil war which even then loomed ahead. It is also interesting to observe that most of the conference proposals were adopted later, during the War or after. Mr. Lloyd George was among those who took a sanguine view of the prospects of the conference, and afterwards he always regretted its failure. He took a long view. He was ready to come to very bold settlements if they would save the country from civil strife. He and Mr. Balfour agreed in this attitude. But public opinion was not ready for compromise. Party tides still ran too strong.

SCHEMES OF SOCIAL REFORM

National Insurance.—The political conflict was resumed. In December there took place the second of the two 1910 general elections. It was, in effect, a test election on the Parliament bill. The Liberal Govt. had refused to go to the polls until they obtained the promise of the King that, if they were successful, he would consent to employ his prerogative of peer-making in order to carry the Parliament bill. That promise was reluctantly given by King George V. Mr. Lloyd George was returned for Carnarvon Boroughs for the seventh time with an enhanced majority (1,208). But a second national campaign within one year proved too much for his strength, and he was struck down by serious throat trouble for some months. During this compulsory retirement he prepared the National Insurance bill of 1911. This was the first of a series of measures for improving the condition of the British working class by the method of social insurance. The idea was first applied by Bismarck in Germany in 1893, and Mr. Lloyd George had made a study of the German insurance system during a holiday visit to Central Europe in the autumn of 1908. Old age pensions had been already passed into law before that visit; and thus it was that the British system of old age pensions originally took a non-contributory form.

Mr. Lloyd George's first general application of the contributory insurance principle was to sickness and invalidity, and the proposal produced a formidable social and political crisis in the autumn of 1911. Mr. Lloyd George was proposing a new habit to the British people, and at the first shock it was profoundly unpopular. All classes rose against it. There followed a succession of political revolts; and it seemed as if the combination of forces—of the Conservatives—of the Press and the public—opposed to the bill would be sufficient to swamp it. By-election after by-election was lost by the Liberal Government. The party managers were in favour of postponement; but Mr. Lloyd George held on. He eased the passage of the bill by a series of conferences with all the disturbed parties. Early in the year he won over the insurance societies. The trade unions were never definitely hostile. The doctors, after a series of protests and defiances, were finally appeased by a combination of firmness and concession. So at last, pushing the bill through the House of Commons with the aid of a strong closure time-table, Mr. Lloyd George achieved its third reading early in Dec. 1911. The House of Lords, tired of conflict with the House of Commons, allowed Mr. Lloyd George's insurance scheme to pass into law without serious amendment. This was followed by Mr. Lloyd George with an Unemployment Insurance bill which broke new ground. It was extended in subsequent years over the whole working class, and did much to carry the country through the dark years of unemployment which followed the World War.

The "Marconi" Affair.—In 1912 Mr. Lloyd George approached the reform of the English land system by way of a land committee, of which Sir Arthur Acland was the chairman. Two reports were published, one on the rural and the other on the urban side of the existing system; and Mr. Lloyd George had already announced his intention of bringing forward a series of bills in the House of Commons to carry out the proposals of his land committee. He sketched the main lines of his policy in a series of speeches throughout 1912 and 1913. But just as he approached this venture his way was barred by two events—one personal, and the other national. The first was known as the "Marconi Affair," which produced a grave crisis in Mr. Lloyd George's career. He had been persuaded by his friend Sir Rufus Isaacs (later Lord Reading) to take £1,000 worth of shares in the American branch of the great Marconi company at a moment when the British Post Office was discussing the terms of a contract with the British company. The two companies were separate, and there could in fairness be no accusation of anything beyond carelessness. But Mr. Lloyd George—at that moment Chancellor of the Exchequer—was too formidable a political figure to be let off lightly. The proceedings became the subject of an inquiry by a committee of the House of Commons, and he was gravely censured in the report of the chairman, Sir Albert Spicer, a prominent Liberal member of Parliament, although the majority of the committee acquitted him of serious blame. A majority of the House of Commons replied to the opposition attacks by a vote of confidence in Mr. Lloyd George. But for the moment his position was shaken.

The Curragh Revolt.—Already overshadowed by these events, the land proposals were now effectively blocked by the far greater crisis of Irish civil war. Mr. Lloyd George always took a mediating attitude in regard to the relations of Ulster and Southern Ireland, but he was now acutely involved in the coming passage of the Home Rule bill with its proposal of a single Irish Parliament under the Parliament Act. Ulster, organised by Sir Edward Carson (later Lord Carson), threatened an armed defiance of the Government. This defiance had now its first effect in the revolt of the officers at the Curragh against the orders issued for carrying out the prospective Home Rule policy. Faced with the possibility of a military revolt both at the Curragh and at Aldershot, Mr. Lloyd George took a very grave view of the situation and devoted all his energies to preserving civil peace. But at this moment, at the very heart of this Irish crisis, there came the vaster and more momentous challenge of the World War.

THE FIRST WAR YEARS

Mr. Lloyd George's Position.—Lord Grey of Fallodon in his memoir, *Twenty-Five Years, 1892–1916* (1925), gives a vivid account of the state of division that prevailed in the Liberal Cabinet in the fortnight before the outbreak of War. During that period the attitude of Mr. Lloyd George was deeply affected by his position as Chancellor of the Exchequer. On the Saturday before the declaration of war—Aug. 1 1914—the Governor of the Bank of England headed a deputation to 11, Downing Street, urging the policy of neutrality upon the Government. The same governor on Monday, Aug. 3, when the Germans invaded Belgium, telephoned to Downing street withdrawing the opposition of the City, and declaring that they were now in favour of war. This change of opinion in the City was highly dramatic, but it reflected the attitude of the Chancellor of the Exchequer. Mr. Lloyd George at first was not in favour of Great Britain being drawn into a contest between the two great warring groups of Europe unless some British interest or some British obligation were clearly involved. Accordingly during the previous week he did not take up the decisive attitude against Germany which he adopted in 1911, when he held the view that the claim of Germany to go to war with France over Morocco clearly involved a British guarantee (under the Entente). Once Belgium was invaded, however, and the neutrality treaty of 1839 defied, all hesitation left him; and never from that moment forward did he doubt that the military machine of the Central European Powers must be destroyed. Thus it was that Mr. Lloyd George entered upon a new phase of his career—that of war statesman.

The first great civilian duty of the War fell on Mr. Lloyd George. As Chancellor of the Exchequer, he had to secure the finances of the country. While Lord Kitchener at the War Office was organising the armies, Mr. Lloyd George had to see that the credit of the country did not collapse. At the very opening of the War he called together the governors of the leading banks and arranged a moratorium which prevented a panic. All the gloomy forecasts of the breakdown of finance so freely indulged in by the opponents of the War were in a moment dissolved into thin air. British finance, thus rallied at the start of the struggle, remained steady throughout; and the good faith thus engendered enabled the Government to borrow the immense sums which alone made it possible to endure and achieve victory. As long as he was Chancellor of the Exchequer, Mr. Lloyd George gave steady attention to this aspect of the war struggle. He knew that war, to be successful, depended, in Milton's phrase, on " two main nerves—iron and gold." His first attention was given to gold. During the first 10 months of the War he remained Chancellor of the Exchequer; and thus on him fell the main financial responsibility. By common agreement of all parties he placed British finance on an impregnable foundation.

The Ministry of Munitions.—It was in June 1915 that Mr. Lloyd George passed from the nerve of gold to the nerve of iron. It was brought to his knowledge that the insufficient supply of shells and guns at the front was exposing our armies to an intolerable inequality of loss. The crisis which followed on the general realisation of this fact in England broke up the Liberal Govt., May 19 1915, and substituted for it the first Coalition administration, of Mr. Asquith and Mr. Bonar Law. The Govt. was entirely reconstituted. Perhaps the most important change was the creation of a Ministry of Munitions—offered to and accepted by Mr. Lloyd George. This ministry was boldly entrusted with the whole function of providing war armaments, hitherto part and parcel of the duties of the War Office. It was natural that the War Office should resent this subtraction from their powers. But it was now quite clear that, in so great a war, the supply of munitions would be a function on a scale so large as to require a separate department. The new enterprise was rather a national movement than an ordinary office of state. The government workshops at Woolwich and elsewhere had been modelled to supply arms for a small peace army. Now that Lord Kitchener was calling forth from the nation by his magnetic appeal an army of 2,000,000 there had to be a corresponding effort to supply them with weapons. In order to achieve this, Mr. Lloyd George put forth all his powers as a democratic orator and organiser. He first called on the private armament firms to make a new and gigantic combined effort; and they gave him splendid support. But this was not enough. He was compelled to create a vast network of new factories and workshops, and to rally to his effort a huge army of workers, both men and women. He set out to supply the army not only with sufficient shells, but also with the great guns and explosives rendered necessary by Germany's extensive preparations. Above all, he had to create the machine-guns, hand grenades, trench mortars, and other equipments which were now absolutely necessary for the efficient conduct of a war which was from day to day taking on new types and forms.

Iron and gold were not, however, the only nerves destined to be necessary for the winning of the World War. It soon became evident that it was also to be a struggle of brains. As the War spread from end to end of Europe, and afterwards to Asia and Africa, it became clear that in this vast struggle statesmanship was just as urgently requisite as strategy for the full achievement of victory. Strategy on so vast a scale passed into the sphere of statesmanship. Much depended, for instance, on the moral appeal to the world against the aggression of Germany. There Mr. Lloyd George, with his golden gift of oratory, took a leading part from the beginning. He helped gradually to detach Italy, and widely affected opinion in all the neutral countries. It was one thing to raise so gigantic an army. It was another thing to apply it to its full use and value. On all these questions Mr. Lloyd George in 1915–6 held vigorous views. He was not content to confine himself to the function of creating guns and shells. In the beginning of 1915 he began to pour out to the Cabinet a succession of memoranda, in which he endeavoured to put before them the full seriousness of the military situation following upon the collapse of the Russian attack in the spring and summer of 1915. The theory of the " Russian steam roller " had proved very comforting to depressed Englishmen during the winter and spring of 1914–5. But when the German advance swallowed up Warsaw and Brest-Litovsk, it became clear that the " steam roller " was not even a good sickle, and that Great Britain would have to rely upon herself. The failure of the Gallipoli attack in the latter part of 1915 only emphasised the same point. It began to look as if victory would depend not so much on numbers as on skill; and all Britain's great armies and splendid armaments might only increase the magnitude of her defeat if such enterprises were repeated.

Mr. Lloyd George and the Eastern Front.—The policy and strategy laid before the Cabinet in the Lloyd George memoranda in the year 1915 were never fully adopted. In the language of the time; the Cabinet was divided between " Westerners " and " Easterners "—those who looked for a decision only on the Western Front, and those who believed that victory could be quickened by transferring part of our effort to the Near East. It all ended in a compromise which resulted in the expedition to Salonika. But Mr. Lloyd George aimed at something far larger—nothing less than a considerable diversion of armies from the West to the East of Europe. He proposed and contemplated the diversion of an army of at least 1,000,000 from the Western to the Eastern Front. With the development of the German submarine warfare Mr. Lloyd George's Eastern idea became less and less practicable; and with the increase of the German armies the danger of a German break-through on the West finally held the British armies to their task. But in early 1915 these facts had not been fully disclosed.

As the year 1915 advanced, Mr. Lloyd George's general discontent with the conduct of the War grew stronger with every month. It extended to home policy as well as foreign. He saw, for instance, that if the generals were to have their way and stake the whole issue on a break-through in the West they would require to be provided with an incessant flow of men. The first response to Lord Kitchener's appeal had been magnificent, and some 2,000,000 volunteers had flocked to the colours. But then came a pause in the recruiting; and yet the fearful wastage continued—and grew worse. The policy of frontal attacks begun at Neuve

Chapelle clearly meant a continual supply of vast armies. Such armies, Mr. Lloyd George now began to perceive, could not be secured by the voluntary principle alone. Having once made up his mind on that point, he became a vehement advocate of conscription in the autumn of 1915. But Liberal sentiment was against it, and Mr. Asquith hesitated. A series of experiments, known at the time as the "Derby Schemes"—distinguishing between married men and single—were attempted from month to month. Mr. Lloyd George advocated the American ballot. But the military councils were not in favour of it. Then came other plans—such as "starring" and "unstarring" of men according to their callings and occupations.

But all these makeshifts ended in leaving a sense of inequality and unfairness which could only be removed by a more comprehensive policy. So at last Mr. Lloyd George swung the Cabinet into conscription; and only one minister—Sir John Simon—resigned. Everything possible had now been done to supply the generals both with men and with munitions. But the question of policy remained, and there Mr. Lloyd George's discontent continued to grow. The tragic death of Lord Kitchener by the sinking of the cruiser H.M.S. "Hampshire" on June 5 1916 created a vacancy at the War Office which could only be filled in one way. So in that month Mr. Lloyd George passed from the Ministry of Munitions to the War Office. In this new position of power he obtained a firmer grip on the military machine at the front, and in particular he carried out a drastic reform of communications in France.

From these lesser tasks his mind was diverted to the main issue of victory or defeat by the tremendous tragedy that befell the Allied cause in the autumn of 1916. Rumania, tempted by Russia into the War on the side of the Allies at an unseasonable moment, was violently attacked by the great German general Mackensen and dramatically crushed before the eyes of her distant and helpless Allies. In vain Mr. Lloyd George appealed to the Cabinet to make some effort to save Rumania. Italy had entered the War in the previous year, and the Russian armies were still in being—could nothing be done? Nothing was done; and for the moment Rumania was blotted out. But the event had a profound effect on the mind of Mr. Lloyd George. It brought him to the parting of the ways. "Is it necessary," he used to say, "that a little nation should be laid on the altar of this war every Christmas? It was Serbia in 1915, now it is Rumania. What nation will come next?" Possessed with this dread, he decided to raise the issue in a definite form, and on Friday, Dec. 1 1916, he laid his views before Mr. Asquith.

Collapse of the Asquith Govt.—His main contention was that so large a War Committee as then existed could not conduct the War to victory. He proposed a smaller and more efficient body of three or four men, solely devoted to this one object of winning the War. What was wanted was unified and unsleeping control. But he proposed—and here was the crux of the political situation—that the existing Prime Minister should not be chairman of the committee. That was where the dividing line came. For frankly and definitely Mr. Lloyd George had ceased to believe in Mr. Asquith as war leader. Mr. Asquith's pride was touched to the quick; and it was quite clear that he profoundly resented the proposal, although he himself had first named Mr. Lloyd George as chairman of the new War Committee. On Saturday, Dec. 2, Mr. Lloyd George was under the impression that his proposal had been accepted. But friends intervened on both sides: the Northcliffe Press in favour of Mr. Lloyd George, and Mr. Asquith's friends in favour of a chief whose loyalty has always commanded a fit return of personal devotion. On Monday, Dec. 4 1916, *The Times* published a leading article displaying exultation over Mr. Asquith's defeat, and immediately Mr. Asquith wrote to Mr. Lloyd George breaking off the agreement. In the afternoon of that day Mr. Asquith resigned office. He received authority from the King to form a new Ministry. He wrote to Mr. Lloyd George asking him to join on condition that he—Mr. Asquith—as Prime Minister must be chairman of the new War Committee. Mr. Lloyd George refused that condition, and placed his office at the disposal of Mr. Asquith.

Already, on Sunday, Dec. 3, the Conservative rank and file had met. They had decided at first against following Mr. Lloyd George, whereupon Mr. Bonar Law had emphatically said that, in that case, they could not count on his leadership. He and his friends refused to join the new Ministry, and so Mr. Asquith's efforts to reform his Coalition without Mr. Lloyd George broke down. The King then sent for Mr. Bonar Law. But as some of the Liberals and the Labour party refused to support him, he too failed to form a government, although Mr. Lloyd George offered to serve under him. The King then called a conference at Buckingham Palace and tried to form a new Coalition Ministry under Mr. Bonar Law, with the offer of the Woolsack to Mr. Asquith. Mr. Asquith refused. Thereupon the King sent for Mr. Lloyd George, as he was clearly the only possible Premier.

Mr. Lloyd George as Premier

The New War Policy.—There was nothing left for Mr. Lloyd George but to accept the call. He attempted to rally all parties behind him. He succeeded with the Conservatives and the Labour party, and a certain number of Liberals. But the bulk of the Liberal ex-ministers stood aside and began to form a group known as the Independent Liberal party. Mr. Lloyd George was now in sole command of his own war policy. The small war committee which he instantly appointed fully carried out the hopes of its founders. It sat from day to day, and very often twice a day. It practically took the place of the Cabinet. Records were kept of its meetings, and Mr. Lloyd George formed a small Downing Street secretariat in order to keep in close touch with the various Ministries. The result was a general quickening up of war decisions and a more decisive control of the whole machine of government.

During the year 1917 Mr. Lloyd George pressed forward his idea of unified command of the Allied armies. He was now completely convinced that the War could only be won if the Allies were to face Germany with the same concentrated authority that Germany had established over her own partners. He was faced, however, with a very steady resistance from the high military command, now from time to time supported by the Independent Liberal party. There was a strong national sentiment against subordinating our armies to the control of foreigners, and there was a firm belief among the soldiers that they could win the War alone by pounding harder at the Western Front. But as the year advanced the sanguine expectations frankly thrown out in interviews in the spring by Sir Douglas (later Earl) Haig were not fulfilled. The Aug. fighting round Lens; the Sept. onslaughts on the east and north of Ypres; finally the assault on Passchendaele—all these battles displayed fully the inexhaustible valour of British, Australian and Canadian troops. But there was no break-through. The British armies were checked by the mud and rain of the Flanders autumn, and in too many cases heroism was literally choked in slime. Mr. Lloyd George contemplated this wastage of Brittish manhood with increased impatience, and on many occasions protested against the sacrifice of volunteers and conscripts.

On Oct. 24 1917 there occurred an event which finally decided him to force the matter of unified control to a decision. On that day the Austro-German armies under Von Bülow broke through the lines of the Italian armies dangerously stretched out between the Eastern Alps and the Adriatic Sea, and drove them back to the line of the Tagliamento with the loss of 300,000 men and 2,000 guns. Italy stood for the moment in peril of a defeat equal to that of Serbia and Rumania in the preceding years. Mr. Lloyd George was determined that this defeat should not take place. He himself journeyed immediately to Italy. By infusing new courage into the Italians he helped to check the confusion and flight of their armies. He compelled the Western commands to send an army of infantry and artillery, English and French, under Gen. Plumer through the Mont Cenis tunnel to northern Italy. These reinforcements arrived in the nick of time, checked the collapse of Italy, and aided greatly to save her from defeat.

The End of the War.—Having achieved this task, Mr. Lloyd George, with characteristic swiftness, determined to press on

with the matter of unified control. On his journey back to England he stopped in Paris on Nov. 12 1917 to make a speech in which he plainly announced that divided control meant defeat. But that speech for the moment only aroused fresh opposition, and when he returned to Parliament he had to face the vehement criticism of the Independent Liberals led by Mr. Asquith. Yet, later, in May 1918, when Sir F. Maurice, challenged his authority in a letter to *The Times*, the consequent vote of confidence in the Commons secured him a decisive majority of 187. But full unity of control was not really achieved until the terrible events of March 1918 brought home to all parties in England the nearness of the peril. During the winter the Germans brought across Europe a fresh army of 2,000,000 men released by the collapse of Russia after the Bolshevik revolution of Oct. 1917. This gigantic new army created a fresh situation in the West, and the first blow fell on March 21, when 40 German divisions attacked and broke through the British line west of St. Quentin. On the following days the British line withdrew 15 m., and the military struggle that followed lasted through five terrible months. Mr. Lloyd George threw into the fighting line all those youthful regiments which he had hoped to keep for home defence. Even so, the German pressure very nearly crashed through to the sea. There was a tense moment when some high military authorities were in favour of bringing the British armies back to England. But Mr. Lloyd George always strenuously refused to face such a possibility. He averted defeat by two principal steps of policy. One was the assertion of full unity of control, and the other was the bringing over of the American armies.

President Wilson had not contemplated sending his armies to Europe until they were fully trained and brigaded. But that process could not have been finished till 1919 at the earliest, and it was now clear that in that case the American armies would be too late. Mr. Lloyd George therefore made a definite appeal to President Wilson to send all he could immediately, and the President instantly responded by a promise to do so on condition that Great Britain provided the transport. Thus with the combined effort of the American command and the British Navy and Marine no less than 2,000,000 American soldiers were carried across the Atlantic, in spite of the submarines, during the months of April and May 1918. Those numbers now enabled the Allies to meet the Germans with a greater sense of numerical equality. But mere numbers were still useless without unity. Visiting France in the first week of May 1918, Mr. Lloyd George held a decisive combined meeting of the military and civil powers, in which, supported by Lord Milner and M. Clemenceau, he was at last able to persuade the British generals to accept the supreme command of the great French soldier Marshal Foch. During the final months of the War the British armies fought loyally under that command. It was by the combined attacks of British and French troops, storming the German lines east of Amiens, that the tide was turned on Aug. 8 1918. Seven great battles were fought after this event, but from Aug. till Nov. the German armies were steadily driven back. Finally, on Nov. 11, came the collapse of the German resistance and the acceptance of armistice terms of defeat by the new German Government. "Germany is doomed," cried Mr. Lloyd George, speaking at the Mansion House on Nov. 9 1918, and he proved a true prophet. The Allies had won the War.

The Peace Conference.—Victory having been achieved, it now remained to make peace. There were inevitable delays. Mr. Lloyd George deemed it necessary first to strengthen his position by an appeal to the country. The polls took place on Dec. 14 1918, and the results were declared on Dec. 28. The effect was an overwhelming victory for Mr. Lloyd George, he being returned to power by a majority of 249 over all the independent groups. He himself was returned for the eighth time as member for Carnarvon Boroughs with a majority of 12,898. These events filled up the pause rendered inevitable by the waiting of Europe for the arrival of President Wilson, who had decided to attend the Peace Conference as American representative. The next step was the choice of the capital in which to hold the Peace Conference. Paris was selected, the intention being to move on to Geneva after the first stage. But once settled in Paris it was found impossible to move so vast an assembly of nations. The first meeting of the conference took place on Jan. 18 1919 at the Palace of Versailles, and it proved an impressive gathering of the representatives of all the 30 countries who had taken part in the defeat of the Central Powers. Mr. Lloyd George took with him from England a joint delegation representing all parties, including Mr. Bonar Law, Mr. Balfour, Lord Milner and Mr. George Barnes. A powerful delegation came from the Dominions, including Mr. Hughes, Premier of Australia, Sir Robert Borden and Gen. Botha. Thus the whole British Empire was represented at Paris among the colleagues of Mr. Lloyd George.

It soon became obvious that so big an assembly could not really arrive at peace. There were too many conflicting views, there was no possibility of secrecy. The allied negotiators gradually narrowed to an inner council of ten, which was soon reduced to five; then from five to four; and finally from four to three—Mr. Lloyd George, President Wilson and M. Clemencean. On them fell the full burden of making the peace. This numerical narrowing of the peace negotiators, together with the increase of secrecy, created widespread discontent among those who had been led to expect a peace by open diplomacy. What happened behind the scenes was this: roughly speaking, the position was that Mr. Lloyd George and President Wilson worked for a peace of conciliation, while M. Clemencean worked for a peace of victory. The French started with a claim to extend their frontier up to the left bank of the Rhine. Wilson and Lloyd George together succeeded in moderating this claim. But they were compelled to hand over the Saar Valley for 15 years as part of the compromise. Smaller compromises took place in regard to Silesia and the Polish corridor. No one was completely satisfied, but every country had its say. President Wilson's unique contribution to the settlement was the League of Nations Covenant. Though Mr. Lloyd George took great interest in the framing of the Covenant, he left the chief British share in its moulding to Lord Robert (later Viscount) Cecil, who sat on the League Committee as the British representative. But when the crisis came, and President Wilson threatened to leave the conference unless the Covenant was placed first in the treaty, Mr. Lloyd George supported the view of President Wilson.

The Treaty of Versailles.—Mr. Lloyd George's freedom was much hampered by Press attacks from home, and at one moment Lord Northcliffe organised a mandatory telegram from over 200 members of Parliament rebuking him for a tendency to weaken on the demands to Germany. Mr. Lloyd George returned to London to face his critics in Parliament and secured a huge majority. There can be no doubt, however, that these symptoms of discontent at home diminished his authority and weakened his resistance to the military policy of France. At this point, for instance, he agreed to the French claim to occupy the left bank of the Rhine for 15 years, which he had hitherto attempted to limit to a much shorter period. On May 6 a draft of the treaty was completed, and was presented to the German Foreign Minister, Count Brockdorff-Rantzau on the following day. Germany instantly pleaded for various important modifications. During the six weeks of parley with Germany that followed Mr. Lloyd George played the part of conciliator. President Wilson hardened against Germany, and took the view that he was pledged to the treaty as it stood. Mr. Lloyd George secured the softening of many harsh terms, and in that way prepared the ground for the return of the spirit of conciliation to Europe. A political crisis in Germany followed, but on June 22 the National assembly authorised the signing of the treaty, and on June 28 it was signed at Versailles by the German envoys. Mr. Lloyd George returned to England and defended the treaty before Parliament, which unanimously ratified it on July 3. Shortly after he was awarded the Order of Merit.

Domestic Discontents.—Having made peace abroad, Mr. Lloyd George returned to restore peace at home, which was just as much in peril. The long strain of the World War and the terrible losses of men and material had left Great Britain gravely wounded and weakened. The impulse of patriotism passed

away; and the idea seemed to spread that every class was to be enabled to "get rich quickly" by the achievement of victory. The result was a series of industrial struggles, beginning with the London railway strike in Feb. 1919, followed a few weeks later by the first of the coal crises. Mr. Lloyd George averted a strike on the coal-fields by appointing a royal commission with Mr. Justice Sankey as chairman, with a promise that the commission should report on wages and hours by March 20. The Sankey commission reported on that day, recommending a two-shillings' increase in wage and an immediate seven-hours' day. The concessions were granted and a strike was averted. But when the majority of the commission went on to recommend nationalisation of the mines, Mr. Lloyd George refused to adopt the suggestion. In Oct. 1919 the railwaymen precipitated a national strike; and once more Mr. Lloyd George had to play the part of national conciliator. He brought the strike to an end by a compromised settlement fixing wages according to the scale of living.

During the next two years the Lloyd George Coalition Govt. passed a series of agreed measures on housing, suffrage and land. But as time went on it became clear that the country was financially more exhausted than had been supposed. The first after-War "boom" gradually passed into a "slump," and there arose from the whole country a cry for economy which expressed itself in an "Anti-Waste" campaign of the utmost vigour. By-election after by-election was lost to the Government, and the country was swept by financial panic. Mr. Lloyd George met it by a drastic measure. He appointed a small committee, with Sir Eric Geddes as chairman, to revise the whole of our national finance. As a result of its sweeping report—the "Geddes Axe"—widespread economies were effected in all departments. The agricultural subsidy was withdrawn and the agricultural wages boards were suspended. The housing scheme was held up: and all progress in education was checked.

Fall of the Ministry.—Those concessions weakened the Radical support of the Coalition. In the autumn of 1922 a similar weakening occurred on the Unionist wing of the Conservative party owing to the policy to which Mr. Lloyd George was driven in Ireland by the course of events. The Sinn Fein trouble which had broken out in the later period of the War worked up in 1920–1 to an actual rebellion. All Mr. Lloyd George's efforts to effect a compromise between Northern and Southern Ireland proved vain. In the spring and summer of 1921 the condition of Ireland grew rapidly worse. Murder and outrage were rampant. The Coalition Govt. initiated a special force, who received the nickname "Black and Tans," to deal with the violent methods of the Sinn Feiners by vigorous reprisals. This produced in England a divided feeling as to the equity of the struggle. In the autumn of 1921 peace overtures began to pass from one side to the other. Mr. Lloyd George decided to make a real effort after a settlement. A truce was declared, and the picked leaders of Sinn Fein came to Downing street, where, after several weeks of discussion, a settlement was reached, at midnight, Dec. 6 1921. This great concession to Ireland was followed by resistance to the Turks at Chanak on the Dardanelles (Sept. 1922), and the two events produced the downfall of the Lloyd George Coalition. The Unionist party, created on the principle of resistance to Home Rule, was riven asunder by so great a concession as that of Dominion Home Rule to Southern Ireland. The threat of renewed war with Turkey was profoundly unpopular, and presented the enemies of the Govt. with an opportunity. Mr. Bonar Law, who had retired from the Govt., returned to a meeting of the Conservative party at the Carlton Club on Oct. 19 1922, at which it was decided that the Conservative party should leave the Coalition. Mr. Lloyd George instantly resigned, and in the election that followed (1922) Mr. Baldwin—who succeeded on the death of Mr. Bonar Law—obtained a majority. (*See* ENGLISH HISTORY.)

AN OPPOSITION LEADER

Throughout the vicissitudes of the general elections which followed in the autumns of the following years (1923 and 1924) Mr. Lloyd George remained a leader of opposition. He reunited his followers with the Independent Liberals after the election of 1922, and devoted his energies to identifying the Liberal party with a policy of economic reconstruction. In 1924 he published *Coal and Power*, which outlined a comprehensive scheme for the more efficient utilisation of the natural resources of the country. Nevertheless the reunited Liberal party failed to gain strength and in the General Election of 1924 its numbers in the House of Commons, controlled by Mr. Asquith and Mr. Lloyd George, sank to 40 members. Mr. Lloyd George continued his active efforts to rouse the country to the need of further domestic reform to meet the home crisis: and in the early autumn of 1925 he issued a big land programme which he proceeded to advocate throughout the country.

By the elevation of Mr. Asquith to the peerage as the Earl of Oxford and Asquith (1925) Mr. Lloyd George earned the succession to the Liberal leadership in the House of Commons, and was elected to that office in the sessions of 1925 and 1926. In Feb. 1926 he carried his land proposals, with few modifications, through a Liberal Convention assembled at the Kingsway Hall in London. But the Liberal party still showed no signs of revival in the country, and in the by-elections of Jan. and March 1926 some of the Liberal candidates lost their deposits to the returning officer. Still, the personal position of Mr. Lloyd George in the country was growing steadily stronger: and his criticism of Sir Austen Chamberlain's new Locarno policy in the House of Commons in March 1926 created a profound impression. His national and parliamentary position was in strange contrast to the size of his following; and that created a strange diversity of opinion in the forecasts of his future. In May, during the course of the general strike, Mr. Lloyd George expressed opinions that were not in accord with those of Lord Oxford and the other Liberal leaders. His idea was that the Government should negotiate with the strike leaders without delay, instead of declining to do so until the strike had been called off. He ridiculed the view that the general strike was aimed at the constitution. A somewhat acrimonious correspondence between him and Lord Oxford followed, and the party, both in and out of the House of Commons, was acutely divided upon the question. (*See* LIBERAL PARTY.)

GEORGE, STEFAN (1868–), German poet, was born at Büdesheim, Hesse, on July 12 1868. After attending the grammar school at Darmstadt, he studied philosophy and the history of art in Paris, Munich and Berlin. He travelled extensively in Italy, France, England, Spain, Holland and Belgium and became associated with the Baudelaire and Mallarmé School in Paris and the disciples of the Pre-Raphaelites in London. His early poems were first published privately for a select circle of friends, for whom in 1892 he founded the *Blätter für die Kunst*. George's poetry which is non-realistic, reflects a heroic and aesthetic world-philosophy; and possesses great beauty of form and an austere power. Among his works are *Hymen* (1890); *Algabal* (1892); *Die Bücher der Hirten* (1895); *Jahr der Seele* (1897); *Die Teppich des Lebens* (1899); *Tage und Taten* (1900); *Die Fibel* (1901); *Der siebente Ring* (1907); *Stern des Bundes* (1914); *Der Krieg* (1917); *Drei Gesänge* (1921). He also translated Baudelaire, Dante and the sonnets of Shakespeare.

See L. Klage, *Stefan George* (1902); F. Düberg, *Stefan George* (1908).

GEORGIA, U.S.A. (*see* 11.751).—The population of Georgia in 1925 was 3,058,260, as against 2,895,832 in 1920 and 2,609,121 in 1910, an increase of 17·2% for the 15 years. During 1910–20 negroes increased from 1,176,987 to 1,206,365, but relatively they decreased from 45·1% of the total population to 41·7%. The urban population was 25·1% as compared with 20·6% in 1910. The density of population in 1920 was 49·3 per sq. m. as against 44·4 in 1910. The census of 1920 revealed an important movement of population from the mountain counties of

the northern portion of the state and from central Georgia to south-central and southeastern Georgia, due to the presence of large areas of undeveloped and fertile land in the southern half of the state. The highest density of population, however, was still to be found in the northern half.

Agriculture.—Although scarcely perceptible in 1914, by 1916 the boll weevil had spread over the coastal plain of Georgia, and in the following years covered the entire state. The growing of long-staple cotton was abandoned and the production of the short-staple was sharply curtailed, falling from 2,718,037 bales in 1914, the largest crop in the history of the state, to an average of 30% less in the four years following. This situation gave a powerful impetus to diversified farming, the movement being aided by the high prices of foodstuffs due to the World War. The most important of the new crops is tobacco. Beginning with a production of 1,088,000 lb. in 1910, this crop in 1925 had grown to 47,880,000 pounds. Meanwhile there have been tremendous increases in the production of hogs, sweet potatoes, peanuts, melons and fruits, particularly peaches and apples, and pecans.

Education.—In 1910 the total enrolment in the public schools was 555,794; in 1924, 709,760; the state appropriation for elementary schools in 1910 was $2,237,000; in 1925, $4,500,000; there was raised by local taxation in 1910, $1,307,000; in 1924, $8,732,923. The total amount spent from all sources for elementary schools in 1924 was $22,701,973. Laws were enacted 1910–20 for the modernising of the educational system. A constitutional clause limiting the taxing power of the counties to taxation for elementary schools only was removed (1910). The state Board of Education, hitherto composed of state officials, was made a professional board (1911), and a uniform text-book law passed, the duty of selecting the books being placed upon the board. Compulsory education dates from 1916. The law, as amended by the new School Code of 1919 required attendance through the seventh grade. Provision was made for attendance officers. A training school for negro teachers was authorised in 1922. The Federal Smith-Lever Act of 1914, and the Smith-Hughes Act of 1917, both accepted by Georgia, provided for extension work in agriculture and home economics, and for the teaching of vocational subjects in the schools.

In 1919 the policy was adopted of setting apart one-half of the total income of the state for the schools. In the same year a constitutional amendment was adopted, by which the counties were required to levy local taxation of not less than one mill nor more than five mills for the support of elementary schools as a supplement to the state appropriation. To encourage the consolidation of small schools, the Legislature appropriated (1919) $100,000 from which the state offered to pay annually a bonus of $500 to any county which combined small schools into larger ones and where a four-year high school was provided, an additional bonus of $1,000 was authorised. This bonus fund was increased to $200,000 in 1924. An illiteracy commission was established (1919) to make a study of adult illiteracy and in 1920 local taxation for the support of schools for adult illiterates was authorised. Noteworthy progress was being made in the eradication of illiteracy. White illiteracy declined from 7·8 to 5·4%; negro from 36·5 to 29·1%. During the period 1905–25 the number of four-year high schools increased from 7 to 275. The total state appropriations for higher institutions, including the district agricultural schools, the academies for the blind and deaf, and various training schools for defective classes, was in 1910 $436,500; in 1924 $1,284,450.

Government.—The period 1910–25 in Georgia was characterised by legislation designed to further social progress and economic improvement. The standard of medical education was materially raised (1913); only four-year medical colleges were recognised and the requirements for entrance were increased. A new Board of Health was established (1914) to exercise control over the county boards of health. Provision was made for paid sanitary commissioners in all sanitary districts, which consist of one or more counties. A Vital Statistics law of 1914 provided for the registration of births and deaths and the publication of statistics. The employment of children under 14 years of age was prohibited (1914), and factory inspectors were provided in 1916. A Training School for Mental Defectives was established (1919); and a state Board of Public Welfare (1919) was set up, charged primarily with the duty of inspecting all state institutions for the dependent, defective, delinquent and criminal classes. An Act of 1920 provided for rehabilitation of persons disabled in industry or otherwise, assented to the Federal Vocational Act and pledged the state to equal appropriations made by the United States. A state Board of Vocational Education was created (1917), charged with the administration of the rehabilitation training. In 1922 a Commission was created to study the laws of this and other states and propose legislation to safeguard the welfare of children within the state.

A Dept. of Commerce and Labour was created (1911), in which was later (1917) included a free employment bureau. The Dept. of Insurance dates from 1912. The State Highway Dept. (1916) was reconstituted in 1919 to bring the state system into harmony with national legislation providing aid in the construction of rural post roads. A Bureau of Markets (1917) was created to gather and disseminate information of value to producers and consumers of agricultural products; and, in 1921 an Act was passed to encourage co-operative marketing of agricultural products, their storage, canning, packing, etc., the supplying of agricultural machinery, and the financing of these operations. To further the erection of modern warehouses for the weighing, grading and storage of lint cotton, a Warehouse Commission was authorised in 1918. A new banking code (1920), modelled on the National Bank Act, corrected many defects in the old banking system and provided for adequate inspection. An Employers' Liability Act (1920) set aside the common law defence of contributory negligence of fellow-employees and provided for compensation for industrial accidents; a commission being created to administer the Act. The Uniform Negotiable Instruments law was adopted in 1924.

Finances.—The assessed value of the taxable property of Georgia in 1910 was $766,000,000 and in 1924, $1,213,423,073. The yield of taxes in 1924 was $16,765,264. The principal source of revenue was the general property tax. In recent years two special tax commissions appointed by the governor have made reports urging the classification of property for taxation purposes, the adoption of the income tax, and other changes in the system; but the Legislature had up to 1925 failed to act. The bonded indebtedness of Georgia was reduced from $6,944,000 in 1910 to $5,284,202 in 1924.

History.—The governors of the state during the period 1911–26 were: Hoke Smith (Dem.), 1911–2 (shortly after his inauguration Smith was elected by the Legislature to succeed J. M. Terrell as U.S. Senator); Joseph M. Brown (Dem.), 1912–3 (elected at a special election to fill Smith's unexpired term); John M. Slaton (Dem.), 1913–5; Nathaniel E. Harris (Dem.), 1915–7; Hugh M. Dorsey, 1917–21; Thomas W. Hardwick (Dem.), 1921–3; Clifford M. Walker (Dem.), 1923–. (R. P. B.)

GEORGIA (*see* 11.758), a Soviet republic forming part of the Transcaucasian Federation of Soviet Republics. The capital is Tiflis (*see* TRANSCAUCASIA).

GERARD, JAMES WATSON (1867–), American lawyer and diplomat, was born at Geneseo, N.Y., Aug. 25 1867. Educated at Columbia University and at the New York Law School, he was admitted to the bar in 1892 and began to practise in New York City. In 1908 he became associate justice of the Supreme Court of New York, resigning in 1913, on being appointed ambassador to Germany. At the outbreak of the World War in 1914 he assumed the care of British, Japanese, Rumanian and Serbian interests in Germany, later visiting the camps where British and other prisoners were confined and doing much to alleviate their condition. His responsibilities were further increased by the fact that German interests in France, Great Britain and Russia were placed in the care of the American embassies in those countries, the American embassy in Berlin thus becoming a sort of clearing house. After the sinking of the "Lusitania" with many Americans on board, on May 7 1915,

the American ambassador's position became more difficult, and finally, on Feb. 3 1917, diplomatic relations were broken off by America and he was recalled. While in Germany in 1914 he was Democratic nominee in New York for the U.S. Senate, but without success. On his return to America he resumed the practice of law in New York City. He received the vote of several states in the Democratic National Convention of 1920 and 1924 and was Chairman of the Finance Committee of the National Democratic Campaign in 1920 and Treasurer in 1924. In 1917 he published *My Four Years in Germany* and in 1918 *Face to Face with Kaiserism.* For his services to England he was decorated with the G.C.B.

GÉRAULT-RICHARD, ALFRED LÉON (1860–1911), French journalist and politician (*see* 11.766), died Dec. 6 1911.

GERMAN LITERATURE (*see* 11.783), like every form of spiritual activity in Germany, experienced between 1910 and 1920 deep alterations in thought, feeling, values and form. Characteristic of the older generation was its pleasure in the external picture of the world. Man, with joy and confidence, felt himself a part of this picture. The younger generation seeks to reveal the inner meanings of the world. A time of suffering leads towards infinite horizons. Former standards of measurement are replaced by a sense of the immeasurable. We no longer tread our bit of the world as a solid piece of reality, but long for escape into the infinite. Its symbol is the horizon always receding, never attained.

The Forerunners of Expressionism.—But what appears at first sight to be a bridgeless gap made by disruption is really only the last stage of a continuous development already begun between 1890 and 1910. During those two decades the point of view had shifted, gradually but steadily, until by 1915 it already had come half-circle. All typical writers of the "impressionist" period had turned symbolists in their later works; Stefan George and his circle, or Rainer Maria Rilke, Gerhart Hauptmann himself in his later work (*Und Pippa tanzt, Emanuel Quint*) are only to be understood from this angle. Even when "impressionism" was at its height there were writers whose work was strange to their age, and only later became quite intelligible when they were seen as the forerunners of an age of "expressionism." In fiction, Hermann Conradi, Johannes Schlaf, Hermann Stehr and Jakob Wassermann looked towards new life and personality; while Julius Hast, Paul Scheerbart and Gustav Meyrink strove for new form and shape; and Heinrich Mann's evolution from Renaissance poet to Central European democrat meant increasing sympathy with the New Youth. Dramatists had already attempted to create a new drama of style to break the supremacy of the old naturalistic drama of situations or the neo-romantic drama of sentiment. Herbert Eulenberg and Wilhelm Schmidtbonn had dared to make a new drama out of passion or excitement; Paul Ernst in a hard struggle for dramatic form sought to create a new classical drama, and thereby was first in the far-reaching fight against the dominant relativist and psychological cult. Frank Wedekind had broken with every tradition and spoken with the voice of primitive impulse. While the lyric poets, Peter Hille, Alfred Mombert, Christian Morgenstern, had one foot in the field of the new art, others from 1900 onwards took their full stand on that ground. Instance the poets of *Charon*, particularly Otto zur Linde (b. 1873, *Collected Works*, 1910 *seq.*), Karl Rottger and Rudolf Paunwitz.

The Expressionist Movement.—The term "expressionism" as applied to the theory and practice of this new art came into general use between 1910 and 1920. The word is, on the whole, felicitous. It shows clearly how the new art contrasts with naturalistic impressionism which was all facts and feelings; as equally with aesthetic, neo-romantic fantasy; opposed thus to Zola and Hoffmansthal alike. Instead of the Impression received from without we have now Expression of the inward self. Instead of transcribing some trait of nature that awakens a certain state of feeling, we have relief of the spiritual tension that conceives all concrete things as signs and symbols devoid of separate meaning and even of incidental help towards the better recognition of the outward world. Instead of being the humble interpreter of any outer thing, the artist's idea now absorbs the object in order that he may free himself from its tyranny and find his own salvation in the Idea. Instead of pleasure in the object, pleasure that enlightens or transfigures, there is now torment from which respite must be won if life is to be borne. Eternal circumstance yields to the eternal act; the cool observer to the ardent believer and worker in a holy cause; the poet to the political leader; description and eloquence to pathetic appeal, even to the scream of pain. Earth and nature yield to Spirit, to the All, to God; positivism to metaphysics and rationalism to the irrational; logic to mysticism, understanding to use, potential ability to active will and decided opinion; form to matter; society to community, the logical and psychological man to the inspired. In short "I" yields to "You" and "One Another;" the mistrusting mood to the trustful. For: "Man is good;" "Man is the centre of his world;" "With man the world begins."

In the history of ideas the new sweep of tendency is thus a variety of those foaming, overflowing movements known in Germany as "Sturm und Drang" or "romanticism." Chronologically, it is the expression of the inevitable change from one generation to another. This new art had, indeed, leaders older than itself; but in the main it manifests the spirit of the New Youth—its will to live, its urge towards artistic creation.

The generation born between 1880 and 1890 or later breaks clean away from its predecessors born in the 'sixties or thereabouts. But what this fresh generation feels, and means to prove, is that its break with the immediate past is something fundamentally different from the new departures of 1880 or 1840 or 1800. This artistic revolution stands out against the world's more profoundly significant background. It begins with a far different spiritual atmosphere—itself only one aspect of a whole world's violent moral crises. Before this, the revolts of Youth against Age were familiar enough, but really meant bolder advance on lines marked out by the fathers, and by the forebears for 400 years. This time the standpoint is quite changed. It is impossible, says youth now, to link up with our predecessors. Their past is worthless; the present is a disgrace; our task to-day is to "break all bridges and begin again." The naturalistic revolution of its fathers is regarded as a false development by their sons who overthrow it. To them it seems merely the last stage of a process set up a century ago or even four centuries ago, when the epoch of Humanism began to make the world "measurable and ponderable." Now, the aim is to make a new beginning.

The former phase displayed the victorious advance of the natural sciences, their processional entry, as it were, into human life, their permeation of all its knowledge, feeling, thought, activity. The resultant rise of machine-industry and technical resources gave an unparalleled command of nature by man. The young generation proclaims the end of this era in a Europe that went to pieces in the World War. It mocks the so-called mighty achievements which only led to unexampled violations of the spirit. This is why they reject and execrate the idols of science and repudiate its votaries, the brain, the head. This is why they acclaim as prophets the idol-breakers Strindberg and Claudel. This is why they reject the "law of causality" in literature, together with the materialist theory of the soul, and the correspondent psychology. Hence, from their language, they banish logic and sweep away the parts of speech like articles and copulatives, which merely serve logical uses. They rather look to children and savages for instruction in the principles of true and direct existence.

Simple as these principles appear on the one hand, not all the young talents are fully able to adapt them, but, on the other hand, they lend themselves to many varieties of imaginative and reflective creation. There is room not only for the despisers of culture and civilisation, but also for those who, like the "futurists," hope to create a new art by the enhanced employment of all new technical possibilities; room no less for a leading expressionist writer of fiction like Alfred Döblin, who answers the almost fashionable derision of modern science by protesting that the need is for "more and more natural science." Besides expressionism of the Western types there is an Eastern cult; while one school is actively political another is mystical and abstract;

while an international school calls for a new humanity, a German school demands a new German type of humanity. These groups are not susceptible to such clear local distinctions as in painting, where the Munich set of the " Blauer Reiter " stands apart from the Dresden " Brücke " set. The Prague group, with Meyrink, Brod, Kafka and Werfel, is perhaps more Eastern and mystical, the group assembled in the *Aktion* in Berlin more " activist " and political. But Berlin is also the home of the poets of the *Charon* and of the *Sturm*, the one an essentially Nordic-Germanic cult of metaphysical " expressionism " while the other bears the stamp of abstract internationalism.

The First Phase of Expressionism.—In point of time, the new literary movement falls mainly within the decade 1910–20. It broke through in two main thrusts. With " manifestos " and " radical strophes " the " apocalyptic striplings " led the onset. Kurt Hiller in Berlin gathered adherents into the " Neuer Klub," the " Gnu " and similar associations; he collected their verses in the *Condor* in 1912. Franz Pfemfert welcomed them in the *Aktion*, Alfred Richard Meyer in the *Bücherei Maiandros* and in his *Lyrische Flugblätter*. So Paul Zech in *Das neue Pathos*, Ernst Blass, in Heidelberg, in *Die Argonauten*, Herman Meister in *Saturn*, and he also published in the *Flut* collection a first *Anthology of the Most Recent Belles Lettres*. In Munich two of F. S. Bachmair's periodicals were entitled *Die Revolution* and *Neue Kunst* respectively. But this poetry, especially at first, often betrayed the influence of George and Rilke in form, and still more in rhythm; although, straining out beyond it. Not for nothing were the new periodicals which Dauer began to issue in Berlin in 1910 and 1911, called *Der Sturm* and *Die Aktion*. After these two, the most important periodical of the new school was the Leipzig *Weisse Blätter*, which first appeared in the autumn of 1913. The many-voiced yearnings of the time, their yeas and nays, find their most emphatic, clearest and purest artistic utterance in Theodore Däubler's three-volume epic *Das Nordlicht* (1910), Otto zur Linde's *Collected Works* (1910 *seq.*), Franz Werfel's poems (*Wir Sind*, 1913), the verses of Georg Heym, Georg Trakl, Ernst Stadler, Gottfried Benn, August Stramm, Carl Sternheim's dramatic work, Reinhard Johannes Sorge's *Bettler* (1912) and George Kaiser's *Die Bürger von Calais* (1914). Already at this time, just before the War, a new publishing house on a large scale (Kurt Wolff) was founded in the interests of the new movement; and its collection, *The Newest Day*, gave a first survey of the new art and its chief authors.

The Second Phase.—The second main offensive, opened in 1914 with Walter Hasenclever's play *Der Sohn*, was held up at first by the War. The radical ideas of the new movement suffered under a rigorous government censorship. The *Aktion*, originally a " periodical for liberal politics and literature," became perforce for years a purely literary affair; the *Weisse Blätter*, of which René Schickele became editor in 1915, was issued outside Germany, in Zürich, where it served as a mouthpiece for young writers such as Johannes R. Becker, Albert Ehrenstein, Leonhard Frank, Rudolph Leonhard, Alfred Wolfenstein, Walter Hasenclever, Ludwig Rubiner. The more revolutionary ideas gained ground as the War dragged on, the more violently did the whole movement break through the dams, until the highest flood-mark was reached in 1918 and 1919. The breakthrough was signalled by a host of periodicals, usually shortlived, whose very titles flamed like beacons; and by new publishing firms. Besides the *Jüngster Tag* series, the *Neue Reihe* appeared, containing old and new names. From 1914 on, the breakthrough had visible effect on artistic forms. In lyrical poetry the change comes with J. R. Becker's *Verfall und Triumph* and August Stramm's *Gedichte*. The " analytic " drama of the immediate past gives way more and more to the new form of a " synthetic " series of pictures. Strindberg set the example. Originally lyrical and ecstatic, given to dramatic monologue—for monologue gives relief from the sober, practical methods or crude psychology of the preceding decades—the movement at the same time invaded prose-fiction. So, by the side of the new lyric and dramatic poets —Fritz von Unruh, Reinhard Goering, Paul Kornfeld—we find new novelists like Leonhard Frank, Gottfried Benn, Franz Kafka, Kasimir Edschmid, Alfred Döblin. The years 1919 and 1920 mark the close of an old period and the beginning of a new one. What real progress had been made was shown in the excellent anthologies and collections of this time. In the *Symphonie jüngster Dichtung—Menschheitsdämmerung*, put together by Kurt Pinthus in 1920, the *Anthologie junger Lyrik—Verkündigung*, issued by Rudolf Kayser in 1921; in Ludwig Rubiner's collections of poems *Weltrevolution—Kameraden der Menschheit* (1919) and in the *Novellen an die Zeit—Die Entfaltung* issued by Max Krell in 1921—in all these works an effort is made to assert the real value of the new achievements. A periodical such as *Der Genius*, which attempted to be for the expressionist era what *Pan* had been for the impressionist; such also as the two year-books of new creative and critical literature issued by Alfred Wolfenstein in 1919 and 1920 under the title of *Die Erhebung*—these were partly retrospective. Dramatic pictures like Alfred Brust's play *Die Schlacht der Heilande* or Arnolt Bronnen's *Vatermord* already indicated new developments, as did Wolf Przygode's series, *Die Dich*.[1]

In the period of naturalism, theory and criticism were the creative and directing forces; they created the novel of experience and frank " realism." Now it is otherwise; theory does not direct the work of art, but develops with it. *Charon* poetry preceded the theory of Charonism. Edschmid's famous discussions on poetic expressionism came after the early works which decided him. Kornfeld's studies of inspired man and psychological man appeared after his *Verführung*. The order is only reversed in the eccentricities of the movement, in the purely intellectual experiments. Yet here, as everywhere, will and deed fertilise each other. The most illuminating of the early books dealing with the movement are really those which treat of it in painting and sculpture; as Kandiusky's book on *Das Geistige in der Kunst*, Wilhelm Worringer's *Beitrag zur Stylpsychologie, Abstraktion und Einfühlung* and his *Formprobleme der Gotik*. Bergson, with his doctrine of creative development, takes the place of Taine. Siegmund Freud's teaching is greedily devoured; his psycho-analysis, the first real investigation of the soul, replaces the old dogmatism. Others are influenced by one who stands at the opposite pole from Hiller and Rubiner—the Zionist Martin Buber, the champion of every kind of belief in the vitality of myth and the redeeming strength of the soul. Rudolph Steiner's anthroposophic writings also have their effect. And if the new artist asks his hearer to rise to his level, to take a creative part in his work, yet two Austrian philosophers of the older generation, born in 1860—Alexander Meinong and Edmund Husserl—had already laid a scientific basis for these emotional demands in their *Untersuchungen zur Gegenstandstheorie und Psychologie*, in which they exploded the " Empiric bases of our knowledge," their *Ideen zu einer reinen Phänomenologie und phänomenologischen Philosophie* and their doctrine of pure " Wesensschau." Then between 1915 and 1920 appeared the publications which summed up what had gone before and laid down definite aims: Ludwig Rubiner's collection of fiery appeals, *Der Mensch in der Mitte* and his *Dokumente der geistigen Weltwende*, known as *Die Gemeinschaft*, Kurt Hiller's year-books of spiritual policy, *Das Ziel* and Kasimir Edschmid's voluminous collection *Tribüne der Kunst und Zeit*.

The New Lyric.—In the period of naturalism prose-fiction predominated, but in the decade 1910–20, the lyric. The drama is lyrical, and even the novel is steeped in lyricism; despite itself, the influence of the lyric gives it something of the ballad in this decade. As every realist drama bore the marks of its derivation from the story or sketch, so every drama of this period bears the marks of its lyrical origin, down to the very stage directions. The lyric poem itself in this period is generally an endless flow of melody; it is also characterised by a wealth of interjections; it relieves its emotions by an excess of O's, Ah's and How's, suggesting an elemental outburst of dark, shapeless, chaotic forces.

[1] Expressionism apparently began as a secret language for the initiated, but within a few years it had become the fashion, the current jargon of the literary market. Its divine fire, its exaltation and ecstasy were made ludicrous by the " Dada " movement; the artist, the prophet, the creator of values were succeeded by mountebanks who denied all values.

At first calmer, more harmoniously restrained temperaments believed fervently in évolution without end, in a new art not needing to renounce a noble heritage. This faith inspires the work of Ernst Lissauer (b. 1882), Leo Sternberg (b. 1876) and Georg Hadwiger. It is significant that these authors are closely bound up with the ballad and the ballad-mind, that when the War affects them it does so as the fate of the German world, German humanity, as a German war—not as a World War, as the murder of man's image as a whole.

But the thought that a new art can only be won at the price of a frightful world catastrophe, darkly foreshadowing itself in art, breaking in advance all moral laws before shaking the world of the past into chaos—this foreboding it is—shown in images, emotions, rhythms, not yet degraded into lyrics of war or revolution—that gives the poems of George Haym (1887–1912), Georg Trakl (1887–1914) or Ernst Stadler (1883–1914) their peculiar position. These are as yet no agitators; they are still pure poets, prophets; they were broken before the War began, or they broke in its first months. Only a happier star preserved Paul Zech (b. 1881) and Armin T. Wegner (b. 1886) from a similar fate; they too might have been broken by the irreconcilable antagonisms of their experience, pit and forest, country and town, had not a new consciousness of community preserved them. It is this same feeling of community, or the longing for it, that gives the analytic " brain poetry " of Hoddis, Lichtenstein, Boldt, Benn, Lotz and Klemm the strength and light which shines through the verses of the *Aufbruch der Jugend*. The same feeling in the poems of Franz Werfel, who as regards form is by no means always a " new " lyricist, accounts for their effect on a whole young generation, which gives him secure significance by taking him for a model. This is the feeling, enhanced by war and revolution, which fills the verses of Alfred Wolfenstein (b. 1888) and René Schickerle (b. 1883), till in the hymns of Johannes R. Becker (b. 1891), the poet of Utopias, it rises to boiling-point and evaporates. Yet it would be a mistake to suppose that this feeling of community, this creed of " Thou and One Another," is the only element in the poetry of the time. There are lonely brooders, like Else Lasker (b. 1876), Theodor Däubler (b. 1876), Albert Ehrenstein (b. 1886), whose poetry springs from quite other sources. Herwarth Walden's *Sturm* united all lyric poets who repudiate any continuity of thought as inartistic and wish to weld the lyric into a pure linguistic form of vowels and consonants, a pattern of " associated " sounds.

The New Drama.—German expressionist drama does not break quite such new ground as expressionist poetry. It has two models, Franz Wedekind and August Strindberg, and it rings continual changes on their themes. In their works they present the new problems, and at the same time solve these problems in the exemplary manner, whether as spectacular or interpretative dramatists. They create the new acting and the new staging. Strindberg and Wedekind are accepted as masters by many without tradition who cherish a confessed or unavowed longing for moorings and firm anchorage. These are lonely bearers of the message of community; the defeated who yet must seek to save either the world or themselves; the godless who yearn after God; slaves of impulse whose instincts are unsure; beast-men in the grip of dark forces, brain-men who have experienced in their own lives the curse of a purely intellectual estimate of all life; those oppressed by a sense of the meaninglessness of many a life, or of all life, who yet long to find a meaning. The votaries of this world, those who adore flesh and blood, live on Wedekind; those of the world beyond, who worship the spirit, live on Strindberg; but both alike are unredeemed victims following a way of the Cross. Whether calling themselves saints or penitents, they are torn by a torment which drives them through " heaven and hell." It is no mere chance that these latter words are the title of an essentially important work of this time, a play, by Paul Kornfeld.

But besides Wedekind and Strindberg there is a third originating ancestor and an earlier—Georg Büchner (1813–1851), the creator of *Woyzek*, that drama which is nothing but a Way of the Cross, nothing but a view of the world through the soul of a hapless martyr. There is hardly one expressionist drama without the Woyzek frame of mind, the Woyzek characterisation, the Woyzek life-blood. These outlines may suffice to show how inadequate is the term " expressionist dramatists; " how varied can be the world which an " expressionist " dramatist reflects. Halfway between the two periods stands Carl Sternheim (b. 1881). In his hatred of the bourgeois which inspired the comedies *Aus dem bürgerlichen Heldenleben* he is akin to Wedekind; but he despises the doctrine of brotherliness and love of mankind, he is dry and cold, crystal-clear, free from mist, a virtuoso of form, his every word plain and unmistakable. Georg Kaiser (b. 1878), the " cubist " of drama, is as true to form, but you cannot grasp him; the man is an enigma like each of his works.

They seem to come out of some other age than ours and to pass into yet another—creations of impassioned suffering or of pleasure in the " game of thinking," as Kaiser once termed his ideal of drama. What have Sternheim and Kaiser in common, beyond the joy in solid construction? Not even that connection exists between them and another pair, the poet of the blessed ego and him of the accursed ego, the poet of *Bettler* and the poet of *Himmel und Hölle*, Reinhardt Johannes Sorge (1891–1916), that pious disciple of Christianity; and Paul Kornfeld (b. 1889), the young apostle of an all-believing orientalism. Or what have these " philosophic politicians " in common with the real politicians, with Ludwig Rubiner (1888–1920) and Ernst Toller (b. 1893), the author of *Masse Mensch*, or with Reinhard Goering, author of *Seeschlacht* and *Scapa Flow*, or with Fritz von Unruh, the writer of *Louis Ferdinand* and *Ein Geschlecht*, whose whole work is inspired by the desire to show the symbolic meaning of the sorrows of mankind to-day in a myth of mankind future? The young humanity of Walter Hasenclever (b. 1890) revealed in his *Der Sohn*, what has it in common with the other young humanity of Hans Johst (b. 1890) in his *Der junge Mensch?* Or that other again of Anton Wildgans (b. 1881) in his *Dies Irae?* What is the link between the two artists from the sister realm of painting and sculpture, the terrified dreamer Oskar Kokoschka (b. 1886) and " Ernst Barlach " (b. 1870), that seeker after God? Or between legend-writers like Dietzenschmidt (b. 1893) on the one hand and Rolf Lauckner (b. 1887) or Alfred Brust (b. 1891) on the other? We see that expressionist drama, almost more even than the expressionist lyric, is the utterance of an age of confusion: it reflects the death-pangs of one world, the birth-pangs of another.

The New Prose-fiction.—The picture that we gain of expressionist prose-fiction is quieter. The reason is not far to seek; for if " the substance of the age "—all it " holds " of the past, present and future—is more clearly shown here than anywhere else, yet the novel seems alien to the " form of the age," the expressionist style. Expressionism is lyrical compulsion, dramatic impulsion, not epic propulsion. The longing of the age for the images of a new humanity and a new community offers many-sided satisfactions to the novelist. He is tempted to bring Utopias nearer our reach. But in conjuring up the picture of a future world, he forsakes to-day's world of chaos; out of its wreckage he makes a new world by new laws; but, above all, he sees one thing: that the spirit can create no world unless it begs Nature to assist it. Many a modern catchword is shattered by the restrictions of tale-telling art: among them phrases like " pure spirit " or " metaphysical space." There have been only isolated attempts to create pure " brain work." In fact, novelists like Gustav Sack, Kasimir Edschmid, Alfred Döblin, have proved, both by their work itself and by their own pronouncements on it, that they will have nothing to do with narrow-minded antagonism to nature. Certainly their work is no mere passive reflection of nature. Prose fiction of to-day requires scenic description, where life and its circumstances must be represented as in the historical or exotic novel; yet this is not now done at a leisurely length unbroken by action, but by a more concentrated method seizing on the decisive moments when significance springs out of circumstance.

Similarly, the outward and surrounding world is always being absorbed into the world within us; each man creates for himself a new outer world, which is nothing but his own soul projected

into external form, the representation of all its impulses, the laying bare of its inmost secrets. The manner of narration, too, with its terse words and concise sentences, the accents of unrest and agitation—this is the very opposite of the old descriptive mode. The impression which all this gives is heightened by an avalanche of incidents. Events come thick and fast to match the hurrying giddy frivolity of life to-day, a whirling vortex chafing nerve and spirit. The long-starved appetite for material is glutted. We have a variegated cinema-world shown often by a cinematic method in novel-writing—jerky, abrupt, tempestuous, with flickering lights. We may pass by the hangers-on and imitators of the true expressionist movement.

The weary search of this age after a meaning in existence is tragically uttered in the works of the best novelists of Expressionism. Metaphysicians and believers like Max Brod (b. 1884), unbelievers like Gustav Sack (1885–1916) and Gottfried Benn (b. 1886), exhaust themselves in struggles of joy or despair. Kasimir Edschmid (b. 1890) flies to adventure for a firm foothold and plain idea; " Klabund " (Alfred Henschke, b. 1892) ceaselessly changes his phases; Leonhard Frank (b. 1882), author of *Der Mensch ist gut* (a collection of short stories), believes that he can find salvation in a renewed feeling of community. Another, Franz Kafka (d. 1924) sees that in this world there is no salvation, that all we can do is to gain a glimpse of the heaven of another world through the artistry of pure literature. Others again, as " Mynona " (Salomo Friedländer, b. 1871), construct a fabulous realm of new forces and seek to prove that nothing is more fantastical, more like a Utopia than nature. The work of Alfred Döblin (b. 1878) is inspired by the same feeling and leads him to the same conclusion in his romance of the future, *Berge Meere Giganten*, which describes titanic battles between mankind and nature.

The Reaction.—As indicated above, the wave of expressionism reached its height in 1920 and then suddenly broke altogether. After the boundless over-conceit which every revolution brings came a moment when the artist paused to reflect while the public was sobered. Will and deed, claim and achievement, promise and performance had been taken as one. In expressionism men had seen the revolt of the spirit against matter, of liberty against mechanical slavery, of creative force against the receptive mood and formal reason. All this was regarded as a vision of the future illuminating the background of a shattered past. But the course of the political revolution, in particular, showed that new humanity, after all, was subject to the original sin of all existence, the luckless children of a luckless age which lets no man be without devouring him again as a victim. Expressionism, in its latest phase, is usually the tortured outcry of the mangled victims of an age who yet believe themselves its saviours.

It is thus not surprising that literature once more seeks and finds contact again with powers and forces to which artistic teaching just before had denied any importance whether for substance or form. In our survey of the development of prose-fiction we have mentioned the return to nature. In literature, as in all art, there was talk of a " new reality," a " new objectivity," a new kind of literal naturalism. This new realism was termed "Magianism," to signify that it had borrowed essential characteristics from expressionism, and like it satisfied metaphysical needs. The name " Verism " means much the same. Hand in hand with a new reverence for nature goes a new regard for science, even for technique where it is creative. A novelist like Josef Ponten (b. 1883) is struggling, consciously or unconsciously, towards a marriage of science and art. The new task appears to be to spiritualise, elevate, to mythify everything belonging to science and mechanism, and all the characteristic factors of civilisation in our time. In the same way re-arises respect for tradition. The consciousness of a culture, nourished by all ages and peoples, comes to its own again; it finds its highest expression in the writings of Albrecht Schaeffer (b. 1885) whose comprehensive three-volume *Helianth* (1920) is one of those romances of education peculiarly significant in German literature, while his *Parzival* (1920) is one of the equally typical poems of deliverance. But another part of German literature took new blood from new spiritual experience. The all-embracing international love which poets and playwrights, especially of Jewish origin, had proclaimed with particular fervour, was ruthlessly destroyed after the War by the events of foreign and domestic politics. Then writers began again to think of the elemental forces of race and nationality, out of which the super-national, super-temporal always sprang. Finally, a German neo-Catholic school of letters is undeniably growing up (R. J. Sorge, 1891–1916; Dietzenschmidt, b. 1893; Leo Weismantel, b. 1888).

This renewal of substance is accompanied by a revision of form. Here, too, faith in the tranquillising, uniting forces tends to gain the upper hand over faith in revolutionary and disruptive forces. Idiom is becoming fixed; dramatic and epic structure more coherent; the form of the lyric more crystallised. In close connection with the new thinking there is a fresh appreciation of workmanship, of ability, of technical mastery—things laughed at by a yesterday which had forgotten the " how " in its concern with the " what." The development of the novel and the drama show most clearly why the art of the most recent years is tending towards a compromise between naturalism and impressionism on the one side, expressionism on the other. How varied can be the forms of this compromise is shown by the work of novelists like Albrecht Schaeffer, Josef Ponten, Wilhelm Lehmann (b. 1882), Rudolf G. Binding (b. 1867), Otto Flake (b. 1882), Frank Thiess (b. 1890), Arnold Ulitz (b. 1888). A good survey of this modern art of prose-fiction may be obtained from the " Library " of modern stories *Der Falke*, which has been appearing since 1923. In drama the tendency to get lost in Utopian ideals, with the vagueness which often accompanied it, has given way to a method that comes nearer to earth with more sureness and firmness of outline. Where the dramas of Arnold Bronnen (b. 1894), Bertolt Brecht (b. 1894), Max Mohr (b. 1891), Otto Brües (b. 1897), Friedrich Griese (b. 1890), Rolf Lauckner (b. 1887), Hans W. Fischer (b. 1876), Paul Gurk (b. 1880) are in advance of the dramas of the pure expressionists is in their genuine feeling for the theatre itself. In lyric poetry the new purpose and the new faculty are seen in the work of Oskar Loerke (b. 1889), Friedrich Schnack (b. 1888), Anton Schnack (b. 1892), Fritz Walter Bischoff (b. 1896), Ina Seidel (b. 1885 and Ludwig Strauss (b. 1892). The word *World-Inwardness* (*Weltinnigkeit*), chosen by Ina Seidel as the title of a volume of poems, well defines the spirit of the new poetry.

GERMAN OFFENSIVE (March–June 1918).—After the loss of the battle of the Marne, in Sept. 1914, and the abortive operations which followed it on the Aisne and in Flanders, the German higher command changed the idea which underlay their strategy. In Aug. 1914 their main blow was to be dealt against their strongest adversary, and France was to be crushed before Russia could develop her strength. The decisive victory of Tannenberg had, however, opened their eyes to the rottenness of the Russian Army, and from Oct. 1914 onwards until March 1918 the aim of the German General staff was to hit at weakness in order to isolate their strongest adversary, namely, the French. The series of battles carried out during the first six months of 1916 in the neighbourhood of Verdun was no exception to this crucial strategical idea, since its aim was defensive—that is, its intentions was not to gain a decisive victory in the West, but to dislocate the impending French and British operations and gain time wherein to defeat Russia.

The campaign in Russia, however, dragged on, the same conditions appearing as in 1812—climate, lack of communications and distance rendering every tactical victory abortive. To make up for this delay, in the autumn of 1916 Rumania is selected as the weakest point of attack, and is overrun. A year later Italy is selected, and the result is the Italian débâcle at Caporetto

Simultaneously Russia, to all intents and purposes, disappears as a hostile power, so that by the end of 1917 Germany could once again turn to the task she had abandoned in the autumn of 1914, namely, the defeat of the French now so strongly supported by the British Empire.

The political situation which faced the Imperial Govt. in Berlin was one which demanded a rapid conclusion of the War. Not only had unrestricted submarine warfare failed to produce the attrition expected, but the stranglehold of the British Navy was daily reducing the morale of the German people. Of her allies, Turkey was the only one who seemed to be in earnest. Bulgaria's interest in the War was waning, and Austria and Hungary were worn out, having lost nearly 2,000,000 men in prisoners alone. These conditions demanded immediate and decisive action if the War was to be won before America could develop her strength.

Whilst the Central Powers had been striking at weakness, Great Britain had been engaged in a similar strategy. The stalemate which had been established on the Western Front, and the abortive campaigns which had followed this stalemate, had forced her into seeking a line of least resistance by means of her navy, with the result that, by the end of 1917, a serious dispersion of fighting force had taken place, extensive operations being in progress in Palestine, Macedonia and Mesopotamia, without counting minor campaigns in Africa. Further, the British forces in France had been bled white, the Arras, Messines, Ypres and Cambrai battles having alone accounted for 650,000 men. The general situation was that whilst France had been recovering her strength the British forces had grown steadily weaker. The offensive initiated by Germany on the Western Front in March 1918 is here described as three main battles, namely, I. St. Quentin; II. The Lys; and III. Soissons-Reims.

I. THE BATTLE OF ST. QUENTIN

General Ludendorff, who by now had become the directing genius of the German war brain, was faced by the problem of where the decisive blow should be struck, and determining to strike at weakness he selected the British front for the decisive attack. This front may be divided into three sectors —Flanders, the Bruay area and the country southeast of it between Cambrai and St. Quentin. The first of these was obviously unsuited for offensive action of a decisive nature, as the British operations of 1917 had clearly shown. The second offered an opportunity of striking at the French coal supply, a vital factor, but the front of attack was restricted and difficult. The third included good offensive country, as it consisted of open field land and led to the valley of the Oise, a natural avenue leading to Paris.

Ludendorff's Opinion.—Though Ludendorff writes that "tacties had to be considered before purely strategical objects which it is futile to pursue unless tactical success is possible," a successful attack in this direction would not only isolate the British forces by severing their connection with the French, but, if pushed towards Paris, would jeopardise the line of communications of all the French forces situated east of Soissons. The strategical possibilities of such an attack are therefore closely comparable with those of the original plan of campaign worked out by Schlieffen long before the War. To deliver this blow Ludendorff proposed to muster every available man and gun and further to accentuate the force of numbers by surprise, for the tank attack at Cambrai and Hutier's gas attack at Riga had demonstrated the overwhelming power of an unexpected assault. He saw clearly that the forthcoming struggle would be no light one, and in an audience at Homburg with the Kaiser and the Chancellor he said:—

"The battle in the West is the greatest military task that has ever been imposed upon an army. . . . It cannot be successfully accomplished unless the authorities who conduct the War are relieved of all intolerable shackles, unless the very last man is employed in the decisive conflict, and is animated, not only by love for his emperor and his native land, but by confidence in the strength of the military leadership and the greatness of our country. These spiritual forces must not be underestimated, they are the foundations of the greatest deeds. . . . We must not imagine that this offensive will be like those in Galicia or Italy; it will be an immense struggle that will begin at one point, continue at another, and take a long time; it is difficult, but it will be victorious."

The Opposing Forces.—Between Nov. 1 1917 and March 21 1918 the German divisions on the Western Front were increased from 146 to 192, troops being withdrawn from Russia, Galicia, Italy and the East. By these means the German armies in the West were reinforced by no less than 18,492 officers and 553,794 other ranks. Finally it was decided to make available 62 divisions and 1,706 batteries for the main attack. These troops were carefully trained for mobile warfare on any sector of the French and British fronts, the greatest secrecy being maintained as to the actual area of attack, which extended from the south of Lens in the north to a little south of La Fère.

On the side of the Allies, except for a few miles in the north, this front was held by the III. and V. British Armies respectively, commanded by Sir Julian Byng and Sir Hubert Gough. The front of the III. Army extended from just south of the village of Gavrelle to half a mile north of Gouzeaucourt (26½ m.), and on March 21 was held by 10 divisions in line and seven in reserve. The V. Army front (42 m.) ran from the right of the III. Army to the village of Barisis, a little south of the river Oise, between the forests of Coucy and St. Gobain. On this extended front there were 11 divisions in line and three in reserve.

German Plans.—The plans of attack were issued by the Supreme Command on Jan. 24 1918. The attack was to be carried out by four armies:—

(*a*) XVII. Army (Below), comprising 17 divisions, was to attack on the frontage Gavrelle-Moeuvres.
(*b*) II. Army (Marwitz), comprising 18 divisions, was to attack from Moeuvres to Pontru (north of St. Quentin).
(*c*) XVIII. Army (Hutier), comprising 24 divisions, was to attack from Pontru to Vendeuil (south of St. Quentin).
(*d*) VII. Army (Gayl) was to demonstrate with three divisions against La Fère.

The various attacks were named as follows: XVII. Army, left wing attack "Mars" (south of Bapaume), right wing "Michael I." (north of Bapaume); II. Army, "Michael II.," to the north of the Omignon brook; XVIII. Army, "Michael III.," north and south of St. Quentin; VII. Army, "Archangel," south of the river Oise. The "Michael" attacks were to be delivered on the first day of the battle, followed a day or two later by the "Mars" and "Archangel" attacks. The object of the "Michael" attacks was to penetrate the enemy's front, and then, supported by the "Mars" attack, both were to push on through Peronne-Arras and Peronne-La Fère.

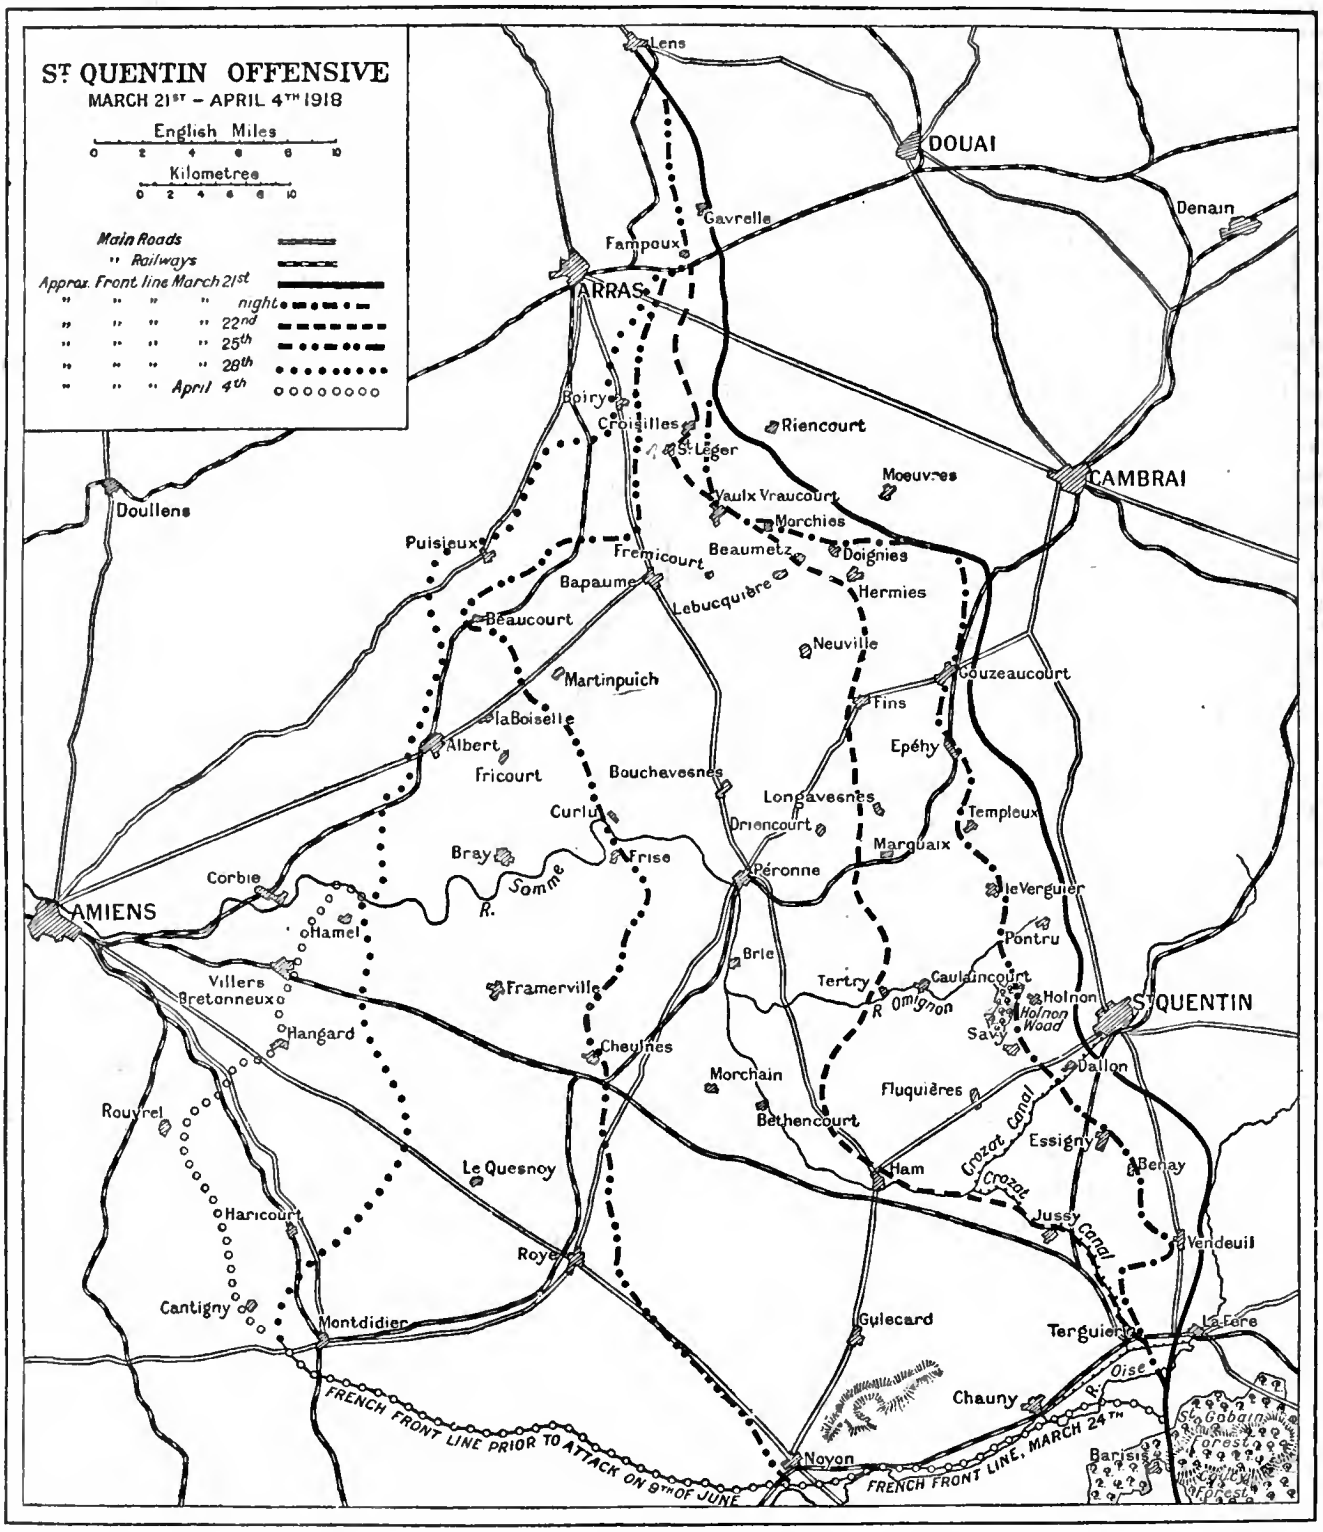
To bewilder the enemy as to the frontage selected for the main attack, subsidiary operations were prepared all along the Allied front, at Ypres-La Bassée, Reims, the Argonne and in Champagne. From March 14 onwards the crown prince was to bombard the enemy's headquarters on his front and make a show of bringing up reinforcements, and Gallwitz was to carry out an attack on Verdun up to the point of engaging his infantry.

Preparations for the Attack.—The forming up for deployment of the attacking armies was begun on March 10, the divisions being organised in groups normally in a depth of three lines. The first or assault line was made the strongest, and was moved close up to the front on March 20. The second line of divisions was some three to five km. in rear, and the third seven to ten km. behind the second line; this third line was to be held in reserve under the higher command, and was only to be used as the operations developed.

On March 20 all was in readiness for the attack, which was to be preceded by a three hours' hurricane bombardment in which gas was to be employed extensively by the artillery and minenwerfers. By this means it was hoped to paralyse the enemy. On the 20th, however, the wind was at first unfavourable, but by midday conditions had sufficiently improved to permit of the bombardment taking place. It was opened at 3:30 A.M. on the 21st, the Allied batteries being first gassed.

The infantry attack did not, however, take place until 9:40 A.M., when a general move forward was made under a creeping barrage supplemented by low-flying aeroplanes.

March 21.—The attack of the XVII. Army was met by strong opposition, which was accentuated by the fact that the infantry



were unable to keep up with the barrage. At Vaulx-Vraucourt and Doignies strong counter-attacks were launched against them, and by nightfall the German divisions had to be reinforced by second line troops. The II. Army advanced to the line Gouzeaucourt-Epéhy-Templeux-Le Verguier, a fierce struggle taking place at Epéhy, which throughout the day remained in British hands. The XVIII. Army was more successful. Its right captured Holnon and Holnon wood; its centre got to Savy and Dallon, and its left captured a part of Essigny and Benay, but was checked a little west of Vendeuil.

On the 22nd the attack was continued with vigour. The XVIII. Army was reinforced and was ordered to advance on Tertry to facilitate the operations of the II. Army, which had outrun its artillery support. The brunt of the fighting fell on the XVII. Army, which attacked the British second line of defence again and again, only to be met by vigorous counter-attacks supported by tanks. Towards the close of the day, but only after having been reinforced by third line units, it succeeded in capturing Croiselles, Vaulx-Vraucourt, Morchies and

Hermies. The II. Army pushed forward to Fins-Longavesnes-Marquaix-Caulaincourt, and the XVIII. Army captured Fluquières and crossed the Crozat Canal between Jussy and Terguier.

From the positions held on the 22nd the XVII. Army advanced on Bapaume and captured Driencourt, St. Léger, Beaumetz and Lebucquière. The II. Army reached the line Neuville-Bouchavesnes-Bric, and the XVIII. Army crossed the Somme at Bethencourt and captured the town Ham.

Between the 24th and the 26th the advance was steadily continued, and on these three days the German front was advanced to the following lines respectively: (*a*) 24th, Chauny—Guiscard—Morchain—west of Peronne—Curlu—Fremincourt—Fampoux; (*b*) 25th, Noyon—east of Roye—east of Chaulnes—Frise—Beaucourt—Boiry; (*c*) 26th, west of Noyon—Le Quesnoy—Framerville—Bray—east of Albert—Pusieux—Boiry.

Ludendorff's Second Plan.—The first great stage of the attack now drew to a close, for not only had British resistance stiffened, but the difficulties of supplying the advancing armies over the old Somme battlefield were so great that it was found impossible to maintain the leading troops. The result of this was that on the evening of the 26th Ludendorff determined on a change in plan. He now decided to separate the British and French forces by wheeling the II. and XVIII. Armies against the latter. The difficulty of supply was, however, too great for this change of front to succeed, consequently on the 27th Ludendorff made a further change. He ordered the XVII. Army to close down the attack, and the XVIII. Army and left of the II. Army to attack the French between the Oise and the Somme. By March 30 this attack advanced the huge pocket which had been found in the Allied front from a little south of Noyon to west of Montdidier, thence through Haricourt and Hangard to the Somme north of Hamel.

Between this date and April 4, further attacks, mostly of a minor nature, extended the pocket from west of Montdidier to east of Rouvrel, thence through Hangard east of Villers-Bretonneux to east of Corbie on the Somme. On April 4 the great battle to all intents and purposes came to an end. The initial success had been great; since March 21 from a base of 74 m. a penetration of no less than 38 m. had been effected; the ground lost in 1916 and abandoned in 1917 had been more than made good, and enormous booty as well as 90,000 prisoners and 1,200 guns had been captured. The British Armies had been seriously defeated, and 20 French divisions had been drawn into the battle; yet, in spite of the fact that 90 German divisions had been engaged, neither the transition to a war of movement nor the separation of the British and French forces had been achieved.

Causes of German Success.—The initial successes of this great battle were due to the length of front attacked; the comparative weakness of the British forces when compared with the length of line held by them; the rawness of these forces due to the losses suffered during 1917 which had been made good by hastily trained troops; and the surprise of the attack itself, for though the British higher command suspected an attack on the fronts of the V. and III. Armies, when the attack was launched many of the reserve divisions were still in the Flanders area. The failure of the battle was due to well ascertainable causes, the two most important being the comparative narrowness of the front when compared with the depth of penetration required in order to obtain a decisive result, and the insuperable difficulty of keeping an advancing front of many divisions supplied. The German front of attack on March 21 stretched from three m. south of La Fère to three m. south of Lens, a distance of about 74 m. and by April 4 the depth of the penetration effected was some 38 miles.

A study of the various pockets formed by frontal attacks throughout the War will show that the depth of penetration was approximately half the length of the front attacked. Consequently, if it was necessary to reach Abbeville, which is about 60 m. from the original German front, in order to effect a separation of the British and French forces, so as to enable a change of front on the line Abbeville-Soissons being made towards Paris, the initial front of attack should have been as least 120 m. in width. Though the German forces were insufficient to attack on such a frontage, had they been sufficient the second factor, namely, difficulty of supply, would in all probability have wrecked their plan.

We thus see that any attempt on the part of the Germans to win the War by an immense frontal attack before the Americans could develop their strength was, as long as the Allies resisted stubbornly, virtually an impossible operation. This by April 4 was realised by the German higher command, for the battle on the Amiens-Noyon front was closed down, save for minor operations south of La Fère, and other fronts of attack were sought, namely, those west of Lille, south of Laon and north of Compiègne, which were attacked on April 9, May 27 and June 9 respectively.

II. THE BATTLE OF THE LYS

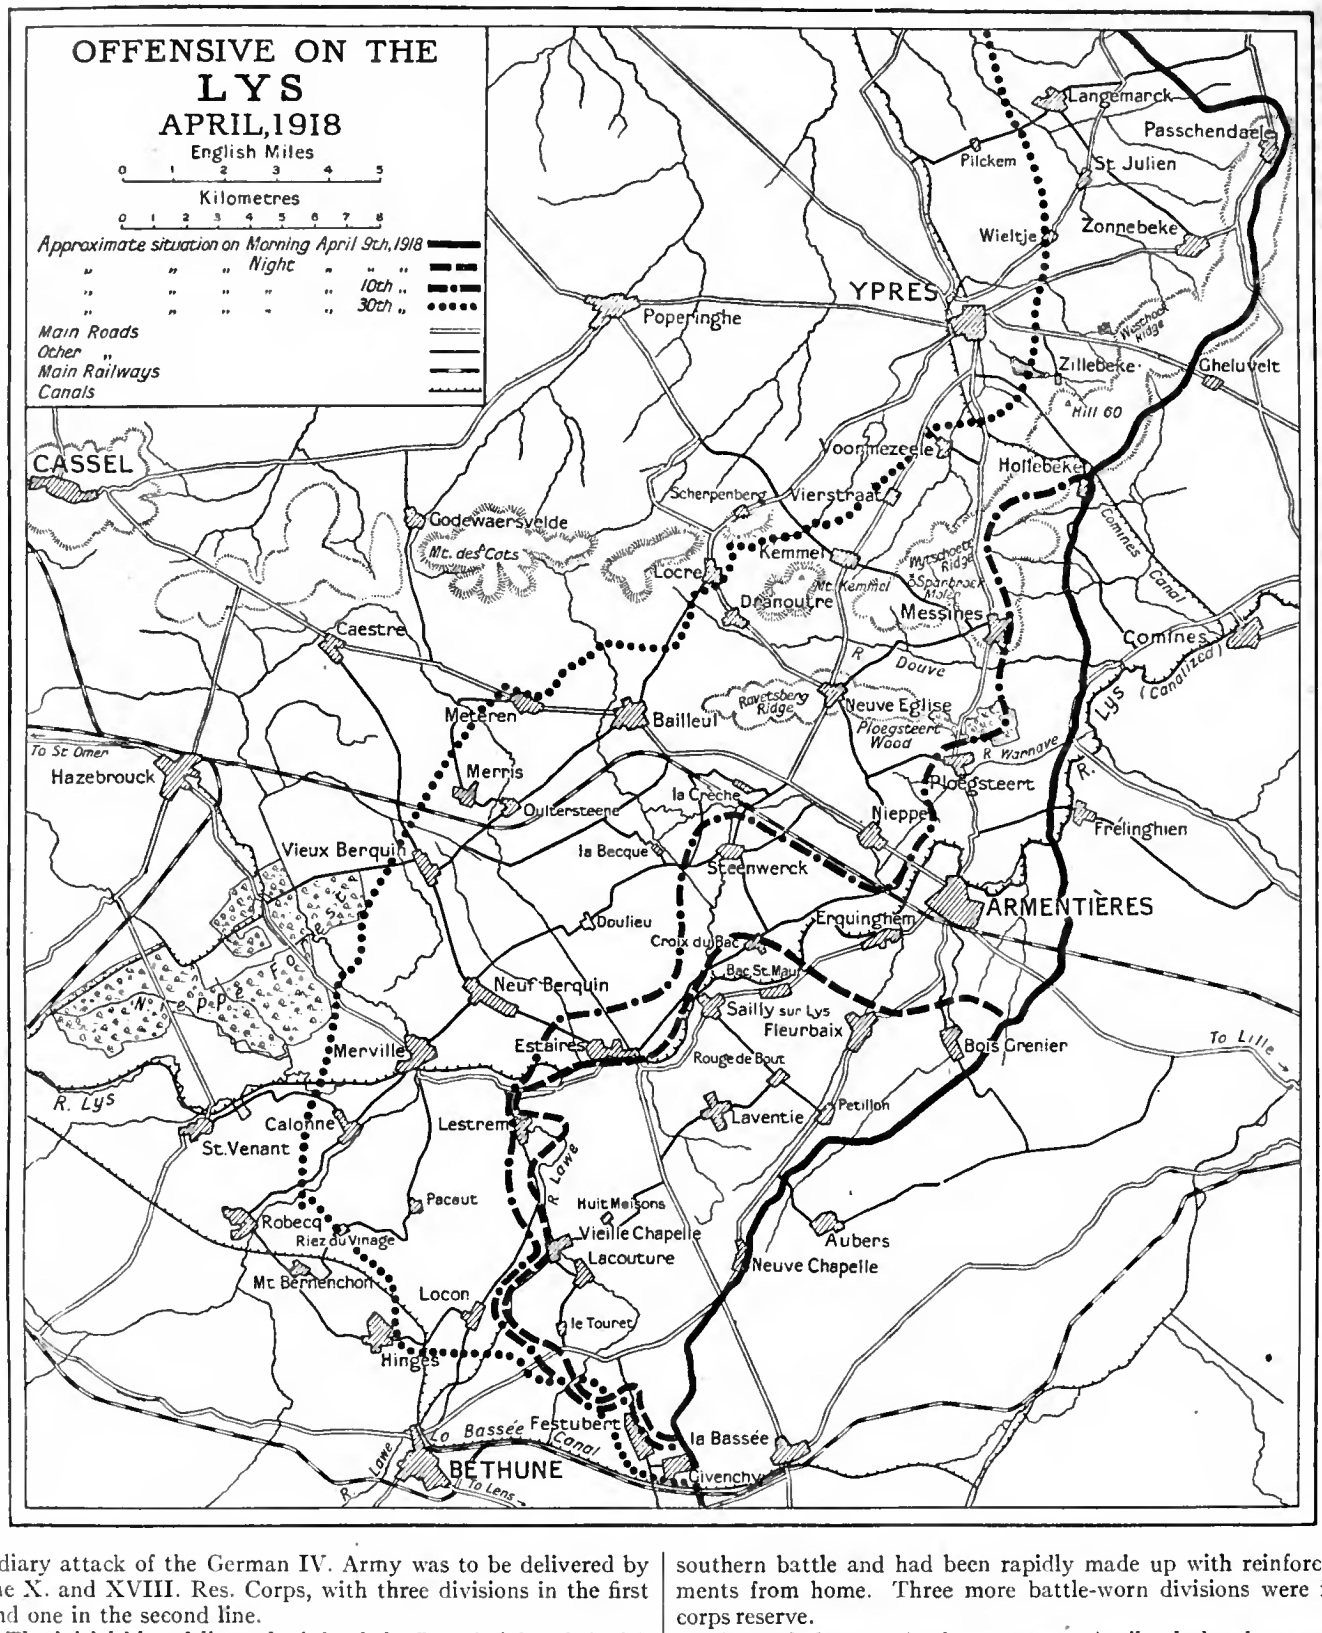
In the general scheme of the great German offensive of 1918, the idea of breaking through the British-Portuguese front in French Flanders was considered by the German High Command. Although this scheme became secondary to the great offensive further south, the preparations for it were carried out, firstly in order to mislead the British and Allied headquarters, and secondly that the Germans might be able to revert quickly to it in case the Somme offensive should come to a standstill.

When on March 30 it became obvious that no further progress was possible in the southern battle area, the German Supreme Command decided to put into effect the Flanders attack, the preparations for which were nearly complete. Although they did not anticipate that they would be able to force a decision in this area, there were certain definite advantages to be obtained from a successful blow in the direction of St. Omer-Hazebrouck and the local situation favoured, in their opinion, the prospect of success. This was to be the second blow struck against the British Army, a great proportion of which had already been employed on the southern front. The main weight of the initial blow was to fall on the Portuguese division, known to be less experienced and of less fighting value than British formations.

The abnormally dry weather gave good grounds for hope that the Lys valley would be practicable, a state of affairs which was not the case till much later in the spring in a normal year. The only lateral lines of communication in this sector of the British zone, other than the coast railway, ran through St. Pol-Lillers-Hazebrouck, and if the use of this could be denied to the British, problems of supply and reinforcement would be immeasurably complicated. It was above all important, in the view of the German Supreme Command, to retain the initiative, and to strike a second blow before the French could organise a counter-attack against the somewhat vulnerable southern flank of the salient which had been created by the success of the Somme offensive.

Plan of Attack.—The general plan of attack was that the main blow should be struck by Quast's VI. Army on the front between Armentières and the La Bassée Canal, in the direction of Hazebrouck. If the VI. Army's attack met with sufficient success, the IV. Army under Arnim was to advance north of Armentières, which was to be made to fall by envelopment, with the eventual object of securing the heights stretching from Kemmel to Mt. des Cats, south of the Ypres-Poperinghe road. If this were achieved the British and Belgian positions in the Ypres salient and on the Yser would be threatened from the rear. The extension of the attack southwards was a secondary consideration, but it was hoped that at least the destruction of the important mining area south of Bethune might be achieved.

Forces Engaged.—The forces available for the operation of the German VI. Army were four corps, from north to south, the Bavarian II. and German XIX., LV. and IV., to which were allotted nine divisions in the first line and five in corps reserve. Three more divisions were retained in army reserve. The sub-



sidiary attack of the German IV. Army was to be delivered by the X. and XVIII. Res. Corps, with three divisions in the first and one in the second line.

The initial blow fell on the left of the I. and right of the II. British Armies, under Sir Henry Horne and Sir Herbert Plumer, the point of junction between which was, on April 9, the Lys, east of Armentières. The XI. Corps (British 55th and Portuguese 2nd Divs.) and the XV. Corps (40th and 34th Divs.) held the front from the La Bassée Canal to the Lys, while the IX. Corps (25th, 19th and 9th Divs.) continued the line from the Lys to the Ypres-Comines Canal. With the exception of the 55th, all these British divisions had already taken part in the southern battle and had been rapidly made up with reinforcements from home. Three more battle-worn divisions were in corps reserve.

The Battle Opens.—At about 4 A.M. on April 9 the battle opened with an intense bombardment of the whole front from Lens to Armentières, with both gas and high-explosive shell. The front trenches were subjected to a rain of high explosive, while battery positions, cross roads, headquarters and railheads far in rear were treated with both gas and high explosive. Armentières itself and the British position south of the La Bassée Canal were deluged with mustard gas. The foggy morning made observation difficult, and, according to German accounts, the counter-

bombardment was ineffective. Between 8 and 9 A.M. nine German divisions, with ample reserves at hand, were launched against the two British and one Portuguese divisions. In the centre the weight of the attack of the German XIX. and LV. Corps overwhelmed the Portuguese 2nd Div., and both corps advanced steadily towards their objectives. The right of the Bavarian II. Corps was held firmly by the 40th Div., but the left of the Bavarians succeeded in advancing past the right flank of that division. On the British right the 55th Div. held stoutly on to Givenchy and north of that place withdrew slowly from the outpost position to the main line of resistance which ran just east of Festubert.

All available British reserves were hurried up; the reserve brigade of the 55th Div. was employed to form a defensive flank facing north, from Festubert, south of Le Touret to the Lawe. The 11th Cyclist Bn. and King Edward's Horse were rushed up to Lacouture, Vieille-Chapelle and Huit Maisons and by their heroic resistance effectually prevented any extension of the break through to the south. The 51st and 50th Divs. were moved up from the back areas to the river Lawe and the neighbourhood of Estaires respectively. Meanwhile the 55th Div. continued to hold its position at Givenchy and Festubert throughout the day and in counter-attacks against elements of the enemy, which had penetrated into their position, captured over 750 prisoners. The magnificent fight put up by this division completely broke the attack of the Prussian IV. Corps.

On the northern flank of the battle, the Bavarian II. Corps succeeded eventually in occupying the forward posts of the right battalion of the 40th Div., and gradually worked their way northwards. By 10:15 A.M. on April 9 the Bavarians were in Rouge De Bout, some 2,000 yd. in rear of the headquarters of the right battalion of the 40th Div., which was still holding out in Petillon. By noon the division was forced back by pressure in front and flank to a position facing south from Bois Grenier through Fleurbaix to Sailly-sur-Lys. Owing to the rapid advance of the German centre the 50th Div. was unable to gain touch with the 40th, the right flank of which withdrew across the Lys at Bac St. Maur early in the afternoon. The remainder of this division, reinforced by troops of the 34th Div., successfully maintained their line covering the approaches to Erquinghem and Armentières from the south, till the evening.

The Saxon XIX. Corps had rapidly followed up the right of the 40th Div. and about 3 P.M. succeeded in passing small bodies of troops across the Lys at Bac St. Maur. During the remainder of the afternoon and evening the strength of the German force north of the river steadily increased, and they eventually reached Croix du Bac, where they were successfully counter-attacked and driven back by a brigade of the 25th Division. During the night the Germans established themselves firmly on the north bank, in the gap between the 40th and 50th British Divisions.

Renewal of the Attack.—On April 10 the attacks were renewed all along the line. Practically no progress was made by the IV. Corps on the left. It was only just before nightfall that the LV. Corps succeeded in gaining a footing on the west bank of the Lawe between Lestrem and Vieille-Chapelle, and at Lestrem itself. At Estaires the 50th Div. defended itself with great gallantry and inflicted very heavy casualties on the enemy in the street fighting which continued all day. It was only at nightfall that this division was forced to withdraw to a prepared position north and west of the town. East of Estaires the German Corps, which had now got up artillery in support of its infantry and machine guns, pushed back the thin British line to a position north of Steenwerck, where the arrival of reinforcements for a time effectually held up the German advance.

Meanwhile, after an intense preliminary bombardment of the British positions between Frélinghien and Hill 60 north of the Ypres-Comines Canal, the German IV. Army about 5:30 A.M. attacked the British VIII. Corps. The outposts of the 25th and 19th Divs. were driven in and under cover of mist the German X. and XVIII. Res. Corps worked their way up the valleys of the Warnave and Douve rivers on the flanks of the British positions in Ploegsteert Wood and Messines. By midday the village of Ploegsteert, the southeast corner of the wood and Messines had been captured. During the afternoon the German attack succeeded in capturing the outpost position as far north as the Ypres-Comines Canal, but was held up on the crest of the Wytschaete Ridge and in front of Hollebeke by the 9th Division. The South African brigade of the same division retook Messines during the afternoon. This further success of the Germans, combined with the progress made by the right flank of the German VI. Army, gravely imperilled the situation of the 34th Div. which was holding the original line east of Armentières and had not been attacked. A withdrawal to the north bank of the Lys was therefore decided on, and was completed by 9:30 P.M. when the Lys bridges were destroyed.

On April 11 the attack was continued. The German IV. Corps again failed to make any progress between Givenchy and the Lawe river. North of Locon the British 51st and 50th Divs., weakened by continuous fighting, were slowly pushed back by the German LV. and XIX. Corps. The British divisions fought with the greatest gallantry and inflicted very heavy casualties, but bodies of German infantry worked their way through gaps in the attenuated line and by nightfall they had reached Neuf-Berquin and were in occupation of Merville. Further east progress was checked by a counter-attack of the 31st Div., which had arrived from the southern battlefield, but the Bavarian II. Corps pushed forward through Nieppe to Steenwerck. Slight progress was made by the German IV. Army between Nieppe and Messines.

Renewed Attacks.—During April 12 the arrival of reinforcements, mostly from the southern battle front, began to have its effect. The right flank of the British still held firm, but the German LV. Corps, attacking before dawn in the mist, broke through the left centre of the 51st Div., and reached Pacaut and Riez du Vinage, where their progress was checked by two batteries of artillery. The British 3rd Div. had come into action about Locon, which village was lost to the German LV. Corps, but the German advance was checked and their troops suffered heavy casualties. The right flank of the same German Corps was checked in Calonne by the 61st Div., which, like the 3rd, had arrived from the Somme battle area.

Meantime the Bavarian II. and German XIX. Corps attacked in great strength between Vieux Berquin and Steenwerck. In spite of the gallant defence put up by the 29th and 31st Divs. they succeeded in occupying Doulieu and La Becque, forming a gap southwest of Bailleul, which enabled the Germans to seize the villages of Outtersteene and Merris. This gap was eventually blocked by a brigade of the 33rd Div. reinforced by a party of cyclists, a pioneer battalion and by every available man from the local schools and reinforcement camps. Further to the left the 25th, 34th and 49th Divs. maintained their positions against all attacks. During April 12 headquarters of Prince Rupert's group of armies issued orders for the continuance of the attack by the inner wings of the two armies, with the dual objectives of Hazebrouck and the range of hills north of Bailleul. The VI. Army was also to prepare to continue the pressure of their left wing towards Bethune. On April 13 the German attacks north of the Lys were continued with great vigour. On the left, elements of the LV. Corps, which had penetrated into the outskirts of the Nieppe Forest, were driven back by the British 5th Div., which, advancing by two roads south of and through the forest, soon established themselves on a firm line clear of the woods, and finally checked the German advance in this area.

The German XIX. Corps continued to attack the 29th and 31st British Divs., now greatly diminished in strength by continuous fighting, but these formations, reinforced by the 4th Guards Bde., held on with the greatest heroism to their extended lines of nearly 10,000 yards. Except at Vieux Berquin, which was captured by the Germans, who brought up guns to point blank range, those divisions carried out their instructions to hold their positions at all costs and cover the detrainment of the Australian 1st Division. The arrival of the Australians in the evening definitely closed the approach to Hazebrouck. Further northeast a succession of heavy attacks was driven off by the 33rd

and 34th Divs. about Meteren and La Creche. In the early morning the German 36th Res. Div. penetrated with heavy loss into Neuve Église, but before noon they were driven out by the British 33rd and 49th Divisions.

Early on the morning of April 14 the British troops withdrew without interference to a new line in front of the Ravelsburg heights between Bailleul and Neuve Église. The latter village, after intense fighting all day, was finally captured by the Germans by midnight on the 14th. Elsewhere all attacks were repulsed, and the British 4th Div., coming up east of Robecq, between the 61st and 3rd Divs., recaptured Riez Du Vinage with a number of prisoners. On April 15 the German attacks were renewed. By this time their troops had been reinforced by the Guard Res. Corps on the left wing of the IV. Army. The IX. Res. Corps had come in on the right of the IV. Corps, and the Bavarian III. Corps had replaced the Bavarian II. Corps. Heavy attacks developed during the day culminated in the capture of Bailleul and the Ravelsburg Ridge.

British Withdrawal.—On the night of April 15–16 a withdrawal of the British troops from the Ypres salient to a line east of Ypres through St. Julien and along the Westhoek and Wytschaete Ridges was completed without interference. This move had been commenced on the night of the 12–13 by direction of British G.H.Q. in order to set free additional troops, and to forestall any plans the Germans might be entertaining for the extension of the battle front to the north. The withdrawal was well timed, as the Germans were preparing an offensive from the Houthulst Forest, and the preparations were almost complete when the British withdrawal took place.

On April 16 strong local attacks were made at various points on the Metheren-Wytschaete front, all of which were repulsed by the 25th, 34th and 49th Divs., except on the extreme flanks, where both villages, after intense fighting, eventually fell into German hands. On the following day determined efforts to take Mt. Kemmel and to advance on the Meteren-Merris front were repulsed, and the Belgian Army achieved a notable success in defeating a powerful assault against their right flank about the Ypres-Staden railway, in which they captured over 700 prisoners.

Meantime the Germans had been preparing to renew the attack on the British right flank, and on the 18th, after a very intense bombardment, the IV. and IX. Res. Corps advanced to the assault of the British positions about Givenchy-Festubert and Mt. Bernenchon-Hinges. On the British right they penetrated at certain points, but were thrown back by the 1st Div. which had relieved the 55th. Everywhere else they failed to obtain even an initial success, and were driven back with great loss by the 4th and 61st Divisions. For nearly a week the battle died down. On the British right minor operations were successfully undertaken to improve the position of the 4th and 61st Divs., northeast of Robecq, which resulted in the capture of numerous prisoners. In the left centre of the British front French troops, which had been brought up from the south, relieved some of the wearied British divisions, and by the morning of the 21st had taken over the sector between Metheren and Spanbroekmolen.

New German Plans.—During this pause the German Higher Command readjusted their plans. On the 18th the Army Group suggested that the main operations should be abandoned, and it was finally decided on the 20th that further operations should be limited to the capture of Mt. Kemmel on the north, and the villages of Givenchy and Festubert on the south. No success whatever was obtained on the southern flank, but the attacks about Mt. Kemmel led to further bitter fighting.

At 3:30 A.M. on April 25 an intense bombardment was opened on the French and British positions extending from Bailleul to the Ypres-Comines Canal. The main object of the attack was the capture of Kemmel Hill by direct assault on the French, combined with an attack on the British right south of Wytschaete, intended to separate it from the French. The attack was entrusted to the XVIII. Res., Alpine and X. Res. Corps, to which were allotted nine divisions, five of which were fresh. Between 6 and 7 A.M. the German infantry advanced, supported by large numbers of squadrons of battle planes and bombers. After intense fighting they succeeded by 10 A.M. in wresting Kemmel Hill and village from the French, detachments of whom, however, though surrounded, held out till late in the day. The weight of the initial attack on the British front fell on the 9th Div., who inflicted very heavy casualties on their enemy but by midday were forced back to Vierstraat. Further north the 21st Div., after a gallant resistance, was in the afternoon compelled to withdraw to a line Hill 60-Vormezeele. On April 26 the attack was renewed, and many counter-attacks were carried out both by British and French troops, the latter recapturing Locre.

On April 27 and 28 local fighting continued without substantial alteration in the situation. During the night of April 26–27 the salient east of Ypres was further reduced by a withdrawal without interference to the line Pilkem-Zillebeke-Lake-Voormezeele.

Final Attack.—The German final effort took place on April 29. The action started with a bombardment of exceptional intensity at 3:10 A.M. At 5 A.M. powerful attacks commenced against the French and British troops from west of Dranoutre to Voormezeele. After very heavy fighting the Germans gained a temporary success north of Locre, but were driven back by the French troops holding the sector. On the British front the positions held by the 21st, 49th and 25th Divs. were again and again attacked by German infantry, which advanced with great courage in massed formation. The assaulting troops suffered the heaviest losses, but their valour was of no avail. The British artillery and infantry fought with magnificent bravery and this final German effort was repulsed with practically no loss of ground.

Results of the Battle.—Thus ended the battle of the Lys. The second great German offensive had succeeded in penetrating the British front on a front of about 20 m. to an extreme depth of about 12 miles. A large number of towns and villages had been taken and nearly 30,000 Allied prisoners and 450 guns had been captured. But the attack had failed to gain its main objects. The lateral railway communication between St. Pol and Hazebrouck was still intact, the mining area south of Bethune was safe. Except for the detached hill of Kemmel, the high ground dominating the Poperinghe-Ypres road still remained in Allied hands. A pronounced salient had been formed in the German front which was to cost them dear in the succeeding months. On the other hand, the British had been forced to abandon the almost equally pronounced salient east of Ypres, and with it all the ground which had been gained at so great a cost in the battle of Passchendaele the previous year. The losses on both sides had been very heavy. To achieve these results the Germans had employed 42 divisions, of which 33 were fresh; 25 British divisions were employed, of which only eight had not been engaged in the battle of the Somme.

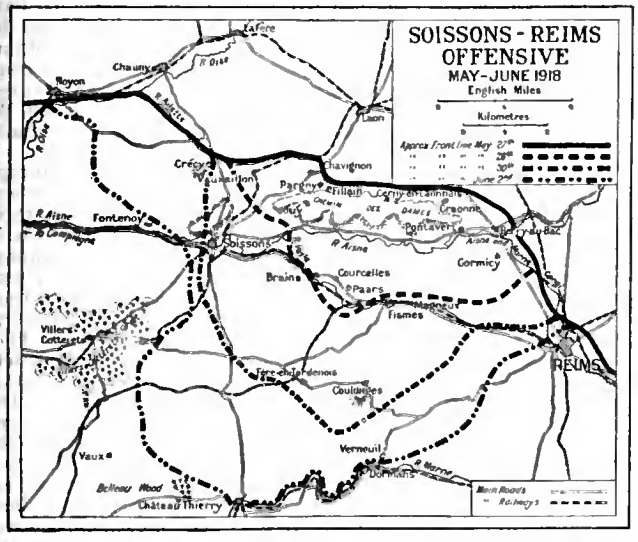
III. THE BATTLE OF SOISSONS-REIMS

After the relative failure of the German offensives of March and April it was incumbent upon the Germans, if they wished to preserve the initiative, to deliver another powerful blow without delay. The choice of the front of attack and the battle-ground fell on the oft-contested chain of heights between the Ailette and the Aisne, the Chemin-des-Dames.

Dispositions for the German Attack.—The German Supreme Command had decided to attack with the VII. and I. armies from the district southwestward of Laon—southwards of Berry-au-Bac in the direction Soissons-Fismes-Reims. If this attack proceeded favourably it was to be prolonged on the right over the Ailette to the Oise and on the left as far as Reims. Simultaneously an attack by the XVIII. Army was to be prepared westwards of the Oise with its centre of gravity in the direction

of Compiègne. The German Supreme Command hoped that the push southward would succeed in reaching the neighbourhood of Soissons and Fismes, and by this means attract strong forces from Flanders, so that it might be possible to continue the attack there according to plan. The army group under the Crown Prince Rupprecht was to remain purely on the defensive. On this front, as on other sections of the Western Front where attack was not intended, feigned preparations for attack were to be made.

Preparations began about the middle of May. The VII. Army under Böhm was charged with the main attack across the Chemin-des-Dames, the I. Army under Below with the neighbouring attack on the left, and the XVIII. Army under Hutier with the attack in the direction of Compiègne. The right wing of the main attack, the LIV. Corps and the VIII. Res. Corps, had the task of pushing forward in a southwesterly direction on both sides of Soissons. The XXV. Res. Corps was to make its way on both sides of Cerny-en-Laonnais direct towards Braisne, and on the east to take as much country as possible towards the south; the IV. Res. Corps was to attack the "Winterberg" (*i.e.*, the height



at the eastern end of the Chemin-des-Dames, immediately north of Craonne) with the main force and advance farther in the general direction of Fismes; in concert with this on the left the LXV. Corps was to occupy with its left wing the river bend north of Berry-au-Bac. Of the I. Army at first only one corps, advancing simultaneously with the VII. Army, was to throw the opposing forces over the Aisne-Marne canal. The corps was to provide itself with bridgeheads in order to take the heights of Cormicy if the attack of the VII. Army proceeded favourably. A further attack to the right of the main attack was prepared by the VII. Corps of the VII. Army, which was to push forward over the Ailette, making its way in a southwesterly direction towards the Oise. The number of divisions taking part in the attack was 41.

For success there were two essentials: the first, surprise; and the second, effective artillery preparation. Most elaborate and thorough precautions were taken to secure secrecy. As regards artillery preparation the ascent of the steep slopes on the heights of the Chemin-des-Dames was only possible if the Germans should succeed in silencing the bulk of the opposing guns. All registration was to be abandoned in order to surprise the enemy as much as possible. The first aim was to be a thorough gassing of the Allied position right down into the Aisne valley. Preparations were completed by the evening of May 26 1918.

In the night of May 26–7 at 2 A.M. the German artillery bombardment began, completely surprising the French and English. The whole valley of the Ailette, the steep slopes of the Chemin-des-Dames, the Chemin-des-Dames itself, and the country lying far behind down to the Aisne, were in a short time thoroughly gassed. After an hour and a half's bombardment, the opposing infantry and artillery were sufficiently subdued to enable the German infantry to venture the assault.

The Infantry Attack.—At 4:40 A.M., while it was still dark, the German infantry advanced to the attack. Without difficulty or delay they crossed the Ailette valley, which was covered with bushes in some places and marshy in others; during the ascent to the Chemin-des-Dames serious infantry fights only developed at Chavignon, Pargny and Fillain; on the other sections of the front the German infantry pushed forward almost without resistance on to the heights of the Chemin-des-Dames. Here the remarkable effect of the artillery preparations was already apparent; the steep slopes had been surmounted and the first lines were taken almost without firing a shot. By 7 A.M. the I. Army had already reached the canal, and part had crossed it. Since they were to await the left wing of the VII. Army before further advance, a halt had to be made there, and the opposing army gained time to reform their units and to rally, while those in front of the VII. Army were overrun by the advance of the attacking divisions so long as they felt the effect of overwhelming German artillery fire. This was an essential difference between the attack of the I. and VII. armies, and was to be of decisive importance. By 9 A.M. the German infantry had reached the line Vauxaillon-Jouy-Pontavert-Berry-au-Bac.

Soon after 11 A.M. the first German companies crossed over to the southern bank of the Aisne on bridges mostly intact. A vast and unexpected success had been gained. A wide and apparently impassable stretch of country, which had been for years the scene of the heaviest fighting, had been captured within a few hours after a short artillery preparation. Of the divisions of the defenders two English and three French had almost ceased to exist. The survivors streamed into the prisoners' collecting stations, while countless guns stood abandoned in their positions, some of them undamaged. In the afternoon and evening the attack on the principal fighting front of the VII. Army went forward without a pause farther in the direction of the Vesle valley. Engineering and road-making troops worked with the utmost effort to level a path for the columns following through the enemy positions and over the steep way up to and down from the Chemin-des-Dames. On the two wings the advance was considerably slower. The Vesle was reached by the XXV. and IV. Res. Corps, and sections of the XXV. Res. Corps passed southwards of Courcelles and Paars, while sections of the IV. Res. Corps occupied the steep slopes at Fismes and Magneux. On this very first day of fighting the Germans had penetrated the enemy positions over a front of about 60 km. to a depth of about 20 kilometers. Over 15,000 prisoners and vast army supplies had been taken. The German losses were proportionately small.

Allied Resistance Increases.—The second day of the battle, May 28, saw the first violent counter-attack of the opposing army against the right flank of the German attacking troops. Nevertheless the speed of the German advance was not lessened on this day. On the right wing the LIV. Corps, after repulsing French counter-attacks, captured the heights north and northeast of Soissons. On the left the German divisions pressed forward until midday, over the whole sector of the Vesle, as far as the northwestern fort of the fortress of Reims. The objective was thus reached after a day and a half's fighting. But in the ardour of the pursuit the troops stormed on without orders, though in agreement with the intentions of the Higher Command, in order to improve their success by determined pursuit. The order given by the Supreme Army Command at noon of the 28th to continue the attack as far as the line of heights southwest of Soissons-Fère-en-Tardenois—the heights south of Coulonges—reached the troops when they were already storming forwards. On the right wing of the VII. Army, the VII. Corps had already joined the attack on May 28 without waiting for the completion of the preparations begun at this point. Here, however, the resistance was so obstinate that it was only in the course of May 29 that the dominating heights at Crecy-au-Mont were captured.

On the following days the VII. Army pushed on with its centre in a southern direction as far as the Marne. The right wing of the I. Army, which had extended the attack towards Reims on the left, pressed forward between the Marne and the Vesle against the wooded hills of Reims, but soon met here with unconquerable

resistance. The right wing of the VII. Army took Soissons, and between the Aisne and the Marne gained ground towards the heights southwest of Soissons, and up to the eastern edge of the Forest of Villers-Cotterêts. On the 29th the occupation of the important road and rail centre of Soissons as well as of Fère-en-Tardenois was of tactical importance. In both places immense masses of material fell into the hands of the Germans. On the left wing all the roads and railways leading from Reims to the Marne lay under German fire.

French Counter-attacks.—On May 30 violent counter-thrusts by the French had held up the advance of the German right wing, while the German centre in a rapid advance had by midday reached the heights of the northern bank of the Marne between Château-Thierry and Dormans. On both days the pursuing German troops had passed beyond the objectives fixed by the Supreme Army Command, so that they reached the Marne earlier than had been thought possible. A further advance of the centre, pushed out southward like a wedge, beyond the Marne, seemed to involve great risk so long as the German wings on the east and west had not won further ground and thus been able to broaden the base of attack.

On May 31 instructions went out from the Supreme Army Command not to penetrate farther south over the Marne, but to extend the successes against the wooded heights of Reims and up the Marne towards the west in the direction of Villers-Cotterêts. On May 30–1, and particularly in the first days of June, strong counter-attacks were made by the French and later by the Americans. In the first days of June the fighting became steadily more severe, as the Allied resistance grew more obstinate and the counter-attacks progressively more violent and extended. The Germans therefore succeeded in gaining only little ground. The powerful impetus of the German attack had come to an end. On June 17 the German armies stood with their right wing and centre roughly on the line Noyon-Fontenoy, the eastern edge of the Forest of Villers-Cotterêts, Château-Thierry, and up the Marne to Verneuil; the left wing had penetrated to the outlying woods west of the wooded heights of Reims, and close to the west, north and east front of Reims, which was closely encircled.

Results of the Battle.—The tactical result of the battle of Soissons-Reims for the Germans was great beyond all expectation. Over 65,000 prisoners fell into their hands. The booty included about 700 guns and 2,500 machine-guns; in addition, the French and English losses in *matériel* were enormous. But there was a reverse side to the shield. The battle had brought home to the Germans that not only were there American troops now on the Western Front but that they possessed a fighting capacity and quality not hitherto suspected by them. The first notable appearance of American troops was at Cantigny on May 28. Here the American 1st Div., in taking and holding the village against the best efforts the Germans could make, had proved itself absolutely dependable. And within a few days the 2nd Div. had shown itself, in front of Château-Thierry, at Belleau wood and Vaux, to be a first class fighting unit. The conduct of these two divisions did much to hearten the Allies, whose morale had been somewhat depressed by the series of German successes since March.

The extent to which the fighting of the Americans impressed the Allied generals can be gauged from the change of opinion as to how best these reinforcements might be employed. For a time it had been thought that it would be too much to expect that America could produce, without a long probationary period, commanders and staffs capable of handling large bodies of troops in action under modern war conditions. By the end of June it was clear that American commanders and staffs were eminently competent to direct divisions in any battle. Early in July the American I. Corps took over a sector from the French VI. Army, a step amply justified by the resistance offered by the Americans at Château-Thierry in the middle of that month.

GERMANY (*see* 11.804), a Republic of Central Europe (Das Deutsche Reich). The German Empire, formed in 1871, included 26 states: the states of the North German Confederation, the South German states and Alsace-Lorraine. Until 1918 Germany retained this form unchanged, having an area of about 208,830 sq. m. and a population (1910) of 64,925,993 (estimated population, July 1914, 67,800,000).

I. AREA AND POPULATION

In Nov. 1918 Germany became a republic, and her states free states and, later, under the Constitution of Aug. 11 1919, territories of the German Reich. There are now 18 of these territories in the Reich, viz.: Prussia, Bavaria, Saxony, Württemberg, Baden, Thuringia, Hesse, Hamburg, Mecklenburg-Schwerin, Oldenburg, Brunswick, Anhalt, Bremen, Lippe, Lübeck, Mecklenburg-Strelitz, Waldeck and Schaumburg-Lippe. Under the Treaty of Versailles (Jan. 10 1920), Alsace-Lorraine was returned to France with validity from Nov. 11 1918; large areas in West and East Prussia, Pomerania, Posen and Silesia fell to Poland; portions of Schleswig-Holstein to Denmark; a small province of Upper Silesia to Czechoslovakia; Eupen and Malmédy to Belgium; the town and area of Danzig became a free state, and the Memel region was allotted to Lithuania. Germany's outline was thus changed, particularly in the east. Part of Germany, consisting mainly of East Prussia, was severed from the remainder by the "Polish Corridor" to the Baltic. The Rhine became to some extent the Franco-German frontier. Direct communication with Russia was cut off by Poland and the border states. Germany's present area is 186,517 sq. m.; it is bounded, W. by Holland, Belgium, Luxembourg and France; S. by Switzerland, Austria and Czechoslovakia; and E. by Poland and Lithuania.

This area had a population of 59,800,000 in 1919. On June 16 1925 the population was 63,250,000 (including the Saar valley, where however the census was not taken). There has been a steady increase in the density of population in Germany from 123·1 to the sq. km. in 1910 to 133·2 in 1925. Apart from the three city states of Hamburg, Bremen and Lübeck, Saxony is the most densely populated area (332 persons to the sq. km.); then Hesse and Baden. The least densely populated are the agricultural territories of Mecklenburg, Waldeck, Oldenburg and Bavaria (97 persons to the square kilometre). Prussia, with 120, is not far below the average for the Reich.

Increase of Urban Population.—In 1871 17·4% of the population lived in towns of more than 10,000 inhabitants; in 1925, 46·1%. The 45 towns with over 100,000 inhabitants absorb 16,500,000 or one quarter of the total population of Germany. The trend towards the towns is identical with the trend towards the workshops. This was specially noticeable during the years 1914–8, when internal migration assumed enormous proportions, being directed away from those places where the conditions of war had restricted production towards the centres of increased production arising out of war requirements. After the signature of the Armistice, there were extensive movements of population, still governed by prospects of production and therefore of wage-earning. At the same time rural districts experienced a not inconsiderable increase in population, as did also the coal-mining districts, the region of the Ruhr, Upper Silesia and the lignite districts, on account of the coal famine and consequent increase in production. In 1926 Germany was in the midst of a new shifting of the population, caused by the excess of coal and the attempt to put industry on a sound footing; this movement would be more pronounced but for the housing shortage.

The proportion of foreigners speaking their own language is now very small. There are many Germans outside the boundaries of the Reich. The contiguous wholly or partly German-speaking areas of Europe cover 15 states and include over 80 million Germans. The present area of the German Reich contained 38·1 million Evangelicals and 19·3 million Catholics in 1910. For figures of emigration and immigration *see* MIGRATION.

The birth-rate from 1870 to 1900 was consistently high (36·8 to 42·6 per 1,000). About 1·8 million children were born alive each year. The average annual surplus of births over deaths was approximately 600,000. The death-rate was also high, fluctuating during 1870–1900 between 21·7 and 31·0 per thousand. From 1900 onwards the birth-rate steadily decreased, and in 1914 it was only 26·8 per 1,000 of the average population. The death-rate declined from 23·2 per 1,000 in 1900 to 15·8 in 1913, and infant mortality from 207 per 1,000 infants born alive fell to 151. From the middle of 1915 the birth-rate dropped rapidly, and reached its lowest point in 1917, namely 14·4 per 1,000 of the population. In this year only 912,109 children were born alive. The rate of mortality rose during the same period owing to the War and the blockade. The highest death-rate was in 1918, when it rose to 25·2, assisted by the influenza epidemic. After the Armistice, the birth-rate began to recover. In 1920 it stood at 26·7, but then fell steadily until in 1924 it reached 21·1. The rate of mortality improved, once the blockade had been removed and the population were again able to obtain adequate nourishment. In 1921 the death-rate stood at 15·6 and sank again to 12·9 in 1924. The year 1925 brought further improvement.

The rate of births and deaths was as follows:—

Year	Total Births (inclusive of still-births)	Deaths (inclusive of still-births)	Still-births	Per 1,000 of the population: Births (inclusive of still-births)	Per 1,000 of the population: Deaths (inclusive of still-births)
1900	2,060,657	1,300,900	64,518	36·8	23·2
1910	1,982,836	1,103,723	58,058	30·7	17·1
1924	1,311,044	802,166	42,502	21·1	12·9

Infant mortality, which in 1913 was 151 per 1,000 born alive, was 131 in 1920 and 108 in 1924. See *Statistisches Jahrbuch des Deutschen Reichs* (Berlin, annual). (W. Gr.)

II. CONSTITUTION

From the Old Reich to the New.[1]—In the German Empire (Reich) the supreme authority was vested in the King of Prussia as German Emperor, the Imperial Chancellor (appointed by the Kaiser) as president of the Government, the Federal Council (*Bundesrat*) representing the individual states, and the National Representative Assembly (*Reichstag*) representing the nation. The states—kingdoms, duchies, principalities and free states—had retained their sovereign rights, which they exercised in a twofold manner: first, in internal politics, by maintaining their own diets or councils, and secondly through the Bundesrat, which, both in accordance with the rules of the Constitution and in practice, had a greater influence on the policy of the Reich than the Reichstag. Prussian hegemony in the Reich was not laid down as a principle of the constitution but was a natural consequence of the disparity in size of the states.

When the new Germany was constituted in 1919, the union of German-Austria and Germany was made impossible by the treaties of peace. This being so, Prussia's natural hegemony in Germany could be avoided only by the formation of a unified Reich or by the division of Prussia into a number of provinces equal in size to the other territories. But when the Constituent National Assembly was elected on Jan. 19 1919 the question of a unified or a federal constitution was overshadowed by other problems. The Communist party and a section of the Left Socialists regarded this election and the demand for a constitution by the other political parties as bourgeois opposition to a dictatorship of the Councils, and the Communists refrained from voting. The 185 Socialist deputies, who, like the Communists, stood for Centralism, were the strongest party, but could only form a majority with the help of the 75 Democrats, and, even so, they would have opposed to them the German Nationals (44 deputies), the German People's Party (19), the Catholic Centre (91) and the soven deputies of the small Agrarian parties. The Socialists and Democrats were obliged to join hands with the third great Republican party, the Catholic Centre, and thus there arose the so-called "Weimar coalition," supported by 329 deputies and over 23,000,000 votes, leaving out of account the Left Socialists, who still cherished hopes of a dictatorship.

The scheme for the new constitution was drafted by Dr. Hugo Preuss, former Secretary of State and at that time Minister of the Interior. It was then reconstituted, by a commission appointed by the territorial Governments (*Staatenausschuss*), in such a manner as to strengthen the position of the individual territories in relation to Preuss's unified Reich. In a special committee of the National Assembly, Erzberger, the actual leader of the Centre, went over to the side of those who advocated a strong central power for the Reich, and a resolution was passed which gave to the Reich the financial authority which had hitherto rested principally with the territories (art. 8). On Aug. 11 1919 President Ebert proclaimed the Weimar Constitution.

The Democratic Republic.—The preamble to the constitution lays stress on the fact that the German people has given itself this constitution as by sovereign right:—

[1] The words *Das Deutsche Reich* were, before the revolution of Nov. 1918, invariably translated "German Empire." But the word *Reich* has, for historical reasons, been retained by the German Republican Commonwealth as its official territorial and political designation. *Reich* is an old Germanic word found in Early and Middle English, and surviving in composition in the word bishopric. (Ed. *E.B.*)

The German nation, united in its peoples (*Stämme*) and inspired by the determination to renew and to establish its Reich in freedom and justice, to promote peace at home and abroad, and to further social progress, has given itself this constitution.

Between a monarchy and a republic there was no longer any choice. The choice lay rather between "direct" and "indirect" democracy.

"Direct" democracy is seen in the election of the president of the Reich by the most extended form of franchise in which "the whole German nation" takes part,[2] and in the Referendum which, however, is only admissible in the case of an adverse vote by the whole nation on a draft or a bill passed by the Reichstag [Initiative or Demand of the People (*Volksbegehren*), and Decision of the People (*Volksentscheid*), art. 73-6].[3]

"Indirect" democracy, on the other hand, is seen in the Reichstag, which has only one chamber, elected by the people entirely on the basis of proportional representation and with *scrutin de liste*,[4] that is, according to the party lists. No by-election takes place during the legislative period. The men at the head of the party list are replaced, when they go, by the men below them (art. 53, 54). The Ministry, which is nominated by the President of the Reich, must possess the confidence of the Reichstag; and, as the Reichstag is elected for a term of four years, and as a presidential election a national vote of censure or dissolution of the Reichstag only rarely occurs, German democracy is far more directly parliamentary than the Swiss or North American, both of which are frequently named as its models.

The President of the Reich may, after obtaining the countersignature of the Chancellor or other competent minister, dissolve the Reichstag, though such an expedient would of course only be resorted to in exceptional cases. Not only can the Reichstag force the Ministry to retire by a vote of no-confidence but, with a two-thirds majority, can submit to the nation a proposal for the deposition of the President (art. 43). A hundred members of the Reichstag can impeach president, chancellor or minister for having culpably violated the constitution or a law of the Reich. Judgment is then given after regular proceedings at law by a special Supreme Court (*Staatsgerichtshof*) (art. 59), not to be confused with the Supreme Court which sits at Leipzig.

The Reich and the Territories.—Of the 26 states which constituted the old Reich, 18 now (1926) remain and are called territories (Länder). The constitution prescribes a republican form of Government, but in other aspects the territories determine their own constitution, some of them having their own presidents. In their Parliaments the majority lies frequently with those parties who belong to the Opposition in the Reichstag. This is particularly the case in Bavaria where, since 1919, the Bavarian National party, belonging to the Right, has had a majority and forms the Government—and temporarily in Saxony and Thuringia, where in 1926 the Left Socialists and Communists held the majority.

The territories are represented in the central Government by the Council of the Reich (Reichsrat), to which their Governments (not their Parliaments as the Preuss scheme prescribed) send representatives. Each territory has at least one vote, but no one territory can have more than two-fifths of the total votes. In any case the number of votes is regulated according to the population (art. 61). Out of the 26 Prussian votes half are assigned to the Prussian provinces (of which Berlin is one) which are thus placed on the same footing as the other territories. On account of the peculiar majority regulations[5] in the provincial diets, these provinces sometimes vote against the policy of the Prussian territorial Government.

Unlike the old Federal Council (*Bundesrat*), the Reichsrat has no direct part in legislation.[6] The Government of the Reich lays its

[2] Hence the expression "plebiscitary president."

[3] President and people may also work hand-in-hand, as when the president lays a bill that has been passed by the Reichstag before the people's referendum (*Volksentscheid*).

[4] The list is chosen, not the single deputy. In each electoral district as many seats are allotted to the list as the number of times by which the number of votes cast for that list is divisible by 60,000. Remainders are worked out in two ways: either by associating the lists within the electoral districts or by crediting the remainder to the Reich list of the party; here again 60,000 votes are necessary to elect a deputy.

[5] A candidate, in order to be elected, must have received one more than half of the number of votes cast.

[6] Still less does the Economic Council of the Reich (*Reichswirtschaftsrat*) possess legislative powers. It consists of representatives of the employers' and workers' organisations and of economists. The Government is obliged to consult the Council before placing social and economic bills of fundamental importance before the Reichstag. The Council can itself prepare such measures and bring them before that body (art. 165).

bills before it in the first instance, but if the Council reject them they can still be taken to the Reichstag. The Council also has the right to veto bills passed by the Reichstag, but this, again, can be overridden by a two-thirds majority in the Reichstag.

In respect of legislation, the competence of the Reich *ipso facto* excludes the competence of the territories in such important spheres as foreign affairs, migration, the army, commerce and communications (art. 7). Taxation is almost entirely administered by the Reich: citizenship, penal laws and legal rights were administered by the old Reich for all Germany, likewise the social laws. Of these, education alone was left to the territories, but now the Reich is concerning itself with that also.

In administration the territories take a larger part. Their Governments are still allowed to nominate the greater number of the officials of the so-called interior administration. The appointment of the revenue officials has, however, been taken from them since Erzberger's reform of the finance department of the Reich, and the Reich has also taken over railway administration, while the post office officials were, with the exception of Bavaria, already under the Reich.

The Reich has power to coerce the territories (art. 48). If they fail in their duties to the Reich or endanger its safety by disturbances in their areas, the President has power to take up arms against them and temporarily to suspend their territorial constitutional rights ("Federal execution"). The Reichstag may insist on the repeal of such measures if it disapproves of them.

The Constitution and Foreign Affairs.—Accepted principles of international law have in Germany the force of laws of the Reich (art. 4). Decisions on war and peace can only be taken subject to a law of the Reich. Alliances and treaties with foreign states require the consent of the Reichstag (art. 45, sections 2, 3). The president of the Reich appoints the officials of the Foreign Office, in the same manner as other officials, with the countersignature of the Chancellor or the Foreign Minister. In the case of ambassadors and attachés the President may claim a personal right of choice. Thus President Ebert associated himself in the selection of new candidates for nearly all the important diplomatic posts after the World War. The Reichstag Committee for Foreign Affairs is permanent (art. 35).

The First Five Years of the Constitution.—The constitution stood the test of its difficult early years well. It gained in the general esteem by the effective use that was made of armed force (placed in the hands of the Government by the constitution) in various emergencies. Its reputation was further enhanced by the stabilisation of the currency, and by the fact that the prime mover in this—Dr. Schacht, president of the Reichsbank—was an avowed partisan of the Republic. It was realised that with such a constitution the economic life of the nation could be revived, in spite of the alarming art. 156, giving "authority for the socialisation of the Reich." The article which is most severely criticised, in North Germany especially, is art. 3, which orders that the colours of the Reich shall be black-red-gold; it is significant, however, that the majority of those who cling to the old Reich colours would be willing to accept black-white-red as the colours of the Republic.

The territories demand greater independence in relation to the Reich, particularly as regards the right to levy their own taxes. This demand was definitely formulated in the memorandum of the Bavarian Govt. on the revision of the constitution (Jan. 5 1924).[1] But even Bavaria, the ancient stronghold of federalism, only asks for the revision and not for the suppression of the constitution.

[1] A change in the constitution can only be made by a two-thirds majority in the Reichstag with two-thirds of the deputies present; in the Reichsrat a two-thirds majority is required, and in a referendum or people's decision a majority of the whole electorate, not only of the actual voters.

Two attempts made in the Prussian provinces to create independent territories by means of a plebiscite were defeated by the people themselves (Upper Silesia Nov. 3 1922; Hanover May 5 1924). On the other hand, Saxe-Weimar, Saxe-Meiningen, Saxe-Gotha, Saxe-Altenburg and four small mid-German states have united to form the free State of Thuringia; Coburg has joined Bavaria and Waldeck Prussia.[1]

The franchise and the one-chamber system have been widely criticised. The first presidential election showed that a candidate who had not figured in the first ballot at all might be elected on a relative majority in the second. But this President, though elected by a minority, had after a year in office gained the confidence of an overwhelming majority of the people, though losing, on the other hand, that of a portion of his electors. Similarly, President Ebert, who was elected by the Reichstag and not by the people, owed the strength of his position, even with the parliamentary parties, to the confidence with which his personality inspired large masses of the people. The franchise not only excludes strong action on the part of the people—a "landslide"—but returns the same parties again and again with only a slight alteration in the mandate, with the result that electors become weary and indifferent. By-elections would serve the purpose of indicating to some extent the political feeling that obtains among the people; and, further, as there is no upper house or senate, independent statesmen have no opportunity of voicing the public opinion of the country. Neither is this want supplied by the big newspapers, which are almost all in the employ of definite parties or definite economic groups.

III. POLITICAL HISTORY

The Domestic Situation 1910–2.—When Th. von Bethmann Hollweg, the fifth Imperial German Chancellor, presented himself to Parliament as Prime Minister of Prussia[2] in Jan 1910, he enjoyed the confidence of the Conservatives, while the Socialists, Liberals and Catholic centre all opposed him. His bill for the alteration of the Prussian franchise of Feb. 4 1910, which upheld the "three class voting system" and open ballot, was rejected even by the National Liberals, while the Left Wing Liberals branded it as an insult to the very principle of franchise, and it was rejected in May, a coalition of all the non-Conservative parties in the Chamber of Deputies having decided to vote for the secret ballot, while the Upper House rejected it.

In the Reichstag the opposition to the Chancellor was similarly composed of the Centre, Liberals and Socialists. The Catholic Centre was the great patron in Germany of the Polish Catholic minorities in the eastern provinces of Prussia. It therefore joined with the Left in embittered protests when disciplinary action was taken against certain non-political government officials (of the the postal and railway services) who had supported the Greater Poland party in the municipal elections in Kattowitz. The antagonism was the more violent since the Chancellor himself belonged to the Prussian Protestant official class which had used its social status to establish an unwritten monopoly over the higher administrative posts.

If Bethmann Hollweg, later in 1917, was the champion of the "great coalition," extending from the National Liberals to the Social Democrats, and the particular *bête noire* of the Conservatives, it was not he but the situation and the parties that had changed since 1910. He remained throughout a perfectly loyal and devoted public official, but stubborn and dogmatic, and contemptuous of the counsels of the outer world.

Bethmann's position, both at home and abroad, was difficult. The differences over the internal shipping dues had been laboriously composed, but the struggle still troubled the harmony of the confederated Governments. Saxony and Baden, in particular, as the two states lying on the upper courses of the Rhine and the Elbe, felt themselves overreached by Prussia, which, situated at the mouth, sought to abolish the traffic-dues on the great rivers in the interests of her schemes for canal construction. In Bavaria under the new Regent, subsequently King Ludwig III., the Government guarded the particularist rights and the parity of the state with Prussia far more jealously than it had done under King Ludwig II. or the Regent, Prince Luitpold. In the Reichstag, on the other hand, there was already a considerable majority which demanded stronger powers for the Imperial Govt. in its dealings with individual states. It called for the removal of the remaining restrictions imposed upon the Catholic Church in predominantly Lutheran states, and urged the Imperial Chancellor to take action in virtue of his imperial powers to abolish the old constitution of estates still in force in Mecklenburg, which entailed the domination of the great landed proprietors, and to establish a Diet with universal suffrage.

The question of framing a constitution for Alsace-Lorraine was particularly difficult. Those sections in the "Reichsland" most anxious for a permanent association with Germany—the German-speaking Old Alsatians and German Lorrainers, the industrialists and traders, the Centre party, official and university circles—demanded a "Home Rule" under which the Reichsland should become a federal state with full parity of rights with powers to frame a state constitution by means of a Constituent Assembly, and representation in the Bundesrat proportionate to the population, the people electing deputies to the Reichstag and to the local Diet. This involved the question of the future position of the German Emperor, who had hitherto ruled as *de facto* sovereign, without a Diet, indeed often against the wishes of the Alsace-Lorraine deputies as expressed in the Reichstag. In any case, his powers as Supreme War Lord in a frontier and fortified region remained very effective even against the civil administration, and would outshadow those of another territorial ruler. Moreover, the mutual jealousies of the reigning houses made it hard to appoint a member of one of them to rule in Alsace-Lorraine. Yet if the Emperor, who was also King of Prussia, retained his position, with the right to appoint the Statthalter, the new state constitution would of itself entitle him to instruct the delegates of Alsace-Lorraine to the Bundesrat, so that their votes would simply strengthen the Prussian vote in that council. Finally, on May 26 1911, the Act embodying the constitution of Alsace-Lorraine was adopted as a compromise.

The territory was now to rank as a federal state; its constitution, however, was fixed by a decision of the legislative body of the Empire. Of the two Houses of Parliament, one was chosen by universal suffrage, while the other was in part nominated by the Government, in part composed of high officials. The Emperor remained reigning Prince, the votes in the Bundesrat thus deriving from his Government; but where a Prussian majority in the Bundesrat depended on the votes of Alsace-Lorraine the latter were not to be counted. Such an intricate constitutional instrument would probably never have been popular. It increased the confidence of the moderate middle-class parties in the Chancellor's domestic policy; but the Right and Left were equally dissatisfied. The Conservatives regarded any step towards constitutional Government in the Reichsland as unsound, and many of them would have preferred the continuance of rigid military rule in the "conquered" territory. Indeed, the hostility of the extreme Conservatives and of the Pan-Germans towards Bethmann Hollweg dates from this period. The Radical Left wing were alienated because they had hoped that the Constitution would do away with the dominance of the Prussian bureaucracy in Alsace-Lorraine and lead to parliamentary Government similar to that of the three South German States.

[1] Other small states will probably later join their greater neighbour states.

[2] He assumed that position in July 1909.

In other directions, also, in domestic politics the parties of the two wings began to move towards extremes. This process, at first interrupted by the War, was renewed with great violence afterwards, and still hampers the formation of anything like a two-party system, or, indeed, of parliamentary government at all. For the Right wing of the group of moderate parties which lies between these extremes cannot sit in the same cabinet with the extreme Left, whilst their Left wing cannot co-operate with the extreme Right. The Conservative party associated themselves with the agrarians, whose organisation, the Farmers Union (*Bund der Landwirte*), from the outset adopted demagogic tactics and appealed frankly to the power of the producers of indispensable foodstuffs. Heavy industry moved away from Liberalism and joined the agrarians; and the Pan-Germans, formerly recruited from the National Liberals, and the Anti semites drew closer to the parties of the Right, voting with them in questions of foreign policy and defence and collaborating with them at elections. In 1914 two of these Right parties, the German Party of Reform and the German Social Party, combined under an Anti semite to form the new Deutschvölkische Partei.

On Dec. 7 1911 the Reichstag was dissolved, the elections being fixed for Jan. 12 1912. The Government called for an alliance of the middle-class parties against the Socialists to "continue our present policy of commercial treaties and protection to German labour," and to "maintain our Army and Navy permanently in a state of the highest efficiency, and to fill up any gaps in our armament." The Association for combating Social Democracy issued the same message, which was indeed the same as had been used in the last elections by the Conservatives and National Liberals, but then against the Centre, to-day on behalf of the "blue and black bloc" of the Centre and Conservatives. The message was unconvincing, and in fact the elections brought the Social Democrats unexpected success. With 110 members they formed the strongest single party in the Reichstag, even as they had proved the largest single party in the electorate. They had gained 69 seats and lost 12. The three Conservative parties between them had gained 14 seats and lost 49, and even if with the Centre they still commanded about 170 votes, to 152 votes of the left, the decision upon tariff and fiscal policy now lay with the 45 National Liberal deputies.

The strength of the parties was tested in the elections of the President and Vice-Presidents of the Chamber. A Socialist—and that Scheidemann, particularly hated by the Conservatives on account of his speech in the Reichstag two years earlier, when he had said, "I am too well acquainted with Prussian history not to know that broken promises belong, so to speak, to the most exalted traditions of the ruling house of Prussia"—was for the first time elected first Vice-President. The President and second Vice-President resigned rather than work with him; in the end, after much juggling, the Progressives (who numbered only 41 deputies) secured the offices of President and first Vice-President, the second Vice-President being a National Liberal. Thus party intrigues perpetuated the curse of German political life, the exclusion of the Social Democrats from all positions of public responsibility; while the Centre, the second strongest party, was also excluded from presidential office. Another grave symptom was the fact that during these elections and in the work of the Reichstag organised commercial interests became an open political force. A vehement protest was made during the elections by an honest and uncompromising deputy, Count Posadowsky.

Foreign Policy before the War.—In foreign policy, too, Bethmann Hollweg had found a much more difficult situation than appeared on the surface. The secret documents of the Foreign Office, published as regards the years 1871–1912 in 30 volumes at the beginning of 1926, show where the key to the policy of the European Powers lay since the beginning of the 20th century, and why the Western Powers could consider themselves endangered by a threat of German hegemony at the same time that Germany could complain of isolation and "encirclement." The key lay in the unreality of the Triple Alliance, the southern partner of which could now only be considered an ally as a matter of form, not in reality. When Bismarck, after long hesitation and consideration, concluded the first treaty of the Triple Alliance in 1882 at Italy's request, relations between Italy and France in the Mediterranean were so strained that war between France and Italy was more probable than a French attack on Germany. The Triple Alliance therefore gave security for immediate mutual help in case of a French attack on Germany or Italy; it afforded Italy security and lent the necessary weight to its claims to the north coast of Africa and to equality of rights with France and Great Britain in all Mediterranean questions. When, however, Italy had come to an agreement with France on the delimitation of her spheres of influence in Tunis, Algiers and Morocco on the one hand and Tripoli on the other, and when the Egypt-Morocco agreement between France and Great Britain (1904) had drawn Britain also into this Mediterranean entente, all danger for Italy of a French attack vanished, and thus any support from Germany became superfluous.

It was remembered also in Italy that it was precisely the foreign ministers who had been true to the Triple Alliance who had complained that Germany was holding Italy back from her natural expansion in North Africa out of fear of being drawn into a Mediterranean conflict. This complaint over the passivity of the Triple Alliance policy, which was especially clearly put by Baron Blanc in his great "Aide-Mémoire" of July 14 1895 to Lord Salisbury and to the other two Powers of the Triple Entente is the direct origin of Italy's *rapprochement* with France at the end of the 19th century. Since 1901 the German Foreign Office and General Staff fully realised that even in case of unconcealed French aggression, if it took place on the Rhine, Germany could not reckon on the military assistance which Italy had promised to send her over the Brenner and through the Tirol and South Germany, and that no Italian Govt. would be able to let Italy fight with Germany against France, in the face of public opinion. It is clear from a communication of Von Schlieffen, chief of the German general staff,[1] that public admission of this fact was only prevented by fear that Austria-Hungary would lose all confidence in the Triple Alliance, and even in the alliance with Germany, if she learnt that in no circumstances could reliance be placed upon Italy's military assistance.

Even Prince Bülow, the most loyal friend of the Italian alliance deliberated whether it would not be better, in view of the real situation, to let the Triple Alliance lapse and openly admit Germany's isolation. He believed, however, that the agitation which such open dealing would at first provoke in Europe would bring such a great danger for peace that again and again he plastered over the rent. Consequently, whenever Germany was confronted with a proposal for conference of the Great Powers, her Foreign Office sought to avoid her participation. Such proposals always looked as though they would lead to an unbiased adjustment of views between two equally strong groups of which neither could outvote the other; for in every issue between the Great Powers, whether it arose over Morocco, the Near East, the Balkans or the Far East, a State of the Triple Alliance and a State of the Entente always at first appeared as adversaries. Their partners played the rôle of mediating powers, two against two, and their parity seemed specially to fit them to bring about a compromise. Such was the apparent position. But the German Foreign Office knew that Italy could not and would not stand by Austria in a German encounter with Great Britain or France, nor by Germany in a conflict between Austria and Russia, but that she would always have closer diplomatic contact with France and Britain, and even with Russia, than with her Allies, who on their side did not usually consult her before negotiating on Balkan questions with one another or with the Entente Powers.

When Germany did take part in the Algeciras Conference (Jan. 10–April 17 1910), in fact insisted against the wishes of France that this conference be held—the reason was that Germany believed that she would be supported outside Europe.

[1] It may be explained that Von Schlieffen retired towards the end of 1905. For the history of "the plan" up to the outbreak of War, see the official record *Der Weltkrieg*, compiled from the archives of the Reich, vol. 1, pp. 6–19 (Berlin, 1925). Ed. *E.B.*

Thanks to the ties which had been formed between the Emperor and President Roosevelt by the German Ambassador Speck von Sternburg, Germany expected that the United States would advocate the principle of the "open door" in the Moroccan question, and would join Germany in opposing the grant of a preferential mandate for France. Therefore Bülow did not then think that Germany's isolation in Europe was an obstacle to the conference. All the greater was the disillusionment when Germany and Austria-Hungary stood alone at Algeciras as elsewhere. Bethmann Hollweg directly experienced not only this disappointment but the effects of Bülow's subsequent procedure in the Bosnian annexation crisis of 1908–9.

The Agadir Incident and the Settlement in Africa.—Since the first Moroccan crisis the Emperor had acquiesced, though unwillingly, in the policy of the Chancellor and of the Foreign Office, particularly in Morocco and the Near East, and therefore the Foreign Office had always to strive to confront him with a *fait accompli*. The Chancellor, who was naturally extremely prudent, took the responsibility for the sensational "Panther leap" to Agadir (July 1 1911). If a conference was to be avoided because Germany was doomed to isolation (shared, at the very best, with Austria), an understanding made directly with France was essential. The Secretary of State, Von Kiderlen-Wächter, thought that this could be appropriately initiated by sending a warship to protect German commercial interests in Southern Morocco. He subsequently secured the Franco-German African Convention of Nov. 4 1911 after negotiations with the French Ambassador Jules Cambon.

Kiderlen was neither a Junker nor a Prussian; he came from Württemberg, home of the South German spirit of independence and democracy. He was, moreover, no militarist. He entertained a keen, even personal hostility towards Admiral von Tirpitz and the Emperor's military entourage, and was convinced that Germany could and must maintain her position by diplomatic means and without war. He claims for himself the credit of averting the danger of hostilities between Austria-Hungary and Russia over the annexation of Bosnia and Serbia's demand for compensation in Novi-Pazar. The Note of March 21 1909, in which Bülow informed the Russian Govt. that Germany would "let things take their course" if Russia did not accept her proposal for mediation, was drafted by Kiderlen; he had made its tone that of an ultimatum in demanding from Isvolsky "a clear and categoric answer, a precise answer—yes or no."[1] Kiderlen was at the time Ambassador at Bucharest, but in the interval he assumed office as Foreign Secretary, in spite of the Emperor's personal dislike of him. He was the more inclined to a repetition of surprise tactics in diplomacy as they enabled him to exclude the Emperor himself from the direction of policy. Incidentally, Kiderlen treated Parliament even more brusquely, if possible, than he did his Sovereign and his military advisers.

The dispatch of the "Panther" to Agadir became known on July 1 1911. On July 9 Kiderlen resumed his conversations with Jules Cambon. At the end of the month the press of the Right and Right Centre began to attack Bethmann Hollweg and the Emperor himself for weakness towards France in Morocco. Kiderlen, in order to conciliate nationalist opposition to negotiations with France, had created the belief that France would cede the French Congo entire to Germany; there was therefore deep disappointment when it became clear that Germany would only receive a strip of territory securing her trade communications with the Congo river and the Belgian Congo. Bethmann Hollweg and Kiderlen, however, continued the negotiations. The Morocco-Congo Agreement was signed on Nov. 4 and published on Nov. 7. Germany accorded a material recognition of the French protectorate over Morocco; France promised only freedom of trade and equality of treatment to the nationals of the European Powers, particularly as regards concessions for public works; but ceded to Germany 275,000 sq. km. in the north and northwest of the French Congo, receiving in exchange 12,000 sq. km. in the region of Lake Chad. Germany obtained access to the Congo river, while France acquired the right to construct military roads and a railway through the territory ceded to Germany, to connect the coast with the interior.

[1] *Grosse Politik*, No. 9,460.

The Morocco agreement was, in general, welcomed by the Left but censured by the Right. The critics designated the newly acquired strip of southern Cameroon as worthless, and qualified the recognition of French predominance in Morocco as a feeble withdrawal before England's menaces, as expressed in particular in Lloyd George's Mansion House speech (July 21). The Chancellor defended the agreement in a great speech before the Reichstag on Nov. 9, in which he dealt in particular with the charge of irresolute policy:—

> From the very beginning our programme has been: to accord increased political rights to France only in return for increased security for our commercial interests in Morocco, and for the acquisition of colonial territory. We have not at any moment sought for territorial acquisition in Morocco itself. Negotiations between ourselves and France *alone*, not before an international congress, nor with the inclusion of a third party—this is the programme which we have laid down, and we have carried it out.

Diplomatic representations had been made in London respecting Lloyd George's speech. In the meantime, the British Govt. itself had held back, not desiring to intervene in the Franco-German negotiations. A "vigorous policy," such as the Right wing critics demanded, was only possible for Germany if she were strong on the Continent and avoided untenable positions outside Europe. Morocco had proved a festering sore not only in Franco-German but also in Anglo-German relations. The cause of peace was served by closing the wound. And finally:—

> Others, gentlemen, would favour a preventive war, against France, or against England, or against both together. But preventive war was a mistake, war must be avoided whenever possible. No one can tell whether hereafter Germany may be called upon to carry on war with her neighbours. The responsibility to-day is mine, and I say that it is my duty to conduct affairs in such a way that a war which might be avoided, a war which is not demanded by Germany's honour, is indeed avoided.

The Conservative opposition was directed by Heydebrand, known as the "uncrowned King of Prussia," and it was observed that the Crown Prince applauded him from the tribune in Parliament. The Crown Prince's criticism was really personal to the Emperor, and so William II. took it; he transferred his son from Danzig, where he was commanding a cavalry regiment, to work on the general staff.

This agreement had removed Morocco from among the direct political causes of a European war, even as the Franco-British Mediterranean agreement had removed Egypt. It was to be expected that new unrest would now break out elsewhere, and since the termination of the Russo-Japanese War the Balkans and the Near East seemed destined for this part.

German foreign policy was now concentrated upon the peaceful settlement of the Baghdad railway question, first by means of the agreement with Russia of Aug. 19 1911, and then on the negotiations which resulted in the agreement with Great Britain concluded in July 1914. The death of Von Kiderlen, on Dec. 30 1912, and of Marschall von Bieberstein, ambassador in London, (Sept. 24) were serious losses to the German diplomatic service. The death of Marschall dangerously reinforced Austrian influence in Berlin. As the most energetic promoter of friendship between Germany and Turkey, Marschall, from his post at Constantinople, had strongly opposed all Austrian encroachments in the Balkans, particularly before and during the Bosnian crisis of 1908–9. Unlike Count Aehrenthal, he never allowed himself to be influenced by prejudices of domestic policy in his idea of the necessary co-operation between the three Empires. As Ambassador in London, a post which he had hardly assumed when he died, Marschall would probably also have easily found the right attitude towards English Parliamentary policy.

The Turco-Italian War, for which Emperor and people alike strongly condemned the Italians, would probably have injured the Triple Alliance more if any illusions had been entertained in Berlin. It was only because nobody expected Italy to have any regard for her Allies that Germany was content to look on while Turkey, the only Power with which she was in close and friendly relations, was deprived of one of her provinces and suffered heav-

ily from the war. During the war, on the occasion of the Emperor's visit to Venice in March 1912, the stability of the Triple Alliance was affirmed. In Dec. 1912 the Alliance was renewed without comment, its renewal on each previous occasion having been preceded by protracted negotiations. When the first Balkan War (1912) gave rise to a new and acute danger, and mobilisation seemed imminent on the Austro-Russian frontier, with all the results which it entailed in the summer of 1914, German policy, in close co-operation with that of Sir Edward Grey, brought pressure on Vienna, whilst the Emperor used his influence with the Archduke Francis Ferdinand, during the latter's visit to Springe (Nov. 22–3 1912), to dissuade Austria from threatening Serbia, and Russia from emphasising her rôle of Serbia's protector. The supporters of the policy of preventive wars were bitterly disappointed, and they spread broadcast an utterance attributed to the Emperor, in which he was said to have insisted that "the Austrians must not rattle the German sword."[1]

Home Politics 1912–4.—In the two years preceding the outbreak of the War, however, the foreign political situation was much less acute than the domestic. In the former field may be mentioned the characteristic incident of the Emperor's visit to Switzerland, with the sincere good feelings which it aroused, and his energetic commendation of the Swiss citizen army (Sept. 3–5 1912). The year 1912 brought the first ominous symptoms: the plans for strengthening the army and navy (the latter unhappily coinciding with the visit of Lord Haldane to Berlin); the resignation of Wermuth, Secretary to the Imperial Treasury, in March 1912, which was interpreted as an abandonment of the death duties; the miners' strike of March 1912, and the much more serious and enduring phenomenon of the rise in meat prices in the autumn and winter of 1912–3—a powerful weapon of agitation in the hands of the Left, for the Agrarians of the Right and Centre opposed the import of cheap foreign meat; the even more threatening insecurity of the Parliamentary majority, for a violent contest had arisen between the two Protectionist parties of the "blue and black" bloc since the campaign opened by the Centre (originating in Bavaria) to secure the abrogation of the Jesuit law. On that question the National Liberals voted with the Conservatives; the Left wing Liberals and Socialists, as opposed in principle to all exceptional legislation, with the Centre.

But, above all, the Emperor and the Prussian Court and military authorities were finding great difficulty in accommodating themselves to the new conditions in Alsace. Almost all the conflicts of this period arose among the German-speaking and German-bred Alsatians and not in predominantly French Lorraine. When the administration of Alsace withheld Government orders from a factory in Grafenstaden on account of the alleged provocative and anti-German conduct of the manager, it had the Landtag against it (unanimous vote of censure by the second Chamber on May 7 1912). At a dinner given by the Governor in Strasbourg the Emperor had expressed the intention of destroying the Alsatian Constitution and converting Alsace-Lorraine into a Prussian province if matters went on like this. This was not taken very seriously by the Alsatians themselves. The Alsatian papers even admitted that it was comprehensible that the Emperor should feel the opposition of the Landtag as ingratitude. In the Reichstag, however, Scheidemann seized upon the Emperor's pronouncement to remark that in any case to become Prussian was the harshest punishment Germany could inflict. The Chancellor and the Ministers walked out, and the President afterwards called the speaker to order. But the Social Democrats had moved a stage further Left.

Social Legislation.—The principal sufferers from stringent conditions in the German Reich were the numerous Government administrative officials (members of the post-office, railways, revenue office, clerks), although their loyalty made them slow to voice their grievances. The manual workers vented upon the big stores, the chief of which were in the hands of Jews, their anger at the high prices of necessaries and became anti-Semites. The workers who were organised in trade unions were materially not badly off. State insurance for disabled persons and dependants of the deceased, for the victims of accidents and for the sick, was now established on a uniform basis for the Empire (Imperial Insurance Act of July 19 1911). Considerable power was assured to the operatives, particularly in the establishment of the local sickness funds, so much so that the doctors constantly complained that they were at the mercy of the local officials concerned with the funds, who were almost all Social Democrats. For a time the doctors even threatened to strike on this issue. A new chapter of jurisprudence of great importance was opened: the "Labour Laws." This summed up in a comprehensive code the regulation of conditions of labour under public and civil law. There was also talk of establishing "labour courts" in which civil cases between workers and employers were to be decided. The court was to consist, on the model of the industrial and mercantile courts, of a lawyer as president and two assessors (one an employer and one a worker), elected by the employers and workers of the district. In these elections the principle of proportional representation was tried for the first time in Germany on a considerable scale. The formation of chambers of labour was also planned. These were to have the same standing in economic life as the chambers of commerce and of agriculture. They were, however, to be formed on a footing of equality—that is to say, workers' representatives were also to be included.

On July 1 1912 persons in receipt of disablement pay numbered 953,057; in receipt of sickness benefit 15,866. Old age pensioners numbered 91,331; and the total pensions paid since Jan. 1 1900, 510,838. Under the provision for pensions for the widows and orphans of insured persons in the Act of 1911, 4,562 pensions had been paid by June 30 1912 and 1,059 single grants.

The Centenary Commemorations, 1913.—The year 1913 opened with festivals commemorating 1813, and what to the German people was the great war of liberation of its history. It was a genuine celebration of freedom and a national festival. The German dynasties, the governments and the political parties showed themselves ready to allay old quarrels. The betrothal of the Emperor's daughter to Prince Ernest Augustus of Brunswick, the grandson and heir of the last Guelph King of Hanover, brought about a reconciliation with the Duke of Cumberland, whose son ascended the throne of the federal state of Brunswick. It was announced on the Emperor's 25th jubilee (June 16) that he had destroyed a secret testament of Frederick William IV. in which the latter had enjoined upon all his successors to abolish the Prussian Constitution before assuming rule. On the occasion of the Emperor's jubilee, for which almost all the federal Princes assembled in Berlin, the Prince Regent of Bavaria, Ludwig, who in Nov. 1913 was empowered by law to assume the royal office in view of the persistence of King Otto's incurable mental ailment, pledged the loyalty of the states to the Empire. In reply, the Emperor styled the sovereigns of the German states and the burgomasters of the free towns his "allies," and declared that in their independence, as guaranteed by the Constitution, lay the strength of the Empire itself. In the Reichstag the motion of the Centre on the Jesuits was adopted on Feb. 19 1913, after a peaceful discussion. During the debates on the colonial budget, Erzberger, formerly the keenest critic of the abuses existing in certain colonies, supported the colonial policy of the Government.

Passing of the Army Reform Bill.—Even the Army bill, officially announced on March 1, encountered no very bitter opposition. The bill increased the peace strength from 544,271 men to 661,176, entailing the creation of 84 new battalions and squadrons. The total cost was to amount to an initial outlay of 1,050 million marks, and subsequently of 180,000,000 to 190,000,000 marks annually. The initial costs were to be covered by a capital impost for one year only, and in the case of high incomes by a single levy on income ("contribution towards national defence") both non-recurring. The current expenses were to be met by an increase of the quota contributed towards the Imperial finances

[1] The official records of the conversations in politics between the Emperor and the Archduke at this meeting, and at the Emperor's subsequent visit to Konopischt in June 1914, will be published in volumes 32 and 35 of the collection of German archives: *Die Grosse Politik der Europäischen Kabinette.* Until their appearance it is wiser to suspend judgment.

by the federal states, which those states levied through their own taxation upon capital or income. The discussions in the Reichstag turned less upon the strengthening of the Army than upon the means of meeting the cost. The Left wing parties demanded, and in part secured, that property, particularly unearned increment, should bear the chief burden of the single levy, and further the introduction of a steep, progressive graduation of the rates of taxation. Apart from the fact that they were in general favourable to the Army bill, the parties of the Right found satisfaction in the abandonment, at any rate for the time, of the plan of permanent death duties. On the death on Aug. 13 of Bebel, the venerable leader of German Social Democracy, all parties united in a tribute of respect to his character, and integrity and none denied that he was a "good German."

The Zabern Incident.—Yet how delusive was this tranquility was manifested by the Zabern incident of Nov. 1913 (*see* ALSACE-LORRAINE); an incident so trivial in itself that its prodigious consequences can only be explained by the existence of a general state of political tension. The Government's position was weakened, for its attitude over the incident was censured by 293 votes against 54 in the Reichstag, unanimously in the lower Chamber of the Alsatian Landtag and by 33 votes against three in the upper Chamber. At the same time the Imperial Chancellor had incurred the definite hostility of the military party. In an important debate in the Prussian Upper House on Jan. 10 1914 Bethmann Hollweg developed his whole policy in a discussion with the spokesman of the Conservatives, Count Yorck zu Wartenburg. Zabern was not discussed, but it was present in the thoughts of every speaker. Bethmann defended the constitution of Alsace-Lorraine. He vindicated his right, disputed by Count Yorck, of calling a commission of inquiry with the co-operation of deputies of the Reichstag to report on the conditions and abuses in the army contracts' department. But he, on the other hand, admitted that precisely in the Empire with its universal and free suffrage and the social tendencies of its legislation a Prussia with a different "internal structure," that is without universal suffrage and without responsible parliamentary government and with a "firm military foundation," seemed essential.

The Government aimed at compromises between the Emperor and Parliament and between Prussia and the Empire. But the parties and the politically minded section of the nation all felt that alike in domestic and foreign politics the Government was lacking in decision. How little, however, the professional politicians knew of the reality may be seen from the fact that the appointment of Herr von Loebell, who during and after the War proved himself a leader of the reactionaries, as Prussian Minister of the Interior was characterised as a concession to Liberalism.

THE WAR PERIOD

The Sarajevo Murder.—When the news of the murder at Sarajevo on June 28 1914 became known in Germany, the horror generally felt was mingled in pacifist circles with a certain silent relief. Rumour had assigned the murdered man to the war party. From the new heir to the Austro-Hungarian throne a peaceful policy might be expected. It was anticipated that Austria-Hungary would take speedy action against Serbia, as far as possible in agreement with Russia. It was thought that the sympathies of the world were on Austria's side, even if she should undertake a short punitive expedition against Serbia.

The most recent and very meticulous examination of all the archives and the utterances of all witnesses have made it clear that in the early days of July the Emperor and his entourage had no thoughts whatever of a European war, and that neither a Crown Council, still less a Council of War—as the American Ambassador Morgenthau claimed to have heard from the German Ambassador in Constantinople—was held in Potsdam or Berlin. But when Von Tschirschky, the German Ambassador in Vienna, reported on June 30 that Vienna desired to use the opportunity to settle accounts with the Serbs thoroughly, but that he himself seized every occasion to "issue calm but very emphatic and serious warnings against precipitate action," the Emperor commented: "Who has authorised him to do so? It is very stupid. It is no business of his. What Austria thinks of doing is solely her affair." Thenceforward the Ambassador let the Austrians go their own way, and as on July 5 the Emperor had received a letter from the Emperor Francis Joseph and a memorandum drawn up by Count Berchtold, and the Chancellor had declared that in harmony with his obligations as an ally the Emperor would stand loyally by the side of Austria-Hungary (July 5 and 6), Vienna felt that it could rely on German aid in its Balkan plans. But the Emperor and the Chancellor merely intended that Austria should demand satisfaction from Serbia as speedily and energetically as possible, before the murder of the heir became a European question. It, therefore, implied no change of view that the Emperor received the Serbian answer to the Austrian ultimatum of July 23 with the comment:—

> A brilliant achievement for a grace of 48 hours. It is more than could have been expected. A great moral triumph for Vienna. But every reason for war now disappears, and Giesl ought to have remained quietly at Belgrade. On the strength of this I would never have ordered mobilisation.

When Austria rejected the Serbian reply, and on July 28 declared war on Serbia without having previously consulted Berlin, the Chancellor and the Secretary of State, Von Jagow, realised the danger of the position—no doubt much too late. On July 29 Bethmann telegraphed to Vienna:—

> I view the attitude of the Government in Vienna and its inconsistent attitude towards the different Cabinets with increasing discomfort. In St. Petersburg it asserts its territorial disinterestedness, it leaves us entirely in the dark as to its programme, feeds Rome with meaningless phrases regarding the compensation question, whilst in London Count Mensdorff gives away portions of Serbia to Bulgaria and Albania and proceeds to contradict the solemn declarations in St. Petersburg. From these contradictions I must draw the conclusions that . . . the Viennese Government harbours plans which it deems it wise to conceal from us, to assure itself in any event of German support and not by an open avowal to run the risk of a possible refusal.

For a conference, however, as proposed in particular by Grey, Berlin was equally disinclined, as conferences had always been unwelcome to her since Algeciras. The last hope, therefore, lay in successful direct negotiations between Vienna and St Petersburg. When these broke down on July 30, Germany supported in Vienna (July 30) the final British proposal for mediation to the effect that after the capture of Belgrade, Austria should announce her intention of advancing no further until the Powers should have mediated between herself and Russia. Count Berchtold's temporising defeated this proposal. With the general mobilisations of Russia and Austria on July 31 and that of Germany on Aug. 1 a state of war was actually in being, although the declarations of war followed later. For in the three states immediately involved the chiefs of the general staffs were now unanimous in asserting that any further delay would endanger the prospects of success in the field, and no civilian Chancellor could take the responsibility of opposing this view. Moreover, the executive power had now passed in accordance with the Constitution to the supreme military authority. (*See* also EUROPE.)

The Invasion of Belgium.—The German plan of campaign for a war on two fronts, as framed by the elder Von Moltke, had envisaged defensive action on the west, offensive on the east. Subsequently for a short time there were two alternative plans. The official account of the War by the German general staff proves that in 1892 under Count Schlieffen the plan of an eastern offensive was abandoned, the offensive on the western front with the march through Belgium being retained as the sole plan. The Foreign Office was not consulted.[1] The Emperor made a single

[1] It is necessary, however, for the understanding of the Schlieffen plan, which originally contemplated the violation of Dutch as well as Belgian neutrality, to read *Graf von Schlieffen*, by Freytag-Loringhoven (Berlin, 1920), and also *Erinnerungen, Briefe, Dokumente 1877–1916*, by the second Von Moltke, especially pp. 429, 430 (Stuttgart, 1922). From before the end of the 19th century the manoeuvres were obviously based on the principle of a turning movement through Belgium and Luxembourg (Reichsarchiv, *Der Weltkrieg*, vol. 1, Berlin, 1925); the Kaiser's statesmen were aware that strategical railway facilities were continually developed in the same direction and provided for in the Budget. There is no doubt that the Schlieffen plan was officially regarded as a life-and-death necessity of German policy in case of war.—Ed. *E.B.*

allusion to the plan in a personal letter to Prince Bülow, who returned a dilatory answer. Bethmann Hollweg and his Secretary of State for Foreign Affairs, Von Jagow, were never asked whether they approved of the military plan which contemplated an offensive against France and the violation of Belgian neutrality. According to the Constitution, the Emperor, as Supreme War Lord, had to decide during war time in cases of differences of opinion between the civil and military authorities. But once set in motion, the machine of mobilisation revolved so rapidly that even the Emperor could no longer have interposed. Bethmann Hollweg declared in the Reichstag on Aug. 4 1914:—

We are now acting in self-defence, and necessity knows no law. Our troops have occupied Luxembourg and have perhaps already entered Belgian territory. This is in contravention of the behests of international law. It is true that the French Government stated in Brussels its intention of respecting the neutrality of Belgium, as long as the enemy respects it. We knew, however, that France was ready to march in. France could wait, we could not. A French flank attack on the lower Rhine might have proved fatal. We were thus compelled to disregard the justified protests of the Governments of Luxembourg and Belgium. The wrong that we are thereby inflicting —I speak openly—we will strive to repair as soon as our military objective is attained.

Early Stages of the War.—The parties concluded a truce, and the Social Democrats voted credits for the War, which they regarded as a defensive war against Tsarist Russia. The people everywhere accepted the situation very gravely. The immediate summons to the colours of the whole Landsturm up to 45 brought home the danger to all. The general nervous feeling during the first weeks was betrayed in the hunts after spies and transports of Russian gold. When the first prisoners of war arrived, the military authorities feared that the people would fraternize with them, and strictly forbade any intercourse. The civil authority at home was transferred to the Generals commanding Army Corps Areas in Germany, whose staffs consisted usually of superannuated and not always very intelligent officers, who were entrusted with all emergency defence measures and with censorship of the press and all other printed matter. Thanks to the censorship, the defeat on the Marne could at first be kept almost entirely secret. The war for positions was declared to be the deliberate plan of the general staff. Although Von Moltke was dismissed, and although it was already determined that the High Seas Fleet should not risk itself in open battle, General Headquarters still hoped for victory. The fatal effects for Austria of the failure to give her speedy help against the Russian army were not realised, especially in view of Hindenburg's striking success in the East.

It thus seemed clear that the prolongation of the War and all the accompanying distress was solely due to the blockade. This blockade, initiated by Great Britain, was regarded, like the sequestration of enemy property, as a violation of international law. Since the Anglo-American conception, which treated individual nationals of enemy states as "alien enemies," was new to Germany the opinion arose that it was the specific English mode of warfare—as distinct from the French or the Russian—which was inhumane and contrary to international law, particularly as the indignation aroused in Europe, and especially in France by the application of the same methods in the Boer War was not forgotten, while of course the decisions in British and American courts on which the blockade rested were unknown.[1] In the first year of the War the conviction had already arisen that the German army was invincible, and that the sole source of danger lay in the "war of hunger" which threatened women and children. If the population at home could "hold out," in the end the War must be won.

As the War dragged on questions of internal politics and economics revived. The people considered that their sacrifices in human lives—volunteers, officers of the reserve, substitutes as well as those on active service—and the privations which they had borne in meeting the costs of the War and in the internal loans, which had been in the first instance subscribed by the holders of small savings-funds, entitled them to claim full political rights. The Reichstag voiced this opinion and the rights of the civil authority with increasing firmness. The civil administration, however, was powerless against the military authorities. Since General Ludendorff had become Quartermaster-General, and a number of his personal adherents had converted the War Press Bureau, and later the "patriotic instruction" given to the troops, into an instrument of political propaganda, the Zabern episode was re-enacted on a large scale. The military authorities thought the Chancellor and the Foreign Office too weak in their attitude towards foreign countries and towards the Reichstag, and that when the civilian authority broke down the military must take over their duties.

The real test of strength came on the question of submarine warfare, to which the Chancellor, the Foreign Office and, of the other ministers in particular, Helfferich, the influential Secretary to the Imperial Treasury, stood opposed, when General Headquarters demanded it again in 1917 after the conferences at Pless of Aug. 30 1916 and Jan. 9 1917.[2] The supreme military authorities, supported by the chief of the naval staff, pointed out that the exchange of Notes between the German and the Entente Govts. with the United States and the other neutral Governments between Dec. 12 1916 and Jan. 12 1917 had proved that peace offers could not be negotiated through diplomatic channels.

The German Peace Offer, Dec. 1916.—That might be true, but the intrinsic weakness of the German Notes (*see* EUROPE) had resided in the fact that public opinion, the Reichstag, and possibly the Government itself, falsely informed by General Headquarters on the military position, considered the offers contained in them to be quite acceptable and even generous. In particular, no plain admission of a duty of reparation towards Belgium was made, because General Headquarters insisted that if Germany was to renounce territorial aggrandisement she must receive guarantees in the West and East. Moreover, heavy industry, at that time closely allied with General Headquarters, desired to see the economic predominance of Germany in Belgium and northeastern France established by the conditions of peace. Bethmann himself and after him Helfferich at length gave way to the military authorities Jan. 9 1917, and the Emperor issued orders to begin unrestricted U-boat warfare on Feb. 1. When on Jan. 23 1917 President Wilson proposed mediation to Count Bernstorff through Colonel House, and inquired the German terms of peace, the Chancellor, who received the communication on the 28th, lacked the strength to stop unrestricted U-boat warfare, and thereby destroyed his own position. He remained in office long enough to issue the so-called Easter message of April 7 1917 from the Emperor as King of Prussia, in which the abolition of the Prussian three-class franchise was promised, in order to reconcile the Social Democrats. But the new "Fatherland party" ("Vaterlandspartei"), which enjoyed the support of General Headquarters, and in particular its co-founder Kapp, attacked the Chancellor without mercy. When he fell at last, this was partly due to Erzberger's attack in the Main Committee of the Reichstag on July 6 1917 (recording the complete failure of U-boat warfare); partly to the military leaders who had come to Berlin on July 7 and, above all, to Ludendorff's *alter ego*, Colonel Bauer; finally, Ludendorff and Hindenburg extorted the resignation of the Chancellor from the Emperor by threatening their own resignation (July 13).

His successor, Michaelis, was nominated at the instance of the Emperor's entourage, without negotiations with the Reichstag. His restrictive interpretation of the peace resolution of the Reichstag, adopted on July 19 1917, deprived it of all value abroad (*see* EUROPE). His ambiguous attitude, moreover, was partly responsible for the failure of the pacific activities of Pope Benedict XV. in Aug. 1917. The Vice-Chancellor Helfferich was the most influential member of the Government. He en-

[1] For the general case *see* BLOCKADE.

[2] The first occasion was Feb. 4 1915, when the Government—this time against the advice of Tirpitz—declared the British territorial waters to be a war-area as from Feb. 18. Mr. Wilson's mediatory proposal, that Germany should recognise the rules in force for cruiser warfare as applying to U-boat warfare, and that in return England should permit the passage of American provisions, failed. When the "Lusitania" was sunk, the protest of the United States of May 15 resulted in the suspension of the U-boat war (July 8 1915; finally on May 4 1916).

joyed the special confidence of the Supreme Command, whose views he regularly imposed on the civilian authorities.

Economic Measures.—In the meantime, the economic structure of the German Empire had undergone a complete change. On Aug. 8 1914 Walter Rathenau founded the department dealing with raw materials for war industries in the Prussian War Office (" Kriegsrohstoffabteilung des preussischen Kriegsministeriums "), which for a considerable time met the demand for the chief imported raw materials of war industries, particularly metals, cotton, grease, india-rubber and glycerine, by economic handling of home supplies, organising imports from neutral countries (" compensation trade ") and by stimulating the discovery of substitutes (nitrogen from the atmosphere, raw material for textiles from nettles and wood, etc.). Foodstuffs were early rationed. The yield of the soil declined owing to the lack of manure and skilled labour. Ration cards were introduced, first for bread, then fats, sugar, milk, eggs, meat and potatoes. From the winter of 1916–7 onwards, the quantities allowed no longer sufficed to nourish children and young people. The home producers were also, in principle, limited to these rations; but watertight control was impossible, and smuggling and illicit sales became habitual. The sequestration of brass and copper articles in the smallest households excited much bitterness, since it was suspected that the treasures of the rich were being spared, those of the poor taken.

While the economic capacity of the individual, particularly of the lower middle-classes and officials, was thus physically and morally undermined and the mass of the population compulsorily socialised, on the basis of a bare subsistence rate, the economic capacity of individual industries expanded enormously, and the workers employed in them demanded a higher standard of living. The so-called " Hindenburg Programme " (Hindenburg's only in name) carried out by the War Department (*Kriegsamt*) founded on Nov. 1 1916 in accordance with the law of auxiliary services (*Hilfsdienstgesetz*), was a prime cause of the economic collapse. By an economically unjustifiable increase in munition workers' wages it disorganised other industries, in some cases brought about a stoppage and constructed at enormous expense blast furnaces which stood idle for lack of fuel. The " conscription of labour " provided welcome material for radical agitators, while the melting down of church bells offended the devout. War expenditure rose from two milliard marks a month in Aug. 1916 to more than three milliards in Dec. 1916, and to almost five milliards by Nov. 1918. Moreover, this programme laid the foundations of the political power of the great Rhineland-Westphalian industrials.

In the autumn of 1917 the civil authority reasserted itself. Helfferich was replaced by the Democrat Payer, from Württemberg. From Nov. 1917 the " Interparty-Commission " of the Reichstag, in which Erzberger and Scheidemann were the chief figures, sat in permanence. On Jan. 24 1918 the Emperor stated to Hindenburg and Ludendorff that he himself and the Chancellor bore the sole responsibility for the direction of political issues. In reality, however, particularly since General Headquarters had forced on him a new Chief of Cabinet, the Emperor was entirely subservient to the military authorities. The Supreme Command took its revenge in 1918; the Peace of Brest Litovsk with Russia (March 3 1918) and of Bucharest with Rumania (May 7 1918) were purely military dictates, bringing no lasting goodwill; although it is true that only a dictated peace could bring Finland and the border states freedom and self-determination.

General Headquarters regarded the spring offensive of 1918 as the last chance of securing a peace " which should strengthen the monarchy and extend Germany's power." When it broke down, the War was lost from a military standpoint; even Ludendorff recognised this on the " black day " of the breakthrough at Villiers-Bretonneux (Aug. 8 1918). In Sept. and Oct. the Bulgarian, Turkish and Austrian fronts collapsed.

On Sept. 24 the Main Committee of the Reichstag brought Social Democrats into the Government as Secretaries of State, reformed the Prussian franchise and proposed full autonomy for Alsace-Lorraine. Prince Max of Baden became Chancellor; but General Headquarters retained their influence, especially as the Emperor always retired to their shelter at any decisive moments. The Supreme Army Command determined the specific character of the notes sent by the German Govt. to President Wilson in Oct. 1918, and demanded that the note asking for an armistice should be sent out on the night of Oct. 3–4 at the latest, in view of the threatened collapse of the German front; and were also responsible for the second note of Oct. 12, dictated by the necessities of the military situation. Only when Wilson's note of Oct. 14 had to be answered did the Cabinet withstand the views of Ludendorff, who now again asserted that the front line could be held, and themselves continue the exchange of notes with President Wilson.

On Oct. 26 the Cabinet obtained Ludendorff's resignation,[1] and Hindenburg thereby regained the simple and honourable position, free from the taint of politics, which had won him the people's confidence in the early years of the War, and now enabled him to lead the army home, in the face of the pursuing enemy, without the occurrence of mutiny or plunder. Ludendorff did not, indeed, leave his post as Quartermaster-General without first disseminating the contention later known as the " legend of the stab in the back," that it had been the slackening of resistance at home which had made it impossible to the army to continue fighting.

THE REVOLUTION AND THE REPUBLIC

The fall of Ludendorff was deeply significant. The essence of Prussian tradition had always been the subordination of the civilian to the military power. In the first successful years of the War this tradition had naturally been fortified, and the military had assumed even more complete control over the conduct of politics. The Emperor and his entourage were entirely dominated by the Supreme Command, as was much of what ought to have been sensible Conservative opinion. When military defeat approached,

[1] For a fuller explanation of the circumstances *see* LUDENDORFF.

the Vaterlandspartei and similar circles, like the Emperor, attributed it, not to errors or weakness of the Supreme Command, but to the fact that civilian authority and opinion had not yet been entirely stifled.

In moderate liberal and democratic circles exactly the opposite process took place. Their leaders were driven by the intransigent and imperialist attitude of the extreme Right into strong sympathy with the Left. The great party of the Left was Social Democracy; but now when events seemed to be laying the future in its hands German Social Democracy found itself fatally disunited. Hampered by the undemocratic Prussian franchise and much frank repression, the German Socialist party had yet grown rapidly during the years of stress and rising prices which preceded the War. It had achieved a stake in the country, a complex organisation and considerable funds. Fear of losing these acquisitions, combined with natural patriotism and the dread of Russian autocracy, determined the attitude of the party leaders towards the War. On the crucial Aug. 4 1914 they abandoned the International; voted unanimously for the War credits in the Reichstag and concluded a " truce " with the other political parties. In return the Emperor, under pressure from the Government removed the restrictions on Socialist literature and admitted organised workmen into the state railway and other services. On Sept. 9 the Socialist leaders protested against the anti-German attitude of the International Socialist Bureau; and their spokesmen vigorously defended their national cause in the already vexed question of War guilt.

The moderate Socialists had really moved towards the left centre. A small fraction, however, dissented. In May 1915 one voice—that of Liebknecht—voted against a fresh War credit; and a group under Liebknecht and Rosa Luxemburg began to agitate for refusal of credits and a general strike to stop the War. In Nov. 1915, 18 Socialist deputies voted against the credits. The opposition now grew rapidly, but was itself divided. The larger group, under Haase, Kautsky, Ledebour and Bernstein, split definitely from the majority in March 1916 over the question of submarine warfare, and formed a separate group which at Easter 1917 took the title of the " Independent Social Democrat Party of Germany," with a programme of early peace without annexations. The extreme Left under Liebknecht (which in 1916 had begun to issue a secret paper named *Spartacus*) was already in touch with Lenin, Trotsky and Radek in Switzerland, and had adopted the programme of the Zimmerwald Congress. Both these parties were still largely heads without bodies, while the extremists were weakened by the imprisonment of Liebknecht in 1916. The Majority Socialists commanded the prestige and the organisation. But although the Russian revolution of March 1917 emboldened them, and at the International Socialist Conference at Stockholm in June 1917 they made a declaration against annexations and indemnities; and although the Emperor found it wise in his " Easter Message " of 1917 to promise a reform of the franchise, they might have been ignored had not Erzberger obtained and communicated to his colleagues of the Centre on July 6 a copy of Count Czernin's famous memoir in which he described Austria-Hungary as being on the verge of revolution, and victory as impossible.

Erzberger now propounded a resolution in favour of " peace by understanding," and the Centre and the Majority Socialists were definitely allied against the Imperialist aims of the Government and the Supreme Command. The latter were not yet ready for concessions; Bethmann Hollweg's successor, Michaelis, was their nominee. Only when Hertling succeeded him was a bill introduced which provided for a really democratic reform of the franchise; and the discussions on it outlasted the fall of the Empire. Certain concessions were, however, introduced; a minor electoral reform was carried on June 8 1918.

The Bolshevik revolution in Russia (Nov. 1917) widened the split in the Socialist camp. The Majority condemned Bolshevik methods in Russia, the Independent Socialists looked on them with much sympathy, and their following was strongly reinforced by unorganised labour, whose imagination was fired by the example of Russia and by the prisoners of war who began to return after the peace of Brest-Litovsk. The Spartacists were frankly out for the establishment of a dictatorship of the proletariat in Germany, and began to organise with the arms and money which the Russian agitators transmitted to them. All three groups, however, were alike emboldened by events in Russia; in Jan. and Feb. 1918 a series of munition strikes broke out in Germany which almost reached the scale of a revolution, their extent and order showing the vast power of the Majority Socialists, who, although they had not organised the strike, put themselves at its head to gain control of it.

The great munitions strikes, which were largely spontaneous, were symptomatic of an almost universal state of feeling. The almost intolerable strain and privations resulting from nearly four years of continuous war and blockade had affected practically the whole population. Hardly one man in a hundred saw in events in Russia the triumph of a new doctrine, the establishment of a new system, but those were innumerable who saw in it the end of a tyranny, of a driving of men beyond their powers, above all, of war and slaughter. The active policy of the Socialist leaders drew its strength from the great passivity of the over-driven masses; revolution was becoming the line of least resistance. The main motive in the German revolution, which substituted a Socialist for a monarchical Government, was to be anything but Socialist; it was the longing of workman and soldier to relieve themselves of the tyranny of the State in army and workshop.

In Sept. 1918 the general staff at last admitted the probability of defeat, and the Government prepared to make concessions to the moderates. Prince Max of Baden, the new Chancellor, asked the Majority Socialists to enter the Government. They made their acceptance conditional on far-reaching internal reforms; the liberation of Belgium; the evacuation of all occupied territory; and the abandonment of the treaties of Brest-Litovsk and Bucharest. Prince Max accepted the conditions, and took Scheidemann and Gustav Bauer, and later other Majority Socialists, into his Cabinet. The party then appealed to the Independents to re-unite; but the latter, who rejected all co-operation with bourgeois parties and demanded an immediate peace, refused brusquely.

The Outbreak of Revolution.—Prince Max filled the remainder of his Cabinet with liberals and democrats, including Erzberger. On Oct. 5 he propounded a programme containing a decided profession of democracy, with self-determination of nations. On Oct. 28, when Germany's allies had already failed her, he introduced a number of measures to democratise the Constitution and control the prerogatives of the Emperor, and especially to reduce the power of the military authorities. Meanwhile, however, Germany's own fighting forces had become infected. On Oct. 28 the fleet received orders to put out to sea " for manoeuvres." The crews, rightly suspecting that the real object was a last and desperate attack, refused to weigh anchor. Their ringleaders were arrested. On Nov. 5 a great meeting demanded their liberation. It was refused, and the demonstrators fired on. The next day the whole fleet was in uproar. There had been a naval mutiny in 1917, and a connection had been traced between the mutineers and the Independent leaders Haase and Dittmann. The situation was obviously critical. Noske, a Majority Socialist leader, was sent to Kiel to negotiate; he arrived to find a Sailors' Council in full control. He recommended that all their requests be granted, and remained in Kiel, where he was joined by Haase and Ledebour. Further Councils were formed. On the 6th the dock labourers in Hamburg revolted; a dictatorship of the proletariat was formed in Lübeck and demanded " immediate armistice and peace." Bremen joined on the same day; Hanover, Brunswick and Cologne on the 7th. The movement spread towards Berlin; revolutionary bodies took possession of Magdeburg, Leipzig and Dresden.

Thanks to the lamentable Socialist split, the whole of these movements were very confused. The Majority Socialists had still far the strongest organisation, but the movements in Northern Germany were largely spontaneous, the work of the unorganised proletariat. It was the outcome of a deep craving for peace

and a reaction against authority. Many concerned in it followed the lead of the Independent Socialists, who were not compromised by their connection with the Government, many that of the Spartacists, whose leader Liebknecht had been released from prison and was conducting a violent extremist agitation. The Spartarcists, numerically the smallest group, had the great advantage of a fixed programme, although, an unattainable one.

The most urgent question, in view of Germany's defeat, was how far continuity with the previous régime should be preserved. The parties of the Centre and Left Centre had not in the main gone further than the idea of a constitutional republic; and the Emperor had subscribed to the Constitution of Oct. 28, and on Nov. 2 had declared that the old order was destroyed and that the Emperor was the "servant of the people." But this declaration was issued from Spa, whither William had fled on Oct. 29. The servant of the people had made an unfortunate beginning in sheltering himself from them behind the bayonets of his soldiers in a town on occupied foreign territory. His conduct disheartened the monarchists and thinned their ranks, besides making it almost impossible for his loyal adherents to concert their policy, with its object away at the safe end of a long telephone wire. The republican movement received a great impetus.

The Majority Socialists were anxious not to break with the bourgeois parties, which enjoyed the confidence of the peasants and middle classes and commanded practically all administrative talent; while the Independents believed that a complete break with the past would ensure Germany better conditions of armistice. The Majority Socialists, carried forward on the tide of events, moved almost daily further Left, since to stand still would have meant losing their adherents to the Independents. On Nov. 4 they made up their minds in favour of a republic; and on Nov. 7 the rapid march of events outside Berlin determined them to present an ultimatum to the Government, demanding the abdication of the Emperor and the Crown Prince, under threat of withdrawing their members from the Government and proclaiming a general strike. The Emperor was still debating whether he could not lead the army back to restore order at home. The new Quartermaster-General, Groener, and Hindenburg pronounced this impossible on Nov. 9. The Emperor therefore telegraphed his abdication as German Emperor. On the 10th he fled to Holland.

Proclamation of the Republic.—Events had outrun him. Prince Max had announced the abdication on the morning of the 9th. His telephone conversations with William had given him the impression that the latter abdicated both as German Emperor and King of Prussia, and he still hoped to save the throne to the dynasty; but republics had already been declared on the 8th in Munich and Brunswick. The general strike was proclaimed; and Prince Max formally appointed Ebert, the leader of the Majority Socialists, as his successor, and retired. Almost his last act was to order the troops not to shoot on the vast processions already filling the streets of Berlin.

The power had thus devolved on the Majority Socialists, who made great efforts at once to preserve order—for which the collaboration of bourgeois parties was necessary—and to restore the unity of the Labour front. In Bavaria and some of the smaller states—every state in Germany, without an exception, was proclaiming the republic and forming more or less revolutionary Governments—this was effected without friction. In Berlin and the Government of the Reich it was more difficult. The Independent Socialists agreed to enter a Government, on condition that the Cabinet be purely Socialist. The heads of non-political ministries were allowed to belong to other parties, but each was "controlled" by a Majority and an Independent Socialist. The Government proper entitled itself a "Council of Commissioners of the People" and was composed of Ebert, Scheidemann and Landsberg for the Majority Socialists and Haase, Dittmann and Barth for the Independents. It exercised dictatorial powers. Scheidemann proclaimed the republic from the buildings of the Reichstag on Nov. 9. The new Government hurriedly passed a series of decrees abolishing the state of siege, with the various restrictions on freedom in force and proclaiming a general amnesty, but affirming the right to private property. Its chief task, however, was to conclude the Armistice; and Erzberger, who had remained in office as Secretary of State, had on behalf of the German Govt. received the conditions of Armistice from the Allies in the Forest of Compiègne on Nov. 8. The conditions made the resumption of hostilities by Germany impossible. As President Wilson had demanded, they laid down the evacuation of the left bank of the Rhine, the occupation of the bridgeheads of Cologne, Mainz and Coblenz, the restitution of prisoners of war without reciprocity and the continuance of the blockade. An answer was required by Nov. 11, and on that morning the Government was obliged to accept the terms without modification. At the same time they asked that peace negotiations should be initiated.

The Struggle Against the Extreme Left.—The severity of the terms was a blow to the Moderates and encouraged the extreme Left. Workmen's and soldiers' councils were already springing into existence everywhere; a last order of the Supreme Command had been to allow their formation unimpeded. Some were quite spontaneous, others organised by the Independents and Spartacists. Liebknecht had refused a generous offer to join the Government, and he and Rosa Luxemburg, assisted by Radek, representing Bolshevik Russia, worked furiously to proclaim a Soviet dictatorship on the spot. The Majority Socialists, on the other hand, considered themselves only mandatories till the real will of the people should have been ascertained by a Constituent Assembly. It was a struggle between dictatorship and democracy, and the issue hung in the balance. On Dec. 1 a "National Executive Committee of Workmen's and Soldiers' Councils" was formed under the Independent Daümig. The extremists in it regarded it as the supreme authority of Germany, which, since the Councils system *ipso facto* excludes the bourgeoisie, involved the dictatorship of the proletariat. On Dec. 16 the Committee met in Berlin. After a stormy debate lasting three days, the views of the Majority Socialists prevailed. The powers of the Committee were limited to summoning and dissolving the Council of Representatives, which received both executive and legislative powers. Elections for a Constituent Assembly to determine the future form of the German State were fixed for Jan. 19. The Independents condemned this decision as "social treachery," and a few days later the Spartacists appealed to arms. The Council called out troops against them, defeating the Spartacists, after heavy fighting, on Dec. 24. The Independents, in consequence, seceded from the Government on Dec. 29.

The Spartacists, who had adopted the name of "Communist Party of Germany" on Jan. 1 1919, prepared to renew the struggle. Meanwhile, however, Noske, who had been appointed Minister of National Defence, had hurriedly organised a force which again defeated the Spartacists after fighting which lasted from Jan. 5–13. Liebknecht and Rosa Luxemburg were arrested and murdered by their escorts, apparently in cold blood. During the next few months, Noske was probably the most powerful man in Germany. He was entirely ruthless. "Somebody," he remarked "must be the bloodhound." Till now, the change of system had been almost bloodless, and had indeed been accomplished with remarkable smoothness. No member of a ruling house was injured, some indeed were genuinely regretted by their subjects. The administration continued to function; the soldiers dispersed to their homes in order, largely thanks to the irreproachable conduct of Hindenburg. The Spartacists alone appealed to arms; and it is probable that in putting them down without mercy, Noske saved his country from much anarchy. But he did it by dangerous methods—although, indeed, these were the only methods open to him; he employed the old corps of officers to serve a republic which most of them loved but little. Thus only a few weeks after the revolution, officers of the former army were appearing as saviours of society against Socialists; and a revival of German militarism so obnoxious both to the Allies and to liberal and Socialist Germany was thus provoked.

The Constituent Assembly and the Treaty of Versailles.—The non-Socialist parties reorganised hurriedly. The Conservatives

founded the German National People's party (Deutschnationale Volkspartei) and announced their readiness to co-operate in "any form of Government in which justice and order held sway." Certain of the National Liberals under Stresemann formed the German People's party. The German Democratic party represented the middle-class electors, but was largely an organisation of leaders, with less backing from the electorate. The Centre styled itself the Christian Democratic People's party. The elections for the Constituent Assembly on Jan. 19 gave the Majority Socialists 163 votes, the Independent Socialists 22, the German Nationalists 44, the German People's party 14, the Centre 91, the Democrats, with the Peasants' League, 81. The Communists abstained from voting. The National Assembly opened its sitting in Weimar on Feb. 6. The Independents refused to enter a coalition with non-Socialist parties; a coalition was therefore formed of the Majority Socialists, the Centre and the Democrats. Scheidemann became Chancellor; and Ebert was elected President of the Reich. A chief task of the Constituent Assembly was the elaboration of the Constitution, which was proclaimed on Aug. 11 1919. Elections in the principal states took place shortly after those for the Constituent Assembly. In Prussia the results were very similar to those for the Reich, Berlin and the industrial districts voting strongly Socialist. In Saxony the two Socialist parties had a majority over all others combined. In Bavaria, on the other hand, the clerical "Christian People's party" formed the strongest group.

The spring of 1919 was accompanied by continued trouble from the Left. The Berlin Spartacists made a fresh attempt to set up a Soviet Govt. in March. It decreed a general strike throughout Germany, which reached considerable dimensions in Berlin. It was quelled with bloodshed in Berlin, Halle, Leipzig, Stuttgart, Hamburg and other cities. In Bavaria the Minister President, an Independent Socialist, Kurt Eisner, was murdered by a Nationalist officer. A violent struggle ensued, and a Soviet Republic was proclaimed in Munich and ruled there till May 1. Much of this unrest was due to the uncontrollable effects of the aftermath of the War, the continuance of the blockade, universal underfeeding and unemployment; some to foreign agitation and some to irresponsibility. The Weimar coalition had undertaken a far harder task than that of opposition; but it struggled manfully to preserve the unity of Germany, to prevent bloodshed and, by disarming and respecting the Armistice conditions, to allow the Allies no excuse for applying sanctions. Exaggerated rumours were current as to the prevalence of democratic feeling and brotherly love in Great Britain and elsewhere, and the Government hoped that the peace terms, when they came, would strengthen their hand. The publication of the terms aroused deep consternation in Germany. Scheidemann resigned, saying "let the hand wither that signs this treaty." The Democrats left the Government. The Majority Socialists and Catholic Centre alone, and they with dissentient voices, agreed to take the responsibility of signing, under threat of the continuance of blockade, an Allied march into Germany and possibly the loss of the country's unity. Germany signed the Treaty of Versailles on June 28 1919 (*see* VERSAILLES, TREATY OF), the National Assembly giving its assent to the signature on July 9 by 208 votes to 115.

The Policy of Fulfilment.—Even while signing Germany refused to admit the sole responsibility for the War, and made every effort to prove by history that the charge was unjust, in the hope that this would lead to a revision of the treaty. The Government hoped and long believed that such a revision would come. Immediately after the ratification of the treaty, on Jan. 10 1920, President Ebert circulated a message that "we shall honestly endeavour to fulfil our engagements towards the Entente according to the Peace Treaty, but if there are clauses which prove to be absolutely unrealisable, we must hope that the Entente will understand this and be able to meet us in our difficulties."

For the time, however, the Government saw no course but to make the best of a bad job, and meanwhile strengthen republican and democratic elements at home. Its position was dangerous. The extreme Left had relapsed into comparative quiescence after the failure of the spring disturbances, but the opposition of the Right now began to rally. They saw that Great Britain and America had favoured more moderate terms in the Treaty of Versailles, but that the die had really been cast against them by the presence of the great French Army. They declared that Germany had only been forced to accept the treaty by her own action in disarming; that the treaty was imposed by *force majeure* and involved no moral obligation; that any attempt to fulfil its terms was high treason; and that the duty of a patriotic German was sabotage of the treaty, to resist disarmament, indeed to re-arm and to repudiate the treaty at the earliest moment when Germany's military power allowed it. Anyone connected with the "policy of fulfilment" was a traitor, and in the views of the extreme secret organisations which rapidly sprang into being, it was a patriotic duty to murder such a person. The advocacy of assassination, disguised as patriotism, became common; and was responsible for the murder, first of Erzberger, then of Rathenau.

Owing to the number of Jews among the Democratic and especially Socialist-politicians, this Nationalist agitation was also preached as the struggle of the pure-bred German against the "hidden hand" of Jewry. Finally, and in reality most essentially, it soon took the form of a conflict of Social Democracy against the anti-Socialist forces of the rural districts and capitalism. Unfortunately for the Socialists, they had been obliged to take almost the sole responsibility for signing the treaty; although refusal to sign had been out of the question. The association of Socialism with national treachery was thus as easy as it was unjust. The industrialists financed the Nationalist movement heavily; the influence of the Roman Catholic Church was generally anti-Socialist and no doubt helped to detach from Socialism the peasants and small tradesmen whose republican sympathies had led them into the enemy camp.

In the autumn the National Assembly returned to Berlin. The Democrats re-entered the Cabinet. The Right was already agitating for new general elections, on the ground that the Constituent Assembly had finished its task by passing the Constitution. The demand was unwelcome to the Social Democrats, who were losing ground in the constituencies; and they hastened to pass what legislation they could. The eight-hour day had already been decreed. A bill, providing for the formation of Works Councils, was now introduced. A Socialisation law laid down in principle the transference of the whole mining industry to state ownership; but the committees of inquiry had not finished their investigations as to how this was to be done before the opportunity passed. Moreover, the fear that the Allied and Associated Powers might take over the nationalised properties acted as a deterrent on the Socialists. Erzberger, as Minister of Finance, introduced some drastic measures of taxation on War increases of income and an emergency contribution which contemplated the sequestration of a considerable percentage of private fortunes. (*See* INDUSTRIAL RELATIONS; WORKS COUNCILS.)

Reactionary and Communist Outbreaks.—On Jan. 10 1920 the Treaty of Versailles came into force. Very soon afterward Germany had to face her first and most serious attempt at a monarchist reaction. What is known as the *Kapp Putsch* was short-lived, and in some aspects almost ridiculous; but it was inevitable that it should be made, and the fact that it failed was momentous. Only now was the German republic firmly established and the unsettled elements left stranded by the end of the War were forced to see that the new order was not merely provisional. Henceforward, gradually, and with an ill-will which is not incomprehensible considering their circumstance and traditions, they adapted themselves and began to look on the new Republican Reich as an established fact. The movers in the *Kapp Putsch* were the old officers who, their occupation gone, comprised a dangerous and unabsorbed element, which at this moment was reinforced by the return of General von der Goltz's formations from the Baltic States. The treaty had provided for the reduction of Germany's army to 100,000 by March 31 1920. This reduction had not been made. Germany desired permission to keep a permanent force of 200,000; but the Allies granted only a fur-

ther grace of three months in which to complete the full reduction. The officers were faced with starvation and ready for any adventure. Kapp, a founder of the "Vaterlandspartei" seized the pretext to agitate against Ebert's position as unconstitutional. On March 13 Kapp, Von Lüttwitz, Erhardt and Colonel Bauer, formerly Ludendorff's chief of staff, seized the public buildings in Berlin with the aid of the marine troops quartered at Döberitz, and proclaimed a "government of order, liberty and action" consisting mainly of themselves. The real Government fled to Dresden and thence to Stuttgart, the Socialists of Berlin proclaimed a general strike. The movement collapsed in a few days. The leaders alone were punished, but most of them made their escape.

The strike had been completely successful; but it soon got out of hand. The threat of a reaction infuriated the workmen; Russian propaganda accused the Majority Socialists of complicity. Instead of returning to work, the workmen formed Soviets. The Communist element had long been secretly organising a Red Army. It now came into action in many parts of Germany. In Leipzig the Government had to use aeroplanes against the city. In Berlin, Württemberg and Bavaria the troops put down the rioters easily, but in the Saxon Vogtland a Communist government maintained power for some weeks. In the Ruhr a Red Army 50,000 strong conducted regular operations. This was a demilitarised zone, into which German troops beyond a small permanent garrison might not enter; and when, after some hesitation, a force of the Reichswehr actually entered the zone, French troops immediately marched in and occupied Frankfurt, Darmstadt and Homburg, remaining until May 17, by which date the German troops had left.

Reorganisation of the Reichswehr.—As a sequel to this incident Noske retired. His place was taken by the Bavarian Democrat Gessler, who together with General von Seeckt reorganised the Reichswehr. Many reactionary elements were eliminated from the Reichswehr (and simultaneously from the civil service), and it was henceforward a sufficiently trustworthy arm of the civil government, although strongly conservative in feeling. Von Seeckt engaged in a prolonged if unacknowledged duel with the Inter-Allied Commissions of Control, which remained in the country for some years. Technically, few violations of the treaty were proved. Great masses of war material were actually surrendered and destroyed; only in July 1920 was Germany admittedly and demonstrably in arrears in this respect. On the other hand, it is scarcely denied that much remained concealed; that a very high proportion of the men of military age and youths of Germany received what was military training in all but name from their respective political party organisations; that Germany was at no time without the nucleus of a highly-trained army, and could at any time have put into the field a formidable force; while her rifles and artillery were short, her chemists and scientists were working hard to discover new offensive and defensive methods which the Treaty of Versailles had not anticipated.

The First Reichstag.—After the collapse of the Communist rising, the National Assembly considered its work as finished. The elections for the first Reichstag (June 6 1920) followed hard on those stormy events. The moderates of each wing feared the violence of the other, and voted in self defence for their own extremists. The Independent Socialists increased their votes to 81, the German People's party to 62, the German Nationals to 66. The Democrats were reduced to 45, the Majority Socialists to 112, the Centre to 70.

To avert the danger from the left, the People's party agreed to enter a coalition with the Centre and the Democrats. The Majority Socialists supported the Government without entering it. Herr Fehrenbach became Premier, Dr. Wirth Minister of Finance and Dr. Simons Foreign Minister. The Government followed the policy of its predecessor. Almost its first action was to meet the Allies at Spa (July 5), a somewhat stormy meeting, chiefly concerned—outside the question of German coal-deliveries and the Inter-Allied arrangements regarding the distribution of reparations—with Germany's failure to disarm. During the remainder of the year, however, Germany enjoyed comparative quiet, and really began to disarm. A number of minor questions arising out of the Peace Treaty were settled during this period. The plebiscites in Schleswig (*q.v.*) had been held on Feb. 10 and March 14; those in Eupen and Malmédy (*see* EUPEN) on July 24; those in East and West Prussia on July 11. The only important territorial arrangement outstanding was that of Upper Silesia.

The question of the trial and punishment of the "war criminals" aroused much ill-feeling. Holland's refusal in Jan., Feb. and March 1920 to extradite the ex-Emperor William probably robbed international law of many interesting decisions. The Allies had demanded the arrest and delivery of many hundreds of war criminals; but in face of German protests, the Allies agreed (Feb. 16 1920) to allow trial before German Courts. Twelve persons were finally tried at Leipzig (May 23—July 16 1921), six being convicted.

The year 1921 saw renewed trouble. A militia known as the Einwohnerwehr had been organised in Bavaria, and Von Kahr, the Bavarian Premier, declared himself unable to dissolve it in view of the Bolshevik danger. Already all the elements of reaction were concentrating in Bavaria. Von Escherich, the prime mover in the Einwohnerwehr, had also formed a second organisation, the "Orgesch" (Organisation Escherich) obscurely connected with the Einwohnerwehr but receiving no official recognition. The Orgesch was spreading throughout Germany and assuming the proportions of a secret army, while the Government professed itself unable to control it in view of its own weakness. The Allied ultimatum of May 5 1921 at last decided Von Kahr, the Bavarian Premier, nominally to disband the Einwohnerwehr under threat of an occupation of the Ruhr.

The Bolshevik danger was real enough. The Majority Socialists had adhered to the Second International at Geneva in Aug. 1920; the Independents had joined the Third International (a minority dissenting) and coalesced with the Communists as the "United Communist party of Germany" (V.K.P.D.). A small and even more radical group formed a section of the Fourth International as the "Communist Labour Part of Germany" (K.A.P.D.). In March 1921 Moscow considered Germany "ripe for revolution" and a widespread rising broke out in Central Germany. The V.K.P.D. maintained a Communist régime in Halle, Mansfeld and Eisleben for several weeks. The insurrection, which spread as far as Hamburg, was put down with great difficulty.

The Reparations Problem.—Meanwhile the question of reparations was assuming the overwhelming importance which it was to retain for four years. Germany's financial situation was curious. Apart from the effects of war and blockade, she had been permanently weakened by the losses of large portions of territory. Nevertheless, her currency was low and her exports cheap, her territory unravaged, her population industrious. The middle-classes and officials were suffering severely, and districts such as Saxony, where industry depended on imported raw material and coal, were badly hit, so that in Germany there were now some 2,000,000 unemployed and at least 4,000,000 working half-time. In other places, however, where raw material was available, industry was flourishing. Notably the great industrial centres of Westphalia were reorganising and expanding most rapidly. Here Germany's chief wealth was concentrating and accumulating, especially in the hands of a few enormous combines, the most sensational of which was that which was founded and directed by Hugo Stinnes.

So long as complete uncertainty reigned as to what sum Germany would have to pay in reparations, the industrialists, who were strongly opposed to any "policy of fulfilment" made no attempt to relieve the financial distress of their country as a whole; they concentrated on maintaining their own prosperity and that of the districts under their own control, transferring capital abroad, speculating *à la baisse* on the mark, and paying their taxes in arrears and incompletely. It must be admitted that by their policy the industrialists did not only amass fortunes for themselves, but also saved the workmen in their concerns from

otherwise inevitable unemployment, which would have had incalculable economic and political consequences. The Reichsbank, by granting the industrialists almost unlimited credit, encouraged this policy.

Enormous wealth had thus accumulated in Germany in a few private hands, while the Government was almost bankrupt. When the Allies, by Jan. 1921, had at last decided on the bill to be presented to Germany and its allotment among themselves, the difference between the wealth obviously present in Germany and that at the disposal of the Government was glaring. The essential problem was that of tapping the wealth of Westphalia. When the German Govt. declared the conditions of the Allied note of Jan. 29 1921 (*see* REPARATIONS) impossible of fulfilment, and Dr. Simons, on a visit to London, was unable to come to any financial terms with the Allies, besides arousing their hostility by again repudiating Germany's war guilt, the Allies occupied Duisburg, Ruhrort and Düsseldorf on March 8 as "sanctions" and drew a customs cordon between occupied and unoccupied territory. It was this move which made possible the later occupation of the Ruhr district and opinion in Germany did not doubt that it was deliberately taken with a view to such later occupation.

The Fehrenbach Cabinet resigned. The Allies threatened to occupy the Ruhr and apply other sanctions. The "policy of fulfilment" became again a burning question; but in order "to save the German Reich and its unity, to save German territory from invasion and to retain German freedom" a new coalition Government under Wirth, composed of the Centre, the Majority Socialists and the Democrats was formed on May 10 and accepted the Allied ultimatum. Germany, by exertions which jeopardised the stability of the mark, paid the first milliard of gold marks on Aug. 31.

An early result of the Nationalist agitation against the "policy of fulfilment," which broke out with renewed violence, was the assassination of Erzberger (whose financial policy was particularly unpopular with the moneyed classes) on Aug. 25. The Independent Socialist Gartis was murdered in Munich, and the publicist Maximilian Harden wounded in Berlin, and an attempt made to poison Stresemann. A monarchist demonstration took place in Berlin; but although monarchist feeling was reviving, it lacked unity owing to the personal unpopularity of the members of the Hohenzollern family.

The Plebiscite in Upper Silesia.—The murder of Erzberger was followed by a further fall of the mark, which grew more pronounced in the autumn. The plebiscite in Upper Silesia had been taken on March 20, and had given 717,122 votes for Germany, 483,514 to Poland. The Polish High Commissioner, Korfanty, had thereupon raised an armed revolt, and the French troops stationed in the district were less successful in dealing with him than with the German defence force raised by General Hofer. As the Supreme Council was unable to agree on the fate of Upper Silesia, it turned the question over to the League of Nations, which awarded practically all the important industrial districts to Poland on grounds which were recondite in the eyes of many. This decision, which was taken in Oct., caused a crisis, more especially as it came at a moment when the "Reichswirtschaftsrat" had just evolved a plan under which the rich landowners and industrialists at last consented to make heavy sacrifices in order to stabilise the financial situation. These offers were now withdrawn.

The Second and Third Wirth Governments—Wirth resigned, but formed a second Cabinet against the opposition of the extreme Right and Left. All other questions were now dominated by that of reparations, which in its turn brought fresh conflicts between Left and Right. The burden of reparations was being borne almost solely by the wage-earning and salaried classes, from whose pay the taxes were deducted on payment. As the fall of the mark accelerated, the proviso under which industry and agriculture were allowed to pay their taxes in arrears reduced their burdens to a trifle, while they were able to pay off debts and mortgages at a fraction of their real value. The reactionary agitation increased daily; but owing to emergency legislation passed in Aug. 1921 the year passed off without disturbance. In 1922, however, the state deficit increased enormously. The Government was obliged to beg for moratoria and to allow the Reparations Commission the right of scrutiny over German financial measures. On June 24 Rathenau, Germany's greatest statesman, was murdered by Nationalists. He was the one man in Germany who had shown himself capable of a positive policy. In June 1921 he had come to a direct agreement with M. Loucheur regarding the reconstruction of the devastated regions of Northern France. On April 16 1922, as one of the German representatives at the conference of Genoa, he had signed the Treaty of Rapallo with Russia. The treaty had slightly eased Germany's financial situation and had opened up a new field of activity to her industry, but by proving her unwillingness to remain a cypher in foreign policy it deeply irritated the Allies.

In Aug. Poincaré came to the conclusion that Germany could only yield reparations if "productive pledges" were seized; that is, if the Allies actually took the Ruhr districts and managed them for their own profit. France's Allies were unwilling to consent to this, but the threat overshadowed the situation. The financial distress and continued fall of the mark made stabilisation the most urgent necessity. But the Allies rejected Germany's suggestion to make this possible by reducing reparations; the Reichsbank was unwilling to risk its last gold reserves; the Socialists refused to increase production by allowing hours of labour to be lengthened, maintaining that the profit would go into the pockets of the capitalists. Thus Germany remained politically disunited.

On Sept. 24 1922 the Majority Socialists, who had revised their programme at Görlitz on Sept. 18 1921, re-united with the Independents.[1] As a counterpoise, the moderate bourgeois parties formed a "working agreement" with the People's Party. The Social Democrats having refused to enter a Government with the People's Party, Dr. Wirth resigned and on Nov. 23 1922 formed a minority "business government" of middle-class representatives and permanent officials. It carried on the financial policy of its predecessor, stabilisation through reduction of reparations.

The Occupation of the Ruhr.—On Dec. 26 1922 and Jan. 9 1923 the Reparations Commission, the British member dissenting, declared an "intentional default" on the part of Germany. On Jan. 11 French and Belgian troops occupied the territory of the Ruhr. The history of this struggle is told elsewhere (*see* RUHR). The population of the Ruhr adopted an attitude of "passive resistance" which was supported by the Government. For eight months the Government maintained as a charge on its finances the population which ordinarily yielded its chief source of revenue. It could only meet this expenditure by unlimited inflation, which was aggravated by singularly incompetent administration of the Reichsbank. By June the mark was quoted at 150,000 to the dollar; on July 30 at 1,000,000; Nov. 20 at 4·2 billions. Austria's financial collapse paled before conditions in Germany; starvation for the working and middle-classes, mushroom fortunes won by speculation, the rise of prices marked by a multiplication so that people entered a shop with a considerable sum in taper and found it too little to buy a crust of bread by the time they reached the counter.

In view of the growing unrest, the Social Democrats agreed to enter a Government on a broad basis, with Stresemann, known to be a strong man, as Chancellor and Foreign Minister. The "Grand Coalition" was at last formed in Aug. 1923. Hilferding, a Social Democrat, became Minister of Finance. An attempt to stabilise the currency under existing conditions broke down. On Sept. 26 the Government proclaimed the abandonment of passive resistance in the Ruhr, and relieved itself of the financial expenditure involved. On the following day, it announced its intention to use all means to put down any attempt to create disturbances, and proclaimed martial law throughout the Reich.

[1] The United Socialists joined the Second International at the Congress of Hamburg May 21–7 1923, when the "2½ (Vienna) International" of the German Independents, the Austrian Social Democrats and the British I.L.P. ceased to exist (*see* SOCIALISM).

Political Unrest.—The appalling financial catastrophe had produced a most dangerous political situation. In the Rhineland and the Bavarian Palatinate (*see* RHINELAND), the French were working to create a separatist movement. In Bavaria proper the agitation was less artificial. There were two great movements in Bavaria. Von Kahr, who had been Premier in 1920 and 1921, based his power on the Bavarian People's party. He wished to transfer the "centre of gravity" of Germany to the Catholic South, and while he denied any aim further than revising the Weimar Constitution in the favour of federalism, he was an avowed monarchist—the Bavarian dynasty occupied a position in Bavaria little inferior to that which it had enjoyed up to 1918—his party had been compromised by revelations of their relations with the French, and he had involved himself in various schemes to create a Catholic Danube monarchy of the South to include parts of Austria. A second party was led by Hitler, an immigrant workman from Austria, and Gen. Ludendorff, supported by numerous refugees from the Kapp Putsch. Its adherents styled themselves "National Socialists" but were in fact not Socialists at all. The programme was to "regenerate the Reich through Bavaria." These two groups were constantly intriguing with each other and with various reactionary and Catholic parties outside Bavaria and outside Germany. A dangerous situation had been created in the summer of 1922, when Bavaria refused to recognise the legislation and tribunals of the Reich. It was smoothed over, and Von Knilling had since acted as Premier, with an unclear policy. Throughout 1923 the agitation of Hitler's "Völkische" party grew so rapidly that a coup was almost daily expected, which would have been accompanied by military reaction in North Germany. The Government considered the monarchists the lesser danger; on Sept. 26 civil law was suspended in Bavaria, and Von Kahr appointed General Commissary with dictatorial powers. He instantaneously consolidated his position by lowering the price of beer.

The state of Saxony and Thuringia were no less disturbed. A new Bolshevik centre had been established in Dresden and the Premier, an extraordinary figure named Zeigner, was ruling at the head of a coalition of Communists and Left Wing Socialists. A Red Army had been formed, and was only waiting for a reactionary outbreak in Bavaria, which would give it the sympathy of the workmen in Berlin, to establish a Soviet Govt. and Red terror. In addition, quite apart from the separatist movement, there were grave Communist disturbances among the unemployed in the Ruhr. The plans of the Third International, which was directing this movement, regarded Saxony only as a "jumping off place" and envisaged a general rising with the centre in West Germany. The Government had, however, searched the offices of the Russian Trade Delegation in Berlin on May 3; and although relations between Germany and Russia were in consequence very strained throughout the summer, the German Govt. had obtained valuable information on the plans of the Communists.

The proclamation of martial law by the Government was answered by defiant demonstrations by all the malcontents and an actual outbreak by the Separatists in Düsseldorf on Sept. 30. The Saxon Finance Minister, Böttcher, called on the proletariat to arm. Fortunately, each side waited for the other to move while the Government of the Reich passed through a fresh crisis.

The German People's party were alarmed at the presence in the Cabinet of Hilferding, who was known to be a champion of nationalisation. They desired legislation for increasing production without regard to the eight-hour day, and that the Government should receive dictatorial powers to issue orders of this nature with the force of law without consulting the Reichstag. The Socialists were determined to oppose any tampering with the eight-hour day. The parties finally agreed on the principle of a "new regulation of laws regarding hours of work, with retention in principle of the eight-hour day." The Stresemann Cabinet was reconstructed in early October. Hilferding left it, and Dr. Luther became Finance Minister. The Cabinet received the desired emergency powers on Oct. 13. It was now able to deal successfully with the Communists. The Military Commander in Saxony called on Zeigner to repudiate Böttcher's speech. Zeigner refused; troops of the Reichswehr then entered Saxony on Oct. 22, forced Zeigner to resign and restored order. Other troops occupied Thuringia and disbanded the Red Army, and a rising in Hamburg was put down.

In Bavaria the military commander, Von Lossow, sided with the Bavarian Govt., refused Von Seeckt's order to resign, and allowed the Bavarian authorities to appoint him Provincial commander. The Bavarian Govt., in defiance of the law, exacted a special oath of allegiance from the Bavarian troops. Many officers of the Reichswehr openly sympathised with Ludendorff against the government of the Reich, and Hitler and Ludendorff were encouraged to believe their hour had come. On Nov. 8 they seized Von Kahr and Von Lossow and proclaimed a government, consisting of themselves. Von Kahr at first appeared to fall in with their plans and announced himself as "viceroy of the King of Bavaria." But as soon as he saw that the Reichswehr would act against the insurgents, he called in troops, which fired on the revolutionaries. Ludendorff fell on the pavement and shammed dead till all was over. His much-enduring reputation could not stand this strain.

His fellow conspirators were arrested, and the pricked bubble of the "Völkische" collapsed. In the following spring the chief participants were tried. Ludendorff was acquitted. Hitler and other leaders imprisoned. The trial aroused great excitement on both sides. The separatist movement in the occupied territory reached its climax about the same time. The "Rhineland Republic" was proclaimed at Aachen on Oct. 31; at Coblenz on Oct. 25; and in other Rhineland towns at the same time. The movement then gradually decayed, and had disappeared by Feb. 11 1924, except in the Bavarian Palatinate. The official birthday of this Government was Nov. 11, and French support of it was more than usually tenacious. It finally vanished at the end of Feb. 1924.

Financial Reconstruction.—This proved to be the climax of Germany's troubles; but her internal political situation was still uncertain. The Socialists withdrew their support from the Government on account of the different treatment of the insurgents in Saxony and in Bavaria. Stresemann failed to secure a fresh vote of confidence and a new emergency powers Act, and resigned on Nov. 23. On Dec. 1, Marx formed a minority "middle-class" Government with Stresemann as Foreign Minister and Luther as Minister of Finance. The Government received a new emergency powers Act to carry through the work of stabilisation and reconstruction during a limited period. By the appointed date (Feb. 15 1924) the budget was balanced by means of these emergency decrees. The first reduced the number of officials, readjusted taxation and ordained pre-payment of taxes. The second stabilised the mark, introducing a strictly limited issue of "Rentenmarks," each equivalent to one billion paper marks, and limiting credits. The third carried through the principle of valorisation of public and private debts which had been inaugurated before the inflation period set in. At the same time the Ruhr industries reached an agreement with the M.I.C.U.M. (*Mission interalliée de contrôle des usines et des mines*) regarding deliveries in kind on reparation account which formed the transition to a new settlement of reparation obligations.

The Dawes Plan.—On Jan. 14 1924 the Committee of Experts for the examination of Germany's capacity to pay met in Paris under Gen. Dawes. Its relations with Germany were not unhappy, and it frequently consulted Schacht, the new President of the Reichsbank. A British Labour Ministry entered office on Jan. 22, and Poincaré gave way to Herriot in France in May. Germany's internal and foreign position now improved very rapidly. On Feb. 5 the British Prime Minister expressed the hope that Germany would join the League of Nations. Soon after, a German Ambassador was appointed to France, for the first time since the War. Von Kahr and Von Lossow retired on Feb. 18, and the powers of the Bavarian general commissariat came to an end. The state of siege in Saxony and Thuringia lapsed on March 1. The Dawes Plan (*see* REPARATIONS) was accepted in principle by the Governments of the Reich and of the Territories on April

14, and by the Association of Industrialists on April 24; but the new elections for the Reichstag had been fixed for May 4, and were fought almost solely on the Dawes Plan as an issue.

In view of the great distress following the sudden deflation, restriction of credit and rise of prices, the extreme parties of both wings gained votes at the elections. All the Government parties lost heavily, while the Communists secured 62 votes, the "Völkische" 32 and the German Nationals 96. Nevertheless a vote of non-confidence in the old Ministry, which had remained in office, was defeated on June 6 by 239 votes to 194 and Marx and Stresemann left for London on Aug. 4 as the representatives of Germany. The decisions of the Conference of London were initialled on Aug. 16. They provided for the restoration of Germany's fiscal and economic unity; the military evacuation of the Ruhr by Aug. 16 1925 (by separate agreement between Marx and Herriot); the issue of a banker's loan to Germany of £40,000,000; and the continuance of reparations deliveries in hand. The Dawes scheme was to come into full operation by Oct. 5.

The Government was just able to carry the acceptance of the Dawes Plan. The German Nationalists consented to allow its members to vote independently. The essential laws (the denationalisation of the state railways, the Bank law, the private Banknote law, the law liquidating the Rentenbank and the coinage law) were passed and the agreement on the Dawes Plan was ratified on Aug. 29. The laws in question came into force on Oct. 12.

The complaisancy of the Nationalists had been bought at a considerable price. They regarded their concessions purely as business arrangements, as facilitating the influx of foreign capital and reducing the danger of fresh Communist disturbances. But they were growing ever less ready to accept Germany's position as an outcast; and demanded from Stresemann a statement repudiating Germany's war guilt, as well as a place in the Ministry. A statement in accordance with the first demand was made in the Reichstag, while in the autumn Stresemann began to sound the ground regarding Germany's entry into the League of Nations. On Sept. 23 the Cabinet arrived at a decision in principle to seek the speedy entry of Germany into the League. As, however, the British and French Govts. could not give a definite answer to the memorandum which she addressed to them on Sept. 29 asking "whether the guarantees requisite for an application for membership and the status of Germany within the League, and also other definite and inseparable questions, were forthcoming," the matter was left temporarily in suspense.

The second Nationalist condition led to the dissolution of the Reichstag on Oct. 20, as it proved impossible to induce the Social Democrats and Nationalists to sit together. The general elections were held on Dec. 7. But by this time the general situation had grown much easier. The Régie railways and mines in the west, and the customs, were again in German hands. The customs barrier between occupied and unoccupied territory had vanished. The M.I.C.U.M. agreement had become void. There were general symptoms of a revival in trade. The extremists lost votes again; the Communists were reduced to 45, the "Völkische" to 14, while the Socialists rose to 131. The numerous parties of the Right Centre formed the strongest Parliamentary group. A Luther Cabinet, including four German Nationalists, held a precarious tenure in which it endeavoured to compromise between the demands of various interests. Protective tariffs for agriculture were introduced, the sales tax lowered, restrictions on deals in foreign currency for commercial purposes abolished, official salaries raised, the goods tariff and certain postal dues reduced, the tax-free limit of income raised to 60 marks a month, and old claims valorised in July 1925 by a law of the Reich. The middle-class Government of the Reich, was, however, confronted by the incessant hostility of the Prussian Govt., where the parties of the Weimar coalition were in power. Although her Parliament was a mass of small, jealous parties, Germany at large was divided into two broad groups of the Right and Left which attacked each other bitterly. Each raked up a series of scandals against the other; this unsavoury process culminated when a judge, in his summing up on a small case, stated that the President of the Reich had been guilty of high treason to the Reich by his part in directing the munitions strike in 1918. The Nationalist Press broke out into violent invective against Ebert; the whole legend of the "stab in the back" was revived. The campaign was the more cruel that it was directed against a sick man. He died after an operation on Feb. 28 1925. Few men have served their country so well.

Von Hindenburg's Presidency.—Seven parties chose to put forward candidates for Ebert's vacant post, and these included such names as Ludendorff and the Communist Thälmann. The first poll gave no candidate a sufficient majority. The Right then united to bring Hindenburg forward; the Left proposed Marx; the Communists stood apart.

On April 26 Hindenburg was elected by 14,639,000 votes against 13,740,000 cast for Marx and 4,900,000 for Thälmann. Many Socialist votes had been withheld from Marx on account of his Catholic tenets. Hindenburg's election aroused great apprehension outside Germany, but in point of fact the old field marshal preserved his dignity and his common sense as perfectly as he had throughout the War and the revolution.

Foreign Relations.—With the balance thus held evenly between Left and Right, the extremists discredited and the unity of the Reich established, the interest in German politics was now almost confined to foreign affairs. If little has been said hitherto on this topic, it is because the course of events in 1918 had assigned Germany an almost purely passive rôle. Of all her old friends or sympathisers, the only one which did not disown her in her defeat (if we except the small minority of die-hard generals in other defeated countries who dreamed of reversing the results of the War with fantastically inadequate means) was the little republic of Austria. The peace treaties forbade the union of Germany and Austria. The decision was a bitter one for Austria, but hardly awoke equal sorrow in Germany. Not only was Austria economically a heavily passive factor, but the inclusion of her would have made it impossible to centralise the Reich as was done by the Weimar Constitution, and that constitution would certainly have to be revised should Austria join Germany at some later date. For the rest, Allied and Associated Powers of older or more recent standing surrounded Germany as soon as the Armistice was signed.

With the Treaty of Versailles, which assigned the whole guilt of the War to Germany, was incorporated the Covenant of the League of Nations, which built up a great structure for the maintenance of the peace of Europe, which Germany was not invited to join. At first, indeed, she showed no anxiety to join. Hostility to the League was almost universal owing to its association with the Treaty of Versailles which even the advocates of the "policy of fulfilment" denounced as unjust in many respects. The feeling was aggravated by doubts as to the impartiality of the League's administration of the Saar basin and reached its climax when the decision of the Council of the League sanctioned arrangements in Upper Silesia which German opinion resented violently. Nor was it confined to the Nationalists. Soviet Russia repudiated the League as a capitalist institution. The German Communists followed the lead of Moscow, and the Socialists saw far more hope in a revival of the International.

After the first passions had cooled, Germany began to distinguish between the various territorial provisions of the Treaty of Versailles. The cessions to Denmark and Czechoslovakia aroused little resentment; those to Belgium were small. The justice of the loss of parts of Alsace-Lorraine was not greatly disputed. The three most important questions remained those of the Rhineland, of the frontier with Poland and of the German colonies.

The problem of Germany's western frontier differed from others, both by its urgent economic importance and by the fact that Germany could claim that here she was only defending her rights within the treaty. She contended that the occupation of the Ruhr was illegal, but so long as the threat of it, or its actuality, was not removed, it was impossible for her to initiate an active policy; it was equally unthinkable for either party that Germany and France could meet as colleagues within the Council of the League of Nations.

Thus up to 1924 Germany's foreign policy was almost entirely defensive. A number of minor treaties and agreements, mainly of commercial character, were concluded; the most important being the Treaty of Arbitration with Switzerland (Dec. 3 1921). But the only treaty of outstanding importance was that concluded with Russia on April 16 1922. The text of this Treaty of Rapallo (*q.v.*) was not in itself such as to justify the protests with which it was greeted. These were rather due to the fear that the treaty contained secret clauses of a political nature, and especially clauses aimed against the integrity of Poland. The existence of such clauses was denied and, in fact, no political developments could be traced as arising out of the treaty during 1923 or 1924. It was a tactical error in so far as it increased France's and Poland's nervous instinct; it certainly looked as though Germany was drawing her conclusions from the Treaty of Versailles with too much logic in associating herself with the second Great Power which remained by mutual consent outside the European concert. Germany, however, claimed that she had no quarrel with Russia.

With the advent to power of M. Herriot in France in 1924 the situation changed. Moderate opinion in Germany was willing to accept the permanent loss of Alsace-Lorraine in return for security on the demilitarised western frontiers. If Germany could become a member of the Council of the League, there was some hope that readjustments on her eastern frontier might prove possible at some future date, and this position would also give her a chance of acquiring some day a colonial mandate. The general improvement of relations between France and Germany made their collaboration within the League possible, while Germany was rapidly freeing herself from the restrictions imposed on her national sovereignty. A sudden shock was given to the improving relations by the report of the Commission of Control on June 29, that Germany had not yet fulfilled the disarmament conditions, and that the Cologne zone could consequently not be evacuated in Jan. 1925. During the year, however, the commission finished its work and the Cologne zone was evacuated on Jan. 31 1926. In July 1925 the troops had been withdrawn from the Ruhr, and in Aug. from the districts occupied in 1921. The question of giving Germany her proper place in Europe now became urgent.

The Pact of Locarno.—On March 4 1925 was published Stresemann's offer of a guarantee pact in respect of Germany's frontiers with France and Belgium and an undertaking to refrain from military means of revision of her Polish frontier. This policy occupied the attention of Europe throughout 1925, and was finally embodied in the Pact of Locarno, after discussions between the European diplomats which lasted from Oct. 5–16. At Locarno Germany concluded a number of treaties which practically guaranteed peace between her and her neighbours (*see* LOCARNO; SECURITY). The Pact was to come into effect on Germany's admission as a member of the Council of the League of Nations.

Stresemann's policy was not easily accepted in Germany. The widespread distrust of the League could not vanish in a day. The Nationalists objected violently to the permanent renunciation of Alsace and Lorraine involved in the Pact. But they had not gained in strength so much as they had hoped during 1925; in particular, Hindenburg's sensible attitude had deeply disappointed them. The Pact was ratified on Nov. 27 1925 and duly signed in London on Dec. 1. Luther's Cabinet then resigned, but after a prolonged crisis Luther formed a fresh minority Cabinet of the Centre on Jan. 19 1926. The Socialists promised him their support on condition that he pursued a republican policy and carried out the terms of Locarno. The Nationalists opened a violent campaign against him, while feeling between Right and Left was further embittered by revelations regarding the naval mutiny of 1918.

It was the more disastrous that, when Germany's application for admission came before the League of Nations in March 1926, Brazil vetoed her admission unless she herself were also given a seat on the Council. Speaking in the Reichstag, on March 22, Stresemann declared that Germany had received "moral rehabilitation" in Geneva, and that the policy of Locarno must not be allowed to lapse. Most of the German parties agreed to support him. The Nationalist spokesman found it easy to revile the League and Germany's attempts at reconciliation.

The Russo-German Treaty, April 24 1926.—Considerable excitement was aroused shortly after, when it was announced that Germany and Russia were again in negotiation for a treaty. This new treaty was signed in Berlin on April 24 1926 and published, together with an exchange of notes between the signatories (Stresemann and Krestinsky) on April 26. The basis of relations between Germany and Russia was stated to be the Treaty of Rapallo. The two Governments promised to remain in friendly touch with one another. Article 2 ran "Should one of the contracting parties in despite of its peaceful attitude be attacked by a third party or by several third parties the other contracting party will observe neutrality during the entire duration of the conflict." By Article 3 each party promised not to participate in any "economic or financial boycott" imposed on the other in times of war or peace. The treaty was to be valid for five years.

The third paragraph of the note for which Stresemann was responsible declared explicitly that "this fundamental attitude of German policy towards the U.S.S.R. cannot be adversely influenced by the loyal observation of the obligations (arising out of Articles 16 and 17 of the Covenant of the League and relating to the application of sanctions) which would come into existence for Germany as the consequence of her entry into the League of Nations," as such sanctions could only come into force if Russia were the aggressor, in Germany's own view, the views of other Powers not being binding on her. Whether Germany would take part in the application of sanctions at all, and to what extent, depended on the interpretation of the note of Dec. 1 1925 on the interpretation of Article 16 addressed to the German Govt. on the signature of the treaty complex of Locarno (the gist of this note being that no state could be held to undertakings manifestly beyond its powers). Germany maintained that this treaty was a necessary and proper adaptation of the situation under the Treaty of Rapallo to that created by the Pact of Locarno. Opinion in France and Czechoslovakia was inclined to question this view.[1]

[1] On May 5 the Luther Cabinet decided that a flag bearing the imperial colours, black, white and red, should be flown over the legations and missions of Germany, alongside with the black, red and gold of the Republic. The Democrats, dissatisfied with the attitude of Luther on this question, carried a motion against him on May 12 by 176 votes to 46. Herr Luther thereupon resigned, and Herr Marx succeeded him as Chancellor.

A serious difference of opinion arose over the proposal to confiscate the property of the former ruling houses, including the Hohenzollerns. Their large properties should, it was suggested, be devoted to benefiting the unemployed, war widows and other necessitous classes, while their castles and palaces should be used for welfare and educational purposes. The measure, which was opposed by President Hindenburg, was submitted to a referendum which took place on June 20. The total vote polled was 15,026,312, of which 14,441,590 were cast for confiscation, and 584,722 against. As, however, the constitution provides that more than one-half of the total votes—at that time 39,690,559—are necessary for success, the proposal failed. (ED. *E. B.*)

General Survey

The chronicler must not aspire to be a prophet. He may, however, reach a point from which he can survey the crowd of personalities and events grouped about him. How fares the Germany of 1925 in comparison with the Germany of 1910?

No such comparison can apply to economic life, since the inroads of the War have been too formidable and the consequences of the false economic policy which accompanied it could only gradually be surmounted. But it may be asserted that Germany has made a relatively rapid recovery from the unsound experiment of forming "vertical" trusts (liquidation of the Stinnes concern in Aug. 1925), and is striving by an energetic concentration of the operations of cognate industries to simplify the official organisation, to effect economies and to strengthen every enterprise included in the combine in its own capacity for output.[1] It is also a good sign that the influence of the most inventive and generally beneficent industry, the chemical industry, particularly the dyes branch (medicines, tropical therapeutics), has increased in industry as a whole.

Education and Justice.—As regards popular education, the arts and science, comparison is easier. For in these realms, where the War and revolution—which even in Germany party-life have strictly speaking only resulted in a change of nomenclature, produced a stagnation, a species of stupor, lasting indeed for years—development has been resumed at the point at which it broke off in 1914. One evil omen for the state is that popular confidence in the law has been shattered (in some cases through no fault of the judges) because during the period of inflation procedure in civil cases became farcical. There are others. The control of industry, which took the place of competition, benefited no one but the profiteers. In political trials the impartiality of the judges was often doubtful; in other trials, owing to the introduction of special courts, erroneous verdicts were laid to the charge of the law itself; young people only 14 or 15 years old, with unformed opinions, become members of contending political associations which do not subsist by their own strength but upon the funds of the adult party organisations. Finally, despite the diminished consumption of alcohol, popular amusements have become less harmless and "sociable." This is due in the great towns to the "revues," and in the medium-sized and smaller towns to the cinematograph, which before the most diverse audiences produces the same pieces and films, thereby destroying a healthy individual attitude towards art and recreation.

The relations between the German citizen and the state remain the same. He continues to regard himself as something distinct from the collective body. Just as during childhood he sees an enemy in the school and the teacher, so as a grown man he regards the State and the Government as an adversary rather than as something in which he himself bears a part and for which he is responsible. If "fiscal" morality is no worse, it is equally no better. The great problem of the schools has, moreover, not yet been solved, although attempts have been made in the Constitution itself and in a law of the Reich. It is sought to establish standard schools (Einheitsschule) providing an uniform education for the children of all classes up to the age of 10, and to give more instruction in German at the expense of the ancient tongues. But the problem of clerical influence in the school is still unsolved, and the process of converting purely scientific teaching into moral training for the young has been barely begun. The "movement of youth," which in the years before the War was making very great strides and led its members to the adoption of a simpler, more natural mode of life, to a greater readiness to help others, and, in many cases too, to a greater love of home, has split up into numerous sects. It has been ruined or impeded by the need for earning a livelihood at an early age by work in the towns.

In many respects, however, improvement is manifest. After the complete ruin of all means of communication in the last year of the War, order and punctuality have been restored within the services with astonishing rapidity. The credit for this belongs to a great extent to the minister for transport, Groener. The system of communications, so important an index for the modern state, is once more as efficient as before the War, and zealous efforts are being made to improve it. The police feel that they are there not so much to command as to render help to the public. Many old officers serve the state honourably as members of the force. The great mass of the official class has remained intact, and performs as much or more work for a salary which commands a purchasing power only equal to about half that of pre-War salaries.

The Arts.—Parallel with the progress made in the chemical industry, in products demanding accuracy of workmanship and in the construction of machinery, taste and the sense of form have undergone a universal improvement. Photography and its application to open-air subjects produce excellent films. Applied art, in which, however, German Austria holds the first place, besides producing masterpieces in the luxury trades and in the form of efficient advertisements, has once more called a genuine popular art into existence. Moreover, although in itself unimportant it is of excellent omen that Germany to-day possesses not only toys but also children's picture-books (E. Kreidolf, Else Wenz, Wanda Ebel, Elsa Eisgruber) such as no other country has. Since the death of Max Reger, Germany has no longer any composer to carry on the tale of her greatest creative minds. The musical tradition is, however, kept alive by distinguished conductors and performers.

Germany has found a new and more serious rendering of music than she possessed at the beginning of the century. In literature the books that are read are of more significance than those that are written. Side by side with Dostoievsky and the Scandinavians, the early German Romantics, Hölderlin and Novalis, are most read, but also Jean Paul, the object of enthusiastic admiration by the young. The writings alike of Goethe and Heine, treating of political and social topics, continue to exercise a powerful influence. The great national poet of German Switzerland, Jeremias Gotthelf, whom Ruskin admired, has been revived; and while young dramatists—Unruh, Toller, Brecht, Bronnen—in part powerfully influenced by Wedekind, espouse an exuberant "activism," Thomas Mann, taking up Theodore Fontane's subtle and genuinely realistic portrayal of North German society, has become, particularly by his last novel of contemporary life, *Der Zauberberg*, the undisputed master of prose narrative. The principal characters in this book, even if to some extent endowed with foreign traits, embody the whole of intellectual Germany in the same sense in which the spirit of English society lived and moved in the greatest novels of George Meredith. The clearest indication, however, of a turn for the better in Germany is given by town-planning and architecture. Even the terrible material stress of the War and post-War period has been unable to hold this in check. Examples may be found in Schumacher's town-planning scheme for Cologne, the railway station by Bonatz at Stuttgart and the Chile House in Hamburg.

(A. M.-B.)

IV. GERMANY'S NAVAL POLICY[2]

It has been frequently asserted that the creation of the German Navy was the main cause of the World War. Such an assertion implies not only that it was admittedly constructed on the right lines from a technical point of view—for no one would plunge into war for the sake of a negligible quantity—but also the admission that Germany's sea power was to be forcibly kept down. From the German standpoint a firm protest must be entered

[1] *E.g.*, the amalgamations effected since Feb. 1925: association of locomotive builders, of steelworks, of spirituous industries, the syndicate of Ruhr coal and mid-German brown-coal industries, of dealers in tubing, of wire-rolling mills, of dye industries, of aerial and shipping communications. In the autumn of 1925 an agreement was reached between the amalgamated German and the Belgian wire industries regulating the conditions of export on lines similar to the earlier Franco-German agreement respecting potash (*see* CARTELS).

[2] Admiral von Scheer's article is full of disputable propositions, but is published unchanged in accordance with the principle of the Thirteenth Edition of *The Encyclopædia Britannica*—to allow each nation to state its own case through recognized spokesmen.—Ed. *E.B.*

against the view that as a political factor the German Navy constituted a menace to foreign interests which could apparently be removed only by warlike methods.

The tendency which emerges from the German naval laws, as carried into effect, is that of aiming only at the preservation of justifiable self-interests without encroaching too much on the maritime interests of other nations. "Defence is one of the most impressive and visible expressions of the State's will to independence." This pronouncement was made in 1922 by the Bundesrat of Switzerland, a country which can in no wise be accused of cherishing schemes for attacking its neighbours.

The preservation of independence is the predominant principle of state for civilised nations to whom the conception of liberty is their very life element, and Germany cannot be reproached for undertaking the construction of a navy proportionate to her economic requirements. For impotence at sea is an intolerable condition of weakness for a seafaring people, let their land defence be what it will. So much was made plain by the German-Danish war of 1848–9, when Prussia, with ten times more inhabitants than Denmark, was forced to yield for lack of a fleet to raise the Danish blockade of the Baltic ports, the economic losses sustained by her sea-trade being greater than the advantages obtainable by a land war against Denmark. It was with a view to readjusting the situation that the Prussian Navy came into existence. Founded in 1853, it passed in 1867 into the possession of the North German federation, established after the separation of the Habsburg dual monarchy from Germany.

This perfectly natural aspiration to escape from the German small state powerlessness and form a national state such as other peoples (England and France) had long since secured for themselves, had its origin in the progressive tendency of the age. The great state-making forces which gripped Europe in the beginning of the 19th century after the Napoleonic wars of conquest were the direct consequence of the overthrow, with British aid, of the French domination of that continent.

Although Germany's expectations of securing State unity by way of reward for her share in the war of liberation were, for the time being, dashed by the ruling of the Vienna Congress of 1815, her ambition, once aroused, left her no peace until she had secured the establishment of the Reich after the war of 1870–1 against France, who stood in the way of a united German state. With the reannexation at the peace treaty of Alsace-Lorraine, the Imperial provinces seized by Louis XIV., the German Empire became—in Bismarck's words—saturated. Territorial expansion in Europe was no part of the programme. Its efforts were directed towards keeping the peace in Europe so that its full strength might be devoted to building up the Reich. The productive capacity of the concentrated and greatly enlarged economic area represented by the Reich grew to considerable importance favoured by the progress of technical methods. International commerce provided goods in bulk, in particular raw material for an enormously expanding industry, and foodstuffs for the rapidly increasing populations of the civilised states. Some of these were utterly unable to supply the needs of life from their own resources, for example England, and also Germany, whose population of over 40,000,000 had risen within a few decades to over 60 millions.

The former large migration of Germany's surplus population to overseas had now ceased. The German colonies by reason of their inadequate development and geographical situation were ill-suited to absorb any numbers worth considering. The growing industrialisation of the country, on the other hand, offered new possibilities of livelihood to the increasing population. As early as the 'eighties, the annual emigration figures fell from 200,000 to one-tenth of that figure. At the same time Germany's dependence on other countries increased, as may be seen from the trade returns. The relations of the new state structure with foreign countries brought about the naval foundation-plan of 1873, which aimed at creating a sea power of the second rank within the space of 10 years. It was not until the close of the 19th century that the possibility of grave conflicts with other European Powers arising out of trade competition became a serious factor.

England, with a technical equipment decades in advance of the German and a predominant position in world commerce, could watch the new competitor the more coolly, in that the opening up of the world offered so many new sources of trade that she alone could never control them. In addition, her established commercial connections, large mercantile marine and colossal colonial possessions placed her in so favourable a position that the development of new trading enterprise could not but be welcome. Germany became almost her best customer, and English exports to that country always exceeded in value the imports therefrom, to which, by her free trade principles, she opposed no obstacle prejudicial to mutual relations.

Now while the great territorial Powers, with their armies pretty evenly balanced, at a time when those armies count millions of men not lightly to be unleashed, it becomes more important to be able to throw the power of a big fleet into the scales. For the personnel needed is small, the country will not be directly plunged into suffering and the population is able to go about its daily task almost unheeding, while the silent pressure of sea power can exercise a definite influence. It was on these grounds that England's influential position in the European concert was founded.

Her rôle emerged the more clearly after two definite groups of powers had been formed in Europe, which, while approximately well balanced, persisted in a state of intent hostility. It therefore became necessary to keep England from throwing her weight against Germany. The construction of the German fleet was a political move against this possibility in that it would prevent a shifting of the European balance to the detriment of the Central Powers.

After the carrying out of the naval programme of 1873 the German Navy had, between 1883 and 1897, fallen completely behind and become obsolete. This stagnation set in with the appointment of General Caprivi to the admiralty. Under his rule coast defence filled the picture. Obsolete ironclads were not replaced because no one had any clear views on naval tactics. The same uncertainty prevailed in other navies continually experimenting to find the best type of battleship. This state of things was brought to an end by the English Admiralty with the Naval Defence Act of 1889.

In Germany, too, it was realised that a coast defence consisting of fortifications and torpedo boats was but an incomplete form of armament, useless for any far-ranging operations at sea. From the time of Kaiser Wilhelm II.'s accession (1888), efforts to modernise the fleet were made, though with small success. Four battleships of the "Brandenburg" class with 10,000 tons displacement were authorised by the Reichstag in 1890, but after that construction again came to a standstill. In spite, however, of the bad quality and insufficiency of building material during those years, the time was well spent in the navy, for definite tactical and strategical conclusions were reached as to the manner of using a fleet.

On these conclusions was based the first navy law introduced after Admiral Tirpitz's appointment as Secretary of State for the Imperial Navy in 1897. This committed the Government as to the number of ships and the Reichstag to the necessary expenditure. The programme was to be spread over six years at an expenditure of 409,000,000 marks (about £21,000,000 sterling). England had thus an advantage of almost 10 years, and was building onto an existing fleet, whereas Germany lacked a working basis.

According to the new scheme the number of ships demanded was based upon their tactical division into two squadrons, each containing eight battleships (16), in addition to which there were to be a fleet flag ship and two reserve battleships, making in all 19 battleships. Besides, 12 large and 30 small cruisers, to serve as scouts for the home battle fleet and for service abroad, were asked for. A navy law in this sense was passed in 1898. The preamble declared that "as opposed to the greater naval powers the battle fleet will have importance solely in sorties." This was evident, both from the limitation in the number of vessels and from the circumstance that 12 of the old battleships were to be included in the figure to be reached in the course of six years.

The conflict of battleships now came to the fore as the strategic task of the fleet. This alone, according to the teaching of naval history, was the means by which command of the sea could be maintained. The limitation of the said control to Germany's home waters, the Baltic and the North Sea, was imposed by the relative strength of the German Navy to other navies. For a time, it is true, Germany was influenced by the young French school, which set forth the destruction of the enemy's sea-trade as the main task of a navy, but the principles were not only never applied but in the end definitely rejected in favour of the decision to build a battle fleet.

Adherence to this decision was the principle underlying the further upbuilding of the German Fleet, a measure that could no longer be delayed in face of the developments in foreign politics at the turn of the century. England's attitude towards Germany had become definitely hostile. The Franco-Russian alliance was obviously directed against Germany, and the clash between France and England over the Fashoda incident was smoothed out of existence by England's vigorous action. The pressure exercised by England through her Fleet on this occasion might well be regarded as a hint of what Germany might expect one day, especially as her interests at sea were definitely on the up-grade owing to the increase in trade. A comparison of the figures showing the rate of this increase for the two countries affords convincing proof of the possibility of peaceful parallel development.

The total foreign trade returns (export and import) amounted in millions of marks (20·4 M. = £1) to:—

	1890	1900	1910	1912	1913
Great Britain	15,300	17,900	24,733	27,409·5	28,632·5
Germany	8,195	11,089	17,615	21,256·6	22,546·6

The increase over 20 years from 1890 to 1910 was thus 9,433 million marks for England and 9,420 for Germany. But the increase in England's population from 38,000,000 to 46,000,000 during the same period was only half that of Germany's, which rose from 50,000,000 to 66,000,000. In proportion to the population, the increase in England's trade returns was therefore twice that of Germany's.

The total foreign trade returns of the more important countries were as follows:—

	Milliard marks
In 1890 roughly	73
In 1900 roughly	92
In 1910 roughly	147
In 1912 roughly	169

think of the better protection of her sea connections. Accordingly, after taking the first step (in 1897) of modernising her out-of-date fleet, she took (in 1899) the second step of doubling her battleship squadrons from two to four on the basis of the declaration: "Germany must possess a battle fleet so strong that war with it would involve even the mightiest naval power in perils of such a kind as to jeopardise its own supremacy." Those who persist in regarding this extended naval programme and its basis as a proof of hostility to English supremacy at sea have misunderstood the development of Germany's economic position and ignored the change which had taken place in the international political situation.

At the time of the great colonial wars of the 17th and 18th centuries, England had to deal with only *one* sea-trade rival at a time—Spain, Holland or France.[1] The commercial centre of gravity in the course of centuries had been shifted by England's historic interventions from Cadiz, Lisbon and Amsterdam to London. But London was no longer all-important. New York, Antwerp and Hamburg were centres also. The trend of circumstances was towards the establishment of a sort of international balance of power. A struggle between England and one of her commercial rivals for the possession of the world's markets would no doubt have ended in her favour, thanks to the overwhelming superiority of British sea power; but the remaining competitors for the world's trade would have taken advantage of England in her inevitable exhaustion after victory to aim blows at her commerce which even she would have difficulty in repelling.

No one will deny that Great Britain, with her divisions of empire scattered all over the globe, with her leading position in international trade, with her dependence upon oversea communications arising from her insular situation and extensive industries, and finally with her strong hold on international commerce, has the right and the duty of maintaining a fleet considerably larger and more powerful than those of other nations. This supremacy is ungrudgingly allowed her. But should it lead to the prevention of free commercial competition, all the other nations interested in international commerce would presumably unite to safeguard themselves. This is the idea which found expression in the German navy law; in adopting it Germany only followed the example of other states.

The table below shows the battleships of over 10,000 tons and armoured cruisers of over 5,000 tons, not more than 20 years old, possessed by various countries in 1900.

With the respective strengths of the fleets thus distributed, England had no need to fear that she would be ousted from her position; but it was necessary for Germany to protect herself against the eventuality of England's weight being thrown on the

1900	Germany		England		United States		France		Japan	
	No.	Displacement	No.	Displacement	No.	Displacement	No.	Displacement	No.	Displacement
Battleships	7	73,300	40	543,800	9	110,550	17	105,920	5	71,030
Armoured cruisers	1	10,690	10	75,580	2	19,270	5	35,910	3	29,720
Total	8	83,990	50	619,380	11	129,820	22	141,830	8	100,750

In 1910 the comparative strengths are shown by the following figures:—

1910	Germany		England		United States		France		Japan	
	No.	Displacement	No.	Displacement	No.	Displacement	No.	Displacement.	No.	Displacement
Battleships	28	360,990	56	859,990	29	451,320	16	207,430	12	174,630
Armoured cruisers	9	95,590	38	475,880	15	208,980	17	172,320	12	125,000

Between 1890 and 1910 an increase of 100% is shown. Increase of population over the same period in England = 20%. As these 20% achieved a trade increase of 62% there could hardly be any serious question of Germany's crowding out England.

In Germany, the growing volume of trade was more and more sea-borne trade; the maritime proportion became 70% of the whole. In view of this development Germany had necessarily to side of the group opposing the Central European Powers. That England would supposedly risk little or nothing in so doing is indicated in Churchill's slogan "Business as usual"[2] at the

[1] In the 18th century and just after England usually had to fight France and Spain together, and had always to reckon with the probability of their combination.—Ed. *E.B.*

[2] This phrase was not Mr. Churchill's.—Ed. *E.B.*

beginning of the War; whether or not he was mistaken those in England can best judge.

The long duration of the War and the unexpected capacity for resistance displayed by the Central Powers affected the technique of the War, on sea as on land, to an extent that could not have been foreseen. Submarines, flying and the use of gas are new and terrible phenomena of great possibilities, still in their infancy. In future, technical power in these respects must play so great a part that insular security will be a thing of the past. The question whether a true insight into such changes in the conditions of power and security might have suggested a less light-hearted view of the consequences of the War is not for discussion here; neither can we discuss the possible results of a different course of English policy. None the less, one is tempted to imagine the reply of the Delphic Oracle if consulted by British statesmen before entering into the War: "If you cross the North Sea you will destroy a great empire"—not the German empire only being meant.

The growth of the fleet by no means represented merely military rivalry at sea; rather ought that development to be regarded as an insurance premium for the great increase in trade interests during the same period, and as one aspect of a general forward movement in all countries chiefly concerned in international commerce. The increase in Germany's naval establishment was probably the most steady and uniform, for the plan laid down in 1900 was strictly adhered to and no surprises were sprung upon the other sea powers. No essential alteration was made in the standard of strength which, up till 1917, was aimed at, viz.: a fleet of two double squadrons and 20 first-class cruisers (58 capital ships). It was also Germany's policy to refrain from such improvements in the ship types as would initiate a process of building. On the contrary, England was invariably allowed precedence in this respect, although Germany was obliged to guard against any inferiority in her material, especially after 1905 when the new type of super-battleship was ushered in by the building of the "Dreadnought." This event had the effect of accelerating the fixed rate of German construction (in 1900 we had eight ships; in 1910, 37, representing an increase of some 30 ships in 10 years), from three capital ships a year at the outset to four per year between 1908 and 1911, in order that, after the start of the new building phase, Germany should not lag too far behind. That England, annoyed by her mistake, should vent her ill-humour on Germany is only another example of the common tendency to make others responsible. To reach the standard set for 1917 (58 capital ships against England's 94 in 1910) it was necessary to lay down three ships yearly, the statutory life of a ship being fixed at 20 years.

The scheme by which the German Fleet was to be brought up to the required standard by 1917, providing for the gradual elimination of obsolete units, was known to all the world. On economic grounds alone, and also because the lines of construction had from the first been on a small scale, all over-haste was avoided. The latest addition to the navy law, in 1912 provided for an addition of not more than three ships to the nominal strength. Its chief aim was to place the navy in a better state of readiness, an aim which the threatening political situation of 1911 appeared to justify. It is not to be denied that it was disagreeable to England's supremacy to watch the growth across the North Sea of a new naval power, whose strength she by no means underestimated. Whether the suppression of this navy has repaid England for her active participation in the World War, when she had the alternative of *not* placing the mighty power of her own Navy at the disposal of Germany's enemies on land, thereby in all probability preserving peace, must remain an open question. Low as Germany has fallen, she can still look back with pride on the fact that the glorious British Fleet did not beat the German in an open fight at sea.

The very regrettable enmity which exists between two racially akin nations who, during centuries of history, have been found side by side, but never as embittered enemies, will, it is hoped, become softened when an unprejudiced appreciation of the circumstances governing Germany's struggle for sea power has been shown; when time and a recognition of the common interest of these "two white nations"[1] have done their work.

(C. Ho.)

V. DEFENCE

The constitution of the armed forces of Germany has not been determined by the nation itself; on the contrary, its size, organisation and armament are fixed by the provisions of the Versailles Treaty.[2]

Army.—The enlistment must be voluntary, not on the basis of compulsory service. The recruit must bind himself to serve for 12 years or—if he wishes to become an officer—for 25 years. The strength of the army allowed is as follows: 3,797 officers, 20,297 N.C.O.'s, 74,490 privates, 1,407 administrative officers; in addition there are 300 medical and 200 veterinary staff. Of these (including N.C.O.'s) 51,506 are infantry, 15,767 cavalry, 10,644 artillery, 2,838 pioneers, 2,079 signalling troops, 5,572 communication troops and 2,800 medical service. The army is divided into seven Infantry and three Cav. Div., which are formed into two group commands.

Territorial Divisions.—Germany is divided into military regions, in each of which one infantry division is stationed. The seven regions are as follows:—

Region I. embraces the countries east of the Vistula (headquarters: Königsberg).

Region II. includes Pomerania, Mecklenburg, Schleswig-Holstein (headquarters: Stettin).

Region III. includes Brandenburg and Silesia (headquarters: Berlin).

Region IV. includes the country and the province of Saxony (headquarters: Dresden).

Region V. includes Thuringia, Hesse-Nassau, Hesse, Württemberg, Baden (headquarters: Stuttgart).

Region VI. includes Hanover and Westphalia (headquarters: Münster).

Region VII. includes Bavaria (headquarters: Munich).

The cavalry regiments are distributed over the whole Reich. The headquarters of the I. Cav. Div. is at Frankfurt-on-Oder, that of the II. Cav. Div. at Breslau, and that of the III. at Weimar.

Each divisional staff includes an infantry commander and an artillery commander. The pioneer battalions are under the infantry commander and the transport under the artillery commander.

Army Units.—There are 63 battalions with 189 infantry companies, 63 machine-gun companies and 21 trench mortar companies; 79 squadrons, of which 72 belong to cavalry divisions and 7 to infantry divisions; 72 batteries, of which 9 go to form the horse artillery brigades of the cavalry divisions; 14 pioneer companies; 14 signalling companies; 28 horse transport squadrons; 21 motor transport companies, and 7 divisional medical detachments. The infantry is armed with the 1898 rifle. It also carries 1,134 light and 756 heavy machine-guns, and 126 light and 42 medium trench mortars. The artillery is armed with 204 field-guns (7·7 cm.) and 84 light field howitzers (10·5 cm.). In addition, the fortress of Königsberg in East Prussia has 22 pieces of heavier calibre. Heavy artillery, tanks and aircraft are non-existent.

Administration.—The Minister of Defence is the highest authority for command and administration. At its head is a political minister, who is assisted in matters of military technique by the *Chef der Heeresleitung*, who, according to the Defence law, is a general and the superior of all soldiers. For training officer candidates there are one infantry, one cavalry, one artillery and one pioneer school. Enlistment is managed by the smallest units (company, squadron, battery). The proviso that soldiers may not leave the army until after 12 years' service is a great obstacle to maintaining the full strength. The Versailles Treaty directs that only 5% shall receive their discharge before the appointed time in any one year, and in practice this percentage hardly covers the discharges for sickness, incompetence and undesirability. An appeal for premature discharge can therefore only be granted in the rarest cases. This naturally deters many young men from joining, as they are alarmed at the idea of being forced to remain 12 years in the army whether promoted to the higher ranks or not.

[1] "The two white nations" was the toast whispered in the ear of the captain of the "Breslau" by the English admiral when dining on board his vessel, together with other commanders of all nationalities, off the coast of Albania in June 1913. (See Preface, *Kiel and Jutland*, Commander Georg von Hase, London,—*Author's note.*

[2] Part V. *Military, Naval and Air Clauses Articles 159–211.*

Recruiting and Training.—Recruiting is, in fact, influenced by the economic conditions of the moment; under present conditions (1926) recruiting is adequate. Recruits first spend six months at the depôts, one of which is provided for each regiment. Only after this half-year's training are they admitted to their companies, etc. Cadets receive at least four years' training before becoming lieutenants; of these, two years at least are spent with the troops and at least two in schools for the different arms. Anyone who has passed the prescribed cadet examination can become an officer. Soldiers who hold a school-leaving certificate can enter for this examination at the end of $1\frac{1}{4}$ years, others at the end of $3\frac{1}{4}$ years; that is to say, after they have acquired the necessary knowledge for passing a preliminary examination. Every cadet is promoted to officer's rank, irrespective of his origin and purely on the merits of his service, knowledge and his abilities.

The men are trained during their period of service for the calling which they intend to follow on discharge. They are assured of a post in the public service at the conclusion of their 12 years unless they prefer an independent career. In every unit some of the soldiers are elected by their comrades as proxies for economic affairs. A soldier takes no part in politics, but is allowed to join economic and non-political societies. The Defence law provides power, however, to forbid his association with such societies should they be subversive of military discipline and order in the army. For the protection of army interests there is an Army Chamber, which is elected by direct voting and is summoned from time to time by the Minister for Defence. Members of the army are under civil law, and only in case of war may courts-martial be appointed.

In view of the historical development of Germany and her army the Defence law takes specially into consideration the interests of the several states, and too rigorous an application of the centralising principle is not allowed to disturb the territorial constitution of the regiment. Regiments are required to draw their recruits from the inhabitants in the neighbourhood of their stations. Bavaria is allowed a special influence in respect of appointments to commands in the VII. Infantry Div., which is stationed entirely in Bavaria. The supreme authority is, however, vested only in the President of the Reich, who nominates, removes, promotes and releases both officers and administrative officials of the army.

On leaving the army the men receive—according to the Defence Forces Pensions law of Aug. 4 1921—a gratuity on which to live until they find other employment and, further, a civil service certificate which entitles them to apply for an official post in the imperial, state or municipal services. In addition, they receive outfit expenses and, on request, government security to assist them in settling on the land. Officers receive retired pay, which may also be commuted as a lump sum.

The Defence Problem.—The Versailles Treaty declares the aim of the German Army to be the preservation of order in the interior and the "control of the frontiers." In the first of these tasks the German Army has until now been successful; the attacks made by the Right and Left Radical parties on the Government at the time of the financial and economic crash of 1923 were defeated and greater disturbances nipped in the bud. The second task is not easy to carry out with the German Army of 100,000 men. Germany's frontiers are 5,000 km. long, exclusive of coastline; one province is cut off by the so-called Polish Corridor; on the west, the country on the bank left of the Rhine and a stretch of 50 km. east of that river may not be entered by German troops—and it is in this unprotected zone that the West German industrial district lies. Beyond Germany's frontiers lie, on the west, the French Army, with a war strength of some 5,000,000 and the allied Belgian Army, with a war strength of about 800,000; on the east the ring is closed by the Czech Army (war strength, 1,000,000) and the Polish Army, with a war strength of 2,000,000 men. All these armies are provided with excellent modern equipment, and are uniformly trained on the French model. The German frontiers are exposed, and have no protection from natural barriers. In the west, fortresses no longer exist, those in the east are out-of-date and without armament. The eastern frontier is only 170 km. from Berlin. The German Army has no possibilities of expansion, since all preparations for mobilisation are forbidden by the terms of the Versailles Treaty. Germany's military inferiority must therefore become greater after the outbreak of hostilities, for the losses could not be made good as fast as they occurred, owing to the absence of any draft organisation, and could in the case of a prolonged war hardly be made good at all; for the German Empire would speedily become the theatre of war and any possible sources from which reserves might be drawn would accordingly be blocked.

Navy.—By the terms of the Versailles Treaty, the German Fleet was allowed to retain 6 battleships not exceeding 10,000 tons, 6 light cruisers not exceeding 6,000 tons, 12 destroyers not exceeding 800 tons and 12 torpedo-boats not exceeding 200 tons. Battleships may be replaced 20 years after being launched, destroyers and torpedo-boats after 15 years. The material is now very much out of date; the battleships were launched in 1902–6 and the cruisers in 1899–1903. One light cruiser in replacement was laid down in 1920 and finished in 1925. In 1924 the first replacement destroyer was authorised, and in 1925 the second replacement cruiser and 5 replacement destroyers. The total personnel of the navy numbers 15,000 men. The control of the navy is vested in the Ministry of Defence (Reichswehrministerium). Under it are placed (1) The Fleet Command at Wilhelmshaven, with the "Braunschweig" as fleet flag-ship; the commander of the fleet also commands the battleship division, and has under him both the commander of the North Sea naval forces at Wilhelmshaven (battleships: "Braunschweig," "Hannover"; cruisers: "Amazone," "Emden" and the 2nd torpedo-boat flotilla) and the commander of the Baltic naval forces at Kiel (battleships: "Elsass," "Hessen"; cruiser:—"Nymphe"; surveying-ship "Panther"; 1st torpedo-boat flotilla and 1st mine-sweeper half-flotilla); (2) the naval stations in the Baltic and the North Sea; (3) the inspection of training at Kiel with the naval schools at Flensburg-Mürwik for training the supply of naval executive officers and quartermasters, those at Kiel-Wik for training technical and non-commissioned officers and also the training ships "Berlin" and "Hamburg" (cruisers) and the "Niobe" (sailing-ship); (4) the inspection of the torpedo and mines department at Kiel; (5) the inspection of the naval artillery at Wilhelmshaven, with the coast defence artillery school (Wilhelmshaven) and the naval gunnery school at Kiel-Wik; (6) the inspection of the naval depôts at Wilhelmshaven. Technical institutes are the naval dockyard at Wilhelmshaven and the naval arsenal at Kiel. Thus Germany has now at her disposal only the navy of a small Power.

Air.—Article 198 of the Treaty of Versailles prohibited Germany from maintaining any military or naval air forces. An inter-Allied aeronautical commission of control, paid by the German Govt. on Reparations account, took charge of the destruction of German aircraft, parts and apparatus. This commission was disbanded on May 5 1922. As civil aviation is allowed to Germany, an agreement was reached with the German Govt. by which certain technical points were enumerated as qualifying aeroplanes for use in warfare, and the possession of aircraft possessing these characteristics was forbidden. A new inter-Allied aeronautical committee of guarantee was established by agreement with the German Govt. (May 1 1922). It is paid by the Governments concerned, has branches in Berlin, France and Great Britain, receives lists of all German workshops in which flying material is manufactured, of machines and of pilots and sees that the provisions of the agreement are not infringed. VI. NATIONAL FINANCE

Financial Situation before the War.—The central problem of German Finance since 1871 had always been the difficulty of

delimiting the limits of the respective powers of taxation of the Reich and the states (the "Länder" of the Constitution of Aug. 11 1919). The financial policy of Bismarck had solved that problem, not formally but in actual practice, by allotting to the Federal Govt. the customs and excise duties, and to the states the power of direct taxation, which were also the main sources of income of local and municipal government. The income of the German Empire from indirect taxation was never adequate; therefore Bismarck made the Reich "a boarder of the states." The latter had to make good the deficiency by contributions (*Matrikularbeiträge*). Before the World War, this system failed once in 1913, when the requirements of pre-War armaments necessitated a larger revenue for the Reich, and the great defence contribution (*Reichswehrbeitrag*) of that year for the first time gave the Reich unprecedented powers in the field of direct taxation. One milliard of gold marks was raised by a non-recurring levy on all property.

Apart from this distinction of federal and state income by the nature of their respective sources, there was a further significant circumstance in the pre-War financial situation. While the Reich administered the postal service except in a few states, the railways belonged to the states; thus Prussia had a revenue of from 220,000,000 to 240,000,000 marks annually from the railways, amounting to from one-third to one-quarter of the total revenue of the state from taxation and state-owned property. The revenue of the Reich derived about 70,000,000 marks annually from the postal service, and every year a large amount of the net revenue of the state undertakings was reinvested. With regard to the railways, the real actual annual excess of revenue over expenditure for the whole of the German systems immediately before the War was estimated at not far below a milliard marks.

The total revenue of the Reich, the states and the municipal corporations from taxation amounted to about 4½ milliards of marks in 1913. The total public expenditure was considerably larger, since the states and municipalities also drew considerable income from state and municipal land property, from water, gas, electricity, etc., works. Of the revenue from taxation about two-fifths went to the Imperial Govt., which, in 1913, failed to balance the budget, and had to carry over a deficit of more than 250 millions. This deficit would have been covered in normal times either by the states or probably by a loan. The total amount of the indebtedness of the Government of the Reich at the beginning of the War was about 4,900,000,000 marks. Thus, the Reich entered the War with a financial system which compared unfavourably with the high degree of economic development of the country at large.

The War Period.—No wonder that the strain of War expenditure broke down the whole system. The optimism, common to all the belligerents, based on the idea that "the others would pay" stimulated the policy of war loans and therefore of some inflation. The latter, tripling the amount of pre-War mark note supply, did not exceed the similar procedure in most of the belligerent nations. By the end of the War, the debt of the Reich had been swollen by 150 milliards of new debts, of which about one-half had been funded; the other half was floating debt in the form of Treasury bills, which after the peace, could only be met when due by printing new mark notes. The revolutionary period of 1919–20 favoured inflation, and the facts indeed made it sometimes even a necessity, the purchasing power of the mark being one of the expedients for the restoration and maintenance of public order under enormously difficult conditions. The requirements of demobilisation, the occupation payments and the numerous kinds of tribute demanded by the Allies added to the financial difficulties of the Reich.

The Erzberger Reforms.—Nevertheless, the whole system of finance was in 1919–20 remodelled by Minister Erzberger, whose work remains the basis of the present financial system. While the federal constitution of 1919 weakened the power of the individual "Länder" and strengthened the Federal Govt., the great financial reform of 1920 fundamentally changed the financial system of Germany, applying the new constitutional principle of unitarism in the field of taxation. Practically the Länder (Territories) became now the "boarders" of the Reich, the exact opposite of the pre-War position.

The first intention of the German republican government was to increase income and property taxes as much as possible. But after a short interval in 1920 inflation was renewed, as heavy reparation payments due under the London ultimatum spoiled any chance of balancing the budget. The bases of the German budget, in addition to the customs duties, which immediately after the War gave very low results, were: the income tax, and, especially, the taxation of wages and the turnover tax. The turnover tax began at the rate of ½%, and was raised steadily until it reached 2½% on any sale made in Germany, and in the occupied territories in 1923 even 3½%. This tax proved to be an enormous burden on consumption, since any commodity on the average changes hands four times in Germany before reaching the consumer. But under a policy of inflation any such burden, heavy at the moment when it fell due, became light at the time of payment, because in the meantime inflation had depressed the purchasing power of money and especially of delayed taxes.

For a time certain taxes based upon the difference of the purchasing power which was high in Germany and lower abroad gave considerable revenues; *e.g.*, the coal tax, which was reckoned at 40% on the price of coal, and from 1920 onwards the newly created export tax which yielded in the most difficult times nearly one-sixth of all state revenues. Both were obviously only transitory in character, the difference between the interior purchasing power of a currency and its value in foreign markets being large during that slow development of a depreciation of currency; if the depreciation becomes rapid, internal prices tend to rise to a gold basis and the gap disappears. The difficulties of German finance were aggravated in the most unhappy manner by the first attempts to finance reparation payments (*see* the other sections of this article on CURRENCY and on ECONOMIC HISTORY). But far more important than the purely financial process of stabilisation was the energy of the Finance Minister, Dr. Luther, who stabilised the budget by strict refusal to pay anything else in other way than by raising taxes. The "miracle of the Rentenmark" is more due to this obstinate determination than to any technical means of stabilisation. Thus Germany entered on her new period of financial and economic life with a very severe taxation.

The mark was stabilised in Nov.–Dec. 1923, and in the beginning of Dec. 1923 the Finance Minister issued two tax decrees, introducing the gold basis for all tax payments and reorganising the whole system of direct taxation. The sales tax was placed on a 2½% basis; income tax was to be paid by all business people on the basis of their turnover, and the tax-free minimum for wage-earners was fixed at 50 marks (£2 10s.) per month. The customs and liquor taxes were completed by a property tax and about a dozen taxes of minor importance. The bulk of the income of the Reich for 1924–5, *e.g.*, about 70% of all, was covered by wages taxes, turnover taxes, customs and indirect taxation of articles of mass consumption. It was a very crude system of taxation which was thus established, though the coal tax necessarily had disappeared with the vanishing difference between interior and world market prices. But it served its purpose. Revenue and expenditure were balanced, and in 1924–5 an unexpected excess of revenue over expenditure became visible. When the Dawes Plan was finally adopted (Sept. 1924) the financial situation of Germany was reasonably sound. The plan brought about two important changes. The railways, which had been forced by the Minister of Finance in 1924 to balance their accounts, were handed over to the Reich's railway company and burdened with a yearly payment for interest and sinking fund of about 660 millions of gold marks for reparations. The customs duties and most of the indirect taxes were to serve as a guarantee for the regular fulfilment of its obligations by the Reich.

Readjustment of 1924.—From Nov. 1924 a period of tax reductions began. Especially the limit of exemption from income tax was raised, and the sales tax rate was lowered, in addition to minor tax reductions. In spite of the reductions, the financial year 1924–5

closed with a large surplus of about two milliards of gold marks (£100,000,000). In July 1925, accordingly, the whole system of taxation was again revised. Income tax rates were lowered, and are now on a progressive scale ranging from 10 to 40%. The tax-free minimum of wage-earners was raised first to 80 marks per month in addition to certain family allowances, then, from Jan. 1926 to 100 marks (£5). The sales tax rate was lowered to 1% on Oct. 1, and in March 1926 to 0·75%. The so-called luxury tax almost disappeared. At the same time consumption taxes on tobacco and beer were raised.

Simultaneously the financial relationship between the Reich and the Länder (Territories) was ordered anew. The Territories receive a fixed amount of the revenue from the income tax and the sales tax, at least 2,300 millions. The most important taxes levied by themselves are the land and rent taxes; this latter tax is practically the only important remainder of a far-reaching price control system established during the War. Rents are fixed by the state Governments; about 50% of the rent goes to the owner of the house, while the states raise the remainder as rental tax; the total receipts are shared between the local authorities for these expenses under this head and the provision of capital for the building of new houses, which is still largely carried out with the help of subsidies financed by the rental tax.

The system of taxation of the Reich draws its most important resources from the income tax (2,200,000,000 marks), the sales tax (1,300,000,000 marks), the customs duties and consumption taxes (1,700,000,000 marks), amounting to about four-fifths of the total tax revenue of the Reich and to about one-half of the total of taxes paid by the German nation.

It is much more difficult to give accurate data with regard to expenditure. The most important change is the reduction of expenditure for the army and navy, which is, however, more than balanced by war pensions and the payments under the peace treaty amounting at present to about 600,000,000 marks annually, but ascending to 1,650 millions in the year 1926–7. The payments to be effected in the "normal year" of the Dawes Plan (*e.g.*, 1928–9) should be covered in the following way:—

	Gold marks
Railways debentures interest and sinking fund	660,000,000
Interest and sinking fund of debentures of industrial and commercial enterprises given to the reparation commission	300,000,000
Budget	1,540,000,000
Total	2,500,000,000

The total expenditure of the Reich, the Territories and the local authorities for 1926–7 is summed up in the following approximate figures:—

	Gold marks
Expenditure of the Reich	4,000,000,000
Reparation payments	1,000,000,000
Expenditure of the Territories:—	
(a) derived from the Reich	2,250,000,000
(b) raised by themselves	1,000,000,000
	8,250,000,000
Local authorities	3,000,000,000
Total	11,250,000,000

In the normal year of the Dawes Plan, *e.g.*, after Oct. 1928, this burden will be about 1,500,000,000 marks higher. Very probably additional expenditure will be incurred on account of unemployment.

(J. H.*)

VII. ECONOMIC HISTORY

The dominating note of Germany's economic development before the War was the growth of industrialism. Her population had increased rapidly. It had grown since the foundation of the Empire from 41 millions to 67·8 millions in 1914. The density per sq. m. had increased from 196.6 to 333.1. Emigration had fallen from about 142,000 in 1880–5 to scarcely 26,000 in 1913; Germany had even become a country of immigrants. Apart from the seasonal labourers who went there regularly mostly from Russia and Austria, returning at Christmas, there was a foreign resident population in 1910 of almost 1·3 millions. In 1882 42·5% of the people had been engaged in agriculture; this percentage had fallen to 27·1 in 1907. The growth of industrialism was accompanied by urbanisation. In 1910 over one third of the German people lived in cities above 20,000, nearly a quarter in cities over 100,000, and the drift to the towns was renewed after the War.

Industrialisation.—Industrialisation had become possible by the growing economic expansion of the world, in which Germany participated through her foreign trade. Her own but recently acquired colonies did not count for much in the actual growth. Though developing at great speed they were rather a reserve for the future than a present source of wealth. Notwithstanding tariffs, the growing development of North and South America, of the African countries and of the Far East, brought about by the great efflux of men, the export of capital and the application of the methods of capitalistic organisation to backward countries, enlarged the markets of the world.

Germany's import trade, which had averaged 19 million tons 1880–5, had risen to 72½ million tons in 1908–13, whilst her exports had grown from 20·8 to 64·9 million tons. Her progress was mainly due to the application of scientific discoveries to industrial purposes, to a very carefully planned out system of industrial and commercial organisation and to the intelligence and adaptability of the German working men. Her commercial policy favouring trusts and combines in industry facilitated exports at the cost of the home consumers who, having to live under a system of agricultural protection as well, would have fared badly if the general development of the world had not lowered the cost of living all round in comparison with days gone by, though after the beginning of the new century an upward tendency in the movement of prices was visible.

The Post-War Crisis

Treaty of Versailles.—The Treaty of Versailles caused a far-reaching disintegration of Germany's economic life. She lost 10% of her population, but over 13% of her territory in Europe. Large agricultural areas were cut off in the east; in the west important industries like the iron industry were deprived of their raw material. The 1913 home supply of iron ore had amounted to 35 million tons; it had fallen to 5·1 million tons in 1923. But for the great importance of scrap iron in after-War days, Germany would have been almost totally dependent on ore imports from abroad. A large part of the metallurgical industry domiciled in Lorraine and Upper Silesia was lost (26·7% of the blast furnaces and 15·8% of the rolling mills), also the important textile industry (5,866 works) mostly in Upper Alsace were lost. German owners were forcibly expropriated in the ceded territories; they had to be compensated by the German Government. The same principle of confiscation of private property was applied to German-owned bonds and shares and to German-owned ships. The total proceeds of these confiscations to the Allies have been valued at 6 milliards gold marks, whilst the actual losses to Germany have been figured at about 30 milliards. The old established relations between the producers of raw material and the manufacturers of finished goods were cut asunder, especially in Lorraine and in Upper Silesia. The German industrialists whose property had been confiscated were bound to use the money they received as compensation in rebuilding new works in Germany. They owned the coal needed for running them, whilst their French competitors had to rely on reparation coal delivered to them under the Treaty of Versailles from the pits of the same rivals, whose works they had bought cheaply. The productive capacity of the iron and the steel industry on the European continent was thus artificially expanded at a time when markets were contracting. The exchange of iron and coal ceased to be a natural process, and became part of international high politics.

The Allied Powers at Versailles assumed that Germany could quickly rebuild her economic life, as little physical destruction had taken place within her boundaries. To even up their own chances, Germany was to be handicapped. She was bound to grant the Allies most-favoured nation treatment for five years; she had to admit during that period the produce of the ceded territories, especially of Alsace-Lorraine and of Poland duty free in such quantities as she had drawn from them formerly. She herself was denied the most-favoured nation treatment, and her nationals were excluded or subject to severe discrimination; she was not allowed a moratorium. Though the total sum of her obligations was not settled owing to the inability of the Allies to agree amongst themselves, she had to pay within two years a milliard sterling.

As she had to hand over a considerable part of her implements of production (ships, mines, cables, etc.) and most of her foreign investments, her future capacity to make payments abroad was limited by the excess of exports over her imports as shown by her balance of trade. Not knowing her total liabilities Germany had no inducement to pay the first instalment as quickly as possible; her capacity to do so would have resulted in an increased burden two years later, when the definite settlement had to take place.

Effects of the War.—German economics were permanently influenced by the War. The cutting off of supplies, the loss of markets, the scarcity of labour due to the demands of the army, and the wear and tear to which the industrial plant had been subjected had forced a system of control on Germany which was more severe than that existing in other belligerent countries. Food and many raw materials was rationed, and the production of many industrial commodities was supervised by centralised authorities. In a country traditionally run by a bureaucratic hierarchy who considered themselves the born rulers of men, always eager for new activities, and where democracy was largely represented by socialists, imbued with the idea of state intervention in business affairs, that situation was bound to produce lasting effects. Though generally speaking the control of economics during the War was not oversuccessful the idea of state socialism appeared to be greatly strengthened.

The collapse of the old régime seemed to clear the way for its advent. But the internecine struggle between the small bolshevist element, who wanted to follow the Russian example and the mass of the organised working men who wanted to bring about socialism in a peaceful orderly way, occupied the revolutionary Government which ruled Germany from Nov. 1918 to Feb. 1919. They succeeded in defeating Bolshevism and in saving Germany (and with it Western Europe) from its ravages. They were very eager for "nationalisation," at least for the socialisation of monopolistic industries. Two commissions were appointed to inquire into this problem, especially into the nationalisation of mines. They issued some very interesting reports but could not agree upon a practical policy.

The Coalition Govt. which came into power early in 1919 was not very keen on nationalisation. They realised that it was easy enough to take over a smoothly running concern and manage it by Government officials; but it was extremely difficult to reorganise a broken-down plant. The more energetic part of the working class demanded nationalisation without compensation; they wanted syndicalised industries rather than Government-run concerns. In these circumstances very little was done. With the object of paying-lip service to the principle of nationalisation and to the council schemes lately imported from Russia, national councils for coal mining and potash mining were set up, where masters and men, producers and consumers, were allowed to sit, to talk and to vote, without being in a position to wrench control from the owners. The Weimar Constitution provides for the creation of a Central Economic Council (Reichswirtschaftsrat), provincial economic councils and works councils for individual concerns. These latter were to send two of their members into the board of the company so as to give the workers partial control of the business—a provision the only effect of which has been to deprive most boards of directors of their former influence, which was concentrated in the hands of some extremely uncommunicative executive officers working hand in hand with a few big shareholders.

Some kind of socialistic tradition survived however. Food prices were controlled for quite a considerable time. Rents even now are still being fixed; in the days of inflation they amounted to next to nothing when calculated in gold. The entire house-owning class was despoiled. Wages were lowered *pro tanto*, as rents did not enter into them, and the cost of production was reduced. In many cases foreign consumers of German exports were thus given the rent taken from the German house-owner.
