Other Learned Societies.—The leading departmental societies, the Society of Antiquaries, the Royal Historical Society, the Royal Society of Literature, the Early English Text Society, the Selden and other societies have all continued, developed and renewed their activities, during the period under consideration. Among newer developments may be mentioned the remarkable progress of the less eclectic institutions, such as the English, classical, historical, geographical and modern languages associations, and the important part played by them in securing due recognition for humanistic studies, in the scheme of national education. The value of classical study is increasingly recognised and there is due appreciation of the danger likely to accrue were it submerged by newer studies. The organisation of cooperative research in studies appertaining to modern languages and literatures was advanced by the foundation, in 1916, of the Modern Humanities Research Association. Many agencies have promoted the recognition of English and its paramount position among modern studies—notably the English Association, and, in more specialised work, such societies as the Early Text Society, the Malone and the S.P.E. (Society of Pure English), of which Dr. Robert Bridges, is the founder and leading spirit.

The Shakespeare Association (incorporating the Shakespeare Day Committee), founded in close connection with the Shakespeare Tercentenary, 1916, has started a survey of Shakespeare in the various countries of the world, and has published a number of papers. The Bibliographical Society, founded in 1892, has since 1910, mainly owing to the activities of Professor A. W. Pollard, issued a number of important publications on English bibliography. In 1920 the society took over *The Library*, founded by the late Sir John MacAlister in 1888, and incorporated its *Transactions* with it, as a bibliographical quarterly. (I. G.)

Societies in the U.S.A.

A feature in the United States during the period 1910–26 has been a marked tendency towards decentralisation and specialism in constantly narrower groups or subjects. The number of societies has increased, with a corresponding increase in the number of individuals engaged in research work, but the professed scope of the large majority of these organisations is local, particularly in the fields of history, ethnology and geology. All the older societies continued to function, with little or no change in organisation or objective. The Smithsonian Institution maintained its pre-eminency, particularly in the fields of American ethnology and astrophysics. The American Oriental Society, founded in 1842 for the promotion of Oriental studies and the encouragement of research in Eastern languages and literature, continued to publish a journal which has appeared without a break since 1843, and extended its activities by including in its field of research the historical study of religion in its widest scope. The National Geographic Society, with possibly a larger membership (700,000) than any other society in the United States, was very active both in organising and financing explorations and in publication.

Of recent formations the Carnegie Institution of Washington, D.C., is the most important. It was endowed in 1902 by the late Andrew Carnegie with a sum of $22,300,000 to encourage in the broadest and most liberal manner investigation, research and discovery and the application of knowledge to the improvement of mankind. Organised in departments, including those of experimental evolution, embryology, botanical research, marine biology, meridian astrometry, eugenics and nutrition, it is working energetically along its selected lines of investigation. In addition to other work in terrestrial magnetism, researches are prosecuted in atmospheric electricity, magnetism in general and other allied topics. The Institution has physical laboratories at National Rock Creek Park, D.C., a nutrition laboratory at Boston, Mass., where studies of the metabolism of normal individuals and of diabetics and other researches connected with metabolism are conducted, and a desert laboratory for botanical research at Tucson, Arizona. In addition it maintains the Mount Wilson observatory at Pasadena, California.

LEATHER (*see* 16.330).—Several noteworthy advances nave been made since 1910 in the science and practice of leather manufacture.

I. IMPROVEMENTS IN MANUFACTURING METHODS

New Institutions.—A notable addition to the institutions engaged more particularly in the study of scientific problems of the leather industry is to be recorded. In 1924 the American Tanners' Council established a leather research department in the University of Cincinnati as a memorial to members of the industry who lost their lives in the World War. In the first place the department is to be devoted to research work, but eventually it will extend its activities to the training of chemists for the industry. A leather research institute has also been established at the Darmstadt Technische Hochschule.

New Bating Materials.—Probably the most notable change in the processes of light leather manufacture is to be found in the utilisation of artificial bating or puering materials in place of the natural materials formerly used. In manufacturing soft flexible leathers the skins were exposed, after removal of hair or wool, to a bate or puer made by fermenting the excreta of fowls or dogs. The researches of J. Turney Wood of Nottingham resulted in the production of a satisfactory substitute from the pancreas of animals, which contains enzymes capable of bringing about most of the desired changes in the skins. Under various proprietary names, and usually mixed with ammonium chloride, pancreatic preparations have superseded the old type of puer to a great extent. The artificial bates are free from the objectionable features inseparable from the use of fermented natural material, are more uniform in composition, and their action upon skins can be better controlled. For a few purposes tanners find that the artificial bate is not entirely satisfactory, but a large proportion of European and American tanneries no longer use the natural bates.

New Tanning Materials.—A great number of new vegetable tanning materials have been brought to the attention of tanners from time to time, but the staple materials now used are not very different from those employed in 1910. The use of mimosa bark as a source of tannin has certainly increased, and this material, grown largely in South Africa, is exported either as such or in the form of a solid concentrated extract of the bark. Several modern extract factories have been erected for this purpose at convenient points in South Africa, and the product competes with the solid quebracho wood extract of South America as a relatively low-priced and efficient tanning material.

The sulphite cellulose liquors, by-products of the paper industry, have found some application in the leather industry. Although not strictly tannins, when suitably treated they combine with hide substance, and have been successfully used in conjunction with ordinary tanning materials in the production of sole leather.

Synthetic Tanning Materials.—As a result of the researches of Dr. E. Stiasny, of the Leather Industries Dept. of Leeds University, synthetic tanning materials have been manufactured and used on a commercial scale, and were particularly useful when the regular supplies of tanning materials were interfered with during the War. In principle the preparation of synthetic tannin is simple. Phenolic bodies such as cresol are treated with sulphuric acid, and under carefully regulated conditions the product is condensed with formaldehyde and partly neutralised with an alkali. The first synthetic tannin of this type was named "Neradol" by Stiasny and manufactured by the Badische Anilin und Soda Fabrik. Various firms now produce similar materials in most European countries and in the United States. The synthetic tannins have many of the chemical properties of tannin, and are capable of converting skin into leather, but they appear to give more satisfactory results in practice when used in conjunction with other tanning materials. A great many modified processes of manufacture have been suggested from time to time, but there is some diversity of opinion amongst tanners as to the merits of synthetic tannins, and in their present form it is improbable that they will replace the natural tanning materials to any great extent.

The Chrome Process.—The chrome tanning process is now utilised in the manufacture of a large proportion of all boot upper leathers. It is estimated that in Great Britain about 80% of such leathers are now chrome-tanned, and this figure probably represents the approximate proportion used in other countries. Chrome-tanned sole leather is now manufactured in appreciable quantity, and as the early disadvantages associated with it have been overcome, a waterproof, non-slipping chrome sole, more durable than the vegetable tanned product, is now produced. It will probably be used in increasing quantity, although more costly to produce than the older type, and this fact may restrict its use.

Use of Pigments.—In the finishing of coloured leathers pigments are now used in increasing quantity, as a more uniformly coloured surface can be obtained than is possible in most cases with coal-tar colours alone. The leather is dyed with solutions of the latter in the ordinary way, and in the final stages of finishing very finely ground pigments suspended in suitable media are sprayed or swabbed over the leather surface. On the highest grade leathers this may be unnecessary, but the appearance of medium and low-grade skins is improved by the treatment.

Machinery.—The developments on the mechanical side of tannery equipment have been concerned chiefly with the improvement of existing types of machinery. Probably the most interesting to the British sole leather tanner is to be found in the perfection of the unhairing and fleshing machinery. Machines which remove hair and flesh from skins and sides (*i.e.*, half hides) have long been available and used in tanneries throughout the world, but the special difficulties connected with the manipulation of heavy whole hides were not met until the Turner Tanning Machinery Co., Ltd., developed the pneumatic roll unhairing and fleshing machine. British sole leather tanners who work whole hides, as distinct from sides, through the earlier processes in the tannery, found this machine particularly useful when manual labour was scarce in 1914–8, and have continued to use it successfully since then.

The Liming of Hides.—Two devices with the same object—the economisation of labour in the liming of hides—have been patented and found some application in sole leather tanneries. In both systems the hides are suspended in pits containing the depilating solution, and in one (Forsare) the liquor is agitated and circulated between the hides by blowing compressed air through perforated pipes fixed at the bottom of the pits. In the other system (Tilston, Melbourne) the liquor is distributed by means of a paddle which moves slowly along the bottom of the pit. The heavy manual labour involved in handling and setting the hides by the orthodox method, where hides are piled in a pit, is avoided, but both of the new systems require a larger pit space for dealing with a given number of hides than does the older method. In the period under review there has been a notable increase in the number of chemists employed in the leather industry, and there are few important tanneries which do not now employ one or more specially trained chemists on their staffs.

(D. McC.)

II. THE TRADE IN LEATHER

The main differences in the distribution of the industry since 1911 affect the position of Great Britain and the United States. Great Britain, with the exception of certain classes of leather, is becoming a bigger producer and much less dependent upon import supplies. Export from the United States has declined in quantity. The rest of the world remains approximately where it was, though there is a tendency to an increase in leather production in those agricultural countries where there is a substantial supply of hides which previously were exported, *e.g.*, South Africa.

World Production of Hides.—There has been a small increase in the world's annual supply of hides, though this increase has not been equal to the rate of increase in population within the same period. Every tanning country has a certain supply of hides of its own, but most of the big ones require to import from other countries. Dividing all countries into the two categories:—(*a*) "tanning countries" and (*b*) "hide exporting countries," there has been an increase in the aggregate in the number of cattle in the "tanning countries" of about 2% on a total of about 200,000,000 which is a rate of increase appreciably less than that of the population of those countries. On the other hand, there has been an increase of about 15% in the aggregate number of cattle in the "hide exporting countries" on a total of about 300,000,000. It is probable, however, that this is an overstatement of the real increase as in one or two countries the pre-War figures were defective.

The most important hide producing country from which heavy leather tanners draw their supplies is Argentina, in which country there has been a substantial increase in the number of cattle, the pre-War figure being 25,800,000 and the latest post-War figure being 37,000,000. In 1913 the export of frozen and chilled beef from the Argentina was only 4,119,000 quarters. In 1921 the figure had risen only to 4,750,000 quarters, but by 1924 the total was 9,547,000 quarters, falling slightly in 1925 to 8,921,000. One of the most significant features about this increase, of considerable interest to tanners in estimating future supplies of hides, is the fact that the increased export has been mainly to the continental countries of Europe. Before the World War Argentina exported practically no beef to those countries, but since the War Germany, Holland, Italy, Belgium and France have all imported beef from Argentina on a substantial scale. If this indicates a change in social habits in these countries leading to an increase in the consumption of meat, there is likely to be a further demand for cattle in South Africa and Australia, as well as in South American countries, which will react favourably upon supplies of hides for tanners.

Against this, however, must be set off the diminution in the supply of dry hides from many parts of the world. The hides from the meat works throughout the world are by-products of the meat and would come forward in undiminished numbers even if the price obtained for them was substantially less than at present. Dry hides, however, come from the outlying parts of the earth, and frequently the hide has to be carried some hundreds of miles by land before reaching the port. These hides are not forthcoming unless there is satisfactory return for the labour and costs involved, and a distinct relationship can be traced between the price and the supply of dry hides. During the period of high prices in 1919, for instance, some millions of hides were brought forth which would never have come forward but for the high prices ruling. Owing to the increase in transport and handling charges, the return to the original holder of the hide now is less than it was before the War, and the diminution in the supply is to be measured by some millions. The United States is now taking practically no dry hides, though the consumption in Great Britain is being maintained.

Tanning Materials.—The chief tanning material supplies before the War were quebracho extract from Argentina and chestnut extract from various European countries as well as the United States. A rapid increase is shown in the exportation of quebracho extract from Argentina and a decline, in comparison with the pre-War figures, in the export of logs, the figures being as follows:—

	Quebracho Logs	Quebracho Extract
	Tons	Tons
1913	383,964	79,684
1920	56,582	122,837
1921	30,857	120,100
1922	124,822	167,845
1923	113,639	208,586
1924	93,797	216,322
1925	116,940	274,245

Supplies of chestnut, however, are diminishing. In France in particular, exports have fallen very substantially, because the forests in past years have not been properly replanted. Imports of chestnut extract into Great Britain from France in 1913 were 35,800 tons, while the figure for 1925 was only 11,000 tons. In the United States also there is a reduction in the production of chestnut extract, due to the ravages of the chestnut blight.

Against this reduction, however, has to be set off the increased consumption of wattle bark as a tanning agent. The wattle tree, which was indigenous to Australia and was introduced into South Africa in the last decade of the past century, has made very rapid strides. The Australian industry has fallen to very small dimensions, but the exports of wattle bark from South Africa increased from 65,000 tons in 1913 to 121,000 tons in 1922, declining slightly since. In addition to these exports of bark from South Africa, substantial quantities are now converted into extract in South Africa and exported to tanners throughout the world in the form of a solid extract, somewhat similar in appearance to quebracho extract. The biggest tanning material company in the world has interested itself in the developments of the South African wattle industry.

Demand for Leather Goods.—On the leather side, there has been a substantial increase in the amount of leather made for the upholstery of motor cars. Although only a relatively small proportion of the cars manufactured in the world are upholstered in leather, the amount of leather required is substantial, and many firms who formerly produced leather for saddlery and harness work have turned over to this class of production.

A further change is the production of fancy leather for boot and shoe purposes, and the extensive use of coloured leathers has caused considerable difficulty to upper leather manufacturers, who find that their industry has become one subject to fashion. It is probable that the consumption of sole leather in the world has not increased, as there have been a substantial number of substitutes which have made a certain degree of headway. The competition of substitutes against leather for the soles of boots, however, is largely an economic one, and with the lower prices of hides which have now been reached, it is probable that the field for the substitute will be limited. In belting leather also, in certain countries, substitutes have made headway, though in the United States, where special propaganda in the interest of leather belting has been undertaken, the substitute has declined in importance. (E. C. Sn.)

LEBEDEV, PETR NIKOLAJEVICH (1866–1912), Russian physicist, a master of experimental research, was born on Feb. 24 (old style) 1866 in Moscow, son of a merchant. He was educated at a German secondary school and a technical college in Moscow, and in 1887 went to study physics under Kundt in Strasbourg. He took his doctor's degree in 1891 and published his first research on the Mossotti-Clausius theory of dielectrics. In the same year he was appointed assistant in physics at the University of Moscow and in 1892 professor. In 1895 he produced very short electric waves and published his work on the double refraction of electric rays. He also succeeded in proving, experimentally (1899), the existence of the extremely small pressure which light exercises on bodies. In 1901 appeared his classical work: *Experimental Research on Light Pressure* (published in 1913 in German in *Ostwald's Klassiker*). Finally in 1910 (*Annalen der Physik*, April) he succeeded in measuring this pressure, theoretically determined by Maxwell. In 1911 Lebedev had to leave the university for political reasons, and started, with his pupils, a private laboratory. His further work was mainly on the origin of the earth's magnetism, but death from heart failure on March 1 1912 stopped his ingenious experiments. He founded in Moscow the Lebedev Physical Society. In 1913 his *Collected Researches* were published in Russian under the auspices of this society. (A. Fo.)

LE CATEAU, BATTLE OF: *see* FRONTIERS, BATTLES OF THE.

LECOCQ, ALEXANDRE CHARLES (1832–1918), French musical composer (*see* 16.355), died in Paris Oct. 24 1918.

LEDGER: *see* BOOKKEEPING.

LEE, SIR SIDNEY (1859–1926), a British man of letters (*see* 16.363), died in London March 3 1926. He was knighted in 1911 and was president of the English Association in 1917. His lectures on *The French Renaissance in England* were published in 1910; and his later works include *Principles of Biography* (1911) and *Shakespeare and the Italian Renaissance* (1915). At the time of his death, he was engaged on the second volume of his official biography of *King Edward VII.*, the first volume of which had appeared a year previously.

LEE, VERNON (pen-name of Violet Paget) (1856–), British author, was born in France, of English parentage, on Oct. 14 1856. She lived almost entirely near Florence, and was a well-informed and acute student of Italian art, history and literature. Her *Studies of the Eighteenth Century in Italy* (1880) is typical of several books of essays; *Miss Brown* (1884); *Hauntings* (1890); *Vanitas* (1892); *Sister Benvenuta* (1906); and *Louis Norbert* (1914) are among her novels. *Satan the Waster*, a philosophic trilogy, was an ambitious dramatic satire on war and civilisation (1920), and among many other works may be mentioned *Gospels of Anarchy* (1908), essays on political subjects, *The Sentimental Traveller* (1908) and *The Tower of Mirrors* (1914), essays on the spirit of places, and *Proteus, or the Future of Intelligence* (1925).

LEEDS, England (*see* 16.368), had a population of 458,320 in 1921, and in 1925 it was stated to be nearly 500,000. Roundhay, Seacroft, Shadwell and part of Crossgates were included in the borough in 1912, Middleton in 1919, and part of Adel-cum-Eccup in 1925, making the total area 30,136 acres. In 1918 the parliamentary borough was redistributed in six divisions, each returning one member. The city museum was acquired by the corporation in 1921 from the Leeds Philosophic and Literary Society. Kirkstall Abbey House, an historic building near Kirkstall Abbey, was bought by the municipality in 1924, and the old Kirkstall bridge over the Aire was replaced by a new bridge in 1912. The corporation owns the fine mansion of Temple Newsam, with an estate of 935 ac., in the Hunslet rural district in the east of the city, where there is a fine collection of arms and art treasures. A farm in connection with the estate has been worked as a municipal dairy farm since 1922. At Middleton 316 ac. have been leased for a public park, and 427 ac. bought for a housing scheme.

In 1924 and 1925 respectively the corporation obtained parliamentary powers to enable them to carry out very extensive street improvements in the city. New office buildings, capable of accommodating a staff of 350, were acquired and equipped in 1925. Under the provisions of the Leeds Corporation Act 1924 the city was constituted one township under a separate board of guardians by the amalgamation of the former townships of Leeds, Armley and Bramley, Holbeck and Hunslet and the former parish of Osmondthorpe. The construction of a reservoir at Leighton, 46 m. distant, was completed in 1926. In 1926 the tercentenary of the granting of the city charter was celebrated.

LEEDS, UNIVERSITY OF (*see* 10.43).—In the period under review, the professorial staff has been strengthened by the institution of chairs in English language, philosophy, medieval history, applied mathematics, physical chemistry, agricultural chemistry, bacteriology, therapeutics and clinical surgery. New departments of Russian and Spanish languages and literatures and of geography have also been established. Provision has been made for the residence of both men and women students. The university now has a hall of residence with accommodation for 120 men and four halls for women with accommodation for about 175 students.

Temporary structures were erected to accommodate the influx of students after the War and private dwelling houses were adapted for various departmental purposes. Considerable additions have been made to the site, however, and the efforts of the university authorities are now being directed to the provision of a range of adequate and permanent buildings. The university council has set aside special funds to aid research in all departments. With the help of grants from the Government, special investigations have been undertaken in animal nutrition, flax-growing, etc. A staff of research chemists has been appointed in the coal gas and fuel industries department, where investigations are carried out in co-operation with the Institution of Gas Engineers and the National Benzole Association. An International Research Laboratory for the leather industries has been established by means of public subscriptions as a memorial to Professor H. R. Procter. Considerable developments have taken place in the department of pathology and bacteriology which works in close association with the Leeds General Infirmary and the Health Committee of the Corporation.

In the department of agriculture a large volume of advisory work is done in the county. More than 1,400 problems were dealt with in 1924, 750 of them involving personal visits. Research is in progress in all branches of agricultural science and organised courses of lectures, demonstrations, etc., are conducted in the three Ridings of Yorkshire. The Rawdon Baptist College, the York Diocesan Training College and the Leeds Central Technical College (printing department) have been affiliated to the university, recognition being given, for purposes of degree work, to certain courses of study at these institutions.

In co-operation with Armstrong College, Newcastle-upon-Tyne, the university, at the request of the North Eastern Railway Company, undertook the conduct of lectures and examinations in connection with the company's educational system—a scheme which has since been extended throughout the area of the London and North Eastern Railway Company's service. Striking developments have taken place in the extra-mural work of the university. Five tutorial classes were conducted in 1910: in 1925 there were thirty-eight. In addition to these regular, three-year courses, a considerable number of one-year

classes, introductory courses, single lectures and extension courses are given each year throughout the university's area. Public lectures are arranged in the university each session on literature, history, art, science, music, etc., while mid-day music recitals have become a regular feature of university life.

Between 1910 and 1914 the average number of students was 650. Between 1914 and 1919 the average fell to 540 but rose in the quinquennium 1919–24 to 1,329. There were 1,435 students in 1925. The appeal for a fund for new buildings produced £263,085 and £124,314 for the development of the university. Sir Edward Brotherton, Bart. gave £20,000 for bacteriological research. The Clothworkers' Company have made capital as well as annual grants amounting in all to £251,333. Sir James Roberts and Lord and Lady Cowdray have been generous benefactors.

LEE OF FAREHAM, ARTHUR HAMILTON LEE, 1ST VISCOUNT (1868–), British politician, was born at Bridport, Dorsetshire, Nov. 8 1868. Educated at Cheltenham and Woolwich, he entered the Royal Artillery in 1888, retiring with the rank of brevet-major in 1900. From 1893 until 1900 he was professor of strategy and tactics at the Royal Military College in Canada, during which period he organised the military survey of the Canadian frontier. He was British military attaché with the United States army during the Spanish-American War in 1898, and in the following year was military attaché to the British Embassy at Washington. In 1900 he entered the House of Commons as Conservative member for the Fareham division of Hampshire, which he represented for 18 years. He was Civil Lord of the Admiralty from Oct. 1903 until the resignation of the Balfour ministry in 1905. In 1912 he carried through Parliament an Act aimed at the white slave traffic. On the outbreak of the World War he rejoined the army, and served as a colonel on the staff. In 1915–6 he was personal military secretary to the Secretary for War (Mr. Lloyd George) and in 1917–8 director general of food supplies. He was made K.B.E. in 1916, G.B.E. in 1918, in which year he was created baron; and was sworn of the privy council in 1919. He joined Mr. Lloyd George's administration in 1919, first as Minister of Agriculture and then as First Lord of the Admiralty (Feb. 1921–Nov. 1922). In 1922 he was made a viscount. He was a member of the Imperial Cabinet in 1921, a delegate to the Washington Conference, Nov. 1921–Feb. 1922; and in 1923–4 chairman of the royal commission on the public services of India, for which he was created G.C.S.I. in 1925. In 1921 he presented to the nation, as a residence for the prime minister for the time being, the house and estate of Chequers on which subject he writes in this Encyclopædia.

LEFROY, HAROLD MAXWELL (1877–1925), British entomologist, was born at Crondall, Hampshire, Jan. 20 1877, and was educated at Marlborough and King's College, Cambridge, where he graduated in 1898. He early specialised in entomology and became in 1899 entomologist to the Imperial Department of Agriculture for the West Indies, a position which he held until his appointment in 1903 as imperial entomologist for India. In 1912 he was appointed to the newly created chair of entomology at the Imperial College of Science and Technology, South Kensington, and in 1913 he became honorary curator of the insect house of the Zoological Gardens, London. He devoted himself particularly to the study of the life history of insects of economic importance in the field, and as imperial silk specialist for India in 1915 and 1916 he did much valuable work for the silk and cotton industries. During the World War as temporary lieut.-colonel in Mesopotamia he conducted sanitary measures against flies, and in 1917 served as an expert on the royal commission on wheat supplies, dealing effectively with the problem of beetles in wheat. He subsequently devised means of combating the depredations of the death watch beetle in old buildings. He died in London on Oct. 14 1925, poisoned by the fumes of a gas with which he was experimenting for insect destruction.

His publications include *Indian Insect Pests* (1906); *Indian Insect Life* (1909); *A Manual of Entomology* (1923); and articles in *The West Indian Bulletin*, the *Agricultural Journal of India*, and many official papers.

LEGAL EDUCATION (*see* 9.603).—The purpose of this article is to indicate the main tendencies of legal education in England and Wales since 1910, and to trace the general development of legal education in the United States from the beginnings to the present day.

I. ENGLAND AND WALES

The most noteworthy feature of the period under review has been the greatly increased interest which law has received at the hands of those interested in education generally. Two principal tendencies have been revealed—first, an increasing demand for scientific legal education for both branches of the legal profession; and, second, the serious consideration by educational bodies of the advisability of including elementary instruction in law in the curriculum of the ordinary schools.

Systematic legal education is now provided by the older and the newer universities, the Council of Legal Education, the Law Society and the approved law schools set up by the Law Society under the provisions of the Solicitors Act 1922. There are faculties or departments of law at the Universities of Oxford, Cambridge, London, Birmingham, Durham (Armstrong College), Leeds, Liverpool, Manchester, Sheffield and Bristol; and departments of law at the following university colleges: Aberystwyth, Exeter, Nottingham, Leicester, Southampton, Bangor, Swansea and Cardiff. In some cases these faculties and departments provide qualifying courses for degrees in other faculties. Thus, at the university of London, the degree examinations for B.Sc. (Economics) include industrial law, and for bachelor of commerce (B.Com.) commercial law, contract, banking and insurance.

Professional Law Schools.—A degree in law, however, is not in England a professional qualification. Before he can practise, the student must pass in the case of a barrister the examinations of the Council of Legal Education, and in the case of a solicitor the Law Society's examinations. The instruction provided by the Council of Legal Education for such Bar students as care to take advantage of it constitutes a complete curriculum in law. The organisation is in the hands of a director of studies and a body of readers of high standing. Lectures are given in the Inns of Court lecture rooms. The Law Society from the year 1903 onwards has held a school of law at the Law Society, Chancery Lane, where lectures and classes under the control of a principal and director of legal studies and a body of readers, lecturers and tutors have been given to increasing numbers of students both for the intermediate examination and the final examination of the Law Society, and in lesser numbers for the degree in law at London University.

From 1903 until the passing of the Solicitors Act of 1922 attendance at a law school was entirely voluntary, and a matter of personal choice for each individual articled clerk. By the Act of 1922, however, subject to certain exceptions, every articled clerk, before presenting himself for his final examination at the end of his period of articles, must have attended substantially for 12 months at an approved law school. To meet this requirement law schools had to be organised in the principal provincial towns.

The contribution of the law schools at Oxford and Cambridge to the cause of legal education is noteworthy. These universities supply practically the whole of the teaching staff engaged on this branch of educational activity as well as the bulk of the research students. Nor are these activities confined to the academic field. At Cambridge there are few colleges that do not possess their law clubs affiliated to the University Law Society; these bodies meet frequently for discussion and debate, and at intervals hold moots. This practice of mooting, which has also been revived in its ancient home, the Inns of Court, is a valuable addition to the practical side of legal education.

Law and General Education.—Apart from the study of law as a professional education, it may be said that educational establishments generally have come to allow a greater importance to the knowledge of law as part of the equipment of every citizen. Considerable attention and prominence has been given to the

matter by distinguished judges and others, and lectures have been given in which the idea has been formulated. It has not yet been found practicable, however, to introduce elementary law into the average school curriculum, and it may be doubted whether such a suggestion is likely to be carried into effect in the near future. Clearly, only those who are approaching the conclusion of their school life would be able to profit by such instruction, and it is notorious that sixth-form students already have a very full curriculum. (E. L. B.*)

II. THE UNITED STATES

American legal education begins in 1784 (or perhaps 1782), when Judge Tapping Reeve of Litchfield, Conn., set up the first school for the teaching of the common law.

Early History.—There had been no legal profession in the colonies until the 18th century. Before the revolution a certain number of lawyers had received their training in England, in the Inns of Court. But a system of courts, manned by lawyers and requiring a trained profession to practise before them, was not called for by the economic conditions of the colonies until toward the middle of that century; nor were the executive and legislative justice, characteristic of the colonial polity, wholly superseded by judicial justice until after the revolution. Legal education was at a low ebb in 18th-century England. The universities had never taught the law of the land. The medieval system of the Inns of Court had decayed, and the system that now obtains had not been set up. Hence there were no good models at hand after the revolution, and American legal education had to develop its own methods. So far as the models were English, they were, first, the purely apprentice training of the lower branch of the profession in England (for in general the United States took the attorney or solicitor for its type, rather than the barrister), and, second, the academic lectures on the law of the land which began with Blackstone's lectures as Vinerian professor at Oxford. This example was followed eagerly in America. Wythe's lectures at William and Mary (1779), Wilson's at the College of Philadelphia, now the University of Pennsylvania (1790), Kent's at Columbia (1793) and Parker's at Harvard (1815) were of this type. They were not instruction in law to prospective lawyers so much as lectures to young gentlemen as part of their general cultural training. Later this plan of academic lectures upon law was grafted upon the apprentice training which was the first type of legal education in America.

After the revolution, students ceased to go from America to the Inns of Court. Then education for the Bar became distinctly American. Beginning from this point, three stages of development may be distinguished. These stages correspond to three periods in American legal history. The method of each stage is a response to the needs of the period in which it grew up.

Apprentice Training.—First, there is a stage of apprentice training, either in the office of a practising lawyer or in a law school organised as an expanded law office and applying office methods of instruction. This sort of training sufficed for the needs of the time immediately after the revolution. The development of judicial justice administered in courts by trained judges called for practitioners who knew the art of the lawyer's craft. When the United States took over English law as the law of its several commonwealths, in the first instance it took over English legal procedure. Except for land law, at the time of the revolution the greater part of English law was expressed in terms of procedure. Thus there was need of lawyers who knew how to bring a lawsuit and how to conduct it through the courts. Apprentice training was adapted to this need. Judge Reeve's law school grew out of the practice of taking a number of students into a country law office where the press of business did not interfere with instruction. Just because it grew out of such a law office, the exact date of establishment of the school at Litchfield cannot be fixed.

The law schools of the period were modelled on that institution. In effect, they were but expanded law offices in which preceptors who were practising lawyers carried on the teaching side of the law office as their chief activity. Such was the Harvard law school, the oldest of the existing law schools in the United States, in its first stage (1817–29).

At this time there was little differentiation of local law. But the whole tendency of the apprentice training was to dwell upon the local and temporary rather than the universal and enduring elements in the body of legal materials, and this unfortunate feature served to develop and entrench many provincialisms in the law of the several states, since, until, much later, the bulk of the profession was apprentice trained. In general the first stage prevailed until Joseph Story began to teach law at Harvard (1829). Also in many parts of the country the simpler needs of a rural or even pioneer society required nothing more than an apprentice-trained profession, so that the method of that stage has persisted in many localities into the present.

College Teaching.—A second stage begins with the appointment of Story as Dane professor at Harvard, and extends until the epoch-making work of Langdell after 1870. There was nothing in the way of a rule-of-thumb apprentice training, which, under 19th-century conditions, could be done better in a law school than in a law office. But with the growth of the law something more than a rule-of-thumb training in practice was required, and the second stage of legal education was a response. From Story to Langdell the law schools continually increased in influence. The accepted mode of training came to be study in a law school in which law was taught by lectures and from text-books with the teaching apparatus of the old-time college.

The era of expansion that followed the adoption of the constitution called for creative juristic activity and creative legislation. Study of substantive law was called for. It was necessary to investigate each item of the common law of England with reference to its applicability to the conditions in the New World. The traditional materials of 17th-century English law had to be reshaped so as to make of them a common law for America. A mere apprentice training could not meet these demands. Text-books had to be written to guide the courts in the new departments of law, which were formative on every hand. These text-books came from the law schools and soon gained the upper hand as the bases of instruction, even where the whole spirit of instruction remained that of the first stage. The best examples of the second stage are the teaching of Story and Greenleaf, and later of Parsons, Washburn and Parker at Harvard, the teaching of Dwight at Columbia, and the teaching of Cooley and his colleagues at Michigan.

Scientific Study of Jurisprudence.—In a third stage there is scientific study of the legal system of English-speaking countries on the basis of the sources. An analytical and a historical method, as methods of a general science of law, are applied to the sources, and thus system is put into each branch and department of the law. By the time of the Civil War the formative period of American law and legal institutions was substantially at an end. With few exceptions, the great text-books that had guided the courts speak from before the Civil War. In the last quarter of the 19th century, law books tend more and more to be mere indexes to the decisions: they cease to be creative. The need of the time had come to be in another direction. Now there was need of systematising the law which had developed in the period of growth. In response to this demand, within less than a decade after the end of the Civil War, Langdell, who was appointed to Story's chair at Harvard in 1870, had inaugurated the method of study from adjudicated cases which has come to prevail in the majority of American law schools of high grade.

This method seeks, through analytical and historical study of the sources, to give a grasp of the traditional art of deciding cases on the basis of reported judicial experience. It teaches the traditional art of developing grounds of decision from the authoritative legal materials. This is the enduring element in Anglo-American law. Conditions in many localities, in which requirements for admission to the Bar are low, and candidates have insufficient preliminary training to enable them to study the sources directly, have led to persistence of the method of lectures and text-book instruction in schools in which the teachers are actively engaged in practice, and hence the spirit is that of

apprentice training. In such schools local law and procedure are chiefly stressed. Probably 60% of those who come to the Bar to-day are trained in such schools. (R. Po.*)

LEGIEN, CARL (1861–1920), German labour leader, was born Dec. 1 1861 at Marienburg (West Prussia). A turner by profession, he entered the trade union movement in Hamburg. In 1887 he became president of the turner's association, and in 1890 member of the general commission of the German trade unions. He was president of this commission from Jan. 1 1891 until the general German trade union association was founded in 1919, when he became its president, which he remained until his death. The leading organiser of the German trade union movement, in 1901 he founded the International Trade Union League, being its first secretary from 1903–19. During the World War he prepared the way for the legal recognition of the trade unions, which was granted in Jan. 1918. Together with Leipart, who succeeded to his post after his death, he formed the Arbeitsgemeinschaft (community of labour) at the end of 1918—an institution destined to set on foot the reconstruction of German economic conditions after the War by co-operation between the employers federations and the trade unions, the latter enjoying equal rights. His last great achievement was putting down the Kapp Putsch in March 1920. He died in Berlin Dec. 26 1920. Legien wrote many works on trade union questions, including *Die deutsche Gewerkschaftsbewegung* (1911).

LEGOUIS, ÉMILE (1861–), French scholar, was born at Honfleur on Oct. 31 1861. Educated at Honfleur and in Paris, after teaching for a year at the Collège d'Avranches, he was made *agrégé d'anglais* in 1885. He was next appointed lecturer at Lyons; and after passing his doctorate in 1896, he became professor at Lyons. In 1904 Legouis was appointed special lecturer in English at the Sorbonne. He is the author of many important critical works on English literature.

Among his publications are *Le Général Michel Beaupuy*, with G. Bussière (1891); *La jeunesse de Wordsworth; Étude sur "Le Prélude,"* crowned by the Académie française (1896); *Shakespeare* (1899); *Morceaux choisis de la littérature anglaise*, with M. Beljame (1905); *Chaucer* (1910); *Edmund Spenser* (1923); and with L. Cazamian, *Histoire de la littérature anglaise* (1924). He also collaborated in the translation of Chaucer's *Canterbury Tales*, crowned by the Académie française, 1908.

LEGROS, ALPHONSE (*see* 16.380) (1837–1911), Anglo-French artist, died in London Dec. 8 1911.

LEHÁR, FRANZ (1870–), Hungarian operetta composer, was born at Komárom, Hungary, April 30 1870. After studying at Vienna and Prague, he became a conductor. His opera *Kukuska*, afterwards called *Tatiana*, was performed in 1896, and since then he has written about 30 operettas. The popularity of his music is due to the charm of its melodies; and especially to the orchestration of his waltz themes, which, with their sensuous grace, are typical of 20th century light opera. His most famous musical comedies are *The Merry Widow* (1905) and *The Count of Luxemburg* (1909). He also wrote *The Man with the Three Wives; Gipsy Love; Eva; Alone at Last; The Blue Mazur; Frasquita;* and *Paganini* (1925).

LEHMBRUCK, WILHELM (1881–1919), German sculptor, was born Jan. 4 1881 at Meiderich near Duisburg, the son of a miner. He received his artistic training at the Düsseldorf Academy, lived from 1910 to 1914 in Paris, where he gained recognition for his art, and afterwards resided in Zürich and Berlin. Lehmbruck was a sculptor of great sensibility, and his art, especially in the last phase, is moving in its spirituality and tenderness. His best known works are: "Weibliche Figur," in Duisburg; "Weiblicher Torso," at The Hague; "Frau Lehmbruck," at Essen; "Knieende" at Mannheim; "Grosse Sinnende"; "Grosse Rückblickende"; "Sterbender Krieger"; "Sitzender Jüngling"; "Emporsteigender Jüngling", and a portrait of Fritz von Unruh in Frankfurt. He also produced numerous etchings of high merit. He died by his own hand in Berlin March 25 1919. See Paul Westheim: *W. Lehmbruck* (1919).

LEICESTER, England (*see* 16.303), with a population of 234,143 in 1921, and an area of 8,582 ac., was created a city in 1919, and has grown rapidly, particularly to the south. At Aylestone a town to accommodate 7,000 to 8,000 people is being built (1926) by the municipality on a site of 206 acres. A scheme has been approved by Parliament, and is now being carried out, for the reconstruction of old, and the construction of new streets in the centre of the city, affecting between 700 and 800 buildings. The erection of a garden city at Braumstone is also contemplated. A measure creating a diocese of Leicester has received the royal assent after passing through the National Church Assembly and Parliament. It will include the whole of Leicestershire, and St. Martin's Church, constituted a collegiate church in 1922, will be the cathedral. The Harvey Lane Baptist Chapel was destroyed by fire in 1921 and replaced by the memorial hall—completed in 1924. The Church of St. Augustine's, Newfoundpool, was finished in 1912, and that of St. James the Greater in 1914. Another new parish was created in 1924, when the Church of the Holy Apostles was consecrated.

De Montfort Hall, built by the corporation, was opened in 1913. In 1921 a University College was founded, the site and buildings in Victoria Road being the gift of Mr. T. Fielding Johnson. An extensive addition to the colleges of art and technology has been decided upon and to this end certain adjoining properties were purchased in 1924. A new central electricity station was opened in 1922, and an extension begun in the following year. Leicester is a partner with Sheffield, Nottingham and Derby in the Derwent Valley Water undertaking. The first part of the scheme, which includes 35 m. of aqueduct from Derwent Valley to the Ambergate Reservoir, was finished in 1912.

LEIPZIG, Germany (*see* 16.309), the fourth city of Germany and a large industrial centre, had a population of 636,485 in 1919, including Mockau and Schönefeld, incorporated in 1915; Eschocker-Windorf, Leutsch, Paunsdorf and Wahren, incorporated in 1922, added a further 32,105 persons to the population. The famous fair has been resumed, and is held yearly in September. The university is one of the largest in Germany. The termina station, through which most of the traffic between Prussia and Saxony passes, was completed in 1915; it contains 26 tracks and covers an area of 172,000 feet. After the Revolution there were serious demonstrations against the Government in the city, and in April 1919 a Soviet republic was set up, but was put down by government troops in the following month.

LELAND STANFORD JUNIOR UNIVERSITY (STANFORD UNIVERSITY) (*see* 16.406).—The work of the university has in recent years been so reorganised that the first two years constitute a so-called lower division with certain specified requirements, including biology, a course in citizenship, etc. The major department system now becomes operative at the beginning of the junior year, and degrees are granted upon the recommendation of the departments. Stanford sold most of its large ranch properties in 1919, and in 1925 had about $28,000,000 in investment securities. Its educational plant on the campus, together with the Stanford Medical School, Lane and Stanford Hospitals, Stanford School for Nurses and Lane Medical Library—all in San Francisco—and the Hopkins Marine Station on Monterey Bay, were valued in all at $11,000,000. The medical school owed its origin to the fact that the director of the Cooper Medical College in 1910 turned over that institution and the associated Lane Hospital to Stanford.

In addition to the schools of law, medicine, and education and the graduate school, there have been organised schools in biology and social science, also in 1925 engineering and a graduate school of business, and in 1926 a school of letters and a school in physical science. In 1921 the Food Research Institute of Stanford University was organised with the help of the Carnegie Corp. of New York to make a study of the production, distribution and consumption of food. New dormitories for men and women have been recently constructed, so that 1,000 men and 250 women live in university buildings. There is a housing scheme by which practically all of the faculty and most of the students live on the campus. Volumes in the library numbered 377,904 in 1924, of which 57,722 were in the Lane Medical Library and 27,067 in the Law Library. Herbert Hoover, a

graduate of Stanford, presented to the university the Hoover War Library, comprising approximately 47,500 volumes and numerous documents covering the history of the World War.

In 1924–5 the students numbered 3,312, of whom 500 were women and 591 graduates. Limitation in funds and equipment resulted in restrictions in the body to something over 2,500. There is now a tuition fee of $75 per quarter, and a tuition note system enables students to postpone payment until three or more years after graduation. Military training is not required, but there is a field artillery unit of the Reserve Officers' Training Corps, and an ordnance unit was established in 1925. During the World War, Stanford was represented by 3,000 of its members, graduates and undergraduates. A students' army training corps unit was organised in the War period. Dr. Rav Lyman Wilbur became president Jan. 1 1916. (R. L. W.)

LEMAÎTRE, FRANÇOIS ÉLIE JULES (1853–1915), French critic and dramatist (*see* 16.408), died in Paris Jan. 21 1915.

LEMBERG, BATTLES OF.—Lemberg (Polish, Lwów), the capital town of Galicia, was twice during the World War the centre of a series of battles. The first series constituted the opening campaign between Russia and Austro-Hungary in Aug. and Sept. 1914; it resulted in the defeat of the Austrians and the occupation by the Russians of the whole of Eastern Galicia. The second series was fought some 10 months later during the great Russian retreat which was started by Mackensen's offensive on the Dunajec in May 1915. It gave Austria re-possession of Lemberg and of practically the whole of Eastern Galicia.

I. THE BATTLES OF 1914

The main concentration of the Austro-Hungarian forces for action against Russia at the opening of war in Aug. 1914 was made in Central and Eastern Galicia. In the general plan of the Central Powers the rôle of the Austro-Hungarian Army was to engage the main Russian forces till the German Army had overwhelmed France and was free to transfer its principal weight to the Eastern theatre.

Alternative Policies.—Two main alternatives were open to the Austrians, to await attack or themselves to take the offensive. If the former course were chosen, the line of the river San, between the Carpathians and the Vistula, was indicated as the strongest available position. On this they might well hope by an active defence to hold up the maximum Russian effort for some time and to win local successes by counter-attack. But defence entailed not only the abandonment of Eastern Galicia but also the surrender of the passes over the Eastern Carpathians and the opening of a road into Hungary. This might have serious political consequences. Moreover, in the years preceding the War, the military opinion of almost every country in Europe had proclaimed insistently that offensive action was the solution of all major difficulties in war. Certainly Conrad von Hötzendorf, the Chief of the Austrian General Staff, optimistic by temperament, was not the man to adopt a defensive attitude willingly. He determined to attack, though the advantages hoped for from a speedier mobilisation were not secured owing to errors made during the preliminary deployment against Serbia.

The chosen line of attack was northwards against one flank of the Polish salient; probably Conrad hoped that a German offensive might eventually be made from East Prussia against the other flank of the salient. The problem of supply was not easy, since the terrain between the Vistula and Bug rivers, where the advance was to be made, had been left, at the instance of the Russian General Staff, without good communications in anticipation of the Austrian plan. It was indeed the obvious direction of any invasion of Russia from Galicia, since an advance eastwards would leave the lines of communication exposed, while to the northeast lay the trackless marshes of the Pripet.

The Rival Forces.—The Austrian main forces were divided into four armies, of which two, the I. (Dankl) and IV. (Auffenberg), were to carry out the offensive, directed on Chełm (Kholm) and Lublin respectively; the II. (Bohn-Ermolli) and III. (Brudermann) were to be deployed east of Lemberg to hold off the Russian armies advancing from the Kiev district. The II. Army had, however, been originally dispatched to the Serbian frontier, and was at first represented by one corps only, the XII. (Kövess). North of the Vistula, Kummer's group of Austrian Landsturm and Woyrsch's corps of German Landwehr were to advance on Sandomierz and Dęblin (Iwangorod) respectively, to protect the left flank of the I. Army and to foster a Polish rising in favour of Austria.

The Russians also deployed four armies on their southwestern front. Their plan was almost the exact counterpart of the Austrian. They purposed to hold the Austrian offensive wing by a defensive force of two armies on the line Lublin-Chełm, and to smash the Austrian defensive wing by an offensive group of two armies advancing west from the Kiev military district on Lemberg. Each of the opponents was thus dependent on the power of his defensive wing to resist the shock of the other's striking force long enough to enable him to gain a decision by his main effort.

Both armies had large masses of cavalry, but there was a pronounced difference in their tactics. The Austrian cavalry seldom practised dismounted fire action and were singularly ineffective on foot; the Russian cavalry, on the other hand, fought largely as mounted infantry. The Russian artillery shot well and was far more effective than the Austrian, but the musketry of the Austrian infantryman was better than that of his rival; he was also handier in manoeuvre. The morale on both sides was excellent at the beginning, although that of the Austrian was to deteriorate rapidly under defeat. In the higher command the Russians held the advantage. Ivanov, the generalissimo of the southwestern front, was no strategist, though an experienced and well-loved commander; but his chief of staff, Aleksyeev, was one of the best brains of the Army; and in Ruzski (III. Army), Plehve (V. Army), Brusilov (VIII. Army), and Ewarth (IV. Army) he had under him probably the four ablest army commanders in Russia—certainly the four most successful. Conrad, the virtual Commander-in-Chief of the Austrian armies—the Archduke Friedrich was the nominal head—was a man of determined and obstinate character, but a better strategist in the office than in the field; nor were the Austrian army commanders the equals of the Russian.

Numerically, the Russians had an advantage, though by no means an overwhelming one. The Austrian striking wing, which comprised 350 battalions, 150 squadrons and 150 batteries, was superior in strength to the Russian IV. and V. Armies which had each four corps and two cavalry divisions; but their defensive wing (200 battalions, 170 squadrons, 130 batteries) was considerably inferior to the Russian III. and VIII. Armies, especially before the arrival of the two corps of the II. Army which had been left opposite Serbia.

On Aug. 15, before concentration was complete, the Austrian cavalry pushed forward to ascertain the Russian movements, but gathered little information. On Aug. 20 the I. and IV. Armies began their offensive. The first engagements in the neighbourhood of Krasnik were favourable to the Austrians, the advanced troops of the Russian IV. Army being driven back on Lublin. The Austrian I. Army was strengthened by Kummer's Landsturm Corps, which crossed the Vistula to join it, while Woyrsch's Corps of German Landwehr was in close touch on the left bank of the Vistula. The mission of these two formations to foment an insurrection in Russian Poland had proved fruitless.

Battle of Komarów.—The Austrian IV. Army now became engaged in a battle with the Russian V. Army, which lasted from Aug. 26 to Sept. 1. Assisted by the Archduke Joseph Ferdinand's group, which had been formed from troops of the III. Army to manoeuvre between its left and the right of the IV. Army, Auffenberg attempted a double envelopment of the Russian force. This manoeuvre met with considerable success; a large part of Plehve's Army was at one time surrounded, and escaped only owing to the sudden withdrawal of the Austrian Corps which had seized its line of retreat—a withdrawal actuated by false reports of Russian troops in its rear. The Russian Army was broken in two, part retiring on Chełm and part on Hrubieszów on the Bug. Before the Austrians could gather the fruits of

their victory, events in Eastern Galicia occasioned their recall. Losses in the battle were heavy on both sides.

Operations in Eastern Galicia.—Meanwhile the Austrian covering force (II. and III. Armies) had met with disaster. Although the II. Army consisted of one corps only and the III. Army was weakened by the absorption of the Archduke Joseph Ferdinand's group in the Kómarow battle, yet the High Command sent the two armies forward to the attack. They joined battle with the Russian III. and VIII. Armies on Aug. 26 on the line of the Zlota Lipa about Złoczów. On the evening of Aug. 27 they were forced to retreat. Reinforced by the VII. Corps from Serbia, they again gave battle on the Gnila Lipa on Aug. 29 and 30, and again suffered defeat. They now fell back through Lemberg, which was evacuated on Sept. 2, and took up a defensive position west of the city on the line of the Wereszyca and the Gródek lakes.

Battle of Gródek—Rawa-Ruska.—The rear of the victorious Austrian I. and IV. Armies was seriously threatened by the failure of the eastern wing. The question now arose of withdrawing the whole of the Austrian forces to the line of the San, or of continuing the battle round Lemberg on a different plan. Conrad chose the bolder course and determined to seek an immediate victory. He ordered the IV. Army to break off pursuit of the Russians and to change front from north to south. The plan was that this army should strike towards Lemberg at the right flank of the advancing Russians, while the II. and III. Armies held them frontally. The complicated wheel of the IV. Army had been executed by Sept. 5. On Sept. 6 it commenced its march southwards, leaving behind a group under the Archduke Joseph Ferdinand to protect its rear. As it advanced south, its left column became engaged with the right of the Russian III. Army and was pinned to the east of Rawa-Ruska, while the centre and right columns, meeting no resistance, continued southwards, and eventually wheeled into line with the Austrian III. and II. Armies, facing east.

Conrad changed his plan again; he had missed with his left, so now, like an obstinate but unskilful boxer, swung his right at the enemy, viciously but ineffectively. On Sept. 7 he ordered the IV. Army to stand fast and hold the Russians to their ground, while the II. and III. Armies left their prepared defensive positions and struck northward at the Russian left wing. A radical change of plan so hurriedly evolved was hardly likely to succeed. The II. and III. Armies could make little ground, while the position of the IV. Army rapidly became untenable. In its rear the I. Army was being forced back from Lublin by the reinforced Russian IV. Army, while the Russian V. Army had rallied and was again advancing, driving before it the Archduke Joseph Ferdinand's weak group. Finally the left wing of the IV. Army itself was being outflanked north of Rawa-Ruska by the Russian III. Army. On Sept. 11 Conrad issued orders for a general retreat to the line of the San.

Austrian Retreat.—The withdrawal was successfully carried out without serious interference by the Russians. The II. Army retired in the direction of Sambor, and the III. towards Przemyśl, the IV. on Jarosław, and the I., together with Kummer's and Woyrsch's forces, to the lower San. The detachments farther east, along the Dniester, retired to the Carpathians. The line of the San was not held for long. The Russian IV. Army had been reinforced by the IX. Army from Warsaw and forced a passage of the lower San on Sept. 14. The Austrians were too shaken and disorganised to enter on a new battle, and resumed their retreat, leaving the fortress of Przemyśl to stand siege. They finally halted on Sept. 26 some 50 m. east of Cracow on the line of the Dunajec by Tarnow and Gorlice to the Carpathians. The Russians, who also required a pause for reorganisation—losses had been very heavy on both sides—made no serious attempt to follow up beyond the San.

Causes of Austrian Failure.—The advantage of "interior lines" which the Austrians enjoyed in this campaign has been partly discounted by the great size of modern armies and the time required to obtain the decision in a battle. It is true that the Germans were at this very period gaining brilliant successes by action on interior lines against Samsonov and Rennenkampf in East Prussia, but their achievements were only rendered possible by the inertia of Rennenkampf. In Galicia, the continued pressure by Ruzski's and Brusilov's armies on the Austrian detaining wing denied to Conrad the time required to complete his successes in Poland. But the Austrian High Command appear to have suffered throughout from lack of a clear-cut plan, and to have depended too much on the course of events. It is difficult to trace in their original organisation for the campaign any recognition of the need for that "mass of manoeuvre," capable of being transferred from one wing to the other, which is the essence of action on interior lines. Also, the ineffectiveness for delaying action of their masses of cavalry deprived the Austrians of a powerful weapon. The Russian scheme of operations was straightforward and demanded only driving power by the higher commanders and hard fighting and marching by the troops. An opportunity of turning the Austrian retreat into a rout seems, however, to have been missed, when the IX. Army from Warsaw directly reinforced the IV. Army instead of being directed west of the Vistula on the Austrian line of retreat.

II. THE BATTLES OF 1915

The fighting which led up to the second series of battles round Lemberg in the summer of 1915 is described under the heading DUNAJEC-SAN. After being driven from the San, the Russian III. Army (now under Lesh instead of Radko Dimitriev) and VIII. Army (Brusilov) took up a position to the northwest and west of Lemberg. Their line ran from the Vistula along the heights north of the Tanew river, thence west of Rawa-Ruska by Magierów and Janów to the Wereszyca river and Gródek lakes. The XI. and IX. Armies continued the line southeast along the Dniester.

Comparison of Adversaries.—Mackensen's pursuing force consisted of the Austrian IV., German XI. and Austrian II. Armies, in that order from north to south. On the Dniester were Linsingen's Southern Army and Pflanzer-Baltin's VII. Army. In the number of available formations there was no great disparity between Mackensen's group of armies and the Russian III. and VIII. Armies; on each side there were about 40 infantry divisions, and the Russians had five or six cavalry divisions to Mackensen's two. But the two Russian armies now embraced an improvised assembly of formations and units taken from all parts of the line; even so their losses had not been made good and they were much under strength; there was a shortage of ammunition, both for guns and rifles; and morale had naturally suffered under two and a half months of continual defeat.

Austro-German Attack.—As usual, the main thrust at the Russian position was delivered by the German XI. Army. It was directed through Magierów against the line Zólkiew-Rawa-Ruska, approximately at the joint between the Russian III. and VIII. Armies. The assault was made on June 19, after the Russian position had been battered by the German guns, and the attackers broke right through to the Rawa-Ruska-Lemberg railway. Brusilov held on to a fortified position west of Lemberg till the 22nd, and then evacuated it under the threat that came from the north and the direct pressure from the Austrian II. Army.

Re-grouping of Armies.—The Russian armies were now split apart; the VIII. Army retired fighting to the line of the Upper Bug and Gnila Lipa; at the same time the XI. and IX. Armies gave up the Dniester line below Halicz. The III. Army meanwhile, to protect the left flank of the Warsaw salient, was forced to retire north towards Lublin and Chelm. To fill the gap between the III. and VIII. Armies, a new army, the XIII. under Gorbatovski, was formed of troops drawn from the right of the III. Army and left of the VIII. The Austrian armies were also re-grouped; the II. Army, the Southern Army and VII. Army were to continue the pursuit eastwards; Mackensen with the IV., XI. and a new "Army of the Bug," to be formed under Linsingen, was to strike northwards between the Bug and Vistula; while the I. Army, withdrawn from the west of the Vistula, was to fill the gap between the two groups.

The Eastern group drove the Russians back at the beginning of July from the Gnita Lipa to the Zlota Lipa; no farther fighting took place here till the end of August. Farther east, Pflanzer-Baltin's VII. Army and Lechitski's IX. were engaged in an indecisive conflict along the Dniester between July 14 and 19. Meanwhile on Mackensen's front the Austrian IV. Army had been heavily counter-attacked near Krasnik by the Russian IV. Army and had been driven back some distance, losing 17,000 prisoners. The check was only temporary, and so soon as the re-grouping was completed, Mackensen again advanced. For the further operations of this force, *see* BREST-LITOVSK, BATTLES OF. (*See* also EASTERN FRONT CAMPAIGNS.)

LEMONNIER, ANTOINE LOUIS CAMILLE (1844–1913). Belgian poet (*see* 16.415), published among his later works *L'amant passionné* (1904); *Tante Amy* (1906); *La maison qui dort* (1909) and *La chanson du carillon* (1911); as well as *L'école belge de peinture, 1830–1905* (1906). He died in Brussels June 13 1913. See L. Bazalgette, *Camille Lemonnier* (1904).

LENGLEN, SUZANNE (1899–), French lawn-tennis player, was born at Compiègne May 24 1899. She was taught to play tennis by her father and began to show brilliance at an early age, winning the championship of Picardy when only 14 years old. In June 1914 she won the hard court singles and doubles in Paris. During the World War she played in exhibition matches on the Riviera for the French Red Cross 1916–8. In 1919 she made her first appearance at the Wimbledon tournament and won both the singles and doubles championships, defeating Mrs. Lambert Chambers in the final round. In the following year she won the ladies' singles at Wimbledon and mixed doubles champion with G. L. Patterson. In Aug. 1921, after again winning the singles and doubles at Wimbledon, she visited America and was defeated (2–6 retired) by Mrs. Mallory in the second round of the U.S.A. ladies' singles championships. At Wimbledon however, in the following year Mlle. Lenglen defeated Mrs. Mallory 6–2, 6–0 in the final round of the ladies' singles. In the same year she also won the French National Championship, took all three championships in the Brussels tournament and was undefeated throughout the season. She again won the singles at Wimbledon in 1923 and 1925, but was obliged to retire in 1924 owing to illness, as she was also in 1926. (*See* LAWN TENNIS.)

LENIN, VLADIMIR ILYICH ULYANOV (1870–1924), founder and guiding spirit of the Soviet Republics and the Communist International, the disciple of Marx both in theory and in practice, the leader of the Bolshevik party and the organiser of the Oct. revolution in Russia, was born on April 9 (22) 1870 in the town of Simbirsk, now Ulyanovsk. His father, Ilya Nicolaevitch, was a schoolmaster. His mother, Maria Alexandrovna, whose maiden name was Berg, was the daughter of a doctor. His eldest brother (b. 1866) joined the "Narodovoltze" (Freedom of the People movement),[1] and took part in the unsuccessful attempt on the life of Alexander III. For this he was executed in his 22nd year. Lenin, the third of a family of six, completed his course at the Simbirsk gymnasium in 1887, winning the gold medal. His brother's execution, indelibly stamped on his consciousness, helped to determine his later life.

In the summer of 1887 Lenin entered the Kazan University to study law, but was sent down in Dec. of the same year for taking part in a gathering of students and was banished to the countryside. His repeated petitions in 1888–9 for permission to re-enter the University of Kazan or to be allowed to go abroad to continue his studies met with refusal. In the autumn, however, he was allowed to return to Kazan, where he began the systematic study of Marx and first entered into relations with the members of the local Marxist circle. In 1891 Lenin passed the law examinations of the St. Petersburg University, and in 1892 he began to practise as a barrister at Samara. During this year and the next he appeared for the defence in several trials. His life, however, was chiefly filled by the study of Marxism and its application to the investigation of the course of the economic and political development of Russia and subsequently of the whole world.

In 1894 he moved to St. Petersburg, where he came into touch with the workers and began his propaganda work. To this period belong Lenin's first polemical writings directed against the popular party, who taught that Russia would know neither capitalism nor the proletariat. These were passed from hand to hand in manuscript form. Soon after, Lenin started a theoretical struggle against the falsifiers of Marx, in the legal Press.[2] In April 1895 Lenin first went abroad with the intention of entering into relations with the Marxist group abroad known as the "Osvobozhdenie Truda," "Deliverance of Labour" (Plekhanov, Zasulich, Axelrod). On his return to St. Petersburg, he organised the illegal "Union for the struggle for the liberation of the Working Class," which rapidly became an important organisation, carrying on propaganda and agitation among the workers and getting into touch with the provinces. In Dec. 1895 Lenin and his closest collaborators were arrested. He spent the year 1896 in prison, where he studied the lines of Russia's economic development. In Feb. 1897 he was sent into exile for three years to the Yenisei province in eastern Siberia. At this time, 1898, he married N. K. Krupskaya, his comrade in the work of the St. Petersburg Union and his faithful companion during the remaining 26 years of his life and revolutionary struggle. During his exile he finished his most important economic work, *The Development of Capitalism in Russia*, based on a comprehensive and systematic study of an enormous mass of statistical material (1899). In 1900 Lenin went abroad to Switzerland with the intention of organising, with the "Deliverance of Labour" group, the publication of a revolutionary paper intended for Russia. At the end of the year the first number of the paper *Iskra* (The Spark) appeared in Munich, with the motto "From the Spark to the Flame!" The aim of the paper was to give a Marxian interpretation of the problems facing the revolution, to give the political watchwords of the struggle, and to organise on this basis a centralised "underground" revolutionary party of Social Democrats, which, standing at the head of the proletariat, should open the struggle against Tsarism, rousing the oppressed masses, and, above all, the many millions of peasants.

The idea of an organised party leadership of the struggle of the proletariat in all its forms and manifestations, which is one of the central ideas of Leninism, is closely connected with the idea of the hegemony of the working class within the democratic movement of the country. This idea of hegemony, having become the central point of the Leninist political conception and practical work, found direct expression in the programme of the dictatorship of the proletariat when the development of the revolutionary movement had prepared the conditions for the Oct. revolution.

The second Congress of the R.S.D.R.P. (Brussels, London) in July and Aug. 1903 accepted the programme worked out by Plekhanov and Lenin, but ended with the historic split of the party into Bolsheviks and Mensheviks. Thereupon Lenin entered on his separate path as leader of the Bolshevik section, later the Bolshevik party. The differences, which began at first with questions of party organisation, gradually extended to fundamental questions concerning tactics and finally to the question of the party programme. The Mensheviks tried to bring the policy of the Russian proletariat into line with that of the liberal bourgeoisie. Lenin saw in the peasantry the closest ally of the proletariat. The occasional agreements and closer relations with the Mensheviks failed to arrest the constant widening of the two lines—the revolutionary and the opportunist—the proletarian and the petty bourgeois. The struggle with the Mensheviks forged the policy which led to the break with the Second International (1914), to the Oct. revolution (1917) and to the change of the party's name from the compromised title of Social Democrat to that of Communist (1918).

A revolutionary situation was created in the country by the defeat of the army and navy in the Russo-Japanese War, the

[1] Narodovoltze was a revolutionary terrorist society.

[2] As distinct from the Press which was published illegally—"underground" by revolutionaries.

shooting of the workers on Jan. 9 (22) in 1905, by the agrarian disturbances and the political strikes. Lenin's programme was the preparation of an armed rising of the masses against Tsarism, the creation of a provisional revolutionary Government which was to organise the revolutionary democratic dictatorship of the workmen and peasants for the radical deliverance of the country from Tsarism, serfdom and all medieval rubbish. Accordingly, the third congress of the party, consisting exclusively of Bolsheviks (May 1905), passed a new agrarian programme which included the confiscation of the domains of the landowners and the Tsar.

In Oct. 1905 the All-Russian strike began. On the 17th of the month the Tsar issued his manifesto about the "Constitution." In the beginning of Nov. Lenin returned to Russia from Geneva, and already, in his first article, appealed to the Bolsheviks, in view of the new situation, to increase the scope of their organisation and to bring into the party wider circles of workers, but to preserve their illegal apparatus in anticipation of the counter-revolutionary blows which were inevitable. In Dec. Tsarism began to counter-attack. The rising in Moscow at the end of Dec., lacking as it did the support of the army, without simultaneous risings in other towns and sufficient response in the country districts, was quickly suppressed.

In the events of 1905 Lenin distinguished three main features—(1) the temporary seizure by the people of real political freedom, real in the sense of not being limited by their class enemies, apart from and in spite of all existing laws and institutions; (2) the creation of new and as yet only potential organs of revolutionary power in the shape of soviets of workers', soldiers' and peasants' deputies; (3) the use of force by the people against those who had employed it against them. Those conclusions, from the events of 1905, became the guiding principles of Lenin's policy in 1917 and led to the dictatorship of the proletariat in the form of the Soviet State.

The suppression of the Dec. rising in Moscow threw the masses into the background. The Liberal bourgeoisie came to the front. The epoch of the first two Dumas began. At this time, Lenin formulated the principles of the revolutionary exploitation of parliamentary methods in immediate connection with the struggle of the masses and as a means of preparation for a fresh attack.

In Dec. 1907 Lenin left Russia, to return only in 1917. Now (in 1907) began the epoch of victorious counter-revolution, prosecutions, exile, executions and emigration. Lenin led the struggle against all decadent tendencies among the revolutionaries; against the Mensheviks, the advocates of the liquidation of the "underground" party—hence those known as "liquidators"—and of the change of their methods of work into purely legal ones within the framework of the pseudo-constitutional régime; against the "conciliators" who failed to grasp the complete antagonism between Bolshevism and Menshevism and tried to take up an intermediate position—against the adventurist policy of the Socialist revolutionaries who tried to make up for the inertia of the masses by personal terrorism; finally, against the narrow partisanship of a part of the Bolsheviks, the so-called "callers-off," who demanded the recall of the Social Democratic deputies from the Duma in the name of immediate revolutionary activity, though conditions at that moment offered no opportunity for this. In this dim epoch Lenin showed very vividly a combination of his two fundamental qualities—that of being an implacable revolutionary at bottom, while yet remaining a realist who made no mistakes in the choice of methods and means.

At the same time, Lenin carried on an extensive campaign against the attempt to revise the theoretic basis of Marxism on which his whole policy was founded. In 1908 he wrote a major treatise dealing with the fundamental questions of knowledge and directed against the essentially idealistic philosophy of Mach, Avenarius and their Russian followers, who tried to unite empiric criticism with Marxism. On the basis of a deep and comprehensive study of science Lenin proved that the methods of dialectical materialism as formulated by Marx and Engels were entirely confirmed by the development of scientific thought in general and natural science in particular. Thus Lenin's constant revolutionary struggle, in which he never lost sight of the smallest practical details, went hand in hand with his equally constant theoretical controversies, in which he attained to the greatest heights of comprehensive generalisations.

The years 1912–4 were marked in Russia by a fresh outburst of activity in the workers' movement. Breaches made their appearance in the counter-revolutionary régime. At the beginning of 1912 Lenin summoned a secret conference of the Russian Bolshevik organisations in Prague. The "liquidators" were declared to be outside the party. The split with the Mensheviks became definite and final. A new central committee was elected. Lenin organised from abroad the publication in St. Petersburg of a legal newspaper, *Pravda*, which in its constant conflict with the censorship and the police exercised a guiding influence on the vanguard of the working class. In July 1912 Lenin, together with his closest collaborators, moved from Paris to Cracow in order to enable him to be in closer touch with Russia. The revolutionary movement in Russia was growing, and was thereby giving the Bolsheviks the preponderance. Lenin, in active contract with Russia, sent articles under different pseudonyms almost every day to the Bolshevik legal newspapers, drawing the inevitable inferences from them in the illegal ("underground") Press. At this time, as well as before and after it, N. K. Krupskaya, as his nearest helpmate, was the centre of the organising work. She received comrades coming from Russia, gave instructions to others on their way there, set up "underground" connections, wrote conspirative letters, coded and decoded. It was in the small town of Poronin in Galicia that the declaration of war found Lenin. The Austrian police suspected him of being a Russian spy and arrested him, but he was released after a fortnight and expelled to Switzerland.

A new and wider phase of Lenin's work now opened. It had an international scope. Lenin's manifesto, published in the name of the party on Nov. 1 1914, denounced the imperialistic character of the War and the war guilt of all the great powers, who for long past had been preparing a sanguinary struggle for the purpose of widening their markets and destroying their rivals. The patriotic agitation of the bourgeoisie on both sides, who threw the blame each upon the other, was shown to be a manoeuvre to deceive the workers. The manifesto points out that the majority of Social Democratic leaders were now on the side of the bourgeoisie of their own country, thus violating the resolution of the International Socialist congresses and bringing about the downfall of the Second International. It points out that from the point of view of the Russian Social Democrats the defeat of Tsarism would be the most desirable issue of the War. The defeat of their "own" governments should be the slogan of the Social Democrats of all countries. Lenin subjects to a merciless criticism not only Socialist patriotism, but different shades of pacifism which dreams of peace but capitulates to war, and, while occupied with platonic protests, withdraws from the revolutionary struggle with Imperialism. The struggle with pacifism develops into a great struggle with centrism, that is, with those elements of the working class movement which are midway between the Social Democrats and the Communists, supporting the former in actual practice (for instance, the I.L.P. in Great Britain).

The theorists and politicians of the Second International redoubled their accusations of anarchism which they had before brought against Lenin. As a matter of fact, all Lenin's theoretic and practical work, both up to 1914 and after, was characterised by a twofold struggle, on the one hand with reformism which from the beginning of the War gave its support to the imperialist policy of the propertied classes, and on the other hand with anarchism and all the different varieties of revolutionary adventurists.

On Nov. 1 1914 Lenin promulgated a programme for the creation of a new International "to undertake the task of organising the forces of the proletariat for the revolutionary attack on capitalist governments, for the civil war against the bourgeoisie of all countries, for the attainment of political power and the victory of Socialism."

In Sept. 1915 (Sept. 5 and 8) there was held at Zimmerwald in Switzerland the first conference of European Socialists who were opposed to the imperialistic war. Thirty-one delegates were present. The left wing of the Zimmerwald conference and of the later one at Kiental adopted Lenin's demand for the transformation of the imperialist war into a civil war, and became the nucleus of the future Communist International. The latter worked out its programme, tactics and organisation under Lenin's guidance, and it was Lenin who directly inspired the decisions of the first four congresses of the Communist International.

Lenin was prepared for his struggle on an international scale not only by his profound knowledge of Marxism and his experience of the revolutionary struggle and party organisation in Russia, but also by his intimate acquaintance with the workers' movement throughout the world. For many years he had followed closely the internal affairs of the most important capitalist States. He was a thorough master of the English, German and French languages, and could read Italian, Swedish and Polish. His realistic imagination and political intuition often enabled him to reconstruct a complete picture from isolated phenomena. Lenin was always firmly opposed to the mechanical application of the methods of one country to another, and he investigated and decided questions concerning revolutionary movements, not only in their international interreactions, but also in their concrete national form.

The revolution of Feb. 1917 found Lenin in Switzerland. His attempts to reach Russia met with the decided opposition of the British Government. He accordingly decided to exploit the antagonism of the belligerent countries and to reach Russia through Germany. The success of this plan gave occasion to Lenin's enemies for a fierce campaign of slander, which, however, was powerless to prevent him from assuming the leadership of his party and shortly afterwards of the revolution.

On the night of April 4, on leaving the train, Lenin made a speech in the Finlyandsky station in Petrograd. He repeated and developed the leading ideas it contained in the days which followed. The overthrow of Tsarism, he said, was only the first stage in the revolution. The bourgeois revolution could no longer satisfy the masses. The task of the proletariat was to arm, to strengthen the power of the Soviets, to rouse the country districts and to prepare for the conquest of supreme power in the name of the reconstruction of society on a Socialist basis.

This far-reaching programme was not only unwelcome to those engaged in propagating patriotic Socialism, but even roused opposition among the Bolsheviks themselves. Plekhanov called Lenin's programme "crazy." Lenin, however, built up his policy not on the inclinations and views of the temporary leaders of the revolution, but on the interrelations of the classes and the logic of mass movements. He foresaw that the distrust of the bourgeoisie and of the Provisional Government would grow stronger daily, that the Bolshevik party would obtain a majority in the Soviets and that the supreme power would pass into their hands. The small daily *Pravda* became at once in his hands a powerful instrument for the overthrow of bourgeois society.

The policy of coalition with the bourgeoisie pursued by the patriotic Socialists, and the hopeless attack which the Allies forced the Russian Army to assume at the front—both these roused the masses and led to armed demonstrations in Petrograd in the first days of July. The struggle against Bolshevism became most intense. On July 5th grossly forged "documents" were published by the counter-revolutionary secret service. These purported to prove that Lenin was acting under the orders of the German general staff. In the evening "reliable" detachments summoned from the front by Kerensky and Cadet officers from the districts round Petrograd occupied the city. The popular movement was crushed. The hounding of Lenin reached its height. He now began to work "underground," hiding first in Petrograd with a worker's family and then in Finland; he managed, however, to keep in touch with the leaders of the party.

The July days and the retributions which followed aroused a burst of energy in the masses—Lenin's forecast proved right in every particular. The Bolsheviks obtained a majority in the Soviets of Petrograd and Moscow. Lenin demanded decisive action to seize the supreme power, and on his side began an unremitting fight against the hesitations of the leaders of the party. He wrote articles and pamphlets, letters, both official and private, examining the question of the seizure of supreme power from every angle, refuting objections and dispelling doubts. He drew a picture of Russia's conversion into a foreign colony if the policy of Miliukov and Kerensky continued, and he predicted that they would consciously hand over Petrograd to the Germans in order to destroy the proletariat. "Now or never!" he repeated in passionate articles, letters and interviews.

The rising against the Provisional Government coincided with the opening of the second Congress of the Soviets on Oct. 25. On that day, Lenin, after being in hiding for three and a half months, appeared in the Smolny[1] and from there personally directed the fight. In the night sitting of Oct. 27 he proposed, at the session of the Congress of the Soviets, a draft decree about peace which was passed unanimously and another about the land, which was passed with one dissentient and eight abstentions. The Bolshevik majority, supported by the left wing of the Socialist revolutionaries, declared that supreme power was now vested in the Soviets. The Soviet of People's Commissaries was appointed, with Lenin at their head. Thus Lenin passed straight from the log cabin where he had been hiding from persecution to the place of highest authority.

The proletarian revolution spread quickly. Having obtained the land of the landed estate owners, the peasants forsook the Socialist revolutionaries and supported the Bolsheviks. The Soviets became masters of the situation both in the towns and the country districts. In such circumstances the constituent assembly which was elected in Nov. and met on Jan. 5 appeared a patent anachronism. The conflict between the two stages of the revolution was now at hand. Lenin did not hestitate for an instant. On the night of Jan. 7 the All-Russian Central Executive Committee, on Lenin's motion, passed a decree dissolving the constituent assembly. The dictatorship of the proletariat, said Lenin, meant the greatest possible degree of actual and not merely formal democracy for the toiling majority of the people. For it guaranteed to them the real possibility of utilising their abilities, putting as it did in the hands of labour all those material goods (buildings for meetings, printing presses and so on) lacking which "liberty" remains an empty word and an illusion. The dictatorship of the proletariat in Lenin's view is a necessary stage in the abolition of class divisions in society.

The question of war and peace provoked a new crisis in the party and the governing body. A considerable proportion of the party demanded a "revolutionary war" against the Hohenzollerns, leaving out of account altogether the economic situation of Russia and the temper of the peasantry. Lenin felt that it was necessary for propaganda purposes to drag out negotiations with the Germans for as long as possible. But he demanded that, in the event of a German ultimatum, peace should be signed even at the price of a loss of territory or the payment of an indemnity —"Let us give way in space, but gain time," he said. The revolution kindling in the west would sooner or later undo the hard terms of peace. Lenin's political realism manifested itself in all its strength in regard to this question. The majority of the Central Committee in opposition to Lenin made a further attempt to avoid yielding to German Imperialism by declaring the state of war at an end, but refusing at the same time to sign an imperialistic peace. This led to a renewed attack by the Germans. After heated debates in the Central Committee at the sitting of Feb. 18 Lenin won a majority for his proposal that negotiations should be reopened forthwith, and that the German terms which were now still more unfavourable should be signed.

The Soviet Govt. on Lenin's initiative transferred itself to Moscow. Peace having been attained, Lenin now brought before the party and the country the whole question of its economic and cultural organisation.

[1] Smolny, originally an institute for the daughters of noblemen, was the headquarters of the Bolsheviks during the revolution.

The greatest trials, however, were still to come. A counter-revolutionary movement was approaching from the borders. By the end of the summer of 1918 Central Russia found itself surrounded by a ring of fire. Hand in hand with the Russian counter-revolution there came the rising of the Czechoslovaks on the Volga; on the north and south came the British intervention (in Archangel on Aug. 2, in Baku on Aug. 14). Food supplies were cut off. In these conditions of unexampled difficulty, when things seemed hopeless, Lenin never even for so much as an hour ceased to direct his party and the Government. He estimated the extent of each new danger and showed the way to safety. He carried on propaganda work in meetings and in the press, roused ever new forces from among the masses, organised the sending of the workers into the country to get corn, directed the creation of new war divisions, followed the enemy's movements on the map; he was in direct telegraphic communication with the young divisions of the Red Army and looked after their equipment and supplies from the centre. He followed the international situation, finding his bearings by the dissensions in the camps of the imperialists. At the same time he found time for attentive interviews, both with the first foreign revolutionaries who appeared on Soviet soil and with Soviet engineers about plans for electrification or for new methods of utilising peat or of developing a system of radio stations, and so on and so on.

On Aug. 30 the Socialist-revolutionary Kaplan aimed two shots at Lenin when on his way to a workers' meeting. This attack intensified the civil war. Lenin's strong constitution quickly recovered from the effect of his wounds. During his convalescence he wrote a pamphlet, *The Proletarian Revolution and the Renegade Kautsky*, directed against the most prominent theorist of the Second International. By Oct. 22 he was again speaking in public.

The war on the home fronts remained as before his chief occupation. Economic and administrative problems had necessarily to take a subordinate place. The civil war fed from abroad was at its height. It was only thanks to Lenin's titanic energy, clear vision and unshaken will that the struggle ended (at the beginning of 1921) with the utter defeat of the counter-revolution. The Government grew in strength. The main instrument of the struggle as also of the further constructive work always was and still remains the party organised by Lenin—the party which received a thorough apprenticeship during its period of work "underground." The hard school of the civil war produced seasoned main cadres of organisers.

Lenin always considered the Oct. revolution from the standpoint of the European and world revolution. The fact that the War had not led immediately to a proletarian revolution in Europe had enormously increased the difficulties of Socialist reconstruction. The roots of these difficulties lay in the interrelation between the town and the village. This roused Lenin at the beginning of 1921 once again to consider the problems of the internal economic régime. The Socialist reconstruction of society was impossible without agreement between the proletariat and the peasantry. It was therefore essential to change radically the régime of "war communism" produced by the civil war. The system of requisitioning superfluities from the peasants must be replaced by a tax correctly assessed. Private interchange of commodities must be allowed. These measures, introduced by Lenin with the full concurrence of his party, began a new phase in the development of the Oct. (Nov.) revolution, that known as the "new economic policy." Lenin pointed out subsequently that such a policy—with of course the necessary modifications—would be an inevitable phase in the Socialist reconstruction of every country.

In his policy within the Soviet Federation Lenin paid the greatest attention to the position of the nationalities which had been oppressed under Tsarism, and he tried in every way to create for them the conditions of free national development. Lenin made unsparing war against all imperialist tendencies within the state organisation, and especially within the party itself—the purity of whose ideas he guarded with the utmost jealousy. The charges of oppressing nationalities made against Lenin and his party with reference to Georgia, etc., were by no means the product of any national struggle, but of the sharp class warfare within the nation.

The principles of national self-determination, which in the western European working class movements extend only to the national minorities of the so-called civilised countries, Lenin insisted on applying in full to the colonial peoples, and he championed their right to separate themselves completely from their mother country. His doctrine was that the Western European proletariat should refrain from mere declarations of sympathy with oppressed nationalities, and instead should join them in the struggle against imperialism.

At the eighth congress of Soviets (1920) Lenin made a report on the work carried out on his initiative for the drafting of a plan for the electrification of the country. The gradual effort towards a high degree of technical development is the mark of the successful transformation from the system of small scale peasant economy, with its lack of co-ordination, to the system of large scale Socialist production based on a single, comprehensive plan. "Socialism is a Soviet Govt. plus electrification."

The exhaustion brought on by excessive hard work over a number of years ruined Lenin's health. Sclerosis attacked his cerebral arteries. At the beginning of 1922 his doctors forbade him daily work. From June to Aug. the disease made rapid progress, and for the first time he began to lose, although transiently, the power of speech. At the beginning of Oct. his health had so much improved that he once again returned to work, but not for long. His last public utterance ends with the expression of his conviction that "from Russia under N.E.P. will come Socialist Russia."

On Dec. 16 he became paralysed in the right arm and leg. However, during Jan. and Feb. he still dictated a number of articles of great importance for the policy of the party on the struggle against bureaucracy in the Soviet and party organisation; on the importance of co-operation in gradually bringing the peasants into the Socialist organisation; on the struggle against illiteracy; and finally on the policy in regard to nationalities oppressed under Tsarism.

The disease progressed and he lost completely the power of speech. His work for the party came to an end, and very soon his life also. Lenin died on Jan. 21 1924, at 6:30 P.M., at Gorky, near Moscow. His funeral was the occasion for an unexampled manifestation of love and grief on the part of millions.

The main work of Lenin's life was the organisation of a party capable of carrying through the Oct. revolution and of directing the construction of Socialism. The theory of the proletarian revolution—the methods and tactics to be pursued—constitutes the fundamental content of Leninism which as an international system forms the culminating point of Marxism. Lenin's single aim filled his life from his school days onwards. He never knew hesitation in the fight against those he considered the enemies of the working class. In his passionate struggle there was never any personal element. He fulfilled what he considered to be the demands of an inevitable historical process. Lenin combined the ability to use the materialistic dialectic as a method of scientific orientation in social developments with the deep intuition of the true leader.

Lenin's outward appearance was distinguished by simplicity and strength. He was of middle or rather below the middle height, with the plebeian features of the Slavonic type of face, brightened, however, by piercing eyes; and his powerful forehead and his still more powerful head gave him a marked distinction. He was tireless in work to an unparalleled degree. His thoughts were equally concentrated whether in his Siberian exile, the British Museum or at a sitting of the People's Commissaries. He put the same exemplary conscientiousness into reading lectures in a small workmen's club in Zurich and in organising the first Socialist State in the world. He appreciated and loved to the full science, art and culture, but he never forgot that as yet these things are the property of a small minority. The simplicity of his literary and oratorical style expressed the extreme concentration of his spiritual forces bent on a single aim.

In personal intercourse Lenin was even-tempered, courteous and attentive, especially to the weak and oppressed and to children. His way of life in the Kremlin was little different from his life as an emigré abroad. The simplicity of his daily habits, his asceticism in regard to food, drink, clothes and the "good things" of life in general in his case did not spring from so called moral principles, but came about because intellectual work and intense struggle not only absorbed his interests and passions but also gave him such intense satisfaction as to leave no room for subsidiary enjoyments. His thoughts never ceased to labour at the task of freeing the workers till the moment of its final extinction.

His works include: *Ekonomicheskoye soderzhaniye narodnichestvai Kritika evo v Knige g. Struve, 1895* (The Economic Content of the popular party and Mr. Struve's criticism of it. The reflection of Marxism on bourgeois literature); *K Kharakteristike ekonomicheskovo romantisma* (1897) (The characteristics of economic romanticism), Sismondi and our Sismondists; *Razvitiye Kapitalisma v Rossie*, 1899 (The development of Capitalism in Russia). The process of making a home market for large scale industry; *Chto Dyelat*, 1902. (What is to be done? French trans. *Que Faire?* The most urgent question of our movement; *Dve taktiki sotsial—demokratii v demokraticheskoi revolyutsii*, 1905 (Two tactics of the Social Democracy in the democratic revolution); *Agrarnaya programma sotsial demokratii v pervoi russkoi revolyutsii 1905–1907* (1907), (The agrarian programme of the Social-Democrats in the first Russian revolution 1905–7); *Za 12 let.*, 1908 (During 12 years), Two tendencies in Russian Marxism and Russian Social Democracy); *Materialism i empiriokritiltsism*, 1909 (Materialism and empiriocriticism). There are two German editions of Lenin's collected works—*Ausgewählte Werke Sammelband*, 1925, and *Auswahl aus seinen Werken*. (L. T.)

LENINGRAD: *see* PETROGRAD.

LEONCAVALLO, RUGGIERO (1858–1919), Italian composer (*see* 16.455), died at Montecatini Aug. 9 1919.

LEPROSY (*see* 16.479).—Since 1910 a new and more hopeful era in the 3,000-year-old leprosy problem has been opened up by the discovery of an improved treatment of at least the earlier stages of the disease. It still remains a great scourge, recent estimates placing the world's lepers, including early little recognised cases, at two to three millions, the great majority being met with in tropical and subtropical Asia and Africa, the last having the highest numbers in proportion to population.

Leprosy is most prevalent in hot damp climates, and least in very dry areas, humidity being apparently favourable to the survival of the lepra bacillus and its transmission to others, usually through long and close contact, 40% of traced infections being due to living in the same house and 30% more to sleeping in the same bed with a leper. Children and young adults are most susceptible. The disease is less infectious than tuberculosis, and many advanced crippled nerve cases lose their infectivity. One-third of the isolated lepers in South African institutions were recently released on this account, with great reduction in expenditure and in opposition to segregation, which is only necessary in infective stages, and has resulted in the reduction of the lepers in Norway to only 5% of the numbers known in 1856, when it was introduced there. Sweden and Iceland show very similar results. Under the more difficult conditions in poor tropical countries such as Hawaii and the Philippines, and in the absence of an effective treatment, the effects of this policy have not been so good and it has led to hiding of the earlier and more amenable cases, from whom infections may arise before they are discovered and isolated.

Treatment.—Numerous suggested remedies, including nastin, having failed to fulfil their early promise, only the old Indian drug, chaulmoogra oil, was known to have some power of retarding the progress of the disease by such doses as could be taken orally on account of its nauseating properties. But slightly better results were obtained by Victor G. Heiser in the Philippines by prolonged painful courses of intramuscular injections of the oil, which few patients would submit to. Real advance was made in 1916–7 when L. Rogers injected the soluble sodium salts of the fatty acids of chaulmoogra and other oils intramuscularly, and still better intravenously. This produced febrile and local reactions, accompanied by extensive destruction of the lepra bacilli in the diseased tissues, with subsequent absorption and eventually complete disappearance of the nodules and the organisms in a considerable proportion of not very advanced cases.

Dean and Hollmann at Honolulu soon after introduced the practically important modification of using intramuscular injections of ethyl esters in place of the more troublesome intravenous ones of the sodium salts, enabling a larger number of cases to be treated. The result was that in the last four recorded years the number of cases discharged as recovered by a board of medical experts, has numbered 53% of the 399 admissions during the same period, and the total lepers, including advanced incurable cases among whom the mortality is high, are being reduced at a rate which will nearly solve the problem in Hawaii within about 25 years.

Further, at the great Culion leper settlement of the Philippines a little over 4,000 cases in all stages have been treated during the last two or three years, and 645 have already cleared up and are bacteriologically negative. Good progress is also being made in many other countries. Many early cases are now coming forward, for the first time in the age-long history of leprosy, in the early amenable stages and asking for admission to the leper institutions in order to obtain the new treatment. They consequently recover before they have reached the more infective stages, cutting short numerous foci of infection in the houses. Active research work, still further to improve the treatment, is going forward in several important centres. The disheartening old asylums for hopelessly advanced and often quite harmless uninfective lepers are giving place to agricultural colonies, much on the lines of tuberculosis sanatoria for the infective cases amenable to treatment.

Hospital clinics are being established to enable the early uninfective cases to be treated as out-patients without the cost and disadvantages of separation from friends and relatives, and only sufficient funds and organisation are required to enable this loathsome disease to be reduced to negligible proportions in many parts of the world within a very few decades. (See F. Oldrieve, *India's Lepers*, 1924.) (L. Ro.)

LEROY-BEAULIEU, HENRI JEAN BAPTISTE ANATOLE (1842–1912), French publicist (*see* 16.485), died in Paris June 16 1912.

LEROY-BEAULIEU, PIERRE PAUL (1843–1916), French economist (*see* 16.485), died in Paris Dec. 9 1916.

LEVASSEUR, PIERRE ÉMILE (1828–1911), French economist (*see* 16.505), died July 9 1911.

LEVELLING: *see* SURVEYING.

LEVERHULME, WILLIAM HESKETH LEVER, 1ST VISCOUNT (1851–1925), British man of business born at Bolton Lancs. Sept. 19 1851, was the son of James Lever, a grocer. His education, received at the Bolton Church Institute, was cut short

in 1867 when he went into his father's wholesale warehouse as an apprentice. With his zeal for knowledge and a wonderful memory, he utilised every opportunity for self education, attending evening classes for shorthand, drawing, French and chemistry, and interesting himself particularly in accountancy, pictorial art and architecture. Persuading his father to make him his commercial traveller, he showed such capacity that in 1874 he was taken into partnership and was thus able to marry the friend of his childhood, Elizabeth Ellen, daughter of Mr. Crompton, linen draper, of Bolton.

In 1877, having foreseen that important economies in transport of goods could be effected by opening a branch of the business in Wigan, he established a centre there which ultimately became more profitable than the Bolton headquarters. It was doing so well in 1884 in the hands of his father and capable assistants that he was on the point of abandoning it to them and seeking a fresh field for his activities; but refreshed by a holiday in the Isle of Lewis he returned to the Wigan shop " full of ideas about soap." These " ideas," it soon appeared, could not be realised until he had personal control of the manufacture. He accordingly leased a small soap works at Warrington, which had previously been carried on at a loss, and speedily, by his energy, activity and general good management, transformed it into a well-organised, flourishing business, with London branch premises and agents all over the country, well encouraged and supported by their chief's extensive advertising schemes of striking novelty and enterprise.

Soon, a freehold site where he would have more space for expansion became urgently necessary, and this he found for himself, near Bebington, Cheshire, where on Bromborough Pool Mrs. Lever on March 3 1888 cut the first sod for the foundations of Port Sunlight, the now famed model industrial village—a conspicuous example of successful town planning, with parks, tree-bordered thoroughfares, open spaces and halls, institutions and dwelling houses of great and varied architectural interest, the last named well adapted in size to the needs of the occupants, and provided with baths and gardens in front and allotments behind. As for " the space for expansion," the original 56 acres (of which 24 were reserved for the works and 32 for the village) were latterly extended to 547 acres, 287 allotted to works and 260 to the village, including its extensions.

The firm's expansion overseas has become world-wide, for in 1925 it was recorded in *Progress*, one of the company's magazines, that over 250 companies in all quarters of the globe were associated with Lever Brothers. Through Bromborough Pool and the Mersey, Lord Leverhulme had from Port Sunlight secured access by water to London and to British ports generally for home trade, and to the waterways of the world for his exports, as well as to the sources of the raw materials for soap manufacture. These facilities, owing to his foresight and enterprise, are about to be greatly increased by the opening of the Bromborough dock under construction on the Mersey side, from and to which ocean steamers will take and bring cargo.

Mr. Lever and his brother, before they moved to Port Sunlight, had determined that their employees should share in their prosperity. The prosperity sharing pledge was primarily redeemed in the creation of Port Sunlight village with its abundant amenities, and in the spaciousness of the factory area and the buildings erected thereon with all the arrangements now comprehended in the term " factory workers' welfare." Those who lived in the village further enjoyed " prosperity-sharing rents," based on the cost of maintenance repairs and renewals, the interest on the capital expended being a charge on the company's profits. The same principle was applied to works welfare expenses, beginning with a pensions scheme called the Employers' Benefit Fund, long service awards, cottage hospital, holiday club, but including in later days the co-partnership scheme and the many benefits flowing from it, *e.g.*, free insurance policies, unemployment and sickness benefits, staff college training and scholarships. The effect of the prosperity-sharing environment on the workers was a frequent subject of inquiry on the part of visitors; to Mr. and Mrs. Lever it was a source of pride, cultivating as they did the affection of the children and missing no opportunity of promoting their health and happiness and entertainment, or of meeting them in their Sunday schools and day school festivals.

In 1906 (12 years after the incorporation of the private company of Lever Brothers Limited into a public company) an attack was directed by a powerful Press organisation against an arrangement made by Mr. Lever with some other soap makers, which was mistakenly denounced as a soap trust. It was shown, however, in the course of the legal action taken by Mr. Lever against his principal assailant, that on the contrary, the object of the plan was to render better service to the public as well as to the distributors, both wholesale and retail. On the third day of Mr. Lever's ordeal in the witness box the counsel for the defence withdrew the plea of justification, as well as every imputation made upon Mr. Levers' honour and integrity, and apologised for having made the attack upon him. Mr. Lever presented the University of Liverpool with the amount of the damages and costs awarded to him, together with an additional sum which brought the endowment up to £100,000.

Mr. Lever was in politics an advanced Liberal and, in aid of his party against strong Conservatives, allowed himself to be nominated a Parliamentary candidate six times in all, thrice for Birkenhead, twice for Wirral and once for the Ormskirk Division of Lancashire. He scored a notable victory on his second candidature for Wirral in 1906, and introduced bills on old age pensions and payment of members, which were afterwards taken up by the Government and became law. After being raised to the peerage he made a favourable impression in the House of Lords by his speeches on labour questions, and on decimal coinage he introduced a bill which was remitted, with another, to a select committee, which, however, did not complete its sittings within the life of that Parliament.

In 1909 Mr. Lever launched his great scheme of co-partnership with employees. " A remarkable year " he characterised this, for it happened to be the centenary of his father's birth, the 21st anniversary of the foundation of Port Sunlight, and the year in which his son was coming of age and entering the business. The scheme, avoiding the objections to ordinary profit-sharing arrangements, was contrived to give to managers and other employees a common interest with the employer in avoiding loss as well as in sharing gain, the motto of all being " Waste not, want not." A reduced *facsimile* of the partnership certificate is bound together with a number of Lord Leverhulme's addresses explaining his scheme, in " The Six-Hour Day " referred to below.

The years 1910–4 brought to the founder of Port Sunlight fresh honours but also severe personal sorrows. In 1910 his brother died. In 1911 he was made a baronet; in 1913 he received from the King of the Belgians the Cross of Grand Officer of the Order of Leopold II. On July 24 of the same year he suffered his heaviest bereavement in the loss of Lady Lever, who had been his companion on many voyages, had visited with him his concessions on the Congo, and, on her return, had been made a Fellow of the Royal Geographical Society. Her memory was honoured, when on the visit of King George V. and Queen Mary in 1914 His Majesty laid the foundation stone of the Lady Lever Memorial Art Gallery. The completion of this building was impossible until the close of the World War, but then became a lordly treasure house, built, furnished, endowed and dedicated to Lady Lever's memory by her husband, the Princess Beatrice opening it in 1922.

Sir William's war activities included the loan of several buildings as hospitals, and service on many committees, including the Liquor Control Board and the Army and Navy Canteen Board. He was also gazetted Hon. Col. of the 2nd Vol. Batt., the Cheshire Regt., in which, in its early days, as a volunteer training corps, he had drilled as a private.

After his baronetcy, many other public honours were bestowed on him. He was raised to the peerage in 1917 as Baron Leverhulme (a name chosen by himself as combining that of his late wife with his own) and the designation " of Bolton-le-

Moors" as indicating his unceasing affection for his native town. He was high sheriff of Lancashire in 1917 and mayor of Bolton in 1918–9. The University of Edinburgh conferred upon him the hon. degree of LL.D. He was also made hon. fellow of the Royal Institute of British Architects.

In 1918 Lord Leverhulme turned his attention to the subject of reconstruction after the War and advocated the running of machinery in factories in double shifts of six hours in order to absorb the unemployed and to increase production at a lower cost. Under the title of *The Six-Hour Day and Other Industrial Questions* a selection of Lord Leverhulme's speeches and writings on co-partnership, education and business was edited by Mr. Stanley Unwin, and published with an introduction by Viscount Haldane. The editor, in his preface, remarked that "Lord Leverhulme prescribes a six-hour day, but manages to work sixteen." He might have added that further time was saved for business transactions by his habit of travelling to and from London by night trains. When at home in London he rose at 4:30 A.M. to read reports and prepare for the day's interviews and correspondence. It was in 1918 also that Lord Leverhulme bought from Col. Duncan Matheson the Island of Lewis, acquiring later North and South Harris also. He spent large sums in a sincere effort to extend and develop the fishing industry and to help the islanders in other ways, but lack of support, especially on the part of the Scottish Office, led to the abandonment of his schemes as far as Lewis was concerned; and he gave the town of Stornoway, including Lewis Castle and its grounds, to the people of Stornoway. He continued his developments in Harris, where more local appreciation was shown, until his death.

One of Lord Leverhulme's personal enterprises for the economic development of his Hebridean properties was the opening or acquisition in 1919 of the retail fish shops, since familiar to the public as "Mac Fisheries," to serve as an outlet for the fishing industry of Lewis and Harris, the catches being conveyed by swift steamers to Fleetwood and then distributed to over 300 shops in England, of which 110 were in London. Lord Leverhulme, having borne the whole of the expenses of the formation and development of Mac Fisheries, handed the business over to Lever Brothers a year or two later with its capital intact.

Among Lord Leverhulme's many benefactions, the presentation to the nation of Stafford House, renamed in compliment to him Lancaster House, and now constituting a home for the London Museum, is conspicuous. He was a generous benefactor to the Congregationalist denomination, of which he was a member; and jointly with his brother he erected the Blackburn Road Church, Bolton, as a memorial to his parents. He also built Christ Church, Port Sunlight, St. George's Church, Thornton Hough, and Neston Congregational Church. He was a renowned collector of antique furniture, pictures and Chinese porcelain, and presented the larger part of his wonderful collection to the Lady Lever Art Gallery at Port Sunlight. In Freemasonry he reached the high rank of Grand Junior Warden of England.

In 1922 Lord Leverhulme was made a viscount. Awarded the Messel memorial medal in 1924, it fell to him to deliver the Messel memorial lecture to the Society of Chemical Industry entitled "Science, Religion and Workshop," a typical example of his happy gift of relieving solid and serious argument with brief intervals of humorous anecdote.

At the 15th distribution of partnership certificates to his employees, on his 72nd birthday, Lord Leverhulme protested against a suggestion that he was without hobbies "other than the unselfish and noble hobby of devising schemes for the benefit and interest of his workpeople." He said he had a great many hobbies, adding, "I think road-making is my greatest hobby, and then I have the building of towns. Port Sunlight was my first. I am now engaged on my 11th—Moor Park in Middlesex. There are five or six in the Congo and others in various places."

Lord Leverhulme began his seventh journey round the world on Nov. 14 1923 and completed it on March 24 1924. His last journey was to West Africa, returning to London on the morning of March 15 1925. He resumed his business activities with his usual unsparing disregard of self, and caught a chill, which suddenly ended his remarkable career, on May 7 1925.

The testimony of Lord Leverhulme's fellow directors, embodied in a resolution drawn up on the morning of his death, summed up his life and work as "distinguished by genius, courage, imagination and devotion to duty, a career inspired by the highest ideals of public spirit and service to his fellow men, and notably by his interest in the welfare, education, better housing and amelioration of the conditions of labour of every rank of industrial worker, as evinced by his creation of co-partnership, life insurance, old age pensions, educational and other schemes for the benefit of his employees and by his gifts to the communities of Port Sunlight and Merseyside, to his native town of Bolton and to the nation." The directors further testified to "his natural simplicity, the charm of his character, the wealth of his affection and the loyalty of his friendship." (A. P.)

LEVI, SYLVAIN (1863–), French orientalist, was born in Paris March 28 1863. Educated at the University of Paris, in 1886 he was appointed a lecturer at the school of higher studies in Paris. As special lecturer in Sanskrit he taught at the faculty of letters from 1889 to 1894 when he was appointed to a professorship at the Collège de France. In 1897 and 1898 he made important tours of scientific research in India and Japan, and from 1921 to 1923 he travelled in India, Indo-China, Japan, Korea, Siberia and Russia. Prof. Levi became a director at the school of higher studies and a member of numerous societies, including the Royal Asiatic Society, the Linguistic Society and the Society of Jewish Studies. In 1923 he was made an officer of the Legion of Honour. His works include *Le théâtre indien* (1890, Prix du Budget, Académie des Inscriptions et Belles-Lettres); *La doctrine du sacrifice dans les Brahmanas* (1898); *Le Népal* (1905–8).

LEVY, AUGUSTE MICHEL (1844–1911), French geologist (*see* 16.519), died Sept. 21 1911.

LEWIS, ISAAC NEWTON (1858–), American soldier and inventor, was born at New Salem, Pa., Oct. 12 1858. On graduating from the U.S. Military Academy in 1884 he was given a commission in the artillery. From 1894 to 1898 he was a member of the board on the regulation of coast artillery fire in New York harbour. In 1898 he became recorder of the Board of Ordnance and Fortification in Washington, and the same year made a study of ordnance in Europe which led to the re-armament of the U.S. field artillery. He is the inventor of a number of range finding and other mechanical and electrical instruments used for artillery fire control purposes in U.S. coast defences. From 1904 to 1911 he was instructor and director of the coast artillery school at Fort Monroe, becoming lieutenant-colonel in 1911. In 1913 he retired from active service with rank of colonel. The same year a machine-gun of his invention (the Lewis gun) was accepted by the British, French and Belgian Govts. after it had been rejected in America. Throughout the World War it was extensively used by all the Allies. Col. Lewis refused to accept the royalties, amounting to $1,276,000, on his guns made for the American Govt. after the United States entered the World War.

LEWIS, SINCLAIR (1885–), American author, was born at Sauk Centre, Minn., Feb. 7 1885. He graduated from Yale University in 1907, and was engaged for a time in newspaper work, being reporter on various papers. He acted in an editorial capacity for the Frederick A. Stokes Co., the Publishers' Newspaper Syndicate, and George H. Doran Co., at the same time writing short stories and novels. Among his works are: *Our Mr. Wrenn* (1914); *The Trail of the Hawk* (1915); *and Free Air* (1919). His early work owed much to the influence of H. G. Wells. By *Main Street* (1920), a study of a small town, he won wide recognition while he provoked much criticism. *Babbitt* (1922) was one of the most discussed novels of the century, and added a new word to the English language. It was followed by the scarcely less popular *Arrowsmith* (1924).

LEYGUES, GEORGES (1858–), French politician, was born at Villeneuve-sur-Lot on Nov. 28 1858, and educated in his native town, Toulouse and Bordeaux. On arriving in Paris he took up the study of the law, but his natural bent inclined him at the same time towards letters and he was well received in the Parnassian group of poets. After pursuing wide travels, ranging from the polar regions to the Levant, he

entered politics. At the age of 26 he was elected deputy for the Lot et Garonne department. In 1894 and 1895 he was given Ministerial posts, respectively in the Dupuy and Ribot Cabinets. In June 1898 he was elected vice-president of the Chamber, but he resumed ministerial office in the 3rd Dupuy Cabinet of the same year. In Waldeck-Rousseau's Cabinet (1899–1902) known as that of "defence and republican action," he held the portfolio of public instruction, while M. Sarrien appointed him Minister for the Colonies in 1906. In the Clemenceau Cabinet of 1917 he was Minister of Marine. In 1920, when M. Millerand became President, M. Leygues was asked to form a Government. He remained until 1921 Prime Minister and Minister for Foreign Affairs. He was again Minister of Marine in the cabinets formed by M. Briand in Nov. 1925 and March 1926. His publications include *Le Coffret Brisé* (1882); *L'École et la vie* (1904); *La Pologne* (1918); *Colbert et son oeuvre* (1920).

LIANG SHIH-YI (1869–), Chinese politician, was born in Kwangtung, and, unlike many other Chinese republican leaders of his time, was educated wholly in China and knew no other language than his own. Graduating with honours in classics, he was appointed secretary to Tang Shao-yi when that statesman led a mission to India in 1906, and then began a successful career in the civil service. He was appointed director of railways and assistant director of the Chiao T'ung Bank in 1907, acting director of Imperial Chinese Posts in 1911, acting minister of communications in 1912, acting vice-minister of finance in 1913, and a member of the council of state and director-general of customs and taxes in 1915. The failure of Yuan Shih-kai's monarchical *coup d'état*, of which he was one of the supporters, compelled him to resign, but in 1918 he returned to favour as Speaker of the Senate. Throwing in his lot with Chang Tso-lin in the contest between the latter and Wu Pei-fu, he became Prime Minister in 1921. The defeat of Chang, however, resulted in his fall, and he left Peking in 1922 to escape Wu's vengeance and took no further part in politics. He visited Europe in 1924.

LIAPUNOV, ALEXANDER MIKHAILOVICH (1857–1918), Russian mathematician, was born April 25 (old style) 1857, a son of the astronomy professor in the University of Kazan, and the brother of the musician and composer Sergei M. Liapunov. In 1901 he was made a member of the Russian academy of science and later was appointed professor at Kharkov University. He died Oct. 31 1918 in Odessa. His mathematical research belongs mainly to hydrodynamics and his chief work is *Sur les figures d'équilibre peu différentes des ellipsoïdes d'une masse liquide homogène douée d'un mouvement de rotation* (1909–12). His voluminous investigations are very specialised and not available to the ordinary reader, but they are of incomparable value to specialists. They are published in French and in the *Memoirs* of the Russian Academy of Sciences (1895, etc.) and his first treatises, which appeared in Russian, are translated into French and published in the *Annales de Toulouse*.

LIBERAL PARTY (*see* 16.538).—When the House of Lords rejected the budget at the end of 1909, Mr. Asquith immediately dissolved Parliament and appealed to the electors. The appeal was not only for the passing of the budget, but also for the permanent removal of any control over finance by the Upper Chamber, and for a time limit on any veto on any other legislation passed by the House of Commons. In the election, the Liberal party lost a considerable section of its enormous majority. But Mr. Asquith had, in combination with the Irish and the Labour members, a majority of 124 pledged to these two operations.

The Parliament Act.—The budget was passed in April, but in May 1910 King Edward VII. died and a kind of truce of God was called on the important constitutional question between Lords and Commons. Delegates from both sides discussed all possible forms of double chamber government for the remaining nine months of the year. Agreement was finally found to be impossible. The conference broke up and immediately Mr. Asquith again dissolved Parliament, this time with the written guarantee of the new King, George V., that if the country again endorsed his policy the royal prerogative would be exercised to create a sufficient number of peers to cause the necessary bill to become law. The election resulted in almost exactly the same balance of numbers as that which was held nearly 12 months before. Mr. Asquith's Veto bill passed through all its stages in the House of Commons by majorities of over 100, and the amendments which the Lords endeavoured to make to it were rejected. The Conservatives were informed they must either allow the bill to pass or its passage would be effected by the creation of several hundred new peers. They chose the former course.

The Liberal Programme.—The Liberal Govt. then proceeded to endeavour to carry measures, the principles of which the House of Lords had previously rejected and the House of Commons previously approved—Home Rule for Ireland, Welsh Disestablishment, and the creation of a more democratic franchise by giving each man only one vote. Of these the last was withdrawn owing to its complication over the question of giving the votes to women. Home Rule passed after many months of most bitter controversy and the organisation of contingent rebellion both in Ireland and in England. But it was only put on the statute book after the opening of the World War in 1914, accompanied by a condition suspending its operation till that War was over. The Welsh Disestablishment bill was also passed and came into operation after the War was over. Mr. Lloyd George also passed his great contributory insurance scheme, and in 1913 he launched an ambitious land policy in town and country, which was accepted by the Liberal party and on which they intended to appeal to the country.

The War Period.—But all such plans were swept away by the outbreak of the World War in Aug. 1914. The Liberal Cabinet was seriously divided between the policy of neutrality and the policy of intervention, and at one time the resignation of the Govt. appeared inevitable. The War was conducted exclusively by the Liberal Cabinet until May 1915, when failures in the field, the anxiety of the people and the bitter attacks by the newspapers, made it essential that a *union sacrée* should be formed in Britain as it had been formed in other countries. There was therefore constructed the first Coalition, in which Mr. Asquith remained Prime Minister and the most important offices—the Foreign Office, the Chancellorship of the Exchequer, the Ministry of Munitions—were still held by Liberals; but in which all the Conservative leaders and some representatives of Labour were included.

This Govt. continued to direct the operations of war until the late autumn of 1916. Owing to that War's prolonged continuance, with many disastrous defeats, the renewed attacks of the popular newspapers, and the gigantic loss of life and treasure, the public mind was prepared for a further change. An intrigue of a few men, ostensibly directed toward giving Mr. Lloyd George control of the War operations but in fact designed to exclude Mr. Asquith and the Liberals from the Cabinet, proved unexpectedly successful. Mr. Asquith resigned with all his Liberal colleagues. Mr. Lloyd George constructed a Cabinet composed of Conservatives, some minor Liberal members, Labour members and business men.

Mr. Lloyd George as Premier.—For the next two years Mr. Asquith and his followers, being a substantial majority of the Liberal members in the House of Commons, confined themselves to suggestions and criticism. But their support for an inquiry into the allegations made by Sir Frederick Maurice on the conditions which led to the greatest defeat the British Army has ever experienced on March 21 1918, created a break between the two sections of the party. In the following autumn, when Germany was utterly vanquished, Mr. Lloyd George issued what was called a coupon, contained in a letter signed by himself and Mr. Bonar Law, which was published as a recommendation to voters in all constituencies to vote against Liberal members and candidates who still declared allegiance to Mr. Asquith.

The Election of 1918.—The result was a débâcle. Mr. Asquith and all the Liberal ex-ministers who were faithful to him were defeated and only some 30 such Liberals were returned. These, under the leadership of Sir Donald Maclean, who had

never held Cabinet office, maintained some sort of opposition against the overwhelming forces of Mr. Lloyd George's Coalition. It soon became apparent, however, that the great mass of the Liberals in the country were bitterly opposed to this Liberal-Tory combination. Mr. Asquith was returned for Paisley at a by-election and assumed the leadership of what was scornfully termed the Wee Frees. In a fierce political civil war, carried on for three years, it was obvious that Mr. Lloyd George's nominees could only be elected by Conservative votes and that the Liberals were either in large numbers joining Labour or remaining doggedly determined to destroy the Coalition.

In 1922 Mr. Lloyd George and his Coalition were overthrown by an intrigue, very similar to, and in part conducted by the same men, the one which had placed him in power. A conservative Govt. was formed and in the appeal to the country Liberal was still found fighting Liberal, the result being the destruction of a considerable section of Mr. Lloyd George's followers, thus leaving the two Liberal sections still in a negligible minority in the House of Commons.

Liberal Reunion.—The year after, however, Mr. Baldwin, who had succeeded Mr. Bonar Law as Prime Minister, unexpectedly appealed to the country for a general tariff as a means of relieving unemployment. The Liberal leaders came together on so vital a question; Mr. Lloyd George accepted Mr. Asquith as leader of the party, and the two ex-Prime Ministers issued a joint appeal. The distrust of the Coalition by the Liberals in the country, however, had caused so many to turn to Labour that, although those who had been followers of Mr. Asquith gained a large number of seats, the number of those who had been concerned with the Conservatives and the "coupon," were still further diminished. Although they had secured substantially the same number of votes, the Liberals found themselves in members 30 behind the Labour party, and with no party in a majority, Mr. Asquith announced the intention of the Liberals to support a Labour Government. For nearly a year that Labour Govt. was retained in office by the votes of Liberal members, although it refused any agreements or consultation concerning policy and set up candidates in almost every constituency against the Liberals who were supporting it in the House.

The Election of 1924.—Such an impossible position was terminated in unexpected and almost casual fashion. The Labour Prime Minister decided to dissolve Parliament in preference to accepting any form of inquiry concerning the vague insinuations associated with the initiation and then withdrawal of a prosecution against a communist newspaper and its temporary editor, Mr. Campbell. In the dissolution which followed, while Labour received a severe setback, the Liberal party in Parliament was almost annihilated although polling more than 3,000,000 votes and the largest Conservative majority was returned since the great Reform bill. Mr. Asquith, who was defeated, retired to the House of Lords as Lord Oxford, but remained leader of the Liberal party. Mr. Lloyd George was elected chairman of the Liberal "rump" of 40 that remained in the House of Commons, of whom some 10 formed themselves into a Radical group and refused to accept his leadership. The remaining 30 were mostly elected by Conservative votes and some were pledged, in critical divisions, never to vote against the Conservative Government.

This desperate condition in Parliament was, however, not reflected by the Liberals in the country who over large areas proceeded to initiate Liberal campaigns, to collect substantial funds, and to prepare for a reversal of the decision when the next general election should come. The Liberal party also set itself down to consider vital social programmes; to issue pronouncements on such subjects as coal and power, the land and the nation and towns and the land. A small group in the House of Commons maintained a lively opposition to Mr. Winston Churchill's Budget of 1925 and to any tampering with free trade in the Safeguarding of Industries bill.

The revolutionary conclusions of Mr. Lloyd George's Land Committee, in part watered down by a compromise with the Liberal candidates association, were accepted by the delegates in a great Liberal convention representing the whole of the country, as an essential part of Liberal policy. This formed a cause or an excuse for flight from the party of certain ex-ministers and persons of wealth. In 1926, however, Lord Oxford remained undisputed leader of the party as a whole, and Mr. Lloyd George chairman of a rather forlorn and divided group in the House of Commons, while great energy was being shown by a land and nation league to spread the new reform doctrines especially in rural England, and vigorous attempts were made to reverse the verdict of the last election and place some 500 Liberal candidates in the field before the next appeal to the electors. (*See* ENGLISH HISTORY.) (C. F. G. M.)

Early in May this co-operation was interrupted by a serious difference between Lord Oxford and Mr. Lloyd George over the general strike which broke out on May 3. Lord Oxford held with the Government that the general strike, being a threat to the constitution, must be defeated before any negotiations for peace were considered. Mr. Lloyd George attributed the strike to precipitate action by the Cabinet, which he condemned and supported the plea of the Archbishop of Canterbury for a negotiated peace. On May 10 Mr. Lloyd George declined in writing to attend a meeting of the shadow Cabinet summoned by Lord Oxford who, in communications of some severity, interpreted this abstention as tantamount to resignation. Mr. Lloyd George refused to resign and at meetings of the Liberals who had seats in the House of Commons was supported in that attitude by 20 votes to 10. The situation was complicated by Mr. Lloyd George's contributions to the Press in the United States and by his alleged but strongly denied negotiations with Mr. Philip Snowden, representing moderate Labour. Also, Lord Gladstone accused Mr. Lloyd George of withholding the funds with which he was entrusted at the late general election. (ED. *E.B.*)

LIBERIA (*see* 16.539).—By an agreement reached in 1910 France obtained some 2,000 sq. m. of hinterland which Liberia had claimed but had not administered. This reduced the area of the republic to about 40,000 square miles. Estimates made up in 1925 put the Americo-Liberians at about 20,000, of whom approximately half live in Monrovia, the capital. The native population is believed to be decreasing, it numbers probably 1,000,000 to 1,250,000. Some thousands of negroes in the coast region have adopted the religion (Protestant forms of Christianity) and the standards and language (English) of the Americo-Liberians, whose authority has become generally recognised over the whole country. Primitive conditions prevail throughout the interior.

History.—The condition of Liberia in 1910-11 was far from satisfactory. It was burdened with debt, it had granted many concessions without being able to control the regions in which the concessionaires were to work, and its authority rarely extended more than 20 m. from the coast. The frontier regions, which adjoined French or British colonies, were in a disturbed condition; the French especially were troubled by the remnants of Samory's army (*see* 24.642) and other malcontents who took refuge in the Liberian forests and raided across the frontier; hence the annexation by France of part of the border region. It appeared as if the experiment of "running" the country by American negroes—as alien to the bulk of the natives as are white men—on the lines of the constitution of the United States would collapse. However the intervention of the United States Govt. led to a financial re-organisation which gave the Americo-Liberians a new start. There was some trouble with Germany in settling the matter. The German Govt. energetically pressed its claims, the gunboat "Panther" being anchored for a month off Monrovia, with its guns trained on the executive mansion. All difficulties were overcome however by June 1912, when an international loan of $1,700,000 (£340,000) was raised, the bonds to be issued for not fewer than 40 years. The customs duties and certain taxes were pledged as security for the loan, and are administered by an American receiver-general, who is also Financial Advisor to the Liberian Government. Thus in effect the control of finances is in the hands of the United States and expenditure is kept within the

limits of the revenue. A frontier police force was also organised by officers of the United States Army, and as a result Liberian authority was better maintained.

During the World War the Germans, deprived by force of arms of their own colonies, found in Liberia their last foothold in West Africa. But in Aug. 1917 Liberia declared herself in a state of war and expelled the Germans. She was a signatory of the Treaty of Versailles, her representative at the peace conference in Paris being Mr. C. D. B. King. Mr. King was in 1920 chosen as president of Liberia and in 1924 was re-elected for a second term. He strove, with some success, to improve conditions in Liberia and was the originator of a system of road building which gave a prospect of opening up the interior.

Economic Conditions.—The natural resources of Liberia are almost untouched; the only cultivated crop of importance for external trade is coffee and the other industries for export are practically confined to the products of the oil-palm and piassava fibre (prepared from the raphae palm). While Monrovia has two wireless stations and direct cable communication with Europe and New York, there are no harbours and no railways and until means of transport are developed the wealth of the forests and the mineral resources cannot be utilised. The Government, however, has no money to spend on reproductive works. In 1925 an American firm obtained a concession of 1,000,000 ac. primarily for the establishment of rubber plantations. Meanwhile the bulk of the trade was in the hands of British and German firms, the Dutch being next in importance. The United States took but an insignificant fraction of the trade. Between 1913 and 1923 the volume of trade about doubled. In the last named year imports were valued at £298,000 and exports at £242,000. Revenue in 1912–3 was $618,800, accounts being kept in American currency, though the money in circulation is British. In 1923–4 revenue was $380,000, expenditure $371,600.

LIBERTY LOANS, the name given to the four loans floated by the U.S. Govt. during the World War. A fifth loan, floated after the Armistice, was called officially the Victory Liberty Loan, but is here considered as the Fifth Liberty Loan. Between May 14 1917, when the First Liberty Loan was offered to the public, and May 10 1919, when the campaign for the Fifth Loan was brought to a close, the people of the United States subscribed $24,072,111,400. Of this amount, $21,432,924,700 was finally accepted by the Secretary of the Treasury. The Fourth Liberty Loan, concluded Oct. 18 1918, was, however, larger than any single loan issued by any of the other belligerents, and realised a total of nearly seven thousand million dollars. The number of subscribers to this loan was more than 21,000,000, or one-fifth of the total population of the United States. Moreover, the U.S. Govt. was able to dispose of the Liberty Bonds on very favourable terms; they were issued at par, the rate of interest varying from 3½% on the First Loan to 4¾% on the Fifth. There were a number of reasons for the favourable terms obtained. The United States was immensely wealthy and had just passed through a period of great prosperity; its record for quick payment was unique; patriotic spirit was at a high pitch; advertising on an unexampled scale was undertaken; and the rate offered, while lower than those of European countries, was high as compared with the 3% and 2% paid in recent years on U.S. Govt. bonds.

When America entered the World War the Govt. realised that, in addition to the money needed to prosecute the War by the United States itself, large sums must be raised to relieve the already overstrained credit of the European Allies. The total amount of these loans to foreign countries was $9,842,468,566, to which was added later from sales of war material, etc., $736,040,776, making a total of $10,578,509,342. This money, excluding that derived from sales of war material, etc., was part of the amounts raised in the Liberty Loans. The financial policy of the Govt. was to raise from one-fourth to one-third of the necessary funds from taxation, the remainder from loans. The Treasury Dept. throughout the War met current obligations by issuing short-term Certificates of Indebtedness, which were absorbed by the Federal Reserve Banks and to some extent by outside banks and private persons. These certificates were retired either by exchange for Liberty Bonds or by redemption from money obtained through the sale of such bonds. The Liberty Loans constituted therefore a series of funding operations. These operations were intended not only to extend the debt over a period of years, but to distribute it as widely as possible. The success of the policy is indicated by the facts that 53% of the individual subscriptions for the Fourth Loan were for $50 bonds, and that approximately 25,000,000 persons were, at the end of the War, holders of Liberty Bonds. Before the United States entered the War such a result would have been thought impossible, for it was then estimated that there were only about 350,000 bond investors in the United States.

Under the Act of April 24 1917 the Secretary of the Treasury was authorised to issue bonds to the extent of $5,000,000,000 at a rate not to exceed 3½%, these bonds to be convertible into bonds of a higher rate if such should be issued before the end of the War. The Secretary of the Treasury made the first issue $2,000,000,000 and proceeded to create a War Loan Organisation in the Treasury Department. The 12 Federal Reserve Banks were used as the central agencies in the 12 Federal Reserve Districts, and each of these banks formed Liberty Loan Committees. To each district a "quota" or proportional part of the whole issue was allotted. The value of advertising in arousing the public had been clearly demonstrated in the campaigns for the British War Loans, and the Treasury Dept. made use of every available means of publicity. As a result the First Loan was oversubscribed by more than $1,000,000,000.

In subsequent campaigns the methods employed in placing the First Loan were developed and extended. In each city an organisation known as Four-Minute Men was formed; these men visited places of public resort, including the play- and motion-picture houses, and spoke for four minutes on behalf of the loans. The Govt. assisted local authorities in organising street parades in which men from the training camps participated; captured German war material was displayed; distinguished soldiers and other visitors from Great Britain, France and the other Allied nations were given elaborate receptions. These campaigns were of great value as a means not only of selling the war bonds but of keeping up the morale of the people.

The following are the figures of the number of persons subscribing to each of the five Liberty Loans, the total of the amount asked for, the subscriptions and the final allotments:—

Loan	Subscribers	Amount asked	Subscriptions	Allotments
		$	$	$
First (1917)	4,000,000	2,000,000,000	3,035,226,850	1,989,455,550
Second (1917)	9,400,000	3,000,000,000	4,617,532,300	3,807,865,000
Third (1918)	18,308,325	3,000,000,000	4,176,516,850	4,175,650,050
Fourth (1918)	22,777,680	6,000,000,000	6,992,927,100	6,964,581,100
Fifth (Victory, 1919)	11,803,895	4,500,000,000	5,249,908,300	4,495,373,000

(F. H. H.)

LIBRARIES (*see* 16.545).—This article is concerned with the main developments of the public library service and with certain special aspects of library work since 1910.

1. GREAT BRITAIN AND IRELAND

Great as was the advance achieved during the last quarter of the 19th century, and especially under the influence of Andrew Carnegie during the years 1900–10, a still greater advance took place after 1910, and especially from 1918 onwards. Up to the latter date the service had suffered in two main respects, namely, the 1d. rate limit which, except in the great cities, prevented anything like adequate expenditure on books and salaries, and the practical inapplicability of the Libraries Act in the smaller centres of population. These difficulties had been set forth with vigour and persistence by the Library Association, and in 1915 the position was restated by Professor W. G. S. Adams in a report

published by the Carnegie United Kingdom Trust, which showed that the great majority of public libraries were utterly unable to provide an adequate service on the 1d. rate, and that the only hope for rural areas and the smaller towns lay in the establishment of a co-operative system.

Acting on this report the Carnegie trustees set up a number of circulating systems on a regional basis.[1] The county was the most hopeful unit, and during the years 1915–8 a number of county councils, through their education committees, and with the aid of substantial trust grants, set up experimental schemes under which, from a central store, collections were sent out on periodic loan to villages where they were as a rule housed in the schools and administered by the schoolmaster. The earliest schemes were those of Staffordshire, Cardiganshire, Carnarvonshire, Perthshire. As the county authority then had no power to levy a library rate, the whole cost was borne by the Trust.

Legislation.—The success of the experiment was immediate and convincing. In the Education (Scotland) Act 1918 it was provided (clause 5) that the county education authority should have powers to levy a library rate. In England and Wales the principle was recognised by the Public Libraries Amendment Act of 1919 by which county councils were empowered to levy a rate, entrusting the administrative arrangements to their education committees. The same powers were set up in Northern Ireland by the Public Libraries Act of 1924, and in the Irish Free State by the Local Government Act of 1925.

After the passing of these Acts the system spread with great rapidity under the encouragement of the Carnegie trustees (who expended altogether £310,300 during the period 1915–25), and by the end of 1925 the only administrative counties which had not received trust grants were: in England, Westmoreland, Hampshire (Isle of Wight)—both of which, however, had less ambitious schemes, not under the 1919 Act—Rutland, Lincolnshire (the Holland division) and Scilly; in Wales, Carmarthenshire; in Scotland, Argyll. In Ireland there were schemes in three of the northern counties, and 14 of the southern counties.

The system began with the distribution of boxes of books to villages. Within 10 years in several counties the motor-van library had displaced the box; co-operation with municipal libraries had begun; sets of books were provided for all organised adult classes; special collections (*e.g.*, for teachers, agriculturalists, students of local history, etc.) had been made; in a few cases, on the basis of differential rating, small libraries of the municipal type were set up in semi-urban areas too large to be served on the purely circulating system.

The Act of 1919, besides establishing the county as a library unit, removed the rate-limit in England and Wales. In Scotland in 1920 the limit was raised to three pence. In Ireland the same extension was sanctioned in 1920, with a further extension to 6d. for county boroughs. The majority of municipal libraries took greater or less advantage of their new freedom, but there was much leeway to make good, and up to 1926 insufficient provision for book purchase and salaries was still common. The American library in 1926 was spending roughly four to five times as much per head as the average British library. Perhaps the most hopeful sign was a tendency on the part of the weaker libraries to co-operate with the new and vigorous county systems, or with other neighbouring boroughs.

The Central Library for Students.—Apart from the borough and the county service, the chief important development is the establishment of a national lending library of serious books,—known as the Central Library for Students—as a reserve to the local services which, under the most favourable conditions, must always find a difficulty in meeting the needs of specialist readers. This library was started in 1917, largely to supply organised adult education classes, but in 1925 it also served 235 borough and 47 county libraries; with a stock of roughly 31,000 books, the issues from the three depots (London, Dunfermline, Dublin) totalled approximately 54,000. The library has been financed chiefly by the Carnegie Trust with substantial contributions from the Cassel Trust, the Thomas Wall Trust, and the United Service Fund and a comparatively small revenue from the voluntary subscriptions of borrowing libraries. Its sponsors have stated a case for a government subsidy, the library being capable of becoming in a real sense the keystone of the national lending service.

Co-operation with Special Libraries.—Thanks to grants from the Carnegie Trust, many special libraries agreed during 1922–5 to place their collections (rare and irreplaceable works excepted) at the disposal of the central library—a step of great importance towards a systematic inter-loan service. This policy of co-ordination was advanced a further stage in 1925 by the establishment of the Association of Special Libraries and Information Bureaux, and the initiation by the Association of University Teachers of a tentative system of exchange between university libraries.

The Carnegie Trustees prepared a fresh report, issued in 1924, which surveyed the situation during the period 1921–3. It showed that the smaller borough libraries were still financially embarrassed, and indicated the desirability of co-operation between them and the county service. Similar conclusions emerged in the report of the adult education committee appointed by the President of the Board of Education (1921–3). Accordingly, in 1924, the President of the Board set up a departmental public libraries committee, under the chairmanship of Sir Frederic Kenyon, Director of the British Museum, and representing both librarianship and education. This committee was expected to report towards the end of 1926 or the beginning of 1927.

Librarianship.—The pressing importance of raising the standard of education among public librarians received continuous attention from the Library Association and the Carnegie trustees. There was a strong feeling in the profession against the appointment of persons over 16 years of age, which automatically excluded university graduates; moreover, up to 1919 and even afterwards salaries were too low to induce university graduates in any numbers to enter the service. In that year, however, with the aid of a Carnegie Trust grant, a school of librarianship was set up in University College, London, and since that date the number of students taking librarianship as a post-graduate course has appreciably increased. Summer schools have been successfully established both by the school and by the Library Association, and a number of chief librarians have arranged special courses for their junior staffs. Library committees in the United Kingdom were still, however, very far behind those of the United States in their appreciation of the importance of a high standard of general education in the ranks of librarianship, matriculation being normally the maximum requirement, with the understanding that promotion would depend upon the taking of the certificates of the Library Association (*see* 16.560).

Building Developments and Equipment.—The progress of library building was seriously interrupted by the World War, comparatively few libraries having been erected since 1914. The Carnegie Trust in 1917 ceased to make grants and in 1925 decided to consider no further applications. Between 1914 and 1926, however, existing promises were honoured in 26 cases, the more important being those made to Barrow-in-Furness, Nottingham (two branches), Barking, Bethnal Green, Ipswich, York, Gateshead, Exeter. The total sum expended by the Trust on public library buildings in 1914–26 was £295,600. In every case the modern system known as "open access" was adopted, and stress was laid upon accommodation for children. Great improvements were effected in design, with the object of securing better lighting, more effective supervision and the greater convenience of public and staff. Card catalogue and subject-lists have almost entirely taken the place of printed catalogues. There was a steady tendency to make the library, as in the United States, a

[1] The idea in itself was not a new one. The principle was already embodied in voluntary schemes in Dorsetshire, in Yorkshire (under the auspices of the Yorkshire Village Library), and had been tried in Scotland as early as the middle of the 17th century; in Indiana, U.S.A., as early as 1816. The trustees, however, for the first time in Great Britain systematised the principle by the adoption of the county authority as the administrative unit. Several attempts to set up rural services based upon a central borough library came to nothing.

more vital and potent factor in communal life, by developing the practice of giving lecture courses illustrative of the use and resources of the stock, of supplying schools with loan collections, and by co-operating generally with education authorities, of admitting non-residents to the reference room and (on payment of a small subscription) to the use of the lending department, and of giving special facilities to teachers and students. Library policy has, in fact, become far more liberal than it was before the War. Of the greatest importance to business men and students has been the establishment in great city libraries, since 1919, of commercial and technical departments, notably those of Birmingham, Manchester, Liverpool and Glasgow. The machinery of distribution, through branches, with the aid of union catalogues, was greatly developed (*e.g.*, especially in Glasgow).

National Libraries.—Since 1910 two new national libraries have come into existence, the National Library of Wales, on a splendid site just outside Aberystwyth and the National Library of Scotland, formerly the Advocates' Library (*see* 16.557*c*), in Edinburgh. The former is a magnificent building begun in 1911, opened in 1915. It was not yet complete in 1926, but it already housed a splendid collection of books, manuscripts, historic papers, etc. It had the finest Welsh collection in existence and was strong in other Celtic languages. Its printed books numbered 450,000. It was erected by funds subscribed by the Welsh people themselves with a pound-for-pound government grant. The Faculty of Advocates presented their historic library to the nation in 1923, and it was duly vested in trustees by Act of Parliament in 1925, having received a generous endowment of £100,000 from Sir Alexander Grant. The Advocates retain the law section. The copyright privilege is enjoyed by both these libraries.

Between 1910–26 considerable development took place in the British Museum library. The accommodation for readers was increased by the addition of a reserve reading-room in the northern extension. There was also an extension of storage room, and a scheme for increasing the book-stack was initiated. The length of shelving grew to some 55 miles. Of the other copyright libraries, plans were prepared for increased accommodation in the Bodleian Library and the library of the University of Cambridge, but financial difficulties prevented progress. The same difficulty confronted the library of Trinity College, Dublin. As regards the last-named, the reluctance of Irish publishers, after the recognition of the Irish Free State, to send books to the copyright libraries in Great Britain seemed likely to imperil the copyright privilege; the right was, however, confirmed. The National Library of Ireland was closed for some time during the period of political unrest, but was subsequently reopened.

II. THE UNITED STATES

The County System.—As in Great Britain, the most distinctive development in the United States since 1910—though not so widespread as in Great Britain—has been the attempt to deal with the needs of rural areas. The county system began in Indiana in 1816; Wyoming legislated in 1886. Travelling libraries were established in New York, Wisconsin and Michigan between 1890 and 1900. Ohio and Maryland adopted the county system in 1898; Wisconsin and Oregon in 1901 and 1903. After 1910, however, the system was put upon an entirely new level of efficiency in California, where there were in 1925 no less than 42 county schemes holding jointly 2,500,000 books, with a total annual income of $1,250,000. The system was greatly strengthened by the existence of the fine state library in Sacramento, which acts as a kind of clearing-house (with a union catalogue) and central reserve for the whole state.

In a single year (1924) county libraries borrowed no less than 37,000 volumes for special readers. It is remarkable that by 1926 some 60 independent town libraries had voluntarily merged themselves in their respective county systems, thus greatly adding to the service of books upon which their readers might draw, and reducing their expenditure. The local centres are as a rule upon a more elaborate scale than their British counterparts: they have small, but admirably arranged, reading-rooms, permanent collections, and paid librarians, the circulating system being, except in the case of very remote centres, only supplementary. A different system obtains, *e.g.*, in the State of Massachusetts and other eastern states, where the unit is the township, and the whole machinery is based upon a central office in the department of education. By 1926 the county systems had been established by statute in 29 states, but schemes were in operation in only 200 counties out of 2,964. There is, however, no doubt that under the influence of the Carnegie Corporation of New York, supported by the fine example of California, the scheme is likely to spread rapidly.[1]

Municipal Service.—There has also been great progress in the municipal library service which, though of the same general type as its British counterpart, has shown itself considerably more elastic. Several magnificent libraries, including those of Detroit, San Francisco and Cleveland, have recently been erected.

Librarianship.—The profession of librarianship is better paid and more highly esteemed than in the United Kingdom. Between 1887 and 1919 no less than 15 schools of librarianship were founded, the more important being the New York State library school at Albany, the Pratt institute school at Brooklyn, the Carnegie library school at Pittsburgh and the Drexel institute school at Philadelphia.[2] The profession is largely in the hands of women, though most of the senior posts in the large cities are still held by men. In 1921 nearly half the students in the library schools were college graduates. The American Library Association (membership nearly 7,000) is an active and efficient body founded in 1876, with headquarters in Chicago. It represents both the United States and Canada. It issues select bibliographies, a specimen catalogue, reading courses (etc.) and, with the aid of subsidies from the Carnegie Corporation of New York, has undertaken important inquiries into the training of librarians, and the relation of the public library to adult education. Some 60 committees were at work in 1925 upon important problems of various kinds. The association in 1924 established a library school in Paris with the aid of funds from the American committee for devastated France.

In 1923 a calculation showed that, as regards places having not less than 1,000 inhabitants, 53·5% of the population had access to public library facilities,[3] of which more than half owed their buildings mainly to Andrew Carnegie. In the more active city systems, *e.g.*, at Cleveland (which in 1925 opened a magnificent new building on the most modern lines at a cost of over $4,000,000 and which spends at the rate of rather more than $1·25 per head), in New York City, at Detroit, Chicago, Pittsburgh, Boston, Newark, Indianapolis, Brooklyn, all kinds of developments have been devised with the object of bringing the service into the closest contact with the life of the community. A great feature is made of commercial and technological collections; juvenile departments (usually under specially trained assistants), service to schools, library clubs for adolescents, service by telephone, teachers' libraries, music departments—all these illustrate the tendency to departmental specialisation which is making the public library a real factor in civic life. In the new Cleveland library the arrangement of book stacks and reading rooms gives a concrete illustration of this important development. The system of distribution through branches and sub-branches, in shops, factories and public buildings of many kinds, is likewise designed to bring the communal stock directly to the service of the public. The public library has in fact become the intelligence bureau of the community.

The Library of Congress.—The Library of Congress is the pinnacle of the whole structure. Unlike the British Museum, this library, under reasonable safeguards, lends the rarer books which state, municipal and county libraries do not possess. There is, in fact, a recognised inter-loan system, working upwards from the village to the Federal library, under which any reader may as a rule obtain access to any publication which

[1] See H. C. Long, *County Library Service* (1925).
[2] See C. C. Williamson, *Training for Library Service* (1923).
[3] W. S. Learned, *The American Public Library* (1924).

exists in the country. In this scheme the universities and many specialist libraries participate. Of the greatest importance in this connection is the national card-index system operated by the Library of Congress, which supplies (at a very low price, and yet on a self-supporting basis) accession cards, fully registered and annotated, to any library in the country. Several thousand libraries buy these cards, and thus tend gradually to standardise their systems of cataloguing and classification.

Special Libraries

The chief development is the tendency, both in the United Kingdom, and in the United States, towards systematic co-ordination with a view to greater accessibility of special resources both on the inter-loan basis and for the benefit of the general public. The American Association of Special Libraries was formed in 1909, and has issued a directory. The formation of a corresponding British Association has already been recorded, and a similar directory was begun by this body in 1926.

In Great Britain, during 1910–26 there was a great development of scientific, technical and commercial libraries and bureaux of information. The scientific and research associations, large commercial and manufacturing firms, and the great industrial groups, awakened to the necessity of having well-organised up-to-date collections for the use of their officials. The same movement has developed in America, probably to an even larger extent, though in that country the public library has, until recently, undertaken a larger proportion of this kind of service. Of great importance in this connection are compilations like the *World List of Scientific Periodicals*, the *Subject Index of Periodicals*, both started since 1915.

Mercantile Marine.—Reference may also be made to efforts on behalf of sailors in the Mercantile Marine. The British Sailors Society has attempted this service for more than a century. Since 1920 it has revived and developed its arrangements under the stimulus of a Carnegie Trust subsidy. The Seafarers' Education Service (founded 1920), also with the aid of a trust grant, and contributions from the owners and the men's unions, has succeeded in placing substantial libraries of a more advanced kind upon 150 ships. The Carnegie Corporation of New York has similarly financed the American Merchant Marine Library Association. In Great Britain a system of supply to lighthouses and lightships was initiated by the Carnegie Trust with the aid of the public authorities concerned.

Libraries for the Blind, etc.—In Great Britain the needs of the blind have been met by the establishment of the National Library for the Blind in London, founded in 1882. The present building was opened in 1916, and a large extension was begun in 1925, the total cost being roughly £50,000. Books in Moon or Braille type are lent freely to public libraries, and individual readers. A sectional library for deaf education was set up in the library of the University of Manchester in 1920. Hospital collections are distributed under the auspices of the Red Cross Society. A collection for the use of nurses and health visitors has been set up by the College of Nursing (1921). The libraries of most of the learned societies were financially embarrassed during and after the World War, but since about 1921 they have been doing their utmost to make up arrears of book purchase, binding and cataloguing. (J. M. M.)

LIBYA (*see* 16.578).—On the occupation of Tripolitania and Cyrenaica (Benghazi) by the Italians in 1911–2 Libya (Libia Italiana) was adopted as the common designation of the two colonies. (*See* Cyrenaica; Trifolitania.)

LICHNOWSKY, KARL MAX, Prince (1860–), German diplomatist, was born March 8 1860 at Kreuzenort in Upper Silesia. He entered the German Foreign Office in 1884 and from 1904 to 1911 held secretarial posts in different German embassies abroad. In 1912 he was sent to London as ambassador, and remained at that post until the outbreak of the World War. He took part in the negotiations for a convention with Great Britain regarding the Baghdad Railway and various colonial questions, which was initialled on June 12 1914. Lichnowsky was convinced that for years the relations between Germany and Great Britain had been mismanaged and misunderstood by the Foreign Office in Berlin, and, in particular, he believed that Bethmann Hollweg and his advisers failed to appreciate the pacific attitude and intentions of Sir Edward Grey and the British Govt. during the crisis that ended in the World War. He embodied his views in the pamphlet entitled *Meine Londoner Mission*, which he circulated privately in manuscript among his German friends. This document came into the hands of an opponent of the war, Capt. von Beerfelde, who was the means of its being published, without authorisation, in 1918. The publication exercised a very prejudicial effect upon the German war spirit and there were loud demands among the Conservatives and National Liberals for the prosecution of the author. The Prussian Upper House, of which Lichnowsky was a member, passed a resolution excluding him from that assembly. It became impossible for him to live in Germany, and he sought refuge in Switzerland.

LIEBERMANN, MAX (1847–), German painter, was born in Berlin July 20 1847. He studied from 1869–73 at the school of art in Weimar, from 1873–8 at the Paris Academy under Munkaczy, then for a short time in Barbizon with Millet, in Holland, and finally from 1878–84 at the Munich Academy. In 1898 he was appointed a professor at the university of Berlin. He became the chief exponent of the impressionist school of painting in Germany and the leader of the "secession." Liebermann won the Grand Prix at Paris in 1889 and received gold medals at Venice, Berlin, Vienna, Dresden, Munich and Antwerp. He became president of the Berlin Academy, a member of the Brussels, Dresden, Milan, Munich, Stockholm and Weimar academies and a corresponding member of the Institute of France. His chief pictures are "Jesus among the Scribes" (1879); "Jam Makers" (1879); "Women Plucking Geese" (1894); "Samson and Delilah" (1902); "The Board of Hamburg Professors" (1906); portraits of F. Maunann, Gerhart Hauptmann, Dehmel and Ed. Meyer.

See C. H. Rosenhagen, *Max Liebermann* (1900).

LIEBKNECHT, KARL (1871–1919), German politician, was born in Leipzig Aug. 13 1871. The son of Wilhelm Liebknecht (*see* 16.592), he qualified as a lawyer, and speedily became a prominent member of the extreme Left wing of the Socialist party. After serving a sentence of 18 months' imprisonment for high treason, in 1908 he was elected to the Prussian Chamber of Deputies, and in 1912 entered the Reichstag as a Social Democrat. Not long after the outbreak of the World War he was expelled from the Social Democratic party on account of his violent opposition to the policy of the Government and the successive votes of credit, and formed a faction of his own, *Die Sozialdemokratische Arbeitsgemeinschaft*. Arrested again in 1916 on a charge of high treason he was sentenced to four years' penal servitude; he was reprieved, however, on the eve of the revolution in Oct. 1918. He at once became the leader of the Spartacists, and was largely responsible for that party's insurrection in Jan. 1919. During the rioting he was arrested; and while being conveyed from military headquarters in the west end of Berlin to the prison at Moabit on Jan. 15, he was shot down by his escort while, as was subsequently alleged, he was attempting to escape. His associate, Rosa Luxemburg, perished the same night.

LIÉGE, Belgium (*see* 16.593), with a population in 1921 of 165,096, has been much improved in recent years, and has grown rapidly; it is a clean, prosperous and well-built city, and is the centre of the iron and armament manufacture of Belgium and of a coal-mining district. The production of zinc and of motor-cars has also become important. Of the 56 blast furnaces in the country in 1925 Liége had 20. There is also a large cattle market. Suburbs have arisen on the heights to the north, and a circular boulevard has been laid out with connecting roads. A number of houses near the university were destroyed by bombardment and by fires started after the German entry, and the bridges over the Meuse were blown up by the Belgians in their retreat; but the town as a whole, being an important centre, was spared by the Germans. The Place de l'Université has been renamed Place du 20 Août, in remembrance of the burning of houses and shooting

of 18 persons as they escaped from the fires, by the Germans. The Place Verte is now Place du Maréchal Foch. Liége was the first large town captured during the War. The valiant defence of its powerful ring of forts delayed the German advance for a week and caused the enemy heavy losses. A number of the citizens were deported in 1916 during the German occupation. The city has since been granted the Cross of the Legion of Honour, and a representation of the Perron Liégeois, which symbolises the liberty of Liége, has been reproduced on a postage stamp. The forts were repaired by the Krupp company in 1914–5 (*see* BELGIUM, INVASION OF).

LIGGETT, HUNTER (1857–), American soldier, was born at Reading, Pa., March 21 1857. He graduated from the U.S. Military Academy in 1879, and saw service in the west against the Indians. In the Spanish-American War in 1898 he served on the staff of the adjutant-general, and later was in the Philippines where, as major of volunteers he served for three years. In 1902 he was appointed a major in the regular army and spent several years with the Dept. of the Lakes and at Fort Leavenworth. In 1909 he attended the War College, and on graduating in 1910 was appointed a director there, and in 1913 president, becoming brigadier-general in the same year. From 1915 to 1917 he was again in the Philippines, being for one year commander of the Department. In 1917 he was made major-general and commander of the Western Dept., but in Sept. went to France as commander of the 41st Div. of the American Expeditionary Force. He was at the second battle of the Marne, at St. Mihiel, and in the Argonne commanding the I. Army Corps and later the I. Army, and commanded the III. Army of Occupation on the Rhine. In 1919 he was commander of the Western Div., and in 1920 commander of the IX. Corps Area, retiring March 21 1921.

LIGHTING: *see* ILLUMINATION ENGINEERING.

LIGHTNING: *see* ATMOSPHERIC ELECTRICITY.

LIGHT RAILWAYS, MILITARY.—These are 60 cm. gauge railways laid with steel rails, weighing 20 lb. to the linear yard of rail, on sleepers weighing from 11 to 22½ lb. each, according to the weight of the rolling stock used, and laid 2 ft. 6 in. apart on a ballast track, the ballast consisting of sand, gravel, mine earth or burnt clay.

Rolling Stock.—The rolling stock consists of three types of wagon:

1. Low-sided four-wheeled trucks with capacity of four tons.
2. Flat bogie wagons with carrying capacity of eight tons.
3. Bogie well wagons with carrying capacity of 10 tons. The latter being used almost entirely for transporting heavy ammunition.

Motive Power.—The motive power consists of:

1. Six-wheeled, coupled locomotives weighing up to 14 tons, capacity 60 H.P., and capable of hauling 65 tons up a gradient of 1 in 40.
2. Four-wheel coupled locomotives weighing up to eight tons, capacity 35 H.P., and capable of hauling 40 tons up a gradient of 1 in 40.
3. Petrol tractors weighing up to four tons and capable of hauling a load of 14 tons up a gradient of 1 in 40; these petrol tractors have two gears, the speed on the low gear being about four miles and on the high gear 10 m. per hour.

During the latter part of the World War 1917–8 light railways were very extensively used on the western front for transporting supplies to the smaller supply depôts away from the standard gauge railways, and ammunition to the heavy gun and howitzer positions. During 1917–8, 1,780 m. of light railway were laid but only about half of this was ever used. While the War was stationary light railways were of very great service to the armies, but as soon as a retreat or a continued advance took place they soon became out of action. They are not economical, the maintenance alone during 1917 being on an average 15 men per mile, which, as the lines became consolidated was reduced to five men per mile. The average effective haul of a locomotive was 23 train m. per day, and that of a tractor was 20 train m. per day. The average coal consumption per locomotive was 62 lb. of coal per effective train mile and the average petrol consumption per tractor was ·56 gal. of petrol per effective train mile. The average loaded wagon mile per day per effective was 4·25.

With the advance in Sept. 1918, light railways were of great assistance in getting forward ammunition and evacuating the wounded. They were joined on to the German 60 cm. railways which had not been destroyed, but they were soon left behind and the armies relied entirely on the standard gauge railways and road transport.

Light railways, when worked to their maximum capacity carry, on an average, about 140 tons of supplies per mile of track per day, according to the grading of the line, and the cost in man power for operating purposes only, as compared with a standard gauge railway, is as 3·45 to 1 per m., and cost in man power for construction as 2·2 to 4·7.

An extension to light railways, known as "*foreways*," and used for carrying supplies from the end of the light railways up to the trenches, consisted of 60 cm. gauge track laid on an unballasted formation; the rails weighing about 9 lb. per linear yard of rail on sleepers weighing 8 lb. and spaced 3 ft. apart, centre to centre; on these lines, flat-topped, four-wheel trollies were pushed by two men during the night right up to the communication trenches. Early on in the War the armies objected to these foreways being laid with steel rails urging that the noise of steel wheels grinding on steel rails would attract enemy fire. The first of these lines were made of pitch pine rails nailed on to wooden sleepers; but the friction between steel wheels and wooden rails was so great that the trollies were continually being derailed. (D. L.)

LILLE (*see* 16.685), the fifth largest town in France, had a population of 200,952 in 1921. About 1,000 houses were destroyed by German guns in 1914, and during the German occupation a munition dump on the southeast ramparts blew up causing much damage. The old church of St. Margaret was partially and the Hôtel de Ville completely destroyed. Before their departure the Germans blew up several of the town bridges. The Palais des Beaux Arts, from which many works of art were removed in 1914, has been reconstructed. Lille was made the seat of a bishop in 1913. Before the War Lille provided some four-fifths of the French production of cotton and linen fabrics and yarn, and both industries were in a flourishing condition, but the War caused immense loss; only one flax spinning mill was in a condition to resume work soon after the Armistice, and it is computed that two-thirds of the total number of spindles were lost. Their replacement, however, was practically completed by 1924, and the industry gradually recovered, though handicapped by scarcity of labour and yarn and the high price of the latter.

The War Period.—Lille was first reached by advance German patrols in Aug. 1914. It was afterwards re-occupied by the French, but they retired again early in Oct., the serious defence of the city not being part of the general plan of campaign. After several days' bombardment the Germans entered on Oct. 12 1914 and remained till Oct. 1918, when they were outflanked by the Allied capture of neighbouring towns. The deportation of a large number of citizens in 1916 was the culminating point of tyranny suffered by the people of Lille under German rule. The city was a favourite resort for German officers on leave, as it was not shelled by the Allies, although it was within range of the guns.

LIMA, PERU (*see* 16.689).—During the 20 years ending in 1926, and particularly since 1920, the city of Lima has experienced a series of modernising influences. The population, including that of Callao, was in 1926 estimated at 250,000 and was slowly rising. Many of the narrow streets radiating from Plaza Mayor, the heart of the city, have been paved, and new business houses have been erected, including one of the finest hotels in South America. Large sums have provided modern sanitation, waterworks and sewerage. In the Exposition and other newer parts of Lima, avenues and boulevards radiate from attractive circles and modern parks; there are thousands of ornamental trees, and many fine residences face these modern streets and boulevards. Seaside resorts at La Punta, Chorrillos,

Miraflores and Ancon are growing, and electric car lines and motor vehicles link them with Lima.

The educational system has made marked progress under revised laws. The general increase of Peruvian cotton, sugar, sheep-farming, petroleum, mining and new irrigated areas is the basis of this progress. Revised taxation provides several million dollars annually for highway construction. A motor-car in 1925 succeeded in making the trip over the trail from Lima to Arequipa. Automobiles can now be operated from Lima to Piura. Cement, cotton and other Lima industries are increasing their output, while land values in the capital and suburbs have more than doubled in a decade.

LIMAN VON SANDERS, OTTO (1855–), German soldier, was born in Stolp, Prussia, Feb. 17 1855. Entering the German Army in 1874, he held various posts in the cavalry and in 1913 he was sent to Turkey as leader of a German military mission. His appointment as commander of the I. Turkish Army was annulled on account of Russian protests, but he remained inspector of the Turkish Army. Made a Prussian general in Jan. 1914, in Nov. of the same year he was given the chief command of the Turkish troops in the Caucasus. In March 1915, as commander of the V. Turkish Army, he successfully opposed the British and French attacks on the Dardanelles and the peninsula of Gallipoli. In 1918 Von Sanders succeeded Von der Goltz as leader of the Turkish forces in the Middle East, and was thus in command in Syria and Palestine when General Allenby was victorious there. Von Sanders escaped capture, but after the Armistice he gave himself up to the Allies and was interned until Aug. 1919. He gave an account of his experiences in Turkey in *Fünf Jahre Turkei* (1920).

LINDAU, PAUL (1839–1919), German dramatist and novelist (*see* 16.717), published in 1909 a collection of short stories *Der Held des Tages*. A volume of memoirs, under the title *Nur Erinnerungen*, appeared in 1917. He died in Berlin Jan. 31 1919. His elder brother, RUDOLPH LINDAU, died in 1910.

LINDENTHAL, GUSTAV (1850–), American engineer, was born at Brünn, Austria, May 21 1850, and was educated there, and at Vienna. Having been engaged in railway and bridge work in Austria and Switzerland, he went to the United States in 1871. He was engineer at the Centennial Exposition, Philadelphia, from 1874 to 1877, after which date he practised in Pittsburgh as consulting engineer in railway and bridge construction till 1890, when he moved to New York City. He was commissioner of bridges for the City of New York, 1902–3. He designed and acted as consulting engineer for the steel arch bridge spanning the East river at Hell Gate. This bridge, known as Hell Gate Bridge, was commenced Nov. 1914, and opened for traffic March 1917. With its approaches, it is about $3\frac{1}{2}$ m. in length, and contains the longest steel arch in the world (1,017 feet). Its cost was approximately $18,500,000.

LINDLEY, NATHANIEL LINDLEY, BARON (1828–1921), English judge (*see* 16.719), died at Norwich Dec. 9 1921.

LINDSAY, NICHOLAS VACHEL (1879–), American writer, was born at Springfield, Ill., Nov. 10 1879. In 1897 he entered Hiram College, O., but left after three years to study art in Chicago and New York. For several winters he was a Y.M.C.A. lecturer, and during 1909–10 lectured for the Anti-Saloon League in his native state. Meanwhile he had begun during the summers a series of wanderings on foot which carried him through many states, reciting or singing his own verses like an ancient minstrel and delivering an occasional lecture, receiving in return food and lodging. In 1920 he visited England, where he gave recitals. Many of his poems have the true ballad ring, and are very popular.

His works include *General William Booth Enters Into Heaven, and Other Poems* (1913); *The Congo, and Other Poems* (1914); *Adventures While Preaching the Gospel of Beauty* (1914, prose); *The Art of the Moving Picture* (1915, prose); *A Handy Guide for Beggars* (1916, prose); *The Chinese Nightingale, and Other Poems* (1917); *The Golden Book of Springfield* (1920, prose); *The Golden Whales of California, and Other Rhymes in the American Language* (1920); *Going-to-the-Sun* (1923); and *Going-to-the-Stars* (1926), the two latter being illustrated by the author.

LINDSAY, NORMAN (1879–), Australian artist, was born at Creswick, Victoria, Feb. 23 1879. He began to draw for a Melbourne newspaper at 16, and in 1901 moved to New South Wales where he afterwards lived. He joined the staff of the Sydney *Bulletin*, and became its chief cartoonist, a post which he retained for many years. His chief characteristics as a cartoonist are imaginative power, grim strength, marked individuality of style and a certain coarseness. All of these qualities are apparent in his illustrations to Theocritus, Boccaccio, Casanova and Petronius, the best of which have been collected in *The Pen Drawings of Norman Lindsay* (1918). As an etcher he shows extraordinary facility in the treatment of flesh and massed figures; and he also achieved distinction as a painter in oils and water colours, a lithographer, an engraver and a maker of model ships. In 1925 an exhibition of his paintings was held at the Leicester Galleries, London.

LINDSEY, BENJAMIN BARR (1869–), American judge, was born at Jackson, Tenn., Nov. 25 1869. He was educated in the public schools and attended Notre Dame (Indiana) University and the Southwestern Baptist University, Jackson, Tennessee. At the age of 16 he began to earn his livelihood in Denver, continuing his studies in a law office. He was admitted to the Colorado bar in 1894. In Jan. 1899 he was appointed Public Guardian and Administrator of Denver. He was instrumental in securing the passage of The Colorado Juvenile Court Law of April 12 1899, which gradually changed the whole system of dealing with juvenile offenders in Denver, the change including the establishment of a Juvenile Court conducted solely in the interest of children. He was appointed judge of that court in Dec. 1900, to which he has since been elected for ten consecutive terms. Because of his championship of Juvenile Courts, he earned for himself the name of "the Father of the Juvenile Court." He was also the author of the first parental laws in the United States making the Juvenile Court a Parental and Family Court as well, and also of the "Chancery Court Procedure" in dealing with adult offenders. He wrote *Problems of the Children* (1903); *The Beast* (with Harvey O'Higgins) (1910); *Children in Bondage* (with George Creel) (1914); *Pan Germanism in America* (1919); *The Doughboy's Religion* (with Harvey O'Higgins) (1920); *The Revolt of Modern Youth* (with Wainwright Evans) (1925); *Childhood, Crime and the Movies* (1926) and a large number of brochures dealing with problems of juvenile delinquency, domestic relations and crime. (*See* CHILDREN'S COURTS.)

LINSEED: *see* OILS AND FATS.

LIQUID AIR.—An intensely cold, blue, somewhat magnetic liquid having a density nearly equal to that of water is obtained by subjecting compressed air to the action of intense cold. At atmospheric pressure, air liquefies at a temperature of $-191{\cdot}4°$ Centigrade. The properties of bodies plunged into it are greatly altered; *e.g.*, flowers and other delicate objects become exceedingly brittle and lead becomes hard, elastic and sonorous.

Cailletet Process.—Many unsuccessful attempts to liquefy air were made before M. Louis Cailletet, of Châtillon-sur-Seine, announced to the French Academy, in Dec. 1877, that he had liquefied air by a process in which cooled, compressed air, previously freed from carbon dioxide and moisture, was caused to issue from a nozzle into a receiver so as to expand suddenly; the receiver was made of glass and liquefaction was apparent from the formation of a mist.

Pictet Process.—At the same time, M. Raoul Pictet, of Geneva, working independently, made known his success, achieved by using a cascade or successive temperature-fall process. He obtained a temperature of about $-65°$ C. by the expansion of sulphur dioxide around an arrangement of tubes in which carbon dioxide was being liquefied and then using the resulting liquid to obtain a temperature of about $-130°$ C. around a tube conveying compressed air to a nozzle whence the air issued.

Other Processes.—By both these processes, liquid air was obtained but only to evaporate almost as soon as it was formed. The next achievement was the production of liquid air in quantities large enough to be collected. The importance of using a temperature as low as possible to effect liquefaction was more

fully appreciated and MM. Olszewski and Wroblewski of Cracow used ethylene instead of carbon dioxide in their cascade process and obtained a temperature low enough to effect liquefaction without final expansion of the compressed air. Another cascade process, carried out at the Cryogenic Laboratory of Leyden, under the direction of Prof. Kamerlingh-Onnes, made use of a temperature of −150° C., obtained by using methyl chloride and ethylene. During a long period of experiments, Prof. Dewar made large quantities of liquid air; he usually obtained the successive falls in temperature by means of liquid carbon dioxide and ethylene.

The cascade processes were complicated and too costly for commercial use and were abandoned in favour of improved expansion methods. As early as 1857, Mr. C. W. Siemens obtained provisional protection for an invention for obtaining very low temperatures by causing cooled compressed air to expand in an engine; the cold air thus produced was used to cool the compressed air on its way to the engine, a cold intensifying effect being thus obtained. No complete patent specification was filed and nothing further seems to have been done by the inventor. An apparatus of this type was patented, however, by M. Ernest Solvey of Brussels (British specification No. 13466 of 1885). It comprised an annular chamber in which compressed air expanded while doing work on a piston fitted in an extension of the outer wall of the annular chamber; this chamber was protected by a jacket packed with a thick layer of non-conducting material. It was assumed that, by the cold-intensifying effect obtained, as in Siemens' apparatus, liquefaction of the air would be effected. In practice, however, this did not take place. The difficulties of lubricating and working the engine and the inefficiency of the jacket prevented attaining a temperature below about −95° C.

Linde Process.—A process depending on reduction of temperature during expansion, but not employing an expansion engine was invented by Prof. Carl Linde, of Munich. The apparatus, described in British Specification No. 12528 of 1895, comprises an air compressor communicating with a cooling coil through which the compressed air passes on its way to a reversed-flow heat interchanger, having two tubes of different diameters and about 300 ft. long; one tube is inserted in the other so as to leave an annular space between them and then both are coiled helically. The convolutions are separated from one another and from the outer casing by raw sheep's wool. Cooled, compressed air passes through the inner coil and issues past a regulating valve into an expansion vessel, whence it flows back, through the annular space between the coils, to the compressor. This cycle of operations is repeated until the cold-intensifying effect of the interchanger becomes so great that some of the compressed air is liquefied, as it passes the regulating valve, and collects in the expansion vessel.

Hampson Process.—In his Patent Specification No. 10165 of 1895 Mr. W. Hampson describes an apparatus in which compressed air is passed through a long pipe and expanded to a lower pressure to return in its expanded state over the pipe in such a way as to intensify the cooling produced by the expansion.

Claude Process.—An ingenious process, invented by M. Georges Claude of Paris, employs an expansion engine working in association with a reversed-flow heat interchanger and a liquefying chamber. Pure, cold air at a pressure of about 40 atmospheres passes through the central pipe of the interchanger, and the greater part of this air is led to the expansion engine and expands therein to a pressure of about four atmospheres, while doing external work. The air leaves the engine at a temperature not substantially lower than −140° C., the critical point for air, enters the lower part of the liquefying chamber, circulates around a series of vertical tubes therein and is led away through the outer annular space in the heat interchanger. The smaller part of the pure, cooled, compressed air passes into the upper part of the liquefying chamber, flows through its tubes and is cooled and liquefied, the liquid air falling into the lower part of the chamber, whence it is withdrawn. By this means, the compressed air is not allowed to liquefy in the expansion engine, which can be worked satisfactorily, lubrication being effected, when necessary, by means of petroleum ether. In a modification, compound expansion is employed, an additional expansion cylinder with its corresponding liquefying chamber being provided. According to M. Claude (*Comptes Rendus*, vol. 142, p. 1335), the output of liquid air may be as much as 0·66 litre per horse-power hour in the single expansion and 0·85 in the compound process.

Manufacture of Oxygen.—The most important use of liquid air is in the manufacture of large quantities of commercially pure oxygen. Prof. Linde, in his British Patent Specification No. 12528 of 1895, describes a process and apparatus, working in association with his liquefying apparatus, for obtaining oxygen from the liquid air by fractional evaporation, the nitrogen being driven off first, since its boiling-point is about −194° C. while that of oxygen is −182·5° C., at atmospheric pressure. The products were substantially pure oxygen and nitrogen mixed with a rather large quantity of oxygen. The purer the oxygen obtained the less was the yield. To remedy this disadvantage, Prof. Linde, in a later improvement, treated the liquid air in a rectifying column and completed the process of separating the oxygen and nitrogen by a fractional evaporation.

Other Gases.—Since the introduction of Linde's process for obtaining oxygen, numerous inventions have been patented for obtaining oxygen, nitrogen, argon, helium, neon, xenon and krypton from the air. In the processes of M. Claude and La Société l'Air Liquide, the air is not liquefied as a whole but in such a way that it yields two liquid portions, one rich in oxygen and the other very rich in nitrogen; each of these liquid portions is rectified so as to obtain oxygen and nitrogen of a high degree of purity. For further information the reader is referred to the reports on the cross-action in the Chancery Division and the Court of Appeal between British Liquid Air Co., Ltd. and British Oxygen Co., Ltd. (*Reports of Patent Cases*, 1908, pp. 218–44; 577–614).

Liquid air is applicable for cooling objects which are required to be hooped and for fitting metal tubes into a tube plate having holes too small to receive the tubes. The use of liquid air as a motive fluid has been often proposed. An early use of liquid air was in the preparation of explosives, some of which were used during the construction of the Simplon Tunnel. Liquid air has also been used in mine rescue apparatus.

LIQUOR CONTROL (*see* 16.759).—In this article it is proposed to give the outlines of restrictive legislation in respect to liquor except as regards prohibition in the United States, which is treated under PROHIBITION. *See* also BOOTLEGGING.

I. IN GREAT BRITAIN

In 1913 the Act was passed granting, *inter alia*, local option to Scotland. The Act provided that one-tenth of the electors of the area concerned could demand a poll to decide on the conditions of sale of intoxicating liquor. If 55% of the poll and 35% of the electors voted for no-licence the resolution to that effect would be carried: for a limitation of licences a bare majority of the poll and the votes of 35% of the electors would be sufficient. The third alternative to be put before the electors in each case was a resolution for no change. The local option sections of the Act did not come into operation until 1920; the result of a poll thereunder is binding in the area concerned for three years, and no further poll can be taken during that time.

Defence of the Realm Regulations.—The outbreak of the European War, in 1914, at once raised the question of the necessity of some form of liquor control alike in the interests of efficiency in the fighting forces and amongst civilians engaged in munition works and other vital industries, and of economy in the provision of essential supplies. The Defence of the Realm Act 1914 authorized the creation by Orders in Council of new authorities to provide for the safety of the Realm, and the delegation to such new or to existing authorities of power to issue regulations for the same purpose.

Under this Act regulations were immediately passed empowering competent naval and military authorities to control the opening of licensed houses in the neighbourhood of defended

harbours, and forbidding the sale or supply of intoxicating liquor to members of H.M. forces on duty or with intent to incapacitate them for duty. By further regulations in subsequent years the same authorities were to close down or regulate the opening of licensed houses and to prohibit trading within the area under their control, and received further special powers over dockyards. In 1916 a general order was made under the Act prohibiting the supply of intoxicating liquor to members of the fighting forces on duty or in hospital. When the food shortage became acute, the Food Controller imposed stringent restrictions on output in 1917–8.

Liquor Control Board.—The Liquor Control Board was created in June 1915, as the authority empowered under the Defence of the Realm Act (No. 3) 1915 to issue regulations under the 1914 Act to control the liquor trade in any district to which such control should be applied by Order in Council. The board was armed with wide discretionary powers including those of closing down licensed premises and clubs, regulating the hours of opening irrespective of the provisions of the Licensing laws, prohibition of the sale of specific liquors and of treating, and generally of regulating the supply and sale of intoxicating liquor. The control by the board was first applied to the Lowlands of Scotland and the more important shipbuilding and industrial centres in England, but it was subsequently extended until, by the middle of 1918, it had been applied to 29 areas covering in all three-quarters of England, Scotland and Wales.

In these areas the Board reduced the permitted hours of sale of all intoxicating liquors on week-days, which before the War had ranged from 19½ hours in London to 11 hours in Scotland, to a general maximum of 5½ hours for consumption on licensed premises and 4½ hours for off-sales, with a further reduction on Sundays of half an hour in each category. In the case of spirits the off-sale was further curtailed to 2½ hours 5 days in the week, and was prohibited altogether on Saturday and Sunday. In certain areas in the North and West of Scotland the sale of spirits was, at the instance of the Admiralty, prohibited absolutely and this prohibition remained in force until 1919. The Board further introduced compulsory dilution of spirits: spirits which before the War were retailed at 25° below proof (or 35·91% pure alcohol) were obliged to be diluted to 30° below proof (or 33·37% pure alcohol), and were permitted to be sold at 50° below proof (or 23·49% pure alcohol). Further regulations were made forbidding treating and extending existing provisions against credit sales of intoxicating liquor in licensed houses and clubs, and making illegal the common practice in the trade of giving an excessive measure to customers known as the "long pull."

Previously to the special powers given to the Liquor Control Board, extended powers had been given to the licensing justices by the Intoxicating Liquor (Temporary Restriction) Act 1914, but in view of the wider powers exercised by the Board these are comparatively unimportant. Many of the Board's regulations continued in force after the termination of hostilities in 1918, and the Board was not finally abolished until the passing of the Licensing Act of 1921.

Licensing Act 1921.—That Act, which applied to both England and Scotland, adopted and made permanent some of the regulations which the Board had instituted, notably the prohibition of the "long pull" and of credit sales in the case of "on" consumption. The Act fixed the permitted hours of sale at 9 hours in London and 8 hours elsewhere, between 9 A.M. and 11 P.M. in London, or 10 P.M. elsewhere, and made them applicable not only to licensed premises, but also to registered clubs which before the War had been free from such restrictions. The times of opening of licensed premises within the fixed limits were left to the discretion of the local licensing authorities, and in clubs at the option of the members, the hours so fixed to be included in the rules. The Act also encouraged dilution by permitting all spirits to be sold without special notice at 35° below proof, instead of the standard of 25° below proof required before the War for all spirits except gin. On the other hand beer of an original gravity not exceeding 1·016° and containing not more than 2% of proof spirit was by the Act not to be treated as intoxicating liquor, and no excise duty was required for its sale.

Sale to Young Persons.—In 1923 a bill was introduced in the House of Commons by a private member, Lady Astor, and became law, prohibiting the sale of intoxicating liquor to young persons under 18 for consumption on licensed premises, with a slight modification allowing certain non-spirituous alcoholic drinks to be served with a meal in the case of young persons over 16.

The Carlisle Experiment.—An important experiment of the Liquor Control Board, which has remained as a permanent institution, was the introduction in 1916 of a system of state purchase and state supply of intoxicating liquor in certain areas. It was first tried in the Carlisle area to combat drunkenness amongst the many thousands of munition workers drafted into the district for the new factories around Gretna. In view of the differences in English and Scottish licensing law, Gretna and Carlisle were made into separate districts for administration, and a third district was subsequently created when the experiment was extended to the area of Cromarty Firth including Dingwall and Invergordon. The working of the system was in the hands of the Board with the assistance of local advisory committees. On the final abolition of the Board its functions were taken over by the Home Office and the Scottish Office respectively.

The system was to purchase all breweries and licensed premises in the districts for agreed sums by way of compensation. Some of the breweries so purchased were closed down, the number in the Carlisle district alone being reduced from five to three, with considerable saving in working expenses in all cases, and the number of licences was cut down by nearly one-half. In addition all grocers' licences were suppressed, and facilities for "off"-sales reduced by about 80%. Many of the licensed premises retained were renovated, and where possible considerable structural improvements were made to allow for the provision of cheap and good meals; and disinterested management was completed by the appointment of salaried publicans who received commissions only on the sale of food and non-alcoholic beverages, and did not have to consider the interests of shareholders or of brewers or of competitors. Under this system no liquor advertisements are displayed on licensed premises, and no money is spent in advertising intoxicants either in newspapers or on hoardings. Further no money made out of the sale of intoxicants can be subscribed by the department which is responsible for providing drink to any political organisation or to any anti-temperance propagandist body.

II. MEASURES IN OTHER EUROPEAN COUNTRIES

Denmark.—A comprehensive licensing law came into force in Denmark on Jan. 1 1913. The new law had for its object the effective regulation and control by the municipal and communal authorities of all places of entertainment where meals, lodgings, refreshment, etc., are provided. A distinction in the regulations was made, as in other Scandinavian countries, between urban and rural districts.

The new law established "off" and "on" licences for the sale of "strong drinks" which included spirits, wines and all beers which contained 2¼% or more alcohol. Special licensing boards were constituted in each municipality, to whose discretion the allocation of licences was absolutely entrusted. The licences which might be issued by the licensing boards were to be for life or a fixed term of years, and all licensed premises were to be closed for at least five hours between 11 P.M. and 8 A.M. The age limit below which it was forbidden to supply young persons with strong drinks was to be fixed by local police regulation. In no case was the limit to be lower than 16, and only in four towns is it as low. Stringent penalties were enacted for violation of the Licencing Law, including heavy fines, imprisonment and forfeiture of the licence.

During the War, the distillation of spirits from home-grown wheat or rye was prohibited, though not from potatoes. An important law which came into operation in 1925 fixes the number of licensed premises in existence on Jan. 1 1924 as the maximum. New licences are subject to a form of local option, and the local authorities are empowered to restrict the issue of a new licence to a public utility company on the Gothenburg principle.

Iceland.—From 1912 there has been complete prohibition of the import or manufacture of liquor containing more than 2¼% of alcohol with limited exceptions for medical and industrial

use. A slight relaxation has, however, since been made, under pressure from Spain, to permit the importation of Spanish wines.

Sweden.—An important piece of liquor legislation was the law of 1917 which made the "Bratt System" universal throughout Sweden. This system of liquor control, which came into force throughout Sweden on Jan. 1 1919, was a striking development, on the basis of the "Gothenburg System" of disinterested management through controlling Companies, or "Bolags." The "Gothenburg System" had been confined to the control of the retail sale and distribution of the national spirit or "bränninin." The sale of wine, beer and imported spirits had been outside its monopoly.

The effect of the new law was to bring the retail liquor trade—the trade in ordinary beer excepted—under the control of the System companies. All intoxicating liquors of an alcoholic strength greater than 3·6% were thus affected. The beer manufactured and sold in Sweden is below that strength.

The transfer of "off" spirit licences was abolished; the import of spirits, wines and beers was only permitted through the agency of the "Bolags"; and the maximum amount of spirits purchasable by each citizen was limited to 4 litres *per mensem*. A new age limit was fixed, and persons under 21 and sometimes 25 were not allowed the right to purchase distilled liquor. Convicted drunkards were also debarred from purchasing intoxicants.

The private trader, however, still retained his interest in the wholesale liquor trade. The organisation of the wholesale trade under the System Companies was brought about through an enterprise founded by Dr. Bratt and his associates in 1917, called "Spritcentralen," which, by an enactment in 1923, obtained from the Government the right to the exclusive wholesale sale of liquors other than beer until 1928. The system worked by the "Bolags" is one of personal control, in which the "motbok" or pass-book, plays a large part. The "motbok," in effect, is a ration book with coupons entitling the holder to purchase his prescribed quantity of liquor in each month, and no more.

Norway.—A system of disinterested management has also been in force in Norway for a considerable period. The "Samlag" in Norway takes the place of the "Bolag" in Sweden, though its powers are more limited. The "Samlags" control the sale of "Braendevin," the national Norwegian spirit, whilst beer and wine, except in rare instances are still in the hands of private traders.

The Norwegian system, based on the Acts of 1871 and 1894, left two options open to each community at the periodical poll:

1. The "Samlag" system for the retail sale of spirits, or
2. Prohibition of all retail sale of spirits.

The results of the 1913 polling showed a definite voting down of existing "Samlags": out of 26 towns polling, the "Samlag" was voted down in 15.

But, outside the "Samlags," the sale of spirits is conducted by means of "privileged" (*i.e.*, life interest) licences, wholesale rights and special "off" and "on" licences issued by magistrates and town councils.

During the war period Norway imposed far-reaching restrictions, leading up to the total prohibition of the sale of spirits, both "on" and "off." The continuance of prohibition was endorsed at a national poll in 1919.

III. TEMPORARY WAR REGULATIONS

Liquor legislation in other European countries, since 1911, has mainly been concerned with the imposition of special restrictions during the War period, and the subsequent modification of those restrictions.

France.—In France, for instance, the need for some control of the liquor traffic was recognised soon after the outbreak of the War, and one of the first War-time restrictions was the absolute prohibition of the sale of absinthe in Feb. 1915.

The opening of new establishments for the sale of spirits and other liquors (except those having a wine basis) was also forbidden. In 1915, the "off" sale of alcohol was forbidden before 12 noon, and the "on" sale of spirits to women and children was absolutely prohibited. The sale of wine, beers and cider was, however, left untouched. The War regulations have since disappeared.

Switzerland.—On the outbreak of War the Swiss Government prohibited the use of potatoes for the manufacture of spirits, and rationed the sale of spirits by the state monopoly.

Italy.—In 1913 Italy prohibited the importation and manufacture of absinthe and enacted a law requiring special permits for the sale of spirits and liqueurs.

Germany.—In Germany the sale of alcohol was forbidden in the towns during the early mobilisation period; and restrictions were placed on the quantity of malt used in German breweries. Subsequently, in 1915, further restrictions were imposed:

1. The manufacture of spirits for beverages from potatoes and grain was prohibited.
2. The manufacture of beer was restricted by 40 per cent.
3. The sale of intoxicants in mobilisation centres was forbidden.
4. In Berlin the sale of spirituous liquors in restaurants was forbidden between 9 P.M. and 9 A.M.

Austria-Hungary.—Similar restrictions on the manufacture of spirits from potatoes and grain were imposed in Austria-Hungary during the continuance of the war emergency period.

Russia.—In Russia, the fact that a Government monopoly of the vodka trade had been established in 1894, enabled the Tsar to establish its total prohibition on the outbreak of the War. This state of things continued under the Soviet *régime* until 1921, when the sale of wine in limited quantities was authorised, whilst the sale of beer was permitted without limitation.

In 1924, by a decree of the Soviet Executive Council, the sale of vodka was permitted once more. The sales are restricted by a card system of control, under which each adult citizen is entitled to purchase one bottle of vodka every 14 days through the agencies of the state spirit monopoly.

Finland.—The prohibition of vodka throughout the war period applied also to Finland and to Estonia. The prohibition of beer over 2¼%, of wine, spirits and stronger beverages was enacted in Finland in 1919, and is still in force.

Estonia.—In Estonia, however, legislation was passed in 1920 for the repeal of prohibition and for the substitution of a "Check" system for the controlled sale of alcohol, somewhat on the Swedish model.

Belgium.—On the outbreak of War in 1914 the Government took prohibitive measures against the sale of spirits which continued in force during the German occupation. In Aug. 1919 an Act was passed prohibiting the sale and supply of spirits for consumption on the premises in any place of public resort, including hotels, restaurants and workshops. The "off-sale" of spirits was authorised provided that at least two litres were sold at a time to each purchaser. This Act was a modification of a scheme of total prohibition which had been promulgated by decree only when the Government had its seat at Havre in Nov. 1918.

In Poland in 1921 a law was passed introducing the local option principle. In 1924 a Government monopoly of the liquor trade was established under which the Government assumed the entire control of the manufacture and sale of all spirits.

Latvia and Lithuania have adopted laws regulating hours and conditions for the retail sale of alcohol.

For the supply of intoxicating liquor in mandated territories, *see* MANDATES.

IV. THE UNITED STATES AND CANADA

The article on Liquor Laws in the United States (*see* 16.766) reviews legislation prior to 1910 in its historical development and under the four chief types of state and local legislative control: (*a*) the licence system, (*b*) state prohibition, (*c*) local option, a combination of licence and prohibition, and (*d*) public dispensaries. It also covers Federal regulation of the liquor traffic: (*a*) in inter-state commerce, (*b*) in Federal territory, such as the District of Columbia, military and naval stations, Indian reservations, and in certain particulars in the insular possessions, and (*c*) the revenue laws where regulation is frequently a dominant motive in tax policy. Since 1910 there have been hundreds of state laws, local ordinances and Federal laws, not directly related to the adoption of national prohibition (*q.v.*) as well as many important decisions of Federal and State Courts. This further illustrates the great diversity of procedure and methods and the wide range of legislative experiment in dealing with the liquor traffic and its attendant evils, which probably has no equal in any other country in the world or in any other period of history. It also reflects the very great difficulties encountered in the enforcement of such legislation and in correcting unforeseen evils arising as by-products of regulatory measures. A fairly complete and accurate descriptive list of these measures will be found under "Chronology" in the Year Books of the Anti-Saloon League (pub. Westerville, O.) especially the Year Book for 1919.

The 18th Amendment.—War-time prohibition became effective on July 1 1919, and the Prohibition (18th) Amendment to the Constitution was ratified Jan. 16 1919, effective Jan. 16 1920,

and the combined War-time Prohibition Enforcement Code and the Constitutional Prohibition Enforcement Code, known as the "National Prohibition Act" and, popularly, as the Volstead law, was adopted Oct. 28 1919, in part effective immediately and in part relating to constitutional prohibition effective Jan. 16 1920 (*see* PROHIBITION).

As far as state and local measures (1910–9) are concerned there were no new devices for regulation, and nothing to show any serious departure from the types of regulation referred to above, and discussed in the previous article. There was a noticeable trend away from the public dispensary and the many proposals to eliminate private profits from the industry or the trade, such as those involved in the Gothenburg system, which was widely discussed, and licensing non-profit trading companies. There was also a marked and increasing trend in all sections of the country toward the extension of dry territory, the protection of dry areas under local option, and the extension of state-wide prohibition.

State Prohibition in 1910.—In 1910 state prohibition was in force in nine states. Large areas of local territory in other states were dry under local option. It was difficult to protect this dry territory from violation through illicit trade aided and promoted by adjacent wet areas. Texas in 1910 passed a law making the sale of liquors in no-licence territory a felony punishable by from three to five years' imprisonment. All the prohibition states had tried in various ways to check the flow of liquor protected in inter-state commerce over which the Federal authority had exclusive jurisdiction and with which no state had any constitutional right to interfere. Congress had sought to aid in this effort in the Wilson Act in 1890 to divest intoxicating liquors of their inter-state character by providing that "Liquors transported into a state . . . shall . . . upon arrival in such state . . . be subject to the operation and effect of the laws of such state enacted in the exercise of its police powers, to the same extent . . . as though such . . . liquors had been produced in such state."

Although the Wilson Act presented grave constitutional difficulties it was sustained by the Supreme Court in *In re Rahrer* in 1898 (140 U.S. 545) but the rule of the decision interpreted the phrase "upon arrival in such state" to mean that state control and regulation operated only "after the shipment had reached its point of destination and had actually been delivered to the consignee." This was not sufficient to stop the flow of liquor from wet areas outside the state. A Missouri statute imposing an inspection fee on all liquors shipped from other states into Missouri and offered for sale was upheld in 1905 (190 U.S. 17) as an exercise of the police power of the state within the meaning of the Wilson Act, and the chief aim of the Act was undoubtedly to increase the state's control over inter-state shipments. The Iowa Legislature had in the previous year 1904 passed a resolution asking Congress to amend the inter-state shipment law to prevent the shipment of liquors from one state to the dry territory of another.

In the meantime the Supreme Court in *Delameter v. So. Dakota* (205 U.S. 93), decided March 11 1907, upheld a South Dakota statute imposing an annual licence charge upon the business of soliciting orders for intoxicating liquors and its application when orders were to be filled from liquors at the time without the state. This was another method of checking inter-state traffic from wet areas to dry and of enforcing state regulation or prohibition. Still another effort was made in the same direction and this time with the direct assistance of Congress in the Act to codify, revise and amend the penal laws of the United States approved March 4 1909. Section 238 forbade any transportation company or its agents to deliver intoxicating liquors in inter-state or foreign commerce to any fictitious person or to any other person than the consignee, unless upon written order of the bona-fide consignee, and Sec. 239 forbade the collection by the transportation company or its agents of the purchase price or in any manner acting as the agent of the buyer or seller of such liquor, and Sec. 240 forbade the shipment in inter-state or foreign commerce of any package containing intoxicating liquors unless "such package be so labelled on the outside cover as to plainly show the name of the consignee, the nature of its contents and the quantity contained therein." Each of these sections provided heavy penalties for their violation.

The Webb-Kenyon Law.—With the passage of the Webb-Kenyon law, March 1 1913, Congress and the Federal Government took the first aggressive step in aiding effective state prohibition. The title of the Act, "An Act divesting intoxicating liquors of their intra-state character in certain cases," indicates its broader scope and purposes as compared with the earlier Wilson Act which merely removed the bar of the Original Package decision (1890) to effective enforcement by holding that a state prohibitory law was inapplicable to sales of liquor in the original packages in which they were received from other states (*Leisy v. Harden*, 135 U.S. 100). The Webb-Kenyon Act removed another bar, namely, the Federal protection of inter-state commerce, from the exercise of a state's conceded powers over inter-state when applied to such inter-state commerce as Congress, in the exercise of its exclusive powers over inter-state commerce, has interdicted or from which it has removed the protection of inter-state commerce. Congress in this Act forbids the transportation of intoxicating liquors into a state by any persons interested therein "to be received, possessed, sold, or in any manner used, either in the original package or otherwise, in violation of any law of such state." The Act presented grave constitutional difficulties, which led President Taft to veto it on purely constitutional grounds, and in this judgment he was supported by his able attorney-general, Mr. George W. Wickersham, and the ablest lawyers in the Senate. Nevertheless, Congress passed the Act over the veto of the President, and the Supreme Court sustained its view in the Clark Distilling Co. v. Western Maryland Railway Co., and Clark Distilling Co. v. American Express Co. and the State of West Virginia cases (242 U.S. 311) decided Jan. 8 1917.

Effects of Webb-Kenyon Law.—The immediate effect of the Webb-Kenyon law was to stimulate state prohibition. The year 1914 saw state constitutional prohibition amendments adopted by popular vote and substantial majorities in Arizona, Colorado and Washington, and rejected by substantial majorities in California and Ohio. A state-wide prohibition law in Oregon was adopted by a popular vote of 136,842 for, to 100,362 against, and in Virginia by a majority of 30,365 out of a total of 150,000 votes. A considerable extension of dry territory was secured under local option votes in many other states. That this rising tide of prohibition was not confined to the states is seen in the adoption for the first time in 1914 in either House of Congress of a resolution submitting a prohibitory amendment to the Federal Constitution. The Hobson resolution passed the House of Representatives Dec. 22 by a vote of 193 to 189, but did not receive the two-thirds majority required. In 1915 Alabama re-enacted a prohibitory law which was adopted in 1907 and repealed in 1911, and Idaho, Iowa, Arkansas and South Carolina adopted state-wide prohibitory laws, Idaho, in addition, submitting to the people of the state a constitutional amendment, which was adopted in 1916 to become effective Jan. 1 1917.

The year 1916 also witnessed constitutional state prohibition adopted in Michigan, Montana, Nebraska and South Dakota. In 1917 Congressional action again moved forward. The resolution for the prohibition amendment to the Federal Constitution received the necessary two-thirds majority in both Houses, and the amendment was submitted to the states for ratification. Congressional enactments also prescribed prohibition for the District of Columbia and for the territory of Alaska. A referendum on prohibition was provided for the I. of Porto Rico, which voted in July 1917 to adopt it by 99,775 for, to 61,295 against. Early in 1917 Congress enacted the anti-liquor advertising law with the so-called Reed "bone-dry" amendment, the whole being an amendment to the Post Office Appropriation Act. This was a drastic prohibition of the use of the mails for advertising, or soliciting orders for liquor in "dry" territory, and was, therefore, a further application of the principle of the Webb-Kenyon Act.

Among the states in 1917 Indiana, New Hampshire and Utah adopted state-wide prohibition statutes, and New Mexico a prohibition constitutional amendment. This made in all 25 of the 48 states, and, in addition the District of Columbia, Alaska and Porto Rico, which had adopted statutory state-wide or constitutional prohibition before the Federal Amendment was submitted for ratification; and in 1918, while ratification was proceeding, Florida, Nevada, Ohio, Texas and Wyoming adopted state-wide prohibition statutes. Utah adopted a prohibitory amendment to the state Constitution. Congress enacted a prohibition statute for Hawaii, and passed the War Prohibition Act as an amendment to the agricultural appropriation bill. A constitutional prohibitory amendment received a majority of 15,932 votes in Minnesota, but failed by 756 votes to receive the majority required by the state election law. A constitutional state prohibition amendment was defeated in Missouri by 300,354 votes against, to 227,501 for; and also in California. Other state measures extended dry territory, and in several states state constitutional amendments were submitted to be voted on in 1919. The war prohibition Federal legislation is noted under *After Ratification-Provisions for Enforcement* in the discussion of prohibition (*q.v.*).

State Action Since 1919.—From Jan. 10 1919, the date when the Federal Constitutional Amendment received the necessary ratification by two-thirds of the states, to 1926 state legislation in relation to prohibition, chiefly consisted in state enforcement measures of great variety based on the concurrent powers provided for in the amendment although in some states, a state constitutional amendment or state-wide prohibition statutes, previously adopted went into effect by their terms after Jan 1 1919. In all to date (1926), 47 of the 48 states (Maryland alone excepted) have adopted state codes or measures to enforce national prohibition. New York alone has repealed such a statute; and no other state has weakened its enforcement legislation by subsequent amendments, and several have repeatedly tried to strengthen their enforcement legislation.

The Laws in Canada

Liquor laws in Canada have followed closely in structure and in the forces determining their modification and enforcement those of the United States. They have not gone as far as to adopt national prohibition except for a brief period during the War, by Order-in-Council, March 11 1918, in force from April 1 1918 until Dec. 31 1919. Since 1910 local option with respect to licence extending to complete provincial prohibition of sale has been permissible under a Federal law, the Canada Temperance Act (1875). But under the British North America Act, which serves as the Constitution of the Dominion, only the Federal authority can prohibit the manufacture, importation, exportation and transportation of liquors for beverage purposes. On May 18 1916 a Federal Act "in aid of Provincial Legislation prohibiting or restricting the sale or use of intoxicating liquors" (6–7 Geo. V. Ch. 19) was adopted and penalised the transportation and delivery of intoxicating liquor or sale for transportation into a province in violation of the law of the province. This effort to remove "Federal protection" from manufacture and shipment, legal under Dominion law, of intoxicating liquors whose sale was prohibited under provincial law or local option votes, was similar to the Wilson and Webb-Kenyon Acts in the United States. This Act was amended Nov. 10 1919 (10 Geo. V. Ch. 21) to include manufacture for illegal sale; but an amendment, adopted on the same day, to the Canada Temperance Act (10 Geo. V. Ch. 9) added Part IV., "Importation and manufacture of intoxicating liquor," and provided an alternative plan which it was thought would be more effective and better applicable locally to accomplish the same purpose. It provided for prohibition of importation and of manufacture for illegal importation in any province by Order-in-Council after an approving referendum had been taken by the Dominion Govt. at the request of the provincial Legislature.

Referenda in All Provinces.—From Feb. 1 1921 to May 21 1923 seven of the nine provinces decided by referenda to prohibit importation. Similarly exportation of liquor from any province, except by brewers and distillers, could be prohibited by Order-in-Council under a further amendment of 1923. Four provinces in 1922 and 1923 invoked this law. Neither the importation nor exportation prohibitions were sufficient without a real Federal prohibition law to enable the provinces to enforce satisfactorily their province-wide prohibition laws after the Dominion declared the War prohibition for the Dominion at an end. So three of the seven prohibition provinces swung over to state control, and there were in 1926 only four (Ontario, New Brunswick, Nova Scotia and Prince Edward Island) wherein prohibition of sale continues. In Feb. 1925 an amendment to the Ontario Temperance Act permitted the sale of 4·4 beer, which does not seem to have made the enforcement of the prohibitory features of the Ontario Temperance Act any easier. Government ownership and sale or state control take various forms in the different provinces. The amount of liquor sold seems to have increased each year since 1921, when British Columbia adopted the system of government warehouses and salesrooms with public liquor stores, only on a local vote which has been favourable thereto, only in the larger cities and towns; and there is said to be little or no curtailment of illegal sale and the abuses therefrom. In Quebec, Manitoba, Saskatchewan, Alberta and British Columbia liquor is sold under government regulations.

See Prohibition and the authorities cited there in addition to the following: U.S. Bur. of Int. Rev., *Laws relating to National Prohibition Enforcement* (1923); Laws of 65th and 66th Congresses relating to Liquor (contains text of laws of previous Congresses since 1890) and Regulations No. 60, app. by Secy. of Treas. Jan. 16 1920, under Prohibition Enforcement Act, 1920; Anti-Saloon League Year Books (1910–25); Ernest H. Cherrington, *Evolution of Prohibition in the U.S.*, a chronological history (1920); *Prohibition and Its Enforcement*, Annals American Academy of Political Social Science, vol. 109 (Phila., 1923); T. (S. McC. L.)

LISTER, JOSEPH LISTER, Baron (1827–1912), British physician (*see* 16.777), died at Walmer, Kent, Feb. 10 1912.

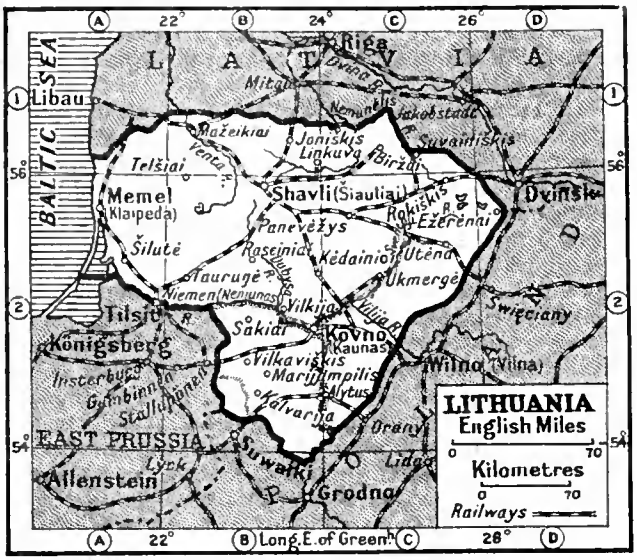
LISZT, FRANZ VON (1851–1919), German jurist, a younger cousin of the composer, Franz Liszt, was born in Vienna March 2 1851. He qualified in 1875 as a teacher of criminal law at Graz in Austria, was a professor at Giessen 1879, Marburg 1882, Halle 1889, and in Berlin in 1899. In 1912 he became a member of the Fortschrittliche Volkspartei (Progressive People's party) in the Reichstag. Liszt's life work was the scientific foundation and reform of the criminal law of which the basic principles are contained in his treatise *Der Zweckgedanke im Strafrecht* (1882). It opposes the principle of regarding punishment as a reprisal and sets up the claim of systematic prevention of a special nature. In the fight against the law breaker, Liszt, together with the Dutchman Van Hamel and the Belgian Prins, founded the *Internationale Kriminalistische Vereinigung* (International Criminalist Union) in 1889 in which all reforms, which became the basis of modern criminal law, were initiated. Liszt's claims in favour of conditional sentence and pardon as well as postponement of punishment later passed into actual practice. At Marburg he created the Criminalist Seminary, which later in Halle and especially in Berlin became a world-famed criminal institute at which students from all lands met. Liszt was also a leading authority on international law. He died at Seeheim June 22 1919.

His chief works are *Meineid und falsches Zeugnis* (1876); *Lehrbuch des deutschen Strafrechts* (1881, 21st ed. 1919); *Lehrbuch des Völkerrechts* (1898, 11th ed. 1918); *Strafrechtsfälle zum akademischen Gebrauch*, 13th ed. (1922); *Strafrechtliche Aufsätze und Vorträge* (1905). See also *Abhandlungen des Kriminalistischen Seminars* (1889, etc.); *Mitteilungen der Internationalen Kriminalistischen Vereinigung* (1890, etc.).

LITHUANIA (Lietuva), an independent European republic and a member of the League of Nations (*see* 9.916). Lithuanian territory includes the former Russian Govt. of Kovno (Kaunas), parts of Suvalki and Vilna governments and the autonomous territory of Memel. The land frontiers are with Latvia on

the north, Poland on the east and the south, and East Prussia on the southwest. The Lithuanian seaboard is short, but is extended by the addition of Memel. The town and territory of Vilna (Wilno), claimed by the Lithuanians as part of their state, is incorporated in Poland (*see* VILNA). The area is (1926) 22,500 sq. m. and the population, 1924 (excluding Memel), 2,203,312, of whom 83·9% were officially given as Lithuanians, 7·6% as Jews, 3·2% as Poles and 2·5% as Russians.[1] The town of Memel includes 24,000 Germans.

Lithuania is, on the whole, a low-lying country watered by the Niemen ("Nemunas"—name of a heathen deity) and its tributaries. The highest part is in the south and east, where the Baltic hills extend in crescent formation from Gumbinnen in East Prussia through Suwalki (Suvalki) and Vilna (Wilno) to Dvinsk. This chain of hills is broken by two valleys, that of the Niemen



flowing through Grodno and Olita (Alytus) to Kovno, that of the Wilija (Nerys), flowing from Vilna to Janow (Jonaya) to its junction with the Niemen below Kovno. In the northwest is situated another triangle of hills, the Telšiai-Shavli (Šiauliai)-Raseiniai. Between these two hilly regions lies the plain of the Niemen with its two principal tributaries, the Nevežis and the Dubysa flowing in from the north. The only other river of importance is the Šventoji, flowing southwest to join the Wilija near Janow, and in the north the Muša, which joins the Aa (Lielupe) at Bauska in Latvia.

I. POLITICAL HISTORY

Early History.—(*See* 16.789.) The union between the kingdom of Poland and the grand duchy of Lithuania was brought about on Feb. 14 1386 by the marriage of the Lithuanian Grand Duke Jogaila (Jagiello) to the Polish Queen Jadviga, and was confirmed by the subsequent pacts of Vilna in 1401 and 1432, of Horodlo in 1413, of Grodno in 1501 and 1512, and, parliamentarily, of Lublin in 1569. Thus was established a political combination in which Lithuania in point of territory was three times the size of Poland. The contracting parties were to retain their names, laws, administrative institutions, financial and military organisations. Through the fact, however, that from 1501 onwards the Lithuanians and the Poles were ruled over by one sovereign and from 1569 onwards had a common legislature, the Lithuanians, though ever anxious to break away, gradually sank into a state of dependence. The Poles, past-masters in the art of political intrigue, never lost an opportunity of imposing their hegemony. Accordingly the dual state was involved in a common downfall, and in the three partitions of 1772, 1792 and 1795, to which it was subjected at the hands of Russia, Prussia and Austria, Lithuania fell a prey to Russia and Prussia. But, while the Tsarist régime, unable to denationalise a homogeneous population of a different religion and language, initially conceded a minimum of rights to the Polish nation, in Lithuania proper from the outset an unrelenting system of tyranny was established which was designed to break by force every non-Russian element in the country.

Russia had annexed the six Lithuanian governments between 1772 and 1795 and united them as the "Litovskaya Gubernia" in 1797, that is to say, before the Treaty of Vienna conceded her the kingdom of Poland in 1815. At the Warsaw diet of 1818, the liberal-minded Alexander I. still spoke of the reunion of Lithuania with Poland under constitutional forms. But the project lapsed because any measure of self-government by extending the power of the Polish "szlachta" (land-owning noble class) in Lithuania menaced Russia's influence in that country. Yet, under the influence of the Polish Prince Adam Czartoryski, Alexander I. encouraged education and enterprise. Under Nicholas I., the plan of the reunion of the two States was definitely rejected, his ukase of 1839 making Lithuania the "Syevero-Zapadni Krai" (northwestern Province).

As a result of the Polish rebellion of 1830, in which the peasantry, whether Lithuanian, Polish or White Russian, did not take so great a part as the upper classes, the Lithuanian Statute, which had remained the law of the land through four centuries of union with Poland, was replaced by the Russian code in 1840. Prominent Lithuanians were forced to emigrate or exiled to Siberia. As even the reign of Alexander II. brought no change in Lithuania, the revolutionary spirit led to the great rebellion of 1863.

This abortive insurrection, in which the Polish nobility and intelligentsia were primarily involved, though the Lithuanians also took a prominent part, led to the suppression of the printing of Lithuanian books by the dictator Gen. Muraviev, which measure was only abolished in 1904. Tsarist policy was henceforth perfectly consistent in that it strove to make Lithuania a genuine part of Russia and sought to extirpate Polish culture beyond the frontiers of the kingdom.

Period of Popular Representation 1905–14.—Russia's defeat in the Russo-Japanese War and the revolution which followed in its wake led, in Sept. 1905, to a measure of reform. The first National Lithuanian Assembly which, however, in the eyes of the Tsar's Govt. was merely a revolutionary body tolerated for the time being, met at Vilna. It consisted of 2,000 delegates who demanded an autonomy for the four governments of Vilna, Kovno, Grodno and Suvalki under a Diet at Vilna. It was the first modern attempt to define Lithuania ethnographically, to respect national minorities and continue the connection with Russia upon the federative principle. The electoral statute of 1905, by granting the four-class franchise (landowners, peasants, townsmen and workmen) favoured the rural population. Only Poles were elected to the first Duma of 1906.

As the Imperial ukase which followed the dissolution of the second Duma of 1907 conferred more power upon the great landowners, it was modified as regards Lithuania by a nationality clause which provided that the total of electors of each class should be in proportion to the amount of land possessed by the respective nationalities in the district. This measure, applied by Russian officials, was designed against the Poles and the Lithuanian Nationalists, for not even the Progressives who favoured autonomy for Poland contemplated its grant to Lithuania. In the third Duma the five delegates allotted to the non-Russian population of the government were all Poles who joined the Polish party; in Kovno three delegates were Lithuanians, one was a Pole and one a Jew.

The War Period.—The outbreak of the World War in 1914 led to a German invasion which, from midsummer 1915 until Aug. 1010, lay heavily upon the land. To further their own purpose, which was the lasting hold over Lithuania, the Germans after the military collapse of Russia allowed the phantom existence of a state. A Lithuanian conference met at Vilna (Sept. 18–23 1917) and, in negotiations which dragged until March 1918, petitioned the German Chancellor, Count Hertling, for the restoration of the country's independence under condition of a perpetual alliance between it and the German Empire (*Bundesverhältnis*). The German clerical party caused the "Taryba," or Council of State, which was then largely under the control of their army of occupation authorities, to offer the Lithuanian crown to Prince William of Urach, a younger member of the Württemberg reigning family. On July 11 1918 he accepted under the title of "Mindove II., King of Lithuania," choosing the style of a heathen prince of the 13th century who had fiercely resisted the Teutonic order. The German annexationists thwarted this candidature, which the Council of State eventually cancelled (Nov. 2 1918), but their delegates at the peace negotiations of Brest-Litovsk, in March 1918, upheld against Trotsky the authority of the Lithuanian Council of State. Their last argument rested upon this, that "Germany had recognised Lithuania's independence only on the condition that the conventions to be concluded among them the form of constitution and the choice of a ruler, shall correspond to German interests" (*Nordd. Allgem. Zeitung*, Aug. 1918). By the peace of Brest-Litovsk (March 3 1918), Germany forced Russia to abandon all claim on Lithuania.

[1] *Economic and financial situation of Lithuania* (Lithuanian State Printing Office, 1925).

By Nov. 1918, the magnitude of Germany's defeat being no longer in doubt, the Taryba, or Council of State, promulgated a provisional constitution under which it became the Lithuanian Parliament. The supreme power was vested in three persons, A. Smetona, J. Staugaitis and St. Silingas, who on Nov. 5 1918 invited Prof. Voldemaras to form the first independent administration on non-party lines, and reach an understanding with the national minorities within the still indeterminate frontiers, viz.: White Russians, Poles, Jews and Great Russians. Alone the Pan-Polish party reverted irreconcilably to the historic solution of union or federation with Poland. The initial difficulties of setting up an administrative machine on national lines were the greater as the troops of the occupying Power were affected by the revolution which had broken out in Germany. Although Kovno itself was evacuated in June 1919 and shortly afterwards Southern and Eastern Lithuania, the area Mitau-Shavli-Taurage remained in German hands until Dec. 13. Upon their final withdrawal, the Germans allowed the Bolshevik troops to march into evacuated zones at a mean distance of 10 kilometres. This was in direct violation of the terms of the Armistice, concluded with the Entente Powers on Nov. 11 1918.

The Voldemaras administration resigned on Dec. 26 1918, the new Premier, M. Slezevicius, widening the Cabinet. Prof. Voldemaras, whom the precarious situation of the country and the approaching Peace Conference called to Paris, served as Foreign Minister, M. Yčas as Finance Minister, M. Velykis as Minister of War. In Jan. 1919 the near approach of the Bolsheviks to Wilno caused the removal of the Government to Kovno (Kaunas) where the Provisional National Assembly recognised the Council of State (" Taryba ") and the Slezevicius Cabinet as the regular Government of Lithuania. The Taryba voted the provisional constitution, elected A. Smetona President of the State and composed the statute for the election of the Constituent Assembly, on the basis of proportional representation. National defence began to be organised. The Bolshevik advance reached its culminating point in May 1919 when Kovno itself was threatened. Until Sept. 1919 fighting took place against the Soviet forces, which were cleared out of the northern districts of the country, and until Dec. against the so-called Bermondt troops. Meanwhile, the Poles also had attacked the Bolsheviks and in April 1919 captured Vilna, establishing themselves there.

On Dec. 8 1919 the Supreme Council of the Allies in Paris laid down a provisional eastern frontier for Poland, the so-called " Curzon line, " which assigned to Poland most territories where the Polish element was in a majority, but excluded mixed and doubtful districts, the principal among which was Vilna, city and province, which fell to Lithuania. The Polish Govt. proposed to the Lithuanian Govt. joint action against the Bolsheviks, but the latter refused pending Lithuania's recognition as an independent State with Wilno for its capital.

The consequence was that the Poles embarked upon large scale military operations against Soviet Russia single-handed. But although their invasion of the Ukraine, in April 1920, was successful, the Bolshevik counter-offensive, in July 1920, compelled the Poles to retreat almost to the confines of Warsaw. The Lithuanians took advantage of the situation and reoccupied Wilno (July 14 1920) which had had a Polish garrison at the time when the Curzon line was laid down. But shortly afterwards the approach of a Red Army caused the Lithuanians to evacuate in all haste, which action laid them open to the reproach that they were not able to hold what they had so long claimed as their patrimony. The Poles believed that they were fighting not only in defence of their own newly resurrected country, but that they were stemming the tide of the Red invasion which threatened to overflow into Central Europe. They accused the Lithuanians of surrendering an important strategic centre and an important railhead, with the consequence that the left flank of the hard-pressed Polish army was exposed. But, as it happened, the face of the war changed and the Poles, turning on their Bolshevik pursuers, defeated them and drove them back into Great Russia. Immediately the Lithuanians reoccupied Vilna (Aug. 24 1920) but came into conflict with the Poles there and at Suwalki.

Meanwhile the Lithuanian Constituent Assembly, or " Seim," composed of 112 members, met on May 15 1920. The President of the State, the National Council and the Cabinet resigned and, all power passing to the Seim, the provisional government gave way to the permanent government. The state of war with Soviet Russia had been concluded by a Peace Treaty signed at Moscow, on July 12 1920, under which the Lithuanian claim to Vilna and Grodno was recognised by the Bolsheviks, and Lithuania received 3,000,000 roubles in gold and 100,000 hectares of forest land for exploitation. A Polish protest to the League of Nations on Sept. 5 1020 was followed by an agreement between the Polish and Lithuanian governments to refrain from hostilities and to respect the limits laid down for them by an Allied Military Commission. A line of demarcation agreed upon at Suwalki on Oct. 7, to come into force on Oct. 10, again left Wilno on the Lithuanian side. But the *coup de main* of Oct. 9 by the Polish so-called " rebel " Gen. Zeligowski (*see* VILNA) placed Vilna in Polish hands. On March 14 1923 the Allies recognised the *fait accompli*.

The Lithuanians were compelled to remove their capital to Kovno (Kaunas) where it has since remained, but the Vilna dispute continued to embitter relations between the two Powers. The Conference of Ambassadors, in a note of June 2 1924, invited the Lithuanian Govt. to enter into diplomatic and consular relations with the Polish Government. The Lithuanian Govt. countered with a proposal that the Allied Powers should call a conference at which their representatives would meet Polish and Lithuanian delegates to reopen the territorial question. The Conference of Ambassadors replied in effect that the frontier question could not be reopened. The Memel (*q.v.*) question proved to be almost as difficult of solution, but the Lithuanians, imitating the conduct of the Poles at Vilna, seized Memel on Jan. 15 1923 by a *coup de main*. The Convention signed at Paris on May 8 1924 laid down that the Memel (Klaipéda) territory constitutes an autonomous unit under Lithuanian sovereignty.

The *de jure* independence of Lithuania was recognised by Germany on March 23 1918, by Soviet Russia on July 12 1920 and by Latvia and Estonia in Feb. 1921, and by the Argentine Republic in March 1921. The long-drawn Vilna dispute delayed formal recognition by the Allies and the United States of America until the end of 1922. Lithuania became a member of the League of Nations on Sept. 22 1921.

Constitution.—Under the provisional constitution of June 2 1920, the then President of the Constituent Assembly, M. A. Stulginskis, acted as Temporary President, his acts being countersigned by the Premier. His election was subsequently confirmed by the Seim. The definite constitution of Aug. 1 1922 provides for a President, elected by the Seim, and for a Cabinet with a Premier responsible to the Seim. The Seim consists of 78 deputies, elected by universal, direct, secret suffrage on the basis of proportional representation, the electoral unit being of 50,000 inhabitants.

Internal Affairs.—In the constituent Assembly, the majority was formed by the Christian Peasant party, which in 1921 carried an agrarian reform bill for the twofold purpose of breaking up large estates and of reducing the influence of the Polish gentry who owned many of the biggest properties. In 1922 the first Lithuanian Seim was constituted, but the German, Jewish and Polish minorities abstained from taking part in the elections on the ground that the Government had treated them unfairly. In that year the revival of trade caused exports to exceed imports by nearly 500,000,000 marks, but the inflationary period in Germany made it imperative for Lithuania to adopt a currency of her own. Accordingly, the gold standard was established and maintained, on the basis of a Lithuanian litai (the litai to be $^1/_{10}$ of a dollar). The exploitation of flax was made a State monopoly.

The necessity of getting an absolute majority caused the dissolution of the Seim in March 1923. The new elections showed the state of parties as follows: Christian Democrats 40, People's Party 15, National Minorities 14, Social Democrats 9. As a result a coalition between the two first named returned the Galvanauskas Cabinet to power, which continued in office until June 1924.

Then the Christian Democratic party took over the administration, M. A. Tumenas becoming Premier. Once again friction occurred with the minorities, especially with the Jews, who make up 14% of the population. But Tumenas prevailed, and the Ministry for Jewish Affairs was abolished.

Foreign Policy.—The feud with Poland caused Lithuania to stand aloof from all negotiations for a Baltic alliance. The resulting isolation was accentuated by misunderstandings with other Powers. First and foremost among these was France, the friend of Poland, which at the time of the Lithuanian *coup de main* against Memel maintained a small garrison in that town. Further, the Agrarian reform bill affected the proprietary interests of "national minorities," Polish, German, Latvian, etc., which endeavoured to secure diplomatic protection outside the limits of Lithuanian territory. Again, the closing of the Niemen, which was an economic measure designed to exert political pressure, invited commercial retaliation, while friction arose within the State itself between the purely Lithuanian clergy and the clergy of Polish extraction and education, which for a time vitiated diplomatic relations with the Holy See. Finally, the circulation of the "Ostmark," which had been issued during the German occupation and was not redeemed, was resented by the people, the more so as the German Reichsmark was legal currency until 1922, with the result that the Lithuanian State suffered heavily by its depreciation. These troubles were, however, to some extent counterbalanced by happy relations with Soviet Russia which culminated in a treaty of non-aggression imposing strict neutrality on both parties in the event of a conflict between either and a third State. This treaty (as yet unratified) was negotiated in April 1926 by Prof. Reinys, Lithuanian Foreign Minister.

In 1922 Lithuania concluded a commercial treaty with Great Britain; in 1924, commercial treaties with Germany and Czechoslovakia. On May 19 1924 she agreed at the Conference of Kovno to enter into a tariff and customs union with Latvia and Estonia; and these three States also agreed to pursue a concerted foreign policy, especially in the Assembly of the League of Nations.

II. ECONOMIC AND FINANCIAL HISTORY

Lithuania is essentially an agricultural state. Of its total population (2,203,312 in 1923), nearly 80% live in the country. The only large town is the capital Kaunas (Kovno), which had 92,446 inhabitants in 1923. The second town was Klaipeda (Memel) with 35,715 inhabitants; then came Panevezys (19,197), Siauliai (Shavli) (21,387) and Ukmerge (10,604); the population of the three last-named towns is, however, largely agricultural.

Education.—Thanks to the cultural conflict between the Russian Govt. and the Lithuanian people before the War, the abolition of the monasteries at the end of the 19th century and the Russianisation of elementary education, a large proportion of the population is illiterate. According to the 1923 census 43·18% of the men and 44·98% of the women could not read. Considerable efforts were made by the Lithuanian Govt. to improve the educational system of the country and the budgetary educational grants rose steadily from year to year. In 1924 there were over 2,000 elementary and over 100 secondary schools. In Feb. 1922 a university was opened at Kaunas.

The economic organisation of the country on its present basis may be considered as beginning after the treaty of July 12 1920 with Russia; but progress was hampered by the protracted disputes over Memel (*q.v.*) and Vilna (*q.v.*).

Agriculture.—The estimated distribution of Lithuanian territory is as follows:—

	Hectares	% of Total area
Arable	2,595,000	46·2
Meadow and pasture	1,415,000	25·2
Orchards and gardens	169,000	3·
Woods and forests	909,000	16·2
Peat bogs	180,000	3·2
Uncultivated	349,000	6·2
	5,617,000	100·

The chief crops are rye, flax, oats and potatoes. The production of potatoes and rye would appear to have increased considerably since the War; but the returns are somewhat doubtful. The figures for 1924 and 1925 are given here.

	Area under Crops Hectares		Harvest (Quintals)	
	1924	1925	1924	1925
Rye	537,600	542,000	4,647,200	7,163,900
Wheat	84,900	112,000	903,200	1,461,000
Barley	196,000	205,000	2,028,600	2,562,500
Oats	325,000	345,000	2,697,500	3,415,500
Flax seed	61,500	76,000	338,300	458,400
Flax fibre			326,000	387,800
Potatoes	176,400	163,000	16,581,500	14,670,000

In spite of a recovery since 1920 the production per hectare of rye in 1923 was only 10·4 quintals, in 1924 8·6; wheat 9·9 and 10·6; barley 9·9 and 10·3. Efforts were, however, being made to improve agriculture with the help of the co-operative organisations. Experimental and model farms were started in different parts of the country, stations for cleansing grain set up and breeding stock imported. As in the other Baltic States co-operative societies play an important rôle. The most popular and numerous are, however, the consumers societies. Indeed, agricultural co-operatives for the marketing of goods only began to develop after the monetary reform at the end of 1922. Since the foundation of the so-called "Gamintojas" (Producer) or League of Agricultural Co-operatives early in 1923 with the object of organising the export of grain, flax, eggs, etc., and the import of fertilisers, implements and other agricultural requirements, the movement, assisted by the Government, made very considerable progress. In 1924 flax was the most important article of agricultural export, accounting for about 20% of the total value of all exports. Great hopes are, however, placed on the development of intensive dairy farming on Danish lines.

As under the Agrarian law (*see* LAND TENURE) no person may own more than 25 hectares of forest, nearly the whole of the forest area is exploited by the State; exclusive of the Memel district, 828,500 out of 872,000 hectares.

Timber.—In the 25 years preceding the War, however, very large districts were denuded of trees, and during the War the forests suffered heavily as a result both of deliberate destruction and of the abnormal demand for timber. It is officially estimated that about 2,200,000 cu. metres could be cut per annum without deforestating the country, granted adequate transport facilities. Timber and manufactured and semi-manufactured wood constitute the most important group of exports. From 1920 on the export of sawn timber made rapid progress as against that of unsawn timber, as shown by the following table:—

Amount in Cubic Metres (000's omitted)						
Principal articles	1920	1921	Jan.–Sept. 1922	Oct.–Dec. 1922	1923	1924
Wood: unmanufactured	317	244	226	19	44	48
Wood: manufactured	122	184	313	70	293	200

Industry.—No coal or mineral ore is mined in Lithuania, and such industries as exist are, therefore, mainly dependent upon agriculture. Industry suffered severely from the wars, and from subsequent political difficulties with Poland, the Memel problem, to some extent from the loss of the Russian market for metal manufactures and more recently from a banking and credit crisis. About half of the existing undertakings are occupied with the preparation of food products and beverages. The export of manufactured products is negligible.

Trade.—Owing to the system of valuation employed the trade statistics up to the end of 1922 probably somewhat exaggerated the magnitude of the imports. The total turnover has increased steadily from year to year.

Imports and Exports of Merchandise and of Bullion and Specie

Special Trade[1] Value in millions of litai						
Merchandise	1920	1921	1922	1923	1924	1925
Import	72	95	75	157	207	253[2]
Export	55	58	77	147	267	243
Balance[3]	−17	−37	+2	−10	+60	−10

[1] Imports for home consumption and exports of domestic produce.
[2] Provisional.
[3] Excluding the movement of bullion and specie.

The chief articles of export are: wood and wood products (about 25% of the total value of all exports in 1924), flax 20%, live stock 13%, eggs 7·5%, leather and hides 5·5% and grain and flour 4%. In 1924 43% of Lithuania's total exports went to Germany and 28% to the United Kingdom. Of her imports, which are essentially miscellaneous in character, over 80% were derived from Germany in 1923 and about 63% in 1924.

Currency.—Since the autumn of 1922 Lithuania has had her own currency: the litai (one-tenth of a dollar). This unit of currency was adopted as, owing to the number of emigrants and the extent to which dollar notes sent from the U.S.A. had circulated in the country during the preceding years when the German Ost marks were depreciating in value, the population had become habituated to it. In connection with the monetary reform a central bank was established which has the sole right of note issue.

National Finance.—In 1923 the budget was balanced and from 1923–5 the proportion of total expenditure for military purposes and of total revenue derived from the felling of timber steadily diminished. The estimates for this period balanced at the following totals:—

	1923	1924	1925
Litai (in millions)	208·3	229·7	259·3

The actual receipts and expenditure in 1923 amounted to 176·9, and 171·8, and in 1924 to 241 and 232·3 million litai. On Jan. 1 1924 the total debt of the republic amounted to 72·8 million litai of which 2·6 million litai was domestic. Arrangements had been made with all creditor countries concerning the service of the foreign debt.

Communications.—The means of communication in Lithuania were constructed to meet the requirements of a province of the Russian Empire and are ill-adapted for present purposes. Thus Memel, which is the chief port for the whole country, can only be reached from Kaunas, either by an extremely circuitous route via Liaulian, Taurage and Papegiai, or over Latvian territory. For this reason the Lithuanian Govt. contemplated laying down two short lines linking Kaunas with Memel and giving northern Lithuania a direct outlet at Memel to the sea via Pelsiai. The length of the railways in 1925 was 1,138 km. large gauge, and 454 km. narrow gauge under State control, plus 48 km. of line under private management and the Highways Board and some 110 km. of private lines in Memel.

The Niemen, however, forms an important natural highway, being navigable for 419 km. and utilisable for the floating of logs for a much greater distance. The rivers Necys and Nevežys are likewise navigable for 20–30 kilometres. But these rivers are all frozen in winter when the transport of timber from the forests to the nearest clearing station is accomplished.

LITTLE ENTENTE.—The Little Entente is a political organisation, created after the World War, which binds together three Central European States, Czechoslovakia, Yugoslavia and Rumania, for purposes of their common interest.

Origins under the Dual Monarchy.—Those nations had in the past been throttled by the Germanising and Magyarising system of the old Austria-Hungary; one of the objects of the Little Entente is to defend the freedom they won after the War against all attempts to restore the former régime. The Little Entente had its roots in a series of political acts and declarations dating back to the days of the old monarchy. In the Austrian half of the Habsburg Empire the representatives of the small nations in the Parliament at Vienna joined in opposition to the centralising system which opposed the non-German peoples. In the Hungarian half the oppressed Slovaks, Serbs, Croats and Rumanians met in 1848 and made a protest against Magyar imperialism; they did so again in 1895 at Budapest; and in 1905 10 non-Magyar deputies of the Budapest Parliament formed a club for a like purpose.

During the World War, when the Austro-Hungarian peoples revolted and helped the Western Entente to break the system of militarist imperialism, a common aim again produced common action. In April 1918 a congress of the oppressed Austro-Hungarian peoples was held at Rome, and in the autumn of that year the Central European Democratic Union was formed in America. A year earlier a great meeting of representatives of the Austro-Hungarian nations had taken place at Kiev in Russia and had established a special committee to fight against German and Austro-Hungarian imperialism. A prominent place was taken in all these actions by the Czechoslovaks, Yugoslavs and Rumanians, supported by Poles, by the Italians of "Italia irridenta" and finally by Ukrainians. The co-operation of the first three nations was particularly close, and toward the end of the War they undertook diplomatic action in common. The Little Entente was formed soon after the Peace treaties had been signed, when attempts began to be made by various elements of the pre-War régime to bring about a restoration of the Habsburg dynasty.

The Formation of the Little Entente.—The Czechoslovaks, Yugoslavs and Rumanians knew that a return of the Habsburgs would mean the restoration of the German-Magyar absolutism and the destruction of the freedom won by the political revolution of 1918. The Habsburg intrigues were chiefly engineered in Hungary, where the new régime in Central Europe was last to be recognised and where intense propaganda was conducted for the recapture of the Slovak, Serbo-Croat and Rumanian territory. The Habsburg menace led to corresponding defensive measures on the part of the threatened States. The Czechoslovak Foreign Minister travelled on Aug. 13 1920 to Belgrade, where, on the following day, a defence treaty, of which the broad outlines had already been negotiated, was concluded between the kingdom of the Serbs, Croats and Slovenes and the Czechoslovak Republic, binding both States, in case of an unprovoked attack by Hungary on either of them, to provide mutual aid the one to the other, and to refrain from making any alliance with a third Power without the consent of both. At Bucharest, whither the Czechoslovak Foreign Minister proceeded from Belgrade, the basis was negotiated on Sept. 17 for an analogous entente.

After all the questions of detail had been settled, that agreement also was given the form of a defensive treaty, and concluded on April 23 1921. On Sept. 19 1920 Rumania informed both those States that she recognised a similar obligation. She concluded special treaties to that effect with Czechoslovakia on April 23 1921, and with Yugoslavia in June of that year. The opportuneness of that defensive alliance was proved in April and in Oct. 1921, when two attempts were made to restore the Habsburgs. Those attempts failed only because they met with the combined armed resistance of Czechoslovakia, Yugoslavia and Rumania.

The European Side of the Little Entente.—The three States forming the Little Entente were aware from the beginning that mere defence measures would not suffice for the maintenance of the new régime if the States concerned were themselves lacking in creative forces, or failed to attain the greatest possible degree of political and economic solidarity and an atmosphere of mutual trust and fruitful co-operation throughout the whole area of Central Europe. The ultimate and wider aim of the Little Entente is therefore to educate Central Europe as to the advantages of universal peace and European consolidation. The progress made in the realisation of this policy is best seen in the political and economic spheres. The main political object was to persuade all the Central European States to work in peaceful co-operation with the new States, and much success has been achieved. Starting from the Treaty of Rapallo between Yugoslavia and Italy and the agreements worked out on the occasion of the visit of the Czechoslovak Foreign Minister to Rome in Jan. 1921, that policy bore fruit in the Czechoslovak-Austrian agreement of Dec. 16 1921, which bound both States to abandon hostile propaganda and to settle all disputes by peaceful arbitration. The same principles were the basis of the Czechoslovak-Polish treaty of Nov. 6 1921, which, although not ratified, created better relations between the two States, and, being followed by the Polish-Rumanian political treaty, materially improved the relations of Poland with the Little Entente as a whole.

In the measures taken to save Austria from financial ruin Czechoslovakia had a large share, and did not hesitate to make sacrifices in the interests of mutual confidence. A like policy was followed by the Little Entente towards Hungary, despite the fact that it had been the nationalist elements of Hungary and their Habsburg sympathies that had brought the defensive alliance of the Little Entente into existence. The latter knew from the beginning that correct and, as far as possible, friendly relations between it and Hungary were essential to the complete pacification and consolidation of Central Europe. The States forming the Little Entente showed the best of good will in this respect, as is proved by the frequently repeated attempts of Czechoslovakia to negotiate with the Hungarian Govt. from as early a date as 1921. If those attempts were unsuccessful, it was because Hungary sought by an adventurous policy to avoid an understanding with her neighbours. The recent change in this respect, clearly due to the failure of that Hungarian policy, is nowhere more welcomed than in the countries of the Little Entente, whose only wish is that the change be permanent, so that a new Hungary, consolidated both economically and politically, may co-operate in the reconstruction of Central Europe.

Economic Policy.—The economic policy of the Little Entente starts from the conviction that in Central Europe it is necessary not only to overcome the harmful results of the depreciated currency, the obstacles to trade connections and the disturbances in the industrial world, but also to make up for the consequences of the disintegration of the old monarchy, which had constituted an economic whole. The basis of its economic policy, therefore, is the minimising of these results by the earliest possible establishment of commercial relations with each other and with the rest of the world. The political negotiations have therefore always been combined with economic negotiations, which have been the basis of a series of commercial treaties, at first between the States of the Little Entente and then with all the neighbouring countries. Questions of common interest to all the States springing from the former Austria-Hungary have been discussed with good results at special conferences, *e.g.*, those at Rome and Portoroso in 1921, and, later, the special conferences dealing with passport, transport and other problems. The results of this economic co-operation have not of course been equally satisfactory in each of the States concerned, nor have they been enough in themselves to restore healthy conditions to those States whose economic, financial and currency difficulties left them with no alternative to calling in international financial help.

Expansion of the System.—The increased activity and the determined policy of the States forming the Little Entente have outgrown the limits of the simple defence treaties which constituted the original basis. On Aug. 31 1922 that formal basis was considerably enlarged by the conclusion of a new treaty, in the second article of which both Czechoslovakia and Yugoslavia recognised the treaties concluded by Czechoslovakia with Rumania, Austria and Poland on the one hand, and by Yugoslavia with Rumania and Italy on the other. In the third article both parties agreed to put their economic, financial and transport relations on a firm basis by co-operation; and finally in a further article they undertook to support one another in their international political and diplomatic relations and to take common measures if their common interests should be threatened.

The principles incorporated in that treaty reveal both the spirit underlying the Little Entente and the basis of its future activity. Emphasis is laid on the importance of economic co-operation and of solidarity in international affairs; the periodical renewal and extension of the existing system of commercial treaties, together with the ever increasing moral weight of the Little Entente in the councils of Europe, prove that the statesmen of the Little Entente have a firm grasp of both political and economic realities. At international conferences, such as those of the League of Nations, the representatives of the Little Entente have regularly spoken as one man, and have therefore contributed to a considerable simplification of international relations; their behaviour is particularly noteworthy in that it is not only of a united but of a pacifist character. The future aim of the Little Entente will be still further to promote the pacification and the consolidation of Central Europe. *See* also CZECHOSLOVAKIA; EUROPE; RUMANIA; YUGOSLAVIA, etc. (E. BE.)

LITVINOV, MAXIM MAXIMOVICH (1876–), Russian politician, was born at Bielostok. When only 17 he entered military service as a volunteer and while in the army became interested in Marxism. When his term of service was completed, he devoted himself to propaganda, and became a member of the Kiev committee of the Social Democratic party. The president of that committee proved to be a police agent and the whole committee was arrested. After a year and a half in prison Litvinov with 11 companions escaped from gaol, went abroad and took an active part in the *Iskra*, the Social Democratic newspaper. When the split in the Social Democratic party occurred, Litvinov joined the Bolsheviks, or majority section, returned to Russia illegally in 1903 and worked there as a member of the central committee until the revolution of 1905. In that year he attended the London Congress as a delegate from the Riga Committee and took part with Gorky in founding *Novaya Zhizn* (*The New Life*), the first legal Social Democratic newspaper to appear within the boundaries of Russia.

During the succeeding years of reaction, Litvinov lived abroad, where he organised the sending of weapons to the revolutionaries in the Caucasus. He took part in the International Socialist Bureau which he left at the beginning of the World War after protesting against the entry of Socialists into bourgeois governments and in general against Socialist support of the War. After the November revolution (1917) in Russia he was appointed diplomatic agent of the Soviet Government in England. He was subsequently arrested as a hostage for Mr. Lockhart, for whom he was exchanged. He afterwards became one of the most important figures in the Soviet diplomatic service, as assistant commissar for foreign affairs taking part in the initiation of peace negotiations with Estonia, in negotiations at Copenhagen with England, in the Genoa conference and, as president of the Russian delegation, in the subsequent conference at The Hague. In 1925 he became a member of the Revolutionary military council of the Union and later chief-of-staff of the Red Army.

LIVERPOOL, England (*see* 16.804).—The population of Liverpool increased from 753,353 in 1911 to 802,940 in 1921. The municipal area was enlarged in 1913 by the inclusion of Allerton, Childwall, Little Woolton and Much Woolton to a total area (exclusive of 2,883 ac. of river bed) of 21,242 acres. The death-rate per 1,000 fell to 13·6 in 1924. The policy of slum clearance and the erection of large numbers of cottages followed by the council, which was begun before the War, has had beneficial results. Over 6,000 houses had been built by 1924 under municipal housing schemes on large estates at Larkhill, Allerton and elsewhere, and 460 ac. were acquired in 1925 for a further big scheme at Norris Green, just outside the city boundaries. Garston has become an important shipping and coal export centre. Since 1918 the borough has returned 11 members to Parliament.

Public Utilities, etc.—The total area of parks and open spaces is 1,306 ac., including the Harthill estate of 32½ ac. (1913), the Walton Hall estate of 130½ ac. (1913), the Woolton Wood estate of 62 ac. (1917) and the Allerton and Allerton Towers estates of 228 ac. (1924). Among important buildings erected since 1910 are the prominent Royal Liver and Cunard buildings, near the landing stage; an art gallery at Port Sunlight, erected in memory of Lady Leverhulme; and the Midland Adelphi Hotel. Recent monuments include a bronze statue of King Edward VII. in front of the Cunard buildings; one to the engine room heroes, erected by international subscription in 1916, overlooking Prince's landing stage; one to Sir A. L. Jones at the George pierhead; and the Cunard company's War memorial column. The proposed Liverpool War memorial is a cenotaph in front of St. George's Hall, in addition to the Cathedral War memorial, which is a cenotaph and includes the Roll of Honour. A holiday home for orphans was opened in 1924 as a memorial gift from the churches of the city.

A Merseyside municipal co-ordination committee was formed in 1922, with the object of improving local communications, particularly across the river. Negotiations for financial assistance from the Government were successful in 1924, and in Dec. 1925 the boring of the Mersey tunnel, which, it is hoped, will provide a solution of the very difficult traffic problem, was begun by the sinking of a shaft on the site of the old George's dock. When completed, the tunnel, 44 ft. across, will contain a roadway for heavy traffic 36 ft. wide, with footways on each side, and beneath one for lighter vehicles. There will be two approaches on the Liverpool side, one for heavy traffic at New Quay and one for lighter at Whitechapel. On the Birkenhead side there will be one approach, near the Woodside Hotel. The urgent need of an additional water supply led to plans for the construction of a third pipe-line from Lake Vyrnwy (to be followed by a fourth), and the crossing of the Mersey is to be effected by laying pipes in the river bed. Work was begun in 1925.

Cathedral.—The work of building the cathedral, practically stopped during the War, was resumed in 1920. Owing to the exigencies of the site on St. James' Mount the building lies north and south, the rubrical "east" thus pointing south. The general plan, which is marked by strong individuality of style, consists of a great central space (200 by 72 ft.) formed beneath a central tower by the crossings of two pairs of transepts, a choir in three bays and a nave—the whole to have an interior length of 480 feet. The principal portal of the cathedral will be at the west side of the tower, not at the traditional west end. The stone is Woolton red sandstone, which weathers to a greyish pink in a smoky atmosphere. The first section, which includes the Lady Chapel, was consecrated in 1910 and the choir, two transepts, and the chapter house were consecrated in July 1924. In the southeast transept is a memorial to the 55th division, and in the War memorial northeast transept there is a cenotaph. The building is heated by the hypocaust system. Work on the great central space and the west transept was begun in 1925. (*See* ARCHITECTURE.)

Markets.—A market was established at Garston in 1920, and in 1922 a general market was set up on the site of the wholesale vegetable market in order to do away with the holding of unauthorised markets on waste ground. In the same year the frozen meat market was acquired, as a preliminary to the building of abattoirs and a meat market on the site of the Stanley cattle market.

Port Improvement Schemes.—Large schemes for the improvement of the port have been in process of execution by the Mersey Docks and Harbour Board since 1906. They include the construction of a great vestibule dock, 1,070 ft. long and 130 ft. wide, with a river lock entrance and two branch docks, at the north end of the dock estate. A lock 645 ft. long and 90 ft. wide, opened in 1921, connects the new dock with the adjacent Hornby dock. These new docks will add 2¾ m. of quays to the port, and will be, it is said, the largest and best equipped in the world. Work was suspended during the War, but was afterwards pressed forward. Large extensions have been made to the electric equipment of the port, the landing stages enlarged to provide further facilities for the embarkation of passengers, and a wireless telephone installed from the Bar Lightship to the Harbour Board offices. About one-third of the total overseas trade of Great Britain passes through Liverpool, but since the War Liverpool has given place to London as the first port for wheat imports. To provide accommodation for the growing oil industry a large area of land, known as the Parkhill and Dingle estate, has been set apart at the extreme south end of the dock estate for the erection of oil tanks, with pipe-lines to berths in the Herculaneum dock. (O. J. R. H.)

LIVERPOOL, UNIVERSITY OF (*see* 10.43).—New chairs have been founded in classical archaeology, geography, commerce, civic design, social science, applied mathematics, organic chemistry, industrial chemistry (fats and oils), bacteriology, geology, oceanography, entomology, parasitology, tropical diseases of Africa, dental surgery, veterinary anatomy, care of animals (causation and prevention of disease), international law, engineering, electrical machinery, applied mechanics, civil engineering, metallurgy and naval architecture. New fellowships have been created for modern history, English literature, Celtic, chemistry, anatomy, orthopaedic surgery, engineering. A number of scholarships have been instituted, in architecture, travelling, research (offered in the faculties of arts, science and engineering in rotation), chemistry, marine biology, medical subjects, engineering and law.

New buildings were erected for arts building extension, Students' Union and Gilmour Hall, engineering building extension, school of tropical medicine, chemistry school extension, department of geology, hall of residence for women extension, dental school extension, athletic pavilion, laboratory for research in tropical diseases (Sierra Leone). Residential buildings have been altered and equipped for accommodating the departments of education, geography, school veterinary surgery, metallurgy, school of social science, hostels for men, institute of archaeology. New departments have been instituted in civic design and town planning, poetry, music, art of the theatre, medieval history, analysis of observations, geology, cytology, pharmacology, radiology and electrology, orthopaedic surgery, parasitology, chemical physiology, public health chemistry and refrigeration. New degrees have been ordered for commerce, architecture, hygiene, orthopaedic surgery, veterinary science and philosophy, while diplomas have been instituted in radiology and electrology, tropical hygiene, archaeology, geography and social studies. In 1919 a tidal institute was established by the university in association with local shipowners. In connection with the department of oceanography, founded in 1919, a sea fisheries laboratory is maintained at Port Erin. Extensive researches are carried on in the local sea fisheries in regard to diseases of fish and kindred subjects.

Extramural Work.—The university extension board extended its influence to the Isle of Man, to Crewe in the south and to Blackpool and Carlisle in the north, at 23 centres, in co-operation with local committees and organising bodies. Christmas lectures for boys and girls have been inaugurated. A scholarship open to extramural students provides the holder with the means of proceeding to a degree course in the university. Free public lectures have become a feature in university life at Liverpool. Courses of lectures and single lectures are given almost nightly, in the winter, in many subjects taught in the university.

Industrial Relations.—For some years advisory boards have been established in commerce and in science and engineering subjects, including representatives of commercial and industrial firms. The university has adopted special regulations for the proper conduct of what is termed "outside work." Facilities are offered by a large number of firms permitting students to visit works and examine processes, etc. Much is done in finding suitable posts for graduates on leaving the university.

Numbers of Students.—The following table shows the increase of students in 1924–5 as compared with the entries for 1910–11:—

1910–1			1924–5		
Full time	Part time	Total	Full time	Part time	Total
919	279	1,198	1,651	400	2,051

The University in Wartime.—During the War the resources of the university (particularly of the science, engineering and medical departments) were devoted to national service, and accommodation in the university buildings was found for many Government departments. Research work was undertaken for the Government in chemistry (dyeing, edible oils, high explosives, etc.), insect pests, mathematics (Admiralty work and guns), optical instruments, engineering and medical science (particularly in tropical diseases, bacteriology, pathology, orthopaedic surgery and dentistry). The engineering staff organised classes for the manufacture of shells, and the staff and students made over 1,500 gauges. The inspection of high explosives for the Liverpool area was centred in the chemical laboratories, and over 250,000 tons of high explosives were passed there. Mem-

bers of the university who served in the War (staff, students and servants) numbered 1,673 of whom 197 were killed in action or died on service, and five gained the Victoria Cross (one with bar).

LLANDAFF, HENRY MATTHEWS, 1ST VISCOUNT (1826–1913), British politician, died in London April 3 1913.

LLOYD OF DOLOBRAN, GEORGE AMBROSE LLOYD, 1ST BARON (1879–), British administrator, was born on Sept. 10 1879, the son of Sampson Samuel Lloyd of Dolobran, Montgomeryshire, and was educated at Eton and Cambridge. He became a close student of politics and travelled widely in Burma, India, Little Tibet, the Himalayas, Egypt, Morocco and Asia Minor. In 1905 he was appointed attaché to the British Embassy at Constantinople, and in 1908 acted as special commissioner for the British Govt. to inquire into and report upon the future of British trade in Turkey, Mesopotamia and the Persian Gulf. During the World War he saw service in Egypt, Gallipoli, Russia, Mesopotamia and with the sheriff of Mecca's forces in the Hejāz, gaining the D.S.O. in 1917. He was Conservative M.P. for West Staffordshire from 1910 until 1918, when he was appointed governor of Bombay, a post which he held until 1923. He was created G.C.I.E. in 1918 and G.C.S.I. in 1924 when he was again returned to Parliament as M.P. for Eastbourne. In May 1925 he was appointed high commissioner for Egypt, and in Oct. was raised to the peerage.

LOCARNO, PACT OF.—Locarno is a fact of European significance. If, therefore, we wish to treat of the particular outlook of one nation or another it cannot be in relation to the great objectives shared by all, towards which the policy of Locarno was directed. The German people, indeed, have expressed their opinion of the actual documents in which the results of Locarno are enshrined, in less unanimous terms than other nations, but it may be said that in the overwhelming majority they are as convinced as any nation of the desirability of those great aims.

It was not altogether easy to make it clear to German public opinion that the problem of security was fundamental to any practical approach to these ends. The man in the street, seeing the harbours empty, the barracks deserted, the armament industries destroyed and the richest areas of his country overrun by foreign troops, found it hard to understand that it was not his own security but that of his armed neighbours, old and new, that stood in need of a guarantee. The difficulties would, therefore, have been excessive had not Great Britain stepped in at Germany's suggestion and declared herself ready to throw the whole weight of her power into the scale in the defence of Germany's western frontier, no less than eastern frontiers of France and Belgium.

It is too much to say that Great Britain's intervention, beneficent as it was, amounted to a solution in itself. The path which it opened was still encumbered by many obstacles. The sincerity of the German proposal was not everywhere realised with the same clear-sightedness shown by the British statesmen. Germany was credited with designing to secure a British guarantee on the Rhine to enable her to effect a forcible rectification of certain frontiers in the east which were not in harmony with racial justice and sound economics. It was feared, moreover, that a separate pact between the Great Powers interested in the Rhine would overshadow a pact concluded within the framework of the League of Nations and undermine the prestige of the League itself. It was by no means easy to remove the first source of anxiety, despite Germany's sincere wish to develop her relations in the east along peaceful lines, since France, as Poland's military ally, could not be seriously regarded as an impartial guarantor of German-Polish relations. The second ground of apprehension would, it seemed, vanish when Germany entered the League of Nations. She was, however, compelled to demand that she should enter as a completely equal partner. It was therefore necessary that consideration of the inequalities of armament be secured beforehand.

An unusual measure of goodwill on the part of all concerned was needed to overcome these and other difficulties. Happily the hour of Locarno was favourable and the statesmen assembled there actually incorporated this goodwill in a high degree. Personal contact strengthened in each that determination to conquer the spirit of mistrust, which in such circumstances is the sole warrant of success. Accordingly, there was little delay in drawing up the documents which were signed in London on Dec. 1.

From the German point of view their immediate significance is clear and simple:—

1. They set Europe free from the nightmare of warlike complications in one of the danger-points of the Continent.
2. They substitute a system of objective legal procedure and amicable arrangement for high-handed militarism and the one-sided interpretation of treaties.
3. They pave the way for Germany's co-operation in the League of Nations, by ensuring that she shall not be involved against her will in conflicts for which she is unfitted by her geographical position and her military situation.

Even if it had no other than this immediate significance, the Pact of Locarno would be one of the most important documents of 20th century history. But it was recognised with a rare unanimity and, further, was emphatically laid down in the protocol of Locarno that its full import entailed further consequences. Everything in fact in this complex of treaties has a bearing upon the future.

The legal disputes, often of a very subtle order, which in recent years have stirred passions to a frenzy, will in future be referred to the calm atmosphere of international courts of equity, so that our generation may acquire a clear outlook, enabling it to co-operate in mutual confidence in the political, economic and cultural reconstruction of Europe. There is hardly any aspect of this infinitely complicated problem which will not sooner or later be made to feel the beneficial influence of this clarifying process. The particular problem, however, which will be most immediately and decisively affected is undoubtedly that of universal disarmament. Germany's practical interest in this issue is less than that of other countries. For the chief financial relief will be enjoyed by those countries which disarm, while the diminution of the military burden will benefit the Powers competing with them in armaments. For Germany, on the other hand, the effect is primarily a moral one in three ways.

Firstly, because disarmament will mean the beginning of the long-delayed fulfilment of a solemn promise, confidence in which brought the German people to lay down its arms; a promise which was solemnly reaffirmed to it in Versailles.

Secondly, because in the words of the distinguished statesman who represented Belgium at Locarno it is impossible "to keep a rich and powerful people disarmed by duress and in a one-sided way for an indefinite period, while its former enemies in Europe remain armed to the teeth."

Thirdly, because this is the best way of convincing the German people that the pledges which Germany has offered of her own free will, and under the guarantees of Great Britain and Italy, for the security of her Western neighbours, are appreciated at their full value by the latter. How could the German people be asked to believe in the security pact if the signatory Powers most immediately concerned continue to base their security exclusively upon heavy artillery, tanks and aerial bombs?

Regarded in this light, it becomes intelligible why public opinion in Germany more than anywhere else looks so eagerly for the realisation of what in Locarno was so justly styled the "logical outcome." Every recognition is due to the fact that the responsible statesmen on their return to the turmoil of their capitals from the calm and reflective atmosphere of Locarno have honourably striven without waste of time to bring about the realisation of a part of that "logical outcome." It must alike be recognised that before the full programme can be realised, time is necessary to prepare public opinion in each country. The document of Locarno is no prescription, merely needing the physician's signature, to allay the fever of mistrust. But in the last resort the prescription of Locarno will have to prove its efficacy by one fact alone: that no State shall ever again hold it necessary or even compatible with the Treaty to seek for the guarantees of its security by accumulating the machinery of violence on the territory of its neighbour. When

that hour strikes, even those sections of German opinion, which are still skeptical of Europe's miraculous healing from the spirit of destructiveness, will no longer be able to stand aside. Then will the whole German people engage its ambition in being outdistanced by none in peaceful co-operation for the welfare of Europe. (*See* SECURITY.) (G. St.)

LOCKJAW: *see* TETANUS.

LOCKOUTS: *see* STRIKES AND LOCKOUTS.

LOCKROY, EDOUARD (1838–1913), French politician (*see* 16.854), died Nov. 22 1913.

LOCKWOOD, WILTON (1861–1914), American painter (*see* 16.855), died at Brookline, Mass., March 20 1914. In 1912 he was elected a member of the National Academy of Design.

LOCKYER, SIR JOSEPH NORMAN (1836–1920), British astronomer (*see* 16.855), died at Sidmouth, Devonshire, Aug. 16 1920. In 1912 he became president of the British Science Guild.

LOCOMOTIVE: *see* RAILWAYS.

LÓCZY, LÁJOS DE LÓCZ (1849–1920), Hungarian geologist, was born at Pressburg (Bratislava) Nov. 2 1849. He studied at the Zurich Polytechnic, obtaining his engineer's diploma in 1874, and from 1877–80 travelled through India and China as geologist to the expedition of Count Bela Szechenyi. In 1886 he became professor of geology at the University of Budapest, and in 1908 director of the Hungarian Geological Institute. He completed geological researches in China, in Hungary and, during the World War, in Serbia. His principal work, *The Scientific Results of the Expedition of Count Bela Szechenyi to Eastern Asia* (1890), comprises the first scientific description of the mountains which connect the Kuen Lun chains with the Northeast Indian chains behind the red basin of Szechwan. His researches concerning the steppe-formations of the Gobi and the northern Hwang Ho territory are also of great importance. His other important work, *The Results of the Scientific Research of the Balaton*, forms a great monograph of the Hungarian lake, in which the formations of the Balaton region are explained. His posthumous works are: *The New Geological Map of (pre-War) Hungary*, and *Geology of West-Serbia*, which revolutionised the geological knowledge of Serbia. He died at Balatonaracs May 13 1920.

LODER, BERNARD CORNELIUS JOHANNES (1849–), Dutch jurist. From 1873 to 1908 Loder practised as a lawyer in Rotterdam and from 1908 to 1921 was a judge of the high court of justice of the Netherlands. In 1905, 1909, 1910 and 1922 he represented the Netherlands at the diplomatic Sea Conferences at Brussels. He presided at the conference of the Scandinavian kingdoms, Switzerland and Holland, held in 1920. The Permanent Court of International Justice at The Hague appointed him its first president in 1922 and he retained this position until early in 1925.

LODGE, HENRY CABOT (1850–1924), American statesman and author (*see* 16.860), in view of his continuous service in the Senate since 1893 was recognised during the closing years of the Roosevelt administration and under Taft as one of the Republican leaders. This position he maintained at the time of the Republican-Progressive split which led to the election of Woodrow Wilson in 1912; his personal friendship with Roosevelt remained unbroken, but he held true to his long-established principles of party regularity. He was well equipped for leadership in opposition, for his talents were critical rather than constructive and he possessed the qualifications of a great parliamentary debater. His prime interest lay in foreign affairs and it was as a member of the Senate Foreign Relations Committee and later as opponent of President Wilson that he exercised his chief interest. This opposition was originally in no way personal, as has been frequently suggested.

In 1914 Lodge supported Wilson's demand for the repeal of the Panama Tolls exemption on the ground that the President had a right to expect such assistance as would enable him to conduct foreign affairs effectively; "the great responsibility," said Lodge "of initiating and shaping our foreign policy must rest with the Executive and cannot rest anywhere else." He lost confidence in Wilson, however, as a result of the President's handling of the Mexican problem in 1914, and thereafter became one of his principal critics. He regarded him as a man of words with no capacity for well-considered action: "I wonder if the future historian will find him out," he wrote in his diary. This distrust increased after the outbreak of the World War. Lodge's intense nationalism, which in the past had given him the reputation of being an Anglophobe, led him to protest strongly against the failure to protect American lives and property, whether destroyed by Mexican revolutionaries or by German submarines. He successfully opposed the Shipping Bill in Jan. 1915, ostensibly on the ground that it would lead to foreign complications, chiefly, however, because he feared it would result in the purchase of the German ships in American harbours, an act which he regarded as unneutral and unfriendly to the Entente. He desired the United States to enter the War against Germany after the sinking of the "Lusitania," and warmly objected to every suggestion of placing an embargo upon the export of American munitions, which he looked upon as a pro-German manoeuvre. He steadily opposed Wilson's Caribbean policy; in Feb. 1914 he refused to support the treaty negotiated with Colombia providing for the payment of $25,000,000 and expressing regret for incidents connected with the United States recognition of the independence of Panama and the acquisition of the Canal Zone; in Jan. 1916 he offered a resolution calling for armed intervention in Mexico. He advocated enthusiastically a larger army and navy.

With the entrance of the United States into the War, Lodge called for non-partisan support of the President in all policies that might increase the War effort of the United States and its assistance to the Entente Allies, and he helped to carry through many of the Administration's War measures, although he opposed one of the most important designed to organise war-making agencies, the Overman Act, on the ground that it gave unlimited power to the Executive. Wilson's peace policies Lodge neither understood nor approved. In 1915 and 1916 he had himself advocated a League of Nations and the principle of compulsory arbitration, but he later confessed that he changed his mind and saw in Wilson's proposals more danger than advantage. In Aug. 1918 Lodge was elected Republican Floor Leader of the Senate, and as a result of the autumn elections which gave control to the Republicans he became chairman of the Senate Foreign Relations Committee. At the moment of the opening of the Peace Conference he was thus titular and actual leader of the opposition to Wilsonian peace policies, a post for which he was fitted by his convictions as well as his ability.

On Dec. 21 1918 Senator Lodge inaugurated what developed into a successful campaign against the Wilson peace plan by a speech in the Senate in which he insisted upon the need of separating the League from the treaty. Under his guidance and that of Senator Knox, both men of long experience in matters of foreign policy, the Senatorial opposition to Wilson developed rapidly; it was not broken by Wilson's conference with the committee on Feb. 26 1919. "The President," recorded Lodge, "answered questions for two hours about the draft of the constitution of the League of Nations, and told us nothing." On March 4, Lodge with 38 Republican Senators issued a declaration expressing disapproval of the Covenant in its existing form and its inclusion in the treaty of peace. Thus when Wilson finally returned from Paris in July 1919 he found a well-organised opposition to the Covenant, which capitalised the increasing protest against the President's alleged autocracy of method and the dissatisfaction with various aspects of the Versailles Treaty, together with the discontent inevitably arising from after-War conditions and directed against the party in power.

Lodge did not hope to defeat the treaty by a straight vote of disapproval; the popular demand for peace was too compelling. He did hope to attach a number of amendments or reservations which would attract the support of the die-hard enemies of Wilson and the Covenant, and which would protect the "interests and safety of the United States." This policy he carried through successfully, aided by the President's illness and his

refusal to consider any compromise. On Sept. 10 1919 Lodge presented the report of the committee to the Senate, which finally adopted 15 reservations to the treaty. When, on Nov. 19, the treaty with these reservations was voted upon, 42 Democrats, of whom nearly all approved the Covenant and treaty but objected to the reservations, voted against it. It was accordingly defeated, 39–55. A motion for ratification without reservations was lost, 38–53. Efforts to secure a compromise followed but proved unsuccessful. Wilson refused to accept the Lodge reservations, and Lodge was able to hold his group firm in refusing to pass the treaty without reservations. His tactical success was unquestionable when on Mar. 19 1920 the treaty, which had been reintroduced, failed to secure the necessary two-thirds vote of the Senate by seven votes, for it was lost through the votes of Democratic Senators who voted against it at the wish of the President. Senator Lodge himself was doubtless sincere in his willingness that the treaty should pass, with his reservations attached, but he later expressed relief that it had failed; writing only a month before his death he seemed convinced that " the League cannot do anything to stop wars."

As the successful leader of the opposition to Wilson, Lodge's prestige was increased and his influence in the succeeding administration was for a time great. He served as permanent chairman of the Republican National Convention in 1920, and as one of the four U.S. delegates at the Washington Conference on the Limitation of Armaments in 1921. Thereafter his influence waned to some extent, especially after he opposed Harding's proposal for joining the World Court. He was re-elected to the Senate in 1922 by a narrow margin; under Coolidge, although leader of the Senate, he did not work in close co-operation with the President. He died at Nahant, Mass., on Nov. 9 1924 at the age of 74.

Senator Lodge was one of the great Congressional figures of the last decade of the 19th and the first two decades of the 20th centuries. Reputed cold and distant in manner, a " Boston Brahmin," he enjoyed the prestige indicated by his popular appellation, the " scholar in politics," and held the respect of his colleagues on both sides of the Senate, who admired his ability as a debater, his tactical skill upon the floor, and the knowledge and experience which he brought to prolonged and assiduous labour in committee. An historical writer of high reputation and productivity, fate denied him the opportunity to become responsible for great legislative measures and forced him at the apex of his career into the rôle of critic. (C. SEY.)

LODGE, SIR OLIVER JOSEPH (1851–), British scientist, (*see* 16.860). After 1910 Sir Oliver Lodge became increasingly prominent as a leader of psychical research and a strong believer in the possibility of communicating with the dead, and he distinguished himself more than any scientist of his time in the serious endeavour to reconcile science and religion. Among his publications dealing with this subject are *The Survival of Man* (1909); *Reason and Belief*, 3rd ed. (1911); *The War and After* (1915); *Raymond, or Life and Death* (1916), a memoir of his son killed in the World War, with an account of communications believed to have been received from him since; *Christopher: a Study in Human Personality* (1918). Early in 1920 he made an extensive lecturing tour of the United States, having just previously retired from his post as principal of Birmingham University; and a few years later he published a series of popular scientific books of which the best known are *The Making of Man* (1924), *Ether and Reality* (1925), *Relativity* (1925), and *Talks about Wireless* (1925). In 1919 he received the Albert Medal of the Royal Society of Arts for his pioneer work in wireless telegraphy. He was president of the British Association in 1913–4, and of the Radio Society of Great Britain in 1925, and had been an F.R.S. since 1902.

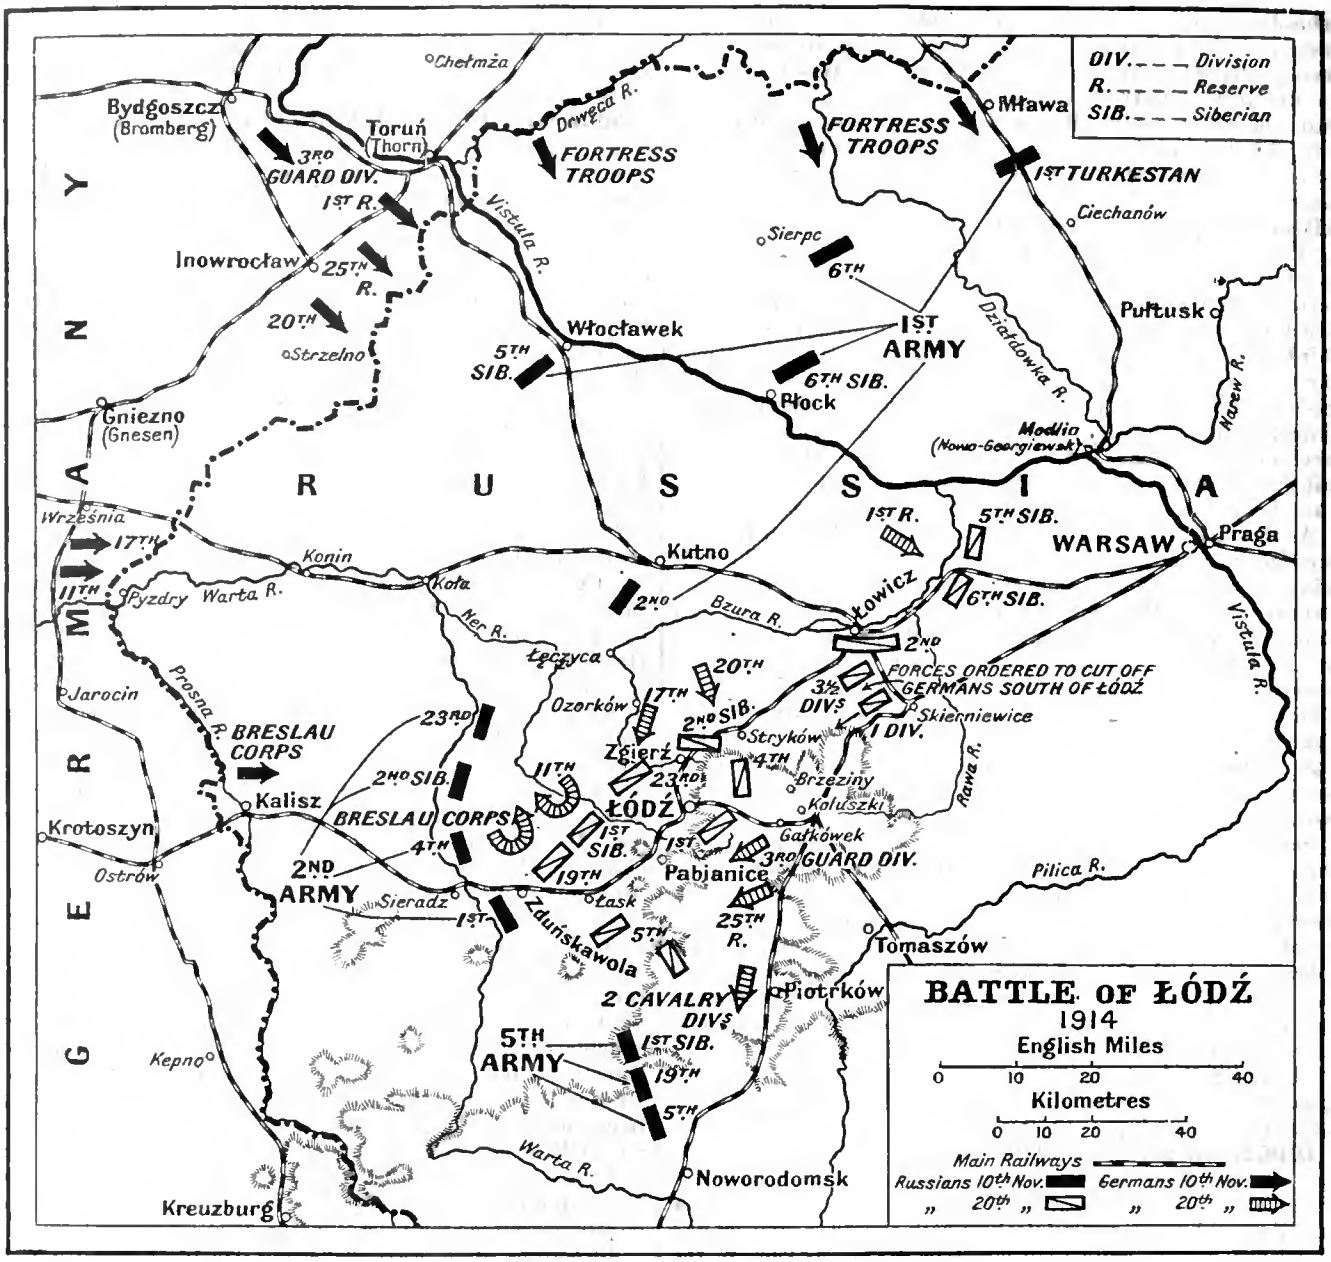
ŁÓDŹ, Poland (*see* 16.862), the most important centre of cotton and woollen manufacture in the country before the World War, has been deprived of its former outlet in the Russian Empire, but cotton spinning and weaving remains its most important industry. Łódź had a population of 451,813 in 1921, of whom 60% were Poles and some 180,000 Jews. An exchange has been established, and a school of social and economic studies was opened in 1925. Work on the drainage system and gas-works was to have begun in 1924. Łódź became the seat of a Roman Catholic bishop in 1920.

ŁÓDŹ-CRACOW, BATTLES OF.—The repulse at the end of Oct. 1914 of their first offensive in Poland (*see* VISTULA-SAN) placed the Germans in a perilous position on the Eastern Front. The Austrian armies were again in retreat, and were rapidly becoming demoralised; the Germans themselves, on the northern part of the Eastern Front, were greatly outnumbered and could expect no considerable reinforcement till the Ypres battle in the west had been decided. The evident intention of the Russian Commander-in-Chief, the Grand Duke Nicholas, was to advance on the great industrial region of Silesia. In their retreat from Warsaw and Poland the Germans had done their best by elaborate destruction of communications to impose as slow a rate as possible on this advance; but their numbers were insufficient to stem the oncoming tide of Russia's hordes by a direct defence. Invasion of German territory might be slow, but it seemed inevitable.

Ludendorff's Plan.—The German High Command solved their portion of the problem by placing Hindenburg, commander of the IX. Army, in charge of all German forces on the Eastern Front (VIII. and IX. Armies and Woyrsch's detachment) and instructing him to do his best without immediate reinforcement. Hindenburg kept Ludendorff as his chief of staff, and the latter at once proposed a characteristically bold solution. This was to withdraw the IX. Army from central and southern Poland and, taking advantage of the excellent railway system, to transfer it north to a base between Posen and Torun (Thorn), from which to strike a blow at the Grand Duke's communications as he advanced southwest on Silesia. The plan was an audacious one. In the first place it left the direct route to the enemy's objective, the province of Silesia, barred only by the unreliable Austrians and by weak German elements. Ludendorff trusted to the destroyed communications and to the customary Russian sluggishness of manoeuvre for time sufficient to carry out the contemplated counterstroke. Secondly, East Prussia, again threatened by invasion, would be further denuded of defenders, for Ludendorff proposed to call on the VIII. Army to furnish a quota to his striking force. Lastly, the manoeuvre involved thrusting a body of between five and six corps within reach of Russian forces twice that size, and the greater the success of the blow, the deeper the penetration into the Russian rear, the heavier would be the weight of the enemy masses concentrated on it. But the result of the battle of Tannenberg had been to persuade Hindenburg and Ludendorff that disparity in numbers could be largely discounted with the Russians as foes.

Disposition of the Russian Forces.—On the Russian side, the first fortnight of Nov. 1914 saw the high-water mark of that onward sweep towards Germany of Russia's exhaustless masses, on which the Allies had built such high hopes. There were at this time eight Russian armies deployed. The X. Army, which had replaced the defeated I. Army on the eastern frontier of East Prussia, had begun to move forward. The I. and II. Armies, to the northwest and west of Warsaw, protected the flank of the main advance by the V., IV. and IX. Armies; on the south, the III. and VIII. Armies covered the left flank by pressure on the Austrian main forces in the direction of Cracow. But progress was slow, hampered by difficulties of supply; and already the Russians were beginning to feel that shortage of munitions and of trained drafts which was to lead to their disasters of 1915. Their armies were strung out in linear formation and no central reserves were available.

The point of attack chosen by Ludendorff for the IX. Army under Mackensen, which now comprised 5½ corps and two cavalry divisions, was the junction between the I. and II. Russian Armies. The Vistula and Warta rivers, to east and west, would protect the flanks of the German advance. To prevent any transfer of Russian forces from north of the Vistula, a detachment, mainly of fortress troops, was to advance on Mlawa, while another pushed up the right bank of the river towards Płock.



The Russian I. Army was spread over a wide front with three corps north of the Vistula between Mława and Płock and two corps south of the river—the V. Siberian at Włocławek and the II. Corps (lately transferred from the II. Army) between Kutno and Łęczyca. The II. Army was on the Warta, west of Lódź, directed on Kalisz. The V. Army was on the left of the II. and was approaching the upper Warta.

First Battle of Lódź.—Mackensen began his advance on Nov. 11. On the 12th the isolated Siberian V. Corps at Włocławek was overwhelmed and driven back on Płock. Two days later the II. Corps acting as a link between the I. and II. Armies about Kutno, and the XXIII., the right corps of the II. Army, were defeated by greatly superior numbers and driven south. Scheidemann, commander of the Russian II. Army, now tried to wheel his corps from their line on the Warta to a position northeast of Lódź, the chief manufacturing town of Poland. But the German movements were too sure and rapid for the ponderous Russian counter-march. The columns of the II. Army were attacked in turn as they came up and were thrown back on Lódź.

Meanwhile the two defeated corps of the I. Army, now joined by the Siberian VI. Corps from north of the Vistula, were forced back towards Warsaw and away from Lódź. Into the gap between the two Russian armies Mackensen thrust three divisions, the two of the XXV. Res. Corps and the 3rd Guard Div. and his two cavalry divisions, with instructions to pass round the right flank of the II. Army and encircle Lódź from the south. A corps formed from the Breslau garrison, which had now come up from the west, was to turn the left wing of the Russian II. Army, pinned in front by the attacks of the German XI., XVII. and XX. Corps. Ludendorff was aiming at a second Tannenberg, in which Scheidemann's army was to fill the same rôle as had the unfortunate Samsonov's. The I. Res. Corps meanwhile was by persistent attack to prevent the I. Army from intervening.

By Nov. 18 the position of the Russian II. Army seemed wellnigh desperate. It was being driven into a narrow semi-circle round Lódź with both flanks turned, and was becoming exhausted and dispirited. But help from the V. Army was now close at hand. Plehve, its commander, on receiving orders to turn back to the assistance of the II. Army, acted promptly and with resolution. He attempted to rail one division north to Skierniewice but only one regiment got through before Mackensen's cavalry cut the line. The rest of the division came into action on Nov. 19, south of Lódź against the turning movement of the German XXV. Res. Corps. The whole of the remainder of the V. Army marched north on the 18th, the gap it left on the

IV. Army's right being filled with cavalry. That same night the Siberian I. Corps relieved the pressure on Scheidemann's left by a successful attack on the German XI. Corps. Next day the XIX. Corps routed the Breslau troops. This restored the situation on the west side of Lódź; but to the east and south of the town Schaffer's XXV. Res. Corps and 3rd Guard Div. were still advancing. By the evening of Nov. 20 they had completely turned the right of the Russian II. Army and were attacking Lódź from the south.

During Nov. 21 Ludendorff persisted in a last effort to accomplish the destruction of the Russian II. Army, but the attacks definitely failed. By the 22nd the tables had been turned, and Schaffer's force was itself completely surrounded. While part of Plehve's army, after rescuing the left of the II. Army, turned to attack Schaffer's group south of Lódź, Rennenkampf, the commander of the I. Army, had been ordered to despatch forces from Łowicz and Skierniewice to gain touch with the II. Army and close the German line of retreat to the north. The Łowicz force, which consisted of 3½ divisions, started on Nov. 20 and by the evening of the 22nd, in spite of three changes of command and indifferent staff work, had captured Stryków and Brzeziny, and had apparently sealed the gap between the Russian I. and II. Armies. The Russians actually ordered up 18 trains to remove the anticipated harvest of prisoners. The Skierniewice column of a division and a regiment accomplished nothing.

Escape of Schaffer's Force.—In the evening of the 22nd, Schaffer, heavily engaged with part of Plehve's army, south of Lódź, received a wireless order from Mackensen to cut his way out by Brzeziny. During the night of Nov. 22, in intense cold, he succeeded in slipping from the grasp of the enemy opposing him and concentrating his weary divisions to make their bid for release. Unknown to him, the Russians had already opened a breach. The centre columns of the Łowicz force had marched on to Lódź, leaving the left column, the Siberian 6th Div., isolated west of Koluszki on the Warsaw-Lódź railway. This division fought gallantly during Nov. 23 and repulsed all efforts of the XXV. Res. Corps to escape. Further west, however, the 3rd Guard Div. moving through the Galkówek forests, found the gap in the Russian net and captured Brzeziny in the early hours of Nov. 24. Encouraged by this success, the XXV. Corps renewed its efforts against the hapless Siberian 6th Div., whose appeals for help were disregarded by other Russian formations within easy reach of the battlefield. Finally, the division, with both flanks turned and overborne by weight of numbers, broke and left the way open for the XXV. Res. Corps to rejoin the 3rd Guard Div. at Brzeziny. Schaffer's line of retreat was now clear, and on the 25th his whole force, moving by Stryków, rejoined Mackensen. He brought with him several thousands of prisoners and a number of captured guns.

Effect of the Battle.—Ludendorff's bold stroke had stopped the grand duke's intended invasion of Silesia as effectively as Sir John Moore, by a similar move, had halted Napoleon's incursion into Spain a little more than 100 years before. Never again during the War were the Russians in a position to threaten German territory. The campaign shows well the value of mobility as a strategical weapon. On Oct. 26 the IX. Army was engaged opposite Warsaw during Hindenburg's first offensive. During the next fortnight it retired 120 m. destroying the communications as it went; reorganised and repaired its losses; was transferred by railway across the enemy front; and deployed in complete fighting trim for its new offensive on Nov. 11. This shows German organisation and efficiency at its highest. The quality of German leadership was also well-displayed, and was in strong contrast with the irresolution and inertia shown by some of the Russian commanders.

Schaffer's exploit was a masterly one; within a few hours of receiving his orders to retire, he had succeeded in breaking off action and setting his columns in motion to seek a way to safety, which his determination and the fine fighting spirit of his troops was to win. Compare this with the inaction of many of the Russian commanders, particularly the failure of the numerous bodies within reach to come to the rescue of the Siberian 6th Div. on Nov. 23. Ludendorff had owed much to Rennenkampf's passivity for his victory at Tannenberg; here again Rennenkampf's inefficiency and lack of the will to victory saved him from the loss of Schaffer's force which his rashness and obstinacy had exposed. Yet Rennenkampf had been accounted a dashing leader of men before the War. The Grand Duke himself, Ruzski (the commander of the Northwest Front), and Plehve, who hid an iron will in a weak and wizened frame, all acted promptly and with determination to take advantage of the opportunity.

Second Battle of Lódź: Dec. 1–15.—At the end of Nov. Hindenburg received reinforcements of four corps from the west, released by the termination of the first battle of Ypres. He now advanced again and captured Lódź on Dec. 6 and Łowicz on Dec. 15. The Russians fell back to the Bzura-Rawka river line in front of Warsaw, which they were to hold until Aug. 1915. Meantime an attack by the Austrian II. Army towards Piotrków in the first week of Dec. had been repulsed.

Battles round Cracow: Nov. 15–Dec. 25.—While the fighting round Lódź was taking place in the north, fierce battles were being waged in southeast Poland and western Galicia between the Austrian main armies and the Russian left wing. These battles were indecisive in their results and have less interest, strategically and tactically, than the battles round Lódź.

After the fighting on the San and round Dęblin (Iwangórod) in the latter part of Oct. the Austrian I. and IV. Armies fell back gradually on Cracow, followed up slowly by the Russian IV. and IX. Armies. The Austrian II. Army (two corps), was railed north to fill the gap on the left of Woyrsch's force caused by the withdrawal of the German IX. Army for Hindenburg's counterstroke in north Poland. The front of the II. Army was taken over by the III. Army, which now held the line of the Carpathians as far east as the Uzsok pass. The eastern Carpathians down to the Bukowina were guarded by Ptlanzer-Baltin's group. To defend western Galicia between the fortress of Cracow and the Carpathians, a group consisting of the XI. Corps and some cavalry was formed and took up station on the line of the middle Dunajec. The Austrian plan was to meet the expected attack towards Silesia of the Russian V., IV. and IX. Armies with Woyrsch's army and the I. Army, while the II. Army from the north and the IV. Army from the south wheeled against the enemy's flanks.

The Russian advance was slower and more cautious than had been expected; their V. Army had to turn about on Nov. 17 to rescue the II. Army at Lódź; while the IV. and IX. Armies on approaching Cracow halted for the III. Army in Galicia to come forward and invest the fortress. On Nov. 17, therefore, as soon as the Austrian II. Army had completed its detrainment and come up into line, the Austrian armies north of the Vistula took the offensive. A week of attack and counter-attack followed with little advantage to either side. Radko-Dimitriev's III. Army had meanwhile come up to the Dunajec; he passed one corps over to the north of the Vistula to enable the IX. Army to parry the thrust at its left flank of the Austrian IV. Army; with the remainder he drove back the Austrian XI. Corps to a defended position east of Cracow.

Final Encounters of 1914.—Conrad, the Austrian chief of the general staff, now planned a new combination. He passed part of the IV. Army over by rail to the left wing of the Austrian III. Army near Limanowa for a counter-stroke at Radko-Dimitriev's left. This was made on Dec. 3, and the fighting soon became general along the whole front between the Vistula and the Carpathians. Brusilov's VIII. Army, facing the Austrian III. Army along the Carpathians, sent a corps by Nowy Sacz to the assistance of Radko-Dimitriev, but was thereafter itself heavily attacked. On Dec. 15, after the loss of Lódź and Łowicz in the north, the Grand Duke issued orders for a general withdrawal in South Poland and Galicia to winter lines. The V., IV. and IX. Armies fell back to the Nida line, and the III. Army to the Dunajec. Brusilov's VIII. Army, however, on the extreme left, counter-attacked the Austrian III. Army between Dec. 18 and 25 and drove it back to its former position in the Carpathians (battle of Jasto). This brought to an end the campaigns of 1914.

The Russian "steam-roller," which the Allies in the West had so confidently expected to see smashing over its foes with irresistible, if deliberate, momentum, had come to a standstill for want of fuel. The Grand Duke's decision in the middle of Dec. to break off battle and retire was occasioned mainly by the shortage of munitions and the impossibility of keeping the ranks filled with trained drafts to replace the heavy wastage due principally to that very lack of a sufficiency of shells and other material of war. But the Russians had most loyally done their best under great disadvantages to live up to the expectations which their allies had formed of them. It was the machine, antiquated and behind the age, that fell short of the stern requirements of modern war.

LOEB, JACQUES (1859–1924), American physiologist, was born in Alsace, France, April 7 1859. Graduating at Ascanisches Gymnasium, Berlin, he studied medicine in Munich and Strasbourg (M.D., 1884). He was assistant in physiology at the universities of Wurtzburg (1886–8) and Strasbourg (1888–90), working also at the Naples biological station from 1889–91. He went to the United States in 1891 and taught biology at Bryn Mawr for a year. He became assistant professor of physiology and experimental biology at the University of Chicago in 1892, being appointed associate professor in 1895 and professor in 1900. In 1902 he became professor of physiology at the University of California. From 1910 to the date of his death he was head of the division of general physiology at the Rockefeller Institute for Medical Research. He died at Hamilton, Bermuda, Feb. 11 1924. Dr. Loeb's work was chiefly directed to a pursuit of the real distinction between living and dead matter, the thesis upon which he worked being that all living things are chemical machines and that their workings are open to the same mechanistic explanation as are those of any machines made of inert matter. Among his published works are *The Heliotropism of Animals and Its Identity with the Heliotropism of Plants* (1890); *Physiological Morphology* in 2 vol. (1891–2); *Comparative Physiology of the Brain and Comparative Psychology* (1900); *Studies in General Physiology* (1906); *The Dynamics of Living Matter* (1906); *The Mechanistic Conception of Life* (1912); *Artificial Parthenogenesis and Fertilisation* (1913); *The Organism as a Whole* (1916); *Forced Movements: Tropisms and Animal Conduct* (1918).

LOEB, JAMES (1867–), American banker and philanthropist, was born in New York City Aug. 6 1867. On his graduation from Harvard College in 1888, he became a member of the firm of Kuhn, Loeb & Co., bankers, New York City, retiring from business in 1901. In 1905 he founded and endowed the Institute of Musical Art in New York City. He devoted much of his time to classical archaeology. He was the founder of the Loeb Classical Library of Latin and Greek authors, works which give text and translation on adjacent pages. The first volume appeared in 1912. He was instrumental in founding the Deutsche Forschungsanstalt für Psychiatrie, an institution in Munich for the systematic study of the causes of mental diseases. He translated from the French: P. Decharme's *Euripides and the Spirit of His Dramas* (1906), M. Croiset's *Aristophanes and the Political Parties at Athens* (1909) and P. L. Legrand's *Daos* (1917).

LOGIC (*see* 16.879).—The most important contributions to logic during the pre-War years, 1911–4, are to be found in two works of H. Driesch, *Ordnungslehre* (1912) and *Die Logik als Aufgabe* (1913), in the *Encyclopaedia of Philosophical Sciences*, vol. 1, *Logic* (1913), and in the new, enlarged edition of B. Bosanquet's *Logic, or the Morphology of Knowledge*, 2nd ed. (1911). J. M. Baldwin's *Genetic Logic*, vol. 3 (1911) only carried a stage further the work which was inaugurated five years earlier; Miss E. E. C. Jones' *New Law of Thought* (1910, etc.) was of limited interest; P. Coffey's *Science of Logic* (1912) was intended as a textbook for Catholic students; C. A. Mercier's *New Logic* (1912) and F. C. S. Schiller's *Formal Logic* (1912) display more contempt than understanding for traditional logic.

Like other human pursuits logic suffered during the World War. The years 1915–8 are almost a blank in the history of logic—J. Dewey's *Essays in Experimental Logic* (1916) being mainly a collection of older essays, and A. E. Davies' *Textbook of Logic* (1915) being only a textbook.

WRITERS AND THEIR VIEWS

Driesch.—According to Driesch, logic is the theory of order. The theory of order results from self-reflection. Its most comprehensive principle is that of the economy of assertions. This principle is not merely a matter of convenience, but expresses the essential nature of thought. In this respect Driesch differs from Avenarius and Mach. According to Driesch the fundamental truth of philosophy is "I think something." Now whatever is thought is thought to be orderly; and the task of logic is to ascertain what makes experience orderly. Thought is always directed to problems, which it endeavours to solve by placing them in some orderly system. It is with the help of thought that life achieves progressive orderliness.

Royce.—Of the six essays on logic contained in the first volume of the *Encyclopaedia of the Philosophical Sciences* the most important is that by J. Royce, who, like Driesch, tries to treat logic as a science of order. In his account of induction, he denies that inductive reasoning is guided by the principle of the uniformity of nature, or by the principle of sufficient reason. Neither helps the investigator to decide whether, or to what extent, he may generalise in a given case. According to Royce the validity of induction rests on the assumption of some order in the objects investigated, and the reliability of a "fair sample" as a means of judging a whole range of facts. A fair sample is one chosen without bias. Of such samples, he maintains, there are always more that more or less resemble the whole than such as differ widely from it; so that judging a whole range of facts by means of a random sample is more often approximately right than wholly wrong. The chief advantage of mathematical sciences is that the mathematical results deducible from hypotheses needing verification present a vast range of samples, and the precision of mathematical concepts renders it easy to decide whether an observed sample agrees with the anticipated result.

Bosanquet.—The new edition of Bosanquet's *Logic* contains considerable additions. Book II., Chapter 8, deals with the criticism that his theory of judgment commits him from the start to metaphysical absolutism. If every judgment qualifies reality by an abstract universal, and no combination of such universals can confer particular individuality, there can be but one ultimate individual to which all predicates belong. This is absolutism. Bosanquet retorts that no finite individual is self-dependent or self-contained, that is, a real substance. Even the self finds its reality in something beyond itself. But an individual not self-complete can be predicated of the whole of which it is a part. Chapter 9 discusses criticisms of the coherence theory of truth. Bosanquet maintains that Truth is its own criterion—it can only be tested by more of itself. Any system can be tested further only by being made more complete. The view that truth is only an adaptation to vital needs, is claimed by Bosanquet to be the same view in principle. But while approving the attempt to claim for logic the realm of life and practice, and to apply the general idea of natural selection to the development of thought, Bosanquet protests against the narrow conception of practice which limits it to external action.

Intimately connected with the coherence theory of truth is his subsequent book on *Implication and Linear Inference* (1920). According to this all inference is of the same type, namely, implication. The essence of implication is interrelation between the parts of a system (or concrete universal), which makes modification in some parts clues to the modification of others. Syllogistic inference is linear, not systematic, and therefore not true inference. In true inference we survey a system of facts, see it in its relation to the whole of reality, and read off the implications. The inference is immediate if we can read off the implica-

tions directly; it is mediate if we must construct this system first. The starting-point of all inference is the realisation that to deny the truth of *all* propositions would involve self-contradiction, denying this very denial. We must consequently believe *some* propositions, even if we question the truth of this or that proposition. In true inference we transfer our certainty that *some* propositions are true to the truth of the proposition inferred. In the last resort, all inferences may be reduced to the alternatives: "Either this proposition is true, or no proposition is." Within the system from which we start we read off conclusions the denial of which would shatter the whole world of our experience.

Bradley.—The philosophical absolutism of Bosanquet is also emphasised in F. H. Bradley's *Essays on Truth and Reality* (1914) and in the new edition of his *Principles of Logic* (published in 1922 with numerous additions). Bradley repudiates his previous assumption of ideas divorced from judgments, and of judgments divorced from inference. The concrete conceptual fact is inference, of which mere ideas and simple judgments are bare abstractions. Inference is the ideal self-development of a given object taken as real. The given object is an ideal content before us, and it is taken to be real as being in one with reality, or the real universe. The possibility of inference rests upon the fact that the object is not only itself, but is also contained as an element in a whole; in fact, it *is* itself only as being so contained. From the nature of the case inference must always be incomplete, and subject to unknown conditions. But this ultimate problem does not concern logic.

Other Writers.—Among new editions of older books on logic mention may also be made of H. W. B. Joseph's *Introduction to Logic*, 2nd ed. (1916), W. Wundt's *Logik* (3 vol., 4th edition, 1919–21), L. T. Hobhouse's *Theory of Knowledge* (1921) and A. Höfler's *Logik* (1922). Wundt's *Logik* has not undergone any radical changes, and retains its important place. Hobhouse reasserts his fundamental principles that the systematic interconnection of judgments is the true line of advance in the interpretation of reality, and that the categorical judgment asserts a reality independent of itself. Höfler's *Logik* is practically a new book. While excluding epistemology it includes a good deal of psychology and philosophy. More particularly it shows the influence of A. Meinong's *Gegenstandslehre*, which distinguishes "existence" from "being," of which it is only one species. Whatever is false has being, but not the being of what is true. On the whole, Hötler defends traditional logic, holding that the syllogism, for instance, formulates a kind of reasoning actually used in practical life, even if there are also other forms of reasoning. One of the novelties of the book is the classification of judgments into four classes according to their evidence, namely, (1) those immediately evident and certain, (2) those mediately evident and certain, (3) those immediately evident and probable, and (4) those mediately evident and probable. The book also contains a number of essays on logistics by E. Mally.

Johnson.—The most ambitious new work on logic during the period 1911–25 is that of W. E. Johnson. His *Logic* is planned in four parts and is intended to cover the whole field. (Part I. appeared in 1921, Part II. in 1922 and Part III. in 1924; Part IV. has not appeared yet.) Logic is conceived to be concerned with the analysis and criticism of thought, and it is considered impossible to draw a rigid distinction between logic and philosophy, or between logic and science. In thought he distinguishes two aspects, an epistemic and a constitutive aspect. The constitutive aspect consists of the content of knowledge (which has itself a logically analysable form); the epistemic aspect is that which depends on the variable conditions and capacities for the acquisition of knowledge. The unit of logic is the proposition (or that of which truth and falsity can be significantly predicated). In contrast with the rather common class-interpretation of propositions, Johnson lays stress on the intensive aspect. "Implication" is potential inference, and assumes different relations in different cases. There are two principles of deductive inference:—(1) The applicative principle states that a proposition of the form *All S is P* warrants the inference of a proposition of the form *The given S is P*. (2) The implicative principle states that a compound proposition of the form '*x*' *and* '*x implies y*' warrants the inference of a proposition of the form '*y*'. The syllogism involves both principles. The following argument may illustrate each of the two principles and their combination in the syllogism.

(1) Applicative principle	All quadrilaterals have their opposite sides equal, if they are parallel (every MP is *p* if *m*). ∴ The quadrilateral ABCD has its opposite sides equal, if they are parallel (the given MP is *p* if *m*).
(2) Implicative principle	The quadrilateral ABCD has its opposite sides paralled (the given MP is *m*). ∴ The quadrilateral ABCD has its opposite sides equal (the given MP is *p*).

Johnson distinguishes between the constitutive and the epistemic conditions of valid inference. The constitutive condition is that the premises must be *true* and must *imply* the conclusion. The epistemic condition is that the thinker must be in a position to *know* that the premises are true, and that they imply the conclusion, without having to know beforehand that the conclusion is true. But now, the two principles of deductive inference require universal premises. How are these obtained? Johnson says, by *induction*. But he uses the term induction in an unusually wide sense, namely:—for any process of starting from certain instantial premises and reaching a generalisation. He formulates four types of induction, namely:— (1) *intuitive*, (2) *summary*, (3) *demonstrative* and (4) *probable*. Of these the last corresponds to ordinary empirical induction; and *summary* induction corresponds to so-called perfect induction. By *intuitive* induction Johnson means the process by which we obtain the fundamental principles of inference and the axioms of pure logic, mathematics, etc. It is not suggested that these are merely empirical generalisations, but that they are obtained by reflection on particular instances of them. This may happen in two ways:— (1) the *counter-applicative* way, when we can see that what is true of this instance is true of any other instance, and (2) the *counter-implicative* way, when, having made a particular inference which is valid, we can see that its validity is due to a certain type of formal relation which holds between the premises and the conclusion. These modes of procedure cannot be safely applied without special insight into the subject-matter of the investigation.

Under *demonstrative* induction are included certain types of hypothetical syllogism in which the instantial premise leads to a universal conclusion. For example:— "Every specimen of argon has some the same atomic weight. This specimen of argon has atomic weight 39·9. Therefore, every specimen of argon has atomic weight 39·9." Under the same head Johnson also includes the familiar canons of induction as reformulated by himself in four figures of agreement, difference, composition and resolution. Of *problematic* induction there are two varieties. There is *pure generalisation*, that "All things which are *m* are *p*," if all the observed things which were *m* were also *p*; and there is *class-fractional* induction (usually called statistical generalisation), that "a certain proportion of things which are *m* are also *p*," that proportion having been noted in the observed cases. From all these forms of induction Johnson distinguishes under the name of *Eduction*, the argument from "certain instances of *s* which are *m* are *p*" to "the next *s* that is *m* will also be *p*." The discussion of various psychological and metaphysical problems is a striking feature of Johnson's *Logic*.

The only other contemporary attempt at a comprehensive logic is Th. Ziehen's *Lehrbuch der Logik auf positivistischer Grundlage*, etc. (1920). This treatise contains not only much that is psychological and metaphysical but also a history of logic, which is perhaps the most useful part of it.

On the whole, logic has not yet reached the stage of having clearly defined boundaries, and is apt to trespass on the domains of mathematics and psychology, of epistemology and ontology,

according to the taste of the writer. Its state is like that of Israel under the Judges, every man doeth that which is right in his own eyes. There are signs, however, that the necessary differentiation may come about in another way. There is a marked tendency towards a greater division of labour, as may be seen from the number of treatises devoted entirely to special groups of logical problems, such as those of formal-symbolic inference (or logistic), the methodology of the sciences, the theory of knowledge (or epistemology) at the basis of science, etc.

Bibliography of books not already mentioned:—
Formal-Symbolic.—L. Conturat, *Algebra of Logic* (1914); C. I. Lewis, *A Survey of Symbolic Logic* (1918); L. Wittgenstein, *Tractatus Logico-Philosophicus* (1922); B. Russell and A. N. Whitehead, *Principia Mathematica* (1925).
Methodological.—J. M. Keynes, *Treatise on Probability* (1921); A. D. Ritchie, *Scientific Method* (1923); J. Nicod, *Le Problème Logique de l'Induction* (1924); A. Wolf, *Essentials of Scientific Method* (1925).
Epistemological.—B. Russell, *Problems of Philosophy* (1912), and *Our Knowledge of the External World* (1914); E. Becher, *Naturphilosophie* (1914); D. C. Macintosh, *The Problem of Knowledge* (1916); E. Mach, *Erkenntnis und Irrtum* (1917); H. Dingler, *Die Grundlagen der Physik* (1919); A. N. Whitehead, *An Enquiry Concerning the Principles of Natural Knowledge* (1919–25), and *Concept of Nature* (1920); E. Meyerson, *De l'Explication dans les Sciences* (1921); E. Becher, *Geisteswissenschaften und Naturwissenschaften* (1921); B. Bavink, *Ergebnisse und Probleme der Naturwissenschaften* (1921); C. D. Broad, *Scientific Thought* (1923); T. L. von Haering, *Philosophie der Naturwissenschaft* (1923); C. D. Broad, *The Mind and its Place in Nature* (1925); E. A. Burtt, *Metaphysical Foundations of Modern Physical Science* (1925); W. P. Montague, *The Ways of Knowing* (1925). (A. Wo.)

LOGUE, MICHAEL (1840–1924), Irish ecclesiastic, was born at Kilmacrenan, Co. Donegal, Oct. 1 1840. He was appointed professor of theology and belles-lettres at the Irish College in Paris, where he was ordained a priest in 1866. He became Bishop of Raphoe in 1870, archbishop of Armagh in 1887, and in 1893 was raised to the cardinalate. During the World War he deprecated participation by the clergy in Sinn Fein agitations, but in 1918 opposed conscription on moral grounds. In 1919 and 1921 he rigorously denounced the campaign of murder against the police and the military, at the same time criticising severely the policy and methods of the British Government. He died at Armagh Nov. 19 1924.

LONDON, JACK (1876–1916), American novelist, was born at San Francisco Jan 12 1876, and educated at the University of California. A born adventurer, he went to sea at the age of 17 and served before the mast. He went with the first rush to Klondike in 1897 and tramped across the States and Canada, being in gaol more than once as a vagabond. In 1904 he went to Japan as war correspondent, and in 1914 to Mexico in the same capacity. In 1906 he started on a voyage round the world in a 50-ft. ketch-rigged yacht and disappeared for two years. His novels, for the most part published first in London, reflect his wild, adventurous life, the best known being *The Son of the Wolf* (1900); *The Call of the Wild* (1903); *Moon Face* (1906); *Martin Eden* (1909); *South Sea Tales* (1912); and his last, *The Little Lady of the Big House* (1916). He died at Glen Ellen, Cal., Nov. 22 1916. See *The Book of Jack London* (1921), by his wife, Charmian London.

LONDON (*see* 16.938).—Greater London had, in 1926, a population of about 7,500,000 persons, but nothing has occurred in the years since 1910 to alter materially the story of its site, although under the heading of climate some diminution in the density of its fogs may be noted.

Divisions, Buildings and Communications

The characteristic divisions so well marked in the past have been gradually broken down since the close of the War, and for various reasons many large private houses have been converted into flats, maisonettes, boarding-houses, and, nearer the centre, business premises. The residential turnover is most marked in regions north and south of Hyde Park, while in boroughs such as Hackney or Stepney or those lining the south bank of the river the tendency is towards the intrusion of business. In the suburbs, after the complete cessation of house building, growth has been resumed, and has been fostered by the electrification of railways or the extension of railways previously electrified and the development of motor transport. An interesting feature before the War was the establishment of the Hampstead Garden Suburb in the north of London, in which the houses were limited to eight per acre. A very important factor in the development of Greater London was the passing of the Unemployment (Relief Works) Act of 1920, designed to benefit ex-service men, which permitted land required for new roads to be entered upon within seven days. Under this Act it was possible to provide in the outer area many of the urgently required main and relief roads before access to the centre was hopelessly blocked by the multiplication of housing schemes.

The period since 1910 included also some very important changes in the aspect of the streets in the central area, the greatest perhaps being the passing of Nash's Regent street and Quadrant. All idea of a unified scheme for rebuilding was abandoned except for the Quadrant itself, where an adaptation of the plan of Shaw's Piccadilly Hotel was followed. The widening of the Strand advanced considerably, and the Kingsway and Aldwych improvement initiated in 1899 was brought appreciably nearer conclusion. Other improvements completed included the Woolwich Tunnel in 1912 and the opening from Trafalgar Square into the Mall by way of the Admiralty Arch. Cross-river communications were improved by the reconstruction of Southwark Bridge, while the money for a new road bridge at Lambeth was voted by the London County Council. A movement that threatened completely to alter the appearance of the western districts was inaugurated by the sale of the garden ground in Mornington Crescent and Endsleigh Gardens, a new building on a portion of the latter open space being finished in 1926.

Parks.—Parks and open spaces continued to be added to the amenities of the city and the outer areas, the most important including the clearance and opening to the public of a portion of the river front at Shadwell and the preservation of Prince's Square, Stepney, in the built-up area. In the outer areas progress was made in the preservation for the public enjoyment of the wooded bastion of Shooters Hill to the south-east, and an important addition to Hampstead Heath and Parliament Hill Fields on the north was secured by the purchase of a considerable portion of Lord Mansfield's estate known as Kenwood.

Monuments.—The historical monuments of the past were not greatly interfered with during the period, although considerable perturbation was caused by the publication of a report containing suggestions for reorganising the work of the Church of England in the City of London that indicated the possible sale of 19 churches, including many designed by Wren. Later still signs of weakness appeared in the foundations of Waterloo Bridge which led to a unanimous resolution of the London County Council to remove the entire structure, action being only delayed on the urgent representations of a number of leading professional and learned societies. The report of the experts on the steps necessary for preserving the dome of St. Paul's Cathedral led to the closing to the public in 1925 of the whole space beneath the dome and the choir. Important works of preservation were also undertaken for the roofs of Westminster Hall and the Great Hall at Hampton Court Palace.

New Buildings.—The modern architecture of the metropolis was enriched by the addition of a number of striking buildings, including (to mention only a few) the new London County Hall at the east end of Westminster Bridge, the Port of London Authority home in Trinity Square, Britannic House and Adelaide House in the City, Bush House at the end of Kingsway, Australia House in Aldwych, the Wesleyan Central Hall and the Middlesex Guildhall in Westminster, the Royal Automobile Club in Pall Mall, the new north frontage of the British Museum and the headquarters of the British Medical Association in Bloomsbury. A considerable impetus was given to the production of fine street architecture by the institution of a medal by the Royal Institute of British Architects for the best street façade completed each year. The first to win the award was the new Wolseley building in Piccadilly, and the next the Shepherds Bush Pavilion. The general tendency towards change was most

marked in the City area, where the spires and towers of Wren that had so long dominated the view were slowly but surely engulfed in the rising tide of commercial architecture, the most notable instance being the almost total eclipse of the view of St. Magnus spire and the Monument from London Bridge by the erection of Adelaide House.

In the west end another marked transformation was the erection of a huge block of millionaire flats and shops on the site of Devonshire House, Piccadilly. The monuments and memorials in the metropolis were added to in a marked degree, though not always as the result of the World War, for the period included the completion of the Queen Victoria Memorial before Buckingham Palace and the King Edward VII. Memorial in Waterloo place. Amongst the many war memorials should be mentioned the Cenotaph in Whitehall, the Grave of the Unknown Warrior in Westminster Abbey, the memorial to London's soldiers in front of the Royal Exchange, Belgium's Gratitude and the Air Force Monument on the Embankment, and the Artillery and Machine Gunners' memorials at Hyde Park Corner. Work on the Guards' Memorial on the Horse Guards Parade was started in 1925. Interesting additions to the nomenclature of London were made in various districts, particularly the revival of the name Aldwych for the crescent section of the Holborn to Strand improvement, and that of Petty France to the roadway in Westminster passing under the shadow of Queen Anne's Mansions.

Communications.—Communications, as far as the trunk lines serving the metropolis were concerned, received no additions, but a vast change was almost imperceptibly carried out by the grouping of the great companies. The introduction of electrical working on many suburban lines was another feature of this period. Although no entirely new tube was opened, the reconstruction of the old City and South London line was taken in hand and completed, with its junction with the Hampstead Tube at Camden Town, and work was started on an extension of the line to Morden. The Golders Green terminus was connected with Edgware, and a new tunnel beneath the Thames from Charing Cross to Waterloo and Kensington was also started. A tube was specially constructed by the Post Office for connecting up the various sorting offices, and private proposals for an even more comprehensive system for goods traffic connecting the various termini were laid before the Ministry of Transport. Horse traction vanished finally from the tramway systems, now operated almost entirely by the London and Middlesex County Councils, and the L.C.C. lines were extended a little nearer the City by being carried over the new Southwark Bridge, but no lines were actually permitted through the City or West End, although proposals for this were discussed.

The principal change in traffic was, however, the enormous increase in the number of motor omnibuses plying in the streets, brought about by the appearance of numerous independent companies, popularly termed "pirates," while the London General Omnibus Co. ran more frequent services and operated many fresh routes, including some running right out into the surrounding country during the summer months; and many new and improved types of omnibuses were placed on the streets, including a few with covered tops. The chaotic conditions introduced by this great increase in the number of vehicles, and by the appearance of independent omnibus companies, combined at times with the operation of a great number of road repairs, some no doubt delayed by the War, finally led to a great step forward in the control of traffic, which took the form of the appointment of a London traffic advisory committee, whose duties were to advise the Ministry of Transport on matters relating to London traffic.

An important addition to the continental facilities of London was the opening of daily Air Services to Paris, Brussels and Amsterdam, connecting with other services to all parts of Europe and also to Africa.

Population, Education and Amenities

The population of Greater London in 1911 was 7,251,358, and in 1921 7,480,201; while that of the administrative county was 4,521,685 in 1911, and 4,484,523 in 1921. That of the outer ring was 2,729,673 in 1911 and 2,995,678 in 1921, while that of the City was 19,657 in 1911 and 13,709 in 1921. Greater London increased by 10·2% between 1901 and 1911, and by 3·2% between 1911 and 1921, while the county of London had decreased by 0·3% and 0·8%. The statistics for the metropolitan boroughs are as follows:—

	Area in statute ac.	Population		Increase (+) or Decrease (−)
		1911	1921	
Battersea	2,163	167,743	167,693	− 50
Bermondsey	1,503	125,903	119,455	− 6,448
Bethnal Green	760	128,183	117,238	−10,945
Camberwell	4,480	261,328	267,235	+ 5,907
Chelsea	660	66,385	63,700	− 2,685
Deptford	1,564	109,496	112,500	+ 3,004
Finsbury	587	87,923	76,019	−11,904
Fulham	1,706	153,284	157,944	+ 4,660
Greenwich	3,859	95,968	100,493	+ 4,525
Hackney	3,287	222,533	222,159	− 374
Hammersmith	2,287	121,521	130,287	+ 8,766
Hampstead	2,265	85,495	86,080	+ 585
Holborn	405	49,357	42,796	− 6,561
Islington	3,092	327,403	330,028	+ 2,625
Kensington	2,290	172,317	175,686	+ 3,369
Lambeth	4,083	298,058	302,960	+ 4,902
Lewisham	7,015	160,834	174,194	+13,360
Paddington	1,357	142,551	144,273	+ 1,722
Poplar	2,331	162,442	162,618	+ 176
St. Marylebone	1,473	118,160	104,222	−13,938
St. Pancras	2,694	218,387	210,986	− 7,401
Shoreditch	658	111,390	104,308	− 7,082
Southwark	1,131	191,907	184,388	− 7,519
Stepney	1,767	279,804	249,738	−30,066
Stoke Newington	863	50,659	52,167	+ 1,508
Wandsworth	9,107	311,360	328,656	+17,296
Westminster, City of	2,503	160,261	141,317	−18,944
Woolwich	8,282	121,376	140,403	+19,027
City of London (County Corporate)	678	19,657	13,706	− 5,951

Health and Hospitals.—The birth-rate for the administrative county was 20·0 in 1922 and 20·1 in 1923 per 1,000 population. In Greater London the figures for the same years were 20·2 and 19·5. The death-rate for the same periods in the administrative county was 13·5 and 11·4 per 1,000 population, and for Greater London 12·5 and 10·7. In the hospital world great campaigns were instituted to place the leading institutions on a firm financial basis, and considerable alterations and improvements were carried out at Westminster and St. George's amongst others, while the removal of King's College Hospital to Denmark Hill was completed. During 1925 it was decided to rebuild the Middlesex Hospital. The growing share of women in the hospital work of London was illustrated by the existence of several hospitals entirely managed by them. The activity of the London County Council was notable in the direction of the improved treatment of tuberculosis and other virulent diseases, and in the campaign against infant mortality.

Water, Lighting and Heating.—The water supply of London was largely increased by the completion in June 1925 of the huge reservoir at Littleton with a capacity of 6,750 million gallons and a water surface of 723 acres. The estimated income of the Water Board for 1925–6 from all sources was £4,695,000, and the estimated expenditure £4,809,120, but as a balance was brought forward no precept on the participating authorities was needed. The policy of the board, adopted in 1916, to save coal by chlorinating raw Thames water, some 70,000,000 to 100,000,000 gal. per day, was entirely successful both financially and from the point of view of the public safety. The treated water is allowed to flow by gravity down the Staines aqueduct instead of being pumped into the reservoir. Figures give but little idea of the size of the board's undertaking to the average person, but it may be stated briefly that in the average daily consumption of water (about 36 gal. per head), London would empty 2½ times daily a tank as large as Trafalgar Square (two and a half acres) and as high as the Nelson Column.

An important step in the lighting (and heating) of London

was the appointment under the Electricity (Supply) Act 1919 of electricity commissioners to supervise the supply of electricity under the Ministry of Transport. The electricity district as determined extends well beyond the area known as Greater London, covering 1,858 sq. m.; the current in this area being distributed by 44 local authorities and 44 private companies. That there is plenty of room for both electricity and gas in supplying the metropolis with light and heat is evident from the fact that one of the largest of the gas companies in 1925 reported an increase of 24% in its sales during the preceding 10 years.

By the end of 1922–3 the cost of the fire brigade had risen to nearly £800,000 (including pensions), and the number of calls attended, other than chimney calls, during the same period was 3,845. The curve of value of insured property in London showed a marked increase in the preceding 10 years, the total reaching over £2,000 million.

Education.—The general trend of education in London is naturally in accordance with that of the whole country, but it is interesting to note that its total cost to London during 1922–3 amounted to over £12,000,000, of which, of course, approximately half was refunded by exchequer grants, so that the actual charge on the rates amounted to a fraction over 31d. in the £1. The London County Council is the statutory authority for the administrative county of London, and the education committee of 50 includes 12 co-opted members who must be persons of experience in education and of whom five must be women. In 1925 there were 17 women members altogether on the committee. The council had not in 1925 availed themselves of the power to extend the age for compulsory attendance at school conferred on them by the Education Act of 1921.

Recreation.—The museums, art galleries, etc., requisitioned for use during the War, gradually resumed their normal functions, and a new feature was introduced in the form of guide lecturers to conduct parties round the various sections. New rooms were added to the Tate Gallery, and the British Museum was greatly enlarged by the wing to the north opened in 1914. The London Museum, on the lines of the Musée Carnavalet in Paris, was removed from Kensington Palace to Stafford (now renamed Lancaster) House owing to the generosity of Lord Leverhulme, and a special museum illustrating the development of furniture making was opened in Hoxton in 1914 in the centre of the cabinet-making district of London.

Several new theatres were opened during the early part of the period under review, including the Winter Garden in Drury Lane, the Ambassadors and St. Martin's in Seven Dials and Princes in Shaftesbury avenue. A movement was started to reconstruct the old Sadlers Wells Theatre and open it on the same lines as the "Old Vic." After the War few new theatres were built, but on the other hand there was an enormous increase in the number and size of cinematograph houses, one of which, namely, that at Shepherds Bush, as already mentioned, won the medal for the best street frontage for the year offered by the Royal Institute of British Architects.

The demand for playing pitches for games of all sorts in public recreation and other open spaces increased exceedingly, and amongst other innovations many hard courts for lawn tennis were laid down by the London County Council. Professional football was largely supported also, and the construction of the British Empire Exhibition grounds at Wembley saw the removal of the Final for the Football Assn. Cup to the Stadium. "Saturday" starts in first-class cricket, and increased interest in county cricket generally, led to considerable additions to the accommodation for spectators at both Lord's and the Oval.

The Government of the Metropolis

At the elections to the London County Council in 1919 (postponed during the War) 68 Municipal Reformers, 40 Progressives, one Independent and 15 Labour members were elected. At the 1922 elections the figures were—Municipal Reformers 82, Progressives 25, Labour 17; and in March 1925, Municipal Reformers 83, Labour 35, Progressives six. In contested elections only, the number voting in 1919 was 16·6% and 36·8% in 1922. For the metropolitan borough councils the figures were—27·9% in 1919 and 36·4% in 1922. For the guardians' elections the results were much lower, being only 7·7% in 1919 and 22·8% in 1922. In Dec. 1924 there were no contested elections for the court of common council of the City of London.

The boundaries of all the London Parliamentary boroughs were re-arranged by the Act of 1918, except those of the City of London, the total number of constituencies being 61, each returning one member and the City two.

Finance.—The financial government of London was not modified to any important extent during the 15 years, although some temporary measures had to be adopted during the War. A 1d. rate over the administrative area was estimated to produce £207,555 for 1924–5 on the statutory assessable value of the county which was computed as £49,813,091 on April 6 1924. The average rate for the area was rather over 11s., the highest figure being 23s. in Poplar and the lowest 9s. 9d. in the city of Westminster. The total net debt of London on March 31 1923 was given as £122,988,798, and the total charge for interest and repayment was £7,492,473. One of the principal financial obligations left by the War was the provision of working-class dwellings, and the net debt on these throughout the county area in the year 1922–3 stood at £20,160,004, with a charge of £1,174,788. The total net debt of London has increased by about £18,000,000 since the year 1918.

The history of London during the period under review has really been the story of the interruption of its natural growth in population, extent, wealth and progress and its gradual resumption. In 1915 the City suffered from the first hostile attacks launched against it for nine centuries, and it was remarkable that in spite of persistent attempts from the air the total material damage throughout the whole area amounted to less than one-fifth of that sustained in the Great Fire of 1666, while hardly a building of historical value was injured.

Bibliography.—The best general reference is *The Subject Index* published by the British Museum Library every five years. The Guildhall Library has prepared a special *Catalogue of London Books* subdivided into an infinite number of subjects. For general information also see *London Statistics*, published by the London County Council, and *The Accounts of the Corporation of London*, as also the annual reports of the L.C.C. and the metropolitan boroughs. Other books relating to London published during the 15 years include: *History, The Survey of London*, published jointly by the London County Council and the London Survey Committee, and the publications of the *London Topographical* and other kindred societies. See also Walter H. Godfrey, *A History of Architecture in London* (1911); G. R. S. Taylor, *Historical Guide to London* (1911); W. R. Lethaby, *Westminster Abbey* (1911); R. Nevill, *London Clubs* (1911); Sir G. L. Gomme, *The Making of London* (1912); H. D. Irvine, *A History of London* (1912); E. Beresford Chancellor, *Annals of the Strand* (1912); W. F. Taylor, *The Charterhouse of London* (1912); Thomas J. Barratt, *Annals of Hampstead* (1912); A. St. John Adcock, *The Booklover's London* (1913); Wilfred Whitten, *A Londoner's London* (1913); A. W. Clapham, *Some Famous Buildings and Their Story* (1913); P. A. Harriss, *London and Its Government* (1913); Hilaire Belloc, *The River of London* (1913); Reginald Blunt, *In Cheyne Walk and Thereabouts* (1914); E. V. Lucas, *London Revisited* (1916); Margaret E. Tabor, *The City Churches* (1917); Sir G. J. Younghusband, *The Tower from Within* (1918); Claude Mullins, *London's Story* (1920); W. G. Bell, *Unknown London* (1920); E. A. Webb, *History of Bartholomew the Great* (1921); the London Society, *London of the Future* (1921); M. H. Cox, *London Government* (1922); Ernest Law, *Kensington Palace* (1923); C. G. Harper, *More Queer Things about London* (1924); H. F. Westlake, *Story of Westminster Abbey* (1924); L. Wagner, *London Inns and Taverns* (1924); *The London County Council and what it does for London* (1924); *Westminster Abbey*, the Royal Commission on Historical Monuments (1925); A. E. Davies, *Story of the London County Council* (1925); Amongst the best *Guides* are Findley Muirhead, *The Blue Guide* (2nd ed., 1921), Alwyn Pride, *Overseas Visitors' Guide* (1922) and Lawrence H. Dawson, *Introductions to London* (1926).

(P. W. L.)

LONDON, CONFERENCES OF.—Five meetings of Allied statesmen for the purpose of adjusting matters arising out of the peace treaties which concluded the World War were held in London in 1921–2.

Feb. 21–March 14 1921.—The representatives of the principal Allied Powers here carried on alternately two separate sets of negotiations, one with the representatives of the Athens, Con-

stantinople and Angora Govts. on the Near Eastern question (*see* TURKEY), and the other with the German Foreign Minister, Dr. Simons. Both sets of negotiations were failures. A week after the conference dispersed the Greeks launched a new offensive in their war with the Turkish Nationalists; while, a week before the conference dispersed, sanctions were taken against Germany by the Allied military occupation of Düsseldorf, Duisburg and Ruhrort, outside the area occupied under the Versailles Treaty, and by the impounding of German customs receipts and the establishment of a new customs cordon between occupied and unoccupied territory. The cause of these measures was the presentation by Dr. Simons of an unacceptable counter-proposal to the reparation demands which the Allied Governments had put forward at the Paris Conference of the preceding Jan. 24–30 (*see* PARIS, CONFERENCE OF). Germany appealed against the Allied sanctions to the League of Nations, but the League took no action.

April 29–May 5 1921.—Under Article 235 of the Versailles Treaty, Germany was required by April 30 1921 to have made a first instalment of reparation payments in cash and kind to a total value of 20 milliard gold marks (approximately one milliard pounds sterling). As this period approached, it became evident to the reparation commission that Germany would be in default under this head, and on April 29 the Allied statesmen, after a preliminary meeting on the 23rd and 24th at Lympne, met again in London to consider what should be done. New sanctions against Germany were discussed, and an additional class of the French Army was actually mobilised; but meanwhile, on April 27, the reparation commission had declared their estimate of Germany's total liability, and the Allied statesmen turned their attention from the non-execution of Article 235 to the drawing up of a "Schedule of Payments describing the Time and Manner for securing and discharging the entire Obligation of Germany for Reparation under Articles 231, 232 and 233 of the Treaty of Versailles." This document, which seems to have been drawn up by the heads of the Allied Governments, though issued in the name of the reparation commission, was sent to Berlin on May 5, together with an ultimatum. Meanwhile the German Govt. had fallen; but on May 11, one day before the ultimatum was due to expire, a new ministry accepted the Allies' terms with the sanction of the Reichstag.

Dec. 18–22 1921.—A meeting between Mr. Lloyd George and M. Briand (accompanied by M. Loucheur), in consequence of a declaration by the German Govt. that it would be unable to pay the two instalments next due under the schedule imposed by the ultimatum of May 5 1921, followed. The Prime Ministers decided to call a meeting of the Supreme Council of the Allies at Cannes, and drafted, for submission to this meeting, a memorandum on the reparation problem in which they proposed to grant Germany a partial moratorium in exchange for an increase in the stringency of Allied control over German finances. At this meeting the eventual convening of a general European conference on reconstruction was also foreshadowed (*see* CANNES, CONFERENCE OF).

Aug. 7–14 1922.—A meeting which arose out of the failure of Germany to carry out the schedule of reparation payments to which she had pledged herself under duress on May 11 1921. The arrangement made between the German Govt. and the reparation commission during the Cannes Conference (*q.v.*) had only postponed disaster, and since then the finances of Germany had gone from bad to worse. At the London Conference M. Poincaré brought forward, as conditions for granting Germany a moratorium, proposals for "productive guarantees" which he had attempted to carry out next year after the Franco-Belgian military occupation of the Ruhr. When these proposals were referred to an inter-Allied committee of experts, the French found themselves in a minority of one, the other experts declaring that M. Poincaré's proposals would bring in diminishing returns. Counter-proposals of a milder kind were put forward by the British delegation, but as these in turn proved unacceptable to M. Poincaré the conference broke up without reaching a decision (*see* REPARATIONS).

Dec. 9–11 1922.—A meeting to consider the conditions for granting a reparations moratorium to Germany, on which no agreement had been reached at the London Conference of the preceding August. At this meeting M. Poincaré again pressed his plan for "productive guarantees," which he expounded in greater detail than four months before. He made it clear that he would not consent to a moratorium without taking these pledges, which included the military occupation of the Ruhr. At the same time he countered the British plan for remitting a portion of Germany's total liability in return for the remission to France of part of her war-debt to Great Britain, by declaring that even in return for this *quid pro quo* he would only be willing to cancel "C" bonds, which were of merely nominal value. As these French terms were not acceptable to Great Britain the conference was adjourned. (A. J. T.)

LONDON, PORT OF (*see* 16.949).—On March 31 1909 the Port of London Authority became the chief body controlling the Port of London.

Before 1909, no public body had been charged with the duty of maintaining and improving the accommodation in the port. The City Corporation, Trinity House, and the Thames Conservancy had each exercised certain powers of conservancy, and the dock companies had enlarged their docks as and when it seemed profitable to them to do so. The outstanding change made by the Port of London Act of 1908 was that it set up a public body whose principal duty is to investigate the accommodation and facilities in the port and execute such works in the river and docks as are necessary to keep the Port up to a standard befitting the first port of the world. The main features of the Authority's policy have, therefore, been more concerned with the improvement of the Port than with the reorganisation of port methods and practice.

A comprehensive programme of new works was tentatively adopted in 1910. The principal works put in hand at once were:—

(*a*) the construction of a modern dock to the south of the Royal Albert Dock, 64 acres in extent with a length of quay of 12,700 ft., capable of receiving vessels of about 35,000 tons burthen.
(*b*) an extension of the Tilbury Dock.
(*c*) the rebuilding of the north quays of the East India and West India Docks.
(*d*) a river cargo jetty at Tilbury.

The World War delayed the completion of the new dock which was opened by George V. on July 8 1921. By the opening of this dock the total water area of the docks was increased to 704 acres and the length of dock quays to 156,450 feet.

Improvements.—An enormous amount of deepening and dredging of the river channels and docks has been carried out between 1909 and 1925. During 1924–5 alone, 3,897,000 cu. yd. of material were removed from the river, and the quantity of mud removed from the docks was 1,206,000 cubic yards. The result of the deepening operations in the river is that for the greater part of the 25 m. below Tilbury and for the 10 m. above Tilbury, the channel at low water had, in 1925, a minimum depth of 30 ft. with a width of over 1,000 feet. For the remaining 6 m. up to the King George V. Dock, the width of the channel is maintained at 600 ft., with a minimum low water depth of about 27 feet. At high water, these channels are wider, while the depths are from 17 to 21 ft. greater. The new works in hand in 1925 included a new dock in the Surrey Commercial system. Preparations were well advanced for a new dry dock, a new river entrance, and a passenger landing stage at Tilbury. Up to March 31 1925 the sum spent on new works by the Port Authority approximated £11,000,000.

Value of the Port Shipping.—The amount of merchant shipping entering and leaving the port was affected by the War, especially during 1918, when the tonnage was only 14,564,000 tons as compared with 40,080,000 tons in 1913. Since 1918, recovery has rapidly taken place, the figure for 1924 being 45,393,000. The total value of the overseas trade of the port for 1924 was £677,342,000, compared with £582,464,000 at Liverpool and £121,186,000 at Hull. Though the Port of London Authority provides most of the accommodation in the port, there is an im-

portant system of private riverside wharves and warehouses, where small vessels are discharged and warehousing business is carried on in competition with the Authority. Recent developments in the river below Barking Creek favour the establishment of industrial enterprises which expect to benefit by their easy access to Thames port facilities.

There have been several labour disputes in the port during the period 1910-25. A general strike for higher wages took place in the summer of 1911; a more serious strike occurred in 1912, when the question at issue was the employment of non-union labour. During the War, labour was comparatively quiescent, threats of trouble being averted by concessions of higher wages to meet the increased cost of living. Another strike took place in 1924, in resistance of a reduction of wages previously agreed upon. The minimum rate of pay in the port in 1925 was 12s per day. The organisation of labour in the port has greatly improved since 1910. The administration of the port by the Authority may, on the whole, be regarded as successful. Dock charges are doubtless higher than they would have been had the dock companies not been dispossessed, but compensation for this is found in the more comprehensive treatment of port problems under the management of a body in which the traders using the port are in a majority. (J. G. B.)

LONDON, UNIVERSITY OF (*see* 27.772).—London University has problems which are directly related to its dual nature and to its immediate history. The first attempt to found a university in London was made by Sir Thomas Gresham in 1548 when seven professorships—divinity, music, physic, astronomy, geometry, law and rhetoric were endowed, but this project never attained full fruition. In 1825 Thomas Campbell, the poet, addressed a public letter to Brougham, as a result of which University College came into being and opened classes in 1828 in arts, law and medicine.

Creation by Charter.—On Nov. 28 1836 the University of London and University College, respectively, received charters. The university was constituted an examining body, while University and King's Colleges were constituted the teaching centres. The university was thus created as an examining body and as such undoubtedly achieved a great reputation for impartiality, thoroughness and high standard, so great being its prestige in medicine and surgery in particular that its degrees were and still are sought after even in preference to those of older universities, especially by students from the Dominions.

Teaching University Established.—The Cowper Commission (1894) submitted a report in 1894, embodied in the University Act of 1898, which forms the present constitution of the university. In accordance with statutes approved by Parliament in 1900, the teaching colleges were federated with the university but were not subject to any financial control. Indeed, the authority of the university is limited to the recognition, or refusal of recognition, as teachers of the university, of teachers in the colleges and to the approval of courses of study. Thus a dual university was established, combining the functions of examination with the functions of teaching in its federated schools.

All affairs appertaining to the teaching institutions of the university fall under the administration of the Academic Council, which reports directly to the Senate. This section of the university has become known as the internal side. All other functions not to do with teaching, which had been performed by the old examining body, fall under the administration of the Council for External Students which also reports directly to the Senate. This section of the work of the university is known as the external side, and the degrees granted to students examined by this body, but not taught necessarily in the schools of the university, are called external degrees. The Senate remains the executive authority to accept, to modify, or to reject as it wills the recommendations coming from these two great statutory councils thus constituted.

The Senate.—The Senate, as the executive and co-ordinating body, comprises three nearly equal sections. One represents the teaching or academic side (16 representatives chosen by the faculties), one represents the external side (16 representatives chosen by the graduates constituting Convocation) and a third section of 21 members consists of representatives chosen by the Crown and other outside electing bodies. The chancellor and chairman of Convocation, who are elected by the whole body of Convocation, complete a Senate of 55 members. The third section named above acts in some sense as a jury between the equal bodies representing the academic and external interests. Practically all the business of the university is conducted by committees. The Senate exercises its important functions by reception of reports from these committees, and has proved in practice a remarkably efficient instrument.

Incorporation of Colleges.—In 1905 University College was incorporated with the university. This was followed in 1908 by the incorporation of King's College. The effect of incorporation is difficult to estimate. Nominally the colleges are under the control of the university; in fact they are very largely independent of that control. No other school has wished to secure incorporation, while King's College has expressed the desire to cancel incorporation if this should be possible.

Royal Commission.—In 1909 a Royal Commission, over which Lord Haldane presided, was appointed with wide terms of reference and after taking evidence published its report in 1913. The following significant remark was made by a commissioner on the first day of taking evidence:—

> My point is this: What is the use of a royal commission or any other body attempting to organise university teaching, and to elevate it and to enhance the value of the degree if the external degree remains, if unrecognised colleges are doing as good work as the recognised ones?

The Commission made recommendations which would result in the complete extinction of external degrees in the more or less near future.

The Commission further recommended the constitution of a Senate of 15 members of whom two only were to be representatives of the teachers with one representative of graduates of Convocation, while the 12 others were to be appointed variously but in such a manner as to ensure bureaucratic control of the university. These drastic proposals met with very little public approval and lapsed during the War. However, a departmental committee was appointed by the Board of Education in 1924, when Lord Haldane was Lord Chancellor in the Ministry of Mr. Ramsay MacDonald, for the purpose of preparing statutes for legislative approval to give effect to the recommendations of the Royal Commission. Vigorous protests have been made against the constitution of the departmental Committee.[1]

Progress and Development.—Notwithstanding the disturbance inseparable from these repeated Commissions, the university under its present constitution has prospered exceedingly. Since 1915, roughly speaking, the internal side has trebled and the external side doubled in the number of students. Inasmuch as the internal side started from zero it has naturally progressed at a greater pace than the external side. Twenty-five colleges have sought and obtained recognition as "Schools of the University." Faithful to its tradition of far-seeing initiative, the university has founded degrees in commerce, which have already proved a most notable success. New chairs have been founded—largely by private munificence—in response to the ever-increasing complexity of modern science and industry. Research in every field of scholarship and science is sedulously encouraged. The university library has been developed and improved.

More recently the university has solved the very difficult problem of its relation with the Imperial College of Science and Technology. This college had long nursed the ambition to form a technological university giving its own degrees. It has now, by the adjustment of certain examinations, accepted wholeheartedly the position of a "School of the University." The

[1] The committee recommend—*inter alia*—the creation of a Council of the University to control finance, and of a Collegiate Council composed of members of the Senate. To give effect to these recommendations, which have been vigorously criticised, legislation will be required. Some financial control is unavoidable if co-ordination is to be secured, and to effect this without discouraging prospective or annoying actual benefactors will not be easy. (ED. *E. B.*)

great medical schools with their splendid traditions, so much older than the university itself, have accepted the system of the appointment of their professorial teachers by the university.

Very significant is the change that has taken place in the relations between the internal and the external sides. The external side, threatened with extermination, was placed upon its defence, and a perfectly unnecessary feud between external and internal interests became thus accentuated. With the increasing prospect that the commission's report would never be carried into effect hostilities died down and when the Haldane recommendations were revived by the appointment of the departmental committee the two sides of the university joined in a united protest which was submitted to the departmental committee in an identical memorandum prepared by the academic and the external council respectively.

The secret of the increasing confidence of the schools in the university central administration is to be found in the lightness and tactfulness of the control exercised by that administration. The colleges are free institutions, voluntarily submitting to guidance and leadership, but retaining essential independence. Any attempt to substitute for this system an encroachment upon the liberties of these federal institutions would spell disaster.

The university has become the largest university in the British Empire. Indeed, it is an increasingly important link of attachment, for it accepts students from every part of it on terms entirely equal. It still holds out an ever more helpful hand to the poor student unable to obtain a collegiate education. At the same time the number of its collegiate students, multiplied threefold in 10 years, testifies to the confidence which academic bodies repose in it. It continues to attract to its governing body men distinguished in every walk of life. (E. G. L.)

LONDONDERRY, CHARLES STEWART HENRY VANE-TEMPEST-STEWART, 7TH MARQUESS OF (1878–1915), British politician, was born in London May 13 1878. Educated at Eton and Sandhurst, he entered the House of Commons in 1906 as Unionist member for Maidstone. From 1914–9 he served in the World War, being twice mentioned in despatches. Made a privy councillor for Ireland in 1918 and a K.G. in 1919, in 1920–1 he was under-secretary for air, and in June 1921 took office as Minister of Education for Northern Ireland. From this position he resigned Jan. 6 1926 and was succeeded by Viscount Charlemont.

His father, Charles Stewart Vane-Tempest-Stewart, the 6th marquess (1852–1915) (*see* 16.069), was a prominent leader of the opposition to the Home Rule Bill of 1912 and was one of the first to sign the Ulster Covenant, Sept. 28 1912. He died at Wynyard Park, Stockton-on-Tees, Feb. 8 1915.

LONG, WALTER HUME LONG, 1ST VISCOUNT (1854–1924), English politician, born at Bath July 13 1854, was the eldest son of Richard Penruddocke Long, of Rood Ashton, Wilts., and his wife Charlotte, daughter of Fitzwilliam Hume Dick. He was educated at Harrow and Christ Church, Oxford. Being the heir of an old county family with a tradition of Parliamentary service, it was natural that he should contemplate a political career. He entered Parliament in 1880 as Conservative member for North Wilts, and sat in every House of Commons till he was created a peer in May 1921, though he changed his constituency several times. He obtained office early, and showed administrative power and common sense in positions agreeable to a capable country gentleman—Parliamentary Secretary to the Local Government Board 1886–92, President of the Board of Agriculture 1895–1900 and President of the Local Government Board 1900–5. His administration at the Board of Agriculture was marked by the stamping out of hydrophobia through the strict enforcement of a muzzling order for dogs; and the tenacity and resolution which he showed in carrying his policy through, in the face of a violent agitation by many dog owners and dog lovers, raised him greatly in public esteem.

In March 1905 Mr. Long was chosen by Mr. Balfour to succeed Mr. Wyndham, after the latter's breach with Irish Unionism, as Chief Secretary for Ireland. He at once restored Unionist confidence by reducing the under-secretary Sir Anthony (afterwards Lord) MacDonnell, to definite subordination to himself as the responsible minister, and by the firmness with which he proceeded to enforce the law and repress agrarian intimidation. The impression which he produced in Ireland in the few months before Mr. Balfour's resignation was so considerable that he, an Englishman, was returned to Parliament in the general election of 1906 for a Dublin seat. In the years of opposition which followed he proved a vigorous opponent of Mr. Birrell's policy of *laissez-faire* in Ireland and of Mr. Lloyd George's proposals with regard to the land; and a more benevolent critic of the Government Old Age Pension scheme and of Mr. Burns's administration at the Local Government Board. When Mr. Balfour resigned the leadership of the Conservative party in Nov. 1911 he was the candidate of the more conservative branch of the party; but both he and his rival, Mr. Austen Chamberlain, agreed to stand aside in favour of Mr. Bonar Law.

With the other conservative leaders he joined the first Coalition Ministry in 1915, returning to his old post of President of the Local Government Board; and in the second Coalition Ministry (1916) he was Colonial Secretary. He had been hitherto a decided opponent of woman suffrage, but, along with Mr. Asquith and others, he was converted by the services of women during the World War, and in 1917 he introduced in the House of Commons the Franchise Bill, which became law in the following year, and under which women over 30 obtained the vote. When Mr. Lloyd George reconstructed his Ministry in the beginning of 1919 Mr. Long became First Lord of the Admiralty and had the difficult task of supervising the reduction to a peace basis of the gigantic navy which had been built up during the War. For some years his health had been periodically unsatisfactory, and in the spring of 1921 he resigned office. Mr. Bonar Law's break-down in health occurred almost immediately afterwards, and Mr. Long heartily supported the election of his old rival Mr. Austen Chamberlain to the leadership of the Conservative party. A few months later he was raised to the House of Lords, amid general approval, as Viscount Long of Wraxall. He did not hold office in either Mr. Bonar Law's or Mr. Baldwin's Government, and died Sept. 26 1924 at Rood Ashton, Wiltshire. He had married in 1878 Lady Doreen Boyle, daughter of the 9th Earl of Cork. His elder son, Brig.-Gen. Walter Long, C.M.G., D.S.O., fell in action Jan. 27 1917, and Lord Long was therefore succeeded in the peerage by his young grandson. (G. E. B.)

LONG, JOHN DAVIS (1838–1915), American lawyer and politician (*see* 16.074), died at Hingham, Mass., Aug. 28 1915.

LOOS, BATTLE OF, was fought between the British and German Armies, Sept. 25–8 1915. The British offensives in the spring of 1915 at Neuve Chapelle, Aubers and Festubert, and the French offensive against the Lorette ridge, made only small gains, at heavy cost, and by July the Arras front was again stabilised. A stalemate ruled on the Western Front for the rest of the summer.

Plans of French Headquarters.—Despite the non-success of their spring offensive, French Headquarters were not disposed to relinquish all efforts to break through the German lines in France until such time as the British could attack on a great scale. It was desirable to do something in the West to relieve the situation in Russia, which was steadily growing worse. Accordingly, Gen. Joffre laid his plans for a big effort in Champagne to be combined with a Franco-British attack in Artois, the French X. Army attacking the Vimy ridge, the British I. Army between Lens and the La Bassée canal. If both succeeded it was hoped to establish touch between them east of Lens, which was to be "pinched out," not attacked direct, and should this coincide with a real break-through in Champagne there might be a chance of intercepting the Germans in the great salient between Soissons and Arras.

Composition of British Force.—The British share was to be on a far larger scale than in May; for the main attack nine divisions were available, six others were to contribute by creating diversions elsewhere. Careful economy in ammunition and the greatly increased output from the factories at home had allowed the accumulation of a fair supply of shells, and the enemy's own

weapon, gas, was to be employed. It was hoped that by using gas it would be possible to attack on a really wide front, much more extensive than would have been possible if the bombardment by the artillery had been the sole means of preparing for the assault.

To the main attack three corps were allotted: on the right, Sir H. Rawlinson's IV. Corps attacked from Loos to Hulluch; Sir H. Gough's I. Corps, on the left, making for the line Hulluch-Haisnes-Auchy. On both wings defensive flanks were to be formed under cover, of which the central divisions would push on towards the Haute-Deule canal, cross it at Pont à Vendin, and connect up with Foch's troops. The cavalry and the newly formed XI. Corps (Sir R. Haking), which included the Guards, making their début as a division, and the newly arrived 21st and 24th Divs., would support this advance.

Assault on German Front Line.—Four days' bombardment, of an intensity as yet unknown, preceded the assault, which was launched at 6.30 A.M. on Sept. 25. The bombardment was as effective as the limited amount of ammunition allowed, and the Germans' deep dug-outs greatly reduced its results by sheltering the trench garrisons, while unluckily the wind practically failed and the gas therefore proved a great disappointment. This was all the more serious because the artillery had been unable to do as much damage all over the wide front attacked as they had accomplished at Neuve Chapelle on the narrow frontage then attacked. However, over most of the front the wire had been well cut and the attackers carried the German front system and swept on towards their second set of trenches, about a mile in rear. On the extreme right the 47th Div. successfully established a defensive flank connecting their old line with Loos, which was reached and carried by the Scots of the 15th Division. The 15th's left, however, was exposed by the failure of the 1st Div's. right brigade, which found a long stretch of uncut wire covering trenches at Lone Tree, so that the left brigade which got in and penetrated to Hulluch, though after heavy losses, found its right uncovered and could not maintain its advanced position. The 7th Div., on the right of the I. Corps, carried its first objective after heavy fighting but could not pierce the German second system of defences in front of Cité St. Elie. On its left the 9th (Scottish) Div. took the Hohenzollern redoubt and Fosse 8, and a detachment reached the German second system but in insufficient strength to break through. The left division, the 2nd, attacking astride the La Bassée canal failed to take its objective.

Results of the Attack.—The attack had resulted in the capture of a long stretch of the German front line with 20 guns and many prisoners; losses, however, had been heavy, and though at several points the second system had been reached there was no touch between the different parties. These, moreover, had pushed beyond the range of effective artillery support, while neither Gough nor Rawlinson had sufficient reserves in hand to link up the different advanced parties; the XI. Corps was too far back to reach the front in time and the check to the 1st Div. at Lone Tree left the 15th's flank dangerously uncovered. As at Neuve Chapelle, there was an opening but there were delays. The Germans threw in their reserves, drove the advanced troops of the 15th Div. back to Hill 70, just east of Loos, ousted those of the 1st from Hulluch, got in after nightfall between the 7th and the 9th, and retook some quarries west of Cité St. Elie and made the 9th's centre recoil to Fosse 8. But at no point could they regain their old front line and they had to pay heavily for the ground they regained.

Second Attack.—On Sept. 26 an effort was made to break through between Hulluch and Loos, using the two "New Army" divisions of the XI. Corps. But the Germans were pressing so hard at the Hohenzollern redoubt and on Hill 70 that two brigades had to be diverted to those points, and the advance of the main bodies was greatly retarded by the congestion of the roads with transport, and other unforeseen delays. They could not reach their assigned position in time, and before the attack could be started a German counter-attack recaptured Bois Hugo, midway between Hulluch and Loos. This point had been reached by the right of the 1st Div. late on the previous evening, the dislodgment of the Germans at Lone Tree having at last let it get forward but too late to do much consolidation or link up with its left brigade at Hulluch or with the 15th Div. at Hill 70. Early in the morning a brigade of the 21st Div. had taken over Bois Hugo but had barely done so before the counter-attack dislodged it. Moreover, the British guns had been unable to register the German second line defences and the bombardment of them was ineffective. The 24th Div. pushed forward across the Lens-La Bassée road but was enfiladed from Bois Hugo by machine-guns, found the German wire and defences practically intact, and fell back in some disorder. The 21st Div. had already done the same after failing to retake Bois Hugo, and the greater part of Hill 70 passed back into German keeping, the defences being outflanked from the north as well as attacked in front. The I. Corps, too fully occupied in holding its ground, could make no progress.

Unsatisfactory Result.—By the evening of Sept. 28 the chance of a break-through was gone. On Sept. 27 the Guards Div. regained much lost ground on Hill 70 and secured a better line from Bois Hugo to Hulluch, but this merely improved the tactical situation at an awkward point. Elsewhere, German pressure was heavy, especially against the I. Corps. Fosse 8 was lost and efforts to retake the quarries failed, and though for several days a hold was with great difficulty maintained on the Hohenzollern redoubt it, too, was lost on Oct. 3. However, a big German counter-attack on Oct. 8 all the way round from Loos to the Hohenzollern, was decisively repulsed, and five days later the 46th (N. Midland T.F.) Div. covered part of the Hohenzollern, and the 12th (Eastern) Div. considerably improved the position nearer Cité St. Elie. This was the last attack on any large scale; the position in the salient which had been driven into the German lines gradually quieted down and before the end of Oct. had become as thoroughly stabilised as any other part of the fronts.

Long before the fighting on the British front had relapsed into normal "trench warfare" the French had abandoned their Artois offensive. The German front line was cheaply carried (Sept. 25), but though for some hours the German defences on the Vimy ridge were only scantily manned the French failed to reach them in time. Their plan of limiting their objectives strictly meant that what they took they secured but it meant also delays in reaching the more distant objectives. By Sept. 27 reserves had filled the gap and brought the French to a standstill, Vimy remaining in German hands.

Thus, Loos, like Neuve Chapelle and the May offensive, had failed to produce any change in the strategical situation, the tactical gains made had been dearly bought and no really substantial relief had been given to the Russians. Still, the Germans also had lost heavily, and the experience gained in the planning of so large an attack, far the biggest operation as yet attempted by the British Army, had been most valuable. At Loos it had been attempted to apply the lessons and to avoid the errors of Neuve Chapelle. There, chances had been lost through over-deliberation and rigidity, through waiting till others were up level, so that all might go forward together; at Loos, pushing on too deep, regardless of what others were doing, had occasioned overrunning and ultimately losing positions which greater deliberation might have secured. But Loos showed the Germans that the "New Army" divisions were a factor with which they must reckon seriously, that when the whole of the "New Armies" were in the field a great British offensive would be a formidable danger.

See J. Ewing, *The History of the 9th (Scottish) Division, 1914–19* (1921); also *see* WORLD WAR: BIBLIOGRAPHY. (C. T. A.)

LOREBURN, ROBERT THRESHIE REID, 1ST EARL (1846–1923), British lawyer and politician, was born at Corfu April 3 1846, and was educated at Cheltenham and Balliol College, Oxford, where he had a distinguished career, winning the Ireland scholarship in 1868. He was called to the bar in 1871, and in 1880 entered politics as Liberal member for Hereford. In 1882 he became a Q.C. and, having in 1885 lost his seat at Hereford,

was returned in 1886 for Dumfries Burghs, retaining the seat until 1905. In 1894 he was for a few months Solicitor-General and was knighted, and during 1894–5 was Attorney-General. He received the G.C.M.G. in 1899, and from that year until 1906 he was counsel to the University of Oxford. On the formation of Sir Henry Campbell-Bannerman's Govt. in 1905, Sir Robert Reid became Lord Chancellor, and was raised to the peerage as Baron Loreburn. To him, while Chancellor, the passage of the Court of Criminal Appeal Act (1907) was largely due. In 1912 he resigned on grounds of health. Lord Loreburn, who was created an earl in July 1911, published *Capture at Sea* (1913) and *How the War Came* (1919). He died without issue Nov. 30 1923, when the title became extinct.

LORENTZ, HENDRIK ANTOON (1853–), Dutch physicist, was born at Arnheim July 18 1853. In 1878 he was appointed a professor in the University of Leyden, a post which he held until 1923. From 1883 to 1895 he worked upon his electron theory and in 1892 published his *Théorie électromagnétique de Maxwell et son application aux corps mouvants*. This was followed in 1895 by the famous treatise *Versuch einer Theorie der elektrischen und optischen Erscheinungen in bewegten Körpern*. In 1900 appeared his *Theory of Electrons and its Application to the Phenomena of Light and Heat*, which gives the résumé of Lorentz's researches and contains the lectures he delivered in New York in 1906. In 1902 he was awarded, with Pieter Zeeman, the Nobel Prize for physics. Among his other works may be mentioned *Text Book of the Differential and Integral Calculus* (1882; German ed., 1900); *Visible and Invisible Movements* (1901); *Abhandlungen über theoretische Physik* (1907); *The Einstein Theory of Relativity: a Concise Statement* (1920); *Clerk Maxwell's Electromagnetic Theory* (1924). From 1919 his lectures for the university courses were published, under his personal supervision, with the title of *Lessons on Theoretical Physics*, eight volumes of which had appeared in 1925.

LORENZ, ADOLF (1854–), Austrian surgeon, was born at Vidnava, Silesia, April 21 1854, of poor parents. He entered Vienna University and studied surgery under Billroth, Nicoladini and Eduard Albert, afterwards becoming a demonstrator, and then a professor at the university. His best known studies are those relating to club-foot and flat-foot. He published numerous studies on his special subjects, the most important being *Die Lehre vom ererbten Plattfusse* and *Ueber die operative Orthopädie des Klumpfusses*. Lorenz also invented the *deutsches Gipsbett* which proved to be a great advance on Bradford's plaster beds which had previously been in general use.

LORIMER, GEORGE HORACE (1868–), American editor, was born at Louisville, Ky., Oct. 6 1868. His early education was received at the Mosely High School, Chicago, whence he proceeded to Colby (Me.) and Yale universities. After being for a short time in business in Chicago, he turned to journalism, becoming a reporter and correspondent on several newspapers. In 1897 he became literary editor of *The Saturday Evening Post*, and in 1899 was made editor-in-chief. The remarkable success of this periodical can be attributed in no small measure to Mr. Lorimer's keen appreciation of the public taste coupled with his ability to meet it. He adopted the policy of selling *The Saturday Evening Post* at a price (5 cents) much below the cost of manufacture, and thereby securing a circulation that made its pages an extremely attractive advertising medium. He wrote *Letters from a Self-Made Merchant to His Son* (1902), which achieved great popularity; *Old Gorgon Graham* (1904); *The False Gods* (1906); *Jack Spurlock Prodigal* (1908).

LORRAINE, EARLY OPERATIONS IN: *see* FRONTIERS, BATTLES OF THE.

LOS ANGELES, Cal., U.S.A. (*see* 17.12), had, at the end of 1925, a population estimated at over a million and an area of 421·71 sq. miles. The population within the city limits increased from 319,198 in 1910 to 576,673 in 1920. There were 15,579 negroes, 14,230 Japanese, Chinese and Indians and 112,057 foreign-born whites. About 1920 began an influx of population to southern California which surpassed even the movement of earlier years. Because of its geographical position and the embryonic state of most of its industries, Los Angeles had no war-time inflation and consequently escaped the experience of post-War deflation. On the contrary, the influx of population and the discovery, at almost the same time, of rich new oil-fields in the vicinity, caused a "boom" which lasted through the first quarter of 1924, reaching its greatest intensity in 1923. Business generally fell off in 1924, and in the first half of 1925 an actual decrease of population was discernible, but this was more than made up by gains in the last six months of the year.

Communications.—In 1919 only six steamship lines made the port of Los Angeles regularly. In 1925 there were 60 lines handling general cargo, 35 tank lines and 35 lumber lines. The total number of ship arrivals in the year ending June 30 1925 was 5,901. The harbour had, at the end of 1925, 10 m. of wharves (6 m. owned and operated by the city) and more than 50 m. of municipal harbour belt-line railway tracks; the channels and basin in the inner harbour had a depth of 30 ft. at low tide; in the outer harbour, at more than a mile of wharfage, of 35 ft.; the main channel had been doubled in width, to 1,000 feet. The electric railways in 1925 operated over 1,508 m. of track, extending to a radius of 75 m. outside the city. A one-mile subway and a terminal building, constructed 1924–6, greatly improved the service between important residential sections and the business district.

Commerce.—Within a few years after the close of the World War the commerce of the port of Los Angeles rose to more than that of any other ocean port in America except New York. The total tonnage (imports, exports, coastwise and inter-coastal) was 2,380,622 short tons in the year 1918–9, 26,550,464 in 1923–4 and 22,268,421 in 1924–5, with a value respectively of $86,481,470, $643,221,303 and $671,406,570. Exports to foreign countries amounted to about $75,000,000 in 1925; imports from foreign countries, to about $35,000,000. The increase was due partly to the demand for lumber (most of it from British Columbia) and other building materials, and for crude rubber, but chiefly to the great increase in the production of oil. It was at first piped out through the harbour in a crude form. With the development of refineries a larger part of it (by 1924) was shipped in a refined state. Great Britain was the principal market for gasolene (162,615,222 gal. in the year 1924–5); China for kerosene; Chile for fuel oil.

Industries.—Between 1910–9 Los Angeles became an important industrial centre, and after 1919 its manufactures grew fully as fast as its population. Factory products, within the city limits, were valued at $68,586,000 in 1909; $278,184,000 in 1919; $313,589,985 in 1921; $417,654,081 in 1923. The Federal census of manufactures, however, limited to factory products, does not include motion-picture films, which until 1924 were the city's most valuable product, or such commodities as manufactured gas; and it does not include any plants outside the city limits. Tabulations by the Chamber of Commerce, including all manufactured products, give the following figures for the metropolitan area: (1919) $618,772,000; (1921) $800,926,641; (1923) $1,151,643,537; (1924) $1,202,677,004. The leading industries in 1924, with the value of their products, were petroleum products, $221,880,293; motion-picture films, $168,000,000 (estimated to be 75% of all produced in the U.S.); iron and steel machinery, $99,117,430; meat products, $67,987,146; lumber and planing-mill products, $64,327,685. Petroleum products occupied the leading position for the first time in 1924, having increased steadily each year from $83,867,716 in 1919.

Water and Power.—The Los Angeles aqueduct, 250 m. long, bringing water from the Owens river in the Sierras, in amounts to supply a population of 2,000,000, was placed in service in 1913. In the process of extending the city service to the vast new areas which had been annexed, new water mains were installed at the rate of over one mile a day during the year ending Sept. 1 1925, bringing the total in service to 2,654 miles. To provide for anticipated needs in the future, plans were already well advanced for constructing a still longer and larger aqueduct to bring water sufficient for a population of 7,500,000 from the Colorado river. A bond issue of $2,000,000 was authorised June 2 1925, to begin preliminary work and acquire the necessary rights of way. The Bureau of Power and Light (established 1909), owned and operated, by 1925, five hydroelectric power generating plants along the line of the aqueduct, producing a total of 110,000 h.p., which furnished 60% of the total amount of energy distributed by the bureau, the other 40% being purchased wholesale from a private corporation.

Public Buildings and Improvements.—A fine Hall of Justice was completed in Dec. 1925, including a county jail to replace the one constructed in 1902. In 1925 plans had been accepted and a site chosen for a new city hall; a new public library was approaching completion (cost $2,000,000); the first unit of the $12,000,000 project for a county museum was completed; also the Coliseum (seating capacity, 77,000) built by the city and county jointly; and the Patriotic Hall, built by the county as a memorial to the soldiers and sailors of the country's wars. A city-planning commission was set up in 1910. By 1925 the city had a plan covering its entire area, and including zoning provisions, major and minor highway system, park, boulevard and channel parkway system.

Education.—The public-school system included (Nov. 1925) 234 elementary schools, 11 special schools, 14 junior and 23 senior high schools, with 7,495 teachers. The University of Southern California (enrolment 12,007 in 1924–5) established about 1920 an extension division known as the Metropolitan University, which had an enrolment of 4,900 in the autumn of 1925.

Government.—A new charter, adopted in 1924 and operative from July 1 1925, provides for the initiative, the referendum, the recall and an executive budget. The mayor (the chief executive, with wide appointive powers), the city attorney, the controller and the seven members of the Board of Education are elected at large. The 15 members of the council (the legislative body) are elected by districts. The principal functions of government are entrusted to 16 commissions of five members each, appointed by the mayor and serving without salary, which in turn appoint and fix the salary of general managers for their respective departments.

LOSSKI, NIKOLAI ONUFRIEVICH (1870–), Russian philosopher, was born at Kreslavka, Vitebsk province. He was educated at Kreslavka and at the University of St. Petersburg (Leningrad) where he studied first science and then philology. From 1916 to 1921 he was professor of the same university, but in 1922 he was compelled to leave Russia and went to live in Prague. Losski is the representative of intuitionalism in epistemology. According to his views, knowledge is immediate contemplation (intuition). His intuitionalism differs from Bergson's in so far as he considers the ideal-rational forms to be elements of realities, intuitively cognisable. His kind of intuitionalism leads to concrete ideal-realism, his idealism being as concrete as realism. He assumes not only concrete real being, but concrete ideal being as well, *i.e.*, supra-temporal and supra-spatial substantial agents with creative force, which are the basis of spatio-temporal being. Abstract ideas obtain their significance and importance exclusively from the substantial agents, who create the real according to constitutive abstract ideas (*e.g.*, mathematical principles) and normative abstract ideas (*e.g.*, moral ideas, etc.). The doctrine of the creative force and superqualitativeness of substantial agents leads Losski to his teaching of the freedom of the will.

Among Losski's most important books are *Die Grundlehre der Psychologie vom Standpunkte des Voluntarismus*, published in Russian (1903), in German (1905); *The Intuitive Bases of Knowledge* (1904; Eng. trans., 1919); and *Handbuch der Logik* (1922), in German (1926). The titles of his untranslated Russian works may be given in English as follows: *Introduction to Philosophy; The World as an Organic Whole; Principles of Epistemology; Matter and Life; Freedom of Will.*

LOUCHEUR, LOUIS (1872–), French politician, was born at Roubaix Aug. 12 1872. After studying at the École Polytechnique he embarked upon a highly successful career as an engineer and contractor. Both in France and abroad he gradually developed an extensive business, and the advent of the World War with its necessities gave fresh prosperity to those industries concerned with the manufacture of arms and munitions. When in Dec. 1916 M. Briand decided to give certain offices to non-political men of high technical ability, he called upon M. Loucheur to be an under-secretary of state. In the Cabinet formed by M. Clemenceau in 1917, which lasted until Jan. 1920, he was Minister of Munitions. After entering Parliament in Nov. 1919 as deputy for the Nord Department, he became Minister for the Liberated Regions in the Briand Cabinet, Jan. 1921. In that capacity he negotiated with the German Minister of Reconstruction, Herr Walter Rathenau, the Wiesbaden Convention for facilitating payment in kind of part of the Reparations. During the two years which ensued, M. Loucheur distinguished himself by upholding before the Chamber, with great argumentative ingenuity, various schemes for remedying the financial situation. On Nov. 28 1925 M. Briand appointed him Minister of Finance in his new Cabinet. But he found every group in Parliament violently hostile to the seven proposals which he submitted for alleviating the financial crisis. The Finance Commission of the Chamber twice rejected five of these proposals and he therefore resigned Dec. 15, having held his portfolio exactly 17 days.

LOUIS III., ex-King of Bavaria (1845–1921), was born Jan. 7 1845 and assumed the regency in succession to his father (*see* 3.550) on Dec. 12 1912. In accordance with the bill passed by the Bavarian diet he assumed the crown on Nov. 5 1913.[1] After the proclamation of the republic on Nov. 7 1918, the King, with the Queen and his daughters, left Munich. The royal family resided first at Berchtesgaden, and afterwards at a castle assigned to them on the shores of Chiem See. On Nov. 13 he formally signed his abdication, and relieved all Bavarian officials, officers and soldiers from their oath of allegiance. He died at Sarvar, Hungary, Oct. 17 1921.

LOUISIANA (*see* 17.53).—The population of the state as estimated in 1926 was 1,918,591, compared with a census enumeration of 1,798,509 in 1920 and of 1,656,388 in 1910. During 1910–20 the negro population decreased from 713,874 to 700,257, or from 43·1 to 38·9% of the total. The population of New Orleans, the principal city, was estimated on July 1 1924 at 409,534 compared with a census enumeration of 387,219 in 1920 and of 339,075 in 1910.

Agriculture.—The most important industry of the state has always been agriculture. The total value of all farm crops in 1920 as reported by the Bureau of the Census was $231,506,000. The total number of farms in 1920 was 135,463, representing a gain of 14,017 during the decade, but a slight decrease occurred in the following four years, there being 132,451 in 1925. Corn, cotton, sugar-cane, rice and hay, in the order named, constituted the most important field crops. The boll weevil temporarily caused a sharp decline in the production of cotton, but with better methods of combatting this pest and the stimulus of high prices the yield increased from 279,000 bales in 1921 to 501,523 bales in 1924. Another effect of the boll weevil has been the trend toward more diversified farming, with a consequent increase in the yield of maize (Indian corn) which reached the maximum of 35,022,000 bu. in 1921. The yield in bushels in subsequent years was as follows: 1922, 29,002,000; 1923, 24,702,000; 1924, 18,998,000. This decline was a result of low prices in this period as compared with the price of cotton, which made the latter the more profitable crop. The livestock industry also gained in importance as a result of this diversification, although the state in 1924 still ranked only thirty-fourth in the value of livestock on the farms. Louisiana leads all other states in the production of rice, the yield over a period of years averaging nearly half the total raised in the United States. The crop of 1924 amounted to 17,078,000 bu., with a value of $23,226,000. Practically all the cane sugar produced in the United States comes from Louisiana. The trucking industry has acquired considerable importance in the vicinity of New Orleans, and the raising of strawberries has proved profitable on the cut-over pine lands of Livingston and Tangipahoa parishes. Citrus fruits are grown in considerable quantity along the Mississippi river below New Orleans.

Manufacturing.—The value of manufactured products, at factory prices, in 1923 was $624,682,620, a gain of 30·4% as compared with 1921. The average number of wage-earners employed in factories during 1923 was 94,597, a gain of 11·1% over 1921. The production of lumber and timber products is the leading manufacturing industry of the state, both in respect to value of products and number of persons employed. The total value of lumber and timber produced in 1923 was $132,682,000, an increase of 44·3% over 1921. Petroleum refining came second in 1923 in value of products, with a total output valued at $102,405,962, representing a gain of 8·6% over 1921. Sugar refining came third, with products in 1923 valued at $88,151,711 and showing a gain of 66% over 1921, when the sugar industry was suffering from severe depression. In spite of the increase in tariff duties on sugar in 1922 the Louisiana sugar industry is at a disadvantage in competing with tropical countries that are free from the hazard of frost and also enjoy the advantage of cheaper labour. The number of sugar factories in the state decreased from 124 in 1921 to 82 in 1924. In 1924 many of these establishments shifted from the manufacture of raw sugar to the production of syrup, the output of which amounted to 9,020,000 gal., compared with 6,718,000 gal. in 1923.

[1] King Otto, who had been kept in confinement as a lunatic, died on Oct. 11 1916.

Minerals.—Until 1924 Louisiana led all other states in the production of sulphur, but late in that year production in Calcasieu parish was suspended because of the exhaustion of the deposit. This came after 25 years of production with a total yield of about 10,000,000 tons of sulphur. It was this deposit which made the United States the chief sulphur-producing country in the world, and the Louisiana product virtually displaced Sicilian sulphur, which at one time held first place in the world's markets. In 1923 Louisiana ranked third in the production of rock salt and fifth in that of all salt. The output in that year was 359,000 tons, compared with 265,000 tons in 1920. The rock-salt deposits lie in the extreme southern portion of the state, and yield a product of unusual purity. Most of the petroleum produced in the state comes from the parishes of Caddo, Red River, De Soto and Claiborne. The state's output in 1924 was 21,124,000 barrels. The record output of 35,714,000 bbl. was attained in 1920 after the opening of the great Homer pool in Claiborne parish. Some of the wells in this district for a time yielded as much as 30,000 bbl. daily, but after 1920 production steadily declined.

Education.—The constitution of 1921 vests control of the public elementary and high schools and all other state educational institutions except the state university in a Board of Education of eleven members. School attendance is compulsory for 140 days in each school year by all children between the ages of 7 and 14 years. This law, however, has not been strictly enforced because of the lack of school facilities, and in 1923 only 76·8% of the white children of school age, and 58·2% of the negro children were enrolled. Substantial improvement in school facilities, however, occurred after 1919. In that year total school expenditures were $9,702,000; by 1923 they had increased to $25,430,000. The average salary for white male teachers in 1923 was $1,353, compared with $1,011 in 1919; for white female teachers $1,009 in 1923, compared with $598 in 1919. Between 1919 and 1923 salaries of negro male teachers increased from $298 to $525, and of female negro teachers from $217 to $408.

History.—Although the state is normally democratic, there was a temporary defection from the Democratic party after 1913 in that section of the state where the production of cane sugar is the chief industry. This was due to the unpopularity of the Tariff Act of 1913, enacted by a democratic congress and materially reducing the duties on sugar. By 1920 the breach in the party was healed. The state ratified the Eighteenth (Prohibition) Federal Amendment Aug. 3 1918. The industrial canal at New Orleans was opened to navigation Feb. 6 1923. This canal connects the Mississippi river with Lake Pontchartrain and gives shipping more direct access to the sea than is possible by following the winding course of the river for 90 m. to its mouth. The canal is 5½ m. long and was 5 years in building. The governors after 1908 were: Jared Y. Sanders (Dem.) 1908–12; Luther E. Hall (Dem.) 1912–6; Ruffin G. Pleasant (Dem.) 1916–20; John M. Parker (Dem.) 1920–4; Henry M. Fuqua (Dem.) 1924– .

(W. O. S.)

LOUISVILLE, Ky., U.S.A. (*see* 17.63), lost one of its principal industries through the elimination of its distilleries by the Eighteenth (Prohibition) Amendment to the Federal Constitution. Its tobacco market was affected by the development of co-operative marketing and loose-leaf marketing of tobacco in Kentucky. In compensation many new industries were added to the already long list. The total output of the plants within the city was valued at $101,284,000 in 1909; $204,566,000 in 1919; $240,537,718 in 1923. In 1922 annexations of territory (11,000 ac.) increased the area to 36 sq. m., but important plants were still outside the corporate limits. The leading industries in the Louisville district in 1925 were tobacco (value in 1923, $25,678,000), car works, sanitary plumbing fixtures, petroleum refining, slaughtering and meat-packing. The population in 1920 was 234,891 (91·4 males to 100 females), of whom 40,087 were negroes (a slight decrease since 1910) and 11,667 foreign-born (a decrease of 34%). A special census in Dec. 1925, under the supervision of of the U.S. Census Bureau, showed a population of 305,935.

Bank clearings increased from $667,947,515 in 1914 to $1,611,927,608 in 1924. Investment in building in the six years following the World War amounted to over $100,000,000, of which more than half was for 10,000 dwellings. Many of the characteristic low structures were replaced by apartment houses, hotels and tall business buildings. By 1925 sewer construction costing $4,600,000 was completed, and additional work of an equal amount was under way; the municipally-owned water company was beginning a four-year programme of expansion, to cost $4,408,000; construction of the war memorial auditorium was awaiting the outcome of litigation over the site; a new municipal highway bridge to Jeffersonville, Ind., was planned; work was begun on the elimination of grade crossings, and also on a hydroelectric plant (initial capacity 108,000 H.P.) at the Falls of the Ohio. Canalisation of the Ohio river from Pittsburgh to Louisville was completed in 1925, and completion of the project to Cairo is expected by 1929.

In 1910 the public schools were placed under the control of a non-partisan Board of Education. The University of Louisville (enrolment, 1925, 1,200) moved its school of arts and sciences to a new 55-ac. campus in Sept. 1925, and $1,000,000 was voted by the city in November for new buildings. Additions to the university include the Speed Scientific School (opened 1925); the Louisville College of Dentistry (formerly affiliated to Centre College); an Art Museum (under construction); and an extension centre for negroes (to be opened 1926). The Southern Baptist Theological Seminary also moved (Jan. 1926) to a new campus of 51 ac. and a fine plant built at a cost of $2,000,000.

LOURENÇO MARQUES, Delagoa Bay (*see* 17.65), has a population (1925) estimated at 22,000, including 8,000 Europeans. There is safe entrance to the harbour and the minimum depth of water in the Cockburn Channel is 25 feet. The port offers ample accommodation and facilities to shipping, including coaling and cold storage plant. Many of the leading merchants are British and most of the traffic of the port is transit trade with the Transvaal, whence it obtains its coal for export and bunkering.

Competition between the port and Durban for the Rand trade led to a convention (known as the Mozambique convention) being made with the Transvaal in 1909. Among other things it provided that 50 to 55% of the railway traffic in the "competitive area" of the Transvaal should pass through Delagoa Bay; the percentage going through the bay in 1914 was 48·79 and never exceeded that figure until 1922, when it was 52·86. The Union Govt. then denounced the convention, which lapsed on March 31 1923. The provisions it contained for the recruitment in Portuguese territory of native labour for the Transvaal mines and forbidding differential duties on merchandise passing between Lourenço Marques and the Transvaal were, however, preserved by a *modus vivendi*. Negotiations for a new convention had not, up to the middle of 1926, resulted in an agreement.

The value of goods in transit through Lourenço Marques was £4,547,000 in 1912; £2,334,000 in 1915; £5,176,000 in 1919 and £4,806,000 in 1923, in which year re-exports were valued at £1,244,000, as against £411,000 in 1912. Exports of local produce were valued at £162,000 in 1913 and at £789,000 in 1923. The number of vessels entering the port in 1924 was 644, the tonnage being 3,060,000 gross. In the latter part of 1925 the depreciation of the Portuguese currency and the abolition of the use of sterling currency caused serious difficulties to importers and led to strikes and disturbances which continued into 1926 when the position began to improve.

See the *Delagoa Directory, 1925* (Lourenço Marques and London) and the *South and East African Year Book* (London, annually).

LOUVAIN, Belgium (*see* 17.67), with a population of 40,693 in 1923, suffered very severely during the World War, and was given the Croix de Guerre in 1925. In Aug. 1914, after the German entry, about one-third of the town was burnt, including the whole of the Rue de la Station and the Place du Peuple, the Vieux Marché, the Palais de Justice, the Théâtre, and the famous Halles Universitaires, with its splendid library; the interior and roofs of the collegiate Church of St. Peter were seriously damaged, and the chimes destroyed. The elaborate Gothic Hôtel de Ville, damaged in 1890 and in process of restoration in 1914, was

used as headquarters by the Germans, and was not further harmed; the restoration has since been completed.

Restoration Works.—Rebuilding, studiously on the old models, was started soon after the War, and early in 1925 few signs of the ruin done were outwardly visible, though much remained to be finished. The Place de la Station, where a number of civilians were killed and buried, has been renamed Place des Martyrs, and the rebuilt Rue de la Station is now called Avenue des Alliés. A striking War memorial has been erected. The university was reopened in 1919, with a larger number of students than before the War. The foundation stone of the new university library was laid in 1921, and the first wing opened in 1923. The building, in the Flemish style, is being paid for by American citizens, and books and fittings have been contributed by many nations. About 500,000 books had been collected when the new wing was opened, nearly 50,000 coming from the John Rylands Library, Manchester. The church of St. Peter was undergoing restoration in 1926.

LOW, SETH (1850–1916), American administrator and educationalist (*see* 17.72), died at Bedford Hills, N.Y., Sept. 17 1916.

LOWELL, ABBOTT LAWRENCE (1856–), American educationalist (*see* 17.73), built for Harvard at his own expense a president's house, which was finished in 1912. From the time that he became president (1909) he took great interest in the social life of the students (*see* HARVARD UNIVERSITY). President Lowell was a strong supporter of free speech among the members of the faculty. After the outbreak of the World War in 1914 he refused to accept the resignation of Prof. Münsterberg, who had defended the German cause. In 1915 Prof. Kuno Meyer, of the University of Berlin, sent a letter of protest because of the publication in one of the college magazines of a satirical poem, *Gott mit Uns*, by an undergraduate. In his reply President Lowell pointed out that freedom of speech was an important characteristic of American universities as distinguished from those in Germany. He was chairman of the executive committee of the League to Enforce Peace, and later was a strong supporter of the League of Nations. Lowell was the author of *Public Opinion and Popular Government* (1913), based on lectures at Johns Hopkins University; *The Governments of France, Italy and Germany* (1914), abridged from his earlier *Government and Parties in Continental Europe;* and *Greater European Governments* (1918), abridged from earlier works.

His brother, PERCIVAL LOWELL (1855–1916), American astronomer (*see* 17.73), died at Flagstaff, Ariz., Nov. 12 1916. In 1910 he lectured in London before the Royal Institute, and in Paris before the Association Astronomique.

LOWELL, AMY (1874–1925), American poet, critic and lecturer, was born Feb. 9 1874 in Brookline, Mass., being a sister of Abbott L. and Percival Lowell She came of a line of public-spirited lawyers and men of affairs, who for three generations had been, like herself, lovers and planters of gardens. She received her education from her mother, who was an accomplished musician and linguist, and from private schools; and she later travelled abroad extensively, visiting Greece, Constantinople and Egypt. After her father's death in 1900 she occupied herself with municipal affairs, until "about 1902," she writes, "I discovered that poetry . . . was my natural mode of expression. And from that moment I began to devote myself to it seriously." But she published nothing for nine years, when, in 1910, her first published poem appeared in *The Atlantic Monthly*. Her first volume, *A Dome of Many-Coloured Glass*, is dated 1912. Thereafter her books followed each other in rapid succession: *Sword Blades and Poppy Seeds* (1914); *Six French Poets: Studies in Contemporary Literature* (1915); *Men, Women and Ghosts* (1916); *Tendencies in Modern American Poetry* (1917); *Can Grande's Castle* (1918); *Pictures of the Floating World* (1919); *Legends* (1921); *Fir-Flower Tablets*, with Florence Ayscough (1921); *A Critical Fable* (1922); *John Keats* (1925); *What's O'clock* (1925); *East Wind* (1926). During all this period Miss Lowell contributed critical articles to various magazines, and lectured extensively. In 1920 she received the degree of Litt.D. from Baylor University. She had suffered from a serious malady for years, and on the eve of a visit to England, during which she was to have lectured at Oxford, Cambridge, Eton, Edinburgh and elsewhere, it became acute, and she died suddenly, May 12 1925, at Brookline, Mass.

Miss Lowell, during her later years, was the most striking figure in contemporary American poetry. Her vivid and powerful personality, her intellectual vigour and independence, and her zest in life gave her a conspicuous and in some respects a unique position. She was an acknowledged leader of the group in America and England which called itself the Imagists. But through all her radicalism ran a strong conservative strain, and she never abandoned conventional verse forms, nor for some years before her death had she been affiliated with any school. Among her contributions to poetry must be reckoned the perfecting, in her best work, of the technique of "free" verse; her almost unrivalled command of the vocabulary of sensuous impressions; the wide range of the themes to which she has given poetical expression, and the clarity and restrained beauty of many of her shorter poems. Her most important critical work, the result of long and devoted labour, is the biography of Keats, which essays to reinterpret him as "a new generation of poets and critics" regards him. (J. L. L.*)

LOWELL, Mass., U.S.A. (*see* 17.76), had in 1920 a population of 112,759, an increase of 6·1% in 10 years. The foreign-born population numbered 38,116 (including 10,180 French Canadians), a decrease of 12·5%. In 1925 the state census showed a decrease of the total population to 110,542. The factory output had a value of $50,688,000 in 1909; $137,802,000 in 1919; $80,645,704 in 1921; $100,098,057 in 1923. Lowell was affected by the long strike of the textile workers in 1922. The commission form of government was adopted in 1911, but in 1920 the charter was again amended, providing for a mayor elected at large and a city council composed of one member from each of the nine wards and six elected at large. On Dec. 9 1925, 10 officials, including the mayor and a former mayor, were arraigned on charge of corruption. A beautiful memorial auditorium was erected (1921) in honour of the men and women of the city who took part in the wars of the country. Lowell has the usual characteristics of a mill town—a preponderance of women in the population (92·8 males to 100 females, 1920), a high proportion of women and children at work (38·7% of all females 10 years of age and over, 8·8% of the children 10–15), a high infant mortality (107 deaths under one year per 1,000 births, 1923) and a low percentage of home ownership (26·1% in 1920), due to mobility of labour.

See George F. Kenngott, *The Record of a City; a Social Survey of Lowell, Massachusetts* (1912).

LOYSON, CHARLES (1827–1912), better known as Père Hyacinthe, a famous French preacher, was born at Orléans. He was educated for the priesthood and entered the Carmélite order. His eloquence drew large crowds to his Advent sermons in Notre-Dame between 1865 and 1869, but his orthodoxy fell under suspicion, and in 1870 he associated himself with Döllinger's protest against the dogma of papal infallibility (*see* 14.512, 20.67). Being excommunicated he broke finally with the Church of Rome, and removed first to Geneva and then to London. He married an English lady, Emily Jane Merriman, and settled in Paris in 1877, where he founded an Old Catholic Church. He died in Paris Feb. 9 1912.

LUCAS, EDWARD VERRALL (1865–), British man of letters, was born at Brighton and educated at University College, London. He then started journalism, working first on a Sussex newspaper, then in London with *The Globe*, and became a frequent contributor to *Punch* and later its assistant editor. He acted for many years as publisher's reader to the firm of Methuen, and became head of this company after the death of its founder (1925). Lucas wrote a very large number of miscellaneous books, but is best known as a light essayist in the vein of Elia, and published many collections of these essays. His edition of the *Letters of Charles and Mary Lamb* (1903–5) and his *Life of Lamb* (1905) likewise showed how congenial was his talent with that of Elia. He was successful also as a writer of travel impressions,

among these being *A Wanderer in Holland* (1905), *A Wanderer in London* (1906) and *A Wanderer in Paris* (1909), and his books on art showed powers of wide appreciation, as in *The British School* (1913), *Vermeer of Delft* (1922), *John Constable* (1924). Light fiction, children's books, humorous skits and many anthologies have also issued from his singularly fluent pen.

LUCAS, JOHN SEYMOUR (1849–1923), British painter (*see* 17.93), died in hospital at Southwold, Suffolk, after an accident, on May 8 1923.

ŁUCK, or LUTSK, BATTLES OF.—Under this heading are described the Russian attacks on their southwestern front—which extended from the Pinsk marshes to the northern frontier of Rumania—during the summer and autumn of 1916. These attacks are generally known as "Brusilov's offensive." The original break-through of the Austrian front occurred near the town of Łuck (Lutsk), in Volhynia, on the river Styr, which thus gives its name to the whole series of operations (*see* EASTERN EUROPEAN FRONT: MAP).

General Situation in May 1916.—After the costly failure of their attacks in March (*see* LAKE NAROCH, BATTLES OF), the Russian supreme command had set to work to prepare a large scale offensive on the front west of Mołodeczno, as their contribution to the great general Allied offensive which was to open on all fronts on July 1. Elaborate preparations were made during April and May for this Mołodeczno attack, in which 26 divisions were to carry out the initial assault. The Russian line was at this time divided into three fronts: the Northern, from the Gulf of Riga to south of Dvinsk, containing 38 divisions; the Western, down to and inclusive of the Pinsk marshes, containing 58 divisions; and the Southwestern, down to the Rumanian frontier, containing 38 divisions. The Pinsk marshes also formed the dividing line between the German and Austrian sectors of the Eastern front. In the German sector there were approximately 42 German and two Austrian divisions; in the Austrian sector there were 38 Austrian and three German divisions. Since the great offensive of the Central Powers against Russia had come to an end in the autumn of 1915, their forces on the Eastern Front had been considerably reduced. The Germans had taken troops for their Verdun offensive, and the Austrians during the spring had withdrawn formations for an offensive against Italy. The Russians, on the other hand, had recovered rapidly from their disasters of the previous year; the ranks were full and munitions more plentiful than before.

Preparation of Brusilov's Offensive.—Gen. Brusilov succeeded Ivanov as Commander-in-Chief of the south-western front in March. He was a cavalry soldier and had commanded the VIII. Army since the commencement of the War with conspicuous success. He received instructions to prepare attacks on the south-western front to distract the enemy's attention from the main Russian effort at Mołodeczno. The four armies under Brusilov were: the VIII. (Kaledin) from the Kowel-Kiev railway near Rafałowka to about Kremenets, 11 divisions and four cavalry divisions; the XI. (Sakharov) from Kremenets to near Tarnupol, eight divisions and one cavalry division; the VII. (Shcherbachev) from near Tarnupol to Potok, seven divisions and $3\frac{1}{2}$ cavalry divisions; and the IX. (Lechitski) from Potok to the Rumanian frontier, 10 divisions and three cavalry divisions. There was one corps (two divisions) in reserve.

The Austrian IV. Army (Archduke Joseph Ferdinand), from near Rafałowka to Dubno, with $10\frac{1}{2}$ divisions and one cavalry division, and the II. Army (Böhn-Ermolli, from Dubno to near Kremenets, with eight infantry and two cavalry divisions, were opposed to Kaledin; the German Southern Army (von Bothmer) with one German and nine Austrian divisions and two cavalry divisions, held a long front, corresponding approximately with those held by the Russian XI. and VII. Armies; while the Austrian VII. Army (Pflanzer-Baltin), with $8\frac{1}{2}$ divisions and four cavalry divisions, opposed Lechitski. In the actual number of divisions there was little disparity between the total forces at the disposal of either side; the Russians had 38 divisions and 12 cavalry divisions to the Austro-German 37 divisions and nine cavalry divisions; but the Russian divisions were larger. The Austrian front had been strongly fortified and organised, and in spite of the removal of some of their most reliable divisions and much heavy artillery to the Italian front the Austrians were confident of being able to hold their ground.

About the middle of April, Brusilov had ordered each of his army commanders to select a sector of attack and to make preparations with the resources at his disposal within his own army to penetrate the enemy's front in that sector. Preparations were to be complete before the middle of May. These attacks were designed simply as aids to the main Russian offensive in the north, timed for July 1. On May 14, however, the Austrians began an offensive in the Trentino against Italy. The Italians appealed to the Russians to relieve the pressure by attacking the Austrians on their front. Brusilov accordingly launched his attacks on all four army fronts on June 4, without any expectation of a decisive break-through or arrangements for exploitation of success on a large scale.

The Break-through at Łuck.—The sector of attack chosen by Kaledin, commander of the VIII. Army, centred on the village of Olika, east of Łuck. The bombardment began on June 4 and the assault was made by the XL. and VIII. Corps early on June 5. The XL. Corps carried three lines of enemy trenches and penetrated over two miles, and the VIII. Corps, though less successful, made considerable progress. The advance continued on June 6 and on June 7 reached Łuck. By this time a wide gap had been made between the Austrian IV. Army and the II. Army further south, and a great opportunity for the numerous Russian cavalry seemed to have come. But of the four cavalry divisions allotted to Kaledin's army, two had been used to hold trenches so as to enable infantry to be concentrated for the assault and one was dispatched by Brusilov in a fruitless raid along the railway towards Kowel through marshes entirely unsuited for cavalry action. The one remaining division could accomplish little. Meanwhile the left wing of the VIII. Army occupied Dubno on June 9; on June 10 the front of the army lay along the line of the rivers Styr and Ikwa, from Rozyszcze through Łuck to Dubno.

Attacks of the XI., VII. and IX. Armies.—The attack of the XI. Army northwest of Tarnupol was a failure. Shcherbachev's VII. Army attacked in a sector on its extreme left near the village of Jaziowec. After two-days' bombardment the infantry assaulted early on June 6 and carried the enemy positions; next day the Austrians were driven behind the Strypa. The Russians crossed the river on the 8th and gained further ground during the next two days. Counter-attacks then arrested their advance for the time being. Lechitski's IX. Army attacked some 20 m. north of Czernowitz, near the village of Okna, with complete success. By June 10 the front was broken and the Austrians retreated in disorder behind the Prut. Czernowitz was captured on June 17.

Consequences of Brusilov's Success.—Thus by the middle of June the Austro-German front south of the Pinsk marshes was completely broken on both flanks, and two armies, the IV. and VII., were in full retreat. In the centre Böhm-Ermolli's and von Bothmer's armies still held, though their outer flanks had been driven in. On three-quarters of the whole Russian southwestern front their armies were moving forward. These entirely unexpected results of an offensive undertaken purely as a demonstration reacted instantly on the whole strategy both of the Russians and of the Central Powers. On the Russian side, the new situation demanded the immediate transfer of the principal reserves from the north, where they had been grouped for the Mołodeczno offensive, if Brusilov's success in the south were to be exploited. The decision was taken promptly enough, the Mołodeczno offensive was abandoned, Lesh's III. Army astride the Pripet was added to Brusilov's command and troops were hurried south as rapidly as the capacity of the railways would permit. Unfortunately for the Russians, the poverty and low efficiency of their communications gave the enemy time to concentrate sufficient reinforcements to restore their front before the full weight of the Russian reserves could give a fresh impetus to the advance.

For the Germans, the sudden reverse came at a difficult time,

for they were fully engaged at Verdun and were expecting a Franco-British offensive at an early date; obviously, too, events might have a decisive influence on the attitude of Rumania. Reinforcements were at once collected to restore the situation; to close the principal gap, it was decided to stage a counter-attack on a large scale on both sides of the Kowel-Rowne railway. This attack was entrusted to von Linsingen, the German commander of the Austro-German Army holding the area of the Pinsk marshes opposite the Russian III. Army. He was reinforced by three German divisions from the northern part of the Eastern Front, four from France and two Austrian divisions from the Trentino. During the whole of the latter half of June, as these reinforcements arrived, he counter-attacked persistently towards Łuck and to the north and south of it. These attacks, though they brought the Austro-German forces little gain of ground, had at least the effect of limiting Kaledin's break-through. On July 4, the left of Lesh's III. Army, in conjunction with Kaledin's right, launched an attack in the bend of the Styr east of Kowel and drove von Linsingen's army back to the Stochód river. This put an end to the Austro-German counter-attacks, and there were no further important operations on this part of the front till the end of July.

Occupation of Bukovina.—Meantime, Lechitski in the south was completing the conquest of the Bukovina. After the capture of Czernowitz, part of the Austrian VII. Army retreated precipitately south to the Carpathians, pursued by the left wing of Lechitski's army, which occupied Kimpolung on June 24. His right wing, advancing between the Dniester and the Prut, won a victory on June 28 and occupied Kolomyja on the following day. At the beginning of July the Austrians in the south received reinforcements and made a series of counter-attacks opposite Kimpolung and Delatyn. These were defeated, and Lechitski's right wing occupied Delatyn on July 10. His army was now, however, enormously extended and had to halt to await reinforcements.

Reorganisation of Command by the Central Powers.—The German command, which had since the beginning of June sent 16 divisions to the front south of the Pinsk marshes, naturally claimed an increased influence on the direction of operations on this front. Very shortly after the first break-through at Łuck they had insisted on the removal from his command of the IV. Army of the Archduke Joseph Ferdinand and on the extension of von Linsingen's sphere of command southwards to the northern frontier of Galicia. The greater portion of Pflanzer-Baltin's VII. Army had also been transferred to von Bothmer commanding the German Southern Army. It was now proposed to appoint Hindenburg to the supreme command of the Eastern Front as far south as Lemberg; the remainder of the front, on both sides of the Dniester and in the Carpathians, was to be under the Austrian heir apparent, Archduke Charles Francis Joseph, with the German General von Seeckt as his chief of staff.

This arrangement was eventually brought into force early in August. The Archduke Charles had originally come from the Italian front at the beginning of July to command a XII. Army, which was to be formed from troops on the spot and fresh reinforcements, and was to deliver a counter attack on a large scale on both sides of the Dniester in a southeasterly direction. But as the incoming reinforcements had always to be thrown into the battle so soon as they arrived, the formation of the XII. Army and the proposed counter-offensive never took place. Instead, the III. Army command from Tirol took over the troops between the Carpathians and the Dniester. The Archduke's command thus comprised the VII., III. and Southern armies.

Battle of Brody.—During the latter half of July, while the VIII. and IX. armies on the flanks paused to await reinforcements, Brusilov ordered Sakharov's XI. Army, which had extended its front northwards to beyond Dubno, to take the offensive. It attacked near Boromel, southwest of Łuck, on July 16 and drove the enemy back across the Lipa. Sakharov then moved south on Brody, which he captured with 40,000 prisoners on July 28—a fine victory. Meanwhile Shcherbachev's VII. Army, in spite of repeated attacks northwest of Buczacz towards Monasterzyska, had failed to make much impression o von Bothmer's Southern Army. Lechitski, however, at the en of July gained some ground towards Stanislau.

Attack on Kowel.—Towards the end of July the Russian Guar Army (I. and II. Guard Corps, I. Corps, XXX. Corps, Guar Cav. Corps) detrained from the north and took up a front be tween the III. and VIII. armies. The Guard had not bee in action since the previous Sept. and had been carefully trained and kept in hand for a great occasion. It was now de cided to use it to force the line of the Stochód river and capture Kowel. It is difficult to understand why this line of advance was chosen for a supreme effort. The terrain is mainly marsh and advance is usually possible only on narrow causeways. The attacks, which commenced on July 28 and were continued up to Aug. 10 resulted in a complete and costly failure. The Guard Army lost 55,000 men for a trifling gain of unimportant ground. Brusilov thereafter abandoned the direct advance on Kowel; but continued up till the middle of Oct. attempts to enlarge the Łuck salient in the direction of Włodzimierz Wolynski. All these attempts ended in failure.

Conclusion of the Offensive.—In the south, Lechitski attacked again south of the Dniester on Aug. 7 and drove back Kövess' III. Army. He occupied Stanislau on Aug. 10 and Nadwórna on Aug. 12. On this latter date the VII. Army occupied Monasterzyska. Under the threat from this flank and pressure from Sakharov's army south of Brody, von Bothmer now at last gave up the original line which he had held throughout all the turmoil, and withdrew towards Brzezany.

Austro-German counter-attacks in the Carpathians in the first half of Aug. had little success. On Aug. 20 the Russians reorganised their front so as to allow Lechitski's IX. Army to have as its only task the forcing of the Carpathian passes between Delatyn and Kimpolung, in order to protect the right flank of the Rumanians, who joined the Allies on Aug. 27. In spite of severe fighting throughout Sept. little progress was made on this front. Nor was any appreciable advance made elsewhere on the southwestern front in spite of repeated assaults. In Oct. the defeat of the Rumanians necessitated the transfer of troops to that theatre and the abandonment of further offensive operations. The summer which had opened so brilliantly ended in disappointment and failure.

Results of the Offensive.—Although Brusilov had recaptured practically the whole of the Bukovina and large portions of Eastern Galicia and Volhynia and had taken some 350,000 prisoners and over 400 guns, the cost had been exceedingly heavy. The casualties on the southwestern front were over a million. These losses and those suffered in the abortive attacks on the Northern and Western fronts in 1916, at Lake Naroch, Baranowicze and Riga, were in the end the principal cause of the rapid infection of the army with anti-war propaganda when the revolution came. In fact the revolution itself was partly due to disappointment at the outcome of the 1916 campaign, from which so much had been hoped. The campaign showed the striking contrast in fighting qualities between Austrian, German and Russian troops. In spite of their lack of artillery and technical equipment, Brusilov's armies broke through the strongly fortified Austrian lines and would have completely destroyed the Austrian armies but for the presence of German troops, against whom their assaults invariably broke down.

It is difficult to trace any strategical conception underlying the Russian operations; the time and place for the various attacks seem to have been chosen on purely local considerations. This was largely due to the unexpected nature of the success and to the poor communications, which prevented the timely transfer of reserves from one portion of the front to another. Hailed by her Allies as proof of the complete regeneration of the Russian Army, Brusilov's offensive was really its death-knell.

(A. P. W.)

LUCY, SIR HENRY (1845–1924), British journalist, was born at Crosby, near Liverpool, Dec. 5 1845. Educated in Liverpool, he began life in a Liverpool merchant's office, but soon became a reporter for a Shrewsbury periodical. In 1870 he joined the staff of *The Pall Mall Gazette*, London, and in 1873 became parliamentary reporter to *The Daily News*, with which paper he had a long connection in various capacities. In 1881 he also joined the staff of *Punch* and won a great reputation as the contributor of its parliamentary sketch signed "Toby M.P." He was knighted in 1909 and retired from parliamentary work in 1916. He published his autobiography, *Sixty Years in the Wilderness*, in 1909, and *The Diary of a Journalist* in 1920. He died Feb. 20 1924.

LUDENDORFF, ERICH (1865–), German soldier, was born at Kruszevnia, in the province of Posen, April 9 1865. When 18 years old, he entered the Prussian Army. In 1894 he joined the General Staff, and, except for an interval of two years as company commander, remained on it from 1894 to 1913, under Count Schlieffen and the younger General von Moltke. As chief of the *Aufmarschabteilung*[1] since 1908 he played a prominent part in the mobilisation preparations. The last great increase in the strength of the army in 1913 was largely due to his initiative and energy. During the year preceding the outbreak of the World War he commanded first the 39th Fusilier Regiment at Düsseldorf, and afterwards an infantry brigade at Strashourg.

At the outbreak of the World War Ludendorff was quartermaster general of the II. Army. His voluntary assumption in the beginning of Aug. of a decisive rôle at the capture of the fortress of Liége gave him his first great opportunity. He took over the command of the 14th brigade of infantry, in the place of General von Wussow who was killed, and, breaking through the ring of fortifications at its head, seized the interior of the town. He was rewarded on Aug. 22 by being made chief of staff to Hindenburg in the VIII. Army which was fighting in East Prussia.

Campaigns in East Prussia.—The battle of Tannenberg revealed his powers of generalship, for he there demonstrated the justice of the theory of annihilation. The victory of Tannenberg over the Russian Army of the Narew was more than another Cannae. For in this case there was not, as in former days on the Aufidus, merely one enemy to be dealt with. On the contrary, the attempt was made to envelop the greatly superior main body of Russians in the presence of a second enemy force threatening the rear. And the attempt proved successful. In the subsequent operations which led to the first battle on the Masurian Lakes and to the heavy defeat of the Russian Army of the Niemen, the enemy's right wing was supported on the lake, and so only an envelopment of the southern wing was possible. The operations, therefore, took the form of an attack on the enemy's front and on his exposed flank.

The strategic success lay in the liberation of East Prussia from the enemy. The German Army of the East became available for the immediate support of the Austro-Hungarian ally, by this time in dire straits. This support was rendered in the brilliant Oct. campaign of the newly-formed IX. German Army directed through Southern Poland upon the Vistula. Its purpose—to facilitate the Austrian efforts in Galicia by drawing off upon the IX. Army the strongest possible body of Russian troops—was attained in a degree entailing grave danger to the outnumbered Germans themselves. The menace of envelopment by a vastly superior enemy, pouring up from the direction of Warsaw, was parried and beaten off by Ludendorff by means of an exceedingly gallant defensive action, carried out during withdrawal. In Nov., after a rapid regrouping of the main German forces, an advance was made from the Wreschen-Thorn line against the right flank of the main body of the Russians, lying in West Poland. In the absence of sufficient strength a simultaneous frontal attack was impossible. But even so, the success achieved in the battle of Łódź was great. The Russians were definitely relegated to the defensive—and, in the pursuit which followed, were flung back behind the Bzura and the Rawka.

During the fighting in Masuria in Feb. 1915 Ludendorff achieved the destruction of another Russian Army in the region of the Upper Bobr. This was followed by a period of relative inactivity on the German Eastern Front lasting for several months. Not before the middle of July 1915 did the army group of Hindenburg resume the war of movement. By an attack directed upon and beyond the Lower Narew it relieved, by means of a converging offensive, the army group of Mackensen which had advanced from Galicia into Southern Poland between the Vistula and the Bug. In the ensuing operations the Russian Army was driven out of the Vistula positions and out of the whole of Poland towards the East. After a brief resistance the fortresses of Warsaw, Nowogeorgiewsk (Modlin) and Kovno fell. But no decisive issue was reached, because General von Falkenhayn, Chief of the German General Staff, rejected the proposal of Hindenburg and Ludendorff, which was to advance with the German left wing in a northerly direction through Kovno and Vilna upon Minsk, thereby cutting the Russian railway communications, north of the Polesia. Had the operations been conducted in accordance with the views of Hindenburg and Ludendorff, the Russian Army might have been dealt a mortal blow in the summer of 1915. Later, in Sept., the attempt was made on the German left wing, but with inadequate forces, to embarrass the retreat of the section of the Russian Army withdrawing northwards from Polesia past Vilna; but the moment for success on a grand scale had gone.

After the victorious conclusion of the Balkan campaign in the winter of 1915–6 Ludendorff contemplated a great offensive into the heart of the Ukraine, with the object of breaking the back of the economic resistance of Greater Russia, which was already cut off from the sea. The offensive necessitated the occupation of Rumania; but General von Falkenhayn rejected this scheme, and chose Verdun instead of Kiev as the objective for operations. Accordingly in the year 1916 the Eastern Front of the allied Central Powers was assigned the duty of protecting the rear of the offensive movement in France. This task was amply fulfilled on the northern wing but on the southern wing, held by the Austrians, the front completely collapsed in June and July at Łuck and in Galicia. The balance in the East was restored with difficulty by the intervention of the German command.

On Aug. 29 Field-Marshal von Hindenburg assumed the office of Chief of the General Staff of the armies in the field, in the place of Falkenhayn, and Ludendorff became First Quartermaster General. In contrast with their predecessor's point of view, the two men still promised themselves triumph, but a triumph which could only result from a more vigorous conduct of the War by drawing upon the whole available strength of the country in wealth and population. The methods adopted for the utilisation of these resources were expressed in the so-called "Hindenburg programme" of war industries and in the so-called law of auxiliary services; and here Ludendorff could only co-operate by means of suggestions and demands. In his own sphere too, he found that, owing to the almost desperate military situation inherited from his predecessor, he was not at first able to put into practice Schlieffen's doctrine of annihilation. The result of the offensive against Rumania was that this new enemy was overthrown in the winter of 1916. This victory was of inestimable value to the Central Powers, for new sources of economic power were thereby opened up.

Submarine Warfare.—After the defeat of the Rumanian Army there remained but one further task. This was the frustration of the attacks of the enemy in the West, greatly superior in numbers and material. The restoration of the balance of strength thus aimed at was to enable the Central Powers later to deliver an offensive with decisive effect. A favourable diversion of this kind, however, could only be counted upon, if, during the strategical defence on land, England could be reduced to desperate straits. An intensified U-boat warfare in the blockade area round England was therefore adopted, a weapon, recourse to which

[1] The department which draws up plans for transport, disposition of troops and advance.

had hitherto always been postponed on the score of political considerations. The disadvantage of this course was that it would give the United States a pretext for war on the side of the Entente; but regarding this as inevitable, Ludendorff hoped to render England disposed for peace before the Americans should be in a position to throw considerable forces into Europe.

Unrestricted U-boat warfare did not altogether fulfil expectations. The technical perfection of the enemy's defensive weapons and the ample scale upon which they had been completed contributed to this in a very material degree. On the other hand, without the adoption of unrestricted U-boat warfare the strategy of the Central Powers would have been altogether unable to hold the balance on land in suspense until, after Russia's collapse in the spring of 1918, there dawned a well-founded prospect of forcing a decision in France before the American forces on land became effective.

In the spring of 1917 in the Western theatre of war Ludendorff was enabled, by a timely withdrawal to the Siegfried position and by the elasticity of his defensive tactics, to impose a check upon the Allied attack carried out with a gigantic expenditure of men and material. Subsequently he had another opportunity of vindicating his theory of annihilation in the warfare on land. Under the blows dealt by the German hammer at Tarnopol, Riga, Dagö and Ösel, Russia fell. The reckoning with Italy followed in the autumn of 1917, but the situation in the West, particularly in Flanders where the fighting raged with undiminished fury, rendered it impossible for Ludendorff to secure a decisive victory.

The Offensive of 1918.—The German resolution to take the offensive in the spring of 1918 was rendered imperative by the general position. The psychological condition of the army peremptorily demanded that the rôle of anvil should be exchanged for that of hammer. Conditions at home called for a potent remedy against the threefold poison instilled by the hunger blockade, enemy propaganda and revolutionary agitation. Germany's hard pressed allies had for long rested their sole hopes of delivery on the efforts of Germany. Ludendorff saw only one road by which a tolerable peace, in harmony with the honour of the German people, could be reached, the road of military victory. This again could be attained solely by means of an offensive which should be decisive, and in taking this course he hazarded everything. A series of small attacks with limited objectives or a powerfully conducted defence would in favourable circumstances only have secured a temporary advantage, but could not prevent the enemy from finally giving full effect to his superior strength in a battle of annihilation. It is questionable whether the choice of direction for the offensive on French territory can be defended. Many critics would have preferred an offensive in Italy, but apart from the natural difficulties, even the destruction of the Italian Army could at best only have preceded the main decisive operations on French soil.

It has been questioned whether Ludendorff assembled adequate forces for the spring offensive of 1918. In March, at the beginning of this offensive, the Germans disposed of 193 divisions and three brigades in the Franco-Belgian theatre of war. The estimates of the forces commanded by the Entente in France and Belgium at the beginning of the spring offensive vary between 167 and 180 divisions. The Germans, therefore, enjoyed a slight superiority in the number of divisions. The original intention that a section of the Austro-Hungarian forces should take part in the decisive encounter in France was finally thwarted by the opposition of the Habsburg Emperor. Ludendorff accordingly chose the expedient of indirect assistance to be rendered by a relieving offensive carried out by the Austro-Hungarian Army in Upper Italy. This offensive, however, was undertaken much too late for the objective in view, in the middle of June, and, moreover, ended with a severe reverse. The occupation of Rumania called imperatively for four divisions and a greater number of Landsturm formations. The invasion of the Ukraine, carried out in Feb. and March, demanded about 20 weak divisions, including eight divisions of Landwehr and three of cavalry. It is disputable whether it would have been wiser to abandon the enterprise in the Ukraine. The secretary of state of the *Kriegsernährungsamt* urged with the utmost emphasis that the economic resources of the Ukraine should be thrown open to Germany. Failing this, the Austrians' system of food supplies would collapse. The delivery of meat was important for Germany, too, and the delivery of horses was, above all, a matter of the greatest urgency.

On political and military grounds Ludendorff had resolved to deal the first decisive blow in the West against the English. For this purpose he chose the southern flank, on both sides of St. Quentin, as tactically the least defensible, with the intention of forcing his way through at this point and by advancing north of the Somme towards the northwest, to roll up the whole front gradually and press the English towards the sea. The southern wing of the German offensive was to guard his flank against a relieving attack on the part of the French. This strategy became subject to certain changes in consequence of the unexpected magnitude of the initial success of the German southern wing, which continued the offensive across the Somme and the Crozat canal against the French, in order to effect a cleavage between the English and French at and beyond Amiens. This end was not completely attained, and the result of the first offensive, though great from the tactical standpoint was strategically nugatory. A second attack on the Lys front, against the English and Portuguese, was made in the middle of April and was designed to gain possession of the commanding heights north of Bailleul and to cut off the Ypres salient; its result, however, was indecisive.

During the following months, in spite of successive brilliant diversive attacks carried out against the French front, no further headway was made in forcing a decisive engagement in Flanders; and the heavy toll of the spring offensives could not be made good rapidly enough. And yet, prior to the last great attempt to break through on both sides of Reims in July 1918, there still remained a prospect of final victory for the German arms. The goal had nearly been reached—which was a proof that the strategy adopted might have succeeded and was, therefore, the right strategy. But the fortune of war was against Ludendorff. His plans were revealed by treachery to the enemy, at a time when everything depended on secrecy and surprise. The great successes hitherto achieved had led to a wide extension of the German front, calling for the employment of disproportionately large forces and offering in its many angles and salients dangerous surfaces to the enemy's attacks. These factors now made their disastrous influence felt.

But the final cause of Ludendorff's inability to resume the initiative lay in the absence of a free command of reserves, due to the drying up of the sources of supply at home. When the German command fell back on the defensive before hostile attacks, Ludendorff realised that there was nothing to be done except to hold out until diplomacy succeeded in securing a tolerable peace, or to perish with honour. On Oct. 26, however, he was overthrown by the Cabinet of Prince Max of Baden. The collapse of Germany's allies, combined with difficulties at home, rendered hopeless any further resistance by the army in the field now thrown upon its own resources.

General Ludendorff was above all a man of action, and one who rated formation of character and the attributes of leadership more highly than the acquisition of comprehensive learning. His resolution, his almost super-human and invincible powers of work and action, his understanding of the moral factors in warfare, inspired the German Army with boundless confidence in his leadership and qualified it for mighty exploits. If like Hannibal and Lee he failed in the final issue, it was through no fault in generalship, but was partly due to slowness in realising that his weapon had grown blunt and that the population at home was no longer capable of the effort of endurance and the indispensable will to victory. His powers of leadership reflected his character; brain, heart and will were all unsparingly enlisted in the service of one aim, the honour of his country. Along this path he was impelled to travel, whether it led to victory or defeat.

LUGARD, SIR FREDERICK JOHN DEALTRY (1858–), British administrator (*see* 17.115), was, on the completion of his term of office as Governor of Hongkong, appointed in March 1912 Governor of both Northern and Southern Nigeria, with instructions to amalgamate the two administrations. The amalgamation became effective on Jan. 1 1914, Sir Frederick being given the personal title of governor-general. He guided the affairs of Nigeria throughout the World War, retiring in 1919, and was made a Privy Councillor in 1920. In 1922 he published *The Dual Mandate*, a book dealing with the duties of European Powers in tropical Africa. In Nov. of that year he became a member of the permanent mandates commission of the League of Nations (*see* MANDATES, NIGERIA).

LUKEMAN, HENRY AUGUSTUS (1871–), American sculptor, was born at Richmond, Va., Jan. 28 1871. He studied at the National Academy of Design, N.Y. City, and was a pupil of Launt Thompson and Daniel Chester French, perfecting his knowledge of anatomy by his year's study at Bellevue Hospital. In 1894 he spent a year in Paris studying under Falquière at the École des Beaux-Arts, and on his return to the United States settled in New York City. His work includes portraits, busts, statues, memorials and bas-reliefs, among the best known being "Mann, the Law Giver of India" for the Appellate Court building, New York City; the statue of President McKinley at Adams, Mass.; "Genoa," the figure of Columbus on the U.S. Customs House, New York City (1905); The Soldiers' Monument at Somerville, Mass. (1908); the group "Women of the Confederacy," at Raleigh, N.C. (1912); the Soldiers' Memorial, Red Hook Park, Brooklyn, N.Y. (1920); the equestrian statue of "Francis Asbury," Washington, D.C. (1921). He was appointed in 1925 to succeed Gutzon Borglum as sculptor in charge of the Stone Mountain memorial near Atlanta, Georgia. (*See* ATLANTA.)

LUNACHARSKY, ANATOLY VASILIEVICH (1873–), Russian politician, author and dramatist, was born in the province of Kiev of well-to-do parents. He joined the revolutionary movement when still at college in Kiev, and afterwards studied natural science and economics at the University of Zurich. He began his revolutionary activities in Russia in 1895 and was deported to Vologda in 1897, where he remained for three years, achieving a reputation as a brilliant writer and lecturer on Socialism. In 1903 Lunacharsky joined the Bolshevik or "majority" wing of the Social-Democratic party. He met Lenin in the following year, and also joined the editorial staff of the Bolshevik paper *Vpered* (Forward). While doing literary work of a general nature he was chiefly concerned with social democratic propaganda and with lectures and political meetings for Russian students and political refugees abroad. During the revolution of 1905 Lunacharsky was imprisoned for his political activities, and when the subsequent political reaction set in he left Russia and went to live in Italy. Together with Gorky and Bogdanov, a well-known Social Democrat, he formed the so-called "left-wing" of Bolshevism (opposed to Lenin on certain theoretical points), and was one of the promoters of the Social Democratic party schools at Capri and Bologna.

From the outbreak of the World War Lunacharsky maintained a determined internationalist attitude and disseminated violent anti-War propaganda in Paris and Switzerland, renewing closer contact with the Lenin group after a temporary estrangement. At the same time he made a careful study of educational problems in Switzerland, and this was to prove extremely useful to him later in his career. The revolution of March 1917 brought him back to Russia, and he immediately joined Lenin and Trotsky in their revolutionary opposition to the Provisional Government. He was arrested after the Bolshevik rising in July; but was subsequently liberated and elected vice-president of the Petrograd municipal board. In the initial stages of the Oct. revolution and during the civil war, Lunacharsky proved himself one of the ablest political speakers of the new Soviet State, and was an energetic and successful emissary of the Military Revolutionary Council to the various war fronts. As people's Commissar for Public Instruction in the new Soviet Govt., Lunacharsky rendered inestimable services by ensuring the preservation of works of culture and art during the civil war. He devoted himself to the promotion of mass instruction, and of culture and art in Soviet Russia, while his especial concern for the welfare of the theatre did much to further the development of the Russian stage.

A man of exceptional culture, steeped in philosophical and scientific studies, Lunacharsky also won his spurs in the field of literature. He wrote 14 plays (published in 2 vol.), of which several were produced with conspicuous success in Russia and in Berlin. "Vasilisa the Wise," "Faust and the City" and "The Magi" were translated into English by Leonard Magnus and published under the title of *Three Plays* (1923). He also wrote books on politics, economics, philosophy, literature and art.

LUNACY: *see* INSANITY.

LUND, TROELS FREDERIK (1840–1921), Danish historian (*see* 17.123), published in 1900 *Nye Tanker i det XVI. Aarhundreds*. In 1911–2 appeared his historical tales, *Tider og Tanker*. He died in 1921. See Knud Fabricius, *Troels Lund* (1921).

LUNG: *see* HEART AND LUNG SURGERY.

LUPU, NICHOLAS (1876–), Rumanian politician, was born at Arsura (Rumania) on Nov. 8 1876. He started his career as a country doctor and entered politics in 1905. He played an important part during the peasant revolt in 1907 when, as prefect of the Falciu district, he succeeded in pacifying the peasants without having recourse to violent measures. In 1913 he was elected deputy and in 1919 he entered the Vaida-Voevod Coalition Cabinet as minister of the interior, representing, together with Mihalache, the Peasant (Tsaranist) party, of which Dr. Lupu became one of the principal leaders. During the World War, Dr. Lupu visited Russia, France, England, Italy and the United States and carried on an active propaganda campaign on behalf of Rumania.

LUSCHAN, FELIX VON (1854–1924), Austrian anthropologist and ethnographer, was born on Aug. 11 1854 in Vienna. He studied medicine in Vienna, anthropology in Paris, became demonstrator in physiology at the university at Vienna, and in 1878 organised the Austro-Hungarian section for anthropology and ethnology at the World Exhibition in Paris. Whilst a military doctor in Bosnia, he studied anthropology and archaeology, and in 1880 travelled in Dalmatia, Montenegro and Albania. During the following 10 years he was often in Asia Minor and Egypt, and in 1883 excavated the ruins of Sendschirli in Northern Syria on behalf of the Berlin Oriental Committee. After a brief period as lecturer in anthropology in Vienna, he became directorial assistant at the Ethnological Museum in Berlin, of which he was director from 1904 until his death, on Feb. 7 1924. His works include: *Beiträge zur Völkerkunde der deutschen Schutzgebiete* (1897); *Die Ausgrabungen von Sendschirli*, 2 pts. (1893, 1898); *Beiträge zur Ethnographie von Neu-Guinea* (1899); *Beiträge zur Anthropologie von Kreta; Rassen und Völker*, (1908); *Völker, Rassen und Sprachen* (1922); *Anthropological View of Race;* Papers on Inter-racial Problems communicated to the First Universal Race Congress (London, 1911); "The Early Inhabitants of Western Asia," *Jour. Roy. Anth. Inst. of Great Britain and Ireland* (1911).

LUTHER, HANS (1879–), German statesman, was born in Berlin March 10 1879, and studied law in Berlin, Kiel and Geneva. After ending his studies he entered the local administration service. At first he was stationed in Charlottenburg, and from 1907–13, in the Magistrat in Magdeburg under the former minister of finance, Lenze. In 1913 he was elected secretary to the German and Prussian "Städtetag," and thus was able during the World War to prove his high administrative abilities. On July 5 1918 he was elected burgomaster of Essen in the Ruhr district. In this responsible position he gained the reputation of being one of the best local administrative officials in the West of

Germany. On Dec. 2 1922 he entered the Cuno Cabinet, and became Minister of Food and Agriculture. He retained his post in Essen and, when the French marched into the Ruhr in Jan. 1923, he returned to Essen immediately. The episode is well-known of how the general commanding the troops marching into Essen wished to speak with the burgomaster at the door of the Rathaus (town hall). Dr. Luther sent a message that he was only to be seen in his office. The order was repeated twice, but at last the General was obliged to give way. This manly attitude of Dr. Luther earned him high esteem in the turbulent, warlike atmosphere in the Ruhr at that time.

After Cuno ceased to be Chancellor, Luther retained his office in the Stresemann Cabinet. In Stresemann's second Cabinet, he became Minister of Finance. As Finance Minister of the Reich, he was able to perform most signal services in stabilising the German currency (which had fallen into an abyss) and in restoring balance to the budget of the Reich. Dr. Luther kept his office in the Marx Ministry which followed, and had a share in the preparations for the Conference of London and the conclusion of the Dawes Agreement. In the autumn of 1924 he concluded the Dawes loan for Germany. He has himself given an account of his work in restoring the finances of Germany (see *Feste Mark—solide Wirtschaft, 1924*). After the elections in Dec. 1924, Marx, in spite of many endeavours, was not able to form a new cabinet, and Luther took over the task in the middle of Jan. 1925. A Cabinet was formed under him, which was the first since the revolution of 1918 to include members of the German National party. Luther carried through a great taxation reform, completed the revaluation legislation and made a provisional customs tariff which made it possible to commence negotiations for commercial agreements with some prospect of success for German economic life. This economic legislation was accompanied by the Locarno policy initiated by Stresemann with the essential agreement of Luther, who, as Chancellor, was responsible for the conduct of policy as a whole.

At the Conference of Locarno, the German delegation which initialled the clauses of the treaty, was led by Luther as Chancellor. After his return from Locarno, the German National party left the Government. In spite of this, the Cabinet found a majority for the policy of Locarno, and on Dec. 1 1925 signed the Rhine Pact and the Arbitration Treaties in London, after which it resigned. After tedious Government crises, Luther again received the mandate to form a Cabinet. As the Social Democrats forsook the Chancellor, there was nothing left but to form a Cabinet out of the moderate bourgeois parties. Dr. Luther was not a party politician, and often proclaimed his freedom from the parties in a pronounced fashion. While in charge of the affairs of the Reich he distinguished himself by extraordinary energy and sober clarity of political judgment, and the German people indubitably made important progress towards reconstruction under his leadership. On May 13 he resigned his office as chancellor. (*See* GERMANY.) (F. KLE.)

LUTHERANS (*see* 17.140).—The Lutheran churches of Europe were profoundly influenced by the War of 1914–8 and its after-effects. The external changes were least marked in Sweden, Denmark and Norway, where the relation between the churches and their states has remained undisturbed; in Germany and the new national states they have been far-reaching.

I. IN THE OLD WORLD

German Lutherans.—The German revolution of 1918 put an end to the *Summepiskopat* (*see* 17.142) and the reorganisation of the German Empire aimed at the separation of Church and State. Since an immediate complete separation would be disastrous to the churches and not to the best interest of the state, the churches were guaranteed diminishing state support, with the ultimate purpose of divorcing them entirely from the state governments. By this arrangement the churches have, in part, the character of voluntary associations and, in part, that of state controlled institutions. To meet this new situation they have been obliged to reorganise. The forms of reorganisation have not been identical in all the states, but two tendencies have been generally observable—one, to increase the powers of the synods at the expense of the consistories (*see* 17.142), the other, to vest the spiritual oversight of the church in a single official, known as bishop, chief pastor, or some other equivalent title.

Two problems have presented especial difficulties. The one is the problem of aim and purpose. Is the Church to continue, under new forms of administration, to be the one recognised institution of religion for that state (*Volkskirche*), or is it to be an institution for the promulgation of a single doctrinal type of Christianty (*Bekenntniskirche*)? The second problem concerns the relation of the Church to the state schools. No fully satisfactory solution of either problem has been reached as yet, though the idea of the *Volkskirche* seems, for the present, to have the stronger following, and the general trend is toward a separation of the Church from the schools.

The acute economic depression of 1922–4 affected most disastrously those elements of the laity from which the greatest measure of church support was to be expected, and it subjected the clergy to severe privations. All the activities of the churches were impaired, and the great voluntary associations for Christian work—the societies for foreign and inner missions—were practically paralysed. Substantial financial support was furnished during this crisis by Lutherans of foreign countries, especially of America, and with the beginning of economic recovery the normal church activities were, by 1926, gradually being resumed.

Central European Countries.—The formation of the new national states of Poland, Latvia, Estonia, Czechoslovakia, Yugoslavia and Hungary has been followed by a new organisation of the Lutheran churches in those countries. The same tendencies that were operative in Germany have shown themselves in these lands. The churches have tended to organise with a large measure of self-support and self-government. Where entire independence of the state has not been feasible it has been apparent as the ultimate aim. An episcopal form of spiritual oversight has also been introduced into most of these churches. All of them have had to contend with economic difficulties similar to those in Germany.

Russia and Rumania.—In 1924 the Lutherans of Russia were permitted, for the first time in their history, to organise as a Russian Church with a synod and two bishops. In Rumania, on the other hand, the disestablishment of the Transylvanian Lutheran Church has caused severe, if temporary, hardships.

Organisation.—The membership statistics for the Lutheran churches of Europe are, as a rule, quite unreliable. This is especially true of those countries where the churches have been in organic connection with the state, and where all those who did not formally withdraw were counted as members of the state church.

On questions of doctrine the same divergences (*see* 17.142) continue to exist. The more conservative element has been organised since 1868 in the General Lutheran Conference (*Allgemeine evangelisch-lutherische Konferenz*), an international society for the maintenance of confessional Lutheran teaching. In 1922 the conference united with the American National Lutheran Council in the calling of the First Lutheran World Convention, held at Eisenach, Germany, in Aug. 1923. The members of the convention came from 20 different countries, including the United States and Canada, and effected a new international organisation, with an executive committee of six members, charged especially to secure co-operation among the Lutherans of the world in works of mercy, foreign missions and care for migratory Lutherans, and "in cases of emergency to speak for the whole Lutheran Church." The Lutheran Alliance is a society of ultra-conservative Lutherans, the members of which are drawn chiefly from the free churches of Germany.

II. IN THE NEW WORLD

United States and Canada.—In 1924 the Lutheran Church in the United States and Canada had 2,622,554 communicant members divided among 20 ecclesiastical bodies. The largest of these were the United Lutheran Church (856,180), the Missouri Synod (645,060), the Norwegian Lutheran Church (209,213), the Augustana Synod (217,010), the Iowa Synod (168,266), the Joint

Synod of Ohio (161,021), the Joint Wisconsin Synod (139,226), the Lutheran Free Church (30,320), the Danish Church in America (20,045) and the Finnish National Church (20,000). The Synodical Conference, a consultative federation, comprising the Missouri Synod, the Joint Wisconsin Synod and two smaller bodies, formed a single well-defined group with a membership of more than 800,000. The names of many of these bodies point to one of the reasons for their separate existence. At their organisation nearly all of them were expressions of the church consciousness of groups of immigrants from the Lutheran countries of Europe, and they continue to perpetuate, to a greater or smaller degree, the religious tradition of the countries of their origin. With the slackening of north European immigration toward the end of the 19th century the nationalistic traits tended to become less marked, and the process of Americanisation was greatly hastened by the World War. Since 1914 the foreign languages are rapidly being replaced in the services by English and the separated bodies have been drawing closer together.

Organisation.—In 1918 the United Lutheran Church was formed by the union of the General Synod, the General Council and the United Synod in the South. These three bodies represented a single line of American tradition reaching back to colonial days. Most of their synods owed their foundation, directly or indirectly, to the work of Henry Melchior Mühlenberg, the great colonial missionary (d. 1787). They had had doctrinal differences, but these were regarded as too small to keep them longer apart. The Augustana Synod, a body of Lutherans of Swedish origin, did not enter the union, though it had been a part of the General Council. In 1917 three bodies of Norwegian Lutherans united to form the Norwegian Lutheran Church in America. Since 1921 discussions have been in progress looking towards the union of other separated bodies. The National Lutheran Commission for Soldiers' and Sailors' Welfare was organised in 1917 to minister to the spiritual welfare of the 400,000 Lutheran men in the army and navy of the United States. Its membership included all the larger bodies except the Missouri and Wisconsin Synods. It was dissolved in 1921. The National Lutheran Council was organised in 1918 by the same bodies that had previously organised the commission. Its purpose was to provide an agency for certain kinds of co-operative work. Its most important task has been to extend aid to the Lutheran churches of Europe during their period of reconstruction. Between 1918 and 1925 it distributed among the Lutherans of 20 different countries more than $6,500,000 in money and goods.

Doctrines.—Doctrinally, the Lutherans of America are pronounced conservatives. All of them subscribe to the Augsburg Confession and the Small Catechism, and most of them accept the whole body of the 16th century Lutheran confessions. Their doctrinal differences have been, at times, acute, but have usually concerned the theological interpretation of the confessions. Their form of government is theoretically congregational, but the whole tendency in the larger bodies is towards a rather highly centralised synodical administration. The most conservative type of American Lutheranism is represented by the Synodical Conference. Its theological standards are those of 17th-century orthodoxy; it strongly opposes any recognition of or co-operation with other churches, and it is vigorously hostile to the membership of its pastors and people in secret societies. The United Lutheran Church, though insistent upon the enforcement of confessional standards, is less rigid both in theology and practice.

LUTSK: *see* LUCK.

LUTYENS, SIR EDWIN LANDSEER (1869–), British architect, was born in London March 29 1869. After a brief training in the South Kensington Schools and in architects' offices, he received his first commission at the age of 19. He afterwards designed a number of country houses, in which he gradually developed an individuality of design which was, however, tempered by a reticence which dissociated his work from any attempts at "originality." Much of his domestic work was done in connection with the restoration of old houses; the largest example of his powers in this direction is the treatment of Lindisfarne Castle, Holy Island (1903–12). He also executed much civic work, being responsible for the *Country Life* offices in London and for the British sections at the exhibitions in Paris (1900) and Rome (1911). The garden suburb at Hampstead, London, has many good examples of his treatment of small houses. It was as the architect of the New Delhi (*see* DELHI) that the culmination of his professional career was reached. He also designed the Cenotaph in Whitehall, London. Sir Edwin, who was knighted in 1918, became an associate of the Royal Academy in 1913 and was elected a full academician in 1920. The Royal Institute of British Architects awarded him its gold medal in 1921.

LUXEMBOURG (*see* 17.145), a neutral and independent Grand Duchy, in economic union with Belgium. Its area is 1,034 sq. m., and the population 267,447 (1922). Luxembourg was admitted to the League of Nations on Dec. 16 1920.

Invasion of 1914.—On Aug. 2 1914 the German armies invaded the Grand Duchy on the pretext that it was necessary to protect the German control and working of the Luxembourg railways against a French invasion. The main line of the railways of the Grand Duchy, which belongs to the railway company of *Guillaume-Luxembourg*, had been first worked by the French railway company of the East, but from 1872, by a condition of the Treaty of Frankfurt, by the German state railways. On Aug. 4 Herr von Bethmann Hollweg admitted to the Reichstag that the violation of Luxembourg neutrality was wrong, and promised reparation.

The invasion was a violation of the Treaty of London of May 11 1867, which had placed the neutrality of the Grand Duchy under the collective guarantee of Great Britain, Austria, France, Prussia and Russia. The Luxembourg Govt. and the sovereign protested against this violation, but the Grand Duchy remained in German occupation for the duration of the War. After the Armistice, the railways of Guillaume-Luxembourg were provisionally run by France.

After the evacuation of the country by the German troops, Luxembourg denounced its accession to the German Zollverein, to which it had belonged since 1842, and from Jan. 1 1919 it constituted an autonomous customs territory, while, by virtue of articles 41 and 268 of the Treaty of Versailles, it enjoyed the right of exporting to Germany for five years, duty free, goods equivalent in quantity to its average pre-War export to Germany.

The Dynasty.—Political complications decided the Grand Duchess, Marie-Adelaide, who had succeeded her father, Grand-Duke William, in 1912, to abdicate Jan. 10 1919, in order to save the independence of the Grand Duchy, and she was succeeded by her sister, Princess Charlotte, (b. 1896). The latter married on Nov. 6 1919 Prince Felix of Bourbon-Parma, brother of the ex-empress Zita of Austria. Marie-Adelaide died Jan. 24 1924.

By the referendum of Sept. 28 1919 the Luxembourg people pronounced by 66,811 votes for the maintenance of the monarchy with the Grand Duchess Charlotte as sovereign, as against 16,885 votes for a republican régime, and by 60,133 votes for an economic union with France against 22,242 votes for an economic union with Belgium. Association with France would have helped the agrarian interest, while the vinegrowers stood to gain from association with Belgium.

Customs Union with Belgium.—After the occupation of Frankfurt, carried out jointly by French and Belgian troops (April 8 1920), the French Govt. made a declaration renouncing the negotiation of a customs union with Luxembourg in favour of Belgium. Relations with Belgium had been strained as a result of the plebiscite, but the new negotiations between

Belgium and Luxembourg culminated in a Convention (signed July 25 1921) establishing an economic union between the two countries which came into force May 1 1922, to last for 50 years. The chief stipulations of this treaty are as follows:—

1. The customs frontiers between Belgium and Luxembourg are abolished, commercial treaties in the name of the Union are to be drawn up by Belgium, Luxembourg adopts customs legislation and tariffs from Belgium, but preserves her own customs administration. The customs receipts of the two countries, as well as the yield of the taxes on beer, vinegar, sugar, tobacco, margarine, etc., with the exception of the tax on alcohol are pooled, and the total, after deducting a certain sum calculated according to the price of cereals, and devoted to the encouragement of the cultivation of cereals in the Grand Duchy, is divided between Belgium and Luxembourg in proportion to the population, approximately in the proportion of 28 to 1.

2. The paper currency in the Grand Duchy of State notes, resulting from the withdrawal of German notes after the Armistice, is reduced to 25,000,000 fr., and may only include notes not exceeding the value of 10 francs. The remainder of the note circulation of the Grand Duchy is made up of notes of the National Bank of Belgium, except a circulation of 6,250,000 fr. in notes of the International Bank of Luxembourg, which has the privilege of issue.

3. The Belgian State should share in working all the Luxembourg railways (standard normal gauge).[1]

4. Belgian consuls have charge of Luxembourg interests wherever there are no Luxembourg consuls. This provision leaves in force the agreement of Jan. 7 1880, between the Netherlands and Luxembourg, which placed Luxembourg political interests under the protection of Dutch diplomatic representatives, in all countries where Luxembourg has no diplomatic agents, except in Paris, Berlin and Brussels.

Constitution.—By a law of May 15 1919 the constitution of the Grand Duchy was revised in a more democratic direction. The powers of the sovereign were limited, universal suffrage, with proportional representation, was instituted, and the franchise was conferred on women. But the most interesting innovation was the creation of the law of April 4 1924, of five Chambers for traders, industrialists, agriculturists, artisans, private employees and workmen, election to the Chambers being by electors in these occupations above the age of 21, and maintenance by compulsory contributions by the electors. These Chambers have the power to create and maintain institutions, the right to propose bills which must be submitted to the Chamber of Deputies, and they have a right to be consulted before laws affecting their professional interests are passed by the Chamber of Deputies.

Population.—According to the census of 1922, the population of the Grand Duchy was 267,447, that is 101 persons per sq. km.; of these 33,436 were foreigners, chiefly Germans (15,500) and Italians (6,170), the latter being employed chiefly in the mining and metallurgical industries. According to the last census of occupations in 1907, 36·8% of the population was occupied in agriculture and gardening, 41·7% in industry and mines, 12·2% in commerce and transport. Since then the proportion in industry and commerce has certainly grown at the expense of agriculture.

The chief towns of the Grand Duchy are, besides the capital, Luxembourg, with 46,709 inhabitants, the three centres of the iron industry: Esch-sur-Alzette, 22,100; Differdange, 13,728; and Dudelange, 10,400 inhabitants.

Production, Industry and Trade.—In 1925 Luxembourg produced 5,984,000 tons of iron ore against 7,333,372 in 1913. There were, in 1925, 47 blast furnaces, out of which only 37 were going, which produced 2,344,000 tons of pig-iron as compared with 2,547,861 tons in 1913. The seven steel foundries of the Grand Duchy produced in 1925 2,084,000 tons of steel compared with 1,182,227 in 1913. German capital, which before the War dominated the metal works of the Grand Duchy, has been replaced since by Luxembourg, Belgian and French capital. Besides the factories which they own in Luxembourg, the Luxembourg metal companies own or control mines, collieries, blast furnaces, steel works and factories for iron and steel manufacture principally in France, Belgium, Germany and in Brazil. Their branches are established in all quarters of the globe.

Besides the ancient industries of sole leather, slates, metal constructions, china, explosives, gloves, drapery, woven wear, brewing and tobacco, long established in Luxembourg, new industries have grown up, and have made considerable way. These are the cement industry, which produced 75,441 tons in 1924, the manufacture of sparkling wines, fancy leather and brushes.

Finance.—In 1913 the public consolidated debt of the Grand Duchy was about 10,000,000 francs. In 1925 this debt had risen, in consequence of the charges which the State had to assume during the War to assure the feeding of the population and to meet the deficits in the budget caused by the upheavals during and after the War, to 196,000,000, plus a loan of 175,000,000 issued in Belgium in 1922 and intended for the exchange of notes of the Luxembourg State for notes of the National Bank of Belgium. Since 1924 the State budget has been balanced.

Railways.—On May 13 1924 a Convention between the Governments of Luxembourg and Belgium was signed at Brussels. Under the terms of this Convention the entire railway system of Luxembourg will be administered by the Société des Chemins de Fer Prince Henri, under the control of the Grand Ducal Govt., conjointly in so far as questions of interest to Belgium are concerned, particularly as regards transit, with the Belgian Government. This agreement was completed by a final protocol signed at Brussels on Oct. 14 1924, which settled the economic and technical questions, relating to the Belgian, Grand Ducal and French interests, raised by the separation of the Guillaume-Luxembourg railway system from that of Alsace-Lorraine.

(A. C.)

LUXEMBURG, ROSA (1870–1919), German Socialist, was born at Zamość, Russian Poland, Dec. 25 1870. Having taken up socialist political activities in Poland, about 1895 she migrated to Germany, where she married a German workman in order to acquire German nationality. In 1898 she edited the Saxon *Arbeiterzeitung*, but shortly afterwards joined the staff of the *Leipziger Volkszeitung*. She took part in the Russian revolution of 1905, and on her return to Germany founded with Karl Liebknecht the Spartacus League. In 1914 she was sentenced to a year's imprisonment for inciting to insubordination and throughout the World War remained in preventive custody. After the revolution she edited, with Liebknecht, the Communist paper, *Rote Fahne*. They were arrested on Jan. 15 1919 on the charge of instigating the street fighting in Berlin which had taken place a few days earlier. Whilst being conveyed to the Moabit prison they were brutally attacked by the mob. Liebknecht was shot dead and Rosa Luxemburg died a few hours later from injuries received.

BIBLIOGRAPHY.—Her works include *Die Krise der Sozialdemocratie; Briefe aus dem Gefängnis* and *Briefe an Karl und Luise Kautsky, 1896–1918*. See also G. Zinoviev, *Karl Liebknecht et Rosa Luxemburg* (1919); C. P. A. F. Liebknecht, *The Murder of Karl Liebknecht and Rosa Luxemburg* (1924).

LVOV, PRINCE GEORGE EUGENIEVICH (1861–), Russian statesman, belonged to the old Russian nobility. He spent the greater part of his life in Zemstvo, that is, local government work (*see* 23.876), being a member of the executive board of the Tula Zemstvo from 1888 and president from 1902–5. In 1905 he was elected member of the first State Duma and joined the right wing of the Constitutional Democratic party. During the Russo-Japanese and World wars he took an active part in the organisation of Zemstvos for the relief of sick and wounded soldiers and in the latter war was president of the All-Russian Union. On March 14 1917 Lvov was elected Prime Minister and Minister of the Interior of the first Russian Provisional Government. Unfortunately his Government proved a complete failure. A new Coalition Cabinet was formed on May 16 and Lvov again accepted the leadership of the Cabinet and the portfolio of the Interior, but he had no real influence in political life, and he resigned from both offices on July 7. (*See* RUSSIA.) After the Bolshevist revolution in November, Lvov was arrested and imprisoned in Ekaterinburg but he escaped to Siberia and eventually settled down in Paris.

[1] Long negotiations on the railways question ended in a convention, signed at Brussels on May 13 1924, under which the Luxembourg system is administered by a Luxembourg company, the Belgian Govt. acting conjointly with the Luxembourg authority where Belgian interests, particularly transit interests, were concerned. But this Convention was rejected by the Luxembourg Chamber of Deputies on Jan. 20 1925. Therefore the line is still under French control. The negotiations between Luxembourg, Belgium and France over the Luxembourg railway are still continuing.

LYALL, SIR ALFRED COMYN (1835–1911), British writer (*see* 17.148), died in the Isle of Wight April 10 1911.

LYAUTEY, LOUIS HUBERT GONZALVE (1854–), French soldier, was born at Nancy (Meurthe-et-Moselle) Nov. 17 1854. Having passed through St. Cyr and the Staff College, he first served as a cavalry officer, and was then appointed in 1894 to the staff of the troops in Indo-China, where he took part, under General Galliéni, in the operations against the pirates of Upper Tongking. He accompanied General Galliéni to Madagascar, where he distinguished himself by repressing an insurrection and by his able government of the southern part of the island. He applied himself to working out and putting into practice new and eminently successful methods of colonial government. Having returned to his regiment as its colonel, he was soon after appointed to the command in the territory of Aïn Sefra, which was being disturbed by incursions from Morocco. He was then placed in command of the Oran division, and was entrusted with the carrying out of international agreements with regard to Morocco. Having restored order on the Algerian-Moroccan frontier, as far as Moulouya and Guis, he took command of the X. Corps at Rennes.

In April 1912, in view of the serious situation at Fez, the Government decided to send him to Morocco as high commissioner and résident-général to quell disturbances and to consolidate the recently declared protectorate. Immediately on his arrival he succeeded in relieving Fez, and initiated the work of pacification and colonisation which was to result in a few years in the creation of a well organised government on a solid basis. On the declaration of the World War, although formally ordered by the Government to evacuate the interior of Morocco, so as to liberate the greater part of his forces, he did not yield an inch of ground, and maintained for four years a glorious struggle against all the efforts of an enemy subsidised by Germany, while he actually increased the subjugated territory.

In Dec. 1917 General Lyautey was appointed War Minister, but resigned after three months in order to return to Morocco. From 1920 to 1924 he continued his work by conquering the Atlas, and by establishing a defensive barrier to the north of Ouergha. As a reward for these services he was made a marshal of France in Feb. 1921. In 1925 he organised a victorious resistance to the attacks of the Rifi under Abdel-Krim, and did not resign the post of résident-général until order was completely restored. The work of Marshal Lyautey in Morocco was of considerable importance. Not only was the country pacified by the adoption of judicious methods of colonial government, but by constructive work and fine organisation a province was built up with a great economic future (*see* MOROCCO). He was made a member of the French Academy in 1914, and wrote numerous articles on colonial administration. His letters from Tongking and Madagascar were published in 1920. (M. Gu.)

LYNN, Mass., U.S.A. (*see* 17.172), increased in population from 89,336 in 1910 to 99,148 in 1920, of whom 27,858 were foreign-born, and 103,147 in 1925 (Massachusetts census). The aggregate value of its manufactures rose from $71,503,000 in 1909 to $160,906,000 in 1919, while the number of wage-earners in the factories remained unaltered. The effect of the post-War depression and of the dispersion of the boot and shoe industry is seen in the figures for 1923: value of products, $95,935,221; number of wage-earners, 22,506. From second place in 1905, Lynn had fallen to sixth in 1923 in the manufacture of boots and shoes, ranking after New York, Brockton, St. Louis, Haverhill and Milwaukee. In 1917 a lock-out in the shoe factories (April 18 to Sept. 20) affected 15,000 workers. The commission form of government, adopted in 1910, was abandoned in 1918 for a charter providing for 11 councillors and for a mayor with large powers.

LYONS, SIR JOSEPH (1848–1917), British business man, was born in London Sept. 29 1848 and educated at a Jewish school. In early life he studied painting and exhibited at the Royal Institute, but by 1886 he had turned to business enterprises, in conjunction with the brothers Isidore (d. 1920) and Montague Gluckstein. This led to the foundation of the catering firm of J. Lyons and Co., Ltd., of which he became chairman. He began by catering at public exhibitions, and next opened tea-shops in London, the first in 1894. Twenty years later these numbered over 200 and provided cheap food for the large class of clerical workers and junior members of professions. Later he opened several restaurants of a more ambitious nature, as well as hotels on the no-tipping principle. He was knighted in 1911, and died in London June 22 1917. See Mrs. Stuart Menzies, *Modern Men of Mark* (1920).

LYONS, France (*see* 17.174), had a population of 561,592 in 1921. In 1922 about 140,000 persons were employed in the silk industry and several large factories were built in 1924. The manufacture of artificial silk is of growing importance. The international fair, first held in 1916, has shown a notable increase of business and aims at rivalling Leipzig. A permanent exhibition building on the banks of the Rhône was nearing completion in 1926, and space for exhibitors was also being reserved on both sides of the road on the left bank of the river and in the square near the main railway station. Poland and Soviet Russia were represented at the exhibition for the first time in 1923. The Wilson bridge over the Rhône was opened in 1918. From 1916, during the War, Lyons was a centre for the exchange of seriously wounded French and German prisoners. A syndicalist congress was held in the city in 1919.

LYS, BATTLE OF THE: *see* GERMAN OFFENSIVE.

LYTTELTON, ALFRED (1857–1913), British politician, was born Feb. 7 1857, the youngest child and eighth son of the 4th Lord Lyttelton. His mother, daughter of Sir Stephen Glynne and sister of Mrs. W. E. Gladstone, died six months after his birth. All the eight boys were brought up to be keen cricketers, the cricket ground at Hagley, Worcs., their home, being close to the house; all went to Eton, and six were in the Eton eleven. The eldest, VISCOUNT COBHAM (1842–1922), became a land commissioner and a railway commissioner; GEN. SIR NEVILLE LYTTELTON, G.C.B. (b. 1845), an experienced soldier, was governor of Chelsea Hospital; SPENCER LYTTELTON, C.B. (1847–1913), was three times private secretary to his uncle W. E. Gladstone when Prime Minister; the RIGHT REV. ARTHUR LYTTELTON, D.D. (1852–1903), was Bishop of Southampton; and the REV. EDWARD LYTTELTON, D.D. (b. 1854) was headmaster, first of Haileybury, and then of Eton.

Alfred was the most famous cricketer of them all. Indeed for nearly all ball games he had an extraordinary aptitude. He excelled in football of three kinds, and in fives, racquets and especially tennis—holding the amateur championship for tennis from 1882 to 1896. At cricket he was equally good as a bat and as a wicket keeper. He was four years, 1872–5, in the Eton eleven, and captain the last year; four years, 1876–9, in the Cambridge eleven, and captain the last year. Moreover, he played for England against Australia, and for the Gentlemen against the Players; and for some years was a notable member of the Middlesex eleven. The infectious joyousness of his nature, his sterling character, his solid, though not brilliant, intellect and his prowess at games gave him an undisputed lead among his contemporaries. He was king of the place before he left Eton; and when he went up to Trinity College, Cambridge, in 1875, he gained a similar ascendancy.

After taking his degree with a second class in history, he was called to the English bar in 1881. Here his reputation stood him in good stead; he soon obtained a considerable practice, and in due course became K. C. His thoughts turned early to politics. Though by family tradition and in idealistic outlook a Liberal, he found himself unable to support the Home Rule policy of his uncle, W. E. Gladstone, and so postponed any attempt to enter Parliament until after the latter's retirement. But in 1895 he became M.P. for Warwick and Leamington as a Liberal Unionist, retaining the seat till 1906, when he was defeated. After a few months' interval, he was returned for a London constituency, St. George's, Hanover Square.

He was appointed, in 1900, chairman of a commission to enquire into the various concessions which President Kruger and the Volksraad had granted to companies and private individuals

in the Transvaal, and to report which should be maintained and which annulled. In pursuance of the investigation he spent the autumn of 1900 in South Africa; and he so impressed Lord Milner by his qualities that the high commissioner hoped to secure him as his successor. It was, however, as Colonial Secretary, in the Conservative Govt. of Mr. Balfour in 1903, that his South African experience was utilised. His tenure of office lasted two years and was marked by the drafting of a temporary constitution which should give representative institutions to the Transvaal until such time as it should be safe to concede responsible government. This constitution was never put in force, as Sir Henry Campbell-Bannerman's Ministry determined that they would risk the grant of responsible government at once. He incurred much odium by sanctioning the scheme for importing Chinese coolies into South Africa in order to remedy the shortage of native labour and to restart the mines and thereby the whole economic machinery of South Africa. When his party went into opposition he took an active share in resistance to the drastic Liberal policy, and especially to the Welsh Disestablishment Bill, which was repugnant to him as a man of deep religious feeling and an earnest Churchman. He also lent a helping hand to many social movements, and was a decided supporter of woman suffrage.

His first wife, whom he married in 1885 and who died in 1886, was the brilliant Laura Tennant, sister of Lady Oxford and Asquith; his second wife, married in 1892, was Edith Sophy, daughter of Archibald Balfour. She, with a son, Captain Oliver Lyttelton, and daughter, survived him. His death came very unexpectedly, on July 5 1913, after an injury in a local cricket match. Mr. Asquith, then Prime Minister, spoke of him in the House of Commons as having come nearest, of all men of his generation, to that ideal of manhood to which every English father would wish to see his son aspire. See Edith Lyttelton, *Alfred Lyttelton*, 1917. (G. E. B.)

McADOO, WILLIAM GIBBS (1863–), American lawyer and politician, was born near Marietta, Ga., Oct. 31 1863. He entered the University of Tennessee but did not finish his course. In 1882 he became clerk in the U.S. circuit court of Chattanooga, read law and three years later was admitted to the bar. He began practice in Chattanooga, but in 1892 removed to New York City. There he became interested in the problem of passenger transportation. In 1902 he formed the New York and New Jersey Railroad Company, which took over the abandoned Hudson river tunnel from Hoboken to New York, and in March 1904 this tunnel was completed. In 1909 the tunnel under the Hudson river to downtown New York was finished. In 1912 he was vice-chairman of the Democratic National Committee. He was a strong supporter of Woodrow Wilson for president, and on the latter's election he was appointed, in 1913, Secretary of the Treasury. In this position he contributed largely to the working-out of the new Federal Reserve Banks system.

At the outbreak of the World War in Europe he favoured strict neutrality. After America's entrance into the War he was called upon to raise unprecedented sums of money. He was successful in floating four Liberty Loans between May 1917 and Oct. 1918, amounting in all to more than $18,000,000,000. He also secured the creation of a Bureau of War Risk Insurance for shipping, later extended to include life insurance for soldiers and sailors in the World War. When the railways were taken over by the Federal Government in 1917 he was appointed director-general. He favoured the League of Nations, woman suffrage and the prohibition amendment. He resigned the secretaryship of the Treasury in Dec. 1918, and the directorship of railways the following January. He then resumed the practice of law in New York City. At the Democratic National Convention held at San Francisco, June 28 1920 and following days, Mr. McAdoo was placed in nomination for the presidency, and on the first ballot obtained the highest number of votes, 266; at the 36th ballot his vote ran to 399, but after that he lost ground, and J. M. Cox received the nomination on the 44th ballot. Mr. McAdoo was again placed in nomination for the presidency at the Democratic National Convention held at New York City in June 1924. On the first ballot he obtained the highest number of votes, 431½, on the 69th ballot he had 530, but after that his strength steadily declined, and on the 103rd ballot, when J. W. Davis was nominated, he received only 12 votes. Mr. McAdoo married, as his second wife, Eleanor Randolph, daughter of President Wilson.

MACARTHUR, MARY REID (1880–1921), British politician, was born Aug. 31 1880 in Glasgow, where her father had a large drapery establishment. Breaking with the Conservative traditions of her family, in 1903 she came to London to be secretary of the Women's Trade Union League, into whose work she breathed new life. In 1906 she founded a new general trade union for women—the National Federation of Women Workers. The Anti-Sweating League, which she helped to found, and her evidence before the Select Committee on Home Work did much to convince the public of the necessity of the Trade Boards Act, passed in 1909. It was mainly due to her efforts that boards were established in various sweated industries. In 1914 she became secretary of the Central Committee for the Employment of Women. Later she was instrumental in improving the condition of the women War workers. In 1911 she married W. C. Anderson, who was chairman of the Labour party in 1914 and M.P. for Attercliffe (Sheffield) from 1915–8. In 1918 she unsuccessfully contested Stourbridge in the Labour interest. After her husband's death in 1919, she lectured, mainly on peace, in the United States which she again visited for the Labour Convention conference at Washington. She died on Jan. 1 1921, leaving one child, a daughter, born in 1915.

See M. A. Hamilton, *Mary Macarthur: a Biographical Sketch* (1925).

McBRIDE, SIR RICHARD (1870–1917), Canadian politician, was born at New Westminster Dec. 15 1870, and was educated first in that city and later at Dalhousie University, Halifax, Nova Scotia. He was called to the Canadian Bar in 1892, and entered the British Columbian parliament as member for Dewdney in 1898. In 1900 he became minister of mines and in 1902 leader of the Opposition. In June 1903 he became Prime Minister for the province and retained that position until 1915, when he became agent-general for British Columbia in London. He was made K.C.M.G. in 1912 and died in London Aug. 6 1917.

M'CARTHY, JUSTIN (1830–1912), Irish politician and writer (*see* 17.200), died at Folkestone, Kent, April 24 1912.

McCORMICK, ROBERT RUTHERFORD (1880–), American editor, was born in Chicago, Ill., July 30 1880. He graduated from Yale University in 1903, studied law at Northwestern University law school and was admitted to the Illinois Bar in 1908, commencing practice in Chicago. He was active in civic circles from 1904 to 1910. In 1910 he became associated with his cousin, Joseph Medill Patterson, as co-editor and publisher of *The Chicago Tribune*, being president of the Chicago Tribune Company. Under their direction the *Tribune* enormously increased both in circulation and the amount of advertising matter carried, becoming one of the most influential papers in the United States. In 1916–7 McCormick served as major in the 1st Illinois Cavalry on the Mexican frontier, and in 1917 was attached to Gen. Pershing's staff, A.E.F., in France. Later he was transferred to the 5th F.A. of the 1st Div., and promoted to the rank of colonel. In 1921 in conjunction with his cousin, he started in New York City a daily illustrated paper, followed in 1924 by *Liberty*, a weekly publication, both of which obtained immediate and large circulations. In 1912 they organised the Ontario Paper Co. to make paper for their newspapers, followed in 1924 by the Tonawanda Paper Co., to make magazine paper, the two producing in 1925 about 500 tons of paper a day.

MACCUNN, HAMISH (1868–1916), British composer (*see* 17.209), died in London Aug. 2 1916.

MACDONALD, JAMES RAMSAY (1866–), British politician, was born on Oct. 12 1866 at Lossiemouth, a little fishing village on the Moray Firth. His father was a labourer, his first home a "hut and a ben." At Drainie Board School he received an elementary education and continued as a pupil teacher. Coming to London at 18, he worked at 12/6d. a week as a clerk. He continued his own education by evening classes, laboratory work and incessant reading. A breakdown in health ended his dream of a scientific career, and sent him to journalism.

MacDonald's experience and reading made him a convinced socialist. He joined, in 1894, the Independent Labour party, founded by Keir Hardie, and in 1895 stood, unsuccessfully, for Southampton. As a member of the London County Council he completed his training for public service, and, after his marriage, in 1896, with Margaret Ethel Gladstone, niece of Lord Kelvin, made frequent journeys abroad. In 1897 he paid his first visit to Canada and the United States; in 1902 he went to South Africa; in 1906, travelled through the Pacific to Australia and New Zealand; in 1910, visited India, whither he returned in 1913 and 1914 as a member of the Royal Commission on the Civil Service. At meetings of the Socialist International, he was the spokesman of British Labour on the Continent.

Stages of His Career.—Three main stages may be noted in his political career: the creation of the Labour Party, the War and the Labour Government. In the 'nineties, the great trade unions still stood aloof from politics, or were satisfied with a vague alliance with the Liberal party. The propaganda of the Independent Labour Party, with which he was prominently associated, was directed to convincing the Unions of the need of a political party for Labour; in 1899 the Trade Union Congress was induced to set up a committee to consider parliamentary action. Out of

this came the Labour Representation Committee, of which Mr. MacDonald was secretary. Thanks to his energy, patience and tenacity, the hostility of some Unions and the apathy of others was broken down and a Labour party came into being in 1900. After the return of 29 M.Ps., run by the Labour Representation Committee in 1906, the battle was won; the party became an effective force. But it was in 1918 that Mr. MacDonald's ideas were fully realised. The party was reorganised and thrown open to all workers by hand or brain, and in 1925 had over 3,000,000 members.

Elected as M.P. for Leicester in 1906, by 1911 he was leader of the Labour party in the House of Commons. A constructive critic of Sir Edward Grey's foreign policy, he opposed, on Aug. 4 1914, the view that there was an "obligation of honour" to go to war. The speech was an agreed one, but the majority of the party broke away. He had already refused suggestions of office; he now resigned his leadership. He was denounced in public and private, and had to face the fact that his views were not accepted by the nation at war. In 1918 he lost his seat at Leicester, and in 1921 failed to get in for East Woolwich.

Although out of the House of Commons till late in 1922, his influence on opinion steadily grew. By 1922, the party took his view of the Peace Treaties, and resisted the tendencies that split nearly every Labour party abroad. In 1912, he had countered the demand for the substitution of industrial ("direct") for parliamentary action in *Syndicalism;* in 1919, when, under the stimulus of Russian events, this demand reappeared as the Communist doctrine of force, he wrote *Parliament and Revolution* and *Parliament and Democracy*, in which he gave a definite and logical lead against the tactics of violence and championed parliamentary democracy. The 1922 election registered his moral ascendancy. Labour, with 140 members, was the second party in the state, and he himself, returned for Aberavon, was chosen by his colleagues leader of the Opposition.

His leadership produced a marked change in public opinion, and focused general interest on himself and on Labour. He raised its claim to be fit to govern at the sudden election of 1923, and came back with 192 followers. The Conservatives had been defeated on the main item in their programme, and, at a great meeting in London, Mr. MacDonald declared that Labour would take office, if given the chance, in order to render national service. On Jan. 21 1924 he accordingly moved a vote of no confidence in the Unionists, which was carried with Liberal support. Next day the King called upon him to form a Government. The first Labour Cabinet was announced on Jan. 24, and on Feb. 12 the new Prime Minister set out its general programme in the House of Commons. In this, the first item was peace; with this supreme object in view, he took the post of Foreign Secretary in addition to that of First Lord of the Treasury.

The unsettled state of Europe, aggravated through the occupation of the Ruhr, was a primary cause of distress and unemployment in Britain. British prestige had fallen low: relations between Britain and France were bad, between France and Germany threatening. The Reparations question blocked the way. In letters to M. Poincaré, published on Feb. 4 and March 3, Mr. MacDonald, with firm friendliness, set out the British point of view, and had soon created a new atmosphere, one of confidence and hope. When, on April 13, the Experts Committee on Reparations issued a unanimous report, he at once accepted it on the part of Britain as a basis for settlement. In May, M. Poincaré was replaced by the Radical M. Herriot, who in June came over to London to discuss the European position with Mr. MacDonald. Friendship with Italy had already been established by the latter's action on Jubaland.

On July 16 1924 an Allied conference assembled in London, over which he presided, for the specific purpose of putting the Experts' Report into operation. Within a fortnight, agreement had been reached and the German delegates called in. On Aug. 16 the London Settlement, the first negotiated agreement since the War, was initialled. By mutual consent, the Experts' Plan was put in effect, and the Reparation problem thus lifted out of the political sphere. France, at the same time, agreed to evacuate the Ruhr within a year and certain towns at once. Negotiations for an Anglo-German Commercial Treaty, since signed, were initialled. In Sept. Mr. MacDonald and M. Herriot attended the Fifth Assembly of the League of Nations at Geneva, and there submitted a plan, the Protocol, for the elimination of private war and the submission of all disputes to arbitration, after general mutual disarmament.

In the House of Commons, meantime, the difficulties of the Government's minority position were growing. Mr. Snowden's Budget met with general approval; a Housing Act was passed, and the machinery for the relief of unemployment improved. But when Mr. MacDonald sought to complete his peace work by making treaties with Russia, whose *de jure* recognition had been his first act as Foreign Secretary, the Liberals broke away. In Oct. the Government was defeated on a motion, calling for a select committee, on their dropping of the prosecution of a Communist named Campbell. In the general election, then declared, the press was exceedingly hostile, and Labour was identified with Bolshevism. The campaign culminated in the publication of a document purporting to emanate from M. Zinoviev, president of the Moscow International, urging British Communists to tamper with the army, and of a note from the Foreign Office, issued without the signature or sanction of the Secretary, animadverting on Russian propaganda. Polling took place on Oct. 29; as a result the Conservatives came back with a great majority. The Labour vote went up by over a million, but its representation was reduced to 150. On Nov. 4 Mr. MacDonald resigned, and resumed his leadership of the Opposition. His party, in conference in 1925, confirmed his leadership with striking enthusiasm, and expressed its pride in the achievement of its first Government. In 1924, while Prime Minister, he was given an LL.D. by Glasgow University, and made a freeman of Glasgow, and of Dundee. In 1925 Edinburgh made him a freeman, and the university conferred an LL.D.

An Estimate.—The permanent significance in British political history of a man who had created a new political party and enabled it to conduct a Government, is obvious. But Mr. MacDonald's contribution cannot be measured by this unless it is also noted that he made the party the vehicle of a new political philosophy, which serves to give precision and content to the idea of democracy. His socialism, derived from wide study of men and institutions, of science and history, has been expressed through writings and speeches which have modified opinion over a wider range than that of professed adherents. In it, two main streams may be detached—the scientific and the moral. Accepting the design suggested by evolution, he postulates, instead of a haphazard and unwilling adaptation, or the resistance to change that provokes revolution, a conscious acceptance of its principle through a planned social organisation based on communal need and service—such an "organisation of things as invites the co-operation of minds." Mind, in his view, is the instrument, consent the method, of social advance. Consistently rejecting violence, he opposes war and revolution alike. A steadying as well as a constructive force in the British Labour movement, he realised that ideas are the moulding force in human development; the moral element colouring his thought and action, gave to his appeal to the masses the accents of a gospel.

MacDonald's views on socialism can best be studied in his books. Among them the more important are: *Socialism and Society* (1905); *Socialism and Government* (1909); *The Awakening of India* (1911); *The Socialist Movement* (1911); *Syndicalism* (1912); *The Social Unrest* (1913); *National Defence* (1917); *Parliament and Revolution* (1919); *Parliament and Democracy* (1919); *The Government of India* (1919); *A Policy for the Labour Party* (1920); and *Socialism, Critical and Constructive* (1921). In addition, his biography of his wife, *Margaret Ethel MacDonald* (1912); and a volume of essays and travel pictures, *Wanderings and Excursions* (1925) may also be mentioned. See C. W. Mullins, *The Patriotism of Ramsay MacDonald and Others* (1916); L. N. Le Roux, *J. Ramsay MacDonald. Sa vie, son œuvre et sa pensée* (1919); "Iconoclast" (M. A. Hamilton) *The Man of Tomorrow, J. Ramsay MacDonald* (1923); *J. Ramsay MacDonald, 1923–25* (1925); H. Tracey, *From Doughty Street to Downing Street. The Rt. Hon. J. Ramsay MacDonald, M.P.* (1924); J. Bardoux, *J. Ramsay MacDonald* (1924); G. Glasgow, *MacDonald as Diplomatist* (1924). (M. A. H.)

MACDONELL, SIR JOHN (1846–1921), British jurist, was born at Brechin, Forfarshire, Aug. 11 1846, and was educated at the universities of Aberdeen and Edinburgh. He was called to the bar by the Middle Temple in 1873 and for some years was counsel to the Board of Trade and the London Chamber of Commerce. In 1889 he was made a master of the supreme court and in 1912 was appointed king's remembrancer. In 1901 he was made Quain professor of comparative law in the University of London and he was president of the society of public teachers of law (1912–3), a member of several royal commissions, and editor, for many years, of *The Journal of Comparative Legislation and International Law*. In 1913 he was elected a fellow of the British Academy and in 1914 was created K.C.B. Besides editing the *State Trials* (1887), the *Civil Judicial Statistics* (from 1894) and the *Criminal Judicial Statistics* (from 1900), he published works on the subjects of capture at sea and the law of master and servant, and was the author of many papers on international law. He was also for 40 years a leader writer on *The Times*, London. He died in London March 17 1921.

MACEDONIA (*see* 17.216), a territory embracing the former Turkish vilayets of Monastir and Salonika, and part of the vilayet of Kosovo, now divided between Greece and Serbia.

All statistics of Macedonian nationalities must be received with the greatest caution and have a very relative value. The "Peace Handbook for Macedonia" states with considerable diffidence that "before 1912 there were approximately 1,150,000 Slavs, 400,000 Turks, 120,000 Albanians, 300,000 Greeks, 200,000 Vlachs, 100,000 Jews and 10,000 Gipsies." M. Palles estimates the population of Greek Macedonia as 43% Greek before the immigration of the Greek refugees and as 90% Greek in 1925. There is a movement among the Greeks of Greek Macedonia for local government; this is quite distinct from the Bulgarian propaganda in favour of an "autonomous" Macedonia, which, like "autonomous" Eastern Roumelia in 1885, could be ultimately annexed to Bulgaria.

Political History.—Since 1911 Macedonia has thrice become a battlefield. When the first Balkan War of 1912 broke out, while the Bulgarians directed their principal efforts against the Turkish armies in Thrace, their Serbian and Greek allies advanced into Macedonia. The great Serbian victory at Kumanovo left Skoplje, the capital of Dushan's medieval Empire, open to the victors, and the Greek successes at Sarantaporos and Yenije-Vardar led to the occupation of Salonika. In 1913 the quarrel which arose out of the division of the Macedonian spoils between Bulgaria and her allies provoked the second Balkan War, of which Macedonia was again the theatre. The Greeks defeated the Bulgarians at Kilkis and the Serbians routed them at Ovčepolje. But the retreating Bulgarians laid Seres, a flourishing town, in ashes, and the writer, visiting it a year later, saw an empty petroleum tin in every Greek house. Violence was also practised at Nigrita, Doxaton and Drama.

The third Treaty of Bucharest, signed Aug. 10 1913, divided Macedonia between Greece and Serbia; the Greek frontier stretched from the Mesta, thus including the rich tobacco plantations of Kavalla, to Kenali near Monastir, which became Serbian. Bulgaria was excluded from what had been to her Nationalists her "promised land," and King Constantine was hailed at Athens as a second "Bulgar-slayer," the successor of Basil II. For the first time for five centuries Macedonia was governed by Christian nations. As inevitably happens whenever Turkish rule ceases there was everything to create. The victors of the wars of 1912–3 took over a land neglected completely by its Turkish governors; its marshes were undrained, its rivers unembanked, its ports undredged, its cultivable lands (with the exception of the tobacco fields) either uncultivated or else cultivated by the most primitive methods. Serbians and Greeks set to work upon this colossal task to the best of their experience and limited means, but they had had no time to achieve much when in 1914 the World War broke out, and in 1915 Macedonia for the third time in three years became the scene of Balkan conflicts and was soon converted into one of the European cockpits.

The entry of Bulgaria into war against Serbia, on Oct. 14 1915, was speedily followed by the capture of Shtip, Radovište, Veles and Skoplje and the evacuation of Monastir, although the Serbians held the Babuna pass between Skoplje and Prilep for more than a week. Meanwhile, the Allied troops had landed at Salonika (*q.v.*) on Oct. 5, which thenceforth became the base of their operations in Macedonia. But they had to retreat from Doiran and Krivolak to the Vardar and thence to Salonika in Dec., while in May 1916 the strategic position of Fort Rupel, commanding the Struma valley, was, with the acquiescence of the Greek Govt., betrayed to the Bulgarians, who occupied Kavalla and all eastern Macedonia. At last, after the appointment of Gen. Sarrail as commander-in-chief, the Allied offensive began. The British advanced on Doiran and along the Struma; the French and the reconstituted Serbian Army retook Monastir, while Italian troops landed at Salonika and the Provisional Govt. of M. Veniselos, now established there, on Nov. 23 declared war on Bulgaria and Germany. When the spring campaign of 1917 began, fighting was resumed near Monastir and Doiran, and the French and Russians extended their front towards the lake of Okhrida, while the Greeks at the battle of Srka in 1918 contributed to the Allied victory. The Franco-Serbian offensive on the Vardar in Sept. of that year, combined with the Anglo-Greek attack near Doiran, where a monument now commemorates the British fallen, led to a complete rout of the Bulgarians, who on the 25th asked for an armistice, signed on the 29th, on the day when the French entered Skoplje. Next day Bulgaria surrendered unconditionally; Macedonia had contributed her share to the defeat and at last had rest.

The peace settlement of 1919 divided Macedonia between Greece and Yugoslavia, while Bulgaria was excluded alike from Macedonia and the Aegean. But that she will permanently acquiesce in that settlement may be doubted from a study of her past claims. Bulgarian *komitadjis* still threaten from time to time the danger zone where the three frontiers converge. Incidents such as that between Greeks and Bulgarians near Petritch in Oct. 1925, referred by both parties to, and settled by, the League of Nations, remind western Europe that Macedonia is still volcanic soil.

Greek Settlement in Macedonia.—The emigration of the Greek refugees from Asia Minor and Turkish Thrace after the Greek disaster in the Asia Minor campaign of 1922 has, however, completely changed the ethnographical situation, and has solved the racial question in Greek Macedonia, whose population, formerly only 43%, is now 90% Greek. Economically the change is equally striking. Thanks to the work of the Refugees' Settlement Commission, created by the League of Nations in 1923, and to the Refugee Loan of £10,000,000, issued under the auspices of the League, villages have arisen throughout parts of Greek Macedonia where there was not a house before. Competent judges believe that the refugees from Asia Minor will in time do for Macedonia what the expelled French Huguenots did for England, for they have brought new industries with them. It is calculated that when the Anglo-American concession for draining the Vardar marshes has accomplished its work, not only will malaria, the curse of Macedonia, be diminished, but also that country will supply the rest of Greece with cereals, now imported, and will thus improve the rate of exchange.

Railway Communications.—Since the opening of the last section of the Greek railway between Thessaly and the Macedonian system in 1916—a connection long refused by the Turks—Macedonia is traversed by the Simplon-Orient and Prague expresses to Athens, and an improvement of the permanent way will further shorten the journey. Difficulties between Greece and Yugoslavia have, however, arisen with respect to the portion of the railway between Salonika and the Yugoslav frontier station, Gjevgjelija, which belonged to a French company, now bought out by the Greeks. The Yugoslavs have obtained a "Serbian zone" in the port of Salonika, but, despite the fact that since Aug. 1925 Serbia has for the first time had direct railway communication with the Adriatic at Spalato, Serbian nationalism tends to regard Salonika—towards which the Croats and Slovenes are indifferent—as the natural outlet of Serbian Macedonia. The signature of the Bulgarian Minorities' Protocol by the Greek representative at Geneva was the occasion of the denunciation by the Yugoslavs of their alliance with Greece, and the subsequent

negotiations for its renewal had (up to April 1926) failed, although the Greek Assembly refused to ratify the Minorities' Protocol. Meanwhile, considerable improvements have been made, notably in the railway stations of Serbian Macedonia, and the frontier question of the Monastery of St. Naum has been settled with Albania.

Production and Industrial Development.—But it would be impossible for Macedonia, after five centuries of Turkish neglect, to achieve a high grade of civilisation in 13 years. Nevertheless, Macedonia has already shown signs of an industrial future. Cotton is grown near Seres, woollen goods are produced and 17,000 tons of tobacco were grown in 1924, and 26,000 in 1923 in Macedonia and Thrace. The refugees have replaced the Turkish tobacco planters in Macedonia, and in 1924 they were cultivating 2,250 acres more than before. In 1923 the value of the tobacco exported from Kavalla reached three milliards of *drachmai*, and an American tobacco company is established there. The usual corollary of industrialism has made its appearance at Kavalla in the form of the labour disputes of 1924. Macedonia is, indeed, the only part of Greece where there are any signs of Bolshevism, a phenomenon to the growth of which the individualism of the Greek character is very unfavourable. The Greek peasant is naturally conservative, and it is only among the new elements of the Macedonian population, Greeks who in some cases speak only Turkish and have little to lose, that Bolshevik propaganda can find disciples.

Jewish Element.—Macedonia is the only Greek territory which furnishes a large Jewish element to the population. The Salonika Jews, settled there for centuries, probably preferred Turkish to Christian rule; but they have accepted Greek citizenship and formed a special electoral college for the elections to the new Greek Senate (still in abeyance). Their traditional business qualities contribute to the economic development of the province, now placed under a governor-general. *See* also BULGARIA.

BIBLIOGRAPHY.—N. B. Many books on this subject have racial bias and are propaganda. See however: Peace Handbooks, vol. 4, No. 21, *Macedonia* (1920); Gen. M. P. E. Sarrail, *Mon Commandement en Orient, 1916-8* (Paris, 1920); William Miller, *The Ottoman Empire and its Successors, 1801–1922*, ed. 2 (Cambridge, 1923); R. F. H. Duke, *Report on the Industrial and Economic Situation in Greece for the Years 1923 and 1924* (London, 1925). (W. Mi.)

McGILL UNIVERSITY (*see* 27.775).—The position of McGill as providing exceptionally ample facilities for instruction and research in applied science has been maintained and strengthened since 1910 in many respects. A new wing giving additional space to the work in electrical engineering has been erected. A university clinic has been established under direction of the professor of medicine who is also chief medical officer of the Royal Victoria Hospital. In 1910 the Carnegie Corporation of New York gave $1,000,000 in recognition of McGill's science and sacrifice in the World War. In 1920 the Rockefeller Foundation gave $1,000,000 for the faculty of medicine, $1,000,000 was given by the Provincial Govt. for general purposes and $4,400,000 was raised from the graduates and citizens of Montreal as a general endowment. The income from investments is about $1,000,000. In 1923–4 the Rockefeller Foundation gave $500,000 for medical research, Lady Strathcona gave $120,000 to endow a chair of zoology, and other substantial gifts and bequests have been made to the university since 1910. After the World War Sir Arthur Currie, G.C.M.G., K.C.B., was chosen principal of the university.

MACH, ERNST (1838–1916), Austrian physicist and psychologist (*see* 17.232), died near Munich Feb. 19 1916.

MACHAR, JAN SVATOPLUK (1864–), Czech poet, was born at Kolin Feb. 29 1864. His early works, such as *Confiteor* consist of sentimental verses written under the influence of Lermontov, Heine and De Musset. He afterwards turned his attention to social and political satire, exemplified in such volumes as *Magdalena* (1894), and *Warriors of God* (1895–6). The most important phase of his poetical activity began, however, with the publication of *Golgotha* (1901), the first of a series of volumes in which the destinies of mankind are surveyed through sceptical and anti-clerical eyes. *In the Glow of the Hellenic Sun* (1906) and *The Poison from Judaea* are titles which sufficiently indicate the point of view from which Machar wrote his historical impressions. He traced, in the form of monologues, portraits and short dramatic scenes, the chief personalities in history, from the earliest times to the Napoleonic era and beyond. As a prose writer, Machar exhibits the same incisive qualities which distinguish his poetry. He attracted much attention by his book, *Rome* (1907) in which personal bias is fully expressed and by *The Jail* (1917–8), a graphic description of his imprisonment by the Austrian authorities during the World War.

MACHINE GUNS (*see* 17.237).—The machine gun is an automatic small-arm weapon, usually provided with a fixed mounting and capable of sustained accurate fire. A heavy machine gun does not differ materially from an ordinary machine gun in design, but as its calibre may be from 0·5 to 0·9 in. it is necessarily of a heavier and stronger make. The weight of a machine gun, however, is limited by the consideration that by whatever means it may be transported, it must in the last resort be "man-handled" into position often over considerable distances and under difficult conditions. On the other hand lightness and portability are desirable only in so far as they are consistent with strength, for to a large extent it is on the strength, and therefore, weight, of the mechanism that the ability of a gun to sustain fire depends.

Ammunition.—Rifle ammunition can be projected by a machine gun with incapacitating effect at ranges at which the fire of the rifleman would be inaccurate and wasteful owing to the big variation caused by the personal error. Theoretically it might be desirable to have special machine gun ammunition such as the long-ranging (6,000 yd.) streamline bullet used by the United States and Swiss armies; but in view of the enormous quantities of ammunition required for the small arms of modern armies, it seems probable that any advantage would be more than counterbalanced by the difficulties of supply, organisation, etc., that would be involved in having different types of ammunition for rifles and machine guns.

Mounting.—The fixed mounting with which the machine gun is provided increases the accuracy of all ordinary shooting, and thus enables the gun to be used either for indirect fire, or for fire over the heads of friendly troops, when supporting an attack or covering a retirement. To support rigidly a machine gun weighing from 40 to 50 lb., the mounting must be strong and fairly heavy, otherwise the combination will be top heavy and unsteady, and the shooting in consequence will be inaccurate. The mounting must permit of the gun being traversed through as wide an arc as possible, and also permit alterations in elevation to be made. The tripod mounting of the American 0·3 Browning machine gun has elevating and traversing dials, graduated in degrees, etc., to facilitate "fire direction."

Fire Capabilities.—Machine guns for ground use normally have a rate of fire of about 450–500 rounds per minute, but, owing to the necessary replenishment of empty belts or magazines, etc., the number of rounds actually fired per minute is much less. In aircraft a higher rate of fire is desirable, and is usually obtained. By reason of its capacity for sustained fire the machine-gun can provide prolonged supporting fire on the battlefield besides being useful for barrage work. The ability to fire single shots is an advantage, because such shots do not disclose the identity of the machine gun and are useful for observation of range, for testing the working and for keeping water-cooled guns from freezing up in cold weather. There are also certain tactical advantages, especially in the case of detached units of cavalry, whose ammunition is on pack transport and is therefore limited.

Cooling Systems.—For sustained fire an efficient cooling system for the barrel is essential. The higher the temperature of the barrel, the less its resistance to wear. There are three systems in use, namely, radiation in air, a combination of radiation and draught of air and water-cooling. In the case of aircraft machine guns no special provision for cooling is necessary as the barrel is exposed to the rush of cold air. Heavy barrels with radiating rings are sometimes employed for ground use (*e.g.*, the French Hotchkiss). Such barrels are comparatively safe from damage by ordinary usage or by small-arm bullets, but they suffer from the disadvantage that when they get hot, the heated air rising from them, known as "mirage," causes the target to appear to be in movement, and thus interferes with the aiming of the gun by eye. The radiation and the draught system is employed in Lewis guns (*see* RIFLES AND LIGHT MACHINE GUNS).

The water-cooling system is the most common. The barrel, for nearly the whole of its length, is surrounded by water contained in a casing which, in the case of recoiling barrels, is fitted with glands to prevent leakage. Inasmuch as prolonged rapid fire causes the water to boil, a steam escape is necessary. In arid countries the renewal of the water given off as steam is often a serious difficulty, and in any case there is always the risk of the escaping steam disclosing the position of the gun. Accordingly a flexible tube is usually attached to the steam escape whereby the steam is led into a portable condensing chamber, and converted back into water for use again in the gun. In cold weather guns having recoiling barrels may be put out of action, except for single shots, by the water freezing, but no instance is known of a water-cooled gun being out of action by reason of heat, provided the water-casing has been kept well supplied. The water increases the weight of the gun by about 9 lb., and for this reason light machine guns rely on radiation for their cooling.

Mechanical Safety.—All automatic weapons are required to be "mechanically safe," that is, the design must be such that the gun cannot be fired unless the action is fully closed and the cartridge properly supported. Even then, it should only be able to fire by means of the trigger mechanism, which itself must be proof against heavy jarring. Safety catch ("applied safety") devices are usually operated by a single, simple movement. To be perfectly efficient, they should operate directly on the firing pin or striker, and should preclude the possibility of its ever being able to reach the cartridge by accident.

Typical Patterns.—A few details of typical different patterns of machine guns are given in the table at the bottom of the page. Bulgaria used a ·315 Maxim (tripod mounting and pack transport) and Switzerland a ·295 Maxim (tripod and reff carriage, pack and man's back). In other details both guns follow the German pattern. The Belgian Hotchkiss differs from the French in calibre (·301), mounting (carriage with removable tripod) and mode of transport (limber). The Czechoslovak Schwarzlose is identical with the Austrian weapon.

For the automatic operation of machine guns power may be obtained in three distinct ways, viz.: from the gases generated by the explosion of the charge, from the recoil of the barrel and from the backward thrust of the cartridge on explosion. In some types of gun two of these principles of operation are combined.

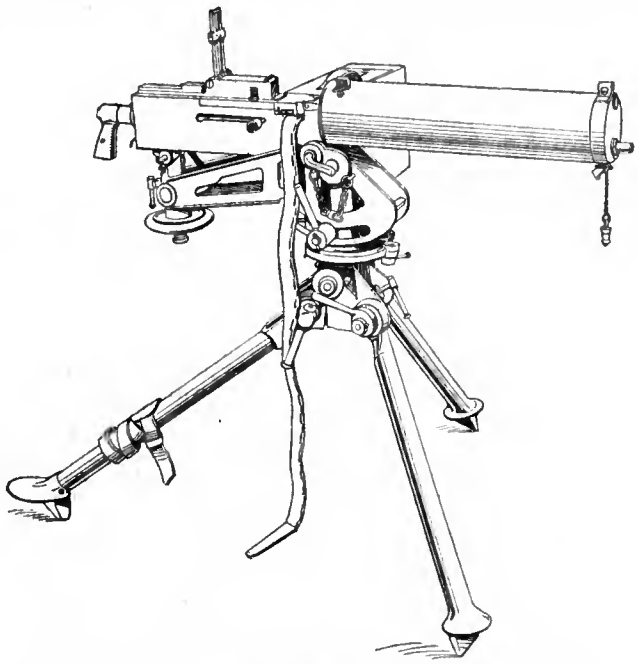

FIG. 1.—Browning water-cooled machine gun (U.S.).

Gas-Operated Guns.—Most light machine guns and the Hotchkiss, which is the primary machine gun of the French Army, are typical of the first method. The gas is diverted through a hole in the barrel near the muzzle to operate a piston or lever. In the Colt machine gun the gas issuing from a hole near the muzzle impinges

The Machine Guns of Six Countries

	Austria	France	Germany	Great Britain	Italy	U.S.A.

[1] Rearward thrust of cartridge projects breech block to rear.
[2] During the World War the Erfurt gun was made. It was very similar to the 1908 gun, but weighed less—empty 31 lb., full 37 lb. Tripod 51½ pounds.
[3] Mark II. gun is for aircraft. It is air-cooled and uses a metal disintegrating link belt (any length).
[4] Belts for aircraft are of metal disintegrating links.

on the front end of a lever hinged at its rear. The front of the lever, being blown down by the gases, revolves backward round its hinge and in so doing extends springs which operate the mechanism. This gun is now practically obsolete.

Barrel Recoil Only.—The U.S. Browning water-cooled gun (see fig. 1) operates by barrel recoil alone. On the explosion of the cartridge the barrel, barrel extension and breech block move backwards locked together for $\frac{5}{8}$ inch. The locking block for the breech block is then forced downwards, and, the action being unlocked, the breech block travels to the rear, compressing the return spring. An extractor pivoted to the breech block then withdraws a live round from the belt in the feed block. At the end of its rearward travel, it is forced down, so placing the new round in grooves on the face of the breech block and in line with the chamber. The empty cartridge case is knocked off the face of the breech block through the ejection opening underneath the gun. The return spring then pushes the breech block forward to close and load the gun. The cartridge belt is led into the feed block by the action of a slide carrying a pawl, which, engaging behind the leading round, forces it into position for the extractor to grip. In this way the belt is led through the gun. A pawl on the floor of the feed block prevents the belt from slipping backwards. The slide is worked to left and right by a lever operated by a stud working on a cam-shaped slot in the top of the breech block.

The firing pin, housed within the breech block, is cocked by the action of a pivoting lever during the backward travel of the breech block. The other end of this lever, engaging with ramps on the top of the gun, is caused to rotate round its pivot. When the breech block goes forward it is pivoted into position for the next cocking action. To release the firing pin to fire the gun, a trigger, when the breech block is fully forward and locked, engages with a sear which holds back the firing pin against its spring. In this way, the "mechanical safety" of the gun is secured. When the trigger is pulled, the sear disengages from the firing pin, which then flies forward to

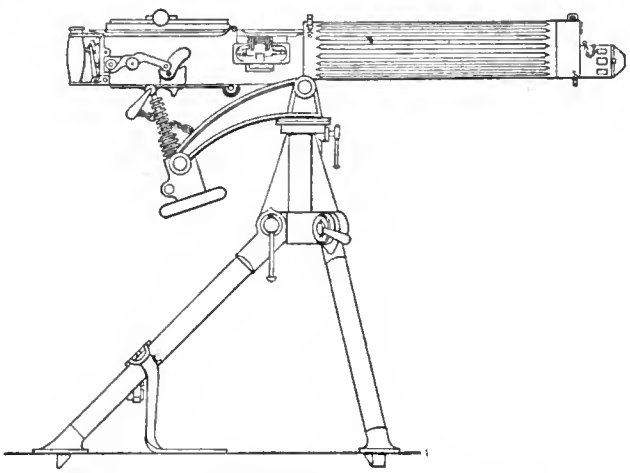

FIG. 2.—Vickers machine gun (Great Britain).

fire the round. So long as the trigger is pressed the gun fires automatically. A springed component called the accelerator is also embodied. Its function is to assist the recovery of the barrel and, cocked by the barrel extension moving backwards and released by the breech block going forward, regulates the timing of the locking of the latter.

Recoil and Gas.—In the Vickers gun (see fig. 2) recoil of the barrel is assisted by the backward thrust of the gases partially trapped at the muzzle. The barrel projects through the front of the water casing, and on it is carried a muzzle cup. Surrounding this is a muzzle attachment, screwed to the water casing and having a small hole in it, through which the bullet passes. The gases following the bullet strike the front end of this attachment and rebound on to the muzzle cup on the barrel, so increasing the recoil energy of the latter. The barrel, with side-plates attached, recoils about one inch. The left side-plate operates a lever, which, with another, works a slide on the feed block, to the right on recoil and to the left on recovery. This feed block is above the breech. The slide has two pawls, which, when it is to the right, engage behind the new round in the cartridge belt and push it to the left into position, where it is withdrawn from the belt by the moving extractor on the lock.

On recoil the lock, locked to the barrel, moves with it. In the rear of the lock is the crank to which the lock is connected by the head of the side levers and connecting rod, in which the former engages. Bearings in the rear of the right and left side-plates carry the crank, the left one being detachable. On the right, outside the casing, is a crank handle. This handle has a curved rearward extension called the tail. Just clear of this tail on the side of the gun is a roller. On recoil, the curved part of the tail hits this roller and is caused to rotate. Being attached to the crank, the latter is rotated, thereby causing the lock to be unlocked and withdrawn from the breech, during which movement the lock is cocked. There is, farther forward on the crank handle, a hump, which, when meeting the roller, causes the crank and side-plates to move forward, so returning the barrel to its forward position. In the left axis of the crank is a recess, into which a feathered lever called the fuzee engages. This, by means of links, engages with the fuzee spring, which is secured to the left of the casing. When the crank rotates, the fuzee rotates, and this spring is extended. When the rearward rotation of the crank is finished, the spring, working through the fuzee, rotates the crank in the opposite direction, so causing the lock to go fully forward into the locked position against the breech, with its firing pin cocked. The extractor is operated vertically on the lock face by side and extractor levers. It has two flanges in which the cartridge rims ride and are so held to it.

When the lock is fully forward, the extractor is at its highest point, and if a round be in the feed block, it is gripped by the extractor. When the lock goes back, this round is withdrawn from the belt, and, after about $3\frac{1}{2}$ in. of travel, the extractor falls and places the round in line with the chamber. When the lock goes forward this round is pushed into the chamber, and the extractor, rising again, grips another round in the feed block, there being then two rounds

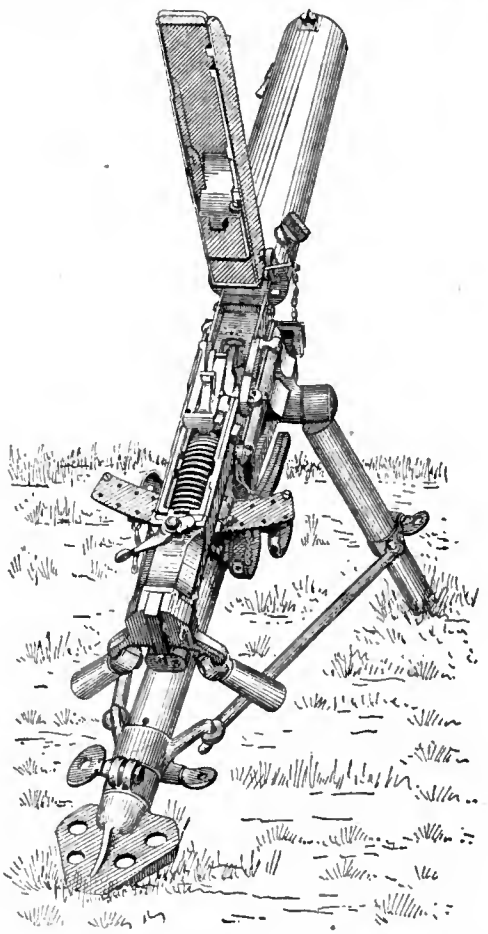

FIG. 3.—Schwarzlose machine gun (Austria).

on the extractor, one in the feed block, the other in the chamber. Through the extractor is a hole, through which the firing pin protrudes to fire the round in the chamber when the extractor is in its highest position. On the recoil of firing, the flanges, still gripping the case in the chamber, withdraw it, and when the extractor drops again, this empty case drops through the bottom of the casing.

Projecting from the top of the lock is the tail of the trigger. Along the cover of the gun is situated a spring-operated sliding trigger bar. The rear of this is connected by the trigger bar lever to the firing lever with thumb piece, which is carried on the rear crosspiece. When the thumb piece is pressed forward the trigger bar is drawn rearwards and pulls or trips the tail of the trigger projecting from the lock, thus releasing the firing pin and firing the gun. A spring-operated safety catch on the rear crosspiece prevents the operation of the thumb piece until disengaged by the fingers of the firer.

Cartridge Projection.—The Austrian Schwarzlose (see fig. 3) is operated on a principle known as "cartridge projection," *i. e.*, by the backward thrust of the cartridge driving the action to the rear. The barrel is fixed, and the moving parts are operated by the thrust of the cartridge head on the breech block. To ensure that the car-

tridge does not grip the chamber after the explosion, and so retard its rearward thrust, provision is made to oil each round entering the chamber. On firing, the breech block is driven to the rear against a strong spring, extracting the fired round from the chamber, and rotating the crank and handle.

In rear of and underneath the breech is the feed wheel, round which are studs. Underneath the bolt is a cam-shaped slot, in which each of these studs ride in turn, thus causing a rotating movement of the feed wheel. At the front of the fore part are two sets of teeth. The belt is led into the gun between these teeth, which then engage the rounds at each end and lift them into position for withdrawal from the belt by means of a claw on the underside of the breech block. The round is thus drawn to the rear into a channel in the feed wheel. During this withdrawal, the channel is rotated slightly to the left, so bringing the round into position in front of the breech block, which is now in its rearmost position. The main spring then drives the breech block forward and the round enters the chamber, rotation of the feed wheel being also effected, and the next round being prepared for a similar operation.

Ejection is effected by a plunger on the right of the breech block face. A heavy firing pin protrudes through the breech block, and at its rear is a solid arm that curves forward. This portion engages with a suitably shaped similar arm in the crank, when the latter is rotated during the backward travel of the breech block, thus withdrawing the firing pin. When withdrawn, the bent of the firing pin engages with the sear on the breech block, and it is cocked. On the left side of the solid arm of the firing pin is a pivoted arm, the trigger, projecting forward and downward. The front end of the trigger bar, which is ramp shaped, is in front of this arm when the firing pin is cocked. Its rear end is engaged with a trigger bar lever, operated by the firing lever thumb piece, mounted on the rear cross piece. On the thumb piece is the safety catch. To fire the gun, the safety catch is pressed towards the right and the thumb piece forward. This withdraws the trigger-bar, and the ramp at its forward end raises the pivoted arm, or trigger, until disengaging its bent from the sear on the breech block, when the firing pin is free to fly forward to fire.

Mechanical safety is provided by (*a*) the cap of the cartridge not being in line with the firing pin hole till the breech block is fully forward, and (*b*) by the main spring bearing against the solid metal at the rear of the firing pin, thus driving the breech block forward, so that it is impossible for the firing pin to strike the cartridge cap if the breech block be not fully forward.

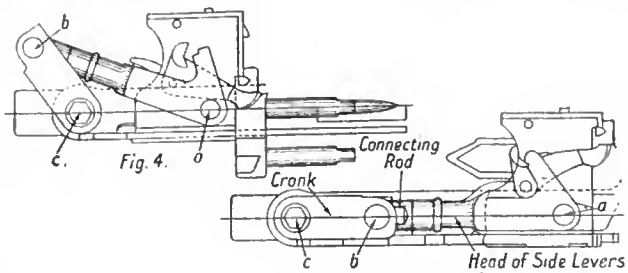
Recoil and Cartridge Projection.—The Italian Revelli uses a combination of barrel recoil and cartridge projection. At the rear of the barrel a sleeve is attached by means of ribs. Inside this sleeve is the breech block. When the gun is fired all three move together to the rear for a distance of 4 mm., after which the breech block goes on free for about 6 in., compressing the recovery spring within it. This spring also operates the firing pin within the breech block. The bent on the firing pin protrudes down through the breech block, and, when this goes forward under the influence of the recovery spring, the bent engages with the right hand, or primary, of two sears projecting upwards through the body casing. This sear is released by a spring plunger connected to a thumb piece in the rear crosspiece, and is disengaged from the bent on the firing pin to fire the gun. By setting a small lever on the rear crosspiece, the spring plunger can be regulated to give continuous or single shots. The secondary or left-hand sear is to ensure "mechanical safety." If the sleeve and breech block are not fully forward, this sear continues to protrude and engages with the bent on the firing pin. It is operated by an arm protruding from a rotary wedge underneath the sleeve. This wedge, by a spring, is rotated fully forward when the sleeve and breech block are in their forward positions. Its arm then rises, and pressing upwards the front end of the secondary sear, clears the rear end of this sear from the path of the bent of the firing pin.

The cartridges are contained in a magazine holding 50 rounds, there being 10 compartments, each with a platform and spring. As each compartment is emptied, the magazine is moved to the right and the next compartment is employed. The breech block, on going forward, takes the top round from the compartment and inserts it in the chamber. The moving across of the magazine as the compartments are emptied is effected by a lever protruding from inside the body casing, and engaging in spaces in the magazine. This lever is kept out of action by a spring plunger engaging with it, but, when the compartment platform rises on being emptied, it disengages the spring plunger, so permitting the lever to function. The lever is on a pivot, to one end of which is attached a strong spring. The other end of this spring is connected to a system of levers working in short grooves in the sleeve, every backward movement of which causes this spring to extend and endeavour to produce the requisite motion in the magazine lever.

Mechanical safety is further effected by means of a little rocking lever on the left front edge of the breech block, into which one end projects. In the body casing is a recess for the other end of this lever. The firing pin on going forward encounters the inner end and forces the other end outward. Unless the breech block be fully forward, the outer end is not in position to enter this recess in the body casing, and the firing pin is intercepted by the inner end of the lever, and so preventing from protruding to fire the round. Ejection with this gun is vertically upwards.

Locking Actions

As the locking action is perhaps the most important part of the mechanism of any automatic weapon, a short description is given of the well-known method employed in the Vickers gun and also the unusual methods employed in the Schwarzlose and Revelli guns.



Figs. 4 and 5.—Locking action of the Vickers machine gun.

The Vickers (see figs. 4 and 5).—The lock is connected to the crank by (1) the side lever head, whose axis is a, and (2) the connecting rod, whose axis is b. The axis of the crank is c. Fig. 4 shows the unlocked position with the lock back. Fig. 5 shows the locked position. In the locked position, axis b is slightly below axis a and c, and the crank, under b, bears hard on the crank stops. The rearward thrust of the cartridge on explosion thus passes through a, b and c. As b is lower than a and c, it cannot under pressure rise above the line ac and so unlock the action. It must tend downwards. However, the crank is already bearing on the crank stops under b, hence no movement here is possible and so the locking action is effected.

Except that the crank revolves downwards instead of upwards, the system of locking in the Maxim gun is practically identical with that employed in the Vickers.

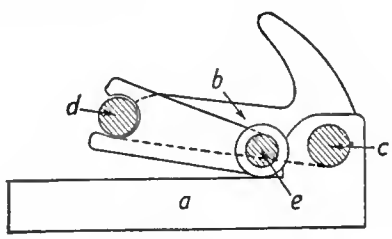


Fig. 6.—Inertia sealing of the breech in the Schwarzlose machine gun.

Inertia Sealing of the Breech in the Schwarzlose.—There is no positive locking in the gun, reliance being placed in heavy moving parts and a strong spring, to induce sufficient inertia to seal the breech. With a view to ensuring the exit of the bullet from the barrel before the inertia is overcome, the barrel is abnormally short.

The mechanism includes a massive, heavy breech block a (see fig. 6), connected by the crank link b (which is attached to it at axis c) to the upper axis of the crank, d. The lower axis of the crank e works in bearings in the body-casing of the gun and has no backward or forward movement. In rear is a strong spring pushing the bolt forward. The thrust on the face of the breech block pulls the crank link to the rear. It, in turn, pulls the crank to the rear.

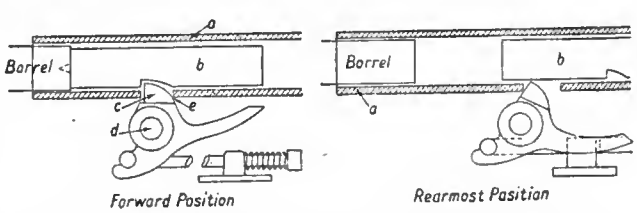

Fig. 7.—Locking action of the Revelli machine gun.

However, owing to the set of the crank with reference to its non-recoiling axis e, considerable resistance to the rearward motion of the breech block is set up. Thus it is that, coupled with the heavy resistance offered by the strong antagonistic spring and the weight of the moving parts, sufficient inertia is created to prevent the breech from opening prematurely.

The Revelli.—On explosion, the barrel with sleeve a (see fig. 7) recoils, and the gases, acting through the cartridge head, impart a rearward movement to the breech block b. At this stage, the breech block and sleeve are locked together by a claw c, on a rotating wedge with axis d. The rearward movement of the breech block causes the wedge to rotate to the rear. In so doing, the claw, which passes through a slot in the sleeve, bears against the latter at the shoulder e, and helps to force the sleeve and barrel rearward. After

a and b have moved about 4 mm., the claw is entirely disengaged from the breech block, which continues to the rear under its own momentum. The wedge in rotating compresses a strong spring, so the tip of the claw bears against the under side of the breech block, and is prevented from regaining its forward position. Hence the sleeve cannot do so until the recess in the breech block returns to within 4 mm. of its forward position.

The long arm of the wedge is that which engages with the secondary sear introduced for " mechanical safety " and referred to in the description of the gun. (H. R. A.)

MACHINERY: *see* AUTOMATIC MACHINERY; TEXTILE MACHINERY.

MACHINE TOOLS (*see* 27.21).—The sixteen years between 1910 and 1926 changed the character of machine tool equipment in many respects. For while the outward appearance may have retained the same general outline, there have been many developments in details that greatly affect productive capacity. Among these details are the use of heat treated alloy steels in spindles and gears, anti-friction bearings in many places, including the main spindle in a few instances, and the placing of the driving motor in the base of the machine itself. Add to these the growing use of individual motor drives, the speeding up of the machines and the tendency toward automatic or semi-automatic feeds, and the changes are very noticeable.

Mass production has been aided by the increasing use of more accurate gauges and better inspection methods. The new visual or projection methods of inspecting screw threads and other contours has enabled interchangeable work to be secured more rapidly. The use of optical methods has also made it much easier to obtain extreme accuracy whenever necessary.

Lathes.—There have been few changes in cutting tools since the advent of the tools suggested by the late Frederick W. Taylor although there is a tendency to use tools with greater top rake. Both A. L. De Leuuw and Dr. Hans Klopstock have advocated changes in tools shapes that, as shown by experiments, make a much higher cutting speed possible. The machines themselves have undergone distinct changes largely by the use of alloy steel shafts and gears, more and more ball or roller bearings and the introduction of automatic stops that put the lathe into the semi-automatic class. The use of multiple tools had also increased to a large extent.

The hand turret or capstan lathe has received much attention, both in making it more convenient to operate and in the methods of tooling. The tools have been simplified so as to enable a comparatively few standard tools to be utilised for a large variety of work, thus making the capstan lathe a more universal machine and materially reducing the cost of tools required for average work. Self-closing chucks, operated both by air and electric motor, are growing in favor where the work warrants. More attention is being paid to the proper lubrication of lathes as well as of other machines. Geared heads are run in oil and in some cases an oil pump forces oil to the main bearings, or to reservoirs, from which it is led to different bearings by suitable pipes. Convenience of operation has also been studied and much lost time eliminated in that way.

Boring and turning machines of the vertical type have advanced in design and in productive capacity. Continuous operation machines are more in evidence so as to avoid idle time while the work is being put in position. This is secured in the station type machine where the work indexes under the cutting tools, one station being left blank for loading the work. In other machines the work table continues feeding but there is sufficient time for the operator to remove the finished piece and replace it with a piece to be machined, before the tools feed into the work; or the feed can be tripped and again thrown in when the operator is ready. One of these, by the same maker as the Mult-au-matic, is called the Continu-matic. This is shown on the plate. There are now several machines built along these general lines.

Drilling and boring machines have been developed to a considerable extent by the demands of the automobile industry. These developments include the special multi-way, multi-spindle machines that drill a large number of holes in from three to five sides of a cylinder block, at one feeding of the drills. The number of holes drilled at once is limited only by the ability to get the spindles close enough together and by the power of the machine. Drilling machines are also made in the station type and many are semi-automatic in their action. In other cases a number of spindles are mounted in a row and work is passed from one to the other. The drills themselves have been improved to such an extent that higher speeds and more powerful motors are now necessary to secure maximum production.

Milling Machines.—While there have been but one or two really new types of milling machines put on the market, the changes in design and capacity have been very marked. Machines are being built heavier and more rigid and the controls are being centralised for the convenience of the operator. Rapid power traverse is universal to save the time and labour of moving the tables or knees by hand. Anti-friction bearings have been largely used in the gear boxes and for thrusts, and now roller bearings are being applied to the main spindle in a few cases. Automatic feeds and stops are being largely used to increase the production and every endeavour is being made to make the cutting action continuous wherever possible. A development along this line is to hold the work on a revolving table that carries it past the milling cutters and allows a new piece to be put in place while the machine is running. These revolving tables are made both vertical and horizontal. With the table in a vertical position and horizontal milling spindles each side of the table, both ends of the piece can be milled at the same time. In one machine of this type the work is held firmly in place by a chain so arranged that the work runs under it before the milling cutters begin working and releases it after the work has passed the cutters. This is a very simple device but one which saves much time and greatly reduces the cost of clamping the work to the table.

The planer type of milling machine is being used more and more in railway shop work on connecting rods and in similar work. We are also learning that a milling machine is only as good as its cutter, and that the designing and making of an efficient milling cutter is an engineering problem. The effect of this cutter development has been to double the feed per minute in many cases and to remove an unbelievable weight of metal per minute. For small pieces the tendency is to use the continuous milling machine rather than the planer type on account of the time lost in loading. On long work however it is still holding its own and the milling machine along the lines of the openside planer is being considered for a variety of large work, too large to go between the housings. Continuous lubrication and the use of motors in the base are also now a part of the development of the modern milling machine. Machines of the knee type are being adapted to special manufacturing by the addition of one or more spindles in a special head, the extra spindles being driven from the main spindle. This head and the use of special fixtures, turns a standard milling machine into a single purpose machine that can be used on other work by the substitution of another spindle head.

Automatic profiling machines as shown have also been greatly developed by the addition of an electric contact device for the follower that makes it possible to use a master of wood or plaster or common building cement. This electric contact device controls the action of the profiling cutter, and though the touch of the follower is very light and delicate, the profiling cutter can take as heavy a cut as the machine or the work will stand. This type of machine not only secures extreme accuracy in the reproduction of any desired pattern but also effects a remarkable economy over the usual methods of making dies or profiling work of any kind.

Grinding Machines.—Grinding machines have probably been more startlingly developed than any other class of machine. Beginning with being practically a polishing machine that removed very small amounts of metal, we now have grinding machines that are driving the grinding wheel with a 75 H.P. motor, and removing metal at a rate that compares favourably with machines and cutting tools of other types. One type of grinding now finding favour is the in-feeding or " plunge-cut " type where a wheel is used that is wider than the length of the work and fed straight against the work instead of being traversed along its

(Courtesy of American Machinist)

length. The present limit seems to be a wheel 10 in. wide. The centreless grinding machine has also made great strides both as to the quantity of work produced and the accuracy obtainable. On such work as automobile piston pins which are fed through the machine in a continuous string, the diameter can be well within a half-thousandth, and with a high production. These pins are also remarkably round. It is also possible to grind shoulder work on the centreless but in that case the work cannot be fed through the machine but must be ground by revolving it in front of the wheel in a fixed position. Centreless grinding machines are being used on work up to eight or 10 in. in diameter.

Another development is in the application of automatic sizing mechanisms to cylindrical grinding, both internal and external, mostly the latter. These machines rough grind the holes at a rapid rate, then automatically reduce the feed as the hole approaches the finished size, and finally finish the hole with a light feed and stop when the hole is of the correct size. Here too the accuracy is well within a half-thousandth of an inch on commercial work.

Grinding machines are being used to remove metal to a greater extent than ever before not only on large and heavy surfacing work but in such work as the grinding of the threads in taps. Instead of merely finishing the thread of a taps that has been previously chased and hardened, some are now grinding the complete thread from the solid metal, and at a remarkably rapid rate. Hydraulic feed has been gaining in favour on several types of machines but has been applied to grinding machines to a greater extent than to any other. Some broaching machines are now hydraulically driven and the same type of feed has been used on boring and other machines. The idea has been lying dormant for a number of years but recent developments seem to have made it very successful in some of its applications.

Honing or lapping has gained in favour during the past few years to a remarkable extent. Honing as applied in automobile cylinder work, is in reality a method of grinding instead of what we formerly knew as lapping or honing. The hones have several strips or blocks of abrasive materials, turned on the outside to suit the bore of the cylinder. These are moved through the cylinder from end to end and revolved at the same time, so that it is really a grinding process with motion different from that of the grinding wheel. Some revolve the hones rapidly and traverse them slowly through the cylinder. Others reverse this, while some make both movements at about the same speed. In most cases the hones are used directly after a finish reaming operation and so eliminate the grinding operation. On a few of the higher priced cars however the honing is an additional operation that virtually polishes the surface and removes the " fuzz " left by the grinding wheel.

The use of magnetic chucks is being extended into new lines of work, but is confined largely to the grinding machine field. These are now made in many styles and shapes to suit individual conditions and are a great aid to production by reducing the time required for chucking any magnetic metal that can be held in this way, to a minimum.

Planing Machines.—Planing machines include shapers and slotters, which also embrace the special types built for gear cutting. All of these with the possible exception of slotters have been much improved, and the slotter has been developed as a tool room machine. The driving mechanism of planers has been vastly improved, which means better bearings, better gearing and improved lubrication of the whole machine. More convenient controls, rapid power traverse on all movements and more rigidity in the machine have added much to its cutting capacity and to the smoothness of the cuts that can be taken. This also applies to shapers, both for regular work and of the gear cutting type. Higher speeds are now possible than ever before and the work is also of better quality.

Broaching and Swaging Machines.—Both broaching and swaging machines continue to find new fields of usefulness. Where irregular surfaces are to be machined, or with internal surfaces that are hard to get at in any other way, the broach is found of great value, in many lines of industry. Broaches are in reality a series of cutting teeth, each cutting a very small amount as the broach is pushed or pulled through the work. The push broach seems to be growing in favour in some classes of work, presumably because of the lower first cost of the broaches and the corresponding lower loss when they break in service. Swaging machines have changed very little except to increase in size and in some cases to be used more on hot work than formerly. The accuracy of the work depends largely on the machine in which it is done and the way in which the machine is cared for and adjusted. Sewing machine needles, spinning frame spindles and much other work, including steel balls, hollow balls used in electrical pull chains and in jewelry, and many other parts, are manufactured by swaging.

The rapid development of machine tools during the last decade has made many first class machines of ten years ago entirely obsolete where low cost production is essential. In some cases machines of this highly productive nature become obsolete in two years, sometimes less. (F. H. C.)

MACKAY, CLARENCE HUNGERFORD (1874–), American capitalist, was born at San Francisco April 17 1874, being a son of John William Mackay (*see* 17.250). He received his education in Europe and at the age of 20 entered his father's office in New York. After his father's death in 1902 he succeeded to his large interests. He was elected president of the Mackay companies, organised in 1903, and owning all the capital stock of the Commercial Cable Co. and a majority of the stock of various cable, telegraph and telephone companies in the United States, Canada and Europe, including the Postal Telegraph Cable Company. In 1921 the Mackay companies operated some 350,000 m. of wires and 29,000 m. of cables, connecting with all parts of the civilised world. Acting under authority of a joint resolution of Congress of July 16 1918, President Wilson took over the wires as from Aug. 1 1918 and placed them under the control of Postmaster-General Burleson. Mr. Mackay opposed many of the Postmaster-General's policies on the ground that he was using War-time control to bring about government ownership of the wires. In Dec. Mackay was removed from control of the Commercial Cable Company. In March 1919 he was also removed from the presidency of the Postal Telegraph Cable Co., but was reinstated after the return of the wires to their private owners in 1919.

MacKAYE, PERCY (1875–), American poet and dramatist, son of Steele MacKaye, actor-dramatist, was born at New York City March 16 1875. He has lived chiefly in rural New England and in New York City. After graduating from Harvard in 1897, he travelled and studied abroad (1898–1900). By his varied imaginative works, he created new forms in native drama and literature and instigated national movements for community theatres, folk-plays and poetry. His outdoor choral masques, performed in stadium-theatres by thousands of actor-citizens, have drawn large audiences.

His many works include—in poetry: *Poems* (collected, 1916); *Dogtown Common* (1921)—plays: *The Canterbury Pilgrims* (1903); *Jeanne d'Arc* (1906); *Sappho and Phaon* (1907); *The Scarecrow* (1908); *Yankee Fantasies* (1901–12); *Washington* (1918); *This Fine-Pretty World* (1923)—operas: *The Immigrants* (1915)—masques: *Saint Louis* (10,000 citizen-actors, 1914); *Caliban* (Harvard Stadium, 1917)—essays: *The Civic Theatre* (1912)—folk-stories: *Tall Tales of the Kentucky Mountains* (1925)—biography: *Steele MacKaye, Genius of the Theatre* (1926).

MACKE, AUGUST (1887–1914), German painter, was born on Jan. 3 1887 at Meschede, Westphalia. His youth was spent in Cologne and Bonn, and he received his artistic training, from 1904, at the Düsseldorf Academy and later in Berlin with Louis Korinth. He was influenced particularly in his earlier work by the older Impressionists: Cezanne, Matisse, Renoir, Picasso; and the Cubists. During his student days he went to Paris, Holland and Italy for the purpose of study. The period of his independent creation embraces the years 1909–14. With Kandinski, Jawlenski and Marc, he was one of the most important representatives of the " Blauen Reiter," the group of painters from which Expressionism in Germany originated. His art combines the cherished tradition of French painting, its sense of the grace of

movement and atmosphere in landscape painting, with the cosmic sentiment of German art, without losing itself in the subtle and problematical. A journey to Tunis which he undertook in the spring of 1914 inspired some of his most beautiful pictures. He was killed in the World War at Perthes-les-Hurlus, Champagne, in Sept. 1914. See Walter Cohen, *August Macke* (Leipzig, 1922).

McKENNA, REGINALD (1863–), British politician and financier, was born in London July 6 1863, and educated at King's College. He went up to Trinity Hall, Cambridge, as a scholar and graduated as senior optime in 1885. He also gained distinction as an oarsman, rowing in the university boat race in 1887. He was called to the bar in that year, and in 1895 was elected Liberal member for North Monmouthshire. When his party returned to power in Dec. 1905, he became Financial Secretary to the Treasury. In 1907 he was promoted to the presidency of the Board of Education, but was no better able than his predecessor, Mr. Birrell, to draft a bill which would satisfy the Nonconformists and yet pass the House of Lords. His tenure of the office was brief, as, on Mr. Asquith's succeeding to the Premiership in the spring of 1908, he was transferred to the Admiralty.

He entered on his new duties at a time when the country was profoundly stirred by the rapid increase of the German fleet, and was in doubt whether the preparations of the Admiralty were on a sufficiently extensive scale. At the same time a large number of Liberals were disposed to belittle the danger and to call a halt to building schemes in the interest of peace and economy. Mr. McKenna, relying upon the advice of his First Sea Lord, Lord Fisher, resisted the section of the Cabinet represented by Mr. Lloyd George and Mr. Churchill, who took this last view; and, supported by the Prime Minister and Sir E. Grey, he persuaded his colleagues to begin the building of four battleships of the dreadnought type in 1909, and to ask for power, if necessary, to prepare for the construction of four more a year later. This programme disgusted the Radical economists, but did not altogether satisfy public opinion. The Conservatives and other friends of a big navy carried on an agitation to the slogan, "We want eight, and we won't wait"; and eventually in July Mr. McKenna announced that the second four dreadnoughts would definitely be ordered. The estimates of 1909 had shown an increase of nearly £3,000,000; those of 1910 showed a further increase of £5,500,000, mainly due to new construction. A still further increase of £3,750,000 in 1911 made it clear that Mr. McKenna and the Admiralty were in earnest in their determination to maintain "a fleet sufficient to hold the seas against any reasonably probable combination."

Work at the Exchequer.—From the Admiralty he went in the autumn of 1911 to the Home Office, and, as Home Secretary, had charge of the Welsh Disestablishment Bill. On the outbreak of the War, it was his duty—a duty on the whole satisfactorily accomplished—to safeguard the country against the machinations of spies. In the first Coalition Ministry in 1915 he was made Chancellor of the Exchequer, and a still more difficult task was imposed on him—to find the money to carry on the War. By a 4½% War Loan a subscription of nearly £600,000,000 was obtained. In the autumn he introduced a supplementary war budget, providing for over £100,000,000 by new taxation. Income tax was raised 40%, and the abatement and exemption limits lowered; the rates of supertax were seriously heightened; all the old duties on sugar, tea, tobacco, cocoa, coffee, motor spirit and patent medicines were almost doubled; the import of luxuries such as motor cars, cinema films, clocks and musical instruments was restrained by an *ad valorem* duty of 33⅓%; and an excess profits tax of 50% was imposed. Other methods of financing the War which he adopted were War Savings Certificates, which realised over £40,000,000 in their first year; 5% Exchequer bonds, replaced after a year for a short time by 6% Exchequer bonds: but for current expenses he relied mainly on the sale of Treasury bills. In his 1916 budget he raised taxation still further. Income tax was increased to 5s. in the £ and excess profits tax to 60%; there were further increases on sugar, cocoa and coffee; higher duties were imposed on motor vehicles; there were new taxes on amusements, railway tickets, matches and mineral waters.

Mr. McKenna went out of office with Mr. Asquith in Dec. 1916, and, along with other Liberal leaders who had refused to serve under Mr. Lloyd George, lost his seat at the general election of Dec. 1918. A year later he accepted the chairmanship of the London City and Midland (now the Midland) Bank, and speedily gained a position of authority in the city of London. At the same time he showed increasing detachment from party feeling, and was ready, as an anti-Socialist, to accept the Chancellorship of the Exchequer in Mr. Baldwin's first Ministry, had it been found possible to provide him a seat without a party contest. He married in 1908 Pamela, daughter of Sir Herbert Jekyll, and had two sons. (G. E. B.)

MACKENSEN, AUGUST VON (1849–), German soldier, was born in Hausleipnitz, Saxony, Dec. 6 1849. Educated at Torgau and the University of Halle, he was commissioned to the army in 1869. By 1903 he was commander of an infantry division; and in 1908 he was given command of the XVII. Army Corps. At the outbreak of the World War he was placed in charge of the IX. Army on the Eastern Front, where he conducted successful operations against the Russians at Kutno, Łódź and Lowicz. In April 1915 he became leader of the German forces in western Galicia and was largely responsible for the German break-through at Gorlice. On June 20 1915 he was made a field-marshal and in Aug. and Sept. of that year had further successes at Brest-Litovsk and Pińsk. In Oct. and Nov. 1916, as commander of the army sent against Serbia, he practically overran that country; and in 1916, with the composite army which invaded Rumania, he subjugated the Dobruja and by the middle of Jan. 1917 had to all intents and purposes occupied the country. He remained in Rumania till the Armistice; and on his retiring into Hungary he was interned by the French at Neusatz, where he was detained till the beginning of Dec. 1919.

MACKENZIE, EDWARD MONTAGUE COMPTON (1883–), British novelist, son of Edward Compton, was born at West Hartlepool Jan. 17 1883, and educated at St. Paul's School, London, and Magdalen College, Oxford. He saw a good deal of stage life before embarking on his literary career which began with *Poems* (1907) and a picturesque "costume" novel, *The Passionate Elopement* (1911). *Kensington Rhymes* and the novel *Carnival* followed in 1912, the long novel *Sinister Street*, characteristic of the quasi-autobiographical novels of childhood and youth which were then attracting some of the younger novelists. Mackenzie served with the Royal Naval Division at the Dardanelles, and held a staff appointment at Athens in 1916. After the War he lived on the Channel Island of Jethou. His work is characterised by a coloured and mellifluous style, picaresque action and humorous character study and, in some of his best work, a sympathetic portrayal of religious sensibility. This last, for instance, is to be seen in the trilogy *The Altar Steps* (1922), *The Parson's Progress* (1923) and *The Heavenly Ladder* (1924). *Guy and Pauline* (1915), *Sylvia Scarlett* (1918) and *Coral* (1925) were successful developments of the *Carnival* and *Sinister Street* milieu.

MACLEAN, SIR DONALD (1864–), British politician, the eldest son of John Maclean of Kilmoluag, Tiree, Scotland, was admitted a solicitor in 1887. After three unsuccessful contests, he entered the House of Commons in 1906 as Liberal member for Bath. He failed to hold his seat at the general election of Jan. 1910, but in Dec. of that year he was elected for Peebles and Selkirk, which he represented until 1918. He was member for Peebles and South Midlothian from 1918 to 1922, when he lost his seat. In the absence of Mr. Asquith, later Earl of Oxford and Asquith, from the House of Commons, he became chairman of the Parliamentary Liberal party, 1919–22, and after Mr Asquith was returned as member for Paisley in 1920, he continued to take an active part in debate. He unsuccessfully contested Kilmarnock in 1923 and East Cardiff in 1924. He was deputy chairman of committee, House of Commons, 1911–8, and chairman of the London Appeal Tribunal, 1916–8.

During the War he was chairman of the Enemy Debt Treasury Commission and of the House of Commons military appeal tribunal. He was sworn of the privy council in 1916, and created K.B.E. in 1917.

MACLEOD, JOHN JAMES RICKARD (1876–), British physiologist, was born on Sept. 6 1876, near Dunkeld, Scotland, and was educated at Aberdeen Grammar School, Marischal College, Aberdeen, and Leipzig University. From 1899 to 1902 he was demonstrator in physiology and then lecturer in biochemistry at the London Hospital, holding also from 1901–3 the Mackinnon Research Scholarship of the Royal Society; and from 1903 to 1918 he was professor of physiology at the Western Reserve University, Cleveland, Ohio, subsequently becoming professor of physiology and director of the physiological laboratory in the University of Toronto in Canada. His most important work was on the nature of the control of the metabolism of carbohydrates in the animal body, and, together with Dr. Banting, with whom he shared the Nobel Prize for medicine in 1923, he achieved fame as one of the discoverers of insulin (*q.v.*) and of its value in the investigation and treatment of diabetes (*q.v.*), and also in connection with other problems of metabolism. He was elected F.R.S. in 1923, and received the Cameron Prize of Edinburgh University in the same year. He has become a member of many scientific societies and was president of the Royal Canadian Institute in 1925. (*See* PHYSIOLOGY.)

His publications include *Practical Physiology* (1903); *Recent Advances in Physiology*, edited by Leonard Hill (1905); *Diabetes, its Physiological Pathology* (1913); *Fundamentals of Physiology* (1916); *Physiology and Biochemistry in Modern Medicine*, 4th ed. (1922); and numerous papers on insulin, etc., published in *The Journal of Physiology* and *The American Journal of Physiology*.

M'NEILL, RONALD JOHN (1861–), British politician, was born April 3 1861, the son of an Ulster landowner, Edmund M'Neill, and was educated at Harrow and Christ Church, Oxford. He became a barrister, but found a career in journalism and from 1901 to 1904 was editor of *The St. James's Gazette*, afterwards assisting Mr. Hugh Chisholm in the preparation of the 11th edition of *The Encyclopædia Britannica*. Having made several unsuccessful attempts to enter Parliament, he was, in 1911, returned as Conservative M.P. for a division of Kent. As a politician he was for some years associated with Sir Edward Carson and the more strenuous opponents of Home Rule. When Mr. Baldwin formed his first ministry in 1922, Mr. M'Neill was appointed Under-secretary for Foreign Affairs; he held that office until early in 1924 and returned to it in Nov. of the same year again under Mr. Baldwin. In 1925 he was made financial secretary to the Treasury.

MacVEAGH, WAYNE (1833–1917), American lawyer and diplomatist (*see* 17.269), died in Washington, D.C., Jan 11 1917.

MADAGASCAR (*see* 17.270) has an area of about 228,000 sq. m., and a population (1911) of 3,153,511; (1921) of 3,272,301. In 1921 Europeans—nine-tenths French—numbered 19,350, Asiatics 8,135. Tananarivo (Antananarivo), the capital, had 58,459 inhabitants. The Comoro Islands (*see* 6.794) were annexed to Madagascar in 1914. They had (1921) 109,860 inhabitants.

History.—French policy in Madagascar since the appointment of M. Picquié as governor-general in 1910 has been directed not only to material development and to attracting French settlers to the island but also to the training of the natives to ways and outlook essentially French. The former dominant race, the Hova, who had adopted Protestant forms of Christianity and had the largest number of educated persons, was deprived of all trace of political ascendancy, and special attention was paid to the Sakavala, the Betsimasakara and other tribes. Nowhere, however, was a purely native rule under tribal chieftains allowed. At the same time, large numbers of natives were employed in the French administration and the few Malagasy who became thoroughly assimilated were given French citizenship (there were about 150 native French citizens in 1924).

Notwithstanding these measures, the growth of a sense of Malagasy nationality could be discerned. Among the educated natives dislike of French rule continued strong for many years after the conquest of the island in 1896. Their discontent culminated during the World War in the formation of an anti-French secret society, whose members included a large proportion of the native officials. The existence of the society which, it was alleged, plotted the simultaneous "removal" of the Europeans by means of poison was discovered early in 1916. The society was rigorously suppressed and hundreds of Malagasy were condemned to hard labour in the Comoro Islands. The death of Ranavalona III., the last Queen of Madagascar, in exile in 1917, was a blow to Hova aspirations. Gradually, conditions in the island improved. Gradually, too, a better class of European official was sent out. The number of French functionaries was, however, large and was a drain on the scanty colonial revenue.

Malagasy troops were employed in considerable numbers in France during the World War and subsequently in Morocco and in Syria. They formed, however, inferior fighting material and the influence of the returned soldiers on their countrymen was not good. Other disturbing factors were the spread of alcoholism and of malaria and pulmonary disease among the people, leading to a marked decrease in the number of Hova and other races.

A brighter prospect was, however, shown in the marked attention paid by the French to education, and largely by this means the party among the natives attached to the French connection was built up. Primary schools were established in the villages, education was made compulsory between the ages of 8 and 14, and in all schools the children had to learn French. Nearly 100,000 children were attending school in 1925. The primary schools were supplemented by excellent regional schools—where lads were trained to become officials—and at Tananarivo and other towns there were means for higher education, including medical and agricultural schools. Another method by which the class of natives supporting the administration was increased was the lavish grant of decorations, including the Dragon of Annam, the Star of Anjouan and the Étoile Noire, as well as grades of Honneurs (12 classes), and medals such as the *mérite agricole*, the *mérite indigène* and *la médaille du travail*.

M. Marcel Olivier, who became governor-general in 1924, adopted a policy of decentralisation of the administration—greater local autonomy and the employment of more natives and in more responsible posts. While there was no form of popular Government economic and financial delegations existed and the plan of the administration was laid before them. The programme for 1925 laid special stress on the need to increase means of education, promote public health and to guide the natives, who after 30 years of French rule were taking larger views of life—and incidentally dressing largely in European fashion—upon the right road. Relations between the Protestant missionaries and the administration, after a period of strain, had reached a generally satisfactory position, and a larger share of the work was undertaken by French Evangelical societies. The Protestant missions had to meet, however, increasing and sustained efforts by the French Roman Catholic missions.

Economic Conditions.—Development of the natural resources of the island, if somewhat slow, was real. The chief products are rice, coffee, manioc, cattle and graphite. Cultivation is mainly by Malagasy; the number of French settlers on the land is small. In 1924 white colonists were cultivating 150,000 hectares; natives 1,110,000 hectares. Although as the result of a protective tariff the great bulk of trade is with France, about one-seventh is with Great Britain and much British capital is invested in the island. A feature of the commerce is that exports exceed imports both in quantity and value. In 1910 the exports amounted to 80,000,000 tons and imports to 61,000,000 tons; in 1924 exports were 302,000,000 tons and imports 90,000,000. As to value, the difference in the exchange rates of the franc and the increased cost of commodities prevent exact comparisons. The figures show the external trade (imports and exports) at 78,875,000 frs. in 1910 and 646,605,000 frs. in 1924.

Means of communication were greatly improved by harbour works and the building of roads and railways. By 1925 there were 1,500 m. of first-class roads and 540 m. of railway. The

chief railway (240 m. long), connecting the port of Tamatave with Tananarivo, was opened in 1918. From this railway a branch line goes northward, and from Tananarivo a railway (107 m. long) opened in 1923 runs south to Antsirabé. There is a road but no railway to Majunga, the chief port on the west coast. Canals have been made and irrigation works carried out. Public buildings are handsome and solid, built with an eye to future developments.

Revenue is derived mainly from customs and a poll tax; expenditure was largely on the civil service. The budget of 1913, the last normal year before the World War, balanced at 32,000,000 frs.; in 1924 the budget was balanced at 100,000,000 frs.; in effect, taxation and receipts had not increased. It was then realised that if economic progress was not to be checked, a revision of taxation was essential.

BIBLIOGRAPHY.—The standard work on the island is the *Histoire physique, naturelle et politique de Madagascar* (1875, etc.), in many quarto volumes by Alfred Grandidier (1836–1921) founded on his exploration of Madagascar in 1865–70 and subsequent researches. Besides this great work, of which the latest volume appeared in 1917, Grandidier edited a *Collection des ouvrages anciens concernant Madagascar* (1903, etc.), of which vol. 9 was published in 1920; see also James Sibree, *A Naturalist in Madagascar* (1915) and *Fifty Years in Madagascar* (1924); G. Grandidier, *Le Myre de Vilers, Duchesne, Gallièni. Quarante années de l'histoire de Madagascar, 1880–1920* (1923); Jean Lefranc, "La Prosperité et les Besoins de Madagascar," in *Renseignements Coloniaux* (Dec. 1925); *Guide-Annuaire de Madagascar et Dépendances*. (F. R. C.)

MADRAS, India (*see* 17.291), capital of the Madras Presidency, and the third largest city of India, had a population of 526,911 in 1921, very largely Hindu. Madras is rapidly growing; the suburbs are extending, and many of the gardens in the city itself have been divided to provide further building sites. Work was in progress on a drainage system in 1924, and new waterworks have much improved the health of the city. There are large industries (12 mills employing 19,000 hands in 1924). The municipality was reorganised in 1919; there are 50 councillors, 41 elected and five appointed by Government, under an annually elected president. A fine council chamber has been erected behind the Government secretariat. Proposals for the improvement of the port, including a new quay, were made in 1924. The present harbour accommodates 15 vessels drawing up to 30 feet. The harbour works act as a breakwater, and since they were built the foreshore has considerably extended.

MADRAS, UNIVERSITY OF (*see* 27.775).—Since 1912 a small teaching staff has been attached to the university, and by an Act passed in 1923 the reorganisation of the university as a teaching and residential university was authorised. It still exercises control over the quality of the teaching in its constituent and affiliated colleges. In 1923 it received Rs. 45,200 under the will of Sir William Meyer, G.C.S.I. Fifty-three institutions are affiliated to it and recognised in degree courses in the faculties of arts and science, education, law, medicine, engineering, agriculture and Oriental learning.

MADRID (*see* 17.292), with a population of 813,991 in 1923, is the capital of Spain and the largest city. Old Madrid is disappearing, and many of the alleys east of the Palace have been pulled down, whilst a number of massive and pretentious buildings have recently been erected. A cathedral is being built on the site of an old church in the Calle de Bailen, and an Anglican church was consecrated in 1925. A large bull ring and stadium have been opened and an underground railway, the first in Spain, was finished in 1924. Owing to violent speeches in criticism of the Government made there, the Athenaeum Club was closed in 1924 and handed over to the production assembly, a newly formed economic body. In 1925 the Rockefeller Institute gave £85,000 for the establishment of an institute of physics and chemistry. It was decided in 1925 to remove the Hippodrome racecourse to allow of extending a housing scheme and the Paseo de la Castellana. The cost of living in Madrid is notably high.

MAETERLINCK, MAURICE (1862–), Belgian essayist and dramatist (*see* 17.298), presents a marked contrast in his later work published during the 20th century, after he settled in France, to his earlier works, published before he left Belgium. Several of his pre-War essays, collected in *The Buried Temple* (1902), *The Double Garden* (1909), *Life and Flowers* (1907), and more particularly his book on *Death* (1912), are inspired by a reaction against his early mystic and fatalistic tendencies. The same contrast applies to the spirit of such plays as *Monna Vanna* (1909) and *Mary Magdalene* (1909), in which the action is concentrated in a few important scenes, more according to the Racinian than to the Shakespearian method.

The keen interest displayed by Maeterlinck in Shakespearian drama is nevertheless shown in his essay on King Lear, *Life and Flowers*, and in the translation of Macbeth (1910), written for a special performance given in the Abbey of Sainte Wandrille. *The Blue Bird* (1910), produced in 1911, still increased the popularity of the Belgian writer in English-speaking countries. It was followed by *The Betrothal* (1919), produced in London in 1921. From the technical point of view, these fairy plays mark a return to the poet's early symbolism. During the War Maeterlinck wrote a war play dealing with the German occupation of Belgium: *The Burgomaster of Stilemonde* (1920) produced in London by Sir J. Martin Harvey. *The Miracle of St. Anthony* and *Mountain Paths* appeared in 1919, and two more plays in a modern setting, *The Cloud that Lifted* and *The Power of the Dead*, in 1923. Most of the works of Maurice Maeterlinck have been translated into English by A. Teixeira de Mattos. After the latter's death Bernard Miall and F. M. Atkinson undertook this work.

MAGNETISM (*see* 17.321). This subject may be studied further in the articles CRYSTALLOGRAPHY, SPECTROSCOPY and TERRESTRIAL MAGNETISM.

Theories of Ferromagnetism.—Langevin's theory of paramagnetism has been extended by Weiss[1] to ferromagnetism by the introduction of a hypothetical molecular field H_2 proportional to the intensity of magnetisation I. This hypothetical force is not necessarily magnetic. The relation between I and the external field H_1 is determined by the equations

$$I/I_0 = \frac{\cosh a}{\sinh a} - \frac{1}{a} \qquad (1)$$

$$a = \frac{MH}{RT}, \quad H = H_1 + H_2, \quad H_2 = \lambda I, \quad I_0 = NM \qquad (2)$$

where M is the moment of a magnetic atom, R the gas constant, T the absolute temperature, λ a constant specific for the substance, N the number of atoms per unit volume and I_0 the maximum possible intensity of magnetisation when all the magnetic atoms point in the same direction. These equations require that in the absence of an external field ($H_1 = 0$) in general the intensity of magnetisation I will not be zero, but will have a definite value given by eliminating a between the equations (1) and

$$I/I_0 = \frac{RT}{\lambda M I_0} a \qquad (3)$$

and solving for I. This gives a single *intensity of permanent magnetisation* which is stable, but disappears, and with it the ferromagnetism, at a definite temperature, the *critical temperature*, given by $T_0 = \lambda M I_0 / 3R$. If by means of this equation $R/\lambda M$ is eliminated from (3) and the value of a thus obtained substituted in (1) the resulting equation is of the form

$$I/I_0 = f(T/T_0) \qquad (4)$$

where the function f is a purely algebraical function of the variable T/T_0 the same for all substances. Thus if the intensity I of permanent magnetisation is expressed as a fraction of the maximum possible intensity of magnetisation I_0, and at the same time the absolute temperature T is expressed as a fraction of the critical temperature T_0, the theory leads to a characteristic equation for the intensity of permanent magnetisation (analogous to the equation of state for a gas) which is identical for all ferromagnetic substances. In the neighbourhood of the critical temperature

$$(T - T_0) I = \frac{H_1 T_0}{\lambda} \qquad (5)$$

[1] P. Weiss, *Journal de Physique*, vol. 6, p. 661 (1907).

where I is the actual intensity of magnetisation in an external field H_1, so that if H_1 is kept constant the I, T diagram will be a rectangular hyperbola. Curie's measurements with iron afford an approximate confirmation of (5).

An alternative theory of ferromagnetism has been put forward by K. Honda and J. Okubo.[1] This theory is largely a mathematical working out of the older ideas of Ewing, and is developed by the authors with a special view to the examples of iron, cobalt and nickel, metals which are known to consist of a mass of cubical crystals. In the natural stable configuration the axes of the elementary magnets are aligned parallel to the axes of the cubic crystals. The actual magnetisation is determined by the displacements under the influence of the external field and of the fields due to the neighbouring magnets. To account for temperature effects some spinning of the elements has to be invoked. The theory is made to give a good account of hysteresis and a number of other phenomena, but the thermal side of it appears rather forced.

Honda[2] states that the investigation of the binary alloys forming a solid solution with each other shows that an alloy of a paramagnetic with a ferromagnetic metal can be obtained which has a susceptibility of any value lying between those of the two metals. Hence the two classes cannot be sharply distinguished by the magnitude of the susceptibility, but each class is an extreme member of a series of which the intermediate members can merge continuously into each other. In high fields the disparity between the intensities of magnetisation of manganese and iron is very much less than in fields of the order required to produce saturation in the iron.

Ewing[3] has recently changed his model to meet some objections applicable to the older form.

Ferromagnetic Crystals.—The magnetic properties of crystals are of fundamental importance, because metals such as iron consist of a mass of interpenetrating crystals. Individual crystals of pyrrhotine,[4] magnetite[5] and iron[6] have been investigated. Pyrrhotine (Fe_7S_8) is a hexagonal crystal. It is very difficult to magnetise along the hexagonal axis. Of the two perpendicular axes one is called the axis of easy magnetisation: the properties in the direction of the other are similar to those along the hexagonal axis, but the difficulty of magnetisation is not so great. The curve of magnetisation (I, H curve) along the easy axis is remarkably simple. If a correction is made for the demagnetising force and some little allowance for the material irregularities which are almost inevitable in most minerals the diagram reduces to a rectangle. If the specimen is unmagnetised at first it remains unmagnetised till the value $H_c = 15{\cdot}4$ of the coercive field is reached, when the intensity of magnetisation suddenly jumps to the saturation value $I_s = 47$ gauss, at which it stays for all values of H between -15.4 and $+\infty$. At $H = -15{\cdot}4$ the magnetisation suddenly reverses and stays at -47 gauss for values of H between $-\infty$ and $+15{\cdot}4$. The constancy of the intensity of magnetisation is actually verified by the experiments directly without any corrections over a range of H from about 700 to 11,000. If the direction of H does not lie along one of the axes the direction of I no longer coincides with it. The intensity of permanent magnetisation has been found to agree with the equation of state (4) above for magnetite from $-79°$ C. to $+587°$ C., at which temperature the ferromagnetism disappears (T_0). Other substances show a fair correspondence with this requirement, but the agreement is not precise. The value of the molecular field deduced by Webster from measurements with single crystals of iron is not only very small compared with the values obtained for pyrrhotine, but is much less than one-thousandth part of the values which have been got by other methods for iron in bulk. This discrepancy would seem to call for serious investigation.

Magnetisation in Iron, Steel, etc., a Discontinuous Process.[7]—If the induced currents used to measure the change of induction are highly magnified by amplifiers, and sufficiently rapid detectors, such as oscillographs or telephones, employed, the I, H curve is found to consist of a succession of vertical and horizontal lines like steps. This is apparently due to the sudden magnetisation of successive elements of the material. These may be of considerable size, but it is doubtful if they are single crystals.

Paramagnetism.—Curie's law

$$kT = I_0^2/3R = C(\text{Curie's const.}) \qquad (6)$$

where k is the susceptibility, has numerous exceptions. Some of these are doubtless due to the universally present diamagnetism, to change of molecular aggregation and the like. In the case of paramagnetic solids the law requires a general amendment, Kamerlingh Onnes and his collaborators having shown that at temperatures down to about 80°K it should be replaced by

$$k(T+\Delta) = C \qquad (7)$$

where Δ is a specific constant for each substance. Equation (7) is sometimes known as Weiss's law. This law breaks down at the very lowest temperatures, the deviations shown by different substances becoming very complicated and individual in character.[8]

Gyromagnetic Effects.—In 1907 O. W. Richardson[9] showed that a delicately suspended rod should spin about the axis of magnetisation owing to the turning of the electron orbits during the act of magnetisation, and calculated the magnitude of the effects to be expected. If U_z and M_z are respectively angular momentum and magnetic moment per unit volume generated for any axis O_z, N,n numbers of electrons per unit volume, M,m masses of electrons and A,a the respective mean areal velocities about the axis O (capital letters referring to positive and small letters to negative electrons), then

$$U_2 = 2(N\ M\ A + n\ m\ a) \qquad (8)$$

and

$$M_2 = N\ E\ A + n\ e\ a \qquad (9)$$

If the positive parts of the atom are stationary the ratio U_2/M_2 reduces to 2m/e, and in any event it should be independent of the strength of the field. A search made at the time did not succeed in satisfactorily separating the effect from parasitic disturbances. It was first clearly established experimentally by Einstein and de Haas[10] in 1915, and has since been carefully measured by a number of experimenters[11] for iron, cobalt, nickel, Heusler alloys and magnetite. Meanwhile, in 1914, S. J. Barnett[12] had established the existence of a converse effect, *viz.*, the development of a magnetic field along the axis of revolution of a body when made to spin in a field-free space. The intrinsic magnetic field which would give rise to an equivalent magnetisation is calculated as

$$H = 2\frac{m}{e}\omega \qquad (10)$$

when only negative electron orbits are considered, ω being the angular velocity. The experiments show that both U_2/M_2 and H/ω are very close to m/e and not equal to 2m/e. This implies that the motions of the positively charged parts of the atom must be considered. If twice as many quanta of angular momentum are assigned to the electrons as to the nucleus this so-called *gyromagnetic anomaly* is accounted for.[13]

A third gyromagnetic effect, viz., a magnetic intensity produced by a revolving perpendicular magnetic field, is anticipated, but has not yet been established experimentally.[14]

The Magneton and Space Quantisation.—As a result of his observations of discontinuous changes in the apparent value of the Curie constant for magnetite, and for other reasons, Weiss[1] put forward the view that the magnetism of para- and ferromagnetic substances arose from a definite atom of magnetism. This *Weiss magneton* had a magnetic moment of $1{\cdot}85\times10^{-21}$ gauss×cm. The experimental evidence for the reality of this fundamental unit is very unconvincing. There is, however, according to the quantum theory (*q.v.*) a kind of fundamental unit of magnetic moment: the angular momentum of the electron orbits is limited to integral multiples of $h/2\pi$, h being Planck's constant, and we have seen above that the magnetic moment of such an orbit is proportional to its angular momentum. The value of this unit of magnetic moment, the "Bohr magneton" is $eh/4\pi m = 9{\cdot}23\times10^{-21}$ gauss×cm. Magnetic moment, however, is a vector quantity, so that the effect of compounding a number of such moments is more than a matter of mere addition. Thus no magnetic atom in the simple sense is to be anticipated. There should, however, be a tendency to certain discrete values owing to space quantisation.[2] In general if there is an axis of symmetry in the structure of the substance, or if such an axis is supplied by an external field, the quantum conditions require not only that the angular momenta about the polar axes of the orbits, but also their components about the axis of symmetry, should be integral multiples of $h/2\pi$. This double limitation restricts the orientation of the orbits to $m+1$ distinct planes where $mh/2\pi$ is the total angular momentum. The numbers of Weiss magnetons per atom have usually been deduced from the Curie constant C by the relation $C=\frac{n^2M^2}{R}\cos^2\theta$ where M is the molar magneton (1123·5 gauss), R the molar gas constant, and θ the angle between the polar axis and the field, the average of $\cos^2\theta$ being taken on the assumption of equal probability for any direction. If, however, the averaging is confined to the discrete values just referred to, the number of Weiss magnetons which should correspond to the successive integral values of m from 0 to 6 are 0, 8·6, 14·1, 10·2, 24·4, 29·4, 34·4. There can be little doubt that the more reliable experimental values have a strong tendency to settle down at these numbers, and a plausible account can be given of such deviations as seem well established.[3] Gerlach and Stern[4] have shown that a fine beam of atoms when passed through a very inhomogeneous and powerful magnetic field is split into two in the case of Cu, Ag, and Au, into at least three in the case of Ni, and there is no effect in the case of Sn, Pb, and Fe. The splitting in the case of Cu, Ag, and Au, corresponds (the accuracy for Ag is about 10%) to a magnetic moment of $9{\cdot}23\times10^{-21}$. Thus this very important experiment establishes the reality at the same time both of space quantisation and the Bohr magneton. Some recently discovered changes with pressure in the susceptibility per unit mass of gases at low pressures are no doubt intimately connected with the phenomena discussed in this section.[5]

Magneto Optics.—Paschen and Back[6] have shown that in strong fields the complex Zeeman effects shown by multiple spectral lines in weak fields become simplified, the separations becoming integral multiples of the Lorentz-Larmor value. The change is a continuous function of the field strength. The magnetic response of multiplets as shown by their Zeeman effects is determined by their natural multiplicity, and there seems little doubt that this latter arises from the magnetic fields of the atoms. In an atom whose maximum permanent multiplicity is r and which is in an excited state such that its azimuthal quantum number is k, a good case can be made out that the maximum magnetic moment is equal to $(r+k-2)\frac{eh}{4\pi m}$. The magnetic moments so deduced show a reasonable agreement with those got from measurements of the paramagnetic susceptibilities of corresponding ions. Each starts from zero, rises to a maximum, and falls to zero again in traversing the successive elements in the period from K through Fe to Cu, and there are other resemblances. One interpretation of the spectroscopic data requires that the magnetic moment of the atomic core should be twice as large as that calculated from the angular momentum, an anomaly like that of the gyromagnetic anomaly already cousidered and capable of the same explanation.[7]

Permalloy.—H. D. Arnold and G. W. Elmen[8] describe a nickel-iron alloy containing 78·5% Ni, which has remarkable magnetic properties. The initial permeability is about 13,000, the area of the hysteresis loop is $\frac{1}{16}$ that for soft iron and the maximum permeability 87,000 for B about 5,000. The saturation intensity of magnetisation is comparable with that for iron, and the alloy approaches saturation in the earth's field.

MAGNETISM, TERRESTRIAL (*see* 17,353c).—Further developments occurring in various directions since 1909 in the study of terrestrial magnetism are dealt with below.

Instruments.—The intercomparison of the magnetic instruments of different countries has a recognised importance. While much was done before the World War by the Carnegie Institution of Washington, the comparisons between adjacent countries, which are specially desirable, have not been numerous. A difficulty increasingly realised is the uncertainty whether any magnetometer, even if never moved, can be considered invariable to the degree of accuracy usually aimed at, viz., 0·1′ in declination (*D*) and 1γ (0·00001 CGS unit) in horizontal force (*H*).

Trouble arises more particularly as regards the collimator magnet's moment of inertia and the "distribution constants" appearing in the deflection formula $2mr^{-3}(1+Pr^{-2}+Qr^{-4})$. The use of a coil and an electrical current promises increased accuracy in the measurement of *H*, and coil magnetometers have been constructed in several countries, but the accuracy actually attained requires further investigation. A coil instrument for the direct measurement of vertical force (*V*) would be of great value in high latitudes.

Surveys.—Observational work on land and sea has gone on continuously under the auspices of the Carnegie Institution of Washington, and many results have been published. Amongst recent surveys or resurveys which have been completed, there may be mentioned those of Belgium, the British Is., Japan and New Zealand. There have also been numerous field observations in Canada, France, Germany, India, the Scandinavian countries, Spain, the United States of America, and in a number of more restricted areas.

Eclipse Phenomena.—Special observations during solar eclipses have been made at many places on a number of occasions, more especially by the Carnegie Institution of Washington, and a good many results have been published in *Terrestrial Magnetism*. No consensus of opinion, however, has yet been reached, beyond the fact that any systematic effect is certainly small. To demonstrate a small systematic effect would require unusually quiet conditions over a period of days including the eclipse.

Sudden Commencements.—Another inquiry depending on co-operation has been into the simultaneity of the so-called "sudden commencements" (S.Cs.) of magnetic storms. It has been suggested by S. Chapman and L. Rodés that the S.C. might be associated with the engulfing of the earth in a jet or cloud of ions emanating from the sun. If the ionic jet rotated with the sun, as Chapman suggests, its time to engulf the earth would be about 30 seconds. If the ionic cloud were stationary, the process would take some 6½ minutes. It seems fairly clear from the several independent investigations which have been made that the difference in the times of S.Cs., if any, is a question of seconds, not of minutes.

Characterisation of Days.—Since 1906, an international scheme has been in operation with its headquarters at De Bilt, Nether-

lands. Each co-operating station assigns to every day a "character" figure 0, 1 or 2, according as the day is quiet, moderately disturbed or highly disturbed. The arithmetic means of the figures so assigned are given in the annual De Bilt lists, so that each day has an international character figure varying from 0·0 to 2·0. Intercomparison of the character figures assigned at different stations has confirmed the view that in ordinary latitudes disturbance is seldom if ever confined to one area.

The De Bilt character figures discriminate on the whole very satisfactorily between the days of the same month or season. But there is a natural tendency in the standard represented by 1 or 2 to vary according as the season is more or less quiet. To remove this difficulty, F. Bidlingmaier suggested the use of "magnetic activity" defined as the mean value throughout the day of $\frac{1}{8}\pi(\alpha^2+\beta^2+\gamma^2)$, where α, β, γ represent the departures of the three rectangular magnetic components from their normal values. "Aetivity" in this sense exists and may be considerable on quiet days. Apart from the difficulty of assigning normal values, the amount of labour entailed in the calculation of "activity" in the absence of some special mechanical means seems prohibitive. Various alternatives have been proposed, including the daily ranges of one or all of the magnetic elements, the squares of the daily or hourly ranges, the variation from day to day in the mean daily value of H, and the number of intersections by the magnetic curve of a series of lines, parallel to the base line. In low latitudes disturbance is largely confined to H, and the character of the day may be fairly diagnosed on the H curve alone, but this is far from the case in high latitudes.

Twenty-seven-day Interval.—The existence of the De Bilt daily characters has enabled the reality of a 27-day interval in magnetic disturbance to be investigated without any possible prejudice. The phenomenon has been found to exist for quiet as well as for disturbed conditions. A day which follows a conspicuously disturbed (or quiet) day after an interval of from 26 to 28 days has decidedly more than the average chance of being itself a disturbed (or quiet) day.

Diurnal Variation.—The primary object of the international character scheme was the selection for each month of five quiet days (commencing at Greenwich midnight) from which diurnal inequalities of the magnetic elements should be calculated, either additional to or in place of those derived from all days. Of late years five international disturbed days a month have also been selected at De Bilt, so that diurnal inequalities may be calculated from them as well. It has been found that in high latitudes the diurnal inequality is extremely sensitive to disturbance. This is illustrated by the vector diagrams (*see* 17.366 and 367) for the horizontal plane in fig. 1. They are for the equinoctial season of 1912 at the two Antarctic stations Cape Evans (77°38′ south, 166°24′ east) and Cape Denison (67°0′ south, 14°40′ east). The curves have been smoothed by the assumption that they are true ellipses, with axes in and perpendicular to the geographical meridian. The hypothesis is certainly not much in error, and it prevents the eye from being distracted by the irregularities inevitable in unsmoothed vector diagrams based on a comparatively few days. Starting from the centre in each case, the successive curves represent groups of days having for their mean international character figures 0·5, 0·15, 0·35, 0·65 and 1·15. The curves are described in the direction of the arrows, *i.e.*, anticlockwise.

Magnetic Poles.—Cape Evans and Cape Denison are on opposite sides of the south magnetic pole. Its position is not exactly known, somewhat conflicting results having been obtained by the different Antarctic expeditions. According to E. N. Webb in the discussion of the results of the expedition led by Sir Douglas Mawson, the approximate position for the epoch 1912 was 71°·2 south, 150°·7 east. This is considerably to the northeast of the positions assigned by the "Southern Cross" and "Discovery" expeditions (*see* 17.384). But all the expeditions agree in placing the south magnetic pole near the direct line from Cape Denison to Cape Evans. Accepting this as a fact, it may be shown that a change of 4·5γ in the horizontal force vector is roughly equivalent to a shift of 1 km. in the position of the pole.

On this basis the curves of fig. 1 constitute independent estimates made at the two stations of the daily track of the south magnetic pole, on days of different international character, according to the kilometre scale supplied. The subject has also been investigated for the north magnetic pole for the epoch 1904 by A. Graarud and N. Russeltvedt, using the observations of Amundsen's expedition. The principal base station, occupied by a magnetograph, Gjöahavn, had a dip of 89°17′, and in fixing the position of the pole use was made of four other stations with dips varying from 89°34′ to 89°52′. Thus the position found for the north magnetic pole in 1904, viz., 70°30′ north, 95°30′ west, cannot be much in error. This position differs by only 25′ of latitude and 1°16′ of longitude from that assigned in 1831 by James Ross (17.384), so there is no suggestion of rapid secular change.

On this basis Graarud and Russeltvedt calculated that a change of 3·2γ in the horizontal force vector answers to a shift of 1 km. in the position of the pole. The curve they give for its daily motion on the average day of 1904 is approximately elliptical, with minor and major axes respectively in and perpendicular to the geographical meridian. The extreme range from east to west is about 22 km., and that from north to south 13 kilometers. The curve, in short, is very similar to the Cape Denison curve for character 1·15, though slightly more elliptical. It is described, however, in the clockwise direction, as is natural for the northern hemisphere. The differences in sunspot frequencies, 42·0 in 1904 as against 3·6 in 1912, would naturally lead to a considerably larger amplitude in the earlier epoch.

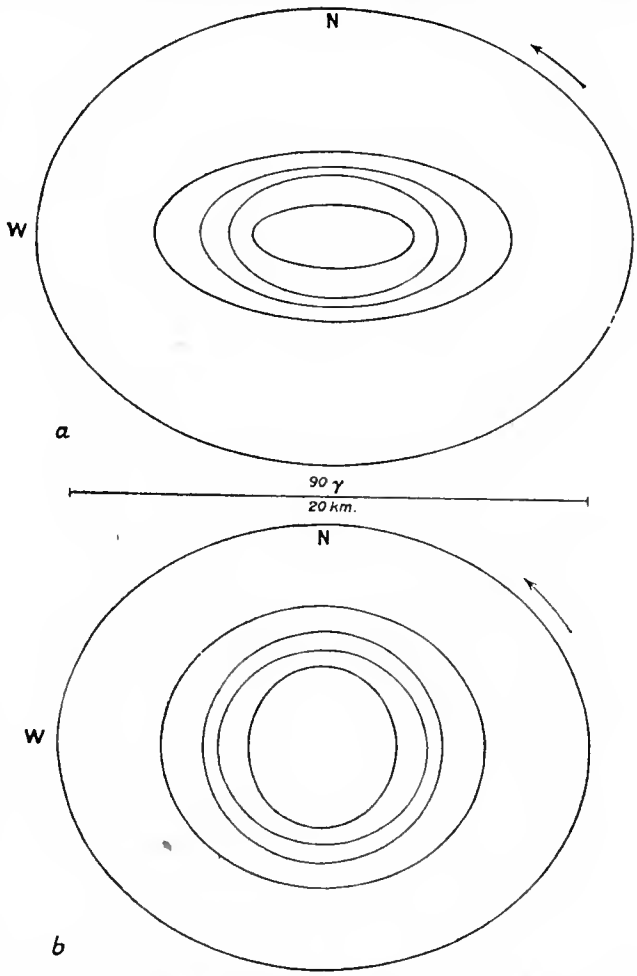

FIG. 1.—Vector Diagrams: (a) Cape Denison; (b) Cape Evans.

Variations of Disturbance with Latitude.—A comparison of the disturbances recorded in 1911–2 at the Scott Expedition's Antarctic station with those at observatories extending from Mauritius to Sitka, Alaska, showed a marked tendency for disturbance to be simultaneously great in high northern and southern latitudes, and to be less at intermediate stations, whether north or south of the equator. Again, comparison of auroras with magnetic character figures got out for individual hours, as well as for individual days, shows that an intimate relation exists between aurora and magnetic disturbance. While long accepted as true of large magnetic storms and aurora in countries where both phenomena are rare, this seems also true in the case of bright

aurora in high latitudes. In the case of faint non-fluctuating aurora, magnetic conditions seem often practically unaffected. Faint aurora, in fact, seems the rule rather than the exception in high latitudes under conditions favourable to its visibility.

Theory of the Regular Diurnal Variation.—The derivation of the diurnal variation from a potential has been further considered. Assuming the derivation possible, the constants occurring in the potential have been calculated by W. van Bemmelen, S. Chapman, F. Bidlingmaier and J. Bartels. A. van Vleuten, who has examined the hypothesis critically, especially as applicable to quiet-day phenomena, has, however, concluded that the balance of evidence is against it. A difficulty in the way of any general theory of the diurnal variation is the varied influence of disturbance. This influence not merely differs at different places, but is not the same for the different elements. It also varies with the season of the year, and is not the same at the same season of different years.

General Theory.—These various phenomena—the synchronous occurrence of magnetic disturbance in different parts of the earth, its special development in high latitudes, the enhancement of the regular diurnal variation during disturbance, the association of disturbance with aurora, and the 27-day interval—all accord *in a general way* with the theory pretty generally held that magnetic disturbance and aurora are both due to the emission from the sun of some species of electrical radiation. The nature of this radiation, whether β or α rays, has been discussed more especially by Kr. Birkeland, C. Störmer and L. Vegard. Difficulties, especially the scattering to be expected from the mutual repulsion of ions, if all of one sign, have been discussed by A. Schuster, S. Chapman and F. A. Lindemann.

When approaching the earth, ions of either sign would naturally spiral round the lines of magnetic force, and so be concentrated in high latitudes. But for ordinary α or β rays the approach to the magnetic poles should be closer than auroral phenomena suggest. To explain the occurrence of aurora in comparatively low latitudes, Störmer has suggested the existence of a ring of ions in the magnetic equator, but no proof of its existence has been advanced. The presence of ions would naturally increase the electrical conductivity, thus enhancing the amplitude of the regular diurnal variation of the magnetic elements, supposing that due (as is generally believed) to electrical currents in the upper atmosphere. The fact that disturbance enhances the diurnal inequality relatively more in winter than in summer would follow naturally from the very probable hypothesis that ordinary solar radiation itself increases the conductivity of the atmosphere. In high latitudes we may suppose that in winter the electrical currents associated with aurora play the part which in summer is largely played by direct solar radiation.

In the simplified mathematical theory of aurora and magnetic disturbance developed by C. Störmer, the earth is treated as magnetised as it would be if only the first order Gaussian harmonic existed. Everything is then symmetrical round the axis of the first harmonic, whose north end according to J. C. Adams was in 1880 at 78° 24′ north and 68° 4′ west, but moving west through about 0°·1 per annum.

In a theory of magnetic storms, S. Chapman also assumes symmetry round an axis, regarded as magnetic latitude 90°. He has derived mean results from 40 storms recorded at 12 stations arranged in five groups according to magnetic latitude. Confining himself to storms having an S. C., he regards the "general storm" phenomena, *i.e.*, the phenomena not dependent on local time, as determined by the "storm time," or time elapsed since the S. C. The phenomena varying with local time, he regards as composed of the ordinary diurnal variation + a "local storm variation," determined like the general storm phenomena by the magnetic latitude. He discusses the electrical current systems supposed to "flow in more or less horizontal strata in the upper atmosphere" to which the magnetic changes he has arrived at may be ultimately ascribed. "The external currents will of course be accompanied by corresponding induced currents within the earth which will modify their effects." Taking what he considered an average storm, Chapman calculated that it called for the expenditure of energy at the rate of about 2×10^{18} ergs per second for 15 hours.

To many minds, theoretical researches of this kind are fascinating, but deductions from them, until confirmed by direct observation, are just as hypothetical as the theories themselves. Magnetic phenomena are much less simple than theories such as Störmer's and Chapman's suggest. The complete Gaussian analysis indicates in reality a considerable departure from symmetry round an axis. High latitudes, moreover, were practically unrepresented in the data used for calculating the Gaussian constants, while the asymmetry in the positions of the two magnetic poles suggests that the results of the analysis may depart most from truth in the very regions where aurora and magnetic storms are most developed. The individual aurora or magnetic storm shows no approach to symmetry round a magnetic axis. The magnetic disturbance on a given occasion is of very different amplitude at stations having the same magnetic latitude. Even when there is a recognisable S. C. the sequence of events at a given station varies much on different occasions.

In low latitudes the S. C. is a change mainly in *H*, almost invariably a rise. In higher latitudes it is usually oscillatory, and may be large in all the elements. The duration of the enhanced value in *H* following the S. C. is sometimes a few minutes, sometimes several hours. Following the enhancement there is generally a pronounced fall, bringing *H* well below its normal value. But the recovery from this depression may set in after a few hours and proceed almost uninterruptedly, a return to comparatively quiet conditions occurring within 12 hours, or there may be a succession of irregular movements, highly disturbed conditions lasting for one or two days. The superposition following "storm time" of unsorted disturbance curves may give us a storm such as never existed. Comparison of magnetic curves from Kew, Stoneyhurst, Eskdalemuir and Lerwick has shown that while the amplitude of magnetic disturbance in the British Is. almost invariably increases with magnetic latitude, the rate of increase differs widely on different occasions. On special occasions there may be very large rapid movements in Lerwick, which are hardly represented in the south of England. The average intensity even of magnetic disturbance must be largely determined by other things than the magnetic latitude, as defined by Chapman, Agincourt (Toronto) and Kew are of nearly the same "magnetic latitude," but disturbance, at least in 1911–2, was almost invariably much larger at Agincourt than at Kew.

Chapman's estimate of the energy of a magnetic storm is certainly much less improbable than the enormously higher estimate made in 1892 by Lord Kelvin on the hypothesis of direct magnetic action between the sun and the earth, but it depends fundamentally on several assumptions, the degree of probability of which is at present entirely a matter of opinion.

MAHAFFY, SIR JOHN PENTLAND (1839–1919), Irish classical scholar (*see* 17.394), became vice-provost of Trinity College, Dublin, in 1913 and provost in 1914. In recognition of the services of the college during the World War, he was in 1918 made a G.B.E. From 1911 to 1916 he was president of the Royal Irish Academy. He died April 30 1919.

MAHAN, ALFRED THAYER (1840–1914), American naval officer and historian (*see* 17.394), died in Washington, D.C., Dec. 1 1914. His later works included *Naval Strategy Compared and Contrasted with the Principles of Military Operations on Land*

(1911); *Armaments and Arbitration* (1912) and *The Major Operations of the Navies in the War of American Independence* (1913).

See C. Carlisle Taylor, *The Life of Admiral Mahan* (1921).

MAH-JONGG.—This is a Chinese game, for four players, which was introduced into Europe and America about 1923. The game is played with a number of pieces known as tiles. There are 144 tiles in all, comprising four "flowers," four "seasons," four white, four red and four green "dragons"; four each of north south, east and west "winds"; and three "suits," namely "characters," "bamboos" and "circles." Each suit consists of 36 tiles, made up of four lots numbered one to nine inclusive.

Each player plays independently, and the procedure is briefly as follows: The tiles are arranged in pairs face downwards in four sides of a square, each side, or wall, containing 17 pairs. The eight extra tiles are left in the middle of the table to be taken up by any player who draws a "flower" or a "season." The bank is allotted by a throw of dice, and the highest throw fixes also the point at which the wall shall be opened. Each player is allotted a wind, the banker taking the east wind. Each player, starting with the banker and working anti-clockwise, draws four tiles at a time from the wall till each has drawn 12, then the banker draws one extra tile. Each player's object is to make a complete hand of twos, threes, or fours of a kind, *e.g.*, three sixes of "characters" and sequences; or four, five and six of "bamboos."

The actual play commences when the banker discards a tile, placing it face upwards on the table. Each player, playing in order clockwise, then draws a tile from the wall and discards one from his hand. Should he draw a "flower" or a "season" he exposes it and draws one of the eight extra tiles from the centre of the table. If a player discards a tile of which another player already has two, such other player may cry "pung" and take the discarded tile, at once exposing the three tiles on the table. The players on the left of the discarder, by crying "chow," may similarly take a discard to complete a sequence of three. A pung or a chow does not affect the order of drawing, nor does it count as a draw. A player punging a tile takes it in preference to a player wishing to chow it. Finally, a player requiring a discarded tile to make his hand complete cries mah-jongg, and takes the tile in preference to all other claimants. A player can go mah-jongg either by claiming a discard, or by drawing a tile in the ordinary way, but such tile must complete his hand without further discarding on his part. The hand finishes as soon as one player goes mah-jongg.

The scoring is somewhat complicated, and various conditions in a hand entitle the player to double his score. The mah-jongg hand is paid in full by all the others except the banker, who pays him double. If he is himself the banker, he is paid double by all. The other players pay differences to each other, the banker paying or being paid double as the case may be. The bank passes anti-clockwise for the following hand, unless the banker went mah-jongg, when it remains with him.

MAHLER, GUSTAV (1860–1911), Austrian composer and conductor, was born at Kalischt, Bohemia, July 7 1860. From 1885 onwards he conducted in Prague, Budapest, Hamburg and London, becoming director of the Vienna Opera in 1897. By unremitting zeal and tireless enthusiasm he brought the Viennese opera to a high state of perfection, but the strenuous work which he exacted from all earned him the name of "the tyrant" and made him many enemies, and in 1907 he was obliged to resign his post. He immediately received the offer of a conductorship in America, which he visited for three seasons, returning to Vienna in 1911, where he died on May 18. Mahler reflected to some extent in his works the classical tradition inherited from Schubert and Bruckner. In addition to his songs and chamber music, he wrote no fewer than nine symphonies, planned on a gigantic scale for an orchestra nearly doubled in strength. These lengthy works, though rarely performed, have nevertheless had a certain vogue in Holland, chiefly owing to the zeal of the eminent conductor Mengelberg. See R. Specht, *Gustav Mahler*, etc. (1913); P. Stefan, *Gustav Mahler, a Study of his Personality and Work* (1913); G. Adler, *Gustav Mahler* (1916); P. Bekker, *Gustav Mahler's Sinfonien* (1921).

MAHOMMED V. (MEHMED) (1844–1918), Sultan of Turkey, was born at Topqāpu Nov. 3 1844, a younger son of the Sultan 'Abdul Mejid (1823–1861). He led a quiet and retiring life, and suffered at times considerably from the jealousy and suspicion of his elder brother, the Sultan 'Abdul Hamid II. On the deposition of 'Abdul Hamid he was invested as caliph (May 10 1909). He was, for the most part, merely a tool in the hands of the committee of union and progress and, though he was supposed to dislike the pro-German policy of Enver Pasha, he was unable to take any effective steps to oppose him. He died at Yildiz July 3 1918, and was succeeded by his brother Vahid-ed-Din (b. 1861) as MAHOMMED VI., the latter resigned in Nov. 1922 and died at San Remo May 15 1926.

MAHOMMEDANISM (*see* 17.399).—Of all the great faiths that have been accepted by large masses of the human race, Islam is one of the most historical. For the details of the life of the Founder the reader is referred to the article MAHOMET. The faith he preached is Islam, *i.e.*, resignation, submission to an Almighty Will. It teaches abstinence from drink, personal cleanliness, and abhorrence of evil, and, above all, the value of human life. The world is a well-ordered creation, regulated and guided by a Supreme Intelligence overshadowing the universe, since "Everything is pledged to its own time." Yet the human will is free to work for its own salvation. The sympathy of Mahomet was universal, and he invoked the mercy of the Creator "on all living beings." He pronounced the saving of one human life to be tantamount to the saving of humanity.

His social conception was essentially constructive, not disintegrating. In his most exalted mood the Teacher never overlooked the sanctity of family life. To him the service of humanity was the highest act of devotion. His call to the Faithful was not to forsake those to whom they owed a duty; but in the performance of that duty to earn merit and reward. Monasticism was disapproved of as contrary to nature. Children were a trust from God, to be brought up in tenderness and affection; parents were to be respected and loved. The circle of duty embraced in its fold "kindred and neighbours, and the lowly and poor."

The Koran.—The Koran has, on mistaken analogy, been sometimes called the Mahommedan Bible. The Old Testament is a record of ancient Israelite traditions which have, in one form or another, become the common property of the three Semitic faiths that now rule over the consciences of masses of mankind. All these traditions have passed through numbers of hands and bear evident traces of revision and editing. The synoptic Gospels, which form the outstanding feature of the New Testament, were not compiled, at least in the shape in which they have come down, until long after the events they purport to record.

The Koran, as a human document, stands on a totally different footing. As such it is *sui generis*. It is a record of the outpourings of one single human heart to whom the Soul of the Universe had spoken, and it has escaped revision. It prescribes religious duties in precise terms. Since men owe gratitude to the Creator for His manifold blessings, he should be glorified daily at stated times, so that there may be no neglect in the performance of His Worship. Five times a day devotions are offered to the Lord of Creation. Man must approach Him in purity of heart and body; and the practice of the Prophet has consecrated the mode of physical lustration and the cleansing of the heart.

Abstinence was also made a part of the religious law. Every able-bodied man or woman is required to abstain from food and drink from sunrise to sunset for one lunar month. The only exceptions to this rule are students and soldiers engaged in defence of their religion or country, and invalids male and female. Charity was incorporated as a part of religion and every person possessed of a sufficiency was required to give a certain part of his income for the support of the indigent.

Social Regulations.—The status of women was raised beyond any known in contemporaneous history. Far from degrading women, the legislation of Mahomet raised her in the social scale. "Paradise," it was declared, "is at the feet of the mother." In

his last sermon the Prophet enjoined his followers thus:—"Ye people, ye have rights over your wives and they have rights over you. Treat your wives with kindness and love. Verily you have taken them on the security of God."

The unrestrained polygamy of pagan times was drastically cut down; and the number of wives was limited to four and subjected to a condition which rendered it impossible under civilised conditions to practice polygamy without infraction of the rule. Owing to this condition in fairly-advanced Moslem communities polygamy has been much reduced.

Human chattelhood was forbidden; bondage was permitted only in the case of prisoners taken in "lawful" warfare in defence of religion; stringent rules were prescribed for the treatment of the unfortunate beings held in bondage; the child was not to be separated from its parents; no husband from his wife or one relative from another; and if a bondswoman bore a child to her master, she became at once a free woman and the child took the status of legitimate issue. The enfranchisement of people held in bond was an act of supreme merit with the Lord. Moslems were enjoined to "feed their slaves as they feed themselves, and clothe them with the stuff they wear."

The Sects of Islam

Islam, like Christianity, has been rent by schismatic strife and sectarian bitterness. The bulk of the Moslem population belong to the Sunni persuasion. Shiahs are found chiefly in Persia, but also in India. The Sunnis and the Shiahs differ greatly in their religious conceptions and doctrinal practices, and the difference extends from doctrines into the region of law, *e.g.*, the Shiah law of succession does not recognise agnacy, and daughters' children are not excluded by an uncle's son. Again, while the Sunni is enjoined to offer the prescribed prayers "congregationally" in a mosque, the Shiah may offer his orisons individually in the privacy of his house.

The principal divisions of the Sunni sect are mainly legal, according as the interpretations of the Hanafite, the Shafiite, the Maliki or the Hanbalite school are followed. Among the Shiahs, also, great jurists flourished who, deriving their inspiration from the medinite school, were liberal in their conceptions.

Wahhabiism.—Conformity was maintained in the Sunni community until the middle of the 18th century, when there arose a man in Central Arabia, named 'Abdul Wahhab, who revived the Khariji cult in all its pristine Calvinistic bigotry. He welded the Arab tribes into a composite force and established his authority from the shores of the Persian Gulf to the Red Sea. The Wahhabis, as his followers have ever since been called, captured Mecca and Medīna, from which they were driven out by the forces of Ibrahim Pasha, the son of Mehemed Ali, the founder of the present dynasty which rules over Egypt.

Ibn Sa'ud, the present chief of the Wahhabis of Nejd, emulated the achievements of his forbears by capturing again the Holy Cities from the hands of King Husain. In 1912 he had begun the formation of the new organisation of the Wahhabis under the name of Ikhwan or "brethren," and established colonies of them in various parts of Arabia, with the design that the settlers should sink their tribal rivalries in a communal religious life.

Senusis.—A religious movement closely connected with Wahhabiism was that of the Senusis, but though its teachings were practically identical, its organisation followed the usual lines of religious orders in the Mahommedan world. Founded in 1837, this order has achieved an immense expansion not only over the whole of North Africa from Egypt to Morocco and far to the south, but also in Mesopotamia and the Malay Archipelago. The order has been zealous in proselytising and has made many converts to Islam. Its activities were for a number of years a source of anxiety to the French as they appeared to be directed against the extension of European influence in Africa, and it took up arms against the Italians after the occupation of Tripoli in 1911, but in recent years has entered into friendly relations with them.

Shiahism.—Shiahism had no such auxiliary as Sunnism possessed in the form of organised political power to prevent its being rent with heresies, and consequently it has been distracted by constant schisms. Some owed their origin to dynastic rivalry; others to survivals of earlier cults in Western Asia.

Imamis.—The followers of the twelve Imams of the House of the Prophet (Ahl-ul-Bait) are commonly called Imamis. Ismail, the founder of the Safavid dynasty, made this branch of Shiahism the state religion of Persia, which character it has retained ever since. The Shiahs in India are also chiefly Imamis.

Zaidis.—The Zaidis are the followers of Zaid, a grandson of Husain, the martyr of Kerbalā. They differ from the general body of the Shiahs regarding the title of Abu Bakr, Omar and Othman to the Caliphate, and agree with the Sunnis on this point. The Zaidis are still found in the Yemen and North West Africa. The Zaidi Imam, Yahya, has recently consolidated his authority in Northern Yemen and is reported to be a ruler of great capacity.

Ismailis.—The Ismailis derive their name from Ismail, the eldest son of the Imam Ja'far as-Sadik, who pre-deceased his father. They hold that on the death of the Imam the religious headship devolved on Ismail's son Mohammed, whom they call al-Maktum (the "unrevealed" Imam), and not on his uncle Ja'far's second son, Musa al-Kazim, as believed by other Shiahs. Al-Maktum was, according to the Ismailis, succeeded by Ja'far al-Musaddak whose son, Mohammed al-Habib, was the last of the "unrevealed" Imams. The Ismailis achieved political importance with the foundation of the Fatimid dynasty in North Africa in 909 and after the conquest of Egypt in 969 the Fatimids ruled over North Africa and Egypt for two centuries. In the realm of thought one of the most remarkable manifestations of Ismaili speculation is found in the treatises of the Ikhwan us-Safa (the Brethren of Purity), a society of rationalists towards the close of the 10th century; they taught that individual souls are part of the world soul, to which they return after the death of the body. Through various stages of emanation the whole universe proceeds from God, and the re-union of the soul with God is effected through the reversal of this process and the purification of the soul from all grosser elements by asceticism, spiritual exercises and philosophy.

Assassins and Druses.—Two sects more permanent and more highly organised, the Assassins and the Druses, still survive as offshoots of the Ismaili movement. The Assassins in 1090 established themselves in the fortress of Alamut, in the north of Persia, and later in a number of other strongholds in that country and in Syria, and thence carried on an active propaganda, and their devoted followers did not hesitate at the risk of their own lives to use the dagger to remove political opponents. Their political independence was brought to an end by the Mongols, who destroyed most of their castles in the 13th century; but this sect still survives in a very altered form under the headship of H.H. the Aga Khan, whose followers in India number more than 127,000, in addition to adherents scattered throughout Syria, Persia, Central Asia and East Africa. His followers in India are known as Khojas and a large number of them are descended from Hindu converts and still adhere, in most important particulars, to the Hindu rules of succession.

A still more heterodox offshoot of the Ismaili sect is the community of the Druses, living in the Lebanon and the Anti-Lebanon and in the mountains of Hauran. They hold that God becomes incarnate in man in every age, and that Hakim, the sixth Caliph of the Fatimid dynasty in Egypt (996–1020), was the last incarnation of God; they believe that Hakim did not die and that he is only absent from human sight and will one day manifest himself again.

Babis and Bahais.—Another outgrowth from Shiahism was the Babi, followed by the Bahai movement, but in their latitudinarianism they have so far diverged from any orthodox form of Islam, that it is very doubtful whether they can properly be reckoned among Mahommedan movements. The Bahais have carried on an active propaganda in America and in certain parts of Europe, and have drifted further and further from the Islamic source from which they originally sprang.

The Ahmadiyya Sect.—In the year 1879 the founder of a new religious movement, named Mirza Ghulam Ahmad, began to

preach in the village of Qadian in the province of the Punjab, India. He claimed to be not only the promised Mahdi but also the promised Messiah—personages generally held to be distinct in ordinary Mahommedan theology. Another modification he introduced into Islamic doctrine had reference to the death of Jesus; the commonly-accepted belief maintains that Jesus was taken by God alive into heaven, while a phantom was crucified in his place; in oppositon to this he declared that Jesus was actually crucified, but was taken down from the cross while still alive by his disciples, was healed of his wounds and afterwards made his way into Kashmīr, where he finally died, his tomb being still in existence in the city of Srīnagar. Having thus removed the ground for any expectation of the second coming of Jesus from heaven to earth, he explained that he himself was the Messiah, not as being an incarnation of Jesus (for he rejected the doctrine of transmigration), but as having come in the likeness of Jesus—being Jesus for this generation just as John the Baptist was Elijah, because he came in the spirit and power of Elijah.

In proof that he had come in the spirit and power of Jesus, Mirza Ghulam Ahmad adduced the likeness of his own character and personality to that of Jesus, his gentleness of spirit, the peaceful character of his teaching, his miracles and the appropriateness of his teaching to the need of the age. In harmony with this pacific claim, he expounded the doctrine of Jihad (usually interpreted as meaning war against unbelievers) as a striving after righteousness. Mirza Ghulam Ahmad died in 1908, and a few years after his death his followers split into two parties, one having its headquarters in Qadian, and the other in Lahore. Both these sections of the community succeeded in enlisting the services of devoted, self-sacrificing men, who are unceasingly active as propagandists, controversialists and pamphleteers. They control an extensive missionary activity, not only in India, West Africa, Mauritius and Java (where their efforts are mainly directed towards persuading their co-religionists to join the Ahmadiyya sect), but also in Berlin, Chicago and London. Their missionaries have devoted special efforts to winning European converts and have achieved a considerable measure of success. In their literature they give such a presentation of Islam as they consider calculated to attract persons who have received an education on modern lines, and thus not only attract non-Moslems and rebut the attacks made on Islam by Christian controversialists, but win back to the faith Moslems who have come under agnostic or rationalist influences.

Modern Literature.—Indeed it has been characteristic of much of the theological literature of the Mahommedan world for the last few decades, to adopt an apologetic tone and to shake off those special features which have exposed it to hostile criticism; thus polygamy, slavery and intolerance are declared to receive no sanction from the Koran, as rightly interpreted; in Islam the reconciliation of religion and science is effected, and the demands of the modern spirit of enlightenment are satisfied. Of such modernist literature there has been a considerable output, especially in Egypt and India; it naturally appeals most to those readers who have come under European influences, and excites considerable opposition among more conservative orthodox circles, who remain loyal to the traditional schools of thought (as enumerated above) and resent the rejection of traditional, mediaeval theology by the modern thinkers. The older sects continue to flourish, and the new thought has not yet attempted to organise itself on sectarian lines and has thus remained largely a matter of individual opinion.

This lack of sectarian development is possibly in great measure due to the absorbing attraction that political problems during recent years have exercised upon the Mahommedan world. Anxiety as to the fate of Turkey after the Armistice, the withdrawal of the Holy Cities from the control of the Caliph and the occupation of Jerusalem by unbelievers, the separation of the Sultanate from the Caliphate (in 1922) and the abolition of the Caliphate altogether (in 1924) were circumstances that profoundly stirred the minds of pious Moslems all the world over and did not create an atmosphere favourable to the calm consideration of purely dogmatic problems. Moreover in many Mahommedan countries some form of nationalism obscured the larger vision of a united Islamic world; in Turkey it took the extreme form of Pan-Turanianism, or Pan-Turkism, which aimed at the union of all sections of the Turkish race in one vast confederacy and sought to purge the national life from all foreign admixture, in language, literature and political institutions; in India nationalist feeling prompted the Hindu-Moslem Entente and gave birth to the oft-repeated sentiment, "I am an Indian first, and a Moslem afterwards"; among the Mahommedan populations of Russia the formation of Soviet Socialist Republics has evoked nationalistic movements which have temporarily thrust purely religious interests into the background; Bolshevik propaganda has also met with a response among the Mahommedans of Java.

But Islam is so closely bound up with every aspect of the life of a Mahommedan people that even a purely nationalist political movement may react strongly on the religious life. This has been notably the case in Turkey, where the Government, besides abolishing the Caliphate, has confiscated the religious endowments and suppressed the religious orders; polygamy has practically been made illegal; the date of Ramadan has been fixed in accordance with astronomical science instead of being made dependent on reports that the moon has been seen (as has been the immemorial custom in the Islamic world); and the discontinuance of the wearing of the veil by women and the adoption of hats by men, are typical of a changed attitude towards the established usages of Mahommedan society. The breach with the past has been nowhere so violent as in Turkey, but throughout the whole Mahommedan world there are indications of a changed attitude towards religious questions. The old orthodoxy still holds the allegiance of the masses, as well as many of the educated, but others, especially those whose education has brought them under European influences, are seeking a re-statement of their religion, more in harmony with their general outlook upon life. To those that seek a solution in the realisation of some nationalist ideal, there remains little save a sentimental attachment to Islam, while they deprive it of any control over law and social organisation; the reformers, on the other hand, claim for the precepts of Islam control over all the relations of human life, but seek to restore it to its primitive simplicity, believing that thus it can be brought into harmony with modern thought and modern conditions.

MAINE (*see* 17.434).—The population of the state in 1920 was 768,014, in 1910 742,371, an increase of only 3·5%, as compared with 14·9% for the United States in the same period and 6·9% for Maine in the previous decade. There was a significant increase in urban population. The proportion living in places of 2,500 or more was 33·5% in 1900, 35·3% in 1910, and 39% in 1920. In 1910 the rural population was 480,123; in 1920, 468,445. The only one of the 16 counties showing a marked increase in rural population was Aroostook, which is one of the richest farming regions of New England.

The principal cities of the state, with their population of 1920 and 1910 and rate of increase, were as follows:—

City	1920	1910	Increase per cent
Portland	69,272	58,571	18·3
Lewiston	31,791	26,247	21·1
Bangor	25,978	24,803	4·7
Biddeford	18,008	17,079	5·4
Auburn	16,985	15,064	12·8
Bath	14,731	9,396	56·8
Augusta	14,114	13,211	6·8
Waterville	13,351	11,458	16·5

Agriculture.—In Maine there were in 1920, 48,227 farms, valued with equipment at $250,000,000. Although the number of farms has decreased since 1910, the value of farm land has greatly increased; and in certain fields such as poultry there have been

gains. The poultry co-operative marketing is being successfully conducted; and in other branches of agriculture newer methods of marketing are making up for decreased acreage. Maine's potato crop in 1924 totalled 41,475,000 bushels. Fifty-five per cent of all certified seed potatoes in the United States was grown in Maine in 1024. Figures for that year show 305 bu. of potatoes per ac.; 42 bu. of corn; 26 bu. of wheat; 37 bu. of oats. One of the chief agricultural industries is the production of sweet corn for canning. In 1924, 38,030 tons of corn were cut. Lately canned green peas are coming into equal popularity. In Washington county blueberry production is one of the staple industries. Maine's annual blueberry crop is valued at a million dollars. Hay still leads other crops: 1,432,000 tons in 1924 as against 1,326,289 tons in 1919. Maine has a very low percentage of mortgaged farms; in 1024, 67·5% were free from mortgage indebtedness as against the national average of 52%. Ninety-six per cent of Maine farms are owned by men who operate them. It is estimated that about one-third of the people living in Maine are engaged in, or are supported by, agriculture. But over one-half of the foodstuffs come from outside the borders of the state—a situation that has led to efforts encouraging the use of markets and the development in Maine of agricultural independence.

Forestry and Lumber.—During the past few years much attention has been given to afforestation. Nearly three-fourths the area of the state, 15,000,000 ac., is forest land. Very recently attention has been called to the abundance of hard wood in the Maine forests, a fact that had been overlooked in the unparalleled consumption of pulp wood. The total stand of timber, spruce and fir is estimated at 25,500,000,000 ft.; pine, 5,060,000,000 ft.; cedar, 2,780,000,000 ft.; hemlock, 880,000,000 ft.; hardwoods, 5,000,000,000 feet. The annual cut of lumber is approximately 1,000,000,000 feet. Figured on the basis of population Maine's forest lands amounted in 1925 to 19·5 ac. *per capita*, a ratio exceeding those of all other states east of the Rockies, except Florida.

Shipbuilding and Fisheries.—The shipbuilding industry was stimulated during the World War to a remarkable activity, which, however, subsided in the years immediately following. Bath, the chief shipbuilding city, attained, during the height of this boom, to a population of 15,000.

Manufactures.—In total value of products, paper and wood pulp manufacturing ranks first among Maine industries; cotton goods are second; boots and shoes third; and woollen goods fourth, followed by lumber and timber products. Maine leads all the states in the production of wood pulp; and Old Town leads the country in the manufacture of canoes. There is still much undeveloped water-power; the U.S. Geological Survey credits Maine rivers with a potential maximum of 1,300,000 electrical horsepower, of which 700,000 is undeveloped. The state still refuses to allow the exportation out of the state of water-power; but there are indications that this policy does not meet with as much popular support as it did a few years ago.

Administration and Finance.—Since 1910 there have been adopted 13 amendments to the state constitution, the total number of amendments numbering 47 in 1025. Of amendments adopted since 1920 the two most important provided for a bond issue of $3,000,000 for a bonus to Maine soldiers and sailors in the World War, and for voting by mail. Maine is fast becoming the summer playground of the country. It has been conservatively estimated that nearly a million tourists visit Maine annually; and the summer visitors furnish an important element in the business life of the state. There are 165 summer camps for boys and girls, with an attendance exceeding 7,500. The recreational advantages of the state were emphasised in 1925 by Gov. Brewster in his inaugural address; and an elaborate programme of publicity, based upon the examples of California and Florida, was undertaken under the auspices of the state and with funds provided in part by appropriations granted by the state.

Education.—During the decade 1915–25 much progress was made, particularly in the rural schools. A well-arranged programme providing for school buildings of modern construction was being carried out in cities and towns; and in rural communities the old-fashioned type of isolated, single school buildings was giving way to consolidated buildings, transportation being furnished to pupils from remote homes. In 1925 the total enrolment of pupils was 163,106, as against 154,604 in 1920; 132,853 were enrolled in the elementary schools, and 30,253 in the high schools and academies. Of the farm population of high-school ages, 49·3% was enrolled in high schools, as compared with 42·3% of the non-farm population. Maine claims to have the highest percentage in the country of farm boys and girls attending high schools. The state dept. of education also put into operation a well-devised plan for the gradual elimination of illiteracy through evening schools and adult classes. There were about 1,400 students in the six normal schools, and about 3,300 students in the state university and Bates, Bowdoin and Colby colleges.

History.—In 1911, for the first time since the Civil War, Maine had a Democratic governor, Frederick W. Plaisted, and two Democratic senators, Charles F. Johnson, of Waterville, and Obadiah Gardner, of Rockland. In 1912 Woodrow Wilson won the electoral vote of Maine by reason of the split in the Republican ranks. But in 1916 the split was healed and Maine in every election thereafter ran true to form as a Republican state. The consolidation of various newspapers with other changes in ownership left the minority party practically with no press. The chief contests consequently were in the primaries for the Republican nominations. In 1924 the choice for governor between Frank Farrington, of Augusta, and Ralph O. Brewster, of Portland, was so close that for some weeks the result was in doubt, a recount held by the governor and council finally giving the nomination to the latter. In view of Federal legislation on prohibition and woman suffrage it is interesting to recall that in Sept. 1911 the state of Neal Dow voted to retain the prohibitory amendment to the constitution by the extraordinarily close vote of 60,853 to 60,095; and in Sept. 1917, in a referendum, woman suffrage was overwhelmingly defeated, 38,858 voting "No" and 20,604 voting "Yes." In 1924 the Ku Klux Klan was a very active factor in politics and one of the most discussed issues in the state campaign. The agitation, however, largely subsided following the election of Brewster as Governor in Sept. 1924.

Governors since 1911: Frederick W. Plaisted (Dem.), 1911; William T. Haines (Rep.), 1913; Oakley C. Curtis (Dem.), 1915; Carl E. Milliken (Rep.), 1917; Frederic H. Parkhurst (Rep.), 1921; Percival P. Baxter (acting) (Rep.), 1921–3, elected 1923–5; Ralph O. Brewster (Rep.), 1925– . (K. C. M. S.)

MAIRONIS, (1862–), Lithuanian poet, whose real name was Jonas Maciulas, was born in 1862 at Pasandvaris, in the Kaunas (Kovno) district. After leaving the Kaunas high school, Maironis continued his studies at the University of Kiev and the Kaunas seminary. On graduating from the latter, he entered the St. Petersburg (Leningrad) theological academy, where he took the M. A. degree. He was for 15 years a professor in the academy and received his D.D. for a scholarly work entitled *De Justitia et Jure.* In 1909 he was appointed rector of the Kaunas seminary. He became in 1922 a professor and deacon of the theological faculty of the Kaunas University which he helped to found, and in 1923 was appointed professor.

Maironis began to write at an early age. His prose, *History of Lithuania*, went into four editions. As a poet he excels alike in dramatic, epic and lyrical composition. His *Song of Spring*, a collection of songs, elegies, sonnets, ballads and satires also ran into several editions. Many of his songs have been set to music and are sung all over Lithuania. His famous poem *Young Lithuania* describes the national re-birth; *Our Sufferings* is a poem descriptive of the Lithuanian national ripening and conquest of independence; his *Magdalen of Raseiniai* castigates the national vices, while his Polish poem *Znad Biruty* appeals to the Polonised Lithuanian nobility. His dramatic works include *Where is Salvation? The Death of Kestutis*, and *Vytautas with the Crusaders*, the two last being historical plays of the 14th century. Maironis also translated the Rigveda into Lithuanian.

MALARIA (*see* 17.461).—Malaria had long been recognised as a disease of world-wide incidence and the cause of a higher sickness and death-rate than any other disease. The finding of malarial parasites in the blood cell by Laveran at Constantine in 1880, the demonstration of the life cycles of the quartan and tertian species of parasite by Golgi in 1885, and of the subtertian fever species by Marchiafava and Celli, and the discovery that the disease is transmitted through the agency of mosquitoes first from bird to bird by Ronald Ross in India 1897–9, and later from man to man, in conjunction with the investigations and teachings of Patrick Manson and other pioneers, were important factors in a great stimulus to the study of tropical diseases, both of men and of animals in general, and the whole of tropical sanitation was powerfully affected.

Parasites.—Malaria is due to small protozoa or animal parasites which pass an asexual stage in man, living and developing in the red blood cells, dividing into young forms or fresh broods in two or three days' time and producing some male and female forms (gametocytes), which are drawn with the blood into the stomach of the female mosquito, and there conjugate and complete a sexual cycle. An oöcyst forms from the female gamete and in this a swarm of young sporozoites develop and, becoming free in the body cavity, pass to the salivary glands, whence they are injected at the bite of the mosquito and begin again the asexual stage in man.

The Parasites.—Malaria parasites are of three species: *Plasmodium falciparum, P. vivax* and *P. malariae*, the causal organisms of "subtertian," tertian and quartan fevers respectively. Following the teaching of Laveran, a small body of workers believed that there was but one species, a theory of unity, and on the other hand certain investigators, because of minute differences between examples of the same species, concluded there were even further species and gave names to them. However, as Professor Marchoux pointed out in a thorough review of the question at the First International Malaria Congress held at Rome in Oct. 1924, experimental research generally tended to support the idea of plurality and existence of the three species above named. This was supported by the difference and practically constant periods of evolution of each, the transmission of the same species to healthy subjects, the specificity of culture of the parasites of each of the three species *in vitro*, and by epidemiological studies.

Symptomology.—In malaria symptomology nothing of fundamental importance has been discovered in recent years. There has been advance on our knowledge of the cause and treatment of Blackwater Fever or Haemoglobinuria, the serious nature of which has called forth many investigations, especially in the particular and heavily infected regions where it occurs. Some investigators hold that this condition may arise not only in infections with *P. falciparum*, but occasionally with *P. vivax* and exceptionally with *P. malariae*. The association of an unknown virus with the malarial parasite has been considered as the cause. J. Thomson's work in Rhodesia in 1923–4 gave strong evidence in favour of *P. falciparum* as the causal organism of all local cases and possibly elsewhere. He showed that *P. falciparum* can almost always be found in the blood; and that cases had been living in a district heavily infected by *P. falciparum*. He found one case after five months and another after 40 years' residence; he noted its occurrence only in people who had had attacks of malaria, though possibly unrecognised as such at the time, and had taken their quinine inadequately in amount and over an insufficient period of time. A similar observation was made in the cases which developed Blackwater Fever on their way home, or after they had left an endemic area even for some time. The finding of the other species of parasite, both of which tend more to chronicity and are readily found in the blood stream, may when present be, in Thomson's view, but an indication of a mixed infection.

Diagnosis.—In the diagnosis of malaria in endemic localities the estimate of inhabitants infected is based on the percentage rate of an enlarged spleen or of a positive blood finding amongst a proportion of the population. For the latter, the examinations of a thick and a thin film of blood are made. In the absence of the parasite an estimate of the relative number of large mononuclear (endothelial) cells to other white cells in the blood may be made in certain cases, but the evidence obtained is not conclusive. An increase above the basic figure of 15% endothelial cells of the total white cells was taken by Stevens and Christopher as indicative of actual or recent malaria in Europeans living in the tropics. Blood cell counts made at some time prior and subsequent to the finding of the malarial parasite did not show the presence of a constant relative increase of endothelial cells, nor was this a constant factor in latent malaria, even when the clinical diagnosis was obvious and the most reliable factor, an enlarged spleen, present. With regard to the finding of the parasite in the blood in these cases of "latent malaria in England" it must be remembered that but a small drop is taken and that parasites are not easily found except at the period of a relapse. The clinical signs of latent malaria most commonly found are, in order of frequency, an enlarged spleen, anaemia, functional disorders of the heart and enlargement of the liver. The tendency to chronicity and febrile relapses in malarial infections is very marked.

Distribution.—Malaria is a world-wide disease with endemic foci in all countries. It is most prevalent and extremely common in the tropics with the native population and high infection rate, constant heat, moisture and water for the breeding of the anopheline mosquito and requisite temperature for the development of the sexual stage of the parasite therein. As the poles are approached, the foci of endemicity gradually become less. For the development of the parasite in the mosquito an adequate temperature is necessary. On an average the three forms, *P. malariae, P. vivax* and *P. falciparum*, take 14, 11 and 6 days, respectively, the time varying with the temperature. In subtropical countries, malarial outbreaks follow the rainy seasons, when opportunities arise for the breeding of the mosquitoes. Norway and Sweden are examples of countries wherein anopheles are present but malaria absent.

In Great Britain malaria was formerly not very uncommon, but became rare until the return of many infected troops. Related to the presence of these carriers there were 235 indigenous cases in England in 1917, the number falling to four in 1924, thus corresponding with the cure of the malarial carriers. There exist in England three species of *Anophelinae* in which the parasites may develop and be transmitted from man to man, but with treatment of infected cases from abroad there is now practically an absence of the human carrier of the parasites, or at least of parasites with sufficiently numerous sexual forms in the blood, a minimum of 12 per cu. mm. of blood being considered necessary for development in the mosquito. Climatic conditions, particularly temperature and humidity, influence the endemic prevalence of malaria. A mean daily temperature exceeding 60° F. is necessary for its propagation for the full development of the parasite in the mosquito, *P. falciparum* requiring a very high temperature; *P. malariae* completing its cycle at a low one, and *P. vivax* over a wide range of low to high. This explains the seasonal incidence of the three types of malaria, the relatively high incidence of *P. falciparum*, the most malignant parasite, and the large number of infected inhabitants and high death-rate in the tropics and subtropics, and its rarity in indigenous cases in temperate climes, the presence of the endemic foci of *P. malariae* in the cooler hill country in the tropics and subtropics and the universal distribution of *P. vivax*

Though *P. falciparum* is the most malignant and spreads most rapidly when anophelism is intense, because of its greater output of gametes in the blood, it does not tend to such chronicity in the absence of reinfection as do the other two forms. In the absence of reinfection *P. malariae*, by far the rarest form, is, however, the most resistant and *P. vivax* holds an intermediate place. Of 28,270 blood examinations made in England at one laboratory on cases of malaria contracted during the War, 777 were found positive, and of these *P. vivax* numbered 750, *P. falciparum* 14, *P. malariae* 4. There was a marked falling off as the time in England lengthened, and it was rare to find the parasite after the quarterly period of 12 to 15 months. Seven

cases were found after 30 months all with *P. vivax*, one in a double insection with *P. malariae* after 39 months, and one case after 51, and another after 59 months; *P. falciparum* was found after three months in a double infection with *P. vivax* at the 11th month, once alone at the 12th month, and once in a triple infection at the 14th month. The third of the four cases of *P. malariae* had also been home a long time, namely, 16 months. In none of this extensive series was the parasite ever found after five years at home. It is not uncommon to hear a person settled in a non-infective country for many years accusing a temporary febrile attack or period of lassitude as a return of malaria which he once contracted abroad. Proof of this seems wanting. Though malaria has been transferred directly from man to man, the parasites infecting man have not been made to infect any animal. Entomologists have furthered their investigations into the bionomics and classification of mosquitoes and the determination of the species of anopheles that carry malarial parasites.

S. P. James and Dale have recently reported that quinine, quinidine and cinchonine possessed the same curative properties for all forms of malaria, and without difference in their toxicity save for the greater cardiac depressant action of quinidine. Fletcher at Kuala Lumpur has made a careful series of observations on this point.

Prophylaxis and Treatment.—The treatment of malaria is intimately bound up with prophylaxis. Particular reference may, however, be made to the recent therapeutic use of horse serum in the treatment of that severe form of malaria, Blackwater Fever, wherein this serum appears to inhibit the action of an autohaemolysin and its destruction of red blood cells in the body.

Many clinicians strongly advocate in tropical regions intramuscular and intravenous injections of the bihydrochloride of quinine in serious cases, and injections do act quickly in severe, malignant, remittent and comatose cases, but in ordinary cases oral administration of the sulphate has been satisfactory. In acute attacks it must be borne in mind that 24 hours or more may elapse before the good effects of quinine become manifest.

The classical successes in the reduction of malaria at Ismailia, Hongkong, Havana and elsewhere have encouraged similar work in other localities, but there are few such examples as the long continued labours of Malcolm Watson in the Federated Malay States and the brilliant sanitary victory of General Gorgas and the Americans over both malaria and yellow fever at Panama. The work of Darling, Bass and others in southern United States and in the Islands must also be mentioned. The method of mosquito reduction against malaria, first suggested and tried under Ross in Freetown, Sierra Leone, in 1899, has not been followed as widely as anticipated, and local authorities too often dislike spending money on sanitation and hamper practical efforts of sanitarians by the attitude that it is better to prevent malaria by quinine or by the use of mosquito-nets, measures which are impractical in an uneducated native community. Local conditions must always determine the most suitable mode of prophylaxis, and it is important, as Étienne Sergent points out, to have several methods of control which may well be combined and include with specific measures an educational propaganda. Obviously there must be action to eliminate infection from all carriers of the parasite: in other words, to prevent the mosquito becoming infected, to destroy the species of anopheles in which the parasite may develop, and to prevent their biting and inoculating the parasite into the blood of man. Good results have attended well-applied efforts of this kind. Better health results and there are real economic returns for expenditure. The native must be looked after and enjoined to adopt some sanitary methods until he is taught to share in systematised efforts to protect and cure himself of malaria as of other endemic diseases.

Measures to rid carriers of the parasite are most difficult to put into practice. There is no settled or fixed dosage, or time of administration, of the specific remedy, quinine or other of the cinchona bark extracts. Acute attacks respond readily to quinine; each dose makes a reduction in the number of parasites, and this reduction occurs every day, until finally none of the parasites is left. Treatment must be continued for a long time. Empirically three months appear to be enough, but there are obstinate cases.

Standard Treatment.—For some years a standard line of treatment to procure disinfestation has been adopted by Bass in America and by Ronald Ross and his colleagues in Great Britain, and the former has been recently introduced by J. Thomson in Rhodesia. The two former vary slightly. Ross gives 30 grains of quinine daily during the attack and for three days after, followed by 10 grains daily, just before or after breakfast, for three months; Bass ceases after two months. Success has attended these standard treatments, and it is well for administrative purposes that a standard be adopted in each country. It will not cure all cases, but the exceptions appear rare and when detected can be specially treated. Stevens found arsenic, after initial doses of quinine, of great value in helping to eradicate the parasite. Together with quinine or other drug therapy, the important factor of building up and maintaining the general health, so as to assist the natural forces of the body to eliminate the malarial parasite, must not be forgotten.

Regarding the value of quinine prophylaxis amongst carriers, the results obtained at the malaria centres and camps during the War showed that any dosage under a total of 60 grains weekly proved insufficient for an adult male. Other salts of quinine, of hydrochloride and bihydrochloride, affect the digestion less and seem to be as satisfactory. The tannate has been much used in Italy, especially for prophylaxis among children. The daily small dose is more easily and therefore more certainly taken by patients (out of hospital) than larger occasional doses which cause some dyspepsia and headache and are therefore frequently postponed. Children can be given a larger proportion by body weight than adults, say, twice as much. Sir Ronald Ross has always felt that, to be effective, quinine should be continued in 10 grain doses daily for three months after a subject has left a malarial country.

Quinine prophylaxis has been of value on particular occasions, such as in tiding a body of troops over a critical period of fighting or passing through a heavily infected area, in that it has kept off attacks of malaria during that time. Bodies of troops in Salonika who were given quinine daily remained free as long as they were taking it, but went down with malaria as soon as they stopped it, showing they were infected in spite of it.

Not all people bear quinine continued over a long period well and they may show symptoms of quininism. Occasionally an individual is hypersensitive to quinine and may show symptoms even following an initial dose. On the first appearance of quininism the drug should be stopped for a time, or arsenical treatment substituted. In the hypersensitive case some begin with very small doses to desensitise the patient. Certain investigators in the tropics consider that it is more difficult to eliminate the parasite by quinine therapy in cases that have been taking quinine consistently and who have become infected in spite of it. The cost of quinine and of its supervised administration has frequently rendered quinine prophylaxis impracticable in certain endemic areas.

Quinine prophylaxis should be supported by measures to prevent mosquito bites as far as practicable. In endemic areas and where there are many carriers the infection rate of the mosquito may be very high and frequent reinfection may occur.

The second measure of prophylaxis, *i.e.*, the reduction of anopheline mosquitoes and the prevention of bites, has received more general application. This is difficult and costly, but it results in a lessened sickness and death-rate from malaria, and in profit from the expenditure incurred.

In subtropical regions or where mosquitoes hibernate in dark places in rooms of homes, cellars, stables, outhouses and such places, often attaching themselves to cobwebs, they should systematically be killed directly or by fumigation. The breeding place of the mosquitoes is any still water on which they lay their eggs, and to kill the larvae and pupal forms through which they pass in development is the object in view. Much can be done by the filling in of small pools, cattle foot-marks, draining of

marshes, clearing out of long grass and reeds from the sides of streams, the conversion of still to running water when in large masses, the clearing away of all cans and unnecessary water containers and the covering by gauze of cisterns and tanks and the like around the homes. A female mosquito lays about 250 eggs at one time and seven to 10 days bring them to maturity. The young aquatic forms may be destroyed by larvicides such as kerosene, waste oil, cresol or "paris green," which, when mixed with 100 parts of dust (1 c.c. of the mixture to 10 sq. metres of water) and blown on to the water, distributed by the winds or dropped from aeroplanes, kills the anopheline larva forms and does not injure the fish or the animals that drink therefrom. Valuable agents against larvae and pupae are the surface-feeding minnows, gambusia, stickleback and perch.

Anopheline mosquitoes do not attack until sunset, when one may remain as far as possible indoors in houses, bungalows and huts protected by close-mesh wire or netted windows and double doors; a bed or head net should cover any exposed part of the body during sleep. In the early evening the wearing of puttees by men and a paper lining under the stockings of women prevents bites on the legs. Coolie lines should be placed when possible a mile from the breeding places of the anopheles, though this does not mean that the mosquitoes cannot fly much farther. There is little danger to be anticipated from breeding places over a mile distant, if the mosquitoes have opportunities of feeding close at hand (*i.e.*, from other mammals), and if the intervening space be raised, wind-swept and clear of all shrubs and trees. The knowledge that the mosquito will attack man or animal in its thirst for blood has raised certain questions regarding the preservation of game, but up to the present no practical studies on any extensive scale have been made.

Use in Psychiatry.—Following the observation of Wagner Jauregg in Vienna in 1917, that certain chronic conditions showed improvement after malarial attacks, the therapeutic use of malaria in psychiatry has been extensively applied in many countries. Many cases of general paralysis have benefited, some sufficiently to be able to return to family and social life. Time must be given to determine the permanency or otherwise of the amelioration. Its use in other cases of cerebrospinal syphilis and also in such mental diseases as *dementia praecox*, confusional insanity and *encephalitis lethargica* is under consideration. The parasite used is the *P. vivax* and it appears more satisfactory to inoculate the patient by an experimentally infected mosquito than by infection with blood from a case of malaria. Thereby all risks of other infection are avoided, a wise precaution, especially in an endemic region where other species of the parasite occur. Infected cases are allowed to have 6 to 10 febrile attacks of malaria and are then given quinine which in these experimental cases readily cures the attacks.

War Malaria.—The following were the British War Office figures of the number of cases admitted to hospital in four of the fighting areas during the War: Mesopotamia: 1916, 680; 1917, 744; 1918, 10,202. Salonika: 1916, 31,059; 1917, 71,413; 1918, 59,087. East Africa: 1917, 58,236; 1918, 20,015. Egypt: 1916, 1,423; 1917, 8,480; 1918, 30,241.

Until the War spread to the eastern fronts British armies suffered little from tropical diseases. In the summer of 1916 an epidemic of malaria occurred among the troops on the Salonika front; and continued until the end of the War.

Following the outbreak of malaria at Salonika, Sir Alfred Keogh, the Director-General, Army Medical Services, early in 1917 appointed a special malaria hospital in each Command in the United Kingdom, for the express purpose of finding a permanent cure if possible, and of treating the thousands of men who were being returned home sick with malaria from the eastern fronts, Sir Ronald Ross being also appointed Consultant in Malaria at the War Office. The fact that moderate doses of quinine will control actual attacks within a few days was fully verified, and with very few exceptions. Almost every form of treatment that had ever been suggested—enormous doses of quinine reaching 100 grains *per diem;* smaller doses continued for three weeks or more; additional medication with arsenic and other drugs; continuous doses lasting for a month, and various kinds of interrupted dosage—all proved uncertain. Thirty grains of quinine, continued every day for three weeks, proved a failure. Intramuscular injections and even intravenous injections did no better. Men who were presumed to be cured relapsed again after returning to duty; a large proportion of those infected with malaria became almost useless for further service. Numerous nostrums advocated for malaria proved valueless, the only exceptions being one or two arsenical preparations, which, however, were *no better* than ordinary quinine.

Now, in all these attempts, treatment had seldom been continued for more than one month and rarely or never for more than two months —owing, of course, to military exigencies. It was decided to deal with the large numbers of discharged soldiers by a longer period of treatment. In 1918 two whole divisions, full of malaria, had been brought from Salonika to France and were there subjected to a longer course of treatment preparatory to their being sent again into the firing-line. The regiments arrived in an extremely bad condition, were all placed in camps in the Dieppe region, and the men were given 15 grains of quinine in solution once daily for a fortnight, followed by 10 grains of quinine in solution daily for 2½ months more. The course, designed and carried out by Col. J. Dalrymple, had marvellous results, almost the whole of the two divisions being found fit for the front at the end of the three months. About the same time large malaria concentration-camps were established in England, where cases were given similar treatment, but for shorter periods; and it was found generally that: (1) doses of less than 10 grains daily did not suffice to prevent relapses even while they were being taken; (2) doses of 10 grains daily did so suffice, except in about 6% of the cases, most of whom, however, relapsed during the first days of the treatment; (3) 15 grains a day reduced the relapses still further, but only to about 4 or 5%.

The long-continued treatment of malaria was now proved to be satisfactory, and was extended to pensioners also. In one London clinic alone nearly 30,000 pensioners have been treated in this way. The results have been admirable, and probably very few men who have taken the treatment properly have returned. But the 10 grains of quinine must be taken religiously every day, and it is well to associate this with or follow it by a course of arsenic. Quinidine replaced the quinine in a small number of these cases. Good food and care in building up the general health are important factors in overcoming malarial infections. Empirically, three months appear to be enough, but in obstinate cases four months might be better. There are rare individuals who are hypersensitive to quinine or who may be desensitised prior to the introduction of the standard dosage. Even long courses of treatment will not necessarily cure people who are subject to reinfection during treatment; and it is even possible that they are not so effective during the first six months or the first year of infection as they are later. The results described above were obtained among returned cases in Britain. Other salts of quinine besides the sulphate were tried. The hydrochloride and bihydrochloride affect the digestion less and seemed to be as satisfactory.

The prevention of malaria on the battle-front was always difficult and sometimes impossible. Mosquito-reduction in the face of enemy fire is impracticable; quinine prophylaxis was under such conditions disappointing; and the armies were obliged to fall back upon mosquito-nets and mosquito-proof tents and bivouac shelters—which were carefully designed by the British War Office. Better results were obtained at the bases of operations, especially in Palestine; and a very successful campaign of mosquito-reduction was carried out by Col. J. C. Robertson at Taranto in Southern Italy.

MALAY STATES, FEDERATED (*see* 17.478).—For over 16 years all matters of common interest to the Federation have been settled by the federal council, a body created in 1909 in accordance with the general wishes of the individual rulers. The council consists of the high commissioner (president), the chief secretary to the Government, the four ruling Sultans, the four British Residents, the legal and financial advisers and eight nominated unofficial members; it meets generally three times a year and all Federal legislation is passed by it.

Population.—The growth of the population is the measure of the States' prosperity. According to the census of 1921, the population was 1,324,890, having increased since 1911 by 27·7%; it is still rising rapidly, and was estimated at the end of June 1924 to be 1,418,455. There are approximately 510,000 Malays, 494,000 Chinese, 305,000 Indians and 5,700 Europeans. The increase among Malays, especially in Selangor, is largely due to the influx of foreign Malays who have settled in the coast districts to plant rubber; and the increase in the Indian population also synchronises with the development of the rubber industry. There are indications that the immigrant races, who have done so much to develop the resources of the Federated Malay States,

are ceasing to regard these States as a place of temporary sojourn and tend more and more to make them their permanent home.

Commerce and Industry.—An indication of the continued prosperity of the States is afforded by the fact that for the six years following the World War there was a considerable trade balance; and for the years 1919, 1923 and 1924, the estimated value of the exports, which consist chiefly of tin, rubber and copra, was well over twice that of the imports. The average value of the exports is over 200,000,000 dollars. The export of tin-ore reduced to a metallic basis and of block tin has averaged 40,000 tons, and the market for this commodity, as also for rubber, has been greatly assisted by the policy of withholding stocks against current prices. In the case of tin the holding or releasing of stocks was arranged by voluntary agreement between the Government, which held large stocks, and private holders.

Government assistance to rubber growers was given by the Export of Rubber (Restriction) Enactment, under which the percentage of release of stocks at the minimum duty rose or fell according to the ruling market price. By this means a fair price was obtained for growers, and many plantations were saved from the ruin that must have resulted from the premature tapping of trees. The Government continues to make a grant to the Rubber Growers' Association in connection with propaganda for new uses and markets for rubber. The establishment of a rubber research institute was approved in 1924, to be maintained by a special export duty on rubber. Important research work had been done, before this, on the deterioration of rubber in storage, which was found to be due mainly to surface oxidation, from which it is indicated that the slab form is preferable to the crêped form for storage. The mouldy rot disease (in Negri Sembilan) and the brown bast disease were further investigated. A Government experimental coconut plantation has been started. The commercial timbers of the country are in process of being scientifically investigated, and the distillation of native woods has also been made a subject of research.

Tin-mining continues to be the chief industry in Perak and Selangor and rubber the chief industry in Negri Sembilan and Pahang. Other ores produced are tungsten (wolfram and scheelite) and gold. The Raub gold mine in Pahang is the only gold mine now working in these States; but alluvial gold is recovered in various places. Coal also is produced, the tonnage averaging between 350,000 and 400,000 tons annually. Coconuts and rice are widely grown in Perak, Selangor and Negri Sembilan, in which last-mentioned state coffee is now but little grown, its place being taken by rubber. The timber industry is in process of development, and the whole question of the exploitation and conversion of timber is receiving the active consideration of the Government. Already there are some 5,000 sq. m. of forest reserves, and the areas are being extended.

Railways.—Communications in the Federated Malay States keep pace with the growing requirements of the tin and rubber industries. The total length of line now open to traffic under the Federated Malay States railway administration is over 1,000 miles. This includes the Johore state railway, which at Gemas branches into the west coast line to Prai and to the Siamese frontier; and the east coast line, which runs northward towards Tumpat. The Kelantan section is being extended southward to the east coast line to provide direct communication between Kelantan and Singapore. Through traffic, over the west coast line, with the Siamese state railways was opened in 1918, and between the Federated Malay States and Kelantan via the Siamese railway in 1921. The Johore causeway, which connects Singapore with the peninsula, was opened in 1924. The causeway carries two lines of rails and a roadway; its total length is 3,465 ft. and its average headway at low tide is 47 feet.

Education.—In 1919 important movements for the extension of education were set on foot, despite difficulties encountered in increasing the number of teachers and the improvement of the teaching standard. A temporary scholarship scheme for sending teachers to Hongkong University was set on foot, to serve until more training colleges were established and pending the opening of Raffles College, founded in Singapore. A Malay college is established at Kuala Kangsan; the Sultan Idris training colleges provide Malay vernacular teachers; and there are many Chinese and Tamil vernacular schools.

MALAY STATES, NON-FEDERATED (*see* 17.482).—These are Johore (*see* 15.475; this form of the name, rather than Johor, has come into official and general use), Kelantan, Trengganu, Kedah and Perlis. The populations according to the census of 1921 were Johore, 282,234; Kelantan, 309,300; Trengganu, 153,765; Kedah, 338,558; Perlis, 40,087.

Malaria is severe except in Trengganu, and infant mortality high, but both this and the general death-rate have been reduced with improvements in sanitation and provisions for medical service introduced under British supervision. To this, and to the more settled conditions brought about under it, is attributed in large part the substantial increase of the population recorded in all the States; although, as in Trengganu about 1920, the benefits to the commercial classes were not immediately reflected in improved conditions for the peasantry.

By an agreement made in 1885, the Sultan of Johore placed his foreign affairs under British Govt. control and undertook, when required, to receive a British agent at his court. No such appointment, however, was made until 1910. In 1914 a subsidiary agreement was concluded whereby a General Adviser was appointed with powers similar to those exercised by British Residents in the Federated Malay States. The other States, Kelantan, Trengganu and Kedah, came under British protection in 1909 by virtue of a treaty signed at Bangkok in 1909 under which the Siamese Govt. transferred to the British Govt. all its rights over them. The officer administering the government of the Straits Settlements is the British High Commissioner for all protected States in the Malay Peninsula.

Johore.—Most of the interior of Johore is covered with jungle, but already over 800,000 ac. have been alienated, chiefly in small holdings, for cultivation. Rubber plantations occupy half this area and coconut crops about 90,000 acres. Other agricultural products are padi, betel nuts, African oil palms, tapioca, sago palm, gambia, pineapples, tuba and patchouli. The chief mineral resources are tin-ore and iron-ore. China-clay is worked, but, owing to impurities, has not been found suitable for use in the Bombay cotton-mills. Good forest country exists north of Labis, and timber production averages 20,000 tons a year. The export trade is of the average annual value of $50,000,000, of which rubber represents three-fifths, copra, tin-ore, preserved pineapples, areca nuts and gambia, the greater part of the remainder. The Johore State Railway from Kuala Gemas to Johore Bahru is now leased to the Federated Malay States. The total length of roads maintained by the Government is over 600 miles.

Kelantan.—The dominating physical feature of Kelantan is the flat plain of 1,000 sq. m., extending behind the low sandy coastline. This plain is densely populated, and closely cultivated with rice, coconut and fruit trees. Of the total population in 1921 286,363 were Malays, for the most part born in Kelantan. Chinese numbered about 12,000. The broken hilly country south of the plain is thinly populated, but it contains the bulk of the foreign-owned estates. The staple produce is rice, most of which is grown for domestic consumption. Rubber, coconuts and betel nuts come next in importance. Other notable industries are fishing and weaving; but there is no mining worth mention, though tin mining is likely to develop with increased transport facilities. Recent prospecting indicates the possibility of gold being found in payable quantities. The total volume of trade is valued at about $9,000,000, of which exports represent about $5,500,000. The chief exports are gums and resins (mainly Para

rubber), copra, dried betel nuts, dry and salted fish, poultry and cattle, silk and cotton goods and dried hides.

Trengganu.—With the transfer to Great Britain of the Siamese suzerainty over the State of Trengganu in 1909, the sending of the triennial tribute of Bunga Mas (gold and silver filigree flowers) to the King of Siam ceased, and a British Agent with consular powers was appointed. In 1910, following the report of a commission of inquiry, the agent was replaced by a British Adviser, whose advice must be sought and followed in all matters of general administration and all questions other than those touching the Mahommedan religion. The soil and climate are suitable for the cultivation of Para rubber, coconuts, coffee and pepper; but the potentialities of the country lie in its mineral resources. Trengganu is the least opened up of the Unfederated States; but it is undoubtedly rich in minerals: tin (lode and alluvial) and wolfram are worked, and graphite, hematite, magnetite and monazite have been found. The total value of the trade of the State is about $9,000,000, of which exports represent nearly $5,500,000. The bulk of these, consisting of Para rubber, dried fish, tin-ore, and copra, go to Singapore. Agriculture employs over 48,000 people and fishing 9,000. About 95% of the population are Malays. Many of the Malay inhabitants show special commercial aptitude, and it is noteworthy that there are here instances, rare elsewhere, of Chinese trade financed by Malay capital.

The suzerainty of Kedah also passed to Great Britain in 1909 and the administration of the country was finally adjusted by a treaty signed at Singapore in 1923. The population in 1921 was 338,544, of whom 237,043 were Malays, 59,403 Chinese and 33,019 Indians. Only about 100 of the aborigines (Sakeis) are left, these being mostly located in the forest region of the Muda river. In North Kedah the people are mainly employed in cultivating rice, and in South Kedah, rubber, coconuts and tapioca. The estimated annual value of the exports is about $21,000,000, over 50% of which represents rubber. There are several good metalled roads communicating with Province Wellesley, Singgor and North Perak. The Federated Malay States railway administration has extended its service through Kedah into the independent and protected State of Perlis and trains have been running regularly since 1915. Bangkok and Singapore are now linked up by a connection through Perlis.

Perlis.—The principal industries in the small State of Perlis are rice cultivation and tin-mining. Most of the exports go to Penang, with which country there is regular and frequent steamer communication.

Survey and Land Settlement.—One of the principal reforms undertaken under British advice has been that in land settlement, the demarcation of property boundaries, and the issue of titles. To this end trigonometrical surveys have been undertaken. In Johore by 1925 a Settlement Act was in force in the districts of Muar and Batu, but not in other districts owing to the want of surveyors. In Kedah the survey is expected to be finished in 1927, and the Survey Department of that State has also supervised the work in Perlis. In Trengganu a settlement enactment was passed in 1924. Education has also received close attention. The new system in Johore, in which English is taught concurrently with Malay, promises success. The chief English school is that of Bukit Zohara at Johore Bahru. Education has also notably advanced in Kedah, where there are government English schools at Alor Star and Sungei Patani.

A notable inscription in Malay on a stone pillar, of date 1303, was discovered in 1923 near Kuala Trengganu. It has a strong admixture of Sanskrit and some of Arabic, and deals with certain phases of Islamic law. No example of this association of languages of earlier date than 1468 was previously known, and this inscription, which has been deposited in the Raffles Museum at Singapore, forms by far the earliest known record of the penetration of Mahommedanism into the Malay Peninsula.

MALINES, Belgium (*see* 17.489), had a population of 60,420 in 1923. The town was bombarded three times during the World War, and much damage done. The old Palais de Justice, restored shortly before the War, the school of music and the picturesque houses round the Bailles de Fer were ruined, and the south side of the cathedral and the chimes badly damaged. The cathedral was in progress of restoration in 1926. The Cloth Hall, also restored before the War, is used as the town hall. In 1924 the conversations between the Archbishop of Malines, Cardinal Mercier, with some dignitaries of the Anglican Church about the cause of Christian Reunion brought Malines again into public notice.

MALLOCK, WILLIAM HURRELL (1849–1923), British author (*see* 17.492), died at Wincanton, Somerset, April 2 1923.

MALMÉDY: *see* EUPEN AND MALMÉDY.

MALTA (*see* 17.507).—The period 1910–25 comprises changes of paramount importance in Malta, of which the most important are consequent on the World War of 1914–8. The Maltese provided a garrison for Malta, many seamen and stokers for men-of-war and minesweepers, and labour battalions for Gallipoli and Salonika; and they did excellent service in the hospitals. These services contributed to the grant of responsible government, which was established by the constitution of 1921.

Constitution.—On June 12 1920 the governor, Lord Plumer, communicated the decision of the British Govt. to grant a form of self-government which provided for responsible control by the Maltese ministers of local affairs. The letters patent came into force on May 16 1921, and provided for the creation of a senate of 17 members, with a legislative assembly of 32, the latter elected by proportional representation and having control of its own ministers. Judges are to be appointed by the governor in council, and can only be removed by a joint address from both Houses of the Legislature. The police are under ministerial control. Each House makes its own standing orders and rules, and defines its privileges; such powers, however, are not to exceed those of the British House of Commons. Debates may be conducted in English, Italian or Maltese; but all official entries are to be in English or Italian. All persons are to enjoy full religious liberty, no person is to be subjected to any disability or exclusion from office on the grounds of religion. A covering despatch empowered the legislature at its first sitting to declare Roman Catholicism the state religion. English is declared the official language of the administration: Italian is to be the official language of record in the law courts. British subjects, not of Maltese birth, may claim to be tried in the English language.

By the new Letters Patent, power to make laws regarding reserved matters—including everything pertaining to defence, the control of foreign relations, coinage and external trade—remains in the hands of the governor and commander-in-chief, assisted by a nominated council consisting of the lieutenant governor and the legal adviser (as ex-officio members) with senior officers of the navy, army and air force.

Population and Emigration.—The civil population, including Gozo and Comino was estimated on Dec. 31 1924 at 223,088; according to the census of 1911 it was 219,311. The death-rate in 1924 was 23.22 per 1,000 as against an average of 22·57 during 1910. Economic conditions became critical after the cessation of the War. The number of unemployed was swollen in 1919 by the discharge of about 15,000 men by the naval and military establishments, whereupon organised emigration was necessarily resorted to in order to ensure a suitable outlet for Maltese labour. The number of emigrants in 1924 reached the total of 3,277. The distress prevailing among the poorer classes after the War caused the Government to continue the bread subsidy in 1920 and a grant in aid thereof amounting to £250,000 was made from Imperial funds. General want and discontent led to serious disorders and to loss of life by riots on June 7 1919.

Schools.—On Dec. 31 1924 the number of Government day schools was 597. There were 58 private schools with a total of 26,744 scholars. The estimated expenditure on all branches of education for the year 1925 to April 1 was £92,370, excluding buildings. The teaching of Italian in the infant schools and in the first and second year of the elementary schools was entirely abolished in 1923.

Finance and Trade.—The revenue for the year ending April 1 1925 was £773,015 and the expenditure was £757,066; as against, in 1910, revenue £436,200 and expenditure £458,012. The amount of British treasury currency notes in circulation on March 31 1925 has been estimated at £750,000.

The total number of acres under crops in 1924 was returned at 42,964. It is estimated that the agricultural produce of the islands could only support the present population for three months in the year; the balance of foodstuffs and necessaries has to be paid for by work done for the Imperial forces, for the dockyard and for visitors and tourists, and also by large remittances to relatives at home which are received from Maltese abroad; moreover interest from investments outside the islands, and accumulated capital furnish margins to adjust the adverse balance.

Trade (inclusive of goods by parcel post but exclusive of bullion and goods in transit) was as follows:—

	1914	1924
Imports	£2,510,934	£4,416,453
Exports	1,053,854	1,451,766

The exports in 1924 include £443,708 value of coal furnished to merchant ships. In 1924 the value of imports from the United Kingdom was £1,367,201. The number of British steamers calling (not including war vessels and transports) was 349, with the aggregate tonnage of 989,517, and of foreign vessels 411, tonnage 606,501.

Defence.—The increased importance of Malta as a naval base was developed considerably in 1925, producing a period of increased prosperity; a floating dock was installed in 1925 capable of lifting the largest ships. An aerodrome has been built at Hal Far, suitable for main line airways. The greater part of the fortifications has been made over for civil purposes, in view that the importance of aircraft has altered fundamentally the needs and methods of military defence.

Antiquities.—Palaeological investigations have been continuous and excavations at the cave of Ghar Dallam have yielded important results among which were the discovery of human teeth assigned to the Neanderthal period and remains of many species of animals. In the period of 1910–25 archaeology has been enriched by further excavations of neolithic temples, and by the announcement of Professor Keith that the collection of bones at Ghar Dallam are due to that locality having been adapted by the prehistoric inhabitants as a pitfall to catch elephants and other wild animals when Malta was part of an isthmus which connected Italy with Africa, and was in the neighbourhood of a fresh-water lake.

See M. H. Egan, *Notes on Malta* (1922); P. F. Bellanti, *Studies in Maltese History* (1924). (G. St.*)

MALVY, LOUIS JEAN (1875–), French politician, was born at Figeac Dec. 1 1875. In 1906 he entered the Chamber as a Socialist-Radical and was an under-secretary in the Monis and Caillaux cabinets (1911), Minister of Commerce and Postal Services under M. Doumergue (Dec. 1913) and minister of the interior in the Viviani Ministry (June 1914). He retained this post under M. Briand and M. Ribot. On July 22 1917 M. Clemenceau charged him with lax administration in dealing with defeatists and agitators, and he resigned on Aug. 31. In October M. Léon Daudet brought against him a general accusation of treason. A commission, appointed at M. Malvy's own suggestion, decided on behalf of the Chamber that the Senate, sitting as a high court, should pronounce judgment on all the stated charges. On Aug. 6 1918 the high court acquitted M. Malvy of the charge of treason, but found him guilty of culpable negligence in the performance of his duties as Minister of the Interior from 1914–7, and sentenced him to banishment for five years, which he passed in Spain. In 1924 he represented France at the Morocco negotiations which took place in Spain, and in Oct. of the same year became president of the finance commission of the Chamber. M. Malvy again became Minister of the Interior in the Cabinet formed by M. Briand in March 1926, but he resigned in the following April. (*See* FRANCE.)

MAN, EVOLUTION OF.—The late Sir E. B. Tylor, writing on the evolutionary theory of man's origin, made the following statement: "In one form or another such a theory of human descent has, in our time, become part of an accepted framework of zoology, if not as a demonstrable truth, at any rate as a working hypothesis which has no effective rival." When Sir Edward Tylor made this statement in 1910 he was in his 78th year; his memory could carry him back to a time when it was believed that man had come into the world as a special creation some 4,000 years before the birth of Christ and owed no kinship to other living things. He was 27 years of age when Darwin's *Origin of Species* was published in 1859; in 1865, two years after Huxley had issued his renowned treatise on *Man's Place in Nature*, he himself published a work which threw a new light on human history, *Researches into the Early History of Mankind and the Development of Civilization*. When Darwin's *Descent of Man* came out in 1871, Tylor's *Primitive Culture; Researches into the Development of Mythology, Philosophy, Religion, Art and Custom*, kept it company. By the end of the 19th century he had seen chair after chair in the universities of the world filled by men who were convinced that evolution was true; at his death in 1917, at the age of 85, he had seen another generation of inquirers grow up who, after applying Darwin's teaching to all departments of man's world—to his body, mind and culture—remained convinced that, as a working hypothesis, the doctrine of evolution had no rival.

Summary of the Evidence

Embryology.—No matter what aspect of man the student of to-day may select for study, the conviction that evolution (*q.v.*) is true is forced on him. If he investigates the development of the child in the womb he comes across a complicated series of appearances which can be explained only if Darwin's teaching is accepted.

Comparative Anatomy.—If he studies the structure of man's body he finds it framed on the mammalian plan, and if he compares it with that of anthropoid apes he finds the points of resemblance to be so numerous and so close that he cannot think that such a degree of resemblance could be a result of mere chance. If he inquires into the periods through which a newly born child passes to reach manhood or womanhood, he finds the animals which are most human in this respect are the great anthropoids—the gorilla, chimpanzee and orang. If he takes into consideration the diseases to which man is liable, he finds that human diseases are more readily communicated to the great anthropoids than to any other living animals. Particularly is he impressed by the fact that the blood of man and of the anthropoid apes, when tested against each other, react almost in the same way. To account for the presence of so many vestigial structures in man's anatomy, he feels impelled to suppose that man has come of an ancestry in which these vestiges were fully grown and useful. A child may be born with its body malformed; it may suffer from hare-lip, cleft-palate or many other kinds of deformity, including the presence of a tail; medical men cannot account for such malformations if they look on man as a special creation; they can give a rational explanation of their occurrence in man's body if they accept the teachings of evolution.

Palaeontology.—In recently formed strata of the earth fossil forms of man are found; those from the older strata are more ape-like than those from the newer. In still older strata are found fossil fragments of great anthropoids; in still more ancient, the remains of small anthropoids; deeper still in the earth's records no trace of anthropoid has yet been discovered. In these older strata occur fossil remains of small monkey-like primates. The geological records, so far as they are yet known, support Darwin's theory of man's origin; they are altogether against the belief that man appeared suddenly—a special act of creation.

Human Races.—More especially is the student of human races driven to Darwinism for an explanation of his many problems; even if he believed that man had appeared originally by an act of special creation he must formulate a theory of evolution in order to account for the divergent races now living.

Although in thought and deed man rises far above any member of the brute creation, yet students of his brain find that it is modelled, part for part, on exactly the same pattern as that of the anthropoid ape. Those who inquire into man's mental qualities, his emotions, his habits, his tendencies and his modes of thought, find much which can be explained only by supposing that he has ascended from a lower order.

For these reasons all present-day students who are applying themselves seriously to the unravelling of man's history accept the theory of evolution as a truth. This conviction has spread from professional circles into the public thought of our time and altered the outlook of a large section of the lay mind; yet there still remain numbers of the public of Europe and of America who, impressed by the great and real differences which separate the mentality of the lowest grades of mankind from that of the highest grade of ape, cannot believe that man has arisen from a lower form by any natural or evolutionary process. The State of Tennessee has passed a law forbidding, in state-supported schools, " the teaching that man has descended from a lower order of animals." In June 1925 Mr. Scopes, a school teacher, was prosecuted under this law, found guilty and fined $100. Since then certain other states have enacted similar laws.

Man's Genealogy

Darwin's Views.—Although there is a complete agreement among professional students that man is a member of that order of mammals to which Linnaeus gave the name " Primates " and that his lineage, when traced backwards, will be found to branch off from the primate tree, there is a sharp difference of opinion as to the exact point in the tree, and the approximate date in geological time, at which the human branch separates from those other main branches which represent the lineage of anthropoid apes and of monkeys. It is clear from statements made in

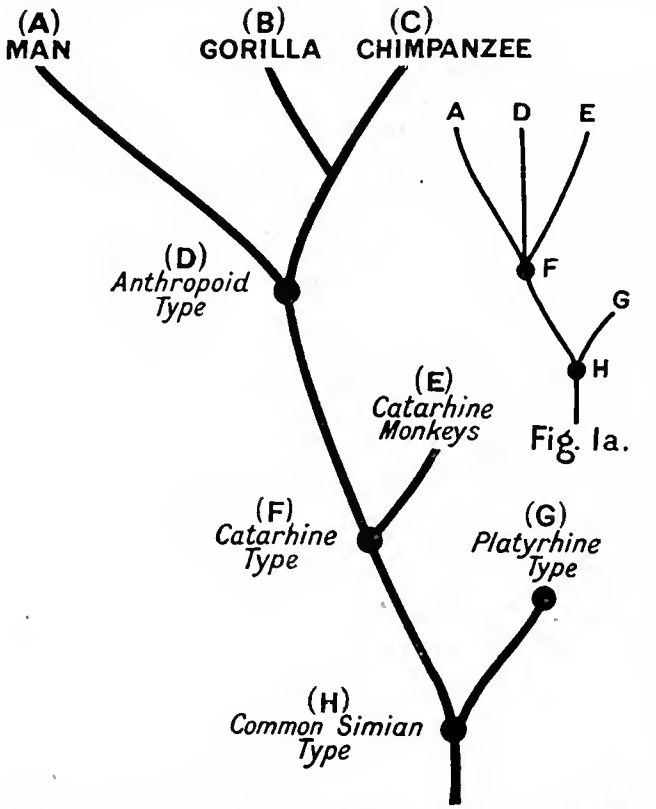

Fig. 1a.

Fig. 1.—A diagram to illustrate Darwin's conception of Man's lineage.

Fig. 1a.—Another possible relationship, also mentioned by Darwin.

the *Descent of Man*, that Darwin regarded the gorilla and chimpanzee as more nearly akin to man than other living primates and, on the evidence available in 1871, thought it probable that man and the African anthropoids were co-descendants of a common anthropoid which had its habitat in Africa (fig. 1). He regarded the catarhine type of monkey—the type exemplified by the monkeys of the Old World—as representatives of a still older ancestral form. Darwin traced the common anthropoid stock, which gave birth not only to the ancestral lines of man, the gorilla and chimpanzee, but also to those of the orang and gibbon, back to a common catarhine type. This catarhine type, he presumed, was the offspring of a still older common simian or monkey-like type, one which existed in the Eocene period of the earth's history and gave origin not only to the catarhine monkeys of the Old World but also to the platyrhine monkeys

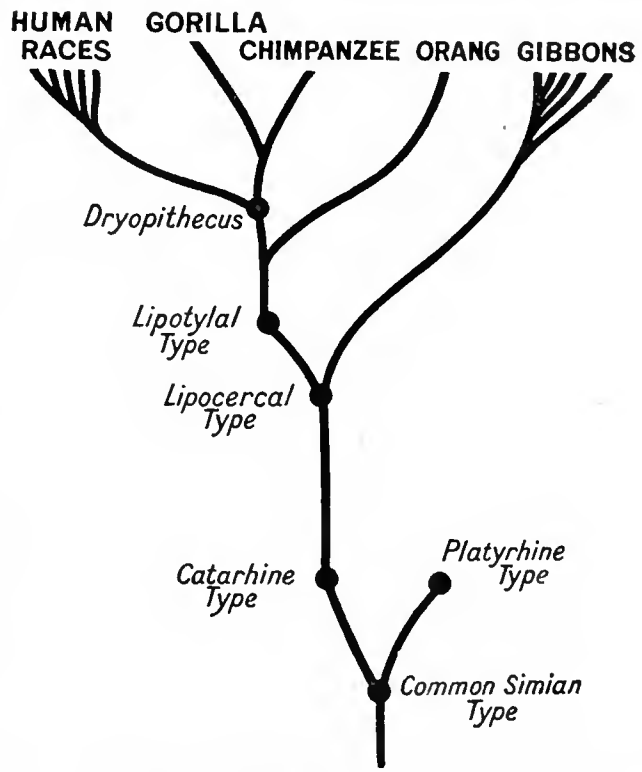

Fig. 2.—Haeckel's conception of Man's descent as illustrated by a phylogenetic tree, published in 1866.

of the New World. Thus man's history, as Darwin saw it, did not begin until after the ancestral type of anthropoid had been evolved; the appearance of an anthropoid type from a common catarhine ancestor and this from a common simian stock, represent prehuman stages in the evolution of the higher primates. It is noteworthy that Darwin's mind remained open as to the exact point at which the human stock branched off from the general primate tree; more than once in the *Descent of Man* he writes as if the human lineage might have come off, not from the anthropoid stem, but lower down in the primate tree, from that of the common catarhine stock (fig. 1a).

Haeckel's Views.—On no occasion did Darwin throw his conception of man's lineage into a diagrammatic form. The first to construct an evolutionary tree of man's descent was Ernst Haeckel; this appeared in his *Generelle Morphologie* published in 1866, five years before Darwin's *Descent of Man* was issued. This pedigree is still worthy of study (fig. 2). Haeckel perceived that the small form of anthropoid ape, the gibbon, was more primitive and earlier in point of evolution than the three living great anthropoid apes (orang, chimpanzee and gorilla) and supposed that in the evolution of the great anthropoids from the ancestral catarhine type there was interposed a small anthropoid stage to which he gave the name Lipocerca (λιπεῖν, to lack, κέρκος, tail). This small anthropoid stock (Lipocerca) gave origin, he supposed, to gibbons and to the ancestral stock of the great anthropoids—for which Haeckel proposed the name Lipotyla (λιπεῖν, to lack, τύλη, cushion)—anthropoids which, unlike the gibbons, were destitute of ischial callosities or natural cushions on which gib-

bons and Old World monkeys seat themselves. This cushionless anthropoid stock (Lipotyla) he regarded as ancestral to the various races of mankind. From the Lipotyla, which gave origin to man, there also branched off, at an early stage, the ancestry of the orang and, at a later, the common ancestry of the chimpanzee and gorilla. Thus Haeckel regarded the gorilla and chimpanzee as more nearly related to man than other living anthropoids. It is also remarkable that he placed the extinct Miocene form of anthropoid ape, known as Dryopithecus, on the line which led up to the gorilla and chimpanzee on the one hand and to human races on the other. Thus it will be seen that in Haeckel's opinion man was the descendant of an anthropoid ape.

Later, he introduced considerable modifications into this family tree. In the third edition of his *Evolution of Man* (English translation, 1879) he interpolated into man's ascent from an anthropoid to a human state an intermediate stage represented by *ape-like* men—beings who were manlike in form and in gait but lacked man's power of speech. To such hypothetical beings he gave the name *Pithecanthropi*.

Modern Views.—In 1892 Prof. E. Dubois discovered in the island of Java the fossil remains of a being which answered very well to this hypothetical stage, and named this fossil form of evolving man *Pithecanthropus erectus*. Haeckel presumed that his pithecanthropi had lived in the Pliocene period; Prof. Dubois is of opinion that his transitional form of man lived in Java towards the end of the Pliocene period. Discoveries made by Dr. G. E. Pilgrim of the Geological Survey of India and by members of that survey in the latter part of the 19th century have

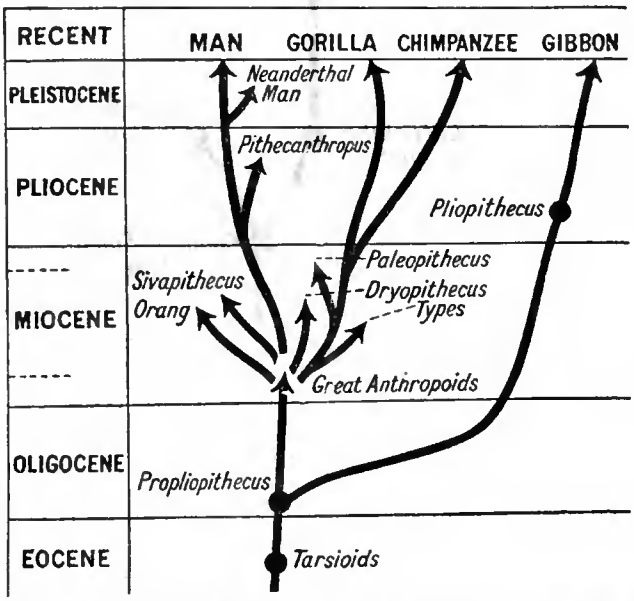

FIG. 3.—A phylogenetic tree of the higher primates (after W. K. Gregory, 1916).

proved that India, during the Miocene period and the earlier part of the Pliocene, was the home of great anthropoids of many and diverse kinds, several of them belonging to the type of Dryopithecus which Haeckel, at an early period, regarded as a possible ancestor to man. Others of these fossil Indian or Siwalik anthropoids show affinities to the orang, to the chimpanzee and to the gorilla, while still another—*Sivapithecus*—is regarded by Dr. Pilgrim as an early representative of the human family. Notwithstanding these revelations from India and taking all their bearings into consideration the majority of modern authorities (Dubois, W. K. Gregory, Elliot Smith, Keith), in constructing diagrams to illustrate the affinities and lines of descent for the higher primates, depict the human stem (fig. 3) as springing from the vicinity of the stem which gave rise to the gorilla and chimpanzee. The conception, first formulated by Haeckel, that a Miocene anthropoid of the type of Dryopithecus (fig. 3) may stand as a common ancestor to man and to the African anthropoids is still regarded as possible.

Doubts Raised by the Occurrence of Parallel Evolution.—There is a line of evidence, accumulating at the present moment, which tends to undermine the confidence of those who have drawn up phylogenetic trees of man's descent. All who have inquired into the evolution of horses and elephants, by the study of fossil forms found in widely separated regions of the world, have become impressed by the fact that horses and elephants in America have passed through evolutionary changes of the same kind and in the same order as have done their representatives in the Old World. This tendency for the descendants of a common ancestry to undergo *parallel* or even *converging* evolution, has been very fully expounded in the published works of Dr. Henry Fairfield Osborn (*Origin and Evolution of Life*, 1918). That parallel evolution has been potent in the order of mammals to which man is assigned there can be no doubt. The monkeys of the New World parted company from those of the Old early in the Eocene period; it is probable that at the time of their separation they had only reached the stage represented by the Tarsioids, a family of monkey-like primates, which has now only one living representative—the Tarsier (*Tarsius spectrum*) of Borneo and other islands of the Malay Archipelago. Although parted thus early, New and Old World monkeys have acquired corresponding structural modifications—modifications of a kind which we cannot regard as having been present in their common ancestor. The brain of the South American spider monkey (Ateles), that of the Old World monkeys of the semnopithek type, and that of the small anthropoid or gibbon, have many common characters which could not have been present in the brain of their Eocene ancestor.

We may legitimately infer, however, that a bias or tendency to produce similar or almost identical modifications was latent in the common ancestor. If parallel evolution has been at work in one section of the order of primates it may have been at work in another, and we must therefore keep in mind the possibility that man and the gorilla may have acquired their many and striking points of structural similarity independently. Cope (1882) and Hubrecht (1897) supposed that human lineage had parted from that of the anthropoids near the base of the primate phylum; if this were so man would have an independent pedigree of immense length. In more recent times Prof. F. Wood Jones (*The Problem of Man's Ancestry*, 1918) has put forward the theory that man, because of the number of primitive and generalised features of his structure, is to be traced back to an independent origin from a tarsioid ancestor. Such a view entails the need of supposing that the multitude of structural similarities shared by man and the great anthropoids must have been acquired by each independently—a supposition which is unacceptable to the majority of those who have made a special study of the higher primates living and extinct.

Klaatsch (*Die Stellung der Menschen im Naturganzen*, 1911), (*Evolution and Progress of Mankind*, 1923) made a larger demand on the powers of evolution to reach the same end by diverse routes. This voluminous author traced the origin of mankind to an anthropoid ancestry, but supposed that the ancient inhabitants of Europe—Neanderthal man, known only from his fossil remains, and the living Negro peoples of Africa had arisen from the same stock as the gorilla and chimpanzee, while Mongolian peoples and men of the modern European type had sprung from the same lineage as the orang. Klaatsch believed in the polygenetic origin of human races, whereas nearly all modern authorities hold a monogenetic theory of man's evolution. They cannot believe that black and white races, which although outwardly dissimilar are yet structurally so alike and freely capable of interbreeding, could have sprung from different branches of the primate tree. They rely on the axiom that likeness in structure means similarity of descent.

Man an Aberrant Primate.—In charting the family tree of the Higher Primates modern authorities differ as to the position which should be assigned to man. Prof. Eugène Dubois represents the human stem as the main and direct continuation of the trunk of the primate tree (*Nature*, vol. 53, p. 245, 1896); from this main trunk all the other members of the primate order

are made to come off as side branches. Man is given the central position of his order; he forms the apex of the primate tree. Prof. Elliot Smith (*Evolution of Man*, 1925) also gives the human family the central position as a direct continuation of the main primate stem. In reality man is the most aberrant member of his order; in brain and in the modifications of his lower limbs he has departed farther from the ancestral primate state, so far as we know that state by the study of fossil remains, than any member of the order; he has retained less of the structural organisation of the original primate than all the others. Apparently in the evolution of the higher primates there has been the same tendency as is to be noted in modern political parties—a tendency for an extreme wing to move ever further from the central group of conservatism. The human family represents the extreme wing in the order of primates; *Tarsius*, greatly modified as it is, retains the essentials of the central or conservative group.

Man's Zoological Position

Zoologists classify animals into families, sub-families, genera and species, according to their degrees of structural likeness; they presume, although fully aware that parallel evolution can and does take place, that two animals, such as the gorilla and chimpanzee, which are so similar in the structural details of their bodies, owe that similarity to their descent from a common ancestry. Darwin urged rightly that in settling the zoological relationship of one group of animals to another, more weight must be attached to the points wherein they agree than to those in which they differ.

Huxley's Views.—In the masterly analysis of man's structural relationships given by Huxley in *Man's Place in Nature* (1863), more stress was laid on the anatomical differences which separate man from the gorilla than on the points wherein they agree. Huxley held that differences of a like kind and of an equal degree separated the gorilla from any form of catarhine or platyrhine monkey a critic might choose for comparison. He held that if evolution could produce the structural gap which separates a monkey from the gorilla it could also bring about the abyss which divides the gorilla from man. Huxley's conclusions are still valid; indeed, the modern anatomist is convinced that the structural hiatus which lies between a baboon or any other form of monkey and the gorilla is much wider than that which lies between the gorilla or chimpanzee and man. When tested by modern methods, the blood of the chimpanzee shows a much closer affinity in its reactions to that of man than to that of any Old World monkey; the blood of monkeys of the New World, when submitted to the same tests, reveals a still more distant affinity (Prof. G. H. Nuttall, *Blood Immunity and Blood Relationship*, 1904). Huxley included in one family the great anthropoids (gorilla, chimpanzee and orang), the small anthropoids (siamang, gibbons), and the various genera of monkeys of the Old World; if we are to be guided by anatomical considerations we must give to each of these groups the rank of a family. The same rank—that of a primate family—must be given to the section which embraces all the various races and types of mankind, living and extinct. The various genera of New World monkeys make up a fifth family of primates.

The Primate Families.—Thus in that part of the living animal kingdom to which man belongs, there are five families—the human family, that of the great anthropoids, that of the small anthropoids, the family of catarhine or Old World monkeys and the family of platyrhine or New World monkeys. These families are separated by structural gaps of about equal magnitude. From the platyrhine monkeys upwards, these families form an ascending series in the sense that each succeeding family marks a further departure from the ancestral tarsioid type, the point of highest differentiation being reached in the human family.

Evidence of Man's Descent

Anatomical.—The members of these five families of primates have a common structural substratum—an inheritance from the ancestral stock from which they have all descended. Each family in the course of evolution has come by anatomical features which are peculiar to itself. A full analysis of the structural details of man's body shows that about 30% of them are peculiar to himself. The corresponding characters of the gorilla number 16%; the gibbon has about the same proportion of features peculiar to its own family (Keith, *Rivista di Antropologia*, vol. 20, p. 1, 1916). As examples of man's peculiar characters we may cite his nude skin, his projecting nose with well marked wings, the size of his brain, the strength of his thigh, the form of his leg, the shape of his foot.

Common Characters.—Further analysis reveals in man's body a series of characters which he shares with only two other living animals—namely, the gorilla and chimpanzee. These amount to nearly 9% of the total points selected for comparison, but if we include in this group features which man shares with the gorilla alone or with the chimpanzee alone, then man has in his body about 26% of characters which he shares with gorilla and chimpanzee or with gorilla alone or chimpanzee alone. Such characters, we presume, are derived from a common ancestor which gave birth to man and to the great anthropoids of Africa. As examples of characters common to the three we may cite the air chambers which branch off from the nasal cavity. These have the same arrangement and are of the same number in man, gorilla and chimpanzee. Another example is to be found in the small bones of the wrist. Of the higher primates, only in these three has the *os centrale* disappeared as a separate unit from the carpus; yet in a foetal stage this bone is present in all three; and as a separate element in adults of all the other higher primates.

Descending still lower in the strata of human anatomy we encounter a group of characters which man shares with the three great anthropoids. We may speak of man and these three as the giant primates, for compared with the earlier types they are giants, or we may apply to this group Haeckel's convenient name—*Lipotyla*. Man shares with the other giant primates 10% of similarities of structural detail; to this we may add 5% which he shares with the orang and with the orang only, characters which the chimpanzee and gorilla have apparently lost or perhaps never possessed. Going still lower in our analysis, we find over 8% of characters which are common to the gibbon as well as to the great anthropoids. With the gibbon man shares 8% of structural features which are not to be seen in the bodies of the great anthropoids. In this case, again, we have to suppose that man and the gibbon came by those characters long after they separated from a common ancestor, or that the great anthropoids have lost them in the course of evolution while man and the gibbon have retained them.

Lower in the scale of our analysis we come upon features in man's body which he has apparently retained from a catarhine ancestry; at least, to find their counterparts we have to go to the bodies of Old World monkeys. In man's body there are 5% of such catarhine features; in the gorilla's body such features are three times as numerous. It is remarkable that platyrhine characters, features to be seen in the bodies of the New World monkeys, should be as numerous as catarhine in man's body.

There is a small residue of anatomical details in human anatomy attributable to a still more distant past, a heritage from a tarsioid or lemuroid ancestry. From the details revealed by anatomical analysis it is plain that evolution has not proceeded in an orderly or simple manner in shaping the bodies of the higher primates; characters are curiously scattered. Yet to explain the distribution of characters in the various families we must suppose that man's ancestry is linked closely to that of the African anthropoids—the gorilla and chimpanzee. In some instances we obtain help in explaining the distribution of characters by calling in the aid of *collateral* or parallel evolution; in other cases Mendel's discoveries in heredity assist us; further, we see that the body of man and of ape is a great mosaic work of structural elements and that progressive changes may occur in one set of units while retrograde changes affect another set.

In recent years the formation of the human embryo in the womb, the complicated changes which transform the embryo into a foetus and the elaborate processes which produce the organs of the ripe child from embryonic rudiments, have been

studied by an ever-growing army of inquirers and by methods which show an ever-increasing precision. Embryologists find it necessary to assume that the law of evolution holds for man; unless they make this assumption they can offer no rational explanation of the complex changes which engage their attention. In its broad lines development pursues the same course in the human body as in that of all vertebrate animals. What Francis Balfour in 1885 saw taking place with diagrammatic clearness in the embryo of the dog-fish has given clues to the more complex and obscure processes now known to occur in the embryo of man.

The developing human egg, when it becomes established in the mother's womb, undergoes a series of elaborate and peculiar changes. The investigations carried out by the late Dr. Emil Selenka (*Menschenaffen. Studien über Entwickelung und Schädelbau*, 1898–1906) revealed the fact that only in the wombs of four other living mammals, the gorilla, chimpanzee, orang and gibbon, do the same changes take place. The process by which the placenta is formed, thus establishing a means of supplying the unborn child with nourishment, is exactly the same in man as in anthropoid apes. It is true that in *Tarsius* we see outlined the basal plan of placentation met with in the higher primates, but it is also true that in the placentation of the monkeys of the Old World and also in that of the New World we see a stage which leads on from the lower or tarsioid condition to the higher or anthropoid form. In the embryos of man and of the anthropoids an external jointed tail is produced in the fifth week of development; by the end of the eighth week it has shrivelled and become submerged, leaving a dimple at the point of the caudal region where it sinks below the surface. These are a few examples of some of the remarkable similarities which link the embryological history of man with that of the anthropoid apes.

Recapitulation, Interpolation, Adaptation.—When in the later decades of the 19th century anatomists applied themselves to unravelling the development of man's body, they expected it to recapitulate, in full detail, the various stages of his evolution. In this they have been disappointed, because in the growth of the embryo and of the foetus we see three different processes at work. We see recapitulation taking place; we also see new characters being interpolated from the time the embryo makes its first appearance until all the parts of a formed child are laid down; further we see at every stage the body of the embryo and of the foetus being adapted to a life within the womb. When gill-clefts appear in the neck of the human embryo towards the end of the first month of development we see a recapitulatory and very distant phase exemplified. When we look at the developing human foot, with the expectation of finding an anthropoid phase, we search in vain. The great toe is never a free and separate member in the human foot as it is in the adults of all other primates. There is a stage in the development of the feet of primates when all the digits diverge equally from the tarsal base; man and ape pass through this stage and man clings to it as it were, whereas all the other primates pass on to a final prehensile stage. Yet in the sole of the newly born child we see the same flexion lines as in that of the gorilla; we find the same muscles in the great toe of the human foot as in that of the gorilla; we find the joint at the base of man's great toe, especially in the foetus, moulded in the same form as the gorilla. We cannot explain these appearances unless we believe that the human foot has been evolved from one like that of the gorilla, more especially as the foot of the gorilla shows a curious blend of human and monkey-like features.

The human great toe does not recapitulate ancestral history; developmental changes which mould the great toe into the human pattern set in just when the simian ones are due; the human changes do not succeed but replace those that give the ape its prehensile foot. New changes have been intercalated in the evolutionary sequence. In a multitude of details the human embryo no longer recapitulates the series of changes gone through by its ancestors. It is true of every part of the human body; human characters begin to peer through its higher primate qualities before development is a month old.

Of the changes which affect the developing human body those which represent adaptations to life within the womb are the most important. The child draws its living from its mother's body; it is sheltered and kept warm; it has not to seek its living nor defend itself; such qualities need not be attained until the time of birth; until then nature is free to work out what experiments she will. It is a remarkable fact that many of man's distinguishing features are to be met with during foetal stages in the development of anthropoid apes. A stage which is transient in the foetal ape becomes permanent in man. We may take as an example the comparative hairlessness of man's body. A foetal chimpanzee, in the eighth month of development, resembles a human foetus of the same age; both have hair growing freely on their scalps, but the rest of their bodies, although provided with lanugo, appear to be nude. By birth the chimpanzee's body is covered with hair, but the human child retains the foetal state. Yet all known primates save man have their bodies thickly covered with hair; hairlessness is not an ancestral condition, but one made possible by the retention of the young in the shelter of the womb. The skin provides us with another example of foetal inheritance. In the fair or white stock of mankind the skin has become relatively free from pigment. In their earlier stages of foetal development apes are unpigmented; they darken as the time of birth approaches. White men have come by their colouring through the inheritance of a foetal condition, one which is certainly not ancestral.

Many examples might be cited of man coming by distinctive characters by retaining foetal states, but the following may be taken as representative. In all foetal primates the brain is relatively large and the jaws absolutely small; this is certainly not an ancestral state, for in all the older forms of primate the brain is small and the jaws large. Man is distinguished by the large size of his brain and the relatively small size of his teeth and jaws. How he compares with adults of great anthropoid apes may be seen from the following data. We may take the capacity of the cranial cavity to represent the size of brain and the area of the palate to represent the size of the jaws. In a well-grown adult European male we expect a cranial capacity of 1,500 c.c. and a palatal area of 25 sq. cm., there being 60 c.c. of brain space for every square centimetre of palate. The average male gorilla has a cranial capacity of 470 c.c., a palatal area of 72 sq. cm., that is, 5·8 c.c. of brain space for every square centimetre of palate. The corresponding figures for the average male orang are: 412 c.c., 62 sq. cm., giving a cranio-palatal ratio 6·6:1; in the average male chimpanzee the figures are: 390 c.c., 46 sq. cm., giving a ratio of 8·5:1. There is a wide gap between the European cranio-palatal ratio 60:1 and that of the chimpanzee, 8·5:1. We may fill the gap somewhat by citing a Tasmanian skull with a capacity of 1,350 cc., a palatal area of 36·7 sq. cm., and a ratio of 36·7:1.

We find a still nearer approach to the anthropoid condition in the fossil skull of Rhodesian man in which the cranial capacity is 1,300 cc., the palatal area 41 sq. cm., the cranio-palatal ratio 31·7:1. Even this ratio is far above that of the chimpanzee, 8·5:1; but if we take a suckling chimpanzee, in which the cranial capacity is 260 c.c. and the area of palate 13·6 sq. cm., we obtain a ratio 19:1, an approach to the human proportion. If we take a still earlier stage, such as may be observed in a chimpanzee foetus during the eighth month of development, we find a ratio which is human in its magnitude. Man has come by his small palate by retaining a foetal anthropoid condition, and this is true of all the parts of man's skull which are concerned in mastication. This tendency to foetal inheritance is not confined to the human branch of primates; in certain genera of New World monkeys, particularly in Chrysothrix and Cebus, we see in their small jaws and large heads the same law at work.

The belief that many of man's foetal characters do not reflect ancestral stages, but foreshadow the trend of future evolution, was held by several anatomists in Germany towards the end of the 19th century, particularly by Ranke. The law of foetal inheritance, so far as it relates to man, has been greatly extended during recent years in a series of papers by Prof. L. Bolk of

Amsterdam (*Proc. of the Roy. Acad. of Sc. of Amsterdam*, 1921–5). Embryological evidence, if it has failed to reveal the pithecoid states through which man has passed in his ascent, does provide conclusive evidence of his simian ancestry. In the development of his brain, for example, we see that the first fissures to appear are those which occur in the brains of the higher monkeys; the next are those which are found in the brains of the great anthropoids, and later still the secondary human sulci are formed; but never at any stage does the human brain correspond to that of monkey or of anthropoid. If embryology has failed to reveal the details of man's history, it has shown that the processes of evolution are at work on the foetal body; if the study of the foetus does not help us to decipher man's past, it does seem to provide a basis on which we may forecast the future of the human body. The brain of the gorilla, in the totality of its characters, is the most like that of man; these two are structural allies, yet evolution has moulded their bodies in opposite directions. During growth the gorilla replaces all its foetal characters by those of brutality and strength; in man the tendency has been to retain the delicate physique of the young and to shed those of a more brutal nature. Why the one fate overtook the gorilla and another fell to man remains an enigma.

Biological Evidence of Man's Evolution

Blood Tests.—Not only are the bodies of man and anthropoid apes fashioned on similar lines, but, as was demonstrated at the beginning of the present century, their living tissues give like reactions. In 1900 Dr. Hans Friedenthal injected a small amount of human blood into the veins of a chimpanzee; its vital qualities were so similar to those of the chimpanzee that no disturbance followed the operation. When an equal amount of the blood of a macaque monkey was injected into the veins of the chimpanzee there was a slight reaction; the corpuscles of the macaque's blood were destroyed and ejected by the kidneys. When the blood of an ox was used a violent reaction was produced, the foreign blood being destroyed and thrown out.

Prof. G. H. F. Nuttall, of Cambridge University, thereafter elaborated a more precise method of estimating blood-affinities, by which very small quantities of blood can be tested against specially prepared antisera. In 1904 appeared his classical work *Blood Immunity and Blood Relationship*, containing the results of tests carried out on three species of anthropoid ape, 28 species of Old World monkeys, and nine species from the New World. The blood of all these species was tested against a human antiserum. The blood of the anthropoids gave a full reaction—100%; that of the Old World monkeys gave a lesser reaction or precipitation, one equivalent to 92% of the full; that of the New World monkeys 78 per cent. At the time Prof. Nuttall was making these investigations in England, Dr. Uhlenhuth was carrying out independent inquiries in Germany, and reached corresponding conclusions as to degrees of affinity. The tests devised by Nuttall and by Uhlenhuth utilise the fluid or serum of the blood. Recently Drs. Landsteiner and Miller (*Jour. Experim. Med.*, vol. 42, p. 841, 1925) have utilised the corpuscular elements of the blood and find that they give more delicate reactions than those given by the serum. They devised tests which serve to distinguish the blood of the chimpanzee from that of man, but which failed to discriminate the blood of the white man from that of the negro.

Disease Reactions.—The reactions of living tissue are also tested by disease. Man is peculiarly susceptible to syphilis; the animals most akin to him in this respect are the great anthropoid apes. Monkeys are difficult to inoculate with syphilis, and when they suffer, take the disease in its mildest form. Anthropoid apes are almost as suceptible to typhoid fever as man is. When chimpanzees are kept in confinement they are liable to that modern disease of man—appendicitis. Anthropoids react to stimulants, sedatives and poisons in the same manner as human beings. The brains of the great anthropoid apes are smaller and are less convoluted than is the case in man, yet when the living cortex is stimulated by electrical methods, be it in man or anthropoid ape, the same reactions follow when corresponding convolutions are excited. Surgeons have found that observations made by experimental physiologists on the brains of anthropoid apes afford reliable guidance when they have to operate on the brain of man. Thus the evidence supplied by vital tests bears out the conclusions forced on anatomists by similarity of structure—namely, that great anthropoid apes, in an evolutionary sense, are near akin to man.

Evidence of Vestigial Structures

Nearly all the structures which have become greatly reduced or are mere vestiges in the body of man have undergone a similar fate in the bodies of the anthropoid apes. In them as in man the tail has disappeared, all save its basal part, which has sunk beneath the surface to form the coccyx. It is true that the vermiform appendix of man is smaller than that of any of the anthropoid apes, and that in half of the Europeans who reach the age of 70 its lumen has become closed, yet it is more than doubtful if this structure should be reckoned vestigial in the body of either man or anthropoid. The *palmaris longus*, the *plantaris*, the *pyramidalis*, muscles which are reduced or fibrous in man, are in the same state in anthropoid apes. Such evidence points to a common origin for anthropoids and man, but it throws no light on man's more immediate relationship to any member of the anthropoid group.

There are two muscular vestiges, however, which point to man's kinship to the African anthropoids. There is a muscle in the neck of monkeys which helps to lift the shoulder; it is called the *levator claviculae*. It has almost disappeared from man's body; it is met with only once in a hundred dissections. This muscle shows definite signs of reduction in the gorilla and chimpanzee, but not in the orang or gibbon. All monkeys have a strong muscle called the *latissimo-condyloideus*. When a monkey is climbing, and has seized a branch with its hand, it uses this muscle to pull the trunk upwards. It is a particularly strong muscle in the gibbon, well developed in the orang, somewhat reduced in the chimpanzee, partly fibrous in the gorilla, wholly fibrous in man, although in 5% of human bodies some muscle fibres may be detected. Lately Dr. A. H. Schultz, of the Carnegie Institution of Washington, has found a remarkable example of the persistence of a vestige in man's body (*Amer. Jour. Physic. Anthrop.*, vol. 7, p. 149, 1924). Lemurs, which branched off from the primate stem at a very distant geological period, have a tuft of touch vibrissae at the wrist. Monkeys were supposed to have lost these vibrissae; Dr. Schultz found them in foetal stages of monkeys both of the Old World and of the New. On examining the wrists of human foetuses in the second month of development he found a raised plaque at the spot where the touch vibrissae are situated in lemurs.

The Evidence of Fossil Remains

Pithecanthropus Erectus.—The discovery which throws most light on the evolutionary progress of man was made in Java during 1891–2 by Prof. Eugène Dubois, then a surgeon in the colonial military service, and later professor of geology in the University of Amsterdam. In a stratum which contained the fossil bones of many extinct species of animals he obtained five fragments of a strange kind of being, one which he regarded as a transitional form between man and ape—a real missing link. He named it *Pithecanthropus erectus*, and assigned it to a separate family of primates—one lying on the borderline between anthropoids and man. (*Pithecanthropus erectus, eine menschenahnliche Uebergangsform aus Java*, 1894.) The five fossil fragments found were: a skull cap which outwardly had the form which might be expected in a giant form of gibbon, a left thigh bone and three teeth. The most distant of the fragments were twenty paces apart. Later he added a sixth fragment—part of a lower jaw found in another part of the island but in a stratum of the same geological age. The skull cap is flat, low and has great eyebrow ridges; its characters are more simian than human, yet when Prof. Dubois succeeded in obtaining a cast from the interior of the skull cap, that cast bore on it the convolutionary pattern of the brain of Pithecanthropus, and that

pattern proved to be altogether human. Pithecanthropus, the fossil man of Java, had a brain which was smaller, simpler and infinitely more primitive than that of the lowest living men.

By this discovery Prof. Dubois caught the human brain in the act of evolving. Certain cortical or convolutionary areas in man's brain are known to be concerned with sight, hearing and touch, and the reception of messages from other sense organs; a "motor" area is concerned in the initiation and control of voluntary movements. Between these primary areas of the cortex lie association areas which have to do with the memory and the interpretation of what is seen, heard or felt. The cortex of part of the frontal lobe—the prefrontal cortex—is concerned in the acquisition of skilled movements. These secondary or association areas of cortex, which lie between and separate the primary areas, are the basis of man's educability—his capacity to learn from experience. In the brain of Pithecanthropus the association areas are much less developed than in the brains of the lowest of living human races. Yet all the essentially human parts are represented. It is even possible that the owner of this brain was capable of speech.

A further study of the brain-cast has convinced Prof. Dubois that Pithecanthropus must be placed in the human family (*Proc. Roy. Acad. Sc. Amsterdam*, vol. 27, nos. 5, 6, 1924). The brain of this "fossil" man is now estimated to have had a volume of at least 900 c.c.; the largest-brained gorillas rarely rise above 600 c.c.; the lowest-brained of human beings occasionally falls below 1,000 cubic centimetres. Pithecanthropus in size of brain lies on the verge of humanity. His teeth, if large, are essentially human in form of crown and root; the socket for the canine, in the fragment of lower jaw, shows that this tooth was not massive and pointed as in anthropoid apes. The thigh bone is human altogether, and gives proof that Pithecanthropus walked as men do.

Pithecanthropus was assigned by Prof. Dubois, on reliable evidence, to a date late in the Pliocene period; others on weighing the evidence suppose that he lived early in the Pleistocene period. If we accept the duration of the Pleistocene as 250,000 years, and regard Pithecanthropus as representing the evolutionary stage reached by mankind at the beginning of this period, then we have to conclude that man's body had become adapted to its peculiar posture and gait before the end of the Pliocene period, and that the higher development of the brain took place in the ensuing Pleistocene period.

Eoanthropus.—The discovery which ranks next in importance to that of Pithecanthropus was made by Mr. Charles Dawson at Piltdown, Sussex, between the years 1911 and 1915. He found the greater part of the left half of a deeply mineralised human skull, also part of the right half; the right half of the lower jaw, damaged at certain parts but carrying the first and second molar teeth and the socket of the third molar or wisdom tooth. The lower jaw, on the region beneath the chin, had a bar of bone known as the "simian shelf," which until then had been regarded as a mark of the ape. Later a pointed upper canine tooth was added; its characters were simian rather than human. The stratum of gravel proved to have been laid down early in the Pleistocene period, and it is certain that the fossil fragments of this human skull were as old as the date of deposition. From the fossil fragments thus found, Sir Arthur Smith Woodward reconstructed an extinct genus of mankind, *Eoanthropus*, the dawn-man (*Quar. Jour. Geol. Soc.*, 1913–5). Subsequently (1915) in the deepest part of the gravel stratum there was found a remarkable bone implement hewn from the thigh bone of an extinct kind of elephant; in a neighbouring field two other fragments of a skull of the same kind came to light, and another molar tooth.

Some experts still doubt whether a lower jaw which resembles that of a chimpanzee in several respects should be assigned to a skull which is purely human in its characters. At first there were differences of opinion as to the size and characters of the brain of Eoanthropus. Amongst British authorities there is now agreement that the skull and jaw are parts of the same individual, and that the brain, as revealed by casts taken from the interior of the skull, is human in its size and in all its characters. If we divide living races into three classes according to the size of brain, the large-brained having a cranial capacity above 1,450 cu.c., the small-brained a capacity under 1,350 cu.c., then Eoanthropus certainly reached the upper limits of the small-brained class if not actually a member of the medium-brained group. The brain of Eoanthropus has risen many stages above that of Pithecanthropus; the bone implement affords evidence of manual skill and of inventive ability on the part of its owner. The eyebrow ridges of Pithecanthropus are shaped as in the gibbon, chimpanzee and gorilla; in Piltdown man they are fashioned nearer to the form seen in the skull of the orang. The discovery at Piltdown shows that at the beginning of the Pleistocene period a race of mankind had come by a brain that had reached a human estate, and that this race still retained certain definite simian characteristics in its jaws, teeth and face.

Neanderthal Man.—In 1857 while workmen were clearing out the Neanderthal cave near Düsseldorf, Germany, they found the vault of a fossilised skull and limb bones of a man who proved to be, in the light of further discoveries, a representative of an extinct species of man—*Homo neanderthalensis*. A fossil skull which was dug up at Gibraltar in 1848 is of the Neanderthal type. Fossil remains of the same kind have been found in Belgium (at Naulette, 1866, and at Spy, 1886), but the caves of France have proved the richest source of Neanderthal remains, particularly those in the valley of the Dordogne.

The evidence found at La Chapelle (1908), at La Ferrassie (1909), at Le Moustier (1908) and at La Quina (1911) made it quite clear that this extinct type of man, marked as he was by many simian traits of body, buried his dead with signs of respect. He worked flint implements with great skill, in the style or culture known as Mousterian. He was a hunter and lived in caves and rock shelters. His molar teeth were often shaped in a peculiar manner; his teeth have been found in cave deposits in Jersey (1911) and in Malta (1917). His remains have been found in Moravia (1906) and at Krapina in Croatia (1899–1906). His culture has been found in Italy and in England, but no trace of his body. Only once have fossil remains of Neanderthal man been found outside the limits of Europe, in a cave situated on the western shores of the Sea of Galilee (1925).

Neanderthal man appears to have been the sole occupant of Europe during the middle of the Pleistocene period—throughout the time in which the Mousterian culture prevailed in that continent. The date of this culture may be put down tentatively as extending from 40,000 B.C. to 20,000 B.C.; perhaps its duration was much longer. Remains of Neanderthal man rather more primitive in type, and found in strata older than the Mousterian strata of France, have been discovered at Taubach (1895) and at Ehringsdorf (1914), both of these sites being near Weimar, Germany. *The Heidelberg mandible* was found at a depth of 78 ft. in a sandpit at Mauer, ten miles to the east of Heidelberg, in 1907. The stratum in which it was found belongs to the deeper and older Pleistocene series; this fossil jaw thus represents a race which lived long before the men who practised the Mousterian culture. Yet so like is the mandible of Heidelberg man to that of Neanderthal man, in the majority of its characters, that we may safely regard him as an ancestral representative of the Neanderthal species. In Heidelberg man the canine tooth did not project above its neighbours as in Eoanthropus.

At one time it was believed that Neanderthal man represented an ancestral phase of modern man. Every bone of his body shows distinctive markings, many of these being of a simian nature. His eyebrow ridges were like those of the gorilla and chimpanzee; the roof of his skull was low like theirs, and yet in size of brain he equalled, if he did not surpass, modern Europeans. He had, however, certain specialisations of structure which modern or Neanthropic man does not possess. Besides, the archaeological evidence is now complete that he was replaced in Europe by the arrival of men of the modern kind—represented by people of the Cromagnon type. For these reasons Neanderthal man cannot be regarded as an ancestor of modern man. Neanderthal man and men of the modern type, however, have so much in common that they must be looked upon as descendants of a common ancestor.

Rhodesian Man.—The fossil remains of Rhodesian man which were discovered in the Broken Hill Mine, Northern Rhodesia, in the summer of 1921, also bear evidence to the truth of man's evolution. His fossil remains lay deep in a filled-up cave; he was probably alive in Africa when men of the Neanderthal type dominated Europe. His limb bones show that he was tall, quite 5 ft. 10 in. in height, and stoutly made, after the manner of modern man. His skull, which is complete save the lower jaw, possesses many primitive traits. His brain space was small (1,300 c.c.); in point of development the brain falls below that of Eoanthropus. The eyebrow ridges are extremely massive, and the face has features which recall those of the gorilla. Yet his teeth, although large, are human in every respect and were ravaged by caries. Rhodesian man might well stand as an ancestral type to modern man.

Cromagnon and Other Races.—The Cromagnon type of man and other forms which appear in Europe after the disappearance of Neanderthal man are fully developed men of the modern type; they differ from us only in robusticity of build and strength of jaw. The fossilised, capacious skull discovered at Boskop, Transvaal, in 1913, represents an extinct form of man of the Bushman type. The Talgai skull, derived from a Pleistocene deposit and described by Dr. S. A. Smith (*Phil. Trans.*, ser. B, vol. 208, p. 351, 1918), is of the same form as that of living Australian aborigines, but possesses additional primitive features. Prof. E. Dubois discovered a Pleistocene form of man at Wadjak, Java, one with a very large cranial capacity (*Proc. Roy. Acad. Sc. Amsterdam*, vol. 23, pt. 7, 1920). Such discoveries, although they bear out the truth of evolution, do not throw light on man's evolutionary pedigree.

Geological Evidence of Man's Antiquity

Artefacts in Pliocene Deposits.—If we accept Pithecanthropus as representative of man's estate towards the end of the Pliocene period, then we must infer that man had come by his posture and his gait before the close of the Pliocene period, and that his brain underwent its greatest expansion in the earlier part of the Pleistocene period; an inference which postulates a rapid rate for human evolution. In size of brain Pithecanthropus was approaching the human minimum. It is difficult to conceive him as a maker of tools, yet in geological deposits which were laid down in East Anglia during the Pliocene period Mr. Reid Moir has found flints which must have been shaped by beings which possessed skilled hands (*Pre-Palaeolithic Man*, 1921. *The Great Flint Implements of Cromer*, 1923). Such evidence indicates that other genera of the human family may have marched towards the human goal more rapidly than Pithecanthropus.

The Early Anthropoids.—If man is a descendant of a great anthropoid, and the great anthropoid of a small, then a knowledge of the geological levels at which these two forms occur should throw some light on the date of man's evolution.

The oldest trace of a small anthropoid so far discovered comes from strata of the Fayum, Egypt, laid down in the earlier part of the Oligocene period. The half of a lower jaw with its teeth is all that has been found of this small anthropoid, which was described by Von Schlosser in 1911. He named it *Propliopithecus*, and regarded it as an ancestral form of gibbon (W. K. Gregory, *The Evolution of the Human Dentition*, 1922).

No fossil remains of great anthropoid apes have been found in strata older than those of the Miocene period. Of Miocene great anthropoids, at least nine species have been discovered; one of them, *Sivapithecus*, known from fragments of jaws and teeth found in the Siwalik deposits of India, is regarded as a possible ancestor of man by Dr. G. E. Pilgrim, but a full consideration of the evidence leaves the expert unconvinced. In 1922 a tooth was found in Pliocene beds of Snake Creek Quarry, Nebraska, which has been attributed to an anthropoid ape with human leanings to which the name *Hesperopithecus* was given by Dr. Henry Fairfield Osborn. Unfortunately, the tooth was worn and its true characters hard to decipher; the fact, however, that such competent authorities as Dr. Osborn, Dr. W. K. Gregory and Dr. W. D. Matthew are convinced that a trace of a humanoid anthropoid has been found in America will secure consideration for Hesperopithecus.

Early in 1925 Prof. Raymond Dart announced the discovery of the fossil skull of a young anthropoid ape, found in a limestone quarry at Taungs, on the eastern border of the Bechuanaland Protectorate, near the Transvaal frontier (*Nature*, 1925, vol. 115, p. 195). The geological evidence goes to show that this anthropoid, which Prof. Dart named *Australopithecus*, cannot be older than the beginning of the Pleistocene period, which eliminates it from any place in the line of man's ancestry. Its anatomical characters place it in the same group of anthropoids as that to which the gorilla and chimpanzee belong. In some respects Australopithecus is more human than either of the two living African anthropoids.

Summary.—Thus, taking all lines of evidence into consideration, anatomical, biological, embryological and geological, we are led to the conclusion that man has been evolved from a lower form, and that human races, as we know them to-day, are the products of evolutionary processes. There remain great blanks in the line of evidence which links the origin of modern man to an extinct form of anthropoid ape. Between the highest kind of anthropoid and the lowest type of man, represented at present by Pithecanthropus, there remains a great gap; the transitional forms which fill this gap still remain to be discovered. Yet the evidence as it stands, imperfect as it is, points to man's departure from an anthropoid status early in the Miocene period, certainly 1,000,000 years ago, perhaps more; that in the Miocene and Pliocene periods his body and limbs became adapted to a plantigrade posture; that his brain underwent expansion in the Pliocene, and particularly in the earlier part of the Pleistocene period, and that as the brain reached a full human status the coarser outward appearances of the ape were shed. Of the vital processes which brought about these changes we are as yet ignorant, but it is manifest that in his evolutionary progress man has tended to acquire and preserve in adult years states which appear at first as transient conditions in foetal or infantile stages.

It is becoming clear that the machinery of evolution is that which regulates development and growth, and in these matters knowledge is growing. Experimental embryologists have proved that one group of developing cells can and does regulate the growth and behaviour of a neighbouring group. The theory of hormones has thrown a flood of light on the machinery of evolution (Prof. Chas. R. Stockard, *Publications of Cornell University Medical College*, 1924, vol. 10; Keith, *Supplement to Nature*, Aug. 18 1923). It has been proved that substances or hormones are carried by the circulation throughout the living body from a series of glands which include those of reproduction, the adrenal, the thyroid, the pituitary and pineal, and that the substances thus liberated in the body do control its vital reactions and its structural form.

MANAGEMENT: *see* SCIENTIFIC MANAGEMENT.

MANCHESTER, England (*see* 17.544), has an area of 21,688 ac. (including areas incorporated in 1910 and 1913), and an esti-

mated population of 761,320. Since 1918 10 members have been returned to Parliament, and the city was brought entirely under one board of guardians in 1915 and one board of overseers in 1916. The birth-rate varied between 1·86 and 2·37 in 1921–5, and the death-rate between 1·36 and 1·44.

Housing and Improvements.—Several housing schemes, including a number of wide new roads, have been undertaken, the largest being at Blackley, Moston, Wilbraham Road, Anson and Gorton, but the house shortage was still acute in 1926, although more than 5,300 houses had been built by the municipality since 1919, besides those erected privately. The council aim at completing 10,000 more by 1930, and had under consideration the question of the purchase of a site of 4,500 ac. in rural Cheshire beyond and to the south of the city limits. In this area stand the Wythenshawe Hall and grounds (comprising 250 ac.), presented to the corporation for park purposes. A number of large parks and open spaces have been acquired, and include Cringle Fields, Burnage (54 ac.); Broadhurst Park, Moston (84 ac.); Fletchermoss Playing Fields, Didsbury (21 ac.); and Green Bank Fields, Levenshulme (24 ac.). New parks are planned for Withington (48 ac.) and Chorlton-cum-Hardy (37 ac.), which have grown rapidly since the World War.

New Buildings.—The Horsfall education museum, Ancoats Hall, has been transferred to the corporation; the old parsonage, Didsbury, was opened as a branch art gallery in 1923; and Platt Hall was handed over in 1925 as a branch art gallery and museum. A new art gallery, surrounded by a wide, open space, for which the design was approved in 1925, is to be built on the site of the old Royal Infirmary in Piccadilly. The infirmary has been moved to Oxford street, and several other hospitals have been built in its vicinity. A large Wesleyan hall and institute was opened in Peter street in 1910, the Y.M.C.A. building in 1911 and the Church House in Deansgate in the same year. The Exchange was extended and reconstructed in 1914–21; the historic Free Trade Hall in Peter street was bought by the corporation in 1921, and plans were made in 1925 for the extension of the town hall, to include the central library, then in temporary buildings on the Piccadilly site.

The new office being erected in King street in 1926 for the Ship Canal Co. will be the highest commercial building in the city. A textile institute, with its headquarters at St. Mary's Parsonage, was founded in 1910; and a British Cotton Industry Research Assn., with offices and laboratories at Didsbury, in 1919. Premises are to be built at Fallowfield for the grammar school. A radium institute, the first in the country exclusively for the use of radium in hospital treatment, was opened in Nelson street in 1921. A statue of King Edward VII. was unveiled in Whitworth Park in 1913, one of Abraham Lincoln in Platt Fields in 1919 and a large war memorial on the foundations of old St. Peter's church in 1924. Playing fields and a pavilion have been acquired at Stretford as a memorial to men of the Manchester Ship Canal Company.

Public Works.—Two additional pipe-lines have been laid from Thirlmere, and the North Cheshire Co.'s water undertaking was purchased in 1921. In 1925 a beginning was made with the large Haweswater scheme, to involve 84 m. of aqueducts, tunnels and pipes. It is hoped to finish the work by 1934. A new electric power station was opened at Barton in 1923, and in 1925 it was decided to double its capacity. Parliamentary powers were obtained in 1921 for the construction of a large gas-generating station at Partington, and the present stations in the city will eventually be used only for distributing. Parliamentary powers were also obtained, in 1911, for a comprehensive scheme to result in the whole drainage of Manchester being carried to works at Davyhulme. In 1925 the possibilities of an electric underground railway were under discussion.

Port Improvements.—In 1925 there were eight docks with a water area of 120 ac. and $5\frac{3}{4}$ m. of quays in the port. Trafford Wharf was rebuilt and re-equipped in 1924, and in 1925 the last five miles of the Ship Canal were being deepened to allow vessels drawing 28 ft. to come up to Ellesmere Port. Road and railway improvements were also in hand at Ellesmere Port, which is leased by the Ship Canal Co., more wharves are to be built, and the company have acquired 1,000 ac. of land for industrial development. The corporation have determined to undertake a comprehensive civic survey. When the survey has been completed, recommendations will be made as to future action in matters municipal, social, economic, housing, parks, recreation facilities, commerce, industry, communications, and transportation.

Though best known as the business and warehousing centre of the cotton industry, Manchester has also become a great manufacturing and distributing centre for chemicals and dyes, and is one of the chief ports for importing oil. Some of the greatest engineering workshops in the world are in the city or its immediate neighbourhood. Motor-cars and commercial vehicles are made, and rubber manufacture and the ready-made industry are extending. (O. J. R. H.)

MANCHESTER, VICTORIA UNIVERSITY OF (*see* 17.545).—The development of the University of Manchester during the 20th century, in common with that of the other English universities, has been greatly affected by the War. At the same time, valuable contributions both to the defence of the country and to knowledge were made, especially by the scientific, technological and medical staffs who were called upon to face problems raised by the War. The number of students, which had reached 1,691 in 1910, increased immediately after the conclusion of hostilities, and in 1920 was 2,000. It had in 1926 apparently stabilised itself at about 2,500. Perhaps the most significant feature of this increase was the continued growth of the number of women students—730 in 1926 as against 336 in 1910. The botanical and physical laboratories and the extensions of the museum and library, completed during the four years 1910–4, were followed by the erection of a building to house most of the departments of the faculty of arts (1919), while new accommodation was provided for the metallurgical department, and the medical school was internally reconstructed. The continued growth of the library, which contains over 200,000 volumes, led to further extension, and a bequest of Mr. Jesse Haworth made possible the erection of a new wing of the museum, to provide galleries for the exhibition of the valuable ethnographical collections made by the late Mr. Charles Heape and presented by him to the university in 1923.

Developments.—An appeal for funds in 1919 produced a sum of £250,000, and this made it possible to satisfy some of the needs rendered urgent by post-War conditions. New chairs have been instituted in Russian and Italian, in addition to a second chair of French. The lectureship in textile technology has been raised to the status of a professorship, and a similar development has taken place in psychology and in commerce and administration. A chair in English language has been instituted in addition to that in literature, and the second chair in law and the chair of comparative religion have been revived. The institution of a faculty of education in 1914, with a post-graduate degree of master in education, led to interesting researches in educational method and administration, and the faculty received a valuable addition by the endowment by Sir James E. Jones of a lectureship in the training of teachers of the deaf. The same donor also endowed a hall of residence primarily for the accommodation of women students preparing for the certificate instituted in that subject. A gift from the Carnegie United Kingdom trustees led to the establishment of a special library available for teachers and others interested in the education of the deaf.

The university athletic grounds have been extended. They now cover 28 ac. and possess a finely equipped pavilion. The facilities for the residence of the men students have been increased by the recognition of two more halls; while for women students three new halls have been recognised, and the existing Ashburne Hall has been extended to accommodate about 130 students. This extension, opened in 1925, includes a central block, providing a large hall, and beneath it a library in which have been placed the 8,000 volumes bequeathed by Lord Morley for the use of women students of the university. Closer

relations between the university and the local education authorities have been established. There are three county and eight municipal authorities contributing annual grants.

The resignation of Lord Morley as Chancellor of the University took place just before his death in 1923. The Earl of Crawford and Balcarres was elected as his successor. Sir Henry A. Miers, previously principal of the University of London, and appointed vice-chancellor of the University of Manchester in 1915, retired during 1926. Mr. W. H. Moberly, principal of University College, Exeter, was appointed to succeed him.

MANCHURIA (*see* 17.552).—In 1911 an agreement was concluded by the "Four Nations" consortium, to finance the development of Manchuria, but was blocked by Russia and Japan until their participation under conditions which secured to them continuance in their privileged position had been conceded. A treaty in 1911 and an agreement in 1916 further strengthened Russia's position in North Manchuria, while the formal annexation of Korea by Japan in 1910 placed the numerous Koreans in Manchuria under Japanese consular jurisdiction. By the beginning of 1911 the "peaceful penetration" of Manchuria and Eastern Inner Mongolia was proceeding steadily and under conditions generally similar to those which had characterised Russia's forward policy from 1898 to 1905.

In 1912 the railway from Changchun to Kirin was opened to traffic. In May 1915, by the terms of a new treaty concluded by China as the result of the Japanese ultimatum accompanying the "twenty-one demands," the lease of the South Manchurian Railway and of the Antung Mukden line was extended to 99 years (*i.e.*, to 2002 and 2007 respectively). By the same treaty Japanese subjects became entitled to lease land for trade, manufacturing and agricultural purposes, and to reside and travel freely in South Manchuria. By notes exchanged as the result of the same "twenty-one demands" China was to permit Japanese subjects to open more mines in South Manchuria. No foreign loans were to be made for the construction of railways in South Manchuria and Eastern Inner Mongolia without the preference being given to Japanese capitalists; preference was to be given Japanese in employing foreign advisers in South Manchuria; and other promises were made favouring the Japanese. In 1917 the whole of the railway system of Korea was linked up with the South Manchurian Railway and placed under its administration. Under these conditions the activities and influence of the railway rapidly became dominant factors in the economic life of Manchuria. In 1916 Japan and Russia agreed by treaty to support each other's rights and interests in the Far East.

In Dec. 1915 a loan agreement was signed between the Chinese and Japanese Govts. for the construction of a railway from Ssupingkai (120 m. north of Mukden) to Chengchiatun; this line was completed in Dec. 1917. In Oct. 1917 a revision of the Changchun-Kirin loan agreement was concluded between the Chinese Govt. and the South Manchurian Railway Company, the result being a loan of 6,500,000 yen for a term of 30 years, during which period the management of the line is vested in the South Manchurian Railway, on behalf of the Chinese Government. In 1918 there were agreements with Japanese interests for the development of mines and forestry and for the construction of four railways.

Russo-Japanese Rivalry.—The disorganisation of the central Government in China and the collapse of Russia after 1917 served to increase the economic, financial and political ascendancy of Japan in Manchuria. For example, after China's entrance into the World War, some of the loans made to Japanese by the Peking Govt. had as security properties and resources in Manchuria. As a result, however, of the negotiations initiated by the United States in July 1918 for the establishment of a four-Power consortium to co-operate in Chinese finance, and of the subsequent *pourparlers* between the British and Japanese Govts. on the same subject, the latter finally agreed (May 1920) —with some important reservations—to withdraw the claims, previously put forward by the Japanese bankers, to exclude from the scope of the Consortium "all the rights and options held by Japan in the regions of Manchuria and Mongolia where Japan has special interests." Japan's power in South Manchuria, however, continues to grow, but at the same time the Chinese have by no means given up control, for they continue to form the great majority of the population, and the provincial organisation and administration are actively maintained. The dominant Chinese figure in Manchuria has increasingly been Chang Tso-lin. General Chang, in 1924 still in middle life, had once been connected with a band of Hunghutze, or bandits, but he had been taken into the service of the Chinese Govt. and in 1911 he was military Governor of Fengtien. From then on, his power grew until by 1920 he was one of the major figures in the Chinese political situation, and Manchuria had become virtually a semi-independent principality under his control. Russian influence, moreover, did not disappear with the collapse of the old régime. For a time it was weakened, but with the establishment of regular diplomatic relations between the Soviet Govt. and China in 1924, Russian power, while by no means fully restored, was again increasing.

Despite an agitation in Japan, the Japanese Govt. has maintained its policy of strict neutrality in the civil war—a policy reiterated by Baron Shidehara, the Japanese Minister for Foreign Affairs, in the Diet in Jan. 1926. Some alarm seems to have been aroused in Moscow by a contract given in April or May of 1925 by Chang Tso-lin to the South Manchurian Railway Company for the construction of a line from Taonanfu in Inner Mongolia to Tsitsihar in northwest Manchuria on the ground that it invades the old Russian sphere of influence in North Manchuria. Rapid progress was made by the Japanese with this railway which was expected to be open for traffic as far as the Nonni river by Aug. 1926. The Soviet authorities are also reported to have protested against the strengthening of the Japanese forces in North Manchuria in 1925 as a violation of the spirit of the Japanese-Soviet Treaty of 1924. (*See* CHINA; CHINESE EASTERN RAILWAY.)

Trade Statistics.—The economic progress achieved in Manchuria had been very rapid since 1912. This might have been expected in regions with vast undeveloped resources and with an increasing, industrious population. Much of the expansion of its trade and industries must also be ascribed to the enterprise shown by the Japanese in the development of mines, forestry and agriculture, and in improving transport, communications and currency.

Figures show the rapid increase of South Manchuria's trade and reflect the effects of the Russian débâcle upon the commerce of the northern province. In 1916 the maritime customs receipts in the northern provinces were 21% of the total for Manchuria. In 1920 they were 12% of the total, and in 1922 17 per cent. In 1919 the total direct foreign trade of Manchuria was taels (Hongkong) 299,523,736 and in 1922 it was 285,861,094. Dairen (Dalny) now ranks second only to Shanghai in the list of China's maritime ports. In 1922, 56·5% of Manchuria's direct foreign trade passed through Dairen (Dalny). In 1908 the trade of Manchuria represented 11·5% of China's total; in 1918 the proportion had risen to 16·8%; in 1922 it was 17·5 per cent. Naturally the bulk of South Manchuria's foreign trade was with Japan. The anarchical conditions prevailing in Russia and Siberia after 1917 served to increase Japan's economic and financial influence in Northern Manchuria, the rouble note being replaced in many parts of the country by the yen notes of the Bank of Chosen, which in Jan. 1918 was given control of the treasury business of the Japanese Govt. in Manchuria. At the end of 1918 this bank had 18 branches operating in Manchuria (as against 10 in Korea), and notes in circulation to the amount of 30,000,000 yen. According to the statistics compiled by the South Manchurian Railway, the population of Manchuria in 1916 was 20,112,100. The post office estimate for 1922 was 22,083,434. (*See* CHINA.)

MANDATE.—The mandate system is a term applied to the conditions set up by the Treaty of Versailles for the administration of the former overseas possessions of Germany and Turkey. Mandatory Powers are those Powers which were selected by the Supreme Council of the Allies to administer these territories under mandate. The system is a novel experiment in the relations

between a sovereign State and a country under its control, involving new departures in international law. It was created by Art. 22 of the Covenant of the League of Nations, which formed part of the Treaty of Versailles, and has thus gained the recognition of all States that are members of the League.

In its origin it was in the nature of a compromise. After the War the victorious Allies naturally wished to retain the German and Turkish colonies, in the conquest of which they had in most cases made great sacrifices. It was believed that these colonies had been subjected to misrule; pledges had been made to the native inhabitants, some of whom had taken part with the victors in the fighting, that they should not be handed over to the vengeance of their former masters; and finally, a misgiving existed lest, in case of rendition, Germany might use them as recruiting grounds for black armies, and their ports as bases for submarines in a future war. On the other hand the Allies had declared—more particularly in the pre-Armistice statement of Nov. 5 1918—that annexation of territory was not their aim in the War.

International control of some kind was the only alternative. Joint administration was condemned as impracticable and opposed to the interests of the people. Even as a condominium between two Powers only, it had given rise to friction in Egypt, Samoa and the New Hebrides. The only other course lay in the appointment of an individual Power in whom could be vested responsibility for the administration of each separate territory as an agent, or mandatory, of the League. For this course there were analogies in the delegation of quasi-sovereign powers to British and Dutch chartered companies and in the control of the Ionian Is. on behalf of the Powers by Great Britain in 1859. Individuals also had been appointed as mandatories of the Powers, as when King Leopold undertook control of the "International Free State of the Congo," or when Prince George of Greece was made Governor of Crete in 1898.

The main defect of these delegations of sovereignty was that they provided no machinery to ensure the due execution of the trust, and it is the distinctive feature of the mandate system that it attempts to remedy this defect. The League of Nations afforded just such a supervisory authority as was needed, and its supervision is exercised through the medium of a standing committee, known as the "Permanent Mandates Commission." The League had nothing to do with the assignment of the mandates or with their terms, or with the extent and boundaries of the territories. These were determined by the Supreme Council. The United States, not being a member of the League, was no party to this arrangement, and she insisted that as an Associated Power her consent was necessary. The mandates therefore were submitted to her, and approved on condition that "free and equal treatment in law and in fact was secured to the commerce of all nations." Where the mandate did not ensure this she negotiated separate treaties with the mandatory concerned.

Terms of the Mandates

The mandates were formed to give expression in detail to the principles embodied in Art. 22 of the Covenant (*q.v.*), and since that article prescribes that their character must vary with the varying conditions of each territory they were divided into three classes to correspond with the three paragraphs of that article.

Class A includes the former Turkish vilayets of 'Iraq, Palestine and Syria whose independence "can be provisionally recognised, subject to the rendering of administrative advice and assistance until they are able to stand alone." The two former were assigned to Great Britain, the latter to France.

Class B comprises the ex-German Central African colonies—Togoland, Cameroons, Tanganyika and Ruanda—in which the mandatory is responsible for the administration and undertakes to promote the moral and material welfare of the people. Tanganyika, and a small part of the Cameroons and Togo fell to Great Britain, the major portions of the two latter being assigned to France, while Belgium became responsible for Ruanda.

Class C territories include those which "can best be administered under the laws of the mandatory as integral portions of its territories, subject to the safeguards in the interests of the indigenous population" which are laid down for Class B. They are South-West Africa, Samoa, New Guinea, the islands north of the equator in the West Pacific and the tiny island of Nauru. For these respectively the Union of South Africa, New Zealand, Australia, Japan and the British Empire accepted mandates.

In the case of Nauru, Great Britain, Australia and New Zealand had by agreement in July 1919 (before the issue of the mandate), jointly acquired control of the phosphate deposits, which constitute the sole value of the island, and they jointly undertook the execution of the mandate. Since, however, the British Empire has no single code of laws, the administration was assigned by the two others to Australia for five years.

The "safeguards in the interests of the indigenous population" to which reference is made are: (1) freedom of conscience and religion, subject only to the maintenance of public order and morals; (2) prohibition of abuses such as the arms and liquor traffic and the slave-trade; and (3) prevention of fortifications, naval and military bases, and the military training of natives except for police and the defence of the territory.

The mandates were conferred by the Supreme Council of the Allies, and after acceptance by each mandatory were submitted to the Council of the League, which was charged with the duty of seeing that their terms were in accord with the Covenant. They were finally approved by the United States. The A class could not be issued until the Treaty of Lausanne came into force (Aug. 1924). Meanwhile an Arab government had been set up in 'Iraq, and a treaty had been concluded by Great Britain with it. On Sept. 27 1925 the Council formally accepted the undertaking of the mandatory to see that the terms of this treaty (which embodied the obligations of the Covenant) were adhered to, and this undertaking was substituted for the mandate. These long delays were very prejudicial to the welfare of the people of Asia Minor. The territories were, however, administered in accordance with the terms of the Covenant or under draft mandates. These terms are explicit. The mandate is a "sacred trust of civilisation" to be assumed by nations who (*inter alia*) "by reason of their resources can best undertake this responsibility and are willing to accept it." The altruistic nature of this pledge was confirmed in a reply to a German protest. "The Mandatory Powers," said the Allies, "in so far as they may be appointed trustees by the League of Nations, will derive no benefit from such trusteeship."

A mandated territory differs from a protectorate in that the protecting Power in the latter obtains rights over the population and against other Powers, whereas a mandatory in its capacity as guardian assumes obligations both toward the population and the League. These thus acquire rights as against the mandatory.

League Control.—The system, it has been said, differs from such partial precedents as have been cited, in that it attempts to set up machinery by which the proper execution of the mandate may be assured. This consists in the unqualified right of supervision vested in the League which imposes upon each mandatory the obligation to submit an annual report on its administration.

The Permanent Mandates Commission examines these reports in the presence of an accredited representative. The commission consists of nine members of the following nationalities: Belgian, British, Dutch, French, Italian, Japanese, Portuguese, Spanish and Swedish—to which has recently been added an "additional member" (Swiss). The majority are nationals of non-mandatory states. They are selected "for personal merit and competence" as private individuals, and not as representatives of their respective nations. They are nominated by their governments, but approved and appointed by the Council of the League, and may not hold any office under their government. A representative of the International Labour Office attends the sessions, and takes part in any discussions relative to labour. This international composition negatives any suspicion of bias, and gives to the commission the aspect of an impartial tribunal of practical men, whose object it is to promote co-operation while fearlessly exposing any breach of the Covenant. Its functions are purely advisory to the Council.

A permanent secretariat, under a director, collects and circulates all documents of interest concerning mandates and conducts the routine business. The duties of the commission are not confined to the annual review of the reports of the

mandatories. It receives any petitions and memorials from inhabitants of the territories and others interested, and these, unless trivial or irrelevant, are forwarded to the mandatory concerned before examination by the commission, which also makes a special study of questions arising either in relation to the system or to the various problems of administration. Notes for guidance in preparing their reports are circulated to mandatories, dealing with such matters as slavery, labour, traffic in arms, liquor and drugs, liberty of conscience, the judicial system, military forces, economic equality, education, public health, land tenure, public finance and matters relating to general administration and the moral and material welfare of the people. The proceedings are conducted in French and English, and are generally held in private to facilitate freedom of discussion. Full minutes are printed, which, together with the memoranda on special subjects and all other pertinent papers, can be obtained from the League publication department, or from its agents in London and other European capitals. The Commission meets at least twice in the year at Geneva, and its procedure is governed by rules approved by the council.

The weak point in the system lies in the impossibility of independent verification of statements contained in the reports. This difficulty is inherent in the circumstances, for it would clearly be impossible either for the whole commission or any part of it to visit a mandated territory officially, and to sit in judgment on the policy of a Sovereign Power. Even an official visit for the purpose of acquiring information would be of doubtful wisdom, as tending to weaken the prestige of the mandatory and to afford opportunity for malcontents to manufacture grievances. For information not contained in the report, therefore, the commission must rely on those public bodies or individuals who interest themselves in the welfare of native races, and on such memorials and petitions as may be presented to it.

The sole means at its disposal—or at the disposal of the League—for compelling the proper execution of the mandate is the force of public opinion, though in case of deliberate violation of the mandate and of gross maladministration, the council could no doubt send a commission of enquiry, and in theory the legal possibility of revocation for failure on the part of the mandatory to fulfil its contract no doubt exists. In order to obtain more accurate information, the actual administrators now generally appear as the mandatory's representatives. Steps are also being taken to secure a wider distribution of the sessional papers of the commission, with a view to enlarging the orbit of well-informed public opinion and perhaps of exerting an influence on the standards of colonial administration.

Interpretation of Article 22.—The creation of the mandates system—though a task of enormous importance, involving issues new to international law and affecting the destinies of many millions of the human race and of property in every quarter of the globe worth many hundreds of millions sterling, was only one of the many preoccupations of the Versailles Conference. Owing to the circumstances of the moment many matters of less permanent and historic importance claimed an undue attention. Critical examination and practical experience have therefore detected many points which require elucidation or authoritative interpretation. In some particulars, for instance, the mandates do not strictly conform to the terms of Article 22. In the A mandates the treaty enjoins that "the wishes of the communities must be a principal consideration in the selection of the mandatory," and it is common knowledge that the communities concerned were never consulted. The paragraphs in Art. 22 on which the B and C mandates were framed do not contain any similar injunction, though explicit statements to the same effect had been made.

Military Service.—Again, the French mandates in West Africa —unlike the British mandates for portions of the same territories (Cameroons and Togo)—contain a clause to the effect that "troops thus raised" (*i.e.*, for purposes of local defence and police) "may in the event of general war be utilised to repel an attack, or for defence of the territory outside that subject to the mandate." It is difficult to reconcile this clause with the words of the Covenant. At the instance of the Mandates Commission the British Govt. was willing to go even further than the Covenant prescribes, and to agree to pledge itself not to enlist the natives of a mandated territory, even though they offered themselves for enlistment outside its frontiers—thus limiting its sovereign rights in adjacent territories not under mandate. The French Govt. has declared its willingness to accept the same restriction.

The original intention of the treaty would seem to have been to exclude all mandated territories and their inhabitants from participation in a general war; but the mandates for Palestine and Syria authorise the mandatory "to make use of the ports, railways and roads for the passage of its troops and of all materials, supplies and fuel," and local forces may be used for purposes other than defence. These countries thus automatically became involved in any war in which the mandatory may be engaged. It is not clear what is the position of the C mandates in this regard.

Liquor Traffic.—The Covenant enjoins the "prohibition of abuses such as the slave-trade, the arms traffic and the liquor traffic." Some have urged that these words mean the enforcement of total prohibition alike for natives and non-natives. The mandates, however, only prescribe a "strict *control* over the sale of spirituous liquors," and the St. Germain Convention (Sept. 1919), concluded soon after the Versailles Treaty by the same signatories, forbids the import of "trade spirits" only. Relying on these facts, others contend that the term "liquor traffic" is used in the Covenant in the technical sense in which it is usually employed in West Africa, and means the "importation of cheap, distilled liquors for sale or barter as an article of trade with the natives." The Mandates Commission has consequently asked the council for an authoritative definition of this and other ambiguous terms used in the Covenant.

In the matter of equal commercial opportunity for all nations, the Covenant itself failed to fulfil the expectations raised by the pre-Armistice declarations of the Allies. No obligation in this regard is imposed in the C mandates, while in the B class it is restricted to States which are members of the League.

Legal System.—The essential distinction between the B and C classes of mandates, in the terms of Art. 22, lay in the dictum that the latter "can best be administered under the laws of the mandatory, as integral portions of its territory," but the British and French mandates for Cameroons and Togo, and the Belgian mandate for Ruanda (all of the B class) contain a clause in identical terms.

Boundaries.—Yet another cause of practical difficulty is presented by the fact that in many cases the boundaries of the territories assigned under mandate were not defined, and it was apparently left to the individual mandatories to adjust them without reference to the League. In the case of 'Iraq this has led to an acute dispute with Turkey. In Palestine the boundaries of Trans-Jordania are still undefined. In Northern Syria the French, having, as it was understood, agreed to accept a mandate for Cilicia, abandoned it to Turkey without apparently any authority from the League to do so, and the frontiers are still indeterminate. So again in Ruanda, where an adjustment, involving the cession of a considerable area by Great Britain to Belgium, was effected and approved by the League. On the northern frontier of South-West Africa negotiations are in progress between the Union Govt. and the Portuguese.

Sovereignty.—Wider issues are raised by such questions as the nature and extent of sovereignty exercised by a mandatory and the international status of the inhabitants of a mandated territory. The former—which has been much debated by American publicists—is rather academic and juridical than of practical interest. It suffices for practical purposes that the mandatory has the absolute right to make and enforce laws, to raise troops, to set up tribunals, to appoint officials and to raise and spend revenues. Sovereignty was not ceded by the Treaty of Versailles to the League, but to the victorious Allies—indeed the highest court in South Africa has recorded the opinion that the territories were not ceded at all, but placed by Germany at the disposal of

the Allies, to be administered under mandate—a status new to international law.

The mandatory's powers are exercised "in its capacity as such." It has, for instance, been satisfactorily established by the Mandates Commission that such terms as "crown (or state) lands" and *domains d'état*, where they appear in local ordinances, refer only to lands which are the property of the mandatory as such, in other words, to the mandated territory, and that any action on the part of the mandatory which had for its object (or would ultimately involve) annexation—as for instance the acquisition of large monopolistic rights, or of essential public services—would be contrary to the spirit of the Covenant and the mandate.

Status of Natives.—The status of the indigenous inhabitants of a B or C mandate territory has on the other hand been the subject of special definition. Obviously, since the country is not annexed, they do not become the subjects of the mandatory. The formula was therefore adopted by the Council that "they should be designated by some form of descriptive title which will identify them as such," viz., as "persons administered or protected under mandate." This confers no juridical status, and no privilege of citizenship, but Art. 327 of the treaty stipulates that they should be entitled to the diplomatic protection of the mandatory when outside the mandated territory, and individuals may if they so desire become naturalised subjects of the mandatory. Since residents in a British Protectorate cannot acquire British nationality, and since a person "protected under mandate" could not be placed in a more favourable position in such a matter than a resident in a British Protectorate it was decided at an Imperial Conference that the power of granting certificates of imperial naturalisation should be extended to persons resident in certain named protectorates, and in mandated territories. Extradition treaties with France have similarly been extended, the natives being regarded for this purpose as "assimilated" to those of a colony.

The application to mandated territories of special conventions, entered into by a mandatory Power, has also been the subject of investigation and recommendation by the Mandates Commission, in order to ensure that "persons protected under mandate" shall not be in a less favourable position in regard to their persons and property and their economic interests than the inhabitants of a protectorate or colony.

Permanence of Mandates.—The revocation of a mandate for maladministration, though theoretically possible, is in practice unthinkable. Voluntary transfer or abandonment (with the sanction of the League) is hardly more conceivable. The terms of the Covenant therefore contemplate self-government as the natural fruition of the mandate—in the case of the A class at no distant date. The new state—as is proposed in the case of 'Iraq—would then take its place as a member of the League, or perhaps, as in the case of South-West Africa, would be federated with the mandatory.

Conclusion.—The mandate system enforces, for the first time in history, the principle of trusteeship, and of public responsibility to a supervising authority for the obligations laid down in the trust deed in regard to mandated territories. The annual report forms an effective means of inviting a popular verdict on the fulfilment of the trust, and this supervision constitutes a fundamental distinction from annexation, whatever the degree of assimilation to other possessions of the mandatory. The League exercises supervision but not control, for the ultimate authority to which the stewardship of the mandatory is submitted is the public opinion of the civilised world. The standards of the Covenant must obviously in the future be regarded as principles of general application. The mandate system is an international acknowledgment of the responsibility which the advantages of a superior intellectual culture and twenty centuries of Christian ethics no less than the physical superiority conferred by the monopoly of firearms impose upon those Powers which have accepted control of backward races. *See* LEAGUE OF NATIONS.

MANGANESE (*see* 17.569).—The principal use of manganese is in the manufacture of iron and steel, about 95% of the world's production of manganese ores, manganiferous iron-ores, and manganiferous zinc residuum being consumed in metallurgical processes. Its chief chemical uses are as a constituent of oxidising agents and colouring materials, and as a flux in the smelting of silver and lead ores. Salts of manganese are used as fertilisers and massive rhodonite as an ornamental stone. Manganese is also used for medical purposes. Ores of the metal are widely distributed, but deposits of commercial importance are known only in a few countries. The principal of these are Russia (Caucasus), the ore of which consists mainly of pyrolusite; India, Brazil and West Africa. Minor producers of the metal are Italy, Spain, the United States, Cuba and Japan; while deposits are also known in Germany, Greece, Egypt, Canada, Mexico, Colombia, Chile and Queensland.

For many years before the World War, Russia was the main producer, the figures for 1913 being 1,234,900 tons. The Russian industry suffered severely during and after the War, however, and the export figures in 1923 had fallen to 407,401 tons. These figures, however, represent a considerable advance on those of the years immediately preceding. The circumstances which acted so detrimentally to Russia imparted great impetus to the Brazilian manganese industry, the United States absorbing practically the whole of the much increased output of the South American States. In 1916 the United States obtained 80%, and in 1917 83%, of its manganese ore from Brazil. In the Morro de Mina mine, in the state of Minas Geraes, Brazil has what is probably the largest manganese mine in the world.

Production in India began in 1892, in the Madras Presidency, but in 1899 rich deposits were discovered in Central India and from this date the industry in India assumed importance. The India ore is more suitable for blast furnaces than the softer ores of the Caucasus, and, owing to more careful selection, is exported in more uniform quality. Its main constituent is psilomelane, with an important amount of braunite.

In the Gold Coast, West Africa, large deposits of manganese were discovered at Dagwin, near Taquah. Work was commenced here in 1916, and the first shipment of 174 tons made in the same year. In 1923 the production had risen to 139,634 tons. The Dagwin mineral generally is psilomelane, though pyrolusite is occasionally found. The average percentage of manganese plus iron is 55–56.

Production of Manganese by Principal Leading Countries.
Quantity (long tons)

Country	1913	1918	1923
India	815,047	517,953	695,055
Gold Coast	..	30,292[1]	139,634[1]
Russia and Georgia	1,234,900	150,000[2]	407,401
Italy	1,596	31,383	9,451
Austria	16,280	177	23,647
Brazil	120,335	387,066	232,041
Spain	21,247	76,465	28,175
United States	4,048	305,869	31,500[1]
Japan	17,755	56,109	4,926

MANGIN, CHARLES EMMANUEL (1866–1925), French soldier, was born at Sarrebourg, Moselle, July 6 1866 of a military family, his father having been a general of division. One of his brothers was killed on active service at Tongking; while another, formerly a White Father but during the War a sergeant in the Senegalese Tirailleurs, died in the North African desert a few months after the Armistice. Mangin, himself, was not unworthy of his family history. He left the École Spéciale Militaire at Saint Cyr in 1888 for Africa, and with the exception of three years spent in Tongking, and 10 months in France, he remained for 26 years in different parts of Africa. In 1891 he became a lieutenant, in Nov. 1897 a captain, in Jan. 1900 the commander of a battalion, in Dec. 1905 lieutenant-colonel, and later, colonel. In Aug. 1913 he was promoted to the rank of general of brigade. His travels in Africa were extensive; he visited Dahomey, Senegal, the Sudan, the Congo, Morocco and Lake Chad. He was a member of Marchand's expedition and was one of the legendary company who were said to have marched "for three days without a halt." It was he who, at the head of 5,000 men, routed the bandit El'hiba and all his followers in the plain of Ben Guerir and so relieved Marrakesh. His considerable literary abilities, which he had rarely the leisure to exercise, were also devoted to Africa; and his book, *La Force Noire* (1910) brought home to Frenchmen the immeasurable resources of their empire.

When the World War broke out General Mangin was 48 years of age. At first in command of the 8th Brigade and, after April 9 1916, of the 5th Infantry Division, he threw the enemy back upon Douaumont, which he reached on May 22. Five months later, on Oct. 24, he hurled two divisions against the Germans and took Douaumont and Vaux. In 1917 he was in command of the V. Army, and in the following year at the time of the April offensive the Supreme Command imposed upon him the hard task of checking the German offensive directed against Compiègne. Eight fresh divisions were entrusted to him, and with these 60,000 men he checked von Hutter's advance at Noyon. Subsequently he was entrusted with the X. Army and was ordered, in conjunction with General Degoutte, to break in the German salient south of the Aisne. This he accomplished; the Chemin-des-Dames, the Château de Coucy and Laon were successfully re-occupied. At the time of the Armistice, he would have been the first to enter Metz at the head of his troops, in company with Marshal Pétain, had not an unfortunate accident at the last moment prevented this. For a year he commanded the Army of Occupation on the Rhine. In June 1921 he was sent as Ambassador Extraordinary to represent France at the celebrations of the centenary of Peruvian independence.

General Mangin held the Grand Cross of the Legion of Honour, was a member of the Supreme War Council, was Inspector General of the Colonial Forces, and presided over the Supreme Council for National Defence. But his life work was to develop to the maximum his country's African resources. He died on May 12 1925, and was buried with military honours in the Montparnasse Cemetery. Above his head stands a simple stone bearing this inscription: "Ici repose un soldat français." (M. Gu.)

MANIPULATIVE SURGERY.—The earliest practitioners of "bone-setting"—the old misnomer for what is now more correctly described as manipulative surgery—date back into very remote times, and Hippocrates, although not versed in a knowledge of structural anatomy, was the author of a treatise on dislocations which will bear comparison with many present-day publications on the subject. The history of the Roman Republic tells of successful practitioners of this ancient craft.

During the years when surgery was gradually being regularised and its seats of learning were being established, "bone-setters" were the only orthopaedic surgeons of those days, and the doctors apparently countenanced them as legitimate exponents of that section of therapeutics. The famous surgeon, William Cheselden, in the middle of the 18th century, who was a warden of "The Master Governors and Commonalty of the Art and Science of Surgeons of London" used to send cases to the bone-setters for treatment, and frankly admitted that he did so because he was not competent to treat them himself.

Hunter's Attitude.—The renowned surgeon, John Hunter, with great foresight and acumen, was amongst the first of eminent surgeons to realise the value of early movements in cases of sprains and joint injuries. He wrote: "Nothing can promote contraction of a joint as much as motion before the disease is removed, but when all inflammation is gone off . . . a little motion and frequently repeated is necessary to prevent healing taking place with the parts fixed in one position."

Paget's Advice.—The world of conservative surgery owes an unpayable debt of gratitude to Sir James Paget who, in his desire for the public weal and the true interests of science, wrote to *The British Medical Journal* in January 1867, urging his professional brethren to "learn what was good in the methods of the bone-setter, and eschew what was harmful." Paget stood on firm ground and spoke with unshakable certitude when he declared that "too long rest is by far the most frequent cause of delayed recovery after the injuries of joints, and not only to injured joints but to those that are kept at rest because parts near them have been injured." But notwithstanding the high position in the profession of this far-seeing practitioner, his exhortations passed almost unheeded and the tradition of rest persisted in spite of its frequently disastrous results.

Later, Dr. Wharton Hood, who had conceived the greatest admiration and respect for Robert Hutton, the bone-setter, and who recognised the false teaching of his profession in regard to many forms of joint injuries and derangements, made a thorough investigation of Hutton's methods, and after the bone-setter's death published a description of them in *The Lancet*. But Wharton Hood's motives were wrongly interpreted. He was accused of associating with a "quack," and prejudice once more dealt a heavy blow at the progress of science. But happily, the seed thus sown is to-day beginning to result in a harvest of delayed therapeutic methods which are of the greatest usefulness to crippled humanity, and the early pioneers who were so bitterly assailed and persecuted will find in posterity their full reward.

Types of Cases.—Flat-foot, with its distressing deformity and painful crippling of the patient, occupies a front place amongst those cases which yield most satisfactorily to skilled manipulative treatment. To commence to correct this abnormality in its early stages is important, though cases might be instanced of patients, even up to 60 years of age, making perfect recoveries. The time of puberty is the period at which the irregularity usually makes its appearance, and the progress of the trouble is usually rapid and the deformation very marked.

It is difficult to assign with certainty the predisposing factor in such cases, though heredity probably plays some part in its origin. As many as four members of one family have been known to suffer from the complaint. The hands of the operator—if sufficiently powerful—constitute a much more effective instrument for forcing the foot and ankle into their normal positions than the Thomas wrench which is largely used even now. Several corrections should be made at short intervals, followed immediately by certain exercises in place of the one or two adjustments which used to be considered sufficient. The encasement of the joint in plaster of Paris is secure immobilisation and rest in bed must on no account be recommended. The anatomical contour of the foot is palpably bettered even after the first manipulation, and each operation brings the patient nearer full recovery. Almost all cases of adhesive and acquired flat-foot should recover. Congenital cases are much less satisfactory, though even in these improvement can generally be looked for. The technique is difficult and should be taught by cinemato-

graphic pictures so slowly reproduced that students can follow each manipulation carefully.

The Shoulder Joint.—The habitual derangement of the shoulder joint—sometimes on the slightest provocation, such as sneezing, stretching or ordinary reaching—is a most troublesome affection and is usually attributed to a rent or tear in the capsule, brought about in the first instance by a severe wrench, although cases could be recorded where no history of accident can be remembered. The disability is probably more often caused by adhesive contracture of a section of the capsule with an accompanying exaggerated relaxation of the remaining portion which allows the dislocation to take place. Although surgeons frequently advise a surgical operation, certain manipulations bring about a condition of the capsule which will enable it to exercise normal control of the head of the bone followed by exercises designed to re-establish the surrounding weakened tissues. Out of a number of cases only 2 or 3 can be remembered as not having yielded satisfactorily to treatment—even after a repetition of the operation. The procedure, under an anaesthetic, is quite devoid of danger, and the after-effects are of brief duration and only slightly painful.

Subluxations and Dislocations.—The actual reductions of gross dislocations do not enter to any great extent into the purlieu of the manipulative surgeon. There is, however, a large number of conditions due to minor displacements which constitute an important branch of his work. Principal among these must be placed displacements and fracture-displacements of the semilunar cartilages of the knee-joint. This field is an enormous and most important one, for the number of persons of both sexes who sustain such injuries is legion. In original unreduced displacements, reduction must be carried out by appropriate manipulation at the earliest possible moment. In chronic or recurrent cases, manipulation is also very frequently effective in bringing about a cure of a very troublesome and disabling condition.

The brilliant results obtained in this type of case have been known for many years, but the underlying pathology has been a profound puzzle until it was recently shown:

(a) that by far the commonest type of injury of the internal semilunar cartilage is the complete longitudinal tear;
(b) that in this type of case, the outer portion of cartilage is nearly always found in the interior of the joint;
(c) that by appropriate manipulative technique this displaced fragment may be made to retrace its steps and come into apposition with the inner fragment;
(d) that when this has been effected, there is a good chance of repair occurring between the two fragments.

Cases with Adhesions.—These constitute another important class. It is essential first of all to make quite clear what we mean by the term "adhesion." It is probably known to most that an inflammatory process is usually accompanied by the exudation of lymph from the blood-vessels of the part. This lymph tends after a short while to become organised, *i.e.*, changed into connective tissue, or, as it is usually called, "fibrous tissue." Let us imagine, for example, that owing to a severe sprain of the knee the lining membrane of the joint has become inflamed. As a result there is an outpouring of this lymph by the blood-vessels of the membrane, and various folds and layers of this selfsame membrane tend to become adherent by this inflammatory exudate. When this has become converted into fibrous tissue, adhesions are actually present which may give rise to marked disability. It is characteristic of adhesions that, when pulled upon or stretched, severe pain usually results. Further adhesions give rise to a variable amount of limitation of some particular movement or movements of the joint, which is apt to be overlooked unless a most careful examination be made.

Swelling of the joint after exercise, muscular wasting, and a sensation of weakness and often an actual giving-way of the joint, are not infrequent characteristics of adhesions.

Danger of Rest for Joint Cases.—As previously stressed, the doctrine "rest inflamed structures" has been responsible for the formation of countless thousands of joints disabled by adhesions. However true the doctrine may be in certain other organs and structures of the body, and even this is debatable, in the case of a joint it is dangerous, for the function of a joint is movement and movement must always be instituted at the earliest possible moment in almost any inflammatory condition, except in those ultra-acute conditions where movement is impossible and in some cases of tubercular disease and of myositis ossificans. When a joint has become crippled owing to the presence of adhesions, how is the joint to be restored to its pristine health and vigour? The answer is manipulation.

It is obviously impossible, in a short article of this nature, to detail the various technical methods of manipulation that apply to the different joints. Anaesthesia, although not absolutely essential, is a valuable aid in many cases, owing to the complete muscular relaxation thereby attained. The cases that are attended with the greatest success are those in which the adhesions are slight and in which the subsequent reaction is negligible. In more marked cases much benefit often follows from a series of manipulations separated by short intervals.

Although particular emphasis has been laid on adhesion in connection with joints, it is most important to remember that this may occur in many other important situations, particularly in the vicinity of muscles, or in their sheaths, or between different groups of muscles. This may also occur in connection with tendons and their sheaths, and in fascial or connective-tissue structures.

Functional or Hysterical Cases.—These constitute an interesting and important group in which good results by manipulation are sometimes attained. It must be remembered that a functional case is primarily mental and this condition is particularly apt to occur after injury in a person of nervous temperament. Although there is no actual organic disease of the joint—at any rate in the early stages—yet it is extraordinary how a functional condition of a joint may simulate some organic disability of the same joint. Great experience and clinical acumen are often required to form a correct diagnosis of such types.

The great value of manipulation in these cases is that a vicious circle is thereby broken, and, although an anaesthetic is not absolutely essential, yet, if some such anaesthetic as gas or gas and oxygen be given, it has a powerful suggestive effect upon the patient. It is usually found that, as soon as the patient is under the influence of the anaesthetic, the joint, which previously was held awkwardly and stiffly, becomes relaxed. The surgeon places the joint in the position which was erstwhile impossible and retains it thus until the patient is fully conscious. The patient is then shown the increased mobility and encouraged immediately to move the joint through this increased range. Much subsequently depends upon the patient being surrounded by an atmosphere of cheerfulness and encouragement, and everyone with whom the patient comes in contact must endeavour to play his or her part in the cure and to assure the patient of its completeness and finality. A great responsibility thus devolves upon friends and relations that the good work of the manipulator may not be subsequently jeopardised by misplaced sympathy or injudicious advice.

It must be borne in mind that in cases of long standing, actual organic changes may occur in an hysterical contracture, and the contracture, which was previously due to muscular sprain, becomes fixed by scar tissue. It is therefore important that manipulation should not be delayed too long in these cases, especially as the mental state becomes more fixed and more difficult to treat with the passage of years.

Cases Relieved by Manipulation.—This large group includes a great many conditions due to disease rather than injury, the principal probably being the group of infections and intoxications usually known by the name "rheumatic," especially in its more chronic forms. Here again it is obvious that those cases in which only a slight degree of stiffness of a joint is present are much more satisfactory from the point of view of treatment than cases of marked stiffness or cases in which well-marked destruction of the joint surfaces has occurred. It is important also to wait until all signs of activity have subsided and furthermore to eradicate the cause wherever possible before having recourse to manipulative measures. In nearly all cases of strains and sprains

gentle manipulation at the earliest moment is recommended because the reparative processes of nature act most effectually when, as far as possible, no interference whatever with their functions is resorted to. (H. B.*)

MANITOBA (*see* 17.584), a province of the Dominion of Canada. By an Act of the Canadian Parliament passed in the session of 1911–2 the eastern boundary of Manitoba was extended north to lat. 60° N. and northeast to the point where the meridian of 89° W. intersects the southern shore of Hudson Bay. This gave the province possession of two ports on Hudson Bay—Fort Churchill and Port Nelson. The effect of the change was to increase the area of Manitoba to 251,832 sq. m., of which about 13,500 sq. m. are covered by lakes. The population of Manitoba in 1921 was 610,118 an increase of 32·23% over 1911. The rural population was 348,502 and the urban 261,616. The legislative assembly consists of 55 members with an executive council of the premier and six members. The province is represented in the Dominion Parliament by 17 members of the House of Commons and six senators. There is an excellent secondary and public school system. Higher education is provided by the University of Manitoba which has affiliated with it several church colleges and professional schools. The Manitoba Agricultural College, near Winnipeg, is supported by the province.

Production and Industry.—The following table shows the total yield in bushels of the principal field crops for 1910, the annual average 1922–4, and 1925:—

Crop	1910	Av. 1922–4	1925
Wheat	34,125,949	45,773,000	39,453,000
Oats	30,378,379	67,955,333	71,770,000
Barley	6,506,634	31,837,333	52,156,000
Rye	29,205	5,857,667	5,152,000
Flax	176,675	1,844,000	1,664,000

In 1925 the number of live stock amounted to: horses, 359,839 cattle, 720,745; sheep, 101,997; and swine, 298,507. Dairying became firmly established after 1915, and both production and export greatly increased. In 1924 the chief dairy products were creamery butter, 12,632,804 lb.; dairy butter, 9,285,464 lb.; cheese, 500,633 lb.; and milk over 200,000,000 gallons. Large quantities of fish are obtained from Lakes Winnipeg and Manitoba, principally whitefish, sturgeon, pike and pickerel. The annual value of the fisheries during the post-War period exceeded $1,000,000.

Copper ore occurs in the Pas district. Gold has been found in contiguous areas. A mottled limestone is quarried at Tyndall, east of Winnipeg, and is in wide demand as building stone. Gypsum deposits are mined northeast of Lake Manitoba. Portland cement is manufactured at Winnipeg and Babcock. The average annual production of minerals from 1919 to 1923 was valued at over $2,500,000. The province possesses extensive water power resources. The available power at ordinary minimum flow is estimated at about 3,250,000 horse-power. The turbine installation in 1925 was only 169,325 horse-power. The chief industries are meat-packing and flour milling. In 1922, 768 manufacturing establishments with a capital of $84,662,378 gave employment to 13,789 employees, who received $17,891,064 in salaries and wages, and utilised $54,619,248 worth of material in producing goods valued at $94,417,608.

Communications.—Railway mileage increased from 3,221 m. in 1910 to 4,521 m. in 1925. The transcontinental lines converge at Winnipeg. Branches have been constructed linking up these lines with the area west of Lake Winnipeg and with Hudson Bay. Direct lines south to Minneapolis and St. Paul give connection with the United States. Great progress was made in the construction of roads after the passing of the Manitoba Good Roads Act in 1914: 6,191 m. of roads had been authorised and $10,985,497 expended by the Government and municipalities between the passing of the Act and Aug. 31 1924. (*See* CANADA.) (D. A. Mac. G.)

MANIU, JULIUS (1873–), Rumanian politician, was born at Simlaul Sylvanie (Transylvania). He studied at the universities of Cluj, Vienna and Budapest, and was for many years professor of law at the theological academy in Blaj. At the age of 26 he joined the National Rumanian party of Transylvania. In spite of the bitter opposition of Count Stephen Tisza, Maniu was elected deputy and sat in the Parliament at Budapest from 1906 till 1910. When the World War broke out Maniu was sent to the front and in 1918 was fighting against Italy. When he realised that the collapse of the Central Empire was in sight, he went to Budapest, where a National Rumanian Council was formed, Maniu taking charge of military and foreign affairs. He then went to Vienna and organised the revolt of Hungarian regiments, composed of Rumanians of Transylvania, stationed in Vienna and Prague. On Dec. 1 1918 the Rumanian National Assembly at Alba-Iulia proclaimed the union of Transylvania and the Banat with Rumania and elected Maniu, president of the *Consiliul Dirigent* (local government) which took over administrative control throughout Transylvania. In 1919 Maniu was elected president of the National Rumanian party of Transylvania, which in 1925 coalesced with the Nationalist-Democratic party. Maniu became the chief of this new formation, which took the name of the National Rumanian party.

MANN, THOMAS (1875–), German poet and novelist, was born at Lübeck June 6 1875. At the age of 19 he went to Munich where he was at first employed in a fire insurance company, but wrote novels at the same time. He then abandoned his practical calling and attended lectures at Munich University in literature, history and the history of art. He visited Italy, and was afterwards, for a time, editor of *Simplizissimus*. His chief work, excellent in both style and construction, is the period novel, the plot of which is laid in Lübeck, *Buddenbrooks, Verfall einer Familie* (1903, Eng. trans. 1924). His other books include *Königliche Hoheit* (1915). *Der Zauberberg* (1925), and a number of shorter novels including *Der Tod in Venedig* (1912) and *Tonio Kröger* (1914). He also wrote one drama, *Fiorenza* (1906) and *Betrachtungen einer Unpolitischen* (1918), a declaration of Conservatism. See Fr. Leppmann, *Thomas Mann* (1916).

MANNING, WILLIAM THOMAS (1866–), American Protestant Episcopal divine, was born in Northampton, England, May 12 1866. He graduated at the University of the South, Sewanee, Tenn., and entered the ministry from the diocese of California, being ordained deacon 1889 and priest 1891. He became rector of Trinity Church, Redlands, Cal., 1892, and was appointed professor of theology in the University of the South, 1893. He became successively rector of St. John's, Lansdowne, Pa., 1896; rector of Christ Church, Nashville, Tenn., 1898; Vicar of St. Agnes's Chapel, Trinity Parish, New York City, 1903. In 1904 he was appointed assistant rector of Trinity Church, New York City, becoming rector in 1908. He was consecrated Bishop of New York May 11 1921. A constant advocate of Christian unity, he was prominent in promoting the World Conference on Faith and Order. In 1925 he inaugurated the public movement for the completion of the Cathedral of St. John the Divine, New York City.

MANOEL II., ex-King of Portugal (1889–), was born at Lisbon Nov. 15 1889, the younger son of Carlos I. by his wife Marie Amélie of Orleans. On the assassination of King Carlos and of the Crown Prince Luis, Duke of Braganza, Feb. 1 1908, Dom Manoel succeeded to the throne of Portugal, but he only retained it for a short time, as the revolution of Oct. 3 1910 forced him to flee the country (*see* PORTUGAL). He took refuge with his mother in England, and finally settled at Fulwell Park, Twickenham. On Sept. 4 1913 he married, at Sigmaringen, Princess Augusta Victoria of Hohenzollern, daughter of Prince Wilhelm of Hohenzollern. Dom Manoel supported the Portuguese Royalist risings of 1911 and 1912, and in the latter year met the pretender to the Portuguese throne, Dom Miguel, at Dover in order to concert a common plan of action. On the outbreak of the World War, however, he appealed to all classes of his former subjects to lay aside political feelings and unite against the Central Powers.

MANSFIELD, KATHERINE (1890–1923), British writer, was born at Wellington, New Zealand, the daughter of Sir H. Beauchamp, and spent most of her girlhood in New Zealand. She published *In a German Pension* (1911), and in 1913 married John Middleton Murry, the critic, with whom she had been associated in the publication of a literary review, *Rhythm*. Her

brilliant talent for the short story form was displayed in a collection issued as *Bliss* (1920), and her acute critical powers in frequent contributions to *The Athenaeum*, then edited by her husband. This was followed by *The Garden Party* (1922), but a career of great promise, and small but perfect achievement, was cut short by death, after a long illness, at Fontainebleau Jan. 9 1923. Further stories, *The Doves' Nest*, appeared later in that year, also a volume of *Poems*, and in 1924, *Something Childish*, tales and fragments of minor interest.

MANSHIP, PAUL (1885–), American sculptor, was born at St. Paul, Minn., Dec. 25 1885. He studied at the St. Paul Institute of Art, the Pennsylvania Academy of Fine Arts at Philadelphia, and in New York City. In 1909 he went to Rome, having been awarded a scholarship at the American Academy there, and remained abroad three years. On his return to the United States his works quickly attracted attention by their individuality and his figures, exhibiting archaic traits skilfully coupled with intensely modern feeling, placed him in the front rank of American sculptors. In 1914 he was awarded the G. F. Widener Memorial Gold Medal at the Pennsylvania Academy of Fine Arts, obtaining also a gold medal at the San Francisco Exposition, 1915. He devoted himself chiefly to classical subjects, but executed two very striking portraits, "John D. Rockfeller" and "Miss Manship," the latter being a study of his daughter, aged three days, which is in the Metropolitan Museum of Art, New York City. Among his other chief works are the J. P. Morgan memorial in the Metropolitan Museum of Art; the "Infant Hercules" fountain in the courtyard of the American Academy at Rome; "Dancing Girl and Fauns" and "Indian and Prong-Horn Antelope" in the Art institute, Chicago; "Yawning," in the St. Paul Institute; and "Centaurs" and "Little Brother" (statuette) in the Detroit Museum of Art.

MAP (*see* 17.629).—Steady progress was made in all branches of map construction until the outbreak of the World War, when a type of map not hitherto in general use in warlike operations came into demand. With regard to normal topographical maps a useful landmark was the publication in 1908 by the U.S. Geological Survey of a book on *The Interpretation of Topographic Forms*. Three matters stand out as deserving of special attention—the revival and standardisation of the *International Map of the World;* the striking progress made in the few years immediately preceding the War with the mapping of the British Empire; and the great part which maps played, in all armies and in the fighting on all fronts, during the War, but especially on the Western Front. (*See* SURVEYING.)

International Map of the World.—The official title of this international undertaking is *Carte du Monde au Millionième*, and references to it will generally be found under this title. It owes its origin to the initiative of Prof. A. Penck, who put forward the project of a map of the world on a uniform scale at the Geographical Congress held at Berne in 1891. The scale proposed was one-millionth of nature, equivalent to 1 km. to 1 mm., or 15,178 m. to 1 inch. The scheme and the scale were accepted by the congress, and an international, but unofficial, committee was appointed for the purpose of prosecuting the idea. This committee reported to successive Geographical Congresses held in London in 1895, in Berlin in 1899 and in Washington in 1904, but not very much progress was made.

An important step was, however, taken at the Geographical Congress held at Geneva in 1908. At this congress the delegates of the United States made a proposal for the definite standardisation of the map and for the drawing-up of fixed rules to govern its production. The next step in its history is that the geographical section of the British General Staff took up the subject, and a promise was given at the Geneva Congress that, if possible, an official conference should be assembled to deal with the matter. This promise was carried into effect in the following year.

In Nov. 1909 an official conference assembled at the Foreign Office in London, on the invitation of the British Government. The countries represented were, in addition to Great Britain, Australia, Austria, Austria-Hungary, Hungary, Canada, France, Germany, Italy, Spain, Russia, the United States, *i.e.*, the British Empire and the other European and American Great Powers. The conference came to unanimous conclusions, and an account of it was published in a report issued by the British Government. The object of having an official, rather than a non-official or academic, conference was that experience had shown that without the support of the official map-making bodies, such as the great survey departments, little or nothing would be done in the way of actually producing the international sheets.

At the Geographical Congress at Rome in 1913 the scheme as formulated in London was accepted generally, but there was a feeling that a more comprehensive official conference was needed in order to put the matter before those countries not hitherto represented officially. Accordingly, after some correspondence between the British and French Governments, it was agreed that the latter should issue invitations to an official conference to be held in Paris in Dec. 1913. Thirty-four states sent representatives, and a very thorough examination was made of the London resolutions. In the main they were accepted, and the modifications made were not in matters of principle but of detail. The scheme had in fact got into a definite standard form, and the *Carte du Monde au Millionième* is now a world undertaking on lines accepted by practically all civilised countries.

The Paris Conference took an important step in approving of the establishment of a "*bureau permanent*," comprising a central office to be located at the headquarters of the Ordnance Survey at Southampton, with a branch office in London, at the Royal Geographical Society, where visitors to London can obtain all information with regard to the international map and its progress.

Maps for War Purposes.—The Conference came to an end on Dec. 18 1913, but the report was not published when War broke out early in Aug. 1914. The effect of the War on the scheme was twofold. First, it resulted in the immediate cessation of all work on the map so far as the belligerent countries were concerned; but in the second place it led to a demand for maps on, or about, the one-to-a-million scale, and so in England and France, particularly the former, much official cartography was carried out on the million scale, and a large series of maps was produced by the initiative of the General Staff.

This important series comprises 90 maps extending from the Persian Gulf to the Arctic Ocean, and from the western shores of Ireland to beyond the Caspian Sea. Its sheets were selected by the Peace Conference for use in determining the new European frontiers. It differs from the regular international series in small technical details. The international map, interrupted by the War, has since been taken up again and satisfactory progress has continued to be made.

The trench warfare of 1914–8 in France and Belgium created a demand for maps on a larger scale than had hitherto been in general use by great armies, and large scale maps became indispensable for the operations of trench warfare particularly in connection with the use of artillery. With regard to that portion of the line which passed through northeast France, the 1:80,000 map, the best then available, was enlarged to 1:20,000 which made an unreliable map. Bit by bit, these enlargements were corrected and eventually all the maps of the Western Front were redrawn from special surveys, air photographs and revised cadastral manuscripts, the chief scale in use being 1:20,000. The map showed the enemy's trench system in detail, and all the maps were provided with a system of "squares," or co-ordinates, which enabled any point to be defined within a few metres. The use of "squares," or co-ordinates, is typical of modern military maps. An example of a typical trench map of the Western Front on the scale of 1:20,000 is shown on the plate.[1]

[1] 1. The large rectangles on the map lettered A, B, C, etc., are divided into squares, 1000 yd. side, which are numbered 1, 2, 3, etc. Each of these squares is subdivided into four minor squares of 500 yd. side. These minor squares are considered as letters a, b, c, d (see square No. 6 in each rectangle). A point may be thus described as lying within square B.6, M.5, b, etc.

2. To locate a point within a small square, consider the sides divided into tenths and define the point by taking so many tenths

Progress of Cartography.—Modern topographical maps increasingly use colour. The old black, engraved maps were beautiful as specimens of engraving, but were never very easy to read, and in no case did they convey so much, or such accurate, information as do the modern topographical maps printed in five or six colours. But it is doubtful how long the modern coloured map will last; the paper is not nearly so durable as that which is used for the printing of copper-engraved maps, and the colours are in some cases none too permanent. These remarks apply with special force to the "layered" maps; changes in the tones of the layers will greatly alter their character.

Topographical Maps.—In Great Britain the new popular edition of the ordnance map on the scale of one inch to one mile is in colours with contours at 50 ft. intervals. It is completed for England and Wales and is one of the best topographical maps in existence. The new quarter-inch ordnance map, in layer form, is completed for Great Britain. An excellent map of Roman Britain has been published by the Ordnance Survey. In Canada an important series of topographical maps on the scale of one inch to one mile is being published by the Dept. of Militia and Defence. These maps have been in progress since 1907. About 90 sheets have been issued covering an area of about 40,000 sq. m. in the provinces of Ontario and Quebec. The only complete series of topographical maps of the Union of South Africa are those of the Orange Free State; these are on the scale of 1:125,000, or about half an inch to one mile. They were painted by the geographical section of the General Staff. There has been a marked improvement in the character of the topographical maps of India. Up-to-date methods of colour printing have been adopted with success. India, also, has produced the largest block of sheets yet published of the regular series of the international map.

Ceylon is gradually being covered by an admirable series of one-inch maps in colour. The new one-inch map of the Federated Malay States is a very satisfactory production. The mapping of Kenya and Uganda, which has made good progress, was stopped by the War and has not been resumed. Work is being carried on in the Gold Coast and Nigeria and in the Sudan.

The admirable and well-known series of maps of the U.S. Geological Survey continues to be issued. The production of the elaborate French 1:50,000 series in colour was completely stopped during the War; it is now being published in a simpler form. The Italians are mapping Tripoli and Italian Somaliland on the 1:100,000 and 1:50,000 scales, and the map of Italy on the 1:100,000 with brown contours and vertical hachures is a clear and useful map. The map of Spain on the 1:100,000 scale in colours, published by the Spanish General Staff, is in progress. There is an excellent series of maps of Denmark on the 1:400,000 scale, published in colours by the Danish General Staff, and some fine maps have been issued by Norway. A good start is being made with the mapping of Poland.

BIBLIOGRAPHY.—For examples and criticism of various kinds of topographical maps, see A. R. Hinks, *Maps and Survey* (Cambridge, 1923); C. F. Close, *Text Book of Topographical and Geographical Surveying* (Stationery Office, London, 1925); see also R. D. Salisbury and W. W. Atwood (U.S. Geological Survey), *The Interpretation of Topographic Maps* (Washington, 1908). (C. F. CL.)

MARC, FRANZ (1880–1916), German painter, was born at Munich July 4 1880, the son of the painter. Wilhelm Marc; his mother was of French extraction. He studied at the academy in Munich under Hackl and W. von Dietz. For the first seven years of his career as a painter he showed little originality. The decisive impulse came only when he got into touch with the group of painters including Kandinski, Jawlenski and Macke who founded the "Blue Knight" (*Blauer Reiter*) in 1911. One of his most famous pictures entitled "Tierschicksale" (Destinies of Beasts) is characteristic of his whole work, which is singularly compact, not merely in choice of motive, but also in pictorial composition. A certain leaning towards metaphysics, towards abstraction from the world of reality, gives many of his pictures a problematic character. He also wrote a series of articles pleading the cause of the new painting. Marc was killed near Verdun on March 4 1916.

MARCH, FRANCIS ANDREW (1825–1911), American philologist (*see* 17.688), died in Easton, Pa., Sept. 9 1911.

MARCH, PEYTON CONWAY (1864–), American soldier, was born at Easton, Pa., Dec. 27 1864. He graduated from Lafayette College in 1884 and four years later from the U.S. Military Academy. He graduated from the artillery school in 1898, and on the outbreak of the Spanish-American War went to the Philippines, remaining there three years and rising to the grade of lieutenant-colonel of volunteers. After honourable discharge from the volunteers in 1901 he was appointed captain of artillery in the regular army. From 1903 to 1907 he was a member of the general staff and in 1904, during the Russo-Japanese War, was with the Japanese Army in Manchuria as observer. He was promoted major in 1907, lieutenant-colonel in 1912 and colonel in 1916. Soon after America's entrance into the World War in 1917 he was made a brigadier-general, U.S.A., and later major-general of the national army and in Sept. 1917, major-general of the regular army. In 1917 he was with the A.E.F. in France in charge of the American artillery forces. In March 1918 he was appointed acting chief-of-staff, and the following May chief-of-staff with the rank of general. On June 30 1920 his rank reverted to that of major-general, and at his own request he was retired from active service Nov. 1 1921. As chief-of-staff of the army, he reorganised the War Dept., consolidated the regular army, National Guard and national army divisions into a single army—the U.S. Army; and initiated and carried into execution a programme which landed in France, by the time of the Armistice, 2,000,000 men.

MARCHAND, JEAN (1883–), French painter, was born in Paris Nov. 22 1883. He studied at first with Bonnat and Merson (1902–6), after which he deserted conventional teaching, and exhibited for the first time at the Salon des Indépendants in 1908. He visited Russia and England on several occasions. Though Marchand came under the influence of cubism between 1910 and 1912, his work in general was not greatly affected by it. His human forms are treated with power and discretion, while his landscapes and still life are tinged with an intense melancholy. Exhibitions of his work were held at the Carfax Gallery, London, in 1915 and 1919. Among Marchand's pictures may be mentioned "Les Gueux" (1906); "Le Départ" (1910); "Suzanne au Bain" (1911); "Trois Baigneuses" (1912); "Le Carafe" (1913); "La Gardienne du Foyer" (1914); "Nocturne" (1915); "Le Soir" (1919).

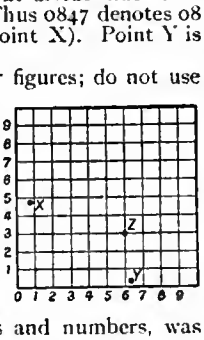
MARCHAND, JEAN BAPTISTE (1863–), French general and African explorer, was born at Thoissey (Ain) on Nov. 22

---

from W. to E. along southern side, and so many from S. to N. along western side, the S.W. corner always being taken as the origin, and the distance along the southern side being always given by the first figure. Thus the point Z would be 63; *i.e.*, six divisions east and three divisions north from origin.

3. When more accurate definition is wanted (on the 1:20,000 or 1:10,000 scale) use exactly the same method, but divide sides into 100 parts and use four figures instead of two. Thus 0847 denotes 08 parts east and 47 parts north of origin (see point X). Point Y is 6303.

4. Use 0 but not 10; use either two or four figures; do not use fractions ($8\frac{1}{4}$, $4\frac{1}{2}$, etc.).



The system of reference by squares shown on the map and described above was used throughout the War by the British armies on the Western Front. Although clear and simple in practice it was not ideal for gunnery purposes. For this reason it was decided shortly before the Armistice to supersede it by another and more universally useful system.

Colours.—The topography was represented in three colours. The detail including towns, houses, railways, roads, woods and grid lines and numbers, was printed in grey, water in blue and contours in brown.

Military details such as trenches, battery positions, mine craters, obstacles, etc., were shown in blue (British) and red (German). British trenches were not shown *in extenso*, but only for such distance from the front line as might be assumed to be already well surveyed by the enemy.

Conventional Signs.—The signs used for objects of military nature changed considerably during the War as the result of alteration of types of defensive and offensive works.

1863. After four years' service in the ranks, he was, in 1887, appointed a sub-lieutenant. In 1889 he was on active service in Senegal, was twice wounded, and made a chevalier of the Legion of Honour. In 1898 he carried out his historic occupation of Fashoda (*see* 1.341), and for this he was promoted to commander in the Legion of Honour, having been previously raised to the grade of officer. In 1900 he became lieutenant-colonel, and was made colonel two years later. Shortly after the outbreak of the World War he was appointed to command the Colonial Brigade of the XIV. Corps, and in Feb. 1915 was promoted a temporary-general of brigade. In the following May he assumed command of the 10th (Colonial) Division. He was wounded in Sept. 1915, and was made a grand officer of the Legion of Honour. On March 25 1916 he was made a substantive-general of brigade. On April 4 1917 he was promoted general of division and confirmed as commander of the 10th Colonial Division. He retired from the army in 1919 and was given the grand cross of the Legion of Honour in the following year.

MARCONI, GUGLIELMO (1874–), Italian wireless telegraphy inventor, was born at Bologna on April 25 1874. His father, Giuseppe, was an Italian country gentleman who, in 1864, married Miss Annie Jameson, daughter of Mr. Andrew Jameson of Daphne Castle, County Wexford, Ireland. The issue of the marriage was two sons, of whom Guglielmo was the younger. He was educated privately at Bologna, Florence and Leghorn. As a boy he took a keen interest in physical and electrical science. In 1895 the idea became firmly rooted in his mind that a system of telegraphy through space could be provided by means of electric waves, the existence of which had been foreseen mathematically by Clerk Maxwell in 1864 and later investigated experimentally by Heinrich Hertz, Oliver Lodge, Righi and others. Interesting scientific experiments had been carried out in London and elsewhere with these electric waves, but Marconi was the first to devise the practical means by which they could be made to provide a new and revolutionary method of telegraphic communication.

In the early summer of 1895, Marconi conducted a number of experiments at his father's country house at Pontecchio, near Bologna. These experiments, made with crude and inefficient apparatus, soon began to give results which appeared to Marconi to be remarkable, communication being established in that year over distances in excess of a mile. The first considerable advance which he made was his discovery of the marked effect of the simultaneous use of elevated transmitting and receiving aerials connected to the ground through the generators (transmitters) and detectors (receivers) of electric waves. He discovered that by connecting one of the spheres of the spark-gap by means of a vertical wire to a metal plate buried in the earth, he was able to multiply many times the range of communication for a given amount of power.

In his receiver Marconi used the form of coherer, or sensitive detector, employing nickel and silver filings, connected to the earth and to an elevated conductor, in the same way as was done at the transmitting end, and provided with connections to a relay and other mechanical arrangements, which made it capable of receiving and recording the impulses of telegraphic signs transmitted through space from the sending station. In these early days, Marconi also discovered that the distance of communication increased very rapidly if the height above ground of the elevated aerials was increased. This fact was pointed out in his first patent and was also clearly described in a letter dated Nov. 14 1896 addressed by him to Mr. William Preece, afterwards Sir William Preece, engineer-in-chief of the British Post Office.

In 1896 Marconi came to England, and on June 2 of that year took out the first patent ever granted for wireless telegraphy based on the use of electric waves. He continued his experiments in London, and in the same year demonstrated his invention before officials of the Post Office and other representatives of British and Foreign Govt. departments. These demonstrations were first carried out on the roof of the General Post Office, St. Martin's le-Grand, London. Later experiments for the Post Office were carried out on Salisbury Plain and across the Bristol Channel from Penarth to Brean Down, near Weston-super-Mare, ranges first of two, then of four, and afterwards of nine miles, were obtained.

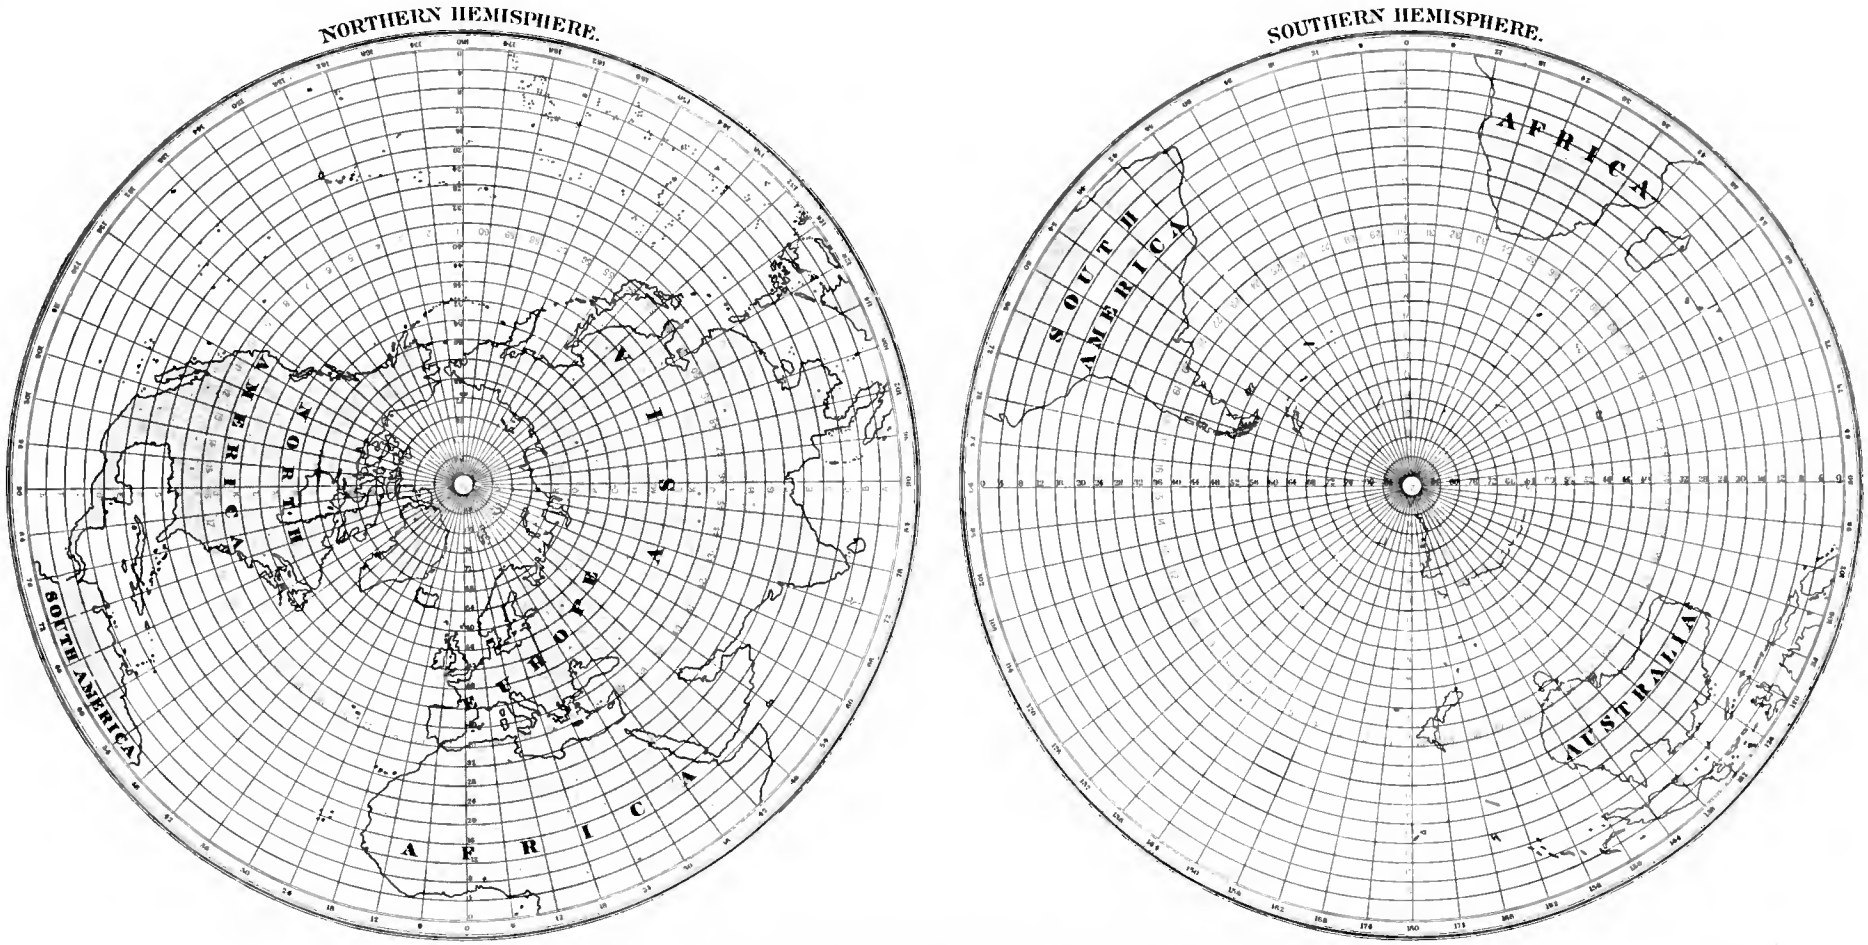
In June 1897, at the invitation of the Italian Govt., Marconi went to Spezia, where a land station was erected and communication with Italian warships was established up to a distance of 12 miles. He was then invited to demonstrate his apparatus in Rome, where successful tests were carried out in the presence of the late King Humbert and Queen Margherita. Other tests also took place at the Italian Chamber of Deputies.

The time was now almost ripe for wireless telegraphy to be applied to commercial and utilitarian purposes, and in July 1897 a company was formed in London to acquire the Marconi patents in all countries except Italy. This company was called the Wireless Telegraph and Signal Company Limited, which in 1900 changed its name to that of Marconi's Wireless Telegraph Company Limited. For some time the company's efforts were confined to furthering Marconi's pioneer work. A number of interesting tests and demonstrations were undertaken round the coasts of the British Isles and abroad. Permanent stations were erected at Alum Bay in the Isle of Wight and at Bournemouth, this station being subsequently removed to Poole, 14 m. from Alum Bay.

Wireless telegraphy was first used for commercial purposes in 1898, when the Kingstown regatta races were reported for *The Dublin Express* by Marconi by means of wireless apparatus installed on a tug which followed the yachts in the Irish Sea. In the same year, during Cowes week, Marconi was called upon to establish wireless telegraphic communication between Osborne House in the Isle of Wight and the Royal Yacht "Osborne," to enable the late Queen Victoria to communicate with the Prince of Wales, later King Edward VII. In this year also wireless telegraphy was first employed as a means of communication between lightships and the shore by installations on the East Goodwin lightship and the South Foreland lighthouse, separated by a distance of about 12 miles. The utility of wireless in saving life at sea was demonstrated for the first time when, on March 3 1899, that lightship was run down by a steamer. The accident was at once reported by wireless to the South Foreland, enabling life-boats to be promptly sent to the assistance of the light vessel. In March 1898 Marconi established communication across the English Channel between England and France. During this year wireless was also first utilised in the naval manoeuvres for communication between warships over distances of 74 miles. The first military application of wireless took place during the South African War.

During this period numerous improvements embodied in patents taken out by Marconi were utilised. On April 26 1900 he applied for a patent for "tuned or syntonic telegraphy as well as multiplex telegraphy with a single aerial." The important novelty was the incorporation of tuned closed with tuned open circuits in both the transmitter and receiver. This patent, the number of which was 7777, became famous in the history of wireless, and its validity was upheld in the High Court by a decision of Mr. Justice Parker. The principles on which this patent was based were fully described in a lecture given by Marconi on "Syntonic Wireless Telegraphy" before the Society of Arts in May 1901.

In Oct. 1900 the erection of a long distance wireless telegraph station in Cornwall was commenced by Marconi and preliminary tests were carried out up to a distance of about 200 miles. On Dec. 12 1901 Marconi, on his first attempt, succeeded in transmitting and receiving signals across the Atlantic Ocean from Poldhu in Cornwall to St. John's, Newfoundland. This achievement completely confirmed Marconi's opinion that electric waves would not be stopped by the curvature of the earth and therefore could be made to travel any distance separating any two places on our planet, a view he had held for many years in the face of considerable opposition. The wireless conquest of the Atlantic may be regarded as the culminating point of Marconi's pioneer work.



INDEX DIAGRAM OF SHEETS FOR THE INTERNATIONAL MAP ON THE SCALE OF 1:1,000,000.

In 1902 Marconi, during a voyage on the American liner S.S. "Philadelphia," received messages up to a distance of 700 miles by day and 2,000 miles by night, thus first discovering the now well-known fact that wireless signals can usually be received over much greater distances at night than during the hours of daylight. Marconi read a paper dealing with this phenomenon before the Royal Society on June 12 1902. At the time his conclusions were severely criticised and his results doubted, but later experience completely confirmed his observations. In 1902 Marconi designed and patented a practical form of magnetic detector based on the effect of electrical waves on iron or steel when subjected to a varying magnetic field. This magnetic receiver replaced the receivers up till then in use, and for over ten years remained the standard receiver on the great majority of sea-going vessels equipped with wireless.

In 1905 he took out his patents for the horizontal directional aerial, which marked an advance in the design of long distance stations. During the same year, in a lecture delivered before the Royal Institution, Marconi first pointed out that most probably wireless transmissions right round the world to places near the antipodes would be carried out with greater ease and at lesser expenditure of electrical energy than would be necessary to much nearer places. Later results fully confirmed the correctness of these views. In 1910 Marconi, assisted by Mr. H. J. Round, received signals and messages at Buenos Aires from Clifden (Ireland) over a distance of about 6,000 miles. In 1912 he devised a new method for generating continuous waves, commonly known as "the timed spark system." This system was employed for several years at many important long distance stations and by its means Marconi sent the first messages ever transmitted by wireless from England to Australia on Sept. 22 1918.

In 1916, during the World War, experiments were commenced by Marconi in Italy with very short waves, with the object of devising a directive, or beam system, of wireless telegraphy for war purposes. This was a principle on which he had also worked during his earliest experiments, but work on these lines had been put on one side in favour of the use of longer and longer waves combined with higher power. Later, in England, with the assistance of Mr. G. S. Franklin, important results were obtained by the use of 15-metre waves between London and Birmingham. The result of the tests with short waves carried out in 1916 and 1922 were fully described in public papers by Marconi and Franklin in 1922. (*See* WIRELESS TELEGRAPHY.)

These anticipations of Marconi were fully justified by the results obtained since that time with short waves by British and foreign experimenters. Marconi was the first to discover in Oct. 1924 that short waves of the order of 30 metres in length could be transmitted and received over the greatest distances during daylight. Short waves have proved themselves capable, even when used with a minimum of power, of carrying out communications by night as well as by day over any distance, even to the antipodes. Marconi demonstrated that short waves are much more amenable to control than long waves and they have the very great advantage over long waves that by the use of suitable reflectors, or by an efficient system of directive aerial, they can be directed in a beam as light waves are directed from a lighthouse or searchlight.

Marconi stated publicly that this possibility of focussing and directing short electric waves would soon be applied universally and that except for broadcasting and shipping purposes it would no longer be necessary to send out waves at random in every direction.

During the World War Marconi served in both the Italian army and navy. He also visited America as a member of the Italian war mission to the United States Government. In 1919 the King of Italy appointed him plenipotentiary delegate to the Peace Conference in Paris, and in that capacity he attended the meetings of that conference and signed on behalf of Italy the Peace Treaties with Austria and Bulgaria. He also attended in the same capacity the meetings of the commission on mandates held in Paris and in London, and in other ways rendered valuable services to the Allied cause.

The value of Marconi's work has been recognised by governments, universities and learned societies all over the world. Amongst the many scientific awards granted to him may be mentioned the Nobel Prize for physics in 1909, the Albert Medal of the Royal Society of Arts, the Franklin Medal and the John Fritz Medal awarded to him in the United States for the "invention of wireless telegraphy." In the same year he was nominated by the King of Italy to be a member of the Italian Senate.

Every great invention, when it has become established, has given rise to controversy as to who was the real inventor. Doubts have been expressed as to whether Marconi was in fact the inventor of wireless telegraphy. In the interests of historical truth, therefore, it is worth while to make the following quotation from the judgment given by Judge William K. Townsend of the United States Circuit Court of May 4 1905, in the action Marconi Wireless Telegraph Company of America versus De Forest Wireless Telegraph Company:—

It would seem, therefore, to be a sufficient answer to the attempts to belittle Marconi's great invention that, with the whole scientific world awakened by the disclosures of Hertz in 1887 to the new and undeveloped possibilities of electric waves, nine years elapsed without a single practical or commercially successful result, and that Marconi was the first to describe and the first to achieve the transmission of definite and intelligible signals by means of the Hertzian waves.

The exact contribution of Marconi to the art of spark telegraphy may be stated as follows: Maxwell and Crookes promulgated the theory of electrical oscillations by means of a disruptive discharge; Hertz produced these oscillations and described their characteristics. Lodge and Popoff devised apparatus limited to lecture or local experiments or to such impracticable purposes as the observation of thunder storms. Marconi discovered the possibility of making these disclosures available by transforming these oscillations into definite signals and, availing himself of the means then at hand, combined the abandoned and laboratory apparatus and by successive experiments reorganised and adapted and developed them into a complete system capable of commercially utilising his discovery.

Other inventors, venturing forth on the sea of electrical movement, met the rising tide of the Hertzian waves and allowed them to roll by without appreciating that this new current was destined to carry onward the freight and traffic of the world commerce. They noted their manifestations, suspected their possibilities, disclosed their characteristics, and hesitated, fearing the breakers ahead, imagining barriers of impracticable channels and shifting sand bars. Marconi, daring to hoist his sail and explore the unknown current, first disclosed the new highway. (F. G. K.*)

MARGARINE (*see* 17.704) was first made from fresh beef fat freed from tissue and digested at a temperature of about 110° F. with the pepsin obtained from pigs' or sheep's stomachs, rendered alkaline by a dilute solution of sodium carbonate. The process of manufacture was improved from time to time, and before the end of the War the product, particularly vegetable margarine, was so like butter in texture, flavour and appearance that it was difficult to distinguish from the product it was made to imitate. Generally speaking, three types of margarine exist: (*a*) animal margarine, (*b*) vegetable margarine and (*c*) mixed margarine.

Varieties of Margarine.—Animal margarine has as a basis the material called *oleo oil* which is made by pressing *premier jus* by hydraulic presses, so as to separate the liquid oil (oleo oil) from the hard fat (stearine). *Premier jus*, as the name implies, is the first running of fat obtained by heating the fatty tissues of the caul and the kidneys of cattle at a temperature not exceeding 100° to 120° Fahrenheit. This fat is washed with brine and allowed to crystallise or "grain," and is pressed to obtain the oleo oil.

The fatty basis of vegetable margarine usually consists of a hard fat mixed with a liquid vegetable oil. The hard fat in this case is usually either about 25% of hardened (hydrogenated) oil, or 65 to 70% of cocoanut or palm-kernel oil. As liquid oils, cotton seed, arachis, soya bean and many others are used in accordance with the price and quality of the product desired. All these materials are subjected to a very drastic process of refinement and deodorisation. In the case of mixed animal and vegetable margarine the solid fat is either *premier jus* itself or *oleo stearine* (*i.e.*, the residue left after pressing premier jus).

Whichever type of fatty basis is used it is subjected to a process of incorporation with milk. Skimmed milk is generally used for the purpose, not so much for the sake of saving the cost as because it is more readily obtained, and has greater bacterial purity than whole milk. The skimmed milk, previously pasteurised, is placed in vats (ripening tanks), and is there inoculated with a pure culture of lactic acid-producing organisms—mainly *Bacillus acidi lactis* Leichmann—which coagulate souring milk.

The temperature is carefully controlled and, in a scientifically organised factory, the souring to the required extent is arranged to take place by a definite time. Great care is taken to keep the culture free from adventitious organisms which would produce undesirable flavours and impair the keeping properties of the finished product. Mould fungi are specially undesirable as they produce an unpleasant rancid flavour in the margarine, particularly when made with vegetable fats.

When the milk has reached the desired state of sourness, it is churned with the fat, with or without artificial colouring matter, in specially constructed jacketed churns fitted with beaters for finely incorporating the previously melted fat with the soured milk. This churning process has to be carried out with great skill, care being taken to maintain the correct temperature and to stop the churning at the exact point when the emulsion reaches its maximum thickness, as continued churning causes the mass to become thin again. Various types of emulsifiers other than churns are in use, some of which are very efficient. When the emulsion has reached the desired state, the product is then finished by either the wet or the dry process.

Wet Process.—In the wet process the emulsion is projected against a violent spray of iced water, which causes the emulsified fat to solidify in fine globules; the solidified mass which is produced subsequently floats on a tank of cooled water, from which it is removed and mechanically worked until the desired consistency is obtained. Salt and preservative, if any, are incorporated into the mass together with more colour. About 30% of milk is used in the wet process.

Dry Process.—The dry process is more economical, and little more than half the amount of milk is then required. In this process the emulsion from the churns is run in a gentle stream on to large rolls cooled inside with brine. The emulsion, as it solidifies on the surface of the rolls, is scraped off by knives and then worked on tables, kneaders and rolls, in the same manner as in the wet process.

Admixture with Butter.—Margarine, like butter, must not contain more than 16% of water. The admixture of butter with margarine to the extent of more than 10% of the former is prohibited. This regulation is still in force, though it seems originally to have been made to dispel the fear of the farmer that butter might be adulterated with small quantities of margarine to make such an excellent product that his trade might suffer, and that the public might be defrauded. Modern methods of analysis are able to determine the percentage of butter fat in margarine to within comparatively narrow limits, which was not the case when margarine was first invented.

Margarine usually contains 0·25% of boron preservative, except the type termed "fresh-roll," in which no preservative is used; at present up to 0·5% of boron preservative is permitted, but under new British regulations which will come into force in 1927 no preservatives will be permitted. The nutritive value of margarine has long been a subject of discussion. The chemical composition of butter is very similar to margarine, which actually gives the same number of calories or heat units as butter, and an average margarine is as digestible as an average butter. The average butter is characterised by considerable vitamin content, whereas margarine is practically devoid of any such characteristic. (See W. Clayton, *Margarine*, 1920.)

(E. R. B.*; R. G. P.)

MARGATE, England (*see* 17.704), with an area of 2,961 ac. (including 468 ac. of foreshore), had a population of 46,475 in 1921. Parts of Garlinge and Northdown were added to the borough in 1913. A town-planning scheme, providing for an industrial zone at the back of the town and restricting the number of houses to the acre elsewhere, has been put into operation. The town is very healthy, the death-rate being usually under 10 per 1,000. The municipality owns over eight miles of seafront, with promenades along almost the whole distance. A pavilion and winter garden have been erected in a hollow on Fort Green, and a pavilion on the jetty; the path along the cliffs to Kingsgate has been made into a wide promenade, with a new bridge at Palm Bay; a seawall and undercliff promenade have been built, and a large bathing pavilion is (1926) in course of erection. A wing for tuberculous ex-service men was opened at the Royal Sea-bathing Hospital in 1919, and a public library in 1923. The War Memorial is in front of Holy Trinity church. During the widening of the Minster-road in 1922 an Anglo-Saxon cemetery was discovered. During the World War 156 bombs were dropped on Margate and 44 shells were fired from the sea; considerable damage was done, but the casualties were few.

MARGHILOMAN, ALEXANDRE (1854–1925), Rumanian statesman, was born at Buzeu July 4 1854. He studied law and political science in Paris. In 1884 he was elected a deputy as a member of the Conservative party, of which he became leader in 1914. At the beginning of the World War, Marghiloman advocated Rumania's neutrality and when in 1916 Bratianu offered him a portfolio in his cabinet, Marghiloman refused on the ground that he could not assume the responsibility of an insufficient military preparation. He remained in Bucharest under the German occupation, where he organised the relief work for the population. He emphatically rejected the proposals of the German commander to form in Bucharest a government for the purpose of concluding a separate peace. In March, 1918, Marghiloman went to Jassy at the request of the King and formed a government which eventually signed the separate peace with the Central Powers. This treaty, however, was never ratified. When the War ended Marghiloman ceased to play any part in Rumanian politics and after his death in Buzeu, May 10 1925, the Conservative party ceased to exist, its members joining Gen. Averescu's (People's) party.

MARGUERITTE, PAUL (1860–1918), French novelist (*see* 17.706), died Dec. 30 1918 in Paris. His later works included *La Maison brûle* (1913) and *Jouir* (1918).

MARIE, Queen of Rumania (1875–), was born at Eastwell Park, Kent, Oct. 29 1875, the eldest daughter of Alfred, Duke of Edinburgh, second son of Queen Victoria. On Jan. 10 1893 she married Prince Ferdinand, afterwards King of Rumania. From this marriage six children were born: Prince Charles, who married Princess Helen of Greece, Princess Elizabeth, married to the ex-King George of Greece, Princess Marie, later Queen of Yugoslavia, the Princes Nicolas and Mircea (d. 1916) and Princess Ileana. The Queen was a Protestant, but the children, in accordance with the Rumanian constitution, were brought up in the Orthodox faith. Queen Marie took a great interest in the development of her adoptive country. Red Cross and charity organisations were formed at her initiative and, as a Red Cross nurse during the World War, she looked after the wounded in hospitals and ambulances up to the firing line. Queen Marie devoted much of her time to writing, and her published works include *The Lily of Life* (1913), *My Country* (1916), *Stealers of Light* (1916) and *Ilderim* (1925). Together with King Ferdinand, Queen Marie was crowned at Alba Julia Oct. 15 1922.

MARINE ENGINEERING (*see* 25.840c).—At the present time there are three distinct types of marine engines, and these may be grouped as follows: (1) steam-engines with coal-fired boilers; (2) steam-engines with oil-fired boilers; (3) internal-combustion engines, such as the Diesel or semi-Diesel type. Of course, groups (1) and (2) may be reciprocating steam-engines, turbines (geared or otherwise) or combined turbine and reciprocating. The three types are described below.

Reciprocating Marine Steam-engines.—To-day, all marine reciprocating steam-engines are stage expansion engines, that is, the steam expands in stages from the highest pressure cylinder, through the intermediate stages, and finally exhausts into the condenser. Modern stage-expansion engines may be grouped as

follows: *Compound.*—In this type there are two cylinders, the high pressure and the low pressure. Steam performs its function in the high pressure cylinder; from there it passes into the low pressure cylinder, completes its work on this cylinder and finally exhausts to the condenser. *Triple Expansion.*—In this engine, as its name implies, steam exerts its power in three stages before exhausting to the condenser. *Quadruple Expansion.*—In this type the steam is used four times before exhausting to the condenser, two intermediate cylinders being fitted.

No marked improvements have taken place in this type of prime mover, except as regards engine refinements, the general design remaining the same. The advent of the marine steam turbine and the marine internal-combustion engine certainly has led many shipbuilders to install one or the other of these types; but it is interesting to note that in some recent large steamers, notably the Peninsular and Oriental "Naldera" and "Narkunda," the carefully balanced triple-expansion engine has been installed. Experiments are being carried out to utilise steam at a much higher pressure than formerly, and excellent results are expected.

Combined Reciprocating Engines and Steam Turbines.—An excellent example of this arrangement is the White Star "Olympic." The arrangement has proved an economical one, and is as follows: Each wing propeller shaft is driven by a reciprocating engine, the low pressure cylinder of which exhausts into a Parsons low-pressure turbine driving the centre shaft; 21 double-ended cylindrical boilers supply the necessary steam.

Marine Steam Turbines.—(*See* TURBINES, STEAM.) The advantages of this prime mover which has led to its adoption during the past few years are as follows:—

(*a*) Fewer working parts, as no slide valves, piston and connecting rods are required.
(*b*) The steam is supplied direct from the boilers with no intervening loss.
(*c*) Considerably less danger of breakdown.
(*d*) Engines placed well down in vessel (a big asset in warships).
(*e*) Less expenditure of lubricating oil.
(*f*) No cylinder lubrication is necessary, and clean feed water is returned to the boilers.
(*g*) Absence of vibration, a big factor in warships and passenger steamers.
(*h*) Smaller attendance required than in the case of reciprocating engines.
(*i*) Superior governing, good parallel running and even turning movement.
(*k*) Priming, which would fracture the cylinder covers of a steam reciprocating engine, has no material effect on a turbine.
(*l*) Overloading (forcing the engines) can be indulged in within reasonable limits.
(*m*) More economical except at the lowest speeds.

The large-sized turbines are more economical in steam per horsepower developed than the best triple or quadruple expansion engine, as the turbine is able to take full advantage of the whole of the expansive energy of the steam. The two types in general use are the Parson combined impulse and reaction turbine, and the Brown Curtis impulse turbine. There are, naturally, many modifications of these types.

Geared Turbines.—These turbines are coming into favour more and more. The chief trouble with the marine turbine arose with the propeller. It is necessary that a turbine for maximum efficiency should run at a high rate of revolution, whilst for maximum propeller efficiency, much lower rates of revolution are necessary. The solution for this was by the introduction of some form of gearing between the turbine and the propeller. Several forms of reduction gearing are being experimented with, such as the electrical, hydraulic and mechanical. Mechanical gearing appears at present to show advantages over the other forms—an efficiency of over 98% being obtained in the case of single reduction, and over 97% with double reduction. There is practically no limit to the ratio of reduction. Double reduction gearing finds favour for the following reasons: (*a*) the type permits larger ratio between revolutions of turbines and propellers without excessive size of gear wheels—higher revolution of turbines permits, for the same power, smaller turbines, and increase in the number of turbines for the same power further reduces the size of each unit; (*b*) high revolutions or greater blade speed are possible, resulting in a nearer approach to the point where the blade speed in relation to steam speed gives maximum economy; (*c*) a small turbine permits of a pivot thrust block being used, as the dummy can be omitted, and all unbalanced load taken by the block; (*d*) small turbines have small rotors and can thus be made of a much more robust construction; (*e*) variations in temperature for any single turbine are kept moderate, and these turbines are therefore suitable for use with superheated steam; (*f*) the parts being smaller, the turbines can be more easily overhauled, repaired or renewed. America favours the electric drive for her navy and mercantile marine.

Marine Internal Combustion Engines.—One of the principal reasons which has led to the adoption of the internal combustion engine for marine propulsion is the thermal efficiency of this prime mover. Compared with a steam engine (reciprocating), and coal-fired boilers, we find: Diesel 40% to 45% thermal efficiency, according to size; steam engine 20% to 25%. As regards running, the fuel bill is about half that for an oil-fired boiler ship fitted with geared turbines; very great saving of space occupied by the machinery; reduction of personnel.

Against these advantages we have the greater initial cost; complication of parts; a greater number of spare parts have to be carried; it is probable that the repair and upkeep bill will exceed that for steam units. Before a big reduction can be made in initial and upkeep costs, all parts must be standardised; and the engines should be built in combinations of various numbers of cylinders for various powers and revolutions. For a given power the Diesel compares unfavourably as regards weight with the steam turbines and oil-fired boiler combination, and the head-room is greatly limited (this, especially from a naval point of view, is a marked disadvantage). The possibilities of this prime mover are endless; but up to the present the Diesel has not been installed in the largest ocean-going liners or cross-channel mail packets. There is no doubt, however, when a speed of, say, 25 knots can be reached, combined with a reliable and simple design of engine, we shall see the mammoth type of internal combustion ship breaking the Atlantic records. The largest ship up to the present with Diesel engines installed has a length of 600 ft. and a breadth of 72 ft.; and another Diesel-engined vessel of 20,000 tons is under construction. The present types work on the two-stroke or on the four-stroke principle; but many competent authorities affirm that the marine oil engine of the future will be a double acting two-stroke with port scavenging—this design giving an engine of low initial cost and simple construction. The solid (or mechanical) injection of the fuel is likely to be generally adopted in preference to the air injection system, owing to the reduction in first cost that is obtained by its use. Experiments are now being carried out with geared Diesel engines, and these will be watched with interest.

Marine Boilers.—It is only within the last few years, comparatively, that the water-tube boiler has been seriously considered as a rival to the cylindrical, or water-tank, boiler. The experience gained after many years with the cylindrical marine boiler proved it to be undoubtedly a good, safe, easily understood generator and also comparatively easy to clean. This type may be said to be the principal boiler of the mercantile marine. For naval purposes, of course, there can be no question as to which type is suitable; but even with such highly trained engine-room ratings as the British Navy possesses the advent of the water-tube boiler was not looked upon at all with favour. Although water-tube boilers are being fitted in increasing numbers in the mercantile marine, their many advantages do not appear to be recognised to the extent they should be, this being due in part to the high initial cost and also to the fact that the fuel consumption is inferior to that of the cylindrical type. However, the outstanding features of the water-tube boiler (*i.e.*, they are much lighter and give greater horsepower for the same space) should further recommend them. The modern trend is toward much higher working pressures, higher temperatures and the more efficient burning of the fuel and generation of the steam in the boiler. There is no reason why pressures of 700 lb. or 800 lb.

per sq. in. should not be reached. Superheating of the steam, air preheating, increase in boiler feed water temperature and careful analysis of the funnel gases are all receiving due attention, as are also the best means to adopt to ensure the cleanliness of the internal surfaces and tubes, and thus prevent or retard corrosion. Zinc slab protection is, to a certain extent, being superseded by electrolytic protection. In this system electrolytic conductivity is produced in the boiler water by a current of electricity from a source outside the boiler to metallic anodes insulated from the boiler shell, the current being regulated at will.

Oil Burning in Marine Boilers.—Within the last few years oil fuel burning has made rapid strides, and but for the question of cost would be much more generally adopted. As an example of saving in boiler-room staff, after the Cunarder "Aquitania" was converted to burn oil, her firemen were reduced to 42 as against 320 when coal-burning. The advantages of oil fuel are: superior evaporative power per weight of fuel carried, giving increased radius of action—1 lb. of oil with a heat value of 19,000 B.T.U. will evaporate 15 lb. of water to and at 212° F., and 1 lb. of coal with a heat value of 14,500 B.T.U. will evaporate 10 lb. of water to and at 212° F.; ease of shipping into bunkers and putting into fires; less stokehold staff and bunker space required; absence of coal dust and ashes; no necessity to open furnace doors with consequent loss; proper regulation of combustion; capability of forcing the boiler. Against those advantages we have: uncertainty of obtaining supplies; complications of piping and machinery; possible leakage; special appliances are required for burning; liquid and solid impurities found in the oil; widespread contamination of water-ways.

Liquid fuel is atomised by one of three methods—steam, compressed air, pressure. The last method is generally adopted in modern marine practice due to the reliability and freedom from breakdown of pressure systems. The system as now adopted is very simple; oil is drawn from the bunkers and strained, which removes all solid impurities. The oil is delivered from the fuel pumps under pressure, an air vessel assisting in maintaining a steady supply. Next, the oil passes through cold filters and thence to the heaters. The heating process may form particles of carbon in the oil, which are removed by passing it through filters fitted on the delivery side of the heater. From these filters, called hot filters, the oil passes under pressure to the distribution boxes on the boiler front, and from there through the burners (where it is atomised) to the furnaces.

Marine Auxiliaries.—The great increase in the number of auxiliary engines now fitted in modern steamships necessitates as much attention as do the main propelling machinery. As regards design, the majority of auxiliaries follow accepted practice; but the following units call for special consideration.

Condensers.—The modern method is to insure high vacuum combined with reliability, and that the weight of the apparatus shall be as low as possible consistent with the work the condenser is called upon to perform. Separate air pumps are installed, one pumping out the feed water, and the other maintaining a high vacuum by pumping air from a cooler part of the condenser. Tube failure—through corrosion—is a frequent source of trouble, and the many experiments now being carried out with tube metal mixtures have not eliminated this.

Electrolytic protection has been adopted with good results. Metallic packing for the tubes, in place of the ordinary tape packing, has recently been introduced, and the results are excellent. In connection with modern condensers a system has been devised known as the "closed feed system." By this method the condensate is removed from the condenser and discharged to the boiler without exposure to the atmosphere; thus preventing air mixing with the feed water and causing boiler corrosion. Another method now coming into favour is the removal of the air in the feed water by mechanical de-aeration; and this method seems to possess advantages over the removal of the air by chemical means.

The Michell Thrust Block.—This block possesses marked advantages over the older form of multiblock. The device consists of one collar on the shaft, the thrust being taken by a series of pads capable of a slight rocking movement. The pads maintain a continuous flow of oil between the metal surfaces, which are thus kept apart by as many oil wedges as there are pads to produce them. This block is essential to the satisfactory working of gears now fitted in many modern ships.

BIBLIOGRAPHY.—F. J. Drover, *Marine Engineering Practice* (1924); R. Sennett and Sir H. J. Oram, *The Marine Steam Engine* (1924). (F. J. D.)

MARINES (*see* 17.719). *Great Britain.*—Marine forces in some instances constituted the whole or the main part of forces told off for coastal descents, *e.g.*, the British expedition to Ostend in 1914 and the Zeebrugge enterprise of 1918. In others they undertook emergency land operations for which no other military force was available, *e.g.*, in the case of the Royal Marine Bde. at Antwerp, 1914; or again, as in the case of the U.S. Marine Bde. in France, 1917–8; and the British 63rd (R.N.) Div., which included marine units, in the composition of a land army in continuous operations. In several instances the marines proper formed a soldier nucleus for formations of which the principal part was made up of sailors, as the British R.N. Div. and even more so the German Marine Corps. France used improvised battalions and brigades of sailors (Fusiliers Marins) in the same way, and a brigade of these under Rear-Admi. Ronarc'h won undying glory by its defence of Dixmude during the first battles of Ypres and the Yser.

The German Marine Corps was composed originally as a division partly of marines and partly of sailors, who were numerically far in excess of naval requirements. It took part in the siege of Antwerp and the advance through Flanders. When stabilisation came the division was raised to the strength of a corps, and the corps commander (Admi. Schroder) was made responsible for the Yser front, for coast defence between Nieuport and the Dutch frontier, and for purely naval operations based on the Belgian coast, having both submarines, surface craft and aircraft under his command for the purpose. Finally, the German corps formed a third mobile division which was sent to any point on the Western Front where reinforcements were needed.

The Royal Marines, 1914–8.—Just before the outbreak of the World War the total strength (all ranks) of the British Corps of Royal Marines was 18,000. During the War, however, the strength of the corps increased steadily, until at the end its numbers had been more than trebled, due to the formation of new units within corps. In 1914 the R.N. Div. was formed; various divisional units of Royal Marines were raised for service with it, such as engineers (transferred to the Royal Engineers in 1917), medical units and transport. The R.M. Submarine Miners (1917), the R.M. Labour Corps, the Home Service Labour Corps (1917) and the R. M. Engineers (1918) were raised. Special units were also provided separately and compositely by the R.M. Artillery and the R.M.L.I. at various times.

In all naval actions, and in naval patrol duties, the Royal Marine personnel took a part. In the early days of the War personnel of the corps served with the armoured cars operating from Dunkirk. Four battalions of the brigade took part in the defence of Antwerp. Details from two R.M.L.I. battalions were involved in the landing at Kum Kale and Sedd-el-Bahr (March 4 1915), and marine artillery siege guns were used at Dunkirk. The corps sent a battery to Egypt in 1916 for coast defence duties. Detachments served also in Cameroon, in the Persian Gulf and with Admi. Troubridge in Serbia, and formed the nucleus of the heavy batteries which were raised for service with Gen. Botha in South-west Africa and with Gen. Smuts in East Africa. The corps furnished gun crews for armed merchantmen and garrisons for naval bases as at Scapa, Cromarty and St. Helena, and for the coast defences at the North Foreland, in the West Indies and elsewhere. (X)

United States.—The United States Marine Corps is a separate military organisation under the administration of the Navy Dept., and as such it forms a part of the naval establishment of the country. It was founded on Nov. 10 1775 when a resolution of the First Continental Congress authorised the raising of two

battalions of marines to assist the continental navy in the defence of the colonies. In organisation, training and duties this force was modelled after the British marines of that date. From then to the present the marines have continued to serve as an integral part of the U.S. Navy, although under the authority of congressional enactment portions of the corps have been temporarily detached for service on shore with the U.S. Army.

The laws provide that marines may be assigned to the following duties: to garrison the different navy yards and naval stations within and beyond the continental limits of the United States; to furnish detachments to serve aboard the battleships and cruisers of the fleet where they form one of the gun divisions of the ship, perform military guard duties and act as a landing force from the fleet or squadrons as required; to act as expeditionary landing forces for service with the fleet to capture and defend such positions as may be required as temporary naval bases for the fleet; to furnish the first line of the mobile defences of naval stations and bases beyond the continental limits; and, when special conditions make it advisable, to be temporarily transferred for service with the army.

The marines have taken a conspicuous part in every war in which the United States has been engaged and have also seen much foreign service in the peace-time occupation of foreign countries for the protection of American citizens and property during revolutions and unsettled conditions, in furtherance of the diplomatic policies of the United States.

Before the Spanish-American War in 1898 the marine corps consisted of 75 officers and 2,000 enlisted men, but was increased thereafter, and at the entrance of the United States into the World War in 1917 it consisted of 511 officers and 13,124 enlisted men, and during that War a total of 31,824 marines were sent overseas for service with the A.E.F. The Fourth Brigade of Marines formed a part of the Second Division of the A.E.F., where they served in many campaigns and battles with conspicuous gallantry and gained many citations and decorations. The peace-time operations of organisations of the marine corps have included expeditions to China, Cuba, Nicaragua, Mexico and Panama, for the protection of American interests, and the recent occupations of Santo Domingo and Haiti to insure the peace and stability of these countries under treaty obligations between them and the United States. The mission of the marine corps under the stated naval policy of the United States is: "To support the fleet, or any part thereof, in the accomplishment of its mission." The emblem of the corps is a hemisphere with the map of the Americas thereon, superimposed upon a foul anchor and surmounted by an eagle with spread wings. The motto of the corps is "*Semper Fidelis*." (D. W.*)

MARINESCU, GEORGE (1864–), Rumanian neurologist, was born at Bucharest Feb. 23 1864. He was educated at the faculty of medicine of Bucharest and then went to Paris where he worked under Dr. Charcot at the *Salpêtrière*, carrying out valuable researches on the histopathology of the nervous system. A year later he went to Frankfort and worked with Professor Weigert. He then continued his research work on nervous diseases in Berlin and Brussels. In the latter town he published his work on the treatment of epilepsy for which he obtained a prize from the *Académie Royale de Belgique*. In 1900 he was appointed Professor of neurology at the University of Bucharest. In the autumn of 1916 Professor Marinescu went to London where the Medical Research Committee made him a whole-time grant. At the L. C. C. Maudsley Hospital, Denmark Hill, in collaboration with Lt.-Col. F. W. Mott, F.R.S., he applied himself to an important series of researches upon the microscopic structure of nerve cells and their changes in different phases of activity or damage. He also took an important part in the investigation of the nervous system in some cases of *Encephalitis lethargica*.

MARINETTI, FILIPPO TOMASO (1878–), Italian writer, was born at Alexandria Dec. 22 1878, and studied in Paris, graduating at the Sorbonne; in 1899 he also graduated in law at the University of Genoa. He was the founder of the futurist movement, publishing the original futurist manifesto in the Paris *Figaro* on Feb. 20 1909. For a time he edited the international review *Poesia*, but his most characteristic work was *Mafarka le futuriste*, published in French in 1910. He also wrote for the stage *Le roi Bombance* (1905), a satirical tragedy, and other plays, and published a volume on the futurist theatre, *Teatro sintetico futurista* (1916). In 1914 he wrote an extraordinary volume entitled *Zang-tumb-tuuum* on the Balkan war, and particularly on the siege of Adrianople. Other futurist essays are *Noi futuristi* (1917), *Manifesti del futurismo* (4 vol., 1920), *Democrazia futurista*. On the outbreak of the World War he was strongly in favour of Italian intervention, as he showed by his volume *Guerra sola igiene del mondo* (1915). *Otto amici in mia bomba* deals with war experiences; while in *Futurismo e fascismo* (1922) he expresses his support of the Fascist movement. Marinetti's futurism, though violent, exaggerated and sometimes ridiculous, is a quite genuine reaction against the excesses of the academic and hidebound tradition in literature and art.

MARKBY, SIR WILLIAM (1829–1914), Anglo-Indian jurist (*see* 17.730), died at Headington Hill, near Oxford, Oct. 15 1914.

MARKETING.—Marketing is essentially buying and selling. The central fact is the sale, but to secure sales the goods must often be assembled from the places where they were produced, graded when qualities differ, sorted when there are different varieties, moved to market and in many cases thence to the place of consumption.

I. IN THE UNITED STATES

Methods of Marketing.—The simplest form of marketing and the most primitive is the sale by the producer directly to the consumer. In the aggregate, sales made in this way even at present run into immense volume, although but a small part of the total of business. Modern business, the development of large cities, an increasing division of labour in industry, all tend to reduce this form of marketing. There is still a considerable amount of marketing of produce, particularly butter and eggs, direct from farmers to consumers, by parcel post and by direct sale. Again, certain specialities, complicated machines and machines requiring much attention and service after the first sale, usually are sold direct by manufacturers to consumers through the medium of speciality salesmen. The salesman is the representative of the producer in the marketing transaction. Again, if a retailing house does so large a business that it can advantageously engage in manufacturing some of the lines of goods it sells, it may combine production with distribution.

Most products of common use, such as foods, clothing, footwear, house furnishings, lumber, fuel and so on, are marketed through middlemen. The manufacturer of men's clothing or of shoes usually sells his product to retailers scattered over the country, who in turn sell to consumers. Manufactured food products, dry goods, drugs, hardware and house furnishings are generally sold first to wholesalers, who in turn sell to retailers.

Farmers' produce, fruits, vegetables, butter and eggs, are commonly marketed through local buyers, then to wholesalers or wholesale distributors, then to retailers and lastly to consumers.

Variations in Method.—Variations are introduced into marketing in many ways. The actual sale may be consummated through personal salesmanship either in the seller's place of business or in the buyer's. If the seller carries a line of goods he must have a store or shop, but even this may not keep him to one location. The old-time pedlar carried his store on his back. More recently grocery stores, meat shops, book and periodical shops and even dry goods and house furnishings have been put on wheels, on automobile trucks and sales routes laid out to be covered periodically, making sales direct to housewives and consumers. Again, the sales may be effected through retail institutions by mail. In the United States a gigantic business has been built up by a few large mail order houses which are really stores or shops selling retail to consumers. Some wholesale concerns selling only to retail dealers have developed enormous businesses founded on the mail order method of selling. In addition to these there is an unknown but certainly large amount of business transacted by ordinary retail and wholesale stores by mail, supplementing personal selling.

Wholesale Marketing

In the case of highly perishable goods, such as fruits, where no time may be lost in effecting sales in order that they may reach the consumer before spoiling, the auction system is used. Wholesale buyers and salesmen come together at a designated place at a set time and clear their transactions. The auction is a much more widely used mechanism of trade in England and in continental Europe, where large quantities of nearly all kinds of goods are thus sold, than it is in America, where the system is declining. In addition to its use in the marketing of perishable

goods it occurs, to a limited extent, particularly in lines of known standards or qualities, which are bought and sold in wholesale quantities at certain dates each year, as carpets, rugs, wool, furs and fruits. It is also a common method of marketing second-hand goods, works of art, antiques and even real estate.

Variation in marketing occurs through variation in ownership of the goods to be marketed. To illustrate: producers or local buyers usually sell outright to wholesalers all goods marketed through the wholesaler-retailer channel of distribution; but in highly perishable goods, such as fruits, dressed poultry, live poultry, etc., and also in cases where the value of the goods runs very high in proportion to the value of the service rendered by the wholesale middleman—as, for example, finished textiles, real estate, commercial paper and stocks and bonds—the wholesaler (or dealer who takes his place) frequently, if not usually, merely sells or buys as the agent of the owner and secures a commission or brokerage instead of a profit for his services. This arrangement in the case of perishable goods relieves the wholesale dealer of the risk from loss, and, in the case of costly goods, of the burden of financing the goods. Such wholesalers are known variously as commission dealers and brokers.

Function of Speculation.—While goods are being gathered together in wholesale quantities and made ready for distribution to the retail trade other factors in marketing frequently enter in, factors of a speculative nature. Standardised goods that are not readily perishable, such as grain, cotton, wool, silk, provisions, coffee, sugar and so on, are likely to be bought purely for speculative purposes. Thus a lot of grain or cotton may be bought and sold several times before being moved to consumption. It is but another step for these speculators to make their ventures in hope of gain on what they think future prices will be. Hence "selling futures" is a common occurrence on the great exchanges that deal in the commodities named.

Under this system grain may be bought and sold long before it has been harvested or grown, or even before it is planted. (*See* GRAIN TRADE.) A flour-miller may quite legitimately ensure his future supply of grain at a certain price by buying "futures." But a great deal of opposition has been aroused at various times by speculation in the necessities of life. It has been charged that dealing in futures enables powerful speculators to combine unjustly to secure success for their ventures, in some cases tending to hold prices down and in others tending to hold prices up. As a result both producers and consumers are suspicious of such traders. The consensus of opinion among those who have studied the course of speculation on exchanges seems, however, to be that if manipulation of prices and monopoly can be kept out of the market, and if the laws of supply and demand are allowed to operate freely, the effect of speculation, particularly of dealing in futures, has a healthful balancing effect on the market. Under such conditions purchase and sale of commodities for future delivery tend to discount and equilibrate all conditions of supply and demand, so that changes of price are made much more gradually than they would be if buying and selling of such commodities were confined solely to the stock offered each day. Dealing in futures is an essential function of marketing, but it needs careful regulation to prevent unfair practices.

Methods of Marketing.—If producers are many and small, and are located far apart, it is almost certain that their products will have to be assembled by a local buyer of some kind; whereas if the producers are able to turn out large quantities they may be able to deal with wholesalers direct.

If consumers use small quantities or small lots of any product at one time it is almost certain that they must purchase from retailers. But a large consumer would be able to buy more advantageously direct from the producer.

Some articles cannot be sold more than once or twice in a lifetime to a customer. If it also happens that such articles require much demonstration and explanation, then the producer is almost forced to sell direct to the consumer or have his sales made by special representatives or agents. Subscriptions to high-priced periodicals, adding machines, life insurance and real estate are illustrations of goods that need such specialised attention.

Time is a very important element in the marketing of perishable goods. There must be no delay, and little time can be given to the sale of any particular unit. An illustration of a perishable article is the daily paper, the weekly or monthly magazine. Timeliness is the essence of their value. This makes necessary a highly specialised marketing organisation to carry papers or magazines over the country and, in the case of magazines, to place them on sale everywhere at the same time. Such specialised handling calls for expense not incurred in goods not perishable.

A low-priced article with a small margin of gross profit to the seller cannot be sold in the same way as an article that offers a wide margin. In the former case the margin above costs of production could not permit the article to be sold direct or to be advertised and sold by itself by the mail-order method. It must take its way to the consumer through the channels of trade followed by thousands of similar articles.

Competition.—The competition in the sales field of any article might readily determine the channel of distribution that is taken. Certain manufacturers of soaps, perfumes and toilet goods have found it so difficult to place their products advantageously in drug stores and similar retail outlets because of the number of competing lines that they have found it advisable to sell, especially in country districts or small towns, direct to consumers by means of agents and canvassers working on a commission basis. A motor-car tire maker found it so difficult to break into the market through automobile dealers and garages that he sold his product to a mail-order house.

A new product must as a rule be sold through specialised marketing systems which may be abandoned after the public has begun to know the article.

THE COSTS OF MARKETING

Table I. contains figures compiled from actual records by the Harvard Bureau of Business Research, Harvard University.

TABLE I. *The Retailing of Shoes: A Comparison of Costs*
Net Sales 100 per cent

	Lowest	Highest	Usual
	%	%	%
Independent shoe stores:			
Low priced shoes	13·3	32·33	20·5
High priced shoes	23·43	32·85	28·8
Chain shoe stores	9·85	57·60	24·6
Department store:			
Shoe departments	19·0	33·4	23·5

It is clear that the statistics do not prove that in the case of shoes either chain stores or department stores can be conducted at less expense than independent stores. It is true that the lowest figure for chain stores is considerably lower than any other, but the chain stores also show the highest costs. The average costs of selling in chain stores seem to run a little higher than in independent low-priced shoe stores and in department stores.

Table II., showing cost of marketing,[1] is compiled and adapted from reports of the Harvard Bureau of Business Research, Northwestern University Bureau of Business Research, several national trades associations and personal studies.

Costs of selling through mail-order houses are not officially known. They are supposed to range from 18 to 30% of sales. But the knowledge of a general figure of this kind for a large mail-order house with many departments would be of little value even if correct. Costs of selling vary from department to department in mail-order houses just as in department stores. To be of value in a comparison of selling expenses, the figures should show the cost of selling shoes, for example, by mail. All things considered, the general costs of running a large mail-order house are probably somewhat lower than those for a large department store handling similar classes of goods.

The mail-order establishment need not be in a shopping district, so that the rent or investment represented by its size is comparatively small; the employees who fill orders do so more rapidly and for less pay than those who sell in a store; advertising is usually confined to the less expensive publications, and in the case of the largest houses the customers are much more numerous, running into millions. Costs in the shoe department of a mail-order house should run lower than in a department store or speciality shop because in the mail-order house there is no time and labour lost in fitting shoes.

[1] Costs of retailing in other lines of merchandise, so far as the figures are available, show about the same relationships. The example presented may be taken as typical.

TABLE II. *Marketing Costs*
Percentage on Sales

	Wholesale			Retail		
	Lowest	Highest	Usual	Lowest	Highest	Usual
	%	%	%	%	%	%
Automotive Equipment	16	26	23·5	15	29	24
Clothing	12	18	16	20	30	24
Drugs	12	20	15	23	33	28
Dry Goods	11	17	14	15	30	23
Electrical Supplies	10	20	14	20	31	26
Groceries	5	15	9	9	22	14
Hardware	13	21	18	11	32	23
Jewelry	15	20	18	24	40	32
Shoes	12	26	15	13	34	24
Furniture				20	35	25
General Merchandise				10	30	16
Department Stores				18	32	28
Chain Stores (Shoes)				10	57	24
Chain Stores (5 and 10c)				..	..	26
Chain Stores (Groceries)				..	..	16
Chain Stores (Drugs)				..	..	28

This saving is counterbalanced somewhat by the number of shoes which are probably returned. The lower costs of selling in the mail-order house, however, are offset in part at least by the costs of transportation and other expenses incidental to ordering by mail.

Economies in the Chain of Distribution.—A part of the competitive battle for trade among these various types of institutions consists in the utilisation of large buying power. Large chain store systems, mail-order houses and large department stores frequently purchase their goods direct from producers and secure the prices usually given wholesale purchasers. In some cases a part of these differences may be used in cutting the prices to consumers, but it would be a mistake to assume that the consumer gets all the benefit from purchases made at lower prices, or that this entire difference is gained for the dealers. Concerns that go direct to the producers, and thereby eliminate the wholesalers, as a rule incur practically all the usual expenses of wholesaling, such as interest on the investment in the larger stock of goods, storage risks, buying expense in dealing with numerous producers instead of a few wholesalers, extra record-keeping and, with chain stores, reshipments to their various stores throughout the country.

The only real saving which buying direct from producers insures is the eliminated profit of the wholesaler, with a possible reduction of the expense for salesmen whom wholesalers must employ. Competition in buying has forced the joint creation by small concerns of buying organisations which, united, represent as large a buying power as the chain or department stores. Co-operation in buying certain classes of goods has strong advantages both for dealers and consumers. Buying in group at one time may secure advantages, not only in price but also in transportation and handling, sufficient to cover the added expenses incurred in buying in quantity. Since 1920 there has been a rapid development in group buying by independent retailers of all kinds. The competition of chain-store systems wielding enormous buying-power advantages has forced independent dealers, both large and small, to associate for the purchase of many items, and in some cases for the joint ownership of full-sized wholesale houses.

Comparing the various methods of retailing as exemplified in the ordinary independent stores, the department stores and the mail-order house, from such facts as are available, it does not seem possible to assert positively that any one method presents decided general economic advantages over the rest. Each presents advantages in point of service, but the difference in service appears to be fully compensated in expense—that is, the public pays for what it gets and in proportion to what it gets.

So far as the public is concerned, it seems safe to say that there are large classes who prefer and who will always continue to prefer to trade in those retail establishments offering them the highest developments of service, the department stores and the independent speciality shops. Other large classes prefer and will probably always prefer to buy in stores offering less service and proportionally lower prices. Undoubtedly there are many who find their greatest satisfaction in purchasing in the stores of the self-service kind, where they may look about and pick up on their own initiative whatever they may wish to buy. Institutions are built to serve people in the way that they want to be served. There is room, therefore, in the retail trade for many types of stores. Speciality shops, department stores, chain stores and mail-order houses will all continue to exist as long as there are numbers of people who want the services each institution offers. It seems impossible to believe that any one type will monopolise the retail business or crowd out all the others.

Avoidable Waste.—The following statements outline briefly a few of the details of distribution which it seems certain must receive attention in order to secure more economical distribution. No doubt many more could be added. Poor roads greatly increase the costs of bringing the farmers' crops and produce to market, costs that must be added to the price that consumers eventually pay. Inadequate railway transportation is another element that makes a considerable addition to the costs. Car shortages at crop-moving time, cars unsuited to the products to be hauled, excessive delays in forwarding, at terminals, on the way and at transfer points, are common sources of expense.

Delay in transportation as a factor of expense in distribution has not been given the attention that it deserves. Poor location of terminals makes a great deal of expensive cartage necessary. Congestion of traffic in city thoroughfares is a growing cause of increased costs in distributing goods. Inadequate, inefficient, poorly located storage facilities cause huge losses. Inadequate, unauthoritative and inaccurate collection and dissemination of market information such as is needed by producers, distributors and consumers is responsible for great wastes. Through lack of such information business in many lines now passes constantly from glut to famine and back again. Poor packing of merchandise, inefficient loading, rough handling and uneconomical methods of handling are causes of waste and therefore of higher costs of distribution.

To refer more specifically to the activities of marketing through wholesalers and retailers, there is a startling loss of the wholesale salesman's time in finding customers, in making appointments, in fruitless interviews. The time of both salesmen and buyers is lost. Probably less than a sixth of a salesman's time, averaging salesmen of all classes, is actually employed in selling or even in displaying and describing merchandise. Anything that can be done to improve this deplorable economic condition will increase efficiency and decrease costs. No one can even begin to estimate the losses resulting from poorly trained salespeople who fail to sell and who waste the time of their purchasers through lack of knowledge of their goods, their customers' wants and their business, or through lack of ability to use their knowledge properly. Owing to lack of incentive most employees give but a fraction of their ability to their work.

Advertising.—Advertising is or should be an invaluable aid to marketing. In the list of expenses of distribution it occupies a prominent place. There is certainly room for improvement in its administration. Much study has been given in some organisations to such problems as the proper selection of mediums and the right use of the space taken. No doubt much greater progress can and will be made in the future in these directions, but the greatest loss in advertising seems to be in the lack of faith of the public in the advertising. If people gave more credence to advertising, much less of it would be needed to secure the same result. The remedy, of course, lies in the direction of raising the standards and shutting out the dishonest advertiser. (*See* ADVERTISING.)

Duplication.—Duplication in delivery organisations by retail stores is a source of economic waste. There are many who think that there are too many retail stores. Would goods be sold for

less if there were fewer? Probably not, because a large part of the competitive losses now occurring are borne by the dealers themselves in unpaid services. It may be argued that if their number were reduced the rentals for the locations that would be eliminated could be saved. This cannot be definitely checked by such experience as has been recorded in any public way. Concentration of retailing seems invariably to result in increasing rents. In fact, rents tend to increase faster than sales, so that the fewer the stores the higher the share of the landlord. More studies are needed to determine the exact effects of restriction of the number of stores on costs of distribution. There is further the fact that the store plant is unused for a large part of the time. Store hours are by custom and legislation steadily growing shorter. This means that the capital invested in stock and plant has fewer hours in which to produce.

Dishonesty.—Finally, there is undoubtedly an enormous loss due to unfairness and dishonesty, a loss that is now carried in large part if not wholly as an expense of distribution, being added to the price paid by the consumer. Failure to return containers lent by distributors seems a small item, but in such a business as milk distribution in large cities the loss to milk distributors due to non-return of empty bottles is enormous. Uncollectable debts and the cost of collecting delayed payments are important items in the expenses of distribution. Disregard of contracts in such matters as refusal of goods after placing orders, failure to deliver goods after orders are placed, abuse of the privilege to return goods, claims for adjustment and many other similar items make up large losses. Unfair competition, efforts made not to increase legitimate business but to impede or even to destroy competitors, commercial bribery, "graft" and the exercise of monopoly, all burden distribution expense far too much. A source of considerable loss is theft by employees, burglars and shoplifters. Some retail establishments count upon a fixed percentage on their sales representing losses due to this cause, a percentage that is added to the gross expenses which form part of the selling prices. Many of the losses of the distributive business, including theft, breakage, fire and so on, are covered by insurance, the cost of which is carried as an expense against the distributing process. Anything that can be done to reduce these losses will by that much reduce expenses of distribution and prices of goods.

Education in Marketing

The leaks and wastes enumerated above are certainly responsible for at least a quarter of the present costs of marketing. They may be responsible for a third or even more. Here, then, is a great field for reducing costs by improving present methods. The first general step towards such improvement is education. A beginning has been made. Before 1860 the apprenticeship system was general in England and to some extent in America, in retail, wholesale and importing houses. The apprenticeship system gradually decreased about the middle of the 19th century, and for years after no systematic training was provided for young people other than the haphazard effect of their experience. The first training of modern salesmen in America seems to have been by the subscription book houses that flourished during the 'seventies and 'eighties. Their canvassers or book agents were thoroughly drilled or schooled in the art of selling or in securing orders. During the 'nineties sales managers in speciality manufacturing concerns, notably the National Cash Register Co., of Dayton, O., began training their men in special schools held at the factory.

Training salespeople for retail stores seems to have begun in the 'nineties in such subjects as arithmetic, spelling and writing and, in 1905, in sales methods, under the auspices of the Women's Educational and Industrial Union in Boston. Educational service to salespeople and other workers is now commonly found in the better classes of both wholesale and retail stores. A beginning has been made also in education in distribution and marketing in American colleges and public schools. Several colleges offer courses in marketing, selling, sales management and advertising. Many high schools give similar but more elementary courses.

The main drawback to a rapid development of public education in marketing seems to be a shortage of teachers who can conduct such courses rather than lack of public interest. Such an organisation as the United States Chamber of Commerce in its relation to distribution is largely a clearing-house for information and educational ideas for its members. One of the notable things in the progress made in educational work for marketing is the growing conception of the relation of the sciences of psychology and sociology when practically applied to the problems of marketing.

II. IN GREAT BRITAIN

Excepting the larger wholesale markets in England, situated in Liverpool, Mincing Lane, E.C., and elsewhere, which handle cotton, wheat and certain other imported products, it may be asserted that much variety, extremely haphazard methods and a considerable degree of inefficiency in organisation are the characteristics of the marketing process throughout the greater part of England, Scotland and Wales. For this unsatisfactory condition many reasons may be given, not the least important of which is the continued existence of market rights in the hands of private individuals or joint stock companies or their assignees enjoyed under royal charter, Act of Parliament, or surviving manorial rights.

Scarcely less important causes are the reluctance of the smaller British producers to form societies for co-operation in the sale of their output and the comparative ease with which, hitherto, a growing home market has absorbed an output which, especially in the case of certain perishable products, has increased less rapidly than the demand. Again, improvements in methods have not been necessary in the absence, until recently, of effective competition from abroad in respect of most of the less important commodities ordinarily handled in the provincial markets; while the inability of many existing markets to cope with an increase in the volume of business—an inability especially marked in some of the larger towns and arising mainly from the difficulty of reconciling numerous and conflicting vested interests—has rendered difficult any large-scale recasting of the marketing process throughout the country.

Location and Organisation of the Principal English Wholesale Food Markets: Fruit and Vegetables.—The smaller centres of population have traditional and established market places originally set apart for the sale of produce direct from the growers to the consumers. In the larger industrial towns these markets have grown in importance (but not in physical dimensions) with the growth of the towns themselves. Some have become retail markets whose continued existence it is not always easy to justify on economic grounds; but others have become wholesale markets, especially in areas where local production is insufficient or erratic and foreign imports are needed to ensure supplies, or again where transport facilities and favourable geographical situation have permitted the extension of their spheres of influence and caused them to become distributing centres for large areas. Many of these are well organised and are sensitive to price movements in other markets. Since, however, they draw a large proportion of

their supplies direct from the producer, and these supplies are liable to fluctuation, they require an additional and a more reliable source from which to supplement the local output and from which special lines and imported supplies may be obtained to balance demand.

This source they find in the central markets at important ports, and especially in the Covent Garden market in London, which has become a national distributing centre for fruit and vegetables. Privately owned by the Covent Garden Estates Company, Ltd., this market handles not only produce raised within carting distance of London, which is required for London consumption, but also main crop produce in general demand, part of which is regularly recodsigned to other distributing centres, and certain produce in limited demand or supply, such as glass-house produce which commands a high price and most of which is reconsigned to other markets. Much of this reconsignment business is economically indefensible; but it cannot be replaced entirely by direct consignment to provincial markets until the latter become more developed and price movements in them much less liable to be influenced by small alterations in supply and demand.

Meat and Fish.—Wholesale meat markets are generally owned and managed by local authorities, and exist only in those centres of population (not more than 20 in number) where the magnitude of possible trade justifies their establishment and where retailers are assured of adequate supply with wide range of quality and prices. In smaller towns the place of the municipally owned market is taken by wholesale butchers who purchase live stock, slaughter it and sell the meat to retail dealers; and in the City of Sheffield, where no meat market proper exists, the wholesalers sell at the slaughter-houses which they rent from the local authority. By far the largest and most important of wholesale meat markets proper is the London Central Market at Smithfield which in a single year handles between 400,000 and 500,000 tons, including 40% of the total imports of meat into the whole country. Unlike Covent Garden, it undertakes practically no reconsignment of produce to other wholesale markets; but its prices for both home and imported meat (although not officially issued under the imprimatur of the City of London Corporation, which is its owner and manager) are largely used as a basis for wholesale dealings in other parts of Great Britain.

In the foreign meat trade a network of depôts has been established by certain large distributing firms in all the principal cities and towns in the country. To them supplies of chilled or frozen meat are despatched from the ports of entry. They, therefore, serve as small markets from which retailers can secure supplies with ease and promptness. The prices charged are fixed with reference to Smithfield and are, therefore, fairly uniform throughout Great Britain; but local circumstances occasionally demand departure from strict uniformity.

Fish is handled at Hull, Grimsby, Fleetwood, Aberdeen and other ports, usually by Dutch auction, and is distributed by the wholesale purchasers to their stalls and to representatives in certain provincial fish markets (Birmingham, Glasgow, Liverpool, Manchester and others) and also to the very important Billingsgate market in London.

Cereals.—Wheat is usually sold by sample in the local corn-market nearest the producer's home. Certain of these small markets, however, attract a considerable quantity of grain from areas outside their immediate neighbourhood, and some of the largest dominate large tracts of country, frequently serving as depôts for the receipt of both home-produced and imported wheat and for its export to other consuming centres. The purchasers at these local markets include millers among their number; but sale outright to merchants and sale by merchants or agents on commission are not uncommon, the latter being, perhaps, the usual plan in Scotland. Producers' co-operative societies may also be employed, which may sell direct to millers, or more frequently to merchants whom the larger milling-firms find it more convenient to employ in their purchasing of home-grown wheat in bulk.

Barley when sold for malting and distilling is usually sold in the larger market-towns by merchants acting on a commission basis on behalf of the farmer. Oats are largely consumed on the farms of the growers, but direct sale by the producer to oatmeal millers is common. Merchants, however, frequently buy outright for sale to large consumers such as collieries and railway companies.

After wheat is milled it is usually sold direct to bakers, confectioners or other users, generally through travellers employed by the milling companies. Occasionally factors or wholesale dealers intervene, who purchase from millers for re-sale on their own account to small bakers in the more sparsely populated districts. Distribution by this method is uncommon, however, in the case of home-milled flour; although imported flour is nearly always handled by wholesale dealers of this kind.

At the next stage, that of baking, a few firms in several of the more important centres of population confine themselves to a purely wholesale trade. A fair number attempt to combine partial retail distribution with wholesale manufacture and usually possess retail shops where the bread is sold over the counter direct to the consumer or from which door to door delivery by van may be undertaken. The majority of baking firms, however, confine themselves strictly to retail trade, selling, in addition to bread, various forms of confectionery, such as cakes, sweets and biscuits, which may be either proprietary articles or manufactured by the bakers themselves; but certain difficulties, occasioned especially in the north of England by housewives buying bread at irregular intervals only, encourage distributors to cease manufacture themselves and to rely on wholesale baking firms entirely for the supplies which they need.

Poultry and Eggs.—Owing to the fact that British producers of poultry and eggs have no export trade to foreign markets, there is no obligation on them to conform to standardised methods in the disposal of their products. There is consequently great variety in the marketing of these commodities and the plan adopted by an individual producer depends partly on the scale upon which he is operating and partly on his situation relative to his market or his customers. Sale may take place (*a*) by private treaty in the producing area; (*b*) by auction in the producing area; (*c*) directly to distant distributors; (*d*) through commission salesmen in distant wholesale markets; (*e*) through co-operative societies. To the first of these classes may be assigned sales at local weekly markets of eggs and dressed poultry to local customers, sales by parcel post or rail direct to the consumer, sales from door to door often in conjunction with milk and vegetables, sale to local distributors in the nearest market town and sales at the farm. This latter plan is common throughout England and Wales, intermediaries known as higglers (also as cadgers and hagglers) going round in districts where the farms are scattered and distant from the larger consuming centres. The higgler calls at the farm with a vehicle once or twice a week, buys all the eggs and poultry available and pays cash without much regard to classification or to quality. He then resells privately or in open market to wholesale and retail distributors; but he may occasionally send consignments to wholesale markets for sale on commission.

The system of selling by local auction has been greatly extended in recent years. The Stirling live-stock mart is a good example, and the Kings Lynn market also is one that has lately made marked progress in this comparatively new development. For sale on commission the Smithfield and Leadenhall markets in London are utilised as well as the various wholesale markets in the provinces.

Costs of Distribution

The costs of distribution vary considerably with the nature of the commodity handled, the method adopted and the degree of efficiency in the market organisation available to the producer. In the case of cereals the fees paid by the farmers in the local corn-exchange are very small. Sixpence per day, one guinea per year, one penny on each occasion the market is entered, threepence per person entrance fee for sale by sample, are a few examples taken at random of the rentals and fees in actual operation at the present time. Cartage to the market or railway station is also the farmers' expense. This is reckoned at 1s. to 2s. 6d. per quarter of grain up to a distance of 8 to 10 miles. Merchants selling wheat on commission for growers are paid 9d. to 1s. per quarter or 2d. or 3d. per hundredweight. These figures are slightly higher in the cases of barley and oats. A rent ranging from 2 guineas to over 8 guineas per annum is charged to merchants who operate in the local exchanges and who require stands, desks or space on the market floor.

Fruit and Vegetables.—For fruit and vegetables the costs incurred in the complete marketing process are proportionally greater than in the case of cereals. Considerable expense arises in the preparation of produce for the market. Dressing potatoes for example costs 4s. to 5s. per ton. Cartage to railway station is estimated in Lincolnshire on the average to amount to 3s. to 4s. per ton. Railway charges are moderate and, on the whole, reasonable. In the distributive

market itself porterage charges and market tolls are an additional burden and then there are the payments to the commission salesman for his services.

It is the practice of the commission salesman to supply the receptacles or containers needed by the producer and generally to act on the latter's behalf once the produce is despatched from the farm. When a sale has been effected the salesman remits to the grower the amount realised less the charges for use of containers, for transport, porterage, market dues and also a commission on the selling price for service rendered. The latter is nominally about 7½%, but actually in cases investigated by the Linlithgow Committee an average of 10 or 12% was found.

In its further passage towards the consumer the produce may find its way direct to the retailer from the commission salesman, or it may be sold to a commission buyer acting for a distant wholesaler, who in turn resells to the local retailers from whom the consumer buys. These agents who buy on commission may act merely on behalf of principals who cannot attend the market in person, or may themselves buy on their own credit and assume full responsibility for the produce and for bad debts, charging up goods at cost price, adding porterage-out and a flat-rate charge to cover labelling, consigning and the clearing of empties. In the former case they receive a flat-rate per package, handled (2d. in Covent Garden). In the latter they charge 2½ to 7½% on the cost price.

It is calculated that the wholesalers on whose behalf they act make a net profit of about 2% on their sales to retailers, and that the latter obtain a net profit of over 6% on the cost of the goods or a little under 4% on turnover. The diversity, however, of retail services demanded by the consuming public and the wide range of costs entailed cannot but make for uneconomic distribution of these products; it would not be correct to state that the middlemen actually engaged in the marketing process make profits that are unduly large.

Meat.—In the meat trade the following estimates taken from the Linlithgow Report exhibit well the costs incurred and prices paid and received in the passage of beef from the English farmer to consumers in larger industrial centres.

	£	s.	d.
Farmer receives for one animal from dealer at local market	31	0	0
Farmer's expenses (tolls, etc.)	..	9	3
Farmer's net receipts	30	10	9
Dealer receives from wholesale butcher	32	10	0
Dealer's expenses (rail, tolls, feeding, etc.)	..	18	6
Dealer's net profit	..	11	6
Wholesale butcher receives from retailer	30	3	9
Wholesale butcher receives for hide and offals	3	10	6
Gross receipts of wholesale butcher	33	14	3
Expenses of wholesale butcher (slaughtering)	..	13	2
Wholesale butcher's gross profit	..	11	1
Retailer's receipts from consumers	36	9	10
Retailer's payment to wholesale butcher	30	3	9
Retailer's gross profit	6	6	1

The weight of meat sold in this instance was 690 pounds. The net price paid by consumer being £36 9s. 10d. and the receipt from offals being £3 10s. 6d. the difference between the net price received by the farmer and the total made by meat and offals is, therefore, the difference between £40 0s. 4d. and £30 10s. 9d., *i.e.*, £9 9s. 7d. The corresponding differences for Wiltshire bacon and for pork were £3 14s. 7d. and £1 16s. 6d. for weights of 140 and 148 lb. respectively.

The same Committee also collected figures showing the receipts from the sale of a forequarter of frozen beef weighing 187 lb. and costing £2 14s. 6½d. or 3½d. per pound. In this case £5 6s. 1½d. was realised, giving a gross profit of 48·6% on sales. In another case New Zealand lamb costing £1 17s. 4d. was retailed at £2 8s. 0d., leaving a gross profit of 22·2% on sales. When it is remembered that the expenses of the retailer in the case of frozen meat are substantially less than in the case of home-killed meat, owing to the absence of slaughtering and dressing costs, the very remunerative character of trade in foreign meat is readily perceived. Again, competition appears to be less active in the retail meat trade generally than it was before 1914, and this notwithstanding an increase in the number of establishments since that date. It would seem to be the case that butchers, having been encouraged to purchase collectively during the War period, still combine to keep down prices both of stock and meat; and further that retailers to a considerable extent agree on the prices consumers are required to pay and on the whole refrain from underselling one another in open competition.

In the distribution of bacon retailers usually purchase supplies of home-cured bacon direct from the factory; but in some cases they may buy from wholesale provision merchants. The margin obtained by the wholesaler is about 2½%. This is ample for the services he renders. The retailer's gross profit is more difficult to ascertain; for this trade is mainly undertaken by grocers who rarely separate it off from other departments of their business. It appears, however, that the profit on English bacon is from 10 to 14% of the sale price.

Poultry and Eggs.—In the selling of poultry and eggs at the local market, apart from the cost of conveying the produce to the place of sale, the vendor usually has to pay market tolls and, in the case of sales by auction, the auctioneer's fee. The average tolls charged (by the local authorities who usually own the markets) are ½d. to 2d. for poultry and from ¼d. per score to 6d. per 100 for eggs. Auction charges generally range from 5 to 7½% of the price realised and, consequently, are higher than those for selling livestock. This, no doubt, is because of the smaller value of the individual lots put up for sale. The higgler's profit in the districts where he flourishes is from 1d. to 2d. per doz. on eggs. This is not excessive; but his service, nevertheless, is not economical.

The dealer's business is more speculative, owing to the rapid fluctuations in prices from day to day and from market to market. His average profit of from 2d. to 4d. per doz. on eggs is, therefore, reasonable, especially as he provides boxes and pays transport charges. Commission salesmen's charge is 5% of the selling price, and wholesale dealers purchasing on their own account aim at a gross profit on eggs of about 2d. per doz. and of 2d. to 3d. per lb. on dead poultry. Probably it is in the retail section that profit margins in this trade are greatest and most open to question, 14% on eggs and 20 to 30% on poultry being the averages for the whole country. Producers complain that the difference between the prices they receive for poultry and those paid by the public has increased disproportionately in recent years. The gross margin formerly to cover profits and expenses of all intermediaries was roughly 1s. per bird. The current margin is about 6d. per lb., which is approximately 1s. 6d. to 2s. 6d. per bird.

Co-operative Marketing

The organisation of producers on a co-operative basis for the disposal of their produce and for the carrying out the processes involved in marketing is not a new development in Great Britain; but the progress made is insignificant compared with what has taken place elsewhere. Figures in the returns furnished to the Chief Registrar of Friendly Societies for the year ending March 31 1924, referring to societies operating only in England and Wales, establish the fact that roughly about 3½% of the total value of agricultural produce marketed in England and Wales was handled by co-operative marketing societies or co-operative societies with marketing branches. The following table which is taken from No. 1, of the Economic Series published in 1925 by the Ministry of Agriculture and Fisheries (Great Britain) sets out in detail the position for the 12 months beginning April 1 1923.

The following table shows the number and turnover of agricultural marketing societies and certain other societies handling agricultural produce as part of their general trading during the period 1923–4. The table excludes turnovers in grain, hay, potatoes, etc., of general trading societies.

Commodity Handled	Number of Societies	Turnover[2]
		£
Dairy produce	63	1,447,627
Eggs and poultry	43	349,262
Fruit and vegetables	18	301,932
Livestock[1]	9	375,128
Auction marts (livestock)	18	1,081,953
Slaughterhouses	11	415,270
Bacon factories	6	694,826[3]
Wool	13	200,000[4]
Total	181	4,865,998

[1] This entry covers societies selling livestock on behalf of members otherwise than through an auction mart owned or rented by the society.

[2] Turnover in respect of produce handled, and not necessarily total turnover of society.

[3] 1924 figures.

[4] Estimated value.

These 181 societies are widely distributed without any union or centralising agency which might secure joint action or otherwise look after common interests. Attempts, however, have been made from time to time to federate them or to institute an advisory body to assist them to sell advantageously. The most recent project of this kind was the establishment in 1918 of the Agricultural Wholesale Society with the object of buying and selling for such societies everything that is best bought or sold on wholesale lines. The capital of this new wholesale body, however, proved inadequate; and in consequence of a period of acute trade depression with insufficient resources and credit to enable it to surmount its difficulties it

went into liquidation in 1924. During its brief existence it seems to have done more bulk purchasing of agricultural implements and seeds than large scale marketing of produce; although it did set up a department to market eggs and established a meat section to help the co-operative slaughterhouses in their sales in Smithfield market. Its downfall involved the Agricultural Organisation Society in such difficulties that the latter body also succumbed a short time after.

Present Development.—The present trend is in the direction of the several groups of societies forming their own trading federations on a commodity basis and thus falling into line with the general course of development towards larger scale marketing and trade. One such central trading body is the English Farmers' Bacon Agency. Another, the British Egg Producers, which took over the business of an earlier body of the same kind, has hardly met with the success it deserves; but a regional trading federation in South Wales, called the South Wales Mutual Dairies, which is a selling agency for four large dairy societies in Carmarthenshire and Pembrokeshire, has had better fortune. There is also a rather undefined union of fruit and vegetable marketing co-operative societies of the counties of Worcester, Gloucester, Warwick and those adjoining, which is growing into a trading federation; but, on the whole, the association of co-operative marketing societies for joint action in the conduct of the sale of their produce is only very slightly developed in Great Britain.

Since 1900 many efforts have been made to establish trading relations between these agricultural producers' co-operative organisations and the industrial co-operative movement. The 1,300 retail consumers' societies of the latter are said, approximately, to feed one-third of the whole consuming population of Great Britain and are, therefore, in a position to offer an assured outlet for the produce of British farms. While some progress has been made in bringing the two organisations into closer relations it is obvious that the natural clash of interests between producers and consumers must always make price-fixing difficult. If this awkward point could be settled satisfactorily, much might be done to eliminate the control now exercised by the many middlemen in the marketing of agricultural produce. (*See* CO-OPERATION, AGRICULTURAL.)

THE FOOD COUNCIL

The general dissatisfaction with retail prices during the years succeeding the period of War-time Government control resulted in the appointment in 1922 of a departmental committee (the Linlithgow Committee) of the Ministry of Agriculture and Fisheries to inquire into the methods and costs of selling and distributing agricultural, horticultural and dairy produce in Great Britain and to consider how the disparity between the price received by the producer and that paid by the consumer could be diminished. This was followed by a Royal Commission on Food Prices in 1924 with terms of reference not very different. As a result of the first (and only) report of the latter body a Food Council was sent up to study current and future problems of wheat and meat supplies and to issue periodical reports. This Council is not endowed with any statutory powers. It seeks to work by focusing public opinion on whatever it judges to be unreasonable prices or unduly high profits; but it shirks definite price-fixing and thus avoids many problems that presented themselves during the period of Government control and to which no satisfactory solution ever was given.

MARKHAM, SIR CLEMENTS ROBERT (1830–1916), British geographer (*see* 17.734), died in London Jan. 30 1916. The principal work of his later years was connected with the two Antarctic expeditions under Capt. R. F. Scott. An important history of Arctic and Antarctic exploration by Markham was completed posthumously by Dr. F. H. H. Guillemard and published in 1921 under the title of *The Lands of Silence*. A *Life*, written by his cousin, Adml. Sir A. H. Markham, was published in 1917.

MARNE, FIRST BATTLE OF THE, the series of actions fought in Sept. 1914, when the French and British Armies turned at bay between Paris and Verdun and defeated the Germans, driving them back to the Aisne.

The Germans had hoped to bring France to her knees in six weeks, but when four weeks had expired France and England were still keeping their opponent at arms' length. The Germans were indeed slightly ahead of their time table, but they had insufficient troops to carry out their grandiose plan. Antwerp and Maubeuge had necessitated a subtraction of strength and the invasion of East Prussia had led to the dispatch of two corps from the German right wing in France. Further, the rapid advance had led to considerable wastage and the comparative breakdown of wireless was hampering the invaders.

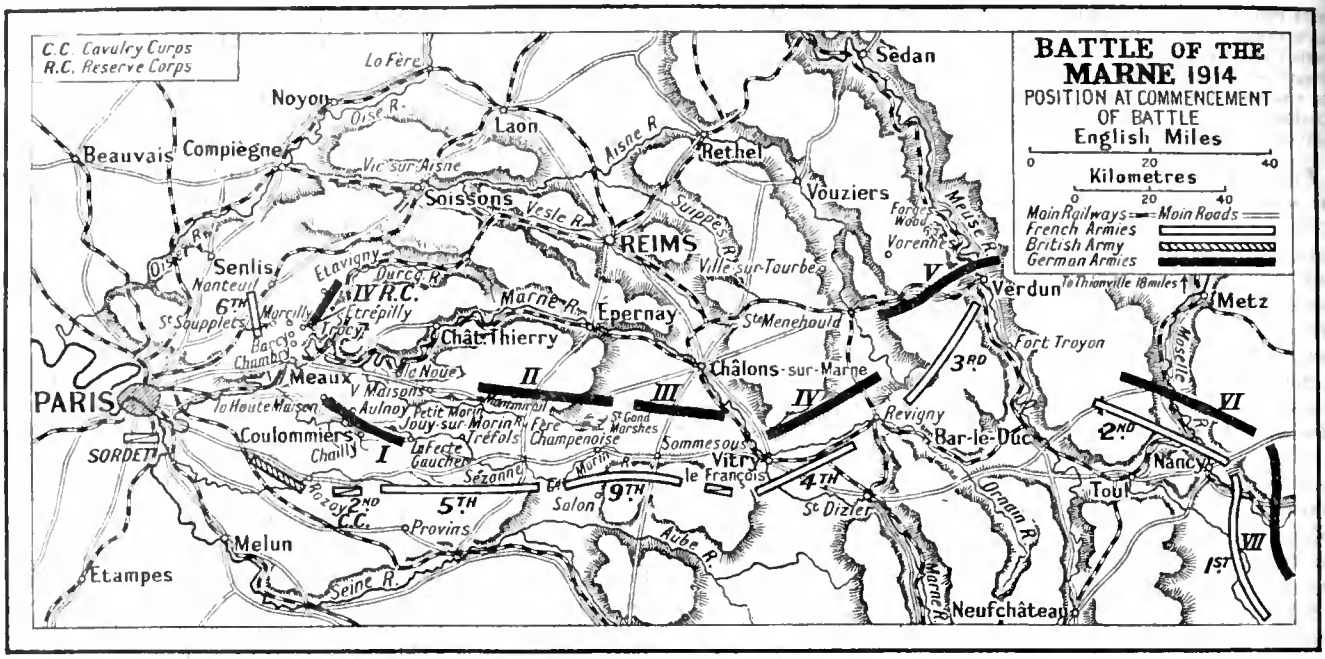
I. THE OPENING OPERATIONS

Advance on Paris.—The original plan had implied that if the French formed a great defensive flank resting on Paris, the capital was to be turned by forces pushed west and south of it; reserve divisions were to be dropped for the investment; and the five field armies, pivoting on Thionville, were to make a stupendous left wheel and to force the Allies against the Swiss frontier. By Aug. 28 this plan had begun to show signs of weakness. The German right wing was not strong enough and was too widely spread out. The II. Army was in comparative isolation and found itself committed to an advance against the great fortress of Paris.

This army was roughly handled by the French at the battle of Guise on Aug. 29 and its commander, Von Bülow, thereupon sent out urgent appeals to the I. and III. Armies on his right and left respectively to close in to his aid. These cries for help altered the whole course of the War. The commander of the I. Army was glad to switch off from the elusive British Army and decided to turn inwards. The hand of German supreme headquarters was now forced. They approved the scheme, although it meant giving up the advance on Paris. The new objective of the right wing was to be the flank of the French main forces opposite the II. Army. Envelopment was still held in view, but the net was to start its scoop east of Paris instead of west of it. Opposed to this wavering was the consistent policy of Joffre. An orderly retirement until he could gain the respite afforded by some topographical obstacle was his dominating thought. Here he proposed to reform and reorganise and then to assume the offensive at the earliest possible moment. The limits of the withdrawal were laid down as the territory immediately south of the rivers Seine, Aube and Ornain. A retirement so far would mean the isolation of Paris, but Joffre clearly realised that the fate of Paris would be decided in a battle fought, not under its walls, but in the open field.

Defence of Paris.—Paris was not undefended. It had, indeed, been proposed to declare it a *ville ouverte*, but the patriotism of its inhabitants decreed otherwise. The military governor was General Galliéni, who had under him four and a half divisions of *territorials*, some cavalry and field artillery, as well as 5,000 *fusiliers marins*. On Sept. 1 the newly formed VI. Army, some 60,000 strong, was placed under his command, and in addition he received Sordet's Cav. Corps, two reserve divisions and a particularly fine reinforcement in the shape of the 45th Div. from North Africa. Galliéni had therefore a respectable mobile force at his disposal, as well as garrison troops.

His first duty was the defence of the capital against which, so far as he knew, the German right wing was steadily advancing. The task was a difficult one, for the apathy and neglect of successive French governments had been reflected in the unreadiness of the fortress. By herculean efforts much was done in the limited time at his disposal, but Galliéni took a grave view of the situation. Then suddenly the whole situation changed. Up to the morning of Sept. 3 it seemed certain that the German right wing was advancing



on Paris with the Senlis-Paris road as the axis of movement; by the afternoon information, transmitted by aeroplanes and cavalry patrols, clearly showed that the German I. Army had switched off from Paris and was heading south-east towards the junction of the right of the British and the left of the French V. Army.

The situation in which Galliéni now found himself was one which demanded exceptional powers of decision. On the one hand there was the German I. Army making a flank march across the north-east of Paris, "trailing its coat" under the very eyes of the garrison, and providing a temptation almost impossible to resist. On the other hand there was the fact that Joffre had declared that he did not wish to undertake an offensive until he had got his army behind the Upper Seine and Aube. At 9 A.M. on the 4th Galliéni, anticipating the sanction of the commander-in-chief, directed the commander of the VI. Army to hold his troops in readiness for an advance against Von Kluck's exposed right flank. Next he communicated with Joffre and Sir John French. All three were equally desirous of assuming the offensive at the earliest possible moment and any divergence of opinion was only on matters of detail.

Joffre's Offensive.—Little reflection was necessary to convince Joffre that a chance not often met with in war was now vouchsafed him. He determined to assume the offensive from where he stood and shortly before midnight he issued his orders stating that advantage was to be taken of the situation of the German I. Army to concentrate against it the efforts of the Allied armies of the extreme left. All preparations were to be carried out on Sept. 5 and the attack was to be made on the 6th.

Disposition of the Forces.—At this moment the position of the Allied armies in France resembled a ribbon attached at its ends to Paris and Verdun and sagging slightly by its own weight in the centre. At Paris was the French VI. Army and other available troops. Next came the British Army. Then in succession the French V., IX., IV., and III. Armies, the right of the latter joining up with the mobile forces of Verdun. The initial orders included the VI., British, V. and IX. Armies only. The first was to cross the Ourcq and make for Château Thierry. The British were to be ready to attack in the direction of Montmirail. The V. Army was, generally speaking, to attack from south to north, its right protected by the IX. Army. During Sept. 5 supplementary orders were issued to the IV. and III. Armies, the general trend of which was that they were to attack inwards and thus to bring about a double envelopment of the German armies.

Facing the Allies were the five German armies to which had been entrusted the great turning movement pivoting on Thionville, numbered I. to V. from right to left. The French, British and German Armies thus enumerated were those immediately concerned in the operations now known as the battle of the Marne. Further to the southeast, between the fortress of Toul and the Swiss frontier, the German VI. and VII. Armies had been heavily engaged with the French I. and II. Armies since the middle of August.

During the evening of Sept. 4 a new directive was issued to the German Forces. By it the I. and II. Armies on the right were now to face west towards Paris. On the left the IV. and V. Armies, by a determined advance south-east, were to open a passage across the Moselle, in which region a lesser Sedan might yet take place. The III. Army in the centre was to push south ready to assist either wing as required. Thus Von Moltke was forced to abandon the hopes founded on the great massive wheel of five armies pivoting on Thionville and instead was compelled hurriedly to assign to his armies three divergent axes of march towards the west, south and south-east. In the new scheme it was Von Kluck's task to remain between the Oise and Marne. Instead of doing so he continued pushing on over the latter river. As the French VI. Army had been ordered to cross the Ourcq and to advance towards Château Thierry a collision between it and the flank guard of the German I. Army was now but a matter of hours. Almost exactly at noon on Sept. 5 a battalion of the French VI. Army came under heavy shell fire from the German flank guard. Some very heavy fighting ensued and by evening the French had made good a little ground, although at the expense of heavy casualties.

II. THE ACTUAL BATTLE

The battle proper may be considered as starting on Sept. 6. The French VI. Army moved out to the attack with both of its flanks protected by cavalry. By then Von Kluck had begun to comply with orders by withdrawing his troops across the Marne. The bulk of the day's fighting took place opposite the right wing of the French VI. Army and especially against the extreme right. It was soon evident to Gen. Maunoury, the French commander, that the German flank guard was being substantially reinforced. Von Kluck could, however, only reinforce his right flank at the expense of his front, and, in consequence, opposite the British there was a noticeable slackening in the advance of the German I. Army. Put briefly, the relative situation of that army had changed. What had been its right flank—consisting of the IV. Res. Corps and a cavalry division—was, by successive reinforcements, to become the front; while the original front, by a corresponding diminution, was transformed

into the left flank, and the army as a whole was to face west instead of south.

The hesitation observable in the German advance was soon followed by an unmistakable retrograde movement. The British lost no time in seizing the heights on the Grand Morin south of Coulommiers, from which German heavy guns had during the morning brought an effective fire to bear. Save for some fighting early in the morning about Rozoy—an action brought on by the Germans to cover their retreat—the British were not heavily engaged, though a few prisoners and machine-guns were taken. To the right of the British, the French V. Army, after a check early in the day, had made a substantial advance, the German I. Army was now in the position of having to fight desperately to hold off the converging attack of the French VI., the British, and the French V. Armies.

The fighting on the Ourcq on Sept. 7 was hard and bitter. Even at the risk of weakening himself elsewhere, even of causing a gap between himself and the II. Army, Von Kluck had to bring every available man to the fight. The effect of his action was that a gap, soon to yawn into a gulf of 30 m., was opened between the German I. and II. Armies. Into this gap the British and the left of the French V. Army were steadily pushing. In other words, Von Kluck found himself committed to an isolated action with his left and rear exposed. Unless he could hold off the British and the French V. Army sufficiently long to enable him to dispose of the French VI. Army he was defeated. But for his task he had neither the time nor the men.

After a day of hard fighting the French VI. Army had made some further progress, and its front ran generally from Chambray through Barcy and Marcilly to the high ground west of Etavigny. The British were now opposed merely by German cavalry reinforced by Jäger battalions and were enabled to push their line to La Haute Maison-Aulnoy-Chailly and Jouy sur Morin. The French V. Army likewise made good progress, reaching the line La Ferté Gaucher-Trefois. Further to the right the fighting had been severe, the left of Foch's IX. Army being heavily attacked and forced to call on the V. Army for help.

A somewhat disquieting feature of the day was the apparent intention of the Germans to make another effort to turn the Paris-Verdun line at Nancy and at Troyon, where a successful thrust would very seriously discount the French efforts on the Ourcq. Worse still, Maubeuge fell on Sept. 7, and the invaders not only gained another rail line of communication but had now another corps available for operations in the field. Against these drawbacks, however, could be set the fact that the gap between the German I. and II. Armies had considerably widened, and into it, the British Army and the left of the French V. Army were now advancing with speed.

Sept. 8 was remarkable for the violence of the German attacks along the Ourcq. Maunoury's plan was to attack with his right centre and left, while the VII. Corps in the centre was ordered to hold its line at all costs. That corps was heavily attacked early in the afternoon, and such was the severity of the fighting that a week later the streets of Etrepilly and Trocy were still blocked with the bodies of the slain. To the north the French outflanking movement was brought to a standstill, while even the superb gallantry of the Zouaves of the 45th Div. on the right centre failed to make any considerable impression on the enemy. During the afternoon Gallièni visited the Commander of the VI. Army at his headquarters at St. Soupplets and pointed out that the greater the resistance offered by the Germans on the Ourcq the less opposition would the British meet with in their advance. Nevertheless, Maunoury considered it advisable to make arrangements for a possible withdrawal on the following day. Meanwhile the British Army was discounting the efforts which Von Kluck was making on the Ourcq.

Sir John French decided that the best method of assisting the French VI. Army implied the speedy passage of the Petit Morin and Marne rivers, for after passing the latter the British army would be facing northwest and thus almost directly threatening the line of retreat of the German I. Army. Orders were accordingly issued for a general attack along the line of the Petit Morin, to begin early on Sept. 8. At first the march was undisturbed, but on reaching the Petit Morin it was soon realised that the German cavalry would not yield without a struggle, especially as the steep valley covered with small but thick woods distinctly favoured the defence. Some severe fighting ensued, but by evening the British had made good the Petit Morin and were on the line La Noue-Viels Maisons, where they joined up with the II. Cav. Corps of the French V. Army, the left corps of which extended to the southern outskirts of Montmirail.

Sept. 9 was to witness Von Kluck's last effort on the Ourcq. The French VI. Army, although it had been reinforced, was at the end of its strength and its left was pushed back. A superb effort, however, restored the day and then it was clear that Von Kluck had shot his bolt. During the day the British crossed the Marne and on its right the French V. Army seized Château Thierry. Thus on the extreme west of the great battle things had gone well for the Allies, and it is now time to turn to the doings in the centre of the field.

German supreme headquarters had ordered the I. and II. Armies to form front facing Paris, the former between Oise and Marne and the latter between Marne and Seine, Château Thierry to be the point of junction of the two armies. This order had at first been disregarded by Von Kluck, who had persisted in his passage over the Marne and in maintaining his position in front of the II. Army. Von Bülow, however, endeavoured to comply with the orders of his superiors, and did make an effort to wheel his army to the right with the object of taking up the line Château Thierry (exclusive)—Marigny-le-Grand. The net result of compliance with orders by one army commander and disregard of them by the other was that the right corps of the II. Army was squeezed out of the line by the left corps of the I. Army. In other words, the two armies were acting upon different plans; overlapping had arisen; and the confusion inevitable in such circumstances began to be revealed upon the evening of Sept. 5. This factor alone was bound to hamper the II. Army, and Von Bülow's task was not lightened by the subsequent conduct of his neighbour. When Von Kluck renounced his plunge southeast he did it with such thoroughness as to lead to the transfer of practically his whole strength to the Ourcq. On Sept. 7 he demanded back the III. and IX. Corps which he had lent Von Bülow but the day before. The withdrawal of these units to the Ourcq exposed Von Bülow's right flank; a great gap was thus opened between the II. and I. Armies and Von Kluck, who had, on Sept. 5, inconvenienced Von Bülow by his undue proximity, was now seriously embarrassing that commander by his aloofness.

III. THE GERMAN RETREAT

Retreat of Von Bülow.—Generally speaking, the task of the IX. Army under Foch for Sept. 6 was to support the advance of the V. Army with its left flank while maintaining a watching attitude along the rest of its front. Foch, however, found himself quite unable to carry out even the moderate programme he had drawn up. Von Bülow was endeavouring to wheel into position between Marne and Seine, and on his left the III. Army's orders were to push due south. As a result the French were attacked with considerable vigour all along the line for, although his right was becoming compromised, Von Bülow was able on the 7th to push on with his centre and left, the latter flank working in conjunction with the German III. Army. But owing to the determined resistance of the French IX. Army under Foch and to the assistance afforded him by the French V. Army on his left, the Germans made no great impression other than to deny the French IX. Army the possibility of making progress north and west. On the following day, Sept. 8, the Germans renewed the attack and a serious position developed for the right of the French IX. Army, which was forced to give ground. Foch refused, however, to be perturbed inasmuch as the news which came in of the course of the fighting east and west of him was reassuring.

On the 9th a sudden German attack told on the French left. Foch's reply was to move his reserve from his shattered left to join in a counter attack from his right, realising as he did that the danger of the German thrust was more apparent than real.

Reports as to the forcing of the line of the Marne by British troops during Sept. 9 forced Von Bülow to the conclusion that retreat was inevitable for Von Kluck, and that his own II. Army must fall back at once, if it were to avoid envelopment on its right flank. With the object of gaining time to get his long trains safely back over the Marne, the offensive by his left and centre was carried out with vigour during the morning, the French right being driven back to Salon; but early in the afternoon the German II. Army and the right of the III. Army were in full retreat, strong rear guards being left facing the French.

Verdun.—The fighting described up to the present, *i.e.*, that between the Ourcq and Fère-Champenoise, must not be allowed to overshadow the operations of the French armies between Vitry-le-François and Verdun. For nowhere on the whole front was the tenacity of the French III. and IV. Armies surpassed. It was towards the east that the Germans hoped to retrieve their failure elsewhere. Here they hoped to cut off Verdun from either side and to bring about a kind of minor Sedan in which the French I., II., III. and IV. Armies might be herded together and destroyed. The German VI. and VII. Armies were to advance eastwards across the Moselle; the IV., with its right passing through Vitry-le-François, was to bear down across Champagne, while the German Crown Prince with his V. Army was to proceed round the entrenched camp of Verdun. Fortunately for the French the Crown Prince based his advance upon a misconception. He assumed that Verdun would be left to its fate, whereas Sarrail commanding the French III. Army kept his right attached to it throughout and, further, on his own responsibility, ordered the fortress commander to use his troops to make an attack on the Crown Prince's communications.

German Retreat.—The attacks of the Germans brought the French into a serious position, especially the IV. Army of Langle de Cary. In fact, at one time there was a serious chance that its right might be rolled up. However, reinforcements from the extreme French right, that is to say the I. and II. Armies in the Vosges, restored the situation. Then, on Sept. 8, the III. Army was called upon to deal with a new peril. Fort Troyon was in serious difficulties and thus a very patent danger to the rear of the III. Army was suddenly revealed. The garrison, however, put up a stout resistance and the place was relieved by a French cavalry division from Toul on Sept. 10. The Germans renewed their attacks on the following day but they were without significance. From Verdun to Paris five German armies were in retreat. The great battle of the Marne had been fought and won.

It was not for several years after the battle that the world learnt how and why it was broken off by the Germans. The truth is that by Sept. 8 Von Moltke had completely lost his grip of the battle. In these circumstances a liaison officer, Lt. Col. Hentsch, was directed to visit the V., IV., III., II. and I. Armies in turn and to bring back a clear idea of the situation. Further, he was empowered to issue such orders as would close the gap between the I. and II. Armies should he find that retreat had set in upon the right wing. The critical point of his tour was his visit to the II. Army where he spent the night of Sept. 8–9.

Von Bülow was considerably disconcerted about the passage of the British over the Marne; he came to the conclusion that the retreat of the I. Army was inevitable, and that therefore his own II. Army must fall back if his right were not to be enveloped. Hentsch agreed and proceeded next day to the I. Army, where he interviewed Von Kluck's chief of staff. Although the latter considered that the I. Army could hold its own there was now no option but to order its retirement. Thus by the late afternoon of the 9th the whole right and right centre of the German Army was falling back. Supreme headquarters, in ignorance of the fact, were preparing for a continuance of the offensive but had to bow to the inevitable. During the 10th orders were issued for the retreat of the five armies behind the Aisne and Vesle. By the 16th the German front was thus traced out—the neighbourhood of Noyon, the plateaux south of Vic-sur-Aisne and Soissons, the tableland of Laon, the heights north and west of Reims north of Ville-sur-Tourbe, Varennes, and thence to the Meuse near Forges wood, north of Verdun.

Conclusions.—Thus tamely petered out the grandiose German plan, and thus ended the great and decisive battle of the Marne. Tactically indeed it was somewhat of a disappointment to the Allies. No part of the German host was annihilated or even immobilised for any length of time. The number of trophies and prisoners was inconsiderable. The Germans broke off the fight in their own time. No great pursuit, as had succeeded Jena, took place, and the Germans were able to retire, if not unscathed at any rate in fair order. From the strategic and moral aspects, however, the battle was of immense importance. It marked for the Allies the definite turn in the tide of defeat, while for the Germans it marked, no less, the collapse of the plan with which they had entered on the War and on which the Great General Staff had been prepared to hazard the fate of the Fatherland. That plan had aimed at securing a rapid decision in France with the bulk of the German armies, and the subsequent and immediate prosecution of a second campaign against the more slowly mobilising strength of Russia. But by Sept. 10 1914 the Germans had definitely acknowledged defeat in France. It is significant that the Battle of the Marne has been called by the Germans themselves *der Wendepunkt* (the turning point) of the War.

MARNE, SECOND BATTLE OF THE.—The second battle of the Marne developed between July 15 and Aug. 4 1918. Beginning with the German offensive of July 15, which was broken on the Champagne front between that date and July 18, it was concluded by the victorious counter-offensive of the French armies of July 18–Aug. 4, extending from the Marne to the Aisne. This was the prelude to the general offensive of the Allied Armies and their uninterrupted march to the victory of Nov. 11. A typical "defensive-offensive" battle, it demonstrated at once the will of the French high command to impose its preconceived plan upon the enemy, and the rare faculty possessed by the French soldier of passing direct from parry to riposte with an energy and vigour that recent ordeals seemed only to have strengthened. (*See* also GERMAN OFFENSIVE.)

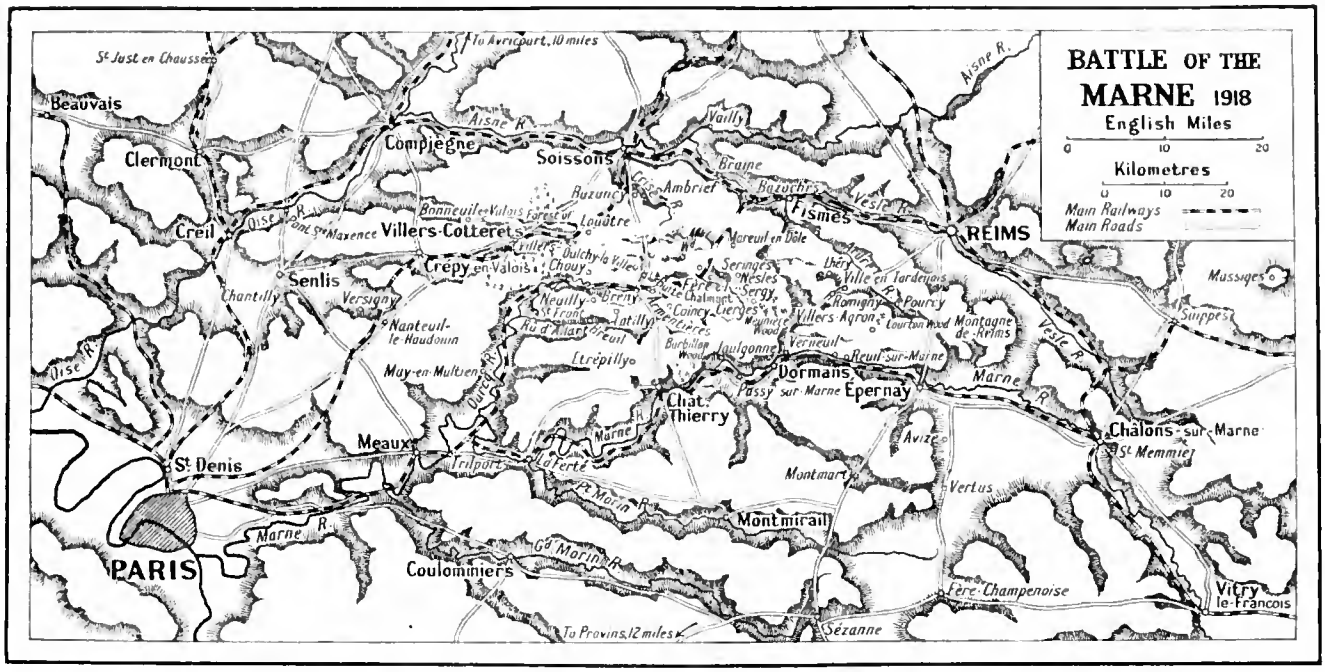
I. INTRODUCTION

Two months earlier, Gen. Foch, Commander-in-Chief of the Allied Armies, had decided to take the initiative at the first possible moment,[1] and, true to the principle that "to make war is to attack," was determined to give the enemy no further respite once he had gripped him. The opportunity he sought was given him by a mistake on the part of the German supreme command, which, having crowded its forces into the pocket of Château-Thierry, was now to find the position made worse by the resounding check to the offensive in Champagne.

German Plans.—The Allies had had information at the beginning of July of two German plans of offensive: one on the French front in Champagne, the other on the British front from Arras to Ypres. It remained to be seen which would be launched first, for the enemy had not the necessary reserves and material for the execution of the two simultaneously on such extended fronts. It soon became known that the attack in Champagne would precede that in Flanders and would take place about July 9 or 10. As it turned out, the check to the first offensive was to prevent the enemy from executing the second. The enemy's plan was known in detail: he was to attack on either side of Reims, the principal effort being entrusted to the I. and III. German Armies, moving on Châlons, while the VII. Army crossed the Marne in the direction of Dormans and rejoined the main attack in the region of Épernay.

Foch's Preparations.—Meanwhile Foch was preparing the severe riposte that he was about to inflict on the enemy. To meet the essential requirements of the expected defensive battle in Champagne and, at the same time, to make provision for the counter-offensive which Pétain was preparing in the Soissonnais,

[1] Order No. 3 of Foch, May 20.



he brought together between the Oise and the Argonne a reserve mass of 38 infantry divisions (29 French, four British and five American) and six French cavalry divisions. These strong reserves were to be augmented at an early date by the arrival of new American divisions, just in time for the critical moment when the adversary could only with difficulty maintain his forces. Thus, in the middle of July, the point was reached at which the balance between the forces became re-established and was about to turn in the Allies' favour. This was the moment chosen by Foch for taking the offensive.

Composition of French Army.—Before defining the part played by the French Armies in the second battle of the Marne, it may be as well to state that they comprised, at that time, 103 divisions, divided into three groups of armies under the command of Gen. Pétain, whose headquarters were at Provins.

TABLE I.

Reserve Group
Gen. Fayolle, at Noailles

	Commander	Headquarters	Area
I. Army	Gen. Debeney	Conty	Amiens region.
III. Army	Gen. Humbert	Clermont	St. Just-en-Chaussée region.
X. Army	Gen. Mangin	Versigny	Villers-Cotterets region.
Centre Group *Gen. Maistre, at Sézanne*			
VI. Army	Gen. Degoutte	Trilport	Château-Thierry region.
V. Army	Gen. Berthelot	Montmort	Reims and the south.
IV. Army	Gen. Gouraud	St. Memmie	East of Reims.
IX. Army	Gen. de Mitry	..	Between VI. and V. Armies.
Eastern Group *Gen. de Castelnau, at Mirecourt*			
VIII. Army	Gen. Gérard	Flavigny	
VII. Army	Gen.de Boissoudy	Lure	

Degoutte with his VI. Army was later placed under the orders of Fayolle, in the reserve group of armies. De Mitry's IX. Army was brought in during the course of the battle.

These forces held 600 km.—this being about two-thirds of the total Allied front.

General Organisation of the Offensive.—The general-in-chief had, on July 12, stated the mission of the two groups of armies to be: "to reduce the pocket of Château-Thierry by means of two lateral thrusts towards the plateau situated north of Fère-en-Tardenois . . . . " so as to bring about the junction in this region of the two groups of armies, the tactical limits for which were clearly marked by the line Château-Thierry (for the Reserve group), Fère-en-Tardenois (for the Centre group). He had, as early as July 8, settled the means that would be at their disposal, defined the action they were to take, and ordered the preparation.

But the Centre group of armies, against whom the imminent attack would be directed, had still first to break this attack and in due course re-establish the continuity and security of its front; after which it would immediately proceed to the counter-offensive with all the means at its disposal, and Gen. Pétain exhorted "the command of every échelon to set themselves resolutely to act on the principle of simple, audacious and rapid methods of attack."

II. THE GERMAN OFFENSIVE IN CHAMPAGNE

From July 1 onward the French IV., V. and VI. Armies were on the alert and ready to receive the assault. The IV. Army (Gouraud), to the east of Reims, occupying a highly organised front, was to make a completely successful test of the new method of disposition in depth, ordered by Gen. Pétain. It had finally been decided to leave nothing along the line of outposts (constituted by the Monts de Champagne) but "islands" of resistance, which would be required to sacrifice themselves for the purpose of dissipating the enemy attack and keeping it under the well-controlled fire of the main position established in the rear. The moral preparation was on a level with the organisation of the defensive, and General Gouraud was able to address his men in such terms as these: "The bombardment will be terrible. You will stand it without flinching. The attack will be formidable, delivered in clouds of dust, smoke and gas . . . . but you will break it and it will be a great day. . . . " It was not possible to prescribe a rigorous application of the principle of defence in depth (as in the case of the IV. Army) for the V. and VI. Armies, as their defensive organisation was recent; it was to be feared that in their case the manoeuvre would develop under less favourable conditions.

On the 14th, at 8 P.M., a *coup de main* by the IV. French Corps brought in 27 prisoners, who, on being questioned, revealed the fact that the German attack was to be launched that night, the artillery preparation being timed for 12:10 A.M. But before it

began, the French counter-preparation and counter-battery fire opened on the whole of the enemy front. The enemy, though stupefied by the number of our batteries, carried on according to programme, and, between 4:15 and 5:30 A.M., the German infantry advanced to the attack on a 90 km. front, from Château-Thierry to Massiges (leaving out the Reims Salient). To the east of Reims, thanks to the steps taken by Gouraud, the attack suffered a complete reverse. The enemy infantry was broken up by French artillery fire and decimated by the machine-guns distributed along the outpost line before even reaching the main line of resistance, which, in spite of repeated assaults, they failed to break at a single point. To the west of Reims the situation was less favourable.

German Success at Dormans.—In front of the V. Army (Berthelot) the enemy made some progress between the Marne and the Ardre in the direction of Épernay, and the French Centre (V. French Corps and II. Italian) was thrown back on the second position along the line Pourcy-Belval-Reuil-sur-Marne. Lastly, the right of the VI. Army (Degoutte) was not able to stop the enemy from crossing the Marne on either side of Dormans, between Jaulgonne and Verneuil. The VII. German Army thus established a bridgehead south of the river, in front of the V. Army's left and the VI. Army's right; it also regained touch with the I. German Army on the slopes of the Montagne de Reims. On this side the situation was therefore serious, and Pétain decided to check the adversary's advance by reducing first of all the pocket which had just been formed. To this end he engaged, on the 16th, practically the whole of the Allied reserves intended for the defensive battle.

The French command was now confronted with a serious problem. It was still three days to the counter-offensive, which the Reserve group of armies had orders to carry out on July 18. The question was, whether to continue the preparations for this counter-offensive and risk losing the Montagne de Reims or to suspend preparations in order to parry the immediate blow. Foch decided to maintain his plan of offensive intact, and gave orders to proceed with the preparation. The general staff of the British XXII. Corps and the 51st and 62nd Divisions were already on the move; these divisions were to appear on the field of battle of the Centre group from the 19th onward. Following them on July 17th the British 15th and 34th Divisions were to march for the neighbourhood of Pont Sainte-Maxence and of Chantilly-Senlis respectively at Foch's disposal.

German Attack Checked.—The German attack had degenerated into local actions, disconnected and therefore useless, from July 16 onward. By vigorous counter-attacks the French had even recaptured some of the enemy's *points d'appui*, while our artillery and aircraft, by bombarding the Marne crossings, made it more and more precarious for him to obtain supplies. The only progress in the attack—to the southwest of Reims between the Vesle and the Marne, on July 16—remained fruitless, for it had cost the enemy too dear for him to repeat such sacrifices.

After two days of useless efforts, therefore, the German command stopped the costly "Friedensturm" operation, on which they had based their supreme hope, and on July 17 their army was on the defensive. The third grand offensive, which the enemy had carried out with even more powerful means than the two preceding ones (44 divisions on a front of 80 km.), had failed completely. On July 18 was to be launched the French counter-offensive, in which British and American divisions were to participate. Fortune had changed sides. The operations of the Centre group of armies for the clearance of the south bank of the Marne, the recapture of Château-Thierry and the disengaging of the Paris-Avricourt railway line, formed part of the general offensive action prescribed for the two groups of armies on July 12 and initiated by the Reserve group on the 18th, under conditions which will be dealt with later.

III. COUNTER-OFFENSIVE OF THE FRENCH

The French counter-offensive comprises two phases: (1) the first extends from July 18–28, and includes the victorious battles of Fayolle's main group of armies in the Soissonnais and on the Ourcq, and the closing stage of the defensive battle of Champagne and Reims during the same period, in which the Centre group under Gen. Maistre re-established its front and passed to the attack. This first phase, again, comprised three successive manœuvres: the breaking of the enemy positions by the Reserve group of armies on July 18 and 19; the re-occupation of Château-Thierry and the south bank of the Marne by the Centre group of armies, in combination with the right of the Reserve group, on July 20 and 21; and the co-ordination by the general-in-chief of the main effort of the two groups of armies on both banks of the Ourcq in the general direction of Arcy-Sainte-Restitue and Fère-en-Tardenois on July 23 and 24. (2) The second phase, sometimes called the battle of Tardenois, extends from July 29 to Aug. 4, and includes the recapture of Soissons and the push towards the Vesle.

French Preparations for Attack.—We have seen that, acting upon Pétain's instructions of July 12, Fayolle prepared a counter-offensive for the 18th, which aimed at reducing the pocket of Château-Thierry. These preparations were continued with the utmost secrecy while the Centre group of armies (Gen. Maistre) were checking the last enemy offensive (July 15 and 16) and (from the 17th) arranging a counter-attack. In this connection it is interesting to take stock of the means which Maistre was to have at his disposal for passing direct from parry to riposte and those which Fayolle, for his part, was assembling in silence in the region of Villiers-Cotterets on the right flank of the enemy's Marne salient.

The counter-offensive of the Centre group was entrusted to two armies, the V. and the IX., the latter having been put into the front between the V. and VI. Armies. The V. Army (Berthelot), which had been so heavily attacked at Reims, had eight divisions in first line (including the Italian 3rd Div.), and one infantry and two cavalry divisions in second line. Three of its divisions, among them the Italian 8th Div., had been withdrawn for reconstruction. At the same time the British 51st and 62nd Divs. were now being held in reserve in the Vertus-Avize zone. The IX. Army (de Mitry) had five divisions, including the American 3rd Div. in first line, one division in second line, and two reserve divisions, including the American 28th Division. Two other divisions were in course of reconstruction. On the 17th the mission of the two armies was confirmed: they were to regain all the ground lost between Reims and the Marne and to clear the south bank of the river at the same time as the Reserve group of armies launched its attack. The reserve group operated with the X. and VI. Armies. The X. Army, under Gen. Mangin (battle headquarters at Bonneuil-en-Valois), who was responsible for the main attack, had 10 divisions in front line, including the American 1st and 2nd Divs., placed on the flanks of the Moroccan Div. in the centre of the army, and six divisions in second line and the II. Cavalry Corps, making a total of 16 infantry divisions and three cavalry divisions. In the rear of the army the British 15th and 34th Divs. were in reserve to the east of Pont Sainte-Maxence and Senlis. In addition, the army was given a large number of tanks and strong artillery reinforcements. The task which Mangin set before his troops was "to break through the enemy front between the Aisne and the Ourcq and push straight on in the direction of Fère-en-Tardenois in liaison with the offensive of the VI. Army."

On his right the VI. Army, commanded by Degoutte, whose own right was engaged in the defensive battle, had only seven divisions in front line—among them the American 4th and 26th Divs. (American I. Corps at la Ferté under Jouarre)—and one division in second line. The battle headquarters was at May-en-Multien. Degoutte was to attack with his own resources only, reinforced, however, by tanks. His orders were that "the main attack would take place between the Ourcq and the Rû d'Alland with the object of reaching the line Neuilly-Saint-Front—rounded hill of Breuil—and eventually of developing the attack in the direction of Coincy in liaison with the X. Army towards Brény-Armentières." He had further at his disposal the British 9th brigade of the Air Division, which was to "support his attacks."

Secrecy of Concentration.—The operations of the Reserve group of armies had been prepared with infinite precautions for maintaining secrecy—the essential factor in a surprise. The reinforcing divisions were only brought up to the front during the last two days, their movements being carried out by night, between July 14 and 16, the mounted elements marching and the unmounted carried by motor transport. No more rapid and complicated concentration had ever been carried out. Pétain had issued an order on the 17th stating the conditions of the counter-offensive for the following day, which concluded with these words: "The general-in-chief expects that the ardour and energy displayed by all will make July 18 a glorious day."

A violent storm which burst noisily during the night of the 17th–18th intensified the darkness and made movements in the woods very difficult; but it was favourable to secrecy and by 4 A.M. on the 18th the X. and VI. Armies were in position and ready to move without any sign of uneasiness being shown by the enemy. At the same hour the Centre group of armies was preparing to counter-attack. At 4:35, without a single preliminary round, the whole of the French artillery opened fire from the Aisne to the Marne, and 16 front line divisions dashed forward with the tanks, while all the air squadrons went up. In the X. Army the infantry and tanks advanced without an artillery preparation behind a rolling barrage, turning the enemy's strong defensive positions and quickly gaining a footing on the plateau northeast of the forest of Villers-Cotterets. In the VI. Army, on the contrary, the attacking divisions continued their artillery preparation against the enemy's defensive position for 1½ hours, and only attacked at 6:05.

The surprise was complete, and, along the whole front, the enemy lost practically all his advanced units and batteries. His resistance was only effective in two localities on the broken ground from Louâtre to the Buisson de Hautwison, at which point the XI. Army Corps, having no tanks, progressed only with difficulty and to the west of Neuilly-Saint-Front, where the II. Corps came under oblique fire from the heights of Chouy. Mangin received information of the first results achieved towards 8 o'clock, and exploited them without delay by the judicious use of his reserves. General Robillot's Cav. Corps had experienced extreme difficulty in debouching from the forest of Villers-Cotterets, which was encumbered with troops and baggage, and could as yet operate only with dismounted squadrons—the hour of the cavalry had not struck! On the first day the enemy lost 12,000 prisoners and 250 guns.

The battle raged through the night of July 18–19 and throughout the day of July 19. The two French armies substantially attained their objectives, even in the difficult region of Louâtre-Chouy-Neuilly-Saint-Front, where the XI. and II. Corps combined their attacks to subdue the enemy resistance. The artillery and air force were both definitely superior to those of the enemy. The artillery pushed its batteries forward and the bombing machines attacked the Marne crossings and the enemy concentrations at Oulchy-le-Château and Fère-en-Tardenois.

The Central Group Reinforced.—While Fayolle's group of armies had, by means of heavy pressure and exploitation of the surprise, penetrated deeply into the enemy's positions, the Centre group was preparing to clear the south bank of the Marne. But its units were exhausted by the resistance they had to put up against the German attacks of July 15–18, and in order to reinforce them with fresh troops the British XXII. Corps (51st and 62nd Divs.) was brought in to relieve the Italian Corps. Pétain took care to insist that it was not a question of a simple relief. "It will be carried out on the move—that is to say, it will take the form of a surprise attack, carried out with the co-operation of the French units on either side."

Foch defined the character that the battle was expected to take as follows: "The battle, when engaged, will be conducted with the utmost energy and without waste of time, in order to exploit the advantage gained by surprise." Nevertheless it was not until the 20th that the Centre group was able to push forward. On that day its IX. Army reached the south bank of the Marne, evacuated by the enemy during the night, while in the V. Army the British XXII. Corps was heavily engaged in the Courton wood, where it took several hundred prisoners.

The fighting continued to be very severe throughout July 21 and 22. On the two wings of the French disposition the enemy offered a stubborn resistance to the attacks of the X. and V. Armies which pressed on their flanks. It was evident that he wished to gain time for evacuating the material and troops that he had risked towards the Marne. At last, however, on July 21, at 7 A.M., the 30th Div. of the XXXVIII. Corps, attached to the VI. Army since that morning, reoccupied Château-Thierry. The American 3rd Div. crossed the Marne in its turn, to the east of the town, and entered the Barbillon wood. In the VI. Army the American I. Corps and the French VII. and II. Corps advanced on the plateau of Etrepilly and Latilly, and on the 22nd, at noon, the VI. Army re-established its communications by way of Château-Thierry. On the same evening elements belonging to the V. Army gained a footing north of the Marne, at Port à Binson and two battalions of the IX. Army crossed the river at Passy-sur-Marne.

Capture of Butte Chalmont.—From the 22nd onward the two groups of armies exercised continuous pressure upon the enemy, the Air Division co-operating in mass in the pursuit. But the whole interest of the battle was focussed, on July 25, on the heights dominating the Ourcq valley from the north—Orme du Grand Rozoy and Butte Chalmont. Once these heights were captured, the X. Army would be able to push on the Arcy-Sainte-Restitue and the VI. Army to move on Fère-en-Tardenois, skirting the wooded region on the north side, in conformity with the plan of the French high command. On July 25 the two divisions of the French XI. Corps took by assault Oulchy-la-Ville and Oulchy-le-Château and gained a footing on the west slopes of Butte Chalmont, thus depriving the enemy of all hope of re-establishing himself on the Ourcq. The two armies[1] lost no time in following up their success, as soon as they had concentrated all their available means and relieved those units which had been most severely tried. The VI. Army was indeed able to shorten its front and rearrange its disposition accordingly. A fresh division, the American 42nd, was also added to it.

Advance Checked at Fère-en-Tardenois.—The attacks went forward on the 27th. "Forward! . . . however tired the troops!" telegraphed Fayolle, and progress continued to be made on July 27 and 28 as follows: the VI. Army reached the Ourcq and gained a foothold in Fère-en-Tardenois; the V. Army reoccupied its positions of July 15, and the divisional cavalry pushed its patrols beyond the infantry's advanced guards. But from the 28th, at noon, the VI. and V. Armies met with a stubborn resistance and a barrage that was solidly established from Fère-en-Tardenois to Ville-en-Tardenois. The II. Corps was unable to debouch from Fère. The American I. Corps, which had advanced as far as Sergy, was violently counter-attacked there by a Guards Division. The village was taken and retaken four times and finally held by the American 42nd Div., though only at the cost of heavy losses.

The advanced guards of the V. Army could debouch neither on Villers-Agron nor on Ville-en-Tardenois. In the centre, therefore, the situation remained practically unchanged on July 29 and 30. On the two wings there was fierce fighting on the 28th, on the west towards Buzancy, where the British 15th Div. gained a footing in the village and was driven out again, but succeeded in holding the park of the château; and on the east, where the enemy made repeated counter-attacks and the Allies had to fight costly engagements in order to hold their recent gains. Only the right of the X. Army made definite progress. On the 28th the XI. Corps took Butte Chalmont, and on the 29th the XXX. and XI. Corps with the British 34th Div. occupied Grand Rozoy; but the divisions in line had reached the limit of their powers after several days of incessant fighting.

First Phase of French Offensive Complete.—The enemy had made heavy sacrifices to gain solid support for his flanks and cover his line of retreat towards the Vesle. The resistance that

[1] The IX. Army had been withdrawn from the front since the 25th. The III. Army Corps had joined the V. Army.

he offered everywhere made it clear that he was not to be underestimated but was capable of violent reactions, and it now became necessary to hasten his retreat by a direct action against the plateaux of the Tardenois. The first phase of the French counter-offensive was now at an end: the Marne valley and the Paris-Avricourt railway line had been completely cleared. This was the first of the "clearance" offensives laid down in the orders of July 24, which had been issued by Foch to the commanders-in-chief of the Allied armies. The second phase was now to begin, and Fayolle's appeal to the endurance of the troops was indeed timely, in view of the severe battles that lay before them without hope of respite before the winter.

The days of July 30 and 31 mark a pause in the progress of the French armies, which on July 29 received fresh instructions from Pétain for the combination of their attacks. The VI. Army, reinforced by the III. Corps and charged with the main action, was to "push vigorously, and without stopping, in the general direction of Fismes and Bazoches with its whole front, its left to establish itself in the region of Saponay so as to facilitate the debouching of the right wing of the X. Army towards Cramaille." The X. Army was to make every effort, by successive actions starting from its right (the south), to reach the line Bois d'Arcy, upper course of the Crise, and then by way of the Arcy-Sainte-Restitue plateau to work in the general direction of Braine. "The V. Army was to support the right wing of the VI. Army, making its effort in the direction of Romigny-Lagery-Crugny, along the heights on the south bank of the Ardre." It was to be kept in mind that the enemy, with his wings reinforced, might launch counter-attacks between the Oise and the Aisne or on the Reims salient. Considering the nature of the coming operations, it was not expected that the two cavalry corps would be used, and the commander-in-chief therefore withdrew them and moved them to the neighbourhood of Vitry-le-François and Beauvais in readiness for the two Franco-American and Franco-British offensives that were being prepared.

Redistribution of Troops.—Reliefs were effected within the armies. The VI. Army put considerable American forces into line: the 42nd and 32nd in the first line, the 4th and 28th in second line, while the 26th and 3rd were being reconstituted in the Marne valley.

In the X. Army, Mangin, convinced that he could obtain a decisive success in carrying the heights north-east of the Grand Rozoy, rested his troops on July 30 and 31 in view of this new effort. The V. Army withdrew the British XXII. Corps and replaced them by two French divisions. The VI. Army resumed its attacks on the 31st. The American 42nd Div. maintained its hold of Seringes-et-Nesles in spite of enemy counter-attacks, and the American 28th, 32nd and 4th Divs. entered Cierges and the Meunière wood. In this way the enemy's attention was drawn to the centre on the evening of the 31st, while the next morning (Aug. 1), at 4:45, the right of the X. Army attacked in its turn and, after severe fighting, occupied the whole crest that extends from L'Orme du Grand Rozoy to Saponay inclusive. On the same day the VI. Army, though it succeeded in capturing the Meunière wood, failed before Saponay on account of the extreme fatigue of its attack divisions. Its artillery gained a definite superiority of fire, however, and the air force reported numerous outbreaks of fire and explosions in the enemy's rear. Nevertheless an obstinate resistance was maintained throughout the night by the enemy.

German Retirement to the Vesle.—At dawn on Aug. 2 the three French armies found themselves facing a void. The enemy had fallen back on the Vesle, where he intended to establish himself firmly. The forward movement of the Allied divisions was preceded by advanced guards, which soon regained contact, and by evening the troops had reached the plateaux of Ambief, Mareuil-en-Dole, Dravegny and Lhery, reoccupying Soissons at 7 P.M. On the 3rd, the left of the X. Army reached the Aisne. Its right, together with the VI. and V. Armies, arrived in the immediate vicinity of the Vesle. Contact was established everywhere. All along the front the enemy artillery and machine-guns became very active. On Aug. 4 and 5 the Allied troops lined the banks of the Vesle, the American 32nd Div. entered Fismes and the advanced guards were even able to push some units north of the river at several points. But the enemy reacted vigorously, and in view of this well-organised resistance Foch had to consider whether to carry on operations beyond the Vesle or to remain on the south side for the time being.

It was obvious that a passage could only be forced by a set battle in great strength. At the moment, other Allied offensives were on the point of being launched in Picardy and Santerre in accordance with the plan made by Foch on July 24 in the midst of the battle of the Marne. It was desirable to reserve any available Allied troops to insure the success of this plan, which was of so varied a character that the enemy, surprised by the points against which attacks were directed, would not have time to parry them. It was for this reason that the order was given not to undertake any strong action north of the Vesle, but yet to keep the enemy under the impression that such an action was in preparation, particularly on the date chosen for the Franco-British offensive, which would thus have more chance of a surprise.

IV. RESULTS OF THE BATTLE

The second battle of the Marne was now over. After three weeks of bitter, vehement and uninterrupted fighting, in which the French armies exerted themselves at times up to the limit of human endurance, the following results had been achieved—of great importance materially and of incalculable moral value: The capture of 30,000 prisoners, over 500 guns, 200 trench mortars and 3,000 machine-guns; the shortening of the front by 45 km.; the restoration of the Paris-Châlons railway line and the removal of the threat against Paris. But above all, the enemy morale was shaken while that of the Allies was strengthened. Finally, the initiative of operations had passed to the side of the Allies, and, in addition, their numerical superiority was assured from that time onward by the arrival of the American forces and their inclusion in the battle, for the battle that was just finished marked the actual entry *en bloc* of American divisions in the offensive battle.

It was not, could not be, a surprise to any Frenchman—and still less to the enemy, who had had four years' experience of the British armies—to see the four British divisions which were fighting among the French divisions cover themselves with glory; but it was questionable whether the enemy had foreseen that the young American divisions, going into the attack with their organisation only just completed and their training still unfinished, would be able to make good both the one and the other by their energy, dash and courage, and by the fine confidence and disdain of danger which is to be looked for in so great a nation.

It was in the height of this struggle that Foch, relying presumably on the results already achieved, forestalled events to some extent in order to hasten them, and, calling together the commanders-in-chief of the Allied armies, issued to them his famous orders of July 24, of which it may be said that they covered the rest of the campaign and contained the germ of victory. Among the so-called "clearance" offensives that he designed in order to get possession of a base of departure for a general offensive, the one developed between the Marne and the Aisne had already done what he required of it. In fact, the action of the troops responded to the idea of the Chief with a rapidity which, so to say, emphasised the excellence of his plan and justified all hopes.

The battle whose scene was in the theatre of the Marne for the second time in less than four years thus marked a turn of the tide in favour of the Allies, and, by associating British, American and Italian forces with the glorious success of the French armies, formed an auspicious prelude to the general offensive. *See* VICTORY, ADVANCE TO.

(E. R.)

MARRAKESH, or Morocco (*see* 17.753), the southern capital and largest town of Morocco, had a population of 139,874 in 1921, 1,956 being Europeans. A European town outside the old city, at the foot of the hills of Geliz and near the military camp, was founded in 1913, and has wide roads planted with trees; it is joined to old Morocco by the fine Avenue de la Koutoubia. There is also a new quarter, with shops and a public garden, in the city itself, and an hotel was opened in 1924. French and Franco-Arab schools have been started. The sub-division of Morocco is under a French military governor, who is in charge of the municipal services, and it has a French court, with right of appeal to the court of first instance at Casablanca. There are good roads to Mazagan, Mogador, Safi and Casablanca, where the trade of the city is handled; and one to Fez was in course of construction in 1925. There is connection by narrow-gauge railway with Casablanca and the rest of Morocco, and a standard-gauge line to Casablanca was under construction in 1926.

MARRIAGE LAWS (*see* 17.753).—It is obviously impossible here to do more than refer very briefly to the more important changes which have taken place in the marriage laws of civilised states since the last article on the subject was published.

I. THE BRITISH EMPIRE

Marriage Abroad.—The object of the Foreign Marriage Act 1892 was to provide that all marriages celebrated abroad—in British possessions outside the United Kingdom as well as in foreign countries—between parties one of whom at least is a British subject, before a "marriage officer" in the manner provided by the Act, should be as valid as if duly solemnised in the United Kingdom. Thus a marriage duly solemnised under the Act before a British Consul in France, although void by French law, was held valid in England (*Hay* v. *Northcote* [1900] 2 Ch. 262). But by the Foreign Marriages Order in Council 1913, where a marriage according to the local law of a foreign country would be valid by English law, the marriage officer must be satisfied (*a*) that both the parties are British; or (*b*) if only one is British, that the other is not a national of the country; or (*c*) if one of the parties is British and the other a national of the country, that sufficient facilities do not exist for the solemnisation of the marriage in the foreign country in accordance with the law of that country; or (*d*) if the man is British and the woman a national of the country, that no objection will be taken by the authorities of the country to the solemnisation of the marriage under the Foreign Marriage Act. From the decision of the marriage officer there is a right of appeal to the Secretary of State.

Further, if it appears to the marriage officer that the woman is British and the man an alien he must be satisfied (*a*) that the marriage will be recognised by the law of the country to which the alien belongs; or (*b*) that some other marriage ceremony, in addition to that under the Foreign Marriage Act, has taken place or is about to take place and that such other ceremony is recognised by the law of the alien's country; or (*c*) that the leave of the Secretary of State has been obtained. Measures have been passed to give effect to these provisions in the Bahamas, Gilbert and Ellice Islands, Gold Coast, Nigeria and Sierra Leone.

Recognition of Banns, etc.—The Marriage of British Subjects (Facilities) Act 1915 provides for the mutual recognition of certificates, publications of banns, or notices of marriage issued in the United Kingdom, and in any part of His Majesty's dominions outside the United Kingdom respectively, in the case of marriages intended to be solemnised in either, between British subjects resident in either respectively. These provisions may be applied to any part of the dominions where the law makes due provisions for the publication of banns, or notices for marriages between British subjects intended to be solemnised or contracted in the United Kingdom, and for the recognition of certificates for marriage. Reciprocal legislation in the dominions is a condition precedent to the issue of an order in council. Such legislation has been passed by the Bahamas, Barbados, Bermuda, British Solomon Islands, Cyprus, Gambia, Gibraltar, Gilbert and Ellice Islands, Gold Coast, Grenada, Hongkong, Mauritius, New Brunswick, New Zealand, Nigeria, St. Lucia, St. Vincent, Sierra Leone, Straits Settlements, Uganda and Victoria.

By the Marriage of British Subjects (Facilities) Amendment Act 1916, however, where the marriage is to be solemnised or contracted in the dominions, and no notice of the marriage under the law in force there is required, the Act of 1915 may be applied to that part of the dominions by order in council. By special statute any marriage celebrated abroad (either in British possessions or in foreign States) and being of doubtful validity may be validated here. There are many instances of this procedure, *e.g.*, the Marriages in Japan (Validity) Act 1912.

Deceased Wife's Sister, etc.—Marriage with a deceased wife's sister has been legalised in the Falkland Islands, Fiji, Jamaica and the Leeward Islands, and also, subject to the proviso that misconduct with the sister makes the marriage void, in Nigeria, St. Lucia, St. Vincent, Straits Settlements, Trinidad and Tobago; the Union of South Africa Act of 1920 legalises such marriages in Natal and the Transvaal, and the Marriage Decree 1915 in Zanzibar.

The Deceased Brother's Widow's Marriage Act 1921 legalises the marriage of a woman with her deceased husband's brother, including the half-blood. The same freedom is accorded in British Guiana, the Isle of Man, Jamaica, Leeward Islands, the Union of South Africa and Western Australia. Legitimation by subsequent marriage is allowed in New Brunswick and British Columbia.

Divorce.—The English divorce law has been modified by the Matrimonial Causes Act 1923 under which a husband's adultery committed since July 18 1923 entitles the wife to divorce without proof of other matrimonial offences.

In New Zealand the Divorce and Matrimonial Act 1908 has been amended by the Act of 1912, which reduces to seven years the period of detention in an asylum as a ground of divorce, while the Act of 1919 provides for the custody of children by the wife of a person of enemy origin. By the Marriage Amendment Act 1920 the allegation that persons are not lawfully married or that children are illegitimate is made a punishable offence on summary conviction by a fine of £100. The Act of 1920 extends the grounds for divorce to failure to comply with a decree for restitution of conjugal rights, and grants a divorce on a petition after three years from a degree of judicial separation or separation order or deed of arrangement or separation by mutual consent. Detention in an institution for insane persons, whether situate in New Zealand or in any other part of the British Dominions, is also a ground for divorce.

In Queensland, by the Act of 1923 lunacy for a period of five years is made a ground for divorce. The Tasmanian Marriage and Divorce Act 1919 enables a husband to petition on any of the following grounds: adultery, desertion for four years, habitual drunkenness and neglect during three years, imprisonment, violent assault, lunacy. The Victorian Marriage Act 1923 amends the Marriage Act 1915, the Marriage (Maintenance) Act 1919 and the Divorce (Insanity) Act 1919. The following are grounds for divorce: wilful desertion by either for three years, habitual drunkenness of husband with lack of maintenance of, or cruelty to, the wife, and habitual drunkenness and neglect of wife, imprisonment, violent assault, adultery of husband in the conjugal residence, or coupled with circumstances or conduct of aggravation, or of a repeated act of adultery, or lunacy, and adultery by the wife.

By the Divorce and Matrimonial Causes Act 1912 of Western Australia the grounds for divorce are adultery of the wife and adultery, sodomy or bestiality of the husband, desertion by either for five years, habitual drunkenness for four years of husband and lack of support of wife, and habitual drunkenness and neglect of wife for like period, imprisonment, violent assault and lunacy. By the Divorce Amendment Act 1919 incontinence by

either before marriage is added, provided the woman was pregnant at the time of the marriage. The Married Women's Protection Act 1922 repeals the Summary Jurisdiction (Married Women) Act 1896 and provides protection to a woman whose husband is guilty of cruelty to her or her children, adultery, desertion, wilful neglect to provide reasonable maintenance for her or her children. In Zanzibar a decree of 1912 regulates marriage. The Marriage (Scotland) Act 1916 provides for the joint application of the spouses for a warrant to register an irregular marriage.

II. OTHER COUNTRIES

Baltic States.—In Estonia, Latvia and Lithuania civil marriage is now compulsory.

Belgium.—Marriage between a brother-in-law and a sister-in-law, whether legitimate or illegitimate, is prohibited by the law of 1920, where the marriage which produced the relationship has been dissolved by divorce, but it is legal where the previous marriage has been dissolved by death.

Cuba.—The Spanish civil code 1889–99 has been amended by the Act of 1918, by which marriage is a civil contract, and is only legally effective if celebrated in accord with the code. Separation and divorce are established by the law of 1918. The grounds for divorce are adultery, prostituting the wife or children, grave injury by violence, words, or conviction for crime, grave crime against the wife or children, habitual drunkenness, confirmed gambling, desertion, failure of husband to maintain the home, contagious disease and mutual consent. A divorced husband is not freed from his obligations to his children.

France.—Marriage between a brother-in-law and sister-in-law, whether legitimate or illegitimate, is prohibited by the law of 1919, where the marriage which produced the relationship has been dissolved by divorce, but it is legal where the previous marriage has been dissolved by death.

Italy.—By the law of 1919 a wife may, without her husband's consent, make a gift *inter vivos*, alienate, or mortgage her real property, make a contract of loan, transfer or collect moneys, enter into a contract of guarantee, compound or appear in court with regard to these affairs, be a trader or accept a mandate.

Mexico.—By the Law of Family Relations 1917 marriage is a civil contract by which the spouses are bound by a dissoluble bond. Community of goods is abolished, subject to any settlement. The impediments to marriage are habitual drunkenness, impotence, syphilis, insanity, and any other chronic and incurable infirmity. The following are causes for divorce—adultery, attempt to prostitute the wife, or make the other commit a crime, or corrupt the children; contraction of syphilis, tuberculosis, incurable insanity or other chronic or incurable disease; unjustified desertion for six consecutive months; absence of husband for more than a year, coupled with the obligations inherent in marriage; ill-treatment; false accusation of crime; commission of crime; incorrigible drunkenness; mutual consent. Adultery of the husband is a sole ground for divorce only in certain circumstances. Upon divorce either spouse may remarry. The custody of the children is granted to the innocent spouse. All proceedings are *in camera* and on the intervention of the Attorney-General.

Norway.—By the law of 1909 a marriage may be dissolved where either spouse unknown to the other at the time of the marriage suffered from bodily defect, epilepsy, leprosy, venereal disease, mental disease, or the wife was pregnant by another man. If divorced, the woman may not remarry within 10 months from judgment or licence.

Portugal.—By decree of 1910 marriage is a civil contract and is evidenced by civil registration, and all contracts under the name of betrothal or engagement are void. Divorce may be granted for complete abandonment of the home for three years, or absence for four years or separation *de facto* during 10 consecutive years, lunacy, contagious disease, incurable disease, conviction of homicide.

Sweden.—Separation and divorce are regulated by the law of 1920. Grounds for the former are mutual consent, neglect, drunkenness or debauchery; for the latter judicial separation for one year, three years' separation, two years' absence, bigamy, adultery, venereal disease, plot against life of spouse or imprisonment.

Switzerland.—By the Swiss civil code, which came into force Jan. 1 1912, the marriage laws were made uniform throughout Switzerland. The legal status of women is raised almost to an equality with that of men. The marriageable age for women has been raised from 16 to 18 and that of men from 18 to 20, but for both sexes under 21 the consent of parents or guardians is necessary. Mentally diseased persons are incapable of marriage. The betrothal, for breach of which damages may be awarded, is followed after publication by a civil marriage. Grounds for divorce are adultery, plot against life of spouse, abuse, gross insult, crime, desertion, mental infirmity or ruin of marital relationship. The guilty spouse may not remarry within the period prescribed by the Court.

Judicial separation may be temporary or permanent. If it has lasted for three years either spouse may sue for divorce. The father of an illegitimate child may be compelled to contribute to its support until the age of 18 in proportion to his social position. The children of a marriage which is declared null are legitimate even when neither spouse contracted it in good faith.

Turkey.—The civil code of 1926 is an adaptation of the Swiss, and radically changes the legal status of women, who obtain *inter alia* equal rights with men in divorce.

United States.—The minimum age for marriage has been fixed at 15 in Missouri, 16 in Arizona, and 18 in Tennessee, whilst in Montana marriage between first cousins and persons either of whom is feeble-minded is forbidden. In North Dakota marriage with a degenerate (if a woman under 45, if a man of any age) is prohibited. New York has reduced the period within which a guilty spouse may not remarry from five to three years, and Tennessee has made a ground for divorce such cruel or inhuman treatment of the husband by the wife "as renders it unsafe or improper for him to cohabit with her."

III. DOMICILE AND MARRIAGE

Desertion.—The rule was laid down in *Mesurier* v. *Mesurier* (in 1895) A.C. 517 and affirmed in the House of Lords in *Lord Advocate* v. *Jaffrey* (1921, A.C. 146) that matrimonial status is governed by the law of the domicile of the parties. Thus the domicile for the time being of the spouses affords the only true test of jurisdiction to dissolve the marriage. This domicile is that of the husband. In *Att. Gen. for Alberta* v. *Cook* (1926, 42 T.L.R. 317) the Judicial Committee of the Privy Council declared that under British law a wife, even when judicially separated from her husband, still retains his domicile and cannot acquire a domicile of choice.

But in certain cases of desertion the wife has been permitted to sue in the domicile from which the desertion took place, and thus was not compelled to follow her husband to his new domicile: *Armytage* v. *Armytage* (1898 p. 178); *Ogden* v. *Ogden* (1908 p. 46); *Stalathos* v. *Stalathos* (1913 p. 46); *De Montaigu* v. *De Montaigu* (1913 p. 154). This undoubtedly is a departure from what has always been the rule of law and practice in Great Britain and Ireland—viz.: that the wife's domicile is the husband's domicile, whatever that may be. But, as Lord Cave said in *Lord Advocate* v. *Jaffrey*, there is no doubt authority for the proposition that "the husband will not be allowed to set up his own wrong as an argument for prejudicing his wife's rights." This proposition has been made statutory in some of the colonies. By the Victorian Marriage Act 1915 "a deserted wife who is domiciled in Victoria at the time of desertion shall be deemed for the purposes of this Act to have retained her Victorian domicile, notwithstanding that her husband may have since the desertion acquired a foreign domicile." The Western Australian Act of 1912 and the Tasmanian Act of 1919 are to the same effect.

India.—It was decided in *Keyes* v. *Keyes et Gray* (1921, p. 204) that the courts in India had no jurisdiction to grant divorce to parties not domiciled in India, though the marriage was celebrated and the parties were resident there. By the Indian Divorce (Validity) Act 1921 divorce may be granted where the proceedings were commenced before the Act. By the Indian Divorce Amendment Act 1926 relief is restricted to parties domiciled in India.

United States.—Throughout the United States matrimonial status is governed by the law of the domicile of the parties only up to a point. This point is reached when the wife separates from the husband for a just cause (*i.e.*, any act of his which would entitle her to a limited or absolute divorce) or where they agree in writing to live apart; the wife may acquire a separate domicile and may obtain a divorce in the State of her domicile. In a nullity suit, since there never was identity of domicile, the wife retains her own domicile. This rule obtains also in England.

Domicile and Validity.—The general rule that a marriage valid by the law of the place of celebration is valid everywhere is usually subject to the condition that it is also valid by the law of the nationality or domicile of the parties. In New York State the guilty spouse, if divorced, may not remarry during the lifetime of the other but it seems that by changing his or

her domicile he or she may remarry, and that by the general rule such marriage will be valid in New York. To prevent such a result, Massachusetts has passed an Act providing that if a person residing in or intending to reside in Massachusetts is disabled by the law of that State from marriage, and marries in another State, such marriage is void in Massachusetts. And if a person residing in another State is married in Massachusetts, such marriage is void if it would have been void in the State where such person is domiciled. Louisiana has also passed an Act providing that marriages contracted between persons, one or both of whom are domiciled in Louisiana and forbidden to marry in that State, shall be deemed to be invalid, even if valid elsewhere.

MARS: *see* ASTRONOMY.

MARSEILLE (*see* 17.766) is the second largest city in France, with a population of 586,341 in 1921. Housing conditions were very bad, dwellings which were condemned before the World War being still inhabited in 1920, and manufacturers in consequence experienced considerable difficulty in procuring labour. There was an influx of workers during the War, when there was considerable industrial development, largely in the provision of foodstuffs and in metal manufacture. Part of the harbour became a British base, and many Indian, Australian and African troops passed through, together with refugees from Europe and the East; after the Armistice an American embarkation camp was established.

Before the War Marseille was extremely prosperous, but during it trade collapsed, and there was less military activity than in the western ports. A period of great difficulty in industry and shipping has since been faced. In 1923 the total of goods discharged at Rouen, where little was shipped, exceeded the total of discharges and shipments at Marseille, hitherto the leading French port. The figures in 1926 were still below those of pre-War years. During the War basins in the harbour were deepened, and a new one has since been taken in hand. A railway now runs along the coast for 60 km. as far as L'Estaque. Much work has been done on the Marseille-Rhône canal. A small port has been built at its opening into the Gulf of L'Estaque; land has been assigned for industrial development, and industrial suburbs are arising along the bank of the canal where, protected by embankments, it runs along the coast and reaches the Lave by a tunnel 7,000 metres long. It is hoped that improved navigation on the Rhône, and the extension of the port to include the lakes of Berre and Caronte, will bring a large influx of trade to Marseille.

MARSHALL, ALFRED (1842–1924), British economist (*see* 17.770). In 1890 he published his *Principles of Economics* which went through many editions and was translated into a large number of foreign languages. He retired from the chair of political economy at Cambridge in 1908 in order to devote himself to writing. His next volume, *Industry and Trade*, a realistic study of industrial organisation, appeared in 1919, and this was followed in 1923 by *Money, Credit and Commerce*. He died in Cambridge on July 13 1924.

Marshall may be said to have been in the lineal descent of the great English economists—Adam Smith, Ricardo and J. S. Mill. Like their chief works, his *Principles of Economics* has become a classic. It was distinguished by its profound and systematic methods of analysis, and introduced a number of new concepts of great importance to the science. Although many years elapsed between the publication of the *Principles of Economics* and that of his next two works, much that was most important in them, especially in regard to the theory of money, has been transmitted orally in his lectures at Cambridge, and has influenced thought both in England and in other countries. While Marshall never tried to found a school of economic doctrine, his genius for stimulating the minds of a long succession of pupils and the example of his methods of reasoning have had a profound effect upon the development of economics in England, the British Dominions and the United States. Further information on his life and writings and a detailed bibliography of his works are to be found in the *Memorials of Alfred Marshall*, edited by A. C. Pigou.

MARSHALL, THOMAS RILEY (1854–1925), American politician, was born at North Manchester, Ind., March 14 1854. He was educated at Wabash College (A.B. 1873; A.M. 1876) and was admitted to the bar in 1875. From 1876 to 1909 he practised law in Columbia City, Ind., and from 1909 to 1913 was governor of Indiana. He was nominated for vice-president on the ticket with Woodrow Wilson at the Democratic National Convention in 1912 and was elected. He was again nominated with President Wilson in 1916 and elected for the term 1917–21. For almost two years after the outbreak of the World War he urged strict neutrality, but in 1918 publicly expressed regret for this attitude. In 1919 he welcomed the King and Queen of Belgium on their visit to Washington during the illness of President Wilson. He was a strong advocate of the League of Nations, but did not favour woman suffrage. He served on the U.S. Coal Commission in 1922. He died in Washington, D.C., June 1 1925. His memoirs, *Recollections of Thomas R. Marshall*, were published posthumously in 1925.

MARX, WILHELM (1863–), German politician, was born at Cologne Jan. 15 1863. He entered the political branch of the Civil Service and became a judge. In 1899 he was elected to the Prussian Diet and in 1910 entered the German Reichstag, where he soon became prominent among the leaders of the Centre. He was elected president of the Centre party in 1921, and on Nov. 30 1923 succeeded Stresemann as chancellor of the Reich. In Aug. 1924 he took part in the Conference of London which determined the acceptance of the Dawes Plan (*see* GERMANY). In the autumn of 1924 Marx dissolved the Reichstag in the hope of getting a government majority, and after the elections retired from the post of chancellor. In Feb. 1925 he became Prussian Minister-President for a short period. After the death of Ebert he stood as candidate for the post of president of the Reich, but was defeated by Hindenburg. In Jan. 1926 he became Minister for Justice and Occupied Territories in the second Luther Cabinet and later in the same year succeeded Luther as Chancellor.

MARY (1867–), Queen Consort of England, daughter of the Duke of Teck and Mary Adelaide, daughter of Adolphus, Duke of Cambridge, seventh son of George III., was born at Kensington Palace May 26 1867, and was baptised as Victoria Mary Augusta Louise Olga Pauline Claudine Agnes. She was affianced in 1891 to Albert Edward, Duke of Clarence, eldest son of Edward VII., who died Jan. 14 1892. On July 3 1893 she married George, Duke of York, and when he succeeded to the Throne, on the death of Edward VII., was crowned with him in Westminster Abbey June 22 1911. Both as Princess of Wales and as Queen she took a prominent part in public life, showing special and well-informed interest in all that concerned the welfare of women and children. This was particularly notable at the outset of the World War, when the organisation of relief, as well as the promotion of the women's part in public service, claimed and received her constant attention. By the universal testimony of those who came into direct contact with her through those anxious years, no one showed a more practical appreciation of the problems to be solved than the Queen. In the first month of the War she inaugurated (Aug. 20) the "Queen's Work for Women Fund" to provide employment for as many as possible of the women thrown out of work by the outbreak of war. Over 70 special relief workrooms were opened, through which about 9,000 women passed before Feb. 1915; after that date, the need became less as the women were gradually absorbed into munition making and other industries. On Aug. 10 1914 the Queen also inaugurated "Queen Mary's Needlework Guild" for the purpose of "organising a collection of garments for those who will suffer on account of the War." On March 11 1921 the

Queen showed her sympathy with the higher education of women by visiting the women's colleges at Oxford and responding generously to their appeal for funds. The interest shown by the Queen in the work of the hospitals and the welfare of the nursing profession during the post-War years was especially signalised when she opened the new College of Nursing (the gift of Lord and Lady Cowdray) in London on May 31 1926, and in other ways. (*See* GEORGE V.)

MARYLAND (*see* 17.827).—The population in 1920 was 1,449,661, as compared with 1,295,346 in 1910, an increase of 11·9% as opposed to 9% in the previous decade. In 1920 the urban population (that is, residents of towns of 2,500 inhabitants or more) was 869,422, while the rural population was 580,239, or 60% urban instead of 50·8% in 1910. A part of this increase of urban population may be accounted for by the annexation of portions of Baltimore and Anne Arundel counties to Baltimore City in 1918 (*see* BALTIMORE), by which the population of Baltimore received more than the normal increase for the decade.

The population of those cities in Maryland having more than 11,000 inhabitants and the percentage of increase for the decade was as follows:—

	1920	1910	Increase Per Cent
Baltimore	733,826	558,485	31·4
Cumberland	29,837	21,829	36·6
Hagerstown	28,066	16,507	70·0
Annapolis	11,214	8,609	30·3
Frederick	11,066	10,411	6·3

The greatest percentage of increase was the 70% (11,559 in number) of Hagerstown, an important railway and manufacturing centre of the Cumberland valley.

Agriculture.—In 1910, 48,923 farms occupied 5,057,140 ac., or 79·5% of the total land area of Maryland, of which acreage 3,354,767, or 66·3%, were improved lands. The slow transition of the state from an agricultural to a manufacturing community is manifested in a comparison of these figures with those for 1920, in which year there were reported 47,908 farms, taking up 4,757,999 ac., or 74·8% of the total land area, and showing 3,136,728, or 65·9%, in improved lands. There were 1,015, or 2·1%, fewer farms in 1920 than in 1910, a decrease of 5·9% in total acreage and 6·5% in the acreage of improved land.

In the same period the value of all farm property in the state rose from $286,167,028 to $463,638,120; of the average value of a farm from $5,849 to $9,678. The total farm value in 1920 comprised $386,596,850 in lands and buildings, $28,970,020 in implements, and $48,071,250 in live stock. The average number of acres per farm decreased from 103·4 in 1910 to 99·3 in 1920. The average value per acre of all farm property in 1920 was $97.44, instead of $56.59 as in 1910, and of land alone was $54·62, instead of $32.32. Of the total number of farms, 41,699 were operated by white and 6,209 by coloured farmers, a decrease in the first class of 2%, in the second class of 2·6%.

Of domestic animals on farms in 1920, the total value was $43,784,464. The number of horses in 1924 on farms was estimated at 135,000; of mules 33,000; of milch cows 196,000; of other cattle 103,000; of sheep 96,000 and of swine 299,000. The total value of livestock had decreased to $33,686,000 in 1924, a decline due partly to a decrease in the number of horses and partly to smaller prices prevailing for some classes of animals. The total farm value of Maryland dairy products in 1919, exclusive of products consumed on the farm, was $13,407,526, as against $5,480,900 in 1909, an increase of 144·6%.

The total area in crops in 1923 was 1,934,000 ac., as opposed to 1,927,000 in 1909. The peak year was 1918, when the total area was 2,245,000 acres. The total value of field crops in 1923 was $67,560,000. The corn acreage of Maryland was 647,000 ac., in 1909 (value of crop $11,015,000), and in 1923 the acreage was 642,000, the production 25,231,000 bu., the value of the crop $20,689,000. The wheat acreage was 589,000 in 1909, 664,000 in 1919, 543,000 in 1923. In the last year 10,426,000 bu. were raised, worth about $1.00 a bushel. Hay was grown on 398,892 ac. in 1909; 662,939 in 1919; 400,000 in 1923. In the last year 420,000 tons were raised, which was about one-half less than in the preceding year. In 1923, 59,000 ac. were sown in oats, producing 1,758,000 bu. valued at $949,000. In barley 4,000 ac. were sown producing 132,000 bu.; 17,000 ac. in rye, producing 269,000 bu.; 0,000 ac. in buckwheat, producing 199,000 bu.; 49,000 ac. in Irish potatoes, producing 3,920,000 bu.; 9,000 ac. in sweet potatoes, producing 1,170,000 bu.; 24,000 ac. in tobacco, producing 19,008,000 lb., with a value of $4,182,000.

The apple crop in 1923 amounted to 2,300,000 bu., with a value of nearly $2,000,000; the peach crop 631,000 bu., with a value of $946,000; the pear crop 374,000 bu., worth about $1.00 a bushel. The tomato crop was very important in 1923; 44,230 ac. were devoted to the crop, which produced 243,300 tons, worth $3,708,000. Most of the tobacco raised is exported to France and other European countries. In 1923, 10,420 ac. devoted to strawberries produced 20,840,000 qt. and Maryland excelled all other states, except Tennessee, in the total number of carloads shipped. The wool crop for 1923 amounted to 467,000 pounds.

Minerals and Manufactures.—The value of the products of all mines and quarries in Maryland in 1909 was $5,782,045, and in 1919 $9,698,577, an increase of 67% in the decade. Of this amount, bituminous coal amounted to $8,195,667, or 84·5%. The production of granite amounted to $627,625; of slate, $652,142. In addition, considerable amounts of limestone, marble, clay, asbestos and iron ore were produced. The coal mining is in the western counties of Alleghany and Garrett. The iron-ore produced is used entirely in the manufacture of metallic paints. In 1919, 5,628 persons were employed in 126 mining industries.

The total value of Maryland manufactures in 1909 was $315,669,150, and in 1919 $873,944,774, a sum which placed the state 17th in the Union in value of manufactured goods. Of the amount named, $677,878,492 was the product of Baltimore plants alone. In the entire state, there were in 1919, 165,875 persons engaged in manufacturing industries and $619,606,983 invested in them. In the period 1914–9, the value of Maryland manufactures advanced 131·4%. The following table shows the value of the products of certain industries in 1914 and 1919:—

Products	1919	1914
Men's clothing	$72,589,000	$39,048,000
Copper, tin and sheet-iron products	40,636,000	25,491,000
Canning and preserving	30,566,000	18,029,000
Lumber and timber products	18,744,000	11,911,000
Foundry and machine products	31,581,000	10,659,000
Meat	43,228,000	17,100,000

By 1919 there had been added to this list: cars and general shop construction and repairs, for steam railways, $22,837,000; printing and publishing, $23,835,000; fertilisers, $37,014,000. Since 1914 there has been a large increase in the number of manufacturing establishments and in capital invested in manufactures in Baltimore, so that the 57% which in that year was the contribution of that city to the value of manufactures in the state, has been increased. Outside of Baltimore, the chief manufacturing centres are the western Maryland cities, Cumberland and Hagerstown.

Fisheries.—A decreased output in fishery products, resulting from a lack of regulation of the taking of oysters from the natural beds, having been recognised, the state created, in 1916, a conservation commission. This commission was replaced by a conservation dept. in 1922. In spite of the attempt of the state to increase the supply of oysters, in 1923 it had further diminished to 3,440,810 bu., as opposed to 4,967,433 bu. by April 15 1921, before the close of the season. In Feb. 1925 an exhaustive investigation proved the healthful condition of the Maryland oyster.

Communications.—Beginning with the passage of the "Shoemaker, or State Aid" Act in 1904, the state entered upon a programme of road construction, the prosecution of which has provided it with one of the best road systems of any state. In 1908 the state roads commission was created by the Legislature to construct all state roads and state-aided roads, and as the result of its activities there have been built of both classes 1,585 m. of

macadam, concrete and other surfaced roads on the foundations of the once privately owned turnpikes and the unmetalled connecting county roads.

Education and Religion.—The development of Johns Hopkins University is given in that article. The small colleges of the state, such as St. John's at Annapolis, and Western Maryland at Westminster, have been engaged in important and successful campaigns for the increase of their endowments. In 1920 the Legislature passed an Act merging the University of Maryland (Baltimore), with its schools of law and medicine, and the Maryland State College of Agriculture (College Park, Md.) under the name of the University of Maryland, and under the control of a board of regents. In secondary education, the further betterment of the school system throughout the state was provided for by the reorganisation of the state Board of Education by legislative enactment of 1916.

History.—A series of Acts passed since 1910 indicates a progressive quality in the administration of the state. These Acts created the Public Service Commission (1910), the state Industrial Accident Commission (1914), the Conservation Commission (1916), the state Board of Prison Control (1916), the state Tax Commission (1914), the state Roads Commission (1908) and the reorganisation of the state Board of Education (1916). In 1916 the budget system was adopted, and in 1920 a merit system for state employees was put in operation.

In 1922, largely through the efforts of Gov. Ritchie, the government of the state was reorganised so as to consolidate and rearrange the executive and administrative departments of the state under 19 divisions. A state purchasing agent now secures supplies for these state departments. Four great military establishments were located in Maryland during the World War; the Aberdeen Proving Grounds, the Edgewood Arsenal, Camp Meade and Camp Holabird. Because of their good location and convenience to Washington, these establishments have been retained for military purposes by the War Department.

Maryland was the sixth state to ratify the prohibition amendment, but never ratified the suffrage amendment. Recent governors have been: Austin L. Grothers (Dem.), 1908–12; Phillips Lee Goldsborough (Rep.), 1912–6; Emerson C. Harrington (Dem.), 1916–20; Albert C. Ritchie (Dem.), 1920–6. The latter was re-elected by a plurality of 40,400 votes in 1923. In 1924 Maryland decided to cast its electoral vote for Coolidge by a plurality of 14,350.

Of late, Maryland has usually been Republican on national issues, but Democratic at state elections. Through the efforts of Gov. Ritchie, a constitutional amendment was passed providing for the election of state officers at the same time as the election of national officers. This reduced the term of many state officers then elected, from four to three years, and provided for a three-year intermission in the meeting of the Legislature. Beginning with Jan. 1927 the Legislature will meet biennially again, and the members of the two Houses will be elected for four-year terms at the same time as the governor.

Flack, Dept. of Legislative Reference, Baltimore, Md.); *Annual Report Commissioner of Labor and Statistics* (1923); *Annual Reports of the Conservation Dept. of Maryland* (1924); *Abstract of Census of Manufactures* (1919); *Maryland Almanac* (1924, 1925). (B. C. S.)

MASARYK, THOMAS GARRIGUE (1850–), first President of Czechoslovakia, was born on March 7 1850 in the Moravian border-town Hodonin. His father was a coachman employed on one of the Austrian Imperial estates, a native of Kopčany in Slovakia (Slovakia then being a part of Hungary); his mother came from a semi-Germanised Czech family of Hustopeč, in the Moravian plains. In his boyhood Masaryk was taught Czech and a smattering of German, and was educated at a Czech school in Čejkovice. His parents sent him for two years to the lower German Realschule of Hustopeč, with the intention of making him a teacher.

The object being abandoned, he became first a locksmith's apprentice in Vienna, then a blacksmith at Čejč. In 1865 his former schoolmaster induced his parents to resume their first idea of making him a teacher, and in that year Masaryk passed the entrance examination to the second grade of the "gymnasium," and began studying at Brno. He supported himself, as did many poor students, by tutoring. He developed a rebellious disposition, disagreed with some of the dogmas of the Roman Catholic Church and refused to go to confession. As a result he had to leave the gymnasium, and he continued his studies in Vienna, where he graduated first from the gymnasium with honours, then from the University, where in 1879 he became a lecturer in philosophy. He spent a year in Leipzig, where he met his future wife, Miss Charlotte Garrigue, daughter of the President of the Germania Insurance Co. of New York. In 1881 he published in German his first great sociological work, *Suicide as a Phenomenon of Modern Civilisation*. In 1882, when the University of Prague was divided into two parts, the one Czech, the other German, he was appointed to one of the Czech professorships. In 1885 he published his larger work on *Concrete Logic*, a study of the methods of classification of sciences, in which he attempted to work out a natural system of all knowledge.

In 1883 Masaryk founded a critical monthly review *The Athenaeum*, which soon sprang into prominence by becoming the battle ground on which the famous MSS. of Krláové Hradec and Zelená (Koeniginhof and Gruenberg) were attacked and proved to be forgeries, manufactured in the early 19th century by two well-meaning men, whose object was to provide text for the theory that in the Middle Ages there had been a high standard of literary culture in Bohemia. The authenticity of the MSS. had before been doubted by Slav philologists, but it was not until 1886, when Masaryk invited the great Czech philologist Gebauer to analyse the MSS. philologically, himself analysing them sociologically, that they were conclusively proved to be forgeries. The fight over the MSS. was the real beginning of the so-called "realist" revolution in Czech politics, literature and philosophy, the guiding principle of which was the application of the scientific method to letters and politics. While at Prague University Masaryk founded in 1893 a monthly review *Naše Doba* (Our Epoch). He became a member and instructor of the "Sokols." He started lecturing in Prague clubs and societies on unconventional subjects and published unpopular books. His sociological work led him to a study of Marxism, whose historical materialism he criticised in his great work *The Social Question* (1898, in Czech and in German).

Masaryk's political career started in the early 'eighties. In 1887 his friends founded a fortnightly paper *Čas* ("Time"), which two years later he took over and transformed into a political weekly. At that time the so-called Old Czech (Conservative) party was losing ground, and Masaryk, invited by the Young Czech (Liberal) party to be a candidate, was elected to Parliament in 1891. He soon resigned his seat in Parliament (1893) to devote himself to a crusade of moral education among the Czech people. He created for the Czechs what he called the philosophy of a small nation taking up the thesis of Palacky, the great Czech historian, who regarded the period of the Hussites and the Bohemian Brethren as the culminating point of Czech history, and drawing the moral that in the long traditional struggle between Slav and Teuton, which formed the main substance of Czech history, the Czech nation preserved itself by an intense love of culture and by a high standard of morality.

Although his opinions on nationalist questions were unpopular—an unpopularity which increased when in 1899 he fearlessly withstood a popular anti-Semitic superstition as manifested in the so-called "ritual murder trial" of a Jew named Hilsner—his ideas made a deep impression. They became the rallying cry of the younger generation not only of the Czechs, but of the Yugoslavs and other Slavs who flocked to Prague.

In 1900 his followers founded a political party which was officially named the "Progressive party," but which continued popularly to be known as the Realist party. The programme was founded on the principles enunciated in Masaryk's books. As a candidate of the Realist party he was re-elected to Parliament in

1907. In Parliament he soon began to criticise Austria's passive subjection to Germany and her own aggressive policy in the Balkans, especially as manifested in the annexation of Bosnia-Hercegovina. In the notorious "high treason" trial of Agram (1909), by which the Austrian Foreign Minister Count Aehrenthal tried to justify his annexation policy, and in the Friedjung trial (1909) which followed, Masaryk played a decisive part. He proved, on the basis of his private investigations, that the case for the Crown rested on documents forged at the Austro-Hungarian Legation in Belgrade. His fearless disclosures in the Austrian Reichsrat (May 1909) and in the Austro-Hungarian delegations (1910) forced the proceedings in the Agram trial to be quashed, compelled Friedjung to retract his accusations against the Serbs, and unmasked the methods of Austro-Hungarian diplomacy. Masaryk incurred the intense displeasure of the official and court circles in Vienna, but made a reputation abroad which proved useful to him during the War of 1914–8.

During the World War he developed his case against Austria-Hungary in detail, and at the end, in his work, *The New Europe*, characterised it as a corrupt, imperialist, militarist, pretentious and senseless relic of the Middle Ages. When the War broke out he was still a member of the Austrian Parliament. In Dec. 1914 he escaped from Austria, and in the following four years conducted a political and propagandist campaign in Switzerland, France, England, Italy, Russia and the United States on behalf of Czechoslovak liberation from Habsburg rule. He founded the propagandist journals *La Nation Tchèque*, which was edited in Paris by Ernest Denis, and *Československa Samostatnost* (Czechoslovak Independence), which was produced in the small town of Annemasse in Savoy, and he was one of the original Board of Dr. R. W. Seton-Watson's *The New Europe*, which was founded in London in 1916.

Masaryk's stand against Austria was publicly proclaimed in his Hus Anniversary speech made in Geneva in July 1915, and reaffirmed in his revolutionary manifesto, issued by him with the sanction of the Czech political leaders at home, on Nov. 14 1915. The signatories of that manifesto, who included representatives of Czech residents in France, Great Britain, America and Russia, formed a central revolutionary committee called the Czechoslovak National Council, of which Masaryk acted as President and Dr. E. Benes as Secretary. Finding his work in Switzerland hampered by enemy spies, he settled in London, where, at the invitation of Dr. Ronald Burrows, principal of King's College, he joined the staff of that college. Here he worked for two years combating, with the help of his friends, Mr. Wickham Steed and Dr. R. W. Seton-Watson, the German-Magyar propaganda, and familiarising Western opinion with Czechoslovak aspirations.

The Russian revolution of 1917 enabled him to go to Russia. Several thousand Czech soldiers—prisoners of war—had gone over to the Russians, and wanted to organise themselves into active military units. After some difficulty Masaryk induced the revolutionary Russian Govt. to agree to the formation and equipment of an independent Czechoslovak Army (92,000), whose exploits as they marched eastwards from Siberia to Vladivostok were one of the impressive later episodes of the War. He transferred some of them to the Western Front. He went to the United States in May 1918. The result was the Lansing declaration (May 29 1918) of sympathy with the cause of Czechoslovak and Yugoslav independence. The Allied Govts. associated themselves with that declaration on June 3 1919. The ice being thus broken, the Allied Powers and America recognised Masaryk's National Council as the *de facto* Government of the future Czechoslovak State. Masaryk was elected first President of the Czechoslovak Republic on Nov. 14 1918 and re-elected on May 27 1920. He had been sentenced to death *in contumaciam*, and in 1923 occurred the death of his wife, largely the result of the persecution to which the Government had subjected his family. For his work as President of the Republic during the years 1918 to 1926 *see* CZECHOSLOVAKIA.

Masaryk ranks equally high as a philosopher and as a statesman. His philosophical treatises were the result of his study of Czech history. His pronounced realism was a reaction both against the Teutonic idealism which developed moral speculation without reference to the practical affairs of life and against the Tolstoyan Slav philosophy of non-resistance to evil. Masaryk, as philosopher, stands for a unified conception of life, in which the spiritual and the religious take their place with the intellectual and the political as aspects of an integral whole. The following are the chief of his many philosophical, sociological and political works:—

O Hypnotismu, On Hypnotism (1880); *Sebevražda*, Suicide and Modern Civilisation (1881, also in German); *Theorie Pravděpodobnosti a Humeova Skepse*, the Theory of Probability and Hume's Scepticism (1882, German trans. 1884); *Blaise Pascal* (1883); *Theorie dějin dle zásad T. H. Buckle*, the Theory of History according to T. H. Buckle (1884); *Základové Konkretin Logiky*, Essay on Concrete Logic (1885, German trans. 1886); *Slavjanofilism I. S. Kirejevskeho* (1889); *Česká Otázka*, the Czech Question (1895); *Karel Havlíček* (1896); *Otázka sociální, filosofické a sociální základy marxismu*, The Philosophical and Sociological Foundation of Marxism (1898, also in German); *Jan Hus* (1899); *Rusko a Evropa*, Russia and Europe (1913, Eng. trans. *The Spirit of Russia*, 1919, 2 vol., 3rd vol. not yet finished); *The Problem of the Small Nations in the European crisis* (1916); *The New Europe* (1918, French trans. 1918. Czech 1919, German 1922); *Světová Revoluce* (1925, German trans. 1925, Eng. trans., *The World Revolution*, 1926).

MASEFIELD, JOHN (1875–), British poet and novelist, was born in Liverpool and spent his early years in many countries and occupations, serving before the mast at sea, and earning a living as best he could in America. The activity of these years was reflected in his work from the first, as *Salt-Water Ballads* (1902) or *Ballads* (1903), in spite of their obviously Kiplingesque inspiration, show. His early novels, *Jim Davis* (1911), *Captain Margaret* (1908) and *Multitude and Solitude* (1909), had merit as tales of action and spirit, but it was in narrative poetry and drama that he found his natural expression. *The Everlasting Mercy* made something of a sensation in 1911; it was followed quickly by *The Widow in the Bye Street* (1912); *Dauber* (1913); and *The Daffodil Fields* (1913), all narrative poems in a key of stern realism. Meantime Masefield had made some successful experiments in drama, with *The Tragedy of Nan* (1909) and *Pompey the Great* (1910), the first allied in subject and setting to his long poems of village life, the second historical in theme. *Lollingdon Downs* (1917) included a noteworthy sonnet sequence, and *Reynard the Fox* (1919) proved one of the most successful of his verse narratives. Later work included *Collected Poems* (1923); *A King's Daughter*, a verse tragedy (1923); *Sard Harker*, a novel of adventure (1924); *The Trial of Jesus*, a play (1925); *Odtaa*, a novel (1926). He published some able prose War sketches in *Gallipoli* (1916) and *The Old Front Line* (1917).

MASON, MAX (1877–), American educationist and inventor, was born at Madison, Wis., Oct. 26 1877. He graduated from the University of Wisconsin in 1895, continuing his studies at the University of Göttingen (Ph.D., 1903). After being instructor in mathematics at the Massachusetts Institute of Technology 1903–4, he became assistant professor of mathematics at the Sheffield Scientific School, Yale University, in 1904. He was appointed professor of mathematical physics at theUniversity of Wisconsin in 1908. He also lectured at Harvard University 1911–2. During the World War he was a member of the staff of the Naval Experimental Station, New London, Conn., and also on the submarine committee of the National Research Council 1917–8. He invented several devices for the detection of submarines. In Aug. 1925 he became president of the University of Chicago.

MASPERO, SIR GASTON CAMILLE CHARLES (1846–1916), French Egyptologist (*see* 17.848), died in Paris June 30 1916. During his second term of office as director-general of the service of antiquities at Cairo he was made K.C.M.G. (1909). He retired in 1914.

MASSACHUSETTS (*see* 17.850).—The population in 1920 was 3,852,356, an increase of 485,940 or 14.4% since 1910, as against

20% in the preceding decade. Nearly one-third of the state's inhabitants lived in metropolitan Boston. Less than 1·3% were negroes; 28% were foreign born, of whom 24·4% came from Canada. The average density of population in 1920 was 470·2 per sq. m., as against 418·8 in 1910. The urban population (in 169 places of more than 2,500) was 94·8% of the whole, as against 92·8% in 1910. According to a census taken by the state in 1925, the population was 4,144,205. The Census Bureau estimated the population as of July 1 1926 to be 4,197,288. The population of the 12 chief cities was:—

Cities	1925	1920	1910	Increase % 1920–5
Boston	781,529	748,060	670,585	4·5
Worcester	192,242	179,754	145,986	6·9
Springfield	142,224	129,614	88,926	9·7
New Bedford	120,494	121,217	96,652	− ·5
Fall River	129,662	120,485	119,295	7·6
Lowell	110,542	112,759	106,294	−1·8
Cambridge	120,053	109,694	104,839	9·4
Lynn	103,147	99,148	89,336	4·0
Somerville	99,206	93,091	77,236	6·5
Lawrence	95,136	94,270	85,892	·9
Brockton	65,731	66,254	56,878	− ·7
Holyoke	60,892	60,203	57,730	1·1

Agriculture.—The total number of farms in 1925 was 33,454 as compared with 32,001 in 1920 and 36,917 in 1910. Farm property in 1925 was valued at $293,405,059, including live stock valued at $21,758,276. The average acreage of farms is decreasing, being 70·8 in 1925 as against 77·9 in 1920, but the average value per acre is increasing, being $107.53 in 1925 as compared with $99.25 in 1920.

The principal crops were as follows, in bushels:—

Crops	1924	1919	1909
Corn (maize)	425,780	1,921,607	2,402,738
Oats	82,668	1,515,933	2,029,381
Buckwheat	11,847	23,238	32,926
Wheat	4,028	33,253	2,404
Potatoes	1,734,210	1,885,655	2,946,178
Tobacco (pounds)	14,058,156	14,282,589	9,549,306
Rye	9,947	46,261	59,183
Apples	3,006,120	3,187,211	2,550,259

Two-thirds of the cranberry yield of the United States in recent years was raised in the bogs along the southeast coast of the state. The live stock on farms in 1924 included 43,537 horses, 192,131 cattle (of which 145,631 were dairy cows) and 63,810 swine.

Mineral Products.—During the past 15 years there was a large increase in the production of building-stone, crushed rock for road and street-making, and sand. The value of marble, slate and stone work in 1923 was $11,285,444. The value of clay products of the state increased from $1,647,362 in 1908 to $4,238,354 in 1923, of which latter amount $3,045,638 was the value of common brick. The total value of mineral products in 1924 was $15,725,000 as compared with $12,411,708 in 1920 and $6,077,370 in 1910.

Manufactures.—Massachusetts, with a limited local market for its manufactured products, scanty resources in the form of raw materials, and a declining trans-Atlantic commerce, has added little to its railway and terminal facilities. Only four states are smaller in area: yet in 1921, only five states exceeded it in the value of its industrial output. Its advantage has lain in having a surplus of capital, in its unsurpassed supply of skilled labour and in the superior organisation of its factories. In its earlier development it utilised its local water-power, of which it had a liberal supply. Then it became largely dependent on coal for fuel, imported at increasingly high cost. In 1910 the total value of products of manufacturing establishments was $1,490,527,386; in 1921, $2,849,413,516; in 1923, $3,571,348,398. While the increase in value is largely to be accounted for by the increased prices, the state as a whole made commendable industrial progress. In textiles (cotton, worsteds and woollens), in boots and shoes, boot and shoe cut stock and findings, rubber footwear and in fine writing paper, Massachusetts in 1923 was the foremost state.

The following table deals with the chief manufacturing industries as ascertained by the census of 1923:—

Industry	No. of establishments	Average number of wage-earners	Wages	Value of products
Cotton goods	191	113,707	$115,080,841	$415,922,838
Boots and shoes	595	69,397	82,916,416	290,674,403
Worsted goods	83	45,806	51,833,609	258,035,615
Electrical machinery and supplies	130	26,350	34,482,705	117,575,926
Foundry and machine-shop products	533	24,660	36,267,289	114,929,133
Dyeing and finishing textiles	75	14,074	16,099,333	101,824,142
Woollen goods	103	19,036	24,356,203	94,100,430

The value of boots and shoes and cut stock in 1923 was 36% of the country's output, New York ranking second with 18·9%. In 1923 the textile industries employed 33% of the manufacturing wage-earners, the products being 28% of the total industrial output. Over two-fifths of this was in cotton goods and formed 22% of the output of the whole country, North Carolina being the next largest producer of cotton goods. The output of woollen and worsted goods in 1923 was about 30% of that of the whole country, Pennsylvania producing the next largest amount. The increase in value from 1900 to 1923 was 536%. The increase in the value of boots and shoes and cut stock for the same period was 154%. Boston and Worcester were the principal centres for foundry and machine-shop products. Other industrial products were: rubber goods, $84,098,920; tanned, curried and finished leather $71,098,478, in the manufacture of which Massachusetts was second among the states; paper and wood pulp, $93,641,621; printing and publishing, $117,436,792, of which $61,326,221 was the value of newspapers and periodicals; cordage, twine and jute goods, $28,477,768, in which the state was second only to New York; furniture, $34,691,239; jewellery, $30,436,712; and confectionery, $48,618,574, in both of which Massachusetts was third among the states.

The state is also noted for its fishing industry, the fleets visiting the Newfoundland Banks being important, with Gloucester and Boston as chief centres of the trade. The value of products in 1920 was $7,596,905. Cod were valued at $2,311,011; haddock, $2,655,303; mackerel, $748,682; and halibut, $518,598.

Education.—In 1925 the total number of pupils enrolled in the public schools was 713,926, the amount expended on education being $71,941,986. In 1910 the figures were 538,441 and $17,110,327 respectively. Several fundamental changes were made in the organisation of the educational enterprises of the state in 1919. Among the most important were: the consolidation into a new department of education of several related activities, the abolition of the Board of Education, and the creation of the Advisory Board of Education, consisting of six members and the Commissioner of Education, who is *ex officio* chairman. In vocational education rapid progress occurred in the period 1909-23 the number of schools in which vocations are taught increasing from six to 80, and the enrolment in vocational classes from 1,400 to 11,870.

Another significant development was in university extension. In the year ending Nov. 30 1923, 5,075 students were receiving instruction by correspondence. In the five years ending Aug. 1923, 27,658 were registered in adult immigrant classes and 27,313 in other extension classes. In 1911 the Teachers' Registration Bureau was established, a free agency which has proved very successful; three years later a retirement system was put into operation, with membership compulsory, and provision for retirement at 60 years of age under certain conditions or by

compulsion at 70. The Legislature of 1921 made several notable changes, among which are the following: Compulsory transportation from towns where there is no high school, with provisions for state reimbursement a provision compelling every town with a valuation of $1,000,000 or more to employ a school nurse, and the requirement of physical training in both elementary and high schools.

The state department may now grant the degree of Bachelor of Science in Education to any person completing a four-year course in a state normal school—one school giving it in the commercial course only, one in household arts, one in art and two in regular courses. Regular public-school teachers cannot be paid less than $750 a year. Reimbursements to small towns and cities are provided, with special arrangements for those of low valuation, enabling them to have good teachers. Civics and history are required to be taught in elementary and high schools, and since 1923, the Constitution of the United States. Pupils 14–16 years of age must have completed the requirements of the sixth grade before being certified for employment.

Finance.—The receipts of the state in 1900 were approximately $14,700,000, and those in 1923 approximately $41,000,000, or nearly three times as much. These figures represent receipts for revenue purposes only, and do not include receipts from the issue of bonds or notes. The payments in 1900 were about $17,100,000, and in 1923 about $42,507,914. These represent governmental cost and include no payments of money borrowed. In 1923 the funded debt of the state was $53,673,740, and the total debt $126,269,011.

Transportation.—There were 4,050 m. of steam railway in 1924 and 2,551 m. of electric street railway. Great attention has recently been given to the highways, and during 1924 nearly 149 m. of highway were constructed. The total length of state highways at the end of 1924 was 1,521 m.; and the amount spent on new roads in that year, about $2,000,000; repairs and maintenance, $4,798,000.

Banking.—The resources in 1923 of the national banks within the state were $1,227,367,000. There were 634 banking institutions and agents under state law, with resources of $2,488,606,935, divided as follows: 196 savings banks, $1,215,244,815; 105 trust companies, $1,076,114,436; 190 co-operative banks, $154,870,638; three savings and loan associations, $2,399,791; Massachusetts Hospital Life Insurance Co., $30,018,328; one foreign banking corporation, $1,838,749; 60 credit unions, $2,791,165; 77 steamship agents, receiving deposits of $3,187,506; one state bank, $1,132,507.

History.—During the years 1910–25 the most important laws enacted by the Legislature were the following: In 1912 a minimum-wage board was established with the right to determine wages of women and children. The inheritance law was amended so that only the real estate of a deceased non-resident is taxed, personal property taxes going to the state of residence. A law of 1913 provided for the establishment and maintenance of continuation schools and instruction for working children. A number of pure-food laws were enacted; also, a law providing for mothers' pensions. The election law was so amended that on application signed by 1,200 voters in any senatorial district, or by 200 voters in any representative district, asking for the submission to the voters of any question of instruction to Senators or Representatives, the Secretary of the Commonwealth shall determine if such a question is one of public policy, and, if so determined, he shall place such question on the official ballot to be used at the next state election. In 1914 a measure was passed submitting to the people a constitutional amendment giving suffrage to women, suffrage being finally granted June 25 1919. In 1916 the civil and criminal jurisdiction of district or municipal courts was extended so that their process runs throughout the state and makes them courts of superior and general jurisdiction. An income tax was enacted, and a law was passed to prevent misstatements in advertising. An Act forbidding the sale of narcotic drugs, except by prescriptions carefully regulated, was passed in 1917. Massachusetts on April 2 1918 ratified the Eighteenth (Prohibition) Federal Amendment, being the eleventh state to do this. That same year a budget system was adopted. The Legislature in 1919 made absentee voting possible for those in military or naval service and for others who made proper arrangements. It also passed a law making all Acts approved by the executive, unless subject to referendum, take effect 30 days after formal enactment. Emergency laws take effect upon passage. The permissible maximum amount of deposits in savings banks per person was raised to $4,000. Manufacturing corporations were enabled to provide for representation of their employees upon the board of directors if more than half the employees so decide by secret ballot. Industrial accident compensation was increased. The income tax was revised. An Act reorganising the executive and administrative functions of the state Government, approved July 23 1919, established new departments, consolidated the 100 odd departments under 20 heads, and a metropolitan district commission was authorised, with general supervision over the metropolitan area. The Legislature of 1920 passed a law providing for a state constabulary. Motion-pictures within the state were censored. Women were allowed to hold office. Suits were permitted by and against voluntary associations. Important "blue sky" legislation was enacted. In 1921 a law was passed making a scientific study of criminals mandatory on the courts in certain cases. Examination is required by the Dept. of Mental Diseases, and the results are admitted as evidence of the mental conditions of the accused. The opening on July 29 1914, of a canal across Cape Cod shortened by 70 m. the distance by water from New York to Boston.

The governors for the past 15 years were: Eugene M. Foss (Dem.), 1911–4; Davis I. Walsh (Dem.), 1914–6; Samuel W. McCall (Rep.), 1916–9; Calvin D. Coolidge (Rep.), 1919–20; Channing H. Cox (Rep.), 1920–4; A. T. Fuller (Rep.), 1924–.

(F. A. Cl.)

MASSENET, JULES ÉMILE FRÉDÉRIC (1842–1912), French composer (*see* 17,866), died in Paris Aug. 13 1912, having composed an opera, *Panurge*, just before his death.

MASSEY, WILLIAM FERGUSON (1856–1925), New Zealand statesman, was born at Limavady, Co. Derry, Ireland, on March 26 1856. His parents emigrated to New Zealand when he was six, and eight years later he joined them at Tamaki. After an elementary education, he went on the land, and 20 years later, as president of the Auckland Agricultural and Pastoral Society, began to play a prominent part in public life. He entered Parliament in 1894 as member for Waitemata, and in 1903 became leader of the Conservative Opposition to Mr. Seddon and Sir Joseph Ward. At first his following was small, but he gained ground to such an extent in the elections of 1911 that in the following year he was able to defeat the Mackenzie Ministry and form a Cabinet. Thereafter he played a dominating part in the Dominion's affairs. His strong personality, sterling honesty of purpose and administrative ability commanded universal respect, and during the World War, at the head of a strong Coalition Ministry, which included his lifelong opponent, Sir Joseph Ward, Mr. Massey led New Zealand with conspicuous ability and foresight. And, just as he had not hesitated to introduce conscription without reference to the people, so he had the courage, when peace came, to enforce unpopular economies. He was a member of the Imperial War Cabinet in 1917–8 and in 1919 was the representative of New Zealand at the Peace Conference in Paris. Shortly after the Imperial Conference of 1923 his health gave way and though he recovered sufficiently to carry on his work for a time, he died on May 10 1925.

MASSINGHAM, HENRY WILLIAM (1860–1924), British journalist, was born at Old Catton, Norfolk. Educated at Norwich Grammar School under Dr. Augustus Jessopp, he began to work for *The Eastern Daily Press* at the age of seventeen. In 1883 he came to London and for some time was on the staff of the National Press Agency. Five years later he became assistant editor of *The Star*, which he edited from July 1890 to Jan. 1891. In 1892 he joined the staff of *The Daily Chronicle* as literary editor, and was editor in chief from 1895 to 1899, when he resigned owing to his inability to support the war against

the Boers. He had made his mark as an influential champion of the Radical wing of the Liberal party and as the pioneer of literary criticism in the daily Press. After a brief connection with *The Manchester Guardian* and *The Speaker*, and a mission to South Africa in 1905 for *The Daily News*, he, in 1907, began a long association with *The Nation*, which he edited till the end of 1923. He was a severe critic of the World War and the Peace Treaty of 1919 and advocated co-operation between the Liberal and Labour parties. An early member of the Fabian Society, Massingham ultimately joined the Labour party, though on ethical, rather than economic, grounds, and his last journalistic work was done for *The New Statesman*. He died at Tintagel, Cornwall, on Aug. 28 1924. One of the best all-round journalists of his day, he was a trenchant writer on politics and a discerning critic of literature and the drama. He published in 1892 *The London Daily Press*, and contributed an introduction to the memorial edition of the works of Mark Rutherford 1923. *H. W. M. A Selection from the Writings of H. W. Massingham*, edited by H. J. Massingham (1925), contains highly appreciative estimates by G. Bernard Shaw and various eminent associates.

MASSON, LOUIS CLAUDE FRÉDÉRIC (1847–1923), French historian (*see* 17.870), died in Paris Feb. 19 1923.

MASS PRODUCTION.—The term mass production is used to describe the modern method by which great quantities of a single standardised commodity are manufactured. As commonly employed it is made to refer to the quantity produced, but its primary reference is to method. In several particulars the term is unsatisfactory. Mass production is not merely quantity production, for this may be had with none of the requisites of mass production. Nor is it merely machine production, which also may exist without any resemblance to mass production. Mass production is the focussing upon a manufacturing project of the principles of power, accuracy, economy, system, continuity and speed. The interpretation of these principles, through studies of operation and machine development and their co-ordination, is the conspicuous task of management. And the normal result is a productive organisation that delivers in quantities a useful commodity of standard material, workmanship and design at minimum cost. The necessary, precedent condition of mass production is a capacity, latent or developed, of *mass consumption*, the ability to absorb large production. The two go together, and in the latter may be traced the reasons for the former.

I. THE ORIGINS OF MASS PRODUCTION

In origin mass production is American and recent; its earliest notable appearance falls within the first decade of the 20th century. The mere massing of men and materials is a procedure as old as the pyramids. Basic industries, like weaving, domestic baking, house construction and wooden ship building, are carried on, with only superficial changes, much as they were in ancient Egypt. Cottage manufactures and handicrafts moulded the practices of industry until the invention of the steam-engine. With the coming of power machines the seat of industry was removed from the homes of the people and a new work centre, the factory, was established. Much harsh criticism has been uttered against "the factory system," but it is perhaps fair to say that its first effect was to emancipate the home from being a mere adjunct to the loom or bench, and its later effect was to provide the home with means to develop the dignified status which it has now attained.

The Factory System Giving Way.—The early factory system was uneconomical in all its aspects. Its beginning brought greater risk and loss of capital than had been known before, lower wages and more precarious outlook for the workers, and a decrease in quality with no compensating increase in the general supply of goods. More hours, more workers, more machines did not improve conditions; every increase did but enlarge the scale of fallacies built into business. Mere massing of men and tools was not enough; the profit motive, which dominated enterprise, was not enough. There remained the scientific motive which grew eventually into what is called mass production.

The new method came after the failure of the mercantile and financial emphasis in manufacture. The advent and progress of financial control of industry were marked by two developments, the corporation and the labour revolt. Artificial combination of industrial plants into vast corporations for financial purposes was the first movement toward *mass* in industry. It proceeded on the theory that complete financial control would automatically bring complete profit advantage. The theory ignored many vital principles of business and its fallacy became apparent, but not before serious social hostility had been incurred.

However, it was out of the social strife thus engendered that the idea began to emerge that possibly the difficulty lay in the neglect of scientific manufacturing principles. Industry was conceded to be necessary and useful; the service it rendered was regarded as of sufficient value to afford fair compensation for all engaged in it: it was therefore urged that the attention of management should be more directly focussed on the actual labour processes that were employed. This led to what was known early in the 20th century as the "efficiency movement" with its accompaniments of time-study and similar methods, although its roots were laid in the experiences of sound industrial observers as early as 1878. It cannot be said, however, that the efficiency experts did more than direct attention to the problem, by showing, in selected instances, how the then current methods were wasteful of men's earning power, and how their correction and improvement could lead to greater production, hence higher wages, and therefore a general betterment of labour relations. They emphasised a more intelligent management of methods than was then in use; they did not see that a wholly new method was possible which would simply abolish the problems of which the old method, under the most intelligent management, was inevitably prolific. For example they dealt with methods which enabled labourers whose task was to load $12\frac{1}{2}$ tons of pig-iron a day, to load $47\frac{1}{2}$ long tons a day for an increase in the day's pay from $1.15 to $1.85. They did not see that another and better method might be devised which would make it unnecessary for a working-man to carry 106,400 lb. of pig-iron to earn $1.85. Mass production was not in their view, but only the alleviation of the worst errors of competitive factory practice.

The Motor Industry Leads the Way.—To the motor industry is given the credit of bringing mass production to experimental success, and by general consent the Ford Motor Co. is regarded as having pioneered in the largest development of the method under a single management and for a single purpose. It may, therefore, simplify the history of mass production and the description of its principles if the experience of this company is taken as a basis. It has been already suggested that mass production is possible only through the ability of the public to absorb large quantities of the commodity thus produced. These commodities are necessarily limited to necessities and conveniences. The greatest development of mass production methods has occurred in the production of conveniences. The automobile represents a basic and continuous convenience-transportation.

Mass production begins, then, in the conception of a public need of which the public may not as yet be conscious and proceeds on the principle that use-convenience must be matched by price-convenience. Under this principle the element of service remains uppermost; profit and expansion are trusted to emerge as consequences. As to which precedes the other, consumption or production, experiences will differ. But granted that the vision of the public need is correct, and the commodity adapted to meet it, the impulse to increased production may come in anticipation of demand, or in response to demand, but the resulting consumption is always utilised to obtain such increase of quality, or such decrease of cost, or both, as shall secure still greater use-convenience and price-convenience. As these increase, consumption increases, making possible still greater production advantages, and so on to a fulfilment that is not yet in view.

The commodities that conduce to civilised living are thus far enjoyed by only a small fraction of the world's inhabitants. The experience of the Ford Motor Co. has been that mass production precedes mass consumption and makes it possible, by reducing costs and thus permitting both greater use-convenience and price-convenience. If the production is increased, costs can be reduced. If production is increased 500%, costs may be cut

50%, and this decrease in cost, with its accompanying decrease in selling price, will probably multiply by 10 the number of people who can conveniently buy the product. This is a conservative illustration of production serving as the cause of demand instead of the effect.

II. THE PRINCIPLES OF MASS PRODUCTION

As to shop detail, the keyword to mass production is simplicity. Three plain principles underlie it: (*a*) the planned orderly progression of the commodity through the shop; (*b*) the delivery of work instead of leaving it to the workman's initiative to find it; (*c*) an analysis of operations into their constituent parts. These are distinct but not separate steps; all are involved in the first one. To plan the progress of material from the initial manufacturing operation until its emergence as a finished product involves shop planning on a large scale and the manufacture and delivery of material, tools and parts at various points along the line. To do this successfully with a progressing piece of work means a careful breaking up of the work into its "operations" in sequence. All three fundamentals are involved in the original act of planning a moving line of production.

This system is practised, not only on the final assembly line, but throughout the various arts and trades involved in the completed product. The automobile assembly line offers an impressive spectacle of hundreds of parts being quickly put together into a going vehicle, but flowing into that are other assembly lines on which each of the hundreds of parts have been fashioned. It may be far down the final assembly line that the springs, for example, appear, and they may seem to be a negligible part of the whole operation. Formerly one artisan would cut, harden, bend and build a spring. To-day the making of one leaf of a spring is an operation of apparent complexity, yet is really the ultimate reduction to simplicity of operation.

A Typical Operation Described.—For its illustrative value let us trace the course of a spring leaf after it has progressed from iron ore through ingot, bloom and billet stages, and is rolled into strips. (1) Beginning as a strip of steel prepared by the steelmill, it is placed in a punch press for cutting and piercing. The workman puts the strip into press until it hits a stop, then trips the press. The cut-off and pierced piece falls on a belt conveyor which runs along the loading end of a series of heat-treating ovens. (2) A second workman takes the pieces from belt conveyor and places them on conveyor which passes through the furnace (in which temperature is automatically controlled); thence they are deposited at a certain temperature by this conveyor at the unloading end of the furnace. (3) The heated piece is lifted with tongs by a third operator and placed in a bending machine which gives the leaf its proper curve and plunges it in oil, the temperature of which is maintained at a definite degree by apparatus beyond the operator's control. (4) As the bending machine emerges from the oil bath, the same operator takes out the leaf and sets it aside to air-cool. (5) The leaf is then drawn by a fourth operator through molten nitrate kept at a regulated temperature. (6) A fifth workman inspects it.

As a set of springs on the Ford automobile requires on an average 17 leaves, and 25,000 springs are an average day's output, this operation must be visualised as employing a great battery of lines similar to the one briefly described. As all the leaves in a spring are of different length and curve, from the bottom or master leaf to the top leaf, this operation must be visualised as one of many carried on simultaneously by different batteries of machines, each battery working on its own special size. All of these lines, with their various machines and operations, are converging on the point where the leaves are assembled into springs. The leaf whose progress we are describing is the simplest one.

We now continue the operation. (7) A sixth workman removes the leaf from the conveyor which carries it from the molten nitrate, and inserts a bolt through this and the other leaves required in the spring. (8) A seventh workman puts the nut on the bolt and tightens it. (9) An eighth workman puts on the right and left hand clips and grinds off the burrs. (10) A ninth workman inspects it. (11) He hangs the spring on a conveyor. (12) The spring passes the tenth workman, who sprays it with paint, and the conveyor carries the spring above the ovens where it was originally heated, and the radiated heat "force dries" the paint. (13) The conveyor continues to the loading dock, where the eleventh workman removes it.

One workman under the old system could attend the leaf through all these phases, or even make a complete spring, but his production would be limited. Where large quantities of the same article are to be made, the simplest operation may involve the whole time of one man. A one-minute operation will require one man a full day of eight hours to accomplish it on 480 pieces. Now this simple part, a spring leaf, must be identical in strength, finish and curve with millions of others designed to fulfil the same purpose, and this becomes a complicated and delicate procedure requiring automatic machinery, the most accurate of measuring devices, pyrometer controls, "go" and "no go" gauges—in fact, the best facilities that can be provided by modern management. The leaf described, which is a minor matter when compared with the whole great process, becomes a major matter when considered by itself; it must have its own supply of material delivered in sufficient quantities at indicated places—for example, steel at 1; heat at 2; power and oil at 3; molten nitrate at 5; bolts at 7; nuts at 8; clips at 9; paint at 12. In this process the secrets of many arts and trades are employed.

The story of this minor part illustrates what is meant by orderly progression of the article through the shop. It goes to meet other parts of the motor-car which have come from other parts of the plant by similar processes. The story illustrates also what is meant by delivering the work to the workman: every workman's task is prepared for him by some other workman, and delivered to his hand. The third principle also is illustrated—the analysis of a single job into its constituent operations. The simplicity of the part here described should not be permitted to exclude from view the multitude of other operations, ranging from the heaviest forgings to the lightest manipulations in bench assembly of delicate electrical instruments. Some gauge inspections involve measurements to the ten-millionth part of an inch.

The economies arising from this method are obvious. The machinery is constantly in use. It would be economically impossible to maintain all this equipment for the service of men occupied in the entire operation of making springs. Presses, furnaces, bending machines, oil baths would be idle while the workman progressed from operation to operation. Under mass production it is the work that progresses from operation to operation. Use-convenience in the commodity would be lessened, while price-convenience would be destroyed. Economy in machine hours is, however, only one element; there is also economy in time and material and labour. Mass production justifies itself only by an economy whose benefits may be transmitted to the purchaser.

III. THE EFFECTS OF MASS PRODUCTION

But it is not the history and principle of mass production which provoke the widest discussions; the *effects* of it have been placed under scrutiny. What have been the effects of mass production on society?

(1) Beginning with management, where unquestionably mass production methods take their rise, there is a notable increase in industrial control, as distinguished from financial control. The engineer's point of view has gained the ascendancy and this trend will undoubtedly continue until finance becomes the handmaid instead of the mistress of productive industry. Industrial control has been marked by a continuous refinement of standardisation, which means the instant adoption of the better method to the exclusion of the old, in the interests of production. Financial control was not, in its heyday, marked by a tendency to make costly changes in the interests of the product. The economy of scrapping the old equipment immediately upon the invention of the better equipment was not so well understood. It was engineering control, entrenched in mass production methods, that brought in this new readiness to advance. In this way management has been kept close to the shop and has reduced the office to a clearing house for the shop. Managers and men have been brought into closer contact and understanding. Manufacturing has been reduced to greater singleness of purpose.

(2) The effect of mass production on the product has been to give it the highest standard of quality ever attained in output of great quantities. Conditions of mass production require material of the best quality to pass successfully through the operations. The utmost accuracy must control all these operations. Every part must be produced to fit at once into the design for which it is made. In mass production there are no fitters. The presence of fitters indicates that the parts have been produced unfit for immediate placement in the design. In works of art and luxury this accuracy is achieved at the cost of careful handiwork. To introduce hand methods of obtaining accuracy into mass production would render mass production impossible with any reference to price-convenience. The standard quality of the product is guaranteed by the fact that machines are so constructed that a piece of work cannot go through them unless it exactly accords with specifications. If the work goes through the tools, it must be right. It will thus be seen that the burden of creation is on

Bodies and chassis having been completed separately, the body is dropped on the chassis as it advances. The chassis in the foreground is just about to receive the body which is seen, slung by chains from the overhead yoke, at the right.

management in designing and selecting the material which is to be produced by the multiple processes utilised in mass production.

(3) The effect of mass production on mechanical science has been to create a wide variety of single-purpose machines which not only group similar operations and perform them in quantity, but also reproduce skill of hand to a marvellous degree. It is not so much the discovery of new principles as the new combination and application of old ones that mark this development. Under mass production the industry of machine making has increased out of all comparison with its previous history, and the constant designing of new machines is a part of the productive work of every great manufacturing institution.

(4) The effect of mass production on employees has been variously appraised. Whether the modern corporation is the destruction or salvation of arts and crafts, whether it narrows or broadens opportunity, whether it assists or retards the personal development of the worker, must be determined by observable facts. A cardinal principle of mass production is that hard work, in the old physical sense of laborious burden-bearing, is wasteful. The physical load is lifted off men and placed on machines. The recurrent mental load is shifted from men in production to men in designing. As to the contention that machines thus become the masters of men, it may be said the machines have increased men's mastery of their environment, and that a generation which is ceaselessly scrapping its machines exhibits few indications of mechanical subjection.

The need for skilled artisans and creative genius is greater under mass production than without it. In entering the shops of the Ford Motor Co., for example, one passes through great departments of skilled mechanics who are not engaged in production, but in the construction and maintenance of the machinery of production. Details of from 5,000 to 10,000 highly skilled artisans at strategic points throughout the shops were not commonly witnessed in the days preceding mass production. It has been debated whether there is less or more skill as a consequence of mass production. The present writer's opinion is that there is more. The common work of the world has always been done by unskilled labour, but the common work of the world in modern times is not as common as it was formerly. In almost every field of labour more knowledge and responsibility are required than a generation or two ago.

Some Criticisms Answered.—Mass production has also been studied with reference to what has been called the monotony of repetitive work. This monotony does not exist as much in the shops as in the minds of theorists and bookish reformers. There is no form of work without its hardness; but needless hardship has no place in the modern industrial scheme. Mass production lightens work, but increases its repetitive quality. In this it is the opposite of the mediaeval ideal of craftsmanship where the artisan performed every operation, from the preparation of the material to its final form. It is doubtful, however, if the mass of mediaeval toil was as devoid of monotony as has sometimes been pictured, but it is absolutely certain that it was less satisfactory in its results to the worker. In well-managed modern factories the tendency to monotony is combatted by frequent changes of task.

The criticism of mass production as a means of reducing employment has long since been out of court. The experience of the Ford Motor Co. is that wherever the number of men has been reduced on manufacturing operations, more jobs have been created. A continuous programme of labour reduction has been paralleled by a continuous increase in employment. As to the effect of mass production on wages and the relations between managers and men, there is little need to speak. It is perhaps the most widely understood fact about mass production that it has resulted in higher wages than any other method of industry. The reason is at hand. The methods of mass production enable the worker to earn more and thus to have more. Moreover, the methods of mass production have thrown so much responsibility on the craftsmanship of management, that the old method of financial adjustment by reduction of wages has been abandoned by scientific manufacturers. A business that must finance by drafts out of the wage envelopes of its employees is not scientifically based. It is the problem of management so to organise production that it will pay the public, the workmen and the concern itself. Management that fails in any of these is poor management. Disturbed labour conditions, poor wages, uncertain profits indicate lapses in management. The craftsmanship of management absorbs the energies of many thousands of men who, without mass production methods, would have no creative opportunity. Here the modern method broadens instead of narrows individual opportunity.

(5) As to the effects of mass production on society, the increasing supply of human needs and the development of new standards of living are the elements to be estimated. The enlargement of leisure, the increase of human contacts, the extension of individual range, are all the result of mass production in various fields. (H. F.)

MASTERS, EDGAR LEE (1868–), American writer, was born at Garnett, Kan., Aug. 23 1868. At the age of 21 he entered Knox College, Galesburg, Ill., but left after one year to read law. He was admitted to the bar in 1891 and practised thereafter in Chicago, being for some years associated with Clarence S. Darrow. The book that first brought him public notice was *Spoon River Anthology* (1915), an extraordinary collection of epitaphs on members, in all walks of life, of a midwestern town. Within three years 50,000 copies were sold.

His other works include: *The New Star Chamber, and Other Essays* (1904); *Blood of the Prophets* (1905); *The Great Valley* (1916); *Toward the Gulf* (1918); *Starved Rock* (1919); *Domesday Book* (1920); *The Open Sea* (1921); besides several plays, *Maximilian* (1902); *Althea* (1907); *The Trifler* (1908); *The Locket* (1910); and *The Bread of Idleness* (1911).

MASURIAN LAKES, BATTLES OF THE.—The terrain of East Prussia is described in some detail under the heading TANNENBERG. It was the lake barrier which had proved the undoing of the Russians in their advance into East Prussia, and twice again was it to bring about their defeat when the Germans in their turn assumed the offensive. Jilinsky had failed to combine the action of his two armies, urging one forward to intercept what he thought to be a beaten enemy and dispatching the other on a subsidiary objective. The disaster to the II. Army had come to him as a crushing surprise, and in his fear that Rennenkampf would share the fate of Samsonov, he ordered the I. Army to halt and act on the defensive until fresh troops could be brought up from the centre of Russia. All chance of catching the Germans at a disadvantage during their temporary disorganisation after the fighting at Tannenberg was thus lost.

I. THE SUMMER BATTLE

Ludendorff was not long in deciding what was to be done after the destruction of Samsonov. Even before the fighting at Tannenberg was over, on Aug. 29 1914, he had commenced moving troops northwards to meet Rennenkampf. He was strongly urged to move southwards to the support of the sorely tried Austrians, but this would have meant leaving a strong and undefeated enemy directly in his rear, whilst attempting to traverse the selfsame desert area which had tried Samsonov so greatly. From the German point of view it was more important to free East Prussia from the invader at once, and the Austrians must therefore wait their turn.

Position before the Action.—All the German divisions had received their first reinforcements and were flushed with victory and full confidence in their leaders. Two fresh corps had arrived from the west. Rennenkampf did not appear to be on the move and was evidently commencing the blockade of Königsberg. Lötzen, the little fortress holding the main gap in the centre of the line of lakes, was still in German hands. Everything therefore seemed favourable for a German offensive.

Ludendorff's plan for his advance was in outline as follows: (1) Von der Goltz with 2½ divisions was to check any advance on the part of the Russian II. Army from Poland; (2) Von François with three divisions and a cavalry brigade was to move round the southern end of the lakes at Johannisburg with the primary object of turning Rennenkampf's left, and at the same time dealing with any Russian forces assembling to the south of the lakes; (3) Von Mackensen with two divisions and two cavalry divisions was to cross the Lötzen gap and join with Von François in the attack against Rennenkampf's left; (4) the main body of eight divisions was to move direct on the Insterburg gap; (5) the Königsberg garrison was to make a demonstration against the blockading troops.

Rennenkampf had commenced withdrawing on Aug. 30, and on Sept. 2 he issued orders for a position to be taken up for defensive action from the sea near Libau to Angerburg at the northern end of the lakes. This position offered many advantages from a defensive point of view, running as it did behind the rivers Deime, Alle and Omet, but it was too extensive for the force of 12 divisions which Rennenkampf had at his disposal, the distance from flank to flank being 60 miles. Moreover, the left flank was exposed to attacks coming from the Lötzen gap and the southern end of the lakes. But

it was chiefly in the manner in which he proceeded to occupy this position that he erred. He had no idea where the Germans were or what they had been doing in the interval since Tannenberg. He only had persistent rumours that the Germans were sending billeting parties to Königsberg. Instead of maintaining strong forces in front of his chosen position, in order to discover the enemy's intentions, Rennenkampf committed his troops at once to a linear defence of the line. He placed four of his divisions along the Deime on a front of 18 m., while keeping seven divisions to hold the remainder of his line of 42 miles. A single division was placed opposite the Lötzen gap to the east of the lakes.

It will thus be seen that from the very start of their manoeuvre the Germans had succeeded in out-generalling Rennenkampf. On the left of their line they were containing four Russian divisions with garrison troops, equivalent to about a division. In the centre they were opposing eight divisions to seven Russian divisions. On the right they were advancing with no less than five divisions and two cavalry divisions against a single Russian division.

German Attack.—Von der Goltz attacked and took Mława on Sept. 4, and thereafter kept in check any of the units of the Russian II. Army which attempted to advance. By the night of Sept. 5 Von François was approaching the southern end of the lakes. By the 6th he had taken Johannisburg and Nikolaiken, driving back the few Russian troops opposing him. By the 7th he was through the lakes and had captured Bialla and Arys. The Russian troops opposing him had been hurried up without proper artillery support and were dispersed in disorder. Eleven Russian battalions were thus dissipated without result. On the 8th Von François turned northwards against the Russian flank. Sept. 9 was to be a fateful day for the Germans. Von Mackensen had commenced his crossing at Lötzen during the 8th, but he could not enlarge the bridge-head. His troops attacked at 5 A.M., 12 noon and 8 P.M. on this day without success and that evening he reported no progress to Von François.

Von François' attack against Soltmahnen on the morning of the 9th came as a complete surprise to the left flank of the Russians opposing Von Mackensen. By noon the Russians were in hopeless rout, leaving 5,000 prisoners and 60 guns in the hands of Von François. The German enveloping movement had met with complete success. Rennenkampf's left flank division had been destroyed and about 8,000 men of the Russian X. Army concentrating about Augustówo and Osowiec had been placed out of action. The left flank of Rennenkampf's army now lay open to the attack of five German divisions. A second Tannenberg seemed more than probable.

Ludendorff had employed the 5th, 6th and 7th in bringing his eight divisions in line facing the Insterburg gap and, on the 8th, contact was gained with Rennenkampf's outposts. On the 9th, coinciding with Von François' attack, the Germans moved forward along the whole front. Little progress was made anywhere, and on the right the Russians made a determined counter-attack which completely held up the German advance. This check seems to have paralysed Ludendorff temporarily, for he ordered his right under Von François and Von Mackensen to hold fast and even to close in to the centre for fear of disaster. But Rennenkampf had taken fright at the menace to his left and had decided to withdraw. That night he ordered a general retreat. He had been just too quick for the Germans. When Ludendorff allowed his right to move forward again, nothing further than cutting off the streams of disorganised transport and breaking up the Russian rear-guards was possible. Rennenkampf had pushed his retreat with desperation. Two of his corps had covered 58 m. in 60 hours. By the 13th he was safe from annihilation, and by the 14th his exhausted troops had crossed the East Prussian frontier between the forest of Rominten and the river Niemen.

Results of the Battle.—Although the Russian I. Army had not been surrounded, it had suffered almost as much as the II. Army. Casualties since Sept. 6. had amounted to 125,000 men and 150 guns. Two corps had been destroyed and the whole army was out of action as a mobile force through lack of transport. The chief credit for this success must lie with Von François. In his march round the southern end of the lakes his men had covered 77 m. in the four critical days Sept. 6–9, and there had been severe fighting on two of those days. Had Ludendorff been quicker to realise that Rennenkampf's counter-attack on the 9th was made in order to disengage himself, and had his orders to Von François for the 10th and 11th not been so cautious, there can be no doubt that Rennenkampf's army would have been all but destroyed.

II. THE WINTER BATTLE

During their 28 days' invasion of East Prussia the Russians had lost some 310,000 men from the flower of their army and 650 guns. Their offensive had been completely defeated and they had been thrown on the defensive. It was not till late in the winter of 1914–5 that they began to show signs of activity once more. From the German point of view it was important to prevent another Russian invasion of East Prussia and it was therefore decided to upset by a strong offensive any Russian plans that were in existence.

German Dispositions.—In Jan. 1915 the German VIII. Army, under Von Below, was holding a line from the frontier south of Lake Spirding, along the line of lakes to Angerburg, and thence across the Insterburg gap between Insterburg and Gumbinnen to the river Memel. Some 100,000 Germans, for the most part of the Landwehr and Landsturm, were facing 200,000 men of the Russian X. Army under Siewers. To the south there were indications of a Russian XII. Army being assembled between Modlin (Nowo Georgiewisk) and Thorn (Toruń). Four fresh corps had been allotted for the offensive, making a total of some 250,000 men. In outline the German plan was as follows: (1) The X. Army (eight divisions and one cavalry division, under Von Eichhorn, was to envelop the Russian right, moving southwards from the Insterburg gap. (2) The right wing of the VIII. Army (three divisions), under Von Litzmann, was to envelop the Russian left by moving round the southern end of the lakes. (3) The remainder of the VIII. Army (four divisions) was to hold the enemy in the centre.

Orders for the advance were issued on Jan. 28. The attack in the south was to commence on Feb. 7, with a view to drawing the attention of the Russians to this quarter. The main attack was then to come from the north on the 8th. Conditions were very different from those of the advance in Sept. of the year before. The weather was bitterly cold and the whole country was deep in snow. Large numbers of sleighs had been collected and the scale of clothing and food greatly increased. The German administration left nothing undone which could be thought out beforehand.

German Line Advanced.—Von Litzmann's advance found the marshy country in front of Johannisburg almost impassable, and the attack of the 7th came to little. Many of the units had to force their way through blinding snow storms, and it was not till the 8th that the Russian positions on the Pisseck were reached and taken, and by the 9th the end of the lakes was passed. This diversion served its purpose well, for the attack of the German X. Army in the north came as a complete surprise to the Russians in their winter quarters, leisurely thinking of an advance in the spring. They were given no time in which to readjust their line, and reserves had to be thrown in piece-meal to save the situation. On the 10th, a determined stand was made by four Russian divisions on either side of Eydtkuhnen, but by evening their resistance had been broken. Everywhere the effect of the German heavy artillery was decisive. Despite the difficulty of bringing forward the heavy wheeled vehicles, which broke through the frozen crust of the ground, the Germans never failed to support their infantry at the decisive point. By the 12th, Von Below's army had reached a line stretching from the forest of Rominten to Ludwinow.

Meanwhile, the German centre had moved forward to keep in touch with the southern wing. Russian resistance in the south seemed to centre round the town of Lyck, and Litzmann was reinforced by a fourth division for its capture. From the 10th to the 13th the fighting round Lyck was desperate. Often the opposing sides could not distinguish each other in the blizzards which swept over them, and owing to the difficulty of ammunition supply the infantry were unsupported by artillery fire of any sort, and fierce hand to hand fighting ensued. Casualities on both sides were therefore heavy and the Russians also lost over 8,000 prisoners and 14 guns. By the night of the 13th the Russians had been forced from their positions and the town was in German hands.

Position after the Battle.—By the 14th, the German line ran from Rajgród in the south, through Suwalki, to Sztabinki in the north, in a semi-circle round Augustówo, at a distance of from 9 to 10 m., from the town. The wooded and close nature of the country made concerted attacks very difficult, but everywhere the superior individual training of the German soldier triumphed over the more ignorant Russian. The Russians fought with

desperation to maintain their positions and it was not till the 17th that Siewers finally gave the order to abandon Augustówo. He succeeded in escaping envelopment by abandoning most of his transport and ammunition columns and retiring in disorder on Grodno. By the 20th the Germans were no longer in touch with the retreating Russians.

In the winter battle the Russians lost 110,000 prisoners and 300 guns, and the X. Army, like the Russian I. and II. Armies, was placed *hors de combat* for several months as a mobile force. Their defeat was certainly greatly due to the superior leadership of the Germans, for they had been caught unawares in winter quarters, without proper protection and with an inferior intelligence service. Had the Germans been able to bring up the whole of their guns and ammunition on Feb. 14 they might have succeeded in surrounding Augustówo, but this the weather prevented them from achieving.

MATERIALS: *see* RAW MATERIALS.

MATERIALS, STRENGTH OF (*see* 25.1007; also CRYSTALLOGRAPHY; METALLOGRAPHY; METALLURGY; METALS, FATIGUE OF; TESTING MACHINERY).—The present article only attempts to describe some of the more important advances which have been made since 1910, and to indicate the trend of modern work.

Mathematical Analysis of Complex Stress Systems: Stresses in Ties.—In the Eleventh Edition it was stated that when a bar is subjected to a simple pull applied axially—that is to say, so that the resultant stress passes through the centre of gravity of every cross-section—the stress may be taken, under ordinary conditions, as (sensibly) uniformly distributed over any section not near a place where the form of the cross-section changes. The design of a tie of specified material to withstand a specified load is thus, as regards the greater part of its length, an easy matter; but it is essential that suitable forms of end attachment be devised, equally able to withstand the imposed load.

The most usual method of connection is by pins or rivets, inserted through the tie in such a way as to operate in virtue of their resistance to "shear"; and in consequence the problem of stress-distribution in the neighbourhood of holes has received much attention. C. E. Inglis[1] has obtained a mathematical solution appropriate to a single elliptical hole, and the special case of a circular hole has also been treated by K. Suyehiro.[2] The more difficult problem of stress-distribution in an "eye end" has been attacked by E. G. Coker[3] with the aid of transparent models of xylonite and the use of polarised light. Fairly complete information is thus available regarding the distribution of stress in tension members, so long as the elastic limit of the material is nowhere exceeded; but a problem of greater practical importance is to proportion the eye ends so that their *breaking load* (after ductility has operated to equalise the stresses) shall be equal to that of the main portion of the tie. This problem has been attacked experimentally by W. A. Scoble,[4] who has interpreted his results in terms of practical rules for design.

Strength of Straight Members in Compression (*Struts*).—Mention was made in 25.1022 of Euler's investigation of the collapsing load of an ideal strut, perfectly straight and uniform, and centrally loaded; also of a semi-empirical formula which has been proposed, to allow for the fact that a short strut may fail by simple crushing. Since 1910 considerable progress has been made in the theory of this and of allied problems. It was recognised by T. von Kármán[5] and (later, but independently) by R. V. Southwell[6] that crushing of the material is not the only alternative to collapse by buckling under stresses within the elastic limit, because plastic distortion may bring about conditions of instability under stresses which are far below the compressive strength of the material, and which Euler's analysis also would indicate to be perfectly safe. An interesting extension of mathematical theory was made by the authors cited, in a formula which modified Euler's result to allow for the new conditions; and the experimental work of A. Robertson[7] has shown that this formula agrees closely with actual results. The whole subject of strut failure, and advances in theory and experiment, have been reviewed by R. V. Southwell.[8]

Collapse of Tubes by External Pressure.—A similar possibility of collapse exists when a circular tube (such as the flue of a steam boiler) has to withstand fluid pressure imposed upon its *external* surface. Distortion of the circular cross-section into an oval form, whilst it involves an increase in the strain energy due to bending, also involves a decrease in the potential energy of the applied pressures; the circular form will thus be unstable when the pressures are sufficiently high.

This phenomenon was investigated experimentally by W. Fairbairn as early as 1858,[9] and has attracted much attention since; an extensive bibliography was compiled by G. Cook for the British Association in 1913.[10] Recent experiments by A. P. Carman,[11] R. T. Stewart,[12] and G. Cook[13] afford satisfactory confirmation of G. H. Bryan's theoretical formula for long tubes[14] and of a more general formula proposed by R. V. Southwell,[15] who investigated the influence of end constraints upon the resistance to collapse.

Other Problems of Elastic Stability.—The general theory of these problems of "elastic stability" has been developed by G. H. Bryan,[16] R. V. Southwell[17] and W. R. Dean.[18] Among other examples of the class may be noticed the collapse of thin tubular struts, in which instability makes its appearance by wrinkling of the tube wall, and of flat plating under forces which involve compression in its own plane. The strength of tubular struts acquires great practical importance in aircraft construction, and has received much attention both in theory and experiment; bibliographies relating to these two aspects may be found in papers by R. V. Southwell[19] and A. Robertson.[20] The stability of flat plating has importance for the design of deep plate girders, and has been studied from this aspect, theoretically by G. H. Bryan[21] and S. P. Timoshenko,[22] and experimentally by W. E. Lilly[23] and others; two special cases—the stability of a long flat strip under uniform shearing actions in its plane (theoretically treated by R. V. Southwell and S. W. Skan[24]) and of a circular disk under forces which tend to twist it in its plane (theoretically treated by W. R. Dean[25]) have recently been made the basis of a suitable "acceptance test" for the thin sheet steel used in the construction of metal aircraft.[26]

"Whirling" and Vibration of Shafting.—Elastic instability is also likely to occur in a long rotating shaft, because any curva-

ture of the axis will be intensified by centrifugal force, which may be sufficient to overcome the restoring effect of the flexural stresses. When this happens, the shaft is said to " whirl." The calculation of " whirling speeds " is evidently a matter of great practical importance (since it would be unsafe to allow a shaft to run at these speeds for any length of time), and various methods have been propounded.[27] Torsion or end thrust, acting upon the shaft, will combine with rotation to promote instability; a theoretical discussion of the problem, taking all three actions into account, has been given by R. V. Southwell and B. S. Gough.[28]

It can be shown that the whirling speeds of a shaft are identical with the frequencies of its free transverse vibrations in the absence of rotation; as the speed increases, these " natural frequencies " decrease, becoming zero at the whirling speeds. The difficult question of stability in the immediate neighbourhood of the whirling speeds has been examined by F. B. Pidduck.[29]

Other Problems of Vibration.—The influence of rotation upon the natural frequencies of free vibration has been examined in two other cases of practical importance: (1) the vibrations of a rotating rod (such as an airscrew blade) have been studied theoretically by R. V. Southwell and B. S. Gough,[30] and experimentally by A. Fage[31]; (2) the vibrations of a spinning disk (representative of the rotor of a steam turbine) have been investigated by H. Lamb and R. V. Southwell.[32]

A problem of greater complexity is presented by the vibrations of a railway bridge under the periodic forces imposed upon it by the " hammer-blow " (the effect of the eccentric weights employed to balance the reciprocating masses) of a locomotive as it passes. The period of these forces may synchronise with the natural period of the bridge, and considerable deflection is then produced; but account has to be taken of the fact that only a few blows are delivered during the transit, so that the problem is not one of " resonance " in the ordinary sense. A formal solution of the idealised problem (in which the bridge is taken to be a uniform girder, and a single travelling load is assumed) has been given by S. P. Timoshenko,[33] and an elaborate investigation of cases representative of practical conditions by C. E. Inglis.[34]

Approximate Methods of Stress Calculation.—A general tendency of the period now under review has been towards the development of approximate methods of solution for problems which cannot be treated by exact theory. The original impetus came from Lord Rayleigh, in relation to the calculation of natural frequencies of vibration;[35] but his methods have since been extended to a wide range of problems.[36]

" Experimental " methods of solution have also been developed, based on analogies obtaining between the equations of elasticity and those of other branches of physics. Thus the deflection of a membrane of uniform tension is governed by equations identical with those which define the distortion of cross-sections in a twisted prism; and this fact[37] has been utilised by G. I. Taylor and A. A. Griffith,[38] who have shown how to solve, by measurements made on a flat soap-bubble, Saint Venant's problem of torsion[39] for shapes of cross-section which are mathematically intractable.

Photo-elastic Methods.—Important advances in the solution of two-dimensional systems of stress have been made by the use of " photo-elastic " methods. Various transparent materials under the action of stress possess double refracting properties—that is, they split up plane polarised light into two rays. The interference obtained by the recombination of such rays produces colour bands which may be viewed on a screen or photographed; the colour varies according to the difference of the principal stresses, and the stress-difference at any place in the material may be estimated by matching it with the colour produced in a tension piece strained by a known and uniform stress. The sum of the principal stresses may be deduced from measurements of the lateral contraction of the specimen. By these methods, E. G. Coker, L. N. G. Filon, W. A. Scoble and A. R. Low have determined the distribution of stress in many cases intractable mathematically, which possess great practical importance.[40] The " stress-optical " properties of xylonite have been studied from this aspect by Coker and K. C. Chakko,[41] and the underlying principles of the method have been critically examined by Filon.[42]

Extension of Theory to Problems of Plastic Distortion.—Some general interest attaches to the formula, mentioned above, which extended Euler's analysis for elastic struts to cases in which elastic break-down precedes collapse, since this appears to be the earliest application of mathematical theory to material in the plastic state. The study of plastic distortion (*i.e.*, distortion which does not disappear when the load is removed), and its representation by mathematical equations, have attracted much attention among continental workers; reference may be made to the proceedings of a special conference on this subject, held at Prague in 1924.

Limitations of Mathematical Theory, as applied to the Elastic Failure and Fatigue of Metals.—Such methods of representation have this feature in common with the older theory of elasticity, that they presuppose the quality of *continuity* in the ideal material with which they deal. Employment of differential equations and the methods of the calculus are not strictly legitimate unless the properties of the material can be assumed to be unaffected by subdivision carried to any extent. Now the ordinary materials of construction are known, from microscopical examination, to be crystalline aggregates of great complexity; if subdivision were carried far enough, we should be left with fragments consisting of single crystals, and therefore having properties certainly aeolotropic, and probably non-elastic. Thus the classical theory of elasticity, as applied to actual materials, must be regarded merely as a method of statistical treatment, valid only to the extent that actual materials may be taken to be " statistically isotropic,"[43] and it would seem that the more recent extensions to the plastic state must have the same restricted interpretation. The foregoing considerations serve to explain why theory has given good results when applied to problems of elastic stability or of vibrations (where the result depends upon the general distortion of the whole body), but has not been so successful in its application to questions of elastic failure or fatigue. Suggested criteria of yielding under compound stress (such as those of Rankine, Saint Venant, Guest and Haigh)[44] which involve the principal stresses as calculated by the ordinary mathematical theory cannot be expected to provide an ultimate explanation of occurrences which must depend largely upon the actual microstructure of the material at the point considered.

Modern Tendencies in the Study of Elastic Failure and of Fatigue.—The outlook of earlier investigators, which tacitly presupposed a degree of continuity, in actual materials, comparable

with that of the ideal material of elastic theory, has been modified by increasing knowledge of the inner structure of metals, as revealed by microscopical study at the hands of Sorby, Ewing, Rosenhain, Humphrey, Beilby, Osmond and Arnold. In all the ordinary tests of material for engineering purposes, in the classical "stress-strain diagrams" of Eaton Hodgkinson and others, even in the notions of the "yield point" and of "ductility," we see a general tendency to analyse *resultant* effects, observed in a specimen of considerable size, as though these were due to *continuous* strains (the word is used in the mathematical sense) in a structureless material. Even in the work of Bauschinger, Muir and others, who investigated the phenomenon of "recovery" under prolonged rest or gentle heating, there is nothing which demands a mental picture of the inner mechanism by which the results are produced; and the extent to which the older ideas suffice for explaining the behaviour of materials from an engineering standpoint is shown by C. F. Jenkin's successful derivation of all the ordinary phenomena of low-speed tests from a conceptual "model" characterised merely by a resistance to distortion due in part to elastic resistance and in part to "solid friction."[45] But to explain the first occurrence of elastic failure, and the circumstances which attend the phenomena of fatigue and ultimate fracture, it is becoming increasingly evident that attention must be concentrated upon the actual structure of the crystalline aggregate.

Thus, A. A. Griffith[46] has been led, by discrepancies found to exist between theory and experiment in regard to stress-concentration in the neighbourhood of scratches and flaws, to propound a theory of rupture, for brittle materials, which takes account of the surface energy generated in the formation of cavities or cracks; and he has verified the consequences of his theory by producing fibres of fused silica exhibiting strength of a quite abnormal order. Attention is now concentrated upon ductile materials such as soft iron, copper and aluminium, which are aggregates of small crystals arranged, in general, with random orientation. The methods of X-ray analysis developed by W. H. and W. L. Bragg have provided a powerful means of investigating the structure of the individual crystal,[47] and the discovery, by H. C. Carpenter, C. F. Elam[48] and others, of methods whereby single crystals of aluminium and other metals can be produced in sizes such that they may be subjected to ordinary engineering tests, has led, at the hands of G. I. Taylor and C. F. Elam[49] and others to more exact understanding of the way in which such crystals distort under static or alternating loads.

The stress which a single crystal of aluminium can withstand without suffering permanent distortion is markedly low as compared with the strength of the crystalline aggregate, and it thus appears that we must look to the crystal boundaries (where the atoms presumably have a more random distribution, owing to the conflicting requirements of the adjoining crystal lattices) for an explanation of the relatively high resistance which the aggregate can oppose. This view is supported by the increased strength which accompanies a reduction in the size of individual crystals, under the influence of hardening processes such as heat treatment or "cold work." It is, of course, in agreement with the concept of the "amorphous phase" propounded by Ewing, Rosenhain and Beilby (*see* 25.1018); but it remains for further investigation, using the more powerful methods which are now available, to give precision to ideas which have proved so useful in the past, for correlating the manifold phenomena of plastic distortion and fatigue. Ultimately, of course, static straining and fatigue must be explained on some common basis (*see* METALS, FATIGUE OF).

Engineering Tests.—Rosenhain's theory of "lattice distortion," propounded in his May lecture to the Institute of Metals for 1923 as an explanation of the hardening effects of alloys, etc., exemplifies the new outlook which has been made possible by the discoveries since 1910; it is to microscopical, chemical and X-ray investigations that engineers are looking for a solution of the ultimate problems of fatigue. But understanding of the properties of materials is only one side of the problem of engineering design, and it is unlikely that the practical rule, that the working stress must be kept within the elastic limit, will lose its validity. The other side of the problem is stress-calculation, and stresses, in the crystalline aggregate, can only be determined in statistical fashion. So the older tests, on specimens large in comparison with the crystal structure, have not ceased to be useful, or reached the limit of their development.

A full account of experimental results will be found in R. G. Batson and J. H. Hyde's *Mechanical Testing* (1922). Considerable attention has been directed to the improvement of experimental technique and of the interpretation of results: thus W. E. Dalby[50] has introduced an improved type of specimen and a calibrated weigh-bar for the measurement of loads; A. Robertson and G. Cook,[51] by means of special apparatus designed to eliminate the effects of inertia in the testing machine, have shown that the observed inflection of "autographic" records at the "yield point" of ductile materials (*see* 25.1014) really masks a *reduction* of stress, which in some metals may be as great as one-third of the stress at which yield commences; T. E. Stanton and R. G. Batson[52] have done much to systematise the results of "impact tests"; B. P. Haigh[53] has developed an electrical machine whereby a sinusoidal wave of simple tension and compression may be impressed upon a specimen, and has conducted interesting investigations into the generation of heat during the progress of fatigue tests; W. S. Farren and G. I. Taylor[54] have made accurate determinations of the heat generated during plastic extension in a static test; C. F. Jenkin[55] has developed apparatus with which fatigue tests can be conducted at speeds up to 5,000 cycles per second.

It is impossible in this article to include any summary of experimental results. The reader is referred to a recently published treatise by H. J. Gough,[56] in which a very clear and exhaustive account may be found, covering all aspects of fatigue as developed up to the latter part of the year 1924. (R. V. S.)

MATERNITY AND INFANT WELFARE.—The period 1910–26 was marked by an increasing consciousness in all civilised countries of the importance of decreasing the heavy losses to the community due to the high death-rate among women at childbirth and among infants under one year of age. There is a considerable body of new legislation intended to supplement and assist welfare agencies and to provide definite state assistance.

I. THE UNITED KINGDOM

The Maternity and Child Welfare Act 1918 gives wide and comprehensive powers to local authorities for taking action designed to preserve maternal and infant life. The passing of this Act consolidated the work commenced in 1906 by the St. Marylebone Health Society. Like nearly every other movement to fight disease, modest experiments by groups of social workers pointed the way to larger state and municipal action.

In 1910 there were 90 infant welfare centres in Great Britain, and by 1914 the number had risen to 400. Owing to the great impetus given to this service during the War, and to the passing of the Maternity and Child Welfare Act in 1918, there were in 1925 no fewer than 1,363 infant welfare centres under the local authorities and 759 voluntary centres, as well as 133 maternity institutions recognised by the Ministry of Health.

Legislation.—The various enactments bearing on the subject are the Factory and Workshops Act of 1901, which endeavours directly to protect the woman who has recently given birth to a child; the Midwives Act of 1902, which laid the foundation of a safe and efficient system of practice by midwives; the Notification

of Births Act of 1907 and the extension of the Act in 1915, which Miss Margaret Llewelyn Davies described as "nothing less than a welcome by society to each of its newly-born citizens, and a signal of help and a message of hope to every mother in the land." Under this Act the father or doctor or midwife must notify the public health authority within 36 hours of the birth of a child. Advice and help, free of charge, are then given by a woman health visitor. The National Health Insurance Act provides a maternity benefit of 40s. for an insured woman or the wife of an insured man.

The Ministry of Health, formerly the Local Government Board, encouraged local authorities to extend and develop their maternity and child welfare services. In a circular letter to local authorities issued in 1914 the board stated that an estimate had been laid before Parliament for a grant to be distributed to local authorities and voluntary agencies in respect of institutions or other provision for maternity and child welfare, that more extended and systematic measures than had hitherto been generally adopted were necessary. Sir Arthur Newsholme, in a report on maternal mortality in connection with childbearing, published in 1915, stated that "the present report is intended to draw attention to this unnecessary mortality from childbearing, to stimulate further local inquiry on the subject and to encourage measures which will make the occurrence of illness and disability due to childbearing a much rarer event than at present." His successor, Sir George Newman, 10 years later (1924), in his preface to Dr. Janet Campbell's *Maternal Mortality*, referring to the fact that approximately 3,000 mothers had died each year at childbirth for the previous 10 years, stated: "That is a serious and largely an avoidable loss of life at the time of its highest capacity and in its most fruitful effort."

Administration.—The local authorities carrying out maternity and child welfare schemes are the county councils, county borough councils and the councils of certain of the larger county districts—as a general rule those having a population of more than 20,000. These are in the main the authorities which adopted the Notification of Births Act referred to above, under which some work for mothers and babies was already being done before the passing of the Act of 1918. The regulations under which a grant is payable by the Exchequer of 50% of the approved net expenditure of local authorities, set out the services which may and should be comprised in a maternity and child welfare scheme, and from them the scope and content of the services may readily be understood.

1. The salaries and expenses of inspectors of midwives and of health visitors and nurses engaged in maternity and child welfare work;
2. The provision of a midwife for necessitous women and for areas insufficiently supplied with this service;
3. The provision, for necessitous women, of a doctor for illness connected with pregnancy and for aid during the period of confinement;
4. The expenses of a centre, *i.e.*, an institution for providing medical supervision and advice for expectant and nursing mothers and for children under five years of age, and medical treatment at the centre for cases needing it;
5. Arrangements for instruction in the general hygiene of maternity and childhood;
6. Hospital treatment for complicated cases of confinement and for children under five years of age found to need in-patient treatment;
7. The cost of food certified as being necessary to expectant and nursing mothers and for children where the case is necessitous;
8. Expenses of crèches and day nurseries and of other arrangements for attending to the health of children under five years of age whose mothers go out to work;
9. Accommodation in convalescent homes for nursing mothers and for children;
10. The provision of homes and other arrangements for attending to the health of children under five years of age of widowed, deserted and unmarried mothers;
11. Experimental work in relation to maternity and child welfare work;
12. Contribution by a local authority to voluntary institutions.

Exchequer grants on the same scale are also paid to voluntary agencies which carry out certain services to the satisfaction of the Minister of Health.

The annual expenditure on maternity and child welfare services provided by local authorities is approximately £1,500,000, in addition to which exchequer grants are made to voluntary agencies. If to these figures is added the £1,500,000 paid in maternity benefit under the national health insurance scheme, a total of over £3,000,000 is spent each year on these services, without taking account of the total expenditure of the voluntary agencies, of other benefits paid from health insurance funds and of the voluntary hospital services.

Infant Mortality.—The services given at the centres by both lay and professional workers helped to secure the reduction of the infant mortality rate from 154 per 1,000 births in 1900 to 75 per 1,000 births in 1924. This gratifying result means that (calculated on the average infant mortality of 1901–10) there was in 1924 a further saving of 39,000 infant lives. "It also implies a better physical condition in children from one to five years of age, and a more enlightened understanding of personal and public hygiene" (Sir George Newman). While this saving of infant lives is all to the good, it is disturbing to find on an analysis of the statistics that the reduction in the infant mortality rate has occurred almost entirely subsequent to the first few weeks of life and that the death-rate of infants up to the age of four weeks has remained almost stationary, being 33 per 1,000 births in 1924 as against 40 per 1,000 births for the period 1906–10.

Maternal Mortality.—So, too, in the case of maternal mortality, notwithstanding that Sir Arthur Newsholme reported in 1915 that "800 mothers die each year in England and Wales as the result of childbearing whose lives would be saved if the experience of the rest of England and Wales were as favourable as London," and that there would be a further saving of 1,100 lives of mothers secured annually in England and Wales if puerperal fever were to be eliminated "as it has been substantially from the experience of many lying-in hospitals." Dr. Janet Campbell, 10 years later, writes that "avoidable maternal deaths are a matter of everyday occurrence," and that "puerperal infection leads to more deaths and more injury than any other complication of childbearing."

It has been shown that the mortality rate of very young babies is nearly as high as it was early in the century. On examining the statistical returns of maternal mortality it is seen that while the death-rate of mothers at childbirth was 3·74 per 1,000 births for the period 1906–10, it was 3·70 per 1,000 births in 1924.

Here then is the problem. Improvements in general sanitation and public health services, a better education in public and personal hygiene, the maternity and child welfare services, the services provided under the National Health Insurance scheme, have had no visible effect upon the vital statistics relating to childbearing. Comparing the period 1906–10 with the year 1924—that is to say, the period prior to the establishment and development of maternity and child welfare services by the local authorities with the latest complete figures available—it is seen that taking the 1906–10 period as 100, the relative mortality rates for 1924 are:—

Maternal mortality	98·9%
Infants under four weeks	82·5
Infants from four weeks to one year	54·5

It seems perfectly clear that the saving of the lives of the mothers and very young babies is one and the same problem. "The unexpected loss of the mother is a tragedy to the family. It is not infrequently associated with the death of the infant for whom the maternal life has been sacrificed, and is often followed by the impaired health and nutrition of the remaining children" (Dr. Janet Campbell).

Disability Among Married Women.—It has been pointed out that the mortality returns "reveal only a part of the total damage and disability, and that an incalculable amount of unreported and often untreated injury and ill-health results from pregnancy and labour." Statistics relating to the comparative heavy incidence of sickness amongst married women were presented to the Royal Commission on National Health Insurance which reported in March 1926. In Appendix A to the report the Government actuary states:—

18. Another matter calling for attention, and in this case calling urgently, is the excess of the claims of married women over those of the unmarried.

At the important groups of ages, 20–25, 25–30 and 30–35, the married woman's rates of sickness are found to represent the following percentages of those of the unmarried class:

Ages	1921	1922	1923
	%	%	%
20–25	242	284	299
25–30	174	198	242
30–35	158	171	198

The majority report of the Royal Commission recommended the provision of improved maternity services "as and when funds are available to meet the cost." The minority report, however, declared that "the high maternal death-rate and the great amount of sickness amongst mothers clearly prove the need of reorganisation and extension of maternity work," and recommended that medical benefit under the Health Insurance scheme should include medical attention at confinement and should be extended to include the wives and dependants of insured men. The provision of more adequate services for women at childbirth is a matter of urgent necessity. "If a woman can rely upon securing the services of a careful up-to-date practitioner, or upon the attendance of a well-trained midwife who is able to obtain prompt and competent medical assistance in case of need, nearly all other conditions become of minor importance" (Dr. Janet Campbell).

Effect of Environment.—The development of antenatal services appears to afford the most likely solution to the problem. Regional distribution of the mortality does not point to industrial factors as being the chief causes of deaths. At the same time, it is not without significance that nine of the 10 county boroughs having the highest rates of maternal mortality in the four years 1919–22 were in Lancashire and Yorkshire, and seven of those nine towns, viz.: Halifax, Rochdale, Huddersfield, Bury, Oldham, Dewsbury and Blackburn, in the report of 1914–5 are among the county boroughs which exact "the heaviest toll of life from mothers in childbearing." Industrial areas can, however, be found with extremely low rates of mortality; the predominatingly working class district of West Ham actually had in 1919–22 the lowest rate of maternal mortality of all the county boroughs.

The same county borough had the lowest rate among the metropolitan boroughs in 1914. In the counties of Lancashire and Yorkshire it is the practice for a considerable proportion of married women to be employed in the textile mills, and it is difficult to resist the conclusion that the nature of their employment, together with the strain of managing the household and bearing large families, is in no small degree responsible for the unenviable position which the towns occupy and have occupied for so many years. The puerperal death-rate in Wales has always been higher than that in England, and, until recently, than in Scotland. That is probably due, not so much to any special cause peculiar to Wales, as to the fact that, broadly speaking, the whole country is either extremely rural or highly industrial. The services available in most rural areas leaving much to be desired, and the exceedingly hard life associated with the mining industry, must be factors contributing to the high maternal mortality rates disclosed.

An enlightened public opinion would encourage and, where necessary, compel the local authorities to provide the services considered by the experts to be essential. The medical profession has the knowledge; administrators, local and national, are capable of creating the administrative machinery; there is no lack of voluntary helpers; the provision of the necessary finance and the co-operation of the mothers are the two factors which depend upon education.

II. THE UNITED STATES

The most important development in this field was the passage by Congress in 1921 of the Maternity and Infancy Act, popularly known as the Sheppard-Towner Act. This Act authorised an annual appropriation of $1,240,000 for a five-year period, of which a sum not to exceed $50,000 may be expended by the U.S. Children's Bureau for administrative purposes and for the investigation of maternal and infant mortality, the balance to be divided among the states accepting the Act as follows: $5,000 unmatched to each state, and an additional $5,000 to each state if matched; the balance to be allotted among the several states on the basis of population and granted if matched.

The national administration of the Act is lodged with the Children's Bureau of the U.S. Dept. of Labor; local administration in the states is in the child-hygiene or child-welfare division of the state agency of health or, where such a division does not exist, the agency designated by the state. In 1925, 43 states—all except Connecticut, Illinois, Kansas, Maine and Massachusetts—had accepted the benefits of the Act, and approximately $1,000,000 was being expended by the national Govt. in subsidies to the states. In 1924 the benefits of the Act were made available to the Territory of Hawaii, which has also accepted and matched the funds available.

Results of the Act.—The report for 1925 of the activities undertaken by the states under the terms of this Act shows continued progress as old activities have spread over a greater territory and new activities have been initiated. These have for their object: (1) better infant care through the teaching of mothers; (2) better care for mothers through education as to the need and value of skilled supervision during pregnancy, childbirth and the lying-in period; and (3) more widespread medical and nursing facilities so that adequate maternity and infancy supervision will be available to all who need it. Children's health centres or conferences and pre-natal or maternity centres or conferences are everywhere recognised as the best agencies for teaching the hygiene of maternity and infancy. An objective in most of the states is the state-wide establishment of permanent, locally supported centres. Demonstration conferences have been held and intensive pieces of work undertaken by the states when there was evidence of special need. In the main these activities have been for the benefit of rural communities and small towns.

State reports of the work during the fiscal year 1925 show 10,802 child-health conferences held by 43 states administering the Federal funds, with 278,016 infants and children of preschool age examined, and 622 children's health centres established through the efforts of the states. Since 1920 child-hygiene or child-welfare divisions or bureaux have been organised in the departments of health in 14 states, so that in all except one state (Colorado) these departments now have an organised agency promoting child health.

Ten states have been admitted to the United States birth-registration area since 1920. At present (1926) 33 states and the District of Columbia (all except Alabama, Arizona, Arkansas, Colorado, Georgia, Idaho, Louisiana, Missouri, Nevada, New Mexico, Oklahoma, South Dakota, Tennessee, Texas and West Virginia) are in the birth-registration area, comprising 75·9% of the total population of the United States. In 1915 the infant mortality rate for the birth-registration area was 100; in 1920, 86; and in 1924 (provisional figures), 72. A general reduction during the five years 1920–5 in the rates in both rural and urban areas is indicated.

On the face of the figures, maternal mortality from all causes appears to have been increasing in the United States. Analysis of the statistics shows that the certification of the causes of deaths has improved during the last 20 years. If allowance is made for the probable effect of this improvement in certification,

the mortality from puerperal septicaemia has fallen throughout the period instead of increasing up to 1911 and falling since that time, as the figures, if taken at their face value, would indicate, and the mortality from other puerperal causes has been approximately stationary. After allowances are made for the margin of errour in the statistics of the United States and of other countries, it seems probable that the rate in the United States is actually considerably higher than in most foreign countries. The maternal death-rate, per 1,000 live births in the birth-registration area of the United States, was 6·6 in 1924, with only five states having a rate below 6.

Great emphasis is being placed on pre-natal supervision by the state bureaux of maternal and infant hygiene, but the programme of work was only just getting under way in 1926. Reports of activities undertaken under the Maternity and Infancy Act show 3,781 pre-natal conferences with more than 36,000 women in attendance, and 65 permanent pre-natal centres established. More than 400 midwife classes were held in 20 states, with an enrolment of more than 10,600 midwives, of whom more than 8,000 completed a somewhat formal course of instruction. Most of these were negro midwives who had had little or no previous training. Women in isolated rural districts are being reached by "pre-natal letters" and itinerant conferences. More generally accessible hospital care during confinement is also receiving consideration.

In 1925, 22 states—Arkansas, Arizona, Colorado, Florida, Idaho, Iowa, Kansas, Kentucky, Louisiana, Massachusetts, Minnesota, Montana, Nebraska, Nevada, New Hampshire, New Jersey, North Carolina, Pennsylvania, Rhode Island, South Carolina, Utah, Virginia—and the District of Columbia have laws making medical inspection of schools mandatory, although in some of these states the examination is required only in case of infectious disease. In 8 states—Alabama, Connecticut, Georgia, Indiana, Maine, New York, West Virginia and Wyoming—it is mandatory for certain districts. Five states—Iowa, Kansas, South Dakota, Nevada and Utah—have laws specifically requiring examination of the teeth of school children; and in 12 other states and the District of Columbia it is included in the requirement of a complete examination. Thirty-three states—all except Arizona, Arkansas, Colorado, Florida, Kansas, Louisiana, Montana, Nebraska, New Hampshire, New Mexico, Oklahoma, South Dakota, Texas, Vermont, Wyoming and the District of Columbia—have laws with reference to physical education in elementary schools which are either mandatory or mandatory in effect. The teaching of health and health habits as distinguished from either medical inspection or physical education has greatly increased in recent years.

In 1923 two private national organisations, the American Child Hygiene Assn. and the Child Health Organisation of America, united to form the American Child Health Association. This association has made an important survey of child health in 86 cities having a population of from 40,000 to 70,000 and has supervised the demonstrations in child hygiene for The Commonwealth Fund and done general educational work in the field of child health.

MATHEMATICS (*see* 17.878).—In the great *Principia Mathematica*, published in 1911, mathematics is rigorously deduced from a few primitive propositions of logic. Since then, not to speak of improvements of detail effected by Sheffer and Wicod, the *Principia* has been subjected to fundamental criticisms which have induced many workers to abandon altogether its line of approach.

I. MATHEMATICAL LOGIC

Theory of Types.—In attempting to provide a firm logical basis for the theories of infinite aggregates and irrational number developed during the 19th century by Cantor and Dedekind, the chief theoretical difficulty is to avoid the famous paradoxes of the theory of aggregates. These are direct contradictions which arise as a result of pursuing apparently ordinary and legitimate mathematical arguments. Such a state of things is intolerable, and shows that there must be something radically wrong with our fundamental ideas. Whitehead and Russell discovered that behind each contradiction lay a "vicious-circle fallacy," due to neglecting the fundamental principle that what involves the whole of a given totality cannot itself be a member of the totality. In order to avoid such fallacies they put forward their Theory of Types, which consisted of two rather different parts. The first part asserted that things were of different logical types, and that for any predicate there was only one type of subject, of which the predicate could significantly be predicated; applying it to a subject of any other type would give not falsehood but literally nonsense. According to this principle many of the paradoxes consist of sentences, which, though grammatically correct, are nevertheless strictly meaningless, and the contradictions are thus completely removed. But not all the paradoxes could be dealt with thus, and the others required the second part of the theory of types, which distinguished further different orders of predicates applicable to the same type of subject.

For instance, the quality of having all qualities of a certain sort cannot itself be a quality of that sort, or it would be involved in its own definition, but must be a quality of a higher order. So, in order to avoid vicious circles, we must never speak of all qualities generally, but only of all qualities of a certain order. If all statements of this kind are made precise as to the order of qualities involved, all the paradoxes which escape the first part of the theory of types in their turn disappear.

Axiom of Reducibility.—The theory of types is thus completely successful in avoiding the contradictions, but this is only half the problem. The arguments leading to contradiction must be invalidated, but this must be done without also invalidating the arguments used in accepted mathematics; and in this Whitehead and Russell failed, for the restrictions imposed by the second part of the theory of types upset an enormous part of ordinary analysis, and this catastrophe was only averted in *Principia* by the introduction of the axiom of reducibility. This axiom asserts that for any predicate of higher order there is a predicate of the lowest order having the same extension (*i.e.*, applying to the same subjects) as the one of higher order. This implies that any class defined as the extension of a higher order predicate will also be the extension of a lowest order predicate; so that thus the totality of classes, whose members are of a given type, can be obtained from the totality of lowest order predicates applicable to that type and will be a legitimate totality. In this way the theory of irrational numbers and the other parts of mathematics threatened by the theory of types can be saved, if we are prepared to accept the axiom of reducibility. But this axiom cannot possibly be regarded as self-evident, and there is really no reason whatever for supposing it to be true, so that anything which can only be proved by assuming it cannot be regarded as proved at all.

Intuitionist Views.—This point was especially emphasised by Weyl in *Das Kontinuum* (Leipzig, 1918) who went so far as to reject not merely as unproved, but as evidently unprovable, much of the general theory of real numbers, bounds, limits and continuous functions, to say nothing of more recent advances. He proposed to confine mathematics to the narrower body of truth, which could be proved not merely without the axiom of reducibility but without using higher order predicates at all. Since then Weyl has moved still further from the standpoint of *Principia Mathematica*, and in his latest work (*e.g.*, in *Mathematische Zeitschrift*, 1921) he appears as a follower of Brouwer, who is regarded as the leader of the "intuitionist" school.

The Excluded Middle.—Brouwer's principal thesis is his denial of the law of excluded middle, which may be illustrated by a case of the following kind. Suppose we wish to establish the existence of a number having a certain property; then we may argue thus: A certain condition, say p, must either be fulfilled or not; if p is true, we can make a construction which will give a number of the required kind; if p is false, we can also make a construction for

such a number, though a different construction from the previous one. So we shall conclude that in either case there exists a number having the required property. Such an argument would, according to Brouwer, be illegitimate, because if, as often happens, we could not tell whether p were true or false, we should not know how to set about actually constructing the number in question. It would be wrong, he thinks, to argue by the law of excluded middle that, because it could not be true in either case that all numbers have not got this property, there must be one number at least which has it.

This criticism, which is supported by several eminent authorities, would annihilate considerable portions of modern mathematics. There are, however, many thinkers to whom Brouwer's criticism seems to have no force whatsoever, and who are determined to find a theory of the foundations of mathematics which will not involve the rejection of any generally accepted parts of the subjects; and of their views we must now give some account.

Axiom Systems.—There are first Zermelo, Fränkel and others, who are working at the construction of axiom systems for the theory of aggregates; they propose to cease using the word class or aggregate in its ordinary sense, whatever that may be, but to mean by it anything satisfying certain axioms; these axioms will be constructed so as to permit the deduction of all the ordinary theory of aggregates, but avoid all the contradictions. But from a philosophical point of view this shirks the real problem, which is to clear from contradiction the notion of class and other allied notions which occur in mathematics, when, for instance, we speak of the class of prime numbers, as well as outside it.

Formalists.—The most prominent opponents of the intuitionists are, however, the formalists, of whom Hilbert (see especially *Mathematische Annalen*, 1922) is the leader. This school regards mathematics as consisting of meaningless symbols manipulated according to formal rules, thus reducing it to something of the nature of a game of chess. Such an account of mathematics is wholly inadequate; since if "two" and "three" were meaningless marks on paper there could be no difference in meaning between "two shillings" and "three shillings." But the formalist attitude, although hopeless philosophically, may be useful in dealing with particular questions, and the essential novelty of Hilbert's work consists not in his formalist theory, but in the propositions he has proved or hopes to prove about mathematical formulae. The chief of these propositions is that it is impossible to deduce a contradiction by permissible operations from the axioms of mathematics, including the law of excluded middle.

This demonstration is only required to convince the sceptics or intuitionists, who will not be satisfied with the simple argument that the axioms are true and that therefore no contradiction can be logically deduced from them. Hence it is essential not to use in the demonstration any principle which the sceptics doubt. This appears to be possible, since, owing to the finite nature of any piece of mathematical reasoning, in proving that it does not lead to contradiction we shall only have to employ the law of excluded middle for finite ranges, for which everyone admits its validity. The science on which Hilbert is now (1926) engaged, which takes for its subject matter the meaningless formulae of mathematics, he calls *metamathematics*, and believes it to be capable of establishing many important results relating to the multiplicative axiom or axiom of selections and to the continuum problem. Interesting, however, as his work is, it does not offer any satisfactory account of the foundations of mathematics as a science, but only deals with it as a game, and contributes no more to the solution of the main problem than does the annihilating scepticism of the intuitionists.

Mathematical Induction.—So that, in view of the bankruptcy of all other proposals, it would seem that the true account of the matter must be on the lines of that of Whitehead and Russell, although this cannot be correct in detail owing to the unsatisfactory nature of the axiom of reducibility. Of great interest from this point of view is the new work in the second edition of *Principia Mathematica* (vol. 1, 1925) and in particular the new theory of mathematical induction, which by most ingenious arguments is established without using the axiom of reducibility. Unfortunately the authors do not see their way to constructing a similar account of Dedekindian Series, for which and for all that part of analysis which depends upon it we are left without any justification.

In this new edition of *Principia Mathematica* some use is made of the theories of *Tractatus Logico-Philosophicus* by Ludwig Wittgenstein, which, although mainly concerned with more purely philosophical problems, also contains contributions of fundamental importance to our subject. Of one of the principal problems in particular he has given an original and possibly final solution; but in order to understand this it is necessary to go back a little.

Mathematics and Logic.—One of the chief objects of the work of Frege and Russell was to reduce mathematics to logic, to show that all mathematical concepts could be defined in terms of "logical constants," and that all mathematical propositions could be deduced from those of formal logic; so that mathematics and logic became one and the same subject. Granting the validity of this reduction, doubt still remains as to what is the peculiar characteristic of logical or mathematical propositions, and how they differ from all others. This question Russell answered in 1903 by saying that logic or mathematics consisted of all true propositions, which were hypothetical in form and contained no constants except logical constants; this amounts practically to saying that any completely general true proposition is a proposition of logic. It subsequently became clear that this definition was much too wide, and that it was necessary to distinguish the propositions which could be stated in purely logical terms and were in fact true, from those which logic alone could assert to be true, which form the science of logic and mathematics. And the distinguishing characteristic of this smaller group of propositions which logic can assert to be true had yet to be found.

Wittgenstein's Work.—This problem Wittgenstein has probably solved; his answer is complicated by the fact that he does not accept the reduction of mathematics to logic, and gives different accounts of the propositions of logic and those of mathematics. Of these his theory of logical propositions is the more important; and if, as is quite possible, his criticisms of the reduction of mathematics to logic are unsound, it would entirely supersede his theory of mathematics, which is given only in barest outline.

Wittgenstein's account of the propositions of logic is that they are tautologies, in a sense of which a precise definition is given in terms of his theory of propositions in general. Any proposition, he maintains, is the expression of agreement and disagreement with certain ultimate possibilities, the possibilities of existence and non-existence of atomic facts. A proposition which agrees with every possibility is a tautology; one which disagrees with every possibility is a contradiction. An ordinary proposition asserts something to be the case and is true if it is the case; a tautology on the other hand asserts nothing but agrees with every possibility and is therefore true unconditionally. This account can be made to cover not only what are called in *Principia Mathematica* "elementary propositions," but also general propositions which involve apparent variables.

Symbolism.—But the importance of Wittgenstein's work does not only consist in his having defined the propositions of logic, and hence possibly those of mathematics, but also in his theory of symbolism, which seems capable of far-reaching applications to the theory of types. The theory of symbolism may indeed be expected to be relevant for the following reason. There is an obvious division of the paradoxes into two groups, which is entirely overlooked in *Principia Mathematica*. The first group of contradictions, such as those about the class of classes not containing themselves and the greatest ordinal, can be stated in purely logical or mathematical terms. They would actually occur in a mathematical treatise if it investigated the problems in question. The remaining contradictions, such as Richard's paradox, involve, besides mathematical terms, terms drawn from psychology or epistemology, such as knowing, asserting, naming or meaning. These contradictions are not therefore purely mechanical, and the responsibility for them need not, as must that

for the first group, lie with faulty mathematics or logic, but may lie in faulty ideas of knowledge and symbolism. This was the view taken of them by Peano; but it cannot be regarded as satisfactory until an adequate explanation is given of where exactly the fault lies. The probability that it lies in the epistemology and not in the mathematics, is strengthened by the fact that this grouping of the contradictions into purely mathematical and mixed coincides with their grouping according to whether their solution in *Principia* requires the first or second part of the theory of types. So that the first part of the theory, which is undoubtedly sound, will suffice for the purely mathematical contradictions, and if the mixed contradictions can be shown to be due to the epistemological element, there may no longer be any need for the second part of the theory of types, which requires the axiom of reducibility and is so responsible for the whole trouble.

By using the work of Wittgenstein a solution has been constructed along these lines, on which the theory of types is so modified that all need for an axiom of reducibility disappears, and mathematics consists entirely of tautologies in Wittgenstein's sense.

II. THEORY OF NUMBERS

In the article NUMBER (19.847) an excellent summary is given of the classical theory. Modern mathematics has seen the rise of a new theory, the "analytic" theory, which has developed with great rapidity, and has almost monopolised the attention of arithmeticians.

(*a*) *Theory of Primes.*—The modern developments of the theory of numbers depend in the main on the application to the theory of the ideas of the theory of functions of a complex variable (*see* 11.301). It was in the theory of the distribution of primes that these ideas first bore fruit.

It is usual to write $\pi(x)$ for the number of primes less than x. It has been known since Euclid that the number of primes is infinite, that is to say that $\pi(x)$ tends to infinity with x. The central problem of the theory has been the determination of the order of magnitude of $\pi(x)$ when x is large, and its solution is embodied in the *Primzahlsatz*, or "prime number theorem," expressed by the formula

$$\pi(x) \backsim \frac{x}{\log x}$$

where the symbol $\backsim$ expresses the fact that the ratio of the two functions tends to unity. This theorem, conjectured by A. M. Legendre (1798) and C. F. Gauss (about 1792), was first proved by J. Hadamard and Ch. J. de la Vallée Poussin in 1896. The real founder of the modern theory, however, was B. Riemann, who, in a famous memoir published in 1859, first indicated the road along which subsequent research has progressed. Riemann did not prove the prime number theorem; strangely enough, he did not mention it, his object being to obtain, not an asymptotic formula for $\pi(x)$ but an exact expression in the form of an infinite series. Nor did Riemann attain the goal at which he aimed, his analysis, profound and beautiful as it is, being altogether incomplete and inconclusive. But it was Riemann who first recognised where the key to the solution lay, viz., in the study of the "Riemann zeta-function,"

$$\zeta(s) = \zeta(\sigma + it) = \Sigma n^{-s} = \Pi\left(\frac{1}{1-p^{-s}}\right)$$

(where $n = 1, 2, 3, \ldots$, and p runs through the series of primes), considered as a function of the complex variable s. Riemann established some, and conjectured others, of the properties of $\zeta(s)$; one famous conjecture, that all the complex zeros of $\zeta(s)$ lie on the line $\sigma = \frac{1}{2}$, remains unsettled to this day.

Riemann's memoir bore no fruit for over 30 years, when the way was cleared by the researches of Hadamard in the theory of analytic functions (*see* FUNCTION, 11.301 *seq.*). These researches led Hadamard himself, de la Vallée Poussin, and other writers, to a proof not only of the prime number theorem but of very much more. Thus de la Vallée Poussin proved that the logarithm integral $\mathrm{Li}x = \int_2^x \frac{dt}{\log t}$ represents $\pi(x)$ with an error of lower order than $x(\log x)^{-k}$, where k is any number however large. He also investigated the distribution of primes of a linear form $am+b$ or a quadratic form $am^2+bmn+cn^2$ where a, b, c are integers without common factor, showing, for example, that the primes are, on the average, equally distributed between the various arithmetical progressions $am+1$, $am+2$, ..., as had been conjectured long before by P. G. Lejeune Dirichlet. There is a corresponding theory for the "prime ideals" of the "corpus" associated with any algebraic number. The analogue of Riemann's zeta-function was discovered by R. Dedekind, but it is only recently that, in the hands of E. Hecke and E. Landau, the development of the theory has been pushed to a point corresponding with that of the ordinary theory.

The outstanding unsolved problem of the theory is that of the determination of the order of the *difference* $\pi(x) - \mathrm{Li}x$. This problem is bound up essentially with Riemann's unproved hypothesis concerning the zeros of $\zeta(s)$. If Riemann's hypothesis is true, the maximum order of the difference differs from that of $\sqrt{x}$ by logarithmic factors only. In any case the difference assumes values *of either sign* which tend to infinity with x. This theorem, proved by J. E. Littlewood in 1914, disposes of the old conjecture of Gauss and B. Goldschmidt that $\pi(x)$ is always less than $\mathrm{Li}(x)$.

Apart from applications to the theory of primes, there is a large literature connected with the pure theory of $\zeta(s)$. It has been shown by H. Bohr, E. Landau and F. Carlson that (to put it roughly) nearly all the zeros lie very near the critical line; by G. H. Hardy and J. E. Littlewood that (equally roughly) a considerable proportion lie actually on it. But the hypothesis itself remains unproved.

(*b*) *Additive Theory.*—The "additive" theory of numbers includes Combinatory Analysis (*see* 6.752), Partitions (*see* 19.865), the theory of the representation of numbers by sums of squares, cubes, or higher powers, and so forth.

The central problem is that of determining (exactly or approximately) the number of representations of an arbitrary positive integer n in the form $a_1+a_2+\ldots+a_s$, where the a's are numbers of some special type (*e.g.* squares), and s may be fixed or unrestricted, according to the particular problem envisaged. There is a fundamental difference between the "additive" theory and what may be called the "multiplicative" theory, in which the central idea is that of the resolution of a number into prime factors. Analytically, this difference expresses itself as follows: the multiplicative theory depends on the theory of "Dirichlet's series" of the type $\Sigma a_n n^{-s}$, the additive theory on that of power series $\Sigma a_n x^n$. A great deal of the additive theory is purely algebraic, and is intimately bound up with the theory of elliptic functions. This side of the theory (founded by L. Euler) has been developed to a high pitch by English mathematicians, notably A. Cayley, J. J. Sylvester, and P. A. MacMahon, while more recently the methods of complex function theory have been applied to the theory and an "analytic additive" theory has been founded. Among many curious results we may mention the theorem of S. Ramanujan, that the numbers of the unrestricted partitions of numbers of the forms $5m+4$, $7m+5$ and $11m+6$ are divisible by 5, 7 and 11 respectively.

One of the most remarkable problems of the additive theory is "Waring's Problem." It was asserted by E. Waring (1782) that any number n is the sum of at most 4 squares, 9 positive cubes, 19 fourth powers, and, generally, $g(k)$ powers, where $g(k)$ is a number depending on k alone and not on n. This problem—in so far as it simply asserts the existence of *some* such number $g(k)$—was solved by D. Hilbert in 1909. J. L. Lagrange (1774) proved that $g(2)=4$ (any number is the sum of 4 squares, and some numbers not of less), and E. Wieferich (1909) that $g(3)=9$ and $g(4) \leqq 37$. Only a finite number of numbers (probably only 23 and 239) require more cubes than 8 (E. Landau, 1908), while an infinite number require 4 at least; and only a finite number of numbers require more than 19 fourth powers (G. H. Hardy and J. E. Littlewood, 1924), while an infinite number require 16 at least; and asymptotic formulae for the number of representations have been found. But our knowledge of this field is still extremely incomplete.

The "empirical theorem" of Chr. Goldbach, that every even number is the sum of two primes, has also received a considerable amount of attention, but is still unproved. Among other unsolved problems of the same character may be mentioned that of proving the existence of an infinity of primes of the form m^2+1 or (more generally) am^2+bm+c. This problem is not to be confused with the problem of primes $am^2+bmn+cn^2$, solved by de la Vallée Poussin.

(*c*) *Miscellaneous Investigations.*—The work of Dirichlet and L. Kronecker on the approximation of irrational numbers by rationals has led to extensive investigations lying on the border line between arithmetic and analysis, developed above all by H. Minkowski under the titles of *Diophantische Approximation* and *Geometric der Zahlen*. The central idea in this theory is that of the lattice (*Gitter*).

A lattice point (*Gitterpunkt*) in space of any number of dimensions is a point with integral co-ordinates, and most difficult and fascinating problems arise when we consider the number of lattice points which lie within a volume of specified form in n-dimensional space. Thus Minkowski proved that any convex figure in space of two dimensions with symmetry about a centre, its centre at a lattice point, and of area 4, includes other lattice points besides its centre; with a whole series of corresponding theorems concerning more general configurations. Another class of lattice-point problems is exemplified by the

"circle" problem of Gauss and W. Sierpinski, that of determining approximately the number of lattice points inside the circle $x^2+y^2=n$ when n is large. A first approximation is naturally given by πn, the area of the circle, but the estimation of the error is a problem of exceptional difficulty. This problem and the analogous problem for the hyperbola $xy=n$ (Dirichlet's divisor problem) were connected with the theory of $\zeta(s)$ [see (*a*) *supra*] by Landau. These problems also are susceptible of manifold generalisation. And in all these problems, we observe the dominating and irresistible tendency of modern higher arithmetic, the tendency to abandon its ancient tradition of isolation and assimilate itself so far as possible to the theory of functions, in order to utilise the immensely powerful weapons which the latter theory alone can provide.

There is one famous problem in which no such reduction of arithmetic to analysis has been effected. "Fermat's last theorem" asserts that there is no integral solution of $x^n+y^n=z^n$ (other than the trivial solution $x=z$, $y=0$) for any value of n greater than 2. It was the attempt to prove this theorem that led to the whole development of the theory of algebraic numbers; but, in spite of the wide-spread attention which it has excited, and the extreme importance of the general theories of which it has been the starting point, the theorem itself remains unproved, though important additions have been made recently to our knowledge by A. Wieferich, D. Mirimanov, L. E. Dickson, and H. S. Vandiver. Thus Wieferich proved that the theorem holds for odd prime values of n, and values of x, y, z, not divisible by n, unless $2^{n-1}-1$ is a multiple of n^2.

One old conjecture has been definitely disposed of. Mersenne asserted that 2^n-1, where n is a prime not exceeding 257, is prime when, and only when, $n=1$, 2, 3, 5, 7, 13, 17, 19, 31, 67, 127, 257. This statement contains at least four errors, relating to the values 61, 67, 89, 107; and it need no longer be taken seriously.

BIBLIOGRAPHY.—An indispensable work for the serious student of higher arithmetic (on any of its sides) is L. E. Dickson, *History of the Theory of Numbers*, 1920. This work is not, however, specially concerned with the analytic theory.

For general accounts of the theory of primes see the article "Die neuere Entwicklung der Analytischen Zahlentheorie" by H. Bohr and H. Cramer in the *Encyklopädie der Mathemotischen Wissenschaften* (2C8); E. Landau, *Handbuch der Lehre von der Verteilung der Primzahlen* (1909), and *Einführung in die elementare und analytische Theorie der algebraischen Zahlen* (1918).

For the additive theory see P. A. MacMahon, *Combinatory Analysis* (1915-6), and *An Introduction to Combinatory Analysis* (1921); P. Bachmann, *Niedere Zahlentheorie: 2. (Additive Zahlentheorie)* (1910); G. H. Hardy, *Some Famous Problems of the Theory of Numbers* (1920). For Fermat's last problem see P. Bachmann, *Das Fermatproblem* (1917); L. J. Mordell, *Four Lectures on Fermat's Last Problem* (1921).

Comparatively little of recent work is accessible in a connected form, and the study of the original memoirs is indispensable.

III. THEORY OF SERIES

The most striking modern developments in the theory of series (*see* 24.668; 10.753; 12.956) have also been suggested by the development of the theory of functions.

The theory of functions of a real variable has been revolutionised by the ideas of E. Borel and H. Lebesgue, and this has inspired a corresponding revolution in the theory of Fourier's series and "series of orthogonal functions" generally.

A system of functions $\phi_m(x)(m=1, 2, 3, \ldots)$ is said to be *orthogonal* if
$$\int_a^b \phi_m(x)\phi_n(x)dx = 0 (m \neq n) \qquad (1)$$
The simplest examples are obtained by taking $\phi_m(x)$ to be $\cos mx$ or $\sin mx$ and the interval (a, b) to be $(0, 2\pi)$; or $\phi_m(x)$ to be Legendre's polynomial $P_m(x)$ and (a, b) to be $(-1, 1)$. There is then a simple procedure by which we may endeavour to expand an arbitrary function $f(x)$ in the form of a series $\Sigma a_m\phi_m(x)$, viz., by multiplying this series by $\phi_m(x)$ and integrating over the interval (a, b): the formula thus suggested is
$$f(x)=\Sigma a_m\phi_m(x),\ a_m=\left(\int_a^b f(x)\phi_m(x)\,dx\right)\Big/\left(\int_a^b \phi^2_m(x)\,dx\right) \qquad (2)$$
A more accurate analysis of this procedure raises a multitude of profoundly interesting and difficult questions. On the one hand we may start from a series with arbitrary coefficients a_m, and inquire whether there exists a function which stands to it in the relation expressed by the equation (2). In particular, given a trigonometrical series $\Sigma a_m\cos mx$ or $\Sigma b_m\sin mx$ or, more generally $\Sigma(a_m\cos mx+b_m\sin mx)$, with arbitrary coefficients, we may ask whether it is a Fourier's series, that is to say, whether there is a function $f(x)$ such that a_m and b_m are given by Fourier's integral formulae. On the other hand, we may start not from an arbitrary series but from an arbitrary function $f(x)$, form the coefficients (a_m or b_m) by Fourier's formulae or the more general formulae (2), and then inquire whether the formal development thus obtained is convergent, and whether, if convergent, it represents the function $f(x)$ and so forth.

The problems thus raised are among the most difficult of modern mathematics; and a very cursory examination of them is enough to show that the methods of the older analysis are not sufficiently powerful for their solution. It is essential that we should enlarge our conceptions, on the one hand, by taking account of the modern generalisations of the notion of an integral, and, on the other, by adopting a broader view as to what is meant by the "sum" of an infinite series.

The modern theory of functions of a complex variable (*see* 11.301) points to the same conclusion. A function $f(z)$ of the complex variable z, regular for $z=z_0$, is defined throughout a certain circle whose centre is z_0 by a power-series $\Sigma a_n(z-z_0)^n$; but the region of existence of the function is very generally more extensive than the circle of convergence of the series; and this fact has led, during the last generation, to a mass of work on the problem of "analytic continuation." This problem is that of discovering analytic representations of the function, whether by integrals, or by continued fractions, or by series of a different form, which are valid throughout a wider region than that in which it is represented by the original power series. Here also we are confronted by the need for a scientific theory of divergent series.

There are passages in the older analysts (*e.g.*, in L. Euler) which suggest a half-conscious anticipation of modern ideas. But it is roughly true to say that they did not concern themselves with the precise meaning of the infinite series of which they made such effective use. A. L. Cauchy and N. H. Abel were the first to give a precise definition of the "sum" of a series $a_0+a_1+a_2+\ldots$ or Σa_n, viz., as the limit of $s_n=a_0+a_1+\ldots+a_n$ when n tends to infinity ($n\to\infty$). Such a series as $1-1+1-\ldots$ has then *no* sum, for s_n is alternately 1 and 0; and it was the tendency, for many years after Cauchy and Abel, to banish such series from analysis entirely. A school of mathematicians survived, among whom one may cite A. de Morgan, who viewed this tendency with obvious discontent, but there was no escape from the conclusion that the followers of Cauchy and Abel were right. It is impossible to say "the sum of Σa_n is so-and-so" except after framing an accurate definition of "sum"; the definition of Cauchy and Abel was the only definition; and, until some new and wider definition was offered, that was the end of the matter.

We may define the meaning of a mathematical word or symbol as we please, provided only that the definition is free from contradiction. Given a sequence of numbers $a_1, a_2, \ldots$ we may associate with the sequence a number s in any manner that we please, and we may say, if we like, that s is the "sum" of the series. We might say, for instance, that the "sum" of every infinite series is, by definition, zero. This definition would be perfectly legitimate but futile, because it would reduce all equations involving infinite series to the trivial form $0=0$; and confusing, because it would conflict with Cauchy's definition. Cauchy's definition is only one among many, but it is admittedly the most important, and a new definition is only likely to be of value if it is consistent with the standard definition. It must satisfy what is called the *condition of consistency:* it must apply to all convergent series, and give a "sum" equal to their sum in the ordinary sense. Its value for analysis will then be measured by the extent and importance of the class of non-convergent series to which it attributes a "sum."

The simplest and most important of the definitions which have been given is that of the "first arithmetic mean." Suppose that $s_n=a_0+a_1+\ldots+a_n$ and $\sigma_n=(s_0+s_1+\ldots+s_n)/(n+1)$, the arithmetic mean of the first $n+1$ values of s_n. If s_n tends to a limit, σ_n tends to a limit also, and the two limits are the same; but σ_n may tend to a limit when s_n does not. For example, if $a_n=(-1)^n$, $s_{2n}=1$ and $s_{2n+1}=0$, and s_n does not tend to a limit; but σ_n tends to the limit $\frac{1}{2}$. If now we agree to call the limit of σ_n, whenever it exists, the "sum" of the series Σa_n, our new definition is in perfect accord with Cauchy's definition, but is applicable to an extensive class of series for which Cauchy's definition fails. It therefore fulfils the conditions required for a theory of divergent series.

The most striking illustration of the importance of these ideas is to be found in the theory of Fourier's series (*see* 10.753). The Fourier's series of a *continuous* function $f(x)$ is not necessarily convergent; further conditions on $f(x)$, of a much more artificial character, are required to ensure convergence. It was, however, shown by L. Fejér that the Fourier series of any continuous function is "summable" by the procedure indicated above; that is to say, that the arithmetic mean σ_n tends to a limit equal to the value of the function; and this fundamental result has been the starting point of a mass of modern research.

Another important definition attributes to the series as "sum" the value of the limit of the power series $\Sigma a_n x^n$ when x tends to 1 through positive values less than 1. A third (of particular importance in complex function theory) was advanced by Borel; and all of these definitions have entailed a host of still more general definitions.

BIBLIOGRAPHY.—For the general theory of divergent series see E. Borel, *Leçons sur les séries divergentes* (1901); T. J. I'A. Bromwich, *Introduction to the Theory of Infinite Series*, ch. x. (1908); G. H. Hardy and M. Riesz, *The General Theory of Dirichlet's Series* (1915). For the theory of Fourier's series, H. Lebesgue, *Leçons sur les séries trigonométriques* (1912); Ch. J. de la Vallée Poussin, *Cours d'analyse infinitésimale*, 2nd ed., vol. 2 (1916); E. W. Hobson, *The Theory of Functions of a Real Variable* (1907, 2nd ed., 1925). The general theory of series of orthogonal functions is, for the most part, still only to be read in the original memoirs, or in works on the theory

of integral equations. A very important generalisation of the concept of a Fourier's series has been developed recently by H. Bohr in a series of memoirs in the *Acta Mathematica*.

IV. THEORY OF FUNCTIONS

The theory of functions (*see* 11.301, 14.53) has two great branches, the real and the complex theories. Recent advances in the complex theory, important as they are, have been of too technical a character for rapid summary. The real theory, on the other hand, has been remodelled from its foundations. The older form of the theory was cumbrous and unattractive. The modern theory has the aesthetic character required of a first-rate mathematical science, and its development has been perhaps the most striking achievement of modern analysis.

1. *Sets of Points.*—The theory of functions of a real variable is based upon the theory of aggregates (*see* 19.847-850) and in particular the theory of "sets of points." A set of points S is an aggregate of real numbers x, such as the aggregate of rational numbers, or of irrational numbers, in the interval (0, 1). A number ξ is said to be a "limit point" (*Häufungstelle*) of S if every "neighbourhood" of ξ, that is to say every interval $(\xi-\epsilon, \xi+\epsilon)$ including ξ, contains points of S other than ξ itself. A limit point of S may or may not belong itself to S. Thus every number of (0, 1), rational or irrational, is a limit point of the set S of rationals of (0, 1). If every limit point of S belongs to S, S is *closed*. If every point of S is a limit point, S is *compact* or *dense*. A set which is both closed and compact is *perfect*. The continuum, the aggregate of all real numbers, is perfect.

An idea of dominating importance in the theory of functions is that of the *content* or *measure* of a set of points. Suppose, for simplicity, that the set S in question is contained in (0, 1). Then Cantor defined the content of S as follows:—Divide (0, 1) in any manner into a *finite* number of intervals δ, and these intervals δ into two classes δ_1 and δ_2, according as they do or do not include points of S; and let $c(\delta)$ be the sum of the lengths of the intervals δ_1. Then the *content* of S is the limit of $c(\delta)$ when the intervals δ tend to zero, if this limit should exist.

There is a striking defect in this definition, the full implications of which were first perceived by E. Borel. *The content of the sum of two sets is not generally the sum of their contents.* Thus the rationals of (0, 1) have content 1 (since every δ is obviously a δ_1), and likewise the irrationals. The sum of the contents is 2, whereas the content of the sum is 1. The rationals of (0, 1) cannot be included in a finite set of intervals whose aggregate length is less than 1. If we abandon the restriction that the set of intervals must be *finite*, the situation is completely changed. Thus Borel observed that we may include the rational p/q in the interval $\left(\frac{p}{q}-\frac{\epsilon}{q^3}, \frac{p}{q}+\frac{\epsilon}{q^3}\right)$, and that the sum of all these intervals may be made as small as we please by choice of ϵ; and this simple remark has revolutionised the theory of functions. The first step was to frame a satisfactory definition of *measure*, and this concept, which has entirely superseded Cantor's "content," is now defined as follows. We consider sets S included in (0, 1). Let S be enclosed, *in any manner whatsoever*, in a system σ of intervals δ; let $m(\sigma)$ be the sum of the intervals of σ; and let m_e be the lower bound (or "inferior limit") of the aggregate of values of $m(\sigma)$. Then m_e is the *exterior measure* of S. The *interior measure* m_i is $1-m'_e$, where m'_e is the exterior measure of S_1, the set complementary to S, *i.e.*, the set of points of (0,1) which do not belong to S. If $m_e=m_i$, the set S is *measurable*, and its measure is m, the common value of m_e and m_i. This definition (due to H. Lebesgue) is of extreme generality, and no example of a non-measurable set is known.

Measure, thus defined, has the properties which measure ought to have, but which Cantor's content lacked. In particular the sum of two mutually exclusive and measurable sets is measurable, and its measure is the sum of the measures of the component sets. The measure of any enumerable set, and in particular of the rationals, is zero. The definition may be extended to sets in space of any number of dimensions.

2. *Integration.*—The new theory of measure has led to new theories of integration, in the light of which the older theories are of historical or didactic interest only. The most important of these theories are due to H. Lebesgue and W. H. Young.

(*a*) Lebesgue's definition of an integral is as follows. A function $f(x)$, defined in an interval (a,b), is *measurable* if the set of points $S(A)$ for which $f>A$ is measurable for every A. All known functions are measurable. We now suppose that f is bounded, so that (say) $h<f<H$, and we divide up the interval (h, H) into a finite number of intervals (l_i, l_{i+1}) or δ_i. It is this subdivision of the range of variation of $f(x)$, instead of (as in the older theory) that of x, that is characteristic of Lebesgue's procedure. The set of points for which $(l_i \leqq f<l_{i+1})$ is measurable. If we denote its measure by m_i, write $J=\Sigma l_i m_i$ and suppose that the intervals δ_i tend to zero. Then J tends to a limit I, and we write

$$I=\int_a^b f(x)dx$$

The integral so defined is a *bona-fide* generalisation of the integral of Riemann, for it exists whenever Riemann's integral exists and agrees with it in value. But it is far more general: thus the function $f(x)$ which is unity when x is a rational of (0,1), and zero otherwise, has no Riemann integral, but has a Lebesgue integral equal to zero. The definition is capable of many-sided generalisation, to unbounded functions, and functions of many variables; it throws entirely new light on the relations between integration and differentiation; and it has proved itself adapted for a mass of analytical applications of the most far-reaching importance, in particular in the theory of Fourier's series and the theory of integral equations.

(*b*) A different definition was proposed by W. H. Young. He adheres to a subdivision of the range of variation (a,b) of the independent variable; but, instead of dividing it into a finite number of intervals, divides it into a finite or infinite number of measurable sets. This procedure leads to results roughly equivalent to those of Lebesgue's theory; but it is somewhat more general and is certainly a more natural development of the older theory of measure.

3. *Geometrical Applications.*—Those new theories have led inevitably to a searching re-examination of the concepts of "curve," "surface," "length," "area," and so forth, which were generally accepted without question by the older analysts on the supposed evidence of geometrical intuition. This unreflective attitude has now been abandoned, and it is recognised that analysis is in no sense dependent upon geometry. The notion of a *curve* was first made precise by C. Jordan. A curve is a set of points (x,y), that is an aggregate of pairs of real numbers x, y, where x and y are functions of a single variable t, subject to appropriate restrictions. A simple closed continuous curve is a curve for which (1) $x=x(t)$ and $y=y(t)$ are continuous for $t_1\leqq t\leqq t_2$; (2) $x(t_2)=x(t_1)$ and $y(t_2)=y(t_1)$, and (3) it is false that $x(t')=x(t'')$ and $y(t')=y(t'')$ for any pair of values t', t'' other than t_1, t_2. A fundamental theorem, due in substance to Jordan, asserts that such a curve C divides the plane into two "regions" D and D′ separated by the curve. Two points which lie in the same region can be connected by a continuous curve which has no point in common with C; but points which lie in different regions cannot be thus connected. We thus define the *inside* and *outside* of a closed curve in strictly analytical terms. A similar account has been given of the concepts of *area* and *length*. In particular the simple closed continuous curve C has both an area and a length if $x(t)$ and $y(t)$ are functions of "bounded variation."

4. *Integral Equations.*—Among the remaining developments of modern analysis, perhaps the most remarkable are in the theory of integral equations. The typical integral equation is

$$f(x)=\int_a^b K(x,t)\phi(t)dt \qquad (1)$$

where $f(x)$ and $K(x,t)$ are given and the unknown function $\phi(t)$ is to be determined. This equation is called an integral equation of the first kind; but it has been found that equations of the form

$$\phi(x)=f(x)+\lambda\int_a^b K(x,t)\phi(t)dt \qquad (2)$$

known as equations of the second kind, are better adapted for the foundation of a general theory. It was shown by I. Fredholm that, if f and K satisfy certain conditions, there is in general one and only one continuous solution $\phi(t)$; the exceptions arise when λ is a zero of a certain transcendental function $D(\lambda)$. When λ has one of these exceptional values, the equation

$$\phi(x)=\lambda\int_a^b K(x,t)\phi(t)dt$$

has a continuous solution other than the obvious solution $\phi(t)=0$, otherwise this is the only solution. The theory has been widely developed by Fredholm, D. Hilbert, V. Volterra and other writers.

MATHEWS, SHAILER (1863–), American educationist and theologian, was born at Portland, Me., May 26 1863. He graduated from Colby College (A.B., 1884; A.M., 1887) and continued his studies at Newton Theological Institution and the University of Berlin. He was associate professor of rhetoric (1887–9) and

professor of history and political economy (1889–94) at Colby College. In 1894 he went to the University of Chicago as associate professor, and in 1897 became professor of New Testament history and interpretation. In 1908 he was made dean of the divinity school. In 1912 he was president of the Federal Council of the Churches of Christ in America, and he visited Japan in 1915 as representative of that body. From 1903 to 1911 he was editor of *The World Today;* from 1913 to 1920, of *The Biblical World.*

He has written a number of books including *The French Revolution* (1901); *History of New Testament Times in Palestine* (1908); *Social Teachings of Jesus* (1910); *Spiritual Interpretation of History* (1916); and *Faith of Modernism* (1924). (*See* BAPTISTS.)

MATISSE, HENRI (1869–), French painter, was born at Cateau (Nord) Dec. 31 1869. He studied at the École des Beaux-Arts, and under Gustave Moreau. He soon showed revolutionary tendencies, and was recognised as the boldest member of the group known as "les fauves." Though a painter of light, he did not treat it as the impressionists had done, by means of the juxtaposition of minute touches of colour, but by employing pure tones on a large scale. In this way he produced the effect of modelling, and, by the contrast of values, was able to give the illusion of space. He was particularly successful in his use of expressive distortion. Matissè spent two years in Morocco, but most of his work was carried on in southern France, at Collioure and Nice. Later, he reduced the size of his canvases, painting still life and landscapes, as well as small feminine figures and brilliantly illuminated interiors. He is entitled to be considered as the most eminent master of the contemporary French School. In his drawing he exhibits sometimes a nervous restrained manner, and by his use of shadow succeeds in reproducing the actual bulk of bodies without having to insist on their contour. Matisse's lithographic work is also of considerable importance.

MATSUDAIRA, TSUNEO (1877–), Japanese diplomat, was born in Tōkyō. He joined the Imperial University of Tōkyō as a student of economics, and in 1902 he entered the Foreign Office. His first experience abroad was gained in Peking where he was a secretary of legation. His determination, however, coupled with his wide theoretical knowledge, pushed him forward until he became first secretary in London and later in Paris; but his criticism of the extreme nationalism of many of his countrymen stood in the way of his receiving imperial honours. From 1918–9 he was Japanese high commissioner in Siberia and in 1920 was appointed director of the bureau for European and American affairs at the Foreign Office in Tōkyō. In 1921–2 Matsudaira was chief secretary of the Japanese delegation to the Washington Conference. In 1924, after the diplomatic blunder committed by the Japanese Ambassador to the United States, Mr. Hanihara, it was considered that some means must be found to improve the situation. As a result, in 1925 Matsudaira was appointed ambassador and he undertook his duties with the avowed intention of bettering American-Japanese relations.

MATSUKATA, MASAYOSHI (1835–1924), Japanese statesman (*see* 17.890), was from 1917–22 keeper of the privy seal, and on resigning from this post was created a prince. He died in Tōkyō July 2 1924.

MATTEI, TITO (1841–1914), Italian musician and composer, was born at Campobasso, near Naples, May 24 1841. He became at an early age a professor at the Santa Cecilia academy of music at Rome, and subsequently had several successful European tours as a pianist. In 1863 he finally settled in London, where he remained for the rest of his life. He composed several hundred songs and pianoforte pieces, many of which became very popular. He died in London March 30 1914.

MATTER (*see* 17.891).—Since 1910 advances have been made which give much more precision to our knowledge of the constitution of matter. The atomic theory of matter, which for long appeared to be of necessity unverifiable by direct experiment on account of the minuteness of the atom (*q.v.*), received almost direct proof in a number of ways. Methods have been developed, for example, to detect the electrical effect of a single α particle from radium, and a single swift electron (*see* GASES, ELECTRICAL PROPERTIES OF).

The α particle has been shown to be a charged atom of helium projected with high velocity; the number of α particles from a given quantity of radium have been counted, and the volume of helium which they produce has been measured. In this direct way it has been shown that about $2{\cdot}7\times10^{19}$ particles or atoms of helium are required to form one cu. cm. of helium gas at normal pressure and temperature. Not only is it feasible to detect the effect of a single atom of matter in special circumstances but also to show the path of a swift α particle or electron through a gas. This has been made possible by the discovery of C. T. R. Wilson that under suitable conditions the charged ions produced in gases by α or β rays become centres for the condensation of water vapours, and are thus rendered visible as the nuclei of visible drops of water. The photographs of these droplets show in a most striking way the track of the particle through the gas, and illustrate with extraordinary detail the main effects produced by the passage of ionising radiations through gases.

The essential correctness of the kinetic theory of matter, which assumes that the molecules of matter are in vigorous but irregular motion, has been clearly demonstrated by the experiments of Perrin and others on the motion and equilibrium of small spheres of matter in suspension in fluids which show the Brownian movement. At the same time the atomic or discrete nature of electricity, which had been implicitly assumed in many theories, has received complete experimental verification, and the magnitude of this fundamental unit of charge has been measured with precision. The most accurate experiments on this subject have been made by Millikan by measuring the electric field required to support a small, charged droplet of oil or mercury. The charge on the drop was varied by ionizing the gas in its neighbourhood. In this way he has been able to show that the charge always varies by integral multiples of a fundamental unit. The charge given to a drop by friction or any other method is always an integral multiple of this unit charge. This fundamental unit is the same both for positive and negative electricity, and is numerically equal to the charge carried by the negative electron, the positive and negative ions produced in a gas by X-rays, and also to the positive charge carried by the hydrogen atom in the electrolysis of water. The magnitude of this unit charge, combined with electrochemical data, gives a most reliable method of measuring a number of important and molecular magnitudes. The value of the fundamental unit of charge and thus the mass of the individual atoms of matter are now known with an accuracy of certainly within one per cent and possibly within one-tenth of one per cent. The data found by Millikan are given in the following table:—

Fundamental unit of charge .	$e=4{\cdot}774\times10^{-10}$ electrostatic units
The Avogadro Constant, *i.e.*, the number of molecules in one gramme molecule . . .	$N=6{\cdot}062\times10^{23}$
The number of molecules per c.c. of any gas at 0°C. and 760 mms.	$n=2{\cdot}705\times10^{19}$
Mass of hydrogen atom in grammes	$m=1{\cdot}662\times10^{-24}$

From these data the number of atoms in one gramme of any element can be determined. While the average distance apart of the atoms or molecules can at once be deduced, the actual dimensions of the molecules or sphere of action of the molecules can only be approximately estimated with the aid of other and much less precise data.

Structure of the Atom.—Since the proof that the negative electron of small mass is a constituent of all atoms of matter, there has been a vigorous attack on the fundamental problem of the structure of the atom. After passing through a number of phases the general ideas on this subject have crystallized into a fairly definite form, and it is now generally believed that the atom is composed of a massive positively charged nucleus of minute dimensions surrounded at a distance by a compensating distribution of negative electricity in the form of negative electrons. Since electricity is atomic the resultant positive charge on the

nucleus must be an integral multiple N of the fundamental unit of charge e and is given by Ne. In order for the atom to be electrically neutral it must be surrounded by a distribution of N negative electrons. The value of N for each of the atoms is a fundamental constant, for on it depends the magnitude of the electric field surrounding the nucleus and the arrangement of the external electrons which in turn determine the main physical and chemical properties of the atom. The idea of the nuclear structure of atoms arose initially from a study of the scattering of α particles in their passage through matter. On account of its great energy of motion the charged α particle penetrates the structure of some of the atoms and comes under the influence of the intense repulsive field of the nucleus. Assuming that the law of force is that of the inverse square the α particle describes a hyperbolic path, and the angle of deflexion depends on the nearness of approach to the nucleus. From a close study of the scattering of α rays by Geiger and Marsden it was concluded that the number of α particles scattered through different angles was in close accord with the idea of the nucleus atom, while the actual number scattered through a given angle gave information on the magnitude of the charge carried by the nucleus. The preliminary experiments indicated that for the heavier atoms the value of N was about half the atomic weight in terms of hydrogen.

A notable advance was made by the fundamental experiments of Moseley on the X-ray spectra of the elements. He found that the X-ray spectrum was similar for all elements, and that the frequency of vibration of corresponding lines in the spectrum was proportional to the square of a number which varied by unity in passing from one element to the next. He concluded that the nuclear charge in fundamental units was equal to the atomic or ordinal number of the elements when arranged in increasing order of their atomic weights. On this view the lightest element, hydrogen, has a nuclear charge 1, helium 2, lithium 3, and so on up to the heaviest element, uranium, of ordinal number 92. This is a generalisation of great importance and simplicity which has guided all subsequent work on the structure of atoms. The essential correctness of Moseley's conclusion has been directly verified in the case of a few representative elements, by Chadwick by accurate measurement of the nuclear charge based on the scattering of α rays. Moseley showed that with few exceptions all values of the nuclear charge between 1 and 92 were represented by known elements. Moreover, when the atomic weight of the element in Mendeleeff's classification was replaced by its ordinal number certain irregularities were removed. For example, the positions of argon and potassium cobalt and nickel, iodine and tellurium were interchanged—a result in complete accord with their chemical properties (*see* CHEMISTRY).

The elements missing in the Moseley classification were of atomic numbers 43, 61, 72, 75, 85, 87. Since the X-ray spectra of these elements could be calculated with accuracy, it seemed likely that these missing elements, if present in appreciable quantity in the earth's crust, should soon be detected. The first element discovered by its X-ray spectrum was number 72 which was called hafnium by Hevesy and Coster. In a similar way, elements of number 43, 75, have been recently found in certain platinum minerals by Nonnack and Tacke, but have not yet been isolated. Thus the number of missing elements from hydrogen to uranium is reduced to three, viz., numbers 61, 85, 87.

It thus follows that the main physical and chemical properties of an element are defined by a whole number which represents both its nuclear charge in fundamental units and the number of external electrons. The atomic weight of an element is in a sense a secondary property, for, as we shall see, elements can exist of the same nuclear charge but of different atomic weights. The number and position of the external electrons, on which the ordinary chemical and physical properties of an atom depend, are defined by the nuclear charge. The mass of the atom which resides mainly in the nucleus exercises a subordinate effect on the external arrangement of the electrons.

Isotopes (*q.v.*).—On Moseley's classification only 92 elements of ordinal numbers 1 to 92 are possible, assuming that uranium (92) is the last of the elements. We shall now briefly discuss some recent advances which clearly show that in some cases several elements can exist with the same nuclear charge but of different atomic masses. Information on this point was first obtained from a study of the radioactive bodies. It was early observed that a number of products which showed different radioactive properties were inseparable from one another by ordinary physical and chemical methods. For example, ionium and thorium, radium and mesothorium, radium D and lead cannot be separated from each other, and appear to be identical in chemical properties. Elements so closely alike in chemical properties were called "isotopes" by Soddy, since they appeared to occupy the same position in the periodic arrangement of the elements. Viewed from the standpoint of the nuclear theory isotopes are elements of the same nuclear charge but of different atomic masses. As we have seen, the nuclear charge controls the ordinary physical and chemical properties of the atom, and the mass which resides almost entirely in the nucleus has only a second-order effect. On the other hand, the property of radioactivity depends on the structure and stability of the nucleus, which may be very different for atoms of the same resultant nuclear charge.

In the article on RADIOACTIVITY attention is drawn to the remarkably simple relation which exists between the chemical properties and radiations of the series of radioactive elements. With the aid of this relation we can at once write down the ordinal numbers and masses of the long series of elements which arise from the transformation of uranium, thorium and actinium, and can follow the origin of the numerous isotopes which arise. One of the most striking results of this generalisation was the prediction that the end product of the uranium and thorium series should be an element of the same ordinal number as lead but of atomic masses 206 and 208 respectively, instead of the mass 207 found for ordinary lead. This result has been directly confirmed by atomic weight determinations of uranium-lead and thorium-lead, and was the first definite proof of the existence of isotopes of a non-radioactive element.

It seemed probable that in a similar way many of the ordinary elements might consist of a mixture of isotopes, *i.e.*, elements with the same nuclear charge but different atomic masses. This has been confirmed in a number of cases chiefly by the work of Aston. The masses of the positively charged atoms present in the electric discharge in a vacuum tube are examined by bending the rays in a combined magnetic and electric field. In this way it was found that neon consisted of two isotopes of masses 20 and 22 and chlorine of isotopes of masses 35 and 37. The relative proportions of the two isotopes in chlorine was in good accord with that to be expected from the ordinary atomic weight of the mixture of isotopes, viz., 35·45.

This new method of analysis had, up to 1925, been employed for more than half of the elements and had yielded results of great interest. Some of the elements, like carbon, nitrogen and oxygen, give no isotopes, and are thus to be regarded as "pure" elements where the atoms have all the same mass and nuclear charge. Others, like chlorine, argon, krypton and mercury, are composed of a mixture of two or more isotopes. In cases like krypton and mercury as many as six well-defined isotopes have been detected. With few exceptions the masses of all the isotopes are expressed by a whole number in terms of O = 16 with an accuracy of about 1 in 1,000. For example, the isotopes of neon are 20·00 and 22·00. This important conclusion, which has been verified in a number of cases, affords a strong indication that the masses of the parts composing the nucleus have a mass either of one or a multiple of one, and are not direct multiples of the mass of the hydrogen atom which is 1·008 where O = 16. The reason of this will be discussed later. In a few cases, however, for example tin and xenon where the isotopes can be obtained together on the same record, Aston has pointed out that the whole-number rule obviously breaks down. It will be of great importance to determine the mass of all the isotopes with the greatest exactitude as the departure of the masses from whole numbers may provide valuable information on the structure of atomic nuclei.

While the ordinary physical and chemical properties of isotopes are closely similar, it is to be expected that they should differ in all qualities which involve directly the mass of the atom, *e.g.*, the coefficients of diffusion and specific gravity. In a similar way second-order effect is to be expected in the rate of vibration of the external electrons, *i.e.*, in the light spectrum of the element, and a small effect has been observed in several cases. The most obvious method of partial separation of isotopes is by the process of diffusion or evaporation. In this way a partial separation into light and heavy fractions has been shown in the case of neon, mercury and chlorine. No evidence of the separation of isotopes in nature has been so far observed except in the case of uranium-lead and thorium-lead already referred to. For example, chlorine obtained from widely different sources shows no difference in the relative proportions of its component isotopes.

Distribution of Electrons.—We have seen that the atom is to be regarded as an electrical structure in which a positively charged nucleus is surrounded by a number of electrons. The magnitude of the nuclear charge and the number of the external electrons are known for each of the elements. In considering the distribution of the external electrons round the nucleus, we are at the outset faced by the great difficulty that no possible arrangement can be permanently stable on the basis of the classical dynamics. For example, an electron in motion round the nucleus must on the classical theory radiate energy and fall into the nucleus. To overcome this fundamental difficulty Bohr has introduced a conception, based on the quantum theory (*q.v.*), in which radiation only occurs in definite quanta. This conception further developed by Sommerfeld and others has been almost completely successful in describing the properties of the simplest atom (hydrogen) with only one electron. It yields not only its natural frequencies but also the detailed changes which they undergo under the influence of electric and magnetic fields.

In atoms with more than one electron, success has so far been less complete. This is probably not entirely due to the mathematical difficulties of the classical problem of three or more attracting bodies (almost insuperable as these are) but even more to deep seated inadequacies in the modifications of classical theory required by atomic theory. The simple modifications introduced by Bohr with success for hydrogen await further development. In spite of this, however, the theory in its present form has already won marked successes. It has accounted successfully for the general structure of the spectra of all atoms and their resemblances to the spectrum of hydrogen, for the general arrangement and actual magnitudes of their X-ray spectra, and for the close analogies which these exhibit to optical spectra. It has enabled the grouping of the electrons in all atoms to be determined, with rough estimates of the size of the orbits to which they are confined. The later developments of the theory (Main-Smith, Stoner) seem to present the details and subgroups of electrons in the atom with some approach to finality, in harmony with all the physical and chemical evidence.

The theory has succeeded in accounting naturally for the form of the periodic table of the elements, especially the occurrence of the transition groups of elements ending at copper, silver and gold, and for the occurrence of the chemically similar rare-earths. It has therefore already played a great part in the simplification and co-ordination of facts of value. Its developments seem likely to supersede suggestions as to the grouping of the electrons in the atom which have been advanced previously from time to time—notably by Kossel, Lewis, Langmuir, J. J. Thomson, with certain measures of success in explaining the periodic table of the elements and the methods of chemical combination. These earlier theories were, however, for the most part descriptive rather than qualitative in character—to a far greater extent than the theory initiated by Bohr. The whole problem of the distribution and motion of the electrons in a complex atom is a very difficult one. While definite progress had been made by 1921, and great advances between 1921 and 1925, much still remains to be done before we can hope to specify with any degree of quantitative completeness the motion, position and mode of vibration of the electrons in any atom of two or more electrons.

Structure of the Nucleus.—While it is difficult to estimate the dimensions of atomic nuclei, the general evidence indicates that the nucleus of a heavy atom like uranium, if assumed spherical, has a radius of less than 10^{-11} cm. or less than 1/1000 of the radius of the external atom. No doubt the dimensions of a nucleus depend on its complexity and are much smaller for the lighter atoms. From experiments on the passage of α particles through hydrogen, it has been calculated that the dimensions of the helium nucleus of mass 4 is of the order 10^{-12} centimetres.

The most direct evidence on the constitution of the nucleus is derived from the study of the radioactive transformations. The disintegration of an atom is accompanied either by the expulsion of an α particle, *i.e.*, in helium nucleus, or the release of a swift electron from the nucleus. This shows that the nucleus of the radioactive atoms contains both positively charged masses and negative electrons, and that the nuclear charge represents the resultant charge. It is natural to conclude that the helium nucleus of mass 4 is one of the secondary units which make up the structure of a complex nucleus. This is supported by the observation that the atomic mass of many atoms is expressed by 4^n where n is a whole number. It is clear, however, from the work of Aston on isotopes that, in addition to the helium nucleus, an element of mass 1 or integral multiple of 1 enters into the structure of all nuclei. This fundamental unit of structure has been named "proton," and its atomic mass is 1 or very nearly 1 in terms of O = 16. On this view the nuclei of all elements are made up of positively charged protons and electrons. The mass of the atom measures the number of protons in the nucleus. This is in a sense a return to the famous hypothesis of Prout according to which all the atoms are supposed to be built up of hydrogen as the fundamental unit.

It seems clear that if a proton could be removed from an atomic nucleus it would prove to be the hydrogen nucleus carrying a unit positive charge. In fact, Rutherford and Chadwick have shown that the hydrogen nucleus can be liberated from certain light atoms by bombardment with swift α particles. It remains, however, to explain why the proton in a nucleus has a different mass from the free hydrogen nucleus. The latter has a mass 1·008 in terms of O = 16 while the proton in the nucleus has a mass unity, or nearly unity.

While the negative unit of electricity exists in the form of the electron of very small mass, no evidence has been obtained that its counterpart, the positive electron of very small mass, exists. The unit of positive electricity has never been found to be associated with a mass less than that of the hydrogen atom. This has led to the view that the hydrogen nucleus is the *positive* electron, and that its mass is about 1,845 times that of the negative electron. This difference in mass between the units of positive and negative electricity appears to be fundamental, and offers an explanation of the asymmetrical distribution of positive and negative electricity in the structure of atoms.

Since the helium nucleus has a mass 4 and charge 2, it should be composed of four hydrogen nuclei and two electrons. Its mass, however, is less than that of four free hydrogen nuclei. Such a change of mass in the very close combinations of positive and negative nuclei is to be expected. According to the theory of relativity energy has mass, and the loss of mass m of a system is numerically given by $E = mc^2$ where E is the energy liberated and c the velocity of light. On this view the combination of the positive and negative electrons to form the helium nucleus is accompanied by a large release of energy. From the difference between the mass of the helium nucleus and that of four hydrogen nuclei, it can readily be calculated that the helium nucleus is such a stable combination that an amount of energy corresponding to four or five α particles from radium would be required to dissociate it. The difference between the masses of the protons in the nucleus and free hydrogen nuclei is thus to be ascribed in general to the close packing of the positive and negative units composing the nucleus.

On the views outlined above the number of electrons in any nucleus can at once be calculated. For example, oxygen of nuclear charge 8 should be made up of 16 positive units and 8

electrons. For such a nucleus to hold together it seems clear that the forces between the charged units at such small distances must be different from that of the inverse square. While it has been experimentally shown that the law of the inverse square holds at any rate approximately close to the nucleus of a heavy atom like gold, this law breaks down in very close collisions of light atoms where the nuclei approach very close to each other. For example, it has been found that the number of hydrogen atoms which are set in swift motion when α particles pass through hydrogen is very different from that to be expected if the nuclei behave as point charges repelling each other according to the law of the inverse square.

By studying the scattering of α particles by the light elements, aluminium and magnesium, it has been found that the law of the simple inverse square no longer holds close to the nucleus. The experimental information at present available is too indefinite to hazard more than a guess as to the nature and magnitude of the forces that come into play when nuclei approach very close to one another, as they must do in the structure of the nucleus of a heavy atom.

Stability of Atoms.—Apart from the heavy radioactive elements which belong to a class by themselves, and two other elements—potassium and rubidium—which spontaneously emit swift electrons, the atoms of the ordinary elements appear to be very stable structures which cannot be broken up by ordinary chemical and physical agencies. In considering the possibility of the disintegration of elements it should be borne in mind that the loss of one or more electrons from the outer electronic system has no permanent effect on the atom, for other electrons ultimately fall into the atom to fill their place. In order to produce a permanent transformation of the atom it appears necessary to remove a positively charged particle or an electron from the nucleus of the atom. This can only be effected by agencies which are able to penetrate the nucleus or to pass very close to its structure.

A number of experiments have suggested that possibly helium and hydrogen may be liberated by the passage of an electric discharge through gases, but on account of the presence of these elements in many materials it is difficult to prove definitely that they arise from artificial transformation. During the last few years there has been a vigorous attack on the question whether transformation of nuclei can be effected by the action of intense electric discharges through gases or vapours. By passing a heavy current through mercury vapour, it is claimed that gold is produced in appreciable quantity. By a similar mode of procedure it is stated that lead can be converted into mercury. For obvious reasons, it is very difficult to be certain that the elements observed were not originally present in some form in the material subjected to the electrical discharge. In the cases mentioned above, we should have expected that the gold or mercury would have a different atomic weight from ordinary gold but definite evidence on this point is not yet available. The whole question whether transformation of atomic nuclei can be produced in such a comparatively simple way and on such a large scale is still *sub judice*. The energy of the electrons in the discharges used is in general small compared with that of the α particle, with the aid of which transformations on a minute scale were first shown.

The α particle expelled from radium is one of the most concentrated sources of energy known to us, and on account of its speed should be able to penetrate the structure of the nuclei of many of the lighter atoms, and still retain sufficient energy to disrupt the bonds that hold the parts of the nucleus together. In the case of an atom of high nuclear charge the α particle may lose so much of its energy in approaching the nucleus that it may be unable to effect its disintegration. It has been found that when α particles pass through hydrogen or any material containing combined hydrogen, some of the particles pass so close to the hydrogen nucleus that they set it in swift motion. These swift hydrogen atoms can be detected by the scintillations they produce on a zinc sulphide screen. This is purely a case of collisions of atomic nuclei, and the speed of the H atom set in motion can be calculated by the ordinary laws of mechanics. The maximum range or distance of penetration of such a particle is about four times that of the incident α particle.

In a similar way other nuclei must be set in swift motion by their collision with α particles, but it can be calculated that in most cases such nuclei are unable to travel as far as the α particle, and thus remain undetected amid the great number of incident α particles.

Rutherford showed that when a strong beam of α particles passes through oxygen or carbon dioxide, only a few H atoms of a penetrating type are present and these appear to have their origin in the radioactive source. When, however, the rays pass through dry nitrogen, a much larger number of penetrating particles is observed. By bending these particles in a magnetic field, it is clear that these swift particles are not charged atoms of nitrogen but projected hydrogen nuclei. These H particles are detected by the scintillations they produce in falling on a screen of zinc sulphide, and progress in this line of work has been much facilitated by the designing of special counting microscopes of wide aperture which have a large field of view. Rutherford and Chadwick found that in addition to nitrogen, swift H particles are liberated from boron, flourine, sodium, aluminium and phosphorus. By a variation in the method, similar H particles, but of lower speed, were observed from neon, magnesium, silicon, sulphur, chlorine, argon and potassium. Kirsch and Petterson claim that H particles are also liberated from carbon and oxygen, but this question is still *sub judice*.

It seems clear that these H particles are liberated from the nuclei of these elements by the bombardment of α particles and in a sense we may say that these nuclei have undergone a nuclear transformation with the ejection of a proton at high speed. For elements like B, N, Na, Al, P, the velocity of expulsion of the H particles is in all cases greater than that for a free H atom in a close collision with an α particle. For example, using α particles of range 7·0 cm. in air, ordinary H atoms can not travel further than 30 cm. of air. On the other hand, the H particles liberated from nitrogen travel 40 cm. and from aluminium 90 cm. It is thus certain that H particles observed from the elements given above cannot be due to the presence of ordinary hydrogen as an impurity. In the case of aluminium, a few of the H particles are released with more energy than that of the α particle which effects their release. No certain evidence has yet been observed that other types of particles are set free in these disintegrating collisions. It might have been expected that nuclei of mass 2 or 3 or 4 should also appear in some cases, as there is some evidence that secondary units of this kind go to build up atomic nuclei.

It is of interest to note that the protons set free by the α particles appear to be ejected equally in all directions, although their speed is somewhat greater in the forward direction of the α particle. This difference is no doubt due to the fact that the bombarded nucleus is set in motion by the collision.

It is difficult to be certain of the mechanism of these collisions and in particular whether the bombarding α particle is captured by the nucleus when the proton is liberated. By photographing several hundred thousand tracks of α particles in nitrogen by the Wilson method, Blackett has observed a number of collisions, involving the escape of a high speed proton. There is, however, no trace of the α particle after the collision, indicating that it is captured by the nucleus. If this be the case, the nucleus gains an α particle of mass 4 and loses a proton of mass 1. No definite evidence of the mechanism of the collision is as yet available for the other " active " elements.

It should be borne in mind that the disintegration observed in this way is on an exceedingly small scale. Not more than 10 particles in a million get sufficiently close to a nucleus to release an H atom. It seems clear, however, that while the ordinary atom is undoubtedly very stable, its disintegration can be brought about by the aid of sufficiently powerful agencies which are able to penetrate its structure. As already pointed out, there are strong reasons for believing that the helium nucleus is a very stable structure which cannot be broken up even by the swiftest α particle at our disposal.

While it is reasonable to suppose that all the elements have been built up by combinations of protons and electrons, there was in 1925 little evidence to throw light on the conditions necessary to lead to the formation of complex nuclei. No doubt, however, this process of aggregation has gone on in the past, and may still be in progress under favourable conditions, if not on this earth, at any rate in some of the stars. (E. Ru.)

MAUDE, SIR FREDERICK STANLEY (1864–1917), British soldier, son of Gen. Sir Frederick Maude, V.C., was born at Gibraltar June 24 1864. He entered the Coldstream Guards in 1884, took part in the Suakin operations, 1885, and joined the Staff College in 1895. In the South-African War, as brigade-major of the Guards Brigade, he took part in the advance to Pretoria. After a spell in Canada as military secretary to the governor-general, he took an active part in the development of the organisation and training of the new Territorial Force. On mobilisation in Aug. 1914 he was posted to the staff of the III. Army Corps and served in France until June 1915. In Aug. he was hurried out to the Dardanelles to take up command of the 13th Division. There he played a conspicuous part in the evacuations of Suvla and of Helles, and in 1916 his division was dispatched from Egypt to Mesopotamia to aid in the relief of Kut-al-Imara. They arrived in time to bear a share in the final desperate endeavours to save the doomed stronghold, but the effort came to naught and after the surrender of Kut-al-Imara, Maude and his division remained facing the Turks on the Tigris. He was advanced in Sept. to the position of army commander in Mesopotamia.

Realising that victory in this theatre of war must hinge on effective organisation and adequate preparation, Maude spent three months at Basra, ensuring that when the time came his field army should be capable of acting with vigour and decision. Then, when all was ready early in Dec., he suddenly pushed forward and within a few weeks had driven the Turks in confusion out of their entrenched camp around Kut. Moving relentlessly on, and making great captures, he occupied Baghdad March 11. He spent the next few months consolidating his position and preparing plans for a fresh offensive. He was, however, struck down by cholera, and died at Baghdad Nov. 18 1917. His conquest of Mesopotamia and his transformation of a depressing situation into one of signal triumph ranks as one of the finest feats in modern military history. (*See* MESOPOTAMIA, OPERATIONS IN.) See Maj.-Gen. Sir C. E. Callwell, *Life of Sir Stanley Maude* (1920).

MAUNOURY, MICHEL JOSEPH (1847–1923), French soldier, was born at Maintenon (Eure-et-Loir) Dec. 11 1847. Commissioned to the artillery from the École Polytechnique in 1869, he saw service in the Franco-German War, and in 1883 was placed on the staff at the military school of St. Cyr. He retired in 1912, having been military governor of Paris and a member of the Conseil Supérieur de la Guerre. On Aug. 19 1914 he was given charge of the army improvised in Lorraine from the reserve divisions, and was entrusted with the investment of Metz. On Aug. 24 he made a brilliant attack on the left flank of the V. German Army; and when, on Aug. 26, a new VI. Army was assembled on the Somme, the command was given to Gen. Maunoury. It was this army, which, on Sept. 4, was launched against the flank of Von Kluck's I. Army—an action which opened and exercised a decisive influence on the battle of the Marne. Maunoury continued to command the VI. Army throughout the development of the Aisne line of battle and in the early phases of trench warfare. On March 15 1915 he was severely wounded, and thereafter held no active command. From Nov. 1915 till March 1916 he was Governor of Paris. He died on March 28 1923 and was created marshal of France posthumously.

MAURA, ANTONIO MONTANER (1853–1925), Spanish statesman, was born in Palma de Mallorca May 2 1853. He was educated at Valencia and Madrid where he studied law. Though his pronunciation of Spanish was first defective, by perseverance and force of personality he became in later years a great forensic and parliamentary orator. Elected deputy for his native city in 1881, he joined the Liberal party; but his instincts were conservative and in 1901 he went over to the Conservative party of which he eventually became leader. He was a constructive statesman, and though the chaotic state of the Spanish political fabric inspired in him a desire for reform, he always regarded the constitution as sacred. In 1903 he became Prime Minister, and his zeal for reform made him many enemies among the corrupt political factions of Spain. He negotiated with France on the subject of Spanish rights in Tangier and Morocco and with Great Britain concerning the *status quo* of the seas. In 1913 he resigned the leadership of the Conservative party, but, in response to appeals from the king, he formed governments in 1918, 1919 and 1921. True to his constitutional ideals, he refused to make common cause with the Directorate of 1923 which superseded parliamentary government in Spain. He died Dec. 13 1925.

MAUREL, VICTOR (1848–1923), French singer (*see* 17.907), died in New York Oct. 23 1923.

MAURICE, SIR FREDERICK BARTON (1871–), British soldier, was born Feb. 1 1871, and was commissioned in the Sherwood Foresters (Notts. and Derby Regiment) in 1892. He saw service in the Tirah campaign 1897–8 and the South African War 1899–1900 and from 1904 until 1914 held a series of general staff appointments, the last year as instructor at the Staff College. On the outbreak of the World War he was appointed General Staff Officer (1st grade) to the 3rd Div., British Expeditionary Force. He became brigadier-general, general staff, in 1915 and the same year he was advanced to the post of Director of Military Operations at the War Office. Here he was, during the middle period of the War, the intimate and valued assistant of Sir William Robertson, until the latter's resignation early in 1918. After the spring disasters Maurice wrote a letter to the Press challenging the accuracy of ministerial statements, considering them an attempt to shift the responsibility on to the army when several hundred thousand troops were retained in England to guard against a hypothetical invasion. By this act of moral courage he fulfilled his sense of honesty at the sacrifice of his career. Retired for the breach of discipline he became a military correspondent, and after the War, as Principal of the Working Men's College, St. Pancras, London, and Vice-President of the British Legion, was prominent in social work. His publications include *Forty Days in 1914* (1920); *Lord Wolseley* (with Sir George Arthur, 1924); *Robert E. Lee, the Soldier* (1925). (*See* WESTERN FRONT.)

MAURITANIA (*see* SENEGAL, 24.643).—This region of French West Africa, between the Senegal river and Rio de Oro, was constituted a colony in 1921. The area, including Saharan regions, is 154,000 sq. miles. The population, mostly Moors, *i.e.*, tribes of mixed Berber and Arab descent, is 280,000. Port Etienne, on Lévrier Bay, Cap Blanc, created since the occupation of the country by the French, is the seat of a growing fishing industry.

MAURITIUS (*see* 17.912).—A British crown colony in the Indian Ocean, 500 m. east of Madagascar. Its area is 720 square miles. The estimated population at the end of 1923 was 381,678. An influenza epidemic swept the island during the months of May, June, July 1918 when 11,000 persons died, the death-rate in that year reaching the high figure of 64·9 per thousand. Primary education is free but not compulsory. The total number of primary schools in 1919 was 148, of which 57 were Government schools and 91 schools receiving state aid. The number of pupils on the registers was 22,120. Of the state-aided schools 67 were Roman Catholic, 10 Church of England, two Mahommedan and one Hindu. In all schools under government inspection the teaching of elementary hygiene and sanitation is compulsory.

Finance and Trade.—The highest figures for the revenue of the colony were reached during the financial year 1920–1 when the total revenue was rupees 40,168,210; expenditure in the same year was Rs. 24,729,510. Figures for subsequent financial years were:—

	1921–2 Rs.	1922–3 Rs.
Revenue	25,599,994	23,547,734
Expenditure	26,307,658	22,031,176

At the close of the financial year 1923 the public debt of the colony was £1,265,724.

Sugar production remains the principal industry of the colony, the total average under sugar cultivation being in excess of 175,923 acres. A record sugar crop was produced during the crop year 1918–9 when the output of the sugar factories was 252,772 metric tons; the output for 1923–4 was 195,356 metric tons. The production of aloe fibre ranks next to sugar in order of importance; rum, copra, coconut oil are other products that have shown an increase. Increased attention has been given to tobacco growing and the cultivation of tea has progressed. Lectures and demonstrations in modern agricultural methods are given by the Government agricultural instructor. The total trade of the colony reached record figures during 1919 when the combined values for the year were Rs. 174,843,348—imports Rs. 47,037,024, exports Rs. 127,806,321. Imports for 1923 were valued at Rs. 76,835,565 and exports Rs. 69,841,935.

The total mileage of the railways on the island in 1923 was 144 miles. The Mauritius Govt. railway main line gauge is 4 ft. 8½ inches. The short Bois Chéri light railway has a 2 ft. 6 in. gauge. The mileage of telegraph lines in 1923 was 415½ m., and of telephone lines 169¼ miles. Cable communication is maintained with Zanzibar, Australia, Réunion, Madagascar, Durban and other places.

See A. Macmillan, *Mauritius Illustrated* (1914); also *Colonial Office List* (Annual Series, London); *Mauritius Blue Book* (Annual, Mauritius). (H. C. Wa.)

MAURRAS, CHARLES (1868–), French writer and politician, was born at Martigues, Provence, of a royalist family. He first became prominent through his literary criticisms in the *Revue Encyclopédique* and the *Gazette de France*. He was at first the only Royalist on the staff of the *Action Française*, but soon converted almost all his colleagues. After visiting Greece and Italy he published *Trois idées politiques* (1898); *Les amants de Venise* (1902); and *L'avenir de l'intelligence* (1905). This was his most productive period, during which his royalist propaganda exerted a powerful influence; he assisted Léon Daudet in transforming the *Action Française* into a daily paper, which took place in 1908, and soon became engrossed in journalistic work. In his *Kiel et Tanger* (1910) he criticised French foreign policy, while *Le dilemme de Marc Sangnier* (1906) dealt with religious problems. Though an avowed atheist, Maurras somewhat paradoxically favoured an alliance with the Catholic Church which he regarded as closely connected with the monarchy. And indeed the *Action Française* lost considerable influence when the French clergy withdrew their support and defeated Daudet during his candidature for Parliament in 1923 and 1925.

During the War Maurras worked for the disintegration of Germany and for an overwhelming victory for France. His war articles appeared in eight volumes entitled *Les conditions de la victoire* (1915–20). Though his polemical writing injured his literary fame, Maurras nevertheless gained the reputation of being one of the most accomplished of modern French authors; and his critical works, such as *L'étang de Berre* (1915); *Le conseil de Dante* (1920) and *L'allée des philosophes* (1924) are written in restrained but powerful prose. His poems, often of great beauty, were collected in *La musique intérieure* (1925). Though the writings of Maurras produced a profound effect on French thought, his influence on practical politics has been but slight; for his political theories suffer from extremism and exaggeration, both characteristics of his race. His nationalist ideas failed to take deep root in his own country, but they triumphed in Italy; and *L'Idea Nazionale* with its fascist doctrines owed much to the *Action Française*. The French movement with which the name of Maurras is associated may be regarded as an inchoate Fascism; a minor intellectual revolution, which has not developed into any great political upheaval. Among Maurras' many works may be mentioned the following: *Jean Moréas* (1891); *Le chemin de paradis* (1894); *Anthinéa* (1901); *L'enquête sur la monarchie* (1900–9); *La politique religieuse* (1912); *Quand les Français ne s'aimaient pas* (1916).

MAX, ADOLPHE (1869–), Belgian politician, was born in Brussels Dec. 31 1869. From 1894 to 1903 he was successively provincial councillor of Brabant, councillor of the Commune and alderman of Brussels, and finally burgomaster (1909). In 1914 when the German troops entered Brussels he refused to perform his duties under the authority of the German governor, and demanded complete freedom of action. He protested vigorously against the abuses of the army of occupation, and fought with indomitable energy for the rights of his fellow subjects, and for the reduction of the heavy taxes and requisitions which were imposed on the town. He further founded a central committee to deal with supplies which, under the name of *Le Comité National*, rendered invaluable services to his countrymen. But the German authorities soon took exception to his spirited resistance, and on Sept. 26 1914 he was arrested and imprisoned in the fortress of Namur, and from there was sent into Germany, where he was closely confined. On Nov. 13 1918 he succeeded in escaping and returned to Belgium, where he was welcomed with delirious enthusiasm. M. Max was elected to the Chamber of Representatives in 1919; he was made minister of state on Nov. 21 1918, and was also elected member of the Belgian Academy.

MAXIM, SIR HIRAM STEVENS (1841–1916), Anglo-American engineer and inventor (*see* 17.918), died in London Nov. 24 1916.

MAXIMILIAN (1867–), Prince of Baden, born June 10 1867 at Baden-Baden, was a son of Prince William of Baden. As the nearest agnate to the reigning grand duke, of whom he was a cousin twice removed, he was heir presumptive to the grand ducal throne. From 1907 to 1918 he was president of the First Chamber of the Baden Diet. During the War Prince Max did much to improve conditions for British prisoners in Germany, as also for German prisoners, especially in Russia. On Oct. 3 1918, when the old military and political system in Germany was on the verge of collapse, he was appointed Imperial Chancellor. It fell to his lot to initiate the negotiations for the Armistice, and also to carry through in hot haste those alterations in the old constitution which had long been demanded by the Liberals and the Socialists, but which now came too late to avert the fate of the Empire and the Prussian Monarchy. It also became his duty to put pressure upon the Emperor in order to induce him to abdicate. As the Imperial decision was delayed from day to day and the revolution became imminent, he declared on Nov. 9 1918 the abdication of William II. as German Emperor and as King of Prussia. It was clear that the Hohenzollern dynasty was doomed; and Prince Max handed over the Government to the majority Socialist leader Ebert, who became the president of the German Reich. He continued, after the abdication of the grand duke, to reside at Karlsruhe. (*See* Germany.)

MAXSE, SIR IVOR (1862–), British soldier, was born Dec. 22 1862 and was commissioned in the Royal Fusiliers in 1882, transferring to the Coldstream Guards in 1891. He served in the Sudan campaigns 1897–9, during which he gained the D.S.O., and in the Boer War 1899, as staff officer to Mounted Infantry and as commander of the Transvaal Constabulary after the capture of Pretoria. From 1902–10 he was regimental commander of the Coldstream Guards, and on the outbreak of the World War he went to France in command of the 1st Guards Brigade, which he led during the retreat from Mons and in the battles of the Marne and the Aisne. In Oct. 1914 he was promoted to the command of the 18th Division. He brought this division to France in 1915, and his unique training methods bore fruit in the battle of the Somme, where the 18th Div. obtained an opening success in brilliant contrast to the fate of other divisions on the tragic July 1 1916. As a consequence his promotion to command of the 18th Army Corps followed in Jan. 1917, and this he led with distinction down to, and including, the St. Quentin battle in March 1918. In 1917 he was created K.C.B.

The British Army was so sorely shattered in resisting the German offensive of 1918 that its reconstruction and transformation into the irresistible striking force of the autumn appears almost a miracle. In the glory of this achievement Sir Ivor Maxse has a notable share. The need for a unified direction of training was realised and he was chosen to be inspector-general

of training to the British Armies in France. By the development of the new tactics of infiltration and manoeuvre, by the improved co-operation between the different armies, and by the new elasticity of tactical handling, his work is engraved in the astounding success and low casualty list of the army during the advance to victory. After the War, at the hand of the Northern Command 1919–23, Maxse's influence in recasting the training of infantry and in making tactics intelligible to the novice was as marked as his practical achievement in the reorganisation of the depôt system. Dynamic in thought and energy, receptive to ideas, and generous in his support of youthful ability, he had a genius for training which was reminiscent of the influence of Sir John Moore, a century before. Sir Ivor contributed to this Encyclopædia the article INFANTRY.

MAYO, CHARLES HORACE (1865–), American surgeon, was born at Rochester, Minn., July 19 1865. After studying at the Rochester High School, Northwestern University and the Chicago Medical College (M.D. 1888), he began the practice of surgery at Rochester, Minn., and with his brother became surgeon at the Mayo Clinic. He made a special study of goitre, and as a result succeeded in reducing the death-rate in this class of cases by half. He has published a number of papers on surgical topics in medical journals. He was elected president of the Minnesota State Medical Society in 1905, president of the surgical section of the International Tuberculosis Congress in 1908, and president of the American Medical Assn. in 1916. He was appointed Mayo Foundation professor of surgery in 1915. During 1917–8 he was president of the examining board of applicants for commissions in the Medical Corps, having supervision over several states, including Minnesota. In 1918 he was appointed colonel in the Medical Reserve Corps, U.S.A., and for a year was associate chief consultant for surgical service. Beginning with 1912, graduate courses in medicine were offered at the Mayo Clinic in Rochester. Early in 1915 he and his brother incorporated the Mayo Foundation for medical education and research at Rochester, and to it the brothers gave $1,500,000. In June of the same year, by mutual agreement, the funds and resources of the foundation were placed under the direction of the regent of the University of Minnesota for promoting "graduate work in medicine and research in this field." On Sept. 13 1917 the Foundation, with its fully-equipped staff, laboratories and clinics in Rochester, became a department of that university. (*See* SURGERY.)

MAYO, WILLIAM JAMES (1861–), American surgeon, was born at Le Sueur, Minn., June 29 1861. He was graduated in medicine from the University of Michigan in 1883 and began the practice of surgery in Rochester, Minnesota. A small hospital was organised under the local branch of the Sisters of St. Francis, which developed into St. Mary's Hospital. Here he, with his younger brother, Charles Horace, developed the Mayo Clinic (organised 1889), which became famous throughout the world for the number and success of operations performed. The records of operations have been so carefully and accurately made and preserved that they form a valuable asset to medical science. Though the clinic has contributed no discovery of new methods or new cures for diseases, all modern methods have been covered and reduced to their ultimate accuracy. Accuracy has been the keynote to the Mayos' success. Goitre, gall bladder, appendix and gastro-intestinal operations constituted the great majority of the cases, and the proportion of deaths to the total number of patients operated upon was remarkably low. Dr. W. J. Mayo specialised in the surgery of the stomach, and published a large number of papers on gastric surgery and kindred topics. He was elected president of the Minnesota State Medical Society in 1895, and in 1907 was appointed a regent of the University of Minnesota. He was elected president of the Society for Clinical Surgery in 1911, and the following year president of the American Surgical Association. On America's entrance into the World War he was appointed a colonel in the Medical Corps, U.S. Army, and chief consultant for surgical service, alternating with his brother, C. H. Mayo, in this capacity. In 1919 he was awarded the medal for distinguished service. (*See* SURGERY.)

MAYOR, JOHN EYTON BICKERSTETH (1825–1910), British classical scholar (*see* 17.937), died at Cambridge Dec. 31 1910.

MEAD, LARKIN GOLDSMITH (1835–1910), American sculptor (*see* 17.945), died at Florence, Italy, Oct. 15 1910.

MEASLES: *see* INFECTIOUS FEVERS.

MEASUREMENTS (*see* 18.134).—The science of measurement is in practice restricted to mean measurement of the three fundamental quantities, mass, length and time, from which all other quantities, such for example as volume, density, velocity, acceleration, force and power, are derived. The problem of measurement of these three fundamental quantities presents itself primarily as a question of providing suitable units of reference against which other quantities whose values it is desired to measure may be compared.

Importance of Metrology.—On the purely scientific side all other scientific quantities are ultimately definable in terms of the three fundamental quantities with which metrology deals, and every quantitative determination resolves itself in the last resort into a measurement of one or other of these quantities. If "science is measurement" then without metrology there is no science. Even in its most direct application it covers a very wide field (*see* MENSURATION [15.134]; SURVEYING; GEODESY; EARTH, FIGURE OF THE [8.801]; MICROMETER [15.38]; TOOL, PART 13 [27.43]; MEASURING INSTRUMENTS; TIME [26.983]; CLOCKS [6.536]; WEIGHTS AND MEASURES [25.477]; WEIGHING MACHINES [25.468]; METRIC SYSTEM [15.299]). The question of the time standard, moreover, is particularly an astronomical one.

The specification of any quantity involves two factors. If we speak of three pounds, two metres, or 24 hours, in each case the complete statement consists of firstly a pure numeric, and secondly of a unit of measurement which is either the fundamental unit of reference, or a definite multiple or submultiple of it. The reference units in themselves are entirely arbitrary. There is no "absolute" standard; all measurement is relative.

Problems Involved.—The problem of metrology is twofold. First to provide and maintain unaltered the standards of reference by which other quantities are compared and measured; and Secondly to provide means by which the comparisons may be made with accuracy sufficient for the particular purpose in view. The demands of science and industry at the present day require, for certain purposes, an extremely high degree of accuracy in these fundamental comparisons, so that what, at first sight, would appear to be a fairly simple problem becomes in fact one of great difficulty, involving the most expensive and elaborate apparatus. No measurement is ever absolutely correct. Some degree of experimental error is always necessarily present, and the approximate degrees of accuracy at present attainable in certain of the more fundamental operations in metrology, are as follows:—

Comparison of two platinum-iridium copies of the International Prototype Kilogramme: 1 part in 100,000,000.
Comparison of ordinary chemical weights: 1 part in 1,000,000.
Comparison of smaller masses by micro-balance: 1 part in 100,000,000.
Comparison of two yard or metre (line or end) standards: 1 part in 10,000,000.
Comparison of end standard with line standard: 1 part in 1,000,000.
Determination of volume and density for very special work: 1 part in 1,000,000.
Determination of volume and density, ordinary: 1 part in 10,000.
Calibration of set of end standards (not less than 1 in. in length): 1 part in 1,000,000.
Calibration of subdivisions of graduated yard or metal scale in terms of whole length: 0·000005 in. or 0·0001 millimetre.

STANDARDS OF LENGTH

The history of standards of length is one of varying ascendency of three principal competing types. A length may be defined by the distance, under certain specified conditions, either between the two end surfaces of a material standard bar, or between two suitable marks engraved upon it. Alternatively reference may be made to some "natural" standard. The standard yards of Henry VII. and Elizabeth preserved in the Standards Department of the Board of Trade, are end standards, incisions marking subdivisions of the yard being secondary only. The

Elizabethan yard was superseded by one defined by the distance between two small dots on gold plugs inserted in it. When this bar was legalised in 1824, it was provided that in the event of loss it should be replaced by reference to a "natural" standard, the length of the pendulum beating seconds in the latitude of London. It so happened that within a very short period this standard was in fact destroyed by the fire in the Houses of Parliament in 1834.

The commission charged with its replacement found, however, that it was impossible to reproduce the seconds pendulum with so high an accuracy as the length of the bar itself could be reproduced by means of direct comparison with other bars which had previously been compared with the lost standard. The legal prescription was therefore abandoned, and the new standard yard, which is that legal at the present day, is a line standard constructed by comparison with other bars, without reference to any control provided by a natural standard. The metre was originally intended to be the 10,000,000th part of the earth's meridional quadrant. But it was soon found that not only was the determination of this natural standard an extremely laborious undertaking, but the accuracy attainable was less than that possible in the comparison of material standards, and the material Mètre des Archives, a platinum end standard, became the accepted standard of reference for the metric system until superseded in 1889 by the present International Prototype Metre, a platinum iridium line standard (*see* WEIGHTS AND MEASURES).

Wave Lengths as Natural Standard.—At the date of construction of the present Imperial Standard Yard, and the International Prototype Metre, sound judgment was exercised in the choice of material line standards as affording the greatest prospect of accurate comparison and reproduction and in the legal provision made for their replacement, if necessary, by reference to other similar standards periodically compared with them. Recent developments, however, have appreciably changed the situation. In the first place the experiments of Michelson, followed by those of Fabry and Perot (*see* INTERFERENCE OF LIGHT, 14.685) have finally established a natural standard (the wave length of the red line in the spectrum of cadmium) which is reproducible with accuracy at least as great as that attainable in the comparisons of material standards, which is definitely free from the suspicion of possible secular variation inevitably attaching to all material standards, and by means of which the material standards necessarily employed in everyday practice can be verified in any part of the world without the risk of accident or damage involved in the periodical transport of material national reference standards to and from the international century laboratory for purposes of comparison with the prototype. Secondly, such improvement has been effected during the last few years in the production of flat-ended standards that bars with accurately parallel ends of the quality of optical mirrors are now available, whose lengths can be more directly determined by the method of optical interference than is the case with line standards, and which are also more accurately comparable with each other than the latter.

The International Committee on Weights and Measures, at its meeting in 1923, decided in principle on the eventual adoption of a wave-length standard of length subject to the determination by experiment in the various national laboratories, of the best method of realising such a standard and the conditions necessary to ensure the greatest degree of constancy in its reproduction. Such experiments are proceeding and it is to be anticipated that within the period beginning in 1925 or 1926 a very important change may be made in the ultimate basis of reference for all measures of length.

Use of Material Standards.—Whatever ultimate basis of control may be selected, for practical purposes, in everyday measurement, material standards will always be needed. Both line standards and end standards will always be required for different purposes. So long as material standards are used for the ultimate reference the primary importance attaches to secular stability of the material. There is evidence to suggest that the present imperial standard yard has probably shortened by about 0·0002 inch since it was originally constructed in 1844, but has remained unchanged for the last 40 years. So far as is known, the international prototype metre has remained unchanged since its verification (1875–9). The evidence for this rests partly on subsequent recomparison with various national copies constructed in the same manner at the same time, and partly on two determinations, by different methods, at an interval of about 15 years, the first by Michelson and Benoit, and the second by Fabry and Perot, against the wave length of the red line of cadmium. These metre standards are all made of an alloy of 90% platinum and 10% iridium, which is now regarded as the most satisfactory alloy for the construction of a material standard for purposes of ultimate reference. Its cost, however, would be prohibitive for any other purpose.

Temperature Conditions.—All materials change in size to a greater or less degree with variation of temperature. It is therefore essential to specify exactly the temperature at which the material standard defines the unit of length, and further either to control the standard exactly to this temperature when making comparisons with it, or at least to ascertain its temperature exactly, and make allowance for its known expansion between that temperature and the standard temperature. The Imperial Standard Yard is correct at 62° F., the International Prototype Metre at 0° Centigrade. Some confusion of thought frequently arises on this point. Each of these bars serves, at its own standard temperature, to define a simple unit of pure length, that is, of absolute extension in space. These units themselves, once determined, are entirely independent of temperature. It is not correct to say that either of the fundamental reference standards is a yard, or a metre, except at its appropriate temperature of definition, 62° F. or 0° C., respectively, nor that a length of any other material is a yard or a metre solely because at 62° F. or at 0° C. it agrees with the fundamental standard. A length of any material is a yard or a metre, at whatever temperature it may be, if at that particular temperature the length is equal to the unit defined by the standard bar when the latter is at its own temperature of reference. There is a definite numerical relationship between the two principal units which has been twice accurately determined: in 1895 by Chaney and Benoit, with the result 1 metre = 39.370113 in.; and more recently (1922–5) at the National Physical Laboratory, with the result 1 metre = 39·370137 inches. The two results may be said to be in agreement within the experimental error of the various observations involved, and for all practical purposes the simple ratio 1 in. = 25·4 mm. (equivalent to 1 metre = 39·370079 in.) may be taken as sufficiently exact.

The use of this ratio implies that the two objects, being compared, are both simultaneously at their common temperature of employment. For all everyday purposes of measurement, as for example in measuring a piece of work in an engineering workshop, it is unnecessary to bring the object to be measured to the standard temperature. If the work and the gauge with which it is being measured are made of materials having the same coefficient of expansion, and the former has been compared with the reference standard at the standard temperature, it is only necessary, when comparing the work with the gauge, to ensure that both are at the same temperature (not necessarily the standard temperature) to ensure that the work will be correctly measured.

Use of Invar.—For many purposes where very precise measurement is involved, it is of great advantage to have a material with a very small thermal expansion. Two such materials have been discovered. The first, known as "Invar," is a nickel-steel alloy, containing 36% of nickel, invented by Dr. Ch. Ed. Guillaume of the Bureau International (Sèvres). Different samples have coefficients ranging from about 1.5×10^{-6} per 1° C., for large bars, down to zero, or even slightly negative values, for smaller bars, pendulum rods, drawn wire or rolled tape. These figures are to be compared with 11×10^{-6} per 1° C. for steel, and 18×10^{-6} per 1° C. for brass. Invar, unfortunately, has one very serious defect as a standard of length. It grows longer, rapidly at first and subsequently more slowly but continuously, so that after

20 years the length of a bar of invar will still be increasing at a rate of about 1 part in 2,000,000 per annum. More recently Dr. Guillaume has introduced a slightly different alloy, containing a percentage of chromium in addition to the nickel, which is described as "stable" invar. This alloy grows at an appreciably slower rate than ordinary invar, but still cannot be regarded as constant. Invar therefore is principally useful in a laboratory, in work where temporary constancy of length is the primary consideration, or in circumstances, as for example in the case of tapes and wires used for geodetic surveying, where the accurate ascertainment of temperature presents considerable difficulty. In these cases it is necessary to return the tapes or wires to the laboratory periodically for reverification. For the reasons indicated above, in everyday workshop measurements, gauges or scales should be made of material having a similar coefficient of expansion to the work to be measured, and invar therefore should not ordinarily be used for the construction of workshop standards.

Fused Silica.—The other material which has a very low coefficient of expansion is fused silica, which expands only $0{\cdot}4\times10^{-6}$ per 1° Centigrade. A metre standard constructed of fused silica, in the form of a tube, with parallel plates fused in at the ends on the platinised surfaces of which the defining lines are ruled, has been made and kept under observation at the National Physical Laboratory since 1913. So far as can be detected, no change has occurred in its length. Such a standard is extremely fragile, and for this reason would hardly be adopted either as a fundamental reference standard or for everyday use, except in a metrological laboratory.

Natural Crystal Quartz.—Reference should be made to the recent work of Perard, at the Bureau International, on end standards of natural crystal quartz. Such standards cannot, of course, be of the full length of the yard or metre. But they present several great advantages. Firstly, since the material is of great age and the molecules of which it is composed are arranged structurally in definite crystallised array, there seems little possibility of any secular change. Secondly, it lends itself to perfect optical finish of the defining end planes, which enables direct determination of length to be made in terms of light waves, with extremely high precision resulting in a proportional accuracy no less than is at present obtained in the comparison of yard or metre line standards, although the largest available specimens of crystal quartz, as well as the method of use, only enable such standards to be made and verified up to a length of about 4 inches.

Line Standards; Mode of Comparison.—The comparison of two line standards is effected as follows: The bars are placed side by side, each on one of two parallel girders contained in a water bath, which is mounted on a carriage capable of being moved in a direction perpendicular to the length of the bars. The bars are constructed with their graduations on polished surfaces in the neutral plane of their cross section, and each is supported on two rollers spaced at such a distance apart that the distance between its graduation marks has a maximum value. Under these conditions any changes in the flexure of the bars due to slight errors in the positions of the supports can have no effect on the measured distances between the graduations. Two micrometer microscopes (*see* MICROMETER, 18.381) are rigidly held in brackets supported in such a manner as to be unaffected by the motion of the carriage. Each girder has independent adjustments by means of which the lines on the bars can be brought into focus in the field of the microscopes. The water in the bath is stirred and the temperature read by means of accurately calibrated thermometers. Readings are taken by means of the microscopes alternately on the defining lines of each bar, and the mean of several independent readings is taken. The comparison is repeated with each of the bars turned end for end in turn in order to overcome any effect of asymmetry in the illumination of the graduation marks, and the bars are then interchanged on the two girders and the whole repeated once more, making eight complete sets of readings in all, from which the difference in length between the two bars is finally computed. In an important determination several bars (say six or eight) may be included, and each will be completely compared in the manner described above, against all the others, the best values for the differences between all the various bars being then computed from the individual observed differences by the method of least squares (*see* PROBABILITY, 22.376), the residual errors serving to indicate the degree of accuracy which has been attained in the work.

Calibration.—The calibration of the subdivisions of a divided scale is done in a similar way, except that in this case the carriage of the comparator moves in the direction of the length of the bar. The microscopes are fixed successively at a series of suitable intervals apart, for example, 1 dm., 2 dm., 3 dm., etc., and each principal interval of 1 dm., 2 dm., etc., is compared with every other interval of the same magnitude throughout the metre. By computation from the results so obtained the value of each decimetre is determined in relation to the whole length of the scale. In a similar manner each centimetre of one decimetre is compared with every centimetre of another decimetre, and as a result the value of each centimetre is found in relation to the whole of the other decimetre, and so in turn, in relation to the whole length of the metre. Millimetres are derived from centimetres in the same way, and so on. The complete calibration of a divided scale will be seen to be a very laborious process involving an enormous number of observations. The process is, however, simplified by the fact that the whole of the measurements are made on the one bar, so that, provided reasonable precautions are taken to ensure constancy of temperature, exact temperature measurements are not important.

The apparatus used to determine coefficients of expansion is similar to the transverse comparator, but has two independent water baths mounted on the carriage. One of these, containing a bar preferably of invar, is kept at a constant temperature, while the other, containing the bar under examination, is brought successively to a series of suitable temperatures. The two bars are compared under the microscopes at each temperature of the second, and so the variations of its length with temperature are determined.

A number of machines of different types, and varying sensitivity, are available for comparing end standards by contact measurement, or, if the end faces are of sufficiently perfect finish, they may be directly compared by the method of optical interference. In the latter case the two bars are brought in turn between two semi-silvered optically flat glass surfaces, and the number of wave lengths in the small spaces at either end between the measuring surface of the bar, and the semi-silvered surfaces of the optical flats are determined by direct measurement of the angular diameters of the interference rings formed by monochromatic light. This enables the fraction of a wave length to be determined with exactness, and if several different wave lengths are used in turn, whose mutual ratios are known, the whole number of waves is easily determined by deduction, as only a particular set of corresponding whole numbers will give fractions agreeing in every case with the series actually observed.

In the mechanical contact type of measuring machine the bar is measured between two opposed anvils, one of which may either be fixed, or may be movable by means of a micrometer screw, while the other is capable of a small movement operating some form of sensitive indicator. The two bars to be compared are inserted in turn between the anvils, and if the whole difference between them is sufficiently small the movement of the indicator over a calibrated scale may suffice to determine it. If the difference is greater, the indicator must be brought to a fixed mark by an adjustment of the moving anvil, the difference in length being then ascertained by the difference in reading of the micrometer wheel.

Mode of Calibration of End Standards.—The calibration of a set of subdivisional end standards is effected by taking them together in pairs of nominally equal added lengths, and comparing their sums, in the manner just described. In the last 20 years there have been developed, first by the firm of C. E. Johansson, Sweden, and later at the National Physical Laboratory, England, and by Hoke in America, methods of producing short flat ended gauges of such perfection that any two of them if put together will adhere firmly to each other by "wringing." The process of wringing is not yet fully understood, but appears to depend essentially on the presence of a very minute trace of liquid (grease or moisture) between the surfaces of the gauges. These gauges are usually made in series, *e.g.*, 1 in., 0·9 in., 0·8 in. . . . 0·1 inch. Suppose we wish to calibrate such a series, of which the 1 in. is supposed to be already known as the result of some previous calibration. For convenience we will assume that we have available a duplicate set of pieces, which we denote by 0·1′, 0·2′, 0·9 foot. To determine, for example, the value of the 0·7-in. gauge, we wring up in turn all the various nominally equal combinations indicated below, and compare them in a suitable measuring machine, the small observed differences being indicated by

0·7		=		0·7	0	0·7	0·5	=	1·0	0·2	5
0·7	0·1	=		0·8	1	0·7	0·6	=	1·0	0·3	6
0·7	0·2	=		0·9	2	0·7	0·7	=	1·0	0·4	7
0·7	0·3	=	1·0		3	0·7	0·8	=	1·0	0·5	8
0·7	0·4	=	1·0	0·1	4	0·7	0·9	=	1·0	0·6	9

Adding up all these equations we see that the sums of the second columns on either side cancel out, and we get

$$10\times0{\cdot}7 = 7\times1{\cdot}0 \qquad \begin{matrix}9\\0\end{matrix}$$

or

$$0{\cdot}7 = \frac{7}{10}\times1{\cdot}0 \qquad \frac{1}{10} \qquad \begin{matrix}9\\0\end{matrix}$$

The sizes of each of the other pieces may be determined in a precisely similar manner.

It may be noted that in the determination of sizes in this manner, the length of each gauge is automatically associated with the thickness of one wringing film, which, for clearness in conception, may be regarded as representing half a film thickness on either end surface, so that when two gauges are wrung together a whole film is established between them. As the gauges are normally used in this manner, this result is logically what is required. The wringing films, moreover, are in any case exceedingly thin. When initially formed, their thickness depends to some extent on the viscosity of the liquid of which they are composed, but if a sufficient length of time is allowed to elapse they tend to thin down to a limiting thickness which is less than 0·000001 in. for all liquids.

There is one more fundamental operation which, whatever may be the nature of the ultimate standard adopted, will always be required in its practical application to everyday requirements, and that is the determination of the length of an end standard in terms of the corresponding line standard, or vice versa. This is a matter of considerable difficulty, and several methods have been employed for the purpose. Probably the best method is that introduced by Mr. H. L. P. Jolly, formerly of the National Physical Laboratory, and now of the Ordnance Survey Department, Southampton. It involves the use of an intermediate end standard, and of two special parallel faced end blocks, which can be wrung on to the ends of this standard.

Each of the end blocks carries graduation marks as shown on its polished upper surface. The composite bar is compared in the ordinary way in a comparator, with the standard line bar. Each of the end blocks is turned round in turn, and re-wrung on the end of the bar, and the comparison repeated. We thus obtain the four results:—

$$\begin{aligned} L\ a_2\ b_1 &= S_L\ 1 \\ L\ a_1\ b_1 &= S_L\ 2 \\ L\ a_1\ b_2 &= S_L\ 3 \\ L\ a_2\ b_2 &= S_L\ 4 \end{aligned}$$

or, adding and dividing by 2

$$2L\ a_1\ a_2\ b_1\ b_2 = 2S_L\ \tfrac{1}{2}\ 1\ 2\ 3\ 4$$

Each of the end blocks is then removed in turn and the other wrung centrally on the end of the bar, the new combinations being compared in a measuring machine with the end standard end bar, with the results

$$\begin{aligned} L\ a_1\ a_2 &= S_E\ 1 \\ L\ b_1\ b_2 &= S_E\ 2 \end{aligned}$$

or adding

$$2\,L\ a_1\ a_2\ b_1\ b_2 = 2\,S_E\ 1\ 2$$

From this equation, and the one previously found, we obtain the result

$$2\,S_L\ \tfrac{1}{4}\ (1\ 2\ 3\ 4) = 2\,S_E\ 1\ 2$$

which gives us the desired value of the line standard S_L in terms of the end standard S_E or vice versa.

To complete our survey of the fundamental operations involved in length measurement, reference must be made finally and very briefly to the process of verifying longer measures, such as are used in surveying. In the first place a long bar, graduated in multiples of the standard length unit, is required. This is compared, yard by yard, or metre by metre, with the standard line bar, in a large comparator. This bar in turn is compared either with suitable reference marks engraved on metal studs let into a mural base at intervals corresponding to the length of the bar, or else directly with the divisions of a graduated tape. The tapes or wires after verification, either directly, or by comparison with the mural base, are used to determine base lines in the field, by comparison with temporary bench marks set up at intervals apart roughly equal to the length of the tape.

Standards of Mass.—No attempt has so far been made to define a unit of mass by means of any natural standard, though a standard of this kind, *e.g.*, a definite multiple, say, of the atomic mass of helium, would not be inconceivable. Prior to the discovery of the radioactive elements mass was regarded as the essentially constant attribute of matter, and there was no reason to anticipate any change in a material standard of mass except by actual damage due to abrasion, oxidation, hygroscopic absorption or other similar causes. And there still remains a reasonable choice of materials, which, given due care in preservation and handling, may be expected with considerable confidence to exhibit constancy of mass.

Platinum and Platinum-Iridium.—Our predecessors, ignorant of radioactive processes, were fortunate in the choice of platinum and platinum-iridium (10% iridium) as the materials of construction for the ultimate reference standards of mass, the Imperial Standard Pound, and the International Prototype Kilogramme, respectively. The degree of consistency (within 1 part in 10^8) with which recomparisons of various national copies of the kilogramme, made after the lapse of many years, have in general repeated the original determinations, speaks convincingly, not only as to the suitability of the standards themselves, but as to the perfection of the balances used in the comparisons. The relation between the two units, according to the best ascertained determination, is 1 kg. = 2·2046223 pounds. This value received legal sanction.

Crystal Quartz.—Another material presenting a high degree of constancy of mass is crystal quartz. This, however, has the disadvantage of having a comparatively low density. In comparing two standard weights, masses in air, allowance must be made for the upward buoyant effect due to the volumes of air which they respectively displace. The less the density of the mass, the greater will be the buoyancy correction. The accuracy attained in the intercomparison of a series of platinum-iridium standards is no doubt attributable to a considerable degree to the fact that they all have comparatively high, and very closely equal, densities, so that the net buoyancy corrections are very small, and a comparatively rough determination of the air density consequently suffices to give the correction with negligible error. In comparing a number of masses differing appreciably in density, *e.g.*, platinum, quartz and brass, the accurate determination of the buoyancy correction presents much greater difficulty, and several attempts have been made to overcome it by actually conducting the weighings *in vacuo*. This involves enclosing the whole balance in an air-tight case, and manipulating the weights entirely by mechanical means from outside, without opening the case. Leakage at the glands where the operating spindles enter the case has, however, so far proved an almost insuperable obstacle to successful weighing *in vacuo*. Everyday weighings for commercial purposes are of course necessarily conducted in air, but the differences in buoyancy between the weights used, and the goods weighed, are negligible for this purpose. It is necessary, however, to provide a basis for the periodical reverification by inspectors of weights and measures of traders' weights, which may be of iron, brass or other materials. For this purpose a "commercial" standard is employed. This standard is of brass (of density 8·143) adjusted to agree *in vacuo* with the Imperial Standard Pound of platinum. Inspectors' standards are also of brass, and all verifications of these standards, and thus indirectly of traders' weights, are made by comparison, *in air*, with the commercial brass pound.

Use of the Balance.—Even when weighings are not conducted *in vacuo* the construction and manipulation of a balance for the accurate comparison of primary standards of mass are distinctly elaborate. It is necessary for the greatest care to be taken to preserve constancy of temperature, in order to maintain a steady zero reading of the balance. For this reason the room containing the balance must be thermostatically controlled, and the observer either works entirely from outside the room, or, if he enters it, must remain at a distance from the balance, all the manipulation of the weights being effected from outside the balance case by mechanical control operated by means of long rods, and the movement of the balance beam being observed either through a telescope, or by the movement across a scale of a spot of light reflected by a small mirror attached to the beam.

Consecutive Weighings.—To eliminate any effect due to slight inequality in the lengths of the two arms of the balance, at the same time to minimise the effect of any small residual drift of zero due to a gradual change in temperature conditions and to obtain a determination of the sensitivity of the balance at the time of weighing, consecutive weighings should be made to the following order:—

Left-hand pan		Right-hand pan		Mean Reading
A	x	B		p_1
A		B	x	p_2
B		A	x	p_3
B	x	A		p_4
B	x	A		p_5
B		A	x	p_6
A		B	x	p_7
A	x	B		p_8

Here A and B are the two masses being compared, and x a small known weight which serves to determine the sensitivity. Each mass is weighed an equal number of times on each pan of the balance, and the mean time of all the weighings of each mass on each pan is the same, so that the effect of any steady temperature drift is eliminated. In weighing, the balance is not brought to rest, but the pointer, or spot of light, is observed while swinging, and the extreme positions of several successive swings to right and left are noted. From these the mean readings or rest points corresponding to each arrangement of weights on the scale pans are calculated. If, for example, four successive readings are 1 2 3 4, then, allowing for the effect of the gradual reduction in the amplitude of the swing, due to damping, the corresponding rest point, p, is $\frac{1}{8}$ (1 3 2 3 3 4).

If p be the rest point when two *equal* masses of values nominally equal to A and B are on the pans, then we have

$$\begin{array}{ll} A-B \quad x=k(p_1-p) & B-A \quad x=k(p_5-p) \\ A-B-x=k(p_2-p) & B-A-x=k(p_6-p) \\ B-A-x=k(p_3-p) & A-B-x=k(p_7-p) \\ B-A \quad x=k(p_4-p) & A-B \quad x=k(p_8-p) \end{array}$$

whence

$$\begin{aligned} 8\ (A-B) &= k(p_1 \quad p_2-p_3-p_4-p_5-p_6 \quad p_7 \quad p_8) \\ 8\ x \quad &= k(p_1-p_2-p_3 \quad p_4 \quad p_5-p_6-p_7 \quad p_8) \end{aligned}$$

$$\text{or } A-B \quad = x\,\frac{p_1 \quad p_2-p_3-p_4-p_5-p_6-p_7 \quad p_8}{p_1-p_2-p_3 \quad p_4 \quad p_5-p_6-p_7 \quad p_8}$$

Usually of course several masses will be compared each with each in turn, and the best values for the differences between them finally computed by the method of least squares from all the observed differences obtained in the above manner.

The construction of the balance must be such as to ensure that after each successive arrestment of the beam and pans, the knife edges are brought into exactly the same relationship with the planes, and to secure this it is necessary to support the pans by means of a series of crossed knife edges below each terminal knife edge on the beam. If the weighings are not conducted *in vacuo*, the air density must be calculated for each weighing from observations of temperature, pressure and hygroscopic state of the air, and each observed reading corrected for air buoyancy, allowing for the effect of temperature on the volumes of the weights.

The volumes, and hence the densities, of the weights are determined by weighing them, first in air, and then immersed in distilled water, against other weights always in air. The density of the air must be calculated as usual from its temperature, barometric pressure and humidity, and that of the distilled water is known from its temperature. The difference between the two weighings, due allowance being made for the air buoyancy corrections on all the weights involved, is equal to the difference in weight between the quantities of water and air at the observed densities of each, which would fill a volume equal to that of the weight being examined. If for any reason it is considered objectionable to immerse a standard weight in water, it is possible to determine its volume, though somewhat less accurately, by means of a volumenometer, which is an apparatus for observing the change of pressure of the air enclosed within a given space, when a definite change is made in its volume, firstly when it is filled with air alone, and secondly when the weight is enclosed within it.

The calibration of a set of fractional or multiple weights in terms of the original unit can be effected by weighing together in groups of nominally equal sum by a process precisely analogous to that described above for a set of fractional end standards.

Ordinary brass weights usually exhibit a certain variability of mass, which is probably attributable to variations of surface condition depending on the degree of humidity of the surrounding atmosphere. Care should, of course, be taken to see that the metal of which weights are made is free from porosity, and weights intended for precision work should be made solid, without screwed-in tops covering holes containing adjusting material. The surfaces of high class weights are frequently electro plated with gold or platinum, with the object of minimising the effects of oxidation and hygroscopic action on the surface. Of the two, platinising is the preferable process, but weights coated with either gold or platinum have been found to exhibit instability to a certain degree, though usually less than in the case of unplated weights. The success of gilding or platinising depends upon the care exercised to obtain a firm and hard deposit.

To minimise the effects of temperature upon the action of a balance, a beam of invar may be used. But it must be remembered that invar is to a certain extent magnetic, and if results of high precision are required, care must be taken with such a beam as to ensure that it is completely screened from any possible magnetic influence. The balance should preferably be entirely enclosed within a sheet iron case.

For weighing very small quantities, and in particular for comparing the densities of small quantities of gases, micro-balances constructed entirely of fused quartz have been used. Such balances have been made both with knife edges, and preferably, with the beam torsionally supported on a thin horizontal quartz fibre at right angles to its length, and the pans supported from its ends by means of other fibres fused directly to it. The weighings are usually made by arranging a small bulb or similar contrivance at one end of the beam, counter-balanced by solid quartz at the other end. The two ends of the beam are therefore differently affected by the buoyancy of the air, and weighings are made by adjusting the pressure of the air in the balance case until the buoyancy just restores the beam to balance. The air pressure is read by means of a suitable manometer, and serves to measure the weight of the object under examination. With such balances loads as small as $\frac{1}{10}$th gramme have been weighed to an accuracy of 1 part in 10^8).

Standards of Capacity

Theoretically, the unit of capacity should be the same as the unit of volume—that is, the volume of a cube each of whose sides is equal to the unit of length. In practice, however, it is extremely difficult to construct such a cube with accuracy, and still more difficult to measure the internal volumes of vessels of different shapes in terms of the unit of length. Practical necessity has therefore ordained the use of a unit of capacity based on the unit of mass, rather than on the unit of length. In the metric system the kilogramme was originally intended to be the mass of one cubic decimetre of pure distilled water when at its temperature of maximum density (4° Centigrade).

Although great care was taken in the construction of the original kilogramme from this definition, and the result attained was closer than might have been anticipated in view of the difficulty of the problem, it has been found by very careful experiment that the litre, which is now defined as the volume occupied by 1 kilogramme of water at 4° C., actually equals 1·000027 cubic decimetres. The gallon is somewhat similarly defined as the volume occupied by 10 lb. of pure distilled water at 62° F. when weighed in air at a barometric pressure of 30 in. of mercury, against brass weights. As the weighing has to be made in air, and the density of the brass weights is not prescribed by the Act (Weights and Measures Act 1878) there is a certain ambiguity about this definition. On reasonable assumptions it has been calculated that 1 gallon = 4·5459631 litres.

It will be noted that in the case of the litre the definition refers to the kilogramme *mass*—that is to say, the weighings are to be reduced to vacuum, by applying a suitable correction for the difference of the air buoyancy on the distilled water and on the weights used for weighing it. This entirely eliminates the difficulty mentioned as regards the exact definition of the gallon. Much confusion of thought has, however, arisen from the preference of some chemists for the use of the so-called "Mohr's litre," which is defined, on the same lines as the gallon, as the volume occupied by 1 kg. of distilled water, when weighed in air, against brass weights, at a temperature which has never been explicitly laid down. Roughly, a Mohr's litre equals 1·002 true litres. It is very unfortunate that the term litre should have been appropriated to a unit so vaguely defined and which differs from the true litre by an amount that, although small, is too great to be negligible. For most purposes the difference between the millilitre and the cubic centimetre can safely be neglected.

Commercial Purposes.—For commercial purposes the gallon and the litre are both represented by material standards of capacity, constructed as nearly as possible in accordance with their respective definitions. These standards are in the form of cylindrical metal vessels with flat brims, and are filled exactly to their brims by the aid of flat glass "strikes." Comparisons with other vessels are made by transfer, the vessel under comparison being first filled and emptied to compensate for the amount of water left behind in the standard when the latter is emptied into the vessel being tested.

Scientific Purposes.—For scientific apparatus, such as flasks, burettes, pipettes, etc., where higher accuracy is needed, it is found necessary as a rule to base the verification directly on the original definition by actually weighing the quantity of pure distilled water contained in, or delivered from, the vessel, making due allowance for the temperature of the water at the time of weighing and for the buoyancy of the surrounding air. In the case of vessels, such as burettes and pipettes, which are intended to deliver, and not to contain, definite quantities of liquid, it must be remembered that after delivery the walls are left wet to an extent which depends not only on the rate at which delivery is

effected and the time allowed for subsequent drainage but also on the viscosity and surface tension of the liquid being measured. The rate of delivery is of more importance than the drainage time, and provided it is sufficiently slow the quantity of liquid delivered will be reasonably constant. Suitable delivery times and error allowances are scheduled in a pamphlet on testing volumetric glassware issued by the National Physical Laboratory.

BIBLIOGRAPHY.—The literature of metrology is somewhat scattered. The best collected account will be found in a series of articles contained in the *Dictionary of Applied Physics* (1922–3) (and in particular vol. 3 thereof), edited by Sir R. T. Glazebrook, K.C.B., F.R.S., and published by Macmillan, London. Many detailed references are given in these articles. For full descriptions of the more fundamental operations the various volumes of the *Travaux et Mémoires du Bureau International des Poids et Mesures* (Paris, Gautier-Villars) should be consulted. In addition, consult the annual reports of the Standards Department, Board of Trade (H.M. Stationery Office, London); Miller, *Phil. Trans.*, 146 (1856), on the construction of the new standard pound; Airy, *Phil. Trans.*, pt. 3, p. 17 (1857), on the construction of the new standard yard; Kaye, "A Silica Standard of Length," *Proc. Roy. Soc.*, A85 (1911); Michelson, *Light Waves and Their Uses* (Chicago University Press); C. E. Soc.*, 32, 374; Sears, *Precise Length Measurements*, Cantor Lectures, Royal Society of Arts (1923).

(J. E. Se.)

MEASURING INSTRUMENTS.—The World War was responsible for a considerable development and improvement of apparatus intended for the measurement of engineers' gauges and products. (*See* MEASUREMENTS.)

Whitworth Gauges.—Improvement in accuracy of measurement necessarily goes hand in hand with improvement in accuracy and perfection of manufacture of the articles to be measured. The original measuring machine of Sir Joseph Whitworth would have been of little value apart from the system of accurate standards (both end gauges and cylindrical gauges) which he produced for use with it. If an object is not regularly formed to a certain degree of accuracy, it cannot be said to possess a definite measurement to that degree of accuracy, and it is useless to employ measuring apparatus capable of yielding results of still higher accuracy. On the other hand, while there is no great difficulty in designing highly sensitive indicating devices, it is practically impossible to calibrate them in the absence of standards measurable to the degree of accuracy aimed at.

Johansson's Gauges.—The first substantial advance in accuracy subsequent to Whitworth's work was the introduction by the Swedish firm of Johansson, in 1908, of flat parallel faced slip and block gauges. of such perfection of workmanship that any two of them, when cleaned, would "wring" together. The gauges were made in series differing by definite small amounts, so chosen that by wringing together a suitable combination of pieces, any desired size, to the nearest 0·0001 in., could be produced. To ensure this accuracy, it is necessary that the individual pieces should each have a guaranteed accuracy of (say) 0·00001 in., in order that the cumulated error of a group of four or five should not exceed 0·00005 inch. And in order to assert with confidence that this degree of accuracy is, or is not, in fact attained in an individual piece it is necessary to be able to measure with an accuracy of the order of 0·000001 inch. When the Johansson gauges were first introduced no appliances were available which could be relied on to give measurements of this accuracy. Three entirely different methods have since been developed, however, which enable it to be done, and which, with due precautions, give mutually consistent results. These are:—

Tilting Level Comparator.—(*a*) the "tilting level" comparator, due to A. J. C. Brookes, in which the two gauges, or groups of gauges, to be compared are stood side by side on a level surface plate, and the difference in their heights is determined by the reading of a highly sensitive level, which rests by point contact upon their upper surfaces, through two ball feet.

Millionth Comparator.—(*b*) the "millionth" comparator, due to J. E. Sears, jun., wherein measurements are made between two flat parallel anvils, giving a local surface contact, the one anvil being fixed, and the other connected, through a series of spring suspensions designed to eliminate all frictional effects, with a sensitive tilting mirror which causes a spot of light to move across a scale, giving a magnified image of the displacement of the anvil on a scale of about 30,000 to 1.

Optical Interference.—(*c*) the method of optical interference developed at the Bureau of Standards, Washington, wherein the whole surfaces of the gauges under comparison may be inspected, being marked out into contours of approximately 0·00001 in. difference in height by the alternate light and dark bands forming the interference pattern.

MEASUREMENT OF INTERNAL DIMENSIONS

Another matter of fundamental importance which has but lately found a satisfactory solution is the measurement of internal dimensions. The transference from external to internal measurement constituted a considerable difficulty, and the sizes of such objects as ring gauges, either plain or screwed, were usually estimated by the nature of their fit upon corresponding plug gauges. As the fit depends to a very marked extent upon the amount and nature of the lubricant used, considerable uncertainty existed as to the correct interpretation of the observed results. If well finished and liberally lubricated with thick grease, a cylindrical plug gauge will enter and pass through a ring gauge definitely smaller than itself without damage to either. Two instruments have now been produced for the measurement of internal diameters of either plain or screwed rings, which give results mutually consistent, if due care is taken, and the work being measured is sufficiently uniform in its dimensions, to the order of 0·00001 inch.

Chord Contact Type.—In the "chord contact" machine, due to G. A. Tomlinson, the diameter of the ring is deduced by calculation from the measured displacement, in a direction perpendicular to its length, of a double ball-ended distance piece of known length, which is allowed to make contact inside the ring, first on one side, and then on the other side, of the diameter.

Displacement Machine.—In the "displacement" type of internal measuring machine, due to J. E. Sears, the position of the ring is so adjusted that measurements are made exactly across the diameter. The ring is mounted on a carriage, which can be moved bodily in the direction of the diameter being measured by means of suitable micrometers. Contact is made first on one side of the ring, and then on the other, with a double-ended stylus attached to a sensitive indicating mechanism, and the micrometer readings are taken when the indicator reads zero. The same is done in turn with a standard plug substituted for the ring, provision being made for withdrawing the stylus temporarily as the plug passes across. If x_1 y_1 x_2 y_2 are the four micrometer readings, the displacements d_1 and d_2 are equal to x_2-x_1 and y_1-y_2 respectively, and it is to be noticed that the pressure on the stylus is in the same direction when both x readings are taken, and also when both y readings are taken, so that any possible errors due to backlash or flexure in the indicating mechanism are eliminated. The transition from external to internal measurement is thus directly accomplished, and the final result is given by the equation

$$R - d_1 + d_2 - P = (x_2 - x_1) + (y_1 - y_2) - P$$

SCIENTIFIC PRINCIPLES

The question of the general geometrical principles underlying the correct design of instruments intended to give the highest accuracy of measurement has received greater attention in recent years. Questions of the proper application of the theory of kinematic constraint to ensure definite and repeatable register of parts, of eliminating backlash and friction effects, of preventing components of errors due to inevitable imperfections of workmanship (*e.g.*, in sliding ways) from becoming effective in the actual direction of measurement, of the design and relationing of parts so that elastic deformations due to changing distributions of load do not affect the results, and so on, are all involved here.

Travelling Microscope Comparator.—These various points have been fully considered in the "travelling microscope comparator" designed by J. E. Sears, jun., for the Metrology Department of the National Physical Laboratory. The long leg of an L-shaped carriage, which bears two microscopes, is sup-

ported on two wheels running in a V-guide along the upper side of the machine bed, so that whatever position is taken up by the carriage its form is undisturbed. The focal points of the two microscopes are arranged to lie in the extension of the axis of the micrometer screw, and the object to be measured is supported on an independent carriage which, by means of a small weight attached to a cord passing over a pulley, is held permanently in contact with a stud at the end of the screw abutment. Thus errors of straightness in the V-groove are non-effective, and so is any distortion of the base of the machine proper, due to the movement of the microscope carriage. Advantage is taken of the simple ratio 1 in. = 25·4 mm. (which is correct to within 1½ parts in 1,000,000) to obtain simultaneous readings of equal accuracy in either British or the metric system, by means of suitable gearing in the compound micrometer head. The verniers read to 0·00001 in. and 0·0001 mm. respectively. The instrument can be used either with one microscope for making direct measurements against its own calibrated micrometer screw, or, using the two microscopes as a comparator, for determining the values of the sub-divisions of short scales. It has been found of considerable value in measuring the spacing intervals of diffraction gratings.

Screw Gauges.—In the course of the War the necessity for rapid measurement of large numbers of screw gauges led to the development of special machines for the measurement of both pitch and effective diameter of screw threads. E. M. Eden, then of the National Physical Laboratory, was largely instrumental in this work and in the development of the optical projection method of examining profiles of gauges, both screws and flat templets. For the latter, he found lens combinations capable of giving an undistorted magnification of 50 times over a field of initial diameter approaching two inches. These combinations were incorporated in the now well-known "horizontal projector." For screw gauges the "vertical projector" was designed, in which the path of the light is vertical, and the image-forming rays are reflected back from an optically flat mirror overhead on to a specially prepared thread-form diagram placed on the table of the machine. The screw in this case is mounted in a carriage provided with two horizontal micrometer traverses in directions parallel and perpendicular to its axis, respectively, so that measurements of pitch and diameter can be made at the same time as the accuracy of the thread form is examined.

Wilson Projection Gauge.—Mention should also be made of the Wilson projection gauge, in which the optical system is duplicated, so that the two opposite sides of a screw can be projected simultaneously on to the screen, in such a manner that the two images of the thread intermesh, and if the screw is of direct form and size, and the apparatus correctly adjusted, exactly meet. If the screw is small a space is left between the images of its two sides; if large they overlap.

The projection method has naturally proved of great value in a number of other ways. In particular, it has been used in connection with the measurement of gear wheels and gear cutting hobs. Machines for this purpose have been designed by G. A. Tomlinson, and depend for their use on the accurate reproduction of the profiles of the teeth of the gear or hob, in the form of traces made on smoked glass, by a needle point attached to a specially designed pantograph. One of the machines is also fitted with a device for recording, in a similar manner, the relative velocities of rotation of two gear wheels when in mesh. In both cases the smoked glass, bearing the record, is put into the projection apparatus and magnified 50 times at the screen. It is found that the traces are quite sharp in the magnified image, and measurements can be made corresponding to an accuracy of about 0·0001 or 0·0002 inch on the original.

MEAT: *see* FOOD SUPPLY.

MECCA (*see* 17.950), capital of the Hejaz, had a resident population of about 70,000 in 1916, including some 12,000 Indians. The annual pilgrimage brings normally at least 200,000 visitors to the city, of whom pilgrims from British India and the Malay States may number 25,000. Pilgrims have been fewer during and since the World War, owing to disturbed conditions in the Hejaz. Mecca was taken by the Arabs in 1916, and bombarded by the Turks, who damaged the Great Mosque. The Grand Sherif of Mecca, Hussein ibn Ali, of the Hushimite dynasty, proclaimed the independence of the Hejaz in 1916, and assumed the kingly title. In May 1924 he proclaimed himself Caliph, but shortly afterwards was driven from Mecca and forced to abdicate in Nov. of the same year by Ibn Saud, Sultan of Nejd, who invaded the Hejaz and entered Mecca without opposition. The holy places were not damaged by Ibn Saud and his Wahabis, who performed the customary rites in the Great Mosque.

The general aspect of Mecca, as observed during the War, had changed but little, though some modern buildings had sprung up; there were a number of stately residences, including the new royal palace of six storeys, and a considerable display of wealth. The sanitation and water supply, previously very bad, had been improved. There was telegraphic communication between Mecca and Jidda, and between Mecca and Taif, the summer residence of the king, 75 m. to the southeast. Representatives of foreign powers live at Jidda, since non-Moslems are not allowed to enter Mecca.

MECHNIKOV, ILYA (1845–1916), Russian biologist, was born at Ivanovka, in the province of Kharkov, May 15 1845. At the age of 17 he entered the Kharkov University and two years later went to Germany. In 1867 he returned to Russia and was a *dozent* in zoology both at Odessa and St. Petersburg, becoming in 1870 professor ordinarius of zoology and comparative anatomy at Odessa. In 1882 he went to Messina and there began his studies into the nature and habits of microbes. Henceforth he devoted himself to pathological study and in 1888 went to Pasteur in Paris, who gave him a laboratory in the École Normale. By 1892 his views on the essential importance of phagocytosis were firmly established. In that year he published *The Comparative Pathology of Inflammation*, followed in 1901 by his chief work, *Immunity in Infectious Diseases*, and a more popular treatise, *The Nature of Man* (1903). In later years he made a special study of the bacteria infesting the alimentary canal of man. In 1908 he was awarded the Nobel Prize for medicine. He died in Paris July 16 1916. See *Life* by his wife, Olga Mechnikov (1920), trans. by Mrs. R. L. Devonshire (1921).

MEDALS AND DECORATIONS (*see* 18.2; 15.860).—These may be divided into two classes, personal and service. Personal decorations are awarded to the individual (Victoria Cross, etc.); service decorations are awarded to all persons who participate in a common service (war medals, etc.). As a result of the World War the issue of medals and decorations was the widest ever recorded, and, of these, the best known is the Victory medal.

FIG. 1.—Allied Victory Medal.

In 1918 the Allies agreed to issue a collective and distinctive medal to commemorate the War. The advantages of this were that it was symbolical of the one purpose which animated the Allied troops, and that it obviated the separate issue by each nation of its own war medal to allied forces which had served with them in their own territories. Each country designed its own medal, the stereotyped features being that each medal is bronze and has on the obverse the figure of Victory, and on the reverse the inscription "The Great

War for Civilisation." The ribbon is coloured in the form of two rainbows joined together, symbolising the calm after the storm.

The following are some of the chief decorations and medals issued since 1910:—

BELGIUM.—Service. War medal, bronze, shaped like a bell or a label. Ribbon, yellow, red edges with inner separation line of black. Victory medal. Obverse, figure of Victory; reverse, Arms of the Allies.

FRANCE.—Personal. Croix de Guerre. Established 1915. Bronze cross with crossed swords in angles. Ribbon, green, seven narrow red stripes. *Service.* War medal. Bronze. Ribbon, red and white stripes. Clasp, "Engagé volontaire" to non-conscripts. Victory medal. Obverse, figure of Victory; reverse, inscription (see above).

GREAT BRITAIN.—Since 1910 the following have been issued: *Personal.* Distinguished Service Medal (Navy), 1914. Ribbon, blue, two white bars in centre. Military Cross (Army), 1914. Ribbon, white, central purple stripe. Military Medal (Army), 1916. Ribbon, dark blue, in centre two crimson and three white alternate stripes. Distinguished Flying Cross, 1918. (Royal Air Force). Ribbon, violet and white broad diagonal stripes. Distinguished Flying Medal, 1918. (R.A.F.). Ribbon, violet and white narrow diagonal stripes. (The above two decorations are for active flying against the enemy.) Air Force Cross, 1918. (R.A.F. and civilians.) Ribbon, red and white broad diagonal stripes. Air Force Medal, 1918. (R.A.F. and civilians.) Ribbon, red and white narrow diagonal stripes. (The above two decorations are for distinguished service to aviation in actual flying.) Recognition Medal. Silver and bronze medals were issued to allies who had rendered service to British Prisoners of War and others behind the enemy lines. Ribbon, yellow; red, white and black edges, blue central stripe. *Service.* Naval General Service Medal, 1915. Ribbon, white, crimson borders and two crimson stripes in centre. African General Service Medal. New issue 1916. Ribbon, black, green and yellow (never seen without a clasp). 1914 Star. Bright bronze. Ribbon, red, white and blue, shaded and watered. Clasp, "5th Aug.—22nd Nov. 1914." 1914–5 Star. Similar to above, same ribbon, no clasp. War Medal, 1919. Ribbon, orange, narrow stripes of white, black and blue at each edge. Clasps sanctioned for navy, but not for army. Victory Medal. Obverse, figure of Victory; reverse, inscription (see above). Oak leaf on ribbon for one or more mentions in despatches. Mercantile Marine War Medal. Bronze. Ribbon, green and red, separated by narrow white central stripe. Territorial War Medal. Bright bronze. Ribbon, yellow, two green stripes. Special Constabulary Long Service Medal. Bright bronze. Ribbon, red, white and black. Clasp, "The Great War, 1914–1918." General Service Medal (Post War). Ribbon, purple, with green central stripe; clasps for service in Persia, 'Iraq and Kurdistan.

ITALY.—Service. War Medal. Bronze. Eighteen stripes of red, white and green. Clasps bearing date of each year. Victory. Conforms to standard specification.

JAPAN.—Service. Victory Medal. Obverse, a Japanese figure of Victory.

RUMANIA.—Service: War Medal. Cross in black bronze, relieved in bright bronze. Ribbon, green with three blue stripes. Victory Medal. Conforms to specification.

UNITED STATES.—Personal. Distinguished Service Cross, Army, 1918. Ribbon, blue; red and white edges. Distinguished Service Medal, Army, 1918. Ribbon, white; red edges, narrow blue separation line. Distinguished Service Medal, Navy. Ribbon, blue, narrow yellow central stripe. Navy Cross. Ribbon, blue, narrow white central stripe. *Service.* Victory Medal. Bright bronze. Obverse, figure of Victory; reverse, design with shield and fasces and names of Allies. Battle Clasps are awarded. The only Service Medal issued by the United States to commemorate service in the World War.

(A. V. W.-H.)

MEDICAL EDUCATION (*see* 18.23a).—A sound general education is necessary for the medical as for all other professions.

I. IN GREAT BRITAIN

In Great Britain before admission to a course of training a boy or girl is required to show in an examination of matriculation, character and standard that he or she has acquired a respectable knowledge of English, a language other than English, mathematics and some other school subjects of the candidate's own selection. Latin is no longer exacted by the General Medical Council (G.M.C.) although in certain universities it is compulsory for students who desire to obtain a medical degree. But the ordinary school subjects are not the only instruments available for the development of intelligence. Physics, chemistry, biology, when well taught also strengthen the mind and develop the faculty of observation which for a doctor is of paramount importance.

The General Council of Medical Education and Registration does not determine directly the requirements of the various licensing bodies, but exercises a measure of control over the doctor's training by deciding the conditions precedent to registration, first as a medical student and finally as a qualified practitioner. Since 1922 the G.M.C. has required an examination in physics and chemistry be passed by him before registration. The gain is two-fold. His school work more efficiently prepares the boy for his profession, and more time is made available in the brief five years, which is the most that can be exacted as a minimum between registration as a student and registration as a qualified practitioner. The council also allows the student to pass the examination in biology immediately after registration. The curriculum recognised as medical carries the student through a succession of stages which merge insensibly one into the other, until his accumulated knowledge and steadily increasing skill justify the conferring upon him of a degree or diploma which admits him to all the responsibilities of medical practice. It is impossible to over-emphasize the statement that the several steps "merge." They are not stepping stones. No subject is left behind when the passing of an examination qualifies a student to approach the next. The examination tests his fitness to approach subject B whilst still carrying forward subject A.

Stages of the Education.—These stages may be defined as (1) The study of the structure of the body and of its behaviour in health, anatomy (*q.v.*) and physiology (*q.v.*), to which two years are assigned. (2) The study of the behaviour of the body when perturbed by abnormal conditions, by malformations, by injury (*see* PATHOLOGY), by the invasion of parasites (*see* PARASITOLOGY) ranging from ultra-miscroscopic "germs" (*see* FILTER-PASSING MICROBES) to intestinal worms, an extension of physiology into the domain of disease. (3) The study of physiological changes which result from the administration of various chemical substances, "drugs," already anticipated by the study of the "drugs" which, in health, various organs pour into the circulation, internal secretions (*see* ENDOCRINOLOGY). (4) The study of the possibilities of modifying the behaviour of the body, when diseased, in a beneficial way by administration of drugs. (5) The proper management of the body in health, preventive medicine. (6) The care of the sick and of women in childbirth.

At all periods medical education has been adapted to the knowledge and practice of the age. Since Pasteur revealed the true cause of the large majority of diseases—the invasion of the body by micro-organisms—the science of medicine may almost be said to have come into existence. Corresponding modifications of the medical curriculum have consequently been called for, and many have been adopted—always with a certain lag. Since 1910 much has been done in adapting training to the new knowledge and new needs. An important change is the disappearance from the curriculum of the subject known as *materia medica*, a subject which used to make a painful demand upon the student's memory. Long after the date at which doctors ceased to make up their own medicines, compounded of a variety of ingredients, with all the mystery of a professional secret, or wrote equally complicated prescriptions in Latin, incomprehensible to anyone but a druggist, the student was required to know the methods of preparation and the composition of the drugs of the pharmacopoeia. He was also required to produce a certificate of having attended a course of instruction in dispensing at a hospital or with a qualified medical man or pharmacist. Modern pharmacology (*see* PHARMACOLOGY) recognises that the body's perturbations may be restrained by certain definite chemical substances, many of them produced synthetically. Of these the practitioner's armamentarium contains relatively few. For flavouring and colouring matters he no longer has much use.

The Object of Medical Training.—With the exception of the changes already referred to, developments in medical education are rather in the manner of presenting knowledge than in the selection of subjects to be studied. When so much of value must be omitted, every subject included in the curriculum should be taught in the most practical way. It must be made a part of the practitioner's outfit, which he can never afford to lose. His

knowledge of the anatomy of the living body must enable him to see its organs in their relation to one another as clearly as if it were transparent. In some degree dissecting room work has given way to surface anatomy and the study of models and frozen sections; although training in the use of scalpel and forceps is still the only means of acquiring dexterity in the surgeon's craft. In physiology, during the first year, the student is in most schools given more practical work than formerly. Beginning with the frog and passing on through isolated mammalian organs to the decerebrate mammal, he is brought in his second year more closely into contact with the human body. He learns to use methods and apparatus with which, later, he will investigate the physiological condition of the organs in disease.

The greatest changes have been introduced in the third and fourth years of the curriculum. Physiology has been extended into pharmacology, an ever-growing body of exact knowledge derived from the study, with instruments of precision, of the effects produced upon guinea-pigs and rabbits by chemical compounds of which some, like caffeine and morphine, are vegetable products, whilst others, such as phenacetin, have been prepared synthetically in the laboratory for the express purpose of modifying the behaviour of the body. When used to correct undesirable habits, these various chemical substances, with the apparatus which has been designed for the purpose of studying their effects, belong to the sphere of therapeutics (*q.v.*).

At about this stage in the student's training, bacteriology (*q.v.*), a science which is growing so rapidly as to be for the most part relatively new, claims his attention. The micro-organisms which cause disease present biological problems of the highest interest. Every medical man needs to be expert in the methods of making preparations for identification with the microscope (*see* MICROSCOPY), of preparing media and of cultivating the various organisms *in vitro*. And since the effects upon the fluids of the body which they induce can be recognised chemically, a new name, "bio-chemistry" (*q.v.*), is usually applied to the department of science in which ascertained facts are grouped together. To the physiologist and physician have been opened up the two provinces of serum and vaccine therapy and immunology (*see* IMMUNITY). Provision is made for teaching the principles of various kinds of drugless therapeutics, such as treatment with ultra-violet light (*see* HELIOTHERAPY) and with radium massage, and the demonstration of the results obtained in special clinics. Pathology (*q.v.*), formerly the post-mortem examination of patients the course of whose illness had been watched in the wards, has become more of a science. As experimental pathology, it is the study of the physiology of disease. Disturbances of function, their causes and progress, are followed by the same methods as if they were variations in the performance of the several organs during health. Autopsies confirm or modify views expressed during life regarding tissue changes which were taking place.

Clinical Units.—The most notable improvement in medical education made during recent years is the organisation of clinical units. Physicians and surgeons still go round their wards at stated hours—usually in the early afternoon—followed by troops of students to whom they point out the features of each case, expound the nature of the malady and explain the reasons for the treatment adopted. But no longer, as formerly, is the student dependent upon "walking the wards," attending lectures and reading about the illnesses of which the cases he has seen are illustrations. The clinical unit is a far more efficient training centre. Its staff consists of a director and three or four assistants. Either the director himself or one of his assistants is a whole-time officer of the university. To the unit are assigned a number of beds—usually 60 or 70—in suitable wards with adequate laboratory accommodation in their near vicinity and an ample supply of apparatus for the examination of the patients and for testing their reactions. An out-patient department is included in the unit. In short, it is a school in the sense in which a physiological institute is a school.

Students examine chemically and microscopically the blood and excreta. They make every kind of measurement, and as the wards are open throughout the day they have the opportunity of seeing how patients should be treated, nursed and cared for in every respect. As the teachers of physiology, bacteriology, pharmacology and other subjects visit the clinic from time to time, the student learns under ideal conditions how all that he has been taught combines to fit him for his life-work, the care of the sick and their restoration as speedily as possible to health. When cared for by a clinical unit patients recover more rapidly than they used to do, and in consequence the efficiency of the hospital is increased.

The Former System Contrasted.—Until comparatively recent times students were required to attend a certain amount of hospital practice during their first two years, usually six months. This was a relic of the apprenticeship through which aspirants for admission to medical, as to legal and other professional guilds, were required to pass. In Britain, this tradition is obsolete at last. No longer is a student required, or even allowed, to listen to bedside disquisitions on maladies of which even the names may be unfamiliar, in terms which carry little meaning to his mind, or to watch the physical examination of organs of which he knows but vaguely the form and situation, and to hear of their perturbations before he knows how they function normally. Not until he knows how the body works in health is he shown how disease may disturb its harmony, or taught the remedial measures which should be adopted with a view to aiding nature to set it right. Too early contact with patients inevitably led to confused thinking and false inferences which had to be corrected by subsequent reading and observation and, it may be added, developed in the tyro a conviction that medical practice consists in "spotting" the disease and administering the drug which will "cure" it. The progressive opening-out of knowledge with the synchronous revelation of ignorance, which is the aim of the modern curriculum, avoids loss of time and secures the highest degree of qualification for the exercise of the medical profession which the limited period of training allows.

Post-graduate and Specialist Work.—As a result of the careful allocation of his time the modern student finds that he has less opportunity than his forerunners of paying special attention to any branch which may attract him. Diseases of the eye, of the throat, of the ear, of the nervous and other organs, are treated with sufficient fullness for the equipment of general practitioners, but not with the thoroughness necessary to make specialists. The student who proposes to specialise must continue his studies after graduation. An increasing number of graduates who do not propose to devote themselves to a single speciality, but wish to make themselves proficient in particular branches of their work, such as gynaecology for example, defer going into practice, or return from time to time to a medical school in order to keep abreast with advances in knowledge and technique. Post-graduation courses are more numerous and better organised than they were before the War, but they are not yet, in Britain, as complete or as intensive as they might be.

Other Countries.—In the universities of Canada and Australia and of most foreign countries, progress has followed the same lines as in Britain. A logical sequence of studies and their integration in the curriculum has been the reformer's aim. In Japan the sequence of studies is much the same as in Britain; but the minimal length of the purely medical curriculum is four years, following on a course in the preliminary sciences. French medical schools still adhere to the system which they regard as "natural." Their students are encouraged to attend clinics from the date of their inscription in the faculty, and the relegation of all lectures and laboratory work to the afternoons almost compels them to devote the mornings to attendance in the wards and out-patient departments.

BIBLIOGRAPHY.—For detailed information consult *Recent Advances in Medical Education in England*, a memorandum addressed to the Minister of Health by Sir George Newman, Chief Medical Officer; and *Medical Education, a Comparative Study*, by Abraham Flexner.

(A. HI.)

United States.—In 1900 there were in existence in America 160 medical schools, mostly in fact, if not in form, private ventures; even the few schools of high grade possessed meagre

endowment and inadequate facilities. By a process of natural selection, the number of schools was rapidly reduced, having fallen in 1925 to 80, and there were grounds for the belief that this number would in the near future be still further reduced. The organisation, endowment and facilities for instruction showed a notable advance. In 1910 few medical schools actually controlled the hospitals in which their teaching was done. Subsequently there was a distinct tendency to give the university medical schools exclusive and adequate control of hospital facilities for clinical teaching and research. Harvard, Yale, Washington and other universities thus came into much more intimate relations with the hospitals in which the clinical staffs teach. The city of Cincinnati built one of the finest public hospitals in the United States and amended the city charter so as to give the University of Cincinnati (a municipal institution) complete control of the hospital for its medical school.

On the financial side, public opinion was brought to realise that the university school of medicine is an expensive enterprise, for which large investments must be made by the public in both facilities and endowment. Mr. John D. Rockefeller gave the General Education Board approximately $35,000,000 to be used primarily for the purpose of co-operating with institutions in raising large sums for the development of their medical schools, and the late Mr. Joseph R. DeLamar gave $5,000,000 each to the medical departments of Harvard, Columbia and Johns Hopkins. Upwards of $12,000,000 was raised for the establishment of a new medical department at the University of Rochester, Rochester, N. Y., and $8,000,000 was raised for the reorganisation of the medical department of Vanderbilt University, Nashville, Tennessee. Columbia University is building a new medical school, and the Presbyterian Hospital, the Sloane Hospital and the Vanderbilt Clinic are providing new clinical facilities for the use of the school, the whole involving a prospective investment of $13,000,000; so at Cleveland an admirable school and laboratory building has been constructed on a new site on which university hospitals are already being located. In this movement the state universities have participated—notably the University of Iowa, which is completing a new plant—laboratories and clinics—at a cost of $5,000,000. Many other endowed institutions also procured considerable sums for improved laboratory and teaching facilities.

In respect to organisation the main change in the period was the introduction of the full-time plan corresponding to the English unit system in the teaching of the clinical subjects. The aim and purpose of this movement are the same in both countries, but in neither had sufficient time elapsed to allow a final verdict to be passed on the merits of the system. The complete satisfaction of the Johns Hopkins Medical School in the working of this plan is shown by the fact that the system, which originally included medicine, surgery and pediatrics, has been extended so as to include gynaecology, obstetrics and ophthalmology. The system has also been adopted in the main clinical branches by the medical departments of Washington University (St. Louis), Yale University, Vanderbilt University, University of Chicago, University of Rochester, the medical clinic of Columbia University, the psychiatric, pediatric and obstetrical clinics of the University of Iowa and the neurological clinic at Harvard.

China.—Through a subsidiary board (the China Medical Board) the Rockefeller Foundation of New York has established in China a modern medical school. The Rockefeller Foundation has furnished funds amounting to $8,000,000 to build and equip the Peking Union Medical College, and in addition it was in 1921 supporting the institution on the basis of a budget for the year amounting to $500,000. The institution furnishes two years of pre-medical work, and intended to develop a four-year medical course. The China Medical Board also aids four other medical schools in China carried on by other organisations.

Belgium.—The University of Brussels had in 1921 planned a complete reorganisation of its medical department. The city, the state and the university co-operated in maturing plans for a modern teaching hospital, and new, well-equipped laboratories on a single site. (A. F*.)

MEDICAL LEGISLATION.—Since 1911 statutes have been passed in many countries creating or reorganising the central public health authority. The Ministry of Health for England and Wales created by the Act of 1919, took the place of the Local Government Board with all its powers and duties and, as regards public health, also those previously exercised by the Board of Education and other departments. Power was further created to transfer from the Ministry duties which were not incidental to health.

Ministries of Health have also been established in Canada (1919), the Union of South Africa (1919), Poland (1919), New Zealand (1920), France (1920) and Rumania (1923). A Dept. of Public Health for the Commonwealth of Australia was created in 1921, and a General Directorate of Public Health in Spain, by a Royal Decree of 1922.

Zymotic Diseases.—In Australia, New Zealand and the Union of South Africa comprehensive regulations regarding the notification and control of infectious diseases were included; similar regulations were issued in Austria (1913), the Straits Settlements (1915), Peru (1916), Chile (1918), Sweden (1919), Brazil (1921) and Venezuela (1921). A Polish law of 1920 created the office of Special Commissioner for dealing with epidemics, and a French decree of 1920 instituted a mobile unit equipped with laboratories, etc., for instant dispatch to parts of the country suffering from or threatened with a disease epidemic.

Vaccination.—By a law of 1914, vaccination against smallpox (*q.v.*) becomes compulsory in Siam whenever the health administrator deems it necessary; in the Straits Settlements (1915) it is compulsory, and re-vaccination also can be made compulsory in the face of danger; in France (1915) vaccination and re-vaccination can be made compulsory by decree, but (1918) vaccination is compulsory for state officials. Chile (1918) has compulsory vaccination in the first, 10th and 20th years of age; in Venezuela (1921) there is infant vaccination and re-vaccination every seven years, failure to comply barring from a large number of employments. In Poland (1919) there is compulsory vaccination for infants, and again at seven years. In Tunis (1922) vaccination against smallpox is compulsory, and also against typhoid, cholera and plague, if there is danger of an epidemic. Uruguay (1923) has compulsory vaccination in the first six months, and again in the 10th and 20th years. A Polish law of 1920 makes vaccination against typhoid fever and cholera compulsory for doctors, nurses, employees at waterworks and for those engaged in other specified callings.

Tuberculosis.—Anti-tuberculosis legislation has been put into force in various directions. Tuberculosis schemes and the legislation involved are discussed in the article TUBERCULOSIS. The Milk and Dairies (Consolidation) Act, 1915, provided, *inter alia*, for the registration of dairies and the inspection of dairies and herds; and prohibits the sale for human consumption of milk from a cow with tuberculosis or other specified diseases of the udder. The Milk (Special Designation) Order, 1922, of the Ministry of Health instituted the licensing of classes of milk, namely, certified, Grade A (tuberculin tested), Grade A (non-tuberculin tested) and pasteurised; and prohibited the sale of milk under a designation to which it is not entitled.

The Public Health Act, 1925, section 62, authorises a court of summary jurisdiction to order the removal to a suitable hospital or institution, of any person suffering from pulmonary tuberculosis in an infectious stage, when a source of danger to others, either from lack of proper accommodation or from failure to observe sanitary precautions. In Denmark, laws of 1912, 1918 and 1919 made compulsory the notification of pulmonary and laryngeal tuberculosis by the doctor in attendance, who is also required to instruct those in charge of the patient as to sanitary precautions.

A Japanese law of 1919 gives power to examine any person whose calling might make him a source of transmission, to forbid the exercise of a particular calling by such, and to forbid or restrict trading in old clothes, old books and other articles which might carry infection. In Denmark, compulsory isolation of infectious cases is also empowered with certain limitations; and laws of 1918 and 1919 provided for the use of public funds to

support hospitals for tuberculosis, sanatoria and convalescent establishments. A French law of 1916 instituted public dispensaries for treatment and for giving instruction in anti-tuberculosis measures. A decree of 1920 laid down regulations for the establishment, working and supervision of sanatoria. An Italian royal decree, 1919, instituted a central anti-tuberculosis committee, and a Swedish royal decree, 1912, regulated subventions to hospitals for treating tuberculosis.

Venereal Diseases.—The English Venereal Diseases Act (1917) prohibits treatment by unqualified persons in areas to which it is applied, when gratuitous treatment has been provided and approved, and prohibits all kinds of advertisements of quack remedies for such diseases. In Sweden (1912) an affected person is obliged to obtain and complete medical treatment; the same applies to the Union of South Africa (1919), where it is also an offence for an infected person to follow certain employments, or to engage such a person in the employment; and to Czechoslovakia, where an infectious person may also be removed compulsorily to hospital if necessary, and an examination by a doctor can be enforced where there is reason to suppose that a person is infected with such a disease. In the state of Rio Grande do Norte, Brazil, by a decree of 1921, a special service for the prevention of venereal diseases was created, and provision was made for action against charlatans and for diffusing information regarding modern methods of avoiding the contagion. In Italy, a royal decree, 1923, approved of regulations for the prevention of venereal diseases, including the examination and treatment of prostitutes. A Danish law of 1922 obliges a person suffering from venereal disease, in a stage when it may be communicated or transmitted, to inform the other party to a proposed contract of marriage, and this party must be instructed by a doctor before contracting. The parties must make a declaration of freedom from such disease. The same procedure must be adopted if one of the parties suffers from epilepsy. When there is reason to believe that one of the parties may have disease or weakness of the mind such party must present a medical certificate of mental health and make a declaration as above mentioned.

Housing.—The British Housing Act, 1925, *inter alia*, makes it a duty of the local authority and the medical officer of health to inspect houses, prohibits the erection of back-to-back houses, and gives power to close and demolish houses deemed unfit for human habitation. The Public Health Act, 1925, gives a local authority power to cleanse, disinfect or destroy articles infested with vermin in dwellings, and to oblige a landlord or tenant to cleanse the dwelling; powers are granted for cleansing of the person also. A Belgian law of 1919 instituted the National Society for Housing, amongst its powers being that of destroying unhealthy dwellings; a revising law of 1921 gave power to expropriate such houses and sites as are required. Similar powers were granted to authorities in France by a law of 1915. A law of 1922 codifies the laws relating to working-class dwellings. A Peruvian law of 1916 obliges landowners to remove and prevent conditions on their land which are deemed to favour the existence of malaria.

Infant Welfare.—The British Notification of Births (Extension) Act, 1915, extended the Act to areas in which it had not been adopted. A Belgian law of 1919 instituted the national work for infant welfare. In France a law of 1917 provided financial help for necessitous women in connection with child-birth, and when the mother nurses the child assistance continues for a period of 12 months. In Germany (1922) help is given to women in the same circumstances, insured and uninsured. An English Act of 1920 regulates the employment of children, young persons and women in industrial occupations; and a Peruvian law of the same year is a similar measure.

Food.—The English Public Health (Milk and Cream) Regulations, 1912, prohibited the addition of any preservatives to milk intended for sale for human consumption, any thickening to cream or preserved cream or any preservatives to cream with less than 35% of milk fat; the only permissible preservatives in cream intended for human consumption are boric acid, borax, a mixture of these, or hydrogen peroxide. By an order, 1917, no more than 0·4% of boric acid may be added and the cream must be sold as preserved cream and labelled as unsuitable for infants and invalids. Public Health regulations, 1923, fixed the minimum percentage of milk fat in dried milk of various descriptions, and that of milk fat and total solids in condensed milks. Containers must declare the contents, and skimmed milk be labelled as unfit for babies.

Drugs.—Most countries have legislated to restrict the use of opium, cocaine and related substances. The English Therapeutic Substances Act, 1925, regulates the manufacture, sale and importation of serums, vaccines, salvarsan, insulin, etc. Other countries have legislated similarly. (R. Sc.)

MEDICAL RESEARCH.—Progress in medical research since 1911 can be subdivided according to the branch of medical science into which it falls most naturally. An arbitrary classification, however, has the drawback that many subjects might be discussed equally well under other headings than those in which they are presented.

Anatomy

First place in this section must be given to the collections of specimens illustrating war injuries and diseases that have been formed by certain museums, notably that of the Royal College of Surgeons of England. Extending to many thousand specimens these collections present a picture of the medical and surgical effects of war in the widest sense, that has never been equalled. Other anatomical researches of note were upon the distribution of the absorbents from the lower intestine and upon the caecocolic sphincter tract. The former offers explanation of many peculiarities of disease in this region and is of value surgically; the latter is a new conception, likens the tract in question to the stomach and supports this contention by numerous references to several species of lower animals.

Physiology

Hormones.—Bier found reason to believe that a chemical stimulus (hormone) secreted by the retina initiates the formation of the lens in the larva of Triton, and that a hormone formed from bone-marrow underlies repair of bone. From this he argued that repair in general is dependent upon special hormones formed at the seat of the injury according to the type of tissue needing repair. The part played by the nervous system in repair still remains obscure.

Shock and Blood Transfusion.—A large amount of work was done upon shock and allied conditions. Shock is of great complexity but sudden removal of large quantities of fluid (blood) with the resulting disturbance of the circulation is a fertile cause. In correspondence with this, treatment by transfusion (*see* Blood Transfusion) is of the greatest value and the methods of transfusion as well as the substances to be used were made the subject of numerous inquiries. Broadly speaking, for surgical shock and loss of blood by haemorrhage, injection of solutions of gum arabic are of great value, particularly if a small amount of glucose be added. Volume of injected fluid and rapidity of action are fundamental considerations, composition of the injected fluid is a matter upon which some latitude can be allowed, and use of blood is by no means obligatory. On the other hand where transfusion is performed for anaemia (*see* Anaemia) due to disease the character of the injected fluid is of first importance. Here, use of human blood is indicated and it is necessary, by careful examination of patient's blood and donor's blood to ensure that they belong to blood groups that are not mutually antagonistic.

Muscle Tone.—Physiological research of unusual importance was carried out (Sherrington, Magnus and others) upon muscle tone in the decerebrated animal by means of which tendon and other reflexes received a clearer explanation and afforded information upon many reflex postural responses to stimuli that appear to be voluntary. This line of research supplements experimental psychology, a branch of investigation that has made strides during the past two decades (*see* Psychology).

Respiration.—In the province of respiration, the relation of lactic acid and muscular exercise to the respiratory quotient

has been investigated. Under exercise a lactic acid maximum of 0·3% in the muscles can be reached in about 30 sec., and this, or rather less, is the longest time that maximal exertions can be kept up. For these short maximal efforts there is reason to believe that carbohydrate alone is used by the muscles. Regulation of rhythmic respiration, from experiments carried out on cats, appears to depend upon the action of an inspiratory mechanism, the apneustic centre, at the level of the striae acusticae, an expiratory mechanism just below it, both of these centres being controlled by the pneumotaxic centre which is situated in the upper half of the pons. The actual stimulating agent is carbon dioxide.

Other Discoveries.—Very many subjects of inquiry must be passed over here, *e.g.*, discovery of rhythmic contractions of capillaries discovered by means of a special modification of the microscope; the behaviour of the spleen in poisoning by carbon monoxide; the action of lead upon red blood corpuscles; researches on bilirubin and urobilin and other pigments in relation to jaundice; on "buffering" of blood whereby the addition of a given amount of acid to blood is represented by a smaller change in reaction than would occur in simple watery solutions because of the existence of weak basic salts of carbonic and phosphoric acid, especially in the red corpuscles; and numerous investigations upon the action of insulin upon blood sugar and other constituents of the body as well as upon the interaction of insulin and other endocrine secretions.

Energy Expenditure.—Of more general interest is a research carried out upon the energy expenditure in sewing with a machine and hemming by hand. Careful measurements were made by means of the respiration calorimeter, but one most instructive result is that influenza exerts a depressant influence on energy output during rest when the patient has apparently recovered completely. In the case of the woman made the subject of measurement for five weeks after her apparent complete recovery, with the body weight returned to normal, energy expenditure was 4% lower than before the illness.

Tissue Culture.—Minute portions of chick and duck embryo heart have been cultivated in special glass cells. Under suitable conditions these portions of tissue live, grow and beat rhythmically in the culture medium for prolonged periods. If two portions of heart from the same species are placed in the same culture cell, each beats rhythmically at an independent rate until the masses fuse by growth when the beats become synchronous. If in the experiment the two portions are chick and duck, fusion by growth may occur but independence of rhythmic contraction persists (*see* also article TISSUE CULTURE).

As an example of information obtainable only by use of apparatus of extreme accuracy, Katz showed from a study of the curves of right and left intraventricular pressure and of aortic and pulmonary artery pressure that during normal experimental conditions right and left ventricular systoles and also their ejection phases neither begin nor end simultaneously and are, as a rule, of unequal duration.

BIO-CHEMISTRY

Insulin.—Much of the research falling into this category is concerned with the minute physical chemistry of the cell and therefore is of a fundamental character though hardly suitable for analysis in this place. An important practical result of laboratory work consisted in a simplification of the method of preparing insulin (*q.v.*) whereby a larger amount of the material of a higher potency was prepared from a given amount of raw material in less time and at smaller cost. Insulin forms a picrate when freshly ground pancreas is mixed with solid picric acid. The insulin picrate is extracted by means of acetone. By this discovery the cost of insulin treatment of diabetics has been reduced to one-third or less.

Vitamins.—Perhaps the most striking subject upon which biochemical investigations have been conducted during recent years has been that associated with accessory food factors (vitamins) and food deficiency diseases. Investigation of *beri-beri*, a nutritional disease associated with various nervous and paralytic symptoms, which occurs in man and can be induced in pigeons by feeding exclusively on polished rice, showed that addition of a minute quantity of the milling was sufficient to prevent onset of the disease or cure it if in existence. Then followed investigations into the causation, prevention and cure of scurvy and inquiries into the factors underlying growth of the body generally or of special systems (*e.g.*, bone in rickets). It cannot be said with certainty that rickets depends exclusively upon absence of a special vitamin, for other factors, such as a sufficiency of calcium and phosphorus, are necessary. Moreover, sunlight, particularly the ultra-violet portion of the spectrum, is no less essential than due provision of the requisite vitamins for production of that normal growth of the body of which normal growth of bones is but a part. As a result of the entire series of investigations upon accessory food factors, it may be said that at the present time fat-soluble vitamin A and water-soluble vitamin B are regarded as being bound up with processes of growth and in addition there are anti-scorbutic and anti-beri-beri vitamins. These vitamins have been found in a great variety of animal and vegetable substances and the amounts present vary within very wide limits. Their nature is unknown, and the most certain points in connection with them are the minuteness of quantity in which they are present and the potency of their activity. As to their origin the suggestion has been put forward on experimental grounds that they are compounds of high energy content produced by the influence of ultra-violet light, but this hypothesis cannot be regarded as proved, indeed, some experimental observations are against it.

DIAGNOSTICS

Radiology (*see* RADIOTHERAPY AND RÖNTGENOLOGY).—On its diagnostic side, quite apart from the use of contrast meals and injections opaque to the rays, it is now possible to produce far better radiographs with exposures measured in fractions of a second than were possible at the beginning of the century with exposures lasting minutes. This is largely due to the employment of X-ray tubes in which the anticathode is a mass of tungsten, heated by an independent current. For treatment, in order to approximate the wave-length of rays emitted by the X-ray tube to the wave-length of the gamma rays of radium, apparatus has been produced with a voltage in the region of 200 kilovolts. So far this type of apparatus is employed chiefly in the treatment of cancer. During the routine examination of large numbers of cases various anatomical peculiarities have been observed and some hitherto unknown morbid processes in bone have been described. Radiology has also proved useful in study of the physiology and pathology of the heart and great blood vessels, in pulmonary conditions, notably tuberculosis and bronchiectasis, in diagnosis of renal and biliary calculi, and it has been suggested as a means of diagnosis when perforation of a gastric or intestinal ulcer is suspected. The intentional injection of oxygen or air into the peritoneal cavity as an aid to radio-diagnosis has been employed somewhat extensively; it is stated to be devoid of risk and renders diagnosis of fluid or solid masses relatively easy. The use of radium (*see* CANCER; RADIUM) is confined chiefly to the treatment of cancer, but in some conditions of skin, *e.g.*, naevi, and in certain uterine conditions it has a well recognised applicability.

Therapeutic Use.—Other forms of radiant energy, sunlight (Heliotherapy), mercury-vapour quartz lamp, carbon arc, radiant heat, all of which depend upon the presence of ultra-violet light in the first instance and warmth in the second, are employed therapeutically to an increasing extent. A disadvantage under which X-ray and ultra-violet forms of treatment labour is the absence of a satisfactory standard of dose. Sabouraud's pastille is only reliable for "soft" radiation. The "skin erythema dose" is unsatisfactory because as used in France it is two and a half times as great as the "Hauterythemdosis" of the Germans. Even in German institutions the erythema dose varies between 285 R units and 1,120 R units (Martius).

Effects of Radiation.—Numerous researches have been made on the effects of radiation, particularly the gamma rays of

radium, upon cells and tissues of the animal body, plants, seeds, bacteria, protozoa. It has been shown that the cell in division is more vulnerable than the cell at rest and that there exists a wide range of radiosensibility amongst animal cells and tissues. Amongst the most radiosensitive are the lymphocytes. So far as composite tissues are concerned the intestinal mucosa is highly radiosensitive, exposure of the abdomen to unduly heavy dosage leading to excessive formation of mucus, mucoid degeneration, intestinal haemorrhage, paralysis of intestinal muscle, desquamation of large tracts of mucosa and death from toxic absorption. While there is universal agreement that, directly or indirectly, rays produce injurious effects upon cells there is doubt whether smaller doses do not stimulate the activity of cells. Opinions are divided upon the point, but the failure to observe any but injurious effects may depend upon the fact that the experimenters have not reduced the amount of radiation they employed to sufficiently low limits. In the case of Ascaris ova increase in rate of division was not observed until the amount of radiation received by the eggs was reduced to that derived from about one ten-millionth of a milligram of radium bromide for a period of about 30 hours.

Pathology

Histology.—Morbid histology has been in some measure at a standstill, although during the War it was employed extensively in striving to unravel the pathology of war nephritis, gas gangrene, gas poisoning and, indeed, of any novel pathological condition. Its most striking success was in reference to the mode of extension of gas gangrene from the seat of infection. The action of the toxin secreted by the infecting bacilli extends along the muscle bundles far in advance of the bacilli themselves, produces glassy changes of the muscle fibres correlated with a loss of contractility that can be demonstrated on the operation table and is a necessary precursor to advance of the bacilli themselves by multiplication. These observations were the prelude to a radical modification of the surgery of the condition and a definite improvement in results.

Bacteriology.—In bacteriology (*q.v.*) a useful step was taken by the Medical Research Council in forming the national collection of type cultures at the Lister Institute. Begun in 1920 it now contains more than 2,000 living strains of bacteria, protozoa and fungi, available for workers in widely different lines of research.

Experiments upon the conditions under which bacilli, particularly the sporing anaerobes of tetanus and gas gangrene, exert pathogenic activity showed that if washed clear of toxin and inoculated without contaminating substances they remained inert. Multiplication, followed by manifestation of the ordinary disease phenomena, occurred only if they were injected along with toxin (not necessarily their specific toxin) or with some solid particles such as lime or silica. In other experiments the presence of silica exerted an important influence on the multiplication of tubercle bacilli in the tissues.

Diphtheria.—Important observations were conducted in many countries upon the so-called Schick test as a means of diagnosing susceptibility to diphtheria (*see* Infectious Fevers). If a minute quantity of diphtheria toxin, highly diluted, were injected intradermally in man there occurred a patch of redness locally about 2 cm. in diameter in certain persons, whereas in others the injection was without effect. Heating of the toxin destroys its power of producing this effect. Further search indicated that in those persons who are negative, diphtheria antitoxin is present in the blood serum, whether naturally, or as the result of having passed through an attack of diphtheria, or of gradual immunisation owing to the fact that the person is a diphtheria carrier. In Schick-positive persons there is absence of antitoxin and therefore the injected toxin is not neutralised and produces its pathological effect. Subsequent examination on a large scale showed that the reliability of the test was of a high order. The natural corollary is that during an epidemic all Schick-positive persons should receive a prophylactic treatment with diphtheria antitoxin. Later work showed that diphtheria "anatoxin," *i.e.*, toxin detoxicated by addition of formaldehyde and exposure to a temperature of 37° C. for a few weeks, was equally efficacious in producing immunity.

Scarlatina.—By a similar process of reasoning the two Dicks in America introduced an intradermal diagnostic test for scarlatina, the toxin being derived from broth cultures of a variety of haemolytic streptococcus found in the throats of scarlatina patients and believed by some to be the cause of the disease. So far the Dick test is not on such firm ground as the Schick test. Nevertheless some authors have expressed their view that the test is of much value in determining susceptibility or insusceptibility to scarlatina and that an anti-scarlatinal serum prepared by means of the haemolytic streptococci is in many instances efficacious in immunising the Dick-positive individual and rendering him negative on subsequent intradermal tests.

Tuberculosis.—A further extension of the principle has been applied in the case of tuberculosis (*q.v.*), but the work is still in its earlier stages and the time is not ripe for dogmatic statement. From time to time papers are published indicating that antibody formation is not a universal function of the tissues but that there are special sites for its formation. So far there is no consensus of opinion on the subject nor are the instances adduced sufficiently marked to be convincing but it is certain that variations occur in local resistance of the tissues to infection. The most recent suggestion is that antibody formation is a function of the reticular endothelial system.

Tularaemia.—A hitherto unrecognised disease was described by McCoy in 1912 when investigating ground squirrels in Tulare county, California, that had been attacked by a plague-like disease not caused by *B. pestis*. Since that time it has been found widely in the United States and was definitely recognised as affecting man in 1914. Since 1914 tularaemia has occurred in at least nine laboratory workers engaged on investigations with *B. tularense*. The micro-organism is an exceedingly minute cocco-bacillus and it is considered that infection in man was by inhalation or by a blood-sucking fly. Transmission from rabbit to rabbit occurs by the rabbit louse and the rabbit tick, neither of which bites man.

Dental Caries.—A bacillus (*B. odontolyticus acidophilus*) has been isolated from carious teeth and in pure culture forms sufficient acid to dissolve the enamel. Undecayed teeth placed in such pure cultures for a period of weeks show loss of enamel at spots and local growth of the bacilli along the dental tubules. Microscopically the appearance of this artificial caries is identical with that of natural caries.

Botulism.—Numerous papers have been published upon botulism, a form of severe food poisoning (*q.v.*) dependent upon an anaerobic bacillus (*B. botulinus*). The nervous system is profoundly attacked by the toxin, difficulty of vision, dilated pupils, ptosis and paralyses being among the earliest symptoms. The toxin differs from other toxins in being pathogenic when administered orally; it is absorbed in the stomach and upper duodenum. An antitoxic serum has been prepared and is useful in treatment. This form of food poisoning was originally associated with sausages but occurs in connection with a great variety of foods. Most of the recorded cases have occurred in America.

Spirochaetes.—During the War there occurred in Flanders amongst the men in the trenches a severe form of disease associated with jaundice and haemorrhage which was traced to a spirochaete similar to or identical with *Sp. icterohaemorrhagica*, which in Japan infects rats and is transmitted by them to man. The same organism was found in the rats infesting the trenches.

Syphilis.—In the case of another spirochaetal disease, syphilis (*see* Venereal Diseases), Brown and Pearce succeeded in transmitting the disease to rabbits by intratesticular inoculation and showed the close resemblance of the pathological and clinical manifestations to those met with in man. By a prolonged series of experiments on rabbits Pearce answered in the negative the long debated question whether yaws and syphilis are manifestations of a single disease. Much work has been done on the Wassermann reaction. All doubts are not set at rest nor is the behaviour of the reaction completely understood, but it has stood the test of time and is considered of some diagnostic value.

In the investigation of spirochaetal diseases caution in deduction from experiment is shown by the fact that spirochaete-like bodies are to be found in the lateral ventricles of normal monkeys, rabbits and guinea-pigs. Only after animals that had been injected long previously with material from disseminated sclerosis (which is regarded by most authorities as of syphilitic origin) had been found to present these bodies in their lateral ventricles, was their existence in normal animals also discovered.

Typhus.—In typhus and trench fevers minute parasites were discovered belonging to the group now named Rickettsia. For a short time the relation of the Rickettsia to the disease was in doubt, but largely owing to the work of Bacot, an eminent entomologist who contracted typhus during his investigations and died therefrom, it is now recognised that both diseases depend upon the presence of varieties of Rickettsia, and that these parasites are conveyed from patient to patient by body lice. One of the most delicate manipulative operations ever attempted, and actually carried out with brilliant success by Bacot, was the filling of the rectum and intestine of lice with Rickettsia-infected blood by means of a fine capillary glass tube.

Bacteriophage.—An interesting phenomenon called after d'Herelle, its discoverer, has attracted much attention. When working with certain cultures of intestinal bacteria d'Herelle observed that on occasions culture apparently failed, the broth remaining quite clear. Subsequently he found that addition of a minute quantity of one of these clear fluids to a culture tube, cloudy with growth, was followed by clarification of the latter; as little as one part in a million was sufficient. He considered that he had obtained evidence of a filter-passing "microbe bactériophage" and obtained the phenomenon by successive culture from intestinal contents, sewage, soil extracts. This clarifying power is a property of leucocytes, tears, nasal mucus, eggwhite and other substances.

From the first the filter-passing microbial explanation met with opposition, many authorities regarding the phenomenon as being due to the action of an autolytic enzyme, or a catalyst causing the micro-organisms to produce autolytic ferments. Later, Fleming described a somewhat similar phenomenon by means of a special micro-organism that he isolated (*M. lysodeikticus*). This organism in thick suspension is in a few minutes completely dissolved by tears in a 1–9,000 dilution and using it as an indicator he found evidence of the lytic principle in nearly all tissues of the body, but not in urine, cerebrospinal fluid or sweat. In the vegetable kingdom he found it in the turnip alone. It is doubtful whether there is a single lytic substance or more than one. The essential difference between this and d'Herelle's phenomenon is that the former cannot be transmitted in series. Fleming therefore speaks of it as a "lysozyme," and points out that some bacteria are sensitive to lysozyme action and others not, thus raising the speculation whether the pathogenicity of bacteria may be determined by the absence of lysozyme.

Filter-Passing Microbes.—Since 1905 papers have appeared from time to time in medical literature on the "filter passer" or "filterable virus" (*see* FILTER-PASSING MICROBES). A series of morbid conditions is now recognised with more or less certainty as being due to a virus so minute that it passes through the pores of a porcelain filter, or in some cases is beyond the lowest limits of microscopic vision. Of these diseases rabies, vaccinia and perhaps, variola are the best known. In lethargic encephalitis and herpes evidence is tending in that direction but is not conclusive owing to the discovery that laboratory animals mainly used for this type of work (monkeys, rabbits) may under normal conditions present appearances in their brains that have been regarded as evidence of experimental transmission from man.

Dengue has been added to the list, while the so-called mosaic disease of the tobacco and tomato plants (*see* PLANT PATHOLOGY) is stated to be due to a filterable virus, and distemper in dogs may show a like origin. In addition a transmissible filter-passing virus has been recognised in the rabbit; at first this virus was thought to be the cause of varicella but it is now recognised to be the cause of a naturally occurring infection of the rabbit.

Gye and Barnard have described and photographed by means of ultra-violet light, respectively, a filterable virus derived from certain malignant tumours, following in this direction the pioneer work of Rous on chicken sarcoma. Finally, in the opinion of some authorities the cause of influenza (*see* INFLUENZA) is not Pfeiffer's *B. influenza*, this being merely a usual concomitant, but is in reality a filter-passing virus that has not yet been determined with certainty.

OBSTETRICS AND GYNAECOLOGY

Eclampsia.—The exact pathology of eclampsia has not yet been solved. Obata, as the result of injecting mice with extracts of human eclamptic placenta, considers that it is an intoxication by placental poisons made possible by a weakening in its normal capacity of neutralisation on the part of the maternal blood. Treatment of the condition on conservative lines has recently gained ground against more radical measures, and control of convulsions by hypnotics with venesection and administration of oxygen have replaced operative procedures. Under these conditions the previous mortality has been reduced by more than 50 per cent.

Fibroids.—The chief direction in which change of view is taking place among gynaecologists is that of the treatment of uterine fibroids. The old method of curetting has given place in large measure to hysterectomy, which in turn may be destined to give place to radiological treatment in a large proportion of cases. In several important gynaecological clinics on the Continent surgical treatment of uterine fibroids is the exception in an uncomplicated case.

MEDICINE

Anaemia.—In pernicious anaemia (*q.v.*) it has been shown that one of the cardinal features is an increase in the mean diameter of the red cells which is independent of the degree of the anaemia and persists through the course of the disease. On the other hand anisocytosis increases with the anaemia. In the remissions which occur naturally or after splenectomy, though the haemoglobin may rise there is little change in the diameter of the red cells. In treatment transfusion has been found of little value, but benefit has resulted in some cases from removal of a portion of the bone marrow from the tibia. Apparently removal of some of the bone marrow acts as a stimulus to regeneration of marrow and therewith of the blood cells that are needed by the body. Purpura is described as being of two varieties (1) that which is dependent upon destruction of blood platelets; (2) that which occurs in anaphylactic conditions and is due to direct injury of blood vessels. In the platelet variety a blood platelet antiserum has been prepared and is of therapeutic value.

Heart Diseases.—Diseases of the heart and great blood vessels have been studied by means of the electrocardiograph and numerous conditions, particularly heart block and those in which the nervous mechanism of the heart beat is concerned, have been investigated. Systematic examination of recruits in whom cardiac symptoms developed during early training resulted in a clearer perception of those abnormalities of heart action which were transient and of little importance as distinguished from those which were significant of disease.

Cerebrospinal Meningitis.—Cerebrospinal meningitis (*q.v.*) and lethargic encephalitis (*q.v.*) have received much attention. In cerebrospinal meningitis it has been shown that three, possibly four, different types of meningococcus occur and that antiserum treatment to be successful must be homologous. Epidemics could usually be traced to a carrier and the chance of their occurrence was greater where men were confined in a relatively narrow space, *e.g.*, barracks. A special method of treating carriers by means of inhaling chloramine-T was instituted with some success. In the case of lethargic encephalitis, it appears probable that the cause will be found to be a filter-passing virus.

Herpes.—In the case of herpes in rabbits and herpes in man, including herpes zoster, it has been found possible to transmit keratitis and some other special conditions from animal to animal and man to animal by means of a filter-passing virus.

When this has occurred microscopical appearances are found in the nervous system apparently identical with those met with in lethargic encephalitis. The whole question, therefore, is in an unsettled condition.

Liver Cirrhosis.—An interesting observation is that a form of progressive degeneration of the lenticular nucleus occurs which is associated with hepatic cirrhosis. Since its first description by Wilson in 1912 over 70 cases have been described but the pathological agent remains completely unknown, though there are indications that the liver is the seat of the primary pathological process. Clinically the symptoms are chiefly cerebral and the hepatic cirrhosis which is so constantly found at autopsy is usually latent.

General Paralysis of the Insane.—In the case of general paralysis of the insane, a form of treatment that has been advocated is inoculation with benign tertian malaria which is then treated with quinine. Maniacal and early cases have been found to respond to this treatment best. Intelligence, articulation, writing and equilibrium improve markedly, but defects of character and manners remain. Some cases may even be able to return to responsible duties. Advanced cases merely remain stationary. The idea underlying this treatment is that the malarial parasites stimulate the body to the formation of spirochaetal anti-substances.

Respiratory Diseases.—In the province of respiratory diseases, gas poisoning necessitated urgent investigation from the commencement of 1915. An intense oedema was produced which blocked the finer air passages and in its minor degrees led to a widespread bronchopneumonia. Variations were met with as the nature of the gas used was changed, but from the respiratory point of view at least the phenomena were fairly constant. In pneumonia, experimental work on monkeys showed that four types of pneumococcus occur and do not protect against one another.

Asthma.—Work on asthma has shown that in a large proportion of cases, if not in all, the disease is of an anaphylactic nature, an intense reaction being produced in the bronchial mucous membrane of a person sensitised to some particular substance of protein origin. Determination of the particular substance in any individual case may be lengthy, but if it be determined there is a possibility of successful treatment by gradual immunisation.

Tuberculosis.—In tuberculosis (*q.v.*) two important methods of treatment have been suggested. In one, an endeavour has been made to increase the antagonising cells in the body by repeated irradiation of the spleen. This organ is a storehouse for lymphocytes and it is known that the lymphocytic content of the blood can be raised by repeated small doses of X-rays. The method has not as yet a great following. The other method is by administration of a gold salt $[Au(S_2O_3)_2Na_3]$ named "sanocrysin" by Möllgard, originator of the method. The underlying idea is not purely chemotherapeutical for it is held that the poisonous action of the organisms killed *in vivo* by chemical means is neutralised by an antiserum. The experimental work was carried out in Denmark and has been confirmed and extended in this country. Careful selection of cases must be made when applying sanocrysin to man as the reaction in pulmonary tuberculosis may be very severe, but with due precautions great benefit may accrue.

Diabetes.—In the case of diseases of endocrine origin the outstanding example of advance is afforded by the insulin (*q.v.*) treatment of diabetes (*q.v.*). The pathology of the condition was fairly well known but the great achievement of Banting and his collaborators was that they succeeded in isolating the material in sufficient quantity for therapeutic purposes. Numerous researches have been undertaken in the endeavour to simplify the treatment but it still remains necessary for insulin to be injected intravenously and repeatedly in severe diabetes.

Goitre.—The relation of iodine to endemic and to exophthalmic goitre (*q.v.*) has been investigated. A close relation between the cellular condition of the thyroid and the amount of iodine has been demonstrated and it is held that relative or absolute deficiency of iodine is the immediate cause of simple goitre however this deficiency may be occasioned. Treatment by internal administration of iodine has met with much success. Success has also been claimed for radiological treatment and for surgery in cases in which iodine and other medical treatment has failed.

Paratyphoid—Description has been given of a paratyphoid epizootic in a flock of sheep with a consequent human epidemic of paratyphoid (40–50 severe cases with four deaths) that occurred in the Essen district. *B. paratyphosus B.* was isolated from the sheep's flesh and from the patients' stools. It was not here a case of contamination but the sheep suffered from the same disease as the human beings.

A peculiar disease has been occurring since July 1924 among the fisher folk of the Frisches Haff, the great freshwater lagoon of East Prussia. Many suggestions were put forward as to its aetiology but finally it was traced to arsenic freely contained in the waste water of two cellulose factories which was pouring into the Haff in large quantities.

Racial Blood Indices.—On the basis of observed peculiarities of group II. and group III. red blood cells, another research would group mankind according to their racial blood index (*see* RACES OF MANKIND). Analysis of the large amount of material accumulated since 1919 suggests that so far as blood groups are concerned races fall into six divisions strikingly different in type. These six divisions are European, Intermediate, Human, Indo-Manchurian, Afro-South-Asiatic and Pacific-American. No better indication could be given, than this last example, of the wide range covered by medical research. (W. S. L.-B.)

MEDICAL SERVICE, ARMY (*see* 20.19).—An Army Medical Service (*service de santé*, Fr.; *Sanitätsdienst*, Gm.; *servizio sanitario*, It.; *eisei kimmu*, Jap.) is an indispensable technical branch of the military organisation. On its efficiency the man-power of an army to a great extent depends. Its duties include the care of sick and wounded, the prevention of disease and the preservation of health, the medical examination of recruits, the invaliding of men unfit for further service, the supply of medical and surgical material, the administration of military hospitals and the command, education and training of a personnel for all these purposes. In time of war the collection, evacuation and distribution of battle casualties and the strategical and tactical employment of a variety of medical units for these duties are additional functions of an army medical service.

Administration.—The army medical service of the British forces is administered by a director-general in the adjutant-general's branch of the War Office, with a staff for personnel and mobilisation services, for preparation of statistical reports and consideration of professional questions, and for the supply of medical and surgical material, together with two new directorates of hygiene and pathology which were instituted after the World War in consequence of the lessons of the War and of the scientific advances in the domain of medical research. The director-general also administers the nursing services and the Army Dental Corps, the former through a matron-in-chief and the latter through an inspector of dental services at the War Office. He is represented in commands at home and overseas by deputy directors and assistant directors with deputy assistant directors for hygiene and pathology. A similar form of administration exists in other armies. In the United States the surgeon-general controls not only the medical, dental, nursing and a new corps, the sanitary corps, but also the veterinary corps.

Advisory Boards.—These are composed of military and civil members and are associated with the British Army medical administration. They meet from time to time at the War Office for consideration of general professional policy, questions of hygiene and of pathological research, nursing services and the co-operation of voluntary aid in war.

Personnel.—The estimated peace establishment of the Royal Army Medical Corps in 1926 was 584 officers and 3,579 other ranks. They serve in all stations at home and overseas where there are British troops, including India. Their work there is supplemented by assistant-surgeons of the Indian Medical Dept., formerly the Indian subordinate medical department, and by natives of an Indian Hospital Corps, formerly the army

hospital corps and army bearer corps, who with soldiers trained for hospital duties from combatant regiments formed the subordinate staff of British military hospitals in India before the War. A separate body of officers, the Indian medical service and sub-assistant-surgeons of the Indian Medical Dept. served until the World War with Indian regiments and in regimental hospitals under much the same conditions as the British regimental medical services of earlier days. Since the World War, station hospitals for Indian troops have been instituted.

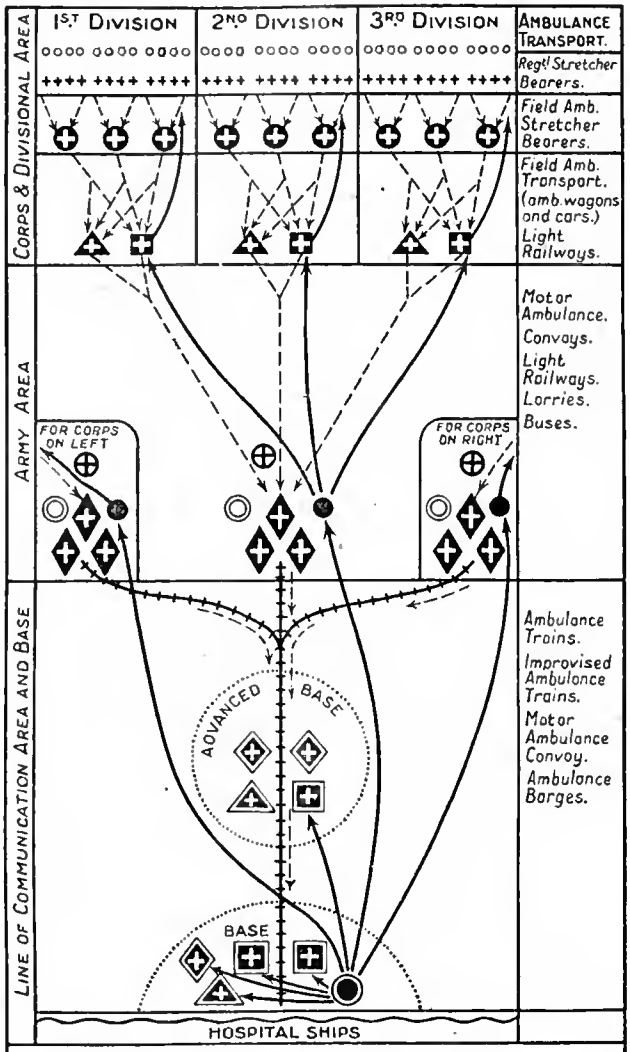

FIG. 1.—Diagram of the organisation of Medical Services, from a corps front of three divisions in an army to a sea base.
(From "History of the Great War" [Medical Services], Vol. II. By permission of the Controller, H.M. Stationery Office, London.)

The army dental corps, with an establishment of 71 dentists, is estimated to provide one dentist for every 600 recruits or for every 1,500 troops in a command. (*See* DENTISTRY.)

Queen Alexandra's Imperial Military Nursing Service (Q.A.I.M.N.S.) has an establishment of 270 nurses and the Queen Alexandra's Military Families Nursing Service (Q.A.M.F.N.S.) an establishment of 91 nurses. They serve in the larger military and families hospitals at home and overseas, except India.

Territorial Army Royal Army Medical Corps.—The personnel is organised in peace to provide a regimental service, one field ambulance for each division of the Territorial Army, eight casualty clearing stations, three general hospitals and eight sanitary sections. These are field service units and form a cadre for the training of the R.A.M.C. (T.A.). Previous to the World War the Territorial Force had three field ambulances, one casualty clearing station and one sanitary section for each division, together with 23 general hospitals. The reduction therefore in Territorial Army R.A.M.C. units since the War has been considerable.

Military Hospitals Reserve.—An establishment of 2,000 other ranks is organised to provide trained personnel to staff military hospitals in England on the outbreak of war when the regular Royal Army Medical Corps personnel is withdrawn, and to furnish reinforcements for an expeditionary force.

Service.—The number of medical officers (1924) was 939, of dentists 155, of nurses 675 and of veterinary officers 124. In continental armies with conscript service the fixed establishments for medical services cannot be computed for purpose of comparison on the same basis as those of the British and American voluntary armies.

Training.—Officers of the R.A.M.C. attend preliminary and post-graduate courses at the Royal Army medical college, and military training with the men at the R.A.M.C. depôt at Aldershot, where there is also an army school of hygiene. In America, an army medical centre was opened in 1923, at Takoma Park, near Washington, District of Columbia. It consists of schools for the training of the medical, dental, nursing and veterinary corps. There is also a medical field service school at Carlisle, Pennsylvania, and a school of aviation medicine at New York. In Italy, there is an army medical school at Florence, and in France, at Lyons, in addition to the post-graduate school at the Val-de-Grâce, for student candidates.

Military Hospitals.—In the British Army, military hospitals and small depôt hospitals are established in all commands. In America, there are garrison hospitals and eight large general hospitals, similar to some of the larger military hospitals in England. In continental armies there are also garrison hospitals, but in France, military sections of the civil hospitals take their place to a great extent.

Army Medical Stores.—In some continental armies most of the medical and surgical material is or was prepared in army medical laboratories and factories. In Great Britain and America it is distributed from army medical stores, that for the British Army being at Woolwich.

War Organisation.—A regimental medical service, field ambulances, casualty clearing stations, general hospitals, convalescent depôts, advanced and base depôts of medical stores, motor ambulance convoys, ambulance trains, hospital ships, sanitary sections and squads, and mobile hygiene, bacteriological, X-ray and dental laboratories come into being for service with a British Expeditionary Force on the outbreak of war; there are equivalent units in other armies under different names and organisation. To complete their personnel on mobilisation the medical and nursing reserves are called up. For this purpose there is a regular reserve of R.A.M.C. retired officers and men liable to be recalled to service, a supplementary reserve of officers, a home hospital reserve of the St. John Ambulance Brigade, the Territorial Army R.A.M.C. and the Voluntary Aid Detachments (under T. A. County Assn.) of the British Red Cross Society, the St. John and the St. Andrew Ambulance Associations. There are also important reserves of the Q.A.I.M.N.S. and the Territorial Army Nursing Service. But in a great war, practically the whole of the country's medical resources may be enrolled within the limits of age. In the World War, the peace establishment of the R.A.M.C. thus expanded to 15,000 officers and 120,000 ranks; while in the U.S.A. the medical service expanded to 30,591 officers and 264,181 other ranks. A similar vast expansion occurred in nursing personnel and in the number of medical units. Military hospital beds, for example, reached a total of 637,746 for the British forces and 353,887 for those of the United States.

The various units are distributed in the war zone, from front to base, in divisional, corps, army and lines of communication, areas of command, according to the nature of the functions

for which they are organised. The regimental medical service consists of an officer and four men of the R.A.M.C. with 16 men of the regiment as stretcher bearers and nine as sanitary detachment. In battle, a regimental aid post (*poste de secours*, Fr.; *Truppenverbandplatz*, Gm.; *posto di medicazione*, It.), to which they collect the wounded, is established. Each division has three field ambulances (the equivalent of the medical regiment of a U.S.A. division, the *groupe sanitaire divisionnaire* of the French, and the *Sanitätsbattalion* of the German organisations). A field ambulance is composed of a headquarters and two companies, each company consisting of a bearer and a tent division, representing the bearer company and the field hospital respectively of the time of the South African War and previous equivalent units of the continental army divisions. With a cavalry division there is an organised field ambulance for each cavalry brigade.

Working of the Systems.—In battle, the tent division opens an advanced dressing station at a point to which its wheeled ambulance transport can be brought, and a main dressing station further back. The bearer company removes the wounded from the regimental aid posts to the advanced dressing station, and the transport brings them from there to the main dressing station. The motor ambulance convoys (*section sanitaire auto*, Fr.), composed of 50 motor ambulance cars each and with one convoy to each corps, bring the wounded from the main dressing stations to the casualty clearing stations (evacuation hospital, U.S.A.; *hôpital d'évacuation*, Fr.; *Kriegslazarett*, Gm.) which are established in the proportion of one to each division, at or near railways and at the head of the lines of communication. From there, when fit to travel, the sick and wounded are taken in ambulance trains to the general hospitals, which are units of 1,000 or less beds placed at sea bases or other convenient centres. Hospital ships transfer the patients to home ports, whence they are distributed to hospitals throughout the country.

Such is the normal system of collection, evacuation and distribution of sick and wounded in a war zone. It is liable to modification according to circumstances and the nature of the terrain, especially as regards methods of transport by road, rail, river, canal or air. It worked well in the World War, where the test was severe. During the battles of the Somme, for example, the British field ambulances collected 316,073 wounded between July 1 and Nov. 30 1916, including 26,675 in the first 24 hours; 304,285 were transferred to the base hospitals, and on one day, July 6, 10,112 arrived in hospital ships at Southampton and Dover.

The mobile laboratories and advanced depôts of medical stores are usually placed with or near the casualty clearing stations. For sanitary duties a sanitary section, of 25 men, is allotted to each division and base, and sanitary squads of five men each to small posts, such as railheads. Their influence and that of medical research had remarkable results during the World War in preventing disease. Enteric and typhus fever, the scourge of armies in past wars, became negligible quantities in the British and American forces, and fatal gangrene of wounds and trench fever, for long a cause of much inefficiency, were brought under control. Indeed, the two outstanding features of the army medical service of the present day are its power of controlling disease and its power of systematically, rapidly and effectually bringing battle casualties under life-saving surgical and hospital treatment.

In this beneficent work it is assisted by voluntary aid organisations. Amongst all civilised nations there are national Red Cross societies (*see* RED CROSS) organised as auxiliaries of their army medical services in time of war. They are of special value in distributing voluntary gifts and comforts, such as are not supplied through official sources, to the various hospitals in the home territory and in the war zone, in organising auxiliary hospitals and in various other activities. Those recognised by their governments, together with the whole of the personnel and units of the medical services of armies, are protected and become the recipients of special privileges under the Geneva Convention of 1906, should they fall into the power of the enemy during war.

(W. G. MA.)

MEDICAL SERVICE, NAVAL.—In Great Britain the Royal Naval Medical Service is administered by the medical director-general, an officer selected from the list of surgeon rear-admirals. He is responsible to the Board of Admiralty for the efficiency of his department. The work of the medical department includes questions regarding the personnel of the Naval Medical Service, the supply of surgical instruments, drugs, medical material, etc., assessments arising from invalidings and claims for compensation, the hygiene and sanitation of ships, hospitals and establishments, preparation of estimates for the medical vote, nursing and sick-berth reserve forces and publication of the medical statistics of the navy.

Conditions of Service.—The medical director-general superintends all professional and administrative details of naval medical establishments and the practice of medical officers. Candidates for cadetships and for commissions in the navy are physically examined at his department. He also nominates the appointments of all naval medical officers which are submitted to the board for confirmation. The existing ranks date from 1919, and are: On entry, surgeon lieutenant; after six years' satisfactory service, surgeon lieutenant-commander; after six years' service in the latter rank, surgeon-commander, providing the necessary promotion examination has been passed; the senior ranks of surgeon captain and surgeon rear-admiral are reached by selection.

Until the outbreak of the War candidates were entered by competitive examination, but, owing to the lack of applicants since the War, these examinations have not yet been resumed, and for the time being officers are entered for temporary service, engaging for three years with the option of turning over to the permanent service if considered suitable. Officers senior to the rank of surgeon-commander do not normally serve afloat, but are employed in hospitals and depôts. Conditions of service, etc., are published in the official monthly *Navy List*.

All ships, except the smallest, carry medical officers, larger ones carrying two. In view of the fact that ships are frequently on isolated service, the medical officer, in addition to his ordinary medical and surgical duties, has to fulfil the function of medical officer of health, and consequently has to advise his commanding officer on all questions relating to the protection of the health of the crew, and suggest any measures considered necessary for this purpose. He must acquaint himself with the conditions of health prevailing at the ports the ship is likely to visit, and veto the introduction into the ship of any water or food likely to carry disease. It is his duty to instruct the ship's company in "first aid" and personal hygiene, with special reference to venereal diseases and the evils resulting from the abuse of alcohol. In fleets and squadrons the hygienic responsibilities are, as far as is compatible with efficiency, relegated to the senior medical officer of the flagship, who is designated the fleet or squadron medical officer as the case may be. This arrangement does not, of course, absolve individual medical officers from responsibilities concerning their own ships. The Royal Naval Dental Service was inaugurated in 1920, and is supervised by a dental officer of commander's rank attached to the staff of the medical director-general. The sick-berth nursing staff, instituted in 1884, has a complement of 1,100 highly trained men who carry out their duties both ashore and afloat.

Equipment and Hospitals.—The special accommodation which is allocated for the sick in all ships is termed the "sick bay." These places, in spite of the fact that all serious cases are, for their own comfort, transferred to hospital on the earliest convenient occasion, are specially equipped for the comfort of patients and for all medical and surgical contingencies. The larger ships have special operating rooms. Also, for the greater safety of the wounded in action, spaces are reserved in the most protected part of the ship. These are known as "medical distributing stations." The nursing on board is carried out by the sick bay staff. The naval hospitals are: Haslar, Chatham, Plymouth, Portland, South Queensferry, at home; and Malta, Hong-Kong, the Cape, Bermuda, Wei-Hai-Wei, abroad. In addition, there is a naval mental hospital at Great Yarmouth.

All these hospitals conform in every way to the most modern requirements of medicine, surgery and hygiene.

Auxiliary Services.—These include the medical officers of the Royal Naval Volunteer Reserve, Queen Alexandra's Royal Naval Nursing Service Reserve and the Royal Auxiliary Sick-Berth Reserve. The personnel of these services is called up for periodical training and would be mobilised on the outbreak of war.

Foreign Navies.—The organisation in the principal foreign navies is similar to the British. Medical officers of the French navy—instead of being selected from candidates qualified in the ordinary way, as is the practice in the British, Italian and Japanese navies—are professionally educated at special naval medical colleges, and subsequently hold purely professional titles of rank. Italian naval medical officers, in common with other non-executive officers of that navy, hold military in contradistinction to naval rank. The medical organisation in the Japanese navy is almost identical with the British.

The World War.—At the outbreak of the War the naval medical service was expanded by mobilisation of its retired, emergency and Royal Naval volunteer reserve officers. Later, a large number of temporary surgeons were entered for general service, and also medical students were taken in for service in destroyers under the title of surgeon probationers. Queen Alexandra's naval nursing service was more than trebled by the mobilisation of the reserve sisters and the sick-berth staff, supplemented by the naval auxiliary sick-berth reserve.

Except under abnormal climatic conditions, and during epidemics of influenza, the health of the navy during the War was remarkably good. This satisfactory state of affairs can be attributed to:—

(*a*) The careful supervision of the personnel by the medical officers and the strict quarantine precautions enforced.
(*b*) The care exercised concerning food, water and victualling arrangements, both in ships and establishments.
(*c*) Preventive inoculation against enteric fever.
(*d*) The comparative isolation of the fleets lessening the chance of venereal infection and abuse of alcohol.
(*e*) Lectures given to the men on personal hygiene.
(*f*) Measures taken to lessen the monotony of ship life in war time.

Casualties.—As compared with land warfare, the number of men killed outright in action was striking, and this, combined with the numbers of deaths from immersion, made the ratio of killed to wounded far higher in the navy than in the army. For instance, at Jutland, out of 6,688 casualties there were 6,014 either killed or drowned. The higher proportion of fatal wounds was due to the conditions of modern warfare—explosion of large shells in closed compartments. In comparison with the wounds in the trenches, where the clothing and skin were ingrained with filth, wounds in the navy were less disposed to become septic. Burns formed a high proportion of the casualties, and were chiefly caused by the ignition of our own cordite or from the momentary flash of a high explosive shell in a confined space. A considerable number of casualties arose from gas poisoning, caused by the explosion of shells, the most lethal factor in these cases being nitric oxide gas. (G. L. B.)

United States.—In 1926 the Medical Corps of the U.S. Navy consisted of 38 medical directors, 4 of which had the rank of rear-admiral and 34 of captain; 66 medical inspectors with the rank of commander; 320 surgeons, with the rank of lieutenant-commander; 217 past assistant surgeons, with the rank of lieutenant; and 147 assistant surgeons, with the rank of lieutenant (j.g.). The Dental Corps consisted of 66 dentists, with the rank of commander; 71 past assistant dental surgeons, with the rank of lieutenant; and 22 assistant dental surgeons, with the rank of lieutenant (j.g.).

The medical and dental officers are admitted to the corps after passing satisfactory examinations and as vacancies occur. Above the rank of lieutenant-commander promotion to each grade is by selection and examination. All medical officers receiving their appointment to assistant surgeon are given a course at the Naval Medical School in Washington, after graduation from which they receive their assignments to different posts of duty, either on board ships, at naval hospitals as internists or at other naval bases. The health and hygiene of the navy personnel are entrusted to the medical and dental officers of this branch of the service. Fully equipped hospital ships with an efficient personnel and skilled medical officers, including specialists, accompany all large fleets.

The Hospital Corps consists of pharmacists, pharmacist mates, first, second and third class, and hospital apprentices, as well as a corps of trained female nurses who serve on special hospital ships and in hospitals ashore. The enlisted men in the Hospital Corps are given special training and instruction at the various pharmacist and pharmacist mate schools throughout the country. During the World War those members of the Hospital Corps who had enlisted or had been drafted into it were put through a special course of training in civilian hospitals. The Naval Medical Reserve is composed of officers taken from civilian life and from among ex-naval medical officers. They receive a certain amount of training each year, are examined annually, and are promoted according to precedence, as in the regular service. They are ready to be called upon in any emergency.

The surgical instruments, medicines and dressings are all supplied, in great part, from the Navy Medical Supply Depot in Brooklyn, New York, and from the Medical Supply Depots in Mare Island, California, and Canacao, Philippine Islands. The entire Naval Medical Corps is under the direct supervision of the surgeon-general of the U.S. Navy, who is appointed by the President for this duty, for a term of four years, after which he may be reappointed. This duty carries with it the rank of rear-admiral.

3,093 commissioned officers of the Medical Corps of the U.S. Navy served in the World War, together with 24,587 enlisted men in the Hospital Corps. (C. C. B.)

MEDICINE, GENERAL.—Since 1910 the progress of medicine has been much influenced by the four years of the War, which, while interfering with steady research, brought with it urgent problems, caused diseases previously rare or unrecognised to become matters of common knowledge, and produced epidemics on an enormous scale, thereby calling forth much investigation and new knowledge.

Influence of the World War.—Trench fever and a special form of kidney affection, called trench nephritis, were practically new diseases; and the serious condition of epidemic (lethargic) encephalitis (*q.v.*), though it may have existed previously, for the first time became common and was recognised during the War. Certain industrial forms of poisoning, namely of trinitrotoluene among munition workers, and of tetrachlorethane among aeroplane makers, were temporarily in evidence, and an impetus was given to research into the conditions modifying efficient performance of labour. Deficient diet caused scurvy, especially in 'Iraq, and other "deficiency diseases" came into evidence, especially in central Europe. Cerebrospinal ("spotted") fever became for the first time epidemic in Great Britain (*see* SPINAL MENINGITIS); as a result of the depressing conditions and the lowered bodily resistance, influenza (*q.v.*) became pandemic all over the world in 1918–9; and a fatal form of infective heart disease (*endocarditis lenta*) became much more frequent in discharged soldiers. A form of infective jaundice (*spirochaetosis icterohaemorrhagica*), formerly known as Weil's disease, became prevalent in Flanders, and its true nature, namely, an infection with an animal microbe, akin to that of yellow fever (*q.v.*) (*Leptospira icteroides*), was found in Europe to be identical with that described in Japan in 1914. Paratyphoid fevers (*see* INFECTIOUS FEVERS) A and B, though of course known before, became much more familiar during and after the War, and it may be noted that the distinction between the forms of enteric fever known as typhoid and paratyphoid was not recognised in the Boer War (1899–1902), when the disease exacted a relatively heavier toll than in the World War, when the troops were eventually extensively protected by T.A.B. vaccination. Dysentery (*q.v.*), as in past wars, became prominent, as did malaria (*q.v.*) in the eastern areas of the campaign. The influence of a Sanitary Corps in the prevention of disease among the Allied Armies was a noticeable feature (*see* MEDICAL SERVICE, ARMY). Much progress has also been made in the prevention of tropical diseases (*see* THERAPEUTICS and TROPICAL MEDICINE).

Mental Diseases.—The War provided a tremendous field for the observation of the mental perturbations commonly designated as "shell shock," due to the psychical effects of long-continued bombardment, mental strain and anxiety, repression or the active forgetting of terrifying experiences, and of fear. Incidentally it gave an opportunity for testing the opinion of the more advanced followers of Sigmund Freud of Vienna, who, on the assumption that the sexual instinct is stronger than those of self-preservation and of the herd, have increasingly tended to refer mental symptons akin to those of shell shock to the conflict resulting when some sexual experience had, in obedience to the conventional influences, been repressed and thus removed out of the zone of consciousness. The value of Freud's contribution to morbid psychology (*see* PSYCHO-ANALYSIS) in the conception of mental conflict resulting from the active forgetting or repression of unpleasant experiences is undoubted, but to refer them mainly to sexual causes was shown by war experience to be too narrow a view, and the treatment by psycho-analysis and interpretation of dreams, and the patient's "associations" aroused much opposition. On the other hand curative measures on psycho-therapeutic lines, such as sympathetic analysis, re-education and occupational therapy, met with success and approval (*see* PSYCHIATRY, PSYCHOSES, PSYCHOTHERAPY).

Orthopaedic Surgery (*q.v.*).—Orthopaedic surgery also made great advances as the result of the numerous cases of injury during the War, and remedial gymnastics and exercises have thus been of great use in furthering recovery in such cases.

Preventive Medicine (*q.v.*).—The prolongation of life and diminution of infant mortality in Great Britain have both improved by about 50% in the last half century, and in the United States of America the average age at death has advanced from 40 in 1855 to 58 years at the present time. This has coincided with improved conditions of hygiene and environment, and has stimulated active measures in the prevention of disease—the ideal of medicine. The establishment in 1919 of the Ministry of Health in Great Britain was a far-seeing advance for the improvement of the national health and the prevention of disease (*see* THERAPEUTICS). In America regular periodic examination of healthy, or supposedly healthy, persons has been begun, and the statistical experience of life-assurance companies has already proved that this practice exerts a beneficial effect on the mortality of those adopting this course. The prevention of disease has been greatly assisted by the Rockefeller Foundation in New York, which has undertaken a world-wide campaign with this object on very broad lines through its International Health Board, its Division of Medical Education and its China Medical Board. In 1913 the Rockefeller Sanitary Commission, founded in 1909 for the eradication of hookworm disease (*q.v.*), was incorporated as the International Health Commission (called the International Health Board after 1916) of the then recently established Rockefeller Foundation, and since then has carried out campaigns against yellow fever (*q.v.*) in South America, which have practically exterminated it and incidentally led to Noguchi's discovery of the cause (*Leptospira icteroides*) of the disease, against malaria (*q.v.*) and tuberculosis (*q.v.*) (*see* also THERAPEUTICS). In connection with the National Insurance Act (1911) the Medical Research Committee (now Council) was created, and research workers have been financed and an enormous impetus given to the advancement of medicine and so to the diminution of disease.

Industrial Health.—The special conditions bearing on health in factories and industries, particularly the dangerous trades, have attracted specialised attention, particularly in America, where a School of Industrial Medicine has been instituted in connection with Harvard University.

Insanity.—The prevention of insanity by early treatment in psychiatric clinics, usually attached to general hospitals and often part of the neurological department, has been an important step in the prevention of mental disorder (*see* PSYCHIATRY). It is connected with the social service and after-care movements. In 1908 the American Council of Mental Hygiene was founded, in 1918 a similar council was started in Canada, in 1920 the French League of Mental Hygiene was inaugurated and in 1922 the British National Council for Mental Hygiene was established. This is evidence of the awakening interest in health of the public at large since the War, as is also shown by the Society for the Prevention of Venereal Disease, the League of Health and the British Empire Cancer Campaign.

Comparative Medicine.—The increase of experimental research has been followed by the study of comparative medicine and pathology, whereby human and veterinary medicine may mutually help and benefit each other; an Institute for research in the pathology of animal diseases and a professorship were established at Cambridge in 1923, and the study of experimental epidemics has been undertaken in laboratories at the Rockefeller Institute, New York, and at Manchester.

Statistical Methods.—Biological, anthropological and statistical methods are now being more formally utilised in medicine than in the past, and exact measurements and skilled calculations are being employed. An individual's constitution, or "the aggregate of hereditary characters, influenced more or less by environment, which determines his reaction to the stress of environment" (G. Draper), was present to the mind of Hippocrates and others, but the rise of bacteriology diverted attention from the internal to the external factors of disease. Anthropological measurements, formerly used for the recognition of the racial characters of mankind, have now been applied by Draper of New York to patients suffering from certain diseases, and the data thus obtained analysed by biometrical experts.

Applied Physiology.—Applied physiology was extensively developed and utilised during the War, for example in aviation, the transfusion treatment of surgical shock and haemorrhage, and the relief of gassing, and has advantageously been continued since on other lines, such as ventilation, the effects of sunlight and ultra-violet rays on bacteria, infections, general health and rickets (*see* PUBLIC HEALTH). Following on the established value of open-air treatment of tuberculosis and other infections, the beneficial influence on bodily resistance induced by sunlight (heliotherapy) and ultra-violet rays has been utilised. Heliotherapy (*q.v.*), practised for 20 years at Leysin by Rollier in surgical tuberculosis, has been adopted in Great Britain. Sunlight prevents and cures rickets, and its relation to the anti-rachitic vitamin D is an addition to knowledge, possibly of potential importance in connection with other "deficiency diseases." Ultra-violet rays act on a complex alcohol, cholesterol, present widely in the body and also in the skin, so as to confer on it the anti-rachitic action of the vitamin; they also raise the amount of calcium, iron, iodine and phosphorus in the blood, increase its bactericidal power and accelerate the healing of wounds. The tungsten-arc and mercuric-vapour arc lamps are employed to provide artificial ultra-violet rays. Diathermy or the application of a special form of intensive heat has been employed in cancer, pneumonia and other infections (*see* ELECTROTHERAPY).

Biochemistry.—Closely associated with applied physiology, of which it is really a part, *biochemistry* (*q.v.*) has developed out of physiological chemistry and has risen rapidly to an authoritative position. At Cambridge the Sir William Dunn trustees have built and equipped a fine institute and endowed the professorship held by Sir Gowland Hopkins, who has 40 advanced students carrying out research under his direction. The Rockefeller Foundation, New York, has provided similar laboratories at Oxford and University College, London.

Metabolism.—Biochemistry is specially concerned with the changes always going on in the body and described by the name metabolism. The basal metabolism means the average minimal chemical changes compatible with life taking place in the body during complete rest and when food is not being digested and absorbed, and corresponds with the minimal heat-production 18 hours after a meal of a mixed dietary—the working expenses, so to speak, of the resting body. This is estimated directly by measuring by respiratory calorimeters the heat evolved, or indirectly, and more easily in practice, by chemical analysis of the respiratory exchange, and has been shown to be remarkably constant in normal conditions. In disease the metabolic rate

may be altered; for example, in myxoedema it is lowered and all the vital processes are on a lower plane; whereas in fever and exophthalmic goitre it is accelerated. In the last-named disease the condition of the patient can be judged by the degree of increase in the metabolic rate. Knowledge of the chemical processes underlying metabolism is rapidly growing in exactness.

Vitamins.—The recognition of the *accessory food factors* or *vitamins* (*q.v.*) has opened a new chapter in nutrition and in the causation and prevention of disease. They are present in food in minute quantities, which greatly contrast with their power, and are essential for health, growth, especially of bone and teeth, and in other ways. New knowledge of the effects of their absence and of the (deficiency) diseases thus caused has accumulated, but more may be anticipated. The vitamins each have their special actions; one prevents scurvy (anti-scorbutic), others rickets (anti-rachitic or vitamin D), beri-beri or polyneuritis (anti-neuritic), and recently, it would appear, one is essential for normal reproduction, the absence of which, at least in female rats, produces sterility. Starvation, partial or complete, and an unbalanced diet entail a corresponding degree of avitaminosis and deficiency disease; war or famine oedema, which resembles the " wet " form of beri-beri, has been ascribed to a diet largely composed of cereal and deficient in protein food.

Blood-Chemistry.—From improved technique chemical examination of the blood for non-protein nitrogen (in kidney disease), sugar and gases, cholesterol, calcium, phosphates, chlorides and bilirubin has become a method of clinical laboratory routine and essential for correct diagnosis and treatment. Much work has been done on the hydrogen ion concentration of the blood and the conditions of (1) acidosis, or diminution in the alkali reserve of the blood, which occurs in two forms, ketosis, as in diabetes mellitus, and another due to retention of phosphates, as in renal disease, and (2) of alkalosis or alkalaemia in which the alkalinity of the blood is increased, as in forced breathing when carbonic acid gas is removed in unusually large quantities from the lungs. Alkalosis has, like a fall in the calcium salts and the poisonous effect of guanidine, been thought to cause a convulsive state—tetany, which forms part of the condition called spasmophilia seen in children.

Bacteriology (*q.v.*) has revealed the organism responsible for a number of diseases and so opened the way to specific treatment and the prevention of the infection. In the case of scarlet fever (*see* INFECTIOUS FEVERS), ascribed to haemolytic streptococci, G. F. and G. H. Dick have elaborated a test (the Dick test), analogous to the Schick test in diphtheria, whereby those susceptible to the disease can be detected and so artificially protected against it by an antitoxin. The recognition of tularaemia (due to a cocco-bacillus), a disease of rodents and transmitted to man by the bite of the horse fly, and of melioidosis also a disease of rodents and due to the *Bacterium whitmori*, in which the exact method of its transmission to man is uncertain, bear on the desirability of the closer correlation of the human with veterinary medicine. Invisible viruses or ultra-microscopic organisms, also called filter-passers (*see* FILTER-PASSING MICROBES), because they are so minute that they pass through the fine pores of a Chamberland or other filter, have attracted much attention and many diseases in man and animals are with a fair degree of certainty or probability ascribed to their agency.

Cancer.—The outstanding discovery of the ultra-microscopic organism of cancer (*q.v.*), which is active only in the presence of a " specific factor," by W. E. Gye and J. E. Barnard, opens possibilities of cure and prevention, for which the medical world has been at work for many years.

Bacteriophage.—D'Hérelle described a phenomenon, previously noted by Twort in 1915, often known by D'Hérelle's name, which he interpreted as the existence of an ultra-microscopic virus which lives as a parasite upon living bacteria and leads to their destruction and solution. The general opinion about the active substance responsible for these changes in bacterial cultures, and called by D'Hérelle the *microbe bacteriophage*, is that it is not an ultra-microscopic virus, but an enzyme or ferment produced by the undoubted bacteria themselves.

Protozoan infections (*see* PROTOZOOLOGY) are the cause of a number of diseases, such as yellow fever (*Leptospira icteroides*), a form of infective jaundice (*Spirochaeta icterohaemorrhagica*), rat-bite fever (*Spirochaeta morsus-muris*), and seven-day fever in Japan (*Leptospira hebdomadis*), and probably sandfly fever (*q.v.*) (a leptospira resembling that of yellow fever). Thus their prevention and the employment of curative antitoxins has been rendered possible.

Immunity (*q.v.*).—After a fever the individual usually becomes immune and protected against another attack, this is acquired immunity; the blood of such a person contains antibodies which antagonise the cause of that disease, and advantage has been taken of this to inject the blood serum of patients convalescent from measles into persons who have not had the disease so as to render them immune.

Anaphylaxis.—The reverse of immunity is hypersensitiveness (anaphylaxis, allergy) which is shown by idiosyncrasies and forms the underlying factor in asthma and other diseases spoken of as " toxic idiopathies; " the substances responsible for the symptoms can be detected by skin tests and the appropriate treatment thus employed. Protein shock therapy is also employed for asthma and chronic arthritis. The importance of " focal infection " such as dental disease (*see* DENTISTRY), is now much more fully recognised (*see* THERAPEUTICS).

Exact studies upon the chemical activities of bacteria now in progress are beginning to throw light on the actions of toxins and the chemical factors involved in immunity reactions.

Radiology (*q.v.*).—In radiology there has been a steady advance in the methods of diagnosis and treatment; technique has been elaborated and special methods have been introduced. Dyes opaque to X-rays have been employed in various directions; thus lipiodol has been injected into the bronchial tubes to demonstrate dilatation of their lumen, into the spinal column to show the position of tumours, and even into the pregnant uterus to detect pregnancy. The condition of the gall bladder and the presence of gall stones can be made evident by organic compounds of iodine and bromine (tetra-iodo-phenol-phthalein and tetra-brom-phenol-phthalein), which after being taken by the mouth are excreted in the bile and show up under X-rays (cholecystography). Injection of air into the peritoneal cavity enables a clearer X-ray picture of the abdominal viscera to be obtained. The skiagrams of the jaws, showing the presence or absence of infection of the apices of the teeth and of the skull, showing the condition of the sella turcica, have facilitated the detection of focal sepsis and of pituitary disease respectively. The improvement of technique has made advances in treatment possible. By intensive X-ray exposures, following the Erlangen practice, the remedial therapy of deep-seated malignant growths has been pursued. The radium treatment of cancer in positions where the radium (*q.v.*) can be brought into close contact with the growth, is now carried out with increasing frequency, and team work in this treatment of cancer of the uterus has been adopted in a number of hospitals. Side by side with advances in treatment the effect of X-rays on the tissue cells has been investigated experimentally; the results have a very definite bearing on the methods and dosage employed in treatment, for the destructive changes induced in the cells may give rise to grave symptoms and even death. It appears that the action of X-rays may set up secondary ultra-violet radiations in the tissues and so cause severe changes.

Diseases of Function.—Functional disorder and the investigation of the early stages of disease, before the physical signs of gross structural changes appear, have attracted increasing attention and are intimately wrapped up with the ideal of medical science, the prevention of disease, proverbially a higher aim than its cure. The first manifestation of disease is commonly disorder of function, which shows itself by symptoms unaccompanied by any structural change. Clinical observation was specially directed to the detection of the earliest signs of disease by the late Sir James Mackenzie, who in 1919 started team work in this direction at the St. Andrews Institute for Clinical Research, where laboratory tests were fully utilised as an aid to the careful

analysis of the patient's symptoms in an intense search for a real understanding of the familiar manifestations of undue fatigue, malaise, shortness of breath on exertion and pain. Tests for disorder of function—some physical, as in disorders of the circulatory and respiratory organs, others chemical, such as examination of the blood and the ability of the organ to excrete coloured dyes, for example, phenol-sulphone-phthalein, as in disease of the kidney and the liver, others psychological, as in nervous disorder—have recently been much elaborated and multiplied, and bid fair to facilitate more accurate and early diagnosis and treatment on scientific lines.

Psychology (*q.v.*).—Experimental psychology, once regarded as an academic pursuit, has been the means of great economic saving in industry, and the results of research work and tests have led to the introduction of rest pauses and other modifications, with the result of an increased output of work on the one hand and benefit to the worker on the other. The Industrial Fatigue Research Board was set up during the War, and The National Institute of Industrial Psychology, established in Great Britain after the War, ensures continued practical guidance for employers and employed (*see* INDUSTRIAL PSYCHOLOGY).

Endocrinology (*q.v.*). *Ductless Glands.*—The part played by the ductless or endocrine glands in the production of disease has attracted increasing discussion, especially on the questions (1) of the endocrine balance, meaning thereby that when one gland is disordered the equilibrium which normally exists between them as a whole is upset, and (2) of the effects of disease of more than one of these glands—pluriglandular disorder. This last problem has on the one hand, from the difficulty of positive proof, aroused scepticism as to its existence, and on the other hand stimulated exploitation of commercial preparations of combined glandular extracts, the activity of which, as regards some of the constituents, is open to serious doubt. The outstanding advance in the medicinal use of endocrine preparations, and indeed in therapeutics generally, is the introduction of insulin (*q.v.*) for the treatment of diabetes mellitus (*q.v.*) (*see* THERAPEUTICS).

The use of the endocrine preparations proved to be active is passing out of the qualitative stage into the further one in which they are being so standardised that the proper dose can be administered; this has been done for insulin, adrenalin, thyroid and parathyroid extracts. The interstitial cells of the testis ("interstitial gland") has attracted much research in connection with its influence on the secondary sex characters and in insanity. Experimental ligature of the duct of the testis (vasectomy) increases the prominence of the interstitial gland and is followed by rejuvenation (Steinach), and with this object the operation has been often performed on men, as has grafting of testes of men or chimpanzees (Voronoff) (*see* REJUVENATION).

Cardiology and Circulatory Organs.—The work of the late Sir James Mackenzie and Sir Thomas Lewis has so revolutionised our knowledge of the heart that there is a new cardiology (*see* HEART, DISEASES OF). By the electrocardiograph, which is specially valuable in showing the condition of the heart muscle, Lewis showed that the extreme irregularity of the heart in cardiac failure, called by Mackenzie nodal rhythm, is due to auricular fibrillation, a circus movement instead of the normal contraction; it is in this condition that digitalis is of value. By means of the graphic methods the irregularities of the heart have been classified.

Angina Pectoris.—Cardiac murmurs have been shown not necessarily to be of grave importance, and much work has been done on angina pectoris. The symptoms—status anginosa—of sudden obstruction of the coronary arteries which supply the heart have been defined, and the cause of angina pectoris has been referred to the failure of the heart muscle (Mackenzie), and to disease of the first part of the aorta (Allbutt); in accordance with the last view operative division or removal of its nerves has been practised and found to relieve the pain, but not otherwise to affect the disease. Bullets embedded in the heart-wall have been removed, and a contracted (mitral) valve has been remedied by surgical measures (*see* HEART AND LUNG SURGERY).

Blood-Pressure.—The existence of high blood-pressure without kidney disease or hyperpiesia (Allbutt) has been established, and it has been suggested that table salt and, probably with more reason, guanidine raise, and that hepatic extract lowers blood-pressure. The state of the capillaries—microscopic vessels—their power to contract, and their influence on blood-pressure have been investigated and much new knowledge has been acquired. The prevention of rheumatic heart disease and the responsibility of tonsils and other sites of focal infection have received considerable attention both in Great Britain and in America.

Bronchoscopy.—In diseases of the lungs the trial of new methods of treatment has gone on, such as specific or chemical remedies, and the production of artificial pneumothorax (*q.v.*) (*see* THERAPEUTICS). As the presence of adhesions inside the chest interferes with the production of a curative pneumothorax, they have been divided by a cautery, the process being watched through a hollow tube, illuminated by electric light, passed into the chest (Jacobaeus' thoracoscopy). Bronchoscopy for the detection and removal of foreign bodies from the air-passages has, in the hands of Chevalier Jackson, become a fine art; the importance of an early removal of these bodies before they have set up destructive changes in the lungs, which in the past have proved obscurely fatal, has now been fully recognised. In the abdomen a method, laparoscopy or coelioscopy, by which the contents can be seen by an arrangement similar to that of thoracoscopy, has been employed; but neither of these difficult methods is likely to come into general use.

Fractional Test Meals.—The adoption of fractional test meals as a more exact method of determining the constitution and variations of the constituents of the gastric contents has, thanks to Rehfuss, superseded the single examination made one hour after a test meal. Absence of hydrochloric acid, a normal constituent of the gastric juice, has been shown to favour the onset of pernicious anaemia (*see* ANAEMIA). Aspiration of the bile by a duodenal tube, after Oddi's sphincter, which closes the lower end of the common bile duct, has been relaxed by a spray of magnesium sulphate, enables a microscopical, chemical and bacteriological examination of the bile to be made, and also does good by drainage in cases of infection and inflammation of the biliary tract.

Tests for Hepatic Efficiency.—The search for tests to estimate the functional capacity, or the way the liver is doing its work, has been carried on with energy, and a number of tests for the individual functions have been introduced; but no one test for them as a whole is satisfactory, and another difficulty is that the liver, like the heart and other organs, has a great reserve, so that it can, although much damaged, discharge its functions so well that tests do not reveal any failure of the compensated condition; this is especially true in chronic disease. By means of a blood test—the Hijmans van den Bergh reaction—obstructive jaundice can be distinguished from other forms.

Neurology.—The physiology and pathology of the nervous system has steadily progressed; the researches into the factors presiding over equilibrium and posture have yielded valuable information; disease of what is called the extra-pyramidal system has attracted attention; acute infections of the nervous system, acute poliomyelitis, encephalitis epidemica ("sleeping sickness") and cerebrospinal fever were more prominent in the conditions of war than before; much valuable scientific research into the method of actions of poisons on the nervous system has been carried out.

Panel Practice.—The conditions of medical practice in Great Britain were profoundly modified by the introduction, as the result of Mr. Lloyd George's National Insurance Act (1911), of the "Panel system," whereby 15,000,000 insured persons are now looked after by practitioners paid at a yearly rate of a sum which has averaged about ten shillings a year, paid partly by insurance contributions and partly by the state; this enormous undertaking is part of National Insurance and is under the control of the Ministry of Health. No one medical man is now allowed to have more than 3,500 persons on his panel. At the time of its initiation the panel system met with great opposition

from the medical profession, but this collapsed, and on the whole the system works well, and is certainly an improvement on the old system of clubs. (*See* HEALTH INSURANCE, MEDICAL ASPECTS.)

Diplomas in Special Subjects.—The enormous advances in medicine have made specialism necessary and inevitable, and as evidence of the general recognition of this need diplomas in these special subjects are granted by the universities and licensing bodies. The General Medical Council in 1922 revised the regulations for one of the oldest diplomas, that of Public Health (D. P.H.), and ordained that two years, instead of one year as formerly, must elapse from the date of a candidate's obtaining a registrable qualification in medicine, surgery and midwifery before his admission to Part II. of the examination for diplomas in sanitary science, public health or state medicine. There are diplomas in psychological medicine, in tropical medicine and hygiene, in ophthalmic medicine and surgery and in laryngology and otology, and since the War the universities of Cambridge and Liverpool have given diplomas in radiology. (*See* MEDICAL EDUCATION.)

Group Medicine.—The specialisation of medicine and the elaboration of technique prevent any one man from being master of the whole field of medicine, and accordingly there has been a tendency for men to combine in team work or group medicine, especially in America. A group of men expert in their own lines may work together or under a general physician or surgeon who, in consultation with them, correlates the collected evidence and comes to a final decision on the whole matter. These diagnostic clinics, which are exemplified by the Mayo Clinic, Rochester, Minn., are commoner in America than in Great Britain. They should have the advantage, from the patient's point of view, of providing for a fixed inclusive fee all the special examinations that may be necessary at a lower cost than in ordinary practice would be required for such a number of tests.

BIBLIOGRAPHY.—*See* Bibliographies to the articles referred to in the text; also Sir T. C. Allbutt and Sir H. D. Rolleston (Editors), *A System of Medicine*, 9 vol., various dates. (H. Ro.)

MEDICINE, PRE-SCIENTIFIC (*see* 18.41).—The aim of primitive medicine, like that of primitive religion of which it at first formed an inseparable part, was to safeguard life, using the same means to attain their common end.

Main Causes of Disease.—Modern investigations reveal that savage races still attribute disease to three main causes:—

(*a*) The projection of some foreign substance into the body;
(*b*) The abstraction of something from the body;
(*c*) A sympathetic process operating on some part of the body or on some object that has been in contact with the victim.

As the supposed results are ascribed to the agency of men or spirits, their machinations have to be circumvented or their wrath diverted. Many practices illustrate these points. Thus suction is a common ceremony, performed upon the sick by many peoples, to extract the offending object. To discover the source of the evil, divination is employed. In many cases the native conception of the nature of the lesion associated with disease is very concrete. Thus certain Australian tribes look upon it as due to the abstraction of adrenal fat. In Melanesia it is held that removal of part of the soul, due to spirits, is the cause of many symptoms. The treatment of disease by savage folk can only be understood in reference to their pathological theory.

Trephining.—Among the most remarkable of the forms of treatment is trephining, which was performed from a very early date with stone implements before the introduction of metals. A decompressive trephining for epilepsy or other disorders of the brain, real or supposed, is still practised among the Aymaras of Bolivia and the Guichuas of Peru. The beliefs at the back of the process are still not clear.

Primitive Surgery.—The surgical measures of uncivilised man are not always as inadequate as might be supposed. Some savage folk have developed more than a rudimentary idea of bone-setting. Moss, fresh leaves, ashes or natural balsams are used to dress wounds, which, when poisoned, are treated by sucking or cauterisation. Among surgical instruments we note horns for cupping, a sharp thorn for opening an abscess, saws of stone and bone for amputations and special instruments for letting blood. The latter operation is very widely practised.

The Medicine Man.—The position of the medicine man is doubtless very similar among savages of to-day to what it was with early races. He exhibits a gradual differentiation from the priest. In Indonesia the medicine man is now quite distinct from the priest, but in Polynesia and North America the relationship is often so close that the two may be indistinguishable.

Survivals.—The remains of the savage's mode of treating disease survive with peculiar persistence even in centres of Western civilisation. Belief in magic and in the efficacy of charms still plays a considerable part in the attempted prevention and cure of many ailments in Europe and America. Thus, for instance, the mountaineers of southwestern Virginia and eastern Tennessee believe that an iron ring, worn on the third finger of the left hand, will drive away rheumatism. This practice shows a persistence of the very ancient belief in magical properties of the third finger and of iron. A modern English herb-doctor will peel the bark of an elm *downwards* if a cold has to be drawn down from the head, and peel it *upwards* if it has to be drawn up from the chest. Warts are rubbed at regular intervals with a gold ring. The persistence of colour as a significant factor in folk-medicine is shown by the use of red flannel as a bandage for sore throats and whooping cough, a case of sympathetic connection between the redness of inflammation and the redness of material. Finsen's red-light treatment to prevent pitting in smallpox has been said to trace back to the same folk-custom, employed in the case of the son of Edward II. In Ireland homeopathic doctors give for jaundice yellow medicines, such as saffron, turmeric, sulphur, even yellow soap.

Egyptian Medicine.—Of the pre-scientific systems of medicine of the ancient civilisations, the best known is that of Egypt. Ancient Egyptian medical treatment, chiefly magical, included a large number of traditional practices which had survived from very early times. For long the art of healing was in the hands of the temple priests. These men formed an organised body with a sort of physician-in-chief at its head. They concentrated on hygiene and diet, advising abstention from many vegetable foods, especially beans and onions, the latter a supposed aphrodisiac which also provokes thirst and tears, from mutton and pork, from certain milks and from salt which produces drunkenness and gluttony. On three days out of every 30, emetics or clysters were to be taken. Among hygienic measures, dwelling houses were to be kept clean and fumigated with resin and myrrh, the body was to be frequently bathed and suitably clothed and gymnastic exercises were recommended. Ointments, potions and poultices were in use. Among drugs were honey, incense, salt, cedar oil, sycamore bark, nitre, sulphate of copper, alum, the brains, liver, heart and blood of various animals, stag's horn and oil of camomile for frictions. Fever patients were wrapped in woollen stuffs to promote perspiration.

Ebers Papyrus.—The Ebers papyrus mentions a number of symptoms and diseases (some difficult to identify) such as intestinal worms, inflammation in the region of the anus, haemorrhoids, disorders at the pit of the stomach, fluttering of the heart, pains in the head, urinary affections, dyspepsia, angina and about 30 different affections of the eyes. Among the remedies are blood-letting, sudorifics, diuretics, drugs to produce sneezing, copper salts and oxymel of squills to produce vomiting, castor oil given in beer as an aperient and pomegranate seeds for the expulsion of worms.

Edwin Smith Papyrus.—The Edwin Smith papyrus, not yet fully described, seems to suggest skill in surgery in advance of that of any of the contemporaries of ancient Egypt. It suggests, too, rather more anatomical knowledge than had hitherto been considered likely among the Egyptians.

Statues of Healing.—On the purely magical level were the Statues of Healing. These were placed in rectangular basins upon which texts and images were carved. The water that flowed through the basins acquired magical properties through contact with the statues and thus became curative for all reptile bites. The water, either taken internally or used as a lotion, was all-sufficient; it was even unnecessary to repeat the magic formulae carved on the garments of the statue or on the basins.

These remedies were therefore more especially used by the illiterate. Statues of *Horus on the Crocodiles* were the most widely-spread and most efficacious instruments of protection against and cure for the bites of scorpions, serpents and crocodiles, their use probably going back beyond the XIX Dynasty.

Coptic Medicine.—During the last few years our knowledge of the medicine of the Copts has been considerably extended by the publication of a long and important text and by several minor finds. The Coptic material exhibits a rapid recession of the ancient Egyptian element. Coptic *materia medica* reveals unmistakable Greek and Arabic influences and magic is of secondary importance. The mouse, goat, wolf, hyaena, and other animals are all mentioned in prescriptions, but the greater number of medicaments are of vegetable or mineral origin and include, as in all early writings, emetics and purgatives. Eye-troubles were always rife in Egypt. It is thus not remarkable that about half of the 237 prescriptions contained in the Cairo papyrus (c. 9th century A.D.) deal with these conditions. For the majority of the ophthalmic remedies there is no indication of the condition for which they were applied. There are, however, 13 for cataract, 18 for dimness of vision, three each for abscesses and inflammation, 13 for trachoma and two for amauroses. Among the skin and scalp affections prescribed for are melanoderma, herpes, itch and lichen. We read of remedies for abscesses, boils, sores, cuts and bites, ulcers, gangrene sores and swellings. Cummin ground with moistened rue is taken for three days for fever. Opium, calf's fat and milk melted together and applied warm cures earache with such rapidity that the physician is advised to collect his fee in advance! A mixture of red and yellow vitriol and alum is recommended for toothache. Two formulae for the extraction of teeth are of interest, for though dental caries and alveolar abscesses have been found in mummies of the Pharaonic period there is no evidence of the extraction of teeth at that early time. Considerable knowledge of and skill in surgery may be gathered from a Coptic surgical instrument case in the Cairo Museum, the space allotted for knives and scalpels showing that operations were no simple affair.

Mesopotamian Medicine.—The civilisation of the valley of the Euphrates and the Tigris had reached an advanced degree of development about 4,000 B.C. Babylonian medicine was purely empirical. It occupied, however, a less important rôle in the art of healing than magic. The liver was regarded as the central organ for the blood, the true life principle, which was divided into two kinds, blood of the day and blood of the night. Disease was a demon that entered the body and must be expelled. The pharmacopoeia made use of mineral, vegetable and animal substances. Among remedial agents were honey and syrup of dates, herbs, blood-letting, use of cups for drawing blood to the surface of the body, cold shower and warm baths, clysters, various salves, friction with oil. An ointment composed of plants cooked in grease, or a decoction of copper-ore in beer, was used in cases of ophthalmia, a very common complaint in Mesopotamia also.

Assyrian Medicine.—The more northern Assyrian medicine had the same foundations and followed the same methods as the southern Babylonian. Therapy was exorcism and incantation was prophylaxis, although the accounts of surgical procedure in the Code of Hammurabi imply an elementary knowledge of anatomy. We gather hints, however, from the medical texts that the physicians of Nineveh may have been less ignorant than has been supposed. Some 250 vegetable drugs and 120 mineral drugs were known, as well as 180 derived from other unidentified sources, making a total of 550. The names of these drugs occur many thousands of times in the medical texts. To the above must be added remedies consisting of various alcohols, fats, oils, honey, wax and various kinds of milk. Among the names most frequently met with in the texts are: pine and fir turpentines, rose, cedar, darnel, marigold, heliotrope, asafoetida, tamarisk, liquidambar, storax, mustard, galbanum, henbane, lupin, myrrh, arnoglosson, castor oil plant, mint, tragacanth, fennel, cypress, nightshade, millet, poppy, fig, laurel, pomegranate, wheat flour and mandrake. The mandrake seems to have entered medical magic from Babylonian sources.

Persian Medicine.—Iranian medicine became laicised in Zoroaster's time when the "mages" were superseded by the physicians whose business was to restore health. It bears points of resemblance to ancient Hebrew medicine which may be dependent on it. Treatment of the sick consisted of incantations, vegetable drugs and the use of the knife. Hygiene was one of Zoroaster's main preoccupations: "A healthy man is a moral man."

Indian Medicine.—Hindu conceptions concerning the causes of disease were very confused. The confusion may be the result of the mixed origin of Indian pathology. The earlier Indian physicians utilised the senses of taste and smell as well as inspection, palpation and auscultation for purposes of diagnosis. Hygiene and diet played an important part in the life of the people. The pharmacopoeia of India is very rich, the great majority of drugs belonging to the vegetable kingdom. Charaka (pre-Buddhistic period) knew of 500 plants that possessed remedial virtues, Susruta mentions 760, of which cinnamon, pepper, cardamons, spices and sugar were native. He also gives lists of drugs classed according to their action into lists of cerebral sedatives, emetics, purgatives, anodynes, etc. Diabetes mellitus was first described by Indian physicians who noticed that flies and other insects were attracted to the urine of patients suffering from this malady.

In surgery the ancient Hindus were probably superior to any of their oriental neighbours. Susruta mentions eight kinds of surgical operations. Fourteen different kinds of surgical dressings were in use; cotton, woollen, linen and silk for bandages. Special splints of withes of bamboo were employed in cases of fracture and dislocation. These were later adopted in the British army as the "patent rattan cane splint." It is regrettable that it continues impossible to assign dates to ancient Indian medical documents with any degree of confidence.

Deteriorated Remains of Scientific Medicine.—It has become increasingly evident that the culture of many savage and semi-savage tribes is in fact little but decayed civilisation. This is particularly true in the department of medicine. Researches, for instance, on Anglo-Saxon medicine have shown it to be little but the system of the classical peoples corrupted, deteriorated and misunderstood. In view of this "derivative" character of much so-called "primitive" medicine, a reinvestigation of the medical customs of savage peoples is demanded.

V. Cowdry, "Taoist Ideas of Human Anatomy," *Annals of Medical History*, vol. 3, p. 301 (1921). For Chinese Medicine see H. A. Giles, "The Hsi Yuan Lu or Instructions for the Coroner," *Proc. Royal Society of Medicine* (*Historical Section*), vol. 17, p. 59. A work having implications with modern medicine is K. Dohi, *Beiträge zur Geschichte der Syphilis . . . in Ostasien* (Tōkyō 1923). . . . For primitive medicine in Western Europe see anthropological publications, especially the journal *Folklore*. So far as primitive Medicine in Great Britain is concerned, the main publications are P. Diverres, *Le plus ancien texte des Meddygon Myddveu* (Paris 1913), Timothy Lewis, *A Welsh Leech Book or Llyfr o Feddyginiaeth* (1914), E. Stanton Roberts, *Llysieulyfr Meddyginiaethol a briodolir i William Salesbury* (*A Herbal attributed to William Salesbury*) (1916), Charles Singer, *Early English Magic and Medicine* (1920), and "The Lorica of Gildas the Briton (?547)," *Proc. Royal Society of Medicine* (*Historical Section*), vol. 12, p. 124 (1920), and Herbert Schöffler, *Beiträge zur Mittelenglischen Medizinliteratur* (Halle 1919). F. Ohrt, *Danmarks Trylleformler* (Copenhagen 1917), texts in Friedrich Wilhelm's *Denkmäler Deutscher Prosa des 11. und 12. Jahrhunderts* (Munich 1914 and following years) and articles scattered through the pages of Johannes Hoops, *Reallexikon der Germanischen Altertumskunde* (Strassburg 1911–9) and the international Dutch journal *Janus*. The surviving Gaelic MSS. contain a surprising proportion of medical texts. By the publication of the catalogues of these MSS. in the Advocates Library at Edinburgh (1912), in the Libraries of Trinity College, Dublin (1926), and in the British Museum (1926), a new source of Folk Medicine has been tapped. (C. Si.)

MEDINA (*see* 18.64).—Before the World War, Medina was less known to Europeans than Mecca, although it was described by the earlier travellers, Burckhardt and Burton, and by Wavell, who visited it in 1908. Before the World War the normal resident population was estimated at 40,000, of whom a large proportion were aliens who had settled after pilgrimage. The Turks deported about three-quarters of the inhabitants during the blockade, and, allowing for further decrease by disease, the population in 1920 was well under 10,000. Much new information regarding existing conditions in the city was obtained as a result of the War operations. The dimensions of the city were overestimated by earlier writers, the walls actually measuring not more than $1\frac{1}{2}$ m. in circumference, with the longest diameter a little over $\frac{1}{2}$ m. east and west. The Hejāz railway has its terminal station outside the city walls at the Bab el 'Ambari, the gate on the southwest through which runs the road to Yenbo'. There are normally three trains weekly from Damascus, and the journey takes $5\frac{1}{2}$ days. During the War a branch was carried from the main line, through a breach in the walls on the northwest side, to the outskirts of the *Haram* or Great Mosque, which was used as a munition store and was intended to serve as an inner citadel in case of siege.

At the outbreak of the revolt in June 1916 the Arabs, unable to take the city by assault, withdrew and began a blockade, which —as they were unwilling to bombard the city for fear of damage to the holy places and refused to cut the water supply conduit— lasted until the Turks surrendered the city in Jan. 1919. In 1917 Fakhri Pasha, commander of the garrison, devised a scheme for the rebuilding and modernisation of Medina, but all that happened was the destruction of a great number of houses for the sake of the beams and woodwork to feed the railway locomotives. Extensive palm plantations outside the walls, east and northeast, were also ravaged for the same purpose. Large palm gardens which formerly occupied much space within the walls were in great part built over, and the Barrel Manakha, or central open space, was encroached upon. Sherif Ali, son of King Husein, became emir of Medina in 1925. In the later part of that year the city was invested by Wahhabi troops.

MEDITERRANEAN SEA (*see* 18.67).—In 1910 the lands which bound the southern and eastern parts of the Eastern basin of the Mediterranean were under real or nominal Turkish control. In theory, that is to say, the Sultan of Turkey was suzerain of the area extending from the frontier of French Tunisia, that is from the Gulf of Gabes, to the Gulf of Alexandretta, and owned also the island of Cyprus. At the present time Tripoli, which abuts on Tunisia, is Italian; Egypt forms an independent kingdom; the mandated territories of Palestine and Syria are attached to Britain and France respectively, and Cyprus has been annexed to Britain. From the whole of this long stretch, therefore, the Turk is now excluded.

Political Changes.—In the northern part of the Eastern basin and in its connected subsidiary seas, conditions were more complicated. The whole of Asia Minor was and remained politically Turkish: from the ethnic and economic standpoint indeed it was more definitely Turkish in 1926 than it was in 1910. But the changes in the European littoral of the Aegean Sea were great. In 1910 Greece was but a small state, though at the same time Greeks were widely distributed around all the shores of the Aegean and within the adjacent lands and had great economic influence there. Crete was still Turkish, as was the whole of Thrace, together with the region vaguely called Macedonia: this meant that politically the Aegean was chiefly a Turkish sea. In 1926 Crete was Greek, and Turkey had also lost the whole of Macedonia and all but an eastern fragment of Thrace. In other words, Greece in 1926 included almost the whole of the European littoral of the Aegean, and to her previously existing ports had been added that of Salonika, which had acquired great significance. The interchange of populations between Greece and Turkey in 1923–4 meant further that the acquired area was in process of becoming ethnically more Greek than it had been in the past. On the other hand, Greek influence in western Asia Minor disappeared, and with it the port of Smyrna lost much of its former trade.

The changes on the Adriatic littoral and on the adjacent parts of the Ionian Sea had been great. In 1910 Turkey held in the Epirus area a frontage on the Ionian Sea and had also a wide window on the Adriatic. The extension of Greece to the north and the establishment of the independent State of Albania, were territorial changes which preceded the outbreak of the World War; but that War resulted in others of even greater importance. Prior to its outbreak, Austria-Hungary, which had annexed Bosnia-Herzegovina from Turkey in 1908, held the eastern coast of the Adriatic, from the edge of the very narrow strip which was Montenegrin to beyond the Isonzo. The Peace Treaties gave the greater part of the littoral to the Serb-Croat-Slovene State, and the smaller part to Italy, and left a cause of discord between the two in regard to the fate of the port of Fiume.

In the Western basin, save for agreements in the case of Morocco, there were no territorial changes: a certain amount of political equilibrium had been reached there long prior to the period under consideration. On the other hand, the new position within continental Europe generally brought about by the War lead to fresh developments within the Mediterranean zone. France, Italy and, to a minor extent, Spain made definite attempts to develop their trans-Mediterranean possessions, and to establish themselves more firmly on the shores of that sea.

Since Spanish action was limited to a coastal belt in Morocco, it may be briefly dismissed. In 1912, the year in which the French protectorate was accepted by the Sultan of Morocco, France and Spain reached an agreement as to the limits of their respective zones within that country. Spanish attempts to make occupation effective in their own zone were probably influenced primarily by the French advance: other influences were the loss of the remnants of the former colonial empire of Spain and the continuous emigration to Algeria, which had acquired a large

Spanish element in its population. The convention of 1923 between Great Britain, Spain and France in regard to Tangier, then placed under a régime of permanent neutrality, indicated the growing importance of France in the Western basin of the Mediterranean. The refusal of Italy to recognise the agreement, on the ground that she was not represented at the convention was similarly an indication that that State, now freed from anxiety as regards her northeastern frontier, was directing her policy more and more definitely towards Mediterranean affairs.

French Policy in the West.—If the developments in Morocco were the chief events in the West since 1910, yet other signs were not wanting of the new orientation of French policy there. As contrasted with Italy and even with Spain, there is in France no surplus population seeking new lands for settlement. Thus the fact that the North African territories, particularly Algeria, give opportunities for European colonisation is not of much direct importance to that country. On the other hand, there is great need of man-power, particularly for the army. Though the territories of the Mediterranean littoral are not densely peopled, they do form a recruiting ground, and Algeria, Tunisia and Morocco all furnish divisions to the French Army. But these lands are but the margin of a vast area which, interrupted politically only by smaller *enclaves*, and physically by the Sahara desert, now extends to the Gulf of Guinea and, further eastward, to far beyond the equator. Parts of this area contain a virile coloured population, whose members make good soldiers. In this connection it may be noted that Senegalese regiments have formed a part of the French Army since 1911, and that in 1919 the native element in the army was greatly increased.

The bearing of these facts is twofold. In the first place it is essential that facilities for transverse traffic between the French and the North African coast opposite should exist in peace, and that so far as possible the safety of the routes should be assured in time of war. Secondly, schemes are in contemplation for overcoming the obstacle presented by the Sahara, in such a way as to ensure easy land communication between the littoral possessions and those further south, in order that the two may develop in combination. A railway connecting French West Africa directly to the Mediterranean coast would have great strategic importance in time of war, while the feasibility of motor communication had already been demonstrated. These possibilities increase the significance of the Mediterranean ports. Bizerta, Algiers and Oran are already important naval stations and submarine bases, and the French are making great efforts to develop and strengthen all the ports on this littoral, as centres of trans-Mediterranean traffic. This emphasis on cross-routes is not only significant in itself, but is something entirely modern.

New Rôle of the Mediterranean.—Previously, as is well shown by the long-drawn-out row of British stations at Gibraltar, Malta and Aden, the Mediterranean was primarily of importance as a longitudinal thoroughfare. Up till the post-War period, between Malta and Aden, there was in Egypt a country under British influence. With the establishment of an independent kingdom there, and the changes just noted, it is obvious both that Great Britain's position in the Mediterranean has been weakened, and that a new set of traffic routes is being superimposed on the old. It may be added that if, as is sometimes stated, French withdrawal from Egypt in 1883 was due to the fear of renewed attack on the northeastern frontier of France, then French acceptance of the mandate in Syria is an indication that this reluctance to extend her extraterritorial commitments has ceased to exist under the new conditions.

Italian policy in the Mediterranean area since the War had been influenced by somewhat different motives. Italy has a steadily increasing population and the emigration laws in the United States tended to restrict one of the pre-War outlets for the surplus. Thus Italian policy was directed towards attempts to promote home industry and commerce in order to attract a part of the dense rural population from the land, and also to find new areas of possible settlement. The latter motive led to efforts to develop Tripoli, obtained from Turkey in 1912, while the former affected Italian policy in the eastern part of the Adriatic. By the acquisition of the peninsula of Istria, with the ports of Trieste, Pola and Fiume, and of Zara and the island of Lagosta, Italy obtained both complete protection for the eastern coast of the peninsula and opened up possibilities of notable commercial developments. The Italian advance meant that Austria and Hungary lost all outlets on the Adriatic, and thus had no direct access to the Mediterranean Sea.

The collapse of the former Ottoman empire resulted in the rise in the eastern Mediterranean of states which were either actually new, as are the Kingdom of Egypt, Yugoslavia and the much smaller State of Albania, or, as in the case of Turkey and Greece had undergone such radical modification—territorial, political and ethnical—as to be to all intents and purposes new. Such states were for the most part characterised by a strongly nationalistic spirit which retarded economic recovery from the effects of the War. The result was that the chief ports at first showed decay rather than advance. This was particularly true of Constantinople and Smyrna, and even Salonika, where the Yugoslav state had had a free zone since 1923, did not make notable progress. Despite their long Adriatic littoral also, the Yugoslavs were not able to develop an adequate outlet there. By an agreement reached with Italy in 1924 the port of Fiume became Italian and the adjacent one of Port Baross, Yugoslav. The friendly adjustment of this difficult question is probably an indication of future closer economic connection between the two Powers.

This summary account of conditions up to 1925 makes it clear that political developments, especially in the southern and eastern parts of the Mediterranean area, took place between 1910–25 with a rapidity all the more startling in view of the long antecedent period of complete or partial stagnation. But the apparent suddenness of the political and territorial changes was due to the fact that they were the consequences of cumulative economic changes which had been going on for a long period of time. In particular, the increased production of cereals for export in central and eastern Europe, and the discovery and working of oil-fields alike along the Carpathian border and in the Caspian region, gave to outlets to the eastern Mediterranean an importance which they did not possess in earlier times, and made readjustments inevitable. The Mediterranean Sea was no longer what the opening of the Suez Canal and the associated growth of European influence in the Far East had made it—primarily a thoroughfare for world commerce. It was becoming also an important outlet for the developing lands round its southern and eastern shores.

Present strategic conditions in the Mediterranean region are discussed in D. H. Cole's *Imperial Military Geography* (London, 1925). See also M. I. Newbigin, *Geographical Aspects of Balkan Problems* (London, 1915); I. Bowman, *The New World: Problems in Political Geography* (London, 1925). (M. N.)

MEHTA, SIR PHEROZESHAH MERWANJI (1845–1915), Indian municipal reformer, was the son of a Bombay merchant. Educated at the Elphinstone College, he was the first Parsee M.A. of Bombay University and coming to London to read at Lincoln's Inn was also the first Parsee to be called to the English Bar (1868). With Dadabhai Naoroji he founded the organisation which grew into the East India Association. Returning to Bombay he rapidly made a name as an advocate. Appointed in 1869 as Justice of the Peace, he served on the new Bombay Corporation from 1872 till his death. He also served for over 30 years on the Bombay legislature. For the last few months of his life he was vice-chancellor of Bombay University. Created a C.I.E. in 1894, he was advanced to the knighthood of the order 10 years later. He died in Bombay Nov. 5 1915.

See the political biography by H. P. Mody, *Sir Pherozeshah Mehta*, 2 vol. (1921). Much light is thrown on Mehta's services to his native city in *Rise and Growth of Bombay Municipal Government* (1913), by his most intimate co-worker, Sir Dinshah Edalji Wacha.

MEIEROVICS, ZIGFRIDS (1887–1925), Latvian statesman, was born Jan. 24 1887, the son of a country doctor in Courland, and was educated at the Riga Polytechnic. He first worked in an insurance company and afterwards in an agrarian bank.

This training gave him an insight into financial problems and prepared him for the prominent part he was to play in the stabilisation of Latvian currency. In Nov. 1918 he became the first foreign minister of independent Latvia and, as delegate to the Peace Conference, he secured Latvia's recognition and later succeeded in gaining her admission to the League of Nations. From 1918 until his death he held office almost continuously as foreign minister and was once prime minister. He was killed in a motor accident on Aug. 22 1925.

Shortly after this date a well-known student of the movement for independence in the Baltic States expressed the opinion that of all the leaders of that movement in the various states involved, Zigfrids Meierovics was at once the most statesmanlike and the most influential. He was a man gifted with an unusual power of looking ahead; and he was able to recognise the real problems facing the Baltic States in the years immediately following the World War with probably greater facility and clarity than any of his colleagues in leadership. One of the foundations of his foreign policy was the conviction that Estonia, Latvia and Lithuania possessed many interests in common and should therefore endeavour to co-operate for the common good of all three states. The confidence which he inspired in his own countrymen is abundantly proved by the insistence with which the latter kept him in office from 1918 onwards.

MEIGHEN, ARTHUR (1874–), Canadian statesman, was born at Anderson, in the county of Perth, Ontario, June 16 1874, the son of Joseph and Mary Meighen. He was educated at St. Mary's Collegiate Institute and at Toronto University, and became a barrister-at-law. He married in 1904 Jessie Isabel Cox, daughter of the late Charles Cox of Granby, Quebec. His political career began in 1908 when he was elected to the House of Commons as the Conservative member for Portage la Prairie in the province of Manitoba. His talent as a debater was at once recognised. In 1913 he became solicitor-general in the Government of Sir Robert Borden; and in Oct. 1917 secretary of state and minister of mines. Later he became minister of the interior. In 1918 he accompanied the Canadian Prime Minister to England to attend the Imperial Conference, and on Sir Robert Borden's retirement Mr. Meighen became Prime Minister and secretary of state for external affairs on July 10 1920. In June 1921 he attended the conference of prime ministers in London, where his representations were said to have had a notable effect upon the political groups in Canada. Mr. Meighen held the office of Prime Minister until the general elections in 1921, when the Conservative party was defeated; he then became the leader of the Opposition, and for four years was a vigourous opponent of the Liberal Government. He supported the disarmament resolution introduced by the Prime Minister, Mr. Mackenzie King.

The Military Service Act, under which conscription was enforced in 1917, was largely, in so far as its legal preparation was concerned, the work of Mr. Meighen, and the vigour with which he supported it in Parliament drew upon him the hostility of all those opposed to that measure. As the sentiment against conscription was especially strong in Quebec, the feeling against him in that province was intense, and prevented the policy of his party from receiving the due consideration of the electors. Mr. Meighen consistently repelled the personal attacks made upon him as the enemy of the French Canadians, but without much success. In the elections of 1925 the Conservatives, under the leadership of Mr. Meighen, were overwhelmingly victorious in Ontario and the maritime provinces, but with a practically solid Quebec against him it was impossible to obtain a majority, and the Government remained in the hands of the Liberals. In June 1926, on the resignation of Mr. Mackenzie King, Mr. Meighen took office as Premier, but his government was immediately defeated and a general election took place.

The adoption by the United States of protection, as well as the great industrial development of that country, placed Canada, in Mr. Meighen's view, at a disadvantage. He therefore strongly advocated protection for his own country, in order to prevent the United States from capturing the home markets. He was convinced also of the necessity for preserving the natural resources of Canada, particularly the almost unlimited water power so envied by the bordering states, as well as the products of the forests. He resisted all attempts made by the United States to secure for their territories electrical power generated from watercourses in Canada. Mr. Meighen made constant efforts to bring about a fusion of the diverse elements in the Canadian population. He was made a member of the Imperial privy council in Oct. 1920. (A. G. D.)

MELBOURNE, Victoria (*see* 18.90), the temporary seat of the Federal Govt. and the capital of Victoria, Australia, with a population of 816,800 (852,850 including suburbs), contains more than half the population of the whole State, and has grown with great rapidity. The formation of a Greater Melbourne council was decided upon in 1925. The city has been much improved in appearance by the planting of trees on the banks of the river and in the chief streets. There were 71½ m. of electric tramways in 1923, and the suburban railways have been electrified. In 1916 a mint for silver and bronze coins was established here. In 1924 it was decided to build a large temple in a commanding position in the city as an Australian War Memorial. In 1917 a Commonwealth Shipping Board, with its interstate headquarters at Melbourne, was set up to deal with all questions concerning shipping, but it was not altogether a success. Melbourne has a large trade, and 35% of the total wool export of Australia is dealt with in sales. Large sums have been spent on dredging and reclamation of land in the river and bay.

MÉLINE, FÉLIX JULES (1838–1925), French statesman (*see* 18.94), died in Paris Dec. 21 1925.

MELLON, ANDREW WILLIAM (1855–), American banker and public official, was born in Pittsburgh, Pa., March 24 1855. After graduating from the University of Pittsburgh, he entered the banking house of Thomas Mellon and Sons, and later became a partner. The business developed into three large institutions, the Mellon National Bank, the Union Trust Company and the Union Savings Bank, all of Pittsburgh. Mr. Mellon was elected president of the first mentioned in 1902, and was vice-president of the other two. He was interested in the development of the coal, coke and iron industry of Western Pennsylvania and was often associated in various enterprises with Henry C. Frick. He founded the town of Donora, Pa., and established a large steel mill there. Another of his enterprises was to promote the building of the first independent pipe-line, in competition with the Standard Oil Co., through Pennsylvania. He was a director in numerous corporations, and was a conservative Republican, opposing the League of Nations. In 1921 he was appointed Secretary of the Treasury in the Cabinet of President Harding, and continued to hold this office under President Coolidge. He was chairman of the Pennsylvania delegation to the Republican National Convention held at Cleveland, O., June 10 1924.

As chairman *ex-officio* of the World War Foreign Debt Commission Mr. Mellon had a large share in formulating the policy of the United States in regard to funding the war debts of foreign governments owed to the U.S. Government. He stressed the importance of debtor nations preserving the sanctity of their respective obligations but laid down that no nation can be asked to pay to another government sums in excess of its capacity, and further, that no settlement which is oppressive and retards the recovery and development of the foreign debtor is to the best interests of the United States or of Europe. In this spirit he conducted negotiations with the various European debtor States which resulted in funding agreements being arrived at with Belgium, Czechoslovakia, Estonia, Finland, Great Britain, Hungary, Italy, Latvia, Lithuania and Poland. The principal obligations funded under these various agreements amounted to $6,383,411,669, in addition to accrued interest, $1,006,502,331.

In the management of the large internal debt of the U.S. Govt. resulting from the World War, Mr. Mellon was equally successful. He laid down and rigidly adhered to a policy of providing for debt redemption annually out of current revenues. As the floating debts and the Liberty Loans fell due they were in

part paid off, in part refunded, at a lower rate of interest. As a result the U.S. national debt fell from $24,330,889,731 in 1920 to $20,298,358,156 in 1925. Mr. Mellon was a strong advocate also of tax reduction, especially in the case of the surtax rates on incomes, maintaining that these should not exceed a maximum of 20% and that such reduction would be a great aid to general business and promote widespread prosperity. Under Mr. Mellon's prompting, Congress gradually lowered the income tax rate until in 1926 the surtax was reduced to 20%, yet without any corresponding fall in the amount of tax receipts. Mr. Mellon, who has written for this *Encyclopædia*, is the author of *Taxation: The People's Business* (1924).

MEMEL (*see* 18.104), a port on the Baltic coast at the mouth of the river Memel or Niemen, with an economic hinterland extending across Lithuania into Poland and Soviet Russia, the principal export being timber floated down the waterway. Politically, Memel is now an autonomous district of Lithuania. The population of the town, approximately 25,000, is almost entirely German, and has been so since the 13th century, when Memel, like Riga and Revel, was founded as a German trading station.

Before the World War the town of Memel, with a strip of territory east of the river, belonged to Germany, while the hinterland belonged to the Russian Empire. Under the Versailles Treaty (Article 99), Germany ceded all her territory east of the river to the Allied and Associated Powers and undertook to accept whatever disposal they made of it. Upon the ratification of the Treaty the Allies occupied the territory and took over the administration. This provisional régime lasted three years, owing to the dispute between the two new states of Lithuania and Poland over Vilna (Wilno) (*q.v.*), and the consequent delay in the official recognition of the Lithuanian Government. The Conference of Ambassadors did not take up the question of Memel till the autumn of 1922, and meanwhile it had been suggested that Memel might be given a status in regard to Lithuania like that which had been given to Danzig in regard to Poland. This was unacceptable to the Lithuanians, since the population of the country districts of Memel territory was Lithuanian in nationality, while the port was almost the only possible maritime outlet and inlet for Lithuania herself. Accordingly the Lithuanians, imitating the conduct of the Poles at Vilna, seized Memel by a surprise attack on Jan. 15 1923, and forced the French garrison to surrender and evacuate.

On Feb. 16 the Conference of Ambassadors proposed that the Allies should transfer the sovereignty over the territory to Lithuania, subject to local autonomy and to freedom of transit for Poland. In the working out of the details so many difficulties were raised by both Poland and Lithuania that in Sept. 1923 the case was referred to the League of Nations. The council appointed a commission of enquiry under the chairmanship of an American citizen, Mr. Norman Davis, and the proposed convention for giving Memel autonomy within Lithuania with freedom of transit for Poland, as revised by the Davis Commission, was eventually accepted by all parties, and signed in May 1924. In March 1924 the commission presented a draft Convention to the Council. This Convention constituted the Memel territory as a unit within the sovereignty of Lithuania with a clearly defined measure of administrative and financial autonomy and with a governor to be appointed by the President of the Lithuanian Republic. The port was defined as a port of international concern to which the provisions of the League's Barcelona transit conference apply, and was placed under a harbour board including a technical expert of neutral nationality appointed by the League.

MEMORIALS: *see* ARCHITECTURE; SCULPTURE.

MEMPHIS, Tenn., U.S.A. (*see* 18.107), developed into a distributing centre covering the entire South after the reopening of the Mississippi river transport by the establishment of the Federal Barge Line in 1918. The population in 1910 was 131,105; in 1920, 162,351, of whom 61,181 were negroes and 5,844 foreign-born; and in 1925, 174,533, this being the census bureau estimate. Annexations in 1919 (4·6 sq. m.) and 1925 (1·2 sq. m.) brought the city area up to 26·5 square miles. The output of factories within the city limits was valued at $30,242,000 in 1900; $117,718,000 in 1919; $95,537,305 in 1923. By 1925 there were 900 industrial plants in or near Memphis, with an output estimated at $200,000,000. The greatest industrial development during the period from 1910 has been in hardwood products, cotton-seed products, heavy bags, steel and iron and automobiles, including an assembly plant of the Ford Motor Co., established in 1924, with a daily capacity of 350 cars.

Noteworthy improvements include the municipal rail and water terminal (1913); the Harahan bridge (1917); the Union Belt Railway; a new water pumping station (1923–5), multiplying by four the potential supply; a municipal auditorium seating 12,000 (1924); and the improvement and expansion of the electric service. Hydroelectric power will be available from the Muscle Shoals district of Alabama and the White river project in Arkansas. A city planning commission, created in 1921, secured the preparation of a comprehensive plan and the adoption of zoning ordinances. The cost of living in Memphis is high. The West Tennessee State Teachers College was established at Memphis in 1912. In Sept. 1925 Southwestern College, a Presbyterian institution, founded in 1875, moved from Clarksville to Memphis.

MENCKEN, HENRY LOUIS (1880–), American critic, was born at Baltimore, Md., Sept. 12 1880. He attended the Baltimore Polytechnic Institute, and in 1899 became a reporter on the Baltimore *Morning Herald*. He left that paper as editor in 1906, and joined the staff of the Baltimore *Sun*, to which he continued to be attached while engaged in many additional literary activities. In 1908 he became literary critic for *The Smart Set*, and was also joint editor 1908–23. In 1921 he became contibuting editor of *The Nation*, and in 1924 was one of the two founders of *The American Mercury*, of which he became sole editor in 1925. He is a satirist rather than a critic, and represents the viewpoint of the extreme anti-academic element in the literary world. Among his numerous publications are *George Bernard Shaw: His Plays* (1905); *The Philosophy of Friedrich Nietzsche* (1908); *A Book of Burlesques* (1916); *Damn; a Book of Calumny* (1917); *A Book of Prefaces* (1918); *The American Language* (1918); *In Defence of Women* (1918); *Prejudices* (five series, 1919–26); and *Americana* (1925). He has also written critical prefaces to the works of Brieux, Swift, Stephen Crane, Cabell, Nietzsche, Ibsen and Wilde. (*See* AMERICAN LITERATURE.)

MENDELISM (*see* 18.115).—The progress in physiological science made possible by Mendelian methods is described in the articles GENETICS and SEX. In the present article the influence of those discoveries on the development of biological thought and their application to the practice of breeding are considered.

Analysis.—Modern genetics introduces into biology a factorial or analytical conception of organisms, which are now recognised as largely possessing attributes behaving as units, and as such capable of being detached and transferred to any other type with which cross-breeding can be effected. The limits governing this principle of segregation and recombination are still undetermined.

Phenotype and Genotype.—In former considerations of biological problems no account was taken of the consequences of the fact that each of the higher organisms is, in modern language, *diploid*, that is to say, a double structure containing factorial contributions derived respectively from the *haploid* or simple male and female cells which in fertilisation united to produce it. Since some of these factors inhibit the effect of others, and since some give no sign of their presence in the organism unless other complementary elements are also present, the appearance of an organism is an imperfect guide to its genetic potentialities. We have thus to distinguish the organism as it outwardly appears to be from that which it actually is by genetic composition, a distinction which Johannsen has conveniently expressed by the use

of the terms *phenotype* for the former and *genotype* for the latter. Systematic or classificatory works, both zoological and botanical, abound with errors arising from want of appreciation of this fundamental distinction, which must constantly be remembered, especially, for instance, whenever the significance of varietal or intermediate forms has to be estimated.

Variability.—Evidence formerly regarded as proof of abundant contemporary variability in the species of animals and plants must be submitted to searching tests before it can be so accepted. Observations of variability once deemed adequate are now seen to be capable of quite different constructions. Proof that an observed departure from type is a contemporary genetic variation can only be obtained in exceptional cases which have been critically observed under experimental conditions. Putative variation is commonly nothing but the recurrence of a recessive form, or the emergence of some other segregant, from a stock genetically impure; more often still the direct product of a cross. The existence, therefore, of a multitude of varietal forms, so far from simply providing a convenient basis upon which a theory of the evolution of species can be erected, becomes itself an antecedent problem; and instead of asking, as they used to do, how the species have been built up out of the varieties, biologists are rather concerned to discover whence and by what process these variations have come to exist. The belief that substantial genetic change commonly accrues by summation of impalpable differences has been generally abandoned as devoid of evidential foundation. Such differences are mostly fluctuational, largely dependent on circumstance rather than on genetical units and hence not transmissible. Summation, when a genuine phenomenon, is a consequence of purification or the attainment of homozygosis. The idea that a characteristic could in any other way increase as a result of selection is out of place in an exact or even a logical science.

Variation by Loss and by Addition.—Whether the evidences of authentic variation remaining after the deduction of spurious testimony has been made, suffice as a basis of evolutionary theory has been questioned by competent naturalists. Lotsy, for example, maintains that we have no proof of contemporary variation arising otherwise than as a consequence of crossing; and apart from such extreme announcements it is noticeable that as regards varieties of animals and plants anciently domesticated, modern authorities usually incline to ascribe a multiple origin even for forms like wheat, the fowls, pigeons, sheep, horses, etc., which used formerly to pass for derivatives from single types, a belief now felt to be inconsistent with what is known of the limits of variability. Distinction must be made between recessive and dominant variations, arising respectively by loss and by addition. As regards recessive variations arising by loss of elements few will doubt the adequacy of the records (*e.g.*, in the sweet pea, *Primula sinensis*, etc.). As regards the *de novo* appearance of dominant characters the evidence is less abundant. Morgan and the American geneticists have made prominent several instances of this kind in Drosophila (fruit fly), of which the spontaneous origin of " eosin " (a new and peculiar pink) eyes in a white-eyed strain may be cited. Admitting provisionally these examples as free from objection they are, nevertheless, extraordinary events and not common occurrences. Were the dominant in question one already familiar we should hesitate to believe in its spontaneous origin. That a pea genetically wrinkled, having the characteristic starch of the wrinkled varieties, should without crossing produce a variety with " round " starch-grains would in modern lights appear not much less improbable than the spontaneous generation of life.

With plausibility a number of human malformations, such as praesenile cataract, claw foot-and-hand, etc., which have been regarded as descending as dominants, may be interpreted on these lines as in reality due to loss. From almost the beginning of Mendelian studies surprise has been felt that so many curious abnormalities in man, of which at least some 30 may be enumerated, should behave as dominants, seeing that novel characters most frequently are demonstrably recessive. Inasmuch as these " dominants " are so abundant in man, though otherwise rare, something no doubt remains to be explained; but we may avoid the difficulty of interpreting them all as factorial additions, for with equal probability the normal may be represented as possessing an element which, when homozygous, maintains development in its proper and normal course. Mohr and Wriedt, discussing the inheritance of a new type of shortened digits, recently made the suggestion that we have here to do with a character which, in the homozygous state, is *lethal*. In other words, if one element of " normality " only be present the individual exhibits the peculiarity, but if both elements of normality are wanting the consequent malformation is so extensive that the embryo perishes at some early stage of development. The normal element would then be recognised as the positive contribution, and in the absence of at least one such contribution the embryo is non-viable. Some slight evidence is already adduced in support of this view; and since lethal contributions certainly play a great part in genetical histories, we should be prepared for a wide application of this principle, especially to the descent of deformity.

But, as explained in the article GENETICS, nothing absolutely forbids us from inverting the representation of positive and negative factors by extension of the conception of inhibitors, of which many are familiarly known; so that we may express the apparent addition of a new element as a loss of one which when present had repressed the new attribute. This symbolism, though admittedly objectionable when dominance is complete, does without strain apply to all cases in which the heterozygote is intermediate, and a large range of alleged new dominants can be covered. In so far as this conception applies, evolution is conceived of as a process of unpacking, a progress consisting in the loss of component elements.

Mutation.—The term *mutation* introduced by de Vries, is now generally accepted to denote definite genetical variations which are sensibly discontinuous. Though contemporary examples which satisfy all tests are not abundant, there is no question that they occur and have occurred in most of the forms of life. They are indeed part of the occasional experience of most breeders of animals and plants. The special example, the Oenotheras, on which de Vries mainly founded his own theory, was singularly unfortunate and must, as explained in the article GENETICS, be now discarded as inapplicable. Mendelian analysis was only lately made known, and the group of discoveries comprised in the term genetics were in an incipient stage; nor had the criteria of genetic purity, which must be applied to a parental form before the production of new types from it can be accepted as proof of original mutation, been clearly established. The Oenotheras which produce the presumed mutations are now proved to be no pure genotypes, and the suggestion that they were in a " period of mutation " arose from a misunderstanding of the nature and consequences of heterozygosis.

Inter-specific Sterility.—The new forms whose productions we witness are never new species. In *Primula sinensis* about 20 pairs of factorial differences have been determined, which in their several combinations present an amazing polymorphism. A systematist, if he met these forms in nature, might and probably would quite justifiably take many of them for distinct species. But interbred, they and their products are perfectly fertile. Polymorphism like this is, even in a state of nature, far more abundant and far greater than the evolutionists of the last century imagined, yet it avails us little as material out of which true specific differences can be supposed to develop. The conspicuous defect in the evidence for the origin of species by common descent remains. Though much is known as to the incidence of variation, not rarely of a magnitude which might naturally be claimed as constituting specific difference, no one has yet raised types from a common origin which when interbred produce sterility of the kind and degree forming one of the commonest attributes of crosses between natural species. By whatever concatenation of arguments theories of evolution have been constructed, the most essential link has never been supplied. The lapse of time is occasionally invoked in the hope of rectifying this and similar evidential defects, a strain which has been maintained distinct for a long period being thought more likely to show

SIMPLE COLOUR INHERITANCE IN THE SEEDS OF THE COMMON GARDEN PEA

When yellow-seeded and green-seeded peas are crossed, all the second generation has yellow seeds, but in the third generation three-fourths of the seeds are yellow, one-fourth green. In the second generation the green is latent, or recessive, being overshadowed by the dominant yellow. If plants from the green seeds of the third generation are crossed green seeds always result. The apparently similar yellow seeds may be pure yellow or hybrid (part yellow, part green). If yellow-seeded plants from any generation are crossed, one-third will breed pure yellow, and two-thirds will breed hybrid yellow, giving in the next generation three yellow to one green.

HOW THE OCCURRENCE OF A NEW SPORT VARIATION MAKES POSSIBLE THE MULTIPLICATION OF EXISTING VARIETIES

In 1911 a yellow rat (a previously unknown variety) was caught in England. It was mated with black-hooded individuals, a recognised tame race which breeds true. The offspring were all brownish-grey like wild rats, but the grandchildren exhibited eight different varieties.

As the crossing of a constant strain with a variant from another and perhaps variable strain gives so many varieties of offspring, it is readily seen that where both the strains crossed already differ in many minor characteristics, there will be (as is observed in actual life) an almost infinite number of small variations from individual to individual.

interracial sterility when crossed with its progenitor than one newly separated. Reasoning of this kind, plausible enough in scholastic days, is not acceptable in an age of chemistry, nor may we suppose that that which is never begun will be attained by mere effluxion of time. The more genetical experience extends, the more serious does this hiatus in the evidence become.

Evolution.—In allusion to this and other difficulties, which genetic research has forced into prominence, the question is sometimes asked whether the theory of evolution holds its place so firmly as it did, or, more crudely put, whether Mendelian discovery has not "upset Darwinism." It should therefore be stated explicitly that in spite of all the objections with which the doctrine of the origin of species by descent is now seen to be beset —objections of which the strength is far more clearly known than before—and though as to the manner by which new species have come into existence geneticists adopt for the most part an agnostic attitude, yet all agree that the lines of argument converging to support the theory of common origin are so forcible and so many that no alternative can be entertained.

The geological record is conclusive.

The following may be taken as a cogent instance of this: if Angiosperms had existed in the carboniferous age their remains must have been preserved; therefore Angiosperms have arisen since that time, and we cannot conceive whence they came if not by descent from the pre-existing plants. Common descent, though rarely if ever a proposition demonstrable in any detail, ranks as an axiom. For Darwin and any other evolutionist before or after him this is a concession of the main claim. Parts of the apparatus by which the validity of that claim was enhanced have fallen into desuetude. In particular the modern geneticist assigns to *natural selection* a subordinate and inconsiderable rôle. Organisms are to be considered as co-ordinated systems. That each particular structure or instinct comprised in the system, which shows permanence or definiteness makes a contribution to the success of the system equivalent to the cost of its production is recognised as a fallacy. We are also reluctant to apply to the interrelations of the collective properties of organisms arguments which would be out of place in similar considerations of the attributes of unorganised substances. We no more look for utility in the details of a peacock's feather than in the iridescence of a Roman bottle or in the regularity of basaltic prisms.

Adaptation.—It is not merely in regard to the mode by which species have arisen that agnosticism has prevailed. While unwilling to accept adaptation, with Darwin, as a summation of happy accidents, we have no alternative to offer, nor is there in the attempts of various experimenters to find that organisms transmit to their posterity structural emendations in response to parental experience anything which sensibly alleviates the difficulty. Most of these claims are obviously faulty and few require serious notice.

Each step in the progress of this branch of science has rather compelled the recognition of genetic determinism; and the hope that by change in the conditions of life or by any external influences significant alteration can be induced in succeeding generations, whether of organisms amenable to experiment or of the human population, must be abandoned.

Classification.—The full implications of factorial analysis in relation to biological classification are not yet appreciated. The fundamental idea of the systematist, that animals and plants can be grouped into species, and that the distinctions between species are of a different order from those characteristic of varieties, is now scarcely open to question. Nevertheless, the belief held very widely by systematists, that certain classes of differences are important as being more fixed, and others trivial as being more liable to variation, is scarcely consistent with genetical knowledge. The frequency and amplitude of variation and the perfection of segregation must be empirically determined for the various organisms and for the various characters. No general rules can be predicated. Anthropologists, for example, are accustomed to regard special features of anatomy as comparatively sure guides to racial origin (*see* RACES OF MANKIND). Knowing what we now do of segregation and recombination we suspect that no characteristic is incapable of segregation and so of transference to another race: given the possibility of cross-breeding, the shape of the skull or other bodily peculiarity may be transferred in its entirety to individuals descending through another parent from a different race, and hence to a resulting population, more slowly but not less completely than a language or a custom.

The classificatory dichotomies in common use in the systematic arrangement of animals and plants have no prerogative significance except for mnemonic or demonstrative purposes; the number of the dichotomies is merely an enumeration of the pairs of factorial differences; and the order in which they are taken into account, though often treated as a matter of cardinal importance, is purely arbitrary. Peas, for instance, are divided first into tall varieties and dwarf varieties, then into round and wrinkled, yellow and green, etc., but it would be logically as sound and physiologically as justifiable to divide them first into yellow and green, then into early and late and so on. If the races of men could be crossed under experimental conditions we should find the same principles governing their distinctions.

Applications.—The applicability of genetic discoveries to the betterment of the human race is discussed in the article EUGENICS, but progress in the art of breeding animals and plants is also possible by the development of Mendelism. The use and consequences of crossing in the search for new forms of economic value are now apparent. The reasons for preserving the first generation (F_1) though it may present no valuable feature and the desirability of raising from it as many individuals (F_2) as space will accommodate, are obvious. The breeder now knows what he is about and is able to interpret countless phenomena previously meaningless. Granting that the chief breeds of animals now in the keeping of civilised man are not capable of much amelioration, experience has shown that enormous improvements can be made by applying accurate knowledge to the breeding of even such old-established crops as wheat, oats, tobacco, etc. If this is true of the crops which have for ages been the object of unremitting care, it will be understood that the cultivated plants of tropical regions offer limitless possibilities.

The breeding of coconut, rubber, jute, cacao and many more has scarcely begun. These are all still raised from seed gathered almost promiscuously, the result of uncontrolled fertilisation, and the product is what we should see if our orchards were raised from seeds and those seeds gathered at random from garden varieties and from wildings in the hedgerows. At first, selection and fertilisation under control will suffice to make great progress. Even at that stage some genetic knowledge will be of value, but when the more difficult task of making genetic recombinations of desirable qualities is begun the breeder will require skill in the management and interpretation of the generations and the various terms in the series of forms which only accurate knowledge of principle can supply. Genetic science shows primarily what can be expected, provides the breeder with an aim, and also indicates how it may be attained. For example, a crop of sugar beet often contains 4% (sometimes many more) of plants which "bolt" or flower in the first year making no "bulb," and so worthless. This state of things has long been accepted as inevitable.

But when the geneticist finds that the annual habit is a recessive, he suspects that the plants which produce the bolters are heterozygous in that respect, and that if he can raise plants homozygous in the biennial habit he will have eliminated bolting. The breeder, whether scientific or practical, ignorant of genetics, would never suspect the nature of the fault, still less could he devise a cure. Common sense in the art of seed-raising is an imperfect guide. Apart from any question of making new races, the purification of existing varieties and their maintenance in a state of purity are exacting tasks. What has been done in these several phases of the industry, in ignorance of principle, is remarkable, but we may confidently foresee that the application of scientific method will, in the case of the breeder's art, effect a change in magnitude no less than that which has been witnessed in the other industries.

of the terms *phenotype* for the former and *genotype* for the latter. Systematic or classificatory works, both zoological and botanical, abound with errors arising from want of appreciation of this fundamental distinction, which must constantly be remembered, especially, for instance, whenever the significance of varietal or intermediate forms has to be estimated.

Variability.—Evidence formerly regarded as proof of abundant contemporary variability in the species of animals and plants must be submitted to searching tests before it can be so accepted. Observations of variability once deemed adequate are now seen to be capable of quite different constructions. Proof that an observed departure from type is a contemporary genetic variation can only be obtained in exceptional cases which have been critically observed under experimental conditions. Putative variation is commonly nothing but the recurrence of a recessive form, or the emergence of some other segregant, from a stock genetically impure; more often still the direct product of a cross. The existence, therefore, of a multitude of varietal forms, so far from simply providing a convenient basis upon which a theory of the evolution of species can be erected, becomes itself an antecedent problem; and instead of asking, as they used to do, how the species have been built up out of the varieties, biologists are rather concerned to discover whence and by what process these variations have come to exist. The belief that substantial genetic change commonly accrues by summation of impalpable differences has been generally abandoned as devoid of evidential foundation. Such differences are mostly fluctuational, largely dependent on circumstance rather than on genetical units and hence not transmissible. Summation, when a genuine phenomenon, is a consequence of purification or the attainment of homozygosis. The idea that a characteristic could in any other way increase as a result of selection is out of place in an exact or even a logical science.

Variation by Loss and by Addition.—Whether the evidences of authentic variation remaining after the deduction of spurious testimony has been made, suffice as a basis of evolutionary theory has been questioned by competent naturalists. Lotsy, for example, maintains that we have no proof of contemporary variation arising otherwise than as a consequence of crossing; and apart from such extreme announcements it is noticeable that as regards varieties of animals and plants anciently domesticated, modern authorities usually incline to ascribe a multiple origin even for forms like wheat, the fowls, pigeons, sheep, horses, etc., which used formerly to pass for derivatives from single types, a belief now felt to be inconsistent with what is known of the limits of variability. Distinction must be made between recessive and dominant variations, arising respectively by loss and by addition. As regards recessive variations arising by loss of elements few will doubt the adequacy of the records (*e.g.*, in the sweet pea, *Primula sinensis*, etc.). As regards the *de novo* appearance of dominant characters the evidence is less abundant. Morgan and the American geneticists have made prominent several instances of this kind in Drosophila (fruit fly), of which the spontaneous origin of " eosin " (a new and peculiar pink) eyes in a white-eyed strain may be cited. Admitting provisionally these examples as free from objection they are, nevertheless, extraordinary events and not common occurrences. Were the dominant in question one already familiar we should hesitate to believe in its spontaneous origin. That a pea genetically wrinkled, having the characteristic starch of the wrinkled varieties, should without crossing produce a variety with " round " starch-grains would in modern lights appear not much less improbable than the spontaneous generation of life.

With plausibility a number of human malformations, such as praesenile cataract, claw foot-and-hand, etc., which have been regarded as descending as dominants, may be interpreted on these lines as in reality due to loss. From almost the beginning of Mendelian studies surprise has been felt that so many curious abnormalities in man, of which at least some 30 may be enumerated, should behave as dominants, seeing that novel characters most frequently are demonstrably recessive. Inasmuch as these " dominants " are so abundant in man, though otherwise rare, something no doubt remains to be explained; but we may avoid the difficulty of interpreting them all as factorial additions, for with equal probability the normal may be represented as possessing an element which, when homozygous, maintains development in its proper and normal course. Mohr and Wriedt, discussing the inheritance of a new type of shortened digits, recently made the suggestion that we have here to do with a character which, in the homozygous state, is *lethal*. In other words, if one element of " normality " only be present the individual exhibits the peculiarity, but if both elements of normality are wanting the consequent malformation is so extensive that the embryo perishes at some early stage of development. The normal element would then be recognised as the positive contribution, and in the absence of at least one such contribution the embryo is non-viable. Some slight evidence is already adduced in support of this view; and since lethal contributions certainly play a great part in genetical histories, we should be prepared for a wide application of this principle, especially to the descent of deformity.

But, as explained in the article GENETICS, nothing absolutely forbids us from inverting the representation of positive and negative factors by extension of the conception of inhibitors, of which many are familiarly known; so that we may express the apparent addition of a new element as a loss of one which when present had repressed the new attribute. This symbolism, though admittedly objectionable when dominance is complete, does without strain apply to all cases in which the heterozygote is intermediate, and a large range of alleged new dominants can be covered. In so far as this conception applies, evolution is conceived of as a process of unpacking, a progress consisting in the loss of component elements.

Mutation.—The term *mutation* introduced by de Vries, is now generally accepted to denote definite genetical variations which are sensibly discontinuous. Though contemporary examples which satisfy all tests are not abundant, there is no question that they occur and have occurred in most of the forms of life. They are indeed part of the occasional experience of most breeders of animals and plants. The special example, the Oenotheras, on which de Vries mainly founded his own theory, was singularly unfortunate and must, as explained in the article GENETICS, be now discarded as inapplicable. Mendelian analysis was only lately made known, and the group of discoveries comprised in the term genetics were in an incipient stage; nor had the criteria of genetic purity, which must be applied to a parental form before the production of new types from it can be accepted as proof of original mutation, been clearly established. The Oenotheras which produce the presumed mutations are now proved to be no pure genotypes, and the suggestion that they were in a " period of mutation " arose from a misunderstanding of the nature and consequences of heterozygosis.

Inter-specific Sterility.—The new forms whose productions we witness are never new species. In *Primula sinensis* about 20 pairs of factorial differences have been determined, which in their several combinations present an amazing polymorphism. A systematist, if he met these forms in nature, might and probably would quite justifiably take many of them for distinct species. But interbred, they and their products are perfectly fertile. Polymorphism like this is, even in a state of nature, far more abundant and far greater than the evolutionists of the last century imagined, yet it avails us little as material out of which true specific differences can be supposed to develop. The conspicuous defect in the evidence for the origin of species by common descent remains. Though much is known as to the incidence of variation, not rarely of a magnitude which might naturally be claimed as constituting specific difference, no one has yet raised types from a common origin which when interbred produce sterility of the kind and degree forming one of the commonest attributes of crosses between natural species. By whatever concatenation of arguments theories of evolution have been constructed, the most essential link has never been supplied. The lapse of time is occasionally invoked in the hope of rectifying this and similar evidential defects, a strain which has been maintained distinct for a long period being thought more likely to show

SIMPLE COLOUR INHERITANCE IN THE SEEDS OF THE COMMON GARDEN PEA

When yellow-seeded and green-seeded peas are crossed, all the second generation has yellow seeds, but in the third generation three-fourths of the seeds are yellow, one-fourth green. In the second generation the green is latent, or recessive, being overshadowed by the dominant yellow. If plants from the green seeds of the third generation are crossed green seeds always result. The apparently similar yellow seeds may be pure yellow or hybrid (part yellow, part green). If yellow-seeded plants from any generation are crossed, one-third will breed pure yellow, and two-thirds will breed hybrid yellow, giving in the next generation three yellow to one green.

HOW THE OCCURRENCE OF A NEW SPORT VARIATION MAKES POSSIBLE THE MULTIPLICATION OF EXISTING VARIETIES

In 1911 a yellow rat (a previously unknown variety) was caught in England. It was mated with black-hooded individuals, a recognised tame race which breeds true. The offspring were all brownish-grey like wild rats, but the grandchildren exhibited eight different varieties.

As the crossing of a constant strain with a variant from another and perhaps variable strain gives so many varietes of offspring, it is readily seen that where both the strains crossed already differ in many minor characteristics, there will be (as is observed in actual life) an almost infinite number of small variations from individual to individual.

MENENDEZ PIDAL, RAMÓN (1869–), Spanish philologist, was born March 13 1869 at Corunna, and studied at the universities of Madrid and Toulouse. In 1899 he was appointed to the chair of romance philology at the University of Madrid. Menendez soon acquired a great reputation as a master of his subject and lectured in South America and the United States. In 1907 he was member of a board created in that year for the development of university education in Spain and in 1913 was appointed counsellor of public instruction for the kingdom. His grammar, text and vocabulary of the *Cantar de Mio Cid* (1908) opened out new possibilities not only to Castilian philology but to historiography in general. Menendez Pidal became the leader of the *Centro de Estudios Históricos*, the main house of learning in philology and historical matters in Spain, and the editor of the *Revista de Filología Española*. His other works include *Primera crónica general* (1906); *L'épopée Castillane à travers la littérature espagnole* (1910); *Gramática Histórica Española* (1914); *Un aspecto en la elaboración del Quijote*, 2nd ed. (1924).

MENÉNDEZ Y PELAYO, MARCELINO (1856–1912), Spanish scholar and critic (*see* 18.128), was at the time of his death working at the second edition of his *Historia de los heterodoxos españoles*. He died at Santander May 19 1912.

MENTAL DEFICIENCY.—Mental deficiency, or amentia (*a*, without, *mens*, mind), has been defined as that state in which the mind has failed to attain normal development, as distinguished from dementia (*de*, down from, *mens*, mind), mental defect occuring subsequently to mental development. Legislation both in England and abroad has recognised the essential difference between these two forms of mental disease, and the class of so called "mental defectives" is generally dealt with by laws differing from those affecting the insane. These laws are based mainly on a recognition of (*a*) the educational, (*b*) the social and racial problem created by the presence of large numbers of uncontrolled mentally defective persons in the community.

I. GREAT BRITAIN AND THE BRITISH EMPIRE

In England the Mental Deficiency Act of 1913 was the outcome of the Report (1912) of the Royal Commission on the Care and Control of the Feebleminded appointed in 1908, and embodied a considerable number of its recommendations.

The Elementary Education (Defective and Epileptic Children) Act, 1899, gave to local education authorities power to provide special schools (day or residential) for mentally defective children between the ages of 7 and 16 who, not being either dull or backward or idiots or imbeciles, were capable of benefiting by the education provided in such schools. Under the Elementary Education (Defective and Epileptic Children) Act of 1914 these powers were made compulsory, and both Acts were embodied in Part V., sections 51–9 of the Elementary Education Act 1921. Attendance at such schools may be enforced by a magistrate, provided it is clearly for the child's benefit that he should attend a special school. Owing to the War and to the relatively high cost of these schools many authorities have failed to provide sufficient, in some cases, any, special schools; there is practically no school provision for defective children in rural areas. The estimated number of defective children is calculated at 8 to 10 per thousand of the school population. The latter figure is probably the more accurate. This gives a total of 50,240 defective children to be provided for, but provision has only been made for 16,392 children in 174 day and 21 residential schools. In addition, the local education authorities must notify to the local control authority children who are incapable of benefiting from education in special schools or who need institutional care on leaving school. In urban areas there are 88 occupation day centres for children excluded from schools, run for the most part by local voluntary mental welfare associations; after-care committees and the above associations look after the children who have left special schools, try to find them employment, supervise them at home and establish handicraft centres for them.

The Mental Deficiency Act.—The Board of Control, a section of the Ministry of Health, administers the Lunacy and the Mental Deficiency Acts. The local control authorities are statutory mental deficiency committees of county and county borough councils, whose duty it is to provide for defectives,[1] only when they can be certified as idiots, imbeciles, feebleminded or moral imbeciles, and who in addition are either (*a*) neglected, without visible means of support, cruelly used, etc.; (*b*) found guilty of any criminal offence, and liable to be sent to or actually sent to an industrial school or prison; (*c*) notified by the local education authorities as ineducable or as needing institutional care on leaving a special school; (*d*) having given birth to or being pregnant of an illegitimate child whilst in receipt of poor relief. The duty of the authority is to (*a*) ascertain the defectives they must deal with; (*b*) provide supervision by visiting and watching over the defective at home. This supervision is in a large number of areas carred out by local mental welfare associations affiliated to the Central Association for Mental Welfare, who supply visitors for defectives living in the community. If this supervision is insufficient the authority may (*c*) send defectives to a certified institution under orders, or (*d*) place them under guardianship under orders, *i.e.*, under the charge of an individual having the powers of a parent over them. This order is made by a magistrate on a petition supported by two medical certificates. Orders are renewable by visiting justices at the end of each of the first two years, then every five years. So long as the order lasts the defective can be compulsorily detained, but defectives can be discharged by a commissioner of the Board of Control at any moment. The parents of defectives, if they oppose the making of the order, must prove that it is for the benefit of the defective that he should remain at home.

Local authorities are required to provide certified institutions for defectives; they can also send defectives to institutions provided by other committees. The War prevented the development of institutions, and a considerable number of poor law institutions have been approved for the reception of defectives under orders. The Royal Commission estimated that there were 4·6 per 1,000 defectives in the population. Some 48,778, or 1·29 per 1,000, have been ascertained, but only 19,076 defectives were in institutions under the Act in Jan. 1926, many being found in institutions and homes as rescue cases, paupers, etc.

The difficulties are: incomplete ascertainment of defective children, which handicaps preventive measures; lack of special educational facilities for training defectives; lack of institution accommodation for adult defectives; and lack of recognition of mental defect in cases coming before the courts. Greater efforts are being made to safeguard the community and the defective by segregating all with anti-social tendencies in institutions.

Scotland.—The Mental Deficiency Act for Scotland, 1913, does not differ very materially from the English Act but the local authorities are local boards of control and the parish councils. There were 2,452 certified mental defectives on Jan. 1 1925. A Scottish Association for Mental Welfare was established in 1922. There is also an active voluntary movement on foot for the establishment of a large colony for the feebleminded.

Ireland.—The Mental Deficiency Act does not apply to Northern Ireland. There was in 1926 but one institution for

[1] For definitions see the Mental Deficiency Act.

defectives in the whole of Ireland, but certain religious communities propose to open others.

British Empire.—Legislation in other parts of the British Commonwealth is generally modelled on the English Mental Deficiency Act.

In South Australia, a Mental Deficiency Act was passed in 1913; in Tasmania, in 1920. The Mental Deficiency Board then established published in 1925 a report on a mental survey of the prisoners in Hobart Gaol. In Melbourne and Sydney special schools and classes for mentally defective and backward children are being established.

The Mental Disorders Act of 1916 regulates the care of defectives in the Union of South Africa. A national council for the care of the feebleminded watches over the interests of individual defectives, and guides public opinion.

In Canada a Federal Act dealing with immigration prohibits the entry of mental defectives into the country. Each provincial government provides grants for the organisation of special classes for mental deficients in school attendance, and in Jan. 1926 there were approximately 140 such classes. Ontario, Alberta, Saskatchewan, Manitoba and Nova Scotia have made institutional provision for approximately 1,500 mental defectives, the largest at Orillia, Ontario, having accommodation for 1,200 cases. Several of the larger cities, including Toronto, Winnipeg and Vancouver, provide routine mental examinations for schoolchildren and for juvenile court cases, and since 1918 the Canadian national committee for mental hygiene has been conducting surveys throughout the Dominion to determine the prevalence and significance of the problem.

In New Zealand, the Mental Defectives Act of 1911 and the Education Act of 1914 are the Acts under which day schools, one or two residential schools and some institutions are established. A committee of enquiry (1925) under the Ministry of Health recommended the establishment of a eugenic board for the compilation of a register of mental defectives, and made recommendations for the sterilisation of certain mentally defective persons.

II. THE UNITED STATES

Americans have given a great deal of study to the proper diagnosis and training of mentally defective persons and to the eugenic aspects of the problem, and there is a very widespread and efficient organisation in many of the States. Each State has its own legislation. There are numerous special day schools, called auxiliary classes, residential schools and institutions. Many of the institutions are on a vast scale, and have thus permitted interesting experiments. One of the pioneers of the work, the late Dr. Walter Fernald, developed the Waverly Institution (Mass.) into a highly successful training colony. One of Dr. Fernald's principles was "paroling," and a very large number of patients, especially men, did remarkably well on "parole" from the institution. Institutions equally interesting are the Rome State School (New York) and Vineland (New Jersey), where Dr. H. Goddard and Dr. S. D. Porteus have carried out numerous experiments in the measurement of intelligence. Psychiatric clinics are attached to many hospitals, and afford considerable opportunities for the study of mental defect. Segregation has been tried on a wide scale in several of the States, and for some years certain States have had laws allowing the sterilisation of mental defectives. Special attention has been directed to the whole problem of defect in its relation to delinquency amongst children and adults. The national committee for mental hygiene and the joint committee on methods of preventing delinquency, the Judge Baker Foundation, Boston, Mass. (which publish numerous monographs) and other kindred associations have done pioneer work in this connection.

III. EUROPEAN COUNTRIES

The work among mentally defective persons in other countries follows much the same lines as are indicated in the description given below. The classification of defect differs somewhat in different countries, and a class of "moral imbeciles" is not universally recognised. Almost all countries have now made some provision for mentally defective persons, but the problem is still inadequately met.

France.—In France, mental defectives are dealt with under the law for "aliénés" passed as long ago as 1838, which has not been amended. Under this law persons can be placed in institutions at the request of their families, or by order of the prefect, if they are considered dangerous or in need of protection. Some difficulty is found in dealing with cases needing treatment but not institutional care, but the work of treating the feebleminded at psychiatric clinics is likely to develop since the establishment of a clinic at Paris in 1921. A law passed in 1919 recommends special classes for children, but does not make them compulsory. No statistics as to the incidence of defect are available. Some French institutions have a fine reputation, notably perhaps the Hospice de Bicêtre, near Paris, which is attached to a general hospital, and has accommodation for about 1,000 males (mostly idiots and imbeciles) and about 217 girls. Seguin, one of the pioneer teachers of defectives, worked at the Bicêtre.

Italy.—In Italy, the class "imbecili morali" is recognised. No exact figures are available as to the number of defectives. A general law on the protection of children was in preparation in 1926. There are only eight institutions set aside for the mentally defective, accommodating 761 persons. Madame Montessori's educational methods (q. v.) were based on the experience gained among defective children at Rome. She made the startling discovery that a mentally defective child taught on her methods was in some instances actually able to attain a higher standard than normal children taught on other methods. She has applied to the teaching of normal children the empirical methods so effective with defectives, and her work has reacted in favour of improved methods for both classes of children.

Belgium.—Another educational pioneer, Dr. Ovide Decroly of Brussels, similarly first interested himself in the study of defectives, and later adapted his methods in use in his special school in Brussels to the teaching of normal children. His normal school in Brussels reveals its purpose by its title, "École pour la vie par la vie," and his methods have been adopted in many of the elementary schools in Brussels. Belgium has a remarkable institution, the colony at Gheel, whose origin goes back to the 6th century, when a shrine was built to St. Dymphna, a martyred Irish saint. At least as early as the 13th century she came to be considered the special saint of "aliénés." From that time through the centuries the work has grown until today Gheel is a place of some 20,000 inhabitants caring for 2,000 "aliénés," including insane and mentally defective, with a school for 160 defective children. The principle of the colony is freedom and home-life in the families of the citizens. Other similar colonies have been founded in the country.

Holland.—The institutional care of the feebleminded is almost entirely in private hands, but special schools exist in the towns.

The Scandinavian countries have a good system of special schools and several institutions, and considerable attention has been given to the training of defectives.

Denmark.—It is estimated that there are in Denmark between 6,000 and 7,000 mentally defective persons in a population of 3,500,000, but there are no exact statistics. There are four large institutions, accommodating about 3,450 persons, and private homes taking 350 patients. Special schools are not compulsory, but they are established in most large towns such as Copenhagen, which has a school for 700. A Marriage Act is on the statute book prohibiting marriage with a mentally deficient person.

Austria.—Developments in Austria have been considerable since the War. There are special schools and classes for 2,794 children, and 20 institutions for the care and instruction of 1,498 mentally defective and epileptic children.

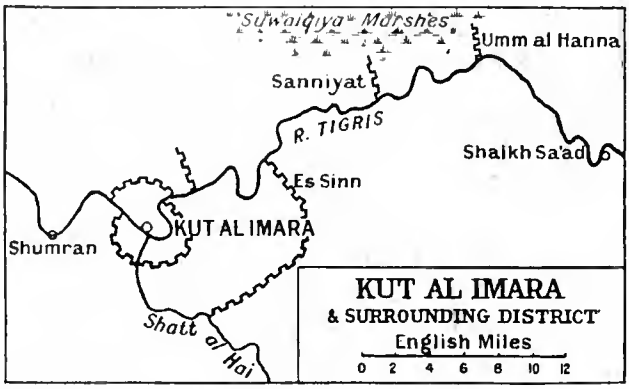
Germany.—Germany has a fine special school system, with schools in about 600 different places. These schools are in some instances very small, more than 200 having only one class, and 150 only two classes. There are in all about 3,500 classes in these schools, with accommodation for 67,000 children. Most of the special schoolchildren have had two years' trial in the elementary school, and those who are not able at the age of six to profit by the elementary school can attend a "Vorklasse" before being drafted into a special or normal school according to their development. In Mannheim since the beginning of the century, and later in Charlottenburg, Frankfurt-on-Main and other towns, a system of so called "Förderklassen" has been established for the backward child whose mental difficulties may be due to exterior or physical causes and not to mental defect. In other towns there are classes for those who in the later years of school life remain backward.

Switzerland.—The Institut J. J. Rousseau in Geneva has been of inestimable value in the scientific study of the child. The founder, Prof. Ed. Claparède, has proceeded on the principle that the abnormal and normal child should be studied at the same time, and the institute has now become a laboratory for the study of the child in all his manifestations. The care of the feebleminded is very well organised in Switzerland. In 1918 preparatory classes were established for the children who cannot keep up with the lowest class, and in some schools there are "crammer" classes with more handwork than in the ordinary classes, for children whose backwardness is due to "neglect," and who are probably able to return later to the ordinary classes. There are also "work-classes," which have more manual work even than the special schools. The employment schemes in institutions are admirably organised. The Basle institution, opened in 1916 for the paid employment of defectives has been most successful, and is being enlarged so as to serve the needs of defectives from any area. A work and welfare home for girls, with similar aims, was opened in 1924 at Komtz, near Berne.

BIBLIOGRAPHY.—*Final Report of the Royal Commission on the Care and Control of the Feebleminded* (Cd. 4202, 1908, vol. 8). For interim

communications which would naturally connect Turkish forces on the lower Euphrates with Baghdad. It was furthermore the most populous spot between Imara and An Nasiriya on the one hand, and Baghdad on the other. But almost the whole of the expeditionary force, apart from detachments on garrison duty lower down, had now been projected into an isolated situation far within the enemy's territory, and it depended upon a long line of water communication—the Tigris—while it was served only by a restricted number of steamers and of smaller craft.

Still, the idea of pushing on to Baghdad had already taken shape even before the occupation of Kut. The Aug. discomfiture in the Gallipoli Peninsula (*see* DARDANELLES CAMPAIGN), coupled with a belated realisation that the Dardanelles venture



would not succeed, had rendered the British Govt. eager for some dramatic achievement in Mesopotamia. The Indian Viceroy had advocated an advance on Baghdad when the start up the Tigris from Imara was materialising, and Townshend's triumph acted as a powerful stimulus to such aspirations. Nixon intimated early in Oct. that he could open a road to Baghdad, under the circumstances then existing, but could not hold the city if it were taken. The military authorities at home, while admitting the possibility of capture, regarded permanent retention as out of the question with the limited numbers available, and they declared that if the place was to be held Nixon must be reinforced by two divisions. But, influenced by political considerations, the Government became more insistent, and in the end, although no reinforcements could be sent him immediately, and although they could not have taken part in the operations had they been sent, Nixon was told on Oct. 31 that he might advance on the city.

First Baghdad Offensive Fails.—Townshend, who had pushed a large part of his force on to Al 'Aziziya while the matter was being debated, found that the Turks were less disorganised than had been supposed, and that his own troops were tired and short of establishment; and he had serious misgivings. He, moreover, was unable to move for a fortnight, even after receiving the order to advance, owing to shortness of supplies and the need of organisation for the hazardous effort. He advanced from Al 'Aziziya on Nov. 11, and on approaching Ctesiphon some days later he found the Turks to be assembled there in strong force and expecting reinforcements. He attacked them on the 21st and was at first successful; but additional Ottoman troops arrived during the fight and recovered much of the lost ground, Townshend's losses in the action proving very heavy. During the next three days Townshend prepared to retreat, and on the night of the 25th he moved off.

No great difficulty was experienced at first; but, in consequence of the flotilla of supply transports and fighting craft being delayed by shoals, a halt had to be called on the 29th. Next day the pursuing Turks came up and delivered a resolute attack which was however beaten off, and after that the sorely tried little Anglo-Indian army was not seriously interfered with on its way to Kut, which was reached on Dec. 3. So, for the moment, ended the ill-advised Baghdad adventure. During the discussions of Oct. the Turks had been strongly reinforced from the northwest, and, by the time that Townshend had advanced from Al 'Aziziya, his adversaries had already grown so formidable that there was little prospect of his opening a road to the city. There never had been any prospect of his being able to hold the place even if he got there. Seldom has a military force been committed to an undertaking that seemed so difficult of attainment.

II. THE SIEGE OF KUT

With the approval of the Home and Indian Governments, Nixon decided that Townshend was to remain where he was, although if he did so he was bound to be invested. They assumed, altogether too readily, that he would be relieved before his supplies ran out. So his sick and wounded, his cavalry, most of the flotilla, and a portion of his animals were sent off down the Tigris (although the civilian population was unfortunately allowed to stop), preparations for standing a siege were put in hand, and on Dec. 8 Kut was hemmed in on all sides. Its situation, in a deep loop on the left bank of the Tigris, rendered the place readily defensible against assault or siege approach, and the German Field Marshal von der Goltz, who had just taken supreme command of the Ottoman forces in Mesopotamia, realised that unless it fell to an early assault the main Turkish task in this region would be to guard against a relief. Nur-ed-Din, the Turkish commander on the spot, had four divisions at his disposal, and on Dec. 10, 11 and 12 he delivered unavailing onsets upon the narrow front that was not covered by the river. After that the siege became a blockade, part of Nur-ed-Din's troops moved down the river some distance so as to confront any relieving force that might try to approach, and fortifications designed to meet such a contingency were erected.

Attempts at Relief.—Meanwhile the 7th and 3rd Indian Divisions had been detached from the Western Front in Europe, and began arriving in the middle of Dec. in the Shatt al 'Arab. General Aylmer took charge of the troops who were to undertake the relief of Kut, and units as they disembarked were pushed on to Imara with all speed and proceeded thence up the Tigris. Owing to a miscalculation as to the length of time that Kut would be able to hold out, the operations of relief were during their early days hurried more than was necessary, with the result that the force under Aylmer was during its operations in Jan. less well organised than it might have been. There was a grievous lack of heavy artillery, as well as a grave deficiency of water transport. Nevertheless the Turks were driven out of their advanced position at 'Ali Gharbi, were again defeated at Shaikh Sa'ad and, after a further defeat, fell back to the lines of Umm al Hanna, 20 m. from Kut on the left bank of the Tigris, at the entrance to a very awkward defile caused by the extensive Suwaiqiya marshes, which here approach to within a short distance of the river. The relieving force had hitherto triumphed over every obstacle; but when on Jan. 21 it essayed the storming of the Umm al Hanna position the effort failed, and so numerous were the casualties that Aylmer felt compelled to pause in his offensive and to await reinforcements. About the same date Sir P. Lake succeeded Sir J. Nixon in the chief command.

Improvement of Organisation.—Lake set himself to place Aylmer's line of communication on a better footing, to improve the medical arrangements and to develop the wharves at Al Qurna and Basra. Material of all kinds was, however, deficient, and the Turks were in the meantime developing their lines of defence on both banks of the Tigris below Kut, rendering the task of a relieving force more and more difficult. The British Government had, on receipt of the bad news about Umm al Hanna, ordered the 13th Div. to proceed from Egypt to Mesopotamia; but to move these troops from Suez to the front of the Tigris necessarily took some weeks, and it was moreover now too late to expand the water transport sufficiently to meet the needs of the growing Anglo-Indian force. Aylmer attempted no forward movement during Feb.; but on the night of March 7–8, without waiting for the 13th Div., he advanced from near Shaikh Sa'ad against the Es Sinn position, intending a surprise.

This was on the right bank of the Tigris, less than 10 m. from Kut, considerably higher up than Umm al Hanna and the defile caused by the Suwaiqiya marshes on the farther bank; but owing to the Turks holding that defile Aylmer's flotilla was prevented from advancing above Umm al Hanna. The operation involved a long march in the dark; when day broke part of the force had not arrived, and, although the enemy was surprised in the first instance, the attack was delayed. When the assailants advanced against the reinforced Turks, they were beaten back and had to retire to Shaikh Sa'ad.

Surrender of Kut.—The garrison of Kut was already on much reduced rations; but Gen. Gorringe, who had succeeded Aylmer, could make no fresh attempt for nearly a month owing to transport and supply problems. On April 5, however, the 13th Div. under Gen. Maude stormed the Hanna lines and penetrated well into the defile on the left bank of the Tigris; but, when first the 7th Div. and then the 13th Div. attacked the Sanniyat lines at its farther end, they were in each case repulsed. Kut could now only hold out a few days longer, so Gorringe tried to advance by the right bank. After its making some progress on the 17th, in spite of almost insuperable difficulties caused by floods, this movement was, however, brought to a standstill. A final effort was made by the 7th Div. on the 22nd against Sanniyat, which nearly succeeded. Finally, on the night of the 24th, a steamer loaded with provisions tried to run the blockade but failed, and on the 29th Kut, with its garrison of 9,000 British and Indian troops, surrendered. The efforts to save it had cost 24,000 casualties, but had it been known in Jan. and Feb. that the place could have held out so long, the relieving army would have enjoyed a better prospect of achieving its object.

British Opinions.—The tidings of this very grave mishap gave rise to profound dissatisfaction in Great Britain, a dissatisfaction aggravated by information gradually leaking out with regard to the sufferings of the sick and wounded after the retirement from Ctesiphon. A Royal Commission was set up a few months later to inquire into the operations that had taken place in Mesopotamia, and its conclusions were to the effect that the undertaking of a campaign on so ambitious a scale without adequate forethought and efficient preparations was worthy of blame; it also animadverted in strong terms on the very unsatisfactory character of the medical arrangements during the early stages of the venture. In the meantime it was decided that Kut must if possible be reoccupied. But the hot season was at hand. The troops had suffered exhausting trials and had met with cruel losses. Water transport, as well as artillery and other war material, remained totally inadequate. There could be no question of resuming the offensive on the hand-to-mouth lines on which the advance from Imara had been initiated in the previous year, and which General Lake had been obliged to continue when striving against time to relieve Townshend. A prolonged pause therefore became inevitable.

No reference has been made hitherto to the Russian forces in Persia. These, based on the Caspian, were actually in occupation of a considerable area of the Shah's northern territories. But they were weak in numbers, were operating in a region of wide extent, and the avenues leading towards the Mesopotamian plain traversed rugged and unproductive uplands. Military contingents so situated could afford no direct help to the Anglo-Indian army during the critical months which followed Townshend's advance to Kut, nor did their activities at any time withdraw an appreciable proportion of the forces under Von der Goltz from the theatre of war on the Tigris.

III. THE BAGHDAD OFFENSIVE

Great developments took place on the Anglo-Indian line of communications, and at the base during the summer. A reasonable amount of heavy artillery was gradually accumulated. An additional division arrived from India. Landing facilities at the ports were vastly improved. A change, moreover, took place in the chief command, for, after replacing Gorringe in charge of the forces at the front in July, Gen. Maude a few weeks later became commander-in-chief *vice* Sir P. Lake, whose health had broken down. Maude realised that there was yet much to be done before his army could hope to act with effect in this peculiarly conditioned theatre of war, and he set to work with indomitable energy to perfect his arrangements. He organised four divisions at the front up the Tigris as two army corps, and from Sept. to the end of Nov. he laboured unceasingly at the base, enjoying full support from the War Office in London, which had definitely taken over charge of the campaign from the Indian authorities. By the beginning of Dec. he had been furnished with enough river craft, his supply system was sufficiently advanced, and he had the necessary war material at his command, to justify his embarking on offensive operations of a far-reaching kind, and on Dec. 13 he struck suddenly and with signal success.

Disposition of the Forces.—Von der Goltz had left Mesopotamia, and Khalil Pasha was now in command of the Turks. They had withdrawn from Es Sinn and had established an entrenched camp nearly all around Kut, while holding on to Sanniyat, and in view of their dispositions Lake had begun a railway-line to run from Shaikh Sa'ad to a point near Es Sinn. It must be pointed out that Maude started his offensive with a force four times the strength of that which, under Townshend, had advanced to Ctesiphon a year earlier. His army astride of the Tigris was of necessity disposed in échelon, with its left (the II. Army Corps under Gen. Marshall) about Es Sinn, and its right (the I. Army Corps under Gen. Cobbe) facing Sanniyat. Maude's plan was to push his left yet farther forward, to clear the right bank of the Tigris to well above Kut, and, when these dispositions should in due course have taken effect, to force the lines of Sanniyat with his right.

Marshall opened the offensive by forcing the Shatt al Hai after a night march, and by capturing some of the Turkish defences which formed a bridge-head south of Kut. During the struggles that ensued, which lasted some weeks, Khalil's troops offered a stout resistance, so that although Maude's operations on the right bank of the Tigris were almost uniformly successful, they proceeded slowly and by successive stages. By the middle of Feb. the whole of the Turkish entrenched camp on that bank was in Anglo-Indian hands, and the Ottoman troops had all withdrawn to the farther side of the great river. No sooner had this part of the programme been accomplished than Cobbe on the 17th attacked Sanniyat. The effort failed for the moment; but when the assault was repeated five days later, it proved completely successful, and after a desperate contest in which the Turks lost very heavily, the formidable lines were at last carried. On the same day Marshall by a brilliant feat of arms forced a passage across the Tigris at Shumran, and no course was then left open to the Ottoman commander but to abandon Kut and retire in haste up the left bank of the river. Maude's flotilla, hitherto blocked by Sanniyat, pushed up at once past Kut, and the Anglo-Indian army could claim to have won a victory that went far towards wiping out the discomfitures of the previous year.

Turkish Retreat from Kut.—With his supplies guaranteed by the arrival of the water transport, Maude pressed on along the left bank of the Tigris on the heels of the fugitive Osmanlis. The river channel between Kut and Al 'Aziziya has many loops and bends, making it difficult for a naval force and a military force to act in concert; but on Feb. 26 the British gunboats after a smart action destroyed or captured practically the entire Turkish flotilla. Great prizes in war material and prisoners were at the same time being made by the advancing army, and the question of proceeding to Baghdad now arose. The army commander had from the outset contemplated the capture of that city after he should have expelled the enemy from Kut, and now received permission to carry out his plan. He found himself obliged to halt for some days at Al 'Aziziya, however, for fear of outrunning his supplies. On March 4 the Anglo-Indian army resumed its advance, and it was found that the Turks had fallen back behind the Diyala. This river presented a serious obstacle, and when an attempt was made to force the passage the effort proved in the first instance unsuccessful. But Maude promptly

threw a bridge across the Tigris, passed the cavalry and Cobbe's corps over to the right bank, and by March 11 Baghdad was in British hands.

The Turks had withdrawn northwards, but Maude allowed no pause in the offensive to take place. Cobbe pushed up the right bank of the Tigris along which a stretch of railway ran from Baghdad as far as Samarra, heavily defeated an opposing force at Mushahida, while Marshall conducted a most successful campaign on the Shatt al 'Adhaim. Cobbe, moreover, completed the operations on the right bank of the Tigris by the capture of Samarra. Then, having secured possession of a wide area of fertile territory to the north of Baghdad and driven the enemy in confusion into the deserts and uplands beyond, Maude was at last able to afford his victorious troops rest—just as the hot weather set in.

Further Progress Northwards.—The virtual conquest of Mesopotamia in a four and a half months' campaign had been brought about by the resolute execution of a plan of operations that was based on correct calculation of requirements—by a triumph of forethought on the part of a chief who always relentlessly followed up his successes in the field. Neither the stout resistance offered by the Ottoman troops, nor the formidable defence works which they had elaborated around Kut, had in reality proved the greatest stumbling block in Maude's path. The vast extent of the theatre of war, and the fact that his army must almost inevitably adhere to the line of the Tigris, which constituted one long military defile, had interposed even greater obstacles in the way. But those obstacles had been overcome by effective preparation.

A railway was constructed from Kut to Baghdad, sanitation and policing were established in the capital, comforts and recreation were provided for the troops, and effective steps were taken to tap the supply resources of the fertile tracts that were in occupation of the army. A division that had been in reserve at An Nasiriya was brought up to the front. Great efforts were also made for a time to arrange for co-operation with the Russian forces in Persia; but the untoward influence of the revolution in Petrograd of March made itself more and more felt in that quarter as the weeks passed, and before long it became manifest that little was therefore to be hoped for in that direction. The situation in Armenia was indeed becoming such as to cause Maude some anxiety, for in the late summer it appeared that the Turks under German instigation were contemplating an effort to recover Baghdad. This made Maude the keener to resume the offensive, and on Sept. 28 he struck his first blow by the capture of Ramadi on the Euphrates. This victory was followed up by successful operations in clearing the Jabal Hamrin, and by the occupation of Tikrit on the Tigris at the beginning of November. A few days later, however, the army commander was struck down by cholera, and he died on the 10th. He was succeeded by Sir W. Marshall.

IV. OPERATIONS IN 1918

The country traversed by the Tigris above Tikrit and extending north for a long distance is a sterile tract, hilly and broken at some points; the ordinary route from Baghdad to Mosul does not therefore follow the river but takes a direction to the east through Kifri and Kirkuk.

Maude's Plan.—Maude had intended to conduct his main advance by this line, but his death just at the moment when the project was to be put in execution created some delay; his successor, however, set troops in motion through the Jabal Hamrin in Dec., and by these Kifri was occupied in Jan. 1918. Having secured that point, Marshall suddenly set his extreme left wing on the Euphrates in motion in the middle of Feb., with the result that Hit was captured and the Turkish division which had retired up the river was surrounded, 5,000 prisoners and all its guns being taken. Transport difficulties were hampering the advance beyond Kifri on the other flank, but on April 29 the Ottoman forces were heavily defeated on the road to Kirkuk, losing 3,000 prisoners, and a week later Kirkuk was taken. Marshall, however, decided to withdraw his advanced troops in this quarter to Kifri, and active operations then practically ceased for five months. The collapse of Russian fighting power in Armenia had enabled the Ottoman staff to move some troops from there down to Mosul and northern Mesopotamia, and scarcely any assistance had been received from Persia; but Marshall's first campaign had nevertheless been remarkably successful and his position to the north and north-west of Baghdad had been effectually consolidated.

The British Mission to Persia.—In the meantime a special British mission, sent off in Jan. under charge of Gen. Dunsterville, and originally intended to proceed to Tiflis with the object of co-ordinating the resistance of the Armenians, Georgians and Russians to the Turks threatening Transcaucasia, had been trying to maintain satisfactory relations with the Russians in Persia. But great difficulties were placed in Dunsterville's way by the Russian officials, who were tending towards Bolshevism, while open hostility was displayed by certain of the Persian tribesmen. Some Russian troops, however, remained loyal to the Entente, and co-operating with these, small bodies of British troops were gradually pushed north so as to establish a line of communications between the Anglo-Indian army in Mesopotamia and the Caspian Sea at Enzeli. Resistance to the Turks in Transcaucasia was gradually breaking down during the early summer, and at the beginning of July the last of the Russian detachments in Persia proceeded thither by ship. The Ottoman troops appeared before Baku shortly afterwards and Dunsterville with a brigade of infantry therefore sailed for that city in August.

He found the Armenian garrison to be unreliable and the attitude of the Russian officials to be suspicious. The lines constructed for the defence of the place were of such extent as to require a large force to man them, Bolshevik armed craft afloat on the Caspian were a source of danger, and it soon became apparent that the safety of Baku depended entirely upon the meagre British force that had been thrust into it, for the Armenian soldiery displayed but little stomach for combat. Dunsterville and his men did what they could to save the place for a few weeks; but on Sept. 14 the Turks broke through the outer defences, and that night the British re-embarked and returned to Enzeli, whereupon Baku passed into the enemy's hands. A somewhat hazardous venture had failed; but it had at least prevented the dispatch of some of the Ottoman troops in Transcaucasia to confront the Anglo-Indian army in northern Mesopotamia.

Closing Stages of the Campaign.—The fall of Baku occurred just when the season had again become suitable for active operations on and about the Tigris, and Marshall was now directed to occupy Mosul, an undertaking for which he had been preparing all the summer. The best of the Turkish divisions were at this time assembled astride of the Tigris at Al Fat-ha, the point where the river breaks through the Jabal Hamrin range of hills. Here a naturally formidable position had been strongly fortified, and another position a few miles higher up the river had likewise been prepared for defence. Realising that a frontal attack would be hazardous and that a tactical turning movement was virtually out of the question, Marshall decided to throw an adequate force across the Ottoman communications between Al Fat-ha and Mosul. He entrusted the conduct of the operations as a whole to Gen. Cobbe, and arranged for a column to advance simultaneously from Kifri by Kirkuk towards Mosul.

Surrender of Ismail Hakki.—The final campaign in Mesopotamia began on Oct. 23 and it lasted only one week. Two cavalry columns, that with the shorter distance to cover being accompanied by some infantry, crossed the Jabal Hamrin many miles to the east of Al Fat-ha, passed the Little Zab a long way above its junction with the Tigris, and hit off that river several miles to the rear of the Turkish positions at and above Al Fat-ha. In the meantime the 17th Div. operating on the right bank and the 18th Div. operating on the left bank of the Tigris moved forward from above Tikrit. Finding himself threatened by the cavalry forces which were approaching the river between him and Mosul, Ismail Hakki Pasha, who commanded the Turks, now withdrew from the Al Fat-ha position to the one higher up at the con-

fluence of the Little Zab, followed up by the two Anglo-Indian divisions. But the 18th Div. advancing on the left bank of the Tigris, forced a passage across the Little Zab on the 25th, thus turning Ismail Hakki's left flank, and the Pasha thereupon transferred those of his troops that were on that side of the Tigris across the river and broke up his bridge.

On the 27th the 17th Div. was pressing the Turks, who were now all collected on the left bank of the river, and on the same day one of the cavalry columns forded the stream and began moving down that side of the channel against the enemy's rear. The 17th Div. was heavily engaged on the 28th before it finally made itself master of Ismail Hakki's position at the confluence of the Little Zab. That commander thereupon retreated to Sharqat, but on the morrow the last hope of the trapped Turkish force was destroyed, when a relieving column that was approaching from Mosul was defeated by Cobbe's cavalry. All that day Ismail Hakki resisted the advance of the Anglo-Indian forces on Sharqat. On the morning of Oct. 30, however, just as the 17th Div. was about to launch a final attack, the white flag was displayed within the Turkish lines, and the whole of one Ottoman division, together with the bulk of another one, surrendered, 11,000 prisoners, 51 guns and imposing stores of war material falling into the victor's hands.

The Kirkuk column had in the meantime been steadily working its way forward towards Mosul, almost unopposed, and Cobbe's forces were about to advance on the city from about Sharqat, when tidings came to hand of the signing of the Armistice. Mosul was occupied a week later, but the Ottoman power of resistance in this theatre of war was in any case shattered as a result of Marshall's final blow. Thus the long drawn-out struggle in Mesopotamia, which had proved so consistently favourable to the Anglo-Indian arms since Maude had launched his offensive at the close of 1916, ended in a blaze of triumph two years later, concurrently with what constituted the most sweeping tactical success that had been gained by either side during the course of the campaign.

MEŠTROVIĆ, IVAN (1883–), Yugoslav sculptor, was born at Vrpolje in Slavonia, the son of Croatian peasants. The rudiments of his art were taught him by his father and at the age of 13 he was apprenticed to a marble cutter at Split (Spalato), and three years later entered the Vienna Academy where he studied under Hellmer until 1904. During the succeeding years he exhibited at the Vienna Secession, at the Austrian Exhibition at Earl's Court, London (1906), at Munich, Venice and Paris—where he attracted the notice of Rodin. He was largely responsible for the formation of a nationalist artistic movement which included the sculptors Rosandić and Dujan Penić, the painter Rački and the architect Plečnik, and which culminated in the exhibition at Zagreb in 1910 and the Rome international exhibition of the following year. His work at this period centred chiefly around a projected Temple at Kosovo, for which he made a model for the building and a large number of figures of Yugoslav heroes—Marko Kraljević, Miloš Obilić, Banović Strahinja and Srdj—caryatid figures and groups and single figures of mourning widows. In 1915 an exhibition of his sculpture was held at the Victoria and Albert Museum, London.

Besides the naturalistic works designed for the Temple, Meštrović made a large number of religious reliefs and figures in walnut, of which two Pietà reliefs, one in the National Gallery of British Art and one in private possession, are typical of his bold cutting and great powers of design. His portraits include those of his mother (1908), Madame Banac (1913 and 1915), his wife (1915), Sir Thomas Beecham (1915, in the National Gallery of British Art), Lady Cunard (1915) and Miss St. George (1915). Among his later works the most important are the richly decorated Račić Memorial Chapel at Cavtat, near Dubrovnik (Ragusa), Dalmatia (1920–2), the designs for the projected mausoleum of Bishop Petar Petrović Njegoš, the Montenegrin poet, to be erected on the summit of Mount Lovćen (1924), and figures of St. Francis of Assisi and "The Artist's Mother in Prayer" (1925). In 1924 exhibitions of his work were held at the Fine Art Society in London and the Brooklyn Museum.

See M. Curčin, *Ivan Meštrović, a Monograph*, with bibliography and list of works (1919). For details of the Račić Chapel, see *Deutsche Kunst und Dekoration*, LII. (1923).

METALLOGRAPHY (*see* 18.2b).—Metallography is the study of the internal structure of metals and alloys, and of its relation to their composition and their physical and mechanical properties. Beginning with the use of the microscope for the examination of polished and etched surfaces of metals by Sorby in 1864, the scope of metallography has been widened to include other methods for the examination of the internal constitution of solids, such as the measurement of changes of volume and of heat content, and of electrical resistance, magnetic quality or behaviour towards X-rays.

The properties of metals and alloys, like those of other solids, depend partly on their chemical composition and partly on the internal arrangement of their constituents. It is possible for two specimens of metal, taken from the same homogeneous mass and identical in chemical composition, to have widely differing properties if they have been subjected to different thermal or mechanical treatments. Since this important fact has become generally recognised, other methods of examination must supplement chemical analysis in the control of materials for engineering and similar purposes, and in recent years there has been a great development of metallographic methods, together with a greatly increased application of them in industry, so that the microscope has become as indispensable as the balance in metallurgical works, whilst dilatometers, magnetic and electrical measuring instruments, and accurate pyrometers are becoming more and more frequent items of the equipment of a laboratory for the control of materials by manufacturers or users.

Preparation of Specimens.—The improved microscopical technique of the present day, and the use of high magnifications, make it necessary to prepare the surfaces of specimens with a very perfect polish. Polishing by hand on fine emery papers is preferred to the use of a machine, except in the last stage, when a rotating disc covered with cloth is used, the finest polish being given by levigated magnesia, although for low magnifications alumina is quite satisfactory. Steels are best etched by a 4% solution of picric acid in alcohol to which a small quantity of nitric acid may be added to bring out the boundaries of the crystal grains. Stainless steel and other highly alloyed steels require special reagents. Many tables are now published giving the most suitable reagents for the etching of the commonly occurring metals and alloys. Much light has been thrown on questions of metallurgical importance by the use of high magnifications, and progress is being made in this direction. It is important to observe the conditions of accurate microscopy by making a suitable choice of objective and eyepiece for the work. Mere magnification without higher resolution gives no information of value. The internal structure of martensite in hardened steel is a severe test of the resolving power of a microscope, and has been studied in detail with some success. The inverted type of microscope, in which the specimen is placed with its polished face downwards on the stage, has many advantages in convenience and rapid working, and has become popular in metallographic laboratories, in spite of certain optical disadvantages due to the larger number of reflections.

Macroscopic Etching.—In another direction, the examination of etched specimens with little or no magnification has proved of great practical value. For this macroscopic etching the surface to be examined is roughly polished and then deeply etched, acid solutions of copper salts being mostly used for steels, the copper which is deposited at first being completely removed by washing. Segregation is revealed by differences of etching, a very distinct pattern being produced, which may be recorded by

photography or by the method employed long ago by Sorby in making "nature prints," and temporarily forgotten, of using the etched surface as a printing block, rubbing printer's ink into the depressions, and transferring to paper by pressure. Macroscopic etching has proved of value in the detection of defects in ingots and castings, and also in following out the treatment of a metal during such processes as forging, the direction of the flow during working being shown by the curving of the lines representing small differences in composition in the original mass. This method is employed in some works as a regular means of control in the forge.

Strain Etching.—In 1921 a method of etching was described by A. Fry, having as its object the detection of plastic strain in mild steel. The steel to be examined is polished, care being taken to avoid any distortion, and is then annealed for a short time at about 200°C., after which it is etched in an acid solution of cupric chloride. Clearly defined dark bands make their appearance where the crystals have been deformed, and much information as to the distribution of plastic movement is obtained from a study of the figures. Rather strangely, whilst some mild steels give well defined patterns with ease, others of almost identical composition give no result, and it has not been possible to trace any connection between the composition and the degree of success of the etching. The method has therefore so far a limited value, but it is almost certainly capable of further development. On a microscopic scale, the mechanism of deformation has been studied by many investigators. Metals and alloys vary greatly in the degree of apparent confusion in the crystalline structure produced by deformation. Cupro-nickel is remarkable for its property of undergoing severe cold-working and continuing to give perfectly sharp and definite structures when etched, and this alloy, together with pure aluminium and an alloy consisting of tin to which 1·5% of antimony has been added, have been largely used in the study of the cold-working of metals and of the microscopic changes which occur on subsequent annealing.

Plastic Deformations.—The nature of plastic deformation being of such great importance to the engineer, this part of the subject has attracted much attention. A mass of metal, such as a forging, consists of an immense number of crystalline grains, the axes of which are directed at random, so that for practical purposes the metal is commonly regarded as isotropic, the individual differences being lost in the aggregate. At the bounding surfaces of the grains there is a discontinuity of properties, the origin of which is a subject of controversy. The failure of metals by fatigue (*see* FATIGUE OF METALS) under rapidly alternating stresses, cannot be explained by any assumption of isotropic character, and it becomes necessary to take into account the stresses in the individual grains. The problem is simplified by the comparatively recent discovery of methods for the preparation of single metallic crystals of such large size that they may be tested in an ordinary testing machine, the microscopic and other changes being observed. Aluminium has been studied in detail in this way by Carpenter and Elam; tungsten (in the form of wire) by Goucher and zinc, tin and bismuth by Polanyi and Weissenberg. In these instances the direction of slip and its relation to the crystalline structure have been determined.

The influence of the crystal boundary is studied by using test pieces composed of two crystal grains, a boundary crossing the specimen. Beyond the fact that the boundary offers an obstacle to slip, little has yet been established in regard to this factor, although the hypothesis of a layer of amorphous material between the grains has been applied with great ingenuity and success by Rosenhain to explain many of the facts of deformation and also of chemical attack on metals. The low tensile strength of metals, as compared with the theoretical cohesion calculated by indirect means, has led to the suggestion by A. A. Griffith that all ordinary solids contain innumerable minute flaws, and this hypothesis has attracted the attention of mathematical physicists, who have applied it with some success. By special devices, vitreous silica and glass have been prepared in an unstable condition in which the strength is of the order of the theoretical cohesion, but this has not been attained with metals.

X-ray Analysis.—Some departments of metallography have been transformed by the introduction of the methods of X-ray (*see* X-RAYS) analysis. The use of X-rays for the penetration of large masses of metal for the detection of blowholes and other defects is obvious, and whilst useful in practice has no theoretical significance; but the refined methods of crystal analysis due to Laue and to Bragg are far-reaching in their effects. The arrangements of the atoms in a space lattice (*see* CRYSTALLOGRAPHY) and the absolute dimensions of that lattice have now been determined for most of the important metals, and many interesting results have been obtained, amongst others the fact, established by Westgren, that α and β iron below 900° C. and δ iron above 1,410° C. have the same space lattice, a body-centred cube, whilst γ iron between 900° C. and 1,410° C. has a face-centred cubic lattice, and this conclusion is in harmony with the physical properties of these modifications of iron. The same method provides an accurate determination of the direction of slip in single crystals during straining, whilst the examination of drawn wires and of rolled sheets has shown that there is a tilting of the space lattices of the individual crystal grains, leading to a more or less parallel direction of one of the crystal axes throughout, this "fibre structure" being similar to that which the X-rays also show to be present in natural fibres. Studies of this kind are throwing much light on the question of the mechanical strength of materials.

Thermal Analysis.—The methods of thermal analysis have undergone comparatively little change. To ensure a uniform rate of cooling, the specimen of metal may be suspended in a furnace in which a steady temperature gradient has been established by winding a metal tube with resistance wire suitably insulated, and making the windings closer at the upper part. The specimen is then lowered through the furnace at a uniform rate by a mechanical device. It has been shown that the specimen should have a spherical or pear-shaped form in order to obtain sharply defined points on the heating and cooling curves. Thermo-couples are almost invariably used for the measurement of temperature, although the platinum resistance thermometer, used in the early and extremely accurate work of Heycock and Neville, has great advantages. Japanese workers, investigating the alloys of iron, have made much use of magnetic determinations as a means of fixing temperatures of transformation, the curves having much the same form as those derived from thermal observations; whilst other investigators have used the changes in electrical resistance with temperature for the same purpose. Several types of dilatometer have also been devised, in which the changes of length of a rod of the metal or alloy during heating and cooling are measured directly or by comparison with a standard or with a rod of vitreous silica with negligible expansion. Where the change of length is indicated by the tilting of a mirror, this method is susceptible of very great accuracy. It has proved of value in the study of hardened steels, and is now making its way from the research laboratory into technical practice.

Practical Applications.—The higher standards of strength and endurance demanded of metallurgical products by the modern motor and aeroplane industries (*see* AERO-ENGINES) and by such other branches of engineering as the manufacture of steam turbines (*q.v.*), have been responsible for the interest now being taken by engineers as well as by metallurgists in the study of metallography. Alloy steels, and many of the higher qualities of plain carbon steels and of non-ferrous alloys, have to be "heat-treated" to develop their maximum toughness or other desirable properties. To determine whether the treatment has been a correct one the methods of the metallographic laboratory must be applied. Moreover, the engineer is concerned with such problems as that of fatigue (*see* FATIGUE OF METALS), and with the general nature of mechanical deformation beyond the limits to which the theory of elasticity is applicable.

The methods devised for the study of metallic alloys have proved to be of value in the scientific examination of other solids. Whilst the original idea of the examination of metals by means of the microscope occurred to Sorby in consequence of his earlier

introduction of microscopical petrography, the technique of metallography has been applied to opaque minerals, and has made possible the detailed study of mineral veins and ore deposits. The work of the Geophysical Laboratory at Washington on the equilibrium in rock magmas (*see* PETROLOGY), with its methods of accurate measurement at high temperatures, is also based to a great extent on experience gained in the study of metallic systems.

BIBLIOGRAPHY.—The most comprehensive treatise is that of W. Guertler, *Metallographie*, Berlin, in course of publication since 1909, and extending to many volumes. Other text-books are: L. Guillet and A. Portevin, *An Introduction to the Study of Metallography and Macrography* (Eng. trans., 1922); E. Heyn, *Physical Metallography* (Eng. trans., 1925); G. Tammann, *A Text-book of Metallography* (Eng. trans., New York, 1925); C. H. Desch, *Metallography* (1922). On plastic deformation, Z. Jeffries and R. S. Archer, *The Science of Metals* (New York, 1924); G. Sachs, *Grundbegriffe der mechanischen Technologie der Metalle* (Leipzig, 1925); G. T. Beilby, *Aggregation and Flow of Solids* (1921). Wyckoff, *The Structure of Crystals* (New York, 1924); whilst papers on metallography are to be found in many journals. The principal sources are the *Journal of the Iron and Steel Institute*, *Journal of the Institute of Metals*, *Zeitschrift für Metallkunde*, and *Revue de Métallurgie*, all of which include abstracts and bibliographies as well as original communications. *The Mitteilungen aus dem Kaiser-Wilhelm Institut für Eisenforschung* contain many important papers. For the practical applications see also the *Transactions of the American Society for Steel Treating*. (C. H. D.)

METALLURGY (*see* 18.203).—Progress in metallurgy after 1911 was profoundly affected by the World War. Modern warfare is so entirely dependent upon the products of metallurgy that the effort to secure military victory to some extent resolved itself into a struggle for supremacy in metallurgical output, in regard to steel products such as guns and shells, ship-plates and armour, etc., to copper and its alloys, to zinc, to lead and antimony, and, in a special degree, to aluminium.

During the war period, therefore, the progress of metallurgy became mainly a relentless struggle for output in which, in some directions, quality was sacrificed and heavy "war risks" were cheerfully taken. After the termination of the War, industrial conditions became extremely unsettled and difficult; the shortage of ships was followed by acute industrial disturbances, particularly in England. The Continental nations only slowly resumed their normal activities, and were gravely hindered on all sides by the direct and indirect economic consequences of the Treaty of Versailles. As the result of continued political and financial uncertainty, recovery in the metallurgical industries remained slow, except perhaps in Belgium, until 1925. Towards the end of that year, following the improved atmosphere resulting from the Locarno Pact, signs of improvement began to set in. Meanwhile, however, the metallurgical industries of America experienced a period of special prosperity, and the relative rate of development in metallurgical practice in the Eastern and Western hemispheres must be in part ascribed to these factors.

DIVISIONS OF THE SUBJECT

The whole period under review thus falls into three main divisions: Prior to 1914, the War period and the post-War period. The influence of the War has left important traces in certain directions but the line of development appears to be tending towards a simple continuation of pre-War lines. Thus, very great efforts in England and in certain of the British Dominions to render those countries metallurgically self-supporting were made either as the result of direct governmental encouragement and support or on account of the abnormally high prices ruling for some of the metals. This led to the development of properties and processes which were, under more normal conditions, uneconomical, and these—with governmental support unavoidably withdrawn and prices at a less abnormal level, have necessarily been abandoned. An important exception is the great development in the zinc industry in Great Britain and Australia, in which, thanks to real metallurgical advances, permanent economic success has been achieved.

In a totally different direction, however, war conditions led to a relaxation of the severity of specifications, particularly for steel products.

After the War, steel makers claimed that their difficulties were almost as great as ever. It was suggested that the relaxed specifications had led to no disastrous results and that, therefore, they might be safely continued. The British Engineering Standards Association adopted a compromise course and, while rejecting the extreme relaxations accepted under War conditions, also refrained from a return to full pre-War severity. It has resulted that "War time products" are looked upon with grave suspicion. A steady tendency towards increasing stringency in specifications, particularly in the direction of higher requirements as to the purity of metals and alloys, is now (1926) making itself felt. A similar tendency appears to exist also in America, but the methods of applying specifications and tests in that country are so widely different from those adopted in England that direct comparison is liable to be misleading.

Another effect of the War, and of the subsequent strong movement towards disarmament, has been the need for industrial rearrangements and reconstructions on a large scale. At the end of 1918, the metallurgical and allied industries were entirely devoted to armament and munitions and had then to find different outlets for their activities. The engineering reconstruction work required in the devastated regions of Europe proved no adequate outlet and in many cases, particularly in England, great works had to close down. In America, with an enormous home market the conversion of armament and munition works to peaceful output was carried through successfully on a large scale. Consequently, the industrial "slump" in that country was comparatively slight and brief.

I. IRON AND STEEL

Prior to 1914 iron and steel metallurgy showed a tendency towards the development of very large plants and larger individual units, both in regard to furnaces and rolling-mills. The tendency towards increased size made itself felt in the blast furnace, particularly in American practice; progress, however, also included development in the direction of furnaces with walls and external water-cooling, such furnaces being driven very hard.

Pre-War Progress.—In the period prior to 1914, considerable attention was given to drying the blast, and it seemed at one time that this would become universal practice. Under war conditions this development was checked, at all events in England, and has not been resumed since 1918.

Increased attention has, however, been given to the utilisation and cleaning of blast furnace gases. This became particularly important in England during the War on account of the shortage of potash, a substantial recovery of this material being obtainable from the flue-gases of furnaces in which the charge included potash-felspar. At the same time satisfactory cleaning of the gas very much increases its efficiency in stoves and under boilers, owing to the absence of fouling with dust. On the other hand, a degree of cleaning which will render the gas fit for direct use in gas-engines is a much more expensive matter, and not so obviously economical. The cleaning processes adopted are mainly of two kinds; one of these depends upon the electrostatic deposition of the dust by the method first suggested by Lodge and developed in America by Cottrell (*see* FUME PRECIPITATION). The other method depends upon filtration of the gas through fabric bags which are kept in a state of agitation, as in the Halberg-Beth system. Although, under normal conditions, potash recovered from flue-dust could not compete with the product of Continental mines, yet cleaning of blast-furnace gas will be continued. The dust itself may be utilised for the recovery of iron contained in it, by briqueting the dust by a modification of the Schumacher process, in which a weak solution of ferrous sulphate is used as binder. A further proposal is to concentrate the iron-content by some adaptation of the flotation process.

The application of flotation processes (see below) to finely divided iron-ores had not been found necessary or practicable up to 1926, but methods dealing with finely divided ores (both ferrous and non-ferrous) have been considerably developed. In addition to the Schumacher process already mentioned, reference must be made to the Dwight-Lloyd process, in which the ore is mixed with a small proportion of finely divided carbon and pressed into briquettes which are then heated to a moderate temperature. A partial reduction of the ore takes place, leading to a sintering of the briquette which thus acquires the necessary strength.

In the production of steel, the open-hearth furnace has made very great progress and appears likely to displace the Bessemer converter, although the latter seems to be holding its own to a certain extent. The steady increase in the application of basic open-hearth steel tends to give the large open-hearth furnace, particularly when working one of the continuous processes, a very great advantage.

War Period.—In the first place it became necessary, particularly in England, to make use of ores and other materials very different from those for which particular furnace plants had been designed, while the supply of operative labour became very difficult. In consequence of these and other difficulties, relaxation of quality, already mentioned above, became inevitable, particularly in regard to those grades of steel which were required in very large quantities.

Apart from the demand for enormous supplies of steels of ordinary grades, War conditions also caused great demands for

steels of the highest quality for special purposes. The production of guns was one of these, and much difficulty was encountered both in England and America with defects—known as "snow flakes" or "gun measles"—occurring particularly in nickel-chrome steels. Reversion to the use of a simple nickel-steel for such purposes followed, but this entailed a serious disadvantage, if only on account of the greater difficulty experienced in securing satisfactory heat-treatment. This difficulty was also encountered in connection with the gearing used for the propelling machinery of turbine-driven ships. High-quality steels, mainly alloy steels, were also required in relatively very large quantities for purposes of air-craft construction, principally for the working parts of aero-engines. This demand led to a great development in the production and treatment of alloy steels.

Here, and generally in the production of the better grades of steel, the electric furnace played a remarkable part. A large number of furnaces, mostly of the arc-resistance type, were installed, particularly in Sheffield. Their value lay in the super-refining of steel, sometimes produced in a basic open-hearth furnace, sometimes obtained by the direct remelting of alloy-steel scrap. Probably the power of the electric steel furnace to deal satisfactorily with such scrap, even when in the form of workshop swarf, constituted its greatest value during the War. Since the end of the War, however, the demand for such steel has almost disappeared, with the result that the greater number of the electric furnaces, both in England and America, became idle. None the less, there must be, in the future, a definite use for a certain number of electric furnaces in steel metallurgy.

Alloy Steels.—In regard to alloy steels, while nickel-chrome and nickel steels have found by far the widest application, particularly for war purposes, other alloy steels have also assumed importance.

Nickel-chrome steel in particular, in addition to the difficulties already mentioned, has been found to be subject to a defect known as "temper brittleness." Alloy steels, in order to assume their most desirable physical condition, require specific heat-treatment, which, as a rule, consists of quenching in oil, or more rarely in water, from a temperature above the critical range of the steel, followed by "tempering" or reheating to a temperature considerably below the critical range. In the majority of steels, the rate of cooling subsequent to tempering is of little importance, but in a certain number of nickel-chrome steels slow cooling after tempering leads to a form of brittleness which is entirely removed if the steel is cooled very rapidly (quenched) after tempering. The cause of temper-brittleness has received much investigation, and the results indicate that it is due to a change or "transformation" which occurs in the steel at or near 300° C.; it appears to be favoured by certain impurities, notably phosphorus.

Further, acute controversy has arisen as to the importance or otherwise of such "temper brittleness" on the ground that it can only be detected by a particular form of test—the "notched bar impact test." Hatfield has repeatedly suggested that this test measures a property of no practical importance, and that therefore temper brittleness is only "apparent" and not "real." This view, however, has not been generally accepted, since a number of investigators (Rosenhain, Greaves and others) have found a very distinct correlation between a low value under the notched bar impact test and cases of actual failure in service.

Chromium Steels.—For certain purposes, where simple nickel steels are not found adequate, a chrome-vanadium steel has been extensively used. The fact that vanadium plays a really important rôle in such steels has come to be recognised, but there are still difficulties in its metallurgical applications. For quite a different range of purposes a steel containing relatively large amounts of chromium (about 13%, Brearley) has found wide applications. Its best-known application is to the production of "stainless" cutlery, which has proved extremely successful in practice, and in spite of the relatively high cost has come into extensive use as a labour-saving device (*see* RUSTLESS STEEL). Some difficulty was at first experienced in hardening this material satisfactorily; it requires a higher quenching temperature than cutlery-hardeners have been accustomed to employ (Hatfield), and, as a consequence, the earlier products were insufficiently hardened, and gave rise to the complaint that such cutlery would not keep its edge. Later practice has overcome this defect, although the fact still remains that "stainless" knives, not being automatically sharpened by daily polishing, require careful sharpening from time to time.

New applications of this steel to other purposes where resistance to corrosion is important are being found almost daily. Incidentally, it was found that this steel is capable of resisting the severe conditions which occur in the service of an exhaust-valve in aeroplane engines, although a high-tungsten steel (18% tungsten) has been found to be slightly better. More recently, special alloy steels for use at high temperatures have been developed both in England and in Germany. These contain considerable proportions of both nickel and chromium, while in some cases tungsten is also present. Unlike the simple chromium steels, these new materials retain a considerable degree of strength at temperatures well above 700° C., particularly if tested in tension at ordinary rates of loading. Testing under prolonged loading—known as "creep stress testing"—has, however, been developed to furnish more reliable data where material is exposed to continued load at high temperatures, and it is as yet difficult to find any material which shows a higher "creep stress" than two tons per sq. in. at 800° Centigrade. This figure is attained both by some of the steels just mentioned and by a non-ferrous nickel-chromium alloy (80% nickel, 20% chromium). This whole subject is attracting much attention in view of the tendency towards the use of higher temperatures and pressures in both steam and internal combustion engines.

While the simple chromium steels of the "stainless" type still hold the field for cutlery and similar purposes where hardness is essential, their powers of resisting corrosion have been surpassed to a surprising degree by the recently developed alloy steels containing considerable proportions of both nickel and chromium, with, however, very little carbon. These are "austenitic" steels, *i.e.*, they consist mainly of what is known as "gamma" iron, are non-magnetic and very tough and ductile. They cannot, however, be hardened by quenching, although they frequently exhibit a tendency to harden very markedly under the action of cold working. The manganese steel of Sir Robert Hadfield, which proved so valuable as a material for shrapnel-proof helmets during the War, is an extreme example of this kind, as this steel becomes intensely hard when subjected to cold working, even if this only takes the form of surface abrasion. The high nickel-chromium steels do not harden to anything like the same extent, but sufficiently so to make them difficult to machine.

Like manganese steel in the quenched or "toughened" condition, they are non-magnetic, but their outstanding feature is resistance to corrosion. The best of them remain unaffected by most liquids, including sea-water, solutions of magnesium chloride and even strong nitric acid. Strong hydrochloric acid alone attacks them. These remarkable materials have only recently (1925) become commercially available, but their application is already developing rapidly. Their good physical properties, combining high strength and great ductility, make them desirable materials for many kinds of structural work, but applications on the very large scale are still hindered by their relatively high cost.

High-speed Steels.—In the metallurgical progress of the period under review, the development of high-speed cutting steels occupied an important place, their possibilities having been steadily exploited to an increasing extent, their development being naturally accompanied by an evolution of machine-tools capable of utilising the high cutting powers of the new steels. Under war conditions the great demand for tool-steels of this kind created a relatively enormous demand for tungsten, and considerable developments in the mining and production of tungsten took place. Efforts to replace tungsten by other metals were also made, and very great claims were advanced for a high-speed steel in which molybdenum in combination with vanadium was used in place of tungsten (Arnold). The action of cutting tools has received careful study by a number of investigators, largely under the auspices of the Cutting Tools Research Committee of the Institution of Mechanical Engineers.

In connection with high-speed steels, mention may here be made of a type of alloy which has been used, with considerable success, in place of such steel. This, known as "stellite," consists, according to a reliable analysis, mainly of cobalt 56%, chromium 34%, tungsten 9%, carbon 1%. Tests with this material have shown that it is capable of cutting rather faster than the best tungsten steel, provided that the cut is smooth and regular, but that for roughing cuts, where the tool is subjected to sudden shocks and jars, the alloy is unsuited, as it is too brittle and the tool frequently breaks off.

These alloys, originating in America, have received much attention and development in Germany. In England the hardness and incorrodibility of these alloys has led to their use as a substitute for platinum for such purposes as standard weights.

Cobalt Steel.—The great development of cobalt production at Sudbury in Canada has made this metal available and has attracted interest to its possible uses. A high-speed tool-steel, containing cobalt has been produced in Sheffield, which has been successful in general use and has the remarkable property that it does not undergo distortion during hardening. Great difficulty existed under war conditions in the production of accurate parts —such as those of shells and fuses—which were required to be strictly interchangeable. This difficulty extended back to the gauges and master-gauges used for the checking of such parts and ultimately in many cases to the cutting-tools used in their production. In other cases, the steel of which the gauges themselves were made gave much trouble owing to distortion during hardening, requiring considerable adjustment by " lapping " of the hardened article.

A cobalt steel has also become important for permanent magnets. Made in the first place of hardened carbon steels, the requirements particularly for the magnetos used for ignition purposes in aircraft engines led to the use of special steels containing about 6% of tungsten. A Japanese invention, based upon extensive researches carried out in that country (Hondo), has produced a cobalt magnet steel which, in its best examples, gives surprising results, combining an exceptionally high coercive force with a relatively large remanence. By the use of this steel a much smaller and lighter magnet suffices for a magneto of given power. The steel is expensive, and when supplied in quantity appears to vary in quality, while there is also some difficulty in its workshop manipulation.

Case Hardening.—Processes for the surface hardening of tough steel have come into increasing use, and methods for securing full hardness of the case, with a tough core and good gradation between the two, have been developed. More recently a method of surface hardening has been worked out in Germany (Krupp) which entirely avoids the necessity for quenching and its attendant distortion. A special steel, containing both chromium and aluminium, is employed, and the surface is hardened by the formation of a layer of intensely hard nitride, produced by prolonged heating at about 500° C. in a gas consisting mainly of ammonia.

Welding.—One of the most remarkable developments (metallurgical in the wider sense) during the period under review has been that of autogenous welding, (*q.v.*) both by the oxyacetylene flame and by the electric arc.

Both these processes afford a relatively cheap and simple means of making joints in metal, particularly in iron and steel, and as the joint consists of " the same metal " as that which is being joined there is a specious suggestion that the joint is " perfect " in the sense of being as good as the unjointed material.

Although it is quite possible to obtain welded test-pieces which break, under a tensile test, away from the actual joint, the joint itself can never be regarded as equal in strength and toughness to the unjointed steel. The reasons are that the material in the weld itself has solidified from fusion and is at best equal in properties to the same steel in the cast condition, while the rest of the plate itself has been immensely improved in quality by forging and rolling and possibly by heat-treatment. Further, adjacent to every such weld there is a region of steel which has either been severely overheated or —a little farther away—which has been heated to a temperature just below the critical range. In both these regions the steel is seriously weakened, and it is in the latter that test-pieces generally break.

The most serious difficulty, however, is that of being sure that any autogenous weld is truly sound. Examination of many welds has shown that complete soundness is difficult to secure, and that it is the exception rather than the rule, even in careful practice. Also, it is not possible to ascertain by any external examination of a weld whether it is sound or not. Examination by the aid of a powerful X-ray installation can sometimes be employed to assure the soundness of an important weld, but as a rule this is not feasible. It would seem, therefore, that there is grave doubt whether welded joints can be relied upon to carry severe working stresses or whether they should be employed in vital parts unless an exceptionally heavy factor of safety can be allowed.

Experience in aeroplane construction supports these doubts, and a construction in which steel tubes are joined together by pinned and soft-soldered joints has been found more reliable than autogenous welding, provided that the working stress on the solder is kept to a low value. On the other hand, the welding processes afford a ready means of making joints and effecting repairs where no other process could be used, and under war conditions particularly rapid repairs were frequently executed with great success. At the same time, welded joints should not be compared with the unjointed material but rather with joints made in other ways, such as riveting; and there the comparison is much more favourable except for the serious element of uncertainty. The application of welding, and particularly of electric arc welding, to such purposes as ship construction, has, however, found considerable acceptance.

Cast Iron.—This metal has received much attention, both on the practical and the research sides. In Germany this is strongly indicated by numerous patents and scientific papers and in Great Britain by the formation and growth of the Cast Iron Research Association. One of the most striking developments is that of so-called " Pearlite " iron, in which the rate of solidification is adjusted, by suitable preheating of the sand moulds, to the thickness of the casting and the silicon content in such a way as to secure desirable (pearlitic) microstructure and specially good physical properties. Special furnaces suitable for the production of cast irons low in total carbon, or specially desulphurised, have also been developed.

In America the production of malleable castings on a large scale has progressed, with the introduction of electric furnace melting for the iron and malleable-annealing in continuous furnaces of the tunnel-kiln type. The casting of grey iron castings in permanent metal moulds has also been developed, the chilling effect of the iron mould being avoided by the interposition of a hard layer of relatively non-conducting refractory material. The exposure of cast-iron to increasingly high temperatures has revived the problem of the " growth " of this metal, particularly on repeated heating and under the influence of superheated steam. The view that growth is essentially due to oxidation occurring in the graphitic pores of the iron is still held, but it is recognised that this action is not solely due to silicon and that it may be as much dependent upon the treatment of the iron and its consequent structure as upon its chemical composition.

II. NON-FERROUS METALS

Flotation Process.—The outstanding feature in the progress of non-ferrous metallurgy is summed up in the one word " flotation." Published scientific research (Langmuir, Sulman and Picard, Edser) has gone far towards the explanation of this process which has made enormous progress and has revolutionised the practice of the extraction of many non-ferrous metals, particularly those occurring in the form of sulphide minerals, such as galena, zinc-blende and the various pyritic copper ores. Its effects have been direct in superseding most gravitational methods of separation, and indirect in view of the fact that flotation deals primarily with very finely divided material, including the " slimes " which were the greatest difficulty of the pre-flotation metallurgist. Not only has this affected ore-grinding and handling practice, but it has brought about a great change in smelting practice also. Thus the treatment of copper concentrates is being carried out to a rapidly increasing extent in the reverberatory furnace to the steady exclusion of the blast furnace.

The Principles of the Process.—The principles of flotation do not appear to be entirely understood, as there is considerable divergence of opinion whether flotation phenomena are the result of purely " surface tension " forces or whether electrical forces play the most important part. The operations involved are, however, sufficiently clearly defined and consist essentially of three steps which may overlap or merge into one another. The first of these may be described as the " oiling " process, which consists in adding to the pulp or mixture of finely ground ore and water some " oiling " reagent. This may be either an essential oil or one of a great range of chemical substances, generally organic in character. Only a very small amount of such a reagent is used, since the addition of larger quantities produces entirely different effects due to the formation of oil films of appreciable thickness.

The minute amount of oil reagent, on the other hand, appears to produce some change on the surfaces of certain minerals having a metallic or semi-metallic character—zinc-blende being a typical example—which makes them less readily " wetted " by the liquor of the pulp, or, put in another way, increases the angle of contact

between these surfaces and the liquid. The gangue of the ore is less affected or not at all affected by the oiling reagent, but in many cases it is necessary artificially to increase the difference between mineral and gangue by the addition of some "gangue modifying reagent" which renders the gangue more readily wetted by the aqueous liquid of the pulp. These "gangue modifiers" are as a rule alkalis or mineral acids.

The third step in the process consists in adding to the pulp some substance which causes the ready production of a stiff and lasting froth when air is introduced, either by agitation or by blowing or drawing it through the liquid in a finely divided state. Very frequently the "oiling reagent" also serves as the froth-producer. When the pulp thus prepared is treated so as to produce a froth, the oiled mineral particles adhere to the air-bubbles very firmly, the mineral-air surfaces evidently being the seat of less potential energy than the mineral-water surfaces and consequently the buoyancy of the combined bubble with its mineral burden causes it to float to the surface, where it accumulates as a very stiff mineralised froth which can be mechanically separated in various ways. A further action appears to take place, which is related to the flocculation of the mineral particles by the oil emulsion in contact with air-bubbles. This results in the attachment to each bubble of the finest mineral particles in large and heavy agglomerations, thus greatly increasing the efficiency of the whole process.

The flotation process has found its largest application in the concentration of various types of sulphide ores, and, on this ground alone, has attained very great industrial and technical importance. Its application to other minerals has, however, been actively pursued and in a great many cases with considerable success. Minerals having a more or less metallic character are particularly suited for flotation, so that native metals constitute an obviously promising application. For the treatment of finely divided gold-bearing ores the older cyaniding processes in their modern forms continue to hold their own, but a few large mines have adopted flotation. In some cases, where graphite has interfered with cyaniding, a little agitation with oil is serviceable in rendering the graphite harmless.

Application to minerals of the oxidised type is less simple, and here it seems to be necessary, in many cases, to submit the ore to a previous "activating" treatment. Considerable success in the treatment of ores of this kind has been attained by the use of sodium xanthate as a flotation reagent. Preliminary roasting in a reducing atmosphere in the hope of producing a more or less metallic surface coating upon the ore particles has been tried, while "sulphidising" by exposing the finely ground ore to the action of hydrogen, ammonium or organic sulphide has also been used with great effect in some cases. Another problem is that of "differential flotation" for the purpose of separating different metalliferous minerals in a complex ore, such as the separation of zinc-blende or sphalerite from galena. In a certain number of cases, oiling reagents have been found which act differentially upon different flotable minerals, but every particular case still requires extensive research which does not always lead to a satisfactory industrial solution.

Smelting.—Beyond its immensely important direct effects in rendering possible the economic concentration of a number of ores and in cheapening the concentration of others, the development of flotation has also profoundly affected smelting practice, since the product of flotation, being very finely divided, differs widely from the product of gravity concentration. The concomitant progress of the reverberatory furnace has been accompanied by the development of the use of powdered coal as fuel, which has attained very wide extension.

Extremely finely divided coal is blown or otherwise forced into the combustion-space of the furnace, where it burns with a flame very similar to that of a jet of gas. The obvious advantages of such a system are that the loss of heat involved in the gasification of coal in producers is saved, together with the labour and the technical difficulties involved, while most of the advantages of gas-firing can also be secured by burning powdered coal. As against this must be set the cost of grinding the coal sufficiently fine and of injecting it into the furnace, while disadvantages also attach to the fact that the ash of the coal is introduced into the furnace and thence into flues, regenerators, etc. The question of the manner in which the coal is to be powdered and conveyed into the furnace receives rather different treatment in different forms of the process, but it is coming to be recognised that extremely fine grinding is advantageous, and in one process the coal is made into an "emulsion" of coal-dust and air which is said to flow and to be capable of being pumped like a dense liquid. The coal particles appear to become coated with a closely adherent (probably "absorbed") layer of air, and as soon as the temperature becomes high enough very rapid combustion takes place.

The use of coal-air mixtures or "emulsions," however, implies the introduction into the furnace of a relatively large amount of cold air, and this materially affects the question of regeneration or recuperation of the heat of the waste gases of the furnace. This is also affected by the presence of the fine ash-dust which tends to clog or even to flux the tubes or chequer-work. In some furnaces, where an extremely high temperature is not required, the problem can be solved by dispensing with regeneration or recuperation entirely and utilising the heat of the waste gases for raising steam, etc. Another point to be borne in mind is that a suspension of coal-dust in air may be a powerful explosive and must be treated with the care due to such substances. The use of oil fuel for firing metallurgical furnaces has also assumed large dimensions, and rivals the extension of powdered coal firing. It possesses many advantages in regard to the points just discussed, so that the relative merit of the two processes becomes mainly a question of cost.

In the methods for the extraction of non-ferrous metals, during the period under review, there has also been an important development in an entirely different direction. This is the great advance in hydrometallurgical processes, such as direct leaching and electrolytic treatment of ores. The elimination of the German zinc smelters during the War, so far as supplies of zinc ores from the British Empire and the Allied countries were concerned, undoubtedly supplied a stimulus to this development, which has been particularly marked in connection with the extraction of zinc from its ores. The treatment of many other ores has also come within reach of "wet way" methods, and these promise to play a large part in metallurgical extraction.

III. COPPER

The effect of flotation, powdered-coal firing and the advance of hydrometallurgical methods on the metallurgy of copper have already been referred to, but mention may be made of the leaching of alkaline ores with solutions of ammonia and ammonium carbonate which has been developed at the Calumet and Hecla mines. Leaching methods are employed by the largest individual producer of copper—in the Belgian Congo. In regard to the metal itself, there is an increasing tendency for the exclusive employment of electrolytic copper. In part, this arises from the increased supplies of this quality of metal, but more from the increasing demand for high purity. "Best selected" and "tough" (arsenical) copper are still in demand for some purposes, particularly for locomotive fireboxes and stays. The value of the arsenic has been found to lie in a certain neutralisation of the effects of oxygen; where more complete deoxidation is possible the value of arsenic is more doubtful.

With regard to finished copper, much attention has been paid to certain anomalies which occur during severe cold-working, such as wire-drawing, while the effect of heating the metal in a reducing atmosphere has also been further studied. A particularly interesting case of failure in copper when heated in a bath of fused sodium chloride has been studied by the Bureau of Standards at Washington. This material became brittle and broke with a typical inter-crystalline fracture. It was shown that this arose from an electrolytic effect produced by the contact of the copper with the iron containing-vessel in the presence of the fused electrolyte (Rawdon). Metallic sodium is formed in contact with the copper and appears to penetrate between the crystals of the metal. A case has also been described where molten solder (lead-tin) acted in a similar manner when in contact with a particular kind of brass, the so-called "manganese bronze" (Dickenson).

Copper Alloys.—With regard to copper alloys, some progress has been made in the difficult question of nomenclature. A committee appointed by the Institute of Metals has issued a nomenclature report which defines the old terms "brass" and "bronze." The former is defined as any alloy of copper with zinc containing more than 50% of copper; if other elements besides zinc and copper are present, they are to be named as a prefix to the term "brass." Thus an alloy containing 2% tin, 28% zinc and remainder copper would be termed a "tin brass." Bronze on the other hand is defined as implying an alloy of copper with tin, containing more than 50% of copper, with the same convention in regard to additional elements. Thus an alloy containing 10% tin, 2% zinc, and remainder copper would be called a zinc bronze. An attempt is also made to systematise nomenclature of more complex alloys. So far as brass and bronze are concerned, these two terms are now rarely used except within the definitions named.

An immense amount of experiment and research has been devoted to copper alloys. A considerable number of special alloys are now known, each possessing valuable properties. The aluminium manganese copper alloys have been very fully described in the ninth

report to the Alloys Research Committee of the Institution of Mechanical Engineers; these include alloys capable of attaining tensile strengths as high as 52 tons per square inch. Other copper aluminium alloys—known as aluminium bronzes—with or without the addition of iron, have found considerable industrial application in America, mainly as forgings, sometimes of considerable size. In Great Britain small die-castings of such alloys are used for parts of electrical switch-gear. Other alloys of special strength have been launched under various proprietary names.

For war purposes a most important part was played by the cupro-nickel alloys, containing either 15 or 20% of nickel, remainder copper. The production of this alloy on the very large scale required for the war revealed difficulties arising mainly from casting-defects in the slabs used for rolling. The remarkable power of this material to undergo severe cold-working, without becoming excessively brittle, suggests that it is likely to have other useful applications beside bullet envelopes, but for industrial purposes these alloys have not been widely exploited. On the other hand, the much more expensive Monel metal has been widely pushed and has found considerable practical application, mainly on account of its valuable combination of great strength with great resistance to corrosion. This alloy is manufactured "direct" by the reduction of ores from the Sudbury district in Canada, and special virtue is claimed on the ground that it is a "natural" alloy and has not been melted together in the foundry. It has been shown that such a claim cannot be substantiated.

Corrosion.—In connection mainly with copper alloys, a large amount of study has been devoted to corrosion, under the auspices of the Corrosion Research Committee of the Institute of Metals. The results have been embodied in a series of extensive reports, and serve to throw new light on the corrosion, particularly, of marine condenser tubes. This is ascribed, essentially, to the formation on the surfaces of the tubes of an adherent, but by no means impervious, deposit of basic salts. By restricting the circulation of water in contact with the metal under these deposits, they lead to the formation of solutions containing a fairly high concentration of cupric chloride, and such a solution rapidly attacks brass, with the resulting formation of pits and ultimately of holes. It is considered that the brass as a whole is dissolved under these deposits, but that in certain conditions the copper is redeposited as a spongy mass, thus leading to the apparent "dezincification" of the brass at such points. The problem is there to prevent such adherent deposits.

The production of protective coatings on metals as a means of preventing corrosion has received much attention, the use both of cadmium and of chromium plating for this purpose having been developed. Cadmium plating is used chiefly for the protection of aluminium, but chromium is applicable alike to steel, copper, brass and other metals. The deposition takes place from an electrolyte of chromic acid and requires a high current density. The deposit is bright, has a bluish white lustre and remains untarnished in the air and in many vapours. Owing to its great hardness as well as its chemical inertness, chromium plating is much superior to nickel or silver plating. The finish, however, is not yet quite as good.

The theoretical aspect of corrosion has also received much attention, and special research on this subject has been initiated. Already, however, a new theory of electrochemical corrosion has succeeded in uniting the views of those formerly advocating divergent views (Bengough, Evans, Bancroft). The scope of the researches undertaken by the above-mentioned committee has been extended to include fresh-water (land) condenser plant, and a special sub-committee has been formed to study the whole question of the corrosion of aluminium alloys, while a parallel investigation into atmospheric corrosion has been undertaken by the Non-ferrous Metals Research Association.

In regard to the corrosion of aluminium alloys and its prevention, important progress has been made by the development of the "anodic oxidation" process. The metal is suspended as anode in an electrolyte and rapidly becomes covered with an oxide or hydroxide coating which stops the passage of the electric current. This coating is strong and flexible and serves as an excellent protection against corrosion, the protective effect being further enhanced by allowing the surface to absorb a coating of lanoline. The treated metal and alloys resist both fresh and salt water and a salt spray. The coating can be applied to alloys of aluminium so long as they do not contain much more than 4% of copper.

IV. PLATINUM, ZINC, ALUMINIUM, ETC.

Platinum.—The metallurgy of the noble metals has not undergone any striking development during the period under review either in regard to extraction or uses.

The cyaniding process has undergone a series of more or less minor improvements, and it was at one time thought that aluminium dust would replace zinc-dust as the precipitant for pregnant solutions. Zinc-dust, however, still predominates, and the same remark applies to the proposed method of precipitating the metal electrolytically. In regard to platinum, there has been an ever-increasing scarcity, enhanced by the complete upheaval in Russia. The Russian supply, however, is potentially the largest in the world, and production has slowly increased. Some new discoveries of platinum have been made in the Waterberg and Lydenberg districts in South Africa. Here some 60% of the metal is too fine to be caught on corduroy strakes, and some other method, such as flotation or smelting with lead, will ultimately have to be used. Another source of platinum whose importance tends to increase is the refining residue of copper and nickel.

The great rise in the price of platinum has led to the study of possible substitutes, and a number of such materials have been put forward. Thus for the "breaks" used in the magnetos of internal combustion engines, tungsten sparking points have been substituted for platinum. For chemical purposes various alloys, some containing gold and palladium, have been tried, but only with partial success, since none of them really possess the combination of properties—chemical resistance and very high melting point—which renders platinum so valuable. A number of special alloys, in which tungsten and chromium generally play an important part, also exhibit great chemical resistance, but in these cases the hardness and brittleness of the material are generally a serious difficulty. For use in chemical work on a large scale, however, a considerable number of alloys have been produced which attain a fair measure of success. Silicon itself has many advantages for some of these purposes, but in the impure form, generally met with, it is relatively weak and brittle. Platinum itself has been prepared of much higher purity than was formerly attainable, owing to contamination by calcium derived from the lime crucibles in which it was melted.

Zinc.—The metallurgy of zinc received much attention during the War. Reference has been made above to the general questions relating to zinc extraction, but mention may be made here of the growth of the enormous electrolyte plant at Risdon, near Hobart, Tasmania, where 33,000 H.P. are employed in dealing with the products of the Australian smelters, producing zinc 99·95% pure, as well as over 150 tons yearly of cadmium. There has also been great development at the United States centre at Picher, Oklahoma. Efforts are being made in Norway and Germany to obtain high recoveries of zinc from lowgrade and complex ores by electro-thermic smelting with a silicide reducing agent.

On the Allied side during the War there was at one time considerable shortage of zinc, and substitute alloys were studied for all purposes which should avoid the use of zinc. The shortage then disappeared, and at a later stage alloys consisting mainly of zinc were tried as substitutes for brass and for certain aluminium alloys. Some of these zinc alloys proved to possess remarkable properties, tensile strength exceeding 20 tons per sq. in. being obtained in cast alloys containing about 3% of copper and 7% of aluminium, remainder zinc. It was further found that these alloys could be extruded and, under certain conditions, rolled. Unfortunately, alloys of this type, when they contain both aluminium and copper, are unstable and undergo serious changes of volume, accompanied by great loss of strength, even at the ordinary temperature if kept for any considerable time.

On the German side, while there was never any shortage of zinc, this metal and its alloys were extensively employed as substitutes for other metals. Pure zinc was widely used in place of copper for electrical purposes, while zinc alloys with copper and aluminium were also largely used. Apparently, cases of failure due to the instability of these materials passed unnoticed under the stress of war; at all events, German metallurgists have described these "war bronzes" without mention of such deterioration with time, except as the result of corrosion. It may be mentioned, however, that alloys rich in zinc, which contain either copper alone or aluminium alone, do appear to be free from the trouble in question.

Aluminium.—Aluminium and its alloys have played a particularly conspicuous part and have undergone remarkable developments since 1910. Prior to the outbreak of War, aluminium itself had become relatively very cheap (below £100 per ton), and this fact stimulated interest in its use. During the War, on the other hand, while the metal itself became scarce and very dear, its applications for military purposes grew very much in importance and raised its alloys for the first time to the rank of important materials of engineering construction. Its uses arose mainly in connection with aircraft, and became increasingly important in the closing years of the War.

This rapid development of aluminium alloys under war conditions was to a considerable extent the result of progress which had been

made prior to 1914. One step in this progress was marked by the section on light alloys contained in the Ninth Report to the Alloys Research Committee (Rosenhain and Lantsberry), published in 1909; but the discovery, by Wilm of Berlin, of the possibility of hardening aluminium and its alloys, when a small percentage of magnesium had been added to them, led to the next and most important forward step.

The application of this discovery to the best of the alloys, described in the above-named report, led to the production of the now widely known and used alloy "duralumin." This contains from 3 to 5% of copper, about 1% of manganese and about 0·5% of magnesium. As rolled, this material has a tensile strength of about 18 tons per sq. in., but if heated to a temperature of 480° C. to 500° C. and quenched, it gradually acquires much greater strength—rising to about 26 tons per sq. in., the ductility remaining the same at about 16 to 18% elongation on two inches.

Such a material, possessing the strength of a very mild steel combined with a density as low as 2·8, constituted a remarkable advance in wrought aluminium alloys. At quite an early stage in its history this alloy was employed for the construction of Zeppelin airships. The manufacture of the alloys was taken up in England under licence from the German patentee, and the alloy has been extensively used in the construction of British rigid airships. Its use has, however, not been free from difficulties and disadvantages, and great efforts have been made to arrive at better alloys by research in Great Britain. As a result, a series of new aluminium alloys for use in the wrought form have been developed.

The most important of these is one developed at the National Physical Laboratory and known as "Alloy Y," having the composition: copper 4%, nickel 2% and magnesium 1½%. This alloy, when quenched from a temperature of 530° C. after previous cold-rolling, can be made to attain a tensile strength of 28 tons per sq. in. combined with an elongation of 20% on two in.; its density is 2·8, and it possesses two very important further properties, viz., remarkable resistance to corrosion, and a relatively very high resistance to fatigue (repetition stresses), particularly at slightly elevated temperatures. Forgings of this alloy have been successfully used as connecting-rods in high-speed internal combustion engines, and it is finding a constantly widening range of engineering uses. More recently, a German alloy—"lautal"—in which the alloying elements are copper and silicon, has been produced industrially. It is not superior to alloy Y or duralumin.

Aluminium Alloys.—Important as are the results achieved with the wrought alloys just described, results of more immediate importance have been achieved with casting alloys of aluminium. At first these were employed mainly on more or less subsidiary castings, such as crank-cases, and for that purpose an alloy containing from 12 to 14% of zinc and about 2½% of copper (generally known by the number of the British Air Board Specification as "L 5") was very widely used. Efforts were soon made, however, to employ light-alloy castings for more important parts in aeroplane engines, viz., cylinders and pistons. Here the value of these materials lies not so much in their specific lightness as in their high thermal conductivity. In the case of the cylinder castings of air-cooled engines particularly, this is valuable in preventing distortion arising from unequal cooling of the windward and leeward sides, while in the pistons it reduces the temperature of the compression space and thus increases the density of the indrawn charge, and at the same time allows of the employment of higher compression ratios. The effect of these advantages is to increase very appreciably the power output of an engine of given size and weight, while also reducing the petrol consumption (*see* AERO ENGINES).

The alloys first and most extensively used were those of aluminium with copper, a 12% alloy being particularly popular. Another widely used alloy contains 7% of copper with 1% of zinc. These alloys, although initially not as strong as some of those containing zinc, do not lose their strength so rapidly when heated, so that at the working temperature of an aluminium-alloy piston (about 250° C.) they are stronger than such an alloy as "L5." Even these alloys, however, are relatively very weak when hot—they register a tensile strength of about six to seven tons per sq. in. at 250° Centigrade. Recently, researches at the National Physical Laboratory have shown that the alloy already referred to above as "Y"—containing copper 4%, nickel 2%, magnesium 1½%—is particularly strong at high temperatures, even in the cast state. It is, further, amenable to hardening by quenching and ageing even in the form of castings, and when thus treated attains a tensile strength as high as 26 tons per sq. in. at the ordinary temperature and 13 tons per sq. in. at 250° Centigrade. Many important applications are opened up as the result of the remarkable properties of this alloy.

An important development in aluminium alloys is the advent of the "modified" alloys of aluminium with silicon, known as "alpax," "silumin," etc. It has been found that an alloy of aluminium with from 10 to 14% of silicon solidifies with a rather coarse, nearly eutectic, structure containing some primary crystals of silicon. If, however, just prior to casting, the alloy is treated either by the addition of a small amount of metallic sodium or by reaction with a flux containing sodium compounds, such as the fluoride or the hydrate, the resulting structure is profoundly altered; the eutectic structure becomes exceedingly fine and the alloy now shows primary aluminium—*i.e.*, the eutectic concentration appears to have been altered. The "modified" alloy shows physical properties much superior to the untreated material, particularly in regard to an exceptional degree of ductility. The alloy yields castings having very good, clean, bright surfaces, although the avoidance of internal unsoundness is not always easy. For castings in which good appearance, ductility and absence of porosity is important, while strength is a lesser consideration, these aluminium silicon alloys offer great advantages.

Important progress has also been made in improving the soundness of aluminium alloy castings and ingots by the recognition of the fact that gases, and particularly hydrogen, dissolved in the molten metal give rise to pin-holing and unsoundness in castings, particularly when cooled at moderate rates. It has been shown (Archbutt) that most of the deleterious gas escapes from the metal if it is allowed to solidify very slowly, as for instance by cooling in the furnace. Subsequent rapid remelting does not allow it to reabsorb much gas, and castings can then be made from it of exceptional soundness. Similar observations in regard to copper were made simultaneously by Edwards and Prytherch. A less expensive method of removing hydrogen or other deleterious gas is that of bubbling nitrogen through the molten metal prior to casting (Rosenhain). This process has proved as successful as presolidification and is coming into use.

An important process for the electrolytic refining of aluminium was worked out in 1925 by Edwards and his collaborators in America. Molten aluminium, to which copper has been added to raise the density, lies at the bottom of the bath; upon it floats the molten cryolite electrolyte, and on this again floats the pure aluminium. The lowest layer is anode and the top layer cathode, and by electrolysis the top layer of high purity metal increases at the expense of the bottom layer. Aluminium has in this way been obtained of more than 99·95% purity, and the properties of this high purity metal are distinctly different from those of the purest commercial metal previously obtainable (99·7%).

Magnesium.—During the latter part of the period under review, this metal began to acquire technical importance. High price and great corrodibility had formerly prevented its use, but the price has been much reduced and, if the demand increases sufficiently, this may become lower than that of aluminium, as satisfactory raw materials are plentiful and the reduction process could be rendered equally economical. As regards corrosion, the production of metal of higher purity, and especially free from chlorides derived from the electrolyte, shows much better resistance to atmospheric corrosion than the older material.

The mechanical strength of magnesium and its alloys never approaches that of the better aluminium alloys, but their greater lightness offers some advantages. Magnesium and some of its alloys have been successfully used, particularly in France, for pistons of internal combustion engines and for other special purposes. The thermal conductivity of these materials, however, is decidedly inferior to that of aluminium alloys, and this is likely to lessen the advantages to be gained from extreme lightness. As further improvements are made, however, magnesium alloys are likely to prove of increasing technical importance.

Berylium or glucinum metal has been produced in reasonable quantities, although still at a very high laboratory cost. The combination of great lightness, considerable resistance to corrosion, high strength and high melting point found in this metal may render it technically interesting provided that the cost can be made reasonable and that it can be produced in a malleable form. The latter has not, so far, been done.

Nickel.—This has received a wide range of new applications, partly as the result of the need of the nickel industry to find new uses when the principal older use—for armament purposes—came practically to an end after the Washington Conference.

Among the more important developments are the alloys for use at very high temperatures. Alloys of nickel and chromium containing various amounts of iron and manganese have been known for a considerable time as "Nichrome," and proved valuable for such uses as electric resistance heaters for temperatures not much above 1,000° Centigrade. More recently these have been improved upon by a high-purity alloy consisting solely of nickel and chromium (80% Ni., 20% Cr.), and this alloy also exhibits remarkable strength at high temperatures (up to 800° Centigrade). In this respect, however, it is not appreciably superior to the best of the special "steels" which have been developed for use at very high temperatures. These usually contain large amounts of both nickel and chromium, to which tungsten is sometimes added, the proportion of iron in some cases falling as low as 54%. The increasing use of very high temperatures in engineering practice lends special importance to these materials.

Other Metals.—Developments in the remaining metals are mostly of a minor nature. Progress has been made in connection with *cobalt*. Its use in steel and in certain special alloys has already been mentioned, but it has also been shown to give a more adherent and more durable electro-plate coating than nickel, and it is important to note that its resemblance to nickel is not nearly so close as was previously supposed. In regard to *lead* and its alloys, a remarkable development has been that of alloys with the rare-earth metals, particularly calcium and barium. These confer a remarkable degree of hardness on lead, and a special alloy of this kind is finding application as a bearing metal.

V. PHYSICAL METALLURGY

Side by side with, and to a great extent furnishing the basis for, the development in the treatment and use of metals and their alloys, there has been a very great development of metallurgical science in the direction of "Physical Metallurgy."

Alloy Systems.—A very large amount of work has been devoted to the further and more detailed study of the constitution of alloy systems. A number of the somewhat rough preliminary determinations of the equilibrium diagrams of most binary alloy systems previously made, have been revised and rendered more accurate. In ferrous alloys, the iron-carbon system has received much further study, particularly in regard to the critical points of iron itself. Important work at the Bureau of Standards, U.S.A. (Burgess and Crowe), has firmly established the three well-known critical points, A_1, A_2 and A_3, and has shown that previous attempts on the one hand to discredit the very existence of A_2 (Carpenter), and on the other to show that it was a double point (Arnold) were based on experimental error. On the other hand, German investigators (Ruer, Hanemann) have established the existence of a higher critical point, which in pure iron occurs at a temperature very close to 1,400° Centigrade.

In connection with the critical points, considerable attention has been devoted to the whole question of allotropy. A Dutch school of investigators (Cohen) have sought to show the existence of numerous allotropic transformations in many metals, but their conclusions are based on extremely slight evidence derived from determinations of minute irregularities in density changes. On the other hand, the Japanese school (Hondo) seek to show that the A_2 transformation in iron is not allotropic in character, and this view is confirmed, to a certain extent, by strong evidence that the passage through this point does not involve any change of crystallisation—evidence which has recently been confirmed by X-ray methods. The matter, however, turns upon the definition of allotropy.

In addition to the iron-carbon system, the iron-nickel, iron-chromium, the manganese-carbon and nickel-carbon systems have been carefully investigated. The systematic study of the alloys of iron, in the first place free from carbon, has been begun at the National Physical Laboratory under the auspices of a special committee. The production of iron, chromium, manganese and silicon in a very high state of purity and a study of the iron-oxygen system are some of the results already obtained. In non-ferrous alloys, considerable attention has been given to the alloys of zinc, a portion of the ternary system copper-aluminium-zinc (alloys rich in zinc) having been very fully worked out (Haughton, Bingham).

The allotropy of zinc itself has also been very thoroughly studied (Benedicks, Bingham) and the reality of the transformations established. Great advances have been made in the knowledge of the equilibria of several of the important alloy systems in which aluminium is the predominant metal. The ternary systems aluminium-zinc-copper, aluminium-iron-silicon and aluminium-magnesium-silicon (Hanson, Gayler) have been fully worked out so far as the alloys rich in aluminium are concerned. For the representation of the results of such investigations a new type of model has been devised (Rosenhain) in which the various equilibrium surfaces are represented by systems of wires coloured to indicate the phases concerned in each transformation.

The Aluminium-magnesium-silicon System.—The study of the aluminium-magnesium-silicon system has proved particularly important, throwing light on the age-hardening properties which are found in many aluminium alloys containing magnesium. The magnesium in these alloys is present as a compound Mg_2Si, which is more soluble in solid aluminium at high temperatures than at the ordinary temperature. Quenching such an alloy from a temperature just below its solidus retains the compound in solid solution and in this state the alloy is soft. Gradually, however, at the ordinary temperature and more rapidly at slightly higher temperatures, this super-saturated solid solution deposits the excess of dissolved compound in an extremely finely divided condition, accompanied by a gradual hardening of the alloy.

This process is strictly analogous to that which can be brought about in certain alloy steels which can be rendered (or kept) completely "austenitic" (homogeneous solid solution) by quenching; they are then soft and ductile, and do not undergo hardening while at rest at the ordinary temperature. If the temperature is raised so as to bring about "tempering" the solid solution breaks down in precisely the same way as indicated above and the steel becomes hard (and also magnetic). It would thus seem that hardening as the result—direct or indirect—of quenching is due to the separation from solid solution, in a state of extremely fine division, of a phase the formation of which had been suppressed by quenching.

According to the theory of amorphous metal (*see* below) each of the minute crystallites of the phase thus separated will be surrounded by a zone of amorphous metal, which is itself very hard. If the minute crystals thus separated are sufficiently small and numerous, the result will be that a considerable proportion of the whole alloy will be thrown into the amorphous state, extreme hardness resulting. On this view, the martensite of hardened steel should consist mainly of minute crystallites of alpha-iron embedded in an amorphous matrix consisting of iron and carbon (or carbide) in solution in it. This suggested constitution of martensite readily accounts for its hardness and for the fact that it is magnetic, and—in view of the intimate manner in which the minute crystallites of alpha-iron are embedded in unyielding and un-magnetisable amorphous metal—accounts also for the magnetic hardness of the martensitic steel. This view is further confirmed by the observation that the chemical behaviour of quench-hardened steel is in certain respects closely similar to that of the same steel hardened by cold work and thus rendered partially amorphous (Whiteley). Finally, it has recently been shown by X-ray methods that the space lattice typical of alpha-iron is present in martensitic steel (Westgren).

Theory of Amorphous Metal.—The theory of amorphous metal just mentioned has played an important part in scientific metallurgical thought during the period under review.

The conception that metal could be rendered amorphous by mechanical disturbance of its crystalline structure was originated by Beilby, in the first instance, to account for the phenomena observed by him and others in connection with the polishing of metals and other substances. Beilby further applied the conception to explain the hardening which metals undergo as the result of plastic deformation (cold work) by suggesting that layers of amorphous metal are formed on the surfaces on which internal slip occurs during plastic straining. Both these theories are widely but not universally accepted in England and America, but find opposition on the Continent. More recently Rosenhain has brought forward a conception which has already been present in the minds of many other investigators (notably Osmond) in a less definite form, that a film or thin layer of amorphous metal exists in the inter-crystalline boundaries of all metals, quite apart from any effects of strain. This view has been vigorously contested, but experimental evidence in its confirmation has been steadily accumulated.

The most striking series of facts supporting the "amorphous cement" theory is connected with the behaviour of the inter-crystalline boundaries under stress. In normal circumstances these boundaries are stronger than the crystals themselves, so that fractures of metals generally occur by breaking through the crystals and not by pulling them apart. It has, however, been shown that at a high temperature near to, but definitely below, the melting point, pure metals can be easily caused to break with a perfectly inter-crystalline fracture (Rosenhain and Ewen). This is ascribed to the greatly decreased viscosity at such temperatures of the inter-crystalline amorphous metal, which is regarded as possessing the properties of a

viscous under-cooled liquid. The actual viscosity, however, depends very much upon the nature of the metal and upon the temperature—the farther a metal is below its normal melting-point the higher the viscosity of the amorphous phase.

Accordingly, in some of the softer metals and alloys the amorphous material is sufficiently mobile to allow of sensible movement in relatively short times. Thus, an alloy of zinc with copper and aluminium has been discovered which, in the cold-worked state when it is partially amorphous, behaves very much like pitch; it will bend to any desired extent if allowed to do so gradually, but breaks short if rapid bending is attempted. Similarly, the inter-crystalline cement in certain metals and alloys, although it proves stronger than the crystals when the metal is loaded at any normal rate, appears to be capable of giving way by some form of viscous or visco-elastic movement under very prolonged loading such as that due to internal stresses.

Season Cracking.—Much attention has been devoted to the study of fractures occurring in various metals as the result of the application of internal or other prolonged stresses. In brass these phenomena have become known by the misleading term "season cracking," but strikingly similar phenomena have been found in a number of other metals, including certain alloys of aluminium, platinum and steel (Rosenhain and Archbutt). In the case of brass, steel and aluminium alloys, certain types of chemical reagents which act preferentially upon the material in the crystal boundaries contribute to the occurrence of such fractures, which are typically inter-crystalline (Moore and Beckinsale). At the same time in the case of the aluminium alloys at all events such chemical action serves to accelerate the fractures, but is not essential to it since it occurs, although more slowly, in high vacuum or in an atmosphere of pure dry hydrogen (Rosenhain and Archbutt). In the case of brass it seems probable that "season cracking" can occur without the intervention of any chemical action.

Similar types of cracking which have been discovered in mild steel, however, appear to be very closely associated with the effects of certain chemicals, such as concentrated solutions of alkalis, fused ammonium nitrate, etc. While there are still some metallurgists who refuse to think in terms of an amorphous inter-crystalline cement (Hatfield, Tammann), the great majority of investigators are agreed that, directly or indirectly, this conception serves to explain the occurrence not only of inter-crystalline fractures under prolonged loading but also a number of other phenomena associated with the crystal boundaries.

Intimately connected, also, with the nature of inter-crystalline boundaries are the important phenomena of recrystallisation and crystal growth, which are of fundamental importance with all annealing and heat-treatment operations, and have been studied in great detail. One of the most striking features is the relatively rapid formation of large crystals in certain conditions. Thus in an oblong piece of metal which has been severely strained, and is then heated in such a way as to be well above the usual temperature of recrystallisation at one end and well below it at the other, a zone is found in which very large crystals are formed; this may occur either as the result of a temperature-gradient being applied to a uniformly strained piece of metal or of the application of a suitable uniform temperature to a piece of metal in which there is a strain-gradient.

The explanation appears to be that for a given degree of previous plastic strain there is a temperature most favourable to rapid crystal growth (Jeffries). An interesting practical application of the ideas derived from the study of these phenomena is the production of wires of certain metals, notably tungsten, which have been so treated as to consist, for considerable lengths, of single long crystals. This result is achieved by drawing the cold-worked wire into an annealing furnace at a suitable temperature, at precisely the right rate. The tungsten wire thus produced is particularly valuable for the manufacture of electric lamp filaments (*see* ELECTRIC LIGHTING), and it has also been shown to possess interesting elastic properties (Wartenberg) which are readily accounted for by the absence in such material of any amorphous inter-crystalline material the viscous or visco-elastic properties of which affect the behaviour of the wire.

Much study has also been devoted particularly to the recrystallisation of aluminium after cold-working, and as a result very large single crystals of aluminium have been produced (Carpenter and Elam). This has opened the way for the study of single crystals under strain (Taylor and Elam) and under fatigue (Gough and Hanson), (*see* FATIGUE OF METALS). It has also given the impulse for the production and study of single crystals in other metals (Davey, Bridgeman, Czochralski). The general result emerges that in most respects single crystals behave very much like aggregates, but possess greater ductility and, in the case of copper, have an appreciably higher conductivity. Their mode of deformation under strain and fatigue is found to confirm the original theory of deformation by slip on crystallographic planes (Ewing and Rosenhain), but extensive research on fatigue phenomena both in single crystals and crystal aggregates (Moore, Jasper, McAdam, Gough, Jenkin) has as yet failed to produce a satisfactory explanation of fatigue failure. The fatigue range, however, has been dissociated from the "elastic limit" and found to be related rather to the ultimate strength.

The application of X-ray methods of crystal analysis to the study of the atomic structure of metals has received much attention. The normal crystal lattices of almost all the known metals have been worked out, as well as those of a number of alloys (W. H. and W. L. Bragg, Hull, Bain, Wyckof, Westgren, Debye, Scherrer, Wever, Owen and Preston and many others). (*See* CRYSTALLOGRAPHY; X-RAY.) The majority of metals have either a face-centred or body-centred cubic lattice; a few (zinc cadmium, etc.) have a close-packed hexagonal structure, while the more brittle metals show structures of lower symmetry. The lattice structures of solid solution alloys are found to be those of the parent or solvent metals often either expanded or contracted by the addition of the dissolved metal. On the basis of this structure a general theory of the properties and behaviour of solid solutions has been worked out (Rosenhain) which affords satisfactory explanations of their behaviour on melting and freezing, their hardness and electrical conductivities and the power of different metals to form solid solutions.

X-ray methods have also been used, as already mentioned, in very important work on the behaviour of metal under strain and fatigue. The effect of cold working on the atomic structure has been particularly fully investigated, and it has been shown (Polanyi, Mark, Körber, Sachs) that cold working, such as cold rolling, not only elongates the crystals of a metal and sets up disturbances of the lattice structure, but sets the crystals in an orientation which tends to place one of their axes in the direction of rolling. Annealing, although it rapidly brings about recrystallisation into equi-axed crystals, does not necessarily abolish the oriented structure, probably because the newly formed crystals tend to assume the orientation of their predecessors. The directional structure—called by German workers the "fibre" structure of cold worked metal—is completely removed only by annealing at very high temperatures.

VI. ORGANISATION OF THE INDUSTRY

Certain institutions and organisations have attained importance as factors in metallurgical progress. The Imperial Mineral Resources Bureau, merged in the Imperial Institute, has published a large amount of information, mainly in regard to the mineral resources of the British Empire. The continued progress and growth of the Institute of Metals has been a marked feature of metallurgical activity; this body has now attained a membership of over 1,700. In America an Institute of Metals has been formed on different lines, as part of the Institute of Mining and Metallurgical Engineers.

The British Engineering Standards Association, formerly the Engineering Standards Committee, exerts a powerful influence on the metallurgy of those metals which form the materials of engineering. The issue of standard specifications for a large number of non-ferrous metals has been undertaken. In connection with the British Government Department of Scientific and Industrial Research, a Non-Ferrous Metals Research Association has been formed and has carried out important researches, particularly in connection with copper, brass, aluminium, the

jointing of metals, die-casting, etc. The British Cast Iron Research Association has been mentioned.

This brief summary of the developments of metallurgical science deals only with a few points of outstanding interest.

BIBLIOGRAPHY.—For iron and steel metallurgy, industrial as well as scientific, the *Journal of the Iron and Steel Institute*, London, should be consulted for original publications and abstracts which cover the literature of the whole world on this subject. In addition, excellent abstracts will also be found in the metallurgical section of the journal of the *Society of Chemical Industry*, and in such journals as *Stahl und Eisen*, the *Revue de Métallurgie* and *The Metallurgist* (supplement to *The Engineer*). In addition *The Iron Age*, *the Iron and Coal Trade Review* and similar journals may be mentioned. For general metallurgy, see the annual volumes of *Mineral Industry* and *The Journal of the Institution of Mining and Metallurgy*. For the non-ferrous metals, see *The Journal of the Institute of Metals* (abstracts as well as original papers), *Revue de Métallurgie* and several German journals, *Zeitschrift für Metallkunde*, *Metall und Erz*, *Zeitschrift für Anorganische Chemie*, and the appropriate section of the *American Institute of Mining and Metallurgical Engineers* (American Institute of Metals). The publications of the U.S. Bureau of Standards (Washington) and of the National Physical Laboratory (Teddington, England) are important. The Faraday Society (London) has published in its *Transactions* several "general discussions," including particularly one on *The Failure of Metals under Internal and Prolonged Stress*, another relating to metallurgical microscopy, one on the application of X-rays and one on *The Physical Chemistry of Steel Making*. (W. RN.)

METCALF, WILLARD LEROY (1858–1925), American artist (*see* 18.257), died in New York City March 9 1925.

METEOROLOGY (*see* 18.264).—Since 1910 considerable advances in meteorological knowledge have been made both on the observational and the theoretical sides.

The Upper Atmosphere.—During the years before the War observations on the temperature and humidity of the air strata were rapidly accumulating, more particularly from a network of stations spread over Europe, and since the W. and N. of Europe is subject during the winter to the passage of many deep cyclonic depressions, the conditions of temperature in cyclones and anticyclones up to a height of some 20 km.(12½ m.) had become known. The brief tables which were all that were available to Cleveland Abbe in 1909 had been supplemented by much information, drawn up and arranged for the European results by Lt.-Col. E. Gold (M.O.No. 210e, *Geophysical Memoirs*, No. 5), by Dr. Wegener for the Continent (*Die Temperaturverhältnisse in der freien Atmosphäre*, III. Band, Heft 2/3, Leipzig, 1909) and for Russia by Dr. Rykatchew (*Meteorologische Zeitschrift*, Jan. 1911). In 1916 a summary of the information available about the upper air was drawn up for the Meteorological Office but not published. It quoted freely from Gold's paper but included the results of observations up to 1916. This summary together with certain theoretical matter was published in 1919 under the title "Characteristics of the Free Atmosphere" (M.O. 220c, *Geophysical Memoirs*, No. 13), and from it the following abstract summarising our present knowledge of the strata from 0 to 20 km. is mostly taken.

Temperature.—As the surface of the earth is left the temperature of the air decreases with increasing height, and when the great variations of climate and of the conditions prevalent in different parts of the earth are considered it is remarkable how uniform is the fall of temperature, now commonly called the lapse rate. The height to which it extends is variable, but in all places in which observations have been made, the lapse rate up to 8 km. has been found close to 6° C. per kilometre. This holds between 2 and 7 km. not indeed exactly but approximately, for summer and winter and for places as far apart as the equator and the Antarctic in lat. 78° S. Thus in Batavia the lapse rate up to 8 km. is 6·1° per km.; at Petrograd it is 5·8°. In England in the winter it is 5·8°, in the summer it is 6·0°. These are means, but the rule holds quite well even for the individual case, for if in one part of the 8 km. the lapse rate is small this is usually compensated for by its being large in the other part. The only important exception that has been found so far is in regions and at times where the temperature is extremely low, as in Siberia or Canada or the Antarctic in the winter. In such instances the bottom layer is unduly cold and the lapse rate is negative over the first 2 km., so that the rule would make the upper air temperature too low. Also it must be remembered that the daily variation of temperature does not extend upward more than one or two km., so that the mean for the day rather than the precise temperature at the moment should represent the surface temperature. This layer, in which temperature falls with increasing height, is called the *troposphere*.

At a certain height, which varies with the latitude, with the barometric conditions, and with the season, the fall of temperature ceases, and the air up to the greatest heights that have been explored remains at a nearly uniform temperature in the vertical direction. This upper part in which there is no lapse rate is called the *stratosphere*. The boundary between the two parts is found at about 16 km. near the equator and at 10 km. in northern Europe. Over England its mean height is 10·5 km., falling to rather below 10 km. in the winter, and rising to over 11 km. in the summer. In the centre of a deep cyclone the value may easily fall to 8 km.; in an anticyclone it may exceed 12 km.

The temperature of the stratosphere is below 200° A. over the equator and in tropical regions; it is above 220° A. in northern Europe. In Canada it seems to be lower in the summer than in the winter. These anomalies are roughly expressed by the rule that the mean temperature of the air column taken with regard to height from 0 up to 19 km. is approximately the same in all parts of the earth. There is probably a physical reason for this, and it explains the unexpectedly low temperature above 14 km. over the equator and the curious reversion of temperature between summer and winter over Canada (Toronto) where the seasonal range is very large.

The annual range of temperature in the troposphere does not differ very greatly from the range at the surface; in island and coastal climates like England it is rather greater in the upper parts than at the surface; in continental climates the surface has the greatest range. In the stratosphere the range is much reduced and, as already stated, appears in Canada to be reversed although enough observations are not yet available to make this absolutely certain.

Whether or not there is any regular diurnal change of temperature above 2 km. height is uncertain; all that can be said is that if there be any its amplitude is certainly less than 1° Centigrade.

The mean annual temperatures are given in the accompanying Table I. In Europe the probable error of any value is about 1° C.; for Canada and the equator owing to paucity of observations it is greater, especially above 15 km., where it may reach perhaps 3° Centigrade. Over Europe the mean temperature does not change from 14 to 20 km. and does not change much over Toronto. Over the equator the lowest temperature, which is about 193° A., is not reached under 16 or 17 kilometres.

TABLE I. *Mean Atmospheric Temperature*

The values are in the Absolute scale with the first "2" omitted. 273·0° = 0° C. = 32° F.

Height km.	Petrograd	Scotland	Manchester	Berlin	England, S.E.	Paris	Strasbourg	Vienna	Pavia	Mean for Europe	Toronto	Equator

Pressure and Density.—The temperature of the air having been found by observation, the pressure and the density are easily found up to the height to which the observations extend. In the same way the mean pressures and mean densities can be determined from the mean temperatures without appreciable error provided the mean pressure at the surface is known.

In the lower strata the pressure at any particular height is naturally most dependent upon the surface pressure, but since the air is lighter, bulk for bulk, when it is warm the pressure decreases less rapidly than usual in a warm area, and the pressure at any given height depends more and more upon the temperature of the underlying air as that height increases. Thus it comes to pass that in the hot regions of the earth, say in the belt included between the two tropics, the pressure at the height of 9 km. is very much greater than it is at the same height over temperate latitudes, and the pressure gradient which causes the prevailing westerly winds of the cirrus level is thus produced. At a height of 20 km. the surface pressure has ceased to have much effect, and it requires a rise of nearly 20 mb.[1]

[1] The average pressure of the atmosphere at sea-level being reckoned as 1 bar = 1000 millibars (mb.). 1 mb. = 0·0295306 in. mercury at 32° F. in lat. 45°.

in the surface pressure to produce a rise of 1 mb. at 20 km., whereas a change of 1·5°C. in the temperature of the air column will produce that effect. It has been stated that the mean temperature of the air column up to 19 km. is much the same in all parts of the world, and it follows that the same level is one of nearly uniform pressure.

The pressures are given in Table II. at various stations for heights up to 20 kilometres. The values for Canada and the equator at heights above 15 km. are not very reliable owing to paucity of data.

The densities are given in Table III. The variations in the density became of great consequence during the War on account of their influence on the range of projectiles; they depend on the connection which has been found to exist between temperature and pressure.

Statistical Methods.—Statistical methods have been much in vogue of late years, and it is necessary to indicate how the method of correlation has been used for forecasting and for elucidating meteorological problems. A large number of correlation coefficients have been determined between various meteorological events, and the values of many of them are given in the *Computer's Handbook*, M.O. 223, Section V.—Tables, published by the Meteorological Office.

The advantage of a correlation coefficient in estimating the connection if any between two events, is that it expresses the connection as a decimal, which must lie between 1 and −1, and thus renders the connections between different pairs of events comparable with each other. The velocity of the wind and the steepness of the barometric gradient may be taken as an example. The actual connection is obvious from the daily weather charts; on some it is well marked, on others badly, but the fact that there is a connection is quite apparent from even two or three charts. The correlation coefficient is about 0·70.

The application of the method of correlation to forecasting can hardly be looked upon as very successful. Two highly correlated events are required happening with a definite time interval between them. A correlation coefficient may be high accidentally if it be founded on too small a number of instances, but genuinely high coefficients between meteorological events occurring with more than a few days' interval between them are hard to find. The most successful instance is perhaps the forecast of the monsoon rain of India by Sir G. T. Walker from the correlation between it and sundry other events occurring in the spring of the same year or earlier. In this case the correlation coefficients on which the forecast is based have values of about ·50; if values of ·80 or ·90 could be obtained very much greater success would be secured. There are a few coefficients of from ·70 to ·80 between the rainfall at various periods and the subsequent yield of sundry crops. Thus in the eastern counties of England if April and May be wet it is a practical certainty that there will be a large hay crop, and if the autumn be dry there will almost certainly be a large crop of wheat the next year. Mr. R. H. Hooker has calculated a most interesting set of figures relating to the correlation between the weather and the crops, and the problem has been re-analysed by R. A. Fisher and W. A. Mackenzie, *Quart. Jour. R. Meteor. Soc.*, July 1922. Similar work has been done for the potato crop in America by J. Warren Smith, and many correlation coefficients relating to agricultural matters are available from Sweden and elsewhere.

The case is different where correlation is resorted to for the purpose of elucidating some physical process in the atmosphere; here a small coefficient is just as likely to give information as a large one But the interpretation of the meaning of the coefficient is often difficult, and in many cases the value obtained is quite different from that which most meteorologists would have expected.

Sir G. T. Walker in addition to his statistical work on the monsoon rain has published several sets of correlation coefficients, and amongst them a set of 100 showing the correlation between the sunspot number and the temperature at 100 stations well distributed over the earth's surface. The correlation is negative and small, but it is large enough to be significant and to prove that during the 40 or so odd years considered the temperature of the earth as a whole was lower at the time of the sunspot maxima than at the time of the minima. It is commonly supposed that the sun is giving out most energy when its surface is most disturbed, and this idea has been confirmed by direct observation of the radiant heat. A perfectly satisfactory explanation is at present wanting. Walker also correlated between sunspots and rainfall, and found the coefficient too small to be significant. However, in none of these cases has the work been wasted, since important conclusions have been established.

For high correlation coefficients one must take data relating to the upper air. The relation between pressure and temperature is so remarkable and has such a close relationship to the theory of cyclones and anticyclones that it will be treated separately. The correlation coefficients between the thickness of the troposphere, a height commonly denoted by H_e, the surface pressure, the temperature of the stratosphere and other variables often exceed 0·70, and the generally high values show quite plainly that there is an ordered sequence in the processes going on above, which is strikingly absent from the surface phenomena.

Cyclones and Anticyclones.—In a cyclone the troposphere is cold and the stratosphere warm, in an anticyclone the reverse is the case; in a cyclone the tropopause is low, in an anticyclone high. Thus as an area of low pressure passes across the map the following changes occur in the various air strata above. The deficiency of pressure is about the same from the surface up to some 10 km.,

above which it falls off rapidly until the normal value for the height is reached at about 18-20 kilometres. The temperature from about 2 to 8 or 9 km. falls, and from 10 to 20 km. it rises. The height at which the lapse rate ceases, the limit of the troposphere falls. These statements are based on the very high correlation coefficients that are found to exist between pressure and temperature. It will be seen from the accompanying Table IV. (which gives the correlation coefficients) that close to the surface the correlation is low, but it is very high from 4 km. to 8 kilometres. There are probably two reasons for this. The surface temperature is governed by many considerations—the time of day, the state of the sky, the strength and direction of the wind; higher up these disturbances do not apply, for, as has been already stated, the diurnal variation is very shallow and the correlation between the components of the wind and the temperature is surprisingly small above a few km. height. Secondly, it may well be that the chief item in determining the temperature is the recent vertical motion of the air, and a systematic vertical flow of air either up or down is plainly impossible quite close to the surface. The rise and fall of the tropopause (H_c) and the regularity with which it occurs is shown by the high correlation, ·84, between it and the pressure at 9 km. height. There is hardly a single instance of observations made in Europe at a time of really low barometer in which H_c has not been found well below its average value. The dependence of the temperature of the stratosphere on the barometric conditions is not so close, the correlation being only ·50; but based on some hundreds of observations as these correlation coefficients are, ·50 is amply significant. Still the importance of a correlation in general depends upon its square rather than upon itself, and the significance of ·50 is very different from that of ·90 or ·85.

TABLE IV. *Correlation Between Pressure and Temperature*

Height, km.	0	1	2	3	4	5	6	7	8	9	10	11	12	13

Means	·11	·42	·66	·77	·4	·85	·86	·86	·86	·72	·32	−·19	−·36	−·28

One noticeable result of this high correlation between pressure and temperature is that the density is not subject to much variation save close to the surface, for a high pressure and a high temperature act upon the density in opposite ways, and since they occur together the density remains comparatively unchanged. (*See* also below, *The Meeting of Air Masses from Different Climates.*)

Stability for Vertical Displacements; Available Energy.—The rate of decrease of temperature with height is normally less than the 10°, C. per km. by which clear ascending air is cooled by adiabatic expansion. Consequently a small portion of air, if forcibly raised or depressed, usually tends to return to its original level. The periodic time T of its vertical oscillation, if undamped, has been calculated by Väisälä (*Soc. Scient. Fennica, Comm. Phys. Math. II.*, vol. 19, p. 38) to be

$$T = 2\pi\sqrt{\frac{\theta_o}{g(\gamma_o - \gamma)}}$$

where θ_o is the absolute temperature of the air in the equilibrium level, g is the acceleration of gravity, γ is the actual decrease of temperature per unit increase of height, γ_o the adiabatic value of γ. Thus at a height of three km. T is normally about ten minutes, while in the stratosphere T is about five minutes.

Any energy that there may occasionally be in a vertical column available for producing thunderstorms or other local disturbances has been made conspicuous by Sir Napier Shaw, who has plotted upon a special chart observations of temperature against those of pressure at the same height, so as to produce, without calculation, the entropy-temperature-diagram familiar to engineers. Fig. 1 is a simplified sketch of it showing the observation for Benson, Oxfordshire, on July 5 1923, 7 P.M. He regards the dry air as the working substance and calls its entropy the "realised entropy," while the moisture he regards as merely a reservoir of latent energy.

Let A and B be two points where the curve representing the observations cuts the same adiabatic for cloud. If a sphere of unit mass of cloud at A is pushed up it will follow this adiabatic. If we may assume that the surrounding air, in descending to take the place of that which has risen, does so by a very small displacement spread over a large horizontal area, and in such a way that unit mass descends across each level surface, then what has occurred will apparently be indistinguishable, as far as energy changes are concerned, from the passage of a unit mass round the thermodynamic cycle from A *via* the adiabatic to B and back by the observed curve. Then, from the known properties of the entropy-temperature-diagram, the mechanical energy will be proportional to the area enclosed between the curves, and will be consumed or given out according as the observed curve lies below or above the adiabatic.

Actually two diagrams are employed, in order to represent humidity as well as temperature and pressure.[1]

Radiation in the Form of Electromagnetic Waves.—Just as a point has no parts and no magnitude, so a single direction contains no radiant energy. To mark off a definite flux of energy we must have two areas not in the same plane. For simplicity let us think of two square centimetres placed one metre apart and both normal to the line P Q joining their centres P and Q.

We are now able to define the "intensity of radiation" in the direction P to Q as being 10^4 times the amount of energy that goes through both square centimetres in the order P to Q in one second.

The intensity of radiation $K_\nu d\nu$ in the range of frequencies of vibration between ν and $\nu + d\nu$ has been shown to have the following value inside a black enclosure at a uniform temperature θ absolute centigrade,

$$K_\nu d\nu = \frac{2h\nu^3}{c^2}\left(e^{\frac{h\nu}{k\theta}} - 1\right)^{-1} d\nu$$

where c is the speed of light, $h = 6{\cdot}55 \times 10^{-27}$ erg sec, $k = 1{\cdot}34 \times 10^{-16}$ erg degree^{-1}. (Planck, *Vorlesungen über die Theorie der Wärmestrahlung*, Barth, Leipzig.) This is known as the "full" radiation. Further it was proved by Kirchhoff that if a portion of air absorbs a fraction a of the energy in a ray of frequency ν then that portion emits in the direction of that ray the same fraction a of the full radiation, $K_\nu d\nu$, corresponding to its temperature θ.

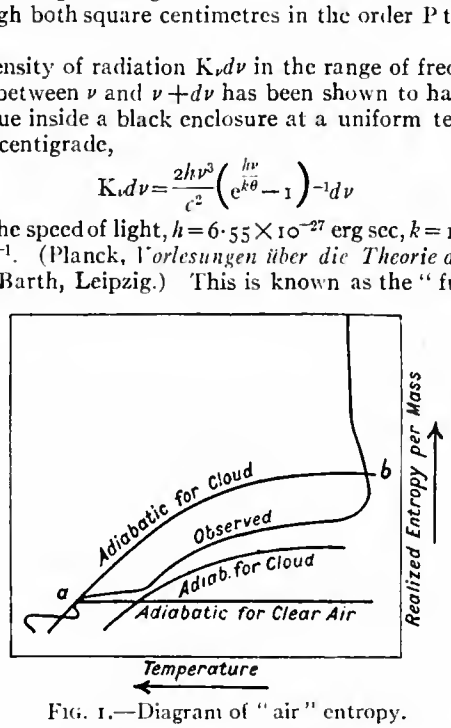

FIG. 1.—Diagram of "air" entropy.

Through any sphere of one centimeter diameter in the atmosphere radiations of various frequencies are passing simultaneously in all directions without blocking each other's paths. A division at a wave-length of three microns has nearly all the energy of solar origin on the short side of it and nearly all the energy of terrestrial origin on the long side.

When a ray passes through a centimetre length of atmosphere its energy is in general divided into three parts. One part, almost unchanged in wave-length, is turned aside and scattered in most directions. Another part is absorbed, that is to say—changed into heat-energy of the air. Whatever is left goes straight on unchanged in wave-length. The fraction that is scattered in unit length of path depends on the wave-length and the

[1] See the report of the meeting of the International Commission for the Investigation of the Upper Air, held in London 1925 (M.O. 281 published by H.M. Stationery Office, London).

presence of dust and cloud particles. Even air molecules scatter, and more so in the shorter wave-lengths. Hence we see a yellowish sun in a blue sky (Rayleigh). The fraction that is absorbed in unit length of path depends on the wave-lengths and the various gases present; N_2, O_2, O_3, CO_2, H_2O, each absorbing strongly characteristic wave-lengths. At the same time each small sphere of atmosphere is sending out, at the expense of its heat energy, long-wave radiations equally in all directions.

With such an abundance of processes going on simultaneously the difficulty of the observer has been to separate that one which he wished to observe; and the difficulty of the theorist has been to include them all without making his theory too cumbrous.

"Long Wave" Radiation.—W. H. Dines (*Geophysical Memoirs of the Meteorological Office*, No. 18) has measured the radiation which will not go through a glass plate and which reaches the earth from different zones of the sky. He finds that the intensity of radiation from a thick fog is within a few per cent. of that from a "full" radiator at the same temperature; whereas the intensity of radiation from a clear zenith sky at sunset ranges from about 0·65 of that from a grass meadow in December to 0·74 of it in September. The meadow was practically a full radiator. From the way in which the intensity increases as the zenith distance increases, W. H. Dines concludes that there must be at least two groups of radiation differently absorbed; one group comprising two-thirds of the energy is half absorbed in passing normally through a horizontal layer of clear air 100 millibars thick, the other group, comprising one-third of the energy, is only 1/20 absorbed in this way; whereas 100 millibars of thick fog absorb eight-tenths or nine-tenths of all the incident energy. The sum of the radiations received by a horizontal square centimetre from all parts of the sky amounts to 500 gr.-cal. per day on the average for clear skies, or 700 for fully clouded skies, while at 10° C. a full radiator gives out 711 of these units.

A similar but not identical account is given by A. Angström (*Quar. Jour. Roy. Meteor. Soc.*, April 1924). He divides the energy sent out by a full radiator into three groups of wave-lengths comprising one-fourth, one-half, one-fourth of the whole energy. For the first group a clear moist atmosphere is almost perfectly transparent. The second group is almost totally absorbed in the first 30 metres above ground when the vapour pressure is 10 mm. of mercury. The third group has a variable absorption chiefly dependent on the amount of water-vapour present.

"Short Wave" Radiation of Solar Origin.—A square centimetre placed outside the atmosphere normal to the sun's rays would receive, according to the extensive researches of Abbot, 1·94 gr.-cal. per minute. The question of natural fluctuations about this mean is still in debate (*vide* the *Monthly Weather Review*, July and Aug. 1925). When the sun is in the zenith of a clear sky a unit of incident energy is divided roughly as follows: 0·78 comes to earth in the direct beam, 0·06 is scattered to space, 0·06 is scattered to earth and 0·10 is absorbed, warming the air. When the sun is nearer the horizon the scattering and absorption are much greater relative to the transmission. Abbot states that clouds reflect about 0·65 of the solar radiation falling upon them. Much further information will be found in the Smithsonian publications, in L. V. King's paper in the *Phil. Trans. Roy. Soc.*, A, vol. 212 (1913), and in recent papers in the *Meteorologische Zeitschrift*. The absorption by ozone is now being studied by Dobson and Harrison (*Quar. Jour. Roy. Meteor. Soc.*, 1925).

Turbulence and Diffusion.—A statement that the wind has a velocity of so many metres per second customarily refers to some mean value taken over say 10 minutes or more. Actually portions of air are moving faster or slower than the mean, as well as up and down and horizontally to and fro across the mean track. These deviations are well shown on the records of pressure-tube anemometers. The wandering portions carry qualities with them. Thus fragments coming from a rapid, damp, hot, smoky current into an adjacent slow, dry, cool, clear layer would bring with them some of the momentum, moisture, potential temperature and dust characteristic of the layer in which they had previously journeyed. The motion of such fragments is too intricate to be analysed in detail; but its general effect can be summed up by a statistical coefficient representing the average rate of transfer of the quantities mentioned. The theory of diffusion, originally worked out by Fourier for the diffusion of heat in metals, and applied by Fick to the diffusion of salts in liquids, has been extended to eddy-diffusion in the atmosphere by Åkerblöm, G. I. Taylor (*London Roy. Soc. Phil. Trans.*, A, vol. 215, pp. 1 to 26), Hesselberg and Sverdrup, and W. Schmidt and others.

If χ be the concentration of the dust or other diffusing substance it has become customary to assume that the changes proceed in accordance with an equation of Fick's type such as

$$\frac{\partial\chi}{\partial t}+\bar{u}\frac{\partial\chi}{\partial x}+\bar{v}\frac{\partial\chi}{\partial y}+\bar{w}\frac{\partial\chi}{\partial z}=K\left(\frac{\partial^2\chi}{\partial x^2}+\frac{\partial^2\chi}{\partial y^2}+\frac{\partial^2\chi}{\partial z^2}\right)$$

where x, y, z, t are rectangular co-ordinates and time; $\bar{u}$, $\bar{v}$ and $\bar{w}$ are the components of the *mean* velocity, and K is the diffusivity. This view of the process has led to K being observed under a variety of circumstances, by the increase of wind aloft, by the rate at which water vapour finds its way upward to the clouds, by the scattering of smoke or of balloons or of volcano ash. It has thus become known that K is of the same order of magnitude whether the diffusing substance be momentum, dust, moisture or potential-heat. It has further appeared that in the first three kilometres K is roughly proportional to the speed of the mean wind, and is decreased when the static stability of the atmosphere increases. But the variation of K which overwhelms all others is that dependent on the size of the portion of atmosphere which is observed. Thus if the air is confined to a capillary tube, K is about 0·2 cm.^{2} sec.$^{-1}$, if the portion is a few metres across K is of the order of 10^3, if a few hundred metres K is about 10^5, if a thousand kilometres across K is of the order of 10^{11} in the same units (Defant). We may explain this by saying that diffusivity is a compensation for neglect of detail, and that the amount of compensation increases as the things neglected include in succession molecular motion, gusts, squalls and cyclones. In other words, the mean-velocity $\bar{u}$, $\bar{v}$ and $\bar{w}$ takes on a new sense whenever the size of the portion of the atmosphere under observation is enlarged, and this enormously affects K. See a paper by L. F. Richardson in the *Roy. Soc. Proc.*, A, 1926.

A vertical gradient of mean wind tends to produce eddies, statical stability tends to damp out eddies. The condition in which these effects just balance has been formulated by L. F. Richardson (*Phil. Mag.*, Jan. 1925). Rayleigh's theory of unstable temperature gradients has been brought into meteorology by D. Brunt (*Meteor. Magazine*, v. 60, 1925, p. 1).

The Heat Balance of the Atmosphere.—Gold (*Lond. Roy. Soc. Proc.*, A, vol. 82, 1909, and simultaneously Humphreys (*Astrophys. Journ.*, vol. 29, 1909, p. 14) showed that the existence of the stratosphere could be explained if it were in radiative equilibrium. The discussion as to the atmosphere generally has been continued by Emden (*Sitz.-ber. d. Akad. Wissensch. Wien*, 1913, p. 55), W. H. Dines (*Quar. Jour. R. Meteor. Soc.*, April 1917), W. Schmidt (*Akad. Wiss., Wien, Mat.-Nat. Kl.*, 127–75, 1918), Chapman (*Quar. Jour. R. Meteor. Soc.*, April 1925) and others, and has joined with theories of radiative equilibrium in stars. (See E. A. Milne, *Phil. Mag.*, Nov. 1922. It is, however, doubtful whether the horizontal transport of heat can be neglected in comparison with that in the vertical.

There are seemingly four methods by which an appreciable vertical flux of heat energy is produced in the atmosphere: (1) Convection, which carries heat upwards from the earth's surface; its action does not extend beyond the first few kilometres. (2) The latent heat set free by the condensation of aqueous vapour, which carries upwards to the regions where clouds are formed the solar heat which has evaporated the water from the sea or wet land surface; this acts in just the same region as convection. (3) Radiation, which mostly carries heat upwards from a lower to a higher stratum. These three methods present no difficulty, but it must be pointed out that "convection" here

means local convection, *i.e.*, heat carried by an ascending current that is produced by local warmth, not heat carried by an air current or by eddy motion due to the general circulation. This distinction, however, is difficult to maintain, because even frictional eddies behave as thermodynamic engines. (4) Stirring by eddies in the wind *i.e.*, turbulence. W. Schmidt has made an estimate which shows that the amount of heat carried downwards across the 2 km.-level in Europe by this cause to be 50 gm. calories per sq. cm. per day.

An important conclusion follows. Since above the region of the formation of heavy clouds neither convection nor the supply of latent heat by condensation is efficacious, the actual lapse-rate there must represent the balance of two opposing tendencies, one radiation, tending toward an isothermal condition, and the other mixing, tending to an adiabatic lapse rate.

Dynamics of Wind.—In the upper air it has been shown by Gold that the wind velocity approximates to the ideal "geostrophic wind" which is imagined as blowing parallel to the isobars with a speed v given by

$$v.2\omega\rho \sin \phi = \partial p/\partial x$$

where ω is the earth's angular speed, ρ is the air density, ϕ is the latitude, ρ is the pressure, and x is horizontal distance normal to the isobars. In the first kilometre this simplicity is modified by eddy-viscosity. Elaborate theories on the dynamics of wind continue to develop.[1]

The Meeting of Air-Masses from Different Climates.—Dr. J. Bjerknes writes as follows:—

Cold currents in the temperate zone can be traced back, more or less directly, to polar regions; in winter also to cold continents. On their way they are heated by contact with the ground and become unstable, provided that no adequate heating takes place in higher layers. Polar currents in temperate latitudes therefore frequently have cumulus or even cumulo nimbus with showery weather.

Warm currents in the temperate zone can be traced back to subtropical regions; in summer also to warm continents. On their way northward they are cooled in contact with the ground and become stable. If the cooling continues to the dewpoint then stratus clouds or fogs are formed.

Where cold and warm currents border each other, in typical depressions or elsewhere, precipitation is usually formed. In cases where the warm current gains terrain (warm front) it climbs upwards on a gently inclined wedge, say 1/100, formed by the underlying cold current. Impervious cloud-sheets are formed in the climbing warm current, low clouds close to the warm front and higher clouds farther forward. Precipitation is usually falling from the whole extensive cloud system, but that falling from the higher parts evaporates before reaching the ground. In cases where the cold current displaces the warm (cold front) the precipitating clouds are likewise formed in the rising warm air. The advancing cold wedges are frequently so steep that violent ascending motion and correspondingly strong precipitation results. On the other hand, such precipitation is mostly confined to a narrow belt along the cold front.

Extratropical cyclones examined individually show a great variety of types. Usually the young cyclones consist of two oppositely directed currents, one cold occupying a little more than the half of the area and one warm current covering the remaining area—the "warm sector." During the development of the cyclone, air from the warm sector ascends and is replaced at the ground by the cold air. This motion transforms potential energy into kinetic energy, which appears in the increasing winds and deepening of the depression. After a couple of days all the air from the original warm sector is lifted off the ground, but can still be found aloft (occluded cyclone). During the ascension the warm air is cooled adiabatically, and finally it reaches a level where it finds surrounding air of its own temperature, so that the buoyancy can lift it no farther. Having reached this stage the cyclone is maintained merely by the inertia of the circulating air masses. If no new energy is supplied the cyclone decays gradually.

Original papers on this subject will be found in Oslo, *Geofysiske Publikationer*, and elsewhere. For the relation between the source of air and its temperature see C. K. M. Douglas, *Quart. Jour. R. Meteor. Soc.*, July 1925.

Antarctic Meteorology.—Great additions to our knowledge of the meteorology of the Antarctic regions were made by the publication of the results of Scott's Antarctic expedition of 1910 to 1912. The observations were taken mostly by Dr. Simpson, who has worked them up and discussed various problems left in a more or less uncertain condition by previous expeditions. He has greatly extended our knowledge both from the observational and theoretical sides. Amongst other matters Dr. Simpson has established the anticyclonic character of the weather in the Ross Sea area, and has shown that the blizzards are not parts of the circulation about the centres of cyclones moving from west to east over the Antarctic Ocean.

New Methods of Observation.—Upper wind was observed during the War (1) at night by pilot balloons carrying candles, (2) by shell bursts observed by two mirrors, (3) by sound-ranging

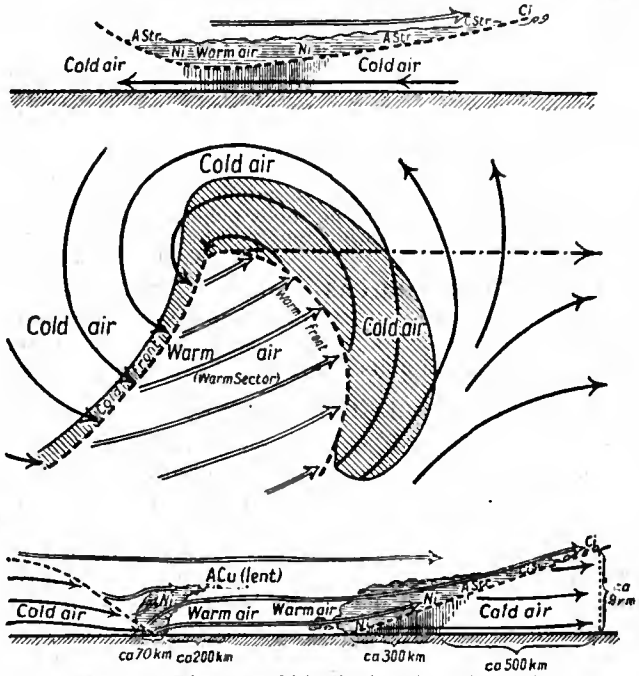

FIG. 2.—Diagram of idealised cyclone (young).

(From "Life Cycle of Cyclones, and the Polar Front Theory of Atmospheric Circulation." J. Bjerknes and H. Solberg, *Geofysiske Publikationer*, Vol. III., No. 1.)

on a balloon that exploded. Subsequently a method has been developed for observing wind above fog by shooting spheres upward. Particulars of such things will be found in the *Computers' Handbook* or the Professional Notes of the Meteorological Office. Clouds can be photographed by moonlight (Oslo, *Geofysiske Publikationer*, vol. 3, No. 12). The amount of water in thin clouds can be measured (*Quart. Jour. Roy. Meteor. Soc.*, Jan. 1925). The upgradient of temperature near the ground can be measured by thermocouples (*Phil. Mag.*, Jan. 1925) and by an optical method (*Quar. Jour. Roy. Meteor. Soc.*, April 1925). Upper air temperature is regularly measured from aeroplanes, and can also be observed by balloons that explode at a prearranged temperature (M.O. Prof. Note 19). For radiation instruments see *Dictionary of Applied Physics*, vol. 3.

Weather Forecasts.—Forecasts for one or more days ahead continue to be made by the process of drawing a map to represent weather observations received by telegraph from an area some thousands of km. in diameter. The accumulated and classified experience of what usually does follow such a distribution of pressure, temperature, cloud and wind is then employed to form the forecast. The Smithsonian Institution is progressing in its studies looking toward weather forecasts based on solar radiation observations.

Organisations.—The International Meteorological Committee and its subcommissions in 1925 reattained their fully international character, which was destroyed by the War. A post-war restricted organisation known as the International Union for Geodesy and Geophysics has a section for meteorology which is active.

METER: ELECTRIC AND GAS (*see* 18.291).—Meters are used to measure the amount of electricity or gas supplied to the customers of the company concerned. In the case of electric meters these register the number of units supplied for light, heat or power.

I. ELECTRIC METERS

These meters include induction-motor, mercury-motor and commutator meters, which register the revolutions of a disk or other armature caused to revolve, by the action of the current, at a speed proportional to the amperes or watts passing through the meter, and electrolytic meters in which the current or a shunted fraction of it passes through an electrolyte and decomposes it, the rate of decomposition being proportional to the current employed.

Induction-motor Type.—In the Ferranti alternating current watt-hour meter, a series coil of a few turns of thick wire carrying the main current is arranged below, and a shunt coil of many turns of fine wire is arranged above a horizontal rotary disk of aluminium. This disk is situated in the gap between the poles of a permanent magnet and the lower bearing of its vertical spindle is a sapphire carefully selected to reduce friction to a minimum. The magnetic fields due to the shunt and series windings produce a resultant rotating or shifting field which interacts with eddy currents, induced in the disk so as to exert a driving torque proportional to the watts. A retarding torque is produced by the action of the permanent magnet also causing the speed of the disk to be proportional to the watts. A worm on the spindle drives the registering train; the registering dials are of the clock pattern, or of the cyclometer pattern.

To read the meter is a simple operation. In the clock pattern, starting from left to right, the figure last passed by the thousands pointer in its revolution is written down and the same procedure is followed for the hundreds, tens and units pointers in succession, the tenths registered on the small lower dial being read only when testing the meter. In the cyclometer pattern, the figures are written down just as they appear on the register. The cyclometer figure wheels are actuated by a falling weight; thus, the changing of the figure wheels does not throw any extra load on the meter.

Mercury-motor Meters.—In the Chamberlain and Hookham direct current ampère-hour meter, a copper disk is caused, by the action of the current, to rotate in a mercury chamber subject to the influence of a magnetic field due to a large permanent magnet. The vertical spindle of the disk, arranged to rotate with the minimum friction, is connected to the registering train with its series of clock dials. The peripheral wall of the mercury chamber is formed by a leather-lined metal band which is readily removable to permit inspection and refilling with mercury.

Commutator Meters.—Commutator meters have a wound armature connected in parallel with a shunt and arranged to rotate in the field of a permanent magnet.

Electrolytic Meters.—In the Reason syphon-tube meter, a solution of a mercury salt is hermetically sealed in a container, at the top of which are arranged a mercury anode and a cathode. During the operation of the meter, mercury is liberated at the cathode and collects in a syphon tube in the container; this tube, when full of mercury, discharges into the lower part of the container. Close to the right limb of the syphon tube is a vertical scale which registers the mercury level; in one form of the meter, this scale reads from 0 to 200 units. Below the scale is another which registers the level of the lower mercury column; this scale may read from 0 to 4,000 units. When reading the meter, both scales are read and the sum of the readings is taken. The Reason single-tube meter has one vertical mercury tube, which is read like a thermometer. In both forms, the mercury can be used repeatedly, the meters being re-set by tilting; the container is flexibly mounted to facilitate this operation.

In the Bastian electrolytic meter, acidulated water is decomposed by the action of the current, and the amount of water decomposed is read off on a vertical scale.

II. GAS METERS

There are two main types of gas meters, viz., wet meters and dry meters. A wet gas meter has a strong iron case containing water, which is normally at a definite level called the "water line." Inside the case is a rotary drum divided into compartments and mounted on a horizontal spindle geared to a vertical spindle operating the registering train. The drum is rotated by the unbalanced elastic pressure of the gas admitted to each compartment in turn on the surface of the water. After leaving the drum, the gas passes to an outlet pipe which delivers it to the burners. In order to maintain the level of the water, when loss occurs through evaporation or other causes, most wet meters are provided with means for automatically making good the loss; these are called compensating meters. In most of them, the water to make good the loss is delivered from a water reservoir within the meter case and communicating with the main body of water.

Dry Meters.—In an ordinary dry gas meter, the upper part of the meter case forms the registering chamber in which are situated the registering train and the valve box, which is shut off from the registering chamber and contains gas inlet and gas outlet valves. The registering chamber is separated by a horizontal partition from a lower and larger chamber, which is divided by a vertical partition into two equal chambers. In each of these a bellows of concertina shape, with flexible leather sides, works to and fro horizontally; the vertical partition forms the

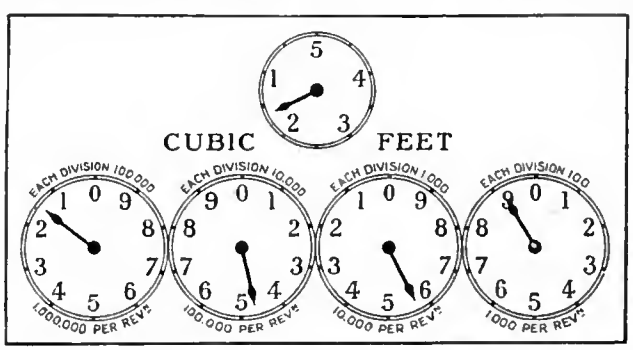

FIG. 1.—Diagram illustrating the registering dials of a 10-light dry gas meter.

fixed base of each bellows. Arrangements of levers and cranks transmit the motions of the bellows to the valves in the valve box and also to the registering train. When the meter is in operation, gas from the main supply pipe enters one of the bellows and inflates it, while the gas in the corresponding chamber is expelled through a delivery pipe to the burners; at the same time, gas is being expelled from the other bellows by the pressure of gas admitted into its bellows chamber. Working in this way, the meter supplies gas continuously to the burners, and the valves in the valve box are opened and closed at the proper times required by the flow of the gas. At the same time the registering train is operated continuously.

Automatic or Prepayment Meters.—Prepayment gas meters are fitted with a box containing mechanism which operates when a coin is passed through a slot in the box and controls the supply of gas to the meter. The value of the inserted coin or token determines the automatic cutting-off of the gas supply.

Reading a gas meter is a simple operation. Fig. 1 represents the registering dials of a 10-light dry gas meter. The registering train is geared so that the hundreds pointer revolves 10 times while the thousands pointer revolves once, the thousands pointer revolves 10 times while the tens of thousands pointer revolves once, and so on; also, adjacent pointers revolve in opposite directions. Starting from right to left, the figure last passed by the hundreds of thousands pointer in its revolution is written down and the same procedure is followed for the tens of thousands, the thousands and the hundreds pointers in succession; thus the reading in fig. 1 is 1,459 hundreds. Assuming that this was the reading at Michaelmas and that 1,356 hundreds was the reading at the preceding Midsummer, then the amount of gas consumed during the summer quarter would be 145,900 minus 135,600 or 10,300 cubic feet.

The small upper dial is not usually read. It records the flow of small quantities of gas and can therefore be used for ascertaining whether all pipes and gas fittings are gas-tight, or what amount of gas is consumed by any of the burners. (T. E. L.)

METHODISM (*see* 18.293).—The official returns of world-wide Methodism presented to the oecumenical conference at Toronto in 1911 showed that there were 55,808 ministers; 98,121 lay preachers; 8,768,616 church members; 99,497 churches, worth over 100 million sterling; 90,124 Sunday schools, with 898,722 officers and teachers and 8,273,809 scholars. The detailed table below shows the position in 1925.

The numerical strength of Methodism is not to be gauged by the number of members. To the members must be added a very large body of communicants and worshippers. About 10% of the population of Great Britain are Methodists. In Canada Methodists are 11% of the population; in Australia, 12%; in New Zealand 6%; in South Africa, including Rhodesia, 7%; and in the United States, 20%.

I. IN GREAT BRITAIN

British Methodism has faced with courage and with a large measure of success the new problems of the 20th century. It has consolidated its sections and, in addition to its ordinary routine of work, has given special attention to three great issues—the reunion of Methodism, temperance reform and foreign missionary enterprise.

At least 450,000 officers and men of the Wesleyan, the Primitive, and the United Methodists fought in the World War, of whom 40,000 fell. Methodism cared for its people and materially assisted its members by its war emergency and sustenation funds, for augmenting ministerial allowances and helping circuits suffering from the higher cost of living. In spite of the serious effect which the War has had upon the spending power of the people, the incomes of the Methodist church funds have largely increased. In all the churches the salaries of the ministers have been considerably advanced. There are no unemployed Methodist preachers, and no dearth for candidates for the ministry.

Missions.—The British Foreign Missionary Societies working under the direction of the three Methodist Conferences also have a record of expansion and success. The Wesleyan Missionary Society has erected and equipped 12 colleges with 5,031 students, and also 36 high schools with 6,068 scholars, in addition to 16 theological and normal training institutions for native preachers. Important Medical, agricultural and industrial hospitals and schools have also been established in West Africa, South India and China. These societies work in close co-operation with other branches of Christendom by adopting the apportionment of regions of missionary enterprise. They develop a missionary

spirit among the native Christians and the creation of a native ministry. Thus, there is a large number of native preachers and generous financial support is given to their missions by the native churches. In 1913 the Wesleyan Missionary Society held its centenary and raised £280,000 as a special fund for development. The women's auxiliary of the society has largely increased, and a plan is being developed for realising closer co-operation with the parent society.

Educational and Social.—The decline in the number of Sunday school teachers and scholars has given serious concern to the conferences. Efforts have therefore been made to increase the efficiency and the attractiveness of the Sunday schools, the work of which is not limited to Sunday, nor to school methods. The boy scouts, girl guides and life brigade movements, summer schools and Bible study circles supplement the work of the Sunday schools. The Wesley Guild and Christian Endeavour societies in British Methodism, and the Epworth League in America are doing much to consolidate the work among young people.

The Wesleyan Church has largely transferred its day schools to the county education authorities under the Acts of 1870 and 1902, and has now only 392 day school departments, with 32,847 scholars. But the same Church has largely developed its higher and secondary educational work. The two Wesleyan training colleges for teachers—for men at Westminster and for women at Southlands (Battersea) have attained a very high standard of efficiency. An increasing number of the students take university degrees. The teachers thus trained hold many of the most important posts as headmasters and mistresses in the London and provincial day and secondary schools and also in the British Dominions.

In addition to a number of important educational institutions, the three British Methodist Churches have six theological colleges for training candidates for the ministry, which are being more and more brought into line with the curriculum of the various universities. In 1926 Oxford celebrated the bi-centenary of the election of John Wesley to a fellowship of Lincoln College, and, to honour the occasion, conferred the degree of Doctor of Divinity upon the Rev. John H. Ritson, the president of the mother conference, a scholar and graduate of Balliol College, and the first Oxford man elected to the chair of John Wesley.

Another department of British Methodism is its home missionary work in the villages and city centres. Wesleyan Methodism has its connectional and lay evangelists. Open air evangelistic services are regularly held, and in many places the theatres and public halls are utilised for extra services. New central halls take the place of down-town churches. The London Mission of Wesleyan Methodism is doing a great work at Westminster, Kingsway, Clerkenwell and other centres. Primitive Methodists have four halls in the poorest parts of London, the principal ones being in Whitechapel and Southwark.

The British Methodist churches have been impressed with the economic and social results which have followed prohibition (*q.v.*) in the United States. Each of the sections has an active temperance and social welfare department. In 1920 the Wesleyan Conference declared that the sale of intoxicating liquors as a beverage was "definitely opposed to the best interests of the State and to the Kingdom of God," and recommended the Methodists everywhere to work and pray for the total and permanent prohibition of the common manufacture and sale of alcoholic drinks. The three Churches have adopted a progressive temperance policy—first of local option, secondly, the complete extension of magisterial licensing authority to all political and social clubs, rich and poor alike; and, thirdly, the entire Sunday closing of all drinking bars in England and Wales.

The Methodist Brotherhood works in unison with the Dominion agents in London, who assist emigrants to the United States, Canada, Australia and South Africa, arrange their passages, and secure them employment. The Brotherhood embraces all Methodist churches, and it has met with conspicuous success in assisting the Methodist emigrant and maintaining his association with Methodism in his new country.

Methodist Union.—Methodist union transcends in importance all other movements in Methodism at the present time, and it is probably fraught with more momentous issues to the churches concerned than anything since the death of Wesley. A great impetus was given to this movement by the decennial gatherings of the Methodist Oecumenical Conference, which, instituted in 1881, meets alternately in London and America. It consists of 600 delegates from all parts of the world, half of whom are ministers and half laymen. Each assembly has been followed by some decisive step forward along the path of union, and in all cases the ministry has loyally accepted the decisions of the majority. The results of union have far exceeded the anticipations of the churches, and there has been a great increase in the membership and financial resources.

In 1913, the Wesleyan Methodist Conference appointed a committee to collect information on the subject of union and to report to the next Conference. A final scheme of union was submitted to the yearly conferences of the three Churches in 1925 and was adopted by a very large majority. The scheme, which has presented no serious difficulties, will be again presented to the three conferences of 1926 together with the drafts of the proposed Parliamentary Enabling Act of Union and of the proposed Chapel Model Deed of the new United Methodist Church of Great Britain. If these are approved an application will be made to Parliament, and there is every prospect of the union of the three Churches in one British Methodist Church being effected in 1928.

II. IN AMERICA

The noteworthy changes in American Methodism since 1909 include (1) the steady growth of all its major branches; (2) movements toward the organic union of various units within the Methodist group and with other evangelical churches; and (3) educational advances resulting in liberalising tendencies in theology, a higher appreciation of non-Christian religious groups with a consequent new approach to the problem of world evangelisation, the further democratisation of Episcopal Methodist Churches and an increasing zeal for social justice, interracial understanding and the application of the teachings of Jesus to all human relationships and affairs, in politics and sociology as well as to purely personal conduct and belief.

Church Union.—The year 1925 saw the consummation of the Union of the Methodist, Presbyterian and Congregational Churches of Canada in the United Church of Canada. The Methodist Church, as the largest of the three denominational units, went into the United Church with 100% of its constituency, which at the time of the merger included 2,475 ministers, 1,946 lay preachers, 414,047 members, 451,636 church-school pupils, with 43,333 officers and teachers. In the United States a plan for the organic reunion of the Methodist Episcopal Church and the Methodist Episcopal Church South failed (1925) by a narrow margin of the combined votes of lay and ministerial members of the southern church. The vote in the Methodist Episcopal Church at the same time was overwhelmingly in favour of the union. The vote of the Methodist Episcopal Church South, while rejecting the specific plan submitted, did not close the issue, which was to be considered again at the next session of the respective General Conferences of the two bodies. In Great Britain the union of the Wesleyan Methodists, the Primitive Methodists and the United Methodist Church was also nearing its consummation.

Educational Advances.—The educational advances to which must be attributed certain tendencies already summarised include the following (1) an increase, commensurate with the growth in church membership of, in the number, enrolment and financial support of secondary schools and colleges; (2) a rapid rise, especially in the United States, from the previous low average educational preparation and professional training of ministers, together with a corresponding advance in the curriculum standards for collegiate and theological institutions; (3) increasing attention to religious education through the church-school with the extension of the programme of religious education to include week-day instruction; (4) the widespread distribution and use of religious-educational literature in text-book and periodical form, the total regular circulation of which exceeds the combined total membership of all Methodist Churches.

Episcopal Methodist Churches.—The coloured Methodist Episcopal Church, an offshoot from the Methodist Episcopal Church South, leads all branches of Episcopal Methodism with increases of over 60% in membership and over 100% in church-school enrolment in 15 years. The Methodist Episcopal Church in 1916 adopted the Episcopal area system with a flexible limit on the residence of a bishop in any one area. A World Service Commission since 1924 acts as an overhead co-ordinating agency for all benevolent boards. The educational activities of the Church have been consolidated in one board of education with separate departments for colleges, negro education, church-schools and the Epworth League. During 1920–5 the centenary of the organisation of the foreign missionary enterprise was celebrated by Episcopal Methodist Churches, notably the Methodist Episcopal Church and the Methodist Episcopal Church South, by a five-year financial campaign, which has quadrupled the annual missionary offerings of the participating churches.

METROLOGY: *see* MEASUREMENTS.

MEUSE-ARGONNE: *see* VICTORY, ADVANCE TO.

MEXICO (*see* 18.317), a federal republic of North America, has an area of 767,198 square miles. In 1912 the estimated population was 15,501,684, of which about 20% were whites. Political disturbances have resulted in a movement towards the cities for safety, and across the frontiers for employment and political asylum. This is reflected in the 1921 census, which gave a population of 14,234,852. The population of Mexico City, the federal capital, was 633,367; Guadalajara, 119,468; Puebla, 96,121; San Luis Potosí, 85,000; Monterey, 85,000; Vera Cruz, 48,633.

I. POLITICAL HISTORY

On Sept. 27 1910 Porfirio Diaz was re-elected president for a seventh term. The closing years of his rule were marked by economic depression, crop failures, excessive importation of foodstuffs and political restlessness, ill-concealed by the festivities of the Centennial of Independence. Since 1908 various political activities had indicated a demand for a change in the presidential office. Conspicuous in this demand was Francisco I. Madero, who supported a nationalistic programme. His *sucesion presidencial en 1910* attacked the administration mildly; but as his adherents increased in number, he became more outspoken. He was arrested on charges of sedition and was imprisoned at San Luis Potosí. Escaping to San Antonio, Texas, he issued the *Plano de San Luis Potosí* demanding electoral reforms, division of agrarian property and the resignation of Diaz.

Armed revolt was planned for Nov. 20 1910, but there were numerous premature outbreaks. Against these a reign of terror was initiated, but resistance spread. By Dec. there was armed revolt in a dozen states. Diaz attempted to meet disaffection by promises and belated reforms. After minor reverses the northern rebels took Ciudad Juarez May 10 1911, thereby showing the military impotence of Diaz. This success, with others at Pachuca and Cuernavaca, induced Diaz to assent to the demand for his resignation. It was agreed that Francisco de la Barra should assume a provisional presidency and call a new election. Diaz resigned May 25, and left the country next day. On June 7 Madero entered Mexico City in triumph. He really controlled the country, De la Barra having scant power. The ensuing election resulted in an overwhelming majority for Madero, who was inaugurated as president on Nov. 6 for a term to end Nov. 30 1916. He soon found himself opposed by reactionary politicians, several of whom he had appointed to his Cabinet. His government was characterised by neglect of the demands of the revolution, by financial blunders, by quarrels with State governors, and by weakness towards the opposition. Revolt by former supporters began at the time of his inauguration. Emiliano Zapatas in Morelos, Bernardo Reyes in the north, Pascual Orozco in Chihuahua, and other rebels were in the field. In the fighting, many foreigners were killed. Conditions were chaotic in 1912. On March 14 President Taft prohibited shipment of arms to Madero's opponents. Americans, advised to leave the country, departed by thousands. The north generally was in anti-Government hands.

Huerta Seizes Executive Power.—On Oct. 12 Felix Diaz revolted in Vera Cruz; he was captured and was confined in Mexico City. On Feb. 9 1913 he and Reyes (who also had been imprisoned) were set free by disaffected soldiers. Gen. Victoriano Huerta, head of the Government troops, turned traitor and imprisoned Madero and Pino Suarez, forcing them to resign. Huerta on Feb. 19 seized the executive power through constitutional forms. Three days later Madero and Pino Suarez were executed. President Wilson rebuffed Huerta's efforts to obtain recognition, believing that he did not represent the will of the people, and that he was responsible for the political executions; President Wilson demanded a general election in which Huerta should not be a candidate. The demand was rejected. On Oct. 10 Huerta seized the legislative and judicial power, arresting 110 members of Congress for inquiring into the mysterious death of Senator Belisario Domingues, who had harshly criticised him.

Meantime revolt, led by Governor Venustiano Carranza of Coahuila, appeared in both the north and the south. In the *Plano de Guadalupe* the rebels declared Huerta a usurper. They won numerous successes, among them the capture of Torreon in March 1914. Following the outbreak of revolution, American war vessels had been observing events in Mexican harbours. At Tampico a boat's crew from the "Dolphin" were arrested on a military reserve. The American commander demanded a salute to his flag for the incident and was supported by President Wilson. Huerta refused unless the Mexican flag were similarly saluted, and the Americans seized Vera Cruz on April 21. Huerta had been embarrassed by the mission of John Lind, whom Wilson sent as a personal representative to induce Huerta to assent to his own elimination. Though unable to effect foreign loans or to make peace with the Carranzistas, and in spite of advice by the foreign diplomats to yield to Wilson, Huerta ended diplomatic relations with the United States on April 22. Argentina, Brazil and Chile proffered their good offices; representatives of these nations met representatives of Huerta and the United States (Carranza holding aloof) in conferences at Niagara Falls, Canada, but the representatives failed to agree on a provisional president. Huerta was finally forced to resign July 15 1914, and was succeeded by Francisco Carbajal, who held office less than a month.

Carranza, though he did not support the Zapata programme, and quarrelled with Villa, still headed the Constitutionalists; after obtaining control of the capital, he set in motion plans for a presidential election. He was unable to control the generals summoned to a nominating convention, and they moved from Mexico City to Aguascalientes, where they nominated Gen. Gutierrez, an adherent of Villa, as provisional president. Villa drove Carranza out of the capital, the latter occupying Vera Cruz as the Americans evacuated that port Nov. 23. Villa and Zapata alternated in control of Mexico City and no fewer than four factions claimed the executive power in 1915. In that year Villa, who had shown strength in the north, was defeated by

Gen. A. Obregon. A conference of Argentina, Brazil, Chile and other American Powers, seeking to stabilise the situation on Oct. 10, recognised Carranza as *de facto* president.

Villistas Murder Americans.—Villa ignored the settlement, and on Jan. 10 1916 a band of his adherents assassinated 18 Americans taken from a train near Santa Ysabel. On March 9 he raided Columbus, N.M., killing 17 Americans. A punitive expedition of 12,000 United States troops, led by Gen. Pershing, invaded Mexico. It penetrated to the vicinity of Parral, but failed to capture Villa, who was reported dead. Carranza had grudgingly acquiesced in the invasion, but now protested, stating that the movement of American troops in any direction other than northward would provoke attack. On June 20 American negro cavalrymen moving eastward were attacked at Carrizal; several were killed and about a score were captured, but were released upon a sharp demand by the United States. The expedition was finally withdrawn Feb. 5 1917. In Sept. a commission attempted to make an agreement for policing the international line, but failed because Carranza denied the right of the United States to pursue raiders into Mexican territory.

In 1917 a new constitution was proclaimed. It incorporated in Art. 27 the principle of nationalisation of subsoil resources, chiefly as a means of controlling the petroleum industry. Decrees attempting to force the oil companies to observe the constitution were protested by foreign powers as confiscatory and subversive of rights acquired under the prior constitution of 1857. During 1919 the controversy was bitter. The companies, threatening cessation of production, forced Carranza in Jan. 1920 to concede the privilege of operating without compliance with the decrees but without prejudice to the final adjudication of the difficulty.

During 1919 rebel activities against Carranza were widespread, and many acts of violence were committed against foreigners and Mexicans by both Government and rebel partisans. A conspicuous case was the abduction for ransom of W. O. Jenkins, U.S. consular agent at Puebla, Oct. 19. He was alleged by the Mexican Govt. to have been implicated in his own abduction, but was released Dec. 5 1920. During the World War Mexico's "rigid neutrality" was highly pro-German. The famous Zimmermann note, by which Germany tried to align Japan and Mexico against the United States, was intercepted and published in March 1917.

Obregon Elected President.—The presidential campaign began in 1919, Carranza's power then reaching its zenith and afterwards rapidly declining. There was corruption in the army, banditry throughout the country and non-enforcement of the constitution Amid widespread unrest two generals, A. Obregon and P. Gonzales, conducted presidential campaigns, while Carranza supported a civilian candidate I. Bonillas, who had been Mexican minister to Washington. When Carranza's efforts to control state administration for the election of Bonillas led him to attempt a military invasion of Sonora, the home of Obregon, armed revolt broke out. On April 9 that State declared its secession until it could be assured of its sovereignty. The defection spread quickly through the north and west. By the end of the month Carranza was isolated in Mexico City. Adolfo de la Huerta was set up by the rebels as provisional president. Carranza attempted to move his Government to Vera Cruz, but his trains were broken up, and when he left them to make his way over the mountains to a Gulf port, he was murdered on May 21 at Tlaxcalantongo. Obregon entered the capital May 8. On May 25 de la Huerta was made substitute president for the unexpired term by the reassembled Congress. In Sept. Obregon was elected president with only nominal opposition. His inauguration Dec. 1 1920 was attended by large delegations from the United States, but by no one representing the Government though many Latin-American and European diplomats were present. Recognition by the United States was delayed by the non-solution of the petroleum controversy and the general spirit of labour unrest.

The distinguishing features of Obregon's presidency were his efforts to obtain recognition and to carry out the revolutionary programme. The two policies were in direct antagonism at many points. The Association for the Protection of American Rights in Mexico demanded that American vested interests, menaced by the new constitution and subsidiary legislation, be protected by a special treaty. The demand was grounded on the realisation that congressional legislation was subject to reversal and that the decisions of the Supreme Court were more in accordance with political exigency than with the principles of jurisprudence. The Obregon Govt. remained firm in its determination to do everything compatible with national integrity to restore harmonious relations, but refused to enter into the proposed treaty. In pursuance of this policy Obregon on July 13 1921 invited the European nations having claims against Mexico to send representatives to a permanent Mexican Claims Commission. This invitation was accepted in Nov. by France, Great Britain, Italy, Spain and the Netherlands. In Sept. of the same year negotiations were begun with a committee of international bankers looking toward a refunding of the national debt.

In June 1921 the U.S. Secretary of State (Hughes) described the fundamental issue as resting on a construction of the confiscatory enactments, which would declare that recognised American property titles must not be invalidated. The decision of the Mexican Supreme Court in 1922 that Art. 27 was not to be construed retroactively, paved the way for a presidential decree to the same effect. Secretary Hughes announced an informal commission composed of Charles B. Warren and John B. Payne, to confer with Ramon Ross and Fernando Gonzales Roa concerning agreements preliminary to recognition. The conferences, begun May 14 1923, were facilitated by promulgation, on April 26 preceding, of a new petroleum law recognising the validity of concessions made prior to May 1 1917, although it required concessionaires to revalidate their claims within three years. Elimination of land difficulties was attempted by legislation increasing the size of individual holdings exempt from partition, and relieving from expropriation large irrigation companies with colonisation contracts. But the provision that land expropriated should be paid for in bonds threatened a deadlock. The Mexican position was weak on this point, as the old legislation had prescribed compensation prior to expropriation.

Despite all difficulties, however, the commission reached a final agreement on Aug. 15. By its terms subsoil mineral rights acquired and developed before May 1 1917 were recognised as valid, and the provisions of Art. 27 of the Mexican Constitution, it was agreed, should apply only to later acquisitions. American properties expropriated by the Mexican Govt. in carrying out its agrarian policy were to be paid for at their equitable value. The U.S. Govt. reserved all rights to which it was entitled under international law in respect of titles acquired by its nationals before May 1917 to properties which were supposed to be petroleum yielding but which had not been developed and proved. Provision was also made for a Special Claims Commission for the settlement of American claims created since 1910, and a General Claims Commission for settlement of American and Mexican claims since 1868. The conventions calling for these commissions were ratified in Feb. 1924. The special commission was composed of Ernest B. Perry, Fernando Gonzales Roa and Dr. Rodrigo Octavio of Brazil, and the general commission of Nathan L. Miller, Aquiles Elurduy and Dr. Cornelis van Vollenhoven of Holland. The special commission held preliminary meetings in Mexico City in Jan. 1925, but postponed regular sessions until September. Claims must be presented before it within two years from the date of its first meeting, with a possible grace of six months. The general commission held preliminary meetings in Washington in 1924. Claims were admissible before it within one year, with six months' possible grace. Following the agreement upon these conventions, the United States extended formal recognition to Mexico, Aug. 31 1923. France shortly followed suit, Great Britain showing reluctance because of the indefinite status of her oil interests.

Papal Delegate Expelled.—The general plan for refunding the Mexican debt, agreed upon in Paris in April 1922, was concluded in New York in May by Secretary of the Treasury Adolfo de la Huerta and the bankers' committee. Mexican rebels, headed by Felix Diaz, made unavailing efforts to prevent consummation of the debt agreement. Mexico assumed full obliga-

tion for all the foreign debt principal, about $500,000,000, for some $200,000,000 interest, and for certain internal debts held outside Mexico. Payments were to begin Jan. 2 1923.

The bandit Villa, who had been bought off by the Provisional Govt. in 1920, was assassinated in 1923. Another outstanding incident of the year was the expulsion of the papal delegate Mgr. Filippi, who had incurred the displeasure of the Government by assisting at the open-air dedication of a shrine at Cubilete Tuanajuato. Open-air religious exercises were prohibited by a State law, though the dedication took place on private property. The episode evoked protest from the Vatican and from Catholic societies throughout Mexico and the American continent.

Preliminary manoeuvring in anticipation of the presidential election set for July 6 1924 began in 1923. The president is constitutionally barred from succeeding himself, and there had been a "gentlemen's agreement" by the Sonora triumvirate, de la Huerta, Obregon and Calles, that Calles should succeed Obregon. Nevertheless there was decided opposition to this programme in the Co-operatist party, which had been formed by the triumvirate and had a majority in the Chamber of Deputies. On Sept. 24 de la Huerta, possessing wide prestige because of the success of his financial negotiations, resigned from the Cabinet to conduct a campaign on his own behalf. Meanwhile Calles, as the friend of Obregon, was canvassing for the Co-operatist nomination. This, however, went to de la Huerta, on a programme promising the extension of Co-operatist ideas in industry, prior indemnification of landholders for expropriations, and guarantees of municipal autonomy. Calles, disappointed at not receiving the Co-operatist nomination, was put forward by the radical National Agrarians, pledged to carry out their programme and protect the rights of labour. The campaign became exciting when Obregon and the new Minister of Finance, Alberto Pani, accused de la Huerta of extravagance in office and of misrepresentation concerning arrangements whereby a bank of issue was to have been created and a loan secured. Recriminations were mutual. The de la Huerta faction alleged that Co-operatist adherents in Congress were menaced with massacre by troops under Gen. Arnulfo Gomez. Meantime the state elections, coloured by the national campaign, caused numerous frays.

On Dec. 5 the de la Huerta movement resorted to a plan of campaign called the *Plano de Vera Cruz*. The military forces of five States rebelled under the leadership of generals Estrada and Guadalupe Sanchez. At least six additional States speedily joined the movement, the conservative elements, the labourites and the agrarians generally supporting de la Huerta. Obregon took the field, conducting a campaign on three fronts. Rebel successes soon showed that the Government was in a precarious condition. Its chief weakness was lack of war materials, of which Mexico produces none. Application was made to the U.S. Govt. for the purchase of arms, munitions, airplanes and war vessels. Arms, munitions and airplanes were supplied. President Coolidge by proclamation forbade export of arms to the rebels, and their attempts at blockading and mining ports were in Jan. 1925 forbidden under threats of naval action. American assistance thus turned the tide. During the closing days of Dec. Government forces had retaken Puebla and driven back the opposition lines which had been concentrating on the capital. During Jan. honours were even, but in Feb. large hostile areas were retaken by the Government. Several rebel armies dispersed and their leaders sought refuge in exile.

The direct intervention of the United States was given in this case because of the recent recognition and a desire to protect the visible agency of the international agreements. The stand of the American Govt. was justified by Secretary Hughes on the ground that it protected constitutional procedure; he added that it must not be held to constitute a precedent, as every instance of intervention must be decided by its individual circumstances. It was in all essential aspects a continuation of the policy initiated by Woodrow Wilson in 1913. The Aguila (British) oil interests were accused by Obregon of assisting de la Huerta; on the other hand, E. L. Doheny, an American oil prospector, announced that he had advanced a loan of $5,000,000 to Obregon.

Election of Calles.—In the presidential elections Calles emerged successful. His Conservative opponent, Gen. Angel Flores, who fell ill during the campaign, received relatively few votes. Rumours of his prospective rebellion were not realised. The announced programme of Calles was to obtain for Mexico the economic and social advantages enjoyed by the American people. From the time of the inauguration of Obregon the labour situation had been steadily growing worse, but a firmer attitude toward labour was seen when Calles federalised the railway service, reducing the likelihood of strikes. Recurrent street railway strikes in Mexico City had marked the rule of Obregon; the first of them to occur under the presidency of Calles demonstrated the precarious position of capital under the existing strike legislation.

During the spring of 1925 Calles ruled illegal a strike by the Tampico Federation of Labour Unions, whose members were employed by the Huasteca Petroleum Co., because the difficulty was between unions, not between employers and labour. Firm presidential action prevented a national sympathetic strike. The Union of Bank Clerks in May 1925 made such demands on the banks that they threatened to close their doors. The Labour leader, Luis Morones, refused to support the Union. The Labour party under the leadership of Morones definitely split with the Agrarian party in May because the Labourites declared that the Agrarian programme was injuring not only agriculture but business and industry as well, and hence the labouring people.

Church and State.—The hostility to the Roman Catholic Church became evident with the promulgation of the constitution of 1917. During 1925 a separatist movement by means of an organisation known as the Mexican Apostolic Church was attempted. During March Separatists and Catholics came into conflict in Guadalajara, Aguascalientes and Queretaro. In Mexico City the Separatists seized the church of La Soledad and ejected its priest. Calles declared the act unconstitutional, but closed the church to worship and declared the Catholic parishioners rebels. Foreign priests were debarred, March 19, from preaching in Mexican churches. Numerous churches were closed because of disorders. The constitution provided that ministers practising religion must be of Mexican birth, and limited the parishioners of each to 1,000.

The troubles between church and state were accentuated by events in 1926. On May 15, George Caruana, the papal delegate, was ordered to leave the country, and on July 3, the Government issued a decree to enforce and strengthen the orders against the clericals. Heavy penalties were specified for any infringement of the regulations. Many Roman Catholics declared their intention to resist and Pope Pius XI. declared Aug. 1 1926 as a day of prayer for intervention in Mexican affairs.

Conditions on the American border, never satisfactory, grew worse after the passage of the law limiting immigration into the United States. In May 1925 a treaty was negotiated covering smuggling of drugs and aliens, migration, deportation, hunting, fishing, and health problems. The terms facilitated the disposal of American undesirables who had infested the Mexican side of the boundary. The treaty controlled also the movement of labourers into the United States. It was estimated that 500,000 Mexicans entered California in 1924.

Public interest was aroused in June by the declaration of Secretary of State Kellogg, made public through the Press, that conditions in Mexico were not entirely satisfactory, and that the United States would support the Government of Mexico only so long as it protected American lives and rights and complied with its international obligations. The statement referred to seizures of American property at the unreasonable demand of Labourites, and was felt in some quarters to have been inspired by friends of Calles himself in order to strengthen his hand against the demands of his radical supporters. The unusual character of this announcement called to public attention the existence of a new treaty between Japan and Mexico which permits settlement of Japanese from California on the west Mexican coast, and concedes special status to Japanese vessels in Mexican waters. It also accentuated the fact that American diplomatic protests concerning land seizures had met with scant attention.

On Aug. 28 1925 relations with Great Britain, severed because of difficulties culminating in the assassination near Puebla of Mrs. Rosalie Evans, were resumed and accredited representatives were exchanged.

Defence.—Military service in the active army or in the National Guard is compulsory. The normal strength of the army has been settled at 50,000. A school for the training of aviators has been established and progress has been made towards organising an air force. The five gunboats, which comprised the Mexican navy, have been reinforced by the addition of a small coastal defence boat bought in 1924.

Education.—Government education in Mexico is compulsory and secular. In 1923 there were 14,231 primary schools with 1,187,407 pupils. A number of private schools conducted by religious societies of the Roman Catholic Church were obliged to close in 1926. In 1925 the National University in Mexico City, which was refounded in 1910, had a student body of more than 6,000. The expenditure on education in 1923 was $24,500,000.

II. ECONOMIC AND FINANCIAL HISTORY

Finance.—On July 1 1922 the public debt of 1,056,073,713 pesos (1 gold peso = $0.4985) included 583,280,887 pesos of pre-revolutionary debt and 473,692,826 pesos of post-revolutionary debt. Revenues and expenditures 1921–5 were, in pesos:—

	Revenues	Expenditures
1925 . . .	145,000,000[1]	143,199,686[1]
1924 . . .	289,959,500[1]	[2]
1923 . . .	278,110,300[1]	347,006,719[1]
1922 . . .	277,567,019	267,137,468
1921 . . .	279,832,932	258,312,774

[1] Estimated.

[2] No estimates of 1924 expenditures were published. The Federal Govt. derives its largest income, outside of petroleum production and mining, from import duties: second in importance is the stamp tax: and third, taxes collected in the Federal district and territories. The income tax was introduced in 1924 in face of marked and widespread opposition.

Production and Industry.—Mexico possesses 30,027,500 ac. of cultivated lands well suited for agriculture. The agrarian reforms, begun in 1915, whereby lands of large estates have been expropriated are responsible for a noticeable decrease in agricultural production. In April 1925 President Calles reaffirmed his campaign pronouncements on the agrarian and labour problems, asserting that land distribution would be continued legally, but that it must not move in advance of means of development. In Aug. 1925 it was announced that one-third of the Government's land division programme had been fulfilled. It was estimated that since 1915, 12,000,000 ac. had been given to small farmers. The grazing lands of the republic are estimated at 120,444,200 ac.; and forest lands at 43,933,200 acres. Estimates of chief crops of 1924 were: corn (maize), 106,293,000 bu.; wheat, 13,962,000 bu.; raw cane sugar, 186,964 short tons; cotton, 138,000 bales (of 478 lb. net). Other important crops are beans, coffee, tobacco and henequen. The census of 1923 showed livestock as follows: horses, 512,336 valued at $20,455,109; mules, 300,960, valued at $18,713,476; cattle, 2,363,427, valued at $95,622,494; sheep, 1,196,098, valued at $5,777,605; goats, 2,106,044, valued at $7,714,330. The decrease in livestock since the enumeration of 1902 was 60%.

Petroleum.—A new petroleum law, published July 20 1925, was pending before Congress during September. It had received presidential sanction as adequately interpretative of Art. 27 of the constitution. It gives the chief executive sole and complete authority to concede and regulate rights to explore for and exploit oil-fields; it confirms leases and concessions as well as titles perfected, if dated prior to May 1 1917. The petroleum industry is defined as a public utility, and the principle is reasserted that the nation exercises direct and permanent ownership of the subsoil.

The total production of petroleum from 1901–23 inclusive was 1,055,257,562 barrels valued at $828,241,710. The peak of production, attained in 1921, was 193,397,587 barrels, about 28% of the world production and worth $182,936,817. In 1922 there were produced 182,278,457 barrels, about 21% of the world production, worth $167,397,872; in 1923, 149,529,088 barrels worth $142,916,885, 14·7% of the world production; in 1924, 139,587,000 barrels, 13·8% of the world total. In 1923 Mexican production was second to that of the United States. Some 15,000 ac. were under exploitation. In May 1925 it was estimated that foreign investments in petroleum concerns totalled $350,000,000. Consistent progress was made in the exploitation of the petroleum-bearing areas, which are known to be more widely distributed than the present development would indicate. During the first 10 months of 1924, 247 new producing wells were brought in with an initial daily production of over 800,000 barrels. At the end of Oct. 1924 there were 1,016 producing wells, their initial daily production running more than 3,344,000 barrels. Most of the producing wells were in the Panuco fields. From Jan. 1 to March 25 1925 new wells numbered 74; their maximum daily production was 364,367 barrels, exceeding the amount produced by new wells during the first three months of 1924, which was 218,596 barrels. In March 1925 the petroleum companies agreed to an added tax of one cent per gallon on gasolene the proceeds from which, estimated at 8,000 pesos daily, are being applied to road construction.

Production of light and heavy crude oils for the first six months of 1925, totalling 65,369,987 barrels showed a decrease of 8,911,376 barrels from the corresponding period in 1924. All the loss was in heavy crude oil, the light crude oil showing an increase of 2,145,172 barrels. Continued salt-water intrusion in the Toteco holding of the Mexican Seaboard diminished their production in 1925; salt water also reduced production in the Cacalilao fields.

Mining.—There was marked resumption of mineral production in 1918 and 1919. Practically all the established mining companies operated continuously during 1924, some of them extending mining and milling facilities so as to increase production and improve metallurgical recoveries. Prospecting and development work increased, notably in Chihuahua, Sonora and Zacatecas. The de la Huerta revolt did not seriously interfere with the operation of established mines. Taxation continued upon the 1923 basis, being so high that the average mine paid as much in taxes as it produced in net profit. Freight rates were approximately 50% higher than those of 10 years earlier. Labour conditions were chaotic because of numerous State laws, and caused much misunderstanding between companies and employees. These conditions discouraged new mining investments, but good prices for lead and silver offset them, and earnings for 1924 were good. Productions of the chief minerals for 1922–4 was (in kgm.):—

	1924	1923	1922
Gold	24,647	24,162	23,276
Silver	2,844,104	2,824,599	2,521,832
Copper . . .	49,113,194	53,371,482	26,977,786
Lead	164,140,130	155,720,342	110,455,912
Zinc	18,936,336	18,481,271	6,141,937

Antimony, tin, tungsten and arsenic are produced in considerable quantities. For the first time in several years quicksilver was exported in June 1925; there was promise of continuous increase. The movement was of 600 kilos shipped from Tampico and produced by a cinnabar mine in Zacatecas. Numerous filings of claims in Chihuahua for gold and silver locations, reopening of old workings in the Santa Barbara district of that State, and the development of electrical power in Durango for mine operations, indicated in 1926 that mining prospects continued good, in spite of the political unrest.

Commerce and Industry.—Notwithstanding political and economic difficulties, trade showed gratifying stability. Mexico sold to the United States in the first 10 months of 1924 products to the value of $167,087,305, or 19·2% over the figures for 1923, and bought from the same source goods worth $135,076,703, an increase of the same percentage. Increased production of lead, copper and silver, with greater shipment of vegetables to Ameri-

can winter markets, permitted purchase of larger quantities of automotive vehicles, agricultural implements, mining machinery and railway equipment.

For the year ending June 30 1913 Mexican imports were $95,857,000, and exports $149,752,000. For 1921 they were respectively $178,775,221 and $203,273,450. Imports from the United States in 1921 were 74·6% of the total, and exports to the United States 88·3%. In 1923 Mexican exports of all classes were: animal products, $2,019,486; vegetable products, $32,782,061; minerals except petroleum, $80,213,217; petroleum $237,213,698; miscellaneous, $2,109,872. Petroleum constituted 67% of the total exports. Minerals reached 22·5%, constituting with petroleum 89·5% of the 1923 exports. Agricultural exports to the United States were 14% of the trade with that country, petroleum 38% and other mineral products 45%. Canadian exports to Mexico were in 1920, $410,825; in 1921, $1,086,197; in 1922, $1,197,597, and in 1923, $3,291,098, and in the year ending March 31 1925, $2,856,409. Imports from Great Britain, high in 1920 and 1921, dropped to pre-War level in 1922–3. The movement of trade has been steadily away from the Gulf ports towards towns on the American border, which in 1923 handled over 42% of the volume. There were 108 mills operating, employing 38,232 hands. The annual production of boots and shoes was over 700,000 pairs. In 1923, 235 sugar-mills produced 121,000 metric tons.

Labour.—Conditions in labour have been disturbed since the revolution began. Strikes and financial losses have been as follows:—

	No. of Strikes	No. of Strikers	Financial Loss	
			To Employers	To Employees
1922	197	63,000	$4,134,680	$2,983,610
1923	146	54,396	3,694,324	1,479,055
1924	138	29,244	4,627,385	1,805,191

Labour troubles at Vera Cruz caused the chambers of commerce to transfer their business to Tampico in Nov. 1924. In March 1925 a federation of land and sea workers, comprising 17 Vera Cruz unions affiliated with the Mexican Federation of Labour, gave up political activities and agreed not to strike without federation approval.

Communications.—In the de la Huerta revolt the railways in rebel hands were badly depleted in stock. In March 1924 an official report of the ownership of railways showed that the National Railways (51% of whose stock is held by the Government) had 13,205 km.; Government railways, 517 km.; private lines 7,529 kilometres. The total in operation was 21,251 km. or 13,197 miles. The Mexican Railway, a British concern, has 520 m. between Mexico City and Vera Cruz; it was in Government hands from 1916–20. The Tepic-La Quemada line of the Southern Pacific was completed April 1926. It connects Mexico City with Nogales. During 1925, 45,000 men were employed on the 100 m. of the road, 17 tunnels having been constructed before June. The new wireless station erected on the Island of Lobis, near the coast of Tampico, affords facilities to the petroleum companies to communicate with ships at sea. There are wireless stations at Mexico City, Tampico, Vera Cruz and on the Pacific Coast at Mazatlan.

(H. I. P.)

MEXICO CITY, capital and metropolis of the Republic of Mexico (*see* 18.344), had a population of 615,367 at the census of 1920 (271,056 males and 343,411 females) of whom 23,668 were foreign-born; estimate for 1924, 880,000. Between 1910 and 1925 several new residential suburbs (*colonias*) were created, which grew rapidly by the cutting up of adjacent estates (*haciendas*) into building lots; many squat buildings of colonial days in the business districts were replaced by sky-scrapers; new streets were cut; dirty squares were transformed into neat flower-decked plazas and the magnificent National Theatre begun in 1900 was partially completed, 12,000,000 pesos having been expended on it up to 1922. The Legislative Palace, however, was still unfinished in 1925, and was about to be torn down instead of completed. In 1923 the area of the city was about 15 sq. m., divided into eight sections (*cuarteles* or *demarcaciones*), and sub-divided further into about a thousand squares (*manzanas*). There were over 200 m. of tramways, and the tram service, furnished by an English company and managed by English and Canadians, was efficient. At different times the official names of many streets were changed, either to commemorate recent events and heroes, or in the interest of convenience; *e.g.*, all the streets in one section received names of trees and flowers, in another names of foreign cities, so that the character of the name of the street would give a general idea of its location.

Industry and Commerce.—Manufacturing, still relatively unimportant, was represented in 1925 by some 215 establishments, with an annual output valued at 10,000,000 pesos, and employing about 10,000 workers, most of whom were Indians and half-breeds (*mestizos*). The leading products were tiles, cigars and cigarettes, textiles, drugs and chemicals, oils and extracts, shoes and other articles of clothing, various articles of food, beer and other beverages, furniture, iron and steel, mosaics and jewelry. Of greater importance were trade and finance. In Mexico City are the headquarters of most of the business carried on in the country, and it is the principal distributing centre of the republic. Deposits in the banks on Oct. 31 1923 (64,278,894 pesos) were 53% of the total for the country. About 30% of all the imports into the republic are received in the capital. The annual sales of the commercial establishments of all kinds were estimated in 1925 at over 250,000,000 pesos. The textile industry was largely in French hands; hardware, cutlery, chemicals and drugs, in German hands; the oil and mining interests were chiefly English and American; banking, predominantly Canadian; retail trade, predominantly Spanish; but both banking and trade were shared by French, Spanish and Americans, and by 1925 there was a successful National Bank of Mexico. The National Railways of Mexico were returned to private management on Jan. 14 1926, under the so-called Pani-Lamont agreement.

Social Conditions.—An increasing number of automobiles, higher wages, and a decreasing number of bare feet, indicated some advance in prosperity; and a brighter outlook for public health was given by President Calles's firm support of clinics, dispensaries and similar improvements. But the general standard of living of the population was still very low; beggars were exceedingly numerous and very importunate; business was "nervous"; and foreign capital was not available in the amounts needed. The organisation of labour advanced rapidly after the foundation in 1918 of the *Confederacion Regional Obrera Mexicana* (usually referred to as "CROM") by L. N. Merones, an electrician, who became Secretary of Industry and Commerce in the Calles Administration. In the demonstration of May 1 1925, in Mexico City, 93 unions, with 100,000 members, took part.

By 1925 collective bargaining was the rule, and it was claimed that "CROM" had effected an increase in the average weekly wage from 50 centavos to 3 pesos.

Education, etc.—By the constitution of 1917 elementary education was made free, compulsory to the age of 15, and secular, but pending the provision of enough secular schools many of the old schools under religious auspices continued to function. The national university, which had been suspended for half a century, from the time of Maximilian, was re-opened in 1910. A summer school was established in 1922, designed especially to attract foreign students for the study of Spanish. The World War increased the interest of Mexicans in reading, and as a result several new periodicals, of a superior quality, were established in the city, which had the first printing press in the new world and the first regularly issued newspaper. Mexico City was the scene of riots during the revolutionary disturbances of 1910 and 1911. On June 7 1911, the day on which Madero made his triumphant entry into the city, there was a severe earthquake, which cost many lives. In Sept. 1921 the centennial of Mexican independence was celebrated with great pomp.

MEYER, EDUARD (1855–), German historian, was born at Hamburg Jan. 25 1855. He was educated at Bonn and Leipzig, where in 1879 he qualified in ancient history. He afterwards became professor of ancient history at Breslau (1885), Halle (1889) and Berlin (1902). Meyer realised the great importance of folklore, historical monuments and numismatics as aids to the study of ancient history, and the value of his original methods in treating the subject was recognised by the universities of Oxford, St. Andrews and Freiburg from which he received honorary degrees.

Meyer's principal works are: *Geschichte des alten Aegypten* (1887); *Forschungen zur alten Geschichte* (1892–9); *Wirtschaftliche Entwicklung des Altertums* (1895); *Die Entstehung des Judentums* (1896); *Zur Theorie und Methodik der Geschichte* (1902); *Geschichte des Altertums* (3rd. ed. 1909); *Caesars Monarchie und das Principat des Pompeius* (2nd ed. 1919); *Preussen und Athen* (1919); *Ursprung und Anfänge des Christentums* (3 vol. 1921–3).

MEYER, MARIE PAUL HYACINTHE (1840–1917), French philologist (*see* 18.340), died at St. Mandé, near Paris, Sept. 8 1917.

MEYERHOLD, VSEVOLOD EMILIEVICH (1873–), Russian theatrical producer, was born in Moscow and from 1898–1905 was well known as one of the most distinguished actors of the Moscow Art Theatre. He then began to produce plays, adopting a new convention in opposition to the "true-to-life" ideas of Stanislavsky, in which the actor and the stage setting presented a complete harmony. After the Revolution he carried these methods to an extreme, using no curtain and a bare stage with purely formal scenery. He managed the Revolutionary Theatre, Moscow, and also acquired a theatre of his own, and in both produced political propaganda plays. His views are set forth in his book, *The Theatre* (St. Petersburg, 1913).

MEYNELL, ALICE (1849–1922), British poetess. By her marriage in 1877 Alice Thompson became Alice Meynell. She had the fortune to find herself in that mid-Victorian era which still held freshly to its heritage from Keats and Shelley, from Wordsworth and Coleridge. It felt its heart torn by the griefs of the Brontës, stirred by their glories; and almost clung to the hand of Elizabeth Browning. Eagerly awaiting every recurring sign of Tennyson's fertility, it yet respected the long pause of Patmore; and took for its own the volumes of Dante and Christina Rosetti, warm from the press. With these two women of song, Elizabeth and Christina, Alice Meynell's name is now commonly tripled. But it was not they who moulded her thought or her expression. Her aloof independence was proof against all precedents; and of her prose it may be noted that, notwithstanding her love for Lamb and Landor, only the American, James Russell Lowell, is mentioned by her as in any way her master in style. She was her very own spiritual and intellectual self as both woman and writer. That was the secret of the singleness of her personal influence while she lived, and secures an enduring freshness and originality in the work she bequeathed.

Mistress Anne Killigrew had been told by Dryden "thy father was transfused into thy blood." That girls alike with boys, inherit from fathers as from mothers, was the theme of a verse where Alice Meynell, after the desolations of the European War, gave the comforting signal:—

> The crippled world! Come, then,
> Fathers of women with your honour in trust,
> Approve, accept, know them daughters of men,
> Now that your sons are dust.

Her own father, having left Cambridge and unsuccessfully contested two costly elections for Parliament as a free trader, became very much a citizen of the world. After his marriage with Christiana Jane Weller, a beautiful and accomplished girl to whom her adoring friend Charles Dickens fitly introduced him, he made his home much in Italy, devoting himself to the liberal learning of the two daughters: Elizabeth, the elder, afterwards Lady Butler, famous as a war painter; and Alice, who early began to put her rhymed thoughts shyly upon paper. Despite the affectionate appreciativeness that ruled her home (usually an English one) her composition remained mostly her own secret until an American friend, to whom they were confided, encouraged her to show, and then print, them.

The volume of *Preludes* was issued (for the girl what an association) by Tennyson's then publisher, Mr. Henry S. King, on the word of his "reader"—later his successor—Mr. C. Kegan Paul, who, not trusting his own judgment all the way, read some of them aloud to George Eliot, receiving her deciding approbation. The critics were mostly silent; and even those who praised hesitated. But the volume made its own quiet way, Ruskin in all ways first in his soaring praises: "The last verse of that perfectly heavenly 'Letter of a Girl to her own Old Age,' the whole of 'San Lorenzo's Mother,' and the end of the 'Sonnet to a Daisy,' are the finest things I have yet seen or felt in modern verse." Rossetti, too, spread the news of the young poet's advent, reciting "Renouncement" by heart to his friends, and saying that it was "one of the three finest sonnets ever written by women." Browning, having read a brief quotation buried in a halting press appreciation, "conceived the desire to read the rest for myself," and found its beauty "even beyond what the indifference of the reviewer should have prepared me for." The volume brought her many a friend—and more. For the reviewer in *The Pall Mall Gazette*—a paper to which she was later to be a conspicuous contributer—quoted the sonnet "My Heart shall be thy Garden," and found for it a reader whom it reached revealingly. A consequent introduction to the sonneteer by a common friend was followed by a marriage that fulfilled for him Crashaw's "heaven-on-earth" for 45 years.

On Mrs. Wilfred Meynell, as she then (1877) became, fell a long silence as a poet. The muse does not ordinarily leave cards on the happily and busily married; the domesticities and the "sweet sense of providing" are not the fashioners of those "sweetest songs" that breed from "saddest thoughts." Eight children were born, one of whom died in infancy: a grief that put into poetry the dread reminder that the giver of life is also the giver of death: "and she who slays is she who bears, who bears." A like sensitiveness to life's cruelties put her, for all her reticence, on political platforms, and marched her in multitudinous processions, in favour of the granting of votes to women and the opening of long closed professional doors. Compassion was the companion of all her walks abroad, for the over-burdened man and animal; for the beggar-woman to whom she cried with her gift, in Portuguese fashion, "Have patience, little saint"; for the underfed in London slums which she at one time sedulously visited; and for the beast in the shambles, in shame for whose martyrdom she refused to eat meat until, after persuasion, she sought by more impersonal methods to further laggard reforms.

Her married life matured her vigilance as a mistress of prose. In W. E. Henley of *The Scots Observer* and *The National Observer*, she encountered an editor who heartened her by his boisterous welcomes: "That woman's taking her place at the steering wheel" was one of his recorded acclaims. Later, in *The Pall Mall Gazette* of Harry Cust's editorship, she was accorded a

weekly column which left her a large range in the choice of subjects. George Meredith, reading here her "princely journalism," sought with her an acquaintance that soon became a "dearest friendship." In a magazine—those were still the days of the magazines—he spoke of her words as having the "living tremor in them," just as he had before said that Carinthia's had the "throb beneath them." Of her essays, he wrote: "The surprise coming on us from their combined grace of manner and sanity of thought is like one's dream of what the recognition of a new truth would be. They leave a sense of stilled singing on the mind they fill. The writing is limpid in its depths."

Coventry Patmore, too, her yet warmer admirer, published, when Tennyson died, his unavailing plea for her succession to the laureateship. Her close friendship for such seniors coincided with that for her contemporaries, and for her juniors, chief among whom was Francis Thompson, who addressed to her his exquisite sequence of poems *Love in Dian's Lap*, of which, Patmore said, Beatrice or Laura might have been proud. Of the homage paid to her, another chosen friend, J. L. Garvin, has well said: "Alice Meynell was in herself a person of her age, sure, as I think, of perpetual remembrance, even if half a dozen of her shining contemporaries had not competed in vain to spoil her with praise. It was what no one could do: recognition only made her humble." And these contemporary praises notwithstanding, G. K. Chesterton predicts: "She was deservedly famous; but I will venture to prophesy that her fullest fame is yet to come. The whole modern world must immeasurably enlarge itself before it comes near the measure of her mind." She died in London on Nov. 27 1922.

Alice Meynell's *Preludes* (1875), long out of print, re-appeared in a volume of *Poems* (1893) including new ones; and these, together with yet later verses separately issued as *A Father of Women* (1917) and *Last Poems* (1923), are all assembled in the complete volume of *Poems* (1923) now in circulation. Of her prose, several small volumes of essays in the eighteen-nineties—*The Rhythm of Life* (1893), *The Colour of Life* (1896) and *The Spirit of Place* (1899)—were followed by *Ceres' Runaway* (1909), by *Hearts of Controversy* (1917), by *The Second Person Singular* (1921) and finally by the standard volume of selected *Essays* (1914)—the selection being her own. Other books were *John Ruskin* (1900), *The Children of the Old Masters* (1903), *Mary, the Mother of Jesus* (1912) and *London Impressions* (1898). Two anthologies give her choice among poems—*The Flower of the Mind* (1897) and *The School of Poetry* (1923), the first including Notes and the second Commentaries. She prefaced editions of *The Sonnets from the Portuguese* and Christina Rossetti's *Poems* (1910), as well as a decade of volumes "The Red Letter Library"; she introduced in 1903 a volume of reproductions of Sargent's Portraits; and she made for English readers a Selection from the Poems of J. B. Tabb (1906).

BIBLIOGRAPHY.—Reference may also be made to the critical chapters concerning her in Alfred Noyes' *Some Aspects of Modern Poetry* (1924), in John Drinkwater's *The Muse in Council* (1925), and in Katherine Brégy's *The Poets' Chantry* (1912); as well as to such notable articles appearing at the time of her death as J. L. Garvin's in *The Observer*, J. C. Squire's in *The London Mercury* and G. K. Chesterton's in *The Dublin Review;* articles that quickened the desire for the authorised biography now (1926) in preparation.

(W. ME.)

MIAMI, Fla., U.S.A. (*see* 18.354), in the centre of the 200-m. strip of the "East Coast" which is dotted with winter resorts, was a focus of the rush to Florida which began about 1922. The population in 1910 was 4,571; in 1920, 29,571; in 1925, according to the state census, it was 69,754. In Sept., after annexations of territory, it was estimated at 100,000 within the corporate limits, and at 150,000 within six miles of the court-house. Between 1914 and 1924 bank deposits increased over 3,000%; post-office receipts and property valuation each over 600%; the value of buildings for which permits were issued, over 2,500%, and the total of such permits for 1924 was doubled in the first eight months of 1925.

At the opening of the winter of 1925–6 all kinds of shelter were at a premium, and tent colonies sprang up until they presented a serious sanitary problem. For the moment, speculation in land was the leading occupation (a third of the members of the Chamber of Commerce were dealers in real estate), but there were solid foundations for future prosperity. Though later in 1926, the value of land fell to some extent. The Federal Govt. had begun work on harbour improvements. Draining of the Everglades by the state was opening to agricultural settlers thousands of acres of rich swamp land, forty-five varied industrial plants were already in existence, and a sugar-mill and refinery were in operation 16 m. out on the Miami canal.

Miami Beach, across Biscayne Bay, one of the most luxurious winter playgrounds of the country, was a mangrove swamp in 1910. Coral Gables, a separately incorporated residential suburb adjoining Miami on the south, was developed in Spanish and Moorish architecture with six miles of Venetian waterways. This was created in a few years by the magic of immense investments of capital, modern engineering and far-sighted planning including a tract for the University of Miami, chartered April 5 1925 which had in view an endowment of $15,000,000.

MICA (*see* 18.355).—The three main contributors to the world's supply in order of importance are the United States, India and Canada. After the outbreak of the War the stoppage of the mica imports to Germany had a depressing effect on the mica industry; but, on the other hand, the large amount of mica required for munition purposes, gas-masks, etc., caused both the Allies and the United States to import increasing quantities of sheet mica from Argentina and Brazil. In the United States the mica mined is mainly muscovite, occurring as irregular masses, sheets and lenses in pegmatite veins traversing metamorphic rocks. The principal producing states are North Carolina and New Hampshire, but Virginia, South Dakota, Georgia, Alabama, Idaho and Colorado also produce considerable amounts.

The chief mining centres in India are the great Bihar mica belt, about 60 m. by 12 m., traversing the Menghyr, Hazaribagh and Gaya districts in the province of Bihar and Orissa; and the Nellore district in the Madras Presidency. Less important areas occur in Ajmer Merwara in Rajputana. The Canadian mica is almost entirely phlogopite. The deposits occur chiefly in Quebec to the north of Hull, and in the townships of North Burgess and Loughborough in Ontario.

The World's production figures in long tons for 1913, 1918 and 1923 were as follows:—

	1913	1918	1923
India (exports)	3,124	2,998	3,948
Canada	986	667	2,331
Other U.K. countries	118	51	127
United States (chiefly sales)	5,511	2,780	8,112
Madagascar	6	4	162
Argentina (exports)	6	169	100
Other foreign countries	10	190[1]	587[2]

[1] Including Brazil 112 tons.
[2] Including Japan 424 long tons.

(N. M. PE.)

MICHELSEN, PETER CHRISTIAN HERSLEB KJERSCHOW (1857–1925), Norwegian statesman, was born at Bergen March 15 1857, the son of a prominent merchant and shipowner. After completing a university education in 1879, Michelsen settled in Bergen as a lawyer and at the same time entered the shipping business in which he achieved considerable success. Known as an administrator, he entered the city council of Bergen and later the Storting where he took his seat in 1891 and quickly became one of the most prominent members. In 1894 he withdrew from politics, returned to Bergen, resumed his activity as a shipowner and re-entered the city council of which he became the chairman. The general elections in 1903 by which he returned to the Storting as a member for the country district outside Bergen initiated the crowning period in Michelsen's public career. Appointed Prime Minister in the spring of 1905 Michelsen played a leading part in the events which resulted in the dissolution of the union with Sweden and the establishment of the new kingdom of Norway. In 1907 he definitely retired from politics and died near Bergen June 20 1925.

MICHELSON, ALBERT ABRAHAM (1852–), American physicist, was born in Strelno, Germany, Dec. 19 1852. His parents moved to San Francisco, Cal., where he studied in the public schools. He graduated from the U.S. Naval Academy in 1873, and was instructor in physics and chemistry there during 1875–9. He was then for a short time in the *Nautical Almanac* office. From 1880 to 1882 he studied in Berlin, Heidelberg and Paris. He resigned from the navy in 1881. In 1883 he was appointed professor of physics at the Case school of applied science, Cleveland, O., and six years later accepted a similar position at Clark University. In 1892 he was appointed professor and head of the department of physics at the University of Chicago. He early directed his researches to the velocity of light, and while in Cleveland invented his interferometer (*see* 14.693), which enabled him to measure distances by means of the length of light-waves. His researches enabled him to revise and improve upon the achievements of Fizeau in respect of the velocity of light. He perfected the methods for experimenting, and determined the rate at which light travels, with an error not exceeding $\frac{1}{10}$ of 1% of the quantity measured. Through one of his experiments it was demonstrated that the speed of light is the absolute superior limit of the rate at which matter can move, because the mass of a body depends upon its velocity —mass diminishing as velocity increases—and a body would vanish completely if it exceeded the velocity of light.

Michelson measured a metre in terms of the wave-length of cadmium light for the Paris Bureau Internationale des Poids et Mésures. The consequence is that the metre bar, hitherto carefully safeguarded in Paris, can easily be replaced, since its length is known in terms of an absolute unit. In 1892 he was a member of the Bureau Internationale des Poids et Mésures and in 1897 of the International Committee of Weights and Measures. He was made president of the American Physical Society in 1901 and of the American Society for the Advancement of Science in 1910. He received medals and prizes from many learned societies, and in 1907 was awarded the Nobel Prize for physics. During the World War he rejoined the naval service and devoted his entire time to new devices for naval use. His range-finder was adopted as part of the U.S. Navy equipment. In 1920 he was able to demonstrate by means of light-interference that the diameter of Alpha Orionis was 260,000,000 miles. This was the first computation ever made of the size of a star. He was the author of *Velocity of Light* (1902); *Light Waves and Their Uses* (1903), and numerous papers contributed to scientific journals. In 1921 he was awarded the gold medal of the Society of Arts, London. (For the "Michelson-Morley experiment" in interference of light, with its bearing on the Einstein theory, *see* RELATIVITY.)

MICHIGAN (*see* 18.371).—The population of Michigan in 1920 was 3,668,412, an increase of 30·5% over 1910. The estimated population as of July 1 1926 was 4,395,651. Of the total population in 1920, 1,670,447 were of native parentage; 1,204,545 of foreign or mixed parentage; 726,635 were foreign-born and 60,082 were negroes. The following cities in 1920 had 50,000 inhabitants or over: Detroit (993,678); Flint (91,599); Grand Rapids (137,634); Lansing (57,327); and Saginaw (61,903). A special census of Detroit on May 31 1925 gave its population as 1,242,044 on that date.

Education.—In 1920 there were in the state 1,048,390 persons of school age, of whom 710,341 (67·8%) were attending school. The illiteracy rate was 3% in 1920 as against 3·3% in 1910. In many of the public schools vocational courses were added in recent years. At the institutions of higher education, attendance greatly increased. Some of the colleges with church connections shared in this growth; but the chief enlargement was at the University of Michigan (*see* MICHIGAN, UNIVERSITY OF) and the Michigan Agricultural College. To add to the facilities for higher education, "junior colleges" with curricula covering two years of college work, were established in Detroit, Grand Rapids, Muskegon, Pontiac and Highland Park, in connection with their secondary school systems.

Agriculture.—In 1925 there were 192,334 farms in Michigan, a decrease of 14,626 as compared with 1910. During the 15 years all farm land decreased from 18,940,614 ac. to 18,036,700. During the same period the average acreage per farm increased from 91·5 to 93·8. The average value of land and buildings per ac. in 1925 was $71.41. In 1925 a total of 9,671,670 ac. was under cultivation, on which crops valued at $268,674,000 were raised. The farming area of Michigan continues to be concentrated mainly in the southern part of the lower peninsula of the state. In the upper peninsula, farms comprise less than 10% of the land area. The area nominally in woodland, including farm woodlots as well as forests and cut-over lands, comprises nearly two-thirds of the state; but of this area not more than about 5,000,000 ac., nine-tenths of which lies in the upper peninsula, now bears timber worth cutting. Most of the rest has come to be stump lands, on which the recurrence of fires prevents any spontaneous reforestation. The barrenness of the sandy soil and the shortness of the growing season have hindered the reduction of land to cultivation, and some 10,000,000 ac. (more than one-fourth of the total surface of the state) are thus a deforested desert. Several thousand acres of it revert to the state each year in default of taxes. These reverted tracts, comprising 566,850 ac. in 1918, are administered by the Public Domain Commission (created in 1915) with a view to the sale of such as can be used as agricultural homesteads and to the setting aside of the rest as forest reserves. These forest reserves (648,000 ac. in 1923) are under state forest management for the prevention of fires and for systematic reforestation.

Minerals.—In mineral production no new resources of importance were developed during the period 1910–25. The mining of iron-ore continued vigorously, that produced in 1923 amounting to 14,069,938 tons. The production of copper was pushed to the fullest capacity during the World War; but the severe decline of the market after the Armistice caused a sharp reduction of output. The amount of copper produced in 1923 was 138,304,680 pounds.

Manufactures.—The manufactured products in 1923 were valued at $3,870,434,000, as compared with $685,109,000 in 1909, an increase of nearly 465%. This advance was mainly due to the extraordinary growth of the automobile industry and its concentration in the state. The value of automobiles manufactured increased from $7,996,534 in 1904 to $96,651,451 in 1909, and to $1,551,990,000 in 1923. In more recent years this industry has continued its rapid expansion. It is estimated that more than two-thirds of the automobiles manufactured in the United States are made in Michigan. The number of wage-earners engaged in the making of automobiles and their parts in 1914 was 67,538, constituting 24·9% of the total number of wage-earners in the state; these were increased to 149,296 in 1923, their proportion to the whole being 29·6%. Foundries and machine shops with an average number of 34,080 wage-earners in 1923 produced products to the value of $165,736,521. Furniture ranked next, with 20,665 wage-earners and products valued at $93,039,416. Other industries, including logging and sawmill operations, engines and water-wheels, paper and wood pulp,

substantially increased. Michigan led all other states in output of chemicals, drugs, engines, threshing-machines, furniture and refrigerators.

Finance.—In 1923 the assessed value of property in Michigan was $5,929,615,241, on which the state levied $25,880,702 in taxes ($6.58 *per capita*). In the same year the funded and floating debt of the state amounted to $70,613,011, with a net debt of $65,655,186, or $16.69 *per capita*. Appropriations by the Legislature, $5,929,306 in 1909, advanced steadily to $9,610,553 in 1915, and then much more rapidly, standing at $28,302,639 for 1926–7. The volume of the general property tax, which comprised nearly all the state's revenue, lagged behind the appropriations at the close of the decade 1910–20, and the prospect of a treasury deficit in 1921 caused the passage of a law for a tax on corporation franchises as an emergency recourse. In 1921 accounting and purchasing were centralised under the state Administrative Board. The result of these measures was that a deficit of approximately $6,000,000 in 1921 was replaced by a surplus on July 1 1925 of $2,292,411.

Legislation and Administration.—Amendments added to the revised constitution of 1908 provided for popular initiative and referendum on constitutional amendments and in legislation (1913); for the recall of elected officials (1915); for prohibition (1916); for woman suffrage (adopted in 1917 after having been successively rejected in 1912 and 1913), and for the issue of state bonds to the amount of $50,000,000 for the improvement of highways (1917). The provisions for initiative, referendum and recall have as yet found little utilisation, but the issue of highway bonds facilitated a marked improvement in roads. An increase of the licence charges on automobiles has also increased the road funds, the application of which is largely determined by an Act of the Legislature (1915) establishing a system of state trunk roads. A further increase of road funds resulted from placing in 1924 a tax of two cents per gallon on gasolene. This yielded a substantial sum.

Among other noteworthy enactments by the Legislature are the Judicature Act of 1915, consolidating and revising the laws of civil practice and procedure; the "blue-sky" law of 1913 and the creation of the Michigan Securities Commission in 1915 to regulate the sale of securities; the provision for juvenile courts (1911); the creation of a Board of Mediation and Conciliation to deal with labour disputes (1915); a Dept. of State Police (1919); a budget commission (1919); and a state Administrative Board, consisting of all the elective state officials (1921). This board was entrusted with a general supervisory control over the functions and activities of the administrative departments, each of which, as reorganised and consolidated, continued to operate separately with an appointive official at its head. The preparation of the budget and matters of state expenditure were placed directly under the control of the board. Michigan ratified the Eighteenth (Prohibition) Federal Amendment Jan. 2 1919.

Political History.—Since 1910 there generally have been large Republican majorities in state and national elections, without appreciable representation of any other parties in the state Legislature. In the presidential election of 1912, however, Michigan gave its electoral vote to the Progressive ticket, and in 1912 and 1914 it elected a Democrat as governor and in 1923 elected the same man to the U.S. Senate. The governors of Michigan, 1911–25, were: Chase S. Osborn (Rep.), 1911–3; Woodbridge N. Ferris (Dem.) 1913–7; Albert E. Sleeper (Rep.), 1917–21; Alexander J. Groesbeck (Rep.), 1921–5 and 1925– . In a conspicuous contest in 1918 Truman H. Newberry (Rep.), was elected to the U.S. Senate by a narrow majority over Henry Ford (Dem.). Charges of excessive expenditures in this campaign were brought against Senator Newberry and numerous associates, and they were convicted in the U.S. District Court (1920) and were sentenced to two years' imprisonment. The U.S. Supreme Court set aside the conviction May 2 1921; on Jan. 12 1922 the U.S. Senate decided by a vote of 46 to 41 that Newberry was entitled to his seat. In the ensuing senatorial election, however, he was decisively defeated at the polls, whereupon he resigned the seat. (U. B. P.)

MICHIGAN, UNIVERSITY OF (*see* 18,378), has continued the promise of its earlier period as the first conspicuously successful state university. The faculty increased from 350 in 1907–8 to 797 in 1925–6, while the student enrolment grew from 5,013 to 12,312 (6,010 in the college of literature, science and the arts; 1,716 in the colleges of engineering and architecture; 536 in the medical school; 541 in the law school; 85 in the college of pharmacy; 358 in the college of dental surgery; 483 in the school of education; 23 in the school of business administration; 758 in the graduate school; 190 in the training school for nurses; and 3,147 in the summer session). On July 1 1925 there were 36,500 living graduates.

Among the buildings erected between 1910 and 1925 were Hill auditorium (1913) bequeathed to the university by Regent Arthur Hill, of Saginaw, seating 5,000 persons; the Natural Science building (1916); the university library (1919), containing approximately 400,000 vols.; the Michigan Union (1919), a student club-house, costing $1,250,000, the gift of students and alumni; the engineering laboratories (1923); the Wm. L. Clements Library of American History (1923), containing one of the three largest collections of Americana in the United States, the gift of Regent Wm. L. Clements, of Bay City; the Yost Field House (1923); James Burrill Angell Hall (1924); the Lawyers club and dormitories (1924), the gift of W. W. Cook, of New York; the physics building (1924); the university high school (1924); the medical building (1925); the university hospital (1925), accommodating 700 patients. Four dormitories for women students were also erected during this period as well as a home for nurses, the gift of Senator James Couzens, of Detroit. A new building for the College of Architecture is in course of construction and a new museum will be built in 1927. A stadium, seating 70,000, will also be completed in 1927.

The income of the university in 1925 was $12,465,160. Of this amount $3,000,000 was derived from the state from the 5/8 mill tax; $2,683,855 was appropriated by the State of Michigan for buildings, and $1,240,889 was received from student fees. Over 12,000 graduates and students of the university were enlisted in the U.S. Forces during the World War. Of these, 237 lost their lives.

Upon his resignation in 1909, President James Burrill Angell was succeeded by Harry Burns Hutchins, dean of the Law School. President Hutchins resigned in 1920 and was succeeded by Marion Leroy Burton, who had been president of Smith College (1910–7) and of the University of Minnesota (1917–20). Upon his death in 1925, Clarence Cook Little, formely president of the University of Maine (1922–5) was inaugurated sixth president of the university.

MICROBE: *see* FILTER-PASSING MICROBES.

MICROPHONE.—The term microphone, originally used by Hughes to describe a loose contact device extremely sensitive to vibration, has been generalised to mean any piece of apparatus for converting rapid vibrational energy into electrical energy with similar vibrational characteristics. A number of such devices are now known; some are of scientific interest only, others are used very extensively in industry.

Microphones Proper.—A loose contact between any two conductors is microphonic—that is to say, when subjected to vibration there is no sharp definition between completely open circuit and completely closed circuit. In between these two states there is a condition where varying pressure alters the resistance, and if one or both of the substances making contact are subject to vibratory pressure, the vibration is reproduced as a varying current. The characteristic between pressure and current is only linear over small limits.

The action at the point of contact is not exactly known. When the current passing through the contact while in the microphonic

condition is examined it is found not to be absolutely constant, and this lack of constancy makes itself evident as a hiss in a telephone receiver. The discharge through a vacuum valve has a very similar sound when amplified.

The change of resistance with pressure varies greatly with materials used. Carbon in one form or another is universally rec-

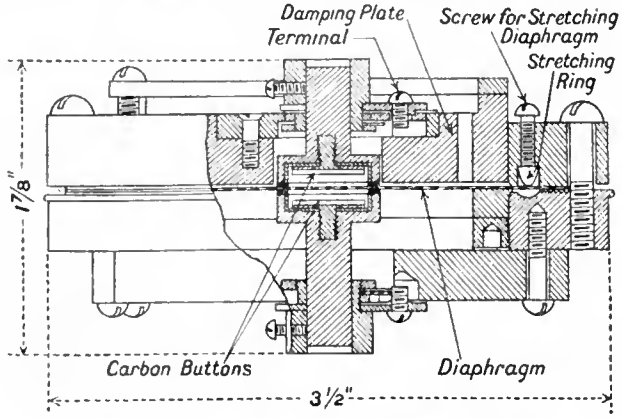

FIG. 1.—Western Electric carbon Microphone.

ognised as the best material, in that the transitory stage between open and closed circuit is more marked than with other materials. This does not mean, however, that it gives the greatest change of resistance for a given change of pressure. A contact between gold electrodes by delicate adjustment can be put in a sensitive condition, and in the adjustment gives greater changes than carbon for the same change of pressure. A considerable amplification can be obtained with microphonic contacts, the output vibratory electrical energy being many times that of the input mechanical energy.

To Edison, Berliner, Hughes and many others we owe the introduction of the contact microphone and its development as a practical device, and microphones to translate noises and music have been produced in many forms. The inventive drift has been towards multiple contacts, and practically all contact microphones are now formed of prepared anthracite granules, the sound pressure being applied in various ways, usually by means of a diaphragm. In later years a more accurate study of the response of microphones to sound pressure has been made, and two modern forms in which the response is practically independent of frequency have been made.

In the first form, the Western Electric carbon microphone (fig. 1), a diaphragm of duraluminium is stretched to a natural period well above the frequency it is required to reproduce. A

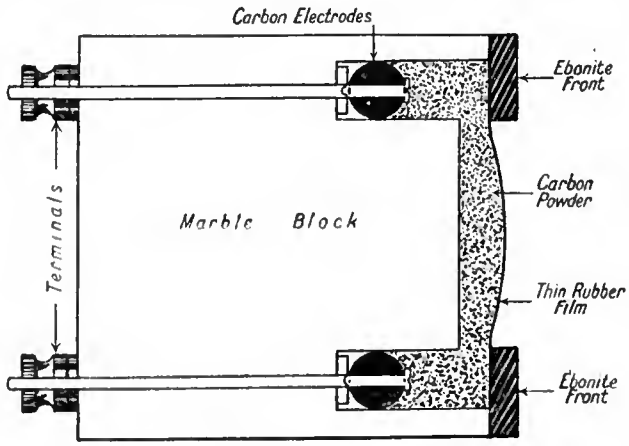

FIG. 2.—Diagram of the Reisz Microphone.

type of air damping is applied to the diaphragm, and it is allowed to rest on carbon granules. The resulting currents are practically independent of frequency. In a second form, known as the Reisz microphone (fig. 2), a diaphragm is practically dispensed with, and a layer of carbon granules is laid on a heavy non-conducting block such as marble, being held in position by some material such as silk or thin rubber. The current response is obtained at right angles to the direction of application of pressure.

The carbon granule-air system of a thickness of about 2 mm. forms a system of a very high natural period in depth, also damped by the natural friction of the carbon. The resulting

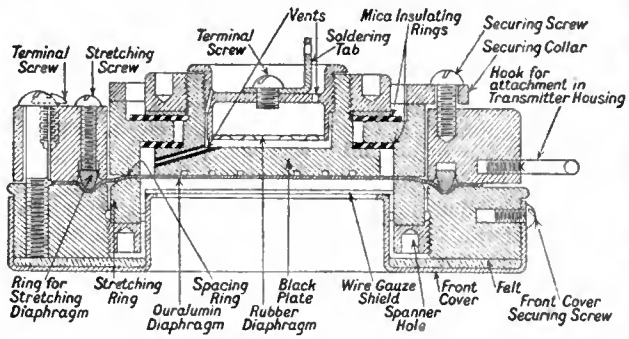

FIG. 3.—Diagram of the E.S. Microphone.

response is similar to that of the stretched diaphragm type described in the last paragraph. Lowering the period of the diaphragm or thickening up the layer of carbon granules in these two types has similar results. These high quality microphones are not sensitive and have to be used with a valve amplifier. In commercial telephony this amplification is not usually permissible, at least to such an extent, so that it is usual greatly to increase the sensitiveness by forgoing some of the accuracy of response.

Fortunately the human voice can be considerably distorted without lack of intelligibility, and by giving the diaphragm of the microphone a natural period in the middle of the important frequency ranges (about 800 cycles) amplifiers can be dispensed with owing to the increased response; music, however, cannot be reproduced with anything like fidelity. These microphones are also used well outside their range of linear response. Granule microphones all suffer to some extent from "packing"—that is, a tendency for the carbon to set itself in a hard contact condition where change of resistance with pressure is least, and much time has been spent in an attempt to overcome this difficulty. The commercial solid back microphone is one of the best forms, but occasional shaking is still necessary.

Other Response Devices.—The best known of non-contact devices is the E.S. microphone, developed into an instrument of precision by the Western Electric Co. Ltd. (fig. 3). Here the same principle is used as in the carbon microphone. A high

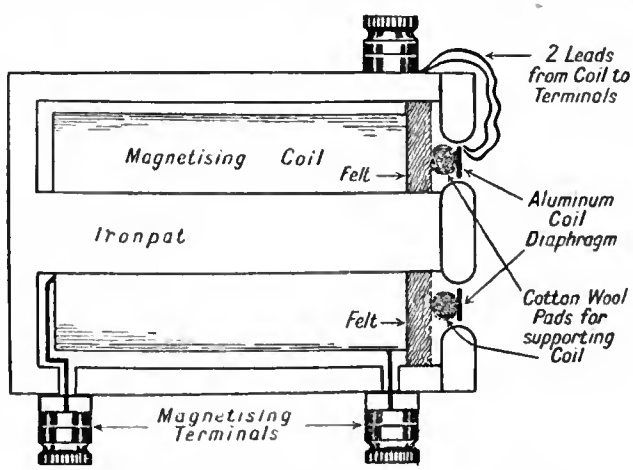

FIG. 4.—Diagram of the Sykes Microphone.

natural period diaphragm, air damped, forms one plate of a condenser, the other being a solid insulated metal piece spaced a few mils from the diaphragm. The chief use of this instrument is for measurement and for broadcasting. The amplification required is large. Various magnetic microphones have been

constructed; in fact, the first Bell microphone was practically the present receiver. The response with frequency is, however, a complex curve, although it is more linear with amplitude than a contact device. Moving coil devices have been produced by Sykes, Siemens-Halske, etc., the later forms of instrument being constructed so that the moving coil is the diaphragm.

In the Sykes microphone (fig. 4) an annular ring of aluminium foil or wire is suspended in a magnetic field, and the response is sufficiently large to enable the method to be used for broadcasting. The law of response with frequency, although not nearly so correct as the electrostatic instrument, can largely be corrected for in the amplifier.

Thermal Devices.—Hot metal wires have been used for microphone purposes. The response is, however, small except for very low frequencies, which property has been used by Tucker for gun-ranging usually in connection with a resonance chamber.

Gas Discharge Devices.—Dr. Thomas, of the Westinghouse Electric Co., and others have investigated the use of point discharges, but these devices have not come into general use. A flame carrying a current is sensitive to sound, but the effect is too small for practical purposes. The piezo electric effect has also been used, but not with much success, except for very high frequency work. See H. M. Dowsett, *Wireless Telephony and Broadcasting* (1923). (H. J. R.)

MICROSCOPY (*see* 18.392).—The modern microscope is essentially a working tool used in every form of scientific and industrial research. Specialised applications have led to the evolution of instruments designed for robust usage as factory appliances, and at the other end of the scale we have the new type of biological research microscope initiated by Mr. J. E. Barnard, F.R.S., F.R.M.S., and manufactured by Beck. In both types there is a marked tendency to forsake the older portable form of stand used in normal laboratory practice and make use of a massive optical bench or lathe bed type of stand. This gives enormously increased rigidity, and freedom from vibration, enables the accessory lighting and condenser systems to be permanently adapted to the optical axis of the instrument, and permits quick change from visual observation to photograph recording without disturbance of adjustments.

Denne Microscope.—In the microscope designed by Mr. M. T. Denne, F.R.M.S., for photomicrography, the whole system of illuminant, condenser, filter, substage condenser, stage and objective are all mounted on a triangular optical bench. This in turn is carried on a carriageway or lathe bed on which it is free to move. No conventional coarse or fine adjustment is fitted to the microscope, and the place of the body is taken by a camera. The coarse and fine focusing are operated by crank handles driving screw rods in the bed. These control handles are situated at the focusing screen end of the camera. For visual observation the whole optical system is brought up to the camera, which is telescoped, the focusing screen is swung to one side and an eyepiece is inserted in its place. The complete apparatus is mounted on a wheeled pedestal carriage, and the operator manipulates the whole from a chair at the focusing screen end of the bench.

Optical Problems.—In biology research has been directed to extending the limits of microscopic resolution by the use of monochromatic light of short wave-length. The limit of resolution—that is to say, the power to see a body composed of two dots as two separate dots in ordinary white light—is reached with standard apparatus, when the distance separating the two dots is reduced to half a wave-length of ordinary light (say 0·2 μ). Bodies far smaller than this can still be perceived as vague disks of light, but the eye cannot distinguish form or structure. There is in theory no limit to the smallness of a body which can be made visible, provided that enough light falls upon it, but the image we see of it is simply a series of diffraction disks, and can give us no further information than that something is there. A reduction in the length of the wave-length of light employed may be looked on as increasing the separation between the two points in a body. Thus an object easily visible, but just too small to be resolved, by ordinary light with a proportion of the long red rays in it, may be resolved and seen by monochromatic light from the blue end of the spectrum. As we pass toward the violet end we find that the eye is not sensitive to the violet, and that both distinct vision and accurate focusing become increasingly difficult. This band of light is, however, suitable for photography, and, although visual observation may be imperfect, photographs taken with this light reveal unseen detail and structure (*see* PHOTOGRAPHY).

In 1904 Dr. Köhler of Jena experimented with the use of ultra-violet light. This band of light is of very short wave-length—275$\mu\mu$—and possesses great resolution, but is invisible. He employed an optical system of quartz lenses, as glass stops these rays, and projected the image on a fluorescent screen where it could be examined with a glass eye lens and focused for photography.

Ultra-violet Ray Illumination.—In Great Britain the use of ultra-violet ray illumination has been applied by Mr. J. E. Barnard, F.R.S., and the technique simplified and developed. In the Barnard instrument quartz lenses, slide and coverglass are used, but in place of the older method of focusing on a fluorescent screen the object is first focused visually by means of a special form of dark ground illumination.

Dark ground illumination is entirely different from the normal illumination by transmitted light, in that the object is illuminated solely by rays of light so oblique that they cannot enter the objective of the microscope. The only light which enters is that reflected or scattered by the object itself. Objects viewed in this manner appear self-luminous against a dark background, and extremely tenuous and transparent material which would display no structure and be almost invisible when examined by transmitted light reveals material detail. Mr. Barnard's method was to focus the object first by means of visual examination against the dark ground. This focusing was necessarily crude, as the smallness of the objects only allowed them to be seen as disks of diffusion, not as distinct objects. It then becomes necessary to adjust the focus for photography with transmitted ultra-violet light. To effect this, the fine adjustment screw of the microscope is fitted with a disk head graduated in wave-lengths. Visual focus having been determined in light of known wave-length, rotation of the graduated head to the degree indicated for light of any other wave-length automatically adjusts the focus. The eyepiece is replaced by a camera body and dark slide. The dark ground illuminator is so contrived that it can be instantaneously changed over to a direct light condenser without disturbance of adjustment, and the lighting arrangement is arranged so that a beam of ultra-violet light of 275$\mu\mu$ from a cadmium arc can be directed into the optical axis. The photograph taken of the objects indistinctly discerned shows them in actual form and with considerable detail.

Special Difficulties.—Many difficulties have had to be met in this new technique. Bacteria are killed by exposure to ultra-violet rays, and search has had to be made for bands in the invisible spectrum whose effect is not immediately lethal. The most important published results to date are those connected with filter-passing organisms associated with cancer research (*q.v.*) by Dr. Gye, but the normal application of the apparatus may find fuller scope in the exploration of the structure of known bacteria of larger size. These are usually only visible under dark ground illumination when alive, and in order to render them visible for examination by transmitted light they are stained with aniline dyes. Staining kills the bacteria and alters structure. With ultra-violet light methods it becomes possible to examine the structure of living bacteria, for the different elements composing the cell present different degrees of absorption or transparency to the rays, and are as well differentiated on the negative as stained preparations (*see* BACTERIOLOGY).

The standardised model of the Barnard microscope will be approved and available as a commercial product for scientific workers. In the meantime experimental work is being done on the utilisation of even shorter wave-lengths in the Schumann region of the far ultra-violet. These rays have little penetrative capacity through air, and apparatus is being constructed to work in vacuum which may lead to a still further advance in our

means of photographically investigating minute structure beyond our present human range of vision with the best of microscopes.

Use in Applied Science.—The extension of microscopic resolution by the use of light of short wave-length and quartz optical systems has not yet found application in other than biological research. The tendency is, however, to apply high power examination to crystal structure in metallurgy, and branches of research dealing with opaque material which cannot be examined by transmitted light. Modern design has endeavoured to simplify the problems of the illumination of metallurgical and similar specimens. Devices embodying a parabolic mirror surrounding and integral with the ordinary objective have proved to be too cumbersome and heavy to be satisfactory in practice. In the same way the claims for the nominal "super microscope" devices, which consist of a primary low power microscope coupled to a second microscope of lower power whose function is to magnify the image given by the first system, have not received general endorsement. The results have been in accordance with optical theory, and have not yielded any increase of resolution. For the observation of incandescent bodies or micrometric measurements at a distance, an achromatic lens of short focus carried in a tube fitting the substage is useful. It acts as a short range telescope, producing an image in its focal plane which can be examined by a low power objective of the microscope, with satisfactory magnification, and gives a convenient depth of focus useful in the examination of large objects with uneven surfaces.

Use in Metallurgy.—For routine metallurgical work the inverted microscope with duplicate tubes for simultaneous visual and photographic work has largely superseded the older types of instrument. With the inverted microscope the specimen of metal is viewed from beneath. Light from an arc or "Pointolite" lamp is led into a vertical illuminating system beneath the objective and projected on to the specimen. The principle is the same as in simpler metallurgical microscopes, but in the newer type a very wide variation of illumination method is possible. Plain glass reflectors, silvered circles, half circles or strips or even parabolic mirrors can be used in the vertical illumination system of the inverted type of microscope. In addition to this convenient command of illumination, the focusing system has only to carry the weight of the objective and is relieved of the conventional tube. This enables a very fine and precise adjustment of focus to be simply obtained. The change from visual observation to the camera is attained by pushing an intercepting prism out of the optical axis of the apparatus.

Use in Engineering Work.—As the microscope is increasingly used as a purely workshop tool in mechanical engineering practice, there has been a demand for simple robust devices consisting of a low power objective and an eyepiece with a simple scale or graticule in its focal plane. These tools have a linear magnification of ×16 or ×20, and enable the tool maker and mechanic to achieve a very high standard of precision. In general, no focusing device is provided for the simpler types, the instrument simply being placed on the flat surface under examination. More complex devices are available for the study of fine screw threads, and the more elaborate types of workshop microscope are fitted with an electrical vertical illuminating device in permanent adjustment. In general these simplified tools may be looked on as precision measuring devices rather than instruments for microscopic investigation. The use of the high power microscope for the examination of the microstructure of metal has led to a realisation of the basic fact that the mechanical properties of metals and alloys, such factors as hardness, ductility and tenacity, are inter-related with the microstructure. The microscope alone does not afford an explanation of many of these properties, but when microscopical examination is used in conjunction with equally accurate chemical and thermal analyses, the behaviour of individual constituents can be determined and information of the greatest possible value has already been gained.

Other Industries.—In the textile industries the microscope is used from the first to the last stages. It is the weapon of the economic botanist studying the insect and fungus pests which attack the plants furnishing the raw material, and it is used by the dye chemist studying the ultimate detail of the decoration of the finished product. Each industry evolves its own particular detail of technique, but, in general, the normal research does not involve special apparatus and the conventional microscope common to all laboratories serves.

Colloid Chemistry.—The research chemist who deals with colloids, a subject of increasing importance, has to meet problems concerning suspensions of ultra-microscopic particles. For this, the apparatus known as the ultra-microscope is used. In this the power of resolution is neglected and the design is to make visible rather than to define extremely small ultra-microscopic particles. The ultra-microscope is essentially a dark-ground illuminating device, employing an intense illumination system and using magnifications up to ×1500, and the particles are seen as diffusion disks. The simplest form is the Siedentopf "Cardioid" condenser, which is a paraboloid dark ground illuminator applicable to the ordinary microscope substage.

It is, however, used with special quartz slides, as the intensity of the illumination is so high that glass fluoresces and destroys the darkness of the background. In order to estimate the quantity of particles present in a given volume, the quartz slides used with the cardioid condenser are similar to those used in the haemacytometer. A central table surrounded by a groove is ground down to a lower level than the surface of the slide, so that a known depth of liquid can be enclosed between cover and slide.

A more precise form of ultra-microscope is the Siedentopf-Zgismondy slit ultra-microscope, in which a beam of light from an arc is passed through a condenser and focused on an adjustable slit, similar to that used in a spectrometer. The image of the slit is reduced to a quarter size by a second condenser, and focused by an independent microscope objective on a small quartz windowed tank containing the liquid under examination. As the length and breadth of the slit can be adjusted and the reduction is known, the volume of the illuminated portion of the liquid under observation can be accurately estimated. The area of the illuminated zone observed is controlled by an eyepiece stop, and it is possible to count the number of particles in a known volume of solution. If a larger known volume of the solution is evaporated and the residue weighed, the total mass of particles can be calculated and the mass and, if its density is known, the volume of a single particle is estimated.

The limitations of the ultra-microscope are those of the refractive index of the objects observed. Cellulose, starch and other low refracting bodies can only be observed in relatively large particles, but metallic colloidal solutions of high refractive index have given extremely favourable results. Colloidal gold particles as small as $1{\cdot}7 \times 10^{-7}$ cm. in diameter can be observed as separate entities.

Modern Apparatus.—These more recent types of research apparatus, the ultra-violet ray microscope, the inverted metallurgical microscope, and the ultra-microscope, are specialists' instruments and will not supersede the standard instruments for ordinary work. The design of the latter may be looked on as stabilised, and no great advance has been made. The modifications introduced in practice are those of detail and convenience rather than material alteration of type. The increasing use of microphotography as a recording device has made the narrow-bodied microscope of Continental design relatively obsolete. The best modern instruments have body tubes of two inches or more in diameter.

Improvements in binocular microscopes have now reached a point where binocular eyepiecing can be used with the highest powers and oil immersion objectives. The advantages of the binocular system are a stereoscopic effect and a great relief from ocular fatigue. In the past, the old-fashioned Wenham prism type binocular was the only satisfactory system, and it was only applicable to very low powers and to the old "long tube" stand. Attempts to adapt a binocular prism system to the higher powers were not successful, and various shortcomings such as unequal light distribution in the tubes have hitherto proved insuperable. The new eyepiece systems have now been adopted by the leading

British and American makers and have proved satisfactory in practice. Monocular and binocular bodies are detachable and interchangeable on the same stands. Eyepiece focusing for disparity of vision between the eyes and interocular width adjustment are provided for.

As a result of research, and in a measure as the outcome of wartime needs, Great Britain is producing the highest grades of optical glasses according to tests carried out by the National Physical Laboratory. This mastery of material (*see* OPTICAL GLASS) has reacted on the microscope manufacturers, and British microscope objectives are being adopted for the most critical research work.

Gye and T. E. Barnard, *The Lancet* (July 18 1925); the *Jour. of the Royal Microscopical Society* can be consulted for particulars of new apparatus and progress in biological and industrial research.

(H. B. C. P.)

MIDDLESBROUGH, England (*see* 18.412), with an area of 4,159 acres, had a population of 131,070 in 1921. The town was given a separate court of quarter sessions in 1910. The efforts of the corporation to deal with the housing shortage have been notable: in addition to 1,283 houses contracted for, of which 877 were finished in 1925, two large buildings were converted into flats, and a number of hutments were erected at Marske-by-the-Sea for the accommodation of Middlesbrough families. The corporation purchased the omnibus and tramways undertakings in 1921. Marton, an estate of 136 acres, was presented for use as a public park in 1924. The sum of £40,000 was given by Mr. J. Constantine for a technical college in 1916, but, owing to the War and the rise in costs, the work could not be proceeded with until a further £40,000 was given by his widow and family. The Constantine Technical College was under construction in 1925. Docks for small vessels and a landing stage were being built in 1926, and an area prepared for extensions of the docks.

MIDLETON, WILLIAM ST. JOHN FREMANTLE BRODRICK, 1ST EARL OF (1856–), British politician (*see* 18.419), did not remain long out of Parliament after his defeat in the general election of 1906, as in the following year his father died, and he entered the House of Lords as 9th Viscount. He took a considerable share in the work of that House, and played an active part behind the scenes in Conservative politics, without returning to office. He had meanwhile become especially prominent as leader of the southern Unionists of Ireland, in virtue of his position as a landowner in County Cork. In the Irish Convention of 1917–8 he and a band of Southern Unionists separated themselves from the Ulster standpoint and expressed a readiness to concede a unitary Home Rule Government for Ireland, subject to provisions for safeguarding the minority of loyalists. At the beginning of 1920 he was created an earl.

MIGRATION (*see* 18.427).—The general characteristics of the movement of population between 1909 and 1924 were:—

Since the opening of the 20th century most states had begun to exert a positive control in questions of migration; its enormous increase made state regulation of overseas migration unavoidable.

With the improvement of communications, many migrants have no intention of settling permanently and becoming naturalised overseas. The annual figures of repatriation from the United States have frequently amounted to more than half of those of immigration. This is no longer due solely to the difference between conditions of living in the countries of emigration and immigration; rather, and in increasing degree, to the more or less conscious efforts of the countries of emigration to preserve their nationals' love of their homes, or those of the countries of immigration to assimilate the new elements. The countries of emigration encourage, as far as possible, temporary migration, to which, however, even before the War the countries of immigration raised economic and social objections.

During and after the War, in addition, national and political points of view began to influence migration policy decisively. In the countries of immigration, especially the United States, legislation governing selection became more stringent, and later a numerical limit was imposed on immigrants. The European states were no longer able to divert their surplus population overseas so copiously as before; even in the case of racially kindred nations, or the British self-governing Dominions. These Dominions too, under the pressure of economic depression, seek to retard immigration.

Migration has diminished, since the supply of emigrants does not tally with the demand in respect of nature and quality (race, sex and age).

The one-sided interference with immigration by the opposing groups of states results in social conflicts within those states and friction between their respective governments.

A peculiar characteristic of recent years is the increasing importance of continental migration within Europe. The social problems arising in the countries concerned are regulated in many cases by inter-state treaties (Migration Treaties, properly so-called, going beyond the International Labour Agreements) and if possible international agreement. This is the only way to avert dangers which threaten peace, and to further the social policy of the world in positive fashion.

The immediate problem is that of successfully settling Europe's surplus urban industrial population in the colonial agricultural areas of overseas countries; the lasting and general world problem is, however, how peoples of different habits and different standards of living and of radically different race (white and coloured), may be distributed evenly over the earth without endangering the peace and progress of mankind.

It is no longer enough to treat immigration purely as a demographic phenomenon occasioned by the decision of those immediately concerned. In order to understand the causes and effects of this phenomenon it is necessary to include in our survey the national and international measures which have been taken in the interests of the community.

I. PROGRESS OF STATISTICS

As early as the first International Labour Conference in Washington in 1919 the International Labour organization (I.L.O.) created under the treaty of Versailles passed various "recommendations" dealing with equal treatment of alien labourers and with collective recruitment of foreign workers, and appointed an international emigration commission, which produced a systematic programme of action at its session in Geneva in 1921. The 4th International Labour Conference of 1922 adopted a "recommendation" relating to the collection and improvement by the I.L.O. of statistical and other information on migration. In addition to current monthly publications of the most important data, the I.L.O. issued in 1925 a first annual report on the statistics of 60 countries and territories, *Migration Movements 1920–1923* (Geneva, 1925). This report embodies the results of exact and uniform statistical inquiries and provides an international co-ordination of statistics. The numbers and details of the migrants (sex, age, profession, nationality, country of last and future permanent residence) have been classified for the first time, in eight homogeneous groups: (1) oversea emigration of nationals, (2) continental emigration of nationals, (3) oversea immigration of nationals (repatriation I.), (4) continental immigration of nationals (repatriation II.), (5) oversea emigration of aliens (generally returning to their country of origin), (6) continental emigration of aliens (generally returning to their country of origin), (7) oversea immigration of aliens, and (8) continental immigration of aliens.

In giving these figures the report explains the very frequent variations in the method of compiling them, and definition of the "migrant" and also draws attention to the gaps and deficiencies of international comparisons. Migration movements during the periods 1909–1913–1914 had a transitional character, but those during the periods 1915–9 and 1920–4 can be illustrated comparatively. The tables on p. 908 show the overseas emigration and immigration (repatriation I.) of nationals in the chief European countries and the overseas immigration and emigration (repatriation II.) of aliens in certain countries of the world.

II. CHARACTER OF MIGRATION MOVEMENTS

Overseas migration has perceptibly declined since the War.

As regards the European countries of emigration the annual average (before the War 1,349,251 and 669,574 after the War), so far as proper statistics are available has decreased by 50·38%. In the countries composing the former Austro-Hungarian monarchy emigration has sunk to 70·4% of its pre-War figures: emigration from Italy 58·8%, emigration from Finland, 56·8%, and Portugal, 51·6% is less than ⅔ of what it was; the percentages for Great Britain are 43·6, for Spain 39·6, for Sweden 38·3, for Norway 34·7, for Belgium 31·6, and for Denmark 29·5%. Emigration has increased

Average 1920–4	398,395	169,364	87,660	74,625	133,677	48,147	90,827	62,169	39,496	30,027	16,863	12,422	83,962	16,986

since the War by 107·5% in Germany, 53·9% in the Netherlands, 24·1% in Switzerland. Thus the proportion supplied by each country to the total of emigrants has altered. Before the War the proportion of the total overseas emigration from different European countries was: Italy 30·05%, the United Kingdom 28·86%, Austria-Hungary 18·51%, Spain 11·22%, Portugal 4·48%, Germany 1·74%, Sweden 1·36%, Finland 1·16%, Norway 0·98%, Denmark 0·61%, Switzerland 0·41%, Belgium 0·38%, Holland 0·19%. It now runs: United Kingdom 32·94%, Italy 24·95%, Spain 13·66%, territory of the former Austro-Hungarian Monarchy 9·71%, Germany 7·29%, Portugal 4·37%, Sweden 1·7%, Norway 1·30%, Switzerland 1·03%, Finland 1·02%, Denmark 0·88%, the Netherlands 0·60%, Belgium 0·53%.

The statistics of immigration show the annual average immigration as falling from 1,720,703 in 1909–13 to 942,711 in 1920–4, five years after it, a decrease of 45·21% falling to 46·1% of pre-War figures in the U.S.A., 41·75% in Canada, 40·76% in Argentina, 55·47% in Brazil, 87·50% in Australia, while the figures for Mexico (6·6%) and New Zealand (3·69%) remained practically unchanged, immigration into Cuba rose by 122·29% and into South Africa by 18·33%. Formerly the United States took the largest proportion of immigrants with 50·25% of the total, Argentina had 15·5%, Canada 12·20%, Brazil 7·82%, Australia 7·33%, New Zealand 2·38%, Cuba 2·20%, Mexico 1·06%, South Africa 0·83%. Now the list runs: U.S.A. 42·26%, Argentina 14·20%, Australia 9·63%, Canada 9·30%, Cuba 8·91%, Brazil 7·82%, New Zealand 4·19%, Mexico 1·80%, South Africa 1·79%.

Differences of direction (nationality of immigrants and country of last and of future residence) are even greater than those of the total volume. This is shown by the following table for the U.S.A., which is still the most important country of immigration.

Immigration of aliens into the United States by principal countries of origin, 1913–4, 1920–1 and 1922–3.

Countries of origin	Numbers of immigrants admitted			Per cent of total		
	1913–4	1920–1	1922–3	1913–4	1920–1	1922–3
Northern and western Europe . .	164,133	138,551	156,429	13·4	17·2	29·9
Southern and eastern Europe . .	915,974	525,548	153,674	75·2	65·3	29·4
British North America .	86,139	72,317	117,011	7·1	9·0	22·4
Mexico . .	14,614	30,758	63,768	1·2	3·8	12·2
Other countries	37,620	38,054	32,037	3·1	4·7	6·1
Totals . .	1,218,480	805,228	522,919	100·0	100·0	100·0

The table above shows two tendencies. First, there is a reduction, already considerable before the new system came into force, of total immigration into the United States as compared with 1913–4, becoming more marked in the year 1922–3 under the influence of the new Quota law. Secondly: in 1922–3 less than one-third of the immigrants came from southern and eastern Europe, as against three-fourths in 1913–4. The number of immigrants from northern and western Europe, which was formerly about one-eighth of the total, became nearly one-third.

In the year 1923–4 the number of immigrant aliens increased to 706,896. The proportion of northern and western European "peoples" increased from 20·8% of the whole in 1913–4 to 55·7% in the year 1923–4 and the proportion of southern and eastern European "peoples" decreased from 75·6% of the whole in 1913–4 to only 27·2% in 1923–4.

Not only the volume and direction of overseas migration movements, but also the character of the migrants has changed greatly. Family migration is on the decrease, outside the British Empire. The preponderance of males is greater than before the War. According to statistics from 13 countries of emigration, males composed 55·6% of the total in 1922, 63·7% in 1923. The same increase in the preponderance of males may be seen from the statistics of the chief countries of immigration (54·2% and 62·4%). This increase is due to the fact that in 1922 the states of western and northern Europe still made little use of their quotas of immigration to the United States, while recently the southeastern states, where family emigration was most common, have not been able to send the wives and children to join the heads of their households so frequently as before. (Percentage of male immigrants to the United States was 48·4% in 1922, 58·8% in 1923.) Even emigration from the United Kingdom was affected as regards the general proportion of the two sexes (51·9% of males in 1922, 59·6% in 1923). The sexes of immigrants were most evenly distributed in South Africa and New Zealand, most unevenly in Cuba, the Argentine and the other South American states, owing to seasonal migration and the greater risk in settling. The decrease of the percentage of child migrants from 1922 to 1923 similarly points to a decrease in family migration. In the United States the percentage of immigrant children dropped from 20·6 to 14·6; in Argentina it was only 10·4% in Cuba only 6·3%. In the British Dominions the proportion rises to 22·5% (New Zealand 23·2%). Jewish immigration into Palestine has a more family character (26·7% children in 1922, 26·9% in 1923). Of able-bodied adults, the young are more numerous than the elderly.

The countries of emigration and immigration complain even more of the alteration in distribution of occupations. Before the War up to two-thirds of the overseas emigrants from Europe were engaged in agriculture, in 1922 and 1923 only 14·6% and 14·0% respectively of the total emigrants from 14 European countries were of this class. Even if domestic servants and day labourers are counted in, this class hardly amounts to a third of the total. The statistics of countries of immigration place the percentage but little higher.

In consequence of the difficulties and restrictions on immigration and unfavourable economic conditions in Europe, repatriation home of previous overseas emigrants has decreased greatly (according to Table II. with 31·96%) and ever more rapidly. In the five years after the War repatriation to Great Britain was 18·3% less than before the War; to Sweden 24·5% less, to Italy actually 63·3% less.

The loss of population through migration per 100,000 inhabitants, arrived at by calculating the difference between figures of immigrants and emigrants, gives the following table for European countries (1920–3): Portugal −1,936, Great Britain and North Ireland −1,429, Italy −1,135, followed at a distance by Spain, Sweden, Czechoslovakia, Poland and Rumania.

The figures for the five overseas countries which have recorded both emigration and immigration show that the gain in population through migration per 100,000 inhabitants is highest in New Zealand (3,906), followed by Argentina (1,826), the United States (758), South Africa (116).

III. RESTRICTION OF IMMIGRATION

The universal depression consequent on the World War could not of itself have brought about, except in a certain degree, the decrease of emigration and its change of direction. The history of migration movements, especially in the United States, shows that for a century past periods of economic depression have coincided with the lowest figures of migration. The supply of emigrants in the European countries remained greater than the overseas labour markets, especially those of the United States, could have absorbed.

United States.—The depression which set in after a brief post-War boom, in the United States as elsewhere, in 1920–1, and the great increase in immigration in 1919–20 increased the apprehension with which organised labour, in particular, had come to regard unregulated immigration even before the War. Moreover, during the War American objections on national grounds to immigrants from south and eastern Europe, who are only assimilated with difficulty, acquired decisive importance, and public opinion was converted by motives of patriotism to a policy of restriction. The clause in the consolidated Immigration Law of Feb. 9 1917 under which persons over 16 years of age who are unable to read are not admitted, proved ineffectual in reducing the undesired element and emergency legislation for the restriction of immigration combined with national discrimination was finally approved on May 19 1921, and came into force on June 2. The number of alien immigrants, in the case of each nationality, was limited to a maximum of 3% of the number of foreign-born persons of that nationality who were resident in the United States at the time of the census of 1910. Certain categories of persons were, however, exempted from these quota.

This emergency law was to operate until June 30 1924 when the Immigration Act,[1] 1924, came into force. The earlier law had already reduced the proportion from southeastern Europe of the total immigrants by one-third. The effect of this reduction was, however, partially annulled because such persons were allowed to immigrate from the countries bordering on the United States and unaffected by this law (Mexico, Canada) even of alien origin, if they had been settled there for two years in the one case, five in the other. Thus the total immigration from Canada and Mexico rose from 66,361 for the financial year of 1922 to 200,026 for 1924. The total of immigrants had therefore not decreased. Economic depression also forced the countries of northwestern Europe to make full use of their high quotas. Clandestine immigration of southeastern Europeans by land and sea is estimated by the best authorities at 150,000

[1] See Immigration Laws and Rules of Feb. 1 1924, issued by the U.S. Bureau of Immigration (Washington, 1924).

annually. Public opinion, at one with Albert Johnson, Chairman of the Committee on Immigration of the House of Representatives, in the opinion that "the melting pot was to have a rest," welcomed the new law.

The law distinguishes three categories of persons:—

1. The old emigration is wound up under the first group; unmarried children under 16 and wives of previous emigrants, now naturalised, and certain other individual desirable types are allowed to immigrate *outside* the *quota*. Immigrants from the American continent do not come under the law at all. Persons who were not born there can no longer, under any circumstances, be accepted outside the quota of the country of origin.

2. As regards immigrants on the quota, the law adopts the following drastic principles for the first three years of its validity. The annual quota of any nationality shall be two per centum of the number of foreign-born individuals of such nationality resident in continental United States as determined by the United States census of 1890. After July 1 1927 the total number of immigrants is to be fixed at 150,000, the quota of each nationality being determined by the relationship between the number of inhabitants having that national origin to the total population of the United States in 1920.

On this basis the annual quotas from the principal countries are as follows:—

	1921–2	1924–5
North and West Europe		
Belgium	1,563	512
Denmark	5,694	2,789
France	5,729	3,954
Germany	68,059	51,227
Great Britain and North Ireland	77,342	34,007
Irish Free State	..	28,567
Netherlands	3,607	1,648
Norway	12,202	6,453
Sweden	20,042	9,561
Switzerland	3,752	2,081
South and East Europe		
Czechoslovakia	14,282	3,073
Italy	42,057	3,845
Poland	25,827	5,982
Rumania	7,419	603
Russia	34,275	2,248
Yugoslavia	6,426	671

3. Finally, persons ineligible as citizens of the United States fall into a separate group. This provision excludes the Japanese, the only Eastern Asiatics who had not already been excluded from the possibility of immigrating by the earlier special "Law of Exclusion" (China), or by the clause on the "barred zone" of Asia adopted into the law of 1917.

The most important result of the new immigration legislation, as compared with the period before the War, is that immigration from the most important European countries of emigration (Italy, the territories of the previous Austro-Hungarian Monarchy and Russian Empire) had been reduced by nine-tenths. The quotas from Sweden, Norway, Denmark and Switzerland have also been reduced by half; those for Germany and the Irish Free State remain practically unaltered. All other countries of emigration, including Great Britain, whose annual quota is now only 34,007, must now in increasing measure seek their outlet in other overseas countries.

Other Countries.—But South American and other countries have adopted similar restrictions on immigration for similar reasons. Before the War these countries—Brazil, Uruguay, Argentina—and others still encouraged white immigration, but they can no longer afford to do so. Not only have they paid more attention to selecting the right class of immigrant, but at times immigration has been suspended altogether. The bad conditions have led to some outbreaks of the proletariat in several ports, these being aggravated by the failures who drifted back from up-country. So in South America too only settlers with capital and able-bodied country labourers are welcomed. No state still grants free land. The minimum capital required, even by Brazil and Argentina, is too high for the unemployed of Europe, and they cannot make their way as unskilled labour in hot countries against the competition of the native coloured population (the North of South America, North and Central Africa, Asia Minor, etc.). Especially intellectuals who have tried their luck in these districts have very often come to grief.

IV. MOVEMENTS OF POPULATION IN THE BRITISH EMPIRE

Great Britain has long endeavoured to divert her surplus population from the United States, and has tried where possible to find it an outlet in her own Empire. The motives and results of these efforts, prosecuted with increased zeal since the War, may be regarded as typical of the migration crisis, since the Empire contains countries of emigration and immigration which are naturally complementary, and the official interpretation of the term "migration" denotes internal movements from one of these territories to another.

Empire Settlement Act.—The importance of the settlement question for the maintenance and consolidation of the British Empire was strongly emphasised by the Dominions Royal Commission, 1911–7, but although since 1890 the theory of state subvention has often been mooted, it was not until 1921 that a scheme for state-aided imperial settlement was adopted by the Imperial Conference of that year. The Empire Settlement Act, passed by the British Parliament in 1922, implemented the scheme. An Overseas Settlement Office was set up under the supervision of a Colonial Office Committee, and in 1925 a new Under-Secretaryship of Dominion Affairs was constituted, with complete charge of migration and settlement policies. Emigration departments were opened by the Dominion Governments in London. England's share of the cost of carrying through any one measure was not to exceed 50%, and the obligation to grant subsidies was not to extend beyond 15 years. The total which might be expended in one year under this was £3,000,000, exclusive of receipts from interest or repayments in later years. The scope of the law could be extended to other parts of the Empire, but in 1926 this had not yet been done. As shown by Table II., emigration to the Dominions was still less than before the War, when the broad, thinly-populated expanses of the overseas portions of the Empire had already begun increasingly to attract the stream of emigration from Great Britain in default of other labour markets. Between 1891–1900 only 28% of English emigrants went to the Colonies, the majority to the United States; between 1901–12 63% went to the Colonies, 1919–23 64%. When the American quota was reduced in 1921 84,261 out of a total of 91,262 overseas emigrants from Great Britain and Northern Ireland went to parts of the Empire.

The comparatively small financial part taken by certain Dominions in carrying through this scheme is due to economic and social difficulties. These districts need mostly agricultural settlers and labourers and female domestic servants willing to live in the country. Great Britain is, however, rather short of these classes, while the Dominions object to the immigration of the superfluous skilled industrial labourers, in view of the unemployment in their own industries and the necessity of protecting the standard of living of their own population. Objections are also raised to agricultural settlement, on the ground that this increases the agrarian losses provoked by the considerable fall of prices of agricultural produce. Then it is feared that most of the former urban elements will soon leave the land again and increase the over-preponderance of the towns which is already very great. The first step should be to settle the urban unemployed of the overseas districts on the land, since they are already used to local conditions. And so all these states, although some have had satisfactory experience with immigration, have imposed strict conditions of selection of human material from the mother-country, or insist on suitable preliminary training for settlers. Families and juvenile emigrants are much preferred. New Zealand and Canada have been comparatively accommodating. Canada, however, has not an exclusively Anglo-Saxon population to increase and makes efforts to attract agricultural labour from other European states as well. South Africa is in general opposed to all European immigration, as she is suffering particularly from unemployment and has native labour to spare.

The British Problem.—The school of Mr. J. M. Keynes holds that the present unemployment in Great Britain is intensified by the fact that 1,000,000 persons remained in Great Britain during the War who would otherwise have emigrated, and considers that the maintenance of the standard of living in the mother-country could only be ensured—imperfectly—by increasing emigration, or more safely, by reducing the birth-rate; but other experts (Sir William Beveridge and Professor A. L. Bowley) are more optimistic—they calculate that after 1931 the decline in births during the War will result in a shortage of productive labour in England, on the assumption that emigration again reaches its pre-War dimensions, the death-rate remains unaltered and the participation of women in the work of the community remains constant. The Overseas Settlement Committee think that it will be possible to secure an adequate outlet by emigration within the Empire for the surplus industrial workmen of the mother-country, although used to a high standard of living and the state unemployment allowance, as soon as world conditions have got back to normal and the agrarian crisis has been surmounted. The financial assistance of emigration by the mother-country should, in any case, further the industrial development of the Dominions and help the overseas portions of the Empire to become self-supporting.

V. LEGISLATION ABOUT EMIGRATION

Before the War freedom of emigration was almost general. Judging by the legislation of the most important countries of emigration, such as Italy, the general character of emigration policy was as follows: emigration was only restricted in the case of persons who had to be kept in the country on account of military service, criminal records or immaturity. Further, persons were prevented in their own interests from emigrating if they did not fulfil the conditions of the countries of immigration, if they possessed insufficient means or ran the risk of getting into an unfavourable position by paid passages or other concessions. In order to protect the emigrants only such shipping companies were allowed to carry them as were under supervision, so as to avoid the activities of secret agents. A special emigration fund was maintained out of various sources which created an emigration authority with local and foreign branches and established or supported special welfare institutions in the ports and elsewhere (emigrants' homes, labour registries). But according as the character and social spirit of the government was more or less democratic, so, in practice, there was more or less hostility towards emigration. These principles of emigration policy were upheld in post-War legislation, and supplemented by fiscal measures and by various restrictions in the recruiting of emigrants.

The impoverished countries of the continent of Europe encountered even greater difficulties than did the British Empire from the attitude of the countries of immigration. In spite of the great and constantly recurring unemployment, it was impossible to let millions emigrate, as had been generally expected after the War. The governments of the emigration states were themselves at first swayed by contradictory motives. Where the military motive no longer weighed in the balance, they were anxious not to increase the price of labour through emigration, so as not to hamper their export trade, or they wished to settle their surplus population at home by agrarian reform. People were mistrustful, and expected, too, a great economic wave of prosperity. Soon, however, certain countries were forced by their great surplus of population to give direct state encouragement and assistance to emigration, but everywhere they found doors shut against them. The example of conscious national emigration policy is Italy. So long as she is forced to place her labour at the service of foreign economic systems, she tries generally to get a suitable return for it (policy of valorisation), to increase the value of her labour by suitable training, in particular not to permit collective recruiting of emigrants except under conditions dictated by the state, to protect the interests of the emigrants against the transport companies and other agents during and after emigration, to preserve the sense of nationality by suitable organisations in the country of immigration (policy of schools, clubs and voting) and finally to place the whole organisation of emigration under a state general commissariat for emigration and its organs.

A whole series of countries of emigration have copied Italian legislation more or less closely since the War in their new emigration legislation. As passports and visas are still compulsory, it is possible to regulate emigration policy towards the different states. All European countries are endeavouring more or less to get their own unemployed industrial labour out of the country where possible, and to shut themselves off from foreign labour at the same time.

Statistics show that countries of emigration have been able to divert their surplus population overseas most easily where the movement is favoured by racial kinship and political interests. Most of the Germanic and Nordic states of Europe were still able to turn to the United States up to 1924 even in greater measure than before the War. The Latin and Slav countries, being almost excluded from North America, compensated themselves mostly in the South American states. So, to take 1924 as an example, 52·5% of the Italian, 44·7% of the Spanish, 37·4% of the Czech emigrants went to the Argentine. The attempts of the Italians and Greeks to get a footing in the British Dominions and South Africa had, however, very little success.

VI. MIGRATION OVER LAND FRONTIERS

Overseas emigration would never have succeeded in satisfying the urgent demand for emigration. Fortunately the European states were able to find an outlet in a few European countries, especially France, Belgium and Luxembourg.

Immigration into France.—France was impoverished in man power, and her labour market, in consequence of the work of reconstruction and the increase in her export industry resulting from the fall of the franc, was able to absorb foreign labour to an extent which varied, but on the whole increased. Statistics of continental migration are still very imperfect, but show great changes since the War. Before the War Germany received about a million continental immigrants, France comparatively very few. This immigration to Germany was almost entirely agricultural and mostly seasonal and non-permanent. In 1924, however, Germany admitted no foreign industrial labourers and only 29,196 agricultural workers, while French national statistics, taken on the frontiers and certainly some 50% too low, show the figure of continental immigrants at 262,877 in 1923 and at 223,495 in 1924. The great majority came from Italy, which now sends two-thirds of its emigrants to France; but there is hardly a country in Europe which has not sent labourers, mostly industrial, in large numbers to France in recent years. Continental migration has the advantage for the countries of emigration that it easily alters its character and often helps to increase technical knowledge.

Regulation.—But the countries of immigration are confronted not only with difficult economic and social problems, but also with problems of national health and security arising out of these mass immigrations. It has proved especially necessary to regulate the national labour market as elastically as possible, so that at any given moment only so much foreign labour as is barely necessary remains in the country. It has proved possible to adapt *collective* migration to the needs of the present labour markets by means of state treaties, and to regulate the legal and social position of those concerned in a proper way. But the good results thus attained have been largely nullified by the insufficient regulation and supervision of individual migrants. The pressure of unemployment has also caused the Central European countries to put severe limitations on the entry and settlement of foreign labour. Certain countries even expel labourers who have long been resident in the country. The resultant insecurity and the rise of prices increases the difficulties of reconstruction caused by tariff policy, etc.

Continental emigration, for example, into undeveloped Russia, is only permitted to agricultural settlers with capital ready to form model settlements in the north. On the other hand, emigration out of European Russia into Siberia has assumed extraordinary dimensions since the War. The chances of normal continental exchange of labour would have been much greater but for the emigration to Western Europe of Russian refugees. Japan and China are now themselves largely reduced to continental migration within Asia, since their only overseas outlet is now South America. Continental migration

in the interior of Africa has also assumed very great importance, and in South Africa especially, the various states have regulated it from a one-sided point of view.

There must be general state regulation for crossing of frontiers and settlement of foreigners. Great Britain, thanks to her insular position has been most successful in this since the introduction of compulsory passports. The German "Labour Centre," which works by compelling foreign hired labour to obtain permission and register, has been much less successful. France is only now beginning to attack the problem by a more exact control of identification cards, unification of the administration (Commission de la main et l'oeuvre étrangère 1924) and a long-promised legal regulation of conditions of immigration.

VII. GENERAL INTERNATIONAL REGULATIONS

The recognition of the necessity of reconciling conflicting interests in migration has led those European states which are subject to continental exchange of labour to make a beginning and conclude comprehensive migration treaties (France with Czechoslovakia, Poland and Italy). But the experience so gained is not enough to allow one simply to apply these methods of regulation internationally to world migration. The development appears here to overlook the regulation of social-political questions of detail. The International Labour Office, which has been entrusted with this task, has declared in principle for equal treatment for foreign labourers in all respects, and in detail has begun by regulating for equal treatment of foreign workers as regards workmen's compensation for accidents during work (1924). The social-political regulation touches on many other questions, notably protection of migrants (especially women and juveniles) and the regulation of the labour market. The programme worked out by the International Emigration Commission 1921 was widened and revised in many respects by the technical Interstate Conference summoned in 1924 by the Italian Govt. and attended by delegates from 57 governments. The Protocol of this conference shows the great number and variety of these problems. The agenda dealt mainly with technical matters; the transport of emigrants, hygiene and sanitary services, assistance at the ports of embarkation and disembarkation, assistance for women and children, information on employment in the countries of emigration, and the principles to which migration treaties should conform, etc.

The actual conditions of emigration and immigration in the different states touch the sovereignty of the states so nearly that most governments at present refuse to admit international regulation. This was shown very clearly by the United States House of Representatives when passing the Immigration Law of 1924. Even the different international federations of Trades Unions have not succeeded in arranging mutual co-operation. It may, however, yet prove possible to secure the collaboration of the states whose interests conflict, and thus eliminate dangers to the peace of the world. Private leagues for the protection of the emigrants are already doing good work towards bringing about a rapprochement of public opinion in different countries on questions of migration. These leagues joined in a common international conference held at Rome in May 1924.

The increase of open and secret emigration from Canada and Mexico into the United States shows that unless continental migration be regulated, the intentions of legislation regarding overseas migrants will merely be paper regulations. Either America must make up her mind to establish an effective frontier police, to register and keep continual track of foreigners, or she will not be able to stop the impulse of the peoples to immigration. In the former case her attraction for the already assimilated elements of Canada and Mexico will grow and the number of territorial disputes over this question will increase; in the latter there will be an intensification of the shortage of labour and high wages.

The Oriental Question.—The problem of Oriental immigration into the United States is of special urgency. Under the "Gentleman's Agreement" of 1907 freedom was given to the Japanese Govt. to issue passports to Japanese labourers who had been resident in the United States before the conclusion of the agreement and were seeking re-entry, and also to parents, wives and minor children of Japanese already resident in the country, but the Japanese Govt. pledged itself not to issue passports to all other Japanese nationals seeking entry into the United States as labourers. This pledge appears on the whole to have been loyally observed by the Japanese Govt., but in practice it afforded certain loopholes for evasion; the number of Japanese residents continued to rise steadily and the agitation in California against their entry increased.

The Gentleman's Agreement was superseded by the Immigration Act of 1924, which declared that no "alien ineligible to citizenship" should be admitted to permanent residence in the United States with the exception of certain specified categories, comprising approximately the classes contemplated under the Gentleman's Agreement. It was decided by the Supreme Court that all aliens who are not white and of European origin or black and of African origin—*i.e.*, essentially all Asiatics—are ineligible to citizenship, excepting those specifically exempted by the Act itself. The political effect of this measure was profound. It substituted a unilateral action based on domestic legislation for an international agreement, and Japanese national honour was wounded by an action which directly discriminated against the Oriental races. The Japanese Govt. protested strongly and proposed that Japanese immigration should be regulated like that of other foreign countries by the quota system. This proposal was rejected by the United States Senate, and the discrimination was upheld. After a brief period of acute agitation in Japan excitement subsided, but the problem remains.

In British Columbia, Japanese immigration is still regulated by a Gentleman's Agreement, but there has grown up an agitation in favour of legislation on the model of that passed in the United States. The British Empire is thus acutely concerned in this question. The British Empire had its own very delicate inter-Imperial problem arising out of the attitude of the populations of certain Dominions towards Indian immigration. Australia views any settlement of Asiatic peoples with disfavour, while in South and East Africa the discrimination in the treatment of Indian nationals under domestic legislation has seriously prejudiced political relations between these countries and India.

MIHALACHE, ION (1882–), Rumanian politician, was born March 3 1882, of a poor peasant family. He became a village school teacher and distinguished himself as an organiser of the Village School Teachers' Federation, of which he was

eventually appointed president. In 1914 he entered politics, and after the World War founded the Peasant (Tsaranist) party first in Bessarabia, and then extended its organisation to the rest of the country. In the first elections held after the War in 1919, the Peasant party won 70 seats in the Chamber of Deputies and Mihalache was appointed Minister of Agriculture in the Vaida-Voevod Cabinet, which office he held until March 1920, when Vaida-Voevod resigned with the entire Cabinet. Mihalache distinguished himself during the World War in which he served with the rank of captain. In addition to the highest Rumanian military decoration (Michael-the-Brave) he was awarded the Legion of Honour, the Order of St. Stanislas and other foreign decorations.

MILAN (*see* 18.437), the second largest town in Italy and the most progressive commercially and industrially, had a population of 712,844 in 1921. The old quarters are giving way to blocks of new buildings, and the circumference of the city in 1926 was about eight miles. Barracks have been erected and exercise grounds made outside. The manufacture of motor-cars and artificial silk are growing industries. A free university was opened in 1924. In 1918 the royal palace to the south of the cathedral was presented to the municipality by the Crown. The Home of Rest for musicians, established by Verdi, has been transformed into a Verdi Museum, and a statue of the composer was unveiled in front of it in 1913. The Museo del Teatro, opened in the building of the famous Della Scala theatre in 1913, contains a collection relating to its history. A larger station, fronting the Piazza Doria, to replace the central railway station, was under construction in 1926.

MILES, NELSON APPLETON (1839–1925), American soldier (*see* 18.442), died at Washington, D.C., May 15 1925.

MILFORD HAVEN, LOUIS ALEXANDER, 1ST MARQUESS OF (1854–1921), British sailor, was born at Gratz May 24 1854, the eldest son of Prince Alexander of Hesse, by his morganatic marriage with the Russian Countess, Julie Thérèse von Haucke. As Prince Louis of Battenberg he was naturalised as a British subject in 1868 and entered the royal navy in the same year. In 1884 he married Princess Victoria, daughter of the Grand Duke Louis IV. of Hesse. From 1891 to 1894 he was naval adviser to the inspector-general of fortifications and in 1900 was appointed assistant director of naval intelligence at the Admiralty, being made director in 1902. In 1904 he was promoted rear-admiral and after serving as second in command in the Mediterranean was made vice-admiral in 1908. After commanding the Atlantic and Home Fleets, he was in 1912 appointed First Sea Lord of the Admiralty, but in Oct. 1914 he was compelled to resign from this position owing to public resentment at his German origin, which persisted in spite of his fine record of service. In 1917 he relinquished his German title, assumed the surname of Mountbatten and was elevated to the peerage as marquess of Milford Haven. In the following year he retired from the active list of the navy. He became an admiral of the fleet in 1921 and died on Sept. 11 of the same year.

MILITARY RAILWAYS: *see* LIGHT RAILWAYS, MILITARY.

MILK AND DAIRY PRODUCTS.—The dairy industry is in many countries the chief agricultural industry and in all countries is of the utmost importance to agriculturists. The fact that this is recognised by agriculturists themselves is evident from the rapid expansion in some countries of the dairy herds. The following statistics give some indication of such expansion and of the state of the industry in various countries:—

THE PRODUCTION OF MILK

Great Britain.—In 1924 the total milk production was approximately 1,300 million gal. (less milk used for calf rearing). Of this, 600 million gal. were consumed as liquid milk; 500 million gal. were consumed in the manufacture of butter and cheese; 35 million as condensed milk and 61 million as cream, etc. The dairy herd numbered 3,111,000.

Australia.—In 1921, 267 million lb. of butter and 32½ million lb. of cheese were produced. The dairy herd numbered 2,343,221, with an average production per cow of 343 gallons.

Canada.—In 1921, 236½ million lb. of butter and 149¼ million lb. of cheese were produced. The dairy herd numbered 3,736,832.

New Zealand.—In 1924, 71½ million lb. of butter and 161 million lb. of cheese were exported. The dairy herd numbered 1,291,000.

United States.—In 1923 the total milk production was 109,736 million lb., of which 54,614 million lb. were consumed as liquid milk, 39,106 million lb. were consumed in the manufacture of butter, and 12,714 million lb. in the manufacture of cheese, condensed milk, ice cream, etc. The dairy herd on Jan. 1 1924 numbered 24,675,000, but this number had decreased in 1925 to 20,965,423.

Argentine.—In 1918, 41,863,000 lb. of butter and 14,177,000 lb. of cheese were exported. The dairy herd numbered 2,378,000.

Denmark.—Denmark is the main European exporting country of dairy products. In 1921, 199,500,000 lb. of butter were exported; the dairy herd numbered 1,184,268.

THE CONSUMPTION OF MILK

The consumption of milk and dairy products varies as much as production. In a survey of 68 American cities which have populations of over 100,000, the consumption of fluid milk was found to be ·66 pt. per head daily. In 1924, in the New York Metropolitan district, where there is a population of about 8·7 million the consumption per head was ·75 pt. daily, an increase of 85% during the preceding 30 years, due largely to improved quality. The following statistics collected by the United States Department of Agriculture give the annual average consumption per head of liquid milk, butter and cheese in various countries:—

Annual Consumption per head of liquid milk (In American Gallons).

Denmark in 1914	68·5 gal.
America in 1925	53 gal.
Canada in 1916	26 gal.
United Kingdom in 1918	22 gal.

Annual Consumption per head of butter.

Canada in 1911	27·7 lb.
Australia in 1913	25·6 lb.
New Zealand in 1914	21·7 lb.
Denmark in 1914	19 lb.
United Kingdom in 1914	17 lb.
United States in 1919	16 lb.
Argentine[1] in 1915	1·8 lb.

Annual Consumption per head of cheese.

Denmark	12·3 lb.
United Kingdom	11·2 lb.
United States	4·2 lb.
Australia	3·63 lb.
Canada	3 lb.
New Zealand	3 lb.
Argentine	2·9 lb.

[1] Factory butter only.

Production and Consumption in Great Britain.—It will be seen from the figures given above of the consumption of milk in the various countries that Great Britain's consumption is low compared with that of other nations. In 1918 the returns of the consumption of liquid milk were obtained through the local food control committees and it was found that these varied from as low as 0·10 pt. in Inverness to 0·31 pt. in London, an average for the whole area being 0·25 pint per head per day. Actual consumption would be above these figures as milk produced and consumed on farms does not appear, whereas the figures include the total population. The London figures would be approximately correct but the production of milk in Great Britain in recent years has not kept pace with the increase in the human population nor with the demand by the latter for milk products. This is shown by the following table extracted from the report of the Astor committee:—

	1871	1914	Increased Percentage
Population	26,100,000	41,700,000	60
Numbers of cows and heifers	2,091,000	2,937,000	40
Weight of cheese imported; cwt.	1,216,400	2,373,091	95
Butter imported; cwt.	1,334,783[1]	3,882,116	304
Margarine imported; cwt.	..	1,501,520	..
Condensed milk imports; cwt.	352,332[2]	771,239	128
Dried milk imports; cwt.	..	30,601	..
Total weight of Dairy produce Imported—cwt.	2,903,515	8,558,567	235

[1] No separate statistics for butter and margarine before 1888.
[2] No separate statistics for condensed or dried milk before 1888.

The relative consumption of milk in Great Britain is much lower than is desirable in the national interest. This is probably due to the fact that it is known that the quality, as regards cleanliness, has been gravely defective and there is no doubt that the larger consumption in other countries is primarily due to a cleaner supply. During the past few years, however, there has been a distinct improvement in the methods both of production and distribution in Great Britain, and as a result it is safe to say that the consumption of milk is gradually increasing and there can be little doubt but that the educational work which has been carried on since 1915 is beginning to have its desired effect.

Imports of Dairy Produce Into Great Britain.—The value of dairy produce imported into the United Kingdom has also steadily risen for the last 50 years until in 1914 it reached a total of £38,000,000. Of this over £27,000,000 was paid to Denmark and Russia for butter and Holland for cream, cheese and condensed milk, whilst the balance, amounting to over £10,000,000, was paid to Australia and New Zealand for butter and to Canada and New Zealand for cheese. It will therefore be seen that Great Britain is anything but self-supporting in its dairy industry whilst many other countries have an exportable surplus. The reasons for the relative importance of dairying probably differ from country to country but in addition to any particular reasons which any country may have there has undoubtedly been a widespread recognition in most lands of the great value of the dairy cow as a producer of human food. As land, labour and feeding stuffs have increased in price, the dairy cow has more and more displaced the strictly meat-producing farm animals as an economical agent for the conversion into human food of those field crops which are not suitable for direct human consumption.

Purity of Supplies

Importance of Milk as a Food.—Most dietetic authorities are satisfied that milk is the most important individual foodstuff and that an abundant supply of milk of good quality is an important factor in the health of a nation, and especially of city dwellers. Milk contains all the nutritive constitutents required by the body—proteins, fats and carbohydrates—in a readily assimilable form, and possesses special properties which promote growth and maintain the body in a healthy condition. It is therefore a valuable food for all classes of the community and especially for children. These special qualities in milk were first made known by Prof. F. G. Hopkins of Cambridge and have since been the subject of research by numerous investigators, notably Professors T. B. Osborne and L. B. Mendell of Yale University and Prof. E. V. McCollum of Johns Hopkins University. The exact nature and composition of these growth-promoting substances or vitamins is at present unknown, but their existence is inferred from the effects produced in respect of growth and health by feeding animals on special and carefully controlled diets.

Investigations into this subject indicate the existence of at least three vitamins, all of which are present in milk. These have been termed: (1) The ricket-preventing vitamin (or fat soluble A) which is necessary to promote growth and to prevent rickets in young animals.[1] The fat of cream and butter are amongst the richest known sources of this vitamin. (2) The anti-neuritic vitamin (or water soluble B) which is also necessary to promote growth, and in addition is essential to prevent the occurrence of the disease known as beri-beri. This vitamin is found in the germ and in the bran or outer layers of certain grains and in milk. (3) The scurvy-preventing vitamin. This vitamin is found in fresh, untreated cow's milk and in fresh fruits and vegetables.

There is no evidence that heating of milk destroys the vitamins described in (1) and (2), above. The scurvy-preventing vitamin (3), above, is however sensitive to exposure to heat, and therefore dried, pasteurised, boiled or condensed milk may be regarded as inferior in varying degrees to raw milk in scurvy-preventing properties. Skimmed or separated milk is deficient in the ricket-preventing vitamin referred to in (1), above, and the development of rickets may follow from its extended use in the feeding of young children unless the deficiency be made good. Attention may here be called to the inferiority in this respect of margarine to butter as a source of fat in the diet of growing children. Margarine is, as a rule, manufactured largely from vegetable oils. These are deficient in the ricket-preventing vitamin and the nutritive value of margarine made from such oil is therefore inferior to the nutritive value of butter. Although vegetable fats and oils are deficient in this vitamin which is also essential to growth, yet the green parts of plants are the chief ultimate source of this vitamin. For this reason the diet of cows, especially of those whose milk is to be used for infant feeding, should contain an abundance of the green parts of plants and there is evidence[2] showing that the milk given by cows in the summer, when the diet consists of fresh, green pasture, is richer in vitamins than in winter when the chief foods are hay, straw, roots and concentrates.

Need for Healthy Cattle.—Healthy cattle are the first requisite for a safe milk supply. Physical inspection by a competent veterinary surgeon will go far towards the elimination of those cows suffering from obvious disease but cannot be relied upon for anything like complete protection. The tuberculin test is more searching with reference to this particular disease. There are only two practical ways in which tuberculosis may be eradicated from a herd, namely, (1) the slaughter of all reactors; (2) the isolation of reactors and the separation after birth of calves born of reacting cows. Both methods raise many practical difficulties and it is therefore worth noting that the English Ministry of Agriculture has reintroduced the tuberculosis order giving compensation for cows slaughtered when suffering from this disease. Although it is admitted that a "considerable amount of tuberculosis of childhood is to be ascribed to infection with bacilli of the bovine type transmitted to children in meals consisting largely of the milk of the cow,"[3] at the same time it is not desirable to create unnecessary alarm by exaggerating the extent of human tuberculosis due to bovine infection. There can be little doubt that much infantile debility, leading to susceptibility to many diseases, including tuberculosis, is due to inadequate milk consumption. All reacting cows do not necessarily give tuberculous milk, and risk from tuberculous milk may be negatived by efficient pasteurisation (see *Lancet*, Jan. 30 1926).

Milk Grading Rules.—There is no question that the adoption in America of the principle of grading milk has resulted in a great improvement in the general supply. As supplied under the regulations of New York City four grades of milk are permitted. Grade A Raw includes the so-called certified milk which is produced under permit and certification by the county medical association. It also includes any other milk meeting the requirements, the principal requirement being the tuberculin test. The other grades do not require tuberculin tests and have progressively less stringent requirements as to bacterial content (taken as a measure of general cleanliness), cooling and age. Grade B is not recommended for children but is considered safe for adults. Grade C is sold to bakers and others for use in cooking. The effect of the grading rules, under which the producer receives more money for the higher grades, has been to raise the general standard of the city supply without arbitrarily cutting off the lower grades from their proper market.

In England the grading of milk has also been adopted, and table on p. 915 gives the standards required under the terms of the Milk Special Designations Order, 1923, for the various designations which it is illegal to use in connection with the sale of milk except under licence granted by or under the authority of the Minister of Health.

The clean milk competitions which have taken place in Great Britain have had a very great influence in improving the production of milk and the standard of production is probably as high in Great Britain as elsewhere. The first clean milk competition was held in Essex in 1920, and in 1925 no fewer than 33 counties

British Definitions of Grades of Milk

Designation	Herds	Bacterial content		Other conditions
		Maximum number of bacilli per cubic centimeter	Coliform bacillus	
Certified Grade A Tuberculin Tested	Tuberculin tested and physically examined at regular intervals	30,000	Absent in 1/10 cubic centimeter	Bottled on the farm, name of farm, day of production and word "Certified" on each bottle cap
	Tuberculin tested and physically examined at regular intervals	200,000	Absent in 1/100 cubic centimeter	Delivered to consumers in (*a*) the bottles or the sealed containers as received from the farm; (*b*) suitable containers of not less than two gallons capacity; (*c*) bottles with the name of the dealer by whom the milk was bottled, the address of the licensed bottling establishment, the day of production and the words "Grade A Tuberculin Tested" or "Grade A" on each bottle cap
Grade A	Physically examined at regular intervals			
Pasteurised Milk				
Grade A Pasteurised	Grade A milk that after pasteurisation, as required by the Minister of Health, contains not more than 30,000 bacilli per cubic centimeter and no coliform bacillus in 1/10 cubic centimeter. All other conditions as required for Grade A milk			
Pasteurised	Any milk that after pasteurisation, as required by the Minister of Health, contains not more than 100,000 bacilli per cubic centimeter. No requirement for bottling			

undertook such competitions. More would have done so had it not been for the outbreak of foot-and-mouth disease.

The Distribution of Milk

While improvements in production have taken place during the last few years methods of distribution have also shown progression, and this has been due mainly to two factors—pasteurisation and bottling.

Pasteurisation.—No reasonable amount of inspection or laboratory control over a raw milk supply can provide a sufficient safeguard against the transmission of disease through milk. This fact is emphasised by milk-borne epidemics which have their sources in carriers or unrecognised cases of disease—hence the use of pasteurisation. Pasteurised milk has now been defined by the Ministry of Health as milk which has been heated to a temperature of not less than 145°F and held at that temperature for at least 30 min. and afterwards immediately cooled. The American cities, however, have adopted a minimum temperature of 142° F for 30 minutes. If milk be overheated the line of demarcation between the cream and the milk becomes indefinite and the milk is then less attractive to the consumer. Pasteurisation must never be regarded as a substitute for clean milk production and cleanliness in handling milk, which are the most important of all conditions affecting the milk supply, yet it does give an added safeguard to the consumer in protecting him from hose diseases which may be milk-borne from human sources.

Bottling.—The second most important advance made in distribution is the delivery of milk in sealed bottles. The improvement in delivery resulting from this method will be still more marked when the present draft order, made by the Minister of Health under the powers of the 1925 Milk and Dairies Act, forbidding the bottling of milk elsewhere than in a properly equipped dairy, becomes law. There is still room for the education of milk producers, milk distributors and consumers, and the continuance of clean milk competitions is of the greatest importance as a means of educating the farmer to the necessity of (*a*) healthy and clean cows, (*b*) healthy and clean milkers, (*c*) properly sterilised equipment and (*d*) covered milking pails. The need for the provision of free instruction to the general public of the value of milk as a food, the influence of a good or bad supply of milk on the life and health of children and the community as a whole, and the best methods of handling and storing milk in a consumer's home, is still urgent. Had the general public been educated in the past in this respect there would now probably be a greater demand for milk, produced and handled under better conditions, and, with the demand, a willingness to pay for milk of guaranteed cleanliness. Such educational work should be on the principle of enlightening, and not frightening the general public.

Condensed and Evaporated Milk.—Sweetened condensed milk, the condensed milk of commerce, is officially defined in the United States as the production resulting from the evaporation of a part of the water from whole milk. It must not contain less than 28% of milk solids, including not less than 8% of milk fat. It usually contains about 40% of added cane sugar. Evaporated milk or unsweetened condensed milk must contain not less than 25·5% of total solids including 7·8% of fat and no added sugar. In Great Britain, under statutory rules and orders made by the Minister of Health, full-cream unsweetened condensed milk must contain 31% of milk solids including not less than 9% of milk fat. Full-cream sweetened condensed milk must contain the same percentage of milk solids and of milk fat. Skimmed unsweetened must contain 20% of milk solids and skimmed sweetened 26%, while all skimmed milk must be labelled "unfit for babies." The amount of imports of condensed and evaporated milk into Great Britain has increased from 26¾ million pounds in 1888 to 251 million pounds in 1925 and, unfortunately, a very large proportion of this increase is due to the importation of condensed skimmed milk.

Dried Milk or Milk Powder.—Dried milk or milk powder is a dehydrated product of milk containing about 5% of moisture. It is used as a substitute for milk in the kitchen and extensively by bakers and confectioners. Either whole milk or skimmed may be desiccated, but the skimmed milk powder will keep almost indefinitely, whereas the whole milk powder has a tendency to become rancid. It is reported that in most processes of manufacture this difficulty has been overcome. The milk is evaporated upon revolving metal drums, internally heated, or by being sprayed into a chamber through which hot air is blown. The drum processes are carried out however at normal atmospheric pressure or in partial vacuum. In Great Britain dried milk is subject to the following requirements: milk described as dried full-cream milk must contain not less than 26% of milk fat. Milk described as dried ¾-cream milk must contain not less than 20%, milk described as dried ½-cream milk must contain not less than 14% and milk described as dried ¼-cream milk must contain not less than 8%.

(E. B. Ph.; A. D. A.)

MILLAY, EDNA ST. VINCENT (1892–), American author, was born at Rockland, Me., Feb. 22 1892, and was educated at Vassar, graduating in 1917. Her work, distinguished by delicacy of sentiment, placed her in the front rank of American contemporary poets. She was awarded the Pulitzer Prize in 1923 for her poem *The Harpweaver*.

She published *Renascence and Other Poems* (1917); *Figs from Thistles* (1920); *Second April* (1921); *Aria da Capo* (1921); *Two Slatterns and a King* (1921); *The Harp-Weaver and Other Poems* (1923); *Lamp and the Bell* (1923); and *Distressing Dialogues* (1924).

MILLER, JOAQUIN (1841–1913), American poet (*see* 18.464), died at Oakland, Cal., Feb. 17 1913. In compliance with his last wishes his body was cremated and the ashes taken up into the Sierras and cast to the winds.

MILLER, OSKAR VON (1855–). German engineer, was born in Munich May 7 1855. After studying electrical technology he became director of the Deutsche Edison Gesellschaft (German Edison Company) from which developed the Allgemeine Elektrizitäts Gesellschaft (the A.E.G., or General Electric Co.). He advocated the full utilisation of electricity by means of propaganda in connection with long distance cables, and wrote articles on the supplying of towns with electricity (1896–1903). He was director of the electrical exhibition, Frankfort-on-the-Main, held in 1891 when the first high tension alternating current power-transmission apparatus was installed. The transmission was accomplished over a distance of 180 km. (from Lauffen on the Neckar to Frankfort) and with only 25% loss. These experiments were of the highest importance in the development of modern electric-technology. He promoted the development of Bavarian water power as well as a systematic electric supply for that country, and was the founder and organiser of the German museum for natural and technical science in Munich.

MILLERAND, ALEXANDRE (1859–), French politician (*see* 18.465). M. Millerand, now only a private member, threw himself into his work as a barrister, and appeared in many important civil cases. In the Chamber he was a fierce opponent of the Combes ministry, which succeeded that of Waldeck-Rousseau; for he objected to its narrow and fanatical anti-clericalism. In July 1909 he became Minister of Public Works in M. Briand's first Cabinet, his principal achievement at this time being the re-organisation of the state railways. Together with M. Briand he took strong measures to suppress the railway strike of Oct. 1910. In Jan. 1912 he was appointed Minister of War under M. Poincaré. His promotion surprised no one, for he had always taken a keen interest in questions of military organisation; and when the menace of Germany increased, he devoted himself to strengthening the national defences. He re-organised the higher command, and by the Act of May 29 1912 he gave a definite status to military aeronautics for the first time. In Jan. 1913 a personal incident brought about his retirement. On Aug. 25 1914 he was invited by M. Viviani to take the place of M. Messimy as Minister of War; and during the terrible situation which then prevailed he had constantly to take the initiative, for example, in attempting to remedy as far as possible the shortage of munitions. He was accused, however, of being too slow in providing the necessary heavy artillery, and he resigned with the other members of the Viviani cabinet at the end of Oct. 1915. In 1918 he was elected a member of the Académie des sciences, morales et politiques.

A few months after the conclusion of hostilities, on March 21 1919, M. Millerand was appointed commissioner general for Alsace-Lorraine. The problem of reuniting with the mother-country two provinces which had been torn from her in 1871 was a most serious one. For 50 years they had been under an administration widely different from that of France. A period of transition, therefore, was essential, alike from the point of view of political expediency, administration, economics and finance. The first French officials sent to Strashourg had not been equal to their task; and for this reason it was essential to appoint a statesman of eminent authority with power to act, who would keep in constant touch with the Government. This post was filled by M. Millerand with complete success. In an important speech delivered in Paris on Nov. 15 1919, on the eve of the elections, he outlined the policy of the coalition which, under the name of the *bloc national*, was returned to power. On the resignation of M. Clemenceau, Jan. 18 1920, M. Millerand was chosen to form a Cabinet, and became both Prime Minister and Minister for Foreign Affairs. His main activities were in regard to the application of the Treaty of Versailles; and in order to force Germany to fulfil her obligations, he ordered the provisional occupation of Frankfort. He was present at the inter-allied conferences at San Remo and Spa, in April and July 1920, and in Aug. of the same year he met Mr. Lloyd George at Hythe. The situation in regard to Poland, who had been attacked by the Bolsheviks, now became grave, and M. Millerand therefore sent to Warsaw a contingent of French officers under General Weygand. With this assistance the Poles gained a complete victory over the Bolsheviks. M. Millerand about this time officially recognised the anti-Bolshevik government of Gen. Wrangel, who was soon after completely defeated. In France itself, in May 1920, he frustrated various attempts, especially by the railwaymen, to organise revolutionary strikes.

In Sept. 1920 M. Deschanel, President of the Republic, was forced by ill-health to resign. M. Millerand was elected as his successor, and out of 892 votes cast, no fewer than 695 were given in his favour. During his candidature, he made it known that if he were elected, he intended to exert a more powerful influence on the policy of the Government than his predecessors had done. He refused to admit that his office of President forced him to comply with a tradition of which he disapproved, by remaining absolutely neutral in politics. He made it clear that he intended to watch closely the foreign policy of the Government, and made no secret of his wish to strengthen the power of the President by a revision of the constitution which would modify the conditions of his election; and he put his ideas into practice, by frequently intervening in diplomatic negotiations. During the inter-allied conference at Cannes in Jan. 1922 he despatched a telegram expressing dissatisfaction at the conduct of affairs, which caused M. Briand to return to Paris, and, in fact, brought about his resignation. Working on the same lines, he summoned to the *Elysée* the prefects, or chief administrative officers of each department from all over France. In a powerful speech at Evreux in the Spring of 1923 he declared that he would not agree to the re-introduction of the *scrutin d'arrondissement*, and showed marked favour to the adherents of the *bloc national*, who had been in the majority in the Chamber since the elections of Nov. 1919, and against whom the radicals and socialists were then carrying on a campaign of public meetings.

M. Millerand's conception of the rôle of President of the Republic brought him into collision with the radical and socialist majority, which, under the name of the *cartel des gauches*, was successful in the elections of May 11 1924. He was violently attacked by the radical socialist press, which accused him of having exceeded his powers by intervening in the party struggle, and called for his resignation. M. Herriot, the leader of the *cartel des gauches*, when asked by M. Millerand to succeed M. Poincaré as Premier, announced that he would do so only on M. Millerand's resignation. The latter replied that he had been elected for seven years, and that the alteration of the party in power could in no way affect his constitutional position nor abrogate his rights. But he made it clear that he had not the slightest intention of obstructing the new Government, and that its leader could count on his impartiality. M. Herriot, however, remained immovable; and M. Millerand therefore invited the Senator M. François-Marsal, who had been his Minister of Finance in 1920, to form a Cabinet. M. François-Marsal declared in the Chamber that the attacks on M. Millerand were contrary to the constitution, and that it was in order to uphold the latter that he had agreed to take office. His Government, however, was immediately defeated; and M. Millerand tendered his resignation, protesting meanwhile against the illegality of the action taken against him. The attitude of the party in power dissatisfied the Senate, which, as a result, voted with the opposition and elected M. Doumergue as M. Millerand's successor, instead of M. Painlevé, the candidate of the *cartel des gauches*.

Some months later through a by-election, M. Millerand was elected Senator for the department of the Seine. He then became president of a group formed to denounce the policy of the *cartel des gauches* throughout the country. His success as an orator was apparent both in the courts and in Parliament. (P. B.)

MILLET, FRANCIS DAVIS (1846–1912). American painter (*see* 18.466), was drowned in the "Titanic" disaster April 15 1912.

MILLIKAN, ROBERT ANDREWS (1868–), American physicist, was born at Morrison, Ill., March 22 1868, and received his education at Oberlin College (A.B., 1891; A.M., 1893) where he was instructor in physics 1891–3. He then proceeded to Columbia University (Ph.D., 1895), and the universities of Berlin and Göttingen (1895–6). In 1896 he was appointed assistant in physics at the University of Chicago, with which institution he continued to be associated for the next 25 years in the department of physics, being professor from 1910 to 1921. In 1921 he became director of the Norman Bridge laboratory of physics and chairman of the executive council of the California Institute of Technology at Pasadena, California. He was vice-chairman of the National Research Council, Washington, D.C., in 1917, and chief of the science and research division of the Signal Corps, U.S.A., with the rank of lieutenant-colonel. In 1922 he was the first exchange lecturer to Belgium on the C.R.B. Foundation.

The best known of his researches were the "oil drop" experiments, undertaken with the view of making measurements of fundamental electrical quantity. They proved conclusively that all electrons are alike. He also undertook researches into photoelectric effect. Later research of his has tended definitely to bridge the gap between light and X-ray phenomena. He was awarded the Nobel Prize in physics in 1923 for his work in isolating and measuring the electron, and in making the first exact photoelectric determination of the light-quant. In the same year he received the Edison Medal for especially meritorious work in the field of electricity, and the Hughes Medal of the Royal Society in recognition of his determination of the electronic charge and other physical constants. (*See* PHYSICS.)

Millikan was the author of the following, among other works:—*Mechanics, Molecular Physics and Heat* (1901); *Electricity, Sound and Light* (1908); *The Electron* (1917); *Practical Physics* (1920); *Science and Life* (1923); in addition to numerous contributions to technical periodicals.

MILLS, ROGER QUARLES (1832–1911), American legislator (*see* 18.475), died at Corsicana, Tex., Sept. 2 1911.

MILNE, SIR GEORGE FREDERICK (1866–), British general, was born Nov. 5 1866 and joined the Royal Artillery in 1885. He served in the Nile Expedition of 1898, and the South African War (1899–1902). In 1913 he became commander of the artillery of the 4th Div., with which he went out to France in 1914. He was given, in July 1915, command of the 27th Div., which, three months later, he took out to the Salonika theatre. At the end of the year he was placed in charge of an army corps there. In May 1916 Milne was advanced to the command of the British forces in Macedonia, and he occupied this responsible position under the orders of three successive French commanders-in-chief until the end of the struggle. During the ensuing two years, the situation scarcely lent itself to effectual offensive operations, and the British military authorities at home were opposed to the using-up of resources in this theatre. Milne, however, filled a difficult position with unfailing tact and sound judgment, and, when a general advance at last took place in the autumn of 1918, after Bulgarian powers of resistance had waned, the forces under his personal command contributed appreciably to the bringing about of the final victory. He remained in charge of the British forces in the Near East and about the Black Sea until 1920, and on return to England was appointed to the Eastern command. In Feb. 1926 he succeeded Lord Cavan as Chief of the Imperial General Staff. Possessed of exceptional strength of character and decision, an eye so keen in its perception of weaknesses as to be proverbial in the army, these qualities were blended with a sympathetic understanding of men and a marked sense of humour. Even more significant, for an era of military transition, was his known receptiveness to new ideas.

MILNER, ALFRED MILNER, VISCOUNT (1854–1925), British statesman (*see* 18.476), occupied himself mainly, after his return from South Africa, with business interests in the City of London. But, though he took up a somewhat detached attitude with regard to ordinary domestic politics, he was active on behalf of causes which appealed to him from the imperial side; and he made several speeches in different parts of the country in the next few years on behalf of Tariff Reform and Colonial Preference. He paid a visit to Canada, where he himself and his gospel of imperialism were well received. He was roused, however, by Mr. Lloyd George's budget of 1909, and he advised the House of Lords to reject the Finance Bill, and, as he said at Glasgow, to "damn the consequences." He made several speeches in the next 12 months in defence of the Lords' position; and when the Parliament Bill came up to the House of Lords in 1911, he was a leading spirit among the "Diehards" who advised resistance to the end. He did not take a very prominent part in the opposition to the Irish Home Rule Bill; but he aptly described the state of affairs in Ireland in the early summer of 1914 as "smouldering war," and he urged the remodelling of the Amending Bill so as to reassure the Ulstermen.

The World War confirmed all his fears as to the disadvantages under which Great Britain and the Empire would labour during hostilities through the practice of unlimited Free Trade by the mother-country for over half a century. He gladly accepted in the summer of 1915 the chairmanship of a committee of technical experts and practical agriculturists, appointed by Lord Selborne as President of the Board of Agriculture, to consider the means of maintaining and increasing food production in England and Wales. The committee reported that farmers should be encouraged to grow more wheat by a guaranteed minimum of 45 s. a quarter for the four years following the harvest of 1916. Mr. Asquith's Coalition Govt. did not think the situation serious enough for this drastic remedy. Lord Milner became critical of this "wait and see" attitude; and especially reprobated on several occasions the policy of concealing disagreeable facts. "Truth all round," he said at Canterbury on Oct. 30 1915, "is the most fortifying thing in the world;" Englishmen could not brace their nerves and steel their hearts to win through by emulating the ostrich. Similarly he did his utmost, in April 1916, to induce doubting ministers to accept the policy, which the country demanded, of universal compulsory service, as absolutely necessary under the circumstances.

Mr. Lloyd George, when he formed his ministry in the following Dec., at once turned to this resolute statesman, the only British administrator who before 1914 had directed a war from the civil side, and constituted him one of his principal colleagues in his War Cabinet of four (or five including Mr. Bonar Law). Considering the attitude of the two men at the time of the South African war, the offer and acceptance argued magnanimity on both sides. From this time to the cessation of hostilities their relations were close, and, after Mr. Lloyd George, Lord Milner took the largest share in the civilian conduct of the War. In vigour, resolution and readiness to take responsibility they resembled each other; but Lord Milner's experience, scholarship, steadiness and somewhat bureaucratic habit of mind supplied an invaluable complement to his chief's daring, impatience of precedent, quickness of apprehension and intellectual agility. In Feb. 1917 he attended, on behalf of the British Govt., a conference of the Allies in St. Petersburg (Leningrad), the object of which was to improve the co-ordination in the prosecution of the War between the Government of the Tsar (then in its last weeks of existence) and the Western Powers.

He devoted himself to his duties in the War Cabinet, never making speeches in the country, and seldom in the House of Lords, where his appearances were mostly in explanation of the policy of the Government in regard to food production and control. In June 1917 he announced that ministers had added between 70,000 and 80,000 men to the people available for agricultural work. In Feb. 1918 he vigorously defended Lord Rhondda's administration at the Food Ministry against ignorant criticism, and said that in regard to food Britain was in a better position than any other country except the United States. Except for what was necessary for the conduct of the War, everything must give way to food supply. The corn production bill of 1917, and

the acceptance by the Government of the principle of Imperial Preference, and of the conservation of the raw materials of the Empire, owed much to his influence and support. He worked heartily for inter-Allied co-operation in the conduct of the War, and with Mr. Lloyd George attended meetings of the Supreme War Council at Versailles. He was in France as the representative of the British Cabinet at the time of the victorious German advance in the last 10 days of March 1918; and it was largely owing to his influence that Gen. Foch was appointed at Doullens on March 26 Generalissimo of the Allied forces in France. It being vital to have a man of unusual capacity and vigour at the War Office in this critical spring of 1918, Lord Milner was given the seals of Secretary of State for War on April 19; and it was he who presided over the Army Council during the succeeding months of the year which ended with victory.

In the reconstruction of the Ministry after the general election, Lord Milner left the War Office and became Colonial Secretary, a position for which his lifelong interest in the Empire peculiarly qualified him. In that capacity he attended the Paris Peace Conference as one of the British plenipotentiaries, and was a signatory to the Treaty of Versailles; and he subsequently helped to deal with a number of difficult questions arising under the treaty out of the disposal of the German colonies conquered in war. But his colleagues utilised his services also in other directions. His financial authority was invoked to defend ministerial finance in the House of Lords; and when a serious revolutionary outbreak took place in Egypt in 1919, he was sent there, as the author of *England in Egypt* (1892), at the head of a special mission to inquire into the causes, and to report on the form of constitution best calculated to promote Egyptian peace and prosperity. The mission arrived at Cairo in Dec. and remained till March; then in the summer of 1920 Lord Milner and his colleagues had long conferences with Zaghlul Pasha, the leader of the Nationalists, in London; and ultimately in Nov. they issued a memorandum recommending the recognition of Egyptian independence. Great Britain was to guarantee the integrity of Egypt against aggression; she would have a privileged position in Egypt and would maintain a garrison in the canal zone. The capitulations were to be abolished, and the veto on legislation affecting foreigners would be vested in the High Commissioner. The new constitution, of which these were to be the principal features, had not yet been adopted when Lord Milner, who had only accepted office because of the national need, resigned in Feb. 1921, and his great services were fittingly recognised by the Order of the Garter. Before the end of the month he married Lady Edward Cecil, the widow of Lord Edward Cecil, formerly Miss Violet Maxse.

Lord Milner returned to his business interests in the city, and during the remaining four years of his life, though he took an active part in the work of the Rhodes Trust, and also published his views (*Questions of the Hour*, 1923), he only once showed any disposition to resume public work. When Mr. Baldwin, in the autumn of 1923, boldly appealed to the country for a mandate to introduce Protection, Lord Milner accepted the chairmanship of a committee to advise the Government as to the proposed tariff. As the electorate rejected Protection, the committee proved abortive. In the winter of 1924–5 Lord and Lady Milner paid a private visit to South Africa, where he renewed old friendships and received a warm welcome from those who appreciated the great services which he had rendered to that country. Shortly after his return he was attacked by sleeping sickness and died on May 13 1925 at his residence Sturry Court, near Canterbury. His death coincided with his unopposed election to the chancellorship of his old university, Oxford; and funeral services in Canterbury Cathedral and Westminster Abbey gave expression to the public sorrow and respect. There was found among his papers, and published shortly after his death, an impressive document containing his *Credo* (1925). (G. E. B.)

MILOVANOVIĆ, MILOVAŃ (1863–1912), Serbian statesman and diplomatist, was born at Belgrade on March 2 1863, and was educated there and in Paris, where he was the first Serb to take his degree as doctor of law and was awarded a gold medal for his thesis. On returning home he was appointed professor of international law at Belgrade University and soon acquired the position of one of Serbia's leading jurists. He was mainly responsible for drafting the new Serbian constitution of 1888; and, becoming secretary of the central committee of the Radical party, he entered politics and held successively the portfolios of Justice, Commerce and Finance during the closing decade of last century. In 1901 he went to Rome as minister, and retained his post after the revolution of 1903. In 1907 he represented Serbia at the Second Hague Conference, and was appointed a member of the international court of arbitration. In July 1908 he was made Foreign Minister in the Vetimirović Cabinet, and thus had to guide Serbian policy through the difficult period of the Bosnian annexation crisis.

In 1911 he succeeded Pašić as Premier, and, being less of a party man than his old Radical colleagues, was able to bridge many gaps, and to acquire within a short space of time a unique position among the politicians of Serbia. Even in foreign politics he showed signal moderation, and though a confirmed Russophil, initiated negotiations for a commercial treaty with Austria-Hungary and actively favoured good relations with Turkey. He was one of the chief founders of the Balkan League, the decisive step towards the creation of which was taken at a meeting between Milovanović and the Bulgarian Premier, Gueschov, on Oct. 11 1911. Secret negotiations continued throughout the winter and led to the conclusion of the Serbo-Bulgarian Treaty of March 13 1912 (*see* SERBIA). Discussions were still pending between the various Balkan capitals for a more precise and comprehensive project of alliance when, on July 1 1912 at Belgrade, Dr. Milovanović died suddenly of heart failure. His removal at so critical a juncture was a grave blow to the cause of peace and moderation, and also deprived Serbia of her ablest statesman since the death of Prince Michael.

MILWAUKEE, Wis., U.S.A. (*see* 18.492), had a population in 1920 of 457,147 (100 males to 100 females); in 1925 the census bureau estimate was 509,192. If suburbs within 10 m. are included the total for the metropolitan district is over 600,000. Between 1910 and 1920 the number of negroes, though still comparatively small (2,229), increased 127%; the number of foreign-born decreased slightly, to 110,068, of whom 30,771 were born in Germany and 23,060 in Poland. Natives of Germany constituted only 8·7% of the total population in 1920, as compared with 18·9% in 1900.

The assessed valuation of all taxable property in the city had risen to $810,509,504 in 1925, more than four times the figure 20 years earlier. Adding to this the value of property exempt from taxation (about $144,000,000) and of public utilities assessed by the Wisconsin Tax Commission (about $102,000,000), a total value for all real estate and assessable personal property of over 1,000 million dollars was indicated. Ranking 13th in population among the cities of the United States in 1920, Milwaukee ranked 12th in the value of its manufactured products in 1919 and 11th in 1923 ($576,161,000 and $514,591,065 respectively, compared with $208,324,000 in 1909), leading all others in the production of cranes and hoists, large shovels, excavators and dredges, steam and water turbines, large hydraulic electric units, rock and ore crushers and many other kinds of machinery, silk stockings, wheelbarrows and work-shoes. Progress in city planning included the preparation of a comprehensive plan (1917), the enactment of zoning ordinances (1920 and 1924), and the acquisition by the city of the greater part of the lake front and of land for a civic centre.

Effect of Prohibition.—The large brewing industry was dissipated by national prohibitory legislation. Some of the companies used part of their plant for manufacturing "near beer," ginger ale and other "soft" drinks, or leased part of it for other industrial purposes, but a large part of the investment in the breweries was still lying idle in 1926.

MILYUKOV, PAUL NIKOLAYEVICH (1859–), Russian politician and historian, was born near St. Petersburg (Leningrad) Jan. 27 1859. He studied history and humanities at the University of Moscow, and received the degree of master in

history for a learned work on the *State Economics of Russia in the First Quarter of the 18th Century*. His liberal opinions brought him into conflict with the educational authorities, and he was dismissed in 1895 after one of the ever-recurrent university "riots." After the meetings of the Zemstvos in 1905 he became the political editor of an important liberal paper, the *Retch*, and took an active part in the formation of the Constitutional Democratic party (Cadets). Milyukov became the leader of that party, although he was not elected a member of the first or the second Duma. When the Tsar dissolved the first Duma he was one of the principal prompters of the "Viborg manifesto," in which the members of the assembly declared themselves ready to follow the people in resisting arbitrary rule. Milyukov did not sign, however, as he was not a member of the Duma, and escaped the persecution which accompanied the Stolypin reaction. He was elected to the third and the fourth Duma, and played the part of a leader of the opposition, systematically criticising the policy of the Government.

When the World War broke out he stood for a policy of national union and active co-operation with the Entente, but the corruption of the War Office drove him into an attitude of increasing hostility. Milyukov took office in Prince Lvov's provisional government as minister of foreign affairs. Later he strongly disapproved of Kerensky's policy, and when the Bolsheviks seized power he escaped to Kiev then occupied by the Germans and gave up the cause of the Allies as lost. After the Armistice Milyukov went to London and subsequently to Paris, where in 1921 he directed a journal (*Last News*) in which he advocated an alliance with patriotic Socialists.

MIMICRY: *see* COLOURS OF ANIMALS.

MINELAYING AND MINESWEEPING.—Explosive contrivances were moored and used against ships, as early as 1800. It was not, however, until the American Civil War that the sea mine became an accepted weapon of naval warfare; nor did it prove a potent danger to the capital ship until it played an all-important part in the siege of Port Arthur some 40 years later.

I. MINELAYING

Amongst the decisions of international conferences at The Hague it was agreed, and ratified by the Great Powers (other than Russia), that mining in war should be limited to operations within territorial waters. The unfortunate result of this was to lull the British Admiralty into a false sense of security, and the mining service thus became a side issue. The German Carbonit mine, used by the Germans throughout the World War had been originally offered to the British Admiralty. It was refused on the plea of expense; and, in its place a mine of about one-quarter the cost was manufactured and supplied to the naval service. The Hague agreement was torn to pieces within a few hours of the outbreak of the World War, and as the War progressed the necessity for constant minelaying became evident.

Elements of Mining Warfare.—Three factors are necessary for successful mining warfare—the strategic function, the operation of laying the mines and the technical efficiency of the mine itself. The first of these factors is woven into the main strategy of a naval war. The stronger fleet, in its anxiety to seek out and destroy its enemy, desires a clear sea; and, to obtain this, must insure that such a means of attrition as the mine is reduced to the utmost. On the other hand, the weaker fleet will use the mine profusely in an endeavour, by attrition, to reach an equality of force: and it will also use this weapon against merchant ships, particularly when they belong to a belligerent dependent on its carriage of foodstuff from overseas. This was the initial stage of naval strategy in the World War; and to some extent it explains the pre-War application of the Germans to mining. The second factor is the operation of laying the mines. To be successful, this must be governed by the element of surprise, and be expeditiously performed; it requires for its purpose a ship of exceptional speed, or one which, by disguise or subterfuge, can carry out the work unmolested. The value of merchant ships for minelaying was recognised, and the Germans had such ships ready at the outbreak of war and speedily augmented the number of them.

The third factor is purely one of technique. No type of mine that does not meet the following requirements is efficient. It must be safe until it is laid. When laid, it must take up and maintain its required depth, throughout all kinds of weather, for an appreciable length of time. It must be immune from mechanical failure when required to function. In the interest of all belligerents, it must automatically render itself safe should it break from its moorings. Mines that fail in any of these respects may become a greater danger to friend than to foe. The German Carbonit mine answered these tests except in the last requirement. The early British mine was unfortunately only fully efficient in the last requirement. Considerable importance attaches to the design of a minefield. A simple straight line of mines is easily and quickly laid, but presents little difficulty to the minesweepers once it is located. Lines of mines laid in zigzags, particularly when spaces of water are left clear, present the greatest difficulty to removal. On the other hand, such patterns will necessarily cover a larger sheet of water, and will require very accurate plotting, if subsequently the vicinity of the mined area is to be approached by the sea forces of the minelayer. An existing apparatus termed "taut wire gear" proved a great aid to accuracy in positioning a minefield.

German Practice.—German submarine minelayers usually confined their mines within an area of two or three sq. miles, laying them in groups of four, or even less. The position chosen was most frequently near some focal point, buoy or lightship, or at the entrance to a naval base or commercial port. For instance, during the War, over 450 mines were laid by German submarines within a mile of the Shipwash Light vessel, a position necessarily passed by all traffic up and down the east coast war channel, by the convoys to and from Holland and by Com. Tyrwhitt's destroyer flotillas whenever they left or returned to their base at Harwich. The Germans also allotted to each of these submarines a particular stretch of the British coast. The flotillas working from Flanders covered the coast from Flamborough Head south about to the Clyde, also the northern French coast; the high sea, or large boats, working from the Elbe, were responsible for the rest of the English and Scotch coasts, and the whole of Ireland. Each commander being restricted to work in his individual area, the danger of striking previously laid mines was minimised. The commanders, moreover, by this arrangement, got quickly into touch with the local movements of the traffic, the method and capacity of their opposing minesweepers and the coastal navigation within their beats. In most cases after some 10 to 14 days a commander would not hesitate to pass over a position where he had previously laid mines. He would be confident that his mines had been discovered and cleared if shipping had been seen in the area.

Moored mines could be laid in any depth up to 100 fathoms, or even more in tideless waters, and they could be regulated to lie at any depth below the surface. Deep mines were used against submerged submarines, and shallow ones against surface shipping. In a strong tide, with a long mooring-rope, the mine will bend over to the tide; so that the mines, under strong tidal conditions, always lay too deep to be harmful to surface ships. In a position such as the Pentland Firth, mines were in fact only a danger at slack water, a period of minutes only. Again, the difference in height between high and low water was an important matter. If, for instance, the tidal range was exceptionally large, as in the Bristol Channel or Bay of Fundy, all types of ships could pass over a minefield at high water in perfect safety, provided no mines had been seen at low water on the surface.

British Minelaying Resources.—At the outbreak of hostilities in 1914 the British Navy possessed seven old cruisers (Latona class) fitted as minelayers. These had a speed of only 14 knots. Shortly afterwards four merchant ships were added; and in the second part of the War a considerable number of submarine minelayers and fast destroyers were used. On Oct. 2 1914 the first line of 1,264 mines was laid by the old cruisers in an area 10 m. north of Ostend. This had the effect of forcing neutral shipping to pass through the Downs. Unfortunately, the British mines then in use proved so defective that for a time minelaying

had to cease; and although in 1915, after some technical improvement, some 15 more minefields were laid, it was not until 1916 that attention was concentrated on providing a mine of the calibre of that used by the Germans.

British Activities from 1916 Onwards.—One of the principal British minelaying operations of 1916 was a coast barrage, consisting of a double line of deep mines, running for 40 m. from the Belgian coast, at a distance of 12 m. from the shore. It was supplemented by mine nets laid by the Dover drifters. The work took five weeks to complete; but only one submarine seems to have been accounted for by it. The end of the year saw the institution of a mining school at Portsmouth for research and development.

On the assumption that the Belgian coast barrage had been effective, a similar barrage was completed in Feb. 1917 across
